AIM AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

i-scan technology is the newly developed image-enhanced endoscopy technology from PENTAX, Japan. This consists of three types of algorithms: surface enhancement (SE), contrast enhancement (CE), and tone enhancement (TE). SE enhances light-dark contrast by obtaining luminance intensity data for each pixel and applying an algorithm that allows detailed observation of a mucosal surface structure. CE digitally adds blue color in relatively dark areas, by obtaining luminance intensity data for each pixel and applying an algorithm that allows detailed observation of subtle irregularities around the surface. Both enhancement functions work in real time without impairing the original color of the organ, therefore, SE and CE are suitable for screening endoscopy to detect gastrointestinal tumors at an early stage. TE dissects and analyzes the individual RGB components of a normal image. The algorithm then alters the color frequencies of each component and recombines the components to a single, new color image. This is designed to enhance minute mucosal structures and subtle changes in color. TE works in real time and consists of three modes such as TE-g for gastric tumors, TE-c for colonic tumors, and TE-e for esophageal tumors. TE is suitable mainly for detailed examination of the lesions that are detected in a screening endoscopy. i-scan technology leads us to easier detection, diagnosis and treatment of gastrointestinal diseases.

INTRODUCTION

Following recent advances in endoscopic treatment of gastrointestinal tumors, early detection and accurate diagnosis of tumors have been increasing in importance. Under such circumstances, a new endoscopic image enhancement technology i-scan has been developed by PENTAX (HOYA Corporation), Japan. This paper describes the features of this i-scan technology, and shows actual images.

i-SCAN

i-scan technology is classified as a digital contrast method among endoscopic imaging techniques^[1]. i-scan has three modes of image enhancement, i.e. surface enhancement (SE; enhancement of the structure through recognition of the edges); contrast enhancement (CE; enhancement of depressed areas and differences in structure through colored presentation of low density areas); and tone enhancement (TE; enhancement tailored to individual organs through modification of the combination of RGB components for each pixel). For SE and CE, switching

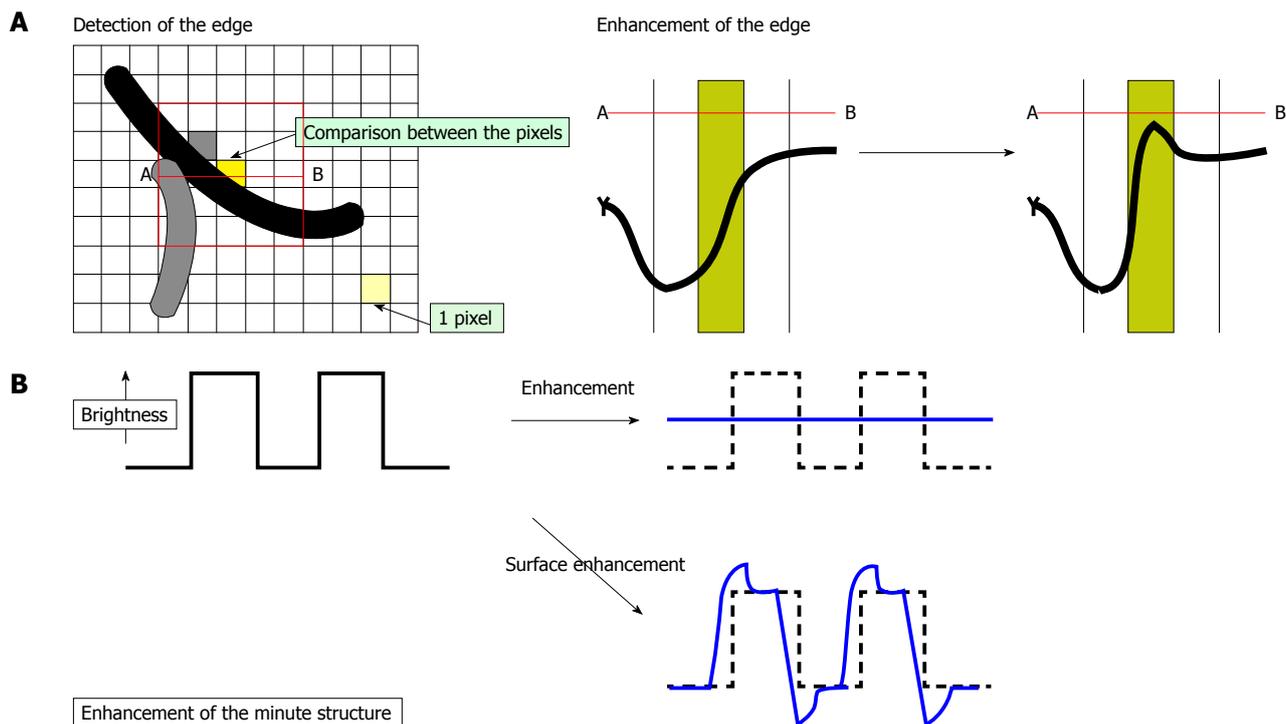

Figure 1 Principle of surface enhancement (SE). A: Enhancement of the edge; B: Enhancement of the minute structure.

among three enhancement levels (low, medium and high) is possible. For TE, switching among three objects (esophagus, stomach and colon) is possible. The three modes (SE, CE and TE) are arranged in series, therefore, it is possible to apply two or more of these three modes at one time. Switching the levels or modes of enhancements can be done on a real-time basis, without any time lag by pushing a relevant button, thus enabling efficient endoscopic observation.

SE

With SE, the difference in luminance intensity between the pixels concerned and the surrounding pixels is analyzed and the edge components are enhanced (Figure 1A). With ordinary enhancement, minor changes in structure are perceived as noise, and the area that shows such changes is smoothed out. With SE, on the other hand, adjustment of the noise erasure function allows more evident enhancement of the edges, which corresponds to minor changes in structure (Figure 1B). As compared to normal images, SE images do not differ in brightness and differ little in color. Furthermore, SE allows more extensive observation of minute glandular structures, which makes it easier to check changes on the basis of structural differences (Figure 2A and B).

CE

With CE, areas lower in luminance intensity compared to surrounding pixels are identified on the basis of pixel-wise luminance intensity data, followed by relative enhancement of the B component through the slight suppression of R and G components in this low luminance area (Figure 3A and B). As a result of CE, the low

luminance area is stained slightly bluish white and minute irregularities on the mucosal surface are enhanced. Even in the case of flat mucosa, the minute glandular structure can be enhanced because the color is changed, which reflects very minute depressions at the gland duct opening. Processing of images with CE does not cause a change in image brightness or a marked change in the color of the images. It causes only slight bluish-white staining of depressed areas (Figure 2C).

TE

With conventional endoscopy, the white reflective rays from the mucosa are caught by the CCD at the tip of the endoscope and are displayed on the monitor. With TE, on the other hand, the RGB components of an ordinary endoscope image are disintegrated into each component (R, G and B), and each component thus isolated is converted independently along the tone curve, followed by a re-synthesis of the three components to yield a reconstructed image (Figure 4A). The tone curve is depicted by plotting input (on the x axis) against output (on the y axis) (Figure 4B). The tone curve can be changed into various forms by modification of the parameters. The tone-curve forms can be divided roughly into S and J types. Figure 4B is an image yielded from modification of the R component alone; this example clearly shows how the image changes as the tone curve is switched from S to J type or vice versa. If the tone curve assumes an S type, the high R-component area is shifted to a further higher range of R to enhance the color tone R, or the low R-component area is shifted to a further lower range of R to elevate the sensitivity to GB components, thus allowing clear enhancement of the differences in

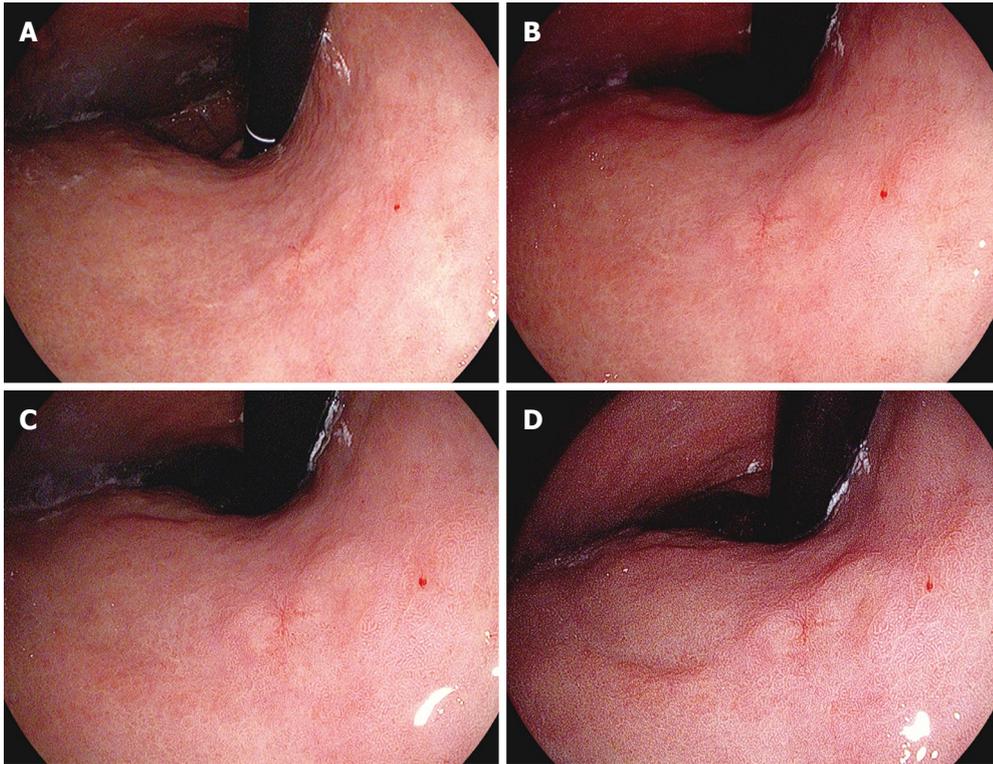

Figure 2 Images using SE and contrast enhancement (CE). A: Conventional image; B: SE image; C: CE image; D: SE + CE image.

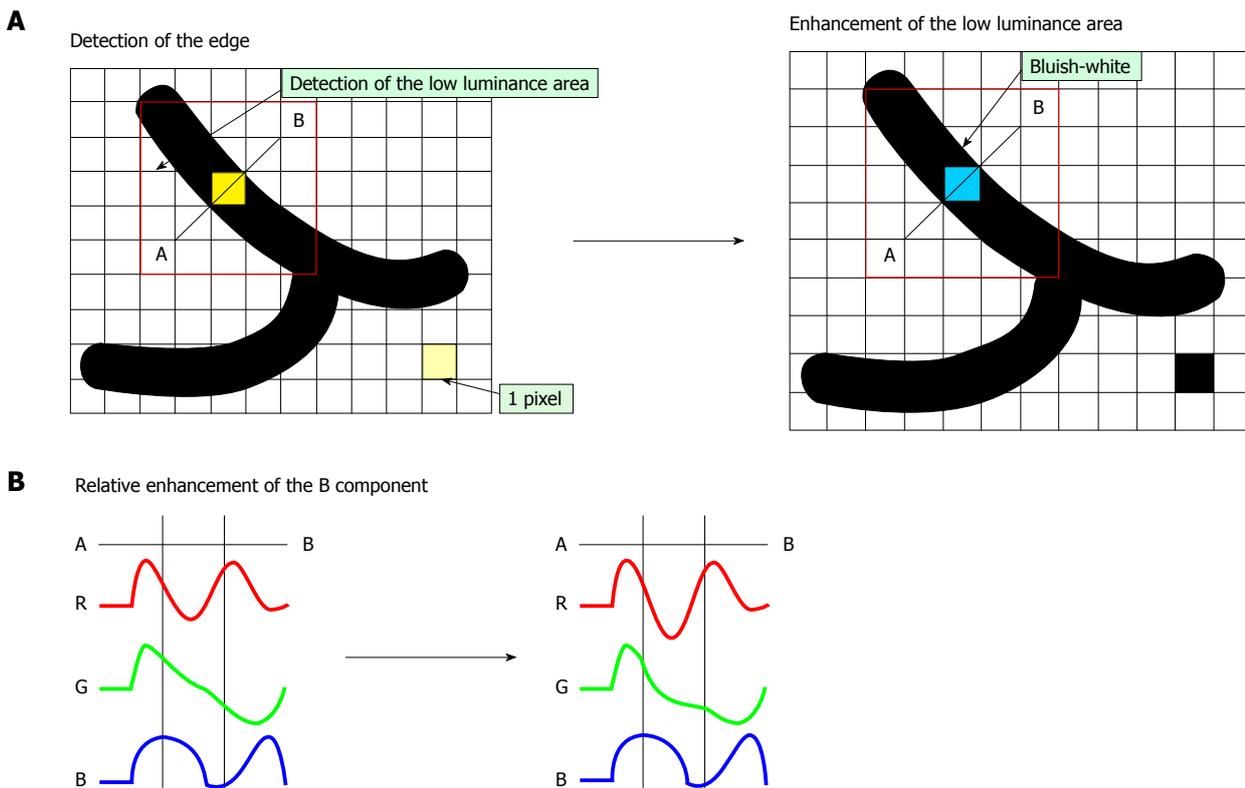

Figure 3 Principle of CE. A: Enhancement of the low luminance area; B: Relative enhancement of the B component.

color tone. If the tone curve assumes a J-type form, the R component is shifted completely to a low R range, to elevate the overall sensitivity to GB components and the brightness/darkness contrast. At present, three types of TE are available, including TE-e (for esophagus), TE-g

(for stomach) and TE-c (for intestines). With TE-e, the J-type tone curve, which suppresses the maximum output, is adopted for the R component, to elevate G/B contrast and make structural changes clearer (Figure 5A). With TE-g, the J-type tone curve, which suppresses the

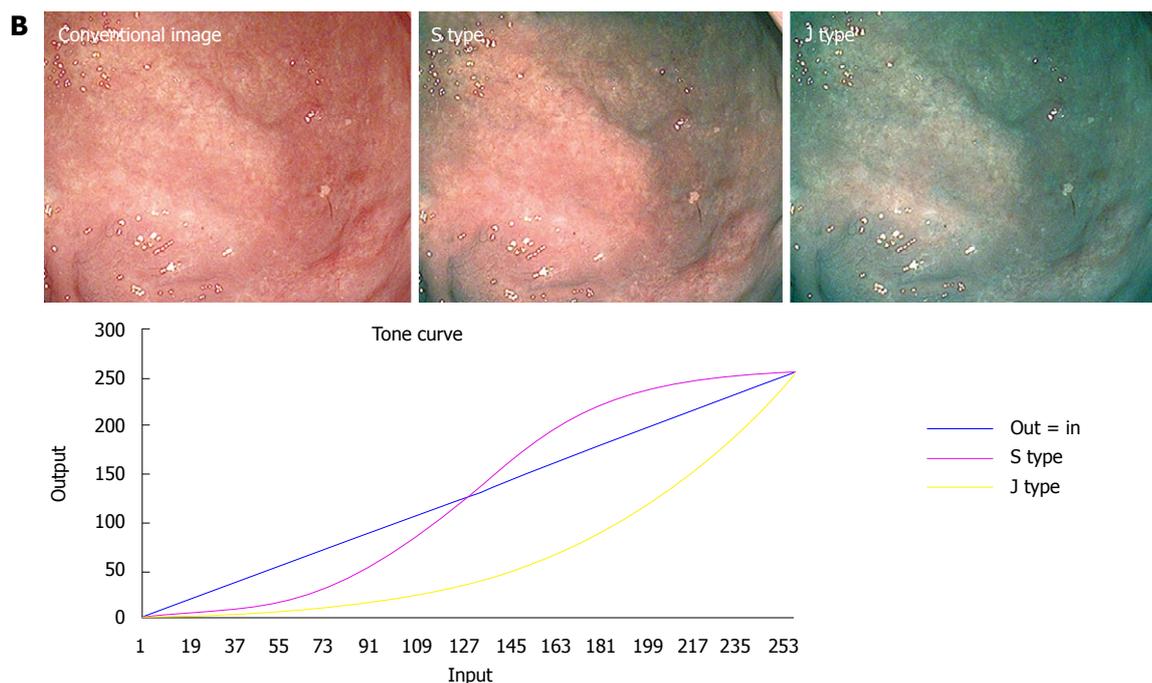

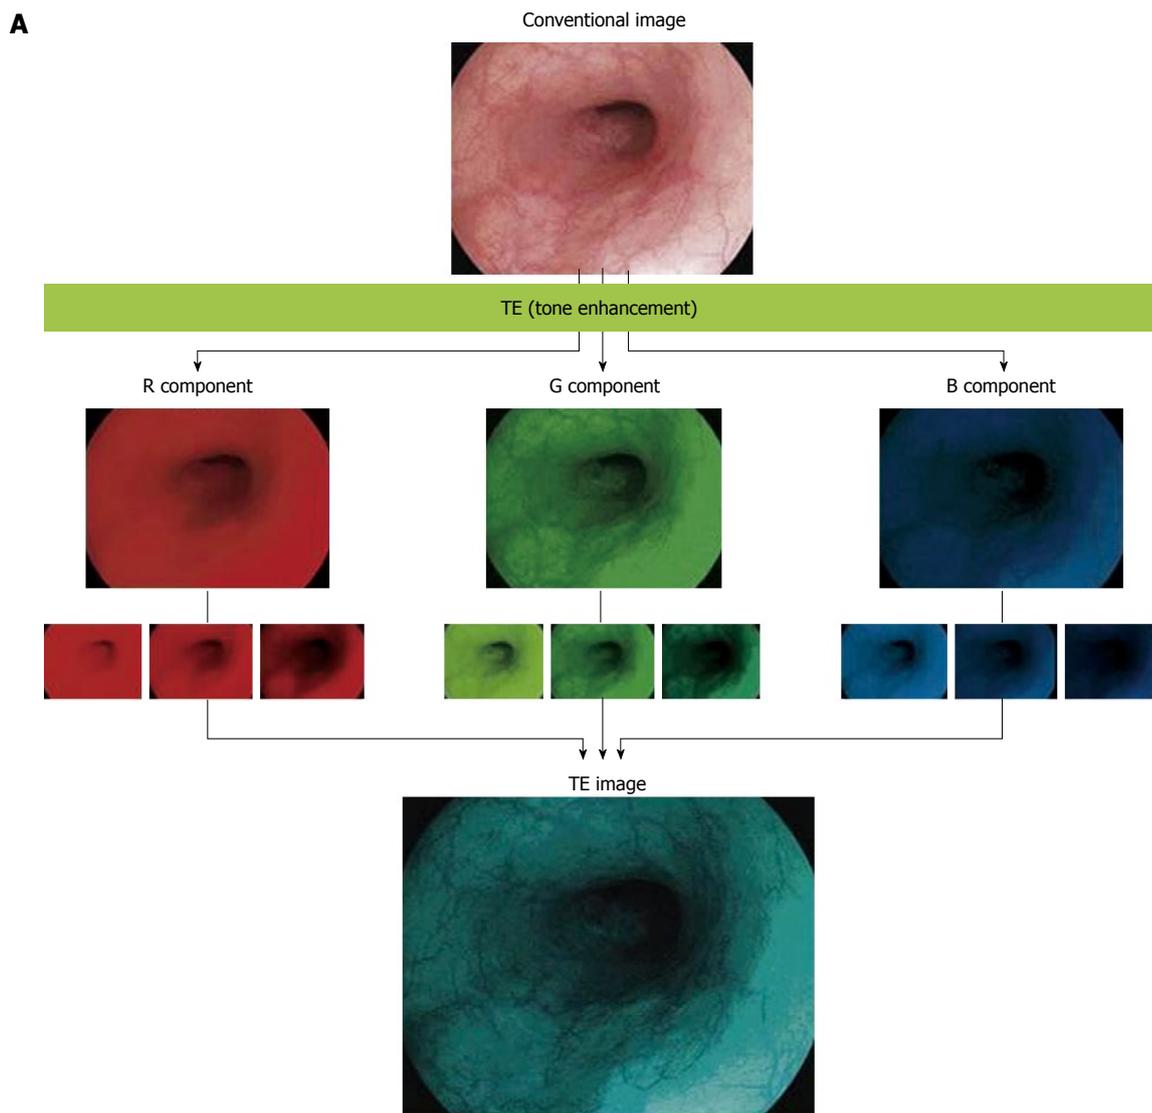

Figure 4 Principle of tone enhancement (A) and tone curve (B). TE: Tone enhancement.

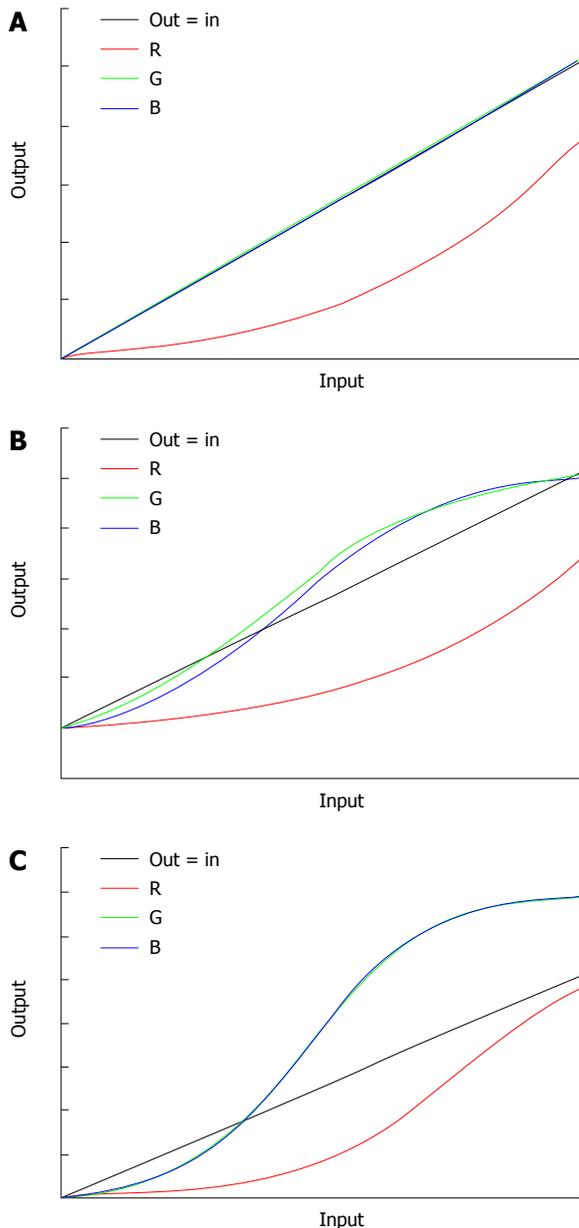

Figure 5 Tone curve. A: TE-e; B:TE-g; C:TE-c.

maximum output, is adopted for the R component to elevate the G/B contrast, and the S-type tone curve is adopted for G and B components to elevate color contrast. In this way, TE-g yields images that allow easy identification of a lesion because it can increase the contrast for even minor differences in color tone (Figure 5B). With TE-c, the J-type tone curve is adopted for the R component, but the output is higher than that with TE-g, which results in a slightly reddish image. The S-type tone curve is adopted for the G and B components with TE-g, and the output is set higher to allow a more evident depiction of the structure of the gland opening in the medium to high range (Figure 5C).

i-SCAN METHOD OF USE

SE and CE are expected to provide a useful means of

screening because they can improve discernment of lesions without altering the color tone markedly and reducing the brightness of images. At our hospital, SE and CE are applied at the same time. Noise increases as enhancement becomes more intense, therefore, we usually apply the lowest levels of SE (low) + CE (low) (Figure 2D). After a lesion is found, TE is applied as a simple means of making changes in the color tone and structure more evident. If the structure or irregularities need to be further enhanced during TE, the level of SE and CE is elevated. TE can be effected quite simply and instantaneously by pushing the button. It may be used to assess the necessity of more detailed testing by means of dye spraying, magnified observation, or biopsy.

USEFULNESS OF i-SCAN

Narrow band imaging (NBI) is an endoscopic imaging technique that emphasizes the mucosal microvasculature and identifies vascular alterations, by placing narrow bandpass filters in front of a conventional white-light source to obtain tissue illumination at selected, narrow wavelength bands^[2,3]. Although NBI is useful for detecting and diagnosing early esophageal cancers with^[4] or without magnifying endoscopy^[5], and identifying the demarcation line and predicting the histological characteristics of gastric cancers with magnifying endoscopy^[6-8], narrow band images are much darker than conventional white-light images, particularly in large luminal diameter regions of the gastrointestinal tract. i-scan images are as bright as conventional white-light images, therefore, i-scan is able to observe much larger areas in a distant view compared with NBI. Moreover, i-scan does not need magnifying endoscopy to observe the demarcation of the lesion. Consequently, i-scan might be more useful for performing screening endoscopy and diagnosing the extent of a lesion, particularly that of a large superficial lesion in the stomach.

On the other hand, chromoendoscopy came into clinical use 40 years ago as a method of identifying lesions and observing them in detail^[9]. In particular, indigo carmine is the dye most frequently used for chromoendoscopy in Japan. Although this method is useful for recognizing a lesion and diagnosing the margin of a lesion more easily than conventional endoscopic observation^[10,11], it may not be time consuming. i-scan can be effected quite simply and instantaneously by pushing a button, therefore, it is an easy method for screening or detailed inspection, and may reduce both time and costs.

i-SCAN CASES

Case 1

On the ordinary image without i-scanning, a slightly irregular mucosal structure was visible on the right wall of the middle thoracic esophagus (Figure 6A). If SE (low) + CE (low) were applied to this image, the irregular mucosal structure could be discerned as an area structurally different from the surrounding normal area, with almost the entire circumference of the boundary

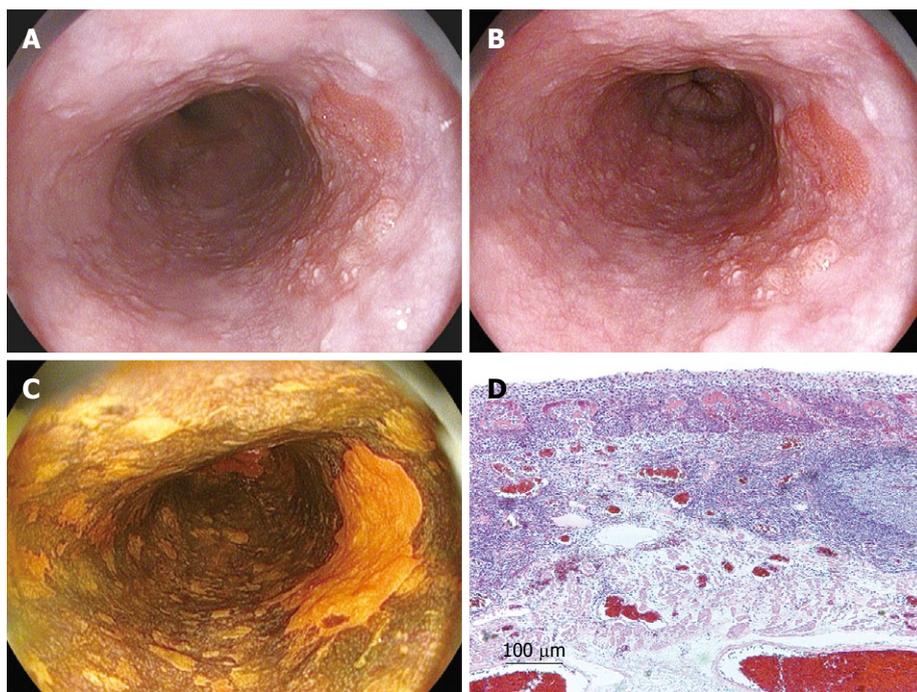

Figure 6 Case 1 (esophageal cancer). A: Conventional image: A slightly reddish irregular area was recognized in the right wall of the thoracic middle esophagus; B: SE + CE image: As compared with conventional image, the lesion could be recognized as an irregular area with clear boundaries; C and D: TE-e image: As compared with conventional image and SE + CE image, the demarcation line of the lesion could be recognized more clearly as a reddish irregular area. This was pathologically diagnosed as carcinoma *in situ* that corresponded to this region.

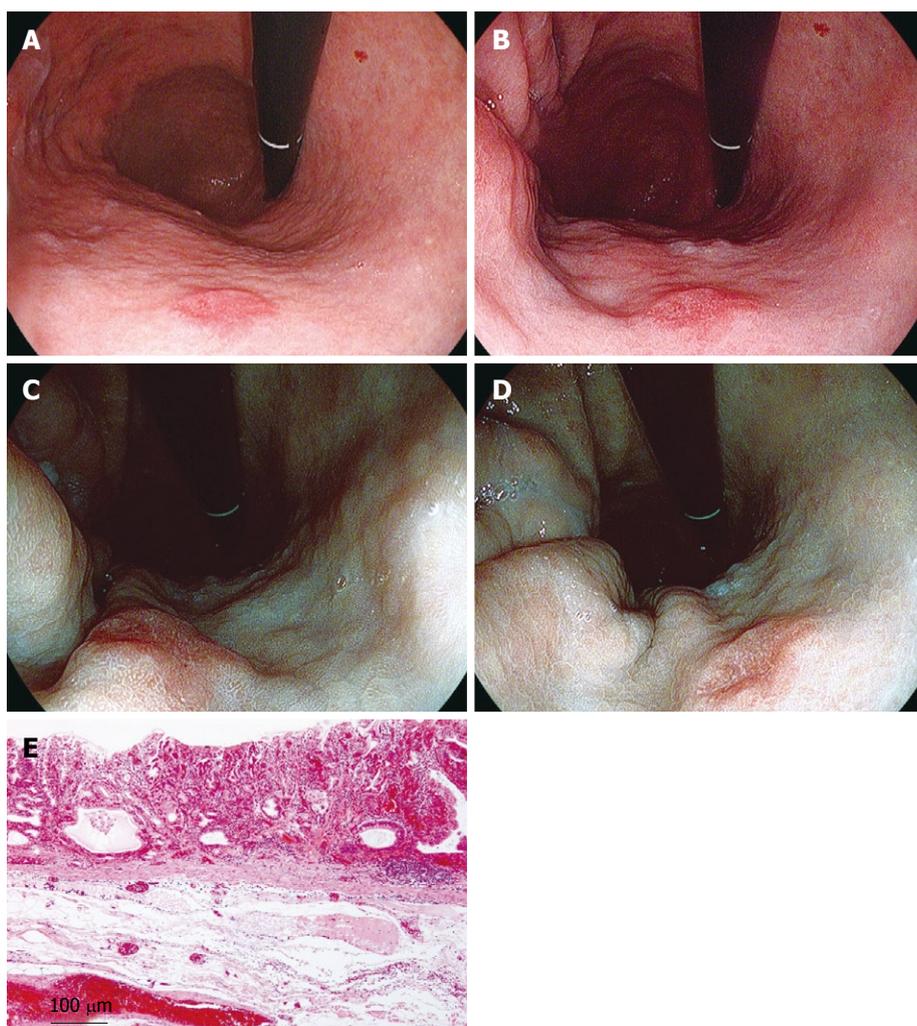

Figure 7 Case 2 (gastric cancer). A: Conventional image: A red depressed lesion was visible on the anterior wall of the lower gastric body, but it was difficult to identify the demarcation of it; B: SE + CE image: The differences of the mucosal structure and color of the lesion could be observed; C, D: TE image: The demarcation of the lesion could be identified more clearly, observing changes in mucosal structure and color tone; E: Pathological diagnosis indicated a well to moderately differentiated adenocarcinoma, localized in the mucosal layer.

visible (Figure 6B). If TE-e was applied to this area (Figure 6C), the irregular mucosal structure was visible clearly as a

structure differing in color tone from the well-demarcated surrounding area. Endoscopic resection was eventually

performed on this lesion, which was rated as carcinoma *in situ* that corresponded to this region (Figure 6D).

Case 2

On an ordinary image without i-scanning, a red depressed lesion with marginal elevation was visible on the anterior wall of the lower gastric body, although the demarcation of the lesion could not be recognized clearly (Figure 7A). If the same area was observed with SE (low) + CE (low), the differences of the mucosal structure and color of the lesion could be observed, although the boundary was not clear (Figure 7B). If TE-g was applied to this image (Figure 7C and D), the normal mucosa changed color into brown or green, the reddish area remained reddish, and the minute glandular structure was clearly visible. Therefore, the difference in color tone from the normal area became clearer and it was possible to make a full-circumferential assessment of the boundary of a lesion based on a check of changes in mucosal structure and color tone. The lesion was finally resected endoscopically and was rated histopathologically as a well to moderately differentiated adenocarcinoma localized in the mucosal layer (Figure 7E).

CONCLUSION

SE and CE can elevate the capability of discerning lesions during screening. TE allows detailed evaluation of the lesion found during screening. All of these three enhancement modes can be switched on/off instantaneously, which reduces the mental stress of the examiners. In addition, because these techniques can reduce the frequency of tests involving dye spraying and biopsy, they are advantageous also for patients. We believe that i-scan can elevate the quality of endoscopic diagnosis and treatment.

Abstract

Inflammatory bowel diseases (IBD) represent important chronic conditions affecting the gastrointestinal tract in man. However, similar disorders are found in several animal species and the IBD affecting dogs are particularly important. These are encompassed by an umbrella of probably several different entities with common symptoms, some of which seem to share striking similarities with human conditions. This review will focus on the actual knowledge of IBD in dogs, and attempt to identify differences and similarities with human IBD conditions.

INTRODUCTION

Inflammatory bowel diseases (IBD) are well known gastrointestinal disorders in humans; however, these disorders are also present and often investigated in animals^[1]. IBD in man [Crohn's disease (CD) and ulcerative colitis (UC)] can be defined as chronic idiopathic multifactorial diseases^[2,3]. CD is typically a disease of ileum and colon, but can also affect other areas of the digestive tract^[4], forms granulomas and involves the whole intestinal wall, while UC is an ulcerative and inflammatory disease usually limited to superficial layers (mucosa, superficial part of the submucosa) of the colon^[5].

Dogs may also develop IBD^[6], being part of the chronic enteropathies if lasting more than three weeks^[7], and are properly defined when there is histological demonstration of mucosal inflammation and all other possible causes of enteritis/infiltrates have been investigated and excluded^[7-10]. Enteritis is classified depending on which predominant cells infiltrate the intestinal wall and where this infiltration takes place^[11].

Thus, chronic diseases of the small intestine that can be included among IBD are lymphocytic-plasmacytic enteritis (LPE), eosinophilic enteritis and eosinophilic gastro-enteritis (EGE)^[10]. With regard to the large intestine, four main conditions are recognized as IBD in dogs: lymphocytic-plasmacytic colitis, eosinophilic colitis,

histiocytic ulcerative colitis (HUC) (mainly PAS-positive macrophages), and regional granulomatous colitis (mainly PAS-negative macrophages)^[10,12-16]. However, it is worth noting that such diseases may frequently involve both the small and the large intestine, or even include the stomach: lymphocytic-plasmacytic enterocolitis, eosinophilic enterocolitis (EEC) or gastroenterocolitis (EGEC) and granulomatous gastroenteritis^[8,10,13,15].

In dogs, another important chronic enteritis, whose causes have not yet been clearly defined, but have been widely investigated and for which underlying allergic factors have been hypothesized, is the so-called food-responsive diarrhoea (FRD)^[6]. This disease is especially important because it is often included in the differential diagnosis of IBD.

IBD is considered to have the same incidence in males and females, and middle-aged dogs seem to be more affected^[10]. With regard to breed predisposition, this has been suggested for some specific forms of IBD such as immunoproliferative enteropathy in Basenjis, protein-losing enteropathy and associated protein-losing nephropathy in Soft-Coated Wheaten Terriers, and HUC in boxers^[10,11]. However, although HUC displays a higher predisposition in boxers^[17], it has also been described in other breeds of dogs such as French Bulldog, Doberman Pinscher, Mastiff and Alaskan Malamute^[16,18].

PATHOGENESIS

Information in dogs

In dogs, the development of IBD is thought to originate as a consequence of a deregulation of mucosal immunity in predisposed animals^[14]. The loss of tolerance to antigens (food, intestinal bacteria, *etc.*) is one of the most studied mechanisms that could justify the development of chronic intestinal inflammation^[8,11,19]. The immune-mediated basis of the disease can be inferred by the response to the administration of immunomodulant drugs; the presence of increased IgE positive cells in diseased dogs compared to healthy dogs is a further aspect that also suggests the involvement of hypersensitivity reactions in the pathogenesis of canine IBD^[20], as well as the increased concentration of eosinophils and mast cells in many dogs with EGE^[8]. Interruption of the mucosal barrier, independently of the primary cause (bacterial, chemical, *etc.*), can also lead to further antigen exposure, allowing the process to become chronic^[21], and is enforced by decreased apoptosis of lymphocytes, as demonstrated in dogs with IBD compared to control dogs^[22].

Homeostasis inside the digestive tract is maintained by the equilibrium between the reactions to pathogens and to commensal bacteria or other inoffensive luminal antigens (tolerance) that are mediated by different molecules^[23]. The presence of mucosal tolerance to harmless antigens is very important, because depending on its absence the subsequent inflammatory response can be exaggerated and even detrimental. Such tolerance is probably based on the fact that the antigen is presented or not, contextually to other danger signals^[10,24]. The difference between toler-

ance and reaction is also based on pattern recognition receptors (PRRs)^[25], which are able to recognize microflora according to their pathogen-associated molecular patterns or microbe-associated molecular patterns^[26].

Similar to humans, the study of IBD in affected dogs has led to the hypothesis that genetic factors and enteric bacteria can play a pivotal role in the pathogenesis of these disorders, owing to the abnormal intestinal response to commensal microflora^[26]. Once stimulated, PRRs such as Toll-like receptors (TLRs)^[27] start their pro-inflammatory activity, and a recent study showed that three TLRs (2, 4, and 9) stimulated by bacteria are up-regulated in dogs with IBD^[26]. These results are similar to those following the activation of TLR4 which has been demonstrated in humans suffering from IBD^[28]. In these patients, both genetic predisposition and environmental factors are considered important elements in the development of the disease. Moreover, as already well known in humans^[29,30], a recent study showed that in IBD dogs, small intestinal bacteria are different from those found in healthy dogs^[31], strengthening the idea of a correlation between microflora and IBD.

Thus, even in small animals, and similar to that in man, intestinal lymphocyte subset distribution and major histocompatibility complex class II antigens, as well as cytokine gene expression and other markers, have yielded interesting and sometimes overlapping results^[9,32-36]. For instance, one study showed that dogs with IBD display a larger number of IgE positive cells than healthy dogs, in a manner similar to that for interleukin 4 (IL-4) expression in man with IBD^[20]. In addition, the modulation of the expression of intestinal *lamina propria* lymphocytes P glycoprotein (P-gp) seems to play a similar role in both human and dog IBD. In fact, in IBD patients scarcely responsive to steroid treatment, P-gp is highly expressed, and in dogs showing a good response to treatment this protein is modestly represented^[37].

As previously documented in humans, in IBD dogs the investigation of specific subsets of cell populations led to the demonstration of decreased numbers of mast cells (MCs) and of an increase in both CD3+ cells and IgG+ plasma cells^[38].

In veterinary medicine, encouraging results also originate from the study of nuclear receptors (NRs, presumably also involved in the genesis of IBD in man), such as peroxisome proliferator-associated receptor α (PPAR α) and especially of NR target genes [such as multi-drug-resistance gene-1 (*MDR1*)], multiple drug resistance-associated proteins (MRP2), cytochrome P450 (CYP3A12), and phenol-sulfating phenolsulfotransferase (SULT1A1)^[39,40]. In a recent study it was highlighted that MRP2, CYP3A12, SULT1A1, and PPAR α are more expressed in FRD and/or IBD dogs and that *MDR1* can also differentiate between them^[21]. Moreover, in a study on German shepherd dogs with IBD, the mRNA expression of many cytokines such as IL-2, IL-5, IL-12p40, interferon- γ (IFN- γ), tumour necrosis factor- α (TNF- α), and transforming growth factor- β 1 (TGF- β 1) has been shown to be higher in diseased animals compared to controls^[34]; however, it must also be kept in

mind that other studies reconsidered the increased expression of some cytokines in dogs with IBD^[35,36].

Information in humans

IBD in man, particularly CD, probably recognise a genetic predisposition and many genes such as *NOD2/CARD15*, *HLA* and *IL-1-Ra* genes have been investigated and are thought to be implicated in CD development^[41-43]. However, environmental factors^[44,45] and gut microbiota can also be involved in IBD^[46-49], as shown by the fact that antibacterial drugs may help in controlling symptoms^[50-52]. An important point for the perpetuation of damage in human IBD is that once stimulated, lymphocytes tend to accumulate in the *lamina propria* because they seem to be more resistant to apoptosis^[53]. Moreover, an imbalance between proinflammatory and anti-inflammatory cytokines may also play a role^[54].

In man, nuclear factor- κ B (NF- κ B) has also been associated with IBD^[55], and it has been shown that IL-23 can lead to the differentiation of Th17 lymphocytes producing IL-17 with subsequent activation of NF- κ B pro-inflammatory signals^[56]. In a recent study, the link between IBD and NF- κ B has also been hypothesized in dogs, where biopsy samples from dogs with IBD showed that the presence of NF- κ B activation in *lamina propria* macrophages was higher than in the control group^[23].

Differences between species

An important development in human medicine has shown the different involvement of lymphocyte subtypes (Th1 and Th2) in IBD, with Th1 being mainly implicated in CD while Th2 predominate in UC^[57], with subsequent different cytokine activation^[23]. In dogs, different to man, there is mixed activation of Th1 and Th2 in IBD^[6,23,38], leading to different expression of some cytokines, even though it has recently been hypothesized that different Th cells can be involved in different IBD types^[8]. Some authors have shown that MC can be increased or decreased, depending on the predominant cellular infiltrate, and that these are predominantly reduced in LPE, and increased in EGE, thus hypothesizing a possible different genesis for the two types of IBD (Th1 for LPE and Th2 for EGE)^[8].

Even though the above studies signify an active interest in IBD pathogenesis, it is also evident that the mechanisms behind the disease are far from understood, both in man and dogs. HUC, a peculiar condition, in which a central role for bacteria has been proposed due to the presence of intraliesional microbes and PAS + macrophages, similar to Whipple's disease in man^[7].

CLINICAL AND DIAGNOSTIC ASPECTS

Clinical manifestations of IBD in dogs are numerous and nonspecific; the most common clinical signs are weight loss, persistent or recurrent vomiting and/or diarrhoea^[8], frequently associated with symptoms that are an expression of eventual complications, such as ascites (if hypoalbuminemia is present) or pallor of mucous membranes (in the case of chronic gastrointestinal bleeding)^[11,58].

Before reaching a diagnosis of IBD it is important to exclude all other possible causes of chronic enteritis^[6,59] by complete clinical examination, laboratory tests and instrumental investigations, including biopsy samples for histological assessment. Diet correction is also an important tool to exclude or eventually confirm FRD^[23].

Since in dogs the diagnosis of IBD is by exclusion, it is obvious that many tests performed during the diagnostic *iter* (for example blood, urine and faeces examinations) are necessary to exclude other causes of inflammation, and are rarely specific for IBD, thus, not overestimating the incidence of such a diagnosis^[10]. This aspect is very important, because if the cause of the chronic enteritis is misdiagnosed and it is treated as an IBD, it is unlikely to resolve^[58].

In diagnosing IBD, instrumental diagnostics are important and often of paramount importance, even though of the three most used techniques, i.e. radiology (X-R), ultrasonography (US) and endoscopy, only the latter yields more specific information for the diagnosis of IBD (Figure 1), especially as it allows biopsy samples, which are indispensable to distinguish the various subtypes of mucosal infiltration^[60]. X-R and US (which give important information on gut layering and wall thickness) seem to be more helpful for the exclusion of other possible causes^[61], and because the importance of intestinal wall thickening in dogs with IBD has recently been reevaluated^[10,62,63].

After having excluded the most common causes of chronic enteropathies, intestinal biopsies, obtained surgically or endoscopically depending on circumstances (endoscopy is less invasive, but sampling is limited in terms of site of execution and/or of dimension), can allow the diagnosis of IBD^[10] (Figure 2). However, it is important to stress that biopsy samples are not unequivocally interpretable^[6,10,64], even though recent work helped in clarifying such interpretation by providing a histopathological score for mucosal changes in dogs^[65].

In humans, to diagnose and/or to monitor IBD, several serological markers such as anti-neutrophil cytoplasmic antibody (p-ANCA), anti-*Saccharomyces cerevisiae* (ASCA), outer membrane porin C antibody (anti-OmpC), anti-laminaribioside antibody, anti-mannobioside antibody, and anti-chitobioside antibody, anti-pancreas Ab and anti-caliciform intestinal cells Ab, faecal calprotectin, lactoferrin and polymorphonuclear neutrophil elastase are available and have been tested, although not all of these are employed in clinical practice^[66-68].

Together with the clinicopathological diagnosis/monitoring of IBD, in veterinary medicine several markers such as p-ANCA and ASCA, have also been investigated for this purpose. However, even if these were indicative of IBD^[69], no correlation with symptoms or pathological aspects was documented for p-ANCA^[19]. Conversely, in dogs with IBD mucosal permeability measured through the administration of lactulose and rhamnose has been correlated to the histological gravity of the lesions^[70]. The serum concentrations of folate and cobalamin have also been investigated, and although

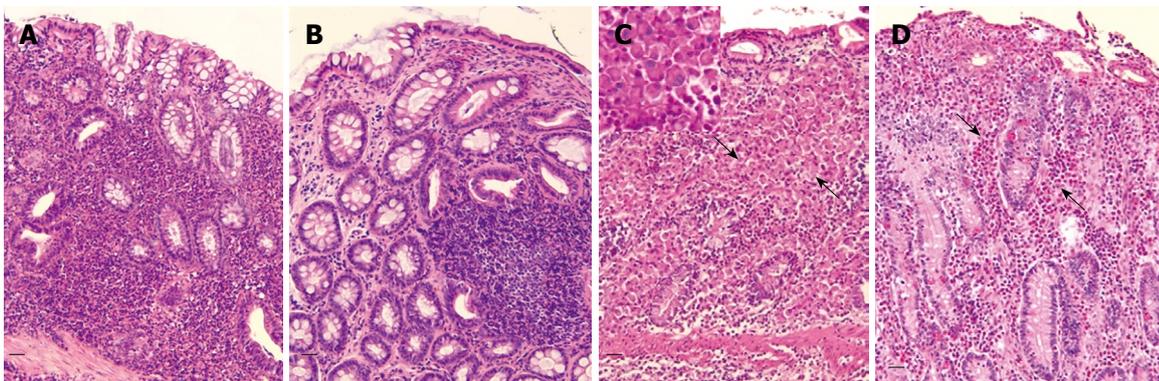

Figure 2 Representative histologic images in the dog (HE, bar = 50 μ m). A: Lymphocytic-plasmacytic colitis. Note the interstitial diffuse pattern of infiltrate represented by a large amount of lymphocytes mixed with plasma cells and some macrophages; B: Lymphocytic-plasmacytic colitis (follicular variant); C: Histiocytic colitis. Severe mucosal abnormalities with loss of crypts and diffuse infiltration by large macrophages (arrows) that in the insert (PAS stain) are shown as the main cells infiltrating the lamina propria; D: Eosinophilic colitis. Note the presence of a large number of eosinophils (arrows).

they represent nonspecific findings^[71] these are important for supplementation during treatment^[10]. Moreover, IgG and nitrite concentrations in colonic lavage fluid can be higher in dogs with IBD than in controls, with important implications in the diagnosis and monitoring of the disease^[72]. Other markers, such as microalbuminuria and C-reactive protein, yielded less encouraging results, since they showed no correlation with symptoms or pathological assessment^[73]. As stated above, IBD in dogs can be accompanied by protein loss, which is easily verified by measuring serum albumins; the presence of a new test to dose α 1-proteinase inhibitor (α 1-PI) in faeces may allow the earlier identification of protein loss, because this protein has a molecular mass similar to that of albumin,

but has the advantage of persisting unaltered in stool^[71].

If diagnosis of the disease necessitates a long and complete diagnostic plan, important tools for the clinical evaluation of IBD are the canine chronic enteropathy activity index and the canine IBD activity index (CIBDAI) (similar to the Crohn's disease activity index in man^[74]) that also allows follow-up of the patient during treatment^[75-77], even though the CIBDAI does not seem to correlate with histopathologic grade^[73]. One important aspect in managing IBD is that it is very difficult to foresee the outcome of the patient; fortunately, many important markers have recently been studied as prognostic indicators, such as canine pancreatic lipase immunoreactivity (cPLI), cobalamin and albumin concentration^[78-80].

TREATMENT

As in human medicine, the main difficulties in treating dogs with IBD originate from an incomplete understanding of the pathophysiological basis of these diseases; thus, it is not surprising that in many cases therapeutic protocols are partially borrowed from those adopted in man^[23,78]. Usually, the therapeutic protocols of choice for IBD in dogs depend on the seriousness of the disease and, eventually, on the resistance to some drugs. Some patients, such as those with FRD, may improve or even resolve their condition following the simple administration of a specific diet, such as those based on hydrolysed proteins^[58].

In general, the first approach in dogs with IBD usually involves some dietary modification, the use of prebiotics-probiotics^[10,11], antimicrobials and, eventually, corticosteroids (prednisolone or, more recently, budesonide)^[58]. Metronidazole represents an important therapeutic agent, because of its simultaneous antimicrobial and immunomodulatory action^[10,58]. Other immunomodulatory or anti-inflammatory drugs, such as azathioprine, cyclosporin, chlorambucil, cyclophosphamide and 5-aminosalicylates can be administered as an alternative or in association with the steroids, depending on the molecule^[10,12,58,78]. When treating a dog with IBD it is also important to add symptomatic therapeutic measures such as gastroprotectors, antiemetics, motility modulators, *etc.*, and to correct any possible imbalance (for example, by means of cobalamin or electrolyte supplementation)^[10,58].

Considering that the knowledge of the cytokine patterns involved in IBD human patients represents an important tool in the development of new therapeutic strategies^[61], this could also supply new therapeutic tools in veterinary medicine^[10,58]; the results of a recent study on intestinal biopsies from dogs with IBD, assessing growth hormone receptor and insulin-like growth factor (IGF-1/-2) mRNA expression, gave further perspectives for IBD treatment^[82].

CONCLUSION

To date, the relationship between IBD in humans and dogs has not been completely defined, especially with regard to pathophysiology and therapeutic protocols; thus, of the aspects investigated in man only a few could probably be successfully translated to dogs. In fact, IBD in the latter displays several and some strikingly different forms with respect to humans, in whom these diseases display more standardized clinical, endoscopic, and pathologic aspects.

However, as suggested by some authors^[83,84], the parallel study of IBD in animals could also lead to important information in man^[85], and hopefully develop better therapeutic measures to alleviate these troubles in our canine friends and companions.

INTRODUCTION

The gut mucosa is a highly organized structure that is adapted to the absorption of dietary components from the gastrointestinal lumen. It is maintained by a critical balance between epithelial cell proliferation, differentiation, migration and apoptosis^[1]. A complex interplay between multiple signaling events within epithelial cells controlling extracellular signals either from neighboring cells (cell-cell or cell-matrix contacts) or from a distant origin (e.g. hormones) maintains the specific organization and function of these cells.

Inflammation, regardless of its location or extent, sends many local and systemic signals, which in turn may cause changes in the intestine. Inflammation alters the metabolic status and elevates energy expenditure, fat metabolism and protein catabolism^[2,3]. The intestine, however, has an inherent ability to adapt morphologically and functionally in response to internal and external environmental stimuli^[4]. The adaptations include modifications of the brush border membrane fluidity and permeability as well as up- and down-regulation of carrier-mediated transporter proteins.

Inflammatory processes initiate a cascade of intestinal events which not only influence the mucosa itself but may also affect the function and integrity of remote organs and tissues. Interleukin-1 β (IL-1 β), for example, has both direct central and indirect peripheral depressant effects on appetite mechanisms, whereas plasma concentrations

Abstract

Independent of the cause and location, inflammation - even when minimal - has clear effects on gastrointestinal morphology and function. These result in altered digestion, absorption and barrier function. There is evidence of reduced villus height and crypt depth, increased permeability, as well as altered sugar and peptide absorption in the small intestine after induction of inflammation in experimental models, which is supported by some clinical data. Identification of inflammatory factors which may promote the process of gastrointestinal dysfunction as well as clinical research to verify experimental observations of inflammatory modulation of gastrointestinal function are required. Moreover, nutritional strategies to support functional restitution are needed.

Peer reviewer: Dr. Shawn David Safford, Department of

of tumor necrosis factor α (TNF- α) are associated with increases in energy expenditure^[5,6]. Lymphocyte activation leads to increased glucose consumption which stimulates major glucose-transporter proteins (GLUT) and insulin receptors^[7,8]. Increased expression of insulin receptors is essential for immune cell division, size and survival, and IL-7 seems to be essential in this process^[9].

This review gives a brief overview of some observations of the morphological and functional changes in the non-inflamed part of the small intestine that are caused by inflammatory events in other parts of the body.

MORPHOLOGICAL ALTERATIONS IN THE INTESTINAL MUCOSA

Gastrointestinal dysfunction is a common complication in patients with traumatic brain injury (TBI)^[10]. It is proposed that TBI sets off a sequence of local and systemic inflammatory events. Hang *et al.*^[11,12] found increased TNF- α and IL-6 concentrations in the jejunal tissue of mice after parietal brain contusion induced by a weight-dropping method. In this TBI model, Hang *et al.*^[11] demonstrated rapidly developing histopathological damage of the gut mucosa, including apoptosis of epithelial cells, loss of tight junctions and mitochondrial damage. They found reduced jejunal villus height, crypt depth and surface area as early as 3 h following induction of brain injury.

Morphological alterations have been confirmed in rats. Chen *et al.*^[13] induced TBI by a weight-dropping method in male Wistar rats. Ileal tissue was analyzed 5 d after brain injury. The villus height and crypt depth of ileal samples were significantly decreased compared to healthy controls. The authors also noticed increased inflammatory markers, such as IL-1 β , TNF- α , IL-6 and intracellular adhesion molecule-1 expression, in the ileal tissue.

Sundaram *et al.*^[14] found similar alterations in the mucosal structure in the non-inflamed part of rabbit ileum after colitis induced by intragastrically inoculated microbes. Despite a clear increase in proinflammatory IL-10 in duodenal, jejunal and ileal tissue samples, however, neither Barada *et al.*^[15] nor Mourad *et al.*^[16], observed any histological alterations in the non-inflamed small intestine of colitis-induced rats. Colitis was induced by intracolonic administration of iodoacetamide or 2,4,6-trinitrobenzene sulfonic acid.

Morphological alterations in the small intestine in inflammatory bowel disease (IBD) patients are conflicting. Whereas Salem & Truelove^[17] and Arvanitakis^[18] found histological changes in the non-inflamed part of the jejunum in almost 70% of IBD patients, Soulé *et al.*^[19] only observed morphological abnormalities in less than 5% of patients.

In chronic heart failure patients, the presence of endothelial dysfunction is associated with increased levels of inflammatory markers^[20]. This may also induce mor-

phological changes in the intestine. Sandek *et al.*^[21] reported thickening of non-inflamed ileal walls and of all parts of the large intestine in chronic heart failure patients compared with control subjects of similar age. The increase in wall thickening was about 30% in the terminal ileum and almost 50% in the transverse colon. Increased bowel wall thickness in the small intestine is a frequent finding in various inflammatory-related conditions, such as acute ischemic colitis, IBD and food hypersensitivity^[22,23].

To summarize, many of the above-mentioned studies in animal models assume the contributory effects of inflammatory mediators to be, at least partly, behind the observed morphological changes in the small intestine. However, there is no clear opinion as to the degree or location of inflammation or the quantity or quality of morphological changes in the small intestine. In addition, the possible route of effects, whether e.g. *via* circulating mediators or the autonomic nervous system, remains to be clarified.

ALTERATIONS OF PERMEABILITY

Tight junctions are dynamic structures that limit the passive absorption of hydrophilic molecules from the intestinal lumen, thereby being crucial in intestinal barrier mechanisms.

Proinflammatory cytokines IL-1 β and TNF- α increased epithelial tight junction permeability *in vitro* in Caco-2 cells dose- and time-dependently^[24,25]. This was mediated by an increase in myosin L chain kinase (MLCK) expression and activity, which in turn was mediated by a nuclear factor- κ B-dependent increase in MLCK gene transcription^[26,27]. In a rabbit jejunal *ex vivo* model, however, added IL-8 had no effect on passive tissue permeability measured with Cr-EDTA in Ussing-type chambers^[28]. Nevertheless, cytokines affected neurotransmitter release and content, suggesting the leading role of the autonomic nervous system^[29].

Intestinal mucosal function can be assessed *in vivo* by measuring the permeability of the mucosal barrier to small or large solutes as in a lactulose-mannitol test. Mannitol (M), a small sugar, passes through the cell membranes. Lactulose (L), a large molecule, is absorbed paracellularly through the tight junctions. Increased absorption of lactulose can reflect mucosal leakiness, and decreased absorption of mannitol can indicate a decreased functional absorptive area. In a rat model of TBI, the L/M ratio increased significantly at 3 h following brain contusion and reached a peak level at 72 h, indicating rapidly increased permeability and disruption of tight junctions between epithelial cells^[11].

Feighery *et al.*^[30] measured ileal permeability *ex vivo* in Sprague Dawley rats after inducing brain injury. After cortical contusion, ileal segments were removed and mounted in Ussing chambers within 30 min. Significantly reduced ileal barrier function was observed by monitoring fluxes of C-mannitol crossing epithelial tight

junctions. The authors assumed this to be mediated by opening of the tight junctions caused by disturbances in the autonomic nervous system or possibly also by hemorrhagic shock. In addition, cerebral stroke leads to immunodepression promoting gut barrier dysfunction, which has led to increased permeability in a mouse model^[31].

In a colitis rat model, Fries *et al.*^[32] found leaky tight junctions in the non-inflamed duodenum and ileum where permeability was increased over 70% compared with healthy controls. This increase correlated positively with the macroscopic colon damage score. In this study, colitis was induced by intrarectal trinitrobenzene sulfonic acid. Changes in the permeability of the non-inflamed part of the small intestine have been previously noticed in Crohn's disease (CD) patients^[33]. Söderholm *et al.*^[34], however, found no changes in baseline permeability in surgical segments of non-inflamed distal ileum of CD patients. In spite of this finding, intestinal tight junctions of CD patients were noticed to be more reactive to luminal stimuli of sodium caprate (a constituent of milk fat affecting tight junctions) compared with ileal segments from colon cancer patients, who served as non-inflamed controls. The authors assumed that the altered function of the small intestinal tight junctions was mediated *via* disturbed cytoskeletal contractility in inflamed patients.

Chronic heart failure patients showed a 35% increase in small intestinal permeability measured by the L/M test and a 29% decrease of D-xylose absorption, which reflects a reduced activity of passive carrier-mediated transport^[21]. This may be due to diminished gut circulation contributing to local edema and leading to reduced barrier function and dysfunction of transport proteins, but proinflammatory cytokines can also influence gut epithelial hyperpermeability. Furthermore, the possible effect of long-term medication cannot be excluded with these patients.

To sum up, increased permeability has been noticed in many experimental animal models of inflammation, which is supported by some clinical observations. Altered permeability is most likely mediated by open tight junctions, but the role of inflammatory agents and the autonomic nervous system in this phenomenon remains to be studied. Changes in the barrier function may have implications for nutrient absorption as well as for multiple organ failure caused by increased systemic delivery of luminal endotoxins.

ALTERATIONS OF INTESTINAL MOTILITY

Gastrointestinal motility is regulated by circulating and local hormones as well as neurotransmitters, mainly of the enteric nervous system. Release of these agents, however, is regulated by the central nervous system (CNS). Brain-gut peptides, such as cholecystokinin (CCK), vasoactive intestinal peptide (VIP) and calcitonin gene-related peptide (CGRP), are important mediators in the regulation of gastrointestinal motility. Several kinds

of stress, such as trauma, cold, and pain, can induce the release of these peptides from the CNS and enteric nerves^[35]. Even psychological stress inhibits small intestinal motility by regulating the expression of CCK and VIP^[36].

Evidence of inflammatory impact on gut motility and gastrointestinal transit is scarce. However, Hang *et al.*^[37] measured gastric distension, delayed gastric emptying and intestinal dilatation in rats after brain contusion induced by a weight-dropping method. They also noticed significant changes of brain-gut peptides CCK, VIP and CGRP both in plasma and jejunum tissue, which were assumed to be involved in the pathogenesis of gastrointestinal dysmotility due to systemic stress.

ALTERATIONS OF NUTRIENT ABSORPTION

There is experimental and clinical evidence that intestinal inflammation is often associated with altered malabsorption of fluids, electrolytes and nutrients - in the inflamed as well as the non-inflamed parts of the intestine^[16-18,33,38-40].

Lactose and sucrose are the major disaccharides in the human diet. Before absorption, they are hydrolyzed to monosaccharides by the microvillus membrane enzymes, lactase and sucrase. Luminal factors, hormones and growth factors regulate the expression of these enzymes along the longitudinal and vertical axes of the small intestine. The iodoacetamide-induced colitis model of Jurjus *et al.*^[41] showed a transient reduction in jejunal lactase and sucrase expression on days two and four after colitis induction in rats. The same observation was made for the jejunal aminopeptidase and GLUT-5 expressions. Aminopeptidases are involved in protein digestion in the jejunum and ileum, and GLUT-5 is a fructose transporter of the small intestine. The expression of lactase, aminopeptidases and brush border GLUT-5 returned to normal in the jejunum following the resolution of colonic inflammation. However, sucrase and crypt GLUT-5 expression remained lower for four or more days. Jurjus *et al.*^[41] suggest that the reduced enzyme expressions are probably due to decreased translation or increased degradation, or both, since transcriptional changes were not noticed. Previously, a significant reduction in disaccharidase activity in the jejunum and ileum of IBD patients has been noticed^[18,33].

Chronic heart failure patients have reduced intestinal sugar absorption, determined by the follow-up of urinary recovery of orally administered D-xylose^[21]. This indicates diminished absorption due to alterations in passive carrier-mediated transport. However, the effects of circulation and heart function cannot be excluded. There is also an increased risk of anemia among heart failure patients, but the mechanisms for this phenomenon are not entirely clear^[42]. In addition to renal dysfunction and decreased renal blood flow, circulating neurohormonal

and proinflammatory cytokines appear to contribute to anemia in chronic heart disease.

Interleukins may modulate intestinal transport function. Some proinflammatory cytokines have been reported to exert significant effects on central and peripheral regulation of glucose metabolism, which may be related to the increased metabolic demands of inflamed tissue. IL-6, IL-1 α and IL-8 seem to improve the absorption of glucose *ex vivo* in rabbit jejunal tissue^[28]. Intracerebroventricular injection of IL-1 α enhances whole-body glucose metabolism and increases insulin levels^[43]. No alterations were seen after intravenous administration of the same dose. Anti-inflammatory IL-10 appears to have no role in the regulation of jejunal nutrient transport^[28].

TNF- α is an important inflammatory mediator that plays a central role in triggering inflammatory reactions. Absorption of monosaccharide galactose in incubated rat intestinal rings is impaired by proinflammatory IL-1 β and TNF- α by 30%^[44]. In an experimental model of sepsis, intravenous administration of TNF- α inhibited intestinal D-fructose absorption in the rabbit jejunum by decreasing the expression of the GLUT-5 transporter at the brush border membrane^[45]. It also inhibited D-galactose transport across the apical membrane of the enterocyte in rabbit intestinal tissue preparations and brush border vesicles by reducing the amounts of Na⁺/glucose cotransporter protein (SGLT1) in the plasma membrane through a mechanism in which several protein-like kinases are involved^[46].

Proinflammatory cytokines IL-1 α and IL-8 significantly increased L-proline absorption *in vitro* in the rabbit jejunal tissue^[28]. However, in rats with intracolonic iodoacetamide-induced colitis, jejunal alanine absorption was reduced 30%-40% at two days following iodoacetamide administration^[47].

Brain injury in a rat model increased the transport and uptake of dipeptides, even though the villus height and surface area were demonstrated to be significantly decreased^[48]. This process was carried out by increases in the intestinal brush border transporter PepT1, which transfers dipeptides from the intestinal lumen to enterocyte cytoplasm. Rat intestinal PepT1 can be up-regulated under the influence of many factors including the dietary protein load^[49]. Up-regulation of this oligopeptide transporter in the intestine suggests that the gut can increase the luminal transport of dietary proteins in the form of di- and tripeptides during intestinal failure, independent of changes in the mucosal surface area. This has pharmacological implications as well, since PepT1 mediates the intestinal absorption of some peptide-like drugs^[50]. There is some evidence that PepT1 may even have a role in inflammatory processes, since it is up-regulated in the colonic epithelial cells of patients with chronic ulcerative colitis and CD^[51].

To summarize, the observations of changed absorptive capacity of the small intestine are mainly from animal models. Maldigestion of carbohydrates and changes in transporters of sugars and peptides have been noticed.

Table 1 Summary of *in vivo* evidence of changes in small intestinal function induced by inflammation markers

Alterations in intestinal	Inflammation model		
	TBI	IBD, colitis	Chronic heart failure with low-grade inflammation
Morphology	A, H	A?, H?	H
Permeability	A	A, H?	H
Motility	A		
Absorption	A	A, H	H

Most observations in this summary are, however, from a single study. TBI: Traumatic brain injury; IBD: Inflammatory bowel disease; A: Evidence from animal studies; H: Evidence from clinical studies; ?: Conflicting results.

The clinical relevance of these observations remains to be elucidated.

CONCLUSION

Systemic or local inflammation may influence the intestinal absorptive area, epithelial cells, and barrier function *via* released inflammatory mediators and products from activated immune cells. Knowledge regarding the interplay of inflammation and intestinal function is scant. The molecular mechanisms of these changes may differ in acute and chronic inflammation.

Even if the number of observations of morphology, permeability, motility and digestion is limited, the results are interesting and indicate possible clinical relevance. Table 1 summarizes the existing *in vivo* evidence. Most of the observations, however, have been made after TBI which is an extreme model for studying inflammatory responses in the intestine. Interesting early clinical results of altered intestinal morphology and function have been obtained in chronic heart failure patients. Chronic heart failure is associated with increased levels of inflammatory markers related to so-called low-grade or minimal inflammation.

More research is needed to verify these mainly experimental observations and to establish their possible clinical relevance.

Abstract

AIM: To evaluate the effect of acute stress, hydrochloric acid, ethanol, aspirin, and prednisolone on the intercellular spaces of the esophageal epithelium.

METHODS: Part I, male Sprague-Dawley rats were randomly divided into eight groups and treated with the damaging or control factors. The esophagus of each rat was macroscopically inspected. Histological changes in mucosal biopsies were examined by light microscopy, and the widths of intercellular spaces were determined by transmission electron microscopy (TEM). Part II, in part I, we found that acute stress and aspirin induced dilated intercellular spaces (DIS) of the esophageal epithelium. Therefore, the effect of acid suppression pretreatment with esomeprazole on esophageal epithelial DIS induced by water immersion and restraint stress (WRS) and aspirin was further investigated to determine the association of DIS with acid reflux. After administration of 0.9% sodium chloride solution or esomeprazole solution orally for five days, rats underwent WRS or intragastric administration of aspirin solution. Esophageal epithelial intercellular spaces were investigated by TEM.

RESULTS: (1) The five damaging factors produced no lesions or inflammation in esophageal mucosa of rats under either gross or routine histological inspections. Esophageal epithelial intercellular space diameters in stress and aspirin groups were significantly greater, nearly three or two-fold respectively, than those in their corresponding control groups (stress model: $0.38 \pm 0.05 \mu\text{m}$ vs $0.13 \pm 0.02 \mu\text{m}$, $P < 0.01$; aspirin model: $0.32 \pm 0.12 \mu\text{m}$ vs $0.19 \pm 0.05 \mu\text{m}$, $P < 0.01$). Neither intragastric administration of hydrochloric acid or ethanol, nor hypodermic injection of prednisolone produced DIS compared with their corresponding control groups (hydrochloric acid model: $0.24 \pm 0.03 \mu\text{m}$ vs $0.19 \pm 0.05 \mu\text{m}$, $P > 0.05$; ethanol model: $0.25 \pm 0.10 \mu\text{m}$ vs $0.19 \pm 0.05 \mu\text{m}$, $P > 0.05$; prednisolone model: $0.20 \pm 0.03 \mu\text{m}$ vs $0.14 \pm 0.03 \mu\text{m}$, $P > 0.05$); and (2) No significant difference in the intercellular space diameters was observed between the group pretreated with esomeprazole and the control group, in both the stress and aspirin models (stress model: $0.35 \pm 0.05 \mu\text{m}$ vs $0.37 \pm 0.05 \mu\text{m}$, $P > 0.05$; aspirin model: $0.24 \pm 0.02 \mu\text{m}$ vs $0.27 \pm 0.03 \mu\text{m}$, $P > 0.05$).

CONCLUSION: Acute stress and aspirin can induce DIS of the esophageal epithelium in rats, and it is not correlated with acid reflux.

INTRODUCTION

Gastroesophageal reflux disease (GERD) covers a broad range of symptoms and signs arising from the reflux of gastric contents into the esophagus. Gastric acid is the most important injury factor in the refluxate. In patients with GERD, only one third of those with heartburn have endoscopic evidence of erosive esophagitis (EE), and the remainder have non-erosive reflux disease (NERD). Mucosal damages are not visible under endoscopy in patients with NERD^[1]. Several diagnostic tests have been established to diagnose GERD, but there is not a gold standard for diagnosing NERD. Many existing methods, such as ambulatory 24-h esophageal pH or bile monitoring, are not satisfactory due to their poor sensitivity, specificity, and reproducibility^[2]. For example, about 50% of patients with NERD were found to have physiological values of acid exposure time with ambulatory 24-h esophageal pH monitoring^[3-5]. Therefore, more effective methods need to be developed for the diagnosis of NERD.

Dilated intercellular spaces (DIS) have been observed in both the early stage of acid-perfused rabbit esophageal epithelium^[6] and the esophageal biopsies of patients with GERD, including NERD and EE^[7,8]. Studies reported that three or six months of acid suppression therapy with omeprazole led to a recovery of DIS in more than 90% patients with GERD, accompanied by regression of heartburn^[9]. Thus, DIS has been considered as a feature of esophageal epithelial damage induced by gastric acid reflux, and serves as a marker for new methods to diagnose GERD, especially NERD^[10-14].

However, the specificity of DIS is questionable. In patients with other esophageal disorders, either with or without acid reflux, DIS was also observed, suggesting that refluxed acid is not the only factor that results in DIS^[15,16]. A number of common damaging factors, such as ethanol, hydrochloric acid, nonsteroidal anti-inflammatory drugs (NSAIDs), corticosteroids, and stress, have been known to induce stomach lesions. The aim of this study was to evaluate the effect of acute stress, hydrochloric acid, ethanol, aspirin, and prednisolone on the intercellular spaces of the esophageal epithelium in rats.

MATERIALS AND METHODS

Animals

Adult male Sprague-Dawley (S-D) rats, weighing 190-210 g, were used in the experiments. The animals were kept in individual cages, and provided with food and water *ad libitum*. They were housed in an air-conditioned room with a temperature of $23 \pm 1^\circ\text{C}$, humidity of 55%, and a 12 h light/dark cycle. All rats were acclimated under the same conditions for three days before study.

Models

In part I we evaluated the effect of different damaging factors on the intercellular spaces of the esophageal epithelium in rats. Subsequently, the effect of esomeprazole pretreatment on esophageal epithelial DIS induced by

water immersion and restraint stress (WRS) and aspirin was further investigated (part II).

Part I : After a three-day acclimation, 45 rats were randomly divided into eight groups (five or six rats per group) and treated as follow: (1) Normal control group (NC): rats remained untreated in their home cage for seven hours, and subsequently were anesthetized using diethyl ether; (2) Normal saline (NS) intragastric administration group (NSIG): rats were anesthetized one hour after intragastric administration of 1 mL of 0.9% sodium chloride solution (NS); (3) NS hypodermic injection group (NSHD): rats were given hypodermic injection of 2 mL of 0.9% sodium chloride solution at cervical part once a day for four days, and anesthetized eight hours after the last injection; (4) WRS group: the four limbs of each rat were bounded on a board, and the rats were immersed in water in a head-up vertical position up to the level of the xiphoid process at a temperature of $20 \pm 1^\circ\text{C}$ for seven hours before they were anesthetized^[17,18]; (5) Hydrochloric acid intragastric administration group (HCLIG): rats were anesthetized one hour after intragastric administration of 1 mL of 0.7 mol/L hydrochloric acid; (6) Ethanol intragastric administration group (EIG): rats were anesthetized one hour after intragastric administration of 1 mL of 100% ethanol; (7) Aspirin intragastric administration group (AIG): rats were anesthetized one hour after intragastric administration of 1 mL of aspirin solution (300 mg/kg, dissolved in 2% sodium bicarbonate solution); and (8) Prednisolone hypodermic injection group (PHD): rats were given hypodermic injection of 2 mL of prednisolone acetate injection (250 mg/kg per day) at cervical part once a day for four days, and anesthetized eight hours after the last injection. All rats were fasted for 24 h but allowed free access to water before anesthesia. The esophagi and stomachs of rats were isolated, opened, and macroscopically inspected. Esophageal mucosal biopsies 0.5-1 cm above Z-line were then obtained to prepare paraffin sections for light microscopy and ultra-thin sections for transmission electron microscopy (TEM).

Part II : (1) WRS model: 12 rats were randomly divided into two groups averagely: control group (C) and esomeprazole group (E), which were given 0.9% sodium chloride solution (2 mL, once a day) or esomeprazole solution (5 mg/kg per day, dissolved in 2 mL of distilled water, once a day) orally for four days, respectively. Rats were then fasted for 24 h but allowed free access to water. On the 5th day, two hours after 0.9% sodium chloride solution or esomeprazole solution were administered, all rats underwent WRS for seven hours as described in part I, and were then sacrificed under ethyl ether inhalation. Esophageal mucosal biopsies 0.5-1 cm above Z-line were taken to measure the width of intercellular spaces with TEM; and (2) Aspirin model: 12 rats were divided into two groups, and treated as described in WRS model for the first four days. On the 5th day, rats received intragastric administration of 1 mL of aspirin solution (300 mg/kg, dissolved in 2% sodium bicarbonate solution) two hours after 0.9% sodium chloride solution or esome-

prazole solution were administered. One hour later, the rats were anesthetized using ethyl ether. Esophageal mucosal biopsies 0.5-1 cm above Z-line were taken to measure the width of intercellular spaces with TEM.

Histology

Biopsies of esophageal mucosal tissues were fixed in formalin immediately after being removed from the rats, and were then embedded in paraffin wax. Serial 5 μm sections were cut and stained with hematoxylin and eosin (HE) for routine histological evaluation by light microscopy.

Transmission electron microscopy

Specimens of esophageal mucosae were fixed in glutaraldehyde immediately after being removed from the rats, rinsed, and processed for TEM. The specimens were post-fixed in 1% buffered osmium tetroxide. They were then dehydrated through a graded acetone series and embedded in Araldite. Blocks were trimmed, and ultra-thin sections on copper grids were post-stained with uranyl acetate and lead citrate. Each specimen was analyzed with a transmission electron microscope (JEOL JEM-1230) and then photographed at an accelerating voltage of 80 kV. Photographs of at least 10 fields were magnified at $\times 5000$.

Ten transmission electron photomicrographs of biopsy specimens from each rat were obtained. In particular, the suprabasal layer of the esophageal mucosa was examined in each image. Photographs with an internal scale marker were digitized and then each field was evaluated using Adobe Photoshop 7.0 software. According to Tobey *et al.*^[7], at least 10 randomly selected perpendiculars transects to adjacent membranes were drawn and measured in each image for a total of 100 measurements in each case. Each transect was drawn at a distance not closer than 1 μm .

Statistical analysis

The measurements obtained were used to calculate the mean intercellular space scores and the mean scores of the minimal and maximal intercellular spaces for each subject and for all cases as a whole. Scores are reported as mean \pm SD. Statistical significances were determined using one-way analysis of variance (ANOVA) and LSD-*t* test for comparisons among multiple groups, and using Student's *t*-test for unpaired samples between two groups. A *P*-value of less than 0.05 was considered statistically significant.

RESULTS

Effect of different damaging factors on intercellular spaces of the esophageal epithelium

Multiple congestion, erosions, ulcers, and hemorrhage in the gastric mucosa were observed grossly in the WRS, HCLIG, EIG, AIG, and PHD groups, while in the other three control groups the gastric mucosa remained intact with no apparent lesions. The esophageal mucosae of all the groups were also examined by gross inspection, and no evident inflammation or lesions were found in any rat. In addition, under light microscopy with magnifica-

Table 1 Effect of damaging factors on intercellular space diameters of esophageal epithelium (μm , mean \pm SD)

Groups	Cases	Mean IS	Mean of minimal IS	Mean of maximal IS
NC	5	0.13 \pm 0.02	0.09 \pm 0.02	0.18 \pm 0.03
NSIG	5	0.19 \pm 0.05	0.10 \pm 0.01	0.29 \pm 0.12
NSHD	5	0.14 \pm 0.03	0.09 \pm 0.02	0.20 \pm 0.02
WRS	6	0.38 \pm 0.05 ^b	0.20 \pm 0.06 ^b	0.64 \pm 0.08 ^b
HCLIG	6	0.24 \pm 0.03	0.14 \pm 0.02	0.40 \pm 0.10
EIG	6	0.25 \pm 0.10	0.16 \pm 0.07	0.37 \pm 0.13
AIG	6	0.32 \pm 0.12 ^d	0.19 \pm 0.07 ^d	0.47 \pm 0.17 ^d
PHD	6	0.20 \pm 0.03	0.13 \pm 0.02	0.30 \pm 0.07

^b*P* < 0.01 vs NC; ^d*P* < 0.01 vs NSIG. IS: Intercellular spaces; NC: Normal control group; NSIG: Normal saline (NS) intragastric administration group; NSHD: NS hypodermic injection group; WRS: Water immersion and restraint stress group; HCLIG: Hydrochloric acid intragastric administration group; EIG: Ethanol intragastric administration group; AIG: Aspirin intragastric administration group; PHD: Prednisolone hypodermic injection group.

tion of $\times 100$ and $\times 400$, no histological evidences of inflammation (intraepithelial inflammatory infiltration, epithelial cellular swelling, submucous dropsy, telangiectasia, papillae elongation, or hyperplasia of the basal layer) were observed in the esophageal mucosa from all eight groups.

The mean and mean scores of the minimal and maximal intercellular space diameters of esophageal epithelium were determined using TEM (Table 1, Figure 1A-H). The mean intercellular space diameter in the WRS group was nearly three times greater than that in the NC group (0.38 \pm 0.05 μm vs 0.13 \pm 0.02 μm , *P* < 0.01). The mean intercellular space diameter in the AIG group was greater, by nearly two-fold, than that in the NSIG group (0.32 \pm 0.12 μm vs 0.19 \pm 0.05 μm , *P* < 0.01). The comparison of mean scores of the minimal and maximal intercellular space diameters showed similar results to the comparison of mean between WRS and NC groups, and AIG and NSIG groups. No difference in mean and mean scores of the minimal and maximal intercellular space diameters was observed between HCLIG and NSIG groups, EIG and NSIG groups, and PHD and NSHD groups (*P* > 0.05).

Effect of esomeprazole pretreatment on esophageal epithelial DIS induced by WRS and aspirin

Esomeprazole inhibits gastric acid secretion with suppression of esophageal acid exposure, therefore the effect of esomeprazole pretreatment on esophageal epithelial DIS induced by WRS and aspirin was further investigated to determine the association of DIS with acid reflux.

In both the WRS model and the aspirin model, no significant difference in mean and mean scores of the minimal and maximal intercellular space diameters was observed between the group pretreated with esomeprazole and the control group (*P* > 0.05) (Table 2, Figure 1I-L).

DISCUSSION

DIS of esophageal epithelium in patients with GERD was first reported 30 years ago^[19]. It was later detected at

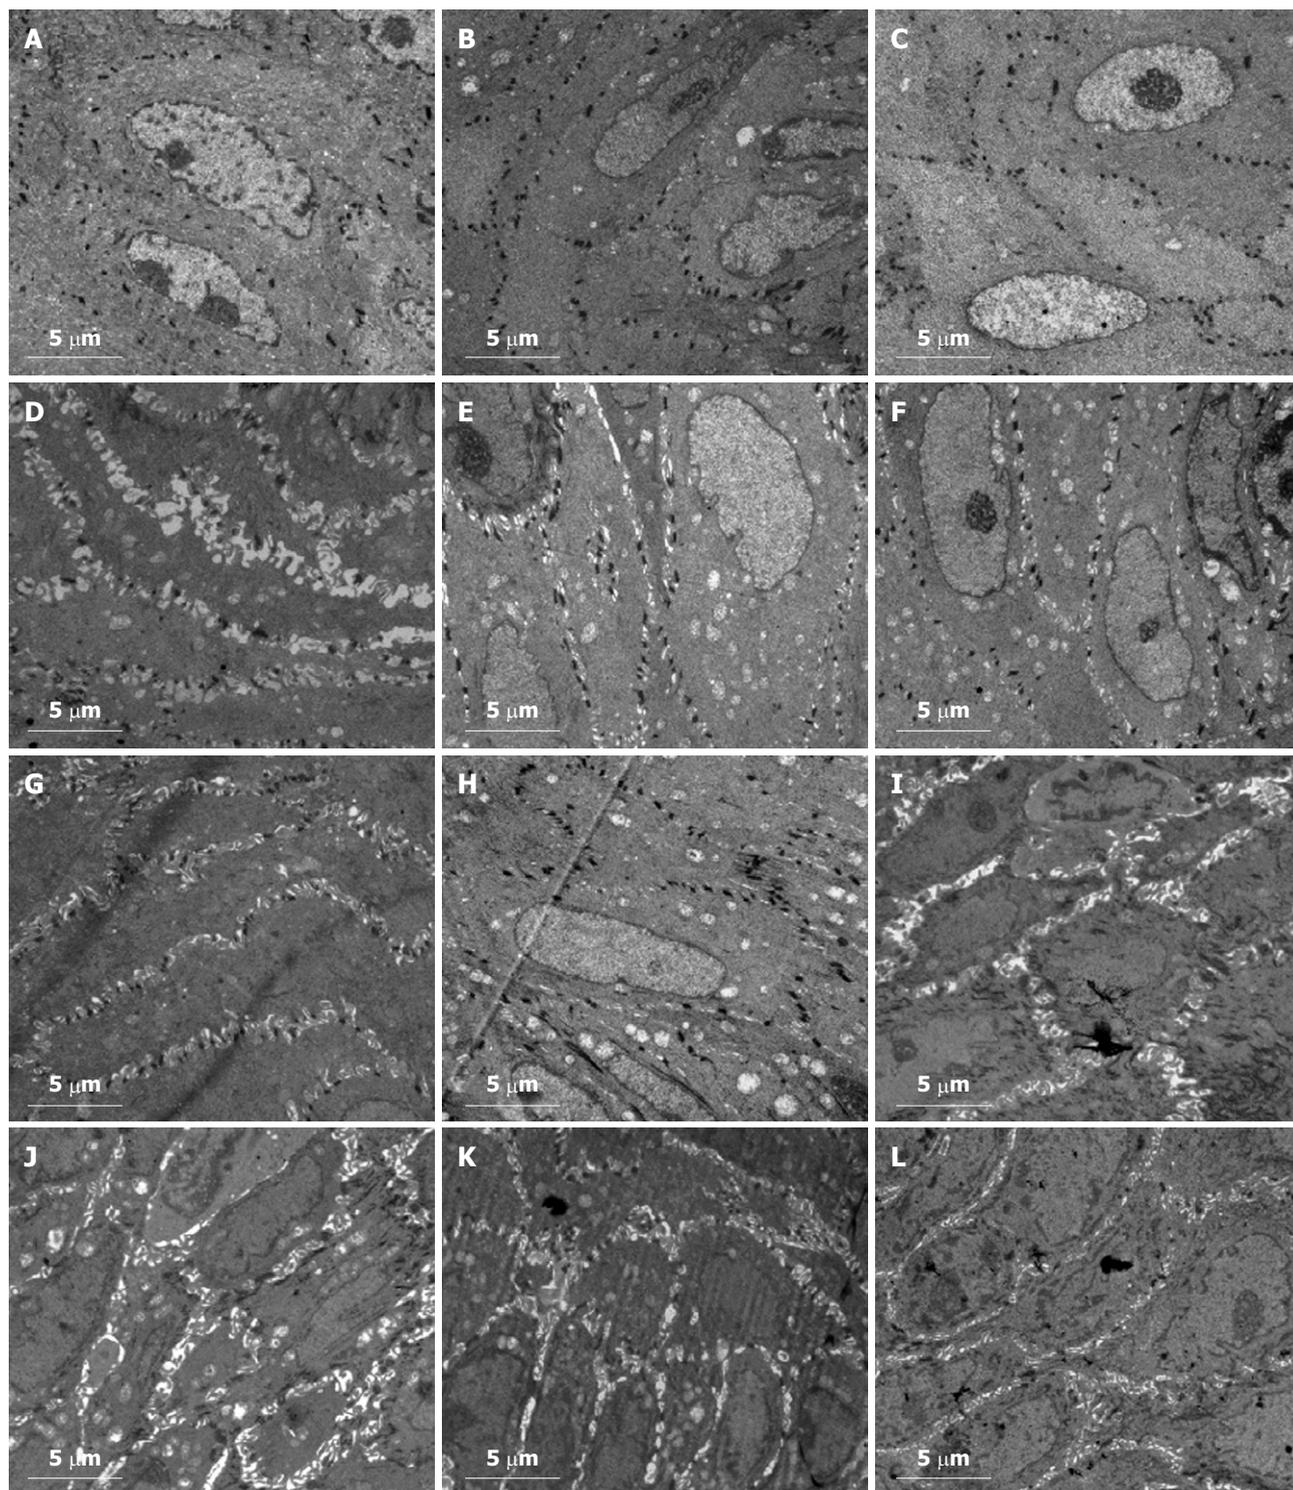

Figure 1 Transmission electron photomicrographs of the esophageal epithelium, showing intercellular spaces in rats of different groups in Part I (A-H) and Part II (I-L) (magnified at $\times 5000$ by transmission electron microscopy). A: Normal control group; B: Normal saline (NS) intragastric administration group; C: NS hypodermic injection group; D: Water immersion and restraint stress (WRS) group; E: Hydrochloric acid intragastric administration group; F: Ethanol intragastric administration group; G: Aspirin intragastric administration group; H: Prednisolone hypodermic injection group; I: NS + WRS group; J: Esomeprazole + WRS group; K: NS + aspirin group; L: Esomeprazole + aspirin group.

the early stage of acid-induced epithelial injury of rabbit esophagus^[6,20]. Using TEM, Tobey *et al*^[7] demonstrated that DIS was a feature of reflux damage to the human esophageal epithelium, irrespective of whether the patient had erosive or non-erosive disease. However, TEM is expensive and thereby difficult to apply to routine biopsies.

Scientists have been trying to establish an equivalent of TEM with light microscopy to detect DIS^[21-23]. Although DIS can be seen under light microscopy, TEM has higher resolution and better quality of visualization. In 2003, DIS was shown to be an extremely sensitive marker of damage in GERD, duodenal gastro-esophageal reflux (DGER)

Table 2 Effect of esomeprazole pretreatment on esophageal epithelial DIS induced by WRS and aspirin (μm , mean \pm SD)

Damaging factors	Mean IS		Mean of minimal IS		Mean of maximal IS	
	Control group	Esomeprazole group	Control group	Esomeprazole group	Control group	Esomeprazole group
WRS	0.37 \pm 0.05	0.35 \pm 0.05	0.27 \pm 0.05	0.25 \pm 0.04	0.49 \pm 0.05	0.45 \pm 0.07
AIG	0.27 \pm 0.03	0.24 \pm 0.02	0.19 \pm 0.02	0.18 \pm 0.02	0.35 \pm 0.05	0.32 \pm 0.03

and NERD, and hence was thought to be the most appropriate marker to evaluate damage in NERD^[24].

In patients with GERD, contact with, and damage to, the esophageal epithelium by gastric acidic refluxate causes microscopic defects, such as DIS. DIS allows luminal acid to diffuse between the intercellular spaces, access the esophageal nociceptors in the intraepithelial sensory nerve endings, and trigger a signal by virtue of changing the pH in the intercellular environment, thereby eliciting symptoms of heartburn and pain^[25]. Among the antisecretory drugs, proton pump inhibitors (PPIs) offer rapid symptomatic relief in the highest percentage of patients with GERD, due to their inhibition of gastric acid secretion with suppression of esophageal acid exposure. Studies demonstrated that three and six months of acid suppression therapy with omeprazole, respectively, led to a complete recovery of DIS in 92.1% and 97.4% of the patients with GERD, accompanied by regression of heartburn^[9]. Similar results were also shown in other two studies^[26,27]. In addition, recently studies have also shown that dilation of intercellular space diameter occurred along the distal and proximal esophageal epithelium in NERD patients and could be responsible for the enhanced perception of proximal acid reflux^[2]. In an experimental model of non-erosive acid-damage esophageal epithelium in rabbits, DIS developed in association with, and as a marker of, reduced trans-epithelial resistance and increased shunt permeability^[28]. All these findings indicate that DIS could be a sensitive histopathological marker of NERD and be related to acid reflux.

However, the specificity of DIS to diagnose NERD is questionable, as it is also present in patients without GERD but with other esophageal disorders. Takubo *et al.*^[6] evaluated nine histological changes that have been previously described in the esophageal mucosa of patients with GERD, including DIS, and found that there was no significant difference in the incidences of DIS between the GERD and esophageal cancer patients. DIS was also found in children with esophagitis due to causes other than acid reflux (Candida infection, food allergy, and eosinophilic esophagitis)^[15]. We designed this study to evaluate whether the common damaging factors, including acute stress, hydrochloric acid, ethanol, aspirin, and prednisolone, can induce DIS of the esophageal epithelium and investigated the association of DIS provoked by any of these factors with acid reflux.

Stress, ethanol, NSAIDs, and corticosteroids are common exogenous injury factors, while acid is an important endogenous injury factor. They have been known to induce damage to the gastric mucosa at certain densities and doses. In this study, lesions were grossly observed

in the gastric mucosa of rats under these conditions, but the esophageal mucosa remained intact, with no evident lesions or inflammation, under both gross and histological inspections. Possibly the contact time of gastric and esophageal mucosa with stimulants is different, or the sensitivities of different epithelial types to stimulants are different.

Stress has been known to induce all kinds of mental and physical disorders. Up to 60% of patients with GERD report an increase in symptoms related to stressful life events^[4,29,30]. WRS has been widely used to induce gastric lesions in animals, providing a model system for studying stress-induced ulcers in humans^[31,32]. This model involves elements of physical stress in addition to psychological stress. Factors known to play a role in the induction of gastric lesions by WRS include gastric acid, oxygen-derived free radicals, cytokines, and bioactive amines^[33]. We found that the intercellular space diameter of the esophageal epithelium in the WRS group was nearly three times greater than that in the control group ($P < 0.01$), suggesting that acute stress is able to induce DIS of the esophageal epithelium. This result also correlates with recent studies by Farré *et al.*^[34]. Twenty percent to thirty percent of the patients treated with NSAIDs have symptoms in the digestive tract. NSAIDs are able to block cyclo-oxygenase-1 (COX-1) and inhibit the synthesis of physiological prostaglandins (PGs); or damage the mucosa of digestive tract directly as a poor organic acid. In our study, the intercellular space diameter of esophageal epithelium in the aspirin intragastric administration group was significantly greater than that in the NS intragastric administration group ($P < 0.01$), indicating that aspirin could provoke esophageal epithelial DIS. Combined with the results showing there were no gross lesions or histological evidence of cell necrosis and inflammation in the esophageal mucosa, both in the stress group and the aspirin group, we speculate that DIS is an early and sensitive marker of esophageal damage, and appears before the changes observable in gross or detectable with routine histological inspections. In a recent study, Shebani *et al.*^[35] showed increased intercellular space diameters in the epithelium in bronchial biopsies of asthmatics versus healthy controls, also suggesting that DIS might simply represent the early epithelial response to diverse insults, regardless of its nature and the type of epithelium.

Acid is the most important endogenous injury factor, and the major component is hydrochloric acid. Gastric mucosal injury induced by ethanol is considered "non-acid related" injury, because acid does not make the main contribution in the injury^[36-38]. We could not detect significant differences in the esophageal epithelial inter-

cellular space diameters between the hydrochloric acid intragastric administration group and the NS intragastric administration group ($P > 0.05$), or between the ethanol intragastric administration group and the NS intragastric administration group ($P > 0.05$) in our study. This discrepancy is likely due to the dose and action time we used in our experiment. Possibly hydrochloric acid and ethanol were not refluxed or the refluxed time was too short under our conditions. Though gastric mucosal lesions were produced in rats, there were no evident lesions or inflammation either in gross or in routine histological inspections. In addition, the intercellular space diameters of the esophageal epithelium did not change. Further studies regarding continuous perfusion with hydrochloric acid or ethanol into the animal's esophagus are required to investigate the effect of hydrochloric acid and ethanol on intercellular spaces of the esophageal epithelium. Our study also showed that there was no difference in the intercellular space diameter between the prednisolone hypodermic injection group and the NS hypodermic injection group ($P > 0.05$). However, other studies showed that incidence rates of peptic ulcers usually increase after treatment with corticosteroids^[39]. We currently do not know the exact reason for this difference. It is possible that prednisolone has no effect on intercellular spaces of the esophageal epithelium. Further studies need to be conducted to determine the reason.

PPIs provide more effective acid suppression and are more effective at reaching target pH values > 4 for ≥ 18 h per day^[40]. Our study showed that there were no significant differences in intercellular space diameters of the esophageal epithelium of rats between the group pretreated with esomeprazole and the control group both in the WRS model ($P > 0.05$) and the aspirin model ($P > 0.05$). This suggests that pretreatment with esomeprazole had no effect on DIS of esophageal epithelium induced by acute stress or aspirin. DIS was still present after acid suppression, indicating that DIS induced by acute stress and aspirin is not correlated with acid reflux. Similar results were also observed by Bradley *et al.*^[29], who showed that acute stress did not increase esophageal acid exposure. Besides acid reflux, other noxious contents of the refluxate, such as bile, were reported to be able to impair mucosal integrity and provoke dilated intercellular spaces after short exposure of the esophageal mucosa to bile acid in both acidic and weakly acidic conditions^[41]. Moreover, more than 50% of patients with NERD have normal esophageal acid exposure^[4]. No difference in intercellular space diameters was observed between NERD pH-positive and pH-negative patients^[8]. Therefore DIS is not related solely to acid reflux.

In conclusion, we find that acute stress and aspirin can induce DIS of the esophageal epithelium in rats, which appears before macroscopically observable changes and before changes detectable with routine histological inspection. This ultrastructural change provoked by acute stress and aspirin is not related to acid reflux, suggesting that other damaging factors can also induce DIS of esophageal epithelium. Therefore DIS is an early, sensitive, but non-specific, ultrastructural feature of NERD. These results

are beneficial for the diagnosis and differential diagnosis of NERD, and provide initial insight to the mechanism of this disease.

COMMENTS

Background

The incidence of gastroesophageal reflux disease (GERD) is rising rapidly. Symptoms of GERD arise from the exposure of increased acid gastric contents into the lower part of the esophageal mucosa. In patients with GERD, two-thirds of them have non-erosive reflux disease (NERD) with invisible mucosal damages under endoscopy. However, there is not a gold standard to diagnose NERD due to the poor sensitivity, specificity, and reproducibility of many existing methods. A prime candidate for this role is dilated intercellular spaces (DIS) in esophageal epithelium, which has been a recent research hotspot.

Research frontiers

DIS has been considered as a feature of esophageal epithelial damage induced by gastric acid reflux, and serves as a marker for new methods to diagnose NERD. However, the specificity of DIS is questionable. In this study, the esophageal mucosal damage in response to various factors in rats, including acute stress, hydrochloric acid, ethanol, aspirin, and prednisolone, were evaluated.

Innovations and breakthroughs

Recent studies have highlighted the importance of refluxed gastric acid in esophageal epithelial DIS. This study demonstrated that acute stress and aspirin can induce DIS of the esophageal epithelium in rats, and it appeared before changes that can be seen in gross and routine histological inspections. Furthermore, DIS induced by acute stress and aspirin was not correlated with acid reflux. Thus, our study suggests that DIS is an early, sensitive, but nonspecific, ultrastructural feature of NERD.

Applications

By showing that DIS is not related solely to acid reflux, this study is beneficial for the diagnosis and differential diagnosis of NERD, and provides initial insight to the mechanism of this disease.

Peer review

A well done investigation in rats that examines esophageal mucosal damage in response to various factors.

Abstract

AIM: To investigate the regulation of mindin expression and the signaling pathway involved during inflammation.

METHODS: C57BL/6 mice were treated with 3% dextran sulfate sodium (DSS) in drinking water for 6 d to induce acute colitis, and then the colon was harvested for histological analysis or for RNA isolation. mRNA expression of mindin and nuclear factor (NF)- κ B p65 was analyzed by quantitative real time polymerase chain reaction (RT-PCR) and mindin expression construct was confirmed by Western blotting. Mouse macrophage and intestinal epithelial lineage cells were stimulated with different cytokines and toll-like receptor (TLR) ligands, before pNF- κ B-luciferase activity was assessed using the Dual-Luciferase reporter assay system.

RESULTS: mRNA expression of mindin was upregulated 4.7 ± 1.1 fold compared with the baseline dur-

ing DSS-induced intestinal inflammation in the mice. Stimulation with CpG-ODN (a known TLR-9 ligand) induced 4.2 ± 0.3 fold upregulation of mindin expression in RAW 264.7 cells. Full-length of mindin was cloned from cDNA of mouse mesenteric lymph node, then the pCMV-Mindin-Flag expression vector was established and the protein expression level was confirmed. Transfection of the mindin construct and stimulation with CpG-ODN significantly increased the NF- κ B-luciferase activity by 2.5 ± 0.3 and 4.5 ± 0.5 fold in RAW264.7 and CMT93 cells, respectively ($P < 0.01$).

CONCLUSION: Mindin expression is upregulated during intestinal inflammation and may induce NF- κ B promoter activation in a TLR-9 mediated manner.

Guleng B, Lian YM, Ren JL. Mindin is upregulated during colitis and may activate NF- κ B in a TLR-9 mediated manner. *World J Gastroenterol* 2010; 16(9): 1070-1075 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i9/1070.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i9.1070>

INTRODUCTION

Mindin (also called spondin 2) is a member of the mindin-F-spondin family of secreted extracellular matrix proteins^[1]. Mindin was initially identified in zebrafish and was found to selectively accumulate in the basal lamina. Subsequently, the genes encoding rat and human mindin were cloned^[2,3]. Mouse Spon2 cDNA encodes an open reading frame of 330 amino acids with a calculated molecular mass of 36 kDa. Spon2 mRNA is abundantly

expressed in the spleen and lymph nodes^[4].

To investigate the involvement of mindin in the immune system, mindin-deficient mice have been generated^[4]. Mice lacking mindin are resistant to lipopolysaccharide (LPS)-induced septic shock and exhibit an impaired ability to clear bacterial infections^[4]. Macrophages and mast cells show defective responses to a broad spectrum of microbial stimuli. Mindin also functions as an opsonin for macrophage phagocytosis of bacteria^[4]. Mice lacking mindin exhibit defective clearance of influenza virus, whereas mindin-deficient macrophages show impaired activation following influenza infection^[5]. Thus, mindin is a pattern recognition molecule that is critical for initiating innate immune responses to both bacterial and viral pathogens^[5,6].

Mindin-deficient mice display severely impaired recruitment of neutrophils and macrophages to inflammation sites^[7]. These effects are mediated through the interaction of mindin with $\alpha_M\beta_2$ and $\alpha_4\beta_1$ integrins on neutrophils. Mindin-integrin interactions also have a key function in T-cell priming by dendritic cells (DCs). DCs from mindin-deficient mice show an impaired capacity to prime CD4⁺ T cells due to inefficient engagement of T lymphocytes. Additionally, these DCs have reduced levels of the Rho guanosine triphosphatases Rac1 and Rac2, which control DC priming capability^[8]. Mindin regulates Rac1 and Rac2 expression by signaling through $\alpha_4\beta_1$ and $\alpha_5\beta_1$ integrins on DCs^[9].

Despite these previous studies indicating that mindin is important in both innate and adaptive immunity, information regarding its regulation is poorly understood and activation of signaling pathways are not well investigated.

The innate immune system uses pattern-recognition receptors (PRRs) to recognize pathogen-associated molecular patterns (PAMPs)^[10,11]. Several cell surface PRRs such as toll-like receptors (TLRs) are essential in innate immune recognition and the microbial components recognized by TLRs have been identified in recent decades^[12-16].

Our data demonstrate that mRNA expression of mindin is upregulated during dextran sulfate sodium (DSS)-induced acute intestinal inflammation and *in vitro* costimulating data suggest that mindin may induce nuclear factor (NF)- κ B promoter activation in a TLR-9 mediated manner.

MATERIALS AND METHODS

Mice and induction of acute colitis

C57BL/6 mice were purchased from the laboratory animal center, Shanghai, China. All procedures involving experimental animals were performed in accordance with protocols approved by the Committee for Animal Research of the University of Xiamen and complied with the Guide for the Care and Use of Laboratory Animals (NIH publication No. 86-23, revised 1985). Mice were housed in a specific pathogen-free animal facility and at 8 to 12 wk of age were treated with 3% (wt/vol) DSS (MP Biomedicals, Irvine, CA) for 6 d, then the colon was harvested, two tissue pieces 0.5 cm in length were dissected out, 2 cm away from the anus of each study mouse. One

piece of colon tissue was fixed in 4% neutral buffered formalin, cut into 6 μ m thick sections and then stained with hematoxylin and eosin (HE) for light microscopic examination and another piece was prepared for RNA isolation. All experiments were repeated at least 3 times.

Cell culture and stimulation

RAW 264.7 (purchased from Sigma-Aldrich), CMT93 and HEK293 cells (both purchased from ATCC, USA) were maintained in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum and a 0.5% penicillin G/streptomycin mixture at 37°C in a 5% CO₂ atmosphere. About 1×10^5 of RAW 264.7 and CMT93 cells were cultured in 12-well plates and stimulated with the cytokines; 10 ng/mL of mouse recombinant tumor necrosis factor- α (TNF- α) and interleukin-1 β (IL-1 β) (both from R&D Systems); and different TLR ligands consisting of 0.05 μ g/mL of Pam3-CSK4, 5 μ g/mL of peptidoglycans (PGN), 0.1 μ g/mL of LPS, 0.5 μ g/mL of flagellin (*S. typhimurium*) and 5 μ g/mL of CpG-ODN 1585 (all of the ligands were purchased from Invivogen), for 8 h, then cells were harvested for RNA isolation.

Quantitative real time polymerase chain reaction

The total RNA from mice colon tissue or RAW 264.7 cells stimulated with different cytokines and TLR ligands was extracted using Trizol reagent (InvitroGen). The cDNA templates were synthesized using the iScriptTM cDNA synthesis kit and quantitative polymerase chain reaction (PCR) reactions were performed with iQTM SYBR green PCR supermix (both from Bio-Rad). Quantitative real time (RT)-PCR analysis was performed using the Bio-Rad iQ5 system and gene expression levels for each individual sample were normalized to GAPDH. Mean relative gene expression was determined and differences were calculated using the $2^{-\Delta C(t)}$ method as described previously^[17]. The following oligonucleotides were used as primers: mindin forward, 5'-CAATGGGCTGAGGGACTTTG and reverse, 5'-TCTCTCCTGCAGCTTCGATCTC, NF- κ B p65 forward, 5'-AGGCTTCTGGGCCTTATGTG and reverse, 5'-TGCTTCTCTCGCCAGGAATAC and GAPDH forward, 5'-TGGCAAAGTGGAGATTGTTGCC and reverse, 5'-AAGATGGTGATGGGCTTCCCG.

For the RT-PCR analysis of mindin expression in different organs, the following primers were employed: mindin forward, 5'-CAGCCCTGACTGGTTTGTGGGC and reverse, 5'-CCCTGGGACTCTGCTGTAGCCGCA CG and hypoxanthine phosphoribosyltransferase (HPRT) forward, 5'-GTTGGATACAGGCCAGACTTTGTTG and reverse, 5'-GATTCAACTTGCCTCATCTTAGGC.

Establishment of mindin expression vector

Full-length of mindin was amplified by PCR from a cDNA template from mouse mesenteric lymph node (MLN) using upstream (containing *Bam*HI site) of 5'-CGGGATCCCGTGATGGAAAACGTGAGTCTTG and downstream (containing *Eco*RI site) of 5'-CGGAA TTCCGACGCAGTTATCTGGGGCACACT primers. Then the fragment was inserted into the *Bam*HI and

*Eco*RI site of the pCMV-Flag-tag 4C (Stratagen) vector, which resulted in the construction of a pCMV-Mindin-Flag expression vector, confirmed by sequencing.

Western blotting analysis

HEK293 cells were transfected with pCMV-Flag, pCMV-Mindin-Flag clone 1 and clone 2 for 24 h, then Western blotting analysis was performed as described previously^[18]. Briefly, 2×10^5 of transfected HEK293 cells were lysed in RIPA buffer (50 mmol/L Tris pH 8, 0.1% SDS, 0.5% deoxycholate, 1% NP-40, 150 mmol/L NaCl, 1 tablet complete mini protease inhibitor/10 mL, Roche Diagnostics GmbH, Germany). Next, equal amounts of total cell lysates were electrophoresed and transferred to Pall Fluoro Trans W membrane (WAKO, Japan). The membranes were incubated with anti-Flag antibody. After washing, the membrane was incubated with horseradish peroxidase-conjugated secondary antibody and visualized using an enhanced chemiluminescence detection system (ECL Advance, Amersham Bioscience, UK).

Dual-luciferase assay

About 5×10^4 of the RAW 264.7 and CMT93 cells were cultured in 24-well plates and transfected with 0.01 μ g of pNF- κ B-Luc (firefly luciferase) (Clontech), 0.001 μ g of pRL-0 vector (Promega) and 0.25 μ g of pCMV-mindin-Flag or pCMV-Flag vectors with Lipofectamine 2000 (Invitrogen, Carlsbad, CA). After 12 h of transfection, the cells were additionally stimulated with 0.05 μ g/mL of Pam3-CSK4, 5 μ g/mL of PGN, 0.1 μ g/mL of LPS, 0.5 μ g/mL of flagellin and 5 μ g/mL of CpG-ODN 1585 for 12 h. Then, luciferase assays were performed using the Dual-Luciferase reporter assay system (Promega, Madison, WI) according to the manufacturer's instructions. *Renilla* luciferase activity was used as an internal control. All experiments were carried out at least 3 times.

Statistical analysis

The data were expressed as the mean \pm SD. Groups were compared using Student's *t*-test. $P < 0.05$ was considered statistically significant.

RESULTS

Mindin mRNA expression is upregulated during acute intestinal inflammation

To investigate the regulation of the mindin gene during acute colitis, we used a colitis model in which 3% of DSS is added to drinking water for six days, which results in epithelial damage and acute inflammation. HE staining of the colon tissue (Figure 1A) revealed that DSS treatment induced severe colitis compared with normal tissue, characterized by epithelial and muscle hypertrophy with patchy lymphocytic infiltrates extending into the muscle layers. Quantitative mRNA expression of NF- κ B p65 (Figure 1C) showed over 15 ± 2.5 fold upregulation compared with control group, supporting the inflammation at the mRNA level. Then we used the same cDNA samples to analyze the mindin expression,

and, surprisingly, mRNA expression of mindin was upregulated in all of the colitis mice (Figure 1B, left graph, $n = 3$, each group). When quantitatively analyzed from triplicate samples of the study mice (Figure 1B, right graph), mindin expression was upregulated 4.7 ± 1.1 fold compared with the baseline during intestinal inflammation.

Mindin mRNA expression is upregulated by CpG-ODN stimulation

To further define the specific regulators of mindin expression *in vitro*, we employed the mouse leukemic monocyte macrophage cell line, RAW 264.7, and stimulated the cells with different cytokines and TLR-ligands. The results show that cytokines of TNF- α and IL-1 β , and the TLR-2, -6, -5 ligands of Pam3-CSK4, PGN and flagellin do not induce upregulation of mindin expression (Figure 2A and B). Of interest, regarding the TLR-9 ligand of CpG-ODN, this ligand induced 4.2 ± 0.3 fold upregulation of mindin mRNA expression. This result suggests that a TLR-9 mediated signaling pathway is involved in this regulation.

Mindin induces NF- κ B promoter activation in a TLR-9 mediated manner

We analyzed mindin expression in multiple mice organs and it was abundantly expressed in intestine, Peyer's patches, spleen, MLN, lung and heart tissue (Figure 3A), in agreement with previous documentation^[4].

To precisely investigate whether the TLRs are involved in a mindin-mediated signaling pathway, we cloned the full-length of mindin from cDNA of mouse MLN and established the pCMV-Mindin-Flag expression vector. HEK293 cells were transfected with pCMV-Flag, pCMV-Mindin-Flag clone 1 and clone 2 for 24 h, followed by Western blotting analysis. As shown in Figure 3B, around 37 kDa of mindin-Flag fusion protein was detected in both clone 1 and 2 lanes and clone 1 was employed in a further experiment, with no detection of protein on control lane at left side.

To define whether NF- κ B pathway activation is involved in this process, RAW 264.7 and CMT93 cells were transfected with pNF- κ B-Luc (firefly luciferase), pRL-0 vector and pCMV-mindin-Flag or pCMV-Flag control vectors. Twelve hours after transfection, stimulation took place with different TLR ligands of Pam3-CSK4, PGN, LPS, flagellin and CpG-ODN 1585 for an additional 12 h, then luciferase assays were performed.

As shown in Figure 3C and D, luciferase activity of NF- κ B promoter was significantly increased by 2.5 ± 0.3 fold and 4.5 ± 0.5 fold, in cells transfected with mindin and stimulated with CpG-ODN, for RAW264.7 and CMT93 cells respectively, compared with the control. LPS induced 2.6 ± 0.2 fold activity in CMT93 cells, but there was no significant difference between mindin and control group. No significant induction of NF- κ B luciferase activation was noted in mindin-transfected cells which underwent Pam3-CSK4, PGN, or flagellin stimulation. This result suggests that mindin induces NF- κ B promoter activation in a TLR-9 mediated manner.

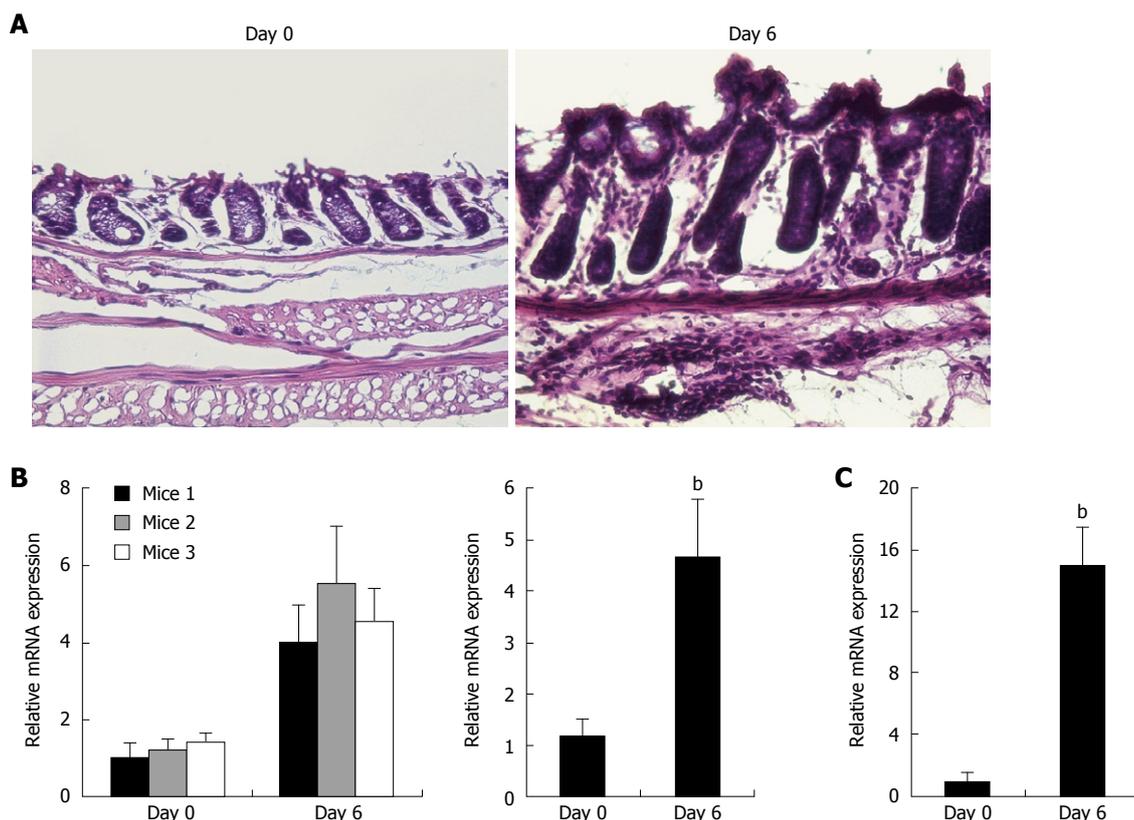

Figure 1 Mindin mRNA expression is upregulated during acute intestinal inflammation. A: Histological analysis of normal tissue and of acute inflammation specimen after 6 d of DSS. HE staining of colonic sections (magnification 40 ×); B: Quantitative mRNA expression of mindin in study mice (left graph, $n = 3$ of each group, triplicate samples from each mouse, right graph combines the data from each group); C: Relative mRNA expression of NF- κ B p65 in study groups. Bars represent mean \pm SD; ^b $P < 0.01$ vs day 0.

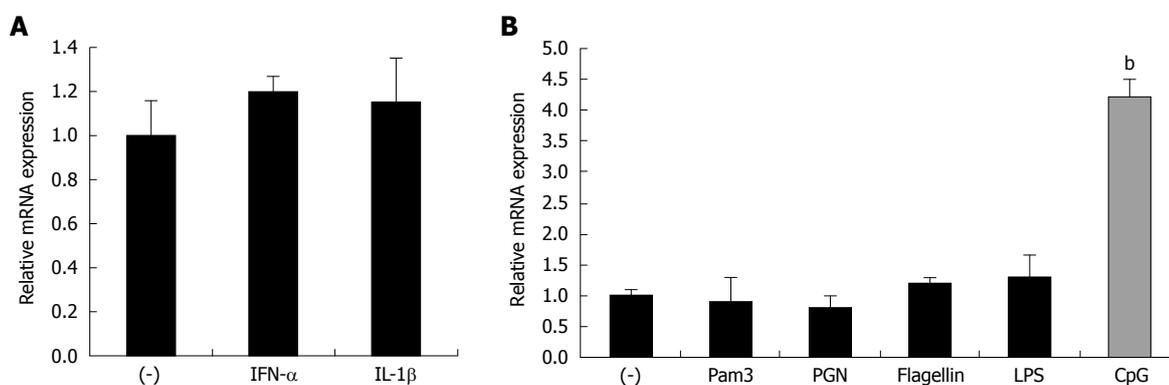

Figure 2 Mindin mRNA expression is upregulated by CpG-ODN stimulation. About 1×10^5 RAW 264.7 cells were cultured in 12-well plates and stimulated with cytokines of mouse recombinant tumor necrosis factor- α (TNF- α) and interleukin-1 β (IL-1 β), toll-like receptor (TLR) ligands of Pam3-CSK4, peptidoglycans (PGN), lipopolysaccharide (LPS), flagellin and CpG-ODN 1585 (B) for 8 h, then cells were harvested for RNA isolation and relative mRNA expression of mindin was analyzed using quantitative real time polymerase chain reaction (RT-PCR). In each group, bars represent mean \pm SD; ^b $P < 0.01$ vs unstimulated cells.

DISCUSSION

Our data demonstrated that mRNA expression of mindin is upregulated during DSS-induced acute intestinal inflammation and *in vitro* co-stimulating data suggested that mindin may induce NF- κ B promoter activation in a TLR-9 mediated manner.

The immune system uses many sensors to detect and report microbial invaders. Most of these sensors are associated with immune cells, but the extracellular matrix

also seems to be essential for this sentinel duty^[19]. Investigators generated mice deficient in mindin; these mice have severe defects in many of their immune responses. The mindin-deficient cells are hyporesponsive to many PAMPs, including lipoteichoic acid, peptidoglycan, zymosan, mannan and CpG DNA^[7]. Other results have indicated that the F-spondin domain mediates integrin binding and identified the binding site by mutagenesis, suggesting that mindin-integrin interactions are critical for inflammatory cell recruitment *in vivo*^[20,21].

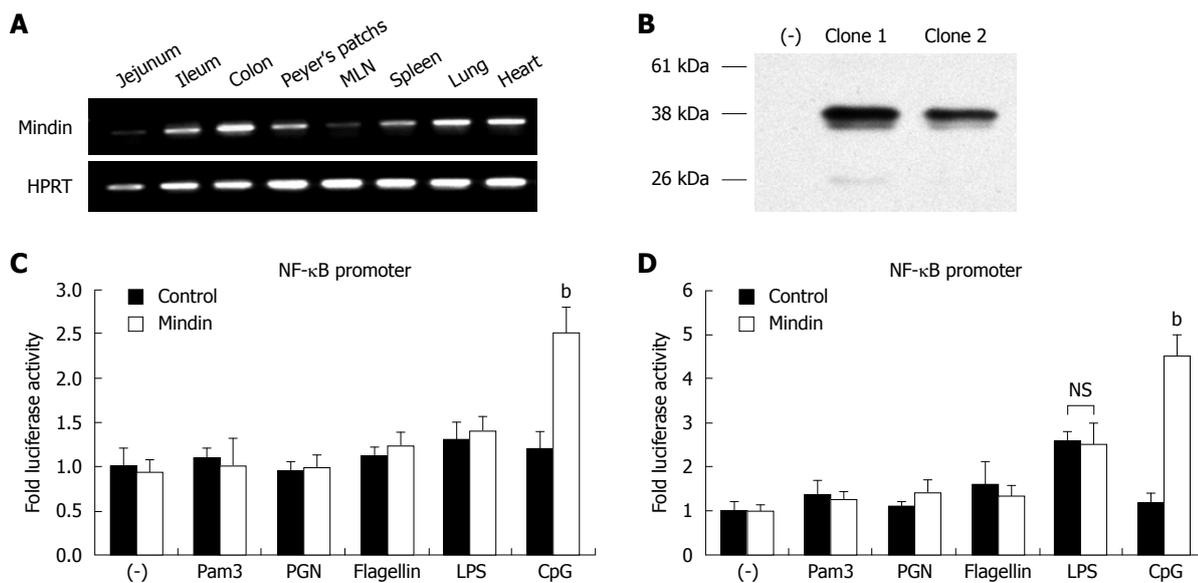

Figure 3 Mindin induces nuclear factor (NF)-κB promoter activation in a TLR-9 mediated manner. A: Mindin mRNA expression in mouse multiple organs, HPRT expression as a total RNA control; B: HEK293 cells were transfected with pCMV-Flag (lane at left side), pCMV-Mindin-Flag clone 1 and clone 2 for 24 h and Western blotting analysis was performed. RAW 264.7 (C) and CMT93 (D) cells were transfected with pNF-κB-Luc (firefly luciferase), pRL-0 vector and pCMV-mindin-Flag or pCMV-Flag control vectors. Twelve hours after transfection, cells were stimulated with the different TLR ligands of Pam3-CSK4, PGN, LPS, flagellin and CpG-ODN 1585 for an additional 12 h, then luciferase assays were performed. NS: Not significant. ^bP < 0.01 vs control.

These studies indicate the essential role of mindin in both innate and adaptive immunity, but information regarding its regulation is poorly understood. Also, the role of other cytokines and the interaction of DCs with T cells need to be further investigated, and different organ-specific inflammation models need to be established. DSS is thought to induce colitis by inducing mucosal erosion which is observed 5 d after DSS administration, allowing commensal bacteria to infiltrate into the lamina propria. Our data showed that DSS-induced colitis is associated with an increased activation of NF-κB. Hall *et al.*^[22] demonstrate that commensal bacterial DNA can suppress Treg cell conversion *via* TLR9-mediated activation of lamina propria dendritic cells and thus potentially disrupt intestinal homeostasis, and also show a relationship with mindin expression^[22,23]. Our data demonstrated that mRNA expression of mindin is upregulated during DSS-induced acute intestinal inflammation and that CpG-ODN stimulation induced 4.2 ± 0.3 fold upregulation of mindin expression in RAW 264.7 cells, suggesting that mindin has indispensable diverse roles in mucosal immunity.

The activation of known signaling pathways in response to LPS is largely unaffected in mindin-deficient cells, implicating that mindin may bind to a distinct receptor and activate other TLRs or different signal transduction pathways. Production of TNF and IL-6 induced by PAMPs is reduced in mindin-deficient macrophages indicating that mindin-induced signaling is as important as those well-defined signaling pathways that are largely transduced through TLRs^[7,10]. However, the exact mechanism of mindin-mediated TLR recognition of microbial components remains unclear. Recent findings suggest that NF-κB has not only proinflammatory but also tissue-protective functions in inflammatory diseases. NF-κB has multiple, often opposing functions in the intestine^[24].

Antiapoptotic actions of NF-κB in intestinal epithelial cells dominate tissue responses to many acute inflammatory and injurious challenges, whereas proinflammatory and cell survival functions of NF-κB in macrophages and T cells govern chronic intestinal inflammation. Our data showed that luciferase activity of the NF-κB promoter is significantly increased in mice macrophage and intestinal epithelial cell lineages stimulated with exogenous mindin and CpG-ODN, but not in the cells stimulated with other TLR ligands, suggesting that mindin induces NF-κB promoter activation through a TLR-9 mediated pathway. While basolateral TLR stimulation mobilizes an inflammatory cascade, apical TLR-9 stimulation delivers negative signals that curtail inflammatory responses to basolateral stimulation *via* different TLRs^[25]. Mindin was initially identified in zebrafish and was found to selectively accumulate in the basal lamina^[1]. Taken together, our data suggest that while basolateral TLR-9 signaling is fully capable of inducing a NF-κB-mediated pro-inflammatory response, apical TLR-9 signaling does not induce an inflammatory response due to a defect in NF-κB activation.

However, while mindin binds to some kinds of bacteria and integrins, it is still unclear whether mindin functions as a coreceptor for several PPRs or other novel receptors and we urge further broad studies to address these questions. Our results raise the importance of the TLR-9 mediated pathway and provide a clue to help define more precisely the function and signaling pathways of the mindin protein.

COMMENTS

Background

Mindin is a member of the mindin-F-spondin family of secreted extracellular matrix proteins. Mindin mRNA is abundantly expressed in the spleen and lymph nodes. Mindin-deficient mice are resistant to lipopolysaccharide-induced

septic shock and exhibit an impaired ability to clear bacterial infections. Mindin-deficient macrophages and mast cells show defective responses to a broad spectrum of microbial stimuli. Mindin also functions as an opsonin for macrophage phagocytosis of bacteria. Despite previous studies indicating that mindin is important in both innate and adaptive immunity, information regarding its regulation is poorly understood and activation of signaling pathways are not well investigated.

Research frontiers

Mindin has an indispensable role in both innate and adaptive immunity. This study investigated regulation of mindin expression and the signaling pathway involved.

Innovations and breakthroughs

Despite previous studies indicating that mindin is important in both innate and adaptive immunity, information regarding its regulation is poorly understood and activation of signaling pathways are not well investigated. The data of this study demonstrated that mRNA expression of mindin is upregulated during dextran sulfate sodium-induced acute intestinal inflammation and *in vitro* co-stimulating data suggested that mindin may induce nuclear factor (NF)- κ B promoter activation in a toll-like receptor (TLR)-9 mediated manner.

Applications

While mindin binds to some kinds of bacteria and integrins, it is still unclear whether mindin functions as a coreceptor for several PPRs or other novel receptors and we urge further broad studies to address these questions. The results of this study raise the importance of the TLR-9 mediated pathway and provide a clue to help define more precisely the function and signaling pathways of the mindin protein.

Terminology

Mindin is an extracellular matrix protein. NF- κ B has not only proinflammatory but also tissue-protective functions in inflammatory diseases. Basolateral TLR-9 signaling is fully capable of inducing a NF- κ B-mediated pro-inflammatory response.

Peer review

In this work the authors propose that mindin expression is upregulated during intestinal inflammation and may induce NF- κ B promoter activation through a TLR-9 mediated manner. The initial observation is interesting, but the authors should include the biological and clinical significance of the mindin upregulation in colitis in the discussion section.

Abstract

AIM: To investigate the effects of sulfated cholecystokinin octapeptide (CCK-8S) on the contractile activity of guinea-pig proximal colon.

METHODS: Proximal colonic smooth muscle (PCSM) strips were obtained from adult female guinea pigs and contractile response of PCSM strips was recorded using a polyphysiograph. PCSM cells were isolated by enzymatic digestion. Resting potential (RP), action potential (AP), large conductance potassium channel currents (I_{BKCa}) and L-type calcium currents (I_{Ca-L}) were recorded by patch-clamp techniques.

RESULTS: (1) CCK-8S (10^{-7} mol/L) enhanced the mean contractile amplitude of colonic circular muscle and longitudinal muscle (LM) strips by $56.53\% \pm 11.92\%$

($P = 0.038$) and $65.93\% \pm 12.98\%$ ($P = 0.019$), respectively, as well as the mean frequency of LM by $31.69\% \pm 13.58\%$ ($P = 0.023$), which were significantly attenuated by pretreating strips with devazepide, nifedipine, iberiotoxin, thapsigargin (TG) and BAPTA-AM (BA) respectively; (2) CCK-8S (10^{-7} mol/L) increased the AP amplitude by $38.6\% \pm 3.2\%$ ($P = 0.015$), decreased AP duration by $36.9\% \pm 8.7\%$ ($P = 0.026$), and depolarized the RP from -61.3 ± 2.7 mV to -29.8 ± 5.9 mV ($P = 0.032$); and (3) Compared with the normal control group, CCK-8S (10^{-7} mol/L) enhanced the peak current of I_{BKCa} by $18.7\% \pm 2.1\%$ (from 916 ± 183 pA to 1088 ± 226 pA; at +60 mV; $P = 0.029$), which was inhibited by respective pretreatment with iberiotoxin and devazepide. Additionally, CCK-8S (10^{-7} mol/L) intensified the peak current of I_{Ca-L} by 40% (from 60 ± 8 pA to 84 ± 11 pA; at +10 mV; $P = 0.012$), compared to the normal control group, which was apparently suppressed by respective pretreatment with nifedipine, devazepide, TG and BA. In the respective presence of heparin and staurosporine, CCK-8S did not significantly enhance I_{BKCa} and I_{Ca-L} .

CONCLUSION: The results suggest that CCK-8S promotes guinea-pig proximal colon contraction by CCK1 receptors, following activation of the inositol triphosphate-protein kinase C signal transduction pathway.

INTRODUCTION

Cholecystokinin (CCK), a gut-brain peptide, plays an important role in regulating a variety of physiological functions such as the stimulation of exocrine and endocrine secretion, mediation of emotion and behavior, and the regulation of gut motor functions^[1-3]. Previous studies investigating the targets for CCK in the gastrointestinal tract have focused mainly on the gallbladder and pancreas. However, recent research has shown that CCK and its related peptides are implicated in the pathophysiology of functional digestive diseases, such as irritable bowel syndrome (IBS). Several early reports also have indicated that either an altered release of CCK or abnormal responses to this peptide could be responsible for the symptoms of IBS^[3-5].

It has been reported that sulfated CCK octapeptide (CCK-8S) is the predominant and major molecular form of CCK peptides^[6,7] and it actions on the gastrointestinal tract through two receptor subtypes, designated as CCK1 and CCK2^[3]. Previous studies have shown that some mechanisms could be involved in the effect of CCK on smooth muscle motility in the gastrointestinal tract. First, it has been reported that CCK1 receptors appear to be involved mainly in the control of gut motility and visceral sensation^[2,3,8-10]. CCK2 receptors mainly contribute to the release of histamine from enterochromaffin-like cells in the stomach^[11], and the stimulation of acid secretion from parietal cells^[12,13]. Second, Morton *et al.*^[14] have demonstrated that CCK-induced contraction of the human colon and gallbladder smooth muscle is mediated solely through the CCK1 receptor, whereas Fornai *et al.*^[3,15] have reported that CCK2 receptors mediate the inhibitory action of the peptide on the contractile activity of human distal colon, *via* the nitric oxide pathway. Furthermore, activation of protein kinase C (PKC) can enhance L-type calcium current (I_{Ca-L}) in a variety of smooth muscles^[16]. It has been shown that CCK can activate phospholipase C through binding to its distinct receptors^[7,17]. CCK-8S-evoked $[Ca^{2+}]_i$ concentration increase in gastric antral smooth muscle cells (SMCs) depends on the release of $[Ca^{2+}]_i$ stores that are regulated positively by CCK1 receptors *via* PKC-mediated phosphorylation of inositol trisphosphate (IP₃) type 3 receptor^[7]. Released Ca^{2+} in turn activates I_{Ca-L} , which ultimately results in the contraction of the gastric smooth muscle^[7]. However, the direct electrophysiological effects of CCK on the contractile activity of the colon and the crosstalk between the CCK-8S-triggered PKC and Ca^{2+} signaling pathways in colon SMCs remain unclear.

Therefore, in the present study, we investigated the effects of CCK-8S on the contraction of proximal colon smooth muscle strips, resting potential (RP), action potential (AP), large conductance potassium channel current (I_{BKCa}) and I_{Ca-L} in smooth muscle cells (SMCs) of proximal colon. In addition, the role of the IP₃-mediated protein kinase C (PKC) pathway in the physiological responses of SMCs to CCK-8S was also studied.

MATERIALS AND METHODS

Experimental animals

Adult female guinea pigs (250-300 g) were obtained by mail from the Experimental Animal Center of Wuhan University and housed under controlled conditions and temperature ($25 \pm 2^\circ\text{C}$). The animal-testing protocol used in the present investigation was approved by the Institutional Animal Care and Use Committee of Wuhan University.

Reagents and solutions

The physiological saline solution (CaPSS) contained (in mmol/L): NaCl 135.0, KCl 5.0, $CaCl_2$ 2.0, $MgCl_2$ 1.2, glucose 10.0, and HEPES 10.0 (adjusted to pH 7.4 with NaOH). The Ca^{2+} -free PSS contained similar ingredients, without $CaCl_2$. Tyrode buffer contained (in mmol/L): NaCl 147.0, KCl 4.0, $CaCl_2$ 2.0, NaH_2PO_4 0.42, Na_2HPO_4 2.0, $MgCl_2$ 1.05, and glucose 5.5 (adjusted to pH 7.4 with NaOH). KB solution contained (in mmol/L): EGTA 0.5, HEPES 10.0, $MgCl_2$ 3.0, KCl 50.0, glucose 10.0, L-glutamate 50.0, taurine 20.0, and KH_2PO_4 20.0 (adjusted to pH 7.4 with NaOH). Digestive solution contained: 0.1% collagenase II, 0.1% trypsin inhibitor and 0.2% BSA dissolved in Ca^{2+} free-PSS. Internal pipette solution used in experiments investigating APs and RPs contained (in mmol/L): K-aspartate 120.0, HEPES 10.0, EGTA 10.0, Na_2ATP 5.0, $MgCl_2$ 4.0, and $CaCl_2$ 3.0 (adjusted to pH 7.4 with KOH). Internal pipette solution of large conductance potassium channel contained (in mmol/L): KCl 20.0, K-aspartate 110.0, $MgCl_2 \cdot 6H_2O$ 1.0, $Mg-ATP$ 5.0, Na_2 creatine phosphate 2.5, EGTA 2.5, and 2.0 $\mu\text{g/mL}$ nystatin (adjusted to pH 7.4 with KOH). Internal pipette solution of L-type calcium channel contained (in mmol/L): CsCl 135.0, $MgCl_2$ 4.0, HEPES 10.0, Na_2-ATP 2.0, EGTA 10.0, tetraethylammonium (TEA) 20.0, and 2.0 $\mu\text{g/mL}$ nystatin (adjusted to pH 7.35 with Tris-HCl). All these chemicals together with CCK-8S, nifedipine, iberiotoxin, thapsigargin (TG) and BAPTA-AM (BA) were purchased from Sigma (St Louis, MO, USA). Devazepide and CI 988 were purchased from Tocris Bioscience (UK).

Preparation of isolated colonic smooth muscle strips

Guinea pigs were sacrificed by ether, followed by cervical exsanguination. The proximal colon was removed, cleaned and opened along the mesenteric border and then placed in Ca^{2+} -free PSS bubbled with carbogen (95% O_2 /5% CO_2). The smooth muscle strips (3 mm \times 10 mm) were obtained after the mucosa and submucosa were excised.

Preparation of isolated colonic SMCs

Single SMCs were isolated by enzymatic digestion as described previously^[18]. The strips of proximal colon were pinned to the base of the sylgard surface of a Petri dish and the mucosa was carefully dissected away under an anatomical microscope. The tissue was cut into small strips (about 2 mm wide and 5-6 mm long) and placed in Ca^{2+} -free PSS solution that contained 0.12% (w/v) collagenase

II supplemented with 0.2% soybean trypsin inhibitor and 0.2% bovine serum albumin (BSA), and incubated for 25 min at 37°C. After completion of digestion, the segments were washed five times in a Ca²⁺-free PSS solution and then triturated gently with a fire-polished Pasteur pipette to create a cell suspension. Cells were stored at 0–4°C and used within 8 h.

Contraction recording of proximal colonic smooth muscle (PCSM) strips

Each fresh smooth muscle strip was mounted in an organ bath and connected to an isometric force transducer (JZJOIH, Chengdu, China). The organ baths contained 10 mL Tyrode's buffer at 37°C and were constantly warmed by a circulating water jacketed at 37°C, and bubbled with carbogen (95% O₂/5% CO₂). One end of the strip was fixed to a hook on the bottom of the chamber, while the other end was connected by a thread to an external isometric force transducer at the top. Each muscle strip was placed under a resting preload of 1.0 g and allowed to equilibrate for 60 min, with solution change every 20 min. The frequencies of contraction were calculated by counting the contraction waves per minute. The mean contractile amplitude and frequency of spontaneous contractions were recorded (control values) and compared with the mean contractile amplitude and frequency when exposed to treatment (response values). The results were presented as the changed percentage (changed percentage = 100% × (response value - control value)/control value)^[19].

Measurement of RPs and APs in isolated colonic SMCs

Several drops of cell suspensions were placed in a recording chamber that was mounted with an inverted microscope. Cells were superfused with CaPSS (3 mL/min) after adhering to the coverslip. Membrane potentials were recorded by EPC-10 amplifier (HEKA, Lambrecht, Germany). Cells were patch-clamped in current clamp mode after a 10-min equilibration. The AP stimulus pattern was composed of a 600-pA current step for 8 ms; the holding current of which was 0 pA. After several minutes equilibration, the current-clamp mode was transformed into the whole-cell voltage-clamp mode and the RP was shown in the V-membrane screen. Drugs were added subsequently to the cell suspension to observe relative effects on AP and RP when their values were stable.

Nystatin-perforated whole-cell patch-clamp recordings

Several drops of cell suspensions were placed in a recording chamber that was mounted with an inverted microscope (Olympus, Japan). After adhering to the coverslip, the cells were infused with Tyrode's buffer (3 mL/min). Pipettes were made using a micropipette puller (PC-10; Narishige, Japan). Typical pipette resistances were 3–5 MΩ. A gigaseal was formed with negative suction. Capacitance was compensated for and the residual capacitance current was removed digitally. Whole-cell currents were recorded by using a *nystatin-perforated* whole-cell patch-clamp configuration with an EPC-10 amplifier (HEKA, Germany). The

effects of CCK-8S at different concentrations were investigated on I_{BKCa} and I_{Ca-L}. Data were filtered at 200 Hz, digitized at 10 kHz (filter 1) and 2.9 kHz (filter 2), and stored in the computer for subsequent analyses. All the experiments were conducted at 25 ± 2°C.

Statistical analysis

Statistical analyses were performed using SPSS for Windows, version 15.0. Results are expressed as the mean ± SD of *n* strips or cells. Data were compared using Student's *t* tests. *P* < 0.05 was considered statistically significant.

RESULTS

Effects of CCK-8S on the contraction of PCSM strips

CCK-8S enhanced the resting tension of PCSM strips when applied for 3–5 min (Figure 1). CCK-8S (10⁻⁷ mol/L) increased the mean contractile amplitude of circular muscle (CM) and longitudinal muscle (LM) strips by 56.53% ± 11.92% and 65.93% ± 12.98%, respectively, as well as the mean frequency of LM by 31.69% ± 13.58% (*n* = 15 for each group, *P* = 0.038, 0.019, 0.023), but CCK-8S had little influence on the frequency of CM (*n* = 15, *P* = 0.087) (Figure 1, Table 1). CCK-8S-intensified effects on proximal colonic strips were significantly attenuated when these strips were pretreated with CCK1 receptor antagonist devazepide (10⁻⁷ mol/L), L-type calcium channel inhibitor nifedipine (10⁻⁵ mol/L), Ca²⁺-ATPase inhibitor TG (10⁻⁵ mol/L), or intracellular calcium chelator BA (10⁻⁵ mol/L) (*n* = 15 for each group, *P* < 0.05). Pretreating CM and LM strips with iberiotoxin (10⁻⁶ mol/L), a selective BKCa channel blocker, did not inhibit the CCK-8S-induced increase in the contractile amplitude of CM and LM strips (*n* = 15 for each group, *P* = 0.096, 0.078 *vs* CCK-8S group), but decreased their frequency (*n* = 15 for each group, *P* = 0.036, 0.041 *vs* CCK-8S group) (Figure 1, Table 1), whereas superfusion with the CCK2 receptor antagonist CI 988 (10⁻⁷ mol/L) did not block the CCK-8S-intensified effect on CM and LM strips (*n* = 15 for each group, *P* > 0.05) (Figure 1, Table 1).

Effects of CCK-8S on RPs and APs of PCSMCs

CCK-8S (10⁻⁷ mol/L) depolarized RP of SMCs from -61.3 ± 2.7 mV to -29.8 ± 5.9 mV (*n* = 15, *P* = 0.032) (Figure 2). In the presence of devazepide (10⁻⁷ mol/L), CCK-8S (10⁻⁷ mol/L) did not depolarize RP (-59.4 ± 3.8 mV, *n* = 15, *P* = 0.065 *vs* control group) (Figure 2). When SMCs were preincubated with CI 988, CCK-8S (10⁻⁷ mol/L) depolarized RP to -32.8 ± 4.2 mV (*n* = 15, *P* = 0.029 *vs* control group) (Figure 2). The AP amplitude was expressed as peak value, and the mean amplitude in the control group (CaPSS) was 169.9 ± 12.3 mV (*n* = 15) (Figure 3A and D). After the addition of CCK-8S (10⁻⁷ mol/L), the AP amplitude was increased by 38.6% ± 3.2% [from 169.9 ± 12.3 mV (in control CaPSS) to 235.5 ± 11.6 mV, *n* = 15, *P* = 0.015] (Figure 3A–C and E), and fast repolarization time (repolarizing to 90% of the peak value of AP, T₉₀) was shortened by 36.9% ± 8.7% [from 48.42 ± 3.38 ms (in control CaPSS) to 30.53 ± 4.15 ms, *n* = 15, *P* = 0.026]

Table 1 Effects of CCK-8S on the contractile amplitude and frequency of CM and LM strips of proximal colon (mean \pm SD)

	CM strips		LM strips	
	Amplitude	Frequency	Amplitude	Frequency
CCK-8S	56.53 \pm 11.92 ^a	0.87 \pm 1.52	65.93 \pm 12.98 ^a	31.69 \pm 13.58 ^a
Devazepide + CCK-8S	3.68 \pm 1.17	1.92 \pm 0.83	2.09 \pm 0.78	1.57 \pm 1.07
Nifedipine + CCK-8S	-79.26 \pm 5.93 ^c	-19.82 \pm 3.92 ^c	-78.69 \pm 6.42 ^c	-21.58 \pm 2.87 ^c
Iberiotoxin + CCK-8S	49.93 \pm 11.81	-36.57 \pm 17.35 ^c	57.47 \pm 10.92	-23.82 \pm 5.97 ^c
TG & BA + CCK-8S	-98.12 \pm 0.72 ^d	-97.42 \pm 2.73 ^d	-97.57 \pm 1.25 ^d	-96.11 \pm 3.26 ^d

^a $P < 0.05$ vs control group; ^c $P < 0.05$, ^d $P < 0.01$ vs CCK-8S group. CCK: Cholecystokinin; CM: Circular muscle; LM: Longitudinal muscle; TG: Thapsigargin; BA: BAPTA-AM.

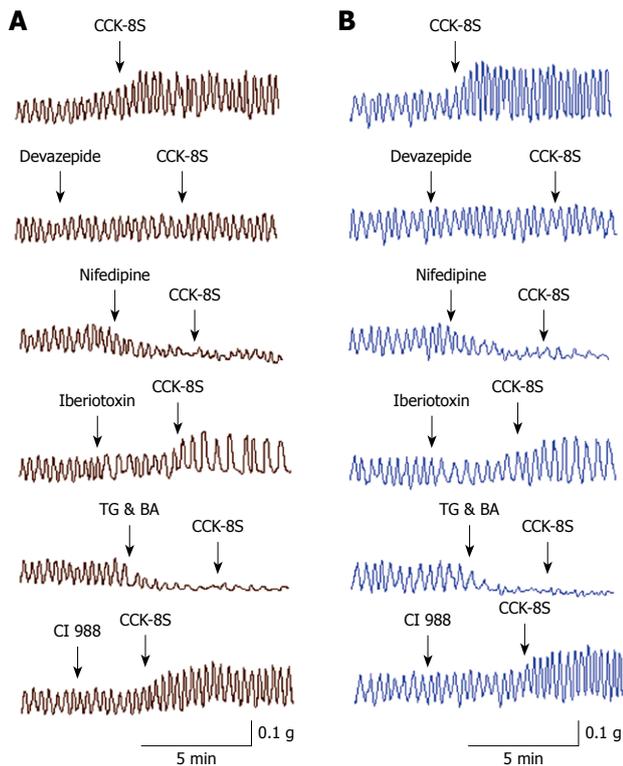

Figure 1 Effects of CCK-8S on the resting tension of guinea pig proximal colonic smooth muscle (PCSM) strips. A: Representative traces of the effect of CCK-8S (10^{-7} mol/L) on the resting tension of circular muscle (CM) strips. CCK-8S increased the mean contractile amplitude of CM strips, which was inhibited by pretreatment with CCK1 receptor antagonist devazepide (10^{-7} mol/L), L-type calcium channel inhibitor nifedipine (10^{-5} mol/L), Ca^{2+} -ATPase inhibitor thapsigargin (TG) (10^{-5} mol/L) and intracellular calcium chelator BAPTA-AM (BA) (10^{-5} mol/L). Pretreating CM strips with iberiotoxin (10^{-6} mol/L), a selective potassium channel inhibitor, did not block the CCK-8S-induced increase in the contractile amplitude of CM strips but decreased the frequency; B: Representative traces of the effect of CCK-8S (10^{-7} mol/L) on the resting tension of longitudinal muscle (LM) strips. The CCK-8S-induced increase in the amplitude and frequency of LM strips was inhibited by pretreatment with devazepide (10^{-7} mol/L), nifedipine (10^{-5} mol/L) or TG (10^{-5} mol/L) and BA (10^{-5} mol/L). Pretreating LM strips with iberiotoxin (10^{-6} mol/L) did not attenuate the CCK-8S-induced increase in the contractile amplitude of LM strips but decreased the frequency. CCK2 receptor antagonist CI 988 had no effect on the CCK-8S-induced contraction of CM and LM strips.

(Figure 3A, B, D and F), which were blocked when SMCs were pretreated with 10^{-7} mol/L devazepide (171.2 ± 13.4 mV, 47.18 ± 3.45 ms, $n = 15$, $P = 0.006$ vs CCK-8S group, $P = 0.074$ vs control group) (Figure 3E and F). In

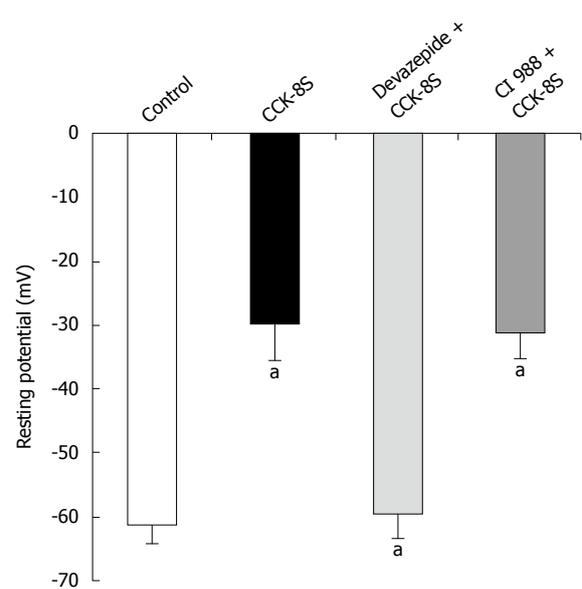

Figure 2 Effects of CCK-8S on resting potential (RP) of PCSMCs. RP rose from -61.3 ± 2.7 mV to -29.8 ± 5.9 mV after superfusion with CCK-8S (10^{-7} mol/L). In the presence of devazepide (10^{-7} mol/L), CCK-8S (10^{-7} mol/L) did not depolarize RP (-59.4 ± 3.8 mV). When SMCs were pretreated with CI 988, CCK-8S (10^{-7} mol/L) depolarized RP to -29.8 ± 5.9 mV. ^a $P < 0.01$ vs control group (CaPSS).

contrast, CI 988 did not inhibit the CCK-8S-evoked effect on AP amplitude and T_{90} (228.8 ± 12.9 mV, 31.26 ± 3.97 ms, $n = 15$, $P = 0.083$ vs CCK-8S group) (Figure 3E and F). After SMCs were incubated with nifedipine (10^{-5} mol/L), the enhancement of AP amplitude by CCK-8S was inhibited (75.6 ± 8.3 mV, $n = 15$, $P = 0.039$ vs CCK-8S group) (Figure 3A and E). In addition, superfusion with iberiotoxin (10^{-6} mol/L) significantly attenuated the effect of CCK-8S on T_{90} (46.54 ± 4.88 ms, $n = 15$, $P = 0.026$ vs CCK-8S group; $P = 0.079$ vs control group) (Figure 3B and F).

Effects of CCK-8S on I_{BKCa} in PCSMCs

With nystatin-perforated whole-cell voltage-clamp recordings, I_{BKCa} was evoked by using a depolarizing step pulse from a holding potential of -60 mV to $+100$ mV for 400 ms, with an interpulse interval of 10 s (Figure 4A). To reduce the amount of non- Ca^{2+} -dependent delayed rectifier K^{+} currents through inactivation, cells were held at

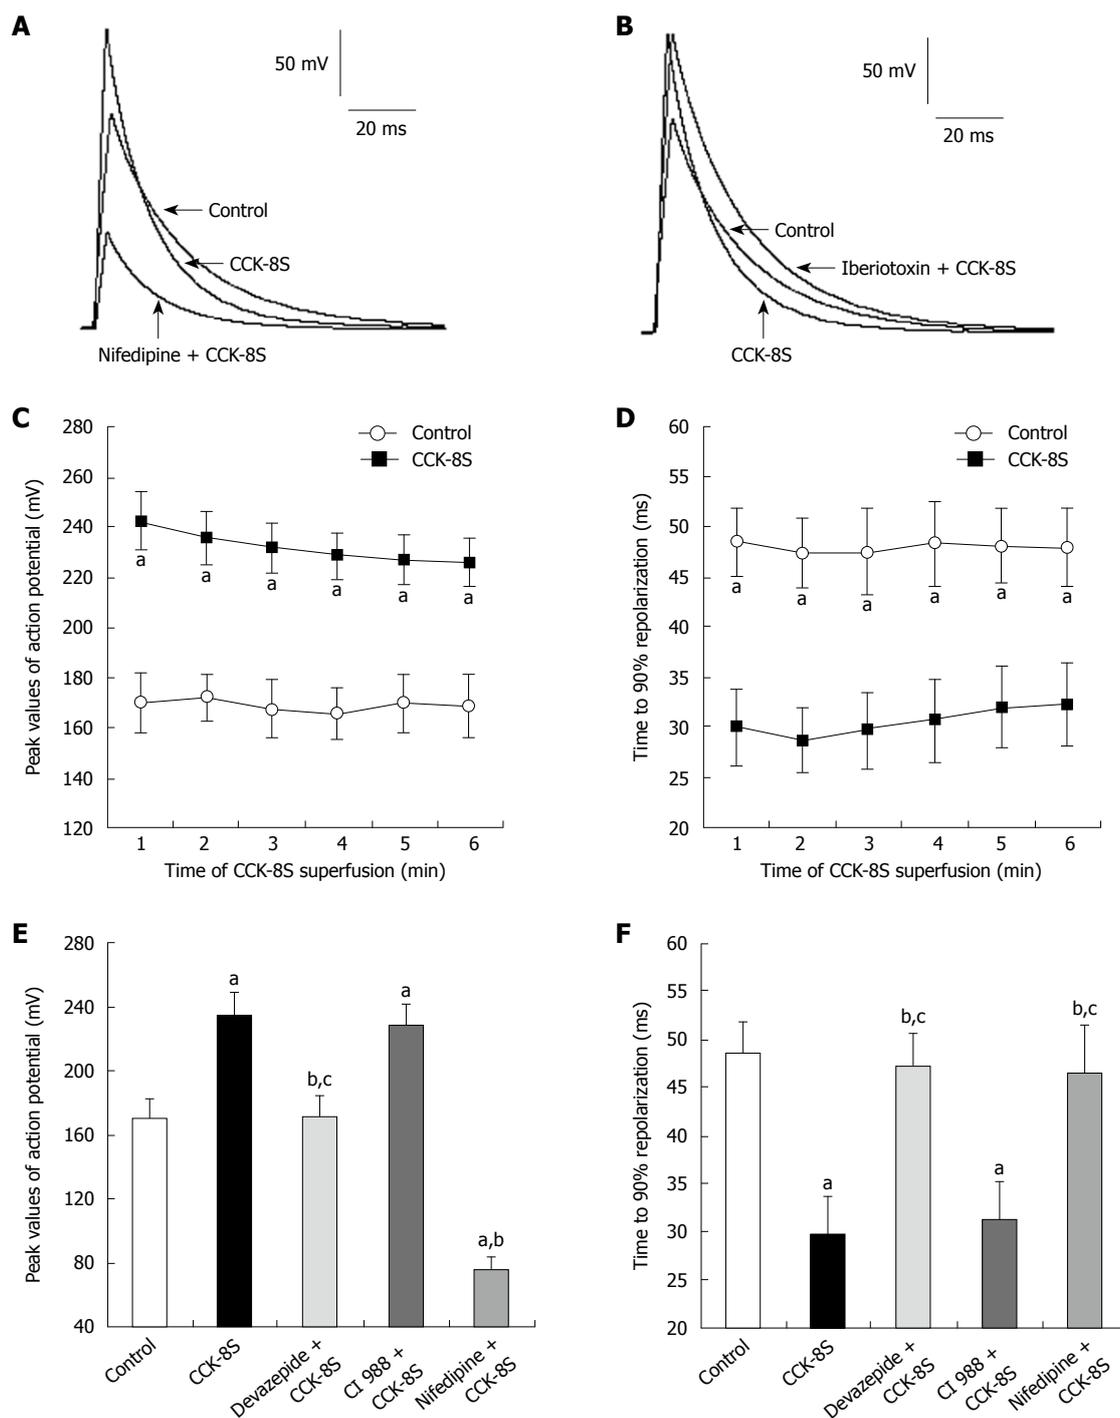

Figure 3 Effects of CCK-8S on AP of PCSMCs. A-C and E: CCK-8S (10^{-7} mol/L) suppressed the amplitude of AP to $38.6\% \pm 3.2\%$ ($n = 15$, $P < 0.01$); A, B, D and F: CCK-8S (10^{-7} mol/L) decreased fast repolarization times (T_{90}) by $36.9\% \pm 8.7\%$ ($n = 15$, $P < 0.01$); A and E: Nifedipine (10^{-5} mol/L) blocked the effects of CCK-8S on the amplitude of AP but failed to have any effect on T_{90} ; B and F: Iberiotoxin (10^{-6} mol/L) blocked the effects of CCK-8S on T_{90} but failed to have any effect on the amplitude of AP; E and F: Pretreating SMCs with devazepide (10^{-7} mol/L) blocked the CCK-8S-evoked effect on AP amplitude and T_{90} , whereas CI 988 had no such effect. ^a $P < 0.01$ vs control group (CaPSS); ^b $P < 0.01$ vs CCK-8S group; ^c $P > 0.05$ vs control group.

0 mV for at least 2 min before being subjected to step depolarization^[18,19], and superfused with 3 mmol/L 4-aminopyridine in the extracellular solutions^[18,20]. The application of iberiotoxin (10^{-5} mol/L) markedly blocked the inward current by 79% (at +60 mV, 192 ± 37 pA) (Figure 4A), which demonstrated that this current was I_{BKCa} . CCK-8S increased I_{BKCa} in a concentration-dependent manner ($n = 8$, $P < 0.05$, at 10^{-8} , 10^{-7} and 10^{-6} mol/L; $EC_{50} = 3.5 \times$

10^{-8} mol/L; Figure 4B). Compared with the CaPSS control group, CCK-8S (10^{-7} mol/L) enhanced peak I_{BKCa} depolarized to +60 mV by about $18.7\% \pm 2.1\%$ (from 916 ± 183 pA to 1088 ± 226 pA, $n = 8$, $P = 0.029$) (Figure 4A). Although this enhancement effect was blocked by pretreatment with 10^{-7} mol/L, devazepide (908 ± 109 pA, $n = 8$, $P = 0.012$ vs CCK-8S group, $P = 0.083$ vs control group) (Figure 4A), the CCK2 receptor antagonist CI 988

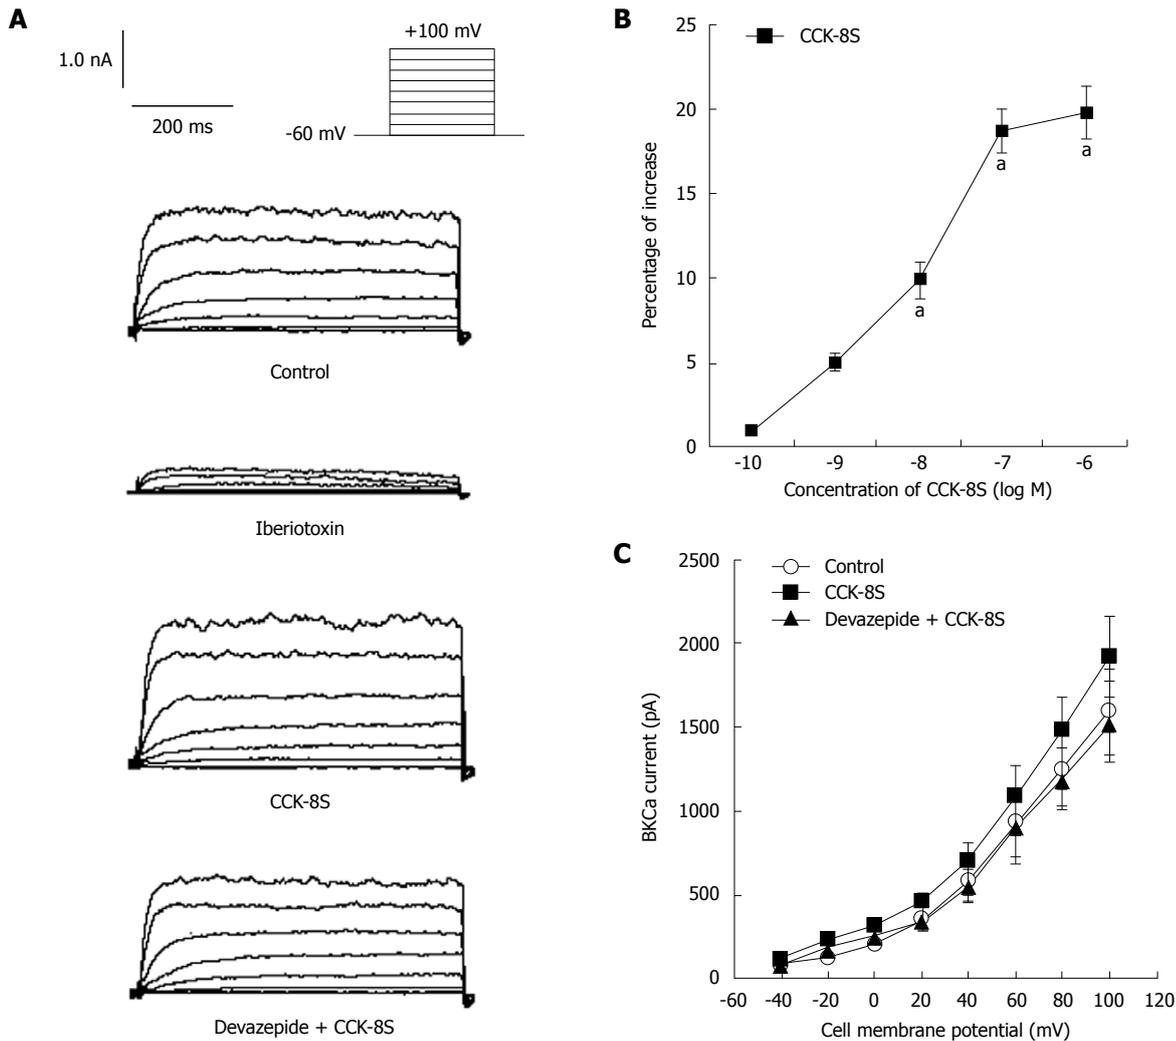

Figure 4 Effects of CCK-8S on I_{BKCa} of PCSMCs. A: Current traces of I_{BKCa} were recorded from -60 mV to +100 mV during 400 ms depolarization; B: CCK-8S increased I_{BKCa} in a concentration-dependent manner ($EC_{50} = 3.5 \times 10^{-8}$ mol/L); CCK-8S (10^{-7} mol/L) enhanced I_{BKCa} depolarized from -60 mV to +60 mV (from 916 ± 183 pA to 1088 ± 226 pA; $n = 8$, $P < 0.01$); C: Current-voltage relationship of average peak I_{BKCa} under each condition. CCK-8S-evoked enhancement of I_{BKCa} was suppressed by devazepide (10^{-7} mol/L). $^{\#}P < 0.05$ vs control group (CaPSS).

(10^{-7} mol/L) had no effect (1052 ± 196 pA, $n = 8$, $P = 0.098$ vs CCK-8S group).

When heparin (10^{-6} mol/L), an inhibitor of IP_3 receptors, was added to the pipette solution, I_{BKCa} in cells depolarized to +60 mV was 813 ± 126 pA. CCK-8S (10^{-7} mol/L) did not enhance I_{BKCa} (879 ± 117 pA, $n = 8$, $P = 0.074$ vs control group, $P = 0.016$ vs CCK-8S group) (Figure 5A and B). To investigate whether the CCK-8S-intensified effect on I_{BKCa} was mediated by the PKC pathway, SMCs were pretreated with the PKC inhibitor staurosporine (10^{-6} mol/L), and I_{BKCa} in cells depolarized to +60 mV was 835 ± 112 pA. CCK-8S (10^{-7} mol/L) had no effect on I_{BKCa} (887 ± 120 pA; $n = 8$; $P = 0.069$ vs control group; $P = 0.041$ vs CCK-8S group; Figure 5C and D).

Effects of CCK-8S on I_{Ca-L} in PCSMCs

With nystatin-perforated whole-cell voltage-clamp recordings, I_{Ca-L} was evoked by using a depolarizing step pulse from a holding potential of -40 mV to +30 mV for 400 ms, with an interpulse interval of 10 ms (Figure 6A). I_{Ca-L} reached a maximum value at around +10 mV and the in-

ward current was markedly blocked by 80% by nifedipine (10^{-5} mol/L), which indicated that this current was I_{Ca-L} (Figure 6C). CCK-8S increased the amplitude of I_{Ca-L} in a concentration-dependent manner ($n = 8$, $P < 0.05$, at 10^{-8} , 10^{-7} and 10^{-6} mol/L; $EC_{50} = 3.2 \times 10^{-8}$ mol/L; Figure 6B). When CCK-8S (10^{-7} mol/L) was applied for 3-6 min, the amplitude of I_{Ca-L} was augmented by about 40% (from 60 ± 8 pA to 84 ± 11 pA), compared to the normal controls (at +10 mV, $n = 8$, $P = 0.012$) (Figure 6A). Although this enhancement effect was completely inhibited by 10^{-7} mol/L CCK1 receptor antagonist devazepide (61 ± 9 pA; at +10 mV, $n = 8$, $P = 0.023$ vs CCK-8S group, $P = 0.079$ vs control group) (Figure 6C), the CCK2 receptor antagonist CI 988 (10^{-7} mol/L) had no effect (84 ± 11 pA, $n = 10$, $P = 0.079$ vs CCK-8S group). CCK-8S-intensified I_{Ca-L} was reduced by $91.7 \pm 5.6\%$ by 10^{-5} mol/L TG and BA (7 ± 5 pA, at +10 mV, $n = 8$, $P = 0.006$ vs CCK-8S group) (Figure 6C). The current-voltage relationships are shown in Figure 6D. The peak current amplitudes of I_{Ca-L} under each condition were normalized relative to the maximum control current amplitude.

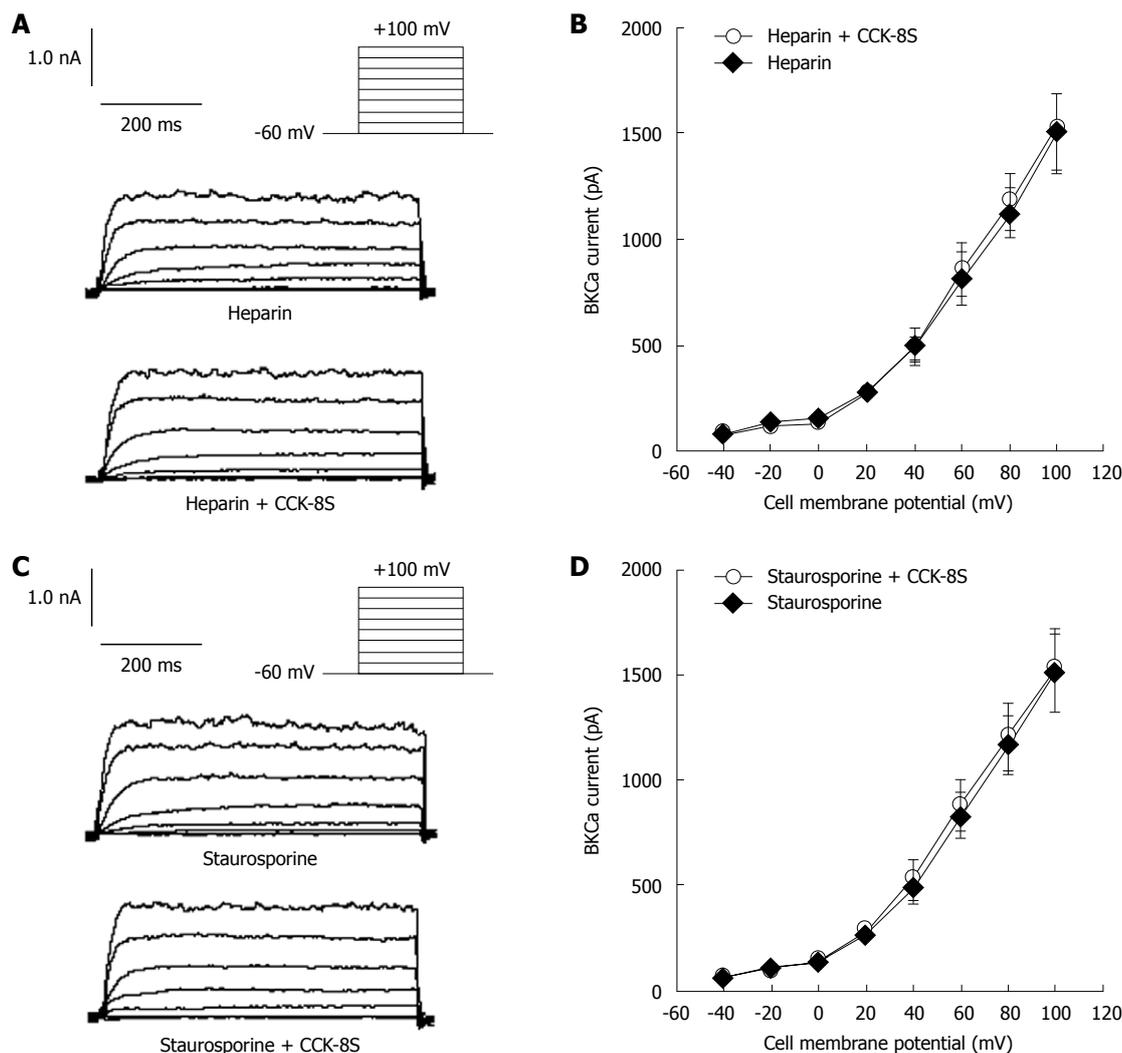

Figure 5 Heparin and staurosporine prevented CCK-8S-intensified I_{BKCa} in PCSMCs. A and C: Current traces of I_{BKCa} were evoked by a step from -60 mV to +60 mV; B: When heparin (10^{-6} mol/L) was present in the pipette solution, CCK-8S (10^{-7} mol/L) did not increase I_{BKCa} ; D: CCK-8S (10^{-7} mol/L) failed to increase I_{BKCa} in the presence of staurosporine (10^{-6} mol/L).

When 10^{-6} mol/L heparin was added to the pipette solution, CCK-8S (10^{-7} mol/L) had no effect on I_{Ca-L} (63 ± 12 pA, at +10 mV, $n = 8$, $P = 0.183$ vs control group, $P = 0.042$ vs CCK-8S group) (Figure 7). When SMCs were pretreated with 10^{-6} mol/L PKC inhibitor staurosporine for 10 min, CCK-8S (10^{-7} mol/L) did not increase I_{Ca-L} (65 ± 10 pA, at +10 mV, $n = 8$, $P = 0.215$ vs control group; $P = 0.032$ vs CCK-8S group) (Figure 7).

DISCUSSION

In the present study, we demonstrated that: (1) CCK-8S prompted the contraction of guinea pig PCSM strips and intensified I_{BKCa} and I_{Ca-L} by CCK1 receptors *via* activation of the IP_3 -PKC signal transduction pathway; and (2) CCK-8S increased AP amplitude through enhancing I_{Ca-L} , and accelerated fast repolarization of AP by increasing I_{BKCa} .

CCK has been implicated in the pathophysiology of functional digestive diseases, such as IBS^[1-3] and exerts its effects by two specific receptors, designated as CCK1 and CCK2, which are expressed in the colon and have

a high affinity for CCK-8S^[3,8-15,21,22]. However, it remains unknown which receptor plays a more important role in mediating colon contractility. Our results showed that CCK-8S not only promoted the mean contractility and frequency of longitudinal PCSM strips, but also the mean contractility of circular PCSM strips. Devazepide and CI 988 are CCK antagonists that are selective for the CCK1 and CCK2 receptor, respectively, and are used widely in scientific research^[23,24]. Pretreatment with CCK1 receptor antagonist devazepide markedly abolished CCK-8S-intensified contraction of PCSM strips, whereas CCK2 receptor antagonist CI 988 had little effect, thus indicating that CCK1 instead of CCK2 receptor plays a major role in mediating the motility of the proximal colon. It is consistent with the effect of CCK-8S on the gastric antral smooth muscle^[7] and human ascending colonic smooth muscle^[14].

Elevation in $[Ca^{2+}]_i$ concentration is an important function in the regulation of cell contraction and can be accomplished by release from internal calcium stores, extracellular Ca^{2+} influx across the plasma membrane, or both^[25,26]. Ca^{2+} -ATPase inhibitor TG and $[Ca^{2+}]_i$ chela-

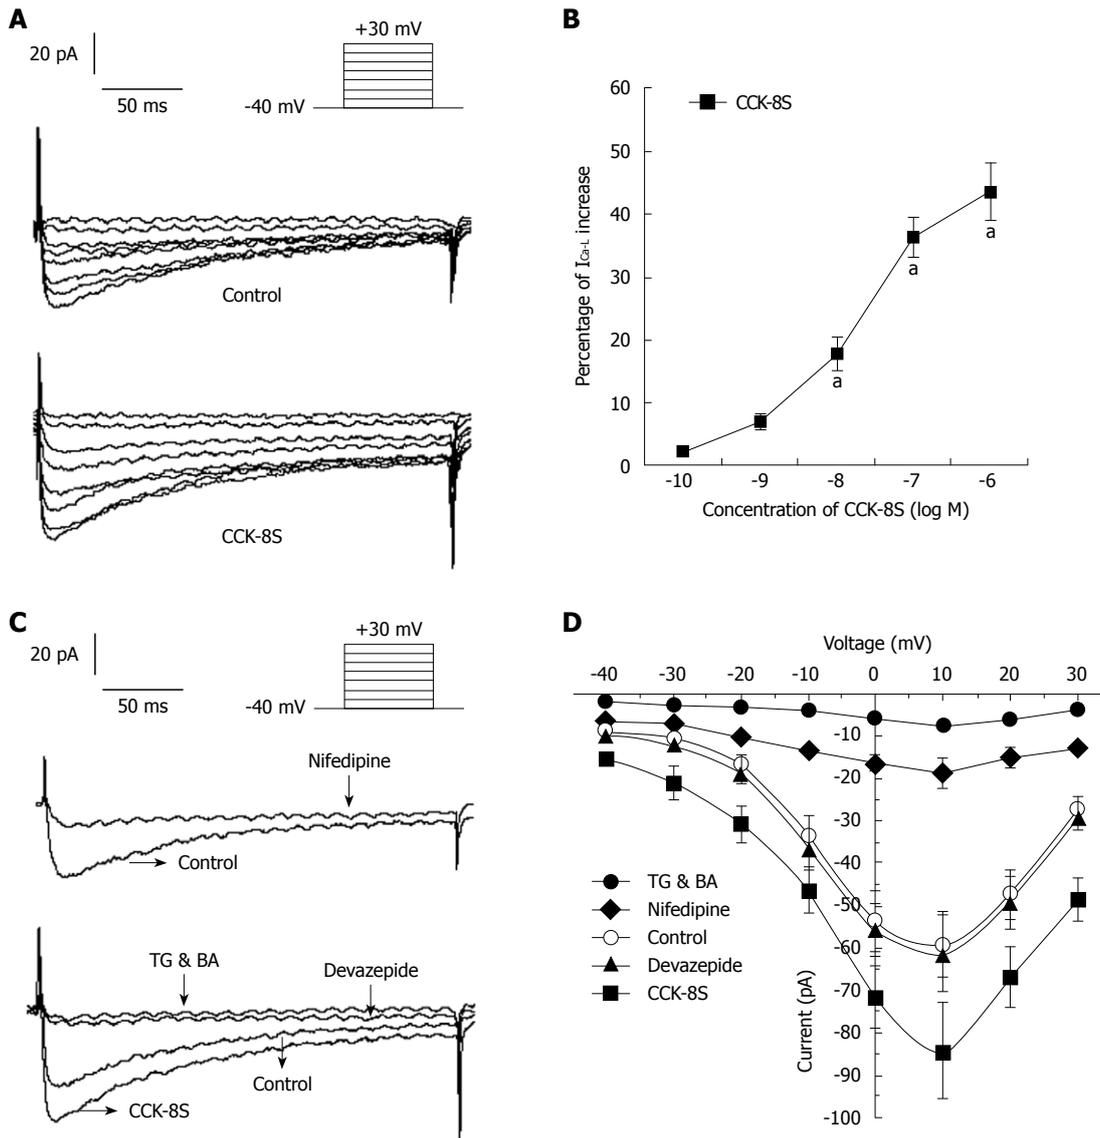

Figure 6 Effects of CCK-8S, nifedipine and devazepide on I_{Ca-L} in PCSMCs. A: Current traces of I_{Ca-L} were recorded from -40 mV to +30 mV during 400 ms depolarization; B: CCK-8S enhanced I_{Ca-L} in a concentration-dependent manner ($EC_{50} = 3.2 \times 10^{-8}$ mol/L); CCK-8S (10^{-7} mol/L) increased I_{Ca-L} depolarized from -40 mV to +10 mV (from 60 ± 8 pA to 84 ± 11 pA; $n = 8$); C: CCK-8S-intensified I_{Ca-L} was markedly suppressed by devazepide (10^{-7} mol/L), nifedipine (10^{-5} mol/L), TG and BA (10^{-5} mol/L); D: Current-voltage curves of whole-cell patch clamp under each condition. Compared with control, CCK-8S (10^{-7} mol/L) significantly enhanced I_{Ca-L} , whereas devazepide, nifedipine, TG and BA inhibited I_{Ca-L} . $^*P < 0.05$ vs control group (CaPSS).

tor BA are used to deplete $[Ca^{2+}]_i$; and are often used in experiments to explore the role of intracellular calcium stores and signaling pathways^[7,27,28], whereas nifedipine is often used to examine the role of extracellular Ca^{2+} influx^[7]. We found that CCK-8S-evoked contraction of PCSM was significantly antagonized by pretreatment not only with CCK1 receptor antagonist devazepide, but also with nifedipine, TG and BA, but CCK2 receptor antagonist CI 988 had little effect, thus indicating that CCK-8S acts on the CCK1 receptor and enhances extracellular Ca^{2+} influx by L-type calcium channels and promotes Ca^{2+} release from intracellular calcium stores by intracellular signaling pathways.

APs are responsible for the contractile activity of colon SMCs. The upstroke of the AP is mainly the result of calcium entry through L-type calcium channels, and the number of APs within a certain period of time can be

regarded as an indicator of contractility of gastrointestinal SMCs^[18,29]. In this study, we demonstrated that CCK-8S enhanced AP amplitude and shortened the period of fast repolarization, by increasing AP generation as well as depolarizing RP. All these effects could be inhibited by pretreatment with CCK1 receptor antagonist devazepide, but CCK2 receptor antagonist CI 988 had little influence. It is also well known that contraction of gastrointestinal SMCs results from the close interaction between the two mechanisms: an initial peak caused by calcium release from stores and a plateau phase caused by calcium influx^[30-33]. Based on these studies, we found that CCK-8S intensified I_{Ca-L} in a concentration-dependent manner, which was significantly attenuated by pretreatment with devazepide and nifedipine, but CI 988 exerted little effect, indicating that extracellular calcium entry through L-type calcium channels is essential for contraction of PCSM cells, and

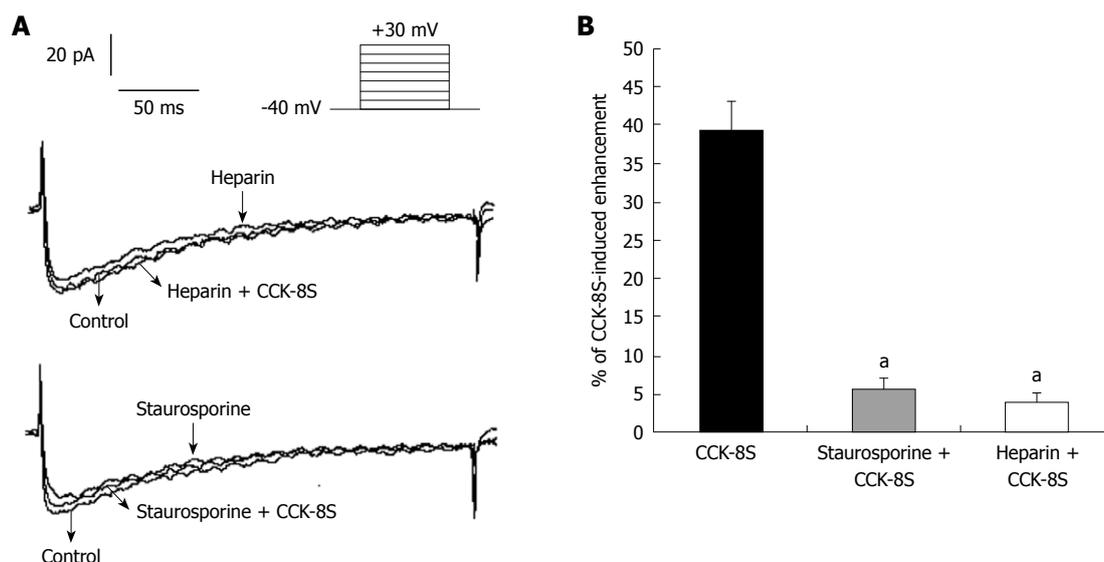

Figure 7 Heparin and staurosporine prevented CCK-8S-intensified I_{Ca-L} in PCSMCs. **A:** Current traces of I_{Ca-L} were evoked by a step from -40 mV to $+10$ mV. When heparin (10^{-6} mol/L) was present in the pipette solution, CCK-8S (10^{-7} mol/L) did not increase I_{BKCa} ; CCK-8S (10^{-7} mol/L) failed to increase I_{BKCa} in the presence of staurosporine (10^{-6} mol/L); **B:** CCK-8S-induced enhancement of I_{Ca-L} in the absence and presence of staurosporine and heparin, respectively. $^aP < 0.05$ vs CCK-8S group.

the increase in I_{Ca-L} induced by CCK-8S through CCK1 receptors can depolarize membrane potentials, which may contribute to the decrease in RP. We also found that the depletion of $[Ca^{2+}]_i$ by the Ca^{2+} -ATPase inhibitor TG and $[Ca^{2+}]_i$ chelator BA completely blocked CCK-8S-intensified I_{Ca-L} and contraction of PCSM. Moreover, the characteristic of the current-voltage curve was not significantly altered. Thus, we can suppose that $[Ca^{2+}]_i$ stores are primarily responsible for the CCK-8S-induced contraction, and this can lead to depolarization of the membrane, which in turn leads to calcium influx through L-type calcium channels, to cause a further increase in $[Ca^{2+}]_i$ and, ultimately, contraction of PCSMCs.

Large-conductance calcium activated potassium channels have been identified in guinea pig colonic SMCs, and are associated with fast repolarization (repolarizing to 90% of the peak value of AP, T_{90})^[18,30]. We thus studied whether CCK-8S could also affect I_{BKCa} . We showed that CCK-8S shortened the time to T_{90} and augmented I_{BKCa} in a concentration-dependent manner, whereas this effect was inhibited by potassium channel blocker iberiotoxin, and the CCK1 receptor antagonist devazepide, but the CCK2 receptor antagonist CI 988 exerted little effect. Furthermore, the characteristics of the current-voltage curve were not apparently altered. Our results demonstrated that CCK-8S shortened the refractory period and accelerated the repolarization of the AP by increasing I_{BKCa} , mediated by activation of CCK1 receptors, which may enhance the contractile frequency and ultimately result in a synergistic effect on the contraction.

It is well established that IP_3 and PKC play an important role in the regulation of smooth muscle movement. Activation of phosphatidylinositol (4,5) bisphosphate can generate IP_3 , which binds to IP_3 receptors in the sarcoplasmic reticulum (SR) and then induces the release of Ca^{2+} from the intracellular calcium stores, which immediately activates PKC to exert its biological effects^[7,33].

Likewise, serotonin promotes contraction of colonic myocytes, mostly as a result of Ca^{2+} release from SR following activation of the IP_3 pathway^[18]. In addition, CCK-induced gallbladder muscle contraction can be blocked by the PKC inhibitor staurosporine^[33]. In agreement with these results, we demonstrated that heparin, an inhibitor of IP_3 receptors, blocked CCK-8S-intensified I_{Ca-L} and I_{BKCa} in isolated PCSMCs. When cells were pretreated with the PKC inhibitor staurosporine, CCK-8S had no effect on I_{Ca-L} and I_{BKCa} . These results may further indicate that CCK-8S regulates I_{Ca-L} and I_{BKCa} by activating the IP_3 -PKC signal transduction pathway. However, the exact mechanism by which CCK-8S enhances the activity of IP_3 -mediated PKC has not been elucidated.

In conclusion, CCK-8S evokes contraction of the proximal colon in guinea pigs, mainly by promoting Ca^{2+} release from the SR and increasing Ca^{2+} influx through L-type calcium channels, *via* the IP_3 -PKC signal transduction pathway by activation of CCK1 receptors. In addition, the decrease in AP duration is caused by the acceleration of fast repolarization of AP by increased I_{BKCa} , and the increase in AP amplitude results from enhancement of I_{Ca-L} , which both ultimately contribute to the contraction induced by CCK-8S.

COMMENTS

Background

Cholecystokinin (CCK) acts as a hormone and neurotransmitter in the gastrointestinal tract, and regulates gut motility *via* two receptor subtypes, which have been characterized as CCK1 and CCK2, although the direct electrophysiological effect of CCK on the contractile activity of colon remains undetermined. The authors investigated how CCK regulates colon contraction through CCK receptors.

Research frontiers

CCK has been implicated in the pathophysiology of functional digestive diseases. In this study, the authors demonstrated the electrophysiological mechanisms that mediate CCK octapeptide (CCK-8S)-induced contraction and the relationship between the CCK-8S-triggered protein kinase C (PKC) and Ca^{2+} signaling pathways in colon smooth muscle cells.

Innovations and breakthroughs

The present study has proved that: (1) CCK-8S elicited stimulant effects on the motor activity of guinea pig proximal colon through CCK1 receptors, following activation of the inositol trisphosphate (IP₃)-PKC signal transduction pathway; and (2) the decrease in action potential (AP) duration was caused by acceleration of fast repolarization of the AP by increased large conductance potassium channel currents, and the increase in AP amplitude was caused by enhancement of L-type calcium current, which both ultimately contribute to the contraction induced by CCK-8S. This is believed to be the first report on the electrophysiological mechanisms of proximal colon contraction evoked by CCK-8S in guinea pigs.

Applications

The results of this study indicate that CCK stimulates proximal colon contraction through CCK1 receptors following activation of the IP₃-PKC signal transduction pathway, which could be useful in further study of functional digestive diseases, such as irritable bowel syndrome.

Peer review

This appears to be a well executed piece of work. The authors have established clearly that CCK-8S stimulates the contraction of colonic circular and longitudinal muscle through the CCK1 receptor, and that enhanced Ca effects are involved.

Abstract

AIM: To investigate the expression of vascular endothelial cell growth factor (VEGF) and its receptors Fms-like tyrosine kinase 1 (FLT-1) and fetal liver kinase 1 (FLK-1) in colorectal carcinoma (CRC), and the blocking effects of small interfering RNAs (siRNAs) on VEGF expression in human colorectal cancer HCT116 cells.

METHODS: Immunohistochemical staining for VEGF, FLT-1 and FLK-1 proteins was performed in 82 cases of CRC and 14 normal colorectal mucosae. A siRNA targeting VEGF was synthesized and transfected into HCT116 cells using lipofectamine 2000. Immunocytochemical staining and Western blotting analyses were performed to detect the expression of VEGF protein. The suppressive effect of the siRNA on cell proliferation was detected using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltertrazolium bromide (MTT) assay. Cellular apoptosis was detected using flow cytometry (FCM).

RESULTS: The expression of VEGF, FLT-1 and FLK-1 in tumor tissues was significantly higher than that in

normal tissues ($P = 0.008$, $P = 0.000$, $P = 0.000$). The expression of VEGF was positively correlated with both lymph node metastasis and clinical stage ($P = 0.009$ and $P = 0.025$, respectively). Immunocytochemistry showed that the expression of VEGF was weakly positive and Western blotting indicated a significant reduction in VEGF-siRNA cell protein levels. VEGF-siRNA cell growth inhibition was assessed by the MTT assay, and the tumor cell proliferation rate was significantly different at 24, 48, and 72 h after transfection. FCM results showed that the VEGF-siRNA group had an apparent aneuploid peak.

CONCLUSION: VEGF, FLT-1 and FLK-1 are associated with colorectal carcinogenesis. siRNA silencing of the VEGF gene suppresses proliferation, and induces apoptosis in HCT116 cells. The results suggest that VEGF may be a new gene therapy target for colorectal cancer.

INTRODUCTION

Colorectal carcinoma (CRC) is one of the most common malignant diseases in China and has a poor survival

rate. The carcinogenesis and development of CRC is a complex process attributable to numerous factors. Angiogenesis plays an important role in tumor growth. Neovascularization is regulated by multiple factors, but the most important one is vascular endothelial cell growth factor (VEGF), which exerts its effects of increasing microvascular growth and permeability *via* specific receptors^[1]. Fms-like tyrosine kinase 1 (FLT-1) and fetal liver kinase 1 (FLK-1) are the most important among these receptors. At present, the main treatment for CRC is excision of the primary tumor, followed by radiotherapy and chemotherapy. However, in many cases, this still leaves problems such as metastatic lesions and subsequent cancer recurrence. Recently, following the development of modern molecular biology, in-depth researches have been conducted in developing new strategy of CRC treatment at a genetic level. In particular, RNA interference (RNAi) technology has the potential to become an effective treatment for tumors^[2], and has established a new area of clinical therapy for CRC^[3]. In this study, immunohistochemical staining using a streptavidin-peroxidase method for the VEGF, FLT-1, and FLK-1 proteins was performed on 82 CRC and 14 normal colorectal mucosal samples in an attempt to explore their roles in CRC. Moreover, a VEGF-targeting small interfering RNA (siRNA) was transferred into human colorectal cancer HCT116 cells to explore its effects on proliferation and apoptosis.

MATERIALS AND METHODS

Patients and samples

Eighty-two CRC specimens and matched adjacent normal mucosae were obtained from the Department of Pathology, First Affiliated Hospital, Anhui Medical University between 2007 and 2008. None of the patients had been treated with radiotherapy or chemotherapy before surgery. Samples were taken from areas of the tumor tissue with no evidence of hemorrhage or putrescence. Samples of matched normal mucosa were collected from the surgical cutting edge, which was approximately 3-5 cm away from the cancerous lesion. The clinical diagnosis of all 82 patients was confirmed by histological examination after surgery. The colon cancer cell line, HCT116, was obtained from the Chinese Academy of Sciences.

Immunohistochemistry

The mouse anti-human VEGF monoclonal antibody (clone VG1), and rabbit anti-human FLT-1 and FLK-1 polyclonal antibodies (clone RAB-0525, clone RAB-0522) were purchased from Maixin Co. (China). Immunohistochemistry was performed as follows: Sections were deparaffinized and rehydrated for 3 × 3 min in xylene; 3 × 2 min in 100% ethanol; 2 min in 95% ethanol, 2 min in 75% ethanol and, finally, 2 × 1 min in distilled water. Antigens were recovered by heating in a microwave oven for 15 min, and the sections were washed for 3 × 5 min with phosphate buffered solution (PBS). Endogenous peroxidase activity was blocked by soaking the slides in

a solution of 3% hydrogen peroxide for 15 min at room temperature (RT), followed by washing for 3 × 5 min with PBS. Non-immune animal blood serum (50 μL) was added to each section for 15 min at RT, followed by primary antibody (50 μL). Slides were incubated overnight at 4°C in a humidified chamber, then washed for 3 × 10 min in PBS. Biotin-labeled secondary antibody (50 μL) was added to each section and kept for 15 min at 37°C, followed by 3 × 5 min washes with PBS. Samples were incubated for 15 min at RT and washed for 3 × 5 min in PBS, before addition of 100 L freshly prepared 3,3-diaminobenzidine (DAB) for approximately 5-20 min. The reaction was stopped by washing in cold water. Slides were counterstained with hematoxylin followed by a sealing procedure using neural gum. A known-positive section served as the positive control, and sections in which the primary antibody was omitted served as negative controls. VEGF, FLT-1 and FLK-1 protein expressions were observed in the cytoplasm and graded according to Volm's standard^[4]: (1) Counting the percentage of positive cells within the total number in each high power field (no positive cells = grade 0, less than 25% positive = grade 1, 25%-50% = grade 2, > 50% = grade 3); and (2) The intensity of staining: no positively stained cells = grade 0, weak staining = grade 1, moderate staining = grade 2, strong staining = grade 3. Aggregate analysis of the results from (1) and (2): grade 0 = negative (-), grade 1-2 = weakly positive (+), grade 3-4 = moderately positive (++) , grade 3-4 = strongly positive (+++). The intensity of the staining was estimated independently by two pathologists.

siRNA design

The sequence of the VEGF-targeting siRNA was as follows: Sense 5'-GGAGUACCCUGAUGAGAUCd TdT-3', Antisense 5'-GAUCUCAUCAGGGUACUC CdTdT-3'. All siRNAs were purchased from Shanghai ShineGene Molecular Biotechnology Co., Ltd. Each siRNA was resuspended in water and the stock solutions (20 μmol/L) were stored at 4°C until use.

Cell culture

The colon cancer cell line, HCT116, was grown as a monolayer in RPMI-1640 (Hyclone) containing 10% fetal bovine serum. Cells were maintained at 37°C in a humidified 5% CO₂ incubator.

Transfection of siRNA

siRNA transfection was done according to the protocol supplied by Invitrogen. Briefly, 1 × 10⁵ cells were seeded into six-well plates containing antibiotic-free medium and incubated overnight. For each well, 5 μL siRNA was mixed with 125 μL OPTI-MEM I. The mixture was then combined with a solution of 5 μL lipofectamine in 125 μL OPTI-MEM I and, after a 20-minute incubation at RT, the mixture was applied to the cells in a final volume of Opti-MEM I, making the final concentration of 100 nmol/L for each siRNA. After incubation for 6 h at 37°C, RPMI-1640 supplemented with serum was added.

Cells were then cultured for an additional 24 h at 37°C before analysis.

Immunocytochemistry

After 48 h transfection, HCT116 cells were fixed in cold methanol/acetone (1:1) at -20°C for 20 min and washed twice in PBS. The fixed cells were treated with 3% hydrogen peroxide for 5 min to eliminate endogenous peroxidase activity. After blocking with 1.5% horse serum for 20 min, the cells were incubated with primary anti-Survivin antibody (Santa Cruz) for 30 min at RT, or overnight at 4°C. The cells were then incubated with biotinylated goat anti-mouse IgG (Dako), followed by peroxidase-labeled streptavidin solution (Dako) for 20 min at RT. Antibodies were visualized using DAB (Sigma). All cells were counterstained with hematoxylin and the experiments were repeated three times. Negative control slides omitting the primary antibody were included for each staining.

Western blotting

Anti-VEGF and anti- β -actin antibodies were obtained from Zhongshan Goldenbridge Biotechnology Co., Ltd. (Santa Cruz). For Western blotting analysis, cells were harvested 48 h after transfection, washed with cold PBS, and lysed with phenylmethanesulfonyl fluoride lysis buffer. After centrifugation at 12000 r/min for 30 min, the supernatant was analyzed for protein content using the bicinchoninic acid reagent. Total protein (50 μ g) was electrophoresed on a 10% SDS-PAGE gel, and transferred onto a polyvinylidene fluoride membrane. The membranes were blocked with PBS buffer containing 5% fat-free milk and 0.1% Tween20 for 30 min at RT, and then incubated with primary anti-VEGF antibody for at least 1 h at RT, or overnight at 4°C. Finally, the membranes were washed three times with PBS containing 0.1% Tween20, incubated with peroxidase-conjugated secondary antibodies, and developed using the ECL reagent (Pierce).

3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltertrazolium bromide (MTT) assay

Cells were grown in 96-well plates (1×10^3 cells/well) and then transfected with VEGF-targeting siRNA. Control cells were treated with DMEM containing 0.1% dimethyl sulfoxide (DMSO). At 24, 48, and 72 h following siRNA transfection, 20 μ L of MTT was added to each well to a final concentration of 0.5%. After a 4-h incubation at 37°C in the dark, 150 μ L DMSO was added to each well for 10 min to dissolve the formazan crystals. The absorbance was measured using an ELISA reader (EXL800, USA) at 490 nm. All experiments were repeated three times. The viability of the siRNA-transfected cells was expressed as a percentage of population growth plus the standard error of the mean relative to that of untransfected control cells. Cell death caused by siRNA-transfection was calculated as a percentage of inhibition as follows: % inhibition = $(1 - \text{mean experimental absorbance} / \text{mean control absorbance}) \times 100$.

Flow cytometric analysis

At 48 h after transfection, samples (1×10^6 cells) were fixed in 70% (v/v) ethanol, washed, and RNase (0.25 mg/mL) and Tween20 [0.1% (v/v)] were added for 30 min at RT. The cells were then stained with propidium iodide and analyzed using a flow cytometer (EPICS XL; Beckman). A sub-G0-G1 peak was detected on the DNA plots using the Cell Quest software. The peak indicates the apoptosis rate of the cells.

Statistical analysis

The statistical software package SPSS 13.0 was used. Data were analyzed using either the χ^2 test or Fisher's exact test. Non-parametric Spearman rank correlation analysis was used for analysis of ranked data. The rates were compared using Z tests. A *P* value < 0.05 was regarded as significant.

RESULTS

Expression of VEGF, FLT-1 and FLK-1 proteins in CRC and normal mucosa

Of the 82 CRC cases examined, 57 (69.5%) expressed VEGF protein. Among them, three cases (5.2%) were weakly positive (+), 30 cases (52.6%) were moderately positive (++), and 24 cases (42.1%) were strongly positive (+++). Of the 14 normal mucosa cases, only 4 (28.6%) were weakly positive for VEGF protein expression. These results confirmed that VEGF protein was present at significantly higher levels in CRC cases than in normal mucosa (*P* < 0.01). Also, FLT-1 (82.9%) and FLK-1 (81.7%) protein expression was significantly higher in CRC cases than in normal mucosa (*P* < 0.01) (Figure 1 and Table 1). We also found a positive correlation between FLT-1 and FLK-1 expression (*r* = 0.457, *P* < 0.05) in the CRC samples.

Relationship between VEGF, FLT-1 and FLK-1 protein expression and clinical pathological features in CRC

The positive rate for VEGF protein in the lymph node-positive group (86.7%) was significantly higher than that in the lymph node-negative group (59.6%, *P* < 0.01), and there were significant differences between the stage A, B, and C + D groups (57.9%, 60.6%, and 86.7%, respectively, *P* < 0.05). The expression of VEGF protein was not correlated with age, gender, depth of tumor invasion, or degree of differentiation (*P* > 0.05). Moreover, the expression of the FLT-1 and FLK-1 proteins was not correlated with any clinical pathological features of CRC (*P* > 0.05, Table 2).

Expression of VEGF protein in HCT116 cells after transfection

The cells positively stained by the anti-VEGF antibody accounted for 92%-100%. The normal control group, Lipofectamine 2000 control group, and mismatched control group all showed strongly positive cytoplasmic

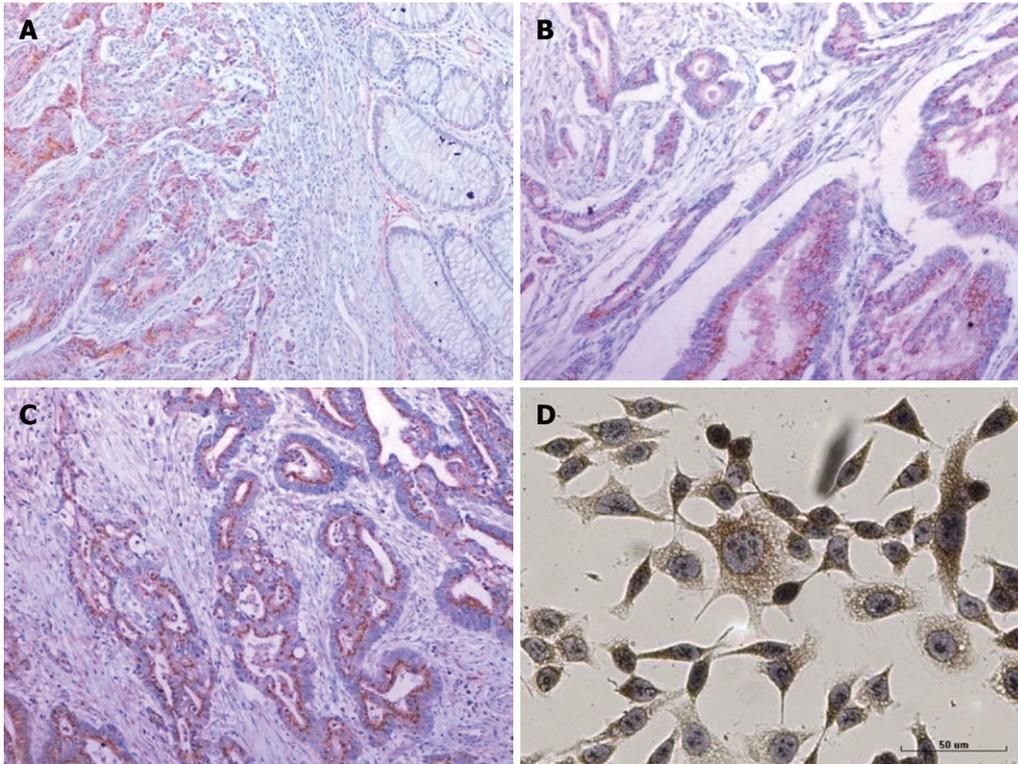

Figure 1 Immunohistochemical staining of colorectal carcinoma (CRC) tissue sections and immunocytochemical staining of HCT116 cells. The expression of vascular endothelial cell growth factor (VEGF) (SP × 100, A), Fms-like tyrosine kinase 1 (FLT-1) (SP × 100, B) and fetal liver kinase 1 (FLK-1) (SP × 100, C) is positive in the CRC sections and strongly positive in HCT116 cells (SP × 400, D).

	<i>n</i>	VEGF		FLT-1		FLK-1	
		Negative	Positive	Negative	Positive	Negative	Positive

expression of VEGF (dark brown yellow), while the VEGF-siRNA group showed only weakly positive cytoplasmic expression (light brown yellow). Western

blotting showed that VEGF-siRNA transfected cells expressed significantly less VEGF than the normal control, Lipofectamine 2000 control, or the mismatched control groups (Figures 1 and 2).

Effect of siRNA on cell proliferation

The proliferation rate of the HCT116 cell line 24, 48, and 72 h after transfection with VEGF-siRNA (22.43% ± 3.08%, 24.53% ± 1.94%, and 28.53% ± 2.00%, respectively) was significantly higher than those of the normal control group (0.00, 0.00, 0.00) and the mismatched control group (5.92% ± 0.49%, 6.10% ± 0.90%, 6.46% ± 0.60%, respectively) as assessed by the MTT assay. These effects were time-dependent. These results clearly showed that cell proliferation was markedly inhibited in the VEGF-siRNA-transfected group (Figure 3).

Cell apoptosis detected by flow cytometry (FCM)

To test for apoptotic cells, we used FCM to look for an apoptotic sub-G0-G1 (M1 value) peak at 48 h after

siRNA transfection. The results showed that, compared with the normal control group (M1 = 0.59), and the mismatched group (M1 = 0.63), the VEGF-siRNA group displayed an apparent aneuploid peak (M1 = 13.88) (Figure 4), suggesting the apoptosis of the cells transfected with VEGF-siRNA.

DISCUSSION

Angiogenesis is necessary for tumors to grow beyond a certain size, and is a prerequisite for tumor invasion and metastasis. VEGF plays a critical role in the process of angiogenesis. VEGF is a glycoprotein of 34-50 kDa, first purified from cattle hypophysis folliculo-stellate cells in 1989^[5,6]. VEGF stimulates the proliferation and migration of vascular endothelial cells, and modeling of the tumor neovasculature. VEGF acts *via* specific recep-

tors, including FLT-1 and FLK-1. FLT-1 is mainly found in vascular endothelial cells^[7]. FLT-1 has a stronger affinity for VEGF than FLK-1, but is unable to activate the proliferation signal in vascular endothelial cells, so probably acts as a down-regulator of angiogenesis triggered by VEGF^[8]. By binding and activating FLK-1, VEGF stimulates the proliferation of endothelial cells, increases vascular permeability and induces neovascularization^[2,6]. Therefore, FLK-1 plays a more important role in tumor angiogenesis. Our study shows that the expression of VEGF, FLT-1 and FLK-1 were all significantly higher in CRC than in normal tissues (*P* < 0.01). The expression of VEGF was positively correlated with lymph node metastasis and with clinical stages of disease (*P* < 0.05). This indicates that VEGF, FLT-1 and FLK-1 are all associated with colorectal carcinogenesis.

One technique that has been used recently for the rapid and efficient identification of gene function is RNAi^[9]. This refers to a group of related post-transcriptional gene silencing mechanisms in which the terminal effector is a short antisense RNA^[10]. The use of RNAi in mammalian cells involves the transfection of an annealed 21-mer comprising sense and antisense RNA oligonucleotides (siRNAs) that correspond to a portion of the genes of interest. These RNAs then bind specifically to the cellular RNA and activate a process that leads to the degradation of the mRNA, and a subsequent 80%-90% decrease in the levels of the corresponding protein. Thus, RNAi is an important technique that specifically down-regulates the expression of cellular genes and has opened the door to the therapeutic use of siRNAs. In our study, we used RNAi technology to transfect a siRNA targeted against VEGF into HCT116 cells using Lipofectamine 2000. Immunocytochemistry

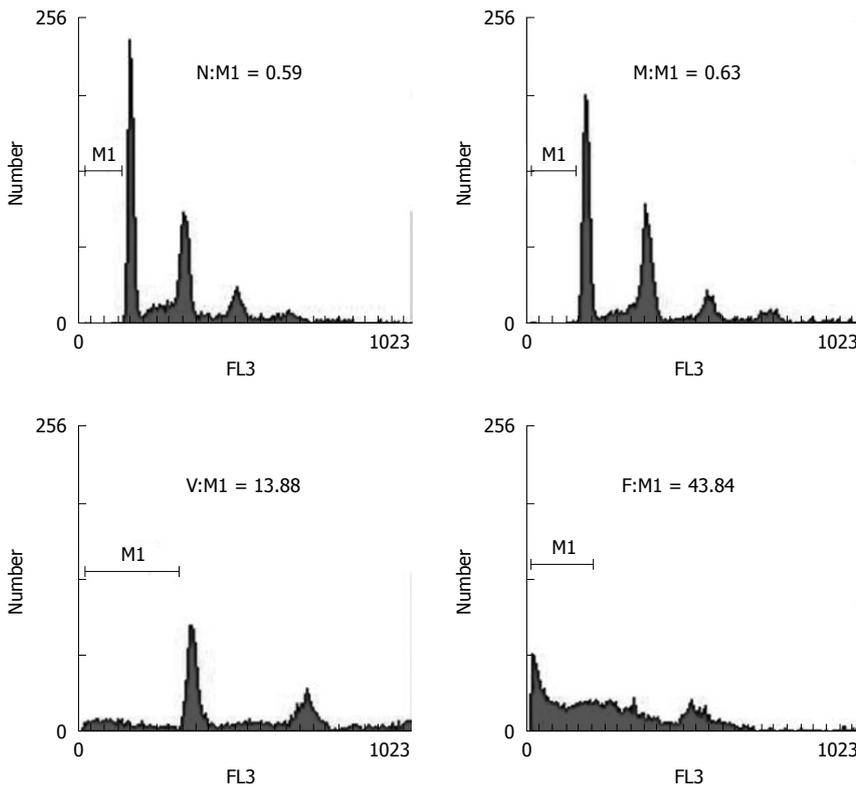

Figure 4 Apoptosis of HCT116 cells measured by flow cytometry (FCM). The percentage of the pre-G0-G1 population (peak) is shown for each histogram. The peak indicates the apoptosis rate of the cells. N: Normal control group; M: Mismatched group; V: VEGF-siRNA group; F: 5-FU group.

and Western blotting both showed that the expression of the VEGF protein was significantly reduced. Our results indicate that VEGF-siRNA can actively suppress VEGF protein expression and inhibit cell proliferation, all consistent with current literature^[11,12].

The appearance of the tumor cell proliferation is an important indicator of its biological function. In our study, blocking the VEGF expression using RNAi resulted in significant inhibition of cell growth in a time-dependent manner. A recent study showed that VEGF is closely associated with apoptosis. Castro-Rivera *et al*^[13] found that VEGF₁₆₅ could suppress apoptosis in lung cancer and breast cancer cells. Pidgeon *et al*^[14] found that VEGF could up-regulate bcl-2 levels in breast cancer cells, thus inhibiting apoptosis in both tumor cells and vascular endothelial cells. Our results show that the rate of apoptosis in the VEGF-siRNA group was significantly higher than that in the normal control group. This suggests that siRNA can effectively silence the VEGF gene and promote apoptosis in CRC cells.

In summary, our study suggests that VEGF is associated with colorectal carcinogenesis. Blocking VEGF expression using RNAi technology significantly reduces VEGF protein levels, suppresses the proliferation of HCT116 cells, and induces apoptosis. Our data indicate that siRNA may have therapeutic potential for inhibiting gene expression, and that VEGF is an attractive therapeutic target for the treatment of colon cancer.

COMMENTS

Background

Colorectal carcinoma (CRC) is one of the most common malignant diseases in

China and has a poor survival rate. Angiogenesis plays an important role in the growth of tumors. Neovascularization is regulated by multiple factors, the most important one is vascular endothelial cell growth factor (VEGF). VEGF acts to increase microvascular growth and permeability through binding to specific receptors, including Fms-like tyrosine kinase 1 (FLT-1) and fetal liver kinase 1 (FLK-1). Recently, RNA interference (RNAi) technology has been regarded as an effective tool that can be used against tumors, and has established a new domain for CRC clinical therapy.

Research frontiers

VEGF plays an important role in tumor angiogenesis through binding to vascular endothelial growth factor receptors, including FLT-1 and FLK-1. RNAi refers to a group of related post-transcriptional gene silencing mechanisms in which the terminal effector is a short antisense RNA. RNAi is an important method for specifically down-regulating the expression of cellular genes, and has opened the door to the therapeutic use of small interfering RNAs (siRNAs).

Innovations and breakthroughs

In this study, immunohistochemical staining for the VEGF, FLT-1, and FLK-1 proteins was performed in CRC samples to explore their roles in carcinogenesis. Also, a VEGF-targeting siRNA was transfected into human colorectal cancer HCT116 cells using Lipofectamine 2000 to investigate the effect of VEGF-targeted siRNA on the proliferation and apoptosis of HCT116 cells.

Applications

As indicated in this study, siRNA may have therapeutic potential for inhibiting the expression of specific genes, and VEGF is an attractive therapeutic target.

Peer review

In this manuscript, the authors demonstrate the relationship between the expression of VEGF and its receptors, FLT-1 and FLK-1, in CRC. The series of experiments was well planned and well performed, and the manuscript well written.

Abstract

AIM: To study factors associated with loss of hepatitis B surface antigen (HBsAg) in patients co-infected with human immunodeficiency virus (HIV) and hepatitis B virus (HBV).

METHODS: We retrospectively reviewed the medical records of 5681 patients followed up at two New York City HIV clinics from January 1999 to May 2007. Clinical and laboratory parameters including baseline and follow-up HIV viral loads, CD4 cell counts, alanine transaminase levels, demographics, presence of hepatitis C infection, and treatment with highly active antiretroviral therapy dually active against both HIV and HBV infection, were analyzed to determine factors associated with loss of HBsAg.

RESULTS: Three hundred and fifty five patients (355/5681, 6.84%) were co-infected with HIV and HBV and were evaluated. Of these, 226 patients with more than 12 mo follow-up were included in further analysis to determine

factors associated with loss of HBsAg in the long-term follow-up. In the univariate analysis, baseline CD4 cell count was associated with loss of HBsAg ($P = 0.052$). Cox regression analysis revealed that loss of HBsAg was associated with baseline CD4 cell count > 500 cells/mm³ ($P = 0.016$, odds ratio: 76.174, 95% confidence interval: 2.233-2598.481).

CONCLUSION: Our study showed an interesting association of loss of HBsAg in HIV-HBV co-infected patients with higher CD4 cell count, suggesting that T-cell cytolytic activity against HBV may still be effective in clearing HBV infection.

INTRODUCTION

Co-infection with human immunodeficiency virus (HIV) and hepatitis B virus (HBV) poses a treatment challenge. In Western Europe and the United States, chronic HBV infection has been found in 6%-14% of HIV-positive patients^[1]. Increased HBV carriage rates, greater levels of HBV viremia, more rapid decline in hepatitis B surface antibody (HBsAb), increased reactivation episodes, faster progression to liver cirrhosis, and development of hepatocellular carcinoma at a younger age leading to increased

liver-related morbidity and mortality, are all characteristic of HIV and HBV co-infected patients. Also, there are lower incidences of spontaneous loss of HBV e antigen (HBeAg) or HBV surface antigen (HBsAg) because of impaired host innate and adaptive immunity^[2-4]. However, factors associated with HBsAg loss in HIV and HBV co-infected patients remain unclear. In this study, our aim was to analyze the characteristics of patients dually infected with HIV and HBV, and to determine factors associated with loss of HBsAg on follow-up.

MATERIALS AND METHODS

We conducted a retrospective medical chart review of 5681 patients followed in 2 HIV/AIDS clinics that comprise the Center for Comprehensive Care at St. Luke's-Roosevelt Hospital Center in New York City, from January 1999 to May 2007. All HIV-infected patients had positive enzyme-linked immunosorbent assay (ELISA) [HIVAB™ HIV-1/HIV-2 (rDNA) EIA, Abbott Laboratories, Abbott Park, IL, USA] and confirmatory Western blotting test (HIV 1/HIV 2 Western blot/Immunoblot, Quest Diagnostics, USA). HIV and HBV co-infection was defined as having both positive HIV infection and HBsAg serology as determined by an ELISA kit (VITROS® Immunodiagnosics, Ortho-Clinical Diagnostics, USA) for at least 6 mo of follow-up. Hepatitis C virus (HCV) serology was determined using ELISA (VITROS® Immunodiagnosics, Ortho-Clinical Diagnostics, USA). We compared patients that lost HBsAg to the rest of the cohort, at baseline and at time of loss of HBsAg. Clinical and laboratory parameters including baseline and follow-up HIV viral loads, CD4 cell counts, alanine aminotransferase (ALT) levels, HCV co-infection, demographics, and duration of anti-HBV therapy were analyzed to determine factors associated with loss of HBsAg. In the earlier study years, HBV DNA viral load, HBV genotype, and HBeAg determinations were not available for every patient, therefore these variables were excluded from the final analysis.

Statistical analysis

Statistical analysis was performed using SPSS, version 15.0 for Windows (SPSS). Dichotomous variables were compared using Fisher's Exact test or the Pearson χ^2 test. For continuous variables, the independent *t* test was used. Univariate analysis and then multivariate Cox regression analysis, with data censored at the time of loss of HBsAg, were conducted to determine factors associated with loss of HBsAg. Odds ratio (OR) and 95% confidence interval (CI) were calculated. A *P* value < 0.05 was considered to be statistically significant.

RESULTS

Of the 5681 HIV infected patients in our cohort, 355 patients (355/5681, 6.84%) who were co-infected with both HIV and HBV were evaluated. Of these, 226 patients with more than 12 mo follow-up were included in the further analysis to determine factors associated with

Hetero: Heterosexual; MSM: Male sex with male; IDU: Intravenous drug use; HIV: Human immunodeficiency virus; HBV: Hepatitis B virus; HCV: Hepatitis C virus; HBsAg: Hepatitis B surface antigen; HAART: Highly active antiretroviral therapy with dually active agents against both HIV and HBV including lamivudine, tenofovir or both for more than 6 mo; ALT: Alanine aminotransferase; CD4 baseline: CD4 cell count baseline cells/mm³; HIV VL: HIV viral load copies/mL; IQR: Interquartile range.

loss of HBsAg in the long-term follow-up. The patients were observed for a mean duration of 45.6 mo (range, 20.8-61.1 mo). During the follow-up period, 21 (9.3%) of the 226 co-infected patients lost HBsAg. Of these 21 patients, 8 patients (38.1%) were noted to have developed HBsAb.

Table 1 shows demographic, virological and immunologic characteristics, and outcomes of the HIV and HBV co-infected patients in 2 groups according to HBsAg status. There were no differences in terms of age, gender, ethnicity, risk factor, HCV co-infection, CD4 cell count, HIV viral load, and ALT level at baseline between these 2 groups. Additionally, patients were categorized by CD4 cell count and HIV viral load. With regard to the patients with a CD4 cell count baseline > 500 cells/mm³, 25 patients (25/205, 12.2%) had persistent HBsAg, and 5 patients (5/21, 23.8%) had seroclearance of HBsAg. Although a higher CD4 cell count, > 500 cells/mm³, was observed in the HBsAg seroclearance group, this difference was

Table 2 Univariate analysis of factors associated with loss of HBsAg

	<i>P</i>
ALT baseline	0.737
HCV co-infection	0.660
HIV VL baseline	0.981
HIV VL end of follow-up	0.790
CD4 cell counts baseline	0.052
CD4 cell count end of follow-up	0.064
CD4 cell count gain	0.118
HAART	0.764

not statistically significant ($P = 0.078$). With regard to the patients with a baseline HIV viral load ≤ 400 copies, 40 patients (40/205, 19.5%) had persistent HBsAg, and 3 patients (3/21, 14.3%) had seroclearance of HBsAg, but there was no statistical significance, $P = 0.763$.

One hundred and ninety four HIV and HBV co-infected patients (194/226, 85.8%) received dually active antiretroviral therapy against HIV and HBV, including either lamivudine or tenofovir or both, for more than 6 mo as part of their highly active antiretroviral therapy (HAART) for HIV. Treatment with these dually active antiretroviral drugs did not differ between the 2 groups.

During the study period, more deaths in the persistent HBsAg group were noted (21/205, 10.2%) than in the HBsAg seroclearance group (1/21, 4.8%) although this was not statistically significant ($P = 0.702$).

In the univariate analysis, baseline CD4 cell count was associated with loss of HBsAg ($P = 0.052$). Other factors, including baseline ALT, presence of HCV co-infection, baseline HIV viral load, HIV viral load at end of follow-up, CD4 cell count at end of follow-up, CD4 cell count gain, and treatment with dually active antiretrovirals were not correlated with loss of HbsAg (Table 2).

Cox regression analysis revealed that baseline CD4 cell count > 500 cells/mm³ ($P = 0.016$, OR: 76.174, 95% CI: 2.233-2598.481) was associated with loss of HBsAg (Table 3).

DISCUSSION

Our clinics serve a large number of ethnically diverse HIV-infected patients in New York City. In our study, the prevalence of HIV and HBV co-infection was 6.84%. These results are consistent with previous data^[1], suggesting that our adult study cohort was representative of the current HIV and HBV co-infection epidemic in the United States.

The results of our study demonstrates that higher baseline CD4 cell count was significantly associated with loss of HBsAg in HIV and HBV co-infected patients. These results correspond with earlier studies which reported that higher initial CD4 cell count was associated with HBeAg seroconversion in HIV and HBV co-infected patients receiving lamivudine therapy^[5,6]. CD4 T-cell responses are believed to play a critical role in maintaining actively functioning cytotoxic T-lymphocytes (CTLs), which aid in release of antiviral cytokines^[7]. Inter-

Data for 226 patients. Data censored at the time of HBsAg loss.

estingly, HBV-specific CD4 T-cell responses are thought to be reduced in HIV and HBV co-infected patients^[8]. However, a recent study showed that the frequency and quality of HBV-specific T-cell responses increased with a higher CD4 cell count and there was no relationship between circulating HBV-specific T cells and liver damage as measured by fibrosis scores^[9]. Therefore a functioning immune system in HIV and HBV co-infected patients with very high CD4 cell count may enable a robust T-cell cytolytic response with production of anti-HBV cytokines such as interferon-gamma to help clear HBV infection in HIV co-infected patients.

Our study showed no significant association between elevated baseline ALT levels and loss of HBsAg. These results differ from those of Lau *et al*^[10] and Bonino *et al*^[11], which have shown a greater treatment response to either interferon or lamivudine in the setting of elevated ALT levels in chronic HBV patients without hepatitis C or HIV co-infection. However, none of our HIV and HBV co-infected patients were treated with interferon. It is also important to note that 53 patients out of our 226 studied patients (23.5%) were also co-infected with HCV. Therefore, findings from previous studies are not directly applicable to our study. A recent review article suggested that baseline ALT levels were not associated with treatment response in patients treated with nucleos(t)ide ana-

logues^[12]. There is conflicting and limited data regarding the utility of baseline ALT levels as a predictor of treatment response especially in the HIV and HBV co-infected patients. Further study is necessary to clarify the role of baseline ALT levels as a predictor of treatment response in this population.

Current guidelines^[13-15] recommend that HIV and HBV co-infected patients should be started on antiretroviral therapy with dually active agents such as lamivudine, tenofovir as part of HAART for HIV treatment regardless of CD4 cell count when treatment of HBV is indicated, based on HBV DNA levels, histological lesions, and serum ALT levels. Also, a significant number (50%) of expert panel members in the guidelines favor starting HAART in patients with CD4 cell count > 500 cells/mm³. Therefore, our study results would support initiating HAART earlier in the HIV and HBV co-infected patients with dually active agents against both HIV and HBV, even in patients with CD4 cell count > 500 cells/mm³ to maximize the T-cell response to both HIV and HBV.

There were some limitations to our study. It was a retrospective chart review. As previously mentioned, many patients did not have determination of HBV genotype, HBV viral load, HBeAg, or HBeAb. Therefore, we were not able to analyze these factors in our univariate and multivariate Cox regression analysis.

In summary, our study showed an interesting association of HBsAg loss in HIV-HBV co-infected patients with higher CD4 cell count, suggesting that T-cell cytolytic activity against HBV may still be effective in clearing HBV infection.

ACKNOWLEDGMENTS

We are grateful to Joyce Park and Tannasia Robinson for assistance with data collection from the Center for Comprehensive Care at St. Luke's-Roosevelt Hospital in New York City. Some of these data were presented in poster format at the XVII International AIDS Conference, 3-8 August 2008, Mexico City.

COMMENTS

Background

Co-infection with human immunodeficiency virus (HIV) and hepatitis B virus (HBV) is associated with increased morbidity and mortality.

Research frontiers

The aim of this study was to determine factors that influence loss of hepatitis B surface antigen (HBsAg) in an HIV and HBV co-infected population.

Innovations and breakthroughs

In this large retrospective study, a strong association between high baseline CD4 cell count (CD4 cell count > 500 cells/mm³) and seroclearance of HBsAg in HIV and HBV co-infected patients was found, suggesting that very high CD4 cell count may enable a robust T-cell cytolytic response with production of anti-HBV cytokines such as interferon-gamma to help clear HBV infection in HIV co-infected patients.

Applications

The authors' study results would support initiating highly active antiretroviral therapy earlier in HIV and HBV co-infected patients with dually active agents against both HIV and HBV, even in patients with CD4 cell count > 500 cells/mm³, to maximize the T-cell response to both HIV and HBV.

Terminology

HBsAg seroclearance, loss of HBsAg; one of the criteria used for determination of resolution of hepatitis B virus infection.

Peer review

This is a large retrospective cohort study demonstrating that HBsAg seroclearance was associated with higher baseline CD4 cell counts in patients with HIV-HBV co-infection.

Abstract

AIM: To investigate omeprazole-induced transepithelial gastric leak and its effects on the permeability of the peptides bradykinin and oxytocin.

METHODS: Rat gastric corpus tissue was isolated and mounted in an Ussing chamber apparatus to evaluate the permeability of ³H-bradykinin, ³H-oxytocin, and ¹⁴C-EDTA in the presence or absence of omeprazole. Thin-layer chromatography was performed to identify any metabolic breakdown products of the peptides resulting from permeation through the gastric tissue, and thereby calculate the true flux of the peptide.

RESULTS: The flux rate of intact ³H-bradykinin increased substantially after omeprazole addition (109.5%) compared to the DMSO vehicle control (14%). No corresponding change in flux of intact ³H-oxytocin was observed under the same conditions (11.9% and 6.4% in the DMSO- and omeprazole-treated conditions, respectively). After exposure to omeprazole, the flux rate of ¹⁴C-EDTA also increased dramatically (122.3%) compared to the DMSO condition (36.3%).

CONCLUSION: The omeprazole-induced gastric leak allows for transmucosal permeability to charged molecules as well as non-electrolytes. This induced leak will allow certain peptides to permeate.

Omeprazole induces gastric transmucosal permeability to the peptide bradykinin. *World J Gastroenterol* 2010; 16(9): 1097-1103 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i9/1097.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i9.1097>

INTRODUCTION

Our group has previously reported in patient-based (*in vivo*) and animal (*ex vivo*) studies that proton pump inhibitors (PPIs) induce a paracellular transepithelial leak in the gastric corpus^[1,2]. The leak allows uncharged, non-electrolyte probes (mannitol, sucrose, polyethyleneglycol) as large as 4000 Da to cross, and is bidirectional in nature. We have also investigated the medical significance of the

PPI-induced leak and have shown that the small molecule drug, digoxin, used to treat congestive heart failure and supraventricular arrhythmias, can cross the gastric mucosa in the presence of omeprazole^[3]. Hopkins *et al*^[4] earlier speculated that PPIs may allow small molecule drugs to permeate across the gastric mucosa. This finding suggests that omeprazole has the potential to alter blood kinetics of certain orally-delivered small molecule drugs whose blood levels must be carefully titrated, and co-administration may therefore pose a significant clinical risk. Kiley *et al*^[5] have very recently shown the clinical ramifications of such PPI-induced leak coinciding with PPI-mediated inhibition of liver cytochrome degradation of certain small molecule drugs such as digoxin. It is currently unknown, however, whether the possession of charge would prevent molecules from permeating through this induced leak. The aforementioned 4000 Da molecular weight “ceiling” on the omeprazole-induced leak was based on study of uncharged molecules only. This led us to investigate a small, charged (non-metabolizable) probe, EDTA (MW 380). The exact charges on the EDTA molecule vary depending upon pH^[6].

The leak induced by PPIs may carry drug delivery potential, due largely to the fairly safe profile of PPIs^[7]. Although the specific mechanism of the gastric leak is unknown, the leak seems to be benign to the tissue, carrying with it no morphological damage to gastric mucosa, a major benefit for a drug delivery vehicle. This current study also examines the gastric permeability of two characteristic small peptides, bradykinin (MW 1060) and oxytocin (MW 1007) (Figure 1) in the presence and absence of omeprazole. If omeprazole were to allow these peptides to leak across the gastric mucosa into the bloodstream, they would thereby avoid proteolytic digestion by trypsin and other digestive enzymes present in the duodenum.

MATERIALS AND METHODS

Animals, tissue dissection, Ussing chambers, incubation salines

Sprague Dawley male rats weighing approximately 400 g were sacrificed by decapitation and the stomach was quickly removed, cut along the greater curvature, and flushed of luminal contents. The serosal membrane was then stripped from the corpus region and two equal sized pieces of corpus mucosa were mounted in two separate Ussing chambers with exposed tissue areas of 1.13 cm²^[2]. Chambers were connected to 15 mL gas-lift reservoirs filled with un-buffered saline aerated with 100% O₂ and bicarbonate-buffered saline (pH 7.3) aerated with 95% O₂/5% CO₂ on the mucosal and serosal sides, respectively. Un-buffered saline was used on the mucosal side to allow for luminal acidification. Saline temperature was held constant at 37°C by a jacketed water bath surrounding the reservoirs. Thirty minutes at 37°C was allowed for tissue equilibration. In paired experiments, one tissue served as (vehicle) “control”, and the other as omeprazole-treated “experimental”.

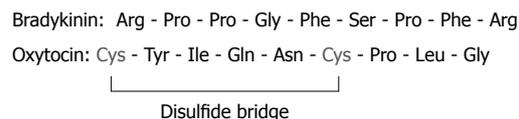

Figure 1 Amino acid structures of bradykinin (top) and oxytocin (bottom). Note the presence of the disulfide bridge in oxytocin.

Electrophysiology and mucosal pH

Electrical parameters were monitored throughout the duration of the experiment. Tissues were maintained under open circuit conditions. Ag/AgCl electrodes were bridged to saline in chambers with 4% agarose bridges stored in 1 mol/L NaCl. Tissue voltage (potential difference), short circuit current, and transepithelial resistance were recorded approximately every five minutes for the duration of the experiment, by passing a one-second current pulse equal to biological current to bring the potential difference to zero using a current/voltage clamp (McGrath Research & Technology). Transepithelial resistance was calculated by dividing open circuit potential difference by short circuit current (Ohm's law).

Mucosal and serosal saline pH measurements were taken at approximately 5 min intervals using a manual pH electrode (Denver Instruments) to ensure that the tissue was secreting acid. Mucosal pH readings were also taken before and after the addition of omeprazole to document the action of omeprazole on inhibiting acid secretion. Tissue viability was confirmed at the end of each experiment by tissue exposure to 10 mmol/L amiloride in the mucosal fluid compartment in order to inhibit short circuit current.

Transepithelial drug flux studies

After 30 min of tissue equilibration time in Ussing chambers, dibutyl cyclic AMP (dBcAMP) (Sigma) was added at a final concentration of 1 mmol/L to the serosal fluid chambers to stimulate acid secretion. Forty minutes following dBcAMP addition, protease inhibitors, pepstatin (1.8 μmol/L) and leupeptin (5 μmol/L), were added to the mucosal and serosal sides to prevent extracellular degradation of the peptide molecules of interest. Radiolabeled peptides under study [³H-bradykinin, ³H-oxytocin (PerkinElmer)] along with their unlabeled forms were added five minutes after the addition of protease inhibitors to the mucosal fluid of both chambers to achieve final concentrations of 0.3 mmol/L bradykinin or 5 μmol/L oxytocin in the mucosal fluid. The addition of the isotope marked the beginning of the flux period. Five hundred microliters of samples were taken from the serosal fluid compartment (opposite from which the isotope was added) for liquid scintillation counting (LSC). Samples were only taken from the mucosal fluid compartment at the end of the experiment to determine the specific activity of radioactivity initially added. The amount of radioactivity present in the mucosal compartment does not significantly change throughout the duration of the experiment. Serosal samples were initially taken at 45 min intervals for 90 min for the ³H-bradykinin

and ^3H -oxytocin fluxes to establish the basal permeability rate ($\mu\text{moles}/\text{min}$ per cm^2) across the tissue. About $200 \mu\text{mol}/\text{L}$ omeprazole (Sigma) (in DMSO) was then added to the mucosal and serosal sides of one chamber and an equivalent amount of DMSO (Sigma) was also added to both sides of the control chamber. Another series of serosal fluid samples were taken for LSC at 45 min intervals for the remaining 90 min of ^3H -bradykinin and ^3H -oxytocin flux experiments to determine flux rate of the radiolabeled drugs after omeprazole addition. In all cases of fluid sampling for liquid scintillation counting, an equal amount of fresh buffered saline was added back to the serosal side to prevent hydrostatic gradients from developing across the tissue. The flux of each isotope ($\mu\text{mole}/\text{min}$ per cm^2) was determined by calculating the linear regression slope of the graph of cpm *vs* time, and converting cpm to picomoles after determining the specific activity of the drug in the mucosal fluid.

A similar flux protocol was followed for ^{14}C -EDTA experiments, with the following differences: ^{14}C -EDTA (ARC, Inc.) was added to the serosal fluid compartment 45 min after the addition of dBcAMP (no protease inhibitors were added) along with its unlabeled form to achieve a final concentration of $10 \mu\text{mol}/\text{L}$. Five hundred and fifty microliters of samples were taken from the mucosal fluid compartment (opposite from which the isotope was added) for LSC every 15 min for 75 min. About $200 \mu\text{mol}/\text{L}$ omeprazole (or DMSO) was then added and another series of mucosal fluid samples were taken every 15 min for the remaining 45 min of the flux period. Fresh unbuffered saline was added back to the mucosal fluid after each sample was taken.

Thin-layer chromatography

Additional saline samples were taken from the mucosal and serosal fluid compartments one minute before the addition of omeprazole/DMSO and at the end of the entire flux period to allow for thin-layer chromatography (TLC) analysis of radioactivity that crossed the tissue. TLC was performed to account for the potential contribution of radiolabeled metabolites to total radioactivity crossing the epithelial barrier, in the event of drugs entering gastric epithelial cells and metabolites being effluxed. Saline samples were taken from both surfaces of the tissue to determine possible degradation of the molecule upon exposure to the mucosal surface of the tissue as well as to analyze the chemical nature of the radioactivity that crossed the tissue. Saline samples from bradykinin and oxytocin flux experiments were concentrated by evaporation (Savant Speed Vac) to dryness and then resuspended in small volumes of double deionized water. TLC was performed on silica gel 60 plates with a 254 fluorescent indicator (Kodak) by spotting very small amounts of the concentrated sample. Plates were then placed in a sandwich tank and a variety of mobile phases were employed, including butanol/acetic acid/water (120:30:50), isopropanol/water/ NH_4OH (120:30:1), isopropanol/water (120:30), and ethyl acetate/methanol/water (81:11:8). After completion of the mobile phase,

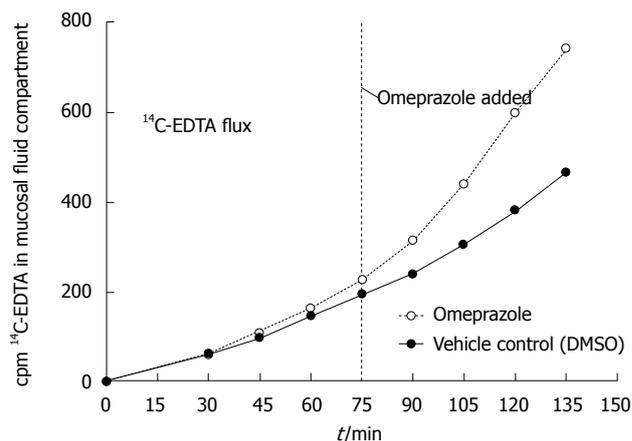

Figure 2 Effect of $200 \mu\text{mol}/\text{L}$ omeprazole on $10 \mu\text{mol}/\text{L}$ ^{14}C -EDTA flux rate across rat corpus mucosa. The flux rate of ^{14}C -EDTA dramatically increases over time after the addition of omeprazole compared to the DMSO vehicle control. Representative of three experiments and three separate animals. Samples were taken at 15 min intervals beginning at 30 min after the addition of the isotope. Omeprazole and DMSO were added to their respective chambers 75 min after the addition of ^{14}C -EDTA. The total flux time was 135 min. ^{14}C -EDTA was added to the serosal fluid compartment and samples were taken from the mucosal fluid compartment.

plates were sprayed with ninhydrin reagent to visually detect the location of proline or tyrosine, likely amino acid degradation products of bradykinin or oxytocin, respectively, and examined under a 254 UV lamp for detection of bradykinin or oxytocin, indicated by blocked fluorescence.

RESULTS

Ex vivo analyses indicate that omeprazole increases the rate at which the non-metabolizable, paracellular probe, ^{14}C -EDTA, diffuses across rat gastric mucosa compared to the vehicle control (DMSO). The amount of radiolabeled EDTA in the mucosal fluid compartment increased linearly over time in both conditions, but upon the addition of omeprazole to one chamber, there was a dramatic increase in the rate of diffusion of radioactive EDTA seen entering the mucosal fluid compartment (Figure 2). The observed increase in flux after treatment with omeprazole is continuous and nearly immediate in each of three experiments. When comparing the post-omeprazole flux values to the post-DMSO flux values, the flux rate of EDTA after the addition of omeprazole increased by $122.3\% \pm 8.5\%$ *vs* $36.3\% \pm 11.5\%$ for DMSO (Table 1). This evidences that the paracellular leak induced by omeprazole does allow a charged particle, ^{14}C -EDTA, to diffuse across the gastric mucosa. In Table 1 the values listed show the picomoles/ min per cm^2 of ^{14}C -EDTA crossing the gastric mucosa in the DMSO and omeprazole conditions, with corresponding percent increases after the addition of each compound. Data from three experiments (and three animals) are shown. There is a consistent dramatic percent increase from the pre- to post-omeprazole addition compared to the pre- to post-DMSO (control) condition. The mean \pm SE of the mean

Experiment 1	1.78	2.03	1.52	3.18	14.0	109.0
Experiment 2	1.65	2.36	1.58	3.48	43.0	120.0
Experiment 3	1.50	2.28	1.69	4.03	52.0	138.0
mean ± SE	1.64 ± 0.08	2.22 ± 0.10	1.60 ± 0.05	3.56 ± 0.25	36.3 ± 11.5	122.3 ± 8.5

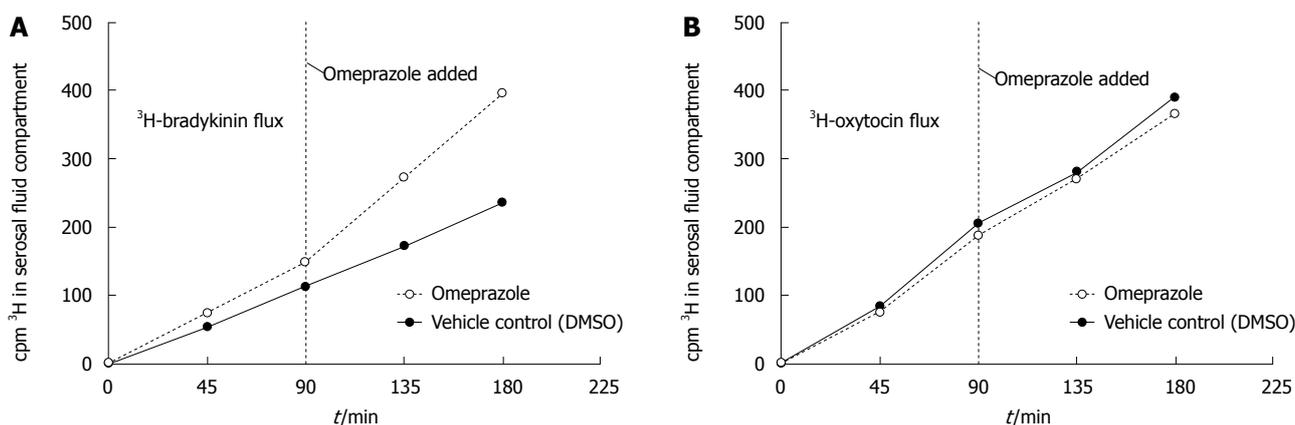

Figure 3 ³H-bradykinin (panel A) or ³H-oxytocin (panel B) was added to the mucosal fluid compartment at *t* = 0 to begin the flux period of 180 min. Omeprazole or DMSO was added to the tissue 90 min after the addition of ³H-peptide. Samples were taken every 45 min for the total 180 min flux period (pre- and post-omeprazole/DMSO) from the serosal fluid compartment for LSC and TLC. Omeprazole increases the rate at which total radioactivity crosses the gastric mucosa compared to the paired vehicle control (DMSO) in a ³H-bradykinin flux experiment (panel A) whereas total radioactivity crossing the tissue in a ³H-oxytocin flux experiment (panel B) remains unchanged after the addition of omeprazole or DMSO. Both panel A and panel B represent two separate experiments and animals.

is also listed from the three experiments.

The total amount of tritium diffusing across the gastric mucosa (in a mucosal to serosal direction) also increased in the presence of omeprazole compared to DMSO in a ³H-bradykinin flux experiment (Figure 3A), but did not increase under the same conditions in a ³H-oxytocin flux (Figure 3B). Since, unlike EDTA, peptides are subject to metabolism by the gastric tissue, TLC was performed to analyze the total radioactivity from each flux experiment and differentiate intact ³H-bradykinin or ³H-oxytocin (data not shown) from ³H-metabolites. TLC results revealed the presence of ³H-metabolites in the serosal fluid after a 180 min ³H-bradykinin flux experiment; however no substantial difference in relative proportions of ³H-bradykinin and ³H-metabolites between the omeprazole and DMSO conditions was seen (Figure 4A and B). Intact ³H-bradykinin migrated with a known pure ³H-bradykinin and unlabeled bradykinin standard (Figure 4C). After TLC analysis, flux values were adjusted to reflect the total amount of radiolabeled intact bradykinin or oxytocin crossing the gastric mucosa over the 180 min flux period. After the addition of omeprazole, there was a 109.5% ± 38.5% (range) increase in the rate of ³H -bradykinin flux compared to the DMSO vehicle control increase of only 14.0% ± 12.0% (range) (Table 2). Both bradykinin experiments performed yielded similar results, with omeprazole increasing ³H-bradykinin flux dramatically more than DMSO did. There was, however, no dramatic

difference in flux rate of ³H-oxytocin after the addition of omeprazole or DMSO, with percent increases in flux being 11.9% ± 42.6% (range) and 6.4% ± 9.9% (range) in the DMSO- and omeprazole-treated conditions, respectively (Table 3). These figures reflect correction of the data for oxytocin metabolites in the 3H-cpm coming into the serosal fluids compartment (Figure 4D-F), as was done for the bradykinin flux measurements. It can thus be concluded that permeability to bradykinin is increased by omeprazole, but permeability to oxytocin is not.

Tables 2 and 3 show the actual flux values in mole/min per cm² and fmole/min per cm² pre- and post-omeprazole (or DMSO) addition. All values are corrected after TLC analysis of radioactivity. Two experiments were performed for each peptide (³H-bradykinin and ³H-oxytocin).

DISCUSSION

In previous patient-based^[1] and animal model studies^[2,3] our group has shown that proton pump inhibitors induce a transmucosal, paracellular “leak” in the gastric corpus. Using nonelectrolyte probes, it was shown that molecules as large as 4 kDa can permeate through this induced leak. Although there are many biomedical considerations to such leak, one possibility is that the leak could be used for oral administration of molecules (e.g. peptides, proteins) that normally could not cross the GI barrier into the

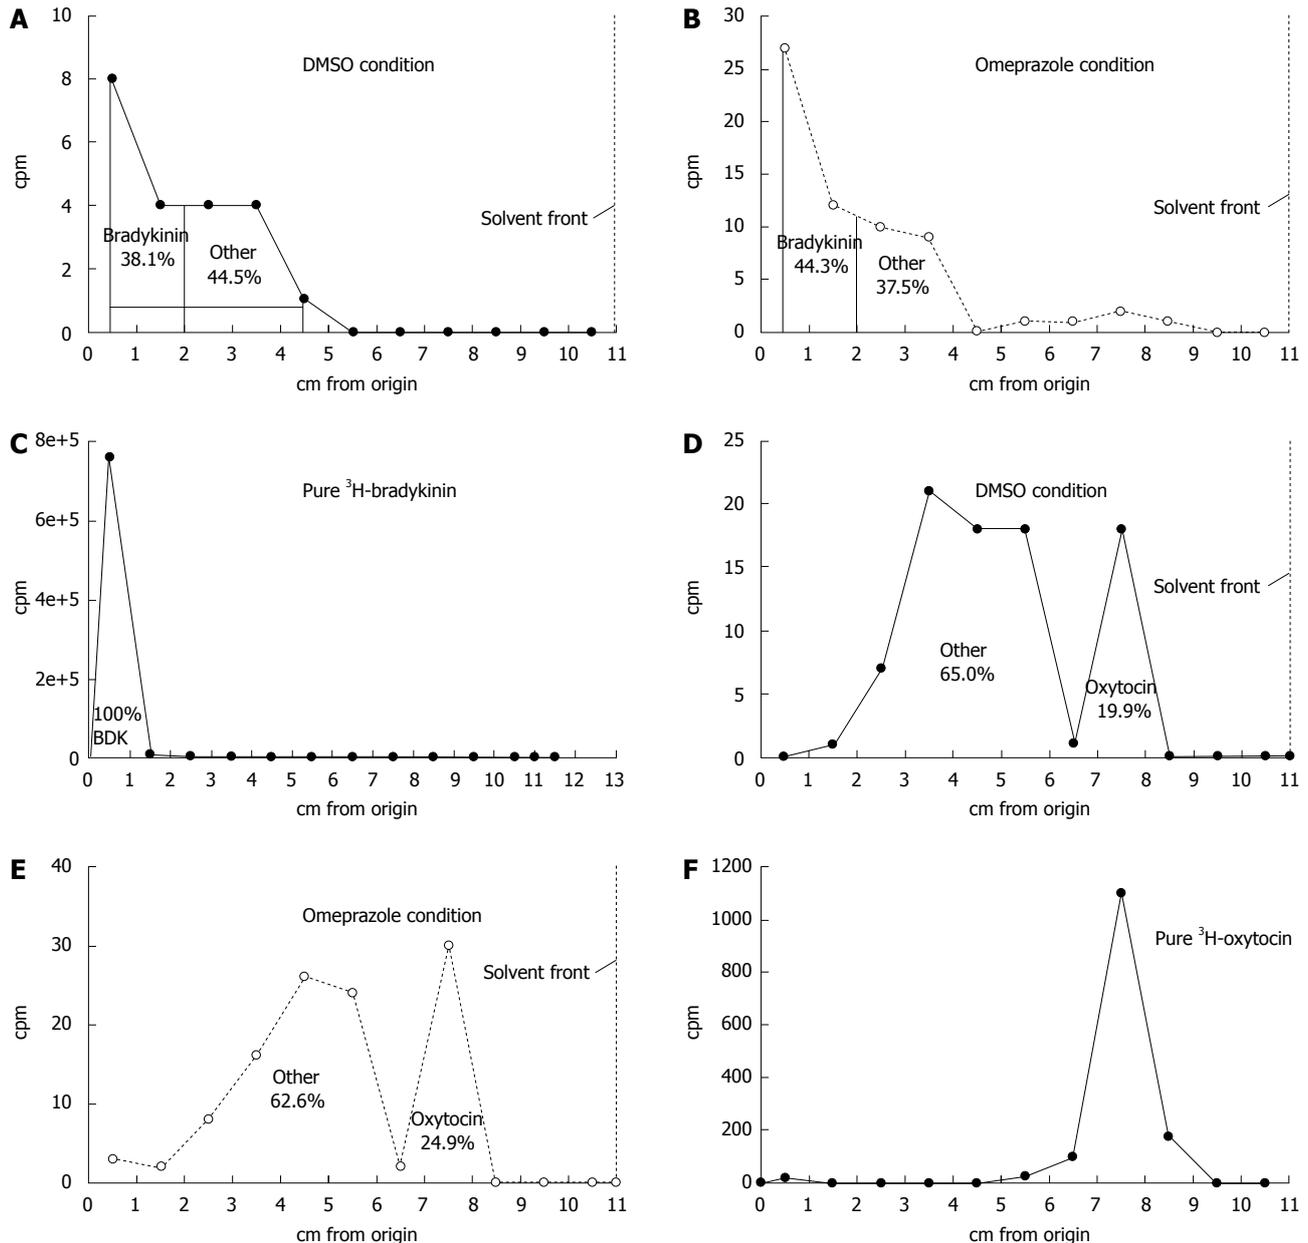

Figure 4 Thin-layer chromatography analysis of ^3H crossing the tissue from selected ^3H -bradykinin and ^3H -oxytocin flux experiments. The radiochromatograms shown are representative of the total radioactivity present in the serosal fluid compartment at the end of a 180 min flux period from the DMSO (A, D) and omeprazole (B, E) conditions. There are no obvious differences in the proportion of ^3H -peptide and ^3H -metabolites in either condition. The chromatographic profiles of pure ^3H -bradykinin (C) and pure ^3H -oxytocin (F) are also shown. 1 cm strips of the chromatogram were cut from the origin to the solvent front. Each strip was counted in a scintillation counter to determine the cpm. The location of ^3H -bradykinin or ^3H -oxytocin on the chromatogram was detected by its blocking of fluorescence at the origin under a short-wave UV lamp. All radiochromatograms were run in an isopropanol/water/ NH_4OH (120:30:1) solvent system on silica gel 60 plates with a 254 fluorescent indicator.

bloodstream and/or are metabolized in the lumen (e.g. duodenum) before uptake is possible. The field of drug delivery has long pursued agents capable of inducing transmucosal permeation without damaging the mucosal tissue.

In this study we have shown that a relatively small, charged molecule (EDTA) can pass through the omeprazole-induced gastric leak, suggesting that the possession of charge by a molecule will not prevent it from crossing through the leak. It made it reasonable to assume that other charged molecules would likely also diffuse through

the “pore”. We can only speculate, however, that the same would be true for a larger, charged molecule. If a charged molecule with a larger radius than EDTA (one closer to the size of the opening) were to come in contact with the omeprazole-induced pore, it may be more likely repelled because of its close proximity to the lining of the pore. In other words, if a charged molecule is small enough compared to the pore, it does not come close enough to be repelled by fixed charges lining the pore.

In the EDTA studies reported here the radioactivity coming across the gastric mucosa after each flux

experiment would be all true EDTA because EDTA does not permeate cell membranes, is metabolized only negligibly and is known to only travel paracellularly^[8,9]. We saw only one peak of radioactivity (data not shown), but because of the many forms molecular EDTA takes on at different pHs, consistent co-migration results were difficult to attain. Given the fact that EDTA will alter its charge as a function of pH it is worth highlighting that EDTA fluxes in this study were conducted in the serosal to mucosal direction. Serosal pH in these studies was maintained at pH 7.3. However in this direction, EDTA must traverse the intercellular space before presenting to the tight junction barrier. We do not know the exact pH of the intercellular fluid, but note that it is in communication with the pH 7.3 serosal fluid compartment.

Because charge was thus found to not be exclusionary for passage through the leak induced by omeprazole, the permeability of two small, similar size peptides (bradykinin and oxytocin) in the presence and absence of omeprazole was also investigated. Similar to EDTA, based on their amino acid moieties, peptides can have dynamically changing charges at different pHs. We observed that bradykinin (MW 1060) was found to diffuse through the omeprazole-induced leak while oxytocin (MW 1007) did not show an increase in flux in the presence of omeprazole. There are obvious differences in the molecular structures of bradykinin and oxytocin (Figure 5) albeit their sizes are very similar. Bradykinin is an open chain of amino acids, while oxytocin is more globular and rigid, containing a disulfide bridge. Also noteworthy is that bradykinin, but not oxytocin, has basic amino acids at its C and N termini. These structural points may be pivotal to permeation through a PPI-induced "pore".

Because the gastric leak induced by omeprazole appears to be benign to the tissue, with no histological pathology or increased occurrence of apoptosis, it is possible it may have value as a drug delivery vehicle for certain biological drugs. Melittin has been used in epithelial cell culture as a barrier manipulator, but was

**Figure 5** Molecular structure of bradykinin (A) and oxytocin (B).

found to cause hemolysis and cytotoxicity in the process of enhancing permeability^[10]. The local toxicity caused by sodium caprate, another drug delivery agent, is a major downfall in its use in absorption enhancement^[11]. Yamamoto *et al.*^[12], in fact, reported a linear relationship between efficacy of various absorption enhancers and their toxicity. Contrary to these other barrier manipulators that are shown to enhance the barrier with negative local and systemic repercussions, omeprazole is a well-tolerated, widely-used, FDA-approved medication that opens the gastric paracellular barrier (tight junction) upstream from the duodenum with seemingly no physiological downside.

The leak exhibits a size limit, is highly specific to what types of molecules permeate, and is reversible upon discontinuation of PPI therapy. We postulate that these specificity characteristics are precisely why this leak occurs with little or no tissue morbidity.

We suspect that this PPI-induced transepithelial gastric leak to bradykinin is paracellular and not transcellular because we already demonstrated that the PPI-induced leak is bidirectional^[2]. In addition, the gastric epithelium is not specialized to transport molecules transcellularly like the duodenum. The gastric mucosa is not absorptive, as the majority of gastrointestinal absorption occurs downstream in the small intestine. Finally, however, note that there is evidence that as a result of PPIs raising gastric luminal pH, the protonation of certain molecules may be changed causing an alteration of their diffusion through the gastric epithelium^[13]. This remains another possible mechanism of how bradykinin may have crossed the gastric mucosa in the presence of omeprazole elevating mucosal fluid pH.

The ability of bradykinin to permeate suggests that this leak may be useful as a drug delivery vehicle for synthetic peptides. The inability of oxytocin to pass suggests that the structure, charge, and hydrophobicity of a peptide will matter considerably to its paracellular permeation, and the exact criteria for permeation of future candidate peptides need to be determined. Future studies will look into establishing both the inclusionary and exclusionary structural criteria of peptide passage through the leak, as well as examine if the leak admits oligonucleotide permeation.

ACKNOWLEDGMENTS

We would like to thank the LIMR Editorial office for their work on the manuscript. Also, thank you to the Lankenau medical residents and GI fellows involved in this project. This work was funded in-part by the Sharpe-Strumia Foundation.

COMMENTS

Background

The very recently discovered transmucosal gastric leak caused by proton pump inhibitor (PPI) drugs may have use in allowing oral delivery of certain peptides and oligonucleotides that might otherwise have to be injected. PPIs have little if any morbid effects on the gastric mucosa, and thus the induced leak appears to not be harming the tissue.

Research frontiers

PPIs are very widely utilized drugs for treatment of reflux disease and gastritis. The ability of PPIs to induce a gastric leak is just beginning to be explored. In this manuscript a positive aspect of such leak, namely a delivery route for other oral medications that normally have no way into the bloodstream, is explored.

Innovations and breakthroughs

In previous work, this leak was shown to be bidirectionally symmetric and allow only molecules less than 10 kDa to pass. In this current study the leak is shown to allow charged molecules in general to pass, and specifically allow the peptide, bradykinin, to pass. The inability of the similarly-sized peptide, oxytocin, to pass through the leak suggests that the leak possesses considerable specificity in the types of molecules it will admit.

Applications

The field of drug delivery has long sought agents that can "open up" epithelial barriers but not cause morbidity for the tissues in the process. It is a significant problem given the physiological importance of these barriers and the noxious nature of many constituents of luminal fluid compartments.

Terminology

These studies utilize the Ussing chamber technique wherein gastric mucosal epithelial tissue is placed between two fluid-filled chambers. The passage across the tissue of radiolabeled probes, in this case, peptides, is then observed and measured, as a function of PPI exposure. These molecules are in all probability moving paracellularly across the tissue, and likely diffusing through altered epithelial tight junctions.

Peer review

This is a very interesting paper in which the investigators examined the gastric permeability of two characteristic small peptides, bradykinin and oxytocin in the presence or absence of omeprazole. This is a carefully conducted study by a well qualified group of investigators.

Abstract

AIM: To study the individual effects of glucocorticoid (GC) therapy on the state of immune activation in patient serum.

METHODS: We developed a novel assay in which the effect of corticosteroid-treated patient serum on healthy donor peripheral blood mononuclear cells (target cells) was studied, with a panel of markers for effector [interferon (IFN) γ and interleukin (IL)-5] and regulatory T cells (FOXP3 and glucocorticoid-induced tumor necrosis factor receptor, GITR). The study group comprised 19 children with inflammatory bowel disease. The individual effect of patient serum on target cells was analyzed prior to GC therapy and 2 wk later.

RESULTS: The effect of GC therapy mediated by patient serum was seen as a decrease in the target

cells expression of regulatory T-cell-related markers GITR (median suppression 24%, range of suppression 1%-63%, in 2 cases increase of 6% and 77%, $P < 0.01$ for mitogen-activated target cells) and FOXP3 (median suppression 33%, range of suppression 0%-79%, in one case an increase of 173%, $P < 0.05$ for resting cells), and secretion of IFN γ [from a mean of 87700 pg/mL (SD 33900 pg/mL) to 60900 pg/mL (SD 44200 pg/mL) in mitogen-activated target cells, 13 of the cases showed a decrease, $P < 0.01$]. The total or weight-related prednisolone dose did not correlate with the patient-serum-induced changes in the target cell markers.

CONCLUSION: GC response could be monitored at an individual level by studying the effect of patient serum on signaling pathways of target immune cells.

INTRODUCTION

Since the description of the life-saving effect of glucocorticoids (GCs) in the treatment of inflammatory bowel disease (IBD), GCs have been the mainstay in the treatment of moderate and severe forms of the disease^[1]. Although widely used, several patients show an

inadequate response to GCs, a phenomenon that could not have been foreseen. In patients with GC resistance, therapeutic effect is lacking. Those considered to be steroid-dependent benefit from the treatment but their disease flares up immediately after lowering the GC dose or discontinuation of the therapy. Among IBD patients, up to 31%-45% seem to become steroid-dependent^[2-4]. Other treatment options have not overcome the need for GCs in IBD, a disease that is constantly on the increase in many western countries^[5,6].

The pathogenesis of IBD is multifactorial. An inappropriate response of a mucosal immune system to the indigenous flora and luminal antigens plays a key role that leads to activation of innate immune cells that direct the effector and regulatory T-cell responses of adaptive immunity^[7].

GC action is mediated by a GC-receptor complex that is translocated into the nucleus. The genomic actions are classified as transrepression, that is, inhibition of the synthesis of the regulatory proteins, which results from the interaction between the activated GC-receptor complex and transcription factors, such as nuclear factor- κ B or activator protein-1, and transactivation, that is, induction of the synthesis of regulatory proteins that leads to downregulation of inflammatory cytokines, such as tumor necrosis factor- α , interleukin (IL)-12 and interferon (IFN) γ , and upregulation of anti-inflammatory cytokines, such as IL-10, and transforming growth factor β ^[8-11]. GCs have also non-genomic interactions with cellular membranes^[12].

Therapeutic response to GCs at an individual level is unpredictable. Here, we searched for new means to monitor the stage of immune activation during GC therapy. We developed a novel assay, in which the effect of patient serum on donor peripheral blood mononuclear cells (PBMCs) was studied using a panel of markers for effector (IFN γ and IL-5) and regulatory T cells (FOXP3 and glucocorticoid-induced tumor necrosis factor receptor, GITR). We found that attenuation of inflammation during GC therapy was reflected in these markers.

MATERIALS AND METHODS

Subjects

Nineteen consecutive pediatric patients with active IBD (Table 1) were prospectively introduced to oral prednisolone (Leiras, Finland), with a constant once daily dose of 1 mg/kg (range 15-60 mg) for 2 wk, as described in detail elsewhere^[13,14]. The need for GCs was based on the physician's global assessment of severe disease. After the 2-wk study protocol^[13,14], the clinicians tapered the GC dose and adjusted the therapy. At the start of GC therapy, the maintenance therapies (Table 1) were unaltered. All patients had undergone gastrointestinal endoscopy to establish the diagnosis of IBD^[15].

Blood samples

The first blood sample was taken prior to the first GC dose on the day that the clinician instructed the start of GC therapy. The second sample was taken after 2 wk

and the two samples were compared individually. Routine samples for blood count, hemoglobin, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were obtained at the start of GC therapy and after 2 wk.

Laboratory assay

PBMCs and the plasma from the blood of healthy donors and patients were separated by Ficoll-Paque (Amersham Biosciences, Freiburg, Germany) centrifugation according to the protocol of the manufacturer. PBMCs were suspended in 1 mL of medium (RPMI with HEPES buffer (Gibco, Carlsbad, CA, USA) with 0.002 mmol/L glutamine (Gibco), 25 μ L/mL gentamicin (Gibco) and 5% serum), for counting. PBMCs were frozen at -136°C with DMSO (Sigma-Aldrich Corp, St. Louis, MO, USA). These cells from healthy donors were used as target cells. Target cells were diluted in cell culture medium (described above) without serum. Target cells, unactivated or activated with phytohemagglutinin (PHA, 5 μ g/mL) were cultured as duplicates in the presence of the IBD patients' inactivated (56°C for 35 min) serum, at a concentration of 8%, for 72 h at 37°C in a humidified atmosphere with 50 mL/L CO₂. After culture, the supernatants and target cells were collected by centrifugation at 400 g for 7 min. RT lysis buffer (Sigma-Aldrich) was added to the target cells, and the supernatants were stored at -70°C. The target cell assay was repeated using PBMCs from two different healthy donors (26-year-old woman and 31-year-old man) as target cells. Results represent one series of experiments.

ELISA for IFN γ and IL-5

IL-5 and IFN γ were measured with ELISA in duplicate from the supernatants collected from the target cell cultures incubated in the presence of patient serum. IFN γ and IL-5 were detected as described previously^[16,17]. We subtracted the non-stimulated value from the stimulated value to obtain the Δ value for statistical analysis.

Quantitative reverse transcriptase-polymerase chain reaction (RT-PCR)

Total RNA was isolated from cell samples with GenElute Mammalian total RNA Miniprep kit (Sigma-Aldrich), and RNA concentration was measured by a spectrophotometer (ND-1000; NanoDrop Technologies Inc, Wilmington, DE, USA). Reverse transcription was performed by using TaqMan Reverse Transcription reagents (Applied Biosystems, Foster City, CA, USA), with additional treatment of total RNA at 10 ng/ μ L with DNase I (0.01 U/ μ L) (Roche Diagnostics, Mannheim, Germany) to eliminate genomic DNA. Quantitative RT-PCR was performed using pre-designed FAM-labeled TaqMan Gene Expression Assay reagents (Applied Biosystems) and the ABI Prism 7700 Sequence Detection System (Applied Biosystems) in triplicate wells. Assay reagents for FOXP3 (Hs00203958_m1), GATA3 (Hs00231122_m1), T-BET (Hs00203436_m1), GITR (Hs00188346_m1), IFN γ (Hs00174143_m1), IL-5 (Hs00542562_m1), IL-10 (Hs00174086_m1), STAT-5b (Hs00273500_m1), and 18s RNA (Hs99999901_s1) were

used. The quantitative value obtained from the TaqMan run was the threshold cycle Ct, which indicated the number of PCR cycles at which the amount of amplified target molecule exceeded a predefined fluorescence threshold value. The difference value (ΔC_t) was the normalized quantitative value of the expression level of the target gene, which was achieved by subtracting the Ct value of the housekeeping gene (18S) from that of the target gene. An exogenous cDNA pool calibrator was collected from PHA-stimulated PBMCs, and considered as an interassay standard to which normalized samples were compared. $\Delta\Delta C_t$ was the difference between the ΔC_t of the analyzed sample and that of the calibrator. Calculation of $2^{-\Delta\Delta C_t}$ gave a relative amount of the target gene in analyzed sample compared with the calibrator, both normalized to an endogenous control (18S). For presentations, the relative amount of target genes was multiplied by 1000 and expressed as relative units. When fold change of gene expression following GC therapy was expressed, it was calculated by dividing the relative expression after therapy by that before therapy. For test reliability, those samples with mRNA expression under 10 ng/ μ L ($n = 14$ for resting and $n = 1$ for activated target cells) between triplicate wells were excluded from the statistical analysis.

Statistical analysis

We used the Wilcoxon rank test, two-tailed Mann-Whitney *U* test, two-tailed Spearman's rho correlation test, and χ^2 test when appropriate (SPSS version 13.0). In the few cases with IFN γ greater than the detection limit of 120 000 pg/mL, this high value was used in statistical analysis. $P < 0.05$ was set for statistical significance.

Ethics

The study was approved by the Ethics Committee of Helsinki University Central Hospital and by the Institu-

tional Review Board. The families attending the study signed an informed consent form.

RESULTS

Serum-induced changes in gene expression of target cells

The median expression of FOXP3-specific mRNA in the resting target cells was suppressed by 33% (range of suppression 0%-79%, in one case, an increase of 173%, $P < 0.05$) and the median expression of GITR-specific mRNA by 46% (range 2%-78%, in three cases, an increase of 6%-124%, $P = 0.050$), when the effect of serum after GC was compared to that before therapy (Figure 1). In PHA-activated target cells, the median expression of GITR-specific mRNA was suppressed by 25% compared to the pre-treatment serum (range of suppression 1%-63%, in two cases, an increase of 6%-77%, $P < 0.01$).

The total or weight-related prednisolone dose did not correlate with the serum-induced GITR or FOXP3 gene expression of the target cells.

Serum-induced changes in secretion of IFN γ and IL-5 from target cells

IFN γ secretion from target cells was lower when cultured with patient serum taken 2 wk after the start of GC therapy, compared to the culture with the serum sample taken before GC therapy. This decrease was seen in resting target cells [from a mean of 68 pg/mL (SD 110 pg/mL) to 1.5 pg/mL (SD 6.7 pg/mL)]; however, because of the low secretion of IFN γ in resting target cells, detectable levels were only seen in seven cases, six of whom showed a decrease, $P < 0.05$]. In activated target cells, 13 cases showed a decrease from a mean of 87 700 pg/mL (SD 33 900 pg/mL) to 60 900 pg/mL

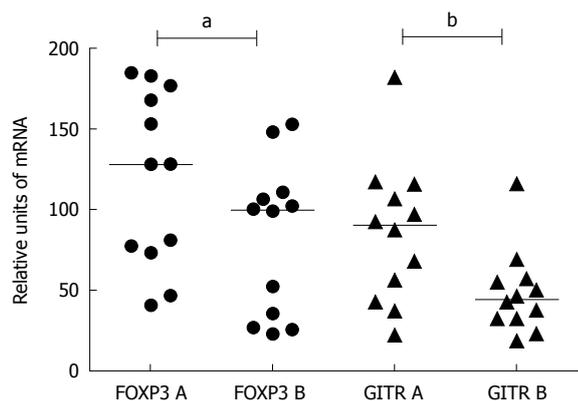

Figure 1 GITR and FOXP3 gene expression in target cells when cultured with patient serum taken before (A) and 2 wk after (B) GC therapy. For test reliability, the patients with low mRNA expression < 10 ng/ μ L ($n = 7$) were excluded from the Figure and the statistical analyses. ^a $P < 0.05$, ^b $P = 0.050$.

Measured with ELISA in the supernatants of healthy donor PBMCs (target cells, stimulated with PHA) cultured with patient serum taken before (A) and 2 wk after oral GC therapy (B).

(SD 44 200 pg/mL) ($P < 0.01$, Table 2). The decrease in serum-induced IL-5 secretion from activated target cells decreased after GC therapy was close to the level of statistical significance [from a mean of 60 pg/mL (SD 50 pg/mL) to 32 pg/mL (SD 46 pg/mL); 12 cases showed a decrease, $P = 0.055$, Table 2]. Serum-induced IL-5 secretion from resting target cells was undetectable.

The total or weight-related prednisolone dose did not correlate with IFN γ or IL-5 secretion from target cells.

Changes of cytokines and transcription-factor-specific mRNA in patient PBMCs

There were no statistically significant changes in the mRNA levels of the cytokines IFN γ , IL-5 and IL-10, or the transcription factors FOXP3, GITR, GATA3, STAT-5b and T-bet, in PBMCs derived from patients with IBD before and after 2 wk of GC therapy.

ESR, CRP and leukocyte count

ESR decreased from a median of 29 (range 0-64) mm/h to 12 (range 4-36) mm/h ($P < 0.01$), and CRP decreased from a median of 10 (range 5-75) mg/L to 5 (range 5-10) mg/L ($P < 0.01$) during 2 wk GC therapy. ESR or CRP did not correlate with the expression of GITR or FOXP3 from target cells, or with IFN γ or IL-5 secretion from target cells.

DISCUSSION

We found that serum from a GC-treated patient modulated *in vitro* the response of healthy donor-derived PBMCs and simulated the effects of GC treatment on the patient immune system. The attenuation of systemic inflammation during GC therapy was demonstrated with this assay at an individual level. The effect of GC treatment was mediated by patient serum, which caused a decrease in the target cell expression of regulatory T-cell-associated markers GITR^[18] and FOXP3^[19], and in the secretion of Th1 cytokine IFN γ .

The serum-induced decrease in cytokine and signaling molecule expression in the target cells was not attributed to the GC dose. This suggests that the observed changes in the levels of cell signaling markers were not solely due to GCs, but rather reflected the net systemic effect in patient serum. It has been reported previously that neither the level of GC in plasma or serum or serum GC bioactivity correlate with therapeutic responses^[14,20,21]. To study whether serum-induced effects on target cells were mediated by GC receptors, we co-cultured the target cells with patient serum and GC receptor antagonist mifepristone^[13,22]. Disappointingly, the results were uninformative as the GC receptor antagonist suppressed the target cell cytokine production and the treatment-mediated effects could not be assessed (data not shown).

It is highlighted that we did not see any direct effects of GC therapy on PBMCs derived from the patients. The PBMC population is heterogeneous and comprises naïve and memory T cells and effector and regulatory T cells. Thus, the net effect of GCs might be covered when studied in patient-derived PBMCs. Instead, we found that the effect of GC treatment was demonstrated as a patient-serum-induced decrease of FOXP3 and GITR in the target cells.

Earlier studies of the effect of GC therapy have focused on the direct changes induced in patient PBMC or lymphocyte subtypes such as regulatory T cells. The observation of GC-induced changes in regulatory T-cell-related FOXP3 is controversial, and there are no data from pediatric IBD. In an *in vitro* study on regulatory T cells of healthy donors, the administration of dexamethasone on purified CD4⁺ T cells induced a transient increase in the expression of FOXP3^[23]. Accordingly, in asthmatic patients, an increase in FOXP3 mRNA expression has been observed in freshly isolated and purified CD4⁺ T cells after oral GC administration^[23]. However, in another study, the counts of FOXP3-expressing CD4⁺CD25^{high} T cells and mRNA expression of GITR in PBMCs were

unaltered after 4 wk treatment with inhaled steroids^[24]. Furthermore, in a study of patients with allergic rhinitis, FOXP3-positive cells from nasal mucosa biopsies decreased significantly after several weeks treatment with intranasal GCs^[25]. These controversial findings of regulatory T-cell activation in different tissues and during different courses of GC therapy underline the importance of further studies to increase our understanding of the anti-inflammatory effects of GCs.

In line with our finding of a decrease in target cell IFN γ secretion, downregulation of pro-inflammatory cytokines, including IFN γ , has been reported in an *in vitro* study using PBMCs from healthy donors stimulated with dexamethasone and studied with DNA microarray chip analysis, online PCR and flow cytometry^[26].

Recently, it has been shown that, in severe pediatric colitis, the response to intravenous GC could be predicted already on day 3, with the aid of clinical activity scores^[27]. However, for oral GC therapy, there are no such data. We assessed the immunological responses of our patients at 2 wk, a time interval that was initially chosen for practical reasons. Therefore, it warrants further study to investigate if our findings could be detected during the first week of GC therapy.

To conclude, we developed a new cell culture assay to study the effect of GC therapy at an individual level, using serum samples taken from patients during GC therapy. We consider that the patient-serum-induced changes in the target cells reflect the net effect of the metabolism of GC and its immunological effects, and this mirrors the systemic inflammatory activity of the disease in the patient's circulation during GC therapy.

COMMENTS

Background

Corticosteroids are widely used in the treatment of several diseases, for example, asthma, rheumatic disease and inflammatory bowel disease (IBD). Corticosteroids are effective in suppressing active inflammation but not all patients respond to treatment, and various side effects are common. To date, the therapeutic effect cannot be foreseen and there are no specific means to monitor the therapeutic response at an early phase of the treatment.

Research frontiers

IBD is a chronic disorder with an increasing incidence in children. In pediatric patients, the disease course is often aggressive and the majority of patients need corticosteroids to suppress their symptoms. There is an urgent need for new means to monitor therapeutic responses to improve patient care.

Innovations and breakthroughs

The authors describe a novel assay that gives the possibility to monitor therapeutic responses to corticosteroids, using a serum sample from the patient. Disease activity is reflected in the serum that is used in an *in vitro* cell assay to stimulate human white blood cells. In cell culture, it is possible to measure how the effect of patient serum on specific white blood cell markers (T

cells) varies according to the given therapy. With this novel assay, it is possible to study the individual effect of corticosteroid therapy.

Applications

The results suggest that the effect of corticosteroid therapy on disease activity can be measured from patient serum at an early phase of the therapy. The authors studied pediatric patients with IBD, and further study is warranted to establish whether this kind of method is suitable for other patients with corticosteroid treatment.

Peer review

This is a well written and interesting manuscript.

Abstract

AIM: To examine the feasibility of predicting the flare-up of ulcerative colitis (UC) before symptoms emerge using the immunochemical fecal occult blood test (I-FOBT).

METHODS: We prospectively measured fecal hemoglobin concentrations in 78 UC patients using the I-FOBT every 1 or 2 mo.

RESULTS: During a 20 mo-period, 823 fecal samples from 78 patients were submitted. The median concentration of fecal hemoglobin was 41 ng/mL (range: 0-392500 ng/mL). There were three types of patients with regard to the correlation between I-FOBT and patient symptoms; the synchronous transition type with symptoms (44 patients), the unrelated type with

symptoms (19 patients), and the flare-up predictive type (15 patients). In patients with the flare-up predictive type, the values of I-FOBT were generally low during the study period with stable symptoms. Two to four weeks before the flare-up of symptoms, the I-FOBT values were high. Thus, in these patients, I-FOBT could predict the flare-up before symptoms emerged.

CONCLUSION: Flare-up could be predicted by I-FOBT in approximately 20% of UC patients. These results warrant periodical I-FOBT in UC patients.

Prediction of flare-ups of ulcerative colitis using quantitative immunochemical fecal occult blood test. *World J Gastroenterol* 2010; 16(9): 1110-1114 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i9/1110.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i9.1110>

INTRODUCTION

Ulcerative colitis (UC) is a chronic intestinal disorder of unknown etiology with a typically relapsing course. Although many UC patients often relapse with flare-ups of symptoms such as diarrhea and bloody stools despite appropriate maintenance therapies, the prediction of flare-ups a few weeks or months before symptoms emerge is impossible. If we could recognize relapses in the early stage, i.e. during the asymptomatic phase,

treatment of the relapse could be started in the early stage and might allow the patient to enter remission again more easily.

The fecal occult blood test (FOBT) is generally used as a screening method for colorectal cancer (CRC)^[1,2]. In many countries, the guaiac-based manual test is mainly used and validated to decrease mortality due to CRC^[3-5]. Recently, however, mainly in Japan, the test has developed into an immunochemical method with instruments for automatic measurement. Immunochemical FOBT (I-FOBT) has been reported to be more sensitive and specific for CRC detection than the guaiac-based test, and its effectiveness has also been accepted and widely used in Western countries^[6-21].

In this study, therefore, we measured fecal hemoglobin concentrations in UC patients in remission using an I-FOBT instrument each time they visited our hospital for regular UC-related check-ups. The aim of our study was to examine the feasibility of the prediction and prophylaxis of UC relapse by comparing fecal hemoglobin concentrations and symptoms in UC patients.

MATERIALS AND METHODS

Patients

Between April 2006 and November 2007, all UC patients who visited Okayama University Hospital were requested to prepare and bring fecal samples each visit. A total of 110 patients routinely came to our hospital every month or every 2 mo for determination of their disease status. Of these, a total of 78 patients with submitted fecal samples were analyzed in this study. The study protocol was approved by the institutional review board of Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences.

Assessment of disease

The diagnosis of UC was based on conventional criteria^[22]. Patients without a definite diagnosis of UC (e.g. indeterminate colitis) were excluded. The duration of disease was defined as the period between the time of onset and the first hospital visit during the study period.

Clinical relapse was defined as follows: active phase with worsening symptoms or emerging new symptoms that required treatment with newly prescribed or increasing doses of 5-aminosalicylic acid, salazosulfapyridine, corticosteroids, azathioprine/6-mercaptopurine, cyclosporine, tacrolimus or infliximab, including enemas or suppositories with such ingredients. The start of apheresis therapy (leukocytapheresis) was also defined as a clinical relapse.

Fecal sampling

Details of the method used for the fecal samplings were described previously^[17-20]. Fecal samples were prepared on the morning of or the day before the visit days. Patients were asked to prepare a fecal sample from a stool specimen by using the collection kit provided by

the manufacturer (Eiken Chemical, Tokyo, Japan). The I-FOBT sampling probe is inserted into an 8 cm × 2 cm test tube-shaped container. The patient inserts the probe into several different areas of the stool and then reinserts it firmly into the tube to seal it. The probe tip with the fecal sample is suspended in a standard volume of hemoglobin-stabilizing buffer.

Instrument for I-FOBT analysis

Submitted stool samples were immediately processed and examined using the OC-SENSOR neo (Eiken Chemical). The OC-SENSOR neo is the further-developed and large-scale version of the OC-SENSOR μ , which was used in previous reports^[17-20].

We assessed patient symptoms and disease activity using the partial Mayo score. Schroeder *et al.*^[23] developed the Mayo score in 1987, which comprises 4 items: stool frequency, rectal bleeding, findings of flexible proctosigmoidoscopy, and physician's global assessment. Each response is graded on a four-point scale ranging from "0" to "3". A score of zero means stool frequency is normal, no rectal bleeding is seen, findings of flexible proctosigmoidoscopy are normal if inactive disease is present, and physician's global assessment is normal. The total worst score is 12 points. This Mayo score is in common use in many clinical trials, and has noninvasive versions: the partial Mayo score (which excludes the mucosal appearance item from the 4-item index). Total worst score of the partial Mayo score is 9 points.

Classification of patients according to I-FOBT data

The patients were classified into three types according to I-FOBT data: synchronous transition with symptoms, the unrelated type with symptoms, and the flare-up predictive type. We first determined the patients who had the flare-up predictive type (the third type). Those patients with an I-FOBT value which was high an average of 1 mo before the flare-up of symptoms were assigned to this type.

After determining the third type, the remaining patients were classified into the first or second type by univariate regression analysis using I-FOBT values and the patient's partial Mayo scores. The first type (synchronous transition with symptoms): Univariate regression analyses appeared significant or produced a *P* value of < 0.20. The second type (unrelated type with symptoms): Univariate regression analyses produced a *P* value of \geq 0.20.

Statistical analysis

Statistical analysis was conducted using the SAS[®] System for Windows, version 9.2 (SAS Institute, Cary, NC, USA). Trends were assessed with the exact trend test to compare three discrete variables. Continuous variables were compared among the three patient groups using the Kruskal-Wallis test. Comparisons of continuous variables were performed using Mann-Whitney's *U* test. The results were considered to be statistically significant when

P values were less than 0.05. To determine the correlation between the value of I-FOBT and the partial Mayo score, a univariate regression analysis was performed.

RESULTS

Patients

A total of 78 patients were analyzed. These patients comprised 33 men and 45 women, with a median age of 40 years. The median disease duration was 9 years (range: 1-37 years). Of the 78 patients, 40 (51%) had pancolitis, 22 (28%) had left-sided colitis, and 16 (21%) had proctitis. During the study period, a total of 823 fecal samples were submitted by 78 patients, with a median of 10 samples submitted per patient. The frequency of submission of fecal samples was 0.74 times per month for each patient.

Range of I-FOBT values

The quantified value of the I-FOBT for each fecal sample was immediately determined by the OC-SENSOR neo. The median concentration was 41 ng/mL (0-392 500 ng/mL), and the distribution of the 823 fecal samples is shown in Figure 1. In general, stools with hemoglobin concentrations of more than 1000-10 000 ng/mL were recognized as bloody stools.

Correlation between the value of I-FOBT and patient symptoms

We examined the correlation between the value of I-FOBT and the partial Mayo score in each patient by univariate regression analysis. We found three types of correlations between the two parameters: synchronous transition with symptoms, the unrelated type with symptoms, and the flare-up predictive type.

First type (synchronous transition with symptoms):

In this type of patient, the values of I-FOBT were stable and did not fluctuate widely when patient symptoms were stable. However, the values increased or decreased along with deterioration or improvement of patient symptoms, respectively. These patients exhibited high I-FOBT values when their symptoms became worse. In turn, once their symptoms were relieved, the value of I-FOBT decreased. Forty-four patients (56%) were categorized into this type.

Second type (unrelated type with symptoms): The values of I-FOBT in this type of patient were not parallel with the symptoms. Of 78 patients, 19 (24%) were classified into this type. The values of I-FOBT in these patients were likely to be extremely high, although their symptoms were generally stable.

Third type (flare-up predictive type): In these patients, the values of I-FOBT were generally low during the period with stable symptoms. Before the flare-up of symptoms, the I-FOBT value was high, although the symptoms

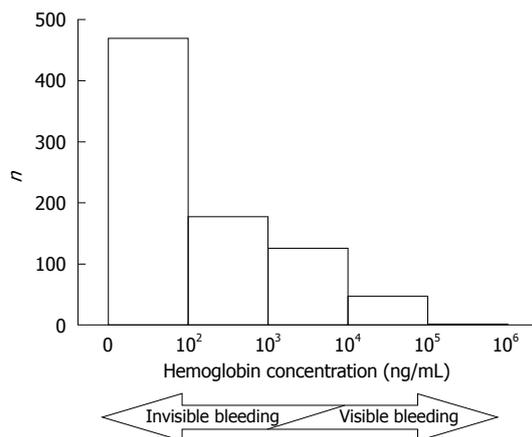

Figure 1 A histogram of hemoglobin concentrations in 823 fecal samples. The distribution of hemoglobin concentration in 823 fecal samples from 78 UC patients is shown. The median concentration was 41 ng/mL (0-392 500 ng/mL). More than 50% of fecal samples exhibited values between 0 and 100 ng/mL. Approximately 20% were between 100-1000 ng/mL, 15% were between 1000-10 000 ng/mL, and the remaining 7% of samples exhibited values more than 10 000 ng/mL. In general, stools with a hemoglobin concentration more than 1000-10 000 ng/mL were recognized as bloody stools.

Table 1 Characteristics of the three types of patients according to the correlation between I-FOBT value and patient symptoms

Data are medians with ranges in parentheses or numbers with percentages in parentheses. ^aExact trend test; ^bKruskal-Wallis test; ^cMann-Whitney's *U* test, 1st type vs 2nd type, *P* < 0.0001; 2nd type vs 3rd type, *P* = 0.021; 1st type vs 3rd type, *P* < 0.0001.

at that point had not worsened. An average of 1 mo after the rise in I-FOBT value (i.e. the day of the next consultation), the patient's symptoms became worse, and additional UC therapies or admission was required. Therefore, the I-FOBT values in these patients could predict the worsening of symptoms nearly 1 mo in advance. Fifteen patients (19%) were classified in this type.

Characteristics of the three types of patients

The demographic and clinical variables of the three types of patients are shown in Table 1. There was a higher proportion of females in the second-type group compared with the first- and third-type groups (*P* = 0.034). Age, disease duration, disease extent, and clinical

course were not significantly different among the three groups. I-FOBT results were significantly higher in the second-type group compared with the first- and third-type groups ($P < 0.0001$).

DISCUSSION

We were able to predict relapse before clinical symptoms emerged in approximately 20% of UC patients by quantifying fecal hemoglobin concentration on consultation days. The feasibility of predicting relapse is attractive, because it would permit earlier and therefore possibly more effective treatment. If colonoscopy is performed at the time when fecal hemoglobin concentration increases, but no symptoms of flare-up are observed, clinical relapse can be detected at the presymptomatic stage. If we start treatment for relapse at this stage, the severity of flare-ups could be reduced. Moreover, prophylaxis of flare-ups may be possible. Thus, follow up of the third-type of patients with I-FOBT would be beneficial.

Although many laboratory parameters (erythrocyte sedimentation rate, CRP, platelet count, white blood cell count, α_1 -antitrypsin) have been proposed as predictors of clinical relapse in UC^[24-31], it is difficult for these markers to predict relapse before symptoms emerge as they are not sufficiently specific or sensitive to inflammation in the colon. In contrast, increases in I-FOBT values are parallel with or predictive of the deterioration of symptoms in more than 80% of UC patients.

One promising predictive marker of relapse in UC is fecal calprotectin concentration. Tibble *et al.*^[32] and Costa *et al.*^[33] reported that in clinically quiescent UC patients followed for 12 mo, median fecal calprotectin levels at the beginning of the study in patients who relapsed were significantly higher than those in patients who did not relapse. In these reports, however, fecal calprotectin was measured once, and the concentration could be a marker of relapse that would occur several months after the measurement. Calprotectin is a granulocyte cytosolic protein, and a high fecal concentration of calprotectin indicates patients who are at risk of relapse. On the other hand, I-FOBT directly measures the fecal hemoglobin concentration, and a sequential change in fecal hemoglobin concentration could be a marker of relapse. Moreover, I-FOBT measurement was automated within a short time during outpatient consultation, and the instrument can be used as a screening method for CRC. Thus, sequential I-FOBT measurement is easier and more useful than the measurement of fecal calprotectin concentration in predicting early relapse.

There are limitations to this study. First, we adopted the 1-d method of I-FOBT. In CRC screening, the 2- or 3-d method is usually recommended because these methods are superior to the 1-d method in terms of sensitivity for colorectal neoplasia^[34-36]. Therefore, in the present UC study the examination of two or three samples of feces in one consultation day may be more reliable. Second, I-FOBT can not be used in women during menstruation

as the value of fecal hemoglobin concentration may be inaccurate.

In conclusion, we prospectively followed-up UC patients with I-FOBT. In some patients, an increase in fecal hemoglobin concentration was a useful marker of early relapse. The potential for sequential measurement is also an advantage of follow-up with I-FOBT. To confirm the usefulness of I-FOBT in the follow-up of UC patients, comparative studies are needed between patients with and without I-FOBT submission.

COMMENTS

Background

Ulcerative colitis (UC) is a chronic intestinal disorder of unknown etiology with a typically relapsing course. Although many UC patients often relapse despite appropriate maintenance therapies, the prediction of flare-ups a few weeks or months before symptoms emerge is impossible.

Research frontiers

Many laboratory parameters (erythrocyte sedimentation rate, CRP, platelet count, white blood cell count, α_1 -antitrypsin) have been proposed as predictors of clinical relapse of UC, but it is difficult for these markers to predict relapse before symptoms emerge as they are not sufficiently specific or sensitive to inflammation in the colon.

Innovations and breakthroughs

This is the first study to report the feasibility of prediction of UC relapse using the immunochemical fecal occult blood test (I-FOBT).

Applications

Starting treatment for relapse in the early stage may allow the patient to enter remission again more easily than if treatment is started after the symptoms of flare-up emerge. In addition, the prophylaxis of flare-ups by modulating the maintenance therapy to anticipate flare-ups by a few days or weeks may become possible.

Terminology

FOBT is generally used as a screening method for colorectal cancer. Recently, mainly in Japan, the test has developed into an immunochemical method with instruments for automatic measurement.

Peer review

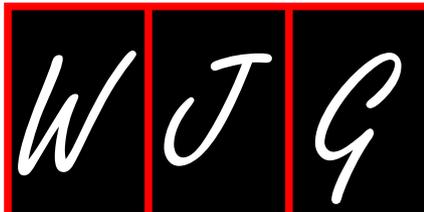

This study aimed to predict flare up of UC by estimating hemoglobin at regular intervals using I-FOBT. The authors evaluated a total of 78 patients over a period of 20 mo.

Abstract

AIM: To evaluate seroprevalence of hepatitis A virus (HAV) antibody and investigate demographic, clinical, and laboratory features of recent cases in Korea.

METHODS: For the evaluation of hepatitis A seroprevalence, we analyzed the data from 3127 subjects including, healthcare workers and patients who visited Konkuk University Hospital, a secondary referral center, from January to October 2009. The sera with positive IgM were excluded from seroprevalence data for total HAV antibody. We retrospectively reviewed the electronic medical records of 419 patients with HAV, who were diagnosed by the presence of serum IgM antibodies against HAV. All patients presented at Konkuk University Hospital between August 2005 and September 2008.

RESULTS: Among 3127 sera tested, 1428 (45.7%)

were positive for anti-HAV antibody. The seroprevalence was very low in teenagers or those in their twenties, increased in those in their thirties, and was > 90% in older patients. In children younger than 10 years, seroprevalence was increased again. Most patients with HAV hepatitis were in their twenties and thirties. The γ -glutamyl transpeptidase increased with age and was significantly higher in patients older than 30 years. Indicators of severity, such as decreased albumin and increased bilirubin, were also more prominent in the older age group; however, the leukocyte count was higher and the frequency of leukopenia was lower in younger patients than in older adults.

CONCLUSION: There has been an apparent epidemiological shift in HAV seroprevalence and a change in the peak age of HAV hepatitis. This study could provide baseline data of recent hepatitis A in Asia.

INTRODUCTION

The hepatitis A virus (HAV) is included in the picornaviridae family of viruses, which are small, non-enveloped,

single-stranded RNA viruses^[1]. They are transmitted almost exclusively by the fecal-oral route, and transmission is enhanced by poor hygiene, overcrowding, and contaminated food or drink^[2]. Infection with HAV is prevalent throughout the world, but it shows diverse epidemiological patterns according to the socioeconomic conditions^[3,4]. A high prevalence of this virus is associated with poor hygiene and living standards^[5]. In hyperendemic areas, almost all people have protective anti-HAV antibodies as a result of subclinical exposure during childhood^[2]; however, improved environmental conditions have resulted in fewer subclinical infections and a subsequent increase in the non-immune population. In Korea, there has been a rapid epidemiological shift in HAV infection as a result of rapid economic development^[3,6,7]. In 1980, most adults had immunity to HAV because of childhood exposure. Currently, less than 10% of people in their teens or twenties have anti-HAV IgG^[6]. Thus, adult cases of acute hepatitis A have increased rapidly during the past 10 years due to the emergence of susceptible adults in Korea^[6,8].

In this study, we evaluated seroprevalence of total HAV antibody and investigated demographic, clinical, and laboratory features of recent cases of hepatitis A in Korea, where there is an ongoing epidemiological shift. Moreover, we compared laboratory characteristics of HAV according to patient age before and after the epidemiological shift.

MATERIALS AND METHODS

Study populations

For the evaluation of hepatitis A seroprevalence, we analyzed the data from 3127 subjects, including healthcare workers and patients, who visited Konkuk University Hospital, a secondary referral center, from January to October 2009. The sera with positive IgM were excluded from the seroprevalence data for total HAV antibody. We retrospectively reviewed the electronic medical records of 419 patients with HAV, who were diagnosed by the presence of serum IgM against HAV. All patients presented at Konkuk University Hospital between August 2005 and September 2008. We investigated the clinical, laboratory, and epidemiological features of these patients and analyzed age-specific characteristics. We compared laboratory findings of patients who are younger and older than 30 years of age because these groups were considered to have been exposed to different epidemiological environments, based on the results of total HAV antibody seroprevalence in other recent studies^[6,7].

Laboratory tests

A routine chemistry test (Neo-200FR autoanalyzer; Toshiba Medical Systems Co., Tokyo, Japan), complete blood count, and coagulation studies (Sysmex Co., Kobe, Japan) were performed. We tested serum total HAV antibody using the HAV Total immunoassay kit (Siemens Healthcare Diagnostics, Tarrytown, NY, USA). To detect serum anti-HAV IgM, we used commercially available

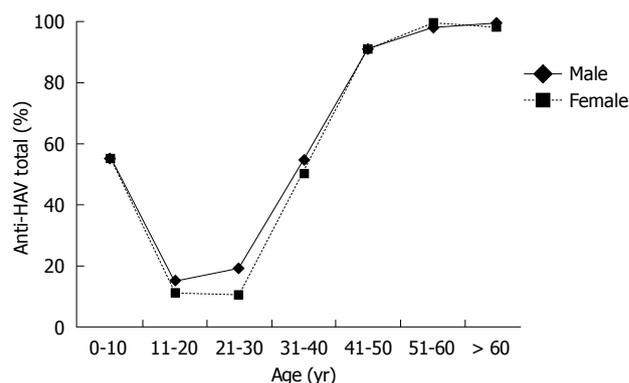

Figure 1 Age-specific seroprevalence of total anti-hepatitis A virus (HAV) antibody in Korea. The seroprevalence was very low in patients in their teens or twenties, increased in those in their thirties, and was > 90% in older patients. In children younger than 10 years, seroprevalence was increased ($n = 3127$).

electrochemiluminescence immunoassay kits (Roche Diagnostics, Mannheim, Germany).

Statistical analysis

Relationships between variables were analyzed using the Fisher exact test for categorical variables and Student's *t* test for continuous variables. Statistical analysis was performed using SPSS software, version 11.0 (SPSS Inc., Chicago, IL, USA). $P < 0.05$ was considered statistically significant.

RESULTS

Age-specific seroprevalence of total anti-HAV antibody

The median age of population tested was 31 years and 43.2% were male. Among 3127 sera tested, 1428 (45.7%) were positive for total anti-HAV antibody. The seroprevalence was different depending on age and sex (Figure 1). The seroprevalence was very low in patients in their teens or twenties, increased in the those in their thirties, and was > 90% in older patients. In children younger than 10 years, seroprevalence was increased.

Characteristics of hepatitis A cases in Korea

The median age of 419 patients with HAV hepatitis was 29 years and 62% were male. Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) showed a marked increase in almost all patients, and ALT was higher in most cases (median AST/ALT ratio 0.7). Variable elevations of alkaline phosphatase (ALP), γ -glutamyl transpeptidase (GGT), and total bilirubin (TB) were evident in most patients. Leukopenia, thrombocytopenia, and prolonged prothrombin times (PT) were common findings. Among 419 cases, 352 patients (84%) needed hospital admission, and the median hospitalization period was 6 d (range: 1-31 d). Frequent symptoms were nausea/vomiting (55%), fever (49%), anorexia (34%), myalgia (32%), abdominal pain (23%), and dark urine (20%).

Twenty-one patients (5%) were chronic hepatitis B carriers. There were no cases of fulminant hepatitis or death in the study period.

Age distribution of recent hepatitis A in Korea and age-specific laboratory findings

Patients with HAV were mostly in their twenties (57.5%) and thirties (31.5%) (Table 1). The number of patients in the other age groups (≤ 20 or > 40 years) were relatively few (5.2% and 5.7%). There was only one patient younger than 10 years old. Men were more prevalent in all age groups, and this tendency was more pronounced for men in their thirties (M/F ratio 2.4). GGT increased with age ($P = 0.011$), but other laboratory findings were not significantly different between age groups.

We compared laboratory findings of the patients who are younger and older than 30 years old (Table 2). Levels of the enzymes AST, ALT, and ALP were not significantly different between the two groups; however, the older age group showed a significant increase in GGT, decrease in albumin, and increase in globulin (decreased A/G ratio) ($P = 0.006$, $P = 0.000$, and $P = 0.012$, respectively). TB was also increased in the older group,

although this was not statistically significant ($P = 0.051$). In contrast, abnormalities in hematological parameters were more severe in the younger group, especially with regard to decreased leukocyte count. The results of coagulation studies and duration of hospital stay were not significantly different.

DISCUSSION

In highly endemic areas with poor socioeconomic conditions, HAV infection occurs in young children, possibly due to a lack of transmission control and the ubiquitous presence of HAV in the environment^[5,9]. In contrast, HAV exposure is relatively rare in developed countries such as the United States, Canada, and countries in Western Europe because possible transmission factors are controlled^[2,4,10,11]. The majority of symptomatic cases occur in adolescents, adults, and people with risk factors^[4]. HAV infection in non-immune adults can cause severe hepatitis^[12-14]. Complications include coagulopathy, encephalopathy, renal failure, prolonged disease, and disease relapses^[9]. In the past in South Korea (1980s), HAV was endemic, and most adults acquired natural immunity through asymptomatic infection^[7,15]. Due to the rapid improvement of socioeconomic conditions, the childhood incidence of HAV infection and the immune population have decreased, thus, the incidence of adult infection has increased steadily due to a lack of natural immunity^[7,8,16,17]. After 2000, symptomatic cases of HAV infection increased markedly and the age of affected patients was significantly higher before 2000 than after 2000^[7]. This transitional pattern also has occurred in other Asian populations that have similar environmental conditions^[2,3]. In our study, seroprevalence increased with age and showed an abrupt rise in patients older than 30 years of age compared to those younger than 30 years of age. These results are consistent with other recent studies in Korea^[6,7]. This is thought to be due to different epidemiological and socioeconomic environments during the economic development of Korea. Of note, with the recent increase of HAV vaccination in childhood, seroprevalence has increased in children younger than 10 years (Figure 1).

We evaluated the features of recent hepatitis A cases at a single center where we have observed a rapid

increase in the number of cases in recent years. These cases were analyzed for age-specific laboratory characteristics. In our study, most patients with HAV were in their twenties and thirties and most were male. The male predominance was especially true of patients in their thirties, which may be due to more exposure to the virus in men of that age. Besides markedly increased levels of enzymes related to acute hepatitis, most patients also showed increased TB levels and PT. Hematological abnormalities such as leukopenia and thrombocytopenia were noted in about one third of patients with hepatitis A (Table 2). These findings reflect more severe manifestations of acute hepatitis. Eighty-four percent of patients required hospitalization, which is much more than previously reported in the United States^[4,9], but similar to other recent reports in Korea^[6,7].

Although other enzymes were not significantly different between age groups, GGT increased with age and was significantly higher in patients older than 30 years ($P = 0.006$). Indicators of severity, including decreased albumin and increased TB^[1,18], were also more predominant in the older group ($P = 0.000$ and 0.051 , respectively) (Table 2). However, the leukocyte count was higher and the frequency of leukopenia was lower in younger patients than older adults ($P = 0.002$ and 0.003 , respectively).

In conclusion, we investigated age-specific seroprevalence and laboratory characteristics of Korean patients recently infected with HAV. There has been an apparent epidemiological shift and change in the peak age of infection. This study could provide valuable baseline data of recent hepatitis A in an Asian area with an epidemiological shift.

COMMENTS

Background

In Korea, there has been a rapid epidemiological shift in hepatitis A virus (HAV) infection over the past decade as a result of rapid economic development. Adult cases of acute HAV have increased rapidly during the past 10 years due to the emergence of susceptible adults in Korea.

Research frontiers

The transitional pattern of HAV epidemiology has occurred in Korea and other Asian populations that have similar environmental conditions. The large scale data from various populations regarding this issue would be valuable for establishing recent epidemiological features of HAV infection.

Innovations and breakthroughs

In 1980, most adults had had immunity to HAV because of childhood exposure. Currently, less than 10% of people in their teens or twenties have anti-HAV IgG. In this study, the authors evaluated seroprevalence of total HAV antibody, with large-scale data, and investigated demographic, clinical, and laboratory features of recent cases of HAV in Korea, where there is an ongoing epidemiological shift.

Applications

There has been an apparent epidemiological shift in HAV seroprevalence and a change in the peak age of HAV hepatitis. Overall, these cases have revealed a severe pattern of acute hepatitis. This study could provide valuable baseline data of recent hepatitis A in an Asian area with an epidemiological shift.

Abstract

AIM: To investigate the safety and diagnostic yield of colonoscopy in Chinese children in whom the procedure is not often done.

METHODS: We conducted a retrospective review of all colonoscopies in consecutive children who underwent their first diagnostic colonoscopy from Jan 2003 to 2008.

RESULTS: Seventy-nine children (48 boys, 31 girls; mean age 9.2 ± 4.2 years) were identified and reviewed with a total of 82 colonoscopies performed. Successful caecal and ileal intubation rates were 97.6% and 75.6% respectively. Forty patients (50.6%) had a positive diagnosis made in colonoscopy and that included colonic polyps (23), Crohn's disease (12), ulcerative colitis (1), and miscellaneous causes (4). 80% of polyps were in the rectosigmoid colon. All but one were juvenile hamartomatous polyps. The exception

was an adenomatous polyp. The mean ages for children with inflammatory bowel disease (IBD) and polyps were 11.3 and 4.3 years respectively. There was no procedure-related complication.

CONCLUSION: Colonoscopy is a safe procedure in our Chinese children. The increasing diagnosis of IBD in recent decades may reflect a rising incidence of the disease in our children.

INTRODUCTION

The safety and effectiveness of colonoscopy in the investigation of lower gastrointestinal tract pathology in children has been established for more than 2 decades^[1]. It remains to be a procedure that mandates highly specialized expertise and is usually performed in a tertiary referral center. Investigation of inflammatory bowel disease (IBD), whether for diagnosis or follow-up evaluation, and suspected colonic polyps are the most common indications for pediatric colonoscopy in European and North American society^[2-5]. Population-based studies suggest

the uneven distribution of IBD throughout the world with the highest disease rates in Caucasian countries^[6]. It has been believed that the incidence of IBD in Chinese children is low and as a result pediatric colonoscopy is not as commonly done in the Chinese population as in Western countries. Recent reports suggested an increasing incidence of pediatric IBD in Western countries while it is unknown whether a similar increase happens in Chinese children as well^[7-9]. In this study, we aimed to investigate the diagnostic yield and safety of colonoscopy, and the pathology pattern of our Chinese children who underwent this procedure.

MATERIALS AND METHODS

A retrospective review was conducted on all consecutive pediatric patients who underwent their first diagnostic colonoscopy during the period from January 2003 to 2008 in a tertiary referral center serving a population of 1.32 million. The data were collected from the hospital electronic database system which required prospective entry of all the patients who underwent endoscopic procedures. Our institution was the only center that provided a pediatric colonoscopy service in the region.

Demographic data, indications for colonoscopy, endoscopic findings, extent of the procedure and follow-up progress were analyzed. All the colonoscopy procedures were performed by a single endoscopist (Tam YH) using a pediatric videoscope (Olympus PCF 200, Tokyo, Japan) in the presence of an anesthetist. Each patient had bowel preparation of low residual diet for 3 d prior to examination followed by admission to our hospital one day before the procedure for anesthetic assessment and further bowel cleansing with either oral sodium phosphate or polyethylene glycol-based solution. The endoscopy suite was equipped with an anesthetic machine and the majority of pediatric patients had the procedure done under general anesthesia by orotracheal intubation with inhalation anesthetic agents. A few exceptions, usually being older children, were put under conscious sedation by anesthetists using a combination of agents including ketamine, midazolam and propofol. Mucosal biopsies were taken whenever indicated and polypectomy were performed by snare with electrocautery.

RESULTS

Seventy-nine children, being all ethnic Chinese, were identified and reviewed. These included 48 boys (61%) and 31 girls, aged from 21 mo to 16 years (mean = 9.2 ± 4.2 years, median = 10 years). The two most common indications were painless per rectal bleeding (*n* = 46, 58%) and suspected IBD (*n* = 23, 29.1%). Other miscellaneous indications included investigation for protein losing enteropathy, enteritis in immunocompromised patients, Graft-versus-host diseases after bone marrow transplant, iron deficiency anemia, change of bowel habit and strong family history of carcinoma of the colon with parental anxiety.

A total of 82 colonoscopies were performed in the

Table 1 Indications and diagnoses of 79 children after colonoscopy

Indications	Diagnoses	<i>n</i>	
Painless per rectal bleeding (<i>n</i> = 46)	Colonic polyps	23	
	Normal findings	23	
	Suspected IBD (<i>n</i> = 23)	Crohn's disease	12
		Ulcerative colitis	1
Miscellaneous (<i>n</i> = 10)	Normal findings	10	
	Eosinophilic enteritis	1	
	CMV enteritis	1	
	GVHD	1	
	Multiple colonic haemangioma	1	
	Normal findings	6	

IBD: Inflammatory bowel disease; CMV: Cytomegalovirus; GVHD: Graft-versus-host disease.

Table 2 Locations of the 25 colonic polyps in 23 children

Sigmoid colon	9 (36)
Descending colon	3 (12)
Transverse colon	1 (4)
Ascending colon	1 (4)

79 patients during the study period. All but 7 of the procedures were done under general anesthesia. Complete colonoscopy was successful in 80 procedures (97.6%). Ileal intubation was routinely attempted in patients with suspected IBD and was successfully performed in 22 out of 23 children (95.7%) investigated for IBD. Ileal intubation was attempted but failed in one patient with Crohn's disease (CD) because of an edematous ileocaecal valve. Overall, ileal intubation was performed in 62 out of the total of 82 colonoscopies (75.6%). Three children had a repeat colonoscopy during the study period for recurrent colonic polyp, follow-up progress of CD and argon beam coagulation for multiple colonic haemangioma respectively.

Forty out of 79 patients (50.6%) had a positive diagnosis made in colonoscopy with or without biopsy. These included colonic polyps (*n* = 23), CD (*n* = 12), ulcerative colitis (UC) (*n* = 1) and other miscellaneous pathology (Table 1). Children diagnosed to have IBD were found to be significantly older than children with colonic polyps (11.3 ± 3.7 years *vs* 4.3 ± 1.9 years; mean age difference = 7.1 years; 95% CI: 5.2-9.0). Of the 12 patients diagnosed with CD, there were 7 girls and 5 boys. The only patient with UC was a girl.

Among the 23 children with polyps, there were 14 males and 9 females. Twenty two of them had solitary colonic polyp while 1 patient had 3 synchronous polyps at multiple sites. Of the 25 polyps, 20 (80%) were located in the rectosigmoid colon (Table 2). Therapeutic colonoscopic polypectomy was successful in all but 1 patient who had a huge polyp with a broad base at the transverse colon and partial resection was achieved during colonoscopy. The patient subsequently underwent elective laparoscopic-assisted bowel resection and pathology was confirmed to

be juvenile polyp. Histological examination revealed all the polyps removed to be juvenile hamartomatous polyps except one which was tubular adenoma that developed in a child who presented with painless per rectal bleeding without any family history of colonic polyp or cancer. One child developed recurrent juvenile polyp 1 year afterwards and required a second colonoscopic polypectomy. There were no procedure-related complications including perforation, bleeding that required re-examination or checking of hemoglobin after procedure, and cardiopulmonary problems caused by general anesthesia or sedation. At a mean follow-up of 22 ± 16 mo, 2 patients died of complications after bone marrow transplant. None of the patients with normal colonoscopy findings had persistent symptoms that required a repeat colonoscopy or further radiological imaging to exclude any pathological conditions.

DISCUSSION

Reports in Western countries have suggested a significant increase in the incidence of IBD in children over the last few decades^[7-9]. The annual incidence rates in United Kingdom and North America were estimated to be 5.2 to 7.05 per 100 000 pediatric populations in recent reports^[10,11]. IBD has been believed to occur rarely in Chinese children. However, a recent population-based study in North America did not find any difference in the incidence between Caucasian children and other racial groups including Asians^[11]. The authors suggested changing environmental factors had played an increasingly important role in the pathogenesis of pediatric IBD.

Our institution serves a population of 1.32 million and is the only center to provide a pediatric colonoscopy service within the region. If we could assume all the newly diagnosed cases of childhood IBD in our region were captured by our study during the review period and based on the population census report of Hong Kong in 2006 that children aged 18 or less accounted for 20.3% population, we could estimate the annual incidence rate in our children to be 7- to 8-fold less than the figures in United Kingdom and North America. Epidemiological data of IBD in Chinese children is scarce. A study conducted two decades ago reported only 1 case of IBD out of 65 colonoscopies in our Chinese children over a six-year period^[12]. We have previously reported 9 children (CD = 7; UC = 2) who were diagnosed and treated in our institution in 10 years from 1992 to 2002^[13], while 13 cases (CD = 12; UC = 1) were diagnosed within 6 years in this study. The increase in diagnosis of childhood IBD in the most recent decade compared with our local data in the 80s and 90s may reflect a possible increase in incidence of the disease although attribution to changes in referral patterns cannot be excluded. A central register of pediatric IBD, which is lacking currently in our locality, is deemed necessary to accurately monitor the incidence of the disease in our children^[14].

We reported a mean age of 11.3 years at the time of diagnosis and a higher incidence of CD over UC in our

childhood IBD. The results are in keeping with data reported in Western countries^[10,11,14-16]. Our finding of more instances of CD in female children was in contrast to the consistent findings of male predominance in Caucasian populations^[10,11,14-16]. Female predominance of CD is noted in the adult population^[17]. However, our small sample size does not allow us to make any conclusion about the gender predominance of IBD in Chinese children.

Our results of male predominance and mean age of 4.3 years in children with colonic polyps are in keeping with previous reports^[18-22]. About 80% of the polyps were found in the rectosigmoid colon of our children and only 8% were proximal to splenic flexure. Our findings are similar to those reported from India and Netherlands^[4,20,22]. Recent data in North America found more proximal polyps with 54% in the rectosigmoid colon and 32% proximal to the splenic flexure^[21]. Genetic and environmental factors may likely account for the difference between races. Despite our small series, there was one case of adenomatous polyp in a child with a solitary polyp in the sigmoid colon. This finding agrees with others that adenomatous polyps do occur in children, though infrequently, and pancolonoscopy is indicated as the initial procedure for investigation of suspected colonic polyps in children in view of the neoplastic potential of an unidentified polyp^[18,20,21].

Despite the small case volume, our reported rates of 97% and 75.6% in caecal and ileal intubation respectively compare well with other series^[1-4]. We did not encounter any complications related to the procedure, in accordance with the universally low complication rates reported in pediatric colonoscopy^[23]. All of our procedures were done by a single endoscopist. Concentration of expertise and experience helps to promote good clinical results. However, the small case volume remains to be a major limitation to training of next generations. In a prospective survey in United Kingdom, specialized pediatric centers perform a mean of 24 colonoscopies over a 4-mo period, which is over 5-fold of our volume^[24]. Pediatric guidelines have been issued in North America to recommend the minimum number of procedures to be performed to acquire competency of skills^[25]. Recommendations in Western countries may not be applicable in our locality. Rotation training in adult colonoscopy and virtual endoscopy training^[26] may provide an alternative way of providing training in pediatric colonoscopy in Hong Kong.

COMMENTS

Background

Colonoscopy in children is a highly specialized endoscopic procedure that is not often performed in the Chinese population as inflammatory bowel disease (IBD), which is an important indication for this procedure, is quite rare in Chinese children. Data of the safety, indications and diagnostic yield of colonoscopy in Chinese children is rarely reported. In this study, the authors retrospectively reviewed all the Chinese children who underwent their first diagnostic colonoscopy in a tertiary referral center within a 6-year period.

Research frontiers

There were 79 children who underwent their first colonoscopy over 6 years in the authors' institution that serves a population of 1.32 million and is the only

center that provides this service in the region. The procedure was successfully completed in 97.6% of cases without any complications. Pathological conditions that could account for the symptoms were identified in 50% of cases by colonoscopy. The two most common positive diagnoses were colonic polyps in 23 children and IBD in another 13 patients.

Innovations and breakthroughs

The results found that there was an increase in the diagnosis of IBD by colonoscopy in the recent decade compared with our local data in the 1980s and 1990s. Data in Western countries have recently suggested an increase in the incidence of IBD in children. The authors' findings suggest the possibility of a similar increase in the occurrence of this disease in Hong Kong Chinese children in whom the disease has been believed to be extremely uncommon for many years.

Applications

The findings suggested that establishment of a central registry for childhood IBD is strongly indicated to monitor its incidence in Chinese children.

Peer review

This is a retrospective cohort study of all pediatric patients undergoing colonoscopy at a tertiary centre over a 6 year period. Though it is a simple observational study of workload undertaken during this period, it does add background value with respect to identified pathologies in a predominantly Asian pediatric population.

Abstract

AIM: To evaluate the short- and long-term outcomes of liver resection for caudate lobe hepatocellular carcinoma (HCC).

METHODS: We retrospectively analyzed 114 consecutive patients with HCC, originating from the caudate lobe, who underwent resection between January 2001 and January 2007. Univariate and multivariate analyses were performed on several clinicopathologic variables to determine the factors affecting long-term outcome and intrahepatic recurrence.

RESULTS: Overall mortality and morbidity were 0% and 18%, respectively. After a median follow-up of 31 mo (interquartile range, 11-66 mo), tumor recurrence had occurred in 76 patients (66.7%). The 1-, 3-, and 5-year disease-free survival rates were 65.7%, 38.1%, and 18.4%, respectively. The 1-, 3-, and 5-year overall

survival rates were 76.1%, 54.7%, and 31.8%, respectively. Univariate analysis showed that subsegmental location of the tumor (45.7% vs 16.2%, $P = 0.01$), liver cirrhosis (12.3% vs 47.9%, $P = 0.03$), surgical margin (18.5% vs 54.6%, $P = 0.04$), vascular invasion (37.9% vs 23.2%, $P = 0.04$) and extended caudate resection (42.1% vs 15.4%, $P = 0.04$) were related to poorer long-term survival. Multivariate analysis showed that only subsegmental location of the tumor, liver cirrhosis and surgical margin were significant independent prognostic factors.

CONCLUSION: Hepatectomy was an effective treatment for HCC in the caudate lobe. The subsegmental location of the tumor, liver cirrhosis and surgical margin affected long-term survival.

Prognostic factors in the surgical treatment of caudate lobe hepatocellular carcinoma. *World J Gastroenterol* 2010; 16(9): 1123-1128 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i9/1123.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i9.1123>

INTRODUCTION

Refined surgical and anesthetic techniques, a better understanding of liver anatomy^[1,2], and improvements in postoperative management have increased the indications for hepatectomy in patients with hepatocellular carcinoma (HCC) in the caudate lobe. Hepatic resections can now

be performed in high-volume centers with an acceptable morbidity of 50%-60% and no mortality^[3,4]. Caudate HCC has a poorer prognosis than HCC originating from other lobes due to its proximity to the portal trunk and inferior vena cava, which facilitates intrahepatic and systemic spread early in the disease^[5,6]. Although some surgeons have reported successful surgical treatment of caudate HCC with transarterial chemoembolization (TACE)^[7,8] or local ablation^[9-11], hepatic resection has been considered to be the treatment of first choice^[12-14]. The most important factor currently limiting the disease-free interval is the high rate of tumor recurrence, which ranges from 50%-60% at 3 years^[15,16]. In order to improve surgical outcome, it is necessary to evaluate the potential risk factors for long-term survival and to establish guidelines for the appropriate use of hepatectomy for caudate lobectomy. We therefore retrospectively evaluated 114 consecutive patients who underwent hepatic resection for HCC originating in the caudate lobe, in order to assess the influence of common clinicopathologic variables on recurrence and long-term survival.

MATERIALS AND METHODS

Between January 2001 and January 2007, 114 consecutive patients with HCC in the caudate lobe underwent hepatic resection at the Eastern Hepatobiliary Surgery Hospital, Second Military Medical University. Computed tomography (spiral-CT), detection of serum α -fetoprotein level (AFP), and hepatic ultrasound-guided fine-needle biopsy were used for preoperative diagnosis of HCC. Needle biopsy was not performed in patients with an elevated serum level of AFP and typical imaging of HCC, to avoid needle tract seeding of tumor cells. Clinicopathologic and follow-up data for each patient were recorded in a computerized database, regularly updated for tumor recurrence and survival status. Resection was considered "extended" if the caudate lobe as well as other lobes or segments were removed, according to Couinaud's classification. Intraoperative ultrasound was routinely performed in all patients, in order to detect tumor invasion into the major branches of the portal vein and hepatic veins, or the presence of lesions in the contralateral lobe. Tumor clearance at the resection margins of at least 5 mm was considered adequate to define the surgical procedures as curative (R0)^[17]. Hospital mortality was defined as death within 30 d after operation, including operative deaths. Tumor recurrence was considered as evidence of hepatic tumoral lesions after a curative resection. All patients discharged were followed-up at our department every 3 mo in the first year, every 6 mo in the second year, and every 6 mo thereafter. The follow-up consisted of physical examination, blood tests, serologic liver function test, detection of serum AFP level and liver ultrasound or CT scan.

Liver resection was carried out using a clamp-crushing technique in all patients. Intraoperative ultrasonography was routinely used to locate the carcinoma, exclude daughter nodules, and identify the relationship of the tumor with the major vessels, so minimizing blood loss and avoiding injury to the main trunk vessels. We used

multiple occlusion techniques, including continuous or intermittent Pringle maneuver, hemihepatic vascular clamping, or total hepatic vascular exclusion, determined on a case-by-case basis.

Statistical analysis

Continuous data were expressed as medians and interquartile ranges. Survival curves were calculated using the Kaplan-Meier method and compared using the log-rank test. For comparison of survival, continuous variables were dichotomized using the respective medians as the cut-off values. Only the variables that were significant in univariate analysis were entered into a Cox regression model to identify the clinicopathologic factors with independent prognostic significance. Patients with hospital mortality (within 30 d) were excluded from the evaluation of these factors with regard to long-term and disease-free survival. Statistical analysis was carried out using SPSS computer software (SPSS Inc., Chicago, IL, USA). Differences were considered significant if the *P* value was < 0.05.

RESULTS

The clinicopathologic characteristics of the 114 resected patients are shown in Table 1. There were 87 males (76%) and 27 females (24%). The median age was 49 years. The Child-Pugh grading system for the prognosis of liver cirrhosis was applied in all patients. All patients were classified as Child-Pugh grade A. Data regarding serum AFP levels were available for all patients, and 90 patients (79%) were AFP-positive. The median preoperative AFP level was 195 ng/mL. Seventy-eight (68.4%) patients had undergone isolated caudate lobectomy and 36 (31.6%) had undergone extended caudate lobectomy (Table 2).

A curative resection (surgical margin > 5 mm) was achieved in 59% of cases (67 patients). Histopathologic examination showed that 84% of patients had a differentiated tumor (74% trabecular type, 1% fibrolamellar type, and 9% mixed type), while 16% had undifferentiated tumors. Vascular invasion was found in 38% of patients. There was no postoperative mortality. The hospital morbidity rate was 18% (21 patients). The most frequent complications were infections (abdominal abscess, pleural effusion and bronchopneumonia), liver failure, hemorrhage, ascites and mild lower limb edema.

The median follow-up period was 31 mo (interquartile range, 11-66 mo). A total of 65 patients (57.0%) died during the follow-up period. Eight patients (7.0%) were lost to follow-up at 4, 7, 9, 18, 30, 42, 50 and 54 mo. Up to the last follow-up date (January 2007), 41 patients (36.0%) were alive, of whom, 21 were disease-free (18.4%). Tumor recurrence occurred in 49 patients (75.4%), and disease progression was the leading cause of death in 65 patients (57.0%). The 1-, 3-, and 5-year disease-free survival rates were 65.7%, 38.7%, and 18.8%, respectively. The 1-, 3-, and 5-year overall survival rates were 76.1%, 54.7%, and 31.8%, respectively (Figure 1).

acteristics are shown in Table 3. There were no associations between age or sex and survival rate. No significant differences in survival rate were noted between patients with AFP levels > or \leq 200 ng/dL, with tumor sizes \leq or > 5 cm, with or without capsulated tumors, or among patients with well-differentiated or poorly-differentiated HCC. The extent of the hepatic resection (isolated *vs* extended) did not influence the long-term survival. The effect of tumor subsegmental location was also investigated and it was shown that there was a significant survival difference between patients with tumors in the Spiegel lobe compared to the paracaval portion and caudate process ($P < 0.01$). There was no significant difference in 3-year survival between solitary and multiple tumors, but a significant difference in overall survival was observed between patients with or without liver cirrhosis. The 5-year survival rate of patients without cirrhosis was

significantly higher than in patients with viral cirrhosis (47.9% *vs* 12.3%, $P = 0.03$). The presence or absence of vascular invasion was also a significant prognostic factor for survival; patients without vascular invasion had significantly higher 5-year survival rates than those with vascular invasion (37.9% *vs* 23.2%, $P = 0.05$).

In multivariate analysis, only subsegmental location, liver cirrhosis and surgical margin were confirmed as independent prognostic factors for overall survival (Table 4). None of the clinicopathologic factors analyzed were significantly correlated with disease-free survival (Table 5).

DISCUSSION

Although HCC arising from the caudate lobe has been reported to be relatively rare, its surgical treatment

presents a challenge and is associated with high risks for the surgeon, due to its unique anatomic location and its complicated relationship with the major vasculature. To the best of our knowledge, the tumor with the largest reported volume was a HCC in the caudate lobe. Local ablation of HCC in the caudate lobe has been reported and evaluated^[12-14], but hepatic resection remains the mainstay for the treatment of HCCs, and is the only approach that provides consistent, long-term survival^[18-21].

Due to the lack of large series of patients with HCC in the caudate lobe, studies have produced conflicting

reports on the effect of this surgery and prognosis following liver resection. During the late 1980s to early 1990s, several groups^[5,12,17] reported that HCCs originating in the caudate lobe easily produced intrahepatic metastases because of the corresponding short portal veins, giving these patients a poor prognosis. Others during the late 1990s^[6,16,22], however, reported comparable survival rates for patients with HCCs in the caudate lobe and those with HCCs in other parts of the liver. Our results were in accord with the former findings. In this study, we performed multivariate analysis and calculated survival rates for patients with caudate HCC after resection, in relation to clinicopathologic factors. Our data showed that long-term survival of patients with HCC after hepatectomy depended on the background of cirrhosis, subsegmental location of HCC, surgical resection margin, and extended caudate resection. The overall survival rates in our group after resection of HCC of the caudate lobe were 76.1% at 1 year, 54.7% at 3 years and 31.8% at 5 years. The disease-free survival rates were

65.7% at 1 year, 36.1% at 3 years and 18.8% at 5 years. The results showed poorer overall survival at 5 years than that reported by Ikegami *et al*^[16] (66.7%). However, the diameter of the tumors in most of the patients in this earlier study was < 5 cm, which was the reason for the limited hepatic resection performed. In contrast, the median tumor diameter in our series was 5.7 cm, which could account for the poorer prognosis. Overall survival rates of 85.3% at 1 year, 67.0% at 3 years and 50.5% at 5 years were reported in a series of 12 118 patients after resection of HCC by Ikai *et al*^[23]. From this point of view, the overall survival of patients with HCC of the caudate lobe after resection was poorer than that of patients with HCCs of other lobes. This survival difference may be related to the anatomy and characteristics of the caudate lobe.

Univariate and multivariate analyses showed significant differences in overall survival depending on subsegmental location of HCC. The results of the current study showed that patients with tumors located in the Spiegel lobe had a better prognosis than those whose tumors were located in the paracaval portion. HCC located in the paracaval portion is contiguous with the major vessels and adequate surgical tumor margins cannot be obtained, especially in the case of liver cirrhosis, making expanded hepatic resection impossible. Asahara *et al*^[24] suggested that caudate lobectomy should extend past the right border of the inferior vena cava for adequate resection of the paracaval portion. Counterstaining can be used to identify the border between the paracaval portion and the posterior segments, but although this can demonstrate the border at the liver surface, it is still difficult to accurately identify the border deep within the liver parenchyma. Exposure of the paracaval portion is also difficult due to its deep location, and the greater manipulation required increases the risk of intrahepatic metastasis through the portal vein to the remnant liver.

The importance of chronic liver disease in the prognosis of patients undergoing resection for HCC is well known^[23,25-27], and patients with hepatitis C- or hepatitis B-related cirrhosis have poorer prognoses than those with cirrhosis due to other causes^[28]. In our study, the cumulative survival rates at 3 and 5 years were 60.6% and 47.9% in non-cirrhotic patients, and 35.0% and 12.3% in cirrhotic patients, respectively. After liver resection for HCC, some reports found that chronic active hepatitis and cirrhosis were the most significant risk factors for intrahepatic recurrence through multicentric carcinogenesis, so-called "multicentric occurrence". This can be explained by the fact that repeated inflammation and cellular necrosis in patients with chronic hepatitis or cirrhosis enhance proliferation and accelerate the development of new foci of HCC, associated with an increased rate of random mutations and promotion due to gene instability^[23,26].

A surgical margin of < 5 mm was also identified as an independent risk factor for poor survival following resection of caudate HCC. Although the importance of the size of the surgical margin is controversial, particularly in large tumors, and although satellite nodules have been found at some distance from the tumor, it is usually

believed that the risk of recurrence is lower when the surgical margin is large^[29-32]. However, obtaining a negative margin may be difficult, particularly in large HCCs, and especially in those located in the caudate lobe. Although we aimed to preserve a wide margin where possible in the current series, it measured < 5 mm in 44% of patients. After analysis of 209 consecutive liver resections in patients with HCC, Tralhão *et al*^[33] failed to identify any factors significantly predictive of a thin surgical margin, but thin margins were more common in patients with large tumors, and particularly in those with centrally located tumors. Even in patients with small but centrally located tumors, surgical margins of > 10 mm were infrequent. In our study, 64% of tumors were > 5 cm and related to the paracaval portion, which may be the main reason for the lower incidence of negative margins. Although extensive hepatectomy can obtain a high negative margin rate, only 32% of patients in this study underwent extended caudate lobectomy due to the presence of liver cirrhosis and underlying hepatitis. These results support the prognostic significance of surgical margin and extended resection for overall survival, and suggest that efforts should be made to increase the tumor-free margin. Extended caudate lobectomy is recommended, so long as acceptable liver function is maintained. It has been suggested that adjuvant intraarterial chemotherapy and/or preoperative TACE may reduce the risk of tumor recurrence and improve long-term survival following liver resection for caudate HCC^[7]. However, this was not confirmed in our study. Prospective, randomized clinical trials are needed to investigate the role of perioperative TACE for caudate HCC.

In conclusion, hepatectomy was an effective treatment for HCC in the caudate lobe. The subsegmental location of the tumor, presence of liver cirrhosis and the surgical margin affected long-term survival.

COMMENTS

Background

Hepatic resection is considered, in principle, to be the first choice for treatment of hepatocellular carcinoma (HCC) in the caudate lobe. However, the surgical treatment for HCC in the caudate lobe presents a major challenge and is associated with high risks for the surgeon, due to its unique anatomic location and complicated relationship with the major vasculature. Until now, the prognosis for patients following resection of caudate lobe HCC has not been fully determined.

Research frontiers

Caudate HCC has a poorer prognosis than HCC originating from other lobes, due to its proximity to the portal trunk and inferior vena cava, which facilitate its intrahepatic and systemic spread early in the disease. A large number of studies have confirmed that liver disease, tumor grade, tumor size, tumor margin, blood loss and other factors influence the incidence of tumor recurrence and long-term survival after resection of HCC.

Innovations and breakthroughs

Hepatectomy was an effective treatment for HCC in the caudate lobe. The subsegmental location of the tumor, presence of liver cirrhosis and surgical margin affected long-term survival.

Applications

The results of this research suggest that surgeons should make every effort to increase the tumor-free margin. Extended caudate lobectomy is recommended, so long as liver function can be maintained.

Terminology

The caudate lobe is generally divided into three regions: the left Spiegel, the

process portion, and the paracaval portion. Isolated caudate lobectomy involves the removal of all or part of the caudate lobe, and extended hepatectomy involves resection of all or part of the caudate lobe, in conjunction with other lobes of the liver.

Peer review

The authors report a series of 114 liver resections in patients with HCC in the caudate lobe. The perioperative data, complications and outcome were analyzed. This study addressed an important and interesting issue.

Abstract

AIM: To investigate the diverse characteristics of different pathological gradings of gastric adenocarcinoma (GA) using tumor-related genes.

METHODS: GA tissues in different pathological gradings and normal tissues were subjected to tissue arrays. Expressions of 15 major tumor-related genes were detected by RNA *in situ* hybridization along with 3' terminal digoxin-labeled anti-sense single stranded

oligonucleotide and locked nucleic acid modifying probe within the tissue array. The data obtained were processed by support vector machines by four different feature selection methods to discover the respective critical gene/gene subsets contributing to the GA activities of different pathological gradings.

RESULTS: In comparison of poorly differentiated GA with normal tissues, tumor-related gene *TP53* plays a key role, although other six tumor-related genes could also achieve the Area Under Curve (AUC) of the receiver operating characteristic independently by more than 80%. Comparing the well differentiated GA with normal tissues, we found that 11 tumor-related genes could independently obtain the AUC by more than 80%, but only the gene subsets, *TP53*, *RB* and *PTEN*, play a key role. Only the gene subsets, *Bcl10*, *UVRAG*, *APC*, *Beclin1*, *NM23*, *PTEN* and *RB* could distinguish between the poorly differentiated and well differentiated GA. None of a single gene could obtain a valid distinction.

CONCLUSION: Different from the traditional point of view, the well differentiated cancer tissues have more alterations of important tumor-related genes than the poorly differentiated cancer tissues.

INTRODUCTION

Malignant tumor is one of the leading causes of death, with a mortality of 12.5%^[1]. Stomach adenocarcinoma is one of the major types of gastric cancer which is the second major cause of oncologic death worldwide. Although the incidence and mortality of stomach adenocarcinoma have been obviously declined, it is still one of the most serious health burdens in the world^[2-4], and surgical resection remains the only curative treatment to improve the survival of patients with gastric cancer^[5,6]. Generally, clinicians consider the degree of malignancy based on the histopathological grade of tumors, and predict the prognosis of patients and estimate the survival rates according to the pertinent criteria and the intraoperative findings^[7,8]. Although histological classifications are widely used for gastric adenocarcinoma (GA), their prognostic value is still controversial. The degree of malignancy always implies the early cancer metastasis, invasion and the mortality rates^[9-11]. Because the occurrence of cancer is closely related to the tumor-related genes, we explored the diverse characteristics of different pathological gradings of GA by investigating 15 tumor-related genes, which have been currently proved to be closely related to carcinogenesis. They represent different cancer formation mechanisms and have tight connection and mutual regulation^[12-15]. Among them, the *C-myc*^[16] is an oncogene, Cyclin D1^[17] is a cell cycle protein, *BCL10*^[18] is an anti-apoptotic gene, *KAI1* and *NM23*^[19] are metastatic suppressor genes, *Beclin1*^[20] and *UVRAG*^[21] are cellular autophagy genes, *TP53*^[22], *RB*^[23], *PTEN*^[24], *Ptch*^[25], *BRCAl*, *BRCAl2*^[26], *FHIT*^[27] and *APC*^[28] are tumor suppressor genes.

MATERIALS AND METHODS

Materials and tissue microarray construction

One hundred and twelve primary samples of GA and normal tissues were snap-frozen and stored at -70°C. There were 40 samples from patients (age range: 42-78 years, 22 males and 18 females) with poorly differentiated GA, 28 samples from patients with well differentiated GA (age range: 50-81 years, 18 males and 10 females), and 44 samples of normal tissues (age range: 38-72 years, 30 males and 14 females). All the patients were Chinese, who underwent operations at the Affiliated Zhongshan Hospital of Xiamen University between 2000-2006.

Tissue blocks measuring approximately 1.5 cm × 1.5 cm × 0.3 cm and non-pathologic organs were fixed in phosphate-buffered saline (PBS) containing 4% paraformaldehyde (1‰ DEPC, pH 7.4) for 24 h, dehydrated through gradient ethanol, and embedded in paraffin. A hematoxylin and eosin (HE)-stained section was made

from each block to define the representative tumor region. Representative areas in different lesions were carefully selected on HE-stained sections and marked on individual paraffin blocks. Tissue cylinders with a diameter of 1 mm were then punched from tumor areas in each “donor” tissue block and put into a recipient paraffin block using a custom-made precision instrument. Five-mm sections of the resulting multiple tumor tissue microarray (TMA) blocks were transferred to glass slides using the paraffin sectioning aid system [adhesive-coated slides (PSA-CS4x), adhesive tape, and UV lamp; Instrumedics, Inc., Hackensack, NJ], supporting the cohesion of 0.6-mm array elements. The final TMA consisted of cores of 1 mm in diameter each spaced at 0.8 mm between core centers. A section stained with HE was reviewed to confirm the presence of morphologically representative areas in the original lesions.

Preparation of the 15 tumor-related gene probes

Antisense probe perfectly matched to corresponding sequence, Lock nucleic acid modified probe increased the stability of the probe and sensitivity. The type of tumor-related gene and probe sequence are shown in Table 1. All probes were synthesized by Shanghai Sheng Gong Corporation.

RNA *in situ* hybridization

Hybridization procedures were performed based on the instructions of RNA *in situ* hybridization (RISH) kits (Cybrdi, USA) with some modifications. The glassware was washed, rinsed in distilled deionized water, and autoclaved before use. Gloves were worn when the glassware and slides were handled to prevent RNase contamination on the tissues. Because of the differences in tissues and probes, we performed different pilot-experiments to achieve the best results (Table 1). Deparaffinized sections were mounted onto Denhardt-coated glass slides and treated with pepsin (0.25 mg/mL in DEPC H₂O-HCl) for 25-30 min in a 37°C water bath. The treated sections were then processed for *in situ* hybridization at 42-45°C for 36-48 h. The hybridization mixture contained the labeled oligonucleotide probe, 50% formamide, 10 mmol/L Tris-HCl, 1 mmol/L vanadyl-ribonucleoside complex (Sigma 94740), 1 mmol/L CTAB (Sigma 855820, pH 7.0), 0.15 mol/L NaCl, 1 mmol/L EDTA (pH 7.0), 1 × Denhardt's mixture and 10% dextran sulfate. After hybridization, the slides were washed three times, 30 min each time, in 0.1 mol/L TBS at room temperature, then treated with TBS (100 mmol/L Tris, pH 7.5, 150 mmol/L NaCl) containing a 1% blocking reagent (Roche) and 0.03% Triton X-100 for 30 min at room temperature and incubated for 30 min with anti-digoxigenin alkaline phosphatase-conjugated antibodies (Roche) diluted at 1:500 in TBS containing 0.03% Triton X-100 and a 1% blocking reagent. After being washed three times, 15 min each time, in TBS and 0.05% Tween, the slides were rinsed in a DAP-buffer (100 mmol/L Tris, pH 9.5, 100 mmol/L NaCl, 50 mmol/L MgCl₂) and subsequently

hybridization signals were visualized using nitroblue tetrazolium and 5-brom-4-chlor-3-indolyl phosphate as substrates [DAP-buffer in 10% PVA (Sigma 341584)].

Gene expression analysis

Two techniques for data analysis were adopted: a statistical method used to calculate the *P* values of genes in different samples, and a machine learning method applied to further discover the relationship between genes and corresponding samples.

The significance level of the 15 tumor-related genes were analyzed by Wilcoxon rand sum test, which is an efficient nonparametric statistical method to compare two groups of data and determine their differences. It is important to choose an efficient machine learning method to further explore the connections between genes and different cancers. However, it is hard to decide what kind of functions the 15 tumor-related genes would have for the different types of cases. So it is necessary to separately analyze the effects of both a single gene and different gene groups in different specimens. However, since there are so many ways to construct a gene group within 15 genes, efficient methods are required to shrink the scope of gene group construction. To achieve this, four classical feature selection methods were used to analyze gene expression levels, including: *t* test, entropy, Bhattacharyya and Wilcoxon. All these methods were provided in bioinformatics toolbox embedded in Matlab 7.1. Based on different criteria for feature selection, different methods would result in genes in different order of importance. The genes were classified into different groups. The discrimination ability of the gene groups was measured by support vector machine (SVM). The genes with biological significance were discovered by comparing the results.

There were three steps to analyze gene expressions: firstly, the gene expressions of different specimens were measured with the Wilcoxon rank sum test, so that *P* value of each gene can be calculated, and then used to evaluate the homologous extent of the two specimens. Secondly, the classification ability of each gene was

analyzed singly among different tissues to further assess the importance of each gene in different tissues. Thirdly, the results obtained by the combination of different genes were investigated. The relationship among genes could be discovered in this way. It is easy to evaluate the classification ability of a single gene using SVM with 10-fold cross-validation (CV) directly. However, since there are many ways to select the 15 genes to form a gene group, it is necessary to take a reliable selection method. In our analysis, a gene group starts from an empty one. A filter method was applied to rank the genes, and then a gene was added to the group according to the score of the rank. The gene group was used to discriminate the samples in two types of tissues using SVM by the 10-fold CV method. This process ended when all genes were added to the group. In addition, as the sample sizes varied in different diseases, the Area Under Curve (AUC) of the receiver operating characteristic (ROC) was deployed in our experiments. A ROC curve represents the true positive rate as a function of the corresponding false positive rate, and AUC provides a measure of performance that is sensitive to the distribution of the activity classes in test sets. Finally, the best gene subsets can be found by the highest AUC.

RESULTS

TMA technical adjustment

The tissue micro-array technology was substantially different from the traditional multi-tissue blocks. The most important advantages of TMA technology include increased capacity, negligible damage to the original tissue blocks, precise positioning of tissue specimens, and possibility of automatic construction and analysis of arrays. In this study, we chose 4% paraformaldehyde in PBS (1% DEPC PBS) as a fixation agent, which can decrease the degradation of RNA and yield a good morphology. The analysis of RISH showed that 80%-95% of tumor samples were interpretable. RISH-related weak hybridization, background, and tissue damage were responsible for about one-sixth of the non-informative cases.

X-axis represents samples, and each unit represents a gene expression level of the corresponding sample. Y-axis represents genes, whose name marked at the right side of the figure. Green color indicates the low-expression level of corresponding gene, and red represents over-expression.

Expression of tumor-related genes in different specimens

RISH was used to detect specific RNAs *in situ*. The typical results of ISH were observed as amethyst dots on arrays, RNA analysis and quantification required completely intact, non-degraded RNA samples to produce optimal results. Vanadium oxide ions and formation of complex nucleoside could protect RNA degradation from RNase. Cetyltrimethylammonium bromide could stabilize the Oligo probe and target sequence formation of double-stranded structures, thus improving the reannealing speed. The monomer containing LNA greatly improved the stability and sensitivity of RNA-targeted *in situ* hybridization. According to the results of RISH, positive organizational coloring cell counts were classified under the microscope (Figures 1 and 2).

Analysis of tumor-related gene expressions

Results obtained at the first step: The gene expressions of different specimens were measured with the Wilcoxon rank sum test. Table 2 shows the *P* value obtained in experiments. From the results, we found that the normal tissues were quite different from the cancer tissues. The *P* value of different genes indicated that there were 12 out of 15 genes and 14 out of 15 genes with significant biological difference in comparison of normal tissues with the cancer tissues.

Results obtained at the second step: The classification ability of each gene was analyzed singly among different tissues. From Figure 3, it could be found that

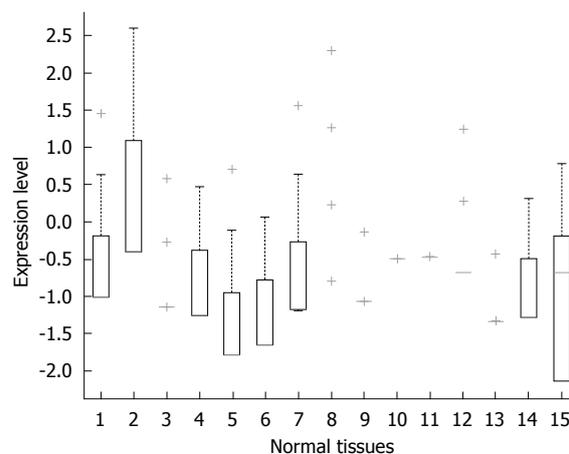

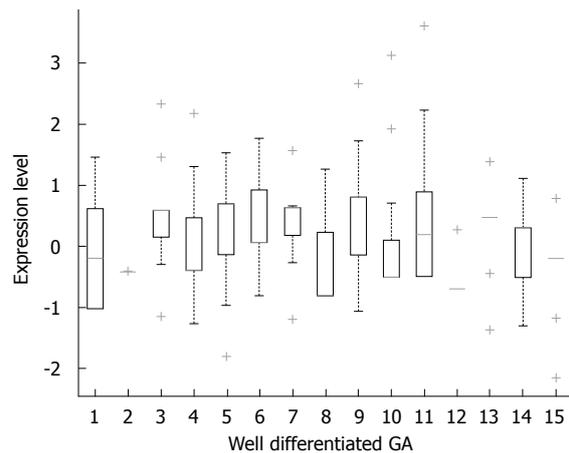

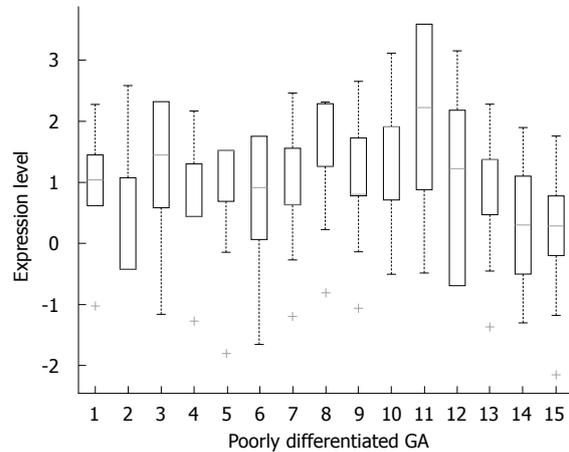

Figure 2 Distribution of gene expression levels. 1: *APC*; 2: *Bcl10*; 3: *Beclin1*; 4: *BRCA1*; 5: *BRCA2*; 6: *FHIT*; 7: *KAI1*; 8: *NM23*; 9: *Ptch*; 10: *PTEN*; 11: *RB*; 12: *UVRAG*; 13: *TP53*; 14: *Cyclin D1*; 15: *C-myc*.

when using a single gene, both well differentiated GA and poorly differentiated GA could be well distinguished

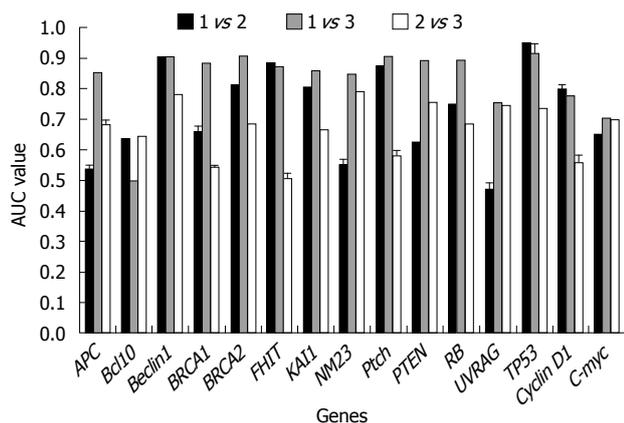

Figure 3 Classification of two sample groups with a single gene. 1: Normal tissues; 2: Well differentiated GA; 3: Poorly differentiated GA. AUC: Area Under Curve.

from the normal tissues. When compared with normal tissues, two different gene subsets were discovered respectively: *Beclin1*, *BRCA2*, *FHIT*, *KAI1*, *Ptc*, *TP53*; and *APC*, *Beclin1*, *BRCA1*, *BRCA2*, *FHIT*, *KAI1*, *NM23*, *Ptc*, *PTEN*, *RB*, *TP53* in poorly and well differentiated GAs. In comparison of well and poorly differentiated GA, none of the single genes could achieve a high classification performance.

In this analysis, when the AUC results were lower than 80%, the corresponding gene(s) had no classification power under our hypothesis. If a gene can improve the AUC by more than 80%, it can be regarded as a key gene as it can classify two different sample groups.

Results obtained at the third step: The results were analyzed in three aspects: (1) The poorly differentiate GA was compared with normal tissues, and the results indicated that *TP53* was the key gene for distinguishing the two tissues (Figure 4). It was obvious that when *TP53* was used, the AUC results were immediately improved; (2) Well differentiated GA was compared with normal tissues, and the results showed that *TP53*, *RB*, and *PTEN* are the key genes, which had high classification abilities (Figure 5); and (3) We compared the poorly differentiated with well differentiated GA, and seven genes (*Bcl10*, *UVRAG*, *APC*, *Beclin1*, *NM23*, *PTEN*, and *RB*) were found to be closely related to different pathological gradings of gastric cancers (Figure 6).

DISCUSSION

Traditional clinical point of view

Histopathological differentiation level represents the deterioration degree of tumors. The stomach carcinoma is one of the most prevalent cancer types in the world^[1,2]. Only a limited number of biomarkers are available for its detection and prognostic evaluation. Up to now, the clinicians still determine the degree of malignancy by histopathological differentiation method. Two major types of stomach carcinoma are distinguished accord-

ing to their morphological and clinicopathological classifications: well-differentiated/intestinal type and poorly differentiated/diffuse type^[6,29]. Here, the well or poorly differentiated level represents the malignant degree of tumors, and implies different prognosis. The study of Muro-Cacho *et al.*^[30] indicated that only the degree of necrosis and phenotypic differentiation toward smooth muscle were found to be indicators of poor prognosis in the multivariate analysis. Based on their observations, a classification scheme for gastrointestinal stromal tumors was proposed. Lee *et al.*^[31] clarified the importance of the mucin phenotype in clinic. Despite a well-defined correlation between histological differentiation and Lauren's classification of GA, the mucin phenotype was not in agreement entirely with Lauren's classification. Instead of the histologic differentiation and Lauren's classification, I-phenotypic expression was an independently important prognostic factor of gastric cancers. We have often observed that the level of pathological differentiation and prognosis are inconsistent in clinic. It is well known that the higher degree of malignancy, the earlier occurrence of cancer metastasis and invasion, and the more important alterations of tumor-related genes. So our research about the relationship between different histopathological grades and the tumor-related genes in GA is of great clinical significance.

TNM-Gene diagnosis of gastric cancer: A better diagnostic criterion in the future

The characteristics of the two major types of gastric cancer can be attributed to different tumor-related gene activations. A large number of tumor-related genes involved in signal transductions and cell cycle regulation have been implicated in gastric cancer progression. The study of Wu *et al.*^[32] indicates that according to the molecular pathological background, mucinous adenocarcinomas of the stomach consist of at least three subtypes: the mutator-type, the suppressor (*p53*-type) and the unclassified tumors. It would provide clinicians with useful information for clinical diagnosis by further exploration of carcinomas with more detailed morphological and biological phenotyping. Wang *et al.*^[33] indicated that the *MUC1* gene might be an indicator of poor prognosis. Based on these studies, we explored the alteration of tumor-related genes in different pathological differentiation levels to obtain TNM-Gene diagnosis in GA. Although the data of gene expressions are complicated and irregular, we attempted to discover their correlations using SVM by a 10-fold CV method^[34-36].

Alterations of tumor-related genes hardly well matching the histopathological grades

Tumor grade represents a gestalt of all molecular changes in malignant tumors and reflects their aggressiveness. In addition, it has been proved to enhance prognostic information. Chandler *et al.*^[37] evaluated the degree of inter-observer variation in grading by conducting a nationwide survey of histopathologists, and drew an important

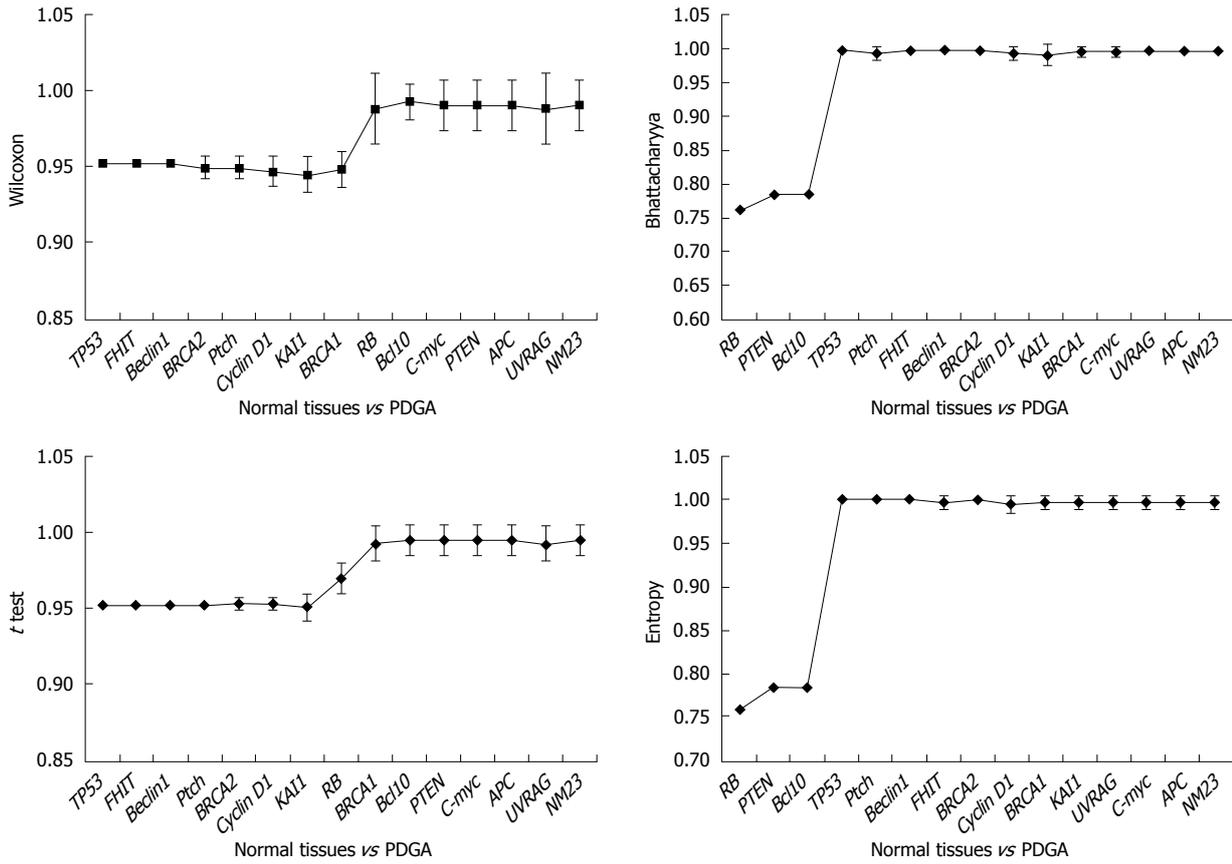

Figure 4 Comparison of normal tissues and poorly differentiated GA (PDGA). X-axis represents the sequence of selected genes, and Y-axis represents the average and standard deviation of the AUC scores obtained in the ten 10-fold cross-validation (CV) with the corresponding gene groups.

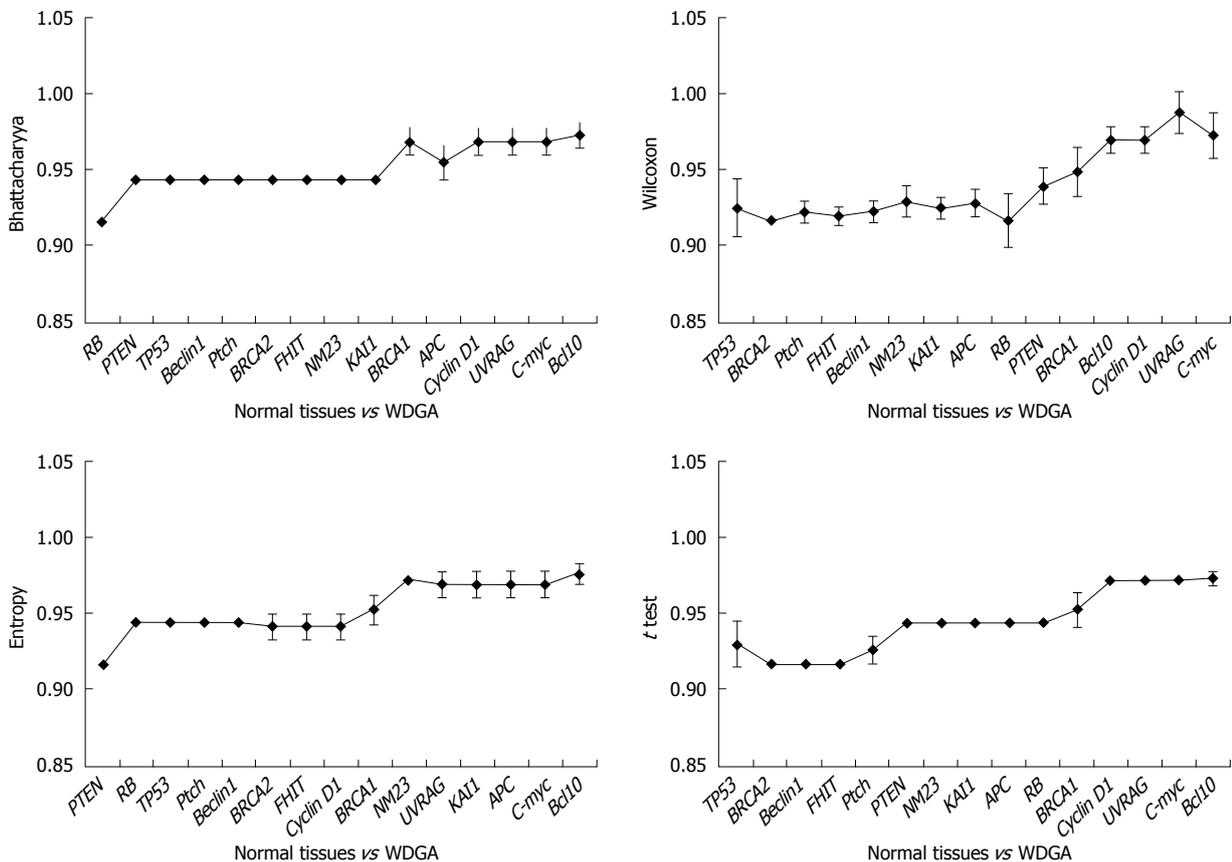

Figure 5 Comparison of normal tissues and well differentiated GA (WDGA).

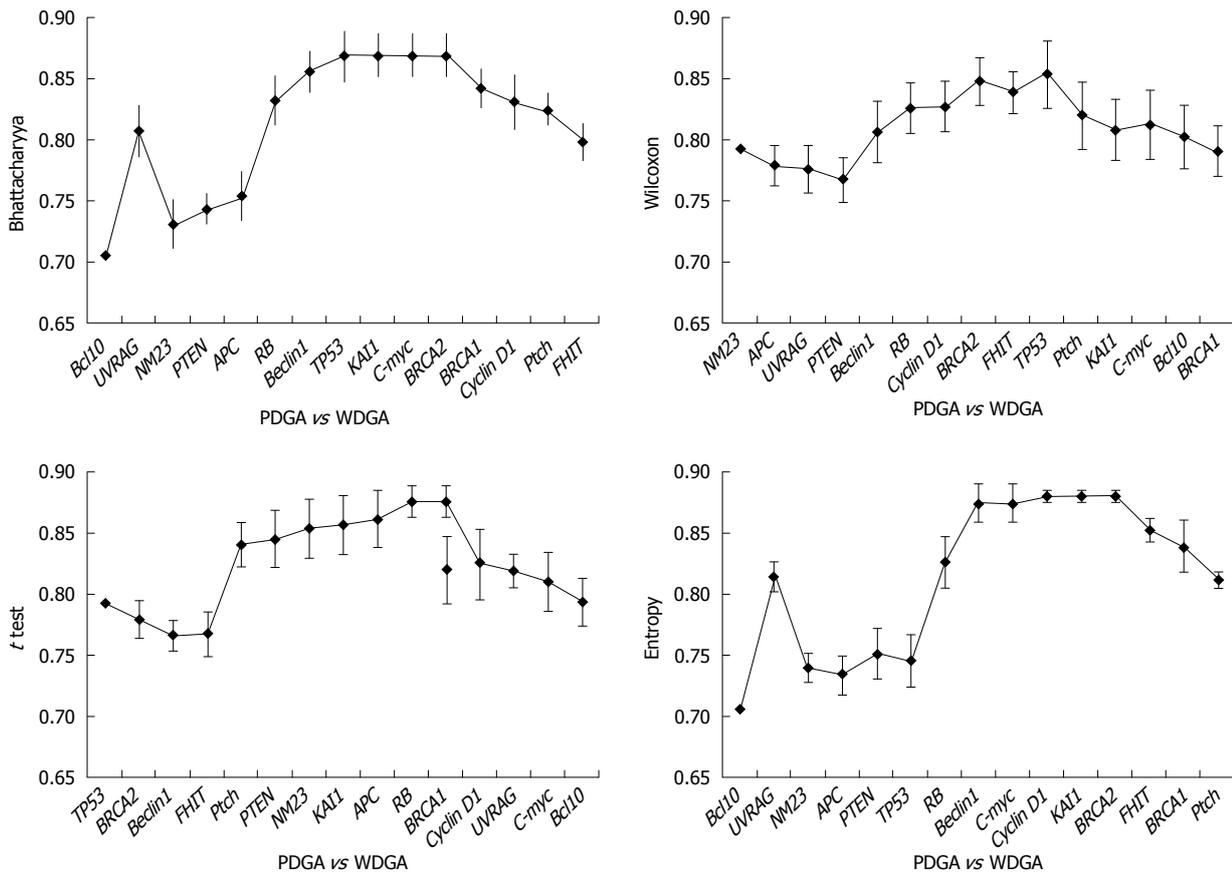

Figure 6 Comparison of WDGA and PDGA.

conclusion: given the fact that the histopathological criteria of stage and grade still provide the mainstay of prognostication and clinical decision-making, we should make more efforts to improve grading criteria and standardize the low- and high-grade categories. However, this conclusion is contradictory to ours. It is usually considered that poorly differentiated GA is a high-grade carcinoma with poor prognosis, and have multiple important alterations of tumor-related genes, and well differentiated GA means low-grade carcinoma with better prognosis, and the reason may be that tumor-related gene alteration was caused by cumulation of injury and repair. But our results indicate that *TP53* is the key tumor-related gene relating closely to the canceration of poorly differentiated GA; and there are multiple tumor-related gene alterations in well differentiated GA. We suggest that the alteration level of tumor-related genes is bound up with grade of malignancy, histopathological grading and prognosis. So we have come up with a conclusion: the alterations of tumor-related genes do not exactly match the histopathological grades. Furthermore, we suspect that histopathological tumor grade does not exactly match the degree of malignancy. There are slight differences between poorly and well differentiated GA. No single tumor-related gene can distinguish the two groups of tumors, and only one gene subset consisting of seven genes can distinguish the two tumors. So we speculate that synergistic actions of multiple genes lead to different specimens.

Outlook and speculation

Compared with general pathological diagnosis, the TNM-Genetic diagnostic methods are more accurate to determine the extent of malignancy of tumors and prognoses. *TP53* is the most important tumor-related gene^[38-45]. Among the 15 genes, only the alteration of *TP53* closely relates to poorly differentiated GA. But besides *TP53*, other ten genes are connected with the well differentiated GA. To sum up the results, *TP53* alters in both groups of tumors, but leading to different Edmonson, we speculate that the alterations of *TP53* may have completely different subtypes, which have the different functions.

COMMENTS

Background

Gastric cancer is the second major cause of oncologic death worldwide. Because the occurrence of cancer is closely related with the tumor-related genes, the authors explored the diverse characteristics of different pathological gradings of gastric adenocarcinomas (GAs) by investigating 15 tumor-related genes. It has been proved that the 15 critical tumor-related genes selected are involved in carcinogenesis, and they represent different formation mechanism of cancers.

Research frontiers

TNM-Genetic diagnosis of gastric cancer is a better diagnostic criterion. The characteristics of two major types of gastric cancer can be attributed to different tumor-related gene activations. A large number of tumor-related genes involved in signal transductions and cell cycle regulation have been implicated in gastric cancer progression. So the authors explored the alteration of tumor-related

genes in different pathological differentiation levels in an attempt to obtain TNM-Genes about different GAs.

Innovations and breakthroughs

Tumor grade represents a gestalt of all molecular changes in malignant tumors and reflects their aggressiveness. The results of this study is different from the traditional opinions as the well differentiated cancer tissues have more alterations of important tumor-related genes than those of the poorly differentiated cancer tissues.

Applications

To sum up the results, *TP53* alters in both groups of tumors, but leading to different Edmonson, the authors speculate that the alterations of *TP53* may have completely different subtypes, which have the different functions. Additionally, there are slight differences among tumor-related genes between poorly differentiated and well differentiated GAs, and the associated alterations of gene subset, *Bcl10*, *UVRAG*, *APC*, *Beclin1*, *NM23*, *PTEN* and *RB*, are closely related to different pathological gradings of GAs.

Terminology

ROC: receiver operating characteristic, a graphical plot of the sensitivity vs (1-specificity); AUC: the area under the ROC curve, reflecting the relationship between sensitivity and specificity for a given test; SVM: support vector machines, a set of related supervised machine learning methods used for classification or regression.

Peer review

The study is aimed to identify biomarkers of poorly and well differentiated GAs. The authors found that among tumor related genes tested only *p53* significantly changed in poorly differentiated GA, whereas well differentiated tumor showed alterations in several tumor-related genes, including *p53*, *Rb* and *PTEN*.

Abstract

AIM: To evaluate the feasibility and therapeutic effects of para-aortic nodal dissection (PAND) for advanced gastric cancer.

METHODS: Randomized controlled trials (RCTs) and non-randomized studies comparing D2 + PAND with D2 lymphadenectomy were identified using a pre-defined search strategy. Five-year overall survival rate, post-operative mortality, and wound degree of surgery between the two operations were compared by using the methods provided by the Cochrane Handbook for Systematic Reviews of Interventions.

RESULTS: Four RCTs (1120 patients) and 4 non-randomized studies (901 patients) were identified. Meta-analysis showed that there was no significant difference between these two groups in 5-year overall survival rate [risk ratio (RR) 1.04 (95% CI: 0.93-1.16) for RCTs

and 0.96 (95% CI: 0.83-1.10) for non-randomized studies] and post-operative mortality [RR 0.99 (95% CI: 0.44-2.24) for RCTs and 2.06 (95% CI: 0.69-6.15) for non-randomized studies]. There was a significant difference between these two groups in wound degree of surgery, operation time was significantly longer [weighted mean difference (WMD) 195.32 min (95% CI: 114.59-276.05) for RCTs and 126.07 min (95% CI: 22.09-230.04) for non-randomized studies] and blood loss was significantly greater [WMD 301 mL (95% CI: 151.55-450.45) for RCTs and 302.86 mL (95% CI: 127.89-477.84) for non-randomized studies] in D2 + PAND.

CONCLUSION: D2 + PAND can be performed as safely as standard D2 resection without increasing post-operative mortality but fail to benefit overall survival in patients with advanced gastric cancer.

INTRODUCTION

Generally, either incidence or mortality of gastric cancer (GC) has fallen dramatically during the past decades in

European and American countries. Despite its recent decline, GC is still the fourth most common carcinoma and the second leading cause of death by tumor worldwide^[1-3]. GC can be divided into two groups, early GC and advanced GC, and advanced GC accounts for 92%-95% of cases in China, 40%-60% in Japan, and 80%-90% in Europe^[4-6] presently. Up to now, treatments for GC include surgery, chemotherapy, radiotherapy and so on. Despite the poor prognosis, surgery is commonly accepted as the preferred treatment for advanced GC^[7]. Five-year survival rate can achieve 45% or even more in Japan, 40% or so in China, only about 20% in Western countries and as low as 6% in sub-Saharan Africa^[8-11] for advanced GC.

Although surgical operation remains the primary therapeutic modality, views over the optimal resection for patients with GC remain controversial^[12]. In patients with GC, lymph node metastasis can occur during the early stages, and regional lymph node dissection (LND) is regarded as an important part of en bloc resection for GC. However, the extent of lymphadenectomy for the greatest result is controversial, and there is no consensus worldwide. Introduced by Japanese surgeons in 1960s, D2 lymphadenectomy is the recommended standard practice in patients undergoing an operation with a curative intent^[13-16], which required the systematic dissection of lymph nodes in the first tier (perigastric) and the second tier (along the celiac artery and its branches). Compared with traditional D1 lymphadenectomy, D2 doesn't increase the operation morbidity and mortality^[17], and shows a higher 5-year survival rate^[18]. Recently, it was reported that 18%-40% of patients with advanced GC had metastasis present in the para-aortic nodes^[19-21], and more often if the tumor was located at the proximal third of the stomach^[22]. Taking this into consideration, some researchers assumed that removing these lymph nodes could accomplish curative resection (R0) which might improve the clinical outcome of advanced GC patients^[19,23,24]. However, this extended dissection not only can increase the post-operative morbidity and mortality but also can affect the function of near abdominal organs, and its survival benefit is still uncertain. Some studies considered that morbidity after para-aortic nodal dissection (PAND) such as pancreatic fistula and respiratory complications were significantly higher^[25], and these complications were considered to be associated with the surgeons' experience. However, some retrospective reports revealed that there was no significant difference in post-operative complications and mortality between D2 and D2 + PAND; D2 + PAND could be performed safely by well-trained surgeons^[26,27]. With respect to long-term survival after the two operations, there was stormy dispute at the same time^[27-29]. At the moment there is no consensus about whether patients with advanced GC should receive PAND or not, who should accept it, and how to ascertain the metastasis of PAN before operations.

Although a systematic review referring to the extent

of lymphadenectomy for GC has been published, it only valued the short-term outcomes^[30] and the assessment of 5-year survival after PAND in patients with GC was not presented. Five-year survival is considered to be an important outcome in evaluating the therapeutic effects of GC. Therefore a systemic review aiming to evaluate the feasibility and therapeutic effects of PAND is urgently needed. In this study, we assessed literature existing and conducted a meta-analysis for comparing the clinical effectiveness of these two operations.

MATERIALS AND METHODS

Search strategy

The following databases were searched systematically in our study: PUBMED, EMBASE, and the China Biological Medicine Database (CBM-disc), CNKI (China National Knowledge Infrastructure Whole Article Database) from January 1980 to February 2009, as well as the Cochrane Central Register of Controlled Trials (CENTRAL) on The Cochrane Library issue 1, 2009. All controlled trials comparing D2 lymphadenectomy and D2 + PAND in the surgical treatment of GC were identified. In this review, the language of search strategy was not limited, and the following search terms were used: stomach neoplasms, stomach cancer, stomach carcinoma, gastric cancer, gastric carcinoma, gastric neoplasms, D2+, D2 plus, D3, D4, R3, R4 (in some studies, the classification of gastric carcinoma are according to the new edition^[31]; it is also called D3 or R3 in the new edition and called D4 or R4 according to the old edition^[32]), superextended lymphadenectomy, para-aortic lymph nodes dissection, para-aortic nodal dissection. Both free text and MeSH search for keywords were employed.

To identify further potentially relevant studies, reference lists from selected studies through electronic searching were hand searched; furthermore in order to obtain any relevant unpublished materials, we contacted scholars in the field of gastroenterology.

Inclusion and exclusion criteria

Types of studies: Comparative trials with recorded 5-year overall survival rate or secondary outcomes (post-operative morbidity and mortality, wound degree of surgery) were included. Non-comparative studies, case series, case reports and studies using historical controls were excluded.

Types of patients: Trials in which patients were pathologically proved to have gastric adenocarcinoma and qualified for gastrectomy were included. Trials in which patients had distant metastasis, gastric stump cancer, disseminated cancer cells, synchronous malignancy in other organs, serious cardiovascular or respiratory disorders, hepatic or renal failure were excluded.

Types of interventions: Trials comparing the results of

D2 and D2 + PAND were included. Trials comparing the results of these two operations but also with pre-operative or post-operative chemotherapy were excluded.

Types of outcome measures: Primary outcome: 5-year overall survival rate; secondary outcome: post-operative morbidity, mortality and potential risk factors for post-operative morbidity, wound degree of surgery (operation time and blood loss during operation).

Data collection and analysis

Method of agreeing inclusion of studies: This course was performed by two authors (Wang Z and Chen JQ) independently according to preformed inclusion criteria. Titles and abstracts were scanned first to make a list of possibly related literature, and then full texts were obtained for those articles identified as either relevant or not clear, only trials coincident with pre-determined criteria of this review were included. Disagreements were settled by consensus.

Quality assessment: Since there was no consensus about quality assessment of non-randomized studies, in our review, the Cochrane Handbook for Systematic Reviews of Interventions in which criteria for non-randomized studies were the same as randomized controlled trials (RCTs) was used to assess the methodological quality of included studies^[33]. The criteria included six items as following: (1) Adequate sequence generation? (2) Allocation concealment? (3) Blinding? In our review, if result measurements (only wound degree of surgery and post-operative morbidity were included, not considering 5-year survival rate and post-operative mortality) were masked, it would be regarded as low risk of both performance and detection bias; (4) Incomplete outcome data addressed? In our review, we considered the missing outcome data which were less than 10% to be low risk of bias, 10%-15% to be moderate risk of bias, and more than 15% to be high risk of bias; (5) Free of selective reporting? and (6) Free of other bias?

Options for the results of quality assessment: Yes (low risk of bias), probably yes (moderate risk of bias), No (high risk of bias). No rating of the studies was performed; each was accepted or rejected based on the six items noted above. The guidelines in the QUOROM Statement^[34] were consulted by us from the literature search to the presentation of the results and discussion.

Data extraction: Using a pre-defined data extraction form, two reviewers (Wang Z and Chen JQ) extracted data about characteristics of included studies and baseline characteristics of patients independently, which included following items: author, publication date, number of patients, age and sex of patients, serosa and lymph node states, 5-year overall survival rate, post-operative morbidity and mortality, operation time and blood loss during operation. If necessary, the authors

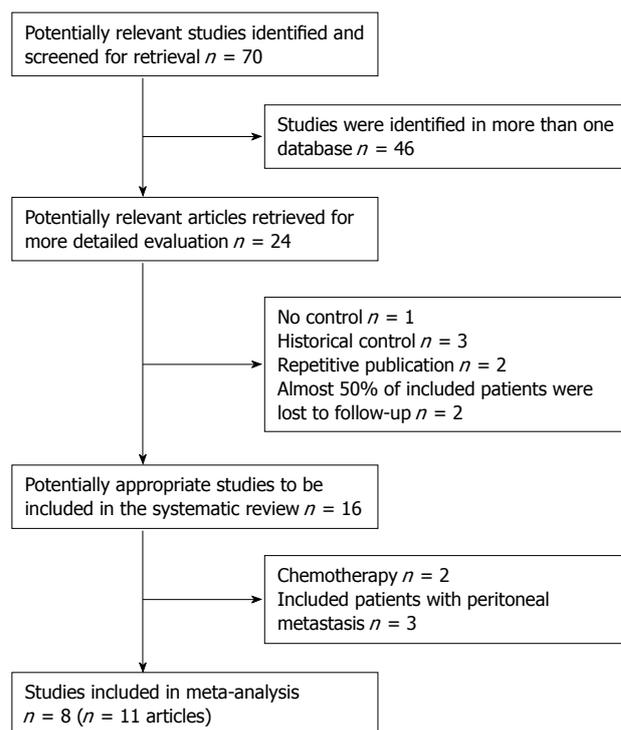

Figure 1 QUORUM flow chart for studies.

of the original articles were contacted for available data. Final agreement was achieved through discussion.

Data synthesis: In our study, the individual and pooled statistics were calculated using the fixed effect model, but a random effect model was used if *P* value of heterogeneity test was less than 0.1. The results were expressed with risk ratios (RR) for dichotomous data and weighted mean differences (WMD) for continuous data^[33], and 95% confidence intervals (CI) were also calculated. Heterogeneity between included studies was tested using χ^2 test. If heterogeneity was present, we would try to check the cause out from aspects of study design and quality, differences in intervention and baseline characteristics of included patients, by using methods of subgroup and sensitivity analysis. Funnel plots were drawn to assess publication bias. The RCTs and non-randomized studies were analyzed separately, and trials with continuous data recorded as the form of median and range were excluded from meta-analysis. Statistical analysis was performed using RevMan 5.0.18, which was provided by the Cochrane Collaboration^[35].

RESULTS

Selection of included studies

According to the search strategy referred to above, a total of 70 studies were yielded: 23 in PubMed, 16 in EMBASE, 11 in CENTRAL, 20 in CBM-disc and CNKI. Many literatures were searched in more than one database; finally 4 RCTs and 4 non-randomized studies (11 articles) were considered eligible for inclusion. The trial selection process was summarised in Figure 1. The reasons for

Table 1 Characteristics of included studies (ITT: intention-to-treat)

Study ID (author, yr)	Design	Methods	Patients	Interventions	Outcomes	Notes
Jiang <i>et al</i> 2000 ^[36]	RCT	Single center, parallel group, not clear about the method of randomization	Histologically proved curable advanced gastric cancer	D2 vs D2+	Post-operative morbidity and mortality; Operation time	Regional lymph nodes were classified according to 1th English edition 1995 ^[32]
Sano <i>et al</i> 2004 ^[37] and Sasako <i>et al</i> 2008 ^[39] and Koderu <i>et al</i> 2005 ^[38]	RCT	Multicenter, parallel group, computer stratified randomization	Histologically proved advanced and curable gastric cancer	D2 vs D2+	Post-operative morbidity and mortality; Operation time; Blood loss during operation; Five-year survival rate	ITT was used in result analysis; Regional lymph nodes were classified according to 1th English edition 1995 ^[32]
Yonemura <i>et al</i> 2006 and 2008 ^[40,41]	RCT	Multicenter, parallel group, computer randomization	Younger than 75-yr old, histologically proved advanced and curable gastric cancer	D2 vs D2+	Post-operative morbidity and mortality; Operation time; Blood loss during operation; Five-year survival rate	Sample size was calculated before trials
Kulig <i>et al</i> 2007 ^[42]	RCT	Multicenter, parallel group, simple computer randomization.	Histologically proved curable gastric adenocarcinoma	D2 vs D2+	Post-operative morbidity and mortality; Operation time; Blood loss during operation	Regional lymph nodes were classified according to 2nd English edition 1998 ^[31] ; ITT was used in result analysis
Maeta <i>et al</i> 1999 ^[43]	non-RCT	Single center, parallel group, without randomization	Histologically proved advanced gastric cancer, younger than 75-yr old	D2 vs D2+	Post-operative morbidity and mortality; Operation time; Blood loss during operation	In D4 group, lymph nodes (a1, a2, b1 and b2) were all removed; Sample size was smaller than that calculated before study
Bostanci <i>et al</i> 2004 ^[44]	non-RCT	Single center, parallel group, prospective study without randomization	Histologically proved gastric cancer	D2 vs D2+	Post-operative morbidity and mortality; Operation time	Surgical procedure was not very clearly described in the article
Kunisaki <i>et al</i> 2006 ^[45]	non-RCT	Multicenter, parallel group, retrospective analysis	Curable advanced gastric cancer proved by histology	D2 vs D2+	Post-operative morbidity and mortality; Operation time; Blood loss during operation; Five-year survival rate	Data about length of post-operative hospital stay were obtained from the author
Hu <i>et al</i> 2009 ^[46]	non-RCT	Single center, parallel group, retrospective analysis	Histologically proved curable gastric cancer	D2 vs D2+	Post-operative morbidity and mortality; Operation time; Five-year survival rate	In D4 group, lymph nodes (a1, a2 and b1) were dissected

RCT: Randomized controlled trial.

excluding studies were as following: study type, baseline characteristics of included patients, repetitive publication, chemotherapy, distant metastasis, confounding allocation and high rate of loss of follow-up.

Description and risk of bias of included studies

Since both RCTs and non-randomized studies were included in our study, we described them both respectively. Additionally, although there was no significant difference in each study, we did not summarize the surgical details as a table in either RCTs or non-randomized included studies since there were different descriptions in different studies. Characteristics of included studies, baseline characteristics of patients and potential bias of included studies were listed in Tables 1-3, respectively.

Description and risk of bias of RCTs

In total 1120 patients in 4 RCTs (7 articles)^[36-42] were eligible for inclusion, 571 patients in the D2 group and 549 patients in the D2 + PAND group, and the sample size of studies varied from 53 to 523. All included RCTs

except one^[36] used computer randomization, but only one trial used a central telephone registration system^[37]; the concealment of allocation was unclear in three trials. Blinding referred to result measurements being blinded in our study, and wasn't clearly described in all trials. Completeness of data was good in 4 included trials. There was no significant difference in baseline characteristics of patients (age, sex, T stage and lymph node states) between D2 and D2 + PAND groups in included trials except the trial reported by Jiang *et al*^[36], in which T stage and lymph node state were not clearly reported. Three articles showed that only surgeons skilled in D2 and D2 + PAND operation participated in their studies^[37,40,42]. Selecting reports and other bias were not clearly recorded in their published reports.

Description and risk bias of non-randomized studies

In total 901 patients in 4 non-randomized studies^[43-46] were included, 620 patients in the D2 group and 281 patients in the D2 + PAND group, and sample size of studies ranged from 70 to 580. No randomization and

concealment of allocation were performed. According to the definition of blinding in our review, blinding was unclear in 4 included studies. Completeness of data was good; the rate of loss of follow-up was less than 15% for all included studies. The description of selective reporting and other bias was not described in detail. Baseline characteristics were similar between D2 and D2 + PAND groups in all included studies.

Effects of interventions (Effectiveness in RCTs)

Five-year overall survival rate: Two RCTs^[39,41] (792 patients) reported 5-year overall survival rate, and the pooled RR was 1.04 (95% CI: 0.93-1.16). There was no significant difference between D2 + PAND and D2 groups. The *P* value of heterogeneity test was 0.88 (Figure 2).

Data from only 1 RCT^[39] could be analyzed, with individual RR 1.14 (95% CI: 1.01-1.29) for the serosa negative subgroup and 0.71 (95% CI: 0.53-0.94) for the serosa positive subgroup. There was a significant difference between these two subgroups. Compared with D2 dissection, five-year overall survival rate for D2 + PAND in the serosa negative subgroup was significantly higher than that in the serosa positive subgroup, but tests for heterogeneity were not applicable in these two subgroups (Figure 3).

Post-operative morbidity and mortality: Since there were different definitions and contents in each study,

post-operative morbidity data couldn't be used in a meta-analysis. All RCTs (1107 patients) reported data on post-operative morbidity, but the results in four included studies were not consistent. Apart from the study reported by Yonemura *et al*^[40] [individual RR 1.52 (95% CI: 1.05-2.18)], three other trials reported there was no significant difference between D2 and D2 + PAND groups (Figure 4A).

The post-operative mortality data of all included RCTs (1107 patients) could be used, and the combined RR was 0.99 (95% CI: 0.44-2.24), which revealed that there was no significant difference between D2 + PAND and D2 groups. The test for heterogeneity was negative with a *P* value of 0.31 (Figure 4B).

Operation time: Data of two RCTs^[36,40] (309 patients) were applicable; the pooled WMD was 195.32 min (95% CI: 114.59-276.05), suggesting there was a significant difference between these two groups. Operation time in the D2 + PAND group was significantly longer than that in the D2 group. The *P* value of the heterogeneity test was 0.24 (Figure 4C).

Blood loss during operation: Only one RCT^[40] (256 patients) was useful for analysis, and individual WMD was 301 mL (95% CI: 151.55-450.45). There was a significant difference between these two groups. Blood loss in the D2 + PAND group was significantly more

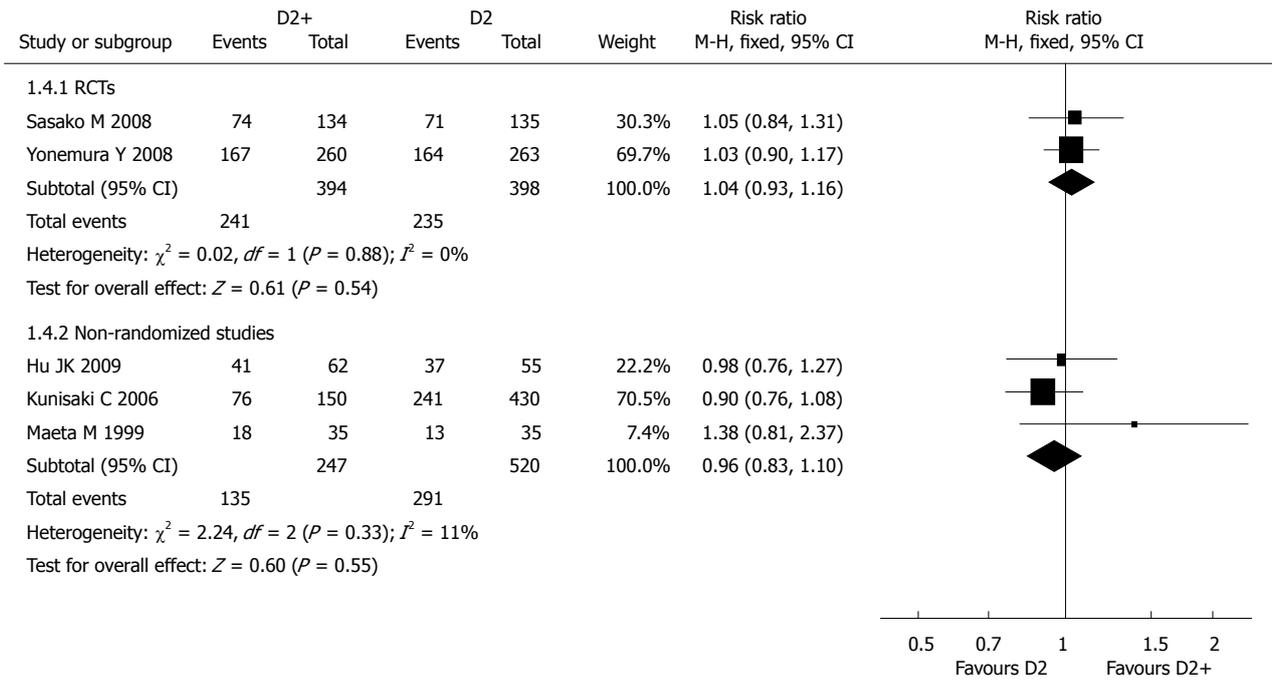

Figure 2 Meta-analysis of 5-year overall survival rate comparing D2 + PAND with D2 gastrectomy.

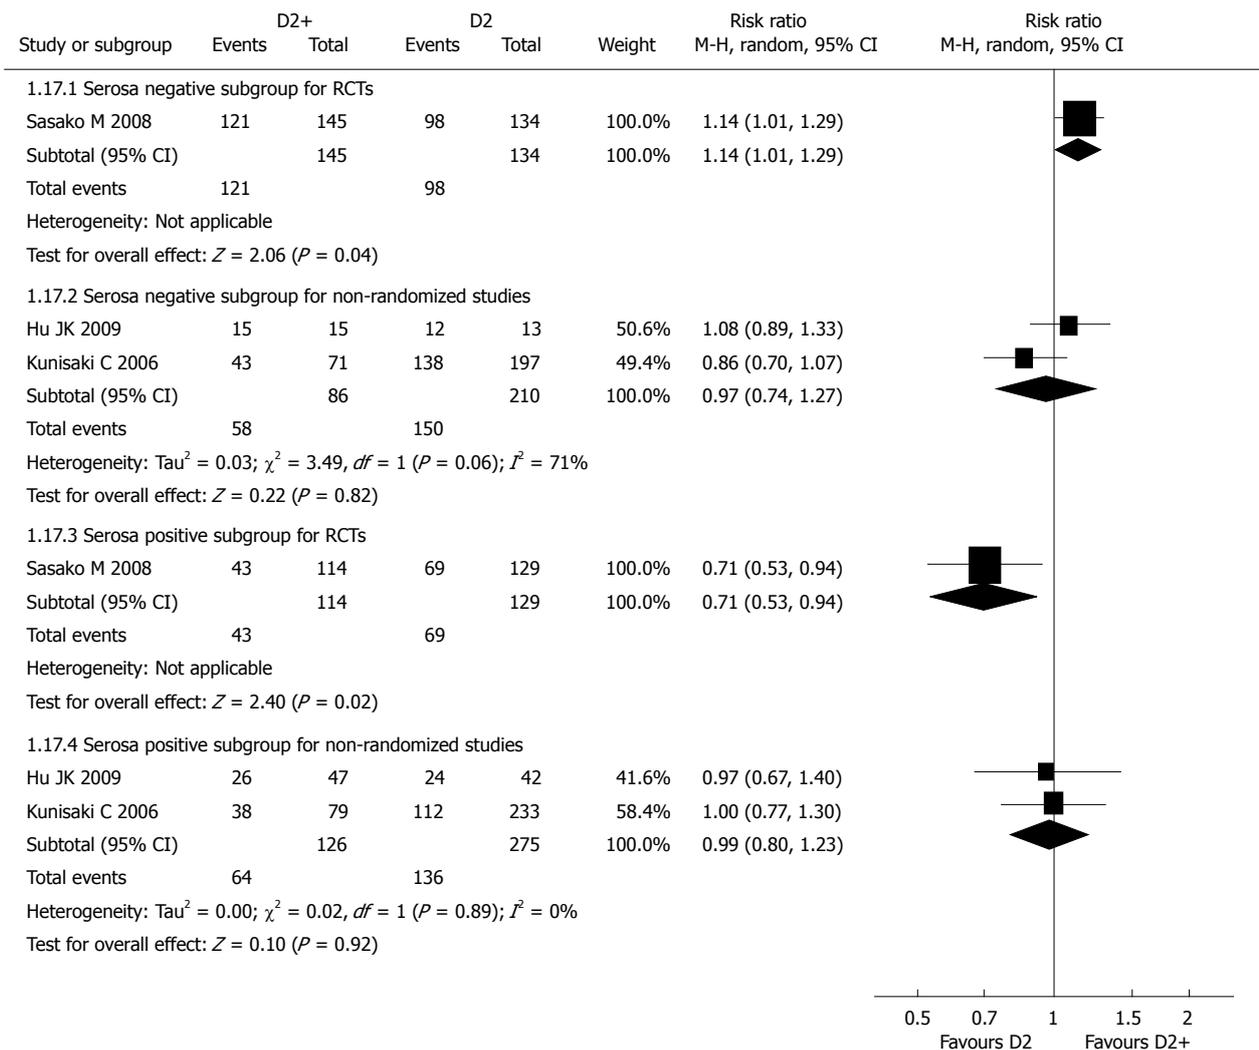

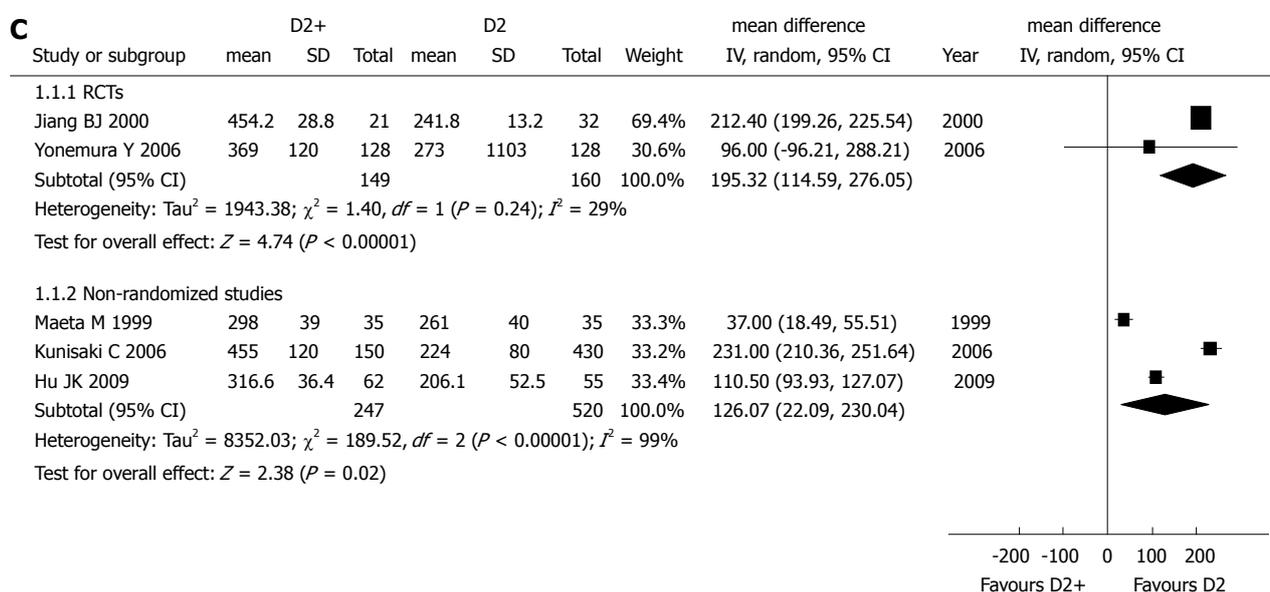

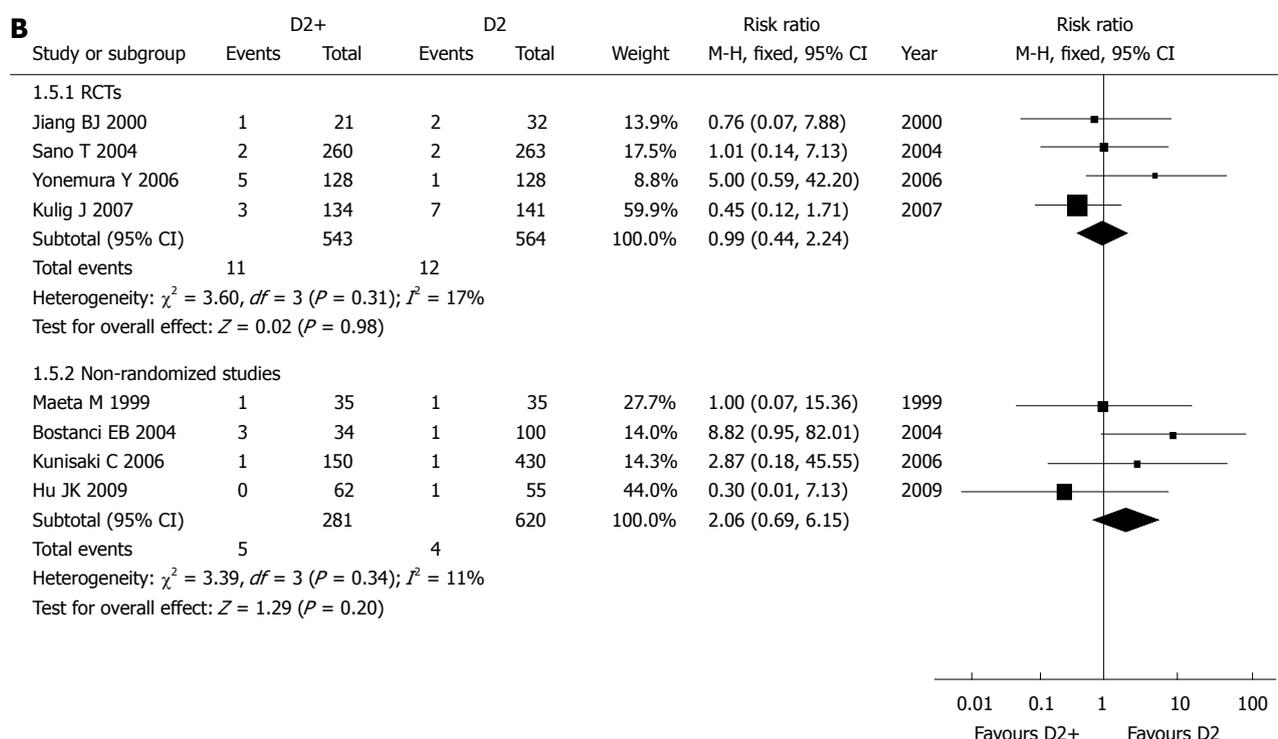

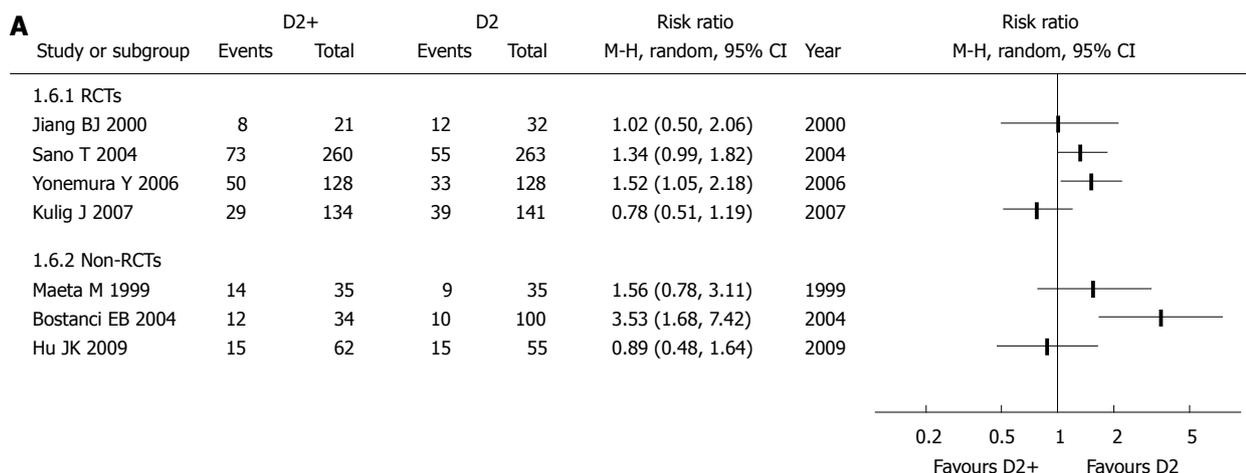

Figure 3 Meta-analysis of 5-year overall survival rate for serosa negative and positive subgroups comparing D2 + PAND with D2 gastrectomy.

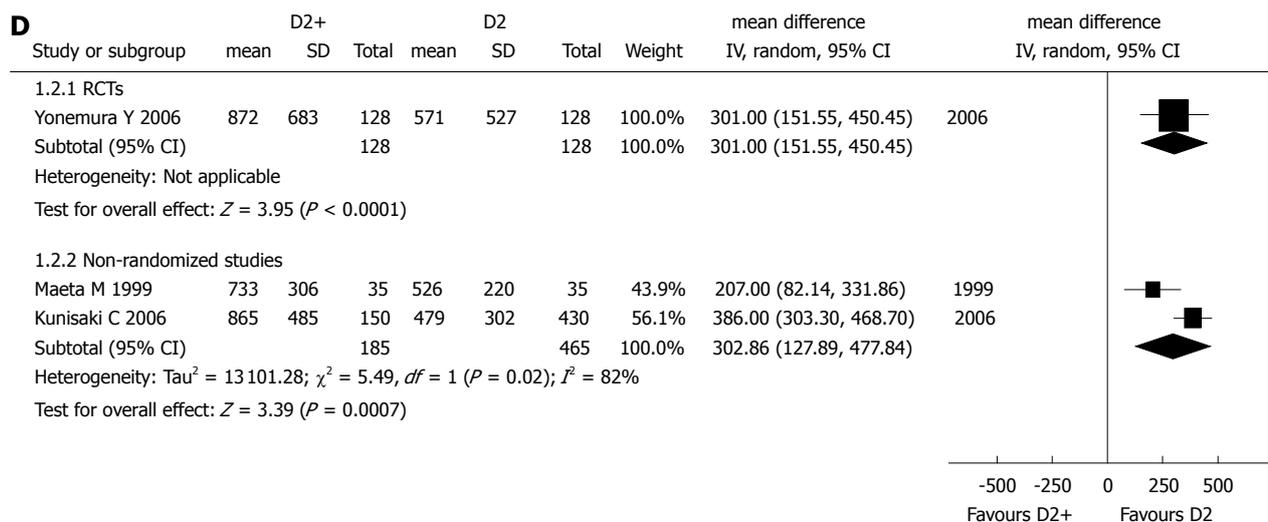

Figure 4 Meta-analysis of post-operative morbidity comparing (A), post-operative mortality (B), operation time (C), blood loss during operation (D) D2 + PAND with D2 gastrectomy.

than that in the D2 group, and the test for heterogeneity was not applicable (Figure 4D).

Effects of interventions (Effects in non-randomized studies)

Five-year survival rate: Three non-randomized studies (767 patients)^[43,45,46] reported 5-year overall survival rate, and the pooled RR was 0.96 (95% CI: 0.83-1.10), suggesting there was no statistical significance between the two groups; the P value of the heterogeneity test was 0.33 (Figure 2).

Two non-randomized studies^[43,46] were included in the analysis. Pooled RR for serosa negative and positive subgroups were 0.97 (95% CI: 0.74-1.27) and 0.99 (95% CI: 0.80-1.23), respectively, revealing there was no significant difference between these two subgroups. Comparing with D2, D2 + PAND didn't improve 5-year overall survival whether in serosa negative or positive subgroups. The P values of heterogeneity tests were 0.06 and 0.89, respectively (Figure 3).

Post-operative morbidity and mortality: For similar reasons as listed for RCTs, the post-operative morbidity data couldn't be combined. Post-operative morbidity was reported in three articles^[43,44,46] (321 patients), but results were not coincident. Higher post-operative morbidity was reported by Bostanci *et al*^[44] (individual RR 3.53 (95% CI: 1.68-7.42)); however, two other articles^[43,46] reported there was no significant difference between D2 and D2 + PAND groups (Figure 4A).

For post-operative mortality, all included non-randomized studies (901 patients) could be analyzed, and the combined RR was 2.06 (95% CI: 0.69-6.15), suggesting there was no significant difference between the two groups. This indicated D2 + PAND could be performed without increasing post-operative mortality; the test for heterogeneity was negative with a P value of 0.34 (Figure 4B).

Operation time: Data of three non-randomized studies^[43,45,46] (767 patients) were useful for meta-analysis, and the pooled WMD was 126.07 min (95% CI: 22.09-230.04), suggesting that there was a significant difference between the two groups. The operation time for D2 + PAND was significantly longer than that for D2. The P value of the heterogeneity test was less than 0.1 (Figure 4C), and a sensitivity analysis identified that the study reported by Kunisaki *et al*^[45] was the main source of heterogeneity.

Blood loss during operation: Two non-randomized studies^[43,45] (650 patients) could be used for meta-analysis, and the pooled WMD was 302.86 mL (95% CI: 127.89-477.84), revealing there was a significant difference between the two groups. This suggested that there was more blood loss in D2 + PAND. The test for heterogeneity was positive ($P = 0.02$, Figure 4D).

Potential risk factors for post-operative morbidity

Univariate and multivariate analysis were used to identify the potential risk factors for post-operative morbidity in only one RCT^[38]; multivariate analysis revealed that pancreatectomy [RR 5.62 (95% CI: 1.94-16.27)] was the most important risk factor for overall complications, but meta-analysis wasn't practicable.

Testing for publication bias

Because there were too few included studies, we didn't draw funnel plots in our review.

DISCUSSION

The choice for the extent of lymphadenectomy in GC has been controversial^[18,30]. To perform a comparison of the effectiveness and safety between standard D2 and D2 + PAND, we conducted a systemic review based on current studies using the method provided by Cochrane

Collaboration^[33]. Four RCTs (total 1120 patients) and four non-randomized studies (total 901 patients) were included in our review. The results of meta-analysis showed that the 5-year overall survival rate was similar between the two operations. Compared with that in D2 resection, post-operative morbidity and mortality didn't increase in D2 + PAND, but the operation time was significantly longer and the blood loss was significantly greater in D2 + PAND in RCTs and non-randomized studies.

Minimal heterogeneity was found between the RCTs for all the measured outcomes, which ensured the quality of the meta-analysis; however, this systematic review was not faultless. First, baseline characteristics were statistically similar in included studies, but were not exactly the same among each RCT; for example, T1 patients were included by Kulig *et al.*^[42] but not by Sano *et al.*^[37], which suggested a potential selection risk. Second, regional lymph nodes were classified by different classifications^[31,32] in included studies, thus the station of lymphadenectomy was confounding in D2 and D2 + PAND groups, which led to the mixture of interventions between included studies. Additionally, surgical outcomes were related to experience of the surgeon^[47]; considering classification standards of lymph node and learning curves of surgeons performance bias might be introduced in our study. Third, from Table 3, blinding could be seen to be unclear in included studies, so measurement bias might exist. Although this was a general phenomenon in surgical clinical trials, it might weaken the reliability of our results. Fourth, completeness of data could affect the statistical results; according to reports of primary literature, the loss rate of data in all included studies was less than 15%, however this does not eliminate the possibility of potential bias. Fifth, stage migration, as it was known, might improve pathological stage- and N-stage-specific survival in GC^[48,49]. However, this factor wasn't taken into consideration in our included studies; this might affect the stage-specific survival after D2 and D2 + PAND. Finally, it was impossible for us to identify all relevant literature, even though we made great efforts; moreover, publication bias might exist due to the low number of included studies.

Because there were few RCTs, non-randomized studies were included in our review to obtain as much comprehensive information as possible, and this problem is common in surgical systemic reviews. Considering the potential heterogeneity induced by methodology, we didn't combine the data of RCTs and non-randomized studies together. Additionally, although combined results of the non-randomized studies were affected by considerable bias in view of differences in methodology and baseline characteristics of included patients, the aim of meta-analysis of non-randomized studies was just to offer an overview of the general trend of outcomes in these studies. In addition, results of non-randomized studies were found to be similar to that of RCTs, which increased the reliability of our review to some extent.

Comparing with that of D2 resection, the survival advantage of D2 + PAND was controversial^[27-29]. It was found that patients with positive PAN and stage IIIb patients got survival benefit from D2 + PAND by some researchers^[20,23,50]. In our review, we failed to discover an overall survival benefit for D2 + PAND [RCTs: RR 1.04 (95% CI: 0.93-1.16); non-randomized studies: RR 0.96 (95% CI: 0.83-1.10)]. In order to identify possible survival discrepancy between D2 and D2 + PAND groups, we conducted a subgroup analysis which used serosa invasion as the only factor due to shortage of primary data. Although it was considered to be an important prognostic factor for GC, we could not analyze TNM stages. In RCTs, there was a survival benefit for serosa negative patients [RR 1.14 (95% CI: 1.01-1.29)], but in non-randomized studies, there was no significant difference in 5-year survival rate between the serosa negative subgroup [RR 0.97 (95% CI: 0.74-1.27)] and the serosa positive subgroup [RR 0.99 (95% CI: 0.80-1.23)]. Theoretically, a larger range of surgery options should produce survival benefit in more advanced carcinoma, so the finding in our meta-analysis seems unbelievable, and is the opposite to some studies^[51]. Although definitive survival data of a study by Kulig *et al.*^[42] are still to come, there is little reason to expect dramatic changes. Therefore, potential survival benefit of D2 + PAND compared with D2 gastrectomy for patients in specific tumor stages, as well as a method to identify para-aortic lymph node metastasis pre-operatively, should be urgently researched in future.

Pancreatic fistula and respiratory complications after PAND were significantly more common in a report by Kunisaki *et al.*^[25]; however, some retrospective reports revealed that there was no significant difference in post-operative complications and mortality between D2 and D2 + PAND, and D2 + PAND can be performed safely by well-trained surgeons^[26-27]. Post-operative morbidity data were not combined by us due to different definitions and contents in each included study, but controversy also appeared in different studies. Generally speaking, the extent of lymphadenectomy could influence the morbidity rates of GC patients, and it was reported that the greater the resection of lymph nodes, the greater the probability of complications^[40,44]. But on the contrary, some researchers^[36,37,42,43,46] revealed that there was no significant difference in the postoperative morbidity between D2 and D2 + PAND patients. In our review, post-operative mortality data were consistent in RCTs and non-randomized studies, with pooled RR 0.99 (95% CI: 0.44-2.24) and 2.06 (95% CI: 0.69-6.15), respectively, suggesting that D2 + PAND might be performed as safely as standard D2. To identify potential risk factors for post-operative morbidity, we searched all relevant literature, and found only one RCT data could be used^[38]. Results of multivariate analysis from this only fit RCT showed that pancreatectomy was the most important risk factor for overall complications, with RR of 5.62 (95% CI: 1.94-16.27). This finding was concurrent with some

other studies^[52], and demonstrated that the resection of combined organs should be prudent.

In this review, we found that PAND, whether in RCTs or in non-randomized studies, was correlated with longer operation time [RCTs: WMD 195.32 min (95% CI: 114.59-276.05); non-randomized studies: WMD 126.07 min (95% CI: 22.09-230.04)] and more blood loss [RCTs: WMD 301 mL (95% CI: 151.55-450.45); non-randomized studies: WMD 302.86 mL (95% CI: 127.89-477.84)], which were different from that of a related meta-analysis published recently^[30], in which blood loss during operation wasn't analyzed, but operation time was similar with a WMD - 112.60 min (95% CI: 286.22-61.02) between the two operations; clinically, the operative procedure to eradicate para-aortic lymph nodes is more complicated, so the wound degree of surgery should be heavier in D2 + PAND, thus our results were more credible to some extent. As we know, wound degree of surgery was intensively affected by skills of surgeons, so if we want to reduce the wound degree of surgery for PAND patients, pre-operative training of surgeon is necessary. Furthermore, in order to reduce the publication bias from different authors in different nations, standard operating procedures or rules for PAND should be achieved by consensus in time; otherwise, in the future, it will be also difficult to judge which RCT is more reliable.

Quality of life after surgery, as we know, is an important index to evaluate treatment effectiveness for patients with malignant tumors. Unfortunately, very few studies reported this clinical outcome of patients with advanced GC after PAND; so quality of life after PAND should be taken into consideration in future clinical studies.

In conclusion, D2 + PAND can be performed as safely as standard D2. Compared with standard D2, D2 + PAND doesn't have any overall survival benefit, but its' wound degree of surgery is significantly higher, demonstrated as a longer operation time and greater blood loss. Consequently we feel D2 + PAND should be performed prudently. For reducing wound degree during D2 + PAND, pre-operative training of the surgeon is necessary and standard operating procedures or rules for PAND should be achieved by consensus. Additionally, research on the relationship between prognosis of GC patients and combined organ resection, and potential survival benefit of D2 + PAND for some specific stages of advanced GC are urgently needed in the future.

COMMENTS

Background

Although radical gastrectomy is thought to be an important treatment measure, prognosis of advanced gastric cancer (GC) is still poor. A reasonable operation procedure for advanced GC is an issue worthy of investigating nowadays.

Research frontiers

It is reported that 18%-40% of patients with advanced GC had metastasis present in the para-aortic nodes and additional dissection of para-aortic nodes is considered to be a necessary procedure as well as standard D2 gastrectomy in order to achieve R0 resection. However, the effectiveness of D2 + para-aortic nodal dissection (PAND) is still controversial.

Innovations and breakthroughs

Some researchers assumed that PAND might achieve R0 resection and benefit the survival of patients with advanced GC, despite its high post-operative morbidity and mortality. The present systematic review found that D2 + PAND failed to benefit the overall survival of patients with advanced GC, but it could be performed as safely as standard D2 resection without increasing post-operative mortality.

Applications

D2 + PAND should be performed prudently and its potential survival benefit for patients with specific tumor stages of advanced GC should be urgently researched in the future.

Terminology

Standard D2 lymphadenectomy refers to systematic dissection of lymph nodes in the first tier (perigastric) and the second tier (along the celiac artery and its branches); and D2 + PAND refers to additional dissection of para-aortic lymph nodes.

Peer review

This manuscript is well prepared, study design is reasonable, statistical methods are appropriate, and conclusions are based on the convincing statistical analysis. The results and information conveyed in the article might contribute to the knowledge of gastric cancer management.

Abstract

Hepatic arterial infusion (HAI) of chemotherapy can be performed in cases of liver-confined metastatic disease, resulting in increased local drug concentrations. Here we report the case of a 61-year-old man who presented with an isolated large unresectable liver metastasis of colon cancer after failure of surgery and multiple administration of systemic chemotherapy. The patient was treated with a combination of gemcitabine and oxaliplatin using HAI. The tolerance was excellent and a radiological complete response was obtained after 8 cycles of HAI. The rationale for the use of gemcitabine and oxaliplatin as well as that for the combination of the 2 drugs is discussed in this paper. HAI of

INTRODUCTION

Hepatic arterial infusion (HAI) of chemotherapy is a treatment option in cases of liver-confined metastatic disease from colorectal carcinoma and results in increased local drug concentrations. Although a recent meta-analysis involving 1277 patients^[1] reported no significant survival benefit of fluoropyrimidine-based HAI in patients with liver metastases from colorectal cancer, the study suggested using novel anticancer agents and/or drug combinations to improve the efficacy of HAI in the future. There is growing evidence for using the combination of gemcitabine and oxaliplatin in different types of malignancies including colorectal cancer.

Here we present a case of radiological complete response after HAI of gemcitabine-oxaliplatin for a large unresectable liver metastasis from a colon cancer.

CASE REPORT

In April 2005, a 61-year-old man was referred to our hospital with rectal bleeding. A colonoscopy revealed a sub-occlusive sigmoid mass 26 cm from the anal margin. A computed tomography (CT) scan performed before surgery revealed one liver metastasis that involved hepatic segment VIII. Carcinoembryonic antigen was not a tumor marker for this patient. The patient underwent sigmoid resection. Pathological examination revealed a sigmoid adenocarcinoma with 7 metastatic regional lymph nodes (pT3 pN2 M1). The patient received 10 cycles of the FOLFOX regimen (fluorouracil + oxaliplatin). The disease was stabilized according to RECIST (Response Evaluation Criteria in Solid Tumours). The patient then underwent segmentectomy of hepatic segment VIII in November 2005. In January 2007, the patient presented with 5 new liver metastases that involved hepatic segments IV and VII. The patient received 12 cycles of the FOLFIRI (fluorouracil + irinotecan) and bevacizumab regimen. A partial response was obtained according to RECIST though the 5 metastases were still present on magnetic resonance imaging (MRI). The patient underwent right hepatectomy with partial resection of hepatic segment IV. This resection was complicated by serious liver failure, from which the patient eventually recovered.

In June 2008, the patient presented with a new liver metastasis measuring 4 cm in diameter. Molecular analysis of the tumor revealed no K-Ras mutation and no B-Raf mutation. The patient was treated with 6 cycles of FOLFIRI + cetuximab. However, in October 2008 the metastasis had progressed and measured 5 cm on the liver MRI (Figure 1). A repeat hepatic resection was contraindicated given the history of serious liver failure and the close proximity of the metastasis to the left portal vein. Therefore, HAI was proposed.

An intrahepatic arterial catheter was percutaneously implanted after hepatic arteriography performed by femoral puncture. The catheter was then connected to a subcutaneous implantable port system, located in the inguinal area. After implantation, CT arteriography and a dynamic contrast-enhanced CT (DCE-CT) scan with injection of 1 mL/s of iodine contrast material (350 mg/mL) through the port were performed to check the absence of misperfusion and to assess tumor perfusion before starting hepatic arterial chemotherapy (Figure 2).

The patient received 2 cycles of gemcitabine and oxaliplatin (1 h infusion of gemcitabine 1000 mg/m² followed by 1 h infusion of oxaliplatin 100 mg/m² every 2 wk. Evaluation by CT arteriography and DCE-CT scan (Figure 2) showed a stable disease according to RECIST, but a dramatic decrease in tumor perfusion. Therefore, the patient received 4 additional cycles. Imaging examinations revealed a partial response (residual tumor diameter: 2.5 cm) as well as an almost complete disappearance of tumor vascularity (Figure 2). After 2 more cycles of arterial chemotherapy, a liver MRI

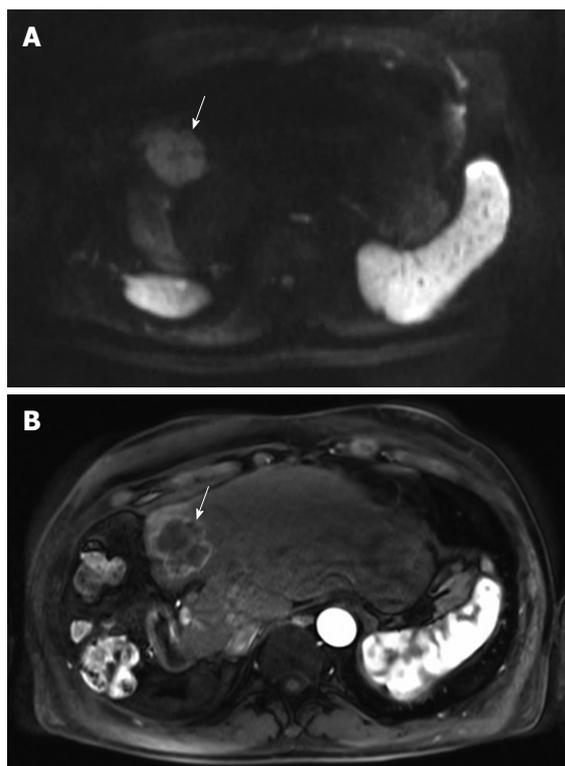

Figure 1 Magnetic resonance imaging (MRI) of the liver before starting hepatic arterial infusion (HAI). A: The hyperintensity of the solitary large (5 cm) metastasis in segment 4 (arrow) on the axial diffusion-weighted image is consistent with malignancy; B: The metastasis is hypervascular (arrow) on the arterial phase after injection of gadolinium chelate.

(Figure 3) showed the absence of tumor hyperintensity on diffusion-weighted imaging and a complete response regarding tumor perfusion. Positron emission tomography-CT with no significant hepatic uptake of ¹⁸F-fluorodeoxyglucose confirmed the absence of a viable macroscopic tumor. Finally, the treatment was completed with radiofrequency ablation of the residual mass. Only mild toxicity was observed, with grade 2 thrombocytopenia and asthenia with no specific toxicity related to the intraarterial procedure. To date, the patient is still in complete remission.

DISCUSSION

HAI of chemotherapy was first described in the early 1960s^[2] and can be proposed in cases of liver-confined metastatic disease. It results in increased local drug concentrations and lower systemic concentrations and hence less toxicity than intravenous administration, provided that the drug is eliminated by hepatic extraction^[3]. The use of HAI is also supported by the fact that, once hepatic metastases grow above 2–3 mm in size, they derive their blood supply from the hepatic artery, while normal hepatocytes are perfused mostly from portal circulation^[4]. Although a recent meta-analysis involving 1277 patients^[1] reported no significant survival benefit of fluoropyrimidine-based HAI in patients with liver

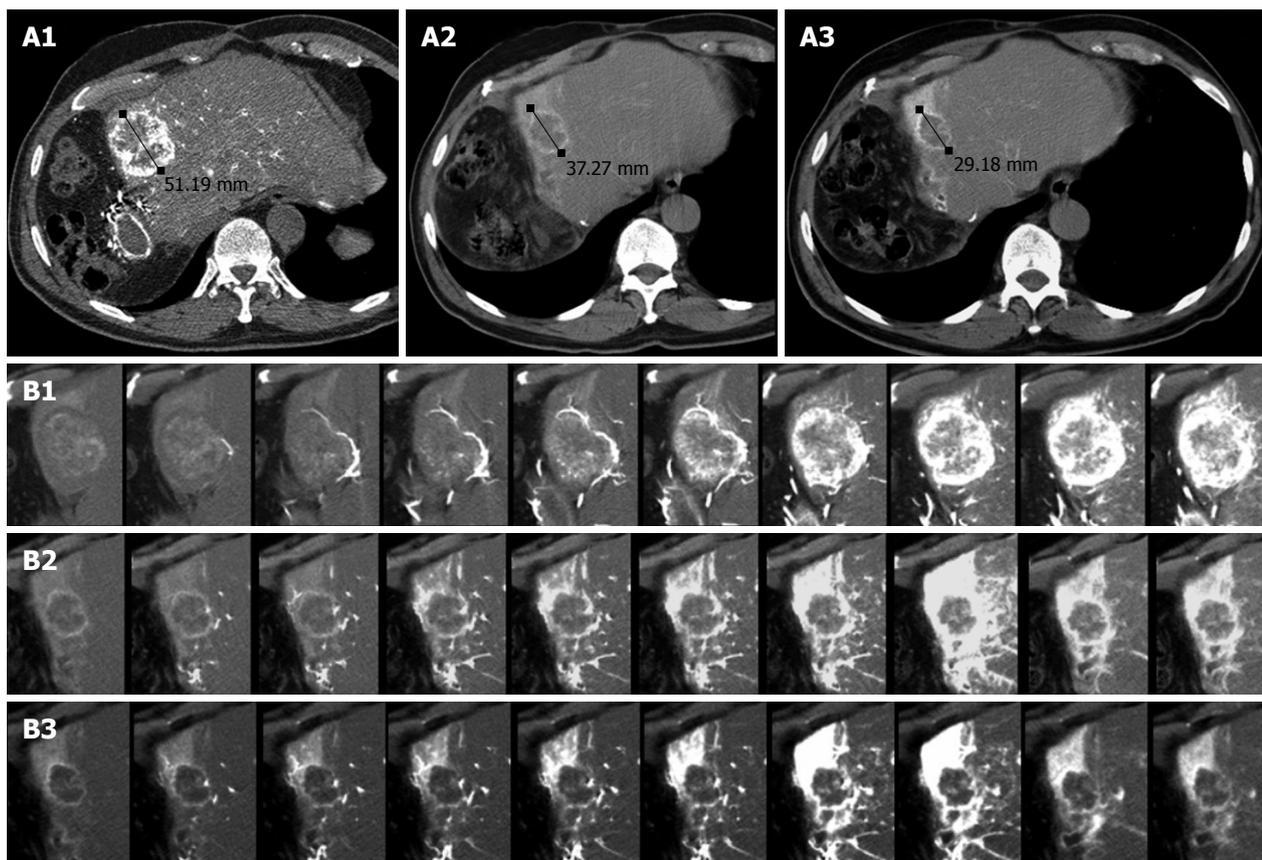

Figure 2 Computed tomography (CT) of liver metastasis. A: CT arteriography at baseline (A1), after 2 cycles (A2) and after 6 cycles (A3) of HAI. The metastasis was hypervascular at baseline. It became shorter after 2 cycles but remained as a stable disease according to RECIST. After 6 cycles, a partial response was observed (43% reduction in diameter); B: Dynamic contrast-enhanced CT (DCE-CT) scan at baseline (B1), after 2 cycles (B2) and after 6 cycles (B3). At baseline, the tumor was progressively and massively enhanced. After 2 cycles, there was a dramatic decrease in tumor perfusion, strongly suggesting the efficacy of HAI. Normal hepatic segment 4 is strongly enhanced. After 6 cycles, only small enhanced areas are visible within the residual tumor.

metastases from colorectal cancer, the study suggested using novel anticancer agents and/or drug combinations to improve the efficacy of HAI in the future. One of the major drawbacks of fluoropyrimidine-based HAI is the prolonged infusion time, which, in addition to causing patient discomfort, is likely to be responsible for chronic hepatobiliary toxicity^[1,5].

To our knowledge, this is the first case to report the combined use of gemcitabine and oxaliplatin for HAI. The addition of oxaliplatin in systemic chemotherapy for metastatic colorectal cancer has resulted in a higher response rate and longer survival than with 5-fluorouracil and leucovorin^[6]. HAI of oxaliplatin in a rabbit VX2 tumor model showed that the drug accumulated in the liver metastases in a 4:3 ratio (tumor/normal liver)^[7]. A high liver extraction ratio has been reported with oxaliplatin administered in HAI^[8], thereby explaining its low systemic bioavailability and thus, the good tolerance^[9]. Human phase I or I / II studies reported a dose-limiting toxicity between 150 mg/m² and 175 mg/m² of oxaliplatin for every 3-wk administration *via* HAI^[10,11]. The 100 mg/m² dose used in our patient was well tolerated and resulted in no specific toxicity. However, since firstly oxaliplatin as a single agent has demonstrated only moderate activity in patients with metastatic colorectal

cancer^[12] and secondly, its combination with fluoropyrimidines would necessitate prolonged infusion with subsequent hepatobiliary toxicity, we needed to use a combination of oxaliplatin with another chemotherapeutic agent.

Gemcitabine is a deoxycytidine analogue which has to be intracellularly phosphorylated to its active forms (gemcitabine diphosphate and triphosphate) by deoxycytidine kinase^[13], increased levels of which are found in liver metastases compared to normal liver tissue^[14]. In addition, an *in vitro* study showed that gemcitabine had concentration- and time-dependent cytotoxic effects on many colon cancer cell lines^[15]. As HAI makes it possible to reach an effective concentration locally, gemcitabine was deemed suitable for HAI. Interestingly, an experimental study conducted by Faivre *et al*^[6] showed, in human colon cancer cell lines, a supra-additive effect of gemcitabine in combination with oxaliplatin, as well as a stronger effect of gemcitabine followed by oxaliplatin than the inverse. In a phase I study by Vogl *et al*^[17], a maximum-tolerated dose of 1400 mg/m² gemcitabine was reached after weekly 20-min HAIs of the drug in patients with cholangiocarcinomas and liver metastases from pancreatic cancer. A recent phase I study reported that gemcitabine given at doses higher or longer than

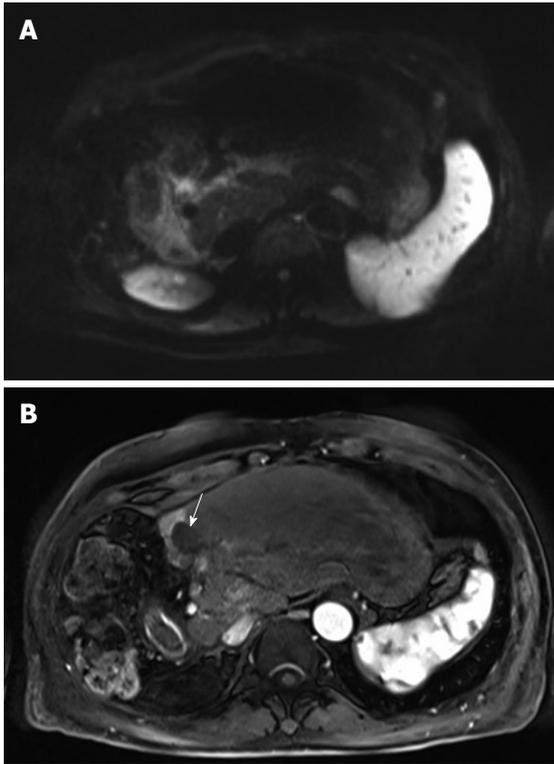

Figure 3 MRI of the liver after 8 cycles of HAI. A: The lesion is isointense to the liver parenchyma on the diffusion-weighted image thereby suggesting the absence of viable tumor; B: The lesion is completely avascular (arrow) during the arterial phase after injection of gadolinium chelate. Note the enhancement of the remnant segment 4.

the recommended systemic dose of 1000 mg/m² over 30 min was well tolerated. All these results are consistent with the excellent tolerance in our patient.

CT arteriography using the implantable port system is useful to detect misperfusion^[18] which may be responsible for undertreatment of liver metastases and/or for inadvertent chemotherapy perfusion of extra-hepatic organs such as the gastroduodenal wall. Early endovascular management prevents gastroduodenal lesions caused by the toxicity of chemotherapeutic drugs and allows treatment by HAI to be continued^[19]. In this case, visual assessment of tumor perfusion on DCE-CT helped us to detect an early response to HAI. Although optimum quantitative perfusion parameters have not yet been determined, visual analysis of DCE-CT may be useful for monitoring the effects of HAI over time.

In conclusion, despite the poor prognosis of colon cancer with synchronous liver metastases, this patient has survived for 52 mo and is to date disease-free. This suggests that further trials involving HAI of oxaliplatin and gemcitabine in metastatic colon cancer are required.

INTRODUCTION

Splenic lymphangiomas are a very rare, benign entity that is characterized by the presence of multiple cystic lesions of different sizes that replace all the parenchyma. It is considered to result from developmental failure in the lymphatic system. In the majority of cases, this disease has an asymptomatic course and, despite the use of modern imaging techniques, often makes preoperative diagnosis difficult. Due to the nonspecific features of this disease, splenectomy is needed to make a definitive histological diagnosis and to exclude the possibility of malignant lesions.

CASE REPORT

In January 2006, a 35-year-old woman was admitted to the General Surgery Unit, Department of Surgical and Oncological Sciences, Palermo, Italy after a hematologist (IE) suggested that she undergo splenectomy.

The patient was referred about 5 wk after her second delivery. About 5 mo before, she had noted increasing pain in the left hypochondrium. Abdominal ultrasound showed an increased in spleen volume with a long axis of 10 cm, with no homogeneous ultrasound structure, which indicated the presence of multiple hypoechoic circular masses with a maximum diameter of 1 cm.

Further abdominal ultrasound performed up to 1 wk before delivery showed that the spleen had no additional changes. Immediately after delivery, the patient began to nurse the baby. In particular, this was the first time she had nursed her newborn, because she did not nurse her first child who was born 3 years before.

Due to recurrence of pain in the left hypochondrium, after about 5 wk from delivery, the patient underwent abdominal ultrasound that showed spleen enlarge-

Abstract

Splenic lymphangiomas are a very rare condition that, from 1990 to date, has been described only nine times. In the present report, we describe the first case of splenic lymphangiomas with rapid growth during lactation in a 35-year-old woman. We also underline the difficulty in making an accurate preoperative diagnosis, despite more modern imaging techniques. Total splenectomy was considered to be the treatment needed, both to make a definitive diagnosis and to exclude the presence of malignancy.

Figure 1 Total body computed tomography. The spleen appeared increased in volume (maximum diameter 18 cm), and it was possible to see multiple low-density lesions with a nodular appearance, which replaced all the parenchyma.

ment, with a long axis that measured up to 18 cm, with a hypoechoic mass that had a diameter of 2.5 cm. Total body computed tomography showed only splenomegaly with multiple low-density lesions with a nodular appearance, which were considered by the radiologist to be features of lymphoma (Figure 1).

There was no fever, nausea or vomiting. Laboratory findings were all within the normal limits. Also, serological screening for hydatid disease was negative.

Due to the rapid increase in spleen volume, the patient suspended lactation and after 2 d, she underwent conventional open splenectomy. During the operation, careful examination of the abdominal cavity was performed to search for the presence of an accessory spleen, which in this case, was not found. The remaining abdominal viscera were normal.

The spleen had an 18-cm long axis, and its macroscopic appearance was characterized by the presence of multiple cystic masses of clear appearance that replaced all the parenchyma, which altered the volume and profile of the spleen (Figure 2). Histological examination revealed various lymphatic space dilatations associated with slow stromal bleeding, which led to a diagnosis of splenic lymphangiomatosis.

Postoperative course was unremarkable and the patient was discharged 6 d after surgery. Additional clinical and instrumental controls did not reveal any further sites of lymphangiomatosis. After a 3-year follow-up, there was no sign of recurrence. The patient did not have a further pregnancy and felt in good health. Ultrasound controls performed on her parents and sons did not show signs of abdominal cystic lesions.

DISCUSSION

Lymphangioma is a cystic, benign, slow-growing tumor and is a very rare condition, usually seen in children, where it is discovered incidentally^[1]. These tumors occur more frequently in females, and 80%-90% are detected before the end of the second year of life. They are generally considered to be a developmental malformation in which obstruction or agenesis of lymphatic tissue results in lymphangiectasia, which is caused by a lack of normal communication of the lymphatic system.

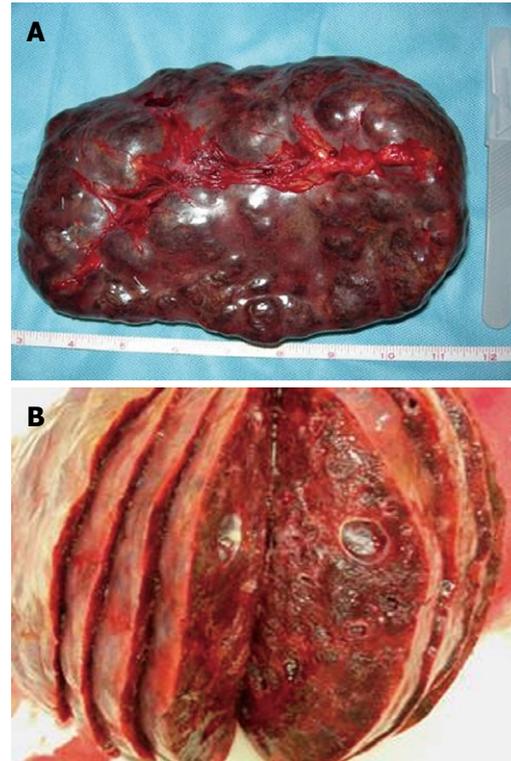

Figure 2 Surgical specimen. A: The spleen was 18 cm on the long axis, and its macroscopic appearance was characterized by the presence of a multiple cystic mass that altered the volume and profile of the spleen; B: A section of the spleen confirmed the presence of a multiple cystic mass with a clear appearance that replaced all the parenchyma.

The neck (75%) and axillary regions (20%) are the most common locations of lymphangioma. However, cases have been reported to originate from any part of the gastrointestinal tract. Lymphangioma can be isolated or diffuse and involve one or more organs. The lymphatic alteration, which involves different organs, is termed systemic lymphangiomatosis. The spleen can be involved alone or it can be a part of multivisceral involvement.

Isolated splenic lymphangioma can arise with different manifestations^[2]: focal lesions of small size, subcapsular rather than intraparenchymal, with no pathological significance; large cystic lesions that may attain sufficient size to cause significant splenomegaly and left-upper quadrant symptoms; and lymphangiomatosis in which the spleen is replaced diffusely by expanding lymphangioma, thus leaving very little splenic parenchyma. Isolated splenic lymphangiomatosis is a rarer form; from 1990 to date, only nine cases have been described in the literature^[1-9]. In this form, the cysts can have different sizes that vary from a few millimeters to two or three centimeters. The spleen, when it is involved, rarely has a normal size, and its volume is frequently greatly increased.

Histologically, lymphangioma is classified as simple, cavernous and cystic, depending on the size of the dilated lymphatics. At gross examination, these cysts have a thick fibrous wall with an internal morphology that is characterized by fibrous trabeculae. Hyalinization and calcification of the fibrous connective tissue may be present. Also, lymphangioma has an endothelial lining, foam cells and a wall that contains lymphatic spaces,

lymphoid tissue and smooth muscle. Histochemical staining of the endothelium demonstrates reactivity with CD31, CD34, factor VIII-related antigen and keratin to varying degrees^[10]. Sexual hormones can influence the growth of lymphangioma. Quack Loetscher *et al*^[11] have described a case of axillary cavernous lymphangioma that rapidly increased in size during pregnancy. They also hypothesized that the possible pathological mechanism for growth of lymphangioma could be related to the overproduction of cytokines such as vascular endothelial growth factor (VEGF)^[11]. Animal studies have shown that prolactin, produced during lactation, stimulates production of VEGF and induces overexpression of its receptor^[12]. In the present case, growth of lymphangiomatosis was observed during the period of lactation.

In the adult population, lymphangioma has an asymptomatic course, and often is found as an occasional feature during instrumental investigations performed for other reasons. When symptoms are present, they are related to the size of the spleen and pain is the most common complaint. Less commonly, patients can present with a palpable mass located close to the hypochondrium.

Due to the rarity of presentation and the asymptomatic course of this disease, it is often difficult to make a correct diagnosis. Imaging studies are useful, both to characterize the splenic malformations and to exclude eventual involvement of other organs. Diagnostic studies of lymphangioma usually begin with ultrasonography, which shows the entire spleen as appearing to be replaced by cystic lesions with an anechoic or hypoechoic pattern^[13]. Color-Doppler integration can demonstrate the vasculature of the mass, including the intrasplenic arteries and veins along the cyst wall, which helps to determine the organ of origin^[13]. Angiography typically reveals an avascular mass. The parenchymogram generally shows multiple focal lucencies of various sizes, the so-called “Swiss-cheese” appearance. Computed tomography demonstrates multiple low-attenuation masses with sharp margins that are typically subcapsular and do not enhance^[14]. Upon magnetic resonance, generally lymphatic malformations appear as hyperdense on T2 imaging, whereas T1 imaging is only slightly increased^[15]. Fine needle aspiration biopsy in splenic lymphangiomatosis is contraindicated because of the bleeding risk and limited amount of tissue for accurate diagnosis^[16]. The differential diagnoses includes malignant (i.e. angiosarcoma or lymphoma) and benign (i.e. hemangioma, littoral cell angioma, and peliosis) splenic vascular proliferation. The instrumental investigations alone are not always useful to make a correct differential diagnosis. This is caused by the rarity of vascular tumors of the spleen and the absence of pathognomonic signs. For these reasons, usually, the correct and definitive diagnosis can be obtained only with histological confirmation; histochemical investigations are needed to make a differential diagnosis among different vascular tumors.

Lymphangiomatosis involves all the splenic parenchyma, therefore, a total splenectomy is the treatment needed. Laparoscopic splenectomy is considered the procedure of choice for normal or moderately enlarged spleens, whereas in the case of severe splenomegaly, open splenec-

tomy is preferred^[17]. During surgery, both open and laparoscopic, the search for accessory spleens is an important step. These must be removed even if they appear macroscopically normal, because they could be involved in the pathological process^[7,10].

Although the development of lymphangioma in pregnancy has been described in the literature^[11,18], the main interest of this case was the rapid growth of splenic lymphangiomatosis, with an increase from 10 to 18 cm in 5 wk during lactation. The rapid growth of the spleen and the suspicion of malignancy led us to perform an open splenectomy.

Abstract

Transjugular intrahepatic portosystemic shunt (TIPSS) is considered a valid therapeutic option for the treatment of portal hypertension and its complications. The guidelines for this procedure have already been established on the basis of the normal vascular anatomy and of various technical radiological aspects. In some few rare cases, diagnosis of a congenital vascular anomaly can be made accidentally by interventional radiologists, making the procedure of the TIPSS placement extremely difficult or in some cases technically

INTRODUCTION

The transjugular intrahepatic portosystemic shunt (TIPSS) is a well known life saving procedure that is performed in patients with complications of portal hypertension, such as variceal bleeding and refractory ascites^[1-5]. The standard technique for this treatment is the right internal jugular vein (RIJV) approach, although some authors have reported the left internal jugular vein (LIJV) approach when the RIJV is not available or cannot be used, due, for example, to vein thrombosis^[6]. Few cases of patients with the absence of the right superior vena cava (RSVC) and the persistence of the

left superior vena cava (LSVC) have been described in the literature^[7]. Even if this is an extremely rare situation, it can create problems during the interventional procedure. We briefly report a case in which a TIPSS was successfully created in a patient with absence of RSVC and persistence of the LSVC.

CASE REPORT

A 69-year-old female with a diagnosis of hepatitis C virus-related cirrhosis was referred to our institute in order to be evaluated for a TIPSS placement because of refractory ascites. In the physical examination the patient had tense ascites despite a consistent use of high dose diuretics and periodic paracentesis (every 1-2 wk). She was well oriented to time and to space and had no episodes of portosystemic encephalopathy in the past. An abdominal computed tomography (CT) scan of the abdomen and a liver Doppler sonography (US) were performed excluding presence of hypervascular focal lesions in the liver and showing patency of the portal vein (PV). The CT scan also showed signs of portal hypertension such as tense ascites, presence of splenogastrorenal shunt, large esophageal and perigastric varices and patency of the umbilical vein. A large volume paracentesis was performed at admission with removal of almost 15 liters of clear ascites. No evidence of infection was found in the fluid (white blood cell count, Gram stain, and culture were negative).

The patient was hemodynamically stable with no need of inotropic drugs. Child-Pugh score was B-8 with a Meld score of 10. She had mild coagulopathy (international normalized ratio 1.4, platelet count 56 000/ μ L), but with good liver function tests (LFTs) (total bilirubin 1.29 mg/dL, albumin 3.4 g/dL). A transthoracic echocardiography showed no evidence of valvular heart disease, and the diameters of the cardiac chambers were within normal limits. Systolic and diastolic functions of the left ventricle were in the normal range. Estimated pulmonary vein pressure was 35 mmHg.

As a result, we decided to perform a TIPSS procedure in order to treat portal hypertension. The procedure was carried out in an angiographic suite under monitored anesthesia care. The right femoral artery was prepared, and an angiogram revealed patency of the superior mesenteric artery. In the venous phase the superior mesenteric and main portal vein were visualized. After sonographic guidance, the RIJV was cannulated, and under fluoroscopic guidance the metallic flexible guidewire was advanced and seen to curve to the left, until reaching the right atrium (Figure 1). A 5 French (F) pig tail catheter was advanced in the right atrium and a venogram revealed a patent LSVC that drained in the coronary sinus and an absent RSVC but in the presence of a viscerocranial situs solitus (Figure 2). Because of the excessive curvature, which made insertion of the Colapinto needle impossible, we decided to use the LIJV and perform a new venogram. Under sonographic guidance, a new catheter was advanced through the LSVC

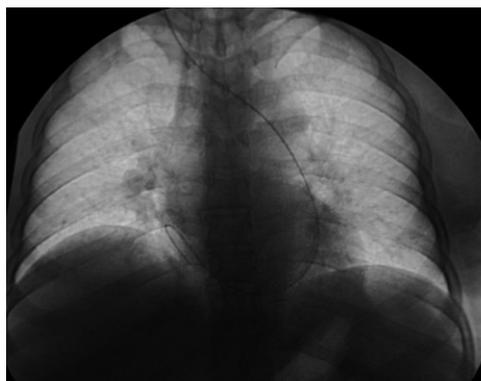

Figure 1 Digital venogram showing the curve of the metallic flexible guidewire from the left to the right atrium.

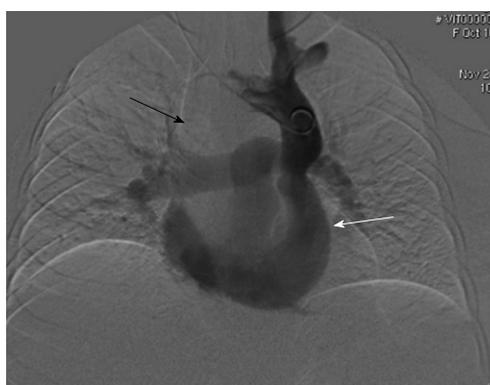

Figure 2 Digital venogram, performed with a 5F pigtail catheter, showing the absence of the right superior vena cava (RSVC) (black arrow) and presence of contrast dye in the left superior vena cava (LSVC) that is draining in the coronary sinus (white arrow).

and the coronary sinus to the right atrium and from the inferior vena cava to the right hepatic vein. The Colapinto coaxial system was applied. The right branch of the main PV was punctured, under fluoroscopic guidance, and a 5F hydrophilic catheter was advanced over a hydrophilic guidewire. Portal hemodynamic measurements were performed and showed free hepatic vein pressure (FHVP) of 12.5 mmHg, right atrial pressure (RAP) of 12 mmHg, and portal vein pressure (PVP) of 23.5 mmHg. A shunt was created employing an 8-mm diameter Viatorr-covered stent which was dilated with a 6-mm angioplasty balloon. New hemodynamic measurements showed FHVP of 14.5 mmHg, RAP of 14 mmHg and PVP of 19 mmHg. A venogram performed after the TIPSS placement showed patency of the stent (Figures 3 and 4) with reduction of the gradient from the portal vein to the right atrium from 11.5 mmHg before stent placement to 5 mmHg after stent placement.

A Doppler US control was performed the day after the TIPSS placement showing good patency and blood flow within the stent. The patient had a good post-procedure course with no complications and was discharged 48 h after the TIPSS creation.

Since then, the patient has had regular clinical and radiological follow-up, having a US exam of the TIPSS

Figure 3 Digital portogram performed after transjugular intrahepatic portosystemic placement showing patency of the stent with good portal flow (white arrow).

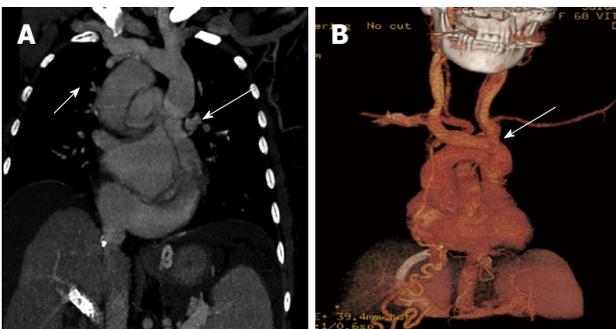

Figure 4 Maximum intensity projection reconstruction in coronal plane (A) and volume rendering reconstruction (B). Absence of the right vena cava (short arrow) with the brachio-cephalic venous trunk, the left jugular vein and the left subclavian vein draining into the left superior vena cava (long arrows). Left SCV is draining into the coronary sinus.

and laboratory tests every 3 mo. The last US exam was carried out 19 mo post-TIPSS creation showing patency of the TIPSS and absence of ascites. Currently the patient is doing well, her Child-Pugh score is B-7, with stable LFTx and no signs of hepatic decompensation.

DISCUSSION

Absence of the right SVC with persistent left SVC in viscerocranial situs solitus is a rare congenital cardiovascular malformation and one of the most common rare thoracic vein anomalies. It is found in < 1% of the general population and in up to 10% of patients with congenital heart disease^[8,9]. The first case was described in 1862 by Halbertsma^[10].

This anomaly is usually diagnosed accidentally, for example, during anesthesiological procedures, such as central vein placement^[7] or, more frequently, during diagnostic and therapeutic cardiovascular procedures, such as right heart catheterization or pacemaker placement^[11,12]. Moreover, it may also emerge during cardiac procedures

in pediatric patients (foramen ovale or atrial septal defect transcatheter closure).

Nowadays, TIPSS is considered to be a valid procedure for the treatment of complications of portal hypertension such as refractory ascites and variceal bleeding. The left internal jugular approach has been reported in previous studies^[6]. To our knowledge, there are a few cases reported in the literature of successful TIPSS placement through the LSVC approach^[13], some of them in patients with a diagnosis of “situs inversus totalis”^[14,15]. Interventional radiologists should be aware of this rare, but possible, vascular anatomy, and understand that it may not represent an absolute contraindication for TIPSS insertion.

Abstract

We describe simultaneous surgery performed on a 71-year-old woman with critical aortic stenosis and gastric cancer that were diagnosed at the same time. The patient qualified for simultaneous surgery for both these diseases. Good early outcome was achieved. There is a lack of standards for treatment of patients with coexistence of two life-threatening conditions. We discuss surgical tactics and potential benefits of such management.

INTRODUCTION

Cardiovascular and neoplastic diseases are the main causes of death in Europe. Aortic stenosis is currently the third most common heart disease in Europe and North America. It is mainly caused by degenerative processes, with secondary calcification of the valve. Moderate stenosis is observed in 5% of the population over the age of 75 years, while critical stenosis occurs in 3% of the population, with half of these cases being asymptomatic. Diagnosis is based on preoperative echocardiographic examination. Severe stenosis can be managed with one of the following procedures: valve replacement, transcatheter aortic valve implantation or, in some cases, percutaneous valvulotomy with Inoue balloon^[1].

Gastric cancer remains one of the most common neoplastic diseases in the world, with fourth highest morbidity. Diagnosis is based on pathologic examination of a specimen obtained at gastroscopy. Infiltration depth is evaluated with endoscopic ultrasound. Computed tomography (CT) enables assessment of regional lymph nodes and presence of remote metastases^[2]. Surgical treatment remains a therapy of choice for gastric cancer; however there are no standard procedures. In

Europe, 5-year survival following R0 gastric resection is 33%-35%^[3].

We present the following case of a patient who underwent simultaneous surgical treatment of gastric cancer and asymptomatic critical aortic stenosis.

CASE REPORT

A 71-year-old female patient (weight 56 kg, height 164 cm) was admitted to the Department of Surgical Oncology because of gastric tumor. She had a history of non-specific epigastric pain and appetite loss for the past 2 mo. Weight loss was 12 kg over 6 mo. Laboratory tests revealed secondary anemia (Hb 10.8 g/dL) and lowered blood ferritin level (5 ng/mL). The patient had a history of melena and loose stool prior to admission to the hospital. She had never been treated for gastrointestinal tract diseases.

Because of non-specific abdominal symptoms and anemia, the patient was referred for endoscopic examination of the upper gastrointestinal tract. Gastroscopy revealed an ulcerated tumor in the upper third of the gastric corpus, reaching over half of its circumference. Pathologic examination of the biopsy specimen revealed gastric adenocarcinoma (adenocarcinoma tubulare G1 exulcerans, intestinal type according to Lauren's classification). Before admission, the patient had never been treated for cardiac or vascular diseases. Cardiac efficiency was classified grade II NYHA (New York Heart Association) scale^[4]. The patient had a history of decreased arterial blood pressure over the past 10 years.

At the age of 38 years, the patient was diagnosed with primary adrenal insufficiency (Addison's disease), treated with hydrocortisone (30 mg orally). One year before admission, after bone marrow biopsy and laboratory findings, the patient was diagnosed with chronic lymphocytic leukemia, requiring only regular control in the hematology out-patient clinic.

At the age of 50 years, the patient underwent two surgeries: left thyroid lobectomy because of nodular goiter (currently in euthyrosis) and left breast amputation because of breast cancer (currently under oncological observation). Allergic history comprised of a pollen allergy.

Electrocardiogram examination revealed regular sinus rhythm with heart rate 71 bpm, PR 156 ms, QT 390 ms, QTc 0.45 ms. Chest X-ray did not show any lung pathology. Sclerotic aorta with typical poststenotic dilation of ascending aorta and hypertrophy of left ventricle were described. Echocardiographic examination revealed critical aortic stenosis with maximal transvalvular pressure gradient of 135 mmHg; mean gradient was 95 mmHg. Valve surface area was estimated to be 0.3 cm². Interventricular septum diameter was 16 mm, and left ventricular ejection fraction was 45%-50%. Additionally, significant calcification of the aortic bulb and aortic valve cusps was found. Subsequently, a coronarography was performed, which showed no significant stenosis in the coronary vessels.

No enlarged lymph nodes in the posterior mediastinum were observed on thoracic CT. On the other hand, on abdominal CT numerous non-characteristic enlarged lymph nodes were observed in the retroperitoneum along the abdominal aorta. This included enlarged lymph nodes surrounding the celiac trunk and in the mesentery of the small intestine. It was not clear, however, whether lymphadenopathy resulted from the chronic lymphocytic leukemia or from metastases of the gastric cancer.

Additionally, gallstones 24 mm in size were found. An anterior gastric wall thickening in the region of lesser curvature was observed. In view of the clinical examination and the results of image studies the patient was classified as having no sign of metastatic disease. During preoperative diagnostic staging, laparoscopy was considered among other available procedures, however, after presenting the case to cardiac surgeons and anesthesiologists, this was called off due to the relatively high risk of sudden cardiac death^[4].

Anesthesiologist consultation assessed the patient's cardiac efficiency as grade II NYHA (New York Heart Association) scale and grade III ASA (American Society of Anesthesiologists) physical status classification^[5,6].

The operation was performed *via* sternotomy and median laparotomy by two surgical teams. There were some doubts about operability of the stomach cancer, therefore the oncological surgeon performed a laparotomy to assess the possibility of radical resection. Subsequently, the thorax was opened by median sternotomy. Massive calcifications in the ascending aorta (porcelain aorta) were found and the cardiothoracic surgeon considered discontinuation (Figure 1A). Ultimately, the decision to proceed with the operation was made. Aortic valve replacement (biological prosthesis Medtronic® Hancock II size 21) with implantation of an ascending aorta prosthesis in the supracoronary position (Vascutek® prosthesis size 26) with extracorporeal circulation (ECC) was performed (Figure 1B). Time of ECC was 148 min. The patient returned to normal circulation without complications. After weaning from ECC, protamine sulfate was administered to reverse the heparin action necessary during cardiopulmonary by-pass. Fresh frozen plasma and platelets were supplemented additionally, to enable the oncological surgeon to perform his part of the operation without disturbance of hemostasis. In the second stage, the oncological team performed total gastrectomy with D1 lymphangiectomy and Roux-en-Y anastomosis (Figure 1C). The procedure was supplemented with feeding jejunostomy. The spleen was removed for technical reasons. Additionally, cholecystectomy was performed because of cholelithiasis. The entire operation finished without complication in a total time of 320 min. Throughout the operation the patient received 4 units of blood, 6 units of fresh frozen plasma, and 2 units of platelet concentrate. The patient was extubated 33 h after the operation. Immediately after the surgery, the patient was admitted to the Intensive Care Unit, staying there for 6 d. She did not

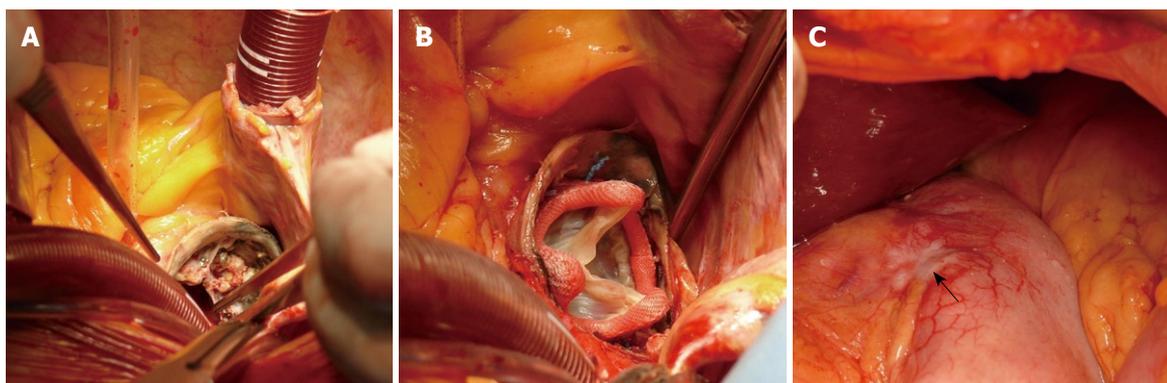

Figure 1 Steps taken in the simultaneous surgery: cardiac (A, B) and oncological (C). A: Excision of the calcified aortic valve; B: Implanted bioprosthesis of the aortic valve; C: Gastric cancer (arrow) seen on gastric wall.

present any abdominal complications. Pericardial drainage was removed on postoperative day 3, and abdominal drainage on day 5. Apart from postoperative depression and slight disorientation, the postoperative course was without problems.

On postoperative day 7, the patient was transferred to the Department of Surgical Oncology for further postoperative care. Psychological care was introduced. Oral feeding was gradually introduced during this period. Postoperative pathological examination of the tumor revealed adenocarcinoma, intestinal type according to Lauren's classification. The subserosal layer was infiltrated (pT2b), and metastases were found in 2 of 8 lymph nodes (pN1) (stage II gastric cancer).

The patient has been followed up for a total of 6 mo to date, with no complications noted.

DISCUSSION

This case is worth presenting because it highlights a number of important issues. Firstly, it is crucial to prepare the patient for surgery thoroughly. This includes taking the patient's history and performing all necessary specialist consultations, bearing in mind various co-existing diseases. Once this has been executed, it becomes possible to plan the optimal treatment. In 2002, recommendations for the management of asymptomatic patients with severe valvular heart disease were established by a European workgroup^[1]. These stated that management of asymptomatic patients with severe valvular heart disease should be based on individual assessment of the risk to benefit ratio. There is a strong need to introduce standards for the diagnosis and management of cardiologic diseases in order to decrease the number of cardiac complications in the perioperative period.

Secondly, the existence of highly specialized Departments (Cardiological, Cardiosurgical, Oncological, Endocrinological, *etc.*) within one unit enabled efficient diagnostics, decision making, simultaneous surgical procedures and safe postoperative care in the Intensive Care Unit. This case shows that complex procedures should be performed in specialist units which should be fully

staffed and resourced, to provide optimal investigation and treatment for patients with complex acquired heart disease.

Thirdly, this case proves that a thoroughly executed taking of the patient's history and physical examination helps to prevent incidental omission of important, potentially life-threatening diseases. Cardiologic consultations ordered more frequently could lead to increased detection of asymptomatic cardiac diseases and help to avoid later cardiovascular complications. The systematic increasing age of oncologic patients has led to the development of a new branch of surgical oncology, called geronto-oncology. This approach may facilitate more individualized treatment, taking into account patient's co-existing diseases.

To optimize the outcome in this case, the decision to perform simultaneous surgical treatment was made. It appeared that there were more arguments supporting the decision to perform simultaneous surgery (even though such a modus operandi is rather rare) than those backing the alternative, i.e. two consecutive surgeries^[7,8]. The grounds for simultaneous surgery were: (1) extension of the sternotomy incision through mini-laparotomy is a standard procedure in cardiac surgery and in coronary artery bypass surgery (assessment of the gastropiploic artery); (2) such a procedure does not increase the postoperative risk; and (3) performance of a mini-laparotomy allowed for evaluation of the extent of the neoplastic process in the abdomen and consequently for deciding whether the cancer was operable and whether its simultaneous resection was feasible. If an extensive spread of the disease had been noted, radical surgery could have not been performed or a two-step surgery might have been necessary after 3-4 wk.

The first step was undertaken by an oncologic surgeon; laparotomy was performed to assess the possibility of radical resection of gastric cancer. Then the chest was opened and cardiac surgery performed, and after finishing the valve replacement and closure of the chest, the oncologic team did their work. In our opinion this was the safest way, which allowed the performance of the second part of the operation without hemostatic

problems that could occur after high dose heparin infusion necessary for the ECC. A different approach could be considered if there was a risk of serious bleeding from the resection lines or anastomoses during the heart-lung machine working time. Additionally, this sequence is important to reduce the risk of mediastinitis. Potential disadvantages of the simultaneous surgery were: (1) increased surgical risk resulting from performing the oncological step after protamine sulfate was administered; and (2) limited operation field allowing for resection of regional perigastric lymph nodes only (i.e. lymphadenectomy type D1).

In a case such as the one we have described here, performing oncological surgery without diagnosing critical aortic stenosis should be treated as malpractice since this scenario could potentially lead to the patient's death.

Abstract

We report three cases of ileocolic mucormycosis in adult immunocompromised patients presenting as acute abdomen. All patients underwent laparotomy but two of them died from multiorgan failure before the diagnoses were confirmed. The diagnosis of gastrointestinal mucormycosis is rarely suspected, and antemortem diagnosis is made in only 25%-50% of cases. These cases illustrate the difficulty encountered by surgeons in managing acute abdomen in neutropenic patients with hematological malignancy. The management of colonic mucormycosis in the published literature is also reviewed.

INTRODUCTION

Neutropenic patients can present with acute abdominal catastrophes of various causes and surgical intervention is required. However, surgery is usually associated with a high mortality and morbidity in the immunocompromised host. With the rising incidence of invasive fungal infection in patients with hematological malignancy and transplant recipients, mucormycosis has been reported to be the third most common cause of fungal infection after candidiasis and aspergillosis^[1,2]. Mucormycosis refers to several different diseases caused by Mucorales^[3,4]. These rare infections usually only occur in individuals with impaired immunity, having associations with diabetes mellitus, hematological or solid-organ malignancies, transplantation, neutropenia and steroid therapy. The diagnosis of mucormycosis is rarely suspected and antemortem diagnosis is made in only 25%-50% of cases^[5].

CASE REPORT

Case 1

A 42-year-old lady received chemotherapy for NK cell lymphoma and, concomitant with disease progression, she presented with ascites and pleural effusion. She complained of abdominal pain and fever in February 2009. Physical examination showed generalized tenderness and the aspirated peritoneal fluid was turbid. Laparotomy was undertaken for suspected perforated viscus. On laparotomy, the ascitic fluid was grossly turbid. The cecum was grossly dilated but no perforation was identified. The rest of the laparotomy was grossly normal except for the in-

Figure 1 Dermal mucormycosis around ileostomy and laparotomy wound.

Figure 2 Fungal colonies over omentum and small bowel surface.

Figure 3 Black ulcer with full bowel infarction at colon on exposed specimen.

flamed omentum which was densely adhered to the pelvic cavity. Peritoneal lavage with saline was the only procedure performed. Postoperatively, Tazocin, amikacin and voriconazole were given as *Klebsiella*, *Escherichia coli* and *Candida albicans* were identified from the peritoneal fluid. However, the patient's condition rapidly deteriorated and she died two weeks after operation. The autopsy showed extensive involvement of fungal elements inside the abdominal cavity. Also, branching septate fungi were isolated in one of the peritoneal fluid cultures after the patient succumbed and later confirmed to be *Rhizopus* species.

Case 2

A 57-year-old man had relapsed diffuse large B-cell lymphoma and underwent palliative chemotherapy and radiotherapy. He presented with peritonitis in September 2008. An urgent computer tomography (CT) scan of the abdomen showed free intraperitoneal gas; emergency laparotomy was undertaken and two 1-cm perforations with indurated edges were identified over the cecum. Ileocecal resection and end ileostomy were performed in view of gross peritoneal contamination. Histological examination showed lymphoma involving the colonic wall and causing the perforations. Broad-spectrum antibiotics (meropenem and vancomycin) and prophylactic fluconazole were given in view of multiple bacteria shown in peritoneal fluid cultures. A well-demarcated gangrenous skin necrosis appeared over the peristomal area and at the upper midline

wound on day 8 (Figure 1). Finally, the patient died of multiorgan failure two days later. Subsequent wound swab culture revealed *Rhizopus* species. No autopsy was performed because of refusal by the family.

Case 3

A 38-year-old male, with persistent precursor B cell acute lymphoblastic leukemia, developed abdominal pain and fever on the eighth day after receiving clofarabine therapy in February 2009. An urgent abdominal CT scan showed features suggestive of appendiceal abscess with suspected pneumoperitoneum. He underwent emergency laparotomy and was found to have gangrenous appendicitis with localized retrocecal abscess. Ileocecal resection and primary anastomosis were performed. Postoperatively, liposomal amphotericin, caspofungin and posaconazole were started immediately as the microbiologist identified *Rhizopus* species in the specimen. Granulocyte colony-stimulating factor was also prescribed for severe neutropenia. The patient recovered well and was transferred back to the general ward. One week later, he still had persistent abdominal distension and developed deep venous thrombosis of the right lower limb. A abdominal CT scan showed that there was no contrast opacification at the right external iliac vessels and impaired contrast enhancement at the terminal ileum. Exploratory laparotomy was undertaken on day 12 after the first operation and multiple hardened fungal colonies were noted over the omentum and small bowel (Figure 2). An inflammatory mass compressed the right iliac vessels, causing decreased venous blood flow. A 20-cm segment of small bowel proximal to the previous ileocolic anastomosis densely adhered to the previous operative site and was ischemic. Small bowel resection, end ileostomy and omentectomy were performed. Multiple patches of full-thickness bowel ischemia were seen over the colonic wall (Figure 3) and mucormycosis was confirmed on histological examination. Though extensive surgical debridement and maximal medical support were administered, the patient died four days after the second laparotomy.

DISCUSSION

Mucormycosis is an opportunistic fungal infection

Table 1 Taxonomic classification of the Zygomycetes

Class	Order	Family	Genus	Species causing human diseases
Zygomycetes	Mucorales	Mucoraceae	<i>Rhizopus</i>	<i>R. oryzae</i> ^{1,2} <i>R. microsporus</i> var. <i>rhizopodiformis</i> ^{1,2} <i>R. pusillus</i> ^{1,2}
			<i>Rhizomucor</i>	<i>M. circinelloides</i> ^{1,2}
			<i>Mucor</i>	<i>A. corymbifera</i> ^{1,2}
			<i>Absidia</i>	<i>A. elegans</i> ^{1,2}
			<i>Apophysomyces</i>	<i>C. bertholletiae</i> ^{1,2}
	Entomophthorales	Cunninghamellaceae	<i>Cunninghamella</i>	<i>C. coronatus</i> ²
		Ancylistaceae	<i>Conidiobolus</i>	<i>B. ranarum</i> ²
		Basidiobolaceae	<i>Basidiobolus</i>	

¹Mucormycosis: Infections caused by Mucorales; ²Zygomycosis: Infections caused by Zygomycetes (Mucorales & Entomophthorales).

caused by fungi of the order Mucorales^[4]. However, it is often inappropriately interchanged with the term zygomycosis (infection caused by the class Zygomycetes) in medical literature. The Zygomycetes are divided into two orders: the Entomophthorales, containing very rare pathogenic species; and the Mucorales, which contain the most common human pathogens, including *Rhizopus*, *Mucor*, *Absidia*, and *Cunninghamellaceae* (Table 1)^[5,4]. Differentiation among these species is based on the morphology of the asexual cycle, physiologic characteristics, and zygospore production. Nonetheless, they rarely cause disease because of the low virulence of the organisms and thus they mainly affect immunocompromised individuals. Novel immunosuppressive therapies and other advances in the understanding of disease pathology and diagnosis have contributed to patients living longer with previously debilitating medical problems and impaired immune systems.

The most common agent of mucormycosis is the *Rhizopus* species, which is considerably more virulent than other fungi in the order. Similar to *Aspergillus*, the pathogenesis may be attributed to the tendency to be angioinvasive (vasculotropism) as blood vessels are the best source of oxygen, resulting in local ischemia, necrosis, and tissue infarction as well as providing the nidus for hematogenous dissemination^[5]. Though being less clearly understood than for aspergillosis, several risk factors or predisposing conditions have been well described in the literature. In a large review of 929 patients with zygomycosis^[6], diabetes was the most common underlying risk factor (36%), followed by malignancy (17%), solid organ transplantation (7%), desferroxamine therapy (6%), and bone marrow transplantation (5%). Most of these conditions are associated with impairment of normal leukocyte immune function. Impairment of this function or a critical decline in white cell number is associated with increased risk for invasive fungal infections. Apart from differences in environmental factors, changes in transplantation procedures, new use of immunosuppressives and the use of voriconazole for the prophylaxis of opportunistic fungal infections have been proposed as risk factors for developing zygomycosis^[7,8]. Voriconazole is not active against Zygomycetes and subsequently may provide selective growth of these fungi. Breakthrough zygomycosis after voriconazole treatment has been re-

ported but the association is still uncertain^[7,9].

Mucormycosis can manifest as different clinical forms, namely rhinocerebral, pulmonary, cutaneous, gastrointestinal, central nervous system, and disseminated/miscellaneous. Gastrointestinal mucormycosis is the rarest form and constitutes only 7% of all mucormycosis cases^[6,10]. It most commonly involves the stomach (57.5%), followed by colon (32.3%) and ileum (6.9%)^[10]. This rare and opportunistic infection has been reported in neonates, probably due to their immature immunity, presenting as necrotizing enterocolitis. In published literature, less than 20 cases of gastrointestinal mucormycosis with colon involvement in adult patients have been published in the last two decades (Table 2)^[10-22]. It also occurs in those with severe malnutrition and intrinsic abnormalities of the gastrointestinal tract, including amoebic colitis, typhoid, pellagra and kwashiorkor^[10]. The infection may arise from ingestion of fungal spores on food or contaminated sputum. Actually, the three patients we have described here were also reported in an outbreak of intestinal infection in our hospital^[23]. They had sole intestinal involvement, likely due to the intake of contaminated allopurinol tablets and commercially packaged food items^[23].

A typical gastrointestinal lesion consists of a dark ulcer with sharply demarcated edges and with necrosis and thrombosis in adjacent vessels. The infection can extend from the lumen of the gut and may cause obstruction, perforation or bleeding. Initial presentations may be abdominal pain and distension, fever, and diarrhea. If there is extensive bowel involvement with multiple ulcers caused by the fungal infection, it may present with gastrointestinal bleeding or even visceral perforation at late presentation^[10]. Consequently, neutropenic fever can be a common presenting feature of mucormycosis, as in our patients. A high degree of clinical suspicion is needed to diagnose this rare condition. Therefore, persistent severe abdominal pain in a patient with neutropenia should alert the clinicians to the possibility of this invasive fungal infection.

Diagnosis depends on histological examination for the presence of predominantly aseptate wide hyphae with focal bulbous and non dichotomous branching occasionally at right angles^[4]. Over 94% of sampled tissues also show infarction and angioinvasion on histology

Table 2 Summary of colonic mucormycosis cases reported in the recent medical literature

examination^[24]. Though culture remains the predominant way in which one can identify fungal species, it is positive in only 52% of autopsy cases and only 30% of surgical specimens^[25]. This is because the infection may be localized and cannot be detected in all portions of the specimen submitted for culture. Nowadays there are no reliable serologic or skin tests for mucormycosis. Recently, some have attempted to improve the diagnosis by detecting fungal nucleic acid in the serum using polymerase chain reaction (PCR) or in situ hybridization techniques^[3]. As an adjuvant diagnostic tool, this can be used for confirming the presence of presumptive organisms when histology is positive and cultures are negative. It may provide some guidance in selecting appropriate antifungal therapy when the histological diagnosis is undetermined. Besides pathological and microbiological diagnosis, CT/MRI scan^[26] and endoscopy examination^[11,14] have been described in the literature. Endoscopic features of colonic mucormycosis have been reported as hemorrhagic, edematous mucosa with erosions, resembling endoscopic features of ischemic colitis. A smooth, mushroom-like greenish fungal mass with a small base of attachment to the bowel wall may be seen. Occasionally a black crust overlies the ulcerated area^[11].

From a surgeon's point of view, the principal of management of colonic mucormycosis in these severely immunocompromised patients largely depends on timely diagnosis, reversal of the underlying predisposing conditions, early surgical debridement, and rapid initiation of effective systemic antifungal therapy^[3]. As neutropenic enterocolitis is the commonest cause in the neutropenic cancer patient, careful serial clinical observation with liberal use of CT scanning is suggested^[27,28]. Contrast CT scans may show a thickened colonic wall with decreased attenuation due to edema, necrosis, or a collection of extraluminal fluid^[28]. Also, the scan may detect the presence of a small amount of free gas or pneumatosis intestinalis not visible on plain films, suggestive of bowel perforation. If the initial conservative treatment is not

successful, including bowel rest, hydration, and broad-spectrum antibiotics, some have advocated a more aggressive surgical intervention^[29-31]. As for our patients, they were initially managed in their medical wards for chemotherapy-induced neutropenic colitis; however, our surgical team was consulted after failed conservative treatment.

In the first patient of our series, exploratory laparotomy was selected for investigating suspected bowel perforation in view of persistent peritoneal signs and turbid peritoneal fluid aspirated. However, only dilated cecum with edematous wall but no perforation were identified; the intraoperative diagnosis of neutropenic enterocolitis was compatible with this finding, so that only peritoneal lavage was performed and conservative management was continued afterwards. Although the patient's condition was rapidly deteriorating, no surgical intervention was considered in view of multiple organ failure.

Continuing aggressive medical treatment and supportive measures after surgery for neutropenic enterocolitis have been reported, with high mortality^[28]. Fungal neutropenic enterocolitis has been reported as fatal^[32] as the mucormycosis is a highly angioinvasive infection, resulting in extensive thrombosis and tissue necrosis, and antifungal agents often display poor penetration at the site of infection. Removal of as much of the infected or devitalized tissue as possible while the infection is localized provides the greatest benefit. In the study by Roden *et al*^[6], the survival rate was 57% (51/90) for those treated with surgery alone and 62% (369/596) for those treated with some form of antifungal therapy alone. However, the survival increased to 70% (328/470) for those treated with combined surgery and antifungal therapy. In our third patient, the diagnosis of mucormycosis was confirmed pathologically soon after the first operation, and he began antifungal therapy immediately. Currently, the recommended antifungal therapy for mucormycosis includes amphotericin B and its liposomal preparation which can be delivered with reduced nephrotoxicity^[3]. The common prophylactic antifungal agents used in neu-

tropenic patients (such as fluconazole and itraconazole) or even new agents (voriconazole and caspofungin) are not active against the Mucorales order in clinical and *in vitro* studies. An orally available broad-spectrum investigational triazole, posaconazole, seems to possess activity against this fungus and improves patients' survival in refractory cases^[33]. Furthermore, in addition to posaconazole treatment, another exploratory laparotomy with extensive small bowel resection and omentectomy was performed in our patient, in order to debride all infection foci. This approach has been reported as providing a survival advantage in the published literature^[16,19,21].

Apart from early diagnosis, as mentioned before, correction of any reversible predisposing factors, such as by rectifying diabetic ketoacidosis, withdrawing desferrioxamine therapy or reducing the level of immunosuppression, is an important consideration in patient management. In neutropenic patients, resolution of neutropenia is directly correlated with clinical improvement and better outcomes^[34]. Without neutrophil recovery, antifungal drugs are ineffective. Cytokines, such as interferon- γ and granulocyte macrophage-colony stimulating factor (GMC-SF), can reduce the degree and duration of neutropenia and subsequent infections in these patients. Other non-medication-based interventions, such as hyperbaric oxygen therapy^[35] and novel iron chelators^[36], have found limited success as an adjunctive treatment.

In summary, we report three cases of ileocolic mucormycosis presenting as acute abdomen in neutropenic patients which failed to respond to combined surgical and medical treatment. Though the new antifungal agent posaconazole is effective against the Mucorales order of fungi, timely diagnosis and adequate surgical debridement are essential for the successful management of colonic mucormycosis.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systematically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Instructions to authors

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/1007-9327/Instructions-toAuthprs.asp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>; Writing requirements of abstract at: <http://www.wjgnet.com/1007-9327/links/Abstract.doc>.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the

main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A...; B...; C...; D...; E...; F...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used

abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr-A*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No. 62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: wjg@wjgnet.com

<http://www.wjgnet.com>

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/1007-9327/news/10.doc>.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/1007-9327/news/12.doc>.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Contents

Weekly Volume 16 Number 10 March 14, 2010

EDITORIAL

- 1171 Steatosis as a co-factor in chronic liver diseases
Persico M, Iolascon A

REVIEW

- 1177 Mechanisms of resistance to anti-EGFR monoclonal antibody treatment in metastatic colorectal cancer
Saridaki Z, Georgoulas V, Souglakos J
- 1188 Influence of interleukin polymorphisms on development of gastric cancer and peptic ulcer
Sugimoto M, Yamaoka Y, Furuta T

ORIGINAL ARTICLE

- 1201 Methylation of *GATA-4* and *GATA-5* and development of sporadic gastric carcinomas
Wen XZ, Akiyama Y, Pan KF, Liu ZJ, Lu ZM, Zhou J, Gu LK, Dong CX, Zhu BD, Ji JF, You WC, Deng DJ
- 1209 Solid pseudopapillary tumor of the pancreas: A review of 553 cases in Chinese literature
Yu PF, Hu ZH, Wang XB, Guo JM, Cheng XD, Zhang YL, Xu Q

BRIEF ARTICLE

- 1215 Bone marrow cells produce nerve growth factor and promote angiogenesis around transplanted islets
Sakata N, Chan NK, Chrisler J, Obenaus A, Hathout E
- 1221 Management of ruptured hepatocellular carcinoma: Implications for therapy
Bassi N, Caratozzolo E, Bonariol L, Ruffolo C, Bridda A, Padoan L, Antoniutti M, Massani M
- 1226 Microalbuminuria in hepatitis C-genotype 4: Effect of pegylated interferon and ribavirin
Derbala M, Shebl FM, Rashid A, Amer A, Bener A
- 1232 Overlapping gastroesophageal reflux disease and irritable bowel syndrome: Increased dysfunctional symptoms
Yarandi SS, Nasser-Moghaddam S, Mostajabi P, Malekzadeh R

BRIEF ARTICLE

- 1239 Management of bleeding from pseudoaneurysms following pancreaticoduodenectomy
Lee HG, Heo JS, Choi SH, Choi DW
- 1245 Specific endoscopic features of ulcerative colitis complicated by cytomegalovirus infection
Suzuki H, Kato J, Kuriyama M, Hiraoka S, Kuwaki K, Yamamoto K
- 1252 Decreased levels of plasma adiponectin associated with increased risk of colorectal cancer
Otake S, Takeda H, Fujishima S, Fukui T, Orii T, Sato T, Sasaki Y, Nishise S, Kawata S
- 1258 T300A polymorphism of *ATG16L1* and susceptibility to inflammatory bowel diseases: A meta-analysis
Cheng JF, Ning YJ, Zhang W, Lu ZH, Lin L
- 1267 Establishment of a new quantitative detection approach to adefovir-resistant HBV and its clinical application
Zhao WF, Shao YL, Chen LY, Wu JH, Zhu YL, Gan JH, Xiong H
- 1274 Clinical significance of Fas and FasL protein expression in gastric carcinoma and local lymph node tissues
Li Q, Peng J, Li XH, Liu T, Liang QC, Zhang GY
- 1279 Influence of efflux pump inhibitors on the multidrug resistance of *Helicobacter pylori*
Zhang Z, Liu ZQ, Zheng PY, Tang FA, Yang PC
- 1285 Heme oxygenase-1 protects donor livers from ischemia/reperfusion injury: The role of Kupffer cells
Zeng Z, Huang HF, Chen MQ, Song F, Zhang YJ

CASE REPORT

- 1293 Malignant transformation of ectopic pancreatic cells in the duodenal wall
Bini R, Voghera P, Tapparo A, Nunziata R, Demarchi A, Capocefalo M, Leli R
- 1296 Concurrent amoebic and histoplasma colitis: A rare cause of massive lower gastrointestinal bleeding
Koh PS, Roslani AC, Vimal KV, Shariman M, Umasangar R, Lewellyn R

ACKNOWLEDGMENTS I Acknowledgments to reviewers of *World Journal of Gastroenterology*

APPENDIX I Meetings
I-IV Instructions to authors

AIM AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

FLYLEAF I-VII Editorial Board

EDITORS FOR THIS ISSUE

Responsible Assistant Editor: *Xiao-Fang Liu*
Responsible Electronic Editor: *Wen-Hua Ma*
Proofing Editor-in-Chief: *Lian-Sheng Ma*

Responsible Science Editor: *Lin Tian*
Proofing Editorial Office Director: *Jian-Xia Cheng*

INTRODUCTION

Lipid accumulation in the liver, so-called hepatic steatosis or non-alcoholic fatty liver disease (NAFLD), is a common condition frequently found in healthy subjects not affected by any other liver disease and not drinking alcohol. Hepatic steatosis prevalence has been estimated by magnetic resonance studies to be 35% in the general population and to be 75% in obese persons, and these figures seem to be increasing over time^[1,2]. Nevertheless, its presence generates liver damage in only a small percentage of subjects not affected by other liver diseases. In fact, in only 2% of the general population does hepatic steatosis constitute a real hepatic disease: non-alcoholic steatohepatitis (NASH) with deranged aminotransferases and fibrosis.

Steatosis is also frequently found in liver specimens of patients who have undergone liver biopsy for all the hepatic diseases [hepatitis C virus (HCV), hepatitis B virus (HBV), alcoholism, hemochromatosis *etc.*] and, in some of them (12%), its presence represents an associated disease: steatohepatitis^[3]. Moreover, it is well known that a fatty liver is less protected from the mechanisms of inflammation and fibrosis^[4].

Data reported in the literature suggest that hepatic steatosis can have different influences on a liver affected by other diseases. Therefore, it cannot always be considered as a "benign" condition and simply ignored. On the contrary, it has to be recognized as a "co-factor" capable of affecting the gravity and progression, and also therapeutic perspectives, of liver diseases.

Abstract

The finding of lipid accumulation in the liver, so-called hepatic steatosis or non-alcoholic fatty liver disease, is a common condition frequently found in healthy subjects. Its prevalence, in fact, has been estimated by magnetic resonance studies to be about 35% in the general population and 75% in obese persons. Nevertheless, its presence generates liver damage only in a small percentage of subjects not affected by other liver diseases. It should be defined as a "co-factor" capable of affecting severity and progression, and also therapeutic perspectives, of liver diseases to which it is associated. Herein we will evaluate the impact of hepatic steatosis and obesity on the most common liver diseases: chronic viral hepatitis C and B, and alcoholic liver disease.

Herein we will evaluate the impact of hepatic steatosis and obesity on the most common liver diseases: chronic viral hepatitis C and B, and alcoholic liver disease.

HCV AND STEATOSIS

Hepatic steatosis is present in about 50% of liver specimens taken from subjects affected by chronic hepatitis C^[5]. This prevalence is higher than that reported in the general population from magnetic resonance studies, and there are findings that suggest a possible direct role of the HCV on its development^[6]. This hypothesis is supported by a large number of studies that link steatosis to both host characteristics [i.e. body mass index (BMI), waist circumference (WC), insulin resistance (IR)] and viral factors (genotype, viral RNA load).

Host factors

Several risk factors for liver disease progression are known for both chronic hepatitis C (CHC) and NAFLD. These factors are: high BMI, type 2 diabetes mellitus, older age and alcohol consumption and these can also affect the presence and the gravity of hepatic steatosis^[7]. In fact, overweight patients with HCV have more steatosis than lean subjects with CHC and this data has statistical relevance independently from the HCV genotype^[8].

Viral factors and genotypes

It is well known that the presence of steatosis in the liver of CHC patients seems to be related to the presence of virus itself, with a distinctive genotype specificity^[8]. Six different HCV genotypes were identified according to Simmonds *et al*^[9], characterized by different epidemiological and clinical peculiarities. In particular, the genotypes 1 and 3, the most prevalent in the western world, were found related to steatosis^[6]. HCV virus has, in fact, demonstrated a direct steatogenic effect in cell cultures and transgenic mice^[10,11]. This seems to be confirmed in human studies: there is considerable evidence that in HCV-infected subjects (particularly genotype 3-infected), the grade of hepatic steatosis seems to be related to viral load^[12]. Moreover, there has been evaluation of steatosis disappearing in response to antiviral therapy and its recurrence in the case of relapse with virus reappearance in the liver^[13]. However, “non-3 genotypes” (particularly genotype 1b) also show a distinct association with steatosis, which has encouraged some authors to coin a new definition: virus-associated steatohepatitis (VASH)^[14,15].

Even if the recent literature reports steatosis as “viral” only in genotype 3-infected patients and as “metabolic” (due to host characteristics) in non-3 genotype-infected patients, it should be more accurate to talk about a combination of these two factors. In fact, some studies observed that in non-3 genotype-infected patients who achieved sustained virological response (SVR) there was a reduction or a total disappearance of liver steatosis. In

particular, one study reported a reduction of steatosis in about 46% of such patients and its disappearance in 29%. Moreover, in the same study the genotype 3 patients markedly reduced their liver steatosis after weight loss, confirming that host factors could also be actively involved in generating steatosis in these patients^[16]. To complete this topic, we should also consider the difficulty in obtaining an accurate evaluation of alcohol consumption history in these patients, as documented by the discordant data with regard to the contribution of alcohol intake to steatosis development in HCV patients^[17-19].

Physiopathology

The physiopathological mechanisms associated with steatosis and obesity leading to liver disease worsening are still under debate. Nevertheless, some plausible assumptions have been made and they seem to be supported by experimental evidence from cellular and animal models. Some of these involve oxidative stress, subsinusoidal stellate cell activation, higher apoptosis susceptibility and altered response to cellular damage. Furthermore, fibrogenesis could be exacerbated by other components of metabolic syndrome (MS) such as hyperinsulinemia and hyperglycemia.

Oxidative stress: Fatty liver seems to be more susceptible to the damage induced by such factors that lead to an increase in liver production of oxidant substances. In particular, on the basis of the immune response to HCV, it was postulated that an increase in oxidative stress produces an intensified lipoperoxidation and inflammatory cytokine production leading to programmed cell death, i.e. apoptosis^[20].

Apoptosis: Apoptosis has a central role in liver disease progression and steatosis^[21]. In CHC, a significant increment of this cellular mechanism together with stimulation of fibrosis and inflammatory activity can be observed in liver specimens which also show moderate or severe steatosis, thus suggesting a similar role of apoptosis to that suggested by the histological presentation in NASH^[22]. This mechanism might involve a synergistic effect of apoptosis acting together with other intrinsic HCV factors of liver damage and thus leading to the worsening of fibrosis progression.

Steatohepatitis: 6%^[23] to 18%^[24] of HCV patients with steatosis have an associated steatohepatitis observed in liver specimens. This could be a direct consequence of oxidative stress and lipoperoxidation^[25]. Nevertheless, HCV interference in the production of inflammatory cytokines such as tumor necrosis factor α (TNF- α), transforming growth factor β (TGF- β), interleukin-1 (IL-1) and interleukin-6 (IL-6) might, *per se*, explain the worsening of steatosis and fibrosis in both “viral” and “non viral” steatosis^[26,27]. However, these mechanisms might act in synergism to worsen fibrosis. Indeed, it has

been demonstrated that there is a significant reduction of both steatosis and portal fibrosis after weight loss by diet^[28] or bariatric surgery^[29] in HCV patients.

Insulin resistance: In the field of this research, it has recently been greatly debated as to whether HCV virus exerts its effects on the liver (and on the organism) by involving the intracellular molecular cascade that follows the activation of insulin receptor after its binding with insulin^[30]. HCV virus might interfere with this cascade in a genotype-specific manner^[31-33]. However, this interference (regardless of genotype) could lead to hepatic steatosis (“viral” at least) and worsening of liver fibrosis by direct stimulation resulting from the action of hyperinsulinemia on hepatic stellate sub-sinusoidal cells, with an increase on extracellular matrix production^[34].

The supposed insulin resistance mechanism involves the reduction of expression of insulin receptor substrates 1 and 2 (IRS1 and 2), which are crucial proteins in the post-receptorial cascade of insulin^[35]. The decrease of IRS1 and IRS2 seems to be mediated by a direct over-expression of another intracellular protein: suppressor of cytokine signaling 3 (SOCS3)^[31-33]. This over-expression has been revealed only in genotype 1b patients and it is associated with metabolic syndrome and no response to antiviral therapy^[32]. Recently, this evidence *in vivo* was reproduced *in vitro*. In fact, it was demonstrated that HepG2 cells infected with genotype 1 positive sera had higher SOCS3 levels than those infected with genotype 2 positive sera and that this was associated with a lower IRS1 expression^[36]. Therefore, there is accumulating evidence of a direct “metabolic” effect of the HCV virus on a large number of molecular pathways that lead to hepatic steatosis, IR, MS, and liver fibrosis^[37,38]. TNF- α , an inflammatory cytokine produced by hepatic stellate cells and adipose tissue, is increased in HCV patients with steatosis^[26] and its serum increase, together with the decrease of the adipocytokine, adiponectin, was also demonstrated as being involved in the pathogenesis of NAFLD and IR^[27,39]. The imbalance between TNF- α and adiponectin serum levels in HCV/steatosis patients seems to be genotype-specific and correlated with the severity of liver steatosis^[26] (Figure 1). These findings, taken together, suggest a definite association between IR and steatosis/steatohepatitis with the HCV virus as the “third player”. However, it is still unclear if steatosis represents the first hit to cytokine production leading to IR or the other way around; IR *via* cytokine inflammatory pathways leading to hepatic steatosis. Recent evidence, discriminating between “systemic” and “hepatic” IR, showed that in young, lean, insulin-resistant subjects there was a low prevalence of liver steatosis and no cytokine/adipocytokine changes. This suggests that steatosis and cytokines interact without assuming a primary and independent role in the early stage of IR^[40]. On the other hand, other authors support the idea that hyperinsulinemia is likely to be the consequence rather than the cause of a fatty liver, as suggested by the fact that fatty liver is associated with both hepatic insulin resistance and impaired insulin clearance^[41,42].

From the observations reported above we can confirm that in CHC, hepatic steatosis has to be considered as an important co-factor in the worsening of liver disease. This co-factor should be inhibited by firstly correcting its possible causes, such as being overweight or obese. This suggestion is supported by data from the literature showing that, in patients with MS or IR, a small weight loss (about 4%-5%), in the same way as it acts on blood pressure and glycemic control^[41], can induce steatosis reduction even if BMI is not restored to normal levels^[28,42]. These factors can influence the response to antiviral treatment: it has in fact been demonstrated that the absence or the presence of lower levels of steatosis are positive predictors of achieving SVR in HCV patients^[16,43,44].

STEATOSIS AND HBV

Given the assumed relationship between HCV and steatosis as specified above, we could surmise that chronic hepatitis B (CHB) has an analogous association with steatosis. Only a small number of studies regarding this argument have been published and some of these report steatosis prevalence in CHB^[45,46] while others report a direct comparison between CHC and CHB for the prevalence of MS, obesity and steatosis^[47,48]. These studies report a steatosis prevalence in CHB patients similar to that of the general population. The presence of steatosis correlates with BMI and MS diagnostic criteria (waist circumference, high blood pressure and dyslipidemia), but not with viral genotype or viral load. Moreover, steatosis does not correlate with fibrosis^[45]. Accordingly, these data indicate that the association between steatosis and HCV is specific, whereas this is not the case in HBV-infected patients. Nevertheless, it seems to be appropriate to hypothesize that in HBV-related chronic hepatitis, steatosis is probably also a co-factor of liver disease worsening, particularly if it is characterized as related to a conspicuous entity and/or in a subject with MS and/or if it translates to the real clinical condition of associated steatohepatitis^[49].

STEATOSIS AND ALCOHOL

The typical histological pattern of alcoholic liver disease (defined as drinking more than 40 g a day in males and 30 g in females) is a steatohepatitis^[50]. In fact, a diagnosis of NASH is established when, simultaneous with clinical and histological observations of a hepatic liver disease that is quite indistinguishable from an alcohol-related disease, there is a total assurance of alcoholic abstinence^[51]. Therefore, it is clear that there is a close association between steatosis and alcoholic liver disease, so close that steatosis cannot be considered as a simple co-factor but as part of the histological damage presentation in this liver disease. Nevertheless, nothing prevents us from supposing that obesity might also increase the severity of steatosis in patients with alcoholic liver disease. Indeed, this hypothesis has been confirmed by some literature findings which indicated that being overweight was

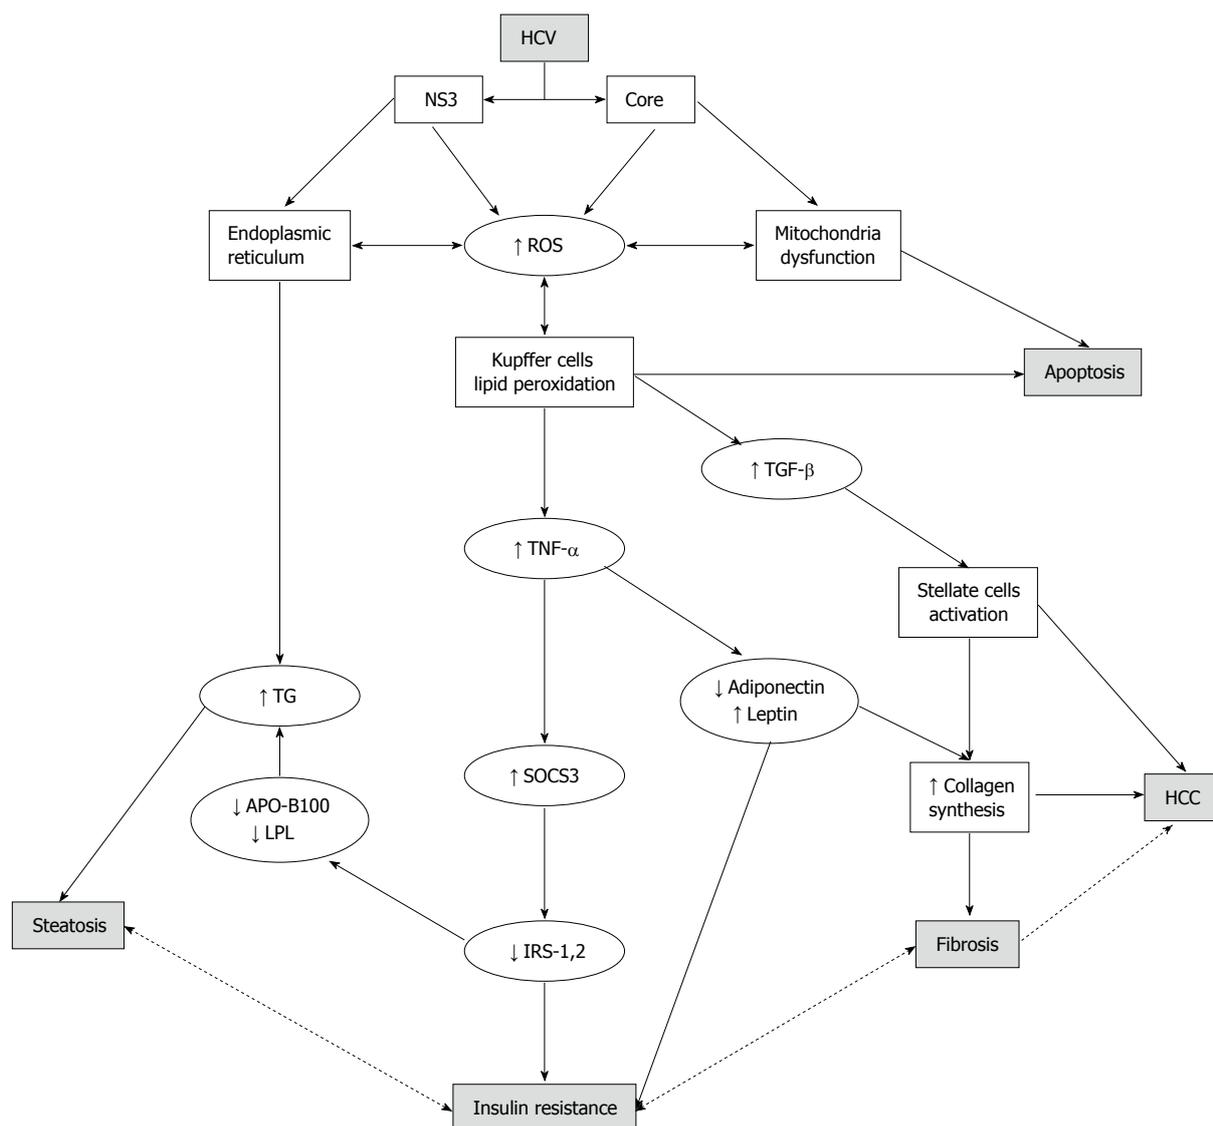

Figure 1 Hypothetical pathophysiological pathways leading to insulin resistance, steatosis, fibrosis, hepatocellular carcinoma (HCC), apoptosis and steatosis in hepatitis C virus (HCV) infection. NS3: Non structural HCV protein 3; Core: Core HCV protein; ROS: Reactive oxygen species; TNF- α : Tumor necrosis factor α ; TGF- β : Transforming growth factor β ; TG: Triglycerides; LPL: Lipo-protein-lipase; SOCS3: Signaling of cytokine suppressor type 3; IRS 1-2: Insulin receptor substrate type 1 and 2.

associated with extent of steatosis^[52] and that it was a risk factor for progression to cirrhosis and HCC in alcoholic liver disease^[53,54]. Moreover, obesity and steatosis seem to use the same metabolic mechanisms to produce a worsening of liver damage; increased lipoperoxidation and pro-inflammatory cytokine production have been noted in obese alcoholics^[55,56]. On these grounds, steatosis seems to have a double role: as a constantly present histological finding and as a possible co-factor responsible for worsening of histological damage. Thus, correct management of these patients should also include adequate dietetic counseling.

HEPATOCELLULAR CARCINOMA AND STEATOSIS

Further evidence from the literature indicates that

steatosis, together with obesity and type 2 diabetes mellitus, is a probable risk factor for hepatocellular carcinoma (HCC) development. This has been reported in HCV liver disease in both experimental models^[57] and clinical studies^[58]. Steatosis seems to play the same role also in alcoholic liver disease: a large multicenter study conducted in 19000 liver transplant patients indicates that obesity and steatosis are risk factors for HCC developing in alcoholic liver disease patients^[59].

CONCLUSION

From the data analyzed in this brief review, we can conclude that hepatic steatosis, a risk-free, benign condition in healthy subjects, becomes a dangerous co-factor of disease progression when it is present in patients affected by another liver disease. It affects the response to

antiviral treatment in HCV patients, and it could also be responsible for the development of HCC, in both HCV and alcoholic patients. Therefore, hepatic steatosis must be considered an important disease co-factor to be taken into account in liver disease patients, in order to make a diagnosis and subsequently to correct the condition.

Abstract

Metastatic colorectal cancer (mCRC) continues to be counted as a major health problem. The introduction of newer cytotoxics, irinotecan and oxaliplatin, has achieved a significant improvement in survival rates. Novel targeted therapies (bevacizumab, and cetuximab) in combination with most efficient chemotherapy regimens have pushed the median survival beyond the 2-year mark and increased the proportion of patients which could benefit from resection of metastatic lesions. In addition, several studies have proved that the CRC mutation profiles should influence patient selection or stratification in prospective trials. *KRAS* mutational status represents a paradigm for biomarker development in the era of molecular targeted therapies. The present article is an overview of the most important studies in the development of biomarkers for the optimization of anti-epidermal growth factor receptor (anti-EGFR) treatment in mCRC, beyond *KRAS* mutations, which is a work in progress. The aim will be to identify molecular markers that might be used to select patients with a higher probability of response to anti-EGFR monoclonal antibodies. Overall the accumulating evidence of the molecular biology of CRC has substantially changed the approach to

Mechanisms of resistance to anti-EGFR monoclonal antibody treatment in metastatic colorectal cancer. *World J Gastroenterol* 2010; 16(10): 1177-1187 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i10/1177.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i10.1177>

INTRODUCTION

Now, more than ever, clinical oncologists are struggling to optimize treatment in cancer patients. With the use of molecular targeted agents and the incorporation of pharmacogenetics and pharmacogenomics in basic cancer treatment, a meaningful relationship between genotype (polymorphisms and mutations), gene expression profiles (level of gene expression of all or of target genes in the genome) and phenotype is being established, aimed at interpreting the variability among individuals in terms of response, resistance and toxicity to different drugs^[1,2].

Pharmacogenetics (e.g. toxicity, age, comorbidities) commonly refers to the effects of a limited number of genes most often associated with drug metabolism, whereas pharmacogenomics (e.g. activity/resistance, gene expression level of all or targeted genes) involves

the study of multigene patterns and pathways within the genome^[5]. Genetic polymorphisms (variants in individual genomes, present in more than 1.5% of the population), somatic mutations in key target genes and differences in gene copy numbers may be responsible for different functional molecular roles and contribute to variability in drug pharmacokinetic and pharmacodynamic processes, altered drug metabolism or activation^[4]. In colorectal cancer (CRC), as well as in other types of cancer, it has long been recognized that the same medications cause different responses in different patients. Genetic variations in drug targets and genes affecting target signal transduction can have a profound effect on drug efficacy and toxicity. This information could help to identify patients who are at increased risk of toxicity and select those likely to respond to specific agents, so that a more patient-specific treatment approach can be initiated^[5].

The epidermal growth factor receptor (EGFR) belongs to the erbB receptor tyrosine kinase family which consists of 4 related transmembrane receptors: erbB1 (EGFR or HER1), erbB2 (HER2/*neu*), erbB3 (HER3) and erbB4 (HER4). Upon ligand binding, EGFR homo- or hetero-dimerizes with other erbB family members and initiates signaling through 2 main intracellular cascades which are mostly involved in cell survival, proliferation and motility. On one side, membrane localization of the lipid kinase PIK3CA counteracts PTEN and promotes AKT1 phosphorylation, and on the other, KRAS activates BRAF, which in turn triggers the mitogen-activated protein kinases^[6]. EGFR is found to be overexpressed in various human malignancies, including CRC, lung, head and neck cancers and, as was initially hypothesized, therapeutic strategies designed to disrupt EGFR function could have anti-tumor activity^[7] (Figure 1).

Two monoclonal antibodies (moAbs) targeting EGFR, the chimeric IgG1 moAb cetuximab and the fully humanized IgG2 moAb panitumumab, have recently entered clinical practice in the metastatic CRC (mCRC) setting. Both bind to the extracellular domain of the EGFR, thus leading to inhibition of its downstream signaling and have been found to provide a modest clinical benefit in pretreated patients^[8-10]. Although they were initially registered for patients whose tumors were found to express the EGFR protein in immunohistochemistry, subsequently, it was clearly demonstrated that this methodology was not adequate to predict treatment efficacy^[11]. Only the development of a skin rash was consistently associated with an increased response rate and progression-free survival in patients treated with anti-EGFR moAbs^[8,10].

Although anti-EGFR therapies are active in some patients, the disease eventually becomes refractory to therapy in nearly all patients. As clinical parameters seem to be inadequate for patient selection, a major challenge is the identification of specific biomarkers that are likely to predict which patients will achieve the best response to such a treatment. EGFR gene status, as it is evaluated by fluorescent or chromogenic *in situ* hybridization (FISH or CISH), the absence or presence of mutations in genes downstream of EGFR and the presence of germline polymor-

phisms are implicated in response to anti-EGFR treatment and can independently impair or enhance its efficacy^[12-15]. As most available data has come from retrospective studies, validation in prospective trials is imperative.

MECHANISMS OF RESISTANCE

Mutations

KRAS mutations: *KRAS* proto-oncogene encodes K-ras G-protein which plays a critical key role in the Ras/mitogen-activated protein kinase (MAPK) signaling pathway located downstream of many growth factor receptors including EGFR and which is involved in CRC carcinogenesis. K-ras recruitment by the activated EGFR is responsible for the activation of a cascade of serine-threonine kinases from the cell surface to the nucleus. *KRAS* mutations (in exon 2, codons 12 and 13) are present in more than one third of CRC patients and lead to the activation of one of the most important pathways for cell proliferation, the Ras/MAPK pathway, by inducing cyclin D1 synthesis. Consequently, in the presence of a *KRAS* mutation this pathway activation cannot be significantly inhibited by an anti-EGFR moAb (cetuximab or panitumumab) which acts upstream of the K-ras protein^[13] (Figure 1).

In 2005, Moroni *et al*^[16] assessed, in a small retrospective study, the mutation status of EGFR downstream intracellular effectors *KRAS*, *BRAF* and *PIK3CA*, and for the first time a trend towards higher response was seen in cetuximab-treated CRC patients whose tumors were of wild-type (WT) *KRAS* status. Subsequently, in 2006 in a study by Lièvre *et al*^[13], *KRAS* mutations were found in 13 out of 30 tumors tested (43%) and this finding was significantly associated with the absence of response to cetuximab (*KRAS* mutation in 0% of the 11 responders *vs* 68.4% of the 19 non-responders; $P = 0.0003$). The overall survival (OS) of patients without *KRAS* mutation in their tumor was significantly higher compared with those patients with a mutation in the tumor ($P = 0.016$; median OS, 16.3 mo *vs* 6.9 mo) (Table 1).

When the results of the 2 above-mentioned studies were analyzed together, the predictive value of the *KRAS* mutation remained significant with a *KRAS* mutation frequency of 52.5% in non-responders compared with 9.5% in responders ($P = 0.001$). Thus, the probability of no response to cetuximab was 91.3% in the presence of *KRAS* mutation whereas as in the absence of such a mutation the probability of being a responder was 50%. The relative risk for a response to cetuximab was 10-fold higher for non-mutated patients compared with that of patients with the *KRAS* mutation [hazard ratio (HR), 10.5; 95% CI: 2.1-51.1]. Accordingly, in 2008, 3 studies, one with panitumumab^[14] and 2 with cetuximab^[17,18], confirmed the importance of *KRAS* mutations in the mCRC setting. In the study by Amado *et al*^[12], *KRAS* mutation status was assessed in tumor samples from mCRC patients who were enrolled in the randomized phase III trial comparing panitumumab plus best supportive care (BSC) with BSC only after failure in 5-fluorouracil (5-FU)-, oxaliplatin- and irinotecan-based chemotherapy^[10]. *KRAS* status was ascertained in 427 (92%)

EGFR pathway components and resistance to anti-EGFR moAbs

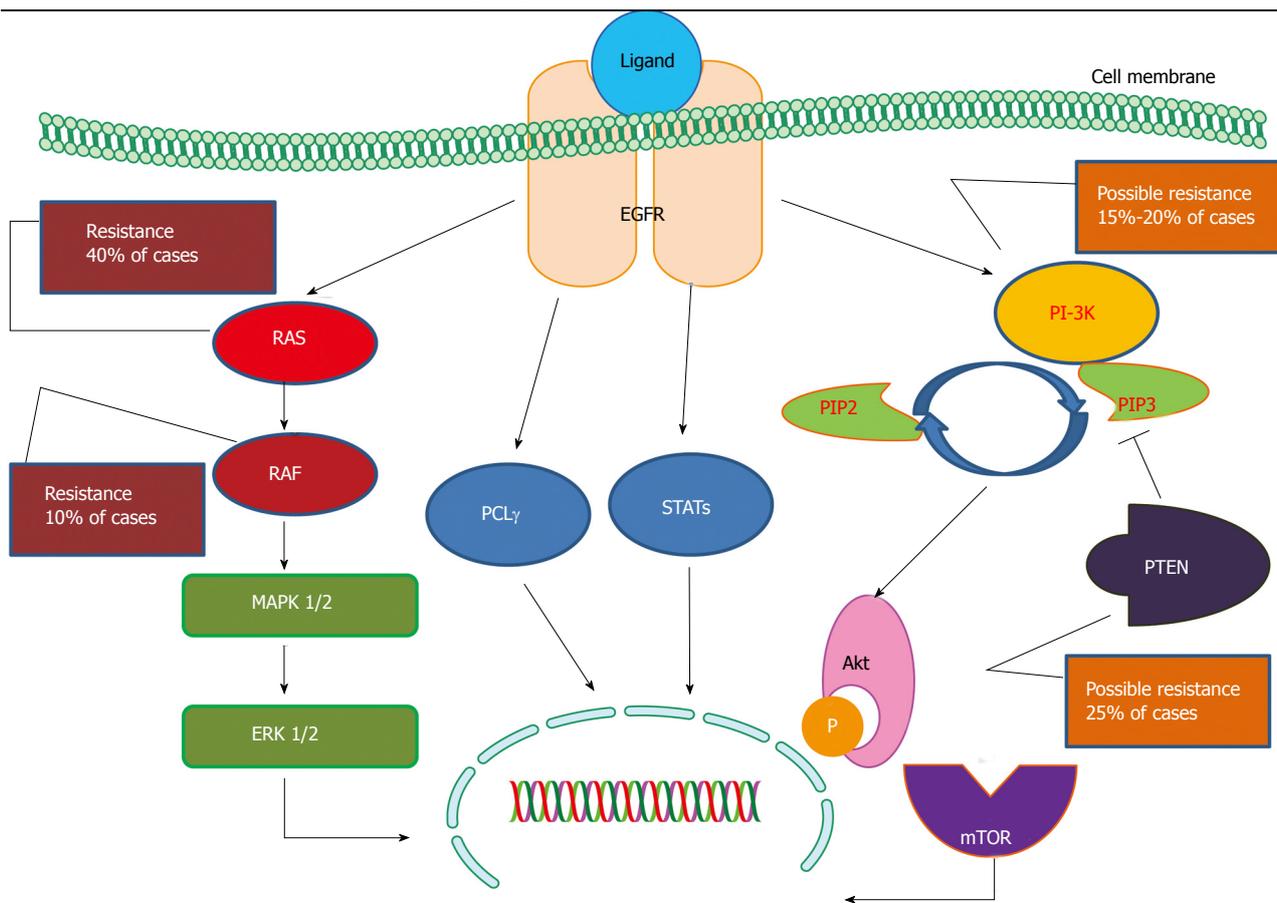

Figure 1 Simplified illustration of the epidermal growth factor receptor (EGFR) pathway with the RAS/MAPK and PIK3CA/PTEN cascades. Specific components of the pathway are correlated with resistance to anti-EGFR monoclonal antibodies (moAbs). As shown, KRAS and BRAF mutations are correlated with resistance to anti-EGFR moAbs, while further evaluation is required for PIK3CA mutations and PTEN loss of expression.

Hecht <i>et al</i> ^[21]	865	40	PFS, mOS
Douillard <i>et al</i> ^[23]	1096	40	RR, PFS

RR: Response rate; mOS: Median overall survival; PFS: Progression-free survival.

of 463 patients (208 panitumumab, 219 BSC). *KRAS* mutations were found in 43% of patients. The treatment effect on progression-free survival (PFS) in the WT *KRAS* group (HR, 0.45; 95% CI: 0.34-0.59) was significantly greater ($P = 0.0001$) than in the mutation group (HR, 0.99;

95% CI: 0.73-1.36). Median PFS in the WT *KRAS* group was 12.3 wk for panitumumab and 7.3 wk for BSC. Response rates to panitumumab were 17% and 0%, for the WT and mutant groups, respectively. WT *KRAS* patients had longer overall survival (HR, 0.67; 95% CI: 0.55-0.82; treatment arms combined). No significant differences in toxicity were observed between the WT *KRAS* group and the overall population^[12]. Lièvre *et al*^[18] assessed *KRAS* status by allelic discrimination in 89 mCRC patients treated with cetuximab in 6 different institutions. *KRAS* mutations were present in 27% of the patients and were associated with resistance to cetuximab (0% *vs* 40% of responders among the 24 mutated and 65 nonmutated patients, respectively; $P < 0.001$) and a poorer outcome (median PFS, 10.1 wk *vs* 31.4 wk in patients without mutation; $P = 0.0001$; median OS, 10.1 mo *vs* 14.3 mo in patients without mutation; $P = 0.026$). When these 89 patients were analyzed together with the 30 patients from the previous study^[13], the multivariate analysis showed that *KRAS* status was an independent prognostic factor associated with OS and PFS. In a combined analysis, median OS for patients with 2, one, or no favorable prognostic factors (severe skin toxicity and absence of *KRAS* mutation) was 15.6, 10.7, and 5.6 mo, respectively. Lastly, De Roock *et al*^[17] studied the

KRAS mutation status in 113 irinotecan-refractory mCRC patients treated with cetuximab in 4 institutions and similar results were observed. Objective responses were detected in 27 of 66 WT *KRAS* patients *vs* 0 of 42 *KRAS* mutants. Median OS was significantly better in WT *KRAS* *versus* mutants (43.0 wk *vs* 27.3 wk; $P = 0.020$). In this study an additional association with radiologic response was made and it was found that the benefit was even more pronounced in patients with an early radiological response. The decrease in tumor size was significantly larger at all time points in WT patients. WT *KRAS* patients with an initial relative decrease of tumor size $> 9.66\%$ at week 6 had a significantly better median OS compared with all other patients (74.9 wk *vs* 30.6 wk; $P = 0.0000025$). Among WT *KRAS* patients OS was significantly better in patients with an initial decrease compared with those without (median OS, 74.9 wk *vs* 30.6 wk; $P = 0.0000012$). *KRAS* WT status was associated with survival benefit in cetuximab-treated mCRC^[17]. An objective response was not observed in patients with mutant tumors treated with cetuximab or panitumumab monotherapy.

The predictive significance of *KRAS* mutations was also retrospectively analyzed in 5 prospective randomized trials. The CRYSTAL^[19] trial was the first randomized trial which proved that the addition of cetuximab to a standard chemotherapy regimen (FOLFIRI) improved the response rate and PFS. Despite the statistically significant decrease in the risk of disease progression (HR, 0.85), the absolute benefit was modest (0.9 mo). Subsequently, when a patients' subpopulation was analyzed according to the *KRAS* mutation status, the benefit from the addition of cetuximab was greater (HR, 0.68) in patients with WT primary tumors. In contrast, patients with *KRAS* mutant primary tumors experienced no benefit from the addition of the moAb^[19]. Similar results have been reported from subgroup analysis in 3 other randomized trials, OPUS^[20], PACE^[21] and CAIRO2^[22], in which different combination regimens were used with anti-EGFR moAbs. Finally, the first prospective analysis of a randomized trial (PRIME) has been recently reported^[23]. The patients were randomized to receive FOLFOX4 or FOLFOX4 plus panitumumab and the *KRAS* mutation status was determined in 93% of the enrolled patients. Significant differences were observed in terms of RR (55% *vs* 48%) and PFS (9.6 mo *vs* 8.0 mo; $P = 0.0234$) in favor of the addition of panitumumab in the WT group. In contrast, a detrimental effect was recorded in the *KRAS* mutant group with the addition of the moAb to FOLFOX4 (7.3 mo *vs* 8.8 mo; $P = 0.0227$)^[23] (Table 1). In all these trials, the objective RR were comparable between patients with *KRAS* mutant and *KRAS* WT tumors treated with chemotherapy alone, indicating that *KRAS* mutations are not predictive of the response to chemotherapy. No studies have been published comparing the impact of the 7 specific *KRAS* mutations on the response to anti-EGFR moAbs.

In conclusion, the present data in the international literature suggest that *KRAS* mutations are a predictor of resistance to anti-EGFR moAb therapy and are associated with a worse prognosis and a shorter survival. Ap-

proximately 40% of mCRC patients (those with mutated *KRAS*) could be selected to avoid costly and potentially toxic treatment. WT *KRAS* status identifies mCRC patients who are likely to respond to such a treatment and, thus, have a longer OS. Prospective randomized studies are needed to validate these results which introduce a new era in mCRC targeted therapy.

***BRAF* mutations:** The role of *KRAS* has been extensively analyzed. However, *KRAS* mutations account for only 30%-40% of patients unresponsive to anti-EGFR moAbs treatment, suggesting that additional genetic determinants of resistance must exist. The RAS-RAF-MAPK kinase pathway mediates cellular responses to growth signals (Figure 1). The 3 *RAF* genes encode for cytoplasmic serine-threonine kinases that are the principal effectors of *KRAS* and are regulated by binding to it^[24]. The single substitution missense mutation V600E, located within the kinase domain of *BRAF* (one of the 3 *RAF* genes), is the most common oncogenic mutation in cancer, accounting for more than 80%. The highest frequency is detected in melanomas (about 65%), the *BRAF* V600E mutation is also found at lower frequencies in a wide range of human cancers, such as CRC (10%), gliomas, ovarian and others. The V600E amino acid change results in constitutive activation of the *BRAF* kinase and promotes cell transformation^[25,26]. *KRAS* and *BRAF* mutations are mutually exclusive in CRC^[27,28].

Di Nicolantonio *et al*^[26] retrospectively analyzed 113 mCRC tumors from cetuximab or panitumumab treated patients for *KRAS* and *BRAF* mutations and correlated the results with response, time to progression (TTP) and OS. *KRAS* mutations were present in 30% of the patients and were associated with resistance to cetuximab or panitumumab ($P = 0.011$). The *BRAF* V600E mutation was detected in 11 of 79 patients with WT *KRAS*. None of the *BRAF*-mutated patients responded to treatment, whereas none of the responders carried *BRAF* mutations ($P = 0.029$). *BRAF*-mutated patients had significantly shorter PFS ($P = 0.011$) and OS ($P < 0.0001$) than WT patients, meaning that the *BRAF* V600E mutation was inversely associated with response to anti-EGFR MoAb therapy and correlated with a worse prognosis. In CRC cell lines, the introduction/presence of the *BRAF* V600E allele impaired the therapeutic potential of cetuximab and panitumumab. Pharmacologic inhibition of *BRAF*, as initially hypothesized, restored sensitivity to anti-EGFR MoAbs in the CRC cell lines carrying the *BRAF* V600E mutation. The clinically approved small-molecule kinase *BRAF* inhibitor sorafenib when administered in combination with cetuximab slightly affected proliferation compared with sorafenib alone, whereas it showed a prominent proapoptotic effect. Thus, in the clinic the therapeutic effect of anti-EGFR MoAbs could be restored by 2-hit approaches aimed at blocking the EGFR pathway in multiple locations^[26].

In the same frame as the Di Nicolantonio *et al*^[26] study, Souglakos *et al*^[29] sought to determine retrospectively the predictive value of the *BRAF* (exon 15), *KRAS* (exon 2) and *PIK3CA* (exons 9 and 20) point mutations with re-

spect to clinical outcomes and response to active agents in 168 mCRC patients treated in the USA and Greece with 5-FU-based first-line chemotherapy (71% in combination with oxaliplatin and 34% with irinotecan and 58% with the addition of bevacizumab). In this study population, *KRAS*, *BRAF* and *PIK3CA* mutations were present in 62 (37%), 13 (8%) and 26 (15%) cases, respectively. Multivariate analysis uncovered *BRAF* mutation as an independent prognostic factor for decreased survival (HR, 3.6; 95% CI: 1.7-7.3). However, patients with *BRAF*-mutant tumors had significantly lower PFS (HR, 1.9; 95% CI: 1.03-3.5; $P < 0.0001$) than those whose primary tumors carried only WT *BRAF*. Of 100 patients treated with cetuximab and chemotherapy (8 in first-line and 92 as salvage treatment), the *KRAS* mutation predicted lack of response ($P = 0.001$) and shorter PFS ($P = 0.015$), in accordance with the international literature. *BRAF* mutations also correlated with reduced PFS in response to second-line use of cetuximab ($P < 0.001$). The likelihood of a response between patients with *BRAF*-mutant or *BRAF*-WT tumors was 0% *vs* 17%, and PFS with cetuximab-based therapy was significantly lower when tumors carried mutations in any of the 3 examined genes. *BRAF* mutations conferred a higher risk of relapse (HR, 3.9; $P = 0.0005$) after treatment with cetuximab-containing salvage combinations. These results underscore the potential of mutational profiling to help identify CRCs with different natural history or differential response to particular therapies. Lack of a cetuximab response observed with *KRAS*-mutant tumors may extend to other oncogene mutations, especially *BRAF*. The adverse significance of *BRAF* mutations should guide patient selection and stratification in future clinical trials^[29].

In CRC tumors, *BRAF* mutations are reported to occur more frequently in those cases characterized by the presence of defective DNA mismatch repair (dMMR)^[28]. Although the etiology is still ill-defined, in subsequent studies these mutations were found to occur almost exclusively in tumors showing the involvement of the *hMLH1* gene (one of the genes involved in MMR) due to promoter hypermethylation. Current studies suggest that the *BRAF* V600E mutation occurs in 10% of tumors that are proficient in the MMR pathway (microsatellite stable - MSS/low microsatellite instability - MSI-L) and in > 50% of tumors that have dMMR (high microsatellite instability - MSI-H) due to promoter hypermethylation of the *hMLH1* gene. *BRAF* mutations rarely, if ever, occur in tumors with dMMR because of the presence of germ-line mutations^[30,31]. Thus, *BRAF* V600E is tightly associated with dMMR due to *hMLH1* promoter hypermethylation and not with dMMR due to germ-line alterations.

In conclusion, it seems that the natural history and treatment response of *BRAF*-mutant tumors differ markedly from all others implying that the *BRAF* mutation does not simply substitute for *KRAS* activation in a linear signaling pathway, but likely confers additional or distinct properties, with ominous consequences. The current evidence supports that *KRAS* and *BRAF* mutations are mutually exclusive events. Of course, all these findings need to be formally confirmed prospectively

in randomized clinical trials but if they are, then patients with the *BRAF* V600E mutation might justify foregoing approved treatments in favor of investigational therapy.

***PIK3CA* mutations:** *PIK3CA* is one of the 2 most frequently mutated oncogenes in human tumors. Most of the reported mutations in the *PIK3CA* cluster are in conserved regions within the region coding for the helical and kinase domains of p110 α . These mutations constitutively activate its kinase activity and, thus, make this enzyme an ideal target for drug development^[32].

The *PIK3CA* gene encodes a lipid kinase that regulates alongside *KRAS* signaling pathways downstream of the EGFR. In addition, the p110 α subunit of phosphatidylinositol-3-kinase (PI3K) which is encoded by *PIK3CA*, can be activated by interactions with the RAS proteins^[33] (Figure 1). The *PIK3CA* gene is found mutated in approximately 20% of CRCs and the majority of the relevant mutations are located in the "hotspots" of exon 9 (E542K, E545K) and exon 20 (H1047R)^[34]. PI3K-initiated signaling is normally inhibited by PTEN (phosphate and tensin homologue deleted on chromosome ten). *In vitro* it has been shown that cell lines with activating *PIK3CA* mutations or loss of PTEN expression (PTEN null) were more resistant to cetuximab than WT *PIK3CA*/PTEN-expressing cell lines (14% \pm 5.0% *vs* 38.5% \pm 6.4% growth inhibition, mean \pm SE; $P = 0.008$). Consistently, *PIK3CA* mutant isogenic HCT116 cells showed increased resistance to cetuximab compared with WT *PIK3CA* controls. Furthermore, cell lines that were *PIK3CA* mutant/PTEN null and *RAS*/*BRAF* mutant were highly resistant to cetuximab compared with those without dual mutations/PTEN loss (10.8% \pm 4.3% *vs* 38.8% \pm 5.9% growth inhibition, respectively; $P = 0.002$), indicating that constitutive and simultaneous activation of the RAS and PI3K pathways confers maximal resistance to this agent^[35]. In addition, *in vivo*, Frattini *et al*^[36] have shown that loss of PTEN expression, which occurs in approximately 30% of sporadic CRC cases, may be associated with lack of response to cetuximab.

Sartore-Bianchi *et al*^[37] analyzed 110 mCRC patients treated with anti-EGFR MoAbs for mutations of the *PIK3CA* and *KRAS* genes along with PTEN expression. Fifteen *PIK3CA* (13.6%) and 32 *KRAS* (29.0%) mutations were present. *PIK3CA* mutations were significantly associated with clinical resistance to panitumumab or cetuximab. None of the mutated patients achieved an objective response ($P = 0.038$) and when only WT *KRAS* tumors were analyzed, the statistical correlation was even stronger ($P = 0.016$). Patients with *PIK3CA* mutations displayed a worse clinical outcome also in terms of PFS ($P = 0.035$). The authors conclude that these results indicate that *PIK3CA* mutations can independently hamper the therapeutic response to panitumumab or cetuximab in mCRC. When the molecular status of the *PIK3CA*/PTEN and *KRAS* pathways are concomitantly ascertained, up to 70% of mCRC patients unlikely to respond to EGFR MoAbs can be identified^[37]. In the study by Souglakos *et al*^[29], *PIK3CA* mutations were also found to be associated with reduced

PFS ($P = 0.06$), in response to second-line use of cetuximab. In addition, *PIK3CA* mutations conferred a higher risk of relapse (HR, 2.1; $P = 0.01$) after treatment with cetuximab-containing salvage combinations. However, regarding the response to first-line therapy, PFS was similar between patients whose tumors carried mutant or wild-type and *PIK3CA*^[29].

In conclusion, the sum of the published data in the international literature imply that patients with *KRAS*-, *BRAF*- or *PIK3CA*-mutant tumors may all derive little benefit from treatment with anti-EGFR MoAbs. *BRAF* or *PIK3CA* mutations may account for about 1/3 of patients whose WT *KRAS* tumors do not respond to cetuximab^[29]. A priori screening of CRC tumors for *RAS*/*BRAF*/*PIK3CA* mutations could help stratify patients likely to benefit from anti-EGFR MoAbs therapy.

Fc γ -R II a exon 4 131G>A, Fc γ -R III a exon 5 158T>G single nucleotide polymorphisms (SNPs)

As has been shown recently, antibody-dependent cell-mediated cytotoxicity (ADCC) mediated through Fc receptors plays an important role in the anti-tumor activity of IgG1 antibodies. ADCC is an immunological mechanism which involves the interaction between Fc receptors carried on the surface of immune cells such as macrophages and natural killer (NK) cells and the Fc fragment of moAbs which are bound on tumor cells^[38]. This way, moAbs may exert an indirect antitumor activity by recruiting cytotoxic host effector cells, such as monocytes and NK cells^[39]. One group of IgG Fc receptors, Fc γ Rs are expressed on leukocytes and are composed of 3 distinct classes: Fc γ R I, Fc γ R II (Fc γ R II a and Fc γ R II b), Fc γ R III (Fc γ R III a and Fc γ R III b). The receptors are also distinguished by their affinity for IgG. Fc γ R I exhibits high affinity for IgG, whereas Fc γ R II and Fc γ R III show a weaker affinity. Fc γ R II a and Fc γ R III a are activating Fc γ Rs which are expressed on monocytes/macrophages and monocytes/macrophages/NK cells, respectively, and can trigger cytotoxicity of human targets^[39].

Cetuximab, an IgG1 moAb, competes with the natural ligands of EGFR, EGF and transforming growth factor- α (TGF- α). When binding to cancer cells, it inhibits EGFR dimerization and downstream signaling, thus inhibiting proliferation and inducing apoptosis^[40]. In experimental models, it has been shown that another mechanism of action of cetuximab against cancer cells is mediated *via* ADCC. The effectiveness of ADCC may depend on the degree of activation of effector cells after Fc γ R II a and Fc γ R III a engagement^[41].

The binding affinity of the Fc γ Rs is under the influence of germline genetic polymorphisms detected on genes encoding for Fc γ R II a and Fc γ R III a. The SNP 131G>A (or H131R) in position 131 of exon 4 of *Fc γ R II a* gene which leads to the substitution of an arginine with an histidine and the SNP 158T>G (or V158F) in position 158 of *Fc γ R III a* gene, which leads to the substitution of a phenylalanine with a valine, are shown to affect the receptors' affinities for the Fc fragment of antibodies and probably ADCC efficiency^[42,43].

In a publication of Zhang *et al*^[44] in 39 patients with mCRC treated with cetuximab, TTP was statistically significantly better for patients with the Fc γ R II a H131R SNP ($P = 0.037$) and for the Fc γ R III a V158F ($P = 0.055$). In a study by Bibeau *et al*^[45], in 69 mCRC patients treated with the combination of irinotecan and cetuximab, it was observed that the patients who were homozygous for the H/H allele of SNP Fc γ R II a H131R and/or for the V/V allele of SNP Fc γ R III a V158F had a greater TTP compared with those who carried the R or F alleles (3.2 mo, 2.8 mo, respectively, $P = 0.015$). Nevertheless, the above-mentioned correlations could not be confirmed in other studies^[46,47].

Other polymorphisms

EGFR intron-1 (CA)_n repeat polymorphisms: A highly polymorphic sequence of (CA)_n repeats ($n = 15-22$) is located in intron 1 of the *EGFR* gene. Allele 16 (with 16 CA repeats) is seen more frequently (42%), followed by allele 20 (26%) and 18 (20%)^[48]. *In vivo* and *in vitro* studies have shown that transcriptional activity of the gene is affected, as a result of a variable impact on DNA binding sites, in such a way that the greater number of CA repeats reflects lower *EGFR* mRNA levels and protein expression^[49,50]. In a study by Amador *et al*^[51], from 19 patients with mCRC treated with gefitinib, those who had a small number of CA repeats more frequently manifested dermatologic toxicity (84% of the patients with ≤ 35 CA repeats and only 33% of those with > 35). In a study by Graziano *et al*^[46] in 110 patients with mCRC who underwent irinotecan-cetuximab salvage therapy after disease progression during or after oxaliplatin-based first-line and irinotecan-based second-line chemotherapy, a small number of intron 1 CA repeats (< 17) was correlated, in a multivariate analysis, with favorable OS (HR, 0.41; 95% CI: 0.21-1.78; $P = 0.006$), treatment response ($P = 0.008$) and more frequent grade 2 and 3 dermatologic toxicity ($P = 0.001$) compared with a larger number of CA repeats (≥ 17). Although the above-mentioned study did not have a control arm and thus the predictive role of the polymorphic repeats could not be determined, it is probable that the higher *EGFR* expression in patients with a small number of CA repeats could also reflect a greater effect of cetuximab^[46].

EGFR exon 13 497G>A (or R521K) SNP

Another SNP, a G>A substitution (rs11543848) in codon 521 (previously described as codon 497) in exon 13, which encodes a part of the extracellular region of the *EGFR*, has been described and results in an amino acid substitution of an arginine (R) with a lysine (K). This is located at the boundary between *EGFR* domain III (the direct interaction site with cetuximab) and domain IV^[52]. This amino acid substitution has been shown to significantly reduce TGF- α binding and ligand-induced *EGFR* signaling, which could make the cell even more sensitive to targeted receptor inhibition through cetuximab, for example^[52,53].

In a study by Gonçalves *et al*^[52], tumor tissue samples from patients with mCRC treated with irinotecan/ce-

tuximab were analyzed and the EGFR exon 13 variant (R521K) was associated with better PFS and OS. Indeed, the above-mentioned SNP was observed in 11 of the 21 patients who achieved an objective response or stable disease and in only 1 of the 11 patients who had disease progression ($P = 0.02$). In addition, in a third study it has been correlated with longer OS in stage II and III patients after surgery^[54]. Nevertheless, in the study by Graziano *et al.*^[46], in mCRC patients treated with irinotecan/cetuximab, this SNP was not found to be associated with response to treatment or OS.

Epidermal growth factor (EGF) 5'-UTR 61A>G SNP

EGF is one of the natural ligands of EGFR and upon binding it may activate DNA synthesis and cellular proliferation and it has been shown to stimulate mitosis in epidermal cells. The EGF protein is encoded by the *EGF* gene which is located on chromosome 4q25-27 and contains 24 exons^[55]. The only functional polymorphism of the *EGF* gene was identified in 2002 and is located 61 base pairs (bp) downstream of the EGF promoter, in the 5'-untranslated region of the gene. It consists of a substitution of guanine (G) for adenine (A), (61A>G), it modulates the transcription of EGF and it has been correlated *in vitro* and *in vivo* with elevated serum levels^[56,57]. Primarily, it has been studied in patients with melanoma and glioblastoma multiforme, but it has also been detected in 44% of the European white population^[56,57].

In the study by Graziano *et al.*^[46], in 110 patients with mCRC treated with irinotecan and cetuximab, the EGF 61G/G allele was associated with a greater OS (HR, 0.44; 95% CI: 0.23-0.84, $P = 0.01$) but not with greater response rate, PFS and skin toxicity. The exact mechanism by which this SNP is associated with greater survival is not yet known, but, in experimental models and with different concentrations, EGF has been shown to induce apoptosis and growth inhibition rather than the usual growth-promoting effect^[58]. In addition, in another study with 133 mCRC patients treated with cetuximab monotherapy the EGF 61G/G allele was associated with greater PFS ($P = 0.04$)^[47]. In contrast, in the Zhang *et al.*^[59] study with mCRC treated with cetuximab, the EGF 61A/A allele was correlated favorably with an increased OS (median OS 15 mo for EGF 61A/A, 2.3 mo for EGF 61G/G and 5.7 mo for the heterozygote EGF 61A/G).

Cyclin D1 exon 4 870A>G SNP

Cyclin D1 is a cell cycle regulatory protein whose upregulation has been associated with increased proliferation and poor clinical outcome in a number of neoplasms including CRC^[60]. Cyclin D1 is a key element in the downstream EGFR signaling pathway; EGFR inhibition results in cyclin D1 downregulation, leading cells into the G1 phase and subsequently to apoptosis^[61]. The 870A>G SNP in exon 4 of the *cyclin D1* gene (A to G substitution) influences cyclin D1 mRNA splicing in the border between exon 4 and intron 4 resulting in 2 different mRNA transcripts, a and b. The G allele encodes transcript a, whereas the A allele encodes transcript b,

which results in a longer half-life cyclin-D1^[61,62].

Zhang *et al.*^[59] in a pilot study of 39 mCRC patients under treatment with cetuximab monotherapy, found that both the cyclin-D1 870A>G SNP, as well as the EGF 61A>G SNP could be used as predictive molecular markers of cetuximab therapy. More specifically, the cyclin-D1 870A>G SNP was statistically significantly correlated with OS. Patients with the A/A genotype had a very short median OS of 2.3 mo, whereas, patients with at least one G (A/G or G/G) had a median OS of 8.7 mo ($P = 0.019$). Furthermore, when combined with EGF 61A>G, the cyclin-D1 870A>G shows an even further significant association with OS. Patients with the favorable genotypes (at least one A for the first one and one G for the second) had a median OS of 12 mo, in contrast with 4.4 mo in the patients with unfavorable genotypes^[59]. Unfortunately, Nagashima *et al.*^[47] and Graziano *et al.*^[46] did not find similar correlations in their studies.

Rare SNPs

The G765C SNP of cyclooxygenase-2 (COX-2) which has been correlated *in vitro* with reduced promoter activity and the T251A SNP of interleukin-8 which has been correlated with increased interleukin-8 production, have not been associated with response to cetuximab treatment in mCRC patients. However, the COX-2 G765C SNP has been weakly correlated with skin toxicity ($P = 0.15$)^[59]. A schematic representation of the above-mentioned SNPs is shown in Table 2.

Gene copy numbers and EGFR ligands mRNA expression:

As initially reported in a cohort study, the objective tumor response to the EGFR-targeted moAbs, cetuximab and panitumumab, in mCRC occurred in a fraction of patients whose tumors had an increased *EGFR* gene copy number (GCN), as assessed by FISH^[16]. Subsequently, in further studies, the predictive role of *EGFR* GCN was evaluated and an association with objective tumor response^[63] and OS^[63] was demonstrated.

Lièvre *et al.*^[13], using CISH instead of FISH, confirmed the results of Moroni *et al.*^[16], but both studies were inconclusive probably due to the limited number of patients tested and the non-homogeneous treatments they received. In the study by Lenz *et al.*^[63], the *EGFR* GCN was evaluated with polymerase chain reaction (PCR) and although no association was detected with objective responses and PFS, increased GCN was significantly positively correlated with OS. The discrepancies between these studies could be a result of different techniques or sample limitations, but the association of *EGFR* GCN with OS could also reflect its role as an independent prognostic variable^[13,16,63].

In an attempt to test *EGFR* GCN in a larger and more homogeneous patient population and clarify its predictive role in terms of OR, PFS and OS Sartore-Bianchi *et al.*^[14] analyzed mCRC patients' tumors from the randomized phase III trial comparing panitumumab plus BSC with BSC only after failure in 5-FU-, oxaliplatin- and irinotecan-based chemotherapy^[10]. In this study *EGFR*

anti-EGFR: Anti-epidermal growth factor receptor; NS: Not significant.

GCN was assessed by FISH and its status was evaluated as the mean value of *EGFR* gene copies/nucleus, as the mean value of *EGFR* gene/CEP7 (α -centromeric probe of chromosome 7) and as the percentage of chromosome 7 polysomy (≥ 3 signals per nucleus) scoring 200 tumor cells. A statistically significant positive correlation between increase in mean *EGFR* GCN and probability of response to panitumumab (odds ratio, 5.62; 95% CI: 1.506-20.974) was found with 98.1% specificity (95% CI: 78.5%-96%). In addition, the best cut-off value of mean *EGFR* GCN, ≥ 2.47 *EGFR* gene copies/nucleus, as assessed by ROC analysis, to discriminate responders from nonresponders, had a sensitivity of 100% (95% CI: 54.1%-100%), since no objective response was observed when the *EGFR* GCN was less than this value. Because of the non-homogeneous pattern of *EGFR* GCN in the tumors, the percentage of cells displaying chromosome 7 polysomy and/or *EGFR* gene amplification was also calculated. In the same way, an increase in the percentage of chromosome 7 polysomy was also significantly associated with the probability of objective response (odds ratio, 1.04; 95% CI: 1.007-1.074), with a specificity of 100% (95% CI: 93.2%-100%) and a negative predictive value of 89.7% (95% CI: 78.8%-96.1%). In other words, in patients treated with panitumumab, a mean *EGFR* GCN of less than 2.5/nucleus or less than 40% of tumor cells displaying chromosome 7 polysomy within the tumor predicted a shorter PFS ($P = 0.039$ and $P = 0.029$, respectively) and OS ($P = 0.015$ and $P = 0.014$, respectively), thus generating the hypothesis that these tumors were probably not driven by the *EGFR* pathway. None of the treated patients with mean *EGFR* GCN of less than 2.47/nucleus or less than 43% of tumor cells displaying chromosome 7 polysomy obtained an objective response compared with 6 of 20 and 6 of 19 patients with values greater than these cut-off limits ($P = 0.0009$ and $P = 0.0007$, respectively). Evaluation of BSC-treated patients showed no correlation between *EGFR* GCN or chromosome 7 polysomy status and PFS. Interestingly, in the tumors of patients from the BSC only arm, no correlation was found between *EGFR* GCN and PFS, thus indicating more its predictive, rather than its prognostic role^[14].

In an exploratory clinical trial conducted by Kham-

bata-Ford *et al*^[64], a large prospective human cohort uniformly treated with cetuximab was exploited in an attempt to systematically identify biomarkers associated with disease control to anti-EGFR MoAb treatment. Transcriptional profiling was conducted on RNA from tumor cells in order to identify genes whose expression correlated with best clinical response. *EGFR* GCN was detected at a frequency of 6% by quantitative PCR but its increase within the disease control group was not statistically significant. In addition, gene expression profiles showed that tumors that express high levels of the *EGFR* ligands epiregulin (*EREG*) and amphiregulin (*AREG*) are more likely to show disease control with cetuximab (*EREG*, $P = 0.000015$; *AREG*, $P = 0.000025$) and have significantly longer PFS than patients with low expression (*EREG*: $P = 0.0002$; HR, 0.47; median PFS, 103.5 d *vs* 57 d, respectively; *AREG*: $P = 0.0001$; HR, 0.44; median PFS, 115.5 d *vs* 57 d, respectively)^[64]. Lately, these results were confirmed in another patients' cohort treated with cetuximab and irinotecan in combination^[65]. The authors found that overexpression of *EREG* and *AREG* in *KRAS* WT patients was associated with a decreased risk of progression (HR, 0.41 and 0.43, respectively) and death (HR, 0.42 and 0.4, respectively)^[65].

Lastly, in a study by Scartozzi *et al*^[66], the role of nuclear factor- κ B (NF- κ B) was investigated. NF- κ B plays a role in the activation of the *EGFR* downstream signaling pathway and was shown to be responsible for resistance to antineoplastic agents. *EGFR* can induce NF- κ B, and high levels of *EGFR* expression are essential for *EGFR*-mediated NF- κ B activation^[67]. In the above-mentioned study, NF- κ B and *EGFR* expression were evaluated retrospectively by immunohistochemistry and the results were correlated with response rate, TTP and OS in mCRC patients receiving irinotecan-cetuximab treatment. The response rate was 10% (4 partial responses) *vs* 48% (12 partial responses; $P = 0.0007$) in NF- κ B-positive and NF- κ B-negative tumors, respectively. Median TTP in NF- κ B-positive patients was 3 *vs* 6.4 mo in the remaining patients ($P = 0.021$). Median OS was 9.5 mo *vs* 15.8 mo for NF- κ B-positive and NF- κ B-negative patients, respectively ($P = 0.036$). The difference in median TTP, OS and response rate could mean that NF- κ B

may play a role in predicting the efficacy of irinotecan-cetuximab therapy in the mCRC setting^[66].

CONCLUSION

The CRC mutation profiles should influence patient selection or stratification in prospective trials. *KRAS* mutational status represents a paradigm for biomarker development in the era of molecular targeted therapies. As a result, *KRAS* testing is now mandatory at the presentation of metastatic disease in patients with CRC. In total, almost 50% of mCRC patients' tumors harbor either the *KRAS* (40%) or *BRAF* (10%) mutation and are not candidates for anti-EGFR moAb therapy. Patients with *KRAS* mutations may benefit from combination chemotherapy and anti-vascular endothelial growth factor moAbs (such as bevacizumab). Patients with *KRAS* mutations and resistance or relapse to chemotherapy and/or bevacizumab have limited treatment options and could be candidates for clinical trials with investigational agents, such as mTOR or extracellular-signal-regulated kinase inhibitors. The *BRAF* V600E mutation identifies a subgroup (less than 10%) of patients with an exceptionally unfavorable prognosis. These patients might justify forego approved treatments in favor of investigational therapy, such as molecules that inhibit the WT (sorafenib) and/or the mutant (PXL 4032) *BRAF* allele, either alone or in combination with chemotherapy. In addition, *PIK3CA* mutations appear to be useful predictors for response to anti-EGFR moAbs, but definitive conclusions should be based on the analysis of larger cohorts of patients in randomized trials that include patients who have not been exposed to anti-EGFR targeted therapies.

In addition, the expression of *AREG* and *EREG* was consistently associated with the outcome of cetuximab and panitumumab combination chemotherapy. The results of SNPs and GCN are premature and controversial, and thus need to be explored in a more systematic approach.

The development of biomarkers for the optimization of anti-EGFR treatment in mCRC, beyond *KRAS* mutations, is a work in progress. The aim will be to identify molecular markers that might be used to select patients with a higher probability of response to anti-EGFR moAbs.

Abstract

Pro-inflammatory cytokines are produced in the gastric mucosa by inflammatory cells activated by chronic *Helicobacter pylori* (*H. pylori*) infection. Polymorphisms of these cytokine genes are associated with individual differences in gastric mucosal cytokine mRNA level, which result in differences in gastric mucosal inflammation, acid inhibition and gastroduodenal disease risk in response to *H. pylori* infection. Although polymorphisms of interleukin (*IL*)-1*B*, *IL*-1*RN* and *TNF*-*A* have been reported to relate well with gastric cancer and peptic ulcer risk, those of *IL*-2, *IL*-4, *IL*-6 and *IL*-8 genes are unclear. In combined analyses using data from previous studies, we found that the risk of gastric non-cardia cancer development was significantly associated with *IL*-4-168 C allele (OR: 0.81, 95% CI: 0.69-1.00) and *IL*-4-590 T allele carrier status (0.61, 0.53-0.73), and *IL*-6-174 G/G genotype (2.02, 1.31-3.10). In peptic ulcer development, *IL*-2-330 G and *IL*-4-590 T allele carriers had a significantly decreased risk (0.37, 0.27-0.50 and 0.58, 0.34-0.99, respectively). Moreover, *IL*-2, *IL*-4, *IL*-6 and *IL*-8 gene genotypes prevalence differs among populations. The inflammatory cytokine gene polymorphisms

(e.g. *IL*-4-590 and *IL*-6-572 for gastric cancer, and *IL*-4-590, *IL*-6-572 and *IL*-8-251 for peptic ulcer) have a more potent influence on development of gastroduodenal diseases in Western than East Asian populations. These cytokine gene polymorphisms, as well as those of *IL*-1*B*, *IL*-1*RN* and *TNF*-*A*, may be used to identify groups at higher risk of gastric cancer and peptic ulcer, and those suitable for their prevention by *H. pylori* eradication therapy in Western populations.

INTRODUCTION

Helicobacter pylori (*H. pylori*) infects > 50% of the world's population, and is particularly prevalent in developing countries (> 90%)^[1-5]. Chronic *H. pylori* infection relates not only to the development of upper gastrointestinal diseases, such as peptic ulcer diseases, gastric adenoma, gastric cancer, and gastric mucosa-associated lymphoid tissue lymphoma, but also with some extra-gastrointestinal disorders, such as idiopathic thrombocytopenic purpura, chronic idiopathic urticaria and iron-deficiency anemia^[4-12]. Prevention and treatment of *H. pylori*-related disease has therefore relied on eradication therapy as first-line treatment^[4-12].

The key pathophysiological event in *H. pylori* infection of gastric mucosa is the induction of a gastric mucosal inflammatory response. Following infection, neutrophils and mononuclear cells activated by *H. pylori* and their products infiltrate *H. pylori*-infected gastric mucosa and stimulate the transcription and synthesis of several pro-inflammatory cytokines [e.g. interleukin (IL)-1 β , IL-2, IL-6, IL-8 and tumor necrosis factor (TNF)- α] and anti-inflammatory cytokines (e.g. IL-4 and IL-10)^[13]. The increased production of inflammatory cytokines in response to *H. pylori* infection results in enhanced gastric mucosal inflammation, through binding to specific receptors on target cells.

Most of these inflammatory cytokine genes have genetic variations that influence cytokine levels in the gastric mucosa. Levels of mucosal IL-1 β , for example, the most studied inflammatory cytokine, differ significantly among the different genotypes in three polymorphisms, *IL-1B-511*, -31 and *IL-RN*^[13,14]. Carriers of the *IL-1B-511* T, -31 C and *IL-RN* *2 alleles have significantly higher IL-1 β levels than those of the other allele^[13]. Consistent with this difference, carriers of the *IL-1B-511* T, *IL-1B-31* C alleles and *IL-1RN* *2/*2 (2 repeats of 86 bp) genotype show enhanced suppression of gastric acid secretion, which results in more rapid development of gastric atrophy, and a consequently greater risk of developing gastric cancer than in those with the *IL-1B-511*C, *IL-1B-31* T and *IL-1RN**1 alleles^[13-18]. However, although IL-2, IL-4, IL-6 and IL-8 levels in gastric mucosa are reported to increase in patients with *H. pylori* infection^[19,20], it remains unknown whether these inflammatory cytokine polymorphisms are associated with gastroduodenal disease development in a similar way as those with *IL-1B* and *TNF-A*. Previously reported associations with disease risk and cytokine gene polymorphisms of *IL-2*, *IL-4*, *IL-6* and *IL-8* are controversial, however, owing to either or both type 2 error and geographical differences (Tables 1-4).

Here, we review differences in the risk of development of peptic ulcer and gastric cancer by different inflammatory cytokine gene polymorphisms of *IL-2*, *IL-4*, *IL-6* and *IL-8*.

IL-2 POLYMORPHISM AND GASTRODUODENAL DISEASES

IL-2, a 15-kDa α -helical cytokine of the Th1 type produced exclusively by activated T cells, promotes the proliferation of lymphocytes, macrophages and NK cells^[21]. IL-2 potently regulates the immune response, and plays important roles in the differentiation of CD41-positive T cells into Th1 and Th2 effector subsets, while inhibiting T-helper 17 differentiation^[22,23]. In T cells, IL-2 binding to the IL-2 receptor activates the Janus kinase (JAK)/signal transducer and activator of transcription (STAT) pathway, as well as mitogen-activated protein kinase (MAPK) and phosphoinositide 3-kinase (PI3K) signaling, which results in the transcription of pro-inflammatory cytokine genes. Through these pathways, IL-2 upregulates the expression of CD25 and IL-2R β , modulates genes involved in cell cycle regulation, and promotes T-cell survival and differ-

entiation into effector and memory cells^[24,25]. IL-2 contributes to the induction and transmission of inflammatory immune responses, including *H. pylori*-induced gastric inflammation.

Two kinds of single nucleotide polymorphism (SNP) occur in *IL-2-330* and -384 (4q26-q27) of the promoter region, which affect IL-2 production^[26,27]. IL-2 expression level with deletion of the *IL-2-289* to -361 region was significantly decreased compared with that with the normal gene. *IL-2-330* polymorphism located in this region is therefore considered to have particular influence on IL-2 levels^[26,27]. In fact, IL-2 production in the *IL-2-330* G/G genotype is about threefold greater than that of the *IL-2-330* T/G or T/T genotypes in healthy subjects^[28]. Consistent with this difference, an association between the *IL-2-330* polymorphism and susceptibility to some inflammatory and immune diseases, such as rheumatoid arthritis, psoriasis and multiple sclerosis, has been reported^[29,31]. IL-2 is therefore also thought to induce *H. pylori*-associated gastroduodenal diseases by regulating Th1 immune responses^[32] and inhibiting gastric acid secretion^[33].

Four studies have investigated the associations with *IL-2-330* (three studies), +114 (one study) and +384 (one study) polymorphisms and development of atrophic gastritis (one study), peptic ulcer (one study) or gastric cancer (three studies) (Table 1)^[34-37]. With regard to *IL-2-330* polymorphism, Wu *et al.*^[37] have reported that subjects carrying the T allele, a low producer allele, have a significantly reduced risk of gastric cardia cancer (OR: 0.68, 95% CI: 0.46-0.99) compared with those with the G/G genotype. *IL-2-330* polymorphisms may contribute to the etiology of gastric cardia cancer in Chinese populations^[37]. However, Shin *et al.*^[35] failed to demonstrate a significant association with *IL-2-330* polymorphism and gastric cancer development in the Chinese, while Togawa *et al.*^[34] conversely have reported that the *IL-2-330* T/T genotype increased the risk of gastric cancer-related gastric atrophy (OR: 2.78, 95% CI: 1.26-6.17) in the Japanese. The results for *IL-2-330* polymorphism are thus controversial. Moreover, no significant association was seen for *IL-2-384* and +114 polymorphisms and gastric cancer development^[36].

When combined, the results of previous studies of *IL-2-330* polymorphism^[34,35,37] surprisingly have shown that the risk of peptic ulcer development is 0.57 (95% CI: 0.33-0.98) for the G/G genotype and 0.37 (0.27-0.50) for G allele carriers compared with the T/T genotype (Table 5). However, no association with *IL-2-330* polymorphism was seen for the risk of gastric non-cardia cancer. This finding is inconsistent with the first hypothesis, which states that patients with the *IL-2* high producer genotype have an increased risk of gastric cancer and gastric ulcer development. Togawa *et al.*^[34] have speculated that one possible reason is that a higher IL-2 level is thought to enhance the immune response to eradicate *H. pylori*, and thereby decrease gastric mucosal inflammation. Moreover, an IL-2 promoter construct in a cell line shows higher levels of gene expression with

Table 1 Association of *IL-2* polymorphism and gastroduodenal diseases

Although Seno *et al*^[55] investigated nine SNPs (*IL-4*-590, -33, 3437, 3557, 4047, 4144, 4271, 4367 and 8427), data concerning the exclusion of *IL-4*+984 and 2983 were unclear. Dys: Dysplasia; DU: Duodenal ulcer.

the *IL-2*-330 G allele, whereas the transcriptional effect of this polymorphism in lymphocytes shows that the *IL-2*-330 G allele is associated with a lower expression of *IL-2*^[50]. In fact, many studies have shown that the *IL-2*-330 T/T genotype increases the risk of a number of diseases, such as Takayasu's disease^[38], subacute sclerosing panencephalitis^[39] and schizophrenia^[40].

All studies that have investigated the relationship of *IL-2*-330 polymorphism and disease development to date were in Asian populations^[34,35,37]. Further studies, including those in Western populations, will be necessary to solve this discrepancy and establish this relationship.

IL-4 POLYMORPHISM AND GASTRODUODENAL DISEASES

IL-4 is an anti-inflammatory cytokine, which inhibits gastric mucosal *H. pylori*-induced inflammation and atrophy by decreasing interferon γ (IFN- γ), which plays an important role in Th1 immune responses. *IL-4* also plays a central role in the maturation of T-helper cells to the Th2 phenotype. With a shift from a Th1 to a Th2 cell pattern, *IL-4* can enhance the production of anti-inflammatory cytokines (e.g. *IL-10* and *IL-13*), including that of *IL-4*^[41,42], and suppress the production of monocyte-derived pro-

Although Kang *et al* and Savage *et al* investigated the association with *IL-6*-174 C/G polymorphism and gastric cancer, data were not described in detail (> 99% of patients were of the *IL-6*-174 G/G genotype).

inflammatory cytokines (e.g. *IL-1* β , *IL-6* and *IL-8*)^[42].

IL-4 is overproduced in *H. pylori*-infected gastric mucosa. However, gastric mucosal inflammation has been shown to significantly reduce *IL-4* administration^[19,20], and *IL-4*-deficient mice infected with *H. pylori* show severe gastric inflammation compared with wild-type mice^[43,44]. A balance between Th1 and Th2 cytokines by *IL-4* therefore crucially influences the outcome of *H. pylori* infection. Moreover, *IL-4* is reportedly associated with cancer development *via* its suppression of inflammation, and directly inhibits the growth of human melanoma, renal cell carcinoma and gastric cancer cells^[45].

The family of the *IL-4* gene, which encodes *IL-4*, is located on chromosome 5q31-33, which contains the *IL-3*, *IL-4*, *IL-5*, *IL-9*, *IL-13*, *IL-15* genes as well as the interferon-regulatory factor and granulocyte-macrophage colony-stimulating factor (GM-CSF)^[46]. There are two common polymorphisms in the *IL-4* gene, -590 C/T and a 70-bp sequence variable number tandem repeat at intron 3; and many minor polymorphisms, such as -168, -33, 3437, 3557, 4047, 4144, 4271, 4367, 8427^[47,48]. The *IL-4*-590 polymorphism is located upstream of all known control elements of *IL-4*, such as the negative regulatory element, the NF- κ B recognition sequence, and the TATA box^[49]. Individuals with the *IL-4*-590 T/T genotype can produce *IL-4* at higher levels than those with the C/C

genotype^[48]. *IL-4* polymorphism is reportedly associated with the risk of cancer development (e.g. colorectal cancer^[50]), and the Th2 T-cell response represented by *IL-4* is expected to play a protective role in the development of cancer.

Seven studies have investigated the association of *IL-4*-590 polymorphism and atrophic gastritis (one study^[51]), gastric cancer (five studies^[52-56]), and duodenal ulcer development (one study^[57]) (Table 2). In 2003, Wu *et al*^[52] first reported that a higher prevalence of diffuse-type gastric cancer (OR: 1.64, 95% CI: 1.01-2.67), particularly in gastric cardia cancer (2.44, 1.13-5.27), is observed in *IL-4*-590 C allele carriers, a low producer allele, compared with the *IL-4*-590 T/T genotype, which suggests that low production of *IL-4* is responsible for the development of gastric cancer. However, other studies have failed to demonstrate any significant association of *IL-4* polymorphisms with disease risk^[37,53,54,57,58]. In a combined-analysis of *IL-4*-590 C/T polymorphism^[52-56], however, the risk of gastric non-cardia cancer development was 0.68 (95% CI: 0.57-0.80) for the C/T genotype, 0.36 (0.24-0.53) for the T/T genotype and 0.61 (0.53-0.73) for T allele carriers (Table 6). Moreover, the risk of peptic ulcer development in T allele carriers (0.58, 0.34-0.99) was significantly lower (Table 6). This protective effect of *IL-4*-590 polymorphism is therefore

Table 4 Association of *IL-8* polymorphism and gastroduodenal diseases

Although Seno *et al*^[55] investigated six SNPs (*IL-4*-352, 289, 294, 680, 2217 and 2670), data were not described in detail. IM: Intestinal metaplasia.

significant for gastric non-cardia cancer and peptic ulcer patients with a higher producer genotype.

The prevalence of *IL-4*-590 C/C, C/T and T/T genotypes differs between Western and Asian populations (Table 7). The prevalence of C/C, C/T and T/T genotypes in a Western population with gastric cancer was 69.8% (362/518), 26.1% (135/) and 4.1% (21/), respectively, whereas that in those with non-ulcer dyspepsia

(NUD) was 55.9% (1448/2592), 36.0% (934/) and 8.1% (210/). In a Western population, the risks for gastric non-cardia cancer and peptic ulcer development were 0.55 (95% CI: 0.46-0.67) and 0.55 (0.32-0.94) for T allele carriers, respectively (Table 8). In an Asian population, in contrast, no significant difference was seen between subjects with gastric cancer and NUD. This difference in the influence of *IL-4*-590 polymorphism on disease development

Table 5 ORs for gastric non-cardia cancer and peptic ulcer development in *IL-2-330* polymorphism

	Genotype	¹ NUD (n)	Cancer (n)	OR	95% CI	P value	Ulcer (n)	OR	95% CI	P value

may have a geographic basis, and the effect appears to be stronger in Western populations (Table 8).

With regard to minor polymorphisms of *IL-4*, *IL-4-168*, -33, 984/2983 SNPs have been reported by one study each^[34,37,55]. Compared with the *IL-4-168* C/C high producer genotype^[37], the *IL-4-168* T allele carrier was associated with a significantly decreased gastric cancer risk (OR: 0.83, 95% CI: 0.69-1.00). Further, this significant protective effect was also seen for gastric cardia cancer patients (0.73, 0.56-0.95)^[37].

Thus, a significant protective effect against gastric non-cardia cancer was seen with the higher producer genotype *IL-4-590* and -168 polymorphisms, particularly in Western populations.

IL-6 POLYMORPHISM AND GASTRODUODENAL DISEASES

IL-6, a multifunctional cytokine produced by immune and

many non-immune cells including monocytes, lymphocytes, macrophages, and endothelial and intestinal epithelial cells, functions as both an inflammatory mediator and endocrine regulator^[59]. IL-6 plays an important role in host defense mechanisms as a messenger between innate and adaptive systems, by stimulating IFN- γ production in T cells and promoting immunoglobulin secretion in activated B cells^[60].

High serum levels of IL-6 family cytokines have been reported in various gastrointestinal cancer cells^[61]. IL-6 and IL-11 belong to the IL-6 cytokines family, which includes ciliary neurotrophic factor, cardiotrophin-1, cardiotrophin-like cytokine, leukemia inhibitory factor, oncostatin M, and IL-27. These act as ligands for the signaling receptor subunit gp130^[62,63]. IL-6 requires specific α receptor subunits and gp130 homodimers of signal transducing receptor^[63]. Recently, mice with a mutation in gp130 (gp130 757^{F/F} mouse) have been established to enhance chronic gastric inflammation and develop gastric neoplasms without *H. pylori* infection, *via* an imbalance between STAT3 and Y-759/SHP-2 signaling^[64]. The presence of the Y757F mutation in the gp130 receptor promotes the failure of SHP-2 phosphorylation and subsequent activation of the pro-apoptotic Ras/Erk and PI3K/AKT pathways, which results in massive STAT3 activation. STAT3 hyperactivity suppresses the cytostatic effect of the stroma on cell proliferation^[65]. Moreover, STAT3 also induces epithelial cell expression of IL-11^[66]. These signaling events promote an oncogenic program in which the expression of anti-apoptotic, pro-angiogenic, and pro-proliferative genes results in inflammation-associated gastric tumorigenesis^[66]. The IL-6 family signaling system is therefore an attractive research target in gastric cancer pathogenesis.

Mucosal IL-6 levels increase in *H. pylori*-associated gastritis^[66,67] and dramatically decrease after eradication of infection^[68]. IL-6 mRNA levels in gastric mucosa correlate with the level of gastric mucosal inflammation^[67,69]. Serum levels of IL-6 are higher in patients with gastric

cancer than gastritis^[70]. IL-6 plays an important role as a prognostic factor in advanced gastric cancer and lymph node metastasis^[71], and a serum IL-6 level > 13 pg/mL correlates with tumor progression and poor survival after resection^[72].

The *IL-6* gene is located on chromosome 7p21 and the SNPs at the 5' flanking region of the *IL-6* promoter have been identified as *IL-6*-174, -572 and -597^[73]. *IL-6*-174 G allele carriers produce higher levels of IL-6 than those with the C/C genotype^[74], and have a higher prevalence of systemic juvenile-onset chronic arthritis, lipid abnormalities^[75] and insulin resistance^[76]. *IL-6*-174 G and -597 G allele carriers are closely linked regardless of ethnic group or disease status^[77]. The *IL-6*-572 G allele is also associated with a higher serum IL-6 level than *IL-6*-572 C/C allele^[78], and is a risk factor for diabetic nephropathy and lung cancer with asthma/asthma^[79,80].

Six studies of the *IL-6*-174 polymorphism^[53,77,81-84], three of *IL-6*-572^[77,84,85], three of *IL-6*-597^[77,83,84] and one of *IL-6*+634^[72] in relation to the development of gastric cancer and peptic ulcer have appeared (Table 3). Gatti *et al*^[81] have reported that the *IL-6*-174 G allele carriers account for a significantly higher incidence of gastric cancer than NUD patients (98.2%, 55/56 and 90.2%, 101/112, respectively). However, Kamangar *et al*^[83] have demonstrated that, compared with G/G genotype IL-6, the low producer genotype *IL-6*-174G/C has an increased risk of gastric cancer, while other studies have shown no significant relationship of *IL-6*-174 polymorphism with gastric diseases. The association of this polymorphism with these conditions thus remains unclear. In contrast, frequencies of the *IL-6*-572 G/G genotype (OR: 0.3, 95% CI: 0.1-0.9) and of G allele carriers (0.5, 0.4-0.8) are lower in *H. pylori*-positive patients with duodenal ulcer than in those with NUD^[85].

In a combined analysis of *IL-6*-174 C/G polymorphism^[13,53,81-84], the risk of gastric non-cardia cancer was 2.02 (1.31-3.10) for the G/G compared with C/C genotype (Table 9). Moreover, the risk of gastric ulcer

¹NUD includes patients with gastritis without gastric cancer and peptic ulcer, and atrophic gastritis. Because we deleted a number of gastric cardia cancer patients, the number of cancer patients shown in this Table does not match that in Table 3.

was significantly higher with the G/G genotype (58.86, 8.27-433.4) and G allele carriers (33.10, 4.59-233.8) (Table 9). However, the prevalence of *IL-6-174* C/C, C/T and T/T genotypes differs among populations, with the C/C genotype being less common in East Asian, South Asian and Latin American populations (0%-9.8%) than in North American and European populations (13.4%-28.3%)^[13,53,81-84]. In East Asians in particular, the *IL-6-174* polymorphism has a C allele frequency of < 1%, not only in patients with gastric cancer, but also in those with NUD^[56,77,85]. This polymorphism may therefore not be useful in identifying the association with disease development in Asian populations. Although the prevalence of gastric cancer is higher in East Asians and Latin Americans than Caucasians, the difference in *IL-6-174* polymorphism may nevertheless explain the difference in prevalence between Asian and Western countries.

On combined analysis, *IL-6-572*, *IL-6-597* and *IL-6+643* polymorphisms have shown no significant relationship with gastric disease. When patients are divided into Asian and Western populations, however, a clear difference in the prevalence of *IL-6-572* genotypes is seen (Table 7). The risk of gastric non-cardia cancer and peptic ulcer development in Western populations was 21.13 (95% CI: 5.56-131.98) and 2.98 (1.05-8.47) for the *IL-6-572* G/G genotype, respectively (Table 8). In contrast, no significant difference has been seen between Asians with gastric cancer or NUD.

This influence of the *IL-6-174* and *IL-6-572* polymorphisms on disease development may have been due to geographic differences. Furthermore, the influence of *IL-4-590* polymorphism on gastroduodenal diseases is particularly strong in Western populations.

IL-8 POLYMORPHISM AND GASTRODUODENAL DISEASES

IL-8, a member of the CXC chemokine family, which

was originally identified as a potent chemoattractant for neutrophils and lymphocytes, induces not only cell proliferation and migration, but also angiogenesis. IL-8 is produced by gastric epithelial cells during *H. pylori* infection, particularly in the *cag*-pathogenicity-island-positive strain of *H. pylori*, one of the major virulence factors^[86,87]. In addition, IL-8 protein levels are 10-fold higher in gastric cancer than in normal gastric tissue^[68], and directly correlate with the vascularity of the tumors^[88]. The transfection of gastric cancer cells with the *IL-8* gene enhances their tumorigenesis and angiogenesis in the gastric wall of nude mice^[88]. Increased IL-8 levels may amplify the inflammatory response to *H. pylori* by recruiting neutrophils and monocytes, thereby resulting in an advanced degree of gastritis, which ultimately predisposes to the development of gastric cancer.

There are three common polymorphisms in the *IL-8* gene, -251 A/T, 396 T/G and 781 C/T^[47,48]. Of these, *IL-8-251* A allele carrier status is associated with increased IL-8 production^[89]. Consistent with these differences, *IL-8-251* polymorphism influences cancer risk, including that of lung^[90], colorectal^[91], bladder^[92], and prostate cancer^[93].

Seventeen studies of *IL-8-251* polymorphism^[58,83-85,94-106], two of *IL-6+396*^[83,101] and two of *IL-6+781*^[83,101] in relation to the development of gastric cancer and peptic ulcer have appeared. Of these, six studies have shown a significantly increased risk of gastric cancer for the *IL-8-251* A/A high producer genotype or A allele carriers^[58,85,95,98,100-102], while four have shown an increase for peptic ulcer^[85,100,103,104] and one for gastric mucosal atrophy^[98]. The *IL-8-251* A/A genotype is more common in *H. pylori*-positive patients with gastric cancer (OR: 2.0, 95% CI: 1.2-3.6) or gastric ulcer (2.7, 1.5-4.8) than in those with NUD^[85]. In addition, the *IL-8-251* A/A genotype is associated with a higher risk for the intestinal than the diffuse type of gastric cancer^[85]. Moreover, Taguchi *et al.*^[98] have reported that the *IL-8-251* A/A genotype correlates with a higher risk of lymph node and liver metastasis, and is histopathologically

NUD includes patients with gastritis without gastric cancer and peptic ulcer, and atrophic gastritis. Because we deleted a number of gastric cardia cancer patients, the number of cancer patients shown in this Table does not match that in Table 4.

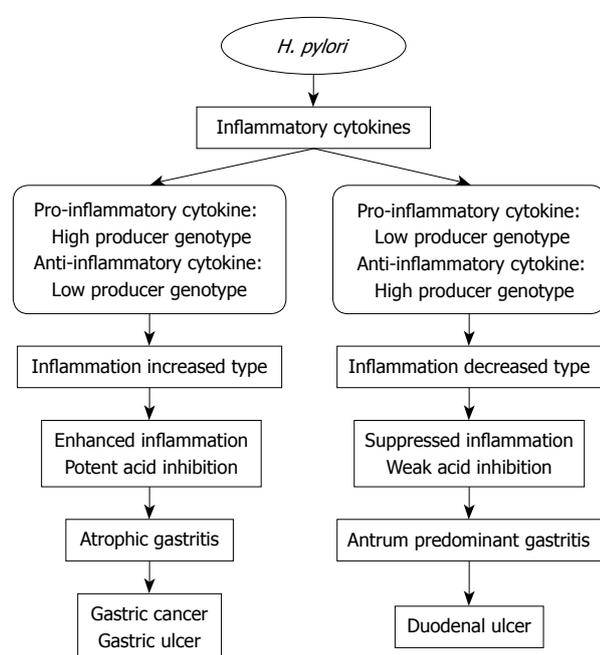

Figure 1 Scheme of the association of inflammatory cytokine polymorphisms and gastroduodenal disease development.

associated with more severe neutrophil infiltration in non-cancerous gastric mucosa adjacent to cancer. These results may be due to the tumorigenic and angiogenic functions of *IL-8* modulating the growth and invasive behavior of malignant tumors by autocrine and paracrine mechanisms, and suggest that genetic variants of *IL-8* potentially affect the prognosis of gastric cancer. Nevertheless, several contrary studies have also appeared. Lee *et al*^[99], for example, have reported that, compared with the *IL-8*-251 A/A high producer genotype, the A/T genotype had a > 60% risk of gastric cancer (1.62, 1.07-2.46), while the T/T genotype had a > 90% risk (1.93, 1.26-2.95), particularly in the diffuse type; whereas Shirai *et al*^[96] have reported that the *IL-8*-251 T/T genotype is significantly associated with an increased risk of microsatellite instability (MSI)-high gastric cancer, which is more frequently associated with active *H. pylori* infection than in microsatellite-stable (MSS) cases,

compared to MSI-low/MSS gastric cancer (5.2, 1.5-18.0) and NUD (3.7, 1.1-12.4).

Most studies that have reported positive associations for gastric cancer risk have been conducted in Asian populations^[98,100-102], whereas those that have reported negative findings were conducted in Western populations^[83,97]. In a combined analysis of the *IL-8*-251 polymorphism, no association was seen for the risk of gastric non-cardia cancer development (Table 10). However, the prevalence of *IL-8*-251 genotypes differs between Western and Asian populations (Table 7), and the risk for peptic ulcer in Western populations is higher [1.53 (1.09-2.14) for the *IL-8*-251 A/A genotype and 1.49 (1.14-1.96) for A allele carriers] (Table 8). The *IL-8*-251 polymorphism more potently influences the development of peptic ulcer in Western than East Asian populations.

In combined analysis, the *IL-8*+396 and *IL-8*+781 polymorphisms have no significant relationship with the incidence of gastric disease (Table 10). However, Savage *et al*^[101] have reported that the *IL-8*-251/+396/+781 AGT/AGC haplotype is associated with a fourfold increased risk of gastric cardia cancer. This haplotypic analysis will help identify groups with a higher risk of disease and should be investigated in a larger study.

Summary of association between *H. pylori*-related diseases and cytokine polymorphisms

In general, gastric mucosal inflammation in *H. pylori* infection of gastric mucosa is exacerbated in patients with high producer alleles of pro-inflammatory cytokines and low producer alleles of anti-inflammatory cytokines, which results in a higher risk for the development of gastric cancer and gastric ulcer (Figure 1). In contrast, low producer allele carriers of pro-inflammatory cytokines and high producer allele carriers of anti-inflammatory cytokines have mild gastric mucosal inflammation (Figure 1). A summary of the association between *H. pylori*-related diseases and cytokine polymorphisms is shown in Table 11. As important points, the prevalence of cytokine gene genotypes differs between Western and Asian populations. Although Asian populations have been reported to be associated

↓ decrease in risk of disease; ↑ increase in risk of disease.

with *IL-1B-511*, *IL-10*, *TNF-A* polymorphisms and development of peptic ulcer and gastric cancer^[13,18], the influence of *IL-4*, *-6* and *-8* polymorphisms on the diseases in the current review may be lower. In Western studies, combination analysis of several cytokine gene genotypes is related to development of diseases^[53]. As shown in Table 11, because *IL-4-590*, *IL-6-174*, *IL-6-572* and *IL-8-251* polymorphisms in Western populations relate to development of gastroduodenal diseases, combination analysis including these gene polymorphisms with previously reported *IL-1* and *TNF-A* is expected to increase detection of elevated risk of diseases. These findings should be further evaluated in a larger population.

CONCLUSION

Many genetic factors are associated with the development of *H. pylori*-related diseases. Of these, we have reviewed here the important role of inflammatory cytokines (*IL-2*, *IL-4*, *IL-6* and *IL-8*) and their polymorphisms in *H. pylori*-related diseases. We recommend intensive endoscopic screening and/or eradication therapy for patients at higher risk of gastric cancer based on genetic inflammatory cytokine polymorphisms, albeit that we are unsure whether all factors should be determined. Further data to refine this recommendation are therefore required.

Abstract

AIM: To understand the implication of *GATA-4* and *GATA-5* methylation in gastric carcinogenesis.

METHODS: Methylation status of *GATA-4* and *GATA-5* CpG islands in human gastric mucosa samples, including normal gastric biopsies from 45 outpatients, gastric dysplasia [low-grade gastric intraepithelial neoplasia (GIN), $n = 30$; indefinite, $n = 77$], and 80 paired sporadic gastric carcinomas (SGC) as well as the adjacent non-neoplastic gastric tissues was analyzed by methylation specific polymerase chain reaction (MSP) and confirmed by denatured high performance liquid chromatography (DHPLC). Immunohistochemical staining was used to detect protein expression. The correlation between *GATA-4* and *GATA-5* methylation and clinicopathological characteristics of patients including *Helicobacter pylori* (*H. pylori*) infection was analyzed.

RESULTS: *GATA-4* and *GATA-5* methylation was frequently observed in SGCs (53.8% and 61.3%, respectively) and their corresponding normal tissues (41.3% and 46.3%) by MSP. The result of MSP was consistent with that of DHPLC. Loss of both *GATA-4* and *GATA-5* proteins was associated with their methylation in SGCs ($P = 0.01$). Moreover, a high frequency of *GATA-4* and *GATA-5* methylation was found in both gastric low-grade GIN (57.1% and 69.0%) and indefinite for dysplasia (42.9% and 46.7%), respectively. However, *GATA-4* and *GATA-5* methylation was detected only in 4/32 (12.5%) and 3/39 (7.7%) of normal gastric biopsies. *GATA-4* methylation in both normal gastric mucosa and low-grade GIN was also significantly associated with *H. pylori* infection ($P = 0.023$ and 0.027 , two-sides).

CONCLUSION: Epigenetic inactivation of *GATA-4* (and *GATA-5*) by methylation of CpG islands is an early frequent event during gastric carcinogenesis and is significantly correlated with *H. pylori* infection.

INTRODUCTION

GATA proteins comprise a small family of transcriptional factors defined by a highly conserved DNA-binding domain that interacts specifically with DNA *cis*-elements. Six distinct vertebrate GATA proteins have been characterized and classified into two subfamilies based on their structural and expression patterns. GATA-1, -2 and -3 are important in the development and differentiation of the hematopoietic cell lineage, while GATA-4, -5 and -6 guide development and differentiation in the endoderm-derived organs, and specification of proper gut embryogenesis^[1-3]. GATA-4 deficient cells exhibit an intrinsic defect in gastric epithelial cell differentiation to parietal cells in mice^[4]. Overexpression of GATA-5 induced TFF1 expression^[5]. Thus, GATA-4, -5 and -6 may play a critical role in the regulation of stomach-specific gene expression and cancer development. GATA-6 may function as an oncogene since it is often upregulated in proliferating progenitor cells^[6-8]. In contrast, GATA-4 and GATA-5 may function as tumor suppressors to drive endoderm-specific differentiation because they are potential upregulators of the differentiation-related genes in the endoderm-derived organs^[9].

The endoderm gives rise to the lining epithelium of the gastrointestinal tract. Loss of GATA-4 and GATA-5 might affect gastrointestinal epithelial cell differentiation, leading to tumorigenesis of these cells. In fact, there is growing evidence linking loss of *GATA-4* and *GATA-5* expression to many malignancies, such as primary esophageal, colorectal, gastric and pulmonary cancers^[5,10-12]. Moreover, in addition to genetic inactivation, epigenetic changes such as methylation of CpG islands may play a major role in the loss of *GATA-4* and *GATA-5* function^[5,10,12]. Since methylation of *GATA-4* and *GATA-5* is a frequent event in gastric cancer cell lines^[5], it is interesting to know that methylation silences of *GATA-4* and *GATA-5* during gastric carcinogenesis.

MATERIALS AND METHODS

Gastric tissue samples

Primary sporadic gastric carcinoma (SGC) and the corresponding normal gastric samples: Fresh-frozen surgical SGC and their corresponding adjacent non-neoplastic "normal" samples were from the Tissue Bank at Beijing Cancer Hospital ($n = 80$; 62 males and 18 females, aged 35-81 years, average age 58.5 years). The clinical and histological information for each case was also collected according to approved institutional guidelines. The 1997 UICC-TNM criteria were used for classification of gastric cancers.

Gastric dysplasia samples: Biopsies of gastric dysplasia lesions [low-grade noninvasive gastric intraepithelial neoplasia (GIN), $n = 30$; indefinite for dysplasia, $n = 77$] (51 males and 56 female, aged 41-65 years, average age 51.7 years) were collected from patients without malignant disease enrolled in a gastro-endoscopic survey in Linqu County, a rural area in Shandong Province, China which has one of the world's highest rates of gastric cancer^[13]. Histopathological diagnosis of each case was made by three senior pathologists at the Department of Pathology in Beijing Cancer Hospital, according to the Padova international classification^[14]. Information on *Helicobacter pylori* (*H. pylori*) infection by the ¹³C-urea breath test was also collected^[15].

Gastric biopsies from patients with and without chronic gastritis: Gastric mucosa biopsies were collected from outpatients undergoing gastro-endoscopic examination at Beijing Cancer Hospital. Of 45 gastric biopsies used in the present study, 18 patients were diagnosed with superficial chronic gastritis and 27 without obvious pathological changes (43 males and 2 female, aged 19-47 years, average age 30.7 years).

Informed consent was obtained from all subjects and the institutional review committee approved this study.

Detection of *H. pylori*

H. pylori in the normal or corresponding normal gastric samples was analyzed with a *H. pylori*-specific 23S rRNA-polymerase chain reaction (PCR) assay as described^[16].

Methylation-specific PCR (MSP)

DNA extraction, bisulfite treatment, and MSP were performed as described previously^[17,18]. The MSP primer sequences for *GATA-4* and *GATA-5* were as follows: GATA-4M sense, 5'-GTATAGTTTCGTAGTTTGCCTTTAGC-3'; GATA-4M antisense, 5'-AACTCGCGACTCGAATCCCCG-3'; GATA-4U sense, 5'-TTTGTATAGTTTGTAGTTTGTGTTTAGT-3'; GATA-4U antisense, 5'-CCCAACTCACAACCTCAAATCCCCA-3'; GATA-5M sense, 5'-AGTTCGTTTTITAGGTAGTTTTCGGC-3'; GATA-5M antisense, 5'-CCAATACAACTAAACGAACGAACCG-3'; and GATA-5U sense, 5'-TGGAGTTTGTTTTTAGGTTAGTTTITGGT-3'; GATA-5U antisense, 5'-CAAACCAATACAACCTAAACAACAACCA-3' as described by Gou *et al*^[12].

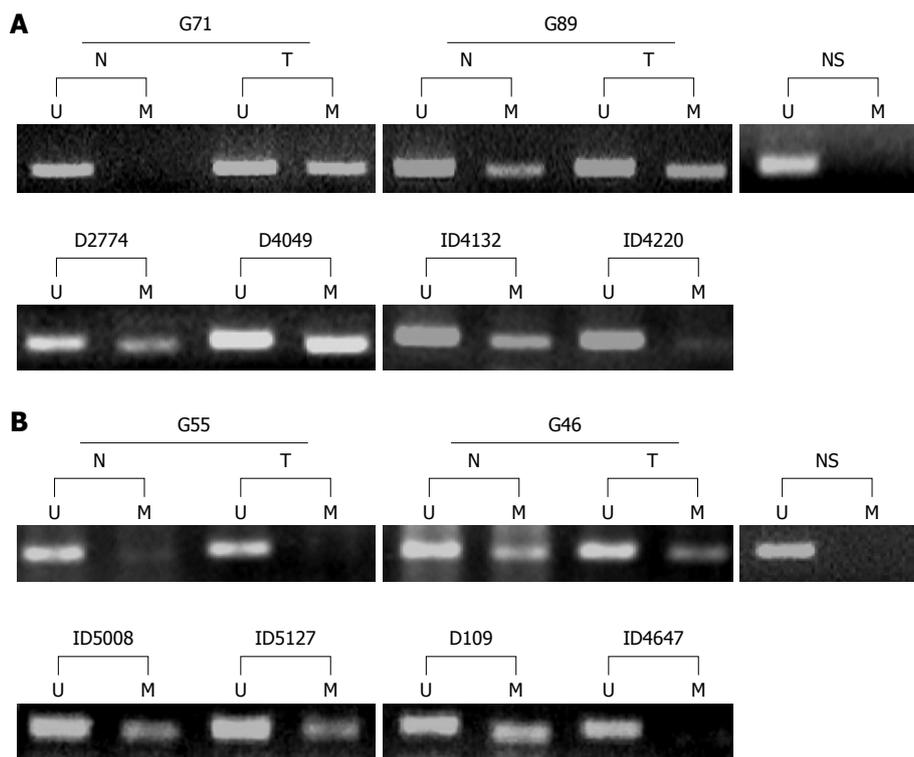

Figure 1 Methylation specific polymerase chain reaction (MSP) analyses of methylation status of the *GATA-4* (A) and *GATA-5* (B) CpG islands in human gastric mucosa samples. The upper panel shows MSP results of gastric cancer tissues (T) and their corresponding non-neoplastic tissues (N). The lower panel shows results of gastric dysplasia. The unmethylated (lanes U) and methylated (lanes M) MSP products were displayed on 2.5% agarose gels. NS: Normal stomach mucosa; D: Definite dysplasia; ID: Indefinite dysplasia.

Sequencing of the MSP products

The MSP products for *GATA-4* and *GATA-5* were sub-cloned with the pEASY-T1 simple clone system (TransGen Biotech Company, Beijing, China), and sequenced on an ABI PRISM 3730 DNA Analyzer.

Separation and quantification of the methylated *GATA-4* by denatured high performance liquid chromatography (DHPLC)^[19,20]

Both methylated and unmethylated *GATA-4* CpG islands were amplified by a universal primer set without CpG (*GATA-4*uni sense 5'-GGAGATTTTAGAGTTTGGAT-3' and antisense 5'-CTCCCACTAACTACCTCTCT-3') under thermal cycle conditions [95°C for 15 min → (95°C for 30 s → 52.8°C for 30 s → 72°C for 50 s) × 40 cycles → 72°C for 10 min]. The 385-bp PCR product of the methylated and unmethylated *GATA-4* were separated by DHPLC at a partial denaturing temperature of 57.1°C and detected by a fluorescence (FL)-detector. The proportion of the methylated *GATA-4* in the testing samples was calculated according to the ratio of the peak area for the methylated *GATA-4* to the total peak area for both the methylated and unmethylated *GATA-4*. Genomic DNA of the HCT116 cell line was used as a *GATA-4* methylation positive control.

Immunohistochemical staining (IHC)

Paraffin sections (4 μm) were dewaxed and rehydrated in xylene and ethanol. For antigen retrieval, the sections were autoclaved in 1.0 mmol/L EDTA for 5 min, followed by

immersion in 3% H₂O₂ methanol for 15 min to block endogenous peroxidase. The sections were then blocked in 15% normal goat serum in phosphate-buffered saline, followed by incubation with polyclonal *GATA-4* or *GATA-5* antibodies (Sigma-Aldrich, Inc., Missouri, USA) (1:100) overnight at 4°C. Then the sections were incubated with biotinylated goat anti-rabbit IgG working solution for 15 min at room temperature. The standard SP (Streptavidin/peroxidase) process was then performed according to the instructions for the HistostainTM-Plus Kits (Beijing Zhongshan Goldenbridge Biotechnology Company, Beijing, China). Diaminobenzidine was used as a chromogen, followed by counterstaining with hematoxylin. Normal gastric mucosa samples were used as a positive control. PBS was used as a negative control to replace *GATA-4/-5* antibody. We regarded *GATA-4* and *GATA-5* expression as positive when 10% or more cancer cells exhibited *GATA-4* and *GATA-5* expression.

RESULTS

Aberrant CpG island methylation of the *GATA-4* and *GATA-5* promoter in primary gastric cancer and their corresponding normal tissues

The promoter methylation status of *GATA-4* and *GATA-5* in eighty SGCs and their corresponding normal samples were analyzed by MSP. *GATA-4* and *GATA-5* methylation was observed in 43 and 49 SGCs (53.8% and 61.3%), respectively (Figure 1, Figure 2A and Table 1). To our surprise, these genes were also fre-

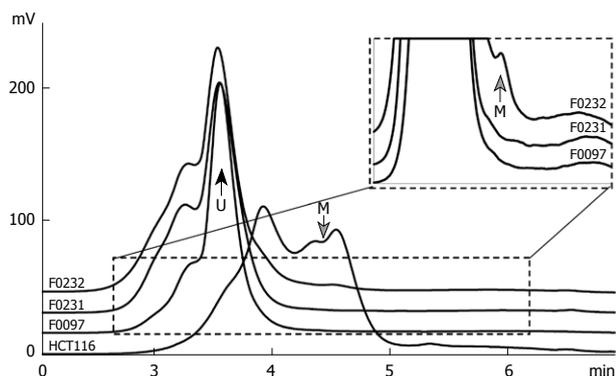

Figure 3 Chromatogram of the methylated and unmethylated *GATA-4* CpG islands by denatured high performance liquid chromatography (DHPLC). The 385-bp PCR product of the methylated and unmethylated *GATA-4* were separated by DHPLC at a partial denaturing temperature 57.1°C and detected by a fluorescence (FL)-detector. The proportion of methylated *GATA-4* in the tested samples was calculated according to the ratio of the peak area for the methylated *GATA-4* to the total peak area for both the methylated and unmethylated *GATA-4*. The gray arrow points to the peak for the methylated *GATA-4* (M) at the retention time 4.5 min; The black arrow points to the peak for the unmethylated *GATA-4* (U) at the retention time 3.6 min. Genomic DNA of HCT116 was used as the *GATA-4* methylation positive control. The inserted chart represents the dashed line surrounding the area. *GATA-4* methylation was detected in the tested sample F0232.

Table 1 Comparison of *GATA-4* and *GATA-5* methylation status with clinicopathological characteristics of SGC

Clinicopathological characteristics	Methylation positive rate (%)			
	<i>GATA-4</i>		<i>GATA-5</i>	
	SGC	N	SGC	N
SGC invasion				
T1&T2 (n = 20)	45.0 ^a	35.0 ^b	45.0	45.0
T3 (n = 50)	54.0	42.0	68.0	48.0
T4 (n = 10)	70.0	50.0	60.0	40.0
Metastasis

Total	46.9 (46/98)	52.9 (55/104)

^a χ^2 test by EpiInfo 6.0 software, with vs without *Hp*-infection, $P = 0.023$; ^bOnly two cases without *Hp*-infection; ^c χ^2 test by EpiInfo 6.0 software, Low-grade noninvasive neoplasia (GIN) vs indefinite for dysplasia, $P = 0.042$.

Table 3 Correlation of the *GATA-4* and *GATA-5* methylation status with their protein expression in sporadic gastric carcinomas with IHC

Protein expression, by IHC	<i>GATA-4</i> methylation status			<i>GATA-5</i> methylation status		
	M	U	<i>P</i> -value ^a	M	U	<i>P</i> -value
Positive (+ ~ +++)	7	11	0.012	5	9	0.011
Negative (- ~ ±)	11	3		16	3	

IHC: Immunohistochemical staining; +~+++; 10% or more cancer cells exhibited a similar positive staining pattern; - or weak: Positive expression in less than 10% cancer cells or a weak staining pattern compared with a non-cancerous area of the same section; M: Methylated; U: Unmethylated; ^aFisher's exact test by EpiInfo 6.0 software.

Among the 45 gastric biopsies (27 normal and 18 superficial chronic gastritis), *GATA-4* and *GATA-5* methylation was only 4/32 (12.5%) and 3/39 (7.7%), respectively (Figure 2C), significantly lower than the methylation in gastric dysplasia and SGCs as well as the adjacent normal samples ($P < 0.001$).

***GATA-4* and *GATA-5* expression was correlated with their methylation status**

We investigated the expression of *GATA-4* and *GATA-5* in normal and gastric carcinoma tissues using IHC. These genes were expressed in the gland region of normal gastric mucosa (Figure 5A and D). In contrast, *GATA-4* and *GATA-5* expression was obviously decreased in many gastric carcinomas (Figure 5B and E, Table 3). A significant inverse relationship was observed between *GATA-4* (or *GATA-5*) methylation and *GATA-4* (or *GATA-5*) protein expression in the gastric samples tested using IHC (Figure 3 and Table 3).

The relationship between methylation frequencies of *GATA-4* and *GATA-5* and clinicopathological parameters including *H. pylori* infection

As shown in Table 1, an increased trend of *GATA-4* methylation was observed in SGCs and the corresponding normal samples with depth of tumor invasion (T1-2, T3, T4), but was not statistically significant. The *GATA-5* methylation positive rate in the corresponding normal tis-

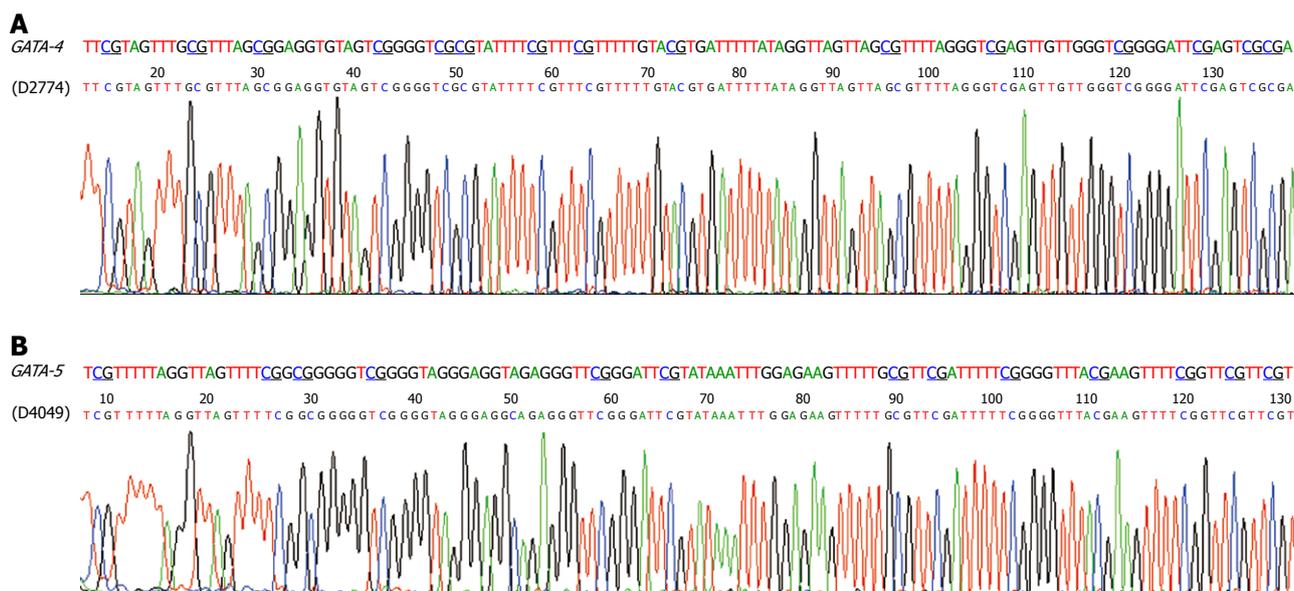

Figure 4 Sequencing of the methylated MSP products for *GATA-4* (A) and *GATA-5* (B) from two representative gastric dysplasia samples. The predicted sequence of bisulfite-modified *GATA-4* and *GATA-5* CpG islands are listed in each panel at the top. The methylated CpG sites are underlined.

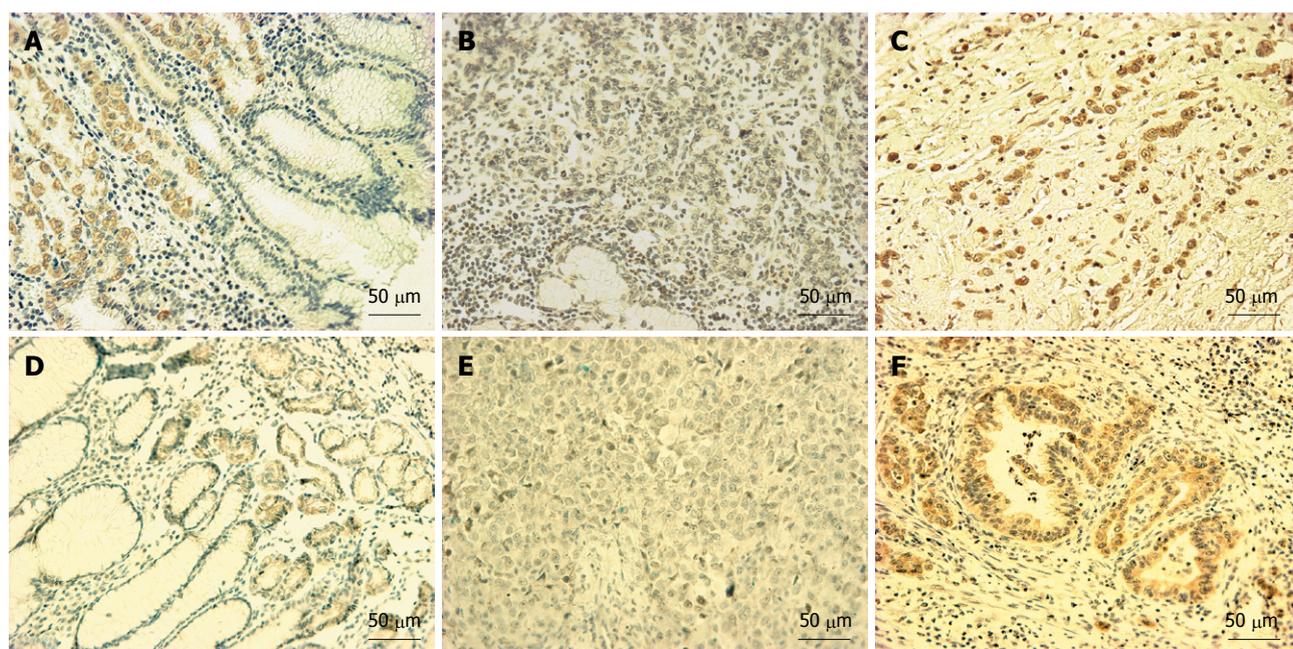

Figure 5 *GATA-4* (A-C) or *GATA-5* (D-F) protein in various gastric mucosa samples by immunohistochemical staining (IHC). A and D: *GATA-4* and *GATA-5* expression were confined to the gland region in the normal gastric mucosa; B and E: Carcinoma cells containing methylated alleles of *GATA-4* (G89) or *GATA-5* (G48) exhibited negative staining; C and F: Unmethylated cancer cells exhibited positive staining in case G27 and G45, respectively. Diaminobenzidine was used as a chromogen, followed by counterstaining with hematoxylin. Black bar, 50 μ m in length.

sues from elderly and male patients was significantly higher than that from young and female patients, respectively (Table 1).

Moreover, a correlation was observed between *GATA4* (or *GATA-5*) methylation and *H. pylori* infection. More *GATA4* and *GATA-5* methylation was detected in SGCs and their corresponding normal samples with *H. pylori* infection than in those without infection, but was not statistically significant ($P = 0.071$) (Figure 2B). In the gastric dysplasia tissues, particularly in those with

low-grade GIN, the *GATA4* methylation positive rate for the patients with *H. pylori* infection was significantly higher than that in patients without *H. pylori* infection (15/21 *vs* 1/7, $P = 0.023$, Table 2).

In addition, all 4 biopsies with *GATA4* methylation were from *H. pylori* infected patients ($n = 14$). No *GATA4* methylation was observed in biopsies from subjects without *H. pylori* infection ($n = 18$, $P = 0.027$, two-sides). Of 3 biopsies with *GATA-5* methylation, 2 were from *H. pylori* infected patients (Figure 2C).

DISCUSSION

Epigenetic silencing of *GATA4* and *GATA5* by DNA methylation has been reported in gastrointestinal cancer cell lines and primary carcinomas^[5,10,12]. However, the implication of *GATA4* and *GATA5* methylation in the development of gastric cancer is unclear. Hence, we analyzed the methylation status of *GATA4* and *GATA5* CpG islands in gastric tissues from different kinds of lesions. We found that *GATA4* and *GATA5* methylation was detected in 53.8% and 61.3% of SGCs by MSP, respectively. These results were confirmed by the quantitative DHPLC assay. Furthermore, a significant inverse relationship was observed between methylation status and their protein expression in the gastric samples tested using IHC. These results indicate that *GATA4* and *GATA5* may be frequently inactivated in SGCs by DNA methylation. Moreover, the high prevalence of *GATA4* and *GATA5* methylation in the corresponding normal tissues suggests that these aberrant methylations may be a gastric field-effect, a phenomenon which happens within the whole target regions during carcinogenesis^[21].

GATA4 and *GATA5* were also methylated in 46.9% and 52.9%, respectively, of gastric dysplasia, a precancerous lesion of gastric carcinomas. However, both of these genes were seldom methylated in gastric tissues with or without chronic gastritis [4/32 (12.5%) and 3/39 (7.7%), respectively]. These results indicate that *GATA4* and *GATA5* methylation is an early frequent event during the development of gastric carcinomas.

In addition, we found that the *GATA5* methylation positive rate in the corresponding normal tissues from elderly and male patients was significantly higher than that from young and female patients, respectively. These results are consistent with the higher incidence of gastric carcinoma in males than in females, and the increasing prevalence of gastric carcinomas among elderly subjects.

H. pylori infection is the main cause of chronic atrophic gastritis, which may play an important role in gastric carcinogenesis. A number of tumor-related genes such as *p16* could be inactivated by DNA methylation in gastric mucosa lesions with *H. pylori* infection^[22,23]. In the present study, we found that more *GATA4* and *GATA5* methylation in gastric samples from patients with *H. pylori* infection were detected than in those without *H. pylori* infection, especially for *GATA4* methylation. The *GATA4* methylation positive rate in the low-grade GIN patients with *H. pylori* infection was significantly higher than that in patients without *H. pylori* infection (15/21 *vs* 1/7, $P = 0.023$). These results suggest that *GATA4* and *GATA5* methylation could be initiated in the precancerous stage by *H. pylori* infection.

In addition, among gastric tissues with or without chronic gastritis, all 4 biopsies with *GATA4* methylation were from *H. pylori* infected patients ($n = 14$), no *GATA4* methylation was observed in biopsies from subjects without *H. pylori* infection ($n = 18$; $P = 0.027$, two-sides), and of 3 biopsies with *GATA5* methylation, 2 were from *H. pylori* infected patients. These results

again support the hypothesis that *H. pylori* infection may contribute to epigenetic inactivation of these genes in gastric mucosa.

In conclusion, *GATA4* and *GATA5* methylation was an early frequent field-effect and significantly correlated with the severity of pathological changes during gastric carcinogenesis. *H. pylori* infection may contribute to *GATA4* and *GATA5* methylation in the human stomach.

COMMENTS

Background

Tumor suppressor genes *GATA4* and *GATA5* are important for development of the stomach during embryogenesis. Epigenetic inactivation of these genes by DNA hypermethylation was previously reported in esophageal and lung cancer.

Innovations and breakthroughs

In the present study, Dr. Wen *et al* found that aberrant *GATA4* and *GATA5* methylation was also a frequent event in gastric carcinomas and their adjacent tissues. Interestingly, their work demonstrated that epigenetic inactivation of *GATA4* and *GATA5* was observed in about 50% of gastric mucosa samples with epithelial dysplasia, a precancerous lesion in the stomach. However, such a phenomenon was very rare in gastric mucosa biopsies from healthy subjects or patients with chronic gastritis. They also observed that *Helicobacter pylori* (*H. pylori*) infection correlated well with *GATA4* and *GATA5* methylation. These results indicate that epigenetic inactivation of *GATA4* and *GATA5* is an early frequent event during gastric carcinogenesis by *H. pylori* and might be used to screen patients with a high risk of stomach cancer.

Peer review

The authors have tried to show that methylation of *GATA4* and *GATA5* could be important in the oncogenesis of gastric mucosa in patients coming from a Chinese area where gastric cancer is common. They showed that in cancer and adjacent mucosa methylation of these two antioncogenes is common and apparently related mostly with chronic *H. pylori* infection.

tail (19.5%). Forty-five patients (9.2%) were diagnosed as malignant SPT with metastasis or invasion. None of the clinical factors was closely related to the malignant potential of SPT. Surgery was the main therapeutic modality for SPT. Local resection, distal pancreatectomy and pancreatoduodenectomy were the most common surgical procedures. Local recurrence and hepatic metastasis were found in 11 and 2 patients, respectively, after radical resection. Four patients died of tumor progression within 4 years after palliative resection of SPT. The prognosis of SPT patients was good with a 5-year survival rate of 96.9%.

CONCLUSION: SPT of the pancreas is a rare indolent neoplasm that typically occurs in young females. It is a low-grade malignancy and can be cured with extended resection. The prognosis of such patients is good although the tumor may recur and metastasize.

Abstract

AIM: To sum up the clinical and pathological characteristics of solid pseudopapillary tumor (SPT) and the experience with it.

METHODS: A total of 553 SPT patients reported in Chinese literature between January 1996 and January 2009 were retrospectively reviewed and analyzed.

RESULTS: The mean age of the 553 SPT patients included in this review was 27.2 years, and the male to female ratio was 1:8.37. Their symptoms were non-specific, and nearly one third of the patients were asymptomatic. Computed tomography and ultrasonography were performed to show the nature and location of SPT. Most of the tumors were distributed in the pancreatic head (39.8%), tail (24.1%), body and

INTRODUCTION

Solid pseudopapillary tumor (SPT) of the pancreas, first reported by Frantz in 1959^[1], is an uncommon but distinct pancreatic neoplasm with a low malignancy, accounting for 1%-2% of all pancreatic tumors^[2]. Different names of this tumor were reported until it was defined by the World Health Organization (WHO) in 1996 as a “solid pseudopapillary tumor” of the pancreas^[3]. SPT occurs mainly in young women and can be treated with surgical resection. SPT patients have a relatively favorable prognosis after surgical resection. With the widespread availability of high-quality imaging systems and a better understanding of its pathology, the number of such patients reported in the literature has been steadily increased. Papavramidis has summarized 718 SPT patients in English literature, mainly from USA, Europe, and Japan^[4]. In this study, the cases of SPT reported in current Chinese literature were reviewed and analyzed.

MATERIALS AND METHODS

SPT-related literatures covered in the Chinese biology and medicine database (CBMD) and the China hospital knowledge database (CHKD) between January 1996 and January 2009 were retrieved. Indexing terms used for the retrieval were SPT, solid cystic tumor, papillary cystic tumor, papillary epithelial neoplasia, solid and papillary epithelial neoplasia, papillary epithelial tumor, Frantz’s tumor, solid and papillary tumor, solid and cystic papillary epithelial neoplasm, benign or malignant papillary tumor of the pancreas. A total of 241 articles were searched. Each article was carefully studied to avoid the repetitive adoption of the saved material. A database of the characteristics of these patients was developed, including age, gender, symptoms, tumor location (data were from radiological investigations or surgical record) and size (data were from radiological investigations or surgical record and finally confirmed by pathology), metastasis or invasion of adjacent tissues (data were from radiological investigations or surgical exploration, and finally was confirmed by pathology), treatment (data were from the record of therapy, including the types of surgery), and follow-up. Each case with at least 6 of these characteristics was defined as well-documented. Thus, a total of 117 articles describing 553 well-documented cases of pancreatic SPT were included in our review and analysis. All statistical analyses were performed using the SPSS 15.0 for Windows (Chicago, Illinois).

RESULTS

Of the 553 patients, 59 were men and 494 were women with a male to female ratio of 1:8.37. Their mean age was 27.2 years (range 6 -71 years).

The features of 473 SPT patients (85.5%) are listed in Table 1. The symptoms were non-specific, and coexistence of two or more symptoms was usually found.

Table 1 Symptoms of SPT patients (n = 473)

Symptoms	Patients (n)	%
Abdominal pain	178	37.63
Abdominal mass	170	35.94
Abdominal discomfort	155	32.77
Asymptomatic	150	31.70
Vomiting	25	5.29
Post-trauma	23	4.86
Nausea	19	4.01
Back pain	17	3.59
Jaundice	17	3.59
Anorexia	11	2.33
Weight loss	9	1.90
Fever	7	1.48
Other symptoms	5	1.06

SPT: Solid pseudopapillary tumor.

Nearly one third of the patients were asymptomatic, with the tumor found at routine physical examination. The tumor was localized in 507 patients (91.7%). The most common sites of the tumor were the pancreatic head (39.8%), tail (24.1%), body and tail (19.5%), body (11.2%), and neck (3.6%). SPT was found in extra-pancreatic tissues of retroperitoneum, mesenterium, and left adrenal gland in 9 patients (1.8%). The tumor sizes in 512 cases (92.6%) were provided. The mean diameter of the tumor was 7.87 cm (range 1-25 cm).

CT, US and magnetic resonance imaging (MRI) were performed for the evaluation of 460 (83.2%), 337 (60.9%) and 43 patients (7.8%), respectively. Preoperative fine needle aspiration cytology (FNAC), endoscopic ultrasounds (EUS), and endoscopic retrograde cholangiopancreatography (ERCP) were seldom performed. Of the 325 patients (75.0%) diagnosed before operation, only 77 (23.7%) were diagnosed as or suspected of SPT. The misdiagnosis rate for pancreatic adenocarcinoma, cystadenoma, cystadenocarcinoma, islet cell tumor, pancreatic cyst, neuroendocrine tumor, teratoma, and others was 24.6%, 10.7%, 3%, 13.2%, 7.3%, 8.6%, 1.9%, and 7%, respectively. The masses were shown on cross-sectional imaging as heterogeneous (n = 300, 60.12%), cystic (n = 78, 15.63%), or solid (n = 121, 24.25%).

Of the 491 patients (88.8%) with metastasis or invasion, 45 (9.2%) were diagnosed as malignant SPT. The liver, portal/splenic vein/superior mesenteric vein, spleen, diaphragmatic muscle, omentum or peritoneum, duodenum, stomach, colon, and left kidney were involved in 6, 11, 4, 1, 7, 7, 3, 2 and 1 patients, respectively. Enlarged lymph nodes and lymph node metastasis were detected in 10 and 3 patients, respectively. The level of tumor markers, including α -fetoprotein (AFP), carcinoembryonic antigen (CEA), carbohydrate antigen (CA) 19-9, CA125 and CA242, was slightly increased in 11 patients, but only two were diagnosed as malignant SPT. Other clinical factors, including sex, age, symptoms, and tumor size, location and characteristics, were analyzed in some reports. However, none of the features was found

Table 2 Surgical procedures for 315 SPT patients

Operation	Patients (n)	%
Local resection or enucleation	104	33.02
Distal pancreatectomy	99	31.43
Pancreatoduodenectomy	81	25.71
Central pancreatectomy	19	6.03
Total pancreatectomy	2	0.63
Palliative operation	10	3.17
Portal vein reconstruction	3	0.95

to be closely related with the malignant potential of SPT in our study.

At present, radial resection is the main treatment of choice for pancreatic SPT. Local resection, distal pancreatectomy, and pancreatoduodenectomy were the most commonly used surgical procedures for the 315 patients included in our study (Table 2). Resection of a cuff of the portal vein was performed in 3 patients with a vein graft repair and palliative operation was performed in 10 patients as the tumor was adhered to the adjacent tissues or its metastasis was not resectable. Of the 6 patients with liver metastasis, 1 underwent liver operation, 2 had liver biopsy for the metastasis followed by dehydrated alcohol injection and transarterial chemoembolization (TACE), and 3 received γ -radiation therapy, chemotherapy and radiofrequency, respectively. The most common complication after operation was pancreatic fistula which occurred in 17 cases (5.4%). Other complications including pancreatitis, steatorrhea, wound infection, biliary fistula, prolonged gastric emptying, gastrointestinal bleeding, diabetes mellitus, and ileus were observed in 3 (0.95%), 3 (0.95%), 3 (0.95%), 2 (0.63%), 2 (0.63%), 2 (0.63%), 1 (0.32%), and 1 (0.32%) patients, respectively.

The data of immunohistochemical profile are listed in Table 3. SPT cells were typically positive for vimentin, a1-antitrypsin, a1-antichymotrypsin, and neuron specific enolase. Focal expression of synaptophysin, cytokeratin and chromogranin A was detected in a few tumors. The positive rate was higher for progesterone receptor than for oestrogen receptor, but usually variable. Immunohistochemical staining of Ki-67 was detected in 12 patients, and 4 of 5 patients positive for Ki-67 immunoreactivity were confirmed to have malignant SPT.

Three hundred and twenty-three patients were followed-up for a mean time of 49.2 mo (range 1-209 mo). Radical resection was performed in 305 patients (94.4%), with a mean disease free-survival time (DFS) of 45.1 mo. Of the 11 patients (3.6%) who had local recurrence, 8 received a second resection with a mean DFS of 23.9 mo. Six patients died after complete resection, including two with unrelated disease. Hepatic metastasis occurred in 2 patients 3 and 46 mo respectively after surgery. One is still alive and the other was dead due to metastasis of the tumor. Of the 10 patients after palliative resection, 4 died with a median survival time of 22.4 mo (range 9-47 mo).

Table 3 Immunohistochemical parameters of SPT

Antigen	Patients (n)	Positivity, n (%)
AAT	276	261 (94.6)
Vim	289	269 (93.1)
AACT	237	215 (90.7)
NSE	221	179 (81.0)
CD56	43	29 (67.4)
CD10	51	33 (64.7)
PR	157	89 (56.7)
Ki67	12	5 (41.7)
Syn	196	83 (42.3)
CK	213	66 (31.0)
CgA	193	45 (23.3)
ER	97	11 (11.3)

AAT: a1-antitrypsin; Vim: Vimentin; AACT: a1-antichymotrypsin; NSE: Neuron specific enolase; PR: Progesterone receptor; Syn: Synaptophysin; CK: Cytokeratin; CgA: Chromogranin A; ER: Estrogen receptor.

The estimated 1-, 3- and 5-year survival rate was 99.4%, 97.5%, and 96.9%, respectively. The clinicopathologic features and outcome of SPT in 5 large series reported in Chinese literature between January 1996 and January 2009 are shown in Table 4^[5-9].

DISCUSSION

SPT of the pancreas is a rare neoplasm with a low malignant potential, usually affecting young women in the second or third decade of life. Its pathogenesis still remains unknown, although its tendency to affect young women is due to the involvement of sex hormones. However, no difference has been found in immunohistochemical staining for sex hormone-receptor proteins or in clinicopathologic characteristics attributable to gender alone^[10]. Sun *et al*^[11] reported that 62.5% of SPT patients are infected with hepatitis B virus (HBV), which can induce over-expression of β -catenin in tumor cells, indicating that HBV infection may be involved in the pathogenesis of SPT, which, however, has not been confirmed.

Although the malignant potential of SPT is low, up to 15% of SPT patients develop metastasis. The most common sites of metastasis are the liver, regional lymph nodes, mesentery, omentum, and peritoneum^[12]. Local invasion of the duodenum, stomach, spleen or major blood vessels may also occur, as reported in our study. Washington *et al*^[13] showed that the clinical and pathologic features of SPT, including diffuse growth, venous invasion, nuclear pleomorphism, mitotic rate, necrosis and dedifferentiation, are related to its aggressive behavior or metastatic potential. Other studies indicate that DNA aneuploidy, double loss of X chromosomes, trisomy for chromosome 3, unbalanced translocation between chromosomes 13 and 17 found in SPT patients are associated with its aggressive behavior and may be indicators of its possible metastatic potential^[14,15]. In our study, the clinical factors, including sex, age, symptoms,

Table 4 Clinicopathological features and outcome of SPT

and tumor size, location and characteristics were not closely related to its malignant potential. Four of the 5 patients positive for Ki-67 immunoreactivity were confirmed to have malignant SPT, which is consistent with the reported findings^[16], suggesting that positive staining of Ki-67 may correlate with the malignant potential and poor outcome of SPT. However, there are some limitations in our study due to the available data, more SPT patients should be studied for Ki-67 and new biomarkers in order to better predict its malignancy.

The clinical presentation of SPT is usually unspecific. Most patients have unclear clinical features including abdominal pain or discomfort, poor appetite and nausea, which are related to tumor compression on adjacent organs. SPT is often diagnosed during complementary imaging investigations such as ultrasound or CT scan of the abdomen, usually showing a well-encapsulated complex mass with both solid and cystic components. Dynamic contrast-enhanced CT can show less enhanced tumor, typical cystic spaces in the center, and enhanced solid areas at its surroundings^[17]. MRI is better than CT in detecting the cystic or solid components of the tumor. If MRI reveals an encapsulated mass with solid and cystic components as well as hemorrhage without obvious internal septum, SPT of the pancreas should be highly suspected^[18]. Percutaneous or EUS-guided FNAC can help to distinguish SPT from other pancreatic tumors. However, reports are also available on seeding of the needle tract by neoplastic cells and complications such as bleeding, pancreatic fistula and biliary fistula during the procedure^[19]. Despite the technological advances, preoperative diagnosis is still difficult and only 77 patients were diagnosed as or suspected of SPT in our series. The results of our study show that CT/MRI scans combined with age and gender should be sufficient for the decision to operate, and diagnostic interventions such as FNAC should be performed when radiology fails in diagnosing it.

At present, radical resection is the treatment of choice for SPT even with metastasis or local recurrence. Local resection or enucleation can be performed for small tumors with complete amacula. Distal pancreatectomy combined with or without splenectomy can be performed for pancreatic body and/or tail tumor, and pancreaticoduodenectomy for pancreatic head tumor. Intra-operative frozen section may help to ascertain

the adequate resection of margins. Extensive lymphatic dissection is not warranted since lymph node metastasis was found in only 3 patients (0.61%) in our study. Surgery should be performed for the tumor with local invasion or metastasis^[20]. Sperti *et al*^[21] have reported 17 patients who underwent vascular resection and reconstruction with no death occurred. In our study, the infiltrated portal veins were reconstructed with vein grafts after *en-bloc* resection and the patients had a long survival time. Martin *et al*^[2] reported that four patients underwent resection of liver metastasis and primary tumor, and two of them survived for at least 6 and 11 years, respectively. Other treatment modalities for liver metastasis, such as alcohol injection, TACE, γ -radiation therapy and even liver transplantation, have been reported^[11,22]. The role of chemotherapy and radiotherapy in treatment of SPT is poorly defined at present, since only few reports are available on them.

Grossly, SPT is well-encapsulated and usually well-demarcated from the pancreas, with large spongy areas of hemorrhage on its cut surface alternating with both solid and cystic degenerations. The tumor contains a mixture of solid, cystic, and pseudopapillary patterns in various proportions. The solid portions of the tumor are composed of uniform and polygonal epithelioid cells with well-vascularized stroma and a discohesive arrangement^[12]. Immunohistochemically, SPT is typically positive for vimentin (Vim), a-1-antitrypsin (AAT), a-1-antichymotrypsin (AACT), and neuron specific enolase (NSE)^[23], which is consistent with the finding in our study. However, the unique immunohistochemical features with expression of CD56 and CD10 have not reached an agreement in a recent study^[24]. SPT cells may also reveal focal immunoreactivity for cytokeratin (CK) and synaptophysin (Syn), abnormal nuclear location of β -catenin, and presence of progesterone receptors (PR), and may express galectin-3, all of which are useful in differentiating SPT from endocrine pancreatic tumor^[24].

The prognosis of SPT patients even with local recurrence and metastasis or invasion is good. SPT is limited to the pancreas in over 95% of its patients and can be radically resected^[25]. Its local recurrence rate is less than 10% and usually occurs within 4 years after surgery^[21]. Recurrence, local invasion, and limited metastasis are not the contraindications for resection,

and some patients with “unresectable” SPT may also have a long survival time^[26]. It has been reported that the overall 5-year survival rate of SPT patients is about 95%^[4]. Due to the favorable prognosis and long survival rate of SPT patients with local recurrence or metastasis, it is difficult to identify the predictive factors for their survival time.

Although this retrospective review has certain limits due to the available data, our results are consistent with the reported findings^[4,11]. Further study should be based on the selective cases with more detailed information.

In conclusion, SPT, an infrequently-encountered tumor, typically affects young women without significant symptoms. Its behavior is relatively indolent and largely benign. Patients may survive a long time after radical resection of the tumor. Whenever possible, surgery is justified for local invasion or metastasis of SPT. The prognosis of SPT patients even with unresectable metastasis is good. The role of chemotherapy and radiotherapy remains to be studied.

COMMENTS

Background

Solid pseudopapillary tumor (SPT) of the pancreas is a rare neoplasm with a low malignant potential, usually affecting young women in the second or third decade of life. With widespread availability of high-quality imaging systems and a better understanding of its pathology, the number of cases reported in the literature has been steadily increased in recent years.

Research frontiers

The clinical and pathological characteristics of SPT are still not fully recognized. Although a variety of radiological investigations have been performed for the evaluation, its misdiagnosis rate is still high. The experience in management of SPT, especially with a malignant potential, is still not adequate enough.

Innovations and breakthroughs

In this study, the authors collected relatively comprehensive data from the published Chinese literature and found that SPT is potentially curable with extended resections. The prognosis of SPT patients even with recurrence or unresectable metastasis is good. In addition, the authors analyzed the potential relation between hepatitis B virus infection and pathogenesis of SPT. The positive staining of Ki-67 may correlate with the malignant potential and poor outcome of SPT.

Applications

The results of this study indicate that the behavior of SPT is relatively indolent and largely benign. However, surgical resection is warranted since patients can survive a long time after it.

Peer review

This is a retrospective study summarizing a considerable number of patients (553 patients) with SPT of the pancreas covered in two Chinese databases. The manuscript is consisted of a good description of the patients with their demographic data, symptoms, imaging studies, location and invasion, surgical data and complications, pathology, immunohistochemical profile and survival time provided.

growth factor (NGF) and glucose tolerance (GTT) up to postoperative day (POD) 14. Histological assessment for insulin, von Willebrand factor (vWF) and NGF was performed at POD 3, 7 and 14.

RESULTS: Blood glucose level was lowest and serum insulin was highest in the islet + bone marrow group. Serum NGF increased in islet, bone marrow, and islet + bone marrow groups after transplantation, and there was a significant difference ($P = 0.0496$, ANOVA) between the bone marrow and sham groups. The number of vessels within the graft area was significantly increased in both the bone marrow and islet + bone marrow groups at POD 14 as compared to the islet alone group (21.2 ± 3.6 in bone marrow, $P = 0.01$, vs islet group, 22.6 ± 1.9 in islet + bone marrow, $P = 0.0003$, vs islet group, 5.3 ± 1.6 in islet-alone transplants). NGF was more strongly expressed in bone marrow cells compared with islets.

CONCLUSION: Bone marrow cells produce NGF and promote angiogenesis. Islet co-transplantation with bone marrow is associated with improvement of islet graft function.

Abstract

AIM: To clarify the mechanism by which bone marrow cells promote angiogenesis around transplanted islets.

METHODS: Streptozotocin induced diabetic BALB/c mice were transplanted syngeneically under the kidney capsule with the following: (1) 200 islets (islet group: $n = 12$), (2) $1-5 \times 10^6$ bone marrow cells (bone marrow group: $n = 11$), (3) 200 islets and $1-5 \times 10^6$ bone marrow cells (islet + bone marrow group: $n = 13$), or (4) no cells (sham group: $n = 5$). All mice were evaluated for blood glucose, serum insulin, serum nerve

INTRODUCTION

Islet transplantation is a promising treatment for type 1 diabetes mellitus (T1DM). However, clinical islet transplantation using current protocols has not yet yielded long-term insulin-independence^[1]. One of the hurdles to overcome is the lack of a vascular network to support the newly transplanted islets. Initial avascularity in the period during islet isolation, transplantation^[2,3], and the establishment of a vascular network around islets renders islets vulnerable to severe hypoxia for up to 14 d after transplantation^[4]. Therefore, the promotion of angiogenesis is an important endeavor to prevent islet graft failure.

Recently, bone marrow transplantation as a cell therapy for resolution of clinical diseases has been studied. Endothelial precursor cells (EPCs), a heterogeneous population originating in the hematopoietic compartment of bone marrow, have an important role in the angiogenesis of adult tissues^[5]. Transplanted EPCs induce hypoxia-inducible factor-1 α (HIF-1 α) under hypoxic conditions which leads to upregulation of vascular endothelial growth factor (VEGF) and promotes vascularization^[5-7]. Our previous study revealed that transplanted bone marrow produces VEGF and promotes vascularization around the co-transplanted islets^[8].

Nerve growth factor (NGF), which plays an important role in promoting growth, differentiation and function of nerve cells^[9,10] has been shown to have an important role in angiogenesis by stimulating VEGF^[10,11]. Moreover, NGF is secreted by islets and may have a beneficial effect on islet function^[12]. In this study, we focused on NGF levels and its effects to clarify the mechanism of angiogenesis brought by bone marrow cell transplantation.

MATERIALS AND METHODS

Animals

BALB/c male mice (22-27 g, Charles River Laboratories, Inc., Boston, MA, USA) were used as both donors and recipients. The mice were housed under pathogen-free conditions with a 12-h light cycle and free access to food and water. All animal care and treatment procedures were approved by the Institutional Animal Care Use Committee.

Induction of diabetes in recipient mice

Streptozotocin (STZ, 200 mg/kg per mouse, Sigma-Aldrich, St. Louis, MO, USA) was injected intraperitoneally and blood glucose levels were measured by Accu-Chek Aviva glucose monitors (Roche, Indianapolis, IN, USA). We used the recipient mice once the blood glucose level was greater than 19.3 mmol/L (350 mg/dL).

Islet isolation

Murine islets were isolated by collagenase (collagenase V, Sigma-Aldrich) digestion, and separated by Ficoll (Sigma-Aldrich) discontinuous gradients and purified as previously

described^[13]. Collected islets were 133-200 μm in size^[14]. Based on previous results^[15], 200 islets were considered a marginal islet mass for restoring normoglycemia in streptozotocin-induced diabetes.

Bone marrow cell isolation

The protocol of bone marrow cell isolation was modified from the Soleimani method^[16]. Under general anesthesia with 2% isoflurane, hind limb extirpations were performed at the hip, knee and ankle joint. Muscle and connective tissue were dissected away from the femur and tibia, the knee joint and both ends of the bones were cut. A thirty gauge needle with a 1 mL syringe was inserted into the bone, and bone marrow was flushed by injection with Hanks balanced salt solution (HBSS) for collection. After a single wash, bone marrow was dispersed by incubation with 0.05% trypsin/0.53 mmol/L EDTA solution (Mediatech Inc., Manassas, VA, USA).

Islet and bone marrow cell transplantation and group classification

Cell transplantation was performed under the left kidney capsule. Recipients were divided into four graft groups: (1) islet-alone (200 syngeneic islets per recipient, $n = 12$), (2) bone marrow ($1-5 \times 10^6$ syngeneic bone marrow cells per recipient, $n = 11$), (3) islet + bone marrow (200 syngeneic islets and $1-5 \times 10^6$ syngeneic bone marrow cells, $n = 13$) and (4) sham (skin and renal capsule incisions with no transplantation, $n = 5$).

Islet function parameters

Blood glucose and serum insulin were measured at postoperative days (POD) 0, 3, 7 and 14. Glucose tolerance was assessed at POD 7 and 14. Achievement of normoglycemia was defined as a non-fasting blood glucose level of ≤ 11 mmol/L (200 mg/dL). Intraperitoneal glucose tolerance tests (GTT) were performed by overnight fasting for 10 h and then injecting mice with a 2.0 g/kg body weight of glucose solution followed by tail vein blood samples at 0, 15, 30, 60, 90 and 120 min after injection. Blood glucose levels were measured by Accu-Chek Aviva glucose monitors and serum insulin was measured with a rat/mouse insulin enzyme-linked immunosorbent assay (ELISA) kit (Linco, MO).

Serum NGF measurement

Blood samples for serum NGF were obtained at POD 0, 3, 7 and 14 as for serum insulin. Serum NGF was measured with a NGF ELISA kit (NGF E_{max}[®] ImmunoAssay System, Promega, Madison, WI, USA).

Correlation between NGF and islet functional parameters

To evaluate whether NGF level affects islet function, simple regression analysis was performed between serum NGF and each of the following parameters: blood glucose, serum insulin and area under the curve (AUC)^[17]. All the data acquired from POD 0 to 14 were applied to the analysis.

Histological assessment

Kidney specimens were obtained from three or more mice at POD 3, 7 and 14 and photographs of the fresh organs were taken to assess the density of new vessels around islets and/or bone marrow. Tissue was then fixed with 10% formalin, embedded in paraffin, and cut into 5 μ m sections. Specimens were stained with hematoxylin and eosin (HE) to identify cellular changes. Apoptosis was detected by the terminal deoxynucleotidyl transferase (TdT)-mediated dUTP-biotin nick end labeling (TUNEL) method using an *in situ* apoptosis detection kit (Promega). Sections were treated with proteinase K and incubated with TdT enzyme for 60 min at 37°C. After washing in Phosphate buffer solution (PBS) the sections were further incubated with streptavidin horseradish peroxidase (HRP) solution and visualized with 3,3'-diaminobenzidine (DAB). Immunohistochemical staining was done for insulin (islets), von Willebrand Factor (vWF, for newly formed blood vessels) and NGF. For vWF, specimens were treated with Proteinase K (Dako, Carpinteria, CA). Primary antibodies were guinea pig anti-insulin antibody (Dako, Carpinteria, CA, USA) diluted 1:100, rabbit anti-vWF (Abcam, Cambridge, MA) diluted with 1:2000 and rabbit anti-NGF (Santa Cruz Biotechnology Inc.) diluted 1:100. After incubating with biotinylated secondary IgG antibody (Vector Laboratories, Burlingame, CA, USA and Santa Cruz Inc.), a peroxidase substrate solution containing DAB (Brown, Dako) or aminoethylcarbazol (AEC, Red for insulin, Dako) was used for visualization and counterstained with hematoxylin.

vWF-positive vessel numbers were calculated from vWF-positive lumens at the transplant site.

Statistical analysis

Data are expressed as mean \pm SE of the mean. All the statistical analyses were performed with JMP 5.0.1J for Macintosh (SAS Institute Inc., Cary, NC, USA). Dunnett *t*-test or analysis of variance (ANOVA) was performed. Significance was designated at $P < 0.05$. Correlation coefficients (R^2) in regression analysis were defined as follows: Very strong correlation as $0.8 < R^2 < 1.0$; strong as $0.5 < R^2 < 0.8$, moderate as $0.25 < R^2 < 0.5$; weak $R^2 < 0.25$. Correlation was designated positive when the R^2 was over 0.25 (moderate).

RESULTS

Blood glucose, serum insulin and GTT

These data were previously published^[8]. In summary, islet co-transplantation with bone marrow yielded lower blood glucose, higher serum insulin, and improved glucose tolerance.

Serum NGF

Serum NGF levels were higher in islet, bone marrow and islet + bone marrow groups than in the sham group, and were higher at all times points relative to pre-transplant levels ($P < 0.05$, Figure 1). The increase was

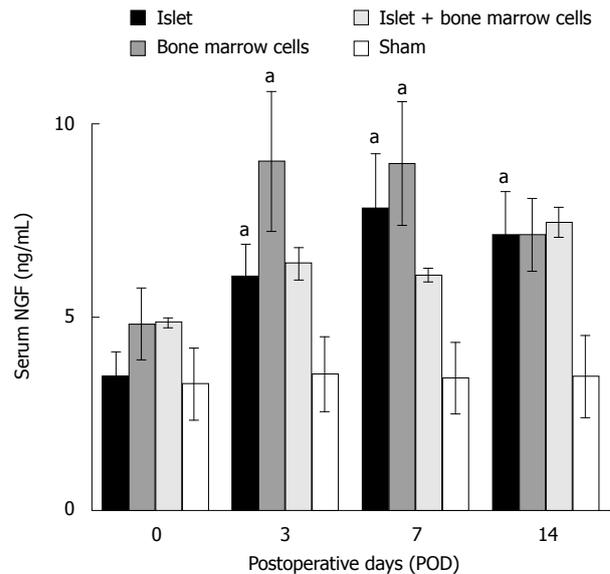

Figure 1 Serum nerve growth factor (NGF) data. Serum NGF levels increased post-transplantation in islet, bone marrow, and islet + bone marrow groups, while there was no increase in the sham group. There was a significant difference between bone marrow and sham group. Statistical analysis was performed by two ways repeated measurement ANOVA and significant difference was $^aP < 0.05$ vs POD 0.

most prominent in the bone marrow *versus* the sham group ($P = 0.0496$, ANOVA).

New vascularization

These data were previously published^[8]. In summary, bone marrow transplantation with or without islets was associated with enhanced angiogenesis which was more prominent in bone marrow alone than in the combined islet-bone marrow group [21.2 ± 3.6 in bone marrow ($P = 0.01$, *vs* islet group), 22.6 ± 1.9 in islet + bone marrow ($P = 0.0003$, *vs* islet group), 5.3 ± 1.6 in islet-alone transplants].

Histological findings

NGF was much more strongly expressed in bone marrow cells as compared to islets at every time point (Figure 2). No apoptotic (TUNEL positive) islets were detected in any of the experimental groups (data not shown).

Correlation between serum NGF and islet function parameters

There were no significant correlations between serum NGF and blood glucose, serum insulin or glucose tolerance (Figure 3).

DISCUSSION

NGF is a neurotrophin that plays a crucial role in promoting growth, differentiation and function of sympathetic nerve cells^[9,10,18]. NGF levels decrease with diabetes and are correlated with neuropathy. Thus a therapeutic trial to increase NGF has been performed to improve diabetic neuropathy^[19]. Recently, some studies

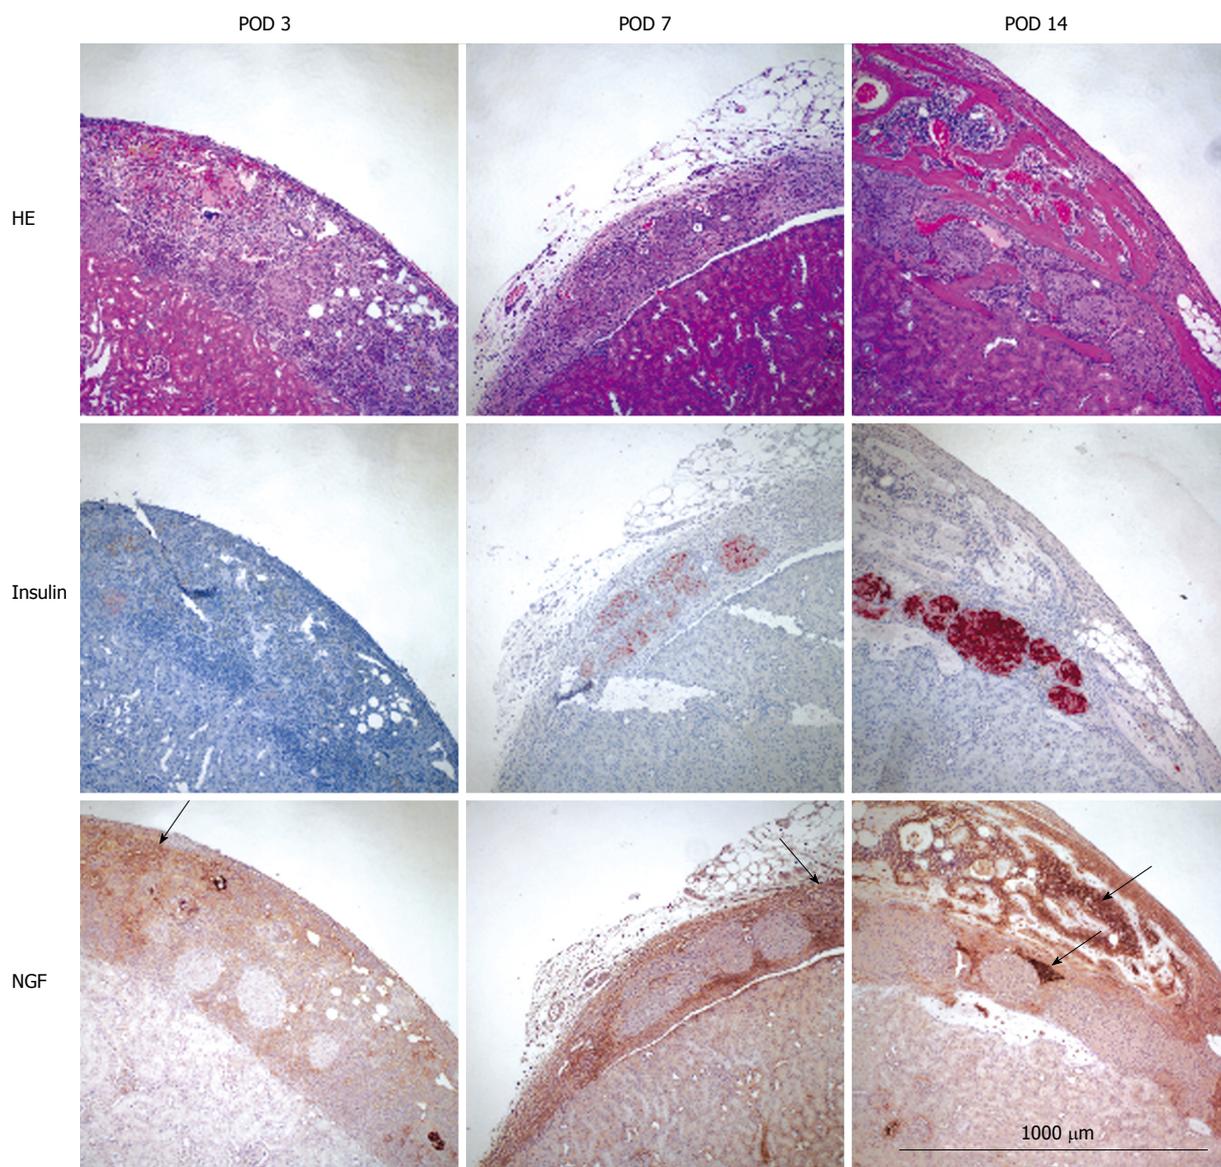

Figure 2 Histological findings. Kidney specimen from islet + bone marrow group stained with HE (top), Insulin (middle) and NGF (bottom) at POD 3, 7 and 14. Bone marrow cells stained strongly for NGF compared to islets at all time points (indicated by arrow). Magnification = 100 ×, Calibration bar = 1000 μm.

have reported the angiogenic effects of NGF^[10,20-25]. Earlier studies showed that NGF promotes the neovascularization of endothelial cells using HUVEC or matrigel assays^[20,24].

In diabetes, NGF has been shown to reverse local tissue hypoxia and endothelial cell impairment^[23,25]. Treatment with NGF prevents apoptosis of endothelial cells related with neovascular formation and progress^[22-25]. Angiogenesis induced by NGF is presumed to help in wound closure^[25] and recovery of ischemia in diabetics^[23], as well as organ remodeling^[26]. NGF may also contribute to the progress, migration and metastasis of tumors^[21,27].

We have previously shown that treatment with NGF improved islet function *in vitro* and *in vivo* and promoted vessel formation around transplanted islets^[12]. NGF may have a role in islet transplantation by promoting angiogenesis and preventing hypoxia at the early post-transplant period. However, this remains to be tested and reproduced

in appropriate trials.

In a previous study, we showed an association between bone marrow cell transplantation and angiogenesis around islets, together with enhanced VEGF expression and improved islet function^[8]. A potential role for NGF in these improvements was the focus of this study in view of reports that NGF is derived from bone marrow stem cells^[28] and stimulates VEGF, promoting angiogenesis^[10,11]. NGF's stronger expression in bone marrow relative to islets in this study was not predicted especially in view of the increase in serum NGF level in the islet group though it may be a function of ambient glucose concentration^[29]. Effects on islet graft function may also be related to the type of NGF receptor activated in the context of bone marrow co-transplantation^[30].

NGF is induced by hypoxia^[23] and also has anti-apoptotic roles^[31], therefore, it has the potential to improve the function and survival of transplanted islets^[12]. No

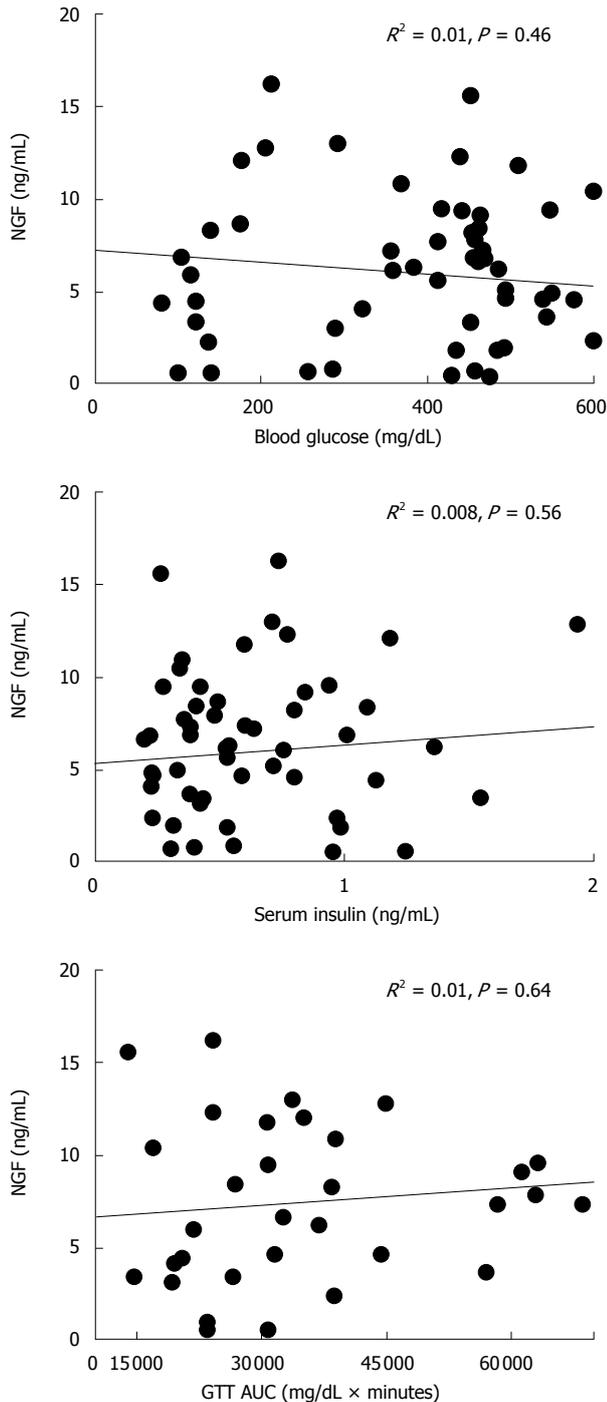

Figure 3 Correlation between serum NGF and blood glucose, serum insulin and GTT AUC. There were no correlation between serum NGF and other islet functional factors. $R^2 > 0.25$ and $P < 0.05$ is significant correlation.

apoptotic islets were detected during the observation span of this study, but renal subcapsular islet transplantation may not uniformly manifest the effects of severe ischemia seen with intraportal islet transplantation^[14]. Therefore, NGF may be particularly beneficial for intraportal islet transplantation.

The lack of correlation between serum NGF and other islet parameters (blood glucose, serum insulin and GTT) remains to be further confirmed. NGF levels vary according to the condition of islets. For example,

one study revealed that STZ stimulation increased NGF secretion^[32] while another showed that NGF is decreased in diabetes-associated conditions^[23]. On the other hand, NGF may reflect the status of islet vascularization rather than its function.

In conclusion, NGF production may underlie the beneficial effect of bone marrow co-transplantation on islet graft function. The mechanism of this potential benefit deserves further investigation.

We are very appreciative of the microsurgical technical support of the Loma Linda University Microsurgery Laboratory and the kind help in specimen processing by John Hough.

COMMENTS

Background

Islet transplantation is a promising treatment for type 1 diabetes mellitus (T1DM). However, clinical islet transplantation using current protocols has not yet yielded long-term insulin-independence. One of the hurdles to overcome is the lack of a vascular network to support the newly transplanted islets. The promotion of angiogenesis is an important endeavor to prevent islet graft failure.

Research frontiers

Nerve growth factor (NGF) is a neurotrophin that plays a crucial role in promoting growth, differentiation and function of sympathetic nerve cells. NGF levels decrease with diabetes and are correlated with neuropathy. Thus a therapeutic trial to increase NGF has been performed to improve diabetic neuropathy. Recently, some studies have reported the angiogenic effects of NGF.

Innovations and breakthroughs

NGF may have a role in islet transplantation by promoting angiogenesis and preventing hypoxia at the early post-transplant period. However, this remains to be tested and reproduced in appropriate trials.

Applications

Bone marrow cells produce NGF and promote angiogenesis. Islet co-transplantation with bone marrow is associated with improvement of islet graft function.

Terminology

Islet transplantation: islet transplantation is one of the therapies for T1DM. Islets are acquired from donor pancreas with the process of islet isolation. Acquired islets are transplanted into liver. Islet transplantation is a possibility for standard treatment of T1DM in the future.

Peer review

In this manuscript Sakata *et al* investigated whether islet transplantation in association with bone marrow transplantation improves diabetes related complications in streptozotocin induced diabetic mice. Although bone marrow cells yield similar results through vascular endothelial growth factor expression and this study is in press, their findings with NGF are still interesting and validates publication.

Abstract

AIM: To assess the treatment and tumor-related variables associated with outcome after treatment of spontaneously ruptured hepatocellular carcinoma (HCC).

METHODS: Patients with ruptured HCC were identified. The complications, mortality and survival were assessed. The relationship between tumor size and the severity of hemoperitoneum and between tumor size and grade were examined.

RESULTS: From January 1993 to January 2008, 556 patients with HCC with or without cirrhosis were evaluated; of which, 16 (2.87%) presented with spontaneous rupture. All but 1 patient had cirrhosis. Twelve patients underwent surgical resection while 4 underwent trans-cutaneous arterial catheter embolization (TAE) (trans-cutaneous arterial embolization). Early mortality (< 30 d) was 25% (4 of 16) and was inversely related

to Child-Pugh score; 3 of the 4 early deaths occurred in patients treated with TAE with 1 of 12 occurring in the resected group. There was no correlation between tumor size and grade or between size and severity of hemoperitoneum.

CONCLUSION: Tumor size did not correlate with severity of the hemoperitoneum. There was an inverse relationship between G1-G3 (grade of cellular differentiation) HCC and dimensions.

Management of ruptured hepatocellular carcinoma: Implications for therapy. *World J Gastroenterol* 2010; 16(10): 1221-1225 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i10/1221.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i10.1221>

INTRODUCTION

Hepatocellular carcinoma (HCC) is a hypervascular tumor that almost always occurs in the setting of liver cirrhosis. It is the fifth most common cancer in the world and is gradually increasing^[1]. Spontaneous rupture is a complication seen in 3%-15% of cases, with an apparent lower incidence reported in Western compared with Asian centers^[2]. The exact mechanism leading to rupture is not clearly defined although it appears to be more

frequent when the tumor protrudes from the glissonian capsule^[3]. Spontaneous rupture is the third leading cause of HCC-related death, after tumor progression and liver failure, and is more common than rupture of oesophageal varices. Previously considered a problem of only large tumors, this is not always the case, and smaller tumors, particularly those with an aggressive behavior, are at risk. The symptoms are related to the position of the tumor. In fact, rupture of deep tumors may be asymptomatic or produce pain while a peripheral lesion will give rise to hemoperitoneum, often with peritonitis and hemodynamic instability.

Appropriate management of this problem remains the subject of some debate. In patients with advanced liver disease or multifocal HCC, trans-cutaneous arterial catheter embolization (TAE) is clearly the most appropriate approach. However, in patients with preserved liver function and resectable tumors, resection may be an option. Although burdened by high mortality in the acute phase and not always feasible, surgical resection offers the indisputable advantage of definitively treating the cancer, in addition to obtaining hemostasis, and may offer a better prognosis^[3]. This study analyzes the management of ruptured HCC in a single, tertiary referral center with experience of this disorder, specifically assessing peri-operative outcome with operative and non-operative therapy.

MATERIALS AND METHODS

Patients with HCC treated at the authors' institution were identified from a prospectively maintained hepatobiliary database and registry of Hepato-Biliary surgery. Patients who presented with ruptured tumors were taken from the database for in-depth analysis. Symptoms and clinical status on presentation were recorded and analyzed. Initial treatment was directed at patient resuscitation and hemodynamic stabilization according to the advanced trauma life support protocol. Blood products were administered as necessary. Cross-sectional imaging was used to determine the disease extent, and standard laboratory studies were used to assess hepatic function.

Definitive therapy was selected based on liver functional reserve according to Child-Pugh score, tumor extent and overall performance status. In patients with advanced cirrhosis (Child-Pugh C) or multifocal HCC, TAE was used as definitive therapy. In cases of surgical treatment, a right 'hockey-stick' incision was used as the favoured access; median laparotomy was used in one case. Procedures were classified based on Couinaud's classification^[4]. Non-anatomic resection (or wedge resection) denotes a non-segmental resection of the liver surrounding the cancer. The hepatic parenchyma was divided using the crush-clamping method and each vessel encountered was ligated or clipped. Hepatic inflow occlusion was carried out using the Pringle manoeuvre. Argon beam coagulator was used on the cut surface of the liver.

Table 1 Patient treatment after ruptured HCC

Patient	Age (yr)	Sex	Cirrhosis	HCC size	Grading	Treatment
1	54	F	C	80	1	Resection
2	42	M	-	80	1	Resection
3	59	F	Alc	40	1	Resection
4	76	M	Alc	30	3	Resection
5	65	M	Alc	40	1	Resection
6	84	M	Alc	20	3	Resection
7	74	M	C	19	3	Resection

15	71	M	Alc	40	-	TAE
16	67	M	C	45	-	TAE

Patient No. 2 cirrhosis was not present; patient No. 3 underwent R2 resection. HCC: Hepatocellular carcinoma; TAE: Trans-cutaneous arterial catheter embolization.

All patients, regardless of treatment, were monitored in the intensive care unit over the immediate post-treatment period. Macroscopic and microscopic histopathology tests were carried out on the resected specimens. The grade of cell differentiation was classified according to the Edmondson and Steiner system^[5]. Maximal diameter of the specimen was taken as the tumor size in patients submitted to resection, while radiological images were used to measure HCC in patients treated with TAE. Postoperative complications were documented and classified as minor or major. Peri-operative mortality was defined as death during the same stay in hospital or within 30 d of the date of operation.

Statistical analysis

Data were processed using Excel. The G1 and G3 groups were compared with the Student's *t* test for continuous data; the level of significance was assumed as $P < 0.05$.

RESULTS

From January 1993 to January 2008, 556 patients with HCC and cirrhosis were seen in our institution. One-hundred and four patients were treated with surgical resection, and 145 underwent percutaneous ethanol injection or radiofrequency ablation. Sixty were treated with TAE with or without chemotherapy. Sixteen patients presented with ruptured HCC, representing 2.87% of the entire population.

Twelve patients underwent surgical resection and 4 were treated with TAE (Table 1). There were 10 males and 6 females with a mean age of 67 years (range: 42-84 years). On admission, hemoperitoneum and abdominal pain were the first presentation in 14/16 cases. Hypovolemic shock was present in 10 patients. Abdominal ultrasonography (US) and/or computed tomography (CT)

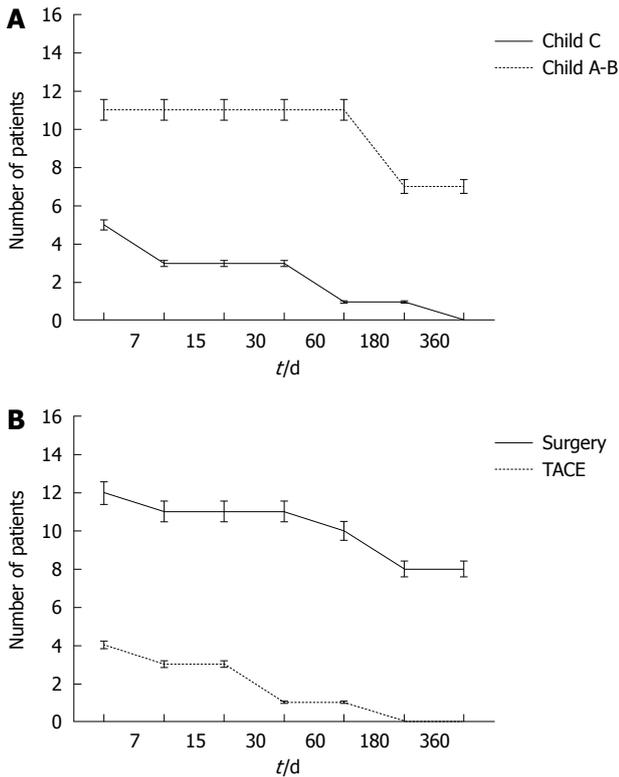

Figure 1 Summarizes early mortality in relation to liver functional reserve (A) and early survival in relation to treatment (B). A: Early overall mortality related to Child status; B: Early survival related to type of treatment.

showed hemoperitoneum in all 14 patients and delineated the liver disease in all but 1 case. Underlying cirrhosis was present in 15 patients (alcoholic in 8, hepatitis C infection in 6 and both in 1). Anemia with a haemoglobin level less than 10 g/dL was present in 7 patients. Four patients had alanine transaminase and aspartate transaminase levels more than twice the upper limits of normal, platelet count less than 100000 mm³, pro-thrombin time less than 70% and albumin level less than 3.5 g/dL. These four patients were excluded from surgery and treated with TAE. One patient was referred to our unit after urgent laparotomy and packing performed in another hospital.

Resection was performed in 12 patients as a single stage operation, ranging from 1 to 6 d from the time of presentation. Seven of these patients had persistent anemia and hemodynamic instability despite aggressive resuscitation and underwent emergency surgery. There were 3 anatomic resections of 2 segments and 4 non-anatomic resections. Four patients stabilized after the initial resuscitative manoeuvres, and surgery was performed from 1-3 d later; the procedures performed in this group were 1 left hepatectomy and 3 wedge resections. One patient required emergency laparotomy for hemorrhagic shock before the investigations were completed and the diagnosis was known; he was found to have multifocal HCC, and a palliative resection of segment 2 and segment 3 was performed to stop the bleeding. This was the only patient with multifocal HCC and/or Child-Pugh C cirrhosis who underwent surgical resection in Child

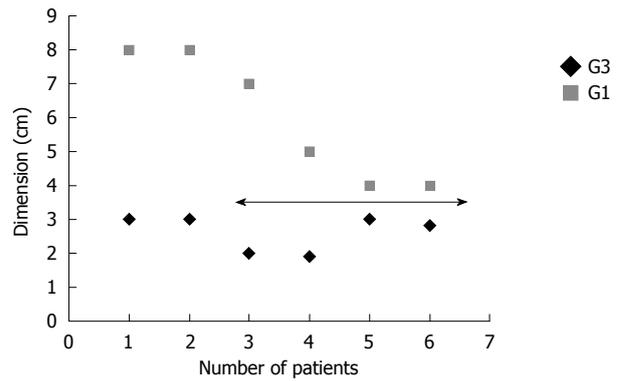

Figure 2 Relation between diameter and grading in ruptured HCC, average diameter of G1 is 60 mm and 26 mm for G3. HCC: Hepatocellular carcinoma.

C status and with multifocal and bilobar HCC; he died shortly after the operation from coagulopathy and liver failure. One patient required reoperation for bleeding on day 2 after the initial operation.

For all patients, the 30 d mortality rate was 25% ($n = 4$ patients, Figure 1A) and was directly related to underlying liver function. All four patients with Child-Pugh C cirrhosis died in the early post-treatment period – one after resection and three after TAE. The causes of death were coagulopathy ($n = 2$), recurrent bleeding ($n = 1$) and liver failure ($n = 1$). Three additional patients with Child-Pugh A or B cirrhosis and treated with surgical resection died within 6 mo due to liver failure (2 mo, $n = 1$), myocardial infarction (3 mo, $n = 1$), liver failure and progression of neoplastic disease (4 mo, $n = 1$, Figure 1B). Two of these patients had G3 HCC with vascular invasion and none of these patients underwent emergency surgery. They were transfused with 17 units of RPC.

Five patients were treated by emergency surgical resection and 2 patients who were treated with delayed surgical resection, survived more than 24 mo (long-term survival 46%).

Seven patients (43%) treated with resection, (emergency $n = 5$ and delayed $n = 2$) survived more than 24 mo. In all of these patients, the tumor grade was G1. Six of these patients were transfused with 27 units of RPC (range: 3-8). Postoperative ascites occurred in 5 patients, while 1 patient developed sub-phrenic abscess with collection drained percutaneously.

Histological study of the specimens confirmed HCC in all cases. Underlying cirrhosis was present in 11 cases. The average diameter of the HCC was 61 mm (range: 60-90 mm) for the patients who underwent TAE (measured with US or CT) and 43 mm for patients with resected HCC (range: 19-80 mm). The study on the histological specimen showed an average diameter of 60 mm for HCC in G1 status and 26 mm for G3 (Figure 2, $P = 0.001$).

DISCUSSION

HCC is the fifth most common tumor in the world and usually occurs in cirrhosis of alcoholic or viral (hepatitis

B or C) etiology^[1]. HCC is a hypervascular tumor with a high propensity for vascular invasion and the capability to produce growth factors which have a direct effect on endothelial cells to induce neo-angiogenesis. The rupture of HCC is a complication that can occur in 3%-15% of patients, although this has decreased now that screening programs for cirrhotics have been implemented^[1,2]. There is a relevant geographical difference between western and oriental countries where a major incidence has been reported in oriental countries^[2,6].

The mortality in the acute phase is very high and stands at around 25%-75% of cases^[6]. This complication is the third most common cause of death for HCC after neoplastic progression and liver failure; the mortality is higher than that due to bleeding resulting from rupture of esophageal varices^[6,7]. Although the incidence of viral cirrhosis is generally predominant, in the northeast area of Italy, as is documented both in the present study and in a recent publication, 50% of HCC occurs in cirrhosis due to alcohol abuse, while the remaining cases can be attributed to hepatitis virus C infection; the incidence of infection related to hepatitis virus B is occasional (Table 1)^[8].

The average age reported in the literature varies between 44 and 68 years, with a high prevalence in males (at least 3 times more frequent), confirming the overall impact of HCC^[6,9]. In this series, there was a high prevalence in men with respect to women (10 men and 6 women) with an average age of 67 years (range: 42-84 years).

According to the literature, the risk factors for rupture are not well known although rapid growth with necrosis, erosion of vessels, thrombosis of veins in HCC by tumor thrombi or direct invasion individually or combined could be responsible^[10,11].

The most common condition for bleeding into the peritoneum is when the HCC is located in one of the free surfaces of the liver. In this case there is no hepatic parenchyma surrounding the tumor and this is free to flood the peritoneum with blood and neoplastic cells. Many intra-parenchymal HCC may spontaneously break, but a deeper position in the center of the liver confines the bleeding around the cancer and the clinical manifestation is only pain without hemoperitoneum. Abnormal clotting and thrombocytopenia typical of cirrhosis may also worsen the hemorrhagic event.

The typical symptoms of spontaneous rupture are epigastric pain associated with clinical signs of shock and peritoneal irritation. This is especially true when the lesion is more peripheral on the liver. Peritoneal irritation due to bleeding is not evident in cases of rupture of a deeper lesion which does not interrupt the liver capsule. In addition to pain and hemorrhagic shock, the risk of peritoneal seeding may worsen the prognosis of these patients. In all of the cases in our study, rupture occurred in a peripheral tumor. A study by Kanematsu *et al.*^[12] in 1992, reported that protrusion of the tumor is a relevant prognostic factor of rupture. The peri-

operative mortality in cases who undergo urgent surgery is considerably higher than those reported for planned liver resections in patients with cirrhosis and is related to Child status before the rupture^[9]. Of course, bleeding and shock are factors which strongly influence the prognosis of these patients, and bleeding “*per se*” worsens the prognosis, however, decompensated cirrhosis may be fatal in cases of poor liver function. Therefore, the first step of treatment is resuscitation and stabilization of the patient, but achieving hemostasis is the primary goal. When facing a rupture of HCC with underlying cirrhosis it is mandatory to obtain a correct diagnosis in order to achieve the best treatment for each patient. The therapeutic approach may be crucial for prognosis. This choice must take into account the hemodynamic conditions, functional status of the liver and stage of cancer.

Although associated with complications such as re-bleeding and a mortality rate of around 30%, TAE is the best method to achieve hemostasis without surgery^[6,13]. Moreover, when feasible, super-selective TAE is able to preserve liver function and has the dual outcome of being a definitive treatment or a bridge to resectable HCC. As in other studies, the four patients in our study treated with TAE should not be compared with those who were treated with surgical resection. In fact, all four patients had severe cirrhosis or bilobar HCC while the resected patients had favourable location of HCC and good functional reserve. For this reason a comparative study and analysis of the results reported in the literature are very difficult. Our experience confirms that TAE is indicated in cases of poor liver function (Child C) or in cases of multifocal or bilobar HCC. Alternatively, TAE can be used as a bridge to surgical resection^[14]. According to previously published reports and analysis of the data from the present study in patients with Child C status who underwent TAE, it is clear that the post-procedure mortality was very high, confirming that poor liver functional reserve determines survival regardless of treatment type^[6]. Moreover, it is worth remembering the demerits of TAE which include rebleeding, liver abscess and implanted peritoneal metastases^[15].

Histological examination revealed that the average size of the lesions in this study was 43 mm. Substantial differences were seen between the dimensions in relation to grading. In fact, G1 HCC had an average size of 60 mm, while G3 HCC had an average size of 26 mm ($P = 0.001$). However, all lesions were on the liver surface. We did not find a relationship between severity of hemoperitoneum and size or grading of HCC.

The experienced liver team should evaluate the next treatment steps according to liver functional reserve and extension of HCC. Preoperative assessment of the patient with blood tests is mandatory as is cancer staging using US and radiological imaging.

It was reported by Tanaka *et al.*^[6] that rupture of HCC should be differentiated when it occurs in the early phase of cirrhosis rather than in the late phase. The prognosis is strongly determined by the functional status of the

liver immediately after bleeding. In fact, 3 patients in the present series were excluded from surgery due to poor liver function and not surprisingly had the worst outcome. In this cohort, functional liver reserve and G3 status influenced outcome, while emergency or delayed surgery and HCC dimensions did not seem to modify the prognosis. Several reports in the literature demonstrate acceptable results even in the case of one stage hepatectomy for ruptured HCC and limited resection is recommended^[2,16,17].

Moreover, peritoneal washing with saline solution can help to reduce the chance of spreading peritoneal cancer which may be a complication of TAE^[18,19].

In conclusion, in cases of ruptured HCC, any lesion should be considered for surgery if a low-risk curative resection is possible in a Child A-B patient. If necessary and possible, the intervention may be delayed. TAE is palliative procedure indicated when the liver function is compromised or in the case of multifocal-bilobar HCC. The introduction of screening programs should reduce the number of large HCCs which have broken, while we may have some concern about the rupture of smaller poorly differentiated tumors.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is a hypervascular tumor that sometimes due to unknown reasons breaks spontaneously regardless of size, grading and state of cirrhosis. Location on the free surface of the liver seems to be a major factor in rupture of HCC. The choice of therapy is closely linked to liver functional reserve, grade of tumor and performance status of the patient.

Research frontiers

Larger prospective studies are necessary to assess the relationship between HCC dimensions and grading and the possibility of rupture.

Innovations and breakthroughs

There is an inverse relationship between G1-G3 HCC and dimensions. In the case of ruptured HCC, resection should not be excluded "a priori" but carefully considered since it has the dual purpose of both achieving hemostasis and being a definitive treatment.

Applications

In the case of advanced liver disease or bilobar multifocal HCC, a non-operative approach such as trans-cutaneous arterial catheter embolization must be attempted. In contrast, preserved liver function and resectable tumor should be considered as clear indications for surgical resection.

Peer review

This study aimed to assess the treatment and tumor-related variables associated with outcome after treatment of spontaneously ruptured HCC. The paper is interesting.

RESULTS: Significantly higher levels of microalbuminuria were detected in HCV-positive patients compared to HCV-negative controls (median 9.5 vs 5.9, respectively, Kruskal-Wallis $P = 0.017$). Log microalbuminuria was significantly correlated with hepatic inflammation ($r = 0.13$, $P = 0.036$) and fibrosis ($r = 0.12$, $P = 0.061$), but not with viral load ($r = -0.03$, $P = 0.610$), or alanine transaminase ($r = -0.03$, $P = 0.617$). Diabetes mellitus neither significantly moderated ($\chi^2 = 0.13$, $P = 0.720$), nor mediated (Sobel test $P = 0.49$) the HCV effect. HCV status was significantly associated with log microalbuminuria ($\chi^2 = 4.97$, $P = 0.026$), adjusting for age, gender, diabetes, cryoglobulinemia, urea and creatinine. A positive HCV status was not significantly associated with low eGFR (< 60 mL/min every 1.73 m²) [odds ratio (OR): 0.5, 95% confidence interval (CI): 0.2-1.4], nor with high ACR (OR: 1.7, 95% CI: 0.7-4.1). End-of-treatment response (ETR) was achieved in 51.9% of patients. Individuals with ETR had significantly lower microalbuminuria post-treatment ($\chi^2 = 8.19$, $P = 0.004$).

CONCLUSION: HCV affected the development of microalbuminuria independent of diabetes or cryoglobulinemia. Combination therapy of pegylated interferon-ribavirin had a positive effect in reducing microalbuminuria.

Abstract

AIM: To study the relation between hepatitis C virus (HCV) genotype 4 and microalbuminuria and renal impairment in relation to hepatic histology, and viremia in the absence of cryoglobulinemia, and to examine the effect of treatment on microalbuminuria.

METHODS: Three hundred subjects, including 233 HCV genotype-4 infected patients, were tested for cryoglobulinemia, microalbuminuria, albumin creatinine ratio (ACR), urea, creatinine, and estimated glomerular filtration rate (eGFR). The parameters were measured again in the HCV patients after 48 wk of treatment with pegylated interferon and ribavirin.

Microalbuminuria in hepatitis C-genotype 4: Effect of pegylated interferon and ribavirin. *World J Gastroenterol* 2010; 16(10): 1226-1231 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i10/1226.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i10.1226>

INTRODUCTION

Hepatitis C virus genotype 4 (HCV-G4) is prevalent in the Middle East and Africa and has spread to several regions in Europe^[1]. HCV infection is associated with several renal diseases including mixed essential cryoglobulinemia, membranoproliferative glomerulonephritis and, less frequently, membranous nephropathy and crescentic glomerulonephritis^[2]. HCV is a significant cause of glomerulopathy in countries with a high prevalence of HCV infection^[3]. Several studies have postulated a causal link between HCV infection and renal diseases through the induction of cryoglobulinemia^[4]. The affinity for the kidney mesangium appears to be a major factor responsible for the precipitation of type-II mixed cryoglobulins in glomerular structures and the ensuing damage^[5]. The principal clinical manifestations of glomerular disease in HCV-infected patients are the presence of proteinuria and microscopic hematuria with or without impaired kidney function^[6]. Diabetes mellitus-mediated glomerulonephropathy in HCV patients may be considered, particularly with epidemiological studies showing a high occurrence of type 2 diabetes in patients with chronic HCV-G4^[7]. Various approaches have been tried for the treatment of HCV-associated glomerulonephritis, including immunosuppressive therapy (corticosteroids and cytotoxic agents), plasma exchange and antiviral agents. Limited data exist regarding antiviral treatment of HCV-associated glomerulonephritis.

We present a novel study reporting the prevalence of microalbuminuria, with other measures of renal insufficiency [albumin creatinine ratio (ACR), estimated glomerular filtration rate (GFR)] in HCV-G4 patients compared to HCV-negative controls, and the effect of viral load on liver histology, microalbuminuria, and renal insufficiency. Also, we investigated the effect of antiviral therapy with pegylated interferon and ribavirin on microalbuminuria, and other measures of renal insufficiency.

MATERIALS AND METHODS

In this prospective study, 300 consecutive eligible subjects who attended the gastroenterology clinic in Hamad Hospital were recruited in the period between January 2006 and 2009. Of these, 233 were chronic HCV-G4 patients who fulfilled the inclusion criteria, and 77 were control subjects who were either non hepatic patients followed in the clinic during the same period or healthy volunteers who were referred to Hamad hospital when they were ill. Controls were eligible if they did not have liver disease, evidenced by: persistently normal transaminases, negative serology for hepatitis serology, negative screening for auto-immune disease and no history of alcohol consumption, normal platelet count and α fetoprotein, and normal ultrasound scans.

All study participants were seen 2-3 times to provide repeated blood samples at baseline. Chronic HCV patients were also seen periodically to assess the response to treatment. All patients provided written informed

consent as stated in the Declaration of Helsinki of 1979, and the ethics research committee of the Hamad Medical Corporation provided ethical approval.

Chronic HCV infection was evidenced by persistently increased alanine aminotransferase (ALT) levels, positive serology for anti-HCV, active virus replication by detection of HCV RNA in serum, and histological findings of chronic active hepatitis according to the Scheur score. The patients were excluded if they had: (1) concurrent hepatitis B or human immunodeficiency virus infections, autoimmune hepatitis, hemochromatosis, or Wilson's disease; (2) systemic hypertension or if they reported current use of antihypertensive medication; (3) active alcohol consumption; (4) antiviral or corticosteroid treatment; and (5) chronic renal disease or history of dialysis.

The HCV patients who were candidates for treatment were given 180 μ g of peginterferon α -2a (Pegasys[®]; Hoffmann-LaRoche, Basel, Switzerland) subcutaneously once weekly and ribavirin (Copegus[®]; Hoffmann-La Roche, Basel, Switzerland) at a daily oral dose of 1000 mg (body weight < 75 kg) or 1200 mg (body weight > 75 kg) for 48 wk.

Laboratory measurement

Testing for anti-HCV was carried out using a commercial ELISA kit (AxSYM HCV version 3.0; Abbott Laboratories, Chicago, IL, USA). All patients were HCV-G4 as detected by the Inno-LiPA HCV II assay (Innogenetics Inc., Alphenet, GA, USA). Monitoring serum HCV RNA levels was by Amplicor (version 2.0, Hoffmann-La Roche) with a minimum detection limit of 50 IU/mL.

Microalbuminuria was measured on a spot of second morning urine after an overnight fast, taking the mean of at least 2 samples collected for each subject. Urine albumin measurements were obtained by an automated immunoturbidometric assay (Roche Hitachi 902, Roche Diagnostics, Indianapolis, IN 46250 USA).

For quantitative determination of creatinine in serum or urine, creatinine blanked kinetic Jaffé (Roche Diagnostics, Hitachi 917, Modulator P analyzer Roche Diagnostics) was used. We estimated GFR (eGFR) using the abbreviated modification of diet in renal disease equation.

After an overnight fast, samples for cryoglobulin measurement were collected at a temperature of 37°C, centrifuged at 37°C for 10 min, and the serum separated; 5 mL of the serum was allowed to stand in a cryocrit tube at 4°C for 2-7 d, with formation of precipitate confirmed visually. If the test was positive we proceeded to electrophoresis and immunofixation for typing. All subjects were tested for cryoglobulin.

Measures of renal insufficiency

Three measures of renal insufficiency were examined, namely eGFR, microalbuminuria, and serum creatinine. Low eGFR was defined as eGFR < 60 mL/min every 1.73 m². The presence of microalbuminuria was tested using (1) albuminuria level; or categories of microalbuminuria, defined as individuals with an albuminuria level higher than the upper tertile of the albuminuria level among controls

(2) ACR: to adjust for the variation in urine concentration, microalbuminuria was assessed by ACR. Gender-specific values for the ACR were 2.2 mg/mmol for males and 2.8 mg/mmol for females. High levels of serum creatinine were defined as > 1.2 mg/dL for males and > 1.1 mg/dL for females.

Outcomes and covariates definitions

Subjects were considered diabetic if they had a fasting blood glucose level ≥ 5.6 mmol/L, or self-reported as being diabetic or on anti-diabetic medication. End-of-treatment response (ETR) was defined as loss of detectable serum HCV RNA at the end of treatment. Normal ALT was defined as ALT ≤ 31 U/L for women and ≤ 40 U/L for men.

Statistical analysis

Unadjusted association between renal insufficiency and HCV infection was evaluated. For categorical variables, the unadjusted association was tested using the Chi-square test (Fisher exact test if there was limited sample size thus violating the Chi-square test assumptions), while for continuous variables, analysis of variance or the Kruskal-Wallis test (when the assumption of normality was violated) were employed. Multivariate logistic regression (for categorical variables) and multivariate linear regression (for continuous variables) were used to test for the null hypothesis of no significant association between renal insufficiency and HCV infection controlling for possible confounders and covariates. Microalbuminuria, ACR and eGFR data were log transformed to adjust for skewedness.

We tested for the presence of an interaction between HCV and diabetes, by adding the cross product term of HCV \times diabetes in addition to HCV and diabetes in the regression model predicting microalbuminuria.

In addition, we employed mediation analysis to test whether the effect of HCV on the risk of developing microalbuminuria was mediated by diabetes. Baron and Kenny's criteria was used to assess the presence of mediation^[8]. Mediation was expected if diabetes accounted for part or all of the relationship between HCV and microalbuminuria, as manifested by a decrease in the magnitude of the previously significant association between HCV and microalbuminuria upon controlling for diabetes^[8]. The significance of the mediation pathway was tested using the Sobel test as described elsewhere^[9].

To test for treatment effect, we examined differences between pre- and post-treatment using the Wilcoxon Signed Rank test which is a non-parametric equivalent of the paired *t*-test. In the multivariate analysis we tested for significant predictors of microalbuminuria post-treatment compared to pre-treatment, using the generalized estimating equation model.

All analyses were conducted using SAS 9.1 software.

RESULTS

The study population consisted of 300 subjects, of

Table 1 Study subjects characteristics by HCV status

Characteristics	HCV status	
	HCV-negative	HCV-positive
Age (yr)	46.0 (57.0)	46.0 (51.0)
Gender ^a n (%)		
Male	44 (18.4)	195 (81.6)
Female	23 (38.3)	37 (61.7)
Diabetes n (%)		
No	31 (19.6)	127 (80.4)
Yes	32 (23.2)	106 (67.8)
Fibrosis ^a n (%)

whom 233 (77.7%) were HCV-positive. At enrolment 138 (46.6%) were diabetics. The majority of the study participants [239 (79.9%)] were male and 195 (81.6%) of the males were HCV-positive compared with 37 (61.7%) of females. Median age of the study participants was 46 years (inter-quartile range, 41-53 years). The histopathological changes of the liver in HCV patients were classified according to the Scheuer score, and fibrotic changes of Stages I, II, III and IV were seen in 58 (25.1%), 89 (38.3%), 60 (25.7%) and 26 (10.9%) patients, respectively. Necro-inflammatory changes were seen in 23 (9.9%), 109 (46.8%), 58 (25.1%) and 4 (1.7%) patients, respectively. A median microalbuminuria of 8.2 (inter-quartile range, 4.4-16.9) μ g/mg was observed, while the median eGFR was 98 (inter-quartile range, 85-112) mL/min every 1.73 m². One hundred and eighteen individuals had microalbuminuria (39.7%), including 44 (37.6%) HCV-positive non-diabetic, 58 (49.6%) HCV-positive diabetic, 7 (6.0%) control non-diabetic, and 8 (6.8%) control diabetic subjects. Forty five individuals had high ACR (15.8%), including 13 (29.6%) HCV-positive non-diabetic, 25 (56.8%) HCV-positive diabetic, 2 (4.6%) control non-diabetic, and 4 (9.1%) control diabetic subjects. Only 15 (5.3%) had low eGFR, of whom there were 3 (20%) HCV-positive non-diabetic, 7 (46.7%) HCV-positive diabetic, 3 (20%) control non-diabetic, and 2 (13.3%) control diabetic subjects. Of 85 HCV patients who were on treatment, 44 (51.8%) showed an ETR.

Table 1 demonstrates the study participants' characteristics by HCV status. HCV-positive individuals had significantly higher ALT levels and higher microalbuminuria. No difference was detected in age, body mass index, urea, creatinine or gender (Table 1).

Microalbuminuria

Levels of microalbuminuria were significantly higher among HCV-positive individuals than HCV-negative patients (median 9.5 *vs* 5.9, respectively, Kruskal-Wallis $P = 0.017$). A significantly higher prevalence of microalbuminuria (defined as albuminuria > upper tertile of the controls) was observed among HCV-positive individuals (53.7%) compared to HCV-negative individuals (31.8%), ($\chi^2 = 9.8, P = 0.002$).

Log microalbuminuria was significantly correlated with grade ($r = 0.13, P = 0.036$), borderline correlated with older age ($r = 0.11, P = 0.069$) and more fibrosis ($r = 0.12, P = 0.061$), but not significantly associated with viral load ($r = -0.03, P = 0.610$), or ALT levels ($r = -0.03, P = 0.617$).

There was no significant interaction between HCV status and diabetes such that the odds ratio (OR) of microalbuminuria among diabetics compared to non-diabetics was not significantly higher in HCV-positive individuals compared to HCV-negative controls (P for interaction = 0.720) (Table 2).

For sensitivity analysis we restricted the analysis to non-diabetics. Among non-diabetics, the prevalence of microalbuminuria was significantly higher in HCV-positive individuals (50%) compared to HCV-negative controls (25.8%) ($\chi^2 = 5.9, P = 0.015$). Restricting the analysis to individuals with no cryoglobulinemia revealed that microalbuminuria was significantly higher in HCV-positive individuals (53.3%) compared to HCV-negative controls (31.8%) ($\chi^2 = 9.4, P = 0.002$).

To adjust for potential confounders and important covariates we employed multivariate regression to test for the significance of HCV as a predictor for microalbuminuria. Log microalbuminuria was used in the linear regression analysis because of the skewedness of the microalbuminuria data. Similar to the unadjusted analysis, we did not detect a significant interaction between diabetes and HCV ($\chi^2 = 1.2, P = 0.272$), thus no interaction term was included in the final model.

After adjusting for age, gender, diabetes, cryoglobulinemia, urea and creatinine, there was a significant association between HCV status and log microalbuminuria ($\chi^2 = 4.97, P = 0.026$). Microalbuminuria was significantly associated with urea ($\chi^2 = 8.2, P = 0.004$), creatinine ($\chi^2 = 27.0, P < 0.0001$), diabetes ($\chi^2 = 8.2, P = 0.004$), but not with age ($\chi^2 = 0.0, P = 1.0$) or gender ($\chi^2 = 0.4, P = 0.530$) or cryoglobulinemia ($\chi^2 = 0.2, P = 0.703$).

We tested whether diabetes mediated the effect of HCV on microalbuminuria risk. Diabetes was not a significant mediator of the effect of HCV on microalbuminuria risk, as manifested by the non fulfillment of the Baron and Kenny criteria for mediation, such that HCV did not significantly predict diabetes ($\chi^2 = 0.56, P = 0.45$), and therefore the Sobel test for mediation was not significant ($P = 0.49$).

Albumin creatinine ratio (ACR)

Median ACR was 1.0 (range, 36.8) mg/mmol in HCV-negative subjects *vs* 1.0 (range, 193.9) mg/mmol in HCV-

Table 2 Renal insufficiency in diabetics compared with non-diabetics among HCV-positive and HCV-negative controls

Renal function	Diabetes	
	OR (95% CI)	<i>P</i> -value ¹
Microalbuminuria		0.720
HCV-positive	1.4 (0.8-2.3)	
HCV-negative	1.7 (0.6-5.1)	
eGFR		0.175
HCV-positive	3.0 (0.8-11.9)	
HCV-negative	0.6 (0.1-4.0)	
Albumin creatinine ratio		0.752
HCV-positive	2.9 (1.4-6.1)	
HCV-negative	2.1 (0.4-12.7)	
Creatinine		0.627
HCV-positive	0.9 (0.3-2.8)	
HCV-negative	0.5 (0.1-2.5)	

¹ P for interaction is the P -value of the cross product term of HCV \times diabetes in the logistic regression models predicting renal insufficiency. OR: Odds ratio.

positive subjects. Positive HCV status was not associated with a significantly high ACR [OR: 1.7, 95% confidence interval (CI): 0.7-4.1], which also did not change by stratifying according to diabetic status (P for interaction = 0.752) (Table 2).

In multivariable regression analysis, and adjusting for age and gender, there was no significant association between HCV status and high ACR ($\chi^2 = 0.86, P = 0.35$).

eGFR

The prevalence of low eGFR < 60 mL/min every 1.73 m² was lower in HCV-positive individuals than HCV-negative individuals (4.4% *vs* 8.9%). Positive HCV status was not associated with significantly low eGFR < 60 mL/min every 1.73 m² (OR: 0.5, 95% CI: 0.2-1.4). Median eGFR was 99.5 (range, 317.0) mL/min every 1.73 m² in HCV-negative subjects and was 98.0 (range, 155.0) mL/min every 1.73 m² in HCV positive subjects. We did not detect a significant interaction between HCV status and diabetic status (P for interaction = 0.175) (Table 2).

Multivariate regression analysis revealed that, upon adjusting for age, and gender there was no significant association between HCV status and low eGFR ($\chi^2 = 1.12, P = 0.29$).

Serum creatinine

Median creatinine was 0.75 (range, 248) mg/dL in HCV negative subjects, *vs* 0.77 (range, 230) mg/dL in HCV positive subjects. Negative HCV status was borderline associated with high serum creatinine (OR: 2.6, 95% CI: 1.02-6.68, $P = 0.05$). There was no statistically significant difference in serum creatinine comparing diabetics to non-diabetics among HCV positive and HCV negative controls (Table 2).

In the multivariable regression analysis, and adjusting for age, and gender, there was significant association between HCV negative status and high serum creatinine (OR: 3.3, 95% CI: 1.2-9.2, $P = 0.02$).

Microalbuminuria and treatment effect

Log microalbuminuria pre-treatment median level was 2.26 (inter-quartile range, 1.5-3.1), while median post-treatment level was 2.04 (inter-quartile range 1.5-2.6), (Wilcoxon signed rank test $P = 0.09$). Adjusting for age, sex, fibrosis, grade, log ACR, ALT, diabetes and viral load the decline was more pronounced in individuals with ETR compared to individuals without ETR ($\chi^2 = 8.19, P = 0.004$).

The pre- to post-treatment log microalbuminuria difference was significantly correlated with pre-treatment older age ($r = 0.37, P < 0.001$), fibrosis ($r = 0.26, P = 0.017$), grade ($r = 0.23, P = 0.042$) and log ACR ($r = 0.38, P < 0.001$), but not correlated with male gender ($r = 0.14, P = 0.222$), diabetes ($r = 0.12, P = 0.265$), urea ($r = 0.015, P = 0.896$), creatinine ($r = -0.05, P = 0.658$) or ALT ($r = -0.07, P = 0.508$).

In multivariate regression, after adjusting for gender, age, pre-treatment ALT, log ACR, diabetes, fibrosis and grade, only log ACR, ETR, and fibrosis were moderately associated with a greater decline in log microalbuminuria post-treatment ($\chi^2 = 8.98, P = 0.003$; $\chi^2 = 8.19, P = 0.004$; $\chi^2 = 9.35, P = 0.053$, respectively), while age, gender, ALT, diabetes, and grade were not associated with log microalbuminuria decline ($\chi^2 = 0.70, P = 0.401$; $\chi^2 = 0.13, P = 0.718$; $\chi^2 = 1.31, P = 0.253$; $\chi^2 = 0.0, P = 0.969$; $\chi^2 = 1.33, P = 0.722$, respectively).

DISCUSSION

Hepatitis C infection is known to have a higher prevalence of some components of metabolic syndrome and to be associated with chronic renal disease. Renal involvement in the course of HCV infection is attributed to a high incidence of intrinsic diabetic renal disease or cryoglobulinemia. Studying microalbuminuria in HCV-G4 patients and its relationship to response to treatment is a novel report, especially after recent evidence for diabetes-inducing effects of HCV-G4^[10]. In the current study, using the same definition of microalbuminuria as Liangpunsakul *et al*^[11], the prevalence of microalbuminuria in HCV-G4 was 20%, similar to that reported by the Third National Health and Nutrition Examination Survey (12.4%). In contrast to the limitations of the NHANES III study, we were able to study the mean of multiple microalbuminuria readings, adjusting for stage of hepatic fibrosis, grade of inflammation, viral load and cryoglobulinemia.

In our study, not only was the prevalence of microalbuminuria higher among HCV-positive individuals but significantly higher levels were noted compared to non-HCV subjects. Although the prevalence of microalbuminuria was higher among diabetic HCV patients, testing for the effect of diabetes did not reveal a significant interaction with HCV infection nor a significant mediation of the HCV effect. In contrast to a previous suggestion of a link between HCV infection and diabetes^[12], our results revealed that HCV infection was not associated

with type 2 diabetes mellitus. Our results are in accordance with other reports that revealed no interaction between HCV infection and diabetes, and the association between HCV infection and albuminuria was not altered upon adjustment for diabetes^[13,14]. In addition HCV infection was not associated with cryoglobulinemia. Therefore, our results suggested that HCV-G4 was associated with microalbuminuria independently of cryoglobulinemia or diabetes status.

HCV-induced glomerulonephropathy in the absence of cryoglobulinemia was explained in previous reports by direct or indirect pathways: deposition in the glomerulus of a monoclonal IgM rheumatoid factor with particular affinity for the glomerular matrix, which is produced by permanent clones of B lymphocytes infected by the virus or immune complexes composed of HCV antigens and anti-HCV IgG antibodies can deposit directly in the glomerular structures in the absence of a concomitant type II mixed cryoglobulin. HCV RNA genomic sequences and HCV core protein detected in kidney glomerular and tubular structures point to distinct pathways of HCV-related damage in glomeruli and tubules^[15]. Kidney disorders constitute patho- and morphogenesis of systemic infection in HCV^[16].

In spite of HCV-induced microalbuminuria, which was in agreement with Liangpunsakul *et al*^[11], Moe *et al*^[17] and Tsui *et al*^[18] but in contrast to Dalrymple *et al*^[13] and Tsui *et al*^[14], we did not find an increased risk for renal disease in HCV-G4 as reflected by undetectable changes in creatinine, ACR or eGFR. This discrepancy might be explained by long-term infection in some studies, the definition of renal insufficiency, or the viral genotype. These findings suggested that the principal clinical manifestation of glomerular disease in HCV-G4-infected patients is the presence of microalbuminuria without impaired kidney function^[19].

The lack of increased risk of renal disease persisted even after restricting the analysis to diabetics which is consistent with a previous report^[20].

We found a significant correlation between microalbuminuria and necroinflammatory changes, but not fibrotic changes; this represents a relation with viral activity rather than progression of liver disease. In the absence of a significant correlation between microalbuminuria and viral load, hepatic fibrotic changes or platelet count, we suggest that HCV infection *per se* in HCV-G4 and not the stage of liver disease is the cause of microalbuminuria.

There was a moderate reduction in microalbuminuria after pegylated interferon therapy which was more pronounced in patients with an ETR, those with higher pre-treatment fibrosis and higher pre-treatment log ACR, regardless of the grade of inflammation, diabetes or liver function. This post-treatment reduction in proteinuria in HCV-G4 indirectly suggested an improvement in renal pathology^[21], and reinforced the hypothesis that the development of microalbuminuria in HCV infection is possibly by mechanisms other than diabetes or cryoglobulinemia.

In conclusion, renal disorders in the form of microalbuminuria increased in HCV-G4 infection, especially in older patients, regardless of the stage of liver disease or viral load. In our study, diabetes did not mediate or moderate the effect of HCV infection, suggesting that HCV independently affected the development of microalbuminuria. Combination therapy of pegylated interferon-ribavirin had a positive effect in reducing microalbuminuria.

COMMENTS

Background

Hepatitis C virus (HCV) is a significant cause of glomerulopathy in countries with a high prevalence of HCV. The principal clinical manifestations of glomerular disease in HCV-infected patients are the presence of proteinuria and microscopic hematuria with or without impaired kidney function.

Research frontiers

Microalbuminuria is observed in HCV-positive individuals. However, the prevalence of microalbuminuria in HCV-genotype 4 (HCV-G4) patients compared to HCV-negative controls and its association with liver histology, viral load, and response to treatment has not been indisputably addressed. In this study, the authors demonstrate that antiviral therapy with pegylated interferon and ribavirin could have a beneficial effect on microalbuminuria.

Innovations and breakthroughs

Latest reports have provided evidence of a significant increase in renal disease in HCV infection, in particular HCV-induced microalbuminuria. This is the first study to report the increase in microalbuminuria in HCV-G4 patients. Furthermore, the study demonstrated that antiviral therapy with pegylated interferon and ribavirin could have a beneficial effect on the microalbuminuria.

Applications

Understanding how *microalbuminuria* is related to HCV infection, grade, fibrosis and response to treatment, may provide an insight for future strategy for post-treatment follow-up and for predicting response to treatment.

Terminology

Microalbuminuria, estimated glomerular filtration rate, and serum creatinine are measures of renal insufficiency. End-of-treatment response is the loss of detectable serum HCV RNA at the end of treatment.

Peer review

In the current study, the authors demonstrated the independent effect of HCV-G4 infection on the development of microalbuminuria through prospective comparison to HCV-negative control groups and the positive effects of antiviral therapy. This study included some interesting points.

Abstract

AIM: To investigate the association of gastroesophageal reflux disease (GERD) and irritable bowel syndrome (IBS) in Iranian patients and examine the prevalence of functional symptoms of the gastrointestinal tract in patients presenting with either IBS, GERD or both.

METHODS: Six thousand four hundred and seventy six patients presented to the Gastro-intestinal (GI) clinic with symptoms of functional dysfunction of GI tract, 1419 patients (62.0% women, 38.0% men; mean age: 37.4 ± 11.5 years) met Rome II or Rome III criteria (depending on the year of diagnosis) for IBS. 2658 patients were diagnosed with GERD based on clinical presentation and endoscopic findings. We assessed other functional symptoms (epigastric pain, nausea, vomiting, belching, constipation and diarrhea) in patients suffering from GERD, IBS or both.

RESULTS: Among IBS subjects, 63.6% (69.0% women, 31.0% men; mean age: 36.4 ± 10.3 years) also had

GERD, whereas 34.7% of the non-IBS patients had GERD [odds ratio (OR) = 3.2, 95% confidence interval (CI): 2.9-3.7, $P < 0.0001$]. Among patients with GERD, 33.9% of subjects met Rome criteria compared to 13.5% of non-GERD patients (OR = 3.6, 95% CI: 3.1-4.3, $P < 0.0001$). Prevalence of all functional symptoms was higher in overlapping GERD and IBS subjects, when compared with their prevalence in the IBS subjects without GERD or GERD only subjects ($P < 0.05$).

CONCLUSION: This finding shows that in overlapping GERD and IBS, other functional abnormalities of the GI tract are also highly prevalent, suggesting a common underlying dysfunction.

Overlapping gastroesophageal reflux disease and irritable bowel syndrome: Increased dysfunctional symptoms. *World J Gastroenterol* 2010; 16(10): 1232-1238 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i9/1232.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i9.1232>

INTRODUCTION

Irritable bowel syndrome (IBS), affecting approximately 10%-15% of the population is defined by Rome criteria as "abdominal pain or discomfort associated with

altered bowel habits and disordered defecation”^[1-5]; gastroesophageal reflux disease (GERD) is characterized by the symptoms of heart burn and regurgitation caused by reflux of stomach content and is experienced once daily by 7% and once monthly by 44%^[6,7] of patients. Originally, GERD and IBS were considered to be distinct issues, but common clinical features between IBS and GERD^[8,9] suggest that an overlap between these conditions might exist. Recently, a considerable overlap between GERD and IBS in both population based and clinical based studies have been reported^[10-13]. In addition, some evidence suggested that GERD, like IBS, should be considered as a gastrointestinal motility disorder, which suggests that similar pathophysiological characteristics might contribute to GERD and IBS^[9,14].

In the current study, we used a large clinic-based data-base to estimate the prevalence of overlap between GERD and IBS. We also examined the prevalence of a number of clinical symptoms of Gastro-intestinal (GI) functional motility disorders like belching, nausea and vomiting, constipation and diarrhea in patients presenting with GERD, IBS or both. We predicted that if GERD and IBS are different presentations of the same pathologic process in function and motility of GI tract, the more severe the disorder, the more prevalent the functional symptoms should be; therefore we expected a higher prevalence of dysfunctional symptoms in patients with overlapping GERD and IBS.

MATERIALS AND METHODS

All patients referred to a subspecialty practice medical group from March 1997 to March 2007 were enrolled. Five hundred and four patients were excluded because of not having follow up sessions, defined as having only one visit or lacking final diagnosis in the records, or having peptic ulcer found on endoscopy, and the remaining 6476 patients (mean age = 37.9 ± 13.4 years) were registered. Patients filled in a questionnaire about presence and severity of functional symptoms at every visit. All of the final diagnoses available in the records had been made by gastroenterologists who were participating in the gastroenterology department related to Tehran Medical University as academic staff.

GERD was defined as having clinical presentations such as heart burn, regurgitation and dysphagia. 91% of patients with clinically assumed GERD had undergone standard upper gastrointestinal endoscopy (UGIE). Patients who showed endoscopic evidence of GERD, like esophagitis, were not tested further. Those who did not show evidence of GERD were confirmed by pH monitoring. Patients with peptic ulcer found on endoscopy were excluded from the study. Subjects were diagnosed with IBS by fulfilling Rome II or Rome III criteria.

The records were then reviewed for the following items: (1) demographic data (including patient's record number, age and sex); (2) symptoms of GERD, IBS and other symptoms related to the dysfunction of upper and

lower GI tract such as: epigastric pain, nausea, vomiting and belching, constipation and diarrhea; (3) non-gastrointestinal complaints which included back pain and headache; (4) being a *Helicobacter pylori* (*H. pylori*) carrier or not. A number of patients diagnosed with GERD or IBS were evaluated for *H. pylori* during the clinical evaluation for the diagnosis and were found to have *H. pylori* infection by means of either C-urea breath test, urease test in obtained biopsies during UGIE or serum checking; (5) whether GERD in clinically suspicious patients is confirmed by UGIE or not; and (6) final diagnosis of GERD and IBS. Patients were classified according to their final diagnosis, as suffering from: (1) IBS (IBS group); (2) GERD (GERD group); and (3) both GERD and IBS (GERD + IBS group).

Statistical analysis

Extracted data was analyzed using SPSS version 14.0 (SPSS Inc., Chicago, IL, USA). χ^2 test was used to compare qualitative variables, whereas *t*-test was used to compare discontinuous quantitative variables. A *P* value less than 0.05 was considered to indicate a statistically significant difference.

RESULTS

Six thousand four hundred and seventy six patients including 3185 (49.2%) men and 3291 (50.8%) women were enrolled in the study. No statistically significant difference was found in mean age of men and women. One thousand four hundred and nineteen (21.9%) of patients were diagnosed with IBS, using Rome II or Rome III criteria for IBS. The IBS group was made up of 539 (38.0%) male and 880 (62.0%) female, with a mean age of 37.4 ± 11.5 years. There were no differences in mean age between men and women. Two thousand six hundred and fifty eight (41%) were diagnosed with GERD, 95.8% were experiencing heart burn, 3.0% presented with regurgitation and 1.2% presented with dysphagia (Figure 1). The diagnosis of GERD had been confirmed in 69.2% of GERD patients with UGIE and in 21.8% with pH monitoring. There was a slight difference in sex distribution of GERD, men making up 44.7% and women making up 55.3% of the patients; the mean age of GERD subjects was 37.9 ± 13.4 years without any considerable difference for men and women.

Among 1419 patients diagnosed with IBS, 902 (63.6%) also had GERD whereas 34.7% of non-IBS patients had GERD [odds ratio (OR) = 3.2, 95% confidence interval (CI) = 2.9-3.7, $P < 0.0001$]. On the other hand 33.9% of GERD subjects met Rome criteria for IBS compared to 13.5% of non-GERD sufferers (OR = 3.6, 95% CI: 3.1-4.3, $P < 0.0001$). 34.4% of the endoscopically diagnosed GERD patients had overlapping IBS; reciprocally 62.4% of the IBS patients had GERD diagnosed by endoscopy or pH monitoring.

69.0% of patients with both GERD and IBS were women and 31.0% were men; while women make up

Table 1 Comparison of frequency of functional symptoms in patients with IBS, GERD and GERD + IBS

Frequency	GERD only patients (n = 1522)	IBS only patients (n = 738)	GERD + IBS (n = 433)	P value		
				IBS vs GERD	GERD + IBS vs IBS	GERD + IBS vs GERD
Nausea	10.8%	6.2%	15.9%	0.02	< 0.0001	< 0.0001
Vomiting	11.6%	3.3%	18.8%	< 0.0001	< 0.0001	< 0.0001
Epigastric pain	18.9%	14.9%	22.9%	0.037	< 0.0001	< 0.0001
Belching	4.1%	6.4%	10.2%	0.03	0.015	< 0.0001
Headache	2.8%	4.4%	6.8%	0.058	0.07	< 0.0001
Back pain	3.6%	3.3%	6.0%	0.74	0.025	0.004

Pair-wise comparison of frequency of nausea, vomiting, epigastric pain, belching, headache and low back pain in patients with IBS alone, GERD alone and GERD + IBS showed that the frequency of all of these functional symptoms was significantly higher in patients in GERD + IBS group. IBS: Irritable bowel syndrome; GERD: Gastroesophageal reflux disease.

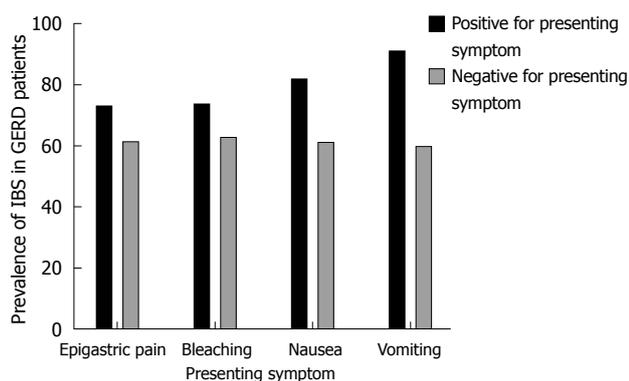

Figure 1 Prevalence of irritable bowel syndrome (IBS) in patients with gastroesophageal reflux disease (GERD) based on their presenting symptoms. The probability of having simultaneous GERD and IBS was significantly higher in patients presenting with either of these functional symptoms; however, nausea and vomiting were more strongly related to the overlap of two diseases.

50.0% of GERD only patients ($P < 0.0001$ vs GERD + IBS group) and 61.1% of IBS only patients ($P < 0.0001$ vs GERD + IBS group). The mean age of patients with GERD and IBS was 36.4 ± 10.3 , statistically similar to IBS patients without GERD and GERD subjects without IBS ($P > 0.5$).

Table 1 presents the prevalence of other gastrointestinal functional symptoms in the three mentioned groups. Remarkably, these symptoms were significantly more frequent in patients with both GERD and IBS compared to non-GERD non-IBS patients. Statistical analysis showed the following significant differences: epigastric pain (22.9% vs 9.6%, $P < 0.0001$), nausea (15.9% vs 4.8%, $P < 0.0001$), vomiting (16.0% vs 5.3%, $P < 0.0001$), constipation (12.2% vs 4.2%, $P < 0.0001$), diarrhea (18.7% vs 7.3%, $P < 0.0001$), headache (6.8% vs 2.4%, $P < 0.0001$), back pain (6.0% vs 3.7%, $P = 0.03$).

In comparison with men, women in the IBS group were more likely to experience epigastric pain (23.0% vs 14.1%, $P < 0.0001$), nausea (14.2% vs 8.7%, $P = 0.003$) and vomiting (15.6% vs 8.5%, $P < 0.0001$). 14.7% and 16.0% of women with GERD suffered nausea and vomiting, respectively, whereas 9.6% and 11.4% of male GERD patients had nausea and vomiting ($P < 0.0001$, $P = 0.001$, respectively). Women complaining of both

GERD and IBS had a trend toward experiencing nausea and vomiting more than men; 17.8% of women and 11.4% of men complained of nausea ($P = 0.015$) and 21.2% of women and 13.6% of men suffered from vomiting ($P = 0.007$, Figure 2).

We determined the differential prevalence of IBS in patients with GERD based on presenting and accompanying functional symptoms (Figure 1). 72.9% of patients with GERD who presented with epigastric pain also had IBS compared to 61.2% of GERD patients without epigastric pain ($P < 0.0001$). 73.6% of GERD patients reporting belching were also diagnosed to have IBS whereas 62.6% of GERD subjects without belching were suggested to have IBS ($P = 0.015$). IBS was present in 81.7% of GERD patients with a complaint of nausea while 61.0% of patients with GERD, not accompanied by nausea also suffered from IBS simultaneously ($P < 0.0001$). 90.9% of patients with GERD and vomiting were considered to have IBS compared to 59.4% of GERD subjects without vomiting who were assumed to have IBS ($P < 0.0001$). These findings suggest a considerable overlap between functional dyspepsia, GERD and IBS. Among the total upper GI symptoms assessed, 40.5% of the IBS group, 39.2% of the GERD group and 47.8% of both GERD + IBS group reported one or more functional symptoms; two or more symptoms were present in 10.9% of IBS group, 10.3% of GERD group and 15.9% of GERD + IBS; 2.7% of IBS patients, 1.7% of GERD patients and 3.9% of GERD + IBS patients complained of three or more symptoms while 0.2% of the IBS group, 0.1% of the GERD group and 0.3% of GERD + IBS group were known to have four symptoms. There was no significant difference when the association between number of overlapping symptoms and GERD and IBS was evaluated.

About 373 of IBS patients, 1323 of the GERD group and 287 of GERD + IBS group were evaluated for *H. pylori* infection. 70.9% of GERD patients were found to have *H. pylori* infection significantly more than non-GERD patients (29.1%, $P < 0.0001$). IBS group patients and GERD + IBS patients were not significantly affected by *H. pylori* infection in proportion to non-IBS and non-GERD + IBS patients ($P > 0.5$). This finding is interesting because it shows that in GERD +

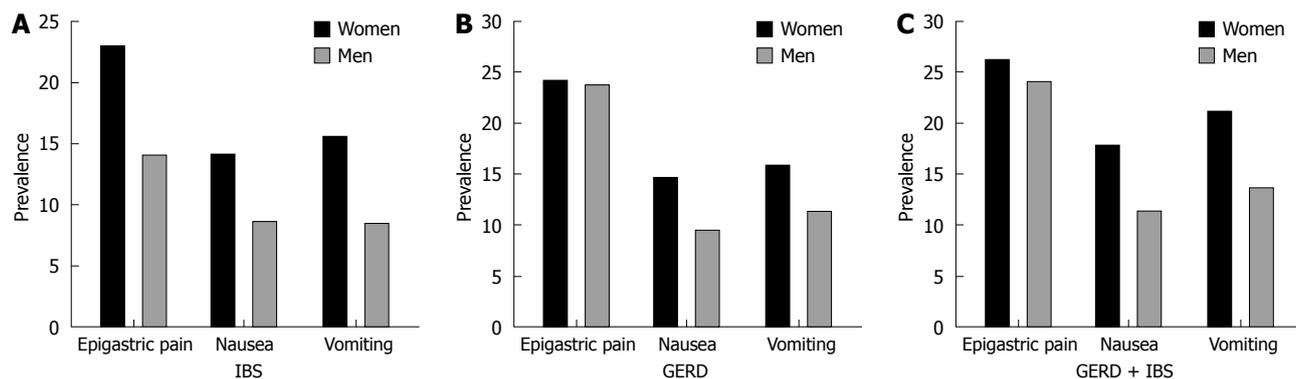

Figure 2 Sex distribution of functional symptoms in patients with IBS (A), GERD (B), GERD + IBS (C). In all of the groups the prevalence of nausea and vomiting was significantly higher in women than in men. Considering that nausea and vomiting were the most frequent symptoms in overlapping diseases, it is explainable by a high prevalence of overlap in women.

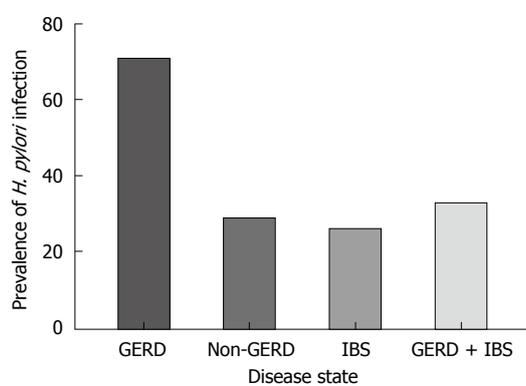

Figure 3 Frequency of *Helicobacter pylori* (*H. pylori*) infection in patients with IBS, GERD, GERD + IBS. The frequency of *H. pylori* infection was significantly higher in patients with GERD alone compared to patients with GERD + IBS.

IBS patients whose symptoms might have a common functional abnormality, the prevalence of *Helicobacter* infection is significantly lower than GERD only patients (Figure 3).

DISCUSSION

IBS and its comorbidities have recently been the focus of extensive research. In spite of the fact that other surveys have indicated the increased prevalence of GERD in IBS and *vice versa*^[8-13] to our knowledge, no similar survey to this study has evaluated the overlap between GERD, IBS and upper gastrointestinal symptoms suggestive of functional dyspepsia in such a large sample consisting of 6476 patients.

21.9% and 41.0% of patients enrolled in the present study had been diagnosed as having IBS and GERD, respectively. The high prevalence of IBS in this survey can be explained by the fact that the place of study had been a referral gastroenterology centre.

63.6% of IBS patients had GERD, and 33.9% of GERD patients also had IBS. Kennedy *et al*^[15] reported 46.5% of GERD patients to have IBS and 47% of IBS patients to suffer from GERD. Hungin *et al*^[2] stated that

IBS sufferers were twice as likely to suffer from GERD (22% *vs* 10%). Guillemot *et al*^[16] in a large clinical based data base reported prevalence equal to 27% for IBS in patients with GERD while Fass *et al*^[17] using a database consisting of about 6000 patients reported a very high prevalence of IBS in GERD patients (60%). Nastaskin *et al*^[18] in a systematic review, reported the prevalence to be about 49%. Lee *et al*^[12] reported a 24% overlap in a Korean population with a sample size of 1400, and a cohort study reported the relative risk of developing IBS in GERD patients to be 3.5^[13].

Although clinical judgment of GERD has a sensitivity of 78% and specificity of 60%^[6,19], in order to strengthen the method of study we also assessed the overlap of IBS with GERD patients whose diagnosis was confirmed by upper gastrointestinal endoscopy. The considerable overlap still existed and 62.4% of IBS patients also had endoscopically confirmed GERD and 34.4% of endoscopically confirmed GERD patients also had IBS.

By evaluating the frequency of these conditions in relation to the demographic aspects of the affected individuals, we found out that women are more likely to experience GERD and IBS at the same time compared to men, despite the similar sex distribution in GERD only patients. Other studies have demonstrated a higher prevalence of IBS in women^[2,20,21], but this study shows a higher proportion of women in GERD + IBS group compared to the prevalence of women in IBS only patients; probably because the same factors which contribute to IBS are more frequent in women than men. One of these factors is sex hormones which was assumed to play a role in IBS, based on the exacerbation of IBS symptoms with the onset of menses^[22]. Another possibility might be a lower pain perception threshold in women compared to men; although visceral hyperalgesia is a leading hypothesis for IBS^[23-27] there is no available data on the differences in pain perception between men and women.

Functional dyspepsia is consistent with gastrointestinal symptoms such as nausea, vomiting, bloating, and postprandial fullness in the absence of organic dis-

ease^[5,20,28,29]. It is stated in a review article that 23%-87% of patients with IBS had also functional dyspepsia and 13%-87% of dyspeptic patients complained of IBS^[30]. In the current study we examined epigastric pain, nausea, vomiting and belching which were shown to have a higher prevalence in patients presenting with both GERD and IBS in comparison to IBS only patients. This finding suggests a more advanced pathology in patients with both GERD and IBS. Other studies have estimated the prevalence of epigastric pain to be 20%-45%, nausea to be 24%-73% and vomiting to be 7%-27% of IBS patients^[31-35]. No similar finding in patients suffering from both GERD and IBS has been reported. 47.8% of patients with both GERD and IBS and 40.5% of IBS patients were associated with one or more functional symptoms. Stanghellini *et al.*^[35] observed a high frequency (66%) of functional dyspepsia in IBS patients.

In the present study, we found nausea and vomiting to be the only symptoms differing between men and women. This higher prevalence in women with IBS, GERD and those with both GERD and IBS simultaneously might suggest that the higher occurrence of nausea and vomiting might be interrelated to sex hormones or some biological and psychological differences in men and women. On the other hand the mean age of IBS, GERD and GERD + IBS patients associated with either nausea or vomiting was lower than patients with other symptoms assessed in our survey.

Assessing the role of *H. pylori* infection in GERD and IBS patients could be a target of future research, as in the present study the prevalence of *H. pylori* infection in GERD patients was found to be greater than in non-GERD patients; however, we did not find any significant difference in the prevalence of *H. pylori* infection in patients with IBS or both IBS and GERD.

IBS is also associated with extra intestinal symptoms like frequency and urgency, sexual dysfunction, pains in muscles and joints, dyspareunia, lower back pain, and headaches^[36,37]. Whether this increase in frequency of extra intestinal symptoms reflects a systemic underlying disease with different manifestations in different organs or shows psychosomatic disorder is not clear. Here we investigated the frequency of two extra-intestinal symptoms, headache and low back pain in patients with IBS, GERD and GERD + IBS. Results showed that the frequency of these symptoms was significantly higher in patients with both GERD and IBS compared to patients with GERD or IBS alone. This finding might suggest that these diseases may have similar underlying pathophysiology, but they differ in severity. Thus, patients with a severe disorder are more likely to suffer from both IBS and GERD and also extra-intestinal symptoms. There are different hypotheses about the relationship between GERD and IBS. Some suggest that although there might be similar pathophysiology, these are two different diseases and therefore require two different treatments^[32,33]. Other groups postulate that visceral hyperalgesia in the GI tract in both GERD and IBS is the

main reason for the observed overlap^[38]. When patients are hypersensitive or hyperalgesic in the GI tract, there is a higher chance of reporting symptoms of both GERD and IBS, or other functional symptoms as reported by the current study. However, in our population of study, most of the patients presented endoscopic evidence of GERD, therefore hypersensitivity does not explain their GERD symptoms. Others suggest that the ineffective esophageal motility which contributes to GERD is part of a general disorder of smooth muscle movement in the GI tract which contributes to IBS as well^[39,40]. There is another hypothesis that suggests GERD might be a systemic disease and IBS like symptoms might be a systemic presentation of GERD^[16]. However, in our study there were many patients whose major complaint was IBS and GERD was found during the clinical evaluation.

In conclusion, we suggest that a considerable overlap between GERD and IBS exists with a remarkable predominance in women; we also point to the association of upper gastrointestinal symptoms with IBS in patients suffering from both GERD and IBS, particularly nausea and vomiting, with a significant trend toward affecting women. Because this is a clinic based study, the limitations of this study include the possibility of over-reporting of symptoms by patients and referral bias. Another limitation is that atypical GERD usually includes wheezing, chronic cough, hoarseness or sleep deprivation, however it might present as abdominal discomfort and alterations in bowel movement which may have led to overestimation of IBS prevalence in GERD patients. There is evidence in the literature that prevalence of GERD and IBS in the Iranian population is similar to those reported from western countries^[41]. Further studies to clarify the reason for the increased prevalence of these complaints in women are warranted.

COMMENTS

Background

Gastroesophageal reflux disease (GERD) and irritable bowel syndrome (IBS) are two very common disorders affecting the gastrointestinal tract. About 10% of the population experience daily discomfort from reflux of gastric contents into the esophagus. More than 10% of the population experience abdominal pain and disturbed bowel movements because of IBS.

Research frontiers

Until recently, the dominant view in clinical practice was that GERD and IBS are two different diseases with no link. This view has been challenged by a body of increasing evidence showing that prevalence of IBS like symptoms is very high in patients with GERD and *vice versa*. This finding inspired research and hypotheses regarding the link between these two diseases. Whether general hyperalgesia in the gastrointestinal tract or a general dysfunction in smooth muscle is responsible for this overlap is not clear.

Innovations and breakthroughs

In the current study, the authors used a large data base from a specialty clinic to investigate the prevalence of overlap between GERD and IBS. They also studied the prevalence of other functional symptoms not related to GERD and IBS in patients in addition to some symptoms outside of the gastrointestinal tract such as headache. They also investigated the correlation between *Helicobacter pylori* (*H. pylori*) infection and severity of symptoms. They found out that in addition to significant overlap between GERD and IBS, prevalence of other functional symptoms is much higher in patients with both conditions.

H. pylori did not play a significant role in this regard. This finding suggests that GERD and IBS should be considered as parts of the same spectrum of diseases.

Applications

Changes in the way that clinicians and scientists think about GERD and IBS could provide opportunities to change the way we treat these conditions. The response rate of treatment for both of these conditions is not very satisfactory at the moment, hinting that our understanding of the main underlying dysfunction might not be complete. This finding might provide further insight about the correct approach in treatment of these diseases.

Terminology

GERD is characterized by the symptoms of heart burn and regurgitation caused by reflux of stomach contents. IBS is defined as abdominal pain or discomfort associated with altered bowel habits and disordered defecation.

Peer review

In this manuscript, the authors suggest a considerable overlap between GERD and IBS. The study was uniquely performed and very interesting.

Abstract

AIM: To review the clinical course and the management of pseudoaneurysms post-pancreaticoduodenectomy.

METHODS: Medical records of 907 patients who underwent pancreaticoduodenectomies from January 1995 to May 2007 were evaluated retrospectively. The clinical course, management strategy, and outcome of ruptured pseudoaneurysms cases were analyzed.

RESULTS: Twenty-seven (3.0%) of 907 cases had post-operative hemorrhage from ruptured pseudoaneurysms. Pancreatic fistula was evident in 12 (44%) cases. Sentinel bleeding appeared in 21 (77.8%) cases. Of the 27 cases, 11 (41%) cases demonstrated bleeding pseudoaneurysm of the ligated gastroduodenal artery, 8 (30%) of the right, proper, common hepatic artery, 2 (7%) of the right gastric artery, and 4 (15%) of the peripancreatic arteries. The remaining two patients died due to sudden-onset massive hemorrhage and pseudoaneurysm rupture was suspected. Emergent operation was performed on 2 cases directly without

angiography. Angiography was attempted in 23 cases. Eighteen (78.2%) cases succeeded to hemostasis; the five failed cases were explored. After embolization of the hepatic artery, five cases developed liver abscesses or infarction and a single case of hepatic failure expired. Gastroduodenal artery embolization with common hepatic artery stent insertion was performed to enhance hepatic artery flow in a single case and was successfully controlled.

CONCLUSION: Bleeding pseudoaneurysms are among the most serious and fatal complications following pancreaticoduodenectomy. Diagnostic angiography has been preferred over endoscopy and is rapidly becoming the standard therapeutic treatment for bleeding pseudoaneurysms.

INTRODUCTION

Major pancreatic surgery has advanced greatly in the last two decades with a dramatic decrease in its mortality rate. In the case of pancreaticoduodenectomy, several recent studies have reported mortality rates of less than

5%, with a few reporting mortality rates of less than 1%^[1,2]. Despite the reduction in mortality, the morbidity remains high at 40%. Some of the complications following major pancreatic surgery include pancreatic fistula, hemorrhage, delayed gastric emptying, and intra-abdominal abscess. Hemorrhage is one of the main complications following pancreaticoduodenectomy. Its incidence is anywhere between 1.5% and 15%^[1,3,4]. Hemorrhage on postoperative day #1 is defined as early, while hemorrhage after postoperative day #1 is termed late or delayed^[5,6]. Early-onset hemorrhage is usually due to poor hemostasis at the operation site. Delayed hemorrhage occurs with pancreatico-enterostomy leakage and pseudoaneurysm formation, intra-abdominal sepsis or abscess, or marginal ulcer^[1,3]. Without prior knowledge and experience, delayed hemorrhage is hard to diagnose and manage. Hence, it is crucial to understand the clinical features and etiology in anticipation and treatment of such delayed bleeding. Delayed hemorrhage, especially from a ruptured pseudoaneurysm, is a rare but rapidly progressing and potentially life threatening complication following pancreaticoduodenectomies. It has been widely studied, yet each study has reported different findings on its incidence, location, and clinical presentation. Recently, positive results have been achieved with angiographic intervention of ruptured pseudoaneurysms and a shift in management strategy from laparotomy to this less invasive alternative has occurred. The purpose of this study was to analyze data on delayed hemorrhage after pancreaticoduodenectomy due to pseudoaneurysm rupture. The clinical features, management strategy, and outcome of delayed hemorrhage from ruptured pseudoaneurysms were evaluated.

MATERIALS AND METHODS

Medical records of 907 patients who received pancreaticoduodenectomies between January 1995 and May 2007 were analyzed retrospectively. Based on the definition of postpancreatectomy hemorrhage from the International Study Group of Pancreatic Surgery (ISGPS), we suggest a definition that includes two times of onset: early hemorrhage, occurring in the first 24 h postoperatively, meaning 24 h after the end of the index operation, and late or delayed hemorrhage, occurring more than 24 h postoperatively. The severity of bleeding can be differentiated into two categories based on the amount of blood loss or transfusion requirements: (a) mild (no clinical impairment and transfusion requirements), or (b) severe (more than 4 or 6 units of packed cells transfused within 24 h; a decrease in hemoglobin of more than 4 g/dL or need for relaparotomy or interventional angiographic therapy due to severe blood loss). Evidence of bleeding in the surgical drains or GI tract 6 to 24 h prior to delayed massive hemorrhage was termed 'sentinel bleeding'. Pancreatic fistula or leakage was identified by the character of the drained fluid in the surgical drain. A definition of pancreatic fistula is a drain output of any measurable volume of fluid on or after postoperative day

Table 1 Clinical features of 27 patients with ruptured pseudoaneurysms

Initial sign or symptom	n (%)
Intraabdominal drain bleeding	11 (41)

Abdominal distension	2 (7)
Syncope	1 (4)
Arrest	1 (4)

3 with an amylase content greater than 3 times the serum amylase activity. Determination of the bleeding focus and management strategy were based on endoscopy, computed tomography (CT), angiography, and the details of the initial surgery. Medical records were analyzed to determine the effectiveness of the treatment provided and to review prognosis. Preceding complications were also evaluated.

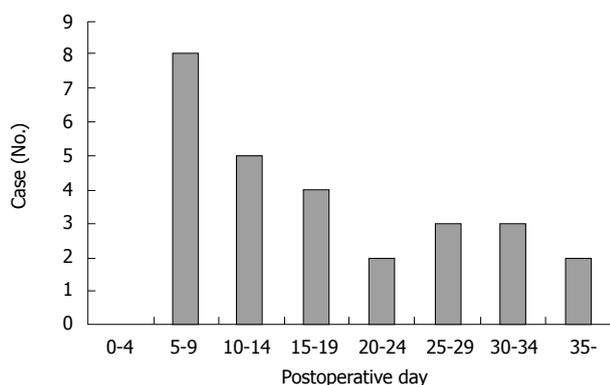

RESULTS

Nine hundred and five patients received pancreaticoduodenectomies [pancreatic duct to jejunal mucosa anastomosis (445 patients), invaginating pancreaticojejunostomy (454 patients), pancreaticogastrostomy (8 patients)]. Total frequency of pancreatic fistula was 43% (389 patients). Thirty-one (3.4%) of 907 patients who received pancreaticoduodenectomies were diagnosed with delayed massive hemorrhage. Twenty-seven [pancreatic cancer (11 patients), bile duct cancer (9 patients), ampulla of vater cancer (7 patients)] of 31 patients were diagnosed with hemorrhage from a ruptured pseudoaneurysm. Twenty-three of the 27 patients were diagnosed by angiography and 2 were diagnosed by re-operation. The remaining 2 patients died due to sudden-onset massive hemorrhage and considering their clinical features, rupture of pseudoaneurysm is suspected in both cases. In total, taking into account both confirmed and suspected ruptured pseudoaneurysms, there were 27 patients with an incidence of 3.0%. Eleven patients died (mortality rate of 1.2%) following pancreaticoduodenectomy. Only 6 of the 11 patient deaths were related to ruptured pseudoaneurysm. Sentinel bleeding was evident in 21 of the 27 cases (prevalence of 77.8%). Reviewing the clinical features of the first episode of bleeding from ruptured pseudoaneurysms, sentinel bleeding appeared in the surgical drains in 11 cases (41%), GI bleeding appeared in 8 cases (30%), and sentinel bleeding and GI bleeding were observed in 2 cases (7%). The clinical features of the ruptured pseudoaneurysms are shown in Table 1.

Twenty-seven cases of first and recurrent hemorrhage were investigated to determine the exact onset of bleeding. Cases were evenly distributed after surgery, with most of the bleeding occurring between day 5 and 9 post surgery. The onset of hemorrhage from ruptured pseudoaneurysms is outlined in Figure 1. Table 2 is a list showing the number of cases for each preceding complication

Table 2 List of complications that present prior to the rupture of pseudoaneurysms

Complication	n (%)
Pancreatico-enterostomy leakage	12 (44)
Wound dehiscence or infection	3 (11)

of ruptured pseudoaneurysm. Pancreaticojejunostomy anastomotic leakage was the most common complication to occur before hemorrhage [12 cases (44%): pancreatic cancer (7 cases), bile duct cancer (4 cases), ampulla of Vater cancer (1 case)]. Other complications include hepaticojejunostomy anastomotic leakage, wound dehiscence and infection, and intra-abdominal abscess formation. Most of the bleeding occurred from vessels around the pancreaticojejunostomy. Eleven patients (40.7%) experienced bleeding from the gastroduodenal artery, 4 patients (14.8%) from the right hepatic artery, 2 patients (7.4%) each from the hepatic artery proper, common hepatic artery and the right gastric artery, and 4 patients (14.8%) from the peripancreatic artery. The bleeding sites of the ruptured pseudoaneurysms are presented in Table 3.

Reviewing the treatment strategy of the 27 patients with ruptured pseudoaneurysms, 23 patients were managed by angiography, 2 patients had surgical intervention, and 2 patients with rapidly escalating hemorrhage could not be intervened and died. Of 23 cases of angiography, hemostasis was achieved in 18 patients. In the other 5 patients, hemostasis could not be achieved and they required surgery; 2 for failed attempts at coil embolization of the bleeding vessel and 3 for clinically continuous bleeding and hemodynamic instability despite successful coiling. Of these latter 3 patients, 2 died. Continuing hemorrhage due to disseminated intravascular coagulation (DIC) after total pancreatectomy was responsible for one death and the other death was due to the development of pulmonary complications namely adult respiratory distress syndrome (ARDS) and pneumonia after becoming hemodynamically stable. Of 18 cases with hemostasis, 14 maintained their hemostatic state. However, 1 of 14 cases died of hepatic failure after common hepatic artery embolization. Four

cases presented with recurrent hemorrhage from ruptures of new pseudoaneurysms. They were successfully treated by another embolization. Evaluating the outcome of 23 angiography cases, 18 cases displayed functional/therapeutic success (success rate of 78.2%), that is, achievement of a hemostatic state by embolization. The outcome of the above mentioned patients is summarized in Figure 2. Figure 3A-C are angiographs of the ruptured pseudoaneurysms of different vessels.

Of the 2 patients who underwent emergent surgery without angiography, 1 recovered without further complications but the other patient died due to rebleeding from an unknown focus.

Eight patients underwent embolization of the right proper common hepatic artery. All 8 patients had normal portal blood flow and this procedure was only considered after thorough review by the radiologist and surgeon. There was a single case of hepatic failure, 2 cases where liver abscesses were detected on CT scans, and 3 cases of liver infarction without hepatic failure. In the remaining 2 cases, no radiological abnormalities were detected. Figure 4A and B are abdominal CT scans showing liver abscess and liver infarction, respectively, which developed after embolization of the common hepatic artery. The patient who died of hepatic failure was a 63-year-old male who underwent a pancreaticoduodenectomy with left lateral sectionectomy for pancreatic head cancer with liver metastases. Following surgery, the patient showed signs of pancreaticojejunostomy anastomotic leakage. Thirty days post operation, common hepatic artery embolization was performed to manage bleeding of a ruptured pseudoaneurysm. However, the patient passed away on day 41 post surgery.

Stent grafts were placed for pseudoaneurysms to maintain liver or visceral blood flow. Stent grafting was successfully attempted in 2 of our cases for hemorrhagic pseudoaneurysm of the gastroduodenal and superior mesenteric artery. For gastroduodenal artery pseudoaneurysm, embolization of the gastroduodenal artery with a short stump was performed with stent grafting (8 mm × 30 mm size) of the common hepatic artery (Figure 5A). In the other case, with the first episode of early bleeding, hemostasis was achieved by laparotomy without any intervention by angiography. This patient presented with recurrent hemorrhage from the rupture of a new pseudoaneurysm of the superior mesenteric artery. Embolization of the

superior mesenteric artery results in severe ischemia of the end-organ and therefore needs careful consideration. Stent grafting (10 mm × 50 mm size) was also performed for recurrent bleeding (Figure 5B). Considering the risk of bleeding, anti-coagulant therapy was not administered and occlusion of the vessel by thrombus was shown on CT angiography taken 3 d later. This patient currently requires continuous total parenteral nutrition for GI malabsorption.

The mortality rate for hemorrhage of ruptured pseudoaneurysms was high at 22% (6/27 patients). As mentioned previously, 2 patients died due to rapidly developing hemorrhage of sudden onset. In these cases, no surgical or other intervening treatment could be applied in time. One patient died of continuing hemorrhage due to

disseminated intravascular coagulation and another due to hepatic failure after common hepatic artery embolization. One patient died of acute respiratory distress syndrome and pneumonia after becoming hemodynamically stable. Another death was due to recurrent hemorrhage from an unknown focus.

DISCUSSION

Hemorrhage after pancreaticoduodenectomy is one of the major life-threatening complications of this procedure and is responsible for 0.4%-5% of its mortality. According to numerous studies, mortality rates can range from 14%-58%^[1,4]. A ruptured pseudoaneurysm is among the

most serious and life threatening causes of post pancreaticoduodenectomy hemorrhage. Pseudoaneurysmal bleeding refers to disrupted vascular wall integrity which becomes continuous with pulsatile hematoma^[7]. Many pseudoaneurysms develop secondary to pancreatitis in association with pseudocyst formation. The etiology of pseudoaneurysm formation after pancreaticoduodenectomy is unclear. Erosion of the arterial wall by trypsin and elastase, in the case of pancreaticojejunostomy site leakage, has been suggested as one of the causes. Furthermore, infections of post-operative hematomas remaining in the abdominal cavity and radiotherapy prior to surgery have both been associated with the development of pseudoaneurysms. According to other authors, preceding sepsis due to anastomotic leakage is evident in the majority of patients who present with hemorrhage from pseudoaneurysms (8%-25% of cases result in anastomotic leak after pancreaticoduodenectomies)^[7,8]. In our study, pancreaticojejunostomy anastomotic leak (44%) was the most common cause of subsequent complications. CT was performed on postoperative day 7 in all patients. Patients with pancreaticojejunostomy leaks are closely monitored and CT scans are taken immediately if there is sentinel bleeding and they are hemodynamically stable.

Sentinel bleeding was first described in 1989 by Shankar and Russell^[9]. They defined it as gastrointestinal (intraluminal) or intra-abdominal (placed drain) hemorrhage which occurs 6 h to 10 d prior to massive hemorrhage. Currently, different authors use different definitions for this term^[1,3,10,11]. Sentinel bleeding is evident in most cases of massive hemorrhage and it starts off as an intermittent or small-volume hemorrhage. Koukoutsis *et al.*^[3] reported that sentinel bleeding was evident in 57.1% of cases of post-operative hemorrhage 7 d after surgery, but they reached the conclusion that sentinel bleeding has no statistically significant association with post-operative mortality. In the study by Sato *et al.*^[8], sentinel bleeding was noted in 10 patients with massive arterial hemorrhage out of 81 pancreaticoduodenectomy patients and only one case of sentinel bleeding was not followed by massive hemorrhage. In our study, sentinel bleeding was evident in 21 of 27 cases (prevalence of 77.8%). It is important to adequately manage sentinel bleeding as soon as possible to prevent massive hemorrhage because sentinel bleeding is an important preceding sign of massive hemorrhage.

Current studies have suggested that angiography should be the treatment of choice for delayed massive hemorrhage after pancreaticoduodenectomies^[5,8,12]. They also argue that the therapeutic value of endoscopy is limited and should only be attempted if the precise location of the bleeding ulcer is obvious. Nevertheless, it is inappropriate to conclude that angiography is always more sophisticated than therapeutic endoscopy as their suitability varies on a case-by-case basis. Not all delayed massive hemorrhages are due to ruptured pseudoaneurysms. Furthermore, hemorrhage from ruptured pseudoaneurysms cannot be completely ruled out based on negative findings on angiography^[10]. Initial intermittent bleeding of ruptured pseudoaneurysms is hard to detect by angiography, which is only sensitive to bleeding greater than 2 mL per minute^[6,10]. In contrast, bleeding foci are hard to find using endoscopy in massive intraluminal hemorrhages^[5,8]. Location of the bleeding focus by endoscopy does not completely exclude bleeding from ruptured pseudoaneurysms elsewhere. Choi *et al.*^[5] stated that diagnostic endoscopy delays treatment in hemodynamically unstable patients and more often than not, intra-luminal hemorrhage is due to erosion of pseudoaneurysms. de Castro *et al.*^[1] recommended CT scanning for patients with sentinel bleeding who are hemodynamically stable. In the case where the bleeding focus cannot be identified by this method, or if the patient is hemodynamically unstable, angiography is suggested. Therefore, diagnosis and treatment strategies should be decided on a case-by-case basis. Angiography should be considered, with the understanding that most cases of hemorrhage from ruptured pseudoaneurysms present with preceding sepsis due to anastomotic leakage.

Transcatheter arterial embolization has been proven by many authors to be an efficacious and minimally invasive alternative to open surgery^[1,7,8]. It has a success rate of 67%-100%, morbidity rate of 14%-25%, and mortality rate of 0%-14%. Thirty-seven percent of patients in these studies required re-embolization either for rebleeding or recanalization of the vessels^[1,7,8]. When the bleeding focus cannot be identified by conventional investigation and hemostasis cannot be achieved by therapeutic angiography or endoscopy, emergency laparotomy is necessary for delayed massive hemorrhage^[1,7]. Thorough examination of the ligated vessel stumps should be carried out. In more difficult cases, inspection of the

anastomoses for suture line bleeding and bleeding of ruptured vessel stumps into the GI lumen is required^[6]. In other words, emergency laparotomy is rarely required for hemorrhagic pseudoaneurysms and therapeutic angiography has become the standard treatment strategy.

Stent grafting was successfully performed in 2 of our cases for hemorrhagic pseudoaneurysms. This procedure can be used as an alternative or in addition to embolization^[13]. This technique has the advantage of providing continued perfusion to the end-organ and, therefore, obviates the risk of occlusion and ischemia often seen with embolization. On the other hand, potential complications do occur and include stent occlusion, stent deformation or kinking, and exclusion of branch vessels. In our study, a stent graft was used for a pseudoaneurysm of the common hepatic artery and superior mesenteric artery to maintain the visceral and liver blood flow. Embolization of the superior mesenteric artery results in severe ischemia of the end-organ and therefore needs careful consideration. Stent grafting has the advantage of maintaining the peripheral blood flow and hence could be considered an alternative to embolization. However, it is a technically difficult procedure and requires adaptation to different-sized vessels. The limitation and the role of the interventions used to manage ruptured pseudoaneurysms need to be studied further.

Various surgeons have developed different surgical techniques in an attempt to prevent pseudoaneurysm formation. Turrini *et al.*^[11] suggested leaving 1 cm of the gastroduodenal artery stump to minimize direct contact of pancreatic juice with adjacent vessels. Koukoutsis *et al.*^[3] suggested spreading an omental flap behind the pancreaticojejunostomy site. We leave behind a long segment (5-10 mm) of the gastroduodenal artery stump to minimize gastroduodenal artery intimal injury with Hemolok[®] clipping.

Bleeding pseudoaneurysms are a rare cause of delayed hemorrhage but these delayed hemorrhages are among the most serious and fatal complications following pancreaticoduodenectomy. A decade ago, diagnostic or therapeutic endoscopy followed by laparotomy was the treatment strategy for delayed massive hemorrhage. However, in recent years, diagnostic angiography has been preferred over endoscopy and is rapidly becoming the standard therapeutic treatment for bleeding pseudoaneurysms. Fundamentally, however, the patient's clinical history and presentation should be taken into consideration when planning an appropriate management strategy that is tailored to that patient.

COMMENTS

Background

Delayed hemorrhage, especially from a ruptured pseudoaneurysm, is a rare but rapidly progressing and potentially life threatening complication following pancreaticoduodenectomies.

Research frontiers

To review the clinical course and the outcome of pseudoaneurysms post-pancreaticoduodenectomy.

Innovations and breakthroughs

It has been widely studied, yet each study has reported different findings on its incidence, location, and clinical presentation. The purpose of this study was to analyze data on delayed hemorrhage after pancreaticoduodenectomy due to pseudoaneurysm rupture.

Applications

Delayed massive hemorrhage following pancreaticoduodenectomies should be ruled out regardless of its association with rupture of pseudoaneurysms. In this study, arterial embolization was shown to be an effective and safe way to manage and control bleeding pseudoaneurysms.

Peer review

Well written article by very experienced authors in the field of pancreatic surgery.

Abstract

AIM: To identify specific colonoscopic findings in patients with ulcerative colitis (UC) complicated by cytomegalovirus (CMV) infection.

METHODS: Among UC patients who were hospitalized due to exacerbation of symptoms, colonoscopic findings were compared between 15 CMV-positive patients and 58 CMV-negative patients. CMV infection was determined by blood test for CMV antigenemia. Five aspects of mucosal changes were analyzed (loss of vascular pattern, erythema, mucosal edema, easy bleeding, and mucinous exudates) as well as five aspects of ulcerative change (wide mucosal defect, punched-out ulceration, longitudinal ulceration, irregular ulceration, and cobblestone-like appearance). Sensitivity, specificity, positive predictive value, and negative predictive value of each finding for CMV positivity were determined.

RESULTS: The sensitivity of irregular ulceration for positive CMV was 100%. The specificity of wide mucosal defect was 95%. Punched-out ulceration and longitudinal ulceration exhibited relatively high sensitivity and specificity (more than 70% for each).

CONCLUSION: Specific colonoscopic findings in patients with UC complicated by CMV infection were identified. These findings may facilitate the early diagnosis of CMV infection in UC patients.

Specific endoscopic features of ulcerative colitis complicated by cytomegalovirus infection. *World J Gastroenterol* 2010; 16(10): 1245-1251 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i10/1245.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i10.1245>

INTRODUCTION

Ulcerative colitis (UC) is a worldwide, chronic, idiopathic, inflammatory disease of the rectal and colonic mucosa. Patients with UC suffer from abdominal pain, diarrhea with blood, tenesmus, and urgency to defecate. In Japan, the number of patients with UC was reported to be only 4400 in 1980. However, the number has increased sharply in recent years, and was estimated to be approximately 100 000 persons in 2008. This number is thought to

increase by about 5000 persons each year.

Cytomegalovirus (CMV) belongs to the herpes virus group and is prevalent in adults. Primary CMV infection in immunocompetent people is usually asymptomatic, but the virus remains in the white blood cells throughout the life of the host. Clinically significant diseases occur in patients with suppressed cellular immunity, especially in transplant patients, acquired immunodeficiency syndrome (AIDS) patients, and patients undergoing chemotherapy. The disease is usually the result of reactivation of the latent virus rather than reinfection with the virus. Significant CMV disease may occur in various organs such as the retina, lung, and gastrointestinal tract, and the target organ may be related to the etiology of immunosuppression. In the gastrointestinal tract, CMV disease can occur in all locations from the mouth to the rectum, and usually forms ulcers in the mucosa, often accompanied by hemorrhage^[1].

CMV infection has been described as a cause of relapse of inflammatory bowel disease^[2-5]. In particular, CMV infection was observed in UC patients, especially those receiving high-dose corticosteroid therapy^[4-7]. Moreover, CMV infection can exacerbate the disease^[2-5]. Retrospective studies of UC patients have found CMV infection in 5%-21% of surgically resected specimens^[2-4,8]. Steroid resistance is also reported to be one of the characteristics of CMV infection in UC^[6,8]. In recent prospective studies, 25%-81% of patients with steroid-refractory UC were found to harbor the virus^[5-7]. Thus, CMV infection in UC patients can have a severe clinical course and may cause death if appropriate treatment is not given. However, with the development of ganciclovir (GCV) therapy, outcomes have greatly improved^[9].

Therefore, it is necessary to make an early diagnosis of CMV infection in UC patients. Although several different methods have been developed to examine CMV infection, such as histology including immunohistochemistry^[10,11], serology^[10-12], CMV culture^[13,14], polymerase chain reaction (PCR) for CMV genome^[14-16], and CMV antigenemia^[14-16], it is necessary, with regard to clinical aspects, to suspect that UC patients also have CMV infection. In general, the symptoms of UC alone are not sufficient to distinguish exacerbation of UC due to CMV infection from exacerbation of UC unrelated to CMV infection. Specific colonoscopic findings for CMV infection, if any, may facilitate the early diagnosis of CMV infection.

Several reports have examined colonoscopic findings related to CMV infection. However, most of these reports focused on colonoscopic findings in patients with AIDS or in transplant patients^[17,18]. The spectrum of colonoscopic findings in those patients was variable and ranged from patchy erythema, exudates, and microerosions to diffusely edematous mucosa, multiple mucosal erosions, deep ulcers and pseudotumors^[1,13,17-22]. In contrast, colonoscopic findings of UC complicated by CMV infection have rarely been reported. Only a few studies have described findings without confirmation by statistical analysis^[20].

Accordingly, the aim of this study was to identify specific colonoscopic findings in patients with UC complicated by CMV infection. To achieve this, we compared

colonoscopic findings in CMV-positive and -negative patients, and determined the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of each specific finding for CMV positivity.

MATERIALS AND METHODS

Patients

This study was a retrospective analysis of medical charts and endoscopic images of UC patients. From January 1999 to August 2007, a total of 200 UC patients were hospitalized in Okayama University Hospital with exacerbation of UC symptoms. We began to routinely examine CMV antigenemia in these patients from 2003. Therefore, of these 200 patients, 111 did not receive a blood test for CMV antigenemia at admission, and 13 did not receive an endoscopic examination. Thus, a total of 76 patients who received both a blood test for CMV antigenemia and an endoscopic examination at admission were analyzed in this study. This study was approved by the institutional review board of Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences.

The diseases in these patients were pancolitis or left-sided colitis with moderate or severe activity, based on clinical, endoscopic, and histological findings according to established criteria^[23-25]. Medical charts provided clinical parameters including demographic data such as age, gender, and duration of the disease, as well as disease status such as severity of disease, extent of disease, and medications.

Diagnosis of CMV infection

Diagnosis of CMV infection was determined by CMV antigenemia, which was examined by detecting CMV pp65 antigen in peripheral blood leukocytes using the direct immunoperoxidase technique with horseradish peroxidase-conjugated Fab' fragment of human monoclonal antibody (C7-HRP) and immunofluorescence staining with monoclonal antibodies C10/11. The examinations were performed in the laboratory of SRL Inc. (Tokyo, Japan). We defined a patient as CMV-positive when one or more positive cells of either C7-HRP or C10/11 were detected in more than 10 000 leukocytes (the minimum number of positive cells).

Endoscopic findings

Endoscopic findings were evaluated by examining recorded colonoscopic images and reports. Two aspects of colonic changes were assessed: mucosal change and ulcerative change. Mucosal change was evaluated according to the following five features: easy bleeding, loss of vascular pattern, mucosal edema, erythema, and mucinous exudates. Each item was expressed as "severe" or "not severe" according to the severity of each change. Easy bleeding was defined as bleeding from the fragile membrane due to slight contact of the endoscope. Loss of vascular pattern was loss of visible vessels under the

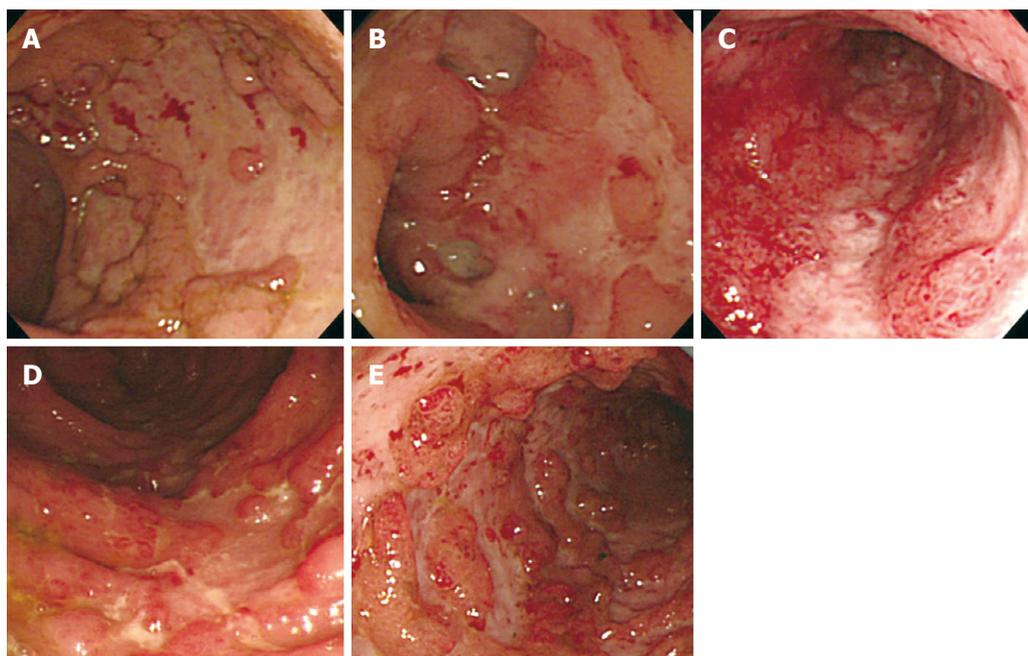

Figure 1 Typical endoscopic findings of ulcerative changes. A: Wide mucosal defect; B: Punched-out ulceration; C: Longitudinal ulceration; D: Irregular ulceration; E: Cobblestone-like appearance.

membrane, generally seen during colonoscopy. Mucosal edema was defined as thick and swollen membrane which pooled fluid. Erythema was red coloration of the membrane composed of dilated veins. Mucinous exudates were exudates composed of blood and pus.

For ulcerative changes, we determined whether or not the following forms of ulceration were observed: wide mucosal defect, punched-out ulceration, longitudinal ulceration, irregular ulceration, and cobblestone-like appearance. A wide mucosal defect was a wide area of this defect with a longitudinal and/or transverse spread, indicating that more than one-fourth of the mucosa in the endoscopic field was defective (Figure 1A). Punched-out ulceration formed an almost round shape of ulceration with clear demarcation (Figure 1B). Longitudinal ulceration had a longitudinal spread along the lumen of the colon (Figure 1C). Irregular ulceration was defined as ulceration with an irregular pattern and a branched shape (Figure 1D). Cobblestone-like appearance was an aggregate of elevated lesions as a result of the changes in the membrane, which looked like half-spheres of subpedunculated polyps with multiple ulceration as seen in Crohn's disease (Figure 1E). Each endoscopic image was evaluated by two (Suzuki H and Kato J) of the authors. If there were any disagreements in these evaluations, a third reviewer (Hiraoka S) made the final evaluation. At the time of interpretation of the images, the CMV antigenemia results were blinded to interpreters. The rate of disagreements between the two authors was less than 5%.

Statistical analysis

Of the clinical characteristics, the χ^2 test and Fisher's exact test were used to compare two discrete variables. The significance of differences for continuous variables was assessed by the Mann-Whitney *U*-test. Of the endoscopic findings, we calculated sensitivity, specificity, PPV, and

NPV for CMV positivity. In addition, odds ratios (OR) with 95% CI were determined by a univariate logistic regression model. The results were considered statistically significant when *P* values were less than 0.05. Statistical analysis of the data was carried out with SAS software version 9.2 (SAS Institute, Cary, NC, USA).

RESULTS

Patients

A total of 76 patients received a blood test for CMV antigenemia and a colonoscopy at admission. Of these, 18 patients were positive for CMV antigenemia, while the remaining 58 patients were negative. Of the 18 CMV-positive patients, symptoms in 3 patients were relatively mild, and those patients entered remission without antiviral therapy. The remaining 15 patients required GCV therapy for a period of two weeks, together with dose reduction of corticosteroids. As a consequence of these treatments, all patients entered remission. Therefore, a comparative analysis was performed on 15 CMV-positive patients *vs* 58 CMV-negative patients.

The clinical characteristics of these 73 patients are shown in Table 1. There were no significant differences in clinical characteristics such as gender, age, duration of disease, disease activity, extent of disease, use of corticosteroids, and use of immunomodulators (azathioprine or mercaptopurine) between CMV-positive and -negative patients. It is noteworthy that all the CMV-positive patients received corticosteroid therapy.

Specific endoscopic findings of UC with CMV infection

To identify specific endoscopic findings of UC complicated by CMV infection, five aspects of mucosal changes (loss of vascular pattern, erythema, mucosal edema, easy bleeding, and mucinous exudates) as well as five aspects of ulcerative change (wide mucosal defect, punched-out

Table 1 Characteristics of enrolled patients

	CMV positive (n = 15)	CMV negative (n = 58)	P value
Gender			
Male	8 (53)	26 (45)	0.55
Female	7 (47)	32 (55)	
Age (yr), median (range)	42 (17-65)	34 (14-81)	0.72
Duration of disease (d), median (range)	528 (15-9358)	1503 (5-10791)	0.40
Disease activity at admission			
Moderate	9 (60)	41 (71)	0.43
Severe	6 (40)	17 (29)	
Extent of disease			
Pancolitis	12 (80)	42 (72)	0.74
Left-sided	3 (20)	16 (28)	
Current use of corticosteroids			
Yes	15 (100)	47 (81)	0.11
No	0 (0)	11 (19)	
Current use of immunomodulators (AZA/6-MP)

No	14 (93)	51 (88)	

Data are numbers with percentages in parentheses or medians with ranges in parentheses. CMV: Cytomegalovirus.

ulceration, longitudinal ulceration, irregular ulceration, and cobblestone-like appearance) were analyzed. The sensitivity, specificity, PPV and NPV of each finding for CMV positivity were determined. In addition, univariate logistic regression analyses were performed to determine the OR and 95% CI of each finding (Table 2).

Of the 5 mucosal changes, loss of vascular pattern, edema, and erythema exhibited relatively high sensitivity for CMV positivity (87%, 80%, and 87%, respectively), whereas easy bleeding and mucinous exudates exhibited high specificity (88% and 81%, respectively). Of the 5 ulcerative changes, irregular ulceration showed 100% sensitivity, but relatively low specificity (41%). Wide mucosal defect and cobblestone-like appearance showed relatively high specificity (95% and 83%, respectively), but low sensitivity. The sensitivity and specificity of punched-out ulceration and longitudinal ulceration were both relatively high (punched-out ulceration, sensitivity 80%, specificity 74%, longitudinal ulceration sensitivity 73%, specificity 78%, respectively).

Univariate logistic regression analysis revealed that severe easy bleeding was seen more frequently in CMV-positive patients than in CMV-negative patients (OR = 2.20, 95% CI: 1.14-4.28). Wide mucosal defect (OR = 4.58, 95% CI: 2.21-10.73), punched-out ulceration (OR = 3.39, 95% CI: 1.78-7.46), longitudinal ulceration (OR = 3.09, 95% CI: 1.66-6.26), and cobblestone-like appearance (OR = 2.05, 95% CI: 1.11-3.82) were more frequently observed in CMV-positive patients than in CMV-negative patients.

DISCUSSION

Colonoscopy is generally performed in UC patients who undergo flare-ups. Direct observation of the colon provides detailed information on the disease status and is useful for comprehending the severity of disease, and thus it is an important tool for formulating

treatments. However, although CMV infection can cause poor prognosis in UC patients (i.e. a high chance of colectomy), reports on the specific colonoscopic findings of UC with CMV infection are scarce. Therefore, in this study we analyzed the colonoscopic findings of UC patients with and without CMV infection, and showed that there were specific findings that predicted CMV infection in UC patients.

There have been reports on the endoscopic findings of CMV colitis in AIDS or transplant patients. These findings include patchy erythema, exudates, microerosions, diffusely edematous mucosa, multiple mucosal erosions, or deep ulcers and pseudotumors^[1,13,17-22]. In UC patients, however, the findings would be more complicated, because inflammatory changes due to UC itself in colonic mucosa exists prior to CMV infection. Therefore, in previous studies, no specific endoscopic findings were observed in UC patients with concomitant CMV infection^[6,26]. In contrast, in our study, specific colonoscopic findings of UC with CMV infection were observed; the sensitivity of irregular ulceration was 100%, the specificity of wide mucosal defect was 95%, and the sensitivity and specificity of punched-out ulceration and longitudinal ulceration were both greater than 70%. Therefore, in cases where these colonoscopic findings are seen in UC patients, examination to confirm CMV infection should be performed as soon as possible.

It is known that UC patients with CMV infection, especially those who are compromised by corticosteroid therapy, experience severe symptoms. These patients are likely to undergo colectomy, and CMV infection has been confirmed in 4.6%-25% of patients who have undergone colectomy^[2,3,7,8]. Recently the efficacy of GCV in CMV infection has become widely recognized. Pfau *et al*^[9] considers GCV a beneficial treatment that significantly decreases the mortality rate and the need for surgery. Wada *et al*^[6] found that GCV was effective in 8 (67%) of 12 patients with CMV infection. They

also reported that steroid withdrawal improved steroid-resistant UC. Matsuoka *et al.*^[27] reported that most CMV reactivation-positive patients responded to conventional immunosuppressive therapies, however, high values of CMV antigenemia may be an indicator for antiviral treatment regardless of histology. Thus, treatment for UC patients with CMV infection should be different from that for UC patients without CMV infection. Therefore, our findings that predict CMV infection should be useful in therapeutic decision-making for UC patients.

In addition, there are several studies on the prophylactic/pre-emptive therapy of CMV diseases in patients with solid organ transplants, hematopoietic stem cell transplants, and human immunodeficiency virus disease^[27-29]. These reports suggested the importance of early detection of CMV reactivation and early administration of anti-viral drugs before the development of CMV disease. Although no concept of prophylactic therapy has been established for UC patients, early detection and early antiviral therapy may be considered because of the high rate of colectomy in these patients. In this context, early prediction of CMV infection in UC patients by colonoscopy would seem helpful in clinical settings.

There are several methods of detecting CMV infection: histology including immunohistochemistry^[10,11], serology^[10-12], CMV culture^[13,14], PCR for CMV ge-

nome^[14-16], and CMV antigenemia^[14-16]. Each method has advantages and disadvantages for the precise diagnosis of CMV infection. For example, histological examination is a relatively easy method, but the sensitivity is not so high (10%-87%)^[10-12]. Meanwhile, PCR for the CMV genome is very sensitive, but the false-positive rate is relatively high. In our analysis, CMV antigenemia was adopted to detect CMV infection, because examination of CMV antigenemia is relatively sensitive (60%-100%) and easy to measure within a short period^[10,14,16,30]. In addition, this method has been used for monitoring CMV infection in heart transplant recipients, and for the early diagnosis of CMV infection in renal transplant recipients^[29]. Moreover, it has been reported that positive or negative results of CMV antigenemia are a good indication for antiviral therapy^[28,31]. In fact, in our study, 15 (83%) of 18 patients who were positive for CMV antigenemia required antiviral therapy with GCV, and all of these patients entered remission without colectomy. In general, immunohistochemistry is considered the gold standard in the diagnosis of CMV infection. In our cohort, however, among 6 patients with positive CMV antigenemia whose biopsy specimens were immunostained with antibody for CMV, only 3 exhibited positive immunostaining. In addition, although we performed immunostaining in 16 of 58 patients with negative CMV

antigenemia, none of them exhibited positive staining. Therefore, the use of CMV antigenemia for CMV detection in this study was appropriate.

Our study has several limitations. First, CMV infection was determined by CMV antigenemia alone. As described above, there are several methods to detect CMV infection. A combination of these methods may have increased the CMV detection rate. Second, of the 18 CMV antigenemia-positive patients, 15 patients who were given GCV were analyzed in our study. However, it is not certain that all 15 patients really required GCV therapy. Some of these patients may have improved without GCV similar to the remaining 3 patients. Third, this is a retrospective study that relied on the examination of recorded colonoscopic images. Therefore, bias due to patient collection and missed recording of colonoscopic findings may inevitably exist. Finally, this is a relatively small scale study in Japan, and it is possible that the results might differ in patients of other ethnicities from other parts of the world.

In the case of a severe flare-up of UC, the possibility of a concurrent CMV infection causing or worsening colitis should be considered, especially when patients are on immunosuppressive medications that may make them more susceptible to this viral infection. The prognosis of UC cases with CMV infection is considered poor. Thus, CMV infection should be closely investigated in such cases, and anti-CMV treatment (GCV) should be given immediately to reduce the rate of colectomy. The specific colonoscopic findings of patients with UC complicated by CMV infection observed in this study may facilitate early diagnosis and treatment of CMV infection.

COMMENTS

Background

In general, the symptoms of ulcerative colitis (UC) alone are not sufficient to distinguish exacerbation of UC due to CMV infection from exacerbation of UC unrelated to cytomegalovirus (CMV) infection.

Research frontiers

Few studies have reported the colonoscopic findings of UC complicated by CMV infection.

Innovations and breakthroughs

Via retrospective research, authors found specific colonoscopic findings in UC patients with CMV antigenemia.

Applications

Specific colonoscopic findings in patients with UC complicated by CMV infection found in this study may facilitate early diagnosis and treatment of CMV infection.

Peer review

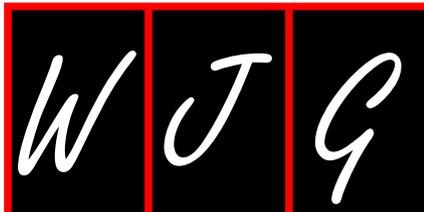

This is a potentially important study that is generally well done, well written, and makes a contribution to the field.

Abstract

AIM: To investigate the association between adiponectin levels and risk of colorectal adenoma and cancer (early and advanced).

METHODS: A cross-sectional study in a cohort of hospital-based patients was conducted between January 2004 and March 2006 at Yamagata University Hospital. Male subjects, who had colorectal tumors detected by endoscopic examination, were enrolled according to inclusion and exclusion criteria. Based on the T factor of the TNM system, intraepithelial carcinoma and submucosally invasive carcinoma were defined as early cancer, and invasion into the muscularis propria or deeper was defined as advanced cancer. The plasma levels of glucose, insulin, total cholesterol, triglyceride, high sensitivity C-reactive protein, insulin like growth factor (IGF)-1, IGF binding protein-3, adiponectin, leptin, and resistin were measured. Each factor level was designated low or high, and the risk of adenoma

or cancer was estimated by univariate and multivariate logistic regression analysis.

RESULTS: We enrolled 124 male subjects (47 with adenoma, 34 with early cancer, 17 with advanced cancer, and 26 without tumors as controls). In patients with adenoma, high triglyceride and low adiponectin were associated with a significant increase in the odds ratio (OR) by univariate analysis. Only a low adiponectin level was related to increased adenoma risk, with an adjusted OR for low level ($< 11 \mu\text{g/mL}$) to high ($\geq 11 \mu\text{g/mL}$) of 5.762 (95% confidence interval (CI): 1.683-19.739, $P = 0.005$). In the patients with early cancer, high body mass index, high triglyceride, and low adiponectin were associated with a significant increase in OR in univariate analysis. In multivariate analysis, only low adiponectin was significantly associated with early cancer, with an adjusted OR of 4.495 (95% CI: 1.090-18.528, $P = 0.038$). However, in patients with advanced cancer, low adiponectin was not recognized as a significant risk factor for advanced cancer.

CONCLUSION: A decreased level of adiponectin is strongly associated with an increased risk of colorectal adenoma and early cancer. These data call for further investigation, including a controlled prospective study.

INTRODUCTION

Colorectal cancer is the world's third most common type of malignancy. Etiological studies have shown that body/abdominal fat or obesity increases the risk of colorectal cancer^[1]. Accumulation of body/abdominal fat is associated with abnormal secretion of adipokines, resulting in either insulin resistance or metabolic syndrome. Metabolic syndrome is clinically defined as an increase in waist circumference and in blood pressure and fasting glucose levels, as well as dyslipidemia^[2]. Many other factors, such as insulin, insulin-like growth factor-1 (IGF-1), IGF binding protein-3 (IGFBP-3), high sensitivity C-reactive protein (hsCRP), and inflammatory cytokines are also involved in the pathophysiology of insulin resistance or metabolic syndrome.

Adiponectin is a unique adipokine secreted from abdominal fat tissue and has anti-diabetic, anti-atherosclerotic, and anti-inflammatory effects^[3]. Previously, we demonstrated that an increase in visceral fat area and a decrease in plasma adiponectin level were strongly associated with an increased risk of colorectal adenoma^[4]. The present study investigated adiponectin levels in patients with colorectal adenoma and cancer. Several studies have previously described the adiponectin levels in patients with colorectal cancer^[5,6]. However, most focused on advanced cancer. Although plasma levels of adiponectin were described, evaluations of risk of cancer by multivariate analysis were not conducted. Therefore, the present study attempted to evaluate the risk of colorectal cancer in patients with decreased adiponectin levels, and elucidated the relationship between adiponectin levels and the risk of both early and advanced cancer, in addition to adenoma.

MATERIALS AND METHODS

A cross-sectional study in a cohort of hospital-based patients was conducted between January 2004 and March 2006 at Yamagata University Hospital.

Ethics

This study was approved by the Ethics Committee of Yamagata University Faculty of Medicine, and written informed consent to participate in the study was obtained from every patient and control subject.

Patients

Patients who visited our hospital for colonoscopic examination in that period were screened for this study. The subjects were enrolled according to the following inclusion criteria: (1) male aged at least 31 years; (2) colonoscopic observations of the cecum were performed successfully; (3a) histopathological confirmation by hospital patholo-

gists (in the case of patients with adenoma or cancer) and (3b) confirmation of lack of obvious polyps upon endoscopic examination of the entire colon and rectum (in the case of controls); and the following exclusion criteria: (a) previous gastrointestinal tract surgery; (b) inflammatory bowel disease; (c) patients with cancers in another organs and currently receiving therapy; (d) diabetes mellitus with insulin injection therapy, and (e) lack of consent to participate in the study. In the present study, only male patients were investigated. It has been shown that, in general, the levels of adiponectin, leptin, and resistin in males are significantly lower than in females^[7,8]. Also, the criteria for metabolic syndrome differ between males and females^[2]. Therefore, for this study, it was considered appropriate to evaluate only males.

Colonoscopy was performed by experienced gastrointestinal physicians using video-endoscopy (CF-240ZI, PCF-240, PCF-P240AI, or PCF-240Z; Olympus Medical Systems, Tokyo, Japan). The lesions of adenoma or cancer were treated appropriately by endoscopic polypectomy, endoscopic mucosal resection, laparoscopic colectomy, or open surgical colectomy. The degree of cancer invasion was evaluated according to the pathologic T factor of the TNM staging system^[9]. Based on the T factor classifications, cancer patients were divided into 2 subgroups: early and advanced cancer. Intraepithelial carcinoma (T_{is}) and submucosally invasive carcinoma (pT₁) were defined as the early cancer group. Those with a pathological depth of pT₂ or greater (muscularis propria invasion or deeper) were defined as having advanced cancer.

Observed factors and evaluations

All patients were interviewed about their smoking habits, alcohol intake, medications, and medical histories. Persons who had stopped smoking more than 1 year previously were counted as ex-smokers. Any person who was drinking an average of more than 15 g of alcohol daily was defined as a regular alcohol drinker. Body weight, height, and blood pressure were also recorded, and body mass index (BMI) was calculated. And blood samples were collected after overnight fasting. Glucose, insulin, total cholesterol (T-cho), triglyceride (TG), hsCRP, IGF-1, IGFBP-3, adiponectin, leptin, and resistin levels were measured in plasma samples. The homeostatic model assessment of insulin resistance (HOMA-IR) was calculated as: $HOMA-IR = \text{fasting glucose} \times \text{fasting insulin} / 405$. The IGF-1/IGFBP-3 ratio was also calculated. The plasma level of each factor was measured as follows: hsCRP by nephelometry (N Latex CRP II CardioPhase hsCRP, Siemens Healthcare Diagnostics Inc., Tokyo, Japan); IGF-1 by a radioimmunoassay (RIA; IGF-I IRMA Daiichi, TFB Inc., Tokyo, Japan); IGFBP-3 by an RIA2 antibody method (IGFBP-3 Cosmic, Bioclone Australia Pty Ltd., Sydney, Australia); leptin by an RIA2 antibody method (Human Leptin RIA Kit, LONCO Research Inc., St. Charles, USA); resistin by an enzyme-linked immunosorbent assay (ELISA; Human Resistin ELISA, BioVender Inc., Modrice, Czech Republic), and adiponectin by enzyme-linked immunosorbent assay (human adiponectin ELISA kit,

Otsuka Pharmaceuticals Inc., Tokyo, Japan).

The measured values of each factor in control patients were divided into 2 categories (Low and High), and the odds ratio (OR) (High *vs* Low) for adenoma or cancer was evaluated by univariate and multivariate logistic regression analysis. Criteria determining Low and High categorization were appropriately determined; the actual categorizations for each factor are described as follows. BMI was categorized as Low (< 22.5 kg/m²) and High (≥ 22.5 kg/m²), systolic blood pressure (BP-S) as < 120 mmHg and ≥ 120 mmHg, diastolic BP (BP-D) as < 80 mmHg and ≥ 80 mmHg, glucose as < 100 mg/dL and ≥ 100 mg/dL, insulin as < 4.5 μU/mL and ≥ 4.5 μU/mL, HOMA-IR as < 2 and ≥ 2, T-cho as < 180 mg/dL and ≥ 180 mg/dL, TG as < 120 mg/dL and ≥ 120 mg/dL, hsCRP as < 500 ng/mL and ≥ 500 ng/mL, IGF-1/IGFBP-3 ratio as < 60 and ≥ 60, adiponectin as ≥ 11 μg/mL and < 11 μg/mL, leptin as < 3 ng/mL and ≥ 3 ng/mL, and resistin as < 42 ng/mL and ≥ 42 ng/mL. Only adiponectin was inversely categorized (High and Low).

Statistical analysis

The SPSS statistical software package for Windows version 11.0J (SPSS Inc. Tokyo, Japan) was used for all statistical analyses. Distributions were evaluated by the χ² test. Comparisons of mean values among groups were tested by analysis of variance, and Dunnett’s test was applied as an additional multiple comparison after the equality of variance had been confirmed. Risks were tested by univariate and multivariate logistic regression. Differences at *P* < 0.05 were considered to be significant. The exact *P* values are indicated when statistically significant.

RESULTS

Clinical background of patients

The study included 124 male subjects (47 with adenoma, 34 with early cancer, 17 with advanced cancer, and 26 without tumors as controls). The early cancer group included 14 T1m and 20 pT1 cases. The advanced cancer group included 6 pT2, 10 pT3, and one pT4 cases.

The clinical backgrounds of the controls and patients are shown in Table 1. There were no significant differences in mean age or blood pressure among the 4 groups (control, adenoma, early cancer, and advanced cancer). There were also no significant differences in the distribution of the numbers of diabetic patients, current smokers, ex-smokers, habitual alcohol drinkers, NSAID users, and other medicine users. Angiotensin II receptor antagonists, angiotensin converting enzyme inhibitors, and statin type anti-hyperlipidemia medicines were designated as other medicines. The BMI in the control group was 21.8 ± 3.1 kg/m². Those in the adenoma, early cancer, and advanced cancer groups were 23.2 ± 3.2 kg/m², 24.4 ± 3.8 kg/m², and 22.7 ± 3.8 kg/m², respectively. The BMI was highest in the early cancer group, and the difference was significant (Dunnett’s test, *P* = 0.015). The BMI in patients with advanced cancer was lower than that in patients with early cancer.

Table 1 Background of the male patients examined by colonoscopy *n* (%)

	Control (<i>n</i> = 26)	Adenoma (<i>n</i> = 47)	Early cancer (<i>n</i> = 34)	Advanced cancer (<i>n</i> = 17)	<i>P</i> -value
Age (yr)	67.9 ± 12.4	65.1 ± 11.7	67.0 ± 8.8	66.5 ± 7.8	0.810
Diabetes	1 (3.8)	6 (12.8)	2 (5.9)	2 (11.8)	0.523
Smokers					
Current-	9 (34.6)	18 (38.2)	13 (38.2)	7 (41.8)	0.977
Ex-	6 (8.5)	14 (21.7)	10 (15.8)	2 (11.0)	0.480
Alcohol	15 (57.7)	30 (63.8)	27 (79.4)	14 (82.4)	0.151
NSAIDs	2 (7.7)	2 (4.3)	1 (3.0)	0 (0)	0.631
Other meds	6 (23.1)	11 (23.4)	8 (23.5)	3 (17.6)	0.965
BMI (kg/m ²)	21.8 ± 3.1	23.2 ± 3.2	24.4 ± 3.8 ^a	22.7 ± 3.8	0.025
BP-S (mmHg)	123 ± 14	129 ± 14	129 ± 13	133 ± 20	0.193
BP-D (mmHg)	76 ± 12	76 ± 10	78 ± 10	81 ± 11	0.331

NSAIDs: Non-steroid anti-inflammatory drug; Other meds: Other medicines such as angiotensin receptor antagonists, angiotensin converting enzyme inhibitors, or HMG-CoA reductase inhibitors; BMI: Body mass index; BP-S: Systolic blood pressure; BP-D: Diastolic blood pressure. Age, BMI, BP-S and BP-D are expressed as the mean ± SD and *P*-value was evaluated by analysis of variance. BMI was additionally evaluated by Dunnett’s test (^a*P* = 0.015). Diabetes (without insulin injections), current smoker, ex-smoker, alcohol habit (ethanol intake more than 15 g/d on average) and NSAID users and Other Meds. users are expressed as the number of patients, and *P* values were evaluated by χ² test.

Evaluation of risk for adenoma, early cancer and advanced cancer

In the patients with adenoma, TG [OR: 3.990, 95% confidence interval (CI): 1.173-13.574, *P* = 0.027] and adiponectin (OR: 6.667, 95% CI: 2.190-20.295, *P* = 0.001) levels revealed significant associations in univariate analysis (Table 2). Multivariate analysis (adjusted for age, BMI, BP-S, TG, and adiponectin) showed that only adiponectin was a significant risk factor for adenoma (OR: 5.762, 95% CI: 1.683-19.739, *P* = 0.005). The other factors including glucose, insulin, HOMA-IR, T-cho, hsCRP, IGF-1/IGFBP-3 ratio, leptin and resistin were not significant risk factors for adenoma.

In the patients with early cancer, BMI (OR: 4.200, 95% CI: 1.344-13.128, *P* = 0.014), TG (OR: 3.958, 95% CI: 1.103-14.201, *P* = 0.035), and adiponectin (OR: 6.300, 95% CI: 1.847-21.485, *P* = 0.003) showed significant associations in univariate analysis (Table 3). Multivariate analysis (adjusted for age, BMI, BP-S, TG, and adiponectin) showed that only adiponectin was a significant risk factor for early cancer (OR: 4.495, 95% CI: 1.090-18.524, *P* = 0.038). As was the case for adenoma, none of the other factors, including glucose, insulin, HOMA-IR, T-cho, hsCRP, IGF-1/IGFBP-3 ratio, leptin and resistin leptin and resistin, were significant risk factors for early cancer.

In the patients with advanced cancer, only BP-D (OR: 4.950, 95% CI: 1.289-19.014, *P* = 0.020) revealed a significant OR in univariate analysis (Table 4). Unlike adenoma and early cancer, changes in adiponectin, BMI, and TG were not associated with a significantly increased risk. Multivariate analysis (adjusted for age, BP-D, hsCRP, and adiponectin) still recognized BP-D as a risk factor for advanced cancer (OR: 5.015, 95% CI: 1.159-21.696, *P* = 0.031).

Table 2 Evaluation of risks for adenoma

	Criteria	(Case/Cont)		Univariate analysis OR (95% CI)	P value	Multivariate analysis OR (95% CI)	P value
		Low	High				
BMI (kg/m ²)	< 22.5, ≥ 22.5	18/14	29/10	2.256 (0.828-6.145)	0.112	1.432 (0.434-4.729)	0.556

Resistin (ng/mL)	< 42, ≥ 42	14/12	16/14	0.980 (0.324-2.808)	0.969		

The OR (High *vs* Low) was evaluated by univariate and multivariate logistic regression analysis. Only the OR of adiponectin was inversely evaluated (Low *vs* High). Multivariate analysis included age, BMI, BP-S, TG, and adiponectin. ^a*P* < 0.05, ^b*P* < 0.01.

DISCUSSION

The present data for adenoma were similar to those of our previous study^[4], and it was also revealed that a decreased level of adiponectin was a strong risk factor for early colorectal cancer. Furthermore, we were able to demonstrate that a low adiponectin level was a stronger risk factor than high TG or BMI in patients with adenoma and early cancer. However, other adipokines, including leptin and resistin, were not direct risk factors for colorectal tumors in this study. In contrast to adenoma and early cancer, a low adiponectin level was not recognized as a significant risk factor for advanced cancer.

In the present study, the mean BMI was significantly higher in the early cancer group than in the control group. However, the mean BMI in the advanced cancer group was lower than that in the early cancer group and nearly equal to that in the controls. One reason may be a reduction of BMI as a result of nutritional deficiencies in some

patients with advanced cancer. Generally, the adiponectin level is known to increase with a reduction in body weight^[10]. Thus the reduction of BMI may have been related to the fact that a low adiponectin level was not a significant risk factor for advanced cancer. As the number of patients with advanced cancer in the present study was relatively small, the low adiponectin level observed in this group must be evaluated carefully in further investigations.

Recently, 2 reports addressing adiponectin levels in patients with colorectal cancer were published. Kumor *et al*^[5] and Erarslan *et al*^[6] revealed that serum adiponectin levels were significantly low in patients with cancer. In fact, our present study revealed results consistent with those reports. Our results enhanced the strength of their data. However, we were able to add some information. Our study evaluated the risk of colorectal tumors, focusing on patients with early-stage colorectal cancer. Besides these 2 reports, Levy *et al*^[11] also reported adiponectin levels in patients with colorectal cancer, and demonstrated that

Table 4 Evaluation of risks for advanced cancer

Criteria		(Case/Cont)		Univariate analysis OR (95% CI)	P value	Multivariate analysis OR (95% CI)	P value
		Low	High				
BMI (kg/m ²)	< 22.5, ≥ 22.5	8/14	8/10	1.400 (0.392-4.997)	0.604		
BP-S (mmHg)	< 120, ≥ 120	6/14	10/12	1.944 (0.545-0.940)	0.306		
BP-D (mmHg)	< 80, ≥ 80	5/19	11/8	4.950 (1.289-19.014)	0.020 ^a	5.015 (1.159-21.696)	0.031 ^a
Glucose (mg/dL)	<100, ≥ 100	6/15	10/10	2.333 (0.638-8.538)	0.201		
Insulin (μU/mL)	< 4.5, ≥ 4.5	5/12	11/14	1.885 (0.510-6.978)	0.342		
HOMA-IR	< 2, ≥ 2	10/15	6/9	1.000 (0.271-3.694)	1.000		
T-cho (mg/dL)	< 180, ≥ 180	7/13	9/10	1.671 (0.462-6.051)	0.434		
TG (mg/dL)	< 120, ≥ 120	10/19	6/4	2.850 (0.650-12.505)	0.165		
hsCRP (ng/mL)	< 500, ≥ 500	5/16	11/10	3.520 (0.941-13.174)	0.062	4.184 (0.896-19.529)	0.069
IGF-1/IGFBP-3	< 60, ≥ 60	7/14	9/11	1.753 (0.499-6.165)	0.382		
Adiponectin (μg/mL)	< 11, ≥ 11	11/12	5/14	2.567 (0.644-9.498)	0.158	3.355 (0.729-15.451)	0.120
Leptin (ng/mL)	< 3, ≥ 3	11/13	5/13	0.455 (0.123-1.680)	0.237		
Resistin (ng/mL)	< 42, ≥ 42	9/12	7/14	0.667 (0.190-2.334)	0.526		

The OR (High vs Low) was evaluated by univariate and multivariate logistic regression analysis. Only the OR of adiponectin was inversely evaluated (Low vs High). Multivariate analysis included age, BP-D, hsCRP, and adiponectin. ^a*P* < 0.05.

adiponectin levels were not influenced by cancer stage, including the early stage. However, their study did not consider the adiponectin levels in normal controls or adenoma patients.

While some reports have indicated a positive relationship between adiponectin and cancer, Lukanova *et al.*¹² reported that the serum adiponectin level was not associated with the risk of colorectal cancer in a case control study in males. Also, Fukumoto *et al.*¹³ demonstrated only a weak correlation between large adenoma and adiponectin level in males working in the Japanese Self-Defense Forces. However, Wei *et al.*¹⁴ demonstrated that low levels of adiponectin were associated with a significantly increased risk of colorectal cancer in a prospective cohort study in males, with a mean follow-up period of 4.5 years. In addition to these epidemiologic studies, genetic polymorphisms of the adiponectin gene in patients with colorectal cancer have been investigated, and these showed that single nucleotide polymorphism of the adiponectin gene was associated with an increased risk of colorectal cancer^{15,16}.

So far, several interesting reports on the molecular mechanism connecting adiponectin and colorectal tumors have been published. Fujisawa *et al.*¹⁷ reported that adiponectin normalized the expression of adenosine monophosphate-activated protein kinase (AMPK) and suppressed colonic epithelial cell proliferation *via* inhibition of the mammalian target of the rapamycin (mTOR) pathway. Moreover, a direct inhibitory effect of adiponectin on colorectal cancer cells *via* the AMPK-mTOR pathway has been demonstrated¹⁸. Thus, the relationship between a decreased plasma adiponectin level and colorectal tumorigenesis is a major issue that needs to be investigated further.

Many studies have noted that a high TG level is associated with colorectal adenoma^{19,20}. Otani *et al.*²¹ have also reported that the OR (highest vs lowest quintile) of TG was significantly increased to 1.5 in Japanese patients. The present study revealed a significantly increased OR of TG in patients with adenoma and early cancer by univariate

analysis. The systemic inflammatory marker, hsCRP, is a factor associated with metabolic syndrome²². The hsCRP levels were relatively increased in patients with advanced cancer (OR: 3.520, *P* = 0.062), but the difference was not statistically significant. CRP levels are increased by inflammatory cytokines. Kim *et al.*²³ found that circulating levels of interleukin-6 and TNF- α were associated with colorectal adenoma risk. Association of inflammatory cytokines with colorectal cancer is also an interesting issue. The circulating IGF-1 level has been discussed in relation to colorectal adenoma and cancer^{24,25}. However, the relationship between IGF-1 and colorectal tumors is still obscure. In the present study, the IGF-1/IGFBP-3 ratio did not show a significant OR.

In our previous study, HOMA-IR was a significant risk factor for adenoma¹⁴. However, HOMA-IR was not recognized as a risk factor for adenoma or cancer in the present study. This factor seemed not to be consistent. However, cohorts of both studies were different, and mean age and gender in the both cohorts were also different. To investigate this issue, further studies involving patients with wide age ranges must be performed.

In conclusion, our study has investigated risk factors for adenoma, early cancer, and advanced cancer. A decreased level of adiponectin was recognized as a strong risk factor for both colorectal adenoma and early cancer. The present results were similar to our previous data for adenoma, and we also demonstrated that a decreased adiponectin level was associated with an increased risk of early cancer. On the basis of these data, we consider that further investigations to clarify the relationship between low adiponectin and colorectal tumors, including controlled prospective studies, are warranted.

COMMENTS

Background

Many biological factors vary according to accumulation of body/abdominal fat. Etiological studies have shown that body/abdominal fat or obesity increases the risk of colorectal cancer. What factors are strongly associated with colorectal tumors?

Research frontiers

Adiponectin is secreted from abdominal fat tissue, and has anti-diabetic, anti-atherosclerotic, and anti-inflammatory effects. A decrease in plasma adiponectin level may be strongly associated with an increased risk of colorectal adenoma or cancer.

Innovations and breakthroughs

The present study investigated the adiponectin levels in patients with colorectal adenoma and cancer (early and advanced). A low adiponectin level was a stronger risk factor than triglyceride or body mass index in patients with early cancer. However, a low adiponectin level was not recognized as a significant risk factor for advanced cancer.

Applications

The study enhanced the strength of previous data. Further investigations to clarify the relationship between low adiponectin levels and colorectal tumors, including controlled prospective studies, are warranted.

Peer review

The author investigate the association of adiponectin levels with risk of colorectal adenoma and cancer (early and advanced). It is a good paper and should be accepted with revision.

Abstract

AIM: To evaluate the association of the autophagy-related 16-like 1 (*ATG16L1*) T300A polymorphism (rs2241880) with predisposition to inflammatory bowel diseases (IBD) by means of meta-analysis.

METHODS: Publications addressing the relationship between rs2241880/T300A polymorphism of *ATG16L1* and Crohn's disease (CD) and ulcerative colitis (UC) were selected from the MEDLINE and EMBASE databases. To make direct comparisons between the data collected in these studies, the individual authors were contacted when necessary to generate a standardized set of data from these studies. From these data, odds ratio (OR) with 95% confidence interval (CI) were calculated.

RESULTS: Twenty-five studies of CD were analyzed, 14 of which involved cases of UC. The variant G allele of *ATG16L1* was positively associated with CD (OR = 1.32, 95% CI: 1.26-1.39, $P < 0.00001$) and UC (OR = 1.06, 95% CI: 1.01-1.10, $P = 0.02$). For child-onset IBD, a higher G allele frequency was found for cases of CD (OR = 1.35, 95% CI: 1.16-1.57, $P = 0.0001$) than

for cases of UC (OR = 0.98, 95% CI: 0.81-1.19, $P = 0.84$) relative to controls.

CONCLUSION: The *ATG16L1* T300A polymorphism contributes to susceptibility to CD and UC in adults, but different in children, which implicates a role for autophagy in the pathogenesis of IBD.

INTRODUCTION

Inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), are chronic inflammatory disorders of the gastrointestinal tract that have an increasing incidence and prevalence in developing countries^[1]. CD can affect any part of the alimentary tract, although it most commonly involves the terminal ileum, and is characterized by transmural discontinuous lesions. UC is a continuous disease that commences in the rectum and extends for a varying distance proximally in the colon, and its continuous inflammation is limited to mucosal and submucosal layers. Currently, the etiology and pathogenesis of IBD are not completely understood. IBDs are complex diseases with a number of contributing factors such as genetic predisposition, environmental factors, intestinal

microbial flora, and aberrant immune responses^[2].

Advances in genetic research, especially the genome-wide association (GWA) studies, have identified a number of IBD susceptibility loci. One of these loci, the autophagy-related 16-like 1 (*ATG16L1*) gene, has been shown to have a role in IBD. The *ATG16L1* gene is located on chromosome 2, at 2q37.1, and encodes a protein that is involved in the formation of autophagosomes during autophagy. Autophagy is a non-selective degradation system that has roles in starvation adaptation, intracellular protein and organelle clearance, development, anti-aging processes, elimination of microorganisms, cell death, tumor suppression, and antigen presentation^[3]. Autophagy has also been implicated in the innate and adaptive immune responses^[4].

Hampe *et al.*^[5] first identified *ATG16L1* as a susceptibility gene for CD in a GWA study of 19 779 non-synonymous single nucleotide polymorphisms (SNPs) present in 735 individuals with CD and 368 controls. Further analysis showed that the marker, rs2241880, was an SNP that encodes a threonine to alanine substitution (T300A) at amino acid position 300, which was correlated with the incidence of CD in two German and one British studies of CD. The rs2241880 SNP directly correlated with the majority of risk associated with this locus. In contrast, no correlation between rs2241880 and UC was detected. Many other studies^[6-29] have assessed the association of rs2241880 with predisposition to CD and UC, however, the results of these studies are inconsistent. In addition, a number of studies included child-onset IBD cases, the results of which were also confusing.

A meta-analysis was recently published that focused on the relationship between the T300A polymorphism and the incidence of CD, but not on the relationship between the T300A polymorphism and risk of UC, or the role of this polymorphism in child-onset IBD^[30]. With the publication of additional studies related to the T300A polymorphism, sufficient data were available to perform a comprehensive meta-analysis of these studies in order to identify consistencies in the data to determine disease susceptibility, as well as to identify areas that need to be further addressed.

MATERIALS AND METHODS

Study selection

As of June 1, 2009, published studies in MEDLINE and EMBASE containing the following key words were included in this study: “inflammatory bowel disease”, “IBD”, “Crohn’s disease”, “CD”, “Ulcerative colitis”, “UC”, “autophagy related 16 like 1”, and “ATG16L1”. The references of the eligible publications were searched manually to identify additional relevant studies. Relevant publications were also identified using the “Related Articles” option in PubMed. Studies reported by the same authors, yet published in different journals, were checked for possible overlapping participant groups. No language restrictions were made. When pertinent data

were not included, or data that were presented were unclear, the authors were directly contacted.

Inclusion criteria

To be eligible for inclusion in this meta-analysis, the following criteria were established: (1) the study must include a case-control study that addressed IBD (i.e. CD or UC) patients and unrelated controls; (2) the study must have evaluated the *ATG16L1* T300A polymorphism and the risk of CD or UC; and (3) the study must have included sufficient data for extraction.

Exclusion criteria

Studies were excluded from consideration if: (1) the study was based on family data; (2) the study did not have the outcomes of comparison reported or it was not possible to determine them; or (3) the study contained a smaller sample size and overlapped others meanwhile.

Data extraction

Using a standardized form, data from published studies were extracted independently by two investigators to populate the needed information. Data collected included first author, year of publication, inclusion and exclusion criteria, study population characteristics, and sample size. Any discrepancies between the two sets of data collected were resolved.

Statistical analysis

Odds ratio (OR) and 95% confidence interval (CI) were calculated for each study using Review Manager version 4.2 software. Between-study heterogeneity was estimated using the χ^2 -based Q statistic. Heterogeneity was considered statistically significant when $P < 0.05$. I^2 was also tested. If heterogeneity existed, data were analyzed using a random effects model. In the absence of heterogeneity, a fixed effects model was used.

A χ^2 test was performed to examine Hardy-Weinberg equilibrium when genotype data were available. $P < 0.05$ was considered statistically significant. If Hardy-Weinberg disequilibrium existed, or it was impossible to evaluate this equilibrium, sensitivity analysis was performed.

RESULTS

Patients and controls

Of the 41 papers identified in a literature search of MEDLINE and EMBASE databases relevant to IBD, CD and UC, 25^[5-29] were included in this meta-analysis, while 16 were excluded^[31-46] (Figure 1). The reasons for exclusion are listed in Table 1. Three of the 41 papers^[5,10,15] evaluated more than one study. Two of these studies contained relevant data and were combined^[5,10], while the third was excluded^[15]. Each of the 25 studies (Table 2) included cases of CD, with various subsets of papers considering different ethnic populations. For example, there were three studies of Asian popula-

¹Data were extracted from the combination of panel A, panel B, panel C, and UC cohort; ²Only GWA study and replication cohort 2 study were included; ³Data from the cohort 1 study were not included in the analysis based on the use of data for controls from 251 families with IBD; ⁴Data of the UC group were obtained by communication with the authors of this publication. CD: Crohn's disease; UC: Ulcerative colitis; NA: Not applicable (no such group); NE: Non-extractable or unavailable data.

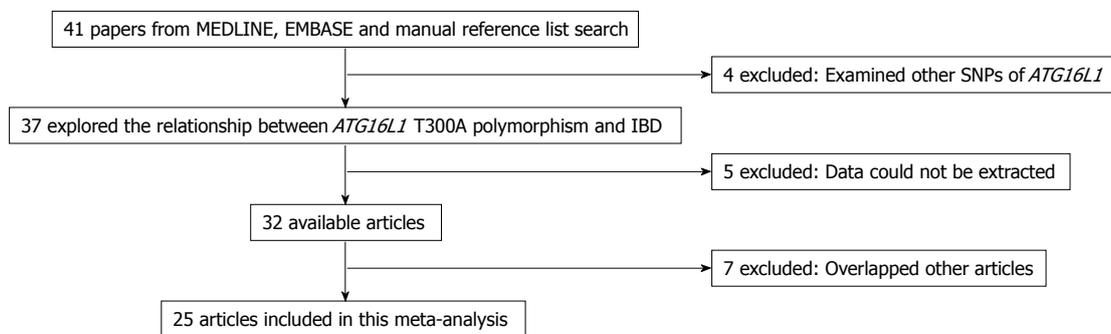

Figure 1 A flowchart illustrating the selection of published studies included in this meta-analysis.

tions^[12,25,28], two of Oceanic populations^[11,15], seven studies based in the United States^[6,10,13,14,21,23,29], and 13 studies of European populations^[5,7-9,16-20,22,24,26,27]. Of the 25 studies, 14 included both CD and UC cases and

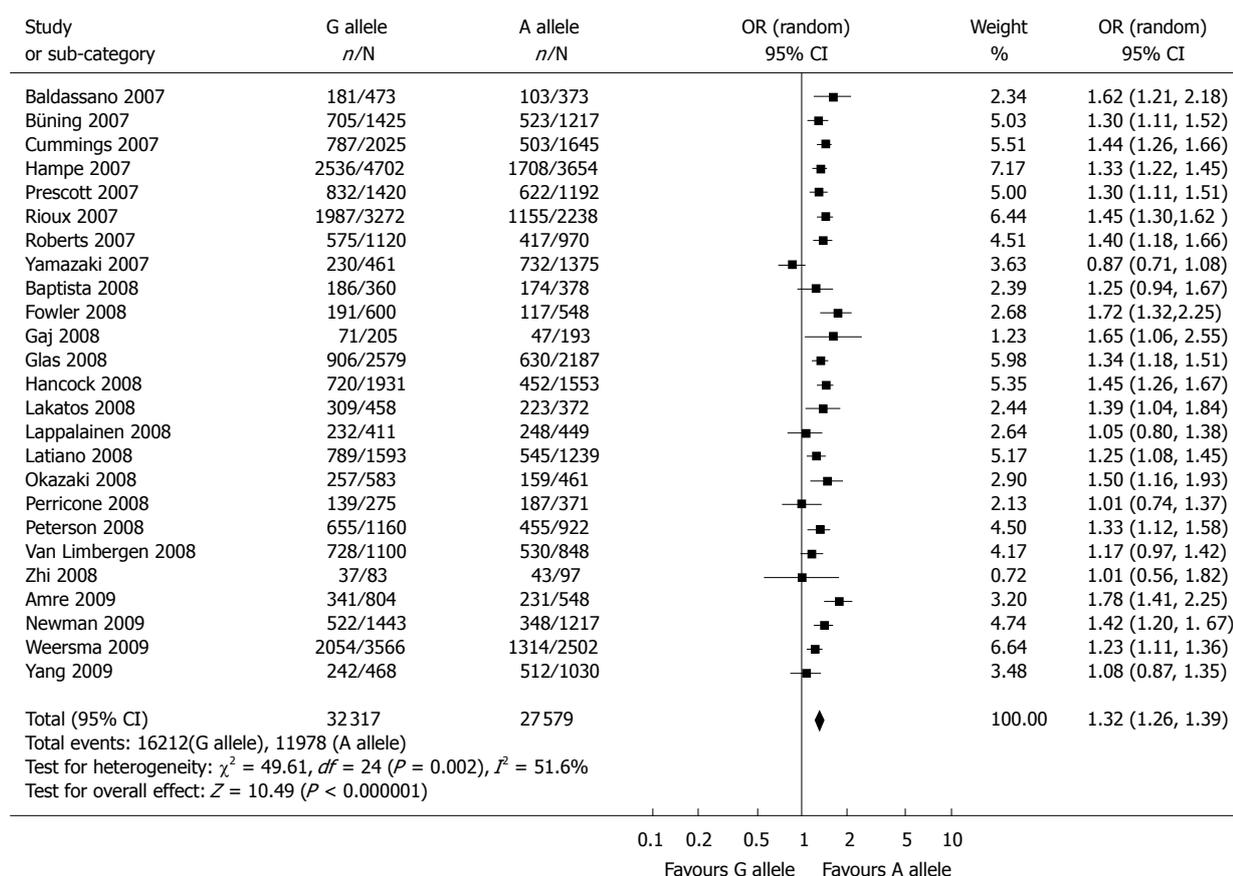

Figure 2 Meta-analysis of the association between the rs2241880 polymorphism of the *ATG16L1* gene and CD for the G allele vs the A allele.

were based on data from an Asian population^[25], an Oceanic population^[11], two studies from the United States^[10,21], and 10 European populations^[5,7-9,17-20,24,26]. Seven of the included studies explored the relationship between the incidence of the T300A polymorphism of *ATG16L1* and child-onset CD^[6,11,13,17,20,23,24], while only two reported cases of child-onset UC^[20,24]. For six of the total studies, genotype data were not available even after authors were contacted for further inquiry. Therefore, a Hardy-Weinberg equilibrium test was performed on the remaining 19 studies, and three of them showed disequilibrium^[15,25,29] ($P = 0.04$, $P = 0.00$, and $P = 0.03$, respectively). Among the six untested studies due to unavailable data, five^[5,8,10,17,26] reported Hardy-Weinberg equilibrium data in the original paper.

Association between *ATG16L1* T300A polymorphism and IBD

Meta-analysis of the 25 studies that fulfilled the inclusion criteria identified a significant association between the G allele of *ATG16L1* and susceptibility to CD (OR = 1.32, 95% CI: 1.26-1.39, $P < 0.00001$) (Table 3 and Figure 2). Sensitivity analysis was performed with the omission of three studies^[15,25,29] and Hardy-Weinberg disequilibrium showed similar results (data not shown). No notable change in the results of the statistic analyses was obtained when the Peterson *et al.*^[23] study was eliminated. As shown in Table 3 and Figure 3, a significant association between

Table 3 Summary of the association of the rs2241880 polymorphism and IBD determined in the meta-analysis

Comparisons	No. of studies	Effects model selection	OR (95% CI)	P-value
CD <i>vs</i> control	25	R	1.32 (1.26-1.39)	< 0.00001
UC <i>vs</i> control	14	F	1.06 (1.01-1.10)	0.02
Child-onset	7	R	1.35 (1.16-1.57)	0.0001
CD <i>vs</i> control				
Child-onset	2	F	0.98 (0.81-1.19)	0.84
UC <i>vs</i> control				

R: Random effects model; F: Fixed effects model.

the G allele of *ATG16L1* and the risk of UC was also detected (OR = 1.06, 95% CI: 1.01-1.10, $P = 0.02$). When the data of Zhi *et al.*^[25] were excluded, similar results were obtained: OR = 1.05, 95% CI: 1.01-1.10, $P = 0.02$.

Association between *ATG16L1* T300A polymorphism and child-onset CD and UC

The pooled analysis for child-onset cases of CD identified the T300A polymorphism of *ATG16L1* as a factor for predisposition to child-onset CD in a total of seven studies^[6,11,13,17,20,23,24] (OR = 1.35, 95% CI: 1.16-1.57, $P = 0.0001$) (Table 3 and Figure 4). When the study of Peterson *et al.*^[23] was excluded, similar data were acquired: OR = 1.35, 95% CI: 1.11-1.64, $P = 0.003$. Two studies^[20,24] discussed the association of the T300A polymorphism of *ATG16L1* and

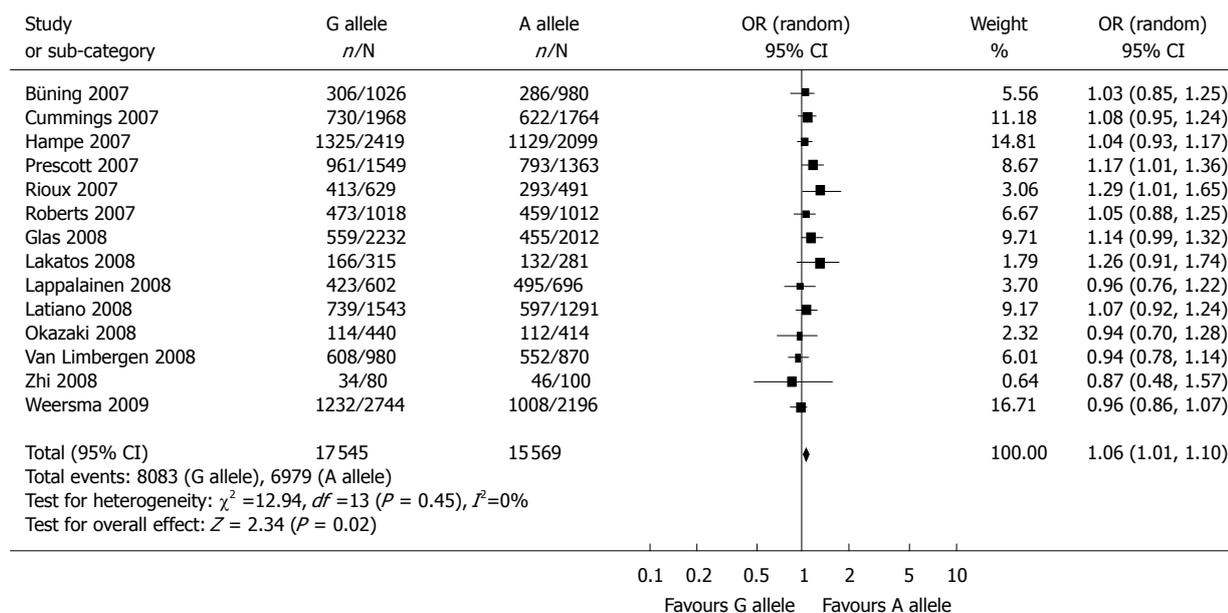

Figure 3 Meta-analysis of the association between the rs2241880 polymorphism of the *ATG16L1* gene and UC for the G allele vs the A allele.

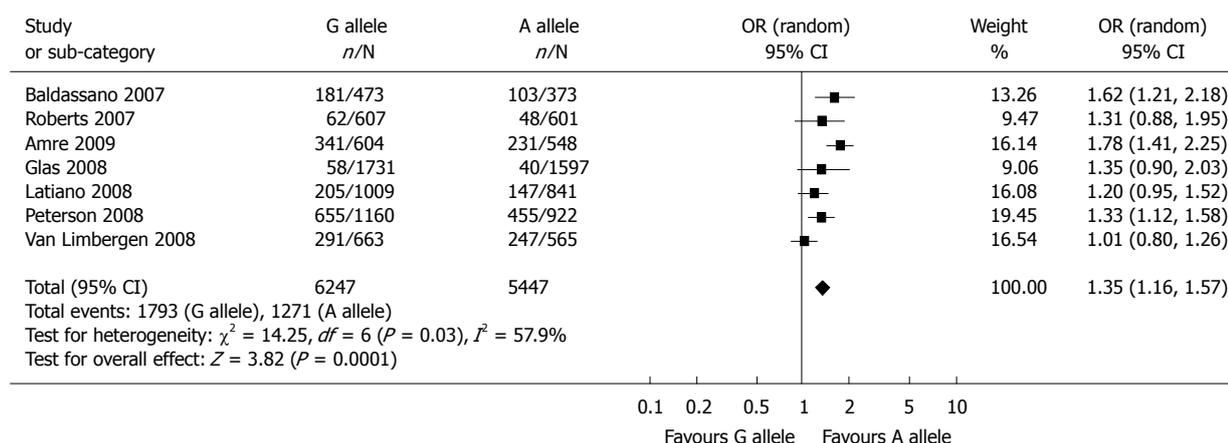

Figure 4 Meta-analysis of the association between the rs2241880 polymorphism of the *ATG16L1* gene and child-onset CD for the G allele vs the A allele.

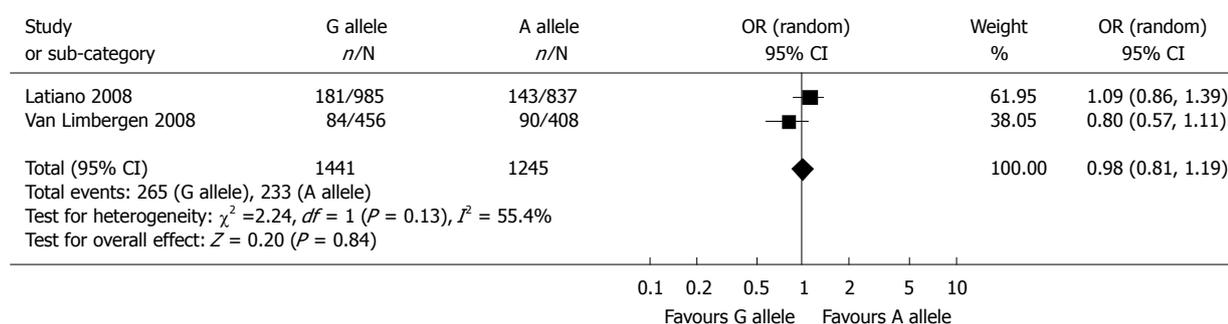

Figure 5 Meta-analysis of the association between the rs2241880 polymorphism of *ATG16L1* gene and child-onset UC for the G allele vs the A allele.

child-onset UC, yet the results of the combined analysis indicated there was no correlation (Table 3 and Figure 5).

DISCUSSION

Over the past few years, knowledge of the genetics of

IBD has advanced tremendously since the first IBD GWA study was published in 2006^[47]. Hence, several novel susceptibility loci have been identified; one of them being the *ATG16L1* gene. Hampe *et al*^[5] first identified the association of the rs2241880 SNP in *ATG16L1* with cases of CD, but not with UC. Several subsequent studies

have tried to verify these results, however, the results of these latter studies were inconsistent, especially regarding the relationship between *ATG16L1* and UC, further perplexing our understanding of the role of *ATG16L1* in IBD. Thus, we conducted a meta-analysis of the currently published reports of CD and UC to attempt to clarify the correlation between *ATG16L1* and IBD. In order to obtain as much relevant data as possible, we retained some studies that presented a Hardy-Weinberg disequilibrium, however, there were no notable change in the results of our analyses whether these studies were included or omitted.

Our meta-analysis confirmed a positive association between the rs2241880 polymorphism of *ATG16L1* and susceptibility to CD. Meanwhile, a modest but significant association of the rs2241880 polymorphism with predisposition to UC was also observed. Taken together, these outcomes demonstrate that the *ATG16L1* variant containing the T300A substitution confers risk for both CD and UC.

Many aspects of child-onset IBD differ from adult-onset IBD, especially in regard to the type, location, and behavior of the disease, as well as sex preponderance and genetically attributable risk^[48]. Considering the relatively short time of exposure to environmental factors (e.g. smoking) in children compared to adults with IBD, genetic background is hypothesized to be a more important factor in early-onset IBD. Therefore, we further analyzed the association between *ATG16L1* and child-onset IBD. Our results indicated that *ATG16L1* was associated with the risk of child-onset CD, but not with child-onset UC. Regarding the negative finding in early-onset UC, small sample sizes must be recognized as a contributing factor. Only two studies were included in the final analysis, therefore, this may have precluded the detection of a significant association. Additional studies are needed to determine whether an association exists in this cohort or not.

There were some limitations in the present meta-analysis. For example, because of publication limitations, some relevant studies could not be included in our analysis. Secondly, heterogeneity existed among studies of CD and child-onset CD, which had the potential to influence the results of our meta-analysis. The lack of information provided by some published studies, especially with regard to genotype data, was another limitation. Although we contacted authors of publications that did not provide a comprehensive set of data, genotype data remained unavailable for six of the total number of studies. Finally, there were only two studies that examined the relationship between *ATG16L1* and child-onset UC. As a result, the small sample size available was not ideal for detecting small genetic effects.

Although the precise impact of the *ATG16L1* variant on the pathogenesis of IBD remains unknown, accumulating evidence suggests that microbes play an important role in the initiation and etiopathogenesis of IBD. IBD lesions have been shown to develop preferentially in regions with the highest concentrations of

bacteria^[49]. In addition, enteric flora has been found to be more commonly associated with IBD patients than with control groups^[50,51]. IBD animal model studies also have demonstrated that gut inflammation does not develop in a germ-free environment^[52]. Autophagy is a fundamental intracellular degradation system that protects cells against various bacterial pathogens and the cytotoxic effect of bacterial toxins. Autophagy also has been identified to play a role in both innate and adaptive immune responses^[53,54]. The specific role of *ATG16L1* in these processes remains unclear. *ATG16L1* is expressed not only in intestinal epithelial cells, but also in lymphocytes and macrophages. It interacts with two other autophagy proteins, *ATG5* and *ATG12*, to form a complex essential for the process of autophagy. Several studies have characterized the influence of *ATG16L1* deficiency. Rioux *et al*^[10] have shown that knockdown of *ATG16L1* mRNA in HeLa cells with siRNA reduced targeting of *Salmonella typhimurium* to autophagic vacuoles, which implicates a role for *ATG16L1* in the clearance of intracellular bacteria *via* autophagy. Saitoh *et al*^[55] have reported that *ATG16L1* deficiency disrupts the recruitment of the *ATG12-ATG5* conjugate to the isolation membrane, which results in loss of microtubule-associated protein 1 light chain 3 binding to phosphatidylethanolamine. Consequently, autophagosome formation and degradation of proteins with a long half-life are severely impaired in *ATG16L1*-deficient cells. *ATG16L1*-deficient macrophages also have been shown to produce large amounts of the inflammatory cytokines, IL-1 and IL-18, and mice that lack *ATG16L1* expression in hematopoietic cells are highly predisposed to dextran sulfate sodium-induced acute colitis. Cadwell *et al*^[56] have generated hypomorphic *ATG16L1* (*ATG16L1*^{HM}) mice that express *ATG16L1* at 30% of its normal level. In this model, notable abnormalities have been observed in Paneth cells. These ileal epithelial cells are hypothesized to play a role in the control of intestinal microbiota by secreting granules that contained antimicrobial peptides and lysozymes. Aberrant Paneth cells exhibit deficiencies in their granule exocytosis pathway, which results in a decreased capacity to eliminate microbes. The mammalian *ATG16L1* protein consists of three distinct domains: the N-terminal region mediates interactions with other autophagy proteins; a coiled-coil domain provides the capacity for *ATG16L1* oligomerization and *ATG5-ATG12* association; and there is a region of 7 WD repeats^[57]. The T300A mutation is located within the WD repeats, which are associated with protein interactions. Therefore, the T300A mutation is hypothesized to affect protein interactions necessary for the formation of autophagosomes, which results in dysfunction of the autophagy pathway and a subsequent decrease in pathogen clearance^[9]. It has been shown that the *ATG16L1* coding variant is defective in mediating efficient antibacterial autophagy in cultured HeLa and Caco2 cells, and the *ATG16L1**300A protein is unstable under conditions of high microbial load^[58]. These observations suggest the effect of this mutation has a direct impact on autophagic effectiveness. In

summary, the T300A mutation of *ATG16L1* impairs specific autophagic, innate resistance mechanisms to gut commensals, which facilitate inflammation after invasion^[59].

In addition to decreased ability to remove intestinal microbes directly, there may be other mechanisms that underlie the association between the *ATG16L1* variant and increased risk for IBD. For example, since autophagy contributes to immune tolerance against self tissues, it seems likely that decreased autophagy may lead to a failure of immune tolerance by autoantigen presentation on major histocompatibility complex class II molecules, which causes immune inflammation^[59]. Another possible mechanism involves autophagy and apoptosis. Accumulating studies have detected an acceleration in the rate of epithelial cell apoptosis and inhibition of inflammatory cell apoptosis in CD and UC^[60-63]. Autophagy and apoptosis share many common triggers and cross-inhibitory interactions^[64], thus, it is hypothesized that defective autophagy might alter the process of intestinal cell apoptosis, ultimately contributing to IBD pathogenesis.

In conclusion, our meta-analysis of published cases of CD and UC suggests that the *ATG16L1* T300A polymorphism is associated with susceptibility to CD and UC. However, the effect of this polymorphism differs between child-onset CD and UC. These findings implicate the role of autophagy and intestinal microbes in the pathogenesis of IBD, and demonstrate the need for further studies.

COMMENTS

Background

Inflammatory bowel diseases (IBD), Crohn's disease (CD) and ulcerative colitis (UC), are polygenic disorders. An A to G transition of the autophagy-related 16-like 1 gene (*ATG16L1*) has been implicated as a risk factor for IBD, but individual studies have been inconclusive or controversial.

Research frontiers

Much attention has been paid to the potential role of autophagy in the pathogenesis of IBD, since Hampe *et al* identified *ATG16L1* as a CD susceptibility gene in 2007. Some of them have been trying to confirm the definite relationship between *ATG16L1* polymorphism and IBD, and meanwhile, others attempting to uncover underlying mechanisms.

Innovations and breakthroughs

The current study demonstrated that *ATG16L1* is a susceptibility gene for CD and UC in adults, but different in children.

Applications

It is seen from this study that the *ATG16L1* T300A polymorphism contributes to susceptibility to CD and UC in adults, which provides an insight into the role of autophagy in the pathogenesis of IBD. Studies for further exploring the mechanism by which altered ability of autophagy predisposes to IBD are needed.

Terminology

Autophagy is a cytoplasmic homeostasis process that cleanses the interior of all eukaryotic cells. It has an important role in cell and tissue homeostasis, and has been implicated in a range of human diseases.

Peer review

This study is an interesting meta-analysis about T300A polymorphism of *ATG16L1* and susceptibility to inflammatory bowel diseases. The authors carefully reviewed the available literature and concluded that *ATG16L1* T300A polymorphism contributes to susceptibility to both CD and UC in adults, but not in children, implicating a role for autophagy in the pathogenesis of IBD.

Abstract

AIM: To establish the more feasible and sensitive assessment approach to the detection of adefovir (ADV) resistance-associated hepatitis B virus (HBV) quasispecies.

METHODS: Based on the characteristics of rtA181V/T and rtN236T mutations, a new approach based on real-time fluorescent quantitative polymerase chain reaction (RT-PCR) was established for the detection of ADV-resistant HBV quasispecies, total HBV DNA, rtA181 and rtN236 mutations in blood samples from 32 chronic hepatitis B (CHB) patients with unsatisfactory curative effect on ADV and compared with routine HBV DNA sequencing.

RESULTS: Both the sensitivity and specificity of this new detection approach to ADV-resistant HBV quasispecies were 100%, which were much higher than those of direct HBV DNA sequencing. The approach was able to detect 0.1% of mutated strains in a total plasmid population. Among the 32 clinical patients, single rtA181 and rtN236T mutation and double rtA181T and rtN236T mutations were detected in 20 and 8, respectively, while ADV-resistant mutations in 6 (including, rtA181V/T mutation alone in 5 patients) and no associated mutations in 26.

CONCLUSION: This new approach is more feasible and efficient to detect ADV-resistant mutants of HBV and ADV-resistant mutations before and during ADV treatment with a specificity of 100% and a sensitivity of 100%.

INTRODUCTION

Chronic hepatitis B virus (HBV) infection affects approximately 400 million people worldwide and is still an important cause of morbidity and mortality, as well as a

source of potential new infections^[1]. Chronic HBV carriers may develop chronic hepatitis, cirrhosis, and hepatocellular carcinoma (HCC) with HBV as the most frequent cause^[2]. Since chronic hepatitis B (CHB) patients require a prolonged if not a lifelong therapy, data about its long-term safety and effect are indispensable for the assessment of its risk and benefit. Treatment of CHB has been improved due to available nucleoside/tide analogues, such as lamivudine (LAM), adefovir dipivoxil (ADV), entecavir (ETV), and telbivudine (LdT), which act as inhibitors of HBV reverse transcriptase and decrease viral load in most cases^[3]. ADV has become a treatment option for HBV infection due to its effect on lamivudine-resistant mutations occurring upon prolonged treatment. However, viral resistance to ADV develops and increases over time. ADV-resistance is mainly associated with rtN236T and rtA181V/T mutations within the D and B functional domains of HBV polymerase^[4]. Many methods have been developed to detect ADV-resistant mutations, such as direct polymerase chain reaction (PCR) sequencing, INNO-LiPA, restriction fragment length polymorphism (PCR-RFLP), matrix-assisted laser desorption/ionization-time of flight-mass spectrometry (MALDI TOF MS)^[4-9], with their respective advantages and disadvantages. Sequencing remains the best approach to the identification of new mutations. However, it cannot detect rtN236T and rtA181V/T mutations in less than 25% of a total viral population and is not appropriate for large-scale use in large cohort studies or clinical laboratories because of its labor-intensive and time-consuming manipulations^[5]. INNO-LiPA and MALDI TOF MS are capable of detecting variants, but more strict experiment conditions and equipments are required. PCR-RFLP^[8] could only detect mutations in a high proportion and is also labor-intensive and time-consuming. This study described a feasible and sensitive approach to quantitative detection of ADV-resistant HBV quasispecies by real-time fluorescent quantitative PCR.

MATERIALS AND METHODS

Materials

Thirty-two patients (29 males and 3 females, mean age 35 years, range 20-63 years) who were diagnosed as CHB from March 2003 to October 2007 in our hospital following the guidelines of prevention and treatment of chronic hepatitis B (2005)^[10] were enrolled in this study. ADV was administered with oral dipivoxil (10 mg) for 58 wk (range: 42-82 wk), during which viral breakthrough, viral rebound, partial or inadequate virus response occurred^[11]. Exclusion criteria included a coexisting severe illness, organ or bone marrow transplantation, recent treatment with systemic corticosteroids, immunosuppressants or chemotherapeutic agents, liver disease not due to hepatitis B, and seropositivity for human immunodeficiency virus (HIV) or hepatitis C or D virus. Informed consent was obtained from each patient in accordance with the Declaration of Helsinki. The study was approved by the institutional review board of So-

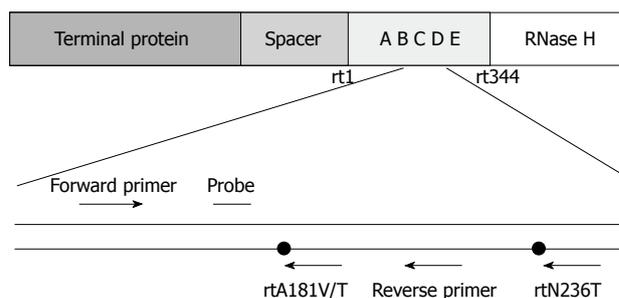

Figure 1 Targeted sequences of primers and probes designed for real-time polymerase chain reaction (PCR) to detect and quantify rtA181V/T and rtN236T adefovir (ADV)-resistance mutations.

ochow University. The average load of HBV DNA at baseline before ADV therapy was $6.30 \pm 0.23 \log_{10}$ IU/mL, and dropped to $5.61 \pm 0.17 \log_{10}$ IU/mL after treatment with ADV for 82 wk.

Serum specimens, quantitative reference substances for correlated mutations

HBV DNA was extracted from 100 μ L of sera as previously described^[6]. Extracted DNA pellets were resuspended in 30 μ L of sterile distilled water and stored at -20°C until use. HBV DNA fragments containing the RT domain were amplified by PCR using special primers (RTS: 5'AAAATCCTCACAATACCAC3', RTSA: 5'GACATACTTTCCAATCAATAG3') as previously described^[6]. The PCR products were cloned into the pUC-18 vector (TAKARA) following its manufacturer's instructions. Following transformation into DH5 α competent cells (Tiangen, Shanghai), each wild strain plasmid, rtA181V/T and rtN236T variant plasmid of types B and C were picked out respectively according to the sequencing results, and standardized with a quantitative test kit for HBV DNA. After serial dilutions, quantitative reference substances for related rt181 and rt236 variant mutations were prepared.

Quantification of HBV DNA and related mutations

Based on the characteristics of rtA181V/T and rtN236T mutations, specific primers and Taqman probes were designed (Figure 1). Mutations of rtA181 and rtN236 and total HBV DNA isolated from the same serum specimens were detected by real-time fluorescent quantitative PCR as previously described^[7].

Direct sequencing of HBV DNA

Primers for PCR were designed to target highly conservative sequences of HBV gene in oligonucleotides: P1, 5'CCTGCTGGTGGCTCCAGTTCAGGAACAG3' (nt56-83), P2, 5'AAGCCCCAACAGTGGGGGTTGCGTCA3' (nt1188-1214). The amplified fragments contained the polymerase RT domain and overlapped the S gene. Viral DNA was amplified with a HBV sequencing kit (Shenyou, Shanghai, China). Positive PCR products identified by agarose gel electrophoresis were directly sequenced with an ABI PRISM 3730 genetic analyzer.

a/b: The total DNA to rtA181 mutation-associated DNA; a/c: The total DNA to rtN236 mutation-associated DNA.

Assessment criteria for HBV DNA mutation

Mutations of rtA181 or rtN236 were assayed with the ratio of total HBV DNA to rtA181 or rtN236 mutation-associated DNA. The assessment criteria used were as follows: (1) If the ratio (a/b or a/c) of total DNA to rtA181 or rtN236 mutation-associated DNA was between 1 and 10, it was defined as complete variants or the proportion of mutations was more than 10% in the pool of quasispecies; (2) If the ratio (a/b or a/c) of total DNA to rtA181 or rtN236 mutation-associated DNA was between 10 and 200, it was defined as the proportion of variants was lower than 10% in the pool of quasispecies; and (3) If the ratio (a/b or a/c) of total DNA to rtA181 or rtN236 mutation-associated DNA was more than 200, it was defined as complete wild strains or the proportion of variants was below the limit of identification.

Statistical analysis

All data were analyzed using the SAS V8.1 statistical package version. Analysis of one way variance (ANOVA) and *t*-test were used to compare the average value. *P* < 0.05 was considered statistically significant

6×10^6 IU/mL was picked out for real-time fluorescent quantitative PCR. The rtN236T and rtA181 were found to be wild type plasmids at positions 181 and 236, respectively (Table 1), indicating that the new approach has a sensitivity of 100% and a specificity of 100%.

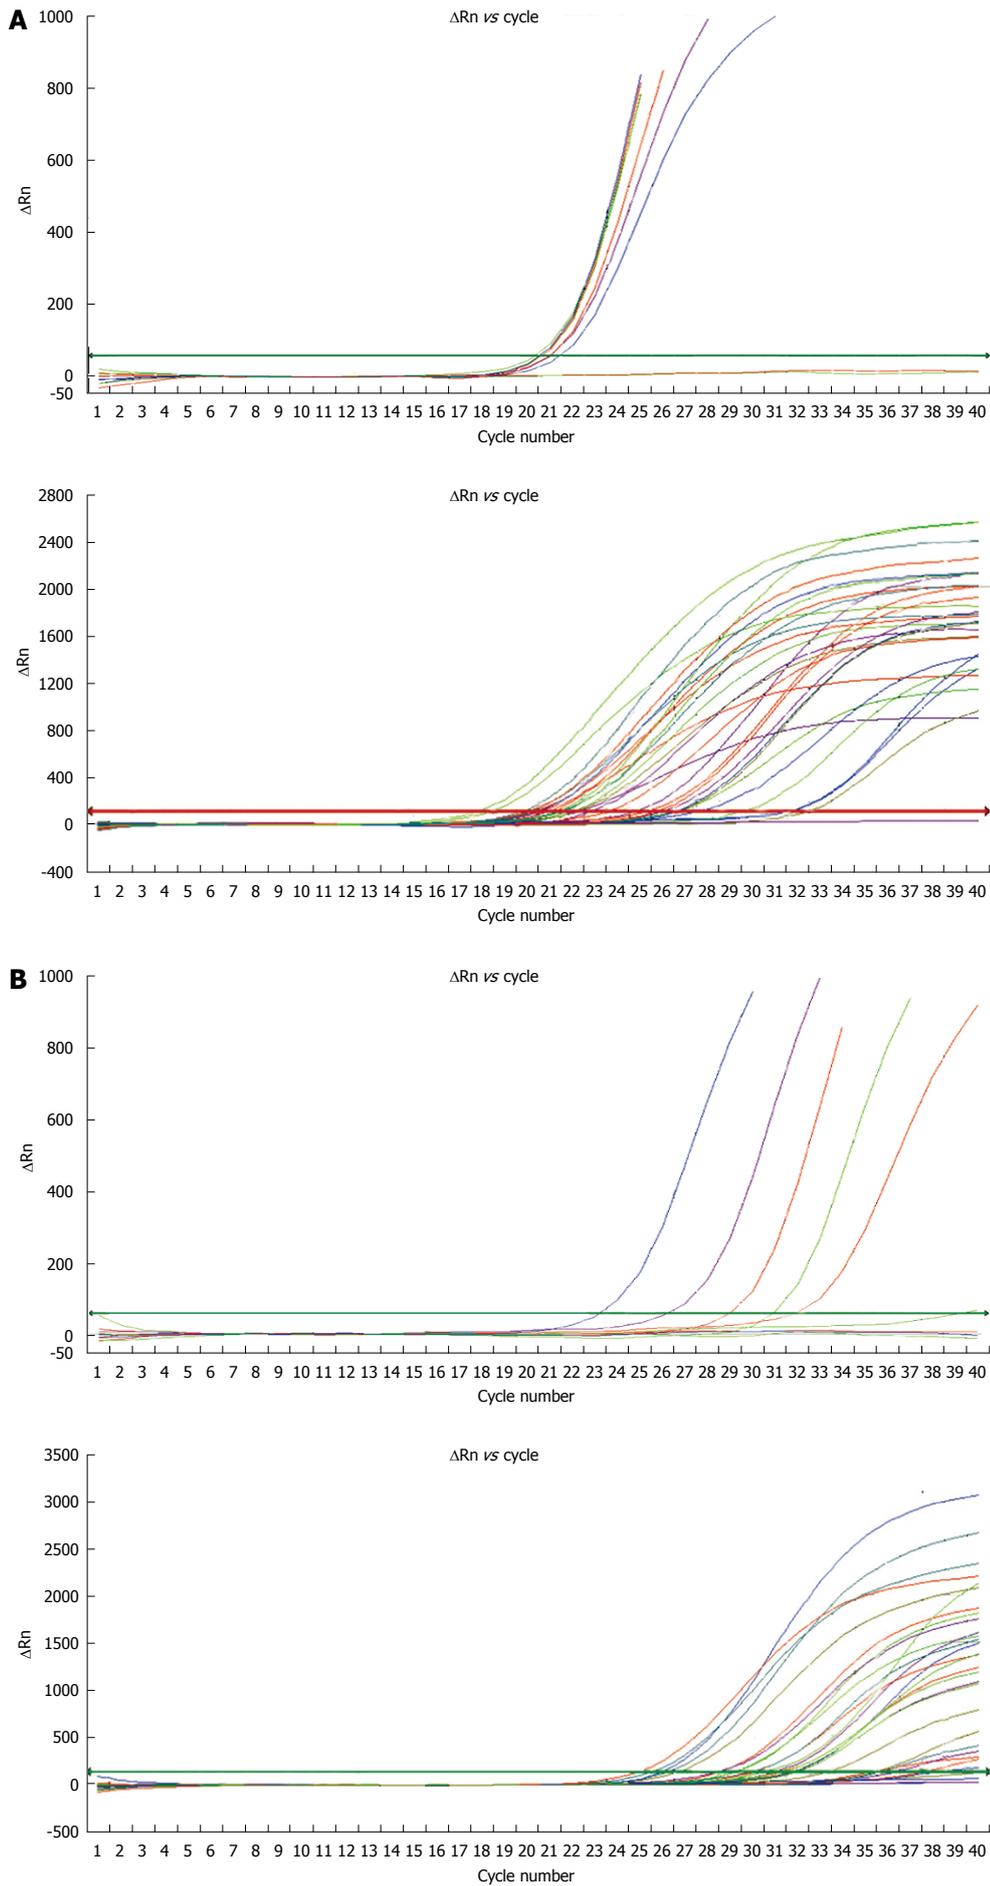

Sensitivity to mixed variants

Variant and wild type plasmids with a concentration of 6×10^6 IU/mL were picked out and diluted at 0/1, 1/1, 1/10, 1/50, 1/200, 1/1000, and 1/10000, respectively. The results of fluorescent quantitative PCR are shown in Figure 2A and Table 2. The Ct value for the wild type plasmids was different.

Total HBV DNA, and rtA181 or rtN236 mutations in 8 serum samples from the patients who did not receive ADV treatment and had no associated mutations detected by sequencing were detected by fluorescent quantitative PCR. The ratio(a/b or a/c) of total HBV DNA to rtA181 or rtN236 mutation-associated DNA was lower than 1000 when the variant plasmids were mixed with wild type plasmids at a dilution of 1:1000 and higher than 5000 in the patients who did not receive ADV therapy (Table 3).

Detection of ADV-resistant mutations

The ratio of total HBV DNA to rtA181 and rtN236 mutation-associated DNA (a/b or a/c) in mutations of variant and wild- type plasmids was less than 1000 at a dilution of 1:1000, while the ratio of total HBV DNA to ADV-resistant mutations was higher than 5000 in the naïve patients. Among the 32 patients, mutations of rtA181 and rtN236T were detected in 20 and 8, respectively. Based on the current assessment criteria (the ratio of a/b cut-off was 1, 10 and 200, respectively), the 32 patients were divided into 3 groups with the a/b ratio = 1 to 10 in 6, = 10 to 200 in 7 and ≥ 200 in 12 patients, respectively, and the a/c ratio = 1 to 10 in 1, = 10 to 200 in 7 and ≥ 200 in 24 patients, respectively. The rtA181 mutation level in HBV DNA was $6.22 \pm 0.55 \log_{10}$ IU/mL, $4.78 \pm 0.21 \log_{10}$ IU/mL, and $3.14 \pm 0.33 \log_{10}$ IU/mL, respectively, in these three groups (*P* < 0.0001). The rtN236 mutation level in HBV DNA was $5.31 \pm 0.25 \log_{10}$ IU/mL and $2.49 \pm 0.19 \log_{10}$ IU/mL, respectively, in patients with their a/c ratio = 1 to 200 or ≥ 200 (*P* < 0.0001) (Figure 2B and Table 4).

Comparison between sequencing chromatograms and quantitative results

Of the 6 patients with ADV-resistant mutations, rtA181T and rtN236T mutations and single rtA181V/T mutation

were observed in patients 1 and 5, respectively. Among the 26 patients with no associated mutations, rtA181 variants and wild type strains were found in patients 1, 5 and 6 (Figure 3) while only rtA181 variants were detected in patients 2, 3 and 4 (Table 5).

DISCUSSION

Dipivoxil, a nucleotide analogue, has become a treatment option for HBV infection due to its efficacy on lamivudine-resistant mutations occurring upon prolonged treatment. However, resistance to ADV develops and increases over time. ADV therapy for naive patients is associated with delayed and less frequent drug-resistant mutations. The reported cumulative incidence of mutations in hepatitis B e antigen (HBeAg)-negative and positive chronic

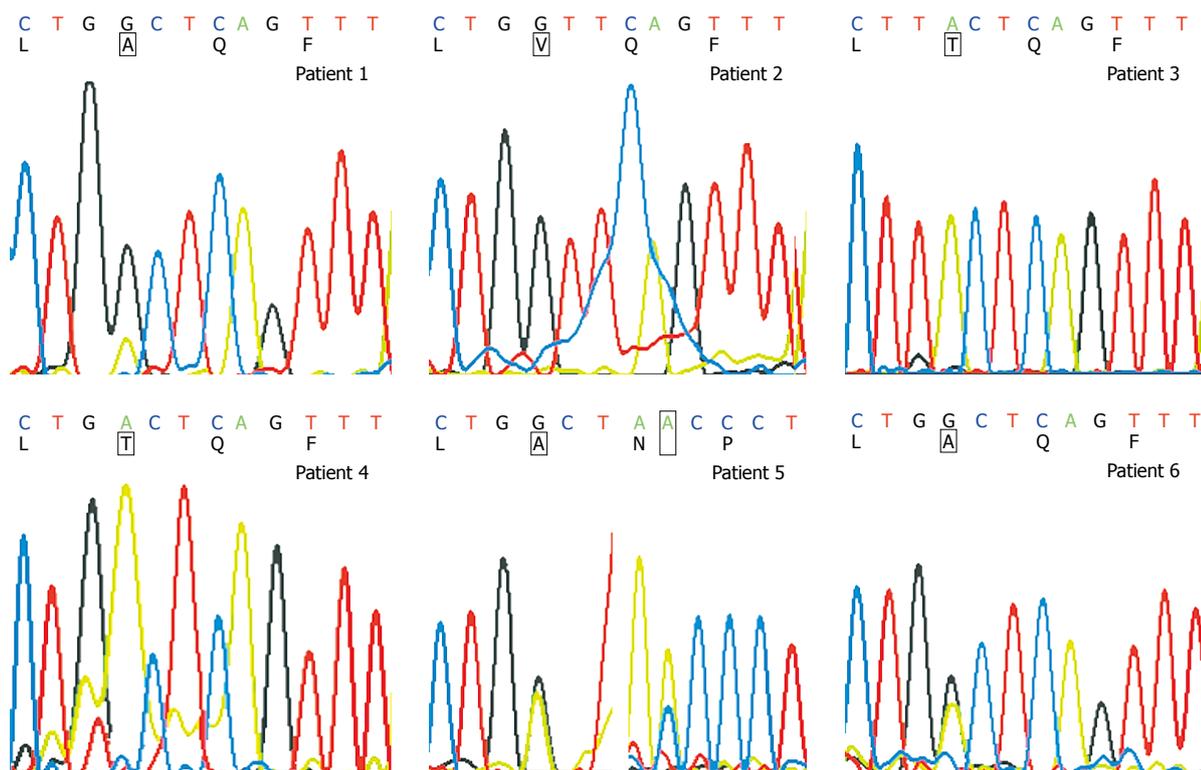

Figure 3 Sequence analysis of ADV-resistant mutations. rtA181 wild strains (amino acid codon: GCT) with few rtA181T mutations (amino acid codon: ACT) in patient 1, rtA181V mutant (amino acid codon: GTT) in patient 2, rtA181T mutant (amino acid codon: ACT) in patients 3 and 4, rtA181 wild strains (amino acid codon: GCT) mixed with half of rtA181T mutant (amino acid codon: ACT) and rtN236 wild strains (amino acid codon: AAC) mixed with partial rtN236T mutants (amino acid codon: ACC) in patient 5, and rtA181 wild strains (amino acid codon: GCT) mixed with partial of rtA181T mutants (amino acid codon: ACT) in patient 6.

hepatitis B patients is 29% and 20%, respectively after 5 years of ADV treatment^[12,14]. LAM-resistant patients treated with ADV monotherapy are at a higher risk of developing ADV-resistant mutations than nucleoside-naïve patients^[7,13]. In accordance with the current guidelines, ADV should be used in combination with other drugs in treatment of LAM-resistant patients instead of ADV monotherapy. It has been shown that ADV-resistant mutants occur infrequently in patients on combined therapy^[15]. An open-label study in HBeAg-negative LAM-resistant patients demonstrated that combined therapy does not result in development of resistance to ADV over a period of 3 years^[16]. It has been recently reported that the rate of ADV resistance is 1% and 4% 1 and 3 years after ADV + LAM therapy^[17]. Two mutations in the HBV polymerase gene, alanine to valine or threonine (rtA181V/T) and asparagine to threonine substitution (rtN236T) have been described to confer resistance to ADV^[4], suggesting that genotypic resistance monitoring is important to anticipate and confirm the observed phenotypic resistance and new treatment modalities can be selected. The incidence of genotypic resistance may vary with the sensitivity of different methods used to detect resistant mutations. Thus, methodological options for detecting HBV mutations are an increasingly important issue in clinical management of CHB. Several other methods have been used to detect ADV-resistant HBV. However, the disadvantages of each method restrict its wide-range use. So

developing a more sensitive, specific and easy approach is always the major concern for researchers. Malmström *et al.*^[18] developed a method based on real-time polymerase chain reaction with TaqMan chemistry which can target wild type and mutant viral strains at rtL180 and rtM204, later, Lupu *et al.*^[19] described a selective real-time PCR (sPCR) for the quantitative detection of rtM204I/V and rtN236T mutations associated with resistance to LAM and ADV, with a lowest limit of 0.1% of strains carrying rtM204V/I or rtN236T mutations for a total of 105 copies of plasmid. In this study, primers and probes for quantitative amplification of HBV DNA, rtA181 and rtN236 mutations were designed, and the results showed that they could detect more than 100 IU/mL of variants. Mutants could be obtained by calculating the ratio of total HBV DNA to the variants. To assess the feasibility of this approach, HBV DNA, rtA181 and rtN236 mutations were detected in 32 patients with unsatisfactory response to adefovir dipivoxil by direct sequencing. The results showed that this new approach could detect rtA181 and rtN236 mutations as well as some ADV mutations not identified by direct sequencing, thus supporting the new approach with a high concordance and a higher sensitivity. ADV-resistant HBV mutations can be pre-monitored, which can provide valuable reference for shifting the treatment in order to prevent hepatitis deterioration and decompensation. Furthermore, real-time fluorescent quantitative PCR can be widely used.

Meanwhile, there is a large room for the improvement of this new approach. The major improvement in RT-PCR is to design the optimal primers for each mutant. Moreover, due to the variability of genotypes, a number of primers may be required for the detection of a single nucleotide polymorphism. In this study, the primers were restricted to the most frequent codons associated with rtA181 and rtN236T mutations. However, further study is needed to verify the other mutations.

In conclusion, the new approach based on real-time fluorescent quantitative PCR is more feasible than direct DNA sequencing. It is more sensitive and specific for the detection of wild-type and variant viruses as well as ADV-resistant mutations. We believe that this easy-to-use approach will play an important role in detection of ADV-resistant mutations and in optimization of ADV therapy.

COMMENTS

Background

With the availability of more potent nucleotide/nucleoside analogues, early detection of drug-resistant mutants of hepatitis B virus (HBV) is important for the treatment of chronic hepatitis B (CHB). The incidence of genotypic resistance may vary with the sensitivity of methods used to detect resistant mutations. Thus, methodological options for detecting HBV mutations are an increasingly important issue in clinical management of CHB.

Innovations and breakthroughs

The study described a practical and accurate method for quantitative detection of adefovir (ADV)-resistant HBV quasispecies using real-time fluorescent quantitative polymerase chain reaction (PCR). The results demonstrated that this method could detect and monitor ADV resistance mutations in patients chronically infected with HBV and is more sensitive than sequencing.

Applications

ADV-resistant HBV quasispecies can be detected by real-time fluorescent quantitative PCR, which should be extensively popularized in clinical practice.

Peer review

The method described in this paper is specific, sensitive and accurate for the detection of ADV-resistant mutants of HBV in ADV-treated patients, thus adding a new tool for monitoring ADV-resistant mutations before and during ADV therapy.

Abstract

AIM: To investigate the relation of Fas and Fas ligand (FasL) protein expression with carcinogenesis and metastasis of gastric carcinoma.

METHODS: Immunohistochemistry was used to detect Fas and FasL protein expression in 64 gastric carcinoma tissue samples and 20 normal gastric tissue samples. Relation between FasL and Fas expression, age and gender of gastric cancer patients, and pathological subtype and lymph node metastasis of gastric cancer was analyzed.

RESULTS: The Fas expression level was significantly higher in normal gastric tissue samples than in gastric carcinoma tissue samples (85.0% vs 25.0%, $P < 0.001$), while the FasL expression level was significantly lower in normal gastric tissue samples than in gastric carcinoma tissue samples (30.0% vs 81.3%, $P < 0.001$). The Fas

expression level was significantly higher in invasive lymph nodes than in non-invasive lymph nodes (82.9% vs 56.5%, $P < 0.003$) and in well-differentiated gastric carcinoma tissue samples than in poorly-differentiated gastric carcinoma tissue samples (50.0% vs 18.0%, $P = 0.015$). The FasL expression level was significantly lower in well-differentiated gastric carcinoma tissue samples than in poorly-differentiated gastric carcinoma tissue samples (42.9% vs 84.0%, $P = 0.021$). The Fas and FasL expression levels (25.0% and 81.3%) were significantly different in gastric carcinoma tissue samples ($P < 0.001$), but had a non-linear correlation ($P = 0.575$).

CONCLUSION: Abnormal Fas and FasL expressions in gastric carcinoma and lymph node tissues are involved in carcinogenesis and metastasis of gastric cancer.

Clinical significance of Fas and FasL protein expression in gastric carcinoma and local lymph node tissues. *World J Gastroenterol* 2010; 16(10): 1274-1278 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i10/1274.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i10.1274>

INTRODUCTION

Gastric carcinoma is one of the most common malignant tumors in the world. Currently, no effective treatment modalities are available for its metastasis and recurrence. Fas, a cell-surface receptor, activates the apoptosis signal

pathway by binding to its ligand, FasL, resulting in cancer cell apoptosis^[1,2]. It has been shown that Fas protein is abnormally expressed in esophageal, colon, and gallbladder carcinomas^[3-5]. FasL is over-expressed in transformation and metaplasia of esophageal carcinoma^[6].

By investigating the role of Fas and FasL expression in the carcinogenesis and metastasis of gastric carcinoma, several investigators have found that Fas expression in gastric carcinoma is decreased^[7]. Bennett *et al.*^[8] showed that the high FasL expression level in gastric carcinoma can induce apoptosis of T lymphocytes infiltrating cancerous regions, suggesting that Fas and FasL induce apoptosis of activated lymphocytes, allowing cancer cells to escape immune attack.

However, no research is available on the clinical significance of Fas and FasL in local lymph nodes. To explore the relation between gastric carcinoma and regional lymph node metastasis, Fas and FasL protein expressions were detected using immunohistochemistry method in this study.

MATERIALS AND METHODS

Materials

Specimens were obtained from 64 cases of gastric carcinoma admitted to the Department of Pathology, Second Affiliated Xiangya Hospital, Central South University, in May 2007-May 2008. Of these specimens, 38 were from male patients and 26 from female patients, (including 3 patients at the age of 20-29 years, 6 patients at the age of 30-39 years, 20 patients at the age of 40-49 years, 19 patients at the age of 50-59 years, and 16 patients at the age of over 60 years), 14 were from well-differentiated adenocarcinoma patients, and 50 were from poorly-differentiated adenocarcinoma patients. Lymph node metastasis was detected in 41 cases. The patients did not receive radiotherapy or chemotherapy before operation. Twenty normal gastric tissue samples were also obtained from the same hospital.

Immunohistochemistry

Specimens, fixed with 10% neutral formaldehyde solution and embedded in paraffin, were cut into 3- μ m thick sections. Streptavidin-biotin complex (SABC) immunohistochemistry kit, primary antibodies: rabbit anti-human Fas and FasL, second antibody: biotin goat anti-rabbit IgG, and 3,3'-diaminobenzidine chromogenic kit were purchased from Wuhan Boster Company (China). PBS was used instead of primary antibody as a negative control following its manufacturer's instructions.

Evaluation of score

Intensity of staining was scored as 0: negative, 1: light yellow, 2: brown-yellow and 3: brown. Eight random high-power fields were observed under optical microscope and 4 high-power fields were recorded as the percentage of positive cells. Extent of staining was scored as 0: < 5%, 1: 5%-25%, 2: 26%-50%, 3: 51%-75% and 4: > 75%.

Table 1 Expression of Fas and FasL in gastric carcinoma and normal gastric tissues

	Fas ^a		FasL ^b	
	Normal gastric tissues	Gastric carcinoma	Normal gastric tissues	Gastric carcinoma
-	3	48	14	12
+	5	6	2	10
++	4	4	3	18
+++	8	6	1	24

^aZ = -4.780, P < 0.001; ^bZ = -4.115, P < 0.001.

Table 2 Expression of Fas and FasL in invasive and non-invasive lymph nodes

	Fas ^a		FasL ^b	
	Invasive	Non-invasive	Invasive	Non-invasive
-	7	10	18	7
+	7	6	6	6
++	9	4	9	6
+++	18	3	8	4

^aZ = -2.954, P = 0.003; ^bZ = -0.534, P = 0.593.

The final score was determined by multiplying the scores of intensity and extent of staining, ranging 0-12. Scores 9-12 were defined as strong staining (+++), scores 4-8 as moderate staining (++), scores 1-3 as weak staining (+), and 0 as negative staining (-)^[7].

Statistical analysis

Statistical analysis was performed using SPSS 15.0. The data were analyzed by rank-sum test and χ^2 test. P < 0.05 was considered statistically significant.

RESULTS

Expression of Fas and FasL in gastric carcinoma and normal gastric tissue samples

The expression level of Fas protein was higher in normal gastric tissue samples than in gastric carcinoma tissue samples (85.0% *vs* 25.0%, Z = -4.780, P < 0.001). The FasL protein expression level was lower in normal gastric tissue samples than in gastric carcinoma tissue samples (30.0% *vs* 81.3%, Z = -4.115, P < 0.001) (Table 1 and Figure 1).

Expression of Fas and FasL in invasive and non-invasive lymph nodes

The expression level of Fas protein was higher in invasive lymph nodes than in non-invasive lymph nodes (82.9% *vs* 56.5%, Z = -2.954, P = 0.003). The expression level of FasL protein was lower in invasive lymph nodes than in non-invasive lymph nodes (56.1% *vs* 69.6%, Z = -0.593, P = 0.593) (Table 2 and Figure 2).

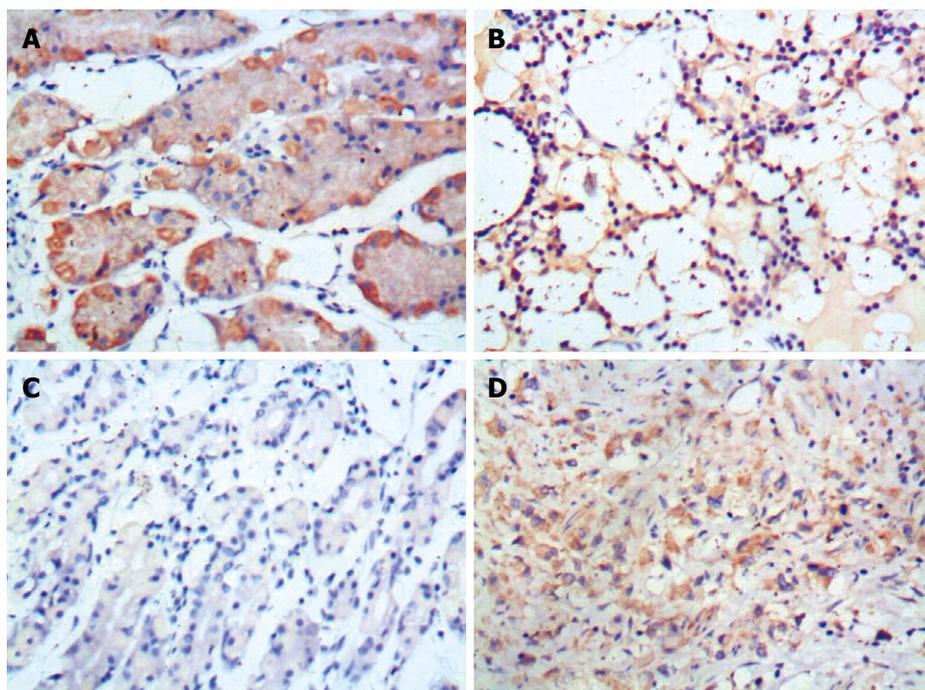

Figure 1 Expression of Fas and FasL in normal gastric tissues (A, C) and gastric carcinoma tissue (B, D) (SABC × 200).

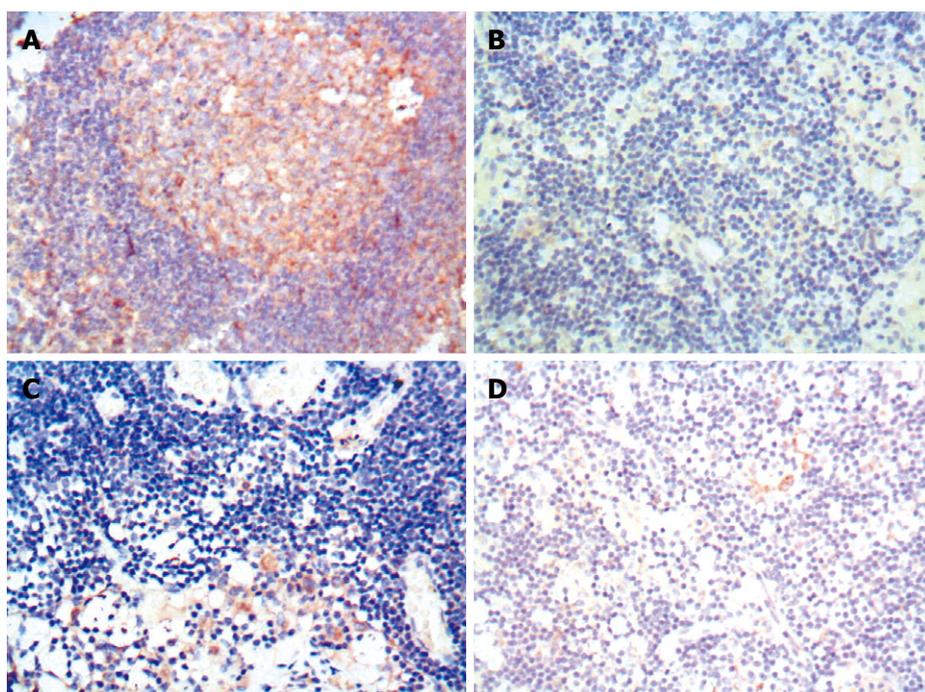

Figure 2 Expression of Fas and FasL in invasive lymph nodes (A, C) and non-invasive lymph nodes (B, D) (SABC × 200).

Expression of Fas and FasL in various pathological subtypes of gastric carcinoma

The Fas expression level was higher in well-differentiated gastric carcinoma tissue samples than in poorly-differentiated gastric carcinoma tissue samples (50.0% *vs* 18.0%, $Z = -2.421$, $P = 0.015$). The FasL expression level was lower in well-differentiated gastric carcinoma tissue samples than in poorly-differentiated gastric carcinoma tissue samples (42.9% *vs* 84.0%, $Z = -2.307$, $P = 0.021$) (Table 3).

The expression level of Fas and FasL protein in gastric carcinoma tissue samples was not significantly different in patients at different ages with or without lymph node metastasis (Table 4).

Expression of Fas and FasL in gastric carcinoma tissue samples

The Fas and FasL expression rate was 25.0% and 81.3%, respectively, in gastric carcinoma tissue samples ($Z = -4.780$, $P < 0.001$). Rank correlation test showed that the Fas and FasL expression in gastric carcinoma tissue samples had a non-linear correlation (correlation coefficient: -0.425 , $P = 0.575$).

DISCUSSION

The binding of Fas to its natural ligand, FasL, induces a signal transduction pathway leading to apoptosis^[9]. Fas is

a type I transmembrane protein belonging to the tumor necrosis factor (TNF) superfamily. Combination of Fas and FasL or a corresponding membrane-antibody, activates caspases, and is a major route to apoptosis^[10].

Dysfunction of Fas or FasL will lead to inactivation of the Fas system and inhibit normal apoptosis, resulting in abnormal survival and proliferation of tumor cells, and may promote malignancies. It has been shown that inhibition of apoptosis plays a significant role in various stages of tumor formation and abnormal expressions of Fas and FasL protein can inhibit apoptosis^[1,2].

In this study, the Fas expression level was lower in gastric carcinoma tissue samples than in normal gastric mucosa tissue samples, and the positive FasL expression in gastric carcinoma tissue samples had a trend to increase, which is considered to be the general mechanism by which tumor cells escape the Fas-mediated host immune system by reducing or inhibiting Fas expression, suggesting that Fas-mediated cytotoxic T cells (CTL) are unable to identify carcinoma cells, and carcinoma cells can thus avoid attack by T-lymphocytes^[11].

Fas and FasL can be simultaneously expressed in tumor tissues. It has been reported that the susceptibility to Fas-mediated cell death is not positively correlated with the expression of tumor cell surface ligand FasL^[12]. The molecular mechanism may be related to the expression of both FasL and decoy receptor 3 (DcR3) in gastric cancer cells. DcR3, a newly identified member of the tumor necrosis factor receptor (TNFR) family, binds to some specific protein ligands and may competitively inhibit Fas binding to FasL, thus blocking FasL and inhibiting apoptosis^[13].

Although activated T lymphocytes and their ligand FasL can combine with Fas receptors in carcinoma cells, they do not induce apoptosis. However, membrane FasL in carcinoma cells can combine with Fas receptors of activated T lymphocytes, resulting in T lymphocyte apoptosis^[14]. In this study, some invasive lymph nodes could over-express Fas, indicating that FasL can combine with over-expressed Fas receptors on T cells, resulting in T cell apoptosis and tumor proliferation. Since a high Fas expression level in lymphoid tissue signifies a higher susceptibility to tumor cells, the Fas/FasL system is involved in gastric carcinoma tumors evading the immune system. On the one hand, since Fas expression is reduced or lost in gastric carcinoma, anti-tumor immune

cells expressing FasL are less able to clear them. On the other hand, gastric carcinoma cells expressing high FasL levels are able to attack tumor-infiltrating immune cells expressing high Fas levels by promoting apoptosis of immune cells, thus allowing gastric cancer cells to escape immune attack^[15]. Kume *et al.*^[16] reported that a large number of lymphocytes in gastric carcinoma can express FasL. In our study, the Fas expression level was significantly higher in invasive lymph nodes than in non-invasive lymph nodes, suggesting that lymph nodes with a high Fas expression level may be more susceptible to self-apoptosis, thereby promoting lymph node metastasis.

In this study, the expression of Fas and FasL in gastric carcinoma tissue samples was not correlated with the sex and age of patients with or without lymph node metastasis, suggesting that the characteristics of Fas and FasL expression may have already formed in malignant transformation of gastric tumor cells^[17].

In this study, the Fas and FasL expression rates were significantly different between well- and poorly-differentiated gastric carcinomas, which is consistent with the reported findings^[7]. A possible mechanism is that a high FasL expression level in well-differentiated gastric carcinoma combines with Fas in an autocrine or paracrine manner to promote gastric carcinoma cell apoptosis and reduces tumor growth, while poorly-differentiated gastric carcinoma can produce soluble Fas (sFas), which competes with tumor cell membrane Fas receptor for FasL, leading to the inhibition of cancer cell apoptosis^[18]. Meanwhile, sFas released from cancer cells plays an important role in the immunosuppressive effect. An elevated sFas level in hepatocellular carcinoma patients is negatively correlated with humoral (IgA, IgG) and cellular immune function parameters (e.g. lymphocyte transformation rate, natural and lymphokine-activated killer cell killing rate). Tumor cells produce sFas and combine with FasL expressed by T lymphocytes, a mechanism to evade immune attack^[19], indicating that sFas may play an important role in carcinogenesis and cancer progression. However, how sFas generates and regulates such a mechanism is unclear, and needs to be further investigated.

In conclusion, abnormal expression of Fas and FasL is involved in carcinogenesis and metastasis of gastric carcinoma by escaping T lymphocyte attack and inducing lymphocyte apoptosis.

COMMENTS

Background

Gastric carcinoma is one of the most common malignant tumors in the world. Fas, a cell-surface receptor, activates the apoptosis signal pathway by binding to its ligand FasL, resulting in cancer cell apoptosis. Abnormal expressions of Fas and FasL are associated with carcinogenesis.

Research frontiers

A high FasL expression level in gastric carcinoma can induce apoptosis of T lymphocytes infiltrating the tumor. However, no current research is available on the clinical significance of Fas and FasL protein expression in local lymph nodes. In this study, the authors showed that a high Fas expression level in lymphoid tissue might indicate a greater susceptibility to tumor cell invasion.

Innovations and breakthroughs

Binding of Fas to its natural ligand, FasL, induces the signal transduction pathway leading to apoptosis. This is the first study to report that Fas-mediated cell death susceptibility and expression of the tumor cell surface ligand FasL are not positively correlated. Furthermore, in the study, lymph nodes with a high Fas expression may be more susceptible to self-apoptosis, thus promoting lymph node metastasis.

Applications

By exploring the relation between the expressions of Fas and FasL in gastric carcinoma and lymph node tissues with regional lymph node metastasis, this study may convey a strategy for therapeutic intervention in gastric carcinoma patients.

Peer review

It is a well written paper. The authors investigated the expression of Fas and FasL in gastric cancer, which helps to understand the pathogenesis of gastric cancer. The experimental procedure is quite well performed.

Abstract

AIM: To evaluate the effect of efflux pump inhibitors (EPIs) on multidrug resistance of *Helicobacter pylori* (*H. pylori*).

METHODS: *H. pylori* strains were isolated and cultured on Brucella agar plates with 10% sheep's blood. The multidrug resistant (MDR) *H. pylori* were obtained with the inducer chloramphenicol by repeated doubling of the concentration until no colony was seen, then the susceptibilities of the MDR strains and their parents to 9 antibiotics were assessed with agar dilution tests. The present study included periods before and after the advent of the EPIs, carbonyl cyanide m-chlorophenyl hydrazone (CCCP), reserpine and pantoprazole, and the minimum inhibitory concentrations (MICs) were determined accordingly. In the same way, the effects of 5 proton pump inhibitors (PPIs), used in treatment

of *H. pylori* infection, on MICs of antibiotics were evaluated.

RESULTS: Four strains of MDR *H. pylori* were induced successfully, and the antibiotic susceptibilities of MDR strains were partly restored by CCCP and pantoprazole, but there was little effect of reserpine. Rabeprazole was the most effective of the 5 PPIs which could decrease the MICs of antibiotics for MDR *H. pylori* significantly.

CONCLUSION: *In vitro*, some EPIs can strengthen the activities of different antibiotics which are the putative substrates of the efflux pump system in *H. pylori*.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is an important human pathogen that infects 50% of the world's population^[1,2]. *H. pylori* infection in humans is associated with the development of numerous gastric pathologies, such as peptic ulcer, chronic gastritis and gastric cancer. Once *H. pylori* is established in the gastric submucosa, infected

individuals usually carry it for life unless treated^[1,2]. In recent years, the rate of resistance of *H. pylori* to standard therapies has increased as a result of the widespread use of antibiotics. *H. pylori* resistance to metronidazole and clarithromycin has increased worldwide, and multidrug resistant (MDR) strains that are simultaneously resistant to amoxicillin, metronidazole and clarithromycin have been reported^[3,4]. Boyanova *et al*^[3] reported that 26.4% of the strains were resistant to metronidazole and clarithromycin among antibiotic-treated patients; Wueppenhorst *et al*^[4] found that 15% of the *H. pylori* isolated from patients showed resistance to 2 or 3 types of antibiotic.

Efflux pump systems in bacteria which can eject the drugs and toxic compounds, including antibiotics, have a critical role in the development of multidrug resistance^[5]. We have observed previously that the efflux pump gene *befA* of *H. pylori* has valuable applications in multidrug resistance^[6]. Until now, efflux pump inhibitors (EPIs) as promising therapeutic agents, have been widely investigated in other bacteria, where they could decrease the intrinsic bacterial resistance to antibiotics, and reverse the acquired resistance associated with efflux pump overexpression. Different classes of EPIs have been exploited and studied, including analogues of antibiotic substrates and new molecules^[7,8]. However, whether the EPIs can also reverse the multidrug resistance of *H. pylori* has not been fully researched. Carbonyl cyanide *m*-chlorophenyl hydrazone (CCCP), as an energy blocker, can induce a decrease in the transmembrane electrochemical gradient, and inhibit the efflux pumps driven by hydrogen ion gradients. Previous research showed that it can inhibit the multidrug and toxic compound extrusion (MATE) family efflux transporter pumps, such as NorM in *Bacteroides thetaiotaomicron*, and the resistance/nodulation/division superfamily (RND) family multidrug efflux transporter (MexAB-OprM system in *P. aeruginosa*), the small multidrug resistance subfamily of the DMT (drug/metabolite transporters) superfamily, such as QacE in *Escherichia coli*, and thus restore the antibiotic sensitivity of the bacteria^[9-11]. Reserpine belongs to the alkaloid family, and could inhibit the major facilitator superfamily (MFS) and the adenosine triphosphate (ATP)-binding cassette (ABC multidrug efflux) superfamilies^[12,13]. CCCP and reserpine are employed in the present study as different types of EPI, and a chloramphenicol-induced multidrug resistance model was developed. The aim of this investigation was to elucidate whether EPIs can influence the antibiotic susceptibilities of *H. pylori* MDR strains.

MATERIALS AND METHODS

Reagents

Chemical reagents were purchased from TaKaRa Biotechnology Co. Ltd (Dalian, China). Chloramphenicol, tetracycline, and CCCP were purchased from Sigma Co. Ltd (Shanghai, China). Quant SYBR Green PCR Kits, polymerases and other molecular biology reagents were purchased from Biosail Biotechnology Co. Ltd (Beijing,

China), and used according to their manufacturers' instructions. Clarithromycin, amoxicillin, penicillin G, cefotaxime, polymyxin B, piperacillin ciprofloxacin clindamycin ceftriaxone ampicillin, metronidazole, erythromycin and other drugs were purchased from the National Institute for the Control of Pharmaceutical and Biological Products (Beijing, China).

Bacterial strains and culture conditions

H. pylori isolates were obtained from routine cultures of clinical gastric biopsies from patients with peptic ulcer or chronic active gastritis at the Second Affiliated Hospital of Zhengzhou University (Zhengzhou, China). *H. pylori* NCTC11637 obtained from Henan Key Laboratory of Molecular Medicine was used as a reference. Isolates were cultured on Brucella agar medium plates containing 7% lysed sheep blood at 37°C under microaerobic conditions (50 mL/L O₂, 100 mL/L CO₂, 850 mL/L N₂) for 48-72 h. Identification of *H. pylori* isolates was based on the results of Gram staining, cell morphology, and positive reactions for catalase, oxidase and urease activities.

Induction of multiple antibiotic resistances of clinical isolates

Susceptible strains were isolated from gastric biopsy samples, with an established protocol^[6], and the MDR strains were developed. Induction of chloramphenicol resistance in susceptible isolates was performed by selecting resistant colonies that arose in the agar plates containing 1/2 × minimum inhibitory concentration (MIC) chloramphenicol. The resistant colonies were incubated for 48-72 h under microaerobic conditions with repeated doubling of the chloramphenicol concentration until no colony was seen. The induced strains were further incubated on fresh plates with no chloramphenicol for 4 generations, to insure that the induced strains were non-adaptive resistance strains, and then transferred onto plates containing 4 × MIC chloramphenicol. Induced colonies were maintained on plates containing 4 × MIC of tetracycline, ampicillin, penicillin G, cefotaxime, piperacillin, ciprofloxacin, clindamycin, ceftriaxone, and erythromycin. The colonies were incubated for 48-72 h under microaerobic conditions.

Real-time reverse transcription polymerase chain reaction (RT-PCR)

RNA was isolated using the total RNA kit (SBS Genetech Co., Ltd Beijing, China) and reverse transcribed into cDNA. *befA*, versus *gyrB* (a housekeeping gene encoding for gyrase B), was utilized to study the relative expression of the *befA* gene in 4 MDR strains and their parent strains. cDNA of *befA* and *gyrB* was amplified using a real-time PCR 5700 sequence detector (Perkin Elmer Company) in the presence of Real Master Mix (SYBR Green). The gene-specific primers used were designed based on the sequence alignments of the genes from *H. pylori* 11637 in GenBank. The sequences of *befA* (accession No: AF059041) are F: (5'-CTCGCTCGCATGATCGC-3')

and R: (5'-CGTATTCGCTCAAAATCCCT-3'). The PCR primers were predicted to amplify a 162-bp amplicon. Expression of the housekeeping gene *gyrB* (accession No: AB084049) was assessed in parallel with the primer pair *gyrB*: F: (5'-TTACTACGACTTATCCTGGGGCTAGCGCTG-3') and R: (5'-CCCCATCAATTTCCACA TTCTCCGC-3'). The PCR primers were predicted to amplify a 267-bp amplicon. According to the methods reported^[6,14,15], *hefA* gene expressions in MDR and parent strains were determined.

Assessment of susceptibilities to antimicrobials

H. pylori strains grown for 48 h on sheep blood agar plates were resuspended in phosphate-buffered saline. Suspensions of *H. pylori* were adjusted to an optical density of 0.1 at 625 nm, and 1 μL of these suspensions containing approximately 10^5 colony forming units/mL, was spread on horse blood agar plates containing approximately 5×10^4 bacteria within 5 mm. (1) MICs of tetracycline, ampicillin, penicillin G, cefotaxime, piperacillin ciprofloxacin clindamycin ceftriaxone, erythromycin in MDR strains and their parent isolates were determined with the conventional 2-fold agar dilution tests; (2) After addition of CCCP (100 $\mu\text{mol/L}$), reserpine (20 $\mu\text{g/mL}$) and pantoprazole (10 $\mu\text{g/mL}$) to the agar, MICs of the antibiotics were determined again; and (3) To determine whether proton pump inhibitors (PPIs) can affect the *H. pylori* eradication effect of the antibiotics, 5 PPIs (omeprazole, rabeprazole, pantoprazole, lansoprazole, esomeprazole, 10 $\mu\text{g/mL}$) usually used in treatment of *H. pylori* infection were added to the incubation media as above, and MICs of metronidazole, amoxicillin, furazolidone and clarithromycin were tested. A 4-fold increase in MIC of antibiotics for the MDR strains was considered significant^[16].

RESULTS

Induction of multidrug resistance in *H. pylori* strains

From 65 *H. pylori* isolates, 9 strains with no antibiotic resistance phenotype were selected. Following consecutive doubling of the concentration of chloramphenicol, MICs of chloramphenicol-induced strains to 9 antibiotics were

Table 2 Relative expression of *hefA* in PT and MDR strains

Strains	PT (<i>hefA/gyrB</i>)	MDR (<i>hefA/gyrB</i>)

determined. The MICs in 4 MDR strains (including 3 clinical isolates and *H. pylori* NCTC11637) were significantly increased (≥ 4 -fold) compared with their parent strains (Table 1).

Expression of *hefA* in MDR strains and their parent isolates

The expression of *hefA* in MDR strains and their parent isolates was assessed by real-time RT-PCR. Each relative expression value was the mean of 3 replications. The relative expression of *hefA* versus *gyrB* in 3 clinical isolates and *H. pylori* 11637 was significantly higher in MDR strains (5.83 ± 0.91) than in parent strains (1.90 ± 0.45). The difference in *hefA* expression was statistically significant ($P < 0.001$) (Table 2).

MICs of the antibiotics in *H. pylori* strains after treatment with CCCP

When treated with CCCP (100 $\mu\text{mol/L}$), MICs of the 9 antibiotics were tested. MICs of 5 antibiotics decreased at least 4-fold in MDR strains: 19-fold with chloramphenicol, 10-fold with tetracycline, 7-fold with erythromycin, 4-fold with cefotaxime and ceftriaxone (geometric mean), while there was little difference in the MIC of antibiotics in parent strains (sensitive strains) after challenge with CCCP (Figure 1).

Difference in MICs of the antibiotics in *H. pylori* strains after treatment with pantoprazole or reserpine

After treatment with pantoprazole (10 $\mu\text{g/mL}$), MICs of the 9 antibiotics were tested. MICs of 5 antibiotics

Table 3 MICs of the antibiotics after treatment with pantoprazole or reserpine ($\mu\text{g/mL}$)

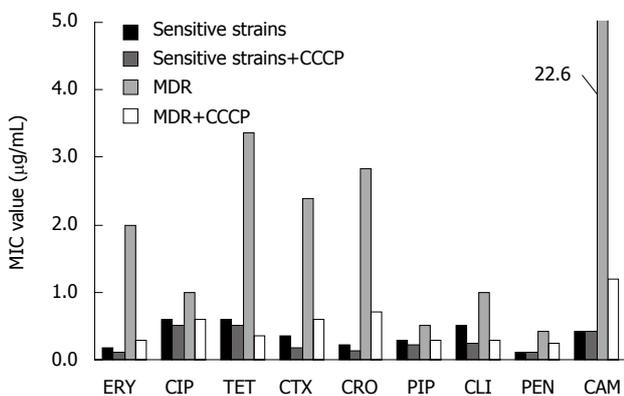

Figure 1 MICs of the antibiotics in *H. pylori* strains after treatment with CCCP (carbonyl cyanide m-chlorophenyl hydrazone). ERY: Erythromycin; CIP: Ciprofloxacin; TET: Tetracycline; CTX: Cefotaxime; CRO: Ceftriaxone; PIP: Piperacillin; CLI: Clindamycin; PEN: Penicillin; CAM: Chloramphenicol.

decreased at least 4-fold in MDR strains: 6-fold with erythromycin, 13-fold with tetracycline, 9-fold with cefotaxime and ceftriaxone, 4-fold with clindamycin (geometric mean), while MICs with erythromycin and ceftriaxone were also decreased 4-fold in their parent strains. MICs of antibiotics in MDR strains and parent strains had no obvious difference after reserpine (20 $\mu\text{g/mL}$) was added to the agar (Table 3).

Influence of PPIs on MICs of the antibiotics in MDR strains

To further clarify the effect of PPIs on MICs of antibiotics used in eradicating *H. pylori* in the clinic, and to determine which PPI was the most efficient in *H. pylori* treatment when combined with 2 antibiotics, MICs of metronidazole, amoxicillin, furazolidone and clarithromycin in MDR *H. pylori* strains were measured after treatment with one of the 5 PPIs (10 $\mu\text{g/mL}$). Our data indicated that MICs of metronidazole and amoxicillin were decreased 4-fold by treatment with rabeprazole, while there was a 3-fold decrease with pantoprazole. There was little effect of omeprazole, lansoprazole and esomeprazole on the MICs of antibiotics (Table 4).

DISCUSSION

With the extended use of antibiotics, the rate of resistance of antibiotics for *H. pylori* has increased worldwide, and appearance of an MDR strain that is simultaneously resistant to amoxicillin, metronidazole and clarithromycin, has been reported. In addition to chromosomally-encoded drug resistance, resistance to toxic compounds through increased export may be of importance in the multidrug resistance of *H. pylori*. Efflux systems have been identified in *H. pylori*^[17], but the mechanism of multidrug resistance

in *H. pylori* is far from well understood, and a tetracycline resistance-related gene (*HP1165*) was found in 2006^[18]. A non-specific MDR protein has also been reported, though we have little knowledge about the function of multidrug resistance^[19,20]. Preliminary studies suggested that overexpression of the efflux pump systems in *H. pylori* were associated with multidrug resistance to antibiotics^[6,21,22]. In the current investigation, the findings suggested that efflux pump systems were overexpressed under the pressure of increasing concentrations of antibiotics, which led to multidrug resistance to antibiotics in *H. pylori* strains, indicating that the long-term administration of antibiotics in the clinic may be responsible for *H. pylori* multidrug resistance.

Five families of multidrug efflux transporters have been described, which are primarily active transporters with energy from ATP hydrolysis or driven by ion gradients^[23,24]. MDR efflux pumps are recognized as an important component of resistance in *H. pylori*. To combat resistant pathogens, in recent years EPIs, as promising therapeutic agents, have been widely investigated in other bacteria^[25,26]. EPIs can be divided into several categories according to their mechanisms^[27]; to interfere with the structural synthesis of the efflux pumps, to block the energy supply of the bacterial membrane, or to act as a competitive substrate of efflux pumps. CCCP, as an energy blocker, can reduce the transmembrane electrochemical gradient, and inhibit the efflux pumps driven by hydrogen ion gradients. The results of this study showed that CCCP could decrease MICs of the 5 antibiotics at least 4-fold in MDR *H. pylori* strains, while it had little influence on MICs of antibiotics in parent strains, indicating that overexpression of efflux pump systems in *H. pylori*, as in other bacteria, can cause multidrug resistance. Only MICs of 5 out of 9 antibiotics were reduced after treatment with CCCP, suggesting that these types of antibiotic are the substrates of the *HefABC-RND* efflux pump in MDR *H. pylori*. Reserpine could inhibit MFS and the ATP-binding cassette (ABC multidrug efflux) superfamilies^[12,13]. MICs of antibiotics in MDR strains and parent strains showed little difference when treated with reserpine, confirming that MFS and ABC family efflux pumps may be not responsible for multidrug resistance in *H. pylori*.

PPIs including omeprazole, rabeprazole, pantoprazole, lansoprazole and esomeprazole combined with 2 or 3 kinds of antibiotics have been used widely in the treatment of *H. pylori* infection. As proton motive forced uncoupling agents, however, less is known about whether PPIs could restore the antibiotic sensitivity of the MDR *H. pylori* strains. Other studies reported that PPIs, as one class of EPI, could decrease the MICs of norfloxacin, ciprofloxacin and levofloxacin by 4-8 fold by inhibiting the NorA efflux pump in MDR *Staphylococcus aureus*^[28]. In this study, when treated with pantoprazole, MICs of the 5 antibiotics were decreased at least 4-fold in MDR strains, indicating that not only could PPIs act as antacids in the treatment of *H. pylori* infection, but also might inhibit the efflux pumps, and strengthen the effect of antibiotics by increasing their

intracellular accumulation. Previous studies have indicated that 5 PPIs used in treatment of *H. pylori* infection had little effect on the eradication rate of *H. pylori*^[29,30]. While 5 different PPIs were compared *in vitro* for their effects on the MICs of antibiotics in MDR *H. pylori* strains, our data showed that rabeprazole was the most efficient in reducing the multidrug resistance of these strains, with pantoprazole in second place. The underlying mechanisms require further study, but, based on the results in this study, it is suggested that rabeprazole could be used in the treatment of MDR *H. pylori* strains rather than other PPIs.

The antibiotic resistance rate of *H. pylori* has increased worldwide, and MDR strains have been reported, though limited information is available on the mechanisms of multidrug resistance and the role of EPIs in MDR *H. pylori*. To our knowledge, this study demonstrates for the first time that EPIs could partly reverse some types of antibiotic resistant phenotype in MDR *H. pylori* strains, and some PPIs contribute to enhance the antibacterial effect in *H. pylori* treatment.

ACKNOWLEDGMENTS

The authors thank Yi-Jun Ma for excellent technical assistance and providing *H. pylori* NCTC11637.

COMMENTS

Background

More than 50% of the world's population have *Helicobacter pylori* (*H. pylori*) infection, which is the major pathogen in human gastritis, peptic ulcers and gastric cancer. Nowadays, because of the extensive application of antibiotics, not only does the *H. pylori* resistance rate continue to rise, but also multidrug resistant (MDR) strains have emerged. The efflux pump systems of bacteria play an important role in the mechanism of multidrug resistance.

Research frontiers

To deal with the problem of multidrug resistance, in recent years, efflux pump inhibitors (EPIs) have been given extensive attention in many other bacteria, such as *Escherichia coli*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, etc. However, whether EPIs could influence the resistance of *H. pylori* has not yet been reported.

Innovations and breakthroughs

In the present study, some types of EPI were used to explore their effect on multidrug resistance of *H. pylori*, and for the first time it was demonstrated that EPIs could partly reverse an antibiotic-resistant phenotype in MDR *H. pylori* strains, and some proton pump inhibitors (PPIs) contributed to enhance the antibacterial effect in *H. pylori* treatment.

Applications

In vitro, the study found that EPIs could improve antibiotic sensitivity of MDR strains of *H. pylori*, and for clinical application, the EPI most efficient in decreasing the resistance should be investigated.

Peer review

The study by Zhang *et al.* explores the hypothesis that bacterial efflux pumps play an important role in the development of MDR *H. pylori*. Three chloramphenicol-induced MDR strains (out of 9 strains) were isolated from stomachs of patients and were shown to express higher levels of *hefA* (a efflux pump gene) mRNA.

Abstract

AIM: To examine whether heme oxygenase (HO)-1 overexpression would exert direct or indirect effects on Kupffer cells activation, which lead to aggravation of reperfusion injury.

METHODS: Donors were pretreated with cobalt protoporphyrin (CoPP) or zinc protoporphyrin (ZnPP), HO-1 inducer and antagonist, respectively. Livers were stored at 4°C for 24 h before transplantation. Kupffer cells were isolated and cultured for 6 h after liver reperfusion.

RESULTS: Postoperatively, serum transaminases were significantly lower and associated with less liver injury when donors were pretreated with CoPP, as compared

with the ZnPP group. Production of the cytokines tumor necrosis factor- α and interleukin-6 generated by Kupffer cells decreased in the CoPP group. The CD14 expression levels (RT-PCR/Western blots) of Kupffer cells from CoPP-pretreated liver grafts reduced.

CONCLUSION: The study suggests that the potential utility of HO-1 overexpression in preventing ischemia/reperfusion injury results from inhibition of Kupffer cells activation.

INTRODUCTION

Orthotopic liver transplantation (OLT) is an effective treatment for end-stage liver diseases^[1]. However, ischemia/reperfusion (I/R) injury of the liver remains a major cause of graft injury, causing liver dysfunction and even failure posttransplantation^[2,3]. The destructive effects of I/R arise from the acute generation of reactive oxygen species subsequent to reoxygenation, which inflicts direct tissue damage and initiates a cascade of deleterious

cellular responses leading to inflammation, cell death, and organ failure^[4]. Endothelial cell damage results from free radicals produced from Kupffer cells and adherent polymorphonuclear leukocytes (PMNs)^[5]. Ultimately, this results in loss of microvascular integrity and reduction of blood flow ('no-reflow phenomenon')^[6]. Methods to protect liver grafts against I/R injury have considerable clinical consequences.

Kupffer cells, the resident macrophages of the liver, are involved in liver I/R injury through the release of cytokines such as tumor necrosis factor- α (TNF- α) and other biologically active mediators^[7-9]. Multiple lines of evidence have suggested that Kupffer cells are critical to the onset of liver injury and following secretion, cytokines aggravate hepatocyte damage. The use of *in vitro* and animal models has shown that inactivation of Kupffer cells prevents liver injury^[10,11]. Activation of Kupffer cells directly or indirectly by endotoxin (lipopolysaccharide, LPS) results in the release of an array of inflammatory mediators, growth factors, and reactive oxygen species.

The heme oxygenase (HO) system is the rate-limiting step in the oxidative degradation of heme into biliverdin, carbon monoxide (CO) and free iron^[12]. Three HO isoforms have been identified: inducible HO-1, also known as heat shock protein 32; constitutively expressed HO-2; and a related but less well-characterized HO-3. HO-1 is induced in a variety of organs during diverse stress-related conditions and is thought to provide cytoprotection^[13,14]. Upregulation of HO-1 is known to be a protective response from cellular stress, following I/R injury, radiation and inflammation^[15]. Overexpression of HO-1 exerts a cytoprotective function in a number of I/R injury and liver transplant models^[16-18]. Thus, HO-1 is an attractive target for anti-inflammatory therapies and potential candidate responsible for cell injury.

Immunochemical studies with specific monoclonal antibodies have revealed the distribution of HO-1 in the rat liver with distinct topographical patterns^[19]. HO-1 has been shown to be expressed principally in Kupffer cells^[16,20-22]. However, exact mechanisms by which HO-1 induction may lead to cytoprotection during I/R injury in organ transplantation have not been fully clarified. We designed a study to evaluate the role of HO-1-mediated cytoprotection in rat liver transplantation models. The aim was to demonstrate whether HO-1 plays a critical role in inhibiting Kupffer cells activation.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley (S-D) Rats (Third Military Medical University Laboratory Animal Center, Chongqing, China) weighing 220-250 g were used. Animals were fed standard rodent chow and water *ad libitum* and cared for according to the local animal welfare guidelines. All procedures used in this study were approved by the ethics committee for the use of experimental animals at Kunming Medical College.

Synthetic metalloporphyrins

Metalloporphyrins (CoPP and ZnPP) were purchased from Sigma Chemical inc. USA. They were dissolved in 0.1 mol/L NaOH, subsequently adjusted to pH 7.4 with HCl, and diluted in 0.85% NaCl. The stock concentration was 0.5 mg/mL (CoPP) and 2 mg/mL (ZnPP).

Experimental design

S-D rats underwent ether anesthesia. The basic techniques of liver harvesting and orthotopic transplantation without hepatic arterial reconstruction were performed according to the method described previously by Kamada *et al.*^[23]. In the control group ($n = 8$), no drugs were applied. There were two treatment groups. In ZnPP group ($n = 8$), donors received ZnPP, an HO-1 inhibitor (20 mg/kg ip) 24 h prior to harvest. CoPP group ($n = 8$) rats received CoPP, an HO-1 inducer (5 mg/kg ip) 24 h prior to harvest. All liver grafts were harvested and stored with UW solution for 24 h at 4°C, and orthotopically transplanted into syngeneic S-D recipients. All transplant experiments in this study were performed by a single person. The anhepatic phase was 11.3 ± 0.7 min. Separate groups of rats were killed at 6 h after their vessels were unclamped, and liver samples were collected for further analysis.

Blood sample collection and serum liver enzymes

At 6 h following by liver reperfusion, blood was collected into ethylenediaminetetraacetic acid (EDTA) tubes. After centrifugation of whole blood (2000 g, 15 min), serum was stored at -70°C until analysis. Serum alanine aminotransferase (ALT) and aspartate transaminase (AST) levels were measured using an automated clinical analyzer (7060 automatic analyzer, Hitachi, Japan).

Histopathology

Liver graft tissues were fixed in 10% formalin, embedded in paraffin. Serial sections of 3 μ m thickness were stained with hematoxylin and eosin for routine pathological examination.

Isolation and culture of Kupffer cells

Kupffer cells were isolated from integral left liver tissue obtained from fresh specimens. The liver was perfused *in vitro* through the vena cava with 80 mL Hanks' balanced salt solution (HBSS) Ca²⁺/Mg²⁺-free (Hyclone, Germany) at 37°C, and transferred to a 100 mm culture dish and perfusion was continued with complete HBSS containing 0.05% collagenase IV (Sigma, USA) and 3 mmol/L Ca²⁺ at 37°C. Liver tissue was finely diced into 2 mm³ sized pieces and the suspension incubated under constant agitation at 37°C for 30 min. The liver homogenate was filtered through gauze mesh and the cells suspension was centrifuged at 50 g for 3 min at 4°C to remove hepatocytes. The non-parenchymal cells-enriched supernatant was centrifuged at 400 g for 6 min. The cell pellet was resuspended in 30% Percoll (Pharmacia, Sweden) with a density of 1.040 g/mL, and this was carefully layered onto 60% Percoll with a density

of 1.075 g/mL. The double layer discontinuous gradient formed was overlaid with 3 mL of HBSS and centrifuged at 400 *g* for 15 min at 4°C. The opaque interface was collected, resuspended in HBSS and centrifuged at 400 *g* for 5 min at 4°C. The cells were seeded onto tissue culture plates at a density of 2×10^6 /mL and cultured in RPMI 1640 medium (Gibco, USA) containing 10% heat-inactivated fetal bovine serum (FBS, Gibco, USA), 100 U/mL Penicillin/Streptomycin (Hyclone, Germany) and 10 mmol/L HEPES at 37°C with 5%CO₂. Nonadherent cells were removed after 2 h by gentle washing the plated cells and replacing the culture medium. Adherent cells were incubated for 48 h before performing uptake assays. More than 95% of adherent cells were ED2 (Serotec, UK) positive.

Reverse-transcriptase polymerase chain reaction (RT-PCR)

Total RNA was extracted from Kupffer cells at 48 h after culture or liver tissues with Trizol (Invitrogen, USA). Reverse transcription was performed on 1 μ g RNA using random primers. Reverse-transcription reaction product (PrimeScript™ RT-PCR Kit, TaKaRa) was used for PCR reaction, with initial heating at 94°C for 5 min, followed by 40 cycles of 94°C for 30 s, 53-55°C for 30 s, 72°C for 1 min, and finally 72°C for 7 min. The primers are listed in Table 1. The PCR products were subjected to electrophoresis on 1.5% agarose gel containing ethidium bromide and visualized by UV illumination. β -actin was used as an internal control for RNA integrity.

Western blotting analysis

Proteins were extracted from Kupffer cells with radioimmunoprecipitation (RIPA) containing phenylmethyl sulfonylfluoride (PMSF). Protein quantification of samples was performed using the BCA assay. Proteins (15 μ g/sample) in SDS-loading buffer were heated to 100°C for 5 min, subjected to 12% SDS-polyacrylamide gel electrophoresis (PAGE) and transferred to nitrocellulose membrane. The membrane was blocked overnight in 5% nonfat dry milk in TBST buffer at 4°C. Blots were incubated at room temperature (RT) for 2 h with anti-CD14 (dilution, 1:200, Santa Cruz Biotechnology, Inc. USA) in TBST buffer with 5% nonfat dry milk. After washing in TBST buffer three times at RT for 10 min, blots were incubated for 2 h at RT

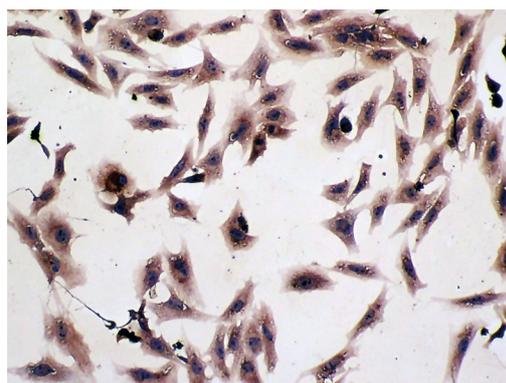

Figure 1 ED2 immunocytochemistry staining of cultured Kupffer cells. More than 95% are ED2 positive. Cells adhere to plastic and exhibit a spread out morphology and irregular shape ($\times 400$).

with horseradish peroxidase-conjugated goat anti-rabbit IgG antibodies (dilution, 1:50 000, Pierce Biotechnology) in TBST buffer with 5% nonfat dry milk. Finally, membranes were washed three times and developed with ECL (Amersham Pharmacia Biotech, Piscataway, New Jersey).

Measurement of cytokine release

The medium from Kupffer cells culture was collected and centrifuged at 1000 *g* for 5 min, and supernatant was kept -70°C until assayed. IL-6 and TNF- α levels in the supernatant were determined with rat-specific enzyme-linked immunosorbent assay (ELISA) kits (R&D Systems, Inc. USA). All samples, including standard and control solution, were assayed in duplicate.

Statistical analysis

Statistical analysis was performed using SPSS Version 13.0 for Windows (SPSS, Inc, Chicago, IL). All data are expressed as mean \pm SE. Difference between experimental groups were analyzed using one-way analysis of variance or Student's *t* test. All differences were considered statistically significant at the *P* value of < 0.05 .

RESULTS

Primary cultures of Kupffer cells

The isolated Kupffer cells were seeded onto tissue culture plates and incubated for 48 h. Cells attached rapidly to the dish surface, and spread in an irregular outline after 48 h in culture (Figure 1). More than 95% were ED2 positive on immunocytochemistry staining.

Liver HO-1 expression levels before transplantation

To assess HO-1 expression in experimental livers that were either untreated or pretreated with an HO-1 inducer or inhibitor, we performed RT-PCR analyses. A wide variation in HO-1 gene expression was detected in liver tissues that were collected before transplantation (Figure 2A). Livers harvested from donors that were pretreated with CoPP significantly up-regulated HO-1 mRNA expression levels as compared with control or the ZnPP

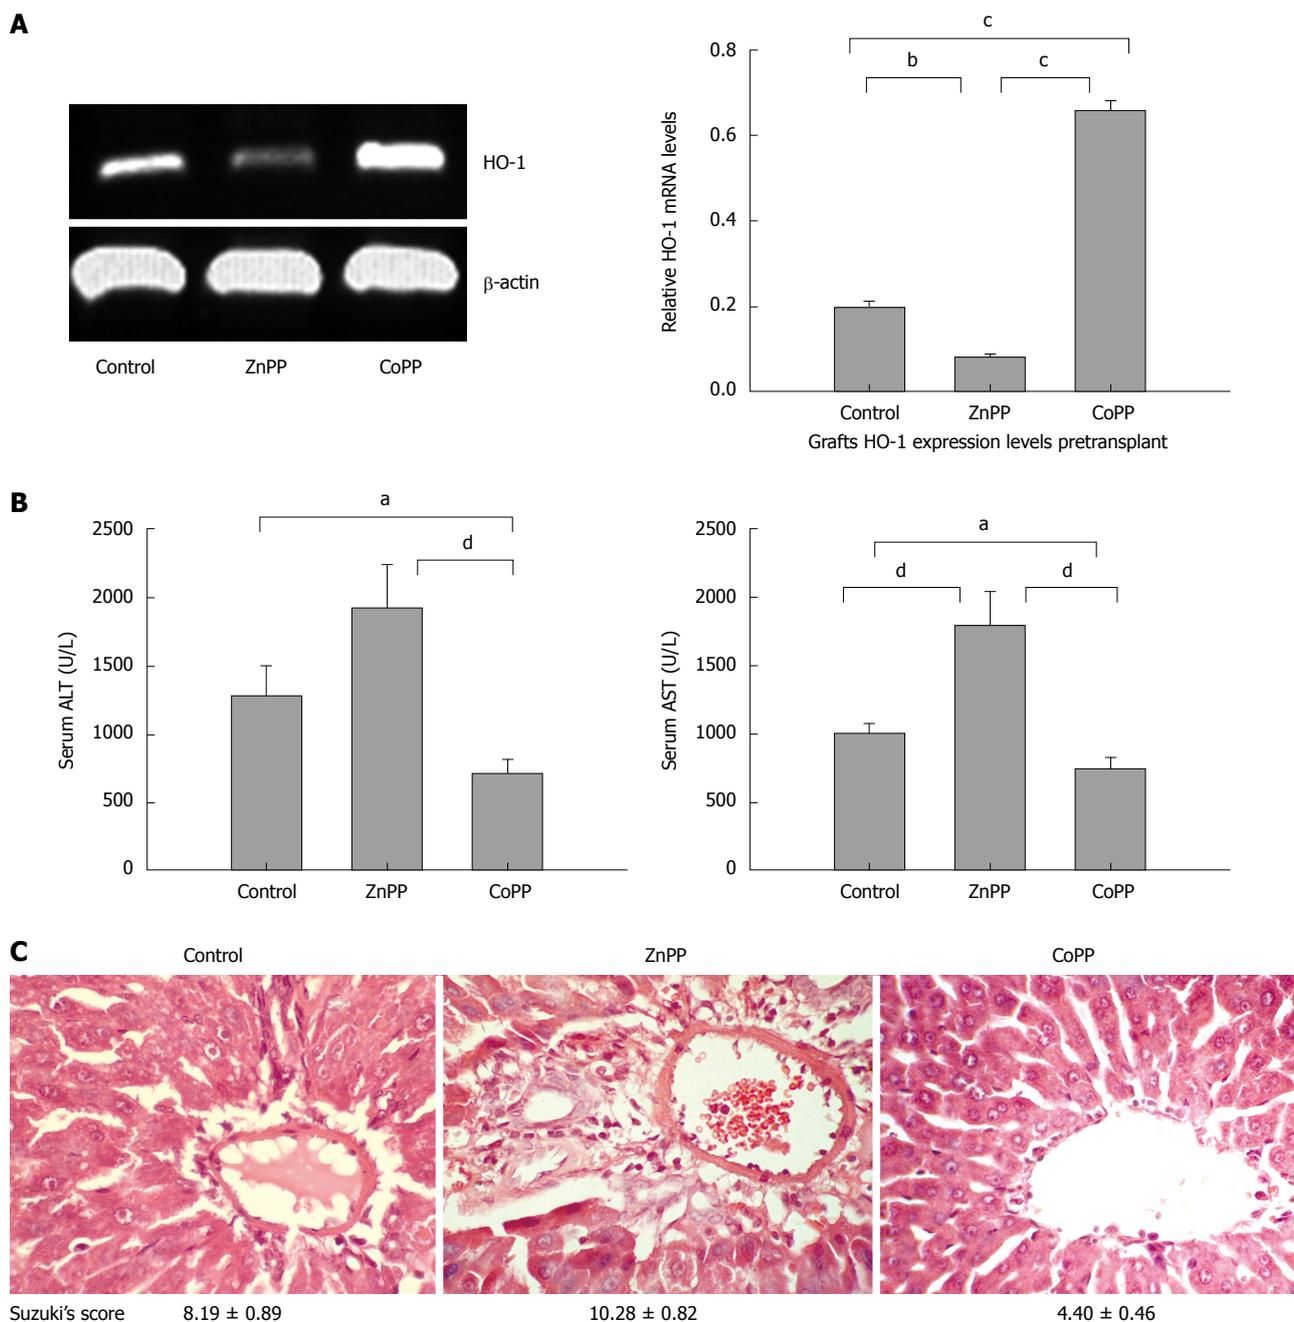

Figure 2 HO-1 overexpression ameliorates hepatic I/R injury. A: The expression of hepatic HO-1 was evaluated by RT-PCR before liver transplantation. β -actin was used as an internal control. Decreased expression of HO-1 mRNA was detected 24 h after ZnPP treatment. CoPP treatment increased HO-1 mRNA ($n = 4/\text{group}$). ^b $P < 0.001$; ^c $P < 0.0001$; B: Hepatocellular function. Serum ALT/AST levels (U/L) were higher in the ZnPP group as compared with controls. Significantly lower serum transaminase levels were seen in the CoPP group ($n = 8/\text{group}$). ^a $P < 0.05$; ^d $P < 0.01$; C: Representative photomicrographs of rat livers following 6 h reperfusion. Livers in ZnPP group show severe lobular distortion, sinusoidal congestion, ballooning, hepatocyte necrosis. Livers pretreated with CoPP exhibit good preservation of lobular architecture. Original magnification, $\times 400$; HE stain.

group (0.658 ± 0.022 , 0.198 ± 0.0165 , 0.083 ± 0.008 , respectively; $P < 0.0001$). ZnPP treatment decreased HO-1 mRNA as compared with control ($P < 0.001$).

HO-1 overexpression improves liver function

We analyzed the hepatocellular function in rats that underwent cold ischemia followed by 6 h of reperfusion in three animal groups. As shown in Figure 2B, pretreatment with CoPP significantly decreased serum ALT levels as

compared with the control or the ZnPP group (711.37 ± 111.13 , 1285.00 ± 219.46 , 1932.13 ± 313.41 , respectively, $P < 0.05$ vs control, and $P < 0.01$ vs ZnPP-treated control). Serum AST levels were also significantly reduced in the CoPP treatment group as compared with both the control and the ZnPP group (740.38 ± 84.71 , 998.63 ± 69.45 , 1795.50 ± 244.59 , respectively, $P < 0.05$ vs control, and $P < 0.01$ vs ZnPP-treated control). Both ALT and AST levels were higher in the ZnPP group.

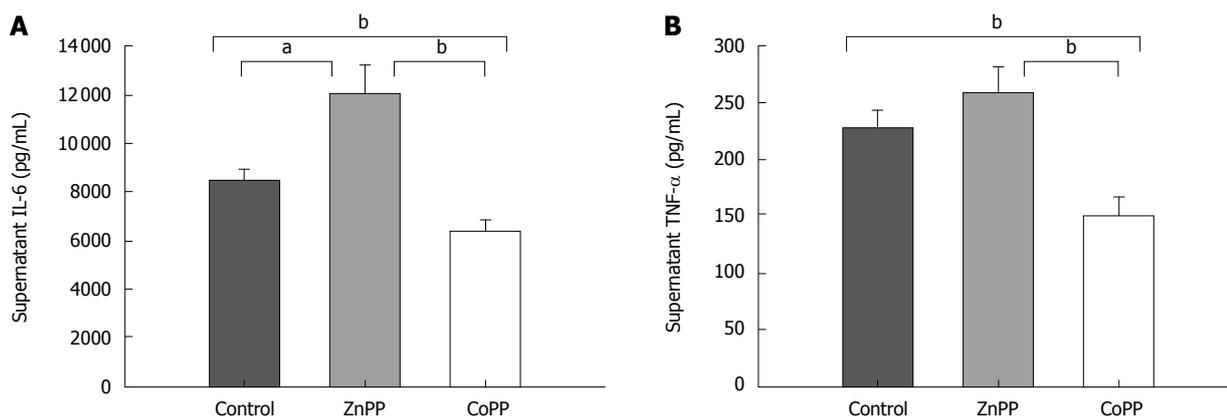

Figure 3 Concentration of IL-6 and TNF- α in cultured supernatant. Detection of cytokines at 48 h of Kupffer cell culture. ZnPP treatment increased cytokine levels of IL-6 (A) and TNF- α (B) were assayed. Significantly lower cytokine levels were detected in the CoPP group as compared with controls. The cytokine levels in cultured supernatant were measured by ELISA technique as described in Materials and methods ($n = 5/\text{group}$). ^a $P < 0.05$, ^b $P < 0.01$.

HO-1 overexpression ameliorates hepatic I/R injury

The hepatocellular damage was evaluated by liver histology. Livers in the ZnPP group showed a more severe hepatocyte necrosis, sinusoidal congestion and ballooning, as compared with controls. In contrast, livers in the CoPP group revealed almost complete preservation of lobular architecture without sinusoidal congestion, ballooning, or necrosis (Figure 2C). The hepatocellular damage was graded using a modified Suzuki's criteria^[24].

Cytokines release

The cytokine levels (IL-6/TNF- α) in supernatant from the release of cultured Kupffer cells revealed a substantial increase in the ZnPP pretreated group as compared with the CoPP group ($12019.25 \pm 1244.89/257.75 \pm 21.56$ pg/mL *vs* $6360.13 \pm 522.36/152.00 \pm 14.66$ pg/mL, respectively; $P < 0.01$). The IL-6/TNF- α levels of supernatant in CoPP pretreated group were significantly lower, when compared to the control group ($8459.86 \pm 453.51/228.38 \pm 15.04$, $P < 0.01$; Figure 3A and B).

HO-1 and CD14 expression of Kupffer cells (Effect of HO-1 on Kupffer cells activation)

HO-1 mRNA expression levels of Kupffer cells pretreated with CoPP were significantly up-regulated, and those pretreated with ZnPP were down-regulated (Figure 4A). A prominent increase of CD14 mRNA levels in Kupffer cells was detected in the ZnPP group as compared with the control group or the CoPP group (1.547 ± 0.227 , 0.772 ± 0.135 , 0.325 ± 0.084 pg/mL, respectively; $P < 0.05$ *vs* control, and $P < 0.01$ *vs* CoPP-pretreated group). CoPP treatment was significantly lower, when compared to the control group ($P < 0.05$). As shown in Figure 4B and consistent with mRNA data, Western blot-assessed CD14 protein levels of Kupffer cells were also significantly up-regulated in the ZnPP group as compared with the control group (1.996 ± 0.446 pg/mL *vs* 1.303 ± 0.081 pg/mL, $P < 0.05$). CoPP treatment reduced CD14 protein levels (0.771 ± 0.136 , $P < 0.05$ *vs* control).

DISCUSSION

I/R injury is one of the major obstacles in liver

transplantation. HO-1 overexpression exerts cytoprotection and ameliorates hepatocellular damage in a number of liver I/R injury models^[25-27], and prolongs cold ischemia followed by *ex vivo* perfusion or OLT^[18]. In our study, CoPP-induced HO-1 overexpression significantly decreased hepatocyte injury posttransplantation. Donor livers with enhanced HO-1 expression reduced serum ALT/AST levels of recipients, ameliorated hepatic injury and suppressed cytokine release. In the transplant model, cultured Kupffer cells from donors pretreated with CoPP down-regulated CD14 mRNA and protein expression levels and reduced cytokine release.

HO-1 has been suggested as a cytoprotective gene during liver transplantation. However, the mechanism of HO-1-cytoprotection against I/R injury remains elusive. Tsuchihashi *et al*^[28] showed that basal HO-1 levels are more critical than the ability to up-regulate HO-1 in response to I/R injury. Generally, the cellular mechanisms of HO-1-derived protection included regulation of the inflammatory response, improvement of microvascular flow and the antiapoptotic effects. The beneficial effects of HO-1 may be the result of the ability of the end-products of heme degradation^[18]. Kaizu *et al*^[29] reported that exogenous CO treatment suppressed early proinflammatory gene expression and neutrophil infiltration, and efficiently ameliorated hepatic I/R injury. CO has vasodilating effects, thereby maintaining microvascular hepatic blood flow^[18,30]. Furthermore, Tomiyama *et al*^[31] recently demonstrated that CO ameliorated hepatic I/R injury and *in vitro* rat primary Kupffer cells culture also showed significant down-regulation of LPS-induced inflammatory responses. Biliverdin and the subsequently formed bilirubin possess potent antioxidant effects.

The mechanism of hepatic I/R injury is largely attributed to Kupffer cell activation and release of proinflammatory mediators such as reactive oxygen species and cytokines. During the initial stages of reperfusion Kupffer cells are activated. Activated Kupffer cells release a large amount of proinflammatory cytokines (TNF- α , IL-6, and IL-1)^[32-34], which lead to aggravation of I/R injury. Liver I/R injury can be attenuated by the suppression of Kupffer cells^[35]. Therefore modulation

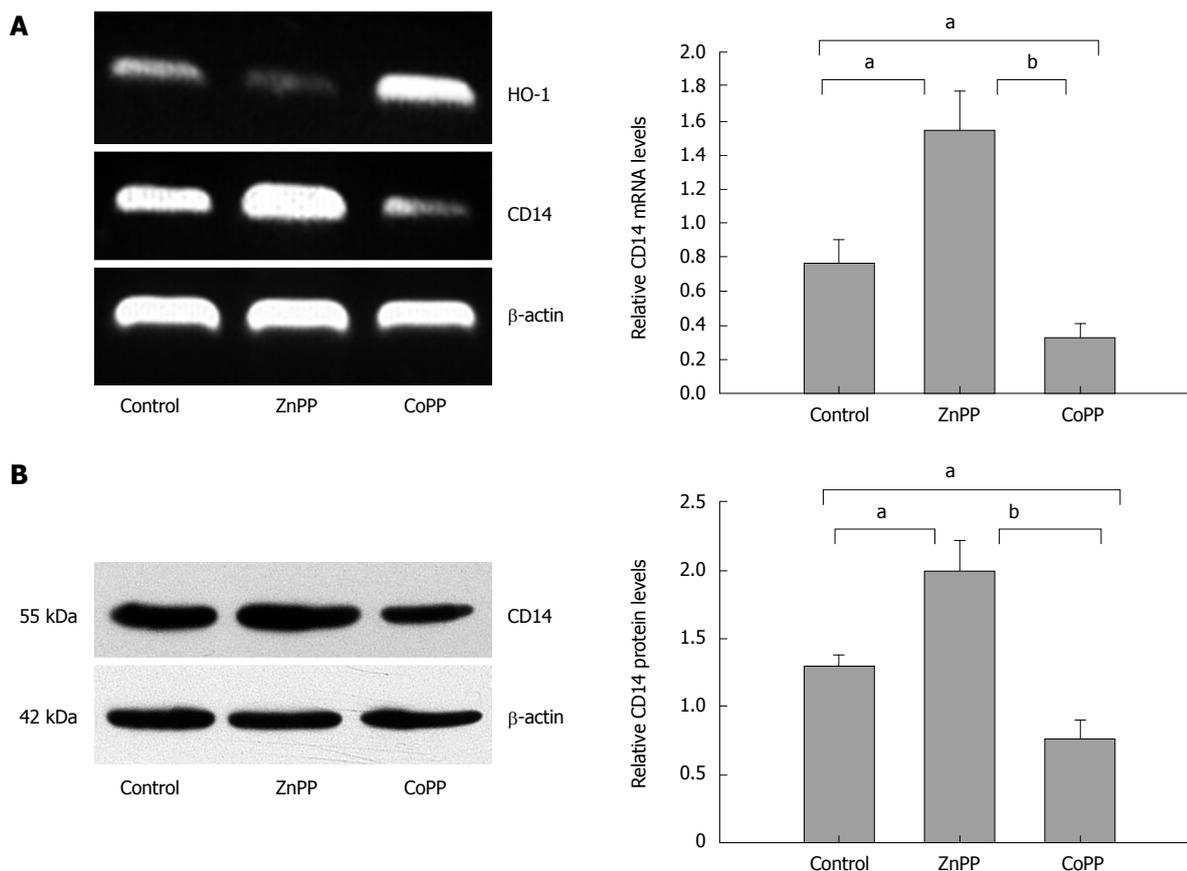

Figure 4 HO-1 and CD14 expression levels of cultured Kupffer cells. A: HO-1 mRNA expression levels of Kupffer cells were significantly downregulated in the ZnPP group and upregulated in the CoPP group. ZnPP treatment CD14 mRNA expression was expressed as relative increase compared with control. CoPP pretreated was lower ($n = 4/\text{group}$); B: Western blot analysis for CD14 protein of Kupffer cells. β -actin was used as internal control. CD14 protein expression levels increased in the ZnPP group and decreased in the CoPP group ($n = 4/\text{group}$). ^a $P < 0.05$, ^b $P < 0.01$.

of Kupffer cell activity can attenuate I/R injury in liver transplantation models.

In this study, we observed that donor pretreatment with CoPP significantly improved liver function, ameliorated hepatic injury and reduced plasma proinflammatory mediators. The elimination of oxidants from the cell is considered to be an important mechanism of HO-1-mediated protection against oxidative stress. Biliverdin (BV) and bilirubin (BR), which have been regarded as toxic metabolites of heme degradation, may serve as important mediators of nitrosative injury through a similar mechanism^[36]. BV and BR were shown to scavenge peroxynitrite. Superinduction of HO-1 leads to BR-mediated reductions in oxidative stress following I/R injury and provides cytoprotection in hepatocytes that are subjected to reperfusion injury^[14,18]. CO, another byproduct of HO-1, has been shown to modulate intrahepatic sinusoidal tone and improve microcirculation of the liver^[29]. Kupffer cells, liver resident macrophages, are the prime source of HO-1. We monitored the circulating levels of TNF- α and IL-6, both of which are proinflammatory cytokines mainly released by activated Kupffer cells. Kupffer cells overexpressing HO-1 exhibit low levels of cytokines in supernatant. In CoPP treatment, the activation of Kupffer cells was suppressed by lower TNF- α and IL-6 levels compared with ZnPP

treatment. In many models of liver injury elevated TNF- α levels are present and correlate with injury, and inhibition of TNF- α activity can decrease liver injury^[9]. As potent producers of inflammatory cytokines, Kupffer cells have been implicated in the pathway leading to liver injury^[37].

Interestingly, there was an association of Kupffer cell HO-1 levels with lower levels of CD14 mRNA and protein seen in the CoPP treatment group as compared with the ZnPP treatment group. Kupffer cells have relatively low baseline expression of CD14^[38]. Some studies showed that activation of Kupffer cells up-regulated expression of CD14 protein and its gene^[39-41]. Interpretations of studies in liver injury should take into account the relative contributions of Kupffer cells and hepatocyte CD14^[9]. Thus, increased baseline HO-1 levels as seen in CoPP treatment may represent a diminished ability to activate Kupffer cells. Kupffer cells are the major site of expression of hepatic HO-1. It is well known that liver I/R injury results in Kupffer cell activation and subsequent cytokines release, leading to localized hepatic damage. However, Devey *et al*^[42] reported that Kupffer cells depletion resulted in loss of HO-1 expression and increased susceptibility to hepatic I/R injury. Therefore, HO-1 expression levels of Kupffer cells are likely to play a crucial role in liver I/R injury.

In conclusion, CoPP-induced HO-1 overexpression

ameliorates liver I/R injury and suppresses cytokine release by inhibiting activation of Kupffer cells. Our data provides evidence for a novel mechanism of HO-1 dependent cytoprotection in liver I/R injury.

COMMENTS

Background

Orthotopic liver transplantation (OLT) is an effective treatment for end-stage liver diseases. However, ischemia/reperfusion (I/R) injury of the liver remains a major cause of graft injury, causing liver dysfunction and even failure posttransplantation. Overexpression of heme oxygenase (HO)-1 exerts a cytoprotective function in a number of I/R injury and liver transplant models. Studies of the mechanism by which HO-1 protects donor livers against I/R injury contribute to the development of liver transplantation.

Research frontiers

The mechanism of HO-1-mediated cytoprotection is complicated. Kupffer cells are critical to the onset of liver injury and following secretion, cytokines aggravate hepatocyte damage. HO-1 is principally distributed in Kupffer cells. Recently, it has been reported that Kupffer cells depletion resulted in loss of HO-1 expression and increased susceptibility to hepatic I/R injury.

Innovations and breakthroughs

Since the mechanism of HO-1-mediated cytoprotection against I/R injury in organ transplantation remains unclear, upregulation of HO-1 is known to be involved in regulation of inflammatory response, improvement of microvascular flow and antiapoptotic effects. Liver I/R injury can be attenuated by the suppression of Kupffer cells. This study is an attempt to evaluate whether activation of Kupffer cells is related to HO-1 expression levels.

Applications

HO-1 can inhibit Kupffer cell activation and reduce release of proinflammatory mediators. This study showed that HO-1 is an attractive target against I/R injury in liver transplantation.

Terminology

Kupffer cells are the resident macrophages of the liver and involved in I/R injury through the release of cytokines and other biologically active mediators. Modulation of Kupffer cells activity can attenuate I/R injury in liver transplantation models.

Peer review

The paper deals with the role of heme oxygenase-1 in connection with ischemia/reperfusion injury in liver. It is important to find methods to prevent or reduce the injury that may follow ischemia/reperfusion, and the results presented may be useful for further research in the field. All the different parts of the paper are concise and clear.

Abstract

Ectopic pancreas (EP) is the relatively uncommon presence of pancreatic tissue outside the normal location of the pancreas. This condition is usually asymptomatic and rarely complicated by pancreatitis and malignant transformation. A few cases of neoplastic phenomena that developed from EP into the duodenal wall are described in the literature. Herein we report a case of gastric outlet obstruction due to adenocarcinoma arising from EP of the duodenal wall. The patient underwent a Whipple's procedure and had an uneventful post-operative recovery. Traditional imaging studies are often inconclusive in the definitive diagnosis, whilst endoscopic ultrasonography and guided biopsy may aid accurate pre-operative diagnosis. Diagnostic uncertainty warrants surgical exploration and if necessary extended resection is indicated.

INTRODUCTION

The presence of ectopic pancreas (EP) is relatively uncommon and generally asymptomatic. EP is defined as pancreatic tissue abnormally situated, without connection to the normal pancreas but provided with its own vascular and ductal systems^[1]. Other terms such as heterotopic and aberrant pancreas have also been described in the literature. EP has been found in both abdominal and extra abdominal locations, but is most frequently encountered in the duodenum (25%-35%)^[2], stomach (25%-60%)^[3], and rarely in the mesocolon^[4,5] and Meckel diverticulum^[6]. The origin of EP is unknown, it is possible that during rotation of the foregut and fusion of the ventral and dorsal parts of the pancreas in early foetal life, small pieces of tissue become detached from the forming organ leading to entrapment in different locations^[7]. The following is a case of upper gastrointestinal obstruction caused by malignant transformation of ectopic pancreatic tissue located into the duodenal wall.

CASE REPORT

A 56-year-old man was admitted to the authors' institution with a one month history of recurrent vomiting after meals. The patient's medical history consisted of type 1 diabetes and polydistrectual vasculopathy with no previous surgical history. The physical examination on admission did not reveal palpable abdominal masses. The vital signs were normal. Serum tumour markers such as CA 19-9, CA 125, AFP (α fetoprotein), CEA (carcinoembryonic antigen) and amylase were all within the normal range as was the basic metabolic screen.

The patient underwent a sequence of radiologic investigations. A double contrast barium meal of the upper gastrointestinal tract demonstrated reduced gastric emptying together with a degree of gastric distension. Contrast-enhanced CT demonstrated significant gastric distension and increased wall thickness in the first portion of the duodenum. The radiologic appearance of the pancreas was normal (Figure 1). We actually perform EGD (esophagogastroduodenoscopy) before CT in case of upper gastrointestinal obstruction.

EGD was used to localize an area of narrowed lumen in the first portion of the duodenum. EUS (endoscopic ultrasonography) showed heterogeneous hypoechoic areas in the submucosal tissue in relation to the narrowed first part of the duodenum, where we performed multiple biopsies. Cytology of biopsy specimens revealed the presence of an adenocarcinoma of uncertain origin. A multi-disciplinary discussion led to surgical resection. The patient subsequently underwent a pancreaticoduodenectomy. A classic Whipple's operation was performed in the distal part of the stomach (antrectomy), the distal portion of the common bile duct (choledochectomy), head of the pancreas, and the entire duodenum and proximal jejunum were resected en-block along with the regional lymph nodes. Gastrointestinal reconstruction was performed with pancreaticogastrostomy, Roux en Y choledochojejunostomy and gastrojejunostomy. Two abdominal drains were inserted and short term antibiotics as well as thrombo-prophylaxis were given according to the institutional protocol.

Figure 2 demonstrates the resected specimen consisting of gastric antrum, duodenum, common bile duct and proximal pancreas. The margins of the resection were negative for tumour and there was no nodal involvement. The conclusive histological report showed an infiltration of the duodenum by adenocarcinoma arising from ductal structures of heterotopic islets of pancreatic tissue into the duodenal wall, and pT4 grading according to WHO G2 (Figure 3A). The neoplasm involved the duodenal serosa with focal invasion of the orthotopic pancreas. The uninvolved EP had a microscopic (Figure 3B) appearance consistent with Heinrich's Class 1, where the EP was characterized by cystically dilated ducts, islets and acini^[8]. The post-operative recovery was uneventful. A nasogastric tube was maintained in aspiration until the sixth post-operative day and total parenteral nutrition was continued for 10 d. Progressive oral feeding was introduced from the sixth post-operative day. Upon discharge the patient

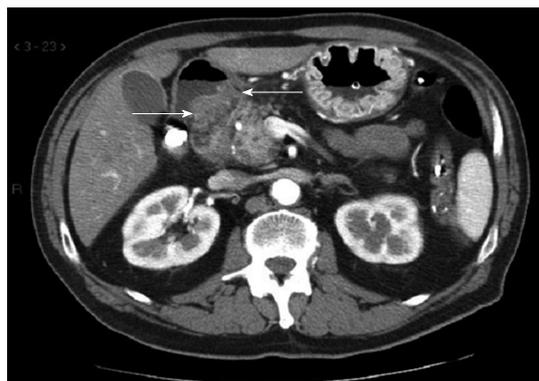

Figure 1 Contrast-enhanced CT of upper abdomen demonstrating a duodenal mass which narrowed the lumen (arrows).

was referred to the oncology department for adjuvant chemotherapy.

DISCUSSION

EP rarely gives rise to symptoms and its discovery is usually accidental^[5]. EP is found in about 1/500 laparotomies carried out for upper abdominal conditions and is reported in 0.6%-13% of post-mortem examinations^[7,9]. Macroscopically EP is often located in the submucosal layer, but may also be found in the muscularis mucosae, sub-serosa and serosa^[10]. According to Guillou *et al*^[11], to confirm the malignant transformation of EP, a series of criteria require to be fulfilled: (1) presence of a neoplasm located in/or in the proximity of the EP site; (2) concurrent presence and continuity of normal ectopic pancreatic tissue and adenocarcinoma; and (3) ectopic pancreatic tissue with normal histological structure. Our report met all the criteria. The simultaneous absence of primary neoplasm of orthotopic pancreas as well as the evidence of EP in the duodenal wall, along with other criteria aforementioned (Guillou *et al*^[11]) confirmed the malignant transformation of duodenal ectopic pancreas in the case described here.

The ectopic tissue may develop the same pathological changes that occur in a normal pancreas, such as cyst formation and acute pancreatitis. Malignant transformation has been rarely reported in the literature in cases of duodenal EP. Depending on anatomical location and pathology involved, EP may also give rise to symptoms such as abdominal pain, nausea, vomiting, gastric outlet obstruction, jaundice and gastrointestinal bleeding.

Pre-operative diagnosis of EP may be difficult with conventional imaging studies such as CT, radiographic contrast study and EGD. EUS is typically used to evaluate the submucosal lesions in the upper gastrointestinal tract^[12]. EUS can in fact determine the layer of origin of the intramural lesion, which is of high importance for the diagnosis^[13]. EP usually appears hypoechoic and heterogeneous with indistinct margins during EUS and most commonly originates from the third or fourth layer or a combination of these two layers of the gastrointestinal (GI) tract^[14]. EUS also allows the use of targeted fine needle aspiration biopsy (FNAB), particularly helpful for

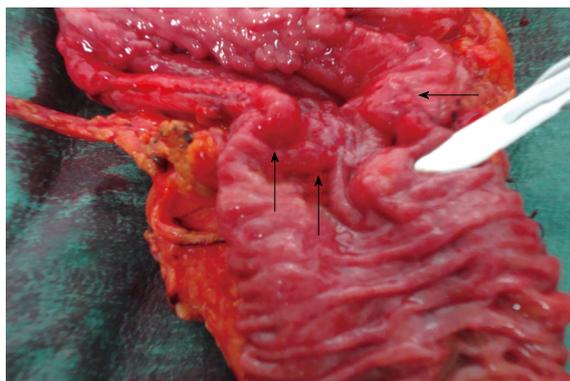

Figure 2 Duodenum. Arrows indicate the EP adenocarcinoma into the duodenal wall; the scalpel indicates the Ampulla of Vater.

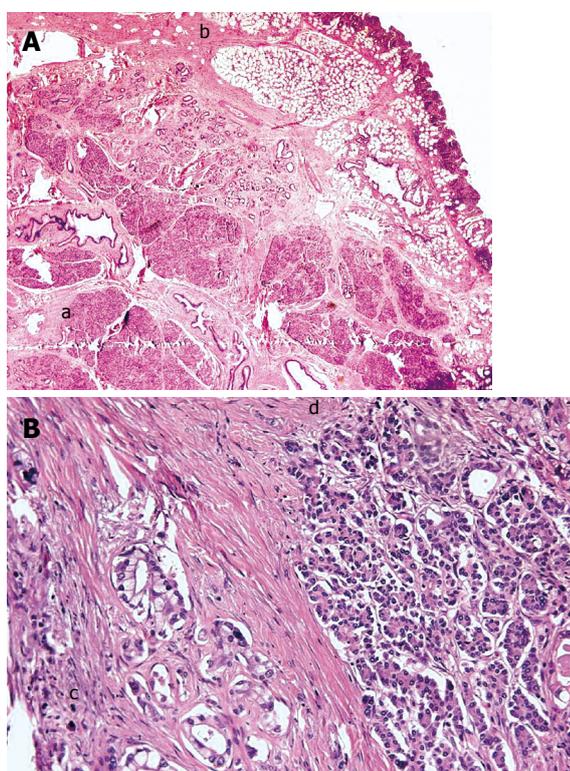

Figure 3 Histological findings. A: Duodenal wall (a) and ectopic pancreatic tissue (b) (HE, $\times 25$); B: Adenocarcinoma arising from ectopic pancreatic tissue (c) and ectopic pancreatic tissue (d) (HE, $\times 200$).

the final diagnosis. However, cytological examinations are inconclusive in about 50% of cases^[7].

Due to its relative rarity, there is no evidence in the scientific literature showing a greater tendency to develop neoplasms in EP as opposed to orthotopic pancreas. Most of the patients with EP are asymptomatic and require no treatment, but on discovery of EP as an accidental finding, its excision is recommended^[10]. In symptomatic EP or in the case of uncertain diagnosis, surgical resection may be both diagnostic and curative. Prognosis of adenocarcinoma arising from EP is not known. In the literature, only ten

cases have been reported with a survival time of between six months and ten years and all with a life expectancy longer than that in the case of orthotopic pancreas surgery^[9].

In summary, we report a rare case of malignant transformation of EP of the duodenal wall in a patient with gastric outlet obstruction. Routine imaging studies provided inconclusive information on the origin of the lesion, whilst EUS was an important adjunct in locating the lesion supplemented by fine needle aspiration cytology. Although rare, EP should be considered in the differential diagnosis of a submucosal mass of the duodenal wall.

Abstract

Infective colitis can be a cause of massive lower gastrointestinal bleeding requiring acute surgical intervention. Causative organisms include entamoeba and histoplasma species. However, concurrent colonic infection with both these organisms is very rare, and the *in vivo* consequences are not known. A 58-year-old male presented initially to the physicians with pyrexia of unknown origin and bloody diarrhea. Amoebic colitis was diagnosed based on biopsies, and he was treated with metronidazole. Five days later, the patient developed massive lower gastrointestinal bleeding with hemorrhagic shock. Emergency total colectomy with end-ileostomy was performed. However, he deteriorated and died on the second postoperative day. Histopathological examination revealed multiple deep ulcers at the hepatic flexure where fungal bodies of mycelial and yeast forms were noted. Isolated lymph nodes showed abscess formation with fungal bodies. Infective fungal

colitis with *Histoplasma capsilatum* was diagnosed. *In vitro*, amoebic parasites can increase virulence and pathogenicity of histoplasma which may account for the fulminant presentation in this patient. Although rare, this unusual dual infection should be considered in the differential diagnosis of infective colitis, as appropriate antimicrobial treatment may prevent progression to massive lower gastrointestinal bleeding, obviating the need for urgent surgical intervention.

Concurrent amoebic and histoplasma colitis: A rare cause of massive lower gastrointestinal bleeding. *World J Gastroenterol* 2010; 16(10): 1296-1298 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i10/1296.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i10.1296>

INTRODUCTION

Massive lower gastrointestinal bleeding can be fatal and emergency surgery may be required. There are various etiologies leading to such a presentation, with infective colitis being one of the causes. Causative organisms in infective colitis include entamoeba, a parasite, and histoplasma, a dimorphic fungus. Both these organisms can be virulent individually, where mortality is estimated to be 50% in fulminant amoebic colitis, and mortality rates of 20%-25% are estimated in gastrointestinal histoplasma

in those who are immunocompromised^[1,2]. However, concurrent infection with both these organisms is very rare. We present a case of amoebic and histoplasmic colitis causing fatal massive lower gastrointestinal bleeding.

CASE REPORT

A 58-year-old male presented initially to the physicians with pyrexia of unknown origin for a month prior to admission. There was associated bloody diarrhea with loss of appetite and weight. There was no history to suggest any respiratory or urinary tract infection and he denied any high risk behavior. There was also no alteration in bowel habit prior to these symptoms.

Blood investigations were unremarkable except for elevated white cell count, erythrocyte sedimentation rate and C-reactive protein levels. Cultures were negative and stools did not show evidence of ova and cysts.

Colonoscopy revealed mucosal inflammation along the rectum and sigmoid interspersed with normal colonic mucosa, with further inflammation and ulcers seen along the hepatic flexure (Figure 1). There was no active bleeding noted. Amoebic colitis was diagnosed based on biopsies from colonoscopy (Figure 2), and he was treated appropriately with metronidazole.

Five days later, the patient developed massive lower gastrointestinal bleeding with hemorrhagic shock. Resuscitation was commenced but he remained unstable and underwent emergency laparotomy. A total colectomy (Figure 3) with end-ileostomy was performed. Mesenteric lymphadenopathy was noted intra-operatively. His condition deteriorated postoperatively with subsequent disseminated intravascular coagulopathy. The patient died on the second postoperative day.

Histopathological examination revealed multiple deep ulcers into the muscularis propria at the hepatic flexure, where fungal bodies with mycelial and yeast formations were seen (Figure 4). Abscesses were also seen in the submucosal and serosal layers containing fungal bodies of yeast form. Isolated lymph nodes showed abscess formation with fungal bodies (yeast form). There was no evidence of malignancy or residual amoebic parasites. Infective fungal colitis with *Histoplasma capsulatum* was diagnosed.

DISCUSSION

Infective colitis can be severe and fatal. The spectrum of clinical presentation ranges from an asymptomatic state, a mild form with symptoms such as abdominal pain, fever or diarrhea, to a severe state which may result in gastrointestinal bleeding or colonic perforation^[3-5]. When presenting with massive gastrointestinal bleeding, surgery is warranted^[6].

Appropriate therapy with antimicrobials is vital in the treatment of infective colitis. Metronidazole had been shown to be effective in treatment of amoebic colitis^[4]. Despite a negative stool culture and examination as seen

Figure 1 Colonoscopic appearance of an ulcer at the hepatic flexure.

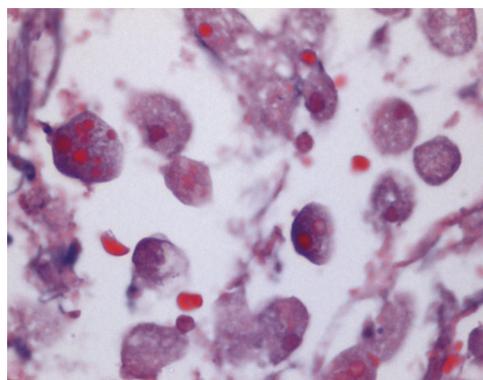

Figure 2 Colonoscopic biopsy showing amoeba (x 40).

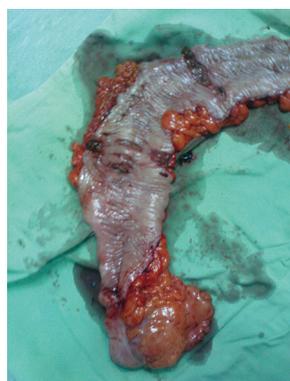

Figure 3 Gross appearance of ulcers in the colectomy specimen.

in our case, the endoscopic biopsy was positive, and this had been shown to be most effective in diagnosing amoebic infection^[7,8]. It is also interesting to note skip colonic ulcerative lesions were present on our endoscopic findings, which may suggest an inflammatory bowel disease. One tends to associate their appearance with Crohn's colitis but skip lesions in infective colitis does occur^[9,10].

Histoplasma infection is an endemic mycosis commonly found in North and Central America, and complete recovery has been well documented with the use of antifungal therapy such as amphotericin B or itraconazole^[11,12]. Isolated gastrointestinal histoplasmosis

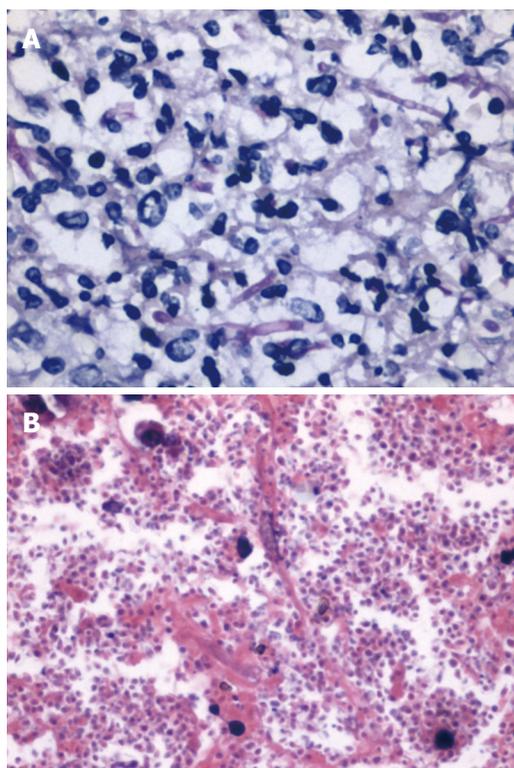

Figure 4 Histopathological examination. A: Mycelial formations (Periodic acid-Schiff, × 40); B: Yeast formations (HE, × 40).

is rare as it is usually asymptomatic with clinical manifestation occurring in less than 5% of the population, though it may be more common in those who are immunocompromised^[12-14].

In our case, concurrent histoplasmic infection was initially unsuspected, which may have caused progression to the severe end of the clinical spectrum. *In vitro* tests have shown that amoebic parasites may contribute to the virulence or pathogenic traits of histoplasma^[15].

Concurrent colonic infection with both amoeba and histoplasma has not been documented in the literature to our knowledge, although it has been reported in lung infections^[15]. The above case presents to us as a very rare form of colitis, which was eventually fatal.

In conclusion, massive lower gastrointestinal bleeding warrants urgent surgical intervention. Infective colitis,

especially with this unusual dual infection, as a cause of such a presentation is rare, but should be considered in the differential diagnosis.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systematically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Instructions to authors

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/1007-9327/Instructions-toAuthprs.asp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>; Writing requirements of abstract at: <http://www.wjgnet.com/1007-9327/links/Abstract.doc>.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the

main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A...; B...; C...; D...; E...; F...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used

abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr-A*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No. 62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: wjg@wjgnet.com

<http://www.wjgnet.com>

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/1007-9327/news/10.doc>.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/1007-9327/news/12.doc>.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

**EDITORIAL**

1299 Current role of hyperthermic intraperitoneal chemotherapy in the treatment of peritoneal carcinomatosis from colorectal cancer

Rampone B, Schiavone B, Martino A, Confuorto G

1303 Alcohol and liver, 2010

Osna NA

TOPIC HIGHLIGHT

1304 Alcohol, inflammation, and gut-liver-brain interactions in tissue damage and disease development

Wang HJ, Zakhari S, Jung MK

1314 Alcoholic pancreatitis: Lessons from the liver

Clemens DL, Mahan KJ

1321 Alcoholic liver disease and the gut-liver axis

Szabo G, Bala S

1330 Anti-inflammatory pathways and alcoholic liver disease: Role of an adiponectin/interleukin-10/heme oxygenase-1 pathway

Mandal P, Pritchard MT, Nagy LE

1337 Impact of alcohol on hepatitis C virus replication and interferon signaling

McCartney EM, Beard MR

1344 Alcohol, nutrition and liver cancer: Role of Toll-like receptor signaling

French SW, Oliva J, French BA, Li J, Bardag-Gorce F

1349 Effects of ethanol on the proteasome interacting proteins

Bardag-Gorce F

1358 Alcohol-induced alterations of the hepatocyte cytoskeleton

Shepard BD, Tuma PL

1366 Hepatoprotective effects of *S*-adenosyl-L-methionine against alcohol- and cytochrome P450 2E1-induced liver injury
Cederbaum AI

1377 Alcoholic liver injury: Influence of gender and hormones
Eagon PK

ORIGINAL ARTICLE

1385 Time-series gene expression profiles in AGS cells stimulated with *Helicobacter pylori*
You YH, Song YY, Meng FL, He LH, Zhang MJ, Yan XM, Zhang JZ

BRIEF ARTICLE

1397 Combined MELD and blood lipid level in evaluating the prognosis of decompensated cirrhosis
Jiang M, Liu F, Xiong WJ, Zhong L, Xu W, Xu F, Liu YB

1402 Effects on the pouch of different digestive tract reconstruction modes assessed by radionuclide scintigraphy
Li DS, Xu HM, Han CQ, Li YM

1409 Role of *BMP3* in progression of gastric carcinoma in Chinese people
Chen XR, Wang JW, Li X, Zhang H, Ye ZY

CASE REPORT

1414 Interferon- α induced severe thrombocytopenia: A case report and review of the literature
Li L, Han DK, Lu J

1418 A case of occult insulinoma localized by pancreatic dynamic enhanced spiral CT
Bao ZK, Huang XY, Zhao JG, Zheng Q, Wang XF, Wang HC

1422 Resection of a giant hepatocellular carcinoma weighing over ten kilograms
Ba MC, Cui SZ, Lin SQ, Tang YQ, Wu YB, Zhang XL

LETTERS TO THE EDITOR

1425 Liver transplantation for polycystic liver and massive hepatomegaly
Gruttadauria S, di Francesco F, Gridelli B

ACKNOWLEDGMENTS I Acknowledgments to reviewers of *World Journal of Gastroenterology*

APPENDIX I Meetings
I-IV Instructions to authors

AIM AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

FLYLEAF I-VII Editorial Board

EDITORS FOR THIS ISSUE

Responsible Assistant Editor: *Xiao-Fang Liu*
Responsible Electronic Editor: *Xiao-Mei Zheng*
Proofing Editor-in-Chief: *Lian-Sheng Ma*

Responsible Science Editor: *Jin-Lei Wang*
Proofing Editorial Office Director: *Jian-Xia Cheng*

NAME OF JOURNAL
World Journal of Gastroenterology

LAUNCH DATE
October 1, 1995

RESPONSIBLE INSTITUTION
Department of Science and Technology of Shanxi Province

SPONSOR
Taiyuan Research and Treatment Center for Digestive Diseases, 77 Shuangta Xijie, Taiyuan 030001, Shanxi Province, China

Abstract

Peritoneal carcinomatosis is one of the most common routes of dissemination of colorectal cancer (CRC). It is encountered in 7% of patients at primary surgery, while it develops in about 4% to 19% of patients after curative surgery and in up to 44% of patients with recurrent CRC. Peritoneal involvement from colorectal malignancies has been considered traditionally as a manifestation of terminal disease, due to limited response to conventional surgical and chemotherapeutic treatments. In the past few years the introduction of cytoreductive surgery combined with hyperthermic intraperitoneal chemoperfusion has shown promising results in selected patients. Currently, the surgical management of peritoneal surface malignancies of colonic origin with this combined locoregional therapy has resulted in a significant improvement in survival of these patients. However, further controlled studies will help to standardize indications and the technique of this locoregional therapy in order to achieve an improvement of morbidity and mortality rates.

INTRODUCTION

Colorectal cancer (CRC) is the second most common cause of cancer-related deaths in western countries. Despite the improvement in its prognosis, recurrence following resection of CRC remains a substantial problem.

Peritoneal carcinomatosis (PC) is one of the most common routes of dissemination of CRC. It is encountered in 7% of patients at primary surgery, while it develops in about 4% to 19% of patients after curative surgery and in up to 44% of patients with recurrent CRC^[1,2].

In the past, PC from colorectal malignancies has been considered as a manifestation of terminal disease, due to limited response to conventional surgical and chemotherapeutic treatments^[3,4].

Sugarbaker^[5], one of the pioneers of treatment of this disease, has suggested that PC is a locoregional cancer spread as a result of a molecular crosstalk between cancer cells and host elements.

For this reason the only chance to achieve long term

survival in these patients is the eradication of microscopic residual disease.

CYTOREDUCTIVE SURGERY AND HYPERTHERMIC INTRAPERITONEAL CHEMOTHERAPY

In 1980 Spratt *et al.*^[6], after an experimental study with hyperthermic peritoneal perfusion in dogs, were first to clinically test cytoreductive surgery followed by hyperthermic intraperitoneal chemoperfusion (HIPEC) with thiotepa in a case of pseudomyxoma peritonei.

Later Sugarbaker *et al.*^[7,8] introduced intraperitoneal chemotherapy as a new innovative therapeutic option for selected patients with PC.

This treatment is based on surgical cytoreduction and HIPEC. The underlying rationale of this combined approach is that on one hand an aggressive surgical approach combining visceral resection and peritonectomy procedures addresses the macroscopic disease, whereas HIPEC is aimed at residual microscopic disease^[9].

Drugs selected for intraperitoneal administration usually are hydrophilic and have large molecular size, so that they pass slowly through a peritoneal-plasma barrier and are therefore more effectively sequestered in the peritoneal cavity. Adding hyperthermia to intraperitoneal chemotherapy may increase the tumor response to cancer chemotherapy drugs by several mechanisms. Firstly, heat alone has a direct anti-tumor effect. Hyperthermia above 41°C induces selective cytotoxicity of malignant cells. Secondly, the cytotoxic effects of some chemotherapeutic agents (doxorubicin, platinum complexes, mitomycin C, melphalan, docetaxel, irinotecan and gemcitabine) are augmented by applying mild hyperthermia^[10].

This locoregional therapy provides an elevated and persistent drug concentration for the tumor, with a limited systemic concentration.

HIPEC with mitomycin C, cisplatin and doxorubicin or oxaliplatin has been used for gastrointestinal PC. Oxaliplatin has been used intraperitoneally in Europe for colorectal PC, as pioneered by Elias *et al.*^[11]. This drug has a very low area under the curve ratio, which means that oxaliplatin is rapidly absorbed and does not require a long dwell time in the peritoneal cavity for maximal local-regional effect^[11].

However, the extent of intraperitoneal chemotherapy penetration into tumor nodules by passive diffusion is limited to a few cell layers. For this reason Elias *et al.*^[11] first suggested that intraperitoneal oxaliplatin should be combined with intravenous 5-FU administered just before HIPEC (bidirectional intraoperative chemotherapy). By combining intraoperative intravenous and intraoperative intraperitoneal cancer chemotherapy a bidirectional diffusion gradient is created through the intermediate tissue layer which contains the cancer nodules. This offers opportunities for optimizing cancer chemotherapy delivery to the target peritoneal tumor nodules.

Nevertheless, further pharmacologic studies are needed to clarify the most efficient method of administration (continuous *vs* bolus *vs* repeated bolus), doses and choice of cancer chemotherapy drugs for this bidirectional approach.

RESULTS TO DATE IN TREATING COLORECTAL PC

Since the introduction of HIPEC, promising results have been reported by several groups in the treatment of PC^[12,13].

In all published series, the most important prognostic factors in predicting survival are the involvement of disease encountered at laparotomy (measured by peritoneal cancer index, PCI) and the completeness of resection^[2].

A retrospective analysis of prognostic factors in 71 patients treated by cytoreductive surgery plus HIPEC for PC from CRC reported a median survival of 41 mo in patients with a PCI < 20, while in cases with PCI > 20 the survival was 16 mo^[14].

When there is extension of disease to six or seven regions of abdomen patients have a poor prognosis, with a median survival of 5.4 mo *vs* 29 mo in patients with a lower number of regions affected^[14-16].

Glehen *et al.*^[17], in a study of 523 patients with PC from CRC, have reported a survival of 32.4 mo in patients who had a complete cytoreduction, compared with 8.4 mo in patients in whom a radical cytoreductive surgery was not possible.

The morbidity rates reported after HIPEC combined with cytoreductive surgery range from 20% to 50% and mortality rates from 1% to 10%^[18,19].

The main morbidities associated with this advanced treatment are caused by complications of surgery and hematological toxic effects. The most frequent surgical complications include anastomotic leakage, intestinal perforation, pancreatitis, prolonged ileus, bile leak, intra-abdominal bleeding/sepsis, wound dehiscence, pulmonary embolism and renal failure.

Intra-abdominal sepsis and enteric fistulas often necessitate re-operation. Most of these complications can be attributed to the extensive surgery performed, especially when the patient has had multiple previous operations. This procedure on average may take up to 10-12 h with a median blood loss of 3-5 L, and necessitates blood transfusion, complex anesthetic management, intensive unit care, and re-operation. To add to the complexity, Sugarbaker stresses that the dosing of intraperitoneal chemotherapy often needs to be modified to keep the morbidity and mortality for these patients at 30% and 2%, respectively. He suggests using a one-third dose reduction in patients who have had prior extensive surgeries, extensive cytoreductive surgery, if multiple anastomoses needed to be performed, those who have had prior chemotherapy or radiation therapy, and those who are older than 65 years^[20].

Results of multivariate analyses have shown that the independent factors affecting morbidity are duration of

surgery, extent of carcinomatosis, the number of anastomoses performed, and sex^[21,22].

The advanced stage of neoplastic disease and immunodeficient status of patients previously subjected to chemotherapy were found to be important factors that probably contributed to the occurrence of septic complications after an extended surgical procedure.

Furthermore, there are several technical and procedural nuances, which mandate that only those who have considerable experience should perform these procedures. Indeed, both the cytoreductive surgery and the administration of HIPEC are technically demanding procedures for which learning curves exist.

In a study of 70 patients treated with HIPEC combined with cytoreductive surgery, Yan *et al*^[23] have reported a mortality of 4%, a moderate morbidity in 44% of patients and that 20% displayed severe morbidity; these workers suggested that there is a learning curve associated with this advanced treatment in order to achieve an acceptable morbidity rate. Smeenk *et al*^[24] observed that the peak of the learning curve, graded by the percentage of complete cytoreductions, was reached after approximately 130 procedures. Therefore, such a complex, aggressive modality can be a considerable drain on the resources of an institution in order to provide benefit for a small group of patients.

Recently, Elias *et al*^[25] reported a multi-institutional retrospective analysis of cytoreductive surgery and HIPEC for patients with PC from CRC. This investigation involved treatment of 523 patients over a 17-year period with almost 30% ($n = 152$) from a single institution whereas, importantly, 18 centers recorded fewer than 20 cases each. The purpose of their study was to evaluate the short and long-term efficacy of this combined approach and determine prognostic factors affecting outcome. The overall mortality was 3.3%, with 31% grade 3 to 4 morbidity, and 30.1 mo median survival. The risk of postoperative morbidity and mortality was significantly influenced by two factors: the peritoneal index (reflecting the peritoneal metastatic burden) and the center in which the treatment was performed (inexperienced centers were those with < 7 years of practice). The center experience was an independent predictor for achieving the important goal of complete cytoreductive surgery^[25].

Currently patients with CRC who develop peritoneal recurrence might benefit from cytoreductive surgery and HIPEC even in the presence of resectable liver metastasis^[15,19,26-29]. Because this treatment has been shown to be most effective in patients with absent or minimal residual disease, there might be a role for preventive HIPEC in patients at high risk of peritoneal tumor spread. In a study of 29 patients with CRC at high risk of peritoneal recurrence, PC not detected by preoperative imaging was present in 16 patients. In these cases, HIPEC resulted in a disease-free status in half of the patients after a median follow up of 27 mo^[30,31].

CONCLUSION

The clinical outcome after a diagnosis of PC has radical-

ly changed during the last two decades due to combined locoregional treatment. At the moment, HIPEC provides a promising therapeutic option for patients with PC from CRC. Patients who have minimal residual disease as a result of cytoreductive surgery are candidates for HIPEC. This approach has become an important part of CRC treatment and should become a standard modality for prevention and treatment of cancer that involves the peritoneal surface. The national health care systems of the Netherlands and France have approved this approach for colon carcinomatosis. In other countries in Europe, approval is given on a case-by-case basis.

In order to achieve maximum benefit, correct selection of the patients approved for submission to this procedure, a radical cytoreduction and an adequate learning curve are necessary.

However, further controlled studies will help to standardize indications and the technique of this locoregional therapy in order to achieve an improvement of morbidity and mortality rates.

Abstract

Liver is known as an organ that is primarily affected by alcohol. Alcoholic liver disease (ALD) is the cause of an increased morbidity and mortality worldwide. Progression of ALD is driven by “second hits”. These second hits include the complex of nutritional, pharmacological, genetic and viral factors, which aggravate liver pathology. However, in addition to liver failure, ethanol causes damage to other organs and systems. These extrahepatic manifestations are regulated *via* the similar hepatitis mechanisms. In the Topic Highlight series, we provide an update of current knowledge in the field of ALD.

Osna NA. Alcohol and liver, 2010. *World J Gastroenterol* 2010; 16(11): 1303 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i11/1303.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i11.1303>

Our Topic Highlight: “Alcohol and liver” is annually published in *World Journal of Gastroenterology* and reviews the most important discoveries in the field of alcoholic liver disease (ALD). In the current third edition of “Alcohol

and liver”, we focus on the ethanol-induced cross-talk between the liver and other alcohol-affected organs, such as gut, brain and pancreas^[1-3]. Also, signal transduction aspects of ALD include the role of an adiponectin/interleukin-10/heme oxygenase-1 pathway^[4], the impact of alcohol on hepatitis C virus replication and interferon signaling^[5] and the role of Toll-like receptor signaling^[6]. In addition, certain reviews published in this issue shed light on molecular mechanisms of liver cell damage, as well as other aspects of ALD pathogenesis, such as the effects of ethanol on proteasome-interacting proteins^[7], alterations of hepatocyte cytoskeleton^[8], hepatoprotective effect of S-adenosyl-L-methionine against alcohol in CYP2E1-dependent liver injury^[9] and gender/hormonal differences in ALD development^[10]. We believe that this issue will be of strong interest not only for gastroenterologists, but also for those involved in alcohol, liver and brain research.

Abstract

Chronic inflammation is often associated with alcohol-related medical conditions. The key inducer of such inflammation, and also the best understood, is gut microflora-derived lipopolysaccharide (LPS). Alcohol can significantly increase the translocation of LPS from the gut. In healthy individuals, the adverse effects of LPS are kept in check by the actions and interactions of multiple organs. The liver plays a central role in detoxifying LPS and producing a balanced cytokine milieu. The central nervous system contributes to anti-inflammatory regulation through neuro-immunoendocrine actions. Chronic alcohol use impairs not only gut and liver functions, but also multi-organ interactions, leading to persistent systemic inflammation and ultimately, to organ damage. The study of these interactions may provide potential new targets for therapeutic intervention.

Key words: Chronic alcohol use; Chronic inflammation; Lipopolysaccharides; Pro-inflammatory and anti-inflamma-

INTRODUCTION

Chronic inflammation is commonly associated with alcohol-related medical conditions. Accumulating evidence suggests that it acts as an etiological factor in the initiation and progression of many of these conditions. A significant number of illnesses of individuals with alcoholic liver diseases can be explained readily by a high level of circulating pro-inflammatory cytokines^[1]. Humans with variants of pro- and anti-inflammatory cytokine genes show increased susceptibility to alcoholic liver disease^[2]. Alcohol-mediated activation of inflammation signaling pathways can increase tumorigenesis in mice^[3]. An alcohol-induced increase of tumor necrosis factor (TNF) α , a pro-inflammatory cytokine, in the mouse brain is closely linked to neurodegeneration^[4]. In addition, mice in which the receptor gene for TNF α has been knocked out are resistant to alcohol-induced liver injury^[5].

There are two broad sources of alcohol related inflammation inducers: those derived from alcohol damaged cells and those derived from gut microflora, specifically, lipopolysaccharide (LPS). Alcohol metabolism

directly leads to the production of reactive oxygen species, known for their ability to stimulate activation of a key inflammation transcription factor nuclear factor- κ B (NF- κ B)^[6]. Hypoxia, resulting from alcohol metabolism, is also known to induce the inflammatory response^[7]. On the whole, information on such inflammation inducers and their contribution to alcohol related inflammatory conditions is still limited.

In comparison, LPS derived from gut microflora has been extensively studied as a key inducer of inflammation in alcohol-related conditions. Alcohol stimulates LPS translocation across the gut *via* a number of mechanisms, and alcoholics with liver diseases are known to have significantly elevated circulating LPS^[8]. LPS is a major cell wall component of all Gram-negative bacteria and can mimic bacterial infection in causing an acute inflammatory response. Humans have evolved complex and coordinated defenses against LPS and its adverse effect, in which the gut, the liver, the brain, as well as innate immune cells within these organs, play crucial roles. Effects of LPS in combination with alcohol on individual organs have been reviewed extensively in the past, but less attention has been given to the communication and cooperation among these organs and their actions against LPS. In this review, our goals are to capture the latest understanding of (1) the effect of alcohol on LPS translocation and dissemination; (2) the actions of the liver and brain to manage the adverse effect of LPS; and (3) the impairment by alcohol use to the integrated host control of inflammation. We hope that such an approach will lead to a better understanding of the pathogenesis of alcohol-related tissue damage and disease.

INFLAMMATORY RESPONSE

Inflammation, mediated largely by the innate immune system, is the physiological response triggered by “danger” signals derived from tissue injury or infection^[9,10]. In response to such signals, innate immune cells, such as macrophages, release pro-inflammatory cytokines and chemokines that stimulate neutrophil recruitment to the site of injury and increase vascular permeability to fluid and plasma proteins. Neutrophils, in turn, release reactive oxygen species and anti-microbial peptides and phagocytose dead and foreign material. The plasma proteins contribute proteases and opsonins to combat infection. The liver is an important innate immune organ that plays a major role in the inflammatory response by producing acute phase reactants, including C-reactive protein, mannose binding protein, complement factors, ferritin, serum amyloid A and P, and surfactant proteins^[11,12]. All acute inflammation facets work together to eliminate the insult, prevent further damage, and promote tissue repair.

An inflammatory response is triggered by the binding of a microbial product or an endogenous product of tissue damage to pattern recognition receptors (PRRs) including toll-like receptors (TLRs). Upon ligand binding, PRRs activate intracellular signaling that ultimately leads

to the expression of genes encoding pro-inflammatory cytokines and other effectors that promote, sustain and amplify the inflammatory response. However, inflammation is a double-edged sword, equipped to destroy invading pathogens, but also equally capable of damaging healthy tissue. Thus, the process also includes the synthesis of anti-inflammatory effectors to regulate the extent and duration of the inflammatory response. Neuroimmunoendocrine mechanisms coordinated in the central nervous system (CNS) also contribute to anti-inflammatory regulation. In contrast to acute inflammation, chronic inflammation in alcoholic liver disease is characterized by persistent expression of pro-inflammatory cytokines and persistent recruitment of monocytes and neutrophils^[13,14]. These cytokines and immune effector cells maintain the damaging oxidative state, leading to sustained damage to host tissue.

INTERACTIONS OF GUT, LIVER AND BRAIN IN INFLAMMATION, AND ALCOHOL'S ROLE IN ORGAN DAMAGE

Translocation of gut microbial products

Gut microflora and translocation of microbial products: The human gastrointestinal tract is home to approximately 10^{14} microorganisms, consisting mostly of commensals. Besides providing the host nutritional and energy needs and shaping host mucosal and systemic immunity, the gut microflora are increasingly recognized as an important pathogenic factor in chronic inflammation-related diseases^[15-18]. These physiological and pathological roles of gut microflora are mediated by two interactions: (1) inside the lumen of the gastrointestinal (GI) tract between microflora, or their products, and different types of host cells at the surface of the intestinal epithelium; and (2) outside the GI tract between microbial products that have translocated across the intestinal epithelial barrier and the host cells in the circulation or in different organs.

A causal role for a bacterial factor in human diseases in the absence of bacterial infection was first demonstrated in animal models of severe hemorrhagic shock-associated mortality and dietary hepatic injury^[19,20]. In both cases, there was no apparent bacterial infection and sterilization of gut microflora with oral administration of non-absorbable antibiotics significantly improved the clinical outcomes. In addition, germfree animals were resistant to diet induced liver injury^[21]. Search for a causative factor led to the findings that the diseased animals had increased circulating LPS or endotoxemia^[22]. Oral administration of LPS resensitized the antibiotic treated animals to diet-induced liver injury^[23]. Later studies showed that in healthy individuals LPS is readily detectable in the portal blood that flows from the GI tract to the liver^[24]. More recently, evidence has emerged for translocation of microbial products and their potential pathogenic role in a variety of chronic diseases including chronic heart failure, spondyloarthritis, chronic fatigue syndrome, HIV/AIDS and AIDS-associated dementia,

chronic hepatitis C, non-alcoholic steatohepatitis (as part of metabolic syndrome), and alcoholic liver disease^[25-33].

Translocation of LPS across the gut epithelial barrier has been frequently ascribed to simple diffusion across epithelial cell membranes or leaking through tight junctions between adjacent cells^[34]. Consistently, factors that reduce membrane permeability to various molecules and improve the function of tight junctions appear to reduce LPS translocation^[35,36]. Tomita *et al.*^[37] have shown that a majority of LPS transport across colonic epithelial cells uses a receptor-mediated endocytosis system involving LPS binding proteins, CD14 and TLR4. A recent study demonstrated that LPS can also be translocated across the gut epithelium by its association with chylomicrons formed on the surface of the epithelium as a vehicle for fatty acid transport^[38]. Whether these two mechanisms, receptor-mediated endocytosis and chylomicron association, represent most, if not all, of *in vivo* LPS transport across gut epithelial cell membranes is not yet known.

Enhancement of LPS translocation by alcohol: It has been well established in humans that heavy alcohol consumption is associated with an increase in gut permeability and LPS leakage, with or without liver disease. Abstinence for 2 wk or longer is necessary for increased gut permeability to return to a baseline level^[39]. Acute heavy alcohol consumption is associated with a transient appearance of LPS in the circulation in normal human subjects^[40]. Individuals with alcoholic fatty liver but not severe liver disease also show an elevated LPS level in plasma^[8]. Studies of animal models show that acute alcohol feeding in mice increases LPS in plasma approximately five-fold within 30-90 min^[41,42]. Daily binge feeding of alcohol in rats for 4 wk increases the plasma LPS level approximately 15-fold compared to control animals^[43].

Alcohol may increase LPS leakage from the gut by a variety of mechanisms. Recent studies have demonstrated that alcohol and/or acetaldehyde can directly alter gut permeability and leakiness by induction of inducible nitric oxide synthase (iNOS) and NF- κ B signaling, which, in turn, modulates a differential expression of tight junction proteins that involves the action of miRNA-122^[44-46]. In addition, chronic alcohol use can cause barrier structure defects^[42,47]. In addition, alcohol can also alter gut integrity and permeability indirectly. First, the Zn²⁺ deficiency that is common in alcoholics also adversely affects gut epithelial integrity^[48,49]. Second, in patients with alcoholic liver disease, increased circulating inflammatory cytokines and LPS may promote further increases in gut leakiness^[50,51]. Third, alcohol use also alters the mucosal immune system, which, in turn, could have an adverse effect on the structure or function of the gut barrier. For example, alcohol feeding in Rhesus Macaques alters the number of CD4+ and the ratio of CD4+/CD8+ cells in the mucosal immune compartment^[52]. Whether these changes affect gut barrier structure and function is yet to be explored. Finally, alcohol might also affect gut permeability *via* its stimulatory effect on neuroendocrine hor-

mones, known to regulate gut permeability. Locally released corticotropin-releasing hormone can stimulate the degranulation of mast cells in the GI tract thus releasing mediators for “enhanced” gut permeability^[53].

In addition to the adverse effect on gut barrier structure and permeability, chronic alcohol exposure also alters microflora content and composition. Alcoholics have an overgrowth of microflora compared to non-alcoholic individuals^[54,55]. Such overgrowth includes LPS-producing Gram-negative bacteria and is expected to increase microbial products in the gut and thus promote their translocation. Chronic alcohol consumption also alters the composition of the microflora^[54,56,57]. Consistent with these findings, probiotic or synbiotic treatments in alcoholic patients and animals with alcoholic liver disease restore gut permeability and reduce tissue injury^[56,58-60].

Routes of LPS dissemination and their distinct responses:

After passing through the gut epithelium, LPS in the interstitial fluid can enter the systemic circulation by two routes: the portal vein and the GI tract lymphatic vessels^[61]. By the lymphatic route, lymph fluid from the GI tract moves through the ascending lymphatic vessel and the mesenteric lymph node and eventually releases LPS into the blood stream at the thoracic duct opening. By the portal vein route, LPS in the portal blood is delivered directly into the liver, where only a minor fraction that is not detoxified or excreted enters the systemic circulation *via* the hepatic central vein. In rats, under normal conditions, a vast majority of LPS absorbed from the GI tract is delivered to the liver *via* portal blood^[62], possibly due to a faster flow rate of portal blood compared to that of lymph.

A recent study revealed, surprisingly, that dietary fatty acids can drive LPS dissemination *via* the lymphatic route^[38]. Significant increases of lymphatic LPS dissemination have also been observed in experimental peritonitis and intestinal ischemic injury caused by hemorrhage or burn^[62-64]. Although experimental data are lacking, increased portal hypertension and intestinal interstitial fluid volume associated with liver disease would be expected to drive more LPS into the lymphatics. Whether alcohol affects the routes of dissemination remains to be explored.

The lymphatic LPS dissemination, rather than the portal vein, plays a dominant role in determining the level of LPS in systemic circulation^[61,62]. Upon entering the liver from the portal route most LPS is detoxified and only that escaping the process can enter circulation. However, the lymphatic route, with no significant detoxification organ in transit, will release most of the bioactive LPS into the circulation and thus make it available to different organs. Consequently, LPS released from the lymphatics is responsible for most of the LPS-induced inflammatory injury in many organs. Indeed, preference of the lymphatic LPS transport in the case of experimental peritonitis is associated with lung injury^[65]. Interestingly, acute alcohol feeding causes a rapid rise of circulating LPS in healthy animals^[41,42], implicating the involvement of the lymphatic route in alcohol use.

The most important host cell types that bind LPS and produce a large amount of inflammatory mediators are macrophages and monocytes. The liver contains the largest pool of tissue macrophages, Kupffer cells (KCs), whereas the spleen contains the largest reserve of monocytes^[66]. In response to LPS, KCs produce a significant amount of both pro- and anti-inflammatory cytokines, whereas monocytes produce predominantly pro-inflammatory cytokines (see below). Therefore, the route of LPS dissemination will also influence the types of inflammatory mediators released into circulation, which would, in turn, affect the inflammatory state in an individual.

Liver plays a key role in controlling the impact of microbial products and bears its burden during pathogenesis

Dampening the inflammatory response by detoxification and induction of anti-inflammatory cytokines:

Both clinical observation and experimental research suggest that the liver plays a critical role in LPS clearance and inactivation. Two of the best known mechanisms for dampening LPS-induced inflammation are: (1) the liver's ability to detoxify (by both Kupffer cells and hepatocytes) and excrete (by hepatocytes) LPS; and (2) the Kupffer cell's ability to generate a large amount of the anti-inflammatory cytokine, interleukin (IL)-10.

This role of liver in LPS detoxification (clearance and inactivation) has been best demonstrated by tracking the fate of labeled LPS introduced by i.v. injection. Most LPS is rapidly concentrated in the liver and either degraded in hepatocytes or excreted into the gut *via* the bile duct^[67-69]. In a healthy liver, LPS rapidly loses its biological activity^[22], and its uptake by the spleen increases when liver is diseased^[69]. Thus, the liver plays a primary role in protecting cells from exposure to microbial products.

IL-10 is a major anti-inflammatory cytokine. Like TNF α , it is produced mainly by KCs in response to LPS. IL-10 has a pleiotropic inhibitory effect on innate and adaptive immune responses. In KCs and macrophages, IL-10 strongly inhibits LPS-induced production of cytokines, including TNF α , IL-1, IL6, and IL-10 itself^[70,71]. IL-10 also inhibits the differentiation and maturation of pro-inflammatory Th1 T cells of the adaptive immune system^[72,73].

Significantly, KCs are responsible for producing most infection- or LPS-induced IL-10 in circulation^[74,75]. Two recent studies reveal that cell-cell interactions in the liver play an important role in KC's ability to make IL-10. A liver endothelial cell-derived factor, hepatocyte growth factor (HGF), enhances the expression of the heme oxygenase-1 (HO-1) gene, which, in turn, stimulates IL-10 production in the KCs^[76]. A study in a hepatocyte-monocyte coculture model also showed that LPS-TLR4 signaling in hepatocytes stimulates IL-10 production in monocytes and likely in KCs^[77].

When liver function is compromised, more microbial products enter and/or stay in circulation^[78]. LPS can ac-

cumulate in other organs, especially the spleen^[79]. Consequently, the inflammatory response to the microbial products becomes amplified and prolonged. The impact of such circulating LPS on many organs might be significant, especially on the brain, and might exacerbate disease conditions in these organs.

Interconnections among microbial products, liver innate immune function, injury, and repair:

Gut microflora and its products also play an important role in shaping hepatic innate immunity. Livers from germ-free animals have a significantly lower number of KCs, which also show reduced activity in response to LPS^[80]. Translocation of microbial products including LPS from the gut is thus necessary for the host to maintain a sufficient number of KCs in the liver *via* proliferation or recruitment, and to stimulate and sustain (by priming) the maturation of these cells. Although additional definitive studies are needed, such primed KCs could play a number of important roles in the liver's innate immune defense. First, by phagocytosis and by producing immune mediators, primed KCs are effectors for immune attack against infection in the liver and for clearing microbial products, damaged tissue and debris. In addition, such primed KCs are responsible for initiating the acute phase response (APR), another important innate immune function of liver, in which hepatocytes synthesize many accessory factors involved in combating infection by phagocytosis, leukocytosis and leukocyte infiltration^[81]. Finally, primed KCs are likely to be competent in producing IL-10 to protect the host against an overzealous inflammatory response.

By playing a central role in detoxifying microbial products and supplying mediators for immune defense, the liver also uniquely subjects itself to non-specific inflammatory damage. The pro-inflammatory cytokines TNF α , IL-1, and IL-6, produced by KCs in response to LPS and endogenous inflammatory inducers (e.g. from apoptotic cells), are critical for inducing secondary cytokines and chemokines, and the acute phase proteins, which, in turn, play roles in other vascular events associated with inflammation, including infiltration of neutrophils. Neutrophils are cytotoxic due to the release of superoxides (*via* the respiratory burst) and proteolytic enzymes that can cause cell injury. Activation of the liver APR and chemokine production, for example, due to injury in the brain, can cause liver injury^[82]. The same cytokines also play important roles in liver tissue regeneration and repair^[83]. Therefore, it is important to identify and recognize those conditions under which this balance of injury and regeneration is disrupted and a pathological course ensues.

Alcohol's synergistic interaction with LPS in amplifying liver and systemic inflammatory conditions:

The liver is the first internal organ after the GI tract to be exposed to alcohol and the principal organ for its metabolism. Simultaneously, the liver is exposed to increased alcohol concentrations and LPS translocated

from the gut microflora. Alcohol and its metabolism can modulate the cellular response to LPS in the liver and independently generate endogenous inflammatory inducers. Thus, both alcohol and LPS act simultaneously to influence the inflammatory response in the liver and other organs.

There are four broad mechanisms by which alcohol can modulate inflammatory conditions in the liver and circulation. First, chronic alcohol exposure can amplify inflammation in the liver *via* a short term sensitizing/priming of KCs. For example, daily alcohol feeding for up to 8 wk sensitizes KCs in their response to LPS. KC sensitization depends on the increased LPS translocation by alcohol feeding^[84]. The sensitized KCs produce an increased amount of the pro-inflammatory cytokine TNF α that contributes to liver inflammation and injury^[5]. Consistent with these observations, depletion of KCs can prevent early liver injury associated with alcohol exposure^[85].

Second, long term alcohol exposure impairs the liver's ability to produce pro-inflammatory, and more significantly, anti-inflammatory cytokines. Circulating monocytes in alcoholics show reduced IL-10 production in response to LPS^[86,87]. Similarly, production of plasma IL-10 in mice is depressed after 7 wk of alcohol exposure^[88]. Although it remains to be confirmed in this setting, KC dysfunction may be responsible for the reduced plasma IL-10 because depletion of them abolishes circulating IL-10^[83]. The reduced IL-10 production in alcoholics coincides with an increased production of plasma TNF α by circulating monocytes^[89]. In supporting the anti-inflammatory function of IL-10, knockout of IL-10 and macrophage/neutrophil specific knockout of STAT3, a key IL-10 downstream target, drastically increased alcohol-induced liver inflammation in mice^[90] (Bin Gao, personal communication). In addition, reduced circulating IL-10, in combination with increased IL-6, might also play a direct role in the appearance of pro-inflammatory Th17 cells in circulation and in the liver^[91]. Thus, chronic alcohol exposure creates an imbalance in the cytokine milieu favoring systemic inflammatory conditions that can cause cell injury in various tissues.

Third, chronic alcohol consumption can independently stimulate inflammation *via* the formation of endogenous inflammation inducers: (1) Alcohol metabolism generates highly reactive byproducts, including reactive oxygen species and acetaldehyde^[92,93]. These reactive byproducts modify proteins and lipids to form adducts that are processed as foreign antigens by the host immune system. Antibodies and lymphocytes against these products are commonly found in patients with alcoholic liver diseases^[94,95]. A recent study has shown that alcoholics with liver disease have increased levels of the pro-inflammatory T-cell, Th17, both in circulation and in the liver^[91], which might be related to a cytokine imbalance caused by chronic alcohol, as in the case of IL-10 knockout mice^[96]; (2) Alcohol metabolism can promote necrosis or apoptosis of hepatocytes that can independently induce inflammation. Alcohol metabolism, especially

by pericentral hepatocytes, can lead to mitochondrial damage and hypoxia, events that cause cells to undergo necrosis and apoptosis^[97-99]. Intracellular components derived from these dead cells can also act as endogenous "danger signals" to activate the inflammatory response^[9]; and (3) Alcohol metabolism also leads to dysregulation of fatty acid metabolism, which invariably contributes to the accumulation of fatty acids in hepatocytes. Fat accumulation in cultured cells can induce the synthesis of IL-8, a pro-inflammatory chemokine important for neutrophil recruitment^[100]. Though the relative contribution to systemic inflammation remains unknown, the above alcohol-involved mechanisms are expected to significantly affect the inflammatory state within the liver.

Finally, chronic alcohol use impairs the liver's ability to detoxify LPS and other microbial products. Circulating LPS increases significantly even in those alcoholics with no clinical liver disease other than fatty liver^[8]. Thus, it is likely that fat accumulation in hepatocytes can significantly reduce their ability to detoxify LPS. Other alcohol-induced effects, such as reactive oxygen species formation, decrease in antioxidants, hypoxia, reduction of ATP production, and mitochondrial defects can cause cell injury or death. Such liver damage is expected to further diminish the liver's ability to detoxify LPS. Consequently, more LPS will escape from the liver and stay in the circulation, which in turn increases systemic inflammatory conditions and injury among different organs. This conclusion is supported by the observations that in alcoholic hepatitis patients there is a significant increase of multi-organ failure^[101]. Interestingly, the rise of circulating LPS and increased production of pro-inflammatory cytokines also raises the possibility that circulating LPS (monocyte response), not liver LPS (KC response), plays a more important role in liver and other organ injury^[87,101,102].

Brain participates in the regulation of peripheral inflammation and also bears its burden

Inflammation induces brain damage: Any event leading to an increased pro-inflammatory cytokine presence in the brain creates the potential for oxidative conditions, which can result in neuronal damage. In cases of CNS trauma or infection, further escalation of the cytotoxic conditions occurs when leukocytes infiltrate the brain. While necessary to stem the infection, leukocytes in the brain are also believed to contribute to neurodegeneration in CNS disorders such as Alzheimer's disease and multiple sclerosis. Surprisingly, even when the injury initiating event is CNS inflammation, chemokines originating in the liver are responsible for mobilizing neutrophils from the bone marrow into circulation, making them available for infiltration into the brain. Although the mechanism by which CNS inflammation is signaled to the liver has not been determined, there is evidence that liver KCs are the source of the chemokines that mobilize the neutrophils^[103,104].

Peripheral LPS injection, as a model of bacterial infection in rodents, leads to elevation of the pro-inflammatory

cytokine TNF α in the serum and the CNS, even though LPS does not cross the blood brain barrier. Remarkably, TNF α remains elevated in the brain for months after exposure to LPS, thus exerting a prolonged detrimental effect on the brain^[105].

The central pro-inflammatory cytokines induced by peripherally-injected LPS, in particular IL-6, inhibit neurogenesis in the hippocampus through blockade of the differentiation of neural progenitor cells into neurons^[106]. The TLR signaling pathway can also be activated by currently unidentified endogenous ligands and is believed to contribute to inflammation-mediated cell damage in neurodegenerative disorders such as Alzheimer's disease^[107-109].

Alcohol-related inflammation causes brain damage:

Even in the absence of specific neurological or hepatic complications, excessive drinking can lead to regional structural brain damage and cognitive dysfunction^[110], neuronal death and inhibition of neurogenesis^[111], resulting in a reduction in brain volume, including white matter^[112].

Similar to the CNS response to peripheral LPS, TNF α , and the pro-inflammatory chemokine MCP-1 are induced in the brains of mice treated intragastrically with alcohol^[4]. Separately, it has been proposed that alcohol causes neurodegeneration by reducing the activity of the pro-neuronal survival transcription factor CREB and by activating the inflammation-promoting transcription factor NF- κ B^[111]. Alcohol can also inhibit neuronal differentiation by disrupting activity-dependent neuroprotective protein signaling^[113].

Neuroimmune sensing and regulation of peripheral inflammation:

The brain plays a vital role in coordinating defense against systemic infection or injury and in restoring homeostasis to safeguard the integrity of the entire organism. Physiologically important CNS responses include fever, hyperalgesia, and other sickness behaviors, as well as activation of homeostatic stress responses [the hypothalamo-pituitary-adrenal (HPA) axis and the sympathetic nervous system (SNS)]. The presence of systemic infection or injury is rapidly signaled to the brain, both by neural routes and by circulating pro-inflammatory cytokines^[114].

The very early effectors of the immune response also communicate to the CNS that homeostasis has been threatened. The CNS, in turn, responds by activating the HPA axis and the SNS, the actions of which are largely anti-inflammatory, to keep inflammation in check. The anti-inflammatory signals of the HPA and SNS supplement intrinsic immune anti-inflammatory mechanisms to restrict the extent and duration of inflammation.

Signals reaching the paraventricular nucleus of the hypothalamus lead to the activation of the HPA axis, resulting in the synthesis of corticotropin releasing hormone by the hypothalamus, which in turn activates the pituitary gland to produce adrenocorticotrophic hormone, which subsequently induces synthesis and release of the

glucocorticoid cortisol from the adrenal cortex. Glucocorticoids inhibit the production of pro-inflammatory cytokines and promote the release of anti-inflammatory cytokines including IL-10 following binding to glucocorticoid receptors on leukocytes^[115-119].

In parallel, the SNS is also activated by peripheral inflammation. SNS activation leads to peripheral release of epinephrine and norepinephrine, which also have anti-inflammatory effects at the systemic level. These catecholamines act through specific receptors expressed on innate immune cells to suppress the pro-inflammatory response and promote anti-inflammatory cytokine synthesis^[120]. Thus, the glucocorticoids and neuroendocrine catecholamines produced by the HPA axis and SNS response work in concert with the anti-inflammatory cytokines produced by immune cells to contain inflammation. Since an unchecked pro-inflammatory response will damage healthy tissue due to the highly oxidative and cytotoxic milieu, the counter-regulatory mechanisms are essential to maintain tissue integrity.

Alcohol interferes with neuroimmune response and regulation:

Alcohol ingestion is recognized as a stressful event by the HPA axis; a single dose of alcohol resulting in a blood alcohol level of 100 mg percent activates the HPA axis, leading to elevated cortisol levels^[121]. Chronic exposure to alcohol increases the tolerance of the HPA axis to alcohol, such that serum cortisol after alcohol consumption is lower than in non-alcohol-dependent controls^[121]. In addition, chronic alcohol also leads to a blunting of the HPA axis in response to external stressors other than alcohol. Tolerance to alcohol by the neuroendocrine system seems to begin to develop prior to full blown alcohol dependence and may correlate with the amount of alcohol consumed^[122]. In addition, alcohol-induced complications can uncouple the HPA axis and the SNS responses to stress. Patients with alcoholic cirrhosis have increased basal sympathetic tone, as measured by neuropeptide Y production, compared to healthy controls while displaying reduced serum cortisol levels compared to controls^[123]. The absence of cortisol due to the blunting of the stress responses allows inflammation to persist beyond the point where it is beneficial. Furthermore, in the context of alcoholic cirrhosis, the uncoupling of the HPA axis and the SNS has harmful hemodynamic consequences^[123]. The potential role of neuroendocrine factors to mediate the effects of acute alcohol on inflammation has been investigated^[124]. However, whether the blunting of the HPA axis directly mediates the effect of chronic alcohol consumption on the inflammatory state remains to be determined.

Since the low-grade chronic inflammation associated with chronic alcohol consumption is present even in the absence of any obvious infection, it is possible that LPS leakage from the gut and poor clearance by the liver may be underlying factors. In view of the tolerance that humans and animals develop to the stimulation of the HPA axis by either alcohol^[125-127] or LPS^[128], LPS will not be able to sufficiently activate the HPA axis and subsequent

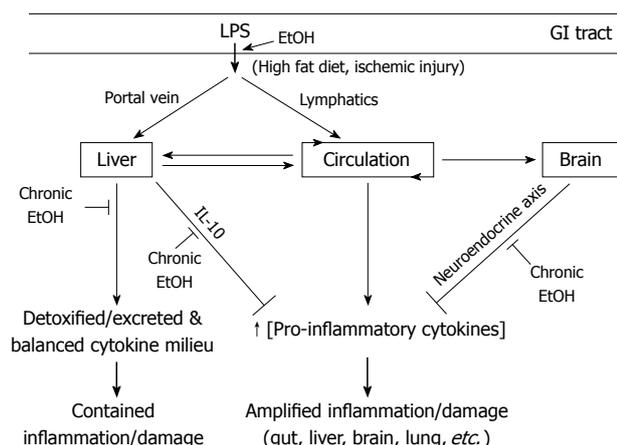

Figure 1 Gut microflora derived lipopolysaccharide (LPS)-dissemination, detoxification, and multi-organ host response and effects of alcohol use.

A number of key events in LPS translocation and host response are depicted. First, upon translocation across the gut barrier, LPS enters circulation via two different routes: the portal vein or lymphatic vessels. LPS in the portal vein is directly delivered to the liver and most of it is detoxified and excreted, whereas most LPS in lymphatics are released into the circulation at the thoracic duct opening. Between the two routes, portal dissemination is dominant under normal conditions whereas a few known conditions including fatty diet and ischemic injury stimulate lymphatic dissemination. Second, a healthy liver plays a key role in the detoxification of LPS in the portal vein and systemic circulation but also generates a balanced cytokine milieu that lead to a contained inflammation and limited damage. Third, LPS in circulation is accessible to many organs and plays a major role in multi-organ damage, especially when LPS detoxification in liver is compromised. Lastly, LPS and its immune mediators (pro-inflammatory cytokines) can activate the neuroendocrine response in the central nervous system (CNS) that leads to the activation of the hypothalamo-pituitary-adrenal (HPA) axis and then the synthesis of cortisol, which down-regulates inflammatory responses in the periphery. A number of key sites under alcohol influence are depicted. First, alcohol enhances LPS translocation across the gut barrier by increasing microflora content and impairing gut barrier function. Second, alcohol stimulates LPS dissemination via lymphatics, evidenced by a rapid rise in circulating LPS in healthy animals fed with acute alcohol. The potential use of the portal route remains to be determined. Third, chronic alcohol use not only adversely affects the liver's ability to detoxify LPS but also affects the liver's ability to synthesize a key anti-inflammatory cytokine, interleukin (IL)-10. Lastly, chronic alcohol reduces the synthesis of neuroendocrine effectors that regulate systemic inflammation. Together, chronic alcohol impairs the balance of microflora in the gut, gut barrier function, the liver's ability to detoxify bacterial products and to generate a balanced cytokine milieu, and the brain's ability to regulate inflammation in the periphery. GI: Gastrointestinal.

glucocorticoid release. The net outcome is that the alcohol-dependent individual would have a reduced capacity to suppress LPS-induced inflammation.

CONCLUSION

Heavy alcohol consumption contributes to systemic inflammation by interfering with the body's natural defenses against the influx of gut microbiota and its products. Chronic alcohol use impairs the balance of microflora in the gut, the gut barrier function, the liver's ability to detoxify bacterial products and to generate a balanced cytokine milieu, and the brain's ability to regulate inflammation in the periphery. When these defenses are impaired, systemic inflammation ensues. The sustained inflammation has the potential to damage host tissues, beyond the local injury to the gut and the liver, including

the brain. It also has the potential to alter adaptive immunity that can lead to lymphocyte-mediated inflammation and tissue injury.

As detailed in this review and Figure 1, many potential sites for alteration of gut and liver function and the complex network of neuroimmunoendocrine interactions by alcohol remain to be explored. Both acute and chronic alcohol consumption can cause devastating morbidity and mortality in the drinking population. Research into the effects of alcohol on gut leakiness and LPS translocation, mucosal and liver immunity, and CNS-liver interactions are important to the understanding of alcohol's potential to disrupt host inflammation control mechanisms and consequent damage to all tissues in the body. Delineating the mechanism by which alcohol disrupts homeostatic control of inflammation may provide insights into effective preventative or therapeutic measures.

ACKNOWLEDGMENTS

The authors are grateful to Dr. Bin Gao, Dr. Gary Murray, Dr. Svetlana Radaeva, and members of the Division of Metabolism and Health Effects, National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, for their critical reading of the manuscript.

Abstract

The association between alcohol consumption and pancreatitis has been recognized for over 100 years. Despite the fact that this association is well recognized, the mechanisms by which alcohol abuse leads to pancreatic tissue damage are not entirely clear. Alcohol abuse is the major factor associated with pancreatitis in the Western world. Interestingly, although most cases of chronic pancreatitis and many cases of acute pancreatitis are associated with alcohol abuse, only a small percentage of individuals who abuse alcohol develop this disease. This situation is reminiscent of the association between alcohol abuse and the incidence of alcoholic liver disease. The liver and the pancreas are developmentally very closely related. Even though these two organs are quite different, they exhibit a number of general structural and functional similarities. Furthermore, the diseases mediated by alcohol abuse in these organs exhibit some striking similarities. The diseases in both organs are characterized by parenchymal cell damage, activation of stellate cells, aberrant wound healing, and fibrosis. Because of the similarities between the liver and the pancreas, and the alcohol-associated diseases of these organs, we may be able to apply much

INTRODUCTION

Alcohol abuse is a major cause of morbidity and mortality in the United States; each year it is responsible for more than 100 000 deaths and directly or indirectly costs over 185 billion dollars^[1]. Alcohol affects every organ system in the body causing a variety of disorders. Although not the most common alcohol-associated disease, alcoholic pancreatitis is one of the more painful and serious consequences of alcohol abuse.

Alcoholic pancreatitis has been recognized for well over 100 years, yet it remains one of the least understood alcohol-associated diseases. The natural course of alcoholic pancreatitis is not well known. This is, in part, a result of the fact that traditionally pancreatitis has been classified by morphology rather than etiology, as well as the fact that confusing and imprecise criteria have been used to differentiate between different types of pancreatitis. Additionally, there is no good animal model of chronic pancreatitis, and progression of this disease in human beings has been difficult to elucidate.

The mechanism(s) by which alcohol abuse induces alcoholic pancreatitis is not well understood. Although it is evident that alcohol abuse can have an important role in the development of pancreatitis, it does not appear that alcohol abuse alone is responsible for the development of pancreatitis. Rather, it appears that ethanol sensitizes the pancreas to injury and other factors are required to actually develop alcoholic pancreatitis. A number of factors, including cigarette smoking, high-lipid diet, genetics, and infections have been suggested as possible cofactors^[2].

There are a number of similarities between alcoholic liver disease and alcoholic pancreatitis; there are also a number of differences. In this review we will attempt to highlight some of the similarities, as well as some of the important differences between alcoholic liver disease and alcoholic pancreatitis. It is hoped that this approach will provide further insight into the pathogenesis of alcoholic pancreatitis.

ALCOHOLIC PANCREATITIS: ACUTE VS CHRONIC

Pancreatitis is a necroinflammatory disease that is normally classified as either acute or chronic. In developing countries, alcohol abuse has been reported to be the second most common factor associated with acute pancreatitis. In these countries, alcohol abuse is associated with approximately 35% of the cases^[3]. Inappropriate intracellular activation of trypsinogen has long been considered an initiating event in acute pancreatitis, resulting in destruction of pancreas parenchymal cells and inflammation^[4]. In most individuals, acute pancreatitis is a mild self-limiting disorder, but in up to 20% of the cases there are severe clinical complications and mortality^[3].

Alcoholic chronic pancreatitis is a complex disease normally thought to have an early stage that is associated with recurrent attacks of acute pancreatitis, and a late stage that is characterized by steatorrhea, diabetes, fibrotic scarring, and pancreatic calcification^[5]. In the western world, chronic alcohol abuse is the major etiological factor of chronic pancreatitis and accounts for approximately 70% of the reported cases^[6]. Although pancreatitis may remain an acute disease, it appears that in many cases alcoholic acute pancreatitis progresses to alcoholic chronic pancreatitis. The progression of alcoholic acute pancreatitis to alcoholic chronic pancreatitis is generally associated with the frequency and severity of acute attacks^[7].

ETHANOL METABOLISM

It is generally thought that the liver is a target of the toxic effects of alcohol because of its ability to metabolize alcohol. Like the liver, the pancreas possesses the enzymes responsible for ethanol metabolism. Therefore, it has been proposed that the pancreas is also a target for the toxic effects of ethanol metabolism^[8-10].

Alcohol can be metabolized by oxidative, as well as nonoxidative, pathways. The oxidative metabolism of ethanol is primarily carried out by two enzymes, the cytosolic enzyme alcohol dehydrogenase and the microsomal enzyme cytochrome P450 2E1. Metabolism of ethanol by either of these enzymes results in the production of the reactive intermediate acetaldehyde, and the production of reactive oxygen species. Although the pancreas expresses both alcohol dehydrogenase and cytochrome P450 2E1, the capacity for oxidative metabolism by the pancreas is significantly less than that of the liver^[11,12].

Nonoxidative metabolism of ethanol is carried out by a number of enzymes, the most important being the fatty acid ethyl ester synthases. Metabolism of ethanol by these enzymes results in the formation of fatty acid ethyl esters (FAEEs). Although the capacity of oxidative metabolism in the pancreas is lower than in the liver, the capacity for nonoxidative metabolism in the pancreas is high because the pancreas has high fatty acid ester synthetic activity^[13]. The nonoxidative and oxidative pathways of ethanol metabolism are linked; when the oxidative pathway is low or impaired the nonoxidative pathway is enhanced^[9]. Because the oxidative metabolism of ethanol in the pancreas is relatively low, the nonoxidative metabolism of ethanol may be more important and the production of FAEEs and their toxic effects accentuated. It has been shown that infusion of FAEEs into rats causes edema, trypsin activation, and vacuolization of pancreas acinar cells^[14]. FAEEs have also been shown to activate the transcriptional activators nuclear factor (NF)- κ B and AP-1, which are involved in the activation of proinflammatory cytokines^[8]. Additionally, FAEEs have been shown to increase the fragility of lysosomes in pancreatic acinar cells^[15]. It has also been shown that FAEEs can inhibit the degradation of extracellular matrix proteins, and therefore may have an involvement in the fibrotic scarring characteristic of alcoholic chronic pancreatitis^[16].

Because the expression of alcohol dehydrogenase and cytochrome P450 2E1 are low in the pancreas, the oxidative metabolism of ethanol is also relatively low and is not considered to contribute a major role in many of the biochemical and pathologic changes associated with pancreas acinar cells. That being said, acetaldehyde, a reactive metabolite of the oxidative metabolism of ethanol, has been shown to mediate some detrimental effects in the pancreas. It has been shown that acetaldehyde is involved in the regulation of the transcriptional activators NF- κ B and AP-1 in pancreatic acinar cells^[8]. Additionally, Masamune *et al.*^[17-19] demonstrated that acetaldehyde, as well as the fatty acid ethyl ester, palmitic acid ethyl ester, activates the mitogen-activated protein kinases p38, ERK1/2, and JNK/SAPK in isolated pancreatic stellate cells. Furthermore, these authors reported that acetaldehyde activated the transcriptional activator AP-1, but not NF- κ B in these cells. In addition, activation of the AP-1 pathway was inhibited by the antioxidant N-acetyl-cysteine (NAC). Because the effects of acetaldehyde were inhibited by inclusion of NAC in the media, the authors concluded

that activation of these signal transduction pathways were mediated by the presence of reactive oxygen species.

Despite the fact that the contribution of the oxidative and nonoxidative pathways of ethanol metabolism differs between the pancreas and the liver, it appears that metabolism of ethanol plays an important role in the disease process in both organs.

CELL DEATH IN PANCREATITIS

Acinar cell death is a major complication of alcoholic pancreatitis and has been linked to the eventual fibrotic scarring associated with this disease. The two major pathways of cell death, apoptosis and necrosis, have both been shown to occur in experimental models of pancreatitis, and it appears that the severity of disease is linked to whether apoptosis or necrosis predominates^[20-22].

Cell death as a result of apoptosis is mediated by a group of cysteine proteases known as caspases. Apoptotic cell death generally preserves the integrity of the cell membrane, whereas necrotic cell death generally results in rupture of the cell membrane and release of the cellular contents. Release of the cellular contents can damage neighboring cells and initiate an inflammatory response^[23]. It has been shown that the severity of experimental pancreatitis directly correlates with the amount of necrosis, and inversely correlates with the extent of apoptosis^[20,22]. Additionally, one of the main indicators of the outcome of pancreatitis in human beings is the extent of necrosis^[24]. In experimental animals, it has been shown that alcohol treatment prior to induction of pancreatitis enhances the necrotic response by decreasing the expression of the initiator caspase, caspase-8. This reduces the apoptotic response, and results in more severe pancreatitis^[25,26]. Thus, modulating the pathway of cell death during pancreatitis may be a mechanism by which alcohol consumption predisposes the pancreas to more severe damage, or alters the severity of pancreatic injury. This modulation can potentially change a subclinical episode of pancreatitis into a clinical episode.

PANCREATIC STELLATE CELLS

The pancreas, like the liver, possesses stellate cells^[27]. Pancreatic stellate cells appear to be morphologically and functionally similar to hepatic stellate cells. In fact, transcriptome analysis of pancreatic and hepatic stellate cells revealed that only 29 of the 23000 genes analyzed differed in expression^[28]. These results indicate that the two populations of cells are very closely related. Stellate cells in the pancreas, as in the liver, are thought to have a major role in extracellular matrix remodeling^[29,30]. Thus, pancreatic stellate cells appear to have a major role in fibrotic disorders of the pancreas, such as chronic pancreatitis and pancreatic cancer^[31,32]. Whereas hepatic stellate cells normally reside in the space of Disse, pancreatic stellate cells are primarily located in the periacinar space,

but are also present in the periductal and perivascular areas of the pancreas^[33,34]. Pancreatic stellate cells comprise approximately 4% of all pancreatic cells; in contrast, hepatic stellate cells comprise approximately 8% of all hepatic cells^[33]. In the normal pancreas, stellate cells are characterized by the presence of vitamin A-containing lipid droplets in their cytoplasm, and by expression of the cytoskeletal proteins desmin and glial fibrillary protein^[33,34]. In response to pancreas injury or acetaldehyde, these cells are activated into a highly proliferative state and are transformed to myofibroblast-like cells^[27]. Activated stellate cells are characterized by the absence of lipid droplets, expression of α -smooth muscle actin, and the production of type-1 collagen, as well as other extracellular matrix proteins^[30]. Activated pancreatic stellate cells have been shown to be closely associated with areas of pancreatic fibrosis. They are the principal source of type 1 collagen in pancreatic fibrosis, both in humans and experimental animal models^[35].

Numerous paracrine factors have been demonstrated to participate in the activation of pancreatic stellate cells. Included in these factors are cytokines such as interleukin (IL)-1, IL-6, IL-8, and tumor necrosis factor α , growth factors such as platelet-derived growth factor (PDGF) and transforming growth factor (TGF)- β ₁, angiotensin II, acetaldehyde, and reactive oxygen species released by damaged parenchymal cells, or leukocytes recruited in response to tissue injury^[36-39]. In turn, the activated stellate cells produce autocrine factors such as PDGF, TGF- β ₁, IL-1, and IL-6, which are thought to perpetuate the activation of the pancreatic stellate cells.

It has been demonstrated that both hepatic and pancreatic stellate cells express NADPH oxidase, and it has been proposed that this enzyme has a role in the fibrosis associated with chronic pancreatitis^[40,41]. NADPH oxidase is a multicomponent enzyme originally described in phagocytic cells as a source of reactive oxygen species. In phagocytic cells, the activated complex produces extracellular superoxide that has an important role in defense against microbial infection. The NADPH oxidase expressed by stellate cells and the enzyme complex expressed by phagocytic cells exhibit some important differences. One of the most important differences is the fact that in stellate cells NADPH oxidase is constitutively active, producing low levels of reactive oxygen species.

Originally, it was shown that angiotensin II mediated its profibrotic action in the liver through NADPH oxidase activity in hepatic stellate cells^[40]. *In vivo*, mice lacking NADPH oxidase activity demonstrated attenuated liver fibrosis after bile duct ligation. Investigation of the role of NADPH oxidase in pancreatic stellate cells revealed that PDGF- $\beta\beta$, IL-1 β , and angiotensin II induced production of reactive oxygen species in cultured pancreatic stellate cells. The increase in reactive oxygen species and subsequent activation of downstream signaling pathways were abolished by inhibition of NADPH oxidase activity with diphenylene iodonium (DPI)^[42].

Additionally, treatment with DPI attenuated the development of pancreatic fibrosis in Wistar Bonn/Kobori rats and in rats with dibutyltin dichloride-induced chronic pancreatitis^[42]. In a separate study, it was shown that ethanol enhanced PDGF-mediated activation of pancreatic stellate cells, indicating that NADPH oxidase may have a role in alcoholic pancreatitis^[41].

The cascade of pancreatic damage, activation of pancreatic stellate cells, and progression to fibrosis has been termed a necroinflammatory response. It has been suggested that alcohol abuse can result in pancreas damage by a nonnecroinflammatory response as well. Interestingly, pancreatic stellate cells express alcohol dehydrogenase and are able to produce acetaldehyde^[27]. Because acetaldehyde has been shown to activate pancreatic stellate cells, it has been suggested that this ability may itself result in the activation of pancreatic stellate cells. In turn, this activation may result in the initiation, as well as the perpetuation of, alcohol induced pancreatitis and pancreatic fibrosis^[27].

Tissue repair is a process that is regulated by an intricate balance between the synthesis and degradation of extracellular matrix components^[43]. As mentioned above, pancreatic stellate cells are critically important in the remodeling of the extracellular matrix. This remodeling involves not only synthesis of extracellular matrix components but their degradation as well. Pancreatic stellate cells secrete a number of matrix metalloproteinases (MMPs), enzymes that are involved in extracellular matrix degradation^[44]. The MMPs are a family of zinc-dependent enzymes secreted by a variety of cells that are able to degrade extracellular matrix components. Thus, pancreatic stellate cells are not only involved in pancreatic damage; they are also critically involved in recovery and repair of pancreatic damage^[45].

Specifically, pancreatic stellate cells have been shown to secrete MMP1, MMP2, MMP3, MMP9, and MMP13^[39,44,46]. MMPs have different substrate specificities; MMP2 and MMP9 primarily degrade basement membrane collagen (type-4), whereas MMP1 and MMP13 degrade type-1 collagen. The secretion of MMP2 is greatly increased by ethanol and acetaldehyde, and is secreted far in excess of MMP13^[44]. This finding led the authors to suggest changes in MMPs secretion as an explanation for the accumulation of fibrotic type 1 collagen in pancreatitis.

Pancreatic stellate cells have also been shown to secrete enzymes that inhibit the activity of MMPs, these enzymes are known as tissue inhibitors of metalloproteinases (TIMPs). TIMP2 is an important inhibitor of MMP2, the matrix metalloproteinase responsible for the degradation of basement membrane collagen. Ethanol and acetaldehyde have been shown to increase the secretion of TIMP2. However, this increase in TIMP2 was significantly less than the increase in MMP2. The overall result was an increase in MMP2 activity^[44]. Interestingly, similar findings have been reported in hepatic stellate cells, again indicating the close functional relationship between these two cell types^[47].

In a model of acute pancreatitis where the fibrotic damage was resolved, both MMP2 and MMP1 activity were shown to increase, but were regulated in a different temporal fashion. MMP2 activity increased soon after injury, while MMP1 activity increased later^[46]. These results indicate different roles for different MMPs in repair and regeneration of the pancreas. They also demonstrate that there is a delicate balance and interplay between different MMPs in the normal recovery of pancreatic injury.

Understanding the factors and mechanisms that maintain stellate cells in a quiescent state or return them to a quiescent state is as important as understanding the factors and mechanisms of stellate cell activation and fibrotic scarring. In both the liver and the pancreas, the nuclear hormone receptor peroxisome proliferator-activated receptor- γ (PPAR- γ) has been implicated as being involved in inhibition of stellate cell activation^[18,48,49]. PPAR- γ is a nuclear hormone receptor that is activated by specific ligands and has been shown to inhibit key characteristics of activation, including induction of collagen synthesis in both hepatic and pancreatic stellate cells^[18,48,49]. Acetaldehyde has been shown to activate hepatic stellate cells, at least in part, by abrogating PPAR- γ -mediated transcriptional activity in cultured hepatic stellate cells^[50]. Additionally, the profibrogenic actions of acetaldehyde were shown to be associated with increased phosphorylation of PPAR- γ at a MAP kinase phosphorylation site. These results demonstrate the involvement of MAP kinases in the inhibition of PPAR- γ -mediated transcriptional activity, and ultimately stellate cell activation^[50].

Vitamin A (retinol) also appears to be a major contributor to the maintenance of quiescence in pancreatic stellate cells; its absence in active pancreatic stellate cells may be related to ethanol metabolism^[51,52]. In support of this notion, McCarroll *et al.*^[52] demonstrated that retinol and its metabolites all trans retinoic acid and 9-cis retinoic acid induce quiescence in activated pancreatic stellate cells. Furthermore, quiescence of pancreatic stellate cells was associated with a decrease in the activity of all three classes of MAP kinases. In the presence of ethanol, retinol was not able to fully inhibit activation of pancreatic stellate cells. Because retinol and ethanol can both be metabolized by either alcohol dehydrogenase or by retinol dehydrogenase, the authors suggest that ethanol may act as a competitive inhibitor of normal retinol metabolism, and that this inhibition may, in part, explain the ability of ethanol to activate pancreatic stellate cells^[52].

REGENERATION AND REPAIR

The pancreas, like the liver, has a tremendous capacity to regenerate after injury^[53,54]. As with all fibrotic diseases, pancreatitis can be considered a result of an aberrant or inappropriate repair process. Thus, it is as important to have a detailed understanding of the mechanisms of pancreas repair and the effects of ethanol on this process, as it is to determine the mechanisms by which alcohol abuse leads to pancreatitis. In animal models of

pancreatitis, normal regeneration is characterized by a sequence of events that includes activation and proliferation of pancreatic stellate cells, deposition of extracellular matrix, and proliferation of acinar cells^[53,55]. It is now evident that this regenerative process is orchestrated by the temporal and sequential expression of growth factors that act in either an autocrine or paracrine manner to stimulate cells. This coordinated process ultimately results in full structural and functional restitution of the pancreas. Little is known regarding the effects of ethanol on this process.

While investigating the effects of ethanol consumption on regeneration after cerulein-induced pancreatitis, one group, using the Lieber-DeCarli diet, found that ethanol feeding of rats for 2-8 wk significantly decreased amylase content of the pancreas. This finding indicated impaired functional regeneration. This treatment did not affect protein, DNA, or RNA content. Although no histological evaluation was performed, these authors concluded that ethanol had no effect on pancreatic regeneration^[56,57]. In contrast, Pap *et al.*^[58] found that gastric intubation of ethanol over a 2 mo period inhibited the recovery of pancreatic weight and enzyme content in rats that had common bile ducts and main pancreatic ducts occluded to induce pancreatic injury. During this 2 mo period, the animals exposed to ethanol developed chronic calcifying pancreatitis. Cessation of the ethanol treatment resulted in recovery of the pancreas. These results led the authors to suggest that inhibition of pancreatic regeneration by ethanol was required to maintain this chronic pancreatitis. Investigating the role of cholecystokinin (CCK) in pancreatic regeneration, it has been shown that alcohol administration reduced CCK release and prevented pancreas regeneration^[59]. Additionally, using a model of virally induced pancreatitis, it has been shown that ethanol administration to mice delays pancreas recovery^[60].

The pancreas and the liver are developmentally very closely related. Therefore, it is tempting to speculate that the regenerative process, and the effects of ethanol on this process, may be similar in the pancreas and the liver^[61]. In the liver, it has been demonstrated that ethanol abuse impairs regeneration^[62,63]. Both the pancreas and the liver contain a population of progenitor cells that are multipotent and able to differentiate into multiple cell types^[64,65]. In the liver, these hepatic progenitor cells have been shown to be important in regeneration in alcoholic liver diseases and in other hepatic diseases where oxidative stress has occurred^[66,67]. Thus, it may be that repair initiated by pancreatic precursor cells may be impaired by ethanol as well. It is clear that more work is required to determine the effects of ethanol on regeneration and repair of pancreatic damage.

CLINICAL IMPLICATIONS AND FUTURE DIRECTIONS

It is obvious that alcoholic pancreatitis is an important

health concern and more focus on this disease is warranted. It appears that, as with alcoholic liver disease, the fibrotic scarring associated with chronic pancreatitis is primarily associated with activation of stellate cells. Because of this, it is likely that future research directed at the mechanisms by which ethanol and its metabolites mediate or enhance the activation of these cells will provide targets for therapeutic intervention. Currently, some promising therapeutic candidates include NADPH oxidase and receptors located on the surface of stellate cells.

Future work should strive to understand the mechanisms by which stellate cells remain quiescent. It is clear that balancing the need for activation of stellate cells for repair and wound healing with maintenance of the quiescent state will be challenging. Because similar mechanisms of fibrotic scarring occur in the liver, it will be prudent to monitor progress in this field and apply it to the pancreas.

CONCLUSION

The pancreas and the liver are developmentally closely related and, in a general sense, share certain structural and functional similarities. It is well known by the general public that alcohol abuse can result in liver damage and lead to cirrhosis. It is not as well known that alcohol abuse can also result in pancreatic damage and ultimately in alcoholic chronic pancreatitis. Although there are many differences between the liver and the pancreas, and the alcohol-associated diseases of these organs, there are also many similarities. Because of these similarities, lessons learned regarding the effects of ethanol on the liver may be useful in determining mechanisms by which ethanol damages the pancreas.

Both the liver and the pancreas possess stellate cells. Although some of the biochemical changes that occur as a result of ethanol metabolism in the liver and the pancreas differ, the end result in both organs is the activation of stellate cells. In both organs the activated stellate cells are the major source of fibrotic collagen. Because fibrosis is a characteristic of alcohol-associated damage in both organs, stellate cells are the focus of therapeutic intervention. Among the questions that require further investigation are the mechanisms that will inhibit hyperactivation or inappropriate activation of stellate cells. Paradoxically, activated stellate cells are also involved in the removal of fibrotic collagen. Therefore, determining the mechanisms of appropriate activation, and enhancing the ability of these cells to degrade fibrotic collagen are paramount. Additionally, mechanisms of repair and regeneration must be further delineated. Are progenitor cells involved in repair of alcohol-associated damage in the pancreas, as they are in the liver?

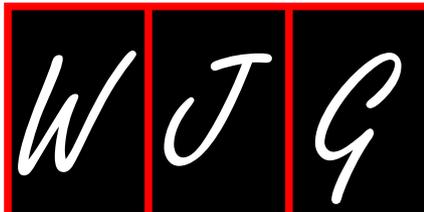

It is clear that although there are differences between the effects of alcohol on the liver and the pancreas, there are also striking similarities. Lessons learned from the liver may be useful in answering questions regarding the pancreas.

Abstract

Alcoholic liver disease (ALD) is one of the leading causes of liver diseases and liver-related death worldwide. Of the many factors that contribute to the pathogenesis of ALD, gut-derived lipopolysaccharide (LPS) plays a central role in induction of steatosis, inflammation, and fibrosis in the liver. In this review, we discuss the mechanisms by which alcohol contributes to increased gut permeability, the activation of Kupffer cells, and the inflammatory cascade by LPS. The role of the Toll-like receptor 4 (TLR4) complex in LPS recognition and the importance of the TLR4-induced signaling pathways are evaluated in ALD.

INTRODUCTION

The clinical spectrum of alcoholic liver disease (ALD) includes alcoholic fatty liver, alcoholic steatohepatitis, alcoholic cirrhosis (Laennec's cirrhosis), and increased risk of hepatocellular carcinoma^[1,2]. The pathomechanism of ALD involves complex interactions between the direct effects of alcohol and its toxic metabolites on various cell types in the liver, induction of reactive oxygen species (ROS), upregulation of the inflammatory cascade, and other cell-specific effects in the liver^[3,4]. Lipopolysaccharide (LPS), also known as endotoxin, has been identified as a major factor in the pathogenesis of ALD. Indeed, LPS can lead to liver steatosis, as it induces inflammation and contributes to cirrhosis, which are all features of ALD^[5,6]. These effects of LPS are manifested in the various cell types in the liver and the source of LPS appears to be the gut in ALD, resulting from alcohol-induced disturbance of gut permeability. At the cellular and molecular level, LPS is recognized by the Toll-like receptor 4 (TLR4) complex and induces specific intracellular activation pathways. This review will focus on the role of LPS in ALD and will summarize the current state of art on alcohol-related changes in the gut-liver axis.

GUT-LIVER AXIS

The gut is a habitat for billions of microorganisms and the gut mucosal epithelium serves as a barrier between microbiota and gut lumen^[7]. LPS (endotoxins) derived from Gram-negative bacteria in the intestinal microflora normally penetrate the mucosa only in trace amounts,

enter the portal circulation, and become cleared in the liver to maintain the control of immune homeostasis. Resident macrophages (Kupffer cells) and hepatocytes both contribute to this process through different LPS recognition systems^[3,8-10]. There is a positive correlation between liver dysfunction and the occurrence of bacterial translocation^[11-14], and the clearance of LPS from the circulation is decreased in states of hepatic dysfunction, such as cirrhosis^[15]. Studies in animals suggest that the liver quickly removes about 40%-50% of an intravenous dose of LPS from the bloodstream^[16,17]. Hepatic uptake and detoxification is important for preventing systemic reactions to blood-borne LPS. It has been proposed that LPS initially is taken up by Kupffer cells and then by hepatocytes^[18]. LPS is removed *via* several mechanisms, including molecules that bind LPS and prevent it from activating TLR4, enzymes that degrade the lipid A moiety to decrease its activity, inactivation of LPS following uptake into the liver and spleen, and cellular adaptations that modify target cell responses^[19]. Another mechanism for LPS neutralization is by serum lipoproteins, HDL, LDL, VLDL, and chylomicrons, apolipoproteins apoE and apoA-I LPS^[20-22]. All of these mechanisms can chaperone endotoxin to hepatocytes, Kupffer cells, or sinusoidal endothelial cells, resulting in clearance of LPS without significant inflammatory cell activation.

ALD AND ENDOTOXIN

The role of LPS in alcoholic liver injury has been shown in several studies^[12,23,24]. The importance of gut-derived endotoxin in ALD was suggested by experiments where treating the animals either with antibiotics or with lactobacilli to remove or reduce the gut microflora provided protection from the features of ALD^[12,25,26]. In mice and rats, circulating endotoxin levels were increased after chronic alcohol feeding^[27,28] and plasma endotoxin levels were also increased in patients with ALD compared to normal subjects^[29]. The persistence of endotoxin not only activates the liver immune cells but also affects the function of liver parenchymal cells.

The progression of ALD is a complex phenomenon, as it not only results from the direct effects of alcohol and its metabolites, but other factors also play an important role in its pathogenesis, such as leaky gut, which results in endotoxemia^[30]. Both chronic ethanol-mediated microbial proliferation^[31,32] and acetaldehyde-mediated opening of intestinal tight junctions (TJs)^[33] enhance the passage or release of endotoxins into the intestinal lumen, which are later transported to liver. However, when excess amounts of endotoxin are not cleared efficiently by the liver and accumulate in blood circulation, innate immune cells, including Kupffer cells, are activated, leading to the release of various pro-inflammatory cytokines, chemokines, and other factors^[34,35].

Kupffer cell activation has been identified as one of the key elements in the pathogenesis of alcoholic steatohepatitis. Studies in mice and rats demonstrated that

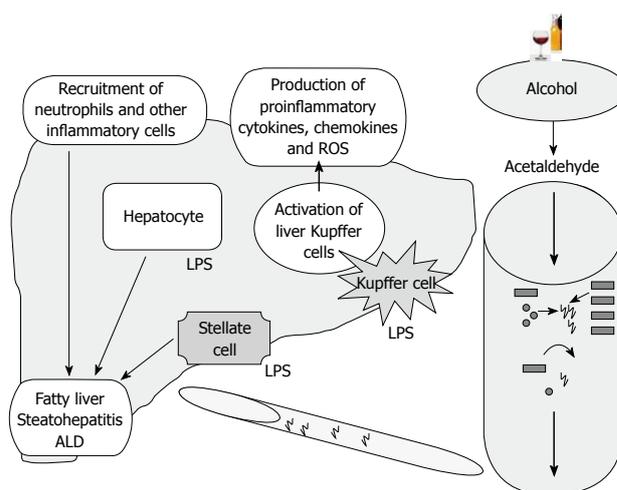

Figure 1 Mechanisms of alcohol induced liver damage. Alcohol consumption alone, or with its metabolites, disrupts the gut integrity by various mechanisms, including increased reactive oxygen species (ROS), inducible nitric oxide synthase (iNOS), alteration of microRNAs, proliferation of Gram-negative bacteria, and changes in bacterial species. These factors alone, or in combination, mediate increased gut permeability and subsequent bacterial or microbial translocation into intestinal lumen and thus an increase in lipopolysaccharide (LPS) in the portal circulation. The excess of LPS in the liver affects immune, parenchymal, and non-immune cells and in response there is release of various inflammatory cytokines, and recruitment of neutrophils and other inflammatory cells. Persistence of the above mentioned factors are hallmark of alcoholic liver disease (ALD).

inactivation of Kupffer cells with gadolinium chloride or clodronate injection can almost fully ameliorate alcohol-induced liver disease^[36,37]. These observations led to the currently accepted model of ALD, where Kupffer cell activation by gut-derived endotoxin, induction of chemokines such as MCP-1, and upregulation of the inflammatory cascade represent a central component of the pathomechanisms of ALD (Figure 1).

MECHANISMS OF GUT BARRIER DISRUPTION BY ALCOHOL

The mechanisms underlying the disruption of the intestinal barrier by alcohol appear to be at multiple levels, including disruption of the gut barrier and changes in microbial flora.

Disruption of gut integrity by alcohol and its metabolites

Tight junctions are scaffolds of various transmembrane proteins (e.g. claudins, occludin, JAMs, and tricellulin) and a complex network of adaptor proteins that cross-link junctional membrane proteins (i.e. ZO-1/2/3, PATJ, PAR-3, and PAR-6) to the actin cytoskeleton as well as to different intracellular signaling components. Both alcohol and its metabolites affect the integrity of TJs.

Several studies in the literature suggest the role of acetaldehyde (one of the metabolites of alcohol) in increasing intestinal permeability^[30,38,39]. Acetaldehyde causes the redistribution of tight junction proteins (occludin and ZO-1) and adherens junction (E-cadherin and

β -catenin) proteins from the intercellular junctions^[40,41]. Furthermore, acetaldehyde increases the tyrosine phosphorylation of ZO-1, E-cadherin, and β -catenin, without affecting tyrosine kinase activity^[40]. Acetaldehyde also disrupts the interactions between E-cadherin, β -catenin, and PTP1B, which are the vital components of adherens junctions and epithelial cell-cell adhesion^[42]. These studies indicate the central role of acetaldehyde in disruption of gut integrity, however, not much is known about the effects of other metabolic products of alcohol on gut permeability.

Increased expression of inducible nitric oxide synthase (iNOS) is another factor by which alcohol disrupts the intestinal barrier function. Increase in iNOS, NO, and superoxide correlates with an increase in nitration and oxidation of tubulin, causing increased levels of disassembled tubulin that subsequently damage the microtubule cytoskeleton and result in disruption of barrier function in alcohol treated CaCo2 cells^[43,44]. NF- κ B is involved in oxidation-induced upregulation of iNOS as well in nitration and oxidation of cytoskeleton^[45]. Interestingly epidermal growth factor has a protective role in intestinal barrier function *via* downregulation of iNOS activity, which results in the stabilization of cytoskeleton^[46-48].

Not only chronic alcohol intake results in the disruption of intestinal barrier, but acute alcohol consumption also damages intestinal mucosal membrane, as reported in a rat model^[49]. In a mouse model, a single dose of acute ethanol (6 g/kg) causes injury to the mucosal lining of the small intestine^[50].

Exploitation of mircoRNAs (miRs) by alcohol to target the tight/adherent junction proteins

Another mechanism by which alcohol increases intestinal permeability is by indirectly affecting tight junction proteins through miRs. In particular, a recent study showed the involvement of miRs in gut barrier disruption in alcohol treated cells. miR-212 targets the ZO-1 protein negatively, thus increasing intestinal permeability^[51]. Consistent with this *in vitro* observation, higher levels of miR-212 and lower amounts of ZO-1 protein were found in colon biopsy tissues from patients with ALD^[51]. However, more work needs to be done to explore the role of miRs in regulating tight and adherent junction proteins in ALD.

Change or increase in gut microflora by alcohol

Chronic alcohol abuse not only causes gut leakiness, but also affects the composition of colonic mucosa-associated bacterial microbiota in alcohol-fed rats^[52]; however, the latter finding needs to be validated in human subjects. While there is evidence of bacterial overgrowth (Gram negative) in the gut of alcoholics^[53], little is known about how alcohol consumption is related to increased intestinal bacterial growth. Interestingly, we do not know whether alcohol consumption affects Gram-positive bacteria, which are the source of peptidoglycan. Nevertheless,

increased peptidoglycan levels were found in mice after prolonged administration of alcohol in their drinking water. Interestingly, this mode of alcohol administration does not result in ALD^[54].

ENDOTOXIN RECEPTORS AND SIGNALING PATHWAYS

LPS is a major component of the outer membrane of Gram-negative bacteria and it comprises three distinct parts: a carbohydrate “O-antigen”, the oligosaccharide core region, and a lipid portion “lipid A”. Only the lipid A moiety is toxic and is responsible for the activation of the innate immune response in mammals^[55]. LPS and other bacterial cell wall constituents are released during bacterial multiplication or when bacteria die or lyse^[56]. As soon the immune system recognizes the presence of microorganisms (bacteremia) or LPS in the blood stream (endotoxemia), various proinflammatory cytokines, chemokines, ROS, and other mediators are released to activate monocytes, macrophages, and to recruit lymphocytes. The liver plays an important role in the body’s defense mechanism against bacteria and bacterial products.

LPS is recognized by various receptors in the cells. CR3 (CD11b/CD18) was the first described LPS receptor^[57] in human macrophages. Later on, cluster of differentiation 14 (CD14) and LPS binding protein (LBP) were recognized as receptors for LPS^[58]. Recently, myeloid differentiation factor-2 (MD-2) was found as another LPS binding molecule (direct binding)^[59]. However, CD14 and MD-2 lack a transmembrane domain and, therefore, a second receptor is required to activate the signaling cascade, which was recently described as TLR4 (indirect binding)^[60,61].

TLR4

Toll receptors were first discovered in *Drosophila*^[62] and later on their human homologs were identified^[63]. TLR4 recognizes LPS with the cooperation of its co-receptors, CD14 or MD-2^[64,65]. LPS recognition by TLR4 results in recruitment of the adaptor molecules MyD88 and TRIF, which each activate separate downstream signaling cascades (Figure 2). Formation of the TLR4-MyD88 complex activates the IRAK kinases, which turn on the IKK complex to activate NF- κ B, which results in increased production of pro-inflammatory cytokines, such as tumor necrosis factor (TNF)- α , interleukin (IL)-6 and IL-1 β ^[64]. Activation of TRIF pathway results in TBK/IKK ϵ phosphorylation and activation of the interferon regulatory factor-3 (IRF3), which leads to induction of Type- I interferons (IFNs)^[66]. Activation of both of the pro-inflammatory and Type- I IFN pathways by TLR4-LPS is unique, and evaluation of these specific pathways has recently received attention in ALD.

The TLR4-LPS signaling pathway plays a critical role in alcohol-induced liver injury. Both chronic and acute (or binge) alcohol use affect the various components of TLR4 signaling^[67-71]. The effect of alcohol use on TLR4

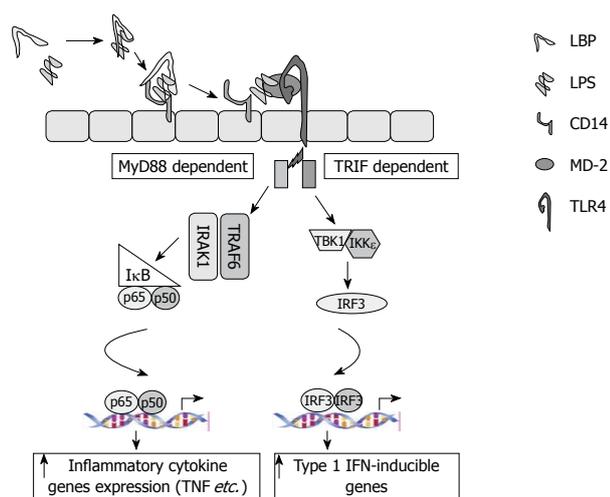

Figure 2 Role of the Toll-like receptor 4 (TLR4)-LPS signaling cascade in alcohol induced liver injury. LPS binds to LPS binding protein (LBP), transfers to cluster of differentiation 14 (CD14) and then to the TLR4 myeloid differentiation factor-2 (MD-2) complex. This signal is passed either through MyD88-dependent or TRIF-dependent intracellular pathways, which activate various transcription factors and induce various pro-inflammatory cytokine and Type I interferon genes.

signaling was recently reviewed in detail^[3]. There is increased expression of TLR4 and its co-receptors, as well as other TLRs, in ALD in mice. Early studies in TLR4 mutant mice demonstrated protection from early ALD^[72] and more recent reports using TLR4 deficient mice validated the important role of TLR4 in the pathogenesis of ALD^[73]. We also investigated the specific role of the MyD88 adapter in ALD and found that MyD88-deficient mice were not protected from alcoholic steatosis and inflammation. Consistent with the hypothesis that MyD88-independent, TLR4-mediated, pathways are involved in ALD, we found protection from ALD in TLR4-deficient, as well as in IRF3-deficient, mice^[73]. The role of IRF3 in ALD was also indicated by another study^[74].

MD-2

MD-2 is a type II acute phase protein and is expressed on the surface of myeloid and endothelial lineage cells^[75,76]. Although it lacks a transmembrane domain, it attaches to the cell surface through its interaction with TLR4^[77,78]. MD-2 also presents in a soluble form (sMD-2) and is secreted by various cells^[79,80]. Increased sMD-2 activity is found in plasma of sepsis patients^[81,82]. It is postulated that at high concentrations, sMD-2 might inhibit endotoxin induced cell activation in a similar way to LBP and soluble CD14^[78,83]. IL-1 β regulates the production of MD-2 in hepatocytes and myeloid cells^[83]. Chronic alcohol feeding results in an upregulation of MD-2 in the liver^[73].

CD14

CD14 is expressed in various cell types, including monocytes, macrophages, B cells, liver parenchymal cells, and some fibroblast cells^[84,85]. It is absent in early myeloid progenitor cells; however, with maturation, its expression increases. Human CD14 transgenic mice are hypersensitive to LPS^[86], whereas CD14 knockout mice are

resistant to endotoxin shock^[87], indicating its crucial role in LPS signaling. CD14 is also present in soluble forms, as sCD14 α and sCD14 β , and is secreted by macrophages^[88] and liver parenchyma cells^[89].

Alcohol consumption affects CD14 expression and plays an important role in LPS induced immune activation in alcoholics. Increased expression of CD14 is found in Kupffer cells or whole livers of chronic ethanol-fed animals^[25,90,91]. A correlation between CD14 expression and the severity of ALD has been reported in humans and it has been suggested that CD14 is one of risk factor in ethanol-induced pathology^[92,93]. Interestingly, acute alcohol treatment also induces CD14 expression in whole liver cells^[94] and CD14-deficient mice were protected from alcohol-induced liver steatosis^[92].

LBP

LBP is an acute phase protein and is induced by LPS, IL-6, and IL-1 β ^[95,96]. Although liver is a major source of LBP production, other organs, such as lungs, kidneys, and heart, also produce LBP^[97]. This protein is present in normal serum; however, its levels become elevated during acute phase responses^[98,99]. LBP catalyzes the transfer of LPS to CD14, and thus enhances the LPS-induced activation of monocytes, macrophages, and other immune cells^[100]. Anti-LBP antibodies, together with LPS, protected the mice from death^[101]. Neutralization of LBP protects the host from LPS-induced toxicity, suggesting its critical role in innate immunity^[102].

In addition to its pro-inflammatory role, it also acts as an antiinflammatory, where it transfers LPS (Gram negative) or LTA (Gram positive) to HDL and other lipoproteins, and also aids the neutralization of LPS^[103]. The antiinflammatory role of this protein is well described in various reports^[99,104-107]. It is postulated that low concentrations of LBP enhance the LPS-induced activation of mononuclear cells, whereas the acute-phase rise in LBP concentrations inhibit LPS-induced immune cell activation^[108].

Not much is known about the role of LBP in alcoholics, except one report where its role is described in early alcohol-induced liver injury where it enhances the production of cytokines, such as TNF- α . Ethanol fed LBP KO mice showed reduced TNF- α expression and reduced liver damage^[109]. There was no change in endotoxin levels of both wild-type and LBP knockout mice; however, decreased steatosis in LBP knockout ethanol-fed mice was observed^[109]. A potential antiinflammatory role of the above mentioned LBPs in the pathogenesis of ALD is yet to be explored.

In summary, it appears that LBPs and receptors modulate the LPS response bifunctionally, either by neutralizing or enhancing its response.

EFFECTS OF LPS ON THE LIVER

Activation of inflammatory cells in ALD

There is ample evidence for increased inflammatory

cascade activation in ALD^[3]. Alcoholic steatohepatitis is characterized by infiltration of various inflammatory cells into the liver, including neutrophils, leukocytes, monocytes, and macrophages and this occurs as a result of chemokine activation (e.g. IL-8, MCP-1, and MIPs)^[110-112]. In humans with alcoholic steatohepatitis, serum TNF- α , IL-6, and IL-8 levels are increased and there is also evidence for activation of circulating monocytes based on increased TNF- α production and increased NF- κ B activation^[113-115]. Serum levels and liver expression of these LPS-inducible pro-inflammatory cytokines are also increased in animal models of ALD^[73]. Isolated Kupffer cells from mice and rats show increased production of TNF- α after chronic alcohol feeding^[116] and this has been linked to increased TNF- α mRNA stability, as well as to upregulation of Erk, MAPK, and Egr-1 kinases^[117]. While LPS has been proposed to play a major role in Kupffer cell and macrophage activation in ALD, *in vitro* studies in human monocytes/macrophages suggest that chronic alcohol exposure itself can promote a pro-inflammatory phenotype and amplify LPS-induced pro-inflammatory responses^[71]. Our laboratory showed that increased LPS responsiveness after chronic alcohol exposure in monocytes is due to reduced expression of IRAK-M, which is a negative regulator of TLR4 activation^[71]. Thus, chronic alcohol exposure alone not only results in pro-inflammatory activation of macrophages, but also sensitizes cells to LPS-induced pro-inflammatory signals^[71].

Effects of endotoxin on the liver parenchymal and other non-immune cells in ALD

TLR4, the LPS receptor, is expressed in all cell types in the liver; thus, gut-derived endotoxin can modulate the function of all liver cells in ALD^[3]. In hepatocytes, LPS can promote apoptosis, particularly in combination with other hepatotoxins^[118,119]. TLR4 expression in hepatic stellate cells (HSC) has been shown to mediate inflammatory signaling by LPS and manifests in activation of Jnk kinase and NF- κ B^[120]. Oxidative stress induced by alcohol and its metabolites has also been shown to sensitize HSC to LPS-induced activation and subsequent induction of hepatic fibrosis^[121,122]. Thus, LPS affects hepatocytes as well as HSC, both directly and *via* inflammatory cell activation.

ROLE OF GUT-LIVER AXIS IN OTHER LIVER DISEASES

The balance of gut microbial flora, intestinal permeability, hepatocyte function, and Kupffer cell activation appears to be critical in the maintenance of normal homeostasis (Figure 1). Indeed, increasing evidence suggests an importance for a gut-liver connection in different liver diseases where gut-derived LPS delivered to the liver through the portal circulation might play a role. For example, increased intestinal permeability was detected

in patients with intrahepatic cholestasis of pregnancy^[123], and in hepatitis C virus (HCV)-induced liver injury in human immunodeficiency virus infected individuals^[124]. An increase in serum endotoxin levels was associated with pro-inflammatory activation of circulating monocytes in chronic HCV infection, even in the absence of cirrhosis^[125]. These observations underscore the importance of the gut-liver axis in the pathogenesis of ALD, as well as in other types of liver injuries.

CONCLUSION

The gut-liver axis, particularly gut-derived endotoxin, seems to play a crucial role in the pathogenesis of liver diseases caused by various insults, including alcohol. However, the mechanisms and source of endotoxin in liver diseases are not fully understood. The importance of alcohol-induced alterations in the gut and the role of the liver in elimination of gut-derived pathogen-derived compounds require further investigation. Furthermore, interactions between immune, non-immune, and parenchymal cells, which take place *in vivo*, contribute and determine the progression of ALD. Understanding the role of TLR signaling and the cell-specific effects of gut-derived microbial products will provide new insights, not only into the pathomechanisms of ALD, but might also reveal new targets for therapeutic interventions.

Abstract

The development of alcoholic liver disease (ALD) is a complex process involving both the parenchymal and non-parenchymal cells in the liver. Enhanced inflammation in the liver during ethanol exposure is an important contributor to injury. Kupffer cells, the resident macrophages in liver, are particularly critical to the onset of ethanol-induced liver injury. Chronic ethanol exposure sensitizes Kupffer cells to activation by lipopolysaccharide *via* Toll-like receptor 4. This sensitization enhances production of inflammatory mediators, such as tumor necrosis factor- α and reactive oxygen species, that contribute to hepatocyte dysfunction, necrosis, apoptosis, and fibrosis. Impaired resolution of the inflammatory process probably also contributes to ALD. The resolution of inflammation is an active, highly coordinated response that can potentially be manipulated *via* therapeutic interventions to treat chronic inflammatory diseases. Recent studies have identified an adiponectin/interleukin-10/heme oxygenase-1 (HO-1) pathway that is profoundly effective in dampening the enhanced activation of innate immune responses in primary cultures

of Kupffer cells, as well as in an *in vivo* mouse model of chronic ethanol feeding. Importantly, induction of HO-1 also reduces ethanol-induced hepatocellular apoptosis in this *in vivo* model. Based on these data, we hypothesize that the development of therapeutic agents to regulate HO-1 and its downstream targets could be useful in enhancing the resolution of inflammation during ALD and preventing progression of early stages of liver injury.

INTRODUCTION

Chronic abuse of ethanol in humans leads to liver disease. An ordered progression of increasingly more serious liver injury, culminating in liver failure in 15%-20% of all alcohol abusers, has been described^[1]. Fatty liver (steatosis) is the earliest stage of liver injury and is characterized by triglyceride accumulation in hepatocytes. If alcohol abuse continues, some patients with steatosis will develop inflammatory changes in their livers, a pathology described as steatohepatitis or simply hepatitis. Hepatitis is characterized by marked hepatomegaly and infiltration

of several different subtypes of leukocytes including neutrophils, monocytes/macrophages and both T and B lymphocytes. Of the patients who develop hepatitis, 50% will progress further and exhibit fibrotic changes in the liver. Of note, alcohol abuse is a leading cause of fibrosis in the USA^[1,2]. Hepatic stellate cell activation is a major contributor to fibrosis through overproduction of excessive extracellular matrix components such as type I and type III collagens and proinflammatory molecules^[3]. Alcohol-induced steatosis and fibrosis can resolve, provided that the underlying stimulus, i.e. alcohol, is removed. Unfortunately, when the liver progresses to cirrhosis, a stage of liver injury characterized by significant hardening of the liver, decreased hepatocyte regeneration and significant loss of liver function, patients are likely to die as a result of liver failure unless they receive a liver transplant^[4]. The medical costs associated with alcohol abuse in the United States is estimated to be \$166 billion per year, of which more than \$30 billion is for direct medical costs^[5].

INNATE IMMUNITY AND WOUND HEALING

Activation of innate immunity is an essential response to infection or injury; the ensuing inflammatory response protects from infection, and also limits cellular and organ damage to the host organism^[6]. A well-controlled innate immune response is characterized by rapid initiation of an inflammatory response. However, this response is sustained only until the immune insult or injury is contained; at that point, the inflammatory response is terminated or resolved. The controlled and appropriate resolution of inflammation is an essential feature of the innate immune response. Despite the beneficial effects of innate immunity, a failure to appropriately regulate activation of innate immunity contributes to a number of chronic inflammatory diseases, including alcoholic liver disease (ALD)^[7]. In addition to the clear role of innate immune responses to alcoholic hepatitis, activation of the innate immune response likely contributes to all stages of liver injury, including steatosis, hepatocellular injury and fibrosis^[8].

Dysregulation in the initiation and/or resolution of the inflammatory process could contribute to the development of ALD. Indeed, there is a growing appreciation that the resolution of inflammation is an active, highly coordinated response that could potentially be manipulated *via* therapeutic interventions to enhance the resolution of inflammatory processes and treat chronic inflammatory diseases, such as ALD.

ROLE OF IMMUNE RESPONSES IN THE INITIATION AND PROGRESSION OF ALD

The innate and adaptive immune systems are 2 distinct branches of the immune response, yet these 2 components of immunity are intimately linked at many stages of an organism's response to injury or stress. Components of the innate immune response, including natural

killer (NK) and NKT cells^[9], Kupffer cells (resident hepatic macrophages)^[10] and the complement system^[11-13], as well as T-cells and antibody-dependent adaptive immune responses^[14], are involved in the hepatic response to various types of injury, including bacterial and viral infections, exposure to toxins (including ethanol), partial hepatectomy and ischemia-reperfusion.

The localized hepatic response of the innate immune system to ethanol may be distinct from the systemic innate immune response and/or localized responses of other organs to ethanol. For example, chronic alcohol consumption generally increases the susceptibility of individuals to infections^[5,15], suggesting that, despite increased inflammatory responses observed in the liver after chronic ethanol exposure, systemic immune responses are suppressed by chronic ethanol exposure. Even within the liver, there may be distinct responses of individual components of the immune response. One example is the interaction of ethanol and hepatitis C virus (HCV) infection. Chronic alcohol abuse is associated with an increased incidence of HCV infection^[16]. This decreased ability to ward off viral infections contrasts with the increased response of the liver to endotoxins. Understanding the localized and specific effects of chronic ethanol on the immune system will help to develop intervention strategies specifically directed at targets of ethanol action leading to the progression of ALD.

Initiation of inflammation: chronic ethanol-dependent sensitization of Toll-like receptor 4 (TLR4)-dependent signal transduction and cytokine production

How does ethanol initiate inflammatory responses in the liver? An important working model for ethanol-induced liver injury proposes that lipopolysaccharide (LPS)-induced tumor necrosis factor- α (TNF α) production by Kupffer cells, the resident macrophage of the liver, is critical for development of ethanol-induced liver injury. Chronic ethanol exposure alters the jejunal microflora leading to an increase in Gram-negative bacteria and/or disrupts the barrier function of the small intestine allowing access of bacterial products to the portal circulation^[17,18]. In support of this hypothesis, endotoxin or LPS, a component of the cell wall of Gram-negative bacteria, is increased in the circulation of alcoholics^[19] and murine models of chronic ethanol exposure^[20,21]. Further, if gut bacteria are diminished using antibiotics, ethanol-induced fatty liver and inflammation are attenuated^[20].

Kupffer cells and TLR4 in the initiation of inflammation: The liver contains the first capillary bed through which blood from the intestine flows. Kupffer cells are located in the hepatic sinusoids and, among other physiologic functions, clear endotoxins from the blood, but usually without discernable inflammation. Chronic ethanol exposure also increases the sensitivity of Kupffer cells to endotoxins^[10]. Therefore, in the presence of persistent ethanol exposure and increased exposure to gut-derived endotoxins, Kupffer cells become activated and contribute to liver disease.

Kupffer cells are innate immune effectors that produce several proinflammatory mediators, including reactive oxygen species (ROS) and TNF α , which promote liver injury after chronic ethanol in response to LPS^[17]. In rats depleted of Kupffer cells by gadolinium chloride treatment, ethanol-induced liver injury is attenuated^[17]. Further evidence for a role of activated Kupffer cells and LPS in the development of ethanol-induced liver injury has been revealed, as mice deficient in LPS receptor complex components TLR4 and CD14, and NADPH oxidase function (*p47^{phox}* -/- mice) are protected from ethanol-induced liver injury^[22-24]. TLR4 signaling *via* its MyD88-independent pathway (TRIF-dependent) is a critical contributor to increased steatosis and inflammation during chronic ethanol exposure^[25,26].

Ethanol and the regulation of TNF α expression: TNF α is produced predominately by cells of monocyte/macrophage lineage and is particularly critical for ethanol-induced liver injury. TNF α concentration is enhanced in the blood of alcoholics^[27] and in the blood of rats and mice exposed to chronic ethanol^[17]. Additionally, if TNF α is blocked in mice using TNF α -specific antibodies or if TNF α signaling is prevented in TNF α receptor-deficient mice, ethanol induced liver injury is diminished^[28].

Enhanced TLR4 signal transduction by ethanol

Production of inflammatory cytokines is a highly regulated process; regulation occurs at the level of transcription, translation and secretion^[29,30]. Ethanol exposure impacts the molecular regulation of TNF- α expression at each level of control in macrophages, resulting in an enhanced initiation of inflammation in the liver^[10]. Ethanol mediates these changes in the activation of Kupffer cells by a profound dysregulation in TLR4-initiated signal transduction^[10]. Interestingly, many of the same signaling pathways targeted by ethanol in neurons, resulting in the complex behavioral effects of ethanol, are also involved in TLR4-mediated signal transduction in macrophages. Briefly, LPS binds to a cell surface receptor, CD14, which, *via* interactions with TLR4^[31], stimulates a complex array of signal transduction cascades^[32,33]. Stimulation of macrophages with LPS activates tyrosine kinases, protein kinase C, nuclear factor κ B (NF κ B), as well as members of the mitogen-activated protein kinase family, including extracellular signal-regulated kinase 1/2 (ERK1/2), p38 and c-jun N-terminal kinase^[32]. Chronic ethanol feeding generally enhances these activation pathways, including increased LPS-stimulated phosphorylation of ERK1/2 and p38^[34-36] and NF κ B activation^[37].

Role of ROS in increased cytokine expression

Increased production of ROS during chronic ethanol exposure, either by hepatocytes during ethanol metabolism^[38] and/or from Kupffer cells during ethanol exposure^[39] and in response to LPS^[40], may contribute to this sensitization in LPS-dependent signal transduction.

ROS play a critical role in the modulation/regulation of a number of signal transduction cascades^[41], including LPS-stimulated signaling pathways both in cells of the innate immune system (monocytes/macrophages, neutrophils, *etc.*) and non-immune cells^[42-44]. Indeed, we have specifically identified NADPH oxidase-derived ROS as an important contributor to LPS-stimulated ERK1/2 phosphorylation in rat Kupffer cells, particularly after chronic ethanol^[45]. Taken together, these data suggest that the chronic ethanol-induced increase in ROS is an important contributor to the dysregulation of LPS-mediated signal transduction and inflammatory cytokine production in Kupffer cells.

Clinical implications of enhanced initiation of inflammation after chronic ethanol exposure

While the role of TNF- α in the development of ethanol-induced liver injury has been well characterized in animal models^[17], clinical investigations of the therapeutic efficacy of antibodies to TNF- α (e.g. infliximab) to treat patients with acute alcoholic steatohepatitis have generated variable results^[46,47]. There is particular concern about side effects of completely inhibiting TNF- α function. For example, since TNF- α is a critical component of immunity, infectious disease is a primary concern during anti-TNF- α therapy^[47,48]. Moreover, TNF- α is required for normal liver regeneration; hepatocyte proliferation in response to injury is impaired in mice lacking TNF- α receptors^[49]. Therefore, therapeutic strategies to normalize, rather than eliminate, TNF- α expression in ALD are more likely to be safe and effective. Interventions that re-establish normal homeostatic control of initiation and resolution of innate immune responses in liver would allow for maintenance of normal immune function and repair of hepatocyte injury during treatment to resolve ALD.

RESOLUTION OF INFLAMMATION: ROLE OF ANTI-INFLAMMATORY MEDIATORS

The controlled and appropriate resolution of inflammation is an essential feature of the innate immune response; failure to terminate an inflammatory response likely contributes to a number of chronic inflammatory diseases, including ALD^[7]. Importantly, the resolution of inflammation is an active, highly coordinated response. Indeed, inflammatory signals initiate the induction of negative regulators. During ethanol exposure, despite high expression of inflammatory mediators, the resolution phase is not functionally appropriate. Understanding the mechanisms for the failure to resolve inflammation, and the identification of effective anti-inflammatory pathways that can be upregulated in the context of chronic ethanol exposure are likely to lead to therapeutic strategies to treat, as well as prevent, ALD.

The mechanisms for resolution of an inflammatory response are complex, requiring the elimination of infiltrating neutrophils, as well as a normalization of

macrophage numbers and activity^[50]. Within the context of this review, we will focus our attention on the identification of specific intrinsic pathways that normalize the increased pro-inflammatory activity of Kupffer cells after chronic exposure to ethanol. In order for a particular anti-inflammatory pathway to have potential therapeutic value, it must remain functional after chronic ethanol exposure, must target the specific pro-inflammatory pathways enhanced by ethanol and must contribute to the prevention of hepatocellular injury. Finally, the pathway must be amenable to therapeutic intervention.

Ethanol and adiponectin

Recent studies have explored the potential of adiponectin, an abundant 30 kDa adipokine with potent anti-inflammatory properties, as a useful anti-inflammatory to exploit in the treatment of ALD. Treatment of mice with supra-physiological concentrations of adiponectin during chronic ethanol exposure prevented the development of liver injury, decreasing both steatosis and TNF- α expression in the liver^[51]. You *et al.*^[52] have recently reviewed the molecular mechanisms for the anti-steatotic effects of adiponectin in liver. In hepatocytes, activation of a SIRT1-AMPK (sirtuin 1-AMP-activated protein kinase) pathway appears to be critical in decreasing ethanol-induced lipid accumulation in the liver^[52].

Adiponectin also normalizes LPS-induced TNF- α production in primary cultures of Kupffer cells after chronic ethanol exposure^[53]. Interestingly, the anti-inflammatory effects of adiponectin appear to be mediated by either globular adiponectin (gAcrp) or full-length adiponectin^[53]. This may be due, at least in part, to the ability of macrophages to cleave full-length adiponectin to its globular form^[54]. gAcrp signals primarily *via* adiponectin receptor 1 in Kupffer cells^[55]. In contrast to the predominant role of AMPK in mediating the effects of adiponectin in hepatocytes^[52], gAcrp activates multiple signaling pathways in macrophages, including the mitogen-activated protein kinase family members, NF κ B and protein kinase A^[56]. Together, activation of these signaling pathways culminates in the expression of anti-inflammatory mediators, including interleukin (IL)-10^[56].

Despite the efficacy of adiponectin in decreasing LPS-mediated responses, both in mouse models and primary cultures of Kupffer cells, the development of adiponectin for therapeutic interventions in patients with ALD is likely of limited utility, because of the high concentration of adiponectin in the circulation, as well as the complex oligomeric structure of adiponectin. Therefore, investigators have begun to focus either on mechanisms to increase endogenous adiponectin expression, such as treatment of mice with rosiglitazone^[57], as well as on the identification of downstream molecular targets of adiponectin in the liver. Recent studies in Kupffer cells have identified an adiponectin-mediated IL-10/heme oxygenase-1 (HO-1) pathway involved in the anti-inflammatory effects of adiponectin in macrophages that may be more amenable to pharmacological intervention.

IL-10/HO-1 pathway

IL-10 is an immunomodulatory cytokine with potent anti-inflammatory properties. IL-10 decreases production of pro-inflammatory cytokines, including TNF- α and IL-1 β ^[58]. While little is known about the regulation of IL-10 expression and activity in the liver in response to chronic ethanol, studies show that impaired expression of IL-10 contributes to inflammation in alcoholic cirrhotics^[59] and IL-10 deficient mice are more sensitive to ethanol-induced liver injury^[60]. Drechsler *et al.*^[61] found that treatment with IL-10 reduced the acute effects of ethanol in monocytes in an HO-1 dependent mechanism.

We have recently identified an IL-10/HO-1 mediated pathway that can be activated in Kupffer cells after chronic ethanol feeding and suppresses LPS-stimulated TNF- α expression^[55]. IL-10 mediates its anti-inflammatory functions *via* induction of IL-10-inducible genes, including HO-1, suppressor of cytokine signaling 3 and BCL3^[58]. There is a growing appreciation that HO-1, in particular, is an important downstream mediator of the anti-inflammatory effects of IL-10 in macrophages^[58]. Interestingly, induction of HO-1 by Kupffer cells after chronic ethanol is particularly robust^[55]; siRNA knockdown or chemical inhibition of HO-1 in Kupffer cells demonstrates that HO-1 is critical to the suppression of TLR4-stimulated TNF- α expression in response to either adiponectin or IL-10 after chronic ethanol exposure^[55].

HO-1 plays an important anti-inflammatory role in a number of chronic inflammatory diseases, and also has anti-apoptotic and anti-proliferative properties^[62]. HO-1 is a 288 amino acid protein that is anchored in the endoplasmic reticulum, although localization of a cleaved form of HO-1 has also been observed in the nucleus under some conditions^[63]. HOs catalyze the initial and rate limiting step in the oxidative degradation of heme, yielding equimolar amounts of biliverdin IX α , carbon monoxide (CO), and free iron^[64]. Three isoforms of the HO protein have been identified, which are encoded by separate genes. HO-2 and HO-3 are constitutive forms, while HO-1 (also known as heat shock protein 32) is an inducible isozyme, with high expression levels in spleen and Kupffer cells^[65]. HO-1 is a stress-responsive protein whose expression is upregulated by a broad spectrum of inducers, including heme, heavy metals, nephrotoxins, cytokines, endotoxins and oxidative stress.

Surprisingly, acute and chronic ethanol exposure do not increase HO-1 expression in Kupffer cells or in the liver^[55]. However, this may be dependent on the age of the animals studied^[66,67]. While ethanol does not increase HO-1 expression, several recent studies suggested that induction of HO-1, as well as increasing concentrations of its downstream mediator CO, prevents ethanol-induced inflammation in the intestine^[68] and liver^[55], as well as oxidative damage to hepatocytes^[69] and hepatocyte apoptosis. Importantly, induction of HO-1 in mice after chronic ethanol exposure by treatment with cobalt-protoporphyrin-IX normalizes LPS-induced TNF α expression in the liver^[55].

HO-1: downstream anti-inflammatory mediators

Induction of HO-1 plays a key role in mediating cellular protection against the insult of oxidants both *in vitro* and *in vivo*^[62]. *In vivo* expression of HO-1 has potent protective effects against atherogenesis, acute cardiac ischemic failure, ischemia/reperfusion injury in liver, as well as hyperoxia-induced liver injury^[62]. The exact mechanisms involved in the anti-inflammatory effects of HO-1 are poorly understood. Recent studies suggested that 2 of the break-down products of heme generated by HO-1, i.e. CO and biliverdin (and its breakdown product bilirubin), are each potential mediators of HO-1 activity^[62]. Release of free iron by HO-1 typically induces the expression of ferritin, which can also have protective properties. In Kupffer cells from ethanol-fed rats, we find that treatment with the CO donor, CORM-2 (CO-releasing molecule), was sufficient to decrease LPS-stimulated TNF- α expression^[55], suggesting CO has strong anti-inflammatory effects in Kupffer cells after chronic ethanol feeding.

CO is also an important regulator of a number of signaling pathways that regulate hepatic metabolism and inflammatory responses, including MAPK family members, peroxisome proliferator-activated receptor- γ , Egr-1 and adenosine 2A receptor^[70-72]. Each of these signaling pathways is also a target of chronic ethanol in hepatocytes and/or Kupffer cells.

CONCLUSION

Considering the strong association between ethanol-mediated activation of the innate immune system and ALD, it is critical to understand the mechanism(s) by which ethanol disrupts the intricately regulated innate immune response. Characteristically, the innate immune response involves both a rapid, yet transient, activation; the transient nature of the innate immune response contributes to an appropriate resolution of inflammation^[50,73]. In the past, studies have focused primarily on the impact of ethanol on activation of the innate immune response *via* production of pro-inflammatory mediators. However, recent studies suggest that ethanol must also impair the “anti-inflammatory” responses elicited during inflammation, thus delaying and/or impairing the resolution of the inflammatory response. Impaired resolution of inflammation contributes to chronic inflammatory states^[6]. Recent studies have demonstrated that induction of HO-1 in primary cultures of Kupffer cells isolated from rats after chronic ethanol exposure normalizes chronic ethanol-induced sensitization to LPS^[55]. Importantly, HO-1 induction also normalizes LPS-stimulated TNF- α expression, as well as hepatocyte apoptosis, in an *in vivo* mouse model of chronic ethanol exposure^[55]. We hypothesize that the development of therapeutic agents to regulate these HO-1-activated pathways will enhance the resolution of inflammation during ALD and prevent progression of early stages of liver injury.

Abstract

Hepatitis C virus (HCV) is one of the main etiological factors responsible for liver disease worldwide. It has been estimated that there are over 170 million people infected with HCV worldwide. Of these infected individuals, approximately 75% will go on to develop a life long necroinflammatory liver disease, which over decades, can result in serious complications, such as cirrhosis and hepatocellular carcinoma. Currently there is no effective vaccine and whilst antiviral therapies have been improved, they are still only effective in approximately 50% of individuals. HCV infection stands as a major cause of global morbidity and suffering, and places a significant burden on health systems. The second highest cause of liver disease in the western world is alcoholic liver disease. Frequently, HCV infected individuals consume alcohol, and the combined effect of HCV and alcohol consumption is deleterious for both liver disease and response to treatment. This review discusses the impact of alcohol metabolism on HCV replication and the negative impact on interferon (IFN)- α treatment, with a particular focus on how alcohol and HCV act synergistically to increase oxidative

stress, ultimately leading to exacerbated liver disease and a reduction in the efficacy of IFN- α treatment. A better understanding of the complicated mechanisms at play in hepatocytes infected with HCV and metabolizing alcohol will hopefully provide better treatment options for chronic hepatitis C individuals that consume alcohol.

INTRODUCTION

Hepatitis C virus (HCV) has emerged as a significant human pathogen worldwide and is now the most common cause of significant liver disease in many countries^[1]. Although the disease is typically not severe in the acute phase, more than 70% of infected individuals develop a persistent infection that, over the course of 2-3 decades, can result in progressive hepatic fibrosis and loss of functioning hepatocyte mass^[2,3]. A proportion of infected individuals will develop cirrhosis and eventually hepatocellular carcinoma (HCC)^[4,5]. This progressive liver disease is thought to arise as a result of the chronic inflammatory response to clear HCV infected hepato-

cytes, resulting in an environment that is favorable for the fibrogenic process^[6].

There are numerous clinical studies that suggest a strong epidemiological link between the consumption of alcohol and accelerated liver disease in HCV infected individuals^[7-9]. The majority of alcohol metabolism takes place in hepatocytes, which is also the primary site of HCV replication, and thus it is logical that interactions between the two will occur, both at the clinical and molecular level. The majority of studies have concluded that HCV infected individuals that consume alcohol show a strong propensity for accelerated liver disease, and that alcohol metabolism and concurrent HCV infection act synergistically to facilitate this rapid disease progression^[7-11]. In fact, excessive alcohol consumption is now a recognized co-factor in liver disease progression, and persons infected with HCV are recommended to limit their alcohol intake^[12]. Despite strong epidemiological evidence, the molecular mechanisms by which alcohol consumption exacerbates chronic hepatitis C (CHC) remain unclear. Furthermore, the interactions between alcohol metabolism, HCV, and the host antiviral immune response are also unknown. Clearly, the relationship between alcohol and HCV is complex, and the mechanisms responsible for accelerated disease progression are most likely not related to a single factor, but are the result of alterations to hepatocyte homeostasis, production of cytokines, and modification of the immune system.

This review will focus on the role that alcohol metabolism has on HCV RNA replication and discuss the potential molecular mechanisms responsible, with a particular focus on oxidative stress. The effect of alcohol on interferon (IFN)- α action and its modulation of signal transduction pathways will also be discussed.

ALCOHOL CONSUMPTION ACCELERATES HCV RELATED LIVER DISEASE

One of the first reports documenting the role of alcohol consumption on CHC progression was published by Seeff *et al*^[5], in which they reported that two thirds of HCV positive patients that died from end stage liver disease were chronic consumers of alcohol. Poynard *et al*^[4] extended this study, showing that the consumption of 50 g/d of alcohol increased the rate at which fibrosis progresses in HCV infected individuals. They also identified three independent risk factors that were associated with increased rates of fibrosis: age greater than 40 years at time of infection, being male, and consuming more than 50 g of alcohol per day. At the virological level, Pessione *et al*^[8] found a direct dose dependent correlation between increasing HCV RNA levels and increasing levels of alcohol consumption. The mechanism for this increase was not established, but it was postulated that the increase in HCV RNA could be due to a direct effect of alcohol increasing viral replication or through reduced clearance of the virus by the immune system. One of the most comprehensive studies investigating

the effect of alcohol on HCV disease progression was performed by Corrao *et al*^[9], in which they studied a large cohort of 417 patients. The most striking finding of this study was a comparison of the associated risk factors for developing cirrhosis between HCV infected patients that abused alcohol and those that abstained. The risk factor for developing cirrhosis in patients that were HCV positive but did not consume alcohol was 9, compared to a significantly higher risk factor of 147 for those patients that abused alcohol. This study added further weight to the hypothesis that HCV and alcohol metabolism synergistically contribute to exacerbated liver disease.

There have been a number of studies that have documented a clear link between excess alcohol consumption and an increased risk of HCC development. It has been suggested that HCV infected individuals that consume alcohol show a 100-fold increase in their risk of developing HCC^[13-18]. Clearly, chronic consumption of alcohol in HCV infected individuals is a dangerous mix, with significant clinical implications.

ALCOHOL AND HCV INDUCE OXIDATIVE STRESS

Reactive oxygen species (ROS) are defined as small highly reactive oxygen-containing molecules that cause oxidative stress when the rate at which they are produced is greater than the rate at which they are removed, leading to a disturbance in the pro-oxidant/anti-oxidant balance. Cytochrome P450-2E1 (CYP2E1) metabolism of alcohol stimulates the microsomal production of ROS, such as superoxide anions (O₂⁻), hydroxyl radicals (OH[•]), 1-hydroxyethyl radicals (CH₃CHOH[•]), lipid hydroperoxides (LOOH), and (when iron levels increase due to alcohol metabolism) the production of ferryl radicals^[19]. Oxidative stress can potentially lead to cellular damage that can play a role in a variety of pathological conditions^[20]. The generation of hepatic oxidative stress in CHC is now well established, and most likely a consequence of HCV proteins disrupting mitochondrial and hepatocyte organelle function, in addition to the inflammatory response directed towards HCV infected hepatocytes. Under normal conditions, oxidative stress exists in a state of equilibrium with cellular antioxidants that scavenge ROS and prevent cellular injury. However, when cellular antioxidant mechanisms are overwhelmed through chronic oxidative stress or disease processes, oxidative stress production continues unchecked, with pathological consequences. This chronic exposure of the liver to oxidative stress in CHC has significant clinical implications, as it is well documented that oxidative stress is a mediator of hepatic inflammation, fibrosis, and the development of HCC^[21].

One of the most significant mediators of oxidative stress in the liver is the metabolism of alcohol by the enzyme CYP2E1. Metabolism of alcohol can also occur *via* the other main alcohol metabolizing enzyme

alcohol dehydrogenase (ADH). Whilst ADH-mediated metabolism of alcohol does produce ROS, CYP2E1-mediated metabolism of alcohol produces levels of ROS that greatly exceed that of the ROS produced by ADH. Alcohol metabolism not only directly produces ROS, but it also creates an environment that is favorable for oxidative stress. It is becoming increasingly clear that oxidative stress plays a prominent role in the pathogenesis of alcohol-induced liver disease^[22] and CHC^[21]. It is therefore not difficult to envisage the potentially explosive situation where oxidative stress produced by HCV and alcohol leads to a synergistic exacerbation of liver disease.

HCV INFECTION INDUCES A STATE OF OXIDATIVE STRESS

While clinical studies have suggested that markers of oxidative stress are increased in CHC, it was the development of mice transgenic for the HCV core protein that clearly demonstrated that HCV directly induces a state of oxidative stress^[23]. Mice expressing either the HCV core or the complete HCV polyprotein developed pathologies consistent with those observed in human HCV infection^[23,24], such as steatosis and development of HCC. Prior to HCC development, the HCV core-expressing mice showed a marked increase in lipid peroxidation and activation of the anti-oxidant system, suggesting that the expression of HCV core is sufficient to induce oxidative stress in the mouse liver and initiate HCC through DNA damage and modulation of signaling cascades^[23]. It was subsequently shown *in vitro* that HCV core expression results in increased generation of ROS and expression of antioxidant enzymes^[25-27]. Mechanistically, it was shown that this increase in oxidative stress was due to interactions between HCV core and destabilisation of the mitochondrial electron transport chain and that this was further enhanced in the presence of alcohol^[28,29].

In addition to the core protein, the HCV nonstructural protein non-structural 5A (NS5A) has also been demonstrated to increase cellular ROS, albeit through a different mechanism to that of the HCV core. HCV NS5A localizes to the endoplasmic reticulum (ER) and lipid droplets, and is part of the HCV replication complex that results in the formation of altered cytoplasmic membrane structures, known as the membranous web. It has been postulated that this change in the membrane structure results in ER stress and the unfolded protein response, leading to the release of ER Ca²⁺ stores and resulting in the formation of oxidative stress^[30]. Expression of ectopic NS5A results in oxidative stress, and NS5A-induced transcriptional activation can be blocked by the treatment of cells with the free radical scavenger pyrrolidine-2,4-dicarboxylate acid and N-acetyl-cysteine (NAC)^[31], suggesting that NS5A induces a state of oxidative stress in the cells. However, these studies should be interrupted with caution, as they are reliant on ectopic

over-expression of HCV proteins in the absence of the complete repertoire of HCV proteins and RNA replication. However, Huh-7 cells harboring the HCV replicon do induce a state of oxidative stress^[32,33]. Thus, it is logical to hypothesize that HCV replication and alcohol metabolism lead to a synergistic increase in hepatic oxidative stress that contributes to accelerated liver disease.

ALCOHOL MODULATES HCV REPLICATION

As previously outlined, there is clinical evidence to suggest that alcohol metabolism increases HCV replication and modulates the host response to HCV^[4,7,8]. While the exact molecular mechanisms are unclear, there have been a number of postulated mechanisms, such as (1) an alcohol-induced increase in HCV RNA replication; (2) enhancement of HCV quasispecies complexity; (3) modulation of the immune system; and (4) synergistic increase in ROS. However, pinpointing the precise mechanism of how alcohol and HCV interact in the laboratory has been hampered by the lack of a small animal model of HCV pathogenesis and, until recently, the inability to culture the virus. However, the recent development of a fully permissive cell culture system for HCV has been a significant advancement for the study of HCV biology^[34]. This is further compounded by the fact that hepatocyte-derived cell lines (including the Huh-7 cell line that is permissive for HCV replication) do not express the alcohol metabolizing enzymes ADH and CYP2E1 in culture. However, numerous studies have been conducted using non-CYP2E1/ADH hepatocyte derived cell lines to determine the impact of alcohol on HCV replication, often with conflicting conclusions. To overcome this limitation, hepatocyte derived cell lines have been engineered to express CYP2E1^[19], including Huh-7 cell lines that support HCV replication and metabolize alcohol^[32]. These cells provide a useful tool to study the molecular interactions between alcohol metabolism and HCV.

There are conflicting reports surrounding the role of alcohol metabolism on HCV replication *in vitro*, which most likely reflects the different model systems used in different laboratories. Using HCV replicon cell lines that constitutively express CYP2E1 (replicon cells constitutively replicate HCV RNA under the control of an antibiotic selection marker, but do not produce infection virus particles), it was shown that physiological concentrations of alcohol (0-100 mmol/L) resulted in a CYP2E1-dependent increase in HCV RNA levels, 72 h following alcohol stimulation^[32]. This alcohol-induced increase in replication was blocked in the presence of the anti-oxidant NAC, strongly suggesting that oxidative stress plays a central role in this alcohol-induced effect. Furthermore, consistent with the data suggesting that HCV induces a state of oxidative stress alone, NAC reduced HCV replication by 50% in both HCV replicon cell lines and Huh-7 cells infected with HCV cell

culture derived virus (JFH-1) (Beard MR, personal communication). Therefore, it is conceivable that HCV uses oxidative stress to its replicative advantage. Moreover, when the infectious HCV JFH-1 virus was used to infect CYP2E1 expressing Huh-7 cells, treatment with alcohol also resulted in a significant increase in HCV (JFH-1) replication (Beard MR, personal communication). Collectively, these results suggest that CYP2E1-mediated metabolism of alcohol results in an increase of HCV replication, at least *in vitro*, and are consistent with the clinical observations described earlier. In contrast, CYP2E1-independent, alcohol-induced increases in HCV replication have been reported using the HCV replicon system^[35,36]. Conversely, it was shown that a single dose of acute ethanol exposure inhibits HCV replication^[37]. There are several methodological issues that explain these apparent discrepancies. Firstly, Huh-7 cells are different between laboratories and it is possible that low basal levels of CYP2E1/ADH exist. Secondly, there are significant differences in these studies in regards to experimental design that could account for the differences noted. For example, significant differences may occur depending on whether experimental conditions mimic acute or chronic exposure to ethanol. Acute alcohol metabolism results in a rapid increase in cellular ROS and it is possible that this burst of oxidative stress can inhibit replication^[38,39]. This correlates with unpublished findings in our laboratory, where the treatment of HCV replicon cells and HCVcc (JFH-1) infected Huh-7 cells with H₂O₂, to induce an acute burst of oxidative stress, results in a decrease in HCV replication, although chronic exposure to alcohol increases HCV replication. We have also shown in our laboratory that there is a bi-phasic effect of alcohol metabolism on HCV replication, suggesting that perhaps moderate levels of oxidative stress stimulate replication whereas more pronounced levels of oxidative stress could repress replication^[32].

The molecular mechanism whereby ROS modulates HCV replication is unknown. However, ROS have the ability to act as potent second messengers and activate cellular transcription factors, such as STAT3, nuclear factor κ B, NF-AT, and AP-1^[31,40]. Interestingly, it has been reported that ROS induced by HCV replication *in vitro* can activate the transcription factor STAT3, which can, in turn, lead to the stimulation of STAT3-dependent genes that are capable of creating a cellular environment favourable for HCV replication^[41]. Our laboratory has also shown this HCV/ROS increase in STAT3 activation. Expression of a constitutively active STAT3 molecule increases HCV replication, while conversely, specific inhibitors of STAT3 (AG490 and STA-21) cause significant decreases in replication (Beard MR, unpublished results). Clearly, the role of STAT3 and STAT3-dependent gene expression warrants further investigation.

However, not all studies implicate ROS in the increase in HCV replication following alcohol stimulation. Seronello *et al.*^[42] suggested that metabolism of alcohol modulates host lipid metabolism, thus, potentiating

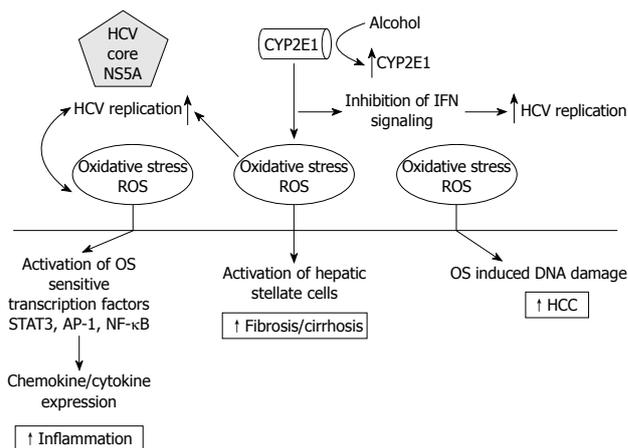

Figure 1 Proposed model of hepatitis C virus (HCV)/alcohol interactions in hepatocytes. Metabolism of alcohol by cytochrome P450-2E1 (CYP2E1) and HCV replication leads to a synergistic induction of oxidative stress in the cell. Oxidative stress inhibits interferon (IFN)- α signalling and also leads to increased rates of inflammation, cirrhosis, and hepatocellular carcinoma (HCC). NS5A: Non-structural 5A; NF- κ B: Nuclear factor κ B; ROS: Reactive oxygen species.

HCV replication. Obviously, the interactions between HCV and alcohol metabolism is a complex and multifactorial process (Figure 1), and further investigations are required to ascertain the role of the alcohol-induced modulation of HCV replication.

EFFICACY OF IFN- α IN THE PRESENCE OF ALCOHOL METABOLISM

IFN- α 2b/Ribavirin combination therapy is the current and only treatment strategy for CHC. Whilst the exact mode of IFN- α action is not well understood, IFN- α therapy is thought to result in the induction of interferon-stimulated genes (ISGs), many of which have antiviral activity. The binding of IFN to its cellular receptor results in rapid autophosphorylation and activation of receptor-associated Janus activated kinases (JAKs), TYK2 and JAK1, and activation of the JAK/STAT signaling cascade^[43]. TYK2 and JAK1 phosphorylate tyrosine residues on the cytoplasmic tail of the receptor, this provides docking sites for the signal transducer and activator of transcription (STATs), which are latent cytoplasmic transcription factors that transduce signals from the cell surface to the nucleus, where they directly regulate transcription. STAT1 is phosphorylated at tyrosine residue 701 (Y-701) and STAT2 at tyrosine residue 690 (Y-690). Once phosphorylated, STAT1 and STAT2 then form active heterodimers and translocate to the nucleus where they directly activate transcription *via* the multi component transcription factor ISG factor 3, which binds to the interferon-stimulated response element (ISRE), a cis-acting DNA element found in the promoters of the majority of type I IFN genes. Within the nucleus, STAT-1 is further phosphorylated on serine residue 727, resulting in an increase in the transcriptional activation ability of this complex. The end step of this signaling cascade cul-

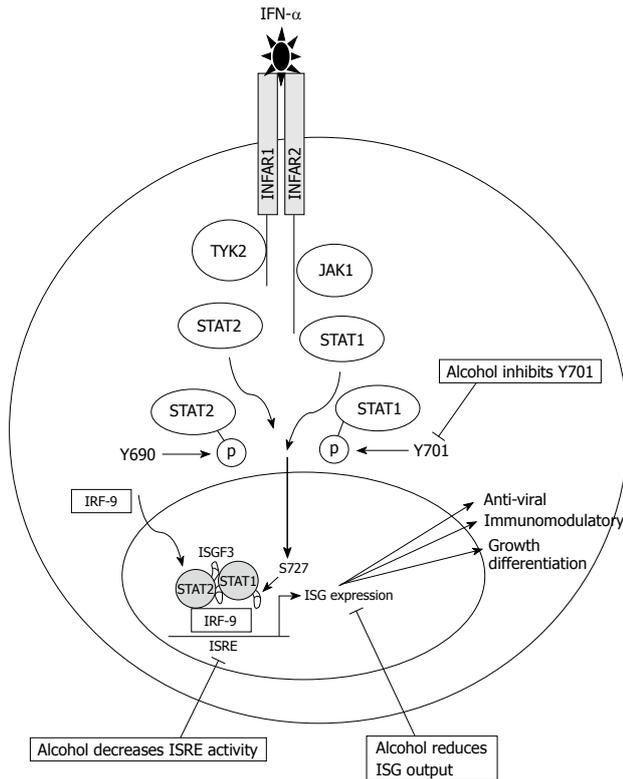

Figure 2 IFN- α signal transduction. Binding of IFN- α to its cognate receptor on the cell surface results in activation of the Janus activated kinase (JAK)/STAT signaling pathway culminating in the production of interferon-stimulated genes (ISGs), many of which have anti-viral properties that act to limit HCV infection. Alcohol inhibits Y701, decreases interferon-stimulated response element (ISRE) activity, and subsequently dampens the ISG response.

minates in the transcriptional activation of hundreds of ISGs. These produce anti-viral proteins capable of limiting HCV replication in hepatocytes and modulating the immune response (Figure 2). As mentioned previously, it is a well established clinical observation that alcohol consumption reduces the efficacy of IFN treatment^[7]. The molecular basis that underlies the reduced anti-viral capacity of IFN- α in the presence of alcohol metabolism remains to be established; however, evidence suggests that alcohol might directly inhibit the actions of IFN- α in patients at the signaling level.

In combination with the effect of alcohol on HCV replication and accelerated disease progression, alcohol metabolism also decreases the efficacy of IFN- α . Patients who consume alcohol do not respond effectively to IFN- α therapy and for this reason alcohol consumption is contraindicated during IFN- α treatment. There have been numerous studies confirming that alcoholics do not respond well to IFN- α therapy. Mochida *et al*^[44] showed that less than 10% of alcoholic patients responded to IFN- α therapy. Loguercio *et al*^[45] showed a direct relationship between alcohol consumption and response to treatment, with the numbers of patients achieving a sustained virological response decreasing as alcohol consumption increased. Safdar *et al*^[7] recently published their findings that alcohol abuse decreases response to IFN treatment in HCV patients and there-

fore, it is recommended that HCV infected patients abstain from alcohol consumption whilst on treatment. A number of studies have shown that alcohol metabolism directly interferes with IFN signaling, indicating that the consumption of alcohol could directly inhibit IFN- α treatment in patients. However, there has been some recent evidence indicating that the high non-compliance rate of alcoholics adhering to treatment programs could account for the reduced response rates of alcoholic patients in the literature^[46]. Whilst this is certainly a contributing factor, it does not detract from the strong *in vitro* data showing that alcohol has a direct inhibitory effect on IFN- α signaling. These studies have implications not only for IFN- α treatment, but also for the activity of endogenously produced type I and II IFN's (IFN- α , β , and γ , respectively) that might result in a weakened host response to HCV infection.

ALCOHOL AND IFN- α SIGNALING

There are a number of reports investigating the effects of HCV on IFN- α signaling, suggesting that HCV negatively impacts on IFN- α signaling^[47-51]; however, there are a limited number of studies investigating the combined effects of HCV and alcohol metabolism on IFN- α signaling. Insights into the effect of alcohol metabolism on IFN- α signaling can be gleaned from the study conducted by Osna *et al*^[52], in which the effects of alcohol metabolism by ADH and CYP2E1 on IFN- γ signal transduction were investigated. This study documented a decrease in STAT1 tyrosine phosphorylation in the presence of alcohol metabolism, suggesting that alcohol can effectively dampen the IFN signaling cascade. The most comprehensive study investigating the effects of alcohol and HCV replication on IFN signaling was conducted by Plumlee *et al*^[57]. This study showed that acute treatment of HCV genomic replicon cells with ethanol lead to the inhibition of the anti-HCV effects of IFN and interestingly, caused a decrease in STAT1 tyrosine phosphorylation, but induced STAT1 serine phosphorylation. This study also showed induction of ISRE promoter activity in the presence of alcohol, which is somewhat contradictory to their finding that IFN signaling was abrogated. It has also been documented that the oxidative stress generated *via* the treatment of Huh-7 cells with H₂O₂, disrupted the JAK-STAT signaling pathway specifically, by blocking STAT1, STAT2, JAK1, and TYK2 tyrosine phosphorylation^[53]. More recently it has been shown that alcohol metabolism decreases the efficacy of IFN- α *in vitro* in genomic replicon cells that express CYP2E1^[52]. In this study, alcohol metabolism preferentially inhibited STAT1 tyrosine phosphorylation at residue 701 (Y701), the critical residue required for STAT1 heterodimerisation with STAT2^[52]. These findings suggest that a decrease in STAT1-Y701 phosphorylation due to alcohol metabolism would decrease downstream ISG expression and, in part, explain the reduced efficacy of IFN- α in HCV positive patients that consume alcohol. Consistent with

this finding, a decrease in ISRE activity in the presence of alcohol metabolism was also observed^[32] and a number of anti-viral ISGs have been shown to be downregulated by alcohol metabolism (Beard MR, unpublished findings). Collectively, these studies suggest that alcohol can specifically inhibit IFN- α at the molecular level.

Clearly, the factors at play in the alcohol-induced suppression of IFN signaling in the background of HCV replication are multifactorial and complicated in an infected patient. It is also possible that alcohol can inhibit other components of the cellular innate immune response, such as components of the cellular recognition of viral pathogen-associated molecular patterns, and by activation of the toll-like-receptor-3 and the retinoic acid-induced gene-1 pathways. Another possibility is that alcohol might modulate SOCS-1 and -3, which are part of a negative feedback loop that acts to suppress IFN-signaling. It has been shown using a concanavalin-A model of hepatitis in mice that activated STAT3 plays an important role in inducing SOCS-3^[54]. Interestingly, as outlined previously, we have been able to demonstrate that both alcohol metabolism and HCV replication are capable of activating STAT3, and it appears that this increase is due to oxidative stress.

CONCLUSION

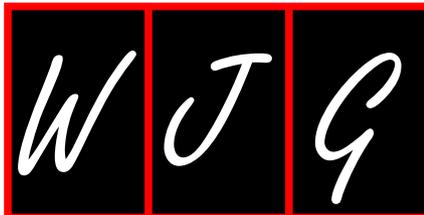

In summary, it is well established clinically that chronic alcohol consumption in the setting of CHC is a dangerous combination leading to exacerbated liver disease. While the factors that lead to increased liver disease are complex, it seems that a common thread throughout many investigations is the generation of oxidative stress by both alcohol metabolism and HCV replication. Thus, it is a logical conclusion that HCV and alcohol metabolism act synergistically to accelerate disease progression *via* oxidative stress. In an attempt to understand these processes we have developed a model to portray these interactions (Figure 1). Evidence suggests that this oxidative stress synergy impacts on HCV replication and the antiviral action of IFN- α , although we are waiting for the development of a small animal model to confirm these *in vitro* observations. Defining the molecular mechanisms and complex interactions between HCV and alcohol will further our understanding of the pathogenic role alcohol plays in CHC development and hopefully lead to novel therapeutic strategies and patient management.

Abstract

This article reviews the evidence that ties the development of hepatocellular carcinoma (HCC) to the natural immune pro-inflammatory response to chronic liver disease, with a focus on the role of Toll-like receptor (TLR) signaling as the mechanism of liver stem cell/progenitor transformation to HCC. Two exemplary models of this phenomenon are reviewed in detail. One model applies chronic ethanol/lipopolysaccharide feeding to the activated TLR4 signaling pathway. The other applies chronic feeding of a carcinogenic drug, in which TLR2 and 4 signaling pathways are activated. In the drug-induced model, two major methyl donors, S-adenosylmethionine and betaine, prevent the upregulation of the TLR signaling pathways and abrogate the stem cell/progenitor proliferation response when fed with the carcinogenic drug. This observation supports a nutritional approach to liver cancer prevention and treatment. The observation that upregulation of the TLR signaling pathways leads to liver tumor formation gives evidence to the popular concept that the chronic

INTRODUCTION

What is the mechanism that explains how alcohol abuse increases the risk of hepatocellular carcinoma (HCC) in hepatitis C, hepatitis B, diabetes^[1], hemochromatosis^[2], and α -1 antitrypsin deficiency^[3]? Evidence is emerging that the synergism is due to an activation of a common pathway in which Toll-like receptor (TLR) signaling induces pro-inflammatory cytokine production through nuclear factor (NF)- κ B activation and growth factors through activation of activator protein 1 (AP-1). A model of chronic ethanol feeding has been used as follows. Transgenic mice with hepatitis C non-structural 5A (NS5A), the NS5A protein of hepatitis C virus (HCV), were fed ethanol chronically. This induced HCC formation and resembled clinical alcohol abuse and hepatitis C progression to HCC^[4].

Likewise, an experimental model of chronic drug toxicity, which induces HCC, resembles clinical drug-induced HCC^[5]. These experimental models are reviewed to help understand how the TLR signaling pathway leads to HCC formation, as a mechanism that is shared by the clinical and experimental models.

TLR SIGNALING PATHWAY IN CHRONIC LIVER DISEASE

There is emerging evidence that upregulation of the TLR signaling pathway occurs in many chronic liver diseases. Many different cell types in the liver express TLRs^[6]. Kupffer cells express TLR2, 3, 4 and 9. Hepatocytes express TLR2, 3, 4 and 5. Stellate cells express TLR4 and 9. Biliary epithelium expresses TLR2, 3, 4 and 5. Sinusoidal endothelium expresses TLR4. TLR-mediated signals result in hepatitis B, hepatitis C, alcoholic liver disease, non-alcoholic liver diseases, primary biliary cirrhosis, primary sclerosing cholangitis, hepatic fibrosis, ischemic-reperfusion injury and liver allograft rejection^[6].

HEPATITIS B

TLR2 is downregulated in hepatocytes, Kupffer cells and peripheral blood monocytes in hepatitis-B-antigen-positive patients^[6]. In hepatitis-B-e-antigen-negative patients, TLR2 expression and tumor necrosis factor (TNF)- α production is upregulated and probably mediated by pre-core proteins^[6].

HEPATITIS C

The HCV core and NS3 protein activate TLR2/TLR1 and TLR2/TLR6 on monocytes to produce inflammatory cytokines^[6]. Patients with hepatitis C lack tolerance to lipopolysaccharide (LPS). Marked upregulation of TLR2 and TLR4 have been observed in patients with chronic hepatitis C and were detected in hepatocytes, Kupffer cells, and peripheral monocytes. TLR2-mediated activation by hepatitis C may contribute to the pro-inflammatory cytokine activation^[7].

ALCOHOL LIVER DISEASE

Alcohol ingestion decreases the intestinal mucosal barrier to LPS, which activates TLR4 on Kupffer cells, which leads to pro-inflammatory cytokine production^[8]. Chronic alcohol consumption activates other TLRs, such as TLR1, 2 and 6-9, which further increases the TNF- α response to LPS in mice^[6]. Human monocytes exposed to ethanol for 7 d develop hypersensitivity to LPS through decreased IRAK-M expression and activation of NF- κ B and extracellular signal-regulated kinase (ERK)^[9]. IRAK-M is part of the cascade that activates NF- κ B and mitogen-activated protein kinase, initiated by TLR4 signaling.

CIRRHOSIS

TLR4 expression is downregulated in monocytes from patients with Child-Pugh C cirrhosis, which indicates LPS tolerance, because the expression returns to normal after antibiotic therapy^[6].

HCC

Mice deficient in TLR4 and MyD88 develop fewer and smaller liver tumors after treatment with a chemical carcinogen, which implies that TLR4-MyD88 signaling is involved in the development of liver tumors^[6]. This suggests that chronic inflammation that results from hepatitis C and TLR-induced increase in NF- κ B activation and TNF α production promotes tumor growth^[10].

ROLE OF TLR4 SIGNALING IN ETHANOL-FACILITATED TUMOR FORMATION IN THE NS5A TRANSGENIC MOUSE MODEL OF HCC CARCINOGENESIS

Ethanol feeding upregulates the TLR4-dependent, MyD88-independent signaling pathway in mice^[11], presumably by increasing endotoxemia due to gut leakage of LPS. TLR-4 upregulation in Kupffer and stellate cells occurs in mice fed ethanol for 1 mo using the intragastric tube feeding model^[12].

Machida *et al*^[4] have taken advantage of upregulation of the TLR4 signaling pathway induced by ethanol, to accelerate HCC formation in NS5A transgenic (NS5A Tg) mice. NS5A Tg mouse livers already overexpressed TLR4, but ethanol and LPS feeding increased the TLR4 signaling due to the endotoxemia caused by ethanol. LPS challenge killed 30% of the NS5A Tg mice, but not the wild-type mice or the NS5A Tg/TLR4^{-/-} mice. The NS5A Tg mice overreacted to LPS, with the development of massive hemorrhagic, necrosis, and inflammation. The TAK1-TRAF6 and TAK1-IRAK1 interactions in NS5A Tg mice given LPS were enhanced, but not enhanced in the wild-type or TLR^{-/-} mice. Phosphorylation of Jun N-terminal kinase (JNK) and I κ B α , two further downstream components of TLR4 signaling, was increased by LPS.

To determine whether TLR upregulation in the NS5A Tg mice was due to overexpression by Kupffer cells or hepatocytes, the Kupffer cells were depleted by injection of liposome-encapsulated clodronate 2 d before LPS injection. This reduced TLR4 activation by 35% in the NS5A Tg mice, and did not reduce the mortality, whereas, in wild-type mice, it reduced the TLR4 activation by 70% to 80%.

Machida *et al*^[4] have tested human liver from patients with hepatitis C, including those who abused alcohol. NS5A was increased in both groups of hepatitis C patients. NS5A expression in the liver from hepatitis C patients was about one-third of the level seen in the NS5A

Tg mice. TLR4, p-JNK, and p-1KB α were upregulated in the hepatitis C livers, which confirmed the clinical importance of TLR4 activation in NS5A Tg mice.

The question was: were the NS5A Tg mice more susceptible to alcohol-induced liver damage? The NS5A Tg mice were fed ethanol for 4 wk by intragastric tube together with wild-type, TLR4^{-/-} and TLR4^{-/-} NS5A Tg mice. The NS5A Tg mice fed ethanol developed higher alanine aminotransferase levels, and spotty liver necrosis with inflammatory cell infiltration. These liver injury markers did not occur in the TLR4^{-/-}/NS5A Tg mice fed ethanol, which confirmed the pathogenic role of TLR4 in this mouse model. LPS levels in the ethanol-fed mice were equally elevated. The liver injury, induced by ethanol feeding, was abrogated by feeding the antibiotics polymyxin B and neomycin, when ethanol-feeding-induced injury was augmented by feeding LPS weekly and ethanol daily. These results indicate the importance of endotoxin in activated TLR4 signaling in alcohol-fed NS5A Tg mice. Lipid peroxidation was increased in the alcohol-fed NS5A Tg mice, compared to the wild-type mice fed ethanol.

The NS5A Tg mice and the same three control groups, wild-type, TLR4^{-/-} and TLR4^{-/-} NS5A Tg mice, were fed the Lieber deCarli diet that contained ethanol for 12 mo to induce liver tumor formation. Liver tumors developed only in the ethanol-fed NS5A Tg mice. TLR4 signaling induced by NS5A and alcohol feeding was documented by showing an increased TAK1 interaction with TRAF6 and by elevation of pJNK and pIKB, which occurred only in the ethanol-fed mice. It was concluded that alcohol and NS5A synergistically induced liver tumors by enhancing the expression of TLR signaling.

To determine the molecular mechanisms that cause synergism between alcohol feeding and NS5A Tg mice, microarray analysis of livers was performed^[4]. The non-tumor areas of the NS5A Tg mice fed ethanol were compared with wild-type controls. Of the 83 genes that were changed > 4-fold, for example Nanog, TLR4 and interferon (IFN)- α 4 were upregulated. By immunofluorescent antibody staining, Nanog was colocalized with the stem cell markers CD133 and CD49f, which suggested that cancer stem cells were present in the non-tumor livers of the NS5A Tg ethanol-fed mice. The TLR4^{-/-} NS5A Tg mice fed ethanol did not develop Nanog-positive stem cells, which implied that the mechanism of stem cell and tumor induction was dependent on TLR4 signaling. To support this idea, NS5A Tg Huh7 cells treated with LPS upregulated the expression of Nanog, and this was reduced in TLR4 knockdown cells using shRNA. Overexpression of TLR4 in Huh7 cells increased the expression of Nanog in the presence of LPS^[4]. LPS increased the reporter activity in NS5A transduced Huh7 cells. The results indicate that the promoter of the Nanog gene is directly activated by TLR4 and that Nanog is a novel downstream gene of TLR4 signaling.

Further studies indicated that Nanog mediated the TLR-dependent liver tumor formation by hepatic progenitor cells^[4], using the hepatic progenitor cell transplant

model. Hepatoblasts were isolated from p53-deficient embryonic liver infected with a retroviral vector that expressed TLR4 or Nanog along with green fluorescent protein (GFP). The cells were transplanted into wild-type mice *via* the spleen. These mice were given three injections of CCl₄ to stimulate the establishment of the progenitor cells. After this, the mice were repeatedly injected with LPS several times a week for 25 wk. Liver tumors formed after 48-52 d, as judged by GFP imaging *in vivo* and by autopsy. Direct Nanog transduction in hepatic progenitor cells also produced tumors, but less than when LPS was injected subcutaneously into nude mice and GFP imaging was performed over 88 d. The TLR4-transduced mice began to form tumors 40 d after LPS treatment. These cells were p53^{-/-}^[4]. Silencing Nanog expression by Nanog shRNA delayed tumor formation. It was concluded that Nanog increases HCC formation by the TLR4-transduced progenitor cells, but Nanog alone does not confer the full oncogenic potential^[4].

If Nanog activation is not the whole story, what else is required to transform progenitor cells into HCC-promoting cells? It turned out that TLR4-dependent, Nanog-expressing HCC stem cells exhibited defective transforming growth factor (TGF)- β signaling^[13]. The TGF- β signaling pathway inhibits liver cell regeneration. It has been shown that the TGF- β defective pathway in mice insufficient for β 2 spectrin (β 2SP) leads to spontaneous development of HCC. Cancer stem cells from alcohol-fed NS5A Tg mice were examined for growth in soft agar. Their lentiviral cDNA library was created and tested for transformation of the oval cell line and screening for oncogenic genes. GFP-labeled cancer stem cells were injected into nude mice that were repeatedly injected with LPS after the initial stem cell injection, and tumor formation was followed by GFP imaging. The interaction of the TGF- β pathway with the TLR4-dependent oncogenic activity was studied. The cancer stem cells had upregulation of Nanog and sex determining region Y-box 2 (Sox-2). Tumors were formed in the nude mice, and knockdown of Nanog prevented tumor formation. The cancer stem cells were defective in the expression of TGF- β 1 and β 2SP. The TLR4 response element promoter activity under TLR4 activation by LPS E2F1 was induced by LPS in the cancer stem cells. E2F1 is a transcriptional activator for Nanog and is inhibited by TGF- β . The authors conclude that heightened TLR4 activation in the Nanog-positive cancer stem cells is associated with and interactive with the defective TGF- β tumor suppressor pathway for oncogene activity of Nanog-positive cancer stem cells^[13].

ROLE OF TLR4/2 SIGNALING PATHWAY IN CHEMICAL-CARCINOGEN-INDUCED LIVER TUMOR MODEL

Oliva *et al.*^[5] have developed a chemically-induced mouse model of liver tumor formation, which recently has been shown to be associated with TLR-4/2 activation^[14]. In

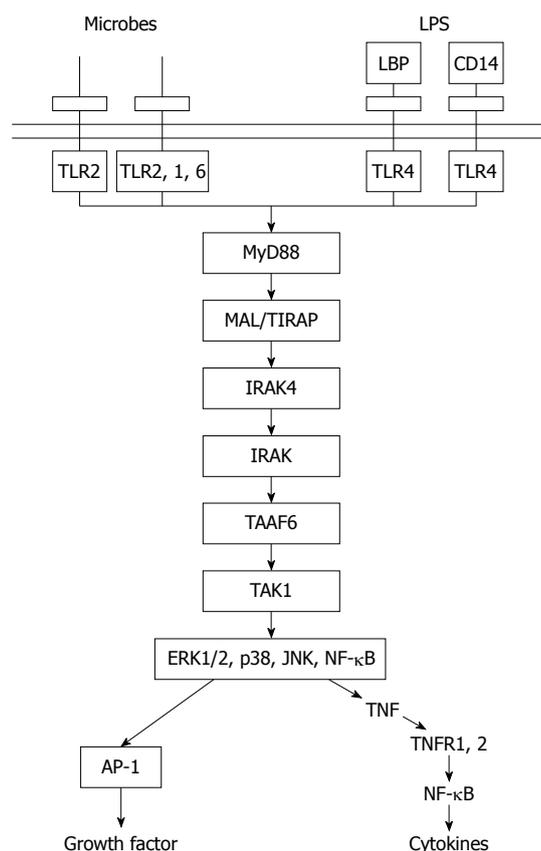

Figure 1 Main relationship between Toll-like receptor (TLR)2 and 4, their adaptors, protein kinases, which are linked to them and downstream signaling effects^[26]. LPS: Lipopolysaccharide; LBP: LPS binding protein; CD14: Cluster of differentiation 14; ERK: Extracellular signal-regulated kinase; JNK: Jun N-terminal kinase; NF-κB: Nuclear factor κB; AP-1: Activator protein 1; TNF: Tumor necrosis factor.

this model of experimental carcinogenesis, mice were fed diethyl 1,4-dehydro-2,3,6-trimethyl-3,5-pyridine decarboxylate (DDC). 0.1% DDC was fed *ad libitum* in the diet for 10 wk, at which time a large percentage of hepatocytes had become transformed into stem cell/progenitors. These cells stained positive for stem cell markers (UbD, OV-6, GSTP), and formed Mallory-Denk bodies. When the drug was withdrawn, these stem cell/progenitors persisted in small numbers scattered throughout the liver lobules. When the drug was reintroduced after 1 mo withdrawal, the stem cell/progenitors proliferated with a growth advantage over the intervening normal hepatocytes^[5,15-17], which indicated that the stem cell/progenitors had been epigenetically changed^[5,18-20]. The replication of stem cell/progenitors was prevented by feeding S-adenosylmethionine (SAm) or betaine as methyl donors^[5,19,20]. The replication of the stem cell/progenitors was stimulated by refeeding DDC or other liver toxins. In primary liver cultures, stem cell/progenitor formation was associated with NF-κB and AP-1 activation, as well as phosphorylation of p38 JNK and ERK^[17,21-25]. All of this could be the result of increased TLR4/2 (Figure 1), according to signaling microarray analysis data mining of livers of control mice compared with mice refed DDC for 7 d and those fed DDC with SAm (4 g/kg body

weight^[14]. TLR2 and TLR4 were both upregulated and this was prevented by SAm. RT-PCR confirmed the upregulation of TLR2/4 expression, and this was prevented by SAm. Levels of MyD88 adapter protein were increased, but the TLR2/4-TRIF-1RF3 pathway (MyD88-independent pathway) was not upregulated, which differs from the case when ethanol is fed^[11]. TRAF6 tended to be upregulated and this was prevented by SAm feeding. TRAF6 is down stream from the MyD88/IRAK complex. TRAF6 leads to activation of NF-κB and cytokine upregulation, and indirectly to the activation of p38, JNK and ERK, which initiates growth of hepatocytes (Figure 1). With an increase in NF-κB activation, TNFα (R21 and 12a) and IFN-γ (21 and 2) receptor expression was upregulated, coupled with the proliferation of stem cell/progenitors when DDC was refed, and SAm prevented these changes^[14,27].

Other signaling pathways such as STAT3, Wnt NOTCH, hedgehog and TGFβ, which are involved in stem cell renewal, differentiation and survival may also be involved in stem cell/progenitor transition to cancer stem cells found in HCC^[28].

CONCLUSION

There are increasing numbers of examples of the TLR signaling pathway in which it plays a key role in activating stem cell/progenitor proliferation and conversion to cancer-stem-cell-based liver tumor formation. Two examples were given in detail, one driven by chronic ethanol and LPS stem cell/progenitor feeding, and the other by chronic drug feeding. These two examples provide proof of the principle that TLR signaling pathway activation is required for stem cell/progenitor activation and transformation, and supports the concept that inflammation leads to cancer formation. Gene knockout of TLR4 expression prevented tumor formation in the first example and SAm prevented all the steps leading to pro-inflammatory activation, including TLR signaling in the second example, therefore, it is likely that blocking TLR signaling would prevent tumor formation prophylactically by feeding SAm.

Abstract

Proteasome dysfunction has been repeatedly reported in alcoholic liver disease. Ethanol metabolism end-products affect the structure of the proteasome, and, therefore, change the proteasome interaction with its regulatory complexes 19S and PA28, as well as its interacting proteins. Chronic ethanol feeding alters the ubiquitin-proteasome activity by altering the interaction between the 19S and the 20S proteasome interaction. The degradation of oxidized and damaged proteins is thus decreased and leads to accumulation of insoluble protein aggregates, such as Mallory-Denk bodies. Ethanol also affects the immunoproteasome formation. PA28a/b interactions with the 20S proteasome are decreased in the proteasome fraction isolated from the liver of rats fed ethanol chronically, thus affecting the cellular antigen presentation and defense against pathogenic agents. Recently, it has been shown that ethanol also affects the proteasome interacting proteins (PIPs). Interaction of the proteasome with Ecm29 and with deubiquitinating enzymes Rpn11, UCH37, and Usp14 has been found to decrease. However, the two UBL-ubiquitin-associated domain (UBA) PIPs p62 and valosin-containing protein are upregulated when the proteasome is inhibited. The increase of these UBL-UBA

proteasome interacting proteins, as well as the increase in Hsp70 and Hsp25 levels, compensated for the proteasome failure and helped in the unfolding/docking of misfolded proteins. Chronic alcohol feeding to rats causes a significant inhibition of the proteasome pathway and this inhibition results from a decrease of the interaction between the 20S proteasome and the regulatory complexes, PIPs, and the ubiquitin system components.

INTRODUCTION

Proteasome dysfunction is well established in alcoholic liver injury. However, the mechanism by which ethanol feeding causes proteasome dysfunction is still unclear. Proteasome chymotrypsin-like activity decrease has been the major finding to explain the proteasome dysfunction and accumulation of misfolded and ubiquitinated proteins in the liver of chronic ethanol-fed animals. Previous studies reported by the author^[1,2] have shown that the dysfunction of the proteasome system in alcoholic

liver disease is caused by structural changes in the α type subunits of the proteasome. However, the dysfunction of the proteasome pathway in alcoholic liver disease is more complicated. There are multiple levels of proteasome activity and specificity regulation. The ubiquitin system and the proteasome interacting proteins (PIPs) are part of the regulation of proteasome activity and specificity. The effects of ethanol feeding on the ubiquitin system and the proteasome interacting protein are still unknown.

PROTEASOME SYSTEM

The proteasome system is a sophisticated, selective, and highly specific proteolytic pathway. It includes the 20S proteasome, also called the catalytic core particle (CP), the regulatory complexes, and interacting proteins. The catalytic core is formed by 28 subunits, arranged into four heteroheptameric rings made of seven subunits each ($7\alpha7\beta7\beta\alpha$). The α -type subunits form the external rings, and the β subunits the internal rings.

CP BINDING TO THE 19S REGULATORY COMPLEX

The CP of the proteasome system binds to the regulatory complex 19S to form the 26S proteasome (Figure 1). The 26S proteasome is involved in the ubiquitin proteasome pathway (UPP), and is responsible for the ubiquitin-targeted protein degradation^[5] (Figure 1).

Cellular key proteins, such as cyclins, cyclin-dependent kinase inhibitors, I κ B, hypoxia-inducible factor-1 α , Nrf2, and p53, are substrates for the 26S proteasome, and their ubiquitin-dependent degradation is highly controlled^[4-6].

The UPP is also responsible for the clearance of misfolded and oxidized proteins. Therefore, proteasome failure is the cause of numerous diseases associated with poor clearance of these often deleterious proteins.

There are two major steps involved in the ubiquitin-proteasome-dependent degradation pathway: (1) the enzymatic polyubiquitination of protein substrates; and (2) the docking and recognition by the 26S proteasome prior to degradation. A cascade of enzymes, including the ubiquitin-activating E1 enzymes, the ubiquitin-carrier protein E2 enzymes, and the ubiquitin-protein ligases E3, which conjugate the ubiquitin residues to the target protein substrate for degradation, are responsible for the ubiquitination of the protein substrate^[7]. There are at least four different E1s, 24 different E2s, and at least 100 E3s ligases^[8].

Several rounds of ubiquitination yield an ubiquitin chain that includes at least four ubiquitin residues, which designates the target protein for degradation by the 26S proteasome. Once the polyubiquitinated protein is delivered to the 26S proteasome, the polyubiquitin chain is freed, and the ubiquitin residues are recycled. Several

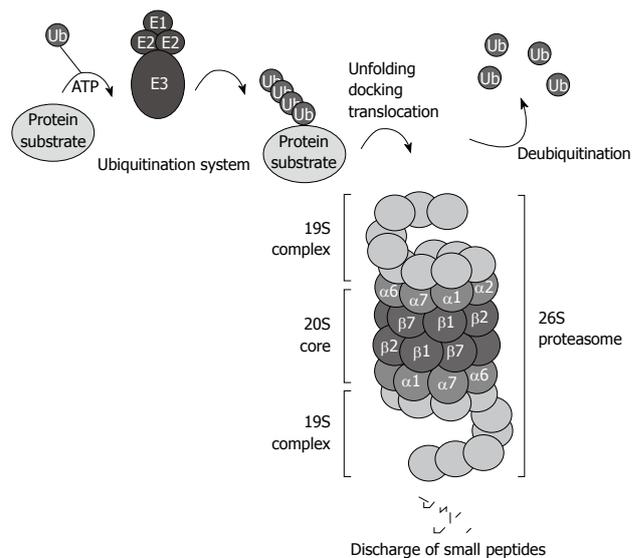

Figure 1 Schematic illustration of the ubiquitin proteasome pathway. The 26S proteasome consists of the 20S core capped with the 19S regulatory complexes that recognize ubiquitinated protein substrates designated for proteolysis.

deubiquitinating enzymes play an important regulatory role in regenerating the ubiquitin protein^[9], and in certain cases, represent a rate-limiting step for proteasome-mediated protein degradation^[10]. When change occurs and interferes with these rounds of ubiquitination, deleterious proteins accumulate and cause cellular dysfunction. For instance, mutation of the E3 ligases and misreading of ubiquitin have been reported to modify the ubiquitin system level and cause a significant inhibition of proteasome activity^[11].

This great diversity in the ubiquitination system and in the interactions of the CP with its regulatory complexes reflects the complexity and the specificity of the UPP. Disruption of the UPP has been implicated in a wide range of human diseases. Therefore, the proteasome and ubiquitination components are highly attractive targets for pharmaceutical intervention.

CP BINDING TO THE PA28 REGULATORY COMPLEX

The 20S proteasome can also bind to the regulatory complex PA28 (also known as REG and 11S) to form the immunoproteasome (Figure 2). PA28 is a heteromeric complex of 28-kDa subunits. It binds to the cylinder end of the 20S, thus opening the gate channel to the catalytic chamber^[12,13].

The immunoproteasome forms under the influence of high levels of cytokines, such as interferon (IFN) γ ^[14]. The immunoproteasome formation also consists of a replacement of the catalytic β subunits of the 20S proteasome, i.e. chymotrypsin-like (β 5), trypsin-like (β 1), and peptidylglutamyl peptide-hydrolase, recently called caspase-like activity (β 2), by the immunoproteasome sub-

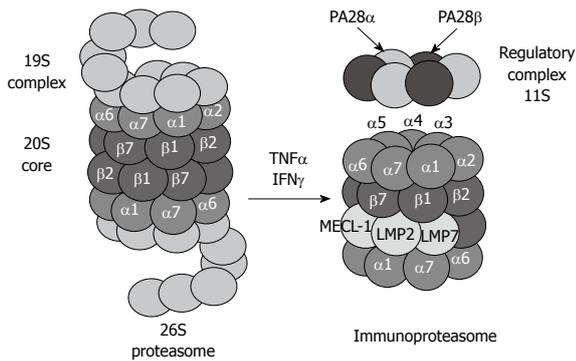

Figure 2 Tumor necrosis factor (TNF) α and interferon (IFN) γ induce formation of immunoproteasome subunits. LMP7, LMP2 and MECL-1 subunits replace the constitutive catalytic subunits $\beta 5$, $\beta 1$ and $\beta 2$, respectively, which shift the catalytic properties of the proteasome to generate MHC-I-binding peptides.

units LMP7, LMP2, and MECL-1, respectively^[15,16]. This replacement is required for the cleavage site specificity of the immunoproteasome for efficient antigen processing and presentation by major histocompatibility complex class I molecules^[17,18]. However, despite the induction of the immunoproteasome subunits, if the α subunits are modified, for instance by chronic ethanol feeding^[1,2], the binding between the catalytic core 20S and the regulatory complex PA28 is blocked, and antigen presentation is thus lowered, which alters the host defense.

CP BINDING TO THE PA200 REGULATORY COMPLEX

The 20S proteasome CP also associates with other activating complexes such as the HEAT-repeat protein PA200 (the homologue of yeast Blm10)^[19], which also opens the gate and stimulates peptide entry. PA200 is present within hybrid complexes (19S-20S-PA200), and is an ATP-independent proteasome regulatory complex. It is known to be involved mainly in the nucleus and DNA repair^[20].

In summary, the role of these different regulatory complexes, binding to the 20S proteasome CP, is to open the 20S proteasome gate at the α subunits, then to confer specificity to the proteolytic activity of the catalytic chamber formed by the β subunits. Numerous studies have focused on the effects of chronic ethanol feeding on the ubiquitin-proteasome pathway (26S proteasome activity) and the consequence of its dysfunction in liver cells^[21,22]. These effects still need further understanding. Substantial studies need to be undertaken to elucidate the effects of chronic ethanol feeding on the immunoproteasome and the nuclear proteasome, with respect to host defense and the epigenetic mechanism regulation.

WHAT ARE THE PIPS?

As much as the proteasome is complex, it does not work alone. There is an orchestra of proteins involved in the

regulation of the proteasome activity. An increasing number of PIPs have been reported, which indicates that the 20S proteasome CP is a dynamic structure that interacts with specific proteins for specific functions. Therefore, any interference with the 20S proteasome and with its interacting proteins would affect the proteasome specific functions.

It has been a decade since Verma *et al*^[23] have reported and analyzed PIPs. These authors used a one-step affinity method to purify intact 26S proteasome and its interacting proteins from budding yeast cells, and reported the existence of PIPs. These newly discovered PIPs were classified in four groups that include proteasome subunits, chaperone, transcription, and ribosomal proteins. New methods to purify the proteasome were then developed. Scanlon *et al*^[24] have used the GST UBL (ubiquitin-like domain as an affinity chromatography matrix), and purified the proteasome from human cell lines. These authors have classified the 26S PIPs into four groups of proteins that include de-ubiquitinases, ubiquitin ligases, ubiquitin domain-containing proteins and conjugating/ubiquitin, and proteins involved in DNA repair. Using the GST UBL matrix to purify the PIPs has helped find proteins dominantly related to the proteasome and ubiquitination systems; probably because of the affinity of UBL for the ubiquitin-proteasome pathway.

Among identified PIPs are a number of abundant cellular proteins, such as heat shock proteins (Hsps), elongation factors, and ribosomal proteins. The Hsps interaction with the proteasome is highly specific because they are induced to compensate for the proteasome failure, when the proteasome activity is decreased. In higher eukaryotes, it has been shown that Hsc70/Hsp70 members facilitate the delivery of aggregation-prone substrates for degradation by interacting with the proteasome through an adaptor protein^[25,26]. Along with Hsp70, Hsp27 assists in the unfolding of the proteins designated for degradation by the proteasome^[27]. In addition, Hsp90 family members have been suggested to play a role in the proteasome structural integrity and assembly through their interactions with the 26S proteasome^[28].

Other proteins work upstream of the ubiquitin system to recognize, unfold, shuttle, dock, and deubiquitinate the protein substrate designated for degradation. The chaperone system Bip/PDI is associated with endoplasmic reticulum (ER)-associated degradation^[29]. Other proteins that contain a ubiquitin-associated domain (UBA), such as Rad23 and p62, are involved in carrying and docking the protein substrates at the proteasome^[30]. These interacting proteasome partners differ in their biological roles, and are chosen to interact with the proteasome according to their specific cellular function. Therefore, different chaperone members may play distinct roles in modulating protein degradation by the proteasome.

A great number of yet-to-be-identified proteins can mediate ubiquitin recognition at the proteasome. UBL-UBA domain-containing proteins associate with

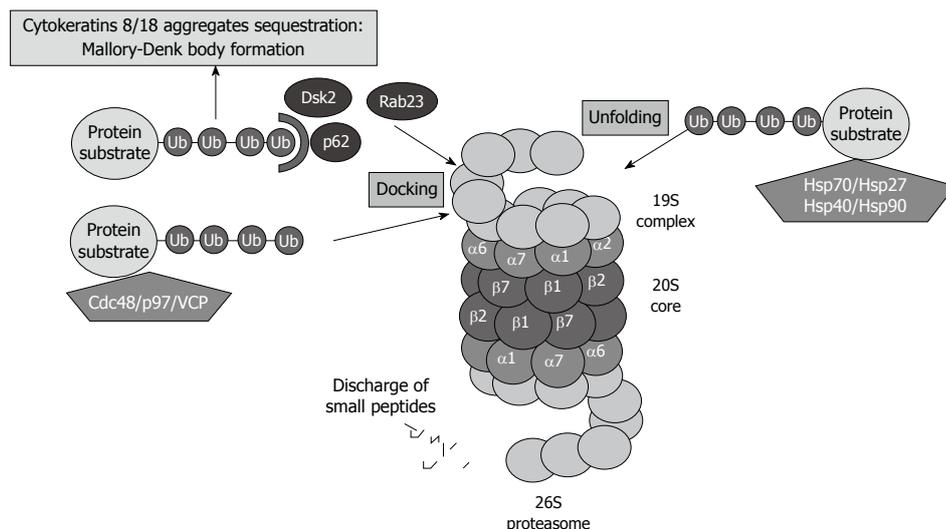

Figure 3 Proteasome interacting proteins (PIPs) involved in unfolding and docking of protein substrates designated for degradation by the proteasome. VCP: Valosin-containing protein.

substrates designated for degradation, as well as with subunits of the proteasome, thus regulating the proper turnover of proteins. The best known UBL-UBA proteins of PIPs are Cdc48/p97/valosin-containing protein (VCP), which present misfolded ER-proteins to the proteasome. P62, also called sequestosome 1, is also involved in presenting ubiquitinated proteins to the proteasome (Figure 3).

VCP and P62 have been reported to be involved in cytokeratin 8/cytokeratin 18 aggregate sequestration and Mallory-Denk body (MDB) formation in alcoholic liver disease^[31] (Figure 3). Both proteins are significantly up-regulated when the proteasome activity is inhibited using PS-341, thus indicating that these proteins play a crucial role in proteasome activity^[32].

The 26S stabilizing protein, Ecm29, has been found in the fraction of the purified proteasome, and is well established as a PIP. Ecm29 tethers the proteasome CP to the 19S regulatory particle, and confers stability of 19S-20S binding in yeast^[33]. It may play a crucial role in the 26S proteasome dysfunction in alcoholic liver disease^[34].

More recently, Kautto *et al*^[35] have developed a rapid method of 26S proteasome isolation using chromatography, and have identified over 100 proteins in the proteasome purified fraction, including the 26S proteasome and 32 proteasome subunits. 14-3-3-like proteins have been identified to interact with the proteasome, and also have been classified as PIPs. In our laboratory, when chromatography and high salt concentration purification was used, only a few proteins were identified by mass spectrometry, which indicates that the salt disrupted the proteasome interactions with its associating proteins. The identified proteins included the 14-3-3 proteins, the kinases protein kinase A (PKA) and transglutaminase, and the phosphatases PP2A and PP1^[36].

The role and function of the 14-3-3 proteins, in the regulation of proteasome function, remain to be elucidated. This protein has been identified by mass spectrometry in the 20S fraction purified chromatographically with a high salt gradient, which reflects the strength

of 14-3-3 interaction with the 20S proteasome. 14-3-3, which is a major scaffolding protein and a phospho-binding protein in the cell, plays a major role in cellular mechanisms, such as signal transduction and regulation of transcription factors^[37-39]. A pilot study has shown that chronic ethanol feeding increases the interaction of 14-3-3 with the 20S proteasome, probably to regulate the 20S proteasome ratio of phosphorylation/dephosphorylation to modulate the proteasome activity changes due to ethanol feeding^[36].

The proteins kinases associated with the 20S proteasome, such as casein kinase II^[40], transglutaminase (TG2), and PKA also co-isolated with the 20S proteasome through multiple chromatographic steps and high salt concentration, as well as the phosphatases PP2A and PP1^[41,42]. These proteins regulate the 20S proteasome activity *via* phosphorylation/dephosphorylation and are believed to regulate also the 20S proteasome binding to its regulatory complexes. TG2 has been found in the fraction of highly purified 20S proteasome^[36], and is known to be responsible for stabilizing macromolecular assemblies^[43,44]. It is possible that TG2 is involved in the stabilization of the proteasome macromolecules *via* its kinase activity. These kinases and phosphatases are crucial for the function of the different types of proteasomes because they regulate the phosphorylation of the α type subunit of the proteasome, thus determining the binding of the 20S proteasome to its regulatory complexes (Figure 4).

Similarly to PKA, TG2 and PP2A, the enzyme δ -aminolevulinic acid dehydratase (ALAD) has been identified by mass spectrometry in the highly purified 20S proteasome fraction^[45]. ALAD, also called porphobilinogen synthase, is a cytosolic sulfhydryl-containing enzyme that catalyzes the condensation of two molecules of aminolevulinic acid (ALA). It has been reported that blood ALAD activity is significantly decreased when rats are chronically fed ethanol, which indicates that ethanol feeding causes an alteration in blood^[46] as well as liver ALAD activity^[47].

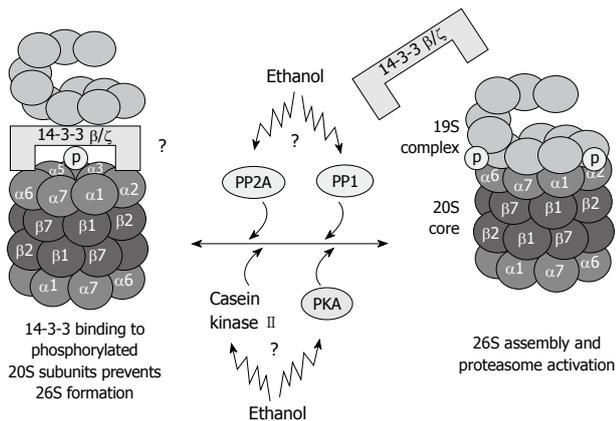

Figure 4 Illustration of hypothetical chronic ethanol feeding effects in 26S dysfunction. As a result of phosphorylation deregulation, 20S and 19S binding is altered, which causes 26S dysfunction. Total dephosphorylation of proteasome subunits by phosphatases is prevented by 14-3-3 protein sequestration of the 20S proteasome.

When this enzyme is inhibited, the ALA accumulates, which may impair heme biosynthesis and cause porphyria in the liver and pro-oxidant activity in the brain^[48,49]. ALAD was among the first PIPs to be identified and its role in the proteasome pathway still needs to be clarified^[50].

The recent and most productive method to investigate the PIPs is the QTAX-based tag-team technique, as used by Guerrero *et al*^[51,52]. These authors have identified at least 471 proteins in the network of the proteasome from yeast. The first group of proteins that have been characterized with high affinity was the ubiquitin receptor proteins. The rest of the identified proteins were grouped in the 35 distinct gene ontology protein complexes that are involved in various biological processes, such as chromatin remodeling, metabolism, translation, DNA replication, endocytosis, and protein folding.

Another method to purify the proteasome is to use multiple centrifugation with ATP and a final glycerol gradient zonal centrifugation. This procedure separates the proteasomes and preserves its binding to its regulatory complexes and interacting proteins^[34]. Then, mass spectrometry analysis is used to identify the PIPs, as well as to quantify their levels, and thus their interaction with the proteasome. The PIPs identified with the other above-mentioned method have also been characterized by our approach, and in addition, the effects of chronic ethanol feeding have been analyzed^[34].

Proteasome activity is regulated at multiple levels. Chronic ethanol feeding, which causes dysfunction of the proteasome pathway, may also occur at the level of PIPs, which could lead to the failure of the proteasome pathway in the liver of alcoholic patients.

EFFECT OF ETHANOL ON THE PIPs

The regulatory control of cellular protein levels by the UPP is essential because inhibition of proteasome activ-

ity leads to the loss of cellular regulation and development of many pathological disorders^[53]. In experimental alcoholic liver disease, chronic ethanol feeding causes significant inhibition of the 26S proteasome in liver cells^[54-57], which results in accumulation of oxidatively damaged and ubiquitinated proteins.

Aggregates of ubiquitinated proteins accumulate and form Mallory-Denk-like bodies^[58], which are characteristic of alcoholic liver disease^[59,60]. Ethanol-induced inhibition of proteasome activity is also associated with a decrease in misfolded protein degradation at the ER^[61,62], which leads to an increased demand on resident chaperones, even though the chaperones and the docking proteins, such as p62^[31,32,63], are helping to unfold and deliver proteins designated to be degraded by the proteasome. The immunoproteasome activity is also altered in the liver of alcoholic patients^[64,65].

The cause of the proteasome system failure in alcoholic liver disease is not fully understood. The mechanism that causes the failure of the 26S proteasome to remove the oxidized and damaged protein resides in the incapacity of the 20S proteasome to bind the 19S regulatory complex^[53]. The proteasome system is under a sophisticated regulation that prevents uncontrolled proteolysis in the cell. The binding between the regulatory complex 19S and the 20S proteasome occurs *via* a phosphorylation/dephosphorylation-dependent interaction between the α subunits at the 20S and the ATPase subunits at the 19S lid, which leads to the opening of the channel at the α subunit, which favors the translocation of protein substrate to the catalytic chamber. The α subunits of the 20S proteasome play a crucial role in proteolysis mediated by the ubiquitin-proteasome pathway. They form the gate to the catalytic chamber, which is composed of the β subunits. Köhler *et al*^[66] have shown that the amino-terminal sequences of α subunits block this channel, thus keeping the opening of the proteasome in the closed state, i.e. when the 20S proteasome is not bound to an activator^[67]. Therefore, any modifications of the phosphorylation level at the α subunits, i.e. modifications caused by ethanol treatment, lead to the closed state of the proteasome because of the dissociation of 20S and 19S. Post-translational modifications at the proteasome subunit have been reported as one mechanism that causes this proteasome inhibition in alcoholic liver disease^[1]. Consequently, there is a decrease in 26S formation, thus leading to a decrease in ubiquitin protein degradation^[1].

In inflammatory and infectious conditions, the induction of the pro-inflammatory cytokines, such as tumor necrosis factor α and IFN γ , causes the three catalytic subunits of the 20S proteasome CP to be replaced by their IFN γ -inducible counterparts, LMP2, LMP7, and MECL-1, which results in alternatively assembled immunoproteasomes^[14,68]. The assembly of the immunoproteasome consists of the binding of the catalytic core that carries the inducible subunits with the regulatory complex PA28. The immunoproteasomes possess

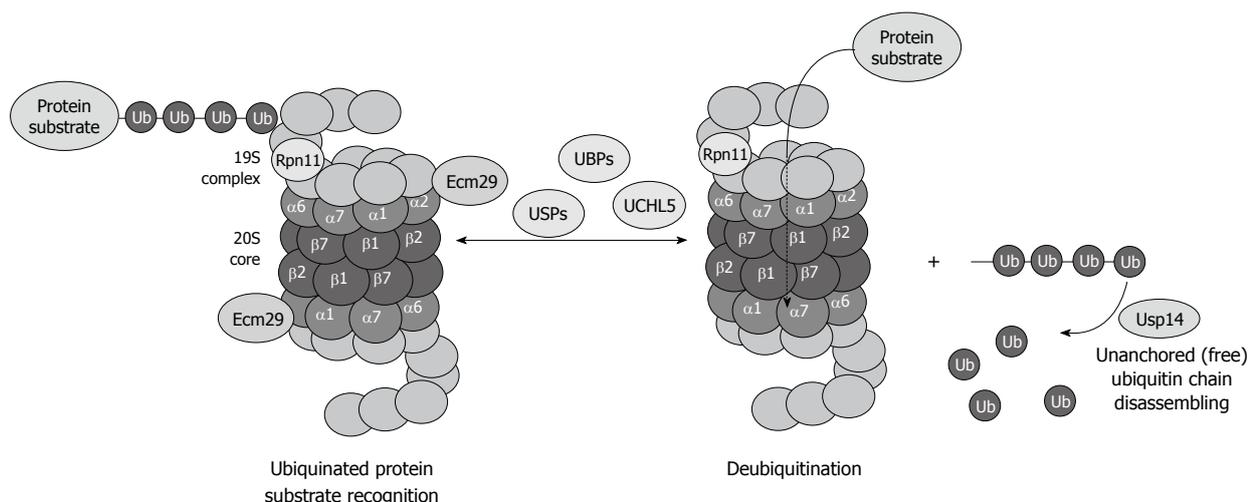

Figure 5 Diagram showing the important role of the deubiquitinases in the process of proteasome function and removal of ubiquitinated protein substrates, as well as recycling of free ubiquitin.

enhanced proteolytic activity, and are expressed constitutively by professional antigen-presenting cells, including B cells^[69]. It is well known that the host defense is reduced in alcoholic liver disease^[64]. This is possibly due to the failure of the immunoproteasome assembly. Recently, it has been shown that chronic ethanol feeding causes a decrease in the binding between the 20S catalytic core and the regulatory complex PA28; binding that is required for the immunoproteasome function, despite the induction of the immunoproteasome subunits^[34]. Results from the latest study have indicated that, similar to the mechanism that causes 26S proteasome dysfunction, the immunoproteasome is also altered in alcoholic liver disease. Post-translational modifications of α -type subunits are the key mechanism that regulates the binding of the 20S proteasome catalytic core to its regulatory complexes 19S or PA28. Phosphorylation/dephosphorylation of these subunits is known to regulate their interaction with the 19S ATPases subunits, and thus, 26S formation^[70]. Chronic ethanol feeding alters α -type subunit phosphorylation^[1]. It is possible that the immunoproteasome assembly is regulated *via* the interaction between the 20S and the α and β subunits of the PA28 regulatory complex.

Studies to date have focused on the changes that can occur either to the ubiquitin system, or to the proteasomes subunits themselves. However, there is increasing evidence that this pathway is also regulated by other proteins that are just as important as the ubiquitin-proteasome pathway elements^[71], and the regulatory complexes 19S, PA28, or PA200.

It is now well established that PIPs are significantly involved in the regulation of proteasome activity. However, the effect of chronic alcohol feeding on these PIPs remains to be investigated. A change in the proteasome interaction with its interacting proteins or modulators, concomitant with the proteasome inhibition due to ethanol feeding, could result in significant inclusion body

formation, a decrease in the anti-inflammatory and immune responses, and apoptotic conditions that lead to liver cell injury. Therefore, it is important to determine the effects of ethanol on the proteasome activity, especially the effects of alcohol feeding on the PIPs. The UBA-UBL docking proteins p62 and VCP have been shown to be induced by chronic ethanol feeding, which reflects the failure of the proteasome system to clear the accumulated damaged proteins^[31,32]. Similar to the UBA-UBLA proteins, Hsps are also affected by alcohol intake^[72], and are generally upregulated when the proteasome is inhibited, mainly to compensate for proteasome failure^[31,32].

Recently, the effect of chronic ethanol feeding has been investigated on PIPs, and it has been shown that chronic ethanol feeding affects PIPs^[34]. Most importantly, the level of Ecm29, a PIP known to stabilize 20S proteasome interaction with the 19S regulatory complexes^[73], is decreased after ethanol feeding^[34]. Proteasomes that lack Ecm29 are prone to dissociate from their regulatory complex 19S^[74] and most likely from the regulatory complexes PA28a/b and PA200. However, the mechanism of the ethanol effect remains unknown. It is possible that the oxidative stress caused by alcohol-induced detoxifying CYP2E1 is one of the mechanisms that modifies the proteasome subunits^[57] and impedes binding between the CP and Ecm29^[74].

The deubiquitination system is also affected by chronic ethanol feeding. Enigmatically, the three deubiquitinases Rpn11, Usp14 and UCHL5 (Figure 5), are decreased in the 26S proteasome fraction that is purified from ethanol-fed animals^[34]. Why the deubiquitination requires at least three enzymes and why alcohol feeding causes a decrease in the three enzymes is not known. However, a decrease in the proteasome activity and the deubiquitination process leads to serious cellular dysfunction that is reflected by accumulation of the ubiquitinated proteins that aggregate and form MDBs.

CONCLUSION

Chronic ethanol feeding modifies the structure of the proteasome subunits, but also alters proteasome interaction with its proteins partners, thus contributing to serious dysfunction in liver cells. However, we are still at the very beginning of understanding the effects of chronic ethanol feeding on the proteasome pathway. The focus has been to determine the post-translational modifications of the 20S proteasome α type subunits caused by ethanol feeding, because modification of these subunits regulates the 26S proteasome and immunoproteasome formation. As Ecm29 is a key protein involved in 26S proteasome formation, and because it plays a crucial role in stabilizing these proteasomal macromolecules, ethanol-induced Ecm29 downregulation merits further analysis. The determination of the effect of chronic ethanol feeding on the ubiquitination/deubiquitination system to maximize clearance of the altered and ubiquitinated proteins and prevent MDB formation associated with alcoholic liver disease should also be the focus of future research.

Abstract

The hepatocyte cytoskeleton consists of three filamentous networks: microtubules, actin microfilaments and keratin intermediate filaments. Because of the abundance of the proteins that comprise each system and the central role each network plays in a variety of cellular processes, the three filament systems have been the focus of a host of studies aimed at understanding the progression of alcohol-induced liver injury. In this review, we will briefly discuss the hepatic organization of each cytoskeletal network and highlight some components of each system. We will also describe what is known about ethanol-induced changes in the dynamics and distributions of each cytoskeletal system and discuss what is known about changes in protein expression levels and post-translational modifications. Finally, we will describe the possible consequences of these cytoskeletal alterations on hepatocyte function and how they might contribute to the progression of liver disease.

INTRODUCTION

The hepatocyte cytoskeleton consists of three major filamentous networks: microtubules, actin and cytokeratins. Recent genomics and proteomics studies have revealed that components of each of these networks are altered in ethanol-treated hepatocytes and/or liver. For example, the expression levels of many different genes encoding for cytoskeletal proteins are changed in ethanol-treated systems (Table 1). Similarly, cytoskeletal protein expression levels are altered by ethanol exposure (Table 2). However, it is important to note that changes in gene expression do not necessarily correlate with changes in protein expression. Furthermore, ethanol metabolites have been shown to form adducts with various proteins of the cytoskeleton (Table 3). More recently, it has become apparent that many post translational modifications of the natural repertoire are also induced by ethanol exposure (Table 3). These alcohol-induced alterations strongly suggest that cytoskeleton structure and function is impaired in ethanol-treated hepatocytes. Because the cytoskeleton is vital to innumerable cellular processes, these alterations likely have profound effects on proper hepatocyte function and lead to the progression of alcoholic liver injury. In this review, we will describe what is

known about specific alterations of components of the three cytoskeletal networks and discuss how they may contribute to ethanol-induced hepatotoxicity.

TUBULIN

Microtubules are made of repeating units of α - and β -tubulin heterodimers that form protofilaments, which in turn assemble into hollow tubes consisting of 13 protofilaments arranged in parallel. Microtubules exist as both dynamic and stable polymers. The latter population is characterized by a longer half-life, resistance to microtubule poisons (e.g. cold and nocodazole) and by specific post-translational modifications on the α -tubulin subunit^[22]. These modifications include the removal of a carboxy-terminal tyrosine, polyglutamylation, polyglycylation and acetylation of lysine 40^[22]. In hepatocytes, cell surface polarity is reflected in the asymmetric organization of microtubules. Unlike in non-polarized cells where microtubules emanate from a juxta-nuclear microtubule organizing center, in polarized cells, there is accumulating evidence that microtubules are instead (or additionally?) organized from sites at or near the apical plasma membrane (Figure 1). The emanating microtubules are oriented with their minus ends at the apical surface and their plus ends attached to or near the basolateral membrane^[23]. Because microtubules are central to multiple cellular processes including organelle placement, mitosis and vesicle motility *via* motor proteins, they have been the subject of a host of studies examining the effects of chronic ethanol exposure on hepatic function.

Acetaldehyde adduction

As ethanol is metabolized, acetaldehyde is produced. This highly reactive metabolite can readily covalently modify proteins, DNA and lipids^[21,24-33]. Many proteins have been shown to be modified by acetaldehyde including tubulin, actin, calmodulin, hemoglobin, hepatic enzymes and plasma proteins^[21,29-31,33,34]. In general, acetaldehyde is thought to form stable adducts with the ϵ -amino group of lysine residues^[32,35,36]. The hypothesis is that these cumulative covalent modifications disrupt the normal functioning of hepatic proteins leading to cell injury.

One of the best-studied target proteins for acetaldehyde is α -tubulin^[32]. *In vitro*, soluble tubulin dimers purified from either bovine brain^[18,19] or rat liver^[20] were found to be much more highly adducted than preformed microtubules (Table 3). Adduction occurred preferentially on the α -tubulin subunit at a highly reactive lysine^[18,19]. Further examination revealed that adduction of this highly reactive lysine on α -tubulin drastically impaired *in vitro* microtubule polymerization^[18,19]. Assays using low acetaldehyde: tubulin dimer levels further revealed that impaired microtubule formation occurred at substoichiometric amounts of acetaldehyde (0.2 mol acetaldehyde/mol tubulin) suggesting that small levels of adduction can have far reaching effects on microtu-

bule function^[37]. More recently it was shown that tubulin purified from ethanol-fed rat livers displayed impaired polymerization relative to control^[7]. Although consistent with an acetaldehyde-induced impairment, the presence of adducts on the purified tubulin was not confirmed.

Impaired microtubule polymerization has also been examined in isolated hepatocytes from alcohol-fed rats^[7]. After removing nocodazole (a reversible microtubule

depolymerizing agent), microtubule regrowth was monitored morphologically and was found to be significantly impaired in ethanol-treated hepatocytes. Ethanol-treated WIF-B cells exhibited a similar tubulin phenotype where microtubule regrowth after nocodazole washout was impaired^[8]. Although the formation of tubulin-adducts has not been defined *in vivo*, these results are consistent with the effects of acetaldehyde on tubulin assembly *in vitro*.

Acetaldehyde has also been shown to form adducts on a purified fraction of microtubule associated proteins (MAPs) and motors at levels 1.5-fold more than tubulin^[18] (Table 3). Although the consequences of these modifications have not been explored, vesicle motility in isolated hepatocytes from ethanol-fed rats was found to be significantly decreased suggesting alcohol-induced motor dysfunction^[38]. Although the microtubule activated ATPase activities of kinesin or dynein purified from ethanol-exposed livers was not altered^[38], this does not exclude the possibility that their microtubule binding properties are altered *in vivo* thereby leading to decreased motility. This is consistent with our recent findings that histone deacetylase 6 (HDAC6) binding to endogenous microtubules was impaired in ethanol-treated WIF-B cells and that this impairment partially required ethanol metabolism^[39]. Measuring HDAC6 tubulin deacetylase activity further revealed that ethanol did not impair HDAC6's ability to bind or deacetylate exogenous tubulin suggesting that tubulin from ethanol-treated cells was modified (acetaldehyde adducted?) thereby preventing HDAC6 binding^[39]. Similarly, tubulin modifications may prevent

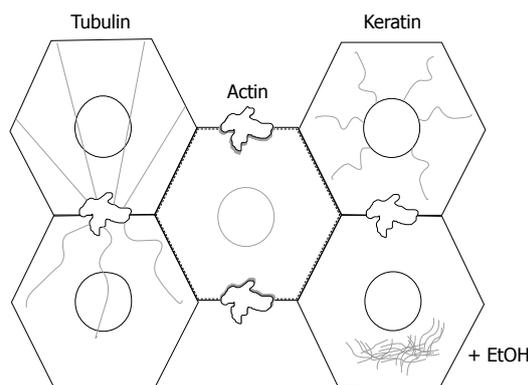

Figure 1 Ethanol alters cytoskeletal organization in hepatocytes. In control cells (top left cell), microtubules emanate from sites at or near the apical plasma membrane with their plus ends attached to or near the basolateral plasma membrane. In the presence of ethanol (bottom left cell), microtubules appear thicker, shorter and more gnarled. In contrast, ethanol does not alter actin filament organization (middle cell). Both control and ethanol-exposed actin filaments form a dense sub-cortical web at both the apical and basolateral plasma membranes. Keratin filaments normally form dense cortical networks originating from the apical and basolateral plasma membrane in hepatocytes (top right cell). In the presence of ethanol, keratin filaments accumulate in dense cytoplasmic inclusions known as Mallory-Denk Bodies (bottom right cell).

motor or MAP binding leading to impaired vesicle motility or altered microtubule dynamics.

Acetylation

Although tubulin polymerization was impaired in ethanol-treated WIF-B cells, when microtubules were examined morphologically, they resembled the so-called "stable" polymers (Figure 1). Antibodies to acetylated lysine 40 on α -tubulin confirmed their identity morphologically and revealed biochemically that ethanol-treated cells had approximately three-fold more acetylated α -tubulin than control cells. Consistent with increased acetylated α -tubulin levels, microtubules in ethanol-treated WIF-B cells were more stable. We further confirmed these results in livers from ethanol-fed rats indicating the findings have physiologic importance^[8]. Because microtubule hyperacetylation and stability increased with increased time of ethanol exposure or concentration, and was prevented by 4-methylpyrazole and potentiated by cyanamide, we conclude that increased acetylation requires alcohol metabolism and is likely mediated by acetaldehyde^[8]. Thus, ethanol metabolism impairs tubulin polymerization, but once microtubules are formed they are hyperstabilized.

Possible consequences of tubulin modifications

Because microtubules are central to multiple cellular processes, changes in their dynamics will likely alter hepatic function. An active area of research has been aimed at understanding the relationship between protein trafficking and alterations in microtubule dynamics. Not only is protein trafficking microtubule-dependent, the trafficking of many hepatic proteins is also impaired by ethanol^[40-43]. Thus, the observed alcohol-induced defects in protein trafficking may be explained by changes

in microtubule dynamics, altered tubulin/MAP/motor post-translational modifications or impaired interactions between microtubules and other proteins. Although the precise relationship between acetaldehyde-modified tubulin and defects in protein trafficking is not known, a link between tubulin acetylation and impaired protein trafficking is emerging. Of particular interest are studies performed in WIF-B cells that used a novel microtubule depolymerizing drug, 201-F^[44]. Poüs *et al*^[44] showed that this drug specifically depolymerized deacetylated microtubules; only acetylated populations remained. This implies that 201-F is a specific poison for dynamic microtubules. They further examined specific protein transport steps and found that secretion and transcytosis are dependent on dynamic (deacetylated) microtubules while delivery of basolateral glycoproteins to the sinusoidal surface is dependent on stable (acetylated) microtubules. Can the defects in protein trafficking in ethanol-treated cells be explained by increased acetylation and increased stability of microtubules?

To test this possibility, we compared the trafficking of selected proteins in control cells and cells treated with ethanol or the HDAC6 inhibitor, trichostatin A (TSA). Importantly, TSA led to increased microtubule acetylation and stability to the same extent as ethanol^[45]. Both treatments led to the impaired clathrin internalization of asialoglycoprotein receptor and aminopeptidase N^[45]. Interestingly, the internalization of 5' nucleotidase a GPI-anchored protein, was not impaired indicating the effect was selective (i.e. only certain internalization mechanisms were impaired) and specific (i.e. the changes were due to altered microtubule dynamics)^[45]. Furthermore, we determined that albumin secretion was impaired in TSA-treated cells. Thus, increased microtubule acetylation and stability, in part, can explain ethanol-induced defects in protein trafficking. It remains to be determined the specific mechanism by which tubulin acetylation impairs protein trafficking and whether tubulin acetaldehyde adducts also contribute to the impairments observed.

ACTIN

Actin is a ubiquitous cytoskeletal protein that exists as both a monomer (G-actin) and a filamentous polymer (F-actin). These dynamic filaments are the primary component of many cellular structures including stress fibers in adherent cells, the contractile ring in dividing cells and lamellipodia at the leading edge of migrating cells. The actin cytoskeleton has a unique organization in many polarized cells. In general, actin microfilaments extend to the basolateral membrane and form attachments through interactions with proteins of zonulae adherens, tight junctions and focal adhesions. At the apical surface, actin is found as the core filament of microvilli and also as a dense sub-cortical web^[46-48] (Figure 1). At the basolateral domain, the actin-associated proteins, fodrin and ankyrin, form a scaffold that restricts the movements of certain integral membrane proteins, thereby stabilizing

the basolateral protein population^[46] (Figure 1). Actin microfilaments are involved in a host of cellular processes ranging from cytokinesis to establishment of epithelial cell polarity. Interestingly, actin is also known to be important in regulating clathrin vesicle fission, vesicle trafficking *via* myosin motor proteins and cell attachment and spreading - important processes known to be impaired by ethanol exposure. Thus, the effects of ethanol metabolism on the actin cytoskeleton deserve close examination.

Acetaldehyde adduction

Like tubulin, actin contains several reactive lysines making it an attractive candidate for acetaldehyde-adduct formation. When the covalent binding of radiolabeled acetaldehyde to purified actin was examined, stable adducts were formed under both reducing and non-reducing conditions^[21] (Table 3). Interestingly, globular (G) actin formed considerably more adducts with acetaldehyde than filamentous (F) actin, and the monomer efficiently competed for acetaldehyde adduction when co-incubated with albumin, another known adducted protein. However, despite the readily adducted G actin, actin polymerization was not impaired^[21]. This does not rule out the possibility that adduction can lead to altered actin dynamics *in vivo* or impair binding of actin to its binding partners or myosin motors that may explain some of the observed defects in cell spreading and protein trafficking described below.

Hepatocyte attachment and spreading

Although actin adduction does not alter actin polymerization, ethanol has been shown to impair the function of actin-regulated processes. Among these are the observed defects in hepatocyte-extracellular matrix (ECM) attachment and subsequent cell spreading. Initially, hepatocyte attachment occurs when the transmembrane adhesion proteins, integrins, bind to ECM components including fibronectin, collagen, and laminin. Integrin clustering leads to the formation of focal adhesions and induces actin reorganization *via* the activation of Rho family GTPases. Focal adhesion turnover and actin dissociation from integrins are required for subsequent cell spreading. In isolated hepatocytes from ethanol-fed livers, a significant increase in the expression of α_1 , α_5 and β_1 integrins was observed^[10,13] (Table 2). Despite the increased levels of these ECM receptors, decreased hepatocyte attachment to their ECM ligands was observed and subsequent cell spreading was significantly impaired^[13,49,50]. These somewhat disparate findings suggest that integrin overexpression was compensating for decreased ECM attachment. Furthermore, this defect was found to be more prominent in the perivenous hepatocytes, sites where alcoholic liver injury predominates^[49].

Because actin cytoskeleton rearrangement is required for cell ECM attachment and subsequent cell spreading, a more recent study examined the downstream Rho GTPases in isolated hepatocytes from ethanol-fed rats.

This family of small molecular weight GTPases regulates actin rearrangement, including the formation of lamellipodia (*via* Rac), filopodia (*via* Cdc42) and stress fibers (*via* RhoA). Like for integrin expression levels, both Rac and Cdc42 levels were increased in isolated hepatocytes from ethanol-fed rats suggesting another possible compensatory mechanism to regain proper adhesion^[12] (Table 1). However, despite the increased total protein levels of these two GTPases, the activated GTP-bound forms of Rac and Cdc42 were significantly decreased in the presence of ethanol^[12]. Because no change in GTP γ S binding to either GTPase was observed, the authors suggest that GTP/GDP exchange by either the guanine nucleotide exchange factors or activating proteins is impaired, not GTP binding itself. Furthermore, when activation profiles of Rac and Cdc42 were examined during cell spreading, decreased Rac activation was observed only for the first 24 h. In contrast, decreased activation of Cdc42 persisted^[12]. This might be due, in part, to the additional role that Cdc42 plays in the establishment of cell polarity such that its activity is required longer. In contrast, RhoA activation or protein expression levels were not changed by ethanol exposure at steady state or during cell spreading assays. This might be explained by the absence of stress fibers in hepatocytes. Together, these studies suggest that decreased hepatocyte ECM attachment and spreading is due to altered Rac and Cdc42 GTPase activity that results in altered actin reorganization such that cell spreading is impaired.

Other actin cytoskeleton modifications

More recently, ethanol has been shown to induce additional protein modifications besides the well characterized acetaldehyde adduction. For example, a recent study examined the widespread CYP2E1-mediated cysteine oxidation in ethanol-fed mouse livers. Over 90 cytosolic proteins were found to be cysteine-oxidized including α and β actin and a dynactin subunit (Table 3). Although the functional consequences of this modification are not currently known^[17], it is attractive to postulate that the modified cysteine residues lead to altered actin dynamics leading to impaired hepatocyte function.

Our recent proteomics studies have identified β -actin as one of 40 other non-nuclear rat liver proteins that is hyperacetylated upon ethanol-exposure^[11,51]. We confirmed its ethanol-induced hyperacetylation and further determined that cortactin, a known actin binding protein, was also hyperacetylated in these samples^[11] (Table 3). Although the acetylated lysine(s) has not been identified, the possible functional consequences of this modification may be gleaned from other studies. Previous work from our lab and others has found that ethanol impairs clathrin-mediated endocytosis, secretion and delivery of newly synthesized membrane proteins to the basolateral membrane^[40-43]. In addition, studies using TSA (a histone deacetylase inhibitor), have linked these impairments to increased protein acetylation^[45]. Since both actin and its binding partner, cortactin, are likely required for clathrin-

vesicle formation at the plasma membrane and TGN^[52,53], an intriguing possibility is that actin hyperacetylation may contribute to the observed alcohol-induced defects in protein trafficking. In general, cortactin is thought to promote actin polymerization at sites of vesicle formation and recruit dynamin (a GTPase required for vesicle fission) to the necks of budding vesicles^[52,53]. At present, the exact mechanism by which cortactin, actin and dynamin function to promote vesicle release is not yet completely elucidated. However, acetylation of cortactin is known to prevent its association with actin and alters its subcellular localization^[54]. From these results, we propose that alcohol-induced hyperacetylation leads to decreased interactions between actin and cortactin such that cortactin is no longer recruited to sites of clathrin-vesicle formation thereby inhibiting associations with dynamin and subsequent vesicle fission. We are currently testing this exciting possibility.

In a recent system-wide survey for lysine acetylation, approximately 200 proteins were found to be acetylated including many cytoskeletal proteins^[55]. In addition to γ -actin, this list included many known actin-binding proteins, suggesting a possible general regulatory role for this modification on actin function. For example, profilin (involved in microfilament elongation) and cofilin and thymosin (involved in actin filament destabilization) were among those identified, suggesting acetylation may regulate actin dynamics. The screen also detected moesin, an ERM family member, required for actin assembly at the apical plasma membrane, suggesting that lysine acetylation may also regulate the formation of the cortical actin web in hepatocytes. However, it is not yet known whether ethanol induces hyperacetylation of these or other actin binding proteins. Nonetheless, we predict that many actin-dependent processes are regulated by lysine acetylation and that ethanol exposure leads to increased hyperacetylation thereby provoking altered regulation. Clearly, these exciting hypotheses need to be rigorously tested.

KERATIN

In general, the cytokeratin intermediate filament system is composed of polymerized dimers consisting of one acidic (Type I) and one basic (Type II) keratin subunit. Although over 50 keratin isoforms have been identified, hepatocytes express only keratin 8 (Type II) and keratin 18 (Type I). The developing embryonic liver also expresses keratin 19 (Type I), and some very low levels of this isoform may be also expressed in adult hepatocytes^[56]. In most polarized epithelial cells, keratin filaments form dense apical cortical networks^[57]. In contrast, apical and basolateral cortical keratin filaments are observed in hepatocytes^[57,58] (Figure 1). The polarized distribution of the keratin filaments have led some researchers to suggest that they play an important role in the establishment and maintenance of epithelial cell polarity and in polarized secretion^[57]. Unlike for microtubules and actin, there are no specific motor proteins

associated with intermediate filament systems suggesting this filament system does not support vesicle motility directly. However, several intermediate filament associated proteins (IFAPs) have also been identified that are thought to modulate filament assembly and associations with actin filaments and microtubules^[59]. These associations are required for the polarized distribution of both actin and microtubules suggesting the role of keratins in regulating polarity and polarized protein trafficking is likely indirect by providing a polarized scaffold for filament orientation^[57].

Keratin post-translational modifications

For almost 100 years, Mallory-Denk bodies have been recognized as a pathological marker in patients with alcoholic liver disease. Because there have been a number of excellent recent reviews^[56,59-62] written about the composition and formation of these inclusions, we will only discuss them briefly here. Morphologically, Mallory-Denk bodies are dense cytoplasmic inclusions formed of fibrillar keratin, chaperones, components of the protein degradation machinery and other proteins^[56,59-62] (Figure 1). Interestingly, the keratin filaments in these inclusions are highly post-translationally modified. They are hyperphosphorylated, transamidated (*via* transglutaminase 2), ubiquitinated and partially degraded^[59,62]. In the alcoholic, Mallory-Denk bodies are thought to form in response to oxidative stress that triggers many interrelated cellular responses including the upregulation of keratin expression (keratin 8 > keratin 18) and its subsequent post-translational modification^[60,62]. Other hepatic proteins are misfolded in response to oxidative stress and associate with chaperones. Damaged proteins are also ubiquitinated and targeted for degradation *via* the proteasome or autophagosomes. The accumulated proteins overwhelm the degradative machinery that is already compromised by ethanol treatment^[63] resulting in the formation of dense inclusions. Whether Mallory-Denk bodies contribute to the progression of alcoholic liver disease, are inert or are hepatoprotective is currently not clear^[59,62].

Another open question is the extent to which keratin intermediate filament function is impaired before the appearance of Mallory-Denk bodies. In general, Mallory-Denk bodies are formed at the expense of an intact keratin filament system. Do keratins present in the intact filament system display lower levels of the various post-translational modifications before inclusion formation? Does this alter keratin function? A few studies performed in rat hepatocytes suggest this is the case. In isolated hepatocytes after acute ethanol exposure both keratins 8 and 18 were found to be hyperphosphorylated^[16] (Table 3). In ethanol-fed rats, the keratin network was also found to be disrupted with increased cytosolic staining observed^[58]. One attractive hypothesis is that keratin phosphorylation leads to altered associations with IFAPs thereby leading to altered keratin function. However, it is important to point out that rats do not form

Mallory-Denk bodies, so whether these changes occur in humans will be important to determine. It is also not known whether keratins 8 or 18 or other hepatic IFAPs are targets for adduction by ethanol metabolites. It is interesting to point out that a number of non-hepatocyte keratin isoforms were found to be cysteine-oxidized in chronically-fed mouse livers (Table 3) suggesting the intermediate filament networks in other cell types may be altered upon ethanol exposure. Clearly, this hypothesis merits further attention.

CONCLUSION

In this review, we have briefly discussed the hepatocyte cytoskeleton and the known ethanol-induced impairments in its structure and function. In general, elements of the actin, microtubule and keratin filament networks undergo changes in distributions, expression levels or post-translational modifications upon exposure to ethanol. While the direct effects of these alterations are still under investigation, it is attractive to speculate that they lead to profound changes in hepatic function. Continued research in this field will not only increase our understanding of the pathogenesis of alcoholic liver disease, but may also provide novel therapeutic approaches to treatment.

Abstract

S-adenosyl-L-methionine (SAM) acts as a methyl donor for methylation reactions and participates in the synthesis of glutathione. SAM is also a key metabolite that regulates hepatocyte growth, differentiation and death. Hepatic SAM levels are decreased in animal models of alcohol liver injury and in patients with alcohol liver disease or viral cirrhosis. This review describes the protection by SAM against alcohol and cytochrome P450 2E1-dependent cytotoxicity both *in vitro* and *in vivo* and evaluates mechanisms for this protection.

INTRODUCTION

S-adenosyl-L-methionine (SAM) is the principal biological methyl donor, the precursor of aminopropyl groups utilized in polyamine biosynthesis and, in the liver, SAM is also a precursor of glutathione (GSH) through its conversion to cysteine *via* the transsulfuration pathway^[1,2]. SAM is important for the metabolism and regulation of nucleic acids and for the structure and function of membranes and many other cellular constituents^[3,4]. SAM is particularly important for opposing the toxicity of free radicals generated by various toxins, including alcohol^[1,2]. Abnormalities in SAM metabolism have been well recognized in liver diseases and in various neurological disorders. SAM is synthesized in the cytosol of every cell, but the liver plays a central role in the homeostasis of SAM as the major site of its synthesis and degradation^[3-5]. Methionine adenosyltransferase (MAT) is the enzyme responsible for the synthesis of SAM using methionine and ATP. SAM can transfer its methyl group to a large variety of acceptor substrates. After methyl transfer, SAM is converted to *S*-adenosylhomocysteine (SAH). SAH is a potent competitive inhibitor of transmethylation reactions, and is removed by hydrolysis to homocysteine plus adenosine. In the liver, there are 3 pathways that metabolize homocysteine. One is the transsulfuration pathway, which converts homocysteine to cysteine. Cysteine is often rate-limiting for GSH synthesis hence methionine metabolism *via* SAM and transsulfuration is very important in regulating GSH levels in the liver. The other 2 pathways that metabolize homocysteine resynthesize methionine from homocysteine, methionine synthase and betaine-homocysteine methyltransferase. This cycle is shown in Figure 1.

In mammals, 2 different genes, MAT1A and MAT2A, encode for 2 homologous MAT catalytic subunits, $\alpha 1$ and $\alpha 2$ ^[6-8]. MAT1A is expressed only in the liver while MAT2A encodes for a catalytic subunit ($\alpha 2$) found in a native MAT isozyme (MAT II), which is widely distributed^[4]. MAT2A predominates in the fetal liver and is progressively replaced by MAT1A during development^[9]. Expression of MAT2A is associated with rapid growth of the liver. A switch in the gene expression from MAT1A to MAT2A in liver cancer occurs^[10-12]. MAT isozymes differ in kinetic parameters and in their regulatory properties so that a switch in MAT expression is likely to affect the steady state SAM level and methylation. Apart from the presence of MAT1A and 2A in liver parenchymal cells, both are also present in hepatic macrophages and endothelial cells, whereas stellate cells only express MAT2A^[13].

Rodents fed diets deficient in lipotropes, such as choline and methionine, develop steatosis, which can proceed to non-alcoholic steatohepatitis (NASH) and to fibrosis and cirrhosis^[14]. A decrease in SAM synthesis in the liver results in a decrease in hepatic GSH levels^[15]. MAT1A knockout mice develop steatosis and hyperplasia^[16]. Liver injury causes a decrease in SAM concentration largely because of decreased MAT1A activity^[17,18]. Prooxidant conditions decrease liver MAT1A activity as a critical thiol residue (cysteine 121) becomes oxidized by reactive oxygen species (ROS) or nitrosylated by nitric oxide^[19,20]. Impairment of SAM synthesis is believed to play an important role in hepatic injury induced by various agents, and indeed there is a considerable literature, which shows that exogenous administration of SAM can protect against injury induced by CCl₄, acetaminophen, galactosamine, cytokines, thioacetamide, and ischemia-reperfusion^[21-28]. The decrease in liver GSH produced by various hepatotoxins was prevented by SAM; conversely, MAT and SAM synthesis is regulated by GSH e.g. treatment with l-buthionine sulfoximine (BSO), which lowers GSH, decreases MAT1A activity *in vivo* or in hepatocytes, probably because of oxidation of cysteine 121^[29,30]. Interestingly, MAT1A mRNA and protein declined during 12 h of rat hepatocyte culture, whereas MAT2A mRNA levels increased.

The effects of ethanol on SAM concentrations are somewhat variable. Baboons fed ethanol chronically had decreased hepatic levels of SAM and GSH, and administration of SAM elevated these and protected against liver injury^[31]. Rats fed the Lieber-DeCarli diet showed no or a small decrease in SAM after 4 wk but a more substantial decrease occurred after 8 wk on the diet^[32,33]. Mini pigs fed ethanol for 1 year had no change in SAM levels^[34]. Rats fed ethanol in the intragastric infusion model for 9 wk had an increase in MAT1A and MAT2A mRNA but only MAT2A protein was elevated^[35]; these changes were associated with a 40% fall in SAM levels. Depletion of mitochondrial GSH appears to be an important sensitizing factor for susceptibility to tumor necrosis factor- α (TNF- α) toxicity after chronic ethanol feeding^[36]. This

depletion results from a decrease in transport of GSH into the mitochondria and can be corrected by administration of SAM^[37]. A carrier transport system for SAM entry into the mitochondria has been characterized^[38]. The correction by SAM appeared to reflect an increase in fluidization of the mitochondrial membrane^[37]. In isolated hepatocytes, SAM prevented the decrease in GSH caused by ethanol^[39] and in perfused rat liver studies, SAM prevented the decline in GSH and oxygen consumption and liver damage produced by ethanol^[40].

Cytochrome P4502E1 (CYP2E1), an ethanol-inducible form of P450, is of interest because of its ability to metabolize and activate many important toxicological substrates including ethanol, carbon tetrachloride, acetaminophen, and *N*-nitrosodimethylamine to more toxic products^[41-43]. Whereas most ethanol is oxidized by alcohol dehydrogenase, CYP2E1 assumes a more important role in ethanol oxidation at elevated concentrations of ethanol and after chronic consumption of ethanol^[44,45]. The major interest in CYP2E1 reflects the ability of this enzyme to oxidize ethanol, to generate reactive products from ethanol oxidation, e.g. acetaldehyde and the 1-hydroxyethyl radical, to activate various agents (CCl₄, acetaminophen, benzene, halothane, halogenated alkanes, alcohols) to reactive products, to generate ROS, and to be "induced" by ethanol^[41-48].

CYP2E1 from rat and rabbit liver exhibits enhanced NADPH oxidase activity as it appears to be poorly coupled with NADPH-cytochrome P450 reductase^[49,50]. Microsomes from ethanol-treated rats, in which CYP2E1 is predominantly induced, displayed elevated rates of production of superoxide and hydrogen peroxide^[49,51-54]. Increases in formation of ROS after ethanol treatment are prevented by anti-CYP2E1 IgG thus linking them to induction of CYP2E1^[55]. There is considerable interest in the role of oxidative stress and ethanol generation of ROS in the mechanisms by which ethanol is hepatotoxic^[56,57]. A major advance has been the development of the intragastric model of ethanol feeding in which prominent induction of CYP2E1 occurs and in which significant alcohol liver injury occurs^[58-60]. In these models, the ethanol-induced liver pathology has been shown to correlate with CYP2E1 levels and elevated lipid peroxidation. Chlormethiazole (CMZ), an inhibitor of CYP2E1, prevented the elevation of lipid peroxidation and partially blocked the ethanol-induced liver pathology^[61].

Understanding the biochemical and toxicological properties of CYP2E1 is important for many reasons, even apart from its role in contributing to alcohol-induced liver injury, since CYP2E1 is induced under a variety of pathophysiological conditions such as fasting, diabetes, obesity, and a high-fat diet^[62-66]. Besides ethanol, CYP2E1 can be induced by drugs such as isoniazid, hydrocarbons such as trichloroethylene, benzene, chloroform, and solvents such as DMSO, acetone, and pyridine^[41-45]. NASH causes steatosis, liver cell injury, inflammation, and variable necrosis. NASH is associated with obesity, type 2 diabetes, and hyperlipidemia, conditions in

which CYP2E1 is induced. Increased CYP2E1 protein, activity, and mRNA levels were observed in a rat nutritional model of NASH^[67]. CYP2E1 was also increased in patients with NASH^[68]. It was concluded that induction of CYP2E1 is involved in the pathogenic mechanisms for NASH^[67,68]. SAM was recently shown to attenuate NASH produced in rats fed with high fat diets by decreasing CYP2E1 mRNA and protein levels^[69]. These decreases in CYP2E1 were accompanied by a lowering of oxidative stress^[69]. In view of the induction of CYP2E1 under a variety of conditions and by many chemicals, further understanding of how levels of CYP2E1 can be downregulated within the cell and how CYP2E1-dependent toxicity can be prevented is important. The goal of this report is to evaluate the effects of SAM on CYP2E1 metabolism and toxicity.

ANTIOXIDANT EFFECTS OF SAM IN VITRO

Our laboratory has investigated the possible direct antioxidant effects of SAM in *in vitro* systems^[70]. This study focused on the effect of SAM on the reactions of Fe²⁺ with dioxygen and Fe²⁺ with H₂O₂, as these are considered to be the most important routes of initiation of biological free radical oxidations. Aerobic HEPES-buffered solutions of Fe²⁺ spontaneously oxidize and consume O₂ with concomitant production of ROS and oxidation of substrates to radical products, e.g. ethanol to hydroxyethyl radical. SAM inhibited this oxidation of ethanol and inhibited aerobic Fe²⁺ oxidation and consumption of O₂. SAM did not regenerate Fe²⁺ from Fe³⁺ and was not consumed after incubation with Fe²⁺. SAM less effectively inhibited aerobic Fe²⁺ oxidation in the presence of competing chelating agents such as EDTA, citrate, and ADP. The effects of SAM were mimicked by SAH, but not by methionine or methylthioadenosine. SAM did not inhibit Fe²⁺ oxidation by H₂O₂ and was a relatively poor inhibitor of the Fenton reaction. Lipid peroxidation initiated by Fe²⁺ in liposomes was associated with Fe²⁺ oxidation; these 2 processes were inhibited by SAM. However, SAM did not show significant peroxy radical scavenging activity. SAM also inhibited the nonenzymatic lipid peroxidation initiated by Fe²⁺ + ascorbate in rat liver microsomes. These results suggest that SAM inhibits alcohol and lipid oxidation mainly by Fe²⁺ chelation and inhibition of Fe²⁺ autoxidation. This could represent an important mechanism by which SAM exerts cellular protective actions and reduces oxidative stress in biological systems.

IN VITRO INHIBITION OF CYP2E1 CATALYTIC ACTIVITY BY SAM

We studied the possible *in vitro* interactions of SAM and its metabolites SAH, 5'-deoxy-5'-(methylthio)adenosine (MTA) and methionine with cytochrome P450 enzymes,

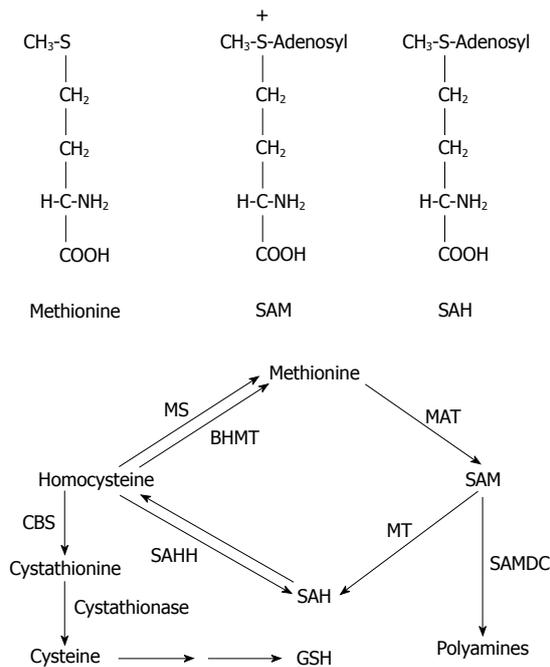

Figure 1 Structure of S-adenosyl-L-methionine (SAM), S-adenosylhomocysteine (SAH), and methionine and hepatic methionine metabolism. BHMT: Betaine homocysteine methyltransferase; CBS: Cystathionine β -synthase; GSH: Glutathione; MAT: Methionine adenosyltransferase; MS: Methionine synthase; MT: Methyltransferase; SAHH: SAH hydrolase; SAMDC: SAM decarboxylase.

in particular CYP2E1^[71]. SAM (but not SAH, MTA or methionine) produced a type II binding spectrum with liver microsomal cytochrome P450 from rats treated with acetone or isoniazid to induce CYP2E1. Binding was less effective for control microsomes. SAM did not alter the carbon monoxide binding spectrum of P450, nor denature P450 to P420, nor inhibit the activity of NADPH-P450 reductase. However, SAM inhibited the catalytic activity of CYP2E1 with typical substrates such as p-nitrophenol, ethanol, and dimethylnitrosamine, with an IC₅₀ of around 1.5-5 mmol/L. SAM was a non-competitive inhibitor of CYP2E1 catalytic activity and its inhibitory actions could not be mimicked by methionine, SAH or MTA. However, SAM did not inhibit the oxidation of ethanol to α -hydroxyethyl radical, an assay for hydroxyl radical generation. In microsomes engineered to express individual human P450s, SAM produced a type II binding spectrum with CYP2E1-expressing, but not with CYP3A4-expressing microsomes, and SAM was a weaker inhibitor against the metabolism of a specific CYP3A4 substrate than a specific CYP2E1 substrate. SAM also inhibited CYP2E1 catalytic activity in intact HepG2 cells engineered to express CYP2E1. These results suggest that SAM interacts with cytochrome P450s, especially CYP2E1, and inhibits the catalytic activity of CYP2E1 in a reversible and non competitive manner. However, SAM is a considerably weaker inhibitor than other typical CYP2E1 inhibitors such as diethyldithiocarbamate or 4-methylpyrazole and it is unclear whether inhibition of CYP2E1 activity by SAM plays a significant role in the protection by SAM against

the hepatotoxicity produced by toxins which require activation by CYP2E1 e.g. acetaminophen, thioacetamide, carbon tetrachloride.

HEPATOCTES STUDIES

The ability of SAM *in vitro* to protect against CYP2E1-dependent toxicity was studied in pyrazole-treated rat hepatocytes, with high levels of CYP2E1^[72]. Toxicity was initiated by the addition of arachidonic acid (AA) or by depletion of glutathione after treatment with BSO. In pyrazole hepatocytes, SAM (0.25-1 mmol/L) protected against AA but not BSO toxicity. SAM elevated GSH levels, thus preventing the decline in GSH caused by AA, and SAM prevented AA-induced lipid peroxidation. SAM analogs such as methionine or SAH which elevate GSH, also protected against AA toxicity. MTA, which cannot produce GSH, did not have a protective effect. The toxicity of BSO was not prevented by SAM and the analogs because GSH cannot be synthesized. In pyrazole hepatocytes, SAM prevented the decline in mitochondrial membrane potential produced by AA. These results suggest that the ability of SAM to prevent the decline in GSH produced by AA blunts the AA initiation of lipid peroxidation and ROS production and the subsequent loss of hepatocyte viability.

The exposure of hepatocytes to ethanol caused c-Jun amino-terminal kinase (JNK) activation, c-Jun phosphorylation, Bid fragmentation, cytochrome c release and procaspase 3 cleavage; these effects were diminished by SP600125, which caused a significant decrease in ethanol-induced apoptosis^[73]. SAM exerted an antioxidant effect maintaining glutathione levels and decreasing ROS generation, without a significant effect on JNK activity, and SAM prevented cytochrome c release and procaspase 3 cleavage. The JNK signaling cascade is a key component of the proapoptotic signaling pathway induced by ethanol. JNK activation may be independent from ROS generation, since SAM, which exerted antioxidant properties, did not have a significant effect on JNK activity. JNK pathway modulator agents and SAM may be components of promising therapies for alcoholic liver disease treatment.

Kharbanda *et al*^[74] compared the effects of betaine and SAM, on ethanol-induced changes of methionine metabolism and hepatic steatosis. Wistar rats were fed ethanol or a control Lieber-DeCarli liquid diet for 4 wk, and metabolites of the methionine cycle were measured in isolated hepatocytes. Hepatocytes from ethanol-fed rats had a 50% lower intracellular SAM/SAH ratio and almost 2-fold greater homocysteine release into the media compared with controls. Supplementation with betaine or SAM in the incubation media increased the SAM/SAH ratio in hepatocytes from both control and ethanol-fed rats and attenuated the ethanol-induced increase in hepatocellular triglyceride levels by approximately 20%. On the other hand, only betaine prevented the increase in generation of homocysteine in the incubation media

under basal and methionine-loaded conditions. SAM can correct only the SAM/SAH ratio and the methylation defects and may in fact be detrimental after prolonged use because of its propensity to increase homocysteine release. Both SAM and betaine are effective in increasing the SAM/SAH ratio in hepatocytes and in attenuating hepatic steatosis; however, only betaine can effectively methylate homocysteine and prevent increased homocysteine release by the liver^[74].

DECLINE OF SAM BY CYCLOLEUCINE TREATMENT POTENTIATES CYP2E1 TOXICITY IN HEPATOCTES

Cycloleucine is an inhibitor of MAT and prevents the conversion of 5'-methylthioadenosine to SAM through the methionine salvage pathway^[75,76]. SAM levels were lower in hepatocytes isolated from pyrazole-treated rats than control hepatocytes. Mato *et al*^[4] found that defective formation of SAM is associated with an impaired synthesis of GSH and that reduced synthesis of SAM and GSH can both act together in a self-perpetuating cycle, where a reduction in hepatic GSH leads to an inhibition of MAT activity *via* a mechanism involving ROS. A critical cysteine residue required for MAT1A activity is oxidized by ROS, with a subsequent decline in MAT1A activity and levels of SAM^[19,20]. Pyrazole increases the expression of CYP2E1, which produces ROS during its catalytic cycle. We speculate that CYP2E1-derived ROS inhibit the MAT1A which results in lower SAM levels in the hepatocytes isolated from pyrazole-treated rats^[77]. We therefore studied whether lowering of SAM levels in hepatocytes by treatment with cycloleucine would increase CYP2E1-dependent toxicity^[77].

Treatment with 5 mmol/L cycloleucine decreased SAM levels to 50% of initial values in pyrazole or saline hepatocytes. This more modest decline in SAM levels allowed the pyrazole hepatocytes to remain viable and thus permitted evaluating the effect of an added prooxidant such as AA on cell viability when SAM levels were further lowered by cycloleucine treatment.

Pyrazole hepatocytes that express elevated CYP2E1 were more sensitive to 20 mmol/L cycloleucine or 5 mmol/L cycloleucine plus 20 μ mol/L AA treatment, and exhibited significant cell death compared with that of control hepatocytes. Cell nuclear morphology, DNA ladder and caspase 3 cleavage revealed that cycloleucine or cycloleucine plus AA treatment induced apoptosis in pyrazole hepatocytes to a much greater extent than in control hepatocytes. The lactate dehydrogenase leakage assay indicated that necrosis may also be occurring and contributing to the pyrazole hepatocyte death^[77]. The CYP2E1 inhibitor, CMZ, protected pyrazole hepatocytes from cycloleucine or cycloleucine plus AA cytotoxicity by decreasing the elevated CYP2E1 activity, maintaining SAM levels and decreasing ROS levels. It is important to emphasize the very effective hepatoprotective effects

of SAM since toxicity is observed only when SAM levels are lowered to undetectable levels. Decreases of “only” 70% to 80% as found with non-treated pyrazole hepatocytes or cycloleucine-treated control hepatocytes did not result in hepatotoxicity even after 3 d in culture.

A likely explanation as to why cycloleucine or cycloleucine plus AA toxicity is increased in the pyrazole hepatocytes is elevated oxidant stress, as ROS is generated *via* the induction of CYP2E1 in the endoplasmic reticulum, and ROS detoxification is reduced as a result of the decline in SAM. The antioxidant Trolox could rescue pyrazole hepatocytes from cycloleucine or cycloleucine plus AA induced cell death. Trolox also decreased the elevated ROS and intracellular $O_2^{\cdot -}$ produced by cycloleucine in the pyrazole hepatocytes, indicating that enhanced ROS production appears to be central to the mechanism leading to the death of pyrazole hepatocytes^[77].

Trifluoroperazine, an inhibitor of the mitochondrial membrane permeability transition, effectively protected pyrazole hepatocytes from toxicity induced by cycloleucine or cycloleucine plus AA treatment, which suggest that a decrease in mitochondrial membrane potential contributes to the potentiation of cell death caused by cycloleucine treatment in the pyrazole hepatocytes.

SAM levels were lowered in animal models of alcoholic liver injury and human alcoholic liver disease^[25,26]. In these situations the CYP2E1 levels are elevated and liver injury is potentiated by diets enriched in polyunsaturated fatty acids^[59,60]. A decrease in SAM (with or without addition of AA) and elevated CYP2E1 expression combine to lead to an increased oxidative stress in pyrazole hepatocytes, which plays a crucial role in execution of downstream events leading to apoptosis.

MAT1A KNOCKOUT MOUSE

The MAT1A knockout mouse has been a most valuable contribution to research^[16,78,79]. Genomic profiling *via* microarrays revealed changes in genes involved in cell proliferation, differentiation and the acute phase response. Of significance for this review is the observation that CYP2E1 mRNA and activity was increased in the MAT1A knockout mouse. Conversely, CYP4A10 and 4A14 were decreased^[79], in agreement with the observations in the CYP2E1 knockout mouse that there is reciprocal expression of CYP2E1 compared to CYP4A10^[67]. Toxicity by CCl_4 was more severe in the MAT1A knockout mouse perhaps because of the 70% decrease in SAM and the increase in CYP2E1; toxicity was prevented by the CYP2E1 inhibitor diallylsulfide. Importantly, the decrease in MAT activity in wild type mice produced by CCl_4 was also prevented by diallylsulfide and the authors suggested that CYP2E1-derived ROS may inactivate MAT during liver injury, and this may sensitize the liver to further oxidative injury^[79]. We recently found that protection by SAM against CYP2E1-dependent toxicity was associated with a decrease in CYP2E1 levels and activity (discussed below). These results suggest possible interac-

tions/modulation between CYP2E1 and MAT1A, which are worthy of more detailed investigations.

ANTI-FIBROGENIC EFFECTS OF SAM AND PROTECTION AGAINST ALCOHOL-DEPENDENT TOXICITY *IN VIVO*

To study the anti-fibrogenic actions of SAM, transgenic mice harboring the -17 kb to +54 bp of the collagen $\alpha 2$ promoter (COL1A2) cloned upstream from the β -gal reporter gene were injected with CCl_4 to induce fibrosis and coadministered with either SAM or saline^[80]. Control groups received mineral oil. SAM lowered the pathology in the CCl_4 livers, and decreased the elevated levels of collagen and trichrome staining. Elevated β -galactosidase activity indicated activation of the COL1A2 promoter in isolated stellate cells from the CCl_4 -treated mice and such activation was repressed by *in vivo* treatment with SAM. SAM also prevented the increase in lipid peroxidation and transforming growth factor- β (TGF- β) and the decline in GSH produced by CCl_4 . Incubation of primary stellate cells with SAM downregulated basal levels of collagen and TGF- β stimulation of collagen protein and smooth muscle actin. SAM repressed basal and TGF- β -induced reporter activity in stellate cells transfected with COL1A2 promoter deletion constructs. SAM blocked TGF- β induction of the -378 bp region of the COL1A2 promoter and prevented activation of ERK and binding of Sp1 to the TGF- β -responsive element. These observations reveal antifibrogenic actions of SAM^[80]. *In vitro*, SAM was found to blunt activation of hepatic primary stellate cells in culture as shown by decreased levels of collagen and smooth muscle actin, and a decrease in DNA synthesis stimulated by platelet-derived growth factor and a decrease in stellate cell contractility^[81].

Chronic ethanol consumption by baboons (50% of energy from a liquid diet) for 18 to 36 mo resulted in significant depletion of hepatic SAM concentration and levels of GSH^[82]. These depletions were corrected with SAM administration. There was a significant correlation between hepatic SAM and GSH level. This attenuation by SAM of the ethanol-induced increase in plasma glutamic dehydrogenase was associated with a decrease in the number of giant mitochondria (assessed in percutaneous liver biopsy specimens), with a corresponding change in the activity of succinate dehydrogenase, a mitochondrial marker enzyme. Succinate dehydrogenase activity was increased in liver homogenates of animals fed ethanol, probably reflecting the increased mitochondrial mass. SAM decreased succinate dehydrogenase levels. SAM supplementation also significantly lessened the ethanol-induced increase of plasma aspartate aminotransferase^[82].

Esfandiari *et al*^[83] reported that feeding micropigs with ethanol at 40% of total calories with folate-deficient diets for 14 wk increased, and supplemental SAM maintained, levels of liver and plasma triglyceride. Serum

adiponectin, liver transcripts of adiponectin receptor-1, and phosphorylated adenosine monophosphate kinase- β were each reduced by ethanol feeding and were sustained at normal levels by SAM supplementation of the ethanol diets. Ethanol feeding activated and SAM supplementation maintained control levels of endoplasmic reticulum stress-induced transcription factor SREBP-1c (sterol regulatory element-binding protein-1c) and its targeted transcripts of lipid synthesizing enzymes acetyl-CoA carboxylase, fatty acid synthase, and glycerol-3-phosphate acyltransferase. SAM attenuated oxidative liver injury in micropigs fed ethanol with a folate-deficient diet^[84]. The elevated transcripts and protein levels of CYP2E1 and activities of NADPH oxidase and inducible nitric oxide synthase were lowered upon supplementation of the diet with SAM. Thus, SAM protected against ethanol toxicity by decreasing oxidative enzymes such as CYP2E1. Liver mRNA and protein levels of CYP2E1 correlated positively to SAH or homocysteine but negatively to the SAM/SAH ratio in minipigs fed ethanol plus a folate-deficient diet, and the authors concluded that induction of abnormal methionine metabolism is associated with activation of CYP2E1^[85].

The protective effect of SAM against rat liver steatosis induced by chronic ethanol ingestion was investigated by Feo *et al.*^[86]. SAM given during ethanol treatment prevented steatosis and accelerated recovery from steatosis when given after ethanol withdrawal. It also caused a slight inhibition of blood ethanol concentration in both acutely and chronically intoxicated rats. About 30% inhibition of alcohol dehydrogenase, but not of the microsomal ethanol oxidation system, occurred in rats subjected to acute ethanol toxicity as well as in normal rats as a consequence of SAM treatment. Ethanol induced a drastic decrease of GSH liver content. SAM treatment almost completely reconstituted the liver GSH pool. It is suggested that, although SAM induced a small inhibition of ethanol metabolism in the liver, its antisteatotic effect could largely depend on its role as a modulator of the GSH liver content^[86].

Bailey *et al.*^[87] found that alcohol feeding to rats for 5 wk caused a significant decrease in mitochondrial state 3 respiration and the respiratory control ratio whereas SAM administration prevented these alcohol-mediated defects and preserved hepatic SAM levels. SAM treatment prevented alcohol-associated increases in mitochondrial superoxide production, mitochondrial DNA damage, and inducible nitric oxide synthase induction, without a significant lessening of steatosis. SAM also prevented alcohol-mediated losses in cytochrome c oxidase subunits, which resulted in partial preservation of complex IV activity. SAM treatment attenuated the upregulation of the mitochondrial stress chaperone prohibitin. Although SAM supplementation did not alleviate steatosis by itself, SAM prevented several key alcohol-mediated defects to the mitochondria genome and proteome that contribute to the bioenergetic defect in the liver after alcohol consumption^[87]. Supplementation of SAM to ethanol diets

which were fed to rats prevented dissociation of hepatic mitochondrial ribosomes and elevated respiratory rates with glutamate/malate or with succinate as substrates^[88]. Thus, SAM is protective against ethanol-induced mitochondrial dysfunction.

Male C57BL/6 mice received ethanol (5 g/kg body weight) by gavage every 12 h for a total of 3 doses. SAM (5 mg/kg body weight) was administered ip before ethanol administration^[28]. Acute ethanol administration caused prominent microvesicular steatosis with mild necrosis and an elevation of serum ALT activity. SAM treatment significantly attenuated the liver injury. In association with the hepatocyte injury, acute alcohol administration induced significant decreases in both hepatic SAM and mitochondrial GSH levels along with enhanced lipid peroxidation. SAM treatment attenuated hepatic SAM and mitochondrial GSH depletion and lipid peroxidation following acute alcohol exposure^[28].

SAM PROTECTS AGAINST CYP2E1-DEPENDENT TOXICITY *IN VIVO*

As CYP2E1-mediated toxicity may play a role in alcoholic liver injury and toxicity of many hepatotoxins, whereas SAM can prevent alcoholic liver injury and toxicity of hepatotoxins, it is of interest to study whether and how SAM can affect CYP2E1-mediated toxicity in the liver *in vivo*. We recently reported that induction of CYP2E1 in mice by treatment with pyrazole increased the hepatotoxicity caused by Fas agonistic Jo2 antibody^[89]. Increased hepatotoxicity in the pyrazole/Jo2-treated mice was associated with increased oxidative and nitrosative stress in association with decreased GSH and other antioxidant levels. CMZ, an inhibitor of CYP2E1, prevented the synergistic toxicity of Jo2 antibody in pyrazole-treated mice. We investigated the effect of SAM on agonistic Jo2 Fas-induced hepatotoxicity following induction of CYP2E1 by pyrazole pretreatment *in vivo* and explored a possible relationship among oxidative stress, hepatic apoptosis, and homeostasis of SAM metabolism^[90]. Suboptimal administration of Jo2 Fas antibody combined with pyrazole pretreatment caused severe hepatotoxicity as determined by elevations in serum transaminase levels and histopathology. Exogenous administration of SAM (50 mg ip/kg body weight every 12 h for 3 d) significantly decreased serum transaminases and ameliorated morphological changes of the liver. Addition of SAM elevated hepatic SAM and total glutathione levels and inhibited CYP2E1 activity. SAM also lowered the elevated oxidative stress (lipid peroxidation, protein carbonyls, and superoxide production) and nitrosative stress (induction of inducible nitric oxide synthase and 3-nitrotyrosine adducts) and lowered increases in caspase-8 and -3 activation produced by the pyrazole plus Jo2 treatment. SAM did not prevent the increase in serum TNF- α levels or the decrease in catalase activity in this model. These results indicate that SAM can have an important hepatoprotective role as an effective

reagent against Fas plus CYP2E1-induced hepatotoxicity by lowering oxidative and nitrosative stress.

A study was carried out^[91] to investigate the effect of SAM on the enhanced hepatotoxicity induced by Fas agonistic Jo2 antibody plus acute ethanol administration in mice. Acute ethanol plus Fas produced toxicity under conditions in which the ethanol or the Jo2 alone had no effect. SAM attenuated this elevated hepatotoxicity. Levels of SAM and activity of MAT1A were decreased by the ethanol plus Jo2 treatment but restored after administration of SAM. The ethanol plus Jo2 treatment elevated levels of CYP2E1, iNOS and TNF- α : these increases were blunted by SAM. SAM also lowered the elevated oxidative and nitrosative stress produced by ethanol plus Jo2. Calcium-induced mitochondrial swelling was elevated by ethanol plus Jo2 and lowered by SAM. The activation of JNK by the ethanol plus Jo2 combined treatment was also prevented by SAM. It was suggested that SAM protects against the acute ethanol plus Jo2 toxicity by restoring MAT activity and levels of SAM, preventing the increases in CYP2E1, iNOS, JNK and TNF- α , which thereby lowers oxidative/nitrosative stress and protects against loss of mitochondrial function^[91].

Obese mice have been used extensively as animal models to study human obesity. We have recently observed that pyrazole-induced CYP2E1 promotes liver injury in ob/ob mice, compared with saline-treated ob/ob mice or with lean controls treated with pyrazole^[92]. We investigated whether SAM can prevent this CYP2E1-mediated toxicity to the obese mouse liver^[93]. Pyrazole treatment of ob/ob mice for 2 d caused necrosis, steatosis, and elevated serum transaminase and triglyceride levels compared with saline-treated ob/ob mice. Administration of SAM (50 mg/kg body wt ip every 12 h for 3 d) prevented the observed pathological changes as well as the increase of apoptotic hepatocytes, caspase 3 activity, and serum TNF- α levels. SAM administration inhibited CYP2E1 activity but not CYP2E1 content. The pyrazole treatment increased lipid peroxidation, 4-hydroxynonenal and 3-nitrotyrosine protein adducts, and protein carbonyls. These increases in oxidative and nitrosative stress were prevented by SAM. Treatment of ob/ob mice with pyrazole lowered the endogenous SAM levels, and these were elevated after SAM administration. Mitochondrial GSH levels were very low after pyrazole treatment of the ob/ob mice; this was associated with elevated levels of malondialdehyde and 4-hydroxynonenal and 3-nitrotyrosine protein adducts in the mitochondria. All these changes were prevented with SAM administration. SAM protected against pyrazole-induced increase in serum transaminases, necrosis, triglyceride levels, caspase-3 activity, and lipid peroxidation even when administered 1 d after pyrazole treatment. In summary, pyrazole induced necrotic changes and apoptosis in livers of obese mice, and SAM pretreatment abrogated these pathological changes. Important mechanisms involved in the protective actions of SAM are the blunting of the increased catalytic activity of CYP2E1, possibly the decline in

TNF- α levels, and the lowering of the elevated oxidative/nitrosative stress produced by SAM treatment. SAM also protected pyrazole-treated obese mice from CYP2E1-generated oxidative and nitrosative stress in the mitochondria, especially the depletion of mitochondrial GSH. Therefore, SAM is effective in protecting against pyrazole-induced oxidative and nitrosative stress and liver injury in obese mice by lowering CYP2E1-generated oxidative/nitrosative stress in the liver and in the mitochondrial compartment^[93].

A model of chronic alcohol-induced liver injury using Cu, Zn-superoxide dismutase deficient mice (SOD^{-/-}) was developed^[94]. Feeding the homozygous SOD^{-/-} mice, but not the wild type mice, with ethanol resulted in liver injury characterized by extensive centrilobular necrosis and inflammation, and increased transaminase levels. Liver injury in the SOD^{-/-} mice was associated with induction of CYP2E1, and increased protein carbonyls, lipid peroxidation aldehydic products and 3-nitrotyrosine protein adducts, indicative of enhanced oxidative and nitrosative stress. SAM protected SOD^{-/-} mice from alcohol-induced liver injury. SAM lowered the serum ALT and AST levels, decreased steatosis, necrosis and inflammation as compared to alcohol alone in treated SOD1 knockout mice (unpublished data).

MITOCHONDRIAL SAM

Normal intra-mitochondrial SAM concentrations play a pivotal role in mitochondrial functions because methylation reactions are required for the methylation of RNA and proteins, and they function as intermediates in the biosynthesis of lipoic acid, ubiquinone and biotin^[95]. Since mitochondria have a relatively large pool of SAM^[96], and the enzyme required for SAM synthesis (MAT) is present only in the cytosol and not in the mitochondria^[97] a specific SAM transporter is needed to maintain normal mitochondrial SAM levels. The human mitochondrial SAM carrier exhibited a high transport affinity for SAM and was found to be expressed in all human tissues examined and was localized to the mitochondria. The physiological role of the SAM carrier is probably to exchange cytosolic SAM for mitochondrial SAH^[98]. It has been reported that increased cytosolic SAH caused a decrease in SAM concentration in the mitochondria in rat hepatocytes^[38]. Furthermore, studies by Colell *et al*^[99] demonstrated that exogenous SAM supplementation prevented the depletion of the mitochondrial GSH pool induced by alcohol consumption and protected hepatocytes from alcohol-consuming rats from TNF- α -induced hepatotoxicity. Bailey *et al*^[87] showed that SAM treatment prevented mitochondrial dysfunction induced by chronic alcohol consumption in rats. Song *et al*^[100] examined the effects of chronic alcohol consumption on hepatic SAM and SAH levels in both the cytosol and mitochondria, and found that mitochondrial SAM was significantly decreased in a mouse model of alcohol liver disease. Supplementation of SAM to rats fed alcohol chronically has been shown

to replenish the mitochondrial GSH levels because of normalization of the microviscosity of the mitochondrial inner membrane. Because of the instrumental role of GSH in mitochondria in hepatocyte survival against inflammatory cytokines, its depletion by SAM feeding may underlie the potential therapeutic use of this hepatoprotective agent in the treatment of alcohol-induced liver injury^[36,37]. Mitochondrial GSH plays an important role in maintaining a functionally competent organelle. SAM administration resulted in a significant increase in the basal cytosol and mitochondrial GSH in both periportal and perivenous cells from both pair-fed and ethanol-fed groups. When hepatocytes isolated from ethanol-fed rats which were supplemented with SAM were incubated with methionine plus serine or N-acetylcysteine, mitochondrial GSH increased in parallel with cytosolic GSH, an effect not observed in cells from ethanol-fed rats not treated with SAM. Feeding equimolar N-acetylcysteine raised cytosolic GSH but did not prevent the mitochondrial GSH defect. In addition, SAM feeding resulted in significant preservation of cellular ATP levels, mitochondrial membrane potential and the uncoupler control ratio of respiration for mitochondria. Thus, these effects of SAM suggest that it may be a useful agent to preserve the disturbed mitochondrial integrity in liver disease caused by alcoholism through maintenance of mitochondrial GSH transport^[37,99].

CONCLUSION

A scheme by which SAM is envisioned to protect against CYP2E1 hepatotoxicity is shown in Figure 2. SAM, at high concentrations, inhibits CYP2E1 catalytic activity, lowering formation of ROS. SAM has antioxidant actions, especially against iron potentiation of ROS production. ROS lower GSH levels, whereas SAM increases GSH levels by providing cysteine *via* the transsulfuration pathway. ROS cause mitochondrial dysfunction and membrane destabilization, events blunted by SAM. Mild or transient oxidant stress produced by CYP2E1 can upregulate cellular protective factors such as GSH, glutathione transferase, heme oxygenase-1, γ glutamyl cysteine ligase *via* activation of Nrf-2^[46-48]. The effect of SAM on this upregulation would be important to evaluate especially in view of methylation reactions as epigenetic regulators.

SAM was first described in 1952 and has been available in the United States as an over the counter supplement since 1999; in Europe, it is a prescription medicine^[100]. SAM has shown protective effects against alcohol and CYP2E1 induced cytotoxicity *in vitro* or in animal models. Although studies in experimental animal models of liver injury support a therapeutic role for SAM, Rambaldi *et al*^[102] identified 9 randomized clinical trials including a heterogeneous sample of 434 patients with alcoholic liver diseases and could not find evidence supporting or refuting the use of SAM in patients with alcoholic liver diseases. Therefore, more long-term, high-quality

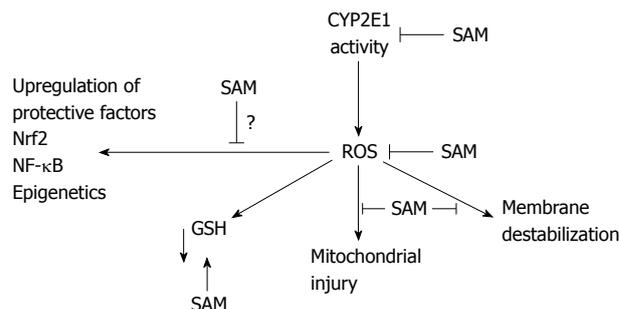

Figure 2 Proposed mechanism by which SAM protects against CYP2E1-hepatotoxicity. ROS: Reactive oxygen species; CYP: Cytochrome P450; NF- κ B: Nuclear factor κ B; Nrf2: Nuclear factor erythroid 2-related factor 2.

ity randomized trials on administration of SAM to these patients are needed before SAM may be recommended for clinical use. The mechanisms of abnormal SAM metabolism leading to liver injury and the mechanisms of pharmacologic actions of SAM deserve more research.

Abstract

This article discusses several subjects pertinent to a consideration of the role of gender and hormones in alcoholic liver injury (ALI). Beginning with an overview of factors involved in the pathogenesis of ALI, we review changes in sex hormone metabolism resulting from alcohol ingestion, summarize research that points to estrogen as a cofactor in ALI, consider evidence that gut injury is linked to liver injury in the setting of alcohol, and briefly review the limited evidence regarding sex hormones and gut barrier function. In both women and female animals, most studies reveal a propensity toward greater alcohol-induced liver injury due to female gender, although exact hormonal influences are not yet understood. Thus, women and their physicians should be alert to the dangers of excess alcohol consumption and the increased potential for liver injury in females.

INTRODUCTION

Much work has been done in recent years to provide insight into the pathogenesis of alcoholic liver injury (ALI). Liver injury from alcohol has many components, including intrahepatic events [such as hepatocyte alcohol metabolism, generation of reactive oxygen species (ROS) that result in cellular oxidative stress, loss of protective enzymes and transporters] and extrahepatic stimuli, such as gut-derived endotoxin, induced by ethanol exposure. These factors can act separately or in concert to trigger common pathways involving an inflammatory cytokine cascade. These cytokines bring about interplay between different functional cell types in the liver, i.e. hepatocytes, Kupffer cells, stellate or Ito cells, mononuclear cells, and neutrophils. The outcome of such interplay between biochemical alterations and changes in stimuli is the induction of early metabolic dysfunction in the form of fatty liver, followed possibly by an inflammatory response (alcoholic hepatitis), and progression to a more progressive liver disease (fibrosis and cirrhosis). The current model of ALI pathogenesis involves roles of different cytokines that induce various transcription factors, which in turn modulate expression of different genes (reviewed)^[1-9]. Contributing to this injury is mitochondrial dysfunction, with resultant reduced cellular ATP

levels, increased oxidative stress brought about by mitochondrial injury and altered activities of enzymes such as CYP2E1 and NADPH oxidase, along with a decrease in protective antioxidant enzymes such as superoxide dismutase and glutathione peroxidase^[8,9].

The aims of this review are to examine the relationship between sex hormones, changes in hormone levels due to alcohol exposure, and potential roles for sex hormones in the pathogenesis of ALI. To explore such relationships, evidence from both human studies and animal models will be considered. Human studies include collection of serum for hormone analysis under a variety of patient populations, including long-term heavy drinkers and alcoholics, and normal subjects challenged with acute doses of alcohol.

Most of the biochemical mechanisms of alcohol-related injury have been discovered using animal models, particularly rodent models. While studies in human populations are critical to determine demographics, risks, and outcomes, human studies have a number of drawbacks, such as the difficulty of reliable reporting of alcohol intake by subjects, genetic differences in ability to metabolize alcohol, coexisting disease, nutritional deficiencies, and individual timelines in progression of disease. In animal models, factors such as alcohol dose, age, sex, and dietary composition can be controlled by the investigator to limit differences among experimental and control groups. From such studies, it is becoming clear that certain dietary factors are critical in the development of ALI. Further, use of animal models allows testing of potential therapeutic agents prior to testing in human populations.

ANIMAL MODELS AND DIETARY FACTORS

The first diet protocol used widely to study ALI was that of Lieber and DeCarli^[10]. This liquid diet is easy to administer and provides nutritional equivalence by pair-feeding, in which the control animal of the pair receives the exact number of calories consumed by the experimental animal the previous day. This model typically results in alcohol-induced fatty liver, but not the degree of fibrosis and/or inflammation observed in human liver disease. Thus, this model is not appropriate for studying factors involved in generation of cirrhosis. More recently, an enteral feeding model, that of Tsukamoto and French (T/F)^[11,12], has been used to induce inflammation and fibrogenic changes more like that seen in human disease. However, major concerns regarding this model are that alcohol is administered 24 h a day, surgery is required for gastric tube placement, infection is a risk, and the equipment to maintain diet administration is expensive. The original T/F diet has been modified by several groups to produce more or less liver injury, based on the type of fat present. For example, Nanji *et al*^[13-15] showed that addition of medium-chain saturated fatty acids result in prevention or reversal of ALI, presumably due to

decreases in lipid peroxidation and CYP2E1 induction. Other studies showed that polyunsaturated fats result in more severe injury^[16]. Of interest with respect to sex, these diets result in an increase of fat, inflammation, and necrosis in females but not males on the control diets containing no ethanol, suggesting that diet alone may have sex-specific effects^[17,18]. Tipoe *et al*^[19] have now refined this dietary approach by developing a diet that results in significant liver injury particularly in females; the details of this fish oil-containing diet have recently been published. Our studies with this diet have shown that female rats fed alcohol have significant elevations of serum markers such as aspartate aminotransferase, alanine aminotransferase, and endotoxin, and much more fatty change and inflammatory foci in their livers than male rats fed the same diet (manuscript in preparation). Thus, the roles of dietary components, along with differences in response to ethanol between the sexes, have only begun to be elucidated.

ALCOHOL INGESTION CHANGES SEX HORMONE LEVELS IN BOTH SEXES

Clinical observations indicate that females are at greater risk than males for liver injury due to several different causes^[20]. One of these causes is ALI; women develop severe ALI and cirrhosis at lesser intake of alcohol and fewer years of exposure^[1]. While exact mechanisms remain obscure, these findings strongly suggest an involvement of sex hormones in the pathophysiology of alcohol-induced liver disease. Much research has shown that chronic alcohol ingestion changes dramatically the hormonal milieu of blood and the liver in both sexes. The liver is a key player in this interplay, because in addition to being the site of steroid hormone metabolism, the liver is responsive to sex hormones. Our laboratory has studied the effect of sex hormones on the liver for more than 25 years; we performed much of the characterization of sex steroid receptors in human and rat liver, and our work has examined the mechanism(s) of alcohol-induced alterations in hepatic sex hormone function and metabolism.

Because the liver itself is an end organ for sex hormone actions, an alcohol-induced disruption in sex hormone status can result in a self-perpetuating and detrimental pattern of sex hormone metabolism. Our studies and those of others have identified specific mechanisms by which sex hormone homeostasis changes in both male and female rats, reviewed in this section and the next. Newer information on the effect of alcohol on the gut barrier function also enhances our understanding of the relationships between sex hormones and injury to the liver.

Chronic alcohol ingestion results in significant alterations in sex hormone levels and function; the spectrum of sexual dysfunction has been reviewed^[21-25]. Alcoholic men often display phenotypic changes due to an inability to maintain appropriate hormone balance, displaying low

serum testosterone and elevated estrogen levels. Such changes have been reproduced in rat models as well. Our studies reveal that in male rats with chronic alcohol exposure, key hepatic enzymes involved in hormone homeostasis are profoundly affected. Alcohol-fed male rats demonstrated a significant reduction in serum testosterone, and reduced hepatic activity of two androgen-dependent estrogen-clearing enzymes [estrogen sulfotransferase (EST) and estrogen 2-hydroxylase (E2-OHase)], resulting in increased serum estradiol levels^[26-29]. Decreases in serum testosterone, due to alcohol's toxicity to the testes, occurs early in alcohol exposure, whereas increases in estrogen levels are evident upon longer periods of feeding, thus hypogonadism precedes liver feminization. The studies emphasize that the disruption of the androgen-estrogen balance resulting from chronic alcohol ingestion in male rats can drastically affect the hepatic route and rapidity of sex steroid metabolism^[26].

Endocrine changes in chronic alcoholic females have been less well studied. Alcoholic females in their reproductive years also display profound abnormalities in hormone homeostasis and reproductive potential. Chronic alcoholic women may have menstrual cycle disorders, including amenorrhea, anovulatory or irregular cycles, and luteal phase dysfunction^[21,23,24,30-33]. Fertility is often (but not always) impaired^[31]. Onset of menopause is earlier in these women^[32]. Hypothalamic and pituitary dysfunction is also observed, with luteinizing hormone (LH) and follicle stimulating hormone (FSH) release suppressed, although hyperprolactinemia is common. Estrogen levels in the amenorrheic women may be reduced or normal^[30-33], and may differ among ethnic groups^[34]. In contrast, other studies showed that acute alcohol ingestion in nonalcoholic women, especially when administered simultaneously with hypothalamic/pituitary stimulation, results in increased estrogen levels^[35]. Whether this increase is due to increased synthesis or decreased hepatic clearance is not known, but the latter is suggested by the results of a study showing that women taking oral contraceptives had higher estrogen levels than control subjects after an acute dose of alcohol^[36]. Rat studies have shown that chronic alcohol ingestion leads to lower estrogen levels, and in anovulatory cycles characterized by reduced progesterone^[37], similar to findings demonstrated in premenopausal alcoholic women. Not all chronic studies in rats show a change in estrogen levels, however; after 18 mo of alcohol treatment, estradiol levels in one study remained normal^[38]. In postmenopausal chronic alcoholic women, however, estrogen levels appear to be higher (approximately 2-fold) than in controls, and even higher when cirrhosis is present^[32,33]. In these women, pituitary hormones (LH, FSH) are lower than in controls, although prolactin is elevated^[33]. In postmenopausal women on hormone replacement therapy, an acute dose of alcohol results in dramatically increased estrogen levels, presumably as a result of decreased hepatic metabolism of estrogens^[39]. Beyond this study, the effect of chronic alcohol ingestion on hepatic metabolism of sex steroids in fertile or postmenopausal women does not appear to

have been studied in any detail. All of these results taken together suggest that if estrogen (and progesterone) status is important in development of ALI, then the impact of hormones can differ, depending on menopausal/postmenopausal status and hormone replacement therapies, when alcohol ingestion is part of the equation.

IS ESTROGEN A PATHOGENIC COFACTOR IN ALI?

Some evidence suggests that estrogen may be an important pathogenic cofactor in development of alcohol liver injury. For example, females are more susceptible to ALI than males, both in human studies^[40-42] and in certain animal models of ALI^[43]. Further, female sex is considered as a risk factor for development of more profound and irreversible types of ALI^[42]. Estrogens are also implicated in other types of liver disease. In acute fatty liver of pregnancy, estrogen results in of mitochondrial injury^[44] by decreasing β -oxidation of fatty acids, altering the function of mitochondrial proteins and enzymes in mitochondrial uptake, and causing ultrastructural changes such as mitochondrial enlargement. These changes lead to fat accumulation in the liver, in the form of micro/macrovesicular steatosis^[45]. Of interest, estrogen also mediates mitochondrial ROS generation in breast cancer cells, resulting in increases in proliferation signals^[46]. It is known that mitochondrial damage is a major apoptosis-triggering event, which is necessary for further development of ALI^[47-49]. In an enteral feeding rat model (T/F), Thurman^[8] documents an increased susceptibility in female rats, showing that females had an increased pathology score, neutrophil infiltration, and increased levels of circulating endotoxin; the authors concluded that increased endotoxin, LPS, and Kupffer cell activation are responsible for the increased ALI in these rats. Further, it has been shown that the sensitivity of Kupffer cells to endotoxin is increased by very high doses of estradiol (a weak estrogen with high levels in pregnancy)^[50]. In a recent study in humans, estrogen treatment was shown to increase inflammatory cytokine production^[51]. Other reports stated that estrogen treatment enhances ALI in ovariectomized females^[52]; however, no data comparing control rats treated with estrogen were presented, so it is difficult to factor out the effects of estrogen alone from the effects of the combined treatment (alcohol plus estrogen). None of these studies determined whether the effect of estrogen is at the level of the liver, the gut, or both. This factor is important, since it is clear that sterilizing the gut with antibiotics prevents much of the ALI in male rats so treated^[53]. In a Lieber/DeCarli model, post-pubertal females have been shown to incur more alcohol-induced oxidative injury than males, as evidenced by increased levels of malonaldehyde^[54]. There is also evidence that estrogens induce potentially more damaging immunological responses^[55], due to estrogen's effects on macrophages^[56], although such effects may be dose-dependent^[57,58]. Estrogen receptors (ER) have been

identified in both Kupffer cells and sinusoidal endothelial cells^[59] as well as in hepatocytes^[27], although the levels of ERs are about 10-fold lower in the nonparenchymal cell types. These latter cells, along with hepatocytes, are major producers of those cytokines shown to have crucial roles in pathogenesis of ALI^[60,61], tumor necrosis factor (TNF)- α , transforming growth factor (TGF)- β , and interleukins, and they also attract PMNs, which produce additional cytokines and ROS, all of which are contributing pathogenic factors in ALD^[11]. One report notes that injury in a low-carbohydrate alcohol feeding model is greater in females^[62], and that such injury is partially prevented by administration of an antiestrogen toremifene^[63]. The antiestrogen primarily reduced inflammation and necrosis, reduced TNF- α release from isolated Kupffer cells, enhanced selenium-glutathione peroxidase activity, and reduced CYP2E1 activity, as compared to the control groups. Lastly, there is known cross-signaling between estrogen and growth factor (EGF, TGF- β , HGF) intracellular pathways. The estrogen appears to act through nuclear and possibly cell-surface ERs, and post-transcriptional regulation of signaling elements, with impact on cell growth, regeneration and fibrosis^[64-67]. Since similar changes are observed in alcohol-induced liver injury, the conclusion was reached that estrogen must play a role in this injury. It is also possible that males might also be susceptible to estrogenic influences, since hyperestrogenization is common with chronic alcohol ingestion, noted above. Our studies^[28] showed that androgen-responsive functions in male rat liver are altered during chronic alcohol exposure, with feminization of male rat liver as a consequence of lowered testosterone levels and elevation of estrogen in liver and serum. The latter appears to be due to a time-dependent reduction in activity of androgen-controlled estrogen metabolizing liver enzymes E2-OHase and EST^[26]. In males, and in both the Lieber/DeCarli^[26] and the intragastric models^[29], the greatest liver injury is observed under circumstances of high estrogen and low testosterone. However, the serum estradiol level in male rats, regardless of alcohol intake, is always several-fold (7-10 \times) lower than in females. Thus, if estrogen is a cofactor in ALI, then it stands to reason that females should be more affected by this hormone than males. In addition, in both female rats and women, progesterone, the "counter-hormone" to estrogen, is reduced with alcohol consumption, since ovulation is less likely to occur. Thus, the estrogen present is less opposed by progesterone. It should also be noted that no studies have been done to determine if the other female sex hormone, progesterone, has any role in causing, or preventing, liver injury.

DIFFERENTIAL GENE EXPRESSION IN FEMALE RATS FED ETHANOL

Several studies have shown that the livers of female rats fed alcohol express different gene sets than males in response to injury. Tadic *et al*^[68] showed that a microar-

ray analysis in the Lieber/DeCarli model of alcohol exposure, female rats fail to up-regulate a number of hepatoprotective genes in response to alcohol, and that those genes that regulate various compensatory metabolic pathways also do not respond appropriately. Using the same model and with addition of lipopolysaccharide treatment, Banerjee *et al*^[69,70] also showed differential expression of genes involved in oxidative stress and inflammation. Sharma *et al*^[71] found similar changes in genes involving oxidative stress and metabolic adaptation. Donohue *et al*^[72] demonstrated a lack of induction of hepatoprotective enzymes and increased lysosomal leakage in female rats fed an ethanol- and fish-oil containing diet. While these studies reveal differences in response to metabolic stress in females caused by alcohol, it is not clear how many of these changes are due directly to hormone influences.

RELATIONSHIP OF GUT INJURY TO ALI

The intestinal barrier to antigens, food materials, bacteria, invasive organisms, such as viruses, is a gatekeeper that is critical in maintaining the health of the host. The barrier is a continuous epithelial cell layer, connected by tight junctions that may permit passage of small amounts of materials under normal circumstances, but in pathological conditions, become leaky, permitting the inappropriate passage of particles, bacteria, macromolecules, and immunogenic substances. Stress, infection, chemical insult, surgery, and burns are among the conditions that result in gut injury. The response of the intestine is to secrete fluid and ions to wash away the causative agent, and an immune response involving recruitment of inflammatory cells, and mucus secretion. Key to host protection, however, is maintenance of tight junction integrity in the gut. The tight junctions are highly specialized complexes at the apical end of epithelial cells, and form the actual barrier between the intestine and the blood. Tight junctions are characterized by complex interactions among a group of transmembrane proteins including claudins, occludins, and junction adhesion molecules that interact with other proteins, such as the family of zonula occludens proteins. Complex interactions among these proteins involve anchoring the protein complexes with the actin cytoskeleton. Loss of the appropriate interactions among members of this complex can lead to loss of integrity, and result in a gut that is leaky to bacteria, bacterial products such as endotoxin and other toxins, immunogenic food particles, and other substances^[73,74].

The evidence linking gut-derived endotoxin in the blood as a factor in ALI is compelling. Endotoxins, for example, lipopolysaccharide originating from the cell wall of gram-negative bacteria that populate the gut, are maintained almost exclusively in the lumen as a result of the intestinal barrier afforded by a healthy gut mucosa. However, in circumstances such as stress, trauma, or other gut injury (such as chronic alcohol ingestion),

the mucosal barrier becomes more permeable, allowing endotoxin to cross the mucosa and enter the portal circulation. In the healthy liver, Kupffer cells maintain a constant surveillance and will sequester and degrade endotoxin. However, if Kupffer cell function is impaired, or if levels of endotoxin are excessive, an inflammatory response can result. In addition, endotoxin will be taken up by the resident macrophage population within the intestinal mucosa, triggering an inflammatory response that can lead to further impairment of mucosal barrier function. Endotoxin is linked to ALI in that clinical observations show that endotoxin levels are high in patients with ALI^[1,73,74]. Animal studies show that circulating endotoxin and subsequent liver injury can be eliminated by sterilization of the bowel with antibiotics^[53] and reduced by dietary strategies such as oat fiber^[75] and zinc supplementation^[76] that presumably help maintain barrier function. While the appearance of endotoxin in the circulation implies the possibility of gut injury, very few studies address directly the mechanism of alcohol injury to the gut beyond nutrient uptake considerations. Several studies in Caco-2 cell monolayers, which are derived from human epithelial colorectal adenocarcinoma, show that alcohol^[77] and its first metabolic product, acetaldehyde^[78] can result in disrupted tight junctions and increased paracellular permeability in these cells. Acetaldehyde treatment results in loss of tight junctions because it results in redistribution of tight junction proteins^[78], an effect that may be mediated by a tyrosine kinase-dependent mechanism. Increased endotoxin in rat alcohol feeding models have been shown, and reports document a greater endotoxin level in female rats fed alcohol, and more liver injury as well^[17,43]. Our recent studies using the Nanji rat alcohol feeding model have indicated that young female rats show significantly more gut inflammation, injury, and loss of barrier function due to alcohol ingestion than do male rats (submitted for publication).

Once endotoxin is released by the intestine to the blood, it is bound with high affinity to lipopolysaccharide binding protein (LBP), an acute phase protein synthesized in the liver. The LBP binds endotoxin to its N-terminus through its lipid A moiety, whereas its carboxy terminus is a ligand for the CD14 receptor on the Kupffer cell membrane. Binding of the LBP-LPS to CD14 triggers the activation of Toll-like receptor 4, with subsequent induction of pro-inflammatory transcription factors (NF- κ B), the production of pro-inflammatory mediators such as cytokines [TNF α , interleukin (IL)-6, IL-18], and the production of COX-2-derived prostaglandins^[79]. The crucial role of the Kupffer cell in this process is illustrated by experiments in an alcohol feeding model where treatment with GdCl₃, an inactivator of cells of macrophage lineage, significantly reduced liver injury^[8].

EFFECT OF SEX HORMONES ON GUT PERMEABILITY AND ENDOTOXIN LEVELS

Very little is known about possible direct effects of fe-

male sex hormones on gut permeability. A recent report shows that increased intestinal permeability is a factor in intrahepatic cholestasis of pregnancy^[80]; this finding is relevant in that pregnancy is characterized by high levels of estrogen and progesterone. A few studies have examined the effects of hormones on liver-enterotoxin interaction. When female rats are treated with a sublethal dose of endotoxin *via* tail vein, those rats also treated with a combination of synthetic estrogen and progesterone identical to that in oral contraceptives showed pronounced gut permeability and liver injury, with increased TNF α production by Kupffer cells^[81]. However, these studies used very high doses of hormones, and the hormones were only used as a combination, and not separately. In an alcohol model, Enomoto *et al*^[50] showed that treatment of female rats with very high doses of estriol, a very weak estrogen, resulted in increased endotoxin levels and increases in Kupffer cell TNF α and CD14 content. Because these effects were blocked with oral nonabsorbable antibiotics, the authors concluded that the estriol treatment resulted in increased gut permeability. In another study using burn and trauma/hemorrhagic models, it was shown that estrogen decreased markers of gut injury, whereas testosterone increased susceptibility^[82]. It should be noted that the mechanisms in these models may differ from that in ours, since in gut trauma models injury to the mucosal barrier is acute and severe, whereas in alcohol models the injury is chronic. Thus, hormonal changes in the acute gut trauma models may be entirely different than in the chronic alcohol models. In Caco-2 cells, Asai *et al*^[83] showed that estradiol treatment potentiated alcohol-induced apoptosis, leading to speculation that estrogen might increase gut permeability *in vivo*. With respect to the liver, an interesting study using cultured hepatic stellate cells showed that estradiol treatment reduced ROS generation through the NADPH oxidase system, and also attenuated TGF β 1 expression, cell activation, MAPK pathways, as well as fibrogenic responses. In contrast, progesterone treatment increased ROS generation, TGF β 1 expression, and stellate cell proliferation^[84]. Thus, a potential role of progesterone in ALI should be considered.

FUTURE RESEARCH AND CLINICAL IMPLICATIONS

Future work will foster further understanding of the roles of sex in susceptibility to and in the pathogenesis of ALI. The role of sex hormones, both estrogen and progesterone, remain to be elucidated in this injury. Furthermore, the influences of age and menopausal status are not clear. Are postmenopausal women who are not using hormone replacement less susceptible to ALI? Another emerging area of interest is whether dietary supplements such as fiber and probiotics can alter the course of gut injury and thus liver injury. Obviously, much work needs to be done to understand the interplay of these factors. However, it remains prudent to advise

women that they are at greater risk for alcohol-induced injury, and that intake should be limited to one drink per day. Further, caution should be exercised with heavy use of alcohol in the setting of oral contraceptives or hormone replacement therapy. Since heavy alcohol use interferes with hepatic metabolism of hormones, circulating levels of hormones may increase, thus also placing women at risk for hormone-responsive tumors of the breast and reproductive tract.

CONCLUSION

The evidence outlined herein strongly points to greater risk for women for developing severe ALI and cirrhosis than men. Although the exact roles of female hormones have not yet been proven or elucidated, women should exert caution by limiting their alcohol intake to one drink or less per day to avoid the complications of alcohol-induced liver injury.

Abstract

AIM: To extend the knowledge of the dynamic interaction between *Helicobacter pylori* (*H. pylori*) and host mucosa.

METHODS: A time-series cDNA microarray was performed in order to detect the temporal gene expression profiles of human gastric epithelial adenocarcinoma cells infected with *H. pylori*. Six time points were selected to observe the changes in the model. A differential expression profile at each time point was obtained by comparing the microarray signal value with that of 0 h. Real-time polymerase chain reaction was subsequently performed to evaluate the data quality.

RESULTS: We found a diversity of gene expression patterns at different time points and identified a group of genes whose expression levels were significantly

INTRODUCTION

Helicobacter pylori (*H. pylori*) have been shown to be the principal cause of acute and chronic gastritis and a major risk factor in gastric cancer development. A chronic inflammatory process induced by the pathogen is thought to be the cause of tumor development. It is well known that *H. pylori* binding to epithelial cells can induce tyrosine phosphorylation of host cell proteins and rearrangement of the cytoskeleton, which may contribute to inflammation and oncogenic transformation^[1]. *H. pylori* colonization to the mucosa may also induce a systemic immune response and be susceptible to Ab-dependent complement-mediated phagocytosis and killing. Infected epithelial cells may also induce a mucosal inflammation under a mechanism of autoantibody-mediated destruction^[2]. Some host factors like interleukin (IL)-1 β , tumor necrosis factor (TNF)- α ,

and IL-10 may influence the disease outcome. One investigation on nuclear factor (NF)- κ B signaling pathway and iNOS suggests that NF- κ B activation may play an important role in protecting mucosal cells from apoptosis through upregulating iNOS^[3]. Many previous studies have performed expression profiling to investigate host changes induced by *H. pylori* infection. These studies have provided some useful and significant information and shed some light for exploring the potential mechanism of *H. pylori* infection and host immunity^[4-10]. However, none of them is designed based on a time-series scheme, the global and sequential profile of *H. pylori* infection that may be involved in the pathogenetic mechanism by which *H. pylori* infects and contributes to gastric carcinogenesis remains poorly understood. In this study, human gastric epithelial adenocarcinoma cells (AGS) co-cultured with an *H. pylori* 26695 strain at different time points were separated and analyzed by a whole genome Illumina microarray. Computer-assisted bioinformatics analysis was conducted to analyze the differential gene expression pattern.

MATERIALS AND METHODS

H. pylori and AGS cell co-culture

H. pylori strain 26695 was routinely cultured for 24 h on Columbia agar plates (Oxoid) containing 5% goat blood under microaerophilic conditions at 37°C, following a wash in sterile PBS and estimation of the quantity of bacteria by OD600. The human gastric epithelial adenocarcinoma cell line AGS (ATCC CRL 1739) was cultured in RPMI 1640 without antibiotic or antifungal agents, and supplemented with 4 mmol/L L-glutamine and 10% fetal calf serum (Gibco) at 37°C in a humidified atmosphere of 5% CO₂. A monolayer of AGS cells grown to 80% confluence was co-cultured with *H. pylori* at a multiplicity of infection of 300:1 in culture media for 0.5, 1, 2, 4, and 6 h.

RNA isolation

Co-culture was stopped at each time point and followed by washing three times with PBS. Total RNA was isolated using Trizol extraction (Gibco/BRL). The quality of the RNA was verified by 1% agarose gel containing ethidium bromide.

Microarray expression profiling and data analysis

Illumina Human-6 v2 BeadChips used for this study contains probes for well characterized genes, gene candidates and splice variants for a total number of 48000 features. The "Detection Score > 0.99" was used to determine the expression. It was a statistical measure in the BeadStudio software, which was computed based on the Z-value of a gene relative to that of the negative controls. The data were normalized using a cubic spline method, which was generally used as a normalization algorithm in BeadStudio. The differentially expressed genes in different time point were identified using the Illumina custom error model implemented in BeadStudio. DiffScore, the expression difference score, takes into account background noise

and sample variability^[11]. The formula for the calculation of the DiffScore is: $DiffScore = 10 \operatorname{sgn}(\mu_{\text{cond}} - \mu_{\text{ref}}) \log_{10} (p)$. The differentially expressed genes with a $|DiffScore| > 13$ were selected for further analysis. The genes with a fold change > 1.5 were integrated and hierarchically clustered using Mev_4_0 (Multiple Experiment Viewer, TIGR). Gene enrichment in KEGG pathways (Kyoto Encyclopedia of Genes and Genomes) and Gene Ontology (GO) were accomplished with Onto-Tool (Pathway Express, OE2GO)^[12,13], and co-expression gene clustering by short time-series expression miner (STEM, Carnegie Mellon University)^[14] with a maximum number of model profiles set as 245, and a maximum unit change in model profiles between time points set at 2. Four interesting co-expression profiles were selected for further analyses. To obtain an optimized GO distribution, we also took all differentially expressed genes including those with a fold change < 1.5 as input for STEM analysis, and chose four profiles for GO enrichment using OE2GO. For pathway level analysis, those genes with a fold change > 1.5 were imported into Pathway-Express to obtain the significantly perturbed pathway list and gene mapping. This program was based on an impact analysis that included the classical statistics but also considered other crucial factors such as the magnitude of each gene's expression change, their type and position in the given pathways, their interactions, *etc.* The *IF* of a pathway is calculated as the sum of the following two terms:

$$IF(P_i) = \log(1/p_i) + \frac{\sum_{g \in P_i} |PF(g)|}{|\Delta E| \cdot N_{de}(P_i)}$$

$$PF(g) = \Delta E(g) + \sum_{u \in U_{Sg}} \beta_{ug} \cdot \frac{PF(u)}{N_{ds}(u)}$$

Then a simplified network construction was completed based on the genes enriched and mapped to KEGG pathways using STRING (version 8.2)^[15], which is a known Predicted Protein-Protein Interactions Database (<http://string.embl.de/>).

Real-time polymerase chain reaction for confirmation of microarray results

Real-time reverse-transcriptase polymerase chain reaction (Q-RT-PCR) validation of microarray results was carried out for the *GFPT2* gene at the five time points which were significantly altered according to the microarray data. RNA samples of different time points were prepared as previously described in RNA isolation. Briefly, 2 g total RNA of each sample was used for cDNA synthesis. Real time PCR was performed on the Rotor-Gene RG-3000 Real-Time Thermal Cycler with the SYBR Premix Ex Taq™ (TakaRa) and *GAPDH* was used as an internal control. The relative quantification of mRNA expression at each time point was calculated and compared with that of the untreated AGS cells as control. The primers of selected gene for RT-PCR were: (1) *GFPT2* forward primer (5'-GACAAGCAGATGCCCGTCAT-3') and reverse primer (5'-AACTTGGAACTTTCAG-TATCGTCCTT-3'); and (2) *GAPDH* forward primer

(5'-AGAAGGCTGGGGCTCATTTG-3') reverse primer
(5'-AGGGGCCATCCACAGTCTTC-3').

RESULTS

Definition of differentially expressed genes

Microarray hybridization results showed that about 3577 genes in total ($P < 0.05$, DiffScore > 13 , named dataset1 in this study) expressed differentially compared with 0 h group. This dataset was generated by taking an integration and alignment for the gene list of different time points using Microsoft Excel software, and the repeated genes were thus excluded. Rows were gene names and columns were differential expression values in different time points. Those genes without fold changes in some time points were set as a value equal to 0. The gene numbers at each time point for the 808 genes ($P < 0.05$, a fold change > 1.5 , named dataset2 in this study) are listed in Table 1 and were selected for further emphatically analysis.

Microarray data analysis

Taking dataset2 as input, hierarchical cluster analysis showed some differentially expressed genes down-regulated at 4 h and up-regulated at 6 h (Figure 1A and B). Eighty of the most differentially expressed genes were extracted by sorting their fold change and were hierarchically clustered as shown in Figure 1C. Immunity and tumor-related genes were labeled with triangles and circles, respectively. Ten significant profiles were obtained by STEM and four interesting profiles were shown with genes in detail (Figure 2 and Table 2). However, GO analysis did not provide significant terms. Taking dataset1 as input, the GO analysis results for the four profiles clustered are listed in Table 3 and Figure 3. Table 4 shows the GO distribution change of each time point by up-regulation and down-regulation, respectively. Analysis of KEGG pathways revealed many enrichment-related pathways including cell adhesion molecules, MAPK signaling, p53 signaling, and TGF- β signaling pathways, complement and coagulation cascades, and epithelial cell signaling in *H. pylori* infection. The top four significantly perturbed pathways are listed in Table 5. Related networks extracted from significant pathways are shown in Figure 4.

Real-time PCR confirmation of microarray results

Relative expression levels of each time point were consistent with that of the microarray profile except at 0.5 h, for which a little higher fold-change was obtained in microarray data.

DISCUSSION

Some previous studies have reported that *H. pylori* type I strains that harbor the *cag* pathogenicity island (PAI) and *cagA* are associated with increased bacterial virulence and a more severe inflammatory response in

Table 1 Number of different genes expressed at different time points compared with those of control AGS cells

Time point (h)	Up-regulation (n)	Down-regulation (n)	Total
0.5	109	209	318
1	140	242	382
2	151	203	354
4	126	291	417
6	198	156	354

$P < 0.05$, fold-change > 1.5 , dataset2.

gastric epithelial cells. These virulence factors have also been considered to be associated with induction of interleukin through an NF- κ B-dependent pathway in host mucosa^[6]. In addition, host protein phosphorylation, cytoskeletal rearrangement, and differential activation of MAP kinases have been described in host cells after infection of type I strains^[1]. Although *CagA* and *Cag PAI* are considered to be factors highly involved in the development of gastritis and carcinoma, more complex as yet undiscovered mechanisms may exist between *H. pylori* and host cells. We aimed to take a global view of gene expression profiles of host response to infection in a time-series interaction model, which may help understand the pathogenesis of *H. pylori* related diseases.

Considering that only genes with fold changes > 1.5 were included in the analysis, the number of differential genes was only 808. This may lead to an ignorance for many important genes. Therefore, we initiated co-expression clustering analysis using STEM for both the 3577 differentially expressed genes (dataset1) and 808 genes (dataset2) with fold-change > 1.5 . For the 808 genes, four significant clusters showed four different co-expression profiles (Figure 2). One hundred and twenty-six genes down-regulated at 4 h were clustered into profile 123, but no significant GO terms were enriched for these genes. In profile 3, some genes related to tumors were consistently down-regulated. For instance, *cdkn1c* had consistently decreased expression of these genes, which may be involved in promotion of tumor formation. Profile 144 was mainly involved in factors regulating cell bioactivity and morphology such as *rflb*, *gdf15*, *sqstm1* and *adm2*. DNA-damage-inducible transcript and *csf2* also had increased gene expression at 4 and 6 h, suggesting that some potential mechanisms for cell differentiation and damage may be triggered beginning at 4 h. Hierarchically clustered results also showed two gene clusters with down-regulation at 4 h and up-regulation at 6 h. Analysis of all differentially expressed genes showed four interesting profiles whose GO distributions included nucleic acid binding, regulation of transcription, oxido-reductase activity *etc.* For the GO distribution of dataset1, profile 71 and profile 83 showed a similar co-expression profile as well as GO terms including nucleus, nucleic acid binding *etc.* (Table 3, Figure 3B and D). However, profile 83 showed an obvious and continuous up-regulated gene cluster. Profile 111 and 108 mainly focused on cell surface and showed a down-regulated

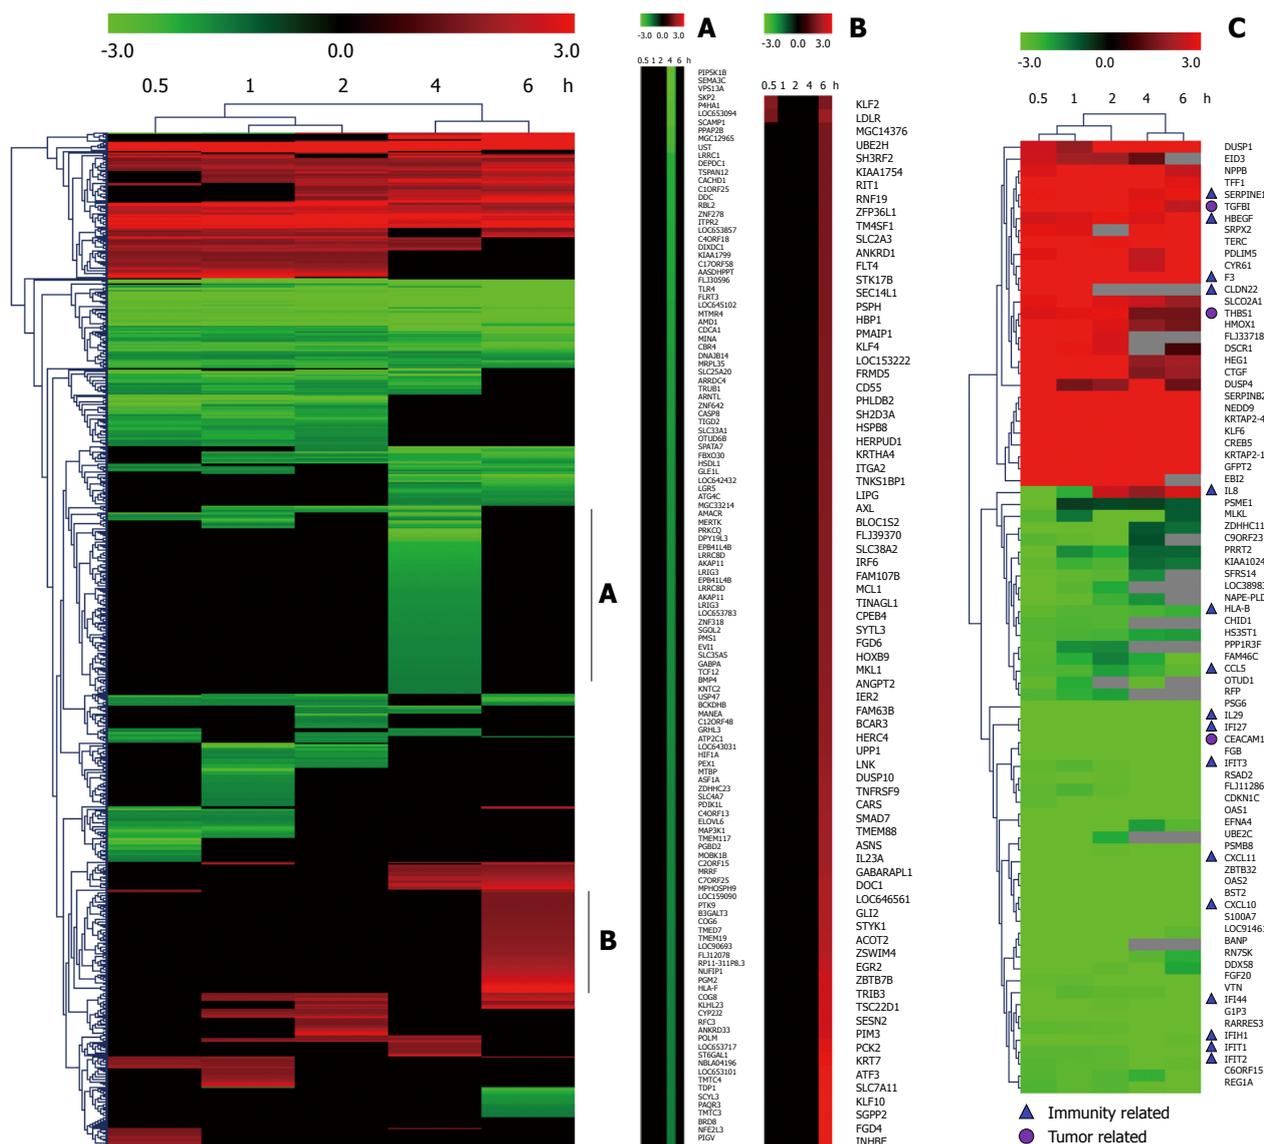

Figure 1 Hierarchical cluster analysis of time-series gene expression alteration after infection of *Helicobacter pylori* at 5 time points. Genes that significantly changed during infection were included in hierarchical clustering analysis using average linkage and Euclidean dissimilarity methods. Significant clusters A and B show the details of genes including name of the gene down-regulated at 4 h and up-regulated at 6 h. Eighty of the most differentially expressed genes were clustered in C. Immunity and tumor related genes are labeled.

gene cluster (Figure 3A and C). All profiles illustrated an obvious expressional change at 4 h. Statistically significant changes in gene ontology at each time point showed that apoptosis appeared from 1 h in up-regulated genes. At the same time, in down-regulated genes, chemokine activity became the most significant term (Table 4). This seemed consistent with results of the pathway analysis, which showed that the P53 signaling pathway became the most significantly perturbed pathway at 1 h in up-regulated genes. In down-regulated genes, the cytokine-cytokine receptor interaction pathway became more significant. Genes involving immune response and other responses to viruses were at the top of the GO list of down-regulated genes. This suggested an inhibition of immune response by *H. pylori* during early infection. Tumor-related pathways like P53 and MAPK may play an important role in determining the development of

special phenotype and disease outcomes according to the results of pathway analysis. For the top 80 differentially expressed genes, 43 (54%) were related to immunity (29, 36%) and tumor development (14, 18%). Many immune factor-related down-regulated genes showed a consistently increasing expression levels. The cell adhesion molecules (CAM) pathway was the most significantly perturbed pathway at several time-points. The increased expression of CAM induced by *H. pylori* may contribute to cell adhesion, invasion and cell proliferation in gastric epithelial cells^[17].

From the reconstructed simplified pathway, we can inspect some important nodes with several interaction edges like *stat1*, *stat2*, *fos*, *csf2*, *pdgfb* and *ccl5* genes. These genes may be the trigger and linker of the pathway net during early infection, which however requires further studies. From Figure 4 and the expression value of each

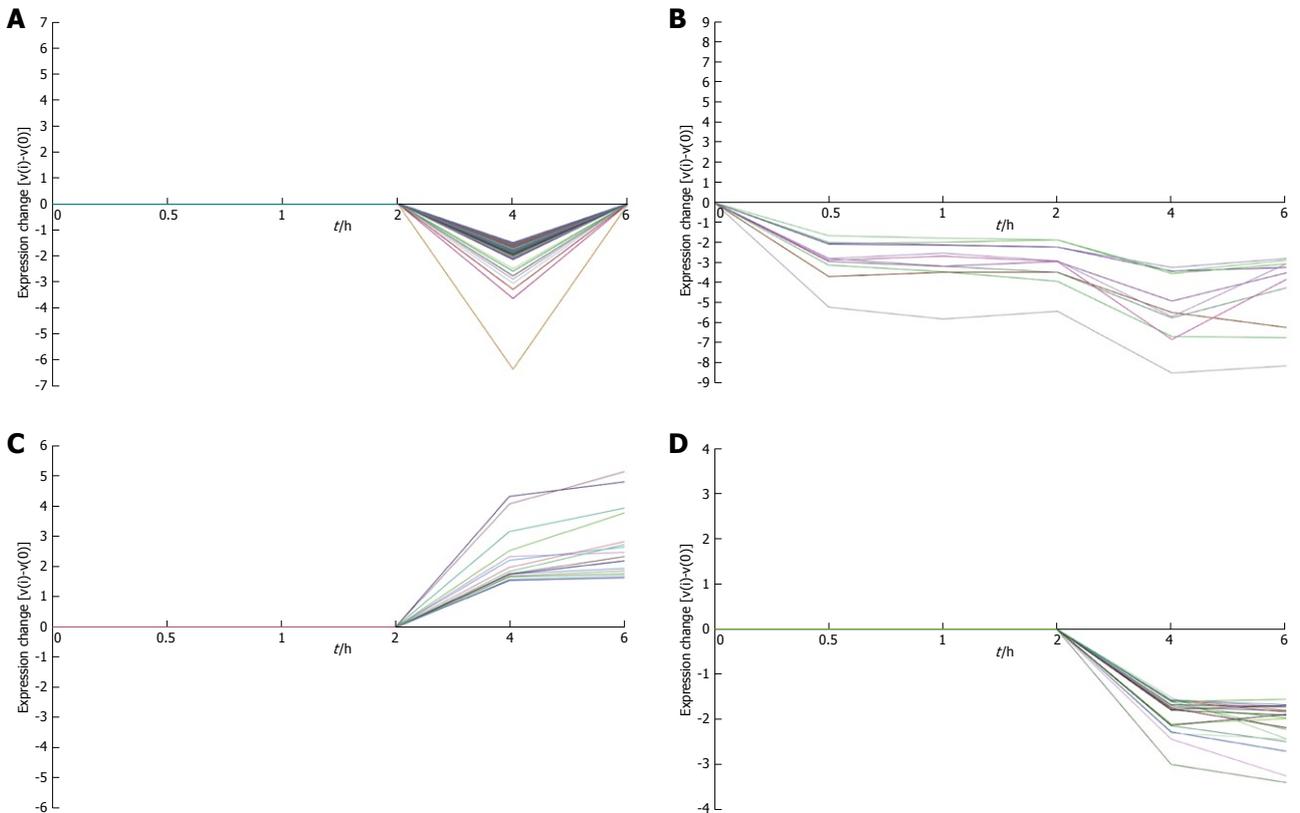

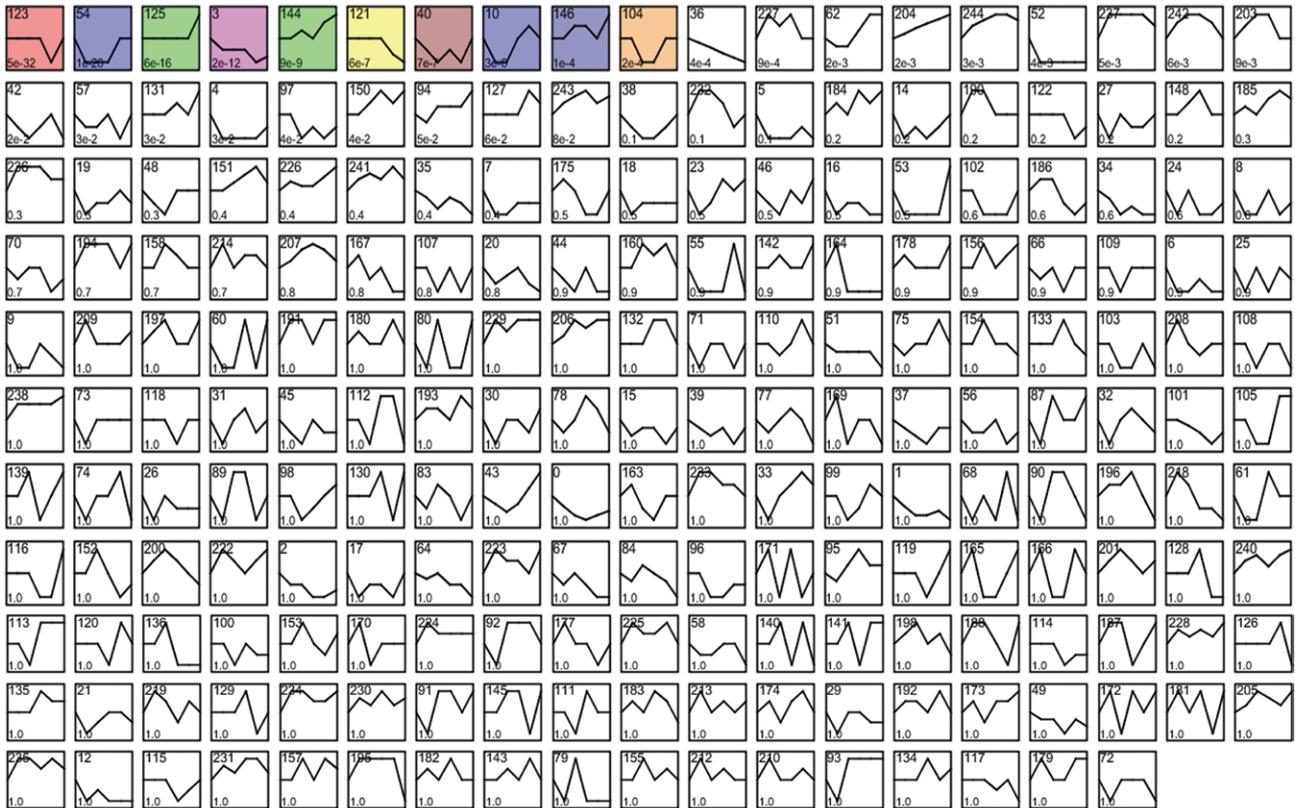

Figure 2 Short time-series expression miner (STEM) clustering of the differentially expressed genes. All profiles are ordered based on the *P*-value significance of the number of genes assigned vs expected. A: Profile 123 (0, 0, 0, 0, -1, 0): 126.0 genes assigned, 37.8 genes expected, *P*-value = 5.4E-32 (significant); B: Profile 3 (0, -2, -2, -2, -4, -3): 11.0 genes assigned, 0.4 genes expected, *P*-value = 1.9E-12 (significant); C: Profile 144 (0, 0, 1, 0, 2, 3): 16.0 genes assigned, 2.5 genes expected, *P*-value = 8.5E-9 (significant); D: Profile 121 (0, 0, 0, 0, -2, -3): 21.0 genes assigned, 5.7 genes expected, *P*-value = 6.3E-7 (significant).

gene, we could learn that most immunity-related genes were down-regulated while many tumor-related genes

were up-regulated. *Il-24* is an important oncogene and could inhibit specifically the tumor growth. The protein

encoded by this gene can induce apoptosis selectively in various cancer cells. Overexpression of this gene has been shown to lead to elevated expression of several GADD family genes, which correlates with the induction of apoptosis^[18,20]. In this study, we examined *il-24* levels which gradually increased more than two-fold from 2 to 6 h. At 6 h, there was a ten-fold change, indicating that after perturbation of P53 and MAPK, *il-24* may participate in maintaining the immune defense against invading pathogens. We also examined an increased level of *gadd45* which can stimulate DNA excision-repair *in vitro* and inhibits entry of cells into S phase. This gene is a member of a group of genes whose transcript levels are increased following stressful growth arrest and treatment with DNA-damaging agents. In the network, both *c-Fos*

and *c-Jun*, two genes considered to mediate inflammation and carcinogenesis, have been found to be up-regulated, which is consistent with the results of this study^[21].

We also analyzed expression profiles of some other important infection-related genes that were reported previously and may play an important role in *H. pylori*-induced diseases, although these genes were not clustered into a special profile in this study using the current analytical tools. MMP is a mucosal matrix metalloproteinase. Previous studies have demonstrated elevated MMP-9 levels in *H. pylori*-infected gastric mucosa, and eradication of *H. pylori* can significantly decrease MMP9 expression levels consistently^[22,23]. MMP1 has been the subject of studies of inflammatory gene profiles in gastric mucosa^[2,24]. MMP7 has been reported to be up-regulated in gastric cancer tissues^[25,26]. However, few studies have reported on MMP24. In this study, the profile of MMP24 showed a consistent and increased level from 1 to 6 h, which suggested a similar function with MMP9 during *H. pylori* infection. Some other genes with similar expression profiles are *il-27ra*, *il-32*, *il-23a*, *il-11*, *il-8* and *ccl20*. This gene cluster showed down-regulation or no change at the first two or three time points and up-regulation in the last two or three time points. *Il-29*, *ccl5*, *cxc10* and *cxc11* showed a consistent down-regulation at all time points with high fold-change. Expression of these genes suggested that the immune defense system may be suppressed during the first 1 or 2 h of *H. pylori* infection and some tumor-related genes and pathways were activated. After this short interaction and competition for about 2 h, the immune defense system may have regained the advantage with increasing expression levels of inflammatory and tumor suppressor factors. CagA translocation might occur 30 min after infection and may be at its maximum level in a time range of about 4-5 h^[27,28]. In this study, the differentially expressed genes significantly increased at the time point of 4 h. This also

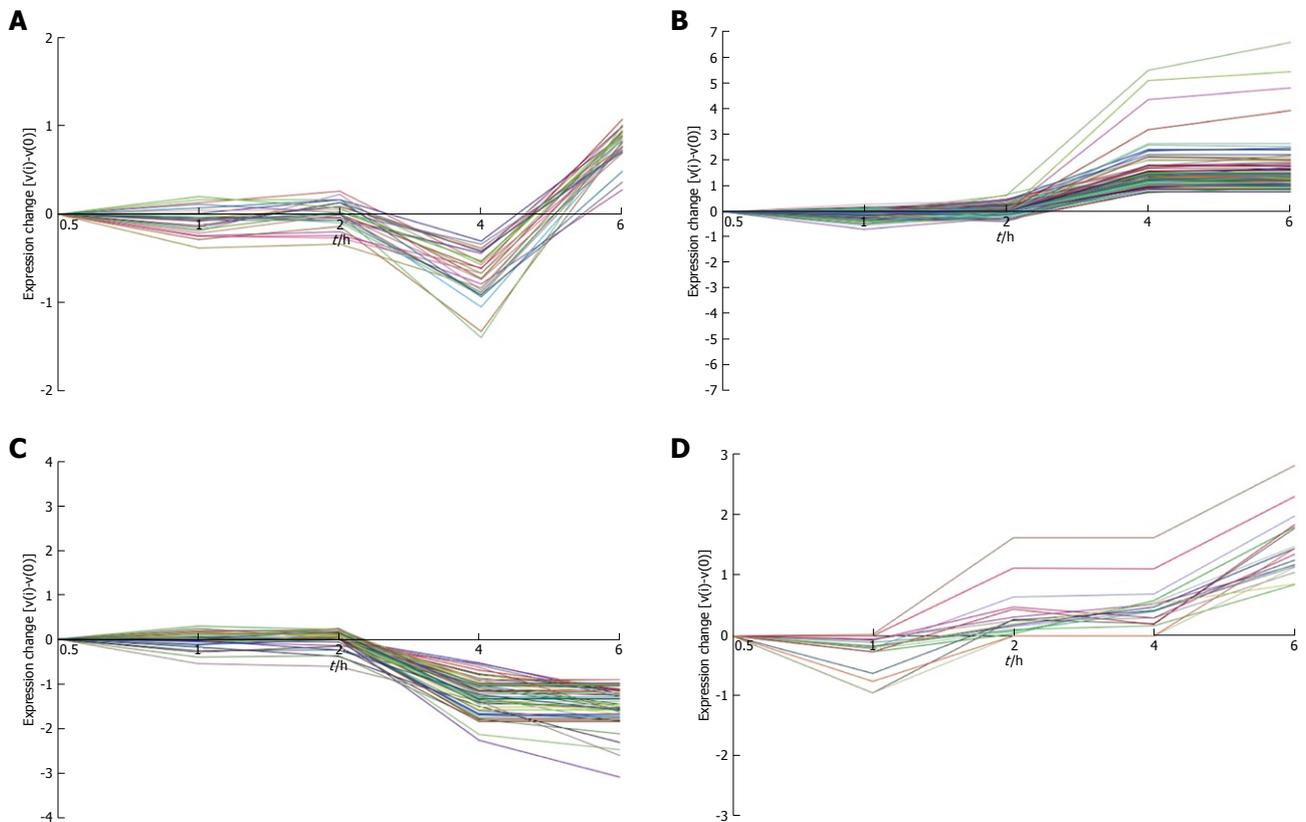

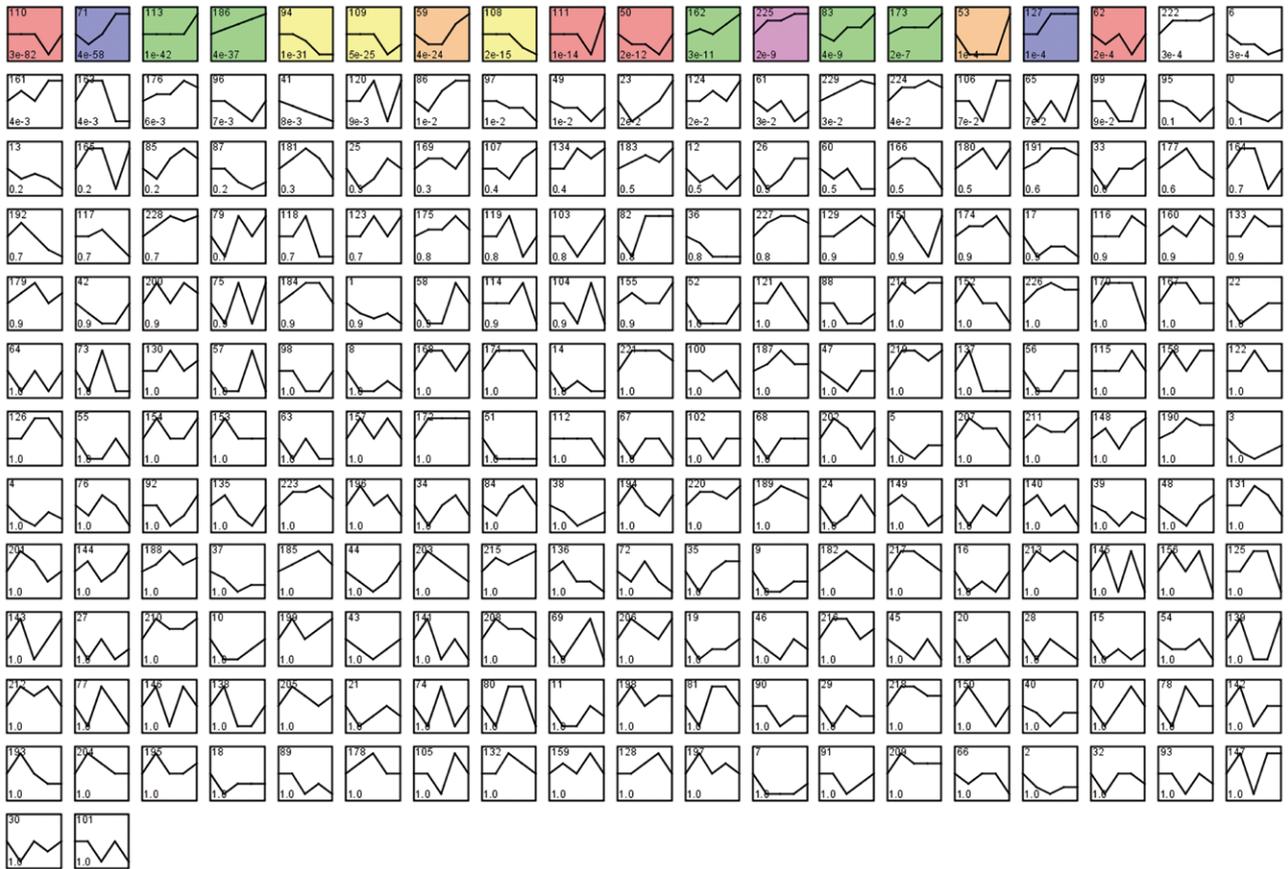

Figure 3 STEM clustering of all the 3577 differentially expressed genes labeled by accession number. All profiles were ordered based on the *P* value significance of the number of genes assigned vs expected. A: Profile 111 (0, 0, 0, -1, 1): 28.0 genes assigned, 4.2 genes expected, *P*-value = 1.2E-14 (significant); B: Profile 71 (0, -1, 0, 2, 2): 123.0 genes assigned, 19.0 genes expected, *P*-value = 4.4E-58 (significant); C: Profile 108 (0, 0, 0, -2, -3): 57.0 genes assigned, 16.2 genes expected, *P*-value = 1.5E-15 (significant); D: Profile 83 (0, -1, 1, 1, 3): 17.0 genes assigned, 2.7 genes expected, *P*-value = 4.3E-9 (significant).

Table 4 Statistically significant changed gene ontology at each time point

Time point (h)	Up-regulation					Down-regulation

ONTO-TOOLS/OE2GO was used to identify the differentially expressed GO terms based on the hypergeometric distribution and corrected P value (< 0.05). The GO identified number (GOID), GO term name (GO name), the number of genes changed within each functional gene category, P values are listed. GO terms with at least 3 genes changed and corrected P values < 0.05 are listed in Table 4.

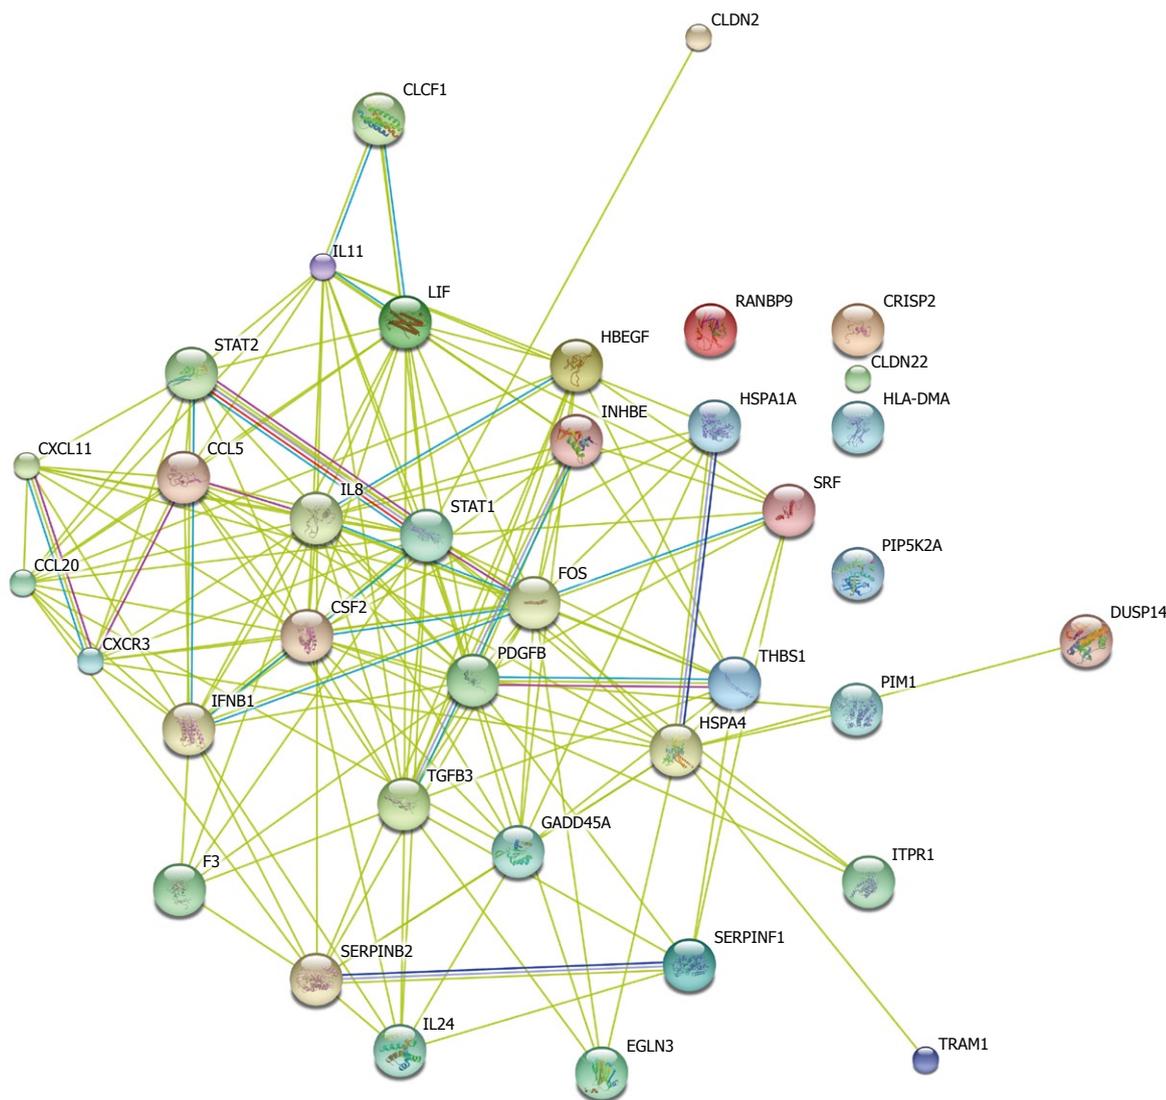

Figure 4 A simplified gene network extracted from significant pathways using STRING database.

suggested that it might be an important turning point between infection and host response. Although a model system of the AGS cell line infected with *H. pylori* was used to explore the host response^[5,29], it should be noted that this is an isolated cell culture system, and cannot account for the varied effects of conditions in a human stomach. Therefore, the speculation generated from this study represents a valuable, but a simplified view of the

situation. More researches are required to confirm these findings. In addition, we also compared our results with the genes with significant change after *H. pylori* infection in another report^[30]. Several genes in that report are consistent with our results in dataset1 like *socs2*, *stat6*, *ccl4*, *cxcl2*, *bla-dma*, *hsph1*, *plat*, *ifitm1*, *alox5*, *thr4*, *faim3*, *cd47*, *ifngr1* and *il8*.

Only part of these genes showed a high fold change > 1.5 in differential expressions, including *il8*, *faim3*, *thr4*, *alox5*, *bla-dma*, *cxcl2* and *ccl4*.

In summary, the results from this sequential expression microarray have extended previous studies that were limited to the comparison of normal and diseased tissues. We took a global view on the genes and pathway net related to *H. pylori* infection, several co-expressional profiles and important new genes like *mmp24* and *il-24* involved in immune response and tumorigenesis during *H. pylori* infection were also identified. Our study also suggested that the outcome of *H. pylori* infection is probably involved in a complex mechanism, and is associated with a number of immune factors. Formation of tumors may be a result

of an imbalance between bacterial attack and immune defense of host. We speculate that this competition may occur at 1-2 h after infection, and 4 h may be a first time point at which the balance is upset.

COMMENTS

Background

It has been indicated that *Helicobacter pylori* (*H. pylori*) infection may highly contribute to gastritis and carcinogenesis in the past two decades since it was recovered from human gastric mucosa in 1983, and many studies have focused on identification of both bacterial factors and host determinants that may contribute to the pathogenic mechanism.

Research frontiers

Gene expression microarray has been widely used in identifying genes associated with *H. pylori* infection and gastric tumor. However, the time-series gene expression profile of *H. pylori* infection remains unexplored. In this study, the authors extended the knowledge of the dynamic interaction between *H. pylori* and host mucosa using a high density human gene microarray and flexible bioinformatics analysis.

Innovations and breakthroughs

Several important genes that have not been reported previously and a pathway net related to *H. pylori* infection were discovered by the sequential microarrays. Based on the co-expressional profile analysis during infection, a new speculation for the pathogenic mechanism has been set up.

Applications

This study has provided a systemic view of expression profile of time-series *H. pylori* infected AGS cells. The new identified genes and pathway net as well as the hypothesis could help researchers in this field further understand the potential mechanism associated with *H. pylori* infection and carcinogenesis, and provide important information for prevention and control of *H. pylori* related diseases.

Peer review

The scientific and innovative contents as well as readability in this manuscript reflect the advanced levels of the clinical and basic researches in gastroenterology both at home and abroad.

MELD \geq 18 and TC \leq 2.8 mmol/L were independent risk factors for prognosis of decompensated cirrhosis. Survival analysis showed that MELD \geq 18 combined with TC \leq 2.8 mmol/L can clearly discriminate between the patients who would survive and die in 1 year.

CONCLUSION: MELD \geq 18 and TC \leq 2.8 mmol/L are two important indexes to predict the prognosis of patients with decompensated cirrhosis. Their combination can effectively predict the long-term prognosis of patients with decompensated cirrhosis.

Abstract

AIM: To evaluate the prognostic value of the combined model for end-stage liver disease (MELD) and blood lipid level in patients with decompensated cirrhosis.

METHODS: A total of 198 patients with decompensated cirrhosis were enrolled into the study. The values of triglyceride (TG), cholesterol (TC), high density lipoproteins (HDL) and low density lipoprotein (LDL) of each patient on the first day of admission were retrieved from the medical records, and MELD was calculated. All the patients were followed up for 1 year. The relationship between the change of blood lipid level and the value of MELD score was studied by analysis of variance. The prognostic factors were screened by multivariate Cox proportional hazard model. Draw Kaplan-Meier survival curves were drawn.

RESULTS: Forty-five patients died within 3 mo and 83 patients died within 1 year. The levels of TG, TC, HDL and LDL of the death group were all lower than those of the survivors. The serum TG, TC, HDL and LDL levels were lowered with the increase of the MELD score. Multivariate Cox proportional hazard model showed that

INTRODUCTION

Cirrhosis is a common disease and the major cause of death in China. There are liver function failure, portal hypertension and a variety of complications during decompensated period, leading to a high mortality. The true and objective judgments on end-stage liver disease conditions are helpful for clinicians to choose appropriate treatment protocols for individual patients. With continuous emergence of new treatments for liver diseases in recent years, the evaluation system used for the severity and prognosis of patients with decompensated

cirrhosis is needed urgently. Model for end-stage liver disease (MELD) established in recent years is a new method to determine the reserved liver function. It has shown many advantages in clinical use, especially in liver transplantation^[1,2]. But the model does not contain all prognostic factors, thus it has become a hotspot in the studies to improve the predictive power of MELD score by combination with other evaluation indexes^[3-5]. The liver is the vital organ to synthesize blood lipid and lipoprotein. Whether it is injured seriously or otherwise determines the level of blood lipids and apolipoprotein to a large extent. Some papers have shown that the lipid level was an important indicator to reflect the liver damage, which can be used to determine the condition and estimate the prognosis of the patients^[6]. In this study, we observed the value of four indexes of triglyceride (TG), cholesterol (TC), high density lipoproteins (HDL) and low density lipoprotein (LDL) to judge the prognosis of patients with decompensated cirrhosis. We also observed the value of combined MELD and TC in evaluating the prognosis of patients with decompensated cirrhosis.

MATERIALS AND METHODS

Patients

A total of 198 patients with decompensated cirrhosis treated in Department of Gastroenterology of Shanghai East Hospital from October 2005 to June 2008 were evaluated, and their medical profiles were retrospectively analyzed. The clinical diagnoses were all based on the program of 2000 for the prevention and treatment of virus hepatitis established in Xi'an congress^[7]. We excluded patients with past or current hepatocellular carcinoma, diseases affecting blood lipid such as hypertension, diabetes, cardiovascular and cerebrovascular disease, kidney disease and so on, use of lipid-regulating drugs recently, admission to hospital repeatedly, incomplete case records and lost to follow-up. The patients aged 26-88 years (61.4 ± 10.5 years), including 122 (61.6%) men and 76 (38.4%) women.

Clinical data

Baseline laboratory results of all the patients obtained at admission (i.e. bilirubin, creatinine, INR, TG, TC, HDL and LDL) were retrieved from the medical records. All the patients were followed up for 1 year. The outcome was assessed based on the 3- and 12-mo mortalities.

Calculation of MELD

All the prognostic models were calculated based on laboratory results obtained on the first day of admission. The MELD equation was used to calculate the severity score: $9.6 \times \log_e [\text{creatinine (mg/dL)}] + 3.8 \times \log_e [\text{bilirubin (mg/dL)}] + 11.2 \times \log_e (\text{INR}) + 6.43$ ^[8].

Statistical analysis

All statistical analyses were conducted with the SPSS for Windows version 13 release. The measurement data be-

tween two sets were compared by Student's *t* test. The data between multiple sets were compared by analysis of variance. The factors affecting the prognosis were screened by the Cox proportional hazards model. The survival curve was established by Kaplan-Meier analysis and compared by Log rank test. *P* < 0.05 was accepted as significant.

RESULTS

Clinical features in the survival group and the death group

Forty-five patients died (22.7%) at 3 mo and 83 patients died at 1 year (41.9%) among the 198 patients with cirrhosis. The scores of MELD (23.3 ± 9.82), TG (0.80 ± 0.29 mmol/L), TC (2.63 ± 1.04 mmol/L), HDL (0.93 ± 0.46 mmol/L) and LDL (1.67 ± 0.77 mmol/L) in the death group at 3 mo were significantly different statistically compared with those in the survival group (13.6 ± 6.40 , 0.86 ± 0.36 mmol/L, 3.22 ± 1.07 mmol/L, 1.30 ± 0.60 mmol/L and 1.88 ± 0.71 mmol/L) (Table 1). The scores of MELD (22.90 ± 8.90), TG (0.76 ± 0.26 mmol/L), TC (2.77 ± 1.00 mmol/L), HDL (1.06 ± 0.62 mmol/L) and LDL (1.66 ± 0.69 mmol/L) of the death group at 1 year were also significantly different statistically from the survival group (12.42 ± 5.29 , 0.94 ± 0.39 mmol/L, 3.36 ± 1.11 mmol/L, 0.93 ± 0.46 mmol/L and 1.67 ± 0.77 mmol/L) (Table 1).

Relationship between lipid levels and MELD score in patients with cirrhosis

The 198 cases of cirrhosis were divided into three groups according to MELD score: < 11 (group 1), $11 \leq$ or < 21 (group 2), and ≥ 21 (group 3). The levels of TG, TC, HDL and LDL declined with increasing MELD score. The TC and HDL were all statistically significant among the three groups (Table 2). There was no statistically significant difference in the level TG and LDL between group 1 and group 2, but between group 2 and group 3 (Table 2).

Multivariate Cox regression analysis in patients with cirrhosis

The prognostic factors (MELD ≥ 21 , TG ≤ 0.8 mmol/L, TC ≤ 2.8 mmol/L, HDL ≤ 1.2 mmol/L and LDL ≤ 1.6 mmol/L) of 198 patients with cirrhosis were included into the multivariate Cox proportional hazard model for regression analysis. As a result, MELD ≥ 21 and TC ≤ 2.8 mmol/L were independent risk factors for prognosis of decompensated cirrhosis. The risk ratios (HR) were 2.69 and 0.68 (Table 3).

Kaplan-Meier fractional survival curves of combined MELD and TC

Based on the results of multivariate Cox regression analysis, the MELD ≥ 21 combined with TC ≤ 2.8 mmol/L was divided into four groups. The 1-year survival curve

HR: Hazard ratios.

was set up by Kaplan-Meier (Figure 1). It showed that MELD ≥ 21 combined with TC ≤ 2.8 mmol/L can distinguish between the patients who would survive and die in 1 year (Figure 1).

DISCUSSION

MELD was created by Malinchoc *et al*^[9] of Mayo Clinic, America in 2000, which was initially used to predict survival following elective placement of transjugular intrahepatic portosystemic shunt to prevent bleeding and cure ascites. Later, MELD score has been proven to effectively reflect the severity of pathogenetic condition and prognosis status of different liver diseases, and it has become the recognized standard to judge the severity of pathogenetic condition for end-stage liver disease. Many studies have reported that MELD was indeed a good indicator in determining the condition of end-stage liver disease such as cirrhosis, hepatitis, liver transplantation^[1,10]. However, Angermayr *et al*^[11] thought that the judging ability of MELD is not superior to CTP score. Earlier reports confirmed that the MELD scoring system had an advantage in assessment of liver transplanted patients, but recent studies showed that the system was still not perfect, which is not suitable for all patients with liver transplantation^[12,13].

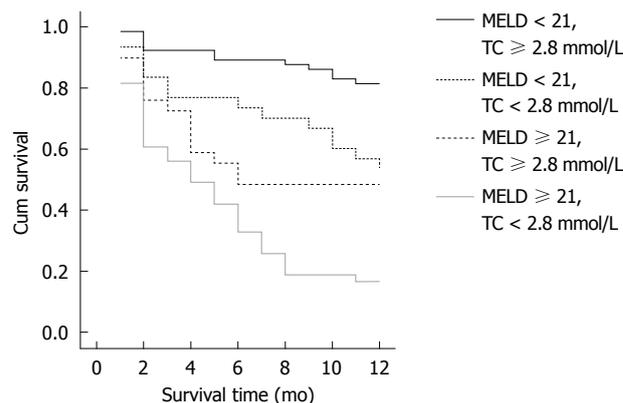

Figure 1 One-year Kaplan-Meier survival curves of 198 cirrhotic patients.

MELD score is still controversial for its ability to determine the pathogenetic condition of end-stage liver disease. Currently, scholars are combining MELD with other indicators in an attempt to estimate pathogenetic condition of liver diseases more accurately^[14]. The liver is the main site to synthesize, store, transport and decompose lipids, including synthesis and secretion of endogenous lipoprotein; synthesis of rate-limiting enzyme of lipoprotein metabolism to regulate mutual conversion and metabolism between a variety of lipoprotein; and absorbing and removing metabolites of lipoprotein through the lipoprotein receptors on the hepatocytes surface to maintain equilibrium of TC and TG metabolism^[15]. The liver cannot esterify fatty acid to synthesize phosphatidyl choline required by TG and TC esterification. The reduced synthesis of TC acyltransferase can decrease the serum TG and TC levels. In addition, damaged hepatocytes, abnormal synthesis of apolipoprotein A by liver and/or the reduced synthesis

of phosphatidylcholine TC acyltransferase may decrease the levels of high-density and very low-density lipoproteins. It has been reported that the Child-Pugh score of patients with cirrhosis was high, the higher severity of the liver damage, the lower the blood lipid level, which is an important indicator to reflect liver damage. The blood lipid level can be used to determine the condition and estimate the prognosis of the patients^[16]. In this paper, the patients with cirrhosis were divided into low-risk, medium-risk and high-risk groups according to the MELD score. It was also observed that the blood lipid levels in the patients were decreased with increasing MELD score. There was no significant difference in the two indicators (TG and LDL) for cirrhosis between low-risk and medium-risk groups. Considering that extrahepatic tissues of patients may still have some degree of synthesizing ability in early stage of cirrhosis, and there is blood lipid elimination disorder in the cirrhotic patients, it is not likely for blood lipid level to reduce. But with a further reduction in cytoactivity of hepatocytes, blood lipid will significantly reduce. Habib *et al*^[6] have studied 248 cases of cirrhosis and found that the HDL, TC and VLDL level of deaths in 90, 180, 365 d were all lower than that of the survivals. This result also showed that all serum lipids of the patients who died within 3 mo and 1 year were all significantly lower than that of survivals.

The liver plays a leading role in the synthesis of TC and maintain the balance in TC metabolism. It can control the dynamic equilibrium of TC *in vivo* through participation in the process of uptake, synthesis, intracellular transport, esterification or hydrolysis of TC, and rotation to the circulating blood, and synthesizing and secreting bile acid. TG oxidation (hydrolysis) is inhibited in patients with hepatitis. On the other hand, due to appetite loss and short-term starvation, the liver metabolism mobilized a large number of stored fat, which can raise the TG levels. The liver function was severely damaged during cirrhosis. The hepatocytes lack of energy result in fatty acid oxidation and TG levels decrease. The liver is not only the organ that synthesizes most TC in human body by up to 60%-80%, but also the site for TC transformation and excretion. In liver disease, the level of serum TC is reduced because of decreased TC synthesis in the liver and blocked esterification. With deterioration of liver cell damage, ALT level increased and the serum TC further decreased. Liver function is seriously and irreversibly damaged during cirrhosis, resulting in significant decrease of TC level. So the level of serum TC is meaningful to determine the severity of acute liver disease, which can reflect the acute processes, it is particularly helpful in severe hepatitis judgment. Selcuk *et al*^[17] analyzed 99 dead patients with cirrhosis and found that their TC levels were all lower than normal. Li *et al*^[18] selected six indicators including TC by Logistic regression analysis as the prognostic indicator of patients with chronic severe hepatitis. In our study, MELD ≥ 21 and TC ≤ 2.8 mmol/L were selected by multivariate Cox proportional hazard model as the independent prognos-

tic factors of patients with cirrhosis. HR was 2.69 and 0.68. MELD and the TC values are corresponding to the severity of illness. Kaplan-Meie survival curve showed that MELD ≥ 21 combined with TC ≤ 2.8 mmol/L can distinguish between the patients who would survive and die in 1 year, which may provide more information in clinical treatment. In addition, 90% of the HDL *in vivo* is synthesized by the liver. The change in serum HDL concentration is closely related to the severity of the liver disease. The progressive reduction of HDL is the performance indicating deteriorated condition, while the level of HDL would gradually increase with the condition improved. Thus, serum HDL is the ideal target for liver disease diagnosis and prognostic evaluation^[19]. Habib *et al*^[6] found that HDL was the marker of liver function and prognostic factor of nonalcoholic cirrhosis. After liver transplantation, the mortality of patients was significantly correlated with decreased serum HDL. Especially the risk of death in cirrhotic patients increased by 3.4% as the serum HDL became lower than 30 mg/dL. However, we did not find that HDL is an independent prognostic factor in cirrhotic patients by Cox regression mode. Larger series of patients is needed to verify the findings.

COMMENTS

Background

Cirrhosis is a common disease and the major cause of death in China. The true and objective judgments on end-stage liver disease conditions is helpful for clinicians to choose different treatment protocols suitable for individual patients.

Research frontiers

Model for end-stage liver disease (MELD) established in recent years is a new method to determine reserved liver function. It has shown many advantages in clinical use, especially in liver transplantation. But the model is not perfect. It is a hotspot in the studies to improve the predictive power of MELD score by combination with other evaluation indexes. This study has shown that the lipid level is an important indicator to reflect the degree of liver damage, which can be used to determine the condition and estimate the prognosis of the patients.

Innovations and breakthroughs

In some studies, the lipid level has been used to determine the condition and estimate the prognosis of patients with liver damage. In this study, the authors observed four indexes of triglyceride, cholesterol (TC), high density lipoproteins and low density lipoprotein to judge the prognosis of 198 patients with decompensated cirrhosis through retrospective analysis, and observed the value of MELD combined with TC in evaluating the prognosis of patients with decompensated cirrhosis as well.

Applications

MELD combined with cholesterol can be used to judge the pathogenetic condition and prognosis of patients with decompensated cirrhosis.

Terminology

Multivariate Cox proportional hazard model is a multivariate technique for analyzing the effect of two or more metric and/or nonmetric variables on survival.

Peer review

The aims of this paper are to see whether modification of MELD can improve accuracy. The rationale for use of lipids needs to be strengthened. The authors should consider using some of the modifications of MELD such as MELD-Na.

Abstract

AIM: To determine the effect of three digestive tract reconstruction procedures on pouch function, after radical surgery undertaken because of gastric cancer, as assessed by radionuclide dynamic imaging.

METHODS: As a measure of the reservoir function, with a designed diet containing technetium-99m (^{99m}Tc), the emptying time of the gastric substitute was evaluated using a ^{99m}Tc -labeled solid test meal. Immediately after the meal, the patient was placed in front of a γ camera in a supine position and the radioactivity was measured over the whole abdomen every minute. A frame image was obtained. The emptying sequences were recorded by the microprocessor and then stored on a computer disk. According to a computer processing system, the half-emptying actual curve and the fitting curve of food containing isotope in the detected region were depicted, and the half-emptying actual curves of the three reconstruction procedures were directly compared.

RESULTS: Of the three reconstruction procedures, the half-emptying time of food containing isotope in the Dual Braun type esophagojejunal anastomosis proce-

dure (51.86 ± 6.43 min) was far closer to normal, significantly better than that of the proximal gastrectomy orthotopic reconstruction (30.07 ± 15.77 min, $P = 0.002$) and P type esophagojejunal anastomosis (27.88 ± 6.07 min, $P = 0.001$) methods. The half-emptying actual curve and fitting curves for the Dual Braun type esophagojejunal anastomosis were fairly similar while those of the proximal gastrectomy orthotopic reconstruction and P type esophagojejunal anastomosis were obviously separated, which indicated bad food conservation in the reconstructed pouches.

CONCLUSION: Dual Braun type esophagojejunal anastomosis is the most useful of the three procedures for improving food accommodation in patients with a pouch and can retard evacuation of solid food from the reconstructed pouch.

INTRODUCTION

Patterns and functions of digestive tract reconstruction

after gastrectomy play a vital role in the quality of life of patients. As to which reconstruction after gastrectomy provides the least complications and best quality of life, much research has been carried out. Most of these studies focus on the function of the pouch built by surgery, including volume of the pouch, storage time of food in the pouch, and emptying mode of the food. In previous studies, most judgments were made from the subjective experience of the inspector, which cannot reveal the true state of the reconstructed pouch function. There is a long way to go, as regards further research, before we know which kind of reconstruction mode will provide patients with a good quality of life with the least problems after gastrectomy is performed.

Radionuclide dynamic imaging is the gold standard for measuring emptying time of the gastrointestinal tract^[1,2]. It has been used to measure gastric emptying function when there is abnormal digestive function with normal anatomy. This is a simple technique and its best advantage is that there is seldom impact from the inspector or subject, and results reflect the actual empty time of the pouch based on objective facts. The method is simple and non-invasive, requiring a single oral administration of the radionuclide tracer. The meal used in the procedure does not alter the normal physiology of the gut. It is possible with this imaging to judge whether a reconstructed pouch matches normal physiological function. The aim of the present study was to quantify pouch emptying time of a solid meal in patients who had undergone gastrectomy surgery by calculating their half-emptying time ($T_{1/2}$) values.

MATERIALS AND METHODS

Patients

This study was conducted in patients who had undergone total and proximal gastrectomy for gastric cancer after a period of 6-36 mo, and who were surviving without cancer. Total number was 34 cases, and the average age of the patients was 28-72 years. Three operation procedures were conducted as follows: proximal gastrectomy orthotopic reconstruction, 10 cases; total gastrectomy P type esophagojejunal anastomosis, 11 cases; total gastrectomy Dual Braun type esophagojejunal anastomosis, 13 cases. Clinical data are displayed in Table 1.

Methods

Meal preparation: The solid test meal was prepared by mixing 1 mCi non-absorbable containing technetium-99m (^{99m}Tc)-DTPA with 100 g flour, a 50 g raw egg and 80 mL clear water (thus containing protein 12.9 g, fat 15.4 g, carbohydrate 72.9 g); this was mixed to a paste. A pancake was heated in a microwave oven for 3 min. Each test meal offered 1814 kJ of calorific energy.

Scintigraphic measurements: Patients were supplemented with potassium chlorate 15 min before scanning, in order to block out hypothyroid and gastric mucosa influence and speed up the excretion of remnant ^{99m}Tc.

Borrmann II	6	4	4
Borrmann III	4	7	9
Borrmann IV	0	0	0
Staging			
Early cancer	1	0	2
I B	2	2	3
II	4	4	3
III A	2	4	4
III B	1	1	1

Emission images were taken by a γ camera. All the patients ate the test meal within a 5 min period. Immediately after the meal, the patient was placed in front of a γ camera in a supine position, representing 0 min, and radioactivity was measured over the whole abdomen. The whole detection process took 90 min, and a frame image was collected approximately every minute. One frame image was consequently obtained which was stored in a computer disk, to measure the period and image of nuclide attenuation. Areas of interest corresponding to the gastric substitute were outlined, and the radioactivity was counted on each image and expressed as the percentage of ingested activity. After revising the half life of ^{99m}Tc and calculating every emission count of every image, the half-emptying actual curve and fitting curve of food containing isotopes in the detected region were depicted according to the computer analyzing processing system.

Two regions from each patient were investigated as follows: upper esophagus anastomosis, detecting reflux; food accommodation region after reconstruction, detecting half-emptying time of food containing the nuclide.

Statistical analysis

The half-emptying actual curve and fitting curve of the radionuclide were analyzed, and the actual half-emptying time of food containing the nuclide was compared among the three different reconstruction procedures using group comparison. Data analyzed among groups: differences in age and postoperative time among groups were tested by variance analysis, and there was no significance among groups; variance analysis of the actual half-emptying time compared between groups was conducted by Mann-Whitney test, and results were considered to be significant at $P < 0.05$.

RESULTS

No differences in esophagus reflux were found during the experiment between the three groups and no increment of isotope radioactivity was detected in the lower

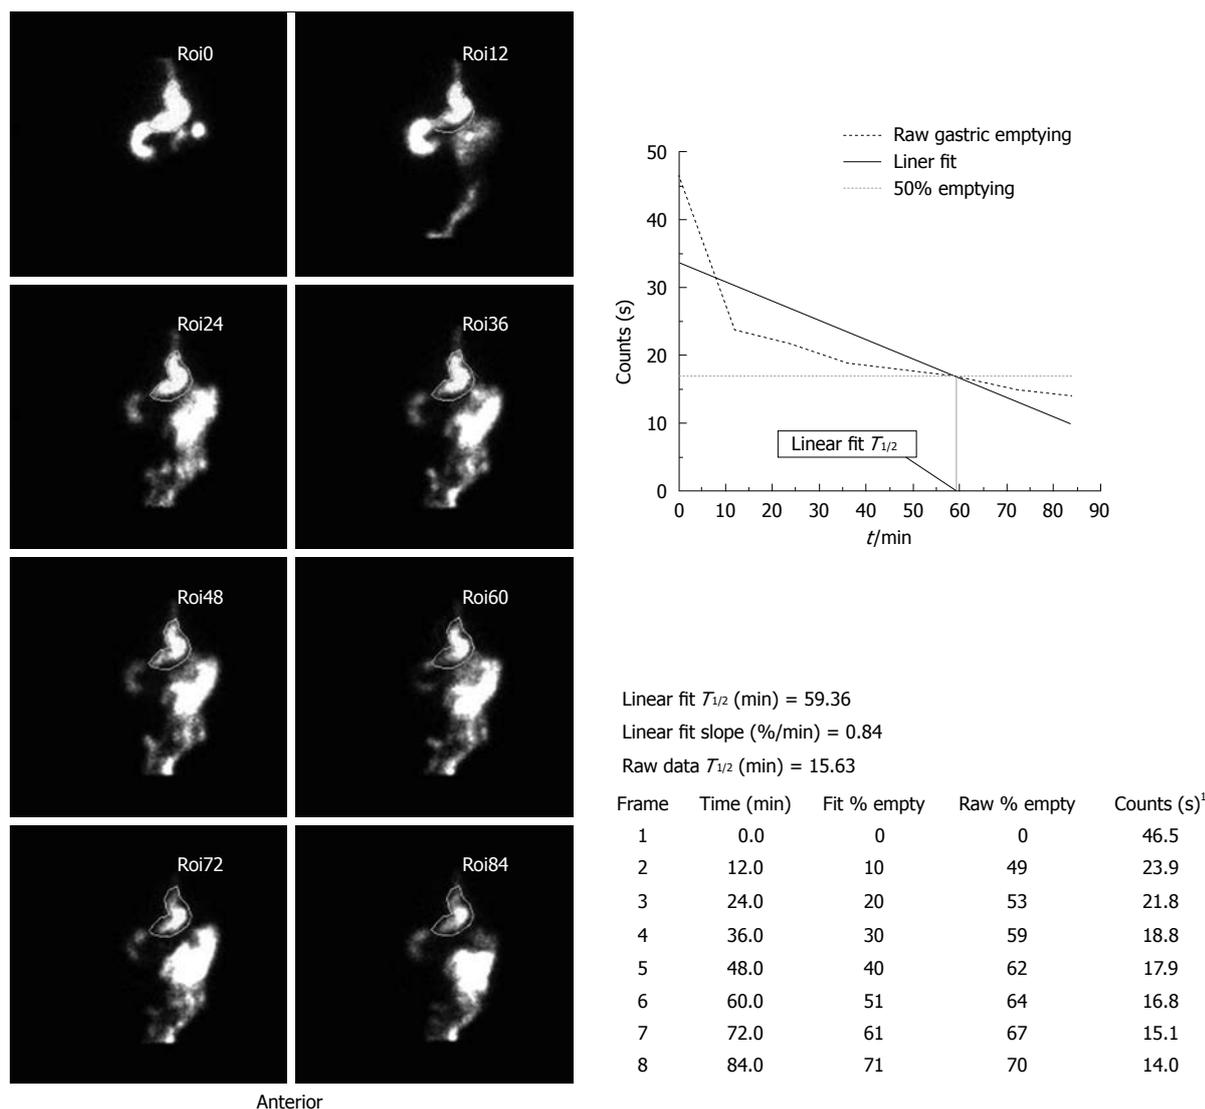

Figure 1 Proximal gastrectomy, 36 mo after operation. Raw data $T_{1/2}$ was 15.63 min, linear fit $T_{1/2}$ was 59.36 min. ¹Anterior only.

esophagus. Increments of isotope radioactivity were detected in the pouch region among some patients, which revealed that the actual curve of half-emptying descended initially and then ascended.

Emptying time of different reconstruction procedures

Proximal gastrectomy: The half-emptying time of the isotope markedly decreased (30.07 ± 15.77 min) with great significance compared to the Dual Braun procedure (51.86 ± 6.43 min). The actual and fitting curves were rather separated. After dietary intake for 20 min, time approached half-emptying, showing a poor food capacity in the remnant stomach (Figure 1).

P type reconstruction: Half-emptying time (27.88 ± 6.07 min) was close to that of the proximal procedure. This reconstruction had a significantly shorter transit time compared to the Dual Braun procedure. The actual and fitting curves were rather separated, which showed a poor accommodation of food in the pouch (Figure 2).

Dual Braun type esophagojejunal anastomosis: Emptying time of this procedure was 51.86 ± 6.43 min, not far from normal (60.00 ± 10.00 min), and its actual and fitting curves were fairly similar, which revealed that the reconstructed pouch could play a role in retarding the excretion of food (Figure 3).

Of the three kinds of reconstruction mode, the differences in emptying time have significant statistical relevance when compared among groups (Table 2).

Characteristics of food discharge from pouch

As seen from emptying images of patients having the proximal gastrectomy procedure and the total gastrectomy P type reconstruction procedure, a strong isotope development was found outside the detected region with the increasing of time, which revealed that food could not be discharged evenly from the pouch, but in an integral transferred manner. However, the double circles of the Dual Braun reconstruction procedure could retard food emptying (Figure 4).

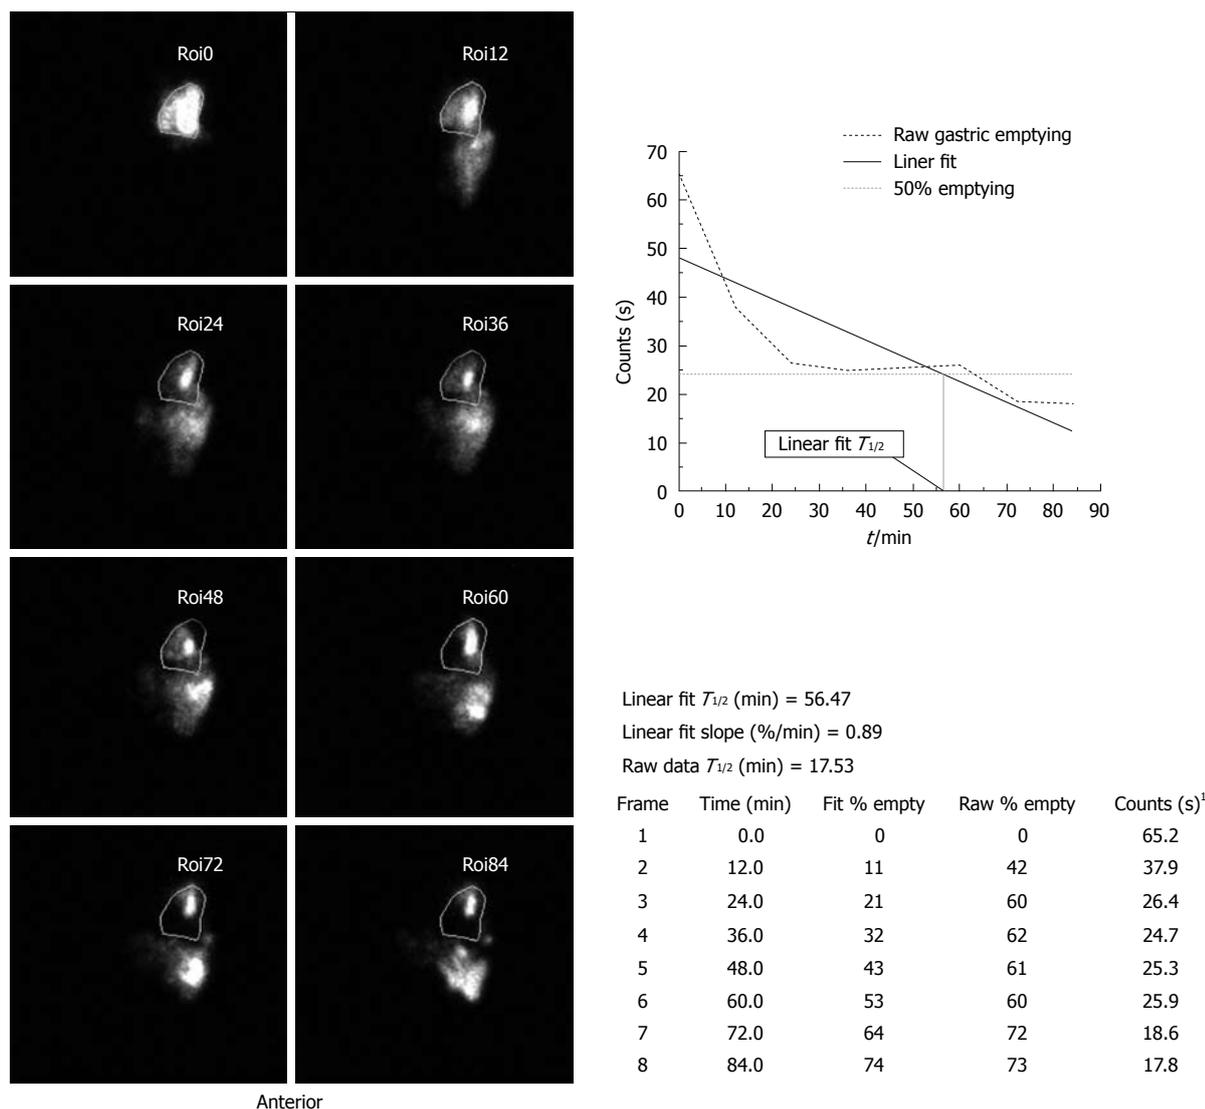

Figure 2 P type reconstruction, 24 mo after operation. Raw data $T_{1/2}$ was 17.53 min, linear fit $T_{1/2}$ was 56.47 min. ¹Anterior only.

Table 2 Emptying times of the three kinds of reconstruction (mean ± SD)

Reconstruction mode	n	Time after operation (mo) ²	Raw data $T_{1/2}$ (min)	Linear fit $T_{1/2}$ (min)	P ¹
Proximal gastrectomy	10	16	35.16 ± 13.51	69.86 ± 11.71	0.706 ^a
P type reconstruction	11	22	29.66 ± 6.07	67.33 ± 8.75	0.002 ^b
Dual-Braun reconstruction	13	24	52.66 ± 10.33	65.77 ± 11.43	0.001 ^c

DISCUSSION

In order to improve the quality of life of patients post-operatively, functions of digestive tract reconstructions after gastrectomy have been frequently studied by many

researchers. A consensus was reached that radionuclide dynamic imaging is the most desirable method among a host of techniques used to detect effectiveness of digestive tract reconstruction. This method is simple and easy to perform; it is a non-invasive examination without any pain and is preferred by patients. Moreover, the results are not affected by subjective factors, and thus reflect pouch efficacy after digestive tract reconstruction objectively.

It has been over 100 years since Schlatter reported the first successful total gastrectomy with reconstruction. During that period, gastric carcinoma surgical techniques evolved into extended resection and ultra-extended resection. Currently, these have been converted into diminution and rational therapeutic protocols. Though many operation protocols have changed with time, they all tightly stick to the principles of radical treatment, aiming to provide security and functionality after gastric carcinoma. In recent years, studies regarding functionality of digestive tract reconstruction after gastrectomy have been progressively increasing. Different methods

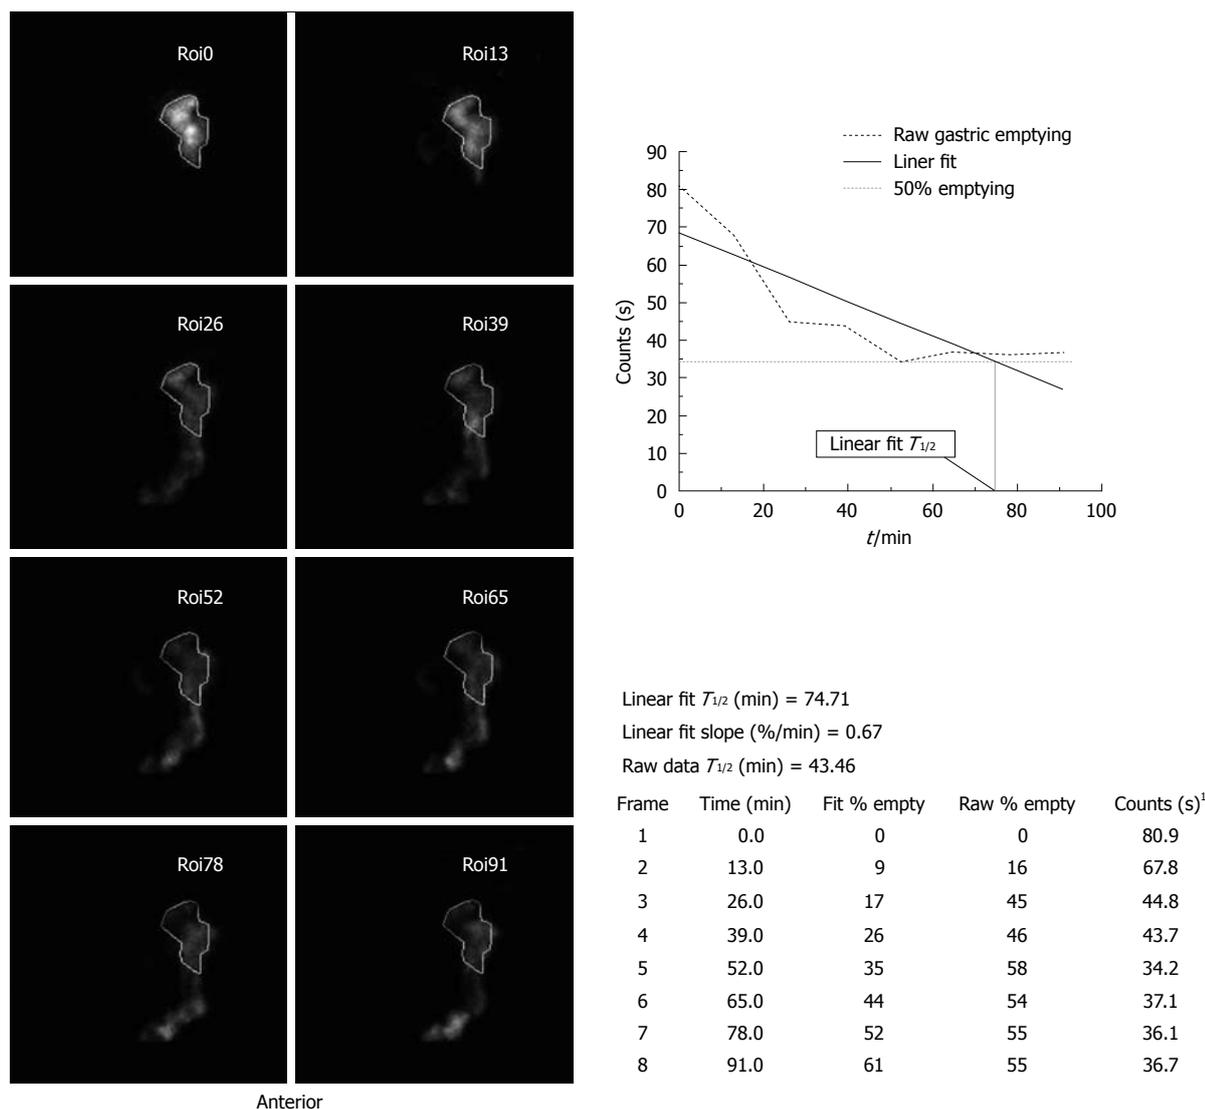

Figure 3 Dual-Braun reconstruction, 17 mo after operation. Raw data $T_{1/2}$ was 43.46 min, linear fit $T_{1/2}$ was 74.71 min. ¹Anterior only.

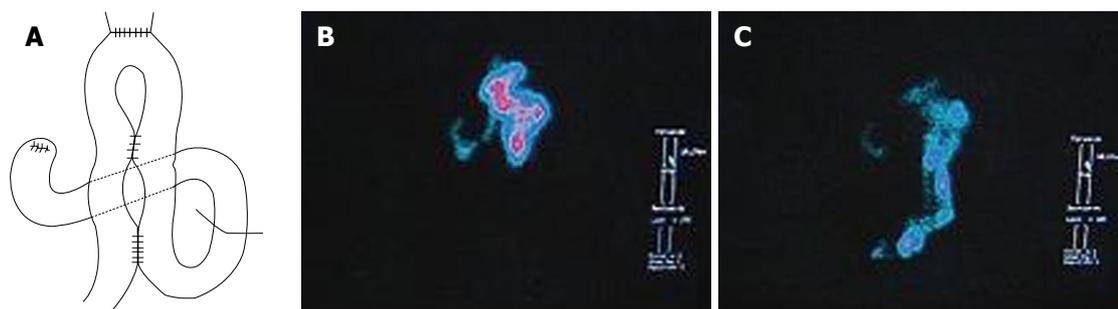

Figure 4 Dual-Braun reconstruction (A) and duodenal reflux seen at examination (B, C).

have their own disadvantages and advantages when viewed from different perspectives^[5-12]. To determine the optimum reconstruction procedure after gastrectomy in terms of the quality of life of patients, we conducted a controlled trial to compare the pouch effectiveness of the three reconstruction procedures by radionuclide dynamic imaging.

We have previously reported a study of the same

three kinds of reconstruction procedure, regarding the quality of life after operation^[13]. We found Dual-Braun reconstruction provided good quality of life compared to the other two construction methods. Results showed patients put on more bodyweight and had less meal frequency. We considered that it could be the pouch that had good function with regard to digestion, so we performed this study in the same patients and confirmed

that Dual Braun reconstruction can increase storage time in the pouch and empty food in a very even manner, nearly at normal levels. Therefore we proposed: (1) Proximal gastrectomy with esophagojejunal anastomosis partly preserves normal gastric tissue with easy operation, allowing a normal physiological pathway of food transit. Due to the small volume of remnant stomach and destruction of pylorus nerves, the remnant pylorus loses its routine function. As seen from the observations, food containing radionuclide was excreted fast from the remnant stomach, and thus incapable of mixing with digestive juice completely, which affects the intake of nutritional substances. The syndrome occurring when food intake of patients decreased and emptying times increased with a resultant weight loss postoperatively, was obvious clinically. The incidence of reflux was also higher postoperatively. All the results were confirmed in our subsequent review of patients; and (2) Total gastrectomy is a common resection used for gastric carcinoma, and its complications are still a cardinal factor affecting the quality of life of patients. Modification of reconstruction methods plays a positive role in avoiding postoperative complications; however, no modified protocols have received a consensus of approval. Among many modifications of pouch reconstruction and capacity, we compared P type esophagojejunal anastomosis and Dual Braun type esophagojejunal anastomosis, which has been advocated recently. In our subsequent review, we found that there was no difference in pouch capacity (food intake) between the two procedures, but from radionuclide dynamic imaging, there was an obvious difference in emptying time. One case even showed that the half-emptying time of nuclide was less than 1 min and emptying time was 3 min, as measured 24 mo after a P type procedure. The body weight of the patient decreased from 80 to 63 kg postoperatively. The patient did not undergo complete lymph node dissection and had no steatorrhea postoperatively, and had no symptoms of celiac plexus injury. Weight loss was mainly ascribed to inflexible function of the pouch in which food transited fast through the upper jejunum and nutritional substance intake was poor. The original intention of the Dual Braun procedure was to reduce reflux postoperatively and to promote functionality of the pouch. Double circles were placed after reconstruction, and the intestinal wall internal plexus was not damaged due to retention of the continuity of the jejunum, which retarded the food excretion from pouch to some extent. The half-emptying time of food containing nuclide was longer and the actual and fitting curves were similar, which showed the superiority of this reconstruction procedure.

A Dual Braun pouch provides a slower transit of food directly below the esophagus, while a double circle slows down the passage at that part of the digestive tract where the food can be mixed with bile and pancreatic juice arriving from the Y limb. This may provide a better utilization of digestive enzymes and probably leads to an improved digestion.

There was reflux noted in almost all patients after reconstruction methods of total and proximal gastrectomy, but there was no obvious reflux of food containing nuclide detected in our observations. After subsequent review, main reflux did not occur immediately after food intake, but during the period beginning from 6 min after food intake. This difference between experimental observation and clinical investigation is mainly ascribed to different detecting conditions. Our results were not in line with some other experimental reports.

Radionuclide solid gastric emptying studies have been performed clinically since 1976^[14]. Many investigations published since then have confirmed the clinical utility of such studies for diagnosis of a variety of gastric motility disorders, but most of the radionuclide scintigraphy research was not in relation to reconstructed gastric tract^[15-18].

The latest paper using radionuclide imaging to detect gastric emptying was published by Bernstine *et al*^[19]; their study was to clarify whether laparoscopic sleeve gastrectomy to treat morbid obesity causes changes in gastric emptying.

Total gastrectomy is accompanied by a host of complications postoperatively, and some symptoms (i.e. malignant anemia) are unable to be avoided by operation. However, reconstruction procedures show a positive inhibitory effect on such symptoms. There are about 60 digestive tract reconstruction protocols at present; however, new prospective clinical trials should be undertaken and optimum pouch reconstruction protocols further investigated in order to ameliorate the quality of life of patients.

COMMENTS

Background

There are more than 60 kinds of reconstruction mode after gastrectomy. The purpose of the different modes is to diminish the complications, such as reflux and dumping syndrome, after operation and improve the quality of life. However, there is no single type of reconstruction mode commonly accepted by all researchers. Radionuclide solid gastric emptying studies have been performed clinically since 1976. Many investigations published since then have confirmed the clinical utility of such studies for diagnosis of a variety of gastric motility disorders. Nevertheless, there is a remarkable lack of standardization of this type of study and no generally applicable reference values. In particular, radionuclide studies have seldom been used in the reconstructed digestive tract.

Research frontiers

The latest paper using radionuclide imaging to detect gastric emptying was published by Bernstine *et al*; their study was to clarify whether laparoscopic sleeve gastrectomy to treat morbid obesity causes changes in gastric emptying. Other research was focused on different reconstruction procedures and there has not been a study comparing emptying between different reconstruction modes.

Innovations and breakthroughs

The authors use the radiolabeled solid food to detect and compare the functions of the postoperative gastric tract, to contrast the pouch function between three kinds of reconstructed pouch. Compared with other research, the authors have used simultaneous patient follow up data to demonstrate their results.

Applications

The authors have concluded through their study that the Dual-Braun procedure was a good mode of reconstruction; it has a comparative emptying time to normal digestive tract (gastric). Radionuclide scintigraphy is a very useful

method to detect the emptying time of the reconstructed pouch, is very simple and non-invasive, and can be used in other kinds of pouch.

Peer review

This manuscript is original, has scientific value, is well written and has clinical value for the readers.
