Abstract

Hepatorenal syndrome (HRS) is a reversible form of functional renal failure that occurs with advanced hepatic cirrhosis and liver failure. Despite mounting research in HRS, its etiology and medical therapy has not been resolved. HRS encompasses 2 distinct types. Type 1 is characterized by the rapid development of renal failure that occurs within 2 wk and involves a doubling of initial serum creatinine. Type 2 has a more insidious onset and is often associated with ascites. Animal studies have shown that both forms, in particular type 1 HRS, are often precipitated by bacterial infections and circulatory changes. The prognosis for HRS remains very poor. Type 1 and 2 both have an expected survival time of 2 wk and 6 mo, respectively. Progression of liver cirrhosis and the resultant portal hypertension leads to the pooling of blood in the splanchnic vascular bed. The ensuing hyperdynamic circulation causes an ineffective circulatory volume which subsequently activates neurohormonal systems. Primarily the sympathetic nervous system and the renin angiotensin system are activated, which, in the early stages of HRS, maintain adequate circulation. Both advanced cirrhosis and prolonged activation of neurohormonal mechanisms result in fatal complications. Locally produced nitric oxide may have the potential to induce a deleterious vasodilatory effect on the splanchnic circulation. Currently medical therapy is aimed at reducing splanchnic vasodilation to resolve the ineffective circulation and maintain good renal perfusion pressure. Terlipressin, a vasopressin analogue, has shown potential benefit in the treatment of HRS. It prolongs both survival time and has the ability to reverse HRS in the majority of patients. In this review we aim to focus on the pathogenesis of HRS and its treatment with terlipressin *vs* other drugs.

Key words: Heptorenal syndrome; Terlipressin; Kidney; Liver

INTRODUCTION

Many studies have been carried out on hepatorenal syndrome (HRS); the pathophysiology and its management

however have not been completely resolved. HRS is a reversible form of functional renal failure that occurs predominantly with advanced liver disease arising from hepatic cirrhosis or severe liver injury from any condition such as severe alcoholic hepatitis or metastatic tumors[1]. The important features of HRS are characterized by peripheral vasodilation with subsequent profound intrarenal vasoconstriction, leading to decreased glomerular filtration rate (GFR)[2,3].

Currently, HRS encompasses 2 distinct types. Type 1 HRS often manifests itself rapidly; without appropriate treatment the mean survival time is approximately 2 wk[4]. The distinguishing feature of type 1 HRS is rapid progressive renal failure that occurs within 2 wk and is associated with doubling of baseline serum creatinine or a 50% reduction in creatinine clearance[5]. In more than 70% of cases there is an identifiable trigger for type 1 HRS[6-9]. A large number of studies have shown that type 1 HRS can be precipitated by preceding spontaneous bacterial peritonitis infections, gastrointestinal bleeding and large-volume abdominal paracentesis without albumin replacement[6,8]. Furthermore, type 2 HRS has a gradual onset with a steady decline in renal function. Interestingly, the hallmark for type 2 HRS is refractory ascites and often has no precipitating factors[4]. The survival time is better in type 2 HRS at approximately 6 mo[1,5]. Some would consider injudicious use of diuretics as a precipitating factor.

Importantly, the core feature of pathogenesis of HRS is peripheral arterial vasodilation, in particular in the splanchnic vasculature[10]. This develops with advanced liver cirrhosis, which causes increased resistance to blood flow with high portal pressure. In turn, to ease the pressure within the hepatic portal system, locally acting vasoactive substances are released that cause vasodilation of the splanchnic vasculature[10]. The overall resultant effect is circulatory dysfunction arising from a depleted intravascular volume that ultimately leads to poor renal perfusion and activation of compensatory mechanisms (renin angiotensin aldosterone system, sympathetic nervous system and vasopressin). These compensatory mechanisms with time become detrimental and result in sustained severe intrarenal arterial vasoconstriction with progressive physiological renal failure[2]. The pooling of blood in the splanchnic vascular bed with the associated hypoperfusion of the kidneys and the ensuing intrarenal arterial vasoconstriction forms the basis for the development of HRS.

HRS has very poor prognosis with spontaneous recovery being unlikely[2]. Treatment of HRS can be divided into medical and surgical, the latter being more beneficial. Current treatment modalities are used as a bridge to surgical intervention (liver transplant), although most patients do not survive long enough to receive a liver transplant[2]. Pharmacotherapy is the initial treatment which buys time for a liver transplant but unfortunately there is no universally agreed first-line therapy. There are a number of pharmacological agents that have been investigated in the management of HRS and thus far most drugs aim to reverse the peripheral and splanchnic vasodilation. Usually treatment is a combined therapy of vasoconstrictors with albumin to augment their efficacy[11].

Vasoconstrictive drugs such as vasopressin analogues (ornipressin, terlipressin), octreotide and noradrenaline have been used in attempts to reduce the pooling of blood in the splanchnic vasculature and the peripheral arterial vasodilation[12]. A few studies have investigated ornipressin combined with albumin or dopamine and they have been shown to reverse HRS[13-15]. Globally the use of ornipressin has been abandoned in HRS because of the high risk of an adverse event, in particular ischemic events. Other studies have shown that with the use of potent vasoconstrictors such as ornipressin, the result can be ischemic mesenteric mucosa, myocardial ischemia, and associated ventricular arrhythmias[16]. A safe alternative treatment is terlipressin (vasopressin analogue) which so far has shown promising results.

Several studies have confirmed that terlipressin combined with albumin achieves acceptable GFR and it almost normalizes the plasma creatinine levels in 42% to 77% of cases[17-20]. The aim of the current review is to evaluate the recent developments made in the pathogenesis of HRS and the role of terlipressin, including its possible mechanism of it action.

PATHOGENSIS OF HRS

The etiopathogenesis of HRS has not been fully resolved and there are possible theories to explain it at a cellular and molecular level. The defining feature of HRS is profound vasoconstriction of the renal vasculature due to inadequate blood flow to the kidneys[21-24]. The culmination of several factors leads to the development of HRS: (1) portal hypertension (PHT); (2) altered peripheral blood circulation; (3) activation of the sympathetic nervous system; and (4) the release of chemical mediators.

PHT AND NITRIC OXIDE

Over time, liver cirrhosis leads to structural changes at both a microscopic and macroscopic level within the hepatocytes. The pressure within the hepatic microcirculation becomes raised and the so-called sinusoidal PHT occurs[25]. Furthermore, this is complemented by the ongoing changes taking place within the myofibroblasts, stellate cells and portal venules which all contribute towards the development of increased resistance to portal blood flow[26,27]. Most research on animals has suggested 2 possible theories to explain the development of PHT: (1) "forward theory" - this theory puts forward that PHT arises as a direct consequence of increased resistance to portal inflow; and (2) "backward theory" which proposes that PHT occurs due to high portal blood inflow because of a hyperdynamic circulation[28,29]. Furthermore, it is insinuated that this abnormally high portal blood inflow sustains the PHT[30].

In spite of the etiology of PHT, some of the portal venous blood gets redirected *via* collaterals vessels and this is partially to take pressure off the portal system[31]. Gradu-

ally, with persistent PHT, local and systemic changes occur; neurohormonal systems are activated and locally produced vasoactive substances such as nitric oxide are released[32]. Other locally acting vasodilatory substances released include carbon monoxide and prostacyclin[33]. Nitric oxide however is widely believed to be one of the main culprits for initiating the splanchnic arterial vasodilation[34].

In animal models nitric oxide has been shown to play an important role in vascular tone and splanchnic vasodilation[35,36]. In other animal studies, it is postulated that the production of nitric oxide may be related to bacteria stimulating macrophages which in turn induce nitric oxide synthase (NOS)[37-39]. NOS is an enzyme that forms nitric oxide from L-arginine, which is found throughout the body in numerous different types of cells. In addition, NOS has been shown to have 3 isoforms which are NOS I - neuronal NOS (nNOS), NOS Ⅱ - inducible NOS (iNOS) and NOS Ⅲ - endothelial NOS (eNOS)[40-42].

Isoform nNOS is primarily found in the central nervous system and it has been shown to have a key role in controlling blood pressure. Several studies on rats have demonstrated that by inhibiting this isoenzyme it generates increased sympathetic activity with ensuing tachycardia, and hypertension[43-45]. Conversely, iNOS is present in humans in several tissues including hepatocytes and alveolar macrophages; its release is induced by several cytokines including interleukin 1, interferon γ, tumor necrosis factor and lipopolysaccharides[46,47]. Finally eNOS, as the name suggests, is predominantly found in endothelial cells in humans in both arterial and venous vessels[48,49]. In the literature, eNOS has been shown to be involved in the peripheral arterial vasodilation that occurs in HRS and there are raised levels of eNOS in the circulation[48]. Overall eNOS has an important role in maintaining sympathetic vascular tone and can be synthesized within the endothelium in response to stimuli.

HYPERKINETIC CIRCULATION AND COMPENSATORY MECHANISM

The hemodynamic changes that develop in cirrhosis in the splanchnic circulation have been studied extensively, and only slow progress has been made in determining its pathophysiology. A number of plausible theories have been postulated in the last 2 decades based on both *in vitro* and *in vivo* studies. Hyperdyanamic circulation is a phenomena that happens over a period of time as a direct consequence of long standing PHT (Figure 1)[50]. The hallmarks of this circulatory dysfunction are tachycardia, increased cardiac output and abnormally low peripheral vascular resistance with decreased arterial blood pressure[31].

Hyperkinetic circulation develops in several steps: (1) splanchnic and peripheral vasodilation; (2) an increase in total blood volume with inadequate circulating volume; (3) increased cardiac output; and (4) the activation of a compensatory mechanism. Initially there is pooling of blood in the splanchnic vasculature due to PHT and this causes decreased circulatory volume.

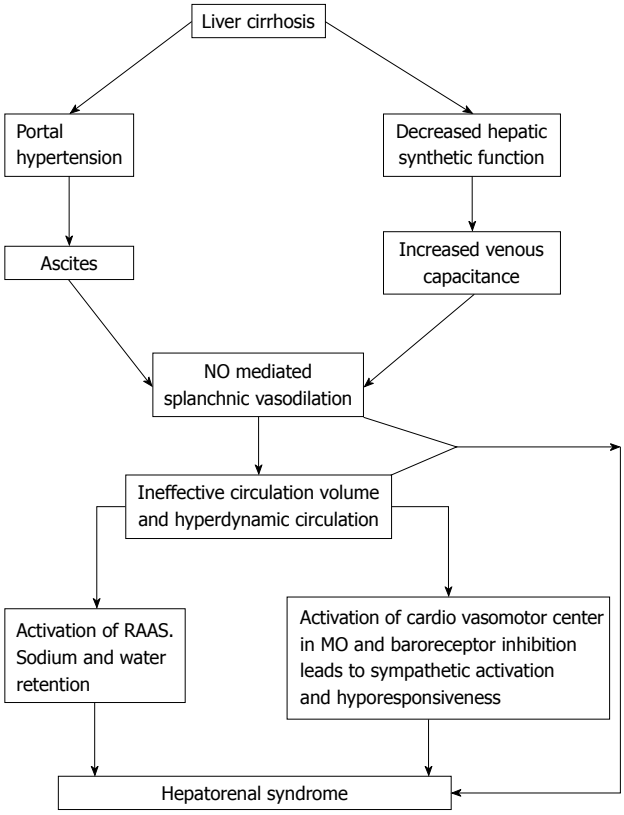

Figure 1 Flow chart showing the vicious cycle that develops with decompensated liver cirrhosis and the serious of events that lead to hepatorenal syndrome. NO: Nitric oxide; RAAS: Renin angiotensinogen aldosterone system; MO: Medulla oblongata.

One of the earliest indicators of a hyperdynamic circulation is the redistribution of blood volume into the splanchnic circulation. This event has been demonstrated in Doppler ultrasonography studies in which patients with cirrhosis had remarkably high splanchnic blood flow when compared to normal subjects[51]. The development of increased blood flow to splanchnic circulation and the pooling of blood produce a decreased circulating volume that triggers neurohormonal responses.

SYMPATHETIC NERVOUS SYSTEM, CARDIAC OUTPUT AND THE BARORECEPTORS REFLEX

A low circulating volume (low blood pressure) is detected by the baroreceptors or pressoreceptors located mainly in the internal carotid artery (carotid sinus) and ascending aorta. They are also found in small quantities in the wall of almost every large artery in the neck and thorax[1]. These are pressure sensitive receptors which are physiologically inactivated when the aforementioned arteries become less stretched as a result of low blood pressure (Figure 1)[52]. Consequently, the carotid and aortic baroreceptors signal conduction to the cardio and vasomotor regulatory centers in the medulla oblongata, *via* the glossopharyngeal and vagus nerves, respectively, is subdued. Thus, the cardio-

vasomotor regulatory centers become more active and sequentially induce the sympathetic nervous system to become active while suppressing parasympathetic (vagus nerve) stimulation to the heart. The sympathetic nervous system through the cardiac accelerator nerve increases the heart rate and cardiac output. Furthermore, the adrenal medulla, under the influence of the sympathetic nervous system, releases both adrenaline and noradrenaline. This eventually leads to an increase in mean arterial pressure through increased cardiac output and peripheral vascular resistance by acting on adrenergic receptors. The sympathetic response is further augmented by the activation of the RAAS and the release of vasopressin[53]. Unfortunately, those complex neurohormonal compensatory responses to low blood pressure are temporary and the whole system that comprises the baroreceptors, RAAS and vasopressin becomes adapted and mal-responsive to the low circulating volume stimulus within 48-72 h[4]. Consequently all the above outlined responses are reversed resulting in profound hypotension, renal hypoperfusion and worsening renal failure.

RENIN ANGIOTENSIN ALDOSTERONE SYSTEM

Arterial hypotension and reduced blood flow to the kidney results in decreased sodium delivery to the macula densa which in turn causes the release of renin from the juxtaglomerular apparatus[54]. The renin release is the rate determining step for the activation of the RAAS. The activation of RAAS causes sodium and water reabsorption and vasoconstriction of the renal arteries (Figure 1)[55]. These compensatory mechanisms maintain effective circulation in the early stages of the disease (compensated) but with time their effects eventually become deleterious and lead to the development of complications. These include ascites, hyperkinetic circulation, nitric oxide release, renal failure, and increased venous capacitance with decreased venous compliance. Essentially all these culminate to form the bases of HRS[55].

Liver cirrhosis has been shown to be associated with activation of RAAS but also an increase in vasopressin secretion[56]. The activation of RAAS may contribute to decreased renal perfusion[56]. Importantly, albumin administration has been shown to be associated with a decrease in plasma renin level[57]. In contrast, administration of vasopressin does not substantially change renal perfusion, though it induces splanchnic vasoconstriction[57]. This may explain the potential benefit of administration of vasopressin and its analogues in HRS. The progression of PHT is associated with an increase in vasodilation of the splanchnic circulation and marked resistant to vasopressin. It is likely that further research is needed to address the interaction between RAAS and vasopressin.

In addition, the activation of the RAAS has an important role in hemodynamic regulation in the liver as well as proliferation of vascular smooth muscle cells and fibrosis through 2 well coordinated complementary pathways: (1) vasoconstriction/proliferative pathway, incorporating the angiotensin converting enzyme (ACE), angiotensin (Ang) Ⅱ-Ang Ⅱ type 1 (AT1) receptor; and (2) a counter- regulatory vasodilatation/antiproliferative pathway, involving ACE2-Ang-(1-7)-Mas receptor[58]. It is important to point out that the ACE, vasoconstriction/proliferation pathway induces contraction and proliferation of hepatic stellate cells, which lead to fibrosis[58]. In contrast, activation of ACE2-Ang-(1-7) is not only associated with liver cirrhosis-induced splanchnic and systemic vasodilatation but also anti-fibrotic effects[58].

Vilas-Boas *et al*[59] suggested that the administration of a combination of propranolol and ACE inhibitor or AT1 receptor blocker may have potential benefit in cirrhotic patients. Furthermore, administration of propranolol *per se* has been shown to be associated with unfavorable consequences on the 2 main RAAS components, Ang Ⅱ and Ang(1-7), in the splanchnic and peripheral circulation[59]. In contrast, inhibition of RAAS by ACE inhibitors and AT1 receptor blockers has been shown to be associated with potential benefit in slowing progression of liver fibrosis and even cardiac and renal fibrosis[60].

Interestingly, it has been hypothesized that the effect of Ang Ⅱ dominates in advanced liver disease while the effect of Ang(1-7) dominates in moderate liver disease[61]. Therefore, the RAAS can be viewed as a dual system that leads to vasoconstriction, fibrosis, vasodilatation and antifibrosis. However, further research is urgently needed to establish a therapeutic benefit of the dual function of the RAAS in targeting liver disease and preventing fibrosis in humans and, in particular, in the management of HRS.

DETRIMENTAL EFFECTS OF THE SYMPATHETIC NERVOUS SYSTEM AND RAAS

These wonderful compensatory mechanisms with prolonged activation result in even more increased sodium and water retention with a subsequent increase in total circulatory volume. RAAS, with its overall effect of salt and fluid retention contributes to the development of ascites usually in the presence of PHT. In addition, splanchnic vasodilation appears to be one of main culprits in the formation of ascites[50]. Ascites develops when there is increased sinusoidal pressure which forces fluid to leak into the abdominal cavity[1]. Ascites further fuels the constant activation of the RAAS and the sympathetic nervous system which fail to maintain effective circulating volume.

The lack of response to neurohormonal mechanisms in the latter stages of cirrhosis may be due to several factors: (1) nitric oxide-mediated pooling of blood in splanchnic vascular bed; (2) hyporesponsiveness of splanchnic vasodilation to neurohormonal mechanism; (3) ascites; and (4) downregulation of receptors.

Eventually the pooled blood in the splanchnic circulation cannot be utilized fully in the presence of ineffective

circulation. This is on account of the fact that the reservoir of blood in the splanchnic circulation continues to increase and is mediated by locally-produced nitric oxide. A recent study by Li *et al*[62] demonstrated that nitric oxide caused changes in mesenteric venous capacitance and increased pooling of blood in rats with liver cirrhosis. In this study it was shown that the cirrhotic rats had a nitric oxide-mediated increase in venous capacitance and decrease in compliance. Nitric oxide is produced locally by eNOS which is activated by the high shear stress in the splanchnic vascular endothelium, which is caused by the increased splanchnic blood flow. In both animal and human studies, nitric oxide appears to be the main orchestrator of the splanchnic vasodilation that facilitates the pooling of blood[63,64], *via* its direct action on the vascular smooth muscles.

Additionally, it is widely accepted that nitric oxide antagonizes the sympathetic and RAAS-driven vasoconstriction thus inducing vasodilatation of the splanchnic vascular bed. Accordingly, ineffective circulation continues to trigger neurohormonal responses, though in the latter stages of the disease there is hyporesponsiveness to these compensatory mechanisms. In the early stages of compensated liver cirrhosis, the neurohormonal activation is able to overcome the splanchnic vasodilation and maintain an acceptable circulating volume. However with decompensated liver cirrhosis; and increased PHT, the hyporesponsiveness is often an indicator of progression towards the end stage.

It is suggested that the hyporesponsiveness may be due to desensitization and downregulation of adrenergic receptors. In cirrhotic rats there appears to be β-adrenergic receptor hyporesponsiveness to catecholamines[65]. This concept is not new; previous studies looking at heart failure have shown that prolonged activation of the neurohormonal response leads to a downregulation of β-adrenergic receptors[66]. The hyporesponsiveness of the myocardium to catecholamine stimulation that is seen in cirrhosis is termed cirrhotic cardiomyopathy[67].

FUNCTIONAL RENAL FAILURE

The renal system, through autoregulation, maintains a physiologically acceptable GFR over a range of blood pressures. Autoregulation consists of myogenic and neurohormonal responses. The development of a hyperkinetic circulation results in renal hypoperfusion despite increased total circulating volume. Initially with low blood pressure, the kidneys respond with smooth muscle contraction in the vessels (myogenic response), which helps to maintain the perfusion pressure[1]. This response alone is not adequate, therefore the sympathetic nervous system and RAAS are activated and subsequently lead to renal vasoconstriction. The peripheral vasodilatation that occurs is perceived by the kidneys as a hypovolemia, that continues to promote renal vasoconstriction. The resultant effect is reduced GFR, oligo-anuria, raised plasma creatinine and the development of hepatorenal failure[2].

Renal biopsies in HRS patients have shown remarkably normal renal histology architecture despite the dismal renal function. The findings have led to the term "reversible functional renal failure" being coined[22]. The primary problem causing renal failure is liver cirrhosis and this functional renal failure can be reversed with liver transplantation. Kidney transplants from palliated patients with HRS into those with intrinsic renal failure, have remarkably been show to have reversed to normal renal function[68,69]. This further supports the concept of reversibility of functional renal failure in patients with HRS. The definitive treatment for HRS is liver transplantation; however with increasing shortages of organ donation and with long waiting lists, patients are more often than not succumbing to the dismal prognosis of HRS. Nevertheless treatment with vasopressin analogues, in particular terlipressin, has been shown to reverse the renal failure and can be used as a bridge to definitive treatment (liver transplant).

TERLIPRESSIN AS POTENTIAL TREATMENT FOR HRS

Terlipressin, an analogue of vasopressin, is used as potential treatment of HRS. In this review we focus on clinical trials and their strengths and weaknesses. It is worth mentioning that in the majority of these studies, terlipressin was used in combination with albumin. Furthermore, other trials compared the effect of terlipressin with noradrenaline. We included clinical trials with evidence-based medicine. Hence, the subsequent discussion will focus on the impact of terlipressin *vs* placebo and terlipressin *vs* noradrenaline with and without albumin.

Terlipressin and clinical trials

Terlipressin (without albumin) *vs* placebo: Hadengue *et al*[70] carried out a double-blind, crossover, randomized study in 9 patients with type 1 HRS. The patients received terlipressin (2 mg/d for 2 d) and a placebo for 2 d in a randomized order. Terlipressin administration significantly increased creatinine clearance and urine output, but did not significantly change urinary sodium concentration. Urinary sodium excretion was not significantly different after placebo administration or terlipressin administration. Terlipressin administration significantly decreased plasma concentrations of renin and aldosterone but not atrial natriuretic peptide levels, and these biochemical changes were not seen in the placebo group. The study by Solanki *et al*[19] was a randomized, controlled, single-blind trial. They assigned 24 consecutive patients with HRS to treatment with terlipressin 1 mg iv at 12 h intervals (group A, $n = 12$) or placebo at 12 h intervals (group B, $n = 12$). The end-point of the study was improvement in renal function defined as reversal of HRS and survival at 15 d. Terlipressin administration was shown to be associated with an improvement in parameters of renal function, mean arterial blood pressure and importantly reversal of HRS in 5 of the 12 patients in group A.

Table 1 Summary of effect of terlipressin associated with albumin on hepatorenal syndrome

Study	Main outcome
Sanyal *et al*[72], 2008	Terlipressin administration with albumin shown to be associated with improvement in renal function and appeared superior to placebo in reversing type 1 HRS
Martín-Llahí *et al*[73], 2008	Terlipressin administration with albumin shown to be associated with improvement in renal function in patient with liver cirrhosis and type 1 HRS, without significant impact on 3-mo survival
Neri *et al*[74], 2008	Terlipressin administration with albumin shown to be associated with improvement in renal function in patients with type 1 HRS and also a high probability of survival
Uriz *et al*[17], 2000	Terlipressin associated with albumin appeared to be a safe and effective treatment of HRS and decreased the frequent ischemic complications associated with terlipressin treatment alone. Terlipressin associated with albumin therapy was associated with marked improvement in renal function, reversal of HRS and improvement in circulatory function with an increase in mean arterial blood pressure

HRS: Hepatorenal syndrome.

Interestingly, Testro *et al*[71] reviewed outcomes of 69 patients treated with terlipressin between 2001 and 2005. Their findings showed that 49 episodes (71%) of HRS were type 1, and 20 episodes (29%) were type 2. Forty-one (59.4%) patients responded to terlipressin. Twenty-one (30.4%) patients survived; 17 (81%) had type 1 HRS while 4 (19%) had type 2 HRS ($P = 0.27$). The only factor predicting transplant-free survival was type 1 HRS. No patients with type 2 HRS survived without transplantation ($P = 0.02$). These trials clearly showed the potential benefit of administration of terlipressin in individuals with HRS. However, Terlipressin administration was associated with minimal reversible ischemic events e.g. crampy abdominal pain and cardiac arrhythmias. We suggest that randomized clinical trials are now warranted.

Terlipressin (with albumin) *vs* placebo: Interestingly, concomitant administration of terlipressin and albumin is shown to be associated with better clinical outcomes. A summary of studies that used terlipressin (with albumin) *vs* placebo is provided in Table 1.

Terlipressin *vs* noradrenaline: The use of noradrenaline, a cheap and widely available drug, in the management of HRS was shown to be as effective as terlipressin but associated with increased risk of ischemic events. Data from an unblinded, pilot study suggested that noradrenaline was as effective and safe as terlipressin in patients with HRS. Twenty-two consecutive cirrhotic patients with HRS (9 with type 1 HRS; 13 with type 2 HRS) were randomly assigned to treatment with noradrenaline (0.1-0.7 μg/kg per minute) and albumin (10 patients) or with terlipressin (1-2 mg/4 h) and albumin (12 patients). Treatment was administered until HRS reversal or for a maximum of 2 wk. Reversal of HRS was observed in 7 of the 10 patients (70%) treated with noradrenaline and in 10 of the 12 patients (83%) treated with terlipressin. Treatment led, in both groups, to a significant improvement in renal and circulatory function; no patient developed signs of myocardial ischemia[75]. Sharma *et al*[76] reported similar beneficial results in treating HRS with noradrenaline, however, they also reported that 2 patients had ventricular ectopies with noradrenaline. We suggest that further studies are urgently needed to evaluate the use of noradrenaline as potential treatment for HRS.

Terlipressin and meta-analyses

Several meta-analyses have been conducted to determine the effect of terlipressin in HRS with regard to the duration of treatment, infusion of albumin and comparison with noradrenaline. Dobre *et al*[77] concluded in their meta-analysis that terlipressin administration was associated with improvement in HRS reversal and that noradrenaline has the same effect as terlipressin in improving surrogate markers of HRS. Sagi *et al*[11] showed that the risk ratio for reversal in type 1 HRS with terlipressin therapy was 3.66 [95% confidence interval (CI): 2.15-6.23]. Recurrence of HRS was low (8%). Serious side effects requiring discontinuation of therapy were seen only in 6.8% of patients on terlipressin therapy. There was a trend towards improved transplant-free survival at 90 d in the Terlipressin group (relative risk 1.86, 95% CI: 1.0-3.4, $P = 0.05$). The conclusion of their meta-analysis was that terlipressin is effective in reversing HRS type 1 and recurrence of HRS is rare with at least 14 d of therapy and associated with an increased survival. Importantly, Fabrizi *et al*[78] showed in their meta-analysis that discontinuation of terlipressin therapy was associated with a significant increase in the number of relapses. Furthermore, Fabrizi *et al*[79], in another meta-analysis, showed that terlipressin was more effective in reversing HRS than placebo without apparent impact of terlipressin on survival in HRS patients. This may again suggest the need for large clinical trials addressing the impact of terlipressin in HRS patient survival. Interestingly, administration of albumin with terlipressin showed a reduction in mortality in type 1 HRS[10]. Therefore, the current evidence suggests that terlipressin can have a potential benefit in treating HRS and that an improvement in survival can be achieved with its concomitant administration with albumin.

CONCLUSION

HRS continues to be a challenging task to manage following chronic liver cirrhosis. The grave prognosis and the short survival times have fuelled great interest in clinical

trials; its reversibility creates scope for prolonging both survival and quality of life. The current literature reviewed has further re-enforced terlipressin as a potential first-line treatment in HRS**.** Terlipressin has so far shown to increase survival rates and reverse functional renal failure. The increased neurohormonal response, especially of the RAAS, has been decreased with the administration of terlipressin. This subsequently improves circulatory dysfunction and lowers plasma creatinine levels near to baseline values. The effects of nitric oxide, which is a factor in the deleterious neurohormonal response, appears to be overcome by the administration of terlipressin through unknown mechanisms.

In addition, terlipressin has few adverse side effects, which allows patients to continue with treatment in order to achieve desirable effects. At present however, we acknowledge that there are a limited number of randomized, controlled studies carried out on terlipressin and therefore there is a real need for large multi-centered trials to be carried out. We recommend that terlipressin, with concomitant administration of albumin, may be the first line treatment in the management of HRS.

Abstract

Liver is unique in its capacity to regenerate in response to injury or tissue loss. Hepatocytes and other liver cells are able to proliferate and repopulate the liver. However, when this response is impaired, the contribution of hepatic progenitors becomes very relevant. Here, we present an update of recent studies on growth factors and cytokine-driven intracellular pathways that govern liver stem/progenitor cell expansion and differentiation, and the relevance of these signals in liver development, regeneration and carcinogenesis. Tyrosine kinase receptor signaling, in particular, c-Met, epidermal growth factor receptors or fibroblast growth factor receptors, contribute to proliferation, survival and differentiation of liver stem/progenitor cells. Different evidence suggests a dual role for the transforming growth factor (TGF)-β signaling pathway in liver stemness and differentiation. On the one hand, TGF-β mediates progression of differentiation from a progenitor stage, but on the other hand, it contributes to the expansion of liver stem cells. Hedgehog family ligands are necessary to promote hepatoblast proliferation but need to be shut off to permit subsequent hepatoblast differentiation. In the same line, the Wnt family and β-catenin/T-cell factor pathway is clearly involved in the maintenance of liver stemness phenotype, and its repression is necessary for liver differentiation during development. Collectively, data indicate that liver stem/progenitor cells follow their own rules and regulations. The same signals that are essential for their activation, expansion and differentiation are good candidates to contribute, under adequate conditions, to the paradigm of transformation from a pro-regenerative to a pro-tumorigenic role. From a clinical perspective, this is a fundamental issue for liver stem/progenitor cell-based therapies.

INTRODUCTION

Liver is unique in its capacity to regenerate in response

to injury or tissue loss. Following two-thirds partial hepatectomy, hepatocytes exit the G0 phase of the cell cycle and synchronously re-enter the cell cycle to regenerate the liver mass completely in 6-7 d in rodents, or 3-4 mo in humans[1-4]. Liver stem/progenitor cells do not seem to be required for this process. However, when this response is impaired, as in the case of a hepatocyte-selective proliferative defect or acute liver failure, the contribution of liver progenitors becomes much more relevant[5,6]. A population of small cells with a low cytoplasmic/nuclear ratio that arose from a small number of portal cells, not from hepatocytes, were first observed in rodents and became known as "oval cells"[7,8]. Although several lines of evidence suggest that oval cells derive from the biliary compartment, other origins have been also suggested[4].

Significant work in the past few years has focused on the signaling pathways, as well as cell-cell interactions, that control the initial proliferation/expansion and the terminal differentiation of liver stem/progenitor cells. Oval cells express MET, the receptor of the hepatocyte growth factor (HGF). The superabundance of HGF-producing cells in the immediate vicinity of oval cell proliferation and differentiation suggests that this growth factor is involved in all aspects of stem cell behavior, proliferation, migration, and differentiation, through a paracrine mechanism[9]. Oval cells also express receptors for epidermal growth factor (EGF)-like ligands, and *in vivo* infusion of a combination of HGF and EGF enhance the mitogenic response of oval cells after administration of 2-acetylaminofluorene[10], which reveals the relevance of both growth factors in liver stem/progenitor cell biology. Additionally, different studies have revealed that oval cells also respond to other growth factors in an autocrine/paracrine manner[11]. The transforming growth factor (TGF)-β family of cytokines play a relevant role in the maintenance of embryonic stem cell identity, and it has been shown that the specification of pancreas and liver progenitors is restricted by the TGF-β pathway[12]. All these growth factors and cytokines might modulate not only proliferation of liver stem/progenitor cells, but also cell death, as well as contributing to their terminal differentiation.

This review gives an update on recent relevant studies of the growth factors and cytokine-driven intracellular pathways that govern liver stem/progenitor cell expansion and differentiation, and the relevance of these signals in liver development, regeneration and carcinogenesis.

TYROSINE KINASE RECEPTOR-MEDIATED SIGNALING PATHWAYS

HGF

HGF was firstly identified in the 1980s as a potent mitogen for hepatocytes[13-15]. A factor secreted by fibroblasts and smooth muscle cells was discover separately, which promoted epithelial cell scattering[16]. Later studies unraveled that HGF and scatter factor were indistinguishable[17,18]. HGF is a growth factor that induces a wide range of biological activities, including stimulation of proliferation, migration, morphogenesis, and survival of a variety of cell types[19-24], which plays a major role in tissue formation and homeostasis. HGF acts through binding to its tyrosine kinase receptor, Met. Ligand-receptor binding results in autophosphorylation of the receptor in specific tyrosine residues located in the C-terminal domain, and subsequent phosphorylation/activation of multiple adapter and signal transducing proteins, such as growth factor receptor-bound protein 2 (Grb2)/Sos, Ras-mitogen-activated protein kinase, Grb2-associated binding protein 1 (Gab1), phosphoinositide 3-kinase (PI3K), phospholipase C-γ, p38, and signal transducer and activator of transcription (STAT)-3, among others, which mediate the biological activities of HGF/c-Met[25,26]. For decades, HGF has been recognized as a growth factor involved in the hepatocyte proliferative response during liver regeneration (a recent review on the role of HGF in liver regeneration can be found in[3]), but an unequivocal demonstration of an essential role of the HGF/c-Met signaling in liver regeneration has only been provided recently. Thus, liver specific c-Met and HGF conditional knock-out mice show an impairment of the regenerative response[27-29]. Hepatocytes that lack a functional c-Met display reduced basal survival and a higher sensitivity to Fas-induced liver damage, both *in vivo* and *in vitro*. Moreover, after toxic liver injury induced by exposure to CCl_4, c-met$^{-/-}$ livers showed delayed healing from necrotic injury[28]. Complete abolition of the cell cycle has also been demonstrated when c-Met is deleted after partial hepatectomy, by using RNA interference techniques[30]. In addition to the effects on proliferation, these authors have described an alteration in expression of apoptosis-related genes, particularly, increased expression of pro-apoptotic genes, and decreased expression of anti-apoptotic genes, and enhanced activation of caspase 3. Altogether, these studies provide clear evidences of a role for this ligand/receptor system in promoting hepatocyte proliferation, survival, and tissue remodeling during liver regeneration.

HGF/c-Met signaling is also essential during fetal liver development. Both HGF- and c-Met-deficient embryos show abnormally small livers and liver-to-body weight ratios and massive hepatocyte apoptosis[31-33]. Recent studies from Dr. Maina's laboratory have demonstrated HGF/c-Met survival properties in primary embryonic hepatocytes, as shown by the ability of HGF to impair Fas-induced apoptosis by acting through PI3K and AKT to prevent FLICE inhibitory protein degradation[34]. Additionally, in the context of the adult liver, numerous works have reported an important contribution of the pro-survival activity of HGF in protecting liver during fibrosis and other hepatic dysfunction[35-40], thus expanding the scenarios in which the anti-apoptotic activity of HGF plays an active role.

Although hepatocytes have long been considered the prime target of the actions of HGF, there is accumulating evidence of an important role for HGF/c-Met signaling on liver stem/progenitor cell function and behavior. Liver stem/progenitor cells express c-met[41]. Furthermore,

during oval cell activation induced by N-acetyl-2-aminofluorene/partial hepatectomy (AAF/PH) in rats, HGF expression increases coincidentally with oval cell proliferation, mainly on the periportal regions where oval cells are located[9,41]. These data suggest that the HGF/c-Met system regulates some aspects of liver stem/progenitor cell biology. In support of this, *in vivo* infusion of HGF during AAF/PH-induced liver regeneration stimulates oval cell expansion into the liver lobules[10]. Similar results have been obtained by *in vivo* transfer of HGF cDNA into liver subjected to the Solt-Farber regime[42]. HGF-dependent mitogenic activity has also been shown in rat and mouse oval cell lines *in vitro* by either adenovirus-mediated transfer of the HGF gene or addition of exogenous HGF[43-46]. The molecular mechanisms that mediate the mitogenic effects of HGF in liver progenitors appear to be cell-type specific, because PI3K/AKT activation[43] and nuclear factor-κB activation, downstream of p38 and extracellular signal-regulated kinase (ERK) MAPKs[44], are involved. Additionally, bi-potential hepatoblast cell lines (precursors of both hepatocytes and cholangiocytes) have been established from transgenic animals expressing a constitutively active human Met[47]. However, HGF is much more than a mitogen for liver stem/progenitor cells. HGF effectively protects WB-F344 cell from apoptosis induced by tumor necrosis factor-α in a dose-dependent manner[44]. More recently, using a novel *in vitro* model of genetically modified oval cells that harbor an inactivated Met tyrosine kinase, we have demonstrated that loss of Met increases sensitivity to apoptosis caused by serum deprivation or treatment with TGF-β[46]. By virtue of these results, we hypothesize that Met-driven anti-apoptotic activity plays an important role supporting the expansion of liver progenitors following liver injury, by helping them to overcome the local tissue injuries and inhibitory signals. Therefore, the HGF/c-Met signaling pathway might be a major survival pathway in liver that operates during liver development, homeostasis, and regeneration (both hepatocyte and oval cell-mediated).

The role of HGF as a morphogen is already established[48]. Morphogenesis is a complex invasive growth program that plays a fundamental role in normal development[49,50]. Not surprisingly, morphogenic properties of HGF are exhibited in embryonic and postnatal mouse non-parenchymal epithelial cell-derived cell lines. In these cells, HGF induces a morphogenic response that includes cell scattering and ductal branching in collagen gels. These changes are not observed by treatment with other liver growth factors including EGF, TGF-β, acidic fibroblast growth factor (aFGF) and insulin, and are not inhibited by TGF-β[51]. A similar response has also been described in pancreatic oval cells *in vitro*; a cell population closely related to its hepatic counterpart[52]. Recently, HGF has been directly involved in promoting motility and invasiveness of human liver progenitor cells through Matrigel; an effect that is partially mediated by matrix-metalloproteinase-mediated extracellular matrix (ECM) proteolytic degradation and activation of the MAPK/ERK pathway[53].

Another important biological activity of HGF in liver progenitor cells that cannot be overlooked is its modulatory effect on the differentiation capacity of these cells. HGF has been reported to be required not only for an efficient proliferation and survival, but for hepatocytic differentiation of embryonic hepatic stem cells *in vitro*[54-57]. Furthermore, virtually all the strategies for *in vitro* differentiation of embryonic and adult stem/progenitor cells of different origin into hepatocytes include HGF as a hepatic-inducing factor (a thorough compilation of *in vitro* differentiation methods is found in[58]). Successful differentiation is generally achieved by step by step addition of growth factors, cytokines, and hormones, trying to emulate the sequence of events taking place during *in vivo* hepatogenesis. The requirement of HGF in this process relies on the specific role played by this growth factor at different liver developmental stages. During the commitment phase, HGF might antagonize differentiation of bipotential hepatoblasts along the cholangiocytic lineage, which results in support of growth and differentiation of fetal hepatocytes[59]. In fact, results from Suzuki *et al*[57] have demonstrated that HGF can initiate differentiation of albumin-negative liver stem cells into albumin-positive hepatic precursors at the same time that allows their expansion and decreases expression of cholangiocyte-lineage markers, such as CK19 or γ-glutamyl transferase, but it cannot induce latter markers of hepatocyte differentiation, such as glucose-6-phosphatase or tryptophan-2,3-dioxygenase.

Later, after birth, the expression of both HGF and c-Met significantly increases in the liver, and activation of this pathway crucially assists during complete functional hepatic maturation[41,60]. We have also described that HGF combined with TGF-β helps to maintain the expression of hepatocyte differentiation markers in rat fetal hepatocytes in culture[61,62]. In rat primary neonatal hepatocytes, HGF promotes scattering, but this effect is not associated with a dedifferentiation process, as shown by an increase in the expression of hepatic differentiation markers using HGF treatment[63,64]. Although a role for HGF in hepatocyte differentiation seems to be beyond reasonable doubt, it should be pointed out that HGF has also been directly implicated in transdifferentiation of hepatocytes to biliary epithelial cells[65]. These data highlight the enormous complexity in terms of signaling networks and molecular mechanisms associated with regulation of phenotypic transitions in liver epithelial cells.

All these results provide sufficient evidence to support a crucial role for an HGF/c-Met-induced signaling pathway in liver stem/progenitor cell biology. What it is not totally clear, however, is its mode of action. HGF is mainly produced by mesenchymal cells, and c-Met is expressed in epithelial cells, therefore, this ligand-receptor system is generally considered to act in a paracrine fashion[66]. Consistent with this, the main producers of HGF in the liver are the stellate cells[67,68], although sinusoidal endothelial cells also express HGF[69]. c-Met is expressed in hepatocytes, biliary epithelial cells, and liver progenitor cells[41,54,70,71]. As men-

tioned above, in rat models of oval cell activation *in vivo*, HGF mRNA has been identified in the desmin-positive stellate cells that surround the ductal structures of oval cells, or interspersed with the oval cells, whereas c-Met expression is detected in oval cells[9,41]. These results have prompted the conclusion that the HGF/c-Met system operates in oval cells *via* a paracrine mechanism. However, *in vitro* studies carried out in our laboratory in oval cell lines have shown an autocrine regulatory mechanism for HGF/c-Met involved in protection against apoptosis[46]. Whether the autocrine regulation plays a role *in vivo* has not been explored, but these data suggest that oval cells might respond to both autocrine and paracrine Met signaling in a context-dependent fashion.

EGF receptor ligands

Another tyrosine kinase receptor family that regulates liver pathophysiology is the EGF receptor (EGFR) family. This receptor is part of a complex signaling system that includes multiple ligands, namely TGF-α, EGF, heparin-binding EGF, amphiregulin, betacellulin, epiregulin, epigen, and crypto; and four transmembrane receptors: EGFR (Her1/ErbB-1), ErbB-2 (Her2/neu), ErbB-3 (Her3), and ErbB-4 (Her4). Complexity of this pathway relies on differential ligand binding affinity to the receptors, as well as formation of receptor homo- and heterodimers, all of which leads to activation of distinct intracellular signaling cascade and diverse biological activities. Among all the ligands, TGF-α and EGF are the most widely studied. Both TGF-α and EGF bind and activate the same receptor, EGFR. Ligand binding results in dimerization and autophosphorylation of EGFR in tyrosine residues of the cytoplasmic domain. This leads to recruitment of adapter proteins, such as Grb2 and Shc, and subsequent activation of multiple downstream pathways, including PI3K, Ras-MAPK, c-Jun N-terminal kinase, p38, protein kinase C and STAT-3, which mediate cell proliferation, migration, differentiation and evasion from apoptosis[72-76]. TGF-α and EGF are well-known regulators of hepatocyte proliferation. Infusion of either one of the two factors initiates DNA synthesis in liver of adult rats[77,78], and when added exogenously, they stimulate growth of primary hepatocytes at all developmental stages: fetal, neonatal, and adult[79-82]. Together with HGF, EGFR ligands represent the only complete mitogens in adult hepatocytes in serum-free medium, and the most important growth factors involved in the proliferative response during liver regeneration[3]. Demonstration of a critical role for EGFR in hepatocyte proliferation during the initial phases of liver regeneration has recently been provided by generating mice with a liver-specific EGFR deficiency[83]. In addition to the regulatory role in proliferation, and similarly to Met, EGFR is a major survival pathway in the liver[84]. EGF-mediated EGFR activation is able to abolish completely the apoptotic response induced by TGF-β in fetal rat hepatocytes[62] or by Fas receptor stimulation in mouse hepatocytes[85]. Furthermore, EGFR ligands appear to be important modulators of hepatocyte differentiation as well. Morphological and gene expression studies from our laboratory and collaborators have shown that EGF, acting in cooperation with other cytokines and hormones, maintains primary fetal and neonatal hepatocyte differentiation[64,86,87].

Expression studies have suggested that ErbB1-triggered signaling also plays a role in stem/progenitor-cell-mediated liver regeneration. Indeed, both TGF-α and EGFR are transcriptionally upregulated during the period of active proliferation and differentiation of progenitor cells in the rat liver subjected to the 2-AAF/PH protocol[88], and they appear to drive the early proliferation of the progenitor cell compartment[89,10]. Although both HGF and EGF promote the expansion of oval cells *in vivo*, some differences are observed. HGF increased number of both ductal and Ito cells at a similar rate, whereas infusion of EGF mostly increases ductal cells. Our laboratory and others have also shown that EGF and TGF-α are mitogens in mouse and rat oval cells *in vitro*[11,46,90].

The effects of this signaling pathway on liver stem/progenitor cells are not restricted to mitogenesis. *In vivo* infusion with either EGF or HGF not only amplifies liver progenitor expansion following liver injury but also decreases apoptosis[10]. We also have evidence of an important role for EGFR-mediated signaling in regulating oval cell survival *in vitro*. Thus, inhibition of EGFR *via* treatment with a synthetic inhibitor increases basal apoptosis (in the absence of serum and exogenous stimuli) and strongly amplifies TGF-β-induced apoptosis (our unpublished results). EGFR-mediated motogenic, morphogenic, and differentiation activities have also been reported. EGF, combined with TGF-β, triggers a scattering response in mouse oval cell lines *in vitro*[11]. In addition to this, EGF is often included as a hepatogenic factor in strategies to induce *in vitro* differentiation of stem/progenitor cells into hepatocyte-like cells[58]. Consistently, TβT-FH cell lines - a cell population of fetal hepatocytes that has suffered an epithelial mesenchymal transition (EMT) and a dedifferentiation process after TGF-β treatment - recover the original epithelial phenotype and gain cytokeratin-19 expression by treatment with EGF and DMSO, which suggests conversion to hepatoblast-like cells[91].

It should be noted that we have seen autocrine regulation for EGFR-dependent signaling in oval cell lines (our unpublished results). Different to the HGF/c-Met system, an EGFR-ligand-mediated autocrine mechanism has been suggested, based on the detection of EGFR ligand transcripts in oval cells during liver regeneration[88]. *In vivo* and *in vitro* studies have shown that choline-deficient ethionine-supplemented diet-treated mouse livers express cytokines such as lymphotoxin-β, interferon-γ, and interleukin (IL)-6[92,93]. Collectively, these data strongly support that autocrine regulatory mechanisms are important in liver progenitor cells. The significance of the c-Met and EGFR autocrine loops in oval cells is not yet totally understood. Certainly, autocrine signaling has been mostly associated with malignancy. This seems to apply to stem/progenitor

cells as well, because tumorigenic conversion of mouse oval cell has been associated with growth factor production and alteration in growth factor responsiveness[11]. More specifically, an HGF/c-Met autocrine loop has been identified in spontaneously transformed WB-F344 rat liver stem-like cells, which contributes to drive autonomous cell proliferation[94]. Spontaneously transformed oval cells express TGF-α. These cells form tumors when injected into nude mice, a capacity that is significantly reduced by transfection with TGF-α antisense gene[95]. A cross-talk between Met and EGFR has also been proposed. Thus, rat liver-epithelial-cell-derived tumor cell lines that constitutively express TGF-α display increased levels of both c-met gene and protein, as well as an amplified response to HGF[96]. However, 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC)-treated mouse liver-derived oval cell lines, which show autocrine activation of Met and EGFR-dependent pathways, do not show any sign of transformation[46] (and our unpublished results). Whether this is due to a matter of time, dose, or lack of critical partners for the neoplastic transformation, it is not yet known. For now, awaiting further conclusive experiments, a direct link between the establishment of functional c-Met and EGFR-dependent autocrine loops and neoplastic transformation cannot be firmly established in liver progenitor cells.

All the data summarized above highlight not only a relevant role of Met and EGFR-triggered signaling pathways in regulating the liver progenitor cell compartment, but a striking parallelism between the two pathways, both of which mediate growth, survival, migration and hepatocytic differentiation (Figure 1). Further studies will clarify which of these biological activities are totally overlapping and which are not. In this sense, Met and EGFR mutant mice and cell models should provide very useful and invaluable tools in this regard.

FGFs

The FGFs are a family of growth factors with high affinity for heparan sulfate proteoglycans, which bind to transmembrane tyrosine kinase FGF receptors (FGFRs). The role of these growth factors in hepatic fate specification of pre-hepatic endoderm cells during liver development is well known. There are a number of excellent reviews on this subject, some of which are cited here[97-99]. Activation of adult stem/progenitor cells is believed to use similar, if not identical, genetic programs as the embryonic progenitors, therefore, FGF is among the main targets to be analyzed in rodent models of oval cell expansion. Indeed, aFGF (also known as FGF-1) is upregulated at the stage of oval cell progression[89,100], being expressed by both oval cells and Ito cells. FGFR1 and FGFR2 are also expressed at high levels during the period of active proliferation and differentiation of oval cells, but exhibit a different pattern. Although FGFR1 is mainly expressed in oval cells, FGFR2 is expressed in both oval and Ito cells[101]. These results suggest a differential role for these two receptors during liver stem/progenitor-cell-mediated regeneration, as well as the establishment of both autocrine and paracrine signaling. In addition to these *in vivo* observations, *in vitro* studies have shown that aFGF is able to push Met murine hepatocytes-bi-potential precursors isolated from transgenic livers, which express a constitutively active human Met - to progress from a very early state of differentiation to a more mature state, associated with the expression of liver functions[47]. Moreover, FGF1-pretreated cells are resistant to the TGF-β dedifferentiation effect[102]. Essentially, FGFs have proved to be effective in mediating early hepatic differentiation, and therefore are included in most *in vitro* differentiation protocols[58].

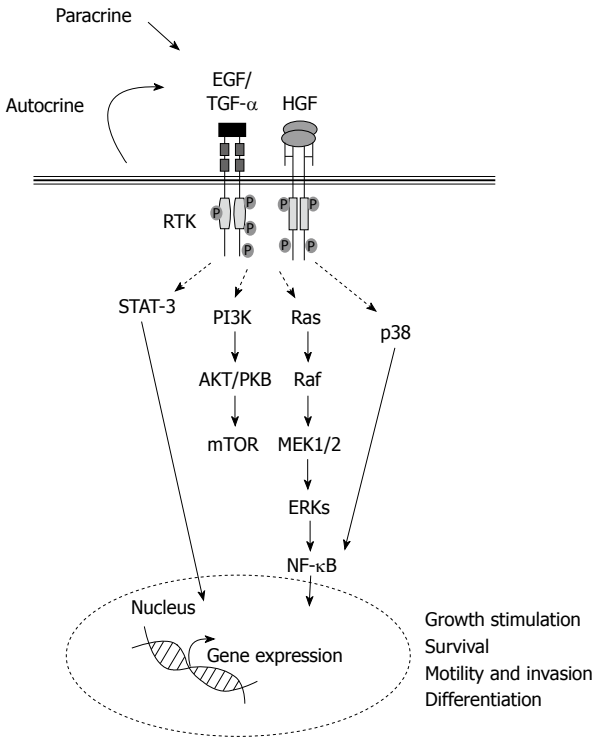

Figure 1 Schematic illustration of the major signaling pathways and biological activities induced by hepatocyte growth factor and epidermal growth factor receptor ligands in liver progenitor cells. HGF: Hepatocyte growth factor; EGF: Epidermal growth factor; TGF: Transforming growth factor; STAT: Signal transducer and activator of transcription; PI3K: Phosphoinositide 3-kinase; NF-κB: Nuclear factor κB; mTOR: Mammalian target of rapamycin; MEK: Mitogen-activated protein kinase kinase; ERKs: Extracellular-signal-regulated kinases.

TGF-β FAMILY

The TGF-β family of cytokines regulates hepatocyte proliferation and death, and plays relevant roles during liver regeneration[103]. However, TGF-β and other pro-inflammatory cytokines are important inducers of fibrocarcinogenesis, due to their ability to induce myofibroblast differentiation and ECM deposition[104,105]. Recent evidence has shown that TGF-β might also regulate liver stemness and phenotype[106].

TGF-β active form acts as a dimer, and signals by bringing together two receptors with serine-threonine kinase activity, which are known as type I and type II receptors (Figure 2). After TGF-β binding, the type II receptor

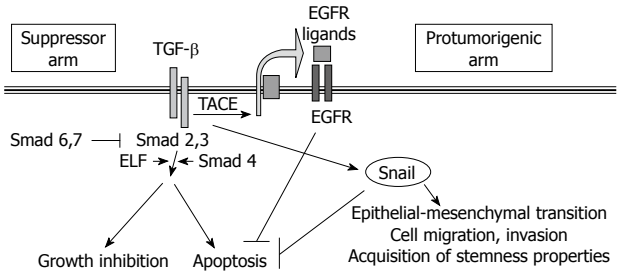

Figure 2 Overview of the major signaling pathways, and their cellular effects, induced by transforming growth factor-β in liver cells. TGF: Transforming growth factor; EGFR: Epidermal growth factor receptor; ELF: Embryonic liver fodrin; TACE: Tumor necrosis factor-converting enzyme.

phosphorylates and activates the type I receptor, which is responsible for phosphorylation of the receptor-regulated Smad family of transcription factors (R-Smads), i.e. Smad 2 and 3 in the case of TGF-β1, β2 and β3[107]. After phosphorylation, Smad 2 or 3 forms a complex with Smad 4 and shuttles to the nucleus, where it possesses DNA-binding activity, although it must associate with other DNA-binding co-factors to achieve high-affinity binding. Indeed, through combination with different transcription factors, the same TGF-β stimulus can induce or repress many different target genes. Activation of the Smad transcriptional activity can be counteracted by the presence of other members of the Smad family that play inhibitory effects (inhibitory Smads), such as Smad 6 and Smad 7, which compete with Smad 2 and 3 for binding either to the receptor complex or to Smad 4.

The most relevant Smad-mediated cell responses to TGF-β are growth inhibition and apoptosis. TGF-β inhibits proliferation in adult[108,109], as well as fetal or regenerating hepatocytes[82,109], and it is a well-known inducer of hepatocyte cell death[110,111]. The inhibitory effects of TGF-β on liver stem/progenitor cell growth and survival are somewhat unclear. TGF-β overexpression results in impairment of oval cell expansion induced by DDC[112]. Consistently, we have shown that treatment with TGF-β inhibits growth and induces apoptosis in DDC-derived oval cell lines *in vitro*[46]. However, when compared to adult hepatocytes, other authors have reported that the majority of the adult liver progenitor cells are more resistant to endogenously produced TGF-β anti-proliferative and pro-apoptotic effects *in vitro*[113], which indicates a differential sensitivity to TGF-β between liver progenitors and mature hepatocytes. Indeed, several mechanisms have been proposed that would explain this differential response. On the one hand, the ratio between R-Smads and inhibitory Smads might be different in oval cells. In this sense, Nguyen *et al*[114] have recently reported that oval cell lines show higher levels of Smad 6 than do adult hepatocytes. On the other hand, oval cells might show over-activation of survival signals, such as the MAPK/ERK pathway[115] that might be related to the autocrine production of growth/survival factors, such as HGF[46]. It is worth noting that, when combined with growth factors such as EGF or HGF, TGF-β might contribute to cellular scattering and morphological differentiation of hepatoblasts and liver stem cells[87,116,117]. In this same line of evidence, hepatocytes are undifferentiated and liver architecture is lost in Smad 2+/- and Smad 3+/- mice, as well as in ELF (a β-spectrin that is crucial for the propagation of the TGF-β signal) mutants[118-121]. Defects in Smad 2+/- and Smad 3+/- mutants are restored by HGF treatment. Although mechanisms by which TGF-β signals can be supplanted by HGF are unknown, data seem to support cooperation between two independent pathways, that converge on β1-integrin expression, rather than direct pathway crosstalk[119]. Emerging new data have reinforced the idea that TGF-β is important for stem cell transitioning to a progenitor cell phenotype, and ultimately, its conversion to a fully differentiated phenotype. Indeed, TGF-β signaling, and particularly ELF, appears to play a crucial role in hepatocyte proliferation and transitional phenotype during human liver regeneration, and its loss is associated with activation of liver progenitor cells[106]. It has also been shown recently that TGF-β might be a determinant in the appearance of progenitor/stem cells in hepatocarcinogenesis. The examination of human hepatocellular carcinoma (HCC) has revealed that cells that are labeled with stem-cell markers have unexpectedly lost the TGF-β receptor Ⅱ and ELF, and show marked activation of the IL-6 pathway, a major stem-cell signaling pathway[121,122]. These data support that absence of TGF-β-driven epithelial differentiation favors carcinogenesis.

However, TGF-β is a pleiotropic cytokine inducing several, and sometimes contradictory, signals in epithelial cells. Indeed, in addition to the well-known Smad-mediated transcriptional responses that predominantly address tumor suppressor actions, TGF-β induces other Smad-dependent or independent effects that contribute to tumor progression[107]. Among these, related to the topic of this review, one of the more relevant is the capacity to induce EMT processes. EMT is a physiological process during embryogenesis, in which an epithelial cell loses expression of adhesion molecules, such as E-cadherin, and other components responsible for cell polarity. Instead, they express mesenchymal components of the cytoskeleton and acquire motility and scattering properties[123]. A closely related phenotypic conversion is also detected in fibrosis and neoplasia and is associated with disease progression[124]. Members of the TGF-β family can initiate and maintain EMT in a variety of biological systems and pathophysiological situations, through activation of major signaling pathways and transcriptional regulators integrated in extensive signaling networks[125,126]. In culture, hepatocytes and hepatoma cells undergo EMT in response to TGF-β[127-130], which support a potentially crucial role for TGF-β in the development and progression of hepatic fibrogenesis and cancer. The mechanisms that allow cells to escape from the apoptotic effects of TGF-β and undergo EMT are not completely understood. However, recent results have indicated that, in some epithelial cells, including fetal rat hepatocytes and hepatoma cells,

TGF-β might induce both pro- and anti-apoptotic signals and their balance defines the cell fate[129,131-133]. In fact, certain evidence indicates a crosstalk between the genetic programs that control TGF-β-induced growth arrest/apoptosis and those that regulate EMT, because once the cell has adopted a mesenchymal phenotype, it does not respond to TGF-β suppressor effects[128,134,135]. Thus, TGF-β might regulate its own signaling to switch from tumor suppression to tumor progression. Indeed, it is interesting to point out that transcription factors of the Snail family, repressors of the E-cadherin gene, are required for cell survival during EMT[136,137].

In recent works from our group, we have demonstrated that transdifferentiation of liver cells from an epithelial to a mesenchymal phenotype, such as that mediated by TGF-β, induces dedifferentiation and allows enrichment in a population of cells with putative liver progenitor properties[91,128,138]. The phenotypic characteristics observed (elongated phenotype, strong expression of Thy-1, vimentin or α-smooth muscle actin) are also highly reminiscent of myofibroblasts[139]. These finding are in agreement with the recently proven fact that EMT not only endows cells with migratory and invasive properties, but also induces stem cell properties[123]. Furthermore, additional works have proved the capacity of TGF-β to induce/maintain a stemness phenotype in other tissues[140]. Preliminary results have indicated that human fetal hepatocytes respond to TGF-β downregulation of E-cadherin and upregulation of Snail, thus acquiring a fibroblastic-like morphology and a liver progenitor cell phenotype (unpublished observations from our group in collaboration with Dr. N. Fausto, University of Washington, Seattle, USA).

These findings might have implications for regenerative biology of the liver and open new perspectives for the *in vitro* isolation of putative liver stem/progenitor cells to be used in basic and translational research in the liver. Moreover, a recent study has also suggested that TGF-β treatment of HCC cells might induce the selection of cells expressing high levels of CD133, a putative stem-cell marker in diverse hematopoietic and non-hematopoietic tissues and cancers[141], through a mechanism partially dependent on the Smads pathway, and that involves epigenetic regulation of the CD133 promoter. These results indicate that TGF-β might also play a role in transdifferentiating liver tumor cells to liver cancer stem cells.

In the embryo, progenitors to pancreatic β cells and hepatocyte lineages arise from neighboring domains of ventral foregut endoderm. It has been recently found that the specification of pancreas and liver progenitors is restricted by the TGF-β pathway[12]. It has been speculated that TGF-β signaling restrains lateral endoderm specification until the cells move sufficiently far from the heart and into a bone morphogenetic protein signaling domain, with the latter then becoming the dominant Smad 4-dependent pathway, which leads to pancreatic induction. TGF-β signaling appears to be strongly inhibitory to the pancreatic lineage and modestly inhibitory to the liver lineage, which suggests that TGF-β also plays a relevant role in maintaining the stemness phenotype of endodermal precursors during liver development.

All these results suggest a dual role for the TGF-β signaling pathway in liver stemness and differentiation. On the one hand, TGF-β mediates progression of differentiation from a stem or progenitor stage, but on the other hand, it contributes to the expansion of liver stem cells. Further work is necessary to understand better the relevance of both effects in liver development, regeneration and carcinogenesis.

HEDGEHOG FAMILY LIGANDS

Hedgehog (Hh) family ligands are widely acknowledged morphogens that regulate tissue remodeling during embryogenesis[142,143]. In particular, Indian hedgehog and Sonic hedgehog ligands, and their receptor, Patched, are expressed at different stages of liver organogenesis, and available data point to dynamic signal activation and temporarily restricted effects on hepatoblast regulation. Thus, Hh signaling is necessary to promote hepatoblast proliferation but it needs to be shut off to permit subsequent hepatoblast differentiation[143-148]. Hh signaling is also involved in the maintenance of a hepatic progenitor reservoir throughout life, both in humans and mice. Blockade of Hh activity in hepatic progenitors *in vitro* decreases survival, whereas stimulation of Hh activity inhibits endogenous apoptosis. Both autocrine and paracrine modes of action are suggested, based on simultaneous expression of Hh ligands and receptors in liver progenitor cells[149]. Additional observations suggest that Hh pathway activation is a common feature of various types of chronic liver injury associated with mobilization of hepatic progenitor populations. Participation of the Hh pathway has been demonstrated in the ductular reaction that is elicited by chronic alcohol-induced liver injury in mice and humans[150]; non-alcoholic steatohepatitis in humans[151]; methionine choline-deficient ethionine-supplemented diet[152] and fatty liver damage[153] in mice. Hh ligands are released by hepatocytes and myofibroblasts, and lead to enhanced viability and proliferation of bile ductular cells and hepatic progenitors, thus promoting the ductular response and fibrogenesis. Myofibroblasts, but not hepatocytes, also respond to Hh ligands with an increase in viability[152,154-157]. Either Hh paracrine signaling between myofibroblast and hepatic progenitors or autocrine signaling, or both, promote EMT in hepatic progenitors, which ultimately contributes to liver fibrosis[157-159].

The way in which Hh signaling interacts with other pathways to control the fate of hepatic progenitor populations during liver repair after damage or neoplasia is still not well understood. Nonetheless, some interesting pieces of information are emerging. Similar to that which has been described in embryogenesis[160], a functional crosstalk between the TGF-β and Hh signaling pathways has been proposed in the context of adult liver progenitor expansion during liver injury. In ethanol-fed mice, TGF-β induces production of Hh ligands in hepatocytes,

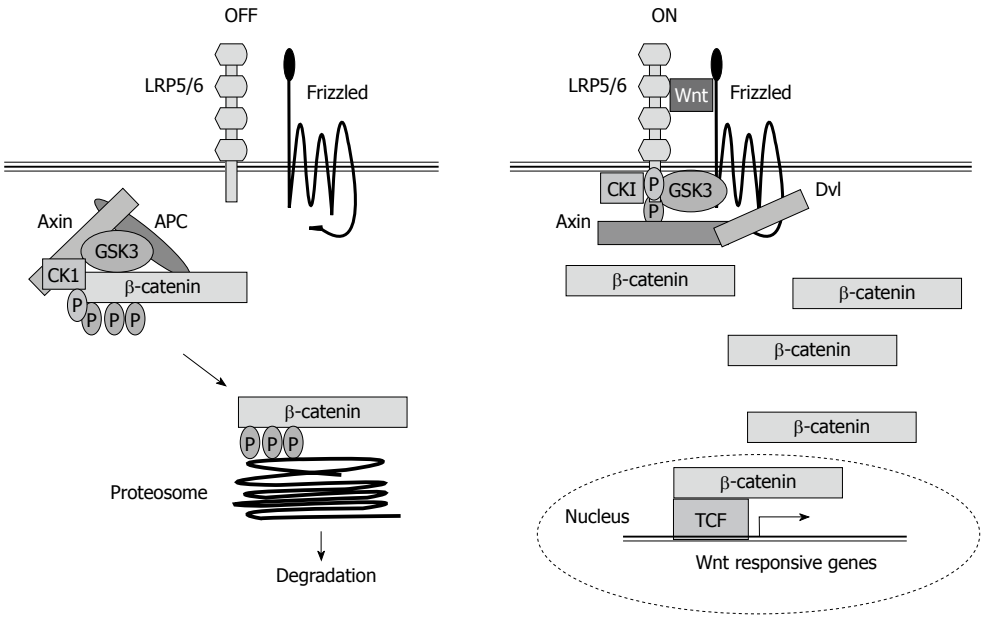

Figure 3 Wnt/β-catenin signaling. Left figure shows how β-catenin is pushed to degradation in the absence of Wnt ligand. Right figure shows how in the presence of Wnt, β-catenin regulates gene expression. TCF: T-cell factor; LRP: Low density lipoprotein receptor-related protein; APC: Adenomatous polyposis coli; CK1: Casein kinase 1; GSK: Glycogen synthase kinase.

which subsequently promotes survival and expansion of ductular/oval cell populations. This supports the concept that enhanced exposure to TGF-β contributes to the accumulation of cells with a ductular phenotype, which are protected from TGF-β-mediated apoptosis[155,161]. Reciprocally, Hh-induced EMT might depend, at least partially, on induction of TGF-β[159]. Further research is required to delineate the Hh-TGF-β interaction.

These findings suggest a role for the Hh pathway as a major mediator in the communication network established between myofibroblast and liver progenitors, which promotes progenitor accumulation and contributes to hepatic fibrosis pathogenesis through EMT induction.

WINGLESS/β-CATENIN PATHWAY

Proteins of the wingless (Wnt) family are secreted signaling molecules that regulate multiple processes in animal development and control tissue homeostasis. The Wnt signaling pathway is highly conserved throughout evolution and plays essential roles in controlling cell proliferation, cell to cell adhesion, and motility[162]. In the liver, it plays many crucial roles during hepatic development and regeneration, and its dysregulation is evident in aberrant growth during hepatocarcinogenesis[163]. Wnt signaling is itself inherently complex[164]. On the one hand, both the ligands and receptors involved in Wnt signal transduction belong to large multi-gene families, which allows for a large number of possible ligand-receptor interactions. On the other hand, Wnt-receptor interactions can elicit a variety of intracellular responses, the best-known of which results in the activation of β-catenin/T-cell factor (TCF) transcriptional complexes. In the absence of signals, β-catenin accumulates in adherens junctions and free β-catenin levels are very low because the tumor suppressor adenomatous polyposis coli forms a trimer complex with glycogen synthase kinase-3-β and axin/conductin, which interacts with and phosphorylates β-catenin, thus targeting it for degradation to the proteasome (Figure 3). Wnts bind a two-part receptor: a seven transmembrane Frizzled and low-density lipoprotein-related protein (LRP)5/6, both being required for canonical signaling. Ligand binding mediates phosphorylation of the cytoplasmic tail of LRP5/6, which creates an axin-binding site. Axin recruitment inactivates the destruction complex. This stabilizes β-catenin, which enters into the nuclei where it displaces Groucho from TCF, nucleating formation of a multiprotein activator complex, and activating Wnt target genes[165] (Figure 3). Furthermore, β-catenin is at the crossroads of growth factor and cytokine signaling. Indeed, certain evidence indicates that TGF-β might induce nuclear β-catenin accumulation, through induction of platelet-derived growth factor signaling[166]. β-catenin expression leads to elevated EGFR levels in hepatocytes and immunohistological analysis shows high correlation between the expression of nuclear/cytoplasmic β-catenin and EGFR in most hepatoblastomas[167]. β-catenin also participates in homotypic cell-cell interactions through its association with E-cadherin. Thus, nuclear β-catenin accumulation in HCC cells might contribute to impaired E-cadherin expression, which mediates the EMT process, migration and survival. It is also known that β-catenin and Met form a complex on hepatocyte membranes. Upon HGF stimulation, the complex is dissociated, in a β-catenin tyrosine phosphorylation-dependent but Wnt-independent manner, which results in β-catenin nuclear translocation[168]. In addition, a role for β-catenin as a downstream effector of HGF in HGF-induced hepatomegaly has been demonstrated[169].

It has been recently suggested that oval cells respond to Wnt ligands *in vitro* with an increase in amino-terminus dephosphorylated β-catenin and cell cycle entry[170], and that canonical Wnt/β-catenin/TCF signaling plays a key role in the normal activation and proliferation of adult hepatic stem cells[171,172]. In this same line of evidence, repression of Wnt/β-catenin signaling in the anterior endoderm is essential for liver and pancreas specification[173], which indicates that turning Wnt signaling off is essential for liver differentiation. An opposite situation might be found during hepatocarcinogenesis, where reactivation of the Wnt/β-catenin pathway, or accumulation of nuclear β-catenin due to other alterations might contribute to the expansion of liver tumor stem cells. Indeed, recent reports have highlighted the relevance of Wnt/β-catenin signaling in the activation of tumorigenic liver progenitor cells[174] and the acquisition of hepatic stem-cell markers[175] in HCC. Accumulation of nuclear β-catenin has been shown to induce an early liver progenitor phenotype in HCC, which correlates with tumor recurrence[176].

In summary, Wnt family and β-catenin/TCF pathways are clearly involved in the maintenance of the liver stemness phenotype, and its repression is necessary for liver differentiation during development. Its overactivation during liver tumorigenesis might contribute to the acquisition of a liver cancer stem cell phenotype.

CONCLUSION

For the past 10-15 years, significant progress has been made in elucidating the cellular and molecular mechanisms that contribute to control of liver stem/progenitor cell behavior. Its complexity and multifaceted nature is evident. Among the diverse signaling pathways at play, the major growth factors, cytokines, and other ligand/receptor systems known to play an important role in liver development, homeostasis and regeneration, certainly occupy a central position. Many of the classical responses elicited by these factors are conserved. However, differences in the downstream mechanisms following ligand-receptor engagement, or signal interaction and crosstalk, as well as specific alterations in intracellular mediators, are being identified as contributing factors to the differential response of liver stem/progenitor cells compared with their mature counterparts. In addition, besides delivery of signals by the surrounding microenvironment, accumulating observations are pointing to co-existence of paracrine and autocrine modes of response as general regulatory mechanisms on this cell population. Collectively, these data indicate that liver stem/progenitor cells follow their own rules and regulations. It is also clear that the same signals that are essential for their activation, expansion, and differentiation, are good candidates to contribute, under adequate conditions, to the paradigm of transformation from a pro-regenerative to a pro-tumorigenic role. Unquestionably, from a clinical perspective, this is a fundamental issue for liver/stem progenitor cell-based therapies. Despite the fact that additional efforts are required to delineate perfectly how the functional switch takes place, the studies summarized here are steps in the right direction.

Abstract

Colonic motility subserves large bowel functions, including absorption, storage, propulsion and defaecation. Colonic motor dysfunction remains the leading hypothesis to explain symptom generation in chronic constipation, a heterogeneous condition which is extremely prevalent in the general population, and has huge socioeconomic impact and individual suffering. Physiological testing plays a crucial role in patient management, as it is now accepted that symptom-based assessment, although important, is unsatisfactory as the sole means of directing therapy. Colonic manometry provides a direct method for studying motor activities of the large bowel, and this review provides a contemporary understanding of how this technique has enhanced our knowledge of normal colonic motor physiology, as well as helping to elucidate pathophysiological mechanisms underlying constipation. Methodological approaches, including available catheter types, placement technique and recording protocols, are covered, along with a detailed description of recorded colonic motor activities. This review also critically examines the role of colonic manometry in current clinical practice, and how manometric assessment may aid diagnosis, classification and guide therapeutic intervention in the constipated individual. Most importantly, this review considers both adult and paediatric patients. Limitations of the procedure and a look to the future are also addressed.

Key words: Colon; Constipation; Manometry; Paediatric; Adult

INTRODUCTION

Constipation is a common condition, with approximately 15% of adults and 9% of children reporting symptoms[1-4]. The direct and indirect costs are substantial; in the USA alone, an estimated $US1.7 billion/year is spent on adults[5] and a further $US3.9 billion/year on childhood constipation[6]. While anatomical malformation (e.g. anal stenosis, imperforate anus), metabolic and gastrointestinal causes (e.g. hypothyroidism, celiac disease, and cystic fibrosis),

intestinal nerve or muscle disorders (e.g. Hirschsprung disease, chronic idiopathic intestinal pseudo-obstruction), childbirth or pelvic surgery are known to cause constipation, for many patients, their condition is regarded as "idiopathic". Indeed, in children, it has been reported that less than 10% of those suffering from constipation have a recognizable underlying organic cause[7,8]. Defects in the nerves and pacemaker cells (e.g. decreased ICC density[9]) could be responsible in a proportion of cases, but as yet, techniques are not sufficiently developed to clearly identify such altered morphology, rendering any attribution to patho-aetiological significance (cause, effect, or epiphenomenon) speculative[8,10,11].

Given that both aetiology and pathophysiology are unclear in many cases, it is perhaps therefore not surprising that up to one-third of adults and children who seek medical help will fail non-surgical therapy[12,13]. Patients refractory to such interventions are debilitated, with physical functioning, mental health, general health and bodily pain all scoring poorly on quality of life questionnaires, compared to the non-constipated population[14]; indeed, the impact is comparable to other chronic conditions, such as inflammatory bowel disease in adults[15] and cancer in children[16]. In refractory cases, surgery, including subtotal or total colectomy, repair of anatomical anomalies believed to impede defaecation[17,18], appendicostomies[19], and more recently sacral nerve stimulation[20] may be considered. However surgical procedures are not without risk, with reported post-operative morbidity often high, and functional outcomes suboptimal[17,21,22]; this, in turn, equates to poor quality of life[23].

Improving therapies for functional bowel disorders is a fundamental goal for all researchers and clinicians working in this field, and to achieve this objective, a better understanding of pathophysiologies that may underpin such disorders is essential. In chronic constipation, altered colonic motor function remains the leading hypothesis to explain symptom generation, and this may be true not only for constipation associated with delayed colonic transit[24], but also for constipation allied to an evacuatory disorder[25]. In clinical practice, routine investigation of colonic motor function is achieved by use of transit studies (typically radio-opaque markers[24,26]), while defecatory function typically is assessed using evacuation proctography or balloon expulsion. Diagnostic manometry, which provides a direct assessment of those contractile activities subserving intestinal functions, is well developed for other parts of the gastrointestinal (GI) tract, notably the oesophagus and anorectum, but its diagnostic potential in the colon remains less certain. This is due to a number of factors including the relative inaccessibility of the proximal large bowel, the technical constrains of current manometric recording systems, and inadequate understanding of normal colonic motor physiology, which is fundamental to confidently diagnosing motor abnormalities in disease states. This review examines the equipment and protocols used to record colonic motor patterns *in vivo* in humans, with particular focus on the diagnostic relevance of data obtained, and the ability of colonic manometry to guide treatment. Current limitations and future direction for the procedure are also covered.

COLONIC MANOMETRY

Manometric studies of true colonic (as opposed to recto-sigmoid) motor function have been reported upon since the late 1980s[27]. However, the colon remains the least well understood section of the GI tract, particularly its proximal portions. For constipation, around 20 studies in adults, and fewer in paediatric populations, have been published. As such, colonic manometry is still largely used as a research tool in adults, with relatively few authors advocating diagnostic use[28,29]. Nevertheless, a recent American Neurogastroenterology and Motility Society consensus statement has recommended this test for the assessment of severely constipated patients (both adult and paediatric) who are unresponsive to medical therapy, and who have evidence of slow colonic transit in the absence of an evacuatory disorder[30]. Furthermore, in children, colonic manometry has been proposed to discriminate normal colonic motility from colonic neuromuscular disorders[31]. It may also help to clarify the pathophysiology of persistent lower GI symptoms after surgery for Hirschsprung disease, evaluate colonic involvement in a child diagnosed with idiopathic intestinal pseudo-obstruction syndrome, assess function of a diverted colon prior to possible re-anastomosis, and to assess colonic motor activity prior to intestinal transplantation to determine if the colon should be kept at the time of transplant[32]. What is certainly true is that colonic manometric procedures lack standardisation, with a variety of catheter types, placement techniques and protocols currently used.

It must also be remembered that colonic manometry is an invasive procedure, and as such should only be performed in those patients with symptoms severe enough to have a marked impact on their quality of life and social well-being. Extensive conventional treatment should be offered before testing colonic motility.

Catheter types

In general, there are two broad types of catheters used: (1) water-perfused; and (2) solid-state. As yet, there have been no studies which directly compare the two types. Preference for one over the other is guided by existing equipment, desired application, study design, and particularly cost.

Water-perfused manometry catheters: Water-perfused manometry is used in children and has been the preferred choice in the vast majority of studies in adults. Catheters are made of flexible PVC[27,33] or extruded lengths of silicone rubber[34]. The latter is highly flexible, and is desirable for patient tolerability if an oral route is used for intubation (see below). The catheters incorporate between 4 and 16 recording ports or side-holes, with an inter-side-hole distance of between 1 and 15 cm[24,35]. Each recording port

consists of an open lumen, which is connected to a pneumohydraulic infusion pump that ensures constant flow of water. The basic premise for recording is that contractions of the colonic wall occlude the manometric ports, thus impeding flow of perfusate (degassed water). Resistance to flow is transmitted as pressure change to external transducers, and the degree of resistance depends upon the amplitude and duration of the contraction. Such catheters are relatively inexpensive and highly versatile with regard to configuration (number, position and orientation of side-holes); in addition, silicone catheters are autoclaveable, and therefore can be re-used many times without fear of contamination. However, due to the requirement of being attached to the manometry system, and need for constant water infusion, studies are always performed in the laboratory setting. This confines the subject to a bed for the length of the recording period with minimal mobility allowed, thus creating a somewhat unphysiological environment. In addition, the volume of water introduced into the lumen is considerable (> 3 litres) if recording from multiple side-holes for prolonged periods of time. Whilst the colon does have the ability to absorb up to 6 litres of fluid a day[36], the effects of introduction of this amount of fluid upon colonic motility remains unknown.

Solid state manometry catheters: So-called 'solid-state' assemblies traditionally consist of strain gauges embedded into a flexible PVC catheter. Each strain gauge is attached to an amplification/recording system *via* fine connective wiring[35]. Until recently, solid-state catheters have typically had between 6 and 10 sensors spaced at 7-15 cm intervals[24]; however, recent technological advances now allow in excess of 20 sensors. Recorded pressure signals can be stored on portable digital recorders enabling the subject to be ambulant[29,37]. However, the cost of these catheters is considerable in comparison to water-perfused catheters, and there has been a tendency in the past for recording channels to break[38,39]. Nevertheless, with further technological improvements, and recent developments in fibre-optic technology, which has seen the emergence of an optical manometry system (see Future directions below), such limitations should be overcome[40,41].

Placement techniques

In human subjects, gaining access to the colon can generally be achieved through two routes: *antegrade* placement *via* the nose or mouth, or *retrograde* placement *via* the anus. Colonic catheters can alternatively be placed through a variety of stomas, a method used particularly in children[42-44] but also in adults[45].

Retrograde placement: This provides the easiest access to the colon, and is by far the most commonly used procedure in both adults and children[33,37,46,47]. In adults, catheters are placed with the aid of a colonoscope and can be positioned in the desired location. To date, most studies utilising this method have located the tip of the catheter at the hepatic flexure or mid-transverse colon, meaning that recordings are only achieved from sites distal to this. However, the Sydney group have achieved true pancolonic recordings over the past few years by securing the tip of the catheter to ascending colonic/caecal mucosal folds using endoclips[20,29,48,49]; this has the advantage of helping to prevent catheter displacement or excretion during defecation[50,51].

In children, the retrograde placement of colonic manometry catheters has also utilised colonoscopic procedures[46]; however, in recent years colonic catheters have also been successfully placed using fluoroscopic guidance alone, both through stomas and *via* the rectum[44]. However, this technique may be associated with prolonged exposure to radiation, in some cases up to 27 min[44].

One of the major advantages of retrograde catheter intubation is subject tolerability. Once the catheter has been sited, there is little or no discomfort. However, in addition to concerns over catheter displacement, there are other potential disadvantages, most notably the requirement for bowel preparation and usually some form of anaesthesia or sedation. The removal of faeces from the colon has recently been shown to result in an increase in the frequency of high amplitude propagating contractions[52,53], and also to disrupt the spatiotemporal organisation of propagating sequences (PSs)[53]. However, the colonic responses to physiological stimuli, such as a meal and morning waking, remain unchanged[53]. Nevertheless, it could be argued that bowel preparation is advantageous, in that the 'starting point' for each study, provided that bowel preparation is performed in an equivalent manner, is standardised.

Antegrade placement: This is a less common method for recording colonic motility and is restricted to adult studies[25,34,39,54]. The catheter is fed through the nasal cavity or mouth, and once through the pylorus (often achieved under fluoroscopic guidance), a balloon on the tip of the catheter is inflated with air or water to facilitate transit through the small and large bowel[25,34]. The main advantage of this procedure is that it obviates the need for bowel preparation, and thus the study is performed under essentially normal basal physiological conditions. The procedure is, however, time-consuming in comparison to retrograde catheter placement. Even in healthy controls, it may take up to 36 h to intubate the distal descending colon[34,35]. Furthermore, with the catheter *in situ* for a prolonged period of time, subject tolerability becomes an issue with nasal/oral/pharyngeal discomfort and nausea commonly reported. Finally, while antegrade placement can be used to study colonic motility in health and in patients with relatively normal colonic transit[25], its use in patients with slow transit constipation (STC) is problematic. As antegrade catheter placement relies on peristalsis to promote the catheter tip through the gut, the process can be greatly prolonged in patients with a disorder characterised by delayed gut transit (the primary clinical indication for this investigation[30]), especially when small bowel motility may also be also abnormal[55].

Placement through a stoma: Intubation *via* appendicostomy, caecostomy, ileostomy or colostomy has been used to successfully investigate children with STC[19,44,56]. In such subjects, after a preceding colonic washout, the in-dwelling device (e.g. Chait caecostomy button) is removed. Two techniques can then be adapted: (1) following sedation, the catheter can be advanced through the stoma with the aid of a guidewire, and positioned under fluoroscopic guidance[44]; and (2) a 10F feeding tube can be positioned through the stoma through which a Bisacodyl solution (2-4 mg) can be instilled directly into the caecum. A manometry catheter can then be introduced through the feeding tube and advanced in an antegrade direction along the colon. The Bisacodyl induces propulsive activity, and a balloon on the tip of the catheter can be inflated with water to aid propulsion through the large bowel[42,43].

RECORDED COLONIC MOTOR ACTIVITIES

Non-propagating motor activity

Non-propagating activity makes up the majority of a colonic manometric recording, consisting of apparently random pressure waves recorded at single or multiple recording sites, often alternating with phases of motor quiescence. Pressure waves may be sub-classified on the basis of duration, and are considered to be of either long duration (the majority) or short duration (often superimposed on long duration pressure waves). The presence of two types of phasic contraction in the colon is unique, compared with the remainder of the GI tract[57]. The functionality of non-propagating activity is outlined below.

Propagating motor activity

Propagating pressure waves are categorised into PSs (also termed propagating contractions) and high amplitude PSs (HAPSs; also termed high amplitude propagating contractions; Figure 1); the latter are recognised as the motor correlate of mass intraluminal movement and are involved in defaecation (Figure 2)[59-62]. Both PSs and HAPSs can be further qualified by the terms antegrade (aboral) or retrograde (oral), depending upon the direction of propagation. However, criteria used to define these events are inconsistent[35]. A general classification includes an array of 3 or more pressure waves recorded from adjacent recording sites, with a trough to peak amplitude $\geqslant$ 5 mmHg per pressure wave, in which the conduction velocity between wave onsets is between 0.2 and 12 cm/s[34,50]. The definition of what constitutes a HAPS is based on a threshold value for amplitude of one or more of the component pressure waves[35]; this varies markedly in the literature from > 50 to 136 mmHg[34,50,63-67]. Consequently, the range of published frequencies is wide[35]; in many cases, the chosen threshold value appears to be arbitrary. Some, however, are based on proven functional characteristics[34].

PSs are identified throughout the large bowel, although they originate with greater frequency in the proximal compared to the distal colon[37,38,58,59,68,69]. The majority of ascending colonic PSs do not migrate beyond the splenic flexure, and conduction velocity of PSs increases as the PS moves distally from the proximal colon, as does the amplitude of the propagating pressure waves[50,58,59,70].

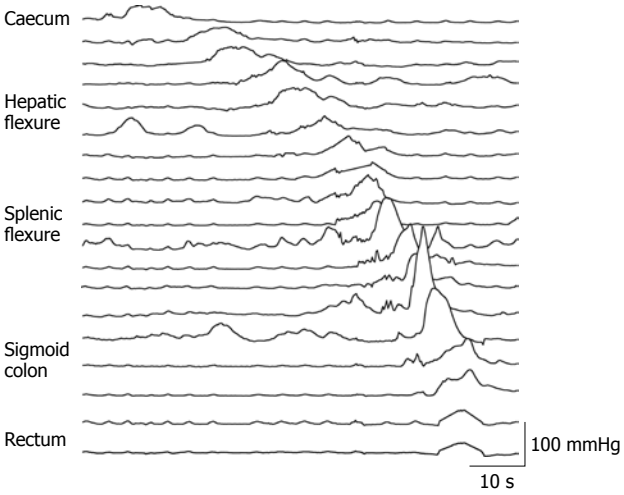

Figure 1 The high amplitude propagating sequence was first described in 1988[27]. The majority of these propagating events originate in the proximal colon and extend to the sigmoid colon. The amplitude of the component pressure waves increase as the motor patterns reaches the descending colon[58].

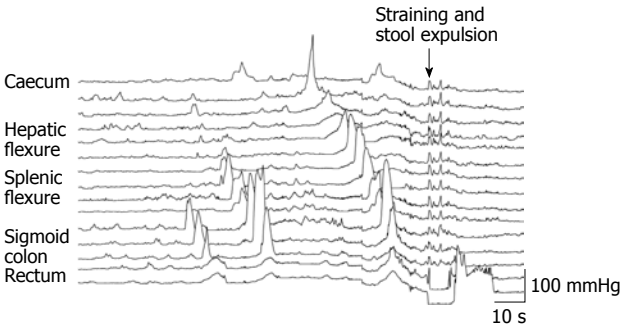

Figure 2 High amplitude propagating sequences are commonly associated with defaecation in healthy controls. Note the series of three high amplitude propagating sequences (HAPSs) prior to stool expulsion. The first originates at the distal descending colon, and with each subsequent HAPS, the site of origin moves to a more proximal location with the final HAPS extending the entire length of the colon[34].

Given their functional significance, HAPSs have garnered most interest in terms of pathological implication, and indeed decreased HAPS frequency is widely accepted as one of the principal hallmarks of STC (see below[27,29]). However, focus on propagated pressure waves alone, as is the case in many published reports, has perhaps led to their clinical impact being over-stressed, particularly given that they occur only a minority of the time during a colonic manometric recording; the organisation of other, more common motor activities may be of similar (or even greater) importance.

Organised colonic motor patterns

Akin to the interdigestive migrating motor complex of the upper GI tract[71], the colon exhibits periodic bursts of regular phasic pressure wave activity, termed either colonic

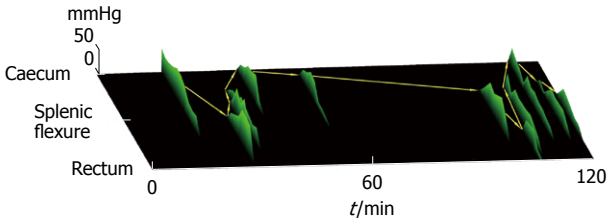

Figure 3 Two hour spatiotemporal maps of colonic propagating sequences in a female healthy control. In this map each individual ridge represents an antegrade propagating sequence. The start of each ridge indicates the site of origin and the time of day the propagating sequence occurred. The length of the ridge indicates the extent of propagation. The heights of the ridge indicate the amplitude of the component pressure waves. The yellow arrows link the site of origin of sequential propagating sequences. While no single propagating sequence spans the entire colon collectively, a linked series of propagating sequences can do so[76].

motor complexes[38,39,58] or rectal motor complexes (MC)[35,72], depending upon their site of origin. MCs predominate in the sigmoid or rectum, where they have also been termed "periodic rectal motor activity"[37,73,74]. The functional significance of these events is unclear, although it has been suggested that they provide a "brake" around the rectosigmoid junction[73], and reflect enteric neuromotor integrity, given that they occur in extrinsically denervated colon preparations[75].

In addition to MCs, sequential PSs have been shown to be linked in organized spatiotemporal patterns throughout the colon[76]. Many of these PSs form series in which three or more consecutive PSs demonstrate a regional shift in the colonic region from which they originate, i.e. each PS in a linked series will originate in a progressively more proximal or distal colonic location. Whilst most single PSs do not span the length the colon, collectively, a series of linked PSs can do so. It is likely that such linkage is important for the transport of content over longer lengths of the colon (Figure 3)[76].

COLONIC MANOMETRY PROTOCOLS

Paediatric studies

Despite the variety of placement techniques and catheter types, once the catheter is positioned, there is commonality to the actual recording protocol. In children, clinical studies generally do not last more than 4-5 h[77], but 24 h studies have been used in the research setting to provide more detailed information on motility characteristics[42,43]. Paediatric colonic manometry catheters typically contain 6-8 recording side holes, evenly spaced at 7.5, 10 or 15 cm intervals[42,43,77]. The paediatric colonic motility test includes at least 1 h of fasting and 1 h postprandial after finishing a high calorie meal. During the test, the child is required to remain in bed and it is important to have a trained observer at the bedside. If HAPSs are not recorded during the fasted or postprandial period, then drug stimulation with Bisacodyl (0.2 mg/kg, max 10 mg, diluted with 0.9% NaCl) is administered. HAPSs induced by Bisacodyl usually occur within a few minutes and are identical to spontaneous HAPSs. A cramping sensation and the urge to defaecate often accompany the presence of HAPSs[47]. If the paediatric test extends to 24 h, then the nocturnal frequency of motor patterns and the colonic response to waking are also measured[42,43,77].

Adult studies

In published adult colonic manometry studies, similar protocols are followed, although the catheter length is generally longer, containing up 16 sensors (water-perfused) spaced at 7.5 cm intervals[25,34]. Recordings are typically of 24 h duration. All studies examine two or more of the following: (1) fasting; (2) meal responses; (3) nocturnal suppression; (4) morning waking; and (5) response to chemical stimuli[24,35].

Normative data

For a clinical diagnosis, data collected from patients is compared to that obtained from healthy controls. In the adult population, recruitment of volunteers is generally not problematic, allowing normal ranges to be developed for various parameters of the motility recording (though it must again be stated that the size of published normative data sets remains inadequate).

By contrast, colonic motility recordings in truly healthy paediatric control subjects are lacking for obvious ethical reasons. Di Lorenzo *et al*[78] attempted colonic manometry in 32 "healthy" paediatric patients, though they were not strictly healthy controls, as they had diagnoses ranging from functional faecal retention (n = 15) and non-ulcer dyspepsia (n = 10), to Munchausen by proxy (n = 7). Other paediatric studies in adolescents with STC have used healthy young adults as the control group; whether this is appropriate is unknown[42,43].

OBSERVATIONS FROM COLONIC MANOMETRY STUDIES

Both propagating and non-propagating motor patterns may be temporally associated with propulsion and mixing of colonic content[59,60,79], signifying that these are important determinants of normal physiology in health and of pathophysiology in patient groups. In adult and paediatric patients with chronic constipation, a number of findings have been made which suggest pathological significance, including: (1) a lack of the normal[37,58,80] increase in colonic motor activity after a high calorie meal[29,43,46,49,80-86] (Figure 4); (2) a lack of the normal[29,50,51,58] suppression of colonic motor activity at night, and a suppressed or absent increase in colonic activity in response to morning waking[25,29,43,80] (Figure 4); (3) a decrease in frequency of HAPSs[27-29,39,47,49,80,83,85-88], although normal daily frequencies have also been reported in some constipated subjects[25,43] (Figure 4); (4) increased non-propagating activity in the left colon[89]; (5) absence[25] of the characteristic spatiotemporal patterning of PSs preceding normal spontaneous defecation[34]; (6) diminished co-ordination between

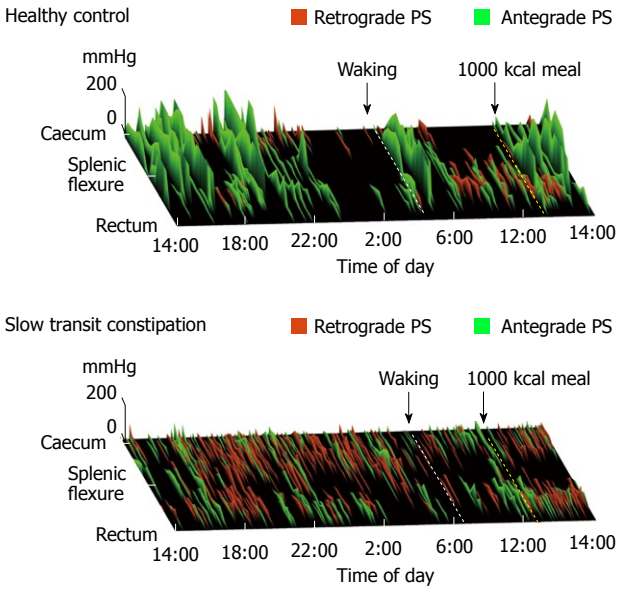

Figure 4 Twenty-four hour spatiotemporal maps[80] of colonic propagating sequences in a female healthy control and a female patient with slow transit constipation. Within each map the ridges represent antegrade (green) and retrograde (red) propagating sequences (PS). The antegrade PSs originate at the orad end of the green ridge and retrograde PSs originate at the anal end of the red ridges. The start of each antegrade and retrograde ridge indicates the site of origin and the time of day the PS occurred. The length of the ridge indicates the extent of propagation. The height of the ridge indicates the amplitude of the component pressure waves. The yellow-hatched line indicates when the 1000 kcal lunch was given, the white-hatched line indicates the time of morning waking. In health the frequency of propagating sequences are reduced during sleep and increase upon morning waking and in response to a high calorie meal. The map in the STC patients is characterized by an increased frequency of short extent PSs and a lack of high amplitude propagating sequences. There is an absent meal response (no increase in PSs) and an absent nocturnal suppression of PSs.

sequential pan-colonic PSs[76,80]; (7) a blunting of the normal[49] increase in PS or HAPS frequency in response to rectal or colonic infusion of Bisacodyl has been shown in a proportion of individuals[47,49,85], although in the majority of patients a normal response is recorded[49,83,85,90-92]; (8) a blunting of the normal increase in colonic HAPS frequency to intravenous injection of the cholinergic agonist edrophonium chloride[92]; (9) a blunting of the normal proximal colonic increase in motor activity in response to a rectal infusion of chenodeoxycholic acid[93]; (10) an increase in the frequency of HAPSs in response to sacral nerve stimulation in patients with STC[20]; and (11) a significant increase in the frequency of rectosigmoid motor complex activity[73,74].

CAN COLONIC MANOMETRY FINDINGS HELP TO DISTINGUISH SUBTYPES OF CONSTIPATION?

Constipation can be conceptualized into two broad overlapping categories: STC, and disorders of evacuation[1,94-96]. In some cases, this distinction among subgroups, based on aberrant physiological measurement, has proven beneficial in planning treatment and in predicting therapeutic outcome[96-99]. For example, identification of dyssynergic defaecation by anorectal manometry and balloon expulsion testing, in the absence of delayed colonic transit, is predictive of a high success rate from biofeedback[97,98]. Likewise, in carefully selected patients with severe STC, where the transit delay is restricted to the colon[17,22,100,101], and there is no evidence of evacuatory dysfunction, surgery such as colectomy with ileorectal anastomosis may be effective. In children this group is successfully managed with an appendix stoma and antegrade enemas[19].

In terms of colonic manometric investigation, specific biomarkers or biosignatures that may help to define constipation subtypes (and thus provide therapeutic targets) have, as yet, not been fully established. In adults, only three studies have addressed the validity of manometric findings between "recognised" subgroups[102-104]. The first concluded that intraluminal measurements could not be used to discriminate between subgroups of patients with either STC or an evacuation disorder[102]. The second study examined three subgroups of constipated patients with either STC, an evacuation disorder, or 'normal transit' constipation, and found that fasting and postprandial motor parameters were not useful for discriminating amongst these subtypes, although colonic compliance was[103]. Bassotti *et al*[104] noted that no colonic motor patterns were able to differentiate between constipated patients with or without delayed transit.

A further study in patients with constipation secondary to antidepressants revealed minimal motility differences compared to patients with idiopathic constipation[85]. Finally, Hervé *et al*[83] took the approach that manometric findings themselves should be used as the basis for subclassification. In a study of 40 adults with STC, they identified 4 subgroups: group 1 displayed no HAPS or a colonic response to a high calorie meal; group 2 showed increased sigmoid motor activity; group 3 had a reduced frequency of HAPSs; and group 4 displayed normal colonic motility. However the clinical impact of such findings, in terms of guiding successful management, remained undetermined. Nevertheless, through sufficiently large scale studies, a classification system incorporating findings from pancolonic manometric investigations, rather than being based on traditional studies of colonic transit and evacuatory function alone, may be merited. Current stratification, where the colon is seen to be responsible for transit, and the anorectum solely responsible for evacuation, is likely a gross oversimplification.

CAN COLONIC MANOMETRY HELP TO GUIDE TREATMENT AND IMPROVE OUTCOMES?

The primary indicators of abnormal colonic motor function in constipation (see above) are reduced HAPS frequency and a diminished or absent response to eating, morning waking or chemical stimulation. The colonic re-

sponse to ingestion of a meal is likely to involve the CNS and neurohormonal pathways; a suppressed response has been proposed as indicative of colonic myopathy and an absent response as a possible neuropathy[29]. Similarly, diurnal variation in colonic motor activity is likely to be mediated by the CNS, and therefore a diminished or absent response to sleep or morning waking supports a neuropathic cause in such patients[29]. With regard to chemical stimuli, a failed response may indicate an abnormality within the myenteric plexus[105], cholinergic pathways[92] or recto-colonic neural pathways[93].

Adult studies

In adults, very few interventional studies have been based upon evidence gained from colonic manometric investigation. In 3 patients with severe constipation who had failed conservative therapy, Bassotti *et al*[28] demonstrated globally reduced colonic motility, a minimal meal response and no response to Edrophonium. Based upon these data, 2 patients underwent a total colectomy and 1 a hemicolectomy, with "fairly good results at follow-up" reported. No long-term data were provided.

In a larger study, Rao *et al*[29] performed 24 h colonic manometry in 21 patients with STC. Utilising the response to ingestion of a meal, response to morning waking, and HAPS frequency as diagnostic criteria, patients were classified as having a neuropathy (n = 10) if they had an absence of two or more, a myopathy (n = 5) if they had a reduced response to two or more, or being normal (n = 6). Those with a suspected neuropathy were offered a colectomy (performed in 7/10, with "improved" bowel symptoms reported; no follow-up duration specified). Those with a myopathy were offered a regime of biofeedback and laxatives, and reported "modest improvement" at 1 year.

Paediatric studies

In children, colonic manometry studies are far more likely to guide treatment options. In a study by Pensabene *et al*[106], results of colonic manometry testing resulted in a recommendation to change therapy (mostly surgical) in 93% of the patients with intractable organic or functional constipation. Importantly, 88% of the 98 parents believed that the therapeutic suggestions made had been helpful in improving their child's health[106].

Di Lorenzo *et al*[107] studied 46 children with constipation and/or faecal incontinence after surgery for Hirschsprung disease. Four groups were established based upon results from colonic manometry: (1) HAPSs propagating from the proximal colon through the neorectum to the anal sphincter, which was associated with faecal incontinence (n = 18); (2) an absence of HAPSs and lack of colonic meal response, which was predominantly associated with constipation (n = 15); (3) a normal manometric study, with a hypertensive anal sphincter, which was invariably associated with constipation (n = 4); and (4) a normal manometric study, but the child presented with fear of defaecation and retentive posturing, which was predominantly associated with constipation and soiling (n = 9). Those in group one were treated with anticholinergics and Loperamide. In group two, resection of the abnormal section of colon was recommended. In the third group, four-quadrant intrasphincteric botulinum toxin injections were recommended, and in the fourth group, a programme of behaviour modification and stool softeners were used[107]. Based upon these treatments, the authors reported an improvement in global health and emotional health scores as well as an improvement in the number of bowel movements and resolution of abdominal pain[107].

Also in paediatric patients, colonic manometry is reported to have value in determining poor outcomes for the surgical treatment of intractable constipation using an appendicostomy or a caecostomy with antegrade irrigation of the colon[47]. For example, those children with a poor outcome also displayed an absence of colonic response to Bisacodyl. However, the fact that 50% of children with no production of HAPS still had good outcomes to antegrade irrigation suggests that the Bisacodyl response is by no means a solid predictor[47].

CURRENT LIMITATIONS

While colonic manometry studies in both children and adults have helped to define some of the physiological and pathophysiological aspects of colonic motor function, there are still no published quantitative data on propagating or non-propagating activity that clearly differentiates healthy subjects from constipated patients[30]. Furthermore, at least in children, morphological changes reflecting possible myogenic or neurogenic disorders in muscle tissue do not correlate with particular features of colonic manometric recordings[108] or anorectal manometry[109]. It also remains unclear whether data derived from adult studies can be extrapolated to children and *vice versa*. No manometric studies using the same equipment and protocols have compared childhood and adult constipation. Indeed, because a normal frequency of HAPSs has been identified in children with STC (contradicting most reported findings in adults), childhood constipation may represent a different entity[43]. The impact of sensory, as opposed to motor dysfunction on the development of constipation is gaining increasing recognition[110,111]. Nevertheless, the two are inextricably linked, and future studies should look to explore both domains concurrently, by the best methods available, rather than consider certain functional bowel conditions as principally motor disorders (e.g. constipation), and others as sensory disorders (e.g. the irritable bowel syndrome).

With variations in protocols, catheter types, numbers of recording sites, spacing between recording sites, placement techniques and definitions of recorded activities, it is perhaps not surprising that consistent findings have not been reported in the literature[24,35]. Furthermore (and as stated above[24]), almost all studies that detail "colonic" manometry have, in reality, recorded colonic motor patterns distal to the mid-transverse colon. Support for the use of true pancolonic manometry resides in the fact that

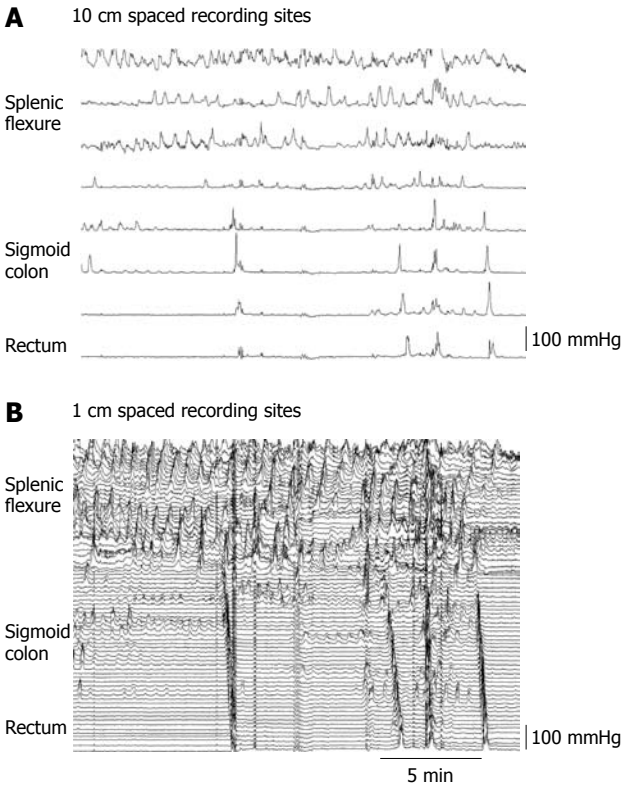

Figure 5 Manometric traces of colonic motor activity recorded by a fibre-optic manometry catheter with 90 sensors spaced at 1 cm intervals. A: To represent common sensor spacing for current published colonic recordings, the data set, obtained through "high resolution" manometry, is sub-sampled to present every 10th channel (10 cm spacing, top); B: The complete data set, captured at 1 cm intervals, is displayed at the bottom. Note that at 10 cm spacing, the most proximal three channels reveal what appears to be non-propagating pressure waves. However, when the full data set is viewed (B), a series of short-extent retrograde propagating events are detected. These events are missed when spatial resolution is poor. Modified from[41].

PS and HAPS are not distributed evenly throughout the colon, and predominantly originate in the ascending and proximal transverse colon, and that the entire colon appears to function in a coordinated fashion[76,112]. 'Partial' colonic recordings thus provide an incomplete picture of colonic (patho)physiology.

FUTURE DIRECTIONS

In the oesophagus and the anorectum, manometry is an established diagnostic tool. In comparison to the colon, these regions afford easier access and therefore have been subjected to far more research and clinical investigation. More recently, development of high resolution manometry (HRM) has further enhanced diagnostic potential, particularly in the oesophagus[113], most notably with regard to standardisation of recording procedures. With the advent of fibre-optic manometry[40,114], HRM recordings are now feasible throughout the entire colon. Catheters incorporating up to 120 sensors spaced at 1 cm intervals have already demonstrated that the vast majority of PSs propagating over short distances are missed by recording sites spaced > 7 cm apart[40,41] (Figure 5). If such technology is able to identify those elusive biomarkers that can help to reliably distinguish constipation subtypes and guide management, then this provides the opportunity to take colonic manometry out of the research arena and into clinical practice. Such progress is only possible through appropriately designed and powered studies, utilising equivalent hardware and software, both in adults and children. The revolution that has been seen with oesophageal HRM, such that traditional manometry is now regarded as obsolete, can serve as a template for the clinical potential of pancolonic manometric investigation.

CONCLUSION

Pancolonic manometric investigation provides a unique window onto motor functions of the large bowel, and through its use we now have a greater understanding of normal colonic physiology and also the pathophysiology of constipation in both adults and children. Although a recent consensus statement[30] advocates use of colonic manometry in patients with "significant motility disorders", the technique is still not refined enough for widespread clinical use, and no prospective and controlled studies have been performed evaluating the clinical value of this tool. Nevertheless, technological advances offer the potential of adding colonic manometry to the available diagnostic armamentarium in broader clinical practice. To achieve such a goal, there is a fundamental requirement for standardisation of methodologies and recording protocols, further development of automated analysis software, and a vital need for generating larger normative data sets, which will enable diagnostic yield to improve. This will be achieved through the coordinated efforts of those dedicated to this field. Further clinical exploration of this technique affords the possibility of a more directed therapeutic approach in patients with chronic constipation. Colonic manometric studies, performed in large numbers of constipated patients, will hopefully establish biomarkers that can distinguish existing (largely predetermined) constipation subtypes (i.e. STC, evacuation disorders), or aid a more contemporary phenotypic classification.

Abstract

Transient elastography (TE) is a new non-invasive tool for assessing liver stiffness, which is correlated with the histologic stage of liver fibrosis. Many studies have reported a good accuracy of TE in predicting significant fibrosis and an optimal accuracy in predicting cirrhosis. Furthermore, the potential role of TE in screening the general population has also been proven. TE thus helps physicians to decide treatment strategies, predict prognosis, and monitor disease progression in patients with chronic liver disease and to screen the general population to identify high risk patients with potential liver disease. However, most data on the clinical roles of TE have been gathered in European patients with chronic hepatitis C (CHC), because TE was first developed in France. Accordingly, much data on the usefulness of TE in patients with CHC has accumulated. Recently, however, vigorous efforts have been made to apply TE to patients with chronic hepatitis B (CHB), and TE has also proved to have acceptable accuracy in diagnosing liver fibrosis and cirrhosis in these patients. Thus, we focused on TE in the Asian population with CHB in comparison with the European population with CHC and found that the diagnostic performance and cutoff values were different between the 2 populations possibly as a result of several different confounders between Asian and European populations (the etiology of chronic liver disease, histologic features, major fluctuation in alanine aminotransferase levels, and the prevalence of high body mass index and metabolic syndrome). Therefore, further studies tailored to the Asian population with CHB should be performed before the widespread application of TE in Asian populations with CHB.

INTRODUCTION

Transient elastography (TE) using FibroScan® (EchoSens, Paris, France) is a newly introduced non-invasive tool, that generates an elastic wave using a vibrator applied to the thoracic wall at the level of the right lobe of the liver and measures the propagation velocity of the wave,

which is directly associated with liver stiffness (LS)[1]. To date, the clinical utility of TE has been widely reviewed, and it is regarded as having considerable accuracy for predicting liver cirrhosis in patients with chronic liver disease (CLD) of diverse etiologies[2-5]. TE is quick, highly reproducible, and completely harmless to patients. In addition, it can be learned and performed easily after a short training period (by nurses or technicians) without consuming the time of clinicians. For these reasons, TE has become popular in clinical practice as a tool for aiding in the diagnosis and follow-up of liver disease.

Because TE was first developed in France, most studies on its benefits have been explored in European countries where chronic hepatitis C (CHC) is prevalent. Accordingly, extensive data on the clinical roles of TE in assessing liver fibrosis in patients with CHC have been gathered. Recently, several meta-analysis studies reported that TE is a reliable non-invasive tool to detect advanced liver fibrosis and liver cirrhosis[6-8]. However, most studies included in the meta-analysis investigated European populations with CHC. Data from Europe cannot be extrapolated to the Asian population, as subsequent trials of TE in Asian countries where hepatitis B virus (HBV) infection is more prevalent than hepatitis C virus (HCV), displayed divergent results. In this Topic Highlight, we will focus on TE in the Asian population with chronic hepatitis B (CHB).

METHODOLOGICAL CONSIDERATION OF TE IN THE ASIAN POPULATION

LS values are defined as the median of 10 valid measurements and at least 60% of TE shots should be successful for each examination according to the manufacturer's recommendations. Accordingly, to date, only the results of TE examinations satisfying the above criteria have been considered as reliable and have been included for the analysis in reported studies.

Another important parameter for confirming the validity of LS values is the interquartile range (IQR), which is defined as the values between which 50% of observations fall. The lower boundary is the 25th percentile (lower quartile), the upper boundary is the 75th percentile (upper quartile). Generally, the IQR/median LS value ratio (IQR/M) should not exceed 30% if the reliability of LS values is to be preserved. However, recently, Lucidarme *et al*[9] proposed new criteria for reliable LS values, using the IQR/M based on the data from more than 250 French patients with CHC. They found, in a multivariate analysis, the fibrosis stage (F0-2 *vs* F3-4) and IQR/M were significantly associated with significant discordances between TE and liver biopsy (LB), with an optimal discriminant cutoff value of 0.21. They thus concluded that the IQR/M can overestimate liver fibrosis using TE, irrespective of success rate, when the significance discordance was defined as a discordance of at least 2 stages of fibrosis between LS values by TE examination and the METAVIR scoring system. From these results, they suggested a novel algorithm for clinical practice as first-line assessment of liver fibrosis in patients with CHC (Figure 1).

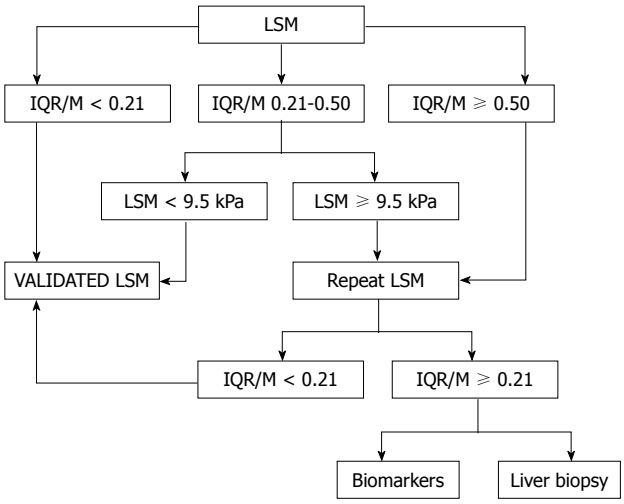

Figure 1 Suggested algorithm for clinical practice as first-line assessment of hepatic fibrosis in patients with chronic hepatitis C. IQR/M: Interquartile range/median liver stiffness value ratio; LSM: Liver stiffness measurement.

Because the IQR/M was confirmed in only one European study with CHC showing relatively high body mass index (BMI) (25 ± 4.1 kg/m^2), its application to the Asian population with CHB (who generally show a lower BMI) is difficult and requires further validation. Although the data are preliminary, we have attempted to validate the IQR/M for our cohort of 156 patients with CHB (mean age 38.8 years, male 75.0%, mean BMI 23.2 kg/m^2) who underwent LB and TE prior to starting antiviral treatment. In this study, we selected the cutoff LS values of Marcellin *et al*[10] (7.2 kPa for ⩾ F2, 8.1 kPa ⩾ F3, and 11.0 kPa for F4) as the reference values between 2 external studies that investigated the performance of TE and then set up the optimal cutoff LS values for each fibrosis stage in patients with CHB[10,11]. We identified 28 (18.0%) patients showing significant discordance between TE and LB. However, the IQR/M was not significantly different between patients with discordance and those with non-discordance (0.125 ± 0.083 *vs* 0.129 ± 0.079, $P = 0.831$), and the success rate also failed to show a significant difference.

Interestingly, the mean IQR/M of our study population was greatly reduced compared to that of subjects in Lucidarme *et al*[9] (0.30 in patients with discordance and 0.22 in those with non-discordance) and the proportion of patients with an IQR/M > 0.03 ($n = 7$, 4.5%) was very small. The reasons are not clear why the IQR/M in our study was reduced in comparison with that in the previous study, and was not selected as a discriminant factor to predict discordance. However, we think that the optimal cutoff value of the IQR/M will be lower than that from patients with CHC even if the IQR/M can be validated in the future for the Asian population with CHB, or that the IQR/M is not a predictor of discordance in the Asian population with CHB due to other potential confounders that overwhelm the influence of the IQR/M, such as the inhomogeneous histological features of CHB which often

makes liver texture inherently macronodular. This would result in LS values that vary depending on the area of the liver and necroinflammatory activity, which has been demonstrated to raise LS values. Therefore, the validation of the IQR/M in the Asian population with CHB requires further studies using increased sample sizes to allow sufficient cases with a spectrum of IQR/M values.

Several issues still remain to be resolved regarding the Asian population with CHB: How many valid measurements do we need to maintain the performance of TE[12]? What is the optimal success rate of the TE measurement to accurately exclude unreliable LS values? Can the IQR/M alone be applied to increase the performance of TE without a sufficient number of valid measurements and an adequate success rate?

WHAT ARE THE NORMAL LS VALUES FOR THE ASIAN POPULATION

Before discussing data on TE in the Asian population with CHB, it is important to first confirm that TE can reliably identify patients with CLD from the normal population. If TE cannot, the clinical meaning of further analysis on the performance of TE in grading the severity of CLD would be significantly lessened. Despite the importance of this, to date, most studies on TE have focused on patients with CLD.

The concept of "what are normal LS values assessed by TE?" is a critical issue that should be addressed to determine whether TE can be used for screening the general population and for subsequent selection of high-risk patients who require periodic follow-up and adequate treatment measures. Indeed, concerns regarding normal LS values are increasing, and several studies (including 2 Asian studies) have proposed normal LS values despite variations in study design[13-19].

In a study by Corpechot *et al*[15], the authors found that the normal LS values in the healthy population were significantly higher in men than in women and that the median LS value was 4.8 kPa (range, 2.5-6.9 kPa). Roulot *et al*[13] examined a large cohort of 429 apparently healthy subjects to establish normal LS values [5.81 ± 1.54 kPa (range, 3.8-8.0 kPa) in men *vs* 5.23 ± 1.59 kPa (range, 3.3-7.8 kPa) in women, $P < 0.01$]. Another study conducted in Romania demonstrated that the mean values of TE in 144 normal subjects were 4.8 ± 1.3 kPa (range, 2.3-8.8 kPa) and that the normal LS values were significantly different between genders[16]. Colombo *et al*[17] also assessed the LS values of 327 voluntary blood donors and found that the mean LS value was 4.9 kPa (95% CI: 4.6-5.1 kPa) and the normal LS values showed no significant differences between genders. However, Colombo *et al*[18] in their follow-up study that enrolled more than 1000 healthy blood donors reported that the normal LS value was 4.4 kPa (95th percentile, 6.7 kPa) and that the male gender presents with increased LS values.

All the aforementioned studies were conducted in Europe. However, normal LS values in the Asian population are now available. Fung *et al*[19] reported a mean LS value in 28 healthy living-related liver donors of 4.6 kPa (range, 2.0-7.1 kPa), and all subjects had LS values of < 7.2 kPa, which indicated that they had no significant fibrosis. We have previously reported that the normal range of LS values was 3.9-5.3 kPa, which was calculated from 69 strictly selected living liver and kidney donors[14].

Table 1 indicates the results of all studies on normal LS values. The upper normal range of LS values was consistently lower than the range generally used for identifying significant liver disease (7-8 kPa) in the majority of previous studies[20-22]. These data demonstrated that TE can perform reliably in identifying high-risk subpopulations without an overlap between the normal and abnormal ranges of LS values. Interestingly, the mean LS values in Asian studies appear lower in comparison with European studies, and the effects of gender on the performance of TE are variable among studies. The discrepancy cannot be fully explained, because the complete histological data of the normal subjects were largely unavailable except a small

number of liver donors in the studies by our group[14] and Fung *et al*[19]. Lower mean BMI, younger age, and lower prevalence of metabolic syndrome in the Asian studies can explain, at least in part, the lower mean LS values observed. Another reasons are that other confounders of TE performance, such as high alanine aminotransferase (ALT) levels and fatty liver, were not sufficiently excluded[17,18] and that the hepatic imaging studies and/or cardiologic evaluation were not fully completed in European studies[13,16]. These reasons may have increased the normal range of LS values in the European studies.

More carefully designed studies with a large number of subjects are thus still required to fully assess the normal LS values for both Western and Asian populations. However, it should be remembered that the actual normal range of LS values cannot be precisely defined without a definition of a "normal liver", sufficient histological evaluation of normal subjects, and further stratified analysis with lifestyle factors between genders (such as alcohol consumption). If these issues are resolved, we can identify the true normal LS value and use this as a reference for future studies.

INFLUENCE OF BMI ON THE PERFORMANCE OF TE IN THE ASIAN POPULATION

Previous work has demonstrated that BMI can affect the performance of TE. This can be explained in 2 ways. First, BMI influences the failure rate of TE, and second, BMI acts to increase LS values. Although previous studies have reported that the success rate of TE decreases in subjects displaying higher BMI[13,23], TE failure may not be significant, because these patients were largely excluded from the analysis. However, in another point of view, this effect of high BMI on TE failure can be a significant pitfall of TE, as the majority of patients with high BMI have an increased chance of suffering from fatty liver and, if TE examination fails, they miss the opportunity to receive rapid and non-invasive methods to exclude significant fibrosis. From the knowledge of the varying failure rates between Asian and European study populations, we can discern the possible influence of BMI on TE failure rate according to the study population.

Table 2 summarizes the failure rates of previous studies conducted in Asian and European populations. Overall, TE failure rates and BMI both appear to be lower in Asian compared to European studies, indicating that the lower BMI found in Asian populations is possibly associated with a lower TE failure rate.

In spite of debate, several European studies have reported that a high BMI (which might cause hepatic steatosis) could potentially increase LS values[13,17], although research to date has not determined whether steatosis itself increases LS value in patients with chronic viral hepatitis[28-30]. For the Asian population, the effects of high BMI on TE performance have not been fully validated, because most Asian studies on TE lack sufficient numbers of patients with high BMI (> 30 kg/m^2). In our previous study, BMI did not influence LS values, although our study population was younger and showed lower BMI values than European studies[14]. This potential effect of high BMI on TE performance should therefore be further investigated for the Asian population.

INFLUENCE OF METABOLIC SYNDROME ON THE PERFORMANCE OF TE IN THE ASIAN POPULATION

Recently, the effects of metabolic syndrome (MS) on TE have been examined in a French study[13]. Here, BMI > 30 kg/m^2 was more frequent among subjects with MS than among normal subjects (49.1% *vs* 8.9%, respectively, $P < 0.001$). The mean LS value was higher in subjects with MS compared to controls (6.51 ± 1.64 kPa *vs* 5.33 ± 1.51 kPa, $P < 0.001$). In a multivariate analysis, LS values were still significantly different between subjects with and without MS, irrespective of BMI and other variables. Because MS

has been demonstrated to increase LS values significantly, and hepatic steatosis which can result in histological progression to cirrhosis and hepatocellular carcinoma is strongly associated with MS[31-33], a potential role of TE in detecting MS was proposed. However, 88% of the subjects with MS had LS values within the defined normal range. This result indicated that not only could TE not precisely perform in the diagnosis of MS, but also that hepatic steatosis differentially affected by MS may have influenced LS values differently for different individuals. One drawback of the study[13] was a lack of ultrasonographic evaluation of hepatic steatosis. It is thus unclear whether the increased LS values in the subjects with MS were dependent on MS itself or on hepatic steatosis associated with MS. Other studies in Italy[17,18] attempted to overcome this drawback by including ultrasonographic evaluation of the healthy blood donors and concluded that the severity of hepatic steatosis was independently related to LS values.

The association between MS or hepatic steatosis and LS values was investigated primarily in healthy subjects, because the effects of MS or hepatic steatosis on TE can be attenuated if the study population presented with background fibrotic liver (the most significant factor for high LS values). Therefore, it is difficult to identify the main factors that increase LS values among MS, hepatic steatosis, associated steatofibrosis, and background fibrosis, if the study enrolls patients already presenting with CLD.

As mentioned above, only one published European study reporting the effects of MS on TE in healthy individuals is currently available. Furthermore, no available European and Asian data address the effects of MS on TE performance in patients with chronic viral hepatitis. Considering the different clinicopathological course of hepatic steatosis in patients with CHC and CHB and the varied distribution of body fat according to race, further studies on the effects of MS and hepatic steatosis should be performed with the Asian populations.

INFLUENCE OF ALT ON THE PERFORMANCE OF TE IN THE ASIAN POPULATION WITH CHB

The most important confounding factor of TE is serum ALT levels. Hepatic inflammation, as reflected by higher ALT levels, tends to increase LS values[11,20,34]. Even minor changes in ALT levels have been shown to influence LS values[35]. Because HBV, unlike HCV, frequently exhibits acute ALT flares[36,37], the interpretation of LS values becomes increasingly difficult in the setting of CHB when major fluctuations of necrosis and inflammatory activity occur[24,38]. It thus becomes more relevant to consider ALT levels when examining TE in the Asian population with CHB.

Considering the significant effects of high ALT levels, several Asian studies with CHB patients attempted to establish varying cutoff LS values according to ALT levels. Chan *et al*[11] proposed ALT-based algorithms when interpreting LS results, and established different optimal cutoff values according to ALT levels (one group with normal ALT *vs* the other group with ALT > upper limit of normal (ULN) and ≤ 5 × ULN). In our previous study, we also stratified the study population according to ALT levels and calculated the optimal cutoff values for each group[34]. For patients with normal ALT levels, 6.0, 7.5 and 10.1 kPa were selected as the optimal cutoff values for ≥ F2, ≥ F3, and F4, respectively, whereas 8.9, 11.0, and 15.5 kPa were selected in those with ALT > ULN and ≤ 2 × ULN. Considering this unreliability of TE performance in patients with high ALT levels, more recent studies began to exclude patients displaying ALT > 5 × ULN for analysis[24]. In addition, the optimal time interval for TE to recover its reliability in patients who experience acute exacerbation of CHB was recently reported[38].

Although it seems reasonable to use different cutoff values according to ALT levels, large-scale validation of these LS values has not been performed for Asian patients with CHB. Furthermore, some issues still remain unresolved, such as how we stratify patients with CHB according to ALT levels to establish the cutoff values, and who should be excluded for TE examination because of unreliability of TE among patients with high ALT levels.

DIAGNOSTIC PERFORMANCE OF TE IN THE ASIAN POPULATION WITH CHB

Few studies have investigated the performance of TE in the Asian population with CHB[4,11,39-43]. The characteristics of studies and the identified performance of TE to predict significant fibrosis and cirrhosis are summarized in Tables 3 and 4 (Marcellin *et al*[10] is listed for comparison with other Asian studies). The listed Asian studies were selected if they evaluated TE in Asian populations with CHB, they used LB as a reference standard, and they assessed the diagnostic accuracy of TE [using area under the receiver operating characteristic curve (AUROC)] for F ≥ 2 or F = 4 fibrosis stage and/or diagnostic indexes (sensitivity, specificity, positive predictive value, or negative predictive value based on some cutoff LS values). Most Asian studies were conducted in Korea and China (Hong Kong) and some studies were available in abstract form from Korea, Singapore, and Thailand.

The AUROCs for predicting F ≥ 2 fibrosis and F = 4 fibrosis stage in patients with CHC were reported as 0.79-0.83 and 0.97-0.95, respectively in the studies by Ziol *et al*[2] and Castera *et al*[44]. However, the AUROCs in Asian studies seems to be lower than those reported in European studies (0.76-0.88 for F ≥ 2 and 0.80-0.93 for F4, Table 4), although TE diagnosed cirrhosis more accurately than significant fibrosis in Asian studies.

Overall, TE is accepted as a promising and accurate tool for the early detection of cirrhosis irrespective of the etiology of CLD, although the optimal cutoff values remain debatable. The range of the optimal cutoff values for diagnosing HBV-related cirrhosis in the Asian population were between 9.0 and 10.1 kPa based on the full-length articles[4,11,39] (Table 4) and the range for cirrhosis was less than 11.0 kPa, which is consistently lower than in

patients with CHC[45,46]. These findings can be explained in several ways. The histopathological characteristics of CHC (including portal lymphoid follicles, bile duct damage, lobular activity, and steatosis) may contribute to the variations in cutoff values compared with those in patients with CHB[47]. Another explanation is that the total fibrotic material in CHB may be lower than that in CHC, because CHB tends to make the liver macronodular and heterogeneous[48]. Other researchers have proposed that the different types and extent of liver inflammatory infiltrate within the liver may account for the different cutoff LS values between CHB and CHC[20].

The performance of TE in prediction of cirrhosis is acceptable for the Asian population with CHB, but increased performance in prediction of significant fibrosis and subsequent precise staging, particularly for patients with CHB who are candidates for antiviral treatment, is needed and should be pursued through future studies. This is particularly important, because the decision to start antiviral treatment and the type of antiviral agents to be used may be affected by fibrosis stage.

CONCLUSION

Because of limitations of LB, prohibiting its routine use for the evaluation of liver fibrosis in patients with CHB, interest in the use of noninvasive TE has increased. Ideally, TE can be used to screen the general population to detect high-risk patients with potential liver disease, to identify patients with significant fibrosis who could benefit from the initiation of antiviral treatment, to select patients with cirrhosis who are at a high risk of developing HCC[25], and to identify patients with cirrhosis and portal hypertension. To date, although numerous European studies have demonstrated that this is possible, data on TE for the Asian population are scarce.

We are now fully armed with nuggets of knowledge that the etiologies of CLD, BMI, MS, cardiac function, cholestasis, hepatic steatosis, and ALT levels can influence the performance of TE, and also that several confounders vary between Asian and European populations, for example, the etiology of CLD, major fluctuation in ALT levels, and the prevalence of high BMI and MS. However, because almost all information on TE has thus far originated from European data, for the Asian population with CHB, TE is not popular clinically. Therefore, further studies tailored to the Asian population with CHB will restore the confidence of Asian clinicians to utilize TE.

Abstract

Although evidence is emerging that the prevalence of *Helicobacter pylori* (*H. pylori*) is declining in all age groups, the understanding of its disease spectrum continues to evolve. If untreated, *H. pylori* infection is lifelong. Although *H. pylori* typically colonizes the human stomach for many decades without adverse consequences, children infected with *H. pylori* can manifest gastrointestinal diseases. Controversy persists regarding testing (and treating) for *H. pylori* infection in children with recurrent abdominal pain, chronic idiopathic thrombocytopenia, and poor growth. There is evidence of the role of *H. pylori* in childhood iron deficiency anemia, but the results are not conclusive. The possibility of an inverse relationship between *H. pylori* and gastroesophageal reflux disease, as well as childhood asthma, remains a controversial question. A better understanding of the *H. pylori* disease spectrum in childhood should lead to clearer recommendations about testing for and treating *H. pylori* infection in children who are more likely to develop clinical sequelae.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is one of the most common chronic bacterial infections world-wide, and it is currently estimated that approximately half of the world's population is infected with the bacterium[1,2]. However, the prevalence of *H. pylori* is not homogeneous world-wide[1,3]. In western countries, the prevalence of infection has been decreasing during the past few decades[4-6]. *H. pylori* infection is acquired early in life (almost always before the age of 10 years), and in the absence of antibiotic therapy, it generally persists for life[1].

It is widely accepted that *H. pylori* infection is the main etiological factor for gastritis and peptic ulcer[3]. Its eradication is associated with healing of these diseases and significant reduction of ulcer recurrence and rebleeding[7,8]. Several studies have demonstrated that inflammation caused by *H. pylori* infection might contribute to the development of adenocarcinoma of the stomach; moreover, it has been involved in the development of low-grade B-cell lymphoma of gastric mucosa-associated lymphoid tissue

type (MALT)[3,9]. Recently, a potential role of *H. pylori* infection in other digestive diseases (gastroesophageal reflux disease; GERD) as well as several extra-intestinal pathologies [iron deficiency anemia (IDA), growth retardation, idiopathic thrombocytopenic purpura (ITP), asthma and allergic disorders] has been suggested[10]. The postulated role of *H. pylori* in the pathogenesis of extra-intestinal manifestations is based on the facts that: (1) local inflammation has systemic effects; (2) *H. pylori* gastric infection is a chronic process that lasts for several decades; and (3) persistent infection induces a chronic inflammatory and immune response that is able to induce lesions both locally and remote to the primary site of infection[11].

The aim of this report is to provide a critical review of the available literature about digestive and extradigestive manifestations of *H. pylori* infection in children. Pertinent articles have been identified through a MEDLINE search. Studies published in English during the past two decades have been identified and reviewed.

GASTRITIS AND PEPTIC ULCERS

During childhood, *H. pylori* is associated with predominant antral gastritis, and duodenal ulcers[12-14]. Successful eradication of *H. pylori* markedly reduces the rate of recurrence of duodenal ulcers in affected children[2,15,16]. Gastric ulcers are much less common in children than they are in adults[17].

A pooled analysis of early reports (1983-1994) has demonstrated that the rate ratio of antral gastritis for children with *H. pylori* infection (compared with uninfected subjects) ranged from 1.9 to 71.0 (median, 4.6)[17]. The prevalence of *H. pylori* in children with duodenal ulcer was high (range, 33%-100%; median, 92%) compared with children with gastric ulcer (range, 11%-75%; median, 25%)[17]. Thus, there was strong evidence for an association between *H. pylori* infection and antral gastritis and duodenal ulcer in children; there was weak evidence for an association with gastric ulcer. Nevertheless, a subsequent retrospective study (1995-2001) from Japan has confirmed that the prevalence of *H. pylori* was very high in antral (nodular) gastritis and duodenal ulcer (98.5% and 83%, respectively), but it has also demonstrated that *H. pylori* was a definite risk factor for the development of gastric ulcer, although the prevalence of infection did not reach 50%[18]. *H. pylori* was significantly linked to duodenal and gastric ulcers in the age group 10-16 years, but not ⩽ 9 years.

More recently, a decreasing proportion of *H. pylori*-positive peptic ulcers in adults has been observed, along with a decrease in the prevalence rate of the infection[19]. In children, there have been few data published in the literature to investigate the trend of *H. pylori* prevalence in peptic ulcer[20-23]. In a prospective European multicenter pilot study on the incidence of gastric and duodenal ulcer disease in children, Kalach *et al*[20] have found that ulcers occurred in 10.6% of cases, with *H. pylori* infection in only 26.7% of these. From January 2001 to December 2002, information on 518 children was collected from the pediatric European register for treatment of *H. pylori*[21]. At endoscopy, 454 children had *H. pylori*-associated gastritis and 64 had an ulcer (12.3%). However, this series included children from Russia and they had a significantly higher prevalence of peptic ulcer (35% *vs* 6.7% in the remainder of European children, $P < 0.0001$; OR: 7.5; 95% CI: 4-13). Thus the prevalence of *H. pylori*-positive ulcers in children differed between countries, and this was not completely explained by the prevalence of the infection in the population studied[22]. In a retrospective review (1998-2006) of 619 Chinese children who had undergone upper endoscopy for investigation of upper gastrointestinal symptoms, Tam *et al*[23] have found that 43 (6.9%) had peptic ulcer. Of these 43 patients, 37 and six had duodenal and gastric ulcer, respectively. The prevalence of *H. pylori* infection was 56.8% (21/37) in duodenal ulcer and 33.3% (2/6) in gastric ulcer. When they arbitrarily divided the study period into two, 1998-2001 and > 2002, no significant difference in the prevalence of *H. pylori* infection between the two periods was found.

GASTRIC MALIGNANCIES

In relation to *H. pylori*-associated gastric malignancies in children, there have been a few cases of gastric MALT lymphoma[14,24,25], but there have been no reports of adenocarcinoma.

There is evidence to support an association between long-standing *H. pylori* infection, gastric atrophy, and intestinal metaplasia with the development of intestinal-type and undifferentiated adenocarcinomas in adults[3]. It has been suggested that chronic gastritis, gastric atrophy, intestinal metaplasia and gastric cancer develop progressively, stepwise over decades, in predisposed individuals infected by *H. pylori*[26]. However, gastric atrophy and intestinal metaplasia have indeed been described in children living in countries with high gastric cancer incidence[27], and they are sometimes found in very young subjects[28-30]. These findings provide support to the hypothesis that host genetic factors that affect the inflammatory and immune response to *H. pylori* infection might determine why some individuals infected with this bacterium develop precancerous lesions and gastric carcinoma while others do not[31,32]. Thus, it is probable that the prevalence of gastric atrophy and intestinal metaplasia varies according to the geographic/genetic origins as well as environmental factors[27-30,33-40], as shown in Table 1. Yet, sampling problems exist. In fact, the non-systematic search during pediatric gastroscopy for these histological states might mask their true prevalence[32]. Most reported studies of the histological features of *H. pylori* infection in children have used either random biopsies[41] or a small number of targeted biopsies[29,34,42,43], taken primarily from the antrum[29,44]. In most studies, the identification of atrophy has been focused on the presence of intestinal metaplasia or has been ill defined[29].

In clinical practice, the updated Sydney system is widely used for grading gastric histopathological findings (density

[1]Atrophic mucosa: 31% as intestinal metaplasia; 63% as pseudopyloric metaplasia; 6% as both. *H. pylori*: *Helicobacter pylori*.

of *H. pylori* organisms, acute and chronic inflammation, atrophy and intestinal metaplasia)[45]. Although this system has been validated in adult patients, interobserver variability is still a problem, primarily in the evaluation of mucosal atrophy[46,47]. Thus, further validation of atrophy parameters needs to be obtained for pediatric biopsy samples[29]. In contrast, metaplastic epithelium is easily detected by the pathologist, owing to the characteristic goblet cells[32].

In adults, five gastric biopsy samples are recommended (two antral, two corporeal and one from the angulus)[45], but no consensus is available about the optimal number and site location of gastric biopsies in children. Clinical practices in this domain are very heterogeneous, which could in part account for the different prevalence figures of atrophic gastritis in children[32]. Of note, in a study of 173 children from countries with high gastric cancer incidence, Ricuarte *et al*[27] emphasized the importance of biopsy site location for identifying the presence of corpus atrophy. In children, atrophy is only identified in biopsies taken near the normal antrum-corpus junction, which is consistent with the notion that atrophy progresses as an advancing antrum-corpus border[27]. Therefore, identification and characterization of the natural history of *H. pylori* gastritis requires, in addition to biopsies that target the antrum and the cardia, targeted biopsies to include the lesser and greater curvature of the corpus, starting just proximal to the anatomical junction of the antrum and corpus. Unfortunately, the sites recommended by the updated Sydney system can identify corpus atrophy only when it is extensive.

Studies from the 1990s have established that the development of low-grade gastric MALT lymphoma is strongly associated with chronic *H. pylori* gastritis. In two large series of adult patients, *H. pylori* was detected by histological examination in 92% and 100% of those with gastric MALT lymphoma[48,49]. Recognition of the responsiveness of MALT lymphoma to antibiotic therapy aimed at eradication of *H. pylori* has changed the approach to its management. Remission rates in the literature range from 60% to 80%, although recurrence can be expected in 5% of cases[50-53]. MALT lymphoma occurs commonly in middle and old age; only a small number of cases have been reported in both immunocompetent and immunocompromised children[14,24,25]. Individual case reports have described the regression of MALT lymphoma after *H. pylori* eradication therapy alone[24,25].

FUNCTIONAL DYSPEPSIA

The role of *H. pylori* infection as a cause of non-ulcer or functional dyspepsia has been one of the most debated controversies in the medical community since the discovery of this bacterium.

Dyspepsia is very common in children with chronic or recurrent abdominal pain (RAP), with as many as 80% reporting this symptom[54]. The relation between RAP in childhood and *H. pylori* infection is not clear[17]. Pediatric studies are limited by the lack of a clear definition for RAP or by the use of nonspecific criteria for the diagnosis of chronic abdominal pain[54]. A pooled analysis of early reports (1983-1994) has demonstrated that prevalence rates of infection in children with RAP were inconsistent (range, 0%-81%; median, 22%),with lower rates (range, 0%-9%; median, 6%), in children who met Apley's criteria (i.e. at least three discrete episodes of abdominal pain of sufficient severity to interrupt normal daily activities or performance occurring over a period of $\geq$ 3 mo)[17].

In adults, several controlled trials have shown a vague connection between *H. pylori* colonization and dyspeptic symptoms[55]. In children, controlled randomized treatment studies have been scant. The results of two uncontrolled trials have suggested improvement of clinical symptoms after treatment of *H. pylori* infection[56,57]. However, the double-blind, randomized placebo-controlled trial by Ashorn *et al*[58] has suggested that RAP is not an indication

for a test and treatment strategy for *H. pylori* infection in children. In fact, in that study, at 52 wk, dyspeptic symptoms improved to the same extent in the treatment group and in children who received placebo, irrespective of the healing of gastritis, which was more commonly achieved along with eradication[58]. Nonetheless, due to the limited number of patients who could finally be included, the results by Ashorn *et al*[58] have to be interpreted with care. Large-scale multicenter trials performed in children are still needed to answer definitively the question whether a connection exists between *H. pylori* infection and RAP. Neither did the results of a very recent study give support for the use of *H. pylori* eradication in children with RAP[59]. Based on a meta-analysis of 38 studies between 1966 and 2009, the study by Spee *et al*[59] has found no association between RAP (fulfilling Apley's criteria) and *H. pylori* infection in children. However, the authors have demonstrated that children who are referred to a gastroenterologist with unspecified abdominal pain (i.e. including children who do not fulfill Apley's criteria) or pain in the epigastric region are at 2-3-fold higher risk for *H. pylori* infection than children without these symptoms. Thus, these authors have postulated that unspecified abdominal pain in a hospital-based setting and epigastric pain in general might be associated with (acute) *H. pylori* infection. The potential for *H. pylori* to cause clinical symptoms that arise from gastric infection, in the absence of mucosal ulceration, requires additional studies using a strict study group definition. Functional dyspepsia and non-ulcer dyspepsia (i.e. epigastric pain in the absence of mucosal ulceration at esophago-gastro-duodenoscopy) must be evaluated as separate entities.

GASTROESOPHAGEAL REFLUX DISEASE

The interaction between *H. pylori* infection and GERD has been widely debated in the literature over the past decade, and the hypothesis that eradication of *H. pylori* leads to increased GERD has been the subject of many publications with contradictory conclusions in children as well as in adults[38,60-76]. There are limited data in children because the prevalence of *H. pylori* infection is low and no randomized controlled trials have been conducted; therefore, inferences about the effects of *H. pylori* eradication and GERD need to be drawn from studies on adult patients[77].

H. pylori has been found to be inversely correlated with the prevalence of GERD, and certain studies have shown aggravation of esophagitis after eradication[60-66]. Suggested mechanisms include presence of atrophic or significant body gastritis that leads to a post-eradication increase in acid output; decreased buffering as a result of elimination of *H. pylori*, which produces ammonia *via* bacterial urease; masking of reflux by acid neutralizing medications given for *H. pylori*-related disease; and increased appetite with weight-gain- mediated reflux. These observations are controversial, because several studies have not found an association between eradication of *H. pylori* and reflux disease[38, 66,70,74,78-80].

Most studies aimed at evaluating the effect of *H. pylori* eradication on reflux in adults have used selected populations such as those with duodenal ulcer or patients with GERD before eradication[63,65,78,80]. The spectrum of risk factors found in adults, such as atrophic gastritis, duodenal ulcer, or significant esophagitis, might influence the outcome of the study. These factors are less common in children, therefore, these results might not be relevant to the decision to eradicate *H. pylori* when found in children[38].

Dent has proposed that the effect of *H. pylori* eradication on GERD is most likely determined by the population studied[67]. Acid secretion in predominant antral gastritis with preserved body mucosa is hyper-responsive, thus enabling increased duodenal or esophageal injury. In these patients, eradication should improve or not affect GERD. This hypothesis is consistent with the results of other studies that have shown improvement in GERD symptoms in patients with duodenal ulcer[80,81]. However, in patients with atrophic gastritis or severe body gastritis, *H. pylori* eradication might result in increased acid secretion. Children and adolescents are more likely to behave like the first group, with predominant antral gastritis[38].

The risks and benefits of *H. pylori* eradication are less well-defined for patients with gastritis alone, and vary according to the severity and pattern of gastritis[67]. Although this is the patient group most likely to develop reflux esophagitis[63], the risks from this are outweighed by those of continued *H. pylori* infection. Reflux esophagitis following *H. pylori* eradication is believed to carry little risk and, in particular, not to lead to intestinal metaplasia. By contrast, the risks of continued *H. pylori* infection are relatively high in patients who have had an episode of chronic duodenal, gastric or gastroduodenal ulceration[67]. What is certain, is that *H. pylori* is a major risk factor for non-cardia gastric adenocarcinoma[82], and children with this infection have at least a fivefold increased risk of developing stomach neoplasia in later life. This risk is likely to be reversed with *H. pylori* eradication[77]. In a study of high-risk adults, no reduction in gastric cancer risk at the end of 7.5 years of follow-up was observed in *H. pylori* carriers who had previously undergone eradication therapy[83]. However, in a subgroup analysis of patients who had no precancerous lesions at baseline, cancer risk was significantly reduced[83]. Additional studies have suggested that prevention of gastric cancer might be possible in infected individuals without precancerous lesions[84,85]. Therefore, children could well be the group to target in an effort to prevent the future development of gastric cancer.

IRON DEFICIENCY ANEMIA

In addition to the already known causes of IDA, over the past two decades, an association between *H. pylori* and pediatric IDA has been established[86-92]. However, the issues of whether *H. pylori* infection is linked causally to IDA in children and whether treatment or resolution of *H. pylori* infection would improve iron stores or resolve IDA in children are still matters of great debate. In 1991,

Table 2 Randomized trials of *Helicobacter pylori* eradication for iron deficiency anemia and iron deficiency in children

Author (yr)/country	No. of children with IDA/*H. pylori*	Follow-up (No. of children)	Outcome	
			IDA	ID
Choe *et al*[89] (1999)/Korea	43/25	8 wk (18)	Hb increased with: eradication + iron, eradication + placebo *vs* iron + placebo ($P = 0.0086$)	No significant differences in serum iron or ferritin
Sarker *et al*[106] (2008)/Bangladesh	260/200	3 mo (260)	IDA persisted with: eradication + iron, 11%; eradication alone, 33%; iron alone, 0%; placebo, 45%	ID persisted with: eradication + iron, 19%; eradication alone, 65%; iron alone, 7%; placebo, 78%
Gessner *et al*[105] (2006)/Alaska	219/219	14 mo (201)	IDA persisted with: eradication + iron, 22%; iron alone, 14%	ID persisted with: eradication + iron, 65%; iron alone, 72%
Fagan *et al*[104] (2009)/Alaska	219/219	40 mo (176)	IDA persisted with: eradication + iron, 5%; iron alone, 19%	ID persisted with: eradication + iron, 52%; iron alone, 58%

Hb: Hemoglobin; ID: Iron deficiency; IDA: Iron deficiency anemia; *H. pylori*: *Helicobacter pylori*.

an association between *H. pylori* infection and IDA due to microscopic blood loss was described in a 15-year-old girl with *H. pylori*-positive chronic active hemorrhagic gastritis, who showed no signs of gastrointestinal symptoms[88]. Two years later, Dufour *et al*[93] reported a 7-year-old child who presented with *H. pylori*-associated chronic antral gastritis without evidence of hemorrhage or clinical symptoms other than sideropenic anemia, which was refractory to oral iron administration and subsided after *H. pylori* eradication. These case reports were followed by other studies that have identified an association between *H. pylori* infection and pediatric unexplained or refractory IDA, and have indicated improvement of iron stores and anemia after successful *H. pylori* eradication[94-100]. Yet, some pediatric studies have implicated *H. pylori* as a cause of IDA that is refractory to oral iron treatment[94,95,99,100]. Thus, the above studies have supported a clinically significant influence of *H. pylori* infection on body iron stores and have led to a recommendation for *H. pylori* eradication in infected individuals with unexplained IDA[101-103]. However, small sample sizes, lack of control groups, and other methodological issues, including the use of validated measures of active *H. pylori* infection such as biopsy-related tests to confirm *H. pylori* infection, are among factors that have limited the interpretation and ability to generalize the importance of the results of these studies in children.

To the best of our knowledge, only four population-based randomized trials of the effect of *H. pylori* infection treatment on IDA have been performed in children[89,104-106], as shown in Table 2. Three of them lacked true placebo groups[89,104,105]. Choe *et al*[89] have demonstrated a beneficial effect of *H. pylori* eradication therapy plus iron or placebo in increasing hemoglobin levels. However, no significant differences among study groups were found at 8 wk follow-up for serum iron level, total iron-binding capacity, and ferritin level. Sarker *et al*[106] have shown, in a relatively large cohort of Bangladeshi children with IDA, a similar improvement of IDA as well as iron deficiency, with anti-*H. pylori* therapy plus iron compared with iron therapy alone. Therefore, the improvement of iron status in children who receive combined therapy could be attributed to the effect of iron rather than anti-*H. pylori* therapy. The findings from the Bangladeshi children corroborated well those of the study from rural Alaska, which showed that treatment and resolution of *H. pylori* infection did not substantially decrease levels of iron deficiency or mild anemia at 14 mo after treatment initiation, despite the relatively low rate of reinfection once the initial infection resolved[105]. When an additional follow-up evaluation at 40 mo after treatment initiation was performed, it was found that sustained resolution of *H. pylori* infection substantially reduced the prevalence of mild IDA but modestly improved iron status[104].

How can *H. pylori* gastritis cause IDA? Several theoretical mechanisms have been proposed to explain the possible relationship between *H. pylori* infection and decreased iron stores. It appears that chronic gastrointestinal blood loss is not the likely culprit, because most published cases and case series have found no bleeding lesions at the time of endoscopy, and have reported negative testing for fecal occult blood[107]. Another explanation for a relationship between *H. pylori* infection and IDA involves the possible effect of *H. pylori* gastritis on gastric acid secretion and iron absorption. Non-heme iron accounts for 80% of dietary iron in industrialized countries[107]. Crucial to the effective absorption of non-heme iron is hydrochloric acid in acid secretions. Reduction of the ferric to ferrous form is dependent upon the pH of the gastric juice, and reduction to the ferrous form facilitates membrane transport[108]. An important promoter of iron absorption is ascorbic acid, which appears to act in two ways: by promoting reduction to the ferrous form, and by forming an absorbable molecular complex with ferric iron, which is insoluble at pH > 5[107,109]. Gastric acid hyposecretion results from atrophy of the gastric glands and fundic mucosa, which has been associated with chronic *H. pylori* infection[107]. It has been shown that adult patients with IDA and *H. pylori* infection are more likely to have a pattern of gastritis that involves the gastric corpus, with related decreases in gastric acid secretion and increases in intragastric pH that might impair iron absorption[110]. There are no comparable data in children.

Another hypothesized mechanism is that *H. pylori* might lead to IDA by sequestering and utilizing iron, thus

Table 3 Cross-sectional studies on the association between *Helicobacter pylori* infection and growth retardation

Author (yr)/country	Total No. of patients (*H. pylori* +)	Age (range, yr)	Diagnostic test	Conclusion

Gulcan *et al*[124] (2010)/Turkey	181 with RAP (121)	6-15	Endoscopy, 181	RAP associated with gastric mucosal injury had a negative effect on BMI independent of *H. pylori* infection
	309 asymptomatic (110)	6-15	Serology, 309	RAP originating from *H. pylori* infection affected both BMI and linear growth

BMI: Body mass index; RAP: Recurrent abdominal pain; IDA: Iron deficiency anemia; *H. pylori*: *Helicobacter pylori*.

competing with the human host[107]. Ferrokinetic studies have suggested the diversion of iron to some extramedullary focus, hypothesized but not proven to be *H. pylori*-associated gastric infection[95]. Like many bacteria, *H. pylori* requires iron as a growth factor, and it possesses a 19-kDa iron-binding protein that resembles ferritin, which has been considered to play a role in storage of excess iron sequestered by the bacterium[111]. Another possible mechanism for IDA in *H. pylori*-infected subjects involves sequestration of iron in lactoferrin in the gastric mucosa, and uptake of iron by *H. pylori*. Lactoferrin is an iron-binding glycoprotein that is found in body fluids, and its secretion in the gastric mucosa seems to be influenced by some signal from *H. pylori*[112]. It appears that *H. pylori* then absorbs the iron from lactoferrin *via* a specific lactoferrin-binding protein that is expressed by *H. pylori*[107]. Lactoferrin levels in the gastric mucosa have been shown to be significantly higher in *H. pylori*-positive patients with IDA compared to those who are non-anemic *H. pylori*-negative, non-anemic *H. pylori*-positive, and *H. pylori*-negative with IDA[112].

We conclude that future work in this area is needed. Randomized, double-blind, and placebo-controlled trials of sufficient size and power should evaluate the long-term effect of *H. pylori* eradication in children with IDA, who are living in developing as well as in developed countries. Additionally, these studies should evaluate the effect of *H. pylori* treatment among different pediatric populations, such as those with and without concurrent gastrointestinal symptoms, and those with a wide spectrum of IDA severity.

Based on our present knowledge, children with a first episode of IDA and no complications should be initially treated with iron supplementation alone, irrespective of *H. pylori* status[2]. Eradication of *H. pylori* could be considered in cases that are refractory to iron supplementation and in the case of frequent relapses, assuming that other causes, such as celiac disease and inflammatory bowel disease, have been excluded[2,102]. Of particular interest is the work by Memeo *et al*[113] who have shown the frequent occurrence of duodenal intraepithelial lymphocyte expansion in individuals with *H. pylori* gastritis, and the considerable overlap of the intraepithelial lymphocyte counts as well as the distribution patterns with those described for celiac disease and other small bowel diseases.

GROWTH RETARDATION

The available evidence regarding *H. pylori* infection and its effect on growth in children is controversial. There have been many cross-sectional studies that point to either the presence or absence of such an association[90,114-124], as shown in Table 3.

The Italian cross-sectional study by Perri *et al*[114] suggests that *H. pylori* infection (as diagnosed by urea breath test) is associated with growth delay in older children, poor socioeconomic conditions, and household overcrowding. The findings by Perri *et al*[114] are consistent with the hypothesis that *H. pylori* infection is one of the environmental factors capable of affecting growth. The cross-section-

al study by Richter *et al*[117] of a large number of 5-7-year-old preschool and school children suggests that *H. pylori* infection (as diagnosed by urea breath test) is associated in German children with growth delay, growth retardation, or both, despite similar socioeconomic status between *H. pylori*-positive and -negative children. Likewise, Ertem *et al*[118] also have suggested that *H. pylori* is associated with short stature through mechanisms that are independent of poor living conditions.

Other investigators have suggested that growth suppression reported in children with *H. pylori* infection could be due to socioeconomic, genetic and environmental factors. In their retrospective chart review of the growth parameters of children with dyspepsia referred to the Regional Paediatric Gastroenterology unit in Manchester, United Kingdom, Sood *et al*[119] found that children with dyspepsia and *H. pylori* infection (as diagnosed by urea breath test) were shorter and lighter than patients with similar symptoms but no infection. Sood *et al*[119] concluded that the differences in anthropometry might have been due to socioeconomic and ethnic factors rather than *H. pylori* infection. Yet, in a cross-sectional study of Turkish dyspeptic children who were evaluated by endoscopic gastric biopsy for *H. pylori* infection, as well as a control group of age and sex cross-matched children, Soylu and Ozturk found that dyspeptic children with and without *H. pylori* infection had worse nutritional status compared to healthy controls[122]. The authors concluded that *H. pylori* infection as a major cause of dyspepsia might be considered to cause malnutrition secondary to decreased caloric intake associated with dyspepsia[122].

In a case-control study of children aged 5-13 years whose height was below the third centile, matched with children of the same age and sex whose height was above the 25th centile, Oderda *et al*[115] found that *H. pylori* (diagnosed by serologic methods) was not a risk factor for short stature, and that reduced growth was related to genetic determinants such as parental height and to mixed genetic and environmental factors such as birth weight. Low socioeconomic status was also relevant[115]. In a cross-sectional study of children aged 5-10 years who were attending an all-girl public school in inner Guatemala City, Quiñonez *et al*[116] investigated the effect of *H. pylori* infection (diagnosed by serologic methods) on the anthropometric nutritional parameters (weight-for-height and height-for-age). After controlling for sociodemographic variables, the authors did not find significant differences in the nutritional parameters between infected and uninfected children. In another cross-sectional study of Turkish children aged 4-16 years who underwent upper gastrointestinal endoscopy for RAP and dyspeptic complaints, Süoglu *et al*[120] found that the effect of *H. pylori* infection on mean SD scores of height for age was statistically insignificant after correction for breast feeding, IDA and socioeconomic level. In contrast, even after controlling for socioeconomic level, *H. pylori* infection remained the single and most important variable that had an effect on mean weight SD score. Among *H. pylori*-positive as well as -negative children[120], IDA had no significant effect on anthropometric measurements *per se*. However, when *H. pylori* and IDA were present, mean weight was found to be significantly lower than that of the *H. pylori*-negative patients without IDA[120].

There are also longitudinal studies that support the hypothesis that *H. pylori* infection might influence growth rate in children. Thomas *et al*[125] conducted two consecutive prospective, longitudinal cohort studies in Gambia, and found that, in both cohorts, children with early *H. pylori* colonization had lower values for both length- and weight-for-age Z scores than their peers in late infancy. No socioeconomic or demographic confounding variables were identified to explain this, and the weight deficit was no longer detectable when the children were aged 5-8 years. The authors concluded that *H. pylori* colonization at critical vulnerable ages might lead to malnutrition and growth retardation among infants in countries such as Gambia[125]. In the prospective, longitudinal study by Bravo *et al*[126], lower-middle class children from Colombia, in general good health, aged 1-5 years, who tested negative by urea breath test at baseline, were monitored over the following 2.5 years for anthropometric measurements every 2 mo, and for *H. pylori* by urea breath test every 4 mo. The authors found significant slowing of growth velocity in children infected with *H. pylori*, independent of socioeconomic variables or overcrowding[126]. Likewise, Mera *et al*[127] prospectively investigated in Colombian children, in general good health, aged 1-5 years, whether a newly acquired *H. pylori* infection affected height and weight of children within 16 mo, by performing breath tests and anthropometry every 2-4 mo. The authors observed that the impact of a new infection on height growth velocity was more pronounced right after the infection was diagnosed and slowly ebbed, and continued to be significant for up to 6 mo after infection, and became borderline significant at 8 mo after infection. No catch-up growth was evident in infected children, with crowding retarding linear growth. Compared with uninfected children, newly infected children also experienced a significant, but small, decrease in weight at the first follow-up visit, which was not statistically significant at 4 mo after infection. There was no catch-up in weight. The authors concluded that *H. pylori* caused a non-transient negative effect on height and weight in affected children, regardless of age at the time of infection[127].

Taken together, the results of these studies pointing to the presence or absence of an association between *H. pylori* and growth are subject to some potential limitations. First, most studies were cross-sectional or retrospective and therefore were unable to evaluate the possible effect of new infections on growth velocity. Second, the definition of socioeconomic status is complex and no set of parameters was fully descriptive in most studies. Third, some studies used serological methods to determine *H. pylori* infection. However, serology does not indicate whether there is active or past infection. Even in those patients who are treated and cured of their *H. pylori* infection, evidence of IgG antibodies may exist for several months

and possibly for years. Serological assays also have varying levels of sensitivity and specificity when used in different populations, particularly in children[128]. Fourth, in community-based studies, for example, in those that involve a blood specimen, participation rate is rarely more than 50%[116,129]. This might also be the case for studies that involve gastrointestinal endoscopy. As such, we have no information on the non-participating children in some of the above studies; thus, we cannot estimate if any bias was introduced in the results or the generalizability of their findings to other populations.

We conclude that future work in this area is needed to elucidate the importance of these factors. One would expect growth velocity to improve following *H. pylori* eradication, if the infection were the primary cause of growth suppression.

IDIOPATHIC THROMBOCYTOPENIC PURPURA

ITP is an autoimmune disease that is characterized by a low circulating platelet count caused by the destruction of antibody-sensitized platelets in the reticuloendothelial system[130]. The mechanisms that trigger the production of platelet autoantibodies remain poorly understood. Persistent thrombocytopenia for > 6 mo defines the chronic form of this disorder (cITP)[130]. Lately, eradication of *H. pylori* from the gastric mucosa has been associated with an improvement of cITP.

Several studies in adults have reported improved platelet counts in *H. pylori*-positive patients following standard triple *H. pylori* eradication therapy[131-140]. A meta-analysis of 13 cohort reports in adult cITP, with combined data from 193 patients, has indicated an overall response rate of 52% of patients after *H. pylori* eradication therapy[141]. A recent systematic review of 25 published studies, with combined data from 696 adult patients with cITP, has demonstrated an overall response in platelet count after *H. pylori* eradication in 50.3% of patients (95% CI: 41.6%-59.0%)[142]. Cohorts from Japan and Italy[132,134,138,140] have reported higher response rates than from other countries[143,144]. Several theories, including direct antigen mimicry between *H. pylori cagA* and platelet glycoprotein antigens, *H. pylori* binding to von Willebrand factor, and the immunomodulatory effect of antibiotics (e.g. macrolides) used in *H. pylori* eradication, have been proposed to explain the platelet response to anti-*H. pylori* therapy[139,141]. It has also been postulated that platelet autoantibodies might be produced by autoreactive clonal B cells that are induced by chronic immunological stimulus by *H. pylori*[141,145]. The relative toxicity profiles of triple therapy compared to standard ITP therapy certainly make eradication an attractive and generally safe option in adults. However, large controlled clinical trials of adult patients from various ethnic backgrounds are necessary to determine the response rate and mechanism of platelet response to *H. pylori* eradication therapy[141].

In children, the natural history of cITP is clearly different from that observed in adults. Spontaneous recovery occurs in one third of childhood cITP cases from several months to many years after their diagnosis, whereas only 5% of adults recover[130,146]. Thus, the effects of *H. pylori* eradication in childhood cITP could be different from those in adults. The issue of whether *H. pylori* eradication has a beneficial effect on the course of cITP in children has been the subject of few, apparently contradictory studies with small sample sizes[147-153]. Yet, the results of pediatric studies are difficult to compare because the prevalence of *H. pylori* infection and diagnostic methods vary among them[154]. Of note, in children with cITP, no studies have assessed, at the initial as well as follow-up visits, *H. pylori* status by upper gastrointestinal endoscopy.

In a study from Taiwan, Jaing *et al*[147] evaluated 22 cITP children, nine of whom were *H. pylori*-infected and were treated with a 1-wk course of triple therapy [including clarithromycin, amoxicillin, and proton pump inhibitors (PPIs)]. Of these nine patients, five (55.6%) were in complete or partial remission over a median of 16 mo follow-up, while four showed no improvement in platelet counts during 8-19 mo follow-up. In a study from the Netherlands, Neefjes *et al*[149] evaluated 47 children with cITP, three of whom were *H. pylori*-infected and were treated with a 2-wk course of the triple therapy mentioned above. Over a 6-mo follow-up, all three children achieved complete or partial remission. In a study from Iran, Hamidieh *et al*[150] evaluated 31 cITP children, four of whom were *H. pylori*-infected and were treated with a 2-wk course of the same triple therapy. None of the four patients achieved complete or partial remission after *H. pylori* eradication. In a study from Japan, Hayashi *et al*[148] evaluated 10 children with cITP, one of whom was *H. pylori*-infected and was treated with a 1-wk course of the same triple therapy. This child achieved complete remission throughout > 1 year of follow-up. In a study from Italy, Bisogno *et al*[151] evaluated 25 children with cITP, nine of whom were *H. pylori*-infected and had *H. pylori* eradication following 1-2 courses of 2 wk of the same triple therapy. Over 6-mo follow-up, of these nine patients, three had an increase in platelet count after eradication therapy, and one had complete remission and two had partial, transient remission followed by relapse a few months later. Over the same follow-up period, no significant increase in platelet count was seen in the other six eradicated patients. In the same study, Bisogno *et al*[151] also reported the platelet response in the 16 *H. pylori*-negative children with cITP. At 6-mo follow-up, two of these 16 patients achieved partial remission without any specific treatment. Yet, four of the *H. pylori*-negative children with cITP achieved spontaneous partial remission 1 year after diagnosis of *H. pylori* infection was excluded[151]. At latest follow-up, the remaining 10 *H. pylori*-negative children presented with a count above 50×10^9/L without any treatment. In another study from Italy, Loffredo *et al*[152] evaluated 39 children (median age, 136 mo) with cITP, eight of whom were *H. pylori*-infected and had *H. pylori* eradication following 1-3 courses of 2 wk of the same triple therapy. Over 1-year follow-up, none of the eight patients achieved complete or partial remission after *H. pylori* eradication[152].

Recently, Treepongkaruna *et al*[153] reported a multicenter randomized controlled trial of *H. pylori* eradication in 55 children with cITP. Of the 16 (29.1%) patients with cITP and *H. pylori* infection, seven were randomly treated with PPI-based triple therapy, while the remaining nine did not receive any specific treatment. If the first-line therapy failed to eradicate *H. pylori,* then second-line eradication therapy was used. Although eradication of *H. pylori* infection was successful in all patients in the treated group, the platelet recovery rate was not significantly different between the *H. pylori* treatment group and control group during the 6-mo period.

From the foregoing, whether antibiotic treatment of *H. pylori* infection should be considered in children with cITP is an unresolved question[154]. In conclusion, in view of the published evidence in children with cITP and the sporadic benefit of *H. pylori* eradication on the platelet response, the relationship between *H. pylori* and cITP in children warrants further investigation with large randomized controlled trials of sufficient size and power and across different ethnic populations[154].

ASTHMA AND ALLERGIC DISORDERS

In industrialized countries, the incidence of asthma, especially childhood asthma, has risen in recent years[155]. Conversely, in developed countries, the rate of acquisition of *H. pylori* has decreased substantially over recent decades[3,9]. The lack of early exposure to *H. pylori* has been suggested to be an important determinant of asthma risk in childhood[156]. In a recent retrospective, cross-sectional study, using data from 3327 participants, aged 3-19 years, *H. pylori* seropositivity was found to be inversely associated with onset of asthma before 5 years of age and current asthma in children aged 3-13 years[157]. *H. pylori* seropositivity also was inversely related to recent wheezing, allergic rhinitis, and dermatitis, eczema, or rash.

Allergic diseases and asthma are caused by exaggerated T-helper 2 (Th2)-biased immune response in genetically susceptible individuals[158]. A number of recent studies have indicated that regulatory T cells (Tregs) play an important role in controlling such Th2-biased responses. Impaired expansion of natural and/or adaptive Tregs is hypothesized to lead to the development of allergy and asthma[158]. Increased numbers of Tregs have been reported in the *H. pylori*-infected human gastric mucosa[159,160]. Thus, the absence of early exposure to *H. pylori* might cause the loss of a metabolically active lymphoid compartment in the stomach, including Tregs, which ultimately could affect the activity of T cells present in other mucosal and cutaneous sites[156,160]. Although this is an undoubtedly interesting theory, future prospective, longitudinal studies are needed to test the strength of the association between *H. pylori* status and asthma risk in children from developed and developing countries[161].

CONCLUSION

Many areas of active scientific inquiry have been reported in the recent literature about the disease spectrum of *H. pylori*. Several studies have demonstrated that *H. pylori* infection is not associated with specific symptomatology in children. Therefore, identification of children with *H. pylori*-associated gastritis on the basis of clinical presentation alone is not possible. Based on the best available evidence, testing for (and treating) *H. pylori* infection should be performed in children with endoscopically proven duodenal ulcer. Evidence from studies in adults supports the recommendation that testing for *H. pylori* should also be performed in children with a documented gastric ulcer. Endoscopy and biopsy are also recommended for children with persistent symptoms.

Pursuing *H. pylori* in asymptomatic children should be indicated for patients at increased risk of gastric cancer, for example, first-degree relatives of patients with gastric cancer, and individualized in populations at increased risk for gastric cancer, taking into consideration comorbid illness. Studies suggest that prevention of gastric cancer is possible in infected individuals with no precancerous lesions. Therefore, children might well be the group to target in an effort to prevent future development of gastric cancer.

Although dyspepsia and *H. pylori* infection are common in the general population, current data in the literature regarding a causal association between *H. pylori* gastritis and dyspepsia are conflicting. It is uncertain whether eradication of the infection leads to an improvement of symptoms. Randomized, placebo-controlled, double-blind trials with minimal loss to follow-up, strict group definition, and standardized and validated outcome measures are needed.

There is no compelling evidence to support routine testing in children with cITP, poor growth, and GERD. In children with refractory IDA, where other causes have been ruled out, testing for (and treating) *H. pylori* infection can be considered. Prospective, longitudinal studies are needed to test the strength of the newly reported association between *H. pylori* status and asthma risk in children. In the absence of these studies, there is little call to leave *H. pylori* infection untreated in patients with asthma and allergy. We believe that *H. pylori* eradication is strongly beneficial for curing peptic ulcer disease and gastric lymphoma and for prevention of gastric cancer, as well as other diseases that are putatively linked to infection, and it must be done in *H. pylori*-infected patients, whether or not they have asthma.

Abstract

AIM: To study the expression of *β-catenin* in esophageal squamous cell carcinoma (ESCC) at stage T2-3N0M0 and its relation with the prognosis of ESCC patients.

METHODS: Expression of *β-catenin* in 227 ESCC specimens was detected by immunohistochemistry (IHC). A reproducible semi-quantitative method which takes both staining percentage and intensity into account was applied in IHC scoring, and receiver operating characteristic curve analysis was used to select the cut-off score for high or low IHC reactivity. Then, correlation of *β-catenin* expression with clinicopathological features and prognosis of ESCC patients was determined.

RESULTS: No significant correlation was observed between *β-catenin* expression and clinicopathological parameters in terms of gender, age, tumor size, tumor grade, tumor location, depth of invasion and pathological stage. The Kaplan-Meier survival curve showed that the up-regulated expression of *β-catenin* indicated a poorer post-operative survival rate of ESCC patients at stage T2-3N0M0 (P = 0.004), especially of those with T3 lesions (P = 0.014) or with stage ⅡB diseases (P = 0.007). Multivariate analysis also confirmed that *β-catenin* was an independent prognostic factor for the overall survival rate of ESCC patients at stage T2-3N0M0 (relative risk = 1.642, 95% CI: 1.159-2.327, P = 0.005).

CONCLUSION: Elevated *β-catenin* expression level may be an adverse indicator for the prognosis of ESCC patients at stage T2-3N0M0, especially for those with T3 lesions or stage ⅡB diseases.

Key words: Esophageal squamous cell carcinoma; *β-catenin*; Prognosis; Receiver operating characteristic curve; Immunohistochemistry

INTRODUCTION

Esophageal carcinoma, an aggressive tumor with a poor prognosis, is one of the most common malignant tumors in Asia, especially in certain areas of China, and South

America[1]. Esophageal squamous cell carcinoma (ESCC) accounts for over 90% of all esophageal cancers worldwide[2]. Despite advances in imaging technologies enabling earlier diagnosis of ESCC, surgery and response rates of radiotherapy and chemotherapy, the clinical outcome of ESCC patients remains unsatisfactory. Even in the developed world, more than 85% of ESCC patients die within 2 years after its diagnosis[3]. In China, the esophageal cancer mortality rate ranks fourth of cancer-related deaths[4]. Thus, improvement in the efficacy of ESCC treatment is a major public health goal. New modalities based on a better understanding of the ESCC biology are indispensable. Since the classical staging criteria fail to differentiate the prognostic characteristics of ESCC patients adequately, molecular tumor analysis may provide a necessary means for defining the prognosis of ESCC patients. In order to further improve the survival rate of ESCC patients, it is essential to identify the relevant biomarkers with adverse prognostic significance, and to modify the therapeutic strategies for individual patients according to their molecular tumor status.

β-catenin is an 88kDa versatile protein that has at least two different cellular functions[5-7]. First, *β-catenin* is an important structural component of both normal epithelium and malignant cells. Together with a structurally homologous *γ-catenin*, *β-catenin* participates in cell-cell and cell-matrix adhesion by binding to the intracellular domain of *E-cadherin*, a homotypic cell-to-cell interaction molecule ubiquitously expressed in epithelial cells[6,8,9]. In addition, these catenins play an important role in cell polarity by binding to the actin filament network of cytoskeleton through *a-catenin* as a linker[6,8]. Unlike other known catenins, *β-catenin* is also a key mediator in the Wingless/Wnt signal transduction pathway[7,8,10]. In cytoplasm of normal cells, the amount and location of *β-catenin* are controlled exquisitely through its association with the adenomatous polyposis coli (*APC*) tumor-suppressor gene product, a scaffolding protein *Axin*, and a glycogen synthetase kinase (*GSK-3β*) enabling phosphorylation and degradation of free *β-catenin*[6-10]. Once located in nuclei, *β-catenin* can act as a transcription factor by serving as a coactivator of the lymphoid enhancer factor/TCF family of DNA-binding proteins[10]. Activation of Wnt signaling involves the inhibition of catenin degradation by proteasomes, resulting in its cytoplasmic and nuclear accumulation and transcriptional activation of the target gene[5-7,10]. It is believed that *β-catenin* integrity impairment -related intracellular network may be closely associated with the dedifferentiation, hyperproliferation, invasion and metastatic potential of malignancy[10,11]. This biomarker has thereby been extensively studied in a variety of neoplasms, such as hepatocellular carcinoma[12], colorectal carcinoma[13], gastric cancer[14,15], pancreatic cancer[16], ovarian cancer[17], lung cancer[18-20], breast cancer[21], nasopharyngeal carcinoma[22], prostate cancer[23] and even lymphoma[24], with regard to its potential role as a prognostic factor in cell polarity. The present findings in ESCC are controversial in the literature[25-28]. The role of *β-catenin* in development of ESCC and its prognostic significance remain to be defined. In the present study, the expression level of *β-catenin* was measured in specimens from a relatively homogeneous cohort of ESCC patients with no lymph node involved, which was correlated with the clinical outcome of ESCC patients.

MATERIALS AND METHODS

Patients and tissue samples

The study was approved by the Ethics Committee of Sun Yat-Sen University Cancer Center. A total of 227 consecutive patients with node-negative ESCC at stage ⅠB-ⅡB who underwent curative surgery from January 1993 to August 2004 were enrolled in this study. *β-catenin* expression level was measured in resected specimens with immunohistochemistry (IHC). Patients were followed up prospectively and their survival data were recorded through October 2009. The inclusion criteria were patients with histopathologically-proven ESCC, those with esophageal cancer at T2-3N0M0 based on the seventh edition of the American Joint Committee on Cancer staging system[29], those with at least 15 lymph nodes to be removed for pathological evaluation, those at the age of at least 18 years, those with no evidence of metastatic disease as determined by history, physical examination, and blood chemistry analysis or routine computed tomography, those with no history of adjuvant therapy. Patients with a history of previously treated cancer other than basal or squamous cell carcinoma of the skin, preoperative chemotherapy and/or radiotherapy, or with unknown causes of death in follow-up were excluded from the study.

Immunohistochemistry

β-catenin (CAT-5H10, Fuzhou Maxim Inc., Fuzhou, Fujian province, China) was diluted at 1:100. ESCC tissue was cut into 4 μm-thick paraffin sections, which were stained with immunoperoxidase. The sections were deparaffinized in xylene, hydrated prior to antigen retrieval by microwaving in sodium citrate buffer (pH 6.0), and incubated with a peroxidase block followed by primary antibody. After washed with PBS, the sections were incubated first with secondary antibody followed by 3,3'-diaminobenzidine, and then counterstained with hematoxylin (Hematoxylin 7211; Richard-Allen Scientific, Kalamazoo, Michigan, USA). The peroxidase block, secondary antibody and 3,3'-diaminobenzidine were all obtained from the Dako-Cytomation EnVision System (Glostrup, Denmark).

Immunohistochemical scoring

β-catenin was scored with IHC using a semi-quantitative system as previously described[30,31]. Each section was assigned a score and the score of tumor cell staining was multiplied by the score of staining intensity. Tumor cell staining was scored using a semi-quantitative six-category grading system: 0 = no tumor cell staining, 1 = 1%-10% of tumor cells staining, 2 = 11%-25% of tumor cells staining, 3 =

26%-50% of tumor cells staining, 4 = 51%-75% of tumor cells staining, 5 = over 75% of tumor cells staining. Stain intensity was scored using a semi-quantitative four-category grading system: 0 = no staining, 1 = weak staining, 2 = moderate staining, 3 = strong staining. Two experienced pathologists blinded to the clinical follow-up data independently scored the 400 ESCC samples including the cases used in this study. The complete score agreement of the two pathologists was 87% of all cases, indicating that the scoring method is reasonably reproducible. A third blinded pathologist intervened and evaluated the patients with different IHC scores. If the third pathologist agreed with one of the previous scores, it was used for analysis. The three pathologists were asked to reach an agreement on the cases from which three different scores were obtained.

Selection of cut-off scores

Cut-off scores for *β-catenin* expression were selected based on receiver operating characteristic (ROC) curve analysis. ROC curve was plotted for the outcome of ESCC patients under study by calculating the sensitivity and specificity on its points. The score closest to the points (0.0, 1.0) on the curve with a maximum sensitivity and specificity was selected as the cut-off score leading to the greatest number of tumors classified with or without clinical outcome. The area under the ROC curve was calculated to estimate the discriminatory power of *β-catenin* over the entire range of scores for overall survival (OS) rate of ESCC patients. The ROC curve was generated and analyzed using the MedCalc statistical software package 11.0.1 (MedCalc Software bvba, Belgium).

Statistical analysis

Association between categorical variables was analyzed by χ^2 test. Survival curves were calculated with the Kaplan-Meier method and compared by the log-rank test. Time of death was calculated from the date of surgery to the date of death. The time variable was censored on the date of last follow-up of event-free subjects. Multivariate analysis of prognostic factors was performed using the Cox's regression model. $P < 0.05$ was considered statistically significant. All statistical analyses were performed using the SPSS 13.0 for Windows software system (SPSS Inc., Chicago, IL).

RESULTS

Characteristics of patients and expression of β-catenin

The demographic and clinicopathological parameters of ESCC patients included in this study are listed in Table 1. Various intensities of positive *β-catenin* reaction were detected in cytoplasm and membrane of cancer cells (Figure 1). According to the ROC curves for OS rate, a threshold value of 1.3333 was the optimal point for maximum sensitivity and specificity, and selected as the cut-off score (Figure 2). The 227 ESCC specimens were then catego-

rized into high and low *β-catenin* expression groups. The expression level of *β-catenin* was up-regulated in 144 cases (63.4%) and down-regulated in 83 cases (36.6%).

Correlation between β-catenin expression and clinicopathological features

The correlation between *β-catenin* expression in and clinicopathological features of ESCC patients are shown in Table 2. No significant correlation was identified between *β-catenin* expression and any clinicopathological parameters, including gender, age, tumor size, tumor grade, tumor location, depth of invasion and pathological stage based on the seventh edition of AJCC staging system[29].

β-catenin expression and survival rate

At the time of data analysis (October 2009), 72 patients (31.7%), with a median follow-up time of 32 mo (range 5-138 mo), remained alive and 155 patients (68.3%) died. The overall 1-, 3- and 5-year survival rates for the patients were 58%, 39%, and 33%, respectively.

The Kaplan-Meier survival curves (Figure 3) showed that the post-operative survival rate of patients with a low *β-catenin* expression level was significantly higher than that of those with a high *β-catenin* expression level ($P = 0.004$). Further stratified analysis split by depth of invasion (Figure 4) showed that the expression of *β-catenin* had a statistically significant influence on the survival rate of patients with T3 diseases ($P = 0.014$) rather than on the survival rate of those with T2 lesions ($P = 0.145$). Furthermore, the stratified analysis split by pathological stage based on the new staging system (Figure 5) revealed that *β-catenin* expression had a significant influence on the prognosis of patients with ESCC at stage ⅡB ($P = 0.007$) but not on the prognosis of those with ⅡA diseases ($P = 0.253$). Patients with ESCC at stage ⅠB were not included in this analysis due to a small sample size.

Factors involved in OS rate of ESCC patients were identified using the Cox proportional hazards model (Table 3). Univariate analysis showed that tumor grade, depth of invasion and *β-catenin* expression were found to be the significant prognostic indicators for the OS rate of ESCC patients, and thereby selected as the parameters to be included in the same Cox regression model. Further multivariate analysis also confirmed that *β-catenin* expression (relative risk = 1.642, 95% CI: 1.159-2.327, $P = 0.005$), tumor grade (relative risk = 1.549, 95% CI: 1.095-2.190, $P = 0.013$) and depth of invasion (relative risk = 1.493, 95% CI: 1.066-2.089, $P = 0.020$) were the independent prognostic factors for the OS rate of ESCC patients.

DISCUSSION

To date, several IHC studies have been performed in order

to elucidate the role of *β-catenin* in ESCC, but the current findings in terms of its expression pattern and potential involvement in formation and progression of ESCC are contradictory in the literature[25-28]. One problem faced by researchers is the determination of tumor immunohistochemical positivity for *β-catenin* which is clinically and biologically relevant. Previous studies have applied different scoring systems in predetermination of cut-off scores

which might be set arbitrarily[30-33]. A lack of consistent, widely applicable methodology may have been primarily responsible for the contradictory results of these studies evaluating *β-catenin* and its prognostic value in ESCC patients. Therefore, our study used a reproducible scoring method which takes both staining percentage and intensity into account, and the cut-off score was selected based on ROC curve analysis, so that the trade-off between sensitivity and specificity was the smallest, leading to the greatest overall number of correctly classified tumors with and without clinical outcome.

In the present study, univariate and multivariate analyses showed that high expression level of *β-catenin* in completely resected samples from patients with ESCC at stage T2-3N0M0 was significantly correlated with the worse post-operative survival rate of ESCC patients, which is consistent with the reported findings[27]. Krishnadath *et al*[34] reported that low expression level of *β-catenin* is significantly correlated with the poor prognosis of esophageal adenocarcinoma patients, especially at early-stage. It has been shown that the higher the expression level of *β-catenin* is, the better the outcome of esophageal adenocarcinoma patients is, and the *β-catenin* expression level is higher in more invasive tumors than in superficial tumors[35]. However, Zhao *et al*[26] and Lin *et al*[28] demonstrated that *β-catenin* expression does not imply more aggressive malignant behaviors of ESCC or predict the poor prognosis of ESCC patients. Krishnadath *et al*[34] and Osterheld *et al*[35] showed a different histological type of tumor (adenocarcinoma) when they analyzed these contradictory results. In addition, esophageal carcinoma at stages I -Ⅳ was involved in the studies[26,28,34,35], suggesting that different therapeutic strategies including adjuvant or neoadjuvant chemotherapy and radiotherapy for more advanced disease may introduce confounding factors affecting the application of molecular analysis in assessing the prognosis of ESCC patients.

β-catenin protein not only serves as a pivotal component of *E-cadherin/catenin* complex which participates in cell-cell and cell-matrix adhesion[6,8,9], but also as a key mediator in the Wingless/Wnt signal transduction pathway[5,7], indicating that disruption of *E-cadherin/catenin* complex or physical and functional loss of *β-catenin* protein can lead to loosening of cell-cell contact and promote tumor invasion and metastasis. On the other hand, *β-catenin* can be oncogenically activated either by direct gene mutation[36] and inactivation of the *APC* tumor suppressor[37], or by activation of the Wingless/Wnt signal transduction pathway[38], thus resulting in post-translational stabilization of *β-catenin* protein. Excess cytoplasmic accumulation of *β-catenin* protein can then increase the influx of this molecule into nuclei, leading to over-expression of tumor-promoting genes, such as *cyclin-D1* and *c-myc*[5,6], and promote cell mitosis and growth[39,40]. Therefore, either up-regulated or down-regulated expression of *β-catenin* contributes to invasive and metastatic potentials of esophageal cancer. Obviously, the question is which physiopathological process takes the advantage in different circumstances, such as different histological types or different pathological stages. Further analysis of the role of *β-catenin* gene and its products in formation and progression of esophageal carcinomas may provide a better understanding of this pathogenic process.

In this study, further stratified analysis split by pathological stage and depth of invasion showed that *β-catenin* exhibited its effect on the prognosis of patients with ESCC at stage ⅡB or with T3 lesions, indicating that this biomarker is more valuable in predicting the outcome of ESCC patients at advanced stages, which is consistent with the findings in other studies[2,22]. Further study is needed to verify this trend. In this study, no significant correlation was found between *β-catenin* expression and prognostic parameters, including tumor grade, tumor location, depth of invasion and pathological stage. Multivariate survival analysis of all potential prognostic variables also confirmed that *β-catenin* was an absolutely independent prognostic factor, which is in accordance with the reported findings[25,28]. However, other studies showed that *β-catenin* is significantly correlated with the accepted prognostic parameters of ESCC[26,27,41]. Further study with a large sample size is needed to obtain a clearer picture.

In conclusion, elevated *β-catenin* expression level is an adverse prognostic factor for ESCC patients at stage T2-3N0M0, especially for those with T3 lesions or with stage ⅡB diseases. However, further study with a larger cohort of patients is required to verify this observation, especially in view of the contradictory results.

COMMENTS

Background

Esophageal squamous cell carcinoma (ESCC), an aggressive tumor with a poor prognosis, is one of the most common malignant tumors in Asia, especially in certain areas of China. Despite advances in early diagnosis and therapies, the clinical outcome of ESCC patients remains unsatisfactory. Since the classical staging criteria fail to differentiate prognostic characteristics of ESCC patients adequately, many efforts have been made to identify relevant biomarkers with adverse prognostic significance, and to modify therapeutic strategies for individual patients. *β-catenin*, as a prognostic factor for ESCC, has been extensively studied in a variety of neoplasms. However, the exact role of *β-catenin* and its prognostic significance in ESCC remain to be defined.

Research frontiers

β-catenin protein not only serves as a pivotal component of *E-cadherin/catenin* complex which participates in cell-cell and cell-matrix adhesion, but also as a key mediator in the Wingless/Wnt signal transduction pathway. The hotspot in molecular tumor analysis of *β-catenin* is whether *β-catenin* involves and how it involves in the formation and progression of esophageal carcinoma.

Innovations and breakthroughs

Previous immunohistochemistry studies showed contradictory results in *β-catenin* expression pattern and its prognostic value for ESCC, due to lack of consistent, widely applicable methods. Therefore, the present study used a reproducible scoring method which takes both staining percentage and intensity into account, and the cut-off score was selected based on receiver operating characteristic (ROC) curve analysis so that the trade-off between sensitivity and specificity was the smallest, leading to the greatest overall number of correctly classified tumors with and without clinical outcome. This is the first study to evaluate *β-catenin* expression in ESCC patients with this novel method, showing that elevated *β-catenin* expression is an adverse prognostic factor for ESCC patients at stage T2-3N0M0, especially for those with T3 lesions or stage ⅡB diseases.

Applications

The novel methods used in this study can be applied in treatment of ESCC patients at stage T2-3N0M0.

Terminology

ROC curve analysis: In signal detection theory, a ROC curve is a graphical plot of the sensitivity, or true positivity *vs* (1-specificity), or false positivity for a binary classifier system as its discrimination threshold is varied. The ROC curve can also be represented equivalently by plotting the fraction of true positivity (TPR = true positive rate) *vs* the fraction of false positivity (FPR = false positive rate). ROC curve analysis provides tools to select possibly optimal models and to discard suboptimal ones independently from (and prior to specifying) the cost context or the class distribution. ROC curve analysis is related in a direct and natural way to cost/benefit analysis of diagnostic decision making. *β-catenin*: *β-catenin* protein was originally identified as a component of adherence junction, a multi-protein complex supporting tight cell-cell contacts in the presence of extracellular calcium. However, *β-catenin* also plays a key role in the Wnt signaling transduction pathway.

Peer review

The authors studied the expression of *β-catenin* in ESCC at stage T2-3N0M0 and its prognostic significance by analyzing the expression of *β-catenin* in 227 ESCC specimens with IHC and ROC curve analysis to select the cut-off score for high or low IHC reactivity. Then, they correlated the *β-catenin* expression with clinicopathological features of ESCC patients and its relation with the prognosis of ESCC patients. No significant correlation was observed between *β-catenin* expression in and clinicopathological parameters of ESCC patients, but multivariate analysis confirmed that *β-catenin* was an independent prognostic factor for the overall survival rate of ESCC patients at stage T2-3N0M0. The manuscript reads nicely and is easy to follow. Tables are legible and easy to understand. I believe that the method used in this study is plausible and the conclusion is well supported by the data. This manuscript adds to the current knowledge on this topic and it is a pleasure to read it.

Abstract

AIM: To classify the histological severity of *Helicobacter pylori* (*H. pylori*) infection-associated gastritis by confocal laser endomicroscopy (CLE).

METHODS: Patients with upper gastrointestinal symptoms or individuals who were screened for gastric cancer were enrolled in this study. Histological severity of *H. pylori* infection-associated gastritis was graded according to the established CLE criteria. Diagnostic value of CLE for histological gastritis was investigated and compared with that of white light endoscopy (WLE). Targeted biopsies from the sites observed by CLE were performed.

RESULTS: A total of 118 consecutive patients with *H. pylori* infection-associated gastritis were enrolled in this study. Receiver operating characteristic curve analysis showed that the sensitivity and specificity of CLE were 82.9% and 90.9% for the diagnosis of *H. pylori* infection, 94.6% and 97.4% for predicting gastric normal mucosa, 98.5% and 94.6% for predicting histological active inflammation, 92.9% and 95.2% for predicting glandular atrophy, 98.6% and 100% for diagnosing intestinal metaplasia, respectively. Post-CLE image analysis showed that goblet cells and absorptive cells were the two most common parameters on the CLE-diagnosed intestinal metaplasia (IM) images ($P < 0.001$). More histological lesions of the stomach could be found by CLE than by WLE ($P < 0.001$).

CONCLUSION: CLE can accurately show the histological severity of *H. pylori* infection-associated gastritis. Mapping IM by CLE has a rather good diagnostic accuracy.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is a well accepted major etiological factor for gastric diseases, such as chronic gastritis, peptic ulcer and gastric carcinoma[1-3]. Therefore, endos-

copists must determine the presence of *H. pylori* infection in the stomach during or after endoscopy. The updated Sydney system for classification of gastritis has established the association between *H. pylori* infection and histological evidence of gastritis[4]. Gastric atrophy especially accompanying intestinal metaplasia (IM), which is the severest stage of gastritis and has a high risk for gastric cancer, is closely associated with *H. pylori* infection[5]. Although the Sydney system has been widely used, multiple biopsies are rarely performed for gastritis evaluation but only for suspected lesions of cancer in clinical practice, thus leading to omission of some precancerous lesions which are difficult to find by white light endoscopy (WLE)[6]. Therefore, *in vivo* detection of *H. pylori* infection and its related complications by endoscopy is a simple, noninvasive and inexpensive procedure. *H. pylori*-induced gastritis must be evaluated and graded especially in Eastern countries because of a high prevalence of *H. pylori* infection and a high incidence of gastric cancer[7]. Furthermore, it can facilitate the clinical assessment and timely treatment of gastritis. The association between *H. pylori* infection and endoscopic findings has been extensively studied using modern endoscopic techniques such as magnification endoscopy and narrow-band imaging[8-10].

Confocal laser endomicroscopy (CLE) can detect gastrointestinal diseases, such as Barrett esophagus, gastric carcinoma and colonic neoplasia[11,12]. CLE can observe real-time histological-like cellular and subcellular conditions of gastric mucosal layer at the magnification × 500-1000. It was reported that acriflavine-aided CLE can observe *H. pylori in vivo*[13]. In addition, gastric pit patterns of various gastropathies have been accurately classified and IM has been studied by CLE[14,15]. However, no systematic data are available on the CLE characteristics of chronic gastritis and the classification of chronic gastritis has not been investigated by CLE.

In this study, the CLE features of gastritis mainly caused by *H. pylori* infection were compared to evaluate the accuracy of CLE in diagnosing *H. pylori* infection and the severity of gastritis.

MATERIALS AND METHODS

Patients

Consecutive patients with upper gastrointestinal symptoms or individuals who were screened for gastric carcinoma, admitted to our hospital from June to November 2009, were enrolled in this study. The following patients were excluded from the study, including those who received proton pump inhibitors, antibiotics, or bismuth subsalicylate in the previous 6 wk, those with a history of using nonsteroidal anti-inflammatory drugs and medication for *H. pylori* infection, those undergone stomach surgery, those with systematic diseases or known gastric carcinoma, pregnant or breast-feeding females, those who did not give their informed consent or had an allergy to fluorescein. All participants gave their written informed consent before endoscopy. The study was approved by the Ethics Committee of Qilu Hospital.

CLE system

A confocal laser endomicroscope (Pentax ISC-1000, Pentax, Tokyo, Japan) was used in this study. It is novel digestive endoscope with a confocal laser microscope integrated into the distal tip, can realize a histological-like examination during routine endoscopy and accurately diagnose gastrointestinal diseases at the magnification × 1000. CLE was performed to scan the gastric mucosa from the top layer to 250 μm beneath the surface. The CLE and white-light endoscopy (WLE) images were captured and stored.

CLE procedure

CLE was performed by an endoscopist experienced with the system. All patients received oral chymotrypsin (20000 U) to eliminate the slime layer of the stomach for better visualization. One mL of 2% fluorescein (a contrast agent) was intravenously injected before endoscopy. After a first WLE of the stomach, 10 mL of 10% fluorescein was intravenously injected, and CLE images could be seen after a few seconds. Five standardized sites (2 from the lesser and greater curvatures of the antrum about 2-3 cm near the pylorus, 2 from the middle portion of the lesser and greater curvatures of the corpus about 8 cm from the cardia, and 1 from the angulus), as recommended by the updated Sydney system, were examined separately on CLE images. Shallow-deep CLE images were captured at each site and stored as digital files for further analysis. At the standardized locations, real-time image assessment and targeted biopsies were performed by CLE for histopathology. For *H. pylori* testing, 2 specimens were taken from the greater curvature of the antrum and corpus, respectively. If necessary, other scanning and biopsies were performed for lesions such as those with color changes or erosions, polyps, ulcers, or abnormal folds.

CLE classification of H. pylori infection-associated gastritis severity

In our study, the severity of gastritis was divided into 6 levels by CLE: normal mucosa, *H. pylori*-associated active inflammation (3 levels), glandular atrophy and IM.

CLE criteria for normal gastric mucosa and *H. pylori*-associated active inflammation: The published CLE classification of gastric pit patterns was used for one part of our classification of *H. pylori*-associated active inflammation[14]. In addition, a new marker, fluorescein leakage, was introduced to define the active inflammation in stomach on CLE images (Figure 1). Each of the 5 standardized sites was assigned to a confocal gastritis score (CGS) and a corresponding histologic gastritis score (HGS).The CGS for normal mucosa, and mild, moderate and marked active inflammation was 0, 1, 2 and 3, respectively. The severity of histological activity and chronic inflammation was also defined as normal, mild, moderate and marked with a score of 0-3, respectively. Finally, the mean CGS and HGS (mCGS and mHGS) were calculated for specimens from each stomach.

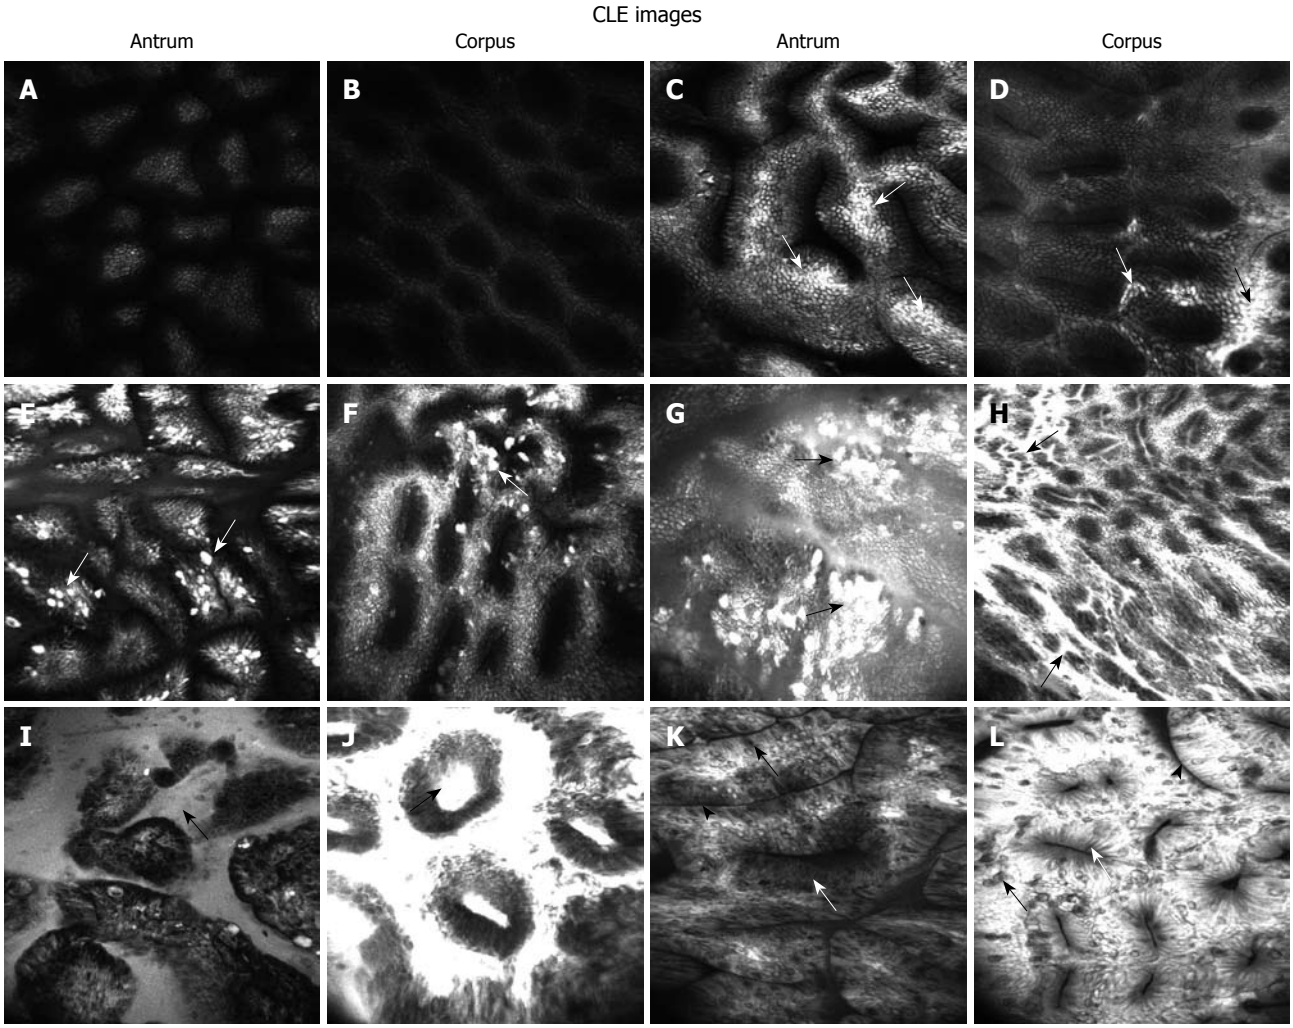

Figure 1 Confocal laser endomicroscopy classification of *Helicobacter pylori*-associated gastritis severity in gastric antrum and corpus. A, B: Normal mucosa with normal antral and corporal pits, and free of fluorescein leakage; C, D: Active inflammation (mild) with slightly distorted pits and intact epithelium, scattered focal fluorescein leakage (arrows); E, F: Active inflammation (moderate) with more distorted pits and partly destroyed epithelium (arrows), and more fluorescein leakage; G, H: Active inflammation (marked) with markedly distorted pits and dilated opening, destroyed epithelium (arrows), and widespread fluorescein leakage; I, J: Glandular atrophy with decreased gastric pits and markedly dilated opening (arrows); K, L: Intestinal metaplasia with villous-like gastric pits and goblet cells (black arrows), absorptive cells (white arrows) and brush border (arrowheads) appearing. CLE: Confocal laser endomicroscopy.

CLE criteria for glandular atrophy and IM: Glandular atrophy and IM are the severest stage of chronic gastritis. The CLE classification of glandular atrophy and IM was defined as decreased gastric pits with a dilated opening and as villous-like gastric pits with goblet cells, absorptive cells and brush border, respectively (Figure 1). To assess the CLE images, the mean number of gastric pits on each grade image was calculated and compared, except for that on IM images. The clinical values for IM features on CLE images were assessed by calculating their mean ratio present in each IM site on CLE images.

Final diagnosis of H. pylori infection

Rapid urease testing and Giemsa staining confirmed *H. pylori* infection. If only one test was positive for *H. pylori* infection, ^{13}C-urea breath test was performed for further confirmation. The *H. pylori* infection was classified into Hp (-), Hp (+), Hp (++) and Hp (+++).

Histopathology

All specimens were fixed in 10% formalin. An experienced histopathologist analyzed the histological features of each sample with hematoxylin and eosin staining and made the diagnosis according to the updated Sydney classification. The histological parameters assessed in this study included histological activity, chronic inflammation, glandular atrophy and intestinal metaplasia, which were identified blinding to the results of CLE or WLE.

Statistical analysis

Data were collected from CLE images and histological examination. analysis of variance and box-plot analysis of mCGS were used in pairwise comparison of mCGS among the 4 *H. pylori* test groups [Hp (-), Hp (+), Hp (++) and Hp (+++)]. $P < 0.05$ was considered statistically significant. The efficacy of CGS for predicting *H. pylori* infection was evaluated by area under the receiver oper-

ating characteristic (ROC) curve analysis. On the other hand, the sensitivity, specificity, positive and negative predictive values (PPV, NPV) of the CLE criteria for diagnosing normal gastric mucosa, *H. pylori*-associated active inflammation, glandular atrophy and IM were calculated, respectively. Correlation between mCGS and mHGS was analyzed with the coefficient of determination. SPSS v16.0 (SPSS Inc., Chicago, IL) was used for all statistical analyses.

RESULTS

Collection of data

One hundred and eighteen patients including 74 males, at a mean age of 49.8 years (range 19-67 years) were enrolled in this study. A total of 12243 CLE images (mean 104 images per patient) and 653 optical biopsy images (mean 5.5 biopsy images per patient) were obtained. The median endoscopy time was 23.2 min (range 15-33 min) (Table 1). The quality of over 90% of CLE images was good, while that of the remaining 10% was not satisfactory because it was difficult to fix the distal tip on the gastric angle and the artifacts were motile in gastrointestinal tract. No endoscopic complications or adverse reactions to fluorescein were observed.

CLE diagnosis of H. pylori infection

Association between mCGS and *H. pylori* infection: Of the 118 patients enrolled in this study, 41 were positive for *H. pylori*. Detailed data on *H. pylori* level are shown in Table 1. The mCGS was significantly differed among Hp (-), Hp (+),Hp (++), and Hp (+++) groups ($P < 0.001$). The median mCGS was significantly higher in Hp (+) and Hp (+++) groups than in Hp (-) and Hp (++) groups ($P < 0.001$), and higher in Hp (++) group than in Hp (+) and Hp (-) groups ($P < 0.001$) (Figure 2).

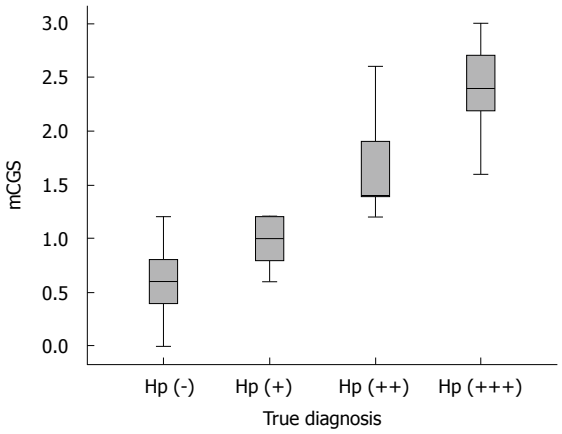

Figure 2 Box plot analysis of mean confocal gastritis score in 4 *Helicobacter pylori* test groups. mCGS: Mean confocal gastritis score.

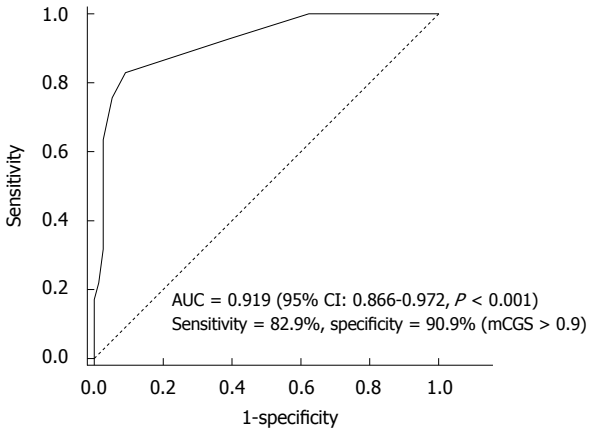

Figure 3 Receiver operating characteristic curve analysis showing the sensitivity and specificity of confocal laser endomicroscopy and mean confocal gastritis score for diagnosing *Helicobacter pylori* infection. AUC: Area under curve; mCGS: Mean confocal gastritis score.

Sensitivity and specificity of CLE for *H. pylori* detection: The ROC curve for mCGS was plotted to determine a cut-off value of sensitivity relative to specificity for diagnosing *H. pylori* infection. The area under the ROC curve was 0.919 (95% CI: 0.866-0.972), showing an excellent accuracy (Figure 3). The sensitivity and specificity of CEL were 82.9% and 90.9%, respectively, for mCGS > 0.9. With this cut-off value, CLE could correctly diagnose *H. pylori* infection.

CLE classification of histological gastritis severity

Normal gastric mucosa: A good correlation was found between normal mucosa detected by CLE and histology. The sensitivity, specificity, PPV and NPV of CLE were 94.6% (95% CI: 91.9%-97.4%), 97.4% (95% CI: 95.8%-99.1%), 96.5% (95% CI: 94.2%-98.7%), and 96.1% (95% CI: 94.1%-98.1%), respectively, for predicting gastric normal mucosa lesions (Table 2).

Chronic active inflammation: The CLE criteria correlated well with the active inflammation detected by histology. The sensitivity, specificity, PPV and NPV of CLE

Table 2 Sensitivity, specificity, positive predictive values and negative predictive values of confocal laser endomicroscopy for the diagnosis of normal mucosa, *Helicobacter pylori*-associated active inflammation, glandular atrophy and intestinal metaplasia (per specimen) [% (95% CI)]

CLE classification	Sensitivity	Specificity	PPV	NPV
Normal mucosa	94.6 (91.9-97.4)	97.4 (95.8-99.1)	96.5 (94.2-98.7)	96.1 (94.1-98.1)
Active inflammation	98.5 (97.2-99.8)	94.6 (91.9-97.4)	95.9 (93.7-97.9)	98.0 (96.3-99.7)
Glandular atrophy	92.9 (87.0-98.9)	95.2 (93.3-97.0)	72.5 (63.4-81.7)	98.9 (98.1-99.9)
Intestinal metaplasia	98.6 (95.7-100.0)	100 (100.0-100.0)	100 (100.0-100.0)	99.8 (99.4-100.0)

Table 3 Confocal laser endomicroscopy and white-light endoscopy in predicting histological changes

Biopsy sites	CLE normal sites[1]	CLE abnormal sites[1]			
		Inflammation	Atrophy	IM	Early cancer
WLE normal sites	216	173	41	45	0
WLE abnormal sites[2]	31	83	25	23	2

[1]The normal and abnormal sites on confocal laser endomicroscopy (CLE) images were confirmed by histology; [2]Abnormal sites include erythema, erosion, nodules and petechiae, *etc.*, with no noticeable lesions such as ulcers or polyps on white light endoscopy (WLE) images. IM: Intestinal metaplasia.

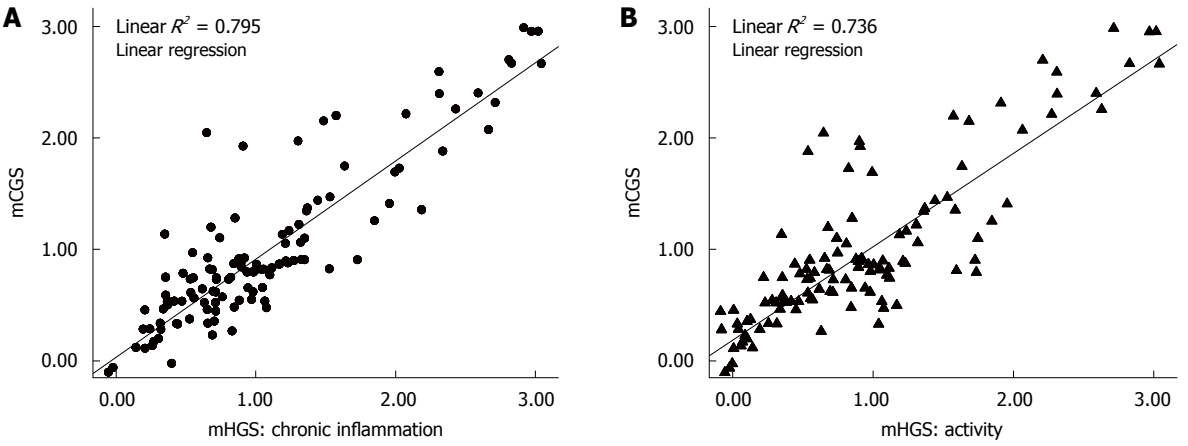

Figure 4 Correlation between mean confocal gastritis score and mean histologic gastritis score for histological chronic inflammation (R^2 = 0.795, A) and activity (R^2 = 0.736, B). mCGS: Mean confocal gastritis score; mHGS: Mean histologic gastritis score.

were 98.5% (95% CI: 97.2%-99.8%), 94.6% (95% CI: 91.9%-97.4%), 95.9% (95% CI: 93.7%-97.9%), and 98.0% (95% CI: 96.3%-99.7%), respectively, for predicting active inflammation detected by histology (Table 2). In particular, the histological activity and chronic inflammation were significantly differed among the 3 levels of active inflammation on CLE images, based on the evidence that histological activity and chronic inflammation were positively and linearly correlated with the mCGS (R^2 = 0.795, R^2 = 0.736, $P < 0.001$) (Figure 4).

Glandular atrophy and IM: The sensitivity, specificity, PPV and NPV of CLE were 92.9% (95% CI: 87.0%-98.9%), 95.2% (95% CI: 3.3%-97.0%), 72.5% (95% CI: 63.4%-81.7%) and 98.9% (95% CI: 98.1%-99.9%), respectively, for glandular atrophy (Table 2). Furthermore, a post-CLE analysis of CLE images showed that the mean number of gastric pits in glandular atrophy was significantly less than that in IM on CLE images ($P < 0.001$) (Figure 5).

The sensitivity, specificity, PPV and NPV of CLE for IM were 98.6% (95% CI: 95.7%-100.0%), 100% (95% CI: 100.0%-100.0%), 100% (95% CI: 100.0%-100.0%), and 99.8% (95% CI: 99.4%-100.0%), respectively, for predicting IM (Table 2). Of the IM features on CLE images, goblet cells and absorptive cells were more common and easier to note than the other features ($P < 0.001$) (Figure 6).

CLE and WLE for predicting histological conditions: In our study, 54.5% (259/475) normal sites were found to be abnormal on WLE by CLE (173 inflamed sites, 41 atrophic sites and 45 IM sites). In contrast, of the 164 abnormal sites on WLE images, 18.9% (31/164) were found to be normal on CLE images. All the findings on CLE images were confirmed by histology, indicating that CLE can show more histological lesions than WLE ($P < 0.001$) (Table 3).

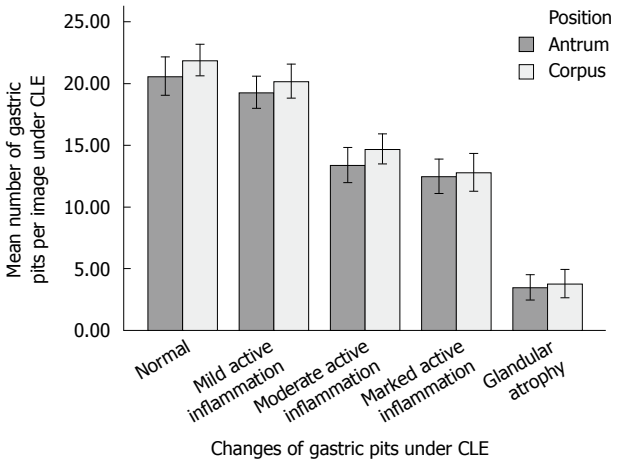

Figure 5 Gastric pits on confocal laser endomicroscopy images. CLE: Confocal laser endomicroscopy.

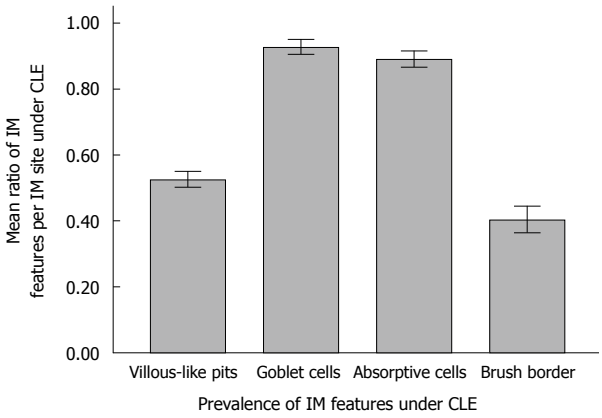

Figure 6 Prevalence of intestinal metaplasia features on confocal laser endomicroscopy images. IM: Intestinal metaplasia; CLE: Confocal laser endomicroscopy.

DISCUSSION

Conventional endoscopy is not frequently correlated with histological alterations, WLE is not accurate for predicting histological gastritis with nonspecific erythema, prominent area gastrica, nodularity, or erosions, *etc.*[16], and gastroscopy without biopsy is incomplete in routine clinical practice. In recent years, novel endoscopies, such as magnification endoscopy and narrow band imaging, have been evaluated for gastric pathologic conditions with a good accuracy[17]. High resolution, magnification and advanced electronic dye techniques, can identify the mucosal and vascular details of *H. pylori* infection and its related complications, with a high diagnostic sensitivity and specificity[18].

More details of gastric pits can be clearly observed on CLE images at the magnification × 1000. Zhang *et al*[14] reported that CLE can reveal inflamed pits with marked morphological alterations. The sensitivity and specificity of type B'+D' pits are 81.9% and 99.3%, respectively, for predicting moderate to severe active inflammation. In our study, *H. pylori* infection was positively correlated with progressively increasing changes in gastric pits due to direct injury caused by *H. pylori* and inflammatory infiltration. CLE could accurately distinguish normal mucosa from *H. pylori*-infected mucosa in the stomach. ROC curve analysis showed a high sensitivity (82.9%) and specificity (90.9%) of mCGS for diagnosing *H. pylori* infection. The mCGS cut-off value was 0.9, indicating an accurate and balanced result. Fluorescein leakage can classify active inflammation in ulcerative colitis[19] and fluorescein leakage into crypt lumen is positively correlated with histological active inflammation, because of increased colonic permeability. Fluorescein leakage is often present in the stomach, which contributes to the diagnosis of *H. pylori*-associated gastritis. When normal gastric mucosa is observed on CLE images, the fluorescence is confined to beneath the subepithelium and evenly distributed, epithelial cells are clearly visible and well-demarcated, showing a uniform gray cytoplasm and black border (Figure 1A and B). However, in *H. pylori*-infected mucosa, fluorescein easily leaks onto the surface through the damaged epithelium or normal epithelium with a high permeability. That is why this region is brighter than the surrounding normal epithelium. Sometimes, with a mass of the seepage, the entire field of vision can be white (Figure 1C-H). However, because fluorescein leakage is only an indirect response to mucosal damage and histological inflammation, the specificity of fluorescein is lower. In our study, fluorescein in combination with other CLE features was used to diagnose *H. pylori* infection following the active inflammation criteria defined by CLE[4]. The CLE scoring system used in our study could offer an objective evaluation of the entire stomach. High mCGS of the stomach indicated severe *H. pylori* infection, whereas low mCGS indicated mild or no *H. pylori* infection. Because the CGS agrees with the grading of confocal images, a high score represents severely injured gastric mucosa. It was reported that *H. pylori* organisms are usually observed singly or in groups along the surface epithelium but rarely in deeper mucosa[20]. Adherence of *H. pylori* to epithelial cells is the first step in *H. pylori* infection. When urease is secreted by *H. pylori,* and inflammatory and immune processes are activated by Vac A and Cag A toxin, the epithelium is depleted of mucin with irregular and missing cells ("drop-out cells"). In our study, similar alterations in moderate and severe active inflammation were found on CLE images, and clusters of destroyed epithelial cells (drop-out cells) on the two grade images were closely correlated with *H. pylori* infection, suggesting that CLE can display the drop-out cells because such microscopic lesions may progress to microerosions and precursors of gastric ulcer. However, when mCGS is less than 0.9, it can result in 7 false-positive and 7 false-negative diagnoses. False-positive cases are mainly diagnosed as mild active inflammation based on the CLE images of antrum, because normal mucosa on CLE images is sometimes misdiagnosed as mild inflammation when some fibrin or debris appears on the mucosal surface. The 7 false-negative cases are diagnosed as mild inflammation with a low *H. pylori* level and the corresponding mucosal changes are thus not obvious to be identified.

The second endpoint was to demonstrate the histologi-

cal severity of gastritis by CLE, which showed that the 6 CLE grades were well correlated with the corresponding parameters of histological gastritis. Active inflammation was classified into 3 levels by CLE. On the other hand, obvious drop-out cells were observed at the moderate and marked levels with a high risk for gastric ulcer formation and management of these groups of patients. The severity of chronic inflammation was much higher at moderate and marked levels on CLE images (R^2 = 0.736 and 0.795), probably because interstitial infiltration of inflammatory cells can easily squeeze the glands and damage the epithelium with an increasing severity of inflammation and *H. pylori* infection, leading to aggravated pit distortion and fluorescein leakage.

Gastric glands would be destroyed, and glandular atrophy and/or intestinal metaplasia would occur when they are infected with *H. pylori* and infiltrated with inflammatory cells. Glandular atrophy is manifested as thinner mucosa without gastric rugae but with visibly vascular pattern on WLE images[21]. However, gastric atrophy is poorly correlated with histological atrophy on WLE images[22]. It was reported that CLE shows a good sensitivity and specificity for gastric atrophy[14]. In our study, the diagnostic sensitivity and specificity of CLE were 92.9% and 95.2% for glandular atrophy. A further analysis of CLE-diagnosed glandular atrophy was performed with a more objective method. The mean number of gastric pits was calculated on different CLE images, and the mean number of pits in glandular atrophy was significantly less than that in gastritis on CLE images ($P < 0.001$). However, IM on CLE images was not analyzed because the gastric pits were replaced by intestinal mucosa, which became another form of atrophy or metaplasia. Although the sensitivity and specificity of CLE were high for glandular atrophy, the PPV was relatively low (72.5%) probably due to the low prevalence of atrophy in histology (71 sites/590 sites, 12.0%), indicating that there is a certain false positive rate when CLE is used to diagnose glandular atrophy, and identification of mild glandular atrophy is a big challenge for CLE.

Although the Sydney system has suggested a definition of endoscopic intestinal metaplasia for "grey-white patches with a slight opalescent tinge and/or a villous appearance on close inspection", studies demonstrated that these features are quite difficult to be identified by conventional endoscopy[21,23]. The detection of IM needs multiple biopsy specimens. Tahara *et al*[18] reported that magnifying narrow-band imaging endoscopy can show IM with a sensitivity of 73.3% and a specificity of 95.6%. In this study, IM was further analyzed following the CLE criteria[15]. The sensitivity and specificity of CLE were 98.6% and 100%, respectively, for IM in our study, and were higher than those reported by Tahara *et al*[18]. In addition, goblet cells and absorptive cells were more frequently and easily observed than other features or parameters in IM on CLE images in our study ($P < 0.001$). Because diagnosis of IM is often disregarded by naked eyes or by chromoendoscopy in clinical practice, more powerful endoscopic techniques, such as CLE and magnifying endoscopy, should be used to map IM[24].

Microscopic examination is essential for endoscopists to make a final diagnosis of gastritis, because the term of gastritis has been used indiscriminately and whether histological inflammation is present or not. However, CLE plays a pathological role in improving the diagnostic rate of WLE. In this study, CLE could discover 54.5% of lesions missed by WLE and correct 18.9% of normal mucosal sites misdiagnosed as abnormal sites by WLE, because the micro-gastric inflammation may appear completely normal on WLE images, suggesting that the presence or absence of gastritis should not be determined only based on gross WLE images. However, CLE can detect these micro-changes.

The main limitations of our study are as follows. First, we did not establish a control group, or a follow-up group to validate our hypothesis from multiple aspects, leading some bias in determination of *H. pylori* infection and histological gastritis. Second, we did not evaluate inter- and intra-observer variability. The repeatability of our CLE criteria should be assessed in a future single study. Third, due to the scanning depth and resolution limitations of CLE, there is still some gap when compared with *in vitro* histology. Therefore, the CLE equipment needs to be constantly upgraded.

In conclusion, *H. pylori* infection is related to its related CLE image features. Histologically active inflammation can be classified by CLE. Two most accurate markers, goblet cells and absorptive cells for IM, are established. Although CLE itself still has some limitations as a novel technique, it is a promising new procedure for accurate histological assessment *in vivo*.

COMMENTS

Background

The accurate diagnosis of chronic gastritis still relies on histopathology. Confocal laser endomicroscopy (CLE) can show gastric pit patterns and epithelial cells *in vivo*, thus, contributing to an accurate diagnosis of chronic gastritis *in vivo*.

Research frontiers

CLE has been extensively investigated in cancerous or precancerous mucosa of Barrett's esophagus and its related neoplasia, early esophageal cancer, gastric intestinal metaplasia, neoplasia and early cancer, colonic neoplasia and cancer, and ulcerative colitis, *etc*.

Innovations and breakthroughs

Endoscopic diagnosis of chronic gastritis and *Helicobacter pylori* (*H. pylori*) infection is still challenge to clinical endoscopists. This study first used CLE to classify *H. pylori* infection-associated chronic gastritis, which could accurately diagnose chronic gastritis *in vivo* without mutiple biopsy specimens.

Applications

By using the classification criteria for chronic gastritis established in this study, clinical endoscopits could use CLE to evaluate the conditions of the entire stomach, and calculate the abnormal mucosal sites in the entire stomach.

Terminology

CLE is novel digestive endoscope. It is a conventional white-light endoscope with a confocal laser microscope integrated into the distal tip. CLE can realize a histological-like examination during routine endoscopy and accurately diagnose gastrointestinal diseases at the magnification × 1000.

Peer review

The authors established the classification criteria for chronic gastritis, and compared CLE and white light endoscopy in diagnosis of gastritis and intestinal metaplasia, thus proving a novel method for the diagnosis of gastritis and intestinal metaplasia by CLE, which has a higher sensitivity and specificity than conventional endoscopy.

Abstract

AIM: To analyse the influence of Smad7, antagonist of transforming growth factor (TGF)-β canonical signaling pathways on hepatic stellate cell (HSC) transdifferentiation in detail.

METHODS: We systematically analysed genes regulated by TGF-β/Smad7 in activated HSCs by microarray analysis and validated the results using real time polymerase chain reaction and Western blotting analysis.

RESULTS: We identified 100 known and unknown targets underlying the regulation of Smad7 expression and delineated 8 gene ontology groups. Hk2, involved in glycolysis, was one of the most downregulated proteins, while BMP2, activator of the Smad1/5/8 pathway, was extremely upregulated by Smad7. However, BMP2 dependent Smad1 activation could be inhibited *in vitro* by Smad7 overexpression in HSCs.

CONCLUSION: We conclude (1) the existence of a tight crosstalk of TGF-β and BMP2 pathways in HSCs and (2) a Smad7 dependently decreased sugar metabolism ameliorates HSC activation probably by energy withdrawal.

Key words: Transforming growth factor-β; Smad7; Hepatic stellate cell; Gene regulation; Glucose metabolism; BMP2

INTRODUCTION

Histopathological changes of chronic liver diseases usually

start with inflammatory hepatitis, followed by fibrosis and the final stage of cirrhosis, possibly leading to liver cancer. Hepatic fibrosis is characterized by increased and altered deposition of newly generated or deficiently degraded extracellular matrix (ECM) in response to injury[1]. Hepatic stellate cells (HSCs) are the major fibrotic precursor cells that transdifferentiate in inflammatory liver tissue to fibrogenic myofibroblasts (MFBs), by undergoing morphological changes, increased expression of α-SMA and synthesis of large amounts of ECM components[2].

Transdifferentiation of HSCs is driven by a variety of cytokines with transforming growth factor (TGF)-β playing a master role. It stimulates quiescent HSCs by paracrine and transdifferentiated MFBs by autocrine mechanisms activating intracellular Smad cascades. A great variety of cytokines, chemokines and mitogens (TNF-α, IFN-γ, EGF, PDGF, CTGF, ID1, YB1) display complex crosstalk with TGF-β[3-6].

Smad7 is a powerful antagonist of TGF-β in HSCs blunting downstream signaling by inhibiting receptor (R)-Smad phosphorylation[7]. In quiescent HSCs, expression of Smad7 itself is induced by the R-Smad cascade, thereby providing a negative feedback loop to terminate TGF-β signals[8]. We demonstrated before phenotypically and functionally that overexpressed Smad7 inhibits HSC transdifferentiation and attenuates the extent of fibrosis[7] suggesting that Smad7 is a promising antifibrotic tool for treatment approaches.

Therefore, in this study we analyzed the influence of Smad7 on the HSC gene expression pattern in great detail using microarray analysis. Its overexpression affects a great variety of cellular pathways involved in development, angiogenesis, differentiation, transcription, immune response, apoptosis, proliferation, signal transduction, ion and electron transport, sugar and lipid metabolism, morphogenesis, protein synthesis and modification, DNA synthesis and repair, cell adhesion, stress response, blood circulation, cell cycle and growth, cell motility, muscle contraction and organization of the cytoskeleton. The strongest regulated proteins are Pla2g2a, Cyp4b1, both upregulated and, Hk2 and VEGFa, which were downregulated significantly. Interestingly, BMP2, a member of the TGF-β family and alternative activator of the Smad1/5/8 pathway, was strongly induced by Smad7 overexpression in HSCs.

MATERIALS AND METHODS

Affymetrix gene chip array

Primary HSCs of male Sprague-Dawley were isolated as previously described[9,10]. To identify Smad7 dependent gene responses, HSCs were infected with adenoviruses encoding for Smad7 (AdSmad7; kindly provided by C. Heldin (Ludwig Institute for Cancer Research, Uppsala, Sweden)) or LacZ (AdLacZ) as control 2 d after seeding[7].

RNA sample collection and generation of biotinylated complementary RNA probes was carried out according to the Affymetrix GeneChip® Expression Analysis Technical Manual (Affymetrix, Santa Clara, CA,USA). In brief, total RNA was prepared at day 4 from 5×10^6 cultured primary HSCs that were infected with AdLacZ or AdSmad7 at day 2. Twenty five micrograms total RNA was reversely transcribed into double-stranded cDNA using HPLC-purified T7-(dt) 24 primers (MWG, Ebersberg, Germany) and the Superscript choice cDNA synthesis system (Invitrogen Corp., Carlsbad, CA). Purified cDNA was used to synthesize biotinylated complementary RNA using the BioArray High Yield RNA Transcription Labeling Kit (Enzo Diagnostics, Enzo Life Science Inc., Farmingdale, NY, USA). Each sample was hybridized to an Affymetrix rat Genome RG-U34A microarray (8799 probe sets) for 16h at 45℃. Expression values of each probe set were determined and AdSmad7 infected samples were compared to AdLacZ infected controls using the Affymetrix Microarray Suite 5.0 software.

Intensities across multiple arrays were normalized to a target intensity of 2500 using global normalization scaling. Two separate experiments with HSCs from different animals were performed under identical conditions. Genes whose expression levels were changed more than 2-fold with $P < 0.001$ in both experiments were considered to be significantly regulated by Smad7. These genes were investigated according to their molecular function and biological process by searching the gene ontology (GO) term database. Genes differentially expressed in AdSmad7 treated compared to controls were classified by "pathway" analysis [KEGG (http://www.genome.jp/kegg/pathway.html), PathwayArchitect, Stratagene].

Reverse-transcription and quantitative real-time polymerase chain reaction

Total RNA was collected from 3 (3 d-) or 7 d old (7 d-)HSCs, which were either infected with AdSmad7 or AdLacZ 2 d earlier or were uninfected[11]. cDNA from cell culture samples was synthesized as described[11]. Quantitative real-time polymerase chain reaction (RT-qPCR) was performed as in[11] with modified conditions: 95℃ for 60 s, then 40 cycles (50 cycles for low copy genes) of 95℃ for 10 s, 60℃ for 10 s and 72℃ for 15 s. Annealing temperature was set at 58℃ for U92564 and 62℃ for rat VEGF.1. Primers are listed in Table 1. The quantity of target mRNA was determined using a TGF-β RI standard curve[11]: A cDNA fragment was amplified and column-purified using the QIAquick PCR purification kit (Qiagen) and the following primers: TGFβ RI (GI: 416397) 180 bp; F (5'-CGTCTGCATTGCACTTATGC-3'), R (5'-AGCAGTGGTAAACCTGATCC-3'). A standard curve was generated from serial 10 time logarithmic dilutions of the cRNA by reverse transcription.

Western blotting analysis

Isolated primary HSCs of female Wistar rats were cultured as in[7]. Following overnight starvation (0.5% FCS) HSCs were stimulated with 5 ng/mL human recombinant TGF-β (Peprotech, Hamburg, Germany) or 20 ng/mL BMP2 (R&D, Minneapolis, MN), respectively.

For Smad7 overexpression studies, HSCs were infected on day 3 or day 6 with 50 IFU/cell (infectious units) Smad7 encoding adenovirus for 24 hr in medium containing 5% FBS. Four days old HSCs are considered to be in the transactivation process, while 7 d old HSCs are considered to be fully activated. After infection cells were serum-starved overnight and stimulated with 5 ng/mL TGF-β1 or 20 ng/mL BMP2. Generally, more than 90% of HSCs were infected.

For Western blotting analysis 20 μg protein was separated (4%-12% Bis-Tris Gel, NuPAGE, Invitrogen) and transferred to nitrocellulose membranes (Pierce, Rockford, IL). Nonspecific binding was blocked with 5% milk/TBST for Smad7 and GAPDH (Santa Cruz, CA, USA) or 5% BSA/TBST for pSmad1/3 antibodies (Epitomics/Biomol). Horseradish peroxidase-linked goat anti-rabbit antibody (Santa Cruz, CA, USA) served as secondary antibody. Membranes were developed with Supersignal Ultra (Pierce, Hamburg, Germany).

RESULTS

Smad7 dependent gene expression pattern

At day 2 of culture, primary rat HSCs were infected with AdSmad7 or AdLacZ (control). Two days later, when HSCs are in the process of transdifferentiation, the expression of genes displayed on 8799 probe sets was compared between cells overexpressing Smad7 and controls. Confirming Western blotting analysis of HSC lysates[12], microarray data revealed tremendous overexpression of Smad7 in AdSmad7 infected HSCs (40.79 times).

One hundred and twenty-nine probe sets were found differentially expressed due to Smad7, including 10 unknown proteins, 1 predicted protein and 89 known proteins (Table 2 provides a full list). According to their biological role, these genes were classified into eight main GO groups (Figure 1A). 37% of the regulated genes are involved in development. 22% can be assigned to signal transduction processes, which was expected since Smad7 represses TGF-β signaling and thus has impact on manifold different cross-talking signaling pathways. 15% refer to multicellular organismal processes (i.e. processes involved in intercellular interaction of any kind), 35% to response to stimulus, 21% to localization, 38% to metabolic processes, 25% to cell differentiation and 5% to cell adhesion. Note that the total percentage is greater than 100% as some regulated genes can be assigned to different ontology groups. A similar classification of all differentially expressed genes was carried out according to their molecular function (Figure 1B). Figures 2 and 3 graphically summarize regulation of all genes according to their ontology groups.

In general, many known mediators of TGF-β signaling were differentially expressed in AdSmad7 infected HSCs, confirming a direct link of Smad7 effects to TGF-β signalling (Table 2). ECM proteins like Col1a1 and Fn1 which are induced during HSC activation and fibrogenesis were negatively regulated upon Smad7 overexpression. Further profibrogenic cytokines like CXCL10 and HGF were upregulated. In addition, Cyp proteins like Cyp1b1, Cyp2E1 and Cyp4B1, Id proteins 1, 2, and 3, as well as PDGFR A were identified as Smad7 dependent in activated HSCs. Unexpectedly, several genes involved in glucose metabolism, so far annotated as predominantly associated with hepatocytes were influenced by Smad7 overexpression in HSCs.

As expected, Smad7 led to an opposite regulation of a number of recently systematically identified genes induced during HSC activation[14]. Table 3 contains a complete list of proteins identified to be regulated in both studies. In total, 37 genes of our study overlapped with the array results reported by[14]. Twenty-two of those (60%), e.g. HK2, were induced during activation[14] and decreased by Smad7 (this study) and therefore probably represent profibrogenic TGF-β target genes. There were also a few genes strongly upregulated by Smad7, which were downregulated during *in vivo* HSC activation, e.g. BMP2. Some of the proteins found to be differently regulated by activation *vs* Smad7 overexpression are already known to be TGF-β target genes and related to fibrogenesis, i.e. BMP2, Cnn1, Col1a1, Ddah1, Fn1, Lox, Pdgfra, Slc2a1, Slc16a3, and VEGF. Others might represent yet unidentified target genes of profibrogenic TGF-β signaling and/or new markers of HSC activation. Their specific influence on HSC transdifferentiation *in vivo* needs to be carefully investigated in future as they display potential antifibrotic target genes. In some cases De Minicis *et al*[14] reported opposite effects in regards to regulation of gene expression

The average change in expression after Smad7 overexpression is given as log2 fold. SD: Square root of the variance; NFκB: Nuclear factor κB.

in "culture activated" cells compared to "*in vivo* activated" cells. This leaves a final evaluation of Smad7 influence on the regulation of these genes in HSC activation processes open.

Confirmation of array data using quantitative real-time PCR

To validate our microarray results, we selected 12 genes from array data identified as highly regulated in dependency to Smad7 for RT-qPCR analysis. Transdifferentiating (3 d in culture) and fully activated (7 d in culture) HSCs were investigated. TGF-β RI mRNA expression is not modulated during transdifferentiation[15,16] and was used as the expression reference. A synopsis of Smad7 associated modulation of gene expression, given in Figure 4 as log2 fold of LacZ, generally supports the array results. We confirmed upregulation of Cyp4B1, BMP2, SGIII, Zfp423, Pla2g2a and downregulation of EST189231, Olr1 and Id1 (Table 4) independent of time during the transdifferentiation process.

Interestingly, when comparing 3 d- with 7 d-HSCs, opposite effects of Smad7 were found for HK2 (0.38-fold in 3 d-, 3.85-fold in 7 d-HSCs), Slc16a3 (0.59-fold in 3 d, 2.25-fold in 7 d-HSCs) and VEGF.1 (0.51-fold in 3 d-, 1.07-fold in 7 d-HSCs), underlining temporal differences and modulation of the TGF-β signal during HSC activation[15].

Smad7 inhibits BMP2 dependent Smad1 expression

BMP2 was strongly upregulated in Smad7 expressing HSCs (Table 2, Figure 4A and B). Here, we further demonstrate that nevertheless Smad7 blunted BMP2 and

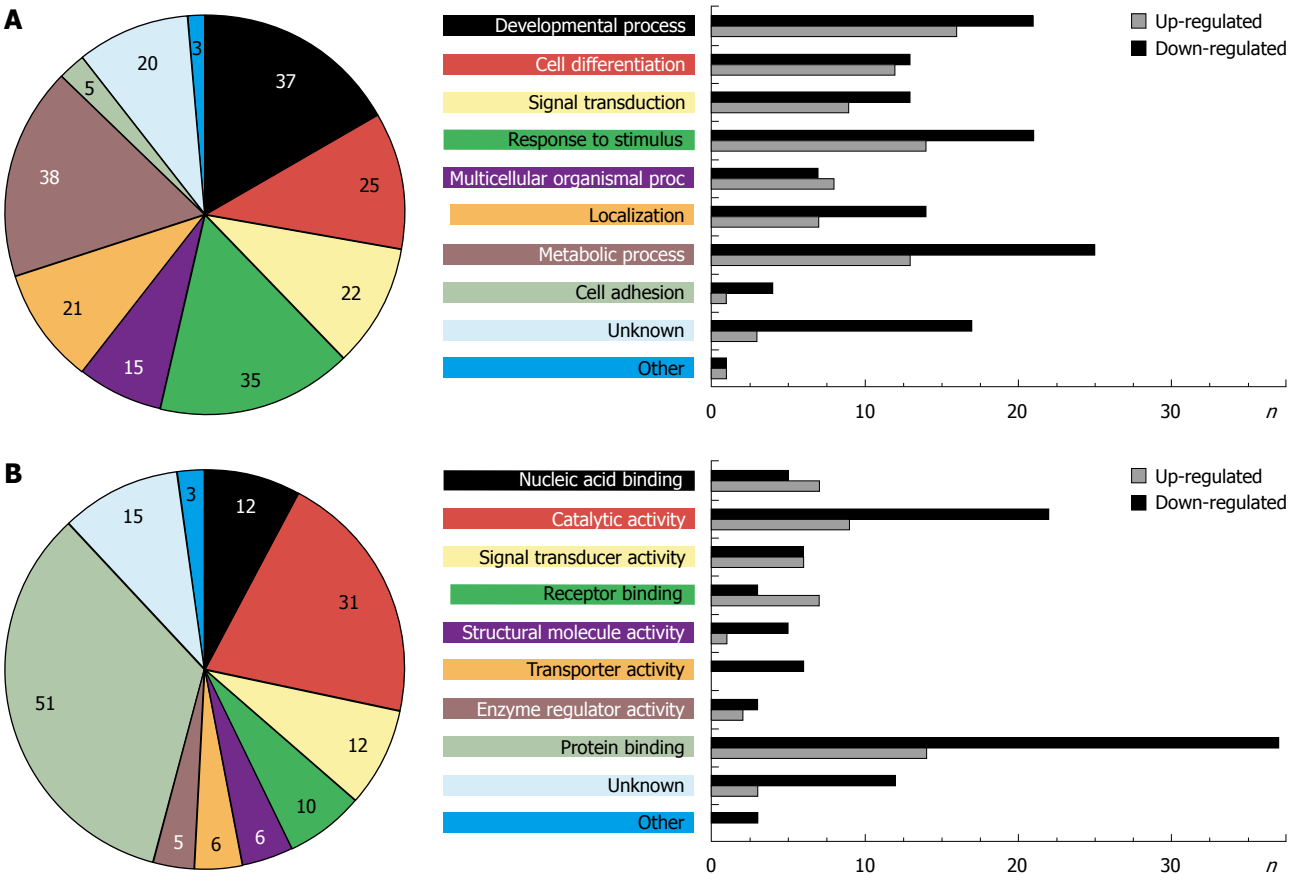

Figure 1 Genes whose expression levels were changed (*n* = 100) after overexpression of Smad7 in hepatic stellate cells are matched to 8 gene ontology annotations using GoMiner[13]. Left part: Percentage of genes matching to the given gene ontology. Note the total percentage is greater than 100% as the same regulated genes can be assigned to different annotations; Right part: Bar diagram shows number of upregulated (grey bars) and downregulated (black bars) genes matching to the given gene ontology (unknown = percentage/number of genes without annotation, other = percentage/number of genes which are not assignable to the given annotations). A: GO group: biological process; B: GO group: molecular function.

TGF-β dependent signalling *via* Smad1 upon AdSmad7 infection in transdifferentiating (4 d in culture) rat HSCs (Figure 5) and infected CFSC (data not shown). Fully activated (7 d in culture) HSCs, which are insensitive to TGF-β, remain responsive to BMP2 mediated Smad1 phosphorylation, show the same tendency when stimulated with BMP2.

DISCUSSION

Using the Affymetrix Microarray approach, we systematically analyzed the effects of Smad7 overexpression during HSC transdifferentaition. About 100 genes were identified to be regulated upon Smad7 overexpression. For obvious reasons, only some of the regulated genes can be discussed below in detail. Nevertheless, all gene expression changes found constitute potential starting points for future research projects to unravel the process of liver fibrogenesis.

Tumor supressor genes were upregulated by Smad7 overexpression in HSCs

Pla2g2a and Cyp4B1 were strongly upregulated after Smad7 overexpression in HSCs. Pla2g2a participates in lipid metabolism/catabolism and was previously described as a tumor repressor in different cancer models, i.e. intestinal tumorigenesis, neuroblastoma, melanoma and colon cancer cell lines[17,18]. VEGF and Glut1, both known to be upregulated in tumor cells[19,20] were Smad7 dependently downregulated in HSCs. These results suggest an influence of Smad7 on tumor development and progression which is a long debated issue considering its regulative impact on ambiguous TGF-β signaling in tumorigenesis.

Cytochrome P450s are haem-thiolate proteins involved in oxidative degradation of particularly environmental toxins and mutagens and play a role in electron transport reactions. Additionally, they are key players in alcohol induced oxidative stress in liver, causing hepatocyte necrosis, apoptosis and liver fibrosis[21]. During steatosis, lipid peroxidation by Cyp2E1 is associated with inflammation and HSC activation including increased TGF-β production, possibly through up-regulation of KLF6[22]. Members of the Cyp P450 family are also upregulated during HSC activation[14].

Interestingly, overexpression of Smad7 increased the expression of some members of the Cytochrome P450 system through HSC activation, i.e. Cyp4B1 which is important in the metabolism of drugs, cholesterol, steroids and lipids, and Cyp2E1, while others are downregulated

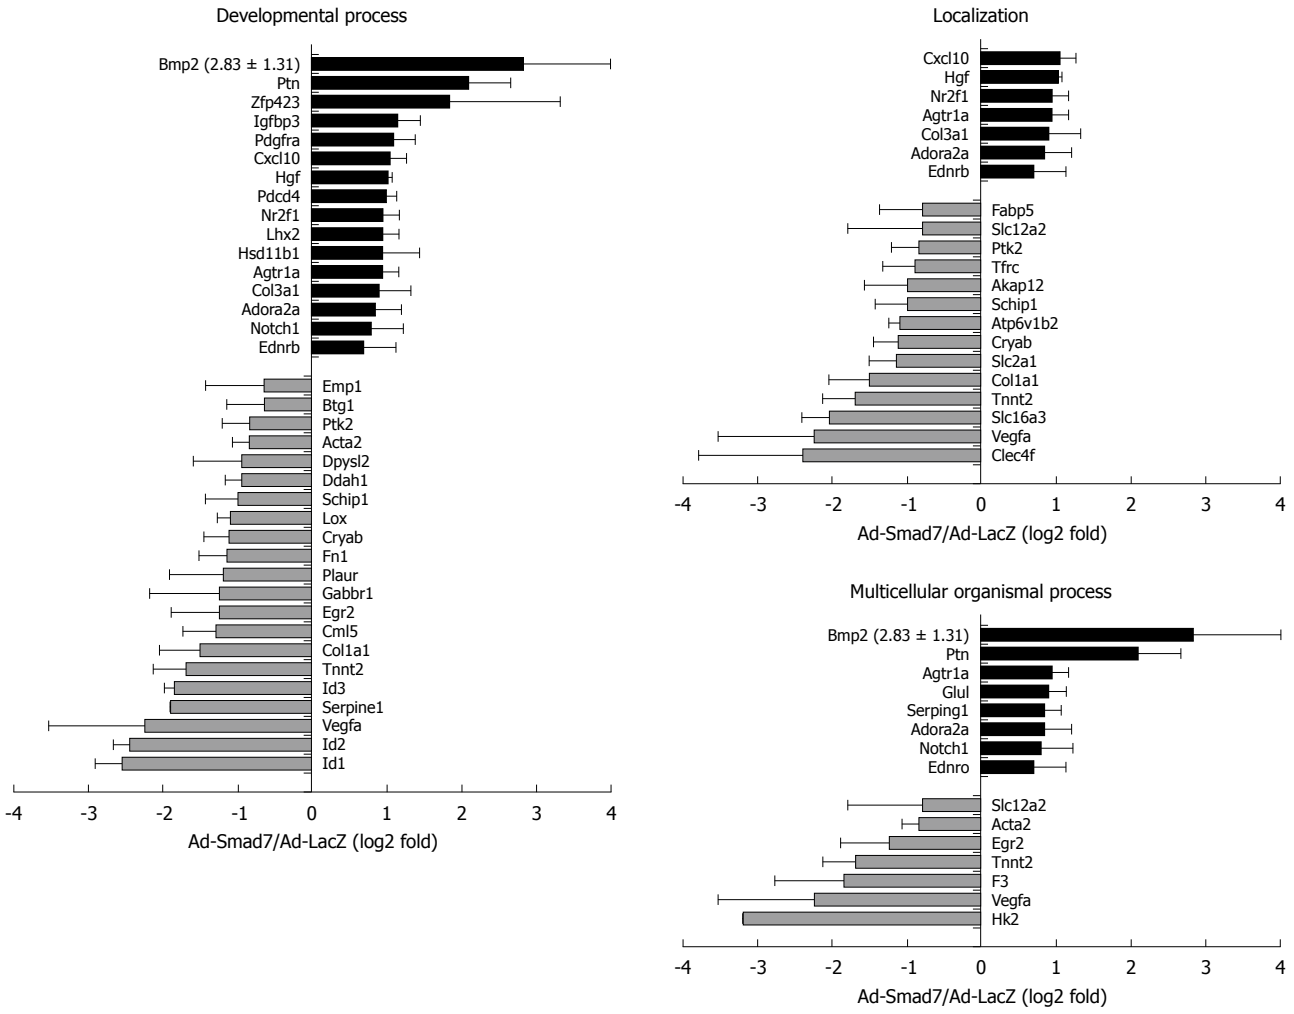

Figure 2 Genes with changed expression levels after overexpression of Smad7 are matched to 8 gene ontology terms of the biological process and to unknown/other. Unknown: Genes without annotation; Other: Genes with another annotation not assignable to the given annotations, details in brackets. Change of expression is given as log2 value of the fold factor with the SD. Black bars: Upregulated; Gray bars: Downregulated.

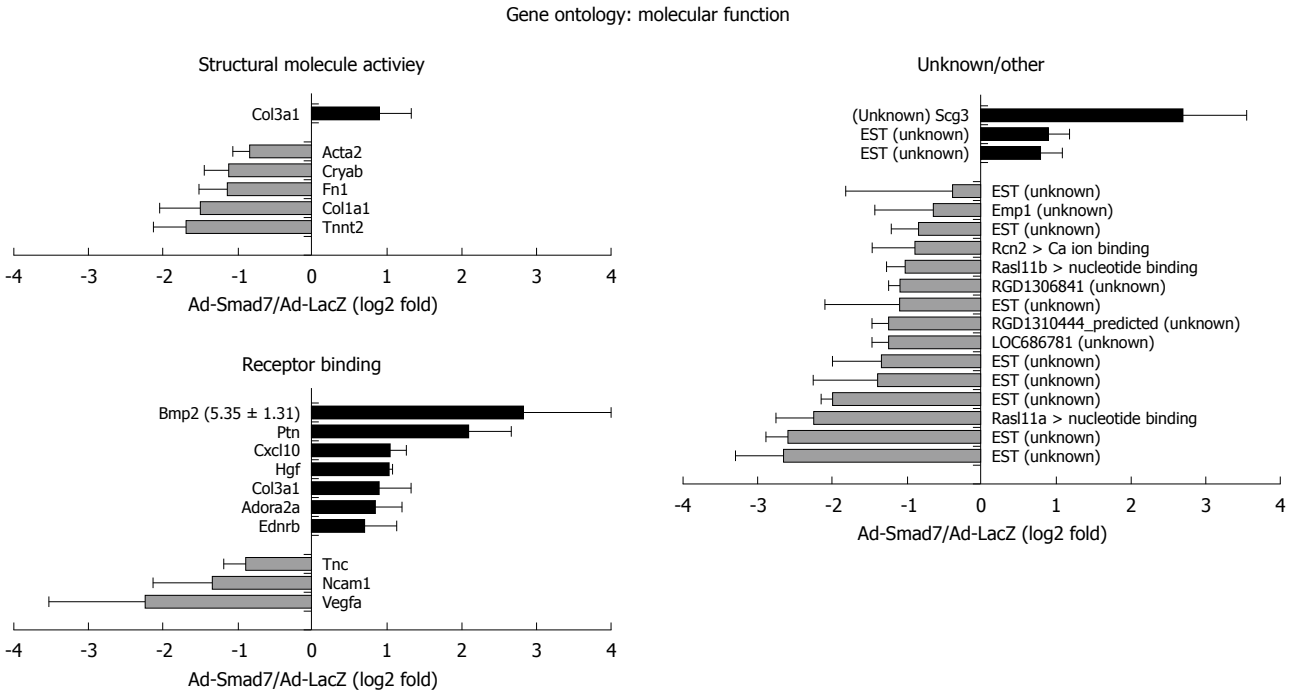

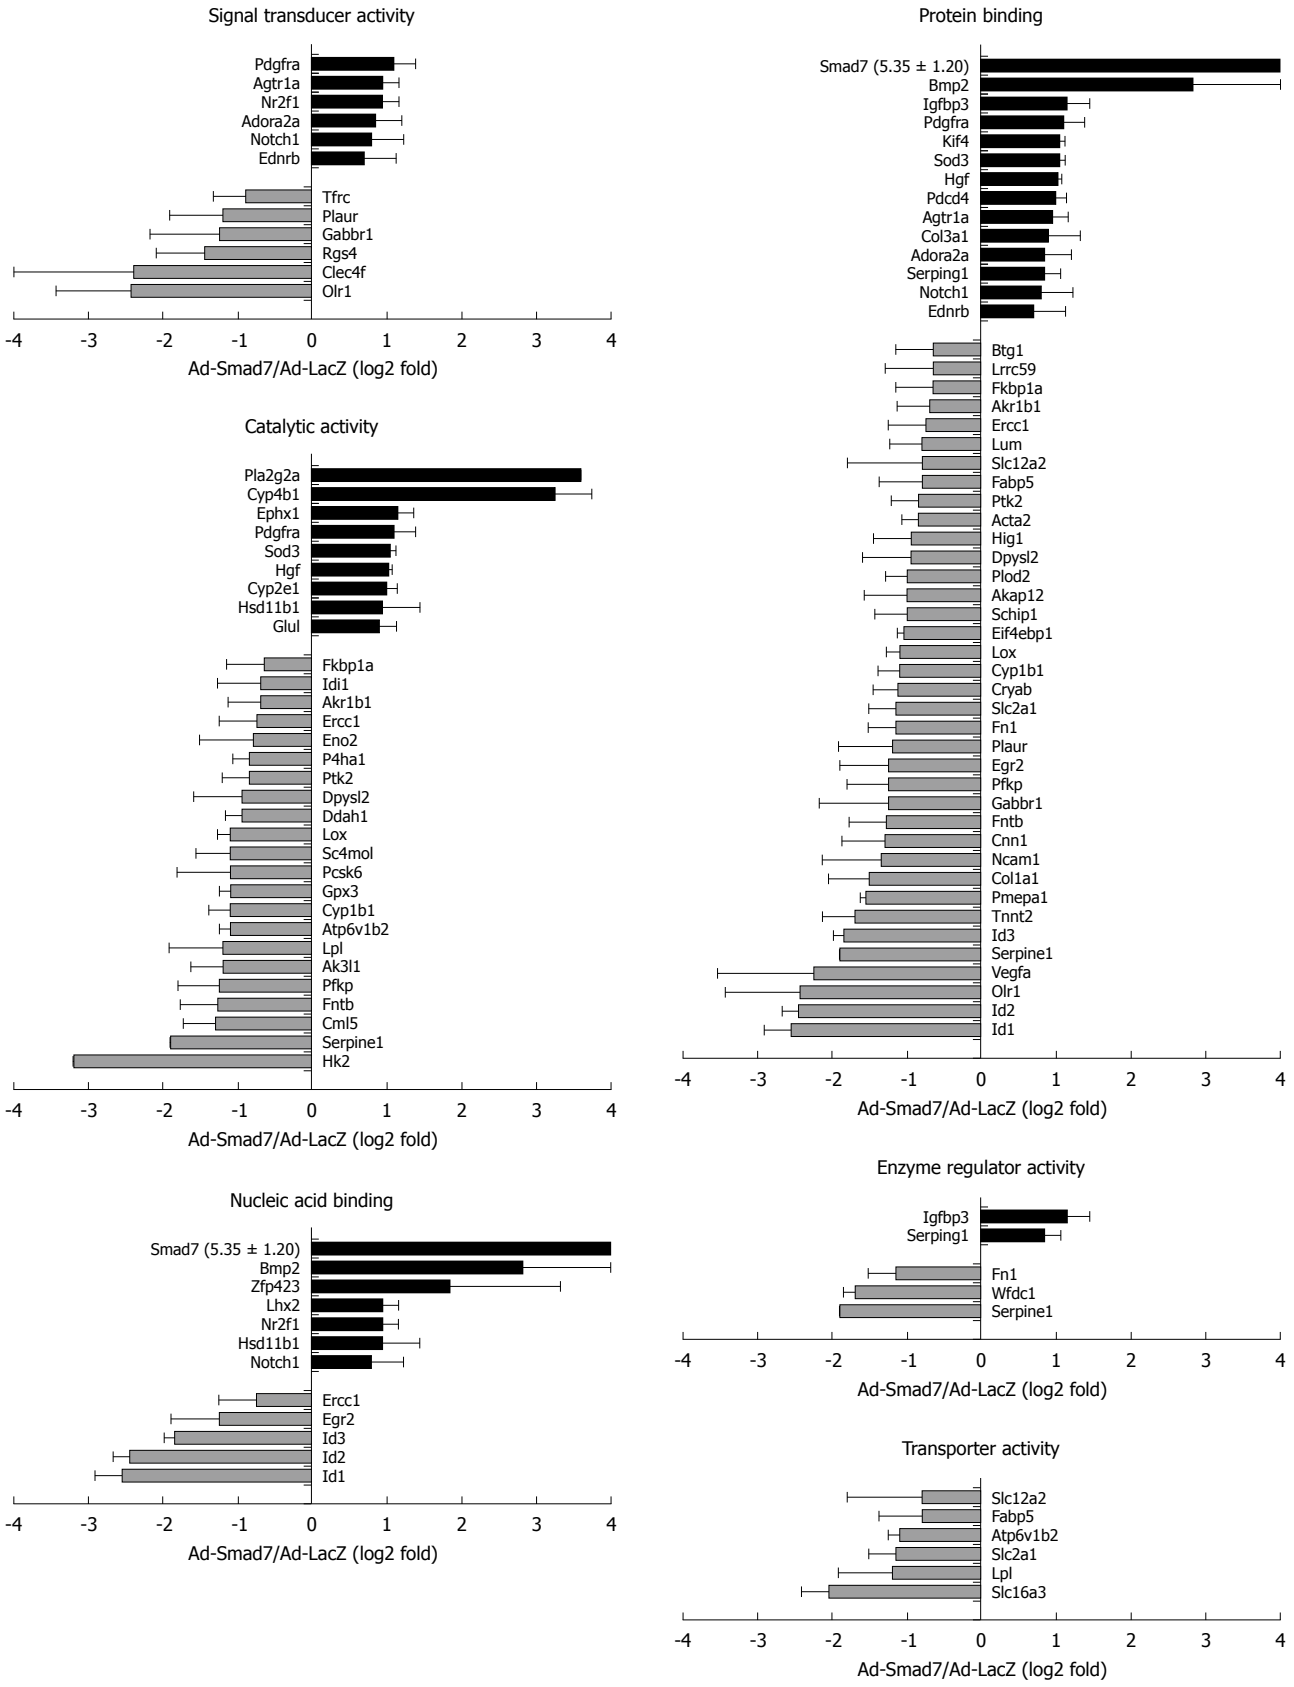

Figure 3 Genes whose expression levels were changed after overexpression of Smad7 are matched to 8 gene ontology terms of the molecular function and to unknown/other. Unknown: Genes without annotation; Other: Genes with another annotation not assignable to the given annotations, details in brackets. Change of expression is given as log2 value of the fold factor with the SD. The term nucleic acid binding includes the annotations nucleic acid binding, transcription factor activity, RNA binding, and transcription regulator activity. Black bars: Upregulated; Gray bars: Downregulated.

Gene expression profiles during hepatic stellate cell activation in culture and *in vivo* (*Gastroenterology* 2007; 132: 1937-1946[113]) and Smad7 overexpressing hepatic stellate cells (HSCs) (our study). [1]Genes regulated the strongest in our study are marked; [2]The regulation of *in vivo* activated HSCs which is different compared to culture activated HSCs in De Minicis study. In total 37 genes overlap in both studies, 22 of those (60%) are oppositely regulated indicating participation of transforming growth factor-β/Smad7 on the regulation of those genes *in vivo*.

upon Smad7 overexpression, e.g. Cyp1B1. These ambiguous effects probably reflect the complex control of oxidative metabolism in the cell.

Glucose metabolism and angiogenesis/vascularisation is downregulated by Smad7

Hk2 is a hexokinase, one of the best known enzymes of glycolysis, and is involved in cell cycle progression. According to the results of the microarray analysis it represents the most downregulated gene in AdSmad7 infected HSCs. One feature of activated HSCs is the ability to proliferate. TGF-β antagonizes proliferation in quiescent HSCs, whereas it has a growth promoting effect in transdifferentiated MFBs. Thus, Hk2 might be induced by TGF-β in HSCs during activation, subsequently stimulating HSC

Different results in array and quantitative real-time polymerase chain reaction (RT-PCR) analysis are marked bold.

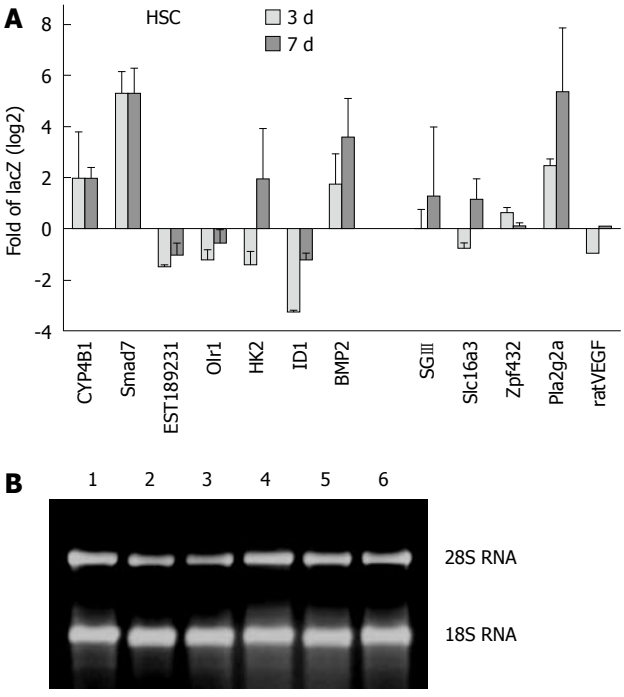

Figure 4 Validation of microarray results using quantitative real-time polymerase chain reaction. A: SYBR Green I-based real-time quantification to compare the mRNA expression patterns of 12 selected genes in hepatic stellate cell which were infected either with AdLacZ or AdSmad7. Transforming growth factor-β RI, not affected by Smad7 overexpression, served as a house-keeping gene. Results are given as relative expression of log2 fold of LacZ. 3 d (light grey column) and 7 d (dark grey column): 3 d and 7 d after adenoviral infection. Values are the mean of three measurements each performed in duplicates ± SD from independent experiments; B: Total RNA purity and integrity was verified by formaldehyde agarose gel electrophoresis. Lane 1: LacZ, 7 d; Lane 2: LacZ, 3 d; Lane 3: Smad7, 7 d; Lane 4: Smad 7, 3 d; Lane 5: Untreated control, 7 d; Lane 6: Untreated control, 3 d.

proliferation and thus providing at least part of the growth stimulatory effect of TGF-β. Although physiological ef-

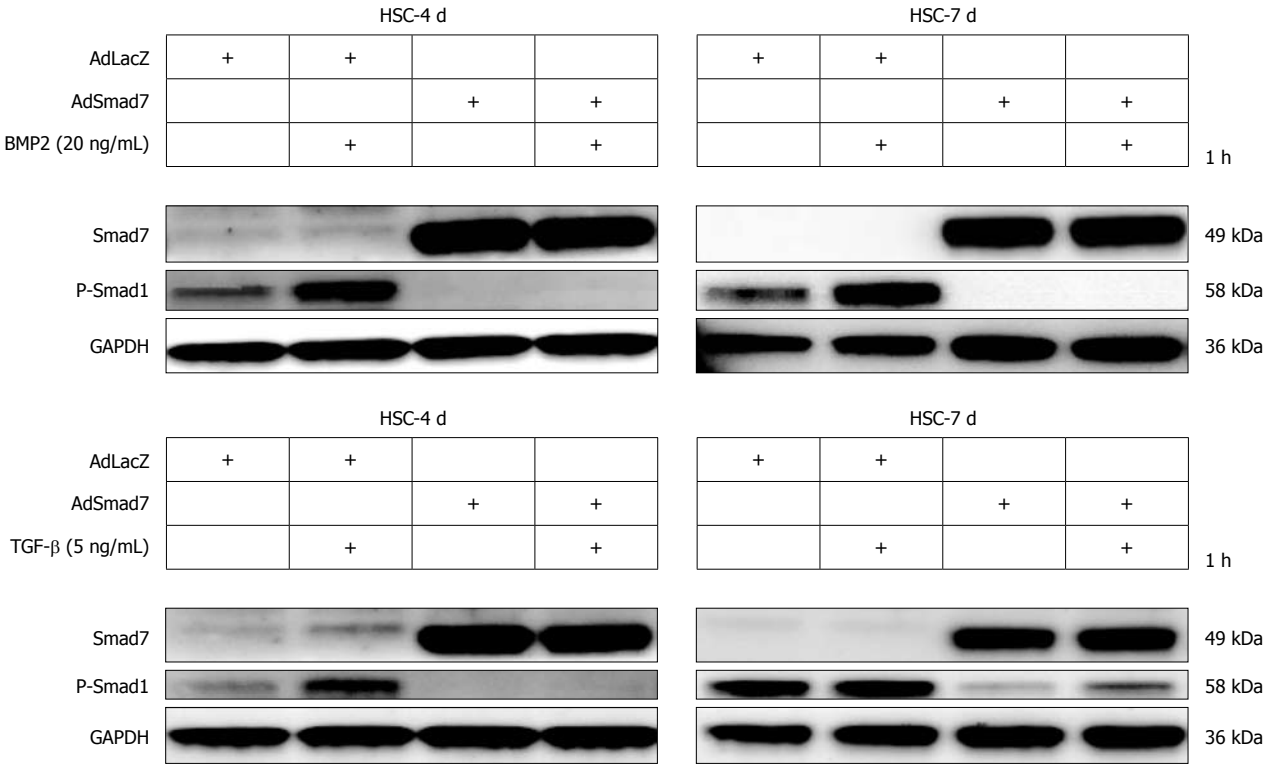

Figure 5 Smad7 overexpression inhibits BMP2 and transforming growth factor-β dependent Smad1 phosphorylation. Transdifferentiating (4 d old) and fully activated (7 d old) hepatic stellate cells (HSCs) infected or non-infected with either AdLacZ (control) or AdSmad7 were stimulated for 1 h with 20 ng/mL BMP2 or 5 ng/mL transforming growth factor (TGF)-β as indicated. Smad7 overexpression and Smad1 phosphorylation were analysed using Western blottings. GADPH served as a reference. While transdifferentiating HSCs are sensitive to both BMP2 and TGF-β stimulation, fully activated HSCs are only responsive to BMP2.

fects of glucose metabolism in the liver are traditionally associated to hepatocytes and provide a direct link to fibrogenesis *via* hyperglycemia and insulin resistance[23-25], one could speculate that activated HSCs need more energy and thus, glycolysis is upregulated TGF-β dependently in this cell type. In line, HSCs become sensitive to glucose signaling during activation, high glucose concentrations stimulate ROS production through PKC-dependent activation of NADPH oxidase and induce MAP kinase phosphorylation subsequent to proliferation and type I collagen production in this cell type[26] suggesting a crucial role of HSC-sugar metabolism in fibrogenesis.

Upregulation of Hk2 during activation of HSCs further suggests that glycolysis induction and increased levels of involved proteins may occur by other means than elevated blood glucose levels ([14], our study). This in turn indicates a direct connection between fibrosis and enhanced glycolysis independent of inducing external stimuli of either process.

Beside Hk2 regulation, other genes encoding enzymes of glycolysis (Eno2, PFKP) or related to glucose metabolism were downregulated Smad7 dependently, e.g. VEGFa, PAI-1 (Serpine1), F3, Slc2a1 (Glut1), FN1, EIF4ebp1 and PTK2 (Figure 6). A list of all references proving the relation of these genes to glucose metabolism will be provided to interested readers on request.

Glut1 is a glucose transporter protein which becomes upregulated in activated HSCs or upon HSC activation[14]. Since Smad7 decreases Glut1 expression levels and other proteins involved in glycolysis, TGF-β seems to enhance glucose metabolism and energy supply during HSC activation thus enabling the cells to proliferate and transdifferentiate towards activated myofibroblasts.

In contrast, decreased numbers of Glut1 molecules are reported in hepatocytes subjected to chronic alcohol consumption[27] resulting in a reduced availability of glucose for glycolysis in hepatocytes. The resulting energy deficiency has been shown to impair this cell type's ability to perform critical functions and to contribute therefore to cell death and alcoholic liver disease.

In line with our results, relations between glucose metabolism and fibroproliferative processes were identified in other organs. For example in human kidney[28,29] exposure of proximal tubule cells and cortical fibroblasts to high extracellular glucose concentrations results directly in altered cell growth and collagen synthesis.

IGFBP3 and Cyp2E1, known to participate in glucose metabolism were upregulated in AdSmad7 infected HSCs, indicating that they might be under negative control through TGF-β. However, upregulation of IGFBP3 in our study could be simply due to "culture" but not "*in vivo* activation" of HSCs (for term definition compare[14]) instead of being mechanistically important. Interestingly, Smad7 even seems to enhance the upregulation of IGFBP3, which already occurs upon HSC activation. If there is any pathologic relevance of this finding, it suggests a mechanism of regulation independent of canonical TGF-β/Smad7 signaling in HSC activation.

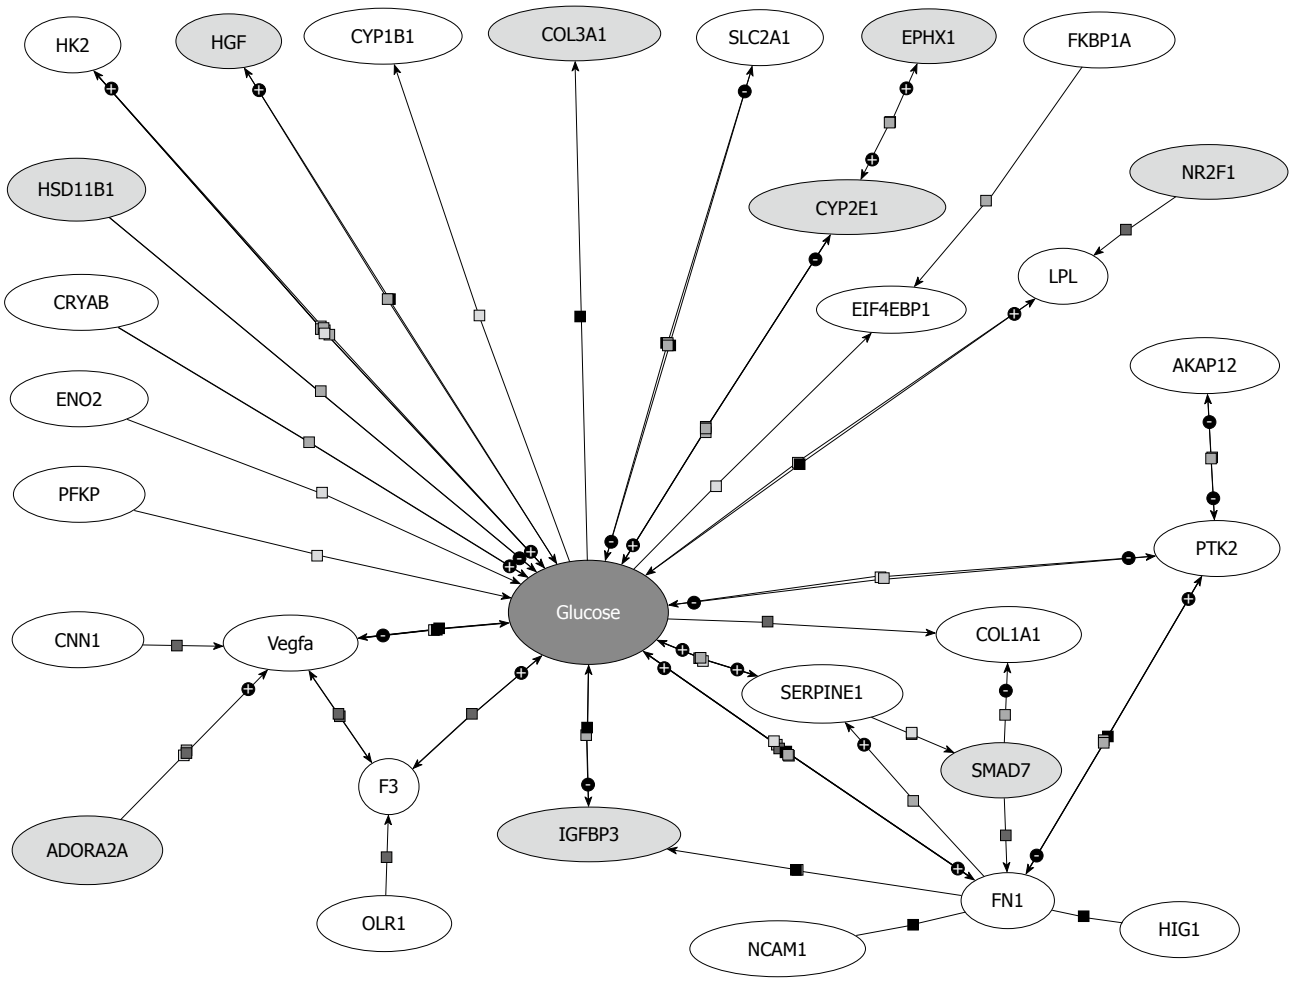

Figure 6 Biological interaction between glucose and genes up- (light grey) or down-regulated (white) in primary hepatic stellate cells after overexpression of Smad7. Genes linked to glucose by binding or regulatory interactions are depicted as interconnecting lines between glucose and the gene symbols. Pathway analysis was done with Pathway Architect software (Stratagene).

VEGFs are growth factors involved in angiogenesis, vasculogenesis and endothelial cell growth, promotion of cell migration, apoptosis inhibition and induction of blood vessel permeabilization. De Minicis *et al*[14] showed VEGFc to be upregulated[14], while in the present report VEGFa was downregulated after Smad7 overexpression in activated HSCs, indicating its induction as a response to profibrogenic TGF-β signaling. Previous investigation of hypoxia in a stellate cell line demonstrates upregulation of VEGF expression[30]. Hypoxia leads to cell dysfunction or death and occurs during liver damage and inflammation. HIF1, considered to be the major regulator of about 100 genes including VEGF and PAI-1, is also upregulated in that study. In contrast HIF1 did not display an altered expression in our study indicating that HIF1 expression in HSCs is TGF-β independent and that another TGF-β dependent route exists to induce PAI-1 (serpine1) and VEGFa expression.

Smad7 decreases cell adhesion regulators in HSCs

Expression of several proteins linked to cell adhesion, i.e. Olr1, Ncam1, Fn1 and Tnc was decreased after Smad7 overexpression in HSCs. Accordingly, Ncam1 and Fn1 were upregulated in activated HSCs[14]. Although for Olr1 no information about the regulation in activated HSCs is available so far, we assume from our results that Smad7 antagonizes cell adhesion features of activated HSCs. This suggests that profibrogenic TGF-β signaling improves cell adhesion for transdifferentiating HSCs. Nevertheless it should be noted that downregulation of Tnc in activated HSCs is supported by Smad7.

Smad7 induces BMP2 expression in HSCs

Generally, TGF-β signals *via* Smad2 and Smad3 but also induces the second canonical pathway *via* ALK1/Smad1/5/8. BMP2, another member of the TGF-β family, solely signals *via* Smads1/5/8 utilizing ALK3 and ALK6[12]. Here we show that (1) BMP2 was strongly upregulated in Smad7 expressing HSCs (Table 2, Figure 4A and B); and (2) Smad7 potently inhibited BMP2 dependent and TGF-β dependent Smad1 phosphorylation. Even in fully activated HSCs which are not responsive to TGF-β concerning Smad1 phosphorylation, BMP2 dependent Smad1 phosphorylation was abolished (Figure 5).

These results indicate a tight crosstalk between TGF-β and BMP signaling pathways in HSCs. It seems that HSCs

try to keep up a functional Smad1 signaling upon blocking TGF-β pathways with Smad7. Accordingly, BMP2 is capable of inducing Smad1 signaling in fully activated 7 d-HSCs which are no longer responsive to TGF-β stimulation. Thus BMP2 expression might be induced to overcome a lack of TGF-β/Smad1 signaling upon Smad7 expression or HSC activation using a corresponding autocrine loop. Although our *in vitro* experiments demonstrate that Smad7 is able to inhibit BMP2/Smad1 signaling effectively, Smad7 dependent induction of BMP2 expression in HSCs *in vivo* might be strong enough to sustain an active Smad1/5/8 signaling pathway. Further experiments could delineate whether BMP2 expression is directly induced by the recently described DNA binding activity of Smad7[31], if a running TGF-β signaling pathway has a negative regulatory role toward the BMP2 promoter or if other mechanisms are responsible for BMP2 induction in Smad7 overexpressing HSCs.

In summary we conclude that genes regulated contrarily during HSC activation[14] *vs* ectopic Smad7 expression (this study) most probably represent critical profibrogenic components. As Smad7 is able to blunt HSC transdifferentiation *in vitro* and *in vivo*[7] we assume glucose metabolism and the crosstalk between the TGF-β and the BMP2 pathways are critical components of HSC activation.

In general our study underlines the potential of top down systemic approaches to delineate effects of cell signaling regulation and opens the opportunity to find targets for drug development.

COMMENTS

Background

Activation of hepatic stellate cells (HSCs) as a consequence of liver damage includes proliferation and extracellular matrix (ECM) deposition and represents a major step in fibrogenesis. Transforming growth factor (TGF)-β is a master contributor and its signaling pathway is modulated during the HSC activation process, whereby its cytostatic action is lost and ECM producing effects become predominant. Smad7 is a powerful antagonist of TGF-β. Expression of Smad7 is transiently induced by the canonical TGF-β/R-Smad signaling cascade, thereby providing a negative feedback loop to regulate TGF-β signals. Smad7 is able to inhibit HSC transdifferentiation and attenuate the extent of fibrosis, suggesting Smad7 is a promising antifibrotic compound.

Research frontiers

The findings offer important new information about the process of HSC transdifferentiation and fibrogenesis as well as cell biology of signal transduction in the liver. Moreover, providing a list of genes previously not known as participants in HSC activation and fibrogenesis, members of the field may use these data as starting points to get new insight into mechanisms of HSC (patho)physiology. Thus, it will definitely be of interest to the scientific community, especially in the field of hepatology and gastroenterology.

Innovations and breakthroughs

In the present report, the authors systematically investigated transcriptional effects of Smad7 overexpression in cultured HSCs by microarray analysis. Using this powerful top down approach, the authors identified 100 target genes to be significantly regulated by Smad7 overexpression. These represent potential targets for delineating mechanisms of HSC activation and to set up therapeutic approaches. The results imply a crosstalk between TGF-β and BMP2 signaling pathways in HSCs and for the first time a significant involvement of glucose metabolism in the HSC transdifferentiation processes.

Applications

The results are of special interest for future attempts to understand the process of stellate cell activation and to set up TGF-β and/or Smad7 directed treatment approaches in chronic liver diseases, especially as they reflect the most powerful negative regulatory process of TGF-β signaling.

Terminology

Bone morphogenetic protein (BMP): BMPs are multi-functional growth factors belonging to the TGF-β superfamily. BMPs were originally discovered by their ability to induce the formation of bone and cartilage, but are now considered to constitute a group of pivotal morphogenetic signals, orchestrating tissue architecture throughout the body. BMP signals are mediated by type Ⅰ and Ⅱ BMP receptors and their downstream molecules Smad1, 5 and 8. Microarray: A method for profiling gene and protein expression in cells and tissues. A microarray consists of different nucleic acid/protein probes that are chemically attached to a substrate, which can be a microchip, a glass slide or a microsphere-sized bead. Hybridization of test samples to these probes can be measured by different means.

Peer review

This is a potentially interesting study aimed at clarifying Smad7-regulated gene expression during the transdifferentiation of hepatic stellate cells, a major profibrogenic cell type in the liver. Overall, the study is well-performed and the manuscript is well-written.

Abstract

AIM: To assess the prevalence of advanced liver fibrosis (ALF) in human immunodeficiency virus (HIV), hepatitis C virus (HCV) and HIV/HCV patients using transient elastography, and to identify factors associated with ALF.

METHODS: Between September 2008 and October 2009, 71 HIV mono-infected, 57 HIV/HCV co-infected and 53 HCV mono-infected patients on regular follow-up at our Center were enrolled in this study. Alcohol intake, the main parameters of liver function, presence of HCV-RNA, HIV-RNA, duration of highly active anti-retroviral therapy (HAART) and CD4 cell count were recorded. ALF was defined as liver stiffness (LS) $\geqslant$ 9.5 kPa. To estimate liver fibrosis (LF) a further 2 reliable biochemical scores, aspartate aminotransferase platelet ratio index (APRI) and FIB-4, were also used.

RESULTS: LS values of co-infected patients were higher than in either HIV or HCV mono-infected patients (χ^2_{MH} = 4, P < 0.04). In fact, LS $\geqslant$ 9.5 was significantly higher in co-infected than in HIV and HCV mono-infected patients (χ^2 = 5, P < 0.03). Also APRI and the FIB-4 index showed more LF in co-infected than in HIV mono-infected patients (P < 0.0001), but not in HCV mono-infected patients. In HIV/HCV co-infected patients, the extent of LS was significantly associated with alcohol intake (P < 0.04) and lower CD4+ cell count (P < 0.02). In HCV patients, LS was correlated with alcohol intake (P < 0.001) and cholesterol levels (P < 0.03). Body mass index, diabetes, HCV- and HIV-viremia were not significantly correlated with LS. In addition, 20% of co-infected patients had virologically unsuccessful HAART; in 50% compliance was low, CD4+ levels were < 400 cells/mm^3 and LS was > 9.5 kPa. There was no significant correlation between extent of LF and HAART exposure or duration of HAART exposure, in particular with specific dideoxynucleoside analogues.

CONCLUSION: ALF was more frequent in co-infected than mono-infected patients. This result correlated with lower CD4 levels. Protective immunological effects of HAART on LF progression outweigh its hepatotoxic effects.

INTRODUCTION

In the last few years, liver disease associated with hepatitis C virus (HCV) has emerged as a significant problem in human immunodeficiency virus (HIV)-infected patients, thanks to improved survival in the highly active antiretroviral therapy (HAART) era[1]. It has been reported that HIV and HCV co-infection leads to a more rapid progression of liver disease to cirrhosis[2,3]. Other factors such as severe immune suppression and alcohol consumption accelerate the progression of HCV-related fibrosis[4,5]. Virologically successful HAART slows the progression of liver fibrosis (LF) and reduces hepatic necroinflammatory activity in HIV/HCV co-infected patients[2,6]. In contrast, antiretroviral-related liver toxicity could contribute to liver damage in HIV- and HIV/HCV-infected patients[7]. Mitochondrial toxicity of nucleoside analogues[8], and glucose or lipid abnormalities, such as hyperglycemia and lipodystrophy, which are particularly common when using some protease inhibitors[9], may produce or enhance LF progression in HIV mono- and HIV/HCV co-infected patients. Currently, in this respect, a growing number of cases of cryptogenetic liver disease in symptomatic and asymptomatic HIV-infected patients has been reported[10,11].

Percutaneous liver biopsy is the gold standard for assessing LF. However, it may be associated with sampling variability[12], is an invasive technique with rates of morbidity of 3% and mortality of 0.03%[13,14], and as a consequence, is not suitable for repeated assessment, which is required when monitoring LF.

For these reasons, new non-invasive methods for the assessment of LF have been developed. Transient elastography (TE) (Fibro-Scan®; EchoSens, Paris, France) is a rapid, reliable and tolerable imaging technique for the assessment of LF by measuring liver stiffness (LS)[15,16].

On the other hand, many biochemical markers have been implemented to estimate LF, with the aim of reducing the number of liver biopsies[14].

The advent of TE and biochemical markers has been demonstrated to be very helpful in the non-invasive measurement of LF, particularly in asymptomatic HIV-infected patients in whom liver biopsy is not recommended[11]. TE has already been validated for the measurement of LF in HIV and HCV seropositive patients[17,18].

The aim of this study was to assess the prevalence of LF and cirrhosis in a group of HIV mono-infected, HCV mono-infected and HIV/HCV co-infected patients using TE and biochemical markers. In addition, we evaluated which of the factors studied correlated with advanced LF (ALF) and cirrhosis.

MATERIALS AND METHODS

Study population

Between September 2008 and October 2009 all consecutive HIV mono-infected and HIV/HCV co-infected patients on regular follow-up at the AIDS Center of the University of Palermo, as well as HCV mono-infected patients seen consecutively at the Outpatient Clinic of the Department of Clinical Medicine and Emerging Pathologies of the University of Palermo were enrolled in this study.

Information on age, gender, risk factors for HCV and HIV infections, cumulative exposure to non-nucleoside and nucleoside reverse-transcriptase inhibitors, protease inhibitors and specific antiretroviral drugs within each class were all recorded in a database designed for this study.

For all HIV-infected patients the absolute number of CD4+ T-cells and plasma HIV-RNA levels was assessed. In HCV-infected patients, HCV-genotype and plasma HCV-RNA levels were also recorded. In addition, at baseline, complete blood cell counts, alanine aminotransferase (ALT), aspartate aminotransferase (AST), γ-glutamyl transferase (γGT), total cholesterol, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, triglycerides and glycemia were measured.

Alcohol intake > 20 g/d either at the time of the study or in the past was recorded through patient interviews. Diabetes or impaired fasting glucose (IFG) were defined according to the Expert Committee on the Diagnosis and Classification of Diabetes Mellitus criteria[19].

Patients with acute liver decompensation, hepatocellular carcinoma or chronic hepatitis B were excluded.

The study protocol conformed to the ethical guidelines of the 1975 Declaration of Helsinki. Patients were enrolled after written informed consent was obtained.

Assessment of LF

LF was assessed by a single certified operator (trained by the manufacturer) using TE (FibroScan®; EchoSens, Paris, France). TE provides an assessment of LS expressed in kPa units. In brief, an ultrasound transducer probe is mounted on the axis of a vibrator. Vibrations of mild amplitude and low frequency are transmitted by the transducer, inducing an elastic shear wave that propagates through the underlying tissues. The speed of propagation of this vibration across the liver is directly related to tissue stiffness.

The tip of the probe transducer was placed in the intercostal spaces at the right lobe of the liver. Only patients with 10 valid elastometric measures, interquartile ranges > 30% and ⩾ 60% success rate (the number of validated

measurements divided by the total number of measurements) were considered to be reliable. ALF (severe fibrosis and cirrhosis) was defined as a median LS of 9.5 kPa. As previously published, this cut-off value is strongly correlated with a Metavir score of F3, both in HCV mono-infected and HCV/HIV co-infected patients[17,18].

LF was also assessed biologically using 2 different well-validated indices, the aspartate aminotransferase platelet ratio index (APRI) index and the FIB-4 index. The APRI was calculated as follows: AST/upper limit of normal × 100/platelet count (10^9/L)[20,21]. The FIB-4 index was calculated as follows: age × AST (IU/L)/{[platelet count (10^9/L)] × [ALT (IU/L)]$^{1/2}$}[22]. The prevalence of ALF was estimated using as a reference a FIB-4 index > 3.25 and an APRI index > 1.5[20,22].

Statistical analysis

When data distribution was Gaussian, values were expressed as mean ± SD and their differences were calculated using the Student *t*-test; otherwise, data were expressed as the median and range and analyzed using the Mann-Whitney *U* test. Fisher's exact and χ^2 tests, the χ^2 test of Mantel Haenszel, Spearman's rank correlations (ρ) and Pearson's correlation (*r*) were used where appropriate. Multiple linear regression analysis was used to study the association between increased values of LS and variables statistically significant at univariate analysis. All analyses were performed using the SPSS software package (version 13.0; Chicago, IL, USA).

RESULTS

Study population

A total of 201 patients on regular follow-up at both our Centers were enrolled in the study.

In 11 patients (4 HIV mono-infected, 6 HCV mono-infected and one co-infected) a valid elastometric assessment could not be obtained because of truncular obesity, therefore 190 patients were finally included in this study. There were 137 HIV-infected patients, including 71 HIV mono-infected and 66 HIV/HCV co-infected, and 53 HCV mono-infected patients. Patient characteristics at the time of LS measurement are summarized in Table 1.

HIV patients were significantly younger than HCV mono-infected individuals ($P < 0.002$). Body mass index (BMI) was significantly higher in HCV mono-infected patients than in HIV and HIV/HCV co-infected patients ($P < 0.002$). The most frequent risk factor of HCV contamination was intravenous drug use in co-infected *vs* mono-infected HCV patients ($P < 0.0001$), while it was transfusion of blood products in HCV mono-infected *vs* co-infected patients ($P < 0.0001$). Most HIV mono-infected (80.2%) and HIV/HCV co-infected patients (90.9%) were under HAART. However, only 62% of HIV mono-infected and 68% of HIV/HCV co-infected patients had an HIV-RNA load of < 47 copies/mL. In addition, 20% of co-infected patients had virologically unsuccessful HAART; in 50% compliance was low, and CD4+ levels were < 400 cells/mm^3. HIV/HCV co-infected patients were more often infected by HCV genotype 3 compared with HCV mono-infected patients ($P < 0.03$).

Table 1 Demographic characteristics of the study populations (mean ± SD) *n* (%)

	HIV (*n* = 71)	HCV (*n* = 53)	HIV/HCV (*n* = 66)
Age (yr)	43.3 ± 10.3[a]	49.7 ± 12.5	45.6 ± 12.5
Male gender	50 (70)	36 (67.9)	49 (74.2)

[a]$P < 0.002$, [b]$P < 0.0001$ *vs* hepatitis C virus (HCV); [c]$P < 0.0001$, [d]$P < 0.03$, [e]$P < 0.001$ *vs* human immunodeficiency virus (HIV)/HCV. IFG: Impaired fasting glucose; BMI: Body mass index; HAART: Highly active anti-retroviral therapy.

Table 2 shows the main hematological and virological parameters in the 3 study groups. Serum ALT levels were significantly higher in HCV mono-infected patients than in HIV/HCV co-infected and HIV mono-infected patients ($P < 0.02$). Serum AST, ALT and γGT levels were significantly higher in HIV/HCV co-infected than in HIV mono-infected patients ($P < 0.0001$). Only γGT levels were more elevated in HIV/HCV co-infected patients than in HCV mono-infected patients ($P < 0.01$). TG levels were significantly higher in HIV mono-infected and HIV/HCV co-infected patients than in HCV mono-infected patients ($P < 0.004$).

Extent of LF

In the overall population LS measured by TE ranged from 3.2 to 48.8 kPa. In 9 HIV/HCV co-infected patients, HCV-RNA was undetectable and for this reason these patients were excluded from the analysis, which was thus carried out only in the remaining 57 co-infected patients. However, their LS was lower than in the remaining co-infected group (data not shown).

Table 3 shows the distribution of LS values measured in all 3 study groups. Co-infected patients had higher LS values than mono-infected patients ($\chi^2_{MH} = 4$, $P < 0.04$). The HIV/HCV-co-infected population had LS ≥ 9.5 kPa (50.9%) more often than HCV and HIV mono-infected patients (28.3%) ($\chi^2 = 5$, $P < 0.03$). In this respect 60% of co-infected patients under virologically unsuccessful HAART showed LS ≥ F3. The individual values of LS increased from HIV to HCV and to HIV/HCV infected patients (ρ = 0.5, $P < 0.0001$) (Figure 1).

Overall, by multiple linear regression analysis, the variables significantly associated with ALF were AST values (β = 0.47, $P < 0.0001$) and HIV/HCV co-infection (β = 0.25, $P < 0.002$). To better understand which variables

	HIV (*n* = 71)	HCV (*n* = 53)	HIV/HCV (*n* = 57)
APRI	0.31 (0.1-1.6)[a,b]	0.93 (0.28-6.07)	0.92 (0.17-19.7)
FIB-4	0.93 (0.39-4.28)[a]	1.62 (0.47-12.6)	1.63 (0.63-23.8)
LS	5.4 (3.2-26.6)[a,b]	7.3 (3.4-40.9)[c]	9.8 (4.3-48.8)

[a]$P < 0.0001$ *vs* hepatitis C virus (HCV); [b]$P < 0.0001$, [c]$P < 0.05$ *vs* human immunodeficiency virus (HIV)/HCV. LS: Liver stiffness; APRI: Aspartate aminotransferase platelet ratio index.

were associated with LS in patients with HIV mono- and co-infection, we also performed multiple linear regression analysis of these 2 groups and found that ALF correlated positively with AST serum levels (β = 0.34, $P < 0.0001$) and presence of HIV/HCV co-infection (β = 0.4, $P < 0.0001$) and negatively with lower CD4+ cell counts (β = -0.21, $P < 0.003$).

Median values of APRI and FIB-4 were significantly higher in HCV mono- and co-infected patients than in HIV mono-infected patients. There were no significant differences in APRI and FIB-4 medians in HCV mono- and HIV/HCV co-infected patients (Table 4). Median values of LS were significantly lower in HIV mono-infected than in HCV mono- and HIV/HCV co-infected patients ($P < 0.0001$). Median values of HIV/HCV co-infected patients were also significantly higher than in HCV mono-infected patients ($P < 0.05$).

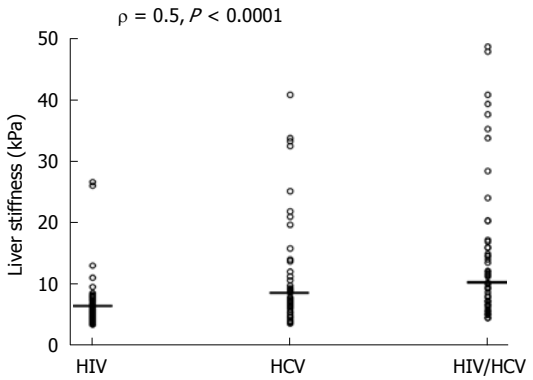

Figure 1 Median and distribution of liver stiffness in human immunodeficiency virus, hepatitis C virus, human immunodeficiency virus/hepatitis C virus patients. HIV: Human immunodeficiency virus; HCV: Hepatitis C virus.

Overall, correlations between LS and APRI values and LS and FIB-4 values were statistically significant ($r = 0.60$, $P < 0.0001$ and $r = 0.64$, $P < 0.0001$, respectively). However, when correlations were made according to the 3 cut-off values of LS, we found a significant correlation only for values of LS ≥ 9.5 ($r = 0.50$, $P < 0.0001$ *vs* APRI and $r = 0.53$, $P < 0.0001$ *vs* FIB-4) (Table 5).

Correlation between LS and risk factors studied

Table 6 shows the factors associated with LS in the 3 groups. No correlation between the studied parameters and LS was found in the HIV mono-infected group. In HCV mono-infected patients, LS positively correlated with alcohol intake > 20 g/d ($P < 0.001$) and AST serum level ($P < 0.0001$), while it negatively correlated with the

LS: Liver stiffness; HIV: Human immunodeficiency virus; HCV: Hepatitis C virus; BMI: Body mass index; HAART: Highly active anti-retroviral therapy; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; T-Chol: Total cholesterol; HDL: High density lipoprotein; TG: Triglyceride; IFG: Impaired fasting glucose; APRI: Aminotransferase platelet ratio index. [a]$P < 0.001$; [b]$P < 0.03$; [c]$P < 0.0001$; [d]$P < 0.02$; [e]$P < 0.04$.

number of platelets ($P < 0.0001$) and serum cholesterol levels ($P < 0.03$). APRI and FIB-4 values were significantly associated with LS both in HCV and HIV/HCV co-infected patients ($P < 0.0001$).

In HIV/HCV-co-infected patients the extent of LS was significantly correlated with alcohol intake ($P < 0.04$) AST level ($P < 0.0001$) and lower CD4+ cells count ($P < 0.02$) and was negatively correlated with platelets ($P < 0.0001$).

BMI, presence of diabetes or IFG, HCV- and HIV-viremia were not significantly correlated with LS in any of the 3 study groups. In addition, there was no significant correlation between the extent of LF under HAART exposure and duration of HAART exposure. There was no significant correlation either between extent of LF and cumulative exposure to each class of antiretroviral drugs (non-nucleoside/nucleoside reverse-transcriptase inhibitors, protease inhibitors) and of specific dideoxynucleoside analogues (didanosine, stavudine, zidovudine).

DISCUSSION

Our results, in agreement with other studies, confirmed that LF is more severe in HIV/HCV co-infected patients than in HCV or HIV mono-infected patients[5,23,24]. In addition, ALF was significantly associated with a lower CD4+cell count in co-infected patients. There is convincing evidence that co-infection with HIV worsens the prognosis of HCV-related liver disease. It has been reported that in patients co-infected with HIV and HCV the risk of progressing to cirrhosis and liver failure is higher than in those infected with only HCV[25,26], especially in individuals with CD4 < 200 cells/μL and alcohol consumption[2].

In our study, 20% of HIV/HCV co-infected patients were under virologically unsuccessful HAART and in 50% CD4+ levels were below 400 cells/mm^3 suggesting, in agreement with former findings, that the less successful the response to HAART, the less marked is its clinical benefit. In fact, immune recovery under HAART has been associated with longer overall survival, slower progression of HCV-related liver damage in HIV co-infected patients and with lengthier survival times before death attributable to liver disease[27]. In the same way, Pineda *et al*[27] demonstrated that liver decompensation emerged earlier in patients who maintained an undetectable HIV viral load for a shorter period during follow-up. Nevertheless, the association between ALF and lower CD4 cell count suggests that the response to HAART, measured using CD4 cell gain and HIV viral load decline, determines the evolution of liver disease and that virologically and immunologically successful HAART may slow progression of LF in HIV/HCV co-infected patients.

On the other hand, antiretroviral-related liver toxicity could have further contributed to liver damage in our HIV population[7]. Mitochondrial toxicity of nucleoside analogues and glucose or lipid abnormalities, particularly common when using some protease inhibitors, may produce or enhance LF progression in HIV-seropositive patients. The correlation between use of antiretroviral drugs and LF in patients with HIV/HCV co-infection has been evaluated in different studies but with contradictory results[21,28-30].

Macías *et al*[21] reported that HAART regimens, including nevirapine, were associated with an increased degree of LF, while the use of protease inhibitor-based HAART was associated with less severe fibrosis and a slower progression of fibrosis in HIV/HCV co-infected patients. In contrast, Berenguer *et al*[28] found that exposure to NNRTI was associated with a reduction in LF progression. In addition, Halfon *et al*[29] showed that exposure to NNRTI was an independent factor in LF while Blanco *et al*[30] highlighted that exposure to dideoxynucleosides was an independent factor associated with ALF.

In our study, no correlation was found between HAART exposure, duration of HAART exposure or cumulative exposure to any class of antiretroviral drugs and LF. In addition, we analyzed the correlation between duration of

exposure to dideoxynucleosides (in particular didanosine, stavudine, zidovudine) and LF but also in this case no correlation was observed, suggesting that these drugs could not play any role in the progression of LF.

ALF was significantly higher in HIV/HCV co-infected patients than in HCV mono-infected patients when the subset of co-infected patients with undetectable HCV-RNA were excluded from the analysis. Overall, HIV/HCV co-infected patients with undetectable HCV-RNA had either no or only mild fibrosis (F0-F1) compared to the remaining co-infected patients, suggesting that the presence of HCV is important in conditioning the progression of LF and that anti-HCV therapy is mandatory in HIV/HCV co-infected patients in order to eradicate the virus. In fact, other authors have reported that achieving HCV clearance may reduce liver-related complications and mortality[31,32] and probably permits at least a partial regression of LF[33]. However, in HIV-positive patients liver cirrhosis may also occur without chronic viral hepatitis, and possible causes of hepatic steatosis in patients with HIV may be due to HIV itself, pathological alcohol use, diabetes mellitus, obesity or antiretroviral medications[34].

Evaluation of LF using the 2 biochemical scores (APRI and FIB-4) was not in full agreement with LS measurement. In fact, these 2 biochemical tests were in agreement with TE values only for high-grade LF, but not in low and moderate LF, suggesting that at least in these cases liver biopsy could be necessary to assess the precise degree of LF. In this respect, we are aware that the lack of liver biopsy, as a reference tool of LF, is a limitation of our study.

More consideration, perhaps, should be given to transaminase levels. In fact, the HCV mono-infected group had the highest levels of transaminases, which may have influenced LS values by increasing them. This result could further support our observation that co-infected patients are at highest risk of LF because of their high AST levels and the immune suppression associated with a low CD4 cell count.

Finally, also in our area, HCV genotype 3 was confirmed to be more associated with HIV-positive patients, because of their habits as drug abusers[35].

In conclusion, in our population, HIV/HCV co-infected patients had more ALF than HCV and HIV mono-infected patients. This result was not correlated with long-term exposure to HAART but with a lower CD4 cell count, suggesting that immunologically successful HAART may protect from progression of liver damage in HIV/HCV co-infected patients. In addition, the detection of unsuspected ALF in HIV mono-infected patients confirms that FibroScan® is very useful in this population. HCV infection, with its different pattern of cytolysis, may condition LS values, but viral eradication is mandatory to reduce fibrosis progression. Finally, the use of these non-invasive parameters of LF should be considered with caution. In fact, from our data it emerges that both TE and the biochemical scores may be suitable only for high grades of LF. In contrast, for mild/moderate degrees of fibrosis, they could not replace liver biopsy in the correct evaluation of LF.

COMMENTS

Background

Liver disease associated with hepatitis C virus (HCV) has emerged as a significant problem in human immunodeficiency virus (HIV) patients, thanks to improved survival in the highly active anti-retroviral therapy (HAART) era. Co-infection with HIV is known to lead to a more rapid progression of HCV liver disease to cirrhosis. Other factors such as severe immune suppression and alcohol consumption accelerate the progression of HCV-related fibrosis. In addition, successful HAART slows the progression of liver fibrosis (LF), but antiretroviral-liver toxicity could contributes to hepatic damage in co-infected patients. The advent of transient elastography (TE) has demonstrated to be very helpful for the non-invasive measurement of LF.

Research frontiers

Percutaneous liver biopsy is the gold standard for assessing LF but it is an invasive technique with risk of morbidity and mortality. For these reasons new non-invasive methods for the assessment of LF have recently been developed. TE (FibroScan®) and biochemical markers have demonstrated to be very helpful in the non-invasive measurement of LF. In this study, using these non-invasive tools, i.e. TE plus 2 biochemical tests, aminotransferase platelet ratio index (APRI) and FIB-4, we showed that advanced LF was significantly higher in HIV/HCV co-infected patients than in mono-infected patients and that it was significantly associated with lower CD4+ cells count. The APRI and FIB-4 tests correlated only with the highest values of TE, i.e. $\geqslant$ 9.5, suggesting that they are useful tools in diagnosing high grade liver disease, but in the case of a low or moderate degrees of LF liver biopsy remains the best means for correctly diagnosing the degree of fibrosis. Furthermore, the results showed that, overall, a greater number of HIV/HCV co-infected patients with undetectable HCV-RNA had either no or mild fibrosis (F0-F1) compared to the remaining co-infected patients with detectable HCV-RNA.

Innovations and breakthroughs

Several studies have been carried out to identify factors related to an accelerated progression of LF in HIV/HCV co-infected patients. Conflicting results have been reported in the literature about the role of antiretroviral therapy on the progression of LF. In the study, information on alcohol intake, duration of HCV infection and cumulative exposure to non-nucleoside and nucleoside reverse-transcriptase inhibitors, protease inhibitors and specific dideoxynucleoside analogues (didanosine, stavudine, zidovudine) was evaluated. The results showed that on univariate analysis liver stiffness (LS) was significantly associated with alcohol intake > 20 g/d in both HCV mono-infected and co-infected patients, but we did not find any correlations between LF and duration of HCV infection, HAART exposure, duration of HAART exposure or cumulative exposure to any class of antiretroviral drugs.

Applications

A good adherence to antiretroviral therapy, when it is indicated, is important to reduce the risk of progression of LF in co-infected patients. In addition, HCV mono- and co-infected patients should modify negative habits and lifestyles, such as alcohol consumption, which could accelerate the progression of LF. Important fields for further study could include the use and evaluation of the applicability of FibroScan® for repeated assessment in the monitoring of LF.

Terminology

Transient elastometry (Fibro-Scan®; EchoSens, Paris, France) is a rapid, reliable and well-tolerated imaging technique for the assessment of LF by measuring LS.

Peer review

The authors aimed to assess the prevalence of advanced LF (ALF) in HIV, HCV and HIV/HCV patients using TE and to identify factors associated with ALF. They concluded that HIV/HCV co-infected patients had ALF more frequently at TE than HCV and HIV mono-infected patients. The title reflects accurately the contents of the article, and the abstract delineates concisely the research.

Abstract

AIM: To investigate variants of immunity-related GTPase family M (IRGM) and NKX2-3 genes and genotype-phenotype in Eastern European patients with inflammatory bowel disease (IBD).

METHODS: We analyzed 1707 Hungarian and Czech subjects with Crohn's disease (CD) (n = 810, age: 37.1 ± 12.6 years, duration: 10.7 ± 8.4 years) and ulcerative colitis (UC) (n = 428, age: 43.7 ± 15.0 years, duration: 12.6 ± 9.9 years), as well as 469 healthy controls. IRGM rs13361189, NKX2-3 rs10883365 and ECM1 rs13294 polymorphisms were tested by LightCycler allele discrimination. Detailed clinical phenotypes were determined by reviewing the medical charts.

RESULTS: NKX2-3 rs10883365 variant allele was associated with increased risk for CD (P = 0.009, OR = 1.24, 95% CI = 1.06-1.48) and UC (P = 0.001, OR = 1.36, 95% CI = 1.13-1.63), whereas variant IRGM allele increased risk for CD (P = 0.029, OR = 1.36, 95% CI = 1.03-1.79). In contrast, ECM1 rs13294 was not associated with either CD or UC. In CD, the variant IRGM allele was associated with a colon-only location (P = 0.02, OR = 1.62, 95% CI = 1.07-2.44), whereas in UC, the ECM1 variant was associated with cutaneous manifestations (P = 0.002, OR = 3.36, 95% CI = 1.48-7.63). Variant alleles did not predict resistance to steroids or azathioprine, efficacy of infliximab, or need for surgery.

CONCLUSION: NKX2-3 and IRGM are susceptibility loci

for IBD in Eastern European patients. Further studies are needed to confirm the reported phenotype-genotype associations.

INTRODUCTION

Inflammatory bowel diseases (IBDs) are multifactorial with both environmental and genetic components; the latter displaying heterogeneity in terms of disease presentation as well as response to treatment[1]. Crohn's disease (CD) has a strong genetic component, and to date, at least nine susceptibility loci have been identified[2]. The first, and most consistently replicated critical mutations have been found in the NOD2/CARD15 gene on chromosome 16 (IBD1). Other loci encode genes that are involved in a number of homeostatic mechanisms: innate pattern recognition receptors (including NOD2/CARD15, TLR4 and CARD9), differentiation of Th17-lymphocytes (IL-23R, JAK2, STAT3, CCR6 and ICOSLG), autophagy [ATG16L1, immunity-related GTPase family M (IRGM) and LRRK2], maintenance of epithelial barrier integrity (IBD5, DLG5, PTGER4, ITLN1, DMBT1 and XBP1), and orchestration of the secondary immune response (HLA-region, TNFSF15/TL1A, IRF5, PTPN2, PTPN22, NKX2-3, IL-12B, IL-18RAP and MST1)[3-6]. As the incidence of IBD is rapidly increasing in some parts of Eastern Europe[1], it is of great importance to study social and environmental, as well as host-genetic factors that might underlie this trend.

The IRGM gene is located on chromosome 5q33.1, and encodes an autophagy-inducing protein and belongs to the immunity-related guanosine triphosphatases (IRGs), also known as p47 guanosine triphosphatases. IRGs play an important role in host defense against intracellular pathogens[7]. Genetic association of the autophagy genes, autophagy-related 16-like 1 (ATG16L1) and IRGM has been suggested in adult-onset CD by genome-wide association scan studies (GWASs), but not in UC[5,6,8-10]. Although a meta-analysis of the three index GWASs has implicated a single nucleotide polymorphism (SNP; rs11747270) based on imputed data with an OR of 1.33[10], other studies including a new meta-analysis[11] have confirmed the IRGM signal on rs13361189 and rs4958847 immediately flanking IRGM.

Recently, the rs13361189 variant, upstream of IRGM, has been shown to be in perfect linkage disequilibrium with a 20-kb deletion polymorphism that affects the expression of IRGM (and cellular autophagy) in a tissue-specific manner[9]. These results suggest that the CD association at IRGM arises from an alteration in IRGM regulation that affects the efficacy of autophagy, and identifies rs13361189 and its strongly correlated neighbors at the 5' end of IRGM, including the 20-kb deletion polymorphism as a likely causal variant.

Association between the rs10883365 variant of NK2 transcription factor related, locus 3 (NKX2-3) gene on chromosome 10q24.2 and susceptibility of CD has been reported in Western Europe, including The Wellcome Trust Case Control Consortium (WTCCC) GWA and a replication study from The Netherlands, and in Japan, with an OR of 1.2-1.6[12-14]. In addition, a modest association ($P = 3.3 \times 10^{-4}$ in the ulcerative colitis panel and $P = 2.4 \times 10^{-6}$ using the expanded WTCCC control panel) has also been reported between rs10883365 and UC in a non-synonymous SNP scan by Fisher *et al*[15]. *NKX2-3*-deficient mice show severe defects in gut development; primarily in the epithelium of the small intestine[16]. In addition, the lymphoid organs of these mice, including the spleen and Peyer's patches, have abnormal tissue architecture and abnormalities in the migration and segregation of B and T cells[17], however, the exact mechanism is unknown.

ECM1, on chromosome 1q21.2, is also a plausible candidate gene for UC; it encodes extracellular matrix protein 1, a glycoprotein expressed in small and large intestine, and it interacts with the basement membrane and inhibits matrix metalloproteinase[18]. Notably, ECM1 strongly activates nuclear factor-κB signaling, a key immune regulator. Expression is upregulated in colorectal cancer and metastases, which implicates ECM1 in epithelial-stromal interaction[18]. Of note, the WTCCC observed modest association between these ECM1 SNPs and ankylosing spondylitis, a related inflammatory disorder ($P = 0.0041$ and 0.0044), respectively[13]. More recently, an association between the rs3737240 and rs13294 variants of ECM1 and UC susceptibility was reported in a GWAS by Fisher *et al*[15], with an OR of 1.3-1.4 for the homozygous carriage of the variant allele. rs3737240 and rs13294 encode substitutions T130M and G290S: Thr130, residing within a collagen IV binding domain, is conserved in primates, whereas Gly290 is not.

Finally, data about the pharmacogenetics of IBD are still limited. Resistance to steroids is associated with high expression of β-glucocorticoid receptors (hGRβ) and overexpression of MDR1 has been found in patients who fail steroid therapy and require surgery[19]. In contrast, according to our group's earlier results, the presence of the DLG5 Arg30Gln variant allele, but not variants in ABCG2 or MDR1 genes, predicted resistance to steroids[20,21]. Vermeire *et al*[22] have reported a lack of association between the

presence of NOD2 mutations and response to infliximab therapy, and later, the same group reported an association between the presence of Fas ligand -843C/T variant and response to infliximab[23].

In light of the lack of data in Eastern European countries, our aim was to investigate the prevalence of IRGM rs13361189, NKX2-3 rs10883365 and ECM1 rs13294 variants in large independent cohorts of Czech and Hungarian IBD patients. We also aimed to investigate a possible association between genotype and clinical phenotype, need for surgery, and response to medical therapy.

MATERIALS AND METHODS

Study population

One thousand seven hundred and seven unrelated IBD patients (CD: n = 810, age: 37.1 ± 12.6 years, duration: 10.7 ± 8.4 years and UC: n = 428, age: 43.7 ± 15.0 years, duration: 12.6 ± 9.9 years) and 469 healthy subjects (blood donors) from Hungary and the Czech Republic were investigated. The clinical data of the CD and UC patients are presented in Table 1. A detailed clinical phenotype was available in 789 CD and 422 UC patients.

The diagnosis was based on the Lennard-Jones criteria[24]. Age; age at onset; presence of extraintestinal manifestations [arthritis: peripheral and axial; ocular manifestations: conjunctivitis, uveitis and iridocyclitis; skin lesions: erythema nodosum and pyoderma gangrenosum; and hepatic manifestations: primary sclerosing cholangitis (PSC)]; frequency of flare-ups (frequent relapses: > 1 clinical relapse/year); therapeutic effectiveness (e.g. steroid and/or immunosuppressive use, steroid resistance); need for surgery (resections); the presence of familial IBD; smoking habits; and in CD, perianal involvement, were investigated by reviewing the medical charts by the physician and completing a questionnaire. The disease phenotype (age at onset, duration, location and behavior) was determined according to the Montreal classification[25].

The control group for mutation analysis consisted of 469 age- and sex-matched healthy blood donors (male/female: 251/218, age: 40.5 ± 11.5 years old). Control subjects did not have any gastrointestinal and/or liver diseases and were selected from consecutive blood donors in Budapest, Veszprem, Debrecen and Prague. The study protocol was approved by the Ethical and Science Committee of the Ministry of Health. Each patient was informed of the nature of the study and gave signed informed consent.

Genotyping and DNA isolation

Genomic DNA was isolated from whole blood according to the manufacturers' description with High Pure PCR Template preparation Kit (Roche, Budaors, Hungary).

Detection of IRGM (rs13361189,g.11386323T>C), ECM1 (rs13294, c.1243A>G, p.Ser415Gly, g.975342G>A) and NKX2-3 (rs1083365, g.20036290G>A) polymorphisms

Genotyping was performed using the LightCycler (Roche Diagnostics, Basel, Switzerland) allelic discrimination system. Amplification primers and hybridization probes were designed by the LightCycler Probe Design software (Roche Diagnostics). All oligonucleotides were synthesized by VBC Biotech (Vienna, Austria). The following amplification primers and hybridization probes were used for genotyping IRGM: IRGM-LCF: 5'-ATGGACAGTCAGTACCCTGCAC-3', IRGM-LCR: 5'-CTCTTTACCATTGTACTCCTTGTGCC-3', IRGM-ANC: 5'-LC Red 640-TGCTCAGCGGGTACAGTTTAGAAAGGGAA-Phosphate-3', IRGM-SENS: 5'-GAAAATCGGATGTATATTAGTAGACCC-Fluorescein-3'.

The amplification primers and hybridization probes used for genotyping of ECM1 were: ECM1-LCF: 5'-ACCCACCACCACTTGTGT-3', ECM1-LCR: 5'-TGCTTGGTGAGAACTCTTTGGTTT-3', ECM1-ANC: 5'-LC Red 640-TCAAGATGTCCCGGTCATAGTTGGGGTAAGGAG-Phosphate-3', ECM1-SENS: 5'-TGACTCGACCGATGTCAAT-Fluorescein-3'.

The amplification primers and hybridization probes used for genotyping of NKX2-3 were: NKX2-LCF:

[1]Clinical phenotype available in 789 Crohn's disease (CD) and 422 ulcerative colitis (UC) patients; [2]Available in 691 CD and 388 UC patients. L1: Ileal; L2: Colon; L3: Ileocolonic; L4: Upper gastrointestinal; B1: Inflammatory; B2: Stenosing; B3: Penetrating. IBD: Inflammatory bowel disease; TNF: Tumor necrosis factor.

5'-CCGCATAAGACGTTACTTAAACATGT-3', NKX2-LCR: 5'-GCTATCTACTCGAAACTGTCT-GC-3', NKX2-ANC-2: 5'-TCTCCCCGGGGGTCAC-GTTG-Fluorescein-3', NKX2-SENS-2: 5'-LC Red 610-ACAAACACCTTCAAACCGTC-Phosphate-3'.

Polymerase chain reaction (PCR) was performed by LightCycler 480 real-time PCR System (Roche), in a reaction volume of 20 μL with 50 ng genomic DNA, 10 μL 2 × PCR Master Mix (Promega), and 5 pmol of the respective labeled oligonucleotides (sensor and anchor). For IRGM and NKX2-3, an asymmetric multiplex system was used for simultaneous amplification of the two fragments with 3:10 pmol forward:reverse (F:R) amplification oligonucleotides and 10:3 F:R amounts for IRGM and NKX2-3 SNPs, respectively. Similarly, for ECM1, an asymmetric PCR was applied with a 10:3 pmol F:R primer mix for amplification in a separate reaction. Cycling conditions were as follows: initial denaturation at 95℃ for 3 min, followed by 35 cycles of denaturation at 95℃ for 20 s, annealing at 55℃ for 30 s, and extension at 72℃ for 45 s, with a ramping rate of 4.4℃/s.

After amplification, a melting curve analysis was performed by cooling the samples to 40℃, followed by gradual heating to 80℃ with a ramp rate of 0.04℃/s. The decline in fluorescence was continuously monitored. Melting curves were converted to melting peaks with wild-type and variant alleles showing distinct melting points. For the IRGM and NKX2-3 multiplex PCR, color compensation was performed to compensate for the fluorescence crosstalk between detection channels. Genotype calling was carried out by two independent investigators.

Statistical methods

Variables were tested for normality using Shapiro Wilk's *W* test. A *t* test with separate variance estimates, χ^2 test and χ^2 test with Yates correction were used to evaluate differences between IBD patients and controls, as well as within subgroups of IBD patients. Logistic regression was used to compare genetic and clinical data and results are expressed as OR with 95% CI. $P < 0.05$ was considered as significant. For the statistical analysis, SPSS version 15.0 (SPSS Inc., Chicago, IL, USA) was used. Statistical analysis was performed by Lakatos PL with the assistance of a statistician.

RESULTS

Association between NKX2-3, IRGM and ECM1 and disease susceptibility

All investigated polymorphisms were in Hardy-Weinberg equilibrium (P = 0.38-0.95). The success rate of the genotyping assays was 98%-99%. The genotype and allele frequencies are presented in Table 2. NKX2-3 rs10883365 variant allele was associated with increased risk for CD (P = 0.018 after Bonferroni correction, OR = 1.24, 95% CI = 1.06-1.48) and UC (P = 0.003 after Bonferroni correction, OR = 1.36, 95% CI = 1.13-1.63), whereas the variant IRGM allele increased the risk of CD (P = 0.04 after Bonferroni correction, OR = 1.36, 95% CI = 1.03-1.79). The association between NKX2-3 rs10883365 variant and IBD was also significant in the genotypic and dominant models. A similar trend was noted between IRGM and CD. In contrast, ECM1 rs13294 was not associated with either CD or UC. The combination of IRGM carrier/NKX2-3 homozygote genotype was significantly higher in CD compared to the controls (7.2% *vs* 2.1%, $P < 0.0001$ after Bonferroni correction, OR = 3.55, 95% CI = 1.80-7.01).

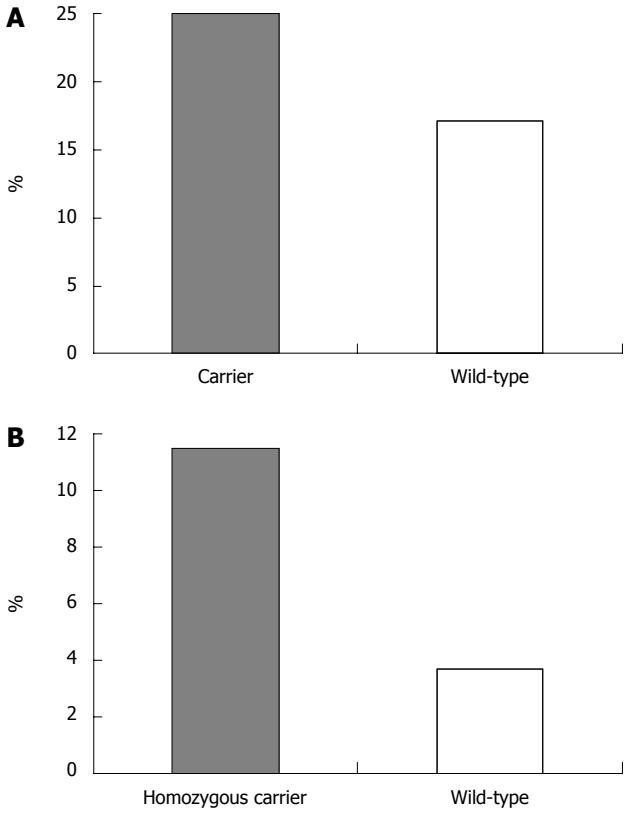

Figure 1 Association between immunity-related GTPase family, M and ECM1 and disease phenotype in patients with inflammatory bowel diseases. A: Association between the IRGM rs13361189 variant and disease location in Crohn's disease. P = 0.04, OR = 1.62, 95% CI: 1.07-2.44; B: Association between homozygous carriage of the ECM1 rs13294 variant allele and cutaneous manifestations in ulcerative colitis. P = 0.004, OR = 3.36, 95% CI: 1.48-7.63.

Role of NKX2-3, IRGM and ECM1 variants in predicting sex, familial disease, age at onset, disease location, phenotype or extraintestinal manifestations

In CD, presence of the variant IRGM allele was associated with colon-only location (in carriers: 25% *vs* wild-type: 17.1%, P = 0.04 after Bonferroni correction, OR = 1.62, 95% CI = 1.07-2.44, Figure 1A). In UC, homozygous carriage of the ECM1 variant allele was associated with cutaneous manifestations (11.5% in homozygotes *vs* 3.7% in patients with other genotypes, P = 0.004 after Bonferroni correction, OR = 3.36, 95% CI = 1.48-7.63, Figure 1B). No other significant associations were found in either CD or UC patients (data not shown).

Association between NKX2-3, IRGM and ECM1 and response to medical therapy or need for surgery

We also investigated the association between the NKX2-3, IRGM and ECM1 variants and the response to steroids,

[1]*P* value *vs* controls; [2]*P* value Crohn's disease (CD) *vs* ulcerative colitis (UC). WT: Wild-type; HET: Heterozygous carrier; HOM: Homozygous carrier; MAF: Minor allele frequency; NS: Not significant.

infliximab or azathioprine or the need for surgery in patients with CD. Two hundred and sixty-three unrelated CD patients were treated with anti-tumor necrosis factor (TNF): 259 received infliximab and four, adalimumab, two of whom were treated after secondary loss of response to infliximab therapy. Overall, there was no association between the presence of the above variants and short-term response (assessed at week 12) to infliximab induction therapy [5 mg/kg at weeks 0, 2 and 6; partial response: Crohn's disease activity index (CDAI) decreased by $\geqslant$ 70 points and/or $\geqslant$ 50% decrease in the number of draining fistulas; remission: CDAI < 150 or closure of all fistulas]; steroid use/resistance; azathioprine use; or need for surgery (data not shown). Similarly, no association was found between either of the variants and steroid use/resistance, azathioprine use or need for surgery in patients with UC (data not shown).

DISCUSSION

This is the first report on the prevalence of the IRGM rs13361189, NKX2-3 rs10883365 and ECM1 rs13294 variants, in large, independent IBD cohorts from Eastern Europe. The variant NKX2-3 allele conferred a risk in both UC and CD, whereas the IRGM rs13361189 variant allele was associated with increased risk for CD. In addition, the IRGM variant was associated with disease location in CD.

The genotype and allele frequencies for IRGM and NKX2-3 variants in CD, UC and controls reported in the present study were in line with most previous reports in Caucasian populations, whereas the frequency of the variant ECM1 rs13294 allele was approximately 10% higher in both IBD and controls, compared to that reported in previous studies[7,8,12,13,15,26].

We confirmed that the IRGM rs13361189 variant was associated with disease susceptibility in CD in Eastern European populations. The allelic OR of 1.36 (95% CI = 1.03-1.79) was in the range reported in Caucasian populations (OR = 1.38-1.56)[7,13] and in a recent meta-analysis (OR = 1.34)[10]. Similar genotype distributions were observed in both the Czech and Hungarian cohort, however, due to the low variant allele frequency, the difference became significant only in the combined analysis. A similar tendency (P = 0.06) was observed in the genotypic and dominant model. In contrast, in the present study we failed to replicate the weak association between IRGM and UC (rs13361189 P = 0.0069, pooled OR = 1.16; rs4958847 P = 0.014, pooled OR = 1.13) that was reported recently in a Spanish meta-analysis[10]. Of note, the present study was underpowered to detect such small

differences, however, there was even no trend for a difference between UC and controls.

In addition, in an Italian study[27], the rs4958847 polymorphism was associated with fistulizing behavior (P = 0.037, OR = 1.54, CI = 1.02-2.31) and perianal fistulas (P = 0.045, OR = 1.55, CI = 1.01-2.38) in a logistic regression analysis. This was later partially confirmed by the Leuven group. Henckaerts *et al*[28] have reported in a very elegant study a significant association between the IRGM rs4958847 variant, U7 gene desert rs12704036 T-allele, NOD2/CAR15 mutation, ileal involvement at diagnosis, male sex, and time to development of non-perianal fistulas in a Cox regression analysis. In a further study from New Zealand[29], rs13361189 variant increased the risk for ileal CD in 507 CD patients and 576 controls. The OR in ileal CD was 1.92 (95% CI = 1.27-2.96). Moreover, Peterson *et al*[30] have suggested an association between IRGM and pediatric disease onset (< 17 years) of CD in a North American cohort. However, only one of the two IRGM variants studied (rs13361189) was weakly associated with CD in their study (uncorrected P = 0.03). In the present study, we could not confirm the association between age at onset and the presence of the IRGM variant, in accordance with Canadian, Italian and Scottish results[29,31]. In contrast, we found an association between IRGM carriage and disease location in CD; colonic location was significantly more common in carriers of the variant allele (OR = 1.62, 95% CI = 1.07-2.44). Of note, however, the rs4958847 variant was not investigated in the present study.

The association between the rs10883365 variant of NKX2-3 gene and susceptibility of IBD was first reported in CD in Caucasian patients and in a Japanese study with an OR of 1.2-1.6[12-14]. In addition, using the UC panel and the expanded WTCCC control panel, Fisher *et al*[15] have reported a modest association ($P = 3.3 \times 10^{-4}$ and $P = 2.4 \times 10^{-6}$) between rs10883365 and UC. In the present study, we confirmed these findings; the rs10883365 variant was associated with UC and CD susceptibility in the allelic and genotypic models with an OR of 1.53 and 1.24, respectively. Based on our data, the association between NKX2-3 and IBD is stronger in UC compared to CD, at least in patients from Eastern Europe. In a recent Dutch study, the association between the rs10883365 variant of NKX2-3 and CD was linked to smoking status, with the risk being more pronounced in active and passive smokers[32]. In the present study, however, we did not find an association between NKX2-3 and smoking status, and similarly, no genotype-phenotype associations were found.

In addition, Weersma *et al*[13] have created genetic risk profiles by combining the presence of variant alleles in IL23R, ATG16L1, IRGM, NKX2-3, 1q24, 5p13, HERC2, CCNY, 10q21 and NOD2/CARD15, and the number of risk alleles was associated with gradually increased risk for CD. Similarly, in the present study, the combination of IRGM carrier/NKX2-3 homozygote genotype was associated with an increased risk for CD, with a much higher OR compared to either of the variant alleles alone.

Recently, an association between ECM1 rs3737240 and rs13294 variants and UC has been reported in a GWAS by Fisher *et al*[15], with an OR of 1.3-1.4 for the homozygous carriage of the variant allele. The association for the rs13294 variant has recently been confirmed in a Dutch study, with an OR of 1.24 in patients with UC[33]. In contrast, no association was found in CD[34], even though a different SNP (rs11205387) was investigated. Although the present study was powered to confirm a difference with an OR of 1.3-1.5 with adequate statistical power, we could not confirm an association between the ECM1 rs13294 variant and either UC or CD. The accidental association between homozygous carriage of the ECM1 variant allele and cutaneous manifestations (P = 0.002, OR = 3.36, 95% CI = 1.48-7.63, Figure 1B) requires further confirmation.

Theoretically, through influencing inflammatory responses, autophagy and epithelial-stromal interactions, polymorphisms in the above genes might be of potential importance in altering the efficacy of anti-inflammatory therapy and thereby the need for surgery. However, in the present study, none of the variant alleles was associated with the response to either steroid or infliximab therapy, or the need for surgery (resection in CD or colectomy in UC) in IBD.

In conclusion, NKX2-3 and IRGM are susceptibility loci for IBD in Eastern European patients. None of the variants investigated were associated with the need for surgery or efficacy of medical therapy. Further studies are needed to confirm the reported phenotype-genotype associations found in this study.

COMMENTS

Background

Sequence variants in the autophagy gene immunity-related GTPase family M (IRGM) and NKX2-3 have been reported to contribute to Crohn's disease (CD) susceptibility, whereas ECM1 contributes to ulcerative colitis (UC) in genome-wide association scans in North America and Western Europe.

Research frontiers

There is a lack of data in Eastern European countries, therefore, our aim was to investigate the prevalence of IRGM rs13361189, NKX2-3 rs10883365 and ECM1 rs13294 variants. In addition, the possible association between genotype and clinical phenotype and the need for surgery is conflictive, and the association between the above genetic variants and response to medical therapy was not investigated.

Innovations and breakthroughs

In the present study, the authors showed in two well-characterized, independent

CD cohorts with strict clinical follow-up, that NKX2-3 rs10883365 variant allele was associated with increased susceptibility to CD and UC, whereas variant IRGM allele increased the risk for CD only. Our data suggest that the variant IRGM allele is associated with colon-only location, whereas in UC, the ECM1 variant was associated with cutaneous manifestations. None of the variants predicted resistance to steroids and azathioprine, efficacy of infliximab, or need for surgery.

Application

The new data presented from Eastern Europe might contribute to better understanding of genetic or environmental differences between populations and the association of those differences with disease susceptibility and phenotype.

Terminology

Vienna-Montreal classification: classification systems of disease phenotypes in CD. The classification assesses the age at presentation, disease location and disease behavior. The IRGM gene encodes an autophagy-inducing protein and plays an important role in host defense against intracellular pathogens. NKX2-3 is a member of the NKX family of homeodomain-containing transcription factors, which are implicated in many aspects of cell type specification and maintenance of differentiated tissue functions. ECM1 encodes extracellular matrix protein 1, a glycoprotein expressed in small and large intestine. Notably, ECM1 strongly activates nuclear-κB signaling, a key immune regulator.

Peer review

The need to extend studies performed in the other parts of the world to Eastern Europe is valid, and provides a point for understanding subtle genetic or environmental differences between populations and the association of those differences with disease.

Abstract

AIM: To clarify the clinical significance of high serum IgE in autoimmune pancreatitis (AIP).

METHODS: Forty-two AIP patients, whose IgE was measured before steroid treatment, were analyzed. To evaluate the relationship between IgE levels and the disease activity of AIP, we examined (1) Frequency of high IgE (> 170 IU/mL) and concomitant allergic diseases requiring treatment; (2) Correlations between IgG, IgG4, and IgE; (3) Relationship between the presence of extrapancreatic lesions and IgE; (4) Relationship between clinical relapse and IgE in patients treated with steroids, and (5) Transition of IgE before and after steroid treatment.

RESULTS: IgE was elevated in 36/42 (86%) patients. Concomitant allergic disease was observed in seven patients (allergic rhinitis in three, bronchial asthma in three, and urticaria in one). There were no significant correlations between IgG, IgG4, and IgE (r = -0.168 for IgG, and r = -0.188 for IgG4). There was no significant difference in IgE in the patients with and without extrapancreatic lesions (526 ± 531 IU/mL *vs* 819 ± 768 IU/mL, P = 0.163), with and without clinical relapse (457 ± 346 IU/mL *vs* 784 ± 786 IU/mL, P = 0.374). There was no significant difference in IgE between before and after steroid treatment (723 ± 744 IU/mL *vs* 673 ± 660 IU/mL, P = 0.633).

CONCLUSION: Although IgE does not necessarily reflect the disease activity, IgE might be useful for the diagnosis of AIP in an inactive stage.

Key words: IgE; IgG4; IgG; Autoimmune pancreatitis

INTRODUCTION

Autoimmune pancreatitis (AIP) is a unique, benign pan-

creatic disease characterized by irregular narrowing of the pancreatic duct, swelling of the pancreas, lymphoplasmacytic infiltration and fibrosis, and favorable response to steroid therapy[1-8]. Serologically, elevation of IgG and IgG4 is the most remarkable characteristic in this disease[9-12]. A recent study showed that IgM and IgA were decreased in AIP[13]. There has been no detailed clinical analysis of IgE, although some clinicians have noted elevated serum IgE in AIP or IgG4-related diseases[14-17].

In most allergic diseases, total serum IgE levels do not reflect disease activity; however, in allergic bronchopulmonary aspergillosis, it is reported that IgE is a useful marker for therapeutic monitoring[18-21]. The expression of T-helper type 2 (Th2) cytokines [interleukin (IL)-4, IL-5, and IL-13] are upregulated in the affected tissues of AIP[22]. Both IgG4 and IgE production are dependent on help by Th2; therefore, all IgG4-inducing antigens are also efficient IgE inducers[23]. As IgG4 reflects the disease activity of AIP[12], it is reasonable to expect that IgE is also related to the disease activity of AIP and could become a clinically useful marker. Thus, we decided to clarify whether IgE is related to the disease activity of AIP from various viewpoints.

MATERIALS AND METHODS

Patients

Between 1997 and 2009, 67 patients were diagnosed as having AIP at the University of Tokyo hospital and affiliated hospitals. All the patients fulfilled the diagnostic criteria of AIP proposed by the Mayo Clinic[3] or the revised criteria by the Japan Pancreas Society[4]. Serum IgE was measured in 48 patients before steroid treatment. As the method of measurement was different in six patients, these patients were excluded. Thus, 42 patients whose IgE level was measured by the same method before steroid treatment were enrolled in this study. Of the 42 patients, 33 were men and nine were women. The mean age of onset was 65 years old. Thirty-seven patients received steroid treatment. Prednisolone at an initial dose of 30-40 mg/d was administered for 2-4 wk in most cases. It was then tapered by 5 mg every 2-6 wk until 10 mg/d, and 2.5-7.5 mg/d was continued as maintenance therapy in principle.

This retrospective study was approved by the review board of our institute.

Methods

Serum IgE was measured by fluorescence enzyme immunoassay. To evaluate the relationship between IgE levels and disease activity, we examined (1) frequency of high IgE (> 170 IU/mL) and concomitant allergic diseases requiring treatment; (2) correlations among IgG, IgG4, and IgE; (3) relationship between the presence of extrapancreatic lesions and IgE; (4) relationship between clinical relapse and IgE in patients treated with steroids; and (5) transition of IgE before and after steroid treatment.

With regard to allergic diseases, only diseases that required treatment during follow-up were counted. There are many extrapancreatic lesions in AIP; however, in this study, only representative and definite lesions, including sclerosing cholangitis[7,8,24], retroperitoneal fibrosis[8,25], sclerosing sialadenitis[17], interstitial pneumonia[26], and tubulointerstitial nephritis[27] were counted. With regard to the number of extrapancreatic lesions, we used the number of extrapancreatic lesions that were observed when IgE was measured. We do not regard intrapancreatic biliary stricture as an extrapancreatic lesion, because it is influenced by pancreatic edema[24]. We defined "clinical relapse" as AIP-related symptomatic unfavorable events; i.e. obstructive jaundice from distal bile duct stenosis due to exacerbated pancreatitis with pancreatic swelling, increased levels of biliary enzymes caused by sclerosing cholangitis (in which extrapancreatic biliary strictures were confirmed on imaging findings), retroperitoneal fibrosis, interstitial pneumonia, and interstitial nephritis (for which simple observation seemed very inadequate and remission induction therapy was introduced). Concerning clinical relapses and IgE, we analyzed patients whose follow-up after the initiation of steroid treatment was more than 6 mo. With regard to the transition of IgE, IgE measured before steroid treatment and during maintenance steroid treatment (2.5-7.5 mg prednisolone/d) were compared.

Statistical analysis

Categorical variables were compared by the χ^2 or Fisher exact test, where appropriate. Continuous variables were reported as mean ± SD and compared by the Student *t* test, Welch *t* test, or paired *t* test, where appropriate. A *P* value of < 0.05 was considered statistically significant. Statistical analyses were performed by the statistical software JMP 7.0.1 (SAS Institute Inc., Cary, NC, USA).

RESULTS

Frequency of high IgE and concomitant allergic diseases

The clinical profiles of 42 patients with AIP are summarized in Table 1. Serum IgE was elevated in 36/42 (86%). The average value of IgE was 679 ± 675 IU/mL (range, 67-3000 IU/mL). No patient had concomitant parasitosis. Concomitant allergic diseases were observed in seven patients, comprising allergic rhinitis in three, bronchial asthma in three, and urticaria in one. There was no significant difference between the average IgE values of these seven patients and those of the other 35 patients (970 ± 775 IU/mL *vs* 621 ± 650 IU/mL, $P = 0.216$). The frequency of high IgE was 100% (7/7) in these patients, and 63% (29/35) in the others; however, this difference was not statistically significant ($P = 0.567$).

Correlations between IgG, IgG4, and IgE

The values of IgG and IgG4, which were measured at the same time as IgE before steroid treatment, were used in this analysis. Elevation of IgG and IgG4 were observed in 20 (47%) and 39 (93%) patients, respectively. The correlation coefficient of IgG and IgE was -0.168 (not significant, $P = 0.290$). The correlation coefficient of IgG4 and IgE was -0.188 (not significant, $P = 0.235$). The correla-

AIP: Autoimune pancreatitis; AR: Allergic rhinitis; BA: Bronchial asthma; SA: Sialadenitis; RF: Retroperitoneal fibrosis; SC: Sclerosing cholangitis.

Table 2 Correlations between IgG, IgG4, and IgE

	Correlation coefficient	*P* value
IgG and IgE	-0.168	0.290
IgG4 and IgE	-0.188	0.235
IgG and IgG4	0.698	< 0.0001

tion coefficient of IgG and IgG4 was 0.698, which was significant ($P < 0.0001$) (Table 2).

Relationship between the presence of extrapancreatic lesions and IgE

Extrapancreatic lesions were observed in 20 patients (48%). Two patients had two lesions, and 18 patients had one lesion. Sclerosing cholangitis, retroperitoneal fibrosis, and sclerosing sialadenitis, were observed in nine, seven, and six patients, respectively. The IgE levels of the patients with and without extrapancreatic lesions were compared, and the same analysis was performed for IgG and IgG4. The results are shown in Table 3. IgG tended to be related to the presence of extrapancreatic lesions, although statistical significance was not attained ($P = 0.093$). No such tendency existed for IgE.

Table 3 Comparison of IgE, IgG, and IgG4 between patients with and without extrapancreatic lesions

	Patients with extrapancreatic lesions (n = 20)	Patients without extrapancreatic lesions (n = 22)	*P* value
IgE (IU/mL)	526 ± 531	819 ± 768	0.163
IgG (mg/dL)	2065 ± 644	1775 ± 396	0.093
IgG4 (mg/dL)	588 ± 505	392 ± 161	0.110

Table 4 Comparison of IgE, IgG, and IgG4 between patients with and without clinical relapses

	Patients with clinical relapses (n = 5)	Patients without clinical relapses (n = 28)	P value
IgE (IU/mL)	457 ± 346	784 ± 786	0.374
IgG (mg/dL)	1898 ± 424	1915 ± 579	0.953
IgG4 (mg/dL)	266 ± 157	558 ± 429	0.148

Table 5 Transition of IgE, IgG, and IgG4 before and after steroid treatment

	Before	After	P value
IgE (IU/mL) (n = 29)	723 ± 744	673 ± 660	0.633
Proportion of high IgE	26/29	23/29	0.470
IgG (mg/dL) (n = 30)	1891 ± 566	1155 ± 315	< 0.0001
Proportion of high IgG	14/30	1/30	0.0002
IgG4 (mg/dL) (n = 28)	557 ± 429	229 ± 112	0.0002
Proportion of high IgG4	27/28	20/28	0.0248

Normal range, IgE: < 171 IU/mL, IgG: 870-1800 mg/dL, IgG: < 135 mg/dL.

Relationship between clinical relapse and IgE in the patients treated with steroids

There were 33 patients whose follow-up period was more than 6 mo. The mean follow-up period was 52 mo (range, 8-141 mo). Clinical relapse was observed in five patients. The style of clinical relapse was pancreatitis in two, interstitial pneumonia in two, and sclerosing cholangitis in one. Their relapses occurred 16 mo after the initiation of steroid therapy on average (range, 3-26 mo). The mean follow-up period was the same between the patients with and without clinical relapse (53.0 mo *vs* 51.8 mo, $P = 0.929$). IgE levels of the patients with and without clinical relapse were compared, and the same analysis was performed for IgG and IgG4. The results are shown in Table 4. Neither IgE, IgG nor IgG4, were related to later clinical relapses.

Transition of IgE before and after steroid treatment

IgE measured before steroid treatment and during maintenance therapy could be compared in 29 patients (Figure 1). IgE increased in 10, and decreased in 18. There was no significant difference in IgE between before and after steroid treatment (723 ± 744 IU/mL *vs* 673 ± 660 IU/mL, $P = 0.633$). Abnormally high IgE (> 170 IU/mL) was observed in 90% (26/29) before steroid treatment, and in 79% (23/29) after steroid treatment ($P = 0.470$). By contrast, IgG and IgG4 did show significant differences before and after steroid treatment (Table 5).

DISCUSSION

High IgE in AIP has been frequently documented[14-17], but its frequency and clinical significance were unknown. Kamisawa *et al*[14] reported that elevation of IgE was observed in 34% (12/35) of patients, and that all the patients with high IgE had present and/or past histories of allergic diseases, although none of the patients with normal IgE had such histories. In the present study, the

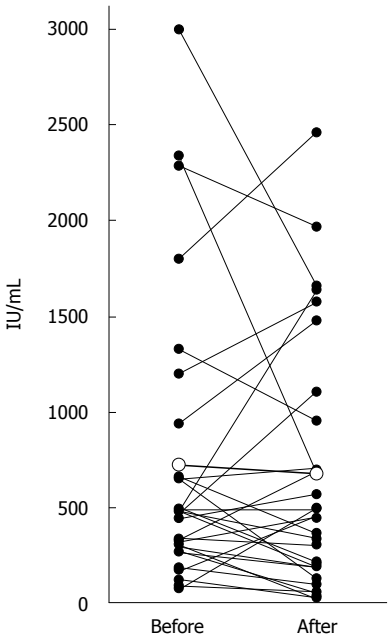

Figure 1 IgE levels measured before steroid treatment (Before) and during maintenance therapy (After) were compared in 29 patients. White circles show average values.

frequency of high IgE was surprisingly high at 86% (36/42), which might be equal to frequency of high IgG4 (73.3%-94.3%)[12]. On the other hand, unlike the previous report, there seemed no definite relationship between IgE and allergic diseases. It seemed unreasonable to count allergic diseases that occurred decades ago. In addition, it is difficult to accurately judge past histories of mild allergic diseases. Thus, we included only concomitant allergic diseases. For reference, there were at least eight patients who had past histories of allergic diseases, but no concomitant ones. Comparison between patients with (n = 15) and without (n = 27) present and/or past histories of allergic diseases showed no significant difference in mean IgE values (654 ± 605 IU/mL *vs* 693 ± 721 IU/mL, $P = 0.860$) and frequency of high IgE (93% *vs* 81%, $P = 0.395$); therefore, the presence of past allergic disease did not affect the results.

From the results shown in Table 3, IgE levels appear to be unrelated to disease activity from the viewpoint of extrapancreatic lesions. On the contrary, it is possible that high IgE is associated with lower disease activity, when considering the higher IgE levels in the group without extrapancreatic lesions, and the negative correlation coefficient of IgG (IgG4) and IgE. It is difficult to analyze the results shown in Table 4 because of the small number of patients with clinical relapses. Nevertheless, it is likely that high IgE is not a risk factor for later clinical relapses, especially considering the higher IgE levels in the group without clinical relapses. IgG4 seems a little high in the group without clinical relapses (Table 4), which is similar to previous reports[8,28].

It was of great interest whether IgE could become a useful marker for therapeutic monitoring in AIP, like IgG and IgG4. From the results shown in Table 5, we

cannot help but conclude that IgE is not a useful marker. However, this phenomenon is not strange in other allergic diseases. For example, Gunnar *et al*[18] reported that steroid treatment did not alter IgE levels in patients with atopic dermatitis. Kumar *et al*[19] showed that changes in serum IgE are not related to severity of asthma or allergic rhinitis. Exceptionally, in allergic bronchopulmonary aspergillosis, it is reported that the response of IgE (35% or more reduction) to steroid treatment is a sensitive marker in the management[20].

Although IgE does not seem to reflect disease activity, we speculate that this feature might be useful for the diagnosis of inactive AIP. Indeed, three patients in the present series showed low IgG4 (65, 98, and 133 mg/dL) at the diagnosis, but all of them showed high IgE (1000, 2339 and 480 IU/mL). When patients with a past history suggestive of AIP, such as voluntarily improved jaundice, do not show high IgG and IgG4, IgE should be measured. If IgE is also low, the possibility that their diagnosis is AIP will be low. If IgE is high, it might indicate AIP in an inactive stage.

In summary, the elevation of serum IgE is very frequent in AIP. It is also observed even in patients without other allergic diseases. IgE might not reflect the disease activity; however, it might be useful for the diagnosis of AIP in an inactive stage.

COMMENTS

Background

It is known that elevation of serum IgE is frequently observed in autoimmune pancreatitis (AIP). However, its clinical significance has not yet been clarified.

Research frontiers

This study demonstrated the frequency of high IgE in AIP, and investigated whether IgE is related to the presence of extrapancreatic lesions and later clinical relapses. In addition, the transition of IgE before and after steroid treatment was investigated to confirm whether IgE can become a marker for therapeutic monitoring.

Innovations and breakthroughs

This study confirmed the high frequency of elevated serum IgE in AIP, although IgE does not seem to be related to the disease activity.

Applications

Measuring IgE might be useful for the diagnosis of AIP especially in an inactive stage.

Peer review

These data about IgE were not positive, which means that IgE is not considered as a useful marker for AIP. However, the author revealed that many (86%) AIP patients have IgE elevation and some AIP patients with low IgG4 have a high level of IgE. IgE should be considered as one of the supportive parameters for diagnosis of AIP and the authors succeeded in clarifying that.

Abstract

AIM: To describe a new surgical technique and evaluate the early results of segmental gastrectomy (SG) with modified D2 lymph node (LN) dissection for early gastric cancer (EGC).

METHODS: Fourteen patients with EGC underwent SG with modified D2 dissection from 2006 to 2008. Their operative results and postoperative courses were compared with those of 17 patients who had distal gastrectomy (DG) for EGC during the same period.

RESULTS: Operating time, blood loss, and hospital stay were similar between the 2 groups. Postoperative complications developed significantly more frequently in the DG group than in the SG group. Mean number of dissected LNs per each station in the SG group was comparable with that in the DG group. Postoperative recovery of body weight was significantly better in the SG group than in the DG group. The incidence of reflux esophagitis and gastritis after surgery was less frequent in the SG group than in the DG group.

CONCLUSION: SG with modified D2 LN dissection may be a new function-preserving gastrectomy that is feasible for treatment of EGC with possible LN involvement.

Key words: Gastrectomy; Early diagnosis; Gastric cancer; Lymph node; Metastasis; Gastrointestinal surgical procedures

INTRODUCTION

Less invasive surgery for early gastric cancer (EGC) has been more commonly employed in Japan[1-4]. Segmental gastrectomy (SG), which was originally applied for peptic ulcers, is one type of limited gastrectomy available for treating EGC[5]. SG for EGC is generally accompanied only by dissection of the lymph nodes (LNs) adjacent to tumors, although only a few studies regarding the application of SG in EGC have been reported[1-4]. To establish SG with adjacent LN dissection as a valid option for surgical treatment of EGC, it is necessary to demonstrate intraoperatively that there is no lymph node metastasis (N0). However, at present, it is difficult to determine the status of LN metastasis intraoperatively, even using the sentinel node (SN) navigation method[6-8].

The superiority of limited gastrectomy over conven-

tional D2 gastrectomy for EGC in terms of postoperative quality of life seems apparent, as previously reported[1,4,9,10]. In 1995, Sawai *et al*[11] developed pylorus-preserving gastrectomy (PPG) with D2 dissection by preservation of the infrapyloric artery as a function-preserving gastrectomy. Although this technique is considered to be applicable to submucosal or undifferentiated gastric cancer, there remains a risk of adverse events such as postoperative gastric stasis and reduced capacity of the remnant stomach.

We developed SG with modified D2 dissection and have applied it to EGC that do not meet endoscopic treatment criteria. We report the technique here and evaluate the early results of SG with modified D2 dissection for EGC.

MATERIALS AND METHODS

Between April 2006 and November 2008, 35 patients with EGC in the middle or lower third of the stomach which did not meet endoscopic treatment criteria underwent gastrectomy at our institution: 17 patients who underwent SG and 18 patients who underwent conventional distal gastrectomy (DG) with D2 dissection. The criteria for endoscopic treatment is EGC with differentiated histology, invasion limited to the mucosal layer, a diameter smaller than 2 cm, and no ulcer findings. In this study, SG was distinguished from PPG by defining that the remaining pyloric cuff needed to be more than 4 cm in SG. When the distance from the distal edge of the resection to the pylorus was < 4 cm, DG was performed instead of PPG.

A total of 14 patients received SG with modified D2 dissection. The remaining 3 patients who were excluded from this study received SG only with adjacent LN dissection because of intraoperative determination of apparent mucosal cancer with no LN metastasis.

In 3 out of 18 patients in the DG group, SG was converted to DG based on intraoperative findings including suspected T2 tumor or positive LN metastasis.

Patients were followed every 3 mo after surgery. The follow-ups also included an endoscopy and computed tomography 1 year after surgery. The operative and postoperative results were compared between the SG and DG groups.

Operative procedures

To make it possible to locate the tumor intraoperatively, proximal and distal margins of the tumor were marked by endoscopic clipping before surgery. After laparotomy, we explored the abdominal cavity and determined if the preoperative diagnosis was correct. If a T2 or T3 tumor was suspected or LN metastases were apparent, DG or total gastrectomy (TG) with D2 dissection was performed. Swollen and/or hard palpable LNs located adjacent to the tumor were excised and immediately examined by frozen section analysis. Infrapyloric LNs (station 6) and those along the common hepatic artery (CHA; station 8a) were also routinely subjected to frozen section analysis. DG or TG with D2 dissection was performed if LN metastasis was proved by frozen section analysis, however, if T1N0 was confirmed SG with modified D2 dissection was carried out.

The resection line of the stomach was made 2 cm and 5 cm away from the tumor margin with differentiated and undifferentiated histology, respectively. The greater omentum was preserved, and the gastrocolic ligament corresponding to the resection area of the stomach was dissected, after separation, at least 3 cm away from the gastroepiploic vessels. For dissection of LNs located in station 6 and along the greater curvature (station 4d), right gastroepiploic vessels were skeletonized, allowing excision of adjacent LNs, and divided at the distal resection line of the stomach (Figure 1A). The suprapyloric LNs (station 5) were dissected in the same manner. The right gastric artery was skeletonized and divided distally to the second or third branch (Figure 1B). The left halves of LNs along the proper hepatic artery (station 12a) were removed, and the hepatic and pyloric branches of vagus nerves were preserved. Right paracardial LNs (station 1), LNs along the lesser curvature (station 3), and the left gastric artery (LGA) (station 7) were dissected by dividing the LGA at its origin. The celiac branch of the vagus nerve was also dissected. Dissection of the upper portion of station 1 LNs was occasionally omitted in order to preserve the origin of the hepatic branch of the vagus nerve and the anterior branch of the Latarjet nerve. LNs along the CHA (station 8a, 8p), around the celiac axis (station 9), and along the proximal splenic artery (station 11p) were routinely dissected. LNs along the left gastroepiploic artery (LGEA) (station 4sb) were dissected by dividing the last few branches of the LGEA. After transection of the stomach, the surgical margins were subjected to intraoperative histological examination by frozen section analysis. Reconstruction was performed using hand-sewn end-to-end anastomosis (Figure 1C).

Statistical analysis

Statistical analysis was performed using either the χ^2 test or Student's *t*-test. A *P*-value < 0.05 was considered significant.

RESULTS

There were no differences between the 2 groups in terms of sex, age, and tumor characteristics, with the exception of tumor location (Table 1). In 1 patient of the DG group and 2 patients of the SG group, LN metastasis was proven to be positive.

Operative data are shown in Table 2. Operating time, blood loss, and hospital stay were similar between the two groups. However, postoperative complications developed significantly more frequently in the DG group than in the SG group. There were no instances of anastomotic leakage, hemorrhage, gastric stasis, wound infection or operative death in either group.

The mean number of dissected LNs per station was comparable between the 2 groups (Table 3).

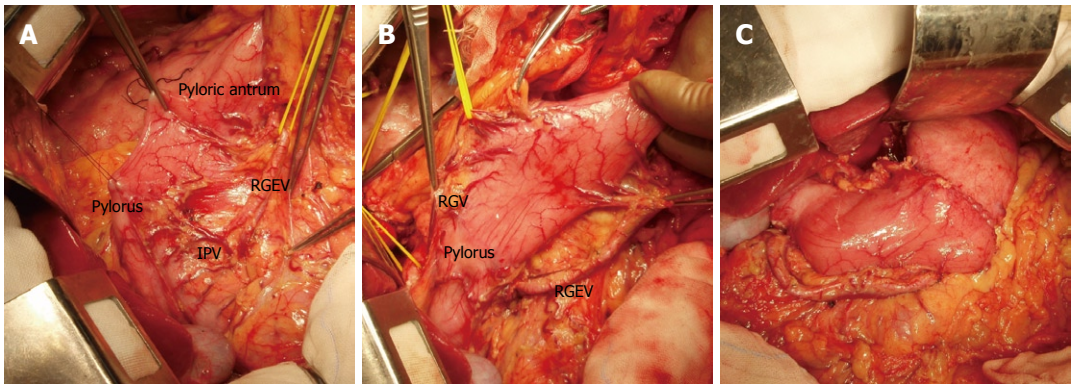

Figure 1 Photographs during surgery. A: The right gastroepiploic vessels were skeletonized allowing excision of adjacent lymph nodes (LNs) (stations 6 and 4 d). The surrounding nerve plexuses were preserved; B: For dissection of the suprapyloric LNs (station 5), the right gastric artery was skeletonized and divided distally to the 3rd branch; C: Reconstruction was performed using hand-sewn end-to-end anastomosis. RGEV: Right gastroepiploic vessels; IPV: Infrapyloric vessels; RGV: Right gastric vessels.

SG: Segmental gastrectomy; DG: Distal gastrectomy; LGEA: Left gastroepiploic artery; RGEA: Right gastroepiploic artery; LGA: Left gastric artery; CHA: Common hepatic artery; SA: Splenic artery; PHA: Proper hepatic artery; SMV: Superior mesenteric vein.

Table 4 Postoperative course (mean ± SD)

	SG (*n* = 14)	DG (*n* = 18)	*P*
Gastric stasis	0	0	1.000
Dumping syndrome	1	1	0.854
Body weight change ratio (%)	96.8 ± 6.1	90.4 ± 7.0	0.012
Laboratory data			
Lymphocytes (/mm^3)	2007 ± 437	1977 ± 646	0.885
Total protein (g/dL)	6.8 ± 0.3	7.0 ± 0.3	0.156
Total cholesterol (mg/dL)	215 ± 34	192 ± 32	0.063
Endoscopic examination			
Reflux gastritis	1	5	0.138
Reflux esophagitis	0	4	0.059

SG: Segmental gastrectomy; DG: Distal gastrectomy.

The postoperative course is summarized in Table 4. Postoperative recovery of body weight was significantly better in the SG group than in the DG group. The incidence of reflux esophagitis and gastritis after surgery was less frequent in the SG group than in the DG group.

No recurrence or death was observed in either group during a median follow-up period of 32.8 mo. One patient in the SG group developed colon cancer during the

follow-up period and subsequently underwent curative resection.

DISCUSSION

SG has not been previously used to treat EGC, since it was first reported by Wangensteen *et al*[5] as an operation for peptic ulcer. In 1999, Ohwada *et al*[2] modified the procedure and reported its use for treatment of EGC of the middle third of the stomach. However, previous studies concerning the use of SG for the treatment of EGC are limited, primarily due to difficulty in diagnosing LN metastasis accurately during surgery, and it being performed with very limited LN dissection. Deterioration of the radicality caused by omitting or limiting LN dissection should be avoided, because EGC can be treated with conventional D2 gastrectomy with excellent prognosis. Therefore, SG with limited LN dissection is not recommended unless T1N0 is confirmed.

On the other hand, a method for accurate intraoperative diagnosis of LN metastasis has yet to be established. Recently, SN biopsy has been used to assist intraoperative diagnosis of LN metastasis during surgical treatment of EGC. The SN concept seems feasible for treatment of EGC as described previously, however, several important issues including optimal tracer, method of injection, and false negative cases, still need to be resolved[6-8].

Our modified D2 dissection was considered to be comparable with conventional D2 dissection, because dissected stations in our SG corresponded with those in conventional D2 dissection. The mean number of dissected LNs of station 1 tended to be smaller in the SG group than in the DG group. This will be because dissection of the upper half of station 1 was occasionally omitted in order to preserve the anterior branches of the vagus nerve along the lesser curvature of the proximal remnant stomach, which may help maintain postoperative motility of this portion. The influence of limited dissection of station 1 on the oncological outcome is unclear, however, tumor recurrence resulting from incomplete dissection of station 1 has not been seen so far. Even in 3 patients whose LN metastasis was positive in the DG or SG group, no recurrence has been observed. In 1 of 2 patients whose LN metastasis was positive in the SG group, positive LN metastasis was proved after surgery in station 7 which belongs to the second tier. In the other 2 patients, LN metastasis was positive in station 3. These results may support the quality and effectiveness of our modified D2 dissection and the impact of D2 dissection.

In our procedures, 2-5 LNs were subjected to frozen section analysis. Station 8a was routinely examined by frozen section analysis. The frequency of LN metastasis in station 8a is relatively high even in EGC, and stations 7, 8a, and 11p are sometimes SN stations although they belong to the second tier[6,8,12-14]. Once the tumor advances to stage T2 or T3, lymphatic vessels can be obstructed by cancerous invasion, and metastasis in distant LNs can occur even in the absence of involvement of LNs adjacent to tumors. In the case where station 7 LN was proved positive after SG, intraoperative frozen section analysis detected no metastasis of stations 3 and 8a. Therefore, it is not recommended to limit LN dissection even if frozen section analysis reveals no LN involvement. Frozen section analysis with LN sampling was performed by us in order to rule out patients with positive LN metastasis rather than to confirm N0.

Unexpectedly, postoperative gastric stasis has not been observed in our patient population thus far. The precise mechanisms of development of gastric stasis after limited gastrectomy such as PPG remain unclear[15-18]. The main causes of gastric stasis are generally thought to include damage to the vagus nerve, insufficient blood supply to the pyloric region, or tonic and phasic contractions of the pylorus. In our procedure, not only the blood supply but also the venous drainage of the pyloric region is more sufficient than in PPG. These findings may have contributed to good maintenance of pyloric motility.

The present study demonstrated the safety and effectiveness of our procedures. This procedure could be a new function-preserving gastrectomy that is feasible for treatment of EGC with possible LN involvement. However, further studies including a larger number of patients and longer follow-up periods are essential for a more definitive conclusion.

COMMENTS

Background

Less invasive surgery for early gastric cancer (EGC) has been more commonly employed based on the background of an increase in EGC. Although it has been reported that pylorus-preserving gastrectomy can be performed with D2 dissection, there has been no report on segmental gastrectomy with D2 dissection.

Research frontiers

A sentinel node navigation method has been developed for accurate intraoperative determination of lymph node (LN) metastasis during surgery for EGC.

Innovations and breakthroughs

This is the first report to demonstrate that segmental gastrectomy can be performed with D2 dissection for treatment of EGC.

Applications

The superiority of function-preserving gastrectomy over conventional D2 gastrectomy for EGC in terms of postoperative quality of life is apparent. However, limited LN dissection accompanying function-preserving gastrectomy may reduce the radicality of gastrectomy for EGC. This procedure may be applicable to EGC with possible LN involvement.

Terminology

Segmental gastrectomy is one of the limited gastrectomies in which the central one third portion of the stomach is resected. The sentinel node is generally defined as the lymph node which receives the lymphatic flow first from the tumor.

Peer review

This is an interesting small series and I think it has value. I would like more information concerning the pathological outcomes before accepting the conclusions and suggestions in the discussion.

Abstract

AIM: To analyze the predictive factors for lymph node metastasis (LNM) in early gastric cancer (EGC).

METHODS: Data from patients surgically treated for gastric cancers between January 1994 and December 2007 were retrospectively collected. Clinicopathological factors were analyzed to identify predictive factors for LNM.

RESULTS: Of the 2936 patients who underwent gastrectomy and lymph node dissection, 556 were diagnosed with EGC and included in this study. Among these, 4.1% of patients had mucosal tumors (T1a) with LNM while 24.3% of patients had submucosal tumors with LNM. Univariate analysis found that female gender, tumors ⩾ 2 cm, tumor invasion to the submucosa, vascular and lymphatic involvement were significantly associated with a higher rate of LNM. On multivariate analysis, tumor size, lymphatic involvement, and tumor with submucosal invasion were associated with LNM.

CONCLUSION: Tumor with submucosal invasion, size ⩾ 2 cm, and presence of lymphatic involvement are predictive factors for LNM in EGC.

Key words: Early gastric cancer; Lymph node metastasis; Endoscopic treatment; Endoscopic submucosa dissection; Depth of tumor invasion

INTRODUCTION

The term early gastric cancer (EGC) describes gastric cancers involving the mucosa or submucosa irrespective of the presence of lymph node metastasis (LNM). Radical surgery including lymph node dissection has been the

standard treatment for early gastric cancer; however, LNM has only been associated with approximately 8% to 20% of EGC cases[1-3]. Unnecessary surgery could be avoided and endoscopic treatment might be a consideration in patients with EGC with negligible risk of LNM. Prior studies have demonstrated that the presence of LNM is the most significant factor for survival in patients with EGC[4,5] and usually constitutes the watershed between radical and endoscopic surgery. Identification of LNM cannot be achieved *via* endoscopic ultrasonography or computed tomography because the lymph node size is not a reliable parameter for detection of metastasis[1,2]. Many retrospective studies on EGC have established an indication for endoscopic treatment[6] and the probability of LNM in EGC has been estimated based on macroscopic-endoscopic tumor characteristics and histopathological findings.

According to the treatment guidelines for gastric cancer in Japan[7] the indication for endoscopic treatment such as endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) are patients with non-ulcerated tumors < 2 cm. Several investigators are currently attempting to extend the indication for endoscopic treatment to include: differentiated type, intramucosal cancer without ulcer, > 2 cm in size; differentiated type, intramucosal cancer, ≤ 3 cm in size if ulcerated; and, undifferentiated type, intramucosal tumor without ulcer, ≤ 2 cm in size (Table 1).

While endoscopic treatment for EGC is widely adapted in Japan and Korea using various criteria[4,8-10], it remains uncertain whether these guidelines for EMR/ESD are applicable to patients in areas outside of Japan and Korea. Japan and Korea have the highest gastric cancer rate in the world[11,12] and between 30% and 70% of all gastric cancers are diagnosed as EGCs. In other countries, EGCs account for only about 5% to 15% of all gastric cancers[13,14]. Japan and Korea have national screening programs in which the use of chromoendoscopy could increase the detection rate of EGC. Race, diet, and other factors such as pathologic diagnosis may explain differences in the diagnosis of EGC between Japan and other countries[15,16]; however, comparable data about EGC from other countries is rare or only involve a small case series[17]. The purpose of this study was to identify factors related to LNM in EGC and to elucidate which subgroup of EGC patients could be treated with EMR or ESD instead of radical surgery.

MATERIALS AND METHODS

Between January 1994 and December 2007, 2936 patients underwent gastrectomy for gastric cancer in the Department of Surgery, Chang Gung Memorial Hospital, Taipei, Taiwan, China. Clinicopathological data were obtained from a retrospectively constructed medical database, which had been reviewed by IRB, Chang Gung Memorial Hospital. In total, 556 of these patients were diagnosed with primary EGC and were included in this study. There were 330 men and 226 women with a median age of 62 years (range: 21-89 years).

Table 1 Extended indications for endoscopic mucosal resection/endoscopic submucosal dissection according to the treatment guidelines for gastric cancer in Japan

Differentiated type, mucosal cancer, ulcer (-), > 2 cm
Differentiated type, mucosal cancer, ulcer (+), ≤ 3 cm
Undifferentiated type, mucosal cancer, ulcer (-), ≤ 2 cm

Additional lymph node resection is not necessary when lymphovascular invasion is absent and also when it is not deeper than SM1 (-500 μm).

Poorly differentiated adenocarcinomas, signet ring cell carcinomas, and mucinous adenocarcinomas were classified as undifferentiated tumors. Well and moderately differentiated tubular adenocarcinoma and papillary adenocarcinoma were grouped together as differentiated tumors. Associations between the various clinicopathological factors and the presence of LNM were analyzed to identify risk factors of LNM. These factors included: gender; age (< 65 years or ≥ 65 years), carcinoembryonic antigen (CEA, < 5 ng/mL or ≥ 5 ng/mL), gross appearance, presence of an ulcer, histological type, depth of invasion (mucosa or submucosa), lymphatic involvement, and vascular involvement. Endoscopic macroscopic appearance was evaluated based on the Japanese Classification of Gastric Carcinoma established by the Japanese Research Society for Gastric Cancer[18]. Gross tumor findings were classified into five groups: type I (protruded); Ⅱa (superficially elevated); Ⅱb (flat); Ⅱc (superficially depressed); or Ⅲ (excavated). Macroscopic findings were defined as elevated types (type Ⅰ, Ⅱa, and combined Ⅰ or Ⅱa with Ⅱb), flat type (type Ⅱb), or depressed types (type Ⅱc, Ⅲ, and any combination of Ⅱb, Ⅱc or Ⅲ). When both elevated and depressed types were observed in one lesion, the lesion was defined as mixed type. An ulcer was identified based on the presence of an ulcer or ulcer scar defined endoscopically as converging folds and recognized histologically as a deformity of the muscularis propria or fibrosis in the submucosal layer[19].

Specimens were fixed in 5% formaldehyde and the tumor area and surrounding normal tissue were completely embedded in paraffin. The size (largest diameter) of each carcinoma was measured by the pathologist after fixation. From each block, 2 μm thick sections were cut and stained with hematoxylin and eosin. The depth of infiltration was measured at the deepest point of penetration of the cancer cells[20]. The pT1 category was confirmed as well as the subdivision in pT1a (limited to the mucosa or muscularis mucosa) and pT1b (submucosa).

All dissected lymph nodes were analyzed microscopically for metastatic disease. When necessary, additional lymph node sections were analyzed and special staining was applied. Immunohistochemistry for micrometastasis was not performed.

Statistical analysis

Calculations were performed using SPSS for Windows

Table 2 Clinicopathological features of 556 patients diagnosed with early gastric cancer and univariate analysis of potential risk factors of regional lymph node metastasis

Variables	Positive rate of lymph node metastasis (%)	*P* value
Age (yr)		0.876
< 65	40/288 (13.9)	
⩾ 65	36/268 (13.4)	
Gender		0.012
Male	35/330 (10.6)	
Female	41/226 (18.1)	
Size (cm)		< 0.001
< 2	34/352 (9.7)	
⩾ 2	42/204 (20.6)	
Endoscopic appearance		0.993
Elevated	9/65 (13.8)	
Depressed	43/307 (14.0)	
Flat	16/123 (13.0)	
Mixed	8/61 (13.1)	
Serum CEA (ng/mL)		0.152
< 5	43/336 (12.8)	
⩾ 5	7/32 (21.9)	
Depth of invasion		< 0.001
T1a	12/293 (4.1)	
T1b	64/263 (24.3)	
Histology differentiation		0.759
Differentiated	41/309 (13.3)	
Undifferentiated	35/247 (14.2)	
Vascular invasion		< 0.001
Absence	68/546 (12.5)	
Presence	8/10 (80.0)	
Lymphatic involvement		< 0.001
Absence	44/517 (8.5)	
Presence	32/39 (8.2)	
Ulcer		0.449
Absence	22/182 (12.1)	
Presence	54/374 (14.4)	

(version 11.5K, Chicago, Illinois). The χ^2 test was used to assess potential risk factors of LNM by bivariate comparisons of the categorical variables. Significant factors noted by univariate analysis were subsequently entered into a multivariate logistic regression model for analysis. *P* values < 0.05 were considered to be statistically significant.

RESULTS

EGCs were diagnosed in 18.9% of the gastric cancer cases (556 cases). Of these 556 diagnosed with EGC, 76 (13.7%) had LNM. As shown in Table 2, 293 (52.7%) were intramucosal tumors and 4.1% of these had LNM. In addition, 263 lesions (47.3%) penetrated the submucosa and 24.3% of submucosal tumors had LNM.

Univariate analysis identified that female gender, size ⩾ 2 cm, tumor invasion to the submucosa, presence of lymphatic involvement, and presence of vascular involvement were significantly associated with a higher rate of LNM (Table 2). Tumor size ⩾ 2 cm ($P < 0.008$), deep penetration into the submucosa ($P < 0.001$), and lymphatic involvement ($P < 0.001$) remained significant in multivariate analysis (Table 3).

Table 4 demonstrates the incidence of LNM of our patients fulfilled the criteria used for endoscopic treatment in EGD Japan[7]. In patients without lymphovascular invasion, 42 (tumor size ⩽ 2 cm) and 77 (any tumor size) patients with differentiated intramucosal cancers and no ulceration did not have LMN; intramucosal lesions with ulcer, size ⩽ 3 cm were found in 78 patients, who had no LNM; 3 of 35 patients with undifferentiated intramucosal tumors, no ulceration and size ⩽ 2 cm had LNM.

Table 3 Multivariate analysis of potential risk factors for regional lymph node metastasis

Variables	Odds ratio (95% CI)	*P* value
Gender (female/male)	1.49 (0.35-1.1)	0.163
Tumor size (⩾ 2 cm/< 2 cm)	2.28 (1.20-4.17)	0.008
Vascular invasion (yes/no)	1.86 (0.23-12.65)	0.598
Lymphatic invasion (yes/no)	27.2 (10.3-74.8)	< 0.001
Depth of invasion (T1b/T1a)	4.91 (2.44-9.89)	< 0.001

Table 4 Incidence of lymph node metastasis in our patients fulfilled the criteria used in endoscopic treatment for early gastric cancer in Japan

Criteria	Patient number with lymph node metastasis/total patient	Incidence (%)
Non-ulcerated, differentiated, intramucosal tumor without lymphovascular invasion, ⩽ 2 cm	0/42	0
Non-ulcerated, differentiated, intramucosal tumor without lymphovascular invasion, any size	0/77	0
Ulcerated, intramucosal tumor, without lymphovascular invasion, ⩽ 3 cm	0/78	0
Non-ulcerated, undifferentiated intramucosal tumor without lymphovascular invasion, ⩽ 2 cm	3/35	8.6

DISCUSSION

The incidence of LNM in EGC ranges from 2.6% to 4.8% in mucosal cancers and 16.5% to 23.6% in submucosal cancers[21,22]. In this study the positive rates of LNM in intramucosal and submucosal lesions were 4.1% and 24.3%, respectively, in line with the previous reports[21,22]. Endoscopic treatment for gastric cancer not only preserves gastric function but also helps maintain the patient's quality of life. For patients with EGC, "early" treatment is advocated as the best option for obtaining a complete cure. At present, a correct diagnosis of LNM is impossible during either EMR or ESD. This means that if LNM exists at the time of EMR or ESD, recurrence is very likely. For this reason, multiple patient- and tumor-related variables are currently under investigation as predictors of lymph node involvement[23], particularly in Japan and Korea. Many investigators have suggested possible extended criteria for local treatment[4].

In areas outside of Japan and Korea, the possibility

of using the above-described criteria remains problematic. Japan and Korea have the highest rate of gastric cancer rate in the world[11,12] and that in these countries, between 30% and 70% of all gastric cancers are diagnosed as EGCs. In other areas or countries, EGCs account for only about 5% to 15% of all gastric cancers[13,14,24].

National screening programs and chromoendoscopy could improve the detection rate of EGC; however, race, diet, and other factors such as pathological diagnosis may explain differences in the diagnosis of EGC between Japan and other countries. For example, there are some intestinal-type mucosal cancers in Japan that are not regarded as cancer in Western countries[15,16]. Hölscher *et al*[17] reported that the rate of LNM in mucosal cancer in one European series (6.5%) is higher than reported in Asian countries (2.7%). These differences are even greater if study data are limited to Japan and Korea; however, no difference in submucosal cancer exists (23.9% *vs* 22.1%). Therefore, whether the standard treatment employed in Japan and Korea can be used in other countries remains unknown. Compared with the data generated in this study, the rate of EGC was 18.9%, which is lower than that previously reported in Japan and Korea and similar to the reports from the United States and Europe. Our results revealed that the rate of LNM in intramucosal cancer was 4.1%, higher than the value published from Japan and Korea[17]. This might be explained due to the bias of histology criteria employed in our study (similar to those used in Western countries) and Japan and Korea.

In this study, various clinicopathological factors including gender, age, CEA levels, gross appearances, histological type, invasion depth, lymphatic involvement, and vascular involvement were analyzed for LNM in EGC. Our results showed that female gender was a significant factor in univariate analyses, but was not evident in multivariate analyses. Other research teams reported that being female was associated with LNM in both depressed EGCs and differentiated submucosally invasive EGC[10,25], possibly related to estrogen level[26]. At present, the precise link between gender and LNM remains unclear and further biologic studies are required to explain this effect.

Many studies suggest that serum CEA is an independent risk factor for hematogenous recurrence of gastric carcinoma[27]. Ikeda *et al*[28], for example, reported that stage Ⅱ and Ⅲ gastric cancer patients with higher preoperative CEA levels had frequent liver metastasis. This analysis, however, included all stages of gastric cancer. In the subgroup analysis of EGC in our studies, serum CEA levels were not a significant risk factor for LNM. Whether increased CEA levels have any impact on survival in patients with EGC needs further study.

Some studies have indicated that histological differentiation and ulceration had no significant association with LNM[25,26,29-31]. In contrast, Gotoda *et al*[4] performed a large study including 5265 patients with EGC. They reported that undifferentiated EGC and ulceration were independent factors. Moreover, Ye *et al*[32] assessed 591 patients with undifferentiated EGC and found that poorly differentiated EGCs had higher rates of LNM ($P < 0.001$). In the current study, histological differentiation was not a predictor of LNM, consistent with previous reports[25,26,29-31]. Nonetheless, our results showed that 3 of 35 cases (8.6%) with undifferentiated intramucosal tumors, which were not ulcerative and ⩽ 2 cm in size, had LNM. It is well accepted that in the presence of LNM, only radical gastrectomy provided a chance for curing patients with EGC. Therefore, we suggest that surgical resection with lymphadenectomy instead of endoscopic management should be the treatment choice for undifferentiated EGC.

Many researchers have accepted that depth of tumor invasion is the major factor relating to regional LNM[4,26,30,31] and endoscopic treatment is considered in EGC even if there is minimal submucosal invasion. Nonetheless, some of these researchers still advise against the use of extended criteria even if minimal submucosa invasion is present because rare cases had LNM that met the extended criteria for EMR/ESD[33].

In summary, tumor with submucosal invasion, size ⩾ 2 cm, and presence of lymphatic involvement appear to be significant factors for LNM. Endoscopic treatment might be an alternative in carefully selected EGC patients without predictors for LNM.

COMMENTS

Background

Endoscopic treatment for early gastric cancer (EGC) has been widely adapted in Japan and Korea to avoid unnecessary gastric resection. However, the presence of lymph node metastasis (LNM) which affects patient survival is considered a contraindication of endoscopic management in this situation. This study was designed to analyze the predictive factors for LNM in early gastric cancer.

Research frontiers

Studies have established an indication for endoscopic treatment for EGC and the probability of LNM in EGC is extremely low based on endoscopic and histopathological findings.

Innovations and breakthroughs

Guidelines for endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) remains uncertain in areas outside of Japan and Korea. The authors identify the predictive factors related to LNM in EGC and test the guideline.

Applications

Endoscopic treatment might be an alternative in carefully selected EGC patients without risk factors for LNM.

Terminology

EMR is an endoscopic technique of resection of a lesion that requires the separation of the submucosa using normal saline solution. ESD is a new method of resection, allowing the dissection of the lesion within the thickness of the submucosa or the interface between the submucosa and the muscularis propria.

Peer review

Excellent contribution highlighting the appropriate selection indicators for endoscopic treatment of early gastric cancer indicating that not all early cancers are the same.

Abstract

AIM: To compare the staging systems for stratifying and predicting the prognosis of patients with hepatocellular carcinoma (HCC) after partial hepatectomy (PH).

METHODS: Clinical data about 438 HCC patients who underwent PH from January 1991 to December 2004 at our hospital were retrospectively analyzed. Tumor stage was evaluated following the Chinese tumor node metastasis (TNM) and barcelona clinic liver cancer (BCLC) staging systems, respectively. Survival curves for the HCC patients were plotted using the Kaplan-Meier method and differences were compared by the log-rank test. The accuracy of each system for predicting death of HCC patients was evaluated by calculating the area under the receiver operating characteristic curve.

RESULTS: The HCC patients were classified into stages Ⅰ-Ⅲ, stages Ⅰ-Ⅳ and stages A-C, according to the 3 staging systems, respectively. Log-rank test showed that the cumulative survival rate was significantly different for the HCC patients at 3 Chinese system stages, TNM stages Ⅰ and Ⅱ, TNM stages Ⅲ and Ⅳ, and 3 BCLC stages ($P < 0.05$). However, no significant difference was found in the HCC patients at TNM stages Ⅱ and Ⅲ. The accuracy of the Chinese and BCLC staging systems was higher than that of the TNM staging system for predicting the survival rate of HCC patients.

CONCLUSION: The Chinese and BCLC staging systems are better for stratifying and predicting the prognosis of HCC patients after PH than the TNM staging system.

INTRODUCTION

Hepatocellular carcinoma (HCC), one of the most common cancers in the world, especially in Eastern Asia, with a poor prognosis[1], is the first leading cause of cancer-related death in the southeast of China[2]. Treatment modalities for HCC are strongly dependent on tumor stage

and the underlying liver diseases. Surgical intervention is the only potentially curative modality for it at present. However, the long-term prognosis of HCC patients remains dismal even after radical excision or liver transplantation[3].

Staging systems are used to define the prognosis of HCC and its treatment[4]. Generally, a better clinical staging system can stratify patients according to their survival time, and is reliable and useful for comparing the curative effects on HCC. Several HCC staging systems have been proposed, such as the Okuda staging system[5], tumor node metastasis (TNM) staging system of the American Joint Committee on Cancer (AJCC)[6], cancer of the liver Italian program (CLIP) scoring system[7], Barcelona clinic liver cancer (BCLC) staging classification[8], Japan integrated staging (JIS) score[9], and Tokyo score[10]. However, no worldwide consensus has been reached on the use of any given HCC staging systems. Therefore, more accurate classification of HCC patients with a homogeneous prognosis would at minimum improve the application of currently available treatment modalities.

The Chinese staging system, established by the Chinese Society of Liver Cancer (CSLC) in 1999[11,12], combines the tumor-related factors and liver function reserve. However, its application in stratifying and predicting the prognosis of HCC patients remains to be defined. This study was to evaluate and compare the Chinese staging system, the AJCC TNM staging system (7th edition) and the BCLC staging system for stratifying and predicting the prognosis of a large cohort of Chinese HCC patients after partial hepatectomy (PH).

MATERIALS AND METHODS

Patients

Four hundred and thirty-eight patients with HCC who underwent PH from January 1991 to December 2004 at our hospital were included in this study. The diagnosis of HCC was pathologically confirmed. Clinicopathological features and survival rates of the patients were analyzed. The study was approved by the Ethical Committee of Sun Yat-Sen Memorial Hospital and in accordance with the Helsinki Declaration of 1975. Written informed consent was obtained from the patients or their guardians.

Tumor stage

HCC was divided into different stages following the criteria for the Chinese, TNM and BCLC staging systems, respectively. The detailed definition and criteria for the Chinese staging system are listed in Table 1.

Treatment

All patients underwent non-anatomical resection. According to the Couinaud's nomenclature for liver segmentation, minor hepatectomy (1-2 segments), major hepatectomy (≥ 3 segments), and wedge resection were performed in 179 (40.9%), 47 (10.9%), and 212 (48.2%) patients, respectively. Of the 438 patients, 24 (5.5%) with unresectable HCC underwent surgery after trans-catheter hepatic arterial chemoembolization (TACE, down-staged). Moreover, HCC patients with inoperable intrahepatic recurrence or extrahepatic metastases received combined therapies, including TACE, radiofrequency ablation (RFA), microwave coagulation therapy (MCT), percutaneous ethanol injection (PEI), and biotherapy or traditional Chinese therapy.

Table 1 Definition and criteria of Chinese staging system for hepatocellular carcinoma (1999)

Stage	Tumor	Thrombi	CLN metastasis	Distant metastasis	Child-Pugh score
Ⅰa	Solitary ≤ 3 cm	No	No	No	A
Ⅰb	Solitary or two ≤ 5 cm in single lobe	No	No	No	A
Ⅱa	Solitary or two ≤ 10 cm in single lobe, or two ≤ 5 cm in bilateral lobes	No	No	No	A
Ⅱb	Solitary or two > 10 cm in single lobe, or two > 5 cm in bilateral lobes	No	No	No	A
	Any	PV-branch, HV or BD	No	No	A
	Any	No	No	No	B
Ⅲa	Any	PV-trunk or IVC	Yes/No	Yes/No	A/B
	Any	Yes/No	Yes	Yes/No	A/B
	Any	Yes/No	Yes/No	Yes	A/B
Ⅲb	Any	Yes/No	Yes/No	Yes/No	C

CLN: Celiac lymph nodes; PV: Portal vein; HV: Hepatic vein; BD: Bile duct; IVC: Inferior vena cava.

Follow-up

During the first 6 mo after operation, the patients were re-examined every 1-2 mo followed by every 3-6 mo. The clinical, laboratory and radiological (abdominal computed tomography scan and chest X-ray) data were collected at each follow-up. Three hundred and ninety-two (89.5%) HCC patients were followed-up until the end of January 2005 or death, while 46 (10.5%) HCC patients were lost during the follow-up. The median follow-up time was 21 mo (range 1-156 mo).

Statistical analysis

Statistical analysis was conducted with the SPSS software package (version 13.0, SPSS, Chicago, IL). Quantitative data were presented as mean ± SE. Survival curves for the HCC patients were plotted using the Kaplan-Meier method and examined by the log-rank test. The accuracy of each system for predicting the 1-, 3-, and 5-year rates of HCC patients was evaluated by calculating the area under the receiver operating characteristic curve. Patients censored before 1, 3 and 5 years were excluded from the analysis. $P < 0.05$ was considered statistically significant.

RESULTS

Clinicopathological features and survival of HCC patients

The general characteristics of the 438 HCC patients are summarized in Table 2. The mean and median ages of the patients were 50.0 ± 0.6 years and 49.0 years (range: 35-68 years), respectively. By the end of follow up, 223 HCC patients (50.9%) died. The 1-, 3- and 5-year postoperative overall survival rates were 72.2%, 53.5% and 43.3%, respectively, for the patients after PH.

Prognosis stratification according to the three clinical staging systems

The 438 HCC patients were classified into stages Ⅰ-Ⅲ, stages Ⅰ-Ⅳ and stages A-C according to the Chinese, TNM and BCLC staging systems, respectively. The log-rank test showed that the cumulative survival rate was significantly different for the HCC patients at 3 Chinese system stages, TNM stages Ⅰ and Ⅱ, TNM stages Ⅲ and Ⅳ, and 3 BCLC stages (Table 3 and Figure 1, $P < 0.05$). However, no significant difference was found in the HCC patients at TNM stages Ⅱ and Ⅲ ($P > 0.05$).

Table 3 Overall survival rates of hepatocellular carcinoma patients according to their tumor stage

Table 4 Accuracy of three staging systems for the death of hepatocellular carcinoma patients 1, 3 and 5 years after partial hepatectomy

System	AUC (95% CI)		
	1-yr death	3-yr death	5-yr death
CS	0.709 (0.658-0.761)	0.703 (0.645-0.761)	0.720 (0.648-0.791)
TNM	0.718 (0.662-0.774)	0.702 (0.646-0.759)	0.695 (0.629-0.760)
BCLC	0.730 (0.675-0.785)	0.701 (0.644-0.757)	0.710 (0.645-0.776)

AUC: Area under the receiver operating characteristic curve; CI: Confidence interval; CS: Chinese staging; TNM: Tumor node metastasis; BCLC: Barcelona clinic liver cancer.

Accuracy of the three clinical staging systems for predicting survival rate of HCC patients

The accuracy of 3 staging systems for predicting the survival rate of HCC patients 1, 3 and 5 years after PH is summarized in Table 4. The accuracy of the Chinese and BCLC staging systems was higher than that of the TNM staging system for predicting the survival rates of HCC patients (Figure 2).

DISCUSSION

HCC is the second most lethal cancer after pancreatic ductal adenocarcinoma, leading to about 600 000 deaths every year worldwide, with nearly 55% of the deaths occurred in China alone[3]. The long term prognosis of HCC patients is extremely dismal and the incidence of HCC is continuously growing globally[1,13,14]. In the southeast of China, HCC is the leading cause of cancer-related death despite aggressive conventional therapies[2]. Surgery remains the most effective treatment of HCC with a curative potential[15,16]. However, HCC patients even after curative resection of the tumor often have a high rate of relapse.

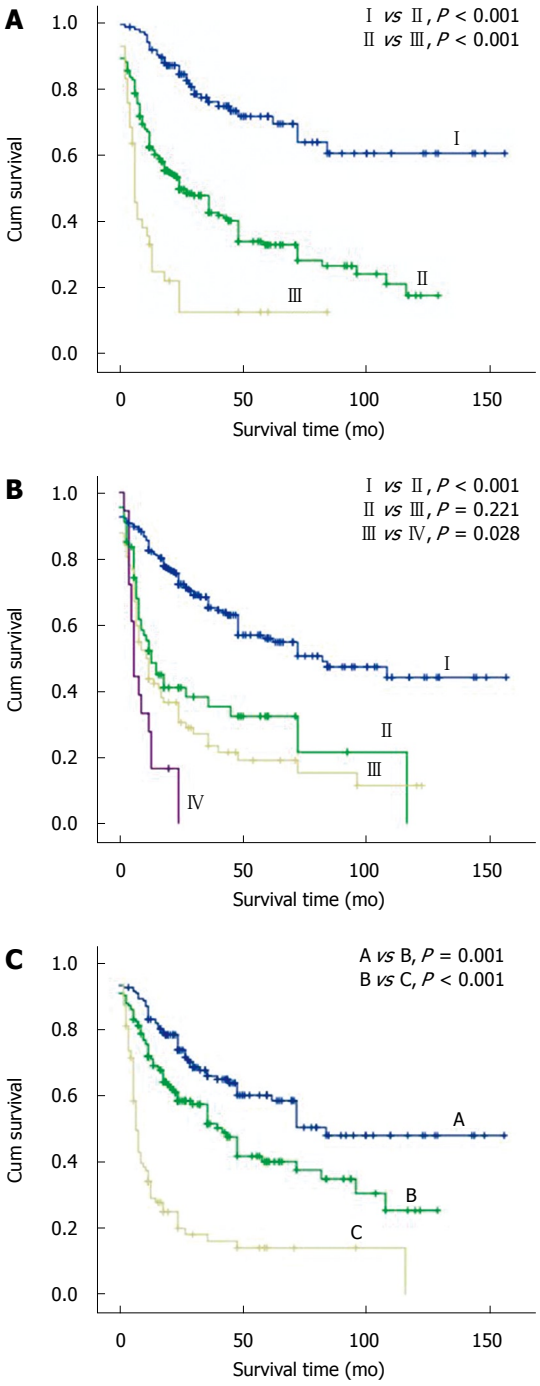

Figure 1 Survival curves for hepatocellular carcinoma patients according to the Chinese staging system (A), tumor node metastasis staging system (B), barcelona clinic liver cancer staging system (C).

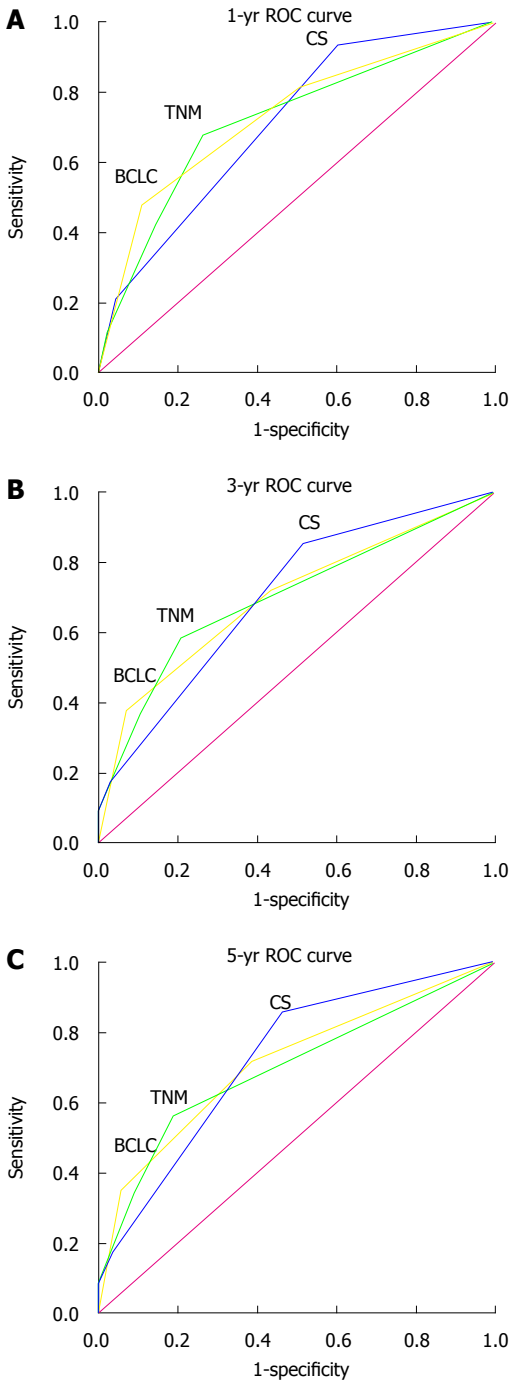

Figure 2 Accuracy of the three staging systems for predicting the 1-year (A), 3-year (B), 5-year (C) survival rates of hepatocellular carcinoma patients. ROC: Receiver operating characteristic curve; CS: Chinese staging; TNM: Tumor node metastasis; BCLC: Barcelona clinic liver cancer.

Therefore, tools that can be used to stratify the prognosis of HCC patients after therapy are urgently needed. Gene-expression analysis has led to the successful molecular classification of HCC according to its prognosis, aetiology and intra-hepatic recurrence[17]. However, it has not been widely accepted due to its high cost.

Staging systems are often used to select primary and adjunctive therapies and to assess their outcome. Generally, a well defined clinical staging system not only can classify HCC patients and predict their survival time, but also can be generally applied globally. Increasing evidence shows that liver function reserve and tumor-related factors can also significantly influence the prognosis of HCC patients[4]. Chen *et al*[18] reported that a better staging system can provide more valid tumor-related factors and liver function parameters. Therefore, both tumor-related features and liver function reserve should be included in the clinical staging systems for HCC[19].

Several clinical staging systems are available for pre-

dicting the prognosis of HCC patients after PH at present. However, no worldwide consensus has been reached on which staging system is the best for predicting the prognosis of HCC patients after surgery[20]. Although the Okuda staging system[5], CLIP scoring system[7], JIS score[9], and Tokyo score[10] are widely used, they have been mostly applied to unresectable HCC, and none is universally accepted[21]. The TNM staging system is the most widely used system worldwide at present[21]. However, the AJCC TNM staging system does not include any measurement of liver functions and is thus not widely used[20]. Llovet *et al*[22] reported that the AJCC TNM staging system fails to adequately stratify HCC patients and predict their prognosis. Lu *et al*[23] also reported that the TNM staging system provides inadequate information for the prognosis of HCC patients.

In the present study, application of the CS system in stratifying and predicting prognosis of a large cohort of Chinese HCC patients (n = 438) after PH was investigated and compared to that of the AJCC TNM and BCLC staging systems. The log-rank test showed that the cumulative survival rate was significantly different for HCC patients at Chinese system stages, TNM stages Ⅰ and Ⅱ, TNM stages Ⅲ and Ⅳ, and 3 BCLC stages, while no significant difference was found in the cumulative survival rate of HCC patients at TNM stages Ⅱ and stage Ⅲ. The accuracy of the Chinese and BCLC staging systems was higher than that of the TNM staging system for predicting the long-term survival (3- and 5-year) rates of HCC patients after PH, indicating that the Chinese and BCLC staging systems are better than the TNM staging system for stratifying and predicting the prognosis of HCC patients after PH. In our study, the AJCC TNM staging system could not accurately stratify the HCC patients with multiple nodules or vascular/peripheral invasion.

In conclusion, the Chinese and BCLC staging systems are better than the AJCC TNM staging system for stratifying and predicting the prognosis of HCC patients after PH. Further studies are needed to establish a single, worldwide staging system that can stratify and predict the prognosis of HCC patients after PH.

COMMENTS

Background

Staging systems are used to define the prognosis and treatment of hepatocellular carcinoma (HCC) patients. Several staging systems are available for predicting the prognosis of HCC patients, but no worldwide consensus has been reached on the use of any given HCC staging systems. Therefore, more accurate classification of HCC patients with homogeneous prognosis is urgently needed.

Research frontiers

Although the Okuda and cancer of the liver Italian program scoring systems, Japan integrated staging score, and Tokyo score are widely used, they have been mostly applied to unresectable HCC patients. The tumor node metastasis (TNM) staging system for HCC does not include any measurement of liver functions and is thus not widely used. The Chinese staging system for stratifying and predicting the prognosis of HCC patients remains to be defined.

Innovations and breakthroughs

The Chinese staging system was studied for stratifying and predicting the prognosis of HCC patients. Furthermore, the applicability of the Chinese staging system was compared with other staging systems for stratifying and predicting the prognosis of HCC patients after partial hepatectomy.

Applications

The results of this study demonstrate that the Chinese staging system can be used for predicting the prognosis of HCC patients after partial hepatectomy.

Peer review

The authors evaluated and compared the Chinese, American Joint Committee on Cancer (AJCC) TNM and Barcelona clinic liver cancer (BCLC) staging systems for stratifying and predicting the prognosis of a large cohort of Chinese HCC patients after partial hepatectomy. The results reveal that the Chinese and BCLC staging systems are better than AJCC TNM staging system for stratifying and predicting the prognosis of HCC patients after partial hepatectomy.

Abstract

Primary malignant liver mesenchymal tumor is a rare condition defined as a tumor with vascular, fibrous, adipose, and other mesenchymal tissue differentiation. We report a case of primary malignant liver mesenchymal tumor in a 51-year-old male with anemia, weight loss and hepatomegaly. Finally unconventional liver biopsy and histological manifestation led to the definitive diagnosis.

Key words: Hepatic mesenchymal tumor; Liver biopsy; Hepatic leiomyosarcoma; Hepatic schwannoma

INTRODUCTION

Primary malignant liver mesenchymal tumor is a very rare tumor, accounting for less than 1% of all hepatic malignancies[1]. Hepatic angiosarcoma, leiomyosarcoma, embryonal sarcoma, schwannoma and lymphoma are the more common mesenchymal tumors. The diagnosis is dependent on histological imaging. However, some cases of multiple nodular lesions can only be diagnosed by percutaneous liver biopsy (PLB) without surgery. We present a case of malignant liver mesenchymal tumor in an adult and its diagnosis and treatment were discussed.

CASE REPORT

A 51-year-old Chinese male was referred to our hospital with a 2-mo history of mild abdominal pain, an abdominal mass in the upper quadrant, fatigue and progressive weight loss. His symptoms gradually worsened with fatigue 1 wk after onset of the disease. He had no fever, cough or skin lesions in the past 2 mo and no family history of liver and autoimmune diseases. Physical examination revealed mild pale conjunctiva and skin, and enlargement of the liver without percussion pain.

His complete blood hemoglobin was 58 g/L. Stool occult blood test was negative. Liver functional test showed that his alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, γ glutamyl tranzpehtidaze, total bilirubin, direct bilirubin, and albumin were 81 U/L, 86 U/L, 224 U/L, 73 U/L, 23.55 μmol/L, 11.74 μmol/L, 30.5 g/L, respectively. Series hepatitis markers (hepatitis A virus, hepatitis B virus, hepatitis C virus, hepatitis D virus, hepatitis E virus, Epstein-Barr virus, and cucumber mosaic virus) were negative. α-fetoprotein, carcinoembryonic antigen and CA19-9 concentrations were also normal. Human immunodeficiency virus and syphilis antibodies were negative. Coagulation profile was normal.

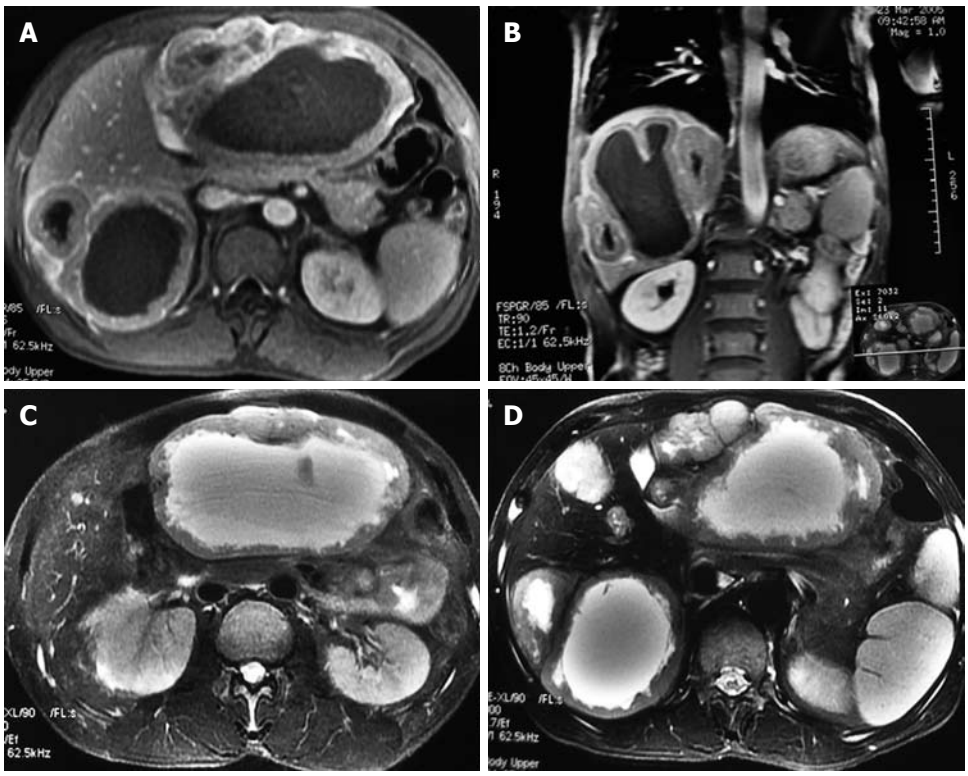

Figure 1 Axial fat-suppressed T2-weighted turbo spin echo magnetic resonance imaging showing two large lesions (A) and several small cyst-like lesions (B) in liver, and coronal and transverse T1-weighted imaging showing thickened wall of lesions with a ragged appearance (C) and enhancement (D) in liver.

Ultrasound and magnetic resonance imaging (MRI) were used as the initial diagnostic tools. Abdominal ultrasound revealed a solid mass in the liver with a low echo, a sharp border, a rich blood supply and liquefaction necrosis. The maximum diameter of the mass was 13.9 cm. Abdominal MRI showed multiple diffuse abnormal signals suggestive of a possible malignant tumor. Axial fat-suppressed T2-weighted turbo spin echo imaging showed two larger and several smaller well-margined cyst-like lesions in the liver (Figure 1A and B). Coronal and transverse T1-weighted imaging demonstrated thickened wall of lesions with a ragged appearance and enhancement (Figure 1C and D). Endoscopy showed duodenal ulcer (S2 stage), normal colon and rectum.

PLB was performed under ultrasonography (US) guidance using a Bard biopsy gun (18-gauge cut needle) to make a final diagnosis of the lesions in liver. During biopsy, bloody liquid was observed in the lesion. Microscopic examination confirmed that the bloody liquid contained a large number of erythrocytes. However, pathology of the liver only showed a spindle cell tumor. The possible reasons are as follows. First, the liver specimen was too small because the lesion contained only fluid and was surrounded by a very thin wall. Second, the location of tumor and its hardness limited the adjustable puncture angle.

To confirm the diagnosis of this patient, another unconventional liver biopsy was performed with gastroscopic biopsy forceps as follows.

At beginning of the procedure, a local anesthetic agent (5% lidocaine) was injected subcutaneously through a 25-gauge needle. Next, a 15 cm long 18 gauge puncture needle was passed into the cyst under US guidance. After the local skin and subcutaneous tissue were dilated, a PTC exchange stainless steel guide wire with a flexible tip was introduced into the cyst cavity through the needle, and then the needle was withdrawn. A 5-French catheter was plated into the cyst using the Seldinger technique. Finally, gastroscopic biopsy forceps was passed into the cyst through the catheter to get the liver tissue sample. The histological results indicated that spindle-shaped tumor cells were well-oriented, arranged in bundles and clustered in some part of the regional tumor. Nuclei with rare mitosis were elongated in a rod-like shape with different sizes and blunt ends. The final diagnosis was established as a low grade malignant liver mesenchymal tumor (Figure 2).

The patient was suggested to receive hepatic arterial chemoembolization. Selective digital subtraction angiography in the early and later phases showed lesions surrounded by abnormal tortuous tumor arteries (Figure 3A) and patchy enhancement (Figure 3B), respectively, in different areas. Then, 5-Fu (750 mg), mitomycin (5 mg), pyrazine imidacloprid Star (30 mg), and super-liquid iodized oil (5 mL) were infused into the tumor arteries. After treatment, liver function of the patient was improved and his hemoglobin level increased (Table 1). The patient died 2 years after treatment.

DISCUSSION

In this paper, we presented a case of multiple nodular cys-

Table 1 Changes in serum biochemical index before and after treatment

	WBC ($\times 10^9$/L)	HGB (g/L)	PLT ($\times 10^{12}$/L)	ALT (U/L)	AST (U/L)	TBIL (μmol/L)	ALB (g/L)
Diagnosis	10.44	58	294	81	86	23.55	30.5
Treatment	6.24	86	241	17	24	20.74	34.1

WBC: White blood cell count; HGB: Hemoglobin; PLT: Platelet count; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; TBIL: Total bilirubin; ALB: Albumin.

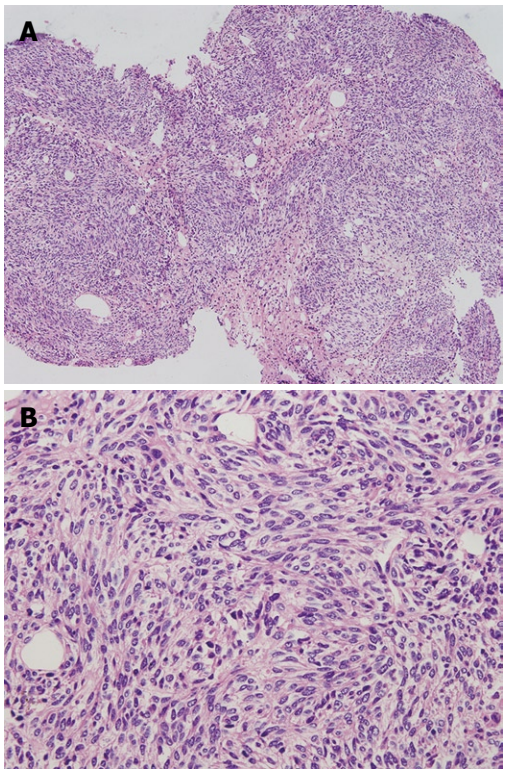

Figure 2 Hematoxylin and eosin staining showing a low grade malignant liver mesenchymal tumor under the magnification × 10 (A) and × 40 (B).

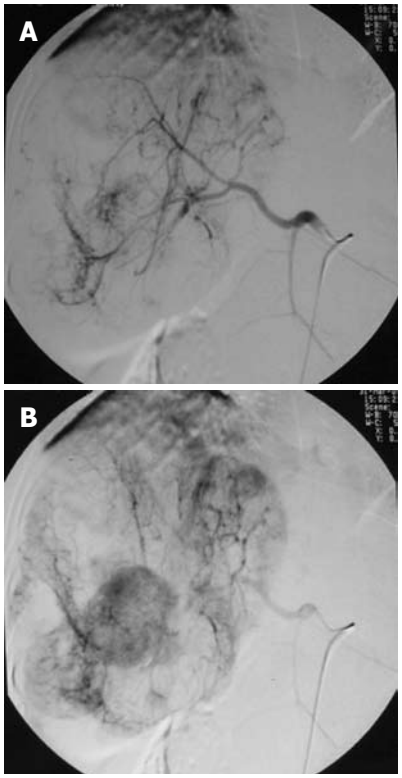

Figure 3 Selective digital subtraction angiography showing abnormal tortuous arteries in the early phase (A) and patchy enhancement in later phase (B) in different areas.

tic lesions in liver. The final diagnosis was established as a low grade malignant liver mesenchymal tumor. However, HE staining could not show the source of mesenchymal cells. Further immunohistochemistry staining with Vimentin, Desmin and α-SMA was performed, which could not sill show the source of mesenchymal cells.

Primary malignant liver leiomyosarcoma and schwannoma are both rare tumors in the liver. Primary liver leiomyosarcoma is a rare malignancy involving the liver, occurring as a primary liver sarcoma in patients without any underlying disorder, and its incidence increases as a primary tumor in immunodeficiency patients[2]. Its usual clinical presentation is painful hepatomegaly or epigastric mass[3]. Malignant liver schwannoma is the most common soft tissue sarcoma in adults, but primary liver schwannoma is extremely rare. Only 12, 8, and 1 cases of benign, malignant, and semimalignant liver schwannoma are available from the literature worldwide[4-12]. Hepatic schwannoma is usually associated with neurofibromatosis. However, two cases of malignant liver schwannoma without neurofibromatosis have been reported[9,11].

Unfortunately, it is difficult to make the diagnosis of malignant liver mesenchymal tumor because both its clinical presentation and imagine are nonspecific.

The common symptoms and signs of patients with malignant liver mesenchymal tumor include abdominal pain, weight loss, weakness, loss of appetite, vomiting, enlargement of the liver, ascites, and jaundice, which lack of specificity in differential diagnosis between benign and malignant mesenchymal tumors.

Furthermore, imaging studies, such as MRI scan, computed tomography (CT) scan and angio photography are the commonly used methods to identify the characteristics of liver tumor. However, imaging findings of liver mesenchymal tumors, including leiomyosarcoma and schwannoma, are nonspecific and infrequently reported[13-19]. It is quite difficult for MRI and CT scan to differentiate primary liver mesenchymal neoplasms from other liver malignancies, although they should be included in differential diagnosis when MRI or CT scan demonstrates hepatic lesions without characteristics of hepatocellular carcinoma,

especially in patients with no extrahepatic primary malignancies.

The diagnosis of malignant liver mesenchymal tumor depends on histological change in either needle or open biopsy, while metastatic status is facilitated by the presence of extrahepatic primary tumor.

Liver biopsy is an important diagnostic tool and helps make therapeutic decision for liver tumor. Open biopsy is a major surgical procedure for liver tumor. PLB under ultrasound or CT guidance is a safe and almost painless procedure for lesions with a soft tissue component or located close to vital structures[20]. Most reported cases of cystic liver mesenchymal tumor were diagnosed by open liver biopsy. In this case, uncommon PLB method was used instead of the routine PLB to make the final diagnosis, avoiding injury and complications of open biopsy. Minimally invasive treatment devices, such as gastroscopic biopsy forceps and catheters used in liver cancer intervention, make the new PLB method possible, which is safe and reliable and can thus be used in diagnosis of cystic liver lesions.

In conclusion, mesenchymal liver tumor is rare in adults and cross-sectional findings are varied, which can be diagnosed with the uncommon PLB method.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statisital review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit on-

line. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use

uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

The role of sphincteroplasty in the treatment of patients with fecal incontinence due to anal sphincter defects has been questioned because the success rate declines in the long-term. A new emerging treatment for fecal incontinence, sacral nerve stimulation, has been shown to be effective in these patients. However, the success rate of sphincteroplasty may depend of several patient-related and surgical-related factors and the outcome from sphincteroplasty has been evaluated differently (with qualitative data) from that after sacral nerve stimulation (quantitative data using scoring systems and quality of life). Furthermore, the data available so far on the long-term success rate after sacral nerve modulation do not differ substantially from those after sphincteroplasty. The actual data do not support the replacement of sphincteroplasty with sacral nerve stimulation in patients with fecal incontinence secondary to sphincter defects.

Key words: Fecal incontinence; Sacral nerve stimulation; Sphincteroplasty

INTRODUCTION

Sphincteroplasty was first described by Lockhart-Mummary[1] in 1923, who reported only on the end-to-end apposition of the margins of the damaged anal sphincter, however, the operation become popular following a publication by Parks *et al*[2], who first described the overlapping sphincteroplasty. Since then, this operation is generally believed to be the treatment of choice for incontinent patients with external anal sphincter defects in whom conservative management has failed. However, this operation has recently been questioned because of its long-term success rate, which like many other operations for functional diseases of the gastrointestinal tract, declines with time. On the other hand, the new procedure of sacral nerve modulation has been demonstrated to benefit patients, even those with damaged anal sphincter, and has raised the question of whether sphincteroplasty still has a role in the management of patients with fecal incontinence after sphincter damage. In this editorial, the reason for the failure of sphincteroplasty and the matter of using sacral nerve stimulation (SNS) instead of sphincteroplasty in patients with sphincter damage are discussed.

PROGNOSTIC FACTORS OF SPHINCTEROPLASTY

Sphincteroplasty is usually indicated after obstetric damage to a normal anal sphincter during childbirth or after an iatrogenic lesion to cure an abscess or a complex anal fistula. It is uncertain whether the etiology of the sphincter lesion can affect the outcome. One of the few papers dealing with this topic suggests that patients with surgical trauma do better than those with obstetric trauma[3]. However, we did not find similar results in the Italian registry of fecal incontinence (data not shown). Of course, the extent of sphincter damage plays an important role in the outcome. It is easier and probably more effective to close a small gap of 30° than a gap of 120°, and in most of the papers dealing with this operation, patients with a gap in the anal defect greater than 120° are usually excluded from this procedure[4]. Another possible factor influencing the success rate after sphincteroplasty could be the occurrence of pudendal neuropathy. Nowadays, the pudendal nerve terminal motor latency test is not generally considered to be predictive of the outcome of several procedures for fecal incontinence such as sacral nerve modulation, however, most of the papers on this topic[5-9] demonstrated that patients without pudendal neuropathy did significantly better than patients with neuropathy (Table 1). The problem is that, almost all these studies are retrospective and it is not possible to demonstrate whether neuropathy existed prior to surgery. Another important factor potentially affecting the outcome is the age of these patients. The literature shows that patients less than 40 or even 50 years old do much better than older patients[10].

Further possible factors which can influence the outcome of this operation are related to the surgical technique. There are many tips on the surgical techniques used which could play a role in the outcome of these patients. For example, early *vs* delayed repair. A recent study[11] demonstrated that early repair, whenever possible, has better cost-effectiveness than delayed repair. In addition, a study by Sultan *et al*[12] indicated that suturing the internal and external anal sphincter separately could give better results, although this data has never been confirmed.

It is generally believed that sphincter overlap is the preferred way to perform a sphincteroplasty. However, in the literature there are only 2 papers on this topic. In particular, the study by Fitzpatrick *et al*[13], which had a very short follow-up, found no difference in outcome. However, the study by Fernando *et al*[14], in a large group of patients, found a significantly better outcome at one year follow-up when the overlapping technique was used.

Other surgical details include the use of resorbable or unresorbable sutures. Some older studies on sphincteroplasty were performed using catgut to approximate the sphincter margins, and this is of major importance when we look at the long-term results. The literature suggests that the use of PDS or prolene is better than Vicryl or Dexon because they need a longer time to be resorbed[15].

Some authors[16] have advocated the need for a diverting stoma to protect the sphincteroplasty, but there is no evidence for this; on the contrary, there is evidence of morbidity following stoma closure and stoma-related disability[17]. Almost all colorectal surgeons do not use a diverting stoma or bowel confinement after a sphincteroplasty and usually these patients can resume oral feeding immediately after surgery[18].

Another interesting factor which potentially affects the outcome of sphincteroplasty, is the puborectalis sling contraction. Roche's group in Ginevra[19] demonstrated that patients with good function of the puborectalis sling measured by perianal echography do better. This means that patients who still have some functionality of pelvic floor muscles have a better chance of obtaining a good result after sphincteroplasty.

FUNCTIONAL OUTCOME AFTER SPHINTEROPLASTY

Patients with fecal incontinence have a normal life-expectancy, so we must look at the long-term results rather than the early results. Table 2 lists the studies dealing with the short-term results of sphincteroplasty, in most cases after obstetric trauma, indicating a very interesting rate of excellent/good results for a pooled good outcome of about 69%. However, if we look at the long-term results, after a follow-up ranging from 5 and 10 years (Table 3), the number of excellent/good results falls to 46%.

Why does the success rate deteriorate with time after sphincteroplasty? Some suture breaks in the muscle can occur in the postoperative period, and other patients may have an undetected cause of fecal incontinence. Furthermore, it is supposed that in women, a deteriora-

tion in muscle trophism and innervation occur with age, particularly after the menopause due to the fall in estrogen levels[35].

WHAT TO DO IN CASE OF EARLY OR LATE FAILURE OF SPHINCTEROPLASTY?

The first question is whether the same operation can be re-done. In the literature, there are two papers on this topic[31,36], both claiming that 50% of these patients can recover their continence after a repeat sphincteroplasty, and that continence can be maintained in the long-term.

SACRAL NERVE STIMULATION *VS* SPHINCTEROPLASTY

In 1995, Matzel *et al*[37] opened a new chapter in coloproctology, showing that sacral nerve stimulation can benefit patients with fecal incontinence. Since then, the indication for this procedure has been extended, even to patients with sphincter defects which were originally excluded. In the literature, there are already 7 papers[38-44] published on this topic showing that there is a very interesting percentage of early success with SNS without doing anything to the damaged sphincter. The question now is, are we justified in skipping sphincteroplasty in the ideal "algorithm" to treat patients with sphincter defects by performing SNS directly? There are several issues that make this option questionable because the data available on sphincteroplasty and SNS have been poorly compared. There are two major issues that must be considered; the short- *vs* the long-term outcome and how the success rate is measured. Four papers dealing with the first topic were published in 2009 (Table 4)[45-48].

When the data was amalgamated a 58% success rate in the long-term was observed. This was quite unexpected after the enthusiasm surrounding the early results of SNS. However, is this long-term outcome data truly comparable with those of sphincteroplasty? When dealing with SNS, we refer to mixed causes of incontinence, in both sexes, and, most importantly, the criterion used to define success is more than a 50% reduction in major incontinence episodes. When we deal with sphincteroplasty, we look at patients with only one defect causing incontinence, the sphincter defect. Almost all patients are female and the criteria used to define success have been categorical and qualitative such as incontinence to solids, liquids or flatus. A good way of measuring the outcome of surgery for fecal incontinence would be patient satisfaction and quality of life, but few papers focus on these measurements. Most papers on sphincteroplasty just classify the outcome into categories of incontinence. In contrast, in all of the papers on SNS, incontinence scores are used. However, even in these cases confusion can arise due to the use of different incontinence scores (Wexner Score[49], Vaizey's score[50], Pescatori's score[51], and many others), making the results between SNS and sphincteroplasty difficult to compare. Furthermore, the criteria for defining success used in SNS studies (< 50% of incontinence episodes) have never been adopted in sphincteroplasty studies.

Table 4 Long term outcome after sacral nerve stimulation for fecal incontinence

Author	*n*	Success (%)	Length of follow-up (yr)
El-Gazzaz *et al*[45], 2009	22	42	2.5
Altomare *et al*[46], 2009	52	62	7
Matzel *et al*[47], 2009	12	75	9
Vallet *et al*[48], 2010	32	53	3

Another argument based on the definition of success is related to the treatment of fecal incontinence, as the success of the techniques is defined by the statistically significant reduction of incontinence scores, however, this information does not give us what we need to know: how many of our patients have had their problems fixed, not the statistical changes in the global scores.

A very interesting recent paper[34] reviewed 160 patients who had undergone sphincteroplasty, with a very long follow-up of about 10 years. The outcome was classified using the two main systems: categorical (excellent, moderate and poor results) and quantitative (number of incontinence episodes/week). The authors found that 37% of patients had an excellent/good result, 23% had a moderate result and 40% had a poor result. However, the group of patients with a moderate result had more than a 50% reduction in incontinence episodes. This means that, if we analyze the data on sphincteroplasty using the criteria generally adopted for patients undergoing SNS, the long-term success rate is 60%, which is at least comparable to that of SNS.

CONCLUSION

From the literature, overlapping sphincteroplasty can achieve satisfactory long-term results, and, at the moment, they are at least comparable to SNS. Repeat sphincteroplasty may be performed and should be considered as the treatment of choice in the case of failure of previous sphincter repair. Sacral Nerve Stimulation is an effective,

fascinating but expensive technique which should be offered to patients who have failed a previous surgical attempt to repair the sphincter.

Abstract

The intestinal mucosa is responsible for the absorption of nutrients from the lumen and for the separation of the potentially toxic luminal content (external environment) from the host (internal environment). Disruption of this delicate balance at the mucosal interface is the basis for numerous (intestinal) diseases. Experimental animal studies have shown that gut wall integrity loss is involved in the development of various inflammatory syndromes, including post-operative or post-traumatic systemic inflammatory response syndrome, sepsis, and multiple organ failure. Assessment of gut wall integrity in clinical practice is still a challenge, as it is difficult to evaluate the condition of the gut non-invasively with currently available diagnostic tools. Moreover, non-invasive, rapid diagnostic means to assess intestinal condition are needed to evaluate the effects of treatment of intestinal disorders. This review provides a survey of non-invasive tests and newly identified markers that can be used to assess gut wall integrity.

COMPOSITION OF THE GUT WALL

The gut wall forms a physical/anatomical and immunological barrier. The physical/anatomical barrier of the gut is formed by a monolayer of epithelial cells, originating from multipotent stem cells present in the crypt. The epithelial cells, together with the lamina propria, form the mucosa of the intestine[1,2]. The epithelial stem cells differentiate into four major epithelial cells: (1) the absorptive enterocytes, which make up > 80% of all small intestinal epithelial cells; (2) the goblet cells, which produce a variety of mucins and trefoil peptides; (3) the enteroendocrine cells, which export peptide hormones; and (4) the Paneth cells, which secrete a wide variety of antimicrobial peptides.

Tight junctions (TJ) are the major complexes responsible for the adherence of intestinal epithelial cells to one another and in this context are an important part of the intestinal barrier[3] (Figure 1). Multiple proteins build up TJ: occludins and members of the claudin family are the major sealing proteins. The sealing proteins interact with cytoplasmic proteins, including zonula-occludin proteins, functioning as adaptors between the TJ pro-

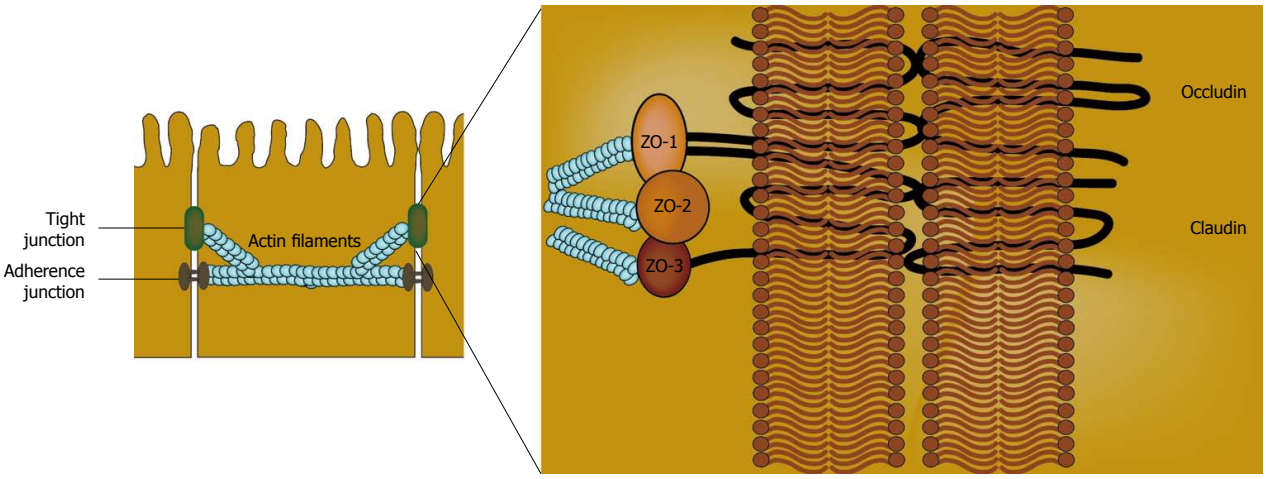

Figure 1 Composition of tight-junctions [in green (left) and in detail (right)] between neighbouring enterocytes (in yellow).

teins and actin and myosin contractile elements within the cells[3]. Breakdown of this barrier potentially leads to translocation of luminal antigens, microbiota, and their toxic products into the circulation. The layers next to the mucosa, the submucosa, muscularis and serosa, are not in direct contact with the lumen. Injury of these layers can result in passage of the luminal content into the abdominal cavity, which is a serious complication.

Next to the physical/anatomical barrier, there is also an immunological barrier. The intestinal epithelium is not merely a static barrier, but participates in immunosurveillance[1,2]. Enterocytes are considered to actively participate as innate immune sensors of microbial pathogens and commensal organisms[4]. Host recognition of microbial components is achieved by so-called pattern recognition receptors (PRRs), such as the NOD-like and Toll-like receptors. Muramyl dipeptide, derived from peptidoglycan, is present in the cell wall of virtually all bacteria and is recognized by NOD2, a PRR expressed in intestinal epithelial cells, including Paneth cells[4]. Crypt Paneth cells secrete defensins, which are antimicrobial peptides, into the villous crypt, maintaining its sterility. Moreover, we recently reported that Paneth cells are equipped with the molecules that recognize and signal endotoxin, one of the most potent immunostimulatory products derived from Gram-negative bacteria[5]. Continuous antimicrobial protection of the crypt is of crucial importance, as the pluripotent stem cells are located there. Damage to stem cells has severe consequences for the maintenance of the homeostasis of normal gut epithelium[6]. Goblet cells secrete mucus, a composition of glycoproteins and water, which provides a filter overlying the intestinal epithelium. Additionally, goblet cells secrete trefoil peptides, small proteins needed for epithelial growth and repair. Furthermore, gut-associated lymphoid tissue is present in the lamina propria and provides immune surveillance. Sampling of luminal antigens occurs by M-cells and dendritic cells, which present antigens to T and B cells, thereby inducing an effector immune response. This response includes secretion of large amounts of IgA by plasma cells. This secretory IgA covers the mucosal surface and has a major role in excluding antigens from passing the epithelium[1,2].

MARKERS OF GUT WALL INTEGRITY

Intestinal permeability

Intestinal permeability is frequently assessed using oral ingestion of small to large-sized probe molecules and measurement of their urinary excretion[7,8]. Large molecules are thought to traverse the epithelium by paracellular pathways *via* tight junctions between the enterocytes. Permeability of the tight junctions presumably increases in diseased or damaged mucosa, resulting in increased absorption of large molecules. Small molecules are postulated to pass predominantly by transcellular pathways through aqueous pores in the enterocyte membranes that are too small to permit the passage of large molecules. The ratio of urinary excretion of the relatively large molecule is compared with that of the relatively small molecule. When a large and small molecule are combined in the test solution at a fixed concentration ratio, the effects of variables, such as gastric emptying, intestinal transit time, and renal clearance will apply equally to both. Thus, the urinary excretion ratio of these two molecules is expected to be influenced only by the difference in gut permeability for each molecule.

Disaccharides (lactulose) or Poly-ethylene-glycol (PEG)-3350 are frequently used as orally ingested large molecules, while monosaccharides (mannitol, L-rhamnose) or PEG-400 are used as small molecular probes[8]. Subsequently, the renal excretion of the two probes is monitored over a defined interval (mostly 5 h), and permeability is then expressed as the quotient (ratio) of the urinary recovery of the large molecule divided by the small molecule[8]. It is assumed that the probes used are non-fermentable by bacteria in the gastrointestinal lumen and that they are not metabolized in the body. These molecules are also supposed to be excreted in urine in proportion to the amount that has been absorbed through the intestinal mucosa[8]. Thus far, contrasting results have been reported for intestinal permeability tests using dual probe molecules in several studies[7,9]. This is mainly attributed to a number of assumptions that have to be made to interpret the test-results[8,9]. In particular, pathways of intestinal permeation of the different molecules

and the mechanisms by which permeability is altered are as yet incompletely understood.

Translocation of bacteria and their products

Breakdown of the mucosal barrier potentially leads to translocation of microbiota or their toxic products. Two promising plasma markers, reflecting translocation of bacteria or their products, are D-lactate and endotoxin lipopolysaccharide (LPS), which are metabolic products or components of the commensal bacteria of the gastrointestinal tract. D-lactate is only produced by bacteria as a product of bacterial fermentation[10]. Baseline levels of D-lactate in healthy subjects are very low. Increased levels of D-lactate have been correlated with conditions in which the number of bacteria elevates rapidly, including in patients with bacterial overgrowth due to infection, short bowel syndrome, and mesenteric ischaemia[11]. LPS, the major constituent of the outer membrane of Gram-negative bacteria, is released by Gram-negative bacteria when replicating or dying. Increased circulating LPS levels have been related to an impaired mucosal barrier. The presence of LPS can be measured directly in blood, e.g. by the Limulus Amoebocyte Lysate assay[12]. In addition, anti-LPS antibodies can be measured by endotoxin-core antibody (EndoCAb), an indirect measurement of LPS leakage into the circulation[13]. A drop in levels of circulating anti-LPS antibodies is considered to indicate consumption of antibodies to LPS by exposure to LPS[14].

Transmural damage

Any part of the gastrointestinal tract may undergo damage to all layers of the GI wall from a variety of causes, releasing gastric or intestinal contents into the peritoneal cavity, which can cause peritonitis. Symptoms develop suddenly, with severe pain followed shortly by signs of (septic) shock. If a perforation is noted, immediate surgery is necessary, because mortality from peritonitis increases rapidly. The diagnosis of transmural damage (i.e. perforation) of a gastrointestinal organ usually depends on the detection of free intraperitoneal air, which is most often located in the right subphrenic space. Traditionally, a chest X-ray and a plain abdominal X-ray in the upright position, or, more recently, ultrasonography, are the diagnostic tools used to detect free air. However, the sensitivity of these tools is < 80%. Currently, a computed tomography scan is sometimes performed, which can detect free intraperitoneal air as well as small fluid collections and subtle tissue-infiltration at different locations.

Splanchnic perfusion

Numerous clinical conditions are accompanied by a reduced splanchnic blood flow, including vascular disease, major surgery, and various types of shock. Prolonged hypoperfusion of the splanchnic region will inevitably lead to hypoxic tissue injury. Furthermore, the splanchnic region is an important source and target of inflammatory mediators, which have a major impact on both systemic and regional blood flow and tissue function[15]. Gut mucosal perfusion can be invasively measured by gastric tonometry. Gastric tonometry assesses the pCO_2 in the gastric mucosa, taking into account that an increase in tissue CO_2 production accompanies anaerobic metabolism, signifying the effectiveness of regional splanchnic perfusion[16].

Functional enterocyte mass

Functional enterocyte mass is reflected by levels of circulating citrulline, an amino acid not incorporated into proteins[17]. Differentiated small intestinal enterocytes specifically produce citrulline from glutamine, and are responsible for the major part of the total amount of circulating citrulline[18]. Loss of small bowel epithelial cell mass results in declined circulating levels of citrulline, as is shown in haemopoietic stem cell transplant recipients suffering from severe oral and gastrointestinal mucositis following intensive myeloablative therapy[17].

Tight junctions

Currently, invasive intestinal biopsies provide the only possibility to detect tight junction breakdown. Endoscopy for biopsy is a time-consuming and invasive procedure.

In a recent translational study, using both a rat hemorrhagic shock model and a human setting of patients with active inflammatory bowel disease (IBD), the immunohistochemically visualized loss of claudin-3, the major sealing tight junction protein, from intestinal tissue resulted in the rapid appearance of this protein in the urine[19]. This was the first study to report that measurement of the status of tight junctions can be performed non-invasively (Figure 2).

Condition of enterocytes

Measurement of endogenous cytosolic enterocyte proteins in urine or plasma has been shown to be useful to estimate enterocyte damage. Fatty acid binding proteins (FABP) comprise a class of low molecular weight (14-15 kDa) cytosolic proteins found in high concentrations in tissues involved in the uptake and consumption of fatty acids. Three isoforms of FABP are present in the intestine: intestinal (I)-FABP, liver (L)-FABP, and ileal-bile acid binding protein (I-BABP)[20]. I-FABP, L-FABP, and I-BABP are in particular highly expressed in cells present on the tops of the villi. The presence of FABP on the tops of the villi, the initial site of destruction in numerous intestinal diseases, makes circulating FABP potentially useful plasma markers in early stages of intestinal diseases. The kidneys remove approximately 30% of FABP in a single pass, leading to a calculated FABP half-life of 11 min[21]. This emphasizes that FABP is an accurate marker for actual cell damage and that assessment of the urinary concentration is potentially useful in reflecting enterocyte damage, as FABP are rapidly cleared by the kidneys. Especially in neonates and children, this is a great advantage, as blood collection for diagnostic purposes is traumatic for children and a major cause for anaemia in neonates. Intestinal FABP (I-FABP) is primarily limited to mature enterocytes of the small and large intestine[20,22,23]. It circulates in low amounts in the blood stream of healthy individuals. I-FABP is a useful plasma/urinary marker for early enterocyte cell death and levels rise rapidly after episodes of acute intestinal ischaemia and inflamma-

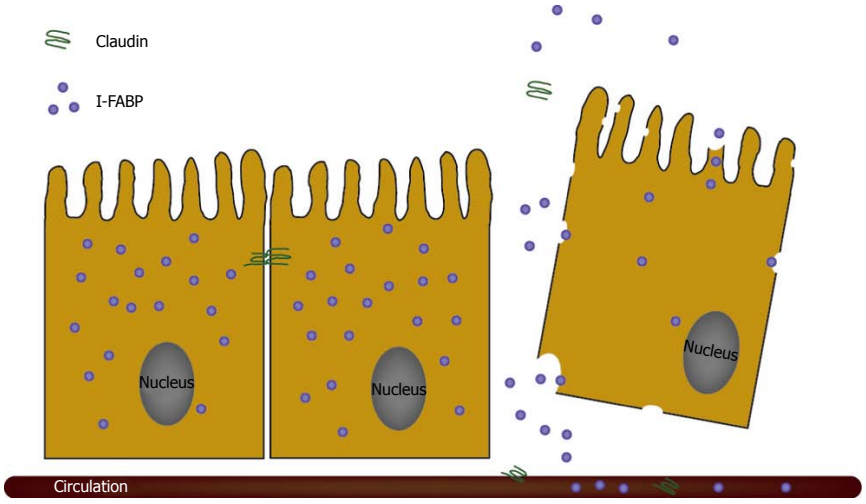

Figure 2 Leakage of fatty acid binding proteins and claudin, reflecting the condition of the epithelial layer of the gut.

tion[20,22,24,25] (Figure 2). The level of circulating I-FABP has been reported to correlate with the histological status of the epithelium after intestinal ischaemia-reperfusion in experimental studies[25,26]. A second gut-specific FABP is Ileal-Bile Acid Binding Protein (I-BABP), which is exclusively present in mature enterocytes of the jejunum and ileum[27]. Enterocytes also contain Liver-FABP (L-FABP), which is localised in the mature enterocytes of the small and large intestine, but is more abundantly present in the liver and to a lesser degree in tubular cells of the kidney[20,23]. Increased circulating and/or urinary L-FABP levels can therefore be derived from other organs than the intestine. Next to FABP, Glutathione S-Transferases (GST) are a family of more or less tissue specific cytosolic enzymes. These proteins are involved in the detoxification of xenobiotic compounds by conjugation to glutathione and grouped into species-dependent families based on their isoelectric point[28]. Alpha and pi GST are found in the small and large intestine[29]. However, these proteins are not organ-specific, as they are also expressed in liver and kidney[30]. Plasma levels of alpha GST are elevated upon ischaemic intestinal damage[31]. In conclusion, I-FABP and I-BABP are the most promising endogenous enterocyte proteins (markers) to assess enterocyte injury, as these proteins are specifically expressed in the gut and released immediately into the circulation upon cell damage.

IMMUNOLOGICAL COMPONENTS OF THE GUT WALL

Gut wall inflammation

A broad range of pathologies can lead to intestinal inflammation: neoplasia, IBD, infections, autoimmune diseases (e.g. celiac disease), ischaemia-reperfusion, intestinal hypoperfusion, and e.g. the use of non-steroidal anti-inflammatory drugs. Generally, defects or increased permeability of the mucosal barrier will cause intestinal inflammation in response to the enormous number of bacteria present in the bowel. Recruitment of leukocytes into the intestinal wall is important in the pathogenesis of intestinal inflammation[32]. Activated neutrophils infiltrate the mucosa and their products can be detected in faeces due to release into the intestinal lumen. Obviously, changes in neutrophil release products can also be detected in plasma/serum, but plasma/serum levels are also increased by various conditions other than gut inflammation. Therefore, faecal markers of neutrophils are specific for the detection of inflammatory intestinal diseases. Numerous neutrophil derived proteins present in stool have been studied, including calprotectin, lactoferrin, and elastase[32]. The most promising marker is calprotectin, because of its remarkable resistance to proteolytic degradation and its stability in stool kept at room temperature for at least seven days[33].

Calprotectin, also known as MRP-8/MRP-14 or S100A8/A9 complex, is a 36 kDa calcium and zinc binding heterodimer protein that plays a regulatory role in the inflammatory process. It constitutes about 60% of the soluble proteins in human neutrophilic cytosol and is also found in monocytes, macrophages, and ileal tissue eosinophils. It is released during cell activation or cell death and has antiproliferative, antimicrobial, and immunomodulating functions[32,33].

Faecal calprotectin is nowadays used in clinical practice to evaluate disease activity in the follow-up of patients treated for active IBD[32]. It was found that faecal calprotectin levels correlated well with endoscopic, as well as histological, disease activity of patients with IBD[32]. Moreover, recent studies showed that normalisation of calprotectin levels in patients with established IBD is a strong indicator of mucosal healing. Furthermore, several studies showed that calprotectin was a very sensitive detection marker of inflammation in patients with inflammatory bowel disease (IBD, Crohn's disease, and ulcerative colitis) compared with healthy controls and patients with irritable bowel syndrome, though not a specific marker, as increased levels were also found in neoplasia, infections, and polyps[32]. Bunn *et al*[34] confirmed these results on calprotectin levels in children with IBD. Carroll *et al*[35] stated that faecal calprotectin might be a useful marker of gastrointestinal mucosal inflammation in neonates in a pilot

study comparing seven patients with proven necrotising enterocolitis (NEC) with seven healthy peers. This is supported by our recent results[36].

CLINICAL IMPORTANCE OF GUT WALL INTEGRITY

Early diagnosis and follow-up of intestinal damage in clinical medicine

Evaluation of intestinal pathology in patients of all age groups has long been a challenge for clinicians. Numerous patients present with abdominal complaints, which are frequently aspecific and therefore correspond to pathologies of most intra- and even to some extra-abdominal organs. Laboratory tests and imaging techniques are often helpful in revealing disorders of organs, including the liver, pancreas, heart, and kidneys. However, it is still difficult to diagnose intestinal pathology in patients presenting with abdominal complaints[37]. The current standard technique for assessing intestinal status is endoscopy with biopsy. For some diseases this is helpful; however, it is invasive, associated with morbidity, sometimes requires sedation, expensive, and only assesses the function of the biopsied fraction. Moreover, for neutropenic and/or thrombocytopenic patients, the procedure is physically hazardous and often ethically unacceptable. Therefore, a major delay in diagnosis occurs in patients with e.g. NEC, chemotherapy-induced mucositis, acute mesenteric ischaemia, and celiac disease[37,38]. Such a diagnostic delay results in delayed treatment, which is accompanied by higher morbidity and mortality rates. In line with these diagnostic concerns, the follow-up of numerous intestinal diseases is hampered by the absence of rapid, non-invasive diagnostic means to assess intestinal damage for evaluation of the effects of treatment on the recovery of the disorder[37].

Potential involvement of the gut in the development of postoperative or posttraumatic complications

Patients undergoing major surgery or sustaining severe trauma are at risk of developing morbidity and mortality from post-operative or post-traumatic systemic inflammatory response syndrome (SIRS), sepsis, and multiple organ failure (MOF). Development of such potentially lethal complications in relatively healthy surgical or trauma patients is poorly understood[7]. Experimental animal studies have generated the hypothesis that the intestines are central in the origin of post-operative and post-traumatic sequelae[39-41]. Human studies have contributed insufficiently to gain insight in the applicability of this hypothesis[7]. Recognition of patients at risk of developing post-operative or post-traumatic SIRS, sepsis, and MOF is important, as patients with these clinical syndromes have the highest noncardiac mortality rate of patients in the intensive care unit (ICU)[39-42].

Experimental animal models, resembling the clinical situation of major surgery and trauma, show that haemorrhagic shock leads to disruption of the gut wall integrity, measured by derangement of tight-junctions and elevated circulating levels of FABP, originating from damaged intestinal epithelial cells[43,44]. Moreover, leakage of macromolecules, microbial products, and microbiota from the intestinal lumen into the circulation and mesenteric lymph nodes, spleen, and liver occurs[44]. The inflammatory response to microbial products, such as endotoxins, has been reported to be provoked *via* various rapidly induced innate immune mechanisms, ranging from Toll Like Receptors to complement activation. Supportive of the importance of the gut in the development of postoperative complications is the observation that protection of the gut wall integrity in hemorrhagically shocked animals by administration of probiotic strains, which inhibit the adhesion of enteric pathogens to intestinal epithelial cells, can result in abrogation of both local and systemic inflammatory responses[45]. However, administration of probiotic strains might also have unwanted side-effects, including disruption of intestinal tight junctions and increase of bacterial translocation[46].

Studies in patients undergoing major gastrointestinal, cardiac, or vascular surgery, investigating the role of the gut in the development of post-operative complications, are largely restricted to data on increased intestinal permeability for sugars, ^{51}Cr-ethylenediaminetetraacetic acid (^{51}Cr-EDTA), and the circulatory levels of endotoxin[14,47-49]. Increased intestinal absorption of sugars or ^{51}Cr-EDTA, indirect measures for gut barrier loss, in patients following major surgery support data obtained from animal studies, indicating that the gut barrier is injured after major surgery[14,48-50]. However, other reports show no changes in intestinal permeability[51]. Moreover, the value of measuring gut integrity with sugar probes is debatable[8,9]. Similar results are reported on the development of endotoxemia. Several authors report on increased circulating levels of endotoxin or reduced values of anti-endotoxin antibody during major surgery, suggesting leakage of gut derived bacterial products from the gut lumen into the circulation due to an impaired epithelial barrier, whereas others show unaltered endotoxin concentrations[49,52]. Data showing better survival in patients with pre-operatively higher anti-endotoxin titres support the theory of intestinal contribution in the development of postoperative complications[53]. In conclusion, the debate regarding involvement of the gut in patients undergoing major surgery is still ongoing.

Three recent studies show the temporary presence of intestinal villous cell damage, measured by increased urinary levels of I-FABP, in patients undergoing cardiovascular surgery with cardiopulmonary bypass (CPB)[54-56]. Patients with high urinary I-FABP levels developed postoperative gastro-intestinal complications[54]. The use of CPB was shown to be responsible for alterations in blood flow with consequent intestinal mucosal hypoxia and villous tip ischaemia[55,56]. Furthermore, intestinal injury correlated positively with markers of systemic inflammation. We recently reported, in patients undergoing major non-abdominal surgery, a similar influence of reduction in blood pressure on the provocation of intestinal villous cell

injury, without the use of extracorporeal circulation[57]. A significant inverse association between mean arterial pressure and succeeding plasma levels of I-FABP and I-BABP was found, which indicates that systemic hypotension is correlated with intestinal mucosal cell injury. Anaesthetics, leading to decreased systemic vascular resistance, mainly cause systemic hypotension. Finally, splanchnic hypoperfusion (measured by gastric mucosal $PiCO_2$ and $P_{r-a}CO_2$-gap) correlated strongly with intestinal mucosal damage (assessed by plasma I-FABP) at all observed time-points during surgery[57].

In conclusion, the results of these studies show, for the first time, the relation between altered splanchnic perfusion and the development of intestinal mucosal cellular damage in patients undergoing major surgery. Collectively, these findings shed new light on the potential role of intestinal barrier compromise during major surgery, which was deduced from numerous animal studies, but has now been reported, for the first time, in relatively healthy children and adolescents undergoing major (non-abdominal) surgery. Furthermore, these results indicate a need to re-examine currently accepted criteria of haemodynamic parameters, both regarding the use of extra-corporeal circulation and accepted systemic hypotension, in patients undergoing major surgery.

The presence of intestinal damage does not show any cause-and-effect relationship with the development of sepsis or MOF. Moreover, intestinal damage may be part of more generalised tissue damage with epithelial barrier dysfunction in lung, liver, and kidney[7]. These studies are, however, the basis for further research to clarify the onset of intestinal damage. In addition, assessment of intestinal epithelial damage in patients with sepsis or undergoing major surgery might have important clinical implications. Evaluation of intestinal epithelial cell damage as a consequence of splanchnic hypoperfusion, could help to monitor preoperative treatment or therapy in patients with shock directed at restoration of peripheral perfusion and prevention of organ damage.

FUTURE DIRECTIONS

Relatively new markers for gut wall integrity (including FABP, claudin-3, and calprotectin) might be useful in the early diagnosis of intestinal diseases. The implementation of these markers in daily clinical practice seems only a matter of time. In addition, these markers are used nowadays to unravel the involvement of the gut in patients undergoing major surgery or sustaining major trauma or sepsis. These results led to studies aimed at re-examining accepted criteria of preoperative haemodynamic parameters, both regarding the use of extra-corporeal circulation and accepted systemic hypotension in patients undergoing major surgery[56,57]. We strongly believe that I-FABP can be used as a clinical marker of intestinal hypoperfusion. First of all, there is a strong correlation between gastric mucosal $PiCO_2$ and circulating levels of I-FABP, in patients with postoperative sepsis who were admitted to the ICU[42]. Splanchnic hypoperfusion in the early phase of abdominal sepsis correlated strongly with intestinal mucosal damage. Moreover, elevated plasma I-FABP values on admission to the ICU were associated with a poor outcome in patients with abdominal sepsis. In children with meningococcal sepsis, it was shown that almost half of the patients presented with intestinal epithelial cell damage, shown by increased plasma I-FABP values, at admission to the paediatric ICU. The children who died were characterised by continued presence of gut damage, while in all survivors this injury came to an end within 12 h after starting intensive treatment[58]. A significant proportion (93%) of adult trauma patients rapidly developed intestinal mucosal cell damage, measured by elevation of plasma I-FABP values[59]. The extent of intestinal damage was readily detectable in blood withdrawn on presentation at the emergency department (ER). Interestingly, the highest 10% of I-FABP values at ER belonged to patients with severe abdominal trauma that required acute surgical intervention, such as ruptures of the diaphragm, liver, and spleen. Circulatory concentrations of enterocyte damage marker I-FABP were related to the presence of shock and the extent of general injury, as well as abdominal trauma, indicating that the level of intestinal cell damage was determined by both systemic and local factors. Moreover, early I-FABP values correlated positively with the inflammatory response that developed in the days following trauma[59].

In conclusion, evaluation of intestinal tissue damage in the early phase of sepsis is an adequate predictor for survival. Furthermore, the adequacy of treatment of circulatory failure in sepsis is currently monitored using indirect parameters of (peripheral) tissue perfusion and oxygenation, including blood pressure, urinary output, metabolic status (lactate, base deficit) skin temperature, $ScvO_2$, and capillary refill time. However, these parameters do not reflect the actual defects in (peripheral) tissue perfusion and subsequent tissue damage. Assessment of plasma I-FABP levels offers the possibility to monitor the presence of intestinal epithelial cell damage as a consequence of splanchnic hypoperfusion, which could help to monitor treatment directed at restoration of peripheral perfusion and prevention of organ damage. Further studies are needed to clarify the diagnostic potential of assessment of plasma I-FABP in monitoring the treatment of sepsis in the acute phase and during follow-up.

Abstract

Nonalcoholic fatty liver disease (NAFLD) is a disease in which excessive fat accumulates in the liver of a patient without a history of alcohol abuse. This disease includes simple steatosis and nonalcoholic steatohepatitis (NASH). NAFLD/NASH is recognized as a hepatic manifestation of metabolic syndrome. In recent years, pediatric NAFLD has increased in line with the increased prevalence of pediatric obesity. The estimated prevalence of pediatric NAFLD is 2.6%-9.6%, and it is associated with sex, age, and ethnicity. With regard to the pathogenesis of NAFLD, the "two-hit" hypothesis is widely accepted and oxidative stress is thought to play an important role in the second hit. Although clinical symptoms, laboratory data, and imaging findings are important, liver biopsy is regarded as the gold standard for the diagnosis of NAFLD/NASH. In addition, liver biopsy is essential for assessing the degree of necro-inflammatory change and fibrosis in NASH. Two different types of steatohepatitis (type 1 and type 2 NASH) have been reported, with type 2 NASH being present in as many as 51% of pediatric NAFLD patients. However, we and others have observed that type 1 and 2 patterns commonly overlap. Although pharmacotherapy has been studied in clinical trials, lifestyle modification by diet and exercise remains the mainstay of treatment for NAFLD/NASH.

INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is a disease in which excessive fat accumulates in the liver of a patient without a history of alcohol abuse. There are two types of NAFLD: simple steatosis, demonstrating only fat deposition in hepatocytes, and nonalcoholic steatohepatitis (NASH), demonstrating not only steatosis but also a necro-inflammatory reaction. NASH can progress to liver cirrhosis and result in complications that include hepatocellular carcinoma[1]. NAFLD/NASH is recognized as a hepatic manifestation of metabolic syndrome[2], and elements of metabolic syndrome, such as central obesity, type 2 diabetes, hypertension, and hypertriglyceridemia, are well-known risk factors for NAFLD[3-5].

In recent years, pediatric NAFLD has increased in line with the increased prevalence of pediatric obesity and has become an important worldwide health problem. Pediatric NAFLD has different histological characteristics

from those of adult NAFLD[6]. In this article, we outline the epidemiology, pathogenesis, diagnosis, histological features, and treatment of pediatric NAFLD.

EPIDEMIOLOGY

Approximately 20% of adults are estimated to have NAFLD, and 2%-3% of adults have NASH[7]. On the other hand, in children and adolescents, researchers from America[8] and Asia[9,10] estimate that the prevalence of NAFLD is 2.6%-9.6%. These data, however, must be interpreted carefully because the diagnostic criteria of NAFLD adopted in these studies are diverse and the accurate diagnosis of NAFLD and NASH requires histological evaluation, which is impossible to obtain for all subjects in population-based studies. Studies from Europe[11-13], Asia[14-16], and America[8] estimate that the prevalence of NAFLD among overweight or obese children and adolescents is 24%-77%. Despite the diversity of diagnostic criteria used in these studies, obesity is thought to be an important risk factor for pediatric NAFLD.

NAFLD is consistently more prevalent in boys than in girls[17] suggesting that sex hormones are associated with the occurrence of pediatric NAFLD. NAFLD is more prevalent in adolescents than in younger children[8] and sex hormones and insulin resistance in puberty may be the cause of this. The rate of NAFLD in African American children is lower than in Hispanic and Caucasian children, despite African American children being prone to having risk factors for NAFLD, such as obesity, insulin resistance, and diabetes[17].

PATHOGENESIS

The "two-hit" hypothesis proposed by Day *et al*[18] is widely accepted as the pathogenesis of NAFLD/NASH; the first hit causes fat accumulation in hepatocytes, and the second hit causes inflammation and fibrosis. Fat accumulation in the liver is closely associated with metabolic derangements that are related to central obesity and insulin resistance. Fat accumulation can be caused by the increased delivery of free fatty acids to the liver, disordered metabolism of fatty acids by hepatocytes, or increased *de novo* synthesis of fatty acids and triglycerides[19-21].

Oxidative stress is thought to play an important role in the second hit by causing peroxidation of lipids that accumulate in hepatocytes. The cause of oxidative stress is the overproduction of reactive oxygen species (ROS) by induction of CYP 2E1 in the liver, mitochondrial dysfunction, and so on[22,23]. Peroxidation of lipids causes mitochondrial dysfunction and results in the overproduction of ROS, thus forming a vicious cycle[24-27]. The immune response toward lipid peroxidation products has been associated with the progression of NAFLD[28]. Other changes that can mediate liver inflammation include an increase in inflammatory cytokines such as tumor necrosis factor-α and a decrease in anti-inflammatory cytokines such as adiponectin[2,29].

DIAGNOSIS

To diagnose NAFLD, the exclusion of other liver diseases such as hepatitis B and C, autoimmune hepatitis, drug-induced liver injury, Wilson's disease, and α1-antitrypsin deficiency is necessary. Pediatric NAFLD is often asymptomatic; however, patients may occasionally complain of abdominal pain, fatigue, or malaise[30-32]. Hepatomegaly is often observed on physical examination, although this finding may be missed in clinical practice[33]. Acanthosis nigricans (black pigmentation at skin folds or axillae that is associated with hyperinsulinemia) has been reported in up to 50% of pediatric NASH cases[30,34]. A family history of NAFLD should be referred to because familial clustering is often detected[35]. Increased serum levels of aspartate aminotransferase and alanine aminotransferase (ALT) are predictors of the existence of NAFLD/NASH; however, normal serum levels of these aminotransferases do not exclude the existence of NAFLD/NASH. Although an elevated ALT and/or an enlarged echogenic liver, as revealed by ultrasonography, in the setting of overweight or obesity and/or evidence of insulin resistance are highly suggestive of NAFLD, histological evaluation remains the only means of accurately assessing the degree of steatosis, necro-inflammatory change, and fibrosis found in NASH and in distinguishing NASH from simple steatosis[36]. In addition, liver biopsy is useful in differentiating NAFLD from other liver diseases. Because pediatric NAFLD has different histological characteristics compared to adult NAFLD, careful histological evaluation is necessary.

Liver biopsy is regarded as the gold standard for the diagnosis of NAFLD/NASH; however, this procedure has some problems, such as high risk, high cost, and sampling error. Therefore, it is necessary to develop improved noninvasive methods for accurate screening and diagnosis. Currently, ultrasonography, computed tomography (CT), and magnetic resonance imaging (MRI) are the imaging modalities generally used for the evaluation of hepatic steatosis. Although ultrasonography has some merits such as widespread availability, lack of radiation, and relatively low cost, it also has some demerits such as operator dependence, subjectivity in interpretation, unclear images in severely obese patients, and inability to detect mild hepatic steatosis. CT is not favored for use in children because it uses ionizing radiation. MRI appears to be a more accurate and reproducible method[37]. In addition, because MRI is not subject to interpretation or interobserver variation, it may be better than ultrasound for quantifying hepatic fat in children[38-40]. However, neither CT nor MRI can judge low-grade fibrosis. Ultrasound elastography and magnetic resonance elastography have been developed as modalities to measure liver stiffness which is a surrogate marker of liver fibrosis. Investigations are needed to determine the usefulness of these modalities in diagnosing pediatric NAFLD.

HISTOLOGY

The histological characteristics of pediatric NAFLD/

NASH differ from those of adult NAFLD/NASH. Schwimmer *et al*[6] examined the histological appearance of 100 pediatric NAFLD cases and identified two different types of steatohepatitis. Type 1 NASH was consistent with NASH as described in adults and was characterized by steatosis, ballooning degeneration, and/or perisinusoidal fibrosis in the absence of portal changes. Type 2 NASH was a peculiar histological pattern in children and was characterized by steatosis, portal inflammation, and/or portal fibrosis in the absence of ballooning degeneration and perisinusoidal fibrosis. Type 1 NASH was reported to be present in only 17% of pediatric NAFLD, whereas type 2 NASH was present in 51%. Simple steatosis was present in 16% of subjects. Advanced fibrosis was present in 8% and liver cirrhosis was present in 3%. In cases of advanced fibrosis, the pattern was generally that of type 2 NASH. Children with type 2 NASH were significantly younger and had a greater severity of obesity than children with type 1 NASH. Boys were significantly more likely to have type 2 NASH and less likely to have type 1 NASH than girls. Type 2 NASH was more common in children of Asian, Native American, and Hispanic ethnicity. Type 1 and type 2 NASH may have a different pathogenesis, natural history, and response to treatment. It is currently unclear whether type 2 NASH changes to type 1 NASH as the patient ages.

Subsequently, Nobili *et al*[41] reported that type 1 NASH was present in only 2% of their 84 pediatric NAFLD subjects and type 2 NASH was present in 29%. The combination of both types was present in 52% of their pediatric NAFLD subjects, and simple steatosis was present in 17%. Accordingly, the overlap of type 1 and 2 was the most common pattern in their study. The discrepancy between the results of these studies may reflect the different ethnicity of subjects, which were mainly Hispanics and Asians in the study by Schwimmer *et al*[6] and were all Caucasians in the study by Nobili *et al*[41].

We compared the histological appearance of needle biopsy specimens from 34 pediatric and 23 adult NAFLD cases in Japan (unpublished data) and found that steatosis tended to be more severe in children as compared to adults (Figure 1A). Perisinusoidal fibrosis was significantly less frequent in children than in adults and intralobular inflammation and ballooning degeneration tended to be milder in children as compared to adults. Although portal inflammation tended to be more severe in children than in adults (Figure 1B), there was no obvious difference in the degree of portal fibrosis between the two groups. Type 2 NASH was present in 21% of pediatric subjects and in 9% of adult subjects. Accordingly, we confirmed that pediatric NAFLD had different histological characteristics from those of adult NAFLD in Japanese patients also. However, we found that the prevalence of type 2 NASH in pediatric subjects was less than that in the study by Schwimmer *et al*[6] and that the overlap of type 1 and 2 patterns was common as noted by Nobili *et al*[41].

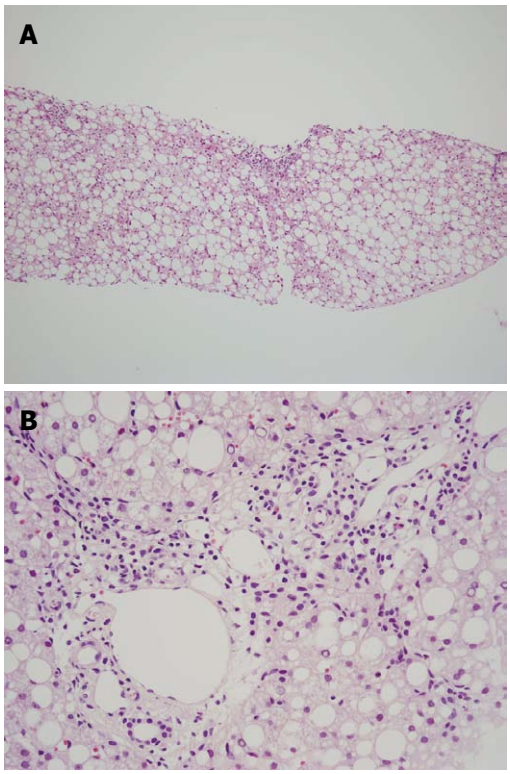

Figure 1 Histological appearance of a case of pediatric nonalcoholic fatty liver disease. A: Marked steatosis with panlobular distribution is observed (HE stain, × 40); B: Moderate inflammation is observed in the portal area (HE stain, × 200).

SPECULATED FACTORS THAT SEPARATE PEDIATRIC NAFLD AND ADULT NAFLD

The abovementioned histological differences between pediatric and adult NAFLD might reflect different etiological factors between them. In a study of morbidly obese adults undergoing bariatric surgery, portal inflammation was reported in 24%[42]. In a study of adult NAFLD subjects, which was composed of mainly male patients, portal inflammation and portal fibrosis were observed in 63% and 6% of patients, respectively[43]. Thus, it is conceivable that adult NAFLD patients, especially severely obese patients and male patients, may also show a pediatric-type histological pattern. As mentioned above, NAFLD is consistently more prevalent in boys than in girls[17], and type 2 NASH was more common in severely obese children and boys in the study by Schwimmer *et al*[6]. Accordingly, obesity and sex hormones might be critical etiological factors in pediatric NAFLD. In our histological investigation, steatosis tended to be more severe in pediatric NAFLD than in adult NAFLD, and its distribution was not restricted to zone 3 in many pediatric cases (unpublished data). Recently, we found that administration of fructose- or sucrose-enriched diet to Wistar rats induces hepatic steatosis that is mainly dis-

tributed in zone 1 (unpublished data). It is conceivable that inappropriate food consumption, especially excessive drinking of sweet beverages, might be an important cause of pediatric NAFLD; thus, the rat model might be a good model of pediatric NAFLD.

TREATMENT

Obesity, hyperlipemia, insulin resistance, and hyperglycemia are well-known risk factors for NAFLD and oxidative stress is thought to be important in the progression from simple steatosis to NASH. Reducing the risk from these factors is considered to be an effective treatment for NAFLD. The main targets of therapy are normalization of the serum ALT level and improvement in histopathology as shown by biopsy. Lifestyle change (diet and exercise) and pharmacotherapy have been studied.

Diet and exercise

Most children with NAFLD are overweight or obese, and weight loss is thought to be an effective preventative measure and/or treatment for pediatric NAFLD. In fact, lifestyle modification remains the mainstay of treatment for NAFLD of obese children. Gradual weight loss by diet and proper exercise has been shown to improve serum aminotransferase levels and liver histology of adult patients with NAFLD[44-46]. In a study of pediatric NAFLD subjects, moderate weight loss by lifestyle intervention lowered serum aminotransferase levels and improved hepatic steatosis, lobular inflammation, and hepatocyte ballooning; however, the degree of fibrosis did not change[47]. Based on the pathogenesis of NAFLD, an appropriate diet for NAFLD treatment is thought to be a low-glycemic index diet. Very rapid weight loss by excessive caloric restriction is not recommended because it may increase dysmetabolism and liver inflammation and fibrosis[48].

Vitamin E

Because oxidative stress plays a pivotal role in the pathogenesis of NASH, administration of antioxidants, such as vitamin E, is expected to be an effective therapy for NASH. In an open-label study, a 2-4 mo treatment with vitamin E (400-1200 IU/d orally) normalized serum aminotransferase levels in obese children with NASH but did not improve steatosis on ultrasonography, and serum aminotransferase returned to abnormal levels when the treatment was stopped[49].

Insulin sensitizers

Most children with NAFLD have insulin resistance, and therefore, insulin sensitizers may be an effective treatment for this disease. Metformin has been used successfully for improving insulin resistance and possibly liver histology in adults[50,51]. In addition, the efficacy and safety of metformin in the treatment of pediatric type 2 diabetes has been confirmed[52,53]. Open-label treatment with metformin for 24 wk showed notable improvement in liver chemistry, liver fat, insulin sensitivity, and quality of life in pediatric NASH patients[54]. Pioglitazone has been reported to improve biochemical and histological features of adult NASH[55,56]; however, data on the safety of pioglitazone in children are currently insufficient, and future investigations are needed in order to use this drug in pediatric NAFLD.

Ursodeoxycholic acid

Ursodeoxycholic acid (UDCA) is a hydrophilic bile acid that operates as an antioxidative and cytoprotective agent. A randomized control trial (RCT) involving 31 obese children with abnormal serum aminotransferase levels, found that UDCA (10 mg/kg per day) was ineffective, both alone and when combined with diet, in reducing serum aminotransferases or the appearance of steatosis on ultrasonography[57]. Similarly, in two RCTs involving adult NAFLD/NASH, UDCA did not exert effects on liver chemistry or histology[58,59]. However, in one RCT, UDCA in combination with vitamin E improved serum aminotransferases and hepatic steatosis in NASH patients[60].

Bariatric surgery

In 2007, Furuya *et al*[61] examined the histological changes in the liver after Roux-en-Y gastric bypass surgery performed in 18 severely obese NAFLD patients. As a result, steatosis disappeared in 84%, fibrosis disappeared in 75%, and hepatocellular ballooning disappeared in 50% of patients after 2 years. These improvements were likely a function of the substantial weight loss. Although the role of bariatric surgery for NAFLD in severely obese adolescents has not been studied, this treatment may be promising.

CONCLUSION

Pediatric NAFLD has been increasing worldwide and this tendency will continue as long as pediatric obesity increases. Liver biopsy is the gold standard for the diagnosis of NAFLD; however, advances in noninvasive tests are expected. Pediatric NAFLD has different histological characteristics compared to adult NAFLD. Diet and exercise are the mainstays of treatment in NAFLD; however, advances in pharmacotherapy are expected.

Abstract

Histological analysis of liver biopsies remains a standard against which other methods of assessment for the presence and amount of hepatic injury due to nonalcoholic fatty liver disease (NAFLD) are measured. Histological evaluation remains the sole method of distinguishing steatosis from advanced forms of NAFLD, i.e. nonalcoholic steatohepatitis (NASH) and fibrosis. Included in the lesions of NAFLD are steatosis, lobular and portal inflammation, hepatocyte injury in the forms of ballooning and apoptosis, and fibrosis. However, patterns of these lesions are as distinguishing as the lesions themselves. Liver injury in adults and children due to NAFLD may have different histological patterns. In this review, the rationale for liver biopsy, as well as the histopathological lesions, the microscopically observable patterns of injury, and the differential diagnoses of NAFLD and NASH are discussed.

Key words: Fatty liver; Steatosis; Nonalcoholic fatty liver disease; Nonalcoholic steatohepatitis; Fibrosis

INTRODUCTION

Liver biopsy evaluation was the foundation for the proposals that certain individuals who do not consume excess alcohol could, in fact, suffer from a form of chronic progressive liver disease characterized by lesions that had been considered those of alcohol, namely, steatosis, ballooned hepatocytes with Mallory-Denk hyaline bodies, and the particular form of fibrosis of alcohol. Several authors had been evaluating this concept[1-5], when the seminal manuscript of Ludwig *et al*[6] was published in 1980 that described 20 subjects. Since that time, much of the progress that has been made in studies of natural history[7-12], clinical associations of histological assessments of activity and fibrosis, correlations with metabolic syndrome[13,14] and serum markers of cardio-vascular disease[15], the variability of ethnic susceptibility[16-18], and the presence of hepatocellular carcinoma in cirrhotics and non-cirrhotics with nonalcoholic fatty liver disease (NAFLD)[19-21] have occurred by evaluating liver biopsies.

The clinical and scientific needs for imaging studies and serum-based assays to "predict" the presence of steatohepatitis, fibrosis, and/or inflammation are based on a well-recognized concept that liver biopsy is invasive, potentially harmful, and may suffer from "sampling error"[22,23]. Furthermore, liver biopsy cannot be considered

a screening tool for population studies. However, it is also recognized that, imperfect as it is, liver biopsy evaluation remains the standard against which other assays and clinical algorithms must be matched, and prospectively validated.

Liver biopsy does, indeed, suffer from challenges. Many can be overcome by the realization that even an adequate biopsy represents only 1/50 000-1/65 000 of this large organ. Therefore, high quality biopsy techniques, such as utilization of appropriately sized needles[24], careful choice of sampled area, and appropriate tissue preparation and interpretation are all important considerations for liver biopsy. Pathologists recognize that wedge biopsies are inferior to appropriately-sized and placed needle core biopsies for evaluation of a diffuse parenchymal disease. In addition, there might be differences between right and left lobes of the liver, as the left lobe is relatively smaller, is covered by more capsule per unit area, and the subcapsular portal tracts can be deceptively more fibrous than those of deeper parenchyma. Differences in histopathological findings have been demonstrated in studies of bariatric patients biopsied concurrently from the right and left lobes[25]; these differences were abrogated somewhat by the use of a large bore needle in another study[24]. Adequate sample length has also been noted as a correlative factor with histological evaluation in NAFLD[26], with biopsies $\geqslant$ 1.5 cm long having a higher yield of definitive nonalcoholic steatohepatitis (NASH) diagnosis compared to those measuring < 1 cm in length (29% *vs* 56%)[26]. Small biopsies (< 1.6 cm) show higher variability for NAFLD fibrosis stage than longer biopsies[27]. It has been proposed that sampling error might be reduced by using larger gauge needles[24], obtaining longer ($\geqslant$ 1.5 cm) biopsies[28], or by taking more than one tissue core when possible[26]. Once in the laboratory, liver biopsies should not be prepared on tissue "sponges", as these create space-distorting artifacts[29]. Of at least equal, if not greater, significance, however, is pathologists' training and focus in the field. Just as one doesn't ask a non-specialized surgeon to perform cardiac bypass surgery, one should also recognize the need for trained liver pathologists. Studies in chronic hepatitis C (CHC) liver biopsy evaluation that compared the expertise of liver pathologists in academic practice with community pathologists showed this to be a potential source of discordance in histological evaluation[30]. The number of independent readings has also been shown to correlate with greater yield of findings[26].

VALUE OF LIVER BIOPSY EVALUATION IN NONALCOHOLIC FATTY LIVER DISEASE

Pro's and Con's of liver biopsy

The large series of over 350 liver biopsies done for clinically unexplained liver test elevation in adults by Skelly *et al*[31] highlights the value of liver biopsy evaluation in this setting. While two-thirds of the biopsies showed some form of nonalcoholic fatty liver disease, the remainder were either "normal" (6%) or had histopathological features of subsequently clinically confirmed liver disease, such as hereditary hemochromatosis, drug-induced liver injury, and autoimmune liver disease. Several series have now shown the lack of correlation of alanine aminotransferase (ALT) levels and both necroinflammatory activity and fibrosis, including cirrhosis, in subjects with known NAFLD[32-34], including obese children[35]. Liver biopsy evaluation is also important for a patient with a clinical suspicion of autoimmune liver disease. Up to 20% of NAFLD have positive serologies for antinuclear antibody, antismooth muscle antibody, and/or antimitochondrial antibody[36-38]; therefore, liver biopsy evaluation might be the only means of determining the underlying cause of the disease. Furthermore, surgeons have shown that intraoperative visualization is commonly not correct for the prediction of either steatosis or advanced fibrosis, and thus liver biopsy is currently being recommended in the morbidly obese bariatric population at the time of surgery[39].

The final "pro" of liver biopsy is both confirmation of the diagnosis, as well as evaluation and semiquantitation of necroinflammatory lesions and fibrosis, and evaluation of architectural remodeling. To date, noninvasive tests have shown to be effective for the extremes: either lack of, or abundance of, inflammation or fibrosis, but overall sensitivity and specificity for the lesions in between are less impressive[22]. A recently studied modification of the European Liver Fibrosis score, named the Enhanced Liver Fibrosis score, has shown the most promise in terms of predicting over 75% of adult patients who would not need a liver biopsy, regardless of stage[40]. Measurement of serum keratin 18 (K18) fragments, a marker of hepatocyte apoptosis, has emerged as a promising biomarker for NASH, with sensitivity and specificity of up to 77% and 92%, respectively[41]. Transient elastography measuring liver stiffness has been recently shown to be a useful noninvasive test to exclude advanced fibrosis in Chinese NAFLD patients, with a negative predictive value of 97%[42]. Limitations and need for further testing of this modality are reviewed[43].

The arguments against liver biopsy in NAFLD include the invasive nature of the procedure, the lack of effective treatments beyond recommendations for dietary changes, weight loss and exercise, the fact that only a minority of NAFLD patients have the progressive lesions of NASH[44], and the known improvements of diagnosis with clinically-derived tests[45,46] and imaging techniques[47]. However, at present, the final correlation for any of the new tests is liver biopsy evaluation.

HISTOLOGY OF NAFLD IN ADULTS

The histological spectrum of NAFLD includes various forms of small and large droplet macrovesicular steatosis, with or without lobular and portal inflammation, and steatohepatitis, which is characterized by steatosis, inflammation, and cell injury, i.e. NASH. Progression of fibrosis and architectural remodeling is thought to develop in 10%-15% of NASH patients, and cirrhosis

in 15%-25%. Thus, of all individuals with some form(s) of fatty liver, 3%-5% may develop cirrhosis[48]. Cirrhosis due to NASH and cryptogenic cirrhosis might both result in hepatocellular carcinoma (HCC)[19,49]. Rarely, HCC may occur in non-cirrhotic NASH[21,50].

NAFLD

The main histological characteristic of NAFLD, as its name implies, is the accumulation of fat in the form of triglycerides within hepatocytes, a lesion originally termed "steatosis" after the ancient Greek word for fat, "stear". The presence of > 5% steatotic hepatocytes in a liver tissue section is now accepted as the minimum criterion for the histological diagnosis of NAFLD[51,52].

Steatosis in NAFLD is usually macrovesicular, referring to hepatocytes with a single large intracytoplasmic fat droplet or smaller well defined droplets displacing the nucleus to the cell periphery. Mixed steatosis might also occur, when, in addition to macrovesicular steatosis, groups of hepatocytes with centrally placed nuclei and numerous minute lipid droplets in the cytoplasm are observed. Pure microvesicular steatosis, needing special stains such as Oil-Red-O to identify the intracytoplasmic material as fat, is not a common feature of NAFLD; however, small, azonal collections of hepatocytes might have this type of fat. In simple NAFLD, in addition to steatosis, foci of lobular inflammation, mild portal inflammation, and lipogranulomas may be seen. However, features of hepatocellular injury and fibrosis, indicating progression to steatohepatitis, are not observed, by definition[51].

The extent of steatosis is commonly evaluated and reported semi-quantitatively. The most reproducible method follows the acinar architecture dividing the liver parenchyma in thirds and assessing percentage involvement by steatotic hepatocytes: 0%-33% (or 0%-5%, 5%-33%)-mild, 33%-66%-moderate or > 66% - severe steatosis[53,54].

One of the distinctive features of steatosis in adult NAFLD, in contrast to most pediatric NAFLD cases, is its predilection to start in acinar zone 3 (perivenular). When steatosis is severe it can occupy the whole acinus. Steatosis might not persist during the progression of fibrosis to remodeling and cirrhosis; thus, steatosis might not be reliably identified in a cirrhotic liver[55].

Adult NASH

Most hepatopathologists agree that the minimal criteria for the histological diagnosis of adult NASH include steatosis, hepatocyte injury, usually in the form of ballooning, and lobular inflammation, typically localized in acinar zone 3. Fibrosis, as in other forms of chronic hepatitis, is not a required diagnostic feature of NASH[56-58].

Hepatocellular injury in NASH can take the form of ballooning, apoptosis, or lytic necrosis[51]. Ballooning is a feature of major importance in NASH as its presence has been associated in prognostic studies with more aggressive disease and high incidence of cirrhosis[59]. Furthermore, the presence of ballooned hepatocytes on liver biopsy has been linked with features of the metabolic syndrome[60]. Ballooned hepatocytes are enlarged, with swollen, rarefied, pale cytoplasm and, usually, show a large, hyperchromatic nucleus, often with a prominent nucleolus. They might be the result of alterations in intermediate filament cytoskeleton[61] and/or presence of microvesicular steatosis[62]. The histological recognition of hepatocellular ballooning can show significant inter-observer variation[63]. Loss of the normal hepatocyte keratins, 8 and 18, as detected by immunostaining, might help in the objective identification of ballooned hepatocytes[64].

Apoptotic (acidophil) bodies, another form of hepatocyte injury and a feature of programmed cell death, are common in NASH[65]. They can easily be identified on routine stains, but are further highlighted by immunohistochemistry for keratin 18 fragments, the same antigen that has been recently proposed as a biomarker of NASH[41,66]. The number of acidophil bodies per mm^2 of liver tissue (acidophil body index) has been proposed to serve as a complementary histological feature when diagnosis of NASH is uncertain[67].

Lobular inflammation is usually mild, and consists of a mixed inflammatory cell infiltrate, composed of lymphocytes, some eosinophils, and, occasionally, a few neutrophils. Polymorphs are occasionally observed surrounding ballooned hepatocytes in a lesion known as "satellitosis". Foci of chronic lobular inflammation, consisting mainly of lymphocytes, are occasionally seen. Scattered lobular microgranulomas (Kupffer cell aggregates) and lipogranulomas are common[57,68].

Portal chronic mononuclear cell inflammation in adult NASH is not uncommon and is usually mild. When severe or disproportionate to the acinar lesions, the possibility of concurrent CHC should be excluded[56,68,69]. In untreated NAFLD patients, increased portal inflammation has been proposed as a marker of severe disease[70], and has been correlated with the diagnosis of definite steatohepatitis[71].

Fibrosis in adult NASH usually starts in acinar zone 3 and has a characteristic "chicken wire" pattern due to deposition of collagen and other extracellular matrix fibers along the sinusoids of zone 3 and around the hepatocytes. Portal fibrosis without perisinusoidal/pericellular fibrosis has been reported in some cases of morbid obesity-related NASH[72,73] and in pediatric NASH (discussed below). In advanced disease, bridging fibrosis and cirrhosis might develop[51]. NASH-related cirrhosis is most commonly macronodular or mixed. At the cirrhotic stage, perisinusoidal fibrosis and other features of "active" disease may or may not be evident. Therefore, in the absence of a previous biopsy with NASH or other disease-specific histology, the cirrhosis may be labeled "cryptogenic". In a recent meta-analysis of ten longitudinal histological studies of NASH, presence of inflammation in the initial biopsy and age emerged as independent predictors of progression to advanced fibrosis in patients with NASH[74].

Sinusoidal collagen formation in NASH, as in other chronic liver diseases, is likely to be the result of hepatic stellate cell (HSC) activation[75,76]. The HSC activation score, as measured by alpha-smooth muscle actin immunohistochemistry, was shown to predict progression of fibrosis in NAFLD[77]. Portal fibrosis, on the other

hand, has been linked to the ductular reaction (i.e. ductular proliferation at the portal tract interface arising from progenitor cells in the periportal area and accompanied by neutrophils and stromal changes). These findings have been correlated with insulin resistance, impaired hepatocellular replication, and advanced stages of fibrosis, indicating that it might provide a pathway for progressive fibrosis[78]. Recent work has found evidence of epithelial-to-mesenchymal transition of ductular cells *via* activation of the hedgehog pathway, a process by which mature epithelial cells differentiate into cells with a mesenchymal phenotype and function, in NAFLD[79].

Other histological lesions that may be seen in NASH include Mallory-Denk bodies (MDB), megamitochondria, glycogenated nuclei, and iron deposition. MDB (previously called Mallory bodies or Mallory's hyaline)[61] are eosinophilic intracytoplasmic inclusions commonly seen close to the nucleus of ballooned hepatocytes in zone 3, usually in areas of perisinusoidal fibrosis. They are composed of misfolded intermediate filaments (keratins 8 and 18), ubiquitin, heat shock proteins, and p62[80]. MDB have been correlated with increased necroinflammatory activity[53] and with a higher incidence of cirrhosis[59]. Although not a requirement for the histological identification of NASH, the presence of MDB strengthens the diagnosis. MDB are not, however, restricted to NASH and can be seen in steatohepatitis due to other causes (alcoholic, drug-induced, etc), as well as in chronic cholestasis, metabolic diseases, and hepatocellular neoplasms[81].

Megamitochondria (giant mitochondria) are round or needle-shaped, eosinophilic, intracytoplasmic inclusions more commonly observed in hepatocytes with microvesicular steatosis. The are not zonally restricted[82]. Ultrastructural studies have shown that these abnormal mitochondria show loss of cristae, multilamellar membranes, and paracrystalline inclusions[82,83]. Megamitochondria in NASH may be the result of injury from lipid peroxidation or represent an adaptive change[84]. Glycogenated nuclei are vacuolated nuclei usually observed in periportal hepatocytes. Their presence in biopsies with steatohepatitis is supportive of nonalcoholic etiology (obesity and/or diabetes) because they are very rarely seen in biopsies of alcoholic steatohepatitis (ASH)[85].

Finally, hepatic siderosis might be seen in NAFLD biopsies. It is usually mild (1+, 2+) and occurs in periportal hepatocytes and/or pan-acinar reticulo-endothelial cells. The significance of liver tissue iron deposition and abnormal iron metabolism genetics in the pathogenesis and progression of NAFLD are under investigation[86,87].

HISTOLOGY OF NAFLD IN ADULTS: PATHOLOGIST REPRODUCIBILITY

Reproducibility studies have shown excellent to good agreement for the extent of steatosis, presence of perisinusoidal fibrosis, and stage of fibrosis in adult NAFLD; the feature with the least agreement between histopathologists is lobular inflammation[54,88,89]. Intra-observer agreement is generally better than inter-observer agreement for all histological features and diagnostic categories.

HISTOLOGICAL FINDINGS OF NAFLD/NASH IN CONCURRENCE WITH OTHER LIVER DISEASE

The increased frequency of NAFLD in the general population makes it important for pathologists to recognize the lesions, especially those of NASH, when concurrent with other clinically suspected liver diseases. The frequency of co-existent NASH in a series of > 3000 non-allograft liver biopsies undertaken for clinical suspicion of CHC, autoimmune hepatitis, hemochromatosis, alpha-1-antitrypsin deficiency, or chronic hepatitis B was 2.6%[90]. This number most likely underestimates the actual prevalence of the concurrence given the very stringent criteria for the diagnosis of SH used in the study[56]. Other groups, however, have found similar results[91].

In CHC, which is the most common chronic liver disease diagnosed with concomitant NASH (5%-10%)[90-93], the presence of NAFLD can accelerate disease progression and decrease response to antiviral treatment with negative consequences on patients' prognoses[94,95]. Other studies have shown that co-existent fatty liver or NASH in CHC, more common in patients with genotype 3, was not related to metabolic disturbances[93]. In a subsequent study, however, this same group showed that insulin resistance was increased in CHC, particularly genotypes 1 and 4, and was independently related to advanced fibrosis[94]. Thus, the data for CHC and NAFLD is still under investigation.

The diagnosis of concurrent NASH can be a challenge. One study required the identification of the characteristic zone 3 perisinusoidal fibrosis[90], as this is not a typical finding in other forms of chronic liver disease; another study only required the prominence of steatosis and inflammation in zone 3, along with hepatocellular ballooning[93]. It is important to understand that hepatocellular ballooning, steatosis, and even MDB, have been documented in CHC[96].

Recently, the co-existence of NAFLD and alcoholic liver disease (ALD) has been increasingly recognised in clinical settings. The presence of NAFLD in alcoholic patients has been linked with progression of ALD[97], while some have shown that moderate alcohol consumption is associated with fibrosis progression in NAFLD[98]. Interestingly, in contrast, several studies have shown a beneficial effect of moderate alcohol intake. Moderate alcohol use was shown to be protective against insulin resistance in morbidly obese individuals[73], was associated with decreased prevalence of fatty liver in asymptomatic individuals[99], and with decreased prevalence of steatohepatitis in NAFLD patients[100]. The pathologist is not able to recognize the relative contributions of NAFLD or ALD to the liver injury in a biopsy with steatohepatitis.

HISTOLOGICAL FINDINGS OF RESOLUTION OF NASH

Resolution of the histological lesions of NASH is one of the primary end-points of many treatment trials. It is now apparent that "spontaneous" resolution of liver injury can occur without treatment (i.e. studies of placebo groups)[101-103]. This observation, therefore, indicates the need for adequate sample size as well as randomized controlled trial for treatment trials of NASH.

Improvement of the major histological features of disease activity (i.e. steatosis, lobular inflammation, and ballooning), grade of steatohepatitis and, occasionally, of fibrosis following therapy using different agents, including thiazolidinediones (pioglitazone and rosiglitazone), metformin, vitamins E and C, dietary interventions, or bariatric surgery have been reported[104]. However, after discontinuation of medical treatment, the initial histological improvement might not be maintained, indicating the need for longer (permanent?) duration of therapy[105]. Nevertheless, the results of one long-term treatment trial with the insulin sensitizer roziglitazone showed that there is no additional anti-steatogenic effect with longer treatment, despite an increase in insulin sensitivity[106]. In contrast, reportedly, surgical intervention for obesity appears to have long-lasting beneficial effects on liver histology[107,108].

Histological evaluation of post-treatment liver biopsies in a small trial[102] showed that increased portal inflammation is a feature related to resolution of NASH; a subsequent review of published treatment trials has confirmed this finding, which is independent of the type of therapeutic intervention (medical, dietary, or surgical)[56]. In some cases, successful treatment with resolution is associated with the change in the quality of zone 3 perisinusoidal fibrosis from dense to delicate[102].

HISTOLOGY OF NAFLD IN PEDIATRIC SUBJECTS

Diagnosis of nonalcoholic fatty liver disease in children continues to be a challenge for pathologists. Clinicopathological studies have confirmed that the lesions may or may not resemble those of adults, including cirrhosis with and without steatosis and inflammation[109-119].

Utilizing a mathematic algorithm of the lesions following evaluation of 100 obese children and their liver biopsies, Schwimmer *et al*[120] proposed the currently utilized schema of types 1 and 2 steatohepatitis in pediatric fatty liver disease. Type 1, the least common overall, but the most common in girls, resembles the adult pattern, with zone 3 accentuation of steatosis. Type 2 is more common in boys, and consists of either zone 1 accentuation of steatosis, or panacinar steatosis. Ballooning was uncommon in both types. Zone 3 perisinusoidal fibrosis was uncommon in type 2, whereas, when fibrosis was present, only portal-based fibrosis was seen. A small percent of cases did not fit completely into either category in the Schwimmer study, and were referred to as "overlap". A subsequent clinicopathological series from children from a single site in Rome[112], as well as multiple centers across North America[115], have found types 1 and 2 less common than overlap patterns, and individual features such as zone 3 steatosis, ballooning, and zone 3 perisinusoidal fibrosis less common in children than in adults[121]. However, no author has yet specified the features and/or patterns of injury that would result in an unequivocal diagnosis of "steatohepatitis" in pediatric cases if there were changes other than the adult-pattern. Thus, this is an area of ongoing investigation in pathology. In addition, there are no natural history studies to date showing evolution of the pediatric pattern in children; whether it evolves to the adult pattern with increasing age or not is unknown. The rate and processes involved in progression to cirrhosis, an unfortunate but growing problem[114] in obese children, are also unknown.

HISTOLOGY OF NAFLD IN SPECIAL POPULATIONS

Asians

It is recognized that the body habitus of individuals of Asian descent differs from that of Caucasoids; there is greater body fat for a given body mass index (BMI) in Asians[122], thus, the prevalence and incidence of NAFLD and advanced fibrosis are related to factors other than BMI. However, histological features, as described, do not appear to differ from those described for Caucasian adults.

Bariatric patients

To date, there is no dedicated literature related to the bariatric population, other than straightforward observations of changes of steatosis, inflammation, and fibrosis following surgery. Many studies are done without a specific protocol requiring follow-up biopsies, and most workers do not require pre and post biopsies to be obtained from the same lobe of the liver, or for surgical biopsies to be obtained as early as possible in the operation to avoid the accrual of polymorphonuclear leukocytes within the lobules (i.e. surgical hepatitis). The former is important because of potential differences between the lobes (capsule: parenchyma ratio) and the latter for obtaining correct lobular inflammation scores. The extant literature is reviewed[108] and highlights the fact that the majority of bariatric patients have varying amounts of steatosis. In addition, a recent study of surgeon ability to detect steatosis and/or cirrhosis has shown that this is not reproducible; thus reinforcing the need for liver biopsy in all bariatric patients[123]. To this, the authors would add unpublished personal observations of the non-cirrhotic biopsies from bariatric surgery, that (1) it is common to see enlarged, prominent portal tracts from biopsies obtained from the left lobe; (2) steatosis is commonly mild and often not in zone 3; and (3) zone 3 perisinusoidal fibrosis is uncommon. It is possible that the very low calorie diet that commonly precedes the actual surgical procedure influences

NAFLD and even NASH that may have been present. Finally, a large European study has shown that after five years, if insulin resistance has not improved, fibrosis might actually show progression[124].

NASH IN THE TRANSPLANTED LIVER

NAFLD can occur in the allograft liver as recurrence or as a *de novo* process[125-136].

The incidence of recurrent steatosis in patients transplanted for cryptogenic cirrhosis or NASH-cirrhosis ranges from 25%-100%, while NASH development is observed in 10%-37.5% of these cases without leading to early allograft failure (reviewed in[135]). Recurrent NASH can progress to advanced fibrosis and cirrhosis, but only rare cases have been re-transplanted as a result of decompensation due to severe NASH in the allograft[137].

Development of *de novo* steatosis and/or NASH in the liver allograft might be the result of metabolic disturbances, as transplanted patients are at increased risk for obesity, diabetes, hypertension, and hypercholesterolemia and have decreased physical activity levels. Moreover, anti-rejection medications, in particular steroid treatment and cyclosporine, are known risks for fatty liver development in the allograft, probably by affecting diabetogenic pathways[51,138]. Therefore, the occurrence of NASH in an allograft liver of a patient transplanted for "cryptogenic cirrhosis" does not justify attribution of the original disease to "burned-out" NASH without appropriate clinico-pathological correlation[139-141].

DIFFERENTIAL DIAGNOSIS

Clinico-pathological correlation is essential for highlighting the underlying cause of steatohepatitis in a liver biopsy, as the histology is similar irrespective of etiology. The differential diagnoses of NAFLD and NASH include ASH, drug toxicity (tamoxifen, glucocorticoids, and highly active antiretroviral therapy in human immunodeficiency virus patients), metabolic diseases (such as Wilson disease, tyrosinemia, and citrin deficiency), lipodystrophy, surgical procedures (such as jejunoileal bypass and biliopancreatic diversion), total parenteral nutrition, and malnutrition[51].

ASH vs NASH

The ongoing discussions of the limits of alcohol intake in "nonalcoholic" fatty liver[142] revolve around the complex interactions of host (genetic and metabolic) factors[143,144], the type of alcohol utilized, patterns of drinking[144], and the potentially beneficial interactions of modest alcohol with insulin resistance[73].

Hepatopathologists agree that the histology of uncomplicated NAFLD and alcoholic steatosis are indistinguishable. Further, NASH might be indistinguishable from ASH; however, there are some histological features observed in ALD that have not yet been described in NAFLD. These include sclerosing hyaline necrosis (a combination of dense perivenular fibrosis, MDB accumulation, and hepatocyte necrosis in zone 3), veno-occlusive lesions, alcoholic foamy degeneration (zone 3 microvesicular steatosis), and cholestasis[51]. Generally, there is consensus that the overall histopathological appearance of NASH is milder than that observed in ASH[145], with the understanding that alcoholic steatosis can be as "mild" as NAFLD.

Certain histological lesions, including severe steatosis, glycogenated nuclei, and lipogranulomas, are more frequent in NAFLD compared to ALD; however, their utility in differential diagnosis on an individual basis is limited[145]. On the other hand, numerous, well formed MDB and dense fibrosis, composed mostly of collagen type Ⅲ might be indicative of an alcoholic rather than metabolic origin[146-148]. One group utilized immunohistochemical detection of the insulin receptor (IR) and increased expression of protein tyrosine phosphatase 1B (PTP1B), a protein that acts as a negative regulator of IR expression, to aid in the histological distinction of ASH and NASH. IR receptor was more frequent in NASH in contrast to normal expression for IR in conjunction with low level expression of PTP1B noted in ASH[149]. The clinical utility of this method, however, has not been tested. The same group also proposed a noninvasive model for the differential diagnosis between ALD and NAFLD using the ALD/NAFLD Index (ANI). This is based on the mean corpuscular volume, aspartate aminotransferase (AST)/ALT ratio, BMI and gender. An ANI greater than 0 indicates ALD, while ANI less than 0 is diagnostic of NAFLD[150]. There has been no published validation of this test.

GRADING AND STAGING OF THE HISTOLOGICAL LESIONS IN NAFLD

The first system for grading necroinflammatory activity and staging fibrosis in NASH appeared in 1999[53] in response to the growing need for standardization of the histological criteria used for the diagnosis of NASH and its differentiation from steatosis, and to meet the necessity for the development of a histological scoring system similar to those already used for other forms of chronic hepatitis. In this scoring system, the features that were shown to contribute the most to the severity of the disease, such as steatosis, lobular and portal inflammation, and hepatocellular ballooning were semi-quantitatively assessed to produce a three-tier global grade of activity (Table 1). Staging was based on the characteristic pattern and evolution of fibrosis in NASH with initial involvement of perisinusoidal spaces in zone 3 (stage 1) and subsequent development of portal/periportal fibrosis (stage 2), bridging fibrosis (stage 3), and cirrhosis (stage 4) (Table 1)[53].

Among subsequently published scoring systems for grading histological activity in NAFLD[54,151] and NASH[152], the current most widely used histological scoring system is the one published in 2005 by the NASH Clinical Research Network (CRN), sponsored by the National Institute of Diabetes, Digestive and Kidney Diseases[54]. The NASH CRN system has several advantages: it is a validated system created from blinded reviews by nine pathologists, it is applicable to the entire histological

Table 1 Grading activity and staging fibrosis in nonalcoholic steatohepatitis according to Brunt *et al* (adapted from[53,54])

	Steatosis (1: ⩽ 33%, 2: 33%-66%, 3: ⩾ 66%)	Ballooning (zonal location and severity recorded)	Inflammation[a]	
			L-Lobular [(0-3): 0: absent, 1: < 2, 2: 2-4, 3: > 4 foci]	P-Portal [(0-3): 0: absent, 1: mild, 2: moderate, 3: severe]
Grade 1 (mild)	1-2	Minimal, zone 3	L = 1-2	P = 0-1
Grade 2 (moderate)	2-3	Present, zone 3	L = 1-2	P = 1-2
Grade 3 (severe)	2-3	Marked, predominantly zone 3	L = 3	P = 1-2

[a]Counted in 20 × fields. Stage of fibrosis: 1: Zone 3 perisinusoidal fibrosis, focal or extensive; 2: As above with focal or extensive periportal fibrosis; 3: Bridging fibrosis; 4: Cirrhosis, probable or definite.

Table 2 Nonalcoholic steatohepatitis Clinical Research Network system for scoring activity and fibrosis in nonalcoholic fatty liver disease (modified from[54])

Steatosis grade (S)	Lobular inflammation[a] (L)	Hepatocyte ballooning (B)
0: < 5%	0: None	0: None
1: 5%-33%	1: < 2	1: Few ballooned cells
2: 34%-66%	2: 2-4	2: Many ballooned cells
3: > 66%	3: > 4	

[a]Counted in 20 × fields. Nonalcoholic fatty liver disease Activity Score: S + L + B (range 0-8). Stage of fibrosis (Fibrosis score): 0: None; 1: 1a, mild, zone 3 perisinusoidal fibrosis, 1b, moderate, zone 3 perisinusoidal fibrosis, 1c, portal/periportal fibrosis only; 2: Zone 3 perisinusoidal fibrosis and portal/periportal fibrosis; 3: Bridging fibrosis; 4: Cirrhosis, probable or definite.

spectrum of NAFLD, it scores both adult and pediatric NAFLD biopsies, and it generates a numeric score for grading activity and NAFLD activity score (NAS) for comparing pre- and post-treatment biopsies in therapeutic trials. The NAS derives from the summation of individual scores for steatosis, lobular inflammation, and hepatocellular ballooning and ranges from 0 to 8 (Table 2). In the validation study, NAS of 1 or 2 corresponded to definitely not NASH, while a NAS score 5-8 correlated with definite NASH. Activity scores 3 and 4 were noted in borderline cases that did not fulfill the pathologists' criteria for definite NASH. It is important to note, however, that the numbers generated by NAS were not created to be used as a substitute for histological diagnosis; properly utilized, the NAS is applied by the pathologist after reaching final diagnosis.

Fibrosis scoring with the NASH CRN system is based on the prototype staging method proposed by Brunt *et al*[53], with the difference that stage 1 is further subdivided into three sub-stages to differentiate between delicate perisinusoidal zone 3 fibrosis (stage 1a), dense perisinusoidal zone 3 fibrosis (stage 1b), and portal fibrosis only (stage 1c)[54]. NASH CRN stage 1c refers to the pattern of fibrosis sometimes seen in severely obese patients and in pediatric NASH (Table 2). The value of histological scoring systems for grading and staging in NAFLD in routine practice has not yet been adequately assessed and, to date, they are mainly used in treatment trials and in natural history studies. Furthermore, the recognition of the significance of other histological features associated with definite NASH and advanced fibrosis, such as portal chronic inflammation[70], and the proposed use of serum biomarkers of hepatocyte apoptosis for risk-stratifying patients with NAFLD[41], indicate that the currently used systems could be improved by including these histological features in the semi-quantitative histological scoring of both adult and pediatric NAFLD[58].

Abstract

AIM: To assess the utility of an autologous CD34$^+$ and CD133$^+$ stem cells infusion as a possible therapeutic modality in patients with end-stage liver diseases.

METHODS: One hundred and forty patients with end-stage liver diseases were randomized into two groups. Group 1, comprising 90 patients, received granulocyte colony stimulating factor for five days followed by autologous CD34$^+$ and CD133$^+$ stem cell infusion in the portal vein. Group 2, comprising 50 patients, received regular liver treatment only and served as a control group.

RESULTS: Near normalization of liver enzymes and improvement in synthetic function were observed in 54.5% of the group 1 patients; 13.6% of the patients showed stable states in the infused group. None of the patients in the control group showed improvement. No adverse effects were noted.

CONCLUSION: Our data showed that a CD34$^+$ and CD133$^+$ stem cells infusion can be used as supportive treatment for end-stage liver disease with satisfactory tolerability.

Key words: CD34; CD133; Stem cell; Liver; Hepatitis C virus

Autologous CD34$^+$ and CD133$^+$ stem cells transplantation in patients with end stage liver disease. *World J Gastroenterol* 2010; 16(42): 5297-5305 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i42/5297.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i42.5297

INTRODUCTION

Cirrhosis is the end stage of chronic liver injury caused by viral hepatitis or alcohol intake. In Egypt, most malignant neoplasms of the liver arise on top of chronically damaged livers, typically a cirrhotic liver due to hepatitis C

virus (HCV) infection. Two main factors are responsible for the irreversibility of cirrhosis. One factor involves the increased and continuous deposition of the extracellular matrix, due to increased collagen synthesis accompanied by insufficient breakdown of collagen. The other is the impaired capability of the liver to regenerate, which predisposes a patient to postoperative dysfunction or liver failure. Previous studies have shown that a fibrotic liver following hepatic resection regenerates very slowly in comparison with a normal liver. However, little is known about the mechanism(s) of retarded liver growth; though, it has been postulated that growth factors can promote cirrhotic regeneration by an as yet unidentified mechanism.

Until now, effective treatments capable of reversing cirrhosis have not been developed. In the last few years, there has been increasing evidence that adult cells have far greater differentiation plasticity than previously thought, with bone marrow turning into skeletal muscle[1] and skeletal muscle back into bone marrow (BM)[2]; brain into blood[3] and back again[4,5]; BM into liver[6,7] and back again[8]. These phenomena occurred in different mammals (including mice, rats, and sheep); however, it is difficult to know the human relevance of the findings without studying human tissues.

In two recently published studies[9,10], the effects of CD34 hematopoietic stem cell intrahepatic injection and whole BM peripheral infusion have been evaluated in five and nine cirrhotic patients; respectively. The results of these two studies showed that BM stem cells transplantation improved the residual liver function in cirrhotic patients. In the study of Gordon *et al*[9], a decrease in serum bilirubin and an improvement in serum albumin were observed in three and four of the five patients, respectively, with disappearance of ascites in one patient only.

Similarly, Terai *et al*[10] reported significant increases in albumin and total protein levels, and an improvement of the Child-Pugh score in all of the nine patients, and a reduction in ascites in six patients. These results, which originated from ongoing research on BM stem cells and the liver, may be considered promising and encouraging, as they demonstrate that clinical results might sometimes precede scientific evidence. However, a more cautious analysis of the results is necessary, considering the clinical course and potential new therapies for complex disorders such as human liver cirrhosis.

These two studies[9,10], however, were conducted on small groups of patients, were not randomized, and also lacked a control group of stem cell untreated patients. The presence of a control group, in particular, is of utmost importance in clinical studies investigating the efficacy of potential new therapies. Using a control group (that should be homogeneous to the experimental group for both epidemiological and clinical characteristics) reduces the likelihood that modifications observed during treatment are accidental and not directly dependent on the therapy administered, and randomization increases the probability that other variables, not considered in the study design, are distributed evenly in both the experimental and control groups.

In the current study, we investigated the possibility of using $CD34^+$ and $CD133^+$ stem cells as a therapeutic modality in patients with end-stage liver diseases.

MATERIALS AND METHODS

Ethics

The ethical committees of Kaser El-Aini School of Medicine and the National Cancer Institute, Cairo University, approved the study protocol and a written informed consent was obtained from each patient.

Studied groups

The present study includes 140 patients with end-stage liver cirrhosis who attended the Hepatology Clinic in Kaser El-Aini School of Medicine, Cairo University, from June 2008 to May 2009.

Patients were randomized into one of two groups: Group 1: 90 patients who received granulocyte colony stimulating factor (G-CSF) (Neupogen, Roche) for five days, followed by autologous $CD34^+$ and $CD133^+$ stem cell infusion in the portal vein; Group 2: 50 patients who served as a control and those received regular liver treatment.

Inclusion criteria

Patients were included in this study if they fulfilled the following criteria: male or female patients aged from 20 to 60 years with evidence of chronic liver insufficiency (decreased serum albumin and/or increased bilirubin and/or increased international normalized ratio-INR), patients unlikely to receive a liver transplant and who had a World Health Organization (WHO) performance score of less than 2 with an ability to give a written consent.

Exclusion criteria

Patients were excluded if they were below the age of 20 or above the age of 60 years, pregnant or lactating women, those with recent recurrent gastrointestinal bleeding, hepatocellular carcinoma or spontaneous bacterial peritonitis, an evidence of human immunodeficiency virus or other life threatening infection, unable to give a written consent, having history of hypersensitivity to G-CSF, or included in any other clinical trial within the previous month. Patients were randomized into either one of these two groups.

Patients in both groups were comparable for baseline characteristics: age and sex, etiology of liver disease and model for end-stage liver disease (MELD) score.

Clinical evaluation was done for all patients in the study, including a detailed medical history and complete clinical examination, with special emphasis on the presence markers of liver cell failure e.g. ascites, jaundice, LL.edema, bleeding tendency, and signs of encephalopathy in addition to the WHO performance score. Abdominal ultrasound scanning was done for both groups using a Hitachi 515 real time scan after overnight fasting.

Laboratory investigations were done for all patients, and included liver biochemical profile [serum bilirubin

and albumin, prothrombin time and concentration, INR, alanine transaminase (ALT) and aspartate transaminase (AST)]; blood urea and serum creatinine levels; blood sugar (fasting and two hours post-prandial); complete blood analysis and α-fetoprotein, as well as a hepatitis serological profile (HBsAg, HBcAb, HCV Ab, HCV RNA by quantitative polymerase chain reaction). The MELD score was calculated to assess the degree of hepatic decompensation for every patient.

Treatment regimen

Group 1: From days one to five, patients received a daily subcutaneous injection of granulocyte colony stimulating factor (G-CSF at 300 μg Neupogen (Roche) - 300 μg/vials) for five days to increase the number of circulating hematopoietic cells. Blood samples were then taken for hematology, biochemical analysis, and coagulation profile on days one and five. Data regarding symptoms and adverse events were collected and recorded. Patients were admitted to the hospital and underwent BM aspiration on day six.

BM stem cell aspiration

Patient's skin was cleaned with 70% alcohol at the iliac crest, which is the usual site for puncture in adults. Skin, subcutaneous tissues, and periosteum overlying the selected site for puncture were infiltrated with xylocaine local anesthesia and serial punctures from multiple sites were performed.

With a boring movement, needles (Salah and Klima) were passed perpendicularly into the cavity of the ileum at a point just posterior to anterior superior iliac spine or 2 cm posterior and 2 cm inferior to the anterior superior iliac spine to aspirate 250 mL of the BM.

Following collection, the BM products were transferred to the stem cell laboratory for immuno-magnetic purification of the $CD34^+$ and $CD133^+$ stem cell population. $CD34^+$ and $CD133^+$ cells were isolated using the positive cell selection kit (MACS System Milteny Biotec, Gmbh, Germany (http://www.miltenyibiotec.com). Collected cells were washed twice with phosphate buffered saline pH 7.4, supplemented with 0.5% bovine serum albumin and 5 mmol/L EDTA, and centrifuged at 1500 r/min for 10 min at 4℃. The cell suspension was counted, adjusted to 0.5×10^8, centrifuged, and re-suspended in 100 mL physiological saline.

Patients were admitted to hospital and infused, while fasting, with the purified human stem cells into the portal vein (as previously determined by duplex Doppler scan to assess its potency) under ultrasound guidance using, diazepam 10 mg IV for sedation and xylocaine local infiltration anesthesia.

Group 2: A daily SC injection of distilled water was given for all patients while receiving their usual supportive measures before and after injection.

Post-treatment follow up of the patients

All patients in both groups were followed up every hour for 24 h, then every week for the first month, and regularly every month for 6 mo. During the follow up, patients were observed for the following: serum bilirubin and albumin, prothrombin time and concentration, INR, ALT and AST; blood urea and serum creatinine levels; blood sugar (fasting and two hours post-prandial); complete blood analysis, together with estimation of the degree of ascites, Child-Pugh score, performance score, hepatic encephalopathy and hematemesis.

Statistical analysis

All patients' data were tabulated using Excel XP. Data were processed by SPSS (Statistical Package for Science and Society) version 12.0 for Windows XP. The descriptive statistics were presented as mean ± SD for quantitative variables. All qualitative data were expressed by frequency (number) and percent. Comparisons between groups were done using χ^2 test, Fischer's Exact test or McNemar test when appropriate for qualitative data but independent sample *t* test and paired sample *t* test were used for normally distributed quantitative variables, while the non-parametric Mann Whitney test and Wilcoxon singed ranks test were used for abnormally distributed quantitative variables. Percent changes in prognostic variables (e.g. albumin) were calculated and compared using the Mann Whitney test. In all tests, *P* values lower than 0.05 were considered as statistically significant. Also, linear regression analysis was employed to determine the degree of improvement of clinical features in relation to response rate to the treatment. Multivariate analysis also showed no significant correlation between HCV viral titer changes and serum albumin, prothrombin concentration (PC), Child score, Performance score ascites grade, and hematemesis attack.

RESULTS

One hundred and forty patients (117 males and 23 females) with a mean age of 50.27 ± 6.05 years (range; 45 to 59 years) were included in the study; 90 of them received autologous, BM-derived $CD34^+$ and $CD133^+$ cell transplantation, and 50 were included as a control. In all studied patients, the cells were injected into the portal vein under ultrasound guidance. The etiology, diagnosis, clinical signs, results of investigations, cell concentrations, and post infusion observations for each patient are shown in Tables 1 and 2. After G-CSF treatment, increased total white blood cell counts indicated mobilization of progenitor cells into the circulation in all patients. Patients were then given 0.5×10^8 $CD34^+$ and $CD133^+$ cells as a single bolus.

No major complications, either local or systemic, occurred as a result of the stem cell transplantation, except for mild pain and discomfort at the site of $CD34^+$ and $CD133^+$ cell infusion. However, a short term fever developed in 15 patients, which subsided in 24 h. Mild bone pain developed in 23 patients after receiving G-CSF, which also subsided spontaneously. However, there was no bleeding, infection, or significant deterioration in liver

function. CT scans showed no evidence of focal liver lesions in any of the treated patients, either before or after infusion. Duplex Doppler ultrasound scans showed patent portal veins with normal hepato-pedal flow.

Monthly assessment of changes in the serum level of bilirubin, albumin, liver enzymes, and fluid collection was performed. Serum albumin, bilirubin, transaminases, prothrombin time and concentration, together with estimation of the degree of ascites, Child-Pugh score, performance score, hepatic encephalopathy, and hematemesis were performed every week for the first month, then every month up to 6 mo (Table 3).

Near normalization of liver enzymes and improvement in the synthetic function of the liver were observed in 54.5% of $CD34^+$ and $CD133^+$ transfused patients and 13.6% of them showed stable states. In comparison, none of the control group showed any improvement (P = 0.069 and 0.023, Table 4 and Figure 1A-E).

None of the responders or patients with stable disease showed progressive or increased ascites or needed taping, and the treatment schedule for diuretic therapy was dramatically reduced. Disappearance of ascites, as demonstrated by ultrasound scan, was detected in 21 patients, and improvement in the degree of ascites was reported in 51 patients (Figure 2A and B). Also, an improvement in Child-Pugh score was detected in 48 patients (Figure 3A and B); performance score in 52 patients (Figure 4A and B). Improvements in hepatic coma and hematemesis (Table 5) were detected in 91.3% and 87%, respectively. Similarly, a significant improvement

was observed in the group of responders compared to the other two groups (Table 6, Figures 2 and 3).

HCV viral titer

In the study population, the mean baseline HCV viral titer value was 1128.23 ± 1810.53 IU/mL. One month after stem cell therapy, it increased to 2749.70 ± 10533.15 IU/mL, then decreased to 848.88 ± 1375.72 IU/mL two months after the study and then to 592.23 ± 1300.90 IU/mL after three months. After 6 mo of the study, the mean HCV viral titer further decreased to 351.84 ± 1068.73 IU/mL in the treated group. However, no significant change in the viral titer was observed in the control group during the study period.

Linear regression analysis was employed to determine the degree of improvement in the clinical features in relation to the response to treatment. A significant improvement was observed among the responders compared to the control groups (Table 7).

Multivariate analysis showed no significant correlation between HCV viral titer and serum albumin, PC, Child score, performance score, ascites grade or hematemesis. However, there was a significant inverse relation between serum bilirubin levels and HCV titer, which reached the highest significance in the 6th month after treatment ($r = 0.56$, $P < 0.002$).

Survival after stem cell therapy (6 mo follow-up): Nine patients with post-HCV liver cell failure died (seven

from attacks of hematemesis, and two from hepato-renal syndrome) and 13 were considered as lost follow up patients, though still alive, because they did not attend at the regular scheduled time for follow-up. In comparison, 26 patients from the control group died (15 from attacks of haematemesis, five from hepato-renal syndrome, and six from hepatic coma) (Figure 5).

DISCUSSION

Until now, liver transplantation has been considered the only curative treatment for decompensated cirrhosis[11]. However, this procedure is limited by technical difficulties, high cost, and also by a lack of donors[12].

Stem cells have recently shown promise in cell therapy because they have the capacity for self-renewal and multilineage differentiation, and are applicable to human diseases. The diseased liver may recruit migratory stem cells, particularly from the bone marrow, to generate hepatocyte-like cells either by transdifferentiation or cell fusion. Transplantation of BMSCs can restore liver mass and function, alleviate fibrosis, and correct inherited liver diseases. Therefore, it can significantly improve the liver function of patients with terminal liver disease, with good safety and effectiveness[13]. BMSCs can be delivered *via* the intraportal vein, systemic infusion, or *via* intraperitoneal, intrahepatic, and intrasplenic routes.

The current study was designed to evaluate the effects of autologous $CD34^+$ and $CD133^+$ hematopoietic stem cell intrahepatic infusion, and to assess the relationship between HCV viral load and the outcome of stem cell therapy, in patients with post HCV liver cirrhosis. This was the basis for conducting a randomized study on 140 patients with chronic HCV liver disease.

Multivariate analysis showing no significant correlation between hepatitis C virus (HCV) viral titer and serum albumin, prothrombin concentration, Child score, performance score, ascites grade, or hematemesis. However, there was a significant inverse relation between serum bilirubin levels and HCV, which reached the highest significance in the 6th month after treatment ($r = 0.56$, $P < 0.002$).

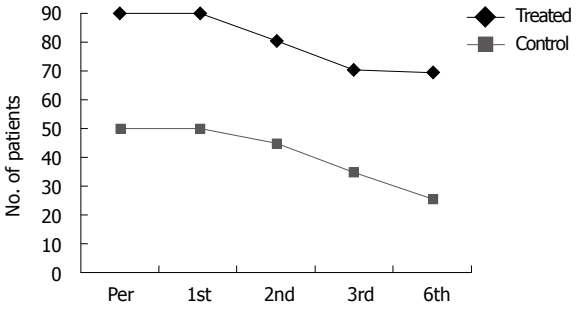

Figure 5 Survival rate in the treated *vs* control group. Per: Pre-treatment; 1st: First month; 2nd: Second month; 3rd: Third month; 6th: Sixth month after treatment.

To improve hepatic homing to the liver, $CD34^+$ and $CD133^+$ progenitor cells were applied into the portal vein directly. Our choice of the portal vein infusion was based on a preclinical model, which reported that HSCs, if applied to the portal vein, demonstrate a high percentage of first-pass entrapment in the liver[14].

We found a significant improvement in the mean serum albumin level in the transplanted patients compared to the control group. Similar results were reported by Gordon *et al*[9]. Similarly, Terai *et al*[10] reported significant improvements in the average serum albumin levels in nine cirrhotic patients that underwent autologous bone marrow cell infusion from the peripheral vein at 24 wk after infusion. Also, Salama *et al*[15] conducted a study on 48 Child C cirrhotic patients and demonstrated that there were borderline significant improvements in the serum albumin levels of the transplanted group compared to the control group at the end of the 6 mo study.

The mean serum bilirubin level showed an improvement in our transplanted patients, starting from the second month after stem cell therapy. These results are also consistent with those of Gordon *et al*[9] and Pai *et al*[13].

In another study, Levicar *et al*[16] isolated and injected 1×10^6 to 2×10^8 $CD34^+$ cells into the portal veins or hepatic arteries of five patients, who were followed up for 18 mo. Four patients showed an initial improvement in serum bilirubin level, which was maintained for up to 6 mo. However, a marginal increase in serum bilirubin was reported in three patients at 12 mo and in one patient, the serum bilirubin increased only at 18 mo post-infusion. They concluded that the beneficial effect seemed to last for around 12 mo.

The mean baseline PC value in our studied population started to improve 1 mo after the procedure, and continued to improve until the 6th month. This improvement was statistically significant. These results agree with those of Salama *et al*[15], who reported that there was an improvement in PC that started in the 2nd month after HSCs transplantation and reached its maximum after 6 mo.

There was a gradual improvement in the hepatic functional reserve of our transplanted patients compared to controls, as assessed by the Child-Pugh score. The maximum improvement in the Child-Pugh score occurred after 6 mo. A statistically significant improvement of Child-Pugh score was demonstrated at four and twenty-four weeks after autologous bone marrow stem cell transplantation therapy by Terai *et al*[10]. In addition, the Child-Pugh score improved significantly in seven out of nine patients studied by Pai *et al*[13].

The quality of life (QOL) in the transplanted patients was assessed using the WHO performance score (PS). There was an improvement in the transplanted patients, as regards PS, starting from the 1st month after the HSCs transplantation until the 6th month post-transplantation.

This improvement has been previously reported by Gordon *et al*[9], who reported a statistically significant improvement in QOL of their patients, as measured by an SF-36 questionnaire after HSCs transplantation.

On the other hand, the present study showed that the number of patients without ascites increased from 6.7% at the start of the study to 27.3% at the end of the study. Maximum improvement occurred after 6 mo, and was of highly significant value as 42 patients (63.6%) showed an improvement in the degree of ascites and 24 patients (36.3%) showed no change in the degree of ascites. However, none of the patients showed deterioration in the degree of ascites. Our results are comparable to those of Terai *et al*[10] and Pai *et al*[13].

At the start of the study, the percent of patients with no history of hepatic encephalopathy was 66.7 % and the percent of patients with history of encephalopathy was 33.3 %. The percent of patients with no attacks of encephalopathy became 96.7 %, 80%, 88.5 % and 91.3% after 1, 2, 3, and 6 mo respectively (maximum improvement occurred after 6 mo). Salama *et al*[15] demonstrated a highly significant improvement in the transplanted group as regards the recurrence of hepatic encephalopathy.

In the study population, the mean baseline HCV viral titer value was 1128.23 ± 1810.53 IU/mL and there was an increase in the transplanted patients during the 1st month only. Thereafter, there was a gradual decrease during the follow-up period. The maximum decrease in HCV viral titer occurred after 6 mo of stem cell transplantation, where 39 patients (59.1%) showed a decrease, 18 patients (27.3%) showed an increase and 9 patients (13.6%) showed no change in their HCV viral titer.

In the study population, the lower pre-transplantation viral load was not due to the intrinsic characteristics of the infective viral strains, but rather to the severity of liver disease. Thus, one month after stem cell transplantation, higher levels of viral replication were restored due to regeneration of liver after stem cell transplantation[17]. Therefore, there was no correlation between HCV viral titer changes and changes in the serum albumin, PC, Child score, performance score, ascites grade or hematemesis attacks. However, there was a moderate negative correlation between HCV titer changes with changes in serum bilirubin in the 3rd month only after stem cell transplantation.

Similarly, there was a negative correlation between HCV titer changes and changes in AST in the 3rd and 6th months only after stem cell transplantation, and a moderate negative correlation between HCV titer changes with changes in ALT in the 2nd month only after stem cell transplantation. These results agree with those of Duvoux *et al*[17], who demonstrated that the severity of liver disease is independent of serum levels of HCV.

From the data presented in the current study, which included the largest cohort of HCV-associated end stage liver disease patients to date, we conclude that autologous stem cell transplantation may be safely administered and appears to offer some therapeutic benefit to patients with viral hepatic end-stage liver disease.

COMMENTS

Background

Stem cell therapy is an innovation technique with promising application in various human diseases. Stem cell plasticity has enabled different researchers to use them in treating different diseases. Recent success using hematopoietic stem cells to support the failing liver in humans has been reported. Stem cells support of the failing liver might reduce or obviate the need for future liver transplantation.

Research frontiers

Stem cells are present in different tissues, with a rich source in the bone marrow. Different manipulation techniques, such stimulation with as granulocyte colony stimulating factor, enabled the scientists to use stem cells effectively to treat different diseases with different etiologies. Due to the high prevalence of hepatitis viruses, such as hepatitis B virus and hepatitis C virus, the proportion of patients with liver cirrhosis and failing liver is increasing linearly. Although liver transplantation is the definitive treatment, its complicated technique, high costs, immune suppression and limited organ supply are major limitations for its wide use. Stem cell therapy is an innovative technique that can offer an effective, safe, and cheap support for patients with failing livers.

Innovations and breakthroughs

Recent reports have highlighted the importance of using stem cells in supporting the failing liver, with promising results for a wide range of etiologies of liver insult. This is the first large, randomized, and controlled study to report the value of using autologous hematopoietic CD34, CD133 stem cells to support the failing liver, with promising 6 mo follow-up results.

Applications

This technique exploits the plasticity of stem cells and the ability of hematopoietic stem cells to change into hepatocytes to support the failing liver in patients with end-stage liver disease of various etiologies. In the future this technique might reduce the need for liver transplantation.

Terminology

Hematopoietic CD34, CD133 Stem cells are bone marrow cells specialized in forming different blood elements and being stem cells, they have the character of plasticity and can change into hepatocytes. Previous human studies and the present one demonstrated, directly and indirectly, the ability of these cells to support the failing liver.

Peer review

In this manuscript, Salama *et al* evaluated the therapeutic efficacy of autologous stem cell transplantation in end-stage liver cirrhosis. They evaluated a large number of patients, and found beneficial effects of this therapy. The issue is not novel, but the current study enrolled the largest series of patients ever evaluated. The study design is fair, and the study is well performed. Findings are sound and of potential impact in the field.

Abstract

AIM: To investigate the effect of total salvianolic acid (TSA) on ischemia-reperfusion (I/R)-induced rat mesenteric microcirculatory dysfunctions.

METHODS: Male Wistar rats were randomly distributed into 5 groups (n = 6 each): Sham group and I/R group (infused with saline), TSA group, TSA + I/R group and I/R + TSA group (infused with TSA, 5 mg/kg per hour). Mesenteric I/R were conducted by a ligation of the mesenteric artery and vein (10 min) and subsequent release of the occlusion. TSA was continuously infused either starting from 10 min before the ischemia or 10 min after reperfusion. Changes in mesenteric microcirculatory variables, including diameter of venule, velocity of red blood cells in venule, leukocyte adhesion, free radicals released from venule, albumin leakage and mast cell degranulation, were observed through an inverted intravital microscope. Meanwhile, the expression of adhesion molecules CD11b/CD18 on neutrophils was evaluated by flow cytometry. Ultrastructural evidence of mesenteric venules damage was assessed after microcirculation observation.

RESULTS: I/R led to multiple responses in mesenteric post-capillary venules, including a significant increase in the adhesion of leukocytes, production of oxygen radicals in the venular wall, albumin efflux and enhanced mast cell degranulation *in vivo*. All the I/R-induced manifestations were significantly reduced by pre- or post-treatment with TSA, with the exception that the I/R-induced increase in mast cell degranulation was inhibited only by pre-treatment with TSA. Moreover, pre- or post-treatment with TSA significantly attenuated the expression of CD11b/CD18 on neutrophils, reducing the increase in the number of caveolae in the endothelial cells of mesentery post-capillary venules induced by I/R.

CONCLUSION: The results demonstrated that TSA protects from and ameliorates the microcirculation disturbance induced by I/R, which was associated with TSA inhibiting the production of oxygen-free radicals in the venular wall and the expression of CD11b/CD18 on neutrophils.

INTRODUCTION

Ischemia-reperfusion (I/R) injury occurs in a wide range of situations, including trauma, vascular reflow after contraction, percutaneous transluminal coronary angioplasty, thrombolysis treatment, organ transplantation, and hypovolemic shock with resuscitation[1], leading to systemic disorders with high morbidity and mortality. I/R-induced microcirculatory disturbance is the pathological basis of I/R injury, manifesting as a complex process that includes endothelial cell dysfunction, enhanced adhesion of leukocyte, macromolecular efflux, production of reactive oxygen species, and mast cell degranulation[2]. The insults triggered by I/R in microcirculation interplay with each other in various ways that creates a vicious circle that exaggerates the impact, among which, the explosively produced peroxides injure the vessels[2], promote expression of intercellular cell adhesion molecule-1 (ICAM-1)[3] and leukocyte adhesion molecules CD11b/CD18[4], leading to an increase in the adhesion of leukocytes to venules[5]. On the other hand, the leukocytes adhered to the venular wall, in turn, release peroxides and protease[6-9] that injure the endothelium and basement membrane of vessels, causing the leakage of serum[2]. Besides, the degranulated mast cell induced by I/R[2] release pro-inflammatory factors and vasoactive substances to attack the vessels from outside[8-10]. Clearly, an agent that targets the multiple insults simultaneously would be appealing for management of I/R-induced microcirculatory dysfunction. However, the study in this regard remains limited.

Total salvianolic acid (TSA) is the major water-soluble ingredient of *Salvia miltiorrhiza* (SM), including 3,4-dihydroxy-phenyl lactic acid (DLA), salvianolic acid A (Sal A), salvianolic acid B (Sal B) and other salvianolic acids[2]. SM and SM-containing preparations have been clinically used in the prevention and treatment of various vascular diseases[2]. Previous studies have shown that pre-treatment with Cardiotonic Pills (CP, the major ingredients of which are DLA and Sal B) attenuated the gut I/R-induced leukocyte adhesion in liver sinusoids and plasma tumor necrosis factor-α (TNF-α) and endotoxin[11], diminished the thrombi induced by photochemical stimulation in rat mesenteric venules[12], and prevented I/R-induced myocardial microcirculatory disturbance and myocardial damage in rats[13]. DLA attenuated the production of oxygen radicals and the expression of leukocyte adhesion molecules CD11b/CD18 in mesenteric microcirculatory disturbance induced by I/R[14]. Sal A has the potential of anti-oxidation[15-19], and may normalize membrane permeability[19]. Sal B could inhibit endotoxin-induced rat mesenteric microcirculation disturbance, inhibit the expression of adhesion molecule CD11b/CD18, production of hydrogen peroxide and negative oxygen anion[20-22]. However, the extraction process of DLA and Sal B is complex and the extraction conditions are hard to control, leading to a high cost for DLA and Sal B production. On the other hand, TSA, as the major water-soluble ingredient of SM, has the advantage that the extraction procedure is easily manipulated with a high output and low cost. However, whether TSA can improve microcirculatory disturbance induced by I/R is not clear. Therefore, in this study, we investigated the effect of TSA on I/R-induced rat mesenteric microcirculatory dysfunctions.

MATERIALS AND METHODS

Reagents

TSA was purchased from Kun Ming Feng-Shan-Jian Medical Company (Yun-Nan, China). Dihydrorhodamine 123 (DHR) was obtained from Molecular Probes Ltd. (Eugene, OR, USA). Fluorescein isothiocyanate (FITC)-albumin and toluidine blue were obtained from Sigma Chemical Co. (St Louis, MO, USA). FITC-labeled anti-CD11b, FITC-labeled anti-CD18 antibodies were from BD Biosciences Pharmingen (USA), all other chemicals used were of the highest grade available commercially.

Animals

Male Wistar rats, weighing 200-250 g, were obtained from the Animal Center of Peking University Health Science Center (Beijing, certificate No. SCXK 2002-0001), and randomly distributed into Sham group, I/R group, TSA group, TSA + I/R group and I/R + TSA group. The rats were fasted for 12 h before the experiment, allowing for free access to water. All animals were handled according to the guidelines of the Peking University Health Science Center Animal Research Committee, and the surgical procedures and experimental protocol were approved by Peking University Biomedical Ethics Committee Experimental Animal Ethics Branch.

Preparation of rats for I/R

Surgical procedure in the present study was almost the same as our previous study. Rats were anesthetized and the left jugular vein was cannulated for the infusion of TSA or saline. After the abdomen was opened, an ileocecal portion of the mesentery was gently mounted on a transparent plastic stage designed for the rat. The mesentery was kept warm and moist by continuous superfusion with saline solution at 37℃. The mesenteric microcirculation was observed by a transillumination method using an inverted microscope (DM-IRB, Leica, Germany). The mesentery was transilluminated with a 12-V, 100-W, direct current-stabilized light source. A color video camera (Jk-TU53H, Toshiba, Japan) was mounted

on the microscope, and the image was transmitted onto a monitor (J2118A, TCL, Korea). The images were recorded with a Digital Video Disk (DVD) videocassette recorder (DVR-R25, Malata, China). Single unbranched venules with diameters ranging between 30 and 50 μm and length longer than 200 μm were selected for study[2].

After 10 min of basal observation of the hemodynamics in the rat mesenteric microvasculature, the I/R was accomplished by ligating the feeding branch of the anterior mesenteric artery and the corresponding vein simultaneously with a snare created by 2-0 silk suture for 10 min and subsequent release of the blood flow. Red blood cell velocity in the vessels during the ischemia was not zero because of the possible collateral perfusion to the observed area. Thus both artery and vein were ligated to stop blood supply and induce venule congestion to enhance ischemia. A previous study showed that 10-min ischemia followed by reperfusion was long enough to induce mesenteric microcirculatory disturbance with minimum intestinal tissue injury[5]. Sham-operated rats without I/R were used as control[14].

Administration of TSA

In the I/R group, the vehicle saline (8 mL/kg per hour) was infused *via* the left jugular vein catheter starting from 10 min before the ischemia and sustained until the end of the observation. The animals of the sham-operated group (Sham group) received the same infusion as those in the I/R group. The animals of the TSA group received only TSA (5 mg/kg per hour) until the end of the observation, without I/R surgery. In pre-treatment with TSA group (TSA + I/R group), the TSA (5 mg/kg per hour) was continuously infused *via* the left jugular vein catheter starting from 10 min before ischemia until the end of the observation. In post-treatment with TSA group (I/R + TSA group), the TSA (5 mg/kg per hour) was continuously infused *via* the left jugular vein catheter at the same doses as those in pre-treatment group but starting from 10 min after reperfusion until the end of the observation (Figure 1).

Measurement of microvascular parameters

Venular diameter was measured on the recorded video images at baseline (before ischemia), 1, 10, 20, 30, 40, 50 and 60 min after reperfusion, using Image-Pro Plus 5.0 software (Media Cybernetic, USA). The diameter was presented as the mean of three measurements at one location[23].

The velocity of red blood cells (RBCs) in the venule was recorded at a rate of 1000 frames/s using a high-speed video camera system (Ektapro 1000, San Diego, CA, USA), and the recordings were replayed at a rate of 25 frames/s from the high-speed stored images. RBCs velocity in the venule was measured with Image-Pro Plus 5.0 software at baseline (before ischemia), 1, 10, 20, 30, 40, 50 and 60 min after reperfusion[23].

The number of leukocytes adhered to the venules was determined off-line during play-back of videotaped images. Leukocytes adhered to the venules were identified as cells that attached to the same site for more than

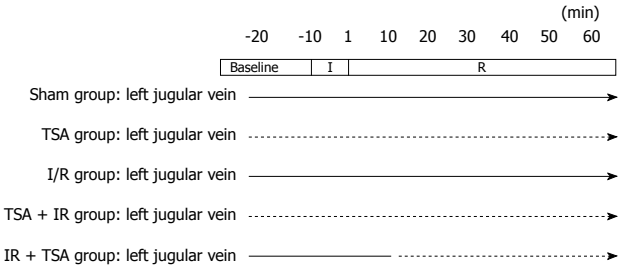

Figure 1 The protocol of the experiment. The saline and total salvianolic acid (TSA) was continuously infused through the left jugular vein in all groups. Solid arrow represents the infusion with saline to the rat; Dotted arrow represents the infusion with TSA to the rat. -20 min represents the time point of 10 min before ischemia; -10 min represents the time point of the beginning of ischemia; 1, 10, 20, 30, 40, 50 and 60 min represent the time point of 1, 10, 20, 30, 40, 50 and 60 min after reperfusion. I: Ischemia; R: Reperfusion.

10 s judging from the replayed video images. The number of adherent leukocytes was counted along venules (30-50 μm in diameter, 200 μm in length) selected from the videotape images recorded and expressed as the number per 200 μm of venule length[23].

The oxidant-sensitive fluorescent probe dihydrorhodamine 123 (DHR; Molecular probes) was added to the mesenteric surface (10 μmol/L) to assess the oxidant stress in venular walls. The excitation light of 455 nm was irradiated from a mercury burner (100 W) to the inverted fluorescence microscope (DM-IRB, Leica, Germany) to observe the fluorescence. The fluorescent image was recorded at baseline (before ischemia), 1, 10, 20, 30, 40, 50 and 60 min after reperfusion, using CD recorder and the fluorescent intensity of venular walls and extravenular interstice was measured with Image-Pro Plus 5.0 software. The difference between the fluorescent intensity of venular wall and extravenular interstice at every time point was determined, and the ratio of the value at each time point to that at baseline was calculated[23].

In another set of experiments, to evaluate the albumin leakage across mesenteric venules, the animals were intravenously injected with 5 mg/kg body weight of FITC-labeled bovine serum albumin. After 10 min of basic observation, an excitation light (455 nm wavelength) was irradiated from a mercury burner (100 W) to the inverted fluorescence microscope (DM-IRB, Leica, Germany). At baseline (before ischemia), 1, 10, 20, 30, 40, 50 and 60 min after reperfusion, the image was recorded using a Compact Disk recorder. The fluorescence intensity of FITC-albumin inside the lumen of selected venules (Iv) and in the surrounding interstitial area (Ii) was estimated. The ratio of Ii/Iv was calculated and compared with the baseline as an indicator of albumin leakage[23].

Sixty minutes after reperfusion, the tissue was stained with 0.1% toluidine blue for 1 min and rinsed with saline. Degranulated mesenteric mast cells were identified by the presence of intracellular granules released into the surrounding tissue, and counted within each circular microscopic field of view with a 20 × objective lens. Five fields were evaluated along the microvasculature for each mes-

enteric window. The numbers of both non-degranulated and degranulated mast cells were scored, and the percentage of degranulated mast cells was thus calculated[23].

Determination of expression of adhesion molecules CD11b and CD18 on neutrophils

In another set of experiments, blood was taken from the abdominal aorta of rats and anticoagulated with heparin, and, afterward, incubated with FITC-labeled anti-CD11b antibody (5 μg/mL) or FITC-labeled anti-CD18 antibody (5 μg/mL) or corresponding FITC-labeled mouse isotype (5 μg/mL) for 20 min at room temperature. The erythrocyte lysis was accomplished using haemolysin according to the manufacturer's instruction, and the cells were washed twice with PBS. The mean fluorescence intensity was calculated with flow cytometry (FACS Calibur; BD Company, USA). Neutrophils were then sorted by characteristic forward-/side-scatter expression as reported previously[23]. Five thousand neutrophils were evaluated for each sample.

Electron microscopy

The mesentery in each experiment condition was also prepared for electron microscopy. Briefly, immediately after 60 min perfusion, the rats, maintained under deep anesthesia, underwent perfusion through the left ventricle with physiological saline followed by 120 mL of phosphate-buffered 40 g/L paraformaldehyde plus 20 g/L glutaraldehyde at a speed of 3 mL/min. The mesentery tissues were then removed, localized and further fixed by immersion in phosphate-buffered 30 g/L glutaraldehyde for 1 h. The tissues were routinely processed for transmission electron microscopy and examined in JEM 1230 (JEOL, Japan)[24].

Statistical analysis

The data were analyzed by one-way ANOVA and Fisher's post test. All values were expressed as mean ± SE of values from 6 rats. $P < 0.05$ was considered statistically significant.

RESULTS

Changes in vascular diameter and velocity of RBC in venules

No significant alteration was observed in the diameter of either arterioles or venules in mesenteric microcirculation during 60 min of observation, and the situation remained unchanged by continuous per- or post-treatment with TSA (data not shown).

I/R induced a significant decrease in the velocity of RBCs over the first 10 min after reperfusion. A similar alteration was observed in the TSA + I/R group and I/R + TSA group. The result demonstrated that pre- or post-treatment with TSA has no significant influence on the decrease of RBCs velocity induced by I/R (data not shown).

Changes in the number of leukocytes adhered to the venular walls

The images of leukocytes adhered to the venular walls in each group at baseline, 10 and 60 min after the reperfusion are illustrated in Figure 2A. No adherent leukocyte was observed before ischemia in each group (a1-e1). At 10 min after reperfusion, a small amount of adherent leukocytes were observed along the venular walls in the animals subjected to I/R (c2-e2). At 60 min after reperfusion, numerous adherent leukocytes were observed along the venular walls (c3) in I/R group. While in TSA+I/R group (d3) and I/R+TSA group (e3), only few of the adherent leukocytes were observed.

The time course of changes in the number of leukocytes adherent to venular walls was examined and the result is depicted in Figure 2B. Obviously, the number of adherent leukocytes in the Sham and TSA group increased only slightly during the whole period of observation. The number of adherent leukocytes was significantly increased from 10 min and further up to 60 min after reperfusion. Pre-treatment with TSA significantly decreased the number of adherent leukocytes at 20 min after reperfusion. Post-treatment with TSA significantly attenuated the further increase of adherent leukocytes from 40 min after reperfusion.

Changes in fluorescence intensity of DHR in the venular walls

The images of fluorescence intensity of DHR in the venular walls in each group at baseline, 10 and 60 min after the reperfusion are illustrated in Figure 3A. No DHR fluorescence was detected on rat mesenteric venular walls before I/R (a1-e1). I/R induced a pronounced DHR fluorescence on mesenteric venular walls (c3). Pre-treatment with TSA significantly attenuated the I/R-induced DHR fluorescence enhancement (d3). Post-treatment with TSA inhibited the I/R-induced increase in DHR fluorescence ratio in a similar fashion (e3).

The time course of changes in DHR fluorescence ratio on the venular walls is presented in Figure 3B. In the Sham group and TSA group, there was no significant change in the DHR fluorescence ratio on the venular wall throughout the observation. In the I/R group, the intensity of DHR fluorescence on the venular wall increased apparently and lineally until the end of reperfusion. Pre-treatment with TSA apparently attenuated the I/R-induced DHR fluorescence intensity on the venular walls at 10 min after reperfusion. Post-treatment with TSA attenuated the further increase of DHR fluorescence intensity on the venular walls at 20 min after reperfusion, with the fluorescence intensity of DHR on the venular wall keeping nearly constant over the remaining time.

Changes in albumin leakage

The images of albumin leakage in each group at baseline, 10 and 60 min after the reperfusion are illustrated in Figure 4A. No albumin leakage was observed before ischemia in all conditions (a1-e1). In the I/R group, apparent leakage was observed at 60 min after reperfusion (c3). Pre-treatment with TSA significantly prevented FITC-labeled albumin leakage from rat mesentery ve-

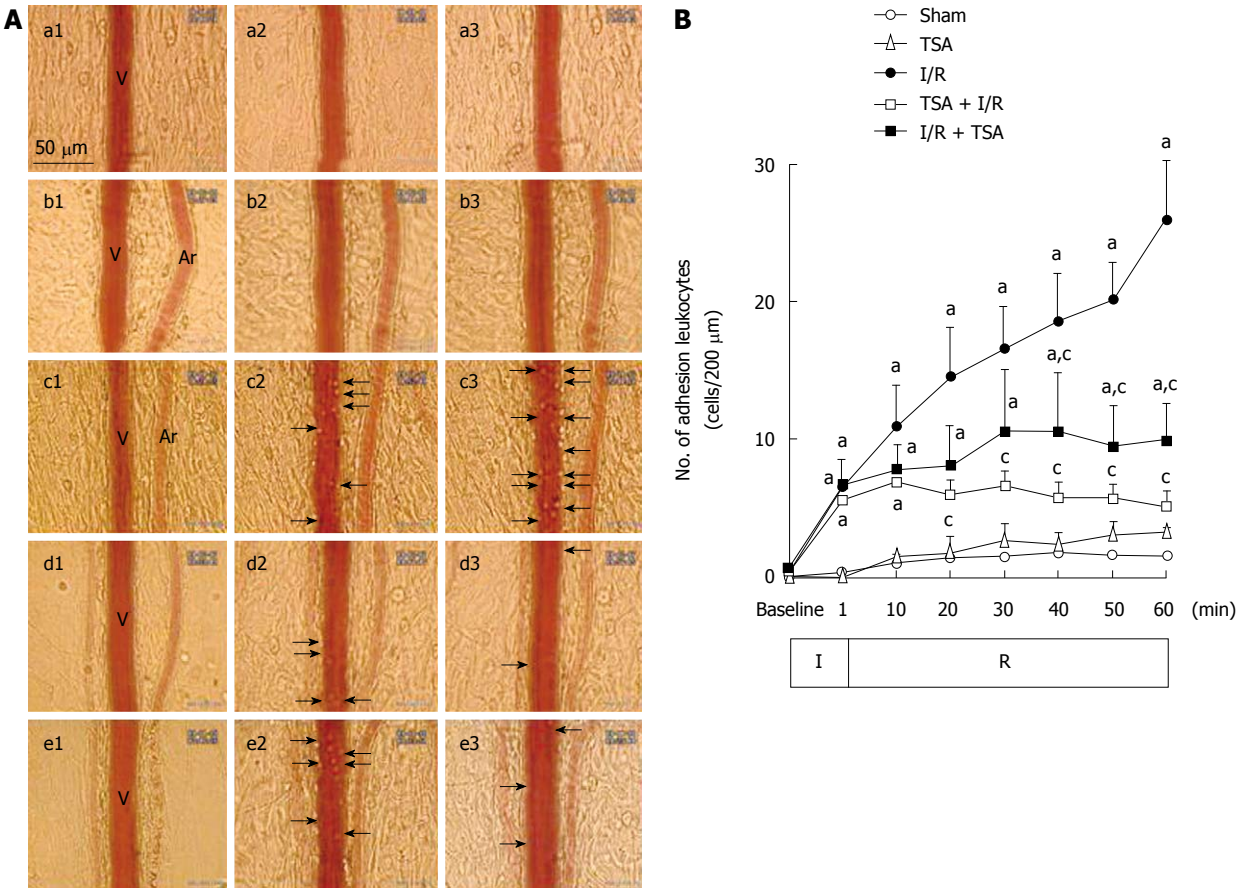

Figure 2 The effect of pre-treatment and post-treatment of total salvianolic acid on ischemia-reperfusion-induced leukocyte adhesion to the rat mesenteric venular wall. A: Representative images illustrating the effect of pre-treatment and post-treatment of total salvianolic acid (TSA) on leukocyte adhesion to the venular wall induced by ischemia-reperfusion (I/R) in rat mesentery. a1-a3: Rat mesentery images of Sham group at baseline, 10 and 60 min, respectively. b1-b3: Rat mesentery images of TSA group at baseline, 10 and 60 min, respectively. c1-c3: Rat mesentery images of I/R group at baseline, 10 and 60 min, respectively. d1-d3: Rat mesentery images of rat mesentery of TSA + I/R group at baseline, 10 and 60 min respectively. e1-e3: Rat mesentery images of I/R + TSA group at baseline, 10 and 60 min, respectively. V: Rat mesenteric venule; Ar: Rat mesenteric arteriole; Arrows: Leukocytes adhered to the venular wall; B: Time course of changes in the number of leukocytes adherent to the mesenteric venules of rat. The number of adherent leukocytes was expressed as the number of cells per 200 μm of venules. Sham: Sham group; TSA: TSA group; I/R: I/R group; TSA + I/R: TSA plus I/R group; I/R + TSA: I/R plus TSA group. Data was expressed as mean ± SE of six animals. $^{a}P < 0.05$ *vs* sham group; $^{c}P < 0.05$ *vs* I/R alone.

nules challenged by I/R (d3). Post-treatment with TSA prevented further increase in the albumin leakage (e3).

The changes in albumin leakage from the rat mesenteric venules were quantitated and the result is shown in Figure 4B. In the Sham group and TSA group, there was no significant change in the albumin leakage ratio from venular walls throughout the observation. In the I/R group, the albumin leakage from venules increased immediately after the initiation of reperfusion in a time-dependent manner. Pre-treatment with TSA significantly attenuated the albumin leakage from venular walls at 10 min after reperfusion. Post-treatment with TSA attenuated the further increase in the albumin leakage from venular walls from 20 min after reperfusion.

Mast cell degranulation

Mast cell degranulation was examined after 60 min of reperfusion in various conditions (Figure 5A). I/R evoked an apparent increase in mast cell degranulation (c), while pre-treatment with TSA significantly inhibited the mast cell degranulation (d). The results were quantified as the percent of the number of degranulated mast cells to the total number of mast cells examined (Figure 5B). The percentages of degranulated mast cells in the Sham group and TSA group were 20.7% ± 0.7% and 21.7% ± 2.5%, respectively, representing the spontaneous occurrence of the mast cell degranulation in the present case. I/R resulted in an apparent increase in the mast cell degranulation (62.2% ± 2.5%), and this increase was suppressed significantly by pre-treatment with TSA (23.7% ± 4.7%). Post-treatment with TSA almost had no effect on mast cell degranulation compared to I/R group (52.4% ± 2.2% *vs* 62.2% ± 2.5%).

Fluorescence intensity of adhesion molecules CD11b and CD18 in neutrophils

An *in vitro* study was performed to determine the fluorescence intensity of adhesion molecules CD11b and CD18 in neutrophils (Figure 6). The fluorescence intensity of CD11b (Figure 6B) and CD18 (Figure 6A) was significantly increased by I/R compared to the Sham group. Pre-treatment with TSA significantly inhibited the increase in

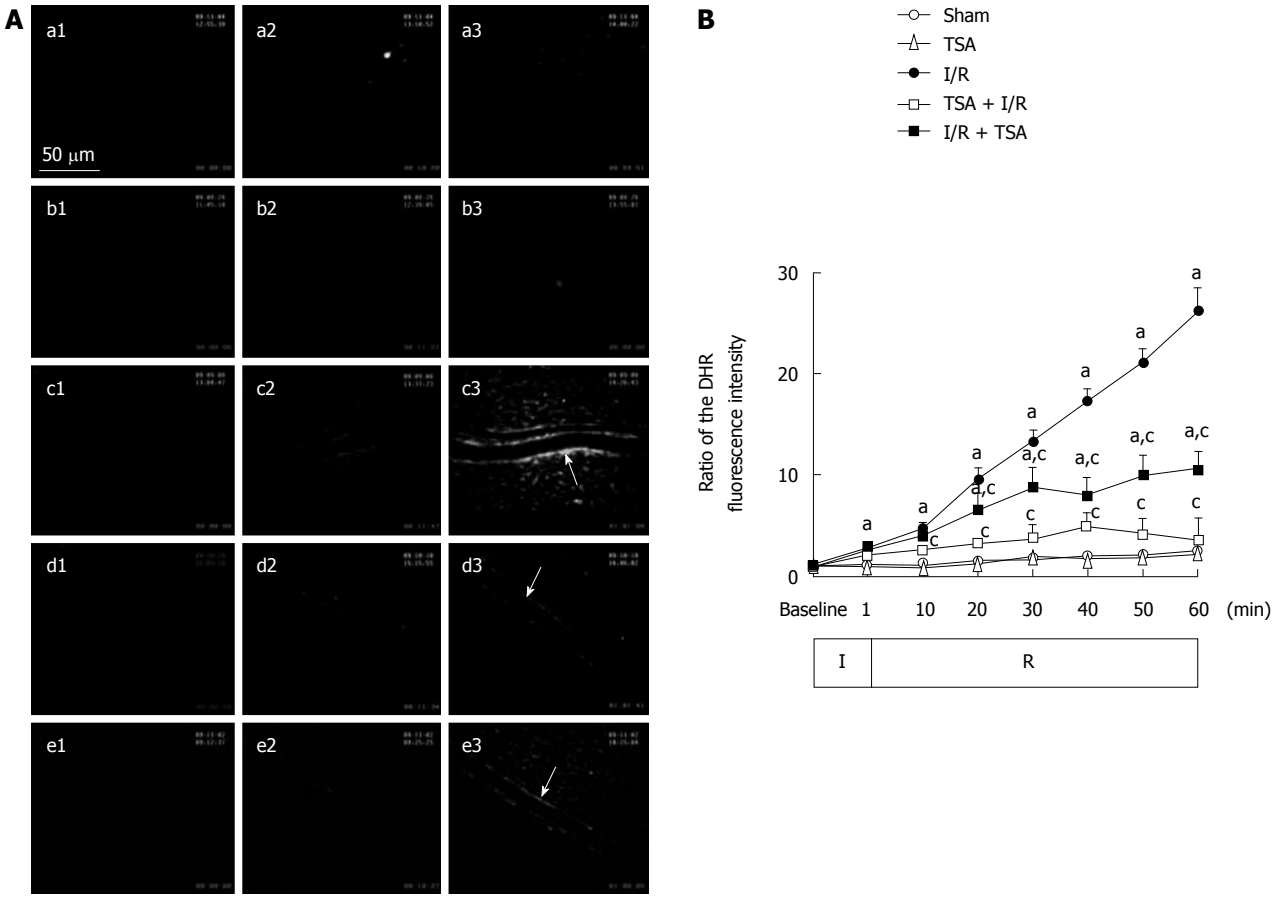

Figure 3 The effect of pre-treatment and post-treatment of total salvianolic acid on ischemia-reperfusion-induced dihydrorhodamine 123 fluorescence in rat mesenteric venular wall. A: Representative images of the changes in fluorescence intensity of the H_2O_2-sensitive probe dihydrorhodamine 123 (DHR) in the rat mesenteric venular wall. a1-a3: DHR fluorescence images of rat mesentery of Sham group at baseline, 10 and 60 min, respectively. b1-b3: Fluorescence images of rat mesentery of total salvianolic acid (TSA) group at baseline, 10 and 60 min, respectively. c1-c3: Fluorescence images of rat mesentery of ischemia-reperfusion (I/R) group at baseline, 10 and 60 min, respectively. d1-d3: Fluorescence images of rat mesentery of TSA + I/R group at baseline, 10 and 60 min, respectively. e1-e3: Fluorescence images of rat mesentery of I/R + TSA group at baseline, 10 and 60 min, respectively. Baseline, no DHR fluorescence is visible in all groups (a1-e1). 60 min after I/R, prominent DHR fluorescence occurs on the wall of venule of rat mesentery (c3-e3). Arrows: DHR fluorescence on the venular wall; B: Time course of changes in DHR fluorescence ratio on the venular walls. Sham: Sham group; TSA: TSA group; I/R: I/R group; TSA + I/R: TSA plus I/R group; I/R + TSA: I/R plus TSA group. Data was expressed as mean ± SE of six animals. $^{a}P < 0.05$ *vs* sham group; $^{c}P < 0.05$ *vs* I/R alone.

fluorescence intensity of CD11b and CD18 in neutrophils induced by I/R. A similar effect was observed for post-treatment with TSA.

Ultrastructure changes in post-capillary venules

Figure 7 presents the electron micrographs of rat mesentery post-capillary venules in each group. In the Sham group (A) and TSA group (B) venules were lined by a layer of endothelial cells, which exhibited a rather smooth inner face with occasionally occurring vesicles in the cytoplasm. At 10 min after reperfusion (C) in I/R group, the adherent leukocyte and platelet were observed within the lumen of venules in rat mesentery, and numerous caveolae emerged in the endothelial cells of post-capillary venules. At 60 min after reperfusion, an even more apparent alteration in the ultrastructure of the endothelial cell occurred, characterized by the increase in the number and size of caveolae in the cytoplasm (D). I/R-induced alterations in the ultrastructures of endothelial cell were abated by pre-and post-treatment with TSA (E and F).

DISCUSSION

With the animal model of rat mesenteric microcirculation disturbance induced by I/R, this research demonstrated that pre-treatment with TSA has an improvement effect on the adhesion of leukocytes to venules, production of peroxides in the venular wall, albumin leakage and mast cell degranulation induced by I/R. Post-treatment with TSA displays an improvement action on the I/R-induced insults likewise, except for the mast cell degranulation.

The diameters of the mesenteric venules were not changed after I/R, and TSA had no effect on venular diameter during I/R, suggesting that TSA does not affect vascular tone. Therefore, TSA exerts protective effects on I/R-induced microcirculatory disturbance through a way other than vasodilation. In addition, both pre- and post-treatment with TSA had no apparent influence on the decrease of RBCs velocity induced by I/R, indicating that TSA does not affect the hemodynamics of the rats.

One of the interesting results in this study is that pre-

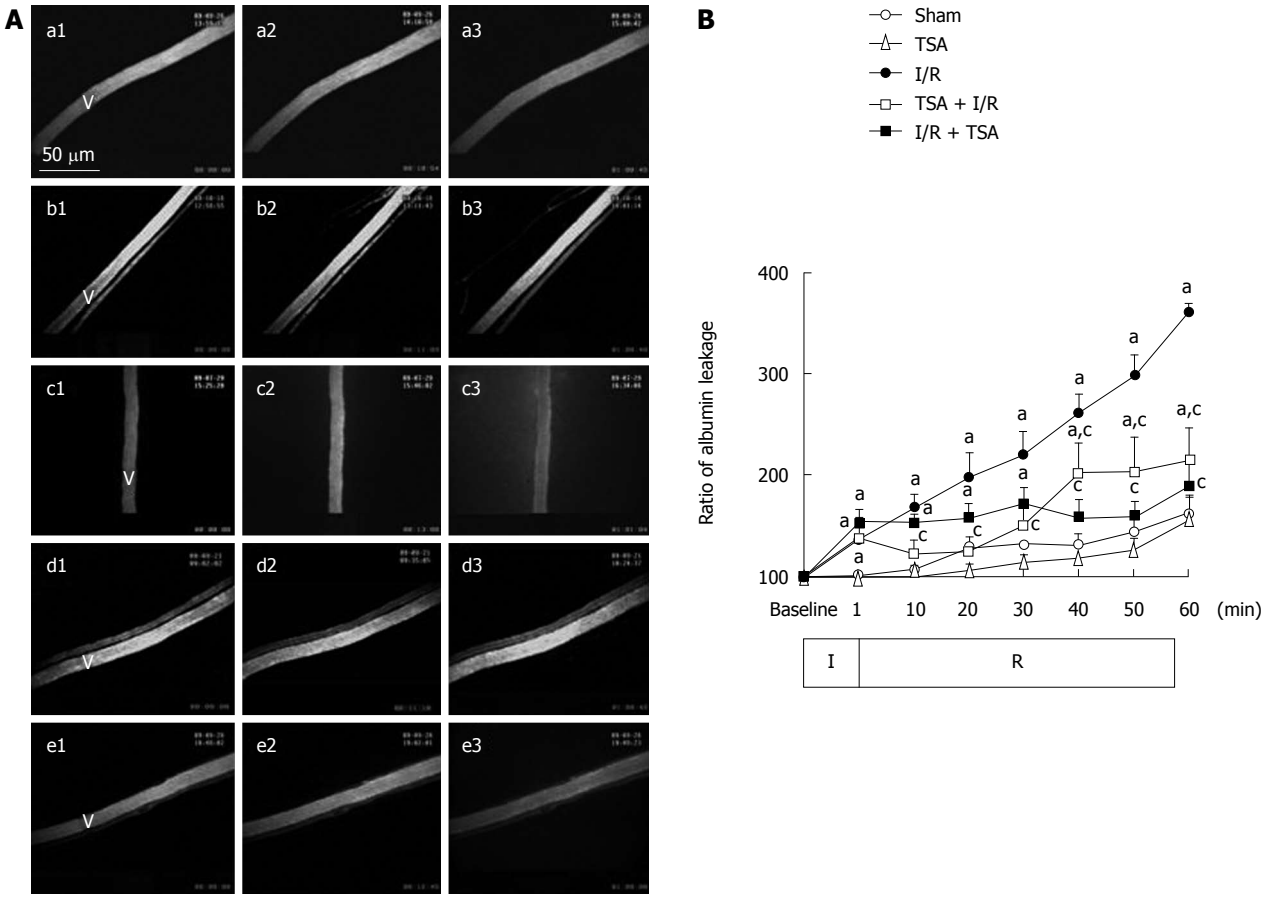

Figure 4 The effect of pre-treatment and post-treatment of total salvianolic acid on ischemia-reperfusion-induced albumin leakage from rat mesenteric venule. and post-treatment with TSA inhibited the DHR fluorescence intensity in the venular walls following I/R. It has been reported that I/R challenge leads to production of oxygen-free radicals by xanthine oxidase[25], and leukocyte adhered to vascular walls generates a peroxide burst through the NADPH oxidase[26-29] is one of the reasons of injury in vascular endothelium and basement membrane[30,31]. So inhibition of the production of oxygen-free radical induced by I/R can help protect the blood vessels. Previous studies have shown that DLA can clear the negative oxygen anions produced through the xanthine oxidase system[32-34]. Sal A was reported to inhibit cerebral lipid peroxidation after I/R, and scavenge oxygen-free radical *in vitro*[18]. Sal B could eliminate 1,1-diphenyl-2-picrylhydrazyl (DPPH), inhibit lipid peroxidation[35] and production of reactive oxygen species[36], remove hydrogen peroxide in a dose-dependent way and inhibit the activity of NADPH and peroxide generation induced by TNF-α[37]. However, the effect of TSA on the production of oxygen free radicals on venular walls induced by I/R *in vivo* has not been reported. In the present study, we assessed the production of hydrogen peroxide (H_2O_2) in the venular wall with the aid of DHR, a fluorescence probe that transforms to rhodamine when reacting with hydrogen peroxide, and proved that TSA can inhibit the DHR fluorescence intensity on the venular walls following I/R. The mechanism for TSA to inhibit the hydrogen peroxide remains to be elucidated, and it is most likely that its ingredients DLA, Sal A and Sal B work in coordination through their own pathways to produce a collective outcome.

Another important observation in this study was that pre- or post-treatment with TSA can inhibit I/R induced adhesion of leukocytes to venular walls. It was reported that I/R promotes the expression of ICAM-1 on endothelium[38] and CD11b/CD18 in neutrophils, leading to the adhesion of leukocyte to vascular wall[39,40]. Inhibiting the adhesion of leukocytes to the vascular wall is another important part of improving the microcirculatory disturbance induced by I/R. Our previous study also demonstrated that DLA can inhibit I/R-induced adhesion of leukocyte to rat mesenteric venule and expression of adhesion molecule CD11 b/CD18 *in vitro*[20]. No report has been published so far concerning inhibition of TSA on

leukocyte adhesion to venular walls induced by I/R. This study proved that pre- or post-treatment with TSA can inhibit I/R induced adhesion of leukocytes to venular walls, which was associated with the inhibition of TSA on the expression of CD11b/CD18 in neutrophils.

I/R induced mast cell degranulation, resulting in release of pro-inflammatory factors[41,42] and vasoactive substances that attack the vessels from outside, increasing the vascular damage. Inhibiting the degranulation of mast cells after I/R can reduce the attacks on vessels from outside. This study proved that pre-treatment with TSA can inhibit I/R induced mast cell degranulation. However, based on the result that post-treatment with TSA could not inhibit mast cells degranulation, the inhibitory effect of TSA upon mast cells degranulation is considered to be an indirect result.

In the present study, we demonstrated that pre- or post-treatment with TSA could inhibit FITC-albumin leakage from venules. It was documented in the lung[43] and myocardium[44] that the increased vascular permeability induced by inflammatory stimulations is due to the enlarged population of caveolae, which play a significant role in microvascular permeability[44]. In line with these findings, the result of electron microscopy in the present study showed that the number of caveolae in the endothelial cells of venules was apparently increased at 60 min after reperfusion, whereas the endothelial cells themselves and the intercellular junctions remained intact, implying that I/R-induced albumin leakage observed in the present situation was mainly accomplished by the caveola. The present study demonstrated that pre- or post-treatment with TSA could reduce the number of endothelial caveola as well as FITC-labeled albumin leakage from venular wall induced by I/R, suggesting that it inhibited albumin leakage from venular wall by modulating the number of endothelial caveola. In addition, the inhibition of TSA on FITC-albumin leakage may be also related to inhibition of peroxide generation and the adhesion of leukocytes to venules, thus protecting the venule from inside.

En: Endothelial cell; CV: Caveolae; L: Leukocyte.

In summary, the present study demonstrated that pretreatment with TSA significantly improved the microcirculatory dysfunction in rat mesentery induced by I/R. TSA post-treatment starting from 20-min reperfusion ameliorated I/R-induced microcirculatory disorders in rat mesentery alike but in a distinct manner. The *in vitro* experiment revealed that H_2O_2-elicited enhancement in the expression of CD11b and CD18 on neutrophils was significantly attenuated by treatment with TSA, raising the possibility that the ability of TSA to inhibit the leukocyte adhesion may be correlated with its potential to suppress the expression of adhesion molecules. It is likely that the antioxidant activity of TSA and its inhibition on the expression of adhesion molecules CD11b/CD18 on leukocyte are underlying its ameliorating action on I/R-induced microcirculatory disturbance in rat mesentery.

COMMENTS

Background

Ischemia-reperfusion (I/R) injury occurs in a wide range of situations, including trauma, vascular reflow after contraction, percutaneous transluminal coronary angioplasty, thrombolysis treatment, organ transplantation, and hypovolemic shock with resuscitation. I/R-induced microcirculatory disturbance with diverse manifestations is considered to be the pathological basis of I/R injury. An agent that targets the multiple insults simultaneously would be appealing for management of I/R-induced microcirculatory dysfunction. However, the study in this regard remains limited. Total salvianolic acid (TSA) is the major water-soluble ingredient of Salvia miltiorrhiza (SM), SM and SM-containing preparations have been clinically used in the prevention and treatment of various vascular diseases. However, whether the TSA can improve microcirculatory disturbance induced by I/R are not clear. The results of the present study provide evidence for the beneficial role of TSA in attenuating microcirculatory disorders, using I/R-induced rat mesenteric microcirculatory dysfunction as a model.

Research frontiers

3,4-dihydroxy-phenyl lactic acid, salvianolic acid A and salvianolic acid B are the main ingredients of TSA. However, the extraction process of 3,4-dihydroxy-phenyl lactic acid, salvianolic acid A and salvianolic acid B is complex and the extraction conditions are hard to control. On the other hand, TSA, if taking as a whole, has the advantage of high output and low cost in preparation. The present work shows the potential of TSA for management of I/R-induced microcirculatory dysfunctions. Innovations and breakthroughs: this study proves, for the first time, the ability of TSA to inhibit I/R-induced dihydrorhodamine 123 fluorescence intensity, and adhesion of leukocytes to venular walls, the latter of which was possibly associated with the inhibition of TSA on the expression of CD11b/CD18 in neutrophils.

Applications

These results provide a theoretical support for TSA containing Chinese medicine intervention in microcirculatory disturbance induced by thrombolytic therapy or other I/R-related clinical events.

Terminology

TSA is the water-soluble extract of SM, consisting of 3,4-dihydroxy-phenyl lactic acid, salvianolic acid A and salvianolic acid B as major ingredients.

Peer review

The authors demonstrated the inhibitory effect of total salvianolic acid inhibiting several markers associated with ischemia-reperfusion injury. This paper was well-organized and well-investigated, and has a novel finding in this manuscript.

Abstract

AIM: To investigate if antibiotics administered within 8 h of endoscopy reduce mortality or increase the incidence of *Clostridium difficile* infection (CDI).

METHODS: A 2-year retrospective analysis of all patients who presented with first variceal hemorrhage was undertaken. The primary outcome measure was 28-d mortality. Secondary outcome measures were 28-d rebleeding rates and 28-d incidence of CDI. All patients were admitted to a tertiary liver unit with a consultant-led, 24-h endoscopy service. Patients received standard care including terlipressin therapy. Data collection included: primary and secondary outcome measures, timing of first administration of intravenous antibiotics, etiology of liver disease, demographics, endoscopy details and complications. A prospective study was undertaken to determine the incidence of CDI in the study population and general medical inpatients admitted for antibiotic therapy of at least 5 d duration. Statistical analysis was undertaken using univariate, non-parametric tests and multivariate logistic regression analysis.

RESULTS: There were 70 first presentations of variceal hemorrhage during the study period. Seventy percent of cases were male and 65.7% were due to chronic alcoholic liver disease. In total, 64/70 (91.4%) patients received antibiotics as prophylaxis during their admission. Specifically, 53/70 (75.7%) received antibiotics either before endoscopy or within 8 h of endoscopy [peri-endoscopy (8 h) group], whereas 17/70 (24.3%) received antibiotics at > 8 h after endoscopy or not at all (non peri-endoscopy group). Overall mortality and rebleeding rates were 13/70 (18.6%) and 14/70 (20%), respectively. The peri-endoscopy (8 h) group was significantly less likely to die compared with the non peri-endoscopy group [13.2% *vs* 35.3%, $P = 0.04$, odds ratio (OR) = 0.28 (0.078-0.997)] and showed a trend towards reduced rebleeding [17.0% *vs* 29.4%, $P = 0.27$, OR = 0.49 (0.14-1.74)]. On univariate analysis, the non peri-endoscopy group [$P = 0.02$, OR = 3.58 (1.00-12.81)], higher model for end-stage liver disease (MELD) score ($P = 0.02$), presence of hepatorenal syndrome [$P < 0.01$, OR = 11.25 (2.24-56.42)] and suffering a clinical episode of sepsis [$P = 0.03$, OR = 4.03 (1.11-14.58)] were significant predictors of death at 28 d. On multivariate logistic regression analysis, lower MELD score [$P = 0.01$, OR = 1.16 (1.04-1.28)] and peri-endoscopy (8 h) group [$P = 0.01$, OR = 0.15 (0.03-0.68)] were independent predictors of survival at 28 d. The CDI incidence (5.7%) was comparable to that in the general medical population (5%).

CONCLUSION: Antibiotics administered up to 8 h following endoscopy were associated with improved survival at 28 d. CDI incidence was comparable to that in other patient groups.

INTRODUCTION

In chronic liver disease (CLD), variceal bleeding occurs in 22%-61% of patients with cirrhosis during study follow-up periods of 12-42 mo[1-5]. Seventy percent of bleeding occurs in the 2 years following diagnosis[6]. Historical data suggest a mortality at the time of first and subsequent variceal hemorrhage of 24%-49% and 30%, respectively[7]. Following variceal hemorrhage, higher mortality is associated with increasing severity of CLD as assessed by both the Child-Pugh score (mean survival 37.3 mo with score A versus 11 mo with score C)[8] and Model for End-stage Liver Disease (MELD) score[9]. More recently, American and European data have shown that 6-wk mortality rates have fallen, ranging from 14% to 20%[9-12], and following a UK-wide audit, a 28-d mortality figure of 14% for first and subsequent variceal bleeds has been quoted[13].

A number of factors are associated with poor outcome following variceal hemorrhage[10], including MELD score, transfusion requirement, alcohol as etiology, bilirubin, albumin, hepatic encephalopathy and hepatocellular carcinoma[9,10]. Higher hepatic venous pressure gradient at the time of variceal hemorrhage predicts length of stay, greater transfusion requirement and death[14].

There are several clinical scoring tools available to predict outcome, rebleeding and need for endoscopic intervention following acute gastrointestinal hemorrhage, including the Rockall and Blatchford scores[15,16]. However, scoring tools for predicting outcome following variceal hemorrhage are not commonly used due to difficulty in the identification of predictive variables. A recent publication has shown that severity of liver disease, renal impairment and infection adversely affect outcome following variceal hemorrhage[17].

Bacterial infection is commonly associated with variceal hemorrhage and appears to be an independent risk factor for failure to control bleeding[18] and predicts both early rebleeding and death[19,20]. The routine use of prophylactic broad-spectrum antibiotics has shown a marked improvement in outcome in acute variceal hemorrhage. Routine intravenous ceftriaxone or post-endoscopic norfloxacin reduces rebleeding rates compared to on-demand antibiotics[21,22]. A Cochrane meta-analysis of antibiotic prophylaxis in cirrhotic patients with gastrointestinal bleeding, given either before and after variceal hemorrhage, revealed a 27% reduction in mortality and a reduction in the incidence of bacterial infections by 60%[23].

United States guidelines for antibiotic prophylaxis in cirrhotic patients admitted with upper gastrointestinal hemorrhage have been published by the American Society of Gastrointestinal Endoscopy, and recommend intravenous ceftriaxone on admission as first-line prophylaxis[24].

The British Society of Gastroenterology has recently updated guidelines on the use of antibiotic prophylaxis in gastrointestinal endoscopy. The recommendation is to administer a ureidopenicillin or third-generation cephalosporin to all patients with suspected variceal bleeding, or those with decompensated liver disease who develop gastrointestinal bleeding, prior to endoscopy[25].

In the Cochrane primary studies, antibiotics were given either before or after endoscopy, therefore, the evidence for when antibiotics should be given remains unclear. Of the studies using post-endoscopic antibiotics, the timing of antibiotic administration has rarely been reported. Indeed, the Cochrane review has acknowledged that evidence for the timing of administration of antibiotics is lacking[23].

The use of broad-spectrum antibiotics raises concerns regarding healthcare-associated infections, particularly *Clostridium difficile* (*C. difficile*) infection (CDI). In the United States, the number of hospital admissions due to CDI has steadily risen over the last decade from 2.7 per 1000 admissions in 2000 to 5.1 per 1000 in 2003, with the highest incidence in patients > 65 years (228 per 100 000 patient-years)[26]. A similar picture has been seen in England until recently[27,28], with 80% of cases occurring in the > 65-year-old population[28,29].

A recent study has shown that CDI in cirrhotic patients is associated with a higher mortality compared to cirrhotic patients without CDI[30]. There is currently no literature on the incidence of CDI in cirrhotic patients admitted with acute variceal hemorrhage who are given prophylactic broad-spectrum antibiotics.

The aims of this study were to determine if prophylactic antibiotics, or more accurately peri-endoscopy antibiotics (administered before, during or up to 8 h following endoscopy), were effective in reducing mortality following first variceal hemorrhage, and to assess the rebleeding rates and incidence of CDI infection in this patient population.

MATERIALS AND METHODS

Patient population

This was a retrospective analysis of cases of first variceal hemorrhage who presented to the Southampton Liver Unit, a tertiary referral centre, from December 1, 2006 to December 1, 2008. Seventy cases were identified from the endoscopy computer database using multiple search strategies. Only first presentation variceal hemorrhages were included. All cases of variceal hemorrhage transferred to the Southampton liver unit from other centers were excluded from the analysis.

All patients were admitted to the liver unit after admission and were treated under the care of a consultant hepatologist and received standard care, including the use of intravenous vasoactive drugs, access to interventional radiology and a 24-h on-call therapeutic endoscopy service. A protocol for the dose and duration of the terlipressin prescription was followed in all cases.

Data collection

Data collection included demographics, etiology of CLD, antibiotic therapy (timing of first dose relative to the endoscopy, type of antibiotic prescribed and duration of therapy), endoscopy details, terlipressin use (dose and duration of therapy), rebleeding rates within 28 d, survival at 28 d, incidence of CDI at 28 d, incidence of sepsis, hepatorenal syndrome, spontaneous bacterial peritonitis and ascites. The data were collected from hospital notes and computerized pathology databases. The microbiology database collected CDI cases from the community and therefore cases occurring after discharge form hospital were also included.

All patients who received antibiotics within the a priori time period of before, at the time of, or within the 8 h following endoscopy were included in the first analysis group [peri-endoscopy (8 h) group]. This group was compared to the second patient group, those patients receiving antibiotics > 8 h after endoscopy or not receiving antibiotics (non peri-endoscopy group).

CDI incidence

To compare the incidence of CDI in cirrhotic patients with general medical patients receiving antibiotics, an additional prospective study was undertaken during the variceal study period. Over one calendar month, all general medical patients admitted for antibiotic therapy of at least 5 d duration for non-gastrointestinal reasons were studied on two general medical wards. All patients were < 80 years of age. Patients were excluded if there was a history of prior CDI infection.

Statistics analysis

To compare demographic data between survivors and non-survivors at 28 d, initial assessments for normality of data distribution were undertaken using the Shapiro-Wilk test and Q-Q plot. The data were found to be non-normally distributed (for example MELD score data has a Shapiro-Wilk P value < 0.01 for normality and a sigmoidal curve on Q-Q plot). As a consequence, all further statistical analyses were undertaken using non-parametric tests.

Initially, univariate analysis was performed on ordinal data using the χ^2 test to compare outcome (mortality, rebleeding or CDI, the dependent variable) with each risk factor (antibiotics within 8 h, hepatorenal syndrome and sepsis, the independent variable). Continuous demographic data (age, INR, creatinine, bilirubin, sodium and MELD score) were compared between survivors and non-survivors using the Mann-Whitney U test.

Following univariate analysis, a forward multivariate logistic regression model was fitted with all statistically significant variables on univariate analysis. However, given the sample size and number of events, only two variables were fitted to the model. The first was the initial study variable, the administration of antibiotics within 8 h of endoscopy, and the second was the MELD score assessment of severity of CLD. All statistical analyses were performed using SPSS (version 16) and STATA 11 software.

RESULTS

Patients

Between December 1, 2006 and December 1, 2008, 70 patients with first presentation variceal hemorrhage were admitted to the liver unit, Southampton General Hospital. Baseline demographics are shown in Table 1. The majority of patients were male (70%), and the most common etiology of cirrhosis was alcohol (65.7%). Patients who died within 28 d of the first variceal hemorrhage had a higher baseline MELD score (P = 0.02), mainly due to a higher admission serum bilirubin level (Table 1, P = 0.01). The other component parameters of the MELD score were similar in both groups.

Sixty-four (91.4%) patients received prophylactic antibiotics during their admission, with median (inter-quartile range; IQR) and mean (SE) times from endoscopy to administration of antibiotics of 3.5 (0-7.0) and 5.9 (1.18) h, respectively. The most common antibiotic prescription was cefuroxime and metronidazole (n = 45), followed by ciprofloxacin alone (n = 8) and cefuroxime alone (n = 7). The remaining patients received meropenem alone, or vancomycin in combination with either metronidazole or gentamicin. The median (IQR) and mean (SE) duration of antibiotic therapy was 5.0 (3.0-7.0) and 5.7 (0.57) d, respectively.

Twenty-one patients received antibiotics before or at the time of endoscopy and a further 32 received antibiotics after but within 8 h of the index endoscopy. Therefore, a total of 53 (75.7%) patients received antibiotics before,

Hepatorenal failure	< 0.01	11.25	2.243-56.421	0.71	1.389	0.249-7.755
Sepsis	0.03	4.029	1.113-14.581	0.89	0.902	0.218-3.730

MELD: Model for end-stage liver disease; OR: Odds ratio; CI: Confidence interval.

during or within 8 h of endoscopy, and were included in the peri-endoscopy (8 h) group.

Of the 17 (24.3%) patients in the non peri-endoscopy group, 11 received antibiotics at > 8 h after endoscopy and six did not receive antibiotic prophylaxis.

The vast majority of patients received endoscopic variceal band ligation therapy during the index endoscopy (n = 54) with only four receiving sclerotherapy. Nine patients required a Sengstaken-Blakemore tube. Eight patients received transjugular intrahepatic portosystemic shunting during their admission. None of these factors were significantly associated with mortality, although banding therapy significantly reduced the incidence of rebleeding [P = 0.01, odds ratio (OR) = 0.191, 95% confidence interval (95% CI) = 0.054-0.680], and the requirement for a Sengstaken-Blakemore tube was significantly associated with rebleeding (P < 0.01, OR = 27, 95% CI = 4.66-156.57). Nine patients failed endoscopic therapy and, while there was a trend towards increased mortality in this group, it was not statistically significantly (P = 0.22, OR = 2.55, 95% CI = 0.545-11.928).

Clinical outcomes

At day 28 following first variceal hemorrhage, 13 patients (18.6%) had died. The peri-endoscopy (8 h) group showed a significant survival benefit when compared to the non peri-endoscopy group. Antibiotics given before, during or within 8 h significantly reduced mortality at day 28 (P = 0.04, OR = 0.279, 95% CI = 0.078-0.997) and showed a trend towards reducing 28-d rebleeding (P = 0.27, OR = 0.491, 95% CI = 0.138-1.741).

CDI incidence

Four patients (5.7%) with first variceal hemorrhage developed CDI within 28 d of admission. All episodes of CDI were in patients who survived at least 28 d post-variceal hemorrhage. CDI did not predict death (P = 0.33) or rebleeding (P = 0.80). During the study period, the prospective study of patients under 80 years of age admitted to one of two general medical wards in Southampton General Hospital for at least 5 d of broad-spectrum systemic antibiotics were monitored. Of the 40 cases identified, two (5%) developed CDI.

Predictors of survival following first variceal hemorrhage

Univariate analysis revealed four risk factors that were significantly associated with death at 28 d (Table 2): receiving antibiotics > 8 h after endoscopy (P = 0.04, OR = 3.584, 95% CI = 1.003-12.808); higher MELD score (P = 0.02); presence of hepatorenal syndrome (P < 0.01, OR = 11.25, 95% CI = 2.243-56.421); and an episode of clinical sepsis (P = 0.03, OR = 4.029, 95% CI = 1.113-14.583). A forward multivariate logistic regression model was undertaken for 28-d survival. A lower MELD score (P = 0.01, OR = 1.155, 95% CI = 1.041-1.281) and administration of antibiotics within 8 h (peri-endoscopy group, P = 0.01, OR = 0.149, 95% CI = 0.033-0.681) were found to be independent variables that predicted survival (Table 3).

Table 3 Multivariate logistic regression analysis for 28-d survival following first variceal hemorrhage

Variable	*P* value	OR	95% CI
MELD	0.01	1.155	1.041-1.281
Antibiotics within 8 h (peri-endoscopy)	0.01	0.149	0.033-0.681

MELD: Model for end-stage liver disease; OR: Odds ratio; CI: Confidence interval.

DISCUSSION

Acute gastrointestinal hemorrhage is associated with significant mortality, particularly when comparing variceal to non-variceal hemorrhage[31]. Historical data have reported a mortality of up to 61% following variceal hemorrhage[1-5], although current 4-6-wk mortality rates range from 14% to 20%[9-13]. Despite the advances in vasoactive drugs and endoscopic therapies, a significant contribution to the observed fall in mortality has occurred with the introduction of prophylactic broad-spectrum antibiotic therapy[23]. It has now become standard practice to administer prophylactic antibiotics in acute variceal hemorrhage and in cirrhotic patients with gastrointestinal bleeding of any cause[24,25,31].

The clear survival benefit associated with prophylactic antibiotics in gastrointestinal hemorrhage associated with cirrhosis is not in doubt. Both American and British guidelines recommend the administration of antibiotics prior to endoscopy. While this seems logical, the timings of antibiotic administration in randomized studies are heterogeneous with prophylaxis occurring before and after endoscopy, thus the exact timings are unclear[23].

The term preemptive has been used in the field of gastrointestinal hemorrhage to describe antibiotics given after an event likely to cause bacteremia (whether due to the initial bleed or subsequent endoscopy) but before clinical evidence of sepsis. We hypothesize that there is a window of opportunity for the administration of antibiotics, after which their benefit is diminished or lost. Windows of opportunity for effective use of antibiotics have been observed for other infections and patient groups. Significantly higher survival is associated with administering antibiotics within 8 h of admission for patients admitted with pneumonia[32] and within 6 h for meningitis[33]. In a mouse model of intraperitoneal infection that produced septic shock, survival was > 80% if antibiotics were given within 12 h of insult, but < 15% if given after 15 h[34]. For patients treated for septic shock in an intensive care environment, a sequential decrease in survival was noted for each hour of delay in administering antibiotics for the first 6 h[35].

The potential benefit of antibiotics in cirrhosis is balanced by the risk of adverse effects. The use of broad-spectrum antibiotics is a contributing factor to health-care-associated CDI. A recent study has shown that patients with cirrhosis who are given antibiotics are at a higher risk of developing CDI, and this is associated with a higher mortality compared to cirrhotic patients without CDI[30].

The rates of CDI within the cirrhotic patients in our study were no higher than in non-cirrhotic, general medical patients who receive a minimum 5-d course of broad-spectrum antibiotics for non-gastrointestinal indications. Both groups of patients were treated in the same ward areas and were matched for environmental risks and isolation procedures that are known to affect rates of CDI[28]. Cirrhotic patients were younger than general medical patients. However, elderly medical patients over 80 years of age and at highest risk of CDI were excluded.

This study has shown that, if given before, during or within 8 h of the index endoscopy, peri-endoscopy antibiotics are associated with a significantly improved survival at 28 d, and show a trend towards reducing 28-d rebleeding rate. The present study did not address the precise time for peri-endoscopy antibiotics, which needs to be addressed by prospective studies. This highlights the requirement for care pathways to be modified, in this unit and similar units, if the current guidelines for antibiotic administration before endoscopy are to be widely adopted.

The administration of antibiotics within 8 h importantly reduces rates of mortality and rebleeding independently of liver disease severity, judged by MELD and Child-Pugh score, in agreement with previous studies[8,11,12]. The proportion of patients who received prophylactic antibiotics in our study (91.4%) is comparable to other recently published data[12]. Similarly, the 28-d survival for first variceal hemorrhage (81.4%) is comparable to that in the current literature for all variceal bleeding (80%-84%)[9-12], and reflects the changes in standard care in the treatment of variceal hemorrhage over the past 30 years[12].

Patients with second or subsequent variceal hemorrhage were excluded from this study. Previous hospital admission for variceal hemorrhage, particularly if the admission was recent, would have been exposed to broad-spectrum antibiotics and nosocomial infection, including *C. difficile*, and potentially created heterogeneous groups. Similarly, patients transferred to the liver unit from another institution were likely to have been exposed to antibiotics prior to their transfer, and were excluded for similar reasons.

There are several strengths to this study. All included cases were first variceal hemorrhages. Medical notes were reviewed to identify hospital attendances during the 28 d prior to admission for variceal hemorrhage and involved an antibiotic prescription. Any patient who received antibiotics in this run-in period was excluded from the study. All patients were managed in a tertiary referral center and received the standard medical management for variceal hemorrhage. The medical records, clinical outcome data and rates of CDI were available for all included cases, which allowed accurate assessment of the timing of antibiotics. The use of the microbiology database ensured all cases of CDI that occurred after discharge from hospital would be included.

It is acknowledged that this is a retrospective study rather than a prospective trial, which has inherent limitations. To minimize the effects of confounding factors, we attempted to study a homogenized population, managed by standard protocols in the same environment. Cases of *C. difficile* toxin-positive stools were not assessed for severity, either clinically or endoscopically. However, all cases of CDI were in patients alive at 28 d and CDI did not predict rebleeding or death. All efforts were made to exclude patients who had received antibiotics within 28 d of admission. However, any antibiotic prescription made by a primary care physician during this period would have been unknown to the authors, unless declared by the patient. Finally, the study did not include cases of non-variceal hemorrhage in patients with cirrhosis, therefore, the findings cannot be extended to this group.

In conclusion, following variceal hemorrhage, the use of peri-endoscopy antibiotics (administered before, during or up to 8 h after endoscopy) is associated with a significant increase in survival and a trend towards a reduction in rebleeding at 28 d. Peri-endoscopy antibiotic administration is an independent variable for survival in addition to the severity of liver disease. Despite growing concerns about rising healthcare-associated infections and the use of broad-spectrum antimicrobials in cirrhosis, the rates of CDI are comparable to other patient groups who receive broad-spectrum antibiotic therapy, and should not be a reason to withhold antibiotics.

ACKNOWLEDGMENTS

We are grateful to Dr. Paul Silcocks and Veronica Moroz for assistance with the statistical analysis.

COMMENTS

Background

Cirrhosis is a common and serious cause of intestinal hemorrhage. Twenty-two

to sixty-one percent of patients with cirrhosis during follow-up studies develop variceal bleeding, usually within 2 years of diagnosis. Variceal hemorrhage is associated with a mortality of 14%-20%. In addition to advances in endoscopic and pharmacological therapies, the prophylactic use of antibiotic drugs has reduced mortality by 27% and infection, the leading cause of death in these circumstances, by 60%. It is unclear if there is a time point after which the benefit of antibiotics is lost.

Research frontiers

Several studied have investigated the use of prophylactic antibiotic therapy following variceal hemorrhage in patients with cirrhosis after the recognition that infection leading to sepsis was a leading cause of death in these patients. Eleven key studies were included in a Cochrane meta-analysis which concluded that antibiotic treatment reduced mortality by 27% and infection by 60%. It is now routine practice to administer antibiotics following variceal bleeding; the timing of administration is unclear in the literature. The increasing use of broad-spectrum antibiotics is associated with serious side effects and complications including *Clostridium difficile* infection (CDI). Patients with cirrhosis are at increased risk of infection due to suppression of the immune system as a direct result of chronic liver disease. It is currently unknown if patients with cirrhosis receiving antibiotics following variceal hemorrhage are at increased risk for acquiring CDI.

Innovations and breakthroughs

Emergency endoscopy is an important technique for the treatment of active variceal bleeding and also for preventing subsequent future episodes of rebleeding. Endoscopic techniques such as variceal band ligation (in which rubber bands are positioned around the bleeding varix) have been shown to be more effective than older therapies such as ethanolamine injection sclerotherapy, and have become the method of choice in these situations. Similarly, vasoactive drug therapies, particularly terlipressin, have been shown to participate in the cessation of bleeding and reduce mortality by redirecting blood flow away from the splanchnic circulation. Transjugular intrahepatic portosystemic shunting is an invasive procedure performed by an interventional radiologist to reduce the portal venous pressure and arrest acute bleeding by placing a stented shunt through the liver, thus connecting the portal and hepatic veins directly. It is currently used in patients with persistent or recurrent variceal bleeding despite maximal endoscopic and pharmacological intervention. It is not currently widely available and is a second-line treatment option in complicated and persistent variceal hemorrhage.

Applications

The article shows that early antibiotics given within 8 h of endoscopy are associated with reduced mortality. Early administration of antibiotics in this situation should be adopted by units that treat patients with acute variceal bleeding and may need to be incorporated into clinical care pathways in acute admission and acute gastrointestinal bleeding units. Further prospective studies might be necessary to clarify the optimal timing of antibiotic administration following variceal hemorrhage. Patients are at no greater risk of CDI than non-cirrhotic patients who are receiving antibiotics, and concerns regarding healthcare-associated infections should not deter clinicians from prescribing antibiotic therapy in this situation.

Peer review

This is a well-written paper that is limited in impact by observational design and single-center patient population.

Abstract

AIM: To evaluate the outcomes of endoscopic mucosal resection (EMR) for colorectal polyps, with particular regard to procedural complications and recurrence rate, in typical United Kingdom (UK) hospitals that perform an average of about 25 colonic EMRs per year.

METHODS: A total of 239 colorectal polyps (≥ 10 mm) resected from 199 patients referred to Rochdale Infirmary, Salford Royal Hospital and Royal Oldham Hospital for EMR between January 2003 and January 2009 were studied.

RESULTS: The mean size of polyps resected was 19.6 ± 12.4 mm (range 10-80 mm). The overall major complication rate was 2.1%. Complications were less frequent with non-adenomas compared with the other groups (Pearson's χ^2 test, $P < 0.0001$). Resections of larger-sized polyps were more likely to result in complications (unpaired *t*-test, $P = 0.021$). Recurrence was associated with histology, with carcinoma-*in-situ* more likely to recur compared with low-grade dysplasia [hazard ratio (HR) 186.7, 95% confidence interval (95% CI): 8.81-3953.02, $P = 0.001$]. Distal lesions were also more likely to recur compared with right-sided and transverse colon lesions (HR 5.93, 95% CI: 1.35-26.18, $P = 0.019$).

CONCLUSION: EMR for colorectal polyps can be performed safely and effectively in typical UK hospitals. Stricter follow-up is required for histologically advanced lesions due to increased recurrence risk.

Key words: Endoscopic mucosal resection; Polyps; Endoscopic; Resection

INTRODUCTION

The use of endoscopic mucosal resection (EMR), pio-

neered in Japan for the treatment of early gastric cancer[1], has expanded to include therapy of other early gastrointestinal malignancies and pre-cancerous lesions such as adenomas[2] or early stage colon cancers[3,4].

EMR allows the removal of tissue to the level of the muscularis propria and is a good alternative to surgery, thereby eliminating the need for surgical intervention and its associated morbidity and mortality. Early stage colon cancer, adenomas and rectal carcinoid have all been successfully removed by EMR. Resection of polyps can be performed *en bloc* or piecemeal according to the size and location of the lesion. The complication rate associated with EMR is low[5]. The most frequent adverse event is bleeding[6-10] followed by perforation[3,11,12]. Another risk following EMR is recurrence[8-10,13].

The use of EMR for colorectal polyps has become increasing popular in Western countries and has been found to be a safe and efficient treatment. However, most reports come from large, tertiary referral practices and the applicability to more typical hospitals in the UK has not been established.

This study aims to evaluate the outcomes of EMR for colorectal polyps with particular regard to procedural complications and recurrence rate across three hospitals in North West England which perform an average of about 25 colonic EMR per year.

MATERIALS AND METHODS

Study population

All colorectal polyps referred to Rochdale Infirmary, Salford Royal Hospital and Royal Oldham Hospital for EMR between January 2003 and January 2009 were considered for the study. There is one endoscopist performing the EMR procedures in each center. Polyps ≥ 10 mm in diameter were selected for the study. Non-lifting lesions or laterally spreading lesions were excluded as these were referred for open surgical resection. Polyps were identified using a detailed record of procedures performed in the endoscopy unit and operating theatres in the three hospitals both for in-patients and out-patients. A total of 239 polyps resected (from 199 patients) were identified for the study.

Resection method

EMR was performed with a standard polypectomy snare (Olympus SnareMaster SD-230U). The lesion was first lifted by injection of a large volume (10-100 mL) of a pre-mixed solution around the lesion. This consisted of 40 mL Volplex (succinylated gelatine 20 g in 500 mL), 2 mL of 1:10 000 adrenaline, and 2 mL of 0.4% indigo carmine. The open snare was placed around the lesion and was gently pressed against the mucosa. Excess air was aspirated from the colon to decrease distension and facilitate grasping of the targeted polyp. The aim was to resect lesions in one single piece rather than piecemeal if possible. After snare excision, air was insufflated to visualize the area of resection and, if needed, any further residual tissue was removed in similar fashion. Adjuvant argon plasma coagulation (APC) therapy was used to remove tiny remnants of lesions visible after resection. The settings used were "auto-cut" at a fixed power of 120 W, as recommended by the manufacturer, along with the "endo-cut" mode. APC was applied in short bursts to avoid thermal damage to the muscularis propria.

Procedures were performed with the patient under conscious sedation (intravenously administered midazolam and/or pethidine/fentanyl). When required, hyoscine-butyl bromide was given intravenously.

Assessment of dimension of polyps and histopathology

The size of polyps was estimated by comparison with open biopsy forceps and when possible after retrieval. All removed tissue was retrieved using a Roth net, retrieval basket, grasper or through the suction channel.

All retrieved polyps were examined and classified by experienced pathologists at the respective histopathology departments of each hospital. Polyps were classified as adenoma, carcinoma-*in-situ* (CIS) or non-adenoma (e.g. hyperplastic polyps, lipoma).

Adenomas were further classified according to the Konishi-Morson system for grade of dysplasia (i.e. low-, moderate-, or high-grade) using a combination of variables, including tubule configuration, nuclear polarity, orientation and structure, mucin content and location, *etc*[14]. The diagnosis of CIS included adenomas with neoplastic cells invading into the lamina propria mucosae[15,16].

Record of complications

Patients were instructed to report symptoms of continuing abdominal pain or bleeding per rectum. The diagnosis of post-procedure bleeding was based on the passage of fresh blood per rectum. Intra-procedural perforation was diagnosed by endoscopy during the resection and confirmed by air on plain abdominal film and/or abdominal computed tomography scan. Post-procedural perforation characterized by abdominal pain and leucocytosis was diagnosed by the presence of free air on plain abdominal film and/or abdominal computed tomography scan.

Follow-up and recurrence

Surveillance colonoscopy was performed at various intervals, at the discretion of the clinician in charge of the individual patient's care. During endoscopic follow-up, any alterations of the mucosa in the area of previous resection (ulcerations, scarring, retractions of mucosa, *etc*.) were biopsied. Recurrence was defined as the presence of adenomatous or polypoid tissue on a follow-up endoscopy. This was treated with a repeat EMR if possible.

Statistical analysis

Data are presented as mean ± SD and range unless otherwise stated.

Association of complications with different variables was assessed using unpaired *t*-test or Pearson's χ^2 test. In patients who underwent endoscopic surveillance, the Cox univariate analysis was used to identify significant prognostic factors. *P* values < 0.05 were regarded as statistically

significant. Statistical analysis was performed using SPSS 15.0 statistical package (SPSS Inc., Chicago, IL, USA).

RESULTS

A total of 239 polyps were treated in 199 patients. Thirty-three patients had more than one polyp. The characteristics of the patient population, and polyp size and location, are presented in Table 1. The mean age of the patients was 68.0 ± 11.4 years and approximately 60% of the patients were male. The mean size of polyps resected was 19.6 ± 12.4 mm (range 10-80 mm).

A breakdown of polyps resected according to histopathology is shown in Table 2. Of the adenomas resected, 47 (26.0%) polyps were classified as low-grade dysplasia (LGD), 77 (42.5%) moderate-grade dysplasia (MGD), 49 (27.1%) high-grade dysplasia (HGD), and the classifications of eight polyps were unrecorded.

Complete resection was achieved in 86.2%. Patients who failed to have polyps completely resected were either referred for surgery or had their polyps resected in a repeat session. These patients were excluded from surveillance analysis (see below).

Table 3 Hazard ratio for risk of recurrence associated with clinical variables (*n* = 164)

[1]Cox univariate analysis. LGD: Low-grade dysplasia; MGD: Moderate-grade dysplasia; HGD: High-grade dysplasia; CIS: Carcinoma-*in-situ*.

Complications

Two patients had significant post-procedural bleeding. One patient responded to intravenous fluid resuscitation and blood transfusion, while the other required a sigmoid colectomy to treat the bleeding. Two patients developed post-procedural perforation. One patient was managed conservatively; while the other went on to have surgery (anterior resection of rectum). No procedure-related mortality was reported. The overall major complication rate was 2.1%.

Complications were less frequent with non-adenomas compared with the other groups (Pearson's χ^2 test, $P < 0.0001$). Resections of larger-sized polyps were more likely to result in complications (unpaired *t*-test, $P = 0.021$).

Surveillance

Seventy-eight out of 139 patients (164 polyps) with completely resected adenomas and CIS underwent follow-up colonoscopy (56.1%). Median follow up was 6.8 mo (range 1.2-26.6 mo).

Local recurrence was detected at 33 resection sites. The histopathology of the recurrent polyps was as follows: 7 (21.2%) LGD, 16 (48.5%) MGD, 7 (21.2%) HGD, and 3 (9.1%) CIS.

On univariate analysis (Table 3), recurrence was associated with histology, with CIS more likely to recur compared with LGD [hazard ratio (HR) 186.7, 95% con-

fidence interval (95% CI): 8.81-3953.02, $P = 0.001$]. Distal lesions were also more likely to recur compared with right-sided and transverse colon lesions (HR 5.93, 95% CI: 1.35-26.18, $P = 0.019$).

DISCUSSION

Several studies have been published regarding the safety and therapeutic potential of endoscopic resection of colorectal polyps. The most frequent adverse event of EMR reported is bleeding, occurring in 1% to 45% of cases[6-10]. Perforation rate has been reported to be between 0.7% and 4%[3,11,12]. The overall serious complication rate in the present study is only 2.1%, although one of the main drawbacks of the study is the lack of data on intra-procedural bleeding. However, this is often self-limiting or can be treated successfully during the procedure. Complication rates of EMR are lower than those of open surgery (2.3% to 6.3%) and comparable to those of laparoscopic surgery (1.9% to 6.9%)[17]. However, mean hospital stay for the patients who undergo colorectal surgery is 9.2-13.2 d, significantly longer than for patients who undergo EMR procedures, which are usually performed as day cases[17]. Therefore, EMR is a good alternative to surgery in a selected group of patients unfit for surgery.

The present study highlights that increasing size of polyp resected is associated with complications and the authors recommend that extra care should be taken in resecting polyps of > 35 mm in diameter.

Where possible all lesions were removed in a single session as this eliminates the discomfort and the inconvenience of repeated procedures for patients. This was achieved in 86.2% of resections in the present study. Preference has been suggested in some studies for *en bloc* resection compared with piecemeal resection, because it provides more accurate histological assessment and reduces the risk of local recurrence[18]. However, in the present study there was no statistically significant difference in the recurrence rate reported between the two resection techniques.

Follow-up is essential because of the risk of recurrence. Aggressive surveillance seems justified because it has been shown, in an animal model, that residual tumor has a high regrowth rate[19]. Unfortunately, only about half of the patients in the present study underwent a follow-up colonoscopy. The main reasons for non follow-up were patient refusal and patient frailty.

Recurrence rates after EMR of colorectal polyps have been reported to be between 0% and 46%[8-10,13]. In the present study, the recurrence rates were 19.5% for non-malignant polyps and 30% for malignant polyps. Several studies have suggested that size of polyps is associated with recurrence. However, this was not found in the present study. Instead, recurrence was more common in distal and/or more histologically advanced lesions.

The present study has shown that EMR for colorectal polyps can be carried out safely and effectively in typical UK hospitals provided the endoscopists carrying out the procedures have the appropriate training and interest in EMR. This procedure should be considered in preference to open surgery, especially in polyps smaller than 35 mm in diameter. Also, a stricter follow-up may be required for more histologically advanced lesions because of a higher risk of recurrence.

COMMENTS

Background

The use of endoscopic mucosal resection has expanded to include therapy of early gastrointestinal malignancies and pre-cancerous lesions such as adenomas or early stage colon cancers, especially in Western countries. However, most studies have come from large tertiary centers in the world.

Research frontiers

In this study, the authors demonstrate that endoscopic mucosal resection of colorectal polyps can be performed safely and effectively in typical United Kingdom (UK) hospitals, with complication rates and recurrence rates which are comparable to tertiary centers.

Innovations and breakthroughs

This is the first study to report results from the practice of endoscopic mucosal resection of colorectal polyps in typical UK hospitals where an endoscopist performs an average of 25 of these procedures per year.

Applications

It can be established from this study that patients from non-tertiary centres which have similar experience in endoscopic mucosal resection may be reassured that the procedures can be performed safely and effectively.

Terminology

Endoscopic mucosal resection allows the removal of tissue to the level of the muscularis propria and is a good alternative to surgery, thereby eliminating the need for surgical intervention and its associated morbidity and mortality.

Peer review

The take home message from this study is that it is feasible to perform endoscopic mucosal resection in a community hospital with a trained endoscopist.

Abstract

AIM: To identify patient risk factors associated with incomplete small bowel capsule endoscopy (CE) studies.

METHODS: Data from all CE procedures performed at St. Paul's Hospital in Vancouver, British Columbia, Canada, between December 2001 and June 2008 were collected and analyzed on a retrospective basis. Data collection for complete and incomplete CE study groups included patient demographics as well as a number of potential risk factors for incomplete CE including indication for the procedure, hospitalization, diabetes mellitus with or without end organ damage, limitations in mobility, renal insufficiency, past history of bowel obstruction, abdominal surgery, abdominal radiation therapy and opiate use. Risk factors were analyzed using a univariable and multivariable logistic regression model.

RESULTS: From a total of 535 CE procedures performed, 158 were incomplete (29.5%). The univariable analysis showed that CE procedures performed for overt gastrointestinal bleeding (P = 0.002), and for patients with a prior history of abdominal surgery (P = 0.023) or bowel obstruction (P = 0.023) were significantly associated with incomplete CE studies. Patients on opiate medications (P = 0.094) as well as hospitalized patients (P = 0.054) were not statistically significant, but did show a trend towards incomplete CE. The multivariable analysis showed that independent risk factors for an incomplete CE procedure include prior history of bowel obstruction [odds ratios (OR) 2.77, P = 0.02, 95% confidence intervals (CI): 1.17-6.56] and procedures performed for gastrointestinal bleeding (Occult OR 2.04, P = 0.037, 95% CI: 1.04-4.02 and Overt OR 2.69, P = 0.002, 95% CI: 1.44-5.05). Patients with a prior history of abdominal surgery (OR 1.46, P = 0.068, 95% CI: 0.97-2.19), those taking opiate medications (OR 1.54, P = 0.15, 95% CI: 0.86-2.76) and hospitalized patients (OR 1.82, P = 0.124, 95% CI: 0.85-3.93) showed a trend towards statistical significance.

CONCLUSION: We have identified a number of risk factors for incomplete CE procedures that can be used to risk-stratify patients and guide interventions to improve completion rates.

Key words: Capsule; Capsule endoscopy; Incomplete endoscopy

INTRODUCTION

Capsule endoscopy (CE) is a novel and non-invasive imaging modality for the small bowel initially described in 2000[1,2]. The procedure utilizes a battery-powered wireless capsule to transmit images of the gastrointestinal tract as it traverses through the intestine. These transmitted images are sent to a recorder worn on the abdominal wall of the patient. The images are later downloaded to a computer and interpreted by a trained physician.

There are a number of indications for the use of CE in small bowel diseases. One of the most common indications for a CE study is to investigate obscure gastrointestinal bleeding, but other indications include inflammatory bowel disease, small bowel tumors, familial polyposis syndromes and celiac disease[1,3-8]. Various studies have shown favorable results in using CE in the aforementioned small bowel diseases[3-10]. Furthermore, studies have also shown that CE has better diagnostic yield when compared to other modalities of imaging the small bowel such as push-enteroscopy or computed tomography angiography in the diagnosis of obscure gastrointestinal bleeding[9,10].

However, it is important to note that CE is not without limitations. There are, albeit rare, reports of capsule retention in the gastrointestinal tract as well as aspiration of capsule devices[11,12]. Furthermore, a retrospective study carried out in 2005 revealed a technical limitation/failure rate of 8.5% which was due to factors such as downloading or transmitting failures, insufficient battery life, or signal interference of the devices[13]. A relatively common limitation is the issue of incomplete CE studies, which can be due to the capsule not reaching the cecum and/or poor visualization of a significant portion of the small bowel due to factors such as poor preparation or excess debris. A number of studies have shown rates of incomplete CE procedures to be greater than 13%[13-15].

CE studies that are incomplete or difficult to interpret due to poor visualization potentially lead to delays in the diagnosis of small bowel pathology. Further investigative tests such as repeat CE studies, radiologic exams, or endoscopic interventions are often required to help delineate the diagnosis. Ultimately, there are increased costs to the medical system and inconvenience to the patient with delays in diagnosis.

The aim of this study is to determine demographic and procedure process related risk factors associated with incomplete CE studies. A number of small studies have identified factors such as diabetes mellitus, hospitalization, slowed gastric transit, previous small bowel surgery, and poor bowel cleansing[14,16,17]. Data for this study are drawn from the capsule endoscopies performed at St. Paul's Hospital, a quaternary referral center for gastroenterology services and the only referral center for CE in the province of British Columbia, Canada.

MATERIALS AND METHODS

CE procedure

All CE procedures were performed at St. Paul's Hospital in Vancouver, British Columbia, Canada. Prior to the procedure, informed consent was obtained and all patients were given a standardized set of instructions. The instructions included an overnight fast beginning at midnight before the procedure, as well as a bowel-cleansing regimen consisting of a single bottle (300 mL) of Magnesium citrate. Motility agents were not routinely used during the procedure; however, if patients were already taking these medications, they were permitted to continue taking them. All CE procedures began at 7 am and were completed by 3 pm on the same day, at which time the data recorders would be returned. The images were subsequently downloaded to a computer and reviewed within 24 h by a single gastroenterologist (RE). Patients were permitted to drink within 2 h and eat within 4 h following ingestion of the capsule. All CE procedures were performed using the PillCam produced by Given Imaging (Yoqneam, Israel). Incomplete CE studies were defined as those that did not reach the cecum or had incomplete visualization of the small bowel due to debris or incomplete cleansing (involving > 25% of the study). We included incomplete visualization of the small bowel to our definition of an incomplete CE study to provide an estimate of incomplete capsules in a real-world clinical setting.

Data collection

Data from all CE studies performed between December 2001 and June 2008 were reviewed and analyzed on a retrospective basis. An incomplete CE study was defined as: (1) the capsule did not reach the cecum by the end of battery life; and (2) poor visualization of > 25% of the mucosa. To determine potential risk factors for incomplete CE studies using univariable and multivariable statistical analysis, data on a number of potential factors were collected: (1) The indication for the CE (iron deficiency, abdominal pain, change in bowel habits, active GI bleed, occult GI bleeding, recurrent GI bleed); (2) Whether the study was performed on a hospitalized patient; (3) Diabetes mellitus with or without end organ damage (defined as diabetic nephropathy, retinopathy, neuropathy or diabetes-associated peripheral vascular disease); (4) Limitations in mobility (i.e. post stroke, hemiplegia), (5) Renal insufficiency; (6) Patient demographics (age, gender); (7) Past history of abdominal surgery, bowel obstruction, or abdominal radiation therapy; and (8) Opiate use.

Statistical analysis

All statistical analyses were performed using STATA 10.0 (College Station, TX). Descriptive statistics were used to characterize the demographics of the patient population. Patients with incomplete studies were compared to those with completed studies and risk factors for an incomplete CE were compared using a univariable and then multivariable logistic regression. Hemiplegia and diabetes with end organ damage were risk factors that occurred in a low

DM: Diabetes mellitus; EOD: End organ damage; BM: Bowel movement; OR: Odds ratio; CI: Confidence interval.

number of patients and were therefore excluded. From the multivariable regression analysis, odds ratios (OR) and corresponding 95% confidence intervals (CI) were generated on all significant variables (*P*-value < 0.05). Patients excluded from statistical analysis include those with evidence of mass lesion or stricture that was responsible for delaying transit through the small bowel.

RESULTS

A total of 653 CE procedures were reviewed in total. However, 118 studies were excluded, as there was evidence of a mass lesion or stricture that clearly delayed transit through the small bowel and was felt to be primarily responsible for the incomplete study. Therefore, statistical analysis was performed on a total of 535 CE procedures. Of those 535 CE procedures, 158 CE were found to be incomplete (29.5%).

Patient demographics

Patient demographic information for complete and incomplete CE studies is seen in Table 1. The mean age of the patients was 58.8 years, and 50.9% of patients were female. There was no significant difference in the demographics as well as the indication for performing the CE procedure between complete and incomplete CE study groups.

Univariable analysis

Results of the univariable analysis are listed in Table 2 for all investigated potential risk factors for incomplete CE studies listed in Table 1. The analysis reveals that factors strongly associated with incomplete CE studies include overt GI bleeding ($P = 0.002$, OR 2.39, 95% CI: 1.36-4.16), as well as prior history of bowel surgery ($P = 0.023$, OR 1.55, 95% CI: 1.06-2.26) and bowel obstruction ($P = 0.023$, OR 2.51, 95% CI: 1.13-5.55). Patients on opiate medications ($P = 0.094$, OR 1.61, 95% CI: 0.92-2.82) as well as those admitted to hospital ($P = 0.054$, OR 2.06, 95% CI: 0.99-4.29) were not statistically significant risk factors, but clearly showed a trend towards significance.

Table 3 Multivariable analysis

	OR	*P* value	95% CI
Sex	0.99	0.975	0.68-1.46
Age	0.99	0.995	0.99-1.01
Hospitalized	1.82	0.124	0.85-3.93
Diabetes	1.25	0.411	0.73-2.17
Renal disease	1.03	0.926	0.50-2.16
Occult bleeding	2.04	0.037	1.04-4.02
Overt bleeding	2.69	0.002	1.44-5.05
PMHx bowel obstruction	2.77	0.020	1.17-6.56
PMHx abdo surgery	1.46	0.068	0.97-2.19
PMHx abdo radiation	0.91	0.890	0.22-3.71
Opiate use	1.54	0.150	0.86-2.76

PMHx: Past medical history; OR: Odds ratio; CI: Confidence interval.

Multivariable analysis

Results of the multivariate analysis, shown in Table 3, using significant risk factors determined from the univariable analysis, show a statistically significant independent risk of incomplete CE study in patients who completed the study for a history of overt (OR 2.69, $P = 0.002$, 95% CI: 1.44-5.05) or occult (OR 2.04, $P = 0.037$, 95% CI: 1.04-4.02) gastrointestinal bleeding as well as patients with a previous history of bowel obstruction (OR 2.77, $P = 0.02$, 95% CI: 1.17-6.56). A prior history of abdominal surgery (OR 1.46, $P = 0.068$, 95% CI: 0.97-2.19) lacked statistical significance, but did show a trend towards an incomplete CE study. Patients on opiate medications (OR 1.54, $P = 0.15$, 95% CI: 0.86-2.76, 130/377 in the complete group, 71/158 in incomplete group) and those who were hospitalized (OR 1.82, $P = 0.124$, 95% CI: 0.85-3.93, 33/377 in the complete group, 23/158 in the incomplete group) also showed a trend towards statistical significance.

DISCUSSION

Our study intended to determine risk factors associated with incomplete small bowel CE studies due to poor visualization or failure of the capsule to reach the cecum. In order to accomplish this task, we have reviewed all CE studies performed at our center over a seven-year period. We identified 158 incomplete studies from a total of 535 eligible capsules (29.5%), showing that our incomplete CE study rate is higher than reports from other papers[13-15]. This is likely because we were more inclusive in the definition of an incomplete CE study compared to previous studies, as we have included poor visualization of > 25% of the mucosa into the definition rather than only counting capsules that did not reach the cecum[13-15]. We added both aforementioned scenarios into our definition to provide a real-world clinical estimate of the rate of incomplete capsule endoscopies.

A number of prior studies have already identified risk factors associated with incomplete CE studies such as hospitalization, diabetes mellitus, prolonged gastric transit times, and poor bowel cleansing[14,16,17]. Our results have largely added to this list of established risk factors. The result of our univariable analysis showed that factors strongly associated with incomplete studies include a past history of bowel obstruction or abdominal surgery, as well as studies done for overt gastrointestinal bleeding. Hospitalized patients and those on opiates showed a trend towards significance for incomplete CE studies. Furthermore, the multivariable analysis revealed that a prior history of bowel obstruction and studies performed for gastrointestinal bleeding (both overt and occult) were independent risk factors for incomplete studies, with a past history of abdominal surgery, hospitalization and opiate use showing a trend towards significance.

Given that there are a number of studies that have investigated risk factors for incomplete CE procedures, including a recent article published by Westerhof *et al*[14,16,17] in 2009 that, like our paper, provided a retrospective univariable and multivariable analysis of factors associated with incomplete small bowel CE procedures, we feel that our study contributes to the literature in a number of ways. Firstly, our study provides a systematic analysis of risk factors for small bowel CE procedures with the largest patient population available in the literature at the present time. Secondly, we have included a variety of potential risk factors such as hospitalization, opiate use, mobility limitations and systemic illness into our statistical model. And thirdly, we have included a functional definition of an incomplete study, being more inclusive than other studies to give a better real-world estimate of the proportion of CE studies that are incomplete or difficult to interpret.

In terms of how this data affects our practice, we have used this information to risk-stratify patients undergoing CE studies to determine if they are indeed at high risk for an incomplete study. If a patient is deemed to be at high risk, we have made changes to our practice such as utilizing the MiRo capsule (IntroMedic Co., Ltd., Seoul, Korea), a device that is capable of a longer battery life compared to other capsules, in order to continue filming the gastrointestinal tract in those with slowed intestinal motility. We also utilize a stronger bowel-cleansing regimen in those who are deemed to be at high risk for an incomplete study, which includes 4 L of Go-Lytely on the day prior to the procedure rather than a standard single bottle of Magnesium citrate.

There have been limited numbers of published studies that have investigated the use of prokinetic agents such as metoclopramide and erythromycin to improve completion rates in CE studies[17-20]. However, because of the paucity of data and heterogeneity of results seen in the literature surrounding prokinetic agents in CE, its routine use has remained controversial[20]. Because of this controversy, we do not routinely use prokinetic agents during CE studies, nor do we use them in patients deemed to be at high risk for an incomplete study. However, we feel that this would be an interesting area of research in the future to see if the routine use of prokinetic agents in a large patient population can improve completion rates.

Finally, it is important to note that our study includes a large patient population where we have retrospectively looked at numerous risk factors for incomplete CE studies. We acknowledge that there are limitations to a retrospective statistical analysis, and as a result, we feel that larger scale studies performed on a prospective basis are required to further delineate the risk factors identified. We hope that further studies can shed light on a number of issues, such as determining optimal preparations for capsule studies since there is much heterogeneity between centers, analyzing the cost-effectiveness of CE given the high incompletion rates quoted in papers, and finally, determining positive predictors of diagnostic yield in CE to aid clinicians in determining appropriate patient selection for this procedure.

COMMENTS

Background

Capsule endoscopy (CE) is a relatively new imaging modality for the small bowel initially described in 2000. It utilizes a pill-shaped camera to image the small bowel as it traverses through. CE is currently being used to diagnose and follow patients with a variety of conditions such as gastrointestinal bleeding, small bowel tumors, inflammatory bowel diseases, and celiac disease. This study focuses on determining risk factors that lead to incomplete CE procedures (i.e. capsules which fail to traverse the entire small bowel or do so but encounter so much debris that the images cannot be interpreted). This study determined that there is an incomplete rate of 29.5% in CE procedures.

Research frontiers

Future areas of research will include determining optimal preparations to be used in patients prior to undergoing a CE procedure. In addition, given the relatively high rate of incomplete procedures, studies that determine cost-effectiveness of the procedure and that determine which groups to offer the procedure to (i.e. which groups of patients will have the greatest yield by completing this procedure) will constitute future areas of research.

Innovations and breakthroughs

Prior studies have already established a number of risk factors for incomplete CE studies. These include patients with a history of diabetes mellitus, procedures performed on hospitalized patients, patients with poor bowel cleansing prior to the procedure, and those with delayed gastric emptying. The authors have added to this list of risk factors patients with a history of bowel obstruction or abdominal surgery, those taking opiate medications, hospitalized patients,

as well as studies performed for gastrointestinal bleeding. To accomplish this, they have collected data and performed statistical analysis on a large patient population at a Canadian academic teaching hospital.

Applications

Once specific risk factors can be determined for incomplete CE studies, one can use this information to provide patients with interventions to modify the risk factors (i.e. different bowel cleansing regimens, prokinetic agents, using capsules with longer battery life) in the hopes of improving CE study completion rates.

Terminology

Capsule endoscopy: A procedure that utilizes a pill-shaped camera that is swallowed by patients and is used to image the gastrointestinal tract as it traverses through. Capsules have a limited battery life and are expected to reach the end of the small bowel before time runs out. Prokinetic agent: A medication given to speed the emptying of stomach contents. Bowel cleansing regimen: A medication given to patients prior to undergoing a CE procedure to clean out the bowels such that improved visualization of the mucosa can be achieved.

Peer review

The paper is well designed and structured for both the aims and results. The discussion is too large and redundant and should be shortened.

Abstract

AIM: To investigate the proliferative effect of advanced glycation end-products (AGEs) and the role of their cellular receptor (RAGE) on hepatocellular carcinoma (HCC) cells, and the inhibitory effects of MK615, an extract from Japanese apricot, against AGEs were also evaluated.

METHODS: Two HCC cell lines, HuH7 and HepG2, were used. Expression of RAGE was investigated by polymerase chain reaction, Western blotting, and flow cytometry (FACS). The effect of MK615 on RAGE expression was also evaluated by FACS. The proliferative effects of a control (unglycated bovine serum albumin), glucose-derived AGEs (Glc-AGE), and glyceraldehyde-derived AGEs (Glycer-AGE), and the anti-proliferative effect of MK615 against AGEs, were evaluated using MTT assays.

RESULTS: Expression of RAGE was confirmed at both the mRNA and protein levels in both HuH7 and HepG2. FACS revealed that the level of RAGE expression was higher in HuH7 than in HepG2. Treatment with 0.1 μg/mL MK615 decreased the expression level of RAGE from 24.3% to 3.7% in HuH7 and from 6.2% to 4.8% in HepG2. The growth indices for the control, Glc-AGE, and Glycer-AGE were 1.06 ± 0.08, 0.99 ± 0.04, and 1.38 ± 0.05, respectively, in HuH7 (P = 0.037), and were 1.03 ± 0.04, 1.04 ± 0.03, and 1.07 ± 0.05, respectively, in HepG2 (P > 0.05). When the cells were cultured simultaneously with Glycer-AGE and MK615, MK615 abrogated the proliferative effect of Glycer-AGE in HuH7.

CONCLUSION: Only Glycer-AGE has a proliferative effect on HuH7, which expresses a higher level of RAGE. MK615 suppresses the proliferative effect of Glycer-AGE on HuH7 by decreasing the expression of RAGE.

INTRODUCTION

MK615, an extract from the Japanese apricot, *Prunus mume* Sieb. et Zucc (*ume* in Japanese), contains several triterpenoids and other unknown components. We have previously demonstrated the anti-cancer effects of MK615, which induces apoptosis[1] and autophagy[2] in cancer cells by modulation of the cell cycle through inhibition of aurora kinases A and B[3,4]. It has also been shown that MK615 exerts its anti-inflammatory effects by inhibiting the release of high mobility group box 1 protein (HMGB1) through activation of the transcription factor, Nrf2[5]. The nuclear protein HMGB1 is released into the extracellular space during necrosis and apoptosis, and causes inflammation[6]. The cellular receptor of HMGB1 is a receptor of advanced glycation end-products (AGEs), and is known as receptor of AGE (RAGE). Thus, HMGB1 and AGEs share the same cellular receptor, RAGE.

AGEs are products of non-enzymatic, irreversible glycation of proteins, and are formed under conditions of sustained hyperglycemia[7]. Binding of AGEs to RAGE initiates a potent inflammation response and induces various pathological conditions[8], such as diabetic complications[9], Alzheimer's disease[10], non-alcoholic steatohepatitis[11], and cancers[12].

Although the cellular events that operate in the AGEs/RAGE system are not fully understood, it has been shown that binding of AGEs to RAGE produces reactive oxygen species[13] and increases the transcription of vascular endothelial growth factor (VEGF), followed by angiogenesis[14]. Also, the AGEs/RAGE system activates p38/MAP kinase[15] and nuclear factor (NF)-κB[16]. These cellular events induce the production of proinflammatory cytokines[6].

Because AGEs constitute a heterozygous group, some molecules that are categorized as AGEs are not particularly toxic, including N-(carboxymethyl) lysine (CML) and pyrroline. Accumulated evidence indicates that glyceraldehyde-derived AGEs (Glycer-AGE) have a predominantly toxic structure, and these are referred to as toxic AGEs (TAGE)[10,17]. Although a number of studies have investigated the roles of various AGEs, including CML, pyrroline, and glucose-derived AGEs (Glc-AGE), and also the function of RAGE in cancers[18,19], the role of Glycer-AGE in tumorigenesis still remains unclear, especially in hepatocellular carcinoma (HCC).

Recently, it was shown that MK615 inhibits the activation of ERK1/2, p38MAPK, and NF-κB by the AGEs/RAGE system, and suppresses the release of proinflammatory cytokines[20].

The purposes of the present study were, using HCC cell lines, to determine (1) the type of effect that MK615 exerts on HCC; (2) whether Glycer-AGE has a proliferative effect on HCC; and (3) whether MK615 attenuates the effect of Glycer-AGE on HCC.

MATERIALS AND METHODS

Cells and culture

Two human hepatocellular carcinoma cell lines, HuH7 and HepG2, were used. HuH7 was purchased from the Cell Resource Center of the Biomedical Research Institute of Development, Aging and Cancer, Tohoku University (Miyagi, Japan), and HepG2 was purchased from DS Pharma Biomedical Co., Ltd. (Osaka, Japan). The cells were maintained in Dulbecco's Modified Eagle Medium (DMEM) containing 10% fetal calf serum (FCS) in an incubator with a 5% CO_2 atmosphere.

Agents

AGEs: Unglycated bovine serum albumin (BSA) (control), glucose-derived AGEs (Glc-AGE:AGE1), and glyceraldehyde-derived AGEs (Glycer-AGE:AGE2) were produced by one of the co-authors, M. Takeuchi, as described previously[21,22]. Briefly, BSA at 25 mg/mL was incubated under sterile conditions with 0.5 mol/L D-glucose for 8 wk (Glc-AGE), or with 0.1 mol/L D-glyceraldehyde for 7 d (Glycer-AGE) at 37℃. Then, low-molecular-weight reactants and sugars were removed using PD-10 column (GE Healthcare UK Ltd., Buckinghamshire, England) chromatography and dialysis against phosphate-buffered saline (PBS). Control unglycated BSA was incubated under the same conditions except for an absence of reducing sugar. Preparations were tested for endotoxin using an Endospecy ES-20S system (Seikagaku Co., Tokyo, Japan). For all experiments, the control, Glc-AGE, and Glycer-AGE were used at a concentration of 0.1 mg/mL in the culture medium.

MK615: MK615 was provided by AdaBio Co., Ltd. (Gunma, Japan). MK615 is derived from Japanese apricot fruit[1-4]. Briefly, the preparation procedure involves extraction of the apricot juice using a press, and this is then heated and concentrated. The concentrate is dissolved in water, and then adjusted to pH 7.0 with NaOH. The solution is finally sterilized in an autoclave. MK615 was used at a concentration of 0.1 μg/mL[5], except for the experiment shown in Figure 1.

Polymerase chain reaction

Cells were plated at 1×10^5/well in 24-well plates and cultured for 24 h. Then, MK615 (0.1 μg/mL) was added to the medium and culture was continued for another 24 h. Total RNA from each cell line was isolated using a Total RNA Isolation kit (MACHEREY-NAGEL, Düren, Germany). Reverse transcription reactions were performed using a Rever Tra Ace α-First Strand cDNA Synthesis Kit (TOYOBO, Osaka, Japan). Briefly, 1 μg of total RNA, oligo dT-primer, and dNTPs were incubated at 65℃ for 5 min, then 10 μL of cDNA synthesis mixture was added and the mixture was incubated at 50℃ for 50 min. The reaction was terminated by adding 1 μL of RNaseH and

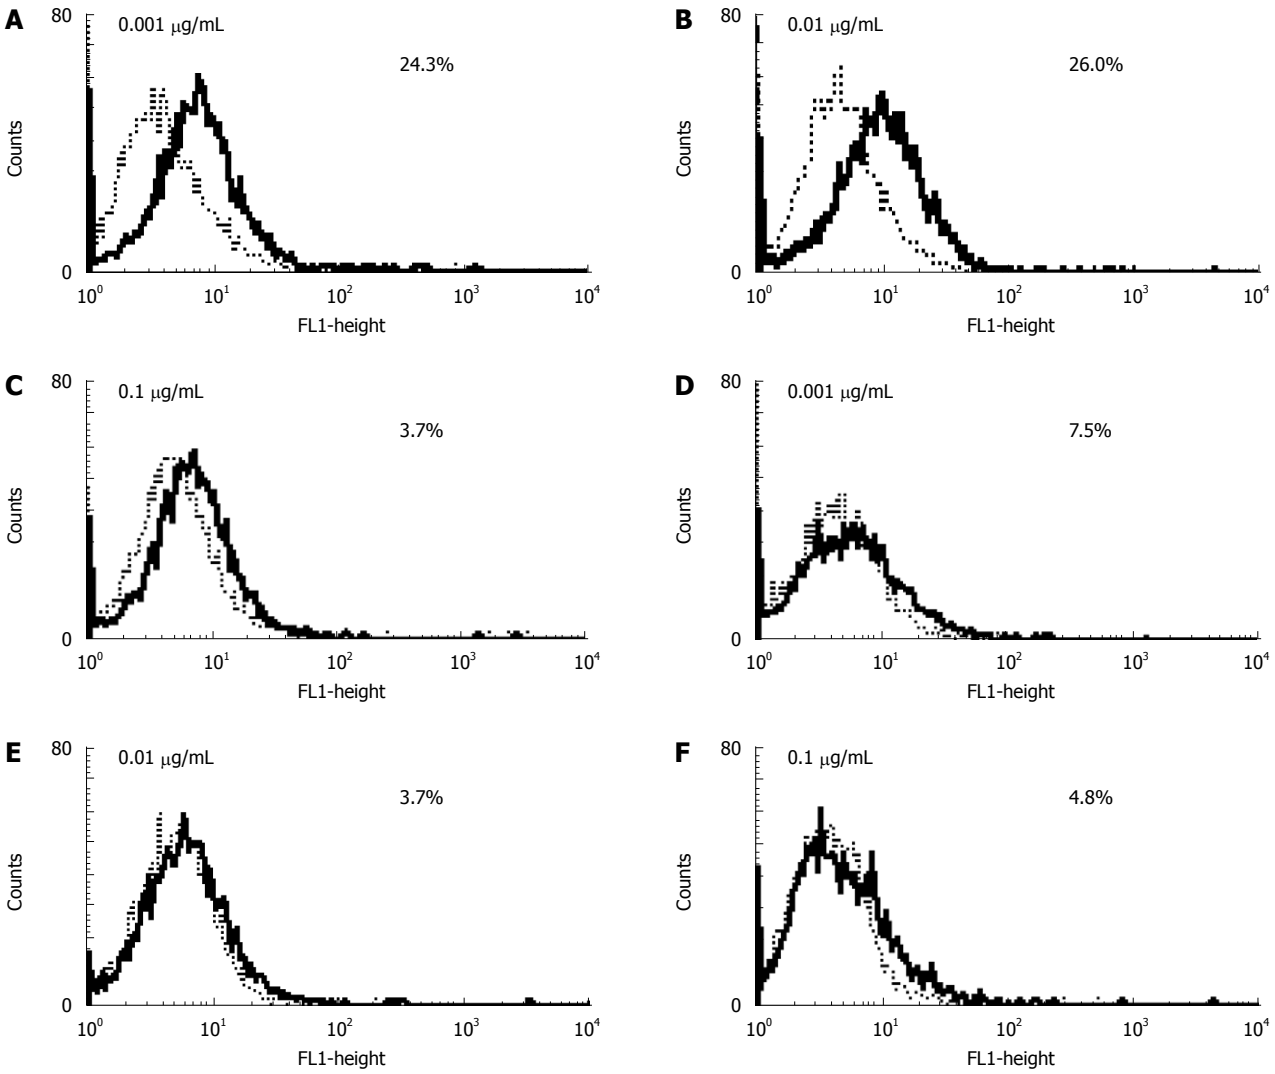

Figure 1 MK615 decreases receptor of advanced glycation end-product expression in HuH7 and HepG2 cells. Cells were plated at 1 × 10^5/well in 24-well plates and then cultured for 24 h. MK615 was then added to the medium, followed by culture for a further 24 h. MK615 (0.1 μg/mL) decreased RAGE expression in both HuH7 (A-C) and HepG2 (D-F).

incubating the mixture at 37℃ for 20 min.

The sequences of the primers were as follows: β-actin: sense-primer 5'-GGACTTCGAGCAAGAGATGG-3', anti-sense 5'-AGCACTGTGTTGGCGTACAG-3'; RAGE: sense-primer 5'-CACACTGCAGTCGGAGCTAA-3', anti-sense 5'-GCTACTGCTCCACCTTCTGG-3'. Conventional polymerase chain reaction (PCR) was performed with Hottaq mix (x,x). The PCR conditions consisted of 95℃ for 5 min, 40 cycles at 95℃ for 30 s, 62℃ for 30 s, and 60℃ for 30 s. The PCR products were separated on 1% agarose gel.

Real-time PCR was performed with an ABI Prism 7700 sequence detector (Applied Biosystems, Warrington, UK). The PCR reaction was carried out in a final volume of 25 μL, which included 2 μL cDNA, 12.5 μL 2 × SYBR Green (Applied Biosystems), 0.5 μL of 25 nmol/L sense and antisense primers, and H_2O. The PCR conditions consisted of 40 cycles at 95℃ for 30 s and 60℃ for 30 s. Samples were assayed in triplicate. Means and standard deviations were calculated from the data obtained. For each sample, at least three assays were performed. The *t* value was calculated as the mean of three different assays. The level of expression was calculated using the formula: Relative expression (*t*-value) = (Copy number of target molecule/Copy number of β-actin) × 1000[3,4].

Western blotting

Anti-RAGE antibodies (#ab54741) were purchased from Abcam Inc. (Cambridge, MA). After cells had been collected, they were washed twice with cold PBS, lysed with 200 μL of 0.5% (w/v) SDS, and centrifuged at 10000 r/min. The supernatants were adjusted by dilution so as to contain equal amounts of protein, as tested using a BCA Protein Assay Kit (Pierce, Rockford, IL). Samples (20 μg protein) were run on 12.5% (w/v) SDS-PAGE with 10% gel and electroblotted onto PVDF membranes. The blots were blocked for 1 h with 5% (w/v) non-fat milk powder and 0.1% (v/v) Tween 20 in Tris-NaCl, then exposed to the primary antibody at a 1000-fold dilution overnight at 4℃. After extensive washing, the blots were incubated

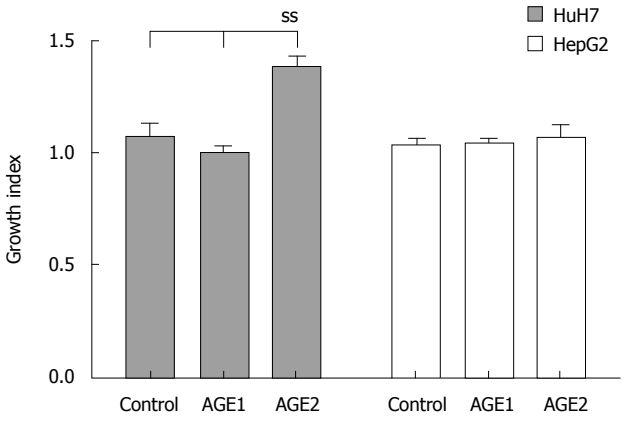

Figure 2 Proliferative effect of advanced glycation end-products on HuH7 and HepG2 cells. Cells were cultured for 24 h, and advanced glycation end-products (AGEs) (0.1 mg/mL) were then added. After 24 h, the MTT assay was performed. Glycer-AGE significantly stimulated proliferation of HuH7 cells. ss: Statistically significant.

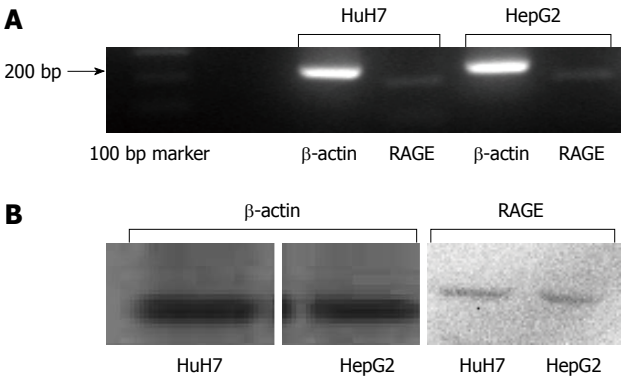

Figure 3 Expression of endogenous receptor of advanced glycation end-product in HuH7 and HepG2 cells. Reverse transcription-polymerase chain reaction (A) and Western blotting (B) showed that HuH7 and HepG2 expressed receptor of advanced glycation end-product (RAGE) endogenously. β-actin was used as a positive control. bp: Base pairs.

with the secondary horseradish-peroxidase-conjugated antibody (1:2000) for 2 h at room temperature. Immunoreactive bands were visualized using an enhanced chemiluminescence detection system (Amersham Life Sciences, Arlington Heights, IL)[2-4].

Flow cytometry

Anti-RAGE antibody was the same as that used in Western blotting. An isotype-matched antibody was purchased from Abcom. The cells were collected and stained with control or anti-RAGE monoclonal antibody for 1 h, washed twice with PBS, and then stained with FITC-conjugated anti-mouse IgG monoclonal antibody for 30 min. Then cells were again washed twice with PBS and analyzed using a FACSCalibur (Becton-Dickinson). The percentage shift was calculated by subtracting the histogram obtained with anti-RAGE monoclonal antibody from that obtained with the control antibody[23].

MTT assay

For the MTT assay, 15 μL MTT (5 g/L) was added to each well, and the cells were incubated for 4 h. Then, 100 μL solubilization solution/stop mix was added, in accordance with the manufacturer's recommendation, and the plates were left to stand for 60 min. The absorbance at 570 and 630 nm was then measured with an ELISA reader. The actual counts were calculated by subtracting the absorbance at 570 nm from that at 630 nm. Each assay was performed in triplicate and the average absorbance was calculated[2-4].

Growth index (Figure 2) was calculated as follows. Cells were plated out at 5 × 10^3 cells/well in 96-well plates and cultured for 24 h, then AGEs were added to the culture medium (Medium) at 0.1 mg/mL. After 24 h, the MTT assay was performed, and experiments were repeated 3 times. The mean values of the counts were calculated for each experiment. Growth index was calculated by dividing the mean for the control, Glc-AGE, or Glycer-AGE by the mean for the Medium. Standard deviation was calculated for all three experiments.

The percentage inhibition was calculated as follows. Two culture sets were set up, the cells being plated out at 5 × 10^3/well in 96-well plates, and cultured for 24 h. The cells were then cultured with Medium, control, Glc-AGE, or Glycer-AGE, and each well was cultured in quadruplicate. One plate was cultured without MK615 and the other with MK615 0.1 μg/mL. The percentage inhibition was calculated as: % inhibition = (count of cells with MK615 - count of cells without MK615) × 100/count without MK615. The experiments were repeated three times, and the means and standard deviations were calculated.

Apoptosis assay

Cells were cultured under control conditions, or with Glc-AGE, Glycer-AGE, or MK615 for 24 h, then harvested by trypsinization and washed twice with PBS. The annexin V binding assay was performed using an Annexin V-FITC Apoptosis Detection kit (Becton-Dickinson) in accordance with the supplier's instructions. At least 1 × 10^6 cells were incubated with FITC-conjugated annexin V at room temperature for 15 min, and the cells were then analyzed on a FACscan (Becton-Dickinson).

Statistical analysis

One-factor analysis of variance (ANOVA) with post-hoc test was used for comparison of the three subgroups by GraphPad Prism 5.0 (Graphpad Software, La Jolla, CA). The results obtained by flow cytometry were analyzed statistically with the Kolmogorov-Smirnov test using Cell Quest software (Becton-Dickinson)[23]. Differences at $P < 0.05$ were accepted as significant. Statistical analysis of percentage growth inhibition was performed using the unpaired, two-tailed *t* test.

RESULTS

Results of RT-PCR (Figure 3A) and Western blotting (Figure 3B) showed that HuH7 and HepG2 expressed RAGE endogenously. Flow cytometry with anti-RAGE

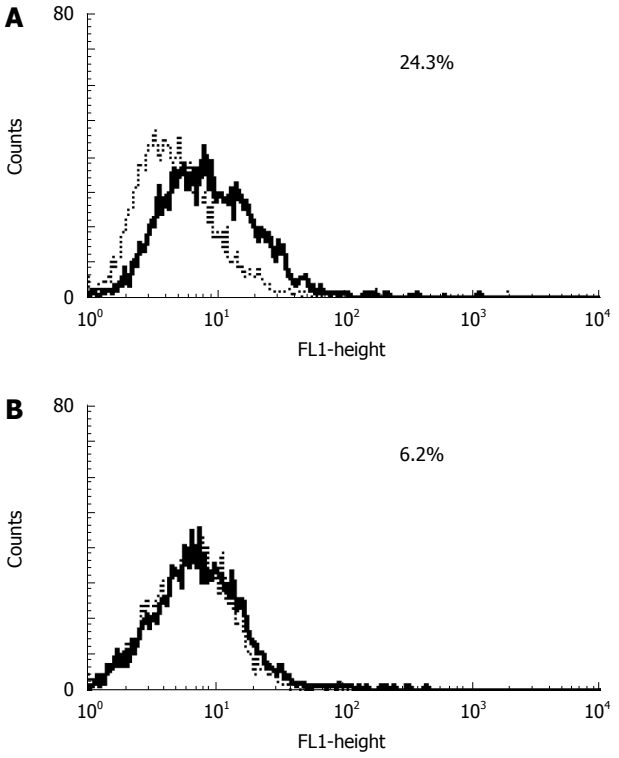

Figure 4 Cell surface expression of receptor of advanced glycation end-product in HuH7 and HepG2 cells. Flow cytometry showed receptor of advanced glycation end-product expression in both HuH7 (A) and HepG2 (B).

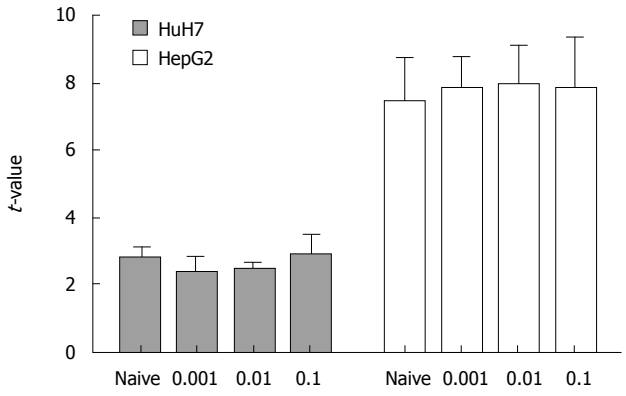

Figure 5 MK615 does not decrease receptor of advanced glycation end-product mRNA. The concentration of receptor of advanced glycation end-product mRNA did not differ between MK615-treated HuH7 and HepG2 cells.

antibody staining demonstrated the expression of membrane-bound RAGE in both HuH7 and HepG2 cells at 24.3% and 6.2%, respectively (Figure 4A and B).

Next, we investigated the effect of MK615 on the cell surface expression of RAGE in HuH7 and HepG2 cells. Cells were incubated with different concentrations of MK615. In HuH7, the expression levels of RAGE at MK615 concentrations of 0.001, 0.01, and 0.1 μg/mL were 24.3%, 26.0%, and 3.7%, respectively (Figure 1A-C), whereas the corresponding levels in HepG2 were 7.5%, 3.7%, and 4.8%, respectively (Figure 1D-F).

The results of real-time PCR using samples of RNA obtained under the same conditions as those for flow cytometry showed that transcription of RAGE mRNA did not differ between MK615-treated and non-treated cells (Figure 5).

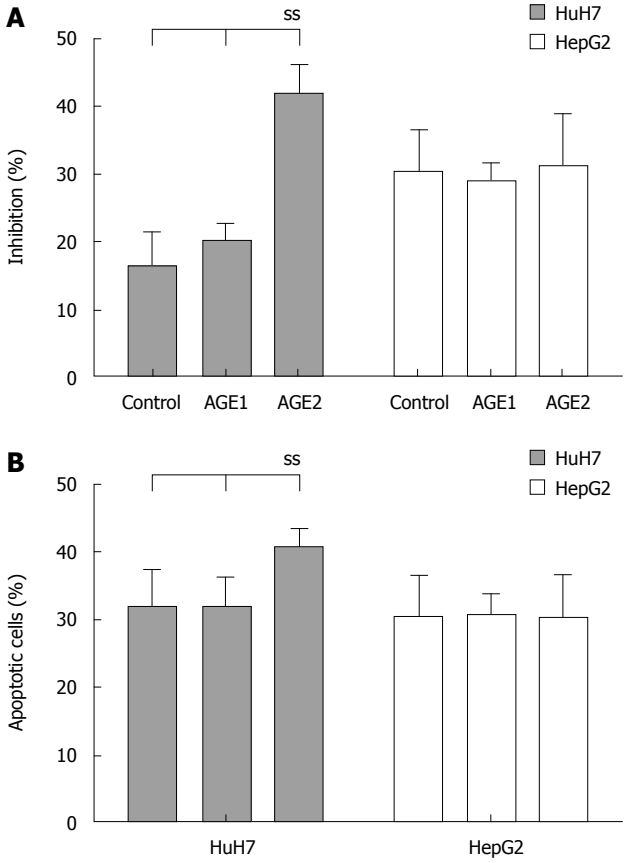

Figure 6 Suppression of advanced glycation end-products-stimulated growth by MK615 and apoptosis induction. A: The percentage inhibition of Glycer-advanced glycation end-products (AGE) by MK615 was significantly higher than those for the control, and Glc-AGE in HuH7 cells. In HepG2 cells, there were no significant differences among the groups. B: Frequency of apoptotic cells of Glycer-AGE by MK615 was significantly higher than those for the control, and Glc-AGE in HuH7 cells. In HepG2 cells, there were no significant differences among the groups. ss: Statistically significant.

To evaluate the stimulation of growth by AGEs, HuH7 and HepG2 cells were incubated with AGEs (Figure 5). The growth indices of the unglycated BSA control, Glc-AGE, and Glycer-AGE were 1.06 ± 0.08, 0.99 ± 0.04, and 1.38 ± 0.05 in HuH7, and 1.03 ± 0.04, 1.04 ± 0.03, and 1.07 ± 0.05 in HepG2, respectively. In HuH7, the growth index of Glycer-AGE was significantly higher than those of the control and Glc-AGE ($P = 0.037$). In HepG2, there were no significant differences in growth index among the three treatments ($P = 0.905$).

Figure 6A shows the suppression of AGEs growth stimulation by MK615. The percentages of inhibition for the Medium, control, Glc-AGE, and Glycer-AGE in HuH7 cells were 29.0% ± 3.5%, 16.2% ± 5.1%, 20.1% ± 2.7%, and 41.7% ± 4.1%, respectively. The percentage inhibition of Glycer-AGE-induced growth stimulation was significantly higher than that for Medium, Control, or AGE1 ($P = 0.02$ by one-way ANOVA). In HepG2 cells, the percentages of inhibition for the Medium, control, Glc-AGE, and Glycer-AGE were 28.9% ± 8.1%, 30.1%

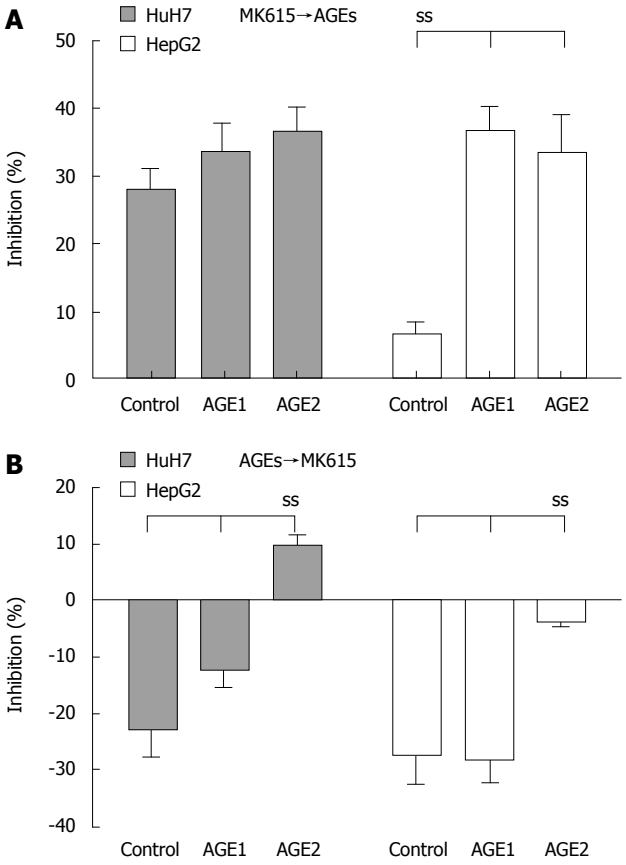

Figure 7 Changes in percentage inhibition resulting from pre- or post-treatment with MK615. A: Cells were cultured for 24 h with MK615, and then advanced glycation end-products (AGEs) were added, followed by culture for a further 24 h. The proliferative effect of Glycer-AGE was abrogated by pretreatment with MK615 in both HuH7 and HepG2 cells; B: Cells were cultured for 24 h with AGEs, and then MK615 were added, followed by culture for a further 24 h. The proliferative effect elicited by Glycer-AGE was still evident, but was reduced. ss: Statistically significant.

± 6.3%, 29.0% ± 2.7% and 31.1% ± 7.9%, respectively. There were no significant differences among the groups (P = 0.18 by one-way ANOVA). For HuH7, the frequencies of apoptotic cells for the control, Glc-AGE, and Glycer-AGE were 31.5% ± 5.7%, 31.3% ± 4.9%, and 40.3% ± 3.1%, respectively (P = 0.04 by one-way ANOVA), and those for HepG2 were 30.2% ± 6.2%, 30.5% ± 3.1%, and 30.1% ± 6.3%, respectively (P = 0.12 by one-way ANOVA) (Figure 6B).

Figure 7A shows the percentages of inhibition when the cells were cultured with AGEs following 24 h of culture with MK615. In HuH7 cells, the percentages of inhibition for the control, Glc-AGE, and Glycer-AGE were 27.9% ± 3.2%, 33.4% ± 4.5%, and 36.3% ± 4.1%, respectively (P = 0.08 by one-way ANOVA), and the corresponding values in HepG2 were 6.7% ± 1.9%, 36.6% ± 3.7% and 30.1% ± 6.3%, respectively (P = 0.03 by one-way ANOVA). Figure 7B shows the percentages of inhibition when the cells were cultured with MK615 following 24 h of culture with AGEs. In HuH7 cells, the percentages of inhibition for the control, Glc-AGE, and Glycer-AGE were -22.3% ± 5.1%, -12.3% ± 3.2%, and 9.6% ± 2.2%, respectively (P = 0.02 by one-way ANOVA), and the corresponding values for HepG2 were -27.5% ± 5.9%, -27.8% ± 4.7%, and -3.9% ± 0.8%, respectively (P = 0.02 by one-way ANOVA).

DISCUSSION

HuH7 and HepG2 cells showed surface expression of RAGE, but the level of expression differed between them. A previous study reported that HepG2 did not express RAGE[24], although the present study confirmed weak expression of RAGE in HepG2 at both the mRNA and protein level. Flow cytometry revealed that HuH7 cells expressed RAGE at a higher level than did HepG2. On the other hand, results of real-time PCR (Figure 5) showed higher t-values for HepG2 than for HuH7. Because we calculated the expression of RAGE mRNA relative to β-actin mRNA, the relative expression of RAGE mRNA would have been influenced by the expression level of β-actin mRNA. However, the reason for the discrepancy in the expression of RAGE mRNA between flow cytometry and real-time PCR was unclear. Although both cell lines were derived from well differentiated HCC, HuH7 was established from a Japanese patient, whereas HepG2 was from a Caucasian. Hiwatashi *et al*[24] reported that expression of RAGE was lower in normal liver and hepatitis, and higher in HCC. Although the mechanism responsible for the difference in RAGE expression is not clear, and the level at which RAGE expression stimulates the growth of HCC was not determined, the difference would have been related to the response of the cells to AGEs, as described below.

HuH7 showed a statistically significant growth response to Glycer-AGE, but not to control or Glc-AGE. HepG2, which expressed a low level of RAGE, did not show any significant growth response to control, Glc-AGE, or Glycer-AGE (Figure 2). Our results indicated that Glycer-AGE stimulated the growth of HuH7 cells, which show higher surface expression of RAGE, whereas the degree of stimulation was not marked in HepG2 cells, which show low surface expression of RAGE. Furthermore, the control and Glc-AGE exerted no proliferative effect on either of the cell lines. It has been difficult to study the biological effects of AGEs because of their heterogeneity. As CML, pyrroline, and Glc-AGE are not as toxic as Glycer-AGE, it is necessary to obtain data using a representative TAGE, of which Glycer-AGE is one of the more toxic forms. Glycer-AGE, but not Glc-AGE, CML, and pyrroline, has strong binding affinity for RAGE and subsequently elicits oxidative stress and vascular inflammation, being implicated in the accelerated atherosclerosis seen in patients with diabetes mellitus[25,26]. Recently, we have also demonstrated that Glycer-AGE plays an important role in the pathogenesis of angiopathy in diabetic patients[27,28]. Moreover, there is a growing body of evidence to suggest that the interaction of TAGE with RAGE elicits oxidative stress in numerous types of cells, thereby possibly contributing to the pathological changes that characterize the vascular complications of diabetes. Glycer-AGE-RAGE interaction triggers the generation of NADPH oxidase-mediated reactive oxygen species (ROS),

and subsequently activates p38/MAP kinase and NF-κB, resulting in cell proliferation[27,28].

As shown in Figure 1, MK615 decreased the expression of RAGE on HuH7 cells at a concentration of 0.1 μg/mL, whereas the effect on HepG2 cells was less marked. This decrease in the expression of RAGE was not due to suppression of transcription, because the results of real-time PCR revealed that the transcripts of RAGE mRNA did not differ between naïve and MK615-treated HuH7 and HepG2 (Figure 5). It remains to be clarified whether the decrease in the cell-surface expression of RAGE is due to solubilization of RAGE, degradation, or other mechanisms.

When cells were cultured with AGEs and MK615 simultaneously, MK615 was found to inhibit the growth effect of Glycer-AGE (Figure 6), and when the cells were cultured with AGEs following exposure to MK615, the growth effect elicited by Glycer-AGE was abrogated (Figure 7A). Furthermore, when the cells were cultured with AGEs followed by MK615, the growth effect elicited by Glycer-AGE was still evident, but was reduced (Figure 7B). MK615 inhibits the activation of MAPK/NF-κB[15,16], which is thought to be a major pathway of the AGEs/RAGE system. Because MK615 contains several triterpenoids and other unknown substances, the mechanism responsible for abrogation of the proliferative effect of Glycer-AGE on HCC cells might be multifactorial. However, the decrease of RAGE expression elicited by MK615 may play a crucial role in suppressing the Glycer-AGE-induced proliferation of HCC cells.

In conclusion, Glycer-AGE (a representative TAGE) exerts a potent proliferative effect on HuH7 cells, which express a high level of RAGE on their surface. The effect of RAGE may be partly dependent on the degree of cell-surface RAGE expression. MK615 inhibits Glycer-AGE-induced proliferation of HuH7 cells by decreasing their cell surface expression of RAGE. Our present results suggest that further studies are warranted to explore the role of Glycer-AGE in HCC, and to examine the therapeutic effect of MK615.

COMMENTS

Background

This study focused on two topics: advanced glycation-end products (AGEs), and MK615, an extract from the Japanese apricot, *Prunus mume* Sieb. et Zucc (*ume* in Japanese). AGEs are the products of non-enzymatic, irreversible glycation of proteins, and the causative agents of various disorders, including inflammation and cancers. AGEs constitute a heterozygous group, and recent studies have revealed that most of them are not really toxic, although glyceraldehyde-derived AGE (Glycer-AGE) is a toxic AGE (TAGE). In the present study, we used purified Glycer-AGE. AGEs bind to the cell-surface receptor of AGE (RAGE) to exert biological effects. It has been shown that MK615 exerts anti-inflammatory affects by modifying the expression of RAGE. Thus, AGEs and MK615 are connected *via* RAGE.

Research frontiers

Glycer-AGE is a real TAGE, and a limited number of studies have been conducted to clarify the role of Glycer-AGE in cancer. As mentioned before, AGEs are a heterogenous group of products, and future studies should focus on AGEs using Glycer-AGE. As shown in the present study, Glycer-AGE exerts stronger effects than glucose-derived AGE. The biological effects of Glycer-AGE remain to be elucidated.

Innovations and breakthroughs

Glycer-AGE potently stimulated the growth of hepatocellular carcinoma (HCC) cells, and the effect was inhibited by MK615. This suggests that Glycer-AGE (TAGE) stimulates the proliferation of HCC, and that MK615 may have a therapeutic effect on this activity.

Applications

Clinically, MK615 ameliorates hepatitis due to hepatitis C virus. Although the mechanism remains unclear, MK615 may exert its effect by downregulating the expression of RAGE. Although further studies will be needed, MK615 may exert a therapeutic effect on HCC by inhibiting Glycer-AGE-dependent cancer growth.

Terminology

MK615 is an extract from the Japanese apricot, *Prunus mume* Sieb. et Zucc (*ume* in Japanese). AGEs are products of the non-enzymatic, irreversible glycation of proteins. RAGE is a cell-surface receptor of AGEs. TAGE is a toxic AGE that is derived from glyceraldehyde (Glycer-AGE).

Peer review

The study is focused on the interesting topic of RAGE-dependent cellular proliferation. The authors demonstrate semi-functional data that RAGE could be of relevance in hepatocellular tumour growth.

Abstract

AIM: To compare the therapeutic effects of proton pump inhibitors (PPI) and histamine 2 receptor antagonists (H2RA) on gastroduodenal ulcers under continuous use of low-dose aspirin.

METHODS: Sixty patients who had a gastroduodenal ulcer on screening endoscopy but required continuous use of low-dose aspirin were randomly assigned to receive PPI (lansoprazole 30 mg, *n* = 30) or H2RA (famotidine 40 mg or if famotidine had been administered before assignment, ranitidine 300 mg, *n* = 30). The therapeutic effects were evaluated by endoscopy after 8-wk treatment. The presence or absence of *Helicobacter pylori* (*H. pylori*) was determined by urea breath test before treatment. Abdominal symptoms were compared with the gastrointestinal symptom rating scale (GSRS) questionnaire before and after treatment.

RESULTS: Twenty-six patients in the PPI group and 26 patients in the H2RA group, excluding dropouts, were analyzed. There were no significant differences in median age, sex, underlying disease, smoking status, *H. pylori* infection, prevalence of ulcers before treatment, and lesion site between the two groups. The therapeutic effects were endoscopically evaluated as healed in 23 patients (88.5%) and not healed in 3 patients in the PPI group and as healed in 22 patients (84.6%) and not healed in 4 patients in the H2RA group. Abdominal symptoms before treatment were uncommon in both groups; the GSRS scores were not significantly reduced after treatment as compared with before treatment.

CONCLUSION: The healing rate of gastroduodenal ulcers during continuous use of low-dose aspirin was greater than 80% in both the PPI group and the H2RA group, with no significant difference between the two groups.

Key words: Low-dose aspirin; Proton pump inhibitors; Histamine 2 receptor antagonists; Gastric ulcer

INTRODUCTION

As the population of Japan ages, the use of low-dose aspirin has increased to prevent cerebral and myocardial infarction. Many reports from Japan and overseas showing evidence that low-dose aspirin is useful for prevent-

ing thrombosis have been published. However, low-dose aspirin use raises concern about its adverse effects such as gastrointestinal mucosal injury[1,2]. Low-dose oral aspirin (300 mg or less) is reportedly associated with a 2.6- to 3.0-fold increased risk of ulcers[3] and a 1.59-fold increased risk of gastrointestinal bleeding[4]. The prevalence of low-dose (200 mg or less) aspirin-associated gastroduodenal ulcers was 11.9% to 15.7% in Japanese patients treated for ischemic heart disease[5], and another case-control study has shown that low-dose aspirin is associated with a 5.5-fold increased risk of gastrointestinal bleeding[6]. However, low-dose aspirin is administered for the purpose of secondary prevention of cardiovascular events, and because drug suspension due to gastrointestinal injury would increase the risk of thrombosis, it is frequently difficult to discontinue the use of low-dose aspirin. In fact, when long-term users of low-dose aspirin suspended the use of the drug, the risk of thrombosis increased[7,8]. Therefore, gastrointestinal injury should be treated under continuous use of low-dose aspirin. Previous studies from Western countries have shown that proton pump inhibitors (PPI) are first-line drugs for the treatment of gastrointestinal injury associated with non-steroidal anti-inflammatory drugs (NSAIDs) including aspirin[9-11]. However, there are no prospective studies focusing on low-dose aspirin, nor are there studies from Japan where *Helicobacter pylori* (*H. pylori*) infection rate is high.

We conducted a prospective, multicenter controlled study to compare the therapeutic effects of ordinary dose of PPI and histamine 2 receptor antagonists (H2RA) on gastroduodenal ulcers during continuous use of low-dose aspirin.

MATERIALS AND METHODS

Patients

Two hundred twenty-nine low-dose aspirin users developed an endoscopy-proven gastrointestinal ulcer between May 2006 and November 2009 at the Hokkaido University Hospital and associated facilities. Out of these patients, 78 patients who did not meet inclusion criteria were excluded. Patients were excluded from the study if they had gastrointestinal bleeding as a complication, underwent gastrectomy, had a serious complication, had been taking non-aspirin NSAIDs regularly, or were under 20 years or over 80 years old. Patients who administered non-aspirin NSAIDs on an as-needed basis were included.

One hundred fifty-one patients were recruited to this study. All of them wished to continue taking low-dose aspirin and gastric acid secretion inhibitors, because they had no vascular events after aspirin therapy. However, the majority of patients rejected a second endoscopy after 8 wk. Finally, 60 patients who provided written informed consent and required continuous use of low-dose aspirin were entered into the study.

This study was approved by the ethics committee of each facility. Written informed consent was obtained from each participant in this study.

Methods

Enrolled patients were randomly assigned to the PPI group (lansoprazole 30 mg, $n = 30$) or the H2RA group (famotidine 40 mg, $n = 30$) by Central Registry *via* the Internet. If patients who had been treated with famotidine before randomization were assigned to the H2RA group, they were treated with ranitidine 300 mg instead.

The presence of *H. pylori* was determined by urea breath test before treatment. An exhaled-breath sample was collected 20 min after patients took ^{13}C-urea 100 mg orally, and the cut-off value was set at Δ^{13}C 2.5‰[12].

Therapeutic effects were based on endoscopic findings obtained at the end of 8 wk treatment. Endoscopy was performed before and after treatment by a single endoscopist at each facility using GIF-XQ 240 (Olympus Corporation, Tokyo, Japan). Mucosal defects were measured with biopsy forceps and an ulcer was defined as a mucosal defect when it was 3 mm or more in diameter. Photographs of lesions were taken before and after treatment and therapeutic effects were evaluated by a single physician. Complete disappearance of a mucosal defect was defined as healed, reduction of mucosal defect as reduced, no change in mucosal defect as unchanged, enlargement of mucosal defect as aggravated.

Patients were instructed to record abdominal symptoms using gastrointestinal symptom rating scale (GSRS) just before the first and the second endoscopic examinations. The GSRS scores were compared before and after treatment to evaluate the improvement of abdominal symptoms.

Statistical analysis

Endoscopic healing rate and self-improvement rate using GSRS were statistically determined by Wilcoxon test. The statistical software used was the SPPS 15.0. A level of $P < 0.05$ was considered statistically significant.

RESULTS

Four patients in the PPI group and 4 patients in the H2RA group dropped out of the study because they refused to undergo endoscopy when their symptoms disappeared or they were moved to another hospital. Medication compliance rate was as high as 80% or more among patients excluding dropouts. Twenty-six patients in the PPI group and 26 in the H2RA group qualified for analysis.

Buffered aspirin tablets (Bufferin 81) and enteric coated tablets (Bayaspirin 100) were continuously used by 11 and 15 patients, respectively, in the PPI group and by 10 and 16 patients, respectively, in the H2RA group. Two patients in each group had used NSAIDs as needed for headache (diclofenac sodium in 3 patients and zaltoprofen in 1 patient). H2RA had been used before enrollment in 3 patients in the PPI group (usual dose of ranitidine, usual dose of nizatidine, and half dose of famotidine respectively) and in 4 patients in the H2RA group (usual dose of famotidine, usual dose of ranitidine, usual dose of nizatidine, and half dose of nizatidine respectively). No patients

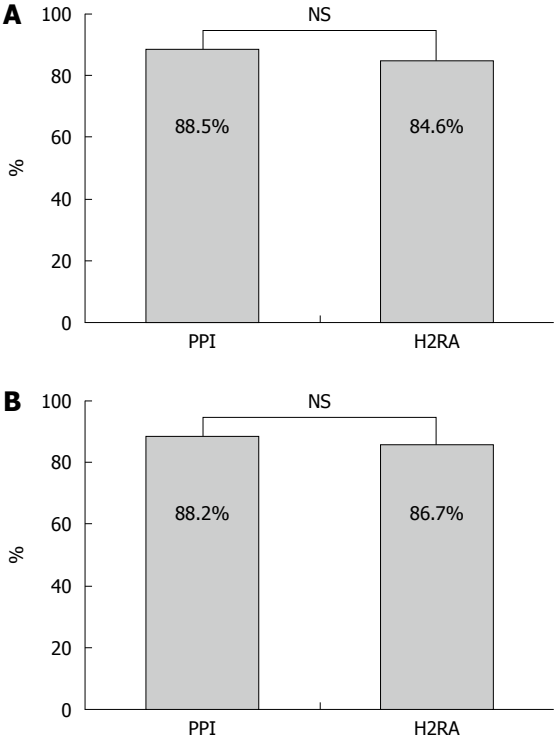

Figure 1 Gastroduodenal ulcer healing was endoscopically achieved in proton pump inhibitors and histamine 2 receptor antagonists group patients. A: Gastroduodenal ulcer healing was endoscopically achieved in 88.5% of proton pump inhibitors (PPI) group patients and in 84.6% of histamine 2 receptor antagonists (H2RA) group patients. There was no significant difference between the two groups; B: Gastroduodenal ulcer healing in patients with non-pangastritis was endoscopically achieved in 88.2% of PPI group and in 86.7% of H2RA group. There was no significant difference between the two groups. NS: Not significant.

Table 1 Background of patients *n* (%)

	PPI group (*n* = 26)	H2RA group (*n* = 26)	*P* value

PPI: Proton pump inhibitors; H2RA: Histamine 2 receptor antagonists; NS: Not significant.

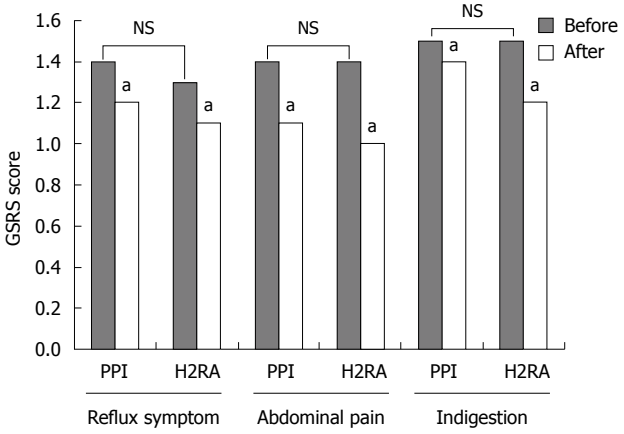

Figure 2 Improvement of abdominal symptoms was evaluated using gastrointestinal symptom rating scale scores. The scores were not significantly reduced after treatment as compared with before treatment in both proton pump inhibitors (PPI) and histamine 2 receptor antagonists (H2RA) groups. [a]NS *vs* before. NS: Not significant.

had used PPI before enrollment. If patients assigned to the H2RA group had a history of famotidine use, they were administered ranitidine 300 mg.

There were no significant differences in median age, sex, underlying disease, smoking status, *H. pylori* infection, prevalence of ulcers before treatment, or lesion site between the PPI group and the H2RA group (Table 1).

The therapeutic effects were endoscopically evaluated as healed in 23 of 26 patients in the PPI group and in 22 of 26 patients in the H2RA group, with no significant difference between the groups (Figure 1A).

Three patients in the PPI group were evaluated as not healed, including 2 evaluated as reduced and 1 evaluated as unchanged. In the 2 patients evaluated as reduced, multiple ulcers were observed at the antrum of the stomach and ulcers 10 and 5 mm in maximum diameter were reduced to 3 and 2 mm, respectively, after treatment. In the patient evaluated as unchanged, the use of 100 mg aspirin enteric coated tablets was continued for the treatment of angina pectoris, endoscopy revealed a solitary ulcer 5 mm in diameter at the body of the stomach, and there was no evidence of *H. pylori* infection.

Four patients in the H2RA group were evaluated as not healed, including 3 evaluated as reduced and 1 evaluated as unchanged. In the 3 patients evaluated as reduced, solitary ulcers 15 mm at the antrum of the stomach, 15 mm at the body of the stomach, and 3 mm at the antrum of the stomach were all reduced to 2 mm after treatment. In the patient evaluated as unchanged, the use of 162 mg buffered aspirin tablets was continued for the treatment of old myocardial infarction, multiple ulcers were observed at the antrum of the stomach 3 mm in maximum diameter on endoscopy, there was no evidence of *H. pylori* infection, diclofenac sodium was prescribed as needed, and usual dose of ranitidine had been administered before assignment to treatment group.

Improvement of abdominal symptoms was evaluated after treatment by comparing the GSRS scores before and after treatment. Pretreatment scores indicated that abdominal symptoms were uncommon in both the PPI group and the H2RA group. The scores were not significantly reduced after treatment as compared with before treatment in either group (Figure 2). No side events were observed in either group.

For research about influence of acid secretion, both groups were subdivided into 2 groups based on whether the patient had pangastritis or not. There were 17 patients in the PPI group with pangastritis and 15 in the H2RA

group. The therapeutic effects were not significantly different between the non-pangastritis groups (Figure 1B).

DISCUSSION

One of the major adverse events associated with low-dose aspirin is gastrointestinal bleeding. However, screening endoscopy is widely used in Japan and peptic lesions are frequently pointed out on screening endoscopy before the development of overt gastrointestinal bleeding. Therefore, the subjects of this study were those found to have gastroduodenal lesions on endoscopy without gastrointestinal bleeding as a complication.

Low-dose aspirin-induced mucosal defect is commonly 5 mm or less[3]. Considering that lesions 5 mm or less in size can cause bleeding, and if left untreated, may be enlarged, we believe that small ulcers should be treated. Thus, patients with ulcers 3 mm or more were included in this study.

Controlled studies of the therapeutic effects of PPI *vs* H2RA for NSAIDs-associated gastric ulcers have shown that the healing rate after 8 wk treatment was significantly higher in the PPI group than in the H2RA group[9-11].

A recent controlled study investigated the preventative effects of PPI *vs* H2RA on the occurrence of bleeding ulcers associated with low-dose aspirin in patients not infected with *H. pylori* and concluded that PPI are significantly more effective than H2RA in preventing the occurrence of bleeding ulcers and abdominal symptoms[13]. However, the results of their preventative effects against ulcers cannot be extrapolated to the healing of ulcers. On the other hand, it was reported that patients who take H2RA with low-dose aspirin had fewer peptic ulcers than patients who take placebo[14].

In the present study, the healing rate of gastroduodenal ulcers associated with low-dose aspirin was similar in the PPI group and the H2RA group. This may be explained by the facts that half of the subjects included in this study were infected with *H. pylori,* the subjects were limited to the Japanese, and they had a lower ability to secrete gastric acid. Previous studies involving patients with duodenal ulcers have shown that average maximum gastric acid secretion was 21.9 mEq/h for Japanese men and 43.2 mEq/mL for American men[15,16]. However, a retrospective study from Western countries investigated the effects of H2RA (famotidine 20-40 mg or ranitidine 150-300 mg) and PPI (omeprazole 20 mg) on lowering the risk of gastrointestinal bleeding in low-dose aspirin users and concluded that both drug classes have similar effects on preventing bleeding[17]. Further studies are needed to evaluate the therapeutic effects of both PPI and H2RA on low-dose aspirin-induced ulcers.

One patient evaluated as unchanged in the H2RA group developed an ulcer 3 mm in diameter, was not infected with *H. pylori*, and had a history of diclofenac sodium on an as-needed basis. One other patient in the PPI group had used diclofenac sodium as needed before assignment, but the ulcer was healed after 8 wk treatment. PPI are also reported to be effective when combined with low-dose aspirin and NSAIDs[18]. The combined use of low-dose aspirin and NSAIDs is known to be associated with an increased risk of gastrointestinal bleeding[3]. When low-dose aspirin is used alone, H2RA is expected to heal ulcers, but it may be better to choose PPI in high risk cases in which low-dose aspirin and NSAIDs are combined. Even in these cases, PPI are considered to be more effective than H2RA for 4 wk treatment[11,18].

The patient evaluated as unchanged in the PPI group had an ulcer 5 mm in size and was not infected with *H. pylori*. This case indicated that some ulcers are not healed even when treated with PPI. Such cases require further investigation for their appropriate treatment.

In this study, none of the patients were treated with combined aspirin and other antiplatelet drugs. However, recently use of combinations of low-dose aspirin and other antiplatelet drugs (e.g. clopidogrel and ticlopidine) have been increased, especially after coronary bypass graft surgery. PPI decrease clopidogrel's inhibitory effect on platelets[19]. It may be better to choose H2RA when low-dose aspirin and clopidogrel are combined. On the other hand, clopidogrel is not associated with an increased risk of gastrointestinal bleeding when used alone, but is associated with a 7.7-fold increased risk when used in combination with low-dose aspirin[20]. Further studies are required to investigate the preventive and therapeutic effects of PPI and H2RA on gastrointestinal events in the presence of combined aspirin and other antiplatelet drugs.

In conclusion, the healing rate of gastroduodenal ulcers was greater than 80% after 8-wk treatment with PPI or H2RA during continuous use of low-dose aspirin, with no significant difference between the two groups.

COMMENTS

Background

The use of aspirin has increased in the aging population. Aspirin increases the risk of gastrointestinal injury. The strategy to treat ulcers during low-dose aspirin treatment is not clear.

Research frontiers

It was reported that proton pump inhibitors (PPI) are more effective than histamine 2 receptor antagonists (H2RA) in prevention of aspirin-induced ulcers.

Innovations and breakthroughs

In this study, the healing rate of aspirin-induced ulcers was greater than 80% in both the PPI and the H2RA groups, with no significant difference between groups.

Applications

This study may be useful for considering changes in treatment of aspirin-induced ulcer.

Peer review

This article demonstrates some interesting points that compare the effects of PPI and H2-blocker in patients taking continuous low dose aspirin. The paper is well written, design is appropriate for end-points stated and patient number is nearly enough to draw conclusions.

Abstract

AIM: To compare the efficacy of self-expandable metal stents (SEMSs) with 10F plastic stents (PSs) in the endoscopic management of occluded SEMSs.

METHODS: We retrospectively reviewed the medical records of 56 patients who underwent SEMS insertion for palliation of unresectable malignant biliary obstruction between 2000 and 2007 and subsequent endoscopic retrograde biliary drainage (ERBD) with SEMS or PS for initial SEMS occlusion between 2000 and 2008.

RESULTS: Subsequent ERBD with SEMS was performed in 29 patients and with PS in 27. The median time to stent occlusion after subsequent ERBD was 186 d in the SEMS group and 101 d in the PS group (P = 0.118). Overall median stent patency was 79 d for the SEMS group and 66 d for the PS group (P = 0.379). The mean number of additional biliary drainage procedures after subsequent ERBD in patients that died (n = 50) during the study period was 2.54 ± 4.12 for the SEMS group and 1.85 ± 1.95 for the PS group (P = 0.457). The mean total cost of additional biliary drainage procedures after the occlusion of subsequent SEMS or PS was $410.04 ± 692.60 for the SEMS group and $630.16 ± 671.63 for the PS group (P = 0.260). Tumor ingrowth as the cause of initial SEMS occlusion was the only factor associated with a shorter time to subsequent stent occlusion (101 d for patients with tumor ingrowth *vs* 268 d for patients without tumor ingrowth, P = 0.008).

CONCLUSION: Subsequent ERBD with PSs offered similar patency and number of additional biliary drainage procedures compared to SEMSs in the management of occluded SEMS.

Key words: Stents; Biliary tract neoplasms; Obstructive jaundice; Endoscopy; Endoscopic retrograde cholangiopancreatography

INTRODUCTION

Endoscopic retrograde biliary drainage (ERBD) is now widely accepted as the standard intervention for the relief of obstructive jaundice in patients with unresectable malignant biliary obstruction[1-3]. Although plastic stents (PSs) were developed earlier, self-expandable metal stents (SEMSs) are now used widely as the initial choice for ERBD in this setting, as SEMSs offer longer patency[4-8]. Although it was suggested that a PS-based biliary drainage strategy may be more economical if the cost of endoscopic retrograde cholangiopancreatography (ERCP) is low relative to that of a SEMS[9,10], our recent retrospective study concluded that a SEMS-based biliary drainage strategy might offer better palliation without a significant increase in drainage-related medical cost, even where the cost of ERCP is low[11].

However, SEMSs do become occluded in some patients. Even covered SEMSs, which were developed to overcome stent occlusion caused by tumor ingrowth, become occluded due to tumor overgrowth, sludge, or migration[12,13]. There are a limited number of reports regarding the management of occluded SEMS, with various results[14-17]. The aim of this study was to compare the efficacy of SEMSs with 10F PSs in subsequent ERBD after the occlusion of initial SEMSs.

MATERIALS AND METHODS

Patients

Patients who underwent SEMS insertion (either endoscopically or percutaneously) for the palliation of unresectable malignant biliary obstruction at Seoul National University Hospital and the National Cancer Center between January 2000 and December 2007, and subsequent ERBD with SEMS or 10F PS for initial SEMS occlusion between January 2000 and December 2008, were evaluated. Patients were excluded when the initial SEMS was occluded within seven days of placement, when the follow-up period after subsequent ERBD was less than eight weeks without documented stent occlusion or patient death, or when endoscopic nasobiliary drainage or a percutaneous transhepatic biliary drainage (PTBD) was performed before the subsequent ERBD. The medical records were reviewed; endoscopic and radiological findings were studied to compare the stent patency and survival of the patients. Additional information on patient survival was obtained by contacting the Resident Service Division of the Ministry of Public Administration and Security, Seoul, Korea.

For patients who died during the study period, the total number and cost of additional biliary drainage procedures after the occlusion of subsequent SEMS or PS (the sum of the costs of ERCP, ERBD, PTBD, PTBD catheter exchange, and stents) were compared between the two groups. The costs were converted from Korean won to U.S. dollars according to annual medical fee schedules and the annual average exchange rate (Table 1)[18-27]. Data were collected until the death of the patient or June 30, 2009. This study was approved by the institutional review boards of the institutions.

Subsequent stent insertion

A diagnosis of SEMS occlusion was made when a patient who had undergone ERBD with a SEMS presented with cholangitis (fever, tenderness in the right upper quadrant or epigastrium, and/or a $\geqslant$ two-fold increase in the serum bilirubin level above the baseline after initial SEMS insertion), or when the total serum bilirubin level was increased $\geqslant$ twofold above the baseline after initial SEMS insertion, even without symptoms or signs of cholangitis. After the diagnosis of SEMS occlusion was made, all patients fit for ERBD underwent the procedure.

ERCP was performed to characterize the cause of the SEMS occlusion using standard- or large-channel duodenoscopes (TJF-240, JF-240, TJF-200, JF-200; Olympus Optical Co., Ltd., Tokyo, Japan). Once stent occlusion was diagnosed, mechanical cleaning with a balloon catheter or a stone extraction basket was usually performed to examine the causes of stent malfunction if the cause was not clear. A guidewire was passed through the stricture, and the stricture length was measured with Tandem RX cannulas (Boston Scientific, Natick, Mass) or Tracer Metro guidewires (Cook Medical, Winston-Salem, NC). After the guidewire had passed through the occluded SEMS, another SEMS or PS was placed through the initial SEMS. Proper placement of the stent was confirmed by fluoroscopy.

In the SEMS group, covered or uncovered Wallstents (Boston Scientific) or uncovered Niti-S stents (Taewoong Medical Inc., Gimpo-si, Korea) were used. In the PS group, 10F Percuflex Amsterdam biliary stents (Boston Scientific), or Cotton-Leung stents (Cook Medical) were used.

Definition of events

Successful subsequent ERBD was defined as placement of the stent across the occluded initial SEMS confirmed by the appropriate radiographic positioning, immediate biliary decompression, and at least a 30% reduction in, or normalization of, the serum bilirubin level ($\leqslant$ 1.2 mg/dL).

Occlusion of subsequent ERBD was diagnosed when the patient developed symptoms or signs of stent occlusion, as described above. Time to stent occlusion was defined as the time between stent insertion and stent occlusion; the overall stent patency was defined as the time between stent insertion and stent occlusion or death of the patient.

Statistical analysis

Qualitative variables were compared using the χ^2 test or Fisher's exact test, where appropriate. The *t* test was used for comparison of quantitative variables. Time to stent occlusion, overall stent patency, and patient survival after the subsequent ERBD were estimated using the Kaplan-Meier method and compared with the log rank test. Factors influencing the time to subsequent stent occlusion were determined using the log-rank test. Two-sided *P*

values of < 0.05 were considered significant. All analyses were performed using SPSS for Windows Ver. 11.0 (SPSS Inc., Chicago, IL).

RESULTS

Patient characteristics

A total of 56 (37 male) patients were evaluated. The median age at initial SEMS insertion was 66 years (range, 38-87 years). The diagnoses were: pancreatic cancer ($n = 21$), gallbladder cancer ($n = 9$), common bile duct cancer ($n = 8$), hilar cholangiocarcinoma ($n = 8$), metastatic lymph nodes ($n = 5$), ampulla of Vater cancer ($n = 4$), and hepatocellular carcinoma ($n = 1$). Thirty-two patients had no biliary drainage procedures prior to the initial SEMS insertion. Initial SEMSs were inserted endoscopically in 46 patients and percutaneously in 10. The median time to occlusion of the first SEMS was 124 d (range, 22-755 d). The causes of the first SEMS occlusion were: tumor ingrowth ($n = 37$), sludge and clogging ($n = 9$), combined ingrowth and sludge ($n = 7$), migration ($n = 2$), and tumor overgrowth ($n = 1$). After occlusion of the initial SEMS, subsequent ERBD with SEMS was performed in 29 patients (uncovered SEMS in 19 and covered SEMS in 10) and PS in 27. Changes in stent selection trends were evident over time. Between 2001 and 2006, 10 SEMSs and 21 PSs were inserted during the subsequent ERBD, whereas between 2007 and 2008, 19 SEMSs and 6 PSs were inserted ($P = 0.001$). No significant difference in the diagnoses of the two stent groups was noted ($P = 0.277$). Twenty-one patients (72.4%) in the SEMS group and 15 (55.6%) in the PS group underwent anti-cancer therapy ($P = 0.188$) (Table 2).

Subsequent ERBD

Stent occlusion after subsequent ERBD occurred after a median of 186 d (range, 11-285 d) in 16 patients (55.2%) in the SEMS group and after a median of 101 d (range, 2-194 d) in 18 patients (66.7%) in the PS group ($P = 0.118$ for time to stent occlusion, $P = 0.379$ for stent occlusion rate). The causes of stent occlusion were tumor ingrowth ($n = 17$), sludge and clogging ($n = 10$), migration ($n = 2$), tumor overgrowth ($n = 2$), duodenal obstruction ($n = 2$), and combined ingrowth and overgrowth ($n = 1$). Overall stent patency was 79 d for the SEMS group and 66 d for the PS group ($P = 0.379$). The cumulative stent patency estimated by the Kaplan-Meier method was 72.4%, 55.2%, 48.3%, and 37.9% for the SEMS group and 66.7%, 55.6%, 40.7%, and 25.9% for the PS group at 30, 60, 90, and 120 d, respectively (Figure 1). There was no correlation between the patency of the first SEMS and subsequent stent that had occluded (correlation coefficient, 0.251, $P = 0.152$).

When adjusted for anti-cancer treatment, the median

	SEMS group (*n* = 29)	PS group (*n* = 27)	*P* value
Follow-up period, median (d)	200	133	0.993
Stent occlusion	16 (55.2)	18 (66.7)	0.379
Time to stent occlusion, median (d)[1]	186	101	0.118
Overall stent patency, median (d)[1,2]	79	66	0.379
No. of additional biliary drainage procedures	2.54 ± 4.12	1.85 ± 1.95	0.457
Total cost of subsequent biliary drainage procedures ($)	410.04 ± 692.60	630.16 ± 671.63	0.260
Survival after subsequent ERBD, median (d)[1]	200	133	0.225

[1]Results of log-rank test; [2]Period between stent insertion and stent occlusion or death of the patient. SEMS: Self-expandable metal stent; PS: Plastic stent; ERBD: Endoscopic retrograde biliary drainage.

time to stent occlusion was not significantly different between the SEMS and PS groups. For the patients who underwent anti-cancer therapy, the median time to stent occlusion was 177 d for the SEMS group and 104 d for the PS group; in patients who did not undergo anti-cancer treatment, the median time to stent occlusion was 186 d for the SEMS group and 79 d for the PS group ($P = 0.120$).

When covered SEMS group ($n = 10$) and uncovered SEMS group ($n = 19$) were compared, the median time to stent occlusion was 208 d (range, 22-268 d) for covered SEMS and 106 d (range, 37-285 d) for uncovered SEMS ($P = 0.659$). The median overall stent patency was 186 d (range, 19-268 d) for the covered SEMS and 60 d (range, 11-285 d) for uncovered SEMS ($P = 0.599$).

Fifty patients died during the study period. The mean number of additional biliary drainage procedures after subsequent ERBD in patients who died during the study period was 2.54 ± 4.12 for the SEMS group and 1.85 ± 1.95 for the PS group ($P = 0.457$). The mean total cost of additional biliary drainage procedures after the occlusion of subsequent SEMS or PS was $410.04 ± 692.60 for the SEMS group and $630.16 ± 671.63 for the PS group ($P = 0.260$). There was no difference in the median follow-up period (200 d for SEMS group *vs* 133 d for PS group, $P = 0.993$). The median survival was not significantly different between the two groups (200 d for SEMS group *vs* 133 d for PS group, $P = 0.225$) (Table 3).

Factors influencing the patency of the subsequent stent, for both SEMSs and PSs, were analyzed. Tumor ingrowth as the cause of the initial SEMS occlusion was the only factor associated with a shorter median time to subsequent stent occlusion (101 d for patients with tumor ingrowth *vs* 268 d for patients without tumor ingrowth, $P = 0.008$). Gender, age at initial SEMS insertion, diagnosis (pancreatic cancer *vs* non-pancreatic cancer), biliary drainage prior to initial SEMS insertion, anti-cancer therapy, and presentation at initial SEMS occlusion with cholangitis had no impact on the subsequent stent patency (Table 4).

Table 4 Univariate analysis of factors associated with time to second stent occlusion

Factor	Time to second stent occlusion, median (d)	*P* value
Sex		0.273

Results of log-rank test. SEMS: Self-expandable metal stent.

Cox regression analysis demonstrated that tumor ingrowth was associated with shorter time to subsequent stent occlusion (hazard ratio, 8.45; 95% confidence interval, 2.44-29.29; $P = 0.001$).

DISCUSSION

In this retrospective study of the endoscopic management of occluded SEMS for unresectable malignant biliary obstruction, no significant difference was observed for the patency or time to stent occlusion between the PS and the SEMS. In addition, no differences were observed with regard to the number or cost of additional biliary drainage procedures and patient survival. Tumor ingrowth as the cause of the initial SEMS occlusion was the only factor associated with a shorter time to subsequent stent occlusion.

There have been a few retrospective studies regarding the management of occluded SEMSs, with variable results. The study reported by Tham *et al*[15] analyzed 38 patients with 44 Wallstent occlusions. Wallstent occlusion was managed by insertion of another Wallstent in 19, insertion of a PS in 20, and mechanical cleaning in 5 cases. No significant difference in the duration of overall stent patency among the three groups was observed. Another report by Bueno *et al*[14] analyzed 34 patients with Wallstent occlusions. Six patients underwent mechanical cleaning, 4 had placement of a second Wallstent, and 24 had a PS insertion. The median duration of stent patency was 192 d for the second Wallstent, 90 d for the PS, and 21 d for the mechanical cleaning. Although the second Wall-

stent showed a significantly longer duration of patency, this study was limited by the relatively small number of patients who underwent second Wallstent insertion.

Two studies regarding this subject were published in 2008. Togawa *et al*[16] evaluated 40 patients with occluded uncovered SEMSs. Covered SEMSs were inserted in 26 patients, uncovered SEMSs in 7, and PSs in 7. The mean overall patency of the subsequent ERBD was 141.3, 219.6, and 57.9 d for uncovered SEMS, covered SEMS, and PS, respectively. It should be noted that the majority of second SEMSs used in this study were Diamond stents. Rogart *et al*[17] reported that in their experience, placing a second SEMS provided the lowest reocclusion rate and the longest time to reintervention. However, the total number of patients in their study was 27, with a second SEMS insertion in 14, PS insertion in 11, and mechanical cleaning in 2.

Since SEMS and PS did not show significant differences in the time to stent occlusion in our study, the factors influencing the time to subsequent stent occlusion in both groups were assessed. Tumor ingrowth as the cause of initial SEMS occlusion was the only factor associated with shorter time to second stent occlusion, regardless of the material used for the second stent. Tumor ingrowth was the most common cause of the initial SEMS occlusion in this study. Unlike other causes of SEMS occlusion such as tumor overgrowth, sludge or migration, ingrowth may be difficult to overcome by subsequent stent insertion because a long segment of the bile duct might be involved with more compressive force on the stent, thus interfering with the expansion of the SEMS. Moreover, the initial SEMS embedded in the tumor tissue may serve as a rigid framework, adding more resistance to the axial force of the subsequent SEMS. If this was the case, a PS with its fixed diameter may not be inferior to SEMS in subsequent ERBD. A covered SEMS or SEMS with a high radial force may be useful in this setting. Previous reports have shown variable results on this issue. Togawa *et al*[16] demonstrated that covered SEMS were superior to uncovered SEMS for the management of occluded SEMSs. However, the study by Rogart *et al*[17] failed to show that the covered SEMS was superior. A prospective study comparing the efficacy of such SEMSs in the management of initial SEMS occlusion is needed.

The limitations of this study include the following. This was a non-randomized, retrospective study which may result in selection bias. No predefined follow-up protocol was available. Patients with less than 8 wk of follow-up without stent occlusion or death were excluded, since most, if not all, of these patients were lost to follow-up right after the subsequent ERBD. However, this study includes the largest number of patients with SEMS occlusion to date.

In conclusion, subsequent ERBD with PS had similar patency, and number and cost of additional biliary drainage procedures, compared to the SEMS in the endoscopic management of occluded SEMS. Tumor ingrowth as the cause of initial SEMS was the only factor associated with shorter time to second stent occlusion. Therefore, strategies to overcome tumor ingrowth during subsequent ERBD might be beneficial to this subset of patients.

COMMENTS

Background

There are limited data regarding the management of occluded self-expanding metal stents (SEMSs) in palliation of unresectable malignant biliary obstruction.

Innovations and breakthroughs

This study identified tumor ingrowth as the factor associated with shorter time to second stent occlusion.

Applications

In the endoscopic management of occluded SEMS, subsequent endoscopic retrograde biliary drainage with a plastic stent had similar patency and number of additional biliary drainage procedures compared to the SEMS.

Peer review

This is an interesting study in an area without high grade evidence. The authors acknowledge the limitations of their methodology (non-randomized, retrospective).

Abstract

AIM: To identify preoperative predictive factors associated with malignancy of intraductal papillary mucinous neoplasms (IPMNs) of the pancreas.

METHODS: Between April 1995 and April 2010, 129 patients underwent surgical resection for IPMNs at our institute and had confirmed pathologic diagnoses. The medical records were retrospectively reviewed and immunohistochemical staining for mucin (MUC) in pancreatic tissues was performed.

RESULTS: Univariate analysis showed that the following five variables were closely associated with malignant IPMNs preoperatively: absence of extrapancreatic malignancy; symptoms; tumor size > 4 cm; main pancreatic duct (MPD) size > 7 mm; and lymph node enlargement on preoperative computed tomography (CT). Multivariate analysis revealed that the following two factors were significantly associated with malignant IPMNs preoperatively: MPD size > 7 mm [odds ratio (OR) = 2.50]; and lymph node enlargement on preoperative CT (OR = 3.57). No significant differences in the expression of MUC1, MUC2 and MUC5AC were observed between benign and malignant IPMNs.

CONCLUSION: MPD size > 7 mm and preoperative lymph node enlargement on CT are useful predictive factors associated with malignancy of IPMNs.

Key words: Intraductal papillary mucinous neoplasms; Malignancy; Predictive factors; Pancreatic neoplasms

INTRODUCTION

Intraductal papillary mucinous neoplasms (IPMNs) of the pancreas are characterized by intraductal proliferation of neoplastic mucinous cells, which usually form papillae, and cystic dilation of the pancreatic ducts, thus forming

a clinically and macroscopically detectable mass[1]. The classification of IPMNs according to the World Health Organization nomenclature[1] is as follows: adenoma; borderline tumor; carcinoma *in situ* (CIS); and invasive carcinoma. Depending on the degree of dysplasia, treatment of IPMNs includes conservative treatment and radical pancreatectomy with extended resection. Therefore, it is important to diagnose the grade of IPMNs preoperatively.

Previous studies have revealed predictive factors of invasiveness or malignancy of IPMNs of the pancreas[2-8]. Factors, such as age at the time of diagnosis, tumor size, main pancreatic duct (MPD) size, duct type, the presence of mural nodules, the presence of symptoms, and thick septum are associated with invasiveness or malignancy of IPMNs. However, the results of predictive factors have not been consistent with each other and some are not diagnostic. The pre-operative differential diagnosis between benign and malignant IPMNs, or between non-invasive and invasive IPMNs is not easy, despite the development of diagnostic modalities.

Recently, several studies have demonstrated the expression of mucin (MUC) on pancreatic tumors by immunohistochemical staining[9-13]. MUC1 (membrane mucin) is related to the invasive proliferation of tumors, while the expression of MUC2 (intestinal-type secretory mucin) is related to noninvasive proliferation of tumors[14].

The purpose of the current study was to identify preoperative predictive factors associated with malignancy of IPMNs of the pancreas by reviewing patients' records, and to reveal the role of MUC expression in differentiating malignant IPMNs using several specific antibodies.

MATERIALS AND METHODS

Patients and clinical characteristics

Between April 1995 and April 2010, 129 patients who underwent surgical resection for IPMNs of the pancreas at the Samsung Medical Center in Seoul, Korea, and had a confirmed pathological diagnosis were included. The medical records were retrospectively reviewed to obtain the demographic characteristics.

We analyzed variable factors, such as age at the time of diagnosis, sex, presence or absence of diabetes mellitus, alcohol intake history, and cigarette smoking. Symptomatic IPMNs were defined as the presence of abdominal pain and/or jaundice. Recently, IPMNs have been shown to be associated with a high incidence of extrapancreatic gastrointestinal neoplasms[15,16], thus, we assessed preoperatively the presence of extrapancreatic gastrointestinal cancers in the study population.

We determined the serum levels of total bilirubin, amylase, lipase, carcinoembryonic antigen (CEA), and carbohydrate antigen (CA) 19-9 within 1 mo preoperatively. All patients underwent preoperative computed tomography (CT). We assessed the duct type, tumor size, location, MPD size, and presence of mural and intra-abdominal lymph node enlargement on CT. Adenomas and borderline tumors were benign tumors, and CIS and invasive carcinomas were malignant tumors.

Immunohistochemical staining

The surgical specimens were fixed with 10% formalin and cut at intervals of 5 mm. The tumor samples were embedded in paraffin, and the histological sections were cut into 5-μm thick slices for hematoxylin and eosin staining. Immunohistochemical staining for p53, MUC1, MUC2 and MUC5AC was performed on the serial sections for IPMN tissues. The 5-μm thick sections were deparaffinized with xylene, and rehydrated in alcohol. After rinsing in PBS, the sections were incubated for 1 h at room temperature with DF3 (1:50 dilution; Toray-Fuji Bionics, Tokyo, Japan) for MUC1 antigen, Ccp58 (undiluted; Biogenex, San Ramon, CA, USA) for MUC2 antigen, and CLH2 (1:50 dilution; Novocastra, Newcastle, UK) for MUC5AC antigen. In addition, sections were incubated for 25 min at room temperature with BP53.12 (1:400 dilution; Zymed, San Francisco, CA, USA) for p53 antigen. The sections were rinsed with tap water. Positivity of the immunohistochemical stain was judged by the presence of staining in the intraductal tumor cells.

Statistical analysis

Continuous data are presented as the mean ± SD or median and range. The χ^2 test or Fisher's exact test was used to evaluate differences between categorical variables. Significant predictors in the univariate analysis were included in the logistic regression model for multivariate analysis. Differences at $P < 0.05$ were considered statistically significant. Statistical analyses were performed using SPSS 17.0k software (SPSS Inc., Chicago, IL, USA).

RESULTS

Patient characteristics

One hundred and twenty-nine patients underwent surgical resection and were confirmed with IPMN of the pancreas (Table 1). The study group included 94 men and 35 women, with a mean age at the time of diagnosis of 60.9 years (range, 32-77 years). More than half of the IPMNs were detected incidentally in asymptomatic patients during routine check-ups. The duct type included the main duct in 56 patients (43.4%), a branch duct in 46 (35.7%), and mixed ducts in 27 (20.9%). Eighty-one of the patients (62.8%) were diagnosed with benign tumors (adenomas and borderline tumors) and 48 (37.8%) had malignant tumors (CIS and invasive carcinomas).

Comparisons of characteristics between benign and malignant IPMNs

There were no differences in age at the time of diagnosis and sex between the patients with benign and malignant IPMNs (Table 2). In both groups, the proportion of current smokers and alcohol drinkers was no different. Of the IPMNs in patients with diabetes mellitus, 37.5% were malignant and 27.1% were benign tumors ($P > 0.05$). Symptomatic IPMNs were observed in 31 of the patients (64.6%) with malignant tumors and 32 (39.5%) with benign tumors ($P = 0.007$). The proportion of patients with tumors > 4 cm in size was greater in patients with malignant IPMNs

Table 1 Demographics and subtypes of intraductal papillary mucinous neoplasms (*n* = 129) (mean ± SD) *n* (%)

Features	Value
Age (yr)	60.9 ± 9.6 (range, 32-77)
Sex (M:F)	94:35
Symptoms	
(-)	66 (51.2)
(+)	63 (48.8)
Mean tumor size (cm)	3.7 ± 3.2 (range, 0.6-16.5)
Mean MPD size (mm)	7.4 ± 4.8 (range, 1.0-30.0)
Tumor location	
Pancreatic head or uncinate process	80 (62.0)
Body or tail	49 (28.0)
Duct types on CT	
Main duct	56 (43.4)
Branch duct	46 (35.7)
Mixed duct	27 (20.9)
Pathologic subtypes	
Adenoma	51 (39.5)
Borderline	30 (23.3)
CIS	5 (3.9)
Invasive	43 (33.3)

MPD: Main pancreatic duct; CT: Computed tomography; CIS: Carcinoma *in situ*.

(37.5%) than benign tumors (18.5%, $P = 0.019$). The MPD was > 7 mm in diameter more frequently in malignant (62.5%) than in benign (33.3%, $P = 0.002$) tumors. According to CT, there were no significant differences in the proportion of patients with mural nodules, the tumor location within the pancreas, and duct types ($P > 0.05$). Intra-abdominal lymphadenopathy, defined as lymph nodes > 1.5 cm in size on preoperative CT, existed in 31.2% of malignant and 9.8% of benign tumors ($P = 0.003$). The mean serum level of amylase in patients with benign IPMNs was higher than in those with malignant tumors (128.0 ± 13.5 U/L *vs* 86.8 ± 61.1 U/L, $P = 0.173$). The mean serum levels of total bilirubin (2.1 ± 4.6 mg/dL), CEA (2.2 ± 1.3 ng/mL), and CA 19-9 (867.9 ± 3958.5 U/mL) in patients with malignant IPMNs was similar to those in patients with benign tumors (0.7 ± 0.4 mg/dL, 6.7 ± 31.9 ng/mL, and 34.5 ± 81.4 U/mL, respectively, $P > 0.05$).

Patients with benign tumors had more extrapancreatic gastrointestinal malignancies before or during the diagnosis of IPMN than patients with malignant tumors (28.1% *vs* 6.2%, $P = 0.014$). Four of 23 patients with IPMNs with extrapancreatic malignancies were women and more than half of all cases were detected at the same time as the diagnosis of IPMN was established. Gastric cancer (10 patients) and lower gastrointestinal tract cancer (eight patients) comprised the majority of extrapancreatic malignancies (Table 3).

Analysis of preoperative findings associated with malignant IPMNs

Univariate analysis showed that the following preoperative variables were closely associated with malignant IPMNs: absence of extrapancreatic malignancy; symptoms; tumor size > 4 cm; MPD size > 7 mm; and lymph node enlargement on preoperative CT (Table 2). Two of five factors that were significant predictors based on univariate analysis were identified as significant on multivariate analysis: MPD size > 7 mm [odds ratio (OR) = 2.50]; and lymph node enlargement on preoperative CT (OR = 3.57, Table 4).

SMT: Submucosal tumor; CIS: Carcinoma *in situ*; Prior: Prior to intraductal papillary mucinous neoplasm (IPMN); Syn: Synchronous to IPMN.

Immunohistochemical expression of malignant IPMNs

The expression of pancreatic tissues was present in 22.2%, 29.6%, 96.3% and 11.1% of benign IPMNs for MUC1, MUC2, MUC5AC and p53, respectively (Table 5). In patients with malignant IPMNs, the expression of mucin genes was 17.6%, 57.1%, 94.1%, and 34.5% with immunohistochemical staining for MUC1, MUC2, MUC5A, and p53, respectively. No significant differences in expression of MUCs were observed according to the degree of dysplasia.

DISCUSSION

Several studies regarding the natural course of IPMNs have shown that tumor size < 3 cm, branch duct type, and no mural nodules are low-risk factors of malignancy[17]; thus, the pancreas can be conserved until the tumor progresses to an invasive carcinoma. Therefore, a therapeutic strategy for IPMNs should be based on the stage of the malignancy.

Previous studies that have investigated predictive factors for malignant or invasive IPMNs preoperatively were based on univariate analysis, with only four studies being performed using multivariate analysis[3,5-7]. Our data showed that the presence of extrapancreatic malignancies, symptoms, tumor size > 4 cm, MPD dilatation > 7 mm, and intra-abdominal lymphadenopathy on preoperative CT were significant predictive factors of malignant IPMNs, based on univariate analysis, and only two of the five factors (MPD > 7 mm and intra-abdominal lymphadenopathy on CT) were statistically significant on multivariate analysis. The present study is believed to be the first to report intra-abdominal lymphadenopathy on CT as a predictive factor, which is not well known for sensitivity and specificity. According to our study, we emphasized the diagnostic importance of CT and recommend it as a follow-up tool to predict malignant changes.

Table 4 Multivariate analysis of preoperative findings associated with malignant intraductal papillary mucinous neoplasms

Factors	OR	95% CI	*P* value

IPMN: Intraductal papillary mucinous neoplasm; MUC: Mucin.

Symptomatic tumors > 3 cm in size are known as important factors for malignancy of branch duct type IPMNs according to international guidelines[18]. In another study[5], the optimal cut-off value for IPMN size in the detection of malignancies was 4 cm. The analysis of our patients divided by tumor size of 3 cm was not statistically significant, thus, we set the cut-off value at 4 cm, which was significantly associated with malignant IPMNs.

A number of previous studies have reported that malignant or invasive IPMNs are more frequently observed in those who have main duct or mixed duct type than branch duct type IPMN[5,18,19]. We showed that the duct type of IPMNs was not affected by malignant transformation of tumors. Patients with the branch duct type in our institute usually underwent wait and watch management, therefore, they were not included with the study group who underwent surgical resection. For the accuracy of predictive factors, follow-up data of branch duct type IPMNs will be necessary in future studies.

The presence of mural nodules has also been reported as a predictive factor of malignant IPMNs[4-7], but it was not associated with malignant tumors in the current study. Mural nodules are usually detected on preoperative multidetector row CT. Mucinous secretions in cystic masses appear to be misdiagnosed as mural nodules because of similarities on CT imaging. Therefore, mural nodules are not diagnostic predictive factors associated with malignant IPMNs.

Our study revealed that benign IPMNs were more likely to have extrapancreatic gastrointestinal malignan-

cies than malignant tumors, which is in agreement with other studies[11,20-22]. The basis for this result has not been explained, but the hypothesis has been advanced that patients with extrapancreatic malignancies were excluded from the study group due to death from underlying cancers[21]. In our study, 28 of 129 patients had an extrapancreatic malignancy and many cases were detected during preoperative evaluation of IPMNs. Gastric or lower gastrointestinal cancers comprised most of the extrapancreatic malignancies, therefore, upper endoscopy and colonoscopy are necessary to detect associations with other gastrointestinal malignancies at the time diagnosis of IPMNs.

IPMN cells secrete a thick MUC that causes dilatation of the MPD. The dysregulation of one or more types of MUCs could lead to formation of malignant IPMNs. There have been several studies[9-14] regarding the expression of MUC in pancreatic tumors. For example, MUC1 is known to be a marker of invasive carcinoma and MUC2 is found only in the intestinal type of IPMNs[10]. In the current study, a difference in the expression of MUC on benign and malignant IPMNs was not demonstrated. Positive staining of MUC1 was shown in 22.2% of adenomas or borderline IPMNs and MUC5AC expression was shown in > 94% of all IPMNs. Cell cycle modulator molecules, for example p53, were similar in both groups.

This study was limited in that it was retrospective and evaluated the predictive factors associated with malignancy, which were diagnosed in most cases by CT. Another limitation was that the examination of MUC expression according to pathological subtypes[23], such as gastric, intestinal, pancreatobiliary, and oncocytic, was not performed, and the study group consisted only of patients who underwent surgical resection. We do not know the significance of patients who received conservative treatment or adjuvant chemoradiation therapy.

In conclusion, a MPD size > 7 mm and preoperative intra-abdominal lymphadenopathy on CT are useful predictive factors associated with malignancy of IPMNs. The proper diagnosis of malignancies in patients with IPMNs is needed for those who are undergoing surgical resection.

COMMENTS

Background

Several investigators have revealed predictive factors of invasiveness of malignancy of intraductal papillary mucinous neoplasm (IPMN), but the results of predictive factors have not been consistent with each other and some are not diagnostic.

Research frontiers

Several recent studies have investigated the role of mucin expression to differentiate the malignancy of IPMN, by using several specific antibodies. Also, it is known that IPMN is associated with a high incidence of extrapancreatic neoplasms.

Applications

It appears to be important to determine the surgical resection of IPMN according to malignant potential.

Terminology

The main pancreatic duct type of IPMNs was treated with surgical resection due to its malignancy, but the branch duct type was sometimes treated without surgery because most tumors of this type of tumor have benign characteristics.

Peer review

This is a good retrospective study. Whether or not the results will prove useful in a prospective fashion is appropriately addressed by the authors.

Abstract

AIM: To investigate *p53* mutations in esophageal cancer in a high-risk population, and correlate them with smoking, alcohol consumption and betel chewing.

METHODS: One hundred and sixty-five tumor samples of esophageal squamous cell carcinoma (ESCC) obtained from a university hospital in Songkhla province, Southern Thailand were investigated for *p53* mutations in exons 5-8, using polymerase chain reaction-single strand conformation polymorphism analysis, followed by direct sequencing. A polymerase chain reaction-restriction fragment length polymorphism (RFLP) assay was additionally used to confirm possible germline mutation in intron 6. A history of risk habits was obtained by interviews. The association between risk habits and mutation frequency was evaluated using the χ^2 test.

RESULTS: The studied specimens were from 139 male and 26 female patients with ESCC, treated at Songklanagarind Hospital. Most of the patients were smokers (86.7%) and alcohol consumers (72.73%), and 38.3% were betel chewers. Forty-three mutations of the *p53* gene were detected in 25.5% (42/165) of tumor samples. Mutations were most commonly found in exon 5 (25.6%) and exon 8 (25.6%). Mutations in the hot-spot codon 248 were found in four cases (9.3% of all mutations). G:C→C:G (30.23%), G:C→A:T (27.90%) and G:C →T:A (16.28%) were the prevalent spectra of mutations. Unexpectedly, among 10 intronic mutations, eight cases harbored a similar mutation: G→C substitution in intron 6 (nucleotide 12759, GenBank NC_000017). These were additionally confirmed by the RFLP technique. Similar mutations were also detected in their matched blood samples using RFLP and direct sequencing, which suggested germline mutations. There was no significant correlation between risk habits and *p53* mutation frequency.

CONCLUSION: A proportion of Thai ESCC patients harbored specific intronic *p53* mutations, which might be germline mutations. Further studies are needed to explore this novel finding.

INTRODUCTION

Esophageal cancer is the eighth most common cancer worldwide, and there were 462 000 new cases in 2002[1]. It is a disease of high mortality, and ranks as the sixth most common cause of cancer death. There is a marked variation in incidence in different regions of the world; a 20-fold difference is observed between high-risk China and low-risk Western Africa. Other areas of moderately high risk are Southern and Eastern Africa, South-Central Asia, and Japan[1]. It seems that environmental carcinogens are responsible for these geographic differences and the different histological types. Tobacco and alcohol use are the main risk factors in Europe and North America[2,3], and other factors including betel chewing, hot beverages, fermented food, nutritional deficiencies or familial predisposition can be responsible for high rates in other high- or moderate-risk regions[4-7].

The incidence of esophageal cancer in Thailand is relatively low when one considers the country-wide estimates, with an age-standardized incidence rate (ASR) of 4.7 per 100 000 males in 1999[8]. However, the incidence is exceptionally high in Songkhla province in Southern Thailand, with an ASR of 8.1 per 100 000 males, which is close to worldwide incidence. In this region, oral cancer is event more prevalent, with the highest incidence (ASR 9.4 per 100 000 males) compared to other regions of the country. Most esophageal cancer cases in Thailand are squamous cell carcinomas. In our previous case-control study, alcohol consumption, cigarette smoking and betel quid chewing were found to be strong risk factors for esophageal squamous cell carcinoma (ESCC)[9].

The *p53* tumor suppressor gene is an important gene in cell cycle regulation and apoptosis. Mutations in the *p53* gene have been implicated as crucial events in the development of various cancers, including ESCC[10], and they have been identified as a vulnerable target for critical DNA damage. Analysis of *p53* mutations in various human cancers has denoted a characteristic mutational pattern that is related to specific endogenous as well as exogenous carcinogen-related agents; a finding that has given rise to the term "mutagen fingerprints" in DNA[11].

p53 mutations in ESCC from Thailand have been reported by two groups in 1997 and 2000[12,13]. However, the numbers of cases were small and the relationship between mutations and risk habits were not explicitly evaluated. Here, we analyzed the *p53* mutation profile of a larger sample set (165 cases) of ESCC using single-strand conformation polymorphism (SSCP) analysis and direct sequencing. In addition, the relationship between mutation frequency and risk habits, namely alcohol consumption, cigarette smoking and betel quid chewing, was examined.

MATERIALS AND METHODS

Patients and samples

Patients who were diagnosed with ESCC and treated at Songklanagarind Hospital during 1999-2005 were considered as candidates for the study. The study was approved by the Ethics Committee of the Faculty of Medicine, Prince of Songkla University, and informed consent was obtained from the patients. Data concerning detailed histories of tobacco use, alcohol consumption and betel chewing were obtained *via* face-to-face interviews using structured questionnaires. Only cases with available fresh-frozen tissue samples were included. Tissue samples were obtained from biopsy or surgical resection specimens, snapped frozen and stored at -80℃ until DNA extraction. All of the cases were primary tumors that had not been treated with radiation or chemotherapy.

Polymerase chain reaction-SSCP analysis

DNA was extracted from frozen tissues by standard methods. The tissue was digested overnight at 37℃ in lysis buffer that contained 10% SDS, 10 mmol/L Tris, pH 8.0, 10 mmol/L NaCl, 10 mmol/L EDTA and 20 μL 10 mg/mL proteinase K. DNA extraction was performed using the phenol-chloroform method and it was precipitated by 1/10 volume of 4.0 mol/L NaCl and two volumes of cold absolute ethanol.

Exons 5-8 of the *p53* gene were polymerase chain reaction (PCR)-amplified from tumor DNA, and mutations were detected by SSCP analysis. Samples that showed band shift were subjected to direct sequencing. Four sets of primer used were as follows: exon 5: TCTTCCTACAGTACTCCCCT sense, AGCTGCTCACCATCGCTATC antisense; exon 6: GATTGCTCTTAGGTCTGGCC sense, GCAAACCAGACCTCAGGCGG antisense; exon 7: TTATCTCCTAGGTTGGCTCT sense, GCTCCTGACCTGGAGTCTTC antisense; exon 8: TCCTGAGTAGTGGTAATCTA sense, GCTTGCTTACCTCGCTTAGT antisense.

PCR reactions were performed in a 50-μL volume reaction mixture that contained 0.5 μg genomic DNA, 10 pmol each primer, 100 mmol/L Tris, pH 8.3, 500 mmol/L KCl, 1.5 mmol/L $MgCl_2$, 200 μmol/L dNTPs, and 1.25 U AmpliTag Gold (Perkin-Elmer, Foster City, CA, USA). Amplification was carried out in a Perkin-Elmer 480 DNA Thermal Cycler. The PCR conditions were 95℃ for 10 min, followed by 35 cycles of 94℃ denaturation for 1 min, 58℃ annealing for 1 min, and 72℃ extension for 1 min. The final extension was conducted at 72℃ for 10 min.

For SSCP analysis, 2 μL PCR product was mixed with 5 μL 95% deionized solution that contained 0.1% bromophenol blue. The mixture was heat-denatured at 100℃ for 5 min and rapidly placed on ice. Four microliters of each denatured product of exons 5 and 8 were loaded on to the 12% polyacrylamide gel (10 cm × 8 cm × 0.75 cm) with 5.26% crosslinking (19:1 acrylamide/bisacrylamide), supplemented with 5% glycerol. For exons 6 and 7, a ratio of 49:1 acrylamide/bisacrylamide (2.04% crosslinking) was used. Electrophoresis was performed in an ice box (12℃) at 2 W and constant 10 mA for 5 h for exons 5 and 8 and 1 h for exons 6 and 7. Positive controls, which consisted of samples that had been confirmed by direct sequencing to contain the *p53* mutation, were run with each SSCP gel that was stained with silver nitrate. All positive cases were confirmed at least once by a separated PCR reaction and SSCP run.

DNA sequencing

The PCR products that showed band shift on the SSCP gel were purified using QIAquick PCR Purification Kit (Qiagen, Hilden, Germany) and then directly sequenced using the Ready Reaction Dye Terminator Cycle Sequencing kit (Perkin-Elmer). The primers used in sequencing were the same as those used in the PCR. Sequencing was performed on an automated sequencer (ABI-Prism 310, Applied Biosystems, Foster City, CA, USA). All mutations were confirmed by sequencing both DNA strands.

For intron 6 mutation at nucleotide 12759, other primers, not overlapped to the mutation point, were used (forward 5'-GCCTCTGATTCCTCACTGAT-3'; reverse 5'-TAAGCAGCAGGAGAAAGCCCC-3'). This experiment was also performed on four available matched blood samples and the sequencing was performed on an automated sequencer (ABI-Prism 3130).

PCR-restriction fragment length polymorphism analysis to detect intronic G→C at nucleotide 12759

As a significant number of cases showed G→C substitution in intron 6 at the 18th base after the end of exon 6 (corresponding to nucleotide 12759 based on GenBank NC_000017), we additionally confirmed this mutation through restriction fragment length polymorphism (RFLP) analysis. This analysis was also performed on matched blood samples of these cases to investigate whether they were germline mutations.

The 181-bp PCR product was amplified using primers, forward 5'-GCCTCTGATTCCTCACTGAT-3'; and reverse 5'-TTAACCCCTCCTCCCAGAGA-3'. The PCR was performed with 100 ng genomic DNA that contained 20 mmol/L Tris-HCl (pH 8.4), 50 mmol/L KCl, 2.0 mmol/L $MgCl_2$, 37.5 μmol/L each nucleotide, and 1.25 U Taq polymerase. The cycling conditions were 95℃ for 5 min, followed by 35 cycles of 95℃ denaturation for 1 min, 60℃ annealing for 1 min, and 72℃ extension for 1 min, with a final extension of 72℃ for 10 min. A 10-μL aliquot of each successful reaction was digested with 10 U *Bsa*HI restriction enzyme (New England Biolabs, Beverly, MA, USA) in 2.5 μL 10 × NEB4 buffer with 12.5 μL water at 37℃ for 2 h. The *Bsa*HI-digested fragments were separated on 10% polyacrylamide gel. A complete digestion (denoted mutation) gave 158-bp and 23-bp DNA fragments.

RESULTS

Patients and clinical data

The study included 165 tumor samples from 139 male and 26 female patients with ESCC diagnosed during 1999-2005. The mean age of patients was 63.4 years with a range of 37-91 years (Table 1). Most patients were habitual current smokers (86.7%) and drinkers (72.73%), with most of them (71.5%) reporting both habits. Habitual betel chewing was reported in 17 out of 26 females (65.4%) and in 45 out of 136 males (33.1%).

Table 1 Summary of patient characteristics

Variable	Category	No. of subjects	Frequency (%)
Sex	Male	139	84.2
	Female	26	15.8
Age (yr)	Mean, range	63.4 (37-91)	
Smoking	Never	19	11.6
	Habitual	143	86.7
	Occasional	3	1.8
Drinking	Never	33	20.0
	Habitual	120	72.7
	Occasional	12	7.3
Betel chewing	Never	78	48.1

Mutation frequency and patterns

A total of 43 mutations were found in 42 tumors of the 165 samples (25.45%). The representative SSCP gels and sequencing chromatograms are shown in Figure 1.

Twenty-five mutations were missense mutations; one was nonsense, four were frameshift deletions, three were stop codons, and 10 were single base substitutions in the intron region. Mutations in coding sequences were most commonly found in exon 5 (25.58%) and exon 8 (25.58%) (Table 2). Among the 10 intronic mutations found, eight were intron 6 mutations.

Of the five major mutation hot spots of the *p53* gene (codon 175, 245, 248, 273 and 282), mutations at codon 248 were observed in four cases (accounting for 9.3% of all mutations), whereas mutations at other codons were not found.

The types of mutations are shown in Table 2. The most common type was G:C→C:G (30.23%), followed by G:C→A:T (27.90%) and G:C→T:A (16.28%). Surprisingly, eight out of 10 intronic mutations were found at the same location, that is, a G→C substitution at the

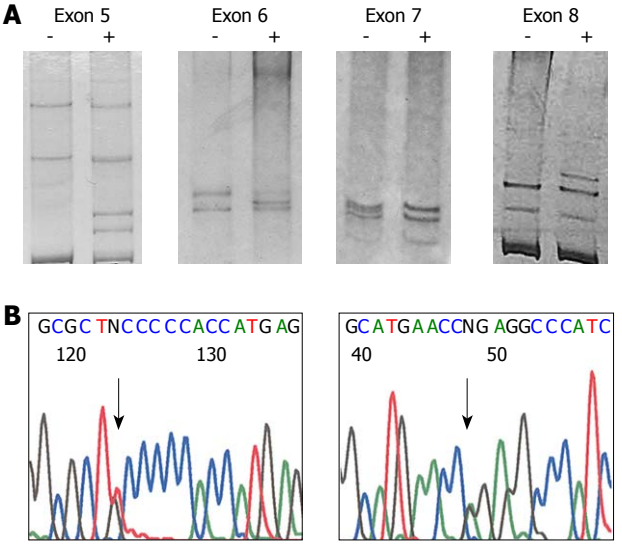

Figure 1 Single-strand conformation polymorphism analysis and direct sequencing of *p53*. A: Single-strand conformation polymorphism of *p53*, exons 5-8 in representative positive cases (+), which showed anomalous bands compared to normal bands in negative cases (-); B: Sequencing chromatograms that represent case E355 (left), which shows TGC-> TTC mutation at codon 176 (arrow) and case E106 (right), which shows CGG-> CAG at codon 248 (arrow).

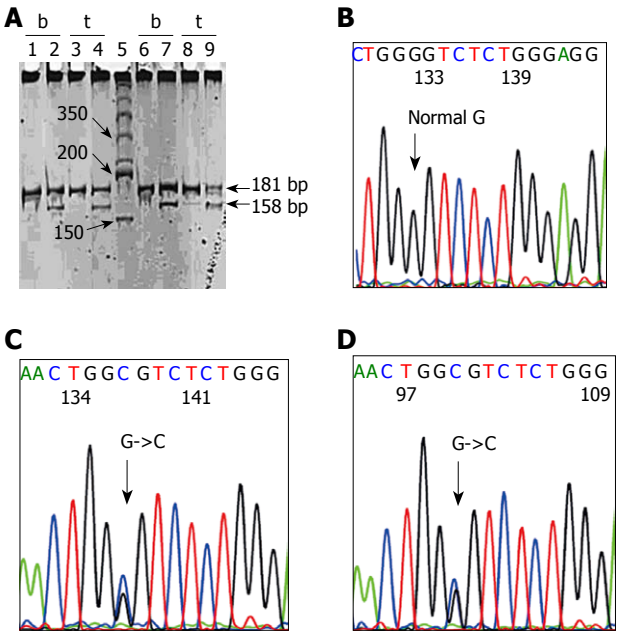

Figure 2 Restriction fragment length polymorphism analysis and direct sequencing to detect intron 6 mutation. A: Detection of the G to C substitution at base 18 after the end of exon 6 by polymerase chain reaction-restriction fragment length polymorphism using *Bsa*HI restriction enzymes. Lane 5 is the size marker. Lanes 1, 3, 6, 8 are uncut 181 bp products of blood (b) and tumor (t) samples of E189 and E199, respectively. Lanes 2, 4, 7, 9 are cut products of the corresponding samples, which show 181 bp and 158 bp fragments, which indicate the presence of a mutation. The 23-bp fragment was not detected in this gel; B-D: Sequencing chromatograms of the corresponding site. Normal sample (B); tumor (C) and blood (D) samples show G to C substitution.

18th base after the last codon of exon 6 (nucleotide 12759, GenBank NC_000017). The details of the mutations of all the cases are shown in Table 3.

Intronic G→C substitution at nucleotide 12759

As a result of the high frequency of intron 6 G→C substitution at 12759 (eight cases), we confirmed these mutations by the RFLP method and the results were similar. We further investigated whether these were germline mutations by examining their matched blood samples through RFLP and direct sequencing. Seven blood samples were available for RFLP and the results denoted a mutation in all of the cases, which suggested germline mutations (Figure 2). The DNA of only four blood samples was available for further direct sequencing and the mutations were confirmed in three out of four samples examined (Figure 2).

We also evaluated functional changes in the p53 proteins of these cases using an immunohistochemistry method (p53 antibody DO-7 clone; DakoCytomation, Carpinteria, CA, USA). Only five cases had adequate tissue for evaluation and the results showed diffuse strong expression in four cases and negative expression in one.

Mutations in relation to clinical factors and exposure

The frequency of mutations in relation to clinicopathological variables is shown in Table 4. Patients younger than 60 years had a significantly higher frequency of *p53* mutations than older patients (38.7% *vs* 17.5%, $P = 0.002$). The mutation frequency was equal in both sexes. In relation to lifestyle habits, the frequency of mutations was slightly higher in non-smokers (36.4%) than smokers (23.8%), and in non-drinkers (33.3%) than drinkers (22.5%). The mutation frequency among betel and non-betel chewers was equal (24.2% and 25.0%). However, there were no statistically significant differences in mutation frequency between exposed and non-exposed patients to all of the three habits.

DISCUSSION

The present study is the third on *p53* mutations in Thai ESCC patients. All of the samples in these three studies were from the same hospital, a university hospital in Songkhla province, Southern Thailand. These studies were conducted at different times, and the present study confirmed the findings of the previous studies and found an additional unique mutation profile.

The present study demonstrated a 25.45% (42/165) frequency of *p53* mutations. This frequency is relatively low compared to those of previous studies; however, wide variations in *p53* mutation frequencies, ranging from 17% to 80%, have been reported. These variations might be related to several factors including the sensitivity of technique used in the detection of the mutations, the length of the examined regions, and the number of cases. However, the most notable factor responsible for the frequency variation could be the difference in mutagens in different populations. A high frequency of *p53* mutation (> 50%) is usually reported in countries with a high incidence of ESCC, such as China and France[14,15], whereas lower frequency of mutation is found in low- or moderate-incidence countries[16-18]. Thailand is a moderate-risk

area for ESCC; therefore, the frequency can be expected to be relatively low.

Nevertheless, the two previous studies from Thailand have demonstrated higher frequency of *p53* mutations compared to the present study[12,13]. The first study by Suwiwat *et al*[12] has reported 10 mutations in eight out of 16 (50%) cases. The second study by Tanière *et al*[13] has reported 25 mutations in 23 out of 56 cases (41%). The lower frequency might represent underestimated data, whereas the higher frequency might represent overestimated data. The low frequency of mutations in the present study might have been due to various factors, among which was the fact that we used tumor samples that could have contained both tumor and non-tumor cells, in contrast to the microdissected tumor cells used in the study of Tanière *et al*[13]. With regard to the screening method used, both SSCP and denaturing gradient gel electrophoresis (Tanière study) have been reported to have comparable sensitivity[19]. However, the small number of cases examined could result in over-figured data due to sampling bias.

The present study demonstrated heterogeneous mutation types, which predominantly involved the G:C base pair. This is similar to previous Thai reports except for a relatively higher proportion of G:G to C:G transversion (30% *vs* 23%) and a lower proportion of G:C to A:T transition at CpG (9.3% *vs* 17.14%). The patterns of predominant G:A to A:T transition and G:C to T:A transversion have also been reported in high-risk areas such as China[14,20] and moderate-risk countries such as Japan and India[18,21]. This is different, however, from the high-risk area of Western Europe where a relatively

higher proportion of mutations at the A:T base pair has been reported[22].

The G:C to A:T transition accounted for 28% of all mutations in the present study. One-third of these (4/12 mutations) were G:C to A:T transition at the CpG site, and all were found at the hot spot codon 248. A G:C to A:T transition at the CpG site was thought to have resulted from spontaneous deamination of 5-methylcytosine to form thymine[23], which preferentially occurred at codons 175, 245, 248, 273 and 282 in the *p53* gene. The previous Thai studies have reported transition at the CpG site of codon 175 (one case), 273 (one case) and 248 (three cases)[12,13]. These findings suggest that codon 248 is the most common hot spot codon in Thai ESCC cases.

In reference to the G:C to A:T transition at a non-CpG site, laboratory studies have found that it is the most common mutation caused by alkylating agents, consistent with O^6-methylguanine mispairing with thymine[24]. Mutagenic alkylating N-nitrosamines in tobacco smoke might be responsible for this mutation. In China and India, dietary *N*-nitrosamines might also contribute to this mutation type[20,25]. Our previous study has demonstrated that betel chewing also is a strong risk factor for ESCC in Thailand[9]. Nitroso derivatives from areca alkaloids have been proven to be oncogenic in animal models[26]. They have been found probably to account for the predominant G:A to A:T transition in betel-chewing-related oral cancers[27]. Most of the patients in the current study had a history of drinking and smoking, as well as betel chewing, therefore, smoking and betel chewing might both contribute to the G:C to A:T transition in Thai ESCC patients. However, it is difficult to identify a specific type of mutation with a specific risk factor because the mutation patterns are considerably heterogeneous and most patients have multiple risk habits.

In the present study, we unexpectedly found a high frequency of G to C substitution at the 18th base after the end of exon 6 (nucleotide 12759, GenBank NC_000017). We additionally found that these were germline mutations because similar mutations were also found in their blood samples. We validated these results by a second method, the RFLP.

From the total of 26597 somatic mutation records in the IARC *TP53* database, version R14[28], intronic mutations have been found in 699 records, which represents 2.63% of the total mutations. G to C substitution at nucleotide 12759, similar to the present study, has been found in three cases; two were gastric lymphomas from Hong-Kong[29] and one was small-cell lung carcinoma from Russia[30]. There was a case of ESCC reported to have intron 6 G to C at nucleotide 12758. Surprisingly, this was a case from the study of Tanière *et al*[13], which was the previous study from our hospital. Looking at the details of the mutation in this published article, we found it to be GGGG→GGCG (case 9, Table II)[13], which represents a change at the 18th base after the end of exon 6 or nucleotide 12759, based on the GenBank NC_000017 reference sequence, rather than at nucleotide 12758. Surprisingly, in this case, a similar mutation was also found in the adjacent uninvolved tissue and gastric mucosa, which suggests a germline mutation. These findings suggest that intronic G to C substitution at nucleotide 12759, which might be a germline mutation, is prevalent in Thai ESCC. It should be noted that the cases included in the Tanière study would not have been included in the present study because the periods of sample collection did not overlap (1990-1998 *vs* 1999-2005).

The role of intronic base changes on the function of genes has been questioned. However, some studies have demonstrated alterations in introns or splice donors that affect the expression or function of the *p53* gene[31,32]. In particular, Lehman *et al*[32] have demonstrated functional change of the immortalized lymphoblastoid cell lines derived from familial breast cancer patients who had germline G to C substitution in intron 6 at nucleotide 13964 (or nucleotide 13274 based on the GenBank NC_000017). In addition, immunohistochemical analysis of breast tumors from these patients also has revealed high levels of mutant p53 protein, which suggests a functional mutation. Our results were consistent with this study, which confirms that cases with suspected germline G to C substitution at 12759 have a high level of p53 expression. All this evidence indicates that germline intronic G to C substitution at 12759 is prevalent and associated with inherited risk of ESCC in Songkhla, Thailand. In a recent IARC *TP53* database, version R14[28], this intronic base change has not been reported as any polymorphic sequence variation (polymorphism) or germline mutation. However, as this mutation was not investigated in healthy controls in the current study, any conclusion on the role of this mutation is still limited. Further studies to detect this mutation in healthy controls as well as in familial members of affected patients should be performed.

It is believed that *p53* mutations result from specific carcinogens[11]. In some cancers, such as those of the lung or urinary bladder, the link between risk factors, in particular smoking, and *p53* mutation frequency and/or

pattern have been consistently demonstrated[30,33]. However, such data on esophageal carcinoma are limited and inconsistent[20,34]. Consistent with some of these reports, the present study did not find any association between *p53* mutation frequency and smoking, alcohol consumption or betel chewing. Various reasons could account for the lack of association. ESCC might be associated with many risk factors. This hypothesis is supported by studies from India that have found a significant correlation of *p53* mutation frequency in ESCC with diets rich in nitrosamines[25,35]. In addition, risk of cancer development might be different among exposed individuals due to genetic polymorphism of carcinogen-metabolizing enzymes, which determine individual capacity to detoxify carcinogens. This could modify the relationship between the exposure and gene mutation. Finally, the sample size in the current study could have been too small to detect any significant association between exposure and *p53* gene mutation.

In conclusion, our results have demonstrated that the Thai population, which is in a moderate-risk area for ESCC, has *p53* mutational spectra that are likely related to specific endogenous and exogenous carcinogens. However, a statistically significant relation between the mutation frequency among exposure groups was not demonstrated. We unexpectedly found a high frequency of G to C mutation at intron 6, which might be germline mutations. Further studies are needed to explore the questions arising from the results observed.

ACKNOWLEDGMENTS

We thank Dr. Chamnong Nopparatana for helpful technical advice on RFLP analysis.

COMMENTS

Background

Cancer of the esophagus is prevalent in some regions of the world including Thailand. It is a dreadful disease that patients may die shortly after diagnosis. Environmental factors as well as familial predisposition have been shown to be associated with the development of this cancer, possibly *via* an alteration of the *p53* tumor-suppressor gene.

Research frontiers

Mutations in the *p53* gene have been implicated to be critical events in the development of various cancers. Significant association between specific exposures and the *p53* mutations has been evident in some cancers, but the data in esophageal squamous cell carcinoma are limited.

Innovations and breakthroughs

The mutation profiles identified are consistent with most previous reports. The mutation types, G:C to C:G (30.2%), G:C to A:T (27.9%) and G:C to T:A (16.3%) were prevalent and likely to be associated with combination of exposures. Exceptionally, a unusually high frequency (8 from 42 cases) of intron 6 mutation (G to C substitution) at nucleotide 12759 was found and they were proofed to be germline mutations.

Applications

The results indicated that a proportion of esophageal cancer in this region is heritable. Further study is to be conducted to identify this specific germline mutation in healthy population and in familial members of the patients. The information would be valuable for designing diagnosis and preventive intervention in high-risk population.

Terminology

An intron is a region within a gene that is not translated into protein. It is transcribed to pre-mRNA and subsequently removed by a process called splicing. A germline mutation is a heritable variation in the lineage of germ cells. Mutations in these cells are transmitted to offspring while those in somatic cells are not. Germline mutations play a key role in genetic diseases and also in certain types of cancer.

Peer review

The authors found intronic *p53* mutation in esophageal squamous cell carcinoma in Southern Thailand, which was considered as a germline mutation. This is a novel finding and interesting.

Abstract

AIM: To investigate the feasibility of radionuclide therapy of colon tumor cells by baculovirus vector-mediated transfer of the sodium/iodide symporter (NIS) gene.

METHODS: A recombinant baculovirus plasmid carrying the NIS gene was constructed, and the viruses (Bac-NIS) were prepared using the Bac-to-Bac system. The infection efficiency in the colon cancer cell line SW1116 of a green fluorescent protein (GFP) expressing baculovirus (Bac-GFP) at different multiplicities of infection (MOI) with various concentrations of sodium butyrate was determined by flow cytometry. An *in vitro* cytotoxicity assay was also conducted after infection of SW1116 cells with Bac-NIS. Iodine uptake of Bac-NIS infected SW1116 cells and inhibition of this uptake by sodium perchlorate was examined, and the effect of Bac-NIS-mediated ^{131}I in killing tumor cells was evaluated by cell colony formation tests.

RESULTS: Infection and transgene expression in SW1116 with Bac-GFP were significantly enhanced by sodium butyrate, as up to 72% of SW1116 cells were infected with the virus at MOI of 400 and sodium butyrate at 0.5 mmol/L. No obvious cytotoxicity was observed under these conditions. Infection of SW1116 with Bac-NIS allowed uptake of ^{131}I in these tumor cells, which could be inhibited by sodium perchlorate. The viability of SW1116 cells infected with Bac-NIS was significantly lower than with Bac-GFP, suggesting that NIS gene-mediated ^{131}I uptake could specifically kill tumor cells.

CONCLUSION: Baculovirus vector-mediated NIS gene therapy is a potential approach for treatment of colon cancer.

Key words: Colon cancer; Baculovirus; Sodium iodide symporter; Radionuclide therapy; Iodine radioisotopes

Baculovirus vector-mediated transfer of NIS gene into colon tumor cells for radionuclide therapy. *World J Gastroenterol* 2010; 16(42): 5367-5374 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i42/5367.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i42.5367

INTRODUCTION

Colon cancer is one of the most common malignant gastrointestinal tumors with a high morbidity and mortality. Currently, surgery and chemotherapy are the primary methods for treating colon cancer. However, surgical removal of the tumor is not an option for 30%-40% of these patients upon diagnosis because of metastasis;

meanwhile, chemotherapy shows a relatively high incidence of severe side effects. Therefore, it is important to find alternative ways to improve the prognosis of patients with colon cancer.

The cloning of the sodium/iodide symporter (NIS) gene and subsequent studies of its properties have resulted in a new approach to targeted radiotherapy of malignant cancers. NIS is a transmembrane glycoprotein located in the basal membrane of thyroid follicular cells. It can effectively co-transport two Na^+ and one I^- into cells[1], and this transportation of iodine is an active process against the chemical gradient. The uptake of radioactive ^{131}I can be achieved by the expression of the NIS protein in tumor cells *via* vector-mediated gene transfer, and the radiotherapeutic destruction of the tumor occurs by emission of β rays from ^{131}I.

Recently, several researchers have treated tumors by delivering the NIS gene *via* vectors based on retroviruses[2], adenoviruses[3] and lentiviruses[4], and achieved a certain level of therapeutic effect. For the purpose of gene transfer, an ideal vector would have high transduction efficiency and robust protein expression so that the uptake of radioactive ^{131}I in tumor cells will reach an effective radiotherapeutic dose. The adenovirus vector system does in fact have high transduction efficiency, but its high immunogenicity and cytotoxicity prevent its further application *in vivo*. The major concern regarding the retroviral or lentiviral system is that the transgenes are easily integrated into the genomic DNA of host cells, which may cause changes in the target genome expression and result in oncogenicity *in vivo*. Moreover, long-term gene expression is not necessary in therapeutic gene-mediated radiotherapy.

We previously performed a pilot study using a baculovirus vector to deliver the NIS gene as a reporter[5]. Our results showed that the large NIS gene could be inserted into the recombinant baculovirus. A follicular thyroid cancer cell line, FTC-133, infected with recombinant green fluorescent protein (GFP) baculovirus previously showed a high expression of GFP, which lasted approximately seven days[5]. Considering the above characteristics, we reasoned that a recombinant NIS gene baculovirus may be beneficial for mediating ^{131}I uptake and the killing of tumor cells. Furthermore, since baculoviruses can only infect arthropods, this vector is highly safe for mammals. In fact, recombinant baculoviruses have been widely used in mammalian cells as a gene transfer vector because of these advantages[6]. However, no reports are available on baculovirus vector-mediated radiotherapy for cancer.

In this study, the recombinant sodium/iodide symporter gene baculovirus (Bac-NIS) was generated and used to infect colon cancer cells to investigate the expression and function of NIS in these cells and to provide an experimental basis for the NIS gene-mediated targeted radiotherapy of colorectal cancer.

MATERIALS AND METHODS

Construction of baculovirus vectors

The baculovirus vector pFBGFPR (kindly provided by the Molecular Institute of the University of Hong Kong) was digested with restriction endonucleases Acc I and Age I. The digested ends of the vector were filled in with Klenow fragment, yielding a 6 kb pFB fragment which was then purified. The target gene was prepared by digesting the recombinant plasmid pCDNA-NIS (kindly provided by Professor Sissy Jhiang of Ohio University, USA) with restriction endonucleases *Bam*H I and *Xho* I and filled in with Klenow kinase to obtain the 2.3 kb NIS gene fragment. The purified NIS target gene fragment was ligated to the phosphatase-treated pFB vector using T4 bacteriophage DNA ligase. The resulting plasmid was transformed into DH5α competent bacteria (Tiangen Biotech Co., Ltd., Shanghai) and screened on ampicillin Luria Burtani (LB) culture plates. White colonies were selected and screened for the correct orientation of the inserted target gene fragment by sequencing. The confirmed recombinant baculovirus pFBNIS plasmid DNA was amplified and purified.

Preparation of recombinant NIS and GFP baculoviruses

The baculovirus vector plasmid pFBGFPR and the constructed recombinant plasmid pFBNIS were transformed into DH10 competent bacteria (Invitrogen). The successfully transpositioned white colonies were selected and amplified. Bacmid plasmids expressing the NIS gene were extracted and transfected into Spodoptera frugiperda (sf9) cells using Lipofectamine 2000 (Invitrogen). The supernatant of the transfected cells containing the virus was collected 5-7 d later. Sf9 cells were infected at a multiplicity of infection (MOI) of 0.1 and harvested after 5-7 d in culture by centrifuging at 10000 × *g* for 15 min. The resulting supernatant was collected, centrifuged again at a high speed of 10000 × *g* at 4℃ for 5 min, sterilized with a 0.45 μm filter and preserved at 4℃ in the dark. Plaque assays were used to determine the titer of baculovirus stocks.

SW1116 cell culture

SW1116 (human Caucasian colon adenocarcinoma) was cultured in DMEM (Gibco-BRL) supplemented with 10% fetal bovine serum (FBS; Gibco-BRL) and 1% penicillin/streptomycin (Gibco-BRL) in a humidified environment with 5% CO_2 at 37℃.

Baculovirus infection of SW1116 cells

SW1116 cells were seeded in 6-well or 24-well plates with DMEM with 10% FBS at least 24 h before infection. The medium was changed to fresh serum-free DMEM just before infection. After infection with the baculovirus vector at indicated MOIs, the cells were incubated with serum-free DMEM for 4 h, followed by addition of FBS to the final concentration of 10%. All infections were performed in triplicate.

Effects of sodium butyrate on the transduction efficiency and fluorescence intensity of SW1116 cells

SW1116 cells were seeded in 6-well plates at a density of 1 × 10^5 cells/well and cultured with DMEM without serum for 24 h. Recombinant green fluorescent protein

gene baculovirus (Bac-GFP) was then added at an MOI of 400, and sodium butyrate was added at different concentrations (0, 0.5, 1 and 2 mmol/L) simultaneously. All experiments were performed in triplicate. Cells were incubated at 37℃ for 4 h after treatment, and FBS was added to the final concentration of 10% and incubated for another 24 h. The expression of GFP and the mean fluorescence intensity were determined by flow cytometry. The excitation wavelength of blue laser was 488 nm, and the detection wavelength was 520 nm.

Infection efficiency of Bac-GFP in SW1116 cells

SW1116 cells were seeded in 6-well plates at a density of 1×10^5 cells/well, and cultured with serum-free DMEM for 24 h. Bac-GFP was added at the MOI of 0, 100, 200, or 400. The final concentration of sodium butyrate was 0.5 mmol/L, and cells without sodium butyrate were used as negative controls at various MOI of Bac-GFP. All experiments were performed in triplicate. After treatment, the cells were incubated at 37℃ for 4 h, and FBS was added to reach the final concentration of 10% and incubated at 37℃ for another 24 h. The expression of GFP was observed under an inverted phase-contrast fluorescence microscope. The expression of GFP and the mean fluorescence intensity were detected by flow cytometry.

Effects of Bac-GFP infection and sodium butyrate on the cytotoxicity of SW1116 cells

SW1116 cells were seeded in 6-well plates at a density of 1×10^4 cells/well and cultured with serum-free DMEM for 24 h. Bac-GFP was added at the MOI of 0, 50, 100, 200 or 400. For testing the effect of sodium butyrate, the final concentration was 0, 0.5, 1, and 2 mmol/L with Bac-GFP at an MOI of 400, and wells without sodium butyrate were used as the control well at an MOI of 400. After treatment, the cells were incubated at 37℃ for 4 h, FBS was then added to reach the final concentration of 10% and incubated at 37℃ for another 24 h. Twenty microliters of 5 g/L MTT (Beyotime Co., Ltd., Shanghai) were added to each well and incubated for another 4 h. Subsequently, 100 μL DMSO was added, and the plate was gently shaken to completely dissolve the blue-violet precipitate. The absorption at 490 nm (A_{490}) was determined using a microplate reader. Cell viability = test well A_{490}/control well $A_{490} \times 100\%$.

Determination of iodine uptake of SW1116 cells infected with Bac-NIS

SW1116 cells were seeded in 6-well plates at a density of 5×10^4 cells/well and cultured with serum-free DMEM for 24 h. Bac-NIS was added at the MOI of 0, 50, 100, 200 or 400. The final concentration of sodium butyrate was 0.5 mmol/L, and cells without sodium butyrate were used as negative controls at various MOI of Bac-NIS. All experiments were performed in triplicate. After treatment, cells were incubated at 37℃ for 4 h, FBS was then added to reach the final concentration of 10% and incubated at 37℃ for another 24 h. The cells were washed twice with bHBSS solution (HBSS solution buffered with HEPES solution to achieve a pH 7.3), and then 0.5 mL bHBSS solution containing 0.1 μCi Na ^{125}I (Shanghai Hinko Co.) with 1 μmol/L NaI were added into each well as reported by Weiss *et al*[7]. Cells were incubated at 37℃ for 30 min, washed with cold bHBSS solution three times and incubated for another 20 min with 1 mL 100% cold ethanol. The samples were then collected to determine the radioactive counts per minute (cpm) by a well γ-counter.

Dynamic determination of ^{125}I uptake of SW1116 cells

SW1116 cells were seeded in 6-well plates at a density of 5×10^4 cells/well and cultured with serum-free DMEM for 24 h. Bac-NIS and Bac-GFP were added at the MOI of 400 respectively. The final concentration of sodium butyrate was 0.5 mmol/L, and Bac-GFP was used as negative controls. All experiments were performed in triplicate. After treatment, cells were incubated at 37℃ for 4 h, FBS was then added to reach the final concentration of 10% and incubated at 37℃ for another 24 h. Cells were washed twice with bHBSS solution, and 0.5 mL bHBSS solution containing 0.1 μCi Na ^{125}I with 1 μmol/L NaI were added into each well, incubated for 5, 10, 15, 30, 60, 90, or 120 min, washed with cold bHBSS solution three times, and incubated for another 20 min with 1 mL 100% cold ethanol. The samples were then collected to determine the radioactive cpm by a well γ-counter.

Inhibition of iodine uptake by $NaClO_4$

SW1116 cells were seeded in 6-well plates at a density of 5×10^4 cells/well and cultured with serum-free DMEM for 24 h. Bac-NIS was added at the MOI of 400. The final concentration of sodium butyrate was 0.5 mmol/L. All experiments were performed in triplicate. After treatment, cells were incubated at 37℃ for 4 h, and FBS was added to reach the final concentration of 10% and incubated at 37℃ for another 24 h. Cells were washed twice with bHBSS solution. Subsequently, 0.5 mL bHBSS solution containing 0.1 μCi Na ^{125}I was added into each well with $NaClO_4$ at concentrations of 0, 30, or 300 μmol/L. After incubation for 30 min, the cells were washed with cold bHBSS solution three times and incubated for another 20 min with 1 mL 100% cold ethanol. The samples were then collected to determine the radioactive cpm by a well γ-counter.

^{131}I-mediated killing of tumor cells in cell colony formation test

SW1116 cells were inoculated in 6-well plate at a density of 5×10^4 cells/well and cultured with serum-free DMEM for 24 h. Bac-NIS and Bac-GFP were added at an MOI of 400 with sodium butyrate at 0.5 mmol/L respectively. Bac-GFP was used as the negative control. The same volume of bHBSS solution was added into a blank well as a control. All experiments were performed in triplicate. After treatment, cells were incubated at 37℃ for 4 h, and FBS was added to reach the final concentration of 10% and incubated at 37℃ for another 24 h. Cells were washed twice with bHBSS solution. After 0.5 mL bHBSS solution containing 0.1 μCi Na ^{125}I was added into each well and incubated for another 6 h, the cells were washed

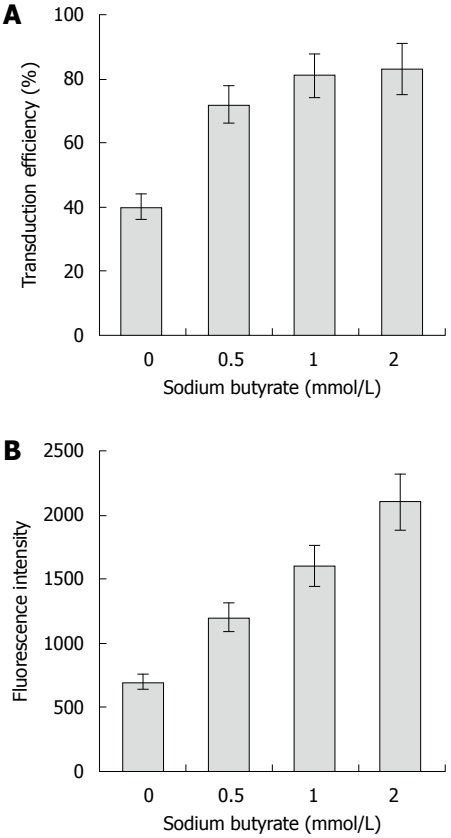

Figure 1 Effects of sodium butyrate on infection efficiency of SW1116 cells. The transduction efficiency (A) and fluorescence intensity (B) of recombinant green fluorescent protein gene baculovirus (Bac-GFP) infection of SW1116 cells at multiplicities of infection (MOI) of 400 in the presence of sodium butyrate at the indicated concentrations. Error bars represent standard deviations.

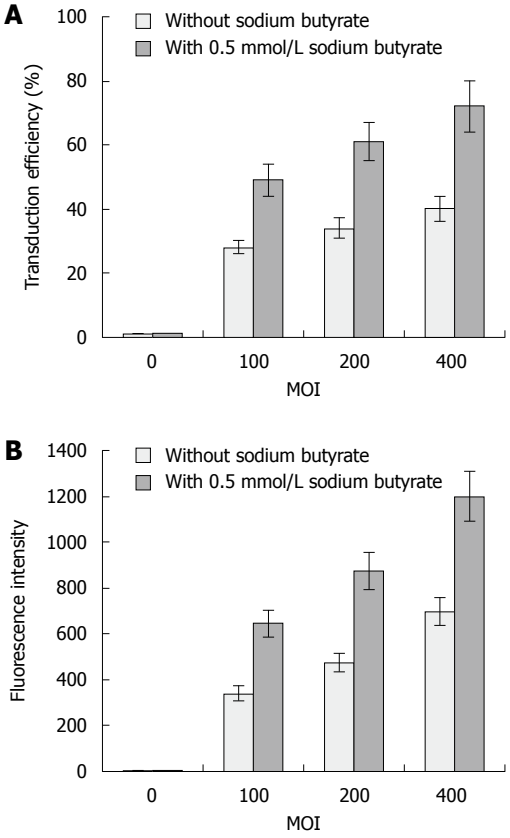

Figure 2 Recombinant green fluorescent protein gene baculovirus infection efficiency in SW1116 cells with or without sodium butyrate. The transduction efficiency (A) and fluorescence intensity (B) of recombinant green fluorescent protein gene baculovirus (Bac-GFP) infection of SW1116 cells at different multiplicities of infections (MOIs) as indicated with or without 0.5 mmol/L sodium butyrate. The infection efficiency (%) and the fluorescence intensity of GFP were determined by flow cytometry. Error bars represent standard deviations.

twice with bHBSS solution, digested, counted, seeded in a 6-well plate (1000 cells/well) and incubated at 37℃ for additional 7 d. Cells were then washed three times with bHBSS solution and stained with crystal violet solution (Sigma). Cell viability was determined in the infected cells by counting colonies visible to the naked eyes and calculated as a percentage of the colonies that were treated with only bHBSS[8].

Statistical analysis

All data are presented as mean ± SD. Differences were considered significant at $P < 0.05$. Statistical analysis was performed using SPSS 11.0 software.

RESULTS

Sodium butyrate enhances infection efficiency of Bac-GFP and expression of the reporter protein

The transduction efficiencies of baculovirus in SW1116 cells were 39%, 71%, 80% and 83% at an MOI of 400 with concentrations of sodium butyrate of 0, 0.5, 1 or 2 mmol/L, respectively. This result indicated that sodium butyrate could significantly improve the transduction efficiency of baculovirus in SW1116 cells, achieving high levels of transduction at concentrations above 0.5 mmol/L. The fluorescence intensity of the infected SW1116 cells increased along with sodium butyrate in a dose-dependent manner, suggesting that the expression of the reporter protein was enhanced by the sodium butyrate (Figure 1).

Transduction efficiency of Bac-GFP at various MOI in SW1116 cells

The transduction efficiency (Figure 2A) of baculovirus (Bac-GFP) in the SW1116 tumor cells gradually increased, and the fluorescence intensity (Figure 2B) was also enhanced with increasing MOI. Additionally, sodium butyrate could significantly improve the transduction efficiency and fluorescence intensity of tumor cells by Bac-GFP at different MOI (Figure 2). The sodium butyrate-mediated transduction efficiency of baculovirus inoculated at the MOI of 400 in SW1116 cells was 72%.

Cytotoxicity of SW1116 cells infected with baculovirus at different MOIs with various concentrations of sodium butyrate

There was no obvious change in cell viability with the dose escalation of recombinant baculovirus (Figure 3A). There was no significant cell death observed at the highest MOI of 400. These results suggested that the baculovirus itself had no obvious cytotoxic effects on the tumor cells.

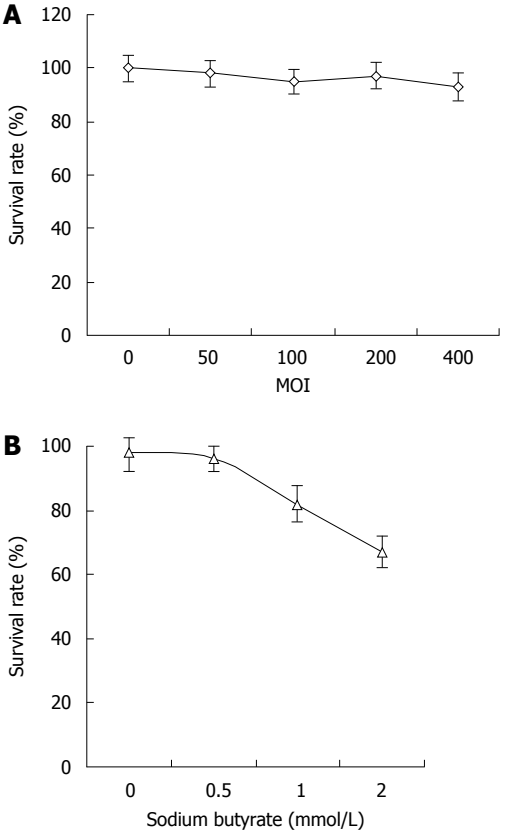

Figure 3 Cytotoxic effects of baculovirus infection and sodium butyrate in SW1116 cells. A: The cytotoxic effects in SW1116 infected with recombinant green fluorescent protein gene baculovirus (Bac-GFP) at different multiplicities of infection (MOI); B: The cytotoxic effects of sodium butyrate at various concentrations in SW1116 cells infected with Bac-GFP at MOI of 400.

On the other hand, the tumor cell viability decreased with increasing concentrations of sodium butyrate with virus at the MOI of 400 (Figure 3B). However, the cell viability did not change significantly when the concentration of sodium butyrate was lower than 0.5 mmol/L.

Determination of iodine uptake in infected SW1116 cells

The radioiodine uptake of tumor cells increased with increasing doses of Bac-NIS, and this uptake was significantly enhanced by sodium butyrate (Figure 4).

Dynamic determination of ^{125}I uptake of SW1116 cells

The radioiodine uptake of infected tumor cells increased over the incubation time with radioiodine which reached the peak at 30 min with Bac-NIS at the MOI of 400 and sodium butyrate at 0.5 mmol/L (Figure 5). This result suggested that the NIS protein expressed in transfected tumor cells could perform its normal function in iodine uptake.

Inhibition of iodine uptake by $NaClO_4$

NIS-mediated iodine uptake in thyroid tissues can be specifically inhibited by ClO_4^-. In the present study, we tested the ability of ClO_4^- at various concentrations to inhibit the iodine uptake by tumor cells expressing the NIS protein. Our results showed that the radioiodine uptake

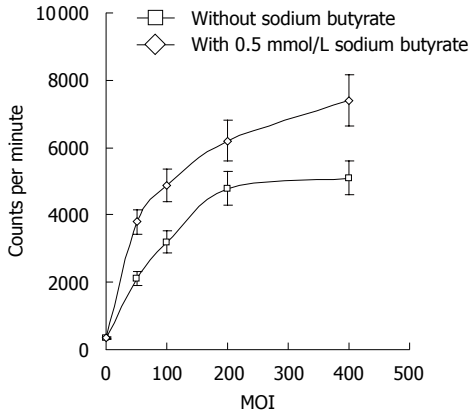

Figure 4 Iodine uptake of SW1116 cells after infection by recombinant sodium/iodide symporter gene baculovirus in the absence or presence of sodium butyrate. ^{125}I iodine uptake (counts per minute) was determined in SW1116 cells infected with recombinant sodium/iodide symporter gene baculovirus at indicated multiplicities of infection (MOI) with or without 0.5 mmol/L sodium butyrate 30 min after exposure to ^{125}I. Error bars represents standard deviations.

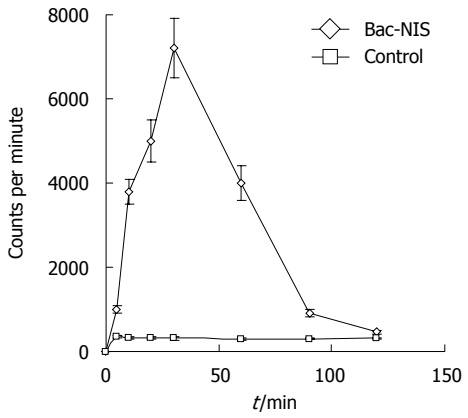

Figure 5 Dynamic changes of iodine uptake in recombinant sodium/iodide symporter gene baculovirus infected SW1116 cells. SW1116 cells were infected with recombinant sodium/iodide symporter gene baculovirus (Bac-NIS) at 400 multiplicities of infection, and iodine uptake (counts per minute) was determined over time when incubated with Na^{125}I and NaI. Error bars represent standard deviations.

of SW1116 cells was significantly reduced with escalating doses of ClO_4^- (Figure 6), indicating that the function of the expressed NIS protein in the infected tumor cells could also be inhibited by the presence of $NaClO_4$.

^{131}I-mediated killing of tumor cells

In order to evaluate the killing effect of ^{131}I in infected tumor cells, a cell colony formation test was performed with cells infected by Bac-GFP as the control. The results showed that the cell viability of SW1116 cells infected with Bac-NIS was reduced to about 20%, and that of SW1116 cells infected with Bac-GFP (70%) was similar to that of the non-infected group (76%) (Figure 7). These observations suggested that NIS-mediated tumor cells could be effectively and specifically killed by ^{131}I.

DISCUSSION

Since 1996 when Dai *et al*[9] and Smanik *et al*[10] cloned the

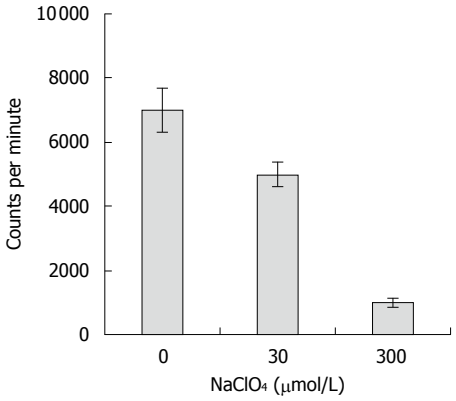

Figure 6 Inhibition rate of $NaClO_4$ in radioiodine uptake in tumor cells after infection. Radioiodine uptake was inhibited by pre-treatment of the SW1116 tumor cells with sodium perchlorate at various concentrations for 30 min. Error bars represent standard deviations.

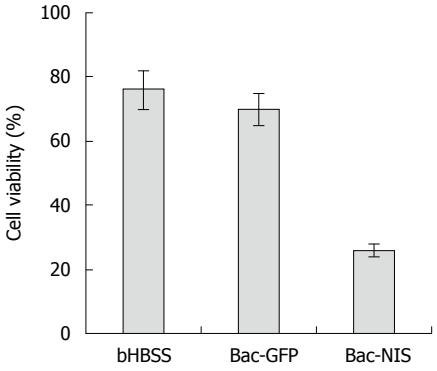

Figure 7 Survival rates (%) of SW1116 cells treated with $Na^{131}I$. Cell viability of infected SW1116 cells was determined after treatment with $Na^{131}I$, SW1116 cells were treated with bHBSS, recombinant green fluorescent protein gene baculovirus (Bac-GFP) with 0.5 mmol/L sodium butyrate, and recombinant sodium/iodide symporter gene baculovirus (Bac-NIS) with 0.5 mmol/L sodium butyrate.

rat and human NIS genes, respectively, researches on the function of these genes have progressed with a breakthrough in the understanding of their role in iodine uptake of thyroid cells. NIS can mediate the active transport of iodine ions. In addition to thyroid tissues, NIS is expressed at low levels in salivary glands, gastric mucosa tissues, breast tissues in secretory phase and other tissues[11]. The ^{131}I therapy for differentiated thyroid carcinoma is performed by expressing the NIS gene in clinical applications.

There have been significant advances in the field of radiotherapy by NIS gene transfer using either non-viral or viral vectors in recent years. Boland *et al*[12] investigated the use of targeted radiotherapy in several tumor cell lines (including cervix cancer, breast cancer and prostate carcinoma) by adenovirus-mediated NIS gene transfer and showed uptake of iodine in tumor cells. Sieger *et al*[13] screened stable cell lines expressing the NIS gene from a retrovirus-infected hepatoma cell line (MH3924A) and showed significant radioiodine uptake as well. While Haberkon *et al*[14] found a low absorbance of radioactive iodine in infected rat prostate carcinoma cells by a retrovirus expressing the NIS gene due to the rapid clearance of iodine in transplanted tumors, Dingli *et al*[15] achieved considerable therapeutic effects by lentivirus-mediated NIS gene transfer in myeloma cells. All of these studies suggest that NIS gene is a promising candidate for targeted tumor radiotherapy.

Presently, viral vectors most commonly used for gene transfer are based on adenoviruses, retroviruses and lentiviruses. Adenoviruses can induce strong host immune responses[16], and antibodies against adenovirus has been found in 97% of the population[17]. These pre-existing antibodies against the viral vector can inhibit the efficiency of gene transfer. Furthermore, transgenes carried by lentiviruses and retroviruses can randomly insert into the genomic DNA of the host cells and potentially activate oncogenes in normal tissues.

Therefore, it is critical to choose a proper vector system to deliver the gene of interest in gene therapy. The baculovirus vector system has a high transduction efficiency and protein expression in mammalian cells[18]. It is a replication competent vector that displays less cytotoxicity to mammalian cells when compared with other viral vectors. Because the baculovirus DNA does not integrate into the host genome, baculovirus vectors have an extremely high biological safety profile. Since baculoviruses also have very species-specific tropisms among the invertebrates, there would be virtually no pre-existing neutralizing antibody and specific T cells in mammals to prevent the application of these vectors *in vivo*. Meanwhile, the packaging capacity of baculovirus is about 38 kb, allowing insertion and expression of large genes, and high titer virus stocks can easily be produced[19]. All these advantages show that the baculovirus is a promising vector for use in gene transfer applications.

In this study, we successfully cloned and purified baculovirus with the NIS gene driven by the cytomegalovirus immediate-early gene promoter. Some studies have shown that the transduction efficiency of recombinant baculovirus can be increased by adding sodium butyrate in SW1116 cells. Infection of Bac-NIS in SW1116 cells showed that it can uptake iodine, and that this process can be specifically inhibited by sodium perchlorate. This suggested that the NIS protein expressed by baculoviruses functioned similarly to the natural NIS protein. The proliferation of SW1116 cell was significantly lower in cells infected with Bac-NIS than those infected with Bac-GFP, indicating that tumor cells infected with Bac-NIS could specifically uptake ^{131}I, and as a result the emitted β-rays could kill the target cells effectively. These experiments provided solid evidence for the feasibility of radionuclide therapy for colon cancer.

The expression level of an exogenous gene positively correlates with the amount of stable transgenes in host cells, and the regulation of the transgene in mammalian cells is the key to its expression. Modifications of the transgenes such as acetylation, methylation and/or the chromatin compactness may play important roles in the expression of the transgenes carried by the baculovirus. Sodium butyrate is a four-carbon short-chain fatty acid derived from dietary fiber in the intestinal tract *via* bacte-

rial fermentation. The concentration of sodium butyrate is very high in the intestinal tract of healthy individuals especially those with a high-fiber diet. Sodium butyrate is a histone deacetylase inhibitor that has been shown to relax chromatin by inducing the acetylation of chromosomes which can in turn facilitate gene expression. Furthermore, it can also significantly improve the transduction efficiency of baculovirus and the expression level of exogenous genes[19]. In this study, we found that sodium butyrate could significantly improve the transduction efficiency of baculovirus and the expression of the NIS transgene in SW1116 cells which led to a significant killing effect (viability = 20%) of SW1116 tumor cells. Therefore, baculovirus-mediated gene transfer of the NIS gene allows targeted radiotherapy for intestinal tumors.

The therapeutic effect of radioiodine therapy depends on the absorbance of target tissues which are affected by the effective half-life of ^{131}I in tumors, the total mass of tumor and the total absorbed dose of ^{131}I. However, iodine uptake in SW1116 cells mediated by NIS gene transfer is rapidly cleared from the body. This is different from the observation in thyroid cells due to the absence of thyroid peroxidase (TPO) in SW1116 cells. Therefore, the organification of inorganic iodine taken up by SW1116 cells to produce thyroid hormone for storage cannot take place, ultimately affecting the therapeutic effect for tumors that can be achieved with ^{131}I. Thus, an important issue in NIS gene-mediated tumor therapy is the improvement of the retention of ^{131}I in tumor cells. Huang *et al*[20] transfected NIS and the TPO gene together into non-small cell lung cancer cell lines and found that the rate of clearance of iodine was reduced. However, it is still controversial whether or not the organification of iodine mediated by TPO would increase the retention of iodine[21].

Various approaches to improve radiotherapy have been reported. It has been shown that NIS-mediated ^{188}Re (Rhenium) radiating β-rays [22] and ^{211}At (Astatine) radiating α-rays[23] in various tissues resulted in better radiotherapeutic effects than with ^{131}I due to higher radiation energy deposition. Additionally, as the serum complement system is the primary inhibitory factor of baculovirus-mediated gene transfer, some researchers have created certain modifications in baculovirus to prevent inactivation by complement in serum. For example, human decay-accelerating factor expressed on the envelope of the virion could render recombinant baculovirus resistant to the complement system, and the expression of transgene could be detected when the modified baculovirus was injected into murine hepatic parenchyma[24]. The inhibition of serum inactivation can also be achieved by injecting complement inhibitors such as cobra-venom factor prior to baculovirus vector delivery[25]. Thus, baculovirus vectors will provide a new approach for the gene therapy of malignant tumors especially when the related techniques are improved.

COMMENTS

Background

Sodium/iodide symporter (NIS) is a transmembrane glycoprotein located in the basal membrane of thyroid follicular cells. It can effectively co-transport two Na^+ and one I^- into cells, and this transportation of iodine is an active process against the chemical gradient. The uptake of radioactive ^{131}I can be achieved by the expression of the NIS protein in tumor cells *via* vector-mediated gene transfer, and the radiotherapeutic destruction of the tumor occurs by emission of β rays from ^{131}I.

Research frontiers

It is a new approach to use NIS gene in radiotherapeutic destruction of the tumor. The authors adopted Bac-NIS to transduce colon cancer cell line, SW1116, to investigate the feasibility of NIS as a therapeutic gene in ^{131}I mediated cell killing. There is currently no report on this.

Innovations and breakthroughs

This is the first report about the baculovirus vector-mediated radiotherapy for colon cancer cell line. NIS was used as target gene, and the results showed that the transduction of baculovirus in cancer cells increased in the presence of sodium butyrate and cancer cells infected with Bac-NIS could be rendered ^{131}I uptake and specifically killed by β-rays from ^{131}I.

Applications

Baculovirus vectors will provide a new approach for the gene therapy of malignant tumors especially when the related techniques are improved.

Terminology

NIS is a transmembrane glycoprotein located in the basal membrane of thyroid follicular cells.

Peer review

^{131}I uptake in cancer cell mediated by NIS gene transfer is rapidly cleared. The therapeutic effects of radiotherapy will be improved with the further research in this field.

Abstract

AIM: To describe patterns of lymph node metastasis in invasive colon and rectal carcinomas.

METHODS: Clinical data of 2340 patients with colorectal carcinoma (stage Ⅰ to Ⅲ) who received radical resection, was retrospectively reviewed. Of the 2340 patients, 1314 patients suffered from rectal carcinoma and 1026 from colon carcinoma. Patients with rectal cancer who received neoadjuvant chemoradiation therapy were excluded. Statistical analysis was performed using Mann-Whitney, χ^2 and Cochran's and Mantel-Haenszel tests (SPSS 15.0). A two-tailed $P < 0.05$ was considered statistically significant.

RESULTS: Lymph node retrieval in the rectal carcinoma group was significantly lower than that in the colon carcinoma group ($P < 0.001$), while positive lymph node retrieval in the rectal carcinoma group was significantly higher than that in the colon carcinoma group ($P < 0.001$). The proportion of lymph node positive (N+) cases was higher (patients with one or more positive lymph nodes) in the rectal carcinoma group ($P = 0.004$). The number of N+ cases was compared at different T stages (T1-T4) to eliminate background bias and the results were confirmed ($P < 0.001$). In addition, the lymph node ratio (the ratio of number of positive lymph nodes over the number of lymph nodes examined) of stage Ⅲ cases in the rectal carcinoma group was significantly higher than that in the colon carcinoma group ($P < 0.001$).

CONCLUSION: Rectal carcinomas seem more prone to metastasize to the lymph nodes than colon carcinomas, which may be of potential clinical significance.

Key words: Lymph node; Metastasis; Colon; Rectum; Neoplasms

INTRODUCTION

Lymph node metastasis in colorectal cancer significantly in-

fluences patient management and prognosis[1-4]. Therefore, the number of positive lymph nodes is regarded as an index to determine different N stages in the extensively accepted colorectal cancer tumor node metastasis (TNM) staging[5,6]. As to the issues of the minimal number of lymph nodes examined[6-9] and lymph node metastasis[6,10,11], colon cancers and rectal cancers are usually treated as a single entity. Some researchers pointed out that the rate of lymph node metastasis in colon cancer and rectal cancer might be different[12,13]. The present study was attempted to describe the possible differences in patterns of lymph node metastasis between colon and rectal tumors so as to provide useful information for more effective clinical treatment and prognostic assessment of colon and rectal carcinomas.

MATERIALS AND METHODS

Patient selection

Patients with invasive colorectal cancer who received surgical treatment at Changhai Hospital between January 2000 and June 2008 were identified from our prospectively collected database as approved by the Institutional Review Board (IRB). Patient characteristics, examination records, operative and pathologic reports were reviewed. The following data were collected from the patients' charts: (1) Demographic data (age and gender); (2) Preoperative examinations including colonoscopy, abdominal ultrasound and chest X-ray; (3) Preoperative adjuvant treatment; (4) Operative records; and (5) Postoperative pathology: tumor grade [low grade (equal to well and moderately differentiated) or high grade (equal to poorly differentiated and undifferentiated)]; tumor size (refers to the maximum dimension of the primary tumor measured in the operative specimen), T stage (depth of invasion), and N stage (the number of total and positive lymph nodes)[5]. Based on the lymph node status, the patients were divided into node positive (N+) and node negative (N-). N+ patients included all patients with one or more positive lymph nodes (N1 and N2), and N- patients included all patients without positive lymph nodes on final pathological analysis.

Inclusion criteria

Inclusion criteria were primary invasive colorectal cancer confirmed by preoperative pathology and treated with radical operation.

Exclusion criteria

Exclusion criteria were recurrent colorectal tumors, Tis tumors, R1 or R2 resection [The resection margin was considered positive (R1 resection) when the invasive tumor was present in the resection margin or the distance between the tumor and the resection margin was less than 1 mm; R2 resection refers to incomplete tumor resection with gross residual tumor that was not resected]. Patients with rectal cancer who received neoadjuvant chemoradiation or with stage Ⅳ colorectal carcinoma, patients who lacked complete information, and patients with synchronous diseases (such as total colectomy for familial adenomatous polyposis) that might affect lymph node harvest were also excluded.

Procedures

For rectal carcinoma, surgery was performed using a standardized surgical procedure with sharp mesorectal dissection techniques as described by Heald *et al*[14]. Standard colectomy and regional lymphadenectomy (right hemicolectomy, transverse colectomy, left hemicolectomy and sigmoid colectomy) were performed according to the location of colon cancer.

Pathology

The surgical specimens were fixed in 10% buffered neutral formalin. The traditional inspection and palpation method was applied for lymph node harvest. No adjuvant technique such as fat clearance was used to help identify lymph nodes.

Statistical analysis

Statistical analysis was performed using SPSS Software system (version 15.0, Chicago, IL). Mann-Whitney test was employed to numerical data that did not show a normal distribution (age, total number of lymph node examined, the number of positive lymph node) or ordinal variables (T stage and N stage). Comparison of proportions was analyzed by χ^2 test. Cochran's and Mantel-Haenszel tests were applied to compare the difference in the number of N+ patients in different tumor groups to stratify the data by T stage. Results were expressed as median (range). A two-tailed P value of < 0.05 was considered statistically significant. The study was reviewed and approved by Changhai Hospital IRB.

RESULTS

Patient population

A total of 2340 patients were identified, including 1314 patients with rectal carcinoma, and 1026 patients with colon carcinoma involving the cecum in 63 cases, ascending colon in 242 cases, hepatic flexure in 118 cases, transverse colon in 67 cases, splentic flexure in 40 cases, descending colon in 79 cases, and sigmoid colon in 417 cases.

There were 977 females (41.8%) and 1363 males (58.2%) with a median age of 61 (51-71) years. The median tumor size was 4.5 (3.5-6.0) cm. The percentages of stage Ⅰ, Ⅱ and Ⅲ tumors were 19.5%, 41.7% and 38.8% respectively.

Comparison of tumor characteristics and the total number of lymph nodes examined between rectal and colon carcinoma groups

The tumors in the rectal carcinoma group were smaller than those in the colon carcinoma group ($P < 0.001$). In addition, there were more low-grade tumors in the rectal carcinoma group ($P = 0.002$). The total lymph node number in the rectal carcinoma group was lower than that in the colon carcinoma group ($P < 0.001$).

Table 1 Comparison between rectal cancer and colon cancer groups *n* (%)

Clinicopathologic factors	Rectal cancer (*n* = 1314)	Colon cancer (*n* = 1026)	*P* value
Gender			
Male	797 (60.7)	566 (55.2)	0.008
Female	517 (39.3)	460 (44.8)	
Age (yr)	59 (50-68)	64 (53-72)	< 0.001
Grade			
Low	1125 (85.6)	830 (80.9)	0.002
High	189 (14.4)	196 (19.1)	
Tumor size (cm)	4.0 (3.0-5.5)	5.0 (4.0-6.0)	< 0.001
Total nodes	9 (7-12)	10 (8-13)	< 0.001
Positive nodes	3 (1-5) (*n* = 544)	2 (1-4) (*n* = 364)	< 0.001
LNR	0.31 (0.14-0.60) (*n* = 544)	0.22 (0.13-0.50) (*n* = 364)	< 0.001
N stage			
N0	770 (58.6)	662 (64.5)	< 0.001
N1	338 (25.7)	267 (26.0)	
N2	206 (15.7)	97 (9.5)	
N+ stage			
N0	770 (58.6)	662 (64.5)	0.004
N+	544 (41.4)	364 (35.5)	
T stage			
T1	49 (3.7)	23 (2.2)	< 0.001
T2	377 (28.7)	121 (11.8)	
T3-4	888 (67.6)	882 (86.0)	

LNR: Lymph node ratio.

Number of positive lymph nodes, N stage and lymph node ratio between the two groups

The number of positive lymph nodes in the rectal carcinoma group was larger than that in the colon carcinoma group ($P < 0.001$). This was confirmed by comparison of N stage between the two groups. It was found that the patients in the rectal carcinoma group had a significantly higher N stage ($P < 0.001$) (Table 1).

The number of N+ patients in the rectal carcinoma group was significantly larger than that in the colon carcinoma group ($P = 0.004$) (Table 1). In addition, comparison of the lymph node ratio (LNR) of the stage Ⅲ cases between the two groups showed that LNR was higher in the rectal carcinoma group ($P < 0.001$).

Comparison of N+ stage stratified by T stage between the two groups

Advanced T stage was more likely to be associated with positive lymph nodes. A comparison of T stage between the two groups was undertaken to explore any possible impact of T stage on positive lymph node harvest. T3 and T4 tumors were taken together because most colon cancers were inherently located intraperitoneally, while more than half rectal cancers presented as extraperitoneal tumors. Considering the different definition of T3 and T4 stage of intraperitoneal and extraperitoneal tumors, it is more reasonable and comparable to put T3 and T4 tumors together to avoid location bias. It was noted that T stage was more advanced in the colon carcinoma group ($P < 0.001$). Moreover, Cochran's and Mantel-Haenszel statistics were used to compare patients with N+ stage between the two groups further stratified by T stage level. The N stage was significantly higher ($P < 0.001$) in the rectal carcinoma group, with an odds ratio (OR) of 1.617 (95% confidence interval: 1.355-1.931) (Table 2).

Table 2 Comparison between the percentage of patients with N+ stage

T stage[1]	N+ stage proportion (%)		*P* value
	Rectal cancer (*n* = 1314)	Colon cancer (*n* = 1026)	
T1	5/49 (10.2)	1/23 (4.3)	< 0.001
T2	84/377 (22.3)	23/121 (19.0)	
T3-4	455/888 (51.2)	340/882 (38.5)	

[1]Stratified by T stage.

DISCUSSION

Lymph node metastasis is an important prognostic factor for patients suffering from colorectal carcinoma without distant metastasis, as well as a risk factor for recurrence and distant metastasis of colorectal carcinoma[1-3]. The five-year survival rate of N+ patients was lower than that of N- patients[4]. In addition, the higher the number of positive lymph nodes examined, the poorer the prognosis would be. So in the colorectal TNM staging system[5,6], the node status was applied as the parameter to determine the stage Ⅲ tumors from the stage Ⅱ lesions, while the number of positive nodes indicated different N stages. In recent studies, LNR was recommended as a significant prognostic factor for both colon and rectal cancer patients[15,16], and thought to optimize staging in colorectal cancer[17]. Lymph node metastasis also affects patient management. It is generally accepted that adjuvant treatment is beneficial to N+ patients, but whether it is appropriate for N- patients remains controversial.

With respect to lymph node metastasis, colon cancer and rectal cancer were not often discussed independently[6,10,11]. Several studies compared the rates of lymph node metastasis between early rectal and colon cancers and found that they were different[12,13]. But the patient population in these studies was too small to draw a convincing conclusion. The present study explored possible differences in the lymph node metastasis pattern between colon and rectal carcinomas using strict inclusion criteria to eliminate patients who received neoadjuvant therapy, and those with stage Ⅳ tumors and incomplete information for the sake of minimizing influences of these factors on lymph node harvest. As several studies including our previous study had shown that neoadjuvant therapy decreased lymph node harvest and down-staged tumors[18], we excluded all patients who received neoadjuvant therapy in the present study. All procedures were performed by seven experienced colorectal surgeons with standard technique in one surgical section, and all specimens were treated in one pathology department to minimize interpretation variability.

In the present study, there was a higher percentage of

positive lymph node retrieval and N+ patients in the rectal carcinoma group in spite of a lowered total lymph node harvest. It is well established that T stage correlates with N stage[19,20], so T stage was investigated between the two groups to decrease background bias. Comparison of the overall lymph node status (N+) between the two groups based on T stage level also confirmed that there were more N+ patients in the rectal carcinoma group. Then the tumor size and grade were compared. Our data showed that the tumors in the rectal carcinoma group were smaller than those in the colon carcinoma group. In addition, there were more low-grade tumors in the rectal carcinoma group. Considering that high-grade big tumors harbored more metastatic lymph nodes[19,21], the primary tumor characteristics of the two groups enforced the hypothesis that rectal cancer is prone to metastasize to lymph nodes as compared with colon cancer. Furthermore, LNR of stage Ⅲ tumors was higher in the rectal carcinoma group than that in the colon carcinoma group.

Nevertheless, there were still some sources of bias in our retrospective study. The median number of total lymph nodes examined fell below 12, which would affect the accuracy of N stage. No long-term clinical follow-up was included, which may limit the ability to interpret the oncological significance of our findings. Further study is, therefore, required.

Different incidences of lymph node metastasis between colon and rectal cancers have several clinical implications. First, the minimal number required for lymph nodes retrieval remains controversial with a range from 7 to 21 in the literature[7-9]. Most of these studies combined colon and rectal cancers and the AJCC and College of American Pathologists recommend a minimum of 12 lymph nodes to be examined for both colon and rectal cancer[6,22]. In our study, the number of lymph nodes was significantly lower in the rectal cancer group compared with the colon cancer group. So the question arises whether the minimal number of lymph node harvest for colon and rectal cancer should be different. Second, the incidence of lymph node metastasis should be taken into account in choosing therapeutic strategies: a more aggressive strategy may be justified in treating rectal cancers than in colon cancers. As rectal carcinomas are more prone to metastasize to lymph nodes and the involved nodes might be the main reason of recurrence following local excision, radical resection rather than local excision seems to be a more reasonable recommendation for early rectal cancer as compared with colon cancer of similar primary tumor characteristics. For the same reason, adjuvant chemotherapy should be more suggestive for rectal cancer after local excision. Third, it is well known that the overall survival rate is lower and the local recurrence rate is higher in rectal caner following radical resection as compared with colon cancer. As we discussed earlier, the lymph node status is a key predictor for the prognosis of colorectal cancer. The differences seen in our study may explain the discrepancy in survival and local recurrence typically observed between colon and rectal cancers.

In conclusion, our study shows that the incidence of lymph node metastasis of rectal cancer is significantly higher than that of colon cancer as stratified by T stage, which may be attributed to different oncological and anatomic characteristics. This finding carries potential clinical significance related to treatment decision making, such as local excision or adjuvant therapy, as well as to prognostic assessment of rectal carcinoma.

COMMENTS

Background

Lymph node metastasis in colorectal cancer significantly influences patient management and prognosis. As to the issue of lymph node metastasis, colon cancers and rectal cancers are usually treated as a single entity.

Research frontiers

This paper essentially audits the colorectal cancer practice in one hospital over an 8-year period. The authors identified 2340 patients (1314 rectal, 1026 colonic) and retrospectively reviewed the pathological data related to these with particular respect to the number and distribution of lymph node metastases.

Applications

The rectal carcinoma seems more prone to metastasize to lymph nodes than colon carcinoma, which harbors potential clinical significance related to treatment decision making and prognosis interpretation.

Peer review

The authors analyzed the different patterns of lymph node metastasis in colon and rectal cancers. Although it is retrospective, the study involves a large patients' population over a relatively short period of time.

Abstract

AIM: To investigate the correlation between gastric cancer growth and signal transducer and activator of transcription-3 (STAT3) expression.

METHODS: We assessed the expressions of STAT3, phosphor-STAT3 (pSTAT3), suppressor of cytokine signaling-1 (SOCS-1), survivin and Bcl-2 in gastric cancer patients after gastrectomy by immunohistochemical method. In addition, *in situ* hybridization was used to further demonstrate the mRNA expression of STAT3 in gastric cancer.

RESULTS: With the univariate analysis, expressions of STAT3, pSTAT3, SOCS-1, survivin and Bcl-2, the size of primary tumor and the lymph node metastasis were found to be associated with the overall survival (OS) of gastric cancer patients. However, only pSTAT3 expression and the lymph node metastasis were identified as the independent factors of OS of gastric cancer with multivariate analysis. STAT3 expression was correlated with the lymph node metastasis. There were positive correlations between expressions of STAT3, survivin, Bcl-2 and pSTAT3 in gastric cancer, whereas there was negative correlation between STAT3 expression and SOCS-1 expression in gastric cancer.

CONCLUSION: STAT3 can transform into pSTAT3 to promote the survival and inhibit the apoptosis of gastric cancer cells. SOCS-1 might be the valid molecular antagonist to inhibit the STAT3 expression in gastric cancer.

Key words: Gastric cancer; Signal transducer and activator of transcription-3; Lymph node metastasis; Apoptosis; Survival analysis

INTRODUCTION

Gastric cancer is the fourth most common cancer worldwide with approximately 930 000 newly diagnosed cases annually, resulting in about 700 000 deaths per year[1,2]. Although the surgical skills and adjuvant chemotherapy have been improved, the survival rate of gastric cancer patients

remains unsatisfactory. Most gastric cancer patients were identified at the advanced stage when they were initially diagnosed, which is deemed as the important factor for the increased recurrence rate and decreased overall survival (OS) after potentially curative resection[3]. Therefore, it is imperative to investigate the molecular mechanism so as to enhance the curative effects for gastric cancer.

Many researchers have demonstrated that the aggressive nature of gastric cancer is related to mutations of various oncogenes and tumor suppressor genes and abnormalities in some growth factors and their receptors[4-6]. Recently, the activation of signal transducers and activators of transcription (STAT) proteins has been shown to have a strong bearing on gastric cancer progression although the detailed mechanism for this relationship has not been available[7]. The STAT proteins, including seven members, are a family of transcription factors which regulate expression of genes involved in both normal and pathological cellular processes. The strong association was demonstrated between STAT proteins and progression of various epithelial cancers[8-11].

Of the STAT family members, STAT3 is the most commonly activated in human cancers[12]. STAT3 is being increasingly recognized as a molecular hub for diverse signaling pathways such as cell cycle progression, apoptosis, angiogenesis and immune evasion, thus being considered as a novel molecular marker for cancer treatment[13,14]. Although STAT3 is constitutively activated and contributes to oncogenesis through preventing apoptosis and enhancing cell proliferation in many kinds of human tumors, the duration of STAT3 activation is temporary under physiologic conditions[15]. Over-expression of the activated STAT3 has been found in various types of malignant tumors, including leukemia, breast cancer. pancreatic cancer, prostatic cancer and melanoma, and STAT3 has played a key role in carcinogenesis[16]. However, the role of STAT3 signaling in gastric cancer is still unclear. Many studies suggested that the phospho-STAT3 (pSTAT3) should be taken as an active form of STAT3 and an independent prognostic factor for disease free survival and poor survival after curative resection[14,15].

Theoretically, STAT3 has to be activated by phosphorylated tyrosine induced by Janus Kinase (JAK) before STAT3 binds to receptor successfully. Subsequently, self-phosphorylated STAT3 protein is released from pSTAT3, assumes the shape of "dimmers" and migrates into the nucleus to activate the transcription of target genes. Jackson *et al*[17] found that pSTAT3 was localized mainly in epithelial cells in both normal stomach and gastric cancer, but there was at least ten-fold more STAT3 activation in the latter, with substantial nuclear staining. Therefore, a higher level of pSTAT3 positive expression represents more nuclear translocations of STAT3, which can stimulate the target gene transcription upon tissue transformation in gastric cancer. Suppressor of cytokine signaling-1 (SOCS-1) seems to be one of the STATs activated genes, which contain the SH2 domains that interact with JAK and prevent activation of STATs[18,19]. Recent findings suggest that SOCS-1 can be significantly up-regulated by interleukin (IL)-6 and is involved in the down-regulation of the IL-6-induced activation of STAT3[20]. Bcl-2 and survivin are the potential downstream molecules to STAT3. These molecules regulate both cell cycle and apoptosis and are the known targets of the STAT3 signaling pathway[21].

In the present study, we evaluated the expressions of STAT3, pSTAT3, SOCS-1, survivin, and Bcl-2 in both gastric cancer and normal gastric tissues after gastrectomy. We correlated these molecular variables, clinicopathologic features and prognoses of gastric cancer patients to study the potential mechanism of STAT3 signaling in carcinogenesis and progression of gastric cancer.

MATERIALS AND METHODS

Tissue specimens and patients

We used the human gastric cancer tissue and normal gastric tissue specimens preserved in the department of pathology and obtained patients' data from Tianjin Medical University Cancer Hospital. Fifty-three gastric cancer specimens from the 53 patients with gastric cancer and 53 normal gastric tissue specimens from 53 patients without gastric cancer were included in this study. Primary gastric cancer in these patients was diagnosed and treated at Tianjin Medical University Cancer Hospital between January 2002 and December 2002. The gastric cancer patients had well-documented clinical histories and follow-up information. None of them underwent preoperative chemotherapy and/or radiation therapy. All of gastric cancer patients had undergone potentially radical gastrectomy with lymphadenectomy. Of them, 37 (69.8%) were male and 16 (30.2%) were female. Ages ranged from 31 to 78 years, with a median age of 55.0 years. The tumor location was as follows: lower third in 28 (52.8%) cases, middle third in 18 (34.0%) cases, and upper third in 7 (13.2%) cases. Thirty-seven (69.8%) patients had lymph node metastasis identified by pathologic examination after surgery, and 16 (30.2%) patients had no lymph node metastasis after surgery. At the end of June 2009, 24 (45.3%) gastric cancer patients were still alive, whereas 29 (54.7%) had died. No gastric cancer patient died during the initial hospital stay or one month after surgery. Follow-up ranged from 4 to 85 mo, and the median was 35 mo. Results of B ultrasonography, CT scans, chest X-ray and endoscopy were obtained.

Methods

For *in situ* hybridization, the biotinylated oligonucleotide probe complementary to STAT3 (CCTTGGATTGAGAGTCAAGATTGGGCATAT) mRNA was synthesized. All *in situ* hybridization was carried out using manual capillary action technology. Briefly, the slides were rapidly deparaffinized, cleared, and rehydrated. The tissues were then digested with pepsin (Boshide, China) at 2 mg/mL for 30 min at 37℃. The probe was applied to the slides, and the tissues were heated at 42℃ for 2 h for denature and secondary mRNA structure. The hybridization of the probe and mRNA target was performed by exposing the slides in a calorstat at 42℃ for 12 h. The biotinylated

hybrids were detected with streptavidin-horseradish peroxidase (Jingmei, China) for 30 min at 37℃. After preincubation with 3,3'-diaminobenzidine solution for 3-5 min at 37℃, the tissues were washed with distilled water. Following the chromogen reaction, the tissues were counterstained with hematoxylin solution, washed with distilled water, air-dried, and cover-slipped with universal mount (Invitrogen US). *In situ* hybridization for negative control was performed with probe diluent.

Paraffin sections (4 μm thick) were deparaffinized and rehydrated. Antigen retrieval treatment was done at 95℃ for 40 min in 0.01 mol/L sodium citrate buffer (pH 6.0), and endogenous peroxidases were blocked using 3% hydrogen peroxide for 30 min. The primary antibodies at 1:100 dilution were purchased from Santa Cruz Biotechnology, Inc. (Santa Cruz, CA); STAT3 (SC-483, rabbit polyclonal IgG), SOCS-1 at 1:100 dilution (SC-9021, rabbit polyclonal IgG) from NeoMarkers Biotechnology, Inc. (Fremont, CA); survivin (RB-9245-P0, rabbit polyclonal IgG) at 1:50 dilution, and Bcl-2 (Ms-123-PABX, mouse monoclonal IgG) at 1:100 dilution from Jingmei Biotechnology (Zhongshan, China). All sections were incubated overnight with the primary antibody at 4℃. The sections were then treated with peroxidase by the labeled polymer method with Zhongshan peroxidase for 30 min. Antibody binding was visualized using the Avidin Biotin Complex Elite Kit and 3,3-diaminobenzine according to the manufacturer's instructions (City Key Laboratory of Tianjin Cancer Center, China). Sections were then counterstained in hematoxylin. Breast cancer and colon cancer specimens confirmed to be immunoreactive for the relevant antigens in preliminary studies were used as positive controls for STAT3, pSTAT3, SOCS-1, survivin and Bcl-2. For general negative controls, the primary antibody was replaced with phosphate buffered saline.

All sections were scored blindly by two independent observers, and in cases of scoring disagreement, a third independent assessment was performed. Staining of STAT3, SOCS-1, survivin, and Bcl-2 was graded according to the intensity and extent of staining of the epithelium. The staining intensity was scored into 4 grades: 0, complete absence of the staining; 1, weak staining; 2, moderate; and 3, strong staining. The extent of the positively stained cells was also scored into 5 grades: 0, a complete negative staining; 1, < 5%; 2, 5%-25%; 3, 25%-75%; and 4, ≥ 75%. The final scores were derived from multiplication of the extent by the intensity. For statistical analysis, scores were further grouped into two categories: negative (final scores, < 3) and positive (final score, ≥ 3).

The staining of pSTAT3 was grouped as positive and negative. The positive staining of pSTAT3 was defined as ≥ 10% of the cells with the nucleus stained dark brown and the negative staining was defined as < 10% of the cells stained.

Statistical analysis

All statistical calculations were performed using SPSS version 13.0 (SPSS Inc., Chicago, IL). Differences in STAT3 expression, pSTAT3 expression, SOCS-1 expression, surviving expression, Bcl-2 expression and clinicopathologic variables of patients were estimated using the χ^2 test for categorical data and independent-paired Student's t test for continuous variables. Overall survival of gastric cancer patients was measured from date of surgery to the date of death by the Kaplan-Meier method. The log-rank test (χ^2 comparison) was used to compare the overall survival based on expressions of STAT3, pSTAT3, SOCS-1, survivin and Bcl-2. Cox regression analysis was used to estimate the independent risk factors of overall survival of gastric cancer patients after radical surgery. In addition, linear regression was used to estimate the correlations among the variables which were significantly associated with the STAT3 immunohistochemical expression.

RESULTS

Expression of STAT3 mRNA by in situ hybridization

Almost all gastric cancer tissue specimens were positive for STAT3 mRNA expression, whereas only 8 of 53 normal gastric tissue specimens were positive for STAT3. STAT3 mRNA expression was strong in the cytoplasm of gastric cancer epithelium, while the epithelium of normal gastric tissues was weak or negative (Figure 1A).

Immunohistochemical differences of STAT3, pSTAT3, SOCS-1, survivin, and Bcl-2 between gastric cancer tissue and normal gastric tissue specimens

STAT3 was detected mainly in the epithelium of gastric cancer tissues and less frequently in the normal gastric tissues. The strong granular patterns of STAT3 staining were observed mainly within the cytoplasm and partially within the nuclear of the epithelium of gastric cancer. Conversely, only weak granular patterns of STAT3 staining were observed within the cytoplasm of a few normal gastric tissue specimens (Figure 1B). STAT3 staining was quantitatively assessed and grouped into positive expression and negative expression. Positive STAT3 expression was detected in 31 of 53 gastric cancer tissue specimens and 6 of 53 normal gastric tissue specimens. The ratio of positive STAT3 expression in gastric cancer tissue specimens was significantly higher than that in normal gastric tissue specimens (58.5% *vs* 11.3%, $\chi^2 = 25.950$, $P < 0.001$).

pSTAT3 was detected mainly in the epithelium of gastric cancer tissues and less frequently in the normal gastric tissues. The strong granular patterns of pSTAT3 staining were observed mainly within the nuclear and partially within the cytoplasm of the epithelium of gastric cancer. Conversely, only weak granular patterns of pSTAT3 staining were observed within the nuclear of a few normal gastric tissue specimens (Figure 1C). pSTAT3 staining was quantitatively assessed and grouped into positive expression and negative expression. Positive pSTAT3 expression was detected in 26 of 53 gastric cancer tissue specimens and 2 of 53 normal gastric tissue specimens. The ratio of positive pSTAT3 expression in gastric cancer tissue specimens was significantly higher than that in normal gastric tissue specimens (49.1% *vs* 3.8%, $\chi^2 = 27.956$, $P < 0.001$).

SOCS-1 was detected mainly in the normal gastric

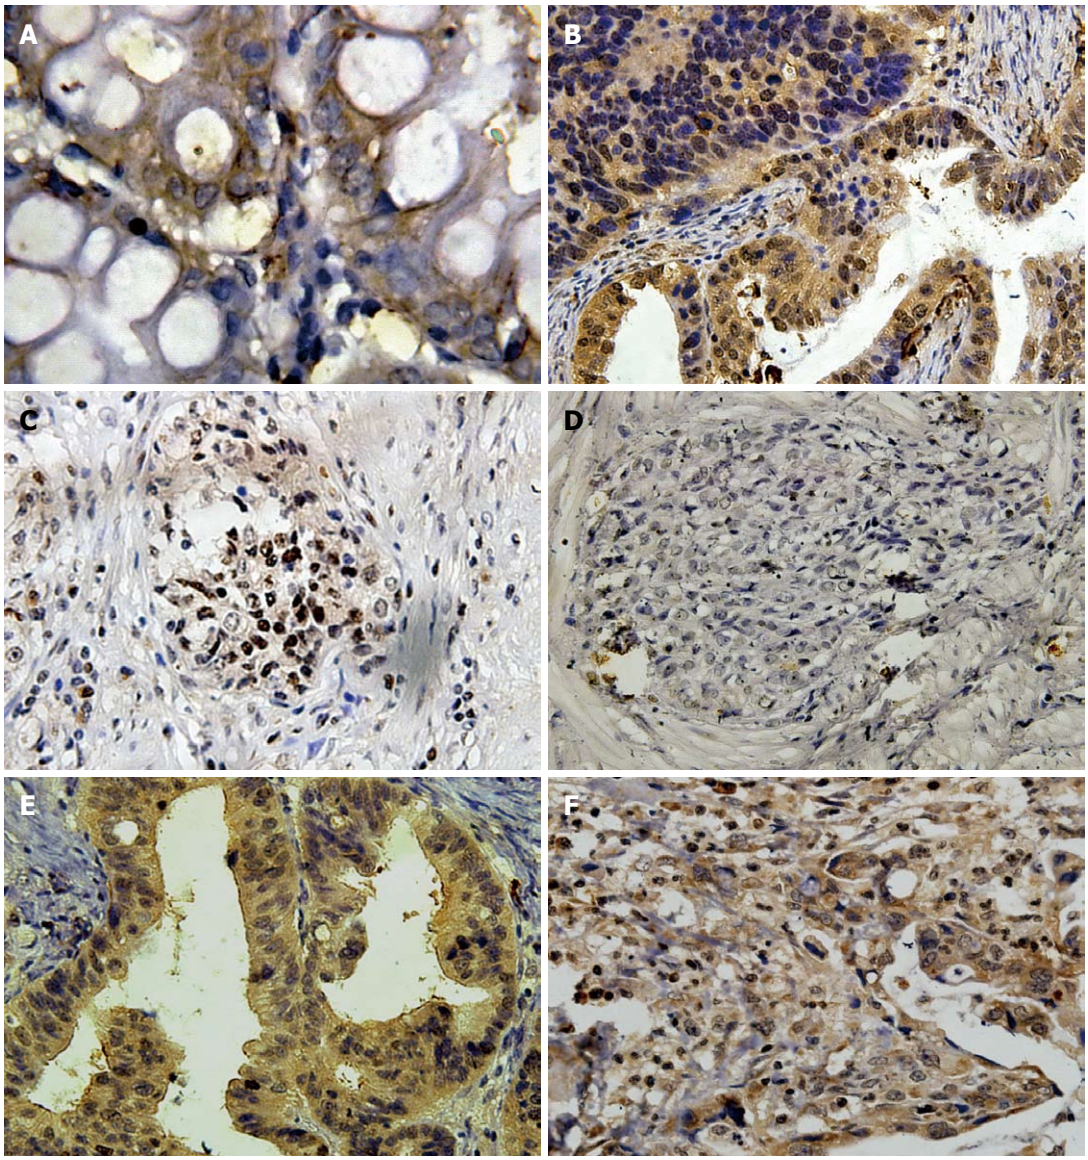

Figure 1 Expression in the cytoplasm of gastric cancer tissues (× 400). A: Detection of signal transducer and activator of transcription-3 (STAT3) mRNA (*in situ* hybridization); B: STAT3 (IH); C: Phosphor-STAT3 (IH); D: Suppressor of cytokine signaling-1 (IH); E: Survivin (IH); F: Bcl-2 (IH).

tissues and less frequently in the epithelium of gastric cancer. The strong granular patterns of SOCS-1 staining were observed within the cytoplasm of the normal gastric tissue specimens. Conversely, only weak granular patterns of SOCS-1 staining were observed within the cytoplasm of a few gastric cancer tissue specimens (Figure 1D). SOCS-1 staining was quantitatively assessed and grouped into positive expression and negative expression. Positive SOCS-1 expression was detected in 6 of 53 gastric cancer tissue specimens and 23 of 53 normal gastric tissue specimens. The ratio of positive STAT3 expression in gastric cancer tissue specimens was significantly lower than that in normal gastric tissue specimens (11.3% *vs* 43.4%, χ^2 = 13.719, $P < 0.001$).

Survivin was detected mainly in the epithelium of gastric cancer tissues and less frequently in the normal gastric tissues. The strong granular patterns of survivin staining were observed within the cytoplasm of the epithelium of gastric cancer tissue specimens. Conversely, only weak granular patterns of survivin staining were observed within the cytoplasm of a few normal gastric tissue specimens (Figure 1E). Survivin staining was quantitatively assessed and grouped into positive expression grade and negative expression. Positive survivin expression was detected in 39 of 53 gastric cancer tissue specimens and 4 of 53 normal gastric tissue specimens. The ratio of positive survivin expression in gastric cancer tissue specimens was significantly higher than that in normal gastric tissue specimens (73.6% *vs* 7.5%, χ^2 = 47.933, $P < 0.001$).

Bcl-2 was detected mainly in the epithelium of gastric cancer tissues and less frequently in the normal gastric tissues. The strong granular patterns of Bcl-2 staining were observed within the cytoplasm of the malignant epithelium of gastric cancer tissue specimens. Conversely, only weak granular patterns of Bcl-2 staining were observed within the cytoplasm of a few normal gastric tissue specimens (Figure 1F). Bcl-2 staining was quantitatively assessed and grouped into positive expression and negative

Table 1 Univariate analysis of factors affecting overall survival of 53 gastric cancer patients by Kaplan - Meier method

Factor	*n*	5-yr survival rate (%)	χ^2	*P* value
Gender			0.217	0.641

STAT3: Signal transducer and activator of transcription-3; pSTAT3: Phosphor-STAT3; SOCS-1: Suppressor of cytokine signaling-1.

expression. Positive Bcl-2 expression was detected in 26 of 53 gastric cancer tissue specimens and in 0 of 53 normal gastric tissue specimens. The ratio of positive Bcl-2 expression in gastric cancer tissue specimens was significantly higher than that in normal gastric tissue specimens (49.1% *vs* 0%, $\chi^2 = 34.450$, $P < 0.001$).

Analysis of clinicopathologic variables and immunohistochemical staining of antibodies in gastric cancer

The following clinicopathologic variables were analyzed: (1) age at surgery (< 65 years or ⩾ 65 years); (2) gender (male or female); (3) tumor location (lower third, middle third, or upper third); (4) tumor size (< 4 cm or ⩾ 4 cm); (5) depth of primary tumor invasion (UICC) (T1+T2, or T3+T4); (6) Lauren's classification of primary tumor (intestinal or diffuse); and (7) metastatic status of lymph nodes (positive or negative). In addition, the following antibodies were analyzed with OS of gastric cancer patients: STAT3, pSTAT3, SOCS-1, survivin and Bcl-2.

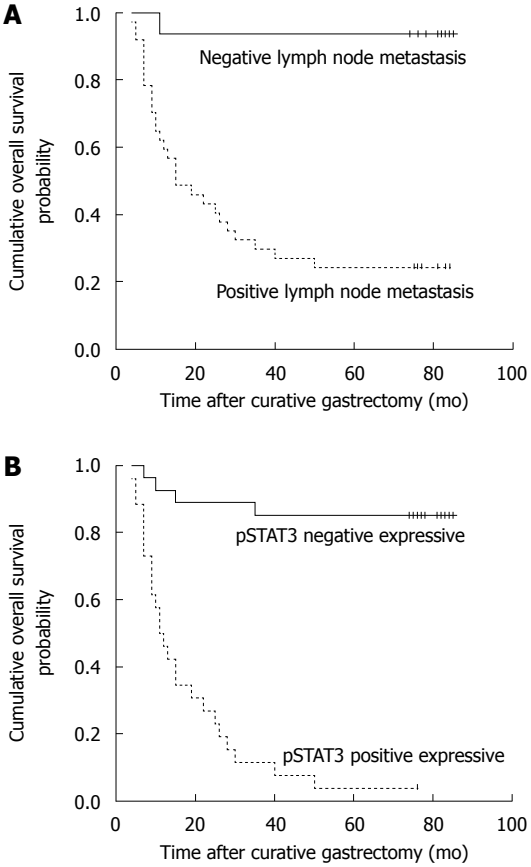

Figure 2 Survival curve in 53 gastric cancer patients following curative resection according to the metastatic status of lymph nodes (A) and different expression levels of phosphor-signal transducer and activator of transcription-3 (B). A: Negative lymph node metastasis and positive lymph node metastasis; B: Negative and positive expression of pSTAT3.

With the univariate analysis, seven factors were found to have statistically significant associations with OS of gastric cancer patients after curative surgery (Table 1), including tumor size, metastatic status of lymph nodes (Figure 2A), and STAT3, pSTAT3 (Figure 2B), SOCS-1, survivin and Bcl-2 expressions.

All above seven variables were included in a multivariate Cox proportional hazards model (forward stepwise procedure) to adjust for the effects of covariates (Table 2). In this model, metastatic status of lymph nodes (HR = 8.591, $P = 0.040$), and pSTAT3 (HR = 9.605, $P < 0.001$) showed significant correlations with OS of gastric cancer patients after curative surgery.

Correlation between immunohistochemical expressions of STAT3, pSTAT3, SOCS-1, survivin and Bcl-2 and status of lymph node metastasis in gastric cancer

We found that the immunohistochemical expression level of STAT3 was positively associated with that of pSTAT3 ($\beta = 0.451$, $P = 0.001$), survivin ($\beta = 0.504$, $P = 0.001$), and Bcl-2 ($\beta = 0.588$, $P < 0.001$). The immunohistochemical expression level of STAT3 was negatively associated with that of SOCS-1 ($\beta = -0.660$, $P = 0.002$). In addition, the STAT3 immunohistochemical expression was positively associated with the status of lymph node metastasis ($\beta = 0.480$, $P = 0.001$).

Table 2 Multivariate analysis of factors affecting overall survival of 53 gastric cancer patients by Cox proportional hazards model

Factors	*P* value	Relative risk	95% CI
Status of lymph node metastasis	0.040	8.591	1.104-66.858
Tumor size	0.701		
STAT3	0.225		
pSTAT3	< 0.001	9.605	3.107-29.694
SOCS-1	0.429		
Survivin	0.749		
Bcl-2	0.213		

STAT3: Signal transducer and activator of transcription-3; pSTAT3: Phosphor-STAT3; SOCS-1: Suppressor of cytokine signaling-1; CI: Confidence interval.

Correlation between immunohistochemical expressions of pSTAT3, SOCS-1, survivin and Bcl-2 and status of lymph node metastasis in gastric cancer

The immunohistochemical expression level of pSTAT3 was positively associated with that of survivin ($\beta = 0.473$, $P = 0.002$) and Bcl-2 ($\beta = 0.623$, $P < 0.001$). The immunohistochemical expression level of pSTAT3 was negatively associated with that of SOCS-1 ($\beta = -0.553$, $P = 0.010$). In addition, the level of pSTAT3 immunohistochemical expression was positively associated with the status of lymph node metastasis ($\beta = 0.524$, $P < 0.001$).

DISCUSSION

Recently, the molecular markers are being studied, as it may improve the prognostic prediction for gastric cancer patients after curative resection. Although many investigators have suggested that several molecular markers should be considered as key prognostic indicators in gastric cancer, such as epidermal growth factor receptor, vascular endothelial growth factor, hypoxia inducible factor 1-α and p53, none of them have been defined as a unified standard in clinical practice[22-24]. The STAT proteins are a family of transcription factors which regulate expression of multiple genes involved in both physiological and pathological conditions, which seems to be one of the most promising molecular markers for predicting the prognosis of patients with various cancers.

Of the STAT family members, STAT3 is the most commonly activated in human cancers[12]. Several previous reports showed increased or activated STAT3 expression in gastric cancer[15,16,25]. Recently, Kim *et al*[7] found that 39% of 100 patients with gastric cancer had positive STAT3 expression, whereas only 14% of 71 patients with normal gastric tissues had positive STAT3 expression. They also demonstrated that positive STAT3 expression was significantly associated with regional lymph node invasion ($P = 0.008$). Jackson *et al*[17] indicated that inappropriate STAT3 activation was an early event in the initiation and progression of gastric cancer. They found that gastric cancer cells showed increased total STAT3 staining in both the cytoplasm and the nucleus, and a high degree of predominantly nuclear pSTAT3 staining as compared with normal gastric cells. At present study, the ratio of positive STAT3 expression in gastric cancer tissue specimens was 58.5%, which was significantly higher than that in normal gastric tissue specimens (11.3%) ($P < 0.001$). Similarly, our results also showed that positive STAT3 expression was significantly associated with the status of lymph node metastasis ($P = 0.001$). Our positive STAT3 expression was higher than that reported by Kim *et al*[7], and lower than that (73%) reported by Gong *et al*[16]. We think these differences might be induced due to the different stages of patients, subjective interpretation by pathologists, and production of antibodies. To avoid the limitation of STAT3 expression detected by the immunohistochemical method, we also adopted the *in situ* hybridization for a more precise detection of STAT3 mRNA expression. All gastric cancer tissue specimens were positive for STAT3 mRNA expression, whereas only 8 of 53 normal gastric tissue specimens were positive for STAT3. With the survival analysis, we found that patients with STAT3 negative expression in primary tumors were more likely to have a longer median OS compared with those with STAT3 positive expression ($P < 0.001$). This result was similar to the above-mentioned studies. Therefore, we thought that the STAT3 positive expression was significantly associated with the progression and prognosis of gastric cancer patients.

Choi *et al*[26] analyzed 137 cases of gastric cancer tissues obtained from radical gastrectomy and found that pSTAT3 positive expression occurred more frequently than in non-neoplastic gastric tissues and pSTAT3 positive expression was significantly associated with low pathological grade and lymph node metastasis. Lee *et al*[14] assessed the STAT3 activation in 311 cases of surgically resected gastric cancer tissues and found that pSTAT3 was an independent prognostic factor for poor survival following curative resection. We also found that pSTAT3 positive expression in gastric cancer tissues occurred significantly more often than that in normal gastric tissues and pSTAT3 was significantly associated with the status of lymph node metastasis. The survival analysis showed that pSTAT3 was an independent factor of OS after curative resection in gastric cancer patients instead of STAT3. Therefore, pSTAT3 might be a functional transformant which could preferably reflect the biological effects of STAT3.

Many studies demonstrated that the inactivated SOCS-1 was one of the targets in cancer development and a tumor suppressor in the JAK/STAT pathway[27-29]. Ni *et al*[30] found that there was down-regulation of SOCS-1 gene in gastric cancer cell line AGS due to gene promoter hypermethylation, which provided evidence that JAK/STAT pathway was activated by aberrant SOCS-1 methylation in gastric cancer. In our study, the SOCS-1 positive expression in gastric cancer was much lower than that in normal gastric tissues ($P < 0.001$). Besides, the SOCS-1 expression was negatively correlated with the expression of STAT3 ($P = 0.002$) or pSTAT3 ($P = 0.010$). We considered that SOCS-1 was an inhibitor for the expression, activation and phosphorylation of STAT3 in gastric cancer.

STAT3 has been considered as a molecular hub for several crucial signaling pathways in different cancer types. It was suggested that the activation of cell proliferation and inhibition of apoptosis were induced by STAT3[30]. Several researchers showed the similar conclusion that oncogenesis of the STAT3 was closely associated with the cell survival and the cell apoptosis[15,25,31]. In our study, the ratio of positive Bcl-2 expression in gastric cancer tissues was significantly higher than that in normal gastric tissues and the Bcl-2 expression was significantly associated with STAT3 (or pSTAT3) expression. Similar results were found in survivin expression. Therefore, we considered that STAT3 could facilitate the progression of gastric cancer by supporting cell survival and inhibiting cell apoptosis.

In summary, the STAT3 expression was significantly associated with the lymph node status, poor prognosis, and the expressions of pSTAT3, survivin and Bcl-2. The SOCS-1 expression was inversely associated with the STAT3 expression. STAT3 could promote tumor cell survival and inhibit cell apoptosis in gastric cancer.

COMMENTS

Background

Signal transducer and activator of transcription-3 (STAT3) was identified as the key factor which was associated with cancers by many investigators. However, the correlation between gastric cancer and STAT-3 is not unclear.

Research frontiers

The authors detected the expressions of STAT3, phosphor-STAT3 (pSTAT3), SOCS-1, survivin and Bcl-2 proteins in gastric cancer and analyzed the clinicopathological variables associated with the prognosis of gastric cancer. Multivariate analysis showed that pSTAT3 expression and lymph node metastasis were independent factors of overall survival of gastric cancer patients. The expression of STAT3 protein was associated with the status of lymph node metastasis of gastric cancer.

Innovations and breakthroughs

STAT3 could transform into pSTAT3 to promote the survival and inhibit the apoptosis of gastric cancer cells. suppressor of cytokine signaling-1 (SOCS-1) might be the valid molecular antagonist to inhibit the STAT3 expression in gastric cancer.

Applications

The molecular contributions of STAT3 to gastric cancer have been elucidated in this study.

Terminology

STAT3 is significantly associated with the lymph node metastasis, cell survival and inhibition of cell apoptosis in gastric cancer.

Peer review

Deng *et al* studied the expressions of STAT3, pSTAT3, SOCS-1, survivin and Bcl-2 proteins in human gastric cancer. The study is of interest and potential clinical importance.

Abstract

The rendezvous procedure combines an endoscopic technique with percutaneous transhepatic biliary drainage (PTBD). When a selective common bile duct cannulation fails, PTBD allows successful drainage and retrograde access for subsequent rendezvous techniques. Traditionally, rendezvous procedures such as the PTBD-assisted over-the-wire cannulation method, or the parallel cannulation technique, may be available when a bile duct cannot be selectively cannulated. When selective intrahepatic bile duct (IHD) cannulation fails, this modified rendezvous technique may be a feasible alternative. We report the case of a modified rendezvous technique, in which the guidewire was retrogradely passed into the IHD through the C2 catheter after end-to-end contact between the tips of the sphincterotome and the C2 catheter at the ampulla's orifice, in a 39-year-old man who had been diagnosed with gallbladder carcinoma with a metastatic right IHD obstruction. Clinically this procedure may be a feasible and timesaving technique.

Modified rendezvous intrahepatic bile duct cannulation technique to pass a PTBD catheter in ERCP. *World J Gastroenterol* 2010; 16(42): 5388-5390 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i42/5388.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i42.5388

INTRODUCTION

Selective deep cannulation of the bile duct is essential for the successful treatment of biliary obstructions. However, even the most experienced endoscopists fail to cannulate the biliary tract in 5%-10% of cases[1-4]. When a selective biliary cannulation fails, percutaneous transhepatic biliary drainage (PTBD) allows successful drainage and retrograde access for subsequent rendezvous techniques. Traditionally, rendezvous procedures such as the PTBD-assisted over-the-wire cannulation method, the parallel cannulation technique, or others may be available when a bile duct cannot be selectively cannulated[5-9]. When a selective intrahepatic bile duct (IHD) cannulation fails, a rendezvous technique may be an alternative.

We describe a modified rendezvous technique in a case of right IHD obstruction caused by metastatic gallbladder malignancy. After end-to-end contact between the tips of the sphincterotome and the C2 catheter at the ampulla's orifice, the guidewire was retrogradely passed into the IHD through the C2 catheter. Clinically this procedure is feasible and timesaving. To the best of our knowledge,

this technique has not yet appeared in the English language literature.

CASE REPORT

A 39-year-old man with no specific medical history presented with right upper quadrant abdominal pain and weight loss that had started to worsen a month before presentation. Laboratory tests revealed the following: total bilirubin, 28 mg/L (normal 2-12 mg/L); aspartate transaminase/alanine transaminase, 132/331 IU/L (normal 0-40 IU/L); alkaline phosphatase, 497 IU/L (normal 39-117 IU/L); γ-glutamyltransferase, 571 IU/L (normal 0-52 IU/L); and CA19-9, 56.3 U/mL (normal 0-34 U/mL). Abdominal computed tomography revealed diffuse low-attenuated wall thickening of the gallbladder with multiple metastatic nodules on the subhepatic and right-lower abdomen. Magnetic resonance cholangiopancreatography images showed severe segmental stricture of the right IHD with mild peripheral ductal dilatation (Figure 1).

Subsequent endoscopic retrograde cholangiopancreatography (ERCP) showed that the contrast did not pass through. Selective cannulation of the right IHD was impossible even using various sized guidewires and papillotomes such as Autotome (Boston Scientific, Microvasive, Marlboro, MA, USA) because of severe obstruction (Figure 2). Access to the strictured IHD was obtained by PTBD using a 5 F, 75 cm C2 catheter (Cook Endoscopy, Winston-Salem, NC, USA). After PTBD, a C2 catheter was placed into the duodenum through the stricture site and CBD (Figure 3). In the second ERCP, a rendezvous procedure was planned to selectively access the right IHD. A guidewire-preloaded sphincterotome was positioned onto the ampulla and the C2 catheter was then slowly pulled out near the ampulla's orifice. After end-to-end contact between the tips of the sphincterotome and the C2 catheter at the ampulla's orifice, the guidewire was passed into the IHD through the C2 catheter, while simultaneously, the sphincterotome was pushed and the C2 catheter was pulled out (Figures 3 and 4). The guidewire was then selectively placed into the IHD. Finally, following balloon dilatation (Hurricane balloon, 4 mm, 60 s; Boston Scientific, MA, USA), a 7 F Amsterdam stent (Cook Endoscopy) was successfully inserted into the IHD. However, endoscopic biopsy or cytology on the stricture site was not performed. A ultrasonography-guided biopsy of the metastatic mass in the right-lower abdomen diagnosed it as an adenocarcinoma (immunohistochemical stains; CK7+, CK20-, and CDX2-). The patient was placed on concurrent systemic chemotherapy and radiotherapy.

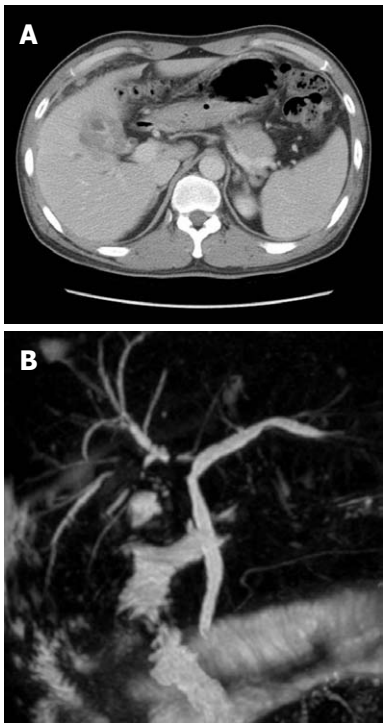

Figure 1 Abdominal computed tomography. A: Diffuse low-attenuated wall thickening of the gallbladder; B: Magnetic resonance cholangiopancreatography reveals a severe segmental stricture of the right intrahepatic bile duct with mild upstream duct dilatation.

Figure 2 Endoscopic retrograde cholangiopancreatography shows severe narrowing of the right proximal intrahepatic bile duct and slight narrowing of the common hepatic duct.

DISCUSSION

When a selective CBD cannulation cannot be performed at ERCP despite trying various endoscopic techniques, PTBD followed by a combined rendezvous technique is often successful[5-13]. This combined technique increases the success rate of biliary tract cannulation and facilitates the diagnosis and treatment of biliary tract diseases. Initially, a PTBD-placed guidewire is grasped at the tip of the duodenoscope; then the duodenoscope and wire are withdrawn[8]. This technique has some limitations, such as the two sessions required for the endoscopic procedure, difficulty grasping the wire with forceps, and kinking of the guidewire. Mönkemüller *et al*[9] recommend advancing the guidewire into the catheter's tip so that it can guide cannulation of the ampulla, but this can be difficult and requires that the wire be passed carefully. Dickey suggested a parallel cannulation technique using a sphincterotome retrogradely, alongside a biliary drainage catheter[7]. This technique can be performed in one session if CBD cannulation is difficult.

However, even if selective CBD cannulation is successful, when a selective IHD cannulation fails, this modi-

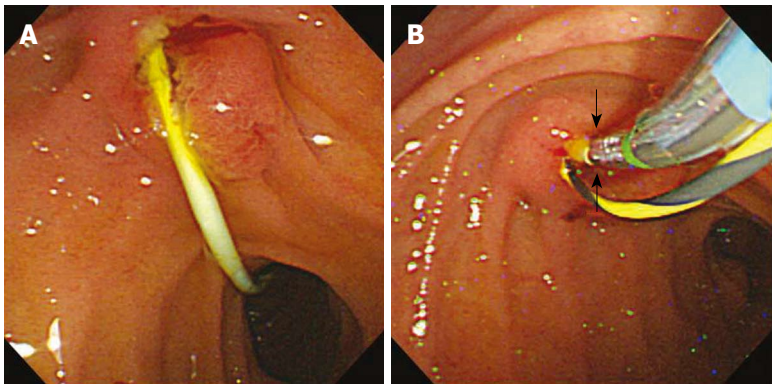

Figure 3 Endoscopic images. A: A C2 catheter in the duodenum; B: A view of end-to-end contact between the tips of the guidewire-preloaded sphincterotome and C2 catheter (arrows) at the ampulla's orifice.

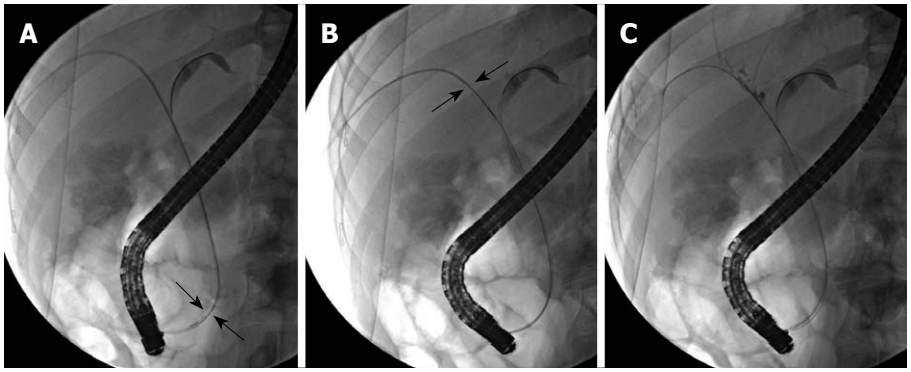

Figure 4 Fluoroscopic views. A: The guidewire passed into the right intrahepatic bile duct through the C2 catheter after end-to-end contact (arrows); B: Simultaneously, the sphincterotome was pushed into the common bile duct and the C2 catheter was pulled out (arrows); C: Finally, the C2 catheter was removed.

fied rendezvous technique may be useful. In our case, the right IHD was almost totally obstructed due to direct invasion of a gallbladder carcinoma, which prevented selective IHD cannulation despite various attempts at cannulation. Moreover, even though PTBD was successful, a 5 F C2 catheter, rather than a 7-10 F catheter which is commonly used, was placed because of severe stricture and abdominal pain during the procedure. The modified rendezvous procedure described above was then performed successfully. In cases of tight bile duct obstruction without marked ductal dilatation, it is difficult to place a metal stent *via* a PTBD route. In addition, plastic stent insertion is not possible *via* PTBD. The size of the transhepatic track necessary to insert a plastic stent percutaneously is related to the high complication rates of percutaneous stenting[14]. Endoscopic retrograde access was also impossible because of the inserted PTBD catheter. In such cases, this rendezvous technique can be a viable alternative.

In conclusion, this modified rendezvous technique for selective IHD cannulation appears to be a safe and feasible procedure. This technique is useful in selected cases such as the one presented here and in cases of failed selective CBD cannulation.

Abstract

A 62-year-old male patient was admitted to our hospital due to severe chest pain, odynophagia, and hematemesis. Chest computed tomography showed an esophageal submucosal tumor. Esophagogastroduodenoscopy (EGD) revealed a longitudinal purplish bulging tumor of the esophagus. Endoscopic ultrasound (EUS) showed a mixed echoic tumor with partial liquefaction from the submucosal layer. The patient was diagnosed with esophageal intramural hematoma as well as achalasia by upper gastrointestinal endoscopy, esophagography and esophageal manometry. The patient was managed conservatively with intravenous nutrition, and oral feeding was discontinued. Follow-up EGD and EUS showed complete recovery of the esophageal wall, and finally, the patient underwent endoscopic dilatation for achalasia. The patient was symptom free at the time when we wrote this manuscript.

INTRODUCTION

Esophageal intramural hematoma (EIH) is an uncommon cause of severe chest pain. More than 63% of patients with EIH have an underlying etiology or predisposing factors such as esophageal instrumentation, vomiting, trauma, pill-induced injury, food impaction-related issue, or coagulation defects[1]. We report a patient with severe chest pain, dysphagia, and upper gastrointestinal bleeding who was subsequently diagnosed with EIH and achalasia. The patient was initially diagnosed by esophagogastroduodenoscopy (EGD) and underwent endoscopic ultrasound (EUS) for further confirmation. After conservative treatment, the patient recovered well and then underwent esophageal manometric examination and a series of EGD and EUS follow-up.

CASE REPORT

A 62-year-old male patient had a history of hypertension

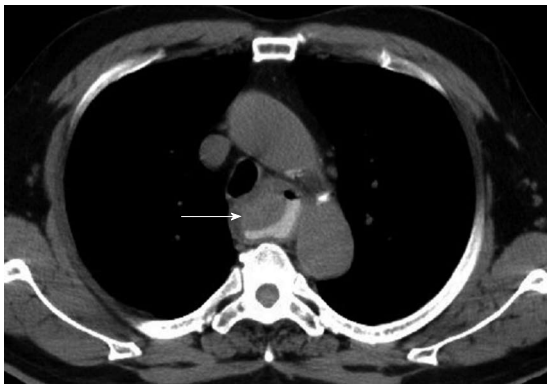

Figure 1 Computed tomography revealing a slight hyperdense tumor lesion (arrow) with a smooth surface over the upper esophagus, and no false lumen.

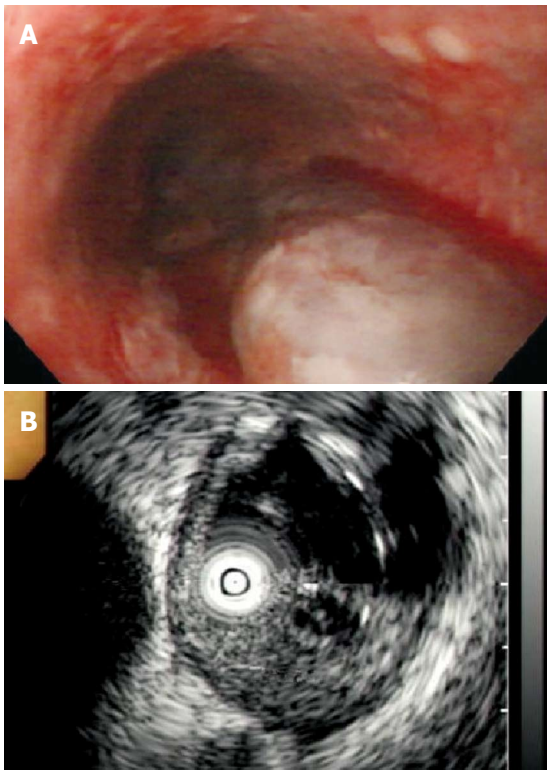

Figure 2 Esophagogastroduodenoscopy revealing a purplish bleeding esophageal submucosal tumor (A) and endoscopic ultrasound revealing a mixed echoic tumor with an anechoic component and an irregular at the submucosal layer (B).

which was treated with regular calcium channel antagonists. He suffered from dysphagia, intermittent anterior chest pain, and poor oral intake for 1 mo but no nausea or vomiting, no acid or food regurgitation, and no significant body weight loss. He did not seek medical aid until he experienced an episode of severe anterior chest pain, odynophagia, and hematemesis. He was sent to the emergency room. Laboratory results revealed a hemoglobin level of 13.5 g/dL and a platelet count of 205000/mL. Electrocardiography showed sinus tachycardia, and chest X-ray was normal. Chest computed tomography revealed a slight hyperdense tumor with a smooth surface over the upper thoracic esophagus anterior wall extending to the subcarina area with no evidence of aortic dissection (Figure 1). He then received EGD which revealed a longitudinal oozing purplish, bulging tumor from the upper to mid-esophagus. Differential diagnosis included metastatic malignancy, submucosal tumor, and hematoma. EUS showed a mixed echoic and partially liquefied mass lesion with irregular margins over the submucosal layer (Figure 2). Intramural hematoma of the esophagus was diagnosed based on these examinations. Two days after the patient was managed as nil by mouth, through use of intravenous nutrition and analgesics, he received a follow-up EGD, which revealed a dissected necrotic mass lesion with submucosal ulceration (Figure 3). Endoscopic biopsy was performed to exclude malignancy, and pathology showed necrosis and acute inflammation but no malignant cells. Follow-up EGD performed 1 wk later revealed complete resolution of the submucosal hematoma with longitudinal superficial ulcer, and EUS showed no mass lesions and only mild thickening of the mucosal and submucosal layer (Figure 4). The patient began to try liquid diet intake and was discharged on the 10th day after admission. One month later, during an outpatient visit, the patient still had dysphagia symptoms. EGD showed an intact esophageal mucosa with a tight esophagocardiac junction (ECJ) and residual food accumulation in the esophagus. Barium esophagography showed a normal esophageal wall contour but a dilated lumen with narrowing of the ECJ (Figure 5), and achalasia was suspected. The patient also received an esophageal manometric examination, which revealed 90% simultaneous contraction of the esophageal body, impaired relaxation of the low esophageal sphincter (LES) and LES pressure of 58 mm Hg. These findings were compatible with achalasia, so he received endoscopic dilatation twice for achalasia. After treatment, the patient returned to normal oral intake and symptom free during the 18-mo follow up.

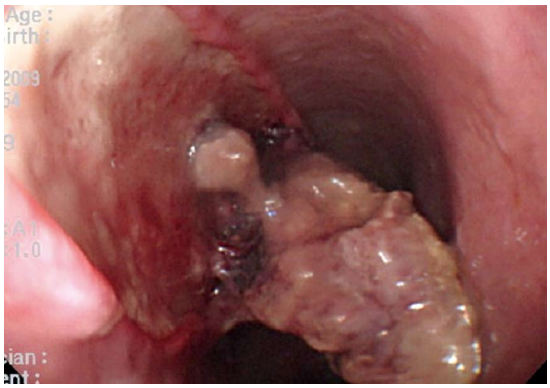

Figure 3 Follow-up esophagogastroduodenoscopy 2 d later revealing a dissected necrotic mass lesion with ulcer formation.

DISCUSSION

EIH is a rare disease that was first described by Williams in 1957[2]. Most reported cases of EIH occurred in women. The age range of patients with EIH is 20-89 years,

Table 1 Reports on achalasia in patients with esophageal intramural hematoma[8-11]

Authors	Age (yr)	Sex	Interval between the diagnosis of achalasia and EIH	Treatment of achalasia	EIH recurrence (Interval between recurrence)
Freeman *et al*[8]	69	F	3 mo[1]	Surgery	No
Herbetko *et al*[9]	43	F	15 yr	Heller's myotomy	No
McIntyre *et al*[10]	48	F	8 yr	Medication	Yes (7 yr)
Hooper *et al*[11]	45	F	19 yr	Heller's myotomy	Yes (15 mo)

[1]Achalasia was diagnosed after esophageal intramural hematoma (EIH) attack.

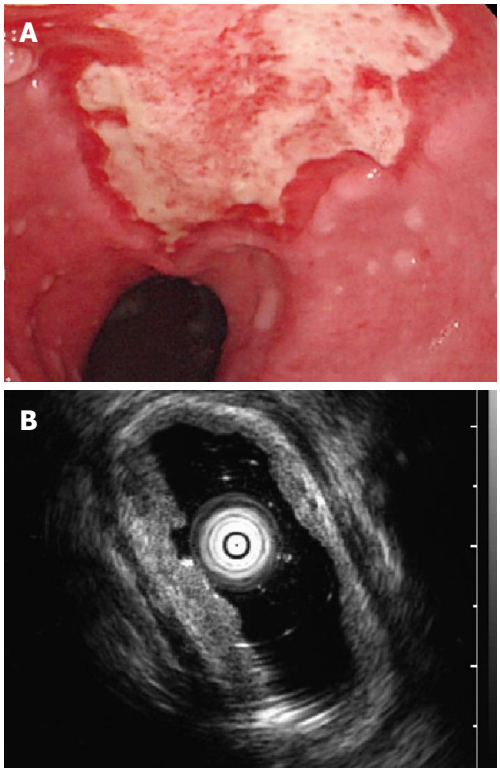

Figure 4 Esophagogastroduodenoscopy revealing a shallow ulcer without a tumor (A) and endoscopic ultrasound revealing thickening mucosal and submucosal layers, an intact muscularis propria layer, and no submucosal tumor (B) during the follow-up one week later.

and most of the patients are in the seventh or eighth decade of life. It has been reported that EIH is associated with coagulopathy[3], variceal injection sclerotherapy[4], and endoscopic instrumentation or foreign body ingestion[5]. It has also been known to occur spontaneously in healthy people[6]. EIH usually presents as a sudden onset of chest pain followed by odynophagia, dysphagia, and mild hematemesis.

EUS examination of EIH is limited. In our case, initial EUS showed a mixed echoic tumor lesion with an anechoic component and a mild irregular surface involving the mucosal and submucosal layers, but the muscularis propria was preserved and partial organization of hematoma was preferred rather than solid tumor. This patient also underwent follow-up EUS 1 wk later, which showed thickening of the mucosal and submucosal layers with a mucosal defect compatible with ulcer and complete resolution of hematoma.

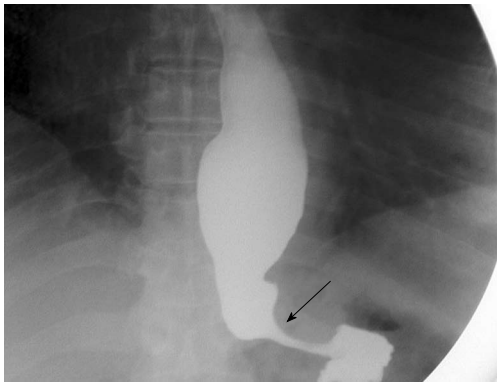

Figure 5 Esophagography revealing a dilated esophageal lumen with smooth narrowing of the esophagocardiac junction (arrow).

EIH occurs as a result of 2 types of trauma to the esophageal wall: barotrauma and direct trauma[7]. Esophageal barotrauma occurs due to a sudden increased transmural pressure associated with coughing, or retching. Direct trauma results from endoscopic injection sclerotherapy, or swallowing of pills or a large food bolus. Our patient was not known to have achalasia prior to this admission, possibly because he was symptom free due to long-term intake of calcium channel antagonists for controlling hypertension. He had intermittent chest pain and dysphagia for 1 mo. These symptoms may have been related to the underlying achalasia, but he denied having nausea, vomiting, or food regurgitation. However, he did experience a feeling of something being stuck in his esophagus. Furthermore, his platelet count and prothrombin time were normal, which prompted us to consider food bolus-related direct trauma to esophageal wall. To our knowledge, achalasia has been reported only in 4 female patients with EIH since 1957s[8-11] and three of them were already diagnosed with achalasia before the attack of EIH. Recurrent EIH has only been reported in 2 patients, with underlying achalasia[10,11] (Table 1). Fortunately, our patient fully recovered from EIH and underwent successful endoscopic dilatation for achalasia. He was in good condition, able to feed orally, and had no more chest pain or dysphagia at the time when we wrote this paper. However, long-term follow-up is needed.

The prognosis of patients with EIH is good, death has only been reported following thoracotomy for this condition[12]. Management should be conservative. Most patients can be treated using intravenous nutrition, analgesics with oral feeding discontinued. Bleeding from EIH is usually mild and spontaneously subsided, but

sometimes if bleeding is severe, endoscopic hemostasis or angiography with embolization even surgical intervention is necessary.

In conclusion, EIH is a rare disease that has different predisposing factors. EGD is a safe procedure for initial diagnosis. EUS findings help differentiate intramural hematoma from a solid tumor, cyst, or vessel. A series of follow-up endoscopies can help understand the natural course of EIH. Management is conservative, and the outcome is excellent with almost full recovery. However, it should be kept in mind that recurrence has been reported especially in patients with underlying achalasia.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statisital review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions
Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit on-

line. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use

uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

Carcinoma of the gallbladder (CaGB) is the fifth commonest gastrointestinal tract cancer and is endemic in several countries. The interplay of genetic susceptibility, infections, and life style factors has been proposed to be responsible for carcinogenesis of gallbladder. Persistence of infection leading to chronic inflammation, and production of certain toxins and metabolites with carcinogenic potentials, by certain bacteria has been speculated to be involved in the transformation of the gallbladder epithelium. Therefore, any bacteria that have evolved to acquire both of the above carcinogenic mechanisms can cause cancer. *Salmonella typhi* has been found to be prominently associated with CaGB. Chronic typhoid carriage (persistence) and production of mediators of chronic inflammation and a genotoxic toxin (cytotoxic distending toxin, CdtB) are also known for this bacterium. Furthermore, the natural concentrating function of the gallbladder might amplify the carcinogenic effect of the mediators of carcinogenesis. In addition to *S. typhi*, certain species of *Helicobacter* (*H. bilis* and *H. hepaticus*) and *Escherichia coli* have also been implicated in carcinogenesis. As the isolation rate is very poor with the presently available culture techniques, the existence of bacteria in a viable but non-cultivable state is quite likely; therefore, sensitive and specific molecular techniques might reveal the etiological role of bacterial infection in gallbladder carcinogenesis. If bacteria are found to be causing cancers, then eradication of such infections might help in reducing the incidence of some cancers.

Key words: Bacteria; Chronic inflammation; Carcinogen; Bacterial toxins; Carcinoma gallbladder; DNA damage

Peer reviewer: Eduardo Garcia Vilela, Professor, PhD, Department of Internal Medicine, Faculty of Medicine, Federal University of Minas Gerais, Avenida Professor Alfredo Balena, 190/ 2 andar, Belo Horizonte 30130-100, Brazil

INTRODUCTION

Carcinoma of the gallbladder (CaGB) is the fifth commonest cancer of the gastrointestinal tract and it is one of the commonest biliary tract (BT) malignancies[1]. Although, gallbladder cancer was described as early as 1777[2], for the majority of patients late diagnosis and lack of effective treatment is a typical feature of the disease even today[2-4]. Carcinoma of the gallbladder is an aggressive disease with dismal prognosis and has marked ethnic and geographical variations in incidence. CaGB is more common in females than males[5], except in Far East Asian countries like Japan and China. The highest documented incidence rate was shown in women from

Delhi, India (21.5/100 000); followed by Karachi, Pakistan (13.8/100 000), and Quito, Equador (12.9/100 000)[5]. High incidence rates have also been reported from Far East Asia, Eastern Europe, South America, and Spain (Granada), the incidence of CaGB has also been reported to be high. However, the incidence rate of CaGB in North Europe and North America has been observed to be quite low (< 3/100 000)[6].

A number of factors, such as genetics, infections, and life style have been reported to be associated with CaGB. Genetic etiology might be more important in Japan, Korea, and China where the sex ratio for CaGB is close to unity. This cancer has also been linked with certain genetic disorders, such as multiple familial polyposis/Gardener syndrome[7], Peutz-Jegher syndrome[8], porcelain gallbladder[9], and anomalous pancreatico- biliary ductal union[10]. The interplay of genetic susceptibility, infections, and life style factors in gallbladder carcinogenesis is still poorly understood[6]. Despite recent insights into the possible mechanisms involved in biliary carcinogenesis, the key events and specific links in this multistage cascade that leads to transformation of gallbladder epithelial cells remain unknown and deserve further investigation. In this review, we have specifically focused on the association of chronic bacterial infection with CaGB.

CHRONIC MICROBIAL INFECTIONS AND CARCINOGENESIS

When bacteria were discovered to be the cause of many infectious diseases, it was accepted that cancer does not behave as an infectious or contagious disease. Thus, the notion of involvement of bacteria in carcinogenesis was rejected. In 1890, Russel[11] for the first time on the possibility of bacteria-induced carcinogenesis. A few years later, Thomas Glover[12] in 1926 stated that specific bacteria could be isolated consistently from neoplastic tissues. In 1931, Hodgkin's disease was found to be associated with acid fast bacteria[13]. Later, in 1941, George Mazet[14] reported that both leukemia and Hodgkin's diseases were consistently associated with bacteria. From 1936-1955, Crofton[15], Livingston *et al*[16], and Villesquez[17] also reported the presence of microbes in cancer tissues. In 1953, White[18] made a claim that antiserum raised against cancer bacteria had a protective effect. Diller[19] in 1953 reported the isolation of extremely polymorphic bacteria from cancer tissues.

However, in 1963, a group of scientists from National Cancer Institute (NCI), USA, rejected the hypothesis of association of bacteria with carcinogenesis. These bacteria were considered simply either as contaminants or having secondarily infected the cancer growth. In addition, this hypothesis could not withstand Koch's postulate. In contrast, a few years later (1969), another group of scientists from NCI, USA, reported positive associations between bacteria and cancers. Barile *et al*[20] in 1965 observed latent infection of Mycoplasma in leukemia cases. Later, Lo[21] in 1992 reported multistage malignant transformations due to Mycoplasma infection, which could be reversed by antibiotic therapy. The best studied relationship between bacterial infection and cancer is that of *Helicobacter pylori* implicated in two different forms of gastric cancers: MALT lymphoma and gastric adenocarcinoma[22]. *Streptococcus bovis* has been implicated in colon cancer, *Chlamydiae pneumonie* in lung cancer and *Bartonella species* in vascular tumor formation[22-25].

Certain animal studies have shown the involvement of *Helicobacter hepaticus* in chronic active hepatitis that progressed to hepatocellular carcinoma in A/JCr mice[26]. Chronic infection with *Citrobacter rodentium*, a mouse pathogen, which is genetically similar to enteropathogenic *Escherichia coli*, can result in colon cancer[27]. Recently, *H. hepaticus* has been stated to promote cancer formation indirectly in the mammary gland of mice[28].

For many years, chronic inflammation has been reported to be associated with a variety of epithelial malignant tumors. Chronic osteomyelitis has been found to be associated with the development of squamous cell carcinoma along the draining sinus of osteomyelitis[29], and chronic inflammatory bowel disease has been associated with increased risk of development of adenocarcinoma[30,31]. *Schistosoma haematobium,* a water-borne parasite that causes a secondary bacterial infection of the urinary tract due to its persistence, is an important cause of squamous cell carcinoma of the urinary tract in the Middle East and Northern Africa[32]. Furthermore, increase risk of developing cancer of the urinary bladder due to chronic inflammation has been confirmed by epidemiological data and by animal experiments[33-35].

MECHANISMS OF BACTERIAL CARCINOGENESIS

Understanding bacteria-induced carcinogenesis might enable us to prevent and cure some forms of cancers[36]. The involvement of bacteria in carcinogenesis is still not without controversy because no clear agreement has been achieved on the molecular mechanism/s by which they might promote carcinogenesis. In the 21st century, scientists started hypothesizing that: (1) Chronic inflammation caused by persistent bacterial infections might lead to carcinogenesis[37-39]; and (2) Bacterial toxins and secondary metabolites produced by the chronic bacterial infection might induce carcinogenesis[37].

Chronic inflammation due to bacteria and carcinogenesis

Bacterial infections are usually believed to cause acute disease, but it has now been accepted that many bacteria can cause chronic infections and diseases, including cancers[37,40].

There may be various mechanisms of carcinogenesis induced by chronic bacterial infections (Table 1[41-50] and Figure 1). Continuous release of mediators of inflammation is a common feature of chronic infections[37,38]. The nuclear factor-κB (NF-κB) family of transcription factors are linked to inflammation driven carcinogenesis[38]. The NF-κB activation pathway is triggered by microbial infections and also by proinflammatory cytokines, such as TNF-α and IL-1. This pathway leads to activation of IKK

Table 1 Chronic inflammatory mechanisms involved in carcinogenesis

Signaling	Sub categories	Role in inflammation assumed cancer
Pro-inflammatory cytokines and immunosuppressant cytokines	ILS: Pro-inflammatory (IL-1, IL-6, IL-8, IL-17); immunosuppressor (IL-10); TNF-α plays dual role in carcinogenesis, usually it is tumor promoter	Over expressed in inflamed and hyperplastic, metaplastic tissues and adenocarcinoma; Induce DNA damage; Pro-angiogenic molecule such as VEGF, VEGFR, IL-8, NO, ICAM-1 VCAM-1; Activation of pro-inflammatory signals mediated *via* JAK-STAT and NF-κB; Maintain inflammatory tumor microenvironment; Stimulate cell proliferation and inhibit apoptosis
Chemokines	Four major groups: CXC, CC, XC, CX3C (primary function is to recruit leucocytes at the site of inflammation)	Responsible for attraction to inflammatory and immune cells to tumor microenvironment; Promotion of tumor cell migration, facilitation of invasion and metastasis; Stimulation of inflammatory angiogenesis
COX-2 and prostaglandins	An inducible form of cyclooxygenase, serves as interface between inflammation and cancer[41-44]	Causes promotion of: cellular proliferation, suppression of apoptosis, enhancement of invasiveness, angiogenesis
iNOS	Expression of iNOS is elevated in various precancerous lesions and carcinomas[45]	Elevated in precancerous and cancerous lesions and cause: DNA damage by nitrosation/oxidative pathways; Produce proinflammatory mediators like NO by catalyzing Arginin metabolism; Acts as a downstream effector of NF-κB and inflammatory cytokines mediated signaling
NO	Elevated in precancerous and cancerous lesions[46]	Selects mutant p53 cells and contribute to tumorigenesis by upregulating VEGF; DNA damaged by nitrosation of nucleotide bases
NF-κB (The NF-κB/Rel family of proteins includes CRel, RelA (p65), RelB, NF-κB1 (p50/100), NF-κB2 (p52/p100)[47]	One of the DNA binding proteins that are aberrantly activated in response to inflammatory stimuli leading to induction of transcription of various proinflammatory genes in tumor cells[48]	Enhances expression/production of proinflammatory mediators: Amplifies inflammation signal transduction; Increased expression of anti-apoptotic protein; Help transformed cells to escape apoptosis
ErbB2 (a receptor strongly involved in carcinogenesis)	Inflammation induces the expression[49-50]	Binding of ErbB1 and ErbB2 to ligands results in prolong activation of intrinsic protein kinase activity, leading to activation of a biochemical cascade responsible for mitogenic cell signal transduction

ILS: Interleukins; IL: Interleukin; TNF: Tumor necrosis factor; CC: Chemotactic cytokine; NF-κB: Nuclear factor-κB; VEGFR: Vascular endothelial growth factor receptor; iNOS: Inducible nitric oxide synthetase; NO: Nitric oxide; VCAM-1: Vascular cell adhesion molecule 1; ICAM-1: Inter-cellular adhesion molecule 1.

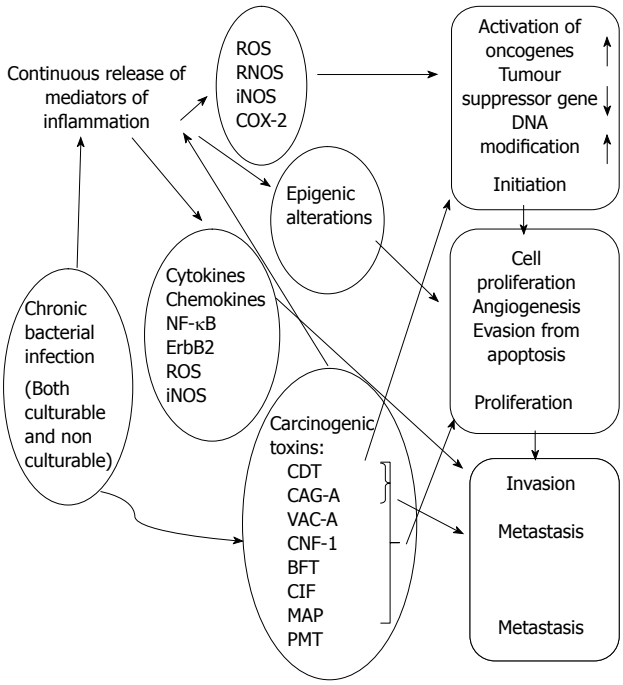

Figure 1 Mediators of inflammation and bacterial toxins in carcinogenesis caused by bacteria. ROS: Reactive oxygen species; RNOS: Reactive nitrogen oxide species; iNOS: Inducible nitric oxide synthetase; NF-κB: Nuclear factor-κB; CDT: Cytolethal distending toxin; CNF: Cytotoxic necrotizing factor; BFT: Bacteroides fragilis toxin; CIF: Cycle inhibiting factor; MAP: Mitochondrial associated protein; PMT: Pasturella multocida toxin.

complex[51] and to degradation of NF-κB inhibitors, thus freeing NF-κB to enter the nucleus and mediate transcription of target genes. Many of genes, such as cyclin D1, CDK2 kinase, c-myc (cell cycle regulators), involved in cell cycle control are upregulated, while the genes responsible for decreased apoptosis, such as p21, p53 and pRb, are downregulated by NF-κB. NF-κB also upregulates numerous cytokines, such as IL-1β, IL6, VEGF (proinflammatory and proangiogenic), but downregulates TNF, thus enhancing tumor growth. Genes responsible for invasion and metastasis are also upregulated by NF-κB. Moreover, downregulation of genes involved in suppression of apoptosis, i.e. Bcl-2 family members and IAP proteins, an important feature of cancer cells, is mostly due to deregulation by NF-κB. NF-κB not only helps in persistence of intracellular as well as extracellular infections, but also leads to suppression of cell death; thus creating a niche for bacterial survival defying the host immune response[52,53]. Survival of such partially transformed cells provides a chance for a higher level of transformation. Reactive oxygen species (ROS) and nitric oxide (NO) are produced by epithelial cells in response to inflammation. These compounds increase mutations in genes responsible for controlling malignant transformations. In particular, ROS can inhibit tyrosine phosphatases, causing overexpression of Mox1 (the catalytic subunit of NADPH oxidases). NO inhibits the Fpg protein, a DNA repair enzyme[54], leading to failure of damage control. HER-2/neu (also known

Table 2 Bacterial toxins and their possible roles in carcinogenesis

Toxin	Source	Activity and outcome
Potential genotoxins		
CDT (three subunits: CdtB is a functional unit, while CdtA and CdtC serve as accessory units for delivery into target cells)	*Haemophilus ducreyi, Helicobacter hepaticus, Salmonella typhi. Actinobacillus actinomycetemcomitans*	DNAase; DNA damage and cell cycle inhibitor[56,57]
Cytolethal distending toxin B	*Salmonella typhi*	DNAase activity, genotoxic by creating DNA lesions[58]
Colibactin	*Escherichia coli*	Mechanism unknown[59]
Potential pro-carcinogenic toxins		
Pasturella multocida toxin	*Pasturella multocida*	Modifies Gq proliferation[60]
CagA	*Helicobacter pylori*	Binds to SHP2 and c- Met cells scattering[61]
Vacuolating cytotoxin A	*Helicobacter pylori*	Upregulation of VEGF expression (seems to depend on the activation of EGFR, MAP kinase and COX-2 mediated)
Bacteroides fragilis toxin	*Bacteroides fragilis*	Cleaves E- cadherin proliferation[62]
Cytotoxic necrotizing factor-1	*Escherichia coli, Shigella dysenteriae, Campylobacter jejuni and Salmonella typhi, Helicobacter hepaticus, Actinobacillus actinomycetemcomitans*	Modifies Rho family proteins, inflammation and inhibition of cell cycle, blocks cytokines[39]
Cycle inhibiting factor	*Escherichia coli*	Inhibit cell cycle at G_2-M transition[63]
MAP	*Citrobacter rodentium*	Multifunctional effectors protein that target host cell mitochondria implicated in the disruption of epithelial barrier function both *in vitro* and *in vivo*[64]
VEGF	*Bartonella species*	Angiogenesis and proliferation[65]

MAP: Mitochondrial associated protein; VEGF: Vascular endothelial growth factor; EGFR: Epidermal growth factor receptor.

as ErbB2) stands for "human epidermal growth factor receptor 2" and is a protein conferring higher aggressiveness in breast cancers. It is a member of the ErbB protein family, more commonly known as the epidermal growth factor receptor family, which is involved in cell proliferation, differentiation, and oncogenesis. Overexpression of ErbB2 can occur due to chronic inflammation. Binding of ErbB1 and ErbB2 to ligands results in prolonged activation of intrinsic protein kinase activity, leading to activation of a biochemical cascade responsible for mitogenic cell signal transduction[49,50]. All these factors contribute to the multistage process of carcinogenesis[55]. These factors all cause oxidative damage to DNA of the cells (Figure 1).

Bacterial toxins implicated in carcinogenesis

The probable bacterial toxins implicated in carcinogenesis are listed in Table 2[39,56-65]. The pathways involved in carcinogenesis have been depicted in Figure 1. Bacterial toxins can either kill the cells or modify the cellular processes that control DNA damage, proliferation, apoptosis, and differentiation. These toxins interfere either with the key eukaryotic processes, such as cellular signaling components, or directly by attacking the DNA[62,66]. The damage to the host cells can be mediated either[67]: (1) directly by: (a) enzymatic attack; (b) DNA damage; or (c) by affecting DNA damage repair mechanisms; or (2) indirectly by: (a) provoking a chronic inflammatory reaction; or (b) producing free radicals.

These changes might be associated with carcinogenesis and might stimulate cellular aberrations, modify the immune response, or inhibit normal cell controls.

BACTERIOLOGY OF THE GALLBLADDER AND BILE

Lykkegaard *et al*[68] reported that the liver is normally sterile, as is bile from individuals with a normal biliary tree. Bile favors the growth of some organisms but inhibits others, such as *Streptococcus pyogenes* and *Streptococcus pneumoniae*.

A positive bile culture might not only be important in the genesis of biliary tree infection, but might also be a significant determining factor in the incidence of various short and long term consequences. The pathological process of cholecystitis can be acute, chronic, or more commonly, a combination of both types. This is evident from the observations that approximately 95% of gallbladders removed for acute cholecystitis exhibit fibrosis and other signs of chronic inflammation.

Routes of infection through which microbes may enter the biliary tract

(1) Ascending route - although the sphincter of Oddi, situated at the junction of the biliary tract and the gastrointestinal tract, forms an effective mechanical barrier to duodenal reflex vis-à-vis ascending bacterial infection, when the barrier mechanism is broken down either by surgical intervention or by certain pathology, microbes can enter the biliary system. It is interesting to note that the type of organisms recovered from bile are not those dominant in the sparse flora of the duodenum but are usually encountered in the ileum and colon[69] (Table 3); and (2) Descending route (hematogenous route) - As a part of the normal innate immune system, Kupffer cells prevent toxic metabolites and bacteria from entering the hepatobiliary system from the portal circulation. Added to this, the continuous flushing action of bile and the bacteriostatic effect of bile salts keep the biliary tract sterile under normal conditions. Moreover, secretory immunoglobulin A (SIgA), the predominant immunoglobulin in the bile and the mucous membrane and excreted by the biliary epithelium, probably acts by its anti-adherent function to prevent microbial

Table 3 Spectrum of bacteria isolated from bile (Brook *et al*[73])

Organism	No. of isolates	%
Aerobic bacteria		
Escherichia coli	71	32.9
Group D streptococci	42	19.4
Klebsiella species	29	15.3
Enterobacter species	26	12.5
Proteus species	15	6.9
α-haemolytic streptococci	11	5.1
Citrobacter species	8	3.6
Staphylococcus species	7	3.2
γ-haemolytic streptococci	5	2.3
Pseudomonas species	2	0.9
Anaerobic bacteria		
Clostridium perfringens	23	29.9
Bacteroides fragilis	9	11.7
Other *Bacteroides* species	5	6.5
B. thetaiotamicron	4	5.2
B. ovatus	2	5.2
B. distasonis	2	2.6
Propionibacterium acne	7	9.1

colonization. Despite these mechanisms, it is likely that organisms in the bile might be derived from blood.

The presence of bacteria in bile may not cause symptoms. In a series of cases, Flemming *et al*[70] observed that only 20 of 32 patients with positive cultures had symptomatic cholangitis, while six of 43 with negative cultures had had symptoms in the recent past. Further, out of 15 patients who had previous biliary intestinal anastomosis, 12 had positive cultures, but only seven had a history of cholangitis. However, efficiency of culture isolation techniques and the type of bacteria associated specifically with symptoms must be explored further. Gallstone formation has been reported to be predisposed by bactobilia[71]. Bacteria themselves might act as a nidus for gall stone formation or may alter the bile composition or damage the wall of the gallbladder. It is difficult to estimate the bacteriology of bile in an absolutely healthy population. The majority of the available reports regarding the microbial spectrum of infected bile are from individuals suffering from hepatobiliary diseases. Interestingly, most of these reports concur with one another[72].

Brook[73] reported the spectrum of anaerobic isolates from the biliary tract (Table 3). Anaerobic bacteria could be recovered from 48% of specimens. Anaerobic bacteria could be isolated exclusively in 3% and mixed in 49% of 123 bile specimens collected. The author suggested that lowering of oxygen tension and pH achieved by initial colonization of aerobic bacteria in acute infection paved the way for predominance of anaerobes in the chronic stage of illness. However, it is difficult to draw any conclusion without knowing the flora of gallbladder in individuals without any sign or symptom. Most studies have reported isolation of the bacteria in bile to be < 50%[74,75]. Lu *et al*[76] detected bacterial DNA in 78.3% of CaGB tissue samples. They used a single amplification cycle targeting 16S r DNA. However, detection rates will rise further if nested PCR (being more sensitive) is used. Therefore, the possibility of the existence of viable but non-culturable (VBNC) forms of bacteria cannot be ruled out in the gallbladder. However, the detection of bacteria causing persistent infection in biliary system is warranted.

Gallbladder cancer and Salmonella typhi

The interplay of genetic susceptibility, life style factors, and infections of the hepatobiliary system in carcinogenesis of the gallbladder is poorly understood; however, a link has been specifically proposed between chronic bacterial infections of the biliary tree and *S. typhi*. An association of chronic typhoid carriage and carcinoma of the gallbladder was first reported by Axelrod *et al*[77]. Welton *et al*[78] observed increased incidence of cancer of the hepatobiliary system in typhoid carriers; this was later confirmed by other studies[79,80]. Caygill *et al*[81] studied cancer mortality in people infected during the Aberdeen typhoid outbreak in 1964; their results suggested a lifetime risk of developing gallbladder cancer in 6% of the carriers. Strom *et al*[82] from Bolivia and Mexico have reported a 12-fold increase in CaGB in subjects with a history of typhoid fever. However, they could not prove the same by serology. Moreover, Shukla *et al*[83] from Northern India, using Vi serology, showed a 7.9 times increased risk for CaGB in chronic typhoid carriers. Earlier also from North India, Nath *et al*[84] demonstrated significantly higher isolation rates of *Salmonella typhi* and *paratyphi*-A from bile, gallbladder tissue, and stones from patients with CaGB as compared to those suffering from benign gallbladder diseases. The relative risk of developing CaGB was reported to be 9.2. Based on serology, Dutta *et al*[85], from North India, reported a 14-fold increased risk of CaGB in a case-control study. In Japan, an area with an extremely low prevalence of typhoid fever, in a large cohort of 113 394, the relative risk of developing CaGB was reported to be 2.1[86]. Recently, Nath *et al*[87] reported the prevalence of chronic typhoid carriers in CaGB patients using a very sensitive and specific nested PCR technique, in hepatobiliary specimens, to exclude the limitations of serology based detection and culture isolation (low sensitivity of culture and variable individual immune response, depending on the stage of the disease). They showed that 67.3% of the CaGB patients were typhoid carriers, as compared to 8.3% of the healthy population (hepatobiliary specimens from dead bodies; victims of unnatural deaths) in the typhoid endemic area of North India (Odds ratio 22.8). In the same study, the authors tried to locate the niche of the *S. typhi* bacterium in chronic typhoid carriers, and found that the bacterium was most prevalent in the liver[88]. Therefore, it could be proposed that *S. typhi* lives in the liver and is excreted into the gallbladder intermittently. Metabolites (mutagens and inflammation inducers) and toxins produced by the multiplying bacteria are further concentrated about 10 times in the gallbladder, which thereby bears the major brunt of the mutational changes. Various carcinogens produced by *S. typhi* have been suggested: Bacterial glucuronidase, yielding some high energy intermediates after acting on bile[89],

bacterial enzymes acting upon primary bile acids and producing carcinogenic secondary bile acids at very high concentrations[90], and the production of nitroso compounds from nitrates by the action of bacterial enzymes[91]. Chronic bacterial infection leads to obstruction and persistent chemical and mechanical injuries[92].

Cytolethal distending toxin (CDT), the first bacterial genotoxin described, is also produced by *S. typhi*[58] in addition to *Escherichia coli*[93] and other causative agents of chronic infection, such as *Campylobacter jejuni*[94], *Haemophilus ducreyi*[95], *Shigella dysenteriae*[96], *Actinobacillus actinomycetemcomitans*[97], *Helicobacter hepaticus*[98], and other species[99,100]. The holotoxin is a tripartite complex, where the CdtB subunit, a structural and functional homolog of mammalian DNAse I, is the active subunit, while CdtA and CdtC mediate the binding of the holotoxin to the plasma membrane of the target cells. In a cell culture study (Cos2 and Henle-407 cell lines), Haghjoo *et al*[58] found that *S. typhi* produced a unique CdtB-dependent CDT that required bacterial internalization into host cells. When Cos-2 cells were transfected with *S. typhi*, the effects of the CdtB subunit were severe fragmentation of chromatin, a typical characteristic of the CdtB subunit of CDT expressed by other species. The authors proposed that *S. typhi* subsequent to internalization deviated from the usual endocytic pathway that leads to lysosomes, reaching an unusual membrane-bound compartment where it can survive and replicate due to its ability to produce abundant antiphagocytic Vi capsule. What is the role of CDT in *S. typhi* pathogenesis? It is worth mentioning that *S. typhi* is the only serovar of Salmonella that encodes CdtB. Furthermore, *S. typhi* is a human-restricted pathogen, causing chronic persistent infections. CDT might facilitate the persistence of infection, because this toxin is known for its immunomodulatory activity[97]. CdtB, after being delivered to the cytosol, reaches the nucleus of the target cell where it causes DNA damage[101]. Therefore, in typhoid endemic areas, *S. typhi* might be one of the important etiologic factors for CaGB.

Gallbladder cancer and Helicobacter species

Helicobacter pylori (*H. pylori*) infection is a well-established cause of stomach cancer[102]. Since the discovery of *H. pylori* in 1982, thirty other *Helicobacter* species have been identified from the stomach, intestinal tract, and liver of mammals and birds. A few species found in human bile and biliary tract tissue biopsies (*H. bilis, H. pullorum, H. hepaticus, H. pylori etc.*) have been suspected to cause biliary tract diseases. As discussed earlier, any bacteria, *Helicobacter* spp. in particular, causing persistent infection in the biliary tract might induce chronic inflammation and gallstone formation, especially due to urease production[103,104]. Gallstones further aggravate chronic inflammation and can induce transformation, which is further amplified many fold by several toxins and metabolites of known carcinogenic potentials produced by the Helicobacters[105,106]. *H. hepaticus* is a known agent causing chronic active infection of biliary canaliculi progressing to liver cancer[2]. PCR-based detection rates of different species of *Helicobacter* spp. in biliary tract cancer vary from 0%-82.8%[107]. Using species-specific primers, *H. bilis* was found in 35 out of 67 specimens (52.2%) from four different studies, whereas *H. hepaticus* was searched for in two studies, but only in one study were four out of 19 specimens (21.1%) found to be positive for the bacterium. In contrast, Pradhan *et al*[108] from Nepal have shown *Helicobacter hepaticus* infection in 82% of non-malignant gallbladders and in 87.5% of malignant cases. Whether *Helicobacter hepaticus* is the number one cause of the type of gallstone formation that ultimately leads to malignancy, or is itself a risk factor for the pathogenesis of carcinoma gallbladder, is yet to be determined. Murata *et al*[109] showed that *H. bilis* specific sequences could be amplified in three of 11 (27.2%) gallbladder cancer cases and in one of three (33.3%) cases with biliary duct cancer. One study conducted in Japanese and Thai populations showed that patients positive for *H. bilis* had a 6-fold higher risk of biliary tract carcinoma. However, it is premature to make conclusion about the role of *Helicobacter species* in causing CaGB. *H. pylori* infection was also identified as a risk factor for biliary tract cancer and the corresponding relative risk (RR) was 9.9 (95% CI: 1.4-70.5) after adjustment for age and sex. *H. bilis* and *H. pylori* have been identified in bile specimens and associated with risk of biliary tract cancer. Another study[109] found a positive association between *H. bilis* and CaGB, with a crude RR of 2.6 (95% CI: 0.6-4.6). Larger epidemiological studies are required before Helicobacters can be in gallbladder cancer, but only after the development and validation of specific serological tests and direct detection of these bacterial species in the gallbladder itself.

Gallbladder cancer and Escherichia coli

E. coli is the normal inhabitant of the human intestine and can become highly pathogenic following the acquisition of virulence factors, usually by horizontal gene transfer. Cytotoxic necrotizing factor 1 is one of the important protein toxins acquired in this way. *Escherichia coli* is the commonest species isolated from gallbladder specimens and CDT is present in many isolates of *E. coli*. Lax[37] reported a novel genotoxin, named as colibactin. The mechanism of action of this toxin is yet to be explored; however, it causes double stranded DNA breaks. It is likely that some of these acquired gene(s) enable these strains cause persistent infection, and facultative or obligate intracellular invasion, leading in turn to more chances of transformation of the host cells. In support of above speculation, Yamamoto *et al*[110] have shown that there was marked enhancement of rat urinary bladder carcinogenesis by heat killed *E. coli*. Furthermore, the occurrence of chronic urinary tract infections leading to carcinogenesis lends support to the above suggestion[111].

Gallbladder cancer and other bacteria

Several bacteria and their products display potentially carcinogenic characteristics. There is ample evidence to support the view that some bacteria can establish chronic infection, often without overt sign of the disease. In fact,

many bacteria form the chronic carrier state, usually in viable but non-cultivable (VBNC) states or in a cell wall deficient form. They are relatively dormant but retain their virulence[112,113]. The poor yield of bacterial isolation as compared to detection by PCR affirms this possibility[87]. Therefore, any bacteria (aerobic or anaerobic) acquiring genes that enable them to cause persistent infection, and are capable of producing carcinogenic toxin, secondary metabolites, and most importantly chronically released inflammatory mediators, might be able to transform the host cells. It must be stressed that the isolates from affected sites with chronic infection or cancer must be characterized in terms of their ability to colonize, and for the production of metabolites with carcinogenic potential.

CONCLUSION

Carcinoma of the gallbladder is one of the commonest malignancies of the biliary tract. The main associated risk factors identified to date include chronic cholelithiasis, chronic infection, obesity, hormonal factors, environmental exposure to specific mutagens, and genetic predisposition. Tumorigenesis is a long and complex process, and the gap between initiation and development of cancer might hide the role of microbial infection. Therefore, a direct link between bacterial infection and cancer is often not detectable, and the etiological role of the former in causation of cancer is mostly underestimated. However, chronic infections lead to the persistent release of mediators of inflammation, toxins, and metabolites and these factors may be potentially mutagenic and/or cell cycle modulators. A strong association between chronic Salmonella carriage and cancer of the gallbladder has now been proposed. However, it is likely that other bacteria in addition to *S. typhi*, which persistently inhabit the gallbladder, might be important etiological factors. Attempts have been made to conquer cancer over many decades, but the conventional strategies like chemotherapy and radiotherapy, often cannot prevent or cure cancer. Eradication of causative microbes by antibiotic therapy, and immunological potentiation by active, as well as passive, methods, will definitely lead to reduction in the incidence of bacteria-induced cancers. In addition to this approach, numerous anti-inflammatory agents of natural and synthetic origin are reported to have inhibitory effects on inflammation-induced carcinogenesis. Cellular miRNAs might also have the potential to control and prevent carcinogenesis. Knowing the genetic susceptibility for persistence of a specific bacterial agent will help in the choice of prophylactic measures in such individuals. Thus, limiting the reservoir and transmission of such potentially pathogenic microorganisms will help in decreasing the incidence of chronic and acute diseases.

FUTURE PERSPECTIVE

There is a strong need for in-depth studies looking into the role of persistent bacterial infections and carcinogenesis of the same or related parts of the body. Further study is required into the mechanism of chronic inflammatory mediators and bacterial toxins in cell transformations. Detailed study needs to be carried out to delineate whether it is the infection or the disease that occurs first in the case of gallbladder pathology. Effort should be made to substantiate the exact role of bacteria like *Salmonella typhi*, *Escherichia coli*, and *Helicobacter* species in the causation of biliary tract cancer in suitable animal models. Once the role of chronic bacterial infection in carcinogenesis is established, ways could be found to cure or eradication such agents from the community by chemotherapy, immunotherapy, and hygienic practices. Anti-inflammatory therapeutic approaches to cancer development, which can block/modify carcinogenic mechanism/s, such as anti-inflammatory agents or miRNA, should be explored.

Abstract

After surgery for Crohn's disease (CD), early endoscopic lesions are frequently observed despite no symptomatic recurrence. The severity of lesions found at postoperative endoscopy is reported to be a strong predictive factor for future clinical recurrence. If endoscopic lesions in the early postoperative period can be reduced with medications, symptomatic recurrence will likely be delayed and decreased. Before the introduction of biologic therapies, various medications were used for the maintenance of clinical remission after surgery; however, few demonstrated consistent efficacy. Infliximab is a recombinant anti-tumor necrosis factor-α antibody. Although infliximab is one of the most effective medications in the management of CD, its efficacy for early endoscopic lesions after surgery has not yet been assessed. The author and colleagues recently conducted a prospective study in order to investigate the impact of infliximab on early endoscopic lesions after resection for CD. We found that infliximab therapy showed clear suppressive effects on clinical and endoscopic disease activity in patients with early endoscopic lesions after resection.

Key words: Crohn's disease; Postoperative recurrence; Endoscopic lesion; Infliximab

INTRODUCTION

Crohn's disease (CD) is a chronic relapsing, remitting inflammatory bowel disease, the cause of which remains unknown. Nearly 80% of patients with CD require surgery during their lifetime[1]. CD can be palliated but not cured by surgery because inflammation tends to return in areas adjacent to those that were previously removed. Postoperative recurrence is common, and many patients require repeat operations. Reoperation rates for recurrence are reported to be 10%-35% at 5 years, 20%-45% at 10 years and 45%-55% at 20 years[1].

Although postoperative recurrence is common in CD, the determinants of disease recurrence remain speculative. Several patients with CD experience frequent recurrences while others have prolonged periods of remission after surgery. Identifying risk factors for postoperative recurrence would be useful to identify patients at a high risk of progressive recurrence and to determine strategies for medical therapy after surgery.

RISK FACTORS FOR POSTOPERATIVE RECURRENCE

The author and colleagues have conducted systematic reviews and meta-analyses of clinical trials reporting on

surgical outcomes for CD in order to determine risk factors for postoperative recurrence[1-5].

Smoking

The most significant factor affecting postoperative recurrence of CD is smoking. In a meta-analysis[2], 16 studies encompassing 2962 patients including 1425 non-smokers (48.1%), 1393 smokers (47.0%) and 137 ex-smokers (4.6%) were investigated. Smokers had significantly higher clinical recurrence than non-smokers [odds ratio (OR): 2.15, 95% confidence interval (CI): 1.42-3.27]. Smokers were also more likely to experience surgical recurrence within 5 years (OR: 1.06, 95% CI: 0.32-3.53) and 10 years (OR: 2.56, 95% CI: 1.79-3.67) of follow-up compared to non-smokers. There was no significant difference between ex-smokers and non-smokers in the reoperation rate at 10 years or in the rate of postoperative acute relapses. In other clinical trials[6,7], quitting smoking reduced the recurrence rate in patients with CD.

Indication for surgery

In one meta-analysis[3], 13 studies reported on 3044 patients, 1337 (43.9%) of whom had perforating disease (perforation, fistula or abscess) and 1707 (56.1%) had non-perforating indications for surgery. The probability of reoperation for recurrence was found to be significantly higher in patients with perforating indications compared to those with non-perforating indications [hazard ratio (HR): 1.50, 95% CI: 1.16-1.93]. The indication for reoperation in CD tends to be the same as the primary operation, i.e. perforating disease tends to re-present as perforating disease, and non-perforating as non-perforating.

Granuloma in the specimen

In a recent meta-analysis[4], 21 studies reported 2236 patients with CD, of whom 1050 (47.0%) had granulomas (granulomatous group) and 1186 (53.0%) had no granulomas (non-granulomatous group). The number of recurrences and reoperations was found to be significantly higher in the granulomatous group compared to the non-granulomatous group (OR: 1.37, 95% CI: 1.02-1.84 and OR: 2.38, 95% CI: 1.43-3.95, respectively).

Duration of disease before surgery

A number of studies have shown a higher risk of postoperative recurrence when the duration of the disease before surgery was short[1]. There were, however, different definitions of "short" among the studies.

Anastomotic configuration

The author and colleagues conducted a meta-analysis to investigate the impact of anastomotic type on the incidence of perianastomotic recurrence[5]. Eight studies reporting on 661 patients who underwent 712 anastomoses, of which 383 (53.8%) were sutured end-to-end anastomosis and 329 (46.2%) were other anastomotic configurations were included. There was no significant difference between the anastomotic configurations in perianastomotic recurrence and reoperation for perianastomotic recurrence. Furthermore, a recent randomized controlled trial (RCT)[8] compared endoscopic and symptomatic recurrence rates between patients who had stapled side-to-side anastomosis and hand-sewn end-to-end anastomosis. The endoscopic recurrence rate was 42.5% in the end-to-end anastomosis group compared with 37.9% in the side-to-side anastomosis group (not significant). The symptomatic recurrence rate was 21.9% in the end-to-end anastomosis group compared with 22.7% in the side-to-side anastomosis group (not significant). Based on these results, the anastomotic technique following bowel resection does not seem to affect postoperative recurrence.

Other factors

The following factors do not seem to be predictive of postoperative recurrence: age at onset of disease, sex, family history of CD, anatomical site of disease, length of resected bowel, blood transfusions and postoperative complications[1].

In summary, risk factors for postoperative recurrence are smoking, perforating disease and granuloma in the resection specimen.

ENDOSCOPIC FINDINGS AFTER SURGERY

Rutgeerts *et al*[9] reported that recurrent lesions were observed endoscopically in the neo-terminal ileum (the proximal site of the ileocolonic anastomosis) within 1 year of resection in 73% of patients, although only 20% of the patients had symptoms. Three years after surgery, the endoscopic recurrence rate increased to 85% and symptomatic recurrence occurred in 34%. In their study[9], patients with severe endoscopic lesions within 1 year after resection developed early clinical recurrence. In contrast, patients with no or mild endoscopic lesions had a low frequency of subsequent clinical recurrence. The severity of the endoscopic inflammation in the neo-terminal ileum during the first year after resection was found to be a reliable predictive risk factor for future clinical recurrence.

The Rutgeerts score is a well-established endoscopic scoring system based on examination of the neo-terminal ileum; i0: no lesions; i1: < 5 aphthous lesions; i2: > 5 aphthous lesions with normal mucosa between lesions, or skip areas of larger lesions or lesions confined to < 1 cm from the ileocolonic anastomosis; i3: diffuse aphthous ileitis with diffusely inflamed mucosa; and i4: diffuse inflammation with larger ulcers, nodules, and/or narrowing[9]. This scoring system is widely used in clinical practice, and endoscopic recurrence after resection for CD is defined as a score of i2, i3, or i4.

The author and colleagues[10] conducted a prospective study to investigate the relationship between endoscopic findings in the neo-terminal ileum (the proximal site of the anastomosis) and subsequent clinical recurrence rates following ileocolonic resection for CD. Forty patients who had maintained clinical remission defined as CD activity index (CDAI)[11] < 150 with 3 g/d mesalamine during 6 mo

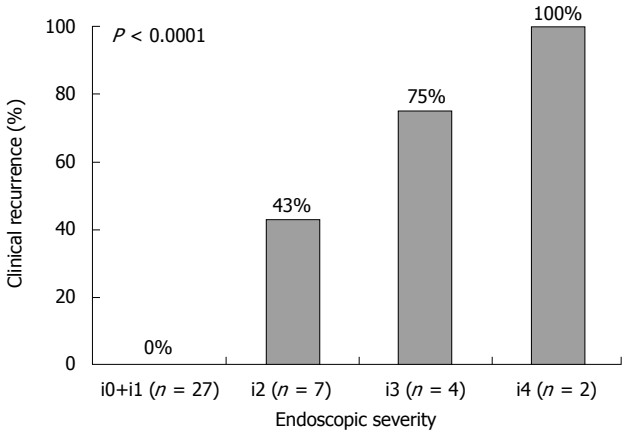

Figure 1 Correlation between the endoscopic severity in the neo-terminal ileum at 6 mo after ileocolonic resection and the clinical recurrence rate during the following 1 year.

after ileocolonic resection were studied. Six months after surgery, ileo colonoscopy was performed, and the endoscopic activity score in the neo-terminal ileum was determined according to the Rutgeerts score. All patients were regularly monitored, and clinical disease activity was assessed. Clinical recurrence was defined as CDAI ⩾ 150. Corticosteroids, immunosuppressants or tumor necrosis factor (TNF)-α blocking agents were not given unless there was clinical recurrence. Six months after surgery, the endoscopic scores were i0 or i1 in 27 patients, i2 in 7 patients, i3 in 4 patients, and i4 in 2 patients. There was a significant positive correlation between the endoscopic severity of the neo-terminal ileum 6 mo after surgery and the clinical recurrence rate during the following 1 year (Figure 1). From these results, the assessment of endoscopic lesions in the neo-terminal ileum appeared to be valuable for predicting subsequent clinical recurrence after ileocolonic resection for CD. Patients who postoperatively develop early endoscopic lesions despite mesalamine therapy do not benefit from continuing mesalamine. For such patients, more aggressive therapies such as TNF-α blocking agents should be considered. Thus, the early endoscopic inflammation in the neo-terminal ileum after ileocolonic resection is a suitable model to investigate the pathogenesis of CD, and also to evaluate new therapeutic modalities for prevention of progressive recurrence.

MEDICAL TREATMENT FOR PREVENTION OF POSTOPERATIVE RECURRENCE

Mesalamine, antibiotics, immunosuppressants, elemental diet

A Cochrane systematic review[12] was conducted to investigate the efficacy of medical therapies for the prevention of postoperative recurrence of CD. Twenty-three RCTs that compared medical therapy with placebo or other medical agents for the prevention of recurrence were included. Mesalamine therapy was associated with a significantly reduced risk of clinical recurrence [relative risk (RR): 0.76, 95% CI: 0.62-0.94, number needed to treat (NNT) = 12], and severe endoscopic recurrence (RR: 0.50, 95% CI: 0.29-0.84, NNT = 8) when compared with placebo. Nitroimidazole antibiotics appeared to reduce the risk of clinical recurrence (RR: 0.23, 95% CI: 0.09-0.57, NNT = 4) and endoscopic recurrence (RR: 0.44, 95% CI: 0.26-0.74, NNT = 4) when compared with placebo. However, these agents were associated with a higher risk of serious adverse events (RR: 2.39, 95% CI: 1.5-3.7). Azathioprine/6-mercaptopurine (6-MP) was also associated with a significantly reduced risk of clinical recurrence (RR: 0.59, 95% CI: 0.38-0.92, NNT = 7) and severe endoscopic recurrence (RR: 0.64, 95% CI: 0.44-0.92, NNT = 4) when compared with placebo. Neither agent had a higher risk than placebo of serious adverse events. When compared to azathioprine/6-MP, mesalamine was associated with a higher risk of any endoscopic recurrence (RR: 1.45, 95% CI: 1.03-2.06), but a lower risk of serious adverse events (RR: 0.51, 95% CI: 0.30-0.89).

The author and colleagues[13] conducted a prospective non-RCT to investigate the impact of enteral nutritional therapy with elemental diet on postoperative recurrence of CD. After resection, 20 patients continuously received enteral nutritional therapy (EN group), and 20 had neither nutritional therapy nor food restriction (non-EN group). In the EN group, an elemental diet was infused through a nasogastric tube in the night-time, and low fat foods were taken in the daytime. The clinical recurrence rate during 1-year follow-up was significantly lower in the EN group than in the non-EN group (5% *vs* 35%). One year after surgery, the endoscopic recurrence rate was also significantly lower in the EN group than in the non-EN group (30% *vs* 70%). We found that enteral nutrition significantly reduced postoperative clinical and endoscopic recurrences. However, an RCT with a larger number of patients is necessary to assess the definite efficacy of enteral nutritional therapy for the prevention of postoperative recurrence.

Infliximab

Infliximab is a recombinant anti-TNF-α antibody, and it reduces intestinal inflammation in patients with CD by binding to and neutralizing TNF-α on the cell membrane and in the blood, and by destroying TNF-α producing cells. Infliximab is indicated for treatment of moderately to severely active CD for the reduction of signs and symptoms in patients who have an inadequate response to conventional medications. In maintenance studies[14-16], a re-treatment regimen of infliximab can provide long-term suppression of disease activity in patients with CD. At the present time, infliximab is one of the most effective medications in the management of CD. However, the impact of infliximab on recurrence in the postoperative setting had not yet been reported.

Recently, Sorrentino *et al*[17] conducted a prospective pilot study, in which infliximab was administered after surgery along with low-dose methotrexate, while controls were treated with mesalamine alone. Infliximab was given as an intravenous infusion (5 mg/kg), with an intravenous

100 mg bolus of hydrocortisone starting from 2 wk after surgery, followed by standard maintenance treatment (2, 6, and then every 8 wk) and therapy with low-dose methotrexate (10 mg/wk, orally). Patients in the control group were given mesalamine-coated tablets, 800 mg 3 times daily, starting from 2 wk after surgery. In the group treated with infliximab and low-dose methotrexate, none of 7 patients had endoscopic or clinical recurrence during 2 years after surgery. In contrast, in the group treated with mesalamine, only 4 of the 16 patients (25%) were disease free during 2 years after surgery. Among 12 patients with recurrent disease, 7 had endoscopic recurrence, while 5 had both endoscopic and clinical recurrences.

Subsequently, Regueiro *et al*[18] conducted a randomized, double-blind, placebo-controlled trial. Twenty-four patients with CD who had undergone ileocolonic resection were allocated to receive intravenous infliximab (5 mg/kg, n = 11), administered within 4 wk of surgery and continued for 1 year, or placebo (n = 13). The primary endpoint was endoscopic recurrence (Rutgeerts score of i2, i3, or i4) at 1 year. Secondary end points were clinical recurrence (CDAI > 150) and histologic recurrence (scoring system according to D'Haens[19]). The endoscopic recurrence rate at 1 year was significantly lower in the infliximab group (9.1%) compared with the placebo group (84.6%). There was a non-significantly lower proportion of patients with clinical recurrence in the infliximab group (20.0%) compared with the placebo group (46.2%). The histologic recurrence rate at 1 year was significantly lower in the infliximab group (27.3%) compared with the placebo group (84.6%). From these results, 1-year infliximab treatment after surgery was effective for preventing endoscopic and histologic recurrences of CD. Albeit a small sample size, this study provides the strongest evidence for the efficacy of postoperative infliximab therapy.

EFFICACY OF INFLIXIMAB FOR EARLY ENDOSCOPIC LESIONS

Infliximab may be useful for the prevention of postoperative recurrence of CD[17,18]. However, this new agent cannot be recommended for all patients after surgery because of potential adverse events and high medical costs. A number of patients can maintain remission without medications or with mesalamine after surgery as shown in our study[10]. Infliximab should be used for patients at high risk of postoperative recurrence. Although smoking and perforating disease are risk factors for recurrence[1-3], these parameters are not so useful and are of limited use in clinical practice. A more practical predictor of postoperative recurrence is the severity of endoscopic inflammation in the early postoperative period[9,10].

Recently, the author and colleagues[20] conducted a prospective pilot study to investigate the efficacy of infliximab on early endoscopic recurrence after ileocolonic resection. Twenty-six patients maintaining clinical remission (CDAI < 150) with mesalamine (Pentasa® 3 g/d) after surgery showed endoscopic recurrence (Rutgeerts score of i2, i3, or i4) in the neo-terminal ileum at 6 mo postoperatively (study baseline). Patients were then allocated to one of 3 treatment groups. In Japan, azathioprine and infliximab maintenance therapy was approved by the Ministry of Health, Labor and Welfare quite recently (in June 2006, and November 2007, respectively). During the first study period (from January 2005 to June 2006), patients were continuously treated with mesalamine (Pentasa® 3 g/d) (mesalamine group, n = 10) for the following 6 mo. During the second period (from June 2006 to June 2007), azathioprine therapy (Imuran® 50 mg/d) was used (azathioprine group, n = 8), and during the last period (from June 2007 to May 2008), infliximab therapy (Remicade® 5 mg/kg, every 8 wk) was introduced (infliximab group, n = 8). In each treatment group, administration of azathioprine or infliximab was started at 6 mo after surgery, and then continued for 6 mo. At baseline and 6 mo later, endoscopic examination was conducted for all patients. During the 6-mo observation, no patients in the infliximab group, 3 (38%) in the azathioprine group, and 7 (70%) in the mesalamine group developed clinical recurrence (CDAI $\geqslant$ 150, P = 0.01). At 6 mo, endoscopic inflammation was improved in 75% of patients in the infliximab group, 38% in the azathioprine group, and 0% in the mesalamine group (P = 0.006). Complete mucosal healing was achieved in 38% of patients in the infliximab group, 13% in the azathioprine group, and 0% in the mesalazine group (P = 0.10). These results clearly showed that infliximab therapy reduced clinical and endoscopic disease activity in patients with early endoscopic recurrence after surgery.

Our infliximab therapy was started at 6 mo after surgery when endoscopic recurrence was confirmed[20]. However, our clinical and endoscopic disease activity at 1 year after surgery was similar to that in Regueiro's study[18]. These results indicate that a 6-mo postoperative observation period does not adversely affect the efficacy of infliximab. It is reasonable to identify patients who require infliximab treatment according to endoscopic findings at 6 mo after surgery.

Sorrentino *et al*[21] studied 12 consecutive patients who maintained clinical and endoscopic remission with maintenance infliximab (5 mg/kg) for 24 mo after surgery, and whose infliximab treatment was discontinued. At 4 mo after discontinuation of infliximab, 10 of the 12 patients (83%) developed endoscopic recurrence (Rutgeerts score of i2, i3, or i3). The 10 patients were treated again with infliximab (3 mg/kg, every 8 wk), and then mucosal integrity was restored and maintained for 1 year. From their findings, long-term maintenance therapy with infliximab is required to maintain mucosal integrity in patients after surgery for CD. However, a dose of 3 mg/kg (a 40% reduction from the standard dose) was sufficient to avoid endoscopic recurrence.

Management strategy for prevention of postoperative recurrence

Our management strategy for the prevention of recur-

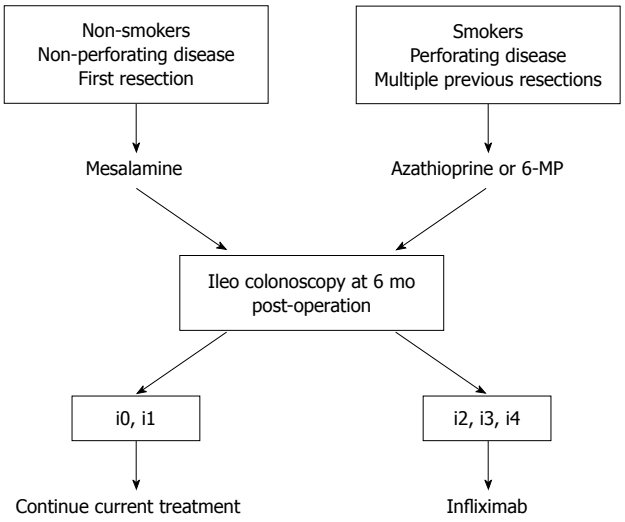

Figure 2 Algorithm for prophylactic medical treatment after ileocolonic resection in patients with Crohn's disease. 6-MP: 6-mercaptopurine.

rence after ileocolonic resection is presented in Figure 2. As a Cochrane review[12] has shown that azathioprine and 6-MP are effective for preventing post-operative recurrence, for patients with known risk factors for recurrence such as smoking, perforating disease, and multiple previous resections, treatment with azathioprine or 6-MP should be started soon after surgery. Patients without these risk factors are treated with mesalamine. At 6 mo after surgery, ileo colonoscopy should be conducted in all patients, and the severity of macroscopic inflammation in the neo-terminal ileum assessed. In patients with no or mild endoscopic lesions (Rutgeerts score of i0 or i1), current management can be continued. However, we recommend repeat endoscopic examination 6 mo later for early detection of endoscopic lesions. For patients who develop early endoscopic lesions (Rutgeerts score of i2, i3, or i4) at 6 mo after surgery despite optimal mesalamine or immunosuppressant therapy, infliximab treatment should be considered.

CONCLUSION

Infliximab therapy showed clear suppressive effects on clinical and endoscopic disease activity in patients with early endoscopic lesions after ileocolonic resection for CD. These data strongly suggest that infliximab can delay the timing of postoperative recurrence and reduce recurrence rates by improving endoscopic inflammation. Patients with early endoscopic lesions are good candidates for infliximab therapy after surgery. However, RCTs with a larger number of patients and a longer duration of follow-up are necessary to more accurately evaluate the efficacy of infliximab in early endoscopic lesions after surgery for CD.

Abstract

The existence and composition of the lateral ligaments of the rectum (LLR) are still the subjects of anatomical confusion and surgical misconception up to now. Since Miles proposed abdominoperineal excision as radical surgery for rectal cancer, the identification by "hooking them on the finger" has been accepted by many surgeons with no doubt; clamping, dividing and ligating are considered to be essential procedures in mobilization of the rectum in many surgical textbooks. But in cadaveric studies, many anatomists could not find LLR described by the textbooks, and more and more surgeons also failed to find LLR during the proctectomy according to the principle of total mesorectal excision. The anatomy of LLR has diverse descriptions in literatures. According to our clinical observations, the traditional anatomical structures of LLR do exist; LLR are constant dense connective bundles which are located in either lateral side of the lower part of the rectum, run between rectal visceral fascia and pelvic parietal fascia above the levator ani, and covered by superior fascia of pelvic diaphragm. They are pathways of blood vessels and nerve fibers toward the rectum and lymphatic vessels from the lower rectum toward the iliac lymph nodes.

Key words: The lateral ligaments of the rectum; Anatomy; Total mesorectal excision; Abdominoperineal excision; Fascia

INTRODUCTION

Surgical approaches in the treatment of rectal cancer have undergone great changes over the past decades. Technical aspects have been studied and reviewed extensively in an attempt to reduce local recurrences and to decrease the incidence of urinary and sexual morbidity, but the existence and composition of the lateral ligaments of the rectum (LLR) are still the subjects of anatomical confusion and surgical misconception up to now[1,2].

Since Miles proposed abdominoperineal excision (APR) as radical surgery for rectal cancer in 1908, APR has been rapidly accepted as a standard surgical strategy for rectal cancer[3]. Since then, most colorectal surgeons accepted that LLR is the pathway of blood vessels and nerve fibers toward the rectum and lymphatic vessels from the lower rectum toward the iliac lymph nodes, and clamping, dividing and ligating LLR are standard and indispensable procedures during APR, which are described in classical surgical textbooks[4-6].

Interestingly, based on cadaveric studies, many anatomists have intensively investigated the anatomy of LLR, but they could not find LLR described in the classical

surgical textbooks[7-10]. In 1982, Heald *et al*[11] demonstrated that total mesorectal excision (TME) alone could lead to a low rate of recurrence of rectal cancer in the pelvis and a high disease-free survival rate. But Heald and others described the sharp dissection of TME under direct view but did not mention LLR at all[12-16]. This phenomenon seemingly testified many anatomists' findings based on cadaveric studies, but many surgeons still remain with confusion and misconception about the anatomy of LLR.

CLINICAL VIEWS ABOUT THE ANATOMY OF LLR

In the past decades, the surgical approach to the treatment of rectal cancer has been greatly refined, and from a gross, blunt, and blind dissection with flush clamping of lateral expansions, it has become a more accurate and less radical procedure. All of these improvements are related to a better understanding and a wider knowledge of the clinical anatomy of the pelvis[17-24]. But there are different interpretations, and clinical studies about the anatomy of LLR still present quite diverse, and sometimes contradictory descriptions[25-28]. The existence and composition of LLR are also issues with considerable controversies[29-31].

In the history of radical surgery of rectal cancer, APR, proposed by Miles in 1908, was undoubtedly a breakthrough which greatly improved the outcomes of rectal cancer treatment[32]. He had already referred to LLR while explaining his dissection procedure, stating that the dissection is carried downward on either side until the upper surface of the levator ani muscles is reached. LLR, which is recognized as a firm vertical band of fascia, requires dissection with scissors[33]. He described that, LLR consists, on either side, of a broad band of dense connective tissues, which passes outward from the lateral walls of the rectum toward the base of the bladder at the point where the ureters terminate[34]. Afterwards, APR was rapidly accepted as a standard surgical strategy for middle and lower rectal cancer.

Goligher *et al*[35] also recognized LLR in a process of dissection around the rectum. LLR appears lateral to the mid-rectum after dissection on the anterior and posterior sides of the rectum is completed. He stressed that the lateral ligament can be clamped between the middle and index fingers of the left hand and then sharply severed. Based on Miles description and many surgeons' clinical experiences, LLR is considered to be a definitely existing anatomical structure, which is the pathway of blood vessels and nerve fibers toward the rectum and lymphatic vessels from the lower rectum toward the iliac lymph node, and clamping, dividing and ligating are required for LLR during APR. For a long time, there have been no controversies about LLR among surgeons.

The technique of TME advocated by Heald *et al*[12] in 1982 is another breakthrough of radical surgery of rectal cancer, which could lead to an amazing low rate of recurrence of rectal cancer in the pelvis and a high disease-free survival rate. Since then, TME has become a basic principle in radical surgery of rectal cancer, and anterior resection (AR) has gradually accepted to be a main surgical therapeutic strategy[36-38]. But in their articles, they did not mention LLR at all, neither did they do so in the subsequent works. And no LLR was mentioned by many other surgeons in their descriptions of mesorectal dissection. With the principle of TME being accepted, LLR seems to be absent in proctectomy[39,40]. Presently, LLR has become almost mythical structures, and met with considerable controversies among many colorectal surgeons about its existence and composition.

CONTROVERSIAL VIEWS OF LLR AMONG ANATOMISTS

With the development of radical surgery of rectal cancer, many anatomists have been engaged in the study of the anatomy of LLR. In contradiction to the classical knowledge of LLR, most anatomists studying cadavers did not find the typical structures of LLR described in traditional surgical textbooks. Their interpretations about the anatomy of LLR are quite different. The controversy focuses on three aspects: uncertainty of the existence, confusion of the composition, and unclear anatomic position in the pelvic cavity.

Jones *et al*[41] noticed that, before TME principle was wildly applied in radical surgery of rectal cancer, identification of LLR is "hooking it on the finger" by surgeons during operation, and clamping, dividing and ligating are indispensable procedures described in surgical textbooks. In contrast, the mesorectum can be dissected by either diathermy or sharp dissection alone. In order to clarify the anatomic misconception about LLR, Jones *et al*[41] studied the anatomy of LLR according to the TME principle for embalmed pelvis. In 1998, in their study of the anatomy of LLR, they concluded that, LLR does not exist; there is no anatomical argument against sharp dissection in the mesorectal plane and as a rule, there is no vessel that requires clamping; and by "hooking the finger" into the tissue literal to the rectum, it may be that the surgeon encounters mesorectal vessels and creates an artefactual ligament. This obviously raises the concern that such blunt dissection results in mesorectal tissue being left behind and increases the risk of local recurrence and severe autonomic nerve injury[42,43].

Interestingly, by reviewing the relative literatures about LLR, and studying fresh cadavers and embalmed pelvis, Nano *et al*[44] reported their interpretations of the anatomy of LLR in 2000, and drew the following conclusions: LLR is the extensions of the mesorecturn and must be cut at their attachment at the endopelvic fascia; LLR contains fatty tissue in communication with the mesorectal fat and possibly some vessels and nerve filaments that are of little importance; LLR at the endopelvic fascia is inserted under the urogenital bundle; the middle rectal artery runs anteriorly and inferiorly in respect to LLR; LLR can be cut at their insertion on the endopelvic fascia without injuring the urogenital nervous bundle, which, however, should be kept visible during this procedure, because it crosses the middle rectal artery and runs out behind the seminal ves-

icles; the lateral aspect of the rectum receives the lateral pedicle, which consists of the nerve fibers and the middle rectal artery[45].

In 2005, through studying the anatomy of human soft cadavers, Pak-art *et al*[46] found that, in 36 hemipelvic specimens, 18 LLRs were found on the right side of the rectum and 18 were found on the left side. The location of LLR was posterolateral to the rectum. The content of LLR consisted of loose connective tissues with cluster of small nerves. No artery was detected in all specimens. The small arterioles and venules were discovered in only four specimens. They concluded that, LLR is located at posterolateral side of the rectum. Its component is loose connective tissues containing multiple small nerves.

Recently, based on dissections of 32 formalin-preserved cadavers, Lin *et al*[47] found that LLR appeared in all 32 cadavers as a bundle of dense connective tissues traversing between rectum and visceral fascia instead of a pelvic sidewall. No substantial tissue strand except pelvic splanchnic nerves was found between visceral fascia and parietal fascia at the same level. The middle rectal artery was observed in only 18 of 64 pelvic-halves. The constant component of LLR was the rectal branches from the pelvic plexus, whereas the middle rectal artery was almost invisible in LLR. They concluded that, during total mesorectal excision, it is impossible to reveal LLR in correct surgical plane. The entire rectum may be mobilized without the need for ligating the middle rectal artery. The clinical significance of LLR is that, during lateral dissection, if LLR is identified, the surgical plane is medial to the visceral fascia, thus the incorrect surgical plane appears.

Obviously, these diverse descriptions and interpretations of the anatomy of LLR by the anatomists inevitably convey confusion and misconception to clinical colorectal surgeons. Meanwhile, their studies undoubtedly contribute to reveal the true nature of the anatomy of LLR.

OUR PERSPECTIVE OF THE ANATOMY OF LLR

According to our clinical observations based on hundreds of cases of AR and APR per year, the anatomical structures of LLR described by Miles and Goligher *et al* do exist, which were repeatedly testified by colorectal surgeons who performed traditional APR[48-51] (Figure 1). Because their descriptions of the anatomy of LLR were entirely based on clinical experience, and they had no idea about the concept of inter-fasciale at their time, during their blind and blunt surgical procedures, they failed to describe the precise anatomical position of LLR[52]. In fact, the structures of LLR are entirely covered by endopelvic fascia according to the modern anatomical point of view[53-57]. In other words, they are outside inter-fasciale, which is a correct surgical plane according to the TME principle. We believe that this is an important reason why LLR is rarely referred to after TME principle was adopted in radical surgery for rectal cancer.

Based on our surgical observation, we found that LLRs are connective bundles; their components include

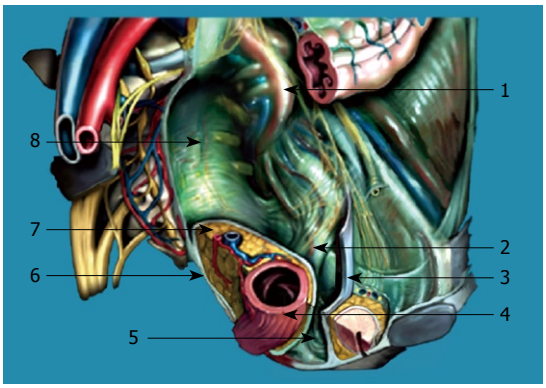

Figure 1 Illustration of the anatomy of the lateral ligament of the rectum. 1: Internal iliac artery; 2: Lateral ligament of the rectum; 3: Denonvilliers' fascia; 4: Distal part of the rectum; 5: Inter-fascial space around the distal rectum; 6: Waldeyer fascia; 7: Mesorectum; 8: Presacral fascia.

middle rectal arteries from internal iliac arteries, the rectal branches from the pelvic plexus, lymphatic vessels, some soft connective tissues and endopelvic fascia; they run between rectal visceral fascia and pelvic sidewall parietal fascia, covered by superior fascia of pelvic diaphragm above the levator ani, and terminate into the base of the distal part of the rectum laterally. Thus, LLR is a constant anatomical structure, which is the pathway of blood vessels and nerve fibers toward the rectum and lymphatic vessels from the lower rectum toward the iliac lymph nodes. The position of LLR is much lower than the surgeons thought to be. Presently, AR has been accepted as a main surgical therapeutic strategy for rectal cancer, LLR seldom needs to be treated during operation. We believe this is another important reason why LLR is rarely described by modern colorectal surgeons.

According to our clinical observations, the rectal visceral fascia extends along the pelvic cavity in the ventrodorsal direction, forming a continuous "hammock-like" sheath, enveloping the rectum[58,59]. Inside the inter-fasciale between rectal visceral and pelvic parietal fascia, there is a continuous soft connective tissue layer which is a potential surgical plane containing no real ligation structures (Figure 2). These anatomical observations were testified by the study of Jones *et al*[42]. And at the middle part of the rectum, LLR described by Nano *et al*[44] is actually artifacts due to not strictly mobilizing the rectum along inter-fasciale between visceral and parietal fascia. But at the lower part of the rectum near the pelvic floor, either side of the rectum receives the lateral pedicle, which consists of nerve fibers and the middle rectal artery (Figure 3). In fact, what they called the lateral pedicle of the rectum is the real LLR described in classical surgical textbooks. Up to now, most anatomists do not acknowledge that LLR can be hooked by the finger of traditional colorectal surgeons. We believe that the real reason is that, LLR described in classical surgical textbooks is located away from where the anatomists are looking for. When they look for some structures without clear location, they may either see nothing, or mistakenly recognize other things as the structures they have already known.

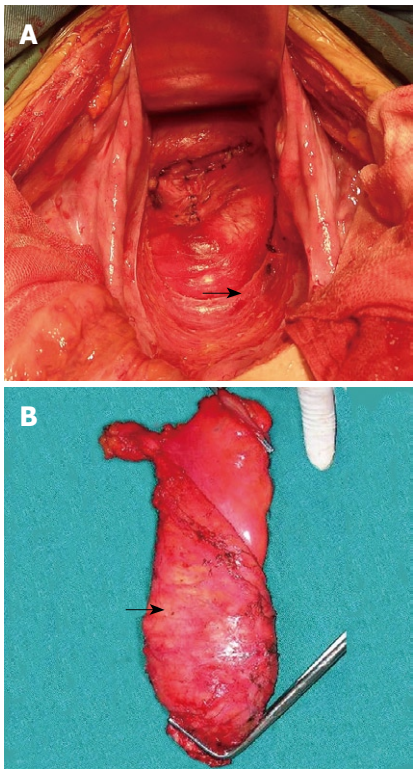

Figure 2 Operative photographs of open total mesorectal excision of rectal cancer. A: Under open surgery view, no ligament structures can be revealed in a correct surgical plane. Arrow indicates parietal pelvic fascia; B: Rectum has been removed completely. Arrow indicates rectum visceral fascia, and the rectum visceral fascia extends around the rectum, forming a continuous "hammock-like" sheath.

CONCLUSION

The existence and composition of LLR are still issues with considerable controversies up to now. Based on our surgical observations, we conclude that, LLRs are constant anatomical structures, which are pathways of blood vessels and nerve fibers toward the rectum and lymphatic vessels from the lower rectum toward the iliac lymph nodes; their components include middle rectal arteries, the rectal branches from the pelvic plexus, lymphatic vessels, some soft connective tissues and endopelvic fascia; their positions are at lateral to either side of the lower part of the rectum; they run between rectal visceral fascia and pelvic parietal fascia, covered by superior fascia of pelvic diaphragm above the levator ani, and terminate into the base of the distal part of the rectum laterally. From these observations, we deduce that, during total mesorectal excision, it is difficult to reveal LLR in a correct surgical plane; the entire rectum may be mobilized between visceral and parietal fascia without the need for ligating LLR; and in the process of AR and APR, we should protect the integrity of rectal visceral fascia and pelvic parietal fascia to avoid the risk of local recurrence and severe autonomic nerve injury[60-62].

Abstract

AIM: To monitor the early responses to irradiation in primary and metastatic colorectal cancer (CRC) with ^{18}F-fluorothymidine (^{18}F-FLT) and ^{18}F-fluorodeoxyglucose (^{18}F-FDG) small-animal position emission tomography (micro-PET).

METHODS: The primary and metastatic CRC cell lines, SW480 and SW620, were irradiated with 5, 10 and 20 Gy. After 24 h, the cell cycle phases were analyzed. A dual-tumor-bearing mouse model of primary and metastatic cancer was established by injecting SW480 and SW620 cells into mice. micro-PET with ^{18}F-FLT and ^{18}F-FDG was performed before and 24 h after irradiation with 5, 10 and 20 Gy. The region of interest (ROI) was drawn over the tumor and background to calculate the ratio of tumor to non-tumor (T/NT) in tissues. Immunohistochemical assay and Western blotting were used to examine the levels of integrin β_3, Ki-67, vascular endothelial growth factor receptor 2 (VEGFR2) and heat shock protein 27 (HSP27).

RESULTS: The proportion of SW480 and SW620 cells in the G_2-M phase was decreased with an increasing radiation dose. The proportion of SW480 cells in the G_0-G_1 phase was increased from 48.33% ± 4.55% to 87.09% ± 7.43% ($P < 0.001$) and that of SW620 cells in the S-phase was elevated from 43.57% ± 2.65% to 66.59% ± 7.37% ($P = 0.021$). In micro-PET study, with increasing dose of radiation, ^{18}F-FLT uptake was significantly reduced from 3.65 ± 0.51 to 2.87 ± 0.47 ($P = 0.008$) in SW480 tumors and from 2.22 ± 0.42 to 1.76 ± 0.45 ($P = 0.026$) in SW620 tumors. ^{18}F-FDG uptake in SW480 and SW620 tumors was reduced but not significantly ($F = 0.582$, $P = 0.633$ *vs* $F = 0.273$, $P = 0.845$). Dose of radiation was negatively correlated with ^{18}F-FLT uptake in both SW480 and SW620 tumors ($r = -0.727$, $P = 0.004$; and $r = -0.664$, $P = 0.009$). No significant correlation was found between ^{18}F-FDG uptake and radiation dose in SW480 or SW620 tumors. HSP27 and integrin β_3 expression was higher in SW480 than in SW620 tumors. The T/NT ratio for ^{18}F-FLT uptake was positively correlated with HSP27 and integrin β_3 expression ($r = 0.924$, $P = 0.004$; and $r = 0.813$, $P = 0.025$).

CONCLUSION: ^{18}F-FLT is more suitable than ^{18}F-FDG in monitoring early responses to irradiation in both primary and metastatic lesions of colorectal cancer.

Key words: ^{18}F-fluorothymidine; ^{18}F-fluorodeoxyglucose; Irradiation; Positron emission tomography; Colorectal cancer

INTRODUCTION

Radiation therapy has long been used for curative or palliative management of colorectal cancer (CRC) patients[1,2]. However, some patients undergoing radiotherapy might present primary CRC lesions as well as metastatic lymph nodes. The current method for assessing the response of a solid tumor to radiotherapy is to measure the change in tumor size on anatomical imaging modalities. It takes weeks to months to detect the change, so it is difficult to evaluate early responses to therapy *via* morphological means. Noninvasive methods for monitoring early responses to radiotherapy would be of great value in individualized treatment.

Positron emission tomography (PET) is a quantitative molecular imaging technique that allows for noninvasive *in vivo* imaging and quantification of biological processes[3-5]. ^{18}F-fluorodeoxyglucose (^{18}F-FDG) is the most widely used PET tracer and has become an indispensable staging modality for many types of cancer. However, ^{18}F-FDG may be unsuitable for monitoring the response after radiotherapy, because increased uptake can appear in inflammatory lesions and fibrosis[6-8].

^{18}F-fluorothymidine (^{18}F-FLT) is a pyrimidine analogue that uses the salvage pathway of DNA synthesis to reveal cell proliferation. ^{18}F-FLT has been found useful for noninvasive assessment of the proliferation rate of several types of cancer, such as colorectal, esophageal, breast and laryngeal cancer. Imaging and measurement of proliferation with ^{18}F-FLT-PET could be a noninvasive tool to monitor the response to anticancer treatment[9,10].

Recently, many studies claimed that PET has a special promise as a biomarker for anticancer treatment, and can be used longitudinally and provide information on the whole body or tumor. Early identification of cancer patients who are responding or resistant to radiotherapy may lead to individualized therapeutic approaches and improved clinical outcomes[11]. Yang *et al*[12] found that tumor uptake of ^{18}F-FLT was reduced significantly at 24 h after radiation with 10 Gy and 20 Gy compared with ^{18}F-FDG. At 48 h after irradiation, ^{18}F-FLT uptake was further reduced, but ^{18}F-FDG uptake was reduced slightly. So, ^{18}F-FLT-PET may be a promising imaging modality for monitoring the early effects of radiation therapy.

Bearing those in mind, we wondered whether ^{18}F-FLT could be used to reflect the early response to irradiation and compared ^{18}F-FLT and ^{18}F-FDG-PET in a possible early response in CRC primary or metastatic lesions. We chose two kinds of human CRC cells, SW480 and SW620[13-15], derived from CRC primary and lymph-node metastatic lesions, respectively, in the same patient to create a dual-tumor-bearing model. PET with ^{18}F-FLT and ^{18}F-F DG was performed before and 24 h after increasing doses of irradiation. The radioactivity uptake in SW480 and SW620 tumors was investigated with small-animal (micro)-PET.

MATERIALS AND METHODS

Chemicals

RPMI1640, Leibovitz's L15 medium, and fetal bovine serum (FBS) were obtained from PAA Laboratories GmbH, Linz, Austria. All the other chemicals were of reagent grade. Cell cycle and cell apoptosis kits were from Nanjing Keygen Biotechnology. Antibodies against K-i67, a cell proliferation antigen, and anti-integrin β_3 were from Santa Cruz Biotechnology. The antibodies anti-vascular endothelial growth factor receptor 2 (VEGFR2) and anti-heat shock protein (HSP) 27 were from Abcam. The diaminobenzidine (DAB) kit was obtained from Zhongshan Biotechnology Co., Beijing, China.

Cell lines

The human CRC cell lines SW480 and SW620 were from the Institute of Cell Biology, Chinese Academy of Sciences (Shanghai, China). SW480 cells were cultured in RPMI 1640 supplemented with 10% fetal bovine serum (FBS) and 1% penicillin/streptomycin (10 000 IU/mL), at 5% CO_2 in a humidified atmosphere at 37℃. SW620 cells were cultured in L15 medium supplemented with 10% FBS and 1% penicillin/streptomycin (10 000 IU/mL) without CO_2 in a humidified atmosphere at 37℃.

Animal tumor model

Eighteen male Balb/C nude mice (6 wk old, 20 g) were obtained from the Animal Laboratory of the Chinese Academy of Sciences. Two tumors per animal were generated by inoculating 5×10^6 SW480 viable cells into nude mice on the lateral side of the left front leg and the same amount of SW620 cells on the right front leg. Mice were kept under sterile conditions with a standard light/dark cycle and had free access to food and water. Tumor size in the front legs was determined by caliper measurement at least twice a week by the formula $V = 1/2 (l \times w \times h)$ (l, length; w, width; h, height of the tumor). Micro-PET/CT scans of ^{18}F-FDG and ^{18}F-FLT uptake were performed for tumors with volumes between 100 and 500 mm^3.

X-ray irradiation

Local external beam radiation was applied using a clinical X-ray therapy unit (Precise ELEKDA, 6 MV X-ray, at a dose rate of 388 MU/min). The mice were anesthetized using 1% chloral hydrate (0.45 mg/g body weight) and

positioned prone on the scanning table. The dual tumors were locally irradiated and the other parts of the mouse body were protected from irradiation with lead shielding. For homogeneous dose distributions, antero-posterior and postero-anterior external beam radiation fields were used. When SW480 and SW620 cells arrived at 50% confluence and when tumor size was about 100-500 mm^3, cells and tumors underwent single-dose irradiation at 5 Gy (n = 6 wells or mice), 10 Gy (n = 6) and 20 Gy (n = 6), respectively. After 24 h, tumors underwent micro-PET/CT scanning. All animal experiments were carried out in accordance with the Dutch Law on Animal Experimentation and approved by the institutional committee on animal experimentation of our institution.

Flow cytometric analysis of cell cycle

At 24 h after irradiation, SW480 and SW620 cells were washed twice with phosphate-buffered saline (PBS), detached with 0.25% trypsin and fixed with 75% ethanol and stored at 4℃. Cells were centrifuged to remove 75% ethanol before cell cycle determination, washed twice with PBS and resuspended in 0.5 mL PBS. After cells were stained with propidium iodide in the dark for 10 min, DNA content was measured by flow cytometry (FACScalibur, Becton Dickinson) to obtain the percentage of cells in each phase.

PET studies and image analysis

PET images of tumors in dual-tumor-bearing mice were obtained using the small animal micro-PET/CT (Explore VISTA micro-PET/CT, GE). At 24 h after irradiation, 3 mice in each group underwent ^{18}F-FLT PET and 3 mice underwent ^{18}F-FDG PET. The mice were anesthetized and positioned prone in the scanner, and ^{18}F-FLT or ^{18}F-FDG was injected *via* the tail vein at 20 ± 1.84 MBq in 0.25 mL saline. Image data were acquired for 10 min at 1 h after injection. For image reconstruction, list-mode data were sorted into 3-D sinograms, then underwent Fourier rebinning and 2-D ordered-subset expectation maximization reconstruction with 2 iterations and 50 subsets. Image pixel size was 0.385 mm × 0.385 mm × 0.335 mm. For quantitation of tumor uptake of ^{18}F-FLT or ^{18}F-FDG, image software was used to analyze the region of interest (ROI) in reconstructed images. Three consecutive coronal slice images containing tumors were selected visually, and ROIs were drawn on the tumor and lung as background, and the ratio of tumor to background (T/NT) uptake was calculated.

Immunohistochemical and Western blotting analysis

The staining procedure has been described elsewhere[10]. Sections of two kinds of tumors were stained with hematoxylin and eosin and antibodies against anti-integrin β3 (sc-52685), anti-Ki67 (sc-52685), anti-HSP27 (ab2790), and anti-VEGFR2 (ab3968) antibody (1:100). For a negative control, the primary antibody was omitted and replaced with PBS. Specimens were examined under light microscopy. The number of integrin β3-, Ki-67-, HSP27-, and VEGFR2-positive and HE-positive cells in adjacent sections was counted in 5 randomly selected fields per section. Western blotting analysis of 150 μg protein from SW480 and SW620 tumors was performed as described earlier[15]. The antibodies were the same as described in the immunocytochemical assay. Integrin β3, Ki-67, HSP27, and VEGFR2 expression was described by gray scale analysis with the Labworks software.

Statistical analysis

Data analysis was performed using SPSS v11.5 (SPSS Inc., Chicago, IL). Percentages of cells in each cell phase after irradiation were compared by one-way ANOVA. Differences in radiotracer uptake before and after irradiation in each mouse were compared by independent-samples t test. Linear regression analysis was used to determine the correlation between radiotracer uptake and radiation dose or cell cycle phase. All data were expressed as mean ± SD. $P < 0.05$ was considered statistically significant.

RESULTS

Cell cycle analysis

We examined the effects of irradiation on cell cycle distribution by flow cytometry. At 24 h after irradiation, the proportion of SW480 cells in the G_0-G_1 phase decreased from 48.33% ± 4.55% at 0 Gy to 26.70% ± 7.09% at 5 Gy, then increased to 87.09% ± 7.43% at 20 Gy, the proportion in the S phase decreased from 33.23% ± 6.09% at 0 Gy to 12.44% ± 4.60% at 20 Gy; and that in the G_2-M phase decreased from 18.44% ± 5.67% at 0 Gy to 0.47% ± 0.34% at 20 Gy (Figure 1A). At 0-20 Gy, the proportion of SW620 cells in the G_0-G_1 phase decreased from 39.37% ± 4.37% to 20.39% ± 5.12%, and that in the S phase increased from 43.57% ± 2.65% to 66.59% ± 7.37%. The proportion in G_2-M phase decreased from 17.07% ± 3.09% to 13.02% ± 4.55% (Figure 1B).

Micro-PET/CT analysis

Micro-PET/CT scanning results of ^{18}F-FLT and ^{18}F-FDG uptake in SW480 and SW620 tumors irradiated with increasing doses are shown in Table 1 and Figure 2. Before irradiation, the T/NT ratio in the ROI for ^{18}F-FLT was higher in SW480 (3.65 ± 0.51) than in SW620 tumors (2.22 ± 0.42). At 24 h after irradiation with 20 Gy, the T/NT ratio for ^{18}F-FLT uptake was significantly decreased in both SW480 (2.87 ± 0.47, P = 0.008) and SW620 cells (1.76 ± 0.45, P = 0.026) (Figure 2A).

Before irradiation, the T/NT ratio for ^{18}F-FDG in SW480 and SW620 tumors was 2.69 ± 0.98 and 3.09 ± 1.26, respectively (P = 0.524). At 24 h after irradiation at 20 Gy, the T/NT ratio for ^{18}F-FDG uptake was reduced but not significantly (2.40 ± 0.52 and 2.89 ± 0.29, both $P > 0.05$) (Figure 2B).

Immunohistochemical and Western blotting analysis

Integrin β3, HSP27, Ki-67 and VEGFR2 proteins were all overexpressed in SW480 and SW620 tumors (Figure

Table 1 Ratio of tumor to non-tumor for ^{18}F-fluorothymidine and ^{18}F-fluorodeoxyglucose uptake in SW480 and SW620 tumors in mice (mean ± SD)

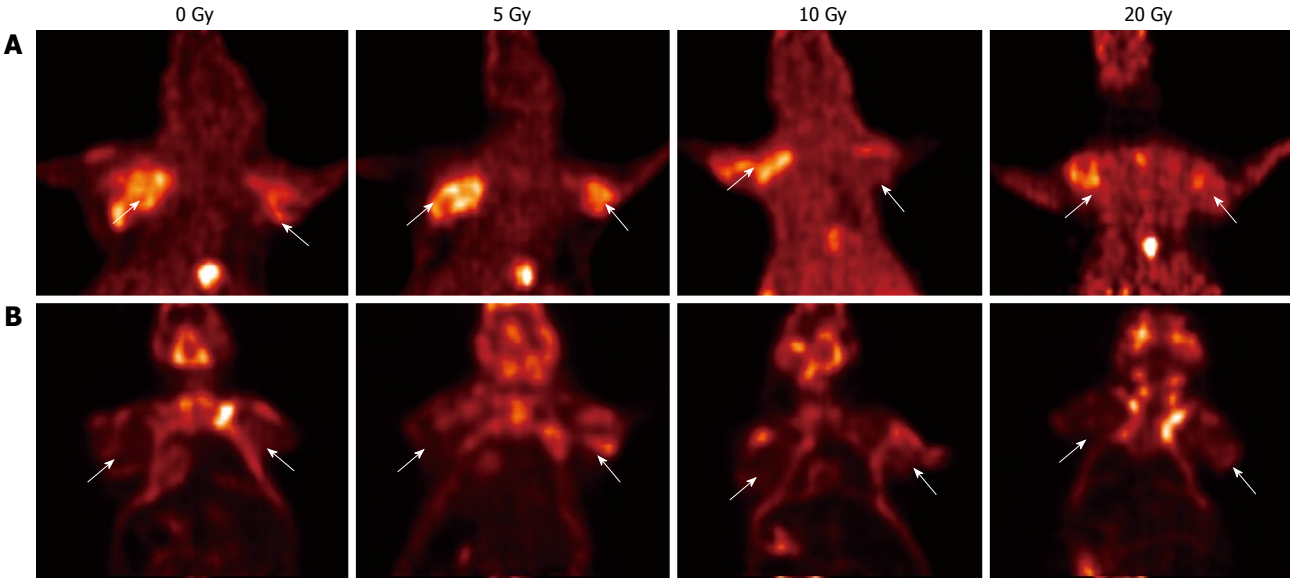

Figure 2 Coronal micro-position emission tomography sections of mice 60 min after injection with ^{18}F-fluorothymidine (A) or ^{18}F-fluorodeoxyglucose (B) before and 24 h after irradiation (3 mice/ group). Implanted tumors (arrows) are located on the left (SW480) and the right (SW620) front legs of mice. Uptake of radiotracers was normalized to lung radiotracer uptake and expressed as ratio to non-tumor (T/NT) uptake.

3). SW480 cells showed more intense staining for integrin β3 and HSP27 protein in cytoplasm or nucleus than did SW620 tumors. Integrin β3 protein was also overexpressed in the tumor matrix near vasculature. Staining for VEGFR2 and especially Ki-67 expression was lower in SW480 tumors than in SW620 tumors.

Western blotting analysis revealed that HSP27 and integrin β3 expression was higher in SW480 than in SW620 tumors (42.86% ± 5.15% *vs* 10.10% ± 3.50%, for Hsp27, $P = 0.002$; and 9.61% ± 3.20% *vs* 8.43% ± 1.85% for integrin β3, $P = 0.164$). The expression of K-i67 and VEGFR2 protein was less pronounced in SW480 than in SW620 tumors (6.5% ± 1.25% and 9.00% ± 2.38% for K-i67, $P = 0.009$; and 25.33% ± 5.59% and 19.96% ± 4.20% for VEGFR2, $P < 0.001$) (Figure 4A and B).

Linear regression analysis

We found a significant negative correlation between dose

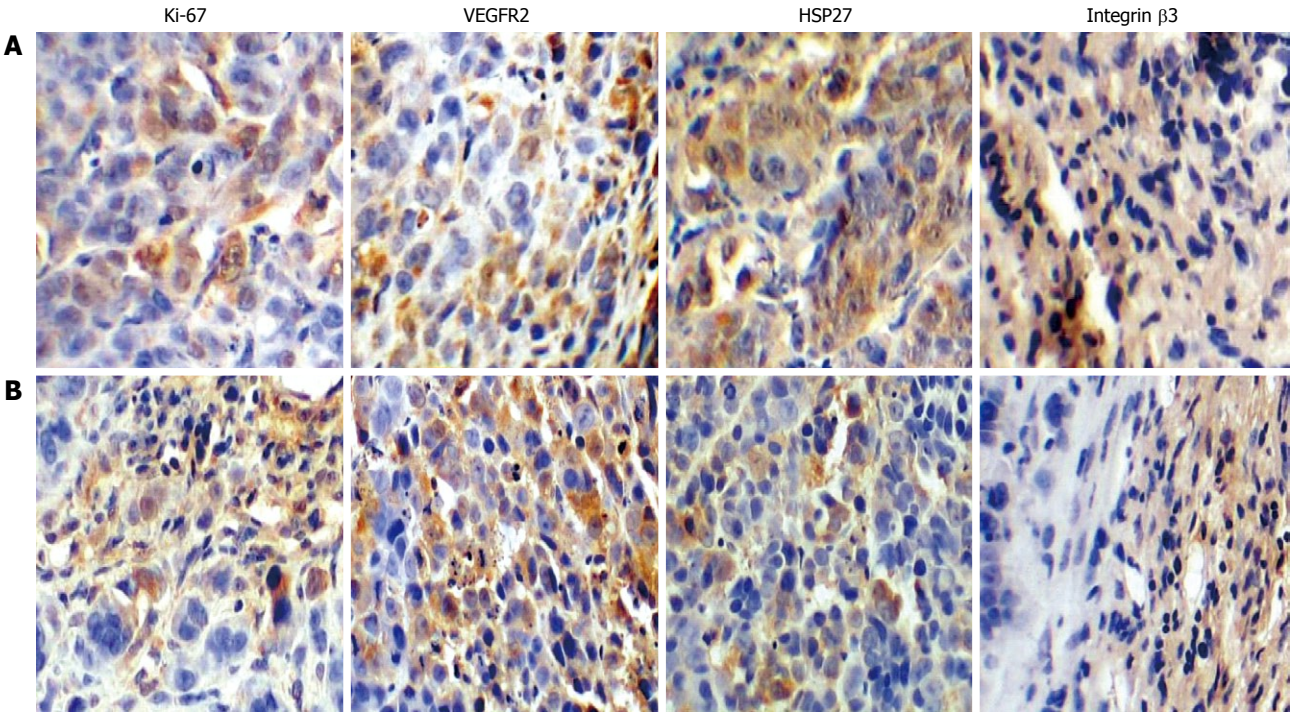

Figure 3 Immunohistochemical analysis of expression of integrin β3, K-i67, heat shock protein 27 and vascular endothelial growth factor receptor 2 protein in SW480 (A) and SW620 (B) cell lines by immunohistochemical detection (400 ×). VEGFR2: Vascular endothelial growth factor receptor 2; HSP27: Heat shock protein 27.

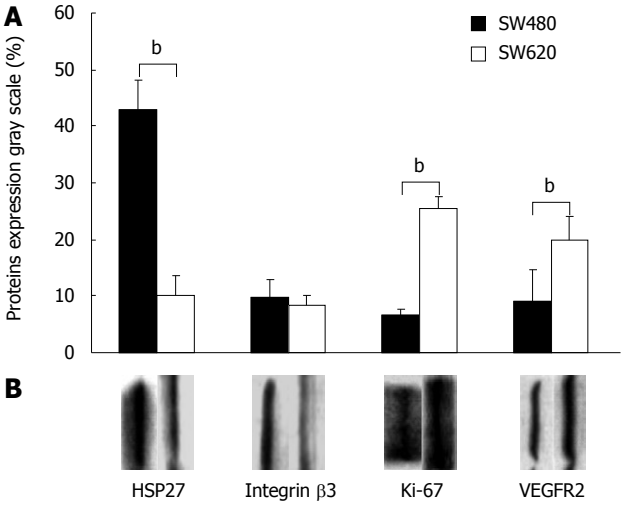

Figure 4 Western blotting analysis and quantitation of heat shock protein 27, integrin β3, Ki-67, and vascular endothelial growth factor receptor 2 protein expression in SW480 and SW620 tumors. $^{b}P < 0.01$. VEGFR2: Vascular endothelial growth factor receptor 2; HSP27: Heat shock protein 27.

of radiation and ^{18}F-FLT uptake in SW480 and SW620 tumors (r = -0.727, P = 0.004, and r = -0.664, P = 0.009, respectively). Dose of radiation was positively but not significantly correlated with ^{18}F-FDG uptake in SW480 tumors (r = 0.401, P = 0.098) and positively but significantly correlated with ^{18}F-FDG uptake in SW620 tumors (r = 0.640, P = 0.013). Dose of radiation was negatively correlated with proportion of SW480 cells in the G_2-M phase (r = -0.798, P = 0.001) and negatively but not significantly correlated with proportion of SW620 cells in the G_2-M phase (r = -0.184, P = 0.283). Dose of radiation was positively correlated with proportion of SW620 cells in the S phase (r = 0.870, $P < 0.001$) and negatively correlated with proportion of SW620 cells in the G_0-G_1 phase (r = -0.6730, P = 0.008). The T/NT ratio for ^{18}F-FLT uptake was positively correlated with integrin β_3 and HP27expression (r = 0.813, P = 0.025, and r = 0.924, P = 0.004), but not with Ki-67 or VEGFR2 expression. Similarly, the T/NT ratio for ^{18}F-FDG uptake was not significantly correlated with integrin β_3, HSP27, Ki-67 and or VEGFR2 expression.

DISCUSSION

Therapy monitoring plays a major role in the evaluation of therapeutic approaches[16-18]. ^{18}F-FDG-PET is clinically used for the diagnosis, staging and re-staging of a wide variety of tumors. However, the technique contains several shortcomings in reflecting changes in tumors after treatment, especially radiotherapy[19-22]. Several research groups have suggested that ^{18}F-FLT, as a cell proliferation tracer, is a more cancer-specific tracer than ^{18}F-FDG[23-27], but some results are contradictory[28]. In the present study, we investigated ^{18}F-FLT-PET as a potential tool for monitoring the early response to irradiation in a mouse model of dual-tumor-bearing CRC. In clinical practice, we have often found primary lesions and metastatic lymph nodes together in the same patient. A model of dual tumors created with CRC SW480 and SW620 cells is similar to clinical practice, so we compared the uptake of ^{18}F-FLT and ^{18}F-FDG in response to irradiation in the two kinds of CRC tumors.

In a micro-PET study, we found a higher uptake of ^{18}F-FLT than ^{18}F-FDG in SW480 and SW620 tumors. After irradiation for 24 h, the uptake of ^{18}F-FLT in SW480 or SW620 tumors increased at a low dose (5 Gy), then reduced gradually with increasing radiation dose. A statistical difference was found in both tumor groups although ^{18}F-FLT uptake reduced more significantly in SW480. Whereas the ^{18}F-FDG uptake was increased at a low dose (5 Gy) and reduced slightly at a high dose (20 Gy) without a significant difference. Liang *et al*[13] did not find a dose-dependent decrease in uptake of ^{18}F-FLT in tumors. However, in the current study, with a dose greater than 5 Gy, the T/NT ratio for ^{18}F-FLT uptake was dose-dependently decreased in both SW480 and SW620 tumors. A significantly negative correlation was found between dose of radiation and ^{18}F-FLT uptake in SW480 and SW620 tumors. No correlation was found between dose of radiation and ^{18}F-FDG uptake. So ^{18}F-FLT uptake can be more sensitive and accurate than ^{18}F-FDG to monitor the response to irradiation after 24 h.

Recent studies have shown that a decrease in cellular proliferation rate is one of the early events in response to tumor treatment. In the present study, after 24 h irradiation, cell cycle redistribution was found, and proliferation inhibition of the two kinds of CRC cells occurred in a dose-dependent manner, and the response to seam dose was different. G_2-M phase decrease and G0-G1 phase arrest were found earlier in SW480 than that in SW620 cells. We also found a decrease in the proportion of SW480 and SW620 cells in the S phase with the increasing radiation dose, and the dose of irradiation was negatively correlated with proportion of G_2-M phase in both kinds of cells. T/NT ratio for ^{18}F-FLT was negatively correlated with proportion of SW480 or SW620 cells in the G_2-M phase. The proportion of cells decreased in the G_0-G_1 arrest and S phases may not be important for the ^{18}F-FLT uptake decrease in SW480 and SW620 tumors.

A previous study with another tumor cell line also showed that tumor uptake of ^{18}F-FDG was decreased at 24 h after irradiation[29]. The mechanism of the increased ^{18}F-FDG and ^{18}F-FLT uptake after 24 h irradiation at a low dose (5Gy) has remained unclear. It may be due to the G_2-M or S phase arrest enhancing metabolism after irradiation in a short time. After 24 h irradiation, the two kinds of tumors were excised immediately. No necrosis formation occurred in the tumors possibly due to the short time (24 h) after radiotherapy.

In our dual-tumor-bearing animal study, the reason for the difference in ^{18}F-FLT and ^{18}F-FDG uptake in response to irradiation is not clear. The different response may be related to different biological characteristics, such as tumor marker expression. A large number of different proteins are expressed in SW480 and SW620 cell lines. In this study, we selected 4 tumor biomarkers, integrin β_3, Ki67, HSP27 and VEGFR2, known as tumor invasion, proliferation, apoptosis, angiogenesis markers, respectively[30-32]. VEGFR2 or Ki-67 expression was stronger in SW620 than in SW480 cells. In contrast, HSP27 and integrin β_3 expression was more intense in SW480 cells. The T/NT ratio for ^{18}F-FLT was significantly correlated with HSP27 and integrin β_3 expression. Tumor biomarkers play a major role in indicating tumor characteristics, exploring possible mechanisms, and in evaluating and suggesting new therapeutic approaches. The results suggest that other factors, besides proliferation, may influence the response to irradiation.

Although our study population is small, differences were found in the ^{18}F-FLT and ^{18}F-FDG uptake response in CRC to radiotherapy on PET. ^{18}F-FLT PET may be a useful noninvasive imaging modality to assess early response to irradiation in both primary and metastatic CRC lesions. ^{18}F-FLT-PET is also quick and effective in monitoring the response to irradiation in primary tumors. The capacity of ^{18}F-FLT to reveal response to irradiation within 24 h may be useful for individualizing therapy. Additional studies are being carried out to investigate other radiation doses and the mechanism among different tumor cells.

In conclusion, compared with ^{18}F-FDG-PET, ^{18}F-FLT-PET might be better in monitoring the response to 24 h irradiation in both primary and metastatic CRC lesions with increasing radiation doses.

ACKNOWLEDGMENTS

We thank Fei Gao and Ke Zou for their training in micro-PET/CT, Xue-Gang Li, Xiao-Jun Zhang and Jian Liu for synthesizing ^{18}F-FLT and ^{18}F-FDG, Ying Gang and Bao-Long Niu for irradiation dose calculations; Zi-Wen Liu and Zhi-Gang Yang for Western blotting and immunohistochemical assay, and Shan Wang for cell cycle analysis.

COMMENTS

Background

Colorectal cancer is one of the most frequently encountered malignancies in China and is associated with a high mortality rate. Irradiation therapy has long been used for curative or palliative management in colorectal cancer (CRC). When irradiation was performed, primary CRC and metastatic lymph node metastatic lesions often appear in the same patient.As it takes weeks to months to detect the change, it is difficult to evaluate the early responses to therapy *via* morphological means. Noninvasive methods for monitoring early responses to radiotherapy would be of great value in individualized treatment. So there are some questions to answer: Weather ^{18}F-fluorodeoxyglucose (^{18}F-FDG) or ^{18}F-fluorothymidine (^{18}F-FLT) could depict the difference earlier, and which is more suitable for doing so? This study was designed to investigate whether ^{18}F-FLT-PET could be used to reflect the early effect of irradiation in both CRC primary and lymph node metastatic lesions as compared with ^{18}F-FDG-PET.

Research frontiers

Recently, many studies claimed that PET has particular promise as a biomarker for anticancer therapies, can be used longitudinally and provides information on the patient or tumor. Early identification of cancer patients who are responding or resistant to radiotherapy may lead to individualized therapeutic approaches and improved clinical outcomes. ^{18}F-FLT-PET may be a promising imaging modality for monitoring the early effects of radiation therapy.

Innovations and breakthroughs

^{18}F-FLT PET may be used as a useful noninvasive imaging modality to monitor early response to irradiation for different CRCs. This is the first study to report in a new angle that ^{18}F-FLT is more helpful than ^{18}F-FDG in reflecting the early effects of irradiation in CRC primary lesions or lymph metastatic lesions.

Applications

SW480 and SW620 tumors, either primary or from metastatic lymph nodes have different responses to irradiation at early phase; ^{18}F-FLT response to irradiation is more sensitive than ^{18}F-FDG. Evaluation of the response to irradiation would be helpful for individualizing treatment and improving outcomes of CRC patients in clinical practice.

Terminology

^{18}F-FDG is the most widely used PET tracer, but it has several shortcomings in reflecting changes in tumors after treatment, especially radiotherapy. ^{18}F-FLT is a pyrimidine analogue and believed to be an agent for imaging cellular proliferation via the salvage pathway of DNA synthesis, which is closely associated with cellular proliferation. The 4 kinds of tumor biomarkers, HSP27, Integrinβ_3, VEGFR2 and Ki67, are related to tumor differentiation, invasion, angiogenesis and proliferation respectively.

Peer review

The authors investigated whether ^{18}F-FLT-PET or ^{18}F-FDG-PET could be used to reflect the early effects of irradiation in CRC primary lesions or lymph metastatic lesions. The results revealed that ^{18}F-FLT-PET might be better in monitoring the response to 24 h irradiation in both primary and metastatic CRC lesions with increasing radiation doses. The results are interesting and helpful for individualized treatment in clinical practice.

Abstract

AIM: To evaluate the role of leptin in the internal disorders during hepatic ischemia/reperfusion injury.

METHODS: A rat model of 70% hepatic ischemia/reperfusion injury was established, with groups of sham-operation (Sham), 60 min ischemia/60 min reperfusion (I60′R60′), I60′R150′, I60′R240′ and I60′R360′. Serum leptin was detected by a self-produced radioimmunoassay; serum glucose, total anti-oxidation capacity, myeloperoxidase, alanine transaminase and diamine oxidase were determined by relevant kits, while histological alterations and protein levels of leptin in the lung, liver and duodenum were examined by hematoxylin-eosin staining and immunohistochemistry. Spearman's rank correlation between leptin and other variables or grading of tissue impairment were analyzed simultaneously.

RESULTS: Serum leptin in I60′R360′ was significantly higher than in Sham and I60′R240′ groups (both $P < 0.05$), serum glucose in I60′R360′ was higher than in Sham and I60′R150′ (both $P < 0.05$), and serum total anti-oxidation capacity in I60′R240′ and I60′R360′ were higher than in Sham (both $P < 0.05$) and I60′R150′ groups (both $P < 0.01$). Serum myeloperoxidase in groups of I60′R240′ and I60′R360′ were lower than in I60′R150′group (both $P < 0.05$), serum alanine transaminase in the four reperfusion groups were higher than in the Sham group (all $P < 0.05$), while serum DAO in I60′R360′ was lower than in I60′R60′ ($P < 0.05$). Histological impairment in the lung, liver and duodenum at the early phase of this injury was more serious, but the impairment at the later phase was lessened gradually. Protein levels of leptin in the lung in the four reperfusion groups were significantly lower than in the Sham group (all $P < 0.01$), decreasing in the order of I60′R150′, I60′R60′, I60′R360′ and I60′R240′; the levels in the liver in I60′R60′ and I60′R240′ were higher than in the Sham group (both $P < 0.01$), while the levels in I60′R240′ and I60′R360′ were lower than in I60′R60′ (both $P < 0.01$); the levels in duodenum in I60′R240′ and I60′R360′ were higher than in Sham, I60′R60′ and I60′R150′ (all $P < 0.01$), while the level in I60′R150′ was lower than in I60′R60′ ($P < 0.05$). There was a significantly positive correlation between serum leptin and alanine transaminase ($\rho = 0.344$, $P = 0.021$), a significantly negative correlation between the protein level of leptin in the lung and its damage scores ($\rho = -0.313$, $P = 0.036$), and a significantly positive correlation between the protein level of leptin in the liver and its damage scores ($\rho = 0.297$, $P = 0.047$).

CONCLUSION: Endogenous leptin fluctuates in he-

patic ischemia/reperfusion injury, exerts a potency to rehabilitate the internal disorders and represents a potential target for supportive therapy.

INTRODUCTION

Hepatic ischemia/reperfusion injury is a complication of liver resection, transplantation and hypovolemic shock, which leads to local and systemic cellular damage as well as organ dysfunction[1]. Several lines of evidence suggest that the first consequence of hepatic ischemia/reperfusion injury is tissue hypoxia, which disturbs the intracellular energy metabolism and enzyme functions, resulting in depletion of adenosine triphosphate, accumulation of free radicals, and lesions in vital organs[2]. This injury is largely a result of an acute inflammatory cascade, and a certain endogenous network may exist to modulate the internal disorders. However, the conceivable mechanism has not been clarified.

Leptin is an *ob* gene-expressed protein mainly secreted by adipose tissues, with a primary role of inhibiting food intake, modulating weight balance and promoting energy metabolism[3]. Previous researches have revealed that leptin is a stress mediator after injuries, and it proceeds to maintain homeostasis by accelerating oxidation of glucose and fatty acids, alleviating reactive oxygen species-induced apoptosis, and ameliorating post-septic multiple organ dysfunction[4-6]. All these results suggest an important role for leptin in the recovery of hepatic ischemia/reperfusion injury, but there is no available report, which prompts us to study the fluctuation of leptin levels and its association with metabolic disorders as well as the functional and structural impairment in vital organs during this injury.

We established a rat model of 70% hepatic ischemia/reperfusion injury, checked serum leptin levels at different reperfusion time points, and detected serum glucose and total anti-oxidation capacity (TAC) for representing metabolic disorders. Serum myeloperoxidase (MPO), alanine transaminase (ALT), diamine oxidase (DAO) and histological alterations were evaluated in the functional and structural impairment in the lung, liver and duodenum. Protein levels of leptin were also examined in the distal, local and proximal vital organs mentioned above. Correlation analysis between serum leptin and other variables in serum, and the same analysis between tissue leptin and histological alterations in each organ were performed simultaneously. We aimed to find out the potential role for leptin in the recovery of internal disorders after hepatic ischemia/reperfusion injury.

MATERIALS AND METHODS

Animals and reagents

Three male New Zealand white rabbits (weight 1.5 ± 0.1 kg) and 45 male Sprague-Dawley rats (weight 250 ± 6.0 g) were supplied by the experimental animal center of our hospital. Animals were maintained in a room at 22-25℃ under a constant day/night rhythm and given food and water *ad libitum*. All animal experiments were carried out in accordance with the NIH Guide for Care and Use of Laboratory Animals and were approved by the Animal Care and Use Committee at our hospital.

Recombined murine leptin was purchased from PeproTech Inc. (London, UK). Complete and incomplete Freund's adjuvant was purchased from Gibco/BRL (Gaithersburg, USA). Sodium iodide ($Na^{125}I$) was purchased from Amersham Biosciences (Piscataway, USA). Immunoturbidimetric kits for serum glucose were purchased from Biosino Biotechnology and Science Inc. (Beijing, China). Colorimetric kits for serum TAC, MPO and ALT were purchased from Jiancheng Bioengineering Institute (Nanjing, China). Spectrophotometric assay for serum DAO was established and kindly provided by Professor Jun-You Li from Burns Institute, the First Affiliated Hospital of Chinese PLA General Hospital. Biotinylated anti-rabbit IgG, peroxidase-conjugated streptavidin and diaminobenzidine chromogenic kits were purchased from Zhongshan Golden Bridge Biotechnology Co. Ltd. (Beijing, China). Other reagents were purchased locally and of analytically pure grade.

Preparation of leptin antibody and iodination of leptin

New Zealand white rabbits were immunized subcutaneously with an emulsion of 120 μg leptin in 3 mL complete Freund's adjuvant for the first injection, then with another emulsion in incomplete Freund's adjuvant for four times to attain antibody. Iodination of leptin was performed according to our previous report[7]. The ^{125}I-labeled leptin with a high specific binding rate and a low fault binding rate was taken as successful iodinated antigen. They were mixed with an equal volume of 1.5% bovine serum albumin and stored at -20℃.

Establishment of a rat model of 70% hepatic ischemia/reperfusion injury

Forty-five rats were divided randomly into five groups, including sham-operation (Sham), hepatic ischemia for 60 min/reperfusion for 60 min (I60'R60'), I60'R150', I60'R240' and I60'R360', and each group contained 9 rats.

Rats were deprived of food 12 h prior to the start of experiment, with free access to drinking water *ad libitum*.

Rats were anesthetized with pentobarbital sodium (60 mg/kg, i.p.), and their abdominal skin was sterilized. After a 2-cm midline incision was made in abdomen, the portal vein, hepatic artery and bile duct of the left and middle lobes were occluded with a microvessel clip for 60 min, and then the clip was released for reperfusion. The three remaining caudal lobes retained an intact portal/arterial blood supply and venous outflow, thus preventing intestinal venous hypertension and possible leakage of bacteria or bacterial products into the circulation that would be found in 100% hepatic ischemia/reperfusion injury[8].

The portal vein, hepatic artery and bile duct of the left and middle lobes were not occluded in the rats of Sham group. The incision was closed in layers, and resuscitation with isotonic saline (30 mL/kg, i.p.) was supplied. Then, rats were sterilized with iodophor on their suture sites and released back to cages, with free access to drinking water *ad libitum*.

Preparation of serum and tissue samples

Blood was collected from the heart of rats at different time points under anesthesia with a syringe, and serum was separated from whole blood through incubating samples in 37℃ water for 20 min and centrifuged by 3000 × *g* for 10 min at 4℃. Lung, liver and duodenum samples of each rat were harvested immediately after attaining blood samples. Each tissue sample was fixed in 40 g/L neutral phosphate-buffered formaldehyde solution and embedded in paraffin, and then serial sections (4 μm thick) were made.

Measurement of serum leptin and other variables in serum

Serum leptin was measured by a self-produced radioimmunoassay according to our previous report[7], using the leptin antibody and iodinated leptin mentioned above. Serum glucose, TAC, MPO, ALT and DAO were measured by the kits or assay according to the provided protocol of the manufacturers.

Histological evaluation

Tissue sections were stained with hematoxylin and eosin, and observed under microscope to investigate histological alterations in the lung, liver and duodenum. Nine microscopic fields of each organ in each group were randomly selected, and grading of the structural impairment in each organ was evaluated according to the criteria outlined in the reference[9].

Immunohistochemistry

Protein levels of leptin in the lung, liver and duodenum were detected by immunohistochemistry. Briefly, tissue sections were collected on 0.1% poly-lysine coated slides, deparaffinized by the xylene-ethanol sequence, rehydrated in a graded ethanol scale and in phosphate buffered saline (PBS). After prior antigen retrieval by heating in a pressure cooker in citrate buffer, the slides were incubated sequentially with the self-produced leptin antibody, biotinylated anti-rabbit IgG and peroxidase-conjugated streptavidin at 37℃ for 1 h, using a dilution of 1:50, 1:200 and 1:200 in PBS. Diaminobenzidine chromogenic kits were used to develop the color.

Negative controls were set up simultaneously by replacing the leptin antibody with PBS. The images were visualized with Leica DC300F Digital Camera Systems, and 9 microscopic fields of each organ from each group were randomly selected. Image-Pro Plus 6.0 software was used to analyze the ratio of accumulated optical density of specific positive staining/specific tissue area in each image.

Statistical analysis

Stata 7.0 software (Stata Corp, USA) was used to analyze the data. One-way analysis of variance and Student's *t* test were applied for the data including serum variables and tissue leptin. Wilcoxon signed-rank test was used for the data about grading of tissue impairment. Spearman's rank correlation was selected for correlation analysis. A *P* value of less than 0.05 was chosen as a threshold for statistical significance, and all data were shown as mean ± SD.

RESULTS

Serum levels of leptin after hepatic ischemia/reperfusion injury

Serum leptin in I60'R360' was significantly higher than in Sham and I60'R240' (t = 3.410 and 2.659, both P < 0.05), while there was no significant difference in the levels among the Sham, I60'R60', I60'R150' and I60'R240' groups, as shown in Figure 1A.

Serum levels of glucose and TAC after injury

Serum glucose in I60'R360' was significantly higher than in Sham and I60'R150' (t = 2.190 and 3.286, both P < 0.05), and it was inclined to be higher than in I60'R60' (P = 0.051). No difference was observed in the levels among Sham, I60'R60', I60'R150' and I60'R240' (Figure 1B). Serum TAC in I60'R240' and I60'R360' were significantly higher than in Sham (t = 3.050 and 2.693, both P < 0.05) and I60'R150' (t = 3.566 and 3.270, both P < 0.01), while there was no difference either between the levels in I60'R240' and I60'R360' or in those among Sham, I60'R60' and I60'R150' (Figure 1C).

Serum levels of MPO, ALT and DAO after injury

Serum MPO in the four reperfusion groups was not different from that in Sham, but the levels in I60'R240' and I60'R360' were significantly lower than in I60'R150' (t = -2.259 and -2.489, both P < 0.05), while no difference was found in the levels among I60'R60', I60'R240' and I60'R360' (Figure 1D).

Serum ALT in I60'R60', I60'R150', I60'R240' and I60'R360' were significantly higher than in Sham (t = 4.132, 5.888, 5.201 and 4.359, all P < 0.01), while there was no difference in the levels among the four reperfusion groups, as shown in Figure 1E. Serum DAO in the four

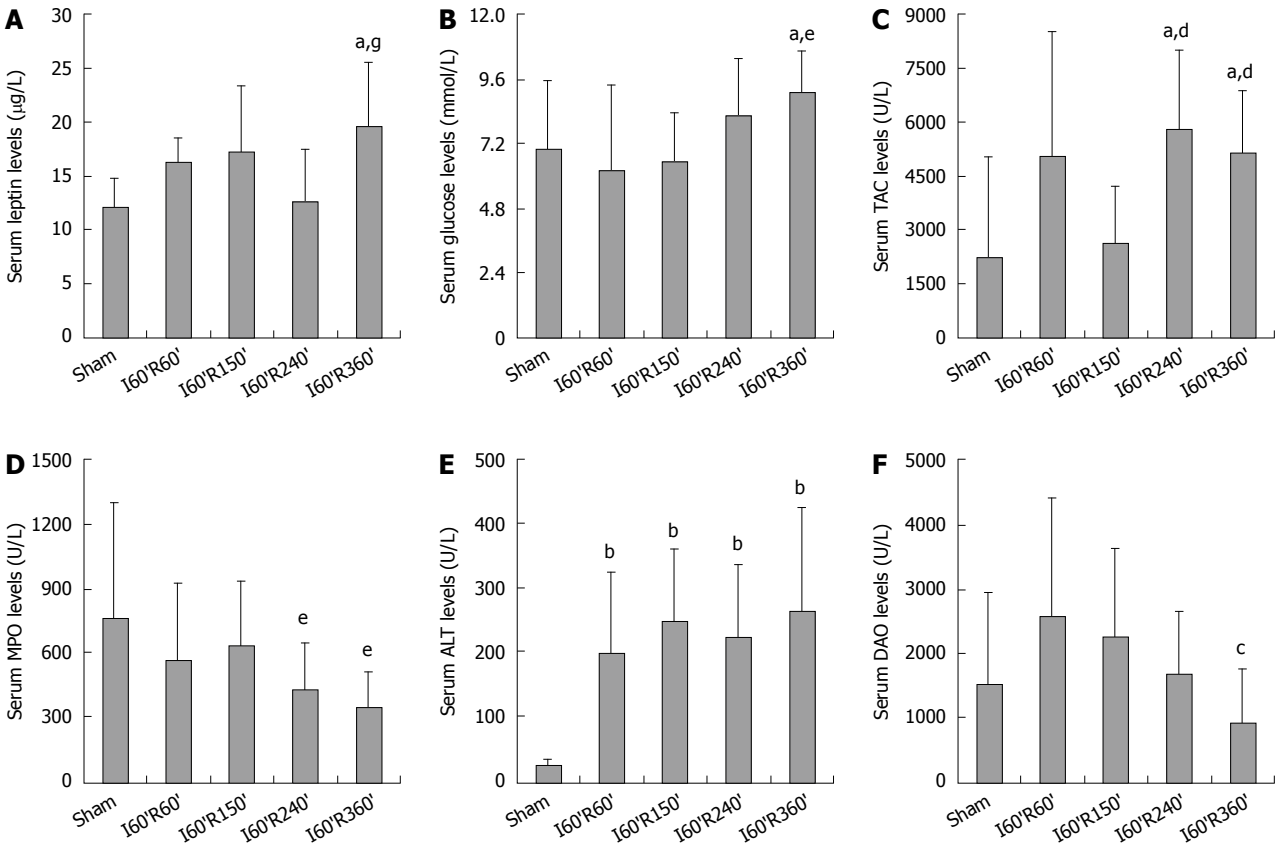

Figure 1 Serum levels of leptin (A), glucose (B), total anti-oxidation capacity (C), myeloperoxidase (D), alanine transaminase (E) and diamine oxidase (F) in the rats after injury. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* sham; $^{c}P < 0.05$ *vs* I60'R60'; $^{d}P < 0.01$, $^{e}P < 0.05$ *vs* I60'R150'; $^{g}P < 0.05$ *vs* I60'R240'. Sham: Sham-operation; I60'R60', I60'R150', I60'R240' and I60'R360': Hepatic ischemia for 60 min/reperfusion for 60, 150, 240 and 360 min; TAC: Total anti-oxidation capacity; MPO: Myeloperoxidase; ALT: Alanine transaminase; DAO: Diamine oxidase.

reperfusion groups was not different from that in Sham, but the level in I60'R360' was significantly lower than in I60'R60' (t = -2.411, $P < 0.05$), demonstrating a decreasing tendency as compared with that in I60'R150' (P = 0.086). No difference was observed in the levels among I60'R60', I60'R150' and I60'R240' (Figure 1F).

Histological alterations in lung, liver and duodenum after injury

Compared with pulmonary alterations in the Sham group after injury, alveolar walls in I60'R60' were disrupted (Figure 2, *A1*) and infiltrated by numerous inflammatory cells (*A2*), and the interstitial tissue was fulfilled with erythrocytes (*A3*). Similar but significantly alleviated alterations were observed in I60'R150' and I60'R240', while apparently minor disruption of alveolar structure, hypercellularity and vascular congestion became evident in I60'R360'. Damage scores of the lung in the four reperfusion groups were significantly higher than in the Sham (all $P < 0.01$), while the scores in I60'R150', I60'R240' and I60'R360' were significantly lower than in I60'R60' (z = -3.000, -2.810 and -2.762, all $P < 0.01$). The scores in I60'R150' and I60'R240' were significantly higher than in I60'R360' (z = 2.762 and 2.887, both $P < 0.01$), but without difference (Figure 2A).

Compared with hepatic alterations in the Sham group after injury, hepatic cords in I60'R60' were widened and arranged disorderly, hepatic sinusoids were narrowed or vanished (Figure 2, *B1*), hepatocytes were found swollen with loosened cytoplasm (*B2*) and a few Councilman bodies were scattered (*B3*). Apparently worsened vacuolization and lytic necrosis of hepatocytes (*B4*), increased Councilman bodies as well as vascular congestion (*B5*) were observed in I60'R150', while minor alterations similar with that in I60'R60' were found in I60'R240', and the lesions in I60'R360' were obviously attenuated. Damage scores of the liver in the four reperfusion groups were significantly higher than in the Sham (all $P < 0.01$), while the scores in I60'R60', I60'R240' and I60'R360' were significantly lower than in I60'R150' (z = -3.000, -2.810 and -2.739, all $P < 0.01$). The score in I60'R60' was significantly higher than in I60'R360' (z = 2.000, P = 0.0455), while no difference was found in the scores between I60'R240' and I60'R360', as shown in Figure 2B.

Compared with duodenal alterations in the Sham after injury, the ciliated epithelial cells in I60'R60' were impaired and arranged irregularly (Figure 2, *C1*), the quantity of Goblet cells (*C2*) and mucus secretion were increased, and mild congestion in the mucosal lamina propria was observed (*C3*). Distinctly aggravated impairment of the ciliated epithelial cells, further increased the quantity of Goblet cells but minor congestions were found in I60'R150' and I60'R240', while significantly alleviated altera-

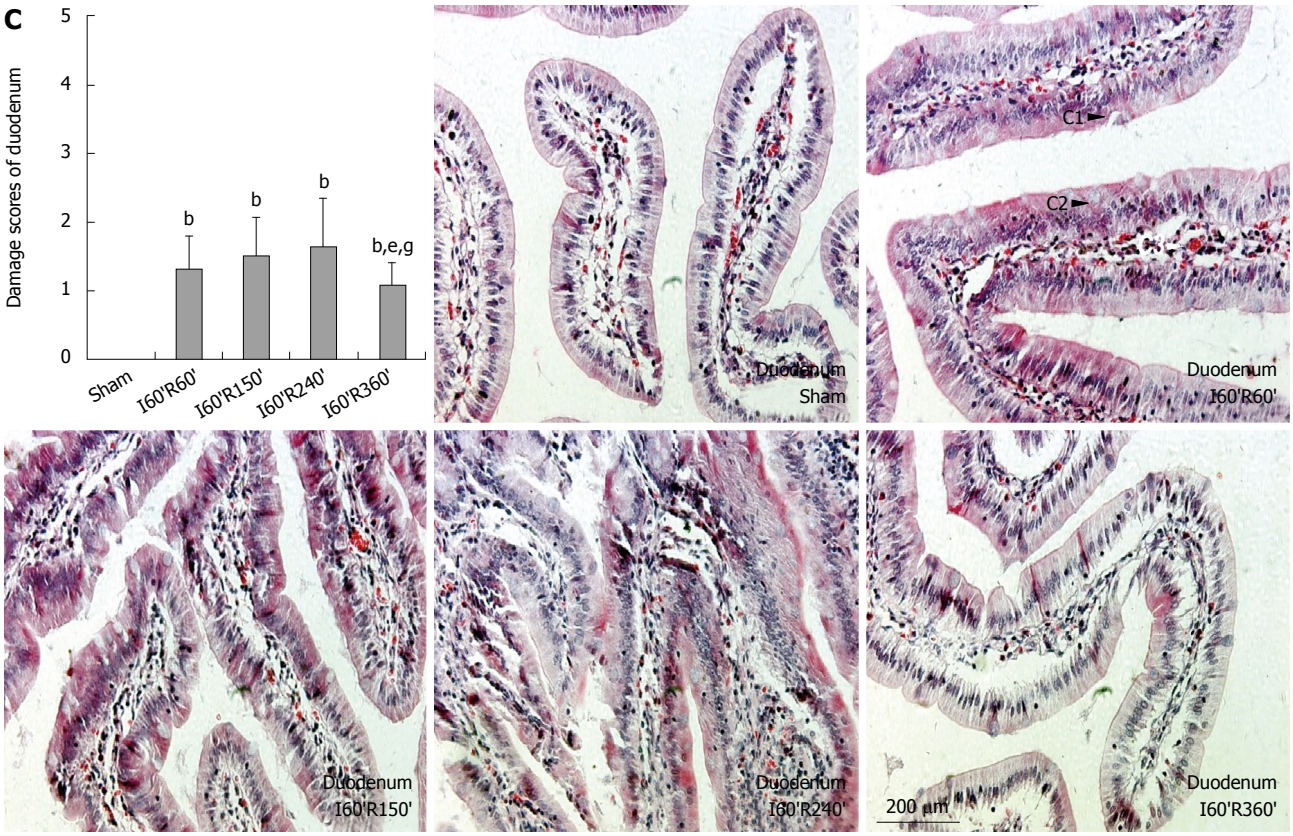

Figure 2 Histological alterations in lung (A), liver (B) and duodenum (C) of the rats after injury using hematoxylin-eosin staining (× 200). Sham: Sham-operation; I60'R60', I60'R150', I60'R240' and I60'R360': Hepatic ischemia for 60 min/reperfusion for 60, 150, 240 and 360 min; $^{b}P < 0.01$ *vs* sham; $^{c}P < 0.05$, $^{d}P < 0.01$ *vs* I60'R60'; $^{e}P < 0.05$, $^{f}P < 0.01$ *vs* I60'R150'; $^{g}P < 0.05$, $^{h}P < 0.01$ *vs* I60'R240'.

tions were observed in I60'R360'. Damage scores of duodenum in the four reperfusion groups were significantly higher than in the Sham group (all $P < 0.01$), while the score in I60'R360' was significantly lower than in I60'R150' and I60'R240' ($z = -2.000$ and -1.987, both $P < 0.05$). No difference was found in the scores among I60'R60', I60'R150' and I60'R240' (Figure 2C).

Protein levels of leptin in lung, liver and duodenum after injury

In the lung, the protein levels of leptin in I60'R60', I60'R150', I60'R240' and I60'R360 were significantly lower than in the Sham ($t = -7.241$, -4.962, -11.970 and -10.821, all $P < 0.01$), while the level in I60'R150' was significantly higher than in I60'R60', I60'R240' and I60'R360' ($t = 4.633$, 13.096 and 11.086, all $P < 0.01$). The levels in I60'R240' and I60'R360' were significantly lower than in I60'R60' ($t = -5.166$ and -3.708, both $P < 0.01$), and the level in I60'R360' was significantly higher than in I60'R240' ($t = 3.046$, $P < 0.01$) (Figure 3A).

In the liver, the protein levels of leptin in I60'R60' and I60'R240' were significantly higher than in the Sham ($t = 13.769$ and 6.952, both $P < 0.01$), while the levels in I60'R150' and I60'R360' showed no difference as compared with that in the Sham. The levels in I60'R240' and I60'R360' were significantly lower than in I60'R60' ($t = -13.754$ and -4.683, both $P < 0.01$), while no difference was observed in the levels among I60'R150', I60'R240' and I60'R360', as shown in Figure 3B.

In the duodenum, the protein levels of leptin in I60'R240' and I60'R360' were significantly higher than in the Sham ($t = 22.847$ and 35.411, both $P < 0.01$), I60'R60' ($t = 6.890$ and 7.760, both $P < 0.01$) and I60'R150' ($t = 12.538$ and 14.237, both $P < 0.01$), while the levels in I60'R60' and I60'R150' were not different from that in the Sham. The level in I60'R150' was significantly lower than in I60'R60' ($t = -2.431$, $P < 0.05$), and there was no difference in the levels between I60'R240' and I60'R360' (Figure 3C).

Correlation between leptin and other variables

There was no significant correlation between serum leptin and glucose, TAC, MPO or DAO, while a significantly positive correlation was found between serum leptin and ALT ($\rho = 0.344$, $P = 0.021$).The protein level of leptin in the lung had significantly negative correlation with its damage scores ($\rho = -0.313$, $P = 0.036$), but the level in the liver showed a significantly positive correlation with its damage scores ($\rho = 0.297$, $P = 0.047$), and no significant correlation was observed between the levels in the duodenum and its damage scores (Table 1).

DISCUSSION

Despite advances in supportive therapy, hepatic ischemia/reperfusion injury continues to negatively affect patient mortality and morbidity[10]. As the liver is the most impor-

Tissue leptin + damage scores of duodenum	0.180	0.237

ρ and *P* values were calculated using Spearman's rank correlation.

tant organ participating in energy metabolism and nutrient absorption, this injury will inevitably lead to variation of endogenous metabolic factors such as leptin. Recent researches have suggested a protective role for leptin in trauma/sepsis-induced organ dysfunction[11,12], but there is no report mentioning the affirmatory linkage between leptin and hepatic ischemia/reperfusion injury, thus our study was the first to investigate whether leptin is a novel strategy aimed at minimizing the internal disorders after this injury. In the early stage after reperfusion, the high metabolic status changed the body into a starvation-like situation[13]. As leptin is down-regulated by the neuroendocrine system during starvation[14] and there exists a possible destructive effect of free radicals on circulating proteins, serum leptin from I60'R60' to I60'R240' remained significantly unchanged though their mean values seemed to increase. In the later stage, the starvation-like status and the negative effect of free radicals recovered gradually, therefore serum leptin in I60'R360' increased significantly and this elevation fluctuation indicated a potential benefit of leptin during this injury.

As serum glucose and TAC represent the energy reserves and the overall ability to eliminate reactive oxygen species, respectively, we chose them as variables reflecting metabolic disorders after hepatic ischemia/reperfusion injury. Although a decrease in serum glucose was observed during starvation[14], the stimulating effect by catecholamines release in the early stage after stress[15] reversed the descent, and no significant change of serum glucose was observed in I60'R60' to I60'R240'. As time went on, the starvation-like status and catecholamines release underwent synergic recovery, but serum glucose in I60'R360' was distinctly higher due to a possible feedback provocation of resumptive energy reserve. Hepatic ischemia/reperfusion injury is characterized by Kupffer cell-induced oxidant stress[16]; our results showed that the anti-oxidation system responded promptly and exerted a valid capacity to eliminate free radicals from I60'R240' to I60'R360', suggesting that a competent endogenous regulation might exist to accelerate the recovery of this injury. The synchronous increase of serum leptin, glucose and TAC in the later stage also indicated a potentiality of leptin to

protect the body by promoting energy metabolism and anti-oxidation capacity. Unexpectedly, no significant correlation was found either between serum leptin and glucose or between serum leptin and TAC, which might be attributed to the non-unique and complex regulation on glucose and TAC by other metabolic factors.

In liver transplantation, prolonged intensive care unit stay or lack of an adequate nutritional support results in starvation of the donor, leading to increased incidence of hepatocellular injury and primary dysfunction[17,18]. Given the fact that leptin decreases under malnutrition and starvation[14,19], it is attractive to speculate that leptin may associate with the liver impairment (even in other organs) during hepatic ischemia/reperfusion injury, and its elevation may proceed to maintain homeostasis. MPO is mainly expressed by neutrophils with a similar amount of nearly 5% of net weight in each cell[20], and it may indirectly reflect the severity of lung injury evoked by neutrophil infiltration. ALT and DAO are sensitive indicators for liver and duodenal injuries, thus we selected these three variables for representing the functional impairment in the lung, liver and duodenum (the distal, local and proximal vital organs), respectively. Our results showed that both serum MPO and DAO in the later stage after reperfusion were significantly lower than in the early stage, while serum ALT in the four reperfusion groups were higher than in Sham but were not aggravated as reperfusion time was elongated. These changes demonstrated that the functional impairment in the vital organs during 70% hepatic ischemia/reperfusion injury were relatively minor compared with 100% injury, and there should be an endogenous regulation to restrict deterioration of this injury and accelerate its recovery, which also indicated a potential benefit of leptin since it elevated synchronously in the later stage. Interestingly, no significant correlation was observed either between serum leptin and MPO or between serum leptin and DAO, while there was a significantly positive correlation between serum leptin and ALT, suggesting a direct protective role for leptin in the local vital organ but an indirect regulatory role in the distal and proximal vital organs during this injury.

A research has revealed that serum leptin is apparently higher in patients after liver, heart or kidney transplantation[21], which provides a clinical probability of leptin as a beneficial cytokine for ischemia/reperfusion-induced organ injuries. However, no histological alterations and their association with leptin were reported. Our results showed that although hepatic ischemia/reperfusion injury initiated distinct and diverse structural impairment, the severity in the later stage after reperfusion were alleviated compared with the early stage, suggesting once again that an endogenous regulation did exist to stimulate the recovery of this injury. Protein levels of leptin in the lung, liver and duodenum underwent different fluctuations due to disparate grades of structural impairment, with a timely response in the lung and liver in the early stage but a delayed response in the duodenum in the late stage, which also indicated a regulatory role for tissue leptin during the injury. Perplexingly, a significantly negative correlation between tissue leptin in the lung and its damage scores was observed, suggesting a conflicting role for leptin in the lung injury. Two critical researches have found that lung injury is moderately attenuated in leptin-deficient mice and intratracheal pretreatment with a leptin receptor inhibitor mitigates leptin-induced lung edema[22,23]. Our investigation also suggested that endogenous leptin might be detrimental to the recovery of lung injury despite that exogenous leptin has been proved beneficial for lung and other organs[24-26]. The significantly positive correlation between tissue leptin in the liver and its damage scores indicated once again a direct protective role for leptin in the local vital organ, while the indistinctive correlation between tissue leptin in duodenum and its damage scores, but a contrary variation in the later stage, still provided a rehabilitative potency of leptin in the proximal vital organ by inhibiting its structural impairment.

Although many studies have been conducted regarding the inflammatory mechanisms during hepatic ischemia/reperfusion injury[16,27,28], little is known about the endogenous network involving leptin that modulates the internal disorders in this injury. Ischemia/reperfusion-evoked activation of Kupffer cells results in production and release of reactive oxygen species and pro-inflammatory mediators such as tumor necrosis factor-α (TNF-α), which further activate and recruit neutrophils into target organs especially in the lung, and they contribute to the inflammatory cascade and have powerful effects on the local environment and remote organ functions[13,29]. Since a rise in TNF-α activity parallels an increase in leptin gene and peripheral expression, it is proposed that leptin participates in a protective mechanism against the inflammatory cascade downstream to TNF-α[30,31]. Despite a decrease in serum glucose and leptin observed in the starvation-like status which augmented susceptibility to inflammatory damage, the synchronous upregulation of serum leptin, glucose and TAC in the late stage still declared a potential rehabilitative role of leptin in metabolic disorders during this injury. Although an ambiguous induction by leptin in the structural impairment in the lung was presented, leptin directly inhibited the functional and structural impairment in the liver, while it potentially suppressed the functional impairment in the lung as well as the functional and structural impairment in the duodenum. Therefore, leptin evolves to harmonize an endogenous network maintaining homeostasis in the distal, local and proximal vital organs during this injury (Figure 4).

In our experimental model, different doses of exogenous leptin can be administered at different time points during the injury, and relevant inflammatory cytokines or growth factors can be measured to elucidate the rehabilitative characteristics of leptin. Signal pathway downstream to leptin can be investigated simultaneously to further clarify the association between leptin and the internal disorders. Moreover, liver cell lines may be used to establish a hypoxia/reoxygenation model, and applied to determine whether endogenous regulation or exogenous supplement of a functional leptin network will represent a beneficial component for the host response to the injury.

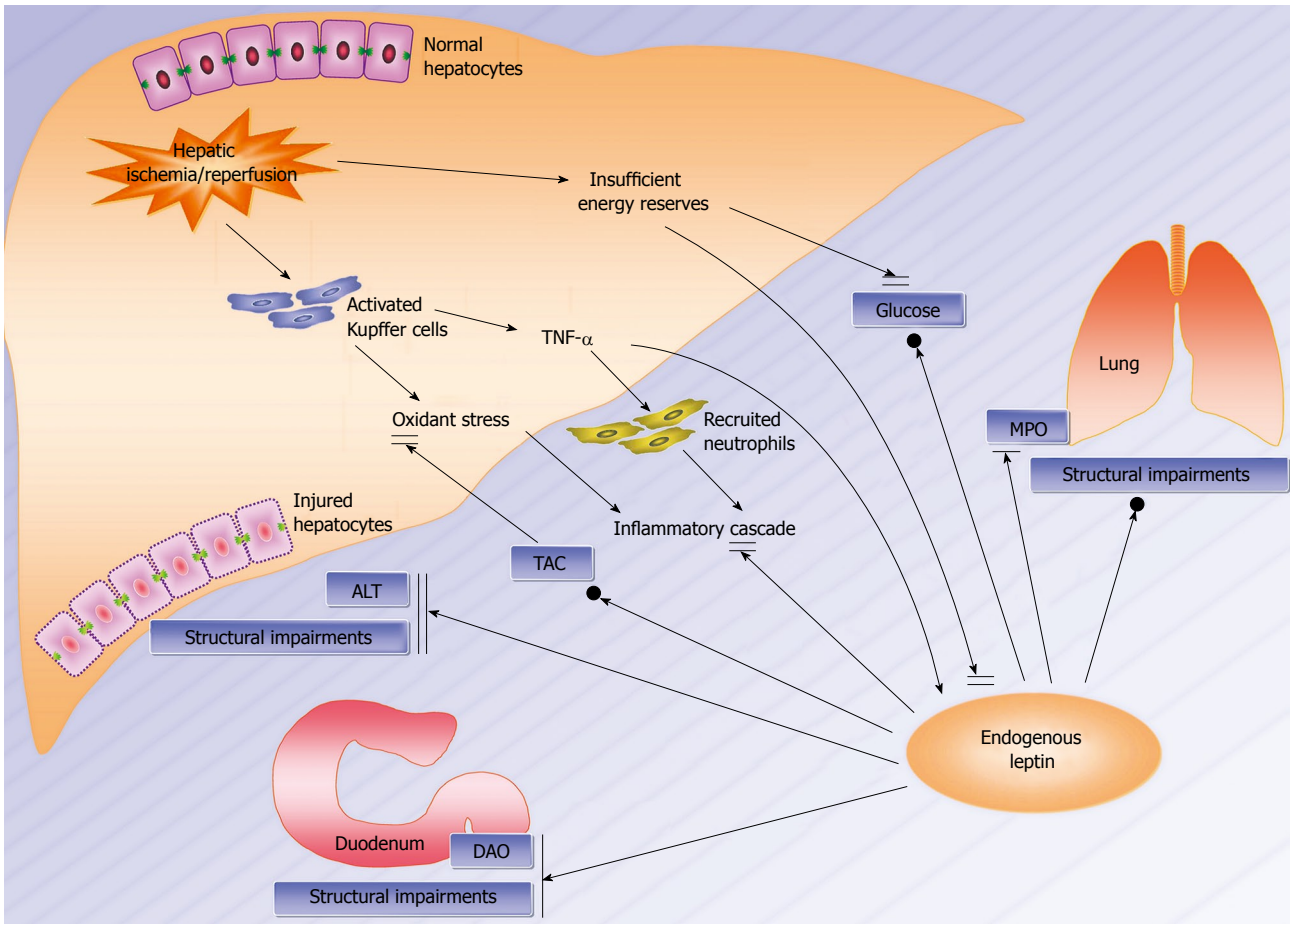

Figure 4 Endogenous network involving leptin that modulates the internal disorders during hepatic ischemia/reperfusion injury. →: Induction; →||: Inhibition; →●: Possible induction; →|: Possible inhibition; TNF: Tumor necrosis factor; TAC: Total anti-oxidation capacity; MPO: Myeloperoxidase; ALT: Alanine transaminase; DAO: Diamine oxidase.

In conclusion, endogenous leptin fluctuates in serum and vital organs during hepatic ischemia/reperfusion injury, and exerts a potency to rehabilitate metabolic disorders as well as the functional and structural impairment in the lung, liver and duodenum, especially in the local vital organ. The association between leptin and the internal disorders has suggested that an artificial nutritional support, adequate content of antioxidants and exogenous leptin recruitment aimed to upregulate endogenous leptin may represent a new supportive therapy for hepatic ischemia/reperfusion injury.

COMMENTS

Background

Recent researches have revealed that leptin participates in the modulation of energy metabolism, neuroendocrine, angiogenesis, reproduction and immune responses, suggesting an important role of leptin in the recovery of functions. To study the fluctuation of leptin and its association with the internal disorders after hepatic ischemia/reperfusion injury may provide a potential target for the treatment of hepatic ischemia/reperfusion injury.

Research frontiers

Liver is the vital organ for nutrition absorption and energy metabolism, its ischemia/reperfusion injury inevitably leads to local and remote dysfunction. As leptin is a stress mediator proceeding to maintain homeostasis and there is no available report about leptin and this injury, to explore the variation and roles of leptin will clarify whether it is a beneficial component for this injury.

Innovations and breakthroughs

This is the first study to report that endogenous leptin fluctuates in serum and vital organs in a rat model of 70% hepatic ischemia/reperfusion injury, and exerts a potency to rehabilitate metabolic disorders, the functional and structural impairment in the lung, liver and duodenum, especially in the local vital organ.

Applications

This study suggests that endogenous leptin may represent a potential target for minimizing the internal disorders after hepatic ischemia/reperfusion injury, and an artificial nutritional support, adequate content of antioxidants and exogenous leptin recruitment aimed to upregulate endogenous leptin may provide a new supportive therapy for this injury and relevant diseases.

Terminology

Hepatic ischemia/reperfusion injury is a complication of liver resection, transplantation and hypovolemic shock, resulting in depletion of adenosine triphosphate, accumulation of free radicals, and lesion in vital organs. Leptin is an *ob* gene-expressed protein with a primary role of inhibiting food intake, modulating weight balance and promoting energy metabolism, but its potential role in this injury has not been reported.

Peer review

The authors illustrated a well designed experiment to evaluate the role for

leptin in the internal disorders during hepatic ischemia/reperfusion injury. Furthermore, relevant background information was given in order to interpret the importance of the trial. The manuscript is interesting and comprehensive. The part of discussion is compactly constructed and brilliant.

Abstract

AIM: To investigate the presence or absence of high amplitude propagating contractions (HAPC), as well as the other measures of colonic motility, in persons with spinal cord injury (SCI).

METHODS: Prolonged colonic ambulatory manometric studies were performed on 14 male volunteers: 8 with SCI (mean age, 59 ± 13 years; mean duration of injury, 13 ± 4 years) and 6 healthy able-bodied controls (mean age, 57 ± 10 years). A solid-state manometry catheter was endoscopically clipped to the splenic flexure. Recording was performed for > 24 h after manometric catheter placement.

RESULTS: HAPC were absent in individuals with SCI during pre-sleep, sleep, and post-sleep phases. HAPC were significantly increased after awakening in non-SCI controls (0.8 ± 0.2 HAPC/h *vs* 10.5 ± 2.0 HAPC/h, $P < 0.005$). The motility index was lower in those with SCI than in controls pre- and post-sleep (SCI *vs* non-SCI: Pre-sleep, 2.4 ± 0.4 *vs* 8.8 ± 1.9, $P < 0.01$; Post-sleep, 4.3 ± 0.8 *vs* 16.5 ± 4.5, $P < 0.05$). However, a sleep-induced depression of colonic motility was observed in both the SCI and non-SCI groups (Pre-sleep *vs* Sleep, non-SCI: 8.8 ± 1.9 *vs* 2.1 ± 0.9, $P < 0.002$; SCI: 2.4 ± 0.4 *vs* 0.2 ± 0.03, $P < 0.001$), with the motility index of those with SCI during sleep not significantly different than that of the controls.

CONCLUSION: HAPC were not observed in individuals with SCI pre- or post-sleep. A sleep-induced depression in general colonic motility was evident in SCI and control subjects.

INTRODUCTION

Neurogenic bowel dysfunction (NBD) is a sequela of spinal cord injury (SCI) that leads to a disruption of normal colon physiology. This condition may be characterized by constipation, diarrhea, fecal incontinence, and/or fecal impaction, and it has a profoundly negative impact on quality of life[1]. In chronic SCI, colonic motor function is disturbed and often presents as difficulty with evacuation, associated with a delay in colonic transit, as evidenced by several colon marker transit studies[2-4]. In addition, our group has reported that colonic contractions after SCI are of lower amplitude and are decreased in frequency compared to those in healthy able-bodied controls[5].

High amplitude propagating contractions (HAPC) are specialized propagating pressure waves with high amplitude (> 105 mmHg) and prolonged duration (> 14 s) observed on manometric recordings[6]. HAPC are often associated with colonic mass movements and are thought to be a precursor of bowel evacuation; they occur mostly after arousal from sleep and after ingestion of meals[7,8]. In a study of non-SCI patients with chronic slow transit constipation, HAPC were either absent or attenuated after arousal from sleep and after ingestion of a meal, and such a finding may be indicative of neurogenic or myopathic colon dysfunction[9].

Given the above findings, it is possible that alterations in HAPC may play a role in the pathophysiology of bowel evacuation in persons with SCI. However, characteristics of HAPC and their relationship to normal physiological stimuli in persons with SCI have not been reported. Thus, our study determined HAPC in relation to sleep in individuals with chronic SCI.

MATERIALS AND METHODS

Subjects

Fourteen male volunteers were studied: 8 with chronic SCI and 6 non-SCI controls. The mean age of the patients with SCI was 59 ± 13 years with a mean duration of injury of 13 ± 4 years. Three of the 8 SCI subjects had tetraplegia (C5 or below) and the remaining 5 had paraplegia (T5 or below). The causes for SCI included trauma (6/8), cervical stenosis (1/8) and transverse myelitis (1/8). Persons with SCI who reported having < 2 spontaneous bowel movements per week were recruited for the study; they had participated in a regular bowel care program for at least 6 mo prior to enrollment in the study. None of the SCI patients enrolled in the study had autonomic dysreflexia. The non-SCI subjects had no previous history of gastrointestinal disease or surgery, had normal physical examinations, and had no electrolyte or thyroid abnormalities. Six healthy non-SCI individuals, aged 57 ± 10 years, served as the control group. Medications that may alter colonic motility and/or hemostasis (e.g. warfarin, aspirin, *etc.*) were withheld for 1 wk prior to the study. The Institutional Review Board of the James J Peters Veterans Affairs Medical Center approved the study protocol, and informed consent was obtained from subjects before enrollment.

Sleep phases

The pre-sleep phase was designated as the time (1 h) before the start of sleep. The reported start and end of sleep was quantified in hours and was designated as the sleep phase. The post-sleep phase was designated as the time (1 h) after the end of sleep. The information regarding sleep duration was obtained from nursing records and self-reported diaries. Subjects avoided strenuous physical activity for at least 1 h before or after sleep.

Manometry assembly and experimental design

All subjects had normal colonic examinations by colonoscopy before the study. Subjects were prescribed either polyethylene glycol (PEG) (4 L of Colyte) or oral sodium phospho soda (OSPS) (two divided doses of Fleets PhosphoSoda 45 mL each separated by 12 h). Sedation with propofol was administered when needed. Fixation of the manometric probe to the wall of the colon at the splenic flexure was accomplished, as previously described[10]. A solid state manometric catheter with four pressure transducers spaced 10 cm apart was used for obtaining intraluminal pressure data (Gaeltec Ltd, Dunvegan, Isle of Skye, UK). The colonoscope and the manometric catheter probe were advanced under direct vision to the splenic flexure. Using fluoroscopy, the last pressure sensor was placed at least 10 cm proximal to the anal verge. The distal end of the manometric probe was securely taped to the skin of the gluteal region to prevent accidental retraction; an abdominal X-ray confirmed the placement of the clipped probe at the region of the splenic flexure. An abdominal X-ray confirmed that all subjects had normal radiographic findings (i.e. none had megacolon). The manometric probe was attached to a portable recorder (type 7-MPR, Gaeltec Ltd., UK). The portable recorder was connected to a shoulder sling, permitting mobility. The subjects were provided with diaries and were instructed to record the timing of specific activities such as meals, sleep, and bowel and bladder events. Subjects were instructed that after a bowel movement care should be taken during perineal hygiene to prevent the inadvertent external displacement of the probe.

After completion of the study, the data were uploaded to a computer for storage and analysis. The probe remained securely in place after placement in the colon in all

subjects. Subjects remained in the hospital overnight for the duration of the study. Because of the possibility that bowel preparation, colonic intubation, and/or sedation may have effects on colonic motility, data collection was begun 12 h after placement of the manometry catheter. Non-SCI subjects meticulously documented events of walking, strenuous activity, movement, cough, sleep and wake, bladder emptying, periods of food ingestion and talking. Because activities may alter HAPC, tracings that corresponded to periods of increased activity were excluded from the data analysis.

From the manometric recordings of the colon, three epochs were determined a priori to measure and analyze the endpoints: pre-sleep phase (i.e. 1 h before sleep), sleep phase (i.e. entire sleep duration), and post-sleep phase (i.e. 1 h after arousal from sleep). The following quantitative and qualitative endpoints were investigated in each epoch: (1) the presence and number of HAPC; and (2) other colonic motility parameters. HAPC were defined as pressure wave sequences that: (a) migrated aborad; (b) travelled across three or more consecutive channels; (c) had an amplitude of > 105 mmHg; and (d) had a duration > 14 s[9]. Other colonic motility parameters measured were the motility index (MI) (i.e. the product of the mean amplitude and percent activity) and the total number of waves. Sleep duration and periods of food ingestion were obtained from nursing records for subjects admitted to the SCI Service and from self-report diaries for non-SCI subjects.

The recordings were analyzed by observing the manometric tracings on a computer monitor and by a software analysis program (AMBB, Gaeltec Ltd, UK). Criteria for waves included in the analysis were: (1) amplitude of > 8 mmHg and; and (2) duration of > 3 s[6]. Movement artifacts (e.g. walking, transferring, coughing, *etc.*) were confirmed by reference to the subject's diary, and these segments (as well as postprandial segments) were excluded from the analysis. The analyses were performed independently by investigators blinded to the subject's identity, and any discrepancies were resolved by the senior author, who was also blinded.

All subjects tolerated the procedure well. The probe was removed after the study by gently tugging along the catheter. No complications were noted after probe removal. For the analysis of HAPC pressure wave forms, data were excluded due to technical reasons in two individuals with SCI and in two healthy controls; in these cases, malfunction of more than one sensor for a period longer than 30 min prevented the ability to observe propagation across channels, hence, preventing the identification or quantification of HAPC.

Statistical analysis

The data were expressed as mean ± SE. All the data represent values obtained per hour. The mean values of the SCI and the control groups were analyzed for differences using unpaired Student's *t* test for parametric variables and Kruskal-Wallis Test for non-parametric variables. The means between phases of sleep were analyzed using paired Student's *t* test in both SCI and control groups. An analysis of variance (ANOVA) was performed to determine significance among the phases of sleep and arousal (i.e. pre-sleep, sleep, and arousal). Multiple regression analysis was performed to determine the effect of level of SCI on quantitative and qualitative wave parameters.

RESULTS

Subjects

In individuals with SCI, the level of injury did not have a significant effect on the quantitative and qualitative wave parameters. Thus, the data obtained in subjects with all levels of SCI were combined for further analysis. A total of approximately 420 h of manometric recording was obtained (range of 26-32 h per patient); 112 h were analyzed for the study. The average number of hours of sleep per subject was 8.0 ± 0.2 h (range: 7 to 10 h), without a significant difference in the average number of hours of sleep between SCI and non-SCI subjects. None of the subjects reported sleep interruption.

High amplitude peristaltic contractions

There were no HAPC observed in the SCI group during pre-sleep, sleep, and post-sleep phases. In the non-SCI group, the numbers of HAPC/h were as follows: pre-sleep phase, 2.0 ± 0.4; sleep phase, 0.8 ± 0.2; and post-sleep phase, 10.5 ± 2.0; a significant increase in the number of HAPC were noted from sleep to post-sleep phases (0.8 ± 0.2 *vs* 10.5 ± 2.0, $P < 0.005$). All non-SCI subjects experienced subjective symptoms (e.g. sensation of flatus) and two had bowel movements in close proximity to having HAPC in the post-sleep phase.

Motility index

In both the non-SCI and SCI groups, the colonic motility index (MI) was significantly suppressed during sleep compared to pre-sleep (Pre-sleep *vs* Sleep, Control: 8.8 ± 1.9 *vs* 2.1 ± 0.9, $P < 0.005$; SCI: 2.4 ± 0.4 *vs* 0.2 ± 0.03, $P < 0.001$) and significantly increased after arousal from sleep (Sleep *vs* Post-sleep, non-SCI: 2.1 ± 0.9 *vs* 16.5 ± 4.5, $P < 0.001$; SCI: 0.2 ± 0.03 *vs* 4.3 ± 0.8, $P < 0.001$) (Figure 1).

Furthermore, the MI during the pre-sleep and post-sleep phases was significantly lower in SCI subjects than that of the non-SCI group (SCI *vs* non-SCI: Pre-sleep, 2.4 ± 0.4 *vs* 8.8 ±1.9, $P < 0.01$; Post-sleep, 4.3 ± 0.8 *vs* 16.5 ± 4.5, $P < 0.05$). However, no significant difference in MI was noted during the sleep phase between SCI and non-SCI groups (SCI *vs* non-SCI: Sleep, 0.2 ± 0.03 *vs* 2.1 ± 0.9, $P = 0.10$).

Total number of waves

In both the control and SCI groups, the total number of waves was significantly suppressed during sleep compared to pre-sleep (Pre-sleep *vs* Sleep, non-SCI: 98 ± 11 *vs* 70 ± 5, $P < 0.005$; SCI: 68 ± 11 *vs* 51 ± 2, $P < 0.001$). The total number of waves was significantly increased in both groups after arousal from sleep (Sleep *vs* Arousal, non-

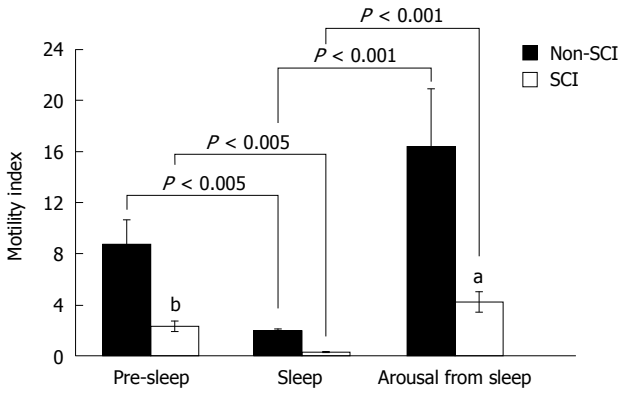

Figure 1 Colonic motility index in relation to sleep. In both the non-spinal cord injury (SCI) and SCI groups, colonic motility index (MI) was significantly suppressed during the sleep phase compared to the pre-sleep phase (Pre-sleep *vs* Sleep, Control: 8.8 ± 1.9 *vs* 2.1 ± 0.9, $P < 0.005$; SCI: 2.4 ± 0.4 *vs* 0.2 ± 0.05, $P < 0.001$) and significantly increased after awakening from sleep (Sleep *vs* Arousal, Control: 2.1 ± 0.9 *vs* 16.5 ± 4.5, $P < 0.001$; SCI: 0.2 ± 0.03 *vs* 4.3 ± 0.8, $P < 0.001$). The MI during the pre-sleep and post-sleep phases was significantly lower in SCI subjects than in the non-SCI (non-SCI *vs* SCI, pre-sleep: 8.8 ±1.9 *vs* 2.4 ± 0.4, $^{b}P < 0.01$; post-sleep: 16.5 ± 4.5 *vs* 4.3 ± 0.8, $^{a}P < 0.05$).

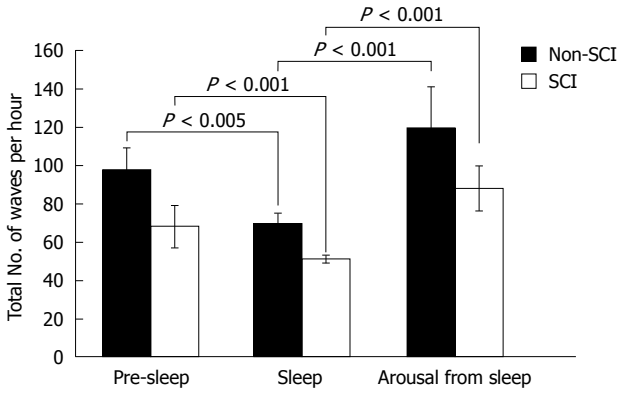

Figure 2 Total number of waves in relation to sleep. In both the non-spinal cord injury (SCI) and SCI groups, the total number of waves was significantly suppressed during the sleep phase compared to the pre-sleep phase (Pre-sleep *vs* Sleep, non-SCI: 98 ± 11 *vs* 70 ± 5, $P < 0.005$; SCI: 68 ± 11 *vs* 51 ± 2, $P < 0.001$), and was significantly increased after awakening from sleep (Sleep *vs* Arousal, non-SCI: 70 ± 5 *vs* 120 ± 21, $P < 0.001$; SCI: 51 ± 2 *vs* 88 ± 12, $P < 0.001$).

SCI: 70 ± 5 *vs* 120 ± 21, $P < 0.001$; SCI: 51 ± 2 *vs* 88 ± 12, $P < 0.001$) (Figure 2).

DISCUSSION

As was previously reported in other studies[9,11-15], HAPC are often observed after awakening or occur after ingestion of a high fat meal[12]. Previously, our group studied the effects of food on colonic motility in persons with SCI and reported that the postprandial colonic response in persons with SCI is suboptimal and confined only to the descending colon[5]. In this study, we restricted our analysis to HAPC in relation to the sleep-wake cycle in subjects with SCI compared to those in able-bodied subjects. Our study revealed that HAPC are absent in individuals with chronic SCI who had reported having fewer than 2 spontaneous bowel movements per week. The absence of HAPC in persons with SCI may be related to abnormalities in the brain-gut control over colonic motility and/or intrinsic disorder of the viscus as a result of chronic SCI. The complete absence of the HAPC after chronic SCI may be a contributing factor to difficulty with evacuation. Our findings are consistent with the study of Rao *et al*[9] who demonstrated that absence of HAPC may indicate colonic neuropathy.

Interestingly, in both SCI and non-SCI subjects, there appeared to be a sleep-induced depression of colonic motor waves measured, i.e. motility index and total number of all waves. Furthermore, in both SCI and non-SCI subjects, there appeared to be a significant increase of peristaltic waves measured after awakening, except for HAPC.

HAPC are thought to be the manometric equivalent of colonic mass movements[16], and they are likely to be associated with transport of intraluminal contents along colonic segments[17]. Prolonged periods of colonic recording in man have reported HAPC to occur between 4 to 10 times per 24-h period[9,11,18]. In non-SCI subjects, 60% of HAPC were associated with symptoms or events (e.g. bowel movement or passage of gas)[1]. The interest in the role of HAPC as a variable that permits discrimination between states of health and disease is evolving, as more sophisticated methodology and technology become available to allow more accurate and prolonged colonic recording under physiological conditions[6,10,11,19,20]. More recently, in a study of patients with slow-transit constipation[9], HAPC were employed to categorize patients with slow-transit constipation as having colonic neuropathy based on the absence of two of three manometric criteria, one being HAPC and the other two being lack of gastrocolonic response and lack of response to waking. The patients who were categorized as having colonic neuropathy were considered to have a refractory colonic neuromuscular disorder; after further evaluation of gastric and small bowel motility, 7 of the 10 patients were advised to have, and subsequently underwent, surgery (i.e. colectomy with ileorectal anastomosis)[9].

The current study has limitations. Initially, the frequency and number of HAPC in the non-SCI group reported in this study were significantly higher than has been previously reported[15,18,19]. The reason for this disparity is not clear but could be due to technical differences, the small number of subjects and/or the study design. Regardless of the cause, the relative differences between SCI subjects and non-SCI controls remain significant because the same procedures and manometric sensors were employed in both groups. Furthermore, studies have shown that in addition to awakening from sleep, movement (e.g. ambulation) also precipitates the generation of HAPC. Thus, activity may have been a significant factor that may serve to explain the difference in HAPC generation in the SCI compared to the non-SCI group. We have carefully excluded motion artifact, especially those related to walking in the able-bodied subjects during the analysis of our wave recordings. However, mobility as a generator of HAPC *per se* could not be addressed because of our study cohort

(non-SCI) and our study design (e.g. non-SCI subjects were not confined to the seated position during the acquisition of data). The number of subjects studied was relatively small, and the SCI group was not uniform. Another limitation of this work was that the sleep phases were not confirmed by polysomnography; because of this limitation, we were also unable to determine if subjects had periods of arousal during the periods of reported sleep. In our study protocol, persons with SCI who reported having > 2 spontaneous bowel movements per week were excluded from study participation. Thus, another limitation of the study was that it did not address possible differences in HAPC in relation to sleep in the subjects with SCI with more normal bowel evacuation patterns (i.e. > 2 bowel movements per week) compared to those of the non-SCI subjects.

In conclusion, subjects with SCI had a complete absence of HAPC. The MI before and after sleep was depressed in persons with SCI compared to able-bodied subjects. Thus, SCI results in disruption of the colonic motility changes that are present in healthy individuals. In our subjects with SCI, a marked depression in sleep-induced colonic activity was demonstrated by the MI and the total number of waves, and this depression in activity related to sleep has also been confirmed, as expected, in healthy controls. The absence of HAPC generation is presumably an important factor in the occurrence of difficulty with evacuation observed in individuals with SCI. Prokinetic drugs, such as bisacodyl and neostigmine[21,22], that result in generation of HAPC, may improve bowel evacuation by increasing HAPC after SCI.

Abstract

AIM: To study a novel technique to record spinal and cortical evoked potentials (EPs) simultaneously in response to electrical stimulation in the human rectum.

METHODS: Eight male and nine female healthy volunteers participated. Stimulating electrodes were attached to the rectal mucosa at 15 cm and 12 cm above the dentate line. Recording skin electrodes were positioned over vertebrae L4 through S2. The electrical stimulus was a square wave of 0.2 ms duration and the intensity of the stimulus varied between 0 and 100 mA. EP responses were recorded using a Nicolet Viking IV programmable signal conditioner.

RESULTS: Simultaneous recording of cortical and spinal EPs was obtained in > 80% of the trials. The EP responses increased with the intensity of the electrical stimulation, were reproducible overtime, and were blocked by application of Lidocaine jelly at the site of stimulation. The morphology (N1/P1), mean ± SD for latency (spinal N1, 4.6 ± 0.4 ms; P1, 6.8 ± 0.5 ms; cortical N1, 136.1 ± 4.2 ms; P1, 233.6 ± 12.8 ms) and amplitude (N1/P1, spinal, 38 ± 7 μV; cortical 19 ± 3 μV) data for the EP responses were consistent with those in the published literature. Reliable and reproducible EP recordings were obtained with the attachment of the electrodes to the rectal mucosa at predetermined locations between 16 and 8 cm above the anal verge, and the distance between the attachment sites of the electrodes (the optimal distance being approximately 3.0 cm between the two electrodes).

CONCLUSION: This technique can be used to assess potential abnormalities in primary afferent neural pathways innervating the rectum in several neurodegenerative and functional pain disorders.

Key words: Spinal evoked potentials; Cortical evoked potentials; Rectum; Electrical stimulation; Primary afferent neurons; Visceral sensation

INTRODUCTION

Evoked potential (EP) recordings in response to peripheral nerve stimulation are useful measures of the conduction characteristics of afferent sensory pathways. EP responses at the cortical level have been recorded in response to mechanical (balloon) or electrical stimulation in the gastrointestinal tract at several locations including the esophagus, colon and rectum[1-4]. These responses are reproducible, at least with electrical stimulation in the rectum[5,6]. The cortical EP responses reflect the cumulative involvement of peripheral and central afferent pathways. Recording spinal EPs that measure the conduction characteristics of the first order primary afferent neurons has been challenging because of technical difficulties. For example, recording spinal EPs in response to balloon distention in the rectum is problematic because the stimulation artifact associated with balloon distension overlaps with the ability to record spinal waveforms with latencies typically < 20 ms[7]. The availability of a reliable method to record visceral EPs at the spinal level would help address an important unresolved issue that involves several gastrointestinal disorders in which dysfunction of primary afferent neurons has been implicated. For instance, visceral hypersensitivity has been reported in patients with irritable bowel syndrome but it remains unresolved whether this disorder is associated with distinct abnormalities involving the first order primary afferent neurons that transmit pain signals and/or higher order processing in pain signaling pathways[8]. We could identify only one publication that has reported simultaneous recording of cortical and spinal EPs in response to visceral stimulation[7]. In that study, recording of cortical EPs in response to rectal electrical stimulation was observed in approximately 90% of subjects, whereas spinal EPs were recorded simultaneously with cerebral EPs in approximately 40% of the subjects (personal communication). This supports the need for improved methods to record spinal EPs in response to stimulation of visceral primary afferent neurons.

Here, we report a new technique to record spinal and cortical EPs simultaneously in response to electrical stimulation in the rectum, which increased the percentage of successful spinal EP recordings to approximately 80%. We propose that the reliability of this method was related to the direct attachment of stimulating electrodes to the rectal mucosa *via* rigid sigmoidoscopy at specific locations, and the distance between the sites of electrode attachment.

MATERIALS AND METHODS

Seventeen healthy male (n = 8) and female (n = 9) subjects, with a mean age of 32 years (range: 20-44 years), completed the recording session. None of the volunteers had a history of medical, gastrointestinal, or neurological problems, or were taking any medication on a regular basis. The protocol was approved by the Institutional Review Board at the University Michigan Medical Center. Written informed consent was obtained from all participants.

Figure 1 Stimulating electrodes. Two electrodes (Medtronic CapSureFix Model 5076) were used in this study. This model had an electrically active helix that was designed to extend easily (up to 2 mm) for active fixation and retraction. The electrodes were positioned at 15 cm and 12 cm above the anal verge.

Rectal electrical stimulation protocol

Subjects fasted overnight before the study to eliminate the confounding influence of recent food consumption. A 200-mL tap water enema was administered prior to the recording session to ensure adequate visualization of the rectum. The participant was positioned in the left lateral decubitus position. All studies were performed in a quiet room with dimmed lighting. Two electrodes (Medtronic CapSureFix Model 5076, unipolar configuration) were used in this study (Medtronic Inc., Minneapolis, MN, USA) (Figure 1). This model has an electrically active helix that is designed to extend easily (up to 2 mm) for active fixation and retraction. The electrodes were attached to the rectal mucosa *via* a disposable rigid sigmoidoscope (Welch Allyn, Model 53130; All Medical Supply, Westland, MI). Typically, placement of the stimulating electrodes was accomplished in 2-3 min with minimal discomfort to the participant.

In preliminary studies, we examined placement of the electrodes at varying distances above the dentate line from 6 to 20 cm, and varied the proximal-distal distance between the attachment sites of the two electrodes from 0.5 to 4 cm. Preliminary studies revealed that the optimal placement to record cortical and spinal EPs simultaneously was between 8 and 16 cm above the dentate line, and 2.5-3.5 cm separation between the two electrodes. Recording of spinal EPs was progressively unreliable at distances < 2.0 cm between the electrode attachment sites. Separation distances > 3.0 cm between the stimulating electrodes required progressively higher intensities of electrical stimulus to produce a threshold response. Based on the preliminary studies, we routinely attached the stimulating electrodes at 15 and 12 cm above the dentate line on the anterior wall of the rectum. A ground electrode was positioned at the back of the neck. Cortical and spinal EPs were recorded simultaneously using Ag/AgCl-skin-electrodes positioned at the vertex [midway between the auricular prominences (Cz)] referenced to linked ears (AlA2) and L4 and L5 and S1 and S2. In some studies, skin electrodes were also attached at L1-3 to provide ad-

ditional spinal EP data. EP responses were recorded using a Nicolet Viking IV programmable signal conditioner (Nicolet Biomedical, Madison, WI, USA). The electrode impedances were < 5 kΩ. Each trial represented the final average of 50 randomly applied stimulations (every 1-3 s) that was repeated three times to ensure intra-run reproducibility. The random stimulation paradigm was employed to minimize any potential contribution of stimulus anticipation by the participant.

The electrical stimulus was a square wave of 0.2 ms duration and the intensity of the stimulus varied between 0 and 100 mA. Recording parameters: sample frequency 2 kHz, amplifier gain 100 K, bandpass filters at 0.5-500 Hz for cortical EPs and 30-10 kHz for spinal EPs. EP waveforms exhibited characteristic prominent negative (N) and positive (P) peaks numbered in order of occurrence, i.e. N1, P1, *etc.* All amplitude and latency measures were calculated from the responses obtained at the Cz and L5 locations because in most subjects, the waveforms were best defined and highest in amplitude at these locations. Relative positivity resulted in a downward deflection in the waveform. The latency (ms) of the spinal and cortical responses was measured at the peak of the major negative deflection (N1) and the positive peak (P1), respectively. The spinal and cortical response amplitude (μV) was measured peak-to-peak (N1/P1). The latency reflects the conduction velocity characteristics of the afferent pathway being investigated and, in the absence of temporal dispersion, the amplitude of a signal reflects the number of afferents contributing to the response[5,6].

Volunteers were instructed before stimulation to report when they first perceived any sensation in the pelvic area. Electrical pulses were initiated at a current shown to be sub-threshold (< 5 mA) and gradually increased by 1-mA increments until perception was reported. All subjects reported a threshold non-painful pulse deep in the pelvis. This was identified as the threshold intensity. The paradigm was repeated three times to ensure reproducibility of the threshold sensation and associated EP profile, and again at current intensities of 1.5 and 2 times above the threshold intensity. The threshold for sensation always corresponded to the initial appearance of the EP waveform. It is noteworthy that in two recording sessions, the EP responses became erratic. In both cases, one of the stimulating electrodes had detached from the mucosa. Reattachment of the electrode to the mucosa resulted in restoration of a reproducible cortical and spinal EP response.

After documenting that the EP waveform was reproducible by repeating each trial three times, the stimulating electrodes were removed in six participants and the rectal mucosa at the site of attachment was swabbed with Lidocaine (Xylocaine) 2% topical jelly (AstraZeneca, Wilmington, DE, USA), using a cotton applicator under direct visualization using the rigid sigmoidoscope. The stimulating electrodes were then reattached at their original sites and the response to electrical stimulation repeated using the same parameters (1.5 times threshold intensity) that were employed to produce the initial EP signal. In addition, six participants underwent repeat testing between 1 and 6 mo after the first recording session, to evaluate reproducibility of the initial EP responses.

Table 1 Summary amplitude data for graded electrical stimulation (mean ± SD)

N1/P1 (μV)	Spinal	Cortical
Threshold	21 ± 4	12 ± 3
2.0 × threshold	49 ± 6	26 ± 5

Table 2 Summary data for latencies and amplitudes for spinal and cortical evoked potentials (mean ± SD)

	Spinal	Cortical
N1 latencies (ms)	4.6 ± 0.4	136.1 ± 4.2
P1 latencies (ms)	6.8 ± 0.5	233.6 ± 12.8
N1/P1 amplitude (μV) (1.5 × threshold)	38 ± 7	19 ± 3

Statistical analysis

For acquisition and analysis of spinal and cortical EP recordings, the stimulus intensity used was 50% (1.5 ×) greater than threshold stimulus. Results were compared by two-tailed Student's *t* test for paired observations. Repeated measures analysis of variance was used to compare the latency and amplitude data from the two recording sessions. The level of significance for all calculations was set at the 95% confidence level ($P < 0.05$).

RESULTS

Reproducible polyphasic cerebral EPs were recorded in 16 of the 17 subjects (94%) who participated in the study. Simultaneous spinal and cortical EPs were recorded in 14 of the 17 participants (82%). All participants demonstrated the typical morphology for cortical and spinal EP recordings of an N1/P1 wave form depicted in Figure 2, which increased with stimulus intensity (threshold intensity, left panel; 2 × threshold intensity, right panel). Note the different scales for measuring the amplitude of EP response in the left panel (cortical, 5 μV/division; spinal, 20 μV/division) and right panel (cortical, 10 μV/division; spinal, 50 μV/division). Summary amplitude data for graded electrical stimulation (threshold and 2 × threshold) are presented in Table 1. The mean threshold stimulus intensity was 28 mA (range: 12-47 mA), which was experienced as a non-painful pulse deep within the pelvis; typically in the midline or left of midline. Participants used the descriptors of a "tapping" or "poking" sensation that increased in intensity and corresponded to the intensity of electrical stimulation. The mean ± SD values for latency and amplitude of the EP responses obtained at a stimulus intensity of 1.5 × threshold for the 14 participants who demonstrated both cortical and spinal EP responses are presented in Table 2.

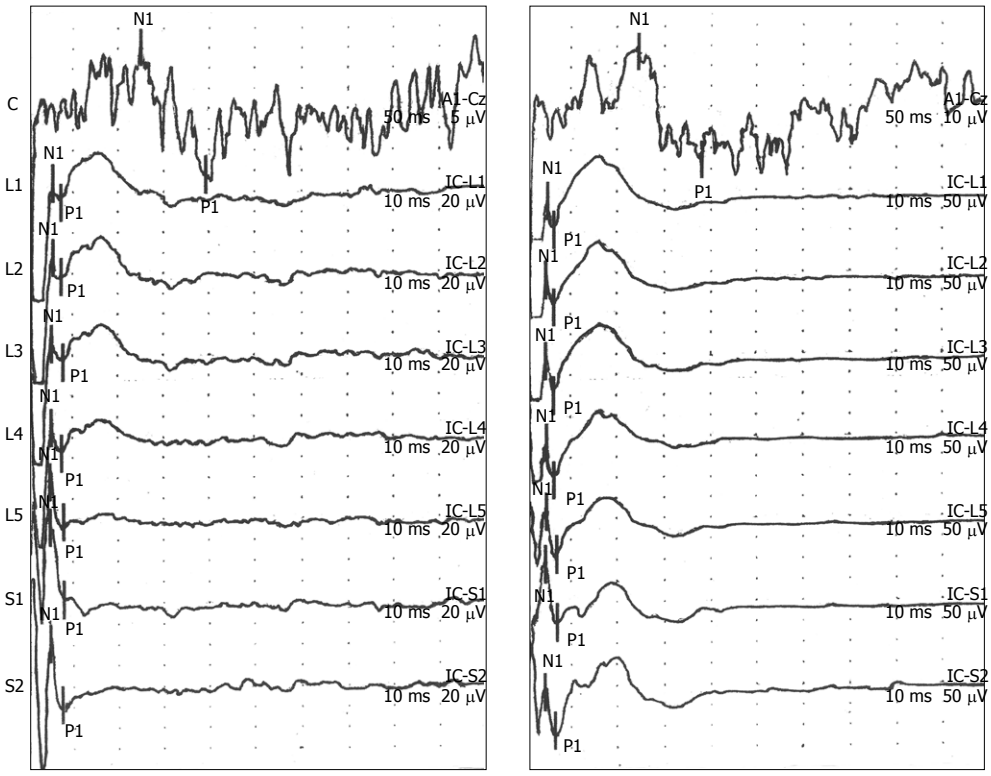

Figure 2 Representative cortical and spinal evoked potential responses to electrical stimulation in the rectum. Evoked potential (EP) responses demonstrated that the typical morphology for cortical and spinal EP recordings including an N1/P1 wave form that increased with stimulus intensity (threshold intensity, left panel; 2 × threshold intensity, right panel). Note the different scales for measuring the amplitude of EP response in the left panel (cortical, 5 μV/division; spinal, 20 μV/division) and right panel (cortical, 10 μV/division; spinal, 50 μV/division). Summary latency and amplitude results for recordings obtained using an electrical stimulus 1.5 × threshold is presented in Table 2.

Table 3 Summary data for reproducibility of latencies and amplitudes for spinal and cortical evoked potentials with repeat testing (mean ± SD)

	Spinal	Cortical
N1 latencies (ms)	4.4 ± 0.5	132.1 ± 6.1
P1 latencies (ms)	6.6 ± 0.6	229.8 ± 15.8
N1/P1 amplitude (μV)	35 ± 8.5	18.6 ± 3.4

The six participants who underwent a second recording session demonstrated reproducible EP wave forms and no significant changes in the latency and amplitude values compared to the first recording session (Table 3). Representative EP responses from two recording sessions for one volunteer are presented in Figure 3.

Application of Lidocaine jelly to the rectal mucosa at the sites of initial stimulation followed by reattachment of the electrodes at the original locations, and restimulation using the same parameters resulted in loss of the EP wave forms at the spine and vertex. In addition, all participants experienced a loss in the perception of the tapping or poking sensation in the pelvis after application of Lidocaine (Figure 4, right panel, $n = 6$).

DISCUSSION

The goal of this study was to evaluate a novel approach to stimulate the rectal mucosa electrically and simultaneously record EPs at the level of the lower spinal column and vertex. We were able to record successfully simultaneous cortical and spinal EPs in approximately 80% of the volunteers, which represents a twofold improvement over a previous study[7]. We were unable to record reliable spinal EPs in three of 17 participants. In these three individuals, we were able to record a cortical EP waveform. We speculate that the inability to record a reproducible spinal wave form in these three individuals may be related to body habitus. All three individuals had a body mass index > 25.

The polyphasic cortical EP wave forms that we recorded demonstrated similar morphology, latencies and amplitudes as described in previous studies[1-4]. We believe that any differences compared to the published literature can be attributed to the methodology that we employed, which involved direct attachment of the electrodes to the rectal mucosa, and the distance between attachment of the electrodes. The sensory innervation of the rectum involves afferent fibers that travel with sympathetic and parasympathetic spinal afferent nerves. The pelvic nerve afferents originate from the inferior hypogastric plexus[9] include a mixture of unmyelinated C fibers and poorly myelinated Aδ fibers that transmit a variety of sensory modalities that range from innocuous to painful[10-12]. Stimulation in this area is complicated by the proximity of

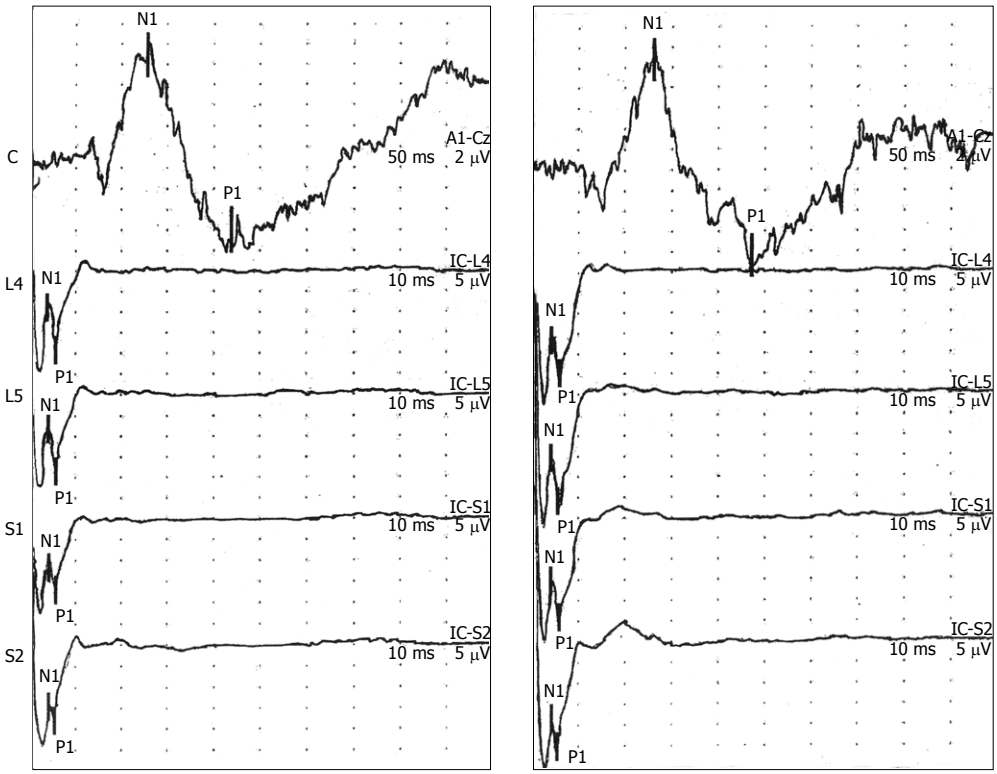

Figure 3 Evoked potential responses were reproducible over time. Representative cortical and spinal evoked potential responses from two recording sessions for one volunteer are shown in this figure. No significant changes in the latency and amplitude values were observed compared to the initial recording session. Summary data are presented in Table 3.

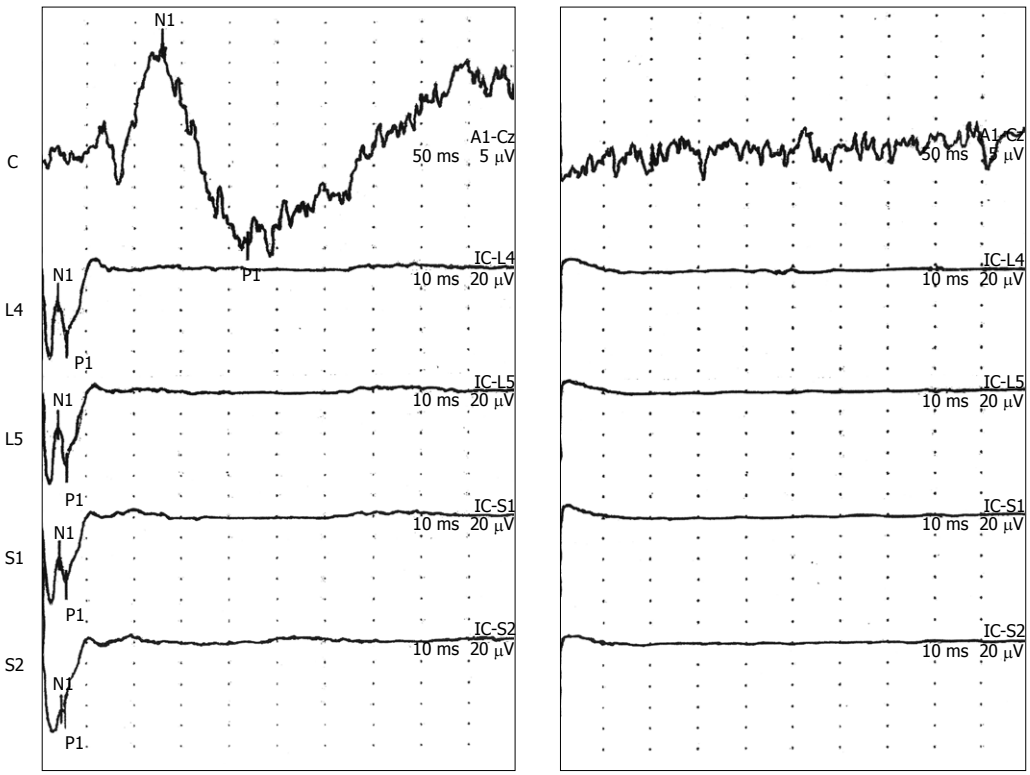

Figure 4 Application of Lidocaine jelly to the rectal mucosa at the sites of electrical stimulation resulted in loss of the cortical and spinal evoked potential responses. A representative evoked potential response (before and after application of Lidocaine) is presented in this figure. In addition, all participants reported a loss in the sensory response to electrical stimulation after application of Lidocaine.

somatic nerves that could be activated by high-intensity electrical stimulation.

Very few published data exist with regard to the characteristic wave form, latencies and amplitudes for spinal EPs using rectal stimulation. The characteristics of the spinal EP wave forms that we recorded were quite similar to those in a previous study that used a different electrical stimulation methodology[7]. Neurophysiological testing has been employed in the diagnoses of neurogenic disorders that involve the lower urinary tract and spinal cord, including somatosensory EP measurements[13,14]. However, the performance of cortical and spinal EP testing in response to bladder or urethra stimulation has not gained broad acceptance in clinical practice because of technical challenges.

We employed electrical stimulation in this study because currently available technologies using balloon distention obscure the recording of spinal EP wave forms. A potential drawback of using electrical stimulation is that this approach can result in nonspecific activation of all afferent pathways, depending on the stimulation parameters. On the other hand, it is possible that specific electrical stimulation parameters can be used to stimulate preferentially subpopulations of primary afferent neurons. For example, using our stimulation parameters, participants reported the perception of a non-painful "tapping" or "poking" sensation that increased with the intensity of electrical stimulus. This is similar to previous studies[1,3,4]. Others have used electrical stimulation protocols (typically involving high stimulation intensities) that evoke the perception of pain[8]. The sensations reported by our participants may be mediated by Aδ-fiber somatic afferents that are thought to encode non-painful stimuli, but saturate at stimulation levels well below pain threshold. It is possible that customized electrical stimulus parameters might prove useful to assess Aδ-fiber afferents in isolation. This may be important in sensitization states because this population of afferents can undergo phenotypic changes after the development of central sensitization[12]. Pain perception is thought to involve slower conducting small myelinated Aδ and unmyelinated C fibers and require more intense stimulation for activation[15]. It remains to be determined whether individuals with neurodegenerative disorders or chronic pain syndromes will demonstrate detectable changes in latency or amplitude of EP wave forms recorded at the lower spinal.

In conclusion, this study demonstrates that is possible to record cortical and spinal EPs simultaneously using rectal electrical stimulation with a relatively high level of reliability, e.g. approximately 80%. We believe that this methodology can be employed to improve our understanding of the potential contribution of rectal primary afferent neurons in various neurodegenerative and functional pain disorders. We anticipate that combining this technology with other assessments of anorectal physiology and functional neuroimaging techniques will result in novel insights regarding the neurophysiological characteristics of visceral afferent pathways in both health and disease.

COMMENTS

Background

Recording of evoked potentials (EPs) is a broadly applied technique to study central and peripheral neural function in health and disease in humans. Recording of EPs at the level of the spine in response to visceral stimulation has been technically challenging. The absence of a reliable method to record spinal EPs in response to visceral stimulation has placed limitations on the study of primary afferent neurons and their role in a variety of neurodegenerative and functional pain disorders. This article reports a new technique that represents a significant improvement in our ability to record cortical and spinal EPs simultaneously in response to electrical stimulation in the human rectum.

Research frontiers

At the present time, we have a limited understanding of the role of the primary sensory neurons that innervate the lower gastrointestinal tract in neurodegenerative diseases such as diabetes mellitus or functional pain disorders such as irritable bowel syndrome. The availability of a technique to record spinal EPs reliably in response to visceral stimulation will help address this deficit in our knowledge base.

Innovations and breakthroughs

The authors believe that the improved reliability of this method to record spinal EPs in response to visceral stimulation is related to the attachment of the stimulating electrodes to the rectal mucosa at specific locations, and the distance between the stimulating electrodes.

Applications

The authors believe that this methodology can be employed to improve their understanding of the potential contribution of rectal primary afferent neurons in various neurodegenerative and functional pain disorders. The authors anticipate that combining this technology with other assessments of anorectal physiology and functional neuroimaging techniques will result in novel insights regarding the neurophysiological characteristics of visceral afferent pathways in both health and disease.

Terminology

An EP is an electrical potential recorded from the nervous system of a human or other animal following presentation of a stimulus such as sound (auditory EP), light (visual EP), or physiological [chemical, mechanical, heat/cold or electrical (somatosensory EP)]. They can be contrasted to spontaneous potentials detected by electroencephalography or electromyography.

Peer review

The authors of the present study report a new technique to measure spinal and cortical EPs simultaneously in response to visceral stimulation. This technique could enable us to determine whether alterations in visceral hypersensitivity involve abnormalities in the first-order primary afferent neurons.

Abstract

AIM: To study the efficacy and safety of entecavir (ETV) as first-line therapy for hepatitis B virus (HBV) reactivation due to immunosuppression.

METHODS: Four patients that were treated with different immunosuppressive regimens for hematological malignancies, who presented with HBV reactivation were treated with ETV. Clinical outcome, biochemical and virological factors, including quantitative hepatitis B surface antigen (HBsAg) were studied.

RESULTS: In all patients, ETV induced suppression of HBV, and rapid clinical improvement without side effects. In one patient with an alanine aminotransferase (ALT) flare, tenofovir was added after 3 mo of treatment. Until death from disease progression at 6 mo after treatment initiation, this patient did not clear HBV infection. Retrospectively, it is highly probable that the patient had been non-adherent. In the other three patients, the virological responses were associated with an expeditious decrease in quantitative HBsAg titers with negativity after 2 mo, and all three had HBsAg seroconversion. In one patient, HBV DNA reached a plateau after 3 mo, before becoming undetectable after 1 year, despite early ALT normalization and undetectable quantitative HBsAg.

CONCLUSION: ETV seems to be effective and safe treatment for HBV reactivation. Monitoring of quantitative HBsAg might be an additional useful tool to monitor treatment response.

INTRODUCTION

In patients with previous exposure to hepatitis B virus (HBV), who are hepatitis B surface antigen (HBsAg)-positive, or HBsAg-negative and hepatitis B core antibody (anti-HBc)-positive, acute exacerbation may occur when they become immunocompromised[1]. HBV reactivation (HBV-R) can be severe and is associated with high fatality rates of up to 20%-30%. The European Association for

the Study of the Liver (EASL) now recommends that all patients who are planned to receive chemotherapy, immunosuppressive therapy or stem cell transplantation undergo a test for HBV serology, including anti-HBc antibody prior to treatment[2]. Prophylactic treatment is recommended for patients with positive HBsAg. For those with positive anti-HBc antibodies and undetectable HBV DNA, monitoring of serum alanine aminotransferase (ALT) and HBV DNA is recommended. Although this consensus for the prevention of HBV-R is now implemented in current guidelines, an effective management strategy for patients who are experiencing HBV-R has not yet been established.

Lamivudine is the most commonly used drug for HBV-R. It has been shown to be safe in reactivation and in severe acute or fulminant hepatitis B[3]. However, prognosis remains poor despite lamivudine therapy if hepatic decompensation occurs[4,5]. Furthermore, the efficacy of lamivudine is hampered by the high rate of drug resistance mutations within the HBV polymerase gene that are associated with treatment failure. Entecavir (ETV) was approved in 2006 for the treatment of chronic hepatitis B and offers the advantage of a higher resistance barrier than lamivudine. The EASL guidelines note that the use of tenofovir or ETV might be considered in HBV-R with high viral load, although there is very limited experience.

The aim of our study was to assess the efficacy and safety of ETV in patients with immunosuppression-associated HBV-R at our center.

MATERIALS AND METHODS

We report on four patients with hematological malignancies, who had been referred to our hepatology department because of HBV-R, after approval of ETV, in August 2006. Median age of the patients was 63 years (Table 1). Patient 1 was male, and the other three were female. Two patients had received hematopoietic stem cell transplantation (HSCT) for treatment of acute myeloid leukemia (AML) (patients 1 and 3), the other two patients suffered from follicular lymphoma (patient 2) and B-cell chronic lymphocytic leukemia (B-CLL) (patient 4, Table 1). The patient with CLL was treated with bendamustine. The patient with follicular lymphoma was managed by observation without specific anticancer treatment, but had been treated intermittently with methylprednisolone for rheumatoid arthritis and was thus, due to hematological malignancy and steroid treatment, considered immunocompromised at the time of HBV-R.

In all patient, HBV DNA was measured prospectively with real-time PCR (Abbott HBV rtPCR; Abbott, Wiesbaden, Germany). On-treatment serum HBsAg kinetics were analyzed retrospectively (Abbott HBSAG). HBsAg was assessed at baseline, during treatment (1-3 mo), and during follow-up.

Only one of the patients (patient 3) had HBV screening prior to immunosuppression and was diagnosed with resolved hepatitis B with surface antigen clearance and an anti-hepatitis B surface antigen antibody (anti-HBs) level of 370 IU/L (Abbott AUSAB). During chemotherapy, quantitative HBsAg titers and HBV DNA were monitored closely and remained negative. When anti-HBs level fell below 10 IU/L, lamivudine prophylaxis was initiated and continued until 4 mo after cessation of immunosuppression with cyclosporine. At this time, HBV DNA was not detectable. HBV-R occurred 8 mo after lamivudine treatment had been stopped.

Prior to the initiation of chemotherapy or immunosuppression, all patients had normal liver values. None of them had a history of prior non-viral liver disease. Co-infection with hepatitis A, C or delta viruses or HIV was excluded serologically at the time of referral to our unit.

RESULTS

At the time of diagnosis of HBV-R, all patients presented with similar clinical, laboratory and virological findings. All patients suffered from fatigue, nausea and jaundice. They all had moderate to high HBV-DNA levels that ranged from 1×10^5 to 8.06×10^7 IU/mL. ALT levels were > 10 times the upper limit of normal in all patients. In one patient, serum bilirubin concentration was normal. In the other three patients, bilirubin levels ranged from 8 to 20 mg/dL. International normalized ratio (INR) was within the normal range in three patients. Only one patient had an impaired liver function with an INR of 1.4 (patient 1). Three of the patients were hepatitis B e antigen (HBeAg)-positive (Table 1).

When HBV-R was diagnosed, all patients were immediately treated with ETV. Three treatment-naïve patients were treated with oral 0.5 mg/d ETV (Baraclude®; Bristol-Myers-Squibb, Munich, Germany), and one patient (patient 3) received 1 mg ETV because of prior prophylactic treatment with lamivudine.

In all patients, ETV induced suppression of HBV that was associated with rapid clinical improvement and ALT normalization (Figure 1A). Three of the four patients had undetectable HBV-DNA levels after 3, 5 and 13 mo of treatment, respectively (Figure 1B).

One of the patients (patient 4) died because of disease progression of CLL after 6 mo of treatment with ETV. After 3 mo of ETV treatment, tenofovir was added because chemotherapy had to be restarted and HBV DNA showed a 4-$\log_{10}$ reduction but was still detectable at about 10^4 IU/mL, and ALT flared. When the patient died after 6 mo of ETV treatment and 3 mo of add-on tenofovir treatment, ALT had normalized and HBV DNA had declined to 136 IU/mL. The patient was tested for ETV resistance by sequencing the s-gene and pol-gene, however, no resistance-associated mutations were detected. Further investigation revealed that this patient had been non-adherent and treatment had been suspended for 8 d because she had run out of medication.

Three patients had been HBeAg-positive and all of them had HBeAg seroconversion during the course of treatment. Three of four patients (patients 1-3) even had HBsAg loss after 1, 2 and 4 mo of treatment, respectively.

On-treatment quantitative serum HBsAg levels decreased rapidly and were undetectable at 8 wk in all pa-

tients who developed HBsAg clearance (Figure 1C).

In two of the patients, ETV treatment was withdrawn after 6 mo following HBsAg seroconversion with a follow-up of 6-8 mo after discontinuation. Treatment was well tolerated in all patients and no side effects were observed.

DISCUSSION

HBV-R occurs in patients who have been exposed to HBV and who are receiving immunomodulatory drugs, after solid organ transplantation or HSCT. It has also been described to appear spontaneously[6,7] or in the presence of malignancies. HBV-R can be severe and result in acute hepatic failure and death.

Here, we report four patients with hematological malignancies, who developed HBV-R. In all of these patients, ETV induced suppression of HBV that was associated with rapid clinical improvement, without any side effects. ETV is known to have a very potent antiviral effect that has been shown to be greater than that observed with lamivudine, and has a high resistance barrier[8]. Also, almost 10 years after the introduction of lamivudine, patients are at considerable risk for primary infection with lamivudine-resistant HBV strains, against which, lamivudine treatment is useless. For these reasons, ETV was chosen as initial treatment in our patients.

Drug-induced liver injury[9] or lactic acidosis[10] that have recently been described in patients undergoing treatment with ETV were not observed in our patients. Safe and efficient use of ETV in HBV-R has also been described in one patient from Spain recently[11]. However, we have to point out that none of our patients suffered from severe hepatic failure as defined previously[3] or liver cirrhosis.

It has already been reported that patients with HBV-R

tend to have a higher rate of sustained virological response and higher rates of HBeAg seroconversion than patients who are chronically infected. This was also true for our patients who cleared HBeAg in all cases, and three even experienced HBsAg seroconversion. In Japan, a patient who was receiving chemotherapy for B-cell lymphoma was also treated with ETV for HBV-R and became HBsAg-negative after 2 mo of treatment[12]. The patient from Spain also cleared HBsAg after 6 mo of treatment with ETV[11]. Another patient with B-cell lymphoma in France received ETV as first-line therapy after HBV-R. This patient also had undetectable HBV DNA after 4 mo of treatment and no side effects[11]. It is not stated whether this patient also cleared HBsAg.

In two of our patients, ETV has successfully been withdrawn after anti-HBs had reached levels > 100 IU/mL, and these patients are currently being followed up closely. The third patient has an anti-HBs level < 100 IU/mL and ETV treatment is being continued at present (Table 1).

We also evaluated quantitative HBsAg to study its behavior and possible role in the various phases of HBV-R. In acute hepatitis, the levels of HBsAg are usually > 10 000 IU/mL[13]. The highest level that we found during reactivation was 3031.5 IU/mL. All patients that achieved HBsAg clearance showed at least a 1 $\log_{10}$ drop of HBsAg at wk 4 of treatment with ETV, and at wk 8, quantitative HBsAg was undetectable in all patients that experienced HBsAg seroconversion during follow-up. An early serum HBsAg decline has already been shown to be predictive of sustained virological response during treatment with nucleosid(t)e analogs or pegylated interferon[14-17]. Patient 1 showed a rapid decline in quantitative HBsAg with negativity at wk 8, and normalization of ALT and HBsAg seroconversion during follow-up. Despite this response, HBV DNA reached a plateau around 10^3 IU/mL for 9 mo after an initial decline for 3 mo, and became negative only after 1 year of treatment. This finding implies that quantitative HBsAg might be an additional useful tool to optimize the clinical management of patients with HBV-R.

In one patient, tenofovir was added after 3 mo of ETV treatment. This patient had a high viral load prior to treatment (4.5×10^7 IU/mL). After 3 mo, she had a 4 $\log_{10}$ reduction in viral load and ALT decreased from 711 to 313 IU/mL. As a result of progression of CLL, chemotherapy had to be re-started. When ALT levels under chemotherapy rose to 752 IU/mL, tenofovir was added. However, there was no increase in viral load under chemotherapy, and the presence of known ETV resistance mutations was excluded retrospectively. At this time, she had already cleared HBeAg. ETV treatment was suspended for 8 d because the patient ran out of medication. Thus, incomplete viral suppression was possibly not due to lack of efficacy of ETV but resulted from nonadherence. However, we cannot completely rule out that viral suppression by ETV in this patient was insufficient, as even fulminant hepatic failure despite ETV treatment following HBV-R has been described in a single case[18].

It is important to point out that only one of our patients had HBV screening prior to initiation of immunosuppressive treatment. We cannot prove if the other patients really had true reactivation of hepatitis B. However, all of these patients had normal liver values before the start of immunosuppression. *De novo* infection during immunosuppressive therapy is rather unlikely, therefore, we believe that these patients had either resolved or inactive hepatitis B prior to the initiation of immunosuppression. The fact that these data are not available is a weakness of our study, but reflects the real-life situation. Although it is widely recognized that HBV-R can occur with conventional immunosuppression and newer drugs, in particular rituximab, HBV screening often is still not performed in these patients. Taking into consideration the possibly fatal outcome of HBV-R and the fact that it is preventable, HBV screening in all of these patients is mandatory, especially as it has been described that HBV is more prevalent among patients with hematological malignancies of B lineage, and has been hypothesized to even play a pathogenic role in these patients[19,20].

In the patient that was screened prior to treatment and received lamivudine prophylaxis, prophylaxis had retrospectively been stopped too early. At that time, there was no clear consensus about the duration of prophylactic therapy after cessation of chemotherapy. The new EASL guidelines now recommend that prophylaxis should be continued for at least 1 year after withdrawal of immunosuppressive drugs[2]. Furthermore, we and others[5] have experienced HBV-R in HBsAg-negative/anti-HBc-positive patients. Therefore, it might be considered to extend prophylaxis for HBV-R to this subpopulation.

We believe that our results justify further controlled prospective studies to confirm the efficacy and safety of ETV in a larger number of patients with HBV-R.

COMMENTS

Background

Resolved or inactive hepatitis B virus (HBV) infection usually does not harm the patient. However, if for other medical conditions immunosuppressive therapies need to be initiated in these patients, HBV might reactivate with potentially fatal outcome.

Research frontiers

It is recognized that HBV reactivation (HBV-R) might occur under immunosuppressive therapy. Therefore, screening for HBV is recommended before the initiation of these therapies. However, despite these recommendations, screening often is not performed and significant liver disease might develop. The optimal treatment for these patients in order to avoid death or the need for liver transplantation is currently not known, and no systematic studies have addressed this issue.

Innovations and breakthroughs

The authors have successfully treated patients suffering from HBV-R with entecavir (ETV). In all patients, ETV therapy induced suppression of HBV and rapid clinical improvement without side effects.

Applications

As the optimal treatment strategy for HBV-R is currently unknown, the data presented in this article provide a rationale for prospectively studying the use of ETV for the treatment of liver disease due to HBV-R under immunosuppressive therapies.

Terminology

Immunosuppressive therapy most frequently refers to chemotherapy for malignant tumors or agents used for treatment of autoimmune-mediated diseases such as rheumatic diseases.

Peer review

The authors have explained their experience with ETV in immunosuppressed patients with HBV-R. This paper adds important information to the literature, especially the usefulness of ETV in this field, in which data are sparse.

Abstract

AIM: To compare the endotics system (ES), a set of new medical equipment for diagnostic colonoscopy, with video-colonoscopy in the detection of polyps.

METHODS: Patients with clinical or familial risk of colonic polyps/carcinomas were eligible for this study. After a standard colonic cleaning, detection of polyps by the ES and by video-colonoscopy was performed in each patient on the same day. In each single patient, the assessment of the presence of polyps was performed by two independent endoscopists, who were randomly assigned to evaluate, in a blind fashion, the presence of polyps either by ES or by standard colonoscopy. The frequency of successful procedures (i.e. reaching to the cecum), the time for endoscopy, and the need for sedation were recorded. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the ES were also calculated.

RESULTS: A total of 71 patients (40 men, mean age 51.9 ± 12.0 years) were enrolled. The cecum was reached in 81.6% of ES examinations and in 94.3% of colonoscopies (P = 0.03). The average time of endoscopy was 45.1 ± 18.5 and 23.7 ± 7.2 min for the ES and traditional colonoscopy, respectively (P < 0.0001). No patient required sedation during ES examination, compared with 19.7% of patients undergoing colonoscopy (P < 0.0001). The sensitivity and specificity of ES for detecting polyps were 93.3% (95% CI: 68-98) and 100% (95% CI: 76.8-100), respectively. PPV was 100% (95% CI: 76.8-100) and NPV was 97.7% (95% CI: 88-99.9).

CONCLUSION: The ES allows the visualization of the entire colonic mucosa in most patients, with good sensitivity/specificity for the detection of lesions and without requiring sedation.

Key words: Colonoscopy; Diagnosis; Endotics system; Polyps; Sedation

INTRODUCTION

Video-colonoscopy is considered the gold-standard for the diagnosis of colonic diseases, including carcinomas and polyps[1]. However, this diagnostic technique presents some limitations, such as invasiveness and patient discomfort, which limit the adherence to programs for the early detection of colon carcinoma[2,3]. When undergoing colonoscopy, patients often require sedation, which may result

in the onset of unintended deep sedation[4]. In addition, standard colonoscopy is associated with various procedural risks, ranging from minor complications[5] to cardiopulmonary events[6,7], colon perforation[8,9], infections[10,11] and, in very rare circumstances, death[12].

Newer diagnostic techniques are therefore advocated to overcome these limitations while maintaining a good diagnostic accuracy[1,13]. While the use of such techniques in clinical practice is starting to emerge, direct head-to-head comparisons between different technologies are still lacking[1].

The endotics system (ES) is a new robotic device composed of a workstation and a disposable probe, which gave promising results in a pilot study for the detection of colonic polyps[14]. We report here the results of a head-to-head comparison of ES and standard colonoscopy in the diagnosis of polyps. To our knowledge, this is the first direct comparison of these techniques.

MATERIALS AND METHODS

Study setting and design

This is a prospective, single-centre study conducted at the Department of Gastroenterology of Pisa University Hospital, from March to August 2009. All patients gave informed consent before inclusion in the trial. The study was conducted in accordance to the Helsinki Declaration (2008 version) and its protocol was approved by the Hospital Ethical Committee.

Eligibility criteria

All adult patients (aged 18-75 years) consecutively seen at our Unit were eligible for this study if they met ≥ 1 of the following criteria: (1) age > 40 years with at least a first-grade relative with a previous diagnosis of colorectal carcinoma or adenoma before he/she was 60 years old; (2) were receiving follow-up evaluations after previous endoscopic polypectomy; and (3) were positive at faecal occult blood test (FOBT), as assessed during screening campaigns. Patients were excluded if they were pregnant, affected by chronic renal insufficiency, active ulcerative colitis or Crohn's disease, bleeding lesions of oesophagus, stomach or small intestine, or had undergone abdominal surgical interventions in the 6 mo period prior to study entry.

The ES

The ES (Era Endoscopy S.r.l., Pisa, Italy) is a new CE-marked (the CE marking certifies that a product has met EU consumer safety, health or environmental requirements) medical device for diagnostic colonoscopy, composed of a workstation and a hand-held console which drives a steerable probe through the colon lumen. A complete description of this device has been provided elsewhere[14]. In this study we used a slightly different ES version from the one used in the previous pilot study (25 cm length in the contracted form and 43 cm in the elongated form, with respect to 23 and 37 cm, respectively, of the previous version).

ES probe is sterile, disposable and soft, in order to allow for adjustment of its shape to colon morphology, and avoid stretching maneuvers to reach the cecum. The probe is composed of a head, a steerable tip, a flexible body (all with 17 mm diameter), a thin tail (7.5 mm diameter and 180 cm length) and a special tank with an electro-pneumatic connector. The head hosts both a vision system, including a camera (110° vision angle) with LED light sources, and channels for water jet and air in order to provide rinsing and suction/insufflation, respectively. The workstation allows the endoscopist to drive the probe using the console and to visualize real-time images on a screen.

The key operations performed by the ES can be summarized as follows: (1) the steering, consisting of an electro-pneumatically driven deflection of the head of the robot (a rotation of 180° can be performed in every direction within a short bending diameter); (2) the elongation of the probe body, visually driven by the endoscopist in order to follow the morphology of the intestine; and (3) the control of rinsing, insufflation and suction. Suction allows the endoscopist to remove liquids from the bowel and convey them to the tank. Insufflation may help unfold the bowel wall in order to have a clearer view of the mucosa.

The motion of advancing the probe through the colon follows a cyclic sequence of steps[14].

Study procedures

All patients underwent a standard preparation to colonoscopy: a fiber-free diet in the seven days preceding the examination and oral administration of phosphate sodium lavage solution (80 mL in 2000 mL of water until evacuation of clear yellowish fluid) on the day before the examination. Both ES examination and standard colonoscopy were performed in each patient on the same day. All procedures were performed by endoscopists with a solid experience (> 500 colonoscopies successfully performed) and after complete training with the ES (> 20 tests on pigs or models). In all patients, the first colonic examination was performed with the ES; after that, the patients underwent standard colonoscopy. This sequence was decided in order to avoid possible alterations of the physiologic features of the colon due to standard colonoscopy. Moreover, the current version of the ES does not allow us to perform polypectomy or biopsies; these procedures, if required, have been performed during the standard colonoscopy. Each patient was examined lying on his/her left side and were later turned to the supine position only if required.

In each single patient, the assessment of the presence of polyps was performed by two independent endoscopists, who were randomly assigned to evaluate, in a blind fashion, the presence of polyps either by ES or by standard colonoscopy. The randomization was performed according to a list of numbers generated by a computer and each operator ignored the results of the evaluation performed by the other examiner.

The colonoscopy was judged successful upon the visual recognition of the ileo-cecal valve by the examiner, confirmed by a third independent endoscopist. The di-

Table 1 Demographic characteristics and indications for colonoscopy

Parameter	Value
Total No. of patients (*n*)	71
Males, *n* (%)	40 (56.3)
Age (yr), mean ± SD, (range)	51.9 ± 12.0 (33-81)
Indication for colonoscopy, *n* (%)	
Follow-up of a previous polypectomy	11 (15.5)
Search for faecal occult blood	21 (29.5)
Familiar history of colon neoplasms	39 (54.9)

Table 2 Operative results observed with the endotics system procedure and with standard colonoscopy (*n* = 71 for each procedure) *n* (%)

Parameter	Endotics system	Standard colonoscopy	*P* value
Procedures reaching cecum	58.0 (81.6)	67.0 (94.3)	0.0300
Complete procedure, mean ± SD (min)	45.1 ± 18.5	23.7 ± 7.2	< 0.0001
Patients requiring sedation	0	14.0 (19.7)	< 0.0001

mensions and sites of the polyps identified during the ES and the standard colonoscopy were recorded. Polyps were then removed and/or biopsies were taken as necessary, according to polyp shape and dimensions. Polyp dimensions were estimated as described by Van Gossum *et al*[15]. Colon cleansing was assessed according to Aronchick's scale and recorded[16]. The time required to perform ES and colonoscopy were also measured. All the patients were contacted 1 and 7 d after the procedures to evaluate the possible onset of adverse events.

Antispasmodic medications were not allowed. Midazolam and meperidine were administered and tailored according to each patient's need. These medications were offered to patients who referred pain during either ES or standard colonoscopy.

Data analysis

All the data were analyzed by descriptive statistics, as appropriate. Comparisons between ES and standard colonoscopy results were performed by Student's paired *t*-test or Fisher's exact test, with a P value < 0.05 considered statistically significant. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the ES were calculated with standard 2 × 2 table analysis.

All statistical analyses were performed with SAS software (SAS Institute, Cary, NC).

RESULTS

A total of 71 patients (40 men; mean age 51.9 ± 12.0 years, Table 1) were included in the study and underwent both ES procedure and standard colonoscopy.

Operative results of the two procedures are summarized in Table 2. Overall, the cecum was reached more frequently with standard colonoscopy (P = 0.03 *vs* ES); moreover standard colonoscopy required a significantly shorter time with respect to ES (P < 0.0001). On the other hand, no patients requested sedation during the ES procedure, while 14 subjects (19.7%) requested the administration of midazolam and meperidine during standard colonoscopy (P < 0.0001).

Table 3 Reasons for incomplete views of the colon during examinations *n* (%)

Reasons	Endotics system	Standard colonoscopy
Anal stenosis	1 (1.4)	0
Sigma stenosis	2 (2.8)	0
Dolicolon	0	1 (1.4)
System failure	3 (4.2)	0
Insufficient length of endoscopic device	1 (1.4)	0
Insufficient cleaning	6 (8.4)	3 (4.2)

Diagnostic accuracy

In total, 14 patients were excluded from the analysis of diagnostic accuracy, as a complete view of the colon was not obtained in them with ES and/or standard colonoscopy (Table 3).

Overall, 14 polyps were detected during ES procedure and 15 were identified during standard colonoscopy. The measured mean diameter of the polyps was comparable with the two procedures (7.64 ± 3.82 mm for ES, 7.50 ± 3.18 mm for standard colonoscopy).

Sensitivity of ES, with respect to standard colonoscopy, was 93.3% [95% confidence interval (95% CI): 68.0-99.0], and specificity was 100% (95% CI: 76.8-100). PPV and NPV were 100% (95% CI: 76.8-100) and 97.7% (95% CI: 88.0-99.9), respectively.

Adverse events

Six patients (8.4%) reported adverse events (nausea, headache, abdominal pain and discomfort). All events were of mild intensity and a spontaneous recovery occurred within 48 h from the onset in all cases. As the onset of adverse events was evaluated 1 and 7 d after the colonoscopy procedures and one single cleaning solution was used, it was not possible to distinguish between adverse events occurring during ES examination and those occurring during standard colonoscopy.

DISCUSSION

Overall, the results of this study suggest that the ES procedure may represent an accurate tool for the detection of colon polyps. Despite the fact that ES was not able to reach the cecum in some cases and was longer than the standard colonoscopy, it had a comparable diagnostic accuracy and did not require the administration of sedating drugs.

It is widely accepted that standard colonoscopy is associated with the possible onset of adverse events and with a low acceptance by patients[2-12]. Newer technologies for colonoscopy are therefore being evaluated in order to over-

come these limitations.Technologies under development for the study of the colon include the Invendoscope™, the Video Capsule Endoscopy and the Aeroscope.

The Invendoscope™ (Invendo Medical, Kissing, Germany) is a single-use colonoscope based on motor driven inverted sleeve technology with a working channel[17]. The results of a single-arm, pilot study on this device conducted on 39 healthy volunteers showed absence of pain in 92% of patients undergoing endoscopy; the cecum was reached in 82% of cases, after a mean time of 23 min[17]. However, no data concerning its diagnostic accuracy are currently available[17].

The Video Capsule Endoscopy (Given Imaging Ltd., Yoqneam, Israel) is a pill-size capsule, activated upon swallowing, which records images of the colonic mucosa[18]. In a pilot study on 41 patients, this device showed a PPV of 59% and a NPV of 84% with respect to standard colonoscopy, with a specificity of 70%[18]. These results were overall confirmed in a larger, recently published multicenter study; however, in this study the sensitivity of Visual Capsule Endoscopy was lower than that associated with standard colonoscopy[15]. Moreover, this device cannot clear colonic debris during the procedure or insufflate air into collapsed intestines[19].

Last, the Aeroscope (GI View Ltd, Ramat Gan, Israel) is a self-propelling, disposable endoscope, that uses low-pressure carbon dioxide to propel a balloon device through the colon, thus facilitating the motion of the colonoscope and reducing discomfort, pain and the risk of perforation[20]. In a study conducted with 12 volunteers, this device reached the caecum in 83% of cases, after a mean time of 14 min. However, 17% of patients requested analgesia, and 33% experienced symptoms consistent with a vagal reaction, including sweating and bloating[20].

The present study lends support to a possible introduction of the ES into clinical practice. In a previous pilot study, conducted in 40 patients, the ES was associated with significantly lower pain intensity and less discomfort, when compared to standard colonoscopy (pain intensity 0.9 *vs* 6.9; discomfort 1.1 *vs* 6.8; both parameters were evaluated on a 1-10 scale)[14]. The high diagnostic accuracy and the lack of need for sedation reported in the present study during the ES procedure may represent further advantages of this technology. In particular, we believe that the reduced need for sedation may have a particular importance: it has been suggested that sedation may be associated with an increase in the onset of cardiopulmonary events and of unintended deep sedation[4,6], although these findings were challenged by a recent meta-analysis[21]. Noteworthy, the ES probe is a single-use device, thus limiting the risk of cross-infections and reducing the overall examination time, since no decontamination is required. Moreover, a single endoscopist may perform the entire procedure, without the need of any assistance by nurses.

However, it must be pointed out that the ES was associated with a lower rate of cecum reach, a more frequent incomplete view of the colon and a longer time to perform the examination than standard colonoscopy. In addition, the current version of this device does not allow the endoscopist to perform polypectomy or biopsies.

We speculate that the higher number of patients with insufficient cleaning during the ES procedure than during the standard colonoscopy may be due to the smaller diameter of the suction device of the ES, when compared to that of the standard video-colonoscopy (1 mm *vs* 3.2 mm, respectively). Moreover, other potential limitations may be also related to low level of training with the ES, since the endoscopist performed > 500 colonoscopies and only > 20 ES in models and pigs with "similar human anatomy".

This study has some limitations that must be acknowledged. First, it was performed in an overall limited number of patients; however, pilot studies with a similar or even smaller sample size have been conducted to evaluate other colonoscopy devices[17,18,20]. Larger studies are required for a more complete evaluation of the ES. Second, inclusion and exclusion criteria were not stringent, potentially limiting the robustness of the analysis; however, this decision was taken in order to better reproduce clinical practice, even in an experimental setting. Third, the ES was compared only with a standard colonoscopic procedure, and not with any other new devices for colonoscopy. However, even if head-to-head comparisons with such devices is still lacking, and the available pieces of evidence do not permit us to retrieve definite findings, the results obtained with the ES may be preliminarily considered at least comparable with those observed with other alternative systems for colonoscopy[17-20].

In conclusion, the ES has shown a high diagnostic accuracy, overall comparable to that reported with standard colonoscopy, and it appeared to be not associated with significant pain/discomfort[14] or with the need for sedation. Although ES seems to show potential shortcomings such as lower cecum intubation rate and/or long duration of endoscopy, it may be considered a promising alterative to standard colonoscopy in the detection of colonic polyps, even if introduction of a tool to perform polypectomy or biopsies is advisable. On this basis, it may be considered a promising alterative to standard colonoscopy in the detection of colonic polyps.

It has been suggested that the introduction of this diagnostic instrument into clinical practice could facilitate the adoption of colonoscopy as first-level screening, with a possible reduction in the incidence of colon cancer-induced mortality[14]. If larger studies, which should also evaluate the optimal bowel preparation conditions and further investigate the need for sedation, will confirm the preliminary evidence collected so far, the ES could play an important role in the detection of colorectal cancer diseases.

COMMENTS

Background

Video-colonoscopy is considered the gold-standard for the diagnosis of colonic diseases, including carcinomas and polyps. However, this diagnostic technique presents some limitations, such as invasiveness and patient discomfort, which limit the adherence to programs for the early detection of colon carcinoma. Furthermore, standard colonoscopy may be associated with various procedural risks.

Research frontiers

Newer diagnostic techniques are advocated to overcome limitations of video-colonoscopy while maintaining a good diagnostic accuracy. The endotics system (ES) is a new robotic device composed of a workstation and a disposable probe, which gave promising results in a pilot study for the detection of colonic polyps. The research hotspot is a head-to-head comparison of ES and standard colonoscopy in the diagnosis of polyps.

Innovations and breakthroughs

The present study lends support to a possible introduction of the ES into clinical practice. The high diagnostic accuracy and the lack of need for sedation reported in the present study during the ES procedure may represent further advantages of this technology.

Applications

The ES has shown a high diagnostic accuracy, overall comparable to that reported with standard colonoscopy, and it appeared to be not associated with significant pain/discomfort or with the need for sedation. It has been suggested that the introduction of this diagnostic instrument into clinical practice could facilitate the adoption of colonoscopy as a first-level screening procedure, with a possible reduction in the incidence of colon cancer-induced mortality.

Terminology

The ES: is a new medical device for diagnostic colonoscopy, composed of a workstation and a hand-held console which drives a steerable probe through the colon lumen. Standard preparation to colonoscopy: a fiber-free diet in the seven days preceding the examination and oral administration of phosphate sodium lavage solution (80 mL in 2000 mL of water until evacuation of clear yellowish fluid) on the day before the examination.

Peer review

The present study described a new device for diagnostic colonoscopy, named "ES". The authors aimed to compare ES with video-colonoscopy in regard to the detection rate of polyps. Moreover, use of sedation, cecum intubation rate and duration of endoscopy were assessed. The authors concluded that ES allowed the visualization of the entire colonic mucosa in most patients, with good sensitivity/specificity for the detection of lesions and without requiring sedation. The study is well-written and designed.

Abstract

AIM: To clarify the incidence of congenital hemolytic anemias (CHA) in young cholelithiasis patients and to determine a possible screening test based on the results.

METHODS: Young cholelithiasis patients (< 35 years) were invited to our outpatient clinic. Participants were asked for comorbidities and family history. The number of gallstones were recorded. Blood samples were obtained to perform a complete blood count, standard Wright-Giemsa staining, reticulocyte count, hemoglobin (Hb) electrophoresis, serum lactate dehydrogenase and bilirubin levels, and lipid profile.

RESULTS: Of 3226 cholecystectomy patients, 199 were under 35 years, and 190 with no diagnosis of CHA were invited to take part in the study. Fifty three patients consented to the study. The median age was 29 years (range, 17-35 years), 5 were male and 48 were female. Twelve patients (22.6%) were diagnosed as thalassemia trait and/or ıron-deficiency anemia. Hb levels were significantly lower (P = 0.046), and mean corpuscular volume (MCV) and hematocrit levels were slightly lower (P = 0.072 and 0.082, respectively) than normal. There was also a significantly lower number of gallstones with the diagnosis (P = 0.007).

CONCLUSION: In endemic regions, for young cholelithiasis patients (age under 35) with 2-5 gallstones, the clinician/surgeon should pay attention to MCV and Hb levels as indicative of CHA.

Key words: Cholelithiasis; Congenital hemolytic anemia; Screening test

INTRODUCTION

Congenital hemolytic anemias (CHA), especially thalassemia and sickle cell anemia (SCA), are endemic in southern Turkey: the prevalence of the β-thalassemia trait is reported to be 1.84%-2.3% and the prevalence of sickle hemoglobin (Hb) is 4.6%[1,2]. Symptomatic exacerbation of severe anemia can be easily diagnosed. Preventive measures and treatment of complications are well known by the hematologists. However, the thalassemia trait and SCA trait patients rarely present with clinical symptoms, and minor hematological findings may be missed in routine clinical practice.

One of the frequent comorbidities of CHA is gallbladder stones. Chronic hemolysis causes increased bilirubin excretion and gallstone formation[3-5]. The most common types of gallstones associated with CHA are pigment gallstones. Even in cholesterol stones, a bilirubin nidus has been documented[6]. Thus, increased bilirubin acts a trigger in the formation of gallstones regardless of stone type[7]. Eighty percent of SCA and β-thalassemia major patients and more than 40% of spherocytosis patients have cholelithiasis detected at a young age, i.e. younger than 30 years[8]. Cholelithiasis would probably be the first clinical finding for these patients, particularly in hereditary spherocytosis or other rare congenital erythrocyte membrane defect patients.

We recognize that there is a distinct number of young patients with cholelithiasis in our region. Therefore, we aimed to clarify the incidence of known and unknown CHA in young cholelithiasis patients in our region. Our secondary aim was to determine a possible screening test based on the results.

MATERIALS AND METHODS

The study was approved by our university's research committee and ethics committee (KA 07/90). Between 1998 and 2007, 3226 cholelithiasis patients were treated in our hospital. Of these, 199 (6.1%) were younger than 35 years. Their files were analyzed retrospectively. Patients with known CHA were excluded. The rest of the patients were contacted by telephone and asked if they had any known hematological disease. Thereafter they were informed of the study and were invited to the outpatient clinic. Written informed consent of all participants was obtained at the clinic visit. Participants were asked to fill in a short inquiry form, which included height, weight, comorbidities, family history of any hematological disease, medications, and number of childbirths and oral contraceptive use for females. The number of gallstones had also been recorded from the preoperative medical records. Blood samples were then obtained for analysis: complete blood count, standard Wright-Giemsa staining, reticulocyte count, high performance liquid chromatography (HPLC), Hb electrophoresis, serum lactate dehydrogenase and bilirubin levels, and lipid profile.

All parameters of all patients were evaluated by the same hematologist (EK) to determine if there was any diagnosis or suspicion of CHA.

Statistical analyses were performed with SPSS 11 for Windows. In order to analyze categorical variables the chi-square test was used. The Student *t* test and its nonparametric counterpart, the Mann Whitney *U* test, were used for continuous variables. The receiver operating characteristics (ROC) curve for the studied variables and diseased patients was also obtained for sensitivity analysis.

RESULTS

Nine of 199 cholelithiasis patients (4.52%) had a previous diagnosis of SCA. The rest of the 190 patients were invited to the hospital and 53 patients (27.9%) consented to the study. The median age of these 53 patients was 29 years (range, 17-35 years), with 5 males and 48 females.

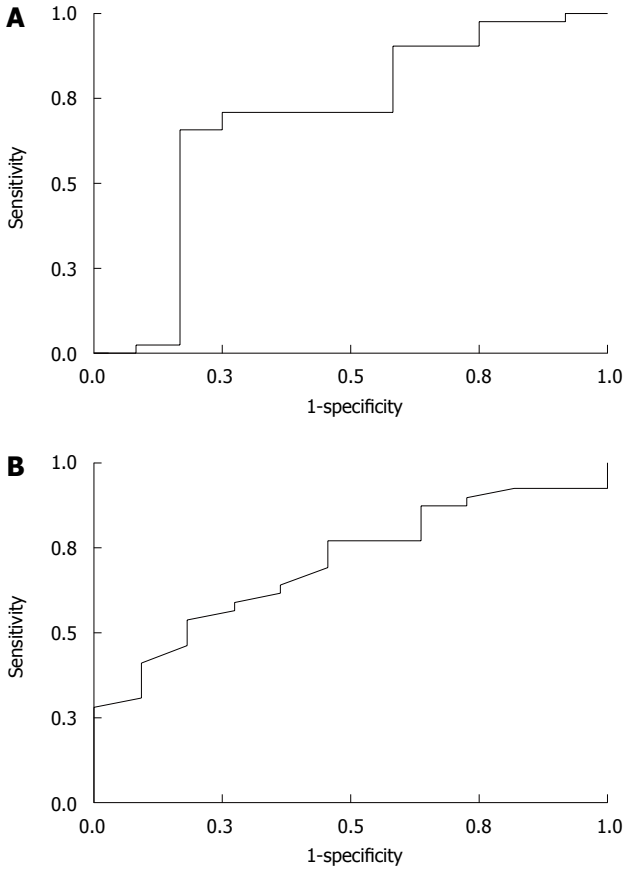

Figure 1 Receiver operating characteristics curve for mean corpuscular volume and α-thalassemia (A), receiver operating characteristics curve for hemoglobin and α-thalassemia (B).

Hematological evaluation of all parameters revealed that there was no patient with SCA or β-thalassemia. However, 12 patients (22.6%) were diagnosed with suspected thalassemia trait and/or ıron-deficiency anemia (IDA).

The mean values of the studied parameters for suspected patients and the patients with normal hematologic findings are shown in Table 1. Hb levels were significantly lower in suspected patients compared to normal (P = 0.046). There was also a trend for lower mean corpuscular volume (MCV) and hematocrit (Hct) in suspected patients (P = 0.072 and 0.082, respectively). There was no significant difference for the other parameters between the groups (Table 1).

ROC curve analysis of MCV, Hb, and Hct for the diagnosis of α-thalassemia were performed separately. MCV and Hb were significantly correlated with the diagnosis of α-thalassemia. The ROC curves of MCV and Hb are shown in Figure 1. For a cutoff MCV of 82 μm^3, and Hb of 120 mg/L, sensitivity, specificity, positive and negative predictive values for diagnosis are shown in Table 2.

Obesity, gender, number of gallstones, MCV and Hb levels (lower or higher than the threshold) were grouped and analyzed to diagnose α-thalassemia. The patient distribution is shown in Table 3. There was a significant difference for the number of gallstones and MCV < 82 μm^3

Total	41 (77.4)	12 (22.6)	53	

MCV: Mean corpuscular volume; BMI: Body mass index.

with the diagnosis of thalassemia trait ($P = 0.004$ and 0.007, respectively).

DISCUSSION

The prevalence of gallbladder stone disease is 10%-20% and is increased in the elderly and female population[9,10].

Diagnosis of symptomatic SCA or β-thalassemia is not difficult. In endemic regions, it is especially important to identify carriers of these diseases. There is no cure, and the affected individuals may pass this disease to the next generation. Until gene therapy becomes a reality, the only approaches to the control of CHA are prevention and avoidance. The prevention strategies for CHA include education, carrier screening, genetic counseling, prenatal diagnosis (by amniotic fluid sampling at pregnancy) and selective termination of affected fetuses[11].

In order to reduce the birth rate of CHA in the areas of risk, efforts should be made to persuade couples to consider screening tests before the first pregnancy. For at-risk couples, details of the disorder should be explained to them so that they can make a decision in the context of their unique medical, moral and social situations[12,13]. In a previous study, premarital couples, who may be carriers for hemoglobinopathies were screened in the southern part of the Turkey by hemoglobin electrophoresis. The frequency of sickle Hb was 4.6% and β-thalassemia 2.3%. In 35 of 2113 prospective families, both partners were found to be carriers[2]. However, carrier screening by Hb electrophoresis is an expensive method for mass screening.

We found that 4.5% of young cholelithiasis patients had a known diagnosis of SCA. In this study, there was no patient with abnormal HPLC electrophoresis results sug-

gesting congenital hemoglobinopathies. However, 22.6% of participants (young cholelithiasis patients) were found to have microcytic anemia. Although they did not present with β-thalassemia or SCA, this result suggested that these patients may have thalassemia trait and/or IDA or any other hemoglobinopathy subtypes. It is reported that in some mutations of β-thalassemia and in heterozygous α-thalassemia, Hb A2 is not elevated[14,15]. Serum iron and ferritin levels must be analyzed to differentiate between IDA and thalassemia. Patients with low serum iron levels should be initially treated with oral iron supplement and then should be re-evaluated according to the response to the treatment. Patients with normal iron levels or those with no response to replacement treatment should be assumed as hemoglobinopathy carriers. However, this is a time-consuming expensive method for differentiation.

For hematological evaluation, it is important to differentiate thalassemia and IDA. Demir *et al*[9] suggested that pre-keratocytes and pencil cells, as morphologic features in the Wright-Giemsa staining, are useful in differentiating IDA and thalassemia trait. However, Wright-Giemsa staining is not suitable for daily practice and needs experienced personal for evaluation. There are other indices reported for differentiation between thalassemia trait and IDA, with sensitivity of approximately 100%[16-18]. The most popular index is the ratio of MCV and red blood cell count, the so-called Mentzer Index, which can be automatically calculated with any of the hematology analyzers. This method can be implemented by hospitals and laboratories to flag positive matches and enables screening of population at risk with little to no additional cost[19,20].

Novel data in this study indicates that general surgeons who practice in CHA-endemic regions, should take care in examining young cholelithiasis patients for CHA. Evaluation of complete blood count should be mandatory for these patients. Physicians should be aware of the MCV and Hb level of the young cholelithiasis patient. A MCV $< 82\ \mu m^3$ and Hb < 12 g/dL should alert the physician to the possibility of thalassemia. A family history of anemia should be sought in these patients and they should consult with a hematologist. Further analysis may be necessary.

Another suggestion which may derived from this study is that young patients with less than 5 (not multiple stones or sludge) gallstones should be suspected for the hemoglobinopathies.

In conclusion, in endemic regions, for the young cholelithiasis patients (age under 35) with few gallstones, the clinician/surgeon should pay attention to MCV, Hb level and Mentzer Index.

COMMENTS

Background

Congenital hemolytic anemias (CHA), especially thalassemia and sickle cell anemia (SCA), are a serious problem in endemic regions. One of the frequent comorbidities of CHA is gallbladder stones. Cholelithiasis would probably be the first clinical finding for these patients.

Research frontiers

In order to reduce the birth rate of CHA in the risk areas, prevention strategies for at-risk couples include education, carrier screening, genetic counseling, prenatal diagnosis (by amniotic fluid sampling at pregnancy) and selective termination of affected fetuses.

Innovations and breakthroughs

Premarital couples, who may be carriers for hemoglobinopathies have been screened in the southern part of the Turkey by hemoglobin electrophoresis. However, carrier screening by hemoglobin electrophoresis is an expensive method for mass screening. The most popular index is the ratio of mean corpuscular volume and red blood cell count, the Mentzer Index, which can be automatically calculated with any of the hematology analyzers. This method can be implemented by hospitals and laboratories to flag positive matches and enables screening of the population at risk with little to no additional cost.

Applications

General surgeons, who practice in CHA-endemic regions, should be careful with young cholelithiasis patients in diagnosing CHA. Evaluation of complete blood tests should be mandatory for young cholelithiasis patients.

Terminology

Thalassemia and sickle cell anemia are congenital hemolytic anemias (hemoglobinopathies) which are endemic in some regions of the world.

Peer review

Because the studied area is an endemic region, findings of this study are not generalizable. However the results should be important for the readers from endemic areas of the world. Low participation rate is another limitation of the study.

Abstract

AIM: To evaluate if traction-assisted endoscopic mucosal resection (TA-EMR) is feasible and if it enables *en bloc* resection of colorectal lesions.

METHODS: Seven patients with a total of 12 colorectal adenomas were prospectively enrolled. All lesions were removed by TA-EMR: one hemostatic clip tied to a white silk suture was applied to the base of the lesion to allow traction through the working channel of the colonoscope. A conventional polypectomy snare was mounted over the suture and the lesion was pulled into the snare and resected in one piece.

RESULTS: All 12 lesions (nine sessile) were resected *en bloc* with free lateral and vertical margins by using this novel technique, including five lesions (5/12, 41.6%) in less-accessible positions, where TA-EMR enabled complete visualization of the base before resection. Mean longest lesion and specimen sizes were 9 mm (range: 6-25 mm) and 11 mm in diameter (range: 7-17 mm), respectively. No serious procedure-related complications were observed.

CONCLUSION: TA-EMR through the endoscope using a hemostatic clip and suture material is technically feasible. Visualization of colorectal lesions in less-accessible locations can be improved.

Key words: Traction-assisted; Endoscopic mucosal resection; Colon polyp; Colonoscopy

INTRODUCTION

Endoscopic mucosal resection (EMR) for removal of neoplastic gastrointestinal lesions and early cancers has been established as a minimally invasive technique. Referring to the "adenoma-adenocarcinoma sequence", benign adenomas are regarded as precursors of cancer and should be completely removed during endoscopic procedures[1].

Besides the conventional inject-lift-cut EMR, i.e. strip biopsy, several variations have been developed such as cap-assisted EMR or EMR using a ligating device to enable safe and complete resection with the polypectomy snare[2-5]. *En bloc* resection with different EMR techniques is limited to adenomas of 15-20 mm in diameter[6-8].

However, smaller lesions, and particularly those in less-accessible locations, are sometimes hard to be ensnared and are challenging to the endoscopist. To improve visualization and make *en bloc* resection easier by exerting traction on the lesions while performing EMR or endoscopic submucosal dissection (ESD), several techniques have been described, such as sinker-assisted ESD, percutaneous traction-assisted EMR, magnetic anchor devices, external grasping forceps, thin endoscope-assisted ESD and the S-O-clip device[9-15]. Jeon *et al*[16] recently have reported peroral traction-assisted ESD for treatment of gastric neoplasms. In this paper, we describe a novel technique for traction-assisted (TA)-EMR through the endoscope, and its early results in treating colorectal lesions.

MATERIALS AND METHODS

Between July 2009 and March 2010, seven patients with a total of 12 colorectal lesions were enrolled. There were four female and three male patients, with a mean age of 75 years (range: 61-79 years). All patients had previous endoscopic investigation with histologically confirmed neoplastic adenomas. Each patient had at least one adenoma, which could not be removed by referring gastroenterologists because of its size or location, therefore, patients were sent to our department. We consecutively used the TA-EMR technique for all lesions found during colonoscopy that were > 5 mm in size. Study approval was given by the local ethics committee and written informed consent was obtained from all patients. The study was registered at ClinicalTrials.gov under NCT00966420.

Bowel preparation was done using 3 L polyethylene glycol solution. Colonoscopy was performed with a narrow band imaging video endoscope (CF-H180AI; Olympus, Hamburg Germany). All patients were initially sedated with midazolam (3-5 mg); propofol boluses of 20 mg were given intermittently to maintain sedation.

Using a white silk suture (Freka® PEG Gastric Set; Fresenius, Bad Homburg, Germany), a loop was tied and mounted between the branches of the hemoclip (Figure 1). Normal saline solution (2-10 mL, mean: 2 mL) was injected into the submucosal layer to lift the lesion from the muscular layer in the case of sessile adenomas. A reusable hemoclip-applicator device (HX-5LR-1, Olympus) or a Resolution® Clip (Boston Scientific, Ratingen, Germany) was inserted with the tied suture into the working channel, and the clip was anchored within healthy mucosal tissue at the base of the lesion (Figure 2A and B). After removal of the hemoclip-applicator device, an electrosurgical snare (AS-1-S, ASH-1-S; Cook Medical, Moenchengladbach, Germany) was mounted over the suture and brought into the working channel (Figure 3). At the tip of the video endoscope, the snare was delivered and placed over the lesion, which was pulled into the snare towards the endoscope while closing the snare (Figure 4A). Resection was performed using forced coagulating current, output power 60 W (ICC 200; ERBE, Tuebingen, Germany). Resected specimen secured to the suture material was easily removed, together with the endoscope (Figure 4B). The remaining mucosal defect was carefully inspected using narrow band imaging (NBI). Closure of the resection site was not performed routinely.

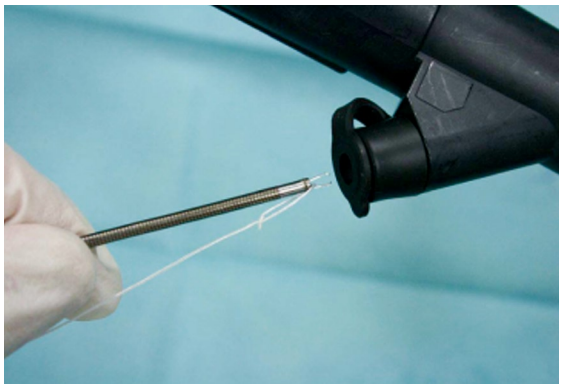

Figure 1 White silk suture loop mounted between the branches of the hemoclip.

All specimens were embedded in paraffin wax. Hematoxylin-eosin-stained sections were evaluated by one pathologist (Beer F) who specializes in gastrointestinal pathology.

RESULTS

Details of the polypectomies are shown in Table 1. Altogether, we removed 12 lesions located in the upper rectum (n = 1), at the rectosigmoid junction (n = 1), in the left (n = 8) or right (n = 1) hemicolon, and at the hepatic flexure (n = 1). Seven small adenomas of 6-9 mm diameter (five sessile) and five large adenomas measuring 10-25 mm (four sessile) were included. On five occasions (5/12, 41.6%), the whole extent and the base of the lesion could not be seen due to the adverse position behind a mucosal fold or at an intestinal bend until traction was exerted. All lesions were resected *en bloc* without any evidence of residual neoplastic tissue using NBI. In addition, histological evaluation confirmed free lateral and circumferential margins (12/12). Advanced pathology, i.e. tubulo-villous adenoma or high-grade dysplasia was found in nine adenomas (9/12, 75%). No neoplastic but hyperplastic tissue was detected once. Mean longest lesion and specimen diameters were 9 mm (range: 6-25 mm) and 11 mm (range: 7-17 mm), respectively. The mean procedure time, starting with injection in the case of sessile adenomas until completion of resection, was 6 min (range: 5-12 min).

No serious procedure-related complications were observed. In one patient (1/12, 8.3%), immediate bleeding after resection had to be controlled using hemostatic clips. All patients were discharged within 1 d after intervention. No delayed complications were observed within 4 wk, when patients were contacted for a final clinical examination.

DISCUSSION

For all neoplastic colorectal lesions, *en bloc* removal is desirable as it enables accurate evaluation of completeness

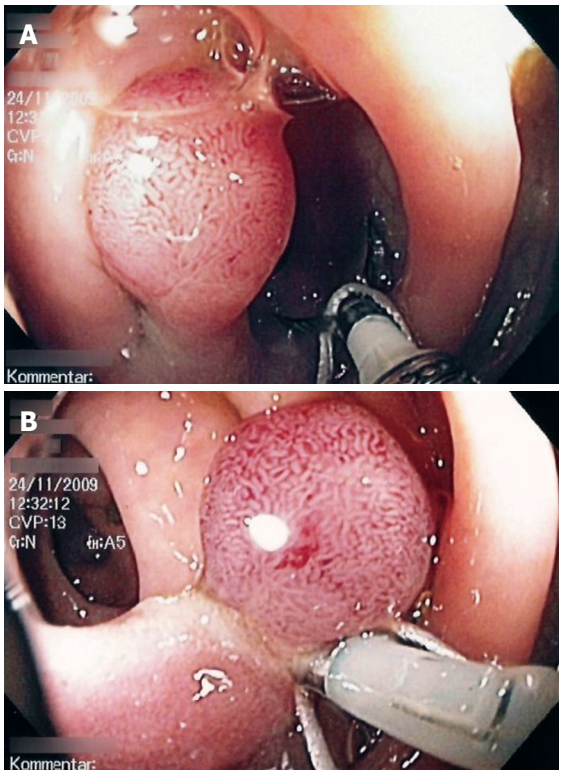

Figure 2 Introduction (A) and application (B) of the clip to the base of the polyp.

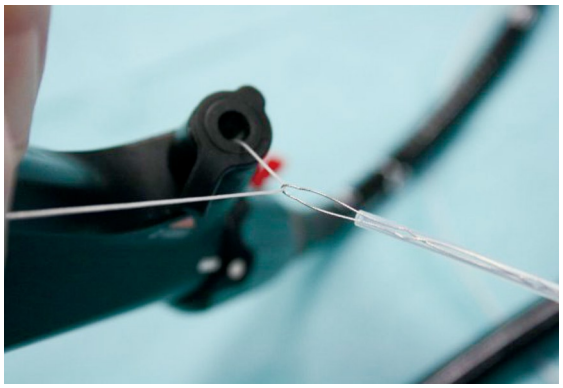

Figure 3 Snare mounted over the suture.

of the resected specimen. Moreover, small adenomas might also carry an increased risk of dysplasia, advanced pathology or even carcinoma[17-20].

En bloc or "single piece" snare polypectomy is regarded as the procedure of choice for polyps larger than 5 mm and up to 15-20 mm. For larger lesions, piecemeal resection or ESD has to be carried out. Despite a smaller size, visualization of lesions in less-accessible locations, e.g. behind mucosal folds or at bends in the bowel, may be hampered. Therefore, exact polypectomy snare placement, particularly in sessile lesions, may be aggravated or even impossible. There are only a few studies that have addressed this problem.

Yoshikane *et al*[21] have described a technique that uses distal attachment to the endoscope to press the semilunar

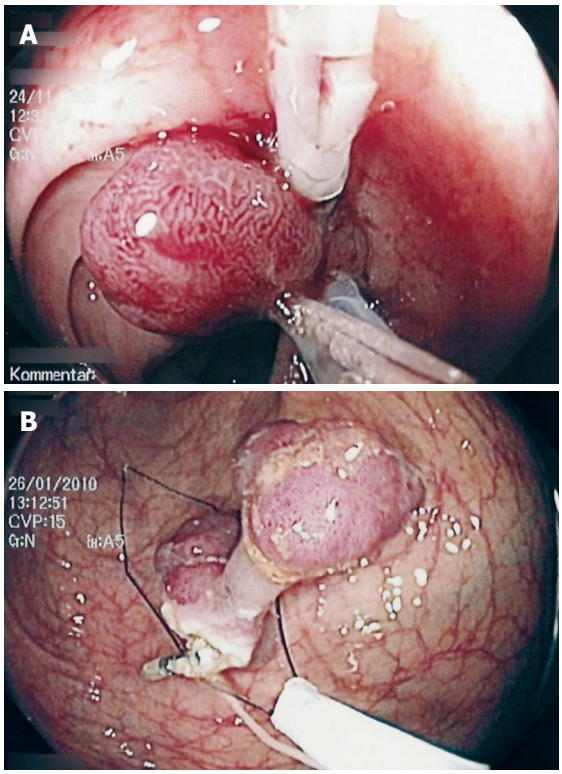

Figure 4 Ensnared polyp (A), polyp retrieval (B).

fold at the anal side of the lesion, to bring the base of the polyp within the visual field. Frimberger *et al*[22] have reported 15 patients treated with polypectomy for problematic polyps, by using a side-viewing duodenoscope as a therapeutic option when polyps were not accessible with the conventional approach. A "suction pseudopolyp technique" for small, flat, non-polypoid lesions of the colon and rectum was published by Pattullo *et al*[23] 2009. This referred to the fact that ensnaring of such lesions may be technically difficult because of minimal or no protruding tissue.

Achievement of good, direct visualization of the base of the lesion is of utmost importance when performing snare polypectomy, to decrease the risk of incomplete resection and complications, such as perforation. Recently, for ESD, different devices and traction systems have been invented to facilitate the resection procedure as mentioned above[10-15]. These various traction methods have their own unique limitations[16].

Our study aimed to evaluate the feasibility of TA-EMR through the endoscope to allow *en bloc* resection of colorectal lesions. Thereafter, we studied if visualization of colorectal adenomas in less-accessible positions can be improved. The technique described uses commonly available and economical materials and can be performed by a single endoscopist using a flexible endoscope with one working channel. Preparation of the hemoclip by mounting a tied loop of a white silk suture between the branches of the clip is easy. Introduction of the clip device and application of the clip to the base of the lesion is not complicated by the suture material.

Table 1 Details of polypectomies

Polyp characteristics	Polyp location	Polyp size	Specimen size (base)	Adverse position	Injection NaCl (mL)	Time (min)	Histology	Grade of dysplasia
Protruded	Descending colon	9	11	No	0	7	Tubulovillous adenoma, R0	Intermediate
Sessile	Descending colon	11	17	No	10	6	Tubular adenoma, R0	High
Sessile	Hepatic flexure	10	15	Yes	2	6	Tubulovillous adenoma, R0	Low
Sessile	Sigmoid colon	12	16	Yes	5	12	Tubulovillous adenoma, R0	Intermediate
Sessile	Sigmoid colon	6	7	No	2	10	Tubulovillous adenoma, R0	Low
Protruded	Sigmoid colon	8	9	No	0	6	Tubulovillous adenoma, R0	Low
Sessile	Rectum, upper third	8	10	No	2	5	Tubular adenoma, R0	Low
Sessile	Ascending colon	9	12	No	4	7	Tubulovillous adenoma, R0	Low
Sessile	Sigmoid colon	6	7	No	2	6	Tubular adenoma, R0	Low
Protruded	Sigmoid colon	25	11	Yes	0	6	Tubulovillous adenoma, R0	High
Sessile	Sigmoid colon	10	15	Yes	2	8	Tubulovillous adenoma, R0	Low
Sessile	Recto-sigmoid junction	7	9	Yes	2	6	Hyperplastic adenoma, R0	/

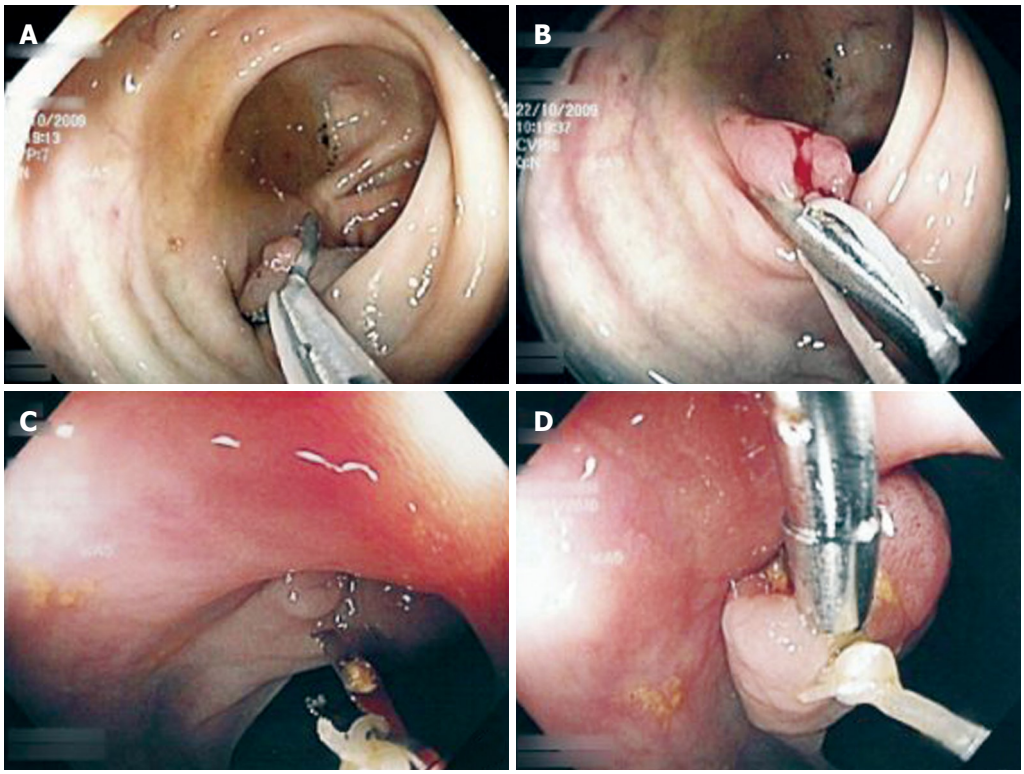

Figure 5 Flat adenoma (A, B) and protruded polyp (C, D) at colonic bend before and after application of traction.

By application of traction, the position of the polyps can be improved for ensnaring and especially the whole amount of lesions and the base can be better visualized (Figure 5). Thereafter, the TA-EMR technique can be used to generate a "pseudo-stalk", and placement of the snare in an adequate distance to the neoplastic tissue is possible.

The materials used are not designed for such an application, therefore, there are some limitations. Assembly of the polypectomy snare over the suture material and bringing it through the working channel can be difficult because the suture has to be gently fixed by the endoscopist at the handle of the endoscope, and the movement of the snare is slightly hindered because of the higher friction due to the suture material in the working channel. Even if it did not happen during this study, there is the possibility that the snare becomes entangled with the clip, or the clip is pulled out of the lesion by excessive traction. We tested clip application *ex vivo* before starting the study. In the case of clip dislodgment, we suggest removal of the endoscope from the bowel; pulling the (potentially crosswise oriented) clip through the working channel may cause damage to the video endoscope. TA-EMR through the endoscope is technically challenging and positioning the snare over the lesion and the clip sometimes can be awkward. Fixation of the suture material to the end of the clip (instead of between the branches) could facilitate this procedure, but it is presently impossible with the available clip devices. A rigid system instead of the suture material would be helpful because it enables a broader range of movements instead of simple traction.

In conclusion, our preliminary limited experience with TA-EMR through the endoscope is promising. Complete *en bloc* resection of colorectal lesions is feasible with the TA-EMR technique, and visualization of adenomas in less-accessible positions can be improved.

COMMENTS

Background

Endoscopic mucosal resection (EMR) for removal of neoplastic colorectal lesions has become established as minimally invasive therapy. Visualization of lesions in less-accessible locations and complete *en bloc* resection, especially of flat adenomas, can be challenging or even impossible.

Research frontiers

Several elaborated techniques have been described to overcome these technical problems, which necessitates special equipment.

Innovations and breakthroughs

Traction-assisted EMR (TA-EMR) uses commonly available and economic materials. Traction is exerted through the working channel of the endoscope, which protects the bowel against the suture material and allows controlled traction by the endoscopist.

Applications

Theoretically, TA-EMR can be performed in every endoscopy unit. Due to the fact that the materials used are not designed for such an application, the technique is challenging. A rigid system instead of the suture material would ease the procedure and allow a broader range of movements.

Terminology

EMR enables removal of neoplastic lesions in one piece by ensnaring adenomas with a polypectomy snare. Lesions at bends in the bowel or behind mucosal folds potentially cannot be ensnared. To bring adenomas to a better position for EMR, traction can be exerted to allow complete visualization and *en bloc* resection.

Peer review

There is an obvious interest in ways to remove difficult polyps, particularly those that lie behind colonic folds. A number of methods have been described to remove these polyps but, thus far, none has been entirely satisfactory. This report describes a relatively simple traction method.

Abstract

AIM: To analyze plasma osteopontin levels and liver stiffness using transient elastography in postoperative biliary atresia (BA) children compared with healthy controls.

METHODS: Thirty children with postoperative BA and 10 normal controls were enrolled. The patients were categorized into two groups according to their jaundice status. Plasma levels of osteopontin were determined using commercially available enzyme-linked immunosorbent assay. Liver stiffness was measured by using transient elastography (Fibroscan). Ten validated Fibroscan measurements were performed in each patient and control with the result expressed in kilopascals (kPa).

RESULTS: Plasma osteopontin was significantly elevated in BA children compared with that of healthy controls (47.0 ± 56.4 ng/mL *vs* 15.1 ± 15.0 ng/mL, $P = 0.01$). The liver stiffness measurement was markedly elevated in the patients with BA compared with that of controls (26.9 ± 24.6 kPa *vs* 3.9 ± 0.7 kPa, $P = 0.001$). Subgroup analysis showed that the BA patients with jaundice had more pronounced plasma osteopontin levels than those without jaundice (87.1 ± 61.6 ng/mL *vs* 11.9 ± 6.1 ng/mL, $P = 0.001$). Furthermore, the mean liver stiffness was significantly greater in the jaundiced BA patients compared with non-jaundiced patients (47.7 ± 21.8 kPa *vs* 8.7 ± 3.0 kPa, $P = 0.001$). Additionally, plasma osteopontin was positively related to serum total bilirubin ($r = 0.64$, $P < 0.001$). There was also a correlation between plasma osteopontin and liver stiffness values ($r = 0.60$, $P < 0.001$).

CONCLUSION: High plasma osteopontin positively correlated with degree of hepatic fibrosis and could be used as a biochemical parameter reflecting disease severity in postoperative BA children.

INTRODUCTION

Biliary atresia (BA) is an intractable liver disease of unknown cause that affects hepatic bile ducts resulting in chronic cholestasis, hepatic fibrosis and biliary cirrhosis. BA children mostly present with a triad of obstructive jaundice, acholic stools, and hepatosplenomegaly. It is the most common indication for liver transplantation in infants and children[1]. Even after effective bile flow has been established by the Kasai operation, the disease still progresses to end-stage liver disease, in which patients will suffer from the complication of portal hypertension and hepatic dysfunction[2,3]. Several etiologies have been considered to account for the pathogenesis of BA, including neonatal viral infections, genetic insults, and abnormalities in immune response, but the precise mechanism of BA is poorly understood[4]. Although it has been documented that a variety of cytokines and growth factors, including bone morphogenetic protein 7[5], basic fibroblast growth factor[6], and stem cell factor[7], play essential roles in the pathophysiology of BA, published data regarding osteopontin expression in postoperative BA is currently limited.

Osteopontin, also known as early T-cell activation gene-1 (Eta-1), is a secreted phosphoprotein 1 (SPP1) that has been implicated in the pathogenesis of various inflammatory and fibrotic disorders. It stimulates T cell proliferation and induces T cells and macrophages to express other T helper type 1 (Th1) cytokines during inflammation[8]. Osteopontin also induces accumulation of extracellular matrix by binding to type I collagen, fibronectin, and osteocalcin, contributing to tissue fibrosis[9,10]. Osteopontin comprises multiple functional domains, with a high sialic acid content, an aspartate-rich domain, calcium-binding domain, thrombin cleavage site, and many residues with consensus for phosphorylation as well as an integrin-binding arginine-glycine-aspartate (RGD) motif, which play a key role in several inflammatory disorders[11]. High levels of circulating osteopontin have been demonstrated in patients with multiple sclerosis[12], osteoarthritis[13], hepatitis C viral infection[14], as well as gastric and liver cancer[15-19]. However, no detailed studies are presently available regarding the relationship between plasma osteopontin levels and the degree of liver stiffness in BA.

It has been recently reported that measurement of liver stiffness using transient elastography or Fibroscan (Echosens, Paris, France) reflects the degree of hepatic fibrosis, which is a principal factor determining the functional liver reserve[20]. In this study, we postulated that elevated plasma osteopontin levels might be associated with the severity of clinical outcomes and the liver stiffness in BA patients. Hence, the objective of this investigation was to analyze plasma osteopontin levels in postoperative BA patients and to evaluate the possible correlations of plasma osteopontin with the disease severity.

MATERIALS AND METHODS

Patients

This investigation was approved by the Institutional Review Board of the Faculty of Medicine, Chulalongkorn University, and was conducted in agreement with the Declaration of Helsinki. All parents of children with BA and healthy controls were informed of the study's objectives, and written informed consent was obtained from the parents prior to the children entering the study.

A total of 30 BA patients after Kasai procedure (13 males and 17 females; mean age 7.2 ± 3.4 years) who attended the follow-up visit at the Pediatric Liver Clinic, and 10 healthy children (4 males and 6 females; mean age 7.4 ± 3.9 years) from the Well Baby Clinic at King Chulalongkorn Memorial Hospital, were enrolled in this study. Children in the healthy control group had normal physical examinations.

Among the 30 BA patients in the present study, none had any symptoms and signs of infection or ascending cholangitis or clotting abnormalities at the time of blood sampling. None had received liver transplantation. To compare the clinical outcomes among BA patients, they were categorized according to their levels of serum total bilirubin (TB) into two groups: patients without jaundice (TB < 20 mg/L, n = 16) and patients with persistent jaundice (TB ⩾ 20 mg/L, n = 14).

Liver stiffness measurement

Liver stiffness was measured using Fibroscan (Echosens, Paris, France), a new medical device based on elastometry (or one-dimensional transient elastography). This technique is used to quantify hepatic fibrosis in a totally non-invasive and painless manner, with no contraindications. Details of the technique and the examination procedure have been described in a previous report[21]. Briefly, this system is operated with a probe, with an ultrasonic transducer mounted on the axis of a vibrator. A vibration of mild amplitude and low frequency is transmitted from the vibrator on to the tissue by the transducer itself, which induces propagation of an elastic shear wave through the tissue. A pulse-echo acquisition is performed at this time to follow the propagation of the shear wave and measure its velocity. This velocity is directly correlated to the stiffness of liver, which reflects the degree of fibrosis. Results are expressed in kilopascals (kPa).

All measurements were performed according to the manufacturer's instructions. Patients were placed in supine decubitus position with the right arm in abduction. The probe was placed on the skin between 2 ribs at the level of the right lobe of the liver. The measurement area was located by A-mode images provided by the probe trans-

ducer. Ten validated measurements were performed for each patient. The median value was considered as representative of liver stiffness. A set of measurements was considered to be reliable if the success rate was at least 60% and the interquartile range was less than one third of the median liver stiffness value. Because normal values have not yet been established in healthy children without liver disease, a control group of 10 healthy gender- and age-matched children was recruited. Measurements were performed by the same operator under the same conditions as for the BA patients.

Laboratory tests

Samples of peripheral venous blood were collected from each patient and healthy control, centrifuged, and then stored at -80℃ until analysis. Plasma osteopontin concentrations were measured using a commercially available enzyme-linked immunosorbent assay (Immuno-Biological Laboratories Co., Gunma, Japan) following the manufacturer's recommendations. In brief, standards of recombinant human osteopontin and plasma samples were added to microtiter plates pre-coated with rabbit polyclonal antibody against osteopontin and incubated for 1 h at room temperature. The wells were then washed 7 times with washing buffer and incubated for 30 min at 4℃ with a horseradish peroxidase-labeled mouse monoclonal antibody to human osteopontin. After washing thoroughly with washing buffer for 9 times, substrate solution was added to each well, and the plate was incubated for 30 min at room temperature in the dark. Finally, the reaction was stopped with the stop solution, and then absorbance was measured at 450 nm using an automated microtiter plate reader. Recombinant human osteopontin was used to generate a linear standard calibration curve (range 5-320 ng/mL). In addition, liver function tests, including TB, direct bilirubin, aspartate aminotransferase (AST), alanine aminotransferase (ALT), and alkaline phosphatase (ALP), were assessed using a Hitachi 912 automated chemical analyzer at the central laboratory of our hospital. The aspartate aminotransferase to platelets ratio index (APRI) was calculated as follows: (AST/upper limit of normal) × 100/platelet count (10^9/L)[22].

Statistical analysis

Statistical analysis was performed using the statistical package for social sciences (SPSS) software, version 16.0 for Windows. All values are expressed as a mean ± SD. Comparisons of demographic data and biochemical parameters between groups were determined by unpaired *t*-test. Correlations between numerical data were acquired using the Pearson correlation coefficient (*r*). A *P*-value < 0.05 indicated statistical significance.

RESULTS

Comparisons between BA patients and healthy controls

Plasma osteopontin levels were measured in 30 BA patients and 10 healthy controls. There were no statistically significant differences with respect to age (7.2 ± 3.4 years *vs* 7.4 ± 3.9 years) and gender (male:female, 13:17 *vs* 4:6) between the BA patients and healthy controls. The baseline characteristics of the BA patients and healthy controls are summarized in Table 1. Mean plasma osteopontin concentration of BA children was significantly higher in comparison with that of healthy controls (47.0 ± 56.4 ng/mL *vs* 15.1 ± 15.0 ng/mL, $P = 0.01$) (Figure 1A). Furthermore, the mean liver stiffness value was markedly elevated in the patients with BA compared with that of healthy controls (26.9 ± 24.6 kPa *vs* 3.9 ± 0.7 kPa, $P = 0.001$).

Table 1 Biliary atresia patient characteristics (mean ± SD)

Variables	Controls (n = 10)	BA patients (n = 30)	*P*-value
Age (yr)	7.4 ± 3.9	7.2 ± 3.4	0.8
Gender (M:F)	4:6	13:17	0.5
Albumin (g/L)	-	43 ± 0.5	NA
Total bilirubin (mg/L)	-	28 ± 4.3	NA
Direct bilirubin (mg/L)	-	22 ± 4.3	NA
AST (IU/L)	-	129.4 ± 100.8	NA
ALT (IU/L)	-	119.4 ± 105.1	NA
ALP (IU/L)	-	469.9 ± 345.6	NA
Platelet count (10^3/mm^3)	-	167.2 ± 96.3	NA
APRI	-	2.9 ± 2.9	NA
Osteopontin (ng/mL)	15.1 ± 15.0	47.0 ± 56.4	0.01
Liver stiffness (kPa)	3.9 ± 0.7	26.9 ± 24.6	0.001

BA: Biliary atresia; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; ALP: Alkaline phosphatase; APRI: Aspartate aminotransferase to platelets ratio index; NA: Not applicable.

Table 2 Comparison of biliary atresia patients without and with jaundice (mean ± SD)

Variables	BA patients without jaundice (n = 16)	BA patients with jaundice (n = 14)	*P*-value
Age (yr)	7.3 ± 3.7	7.0 ± 3.1	0.9
Gender (M:F)	7:9	6:8	0.5
Albumin (g/L)	46 ± 0.3	39 ± 0.4	0.001
Total bilirubin (mg/L)	5 ± 0.2	55 ± 5.5	0.001
Direct bilirubin (mg/L)	2 ± 0.1	46 ± 5.5	0.003
AST (IU/L)	64.9 ± 46.9	203.1 ± 95.5	0.001
ALT (IU/L)	73.6 ± 61.2	171.8 ± 121.5	0.01
ALP (IU/L)	287.9 ± 116.8	677.9 ± 404.1	0.001
Platelet count (10^3/mm^3)	215.8 ± 81.3	111.6 ± 81.0	0.002
APRI	0.8 ± 0.8	5.1 ± 2.7	< 0.001
Osteopontin (ng/mL)	11.9 ± 6.1	87.1 ± 61.6	0.001
Liver stiffness (kPa)	8.7 ± 3.0	47.7 ± 21.8	0.001

BA: Biliary atresia; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; ALP: Alkaline phosphatase; APRI: Aspartate aminotransferase to platelets ratio index.

Comparisons between BA patients with and without persistent jaundice

The demographic data and biochemical parameters including liver function tests, plasma osteopontin levels and liver stiffness values based on jaundice status are given in Table 2.

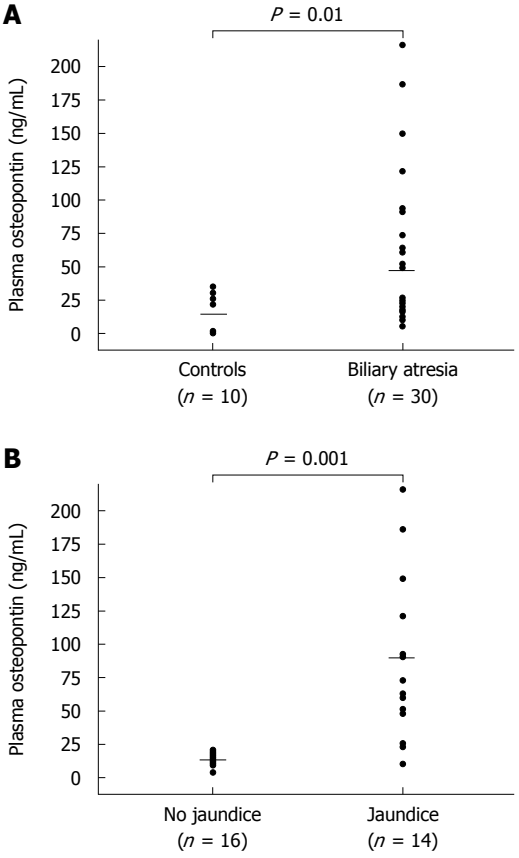

Figure 1 Plasma osteopontin levels. A: In biliary atresia (BA) patients and healthy controls; B: In BA patients without and with jaundice.

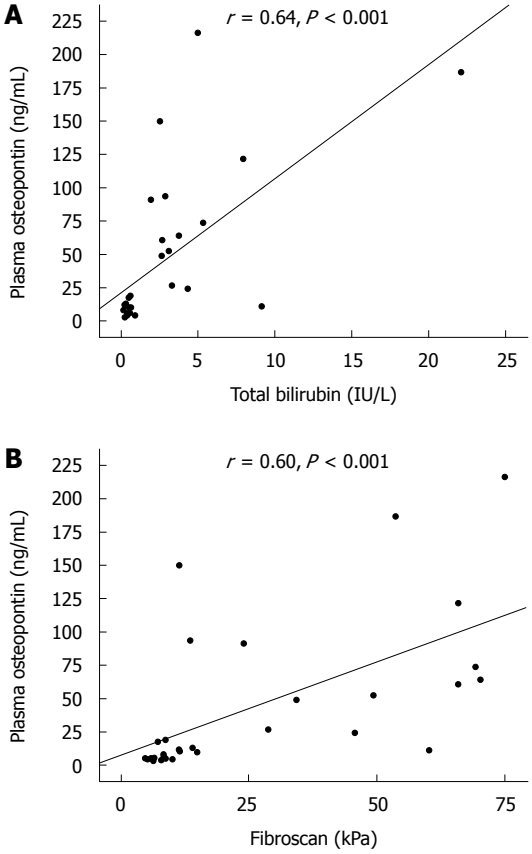

Figure 2 Correlation analysis in biliary atresia patients. A: Correlation between plasma osteopontin and serum total bilirubin in biliary atresia (BA) patients ($r = 0.64$, $P < 0.001$); B: Correlation between plasma osteopontin and liver stiffness using Fibroscan in BA patients ($r = 0.60$, $P < 0.001$).

Subgroup analysis demonstrated that BA patients with persistent jaundice had significantly higher serum levels of AST, ALT, ALP, and APRI than those without jaundice. As shown in Figure 1B, the BA patients with persistent jaundice had more pronounced plasma osteopontin levels than those without jaundice (87.1 ± 61.6 ng/mL *vs* 11.9 ± 6.1 ng/mL, $P = 0.001$). There was no significant difference in plasma osteopontin between BA patients without jaundice and healthy controls. In addition, the mean liver stiffness was significantly greater in the jaundiced BA patients compared with non-jaundiced patients (47.7 ± 21.8 kPa *vs* 8.7 ± 3.0 kPa, $P = 0.001$). Moreover, plasma osteopontin was positively related to serum TB ($r = 0.64$, $P < 0.001$) (Figure 2A). There was also a correlation between plasma osteopontin and liver stiffness score ($r = 0.60$, $P < 0.001$) (Figure 2B).

DISCUSSION

BA is one of the most serious digestive tract disorders characterized by progressive, fibrosclerotic cholangiopathy affecting both intrahepatic and extrahepatic bile ducts. It may lead to obstruction or discontinuity of the biliary tract at any point between the porta hepatis and the duodenum. Without medical and surgical treatment, the majority of BA patients will develop severe cholestasis, hepatic fibrosis, and eventually die within a few years[1].

It is accepted that Kasai hepatoportoenterostomy is the first line of surgical treatment. Despite early diagnosis and successful Kasai operation, more than half of the BA patients inevitably develop biliary cirrhosis, portal hypertension, and end-stage liver disease[2]. Alternatively, liver transplantation is an effective treatment modality when the Kasai hepatoportoenterostomy has failed and serious complications occur such as recurrent ascending cholangitis, persistent jaundice, cirrhosis, progressive ascites, and bleeding esophageal varices[3]. Nonetheless, the exact pathophysiology of liver fibrosis or cirrhosis in BA children remains unknown.

Osteopontin is a highly phosphorylated acidic glycoprotein that is not only present in bone, but also is produced by a number of cell types including chondrocytes, immune cells, smooth muscle cells, epithelial cells, and endothelial cells[23,24]. It is now considered as a potent chemo-attractive and pro-inflammatory mediator which is involved in a variety of physiologic and pathologic events, such as cell adhesion, proliferation, migration, inflammation, apoptosis, vascular remodeling, and wound healing[25,26]. The role of osteopontin in liver diseases has not been completely elucidated. Carbon tetrachloride administration has been shown to increase osteopontin expression in the rat liver where it was localized mostly

to activated Kupffer cells, hepatic macrophages, and stellate cells[27,28]. Recombinant osteopontin also activated rat hepatic macrophage migration *in vitro*, whereas *in vivo*, the levels of macrophage infiltration in injured liver were reduced in osteopontin-knockout mice[28]. These findings indicate that osteopontin may be involved in the initiation of inflammatory reactions in the liver and activation of hepatic fibrosis.

In recent years, the upregulation of osteopontin expression has been documented by using gene expression microarray and Northern blot analysis of liver samples from BA patients[29]. It has been shown in previous studies that gene expression of hepatic osteopontin is highly upregulated in BA. This finding suggests that human bile duct epithelial cells are able to synthesize osteopontin[30,31]. These observations prompted us to speculate that osteopontin may be responsible for the pathogenesis of BA. However, plasma osteopontin level at various clinical stages of BA and its possible role in BA patients has not received much attention.

In the present study, we demonstrated that plasma osteopontin levels in BA patients were significantly elevated compared to those in healthy controls. Further analysis revealed that plasma osteopontin levels were markedly higher in BA patients with persistent jaundice than those without jaundice. High plasma osteopontin was positively correlated with serum TB in postoperative BA patients. These findings suggest that plasma osteopontin is associated with jaundice status in postoperative BA patients. Additionally, jaundice status in BA patients is likely to be a parameter for intrahepatic biliary obstruction. Hence, these results suggest that osteopontin plays a possible role in the pathogenesis of hepatocellular damage in BA, and that it seems to be correlated with the degree of biliary obstruction.

To the best of our knowledge, this study is the first to show that plasma osteopontin is elevated in BA patients compared with healthy controls, and that osteopontin concentration is associated with clinical outcome (status of jaundice, hepatic dysfunction, and hepatic fibrosis) in BA. Increased plasma osteopontin has been documented in a variety of liver disorders, including acute hepatic dysfunction, chronic hepatitis, liver cirrhosis, hepatocellular carcinoma, and primary biliary cirrhosis[16-19]. In accordance with our study, plasma osteopontin was shown to be significantly elevated in cirrhosis patients, and was correlated with the severity of hepatic injury[17]. Kim *et al*[19] also revealed an elevation of plasma osteopontin with advancing degree of hepatocellular carcinoma. These findings suggest that high plasma osteopontin is associated with hepatic damage and hence reflects liver dysfunction. Accordingly, our results also showed that plasma osteopontin was positively associated with degree of liver stiffness determined using transient elastography or Fibroscan. Liver stiffness measures are well correlated with advanced stages of hepatic fibrosis and cirrhosis in adults and children[20,32,33]. These findings suggest that plasma osteopontin could serve as a potential biochemical parameter for measuring progression of liver impairment and development of hepatic fibrosis in postoperative BA patients and, therefore, may be predictive of prognosis with respect to the progression of liver dysfunction.

Several possible mechanisms could contribute to high plasma osteopontin in BA. Firstly, production of osteopontin in the damaged liver may lead to elevation of plasma osteopontin. Secondly, elevated osteopontin levels could be attributed to an imbalance between osteopontin production and osteopontin clearance. In advanced BA stages, reduced osteopontin clearance could be responsible for increased circulating osteopontin levels. Additionally, because other organs apart from the liver can synthesize and secrete osteopontin, the main sources of elevated plasma osteopontin in the present study might be extrahepatic organs. Further research will be necessary to clarify this observation.

Inevitably, we are aware of some limitations in our study. Firstly, the sample size of patients enrolled in this study was small and could preclude us from making a strong conclusion. Secondly, incomplete assessment of potential confounding factors (age, sex, medical comorbidities) needs to be taken into consideration. Lastly, as this study was designed as a cross-sectional study, a definite cause and effect relationship cannot be concluded. In order to overcome these limitations, a well-designed, well-controlled, randomized study of a large population will be needed to draw a more definite conclusion. However, with the supporting evidence from other studies regarding the potential role of osteopontin expression and the degree of systemic inflammatory response in BA[29-31], it is likely that the high plasma osteopontin levels observed in postoperative BA patients may be involved in the pathophysiology of hepatocellular injury and development of hepatic fibrosis. Biochemical parameters and clinical characteristics of some BA subjects have been reported recently[34]. We have not previously reported liver stiffness measurement or the relationship of liver stiffness with osteopontin in BA.

In conclusion, this investigation showed that BA patients had significantly elevated concentrations of plasma osteopontin in comparison with healthy controls. Plasma osteopontin and liver stiffness values were remarkably higher in the BA patients with persistent jaundice than in those without jaundice. Moreover, there was a positive correlation between plasma osteopontin, TB and liver fibrosis. Delineation of the mechanisms underlying bile duct injury will be advantageous in the development of new potential therapeutic treatments for this serious pediatric disorder.

COMMENTS

Background

Biliary atresia (BA) is an intractable liver disease of unknown cause that affects hepatic bile ducts resulting in chronic cholestasis, hepatic fibrosis and biliary cirrhosis. Human bile duct epithelial cells are able to synthesize osteopontin, a highly phosphorylated acidic glycoprotein.

Research frontiers

Osteopontin has been implicated in the pathogenesis of various inflammatory

and fibrotic disorders. However, no detailed studies are presently available on the relationship between plasma osteopontin levels and the degree of liver stiffness in BA. In this study, the authors demonstrate that elevated plasma osteopontin levels could be associated with the severity of clinical outcomes and the liver stiffness in BA patients.

Innovations and breakthroughs

Recent reports have highlighted the importance of hepatic osteopontin expression in chronic liver disease, including BA. This is the first study to report that plasma osteopontin is elevated in BA patients compared with healthy controls, and that osteopontin concentration is associated with status of jaundice and hepatic dysfunction in BA.

Applications

High plasma osteopontin levels positively correlate with the degree of hepatic fibrosis in postoperative BA children. Therefore, plasma osteopontin may be used as a biochemical parameter reflecting disease severity and for monitoring the progression of liver fibrosis in BA patients after Kasai operation.

Terminology

Osteopontin, also known as early T-cell activation gene-1, is a secreted phosphoprotein 1 that comprises multiple functional domains, with a high sialic acid content, an aspartate-rich domain, calcium-binding domain, thrombin cleavage site, and many residues with consensus for phosphorylation as well as an integrin-binding arginine-glycine-aspartate motif, which play a key role in several inflammatory disorders.

Peer review

Nice article about BA. I am unsure what the mechanism of the osteopontin levels are, but further research should surely tell us.

Abstract

AIM: To evaluate duodenal polyps, divided into non-neoplastic and neoplastic lesions. In addition, the clinical characteristics of duodenal hyperplastic polyps are determined.

METHODS: We analyzed medical records of 50 114 consecutive patients submitted to for first diagnostic esophago-gastroduodenoscopy between January 2004 and December 2009. We excluded lesions on the ampulla of Vater and submucosal tumors. We studied 510 cases that were diagnosed endoscopically with duodenal polyps and enrolled a total of 221 cases that had undergone tissue biopsy. We analyzed the differences between non-neoplastic and neoplastic lesions, and determined the clinical features of duodenal hyperplastic polyps.

RESULTS: Non-neoplastic lesions were found in 196 patients and neoplastic lesions in 25 patients. On univariate analysis, there were significant differences in shape, location, and size. Polyps more than 10 mm in diameter or polyps in the second portion had independent risk factors for being neoplastic lesions, as identified by multivariate analysis. In 23 cases of hyperplastic polyps (79.3%), they were accompanied by gastroduodenal pathology, which was possibly associated with *Helicobacter pylori*.

CONCLUSION: Polyps of more than 10 mm or polyps in the second portion of the duodenum should be evaluated by histological examination.

Key words: Duodenum; Polyp; *Helicobacter pylori*

INTRODUCTION

The prevalence of duodenal polyps is estimated to be 0.3%-1.5% in patients referred for upper endoscopy, on the basis of extensive retrospective studies[1,2], and 4.6% reported from a prospective study[3]. Although duodenal polyps are rare, the diagnosis appears to be increasing, possibly due to the wide use of diagnostic esophago-gastroduodenoscopy. Duodenal polyps are commonly sessile,

but may also be pedunculated in nature. Most duodenal polyps are inflammatory polyps and have ectopic gastric mucosa[1,2]. Multiple and small polyps in the duodenal bulb are always benign and need neither biopsy nor treatment; except in patients with familial polyposis, where routine upper gastrointestinal surveillance endoscopy and biopsy of the duodenal polyps are mandatory[3]. Cases requiring clinical treatment are rare; however, a biopsy occasionally shows an adenoma or carcinoid tumor. These lesions require treatment due to their potential of malignant transformation. Until now, the clinical findings associated with non-neoplastic and neoplastic duodenal lesions have not been well described.

Hyperplastic (metaplastic) polyps have rarely been described in the duodenum, and published data on these lesions are limited to case reports or small case series[4-6]. They almost always occur in the setting of ectopic gastric mucosa and therefore have an appearance that more closely mimics hyperplastic polyps of the gastric type, rather than the colonic type. Moreover, when hyperplastic polyps are found in the duodenum, they can be associated with colonization by *Helicobacter pylori* (*H. pylori*)[7], and appear to occur most commonly in the setting of peptic ulcer disease or with other gastric disorders[5].

This study is the largest single-center study to date that reports on the clinical characteristics of non-ampullary duodenal elevated lesions. We aimed to evaluate the frequency, endoscopic findings, and histological characteristics of non-neoplastic and neoplastic lesions. We also analyzed a spectrum of patients with duodenal hyperplastic polyps.

MATERIALS AND METHODS

Study population

We searched the medical records of 50 114 consecutive patients that had a first diagnostic esophago-gastroduodenoscopy between January 2004 and December 2009. Most of patients had visited the gastrointestinal department and had dyspeptic symptoms. We used the electronic database of St. Vincent's Hospital, the Catholic University of Korea and searched the keywords of "duodenal polyp" (K317; International Statistical Classification of Disease, the 10th Revision, ICD-10) or "benign neoplasm of duodenum" (D132). Cases were accrued by searching the database. Among 510 cases diagnosed endoscopically with duodenal polyps, 221 cases that underwent tissue biopsy were enrolled. Lesions of the ampulla of Vater (D135) and submucosal tumors (D372) - cysts, lipomas, lymphangiectasia, and gastrointestinal stromal tumors, were excluded and were traditionally recognized as submucosal lesions (Table 1). Endoscopic and histological features of the ampullary tumors and submucosal tumors are shown in Figure 1. This study protocol was approved by the Ethics Committee of the Catholic University of Korea.

Endoscopy

Data collected on the study subjects included age, gender, family history of polyposis, and location, size, and histology of the duodenal polyp. All tissue specimens were obtained using biopsy forceps (FB-19K-1, Olympus, Tokyo, Japan), polypectomy, or endoscopic mucosal resection. The size of the polyp was measured endoscopically using the "open biopsy forceps method". Biopsy forceps with a diameter of 4 mm when fully opened were used. The forceps were withdrawn in the open position toward the endoscope tip as far as possible, until both cups were fully visualized. The open forceps was then advanced until they were aligned against the largest diameter of the polyp, with the tip of the endoscope still placed at approximately 3 to 4 cm from the polyp[8].

Table 1 Lesions in the ampulla of vater and submucosal lesions of the duodenum

Histologic diagnosis	No. (n = 44)
Lesions in the ampulla of vater	
Adenoma	12
Focal carcinomatous change	1
Inflammatory myofibroblastic tumor	1
Carcinoid	1
Submucosal lesions	
Lipoma	14
Cyst	9
Lymphangioma	3
Gastrointestinal stromal tumor	2

Study design

The endoscopic, histological, and clinical characteristics of the duodenal polyps were recorded; subsequently, the duodenal polyps were divided into non-neoplastic and neoplastic lesions. The non-neoplastic lesions included Brunner's gland hyperplasia, Brunner's gland hamartoma, ectopic gastric mucosa, ectopic pancreas, hyperplastic polyps, and inflammatory polyps. The neoplastic lesions included adenomas, carcinoid tumors, and miscellaneous lesions. We analyzed the differences of age, sex, size, shape, location and multiplicity between the non-neoplastic and neoplastic lesions. In addition, we evaluated the clinical features of the duodenal hyperplastic polyps. Each case was classified as *H. pylori* positive or negative according to the histological results (CLO test or silver stain) using two pieces of biopsy specimen taken from the antrum and the body of the stomach.

Statistical analysis

All data were recorded on standard forms and computer analyzed. The Mann-Whitney *U*-test was used to compare the continuous variables between the two groups. Differences between dichotomous variables were evaluated with the Pearson Chi-square test. Calculations were performed with the SPSS package software (SPSS version 12.0, Chicago, IL, USA). P values less than 0.05 were considered significant.

RESULTS

Demographic features

The frequency of duodenal polyps was 1.02% (510 of

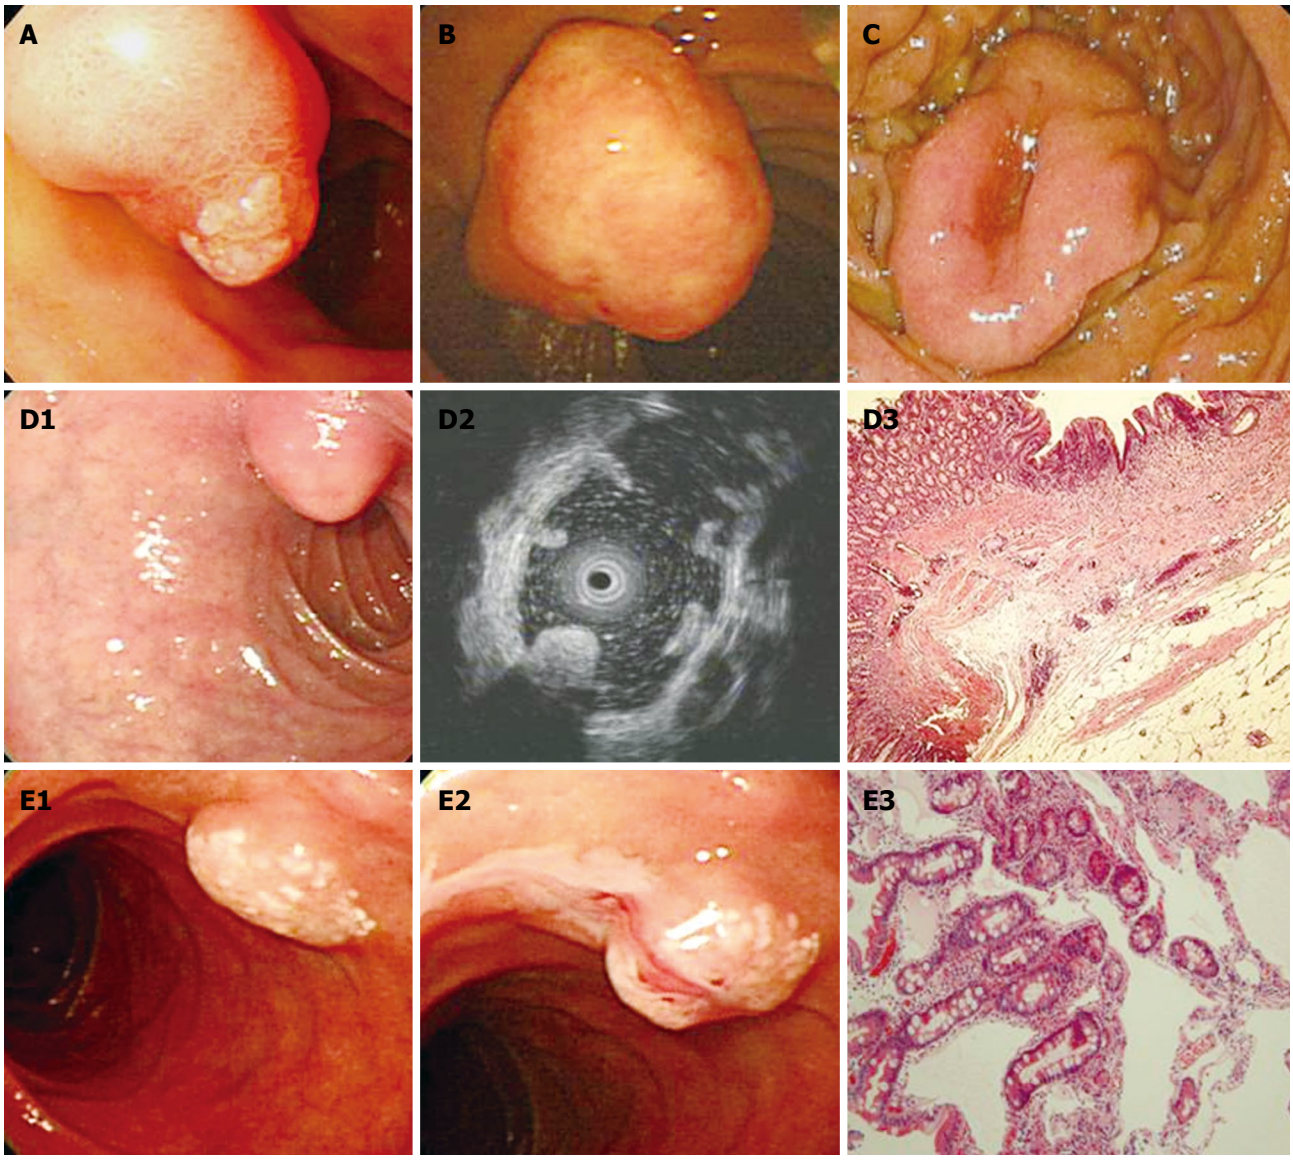

Figure 1 Ampullary polyps and submucosal lesions in the duodenum. A: Ampullary adenoma; B: Inflammatory myofibroblastic tumor; C: Gastrointestinal stromal tumor; D: Duodenal lipoma. The surface of the tumor was covered by a normal mucosa, but it had a yellowish coloration (D1). Endoscopic ultrasound showed a homogeneous and hyperechoic mass with post-acoustic shadowing (D2). Histopathological examination revealed the tumor that was composed of mature adipose tissue (HE, × 40) (D3); E: Duodenal lymphangiectasia. On the surface of the tumor, focal small whitish macules or nodules were observed (E1). After forceps biopsy, whitish milk-like material flowed out (E2). A dilated lymphatic duct in the subepithelial area was observed under microscopic examination (HE, × 40) (E3).

50114 patients). Among 221 patients, forceps tissue biopsy, and endoscopic or surgical resections were performed and a histological diagnosis was obtained. We divided them into non-neoplastic and neoplastic lesions. Non-neoplastic lesions were found in 196 patients and neoplastic lesions in 25 patients. For the non-neoplastic lesions, Brunner's gland hyperplasia/hamartoma, ectopic gastric mucosa, ectopic pancreas, hyperplastic polyps and inflammatory polyps were found. Adenomas, carcinoid tumors, and metastatic cancer were found in neoplastic lesions (Table 2). The mean age and gender ratio were not significantly different between patients having non-neoplastic and neoplastic lesions.

Endoscopic and histological features

The characteristics of the non-neoplastic and neoplastic lesions are shown in Table 2. The size of the neoplastic lesions was larger than the non-neoplastic lesions ($P < 0.01$). Non-neoplastic duodenal polyps were more frequently localized in the bulb (156/196, 79.6%) than in the second portion. In the bulb, approximately 90% of duodenal polyps were non-neoplastic. Neoplastic duodenal polyps had a tendency to be located in the second portion. Twelve (48%) out of 25 neoplastic lesions were encountered, whereas 42 (21.4%) out of 196 non-neoplastic lesions were noted ($P < 0.01$). In the bulb, neoplastic lesions comprised six cases of carcinoid tumor and seven cases of adenoma. The endoscopic findings for duodenal carcinoid tumors revealed a smooth and round elevation with an erythematous change or central depression. In one case of carcinoid tumor, a pedunculated type polyp was observed. Except for carcinoid tumors, only one case of adenoma was smaller than 10 mm in diameter. In the

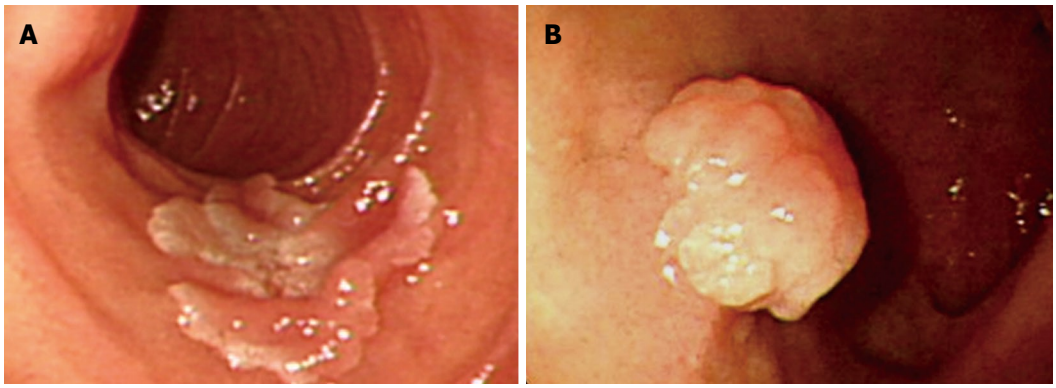

Figure 2 Endoscopic findings of duodenal adenomas. Geographic shaped flat elevated lesions (A) or semi-pedunculated polyps (B) were found in the duodenum.

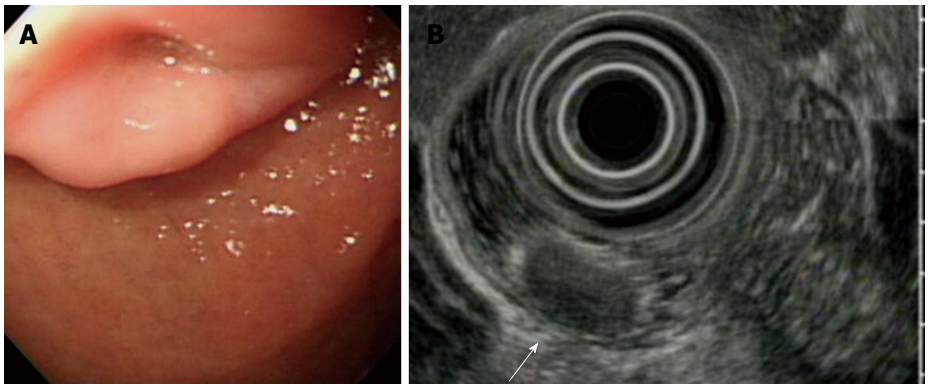

Figure 3 Endoscopic findings of carcinoid tumors. A: Endoscopy revealed an elevated lesion with a central dimpling in the bulb of the duodenum; B: Endoscopic ultrasound finding showed a round-shaped homogenous hypoechoic mass in the mucosal and muscularis mucosal layer (arrow).

Table 2 Non-neoplastic lesions and neoplastic lesions

Non-neoplastic lesions	No. (n = 196)	Neoplastic lesions	No. (n = 25)
Brunner's gland hyperplasia	17	Adenoma	14
Brunner's gland hamartoma	4	Serrated adenoma	1
		Focal cancer change in adenoma	1
Ectopic gastric mucosa	12	Originated in Brunner's gland	1
Ectopic pancreas	1	In familial adenomatosis polyposis	1
Hyperplastic polyp	29	Carcinoid tumor	6
Inflammatory polyp	33		
Normal pathology	100	Metastatic cancer	1

Table 3 Characteristics of non-neoplastic and neoplastic lesions

	Non-neoplastic (n = 196)	Neoplastic lesions (n = 25)	P value
Sex			0.66[1]
Male	122	17	
Female	74	8	
Age (yr)	56.17 ± 12.70	60.04 ± 11.24	0.14[2]
Shape			< 0.01[1]

second portion of the duodenum, most of the neoplastic lesions were adenomas.

With regard to polyp shape, 9 (36%) of the 25 patients had neoplastic lesions with a semi-pedunculated or pedunculated appearance, whereas 25 (12.8%) patients had non-neoplastic lesions of similar shape (P < 0.01). Regarding the number of polyps in a single subject; 26 patients had multiple non-neoplastic lesions and only two patients had multiple neoplastic lesions. On multivariate analysis, lesions of more than 10 mm or located in the second portion of the duodenum had independent risk factors for being neoplastic lesions (Table 3). The endoscopic and histological features of the duodenal polyps are shown in Figures 2-5.

Therapeutic resection of duodenal polyps

For patients with neoplastic lesions, 20 (80%) of 25 patients had therapeutic removal and 16 (64%) patients had

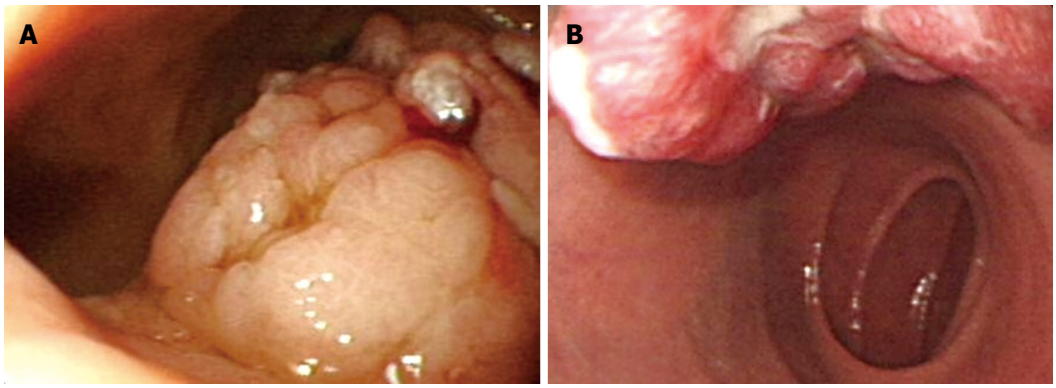

Figure 4 Serrated adenoma (A) and focal cancer change of adenomas (B). Large pedunculated polyps were observed in the duodenal bulb. They had multilobulated and friable surfaces.

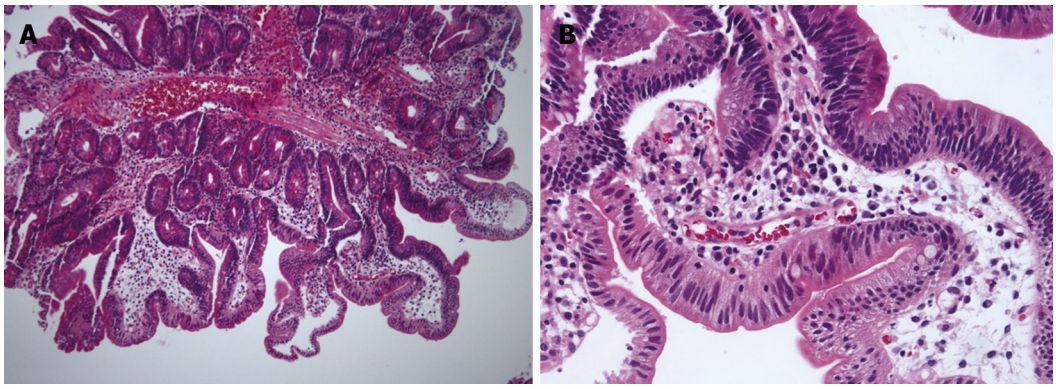

Figure 5 Microscopic finding of serrated adenomas. A: Vascular stalk and saw-tooth appearance were observed (HE, × 40); B: At high magnification, hyperplastic foveolar cells were found. In part, epithelia with pleomorphic, stratified nuclei and irregular chromatin deposits were observed (HE, × 200).

successful endoscopic resection. Two of the remaining five patients have chosen surveillance endoscopy, because the lesion was small and the patients had co-morbid diseases. Two cases were lost to follow-up. One patient with a metastatic lesion from esophageal cancer has received radiation therapy.

Duodenal hyperplastic polyps

Hyperplastic polyps were detected in 29 patients. Two cases had adenomatous changes or focal cancer changes with an adenomatous component. Gastroesophageal lesions identified with duodenal hyperplastic polyps are shown in Table 4. In 21 patients, the *H. pylori* status was evaluated according to the histological results and 12 (57.1%) patients had *H. pylori* infection. The clinical features accompanying duodenal hyperplastic polyps are shown in Table 5. Twenty-three patients (79.3%) were had associated gastroduodenal pathology; peptic ulcer, gastric cancer, gastric hyperplastic polyp, and chronic atrophic gastritis, which was possibly associated with *H. pylori* infection.

DISCUSSION

In our retrospective study, the prevalence of incidentally found duodenal polyps was 1.02% among cases undergo-

ing routine diagnostic esophago-gastroduodenoscopy. The prevalence confirmed by histology was 0.44%. These results were consistent with the frequencies disclosed in previous reports. However, there were several limitations. First, the study population and the object of esophago-gastroduodenoscopy were not uniform-screening or diagnostic procedure for the gastrointestinal symptoms. Second, a tissue biopsy was not performed in all cases of duodenal polyp. Out of 510 polyps, only 221 were biopsied and the others were probably considered as non-neoplastic.

Several types of polyps can occur in the duodenum and most of them are non-neoplastic. Non-neoplastic duodenal polyps include Brunner's gland hyperplasia, ectopic gastric mucosa, and hyperplastic polyps. Previous retrospective studies showed that ectopic gastric mucosa and Brunner's gland hyperplasia are common in the duodenum, and that hyperplasic polyps were extremely rare[6,9,10]. However, in this study, most of the non-neoplastic polyps had normal duodenal mucosa or the lesions had distinguishable histopathology suggestive of an inflammatory polyp. In addition, hyperplastic polyps are a common type of duodenal polyp. Our results are similar to those of a previous prospectively designed study[3]. Inflammatory polyps are presumed to be part of a diffuse inflammatory process, with metaplastic or regenerative changes of the overlying mucosa on histology[4]. The duodenal inflammatory polyps were smaller than the other types of polyps.

Brunner's gland hyperplasia and hamartomas were often encountered in the bulb of the duodenum[11,12], and our results showed that 76.2% (16/21 cases) were located in the bulb. The pathogenesis of these lesions is mostly unknown, and might be associated with duodenal injury observed in patients with acid hypersecretion. Macroscopically, they tend to be solitary sessile or pedunculated polyps with a central pore and are located in the posterior wall of the duodenal bulb. Their histological features include the proliferation of a mixture of mesenchymal tissues, such as adipose, smooth muscle, and Brunner's gland, and cystic dilation of the Brunner's gland. Rarely, adenoma or carcinoma can develop from a Brunner's gland and in symptomatic cases with bleeding, endoscopic removal is necessary[13,14]. In our data, three cases were treated with a polypectomy for Brunner's gland hyperplasia/hamartoma; in one case an adenoma developed from a Brunner's gland and two cases were large polyps.

Although most duodenal polyps had a benign clinical course, some of them can show malignant transformation into adenomas or carcinoid tumors. Therefore, early diagnosis and treatment are important for these cases. In this study, adenomas were the most frequently detected neoplastic lesions, consistent with the findings of previous studies[6,9,10,15]. One case of an adenoma developed from a Brunner's gland, and another case was associated with familial adenomatous polyposis (FAP). In addition, an adenoma of mixed hyperplastic and adenomatous morphology was observed as a serrated adenoma. A serrated adenoma of the duodenum is a very uncommon lesion and has been described in association with FAP[16]. A sporadic case of serrated adenoma has not been previously reported in the duodenum, and this appears to be the first report of one in the literature.

The results of this study showed that the neoplastic lesions were larger than the non-neoplastic lesions, and had a significant predilection for the second portion of the duodenum compared with the non-neoplastic lesions. In addition, a previous report suggested that multiple, small polyps in the duodenal bulb are always benign and need neither biopsy nor treatment. Moreover, polyps in the second portion of the duodenum are rare. If polyps were present in the second portion of the duodenum, a substantial number would be adenomas[17]. Although duodenal carcinoid tumors were rare, their detection and treatment are important. On endoscopic examination, they were yellowish colored and had central dimpling or ulceration with erythematous changes[18]. It should be kept in mind that a polyp-like lesion might be a carcinoid tumor. For the subset of lesions measuring between 1 and 2 cm in diameter, endoscopic ultrasound (EUS) may ultimately offer the best diagnostic method to help guide the management of individual patients[19]. Nearly all neoplastic lesions were treated by local resection (e.g.: polypectomy or mucosal resection) or surgery, except for a metastasis from an esophageal cancer. Most of them could be managed with endoscopic therapy with minimal morbidity. If the lesions located in the second portion of the duodenum cannot be excised by endoscopic therapy, a pancreatico-duodenectomy may be required. However, this technique is associated with a high complication rate.

There have been several reports of hyperplastic gastric polyps associated with persistent *H. pylori* gastritis[20-22], but the association of *H. pylori* with duodenal hyperplastic polyps has been rarely described. Two case reports suggested that these lesions are rare and associated with *H. pylori* infection[6,7]. As a result, their clinical features are poorly understood. Based on our results, most of the patients with duodenal hyperplastic polyps had inflammatory mucosal pathology of gastric mucosa: chronic atrophic gastritis, peptic ulcer, or gastric cancer. A large number of patients were infected with *H. pylori*. Moreover, the association of *H. pylori* might have been underestimated because of the retrospective study design, and the fact that we could not exclude past exposure to *H. pylori*. Unfortunately, there was no control group and the interpretation of this result is limited.

In conclusion, although the frequency of clinically significant duodenal polyps was low, the polyps of more than 10 mm or polyps in the second portion of the duodenum should be carefully observed and evaluated by histological examination. Duodenal hyperplastic polyps might have an association with *H. pylori* infection and with various forms of gastro-duodenal disease.

COMMENTS

Background

Duodenal polyps are rare, although the diagnosis appears to be increasing, possibly due to the wide use of diagnostic endoscopy. Several types of polyps can oc-

cur in the duodenum. However, the clinical importance of non-ampullary duodenal polyps is not well understood and clear management guidelines do not exist.

Research frontiers

The clinical and endoscopic characteristics of neoplastic non-ampullary duodenal polyps are not well known; therefore, this study evaluated their features, including age, sex, size, and endoscopic characteristics (location and gross appearance). In addition, the clinical characteristics of duodenal hyperplastic polyps were determined.

Innovations and breakthroughs

On univariate analysis, there were significant differences in shape, location,and size. Polyps of more than 10 mm in diameter or polyps in the second portion had independent risk factors for being neoplastic lesions identified on multivariate analysis. 79.3% of the hyperplastic polyps were accompanied by gastroduodenal pathology that was possibly associated with *H. pylori* infection.

Applications

This study provides a consensus on guidelines for clinical management of non-ampullary duodenal polyps and helps to discriminate neoplastic polyps.

Peer review

The study reports a retrospective single center evaluation of the prevalence and histology of duodenal polyps in over 50 000 subjects undertaking upper G-I endoscopy for several reasons. The main finding of the authors, on multivariate analysis, is that polyps of the 2° duodenal portion have a greater risk of being neoplastic. The study is interesting because of the large database analyzed; however the retrospective and hospital-based modality of screening should be better acknowledged as a limitation.

Abstract

AIM: To investigate symptoms and brain activity following esophageal acid infusion.

METHODS: Fifteen healthy volunteers were recruited for the study. Hydrochloric acid (pH 1 and 2) and distilled water (pH 7) were randomly and repeatedly infused into the esophagus. The brain activity was evaluated by positron emission tomography. The severity of heartburn elicited by the infusion was rated on an auditory analog scale of 0-10.

RESULTS: The severity of heartburn following each infusion showed a step-wise increase with increasing acidity of the perfusate. The heartburn scores were significantly higher in the second pH 1 infusion compared with the first infusion. Acid and distilled water infusion induced activation of various brain areas such as the anterior insula, temporal gyrus, and anterior/posterior cingulate cortex. At pH 1 or 2, in particular, activation was observed in some emotion-related brain areas such as the more anterior part of the anterior cingulate cortex, parahippocampal gyrus, or the temporal pole. Strong activation of the orbitofrontal cortex was found by subtraction analysis of the two second pH 1 infusions, with a significant increase of heartburn symptoms.

CONCLUSION: Emotion-related brain areas were activated by esophageal acid stimulation. The orbitofrontal area might be involved in symptom processing, with esophageal sensitization induced by repeated acid stimulation.

Key words: Esophageal acid infusion; Brain imaging; Positron emission tomography

INTRODUCTION

Gastroesophageal reflux disease (GERD) causes reflux symptoms such as heartburn and regurgitation due to reflux of the gastric contents into the esophagus, with or without mucosal damage[1]. Although there is a correlation between the severity of esophagitis and acid reflux, it is known that the severity of subjective symptoms is not necessarily correlated with that of acid reflux[2]. In particular, heartburn symptoms are weakly correlated with acid reflux in non-erosive reflux disease (NERD)[3], and NERD patients are often resistant to treatment with acid-suppressive medication[4]. Therefore, the possible involvement of esophageal hypersensitivity in NERD patients has attracted attention[5].

It has been shown that NERD patients show hypersensitivity not only to mechanical stimulation, but also to acid and/or non-acid chemical stimulation[6-8]. Some investigators have argued that the susceptibility of afferent nerve terminals to luminal acid based on the dilated intercellular space in the esophageal mucosa is important as a causative factor for acid hypersensitivity[9,10]. Recent studies have demonstrated that weak acid or gas reflux is associated with the generation of reflux symptoms[11]. However, perceived acid reflux accounts for only a minority of reflux events[12], and the mechanism of heartburn symptoms remains to be elucidated[13].

Recently, brain imaging analysis using positron emission tomography (PET) and functional magnetic resonance imaging (fMRI) has been employed in visceral sensation studies as an objective evaluation tool for the processing mechanism of perception[14]. This advanced approach has demonstrated that some important brain areas, such as the anterior cingulate cortex (ACC) or insula, are involved in the processing of visceral sensation and pain, and abnormality or modulation of these brain areas in patients with irritable bowel syndrome[15-17]. Until now, these brain imaging studies of the viscera, especially of the rectum or colon, have been mainly conducted using barostat-controlled methods; a mechanically extended stimulation device[18]. Only a few studies have investigated brain activity after esophageal chemical stimulation, such as hydrochloric acid[19-21]. The aim of this study was to investigate induced symptoms and brain activity using PET in esophageal acid stimulation.

MATERIALS AND METHODS

Subjects

Fifteen right-handed healthy adult male volunteers (mean age: 26.7 years; range: 21-37 years), who had no typical reflux symptoms such as heartburn and regurgitation, were recruited for the study that was conducted from October 2005 to June 2007. All subjects were healthy volunteers with no gastrointestinal disorders and signs. It was confirmed that they had no prior history of craniocerebral trauma or intracranial diseases.

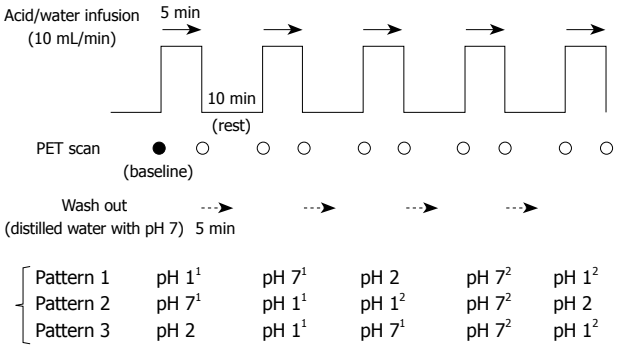

Figure 1 This schema illustrates the procedure of esophageal infusion and brain positron emission tomography scanning. The infusions were performed twice for pH 1 and 7 solutions (distilled water) and once for the pH 2 solution. In order to counterbalance the effects of the infusion order, the order was randomly selected per each subject from pH 1-7-2-7-1, pH 7-1-1-7-2 and pH 2-1-7-7-1 as shown. [1]First infusion; [2]Second infusion; PET: Positron emission tomography.

A small-diameter catheter (new enteral feeding tube 3393-5; Nippon Sherwood Medical Industries Ltd., Tokyo, Japan) was inserted transnasally into the esophagus, and fixed at 35 cm from the exterior nostril. A wired pH glass electrode (CM-181; Chemical Appliance Co. Ltd., Tokyo, Japan), pre-attached at its proximal side 3 cm from the infusion catheter, was connected to a pH meter. The placement of the catheter and pH electrode in the middle esophagus was confirmed by chest X-ray. Subjects were placed in a supine position in the PET scanner with their heads immobilized in a head immobilization device to control head movement during scanning. In order to obtain correction data for γ-ray absorption in the body, subjects initially underwent a transmission scan using a ^{68}Ge/^{68}Ga radiation source. This study was approved by the Ethics Committee for Human Research at Tohoku University Graduate School of Medicine, Sendai, Japan. Informed consent was obtained from every subject.

Esophageal acid infusion

The procedures for esophageal infusion and PET scan are schematically shown in Figure 1. Infusions of 50 mL HCl (pH 1 and 2) or distilled water (pH 7) were provided by a catheter using an automatic syringe pump (Terufusion syringe pump TE-312; Terumo Co. Ltd., Tokyo, Japan) for a total of 5 min at 10 mL/min. The infusions were performed twice for pH 1 and pH 7 solutions and once for the pH 2 solution. In order to counterbalance the effects of the infusion order, the order was randomly selected from pH 1-7-2-7-1, pH 2-1-7-7-1, and pH 7-1-1-7-2. Then ^{15}O-labeled water was administered intravenously in synchronization with the completion of each 5-min infusion. After confirming that the brain activity could be detected, a PET emission scan of the head was performed for 60 s prior to the PET scan; the subjects were instructed to remain awake during the scan that was performed in a darkened room. Using a PET scanner (Headtome-V set- 2400 W; Shimadzu, Kyoto, Japan)[22] in a 3D data acquisition mode, a total of 10 scans were taken

before and after each of the five infusions, to measure the regional cerebral blood flow in each subject. After each acid infusion, the esophagus was neutralized by an infusion of distilled water (pH 7) over 5 min at 10 mL/min and by additional swallowing. During 10-min intervals between infusions, it was confirmed that the esophageal pH was 4 or higher, as an indicator of the non-acidic status[23], and that the radioactivity in the heads of the subjects had returned to baseline (pre-scan) levels. Subjects were asked to rate the severity of heartburn symptoms on an analog scale of 0-10 after each infusion, and the resultant scores were used in the analysis of data. The incidence of heartburn symptoms and the heartburn scores elicited after the five infusions for each of the two groups were statistically analyzed by Fisher's test and the Wilcoxon signed-ranks test, respectively. Differences were considered statistically significant when the P value was < 0.05.

PET data analysis

The PET data were transferred to a super computer (NEC, SX-4/128H4, Tohoku University Cyberscience Center, Sendai, Japan) and PET images were reconstructed using a 3D filtered back projection algorithm[24]. Realignment, spatial normalization, and smoothing of images were performed using statistical parametric mapping (SPM) software (SPM 2, Wellcome Department of Cognitive Neurology, London, UK), and significantly different changes in regional cerebral blood flow were mapped. All regional cerebral blood flow images were anatomically normalized against a standard brain space such as the Montreal Neurological Institute atlas[25]. The standardized images were smoothed using a 12 mm × 12 mm × 12 mm Gaussian filter. Evaluations of regional cerebral blood flow were adjusted using analysis of covariance and mean scaling set at 50, and expressed in mL/min per 100 g. The effects of grouping and co-variability were each evaluated using a general linear model of voxels.

The following two analyses were performed to determine the areas of regional brain activity that correlated with the esophageal acid infusion. First, brain images taken following infusion with hydrochloric acid (pH 1 and 2) or distilled water (pH 7), as well as images taken at baseline (prior to all infusions) were subjected to subtraction analysis to investigate the brain regions that were activated by each infusion. Next, the effects of repeated infusion of acid or distilled water were assessed by subtraction analysis of images obtained following the first and second infusions with pH 1 and pH 7 solutions. All statistical methods were evaluated using linear convolution and contrasts, and the voxel values for each image were constructed using a statistical parametric map of the t-statistic statistical parametric mapping. The location of statistical peaks was determined in Talairach and Tournoux atlas. P (uncorrected) < 0.001 was defined as statistically significant for increased cerebral blood flow.

RESULTS

Enhanced incidence and severity of symptoms following acid infusion

The incidence of heartburn symptoms following each infusion was 33.3% for the first pH 7 infusion, 33.3% for the second pH 7 infusion, 46.7% for pH 2, 66.7% for the first pH 1 infusion, and 80.0% for the second pH 1 infusion. The incidence of heartburn symptoms following each infusion showed a step-wise increase with increasing acidity of the perfusate. The incidence of heartburn tended to be higher after the second pH 1 infusion than after the first, and these scores were significantly increased following the second pH 1 infusion. On the other hand, the heartburn incidence and scores in both pH 7 infusions were much lower compared to the pH 1 infusions. Symptom scores were significantly increased after the pH 2 infusion compared to the second pH 7 infusion, and after the second pH 1 infusion compared to the pH 2 infusion (Table 1).

Table 1 Incidence of heartburn symptoms and heartburn scores induced by each infusion

	Heartburn incidence	Mean heartburn scores (range)
pH 7 (first infusion)	5/15	1.4 (0-7)
pH 7 (second infusion)	5/15	1.0 (0-6)
pH 2	7/15	1.9 (0-9)[b]
pH 1 (first infusion)	10/15	3.2 (0-10)[c]
pH 1 (second infusion)	12/15[a]	5.0 (0-10)[d]

[a]$P = 0.0253$ *vs* pH 7 (first infusion) and pH 7 (second infusion); [b]$P = 0.0269$ *vs* pH 7 (second infusion); [c]$P = 0.0464$ *vs* pH 7 (first infusion), $P = 0.0253$ *vs* pH 7 (second infusion); [d]$P = 0.0040$ *vs* pH 1 (first infusion), $P = 0.0075$ *vs* pH 2, $P = 0.0041$ *vs* pH 7 (first infusion), $P = 0.0071$ *vs* pH 7 (second infusion).

Activated brain areas following acid infusion

Comparison of brain images following each infusion: The brain image obtained at rest prior to all infusions was defined as the baseline image. Differences between brain images at baseline and those taken after infusion with acid or distilled water were subjected to subtraction analysis. Brain regions with increased blood flow were defined as those neurologically activated by each infusion. The details of the brain regions activated following each infusion are shown in Table 2 and are summarized in Table 3.

After the first pH 7 infusion, activation was observed in the right precentral gyrus, left superior temporal gyrus, right and left ACC, right anterior insula and, after the second pH 7 infusion, in the right middle frontal gyrus, cuneus (center), right posterior cingulate cortex (PCC), right postcentral gyrus, right ACC, left inferior frontal gyrus, left middle temporal gyrus, right and left thalamus, and right superior temporal gyrus. The regions activated at pH 2 were the left cerebellum, right inferior frontal gyrus, left superior temporal gyrus (temporal pole, BA38), right anterior insula, left putamen, left PCC, right ACC, mid pons, and left superior temporal gyrus. After the first pH 1 infusion, activation was observed in the right precentral gyrus, right superior temporal gyrus (temporal pole, BA38), left middle temporal gyrus, left parahippocampal gyrus, left ACC, and left middle temporal gyrus. After the second pH 1 infusion, activation was observed in the right parahippocampal gyrus (Figure 2A), left superior temporal gyrus (temporal

PHG						L	R

PMA: Primary motor area; PSA: Primary somatosensory area; ACC: Anterior cingulate cortex; PCC: Posterior cingulate cortex; PHG: Parahippocampal gyrus; BA: Brodmann area; R: Right; L: Left; C: Center.

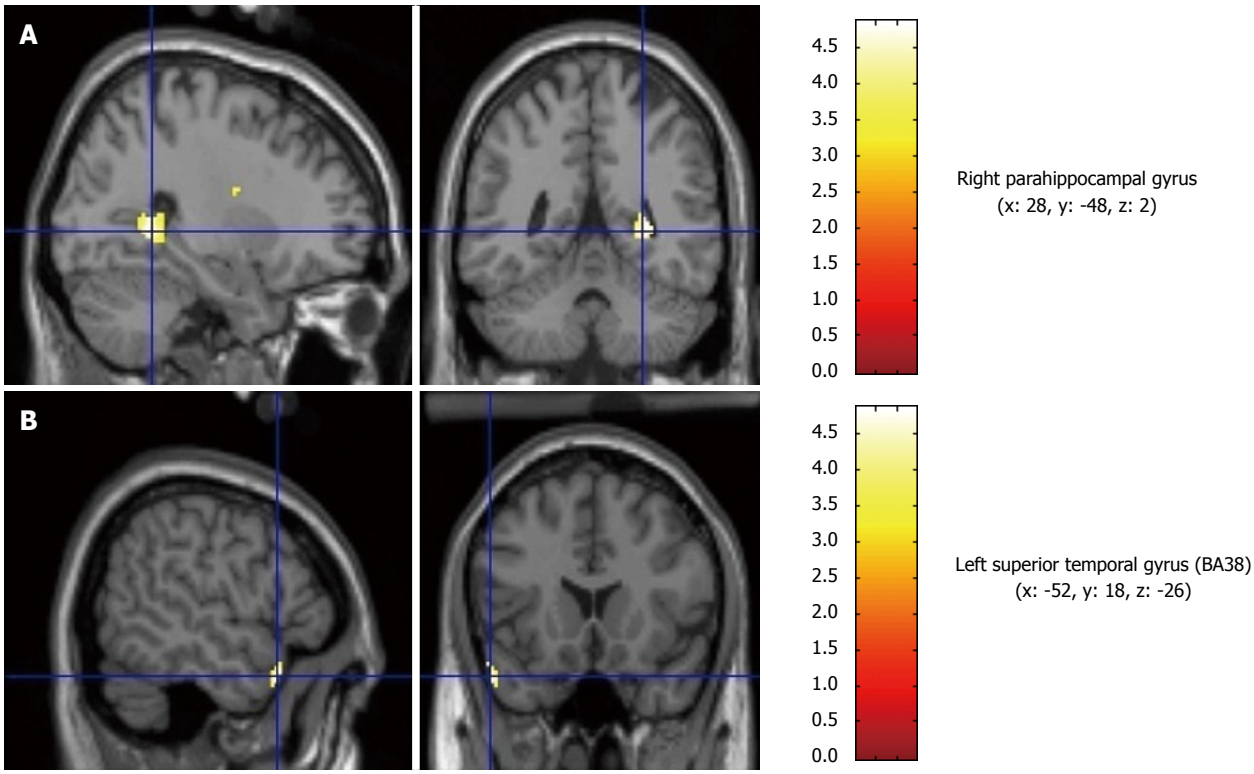

Figure 2 Representative images from the subtraction analysis of the second pH 1 infusion minus the baseline. Left: Sagittal view; Right: Cranial view. A: Right parahippocampal gyrus (x: 28, y: -48, z: 2); B: Left superior temporal gyrus (temporal pole, BA38) (x: -52, y: 18, z: -26).

pole, BA38) (Figure 2B), left cerebellum, left PCC, left caudate nucleus, right anterior insula and right pons.

In view of the acidity level of the perfusate, brain activation was observed in the prefrontal area at pH 2 and 7 but not at pH 1. In the insula, activation was observed at the second pH 1 and 2 and first pH 7 infusions. Activation in the cingulate cortex was observed in nearly all infusions, with no particular trend observed for the topography of the activated sub-regions. At pH 1 and 2, activation was observed in the more anterior (rostral) part of the ACC (BA 24a) and, at pH 7, in the more posterior (dorsal) part of the ACC (BA 24a'). Many activated areas were observed in regions of the temporal gyrus, with no particular trend observed for the topography. After infusions at pH 1 and 2 but not pH 7, activation was observed in the temporal pole (BA 38). Activation was also observed in the cerebellum following infusions at pH 1 and 2, and in the parahippocampal gyrus after both pH 1 infusions. On the other hand, the frontal area, precentral gyrus, and thalamus were less activated after each infusion.

Comparison of brain imaging with first and second infusion at pH 1 and 7: As described above, the scores for heartburn symptoms after the pH 1 infusions were significantly increased after the second infusion compared to the first. When we analyzed the difference of these two conditions using subtraction analysis, the second pH 1 infusion minus the first showed that cerebral blood flow was increased in the right orbitofrontal cortex (Figure 3A), right cuneus, left cerebellum, right superior temporal gyrus, right middle frontal gyrus (Figure 3B), right pons, right lingual gyrus, left putamen, and right caudate nucleus. On the other hand, the result of the second pH 7 infusion minus the first showed an increase in cerebral blood flow in the right middle frontal gyrus, left cerebellum, right midbrain, left PCC, and right superior frontal gyrus. Those brain areas are summarized in Table 4.

DISCUSSION

In the present study, we found that brain activity was substantially increased in the cingulate cortex and frontal lobe following esophageal acid infusion, with little activity observed in the thalamus and somatosensory areas. The insula was not consistently activated by acidic or non-acidic stimulations in this study, but in previous studies, the activation of the insula and ACC has been highly reproducible, and is considered to play a central role in the integration of visceral sensation[14,17]. ACC is functionally and anatomically divided into several subregions[26]. The more anterior part of the ACC (BA 32, 25, 24) is involved in affective and emotional responses and the dorsal part (BA 32', 24') is involved in cognitive processes[27]. Activation of the ACC predominantly occurred in the anterior part (BA 24) at pH 1 and 2, and in the posterior part (BA 24') at pH 7 in this study, which supports the fact that heartburn is uncomfortable and troublesome[1].

The heartburn symptom scores following infusions at pH 1 and 2 were higher compared with those at pH 7. We found that the parahippocampal gyrus was activated only by pH 1 infusion. This area is an important part of the limbic system, which plays a major role in the processing

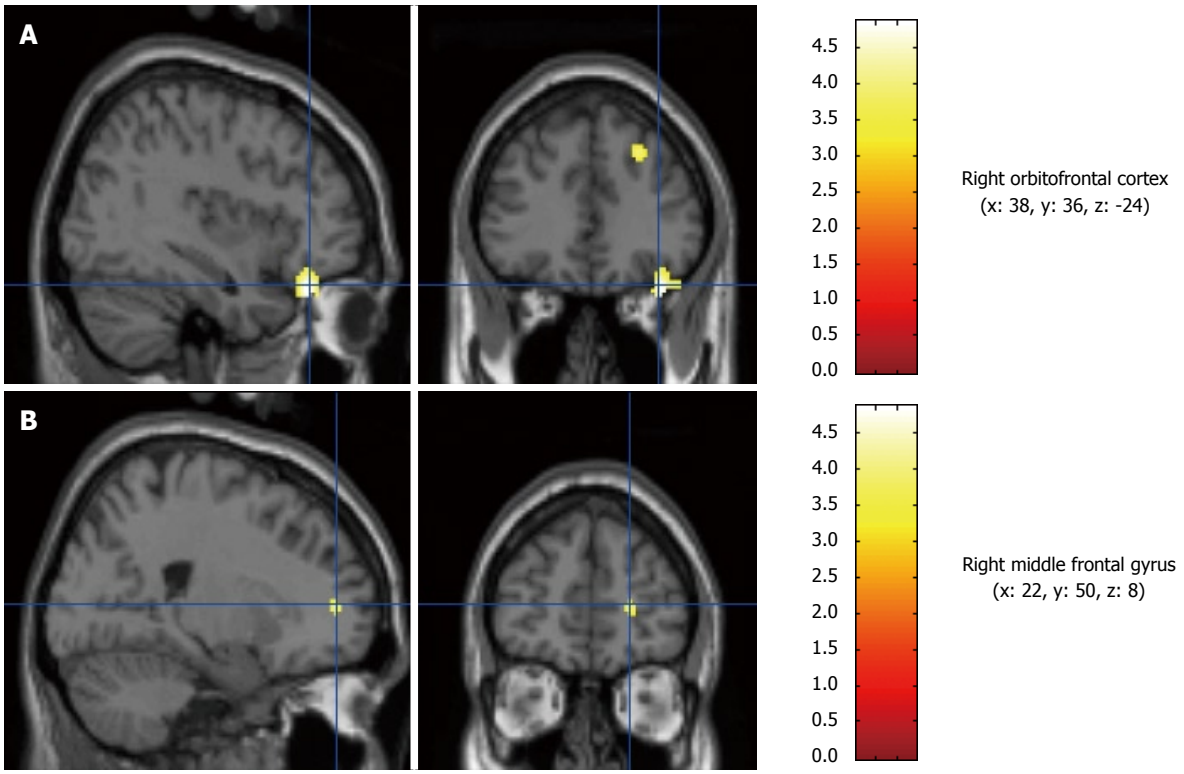

Figure 3 Representative images from the subtraction analysis of the second pH 1 infusion minus the first. Left: Sagittal view; Right: Cranial view. A: Right orbitofrontal cortex (x: 38, y: 36, z: -24); B: Right middle frontal gyrus (x: 22, y: 50, z: 8).

Table 4 Results of subtraction analysis of brain images after the first and second infusions at pH 1 and 7

Condition	Region	Side	Brodmann area	x	y	z	Z-score	Voxels in cluster
Second pH 1 - first	Orbitofrontal cortex	Right		38	36	-24	4.44	167
	Cuneus	Right	19	2	-82	36	3.79	51
	Cerebellum	Left		-22	-40	-50	3.74	23
	Superior temporal gyrus	Right	8	26	36	40	3.69	37
	Middle frontal gyrus	Right	32	22	50	8	3.69	23
	Pons	Right		10	-36	-12	3.47	31
	Lingual gyrus	Right	19	4	-60	-2	3.37	12
	Putamen	Left		-24	-8	2	3.32	16
	Caudate nucleus	Right		18	-34	16	3.30	16
Second pH 7 - first	Middle frontal gyrus	Right	10	36	46	0	4.03	47
	Cerebellum	Left		-18	-98	-18	3.98	40
	Midbrain	Right		2	-40	2	3.65	27
	Posterior cingulate cortex	Left	23	-14	-16	30	3.61	11
	Superior frontal gyrus	Right	8	14	22	42	3.57	33

of emotional reaction or memory[28]. Therefore, activation of the parahippocampal gyrus is compatible with induction of uncomfortable heartburn by acid infusion. Also, activation was observed in the temporal pole following infusions at pH 1 and 2, but not at pH 7. The temporal pole (BA 38) is located at the anterior extremity of the temporal lobe, which includes the superior and middle temporal gyri. There have been few reports regarding activation of the temporal pole in previous studies of esophageal sensation. However, a recent study has shown that this area is activated by distention in the proximal stomach[29], and another report has described activation of the temporal pole by distention of the descending colon, with a feeling of anxiety[30]. In a study using photographs as visual stimulation, the temporal pole was activated by emotions of comfort and discomfort, wakefulness, and attended stimulation[31]. Therefore, the activation of the temporal pole observed in our study could have been due to alterations in the level of arousal, attention and emotion following acid infusion. These observations also suggest that, as shown by the activation pattern of the ACC in this study, high-acidity stimulation in the esophagus can induce emotional responses.

It has been shown that heartburn is apt to be perceived when preceding acid reflux or prior acid stimulation exists[11,32,33]. Also in this study, the heartburn scores were significantly higher after the second pH 1 infusion compared to the first, which suggests that esophageal sensation was

sensitized by repeated acid infusion. These changes were not observed after repeated infusion at pH 7. Visceral sensitization, which can occur at the primary afferent nerve level (peripheral sensitization) and/or the spinal cord level (central sensitization), is considered as a very important phenomenon in the development of visceral sensation[34]. Finally, visceral sensation is perceived through intracerebral processing and modulation[34]. Recent studies using cortical evoked potentials or fMRI have reported that esophageal sensitization induced by acid stimulation results in alterations in the neural activity of the ACC and insula[35-37]. In our present study, subtraction analysis of the second pH 1 minus the first showed that increased brain activity occurred in several areas, including the right orbitofrontal cortex, right supratemporal gyrus and right middle frontal gyrus. Of those brain areas, the orbitofrontal cortex had the highest Z-score and cluster level in our study. The orbitofrontal cortex, which is frequently observed to be activated following stimulation of the lower gastrointestinal tract, was less activated following esophageal stimulation in previous studies[14,38,39]. As a higher center of sensory integration, this area is thought to participate in the assessment of reward, punishment, comfort, discomfort, and memory or its verification[40]. Thus, our findings showed that the orbitofrontal cortex, besides the ACC or insula, shown in other studies[35-37], might also play a role in symptom processing with esophageal acid sensitization.

Chemoreceptor stimulation of the esophagus is also thought to activate fine sympathetic and parasympathetic afferents. Fine sympathetic afferents ascend the lamina I of the spinal cord, and parasympathetic afferents provide input to the solitary tract nucleus[28]. These activities are integrated in the parabrachial nucleus, which projects to the posterior dorsal insula by way of (or by passing) the ventromedial thalamic nuclei[28]. In humans, this cortical image is represented in the anterior insula[28]. This is compatible with our findings documenting the activation of the anterior part whenever the insula is activated, although its activation was not detected under condition with the second pH 1 infusion minus the first. However, these representations provide the foundation for a subjective evaluation of the interoceptive state, which is forwarded to the orbitofrontal cortex, where hedonic valence is represented[40], and was depicted as discrimination between the first and the second acidic stimuli in the present study.

In the present study, little activation was observed in the thalamus and primary somatosensory cortex. Based on previous reports of visceral and somatic sensation, the activation in the primary somatosensory cortex has poorer reproducibility compared with activation in the insula; possibly due to variations in the intensity, property, and spatial and temporal amount of stimulation in the respective studies[14,17,41]. Especially in visceral sensation, the total amount of spatial and temporal stimulation is very difficult to evaluate, which could account for the variation in brain activation. Alternatively, the lower activation in the primary somatosensory cortex suggests vague localization of pain originating from the viscera[17]. Moreover, in esophageal acid infusion tests, including our present and previous studies, it is necessary to take into account the differences in the acidity, infusion rate, total volume of the perfusate, and the position during infusion, which probably influence the induction of symptoms and concomitant brain activation[20,21,42,43]. Kern *et al*[21] have reported in an fMRI study that activation in the sensory motor cortex among GERD patients with luminal/perceived esophageal acid exposure was substantially higher than that in healthy controls with subliminal acid stimulation. This study suggests that the sensory motor area is associated with the perception of heartburn symptom in GERD patients, although it does not apply to healthy controls. A further study of our patients with GERD is needed.

In the present study, pH 1 and 2 hydrochloric acid was chosen as an acidic stimulant of the esophagus. pH 1 hydrochloric acid has been traditionally and widely used as an esophageal chemical stimulant[6,20,21,32,33,44], and there is a report that pH 2 represents a critical level of acidity in inducing heartburn symptoms[45]. Due to the time constraints of our PET facility, infusions at pH 2 were performed only once, whereas infusion at pH 1 and 7 was performed twice. This could be a limitation of our study. We also randomly selected one of the three aforementioned infusion orders for each subject to counterbalance the influence of the infusion order. The infusion order was not revealed to the subjects, but anticipation of the infusion might have influenced the brain activation[46]. On the other hand, the physical and mental stress associated with keeping still for a long period, the gag reflex and swallowing with an indwelling intranasal tube might have an adverse effect on brain activation[43].

In summary, this present study using PET showed that the insula, cingulated gyrus, temporal gyrus, and cerebellum were activated in esophageal acid perception in healthy volunteers, and that involvement of the somatosensory and prefrontal areas was minimal. In particular, emotion-related brain regions such as the anterior part of ACC, the parahippocampal gyrus and the temporal pole were activated under acidic conditions in the esophagus. It is also suggested that activation of the orbitofrontal area is involved in esophageal sensitization to repeated acid stimulation at the cerebral level. Dysfunction of these brain areas may be associated with the pathogenesis of functional heartburn or non-erosive reflux disease. Further studies of brain imaging to elucidate the mechanism of esophageal acid perception and sensitization in healthy subjects and patients with GERD, including NERD and functional heartburn, are warranted.

COMMENTS

Background

Esophageal hypersensitivity is a potentially causative factor in the pathogenesis of non-erosive reflux disease (NERD) or functional heartburn. In those patients, there may also be a neural alteration at the brain level against esophageal acid reflux, but little is documented on this issue.

Research frontiers

Using brain positron emission tomography (PET), we sought to analyze the symptoms and brain activity following esophageal acid infusion with different pH levels in healthy volunteers.

Innovations and breakthroughs

Several emotion-related brain areas such as the anterior part of the anterior cingulate cortex, parahippocampal gyrus or the temporal pole were activated by esophageal acid stimulation. In addition, a strong activation of the orbitofrontal cortex was observed with repeated pH 1 HCl perfusions, with a significant increase of heartburn symptoms.

Applications

This preliminary study might contribute to the authors' understanding of the pathogenesis of NERD or functional heartburn, and could provide a newly therapeutic agent that targets an alteration in brain activity induced by acid reflux.

Peer review

The authors investigated the symptoms and brain activity following esophageal acid infusion, by PET and auditory analog scale in healthy volunteers. They found that emotion-related areas were activated under conditions of high acidity, with heartburn symptoms, and that the orbitofrontal area might be involved in symptom processing, with esophageal sensitization induced by repeated acid stimulation. Their observations could contribute to an elucidation of the pathogenesis of NERD or functional heartburn, and could be helpful for development of new therapeutic options.

Abstract

AIM: To identify the predictors of rebleeding after initial hemostasis with epinephrine injection (EI) in patients with high-risk ulcers.

METHODS: Recent studies have revealed that endoscopic thermocoagulation, or clips alone or combined with EI are superior to EI alone to arrest ulcer bleeding. However, the reality is that EI monotherapy is still common in clinical practice. From October 2006 to April 2008, high-risk ulcer patients in whom hemorrhage was stopped after EI monotherapy were studied using clinical, laboratory and endoscopic variables. The patients were divided into 2 groups: sustained hemostasis and rebleeding.

RESULTS: A total of 175 patients (144, sustained hemostasis; 31, rebleeding) were enrolled. Univariate analysis revealed that older age (≥ 60 years), advanced American Society of Anesthesiology (ASA) status (category Ⅲ, Ⅳ and Ⅴ), shock, severe anemia (hemoglobin < 80 g/L), EI dose ≥ 12 mL and severe bleeding signs (SBS) including hematemesis or hematochezia were the factors which predicted rebleeding. However, only older age, severe anemia, high EI dose and SBS were independent predictors. Among 31 rebleeding patients, 10 (32.2%) underwent surgical hemostasis, 15 (48.4%) suffered from delayed hemostasis causing major complications and 13 (41.9%) died of these complications.

CONCLUSION: Endoscopic EI monotherapy in patients with high-risk ulcers should be avoided. Initial hemostasis with thermocoagulation, clips or additional hemostasis after EI is mandatory for such patients to ensure better hemostatic status and to prevent subsequent rebleeding, surgery, morbidity and mortality.

Key words: Epinephrine injection; High-risk ulcers; Initial hemostasis; Predictors; Rebleeding

INTRODUCTION

Bleeding peptic ulcer is a common and life-threatening

medical emergency[1]. With regard to endoscopic hemostasis, epinephrine injection (EI) monotherapy is a common and effective endoscopic method of hemostasis because of its low risk, low cost and high accessibility[2-4]. Although EI monotherapy has good efficacy in the hemostasis of bleeding peptic ulcers, bleeding recurs in about 10%-30% of the population[5-8]. Undoubtedly, recurrent bleeding remains the most important adverse independent prognostic factor[9,10]. Recent studies have revealed that thermocoagulation, sclerosant injection or clips alone, or combined with EI are superior to EI alone for preventing rebleeding, surgery and mortality. EI alone is not recommended[11-15]. However, the reality is that EI monotherapy to arrest ulcer bleeding is still commonly practiced, in part, because it is a relatively simple and effective hemostatic method and because some patients are intolerant of time-consuming EI combination therapy[16-18]. As sustained hemostasis is the goal of endoscopic therapy, we tried to identify factors which predicted recurrent bleeding after achieving initial hemostasis with EI monotherapy. Therefore, an additional hemostatic method to EI, or initial thermocoagulation, sclerosant injection or clips is warranted in such high-risk patients to ensure better hemostatic efficacy.

MATERIALS AND METHODS

Patient selection

Based on previous validations, those ulcers with spurting bleeding (Ⅰa), oozing bleeding (Ⅰb), non-bleeding visible vessel (NBVV, Ⅱa) and adherent clots (Ⅱb) were high-risk ulcers according to the Forrest classification and should be considered for endoscopic therapy[4,19]. From October 2006 to April 2008 in the Medical Center, Chang Gung Memorial Hospital, Kaohsiung, Taiwan, we enrolled patients with high-risk ulcers (Ⅰ, Ⅱa and Ⅱb) who achieved initial hemostasis with EI monotherapy (epinephrine solution, 1:10000) into this study. Patients who failed to achieve hemostasis during EI monotherapy or received endoscopic combination therapy were excluded. Moreover, patients with malignant ulcers were also excluded. Pharmacotherapy with proton pump inhibitors (PPIs) in these patients was also recorded.

Clinical, laboratory and endoscopic assessments

We analyzed the possible factors which predicted recurrent bleeding in patients with successful initial hemostasis. The clinical, laboratory and endoscopic variables investigated included age, sex, Forrest class, ulcer size, ulcer location, hemoglobin level, blood transfusion, difficulty in the injection approach, injection dose, patient status including outpatient (in the emergency room due to ulcer bleeding) and inpatient (development of ulcer bleeding during admission) and bleeding presentation including severe bleeding signs (SBS; hematemesis or hematochezia) or mild bleeding signs (MBS; coffee ground vomitus or melena). Shock status was defined as either a systolic blood pressure of less than 90 mmHg, or less than 100 mmHg plus a pulse rate of more than 100 beats per minute. The clinical risk status of the patients was assessed by means of the American Society of Anesthesiology (ASA) classification[20]. That is, ASA Ⅰ = healthy patient, ASA Ⅱ = patient with mild systemic disease without functional limitation, ASA Ⅲ = severe systemic disease with definite functional limitation, ASA Ⅳ = severe systemic disease that is a constant threat to life, and ASA Ⅴ = moribund patient not expected to survive for more than 24 h with or without surgery. The hemoglobin level was recorded before blood transfusion and endoscopic therapy. The total amount of packed red blood cells (pRBC) transfused was recorded until endoscopic hemostasis was achieved. Use or non-use of nonsteroidal anti-inflammatory drugs (NSAID) and aspirin was also recorded. The accessibility of injection therapy was categorized into an easy or difficult approach depending on the location of the ulcers. Peptic ulcers located in the lesser curvature and posterior wall of the gastric body and posterior wall of the duodenum were regarded as those that required a difficult approach for injection therapy. Peptic ulcers located in areas other than the above-mentioned were regarded as easy approach. Rebleeding was defined as the recurrence of bleeding within 2 wk of initial hemostasis.

Statistical analysis

Univariate analysis for possible factors predicting recurrent bleeding was performed using the Pearson χ^2 test and Fisher's exact test for categorical variables and the Student's t test for continuous variables. Variables with a $P < 0.05$ were considered statistically significant. Variables with a $P < 0.4$ in the univariate analysis were used for multiple logistic regression analysis with backward stepwise correction and were considered independent predictors of recurrent bleeding with a $P < 0.05$.

RESULTS

From October 2006 to April 2008, a total of 662 sessions of EI-based procedures to treat upper gastrointestinal bleeding were recorded in our computerized medical record system. After excluding patients who underwent endoscopic combination therapy, endoscopic hemostasis failure, and those who had malignant ulcer bleeding or Mallory-Weiss tear bleeding, a total of 175 patients with high-risk ulcers (Ⅰ, Ⅱa and Ⅱb) who achieved initial hemostasis were enrolled. All these patients received intravenous PPI therapy during the acute bleeding period followed by oral PPIs to maintain hemostasis. Our records indicated that 144 patients (82.3%) achieved sustained hemostasis and 31 patients (17.7%) suffered from recurrent bleeding. Univariate analysis revealed that older age (age ≥ 60 years), advanced ASA status (category Ⅲ, Ⅳ and Ⅴ), shock, severe anemia (hemoglobin < 80 g/L), injection dose ≥ 12 mL and SBS were risk factors of recurrent bleeding (Table 1). However, backward stepwise correction (Table 2) revealed that only older age ≥ 60 years, odds ratio (OR) 5.11, 95% confidence interval (CI): 1.34, 19.48,

Sepsis	8
Renal failure	2
Respiratory failure	8
Hypovolemic shock	2
Death	13 (41.9%)

[1]Some patients suffered 2 or more major complications related to recurrent bleeding.

DISCUSSION

Due to medical progress in the management of ulcer hemorrhage, pharmacotherapy with PPIs and endoscopic hemostasis are standard treatments. PPIs are the first choice of pharmacotherapy to control ulcer bleeding at present due to their strong inhibition of acid secretion and promotion of platelet aggregation[21]. PPIs have also been demonstrated to reduce rebleeding, the need for surgery and repeated endoscopic therapy[22]. With regard to endoscopic therapy, this treatment also reduces the occurrence of rebleeding, the need for surgery and the morbidity and mortality of patients. When bleeding recurs, however, repeated endoscopic therapy may either prevent patients from undergoing surgery or delay surgical hemostasis[23,24]. Therefore, the most important goal of endoscopic therapy is to initially achieve permanent hemostasis. Recently, numerous meta-analyses have indicated that adding a second procedure, such as a second injectate (alcohol, thrombin, sclerosant or fibrin glue), thermocoagulation or clips to EI significantly reduced rebleeding, surgery and mortality compared with EI alone in high-risk ulcer patients[11-15]. EI alone is not recommended in the management of bleeding ulcers; however, the reality is that endoscopic hemostasis with EI alone is still commonly practiced[16-18]. There are several reasons for this: first, injection monotherapy is a simple and effective hemostatic method (82.3% in the current study). Second, EI combination therapy is

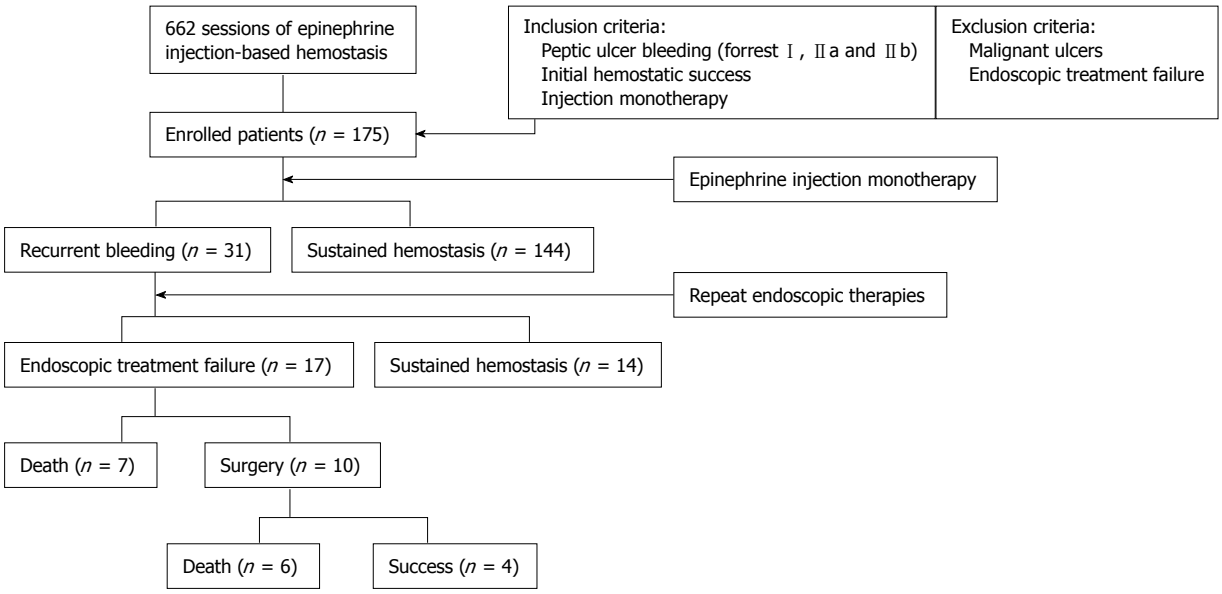

Figure 1 The clinical course of 175 patients with successful initial hemostasis after endoscopic epinephrine injection monotherapy.

a relatively time-consuming procedure, so patients may not tolerate or complete the process, particularly those in a hemodynamically unstable status. Third, thermotherapy such as argon plasma coagulation (APC) or mechanical hemostasis with clips may not be available in every endoscopic unit, particularly in local hospitals. Therefore, to identify predictors of recurrent bleeding in high-risk ulcer patients after EI alone may justify the benefit of endoscopic combination therapy or initial replacement by thermocoagulation or clips for a better treatment outcome. Those patients with such risk factors treated with EI only should be closely monitored or referred to other hospitals with a well-equipped endoscopic unit. From the high-risk ulcer patients treated by PPIs pharmacotherapy and EI alone in our study, we found older age (≥ 60 years), advanced ASA categories (Ⅲ, Ⅳ and Ⅴ), shock, severe anemia (hemoglobin < 80 g/L), injection dose ≥ 12 mL and SBS were the factors which predicted rebleeding. Older age, severe anemia, high injection dose and SBS were independent predictors in multivariate analysis.

Compared to ulcers with NBVV or black spots, active ulcer bleeding tends to rebleed if left untreated. After successful endoscopic hemostasis and administration of PPIs, there were no statistical differences observed in this study. Severe anemia and SBS were relevant to the amount of blood loss and the severity of ongoing bleeding, and were risk factors for recurrent bleeding. The amount of blood transfused before endoscopic therapy may not correlate well with the severity of blood loss. In our hospital, a 24-h emergency endoscopy service is provided and patients often undergo early therapeutic endoscopy within 24 h of either visiting the emergency room or the occurrence of bleeding after admission. Thus, the amount transfused prior to early endoscopy cannot be considered as a risk factor of rebleeding. As for the use of large and small volumes of EI in bleeding ulcers, there are two prospective studies which refer to the hemostatic effectiveness of injection volume. In these studies, the injection of a larger volume might reduce the rate of recurrent bleeding compared to a smaller volume in a prospective design[25,26]. On the other hand, the need for a higher injection dose to arrest bleeding might imply a difficult hemostasis and a higher risk of recurrent bleeding from a retrospective viewpoint. In our study, an injection dose ≥ 12 mL was an independent risk factor of recurrent bleeding.

NSAID and aspirin also cause peptic ulcer bleeding. Prior use of NSAID/aspirin was reported to increase the risk of rebleeding in bleeding ulcer patients[27,28]. If the use of NSAID is discontinued, PPI therapy is very effective in treating NSAID-related ulcers and preventing further bleeding.

It is well known that *Helicobacter pylori* (*H. pylori*) infection can cause peptic ulcers. The detection of *H. pylori* was not performed in our study as these patients were in an acute bleeding phase. The rapid urease test during the acute bleeding phase is unreliable for the detection of *H. pylori* infection[29]. Furthermore, Schilling *et al*[30] also revealed that *H. pylori* infection does not affect the early rebleeding rate in patients with peptic ulcer bleeding after successful endoscopic hemostasis, however, patients should be tested and treated for *H. pylori* infection once their condition has stabilized to prevent recurrent ulcers.

EI monotherapy is commonly practiced in endoscopic hemostasis due to its good efficacy, and because it is a simple and time-saving technique[2-4]; however, it should be replaced by combination therapy, clips, sclerosant injection or thermocoagulation based on more recent evidence. Sclerosant injection, clips or thermocoagulation alone or in combination with EI are more effective methods than EI alone. Although we achieved sustained hemostasis in 82.3% of our patients with bleeding ulcers treated by endoscopic EI monotherapy, 31 patients suffered from recurrent bleeding. The outcome of the patients with re-

bleeding was discouraging as 15 patients (48.4%) suffered from major complications and 13 patients (41.9%) died of complications. Among the 31 rebleeding patients, 10 patients underwent surgical hemostasis but only 4 patients survived. Although these rebleeding patients often had underlying major diseases, to achieve sustained hemostasis using sclerosant, thermocoagulation, clips or EI combination as soon as possible would allow these patients to have a better prognosis. Therefore, we suggest that all patients with high-risk ulcers should undergo sclerosant injection, thermocoagulation or clips in index endoscopy because they are more effective and time-saving. EI followed by thermocoagulation, clips or another injectate should also be considered, however, these are more time-consuming and some patients cannot tolerate or complete the procedures. Unless sclerosant, APC or clips are unavailable, EI alone is not recommended, particularly in older patients (> 60 years), SBS, severe anemia, and those in need of a higher EI dose to arrest bleeding during endoscopic therapy. Additional endoscopic therapies to EI are mandatory or these patients should be referred to a hospital with a well-equipped endoscopic unit for close monitoring.

In conclusion, endoscopic EI monotherapy in patients with high-risk ulcers should be avoided. Initial hemostasis with thermocoagulation, clips or additional hemostasis after EI is mandatory, particularly in older patients, SBS, severe anemia and where a higher injection dose in need. Then, it is possible to ensure that such patients have a better hemostatic status and will avoid subsequent rebleeding, surgery, morbidity and mortality.

COMMENTS

Background

Recent studies have revealed that thermocoagulation, sclerosant injection or clips alone, or combined with epinephrine injection (EI) are superior to EI alone in preventing rebleeding, surgery and mortality. EI alone is not recommended. However, the reality is that EI monotherapy to arrest ulcer bleeding is still common practice, in part, because it is a relatively simple and effective hemostatic method and because some patients are intolerant of time-consuming EI combination therapy.

Research frontiers

Sustained hemostasis is the goal of endoscopic therapy. This study identified the factors which predicted rebleeding if patients with high-risk ulcers were treated using EI alone to achieve initial hemostatic status.

Innovations and breakthroughs

Endoscopic EI monotherapy in patients with high-risk ulcers should be avoided. Initial hemostasis with thermocoagulation, clips or additional hemostasis after EI is mandatory, particularly in older patients, SBS, severe anemia, and where a higher injection dose is needed to prevent subsequent rebleeding, surgery, morbidity and mortality.

Applications

This article further emphasized the need to follow the existing guidelines for the treatment of high-risk ulcers to possibly avoid a poor outcome when EI is performed alone.

Terminology

High-risk ulcers refer to ulcers with active bleeding, or with non-bleeding visible vessels or adherent clots, and endoscopic therapy is necessary in these ulcers to prevent further bleeding.

Peer review

The clinical study focused on identification of predictors of rebleeding after initial epinephrine hemostasis in the upper gastrointestinal tract. The statistical approach revealed age, severe bleeding signs, hemoglobin, and epinephrine injection dose more than 12 mL as predictors.

Abstract

AIM: To search the independent factors determining gastric juice acidity and to investigate the acidity of gastric juices in various benign and malignant upper gastrointestinal diseases.

METHODS: Fasting gastric juice acidity of 165 healthy subjects and 346 patients with esophageal ulcer (n = 21), gastric ulcer (n = 136), duodenal ulcer (n = 100) or gastric cancer (n = 89) were measured and compared. Additionally, gastric specimens were taken from the antrum and body for rapid urease test and histological examination.

RESULTS: Multivariate analysis revealed that bile stain of gastric juice, high acute inflammatory score of the corpus, and atrophy of the corpus were independent risk factors for the development of gastric hypoacidity with odds ratios of 3.1 (95% CI: 1.3-7.3), 3.1 (95% CI: 1.2-7.9) and 3.5 (95% CI: 1.3-9.2). Esophageal ulcer and duodenal ulcer patients had a lower pH level (1.9 and 2.1 *vs* 2.9, both $P < 0.05$) of gastric juices than healthy subjects. In contrast, gastric ulcer and gastric cancer patients had a higher pH level (3.4 and 6.6 *vs* 2.9, both $P < 0.001$) than healthy controls. Hypoacidity existed in 22%, 5%, 29%, 5% and 88% of healthy subjects, esophageal ulcer, gastric ulcer, duodenal ulcer and gastric cancer patients, respectively.

CONCLUSION: Bile reflux, atrophy and dense neutrophil infiltrate of the corpus are three independent factors determining the acidity of gastric juice.

Key words: Acidity; Gastric juice; Gastric cancer; Peptic ulcer; Esophageal ulcer

INTRODUCTION

Gastric juices are liquids found in the stomach. They contain numerous compounds, including hydrochloric acid (HCl), pepsin, lipase, mucin, intrinsic factor, peptides, nucleic acids and electrolytes[1]. Additionally, they may also contain salivary constituents due to swallowing, bile due to gastroduodenal reflux and inflammatory mediators or blood from damaged gastric walls[2]. In their normal state, gastric juices are usually clear in color.

HCl is an important component in gastric juice. It is a strong acid produced by the parietal cells in the corpus generating a gastric pH of 2-3[1]. Activation of pepsin and absorption of nutrients relies on an acidic pH in the stomach. HCl is also important in protecting the stomach and intestines from pathogens. Increased gastric pH induced by disease process, reflux of bile or pharmaceuticals allows for bacterial overgrowth in the stomach[3]. These pathogenic bacteria in the hypochlorhydria stomach can produce nitrite and nitroso-compounds, which act as one of the triggers in the atrophy-metaplasia-dysplasia-carcinoma pathway[4].

Helicobacter pylori (*H. pylori*) infection is an important biological factor which can induce marked alterations in gastric acid secretion of hosts[5,6]. In subjects with an antrum-predominant gastritis following *H. pylori* infection there is increased release of gastrin and consequently increased acid secretion. Such subjects have an increased risk of developing duodenal ulcers (DU)[7,8]. In contrast, the infection induces a corpus-predominant gastritis with hyposecretion of acid in some subjects. These infected subjects have an increased risk of developing gastric cancer (GC)[9,10]. Gastric juices can lead to mucosal damage when they enter the esophagus. Patients with gastroesophageal reflux diseases (GERD) may develop esophageal breaks, along with damage to the enamel of the teeth caused by the high acidity of the stomach contents[11].

Since the acidity of gastric juice is one of the crucial factors in the development of most upper gastrointestinal diseases, we designed this study to search the independent factors determining gastric juice acidity and to investigate the acidity of gastric juices in various upper gastrointestinal diseases.

MATERIALS AND METHODS

Subjects

One hundred and sixty-five consecutive healthy subjects (HSs), 21 patients with esophageal ulcer (EU), 136 patients with gastric ulcer (GU), 100 patients with DU and 89 patients with GC participated in the study. The HSs recruited from our health examination clinics had no clinical history of gastrointestinal diseases, and their endoscopic findings were normal or showed mild gastritis only. The diagnoses of EU, GU and DU were confirmed by endoscopic examination. An EU was defined as a well-defined mucosal break present in the lower esophagus[12]. A gastric or duodenal ulcer was defined as a circumscribed mucosal break 5 mm or more in diameter, with a well-defined ulcer crater in the stomach or duodenum, respectively[13]. The size of ulceration was measured by opening a pair of biopsy forceps of known span in front of the ulcer. The diagnosis of GC was confirmed by histology. Additionally, GC was classified as intestinal (n = 50), diffuse (n = 31) and mixed (n = 8) according to the Lauren's classification[14]. The patient exclusion criteria included (1) the use of proton pump inhibitors or H2-receptor antagonists within 4 wk prior to the study; (2) coexistence of two kinds of gastroduodenal lesions; (3) presentation with upper gastroduodenal bleeding; and (4) coexistence of severe systemic diseases. The study was approved by the Medical Research Committee of the Kaohsiung Veterans General Hospital. All patients and controls gave informed consent.

Clinical methods

Endoscopies were performed with the Olympus GIF XV10 and GIF XQ200 (Olympus Co., Tokyo, Japan) after patients had fasted overnight. Immediately after insertion of the scope into the stomach, 5 mL of gastric fluid was aspirated through the suction channel of the endoscope and collected in a sterile trap placed in the suction line for acidity assay and color assessment. Routine inspection of the upper gastrointestinal tract was then performed. Additionally, gastric specimens were taken for rapid urease test (one specimen from the antrum) and histological examination (two specimens from the antrum and another two from the body)[15].

To adjust for clinical characteristics, the following data were recorded for each subject: age, sex, family history of gastric cancer, smoking, alcohol drinking, coffee consumption, tea consumption.

Acidity and color of gastric juice

The pH of gastric juice was measured just after collection with a glass-electrode pH meter. Hypoacidity was defined as pH level of gastric juice greater than 3.5[16]. The color of gastric juice was carefully assessed, and bile stain of gastric juice was defined as yellowish or greenish discoloration of the gastric juices.

Rapid urease test

The rapid urease test was performed according to our previous studies[17]. Each biopsy specimen was placed immediately in 1 mL of a 10% solution of urea in deionized water (pH 6.8) to which two drops of 1% phenol red solution had been added and incubated at 37℃ for up to 24 h. If the yellowish color around the area of inserted specimen changed to bright pink within the 24-h limit, the urease test was considered positive. In our laboratory, the sensitivity and specificity of the rapid urease test were 96% and 91%, respectively.

Histological assessment

A histological examination of the stomach was carried out for the subjects who provided informed consent for topographical histopathological study. The biopsy specimens were fixed in 10% buffered formalin, embedded in

[a]$P < 0.05$, [b]$P < 0.01$, [c]$P < 0.001$ *vs* healthy subjects. HS: Healthy subjects; EU: Esophageal ulcer; GU: Gastric ulcer; DU: Duodenal ulcer; GC: Gastric cancer.

paraffin, and sectioned. The sections were stained with a haematoxylin and eosin stain and a modified Giemsa stain as previously described[18]. Sections were examined blinded to the patient's clinical diagnosis. The scores of acute inflammation (neutrophil infiltrate), chronic inflammation (mononuclear cell infiltrate), glandular atrophy, intestinal metaplasia and *H. pylori* density were graded from 0 to 3 as described by the updated Sydney system[19].

Statistical analysis

Statistical evaluations were performed using the SPSS program (version 10.1, Chicago, Illinois, USA). The differences in gastric juice acidity between HSs and patients with EU, GU, DU or GC were assessed by Student's *t*-test. The chi-square test with or without Yate's correction for continuity and Fisher's exact test, when appropriate, were applied to analyze the categorized variables. Differences were considered to be significant at $P < 0.05$. A multivariate analysis with logistic regression method was carried out to assess the independent factors influencing gastric acidity of gastric juices. The studied variables included the following: age (< 60 years or ≥ 60 years), gender, family history of gastric cancer (presence or absence), history of smoking (< 1 pack/wk or ≥ 1 pack/wk), history of alcohol consumption (< 80 g/d or ≥ 80 g/d), history of tea consumption (< 1 cup/d or ≥ 1 cup/d), coffee consumption (< 1 cup/d or ≥ 1 cup/d), bile stain of gastric juice, *H. pylori* status (presence or absence) and parameters of histological gastritis.

RESULTS

Table 1 shows the demographic characteristics of HSs and patients with EU, GU, DU and GC. Patients with GU and GC were significantly older than HSs (63 ± 15, 67 ± 14 years *vs* 54 ± 12 years, both $P < 0.001$). Additionally, the EU, DU and GC patient groups had higher male-to-female ratios than the HS group (all $P < 0.05$). No significant differences in history of alcohol consumption were identified between groups. However, the rates of cigarette smoking in EU, GU and DU patients were significantly higher than that of HSs ($P < 0.05$, 0.05 and 0.01, respectively). Furthermore, the rates of *H. pylori* infection in GU, DU and GC patients were also significantly higher than that of HSs ($P < 0.05$, < 0.001 and < 0.05, respectively).

Independent factors determining the acidity of gastric juice

Univariate analysis of 15 clinical and histological factors demonstrated that the following nine factors were significantly associated with hypoacidity: old age ($P < 0.001$), family history of GC ($P < 0.05$), bile reflux ($P < 0.001$), *H. pylori* infection ($P < 0.05$), intestinal metaplasia of the antrum ($P < 0.01$), and acute inflammatory score, chronic inflammatory score, atrophy and intestinal metaplasia of the corpus (all *P* values < 0.001, Table 2). Smokers had a lower frequency of gastric hypoacidity than non-smokers, and alcohol drinkers also had less hypoacidity than drinkers. However, the differences concerning smoking and drinking did not reach statistical significances ($P = 0.258$ and 0.100, respectively). Multivariate analysis with a stepwise forward logistic regression method disclosed only bile reflux, high acute inflammatory score of the corpus, and atrophy of the corpus were independent risk factors for the development of gastric hypoacidity with odds ratios of 3.1 (95% CI: 1.3-7.3), 3.1 (95% CI: 1.2-7.9) and 3.5 (95% CI: 1.3-9.2, Table 3).

The subjects with *H. pylori* infection had higher frequencies of high acute inflammatory score (76% *vs* 37%, $P < 0.001$) and high chronic inflammatory score (96% *vs* 74%, $P < 0.001$) in the antrum than those without *H. pylori* infection. Additionally, they also had higher frequencies of high acute inflammatory score (50% *vs* 31%, $P = 0.018$), high chronic inflammatory score (80% *vs* 60%, $P = 0.006$) and gland atrophy (38% *vs* 21%, $P = 0.028$) in the corpus than uninfected subjects.

Acidity of gastric juices in HSs and upper gastrointestinal diseases

Table 4 showed the pH levels of gastric juices in benign and malignant gastrointestinal diseases. EU and DU patients had a higher gastric acidity than HSs (1.91 ± 0.28 and 2.09 ± 0.09 *vs* 2.90 ± 0.16, both $P < 0.05$). In contrast, GU and GC patients had a lower gastric acidity than HSs (3.42 ± 0.20 and 6.62 ± 0.22 *vs* 2.90 ± 0.16, both $P < 0.001$). Overall, hypoacidity existed in 22%, 5%, 29%, 5% and 88% of HSs, EU, GU, DU and GC patients, respectively.

DISCUSSION

This work demonstrated the differences in acidity of

gastric juices among patients with upper gastrointestinal diseases. EU and DU patients had a higher gastric acidity than HSs. In contrast, GU and GC patients had a lower gastric acidity than HSs. This study is the first to verify higher gastric acidity in EU patients compared with HSs. In this study, only 5% of EU patients possessed hypoacidity of gastric juice, whereas gastric hypoacidity existed in 22%, 29% and 88% of HSs, GU and GC patients, respectively. The data imply that normal or higher acidity of gastric juice is an important factor for the development of GERD besides lower esophageal pressure abnormalities, hiatal hernia and delayed gastric emptying[20].

Several histological studies also showed chronic atrophic gastritis present in 80%-90% of GC patients[21]. In this study, gastric hypoacidity existed in 88% of the patients with GC. This finding indicates atrophic gastritis with gastric hypoacidity is a crucial step for the development of gastric adenocarcinoma. *H. pylori* infection, old age and cagA and vacA m1 positivity have been identified as independent risk factors for the development of atrophic gastritis[22]. We propose that the high prevalence of *H. pylori* infection, advanced age, some bacterial virulent factors and susceptible host factors may contribute to the development of gastric atrophy and hypoacidity of the GC patients in this study.

The current work also showed that DU patients had a higher gastric acidity than HSs. This result supported previous observations demonstrating increased basal and stimulated acid secretion by the body of the stomach and increased acid load in the duodenum in patients with DU[23]. On the contrary, GU patients in this study had a lower gastric acidity than HSs, suggesting that mucosal defensive impairments are more important than increased acid load in the pathogenesis of GU. The findings were consistent with previous reports[24] revealing that the majority of gastric ulcers do not have increased gastric acid secretion.

Multivariate analysis in this study revealed that bile stain of gastric juice, high acute inflammatory score and atrophy of the corpus were independent factors for the development of gastric hypoacidity. The atrophy of the corpus was the most important factor for gastric hypoacidity with an odds ratio of 3.5. Since gastric acid is secreted by the parietal cells in the corpus, gland atrophy of the corpus leading to hyposecretion of acid and gastric hypoacidity is logical.

In 1988, Correa *et al*[25] proposed a human model of gastric carcinogenesis that gastric cancers develop through a complex sequence of events from normal mucosa to superficial gastritis, atrophic gastritis, intestinal metaplasia, dysplasia and finally to intestinal-type adenocarcinoma[21,26,27]. Gland atrophy resulting in hypochlorhydria is a key step in this theory and accounts for gastric bacterial colonization, reduction of dietary nitrates to nitrites and the formation of potentially carcinogenic N-nitroso compounds[4,25]. In this study, *H. pylori*-infected patients had higher frequencies of gland atrophy in the corpus (38% *vs* 21%) and gastric hypoacidity (37% *vs* 26%) than uninfected subjects. Additionally, they also had stronger acute and chronic inflammation in the corpus than uninfected

subjects. These findings suggest that *H. pylori* infection is an important factor contributing to the development of atrophic gastritis in the corpus and hypo-secretory status of the stomach.

Primary duodenogastric reflux may occur due to antroduodenal motility disorder or incompetent pyloric sphincter[28]. The retrograded bile and duodenal contents can induce damage of the gastric mucosa[29]. It has been observed that duodenogastric reflux plays a crucial role in the pathogenesis of alkaline gastritis and GU[29]. Since the presence of bile in the gastric juice implies retrograde passage of alkaline duodenal contents into the stomach, it is reasonable to expect increased pH levels of gastric juice in the subjects with bile in gastric juice.

A higher degree of acute inflammation was the other histological factor predicting gastric hypoacidity in this study. Currently, we have no definite rationale to explain the association between dense neutrophil infiltrate and increased pH level in gastric juices, but dense neutrophil infiltrates may reflect the high density of *H. pylori* in the stomach[30], and have also been reported as one of the important factors related to the progression of atrophic gastritis[26].

In this study, smokers had a trend of less hypoacidity than non-smokers. The finding was supported by previous studies showing that nicotine increases acid secretion and decreases prostaglandin synthesis[31]. It is interesting to note that alcohol drinkers also had a trend of less hypoacidity than nondrinkers. The reasons for this finding remain unclear, but some studies demonstrated that fermented and nondistilled alcoholic beverages increase gastrin levels and acid secretion[32]. Additionally, succinic and maleic acid contained in certain alcoholic drinks also stimulate acid secretion[32].

In conclusion, bile reflux, atrophy and neutrophil infiltration of the corpus are three independent factors determining the acidity of gastric juices. Gastric acidities in patients with various upper gastrointestinal diseases are quite different. EU and DU patients have a higher gastric acidity whereas GU and GC patients have a lower gastric acidity compared with HSs.

ACKNOWLEDGMENTS

The authors express their deep appreciation to Dr. Feng-Woei Tsay and Miss Yu-Shan Chen for their generous support.

COMMENTS

Background

The acidity of gastric juice is one of the crucial factors in the development of most upper gastrointestinal diseases.

Research frontiers

The authors designed this study to search the independent factors determining gastric juice acidity and to investigate the acidity of gastric juices in various upper gastrointestinal diseases.

Innovations and breakthroughs

This study is the first to verify higher gastric acidity in esophageal ulcer patients compared with healthy subjects. The results showed that bile stain of gastric juice, high acute inflammatory score and atrophy of the corpus were independent factors for the development of gastric hypoacidity.

Applications

Results of this study are helpful for understanding the pathogenesis of upper gastrointestinal diseases and the factors influencing the acidity of gastric juice.

Terminology

The updated Sydney System is a schema for the classification and grading of histological gastritis established by an International Workshop on the Histopathology of Gastritis, Houston 1994.

Peer review

The study shows evidence collected in large population, however, there is lack of the definite conclusion in this paper. Instead of that, the authors made a comment in conclusion on the results, not providing the idea about the potential mechanism of changes in the acidity of gastric secretion in different group of patients. The Discussion is too general and not always linked to results obtained.
