(23.1%, 3 of 13 patients) in group C was lower than that (61.5%, 8 of 13 patients) in group B ($P = 0.047$). At the 2 years follow-up, the relapse rate (38.5%, 5 of 13 patients) in group C was lower than that (76.9%, 10 of 13 patients) in group B ($P = 0.047$). Adverse events in group C were fewer than in groups A and B.

CONCLUSION: Early induction with infliximab at diagnosis, known as "top-down" therapy, was effective for reducing the relapse rate compared to conventional therapies for at least 2 years.

Lee JS, Lee JH, Lee JH, Lee HJ, Kim MJ, Lee HJ, Choe YH. Efficacy of early treatment with infliximab in pediatric Crohn's disease. *World J Gastroenterol* 2010; 16(14): 1776-1781 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i14/1776.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i14.1776>

INTRODUCTION

Although the etiology of Crohn's disease remains incompletely understood, environmental factors, infectious microbes, ethnic origin, genetic susceptibility, and immune system dysfunction have been implicated in the associated chronic mucosal inflammation^[1]. There is no known cure for Crohn's disease. Therefore, the goal of treatment is to mitigate inflammation and the associated clinical symptoms. The current treatment

guidelines are designed to maintain remission after induction therapy.

Conventional therapy for active disease includes treatment with corticosteroids. Initially, corticosteroids are very effective and fast acting, but long term exposure to corticosteroids becomes problematic with issues of dependency and/or resistance^[2]. Infliximab is an anti tumor necrosis factor (TNF)- α monoclonal antibody that was introduced for the treatment of moderate to severe Crohn’s disease^[3,4]. The efficacy of infliximab suggests a new concept; that early induction with intensive therapy may reduce complications associated with conventional treatment and may improve the quality of life. Therefore, intensive therapy with early use of this biological agent has been proposed, and is known as ‘top-down’ therapy. The results of some studies suggest that infliximab is more effective in children than in adults^[5,6].

Ethnic differences in the clinical characteristics of Crohn’s disease have been noted. Crohn’s disease is relatively common in developed countries, while it is not as common in Asian countries^[7]. In addition, recent studies from Far East Asian countries reveal that the prevalence of *NOD2* mutations, associated with increased susceptibility to Crohn’s disease in Western populations, is lower than that found in other populations^[8-10]. Therefore, the clinical response to treatment for Crohn’s disease in Asian countries might differ from patients in Western countries.

The purpose of this study was to evaluate the efficacy of the early use of infliximab, compared to conventional treatments, at 1 and 2 years of follow-up, in Korean pediatric patients with Crohn’s disease.

MATERIALS AND METHODS

Patients

We included newly diagnosed pediatric patients with Crohn’s disease. All included patients had not been treated with agents such as corticosteroids, mesalamine, or infliximab, and were followed for at least 24 mo at our clinic. Forty-three patients confirmed to have Crohn’s disease at Samsung Medical Center, Korea, between March 2001 and February 2007 were enrolled. Seven patients were excluded: four patients were lost to follow-up and three patients did not respond to the induction regimen with prednisolone or infliximab. Among three patients who did not achieve induction, 2 patients did not stop corticosteroids and one patient did not respond to three infusions of infliximab for induction. Therefore, 36 patients were eligible for inclusion in the study. A retrospective chart analysis was conducted of physician notes, laboratory studies, radiology reports, endoscopy records, and histology reports. Biopsies were obtained by endoscopy in all eligible patients. The diagnosis of Crohn’s disease was made in accordance with the ESPGHAN - Porto criteria^[11]. Infectious diseases such as tuberculosis were ruled out by taking a detailed family history, imaging

studies and confirmation of a negative purified protein derivative tuberculin (PPD) test result and a negative PCR-hybridization of *Mycobacterium tuberculosis* on biopsy tissue. Our study was approved by the institutional review board of our institution.

Grouping by treatment regimen

The patients ($n = 36$) were divided into three subgroups according to the treatment regimen. Ten patients (group A) were treated with mesalamine after induction therapy with oral prednisolone and 13 patients (group B) were treated with azathioprine after induction therapy with oral prednisolone. In the third subgroup, 13 patients (group C) received infliximab and azathioprine for induction and maintenance therapy for the first year, and were treated with azathioprine after 1 year. The patients in group A were treated mainly from 2001 to 2003. Treatment in groups B and C occurred mainly from 2003 to 2005 and from 2005 to 2007, respectively. The oral corticosteroid, prednisolone (1-2 mg/kg per day), was used for induction therapy. Mesalamine (Pentasa, 50-80 mg/kg per day) or azathioprine (Imuran, 2-3 mg/kg per day) was provided for maintenance therapy as the conventional treatment. Infliximab (Remicade, 5 mg/kg) was administered by intravenous infusion at weeks 0, 2 and 6, in combination with daily azathioprine and subsequently every 8 wk for 10 mo. After treatment with infliximab and azathioprine for the first 12 mo, only azathioprine therapy was continued.

The group treated with early infliximab was not previously treated with other medications such as corticosteroids or immunomodulators. All patients were followed for at least 24 mo.

Adverse events

Adverse events and laboratory results for side effects were investigated. Patients treated with mesalamine underwent evaluations for hypersensitivity, rash, alopecia, anorexia, headache, elevated liver enzyme, pancreatitis, serum creatinine and urine analysis. For azathioprine, patients were evaluated for pancytopenia, pancreatitis, hepatotoxicity, rash, alopecia, anorexia and arthralgia. Patients receiving infliximab were assessed for anaphylaxis, dyspnea, rash, headache, nausea, elevated liver enzyme, pancreatitis, pancytopenia and serious infections. Evaluation of the well-known adverse effects of prednisolone was not included in the analysis.

Relapse rate

We defined remission of disease as a pediatric Crohn’s disease activity index (PCDAI) score of less than 10 points and a relapse was defined as greater than 10 points^[12,13]. The relapse rate was defined as the rate of the presence of relapse, more than once, after a remission was achieved with treatment. Moderate to severe disease was defined by a score greater than 30 points by the PCDAI. The relapse rate was obtained using the

Table 1 Baseline characteristics

Gender (male/female)	27/9
Median age (range, yr)	13 (1-16)
Duration of follow up [mean (range), mo]	51.9 (24-101)
Disease location	
Small intestine	3
Colon	10
Small intestine & colon	23
PCDAI at diagnosis (mean \pm SD)	32.9 \pm 8.6

PCDAI: Pediatric Crohn’s disease activity index.

Table 2 Differences in baseline characteristics of each treatment group

	Group A	Group B	Group C	P
Median age (range, yr)	13 (10-14)	12.5 (4-14)	14 (1-16)	0.520
Duration of follow up (mo) (mean \pm SD)	82.7 \pm 29.1	50.3 \pm 15.5	29.6 \pm 7.4	0.234
PCDAI (mean \pm SD)	30.3 \pm 6.5	33.1 \pm 9.9	34.8 \pm 8.8	0.464

Group A: Treated with mesalamine after induction therapy with oral prednisolone; Group B: Treated with azathioprine after induction therapy with oral prednisolone; Group C: Treated with infliximab and azathioprine for induction and maintenance therapy.

PCDAI score. The efficacy of the early use of infliximab was evaluated by the relapse rate in each group at 12 and 24 mo.

Statistical analysis

A comparison of the study groups was performed using the χ^2 test for variables, and Fisher’s exact test was used to compare each of the measurements. All statistical analyses utilized a 0.05 level of significance.

RESULTS

Baseline characteristics

The study population at diagnosis included 27 males (75.0%) and nine females (25.0%), with a mean age of 11.9 ± 3.5 years (Table 1). The mean age of the patients in group A was 12.9 ± 1.4 years, for group B it was 11.5 ± 2.7 years and for group C, 12.9 ± 4.0 years; there were no statistical differences between these groups ($P = 0.520$). The mean overall follow-up period was 51.9 mo (range: 24-101 mo) and the minimal duration of follow-up was 24 mo. The location of disease was the terminal ileum in three patients (8.3%), the colon in 10 patients (27.8%) and the ileocolon in 23 patients (63.9%). The mean PCDAI score at baseline was 32.9 ± 8.6 points. There was no significant difference in the PCDAI scores between the groups. The mean PCDAI score was 30.3 ± 6.5 in group A, 33.1 ± 9.9 in group B and 34.8 ± 8.8 in group C ($P = 0.464$). Baseline characteristics were not significantly different between the treatment groups (Table 2).

Relapse rate

The cumulative relapse rate, including infliximab use, was

Table 3 Relapse rate by characteristics

	n (%)	P
Age at diagnosis		
< 13 yr ($n = 13$)	9 (69.2)	0.553
≥ 13 yr ($n = 23$)	15 (65.2)	
Involvement		
Colon ($n = 10$)	5 (50.0)	0.416
Terminal ileum ($n = 3$)	2 (66.7)	
Small and large bowel ($n = 23$)	17 (73.1)	
PCDAI at diagnosis		
< 30 ($n = 11$)	7 (63.6)	0.544
≥ 30 ($n = 25$)	17 (68.0)	

52.8% (19 patients) at 12 mo and 66.7% (24 patients) at 24 mo; there was no significant difference in the relapse rate between the different age groups ($P = 0.553$); 69.2% (9 out of 13 patients) for patients less than 13 years of age and 65.2% (15 out of 23 patients) for those more than 13 years of age (Table 3). The relapse rate in patients who had colon only involvement was 50.0% (5 out of 10 patients). The relapse rate in patients with terminal ileum only involvement was 66.7% (2 out of 3 patients), and for patients with ileocolonic involvement the relapse rate was 73.9% (17 out of 23 patients). There was no difference in the relapse rate between patients with mild disease, with a PCDAI score less than 30 points at diagnosis (7 out of 11 patients, 63.6%), and moderate to severe disease, with a PCDAI score more than 30 points (17 out of 25 patients, 68.0%).

The relapse rate at 1 year was 23.1% [95% confidence interval (CI): 0.2%-46.0%] in group C (3 out of 13 patients), 61.5% (95% CI: 35.1%-88.0%) in group B (8 out of 13 patients) and 80.0% (95% CI: 55.2%-100.0%) in group A (8 out of 10 patients). At 1 year, the absolute difference between groups C and B was 38.5% (95% CI: 3.5%-73.4%) and was 56.9% (95% CI: 23.2%-90.7%) between groups C and A. There was a significant difference between each of the groups ($P = 0.047$, $P = 0.012$) (Figure 1A). At the 2 years follow up, the relapse rate in group C [38.5%, 5 out of 13 patients (95% CI: 12.0%-64.9%)] was lower than the relapse rate in groups B [76.9%, 10 out of 13 patients (95% CI: 54.0%-99.8%)] and A [90.0%, 9 out of 10 patients (95% CI: 71.4%-100.0%)]. At 2 years, the absolute difference between groups C and B was 38.5% (95% CI: 3.5%-73.4%) and was 51.5% (95% CI: 19.2%-83.9%) between groups C and A. There was a statistically significant difference between each group ($P = 0.047$, $P = 0.029$) (Figure 1B).

Adverse events

Patients treated with mesalamine had three adverse events. Five patients treated with azathioprine were found to have adverse events. Only one patient had dyspnea and tachycardia after the third infusion of infliximab (Table 4).

DISCUSSION

To our knowledge, this is the first study reported in Asia

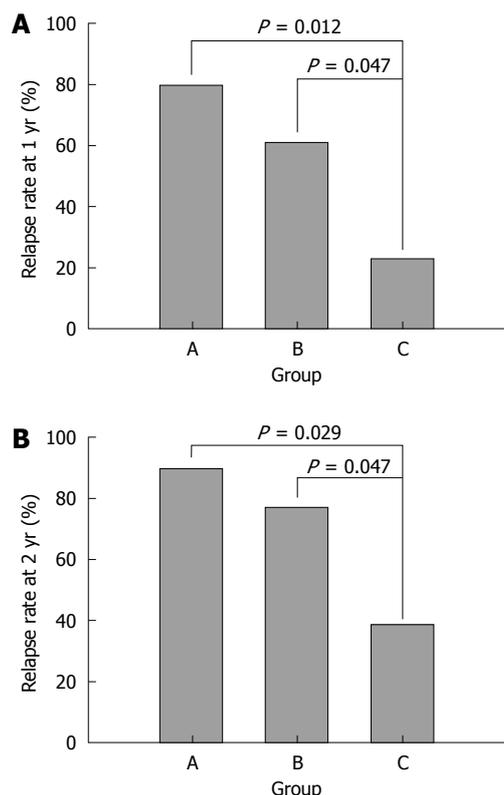

Figure 1 Relapse rate at 1 year (A) and 2 years (B). Group A: Treated with mesalamine after induction therapy with oral prednisolone; Group B: Treated with azathioprine after induction therapy with oral prednisolone; Group C: Treated with infliximab and azathioprine for induction and maintenance therapy.

on the long-term efficacy of ‘top-down’ infliximab treatment for newly diagnosed pediatric Crohn’s disease. We have used infliximab as induction therapy since 2005. Our patients had a better response to infliximab treatment compared to conventional therapy. The improved response, when compared to Western data, suggests that there might be ethnic differences in the response to treatment. A review of the medical literature showed that the incidence and prevalence of Crohn’s disease in Korea is lower than in developed countries; however, it is rapidly increasing^[7]. In addition, the pathogenesis associated with the common *NOD2* variant in Asian populations differs from Western countries.

The results of our study showed that induction and maintenance therapy with infliximab and azathioprine was more effective than conventional treatments in children. After discontinuation of infliximab maintenance therapy for 1 year, we showed that the relapse rate in group C was lower than that in the other groups. The remission rate achieved with infliximab was higher in our study than in the study reported by Hyams *et al.*^[14]; at 1 year, 55.8% (29 out of 52) of patients in the study by Hyams receiving infliximab every 8 wk were in clinical remission; on the other hand, 76.9% (10 out of 13) of the patients in our study group C achieved remission. There was no difference in the PCDAI score between the study by Hyams and our study, 42.1 ± 9.2 and 34.8

Table 4 Adverse events

	<i>n</i> (%)	Details
Group A (mesalamine)	3 (30.0)	Anorexia (<i>n</i> = 2), Pancreatitis (<i>n</i> = 1)
Group B (azathioprine)	5 (38.5)	Anorexia (<i>n</i> = 1), Pancytopenia (<i>n</i> = 3), Pancreatitis (<i>n</i> = 1)
Group C (infliximab)	1 (8.3)	Dyspnea and tachycardia (<i>n</i> = 1)

± 8.8 , respectively. The reason why remission was maintained longer in our study compared to the findings from other developed countries remains unclear. Three hypotheses can be posited: first, it is likely that there are ethnic differences in the clinical response to infliximab, as seen with *NOD2* variations; second, we used infliximab as ‘top-down’ therapy, while in the study by Hyams the patients who had received other drugs such as oral corticosteroids and aminosalicylates were also included in the infliximab treatment group; finally, the number of patients in our study was relatively small, and a selection bias cannot be ruled out. Further study is needed to confirm our findings. However, even with the differences in the number of patients and inclusion criteria, the clinical response to early use of infliximab in our report was much better than the responses reported by Hyams.

Pediatric Crohn’s disease is characterized by frequent relapses, a widespread disease extent, a high prevalence of extraintestinal manifestations, and in general a severe clinical course^[15,16]. In pediatric patients, both the disease itself and the treatment used to control it, most commonly corticosteroids, can seriously impair quality of life as well as cause significant side effects such as growth failure and an increased risk of infections. For these reasons clinicians tend to use corticosteroids for short durations. Although corticosteroids are effective in inducing clinical remission in patients with active Crohn’s disease, these agents have limited efficacy for maintaining remission and the healing of mucosal lesions^[17].

Infliximab, is an anti TNF- α monoclonal antibody that was initially used in corticosteroid-dependent and corticosteroid-refractory Crohn’s disease^[18]. The use of infliximab has been well documented as an effective treatment for moderate to severe Crohn’s disease in children, in several studies^[14,19]. Infliximab, as a scheduled treatment, is effective for the induction and maintenance of remission in patients with Crohn’s disease^[20,21]. Early use of infliximab with immunosuppressants, known as ‘top-down’ therapy, in patients with newly diagnosed Crohn’s disease has resulted in better outcomes in adult patients^[22]. An 8-wk maintenance treatment schedule with infliximab has been shown to be a cost-effective approach in adult patients with active luminal or fistulizing Crohn’s disease^[23]. Such therapy offers the potential for altering the natural history of Crohn’s disease, and is changing treatment paradigms. One possible explanation for the prolonged remissions with infliximab treatment

is that this medication might help heal the mucosal lesions in patients with severe as well as those with mild disease^[24]. However, the new concept of an early aggressive or ‘top-down’ treatment approach is not widely accepted yet, especially in children, even though a few studies have reported that infliximab was more effective in children than in adults^[5,6].

The limitations of this study include the following: This was a single center study with a small number of patients who were reviewed retrospectively. As an open trial, the physicians and patients knew the treatment regimen, which could have biased the assessment of treatment efficacy. However, selection bias was unlikely because the distribution of treatment regimens among the three groups was made based on chronological grouping.

In conclusion, the results of this study showed that early and intensive treatment of pediatric Crohn’s disease patients with infliximab, at initial diagnosis, was more effective for maintaining remission and reducing flares. Treatment with azathioprine monotherapy, after discontinuation of infliximab, for 1 year, provided prolonged remission.

COMMENTS

Background

The etiology of Crohn’s disease remains incompletely understood. There is no known cure for Crohn’s disease. Therefore, the goal of treatment is to mitigate inflammation and the associated clinical symptoms. Conventional therapy for active disease includes treatment with corticosteroids, which is very effective and fast acting. However, long-term exposure to corticosteroids becomes problematic with issues of dependency and/or resistance.

Research frontiers

Infliximab is an anti tumor necrosis factor α monoclonal antibody that was introduced for the treatment of moderate to severe Crohn’s disease. The efficacy of infliximab suggests a new concept; that early induction with intensive treatment, known as ‘top-down’ therapy, may reduce complications associated with conventional treatment and may improve quality of life.

Innovations and breakthroughs

This is the first study reported in Asia on the long-term efficacy of ‘top-down’ infliximab treatment for pediatric Crohn’s disease. The results of this study showed that early and intensive treatment using infliximab, at initial diagnosis, was more effective for maintaining remission and reducing flares for 2 years.

Applications

Early induction treatment with infliximab at diagnosis, known as “top-down” therapy, was effective in reducing relapse rate and adverse events compared to conventional therapies for at least 2 years.

Peer review

This is a useful cohort that will serve as a useful reference for pediatricians considering infliximab induction therapy for Crohn’s disease.

categories (upper and lower GI symptoms), and consisting of 11 individual symptoms. In the diabetic patient group, diabetic complications including peripheral neuropathy, nephropathy and retinopathy, glycosylated hemoglobin (HbA1c) level and diabetes duration were evaluated.

RESULTS: Among the total 190 diabetic patients and 190 controls enrolled, 137 (72%) of the diabetic patients and 116 (62%) of the controls had GI symptoms. In the diabetic patient group, 83 (43%) had upper GI symptoms and 110 (58%) lower GI symptoms; in the control group, 59 (31%) had upper GI symptoms and 104 (55%) lower GI symptoms. This difference between the two groups was significant for only the upper GI symptoms ($P = 0.02$). Among the diabetic factors, the HbA1c level was the only independent risk factor for upper GI symptoms in the multiple logistic regression analysis (odds ratio = 2.01, 95% confidence interval: 1.02-3.95).

CONCLUSION: Type 2 diabetes was associated with an increased prevalence of upper GI symptoms and these symptoms appeared to be independently linked to poor glycemic control, as measured by the HbA1c levels.

Abstract

AIM: To determine whether gastrointestinal (GI) symptoms are more frequent in type 2 diabetic patients and to examine which diabetic factors are associated with the symptoms.

METHODS: Consecutive subjects with diabetes and age-/gender-matched normal controls were recruited for this study. GI symptoms were assessed using a structured questionnaire divided into two GI symptom

gastrointestinal symptoms in patients with type 2 diabetes. *World J Gastroenterol* 2010; 16(14): 1782-1787 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i14/1782.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i14.1782>

INTRODUCTION

Diabetes mellitus (DM) is becoming increasingly common because of the epidemic of obesity and sedentary lifestyles in South Korea and worldwide^[1-3]. The prevalence of gastrointestinal (GI) symptoms in diabetic patients has been investigated previously in several studies; however, the results are inconsistent due to the different ethnic groups and populations studied^[4-9]. Diabetes-related GI motor dysfunction is common and affects the esophagus, stomach and the lower GI tract^[10]. Many patients with diabetes have upper and lower GI symptoms. The complications involving the GI tract are now recognized to be an important cause of morbidity in patients with diabetes^[11]. Although several pathogenic mechanisms may be involved in these GI symptoms, such as autonomic neuropathy, diabetic peripheral neuropathy, glucose imbalance, diabetic duration, and psychiatric disorders, there is substantial controversy about their etiology.

Therefore, the aim of this study was to determine the frequency of GI symptoms in type 2 diabetic patients and whether GI symptoms are more common in diabetic patients than normal controls. In addition, the diabetic factors associated with the GI symptoms were studied.

MATERIALS AND METHODS

Subjects

We performed a prospective study of a consecutive series of outpatients with type 2 diabetes who visited Konkuk University Medical Center from October 2005 to September 2007 for the first time. All patients were referred by an endocrinologist after a comprehensive evaluation at the endocrine center. These patients underwent screening with esophago-gastro-duodenoscopy (EGD) and colonoscopy (or sigmoidoscopy with fecal occult blood test) to rule out upper and lower GI organic disorders, such as a malignancy, peptic ulcer, or erosive esophagitis. The control subjects were carefully matched for age and gender, and were randomly selected from subjects who underwent a screening EGD and colonoscopy at the Health Promotion Center of Konkuk University Medical Center. The exclusion criteria were the presence of upper and lower GI organic disorders on the EGD; a history of upper and lower GI malignancy, peptic ulcer, major abdominal surgery, or underlying psychiatric illness; a medical history of taking a proton pump inhibitor within the last month; severe liver, lung, renal, or hematological disorders. Patients were also excluded if they were unwilling or unable to provide informed consent, or if they could not complete all phases of the study. Subjects pro-

vided written informed consent before enrollment, and the study protocol was carried out in accordance with the Declaration of Helsinki, Good Clinical Practice, and was approved by the human ethics review board of Konkuk University Medical Center. After enrollment, each subject completed a structured questionnaire to precisely assess the GI symptoms, in the absence of organic, systemic or metabolic diseases; data on smoking and alcohol consumption (> 40 g/d) was included. In addition, for the diabetic patients, diabetic complications including peripheral neuropathy, nephropathy and retinopathy, glycosylated hemoglobin (HbA1c) level, the treatment of diabetes and the duration of diabetes were recorded.

Symptom assessment

The questionnaire contained questions regarding GI symptoms and consisted of two subgroups: an upper GI symptom group and a lower GI symptom group. The upper GI symptom group included six items (globus, heartburn, acid regurgitation, non-cardiac chest pain (NCCP), ulcer-like dyspepsia and dysmotility-like dyspepsia) and the lower GI symptom group included five items (irritable bowel syndrome, abdominal bloating, constipation, diarrhea and anal discomfort). A 'predominant upper GI symptoms' classification was defined as: more frequent and/or more severe upper GI symptoms than lower GI symptoms reported on the questionnaire, and assessed separately. A 'predominant lower GI symptoms' classification was defined in the same way. The questions were analyzed inclusive of all symptoms regardless of the severity or frequency of each item. An interview, using the structured questionnaire, was conducted by two investigators, who provided the patients with standard explanations of the questions and definitions of the symptoms. All symptoms that were not completely self-explanatory were explained by a standard description. The 11 items used for the GI symptoms were constructed to comply as closely as possible with the Rome II criteria for functional GI disease^[12].

Diabetic factors

In the diabetic patient group, diabetic complications were evaluated including peripheral neuropathy, nephropathy and retinopathy. In addition, the HbA1c level and duration of diabetes in each patient were evaluated. The diabetic complications were classified according to the following definitions: (1) Nephropathy was defined as prominent proteinuria on the urine analysis or a serum creatinine that exceeded 133 $\mu\text{mol/L}$; (2) Peripheral neuropathy was assessed by the recommended protocol of nerve conduction study (NCS), including six sensory nerves and six motor nerves^[13]; and (3) Retinopathy was diagnosed based on fundoscopic examination by a skilled ophthalmologist. In addition, HbA1c level was measured using the high performance liquid chromatography method within 1 mo of the questionnaire study. Furthermore, treatment of diabetes included oral hypoglycemic agents and insulin.

	DM group (<i>n</i> = 190)	Control group (<i>n</i> = 190)	<i>P</i> -value
Age (mean ± SD, yr)	57.1 ± 12.5	57.0 ± 10.6	NS
M/F	86 (45)/104 (55)	86 (45)/104 (55)	NS
Smoking	52 (27)	61 (32)	NS
Alcohol use	51 (27)	78 (41)	NS

DM: Diabetes mellitus; NS: Not significant.

Statistical analysis

Statistical analysis was performed using the χ^2 test for comparison of discrete variables and the *t*-test was used for comparison of continuous variables. The continuous variables measured in this study are expressed as the mean ± SD. Multivariate analysis was performed using logistic regression. To examine the association between GI symptoms and type 2 diabetes, multivariate models included adjustment for smoking and alcohol as categorical factors. In the models used to examine the diabetic factors associated with upper GI symptoms, adjustments for smoking, alcohol, the treatment of diabetes, and other diabetic factors were included. For each variable, the odds ratio (OR) and 95% confidence interval (CI) were determined. A two tailed *P* value of < 0.05 was considered statistically significant.

RESULTS

Ten out of a total of 200 subjects with type 2 diabetes who were recruited for the study were excluded because they were unwilling or unable to provide informed consent, or could not complete all phases of the study. Finally, 190 subjects with type 2 diabetes and 190 controls were included in this study. The diabetic and normal subjects were well matched in terms of age and gender (86 men and 104 women with a mean age of 57 years). The clinical factors, including a history of current smoking and alcohol use are shown in Table 1.

The frequency of GI symptoms (any or several) was 72% in the diabetic subjects and 62% in the controls (*P* = NS). Among the upper GI symptoms and the lower GI symptoms, the multiple logistic regression analyses showed that the diabetic patients presented with a significantly higher frequency of upper GI symptoms than the controls (43% *vs* 31%, *P* < 0.05, OR = 1.68, 95% CI: 1.07-2.63); however, no differences were observed for the lower GI symptoms (Table 2). When the individual items of the upper GI symptoms were analyzed separately, globus, heartburn and dysmotility-like dyspepsia were more common in the diabetic patients than in the controls (Figure 1).

The demographic and diabetic characteristics according to the presence or absence of upper GI symptoms in the diabetic patient group are shown in Table 3. Subjects with upper GI symptoms tended to have more complications (66% *vs* 46%), a higher HbA1c level (8.06% *vs* 7.39%) and a longer duration of symptoms (10.4 years

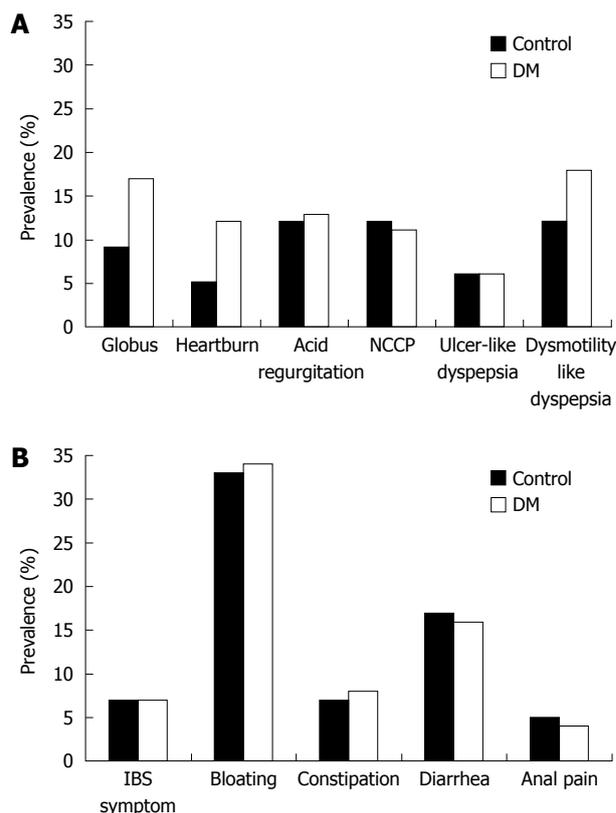

Figure 1 Differences in individual upper (A) and lower (B) gastrointestinal (GI) symptoms between diabetic patients and control groups. A: The diabetic patients had a higher frequency of globus, heartburn and dysmotility-like dyspepsia than the controls; B: There was no difference for any item of the lower GI symptoms between the two groups. DM: Diabetes mellitus; NCCP: Non-cardiac chest pain.

vs 6.5 years) than the upper GI symptom-negative group. On multiple logistic regression analyses, only the higher HbA1c level was significantly associated with smoking, alcohol, the treatment of diabetes, and other covariate factors by the adjusted OR for upper GI symptoms (OR = 2.01, 95% CI: 1.02-3.95) (Table 4).

The relationship of the HbA1c level with upper GI symptoms was studied using the normal HbA1c group (HbA1c < 6%) as the reference standard. There was a significant increase in the prevalence of upper GI symptoms in subjects with an 8% ≤ HbA1c < 9% (OR = 3.38%, 95% CI: 1.06%-10.71%), in subjects with a HbA1c ≥ 9% (OR = 3.23%, 95% CI: 1.13%-9.24%) (Figure 2), and in subjects with HbA1c ≥ 8%. All individual upper GI symptoms including globus, heartburn, acid regurgitation, NCCP, ulcer-like dyspepsia and dysmotility-like dyspepsia were more common than in subjects with a HbA1c < 8% (Figure 3).

DISCUSSION

The prevalence of DM worldwide is estimated to be around 200 million people, more than 5% of the adult population, globally. The current high prevalence of type 2 diabetes is likely to eventually result in a heavy burden of diabetes complications; this will pose a significant

challenge to individuals, communities and healthcare systems during the coming decades, worldwide^[14].

Chronic GI symptoms may represent a clinically important problem in a substantial number of patients with diabetes^[15]. There are several papers which report the association of GI symptoms with diabetes. Epidemiological data regarding the association of GI symptoms with diabetes are, however, inconsistent^[6], and the reported frequency of upper and lower GI symptoms varies among different ethnic groups/populations, although population-based studies, in general, have demonstrated an increase in upper and lower GI symptoms^[16]. Our present study is the first study in Korea to examine the GI symptoms in type 2 diabetic patients and to analyze the diabetic factors associated with these symptoms. We found that the frequency of overall GI symptoms, upper GI symptoms and lower GI symptoms in the 190 patients with diabetes studied was 72%, 43% and 58%,

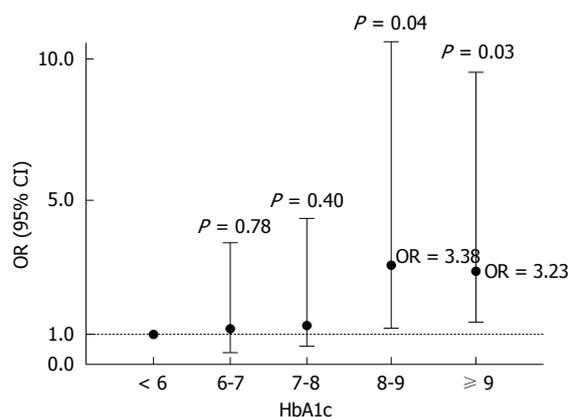

Figure 2 Differences in upper GI symptoms according to the HbA1c level. There was a significant increase in the prevalence of upper GI symptoms in subjects with 8% ≤ HbA1c < 9% and in subjects with HbA1c ≥ 9%; subjects with normal HbA1c (HbA1c < 6%) were used as the reference group. OR: Odds ratio.

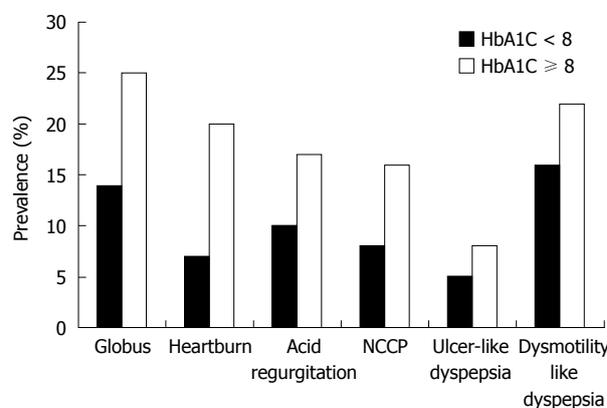

Figure 3 Differences in individual upper GI symptoms according to the HbA1c Level. In subjects with an HbA1c ≥ 8%, all upper GI symptoms were more common than in subjects with an HbA1c < 8%.

respectively. Comparison of the frequency of the overall GI symptoms, upper GI symptoms and lower GI symptoms between the diabetic patient group and the age- and gender-matched control group showed 1.45 times as many overall GI symptoms, 1.68 times as many upper GI symptoms and 1.10 times as many lower GI symptoms in individuals with diabetes. The risk of only upper GI symptoms in this group showed a statistically significant increase, with adjustments for age, gender, smoking and alcohol consumption.

The natural history and pathogenesis of GI symp-

toms in patients with diabetes remains poorly defined. Several pathogenic mechanisms such as autonomic neuropathy, diabetic peripheral neuropathy, glucose imbalance, diabetic treatment, diabetes duration, and psychiatric disorders may be involved in GI symptoms. Traditionally, GI symptoms in diabetic patients have been attributed to disordered motor function as a result of the irreversible autonomic neuropathy that frequently accompanies diabetes^[17]. Also, the hypothesis that poor glycemic control by itself is a major cause of chronic GI symptoms has been raised recently, based primarily on data from large population studies^[16,18,19] as well as small physiological studies^[17,20-22]. Other factors that may be important in the etiology of GI symptoms in patients with diabetes include the duration of diabetes^[23] and psychiatric comorbidity^[24,25].

Systematically, we attempted to evaluate the relationship between upper GI symptoms and the various features of diabetes such as diabetic complications (including peripheral neuropathy, nephropathy and retinopathy), HbA1c level, the treatment of diabetes and the duration of diabetes. Among several diabetic factors, only the HbA1c level reflecting glycemic control was found to be significantly associated with the upper GI symptoms in the diabetic patients when the individual factors of diabetes were analyzed separately by multiple logistic regression analyses. Hyperglycemia has been shown to affect the perception of GI sensations^[17,20-22,26] such as nausea and fullness, produced by distension of the proximal stomach or duodenum; such sensations are more intense during hyperglycemia than during euglycemia. Acute changes in the blood glucose concentration have also been shown to impair autonomic nerve function^[27] and lower pain thresholds in patients with diabetes^[28]; although there appear to be regional variations in the effects of the blood glucose concentration on both GI motility and the perception of sensations from the GI tract^[21,29]. In addition, these effects have been reported to have less of an impact on lower GI symptoms, similar to the results of this study.

In our study, we focused on the association between upper GI symptoms and HbA1c levels. As a result, we found 3.38 times as many upper GI symptoms in the cases with HbA1c \geq 8% compared to those with HbA1c < 6%; all individual upper GI symptoms were common in the cases with HbA1c \geq 8%. This result is in agreement with the recommendation for a maintenance of HbA1c < 8% to prevent serious diabetic complications^[30].

The limitations of this study include the following: only the presence or absence of individual GI symptoms, not the severity and/or frequency, was examined in the symptom assessment, regardless of the major symptoms. There were no data collected on coexisting psychiatric disorders associated with GI symptoms in patients with diabetes; this might be an important factor according to the recent reports by Quan *et al.*^[24,25]. Nevertheless, our present study is a case-control study with age- and sex-matched controls and is the first of its kind

performed in Korea. In addition, this study has a large methodological advantage with regard to the well established subjective analysis for diabetic complications such as peripheral neuropathy, and not objective answers such as the 'yes' or 'no' of self-reports.

In conclusion, upper GI symptoms were more common in patients with type 2 diabetes than in well-matched control subjects. The results of this study provide evidence that upper GI symptoms appear to be independently linked to poor glycemic control as measured by HbA1c level. Therefore, we cautiously suggest that chronic upper GI symptoms may be reversible with tight control of blood glucose level.

COMMENTS

Background

Diabetes is known to be associated with gastrointestinal (GI) symptoms and several mechanisms have been implicated in the pathogenesis of GI symptoms. However, there is little information from Korea as well as few reports from Asia.

Research frontiers

Researchers have previously assessed the increase of the prevalence of GI symptoms in diabetic patients and the diabetic factors associated with the GI symptoms. However, results of the prevalence of GI symptoms in diabetic patients and the diabetic factors associated with these GI symptoms are inconsistent due to the different ethnic groups and populations assessed.

Innovations and breakthroughs

This study is a case-control study with age- and sex-matched controls and is the first study of its kind performed in Korea. In addition, this study has a methodological advantage with regard to the well established subjective analysis for diabetic complications such as peripheral neuropathy.

Applications

Upper GI symptoms were more common in patients with type 2 diabetes than in well-matched control subjects and appeared to be independently linked to poor glycemic control as measured by the HbA1c levels in Korean individuals. Therefore, chronic upper GI symptoms may be reversible with tight control of blood glucose level.

Peer review

This is a purely observational, prospectively planned study. Prevalence of GI symptoms in diabetic patients and non-diabetic healthy subjects has been widely studied and well documented. The fact that poor glycemic control is associated with increased frequency of upper and lower GI tract symptoms also has been well established. On the other hand, this topic still may be interesting to readers since the study focused on different ethnic groups.

Abstract

AIM: To investigate the effects of interleukin-8 (*IL-8*), macrophage migration inhibitory factor (*MIF*) gene polymorphisms, *Helicobacter pylori* (*H. pylori*) infection, on the risk of developing severe chronic atrophic gastritis (SCAG) and intestinal metaplasia (IM).

METHODS: A total of 372 cases were selected from a cohort study in Linqu County, a high risk area for gastric cancer (GC) in northern China. To obtain a sufficient group size, patients with normal or superficial gastritis were included. Based on an average follow-up period of 56 mo, the 372 cases were divided into no progres-

sion group (no histological progression from normal or superficial gastritis, $n = 137$), group I (progressed from normal or superficial gastritis to SCAG, $n = 134$) and group II (progressed from normal or superficial gastritis to IM, $n = 101$). *IL-8*, *MIF* gene polymorphisms were detected by polymerase chain reaction-based denaturing high-performance liquid chromatography analysis and DNA sequencing.

RESULTS: An increased risk of SCAG was found in subjects with *IL-8*-251 AA genotype [odds ratio (OR) = 2.62, 95% CI: 1.23-5.72] or *IL-8*-251 A allele carriers (AA + AT) (OR = 1.81, 95% CI: 1.06-3.09). An elevated risk of IM was found in subjects with *IL-8*-251 AT genotype (OR = 2.27, 95% CI: 1.25-4.14) or *IL-8*-251 A allele carriers (OR = 2.07, 95% CI: 1.16-3.69). An increased risk of SCAG was found in subjects with *MIF*-173 GC genotype (OR = 2.36, 95% CI: 1.38-4.02) or *MIF*-173 C allele carriers (GC + CC) (OR = 2.07, 95% CI: 1.21-3.55). An elevated risk of IM was found in subjects with *MIF*-173 CC genotype (OR = 2.27, 95% CI: 1.16-4.46) or *MIF*-173 C allele carriers (OR = 3.84, 95% CI: 1.58-9.34). The risk of SCAG and IM was more evident in subjects carrying *IL-8*-251 A allele (OR = 6.70, 95% CI: 1.29-9.78) or *MIF*-173 C allele (OR = 6.54, 95% CI: 2.97-14.20) and positive for *H. pylori* infection.

CONCLUSION: *IL-8*-251 and *MIF*-173 gene polymorphisms are significantly associated with the risk of SCAG and IM in a population with a high risk of GC in Linqu County, Shandong Province, China.

Li ZW, Wu Y, Sun Y, Liu LY, Tian MM, Feng GS, You WC, Li JY. Inflammatory cytokine gene polymorphisms increase the risk of atrophic gastritis and intestinal metaplasia. *World J Gastroenterol* 2010; 16(14): 1788-1794 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i14/1788.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i14.1788>

INTRODUCTION

Atrophic gastritis (AG) and intestinal metaplasia (IM) are two important precursor lesions of intestinal type gastric cancer (GC)^[1]. These precursor lesions may significantly elevate the risk of intestinal type GC^[2,3].

Some bacterial factors, such as the pathogenic island of *Helicobacter pylori* (*H. pylori*) including *cagA*, *sIm1 vacA*, *babA2*, *sabA*, and *oipA*, are correlated with the severity of atrophic gastritis and occurrence of IM^[4-9]. However, bacterial factors alone are not sufficient to explain the diverse results of *H. pylori*-related diseases. Our previous study has shown that the proportion of *cagA* + *H. pylori* strains in children living in Linqu County, an area with a high risk of GC in China, is very high (88.5%)^[10]. It has also been demonstrated that almost 100% of *H. pylori* strains isolated from Chinese population are *cagA* positive^[11].

There is increasing evidence that host inflammation-related cytokines and their gene polymorphisms are related with atrophic gastritis and IM^[12,13]. Interleukin-8 (IL-8), a member of Cys-X-Cys (CXC) chemokine family, is an activator and chemoattractant of neutrophils and lymphocytes^[14]. Gastric mucosal levels of IL-8 increase significantly after *H. pylori* infection and parallel to the severity of gastritis^[15]. Macrophage migration inhibitory factor (MIF), an important activator of T lymphocytes and macrophages, plays a pivotal role in inflammatory and immune diseases^[16,17]. *H. pylori* infection is associated with an increased expression of MIF mRNA and protein in gastric epithelial and inflammatory cells. Increased expression of the MIF protein correlates with histological severity of GC and its precursor^[18].

As these inflammatory cytokines and their gene polymorphisms may potentially influence the outcome of *H. pylori* infection, a few studies have investigated the association of gene polymorphisms in these inflammatory cytokines with the risk of atrophy and IM^[15,19,20].

However, these studies were limited by their single time-point assessment for pathological diagnosis. Therefore, we conducted a prospective study to investigate the association of *IL-8* gene polymorphisms with the risk of atrophic gastritis, and *MIF* gene polymorphisms with IM, showing that the high expressing genotypes of *IL-8* are significantly associated with the increased risks of severe chronic atrophic gastritis, and *MIF* is significantly associated with IM.

MATERIALS AND METHODS

Study protocol

The initial study included over 3399 people from Linqu

County, a rural area of Shandong Province, China, which has one of the highest GC mortality rates in the world (70/10000 males and 25/10000 females per year)^[21]. In brief, we launched an endoscopic-pathological screening program for GC and precancerous lesions of GC in 3399 residents from 14 randomly selected villages of Linqu County in autumn of 1989 or in spring of 1990. In 1994, a follow-up endoscopic screening was performed in 83% of eligible members. People, diagnosed as normal or superficial gastritis in 1989 or in 1990, were subsequently genotyped for *IL-8* and *MIF*. We analyzed the relation between genotypes and progression of gastric disease. The study design received approval from the Institutional Review Board of Peking University School of Oncology, and was conducted in accordance with the Helsinki Declaration. Informed consent was obtained from all participants.

Endoscopy and pathological diagnosis

Seven biopsies were taken from standard locations in each subject. The procedures and histopathologic criteria have been described elsewhere^[22,23]. We reviewed all slides of 372 patients in our study according to the updated Sydney system^[24]. Each subject was assigned a global diagnosis based on the most severe diagnosis among the seven biopsies. Independent examinations were performed by three experienced gastroenterologists. If there was any disagreement, the final decision was made based on the majority or subsequent discussion of the case.

Grouping

After the first examination in 1989, 372 of the 3399 subjects including 172 males and 200 females with a mean age of 42.2 years (range: 24-65 years) were enrolled in this study. All these 372 subjects were initially diagnosed as normal or as superficial gastritis (baseline). After a 56-mo follow-up, these 372 subjects were subdivided into group I ($n = 134$), group II ($n = 101$) and no progression group ($n = 137$). Lesions in patients of group I were progressed from baseline to severe chronic atrophic gastritis (SCAG). According to the updated Sydney system, recognition of minor degrees of atrophy without intestinal metaplasia in the antrum was difficult, marked degrees of atrophy without intestinal metaplasia in the antrum were selected as the presence of atrophic gastritis. Lesions in patients of group II were progressed from baseline to IM, and lesions in patients of no progression group did not progress from baseline lesion.

Blood sample collection

In 1994, blood samples were collected and allowed to clot for 30-40 min at room temperature in the dark. Serum was harvested, the clot was frozen immediately at -20°C , and stored at -70°C for 2 or 3 d. During the transfer, dry ice was used.

Diagnosis of *H. pylori* infection

The detailed serologic assay has been described elsewhere^[22]. Serum level of *H. pylori*-specific IgG and IgA in all samples was measured by enzyme-linked

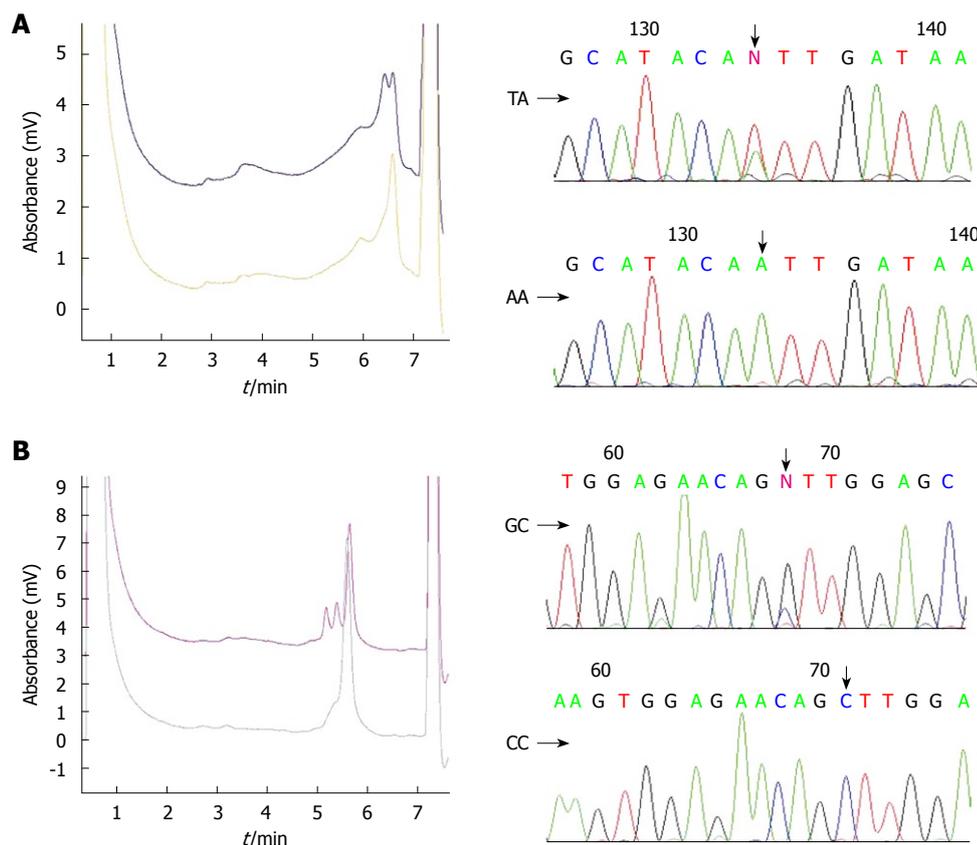

Figure 1 Denaturing high-performance liquid chromatography (DHPLC) and sequence analysis. A: Interleukin-8 (IL-8)-251 A/T polymorphism; B: Macrophage migration inhibitory factor (MIF)-173 C/G polymorphism.

immunosorbent assay (ELISA). Quality-control samples were assayed at Vanderbilt University (Nashville, TN). An optical density ratio (ODR) value > 1.0 and < 1.0 was considered seropositive and negative, respectively.

The presence of *H. pylori* was further confirmed by immunohistochemistry (IHC). Briefly, paraffin-embedded tissue sections were stained using IHC with an avidin-biotin complex immunoperoxidase kit. Polyclonal rabbit anti-*H. pylori* (ab7788, Abcam, Cambridge, UK) was used as a primary antibody as previously described^[25].

DNA preparation

Blood clots were thoroughly washed with Tris-EDTA (TE) buffer containing 50 mmol/L Tris-HCl (pH 8.0) and 1 mmol/L EDTA. After centrifugation, pellets were incubated with rotation in a lysis buffer (TE buffer containing 2 g/L SDS and 200 μ g/mL proteinase K) overnight at 37°C. Lysate was then extracted with phenol and precipitated with isopropanol. The precipitate was washed with 70% ethanol, dried, and dissolved in TE buffer. Concentration and purity of DNA were determined by spectrophotometry at $A_{260\text{ nm}}$ and $A_{280\text{ nm}}$. Then, DNA was aliquoted and stored at -80°C until use.

Cytokine genotyping

Polymerase chain reaction (PCR) was performed in a 25 μ L reaction mixture containing 100ng of DNA, 0.1 μ mol/L of each primer, 0.2 mmol/L of deoxynucleosidetriphosphate, 1.0 U of *Taq* DNA polymerase (Promega, Madison, WI), and 1 \times reaction buffer. The primer sequences of MIF-173, IL-8-251 have been described elsewhere^[26]. PCR-based denaturing high-performance

liquid chromatography (DHPLC) and single nucleotide polymorphisms (SNP) were further confirmed by direct sequencing.

DHPLC analysis was performed on a transgenomic WAVE system (Transgenomic Inc., Omaha, NE). The detailed genotyping process has been described elsewhere^[27]. In brief, PCR products were denatured for 1 min at 94°C and then gradually re-annealed by decreasing the sample temperature from 94°C to 45°C for 30 min to form homo- and/or hetero-duplexes. The PCR products were then applied to the DHPLC column at an optimal oven temperature and eluted with a linear acetonitrile gradient at a flow rate of 0.9 mL/min. The results of DHPLC were further confirmed by DNA sequencing with an ABI Prism 377 DNA sequencer (Applied Biosystems, Foster City, CA) (Figure 1).

Statistical analysis

Data were analyzed using the SPSS 13.0 (SPSS Inc., Chicago, IL, USA). Multiple linear regression analyses were performed with gender, age, smoking, and drinking as explanatory variables to determine which factors influence the progression of gastric lesions. Genotypes of IL-8-251 and MIF-173 loci were also included as explanatory variables when difference in groups I and II and no progression group was detected. Odds ratios (OR) with 95% confidence interval (CI) were computed. $P < 0.05$ was considered statistically significant.

progression and no progression are listed in Table 1. The number of patients under the age of 40 years was greater in groups I and II than in no progression group. The percentage of *H. pylori* infection was significantly higher in group I than in no progression group.

The patients expressed Alleles at the individual loci were expressed in patients showing no progression of the lesions, with no significant χ^2 values.

Effect of IL-8-251 polymorphism on development of SCAG and IM

Multivariate analysis showed that the frequencies of IL-8-251 in groups I and II were significantly different from those in no progression group (Table 2). Compared with IL-8-251 TT genotype, IL-8-251 AA genotype and IL-8-251 A allele carriers exhibited a significantly increased risk for progression from baseline lesions to SCAG (Table 3). The patients with IL-8-251 TA genotype or IL-8-251 A allele carriers had an increased risk for progression from baseline lesions to IM.

Effect of MIF-173 polymorphism on development of SCAG and IM

Multivariate analysis showed that the MIF-173 GC geno-

type or MIF-173 C allele carriers were significantly associated with an increased risk for progression from baseline lesions to SCAG and IM (Table 3).

The risk for SCAG in association with IL-8-251 and MIF-173 genotypes was further examined with stratification by *H. pylori* infection. The OR for development of SCAG in subjects carrying IL-8-251 A allele or with *H. pylori* infection alone was 2.34 (95% CI: 0.95-2.83) or 3.28 (95% CI: 1.09-9.78), respectively. However, the OR was significantly elevated in subjects carrying the AA genotype and with *H. pylori* infection (OR = 6.70, 95% CI: 1.29-9.78) (Table 4). There was an interaction between IL-8-251 A allele carriers and *H. pylori* infection, with a relative risk for development of SCAG due to the interaction of 6.70, and a synergy index of 1.57.

A similar trend to develop SCAG was observed between the MIF-173 C allele carriers and *H. pylori* infection. The OR of developing SCAG significantly increased in subjects carrying at least one MIF-173 C allele and with *H. pylori* infection (OR = 6.54, 95% CI: 2.97-14.20) (Table 4). An interaction between the MIF-173 C allele carriers and *H. pylori* infection was observed (OR = 2.26, synergy index = 3.15).

The association of IM and IL-8-251 with MIF-173 genotypes was further examined with stratification by *H. pylori* infection. However, the OR for IM in subjects carrying MIF-173 C allele and with *H. pylori* infection was elevated significantly (OR = 2.93, 95% CI: 1.28-6.60) (Table 5). There was also an interaction between the MIF-173 C allele carriers and *H. pylori* infection (OR = 2.20, synergy index = 1.25).

DISCUSSION

In this study, all tested genetic polymorphisms in IL-8 and MIF increased the risk of SCAG and IM. IL-8 and MIF are inflammatory cytokines expressed in injured mucosa after *H. pylori* infection. IL-8 is an important mediator of the inflammatory response and increases mucosal injury in *H. pylori* infected patients because IL-8 is a major activator and chemokine for neutrophils which

contribute to mucosal damage by secreting NO and H₂O₂^[28] and significantly augments T helper 1 (Th1) immune response by inducing proinflammatory cytokines such as TNF- α , interferon- γ , and IL-1 β secretion. It has been shown that Th1 predominant immune responses inhibit acid secretion from gastric glands, and cause gastric atrophy and metaplasia in a *H. pylori* infected mouse model^[29,30].

The transcript activity is significantly higher in the IL-8-251 A promoter than in the IL-8-251 T promoter^[31]. Furthermore, the DNA sequence around the IL-8-251 A allele region may produce a potential binding site for C/EBP, and induce IL-8 expression through the nickel subsulphide dependent pathway^[32].

In this study, the risk of progression from baseline lesions to SCAG and IM was significantly increased in patients carrying the IL-8-251 AA and IL-8-251 AT genotype or the IL-8-251 A allele, which is consistent with the reported findings^[19,31]. Furthermore, SCAG occurred due to the interaction between IL-8-251 A allele carriers and *H. pylori* infection. A previous study on the same population also demonstrated that the IL-8-251 AA genotype significantly increases the risk of GC^[33]. In the present study, IL-8-251 A allele carriers were positively correlated with the development of SCAG and IM, implying that *IL-8-251* gene polymorphism plays an important role in the development of GC.

MIF promotes the recognition of Gram-negative bacteria by the innate immune system^[34]. The *MIF* gene appears to be a strong candidate susceptibility gene for *H. pylori*-related diseases. Xia *et al.*^[17] reported that both mRNA and protein levels of MIF are up-regulated in *H. pylori*-infected patients and parallel to the severity of gastritis. Moreover, the expression level of MIF protein is markedly different in patients with gastritis, IM, DYS, GC^[17,18].

Functional studies, both *in vivo* and *in vitro*, demonstrated that the mutant allele MIF-173 C is associated with an

increased MIF protein production^[31,35]. The presence of MIF-173 C allele stimulates protein 4 (AP-4) transcription factor binding site that may up-regulate MIF expression^[36].

In our study, the MIF-173 C allele was found to be associated with the high risk of SCAG and IM. Moreover, an interaction occurred between MIF-173 C allele carriers and *H. pylori* infection, thus promoting progression from baseline lesions to SCAG and IM. Other studies found that MIF not only modulates the expression of proinflammatory mediators such as TNF- α , IL-1 β , IL-8, IFN- γ , but also regulates the activation of T cells^[35,37].

Therefore, we hypothesize that variants of *MIF* gene polymorphism may contribute to the different outcomes of *H. pylori*-related gastritis. Moreover, *MIF* gene polymorphisms may be another important candidate gene marker for the outcomes of patients infected with *H. pylori*.

The fact that the population in our study lived in a relatively closed society and had similar living conditions or habits, may minimize the effects of other mixed factors such as intake of fresh vegetables, salt consumption, water intake. Furthermore, the subjects in our study were followed up for an average period of 56 mo, and the final pathological diagnosis was made in 1994. Although more recent pathological assessments may provide additional insights, an average follow-up period of 4-5 years provides a more dynamic process for the assessment of risks than a single time point analysis^[15,19,20].

In summary, *H. pylori* infection and variants in IL-8-251 or MIF-173 polymorphisms influence the occurrence of SCAG and IM. Because of the high prevalence of *H. pylori* infection, antibiotic resistance, and some potential drawbacks associated with *H. pylori* eradication therapy (e.g. reflux esophagitis), our study may provide a reasonable basis for therapeutic decisions even at the early stage of GC.

COMMENTS

Background

Atrophic gastritis and intestinal metaplasia are two important precursory lesions of intestinal type gastric cancer (GC), except for factors of *Helicobacter pylori* (*H. pylori*). Host gene polymorphisms also play a very important role in the development of GC.

Research frontiers

To date, a few studies are available on the relation between gene polymorphisms of inflammatory cytokines and risk of atrophy and intestinal metaplasia (IM).

Innovations and breakthroughs

In this study, the authors conducted a prospective study using the data obtained during the 56-mo follow-up (including both gastroscopic and histopathological information). The relation between interleukin-8 (IL-8), migration inhibitory factor (*MIF*) gene polymorphisms and risk of atrophic gastritis and IM was also studied.

Applications

Because of the high prevalence of *H. pylori* infection, antibiotic resistance, and some potential drawbacks in *H. pylori* eradication therapy (e.g. reflux esophagitis), the result of this study may provide some new evidence for the selection of patients infected with *H. pylori* and for the prevention of progression of *H. pylori*-related gastritis.

Terminology

IL-8, a member of Cys-X-Cys (CXC) chemokine family, is an activator and chemoattractant of neutrophils and lymphocytes, thus playing an important role in the development of gastritis and GC. Macrophage MIF, an important activator of T lymphocytes and macrophages, plays a pivotal role in inflammatory and immune diseases. The expression of MIF is increased after *H. pylori* infection and related with histological severity of GC and its precursor.

Peer review

The authors studied the role of different IL-8 and MIF genotypes in the development of precancerous gastric lesions, severe atrophic gastritis or intestinal metaplasia, in a cohort of 372 patients. The study defined *H. pylori*-infected patients at the risk for GC.

Abstract

Twenty-four hours multichannel intraesophageal impedance and pH monitoring in a patient who suffered from recurrent hiccups for more than a year revealed frequent supragastric belching and pathological oesophageal acid exposure. Furthermore, a temporal relationship between the start of a hiccup episode and gastric belching was observed. The data support the hypothesis that there is an association between supragastric belching, persistent recurrent hiccups and gastro-oesophageal reflux disease, and that gastric belching may evoke hiccup attacks.

INTRODUCTION

Hiccups are mostly a transient phenomenon that do not require medical attention. Prolonged hiccups are rare and can be indicative of a serious underlying disease process. Gastro-oesophageal reflux disease (GORD) has been associated with protracted hiccups^[1-3]. Previous reports on functional disturbances of the oesophagus in patients with hiccups are sporadic and confined to conventional manometry and pH monitoring. Multichannel oesophageal impedance measurement is a recently developed technique that detects both liquid and gas transport in the oesophagus. In this report we present detailed results of 24 h intraesophageal impedance measurement and pH monitoring in a patient who suffered from persistent recurrent hiccups for more than a year. In addition, we had the unique opportunity to monitor intraluminal pressure and impedance signals of the oesophagus during the spontaneous onset of a hiccup attack.

CASE REPORT

A 74-year-old man suffered from chronic recurrent hiccups for more than 18 mo. Upper gastrointestinal endoscopy showed reflux oesophagitis grade A (Los Angeles classification). Proton pump inhibitor (PPI) therapy was successful for heartburn, but hiccups and belching persisted. Extensive clinical evaluation did not reveal other abnormalities that could explain the hiccups. Treatment with metoclopramide, baclofen and gabapentin did not relieve symptoms. During hiccup episodes, hiccups

were continuous, lasted all day and were even present at night. Severe belching sometimes preceded the start of a hiccup attack. Hiccups were absent approximately 1 d per week.

24-h ambulatory impedance-pH monitoring

Electrical impedance was recorded at 3, 5, 7, 9, 15 and 17 cm and pH at 5 cm above the upper border of the lower oesophageal sphincter (LOS) with a transnasally positioned disposable catheter (reference code K6011-EI-0632 Unisensor AG, Attikon, Switzerland). A commercially available ambulatory system (Ohmega, MMS, Enschede, The Netherlands) was used for storage and subsequent analysis of data according to previously described criteria^[4-7]. The study was performed once on and once off PPI therapy.

pH-metry off PPI revealed severely pathologic oesophageal acid exposure (Table 1). Basal impedance was below 1000 Ohm for more than 90% of the time at all measurement sites in the oesophagus, prohibiting reliable detection of swallow- or reflux-induced impedance drops. Impedance patterns consistent with “supragastric belches (SGBs)” were observed frequently^[6]. These consisted of impedance increments exceeding 3000 Ohm with a rapid aboral propagation (velocity > 10 cm/s). These impedance peaks started in the proximal oesophagus and were followed by a retrograde return of impedance to baseline (Figure 1). A total of 188 SGBs were observed in our patient (Table 1). Based on these findings the patient was treated with PPI (20 mg rabeprazole twice daily) and referred for behavioral therapy in an attempt to reduce supragastric belching.

Twenty-four hours ambulatory impedance-pH monitoring on PPI 1 mo after behavioral therapy revealed a considerable reduction of SGBs by 90% (Table 1). The treatment by a speech therapist focused on teaching abdominal breathing and controlled swallowing to avoid influx of air. Oesophageal acid exposure was reduced (Table 1) and heartburn completely disappeared after PPI therapy. However, after 1 year follow-up, the patient reported only a minor and transient reduction of hiccups.

Oesophageal impedance measurement and perfusion manometry

Stationary manometry and impedance measurements were performed with a perfused multi-lumen manometric and impedance assembly in combination with a sleeve sensor (reference code CE5-0010, Dentsleeve international, Mississauga, Ontario, Canada) connected to the Solar GI system (MMS) as described previously^[8]. Intraoesophageal pressures and impedance signals at 2, 7, 12 and 17 cm above the upper border of the LOS revealed ineffective oesophageal motility characterized by non-transmitted contractions with absence of pressure responses at 2 cm and in 3 out of 14 liquid swallows also at 17 cm. In 2 out of 14 swallows a simultaneous contraction was observed with mean amplitude > 30 mmHg. In addition, impedance tracings showed abnormal bolus transport as only 41% (normal \geq 80%) of saline swallows were followed by normal transit. During these routine measurements hiccups were absent. Recording was continued for 3 h with the patient comfortably seated in a chair. After 20 min an episode of hiccups began. Approximately 20 s before the onset of the hiccups a sequence of gastric belching followed by simultaneous oesophageal contractions was observed (Figure 2).

DISCUSSION

In our patient presenting with recurrent hiccups, excessive supragastric belching was found by 24-h impedance measurement. In addition, gastric belching and oesophageal spasms were observed by combined oesophageal impedance monitoring and manometry immediately preceding the onset of a hiccup attack.

The typical impedance pattern of SGBs was previously observed in patients with severe belching by Bredenoord *et al*^[6]. It was attributed to rapid entrance of air into the oesophagus from proximal that was almost immediately expelled. The pattern was clearly distinct from normal air swallowing in which a fall in impedance was associated with a more slowly propagated impedance peak and also from gas reflux or gastric belches in which the impedance peak started in the distal oesophagus and moved in a retrograde direction^[4-6]. SGBs were not reported in healthy controls and in patients with functional dyspepsia^[4-6]. In patients with GORD SGBs were found to occur more frequently, either as a putative trigger of reflux episodes or as a response to a perceived reflux episode^[9].

The pathophysiology of hiccups is not clear. It has been suggested that sudden rapid distension of the proximal oesophagus by excessive food ingestion, carbonated beverages or aerophagia can trigger the hiccup reflex^[10,11]. The present report provides evidence for an association between belching and hiccups. The observation that two gastric belches preceded the onset of a hiccup episode in our patient supports the hypothesis that

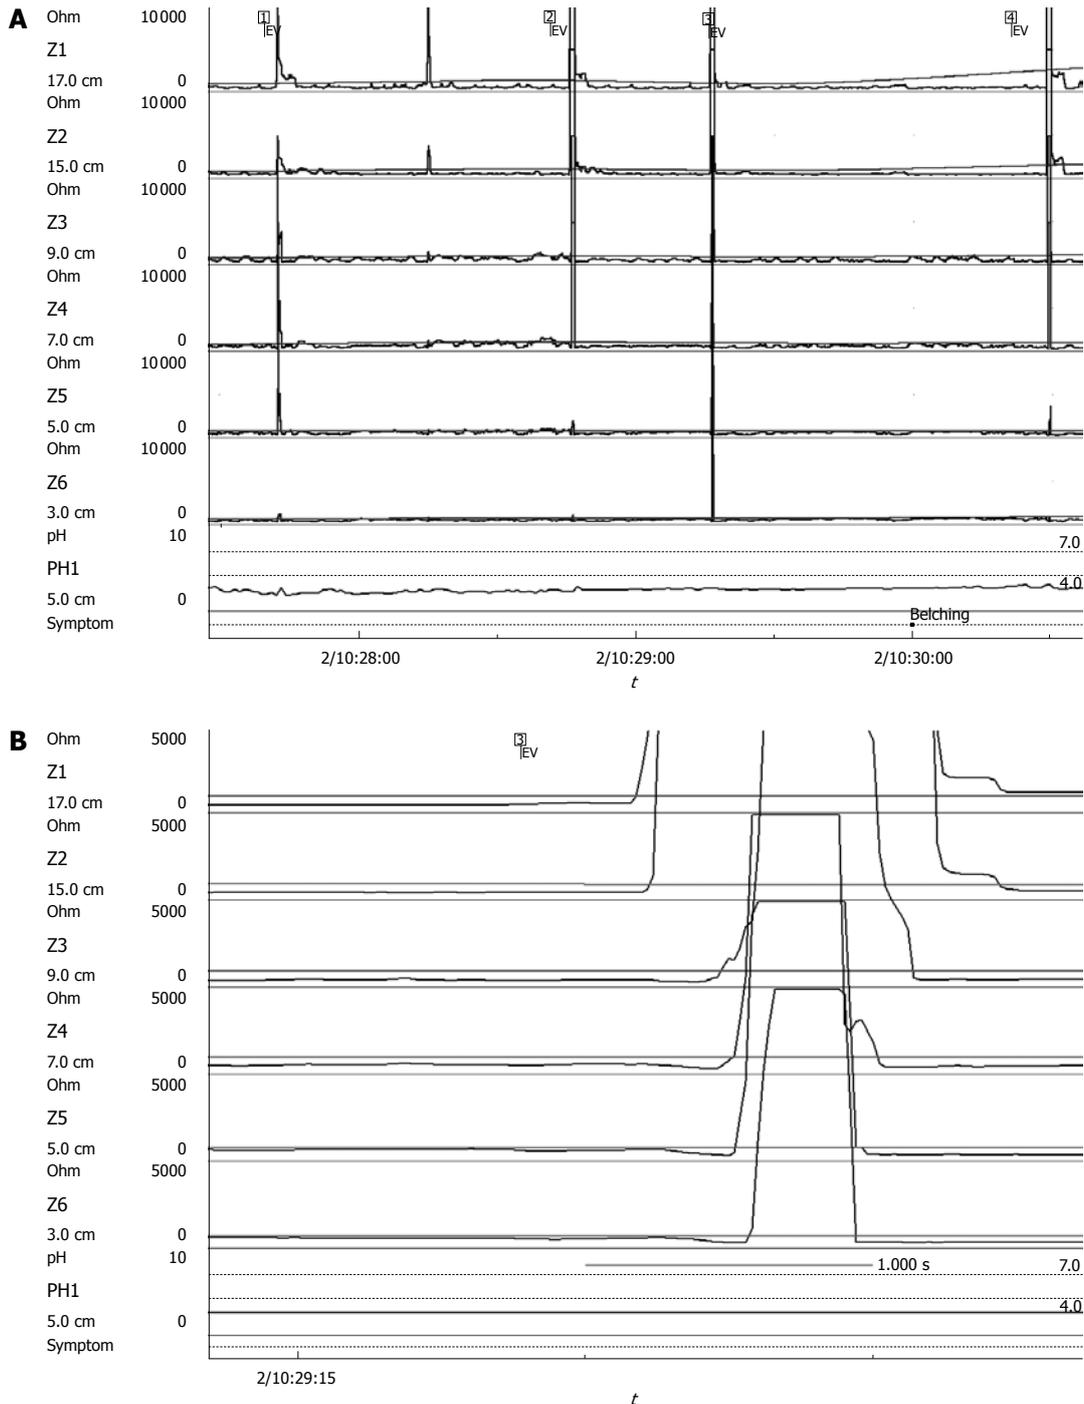

Figure 1 Oesophageal intraluminal impedance monitoring combined with oesophageal pH measurements. A: Three minutes stretch of the tracings showing an abnormally low basal impedance with repetitive impedance peaks in all channels marked EV 1-4; B: Zoomed-in segment of the recording shows that an impedance peak (EV3) starts in the proximal channel, moves in the antegrade direction and is cleared in the retrograde direction. The horizontal bar represents 1.000 s. The patient reported severe belching at 10:30:00 during this period of repetitive supragastric belches (SGBs). Oesophageal pH is continuously below 4.

rapid distension by oesophageal gas transport can trigger hiccups. Our patient also suffered from severe pathological acid reflux, ineffective oesophageal motility and impaired transit for liquid boluses. GORD was associated with protracted hiccups in previous case reports^[1-3]. Disappearance of protracted hiccups after treatment with PPI in some patients suggests that reflux may precipitate hiccups^[2]. However, persistence of hiccups after

antireflux surgery in some reports^[1,3] or treatment with PPI, as in our patient, suggests that other factors may be involved in patients with GORD.

In conclusion, in a patient with recurrent hiccups and GORD multichannel intraluminal impedance, pH and pressure measurements show (1) excessive supragastric belching and (2) a temporal relationship between the start of a hiccup episode and gastric belching.

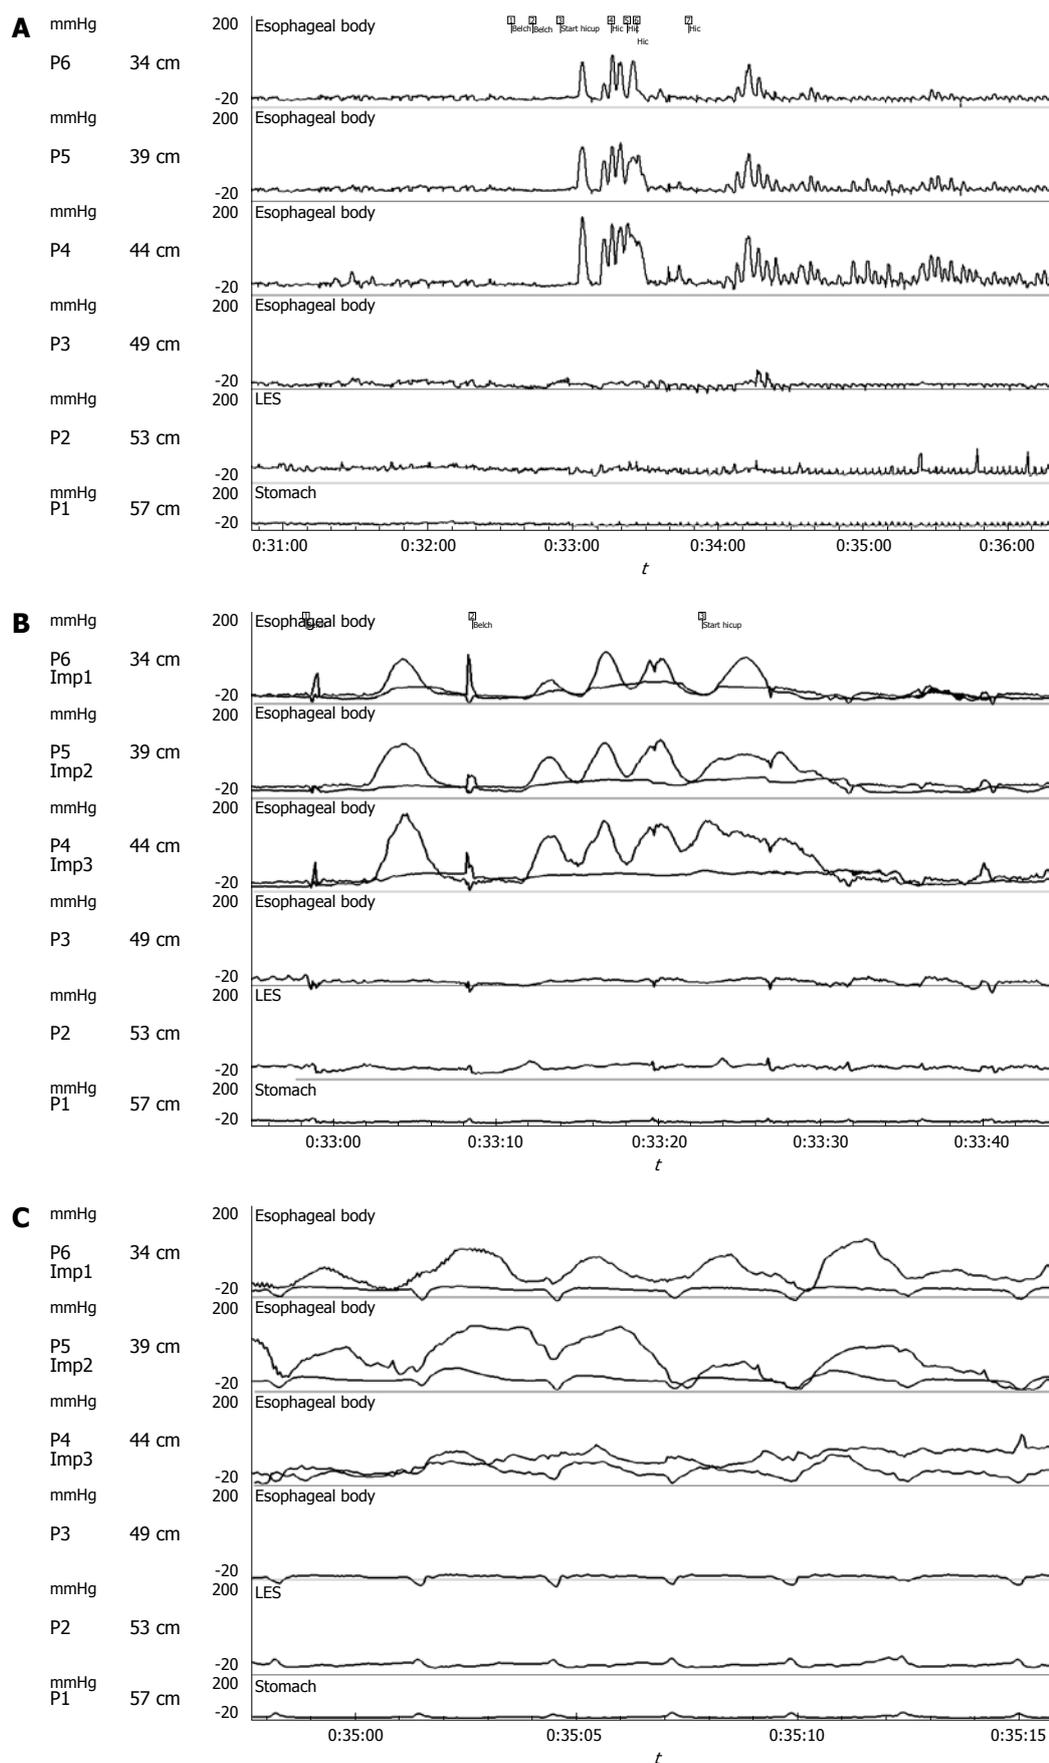

Figure 2 Combined impedance and perfusion manometry. A: Pressure tracings from 31-36 min during spontaneous onset of a hiccup attack at time 33:20 min; B: Combined impedance and manometry of a zoomed in segment of Figure 2A shows that the hiccup episodes are preceded by 2 gastric belches and high pressure simultaneous, repetitive contractions; C: Another zoomed in segment of Figure 2A shows that hiccups are accompanied by sharp positive pressure peaks in the lower oesophageal sphincter and stomach, and by negative peaks in the esophagus. The upper border of the lower oesophageal sphincter (LOS) was located at 51 cm from the nostrils.

Abstract

Few potentially curative treatment options exist apart from hepatic resection for patients with huge hepatocellular carcinoma (HCC). Proton radiotherapy is a promising new modality which has an inherent anti-tumor effect against HCC. However, the application of proton radiotherapy for tumors adjacent to the gastrointestinal tract is restricted because the tolerance dose of the intestine is extremely low. A novel two-step treatment was developed with surgical spacer placement and subsequent proton radiotherapy to administer proton radiotherapy with curative intent. This report presents a case of a patient with a huge unresectable HCC treated by this method who achieved disease-free survival of more than 2 years. This new strategy may potentially be an innovative and standard therapy for unresectable HCC in the near future.

INTRODUCTION

Hepatocellular carcinoma (HCC) accounts for between 85% and 90% of primary liver cancer and is one of the most frequent malignancies^[1]. Currently, several treatment modalities are available for the treatment of patients with HCC, including hepatic resection, liver transplantation, transarterial chemoembolization (TACE), percutaneous ethanol injection, percutaneous microwave coagulation therapy, radiofrequency ablation, and radiotherapy^[2,3]. Although TACE is the only nonsurgical treatment option for HCC measuring above 10 cm × 10 cm, the 5-year survival rate is less than 10%, and its efficacy remains uncertain^[4]. At present, a hepatic resection is regarded as the only curative treatment for a huge HCC, if the patient's hepatic functional reserve is acceptable for resection^[5,6].

Proton radiotherapy is a new mode of radiotherapy that has an inherent advantage over photon radiotherapy. Owing to the defined range of protons exhibited by the Bragg peak, they allow reduction of the irradiated volume and the dose administered to the normal tissues^[7,8]. Recently, many reports have demonstrated the effectiveness and safety of proton radiotherapy and it has

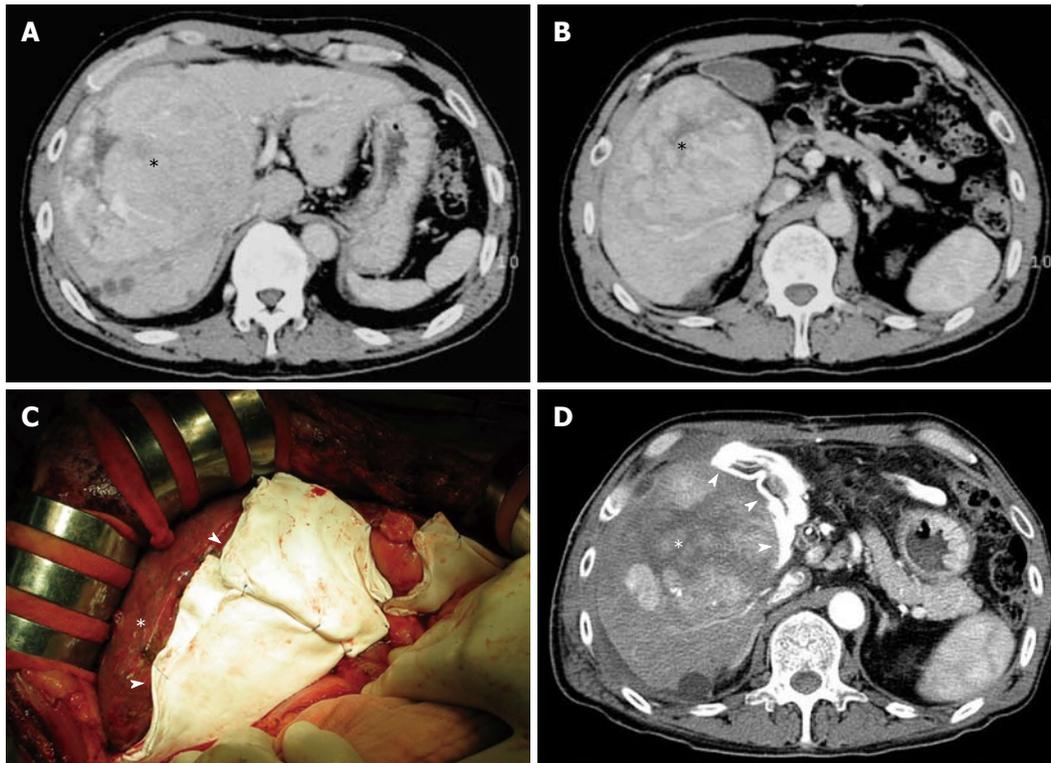

Figure 1 A huge tumor occupying a wide area of the right lobe. A: Abdominal computed tomography (CT) showing a pre-treatment dominant lesion located widely in the right lobe (asterisk); B: The tumor (asterisk) has extended contact with the gastrointestinal tract; C: Intraoperatively, Gore-Tex sheets (arrowheads) maintained a space between the tumor (asterisk) and the gastrointestinal tract (under the fingertips); D: Post-operative abdominal CT showing the spacer (arrowheads) around the tumor (asterisk); the spacer maintained a sufficient open space between the tumor and the gastrointestinal tract.

become an acceptable modality for various malignancies including HCC^[7-9]. However, the application of proton radiotherapy for huge HCC is restricted because most of these lesions are in contact with the gastrointestinal tract that cannot tolerate a radical dose of proton beams^[10,11]. Recently, we developed a novel 2-step treatment with surgical spacer placement and subsequent proton radiotherapy^[12]. In this case report, we employed this strategy for a huge unresectable HCC and achieved a long-term survival benefit without recurrence.

CASE REPORT

A 59-year-old male was referred for the treatment of a huge HCC in the right lobe of the liver. He had developed hepatitis B 50 years earlier and received no medical treatment. A physical examination revealed general fatigue and abdominal distension as a result of the huge tumor. Abdominal computed tomography (CT) showed a massive tumor, measuring 12 cm × 12 cm, occupying a wide area of the right lobe (Figure 1A). There was no sign of tumor vascular invasion in the hepatic or the portal vein and the tumor broadly abutted the gastrointestinal tract on CT images (Figure 1B). Liver function tests showed a total bilirubin of 1.0 mg/dL, aspartate aminotransferase of 33 IU/L, alanine aminotransferase of 24 IU/L, prothrombin time-international normalized ratio of 1.16, and an indocyanine green retention rate at 15 min of 19.6%. Serological analysis showed that the

serum level of α -fetoprotein and PIVKA II (protein induced by vitamin K absence II) were 3.7 ng/mL and 3910 mAU/mL, respectively. There was no regional lymph node metastasis. A right trisegmentectomy was not acceptable judging from the criteria for a safe hepatic resection^[13]. Proton radiotherapy with curative intent also was not acceptable since the tumor was located broadly adjacent to the gastrointestinal tract. Therefore, a novel 2-step treatment was employed with surgical spacer placement and subsequent proton radiotherapy^[12]. Eight Gore-Tex sheets (20 cm × 15 cm × 2 mm) were superimposed and applied as a spacer and sutured tightly to the inferior surface of the liver to keep the gastrointestinal tract away from the tumor (Figure 1C). No part of the tumor was resected during the spacer placement surgery, because it was just a first step to allow proton radiotherapy. Abdominal CT after the operation showed the spacer maintained a sufficient open space between the tumor and the gastrointestinal tract (Figure 1D). The postoperative course was uneventful and 1 mo later, proton beams of 84GyE were administered in 20 fractions over 30 d (Figure 2). No acute or late treatment-related toxicities (grade 2 or more) were observed and liver function was unchanged for up to 2 years after the proton radiotherapy. In addition, abdominal CT showed regression of the tumor. Areas of high signal intensity on the CT images correlated with liquefaction necrosis, granulation tissue, and the tumor (Figure 3A). Notably, the serum PIVKA II level remained within normal limits for up to 2 years,

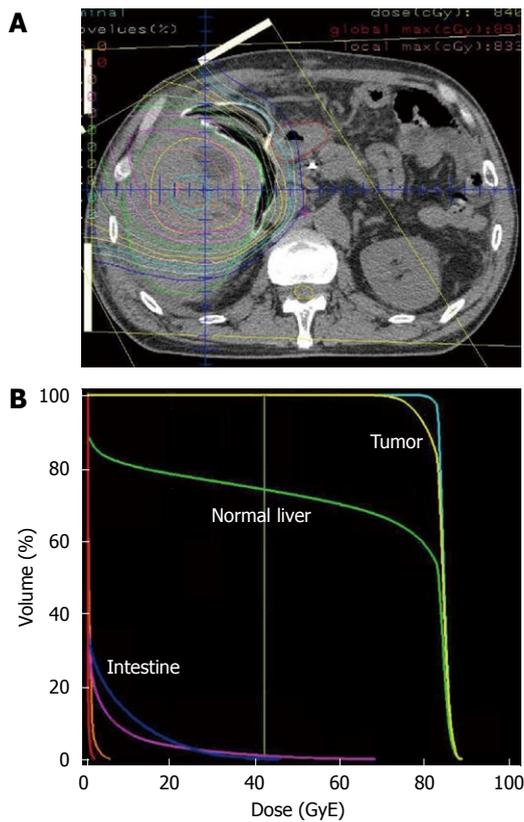

Figure 2 Treatment plan for proton radiotherapy with a total dose of 84 GyE in 20 fractions. A: Isodose curves demonstrate 100% of the prescribed dose at the center and decreasing by 10% of the dose from the inside out; B: Dose-volume histogram of the target volume and the intestine shows that the tumor is entirely irradiated by almost 100% of the prescribed dose, and the intestine is hardly irradiated.

indicating no sign of recurrence, consistent with other modalities (Figure 3B). As there was no convincing evidence for the safety of hepatic resection after proton radiotherapy, we decided not to perform any surgery even after shrinkage of the tumor.

DISCUSSION

Among various malignancies, HCC is one of the most suitable malignancies for the treatment of particle radiotherapy with several excellent treatment results^[7,14,15]. However, the application of particle radiotherapy for tumors adjacent to the gastrointestinal tract is restricted because the tolerance dose of the intestine is extremely low^[14,16]. An adequate margin of more than 10 mm is absolutely necessary for the administration of full-dose irradiation^[17].

There have been many reports describing surgical methods for removal of the gastrointestinal tract from the irradiation field to prevent radiation-induced gastrointestinal damage during conventional photon radiotherapy^[10,11]. However, the dose distribution of photon beams is generally inadequate for local tumor control, and the impact of combination therapy with surgery and subsequent photon radiotherapy has remained uncertain.

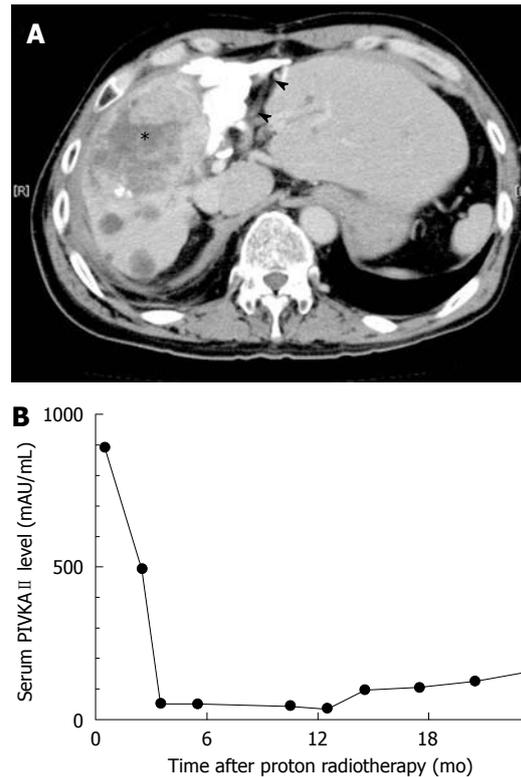

Figure 3 Two years after the proton radiotherapy abdominal CT reveals distinct shrinkage of the tumor (asterisk). Arrowheads indicate the gastrointestinal tract (A) along with reduced serum levels of the tumor marker, PIVKA II (protein induced by vitamin K absence II) (B).

Unlike conventional photon radiotherapy, proton radiotherapy is considered a curative treatment. Tumors can be controlled at a high rate as long as a sufficient dose can be administered. The 2-step treatment is an evolving strategy that enables the delivery of a sufficient dose to the tumor.

Curative treatments for HCC are limited to hepatic resection, liver transplantation and local ablative therapies^[3]. In addition, in the absence of other treatment options, hepatic resection is the only treatment modality for a huge HCC that can produce notable survival, but the 5-year survival rate is only 16.7%-33%^[6]. There was no possibility of treating this case in a curative manner or achieving disease-free survival of more than 2 years using a conventional strategy. The 2-step treatment achieved complete local control of the huge primary HCC and excellent disease-free survival. Surgical spacer placement can maintain a safety margin from the gastrointestinal tract and full-dose particle radiotherapy can be achieved without serious toxicities under that condition. It is highly important in terms of a new option for curative treatment of a huge unresectable HCC. This new strategy might potentially be an innovative and standard therapy for unresectable HCC in the near future.

Abstract

We report an extremely rare case of adult intussusception caused by anisakiasis. A 41-year-old man was admitted into our hospital for right lower abdominal colicky pain. Ultrasonography and computed tomography revealed the presence of intussusception. As pneumodynamic resolution by colonoscopy failed, surgery was performed. The anisakis body was found in the submucosal layer of the resection specimen. The patient was discharged 9 d after the operation. Anisakiasis may cause intussusception in any country where sushi or sashimi now exists as a popular food. If suspicious, detailed clinical interview as to food intake prior to symptom development is crucial.

INTRODUCTION

New food culture may bring a new cause of disease. The culture of eating raw fish, such as sushi and sashimi, has been spreading worldwide and now exists in the United States, European and Asian countries. This may provide the possibility of accidentally contracting anisakiasis, a parasitic disease. We report an extremely rare case of adult intussusception caused by anisakiasis.

CASE REPORT

A 41-year-old man was admitted into our hospital for right lower abdominal colicky pain that had abruptly occurred at midnight of the day before, and which had gradually worsened.

Physical examination revealed a 5 cm-sized, hard and non-mobile mass with extreme tenderness in his right middle abdomen. Ultrasonography (US) showed multiple

Figure 1 Abdominal contrast-enhanced computed tomography (CT) imaging. The coronal multiplanar reconstruction imaging in abdominal contrast-enhanced CT clearly reveals the invaginations of the ascending colon itself (arrows).

Figure 2 A gross view of the resection specimen. The extirpated mass is 4 cm in diameter and its surface is smooth, yellowish, edematous and slightly soft (arrow).

concentric ring signs and hay-fork signs. Thus, he was diagnosed as having intussusceptions. Abdominal X-ray revealed null colon gas but feces in the right lower abdomen. Contrast-enhanced abdominal computed tomography (CT) showed invaginations of the ascending colon (Figure 1), the wall of which looked highly edematous. As the ascending colon was obstructed by these invaginations, the colonic lumen was filled with stool at the oral side of this obstruction. No solid tumor was detected at the top of these invaginations and the colonic wall was well enhanced, indicating no ischemic change existed.

First of all, we performed colonoscopy an hour after admission, hoping for both differential diagnosis of intussusceptions and pneumo-dynamic resolution. The leading top of the invaginations was yellowish, edematous and tensioned. No tumor was discernible. As pneumo-dynamic resolution of the intussusceptions by colonoscopy was not achieved, open surgery was performed 3 h after admission.

Normograde invaginations of the ascending colon were demonstrated during the operation. The ascending colonic wall was edematously swollen and showed no apparent ischemic change. Since the manipulative resolution of the invaginations was impossible, ileocecal resection was performed.

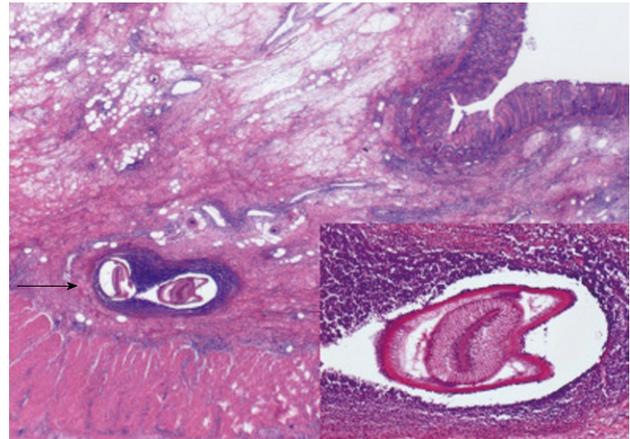

Figure 3 Histopathological findings of the resection specimen. An anisakis body (arrow) is demonstrated in the edematously inflamed submucosa of the extirpated ascending colon (hematoxylin and eosin stain; $\times 20$). Note that many eosinophils and lymphocytes infiltrate around the anisakis body, forming an eosinophilic granuloma. A magnified picture of the anisakis body is shown in the inset below right (hematoxylin and eosin stain; $\times 40$).

The resection specimen contained a 4 cm-sized yellowish inflammatory mass (Figure 2) at the leading top of these invaginations. The mass was edematous, well tensioned and the mucosal surface that surrounded the mass was normal.

We pathologically demonstrated the body of anisakis in the midst of eosinophilic granuloma in the submucosal layer (Figure 3). Marked inflammation and edema in the submucosal layer formed an inflammatory mass.

A retrospective clinical interview was performed where the patient told us that he had eaten marinated mackerel 2 d before admission. A retrospective analysis of his serum revealed that an anti-anisakis antibody test was positive. Based on these findings, we finally diagnosed this case as intussusceptions of the ascending colon caused by anisakiasis.

The patient's abdominal pain immediately disappeared after surgery. He clinically recovered well and was discharged 9 d after the operation.

DISCUSSION

Adult intussusception (AI) occurs much less often than in children and accounts for only 5% to 10% of all intussusceptions^[1]. More than 90% of AI derive from tumorous lesions^[1], 60% of which are malignant and the remaining 40% are benign tumors^[2]. Thus, almost all surgeons agree that operation is strongly recommended as a treatment for AI because of the high incidence of malignancy^[1].

US^[3-5] and CT are very useful for diagnosis of AI. There are specific US findings named as "multi concentric ring sign"^[4], "target ring sign"^[3], or "hay-fork sign"^[5]. However, these signs are often hard to determine, being masked by a fully gas-filled bowel^[6].

CT is the best modality to diagnose AI, visualizing "target signs", or "bowel-within-bowel" appearances^[7].

M: Male; F: Female; ND: Not documented.

The location or nature of tumors if present, soft tissues involved in the invaginations, obstruction and threatening signs of bowel viability, can all be evaluated by CT^[7]. Recently, multiplanar reconstruction (MRP) imaging by the multi-detector row CT has been developed and is more useful for diagnosing intussusceptions than other imaging examinations^[8].

Most surgeons agree that surgery is preferable as a treatment for AI because of the high frequency of malignancy^[1,2,9]. The resolution of intussusceptions has some risks, such as (1) intraluminal seeding and dissemination, (2) perforation and peritoneal dissemination and (3) anastomotic complication with edematous and fragile bowel wall^[1,2,9,10].

Anisakiasis is one of the parasitic diseases and is regarded as larva migrans of *Anisakis*^[11]. A person is accidentally infected by eating raw or uncooked fish containing the parasites. The larva of *Anisakis* penetrates into the mucosa of the digestive tract and causes anisakiasis^[12]. The preferential location of anisakiasis in Japan is the stomach (96%) rather than the intestine (4%)^[13]. On the other

hand, Van Thiel *et al*^[14] and Smith *et al*^[15] reported that intestine was more frequent than stomach in European countries. The symptoms of intestinal anisakiasis are non-specific, sometimes colicky and diffuse abdominal pain, nausea and vomiting^[12]. Patients are often misdiagnosed as having acute appendicitis or terminal ileitis^[12]. Clinical symptoms appear within 48 h after food intake, continue for 1 to 5 d and spontaneously recover^[16]. Our case had an operation since the conservative therapy was not effective in the resolution of intussusception.

AI caused by anisakiasis is extremely rare. There have previously been two English and nine Japanese reports about AI caused by anisakiasis (Table 1)^[17-27]. All cases ate raw or marinated fish from half a day to 7 d before the symptom onset. Colon and jejunum were usually involved. The common symptom was abdominal tenderness, although with no palpable mass in jejunum cases. Since the ascending colon is fixed in the retroperitoneum and exists near the abdominal wall, we can physically detect a mass at ease. On the other hand, jejunum, transverse colon and sigmoid colon are not fixed and not

necessarily near to the abdominal wall, so it is usually hard to detect a mass. Pneumo-dynamic resolution of AI by colonoscopy was successful in two of the twelve cases in whom emergency operation could be avoided. Correct diagnosis could be preoperatively made in only one of these two by a detailed clinical interview. Ten of the twelve cases had eosinophilic granuloma. Thus, it has been shown from the literature that if raw fish intake is not discovered at interview, or incidental detection of anisakis body fails, it is hard to determine what caused intussusception prior to surgery. That is the reason why surgery was indicated in almost all cases. Therefore, AI is, in general, a good indication for operation although we do not know what would happen if surgery was not performed.

We would like to draw attention to the risk of anisakiasis since it may occur in Japanese, Chinese and European countries and also the United States of America where sushi or sashimi is now prevailing as a popular cuisine. Thus, we believe that if suspicious, detailed clinical interview as to food intake prior to symptom development is crucial.

Abstract

Gastrointestinal stromal tumor (GIST) is the most common mesenchymal tumor in the alimentary tract. To the best of our knowledge, few cases have been reported in the literature about the peripheral lymph node metastasis of GIST. Here we report an unusual case of gastric GIST with inguinal lymph nodes metastasis. After the metastatic lymph nodes were resected, the patient started to take imatinib 400 mg/d for 12 mo. There were no signs of tumor recurrence at follow-up after 29 mo. This case suggests that the inguinal lymph nodes can be a potential metastatic site of GIST.

INTRODUCTION

Gastrointestinal stromal tumor (GIST) is the most common gastrointestinal (GI) mesenchymal tumor, which accounts for 0.2% of all GI tumors and 80% of sarcomas^[1]. GIST most commonly arises from the stomach and accounts for about 1% of gastric malignancies^[2]. Liver and peritoneal metastatic lesions are often observed but lymph nodes metastasis is rarely found in GIST^[3]. Moreover, there are few reports about the peripheral lymph nodes metastasis of GIST in literature. Here we report one interesting GIST case with inguinal lymph nodes metastases 3 years after distal gastrectomy and hepatectomy due to gastric GIST with liver metastasis.

CASE REPORT

A 60-year-old Chinese man came to the clinic on August 8th, 2007, complaining of his feeling of an inguinal mass gradually growing for 5 mo. He received distal gastrectomy, perigastric lymphadenectomy and hepatectomy in July 2004 for gastric GIST with liver metastasis. Physical examination revealed a 4 cm × 3 cm round and nontender mass which was located in the right inguinal region. Inguinal ultrasonography showed a low echo-level mass (Figure 1). Computed tomography (CT) revealed a 4 cm × 5 cm low density mass (CT value = 68.8 HU) which was unenhanced during contrast-enhanced scan (Figure 2). A complete gross excision of the mass was carried out for this patient on August 13, 2007. Grossly, the surgical specimen consisted of a 4.0 cm × 3.5 cm × 3.0 cm large, nodular, whitish-gray and firm lymph node. Microscopically, it was confluent and was infiltrated with spindle cells. These spindle cells were predominantly arranged in inter-

Figure 1 Ultrasonography. Inguinal ultrasonography shows a low echo-level lesion in the right inguinal region.

Figure 2 Computed tomography (CT). A low density lesion with weak, uneven enhancement during contrast-enhanced scan (arrow).

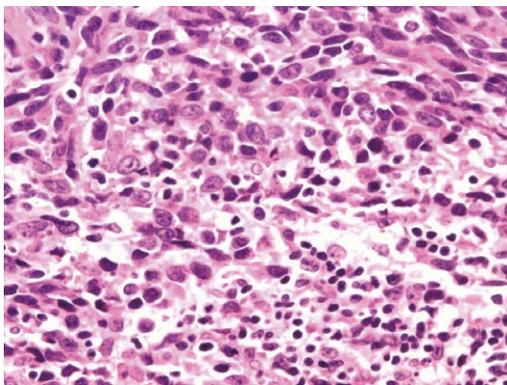

Figure 3 Hematoxylin & eosin (HE) staining. Spindle cells were predominantly arranged in interweaving fascicles (HE stain, $\times 100$).

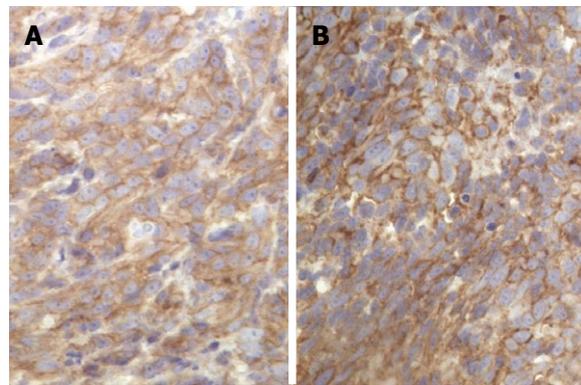

Figure 4 Immunohistochemical staining. A strong positivity for both CD117 (A) and CD34 (B) (CD117 stain, $\times 400$, CD34 stain, $\times 400$).

weaving fascicles (Figure 3). Immunohistochemical stains demonstrated a strong positivity for both c-kit (CD117) and CD34 (Figure 4), which was consistent with the primary tumor. Gene sequence analysis showed that all the primary tumors, the metastatic tumor in liver and the resected inguinal lymph nodes harbored deletion mutations affecting codons 557/558 of exon 11 in the KIT. After the operation, the patient took imatinib 400 mg/d for 1 year. And there was no sign of tumor recurrence during 29 mo of follow-up.

DISCUSSION

The case we reported herein is a high grade GIST according to the Bucher grading system^[4]. Unlike gastric adenocarcinoma, regional lymph nodes including perigastric and mesenteric lymph nodes metastasis of GIST is unusual. The prevalence is reported to range from 1.1% to 3.4%^[5-7]. In this case, perigastric lymphadenectomy was performed and no metastasis was observed in all of 19 lymph nodes at the first operation, although liver metastasis was detected.

To the best of our knowledge, this is the first reported case of GIST with inguinal lymph nodes metastasis. However, the distinct pattern of inguinal lymph node metastasis of gastric neoplasm is unclear. In the case of

gastric adenocarcinoma, tumor cells can metastasize to para-aortic lymph nodes which have a chance of retrograde dissemination to the pelvic lymph nodes and also inguinal lymph nodes. It is unclear whether this metastatic mechanism is applicable for GIST with inguinal lymph nodes metastasis. In this case, since liver is the first organ of metastasis occurrence, we can hypothesize that when tumor cells invade the liver, they have a higher probability to spread into peripheral blood, and tumor cells can migrate into peripheral lymph node *via* high endothelial venule, which finally results in lymph nodes metastasis.

At present, surgery remains the mainstay of treatment in GIST patients with isolated resectable GIST. Imatinib is currently indicated for the first-line treatment of metastatic or unresectable KIT-positive GIST. The persistent use of imatinib was necessary for this patient after complete resection of primary gastric and hepatic metastatic GIST. Unfortunately, this patient did not take imatinib after his first operation which led to further metastasis. After his second operation, the patient started imatinib treatment and survived without recurrence till now.

In conclusion, GIST can involve the inguinal lymph nodes as a metastatic site and further studies are necessary to clarify the mechanism of this metastasis.

November 13-14
 San Francisco, CA, United States
 Case-Based Approach to the Management of Inflammatory Bowel Disease

December 02-04
 San Francisco, CA, United States
 The Medical Management of HIV/AIDS

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systematically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Instructions to authors

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Books

Personal author(s)

- 10 **Sherlock S**, Dooley J. Diseases of the liver and biliary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

Chapter in a book (list all authors)

- 11 **Lam SK**. Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

Author(s) and editor(s)

- 12 **Breedlove GK**, Schorfheide AM. Adolescent pregnancy. 2nd ed. Wiczorek RR, editor. White Plains (NY): March of Dimes Education Services, 2001: 20-34

Conference proceedings

- 13 **Harnden P**, Joffe JK, Jones WG, editors. Germ cell tumours V. Proceedings of the 5th Germ cell tumours Conference; 2001 Sep 13-15; Leeds, UK. New York: Springer, 2002: 30-56

Conference paper

- 14 **Christensen S**, Oppacher F. An analysis of Koza's computational effort statistic for genetic programming. In: Foster JA, Lutton E, Miller J, Ryan C, Tettamanzi AG, editors. Genetic programming. EuroGP 2002: Proceedings of the 5th European Conference on Genetic Programming; 2002 Apr 3-5; Kinsdale, Ireland. Berlin: Springer, 2002: 182-191

Electronic journal (list all authors)

- 15 Morse SS. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 $\mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG,

WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No. 62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: wjg@wjgnet.com

<http://www.wjgnet.com>

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekaAlert/AAAS (<http://www.eurekaalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

ISSN 1007-9327

- 1937** Hepatoprotective effects of antioxidants in chronic hepatitis C
Moreno-Otero R, Trapero-Marugán M

ACKNOWLEDGMENTS I Acknowledgments to reviewers of *World Journal of Gastroenterology*

APPENDIX I Meetings
I-IV Instructions to authors

AIM AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

FLYLEAF I-VII Editorial Board

EDITORS FOR THIS ISSUE

Responsible Assistant Editor: *Xiao-Fang Liu*
Responsible Electronic Editor: *Yin-Ping Lin*
Proofing Editor-in-Chief: *Lian-Sheng Ma*

Responsible Science Editor: *Ye-Ru Wang*
Proofing Editorial Office Director: *Jian-Xia Cheng*

Abstract

Acute liver failure (ALF) is a devastating clinical syndrome characterised by progressive encephalopathy, coagulopathy, and circulatory dysfunction, which commonly leads to multiorgan failure and death. Central to the pathogenesis of ALF is activation of the immune system with mobilisation of cellular effectors and massive production of cytokines. As key components of the innate immune system, monocytes and macrophages are postulated to play a central role in the initiation, progression and resolution of ALF. ALF in humans follows a rapidly progressive clinical course that poses inherent difficulties in delineating the role of these pivotal immune cells. Therefore, a number of experimental models have been used to study the pathogenesis of ALF. Here we consider the evidence from experimental and human studies of ALF on the role of monocytes and macrophages in acute hepatic injury and the ensuing extrahepatic manifestations, including functional monocyte deactivation and multiple organ failure.

INTRODUCTION

Acute liver failure (ALF) is characterised by overwhelming hepatic injury with failure of hepatocyte function, resulting in a devastating clinical syndrome of coagulopathy, encephalopathy, and circulatory dysfunction^[1,2]. Phenotypically, there are striking similarities between septic shock and ALF. Both conditions are characterised by activation of a systemic inflammatory response syndrome (SIRS), resulting in circulatory dysfunction with systemic vasodilatation and refractory multiorgan failure^[3]. ALF, like septic shock, is associated with an overwhelming activation of the immune response, including the production of inflammatory cytokines and mobilisation of cellular components of the immune system. Monocytes and macrophages are key orchestrators of the innate immune system and are postulated to play a pivotal role in the initiation, propagation and resolution of ALF.

The paucity of effective clinical treatments for ALF, except for supportive care and liver transplantation, re-

flects our poor understanding of the pathogenesis of ALF. Clinical trials and studies on patients with ALF are limited by small numbers of subjects with heterogeneous causes of ALF and are confounded by inherent difficulties in studying patients with rapidly progressive pathology. There are a number of animal models of acute liver injury commonly used to study ALF: murine models of acetaminophen (APAP) toxicity, concanavalin-A (Con-A) T-cell mediated hepatitis, carbon tetrachloride (CCl₄)-induced injury, and other models including galactosamine/lipopolysaccharide (Gal/LPS) (for a review^[4]). Unfortunately, these are models of acute liver injury and cannot truly reflect the human syndrome of ALF.

In this article we consider the role of macrophages, monocytes, and the inflammatory cytokines they produce, in the progression of acute liver failure in human and experimental models. We consider monocyte/macrophage function in the hepatic and systemic compartments, including their role in initial injury, the process of recruitment of monocytes to the injured liver and the possible influence of hepatic inflammatory events on the functional monocyte deactivation encountered in ALF.

RECRUITMENT OF MONOCYTES TO THE INJURED LIVER

Expansion of hepatic macrophage populations

Following an acute hepatic insult, there is a rapid and marked increase in the number of inflammatory cells within the liver. Recent studies have shed light on the process by which circulating monocytes are recruited to the injured liver, where, due to their plasticity, macrophages are implicated in both tissue destructive and reparatory processes of the inflammatory response.

Karlmark *et al.*^[5] demonstrated, in a murine model of acute CCl₄ hepatotoxicity, that a sub-population of infiltrating macrophages account for 10%-12% of total hepatic cells 24-48 h after the onset of liver injury. This massive recruitment of macrophages and their contribution to evolving acute liver failure have attracted much interest recently. Two distinct populations of macrophage have been described in both APAP and acute CCl₄ models of hepatotoxicity^[5,6]. The first is a CD11b⁺ F4/80⁻ population that resembles the sub-group of circulating monocytes that are the origin of stable populations of tissue macrophages. This population shows only a modest increase in number following acute liver injury by CCl₄. The second population is CD11b⁺ F4/80⁺ and this resembles the subset of circulating monocytes from which activated macrophages in inflammatory conditions are thought to be derived. It is this population that shows marked expansion in number following acute hepatic injury^[5].

Holt *et al.*^[6] 2008, in an APAP model of hepatotoxicity, showed that these "inflammatory macrophages" were derived from circulating monocytes rather than from proliferation of the resident Kupffer cell (KC) population. They noted preservation of the macrophage response to acute APAP toxicity when the KC population was depleted prior to APAP challenge. Conversely, when

circulating monocytes were depleted by bone marrow irradiation prior to APAP, the number of intrahepatic macrophages seen after tissue injury was diminished.

The role of chemokine: Monocyte chemoattractant protein-1

Monocyte chemoattractant protein-1 (MCP-1) is a member of the C-C chemokine family, which acts on the chemokine (C-C motif) receptor 2 (CCR2) that is expressed on macrophages, monocytes, and to a lesser extent, T and NK cells^[7]. Though initially described as a monocyte chemokine it also plays a role in the recruitment of NK cells and T cells in a wide range of inflammatory conditions^[8]. An early increase in hepatic expression of MCP-1 and other chemokines is a consistent feature of murine models of ALF. An increase in MCP-1 mRNA or total hepatic levels of MCP-1 have been reported within 12 h of liver insult in APAP, Con-A, Gal/LPS, and CCl₄ models of acute liver failure^[5,9-12]. The origin of hepatic MCP-1 in ALF is thought to be both resident KCs and injured hepatocytes^[13].

MCP-1/CCR2 interaction in animal models

Experiments using CCR2 -/- knockout mice suggest that functional CCR2 is necessary for egress of F4/80⁺ monocytes from the bone marrow. In the acute liver injury model induced by CCl₄, CCR2 -/- mice demonstrated a decreased number of hepatic and serum CD11b⁺ F4/80⁺ cells following liver injury, but an increase in this cellular fraction in bone marrow when compared with wild-type mice^[10]. When this population of monocytes was adoptively transferred into the circulation of CCR2 -/- mice they were able to traffic unhindered into the injured liver^[5]. Similarly to the liver injury model, CCR2 has been shown to be essential for monocyte mobilisation from the bone marrow, but not for efflux into inflamed tissues, such as in murine *CMV*, *L. monocytogenes*, and urinary tract infection models^[8,14,15].

This evidence suggests that hepatic-derived MCP-1 is able to stimulate the expansion of a bone marrow population of CD11b⁺ F4/80⁺ monocytes, and CCR2 is necessary for these cells to exit the bone marrow, but not essential for influx into the injured liver^[5].

MCP-1 in human ALF

In human ALF, there is also evidence of early upregulation of hepatic chemokines. Leifeld *et al.*^[9] demonstrated serum MCP-1 levels that were, on average, five times higher in patients with ALF when compared to patients with self-limiting acute hepatitis. MCP-1 levels were also significantly elevated above healthy control populations and those with chronic liver disease. There was a trend suggesting that higher serum MCP-1 levels were associated with poor outcome (death or transplantation) from ALF. Upregulation of chemokines, including MCP-1, was demonstrated by reverse transcriptase-polymerase chain reaction (RT-PCR) and immunohistochemistry. The latter technique showed that MCP-1 expression was not limited to inflammatory cells only, but was also de-

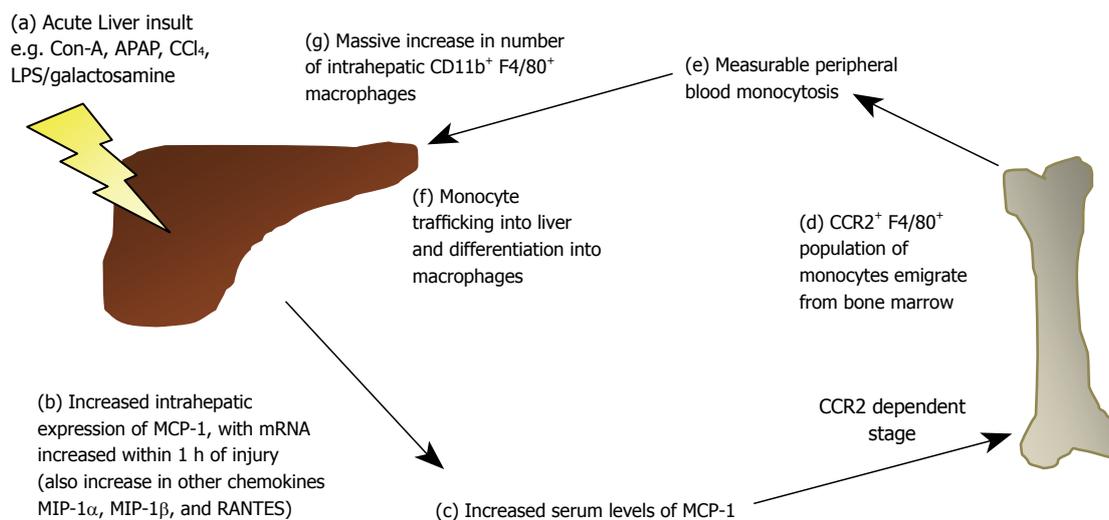

Figure 1 Summary of monocyte/macrophage recruitment to the liver following an acute hepatic insult. Con-A: Concanavalin-A; APAP: Acetaminophen induced hepatotoxicity; CCl₄: Carbon tetrachloride; LPS: Lipopolysaccharide; CCR2: Chemokine (C-C motif) receptor 2; MCP-1: Monocyte chemoattractant protein-1; MIP: Macrophage inflammatory protein; RANTES: Regulated upon Activation, Normal T-cell Expressed, and Secreted, abbreviated (CCL5).

tected in hepatocytes, biliary epithelial cells, and sinusoidal endothelial cells (SEC) in human ALF.

These findings have been replicated in patients with acute severe alcoholic hepatitis with clinical liver failure. MCP-1 is seen to be upregulated throughout the liver, with expression observed in hepatocytes and sinusoidal endothelial cells^[16]. Conversely, in control patients with stable alcoholic liver disease, MCP-1 expression is limited to non-parenchymal cells.

In paediatric patients with acute acetaminophen hepatotoxicity, serum MCP-1 levels showed a strong correlation with clinical parameters of severe liver injury, including elevated levels in patients in whom treatment with N-acetyl cysteine was delayed^[17].

Thus evidence from both murine and human studies suggests that early release of chemokines from injured hepatocytes, SECs and KCs in ALF is responsible for the mobilisation and subsequent trafficking of a population of activated monocytes/macrophages to the liver from the bone marrow (summarised in Figure 1).

THE ROLE OF HEPATIC MACROPHAGES IN THE PROGRESSION OF ACUTE LIVER FAILURE

Having established that macrophages are recruited to the liver in acute injury, the challenge that remains is determining what role these cells play in liver damage or repair.

Two early studies in animal models of APAP-induced hepatotoxicity suggested that depletion of macrophage numbers with gadolinium chloride or dextran sulphate prior to APAP dosing offered protection from liver damage^[18,19]. However, neither of these studies confirmed successful depletion of intrahepatic macrophages, and in one study, the number of intrahepatic F4/80⁺ cells post-APAP treatment was actually increased, suggesting their prior treatment with KC depleting agents had not

prevented an expansion in the macrophage population following the toxic insult^[19]. Subsequent studies have used the more effective technique of macrophage depletion with liposome/clodronate. An APAP model of acute liver failure has shown macrophage depletion increases sensitivity to toxic injury, as measured at 8 and 24 h post-APAP alanine transaminase (ALT) values^[20]. Conversely, in an acute CCl₄ model, macrophage depletion was reported to have no effect on ALT levels four and 24 h after toxin administration^[5].

Prevention of liver injury-induced macrophage population expansion by inhibition of the MCP-1/CCR2 interaction has been demonstrated in a number of studies using CCR2 knockout mice. As described above, these animals show a marked reduction in intrahepatic macrophages following liver injury compared with wild-type (WT) mice, due to failure of monocyte recruitment from bone marrow. Two studies in CCR2^{-/-} mice treated with toxic doses of APAP have shown ALT levels in the first 24 h comparable to WT controls^[6,13]. Histological evidence of liver damage was also comparable between CCR2^{-/-} and WT mice at 24 h in both studies. At later time points, the two studies showed divergent results, with Dambach *et al*^[13] showing less inflammation in CCR2^{-/-} mice. However, Holt *et al*^[6] described CCR2^{-/-} mice showing persisting necrosis and ongoing inflammation at 72 h, whereas the wild-type animals showed almost complete histological resolution. Hogaboam *et al*^[12] used a similar model of acute APAP toxicity in CCR2^{-/-} mice and results seemed to concur with Holt's study, showing a worsening of liver injury by ALT values and histology in the knockout animals at all time points when compared to WT controls.

Overall current evidence in murine models is conflicting (Table 1). It appears that depletion of resident KCs prior to, and at the onset of, liver injury reduces the extent of liver damage. Kupffer cells are partly responsible for the initial pro-inflammatory response to injury with cytokine production and the recruitment of multiple in-

Table 1 Literature summary on the effect of hepatic macrophage depletion on the extent of liver injury in experimental models of ALF

Study	Model	Method of macrophage depletion/inhibition	Affect on severity of acute liver injury	Conclusion
Laskin <i>et al</i> ^[18] , 1995	APAP (rat)	Gadolinium chloride/dextran sulphate	Decreased ALT at 24 h in treated groups; Decreased necrosis	Macrophage depletion was protective
Michael <i>et al</i> ^[19] , 1999	APAP (mouse)	Gadolinium chloride/dextran sulphate	Decreased ALT at 8 h in treated groups	Macrophage depletion was protective
Hogaboam <i>et al</i> ^[12] , 2000	APAP (mouse)	CCR2 -/-	ALT at 24 and 48 h, hepatic necrosis and TUNEL staining all increased in KO; Increase in IFN- γ and TNF- α	CCR2 KO - macrophage depletion worsened liver injury
Dambach <i>et al</i> ^[13] , 2002	APAP (mouse)	CCR2 -/-	ALT levels similar in WT and KO mice; Histologically KO mice showed less inflammation at 72 h	CCR2 KO - macrophage depletion, caused less inflammation at 72 h but no overall difference in outcome
Ju <i>et al</i> ^[20] , 2002	APAP (mouse)	Liposome/clodronate	Increased ALT at 8 and 24 h in treated group	Macrophage depletion increased liver damage
Holt <i>et al</i> ^[6] , 2008	APAP (mouse)	CCR2 -/-	ALT same at 10 and 24 h; Comparable histological necrosis at 24 h but delayed recovery at 48 and 72 h in CCR2 -/-	Reduction in infiltrating macrophage population causes delayed recovery
Karlmark <i>et al</i> ^[5] , 2009	CCl ₄ (mouse)	Liposome/clodronate	Unaltered ALT level at 4 and 24 h post-CCl ₄	Reduction in infiltrating macrophages had no effect on severity of liver damage

flammatory effector cells including neutrophils, NK cells, NKT cells, and T cells that mediate tissue injury. However, there is some evidence to suggest that the population of hepatic macrophages derived from newly recruited infiltrating monocytes possess anti-inflammatory activity and may play a role in recovery from acute liver damage. Though it is beyond the scope of this review to discuss in detail, evidence also suggests that it is this same population of immigrant macrophages that is responsible for driving the fibrosis that follows acute liver injury^[5,10].

THE BALANCE BETWEEN PRO- AND ANTI-INFLAMMATORY CYTOKINES

Macrophage-derived inflammatory cytokines in experimental models of ALF (Table 2)

Tumour necrosis factor- α : Tumour necrosis factor- α (TNF- α), a macrophage derived pro-inflammatory cytokine, has a central role in the pathogenesis of many inflammatory clinical syndromes. TNF- α can enhance the production of other pro-inflammatory cytokines and provoke cellular recruitment to sites of injury. It also has an important direct effector function by inducing hepatocellular apoptosis through its interaction with TNF-receptor 1. This cell surface receptor is connected to an intracellular death domain whose activation ultimately leads to the induction of effector caspases and the execution of cellular apoptosis.

In experimental models of acute liver failure, elevated serum levels of TNF- α and increased mRNA have been observed shortly after the initiating insult^[21,25,48]. Studies in the murine Gal/LPS and Con-A models of hepatic failure have shown that treatment with neutralising anti-TNF antibodies provides protection against liver damage^[24,25]. A recent study using targeted antisense oli-

gonucleotides to inhibit expression of the TNF- α gene, limited the hepatic damage and subsequent mortality from Gal/LPS in a rat model of acute hepatic failure^[26]. TNF- α -driven hepatocyte necrosis through the TNF-R1 pathway has been well described in a number of experimental models of acute liver injury^[21,23,49].

Interferon- γ : Interferon- γ (IFN- γ) is a pro-inflammatory cytokine released by T-cells, NK cells, and macrophages. It has a variety of anti-viral, anti-bacterial and pro-inflammatory effects. In models of acute liver injury, increases in serum IFN- γ and intrahepatic IFN- γ mRNA are seen as part of the initial response to injury^[28,29]. IFN- γ -/- knockout mice show resistance to toxic and T-cell mediated acute liver failure, with improved survival and reduced hepatic necrosis and apoptosis^[30]. Neutralisation of IFN- γ with antibodies in WT mice confers a dose-dependent protective effect following APAP or Con-A administration^[28,29].

IFN- γ deficient mice show a decrease in Fas induction after liver injury; hence it has been postulated that IFN- γ contributes to liver injury by the upregulation of Fas on hepatocytes, rendering them susceptible to apoptotic cell death^[30].

Macrophage migration inhibitory factor: Macrophage migration inhibitory factor (MIF) is a multi-functional inflammatory cytokine that is constitutively expressed in many cell types, including centrilobular hepatocytes and Kupffer cells^[50]. Pre-formed MIF is released early in response to stress (glucocorticoid) and infectious stimuli (LPS). It has an important role in stimulating the inflammatory response through cellular recruitment, stimulation of cytokine production, and counteracting the inhibitory effect of glucocorticoid on the production of pro-inflammatory cytokines. Though initially described as a T-cell cytokine, it has since been

Table 2 Pro- and anti-inflammatory cytokines in experimental models of ALF

Cytokine	Model	Source	Mechanism of action
TNF- α	Murine hepatic ischaemia ^[21,22]	Macrophage	Hepatocellular apoptosis
	Murine α -amanitin or actinomycin D ^[23]		Cellular recruitment
	Murine Gal/LPS ^[24]		
	Murine Con-A ^[25]		
IFN- γ	Rat Gal/LPS ^[26]	Macrophages NK and T cells	Induce iNOS
	Murine Gal/LPS ^[27]		Upregulates Fas, sensitising hepatocytes to apoptosis
	Murine APAP ^[28] Murine Con-A ^[29,30]		Upregulates adhesion molecules and chemokines resulting in leucocyte accumulation
MIF	Guinea pig halothane ^[31]	Preformed stores released from hepatocytes and KCs early in injury	Stimulate release of proinflammatory cytokines
	Murine APAP ^[31]		Counter-act glucocorticoid anti-inflammatory effects
	Murine LPS in BCG-primed mice ^[32]		Cellular recruitment
	Rat ethanol ^[33]		
IL-6	Murine APAP ^[22,34,35]	Released from macrophages and T cells	Reduced TNF- α secretion
	Murine alcohol and TNF- α ^[36]		Activation of STAT3 signalling pathway
	Murine Con-A ^[37,38]		Induction of anti-apoptotic proteins e.g. Bcl-2, Bcl-xL, FLIP

Con-A: Concanavalin-A; Gal/LPS: Galactosamine lipopolysaccharide; TNF- α : Tumour necrosis factor- α ; IFN- γ : Interferon- γ ; MIF: Macrophage migration inhibitory factor; IL-6: Interleukin-6.

established that macrophages are an important source of MIF^[51]. An increase in MIF mRNA is seen in KCs following acute injury^[50].

MIF has a role in a number of experimental models of acute liver injury^[31-33]. Significant increases in serum MIF are detectable in the early stages following acute liver injury by toxins or LPS^[31,32]. MIF -/- knockout mice demonstrate resistance to APAP-induced hepatotoxicity, displaying lower ALT levels, less histological necrosis, and improved survival compared to WT counterparts^[31]. In a BCG-LPS model of murine ALF pre-treatment with anti-MIF antibodies prevented the development of liver failure and death in response to LPS challenge^[32].

Interleukin-6: Interleukin-6 (IL-6) is a macrophage and T cell-derived multifunctional cytokine with both pro- and anti-inflammatory actions. In a number of acute liver injury models, IL-6 has been shown to play an important protective role. IL-6 -/- knockout mice display increased sensitivity to liver injury, impaired regeneration, and poor outcomes in APAP^[22,34], alcohol and TNF- α -mediated liver cell apoptosis^[35], acute CCl₄ toxicity^[39], Fas-mediated apoptosis^[40], and ischaemia-reperfusion injury^[41]. In a number of these experiments, the treatment of knockout and wild-type mice with recombinant IL-6 prior to the liver insult conferred protection against hepatic damage^[37,39-41]. Experimental evidence suggests the hepatoprotective effects of IL-6 in acute liver damage are mediated through the activation of the STAT3 signalling pathway, with induction of anti-apoptotic proteins such as Bcl-2, Bcl-xL, and FLIP and inhibition of NKT cells *via* targeting of CD4⁺ T cells^[38,39,52].

Interleukin-10: IL-10 is a pleiotropic anti-inflammatory cytokine that is capable of downregulating several aspects of the pro-inflammatory cascade, including activated macrophage function. IL-10 is secreted from various cell types, including monocytes and macrophages, in response to injury. The liver is a major source of IL-10 in systemic inflammatory conditions.

In experimental models of acute liver injury, IL-10 has consistently been shown to be protective against liver damage^[27,42-47]. IL-10 serum levels and mRNA expression in liver tissue are seen to rise early after hepatic insult in APAP, Con-A, and Gal/LPS models^[42,46,47]. The kinetics of IL-10 production parallel TNF- α secretion in a murine Gal/LPS model, suggesting both pro- and inflammatory cytokines are released together and act concurrently during the early acute inflammatory response^[42].

In a Con-A model of ALF, neutralisation of IL-10 with monoclonal antibodies exacerbated liver damage, as measured by serum transaminases and liver histology. Serum levels of TNF- α , IFN- γ , and IL-12 were augmented by neutralisation of IL-10^[47]. Similar findings were demonstrated in an APAP model utilising IL-10 knockout mice, where the absence of IL-10 was associated with increased ALT, worse histological necrosis, and reduced survival. Again this increased susceptibility seemed to be attributable to upregulation of pro-inflammatory cytokines and the effectors TNF- α , IL-1, and iNOS^[46]. Treatment with recombinant IL-10 in Gal/LPS models caused a dose-dependent reduction in liver damage and hepatic and serum TNF- α expression^[27,42,43]. *In vitro* work on isolated rat hepatocytes demonstrated that IL-10 was expressed early following LPS challenge. Treatment of

KCs with exogenous IL-10 downregulated production of superoxide dismutase and TNF- α responses following LPS challenge; a phenomenon analogous to the functional monocyte deactivation described later^[45].

Thus, in animal models of acute liver injury there is consistent evidence that IL-10 is expressed in the early phases of liver damage, simultaneous to pro-inflammatory effectors. It acts to abrogate liver injury by limiting the release of pro-inflammatory cytokines and effectors. *In vivo* it is likely to be the balance of these inter-related and mutually regulating factors that determine the extent and outcome of the hepatic insult.

Macrophage-derived inflammatory cytokines in human studies of ALF

As in experimental models of acute liver failure, ALF in humans is known to be associated with massive activation of pro- and anti-inflammatory mediators. A number of studies have looked at patient populations and correlated serum levels of inflammatory cytokines with clinical parameters of ALF severity. TNF- α has been shown in a number of clinical cohorts to be elevated in patients with ALF compared with controls with acute hepatitis or chronic liver disease^[53-57]. In two of these studies, elevated TNF- α levels correlated with poor clinical outcomes^[53,58]. IL-6 and IL-10 have been shown to possess hepatoprotective properties in experimental models of ALF models^[53-56,59]. However, human studies of ALF have detected higher levels of IL-6 and -10 in non-surviving ALF patients compared to spontaneous survivors^[53,56,59].

Interestingly, a number of recent studies have measured proxy markers of macrophage and monocyte activation and shown that increases in these markers correlate with poor outcome in patients with ALF. CD163 is a macrophage lineage-specific scavenger receptor that is expressed by activated macrophages (and to a lesser extent by circulating monocytes) and can be shed in the circulation as a soluble receptor^[60]. Hiraoka *et al*^[60] showed that, in a small population of patients with ALF, mean levels of serum CD163 were elevated when compared with either healthy controls or patients with acute hepatitis. There was a trend towards increasing CD163 in non-survivors, however this did not reach significance. Møller *et al*^[61] used a larger cohort from the US ALF study group and replicated the finding of elevated CD163 in ALF patients compared with controls. They also showed a significant difference between CD163 levels on day three between survivors and non-survivors.

FUNCTIONAL MONOCYTE DEACTIVATION IN HUMAN ALF

Infectious complications are a common feature of established acute liver failure and account for a significant proportion of overall mortality^[1,62]. A number of recent studies have investigated the phenomenon of functional monocyte deactivation that occurs in patients with acute and acute-on-chronic liver failure, and that might be partially responsible for the observed susceptibility of these

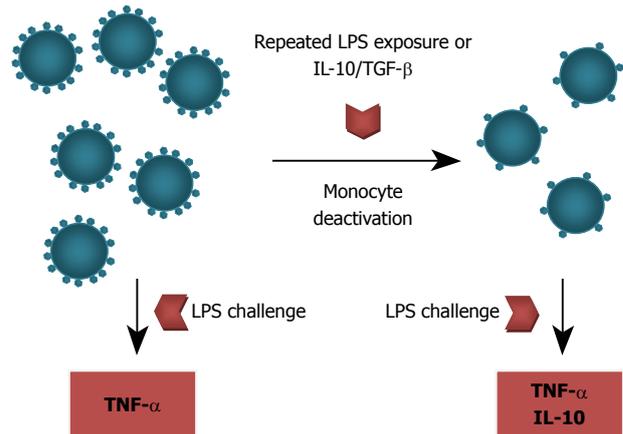

Figure 2 Circulating monocytes express abundant cell surface HLA-DR. Initial exposure to LPS provokes a massive tumour necrosis factor- α (TNF- α) response. Repeated exposure to LPS or the presence of interleukin-10 (IL-10)/transforming growth factor- β (TGF- β) causes monocyte deactivation with downregulation of cell surface HLA-DR expression, impaired antigen presenting capability, and an attenuated TNF- α response to future LPS challenge.

patients to overwhelming sepsis^[53,63-65].

Monocyte deactivation was first described in the early 1990s in clinical populations of post-trauma and sepsis patients^[58,66]. This phenomenon shares many features with the experimental model of “endotoxin tolerance”, which is characterised by a refractory monocyte phenotype with decreased expression of HLA-DR, impaired ability to present antigens, and a profoundly attenuated TNF- α response to LPS challenge (Figure 2). This monocyte phenotype can be induced experimentally by repeated LPS challenge (hence endotoxin tolerance) or exposure to IL-10 and TGF- β ^[66].

Antoniades *et al*^[53] demonstrated monocyte deactivation in a group of patients with acetaminophen-induced acute liver failure (AALF). Patients with AALF who had adverse outcomes (death or transplantation) had significantly lower expression of HLA-DR than transplant-free survivors with AALF, control patients with chronic liver disease, and healthy controls. A reduction in the percentage and total number of HLA-DR positive monocytes was observed, as was a reduction in HLA-DR expression on individual monocytes. Longitudinal follow up of non-surviving and surviving patients showed the former group had persisting evidence of monocyte deactivation, with suppressed HLA-DR at days 3-6, whereas the later group showed recovery of monocyte function between day 1 and days 3-6.

Three studies have looked at this phenomenon in patients with acute-on-chronic liver failure and shown a similar reduction in monocyte HLA-DR in this group^[63-65]. Furthermore, they all demonstrated that monocytes derived from acute-on-chronic liver failure patients show impaired *ex vivo* TNF- α secretion in response to LPS exposure. Berres *et al*^[64] and Xing *et al*^[65] also replicated the finding that low monocyte HLA-DR has a strong association with poor outcome in liver failure patients.

The confirmation of immune dysfunction with functional monocyte deactivation in ALF begs the question

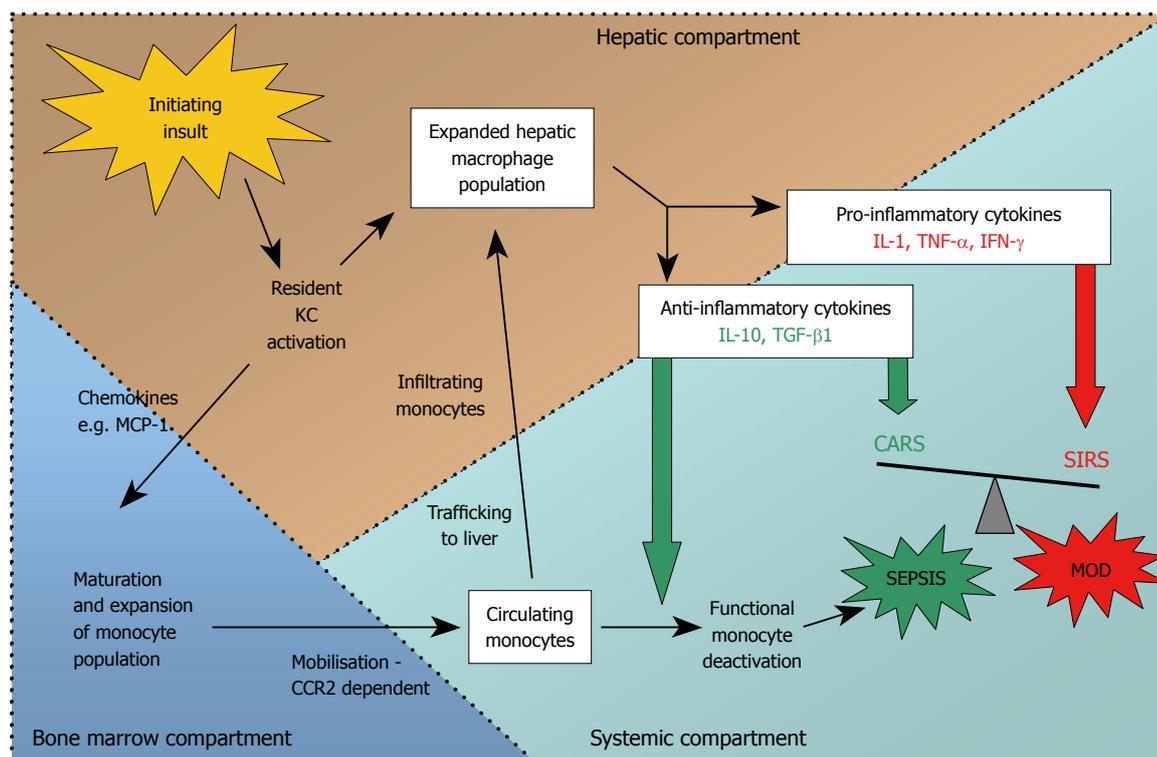

Figure 3 Summary of pathways. The initiating hepatic insult causes early release of chemokines, which promote the maturation of a population of bone marrow monocytes. These activated monocytes enter the circulation and some will traffic to the liver and differentiate into macrophages, accounting for the marked expansion in hepatic macrophage numbers seen after acute liver injury. Pro and anti-inflammatory cytokines are released simultaneously, early in the course of ALF. High levels of both pro and anti-inflammatory cytokines can be measured in the systemic circulation and drive the systemic inflammatory response (SIRS) and compensatory anti-inflammatory response (CARS) respectively. Imbalance in these two opposing forces in favour of an anti-inflammatory milieu can lead to functional monocyte deactivation, recurrent sepsis and multiple organ dysfunction (MOD). MCP-1: Monocyte chemoattractant protein-1; CCR2: Chemokine receptor 2.

of what is driving this phenomenon and how might it be modulated to improve clinical outcomes. The presence of high levels of circulating anti-inflammatory cytokines, IL-10, TGF- β as part of the compensatory anti-inflammatory response (CARS) in ALF are obvious culprits, in that *in vitro* studies have clearly demonstrated their ability to induce monocyte deactivation (Figure 2). Thus it appears that the anti-inflammatory cytokines that provided early hepatic protection in acute liver failure, can, if unchecked, cause subsequent systemic immune paralysis that leads to a worse outcome.

CONCLUSION

Monocytes and macrophages are central players in the complex process of initiation, propagation, and resolution of acute liver injury. Current evidence from experimental and human models suggests that macrophages are activated early in the evolution of acute liver injury and respond with vigorous release of chemokines and pro-inflammatory cytokines that drive the acute inflammatory response to injury. Simultaneously, macrophages initiate a counter-acting anti-inflammatory cascade that moderates the degree of acute hepatic inflammation. As ALF progresses, circulating monocytes are recruited to the liver and are implicated in the resolution of inflammation and tissue repair processes. Meanwhile, the intricate balance between pro- and anti-inflammatory

cytokines released from blood monocytes, hepatic macrophages, and other immune cells, is maintained through multiple interrelated regulatory mechanisms. However, in ALF, the immune response is skewed towards an anti-inflammatory-predominant environment, which could account for functional monocyte deactivation encountered and its attendant clinical sequelae of recurrent sepsis and multiple organ failure (Figure 3).

FUTURE DIRECTIONS

Further studies should aim to dissect the temporal relationship of macrophage recruitment and activation, in both circulating and hepatic inflammatory compartments, during the evolution of acute liver failure. Insight into the mechanisms that influence macrophage function during the process of acute hepatic injury will enable the development of therapeutic strategies that can be administered in a timely fashion to modulate the activity of this pivotal immune cell during acute liver failure.

Abstract

In the modifier concept of intestinal carcinogenesis, lipids have been established as important variables and one focus is given to long-chain fatty acids. Increased consumption of long-chain fatty acids is in discussion to modify the development of colorectal carcinoma in humans. Saturated long-chain fatty acids, in particular, are assumed to promote carcinogenesis, whereas polyunsaturated forms are likely to act in the opposite way. At present, the molecular mechanisms behind these effects are not well understood. Recently, it has been demonstrated by lipidomics and associated molecular techniques, that activation and metabolic channeling of long-chain fatty acids are important mechanisms to modify colorectal carcinogenesis. In this Editorial, an overview about the present concept of long-chain fatty acids and its derivatives in colorectal carcinogenesis as well as technical algorithms in lipid analysis is given.

INTRODUCTION

Colorectal adenomas and carcinomas are much more common than small bowel tumors, and colorectal cancer (CRC) is a leading cause of cancer deaths in Europe and the United States. The clinical symptoms of bleeding and/or obstruction found in the presence of large intestinal neoplasias are similar regardless of histologic type or etiology. It has been suggested that there is an association between colorectal carcinogenesis and pathways of fatty acid metabolism, with long-chain acyl-CoA thioesters as essential intermediates and cyclooxygenases (COXs) and acyl-CoA synthetases (ACSLs) as important enzymes. This observation is determined by molecular data indicating high functional diversity of activated lipid intermediates including formation of complex lipids (e.g. ceramide) and utilization in beta-oxidation as well as regulation of cellular signaling, transcriptional activity, cellular structure, and cellular behavior. Dietary lipids have been assumed as important additional variables in colorectal carcinogenesis.

In the following paragraphs the modifying role of lipids in colorectal carcinogenesis and the innovative technical approaches to elucidate the complex molecular network of lipids are addressed in detail.

EPIDEMIOLOGY AND DIVERSITY OF COLORECTAL CANCER

CRC continues to be one of the most common malignancies worldwide and the third leading cause of death among cancers^[1]. In industrialized Western countries, the incidence and prevalence are higher than in Asia or developing countries. Although the molecular mechanism of CRC has become better understood in the past 2 decades, the prognosis of CRC, especially advanced cancer, has not significantly improved. Five-year survival rates have risen from 56.5% for patients diagnosed in the early 1980s to only 63.2% for those diagnosed in the early 1990s, and most recently to 64.9%^[2]. The sparsely improving trend is most likely due to the fact that the prognosis for patients with CRC is highly dependent on disease stage at the point of diagnosis. Only 10% of CRCs are diagnosed early, and in most patients advanced disease is found. Therefore, early detection of CRC is essential in improvement of a patient's prognosis.

CRCs comprise a heterogeneous group of malignancies including hereditary forms and so-called sporadic tumors^[3,4]. At the current state of knowledge, the majority of CRCs are sporadic. However, experimental and epidemiological data give evidence that the class of sporadic CRCs comprises a heterogeneous group of malignancies with differences in pathogenesis and prognosis. It is suggested that the pathogenesis of some sporadic CRCs does not follow the traditional adenoma-carcinoma sequence. Recently, a new pathway in "sporadic" CRC development, the serrated pathway, has been discovered^[5]. The molecular alterations seen in serrated tumors are different from those traditionally found in the adenoma-carcinoma sequence. In serrated lesions, loss of heterozygosity and mutations in *APC* or *TP53* are rare, whereas hypermethylation of CpG islands and microsatellite instability are frequent. At present, 2 categories of serrated carcinogenesis are defined including 2 basic pathways, the sessile serrated pathway and the traditional serrated pathway. While in the sessile serrated pathway *BRAF* mutation and high-level microsatellite instability are molecular hallmarks in carcinogenesis, and tumor location is predominantly in the right colon, *KRAS* mutation and microsatellite stability have been characterized as important steps in the traditional serrated pathway, where cancers arise mainly in the left colon.

The diversity in colorectal carcinogenesis is accompanied by numerous genetic and epigenetic alterations. Epidemiological data indicate that the heterogeneity of such genomic lesions is determined by additive factors, called the modifiers of colorectal carcinogenesis^[6]. Evidence is given that diet and nutrition are key factors acting as carcinogenesis modifiers. This activity is probably relevant in both steps of colorectal tumorigenesis, initiation and progression. Therefore, identification and characterization of nutritional components as promoters or silencers of intestinal cancer are of high interest in tumor preventive strategies, tumor epidemiology, and the health economy.

THE MODIFIER CONCEPT OF COLORECTAL CARCINOGENESIS

At present, the model of tumor genotype to phenotype/histomorphology correlation, best-known as the adenoma-carcinoma sequence, is well accepted. The genetic changes that occur in colorectal carcinogenesis are paralleled by the progression from small pre-malignant lesions to advanced carcinomas indicating that each successive genetic injury/modification confers an advantageous characteristic upon the expanding tumor. The MAPK-ERK (mitogen-activated protein kinase-extracellular signal-regulated kinase) pathway, which mediates cellular responses to many extracellular inputs, is involved in regulation of apoptosis, cell growth, secretion, and cellular differentiation. K-ras and B-raf are key players in this signaling cascade, because mutations result in continuous gene activation leading to autonomous cell proliferation and tumor growth. The *KRAS* gene belongs to the Ras oncogene family and encodes a 21 kDa protein with intrinsic GTPase activity. This protein is regulated by a cycle of de- and re-palmitoylation, which promotes its rapid exchange between the plasma membrane and the Golgi apparatus. While numerous different genes can become altered in carcinogenesis, it has been recently proposed that the number of deregulated signaling pathways is relatively small^[7].

Over the last few decades it has been shown that aberrant activity of some cellular pathways is crucial in colorectal carcinogenesis. Alterations in the coding genes, e.g. *APC* or *TP53* mutations and loss of heterozygosity, were elucidated as key mechanisms for misdirected signaling^[8]. Important insights into such principles of cancer-relevant molecular signaling were given by the characterization of hereditary colorectal carcinoma syndromes, i.e. hereditary non-polyposis colon cancer, familial adenomatous polyposis, and MUTYH-associated polyposis. Genotype to phenotype correlations in affected patients revealed that the type of variation in gene sequence and epigenetics is essential for onset and progress in cancer development. However, some inter-individual discrepancies were found in this correlation analysis, indicating additional molecular mechanisms that are likely to modify pathway execution^[9-11]. These observations were substantiated by several experiments including studies in *APC* mice revealing examples of modifying genetic loci and non-genetic co-factors, e.g. nutritional components^[12]. In mice, modifying genetic loci were addressed with the acronym Mom (modifiers of min) and demonstrated the genetic-based principle of modulation in gene expression with relevance to disease severity. One interesting candidate gene, firstly identified in the *APC* mice, is *Pla2g2a* coding secretory phospholipase A2 (PLA2)^[13]. Activity of this enzyme (prototype group I) is associated with diverse functions including digestion, smooth muscle contraction, and cell proliferation. In addition, PLA2s of prototype group II are involved in inflammatory conditions and are upregulated

by pro-inflammatory cytokines such as tumor necrosis factor and interleukin-1B. Recently, the PLA2-receptor (PLA2R) has been identified as a potential new tumor suppressor gene crucial in the induction of cellular senescence through activation of the p53 pathway^[14].

In addition to genes acting as defined modifiers in colorectal carcinogenesis, matrix composition has been identified as an important factor to modify epithelial cell behavior and intestinal tumorigenesis^[15]. The heterogeneity in matrix composition is marked and is a result of the complex mixture of non-epithelial cells embedded in a well-adapted set of extracellular stored lamellar and non-lamellar molecules. Additionally, different types of secreted intestinal products, such as mucins and other glycoproteins which are non-cellular matrix-components have been identified as important modifiers in intestinal pathogenesis^[16]. Muc2, expressed by goblet cells, is the most abundant secreted intestinal mucin and important in intestinal homeostasis. The impaired expression and/or secretion of Muc2 have been correlated with the development of inflammatory intestinal conditions and colorectal carcinogenesis^[17-20]. Recently, the molecular basis for this phenomenon was identified, when an interaction of Muc2 and Apc resulting in modification of Wnt signalling was determined^[21,22].

In addition to Muc2, other molecules such as cytokines are suggested as important mediators in chronic intestinal inflammation and modifiers of intestinal tumor development. In the intestine, the main sources of cytokines and inflammation-triggered molecules are lymphocytes. The pathophysiological association of chronic inflammatory activity and intestinal tumorigenesis has been substantiated by epidemiological data demonstrating a high incidence of CRC in patients with chronic inflammatory bowel disease, a condition additionally associated with disturbances in composition of non-cellular matrix components.

Over the last decade, an additional modifier of colorectal carcinogenesis and pathogenesis of non-neoplastic intestinal diseases has been identified and characterized, namely the microbiome. The term intestinal microbiome describes the taxonomically complex and micro-ecological highly dynamic community of microorganisms on the gut mucosal surface^[23]. The interaction of surface lining mucosal cells and the microbiome has an impact on the metabolome and lipidome, the maturation and proliferation of intestinal cells along the crypt-plateau axis, tissue homeostasis, and can be a factor in various diseases, such as inflammatory bowel disease and obesity^[24,25]. The successful use of designed bacterial strains in the treatment of inflammatory intestinal conditions, such as necrotizing enterocolitis in preterm infants, underline that the microbiome modificatory activity is fundamental in intestinal homeostasis^[26].

In summary, colorectal carcinogenesis is based on a sequence of molecular events in enterocytes including gene mutations, epigenetic modifications, and aberrant signaling in basic cellular pathways. However, proliferation, cellular activities, and cell death of enterocytes and the execution of so-called modifier genes of CRC-relevant pathways

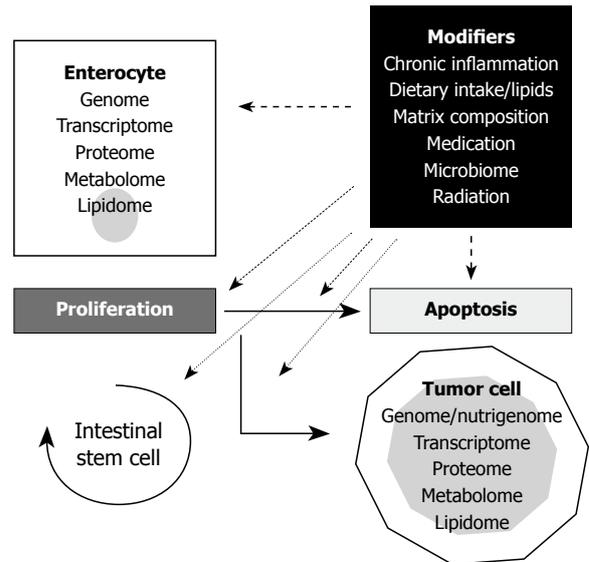

Figure 1 The modifier concept of colorectal carcinogenesis. The important key points in enterocytic life span, proliferation and apoptosis, are connected by basal molecular pathways. Such pathways, as well as cell behavior determining molecular entities such as the genome, transcriptome, proteome, metabolome, and lipidome, are exposed to cellular stress and act as modifiers. In addition to enterocytes, the intestinal stem cells are affected by this evolutionary principle. The aberrant modification of pathways is suggested as an important variable in colorectal carcinogenesis. The term nutrigenome of tumor cells reflects the genome modification of malignant cells by dietary components with expression of so-called modifier genes as demonstrated in APC mice.

strongly depend on additional variables including matrix composition, the microbiome, chronic inflammatory activity, environmental effects, and dietary components. In particular, nutrition and diet, as stated below, are suggested as fundamental in modifying the initiation and progression of CRCs^[6]. Key aspects in the current view of the CRC carcinogenesis modifier concept are summarized in Figure 1.

NUTRITION AND CRC - DIETARY FAT AND INTESTINAL LIPIDS

Among the many aspects of industrialization, such as obesity, exposure to electromagnetic fields, radiation, medications, and a reduced physical activity, diet seems to be a plausible variable in colorectal carcinogenesis because of its direct contact with the intestinal mucosa, i.e. the surface lining epithelial cells^[27]. The literature is marked by epidemiological studies aiming to elucidate the constituents of a CRC-preventive diet, the optimal amount of dietary fiber, and to define biologic markers for nutritional epidemiology of CRC^[28]. A reason for the controversial outcome of such studies could be that the entire diet, with its balance of animal and vegetable products, and grains that have been processed to varying degrees, is highly variable and not a single entity. However, some dietary components are described as putative candidates in modifying colorectal carcinogenesis. An increased risk for cancer development is found in individuals consuming diets high in red and processed meat^[29]. In

addition, alcohol in combination with a diet low in folate and methionine appears to increase cancer risk^[30-32]. Vitamin D and calcium are suggested to have a protective effect in CRC carcinogenesis, but the molecular mechanism behind this has not been elucidated. Recently, it has been shown that deep-fried/oxidized fats such as hydroxyl- and hydroperoxy fatty acids, are able to influence lipid metabolism by activation of the transcription factor, peroxisome proliferator-activated receptor α (PPAR α)^[33]. Oxidized fats are established in diets containing large quantities of polyunsaturated fatty acids (PUFAs) by heating. Expression of PPAR α -related genes is involved in degradation of fatty acids, affects the synthesis of cholesterol/triacylglyceride, and is associated with cellular behavior. These data indicate that lipid metabolism activity and cellular lipid-dependent signaling could be modified by a diet enriched in deep-fried fats.

In the last few decades, the highly diverse class of lipids has become the focus of intensive research activities, because epidemiological data have indicated a link between the intake of dietary lipids and development of (sporadic) CRCs^[34,35]. In this concept, the composition of the different types of fatty acids and the expression/activity of lipid-metabolizing enzymes such as COXs and ACSLs are of high importance^[36]. A growing number of reports support the findings that bioactive dietary components containing long-chain PUFAs modulate important determinants that link inflammation to cancer development and tumor progression^[37], whereas short-chain fatty acids, e.g. acetate, propionate, and especially butyrate, mainly produced by the microbiome using fermentable dietary polysaccharides, are suggested to be cancer-preventive^[38,39]. Propionate and acetate are utilized preferentially by extra-intestinal tissues, whereas butyrate is suggested to play an important role in intestinal mucosa homeostasis as an energy source for enterocytes. It has been shown that cancer-preventive intestinal butyrate levels correlate with increased epithelial cell differentiation, cell cycle arrest, and apoptosis of enterocytes. Additional aspects of butyrate activity, namely inhibition of the enzyme histone deacetylase, and a decrease in the transformation of primary to secondary bile acids as a result of colonic acidification, could be of relevance in colorectal carcinogenesis^[40]. Recently, multiple free fatty acid receptors (FFAR) have been identified in the intestine^[41]. The receptor activity highly depends on the length of the free fatty acids. Short-chain fatty acid signaling is mediated by FFAR2 and FFAR3, whereas FFAR1 and GPR120 can be activated by medium- and long-chain free fatty acids. It is suggested that defects in FFAR3 are associated with reduced extraction of energy from short-chain free fatty acids. The first experimental evidence was that at least FFAR2 could be associated with cellular transformation and colorectal carcinogenesis. In this experimental setting the putative mitogenic action of FFAR2 was aggravated by short-chain free fatty acids.

The important role of lipids, especially fatty acids, in the modifier concept of CRCs is underlined by the plethora of intestinal long-chain fatty acid (LCFA) activi-

ties. LCFAs were suggested as important cell cycle modifiers, particularly in enterocytes. In ACSL5-overexpressing enterocytes, an increase in apoptosis susceptibility was found, probably as a result of an aberrant and locally restricted increase in LCFA derivatives^[42]. These investigations underline the importance of ACSL-mediated metabolic channeling of fatty acids in the regulation of cell behavior^[43]. In addition, lipidation of proteins is suggested as a basic mechanism in the translation of LCFA modifier activities in several signaling cascades and receptor structures^[44]. This mechanism was recently demonstrated for the CD95 death-inducing signaling complex (DISC)^[45]. In the earliest events in DISC formation, palmitoylation of CD95 on cysteine 199 enhances receptor aggregation to a high molecular complex. Palmitoylation, as an important mechanism in fatty acid-based protein modification *via* thio-ester linkage to cysteine (S-palmitoylation), has been recently classified into 5 general classes^[46]. The first class comprises transmembrane proteins S-acylated on cysteines adjacent to or in the transmembrane domain. In the second class, proteins are typified by Ras family molecules, where S-palmitoylation is dependent on prior prenylation within the C-terminal "CAAX" box. In the third class, palmitoylated proteins include molecules with S-palmitoylation at one or more cysteine residues near the N- or C-terminus. Dual acylation is found in the fourth class proteins such as members of the Src and G protein families. N-myristoylation is suggested to improve accessibility of the protein to a membrane-bound palmitoyl acyl transferase and subsequent protein palmitoylation. The hallmark of class 5 proteins is covalent binding of palmitate *via* amide-linkage to an N-terminal cysteine residue.

In summary, dietary fatty acids are suggested as important substrates for protein modification *via* direct molecular interaction. A complex metabolic conversion of absorbed lipids into cell-synthesized LCFA is not mandatory. However, synthesis of acyl-CoA derivatives from dietary fatty acids seems an important step for the modifying activity and bioavailability of lipids. Palmitoylation has been shown as a basic molecular mechanism in lipid-dependent protein modification. As detailed below, lipidomics is a powerful technical algorithm to elucidate key aspects in the interaction of dietary lipids and cellular lipid metabolism.

LIPIDOMICS - A PROMISING TOOL IN CRC-RELATED LIPID ANALYSIS

In the last 2 decades, laboratory technology to investigate carcinogenesis has primarily focused on genomic and proteomic analyses^[47]. Many research-based studies on CRC combined genetic, translation-related and/or biochemical approaches to discover clinically useful DNA- or protein-based biomarkers for CRC screening, diagnosis and response to treatment. Since the crucial roles of lipids in numerous signaling pathways including carcinogenesis, apoptosis and proliferation, has been identified, the necessity to understand and analyze the impact of lipids in

colorectal carcinogenesis, diagnosis, prognosis and treatment becomes more and more important.

In recent years, lipidomics, a novelty in the “-omic” research, has emerged as a promising tool to investigate cellular lipid metabolism and pathogenic alterations in lipid pathways^[48]. Lipidomics, defined as the large-scale study of the pathways and networks of cellular lipids, is a chromatography- and mass-spectrometry-based research area that includes the study of cellular and functional lipidomics as well as lipids in health and disease. The cellular lipidome comprises over 1000 different, highly diverse and complex lipids of which many are metabolically interconvertible and structurally similar^[49]. Because of this complexity, comprehensive lipid analyses are required to elucidate the physiological properties and functionality of different lipid metabolites. The ability to analytically distinguish different lipid species is critical. Despite these experimental challenges and the fact that lipidomics has only emerged as a distinct field within the past few years, the number of compounds that can be analyzed is growing rapidly^[50]; including fatty acids, sphingolipids, glycerolipids, glycerophospholipids, sterol lipids and prenol lipids, each containing distinct classes and subclasses of molecules^[51-56]. The following section gives a short overview of classical and state-of-the-art analytical techniques that are commonly used by lipidologists to investigate lipids in health and disease.

Thin layer chromatography (TLC) has been used for the qualitative study of lipids since the early 1960s^[57,58]. The technique uses a thin layer of a stationary phase such as silica or cellulose on a flat support, usually a glass or aluminum plate. Although the combination of a wide variety of silica-based solid-phase and organic mobile-phase protocols enables the separation of almost all lipid classes, TLC does not offer sufficient structural specificity and sensitivity as other methods of lipid detection. This has led to its use primarily as a screening tool prior to use of more sensitive and elaborated methods.

High pressure liquid chromatography (HPLC), a more sophisticated chromatographic technique, is routinely employed in lipidomic analysis for separation and identification of lipid species. HPLC provides resolution of lipids based on headgroup/class (normal phase) or fatty acid residues (reverse phase). For example, fatty acids and acyl-CoA are almost always separated on a reverse-phase column where the separation occurs on the basis of polarity, effective chain length, and degree of unsaturation^[51], whereas separation of phospholipids can be achieved by either normal-phase HPLC^[59] or reverse-phase HPLC^[60]. However, HPLC alone can not guarantee the accurate quantification of lipids since this often depends on definite resolution and structural elucidation.

Mass spectrometry based techniques are currently the analytical tool of choice in lipidomic methodology. Two powerful approaches that provide sensitivity and structural specificity are electrospray ionization (ESI) and matrix-assisted laser desorption ionization (MALDI) mass spectrometry. ESI allows lipids in solution to be continuously infused directly into the ion source of a

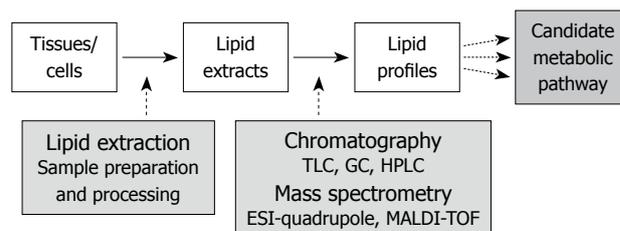

Figure 2 Summary of the lipidomics work flow - lipid extraction and analysis. TLC: Thin layer chromatography; GC: Gas chromatography; HPLC: High pressure liquid chromatography; ESI: Electrospray ionization; MALDI-TOF: Matrix-assisted laser desorption ionization-time-of flight.

mass spectrometer, typically a triple quadrupole mass analyzer. By applying a high voltage to the infusion capillary, an electric field is created along which the charged droplets travel. As they travel, the solvent rapidly evaporates and droplets divide into individual charged ions to enter the mass spectrometer. The combination of classical separation techniques such as HPLC with state of the art ESI-mass spectrometry provides the necessary quantitative accuracy, sensitivity and structural specificity to detect and quantify a wide range of lipid species. Thus, liquid chromatography-mass spectrometry (LC-MS) and tandem mass spectrometry (LC-MS/MS)-based methods are currently one of the most popular technologies in lipid research^[52,61-63].

In contrast to the LC-based lipid analysis, the recently developed direct infusion-based shotgun lipidomics approach, an analytical platform without direct coupling of any chromatography for lipid separation, allows the absolute quantification of hundreds of lipid species in small quantities with high throughput. This powerful strategy provides a promising future application in clinical studies and medical approaches to investigate pathogenic changes in lipid metabolism and lipid-mediated disorders^[64,65].

In addition to ESI mass spectrometry, MALDI mass spectrometry, typically used in conjunction with time-of flight mass analyzers, is a laser-based soft ionization method that has been successfully used for large lipid species. Here, the lipid sample is mixed with an energy absorbing matrix and irradiated with a laser to ionize the lipid molecules which then enter the mass spectrometer. Although MALDI is most often used for protein analyses and only used to a small extent for lipid analyses, the power of this technology lies in its application for tissue-imaging mass spectrometry. Direct tissue analysis of lipid species provides the opportunity to identify not only quantities but also the distribution and subcellular localization of lipids within the tissue^[66,67]. MALDI tissue imaging (MSI), thus, greatly enhances the application spectrum of lipidomic analysis in disease-related alterations in lipid metabolism. A typical lipidomic work flow, including sample preparation and analysis is summarized in Figure 2.

The potential and the feasibility of lipidomic technologies in studies of diabetes, obesity, atherosclerosis and Alzheimer's disease have been described recently^[68]. A lipidomic study of breast cancer pathogenesis demon-

strated that the complete profile of adipose tissue lipids in patients with benign and malignant breast tumors, rather than a single lipid has the capability to quantify the dietary part of breast cancer risk and to identify dietary modification in order to reduce breast cancer occurrence^[69]. As the relevance of lipids as potential biomarkers becomes apparent, an increasing number of studies have focused on the discovery of reliable lipid biomarkers for disease prognosis, prevention and therapeutic application. A recent study showed that the analysis of fatty acyl chains from ethanolamine-containing plasmalogens provided a suitable biomarker to identify malignancy and metastatic capacity of frequent human cancers, such as breast, lung, and prostate cancer^[70]. Although there are currently not many studies focusing on lipidomics-based approaches in colorectal carcinogenesis, the implications of this strategy for the future of CRC treatment and prevention are vast. As the field of lipidomics advances, the role of the lipidome in cellular functions and pathologic states will become clearer, and the identification and establishment of preventive and therapeutic approaches will become more focused. The integration of lipidomic data with genetic, proteomic and metabolomic data will provide a powerful analytical platform for elucidating the mechanism of lipid-based disease, for biomarker screening, and for monitoring pharmacological therapy^[71].

CONCLUSION

In current opinion, the basic molecular pathways determining colorectal carcinogenesis are few in number. However, the number of mechanisms that could act in modifying initiation and progression of intestinal neoplasia is constantly growing. Among dietary components, the modifying capacity of lipids, especially of LCFAs, has been demonstrated by experimental and epidemiological studies. Lipidomics, the large-scale study of the pathways and networks of lipids in cells or tissues, is established as a modern and powerful tool to further elucidate the colorectal carcinogenesis modifying activities of lipids.

Abstract

Celiac disease has been reported in up to 2% of some European populations. A similar risk has been identified in the America and Australia where immigration of Europeans has occurred. Moreover, an increasing number of celiac disease patients are being identified in many Asian countries, including China and India. Finally, celiac disease has also been detected in Asian immigrants and their descendants to other countries, such as Canada. Within these so-called "general" celiac populations, however, there are specific high risk groups that have an even higher prevalence of celiac disease. Indeed, the single most important risk factor for celiac disease is having a first-degree relative with already-defined celiac disease, particularly a sibling. A rate up to 20% or more has been noted. Risk is even greater if a specific family has 2 siblings affected, particularly if a male carries the human leukocyte antigen-DQ2. Both structural changes in the small bowel architecture occur along with functional changes in permeability, even in asymptomatic first-degree relatives. Even if celiac disease is not evident, the risk of other autoimmune disorders seems significantly increased in first-degree relatives as well as intestinal lymphoma. Identification of celiac disease is important since recent long-term studies have shown that the mortality of celiac disease is increased, if it is unrecognized and untreated.

INTRODUCTION

Only a few decades ago, celiac disease was considered an uncommon disorder present mainly in Europe or in countries where Europeans had emigrated, including Canada and Australia^[1]. In Ireland, and in particular, Galway in the West of Ireland, appears to have an especially high prevalence of celiac disease with an estimate of up to 1 in 300 persons^[2]. Similar experiences have been noted in Scandinavian countries. In the United States, however, earlier reports suggest that the detection of celiac disease is surprisingly low^[1,3]. With the emergence of modern serological screening tests for celiac disease and increased efforts to use these screening measures, celiac disease has become more readily detectable.

EMERGING RISK ESTIMATES

In recent years, changes have occurred with an estimate of overall prevalence rates increased in most countries, often in the region of about 1%-2%^[4]. Interestingly, in a longitudinally-based study from Olmstead County in the United States over many decades, increased detection has been reported, in part, due to increased use of serological screening^[5]. Recently, a report from Hangzhou in China has also suggested that the prevalence of adult celiac disease may be more common in China than previously appreciated^[6]. Of note, celiac disease has also been

reported in immigrants to Canada from China, Japan and South Asia, particularly from the Punjab region of India^[7]. Even in the United States, celiac disease is now generally believed to affect 0.5%-1.0% of the general population^[8].

HIGH RISK GROUPS FOR CELIAC DISEASE

These reported numbers often reflect prevalence estimates, usually resulting from screening of selected groups, e.g. blood bank serum samples, thought to be representative of the entire population from a specific geographic area. Confirmatory small intestinal biopsies have often been done in sero-positive cases to provide an overall “minimal” estimate of population prevalence (since all sero-positive patients may not be available for biopsy). As shown in Table 1, there are also some high risk groups within the general celiac population, often without typical clinical symptoms, such as diarrhea or weight loss, that may have even higher prevalence rates. Among these factors that specifically denote a higher risk for celiac disease, the single most important is a familial history of biopsy-defined celiac disease with some estimates up to 20% or more of first-degree relatives. Diagnosis of celiac disease in all of these high risk groups, however, is especially important since failure to detect celiac disease coupled with failure to treat the disease may lead to an increased morbidity, and critically, a nearly 4-fold increased risk of mortality from celiac disease^[9].

FAMILIAL RISK FACTORS

Evidence for a familial risk in celiac disease has been accumulated from many sources (Table 2), including biopsy and serological studies in families with known celiac disease^[10-17], animal model studies in the Irish Setter dog^[18,19], functional studies based on evaluation of intestinal permeability or other absorptive indices^[20-23], human leukocyte antigen (HLA)-genotyping studies^[24-26], and more recently, genome-wide expression and linkage studies^[27].

Biopsy and serological studies

Early family studies using small intestinal biopsies have provided strong evidence for the familial nature of celiac disease^[10,11]. A systematic review of these earlier studies using MEDLINE and EMBASE databases concluded that up to 20% of first-degree relatives of European descent may be at risk for celiac disease^[12]. Similar results have been reported from non-European populations, including a recent report from the Punjab region of India^[13]. In addition, more extensive studies in biopsy-defined celiac disease have further confirmed these findings, particularly in “at-risk” first-degree (1:22) and second-degree relatives (1:39), compared to a control “not-at-risk” group (1:133)^[14]. This risk appears to be especially increased in families with at least 2 siblings diagnosed as celiac disease^[15], and in this setting, more males were detected compared to females^[16]. Particularly significant predictors

Table 1 High risk populations for celiac disease

Relatives, especially first-degree
Anemia, especially iron deficiency
Osteopenic bone disease
Insulin-dependent diabetes (type 1), especially children
Liver disorders, especially AIH and PBC
Genetic disorders, including Down and Turner’s syndrome
Autoimmune endocrinopathy, especially thyroid disease
Skin disorders, particularly dermatitis herpetiformis
Neurological disorders, including ataxia, seizures, MG
Others, including IgA nephropathy

AIH: Autoimmune hepatitis; PBC: Primary biliary cirrhosis; MG: Myasthenia gravis.

Table 2 Evidence of familial risk

Biopsy and serological studies

Functional permeability studies
HLA marker studies
Genome wide expression/linkage studies

HLA: Human leukocyte antigen.

of familial risk include carrying HLA-DQ2 and being a sibling of the proband^[17].

Animal model studies

Animal studies have provided some indirect, but important evidence. Gluten-sensitive enteropathy has been reported in a family of Irish Setter dogs^[18] along with the association of a canine major histocompatibility complex (MHC) DQ haplotype^[19].

Functional studies

Earlier studies showed that an intentional increase in gluten intake may provoke jejunal mucosal architectural changes in some first-degree relatives along with reduced xylose absorption, even in those without clinically overt disease^[20], suggesting that, in the genetically-predisposed, both structural and functional changes may be induced in familial celiac disease. Abnormal permeability to lactulose and mannitol in first-degree relatives also suggests that functional changes may occur in biopsy-defined disease^[21] as well as in first-degree relatives with apparently normal small bowel biopsies^[22]. Importantly, this familial risk in first-degree relatives is genetically-based and not related to their daily calculated gluten intake^[23]. In other words, familial celiac disease is not due to a common environment with increased intake of gluten-containing foods, but has a definitive genetic basis.

Human leukocyte antigen marker studies

HLA markers have been popularly used for decades in clinical studies of celiac disease. These clinical studies have served to emphasize the strong genetic component involved in the development of celiac disease. In large part, possession of the HLA-DQ2 variant, necessary for presentation of dietary antigens to intestinal T-cells, is

critical. Non-HLA genetic factors are also increasingly recognized as a very important, and possibly even a more significant and critical risk factor in the development of familial celiac disease. Furthermore, a recent HLA-genotyping study (i.e. DQA1*0501, DQB1*0201, DRB1*04) with small bowel biopsies from Finland has suggested a practical means of exclusion of some first-degree relatives without celiac disease for screening purposes^[24]. However, it has been reported that some asymptomatic first-degree relatives may show only minimal changes in intra-epithelial lymphocyte numbers^[25]. In addition, with a prolonged follow-up, flat small bowel mucosal biopsies have been reported in familial disease without initially abnormal biopsies^[26]. These findings are important and need to be confirmed as further longitudinal studies may be required in first-degree relatives without initial biopsy evidence of celiac disease.

Genome-wide studies

Most exciting are the recent genome-wide expression and genome-wide linkage studies done to explore a number of clinical disorders, including celiac disease. A recent meta-analysis of 8 genome-wide linkage studies in celiac disease permitted definition of both HLA and non-HLA chromosome regions that appear to predispose to celiac disease and suggested the possibility of different types of disease-predisposing variants^[27].

RISK OF ASSOCIATED DISEASE IN RELATIVES

Of potentially even greater significance are reports on relatives without celiac disease at risk for other diseases, often associated with celiac disease. For example, a serological survey study of first-degree relatives of children with documented celiac disease suggested that autoimmune diseases may be increased in addition to biopsy-defined, but “sub-clinical” celiac disease^[28]. In addition, first-degree relatives may also develop the closely linked dermatological disorder, dermatitis herpetiformis^[29]. Moreover, patients with type-1 diabetes have an increased risk of celiac disease and biopsy-defined, but essentially asymptomatic and unrecognized celiac disease^[30]. Finally, although lymphoma risk seems to have fallen in the past 4 decades, individuals with a sibling affected with celiac disease have an increased lymphoma risk^[31]. These studies, then, have important implications for risk of familial forms of celiac disease in relatives, particularly first-degree, but also for a host of other genetically-related clinical disorders, even in the absence of celiac disease. In future, expression of different celiac disease phenotypes and their individual specific risks of different diseases may be more readily defined with precise genetic markers or more precise genetic signatures.

INTRODUCTION

Chemokines in humans are a family of small proteins of 45-50 kb which contain a structural homologous conservative family of cysteine residues. Chemokines are classified into four families, namely CXC, CC, CX3C and C according to the presence of four cysteine residues in conserved locations. CXC are subdivided into two categories, those with a specific amino acid sequence (or motif) of glutamic acid-leucine-arginine (or ELR for short) immediately before the first cysteine of the CXC motif (ELR-positive), and those without an ELR motif (ELR-negative). CXC and its cognate receptor are combined and activated. The receptors are mainly found in neutrophils, lymphocytes, endothelial cells and epithelial cells. Typical chemokine proteins begin with a signal peptide of approximately 20 amino acids that is cleaved from the mature portion of the molecule during its secretion from the cell. All chemokines share a typical 3-dimensional structure which is stabilized by two disulfide bonds joining the first to the third, and the second to the fourth cysteine residues. CC receptors are mainly distributed in dendritic cells, lymphocytes, macrophages, eosinophilic leukocytes, and natural killer cells, but they do not activate neutrophils. Currently, more than 50 kinds of chemokines have been found with only 20 kinds of chemokine receptors, therefore, in this system a considerable number of useless receptors (receptor, R)/ligand (ligand, L) interact with each other.

Chemokines play a central role in many biological events, such as embryonic development, wound healing, angiogenesis, Th1/Th2 development, leukocyte homeostasis, lymphatic organ development, inflammatory diseases, and tumors. Previous studies suggest that

Abstract

Chemokines play a paramount role in tumor progression. In hepatocellular carcinoma (HCC) progression, chemokines and their receptors play an intricate role. Currently, chemokines and their receptors such as the CXCL12-CXCR4 axis, CX3CL1-CX3CR1 axis and the CCL20-CCR6 axis have received much research attention. Although a large number of studies show that these axes are strongly associated with HCC, the exact mechanism by which these axes promote the growth and progression of HCC remains unknown. In this paper, several chemokines and their receptor interactions in HCC progression, growth and metastasis and immune response to HCC are reviewed.

chemokines are soluble molecules, and are involved in inflammatory response by regulating the transfer of white blood cells. Chemokines are now considered to play a critical and complicated role in a variety of cells such as tumor cells. Chronic inflammation is a long-term and low-grade injury caused by chemical factors, bacteria, and viruses, and there is a strong association between chronic inflammatory conditions in a particular organ and cancer specific to that organ such as colon cancer and ulcerative colitis, colorectal cancer and inflammatory bowel disease, pancreatic cancer and chronic pancreatitis, esophageal adenocarcinoma and Barrett's esophagus, liver cancer and hepatitis^[1-3]. The most striking evidence of the direct regulation of tumors and tumor growth by chemokines is the over-expression of GRO (CXCL1, growth-related oncogene), α , β , γ in human melanoma cells, and its tumorigenicity in nude mice from *in vitro* research^[4,5]. Recent studies have been focused on the roles of chemokines and their corresponding receptors in the growth and progression of tumors. The chemokines and their receptors involved in these processes are known as axes. At present, a large number of studies have demonstrated that the CXCL12-CXCR4 axis may be related to distant organ metastasis of tumors while the CCL21-CCR7 axis may be associated with lymph node metastasis.

Many studies have been conducted on chemokines and their receptors in hepatocellular carcinoma (HCC). However, various axes may not play the same role in HCC as they do in other tumors. Currently, chemokines and their receptors such as the CXCL12-CXCR4 axis and the CCL20-CCR6 axis have received much research attention. This paper will analyze the relationship between chemokines and their receptors in HCC.

CXCL12-CXCR4 AXIS IN HCC

The CXCL12-CXCR4 axis is considered to be an important factor in the regulation of angiogenesis which is essential for growth and progression of HCC. Using immunohistochemistry, Li *et al.*^[6] found a much higher expression of the CXCL12-CXCR4 axis in HCC specimens than in adjacent, cirrhosis, liver adenocarcinoma, and normal liver tissues. The findings of the study by Sutton *et al.*^[7] indicated that the CXCL12-CXCR4 axis in HCC cell lines promoted the growth, invasion and metastasis of these cell lines. Liu *et al.*^[8] suggested that CXCR4 and CXCL12 may play an important role in the metastasis of HCC by promoting the migration of tumor cells. In addition, some researchers found that fucoidan exhibited antitumor activity toward Huh7 cells through the down-regulation of CXCL12 expression^[9]. Data from recent research strongly suggests that CXCL12-CXCR4 stimulates the proliferation of oval cells, and HCC occurrence correlates with the abnormal differentiation of these cells^[10]. All these studies reveal a strong association between CXCL12-CXCR4 and the incidence of HCC development, however, the exact mechanism remains unknown. Chu *et al.*^[11] conducted studies on HCC cell lines which suggested that the CXCL12-

CXCR4 system mediates active MMP-9 and MMP-2 secretion, which facilitates the consequent metastasis of those cells. Schimanski *et al.*^[12] found that in patients with HCC, the expression of CXCR4 significantly correlated with the progression of local tumor, distant dissemination of lymphatic metastasis, as well as a decreased 3-year-survival rate. Strong expression of CXCR4 was significantly associated with HCC progression. They also found that loss of p53 function did not impact on CXCR4 expression, which indicated that CXCR4 influences HCC progression through other channels. However, Schimanski's work did not suggest which channel may be involved.

Some researchers have shed doubt on whether CXCL12-CXCR4 promotes the growth and progression of HCC. Using immunohistochemistry and RT-PCR, Shibuta *et al.*^[13] detected the down-regulation of CXCL12/CXCR4 expression in HCC and also found that CXCR4 expression correlated with the cell cycle when studying HCC cell lines. Nahon^[14] conducted a retrospective analysis on 120 HCV-infected HCC patients, and suggested a lack of association between CXCL12/CXCR4, death and HCC recurrence. New research shows that SDF-1-3'A (CXCL12) gene polymorphisms are considered to be relevant factors in HCC occurrence and development which have little to do with CXCR4^[15]. Different findings from previous studies can be attributed to the various research methods and statistical methods adopted. These studies need to be improved. For example, in Nahon's study, results could be achieved if the sample size was increased. In addition, most of the HCC studies did not include different forms of hepatitis (HBV and HCV) as a variable.

Therefore, even though most of the research data show that the CXCL12-CXCR4 axis is important in HCC, its specific role is still unknown and some evidence to the contrary can not be explained. Further study and discussion are needed to clarify these issues.

CCL20-CCR6 AXIS IN HCC

There is currently an increasing interest in the CCL20-CCR6 axis in HCC. Fujii *et al.*^[16] found in *in vitro* experiments that the CCL20-CCR6 axis may promote the growth of the hepatoma cell line Huh7 through phosphorylation of mitogen-activated protein kinase (MAPK).

Rubie *et al.*^[17] also studied CCL19, CCL20, CCL21, CXCL12 and the expression of their receptors in HCC, and found that all chemokines were found to be expressed in normal liver and HCC tissues, yet CCL20 was the only chemokine which showed significant up-regulation in HCC tissues. The only chemokine receptor to show significant up-regulation in HCC tissues was CCR6. Clinicopathological analysis revealed a strong association between the levels of expression and the degrees of differentiation. That is, with high differentiation, the expression was low. Therefore, the authors proposed that the CCL20-CCR6 axis plays an important role in the growth and progression of HCC, namely a distinct increase in CCL20 expression rates in HCC tis-

sues of grade III tumors in comparison to grade II tumors. In addition, high expression of CCL20 is often accompanied by high expression of CCR6. Therefore, the authors suggested that CCL20-CCR6 may be involved in the formation and development of HCC.

Uchida *et al.*^[18] observed the formation of pseudopodia in HCC cell lines with high expression of CCR6, which was not observed in cells low in CCR6. The incidence of intrahepatic metastasis was higher in patients with increased expression of CCR6 than in patients with low expression of CCR6. Disease-free survival was significantly poorer in the high CCR6 expression group than in the low CCR6 expression group. The author concluded that CCR6 might be associated with the intrahepatic metastasis of HCC and may be used as a prognostic factor after hepatic resection for HCC.

In addition, researchers have studied the differences in RNA and protein expression of the chemokines CXCL12, CCL19, CCL20, CCL21 and their receptors in primary liver cancer and colon cancer metastasis; even though they have a high expression of CCL20 and CXCR4, the expression in colon cancer liver metastasis was significantly higher than that in primary liver cancer, thus CXCR4 is important in differentiating primary and secondary liver tumors, while CCL20 and its receptor CCR6 may promote tumor growth in addition to their role in identifying primary and secondary liver tumors^[19].

Although a large number of studies show that the CCL20-CCR6 axis is strongly associated with HCC, the exact mechanism by which the CCL20-CCR6 axis promotes the growth and progression of HCC remains unknown.

FRACTALKINE-CX3CR1 AXIS IN HCC

Fractalkine (CX3CL1) and its receptor CX3CR1 are expressed in DC, NK cells, CD8+ T cells, and macrophages. Although studies have shown that fractalkine can regulate the host immune response, the relationships between the fractalkine-CX3CR1 axis, tumor biochemistry and HCC are unclear. According to recent studies, the fractalkine-CX3CR1 axis is critical in the diagnosis of HCC, because it can not only regulate the immune response, but can also regulate the cell cycle of HCC^[20]. Relevant experiments indicate that fractalkine can enhance the anti-tumor effect of the immune system against HCC in mice. Tang *et al.*^[21] observed that CX3CL1 could elicit tumor-specific cytotoxic T cells and an increased production of IL-2 and IFN- γ capable of inhibiting tumor growth. Matsubara *et al.*^[20] found that HCC patients with an high expression of fractalkine and its receptor CX3CR1 have a low rate of recurrence of intrahepatic metastasis or extrahepatic metastasis, which suggest that the expression of fractalkine and its receptor CX3CR1 may be related to the prognosis of HCC patients, and may be involved in tumor immunity by killing tumor cells.

However, some researchers have proposed that there is a lack of association between the CX3CL1-CX3CR1 axis and HCC, as studies have demonstrated that CX3CR1

is not a risk factor for HCC^[22]. These researchers believe that tumor-derived chemokines have dual roles. Leukocyte aggregation following a signal of increasing chemokine concentration may not only be beneficial to the host, but also contribute to tumor growth. The roles virus-related chemokines play in tumors may be multiple, therefore the specific role of CX3CR1 in the formation of chronic hepatitis and liver disease needs to be elaborated.

In addition, the up-regulated expression of CX3CL1-CX3CR1 in ischemia-reperfusion injury suggests that CX3CL1-CX3CR1 is crucial in reperfusion injury^[23].

OTHER RELATED CHEMOKINES IN HCC

Recent studies have found that the combination of CCL5 with the CCR1 receptor can promote metastasis and invasion of the HCC cell line Huh7^[24]. Furthermore, studies of the expression of CCL3 and its receptor CCR1 in liver cancer have shown a significantly higher level of expression in cancer tissues. Animal experiments also confirmed the essential contribution of CCL3 and CCR1 to the growth and progression of HCC^[25]. Recent studies indicated that CCL3 induced by IL-1 combined with its effective receptor CCR1 may be involved in the growth and progression of HCC. The authors studied six chemokines in six types of HCC cell lines and found that all the hepatoma cell lines constitutively and exclusively expressed CCR1 mRNA and its protein on their cell surface, however, the expression of CCR1 was not detected in normal liver cells^[26]. This research suggested a close relationship between the CCL3-CCR1 axis and HCC.

VCC-1 (VEGF correlated chemokine-1) is a newly discovered chemokine, and has a high expression in breast and colon cancer. Studies have demonstrated that it promotes tumor growth by increasing angiogenesis^[27]. Our recent studies have shown (findings are not yet published) that the expression of VCC-1 in cancer tissues of HCC patients is much higher than that in paracancerous tissues and normal liver tissues. This expression is related to tumor size and tumor differentiation. The findings suggest that VCC-1 may be involved in the growth and progression of HCC, but whether it plays a role in HCC recurrence and metastasis remains unknown. In addition, it is not clear with which receptor VCC-1 interacts.

CHEMOKINES AND THEIR RECEPTORS INVOLVED IN HCC TUMOR IMMUNITY

As mentioned above, not all chemokines promote tumor growth and metastasis. Fractalkine/CX3CL1 is believed to be able to inhibit tumor growth^[21]. Hirano *et al.*^[28] discovered that some chemokines induced by IFN- γ such as Mig (CXCL9) and IP-10 (CXCL10) can promote the gathering of lymphocytes in HCC, and are essential in tumor immunity.

Despite lymphocyte infiltration in liver tumors, the tumor grows and spreads rapidly. Liu *et al.*^[29] studied the expression of chemokines in HCC tissues and HCC cell lines, and found that IP-10 and Mig were expressed in

serum and tissues. The expression of IP-10 in cancer tissues was higher than that in paracancerous tissues. Auto-craine chemokines in HCC cell lines can lead to CXCR3-specific lymphocytes infiltration. However, if the liver cancer cell lines and normal lymphocytes are cultivated, the expression of CXCR3 in lymphocytes shows a distinct decrease. As a result, the combination of CXCR3 and IP-10 and metastasis of T cells to tumor cells are both reduced. *In vitro* experiments show weakening chemotactic effects of CD4+ and CD8+ T cells from liver cancer cells on IP-10, whereas the chemotactic effects of T-cells from normal tissues on IP-10 were enhanced. This study demonstrated the functional desensitization of the chemokine receptor CXCR3 in lymphocytes from HCC patients by CXCR3 ligands secreted by tumor cells. This may cause lymphocyte dysfunction and subsequently impaired immune defense against the tumor.

CONCLUSION

In summary, the roles of chemokines in HCC are multiple, and range from promoting to inhibiting. But which role is dominant? HCC may be regulated by complicated chemokines and their receptors. Current studies show that in tumors such as lung cancer, colon cancer and prostate cancer, the CXCL12-CXCR4 axis may be related to tumor metastasis of distant organs and the CCL21-CCR7 axis may be associated with lymph node metastasis. However, further study is needed to clarify these associations in HCC. In addition, there are few reports on the expression of the CCL21-CCR7 axis in HCC although much research has been carried out on the relationship of this axis with lymph node metastasis in other tumors.

Researchers are expected to explore the possibility of chemokines and their receptors being target genes and to utilize their anti-tumor function when treating HCC. Recent studies have shown that co-expression of suicide genes and MCP-1 (monocyte chemotactic protein-1) in rat liver and colon cancer has a significant anti-tumor effect^[50]. Gene therapy based on a variety of chemokine axes such as the CXCL12-CXCR4 axis is being studied. The desired effect can only be achieved by combining several chemokine axes rather than focusing on a single axis.

Abstract

AIM: To explore the role of heat shock protein-90 (HSP-90) for nitrgenic vasorelaxation in the splanchnic circulation in rats with and without portal hypertension.

METHODS: Neuronal nitric oxide synthase (nNOS) and HSP-90 were analyzed by immunofluorescence, western blotting and co-immunoprecipitation in the mesenteric vasculature and isolated nerves of portal-vein-ligated (PVL) rats and sham operated rats. *In vitro* perfused de-endothelialized mesenteric arterial vasculature was precontracted with norepinephrine (EC_{80}) and tested for nNOS-mediated vasorelaxation by periarterial nerve stimulation (PNS, 2-12 Hz, 45V) before and after incubation with geldanamycin (specific inhibitor of HSP-90 signalling, 3 μ g/mL) or L-NAME (non-specific NOS-blocker, 10^{-4} mol/L).

RESULTS: nNOS and HSP-90 expression was signifi-

cantly increased in mesenteric nerves from PVL as compared to sham rats. Moreover, nNOS and HSP-90 were visualized in mesenteric nerves by immunofluorescence and immunoprecipitation of nNOS co-immunoprecipitated HSP-90 in sham and PVL rats. PNS induced a frequency-dependent vasorelaxation which was more pronounced in PVL as compared to sham rats. L-NAME and geldanamycin markedly reduced nNOS-mediated vasorelaxation abrogating differences between the study groups. The effect of L-NAME and geldanamycin on nNOS-mediated vasorelaxation was significantly greater in PVL than in sham animals. However, no difference in magnitude of effect between L-NAME and geldanamycin was noted.

CONCLUSION: HSP-90 acts as a signalling mediator of nNOS-dependent nerve mediated vascular responses in mesenteric arteries, and the increased nitrgenic vasorelaxation observed in portal hypertension is mediated largely by HSP-90.

INTRODUCTION

Arterial vasodilation and vascular dysregulation represent the initiating as well as perpetuating mechanism in the pathophysiology of the hyperdynamic circulatory syndrome in portal hypertension^[1]. This arterial vasodilation occurs early and is most pronounced in the splanchnic circulation which therefore has been suggested to be the main culprit for reduced peripheral vascular resistance occurring with progression of portal hypertension^[2,3]. A strong line of evidence suggests that vascular overproduction of nitric oxide (NO) plays a pivotal role for the development of splanchnic arterial vasodilation in this condition^[4-6]. In fact, non-specific inhibition of NO synthesis has been shown to restore mesenteric vascular responsiveness^[7] and to almost normalize splanchnic vascular resistance^[8] thereby markedly ameliorating portal-systemic shunting and the hyperdynamic circulation^[9,10].

Three isoforms of NO-synthases (NOS) have been cloned. Vascular overproduction in the splanchnic circulation in portal hypertension is derived from endothelial (eNOS) and neuronal (nNOS) but not inducible NOS (iNOS)^[4,11,12]. eNOS as well as nNOS-derived NO production are regulated through distinct posttranslational modifications, one being the interaction of NOS with regulatory proteins^[13]. The molecular chaperone heat shock protein-90 (HSP-90) facilitates folding and stabilization of cellular proteins thereby promoting specific signalling pathways^[14]. In support of this concept, interaction of eNOS and nNOS with HSP-90 has recently been shown to facilitate NO synthesis^[15,16]. In fact, in portal hypertension we have observed increased eNOS activity and an associated enhanced eNOS-dependent vasorelaxation in mesenteric arteries, which was markedly inhibited by geldanamycin, an ansamycin antibiotic and specific HSP-90 antagonist^[17]. Whether HSP-90 likewise plays a crucial role in nNOS-mediated vasodilation in the splanchnic circulation in healthy as well as portal hypertensive conditions is currently unknown.

Chronic specific nNOS-inhibition markedly attenuates the hyperdynamic circulatory syndrome in experimental cirrhosis^[18] underlining the relative importance of nNOS-derived NO in this scenario. Moreover, we recently reported an increased nNOS expression in the whole mesenteric vascular bed of portal vein-ligated (PVL) rats^[12], and nNOS has been demonstrated to be up-regulated and to be highly expressed in vascular smooth muscle cells of the mesenteric arteries during portal hypertension^[19]. nNOS expression and function in mesenteric nervous tissue independent of the arterial smooth muscle layer, however, has not been investigated so far.

Thus, the aim of our study was to analyse (1) nNOS expression in mesenteric nerves during portal hypertension; (2) whether HSP-90 co-localizes with and regulates nNOS-mediated vasorelaxation in the mesenteric arterial vasculature; and (3) if this is the case, whether alterations in HSP-90 function occur during portal hypertension.

MATERIALS AND METHODS

Animals

The investigation was performed in male Sprague-Dawley rats (Harlan Sprague Dawley Laboratories, Indianapolis, IN), weighing 300-399 g. Rats were caged at a constant room temperature of 21°C, exposed to a 12:12 hour light:dark cycle, and allowed free access to water and standard rat chow *ad libitum*. All experimental procedures in this study were conducted according to the German Physiological Society principles for the care and use of laboratory animals (Granted permission number 621-2531.1-23/00, Government of Oberpfalz, Bavaria).

Drugs

Acetylcholine, Sodium-Nitroprusside, Norepinephrine, Guanethidine, Atropine, Timolol, L-NAME and geldanamycin were purchased from Sigma (Deisenhofen, Germany).

Induction of portal hypertension

A prehepatic portal hypertensive animal model extensively studied in our laboratory was used^[20]. Portal hypertension was induced surgically in aseptic conditions. Briefly, the rats were anaesthetized with ketamine hydrochloride (Ketalar, 100 mg/kg bw; Parke, Davis, Avon, CT). After a midline abdominal incision, the portal vein was freed from surrounding tissue. A ligature (silk gut 3-0) was placed around a 20-gauge blunt-tipped needle lying alongside the portal vein. Subsequent removal of the needle yielded a calibrated stenosis of the portal vein. In sham-operated rats, the same operation was performed with the exception that after isolating the portal vein no ligature was placed. All studies were performed in 12-18 h fasted animals 10-14 d after surgery.

In vitro perfusion

The *in vitro* perfusion system used was a partial modification of that originally described by McGregor and used extensively in previous studies from our laboratory and others^[5,21,22]. Briefly, the superior mesenteric artery (SMA) was cannulated with a PE-60 catheter and gently perfused with 15 mL warm Krebs solution to eliminate blood. After isolating the SMA with its mesentery, the gut was cut off close to its mesenteric border. The arterial vasculature was then transferred to a 37°C water-jacketed container and perfused with oxygenated 37°C Krebs' solution (95% O₂, 5% CO₂) using a roller pump (Ismatec, IPC 8-channel, Zürich, Switzerland). The Krebs solution had the following composition (mmol/L): NaCl, 118; KCl, 4.7; KH₂PO₄, 1.2; MgSO₄, 1.2; CaCl₂, 2.5; NaHCO₃, 25; disodium EDTA, 0.026; and glucose, 11.0; pH 7.4. The effluent of the perfused tissue was continuously removed from the perfusing chamber. The perfusion pressure was measured with a P-23-Db strain gauge transducer (Statham, Oxnard, CA) on a side arm just before the perfusing cannula and continuously

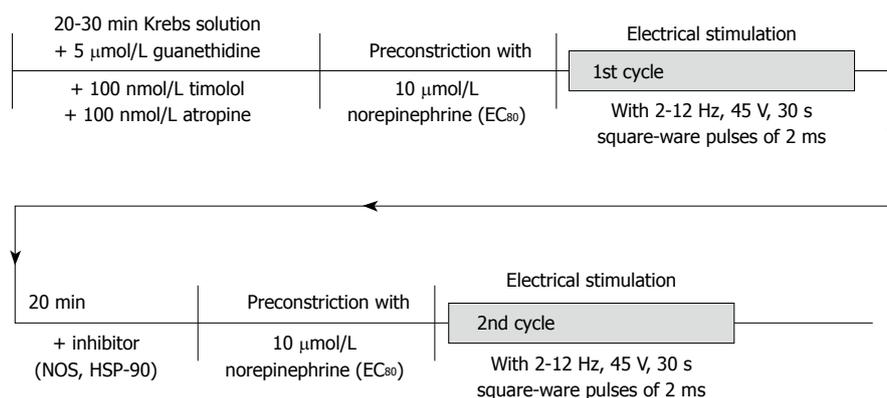

Figure 1 Experimental study protocol. In this illustration, the chronological order of applications of drugs and performance of peri-arterial nerve stimulation (PNS) is shown. EC₈₀: Concentration achieving 80% maximal vasoconstriction; NOS: Nitric oxide synthase; HSP-90: Heat shock protein-90.

recorded (Powerlab Quadbridge and Powerlab 4/20, from AD Instruments, Spechbach, Germany).

Where indicated endothelial denudation of the mesenteric vasculature was performed by a combined treatment of cholic acid (sodium salt) and distilled water as has been used before^[21]. In brief, after cannulation of the SMA and gentle flushing with 10 mL of warmed Krebs' solution to eliminate blood, perfusion with cholic acid (0.5%/1.5 mL for 10 s) followed by 15 mL of Krebs solution (to eliminate cholic acid) was performed. The preparation was then transferred to the 37°C waterjacketed container and perfused with oxygenated 37°C Krebs solution (4 mL/min) for 10 min. After the mesenteric vasculature was relaxed, 37°C warmed distilled water was perfused for 10 min before starting Krebs perfusion again. After an equilibration period of 45 min, experimental perfusion protocols were performed (Figure 1). At the end of each experiment we assessed whether the vessel was completely de-endothelialized and whether the smooth muscle function was maintained. The mesenteric preparation was kept precontracted with methoxamine (MT; α -1-agonist: 100 μ mol/L) and dose-dependent vasorelaxation to the endothelium-dependent vasodilator acetylcholine (ACh: 10^{-8} to 10^{-6} g, bolus of 0.1 mL) and the endothelium-independent vasodilator sodium nitroprusside (SNP: 10^{-6} to 10^{-5} g, bolus of 0.1 mL) was tested. Only experiments with ACh- and SNP-induced relaxation being less/more than 15%/60% were accounted as valid.

Periarterial nerve stimulation

Two platinum electrodes, one placed around the SMA and the other shaped as a wire grid the tissue was resting on, were used for transmural electrical field stimulation. The nerves of the preparation were stimulated by means of an electronic stimulator (I-ZQ4v, Hugo Sachs Electronics, Hugstetten, Germany), delivering single square-wave pulses (2 ms) at 45 V with a train duration of 30 s and frequencies of 2-12 Hz. In order to evaluate vasodilatory responsiveness vessels were precontracted submaximally (EC₈₀) using norepinephrine (NE 10^{-5} mol/L) before applying periarterial nerve stimulation (PNS) (Figure 1). nNOS-mediated vasorelaxation is known to be non-adrenergic and non-cholinergic in origin. Therefore, guanethidine (5×10^{-5} mol/L), atropine (10^{-9} mol/L) and timolol (10^{-9} mol/L) were added from the beginning in order to deplete endogenous noradrenaline stores and to prevent

its uptake as well as to avoid cholinergic stimulation. When a stable precontraction level was achieved, PNS was applied in a non-cumulative fashion. Sufficient time was allowed between each stimulation train for the perfusion pressure to return to a stable level, usually 5-10 min. PNS responses are expressed as percentage change of the pre-contraction level being present before PNS. Nitroergic vasodilation is known to be independent of prostaglandin synthesis^[23] and it is not subject to pre-junctional inhibition by α -adrenoreceptors^[23]. Moreover, in previous experiments tetrodotoxin has been used to evidence the neural origin of the hemodynamic response^[12].

Role of HSP-90 for nNOS-mediated vasorelaxation

Most importantly, all PNS experiments were performed in de-endothelialized mesenteric vasculature in order to exclude any hemodynamic effects of endothelium-derived vasodilators. In order to evaluate the magnitude of nNOS-mediated vasorelaxation, PNS experiments were performed in the absence (1st perfusion cycle) and presence of L-NAME (10 μ mol/L) (2nd perfusion cycle after incubation with L-NAME for 20 min). The differences in PNS-triggered vasorelaxation induced by L-NAME correspond to nNOS-mediated vasodilator effects. As for the role of HSP-90 in mediating this nNOS-vasodilation, vessel preparations were correspondingly pre-incubated with the HSP-90 inhibitor geldanamycin (GA 3 μ g/mL) for 20 min before performing the 2nd perfusion cycle (Figure 1). GA is a benzoquinone ansamycin antibiotic that binds to the nucleotide-binding site of HSP-90 and specifically blocks HSP-90 function^[24,25]. GA was first reported to inhibit iNOS activity in rat smooth muscle^[26], however, as reported earlier no iNOS protein was detected in the vasculature studied, ruling out a hemodynamic role of HSP-90 related to iNOS-derived NO. As shown previously, incubation with GA does not directly affect soluble guanylate cyclase or other smooth muscle cell machinery required for NO-dependent vasodilation since vasodilation is not altered in response to SNP^[17].

Immunofluorescence analysis

Mesenteric tissues were harvested by dissecting and removing the highly vascular tissue situated between the mesenteric lymph nodes and small intestine. The tissue was freed, washed in PBS, stored in 3.7% formaldehyde at 4°C over night, and then transferred into 20% sucrose solution

for more than 12 h at 4°C. After this procedure the SMA were embedded in tissue tek (Herstetter, Stadt, Land) and stored at -80°C. Frozen sections (Frigocut 2800 E, Leica, Wetzlar, Germany) were incubated overnight with monoclonal antibodies directed against nNOS or HSP-90, respectively (both BA, Transduction Laboratory, San Diego, CA, USA). Immunofluorescence staining was performed by utilizing either red fluorescent or green fluorescent anti-mouse IgG (Alexa 46, MoBiTec, Göttingen, Germany) as secondary antibodies. Sections treated with secondary antibody only or with control IgG (as first antibody) did not reveal an immunosignal (data not shown).

Immunoprecipitation and Western blotting

Mesenteric nerves located in near proximity to the SMA were dissected microscopically and washed in PBS and homogenized in a lysis buffer. Protein quantification of tissue samples was performed using the Lowry assay. In experiments examining the level of nNOS and HSP-90 protein in mesenteric tissue, 100 µg of protein were used for electrophoresis. For nNOS immunoprecipitation, about 1500 µg of detergent-soluble protein was incubated with excess nNOS mAb overnight after samples were pre-cleared with Pansorbin (Calbiochem, CA, USA). Immune complexes were precipitated by the addition of protein A-Sepharose. Protein samples were boiled in Laemmli loading buffer and separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) on a 7.5% acrylamide gel, and proteins were electroblotted onto nitrocellulose membranes. Subsequently, the membranes were washed with Tris-buffer saline with 1% Tween, blocked with 5% milk, and incubated with either HSP-90 mAb or nNOS mAb. Densitometry was performed with a scanner and analyzed with the Software Image Quant (Personal Densitometer Si, Amersham, Bioscience, UK).

Statistical analysis

Results were expressed as mean ± SE. Statistical analysis was performed using ANOVA (two-way, with repeated measurements) for comparison of study groups for PNS-induced vasorelaxation. Unpaired non-parametric tests were used for comparison of individual values between study groups. The level of statistical significance was set at $P < 0.05$.

RESULTS

Animals

There were no differences in body weight in the experimental groups (349 ± 36 g for PVL and 363 ± 42 g for sham rats, respectively). PVL rats showed elevated spleen weights, expressed in relation to body weight (PVL: 3.25 ± 0.30 g/kg bw *vs* sham: 2.48 ± 0.50 g/kg bw, $P < 0.0001$).

Western blotting and co-association of nNOS and HSP-90 in mesenteric nerves

To determine the importance of HSP-90 for neuronal vascular control in mesenteric arteries, we first examined expression, association and localization of nNOS and HSP-90 in mesenteric nerves. nNOS expression was

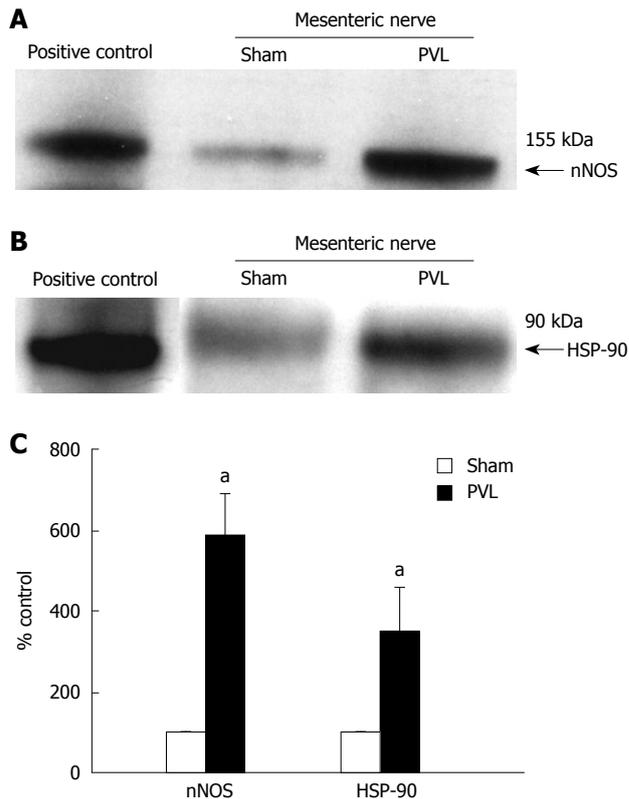

Figure 2 n-nitric oxide synthase (nNOS) and HSP-90 expression in mesenteric nerves. nNOS (A) and HSP-90 (B) in mesenteric nerves of portal-vein-ligated rats (PVL) and sham rats by Western blotting analysis. Protein lysate from rat brain tissue was used as positive control; C: Densitometric analysis of Western blottings revealed a more than 5-fold increase of nNOS and approximately 3-fold increase of HSP-90 protein expression in mesenteric nerves of PVL rats as compared to sham rats. ^a $P < 0.05$, $n = 3$ per group.

found to be increased in PVL rats as compared to sham rats (Figure 2A and C). In addition, HSP-90 expression was enhanced in mesenteric nerves in PVL rats as compared to sham rats (Figure 2B and C) and nNOS co-precipitated with HSP-90 from mesenteric nerves (Figure 3) evidencing direct protein-protein interaction.

Immunofluorescence of nNOS and HSP-90 in mesenteric nerves

We previously reported that both nNOS and HSP-90 are abundantly expressed in mesenteric vasculature in rats^[17]. Here we extend this information with a focus on the mesenteric neurons. In fact, immunofluorescence revealed co-localization, with nNOS and HSP-90 being distributed equally in perivascular neurons (Figure 4A and B). Indeed, identical localization and most obviously similar magnitude of protein expression for nNOS as well as HSP-90 were observed at the entry of the nerve supply into the mesenteric vasculature.

nNOS-dependent mesenteric vasorelaxation and HSP-90

Baseline perfusion pressures before removal of the endothelium were significantly lower in PVL as compared to sham rats (16.0 ± 6.1 mmHg *vs* 23.4 ± 8.0 mmHg, $P < 0.01$). After removal of the endothelium no difference in basal perfusion pressure between study groups was noted anymore (data not shown). The vasodilator response to

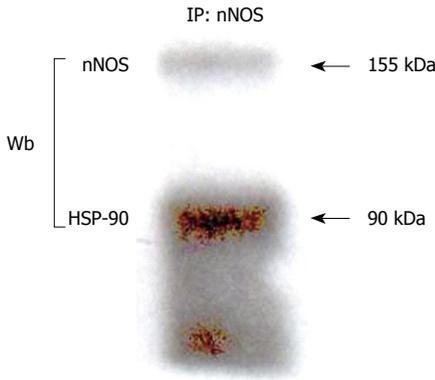

Figure 3 Co-immunoprecipitation. nNOS was immunoprecipitated from detergent-soluble protein lysates prepared from de-endothelialized mesenteric tissue harvested as described in materials and methods and prepared for gel electrophoresis or, alternatively, protein samples were directly prepared for gel electrophoresis. nNOS and HSP-90 are both abundantly expressed in mesenteric tissue and immunoprecipitation (IP) of nNOS coprecipitates HSP-90 under basal conditions. Wb: Western blotting.

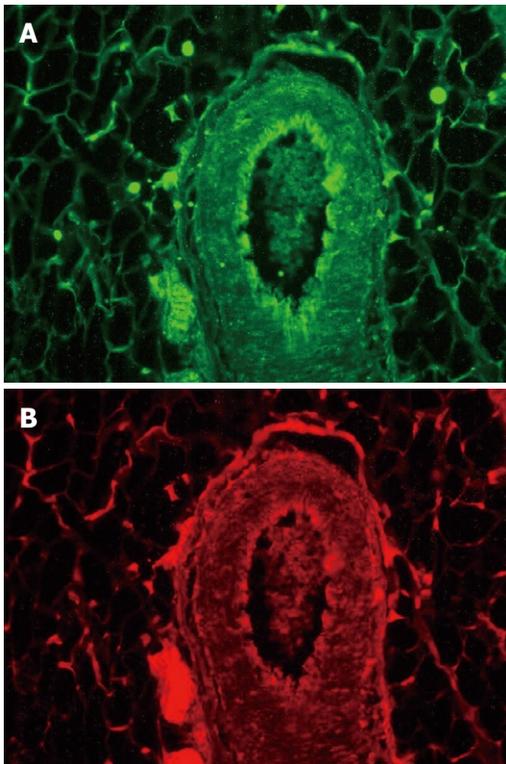

Figure 4 Immunofluorescence analysis of nNOS and HSP-90. As can be seen immunofluorescence shows strong signals for nNOS (A) and HSP-90 (B) mainly at the entry of the nerve bundle along the adventitia revealing identical localization of nNOS and HSP-90 protein in mesenteric nervous tissue.

acetylcholine at the highest dose used was $7.5\% \pm 5.0\%$ and $9.0\% \pm 6.0\%$ in PVL and sham rats, respectively (NS), demonstrating a sufficient de-endothelialization. The vasodilator response to sodium nitroprusside at the highest dose applied was $65\% \pm 7\%$ for PVL and $58\% \pm 9\%$ for sham rats (NS) demonstrating the functional integrity of the vascular smooth muscle cells in the vascular bed studied. NE-induced pre-constriction levels were similar in both study groups (95 ± 5 mmHg *vs* 88 ± 6 mmHg) indicating

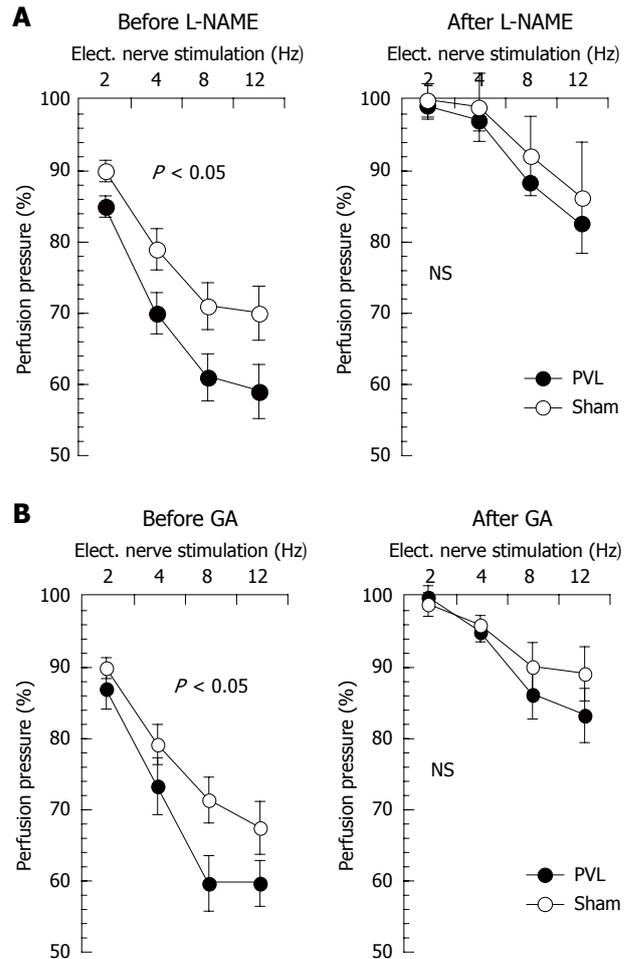

Figure 5 nNOS- and HSP-90-mediated neuronal vasorelaxation in PVL and sham rats. PNS-induced nitergic vasorelaxation in de-endothelialized mesenteric vasculature is depicted before and after L-NAME (A) as well as before and after HSP-90-inhibition with geldanamycin (B). It can be appreciated that no more significant differences in frequency-dependent neuronal vasorelaxation were observed between the study groups after L-NAME as well as after geldanamycin. Values given as mean \pm SE. PVL-group: $n = 6$; Sham group: $n = 6$. $P < 0.05$ for ANOVA comparing study groups. Elect. nerve stimulation: Electric nerve stimulation; NS: Not significant.

similar vascular tone before neuronal stimulation. Incubation with either L-NAME or GA did not affect baseline or pre-constriction levels in either group. All vessels responded to PNS with a frequency-dependent decrease in perfusion pressure (Figure 5). This neurally mediated vasodilatory response was significantly more pronounced in PVL as compared to sham rats (Figure 5). Non-specific NO-inhibition by L-NAME (Figure 5A) abolished the difference in PNS-induced vasorelaxation between the study groups evidencing NO as being the vasodilator mediating this difference and thus reflecting nNOS-mediated vasorelaxation. Moreover, HSP-90 inhibition using GA likewise abolished the difference in PNS-induced vasorelaxation between PVL and sham rats (Figure 5B). This indicates that the observed increase in nNOS-mediated vasorelaxation in PVL rats is dependent on HSP-90 signalling.

When expressing PNS-induced vasorelaxation as percent change from the pre-constriction level a markedly increased response was observed in vessel preparations from

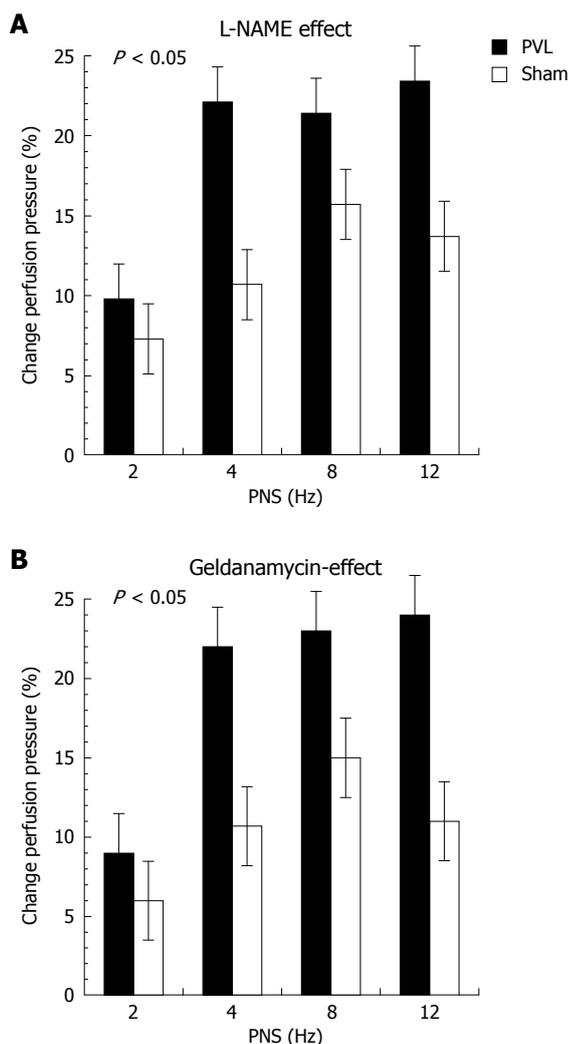

Figure 6 Changes in PNS-induced vasorelaxation induced by inhibition of NOS or HSP-90. Changes in pressure response to PNS induced by L-NAME (A) and geldanamycin (B) presented as percent change in perfusion pressure as compared to values obtained during the first perfusion cycle. $P < 0.05$ (ANOVA comparing all conditions between study groups) vs sham, respectively.

PVL rats as compared to sham rats (Figure 6). Maximal vasodilation was reached at 8-12 Hz, confirming previous investigations of SMA in rats^[27]. Finally, the effect of NO inhibition (Figure 6A) and HSP-90 inhibition (Figure 6B) expressed as percent change in perfusion pressure from PNS-induced vasorelaxation observed during the corresponding 1st perfusion cycle induced by L-NAME or GA was significantly more pronounced in PVL rats as compared to sham rats ($P < 0.05$). In addition, the magnitude of effect induced by L-NAME and GA was almost identical indicating that the majority of nNOS-mediated vasorelaxation is dependent on HSP-90 signalling.

DISCUSSION

HSP-90 acts as an intermediate in the signalling cascade leading to activation of nNOS^[28,29]. In this study, we examined the role of this protein interaction in mediating neuronal regulation of vascular tone in the mesenteric vascular bed, where vascular resistance contributes to the regulation

of portal pressure. The novel findings of this study include the interaction of HSP-90 and nNOS in mesenteric nerves and the participation of this interaction in regulating vasomotor function in resistance vessels based on inhibition of HSP-90 with GA. Moreover, we demonstrate that after PVL, enhanced HSP-90 signalling contributes to the well-known elevated nNOS-dependent vasorelaxation.

Numerous investigations have presented evidence that nitric nerves are involved in vascular homeostasis^[30,31]. However, mechanisms leading to nNOS-derived NO release from nitric nerve endings are missing. Under physiological conditions, NO production is strictly modulated to accommodate the need of homeostasis because abnormalities of NO formation cause disease^[32,33]. Since NO is highly diffusible and cannot be stored in intracellular compartments modulation of NO production in cells is primarily mediated through regulating NOS activity. Several mechanisms have been revealed in NOS regulation. These include protein-protein interactions, protein phosphorylation, and subcellular targeting^[34]. For example, regulation *via* protein-protein interaction such as HSP-90 and NOS appears particularly important. HSP-90 is one of the most abundant proteins in cells^[35] constituting 1%-2% of total intracellular proteins. As a molecular chaperone, HSP-90 has been shown to regulate more than 100 signal transduction pathways by controlling function, trafficking and turnover of a variety of signalling proteins^[36]. In respect to NOS regulation, HSP-90 was first reported to associate with eNOS acting as an allosteric enhancer^[15]. Subsequent studies with purified nNOS preparations indicated that HSP-90 likewise functions as an allosteric enhancer for nNOS and inhibition of HSP-90 results in the inability to form the dimeric active nNOS^[28]. Coupling of nNOS with HSP-90 is crucial for normal nNOS function^[37]. Here, we report co-localization of HSP-90 and nNOS in mesenteric nerves. In addition, nNOS of mesenteric nerves co-immunoprecipitates with HSP-90 indicating protein-protein interaction in this neuronal tissue. Finally, GA was used to probe the importance of HSP-90 in cellular pathways, since it directly binds to the amino-terminal ATP binding domain of HSP-90^[38] and specifically labels HSP-90 in cellular extracts^[25]. Since NANC-induced vasorelaxation in the mesenteric vasculature is reduced after inhibition of HSP-90 by GA, the hemodynamic functional relevance of the stated protein-protein interaction is demonstrated. To our knowledge, this is the first report to demonstrate a physiological role of HSP-90 for regulation of neuronal control of vascular tone via modulation of nNOS-derived NO release. This is in accordance with previous reports demonstrating that HSP-90 inhibition causes a decrease of NO production in nNOS-transfected cells^[16,39].

Portal hypertension is characterized by decreased systemic and particularly splanchnic vascular resistance which is the initiating mechanism for the development of the hyperdynamic circulatory syndrome in this entity^[40]. Therefore, any measure improving splanchnic vascular resistance is of high hemodynamic and clinical relevance. Vascular overproduction of NO has been shown to be the pathophysiological hallmark leading to this splanchnic vasodilation and to be due to a marked upregulation of

eNOS and nNOS-derived NO synthesis^[4-6,12]. Indeed, either non-specific or nNOS-specific NOS inhibition has been demonstrated to ameliorate the development of the hyperdynamic circulatory syndrome in experimental portal hypertension^[9,18]. In addition, enhanced eNOS and nNOS protein expression as well as an increased vasodilatory response to eNOS and nNOS stimulation has been reported by us and others in the mesenteric vasculature during experimental portal hypertension^[5,12,41]. Beside AKT phosphorylation^[42], a marked contributory role of HSP signalling for eNOS-derived NO overproduction has been reported by us previously^[17]. Here, we show that HSP-90 also largely mediates the enhancement in nNOS-dependent NO release in the mesenteric vasculature of pre-hepatic portal hypertensive rats. This is based on the observation of enhanced HSP-90 expression in mesenteric nerves of portal hypertensive rats and the finding that inhibition of HSP-90 signalling preferentially blocks NANC vasorelaxation in these animals.

Enhanced HSP-90 protein expression has been reported previously in whole mesenteric tissue of portal vein ligated rats^[43]. However, evaluation of HSP-90 expression in mesenteric nerves has not been reported before. Nonetheless, it has been evidenced in cell lines as well as in studies with purified nNOS that HSP-90 directly augments NO synthesis of nNOS in a dose-dependent manner^[16,37,44]. This effect has been attributed mainly to an increase in binding of calmodulin to nNOS mediated by HSP-90^[44]. By this mode of action, most importantly HSP-90 treatment has been shown to increase even the maximal nNOS activity and associated maximal nNOS-dependent NO synthesis achievable^[44]. Therefore, we propose that increased HSP-90 protein expression observed in mesenteric nerves of portal hypertensive rats results in enhanced nNOS-mediated vasorelaxation in the mesenteric vasculature of these animals due to its well-known augmenting effect on the nNOS-machinery. However, neither inhibition of NO nor HSP-90 did completely abrogate NANC vasorelaxation. Remaining vasodilation may well be mediated by other endogenous neurogenic vasodilators such as calcitonin-gene-related peptide or vasoactive-intestinal peptide known to be released from NANC nerves, particularly in rats. Nonetheless, these mediators are not mediating any differences in NANC-vasodilatory responses between the study groups since no significant difference in NANC vasorelaxation remained after NOS inhibition.

In summary, HSP-90 co-localizes with and binds to nNOS in mesenteric nerves playing a key role in nNOS-dependent vasoregulation in the mesenteric vasculature. This interaction serves to mediate the increased nitrgic vasorelaxation observed in the splanchnic circulation during experimental portal hypertension. In conjunction with our previous report on the excessive eNOS-derived NO overproduction depending mainly on HSP-90 signalling this study may provide the rational for pharmacological inhibition of HSP-90 as a novel target for the treatment of the hyperdynamic state in portal hypertension.

COMMENTS

Background

Portal hypertension is the main cause of death in end-stage liver disease leading to multiple complications such as variceal hemorrhage, ascites and hepatorenal syndrome. Vasodilatation in the mesenteric circulation is of essential pathophysiological relevance in portal hypertension and n-nitric oxide synthase (nNOS) has gained much attraction as a vasodilation mediator in other clinical entities recently.

Research frontiers

Heat shock protein-90 (HSP-90) is a molecular chaperone required for the stability and activity of a diverse range of client proteins that have critical roles in signal transduction, cellular trafficking, cell growth, differentiation *etc.* but also vasoregulation. Among NOS it has been shown to be critical for full e- and nNOS activity. However, the role of HSP-90 in respect to neural nNOS-mediated vasoregulation has not been addressed in healthy or in portal hypertensive conditions. The strength of the current investigation relates to the utilization of the McGregor preparation enabling physiological and pharmacological testing of the whole mesenteric vasculature in its original anatomy and innervations. In contrast to arterial strips, this ensures testing of neural vasoregulation at close to *in vivo* conditions.

Innovations and breakthroughs

By this approach, pronounced nNOS-mediated vasodilation is confirmed in pre-hepatic portal hypertension and most strikingly is shown to be in large parts due to HSP-90 signalling. This is also the first time that HSP-90 has been established as a signaling mediator in neural vascular responses in healthy conditions.

Applications

Considering the well-known role of HSP-90 as an eNOS chaperone and enhanced eNOS-derived NO overproduction in portal hypertension, HSP-90 may well be an ideal target in treatment of portal hypertension.

Peer review

This is a good experimental investigation in which authors analyze the role of HSP-90 for neural vasoregulation in the mesenteric circulation in healthy and portal hypertensive conditions. The results are interesting and suggest that HSP-90 indeed is the main signaling intermediate translating into enhanced nNOS-dependent vasodilation during portal hypertension. Therefore, inhibition of HSP-90 could be used to treat portal hypertension.

Abstract

AIM: To study secretion patterns of pro- and anti-inflammatory cytokines, and activation of various cellular subsets of leukocytes in peripheral blood.

METHODS: We have conducted a prospective observational study. One hundred and eight patients with a diagnosis of acute pancreatitis and onset of the disease within last 72 h were included in this study. The mRNA expression of 25 different types of cytokines in white blood cells was determined by quantitative real time polymerase chain reaction. Levels of 8 different cytokines in blood serum were measured by enzyme

linked immunosorbent assay. Clinical data and cytokine expression results were subjected to statistical analysis.

RESULTS: Severe and necrotizing acute pancreatitis (AP) is characterized by the significant depletion of circulating lymphocytes. Severe acute pancreatitis is associated with a typical systemic inflammatory response syndrome and over-expression of pro-inflammatory cytokines [interleukin (IL)-6, IL-8, macrophage migration inhibitory factor (MIF)]. Serum IL-6 and MIF concentrations are the best discriminators of severe and necrotizing AP as well as possible fatal outcome during the early course of the disease.

CONCLUSION: Deregulation of cellular immune system is a key event leading to severe and necrotizing AP. IL-6 and MIF could be used as early predictors of complications.

Different profiles of cytokine expression during mild and severe acute pancreatitis. *World J Gastroenterol* 2010; 16(15): 1845-1853 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i15/1845.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i15.1845>

INTRODUCTION

Incidence of acute pancreatitis (AP) is about 30-40 cases per 100 000 individuals, and it carries an overall mortality

rate of 10%-15%^[1-3]. Mortality of patients with severe acute pancreatitis approaches 30%-40%^[4-6]. Pancreatic necrosis develops early in the course of the disease and usually is well established by 96 h after the onset of clinical symptoms^[7,8]. Both the risk of multiorgan failure (MOF) and infectious complications appear to be related to the degree of pancreatic necrosis^[9]. If patients survive the critical early stages of systemic inflammatory response, development of septic complications is a major determinant of survival. Infected pancreatic necrosis and sepsis-related multiple organ failure account for up to 40%-50% of all deaths among AP patients^[10-13].

At present it is widely accepted that the premature activation of digestive enzymes within pancreatic acinar cells is an initiating event that leads to the autodigestion of pancreas^[14-16]. Once the disease process is initiated, common inflammatory and repair pathways are invoked. There is a local inflammatory reaction at the site of injury; if marked, this leads to a systemic inflammatory response syndrome (SIRS). An imbalance between the early SIRS, and the later compensatory counter-inflammatory response (CARS), and development of MOF are considered to be the primary causes of morbidity and mortality in severe acute pancreatitis. Excessive leukocyte activation (including neutrophils and monocyte-macrophage lineage) with cytokinemia plays a critical role in the pathogenesis of pancreatitis and even more so, of the subsequent inflammatory response^[14-17]. It has been hypothesized that fatal pancreatitis is a consequence of abnormal phagocytic leukocyte hyperstimulation due to deregulation in T- and B-lymphocyte activation. However, the role of lymphocyte activation and its relation to the severity of disease in humans is still poorly understood^[18-21]. Another important drawback, in our opinion, is that the majority of information about the alterations of the immune system during the AP comes from *in vitro* and *in vivo* studies, and therefore it is not always directly applicable and relevant to the clinical situation in human acute pancreatitis.

Several methods for estimating severity of acute pancreatitis are widely used today and include APACHE II, Imrie and Ranson scores, the CT scoring system, and measurement of C-reactive protein and a number of laboratory markers^[22-28]. Most of these multifactorial scores and laboratory tests are very good at identifying the critical situation, when MOF or local complication supervene, however, none can accurately predict the disease severity, development of pancreatic necrosis and/or possible fatal outcome during the first hours of hospitalization.

Thus, the aims of this study have been to investigate the secretion patterns of pro- and anti-inflammatory cytokines, and to estimate the activation of various cellular subsets of leukocytes (including lymphocytes, neutrophils, and monocyte-macrophage lineage) in peripheral blood of patients with severe and mild AP. Another goal of this study was to identify the serum soluble molecules that are associated with the development of severe acute pancreatitis, and which could be used as early markers to assess the local (pancreatic necrosis) and systemic complications (SIRS, MOF) later in the course of the disease.

MATERIALS AND METHODS

Study design and patient population

We have conducted a prospective observational study in the period between June 2005 and December 2007. All patients admitted to the Department of Surgery at Kaunas University of Medicine Hospital (Lithuania) with a diagnosis of acute pancreatitis and onset of the disease within last 72 h were included in this study ($n = 108$). The Regional Ethics Committee approved the study (protocols No. BE-2-47 and P1-113/2005) and all the patients provided written informed consent.

The diagnosis was established on the basis of acute abdominal pain, at least 3-fold elevated levels of serum amylase and typical radiological findings. A contrast-enhanced CT scan was performed on days 4 to 7 after onset of the disease to demonstrate the presence of pancreatic necrosis. According to the clinical course and clinical severity scores (APACHE II > 7; Imrie-Glasgow > 2; MODS > 2), patients were stratified into mild and severe acute pancreatitis groups. Clinical data relating to the severity of disease, development of organ dysfunction and/or septic complications were prospectively collected in a standardized fashion. Patients with underlying chronic pancreatitis and patients with acute pancreatitis referred to our hospital from other institutions after management for more than 3 d were excluded from this study. Age- and sex-matched healthy subjects ($n = 18$) without previous medical history were enrolled as controls.

Peripheral blood samples from patients were drawn on admission to the hospital and, after centrifugation, samples were stored at -80°C until analysis. The blood samples of control group underwent a similar process. Blood sample analysis was uniformly performed at the Laboratory for Molecular Research of Pancreas, Department of Surgery, Heidelberg University (Germany). The mRNA expression of 25 different types of cytokines in white blood cells (WBCs) was determined by quantitative real time polymerase chain reaction (QRT-PCR). Levels of 8 different cytokines in blood serum were measured by enzyme linked immunosorbent assay (ELISA) according to the manufacturer's instructions (Sigma-Aldrich GmbH, Steinheim, Germany).

Statistical analysis

Clinical data and cytokine expression results were used for statistical analysis. Statistical analysis was performed using SPSS® for Windows release 14.0 (SPSS, Chicago, Illinois, USA). Discriminant function analysis was used to determine differences between the groups. The diagnostic performance of a test, with a particular cut-off value, was established using Receiver Operating Characteristic (ROC) curve analysis. The data are presented as mean \pm SE or median. For comparison between groups, the Mann-Whitney test or Student's *t* test were employed where appropriate. Results with $P < 0.05$ were considered statistically significant.

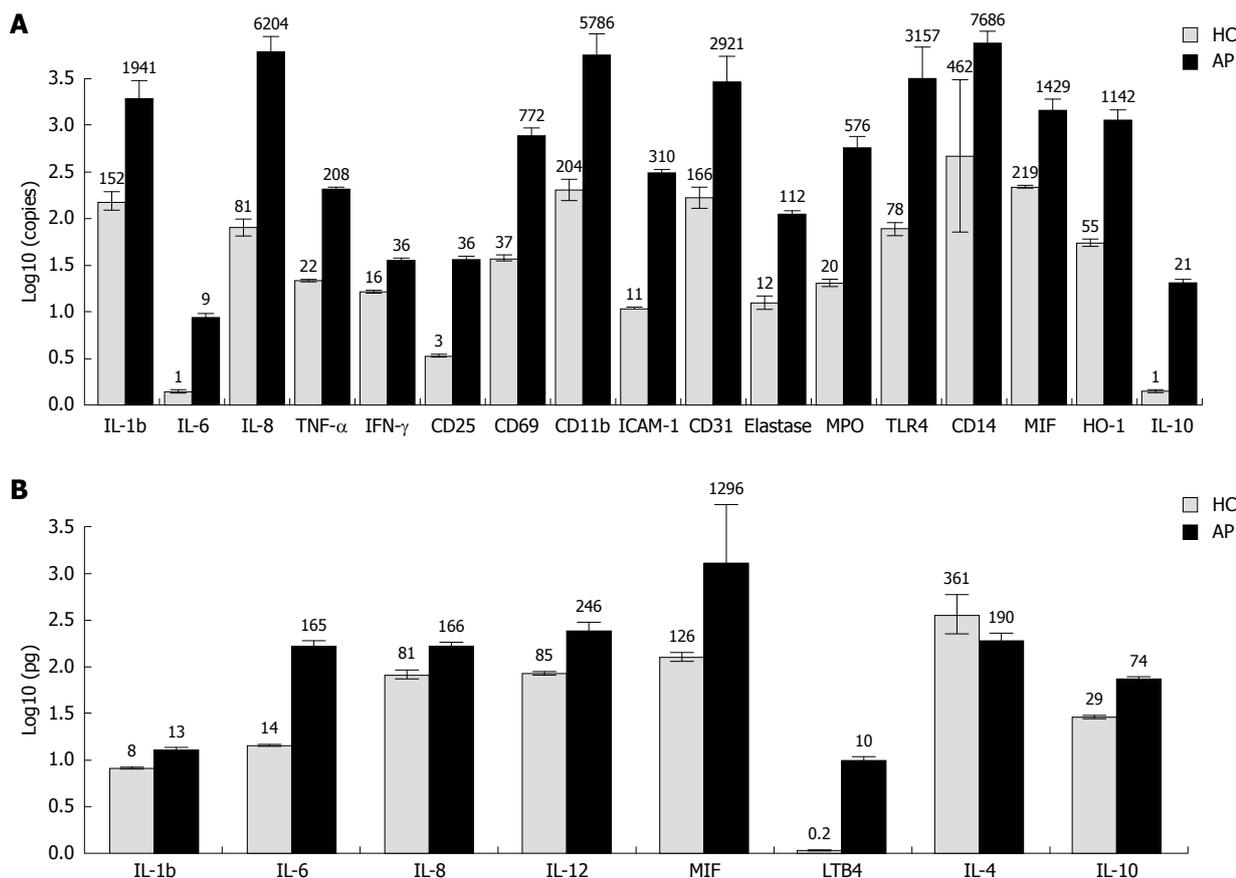

Figure 1 Cytokine expression at mRNA and protein level in peripheral blood of healthy subjects and acute pancreatitis (AP) patients. **A:** Gene expression in peripheral blood leukocytes of healthy subjects and AP patients. Gene expression at mRNA level of 25 different cytokines, adhesion molecules, lymphocyte activation markers, and other biologically active substances known to be linked to the inflammatory response were assessed by quantitative real time polymerase chain reaction (QRT-PCR) in peripheral blood leukocytes of AP patients and healthy controls. A median 18-fold (range: 2-77) increase in mRNA expression of pro-inflammatory molecules was observed in the AP group in comparison to healthy control subjects (HC). Activation of the anti-inflammatory system and some cytoprotective molecules was also notable in the AP patient group. Cytokine mRNA expression levels with statistically significant differences between AP and healthy control groups are shown; **B:** Cytokine concentration in blood serum of healthy controls and AP patients. Expression of eight different soluble molecules at protein level was assessed in serum of AP patients and healthy subjects using the enzyme linked immunosorbent assay (ELISA) method. A median 3-fold (range: 2-59) increase in protein expression of pro-inflammatory molecules was observed in the AP group when compared to HC. Cytokine expression levels with statistically significant differences between AP and healthy control groups are shown. IL: Interleukin; TNF- α : Tumor necrosis factor- α ; IFN- γ : Interferon- γ ; MPO: Myeloperoxidase; MIF: Macrophage migration inhibitory factor.

RESULTS

One hundred and eight patients (55 male and 53 female, mean age 54.1 ± 16.7 years) diagnosed with AP were included in the study. The main etiological factors of AP were alcohol (42.6%), high-fat diet (25.9%) and biliary stones (25.0%). Idiopathic pancreatitis was diagnosed in 7 cases (6.5%). Severe acute pancreatitis (APACHE II > 7) comprised 44.4% of all cases. Necrotizing AP was detected by contrast-enhanced CT in 52 patients (48.1%), and high volume (> 30%) necrosis was present in 34 cases (31.3%). Multiple organ failure (> 2 systems) developed in 18 cases (16.7%). Overall mortality in our follow-up group was 12.9%; 9 patients (8.3%) died within first 2 wk of the disease and 5 patients (4.6%) later in the course of the disease. Eighteen healthy subjects (10 male and 8 female, mean age 40.1 ± 19.8 years) were studied as controls.

Gene expression at mRNA level of 25 different cytokines, adhesion molecules, lymphocyte activation markers, and other molecules known to be linked to the inflammatory response were assessed in peripheral blood

leukocytes of AP patients and healthy controls. Results showed a typical pro-inflammatory cytokine profile in AP patients with an activation of different subsets of leukocytes (lymphocytes, monocyte-macrophage lineage and neutrophils). Activation of anti-inflammatory system and some cytoprotective molecules was also notable in the AP patient group (Figure 1A). A median 18-fold (range: 2-77) increase in mRNA expression of pro-inflammatory molecules was observed in the AP group in comparison to healthy controls. Expression of eight different soluble molecules at protein level was also assessed in peripheral blood serum of AP patients and healthy subjects using the ELISA method. Analysis revealed a typical over-expression of pro-inflammatory cytokines and altered expression of anti-inflammatory cytokines in AP patients compared to the healthy volunteers (Figure 1B). A median 3-fold (range: 2-59) increase in protein expression of pro-inflammatory molecules was observed in the AP group in comparison to healthy controls. Since many of these changes have been shown in other animal and clinical studies, this served as a

Table 1 Differences in clinical course of mild and severe acute pancreatitis (mean ± SD/count)

Clinical severity scores and patient characteristics	Mild AP	Severe AP	P
Apache II (score)	3.6 ± 1.9	11.6 ± 4.7	< 0.01
Imrie-Glasgow (score)	2.2 ± 1.2	4.4 ± 1.5	< 0.01
MODS (score)	1.1 ± 1.3	4.3 ± 3.4	< 0.01
Necrotizing AP (count)	16	36	< 0.01
C-reactive protein (mg/L)	91.8 ± 18.7	152.9 ± 21.5	< 0.01
Necrosis volume > 30% (count)	8	26	< 0.01
Infectious complications (count) ¹	2	12	< 0.01
Presence of MOF (count)	0	18	< 0.01
Need for surgery (count) ²	1	5	0.06
ICU stay (d)	1.0 ± 1.0	9.0 ± 2.0	< 0.05
Total hospital stay (d)	12.0 ± 1.0	19.0 ± 3.0	< 0.05
Number of early deaths (< 2 wk)	0	9	< 0.01
Number of late deaths (> 2 wk)	0	5	< 0.01

¹Infectious complications: proven sepsis, infected pancreatic necrosis, lung and urinary infection; ²Need for surgery: fasciotomy for intraabdominal compartment syndrome and/or necrosectomy. AP: Acute pancreatitis; MOF: Multiple organ failure; ICU: Intensive care unit.

control and proved that our methods function well.

For the next step of statistical analysis, AP patients were stratified into groups according to the severity of the disease based on presence of systemic (development of MOF) and local (pancreatic necrosis > 30%) complications, since these are the factors know to be associated with a poor outcome. Groups were formed on the basis of radiological findings on contrast-enhanced CT and APACHE II clinical score, where all patients with score > 7 were ascribed to the severe acute pancreatitis (SAP) group. Both SAP and necrotizing AP were associated with higher incidence of MOF, higher mortality and prolonged ICU and overall hospital stay. Whereas mild AP patients showed 0% mortality, overall mortality rate among SAP patients was 27% (*P* < 0.01) and early mortality (during first two weeks from the onset of the disease) was 64% (*P* < 0.01). In the necrotizing AP group overall mortality rate was 25% (*P* < 0.01), and early mortality was 62% (*P* < 0.01), compared to the 1.8% mortality rate seen in the edematous pancreatitis group. The main differences in clinical course and outcome of patients with mild and severe disease are revealed in Table 1. Interestingly, both severe and necrotizing AP were associated with a significant reduction in number of circulating blood lymphocytes, although there was no statistically significant difference in total WBC count (Figure 2). The mean WBC count in the SAP group was $14.76 \pm 0.95 \times 10^9/L$ compared to $13.92 \pm 0.62 \times 10^9/L$ in the mild AP group (n.s.). The mean WBC count in the necrotizing AP group was $14.38 \pm 0.91 \times 10^9/L$ compared to $14.27 \pm 0.75 \times 10^9/L$ in the edematous AP group (n.s.). However, the number of circulating lymphocytes in peripheral blood was reduced by 25% in the SAP compared to the mild AP group (*P* < 0.05), and by 17% in the necrotizing AP group compared to the edematous AP group (*P* < 0.05). Based on the significance and clinical relevance of these findings we investigated the presence of possible common molecular pathways leading to development of severe and necrotizing AP.

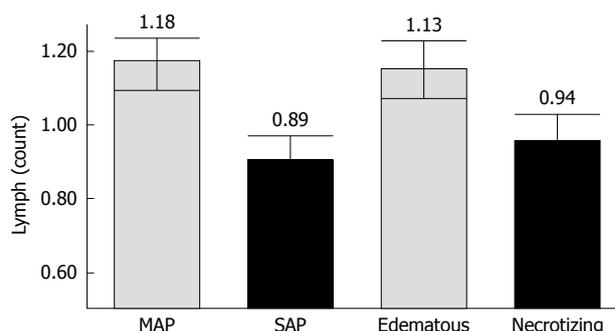

Figure 2 Reduction in number of lymphocytes during severe and necrotizing AP. Number of circulating lymphocytes in peripheral blood was significantly reduced in severe acute pancreatitis (SAP) compared to mild AP groups ($0.89 \pm 0.08 \times 10^9/L$ vs $1.18 \pm 0.07 \times 10^9/L$, *P* < 0.05), and in necrotizing compared to edematous pancreatitis groups ($0.94 \pm 0.08 \times 10^9/L$ vs $1.13 \pm 0.08 \times 10^9/L$, *P* < 0.05). These findings demonstrate the presence of possible common molecular pathways leading to the development of severe and necrotizing AP.

QRT-PCR analysis of cytokine mRNA expression levels in patients with severe and mild disease revealed some conflicting results (Figure 3A). Firstly, study showed that SAP is characterized by decreased intracellular mRNA levels of interleukin (IL)-1 and interferon- γ (IFN- γ). Secondly, SAP was also associated with a marked decrease in the levels of CD25 and CD69 mRNA in peripheral blood leukocytes. However, severe and necrotizing pancreatitis was associated with a very high activation of neutrophils and macrophages as demonstrated by nearly ten-fold higher mRNA expression of elastase and myeloperoxidase in peripheral WBCs. Another quite unexpected result showed a significantly lower mRNA expression of ICAM-1 and macrophage migration inhibitory factor (MIF) in peripheral WBCs (but not in the blood serum) from patients with SAP compared to that of mild AP patients. Analysis of cytokine protein expression levels showed that SAP was associated with a typical SIRS and 2-5 fold increase in expression of pro-inflammatory cytokines (IL-6, IL-8, MIF), as well as induction of compensatory and regulatory mechanism (IL-10) (Figure 3B). Enormously high levels of leukotriene B4 (LTB4) associated with neutrophil activation and injury to the vital organs were recorded in patients who died during the early stages of the disease.

Another important issue is whether the serum soluble molecules could be used as accurate early markers to predict the development of local (pancreatic necrosis) and systemic complications (SIRS, MOF) later in the course of the disease. Discrimination function analysis was used to determine differences between the groups of patients with mild and severe AP, edematous and necrotizing AP, and between survivors and those with fatal outcome. We included five variables (IL-6, IL-8, IL-10, MIF and LTB4) in a study in order to find out which serum markers are the best discriminators of the above mentioned groups. At each step, the variable that minimized the overall Wilks' Lambda was entered into the discriminant model thus revealing that IL-6 and MIF values were significant discriminators between groups of patients with mild and severe disease, as well as between survivors and non-survivors.

Table 2 Serum IL-6 and MIF are significant discriminators between groups of AP patients

Step	Entered	Wilks' Lambda							
		Statistic	df1	df2	df3	Exact F			
						Statistic	df1	df2	P
Severe vs mild									
1	IL-6	0.739	1	1	70.000	24.696	1	70.000	0.000
2	MIF	0.675	2	1	70.000	16.635	2	69.000	0.000
Edematous vs necrotizing									
1	IL-6	0.851	1	1	70.000	12.261	1	70.000	0.001
2	MIF ¹	0.943	1	1	70.000	4.247	1	70.000	0.043
Survivors vs non-survivors									
1	IL-6	0.761	1	1	70.000	22.005	1	70.000	0.000
2	MIF	0.709	2	1	70.000	14.153	2	69.000	0.000

¹Not included in the original model using the standard stepwise method due to its low discrimination value. At each step, the variable that minimizes the overall Wilks' Lambda is entered. IL-6: Interleukin-6; MIF: Macrophage migration inhibitory factor.

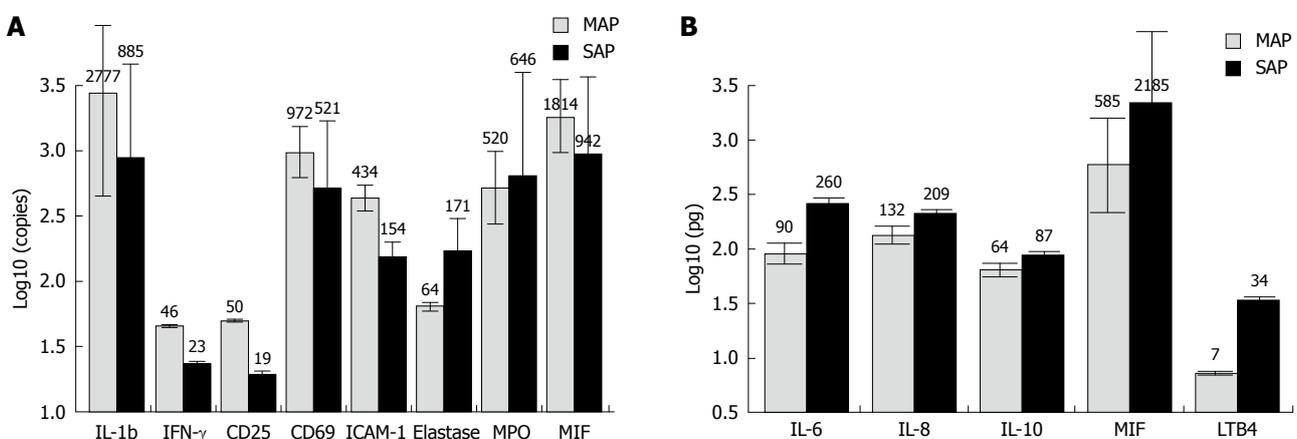

Figure 3 Cytokine expression at mRNA and protein level in peripheral blood of patients with mild and severe AP. A: Gene expression in peripheral blood leukocytes of MAP and SAP patients. QRT-PCR analysis revealed that SAP is characterized by significantly decreased intracellular mRNA levels of interleukin (IL)-1 and interferon (IFN)-γ. SAP is also associated with markedly lower mRNA expression levels of CD25 and CD69 in peripheral blood leukocytes. However, severe and necrotizing pancreatitis was associated with a very high activation of neutrophils and macrophages as demonstrated by nearly ten-fold higher mRNA expression of elastase and myeloperoxidase in peripheral white blood cells (WBCs). A significantly lower mRNA expression of ICAM-1 and macrophage migration inhibitory factor (MIF) was observed in peripheral WBCs (but not in the blood serum) from patients with SAP compared to that of MAP group. Cytokine mRNA expression levels with statistically significant differences between MAP and SAP groups are depicted; B: Cytokine concentration in blood serum of MAP and SAP patients. Analysis of cytokine expression at protein levels shows that SAP is associated with a typical systemic inflammatory response syndrome (SIRS) and 2-5 fold increase in expression of pro-inflammatory cytokines (IL-6, IL-8, MIF). Induction of a compensatory and regulatory mechanism (IL-10) is also observed in this group. Up to 4-5 fold higher levels of LTB4 were recorded in patients who died during the early stages of the disease. Cytokine expression levels with statistically significant differences between AP and healthy control groups are shown.

Statistical analysis revealed that IL-6 values differed significantly in groups of patients with and without pancreatic necrosis (Table 2). A particular cut-off value for IL-6 and MIF was established using Receiver Operating Characteristic (ROC) curve analysis to practically discriminate cases with severe, necrotizing and fatal acute pancreatitis (Figure 4A and B). Comparison of ROC curves for IL-6 and MIF showed no significant differences in diagnostic performance of these two routine tests, except for the discrimination of edematous and necrotizing pancreatitis where IL-6 proved to be of superior value.

DISCUSSION

Alteration of the immune system is one of the major mechanisms responsible for early and late mortality in severe AP. Excessive inflammatory reaction, known as

systemic inflammatory response syndrome (SIRS), is considered as the leading cause of death in early AP^[14,19,20,29]. The role of lymphocytes in this phenomenon has been partly studied and the knowledge of the mechanisms in humans is still incomplete^[20,30-35]. In agreement with previous studies, we found a significant depletion of circulating lymphocytes which was much more profound in the severe and necrotizing forms of pancreatitis^[20,30-35]. In our study, significant activation of lymphocytes was observed in the case of AP compared to healthy controls, as shown by strong expression of CD69 and CD25. The surface receptors CD69 and CD25 (IL-2 receptor) are early markers of lymphocyte activation. Increased expression of CD69 as well as of CD25 on CD3+, CD4+ and CD8+ cells have recently been reported in mild AP. It has also been suggested that the number of B-lymphocytes (CD19+) expressing CD69 was significantly lower in patients with

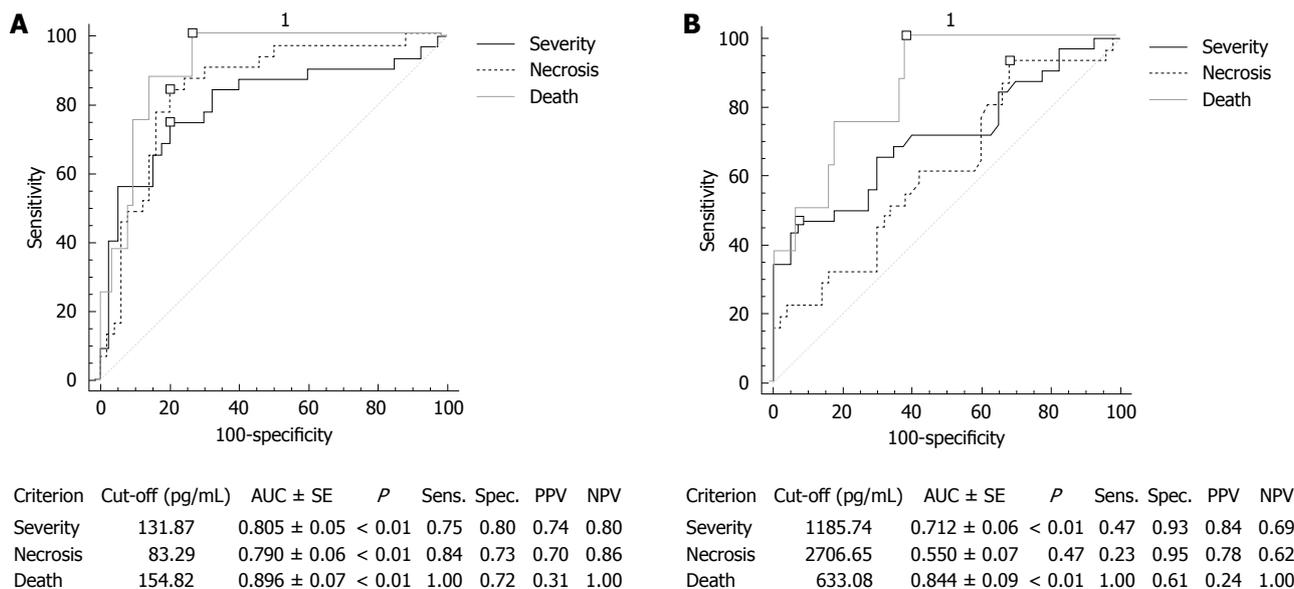

Figure 4 Prognostic utility of IL-6 and MIF in diagnosis of severe, necrotizing and fatal AP. A: Performance of serum IL-6 in diagnosis of severe, necrotizing and fatal AP. The diagnostic performance of a test for discriminating severe, necrotizing and fatal cases of AP was evaluated using Receiver Operating Characteristic (ROC) curve analysis. Study revealed that serum IL-6 concentration is a good predictor of the severe disease and systemic complications (SIRS, MOF); this marker could also be utilized for the stratification of patients with necrotizing AP and those with possible fatal outcome; B: Performance of serum MIF in diagnosis of severe, necrotizing and fatal AP. The diagnostic performance of a test for discriminating severe, necrotizing and fatal cases of AP was evaluated using ROC curve analysis. Study revealed that serum MIF concentration is a good predictor of the severe disease and systemic complications (SIRS, MOF); this marker could be used for early identification of patients with possible fatal outcome. Comparison of ROC curves for IL-6 and MIF showed no statistically significant differences in this respect ($P = 0.18$ for severity; $P = 0.58$ for mortality). However, serum MIF concentration has very poor prognostic value in predicting the development of pancreatic necrosis and is inferior to IL-6 serum concentration in this respect ($P < 0.01$). AUC: Area under curve; Sens.: Sensitivity; Spec.: Specificity; PPV: Positive predictive value; NPV: Negative predictive value.

severe pancreatitis than in patients with mild pancreatitis^[20,31,32]. We have also observed a significantly lower expression of both CD69 and CD25 surface receptors in peripheral blood leukocytes from SAP patients. Marked activation of different subsets of lymphocytes may explain why we have observed strong elevation of different cytokines in peripheral blood, despite a significant decrease in the number of circulating lymphocytes. One of the possible reasons for the decreased number of circulating lymphocytes is strong migration of activated cells to the sites of inflammation, including the pancreas and other tissues such as lungs or kidneys, as an element of SIRS^[16,20,36]. Another possible explanation is an excessive elimination of lymphocytes by apoptosis. Interestingly, the available data indicate that lymphopenia caused by the decrease of different lymphocyte subpopulations is also characteristic for other diseases with severe tissue damage, e.g. critical injury, sepsis and acute severe respiratory syndrome (ARDS)^[37-40].

Polymorphonuclear leukocytes, monocytes, tissue macrophages, lymphocytes, natural killer cells, and parenchymal cells are involved in a complex network of the host defense response in the case of tissue damage caused by severe AP, burns, accident trauma, major surgical interventions or sepsis^[20,39,41,42]. An overwhelming pro-inflammatory response (hyperinflammation) leads to the clinical manifestations of SIRS and finally to host defence failure expressed by multiple organ failure (MOF). The up-regulation of pro-inflammatory factors, such as TNF, IL-1 and IL-6, observed during the SIRS phase can be followed by

a second response that involves down-regulation of IFN- γ and increase in anti-inflammatory cytokines, such as IL-10 and transforming growth factor- β . This counter regulatory phenomenon is called the compensatory anti-inflammatory response syndrome (CARS)^[17,20,39]. However, this can result in the development of immunosuppression and is often associated with elevation of IL-10 and the shift of the Th1/Th2 balance towards a Th2 response^[17,20,39,42]. The network of various cytokines and other molecules participating in the regulation of the inflammatory processes is indeed very complex, and the precise timing of the release and activation of these mediators is not well known. Nevertheless, our study also shows that both SIRS and CARS occur in a real clinical situation and at a certain stage of the disease might even develop simultaneously. However, in the case of severe AP, the counter-regulatory mechanisms may lead to the dysfunction of immune cells mainly due to the significant decrease in total systemic lymphocyte count and the hyper-production of IL-10, which might suggest that T regulatory 1 cells (Tr1) are especially active in the course of severe disease^[43].

Involvement of other cellular subsets of leukocytes, mainly neutrophils and monocyte-macrophage lineage, in the development of SAP is also readily supported by our study. Neutrophils exert their toxicity by releasing myeloperoxidase (MPO), proteases such as elastase and reactive oxygen species (ROS) such as H₂O₂^[36]. In our study we have observed a very high mRNA expression of MPO and polymorphonuclear leukocyte elastase in cases of severe and necrotizing pancreatitis. Increased production

of platelet activating factor (PAF) and LTB4 is also closely associated with an activation of monocytes and neutrophils, and increased migration of neutrophils to pancreas and other target organs, including lungs and kidneys^[36,44,45]. We have also recorded noticeably higher levels of serum LTB4 in patients suffering from severe and fatal acute pancreatitis. Furthermore, patients with severe and necrotizing AP exerted very high serum levels of MIF. MIF is predominantly released by monocytes, macrophages and Th2 T-cell clones; it is associated with activation of immune cells and release of pro-inflammatory cytokines overriding glucocorticoid action at the site of inflammation. It is also known to be associated with a lung injury during SIRS through counter-regulation of the effect of glucocorticoids and through up-regulation of macrophage inflammatory protein-2, which itself serves as a potent chemo-attractant to the neutrophils^[46-49].

The infiltration of inflammatory cells into the pancreas is an early and central event in acute pancreatitis that promotes local injury and systemic complications of the disease. Recent research has yielded the important finding that resident cells of the pancreas (particularly acinar and pancreatic stellate cells) play an important role in leukocyte attraction *via* secretion of chemokines, cytokines and expression of adhesion molecules^[36,50-53]. We believe this could at least partially explain the occurrence of systemic lymphopenia, lower CD25, CD69 and ICAM-1 mRNA expression in cases of SAP. Activation of inflammatory cells and release of cytokines into the systemic bloodstream at the site of injury is possibly also an explanation for the discrepancy of low MIF mRNA expression in peripheral WBCs in association with high serum concentration of MIF in the case of severe and necrotizing pancreatitis.

Having identified the inflammatory mediators that are significantly up-regulated in serum of patients with severe and necrotizing AP (IL-6, IL-8, IL-10, MIF and LTB4) in comparison to those with mild disease, we have also evaluated the prognostic utility of these molecules in predicting the negative outcome of the disease. In accordance with the findings of other studies we have confirmed that both serum IL-6 and MIF concentrations are very good discriminators of severe AP accompanied by MOF, and could be used as early markers of possible fatal outcome. However, in contrast to the recent study of Rahman *et al.*^[54], we failed to demonstrate that MIF is an early specific prognostic marker for the development of pancreatic necrosis. In our experience, serum IL-6 concentration was superior in this respect^[28,55-57]. Nonetheless, serum MIF concentration may serve as an important prognostic marker that could identify patients likely to benefit from aggressive medical treatment and early transfer to specialist pancreatic units. At the molecular level, targeted disruption of these proteins with monoclonal antibodies may afford some therapeutic benefit in preventing the development of MOF, pancreatic necrosis, and septic complications.

Deregulation of the cellular immune system is a key event leading to the development of severe and necrotiz-

ing AP. Severe and necrotizing AP is characterized by the significant depletion of circulating lymphocytes in the bloodstream as a result of increased migration of these cells to the site of injury and other vital organs, including lungs and kidneys. Infiltration of pancreas and other peripheral organs by aberrantly activated inflammatory cells occurs within the first hours after onset of acute pancreatitis and leads to the development of SIRS and MOF. This whole process is regulated by a large number of cytokines and is an extremely complex network of intercellular interaction. It is clear that detailed elucidation of the numerous processes in the inflammatory cascade is an essential step towards the development of improved therapeutic strategies in acute pancreatitis. Published studies suggest that combination therapy targeting different steps of the inflammatory cascade may be the treatment of choice for this disease.

Data from other authors and from our current study demonstrate that serum IL-6 and MIF concentrations are very good discriminators of severe and necrotizing AP as well as of possible fatal outcome during the first hours and days after the onset of the disease. Therefore, these molecules could be used as markers for patient stratification and/or predicting the outcomes of AP in the early stages of the disease. However, their true prognostic utility, clinical and health care resource implications need to be further evaluated in a larger patient population and in the context of other currently existing diagnostic markers and indices.

COMMENTS

Background

Mortality of patients with severe acute pancreatitis (SAP) approaches 30%-40%. An imbalance between the early systemic inflammatory response syndrome (SIRS), and the later compensatory counter-inflammatory response, and development of multiple organ failure (MOF) are considered to be the primary causes of morbidity and mortality in SAP. Excessive leukocyte activation (including neutrophils and monocyte-macrophage lineage) with cytokinemia play a critical role in the pathogenesis of pancreatitis and even more so, of the subsequent inflammatory response. Thus, the aims of this study have been to investigate the secretion patterns of pro- and anti-inflammatory cytokines, and to estimate the activation of various cellular subsets of leukocytes (including lymphocytes, neutrophils, and monocyte-macrophage lineage) in peripheral blood of patients with severe and mild AP.

Research frontiers

It has been hypothesized that fatal pancreatitis is a consequence of abnormal phagocytic leukocyte hyperstimulation due to deregulation in T- and B-lymphocyte activation. However, the role of lymphocyte activation and its relation to the severity of disease in humans is still poorly understood. Another important drawback is that the majority of information about the alterations of the immune system during the AP comes from *in vitro* and *in vivo* studies, and therefore is not always directly applicable and relevant to the clinical situation in human AP.

Innovations and breakthroughs

This study by Dambrauskas *et al* confirms that human severe and necrotizing AP is characterized by the significant depletion of circulating lymphocytes. SAP is associated with a severe systemic inflammatory response syndrome (SIRS) and over-expression of pro-inflammatory cytokines [interleukin (IL)-6, IL-8, macrophage migration inhibitory factor (MIF)]. The study demonstrates that serum IL-6 and MIF concentrations are the best discriminators of severe and necrotizing AP as well as possible fatal outcome during the early course of the disease. These cytokines could also be used as early predictors of local (pancreatic necrosis) and systemic complications (SIRS, MOF) later in the course of the disease. Deregulation of the cellular immune system is a key event leading to

the development of severe and necrotizing AP. Infiltration of peripheral organs by aberrantly activated inflammatory cells leads to the development of MOF.

Applications

Data from other authors and from the authors' current study demonstrate that serum IL-6 and MIF concentrations are very good discriminators of severe and necrotizing AP as well as possible fatal outcome during the first hours and days after the onset of the disease. Therefore, these molecules could be used as markers for patient stratification and/or predicting the outcome of AP in the early stages of the disease.

Terminology

Pancreatitis is a condition associated with development of acute and sudden inflammation of the pancreas. In about 85% of patients, acute pancreatitis is a mild disease and is usually associated with a rapid recovery within a few days of onset of the illness. However, in 15%-20% of patients with acute pancreatitis, severe damage to the pancreas may lead to a life threatening illness that is often associated with prolonged hospitalization, multiple surgical procedures, development of multiple organ failure, severe infective complications, and death in some patients.

Peer review

This prospective observational study seeks to characterise the cytokine expression profiles (at mRNA and protein levels) of patients with acute pancreatitis and to correlate the profiles with disease severity.

Abstract

AIM: To develop a molecular therapy for pancreatic cancer, the insulin-like growth factor-I (IGF-I) signaling pathway was analyzed.

METHODS: Pancreatic cancer cell lines (MIA-Paca2, NOR-P1, PANC-1, PK-45H, PK-1, PK-59 and KP-4) were cultured in media with 10 mL/L fetal bovine serum. Western blotting analysis was performed to clarify the expression of IGF-I receptor (IGF-IR). Picropodophyllin (PPP), a specific inhibitor of IGF-IR, LY294002, a specific inhibitor of phosphatidylinositol

3 kinase (PI3K), and PD98059, a specific inhibitor of mitogen-activated protein kinase, were added to the media. After 72 h, a 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium inner salt (MTS) assay was performed to analyze cell proliferation. A wound assay was performed to analyze cell motility with hematoxylin and eosin (HE) staining 48 h after addition of each inhibitor.

RESULTS: All cell lines clearly expressed not only IGF-IR but also phosphorylated IGF-IR. PPP significantly suppressed proliferation of MIA-Paca2, NOR-P1, PANC-1, PK-45H, PK-1, PK-59 and KP-4 cells to $36.9\% \pm 2.4\%$ (mean \pm SD), $30.9\% \pm 5.5\%$, $23.8\% \pm 3.9\%$, $37.1\% \pm 5.3\%$, $10.4\% \pm 4.5\%$, $52.5\% \pm 4.5\%$ and $22.6\% \pm 0.4\%$, at 2 $\mu\text{mol/L}$, respectively ($P < 0.05$). LY294002 significantly suppressed proliferation of MIA-Paca2, NOR-P1, PANC-1, PK-45H, PK-1, PK-59 and KP-4 cells to $44.4\% \pm 7.6\%$, $32.9\% \pm 8.2\%$, $53.9\% \pm 8.0\%$, $52.8\% \pm 4.0\%$, $32.3\% \pm 4.2\%$, $51.8\% \pm 4.5\%$, and $30.6\% \pm 9.4\%$, at 50 $\mu\text{mol/L}$, respectively ($P < 0.05$). PD98059 did not significantly suppress cell proliferation. PPP at 2 $\mu\text{mol/L}$ suppressed motility of MIA-Paca2, NOR-P1, PANC-1, PK-45H, PK-1, PK-59 and KP-4 cells to $3.0\% \pm 0.2\%$, 0% , 0% , $2.0\% \pm 0.1\%$, $5.0\% \pm 0.2\%$, $3.0\% \pm 0.1\%$, and $5.0\% \pm 0.2\%$, respectively ($P < 0.05$). LY294002 at 50 $\mu\text{mol/L}$ suppressed motility of MIA-Paca2, NOR-P1, PANC-1, PK-45H, PK-1, PK-59 and KP-4 to $3.0\% \pm 0.2\%$, 0% , $3.0\% \pm 0.2\%$, 0% , 0% , 0% and $3\% \pm 0.1\%$, respectively ($P < 0.05$). PD98059 at 20 $\mu\text{mol/L}$ did not suppress motility. Cells were observed by microscopy to analyze the morphological changes induced by the inhibitors. Cells in medium treated with 2 $\mu\text{mol/L}$ PPP or 50 $\mu\text{mol/L}$ LY294002 had pyknotic nuclei, whereas those in medium with 20 $\mu\text{mol/L}$ PD98059 did not show apoptosis.

CONCLUSION: IGF-IR and PI3K are good candidates for molecular therapy of pancreatic cancer.

INTRODUCTION

Molecular alterations of pancreatic cancer need to be clarified to develop molecular therapy. Growth factors transmit signals to stimulate tumor growth and enhance metastasis. Insulin-like growth factor (IGF)-I signaling plays an important role in the growth and development of many tissues^[1]. IGF-I signaling is also thought to be involved in tumorigenesis. Upon ligand binding, the tyrosine kinase of IGF-I receptor (IGF-IR) is activated, and results in autophosphorylation of tyrosine^[2]. This initiates a phosphorylation cascade to the phosphatidylinositol-3 kinase (PI3K) and mitogen-activated protein kinase (MAPK) pathways.

IGF-I is upregulated in human pancreatic cancer tissues but is not expressed in surrounding non-cancerous tissue^[3]. Serum level of IGF-I is elevated in pancreatic cancer patients^[4]. Histological analysis has shown that IGF-IR is positive in the membrane of cells of pancreatic cancer tissues but is not expressed in surrounding non-tumorous tissues^[3,5]. These facts imply that IGF-I acts as a growth factor for pancreatic cancer. IGF-IR is phosphorylated solely in pancreatic cancer tissues, and not in surrounding non-tumorous tissues^[6]. The present study suggests that IGF-IR transmits signals to downstream pathways. This hypothesis is supported by the facts that IGF-I stimulates DNA synthesis of PANC-1 and MIA Paca2 pancreatic cancer cell lines, and motility of HPAF-II, another pancreatic cancer cell line^[7,8].

IGF-IR is not involved in metabolism, therefore, it was expected that inhibition of IGF-IR and its downstream pathway would not cause any adverse effects^[1]. We therefore focused on the IGF-IR signaling pathway. Pancreatic cancer tissues express growth factors other than IGF-I^[9]. We used fetal bovine serum (FBS) as a growth model of pancreatic cancer cells instead of addition of IGF-I in serum-free medium, because pancreatic cancer tissues and serum from patients contain various growth factors.

MATERIALS AND METHODS

Culture and reagents

Pancreatic cancer cell lines, PANC-1, NOR-P1, PK-45H,

PK-1, PK-59, and MIA-Paca2 were purchased from RIKEN Cell Bank (Tsukuba, Japan)^[10]. NOR-P1 was cultured in Dulbecco's Minimum Essential Medium (DMEM): F12 medium and MIA-Paca2 was cultured in DMEM, and the others in Roswell Park Memorial Institute (RPMI)-1640 (Sigma, St. Louis, MO, USA). All the media were purchased from Sigma, and supplemented with 100 mL/L FBS (Trace Scientific, Melbourne, Australia). All the cell lines were cultured in 50 mL/L carbon dioxide at 37°C in a humidified chamber. LY294002, a specific inhibitor of PI3K, and PD98059, a specific inhibitor of MAPK, were purchased from Wako Pure Chemicals (Osaka, Japan), and picropodophyllin (PPP), a specific inhibitor of IGF-IR, was from Calbiochem (Darmstadt, Germany)^[11].

Western blotting analysis

Protein was isolated from cells after 72 h culture. Twenty micrograms of protein was subjected to sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE), and transferred to a nylon filter. Primary antibodies were polyclonal rabbit anti-IGF-IR antibody, anti-phosphorylated IGF-IR (Cell Signaling Technology, Danvers, MA, USA), and mouse monoclonal anti-tubulin- α antibody (Lab Vision, Fremont, CA, USA). Second antibodies were horseradish peroxidase (HRP)-linked anti-rabbit antibody (Amersham Bioscience, Tokyo, Japan) and HRP-linked anti-mouse antibody (Amersham Bioscience). Dilutions were 1:500 for primary antibodies, and 1:1000 for second antibodies. The filter was reprobated with anti-tubulin- α antibody. The specific antigen-antibody complexes were visualized by enhanced chemiluminescence (GE Healthcare Bio-Sciences Corp, Piscataway, NJ, USA).

Cell proliferation assay

Cells were trypsinized, harvested, and spread onto 96-well flat-bottom plates (Asahi Techno Glass, Tokyo, Japan) at a density of 1000 cells per well. Following 24 h of culture under RPMI-1640, DMEM, or DMEM: F12 with 100 mL/L FBS, medium was changed to RPMI-1640, DMEM, or DMEM: F12 without FBS, respectively, to quench the FBS effects. After 24 h of culture, the medium was changed to RPMI-1640, DMEM, or DMEM:F12 with 100 mL/L FBS, in addition to LY294002, PD98059, or PPP. After 72 h, a 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium inner salt (MTS) assay was performed according to the manufacturer's instructions (Promega Corporation, Tokyo, Japan). MTS was bio-reduced by cells into a colored formazan product that reduced absorbance at 490 nm. Absorbance was analyzed with a multiple plate reader at a wavelength of 490 nm with a BIO-RAD iMark microplate reader (Bio-RAD, Hercules, CA, USA).

Wound assay

Wound assays were performed according to a previously described procedure^[12]. Briefly, cells were spread onto four-well chambers (Becton Dickinson, Franklin Lakes, NJ, USA). Cells were then cut with a sterile razor, and stained with hematoxylin and eosin (HE). Five images were taken by a light microscope (Olympus, Tokyo, Japan). For each

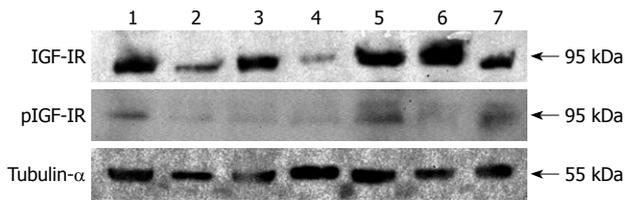

Figure 1 Western blotting analysis of pancreatic cell lines. Protein was isolated from cultured pancreatic cancer cell lines in 100 mL/L fetal bovine serum (FBS), and subjected to western blot analysis. It was shown clearly that all cell lines expressed IGF-IR as well as phosphorylated IGF-IR (pIGF-IR). Tubulin- α was used as an internal control. 1: MIA-Paca2; 2: NOR-P1; 3: PANC-1; 4: PK-45H; 5: PK-1; 6: PK-59; 7: KP-4.

experiment, the number of cells that migrated more than 150 μm per 100 μm cut surface was counted.

Statistical analysis

Cell proliferation and wound assay were analyzed statistically by one-factor analysis of variance. Statistical analysis was performed with JMP5.0J (SAS Institute Japan, Tokyo, Japan). $P < 0.05$ was accepted as statistically significant.

RESULTS

Expression and phosphorylation of IGF-IR in pancreatic cancer

To reveal involvement of IGF-IR in proliferation of pancreatic cancer cell lines stimulated with FBS, protein was isolated and subjected to Western blotting analysis. All cell lines clearly expressed not only IGF-IR but also phosphorylated IGF-IR, which suggested that IGF-IR played a role in proliferation with FBS (Figure 1). This result prompted us to analyze the effects of IGF-IR inhibitors.

Suppression of proliferation of pancreatic cancer with inhibitors

The MTS assay was performed to clarify whether PPP, LY294002, or PD98059 suppressed proliferation of pancreatic cancer cell lines. PPP suppressed proliferation of all the cell lines examined (Figure 2A). At 2 $\mu\text{mol/L}$, MIA-Paca2, NOR-P1, PANC-1, PK-45H, PK-1, PK-59 and KP-4 proliferation was reduced to $36.9\% \pm 2.4\%$ (mean \pm SD), $30.9\% \pm 5.5\%$, $23.8\% \pm 3.9\%$, $37.1\% \pm 5.3\%$, $10.4\% \pm 4.5\%$, $52.5\% \pm 4.5\%$ and $22.6\% \pm 0.4\%$, respectively ($P < 0.05$, $n = 3$). Next, we analyzed the downstream pathway of IGF-IR. LY294002 suppressed proliferation of all the cell lines examined (Figure 2B). At 50 $\mu\text{mol/L}$, proliferation of MIA-Paca2, NOR-P1, PANC-1, PK-45H, PK-1, PK-59 and KP-4 cells was reduced significantly to $44.4\% \pm 7.6\%$, $32.9\% \pm 8.2\%$, $53.9\% \pm 8.0\%$, $52.8\% \pm 4.0\%$, $32.3\% \pm 4.2\%$, $51.8\% \pm 4.5\%$, and $30.6\% \pm 9.4\%$, respectively ($P < 0.05$, $n = 3$). PD98059 did not suppress cell proliferation (Figure 2C). Although NOR-P1 and KP-4 cells showed a marginal decrease in proliferation in the presence of 20 $\mu\text{mol/L}$ PD98059, we could not analyze higher concentrations because PD98059 precipitated in the medium. Analysis with 50 $\mu\text{mol/L}$ PD98059 failed since PD98059 crystallized and precipitated. The other inhibitor of MAPK was not analyzed.

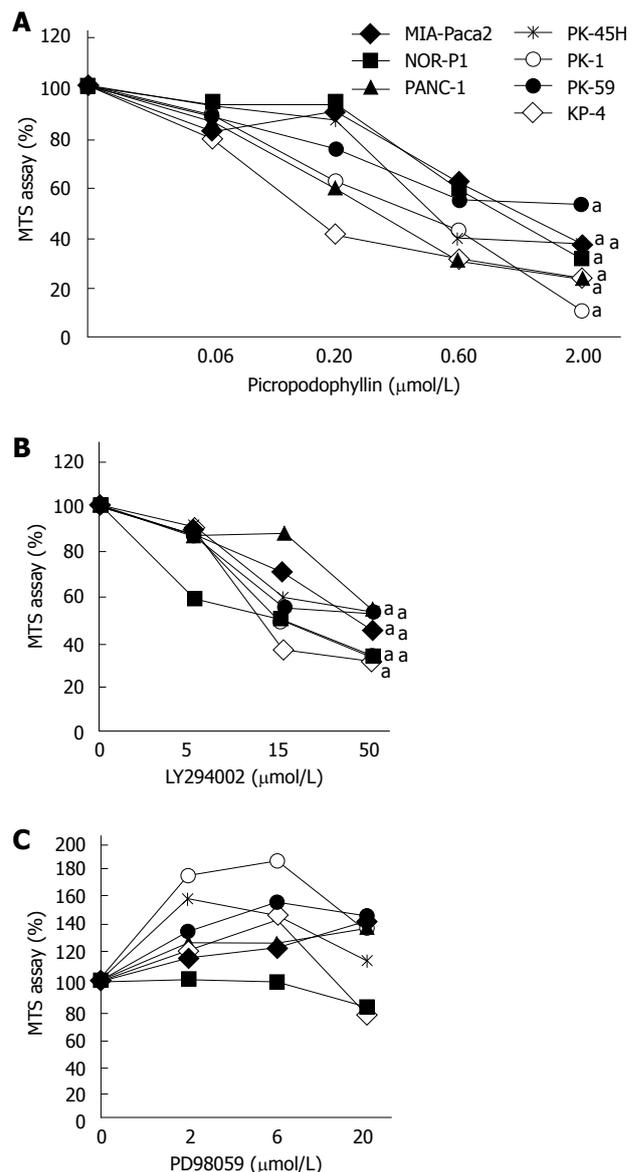

Figure 2 MTS assay of cells cultured with inhibitors. Pancreatic cell lines were cultured in 100 mL/L FBS with picropodophyllin (PPP) (A), LY294002 (B), or PD98059 (C). After 72 h, MTS assay was performed to analyze the change in cell numbers. PPP and LY294002 significantly suppressed cell numbers, whereas PD98059 did not ($^aP < 0.05$, $n = 3$).

Suppression of motility of pancreatic cancer with inhibitors

Suppression of motility is the initial step in the inhibition of metastasis. We analyzed changes in motility with inhibitors, by the wound assay (Figure 3). PPP at 2 $\mu\text{mol/L}$ suppressed motility of MIA-Paca2, NOR-P1, PANC-1, PK-45H, PK-1, PK-59 and KP-4 cells to $3.0\% \pm 0.2\%$, 0% , 0% , $2.0\% \pm 0.1\%$, $5.0\% \pm 0.2\%$, $3.0\% \pm 0.1\%$, and $5.0\% \pm 0.2\%$, respectively ($P < 0.05$, $n = 3$). LY294002 at 50 $\mu\text{mol/L}$ suppressed motility of MIA-Paca2, NOR-P1, PANC-1, PK-45H, PK-1, PK-59 and KP-4 cells to $3.0\% \pm 0.2\%$, 0% , $3.0\% \pm 0.2\%$, 0% , 0% , 0% and $3\% \pm 0.1\%$, respectively ($P < 0.05$, $n = 3$). PD98059 at 20 $\mu\text{mol/L}$ did not suppress motility, although NOR-P1 cells showed a marginal, non-significant decrease.

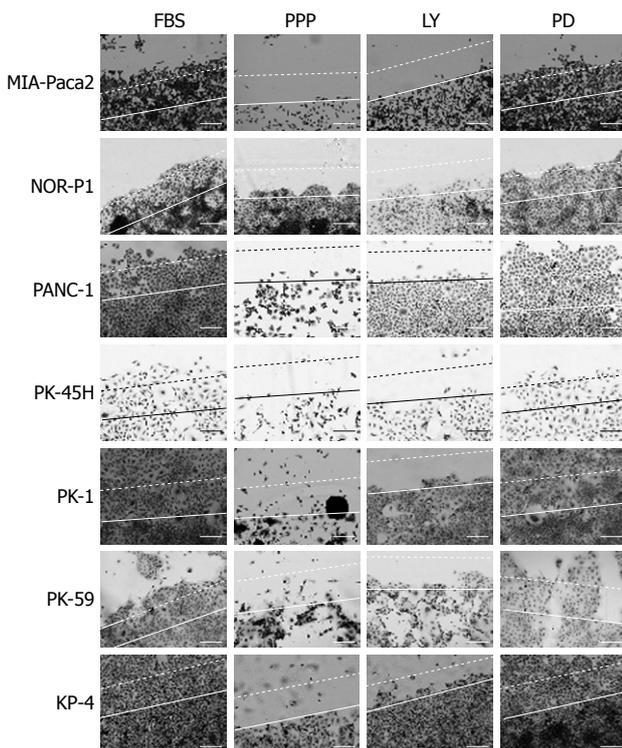

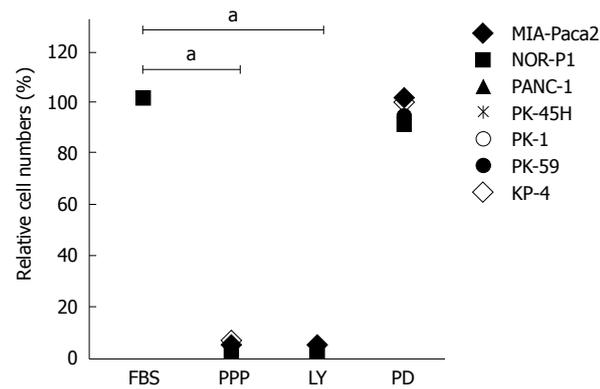

Figure 3 Wound assays with inhibitors. Wound assay was performed to analyze cell motility. Almost no cells cultured with PPP or LY294002 migrated $> 150 \mu\text{m}$, whereas those with PD98059 showed motility of $> 150 \mu\text{m}$ ($^*P < 0.05$, $n = 3$). Solid line: Edge of scratch; Dotted line: $150 \mu\text{m}$ from a solid line. Original magnification: $4 \times$; Scale bar: $100 \mu\text{m}$. FBS: Medium with 100 mL/L FBS without any inhibitors; PPP: Medium with $2 \mu\text{mol/L}$ PPP; LY: Medium with $50 \mu\text{mol/L}$ LY294002; PD: Medium with $20 \mu\text{mol/L}$ PD98059.

Microscopic features of pancreatic cancer with inhibitors

Cells were observed under the microscope to analyze the morphological changes induced by inhibitors. Cells in medium with $2 \mu\text{mol/L}$ PPP or $50 \mu\text{mol/L}$ LY294002 had pyknotic nuclei, which suggested that they were apoptotic (Figure 4). Cells in medium with $20 \mu\text{mol/L}$ PD98059 did not show signs of apoptosis (Figure 4).

DISCUSSION

IGF-I stimulates thymidine incorporation of pancreatic cancer cell lines, such as MIA-Paca2, as strongly as FBS, which suggests that it is an autocrine growth factor^[13]. It

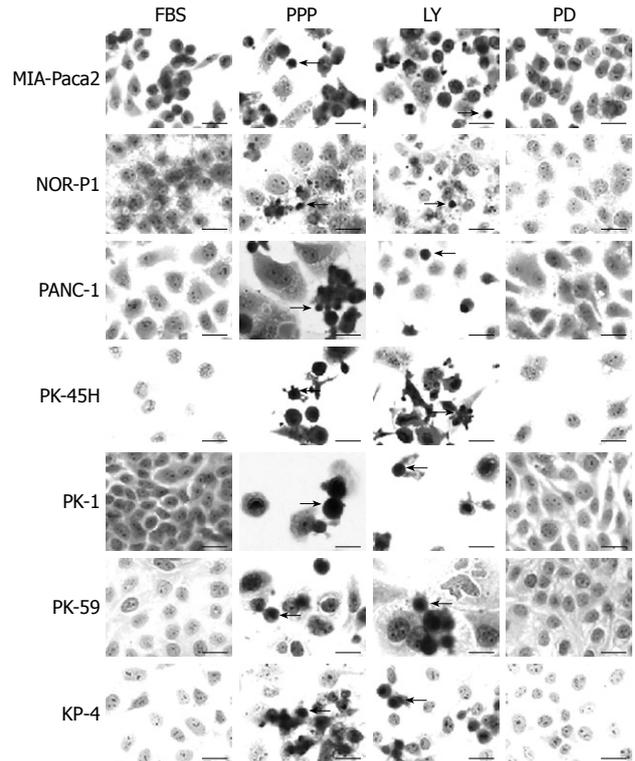

Figure 4 Apoptotic cells with PPP or LY294002. Under the microscope, cells with pyknotic nuclei (arrows) were observed in medium with PPP or LY294002, whereas there were no apoptotic cells in medium with PD98059. FBS: Medium with 100 mL/L FBS; PPP: Medium with $2 \mu\text{mol/L}$ PPP; LY: Medium with $50 \mu\text{mol/L}$ LY294002; and PD: Medium with $20 \mu\text{mol/L}$ PD98059. Original magnification: $20 \times$; Scale bar: $25 \mu\text{m}$, the arrows indicate cells in apoptosis.

was expected that inhibition of IGF-IR activity would lead to pancreatic cancer regression. Antisense oligonucleotide to IGF-IR suppresses proliferation of ASPC-1, a pancreatic cancer cell line^[3]. Antisense oligonucleotide to K-ras synergistically enhances the suppression of pancreatic cancer cell lines by antisense oligonucleotide to IGF-IR^[14]. Antisense oligonucleotide is unstable in blood, therefore, small molecules that inhibit the tyrosine kinase of IGF-IR are desirable. NVP-AEW541, an IGF-IR inhibitor, suppresses growth of HPAF-II cells, a pancreatic cancer cell line^[15]. However, it is possible that NVP-AEW541 does not affect other cell lines. PPP is the first inhibitor to discriminate IGF-IR and insulin receptor^[16]. In our experiments, PPP suppressed proliferation of all pancreatic cancer cell lines. Previous studies and the present one indicate that IGF-IR is a good candidate for molecular therapy of pancreatic cancer.

The downstream pathway of the IGF-I receptor is intriguing since shutting down the pathway could reduce cancer. Antibody to IGF-IR suppresses phosphorylation of Akt, a downstream molecule of PI3K and MAPK^[13]. LY294002 significantly suppresses proliferation of PANC-1 and BxPC3 cells, and viability of KP-4 and PANC-1 cells^[7,17]. Our results showed that LY294002 suppressed proliferation of all the pancreatic cancer cell lines examined. In addition to proliferation, our data clearly demonstrated that LY294002 suppressed cell migration. We conclude that PI3K is a suitable target for molecular therapy of pancreatic cancer.

MAPK is another downstream pathway of IGF-IR. MIA-PaCa2 treated with 20 $\mu\text{mol/L}$ PD98059 in 100 mL/L FBS showed downregulation of phosphorylated extracellular signal-regulated kinase 1/2^[18]. Although it was expected that PD98059 would suppress proliferation of pancreatic cancer cells, 20 $\mu\text{mol/L}$ PD98059 did not suppress proliferation and motility of pancreatic cancer cells in our experiments. PD98059 at 20 $\mu\text{mol/L}$ does not suppress DNA synthesis stimulated by IGF-I in the culture medium, although phosphorylation of MAPK is suppressed^[19]. Curiously, PD98059 stimulates cell growth at concentrations of 0.1 $\mu\text{mol/L}$ to 0.1 pmol/L^[20]. SB203580, another inhibitor of MAPK, stimulates growth of PANC-1 cells in serum-free conditions^[21]. In our experiments, PD98059 marginally stimulated growth of PANC-1 cells with 10 mL/L FBS. These results suggest that inhibition of MAPK does not always suppress growth of pancreatic cancer cell lines with unknown mechanisms.

It may be concluded that IGF-IR and PI3K are good candidates for molecular therapy of pancreatic cancer.

COMMENTS

Background

Insulin-like growth factor-I receptor (IGF-IR) is expressed in pancreatic cancer tissues but not in surrounding non-cancerous tissues. Although it was speculated that IGF-I might play a role in proliferation of pancreatic cancer, the detailed mechanism is not known.

Research frontiers

IGF-IR is not involved in metabolism, therefore, it is expected that inhibition of IGF-IR and its downstream pathway should not cause adverse effects when used as a target for molecular therapy of pancreatic cancer.

Innovations and breakthroughs

IGF-IR was phosphorylated in cultured pancreatic cancer cell lines, which suggested that IGF-IR and its downstream pathway were activated. Each inhibitor of IGF-IR or phosphatidylinositol-3 kinase (PI3K) suppressed not only cell proliferation but also motility.

Applications

By revealing that IGF-IR was activated, this study indicated that IGF-IR might be a good candidate for molecular therapy of pancreatic cancer.

Terminology

IGF-I is a growth factor that is involved in cell proliferation and differentiation. Stimulation of IGF-I is transmitted via IGF-IR to downstream pathways, such as PI3K and mitogen-activated protein kinase.

Peer review

The authors have demonstrated that IGF-IR, phosphorylated and total, is involved in the proliferation of pancreatic cell lines. In Figure 1, we see that all cell lines expressed phosphorylated and total IGF-IR. Their experiments have shown that inhibition of IGF-IR activity results in a decrease in proliferation and motility of pancreatic cancer cell lines. These findings, along with the inhibition of PI3K, are interesting and show promise.

and migration to S1P and S1P5 expression was evaluated by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide and migration assay, respectively.

RESULTS: Both normal human esophageal mucosal epithelium and Eca109 cells expressed S1P1, S1P2, S1P3 and S1P5, respectively. Esophageal mucosal epithelium expressed S1P5 at a higher level than Eca109 cell line. S1P5 over-expressing Eca109 cells displayed spindle cell morphology with elongated and extended filopodia-like projections. The proliferation response of S1P5-transfected Eca109 cells was lower than that of control vector-transfected cells with or without S1P stimulation ($P < 0.05$ or 0.01). S1P significantly inhibited the migration of S1P5-transfected Eca109 cells ($P < 0.001$). However, without S1P in transwell lower chamber, the number of migrated S1P5-transfected Eca109 cells was greater than that of control vector-transfected Eca109 cells ($P < 0.001$).

CONCLUSION: S1P binding to S1P5 inhibits the proliferation and migration of S1P5-transfected Eca109 cells. Esophageal cancer cells may down-regulate the expression of S1P5 to escape the inhibitory effect.

Abstract

AIM: To investigate the sphingosine 1-phosphate (S1P) receptor expression profile in human esophageal cancer cells and the effects of S1P5 on proliferation and migration of human esophageal cancer cells.

METHODS: S1P receptor expression profile in human esophageal squamous cell carcinoma cell line Eca109 was detected by semi-quantitative reverse transcription polymerase chain reaction. Eca109 cells were stably transfected with S1P5-EGFP or control-EGFP constructs. The relation between the responses of cell proliferation

Effect of S1P5 on proliferation and migration of human esophageal cancer cells. *World J Gastroenterol* 2010; 16(15): 1859-1866 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i15/1859.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i15.1859>

INTRODUCTION

Esophageal cancer is one of the most common malignancies worldwide, occurring mostly in developing countries with marked regional variations in incidence. Its mortality is very similar to its incidence due to relatively late diagnosis and inefficient treatment. About 300 000 people would die of esophageal cancer each year in the world^[1]. The incidence and mortality of esophageal cancer are unusually high in China, especially in Henan, Shanxi, Hebei and Sichuan Provinces^[2]. Even though a small number of esophageal cancer patients can survive more than 5 years after initial surgical treatment, over 60% of patients still die of metastasis and local recurrence^[3,4]. The ability to reverse the outcome of esophageal cancer is limited due to a poor understanding of its biology.

Sphingosine 1-phosphate (S1P) is a pleiotropic phospholipid mediator that mediates diverse cellular responses, such as cell proliferation, differentiation, migration, adhesion, and morphogenesis. S1P with a low nanomolar affinity binds to its 5-related G-protein coupled receptors (GPCR), and is designated as S1P1-5 (originally termed EDG-1, 3, 5, 6, and 8, respectively). S1P1, S1P2, and S1P3 receptors are ubiquitously expressed, whereas S1P4 is only expressed in lymphoid tissues and platelets, and S1P5 is predominantly expressed in the central nervous system^[5-11].

Previous reports have highlighted the importance of S1P and its receptors for the growth, metastasis and infiltration of tumors, such as gastric cancer^[5], thyroid cancer^[12], ovarian cancer^[13-16], and glioma^[17]. In general, S1P stimulates the migration of S1P3 dominantly expressing cell lines and inhibits the migration of S1P2 expressing cell lines. S1P1, S1P2 and S1P3 contribute positively to S1P-stimulated glioma cell proliferation, and S1P5 blocks glioma cell proliferation. S1P1 and S1P3 enhance glioma cell migration and invasion, while S1P2 inhibits cell migration but unexpectedly enhances glioma cell invasiveness by stimulating cell adhesion^[17].

The possible role and importance of S1P and its receptors in the growth and metastasis of human esophageal cancer have not been investigated. In this study, we focused on esophageal squamous cell carcinoma (ESCC), characterized S1P receptor expression patterns and investigated the role of S1P receptors in proliferation and migration of ESCC cells. ESCC cell line Eca109 expressed 4 S1P receptors (S1P1, S1P2, S1P3 and S1P5). Compared with normal esophageal mucosa epithelium, Eca109 cells expressed a very low level of S1P5. Furthermore, by over-expressing human S1P5 in Eca109 cells, the effects of S1P5 on esophageal cancer cells were partly clarified.

MATERIALS AND METHODS

Materials

S1P was obtained from Cayman Chemical (Ann Arbor, MI, USA). Dispase II, fibronectin and fatty acid-free bovine serum albumin (BSA) were purchased from Sigma

(St Louis, MO, USA). SV total RNA isolation system and pGEM-T easy vector system were bought from Promega (Madison, WI, USA). PrimeScript™ reverse transcription polymerase chain reaction (RT-PCR) kit and PrimerSTAR HS DNA polymerase with GC buffer were purchased from TakaRa Biotech (Dalian, China). Lipofectamine 2000 and G418 were obtained from Invitrogen (Carlsbad, CA, USA).

Preparation of normal human esophageal mucosal epithelium

Normal human esophageal mucosa samples were obtained from surgically resected esophagus of patients with esophageal carcinoma, and then confirmed by an experienced pathologist to contain neither macroscopic tumor nor histologically detectable metaplastic cells or cancer cells. Samples were collected with the signed informed consent from patients. Tunica mucosa was separated from the tissues with forceps, and cut into 1 cm × 1 cm sections which were then transferred to a 100 mm culture dish containing 10 mL PBS with 0.25% dispase II and incubated for 18-24 h at 4°C. Epithelial layers were separated from the full-thickness mucosa with forceps.

Cell culture

Human ESCC cell line Eca109 was obtained from Shanghai Institute of Cell Biology, Chinese Academy of Sciences. Eca109 cells were cultured in RPMI 1640 medium supplemented with 10% (v/v) fetal bovine serum (FBS) and 100 U/mL of penicillin and streptomycin at 37°C in a humidified incubator containing 5% CO₂.

Preparation of total RNA and semi-quantitative reverse transcription polymerase chain reaction

Total RNA was isolated with the SV total RNA isolation system following its manufacturer's instructions. RNA quality and integrity were checked by absorbance spectrometry and agarose gel electrophoresis. Semi-quantitative RT-PCR was performed to confirm differential expression of S1P receptors in Eca109 cell line. The sequences of primers used are as follows: 5'-TATCAGC GCGACAAGGAGAACAG-3' (sense) and 5'-ATAG GCAGGCCACCCAGGATGAG-3' (antisense) for S1P1 receptor (429-bp product), 5'-TCGGCCTTCATCGTC ATCCTCT-3' (sense) and 5'-CCTCCCGGGCAAACCA CTG-3' (antisense) for S1P2 receptor (220-bp product), 5'-CTGCCTGCACAATCTCCCTGACTG-3' (sense) and 5'-GGCCCGCCGCATCTCCT-3' (antisense) for S1P3 receptor (394-bp product), 5'-GAGAGCGGGGCCACC AAGAC-3' (sense) and 5'-GGTTGACCGCCGAGTTGA GGAC-3' (antisense) for S1P4 receptor (454-bp product), 5'-GGAGTAGTTCCCGAAGGACC-3' (sense) and 5'-T CTAGAATCCACGGGGTCTG-3' (antisense) for S1P5 receptor (236-bp product), 5'-GATGACATCAAGAAGG TGGTGAA-3' (sense) and 5'-GTCTTACTCCTTGGAG GCCATGT-3' (antisense) for glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (246-bp product). Thirty-two cycles of amplification were performed using a thermal

cycler, Mastercycle[®] gradient (Eppendorf, Hamburg, Germany) at 94°C for 30 s, at 60°C for 30 s, and at 72°C for 1 min. The PCR products were electrophoresed on a 1.6% agarose gel and visualized with ethidium bromide staining.

Generation of stably-transfected Eca109 cell line

Human S1P5 open reading frame was cloned from normal esophageal mucosal epithelium cDNA *via* PCR using the PrimerSTAR HS DNA polymerase with GC buffer. The sequences of primers used are 5'-CATTG AAGCTTCCACCATGGAGTCGGGGCTGCTG-3' (sense) and 5'-CATTGTCTAGAGTCTGCAGCCG GTTCTGATA-3' (antisense). The sense primer was designed to add a *Hind*III site upstream of a consensus Kozak sequence and the S1P5 initiating Met (*italics*). The antisense primer was designed to remove the S1P5 stop codon and to add a *Xba*I site. PCR conditions, established to amplify the S1P5 receptor sequence, were 94°C for 1 min, followed by 35 cycles at 94°C for 30 s, at 60°C for 30 s, at 72°C for 2 min, and a final extension at 72°C for 8 min. The PCR products were electrophoresed on 0.8% agarose gel and the corresponding band was cut and purified. The purified PCR products were ligated into the pGEM-T easy vector and the sequence was confirmed by sequence analysis. The *S1P5* gene was spliced out with *Hind*III/*Xba*I and ligated into the Myc-His-EGFP-N1 frame, which was purified from similarly digested S1P1-Myc-His-EGFP-N1 as previously described^[18]. The initiating methionine of the GFP open reading frame in pEGFP-N1 was mutated to alanine. The resulting plasmid was designated as S1P5-EGFP. A *Hind*III/*Xba*I-digested DNA oligonucleotide containing both sense (5'-CATTGAAGCTTCCACCATGGAATTCTGCAGT CGACGGTACTCTAGACCG-3') and antisense (5'-CG GTCTAGAGTACCGTTCGACTGCAGAATTCCATG GTGGAAGCTTCAATG-3') sequences was cloned into similarly digested Myc-His-EGFP-N1 frame as a control vector. The DNA oligonucleotide contained initiating Met and multiple cloning sites. The plasmid was designated as control-EGFP.

Cells were transfected using Lipofectamine 2000, according to its manufacturer's instructions. Briefly, 5×10^5 Eca109 cells in 2 mL of growth medium without antibiotics were seeded into each well of 6-well plates and grown overnight, then transfected using Lipofectamine 2000. The cells were split at a 1:20 dilution into a fresh growth medium 24 h after transfection. G418 was added at a concentration of 0.8 mg/mL the following day. Resistant colonies were picked to a 96-well plate 14 d after selection and several clones were analyzed. The cells were subsequently maintained in a medium containing G418 at 0.2 mg/mL.

Proliferation assay

Cells (5×10^3 /well in 100 μ L/well) were seeded into a 96-well plate and cultured in RPMI 1640 medium containing 10% FBS for 8 h at 37°C in an atmosphere

containing 5% CO₂ to allow attachment. The medium was then aspirated and a fresh medium containing 0.1% fatty acid-free BSA and varying concentrations of S1P was added into three replicate wells every 48 h. After incubation at 37°C in an atmosphere containing 5% CO₂ for 72 h, the number of living cells was calculated by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay. Briefly, a MTT solution was added into each well and the cells were incubated for an additional 4 h. The number of living cells was then counted by measuring the absorbance at 490 nm.

Migration assay

Migration assay was performed on a 6.5 mm-diameter transwell chamber with an 8 μ m pore size (Corning, NY, USA). The underside of transwell membranes was precoated with fibronectin (10 μ g/mL) and allowed to dry. Cells at 70%-80% confluence were serum starved overnight, detached from culture plates by 0.02% EDTA, washed and resuspended in RPMI 1640 medium with 0.1% fatty acid-free BSA at 1×10^6 cells/mL. For migration assay, cells (1×10^5 cells/well) were added into the upper chamber of transwell chambers separated by inserts with 8 μ m pores in the presence or absence of S1P. Following an 8-h incubation, nonmigrating cells on the upper surface of membranes were removed with cotton swabs, fixed and stained with 0.1% crystal violet in phosphate-buffered saline (PBS) at the ambient temperature, and then destained with PBS. Migrating cells were counted in 5 randomly selected high-power fields per membrane under an Olympus IX71 inverted microscope.

Statistical analysis

Data are expressed as mean \pm SD and shown as error bars in the figures. Statistical comparisons were made by Student's *t*-test. One-way ANOVA with a *post hoc* Bonferroni testing was employed in case of multiple comparisons. *P* < 0.05 was considered statistically significant.

RESULTS

Expression of S1P receptors in normal human esophageal mucosal epithelium and Eca109 cell line

Semi-quantitative RT-PCR of mRNA was performed to observe which S1P receptors are expressed in Eca109 cell line and normal human esophageal mucosal epithelium. For comparison, data were also normalized to the expression of the reference gene GAPDH, which gave similar results. Four S1P receptors were found in normal human esophageal mucosal epithelium with the following rank order of mRNA abundance: S1P1>S1P5>S1P3>S1P2. In contrast to Eca109 cell line, the mRNA abundance in S1P receptors was S1P3>S1P1>S1P5>S1P2. S1P4 expression was absent or minimal in Eca109 cell line and normal human esophageal mucosal epithelium (Figure 1). Eca109 cell line expressed S1P3 at a higher level than normal esophageal mucosal epithelium. In contrast, normal

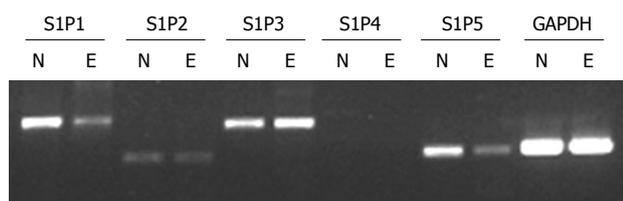

Figure 1 Expression of sphingosine 1-phosphate (S1P) receptors in normal human esophageal mucosal epithelium and Eca109 cell line. N: Normal human esophageal mucosal epithelium; E: Eca109 cell line.

esophageal mucosal epithelium expressed S1P1 and S1P5 at a higher level than Eca109 cell line. On the basis of these results, S1P5 was chosen for further study.

Generation of S1P5 overexpressing Eca109 cell line

Eca109 cells transfected with the S1P5-EGFP or Control-EGFP constructs were cultured in a medium containing 10% FBS. Their localization was visualized by fluorescence microscopy. As shown in Figure 2, control-EGFP was localized at the cytosol of Eca109 cells. In contrast, the S1P5-EGFP was localized at the plasma membrane. Interestingly, control-EGFP-transfected cells displayed the characteristic Eca109 cell morphology. In contrast, S1P5-EGFP-transfected cells displayed spindle cell morphology with elongated and extended filopodia-like projections in a medium containing 10% FBS or 0.1% fatty acid-free BSA.

Effect of S1P on proliferation of control-EGFP or S1P5-EGFP expressing Eca109 cells

Since S1P regulates the proliferation of many cell types, including cancer cells, it is of great interest to investigate whether S1P5 or S1P binding to S1P5 has an effect on the proliferation of control vector and S1P5 transfected Eca109 cells. To assess induction of proliferation, stably transfected cells in 96-well plates containing 10% FBS or 0.1% fatty acid-free BSA were counted after treatment with a vehicle (DMSO) and 10 or 100 nmol/L S1P for 72 h. The number of cells from both control vector and S1P5 transfectants did not increase in response to S1P ($P > 0.05$), suggesting that S1P does not behave as a mitogen at S1P5 (Figure 3).

Interestingly, the proliferation response of S1P5-transfected Eca109 cells was lower than that of control vector-transfected cells in a medium containing 10% FBS (8% lower, $P < 0.05$) or 0.1% fatty acid-free BSA with or without S1P (20%-29% lower, $P < 0.05$ or 0.01), suggesting that S1P5 has an intrinsic activity and inhibits cell proliferation.

Effect of S1P on migration of control-EGFP or S1P5-EGFP expressing Eca109 cells

Migration of Eca109 cells was quantified by transwell-based assay. Transwell membranes were precoated with fibronectin. At a concentration of 10 or 100 nmol/L S1P, the migration of S1P5-EGFP-transfected Eca109 cells was significantly lower than that of control-EGFP-transfected Eca109 cells (48% *vs* 84% at 10 nmol/L S1P,

39% *vs* 94% at 100 nmol/L S1P, $P < 0.001$) (Figure 4A and B). Interestingly, without S1P in the lower chamber, the migrated number of S1P5-EGFP transfected Eca109 cells (145 ± 10) was more than that of control-EGFP-transfected Eca109 cells (51 ± 4 , $P < 0.001$) (Figure 4A and C). Both cells failed to migrate on gelatin-coated or non-coated transwell membranes (data not shown). Control-EGFP and S1P5-EGFP transfected Eca109 cells exhibited spontaneous migration without S1P, and the addition of S1P to the lower chamber potentially inhibited cell migration.

DISCUSSION

In the present study, normal esophageal mucosal epithelium expressed S1P5 at a high level, and Eca109 cells expressed S1P5 at a low level. S1P5 was predominantly expressed in the white matter tracts and oligodendrocytes, and was particularly abundant in the anterior commissure, corpus callosum, and optic tract. S1P5 mRNA was detected in spleen, peripheral blood leukocytes, placenta, lung, aorta, and fetal spleen. A low level of signals has been detected in many tissues^[19,20]. In this study, normal human esophageal mucosal epithelium expressed S1P5 at a high level, suggesting that S1P5 is also a ubiquitous S1P receptor and plays an important role in different tissues and cells.

S1P is believed to be generated intracellularly by all cell types during sphingolipid degradation. Plasma S1P is mainly hematopoietic in origin with erythrocytes as a major contributor to the sources of extracellular S1P, whereas lymph S1P is from a distinct radiation-resistant source^[21,22]. The concentration of S1P in plasma and serum is 0.1-0.6 $\mu\text{mol/L}$ and 0.4-1.1 $\mu\text{mol/L}$, respectively, while the S1P level in tissues is 0.5-75 pmol/mg ^[23]. Although S1P was originally thought to act as an intracellular second messenger, it has been widely accepted as an intercellular agonist. S1P binding to its receptors activates different intracellular signaling pathways depending on which intracellular $G\alpha$ protein they couple to. The S1P1 receptor primarily couples through $G\alpha_{i/o}$, whereas S1P2 and S1P3 can couple through $G\alpha_{i/o}$, $G\alpha_q$ and $G\alpha_{12/13}$, S1P4 and S1P5 can couple through $G\alpha_{i/o}$ and $G\alpha_{12/13}$ ^[6,7,24-26]. Signaling through $G\alpha_{i/o}$ has been associated with the activation of small guanosine triphosphatase (GTPase) Ras and extracellular signal-regulated kinase (ERK) to promote proliferation, and induction of Pi3K and small GTPase Rac to promote migration. Signaling through $G\alpha_{12/13}$ can promote the activation of small GTPase Rho and Rho-associated kinase (ROCK) to inhibit migration^[6]. Furthermore, S1P5 is also a constitutively active receptor with the ability to intrinsically stimulate various effector pathways *albeit* at a different extent in the absence of stimulating ligand^[27].

In the present study, normal esophageal mucosal epithelium expressed S1P5 at a higher level than Eca109 cell line. Therefore, Eca109 cells were transfected with the expression constructs of S1P5 or control vector in order to delineate the effects of S1P5 on the growth, migration

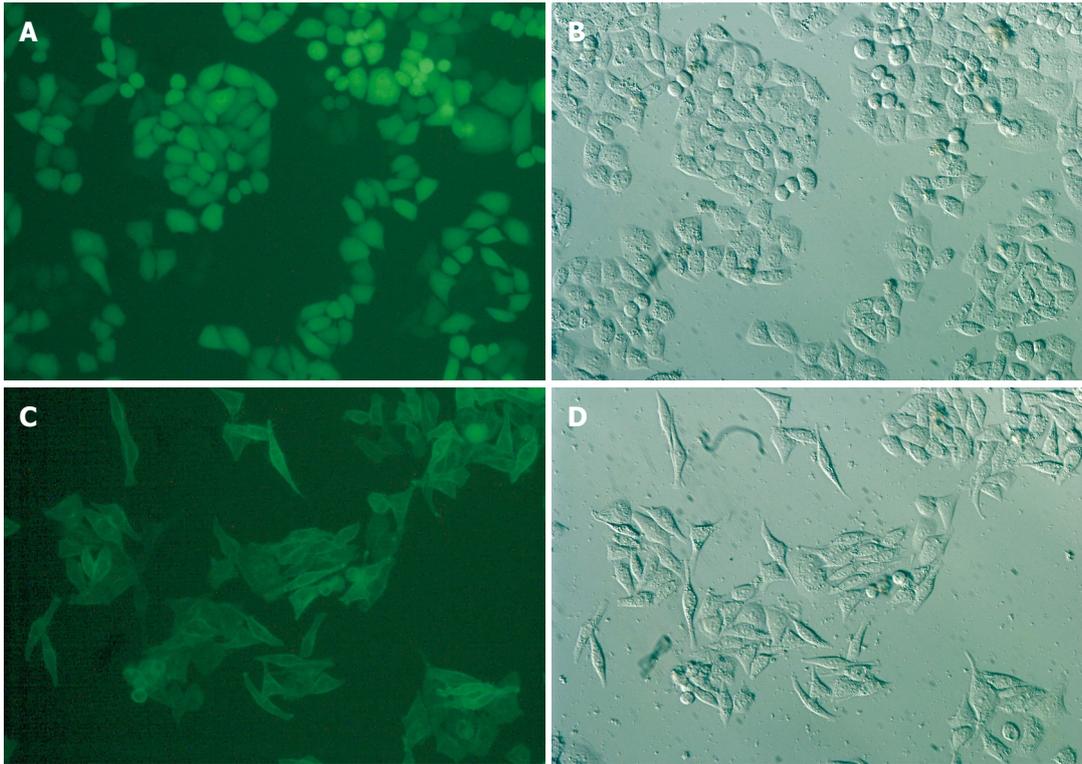

Figure 2 S1P5 receptor overexpression in Eca109 cells causes cell spindle change with elongated and extended filopodia-like projections in a medium containing 10% FBS or 0.1% fatty acid-free BSA ($\times 200$). A, B: Eca109/control-EGFP; C, D: Eca109/S1P5-EGFP.

and morphogenesis of esophageal cancer cells. Eca109 cells that overexpress S1P5 were analyzed by phase contrast microscopy. Increased expression of S1P5 induced cell spindle change with elongated and extended filopodia-like projections in a medium containing 10% FBS or 0.1% fatty acid-free BSA. This morphological change is characterized by motile cells. However, transfection of several mammalian cell lines (CHO-K1, HEK293, NIH3T3, RH7777) with the S1P5 receptor induced cell rounding change, which is more pronounced in the presence of S1P-containing serum^[27]. Differences in morphological alteration may correlate well with cell type or malignant degree, because CHO-K1,

HEK293, NIH3T3 and RH7777 are the normally-derived mammalian cell lines.

In this study, the expression of S1P5 receptor in Eca109 cells reduced the proliferation of Eca109 cells whether or not the medium contained S1P, indicating that the S1P5 receptor is constitutively active in the absence of stimulating ligand. Antiproliferative effect is an intrinsic ability of the S1P5 receptor that is insensitive to ligand stimulation. Analogously, S1P5-transfected CHO cells exhibit an intrinsic activity and inhibit serum-stimulated cell proliferation^[28]. S1P5 can negatively and constitutively regulate cellular proliferation by reducing ERK1/2 activity *via* protein-tyrosine phosphatase. $G\alpha_{12/13}$ is a likely candidate G protein for the inhibitory effects of S1P5 on ERK activity. It has been shown that mutation-activated $G\alpha_{12/13}$, but not $G\alpha_q$, $G\alpha_s$, or $G\alpha_{12}$, can inhibit EGF stimulation of ERK activity in COS-7 cells in a Ras- and Raf-independent manner^[29]. Down-regulation of S1P5 in esophageal cancer cells may weaken its antiproliferative effect.

In this study, overexpression of S1P5 receptor constitutively increased the migration of esophageal cancer cells to fibronectin in the absence of S1P, which was consistent with morphological alteration. However, addition of 10 and 100 nmol/L S1P significantly inhibited the constitutive migration of S1P5-transfected Eca109 cells. It has been shown that small GTPases of the Rho family, including Rac, Cdc42, and RhoA, are well-known regulators of cell migration^[5,30]. Cell migration induced by S1P receptors (S1P1 and S1P3) involves $G\alpha_{i/o}$ -mediated activation of phosphatidylinositol 3-kinase (Pi3K) and

NS: Not significant.

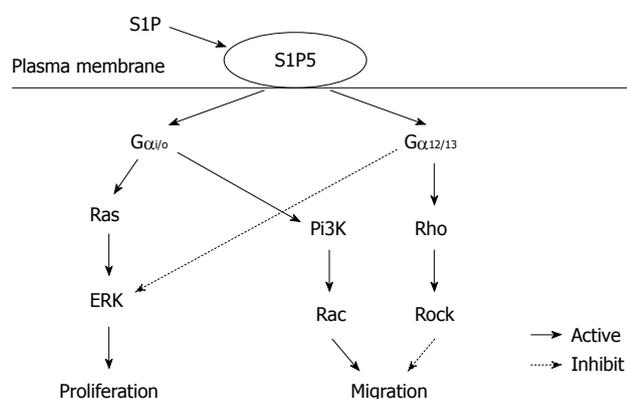

Figure 5 Putative signaling pathway of S1P5.

Rac. S1P receptors (S1P2 and S1P5) mediate inhibition of cell migration by $G\alpha_{12/13}$ -evoked stimulation of Rho^[12]. It was reported that fibronectin binding to $\alpha_3\beta_3$ integrin can decrease Rho activity and stimulate cell motility and spreading, suggesting that enhanced Rho activity may reduce integrin-driven cell migration^[7,31]. Our data support that S1P5 may constitutively induce cell migration due to $G\alpha_{i/o}$ -activated Rac and inhibit cell migration due to $G\alpha_{12/13}$ -stimulated Rho. In a microenvironment containing S1P interstitial fluid, esophageal cancer cells may escape the inhibitory effect of S1P-S1P5 on their migration by down-regulating the expression of S1P5. The putative signaling pathway of S1P5 is shown in Figure 5.

In summary, S1P5 is a constitutively active receptor

with the ability to intrinsically inhibit cell proliferation and induce cell migration. Cell migration can be inhibited by stimulating extracellular S1P. In normal esophageal mucosa cells, a high expression level of S1P5 may inhibit cell proliferation and migration while esophageal cancer cells may down-regulate the expression of S1P5 to promote cell proliferation and escape the inhibitory effect of S1P-S1P5 on cell migration. Our study is the first to show that the deficiency in inhibitory effect of S1P-S1P5 is of importance in the growth and metastasis of esophageal cancer cells. Further study is needed on the role of S1P and S1P5 receptor in esophageal cancer.

COMMENTS

Background

Esophageal cancer is one of the most common malignancies worldwide. Its mortality is very high due to relatively late diagnosis and inefficient treatment. The ability to reverse the outcome of esophageal cancer is limited due to a poor understanding of its biology. Progression of esophageal cancer may be associated with sphingosine 1-phosphate (S1P) and its receptors S1P1-5, which play an important role in other cancers.

Research frontiers

S1P is a pleiotropic phospholipid mediator. S1P binding to its 5 receptors S1P1-5 mediates diverse cellular responses such as cell proliferation, differentiation, migration, adhesion, and morphogenesis. Recent studies have shown that S1P and its receptors are related with cancer growth and metastasis. In this study, esophageal squamous cell carcinoma (ESCC), S1P receptor expression pattern, and the role of S1P receptors in proliferation and migration of ESCC cells were studied.

Innovations and breakthroughs

Recent reports have highlighted the importance of S1P and its receptors for the growth, metastasis and infiltration of tumors, such as gastric cancer, thyroid cancer, ovarian cancer, and glioma. This study showed that deficiency in inhibitory effect of S1P-S1P5 may be of importance in the growth and metastasis of esophageal cancer.

Applications

The results of this study indicate that deficiency in inhibitory effect of S1P-S1P5 may be of importance in the growth and metastasis of esophageal cancer. S1P5 or its associated signaling molecules may serve as a future strategy in biotherapy for esophageal cancer.

Terminology

S1P is a bioactive lipid that regulates central cellular processes such as cell proliferation, differentiation, migration, adhesion, and morphogenesis. S1P is present in plasma and serum at high nanomolar concentrations. S1P binding to related G-protein coupled receptors is designated as S1P1-5. S1P1, S1P2, and S1P3 receptors which are ubiquitously expressed, whereas S1P4 is restricted to lymphoid tissues and platelets and S1P5 is predominantly expressed in the central nervous system. Binding of S1P to its receptors activates different signaling pathways via the heterotrimeric G proteins.

Peer review

The paper is well written and presents an interesting aspect of the pathophysiology of esophageal mucosa which is related to the evolution of esophageal cancer.

Abstract

AIM: To evaluate the incidence and risk factors for the development of anemia after Roux-en-Y gastric bypass (RYGB).

METHODS: A retrospective analysis of patients undergoing RYGB from January 2003 to November 2007 was performed. All patients had a preoperative body mass index > 40 kg/m². A total of 206 patients were evaluated. All patients were given daily supplements of ferrous sulfate tablets for 2 wk following their operation. Hematological and metabolic indices were routinely evaluated following surgery. Patients were followed for a minimum of 86 wk.

RESULTS: There were 41 males and 165 females with an average age of 40.8 years. 21 patients (10.2%) developed post-operative anemia and 185 patients (89.8%) did not. Anemia was due to iron deficiency in all cases. The groups had similar demographics, surgi-

cal procedure and co-morbidities. Menstruation ($P = 0.02$) and peptic ulcer disease ($P = 0.01$) were risk factors for the development of post-operative anemia.

CONCLUSION: Iron deficiency anemia is frequent. RYGB surgery compounds occult blood loss. Increased ferrous sulfate supplementation may prevent iron depletion in populations at increased risk.

Incidence and risk factors for the development of anemia following gastric bypass surgery. *World J Gastroenterol* 2010; 16(15): 1867-1870 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i15/1867.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i15.1867>

INTRODUCTION

Morbid obesity is one of the most common causes of morbidity and mortality in Western countries, and its incidence is rising with unpredictable consequences. It has been estimated that in the next 20 years, 40% of the population in the United States will be morbidly obese with a body mass index (BMI) greater than 30 kg/m²[1].

Roux-en-Y gastric bypass (RYGB) has become a common procedure for achieving short- and long-term weight loss. It has gained great popularity among surgeons and patients in recent years. Long-term complications are still being discovered, and a variety of nutritional problems have been reported[2]. Because of the altered anatomy, absorption of iron from the proximal

gastrointestinal tract is impaired. Anemia develops in some patients with inadequate oral supplementation or chronic occult blood loss. The purpose of this study is to identify the incidence and risk factors of anemia in morbidly obese patients who underwent RYGB.

MATERIALS AND METHODS

Patients

After approval by the Institutional Review Board of Beth Israel Medical Center, a retrospective review of 206 medical records of patients who had undergone RYGB for the treatment of morbid obesity from January 2003 to November 2007 was conducted. Information gathered included demographic characteristics (age, gender, and ethnicity); BMI; past medical and surgical history; relevant laboratory values (pre- and post-operative levels of serum hemoglobin (Hg), hematocrit, mean corpuscular volume, iron, ferritin, and total iron binding capacity); length of bypass; and degree of weight loss after surgery.

One surgeon (IML) performed all gastric bypass operations using the same operative technique. All patients included in the study underwent standard RYGB surgery with the biliopancreatic limb measured to be 70 + BMI (in cm). The alimentary limb was 75 cm in length. Post-operatively, all patients were given a standard chewable multivitamin (Centrum Chewable, Wyeth Consumer Health Care) and ferrous sulfate tablets, 320 mg daily, starting on the 12th d after the operation. All patients were followed closely by a team of dietitians, bariatric surgeons, and psychologists, both before and after the operation. Laboratory data for hematologic and metabolic indices were obtained at frequent intervals post-operatively. Anemia was defined as serum Hg < 11 g/dL in men, and < 10 g/dL in women. Patients with epigastric pain and/or anemia underwent diagnostic upper gastrointestinal endoscopy. Marginal ulcer was treated with sucralfate slurry and oral proton pump inhibitors for a minimum of 2 wk and patients were reexamined endoscopically 6 wk later.

Statistical analysis

Statistical analysis using the Student *t*-test was used to compare pre- and post-operative serum levels of Hg, iron, and total iron binding capacity, and the χ^2 test was utilized to compare categorical data. The level of statistical significance was set at $P \leq 0.05$.

RESULTS

Of 206 patients analyzed, 41 (19.9%) were men and 165 (80.1%) women, with a mean age of 40.8 years (range: 18-60 years). A total of twenty-one (10.2%) patients developed anemia at some point during the post-operative period (Figure 1). Following statistical analysis, patients with the greatest risk for anemia were menstruating females ($P = 0.02$) and patients found to have marginal ulcer on endoscopy ($P = 0.01$). In all cases the anemia was due to iron deficiency (low serum ferritin, elevated total

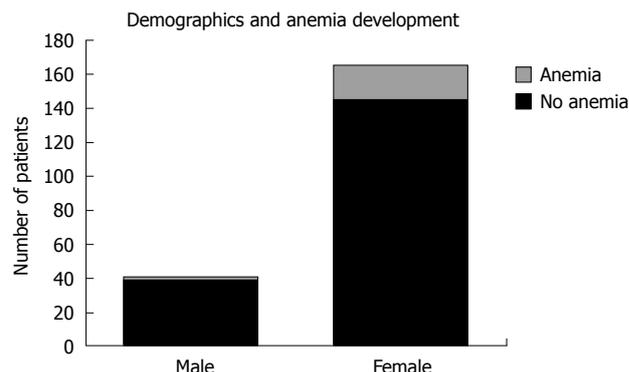

Figure 1 Number of patients who developed post-operative anemia.

Table 1 Associated co-morbidities in the patients who did not develop anemia compared with those who did develop anemia in the post-operative period

Co-morbidity	% of patients without anemia	% of patients with anemia	<i>P</i>
Hypertension	81.1	79.5	0.72
Diabetes mellitus	24.2	21.0	0.71
Asthma	29.5	19.8	0.89
Smoking	49.0	44.1	0.86
Menstruation	67.7	84.2	0.02
Peptic ulcer disease	6.0	22.0	0.01
Coronary artery disease	7.9	14.2	0.75
Thyroid disease	13.2	5.6	0.19

iron binding capacity, and low mean corpuscular volume). Table 1 shows the associated co-morbidities in the patients. The mean values of serum Hg and iron pre- and post-operatively (at 18, 44, 51, and 86 wk after the operation) for all patients are shown in Figure 2A and B. In the immediate post-operative period, serum Hg increased compared to the pre-operative state, and then decreased slowly over time. In contrast, serum iron dropped significantly in the immediate post-operative period, and then rose gradually with oral supplementation.

DISCUSSION

Nutritional deficiencies following RYGB have been previously reported. Vitamin deficiencies^[3], disorders of calcium^[4] and copper homeostasis^[5] have been reported elsewhere. Iron deficiency anemia presents a special clinical challenge. Disturbing behaviors such as pica (eating of non-food substances) and pagophagia (excessive ice-eating) have been observed in patients with anemia following gastric bypass surgery^[6,7]. Severe iron deficiency anemia may require parenteral injection of iron or even packed red blood cell transfusion^[8].

Anemia after RYGB may be multi-factorial; resulting from impaired absorption due to the surgically altered gastrointestinal tract, inadequate oral intake, or due to occult blood loss. Anemia may result from bleeding due to the operation itself, such as oozing from the staple or suture lines, marginal ulcers, gastritis, and anastomotic bleeding or due to malabsorption of compounds im-

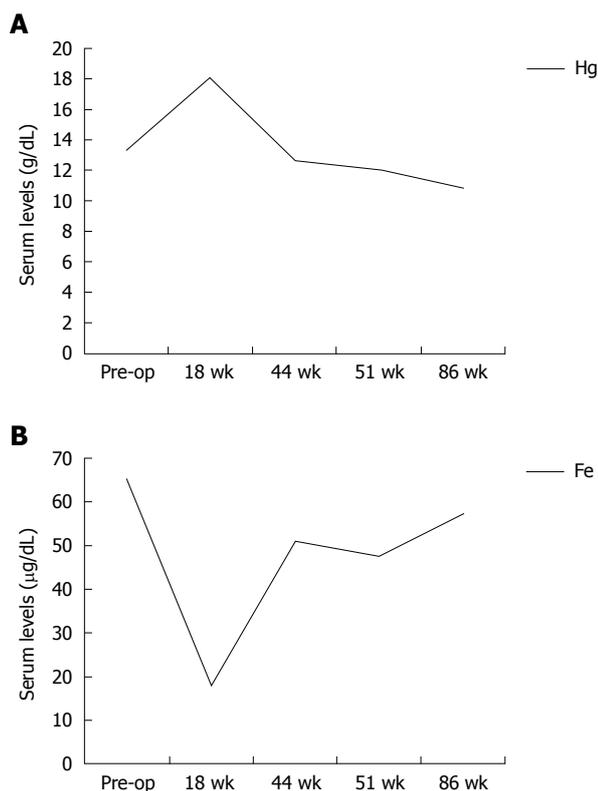

Figure 2 Serum hemoglobin (Hb) (A) levels (g/dL) and iron (Fe) (B) levels (µg/dL) pre- and post-operatively.

portant for the metabolism of Hg, such as iron, folate, thiamine, vitamin B₁₂, niacin, riboflavin, vitamin C, zinc, and copper^[1,9]. Diminished intake of red meats (a major natural source of iron) after gastric bypass surgery may further contribute to iron deficiency in these patients^[10]. The most prevalent type of anemia is iron deficiency, since iron is absorbed by the duodenum, and this type of anemia results from direct malabsorption due to exclusion of the duodenum from orally ingested nutrients. In addition, the food bolus does not encounter normal amounts of gastric acid secreted by the distal stomach which results in impaired conversion of ingested ferric iron to absorbable ferrous iron^[9]. Although prophylactic multivitamin supplements are routinely prescribed for RYGB patients, there are limited data in the medical and surgical literature demonstrating the efficacy of these supplements in the prevention of anemia after gastric bypass surgery^[11].

Symptoms of iron deficiency anemia may be nonspecific but include fatigue and muscle weakness, dyspnea, and chest discomfort^[12]. Typical laboratory findings include low serum ferritin, elevated total iron binding capacity, low mean corpuscular volume, and decreased intracellular Hg concentration. As such, iron deficiency anemia is typically hypochromic and microcytic^[13].

The results of the present study show that 10.2% of our patients developed iron deficiency anemia after RYGB, which is lower than the published data^[14]. It has been reported that anemia correlated best with serum transferrin saturation^[15]. Coupaye *et al*^[8] also reported

an incidence of anemia in 10% of patients. The present study demonstrates that risk factors for the development of iron deficiency anemia following RYGB are menstruation ($P = 0.02$) and peptic ulcer disease ($P = 0.01$). It is important to note that these patients developed anemia at some point during the post-operative period, despite being on standard iron supplementation. This may indicate that the current iron supplementation regimens used may not be adequate to prevent the development of iron deficiency anemia in certain patients after RYGB surgery. Love and Billett^[16] suggested that the risk of anemia following bariatric surgical procedures continues for life. The incidence of anemia does not appear to be greater following duodenal switch operations^[17].

Brolin *et al*^[11] found that multivitamin supplements lowered the incidence of folate deficiency, but did not prevent iron or vitamin B₁₂ deficiency. However, the authors did not suggest the prophylactic supplementation of vitamin B₁₂, simply because the patients did not develop clinically important deficiency of this vitamin post-operatively. On the other hand, they found that iron deficiency is very resistant to oral iron supplementation, especially in menstruating women, leading them to prescribe prophylactic high doses of oral iron (50 mg or more)^[11]. Varma *et al*^[18] found that menstruating females were more likely to require parenteral iron therapy after bariatric surgery. Other authors have suggested the addition of vitamin C to oral iron supplementation, but without great success^[19]. Previous reports suggest early parenteral iron replacement therapy in patients who do not respond to oral iron therapy in order to prevent anemia-related complications and to maintain patients' quality of life^[2,17]. In a prospective, double-blind, randomized study, Brolin *et al*^[20] found that prophylactic oral supplementation of 320 mg iron twice daily consistently prevented iron deficiency in menstruating women after RYGB.

In conclusion, it is characteristic that iron deficiency anemia secondary to malabsorption may not start until 2-3 mo after RYGB and can be present up to 2 years later^[1] as well as refractory to oral supplementation^[20]. As a result, it is of utmost importance that a protocol of long-term follow-up and close biologic and metabolic monitoring of patients after RYGB and the need for a more aggressive therapeutic approach when anemia has been diagnosed is established. Increased ferrous supplementation may be necessary to prevent iron depletion in populations at increased risk of developing iron deficiency anemia after RYGB surgery, such as menstruating women and patients with peptic ulcer disease.

COMMENTS

Background

With the wide application of bariatric surgery in young patients, long-term follow-up is necessary. Iron deficiency and other causes of anemia are prevalent in a large percentage of patients.

Research frontiers

Females of childbearing age and patients with peptic ulcer disease are at the greatest risk for anemia following gastric bypass surgery.

Innovations and breakthroughs

Routine blood work with regular complete blood counts and serum iron levels are required to prevent severe anemia, which may become refractory to oral supplementation.

Applications

Patients with anemia should have endoscopic evaluation to determine possible peptic ulcer disease or other etiologies. Women with heavy menstrual flow should be counseled about the need for routine supplementation.

Terminology

Bariatric surgery is performed for patients with morbid obesity (body mass index greater than 40 kg/m² or greater than 35 kg/m² for patients with weight-related morbidities) hypertension, non-insulin diabetes or obstructive sleep apnea.

Peer review

This paper looked for the anemia commonly encountered problem after bariatric surgery.

Abstract

AIM: To characterize the impact of the Pringle maneuver (PM) and ischemic preconditioning (IP) on total blood supply to the liver following hepatectomies.

METHODS: Sixty one consecutive patients who underwent hepatic resection under inflow occlusion were randomized either to receive PM alone ($n = 31$) or IP (10 min of ischemia followed by 10 min of reperfusion) prior to PM ($n = 30$). Quantification of liver perfusion was measured by Doppler probes at the hepatic artery and portal vein at various time points after reperfusion of remnant livers.

RESULTS: Occlusion times of 33 ± 12 min (mean \pm SD) and 34 ± 14 min and the extent of resected liver

tissue (2.7 segments) were similar in both groups. In controls (PM), on reperfusion of liver remnants for 15 min, portal perfusion markedly decreased by 29% while there was a slight increase of 8% in the arterial blood flow. In contrast, following IP + PM the portal vein flow remained unchanged during reperfusion and a significantly increased arterial blood flow (+56% vs baseline) was observed. In accordance with a better postischemic blood supply of the liver, hepatocellular injury, as measured by alanine aminotransferase (ALT) levels on day 1 was considerably lower in group B compared to group A (247 ± 210 U/I vs 550 ± 650 U/I, $P < 0.05$). Additionally, ALT levels were significantly correlated to the hepatic artery inflow.

CONCLUSION: IP prevents postischemic flow reduction of the portal vein and simultaneously increases arterial perfusion, suggesting that improved hepatic macrocirculation is a protective mechanism following hepatectomy.

INTRODUCTION

The common strategy to reduce intraoperative blood loss in human liver resection consists of temporary clamping

of the portal triad (Pringle maneuver, PM)^[1]. The extent of bleeding during surgery is associated with higher postoperative complication rates^[2], and the need for autologous blood transfusion may correlate with earlier recurrence of malignancies^[3]. The length of the ischemic time strongly determines the release of liver enzymes after hepatectomy^[4] indicating considerable hepatocellular injury caused by PM^[5]. After declamping of the portal triad, reperfusion of the remnant liver causes additional damage to its parenchymal and non-parenchymal cells^[6] which may cause the loss of functional integrity and consecutive hepatic failure^[7,8].

Several strategies against the deleterious ischemia-reperfusion (I/R)-induced complications have been suggested^[9-11], but these were not routinely introduced in the field of hepatic surgery in humans. This is mainly because of the complex mechanisms involved in I/R, including metabolic, immunological, and microvascular changes which exhibit numerous interactions, rendering the liver a difficult target for preventive strategies.

A new experimental approach to reduce I/R-related injury in the myocardium was firstly presented by Murry^[12] who referred to “ischemic preconditioning” (IP) as an adaptation of the myocardium to ischemic stress induced by repetitive short periods of ischemia and reperfusion. Meanwhile, it could also be demonstrated that IP prior to sustained warm ischemia can protect parenchymal and non-parenchymal liver cells by increasing the tolerance against I/R-related organ hypoxia under experimental as well as clinical conditions^[13-16]. An important observation was also that IP in human liver surgery was associated with better intraoperative hemodynamic stability, particularly on reperfusion of warm ischemic livers^[17].

Although the underlying protective mechanisms of IP are still not fully understood^[18], some studies have shown that the activation of Kupffer cells, leucocytes and the release of cytotoxic mediators on reperfusion may lead to a substantial breakdown of the hepatic microcirculation, an event which seems to play a key role following warm and cold ischemia^[19-21]. For example, Klar *et al.*^[22] observed an inverse correlation between the hepatic microvascular blood flow rate and the maximum postoperative enzyme release from the liver. On the other hand, in healthy livers, a balanced portal vein (PV) and hepatic artery (HA) inflow are significantly dependent on the arterial buffer response, an autoregulation system which influences the whole blood supply to the liver at the level of the hepatic arterioles and portal venules, and which is assumed to be predominantly the result of adenosine action^[23,24].

At this time, there is evidence that IP improves the hepatic microcirculation after warm as well as cold ischemia, but the influence of PM and IP on macrocirculatory parameters have not been elucidated as yet. In this study, we therefore investigated the hepatic inflow in patients undergoing liver resections with special regard to postischemic liver injury and patient outcome.

MATERIALS AND METHODS

Patients and randomization

The study was approved by the local Ethics committee

and written informed consent was obtained from each patient before randomization. We investigated 116 consecutive patients at our institution who were subjected to liver resection (time period 12 mo). Of these, only 68 patients could randomly be assigned according to the inclusion criteria. These were defined as “significant” hepatectomies, i.e. removal of at least one segment. A total of 48 patients were excluded from randomization for the following reasons: (1) extent of liver resection less than one segment according to Couinaud ($n = 16$); (2) anticipated necessity of total vascular exclusion ($n = 8$); (3) necessity of additional surgical procedures such as bilioenteric anastomosis or associated gastrointestinal procedures ($n = 3$); (4) laparoscopic liver resection ($n = 10$); (5) underlying liver cirrhosis ($n = 9$); and (6) emergency surgery ($n = 2$). Of the 68 randomized patients, 7 were withdrawn from the analysis because of intraoperative detection of inoperability. Finally, 61 patients were randomized to a control group (A, $n = 31$), receiving PM, and to a study group (B, $n = 30$), who received IP by cross-clamping the portal triad for 10 min followed by 10 min of reperfusion prior to PM. Determination of blood flow of the common HA and PV was carried out simultaneously before starting PM or IP (baseline) as well as 10 min after IP (only group B), and at 15 min of reperfusion as well as before abdominal closure (group A, 32 ± 4 min; group B, 29 ± 6 min after declamping the portal triad) using the transit-time flowmeter (CardioMed CM 2005; MediStern AS, Oslo, Norway). This device measures the difference in travel time between pulses transmitted in the direction of, and against, the flow. The blood flow velocity is directly proportional to the measured difference between upstream and downstream transit times. Because the cross-sectional area of the probe/vessel was known as the probes were individually adapted to the vessel diameter, the product of that area and the flow velocity provided a measure of volumetric flow. The calculations were easily performed by a microprocessor-based converter and displayed online on a computer during surgery.

Study design

The targeted endpoints were the occurrence of IP- and PM-related flow changes of the HA and PV at defined time points. Secondary endpoints were serum levels of alanine aminotransferase (ALT) on postoperative day 1 and complication rates. Operations were performed by 4 experienced abdominal surgeons in a routine clinical setting. Transection was started immediately after inducing PM which was maintained until the transection was finished. Parenchymal transection was performed using a water jet cutter (Saphir Medical, Lyon, France). The volume of the resected liver was determined by the quantity of displaced fluid in a pre-filled trough.

All anesthetic procedures were performed by the same team of experienced anesthesiologists ensuring a standardized protocol. To meet intraoperative fluid demand and to compensate for blood loss, crystalloids and colloidal solutions, respectively, were infused as described elsewhere^[17]. Adequate mean arterial pressure (MAP >

Table 1 Baseline data of study patients

Group	Age (yr)	Sex (n) M/F	Tumor (n) mal/non mal	Fibrosis (n) none/mod/sev	Steatosis (n) none/min/mod/sev
Control (A) (n = 30)	57 ± 14 (26-81)	18/12	26/4	10/15/5	8/16/5/1
IP (B) (n = 31)	55 ± 13 (28-77)	19/12	28/3	12/14/5	10/14/5/2

OP: Operation; PM: Pringle maneuver; LR: Liver resection; LV: Liver volume.

65 mmHg), central venous pressure (CVP 9-14 mm Hg), and diuresis (> 100 mL/h) were maintained throughout the operation by fluid infusion and, when necessary, by administration of vasopressors (dopamine 2-3 $\mu\text{g}/\text{kg}$ per hour and/or norepinephrine) as appropriate.

Laboratory parameters of hepatocellular injury (ALT) and liver function (bilirubin) were obtained before surgery and on postoperative days 1, 2 and 7. Transient liver failure was defined as bilirubin levels > 5 mg/dL and/or prothrombin activity $< 40\%$ for at least 3 postoperative days. Fatal liver failure was defined as death from irreversible hepatic dysfunction in the absence of other causes.

Statistical analysis

Numerical values are presented as mean and standard deviation unless otherwise noted. All significance tests were 2-sided and a P -value < 0.05 was considered statistically significant. Data analysis was performed using SPSS 11.0 (SPSS Inc., Chicago, USA). Comparison between the 2 groups (with/without IP) was performed using the Mann-Whitney U test, the χ^2 test or the Fisher exact test, as appropriate. The association between flow parameters and peak levels of postoperative ALT (day 1) was evaluated by the Pearson Product Moment Correlation. Multivariate analysis of complications was performed by means of logistic regression (backward selection). A multivariate analysis was performed by entering parameters that appeared to be of significance on the univariate analysis into a Cox proportional hazard model to test for significant effects while adjusting for multiple factors.

RESULTS

Baseline data

The analysis of collected data was based on the criteria of the CONSORT group^[25]. There were no differences in demographic data and liver histology between the 2 groups (Table 1). Intraoperative parameters were also comparable between the controls and the study population (Table 2).

Flow characteristics

The perfusion data of the HA and PV prior to any intervention (baseline) did not differ between groups (Table 3). Patients who did not receive IP (controls), showed a markedly decreased PV flow by 29% at 15 min reperfusion and by 26% before abdominal closure (32 ± 4 min after declamping). Simultaneously, a slight increase in HA flow of 8% and 3.5% was observed after 15 and 32 min, respectively, of reperfusion of the liver remnants (Figure 1A). In contrast, patients who received IP (group B), maintained stable PV flow during the IP procedure as well as at 15 and 29 min after declamping the portal triad (Figure 1B). In addition, IP induced a more than 200% increase in HA perfusion immediately after IP and the significantly elevated arterial flow was maintained at 15 min (+56%) as well as at 29 min (+38%) after starting reperfusion of the liver remnants, demonstrating a continuing influence of IP on the postischemic blood supply (Table 3, Figure 1B). This results in a total increase in liver perfusion *via* HA and PV of 27% when patients underwent the IP procedure ($P < 0.01$, Table 3).

Laboratory parameters

Postischemic liver damage was measured by ALT levels during the postoperative course. In controls, we observed a significant ALT increase from 28 ± 12 U/L to 550 ± 659 U/L on day 1 when compared to preoperative values, which clearly suggests the PM as the cause of enzyme release. In contrast, IP-treated patients showed markedly reduced ALT levels of about 50% (247 ± 210 U/L, $P < 0.05$), indicating substantial hepatoprotection by this procedure (Table 4). In the further course, postischemic elevated ALT levels in both groups returned to normal within 7 d of hepatectomy. Serum bilirubin levels were determined as a parameter of hepatocellular function, but did not show notably different values at any time during the postoperative course (days 1-7, Table 4).

Intraoperative parameters and postoperative course

Blood loss as well as the need for autologous transfusion

Table 3 Flow characteristics of patients undergoing PM (control, *n* = 30) and IP + PM (study group, *n* = 31)

Group	Vessel	Baseline (mL/min)	After IP (mL/min)	15 min (mL/min)	Before abd. closure (mL/min)
Control	HA	141 ± 24	-	152 ± 29	146 ± 18
IP	HA	126 ± 19	263 ± 51	196 ± 38 ^a	174 ± 22 ^a
Control	PV	1023 ± 130	-	726 ± 121	757 ± 58
IP	PV	930 ± 94	920 ± 81	919 ± 75 ^b	949 ± 62 ^a

^aDeath; ^bRequiring re-operation. Total complication rate was 14/30 (45%) in controls (A) and 6/31 (20%) in the IP group (B). One death in the study group (B) resulted from a perforated duodenal ulcer (postoperative day 21). RPC: Red packed cells; ALT: Alanine aminotransferase; LF: Liver failure; compl.: Complications.

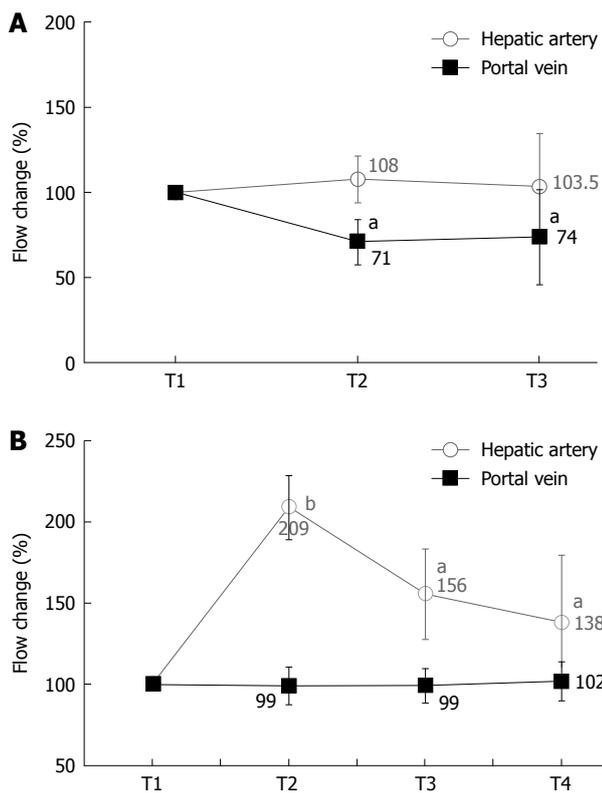

Figure 1 Changes in portal vein (PV) and hepatic artery (HA) inflow (100% = baseline) at operation (mean ± SD) in the control group (A) and study population (B). T1: Before starting the Pringle maneuver; T2: At the end of the IP procedure, i.e. 10 min ischemia and 10 min of reperfusion; T3: One minute of simultaneous reperfusion of PV and HA; T4: Immediately before abdominal closure (29 ± 6 min and 32 ± 4 min after stopping portal triad crossclamping in group A and B, respectively). ^a*P* < 0.05, ^b*P* < 0.01 vs baseline.

were significantly lower in the IP-treated group with 17% of patients receiving blood transfusion vs 48% in the control group (*P* < 0.05, Table 4). The postoperative

course was uneventful in 24/30 (80%) patients in group B but only in 17/31 (53%) patients in group A (*P* < 0.05). Liver dysfunction, as previously defined, occurred in 2 patients of group A, but only in one patient of the IP-treated group (Table 4). Biliary leakage ceased spontaneously in 4 of the 6 patients (67%) of controls, but the other two patients required re-operation and bilioenteric anastomosis. In the study group, 2 patients had transient bile secretion and one patient of this group needed re-operation (bilioenteric anastomosis) (Table 4).

Blood supply to the liver and hepatocellular injury

With regard to earlier work, demonstrating a strong correlation between microcirculatory failure and postischemic enzyme release^[22,26], it was of particular interest to determine whether there were changes in macrohemodynamic parameters, i.e. the PM and IP may have an impact on parenchymal cell damage. Firstly, we analyzed the correlation between PV flow and ALT levels on day 1. Interestingly, by applying the Pearson Product Moment Correlation we did not find a significant association between the amount of the hepatocellular injury and quality of PV perfusion, either in controls (*r* = -0.38, *P* = 0.3) or in IP-treated patients (*r* = -0.41, *P* = 0.2). In contrast, when the HA flow of patients with PM (controls) and the corresponding ALT values on day 1 were analyzed, we found a weak, but significant inverse correlation, indicating a substantial influence of the macrocirculation at reperfusion on post-ischemic liver injury (*r* = -0.62, *P* = 0.042, Figure 2A). This correlation was even more evident, when patients underwent IP prior to PM as shown in Figure 2B (*r* = -0.73, *P* = 0.024), suggesting the HA perfusion was more susceptible to the procedure of IP in warm liver I/R.

Predictors of postoperative morbidity

Parameters which were predictive for the development of

Table 5 Factors predicting occurrence of postoperative complications by multivariate logistic regression (backward selection) of factors of importance or significance on univariate analysis

Analysis (<i>P</i> -value)	IP treatment	Length of PM	Resected LV	HA flow	PV flow	Liver steatosis	Liver fibrosis
Univariate	0.038	0.043	0.067	0.044	0.72	0.81	0.94
Multivariate	0.047	0.022	NS	NS	NS	NS	NS

Treatment with IP and length of the PM are the only independent predictors of complications. NS: Not significant.

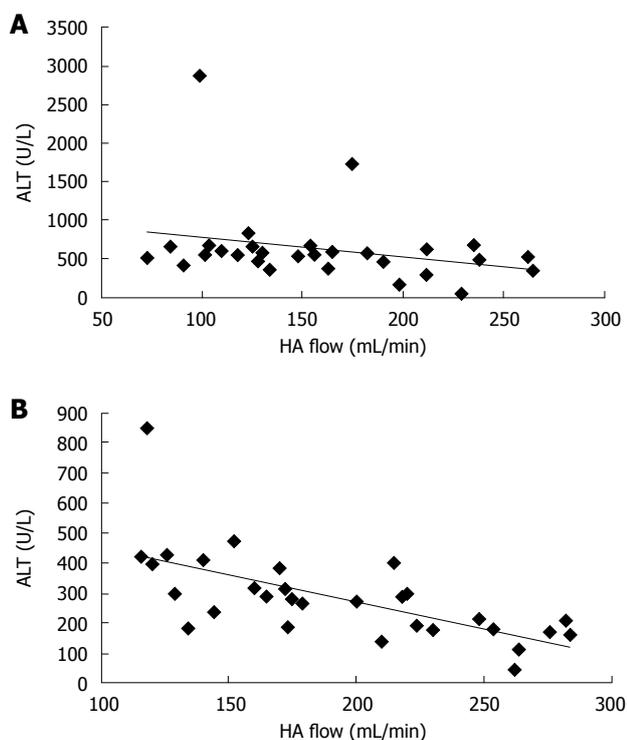

Figure 2 The Pearson product moment correlation between HA flow and alanine aminotransferase (ALT) levels. On day 1, there is an inverse correlation ($P < 0.05$) in the control group (A) undergoing PM ($r = -0.62$). In patients undergoing IP prior to PM (B), an even stronger correlation ($r = -0.73$, $P < 0.01$) was found. Straight lines represent regression analysis; data include values of all patients.

postoperative complications (ALT release, hepatic failure, biliary complications) are given in Table 5. Of 7 investigated parameters only the length of the PM and the procedure of IP were factors independently influencing the outcome of patients after hepatic resection. In particular, it was also found that the quality of HA perfusion was not predictive of complications, presumably reflecting the complex downstream mechanisms of liver I/R which might only in part be related to macrohemodynamic changes of blood flow to the postischemic liver.

DISCUSSION

This study presents the first assessment of human hepatic macrocirculation in response to I/R injury after the PM and IP in human hepatectomy. The main results obtained are: (1) that IP significantly improves hepatic macrocirculation upon reperfusion of liver remnants; (2) that the HA contributes most to the improved blood supply of the

liver; and (3) that the quality of HA flow exhibits a strong correlation with postischemic ALT release.

During liver surgery in humans clamping of the portal triad (PM) is practiced to minimize intraoperative blood loss, but can lead to serious liver dysfunction^[2,7,27]. Consequently, it has been generally accepted that periods of warm and cold ischemia of the liver should be shortened as much as possible^[4,28]. Some experimental and clinical studies suggested that intermittent clamping of the portal triad reduced the negative effects of prolonged continuous warm ischemia on hepatic reperfusion injury^[7,29]. However, the most important problems associated with that procedure are an increased blood loss during the episodes of reperfusion^[7,30] and a marked prolongation of the operation time^[30,31]. Ischemic preconditioning may combine the beneficial effects on reperfusion injury with the avoidance of additional blood loss during surgery^[30,32].

In animal experimental studies, hepatic I/R is associated with perfusion failure of sinusoids due to significant hemoconcentration, reduced perfusion pressure, pressure-related sinusoidal leukostasis, as well as sinusoidal narrowing caused by hypoxia-induced endothelial swelling^[33]. The impaired restoration of hepatic microvascular flow correlates also with the extent of liver injury after hemorrhagic shock and resuscitation^[34]. Prevention of microcirculatory failure may largely protect the liver from parenchymal cell necrosis after I/R, suggesting that the degree of microvascular failure determines the extent of lethal hepatocyte injury^[34]. Similar relationships between liver perfusion and injury could be observed in humans after warm and cold ischemia^[26,35]. Interestingly, Puhl *et al*^[26] could demonstrate a significant inverse correlation of the quality of the microvascular perfusion with postoperative liver enzyme release as well as bilirubin elimination in human liver transplants. This indicates that the observed (relative) hyperemia in the sinusoids might confer protection against postischemic liver injury. Another study by Klar *et al*^[22] could also demonstrate in patients an inverse correlation between the intraoperatively measured hepatic microvascular blood flow rate and the maximum postoperative enzyme release from the liver. However, neither study included data on macrohemodynamic parameters, i.e. flows in the HA and PV in these clinical settings. Therefore, it cannot be concluded that the preservation of the sinusoidal blood flow after I/R can be the result of preservation of the HA and PV inflow during the reperfusion period.

While changes in the nutritive sinusoidal blood flow are the result of complex humoral, cellular, and immunologic interactions, the mechanisms leading to microcirculatory shutdown after liver I/R are related, at least in part

also to upstream mechanisms, i.e. regional macrocirculation of the liver^[23,36]. Consequently, efforts should also focus on the preservation of an optimal blood supply to the liver under different pathological conditions at the levels of the HA and PV. In line with this, it was demonstrated that hepatosplanchnic blood flow was still reduced in humans at 60 min of reperfusion after severe hypovolemia, even though arterial blood pressure, cardiac output, and blood flow to other organs was already fully restored^[37].

In the present study, we observed a severely decreased portal blood flow and a minimal increase in the HA flow on reperfusion of livers undergoing more than 30 min of portal crossclamping, a time period which is known to induce significant hepatocellular injury in humans^[16]. We also found that IP could abolish the postischemic PV flow decrease and, *vice versa*, IP induced a significantly better HA flow throughout the reperfusion period, resulting in a markedly improved overall blood supply to the liver. This might be of substantial importance with regard to the nutritive sinusoidal perfusion, given that the autoregulatory capacity of the HA to maintain a constant flow rate in the presence of pathological conditions is limited, known as the hepatic arterial buffer response^[23,24]. Therefore, IP effectively restored the total hepatic flow to almost normal values during reperfusion whereas in the control group the minimal increase of the HA flow failed to compensate for the postischemic perfusion deficit at the PV (Table 3). Because hemodynamic parameters, like MAP, CVP, and heart rate were kept stable upon reperfusion, and IP-treated patients did need significantly lower norepinephrine administration to maintain an adequate MAP, this observation can only be explained by an IP-mediated effect^[17]. However, the exact mechanisms for that observation cannot be answered in the present study, although it was reported that both the hepatic arterial pressure-flow autoregulation and buffer response are mediated through changes in the wash-out of locally produced adenosine^[38], and that IP may effectively increase the formation of the vasodilator adenosine while the unwanted degradation of adenine nucleotides to purines caused by the PM can be attenuated by IP^[39].

Interestingly, we observed also a significant correlation between the postischemic ALT release on day 1 and the HA flow in controls, and this was even more pronounced in IP-treated patients, which clearly demonstrates that local macrohemodynamic changes at the HA may play an important role in the prevention of hepatic I/R injury. Because in our study hepatocellular damage was independent of postischemic PV flow changes, one can only speculate about the relevance of this observation, in particular with regard to the “small for size” problem in living related donor liver transplantation. This phenomenon, referred to as portal venous hyperperfusion of the partial liver allograft and associated with severe transplant dysfunction is thought to be the result of an imbalanced autoregulation of the arterial buffer response, resulting in a low concentration of adenosine-mediated HA branch constriction in the presence of increased portal perfusion^[40]. Because hepatectomies with the loss of up to 5 liver segments as in our study may be compared to the above-mentioned

situation, it was interesting that we found a substantial decrease of the PV flow upon reperfusion in controls which was not adequately compensated by an increase in the HA flow whereas in IP-treated patients the HA flow was significantly enhanced while the PV flow was kept stable during the reperfusion period, suggesting an impact of IP on the empirically observed reciprocal regulation between PV and HA inflow^[37]. However, the previously described substantial alterations of nutritive sinusoidal flow impairments may occur, even in the absence of overt macrohemodynamic changes, as a result of an I/R-induced heterogeneity of hepatic microvascular downstream mechanisms^[36,37]. In addition, despite postischemic ALT release being a well-established parameter for the estimation of hepatic injury following I/R, ALT levels alone are not predictive of the occurrence of postoperative liver failure following liver resection or transplantation^[14,41].

In summary, this study provides some new insights into macrohemodynamic changes during liver resection under inflow occlusion and on treatment with IP in humans. As we could not simultaneously investigate the hepatic microcirculation in this setting, the impact of HA and PV perfusion alterations on the nutritive blood supply in sinusoids remains speculative. Further studies are necessary to clarify this aspect, and in particular, the impact of macro- and microhemodynamic changes on postischemic liver function in humans.

The authors thank the members of the Institute of Pathology, LMU Munich for histological examination of liver samples.

COMMENTS

Background

Liver surgery has become a safe procedure in the past years and is mainly done because of malignant tumors. A common strategy to reduce blood loss during surgery is to temporarily shut down the blood supply to the liver [pringle maneuver (PM)], which, however may be associated with severe hepatocellular injury and consequent enhanced morbidity.

Research frontiers

Many efforts were undertaken to overcome the deleterious effects of ischemia-reperfusion injury of the liver caused by the PM. A new method of hepatocellular protection comprises ischemic preconditioning (IP), i.e. an additional short ischemia and reperfusion period prior to sustained ischemia, as set by the PM. However, mechanisms of protection by IP are still largely unknown.

Innovations and breakthroughs

Recent reports have highlighted numerous mechanisms which are involved in the protection of ischemic livers, including humoral, cellular, and immunologic interactions. Furthermore, an improved hepatic microcirculation seems to play a key role in liver protection following IP. However, no data were available which comment on hepatic macroperfusion under different conditions, such as IP.

Applications

By understanding how changes of blood flows of the portal vein and hepatic artery under inflow occlusion or IP may influence hepatocellular damage, this

study may provide some strategies for therapeutic intervention during liver surgery, such as selective portal triad clamping.

Terminology

IP of the liver consists of a short ischemia-reperfusion period (e.g. 10 min/10 min) immediately prior to longer periods of liver ischemia, which are often necessary during extended liver resections. Although it seems paradoxical, this additional short ischemia-reperfusion period confers protection on the liver by different mechanisms.

Peer review

This is a good study from a well-known liver surgery group with excellent methodology and adequate data analysis. The group expanded on their previous investigations on the role of IP in liver protection following resection. In the current study, the authors intuitively studied the effect of IP on hepatic artery and portal vein blood flow and demonstrated that IP prevented posts ischemic flow reduction of the portal vein and significantly increased the arterial perfusion.

Abstract

AIM: To perform a comparative analysis of clinicopathological correlations of cyclooxygenase-2 (COX-2) expression in pancreatic cancer, examined by monoclonal and polyclonal antibodies.

METHODS: The COX-2 expression in 85 resection specimens of pancreatic ductal adenocarcinoma was immunohistochemically examined using both monoclonal and polyclonal antibodies. The final immunoscores were obtained by multiplying the percentage of positive cells with the numeric score reflecting the staining intensity.

COX-2 expression levels were classified into three categories (0, 1+, and 2+) and the clinicopathological correlations were statistically evaluated and analyzed.

RESULTS: The positive tumor expression rates of COX-2 were 80.5% using monoclonal antibody and 69.4% using polyclonal antibody. In the Kaplan-Meier analysis, no significant correlations were found between levels of COX-2 expression and overall survival (OS), but trends to longer OS were found in COX-2 negative cases using monoclonal antibody. Significantly longer disease free survival was revealed in COX-2 negative cases using monoclonal antibody ($P = 0.019$). No correlations between COX-2 expression levels and grade (G), tumor (T) status and nodal (N) status were demonstrated. Low histological grade showed a strong association with a longer OS ($P < 0.001$). Correlation of survival and T status revealed a shorter OS in T3 tumors, but the results reached only marginal statistical significance ($P = 0.070$). In the multivariate Cox proportional hazards regression model, histological grade, T and N status remained valuable predictors of a worse survival with borderline significance for T [hazards ratio (HR) = 4.18 for G (if G = 3, $P < 0.001$); HR = 1.64 for T (if T = 3, $P = 0.065$); HR = 2.53 for N (if N = 1, $P = 0.006$)]. Higher grade, T or N status was associated with a worse OS.

CONCLUSION: The immunohistochemically assessed level of COX-2 expression does not seem to represent a valuable independent prognostic factor and is not superior to the conventional prognostic factors.

INTRODUCTION

Invasive ductal adenocarcinoma is the most common neoplasm in the pancreas, constituting about 90% of all pancreatic tumors^[1]. Pancreatic cancer represents the fourth leading cause of cancer-related death among men and women in western countries^[2,3]. Pancreatic cancer has no early warning signs and symptoms, so most patients present with advanced disease. Despite improved diagnostic and therapeutic modalities, pancreatic cancer still has a very poor prognosis. The incidence of pancreatic cancer almost equals the mortality rate, and it has one of the lowest overall 5-year survival rates (under 5%) among the epithelial cancers^[4-6].

The currently accepted model of the development of pancreatic ductal adenocarcinoma (PDAC) understands the oncogenesis of this malignancy as a multistep process, characterized by the progression from the normal ductal epithelium through the spectrum of duct lesions known as pancreatic intraepithelial neoplasia (PanIN) to invasive ductal adenocarcinoma^[7,8]. PanINs represent precursor lesions of ductal adenocarcinoma and their classification system distinguishes three grades of PanINs, which harbor a number of well-established molecular events including activation of oncogenes, inactivation of tumor suppressor genes, inactivation of DNA mismatch repair genes, various epigenetic alterations, dysregulation of oncoproteins, and others^[9-11]. Mediators of inflammatory pathways [e.g. cyclooxygenase-2 (COX-2), nuclear factor- κ B (NF- κ B), 5-lipoxygenase (5-LOX), interleukin-8 (IL-8) *etc.*] are also known to play an important role in carcinogenesis of pancreatic cancer and represent a key link between chronic inflammation and cancer^[12-14]. Prostaglandin H2 synthase (COX) represents an enzyme which is involved in the conversion of arachidonic acid to prostaglandins. Two COX isoforms, COX-1 and COX-2, have been identified to date^[15]. COX-1 is constitutively expressed in many tissues, and is involved in prostaglandin synthesis under physiological conditions. COX-2 is expressed under certain extracellular or intracellular stimuli, including mitogens, growth factors, proinflammatory cytokines, hormones and infectious agents, and is a component of cellular responses to inflammation. COX-2 is overexpressed in many human solid tumors including pancreatic cancer^[16,17]. Several studies have suggested a potential involvement of COX-2 pathways in the regulation of tumor-associated angiogenesis and cell growth in pancreatic cancer. COX-2 has been demonstrated to inhibit apoptosis, promote cell proliferation and to induce the expression of vascular endothelial growth factor^[18-21]. COX-2 overexpression has been reported in 56% to 90%

of ductal adenocarcinomas^[22]. A high level of COX-2 overexpression has also been described in PanIN lesions^[23-25], and COX-2 was suggested as a potential therapeutic target for chemoprevention and therapy of pancreatic cancer^[22,26].

A significant inverse relationship between COX-2 overexpression and survival rates has been reported in retrospective studies of different types of malignancies^[27-32]. Conflicting results have been shown in pancreatic cancer^[33-39] and the possible role of primary antibody used for the detection of COX-2 expression has been suggested^[33,40]. Comparative analysis has not yet been performed. In our study the expression of COX-2 in resectable pancreatic ductal adenocarcinomas was immunohistochemically examined using both monoclonal and polyclonal antibodies, and analyzed and correlated with clinicopathological parameters.

MATERIALS AND METHODS

Study group and tissue specimens

The study group (summarized in Table 1) consisted of 85 patients [41 males (48.2%) and 44 females (51.8%); median age 61 \pm 9.5 years (range 39-85 years)] with resectable pancreatic cancer who had undergone pancreatotomy at the Faculty Hospital Brno and the Masaryk Memorial Cancer Institute between 2000 and 2006. Seventy eight patients underwent hemipancreaticoduodenectomy, 5 patients caudal pancreatectomy and 2 patients total pancreatectomy. No distant metastases were found at initial diagnosis (M0). Selected tumors were histologically confirmed to be invasive ductal adenocarcinomas of the pancreas, and in all patients the formalin fixed paraffin embedded tissues were available for immunohistochemistry. Grading of tumor differentiation was done based on WHO criteria combining the judgment of glandular differentiation including mucin production, mitotic count and nuclear features. Tumor staging was performed according to the International Union Against Cancer TNM System (the 6th edition). The follow-up was available for 75 patients, with five patients alive at the end of the study. Survival data for the patients were obtained from the National Oncological Register of Czech Republic. Resection specimens were fixed in 10% neutral buffered formalin for 24 h and then embedded in paraffin. Hematoxylin-eosin (HE) staining of tissue sections was used to identify representative samples with structures of pancreatic invasive ductal adenocarcinoma (up to three tissue blocks for sectioning were selected for each individual PDAC case). These were selected for immunohistochemical (IH) analysis.

Immunohistochemistry

The results of IH analysis of COX-2 expression using polyclonal anti-COX-2 antibody [rabbit polyclonal antibody against COX-2 (H-62), dilution 1:50; Santa Cruz Biotechnology, Inc., Santa Cruz, California, USA] were retrieved from our previous study^[38], in which the identical study population was examined.

COX-2: Cyclooxygenase-2.

In the present study, the COX-2 expression was evaluated using mouse monoclonal anti-COX-2 antibody (dilution 1:50, clone CX229; Cayman Chemicals, Ann Arbor, MI, USA). IH detection of COX-2 was performed on 4 µm thick tissue sections applied to positively charged slides. The sections were deparaffinized in xylene and rehydrated through a series of alcohols. Antigen retrieval was performed in the lab microwave (Milestone, Sorisole, Italy) by heating in citrate buffer at pH 6.0 for 20 min at 98°C. The slides were incubated with anti-COX-2 antibodies overnight at 4°C. A streptavidin-biotin peroxidase detection system was used for COX-2 IH using monoclonal antibody (mouse IgG Vectastain Elite Kit, Vector Laboratories, Burlingame, California, USA). The visualization was performed using 3,3'-diaminobenzidine as a substrate (Fluca, Buchs, Switzerland). The slides were counterstained with Gill's hematoxylin.

Sections from COX-2 strongly positive colon carcinoma (immunoreactive 2 - see explanation below) were used as positive controls for COX-2 IH in each run. Additionally, COX-2 immunoreactivity in islets of endocrine pancreas served as an efficient internal positive control^[25]. Nega-

tive controls of COX-2 IH were performed by incubating samples without the primary antibody.

Evaluation of immunostaining

At least three different representative high-power (× 400) fields of tumor infiltration were examined. Cases with no stated minimal amount of the representative tumor tissue available were excluded. For both monoclonal and polyclonal antibody COX-2 IH, the percentage of positive cells was assessed, and the immunostaining intensity was classified into three categories: numeric score 0, no staining; numeric score 1, weak staining; numeric score 2, moderate and strong staining. The final immunoscore was obtained by multiplying the percentages of positive cells with the numeric score reflecting the staining intensity. Immunoscores were categorized into three levels: 0 (immunoreactive < 20); 1 (immunoreactive 20-49); 2 (immunoreactive 50-200). In cases with heterogeneous expression of COX-2, the average score was counted.

Statistical analysis

Association of categorical parameters was analyzed and presented in contingency tables and tested using Pearson Chi-square test. Kaplan-Meier curves were constructed and median survival times were computed for survival data. Log-rank test was used to test differences between groups. Univariate and multivariate analyses of survival data were performed using Cox regression model to evaluate the predictive value of analyzed parameters (COX-2, histological grade, T status, N status). The level of significance was considered *P* < 0.05. All analyses were done using Statistica for Windows 8.0.

RESULTS

Patient, tumor and treatment characteristics, and levels of COX-2 expression are summarized in Table 1. The immunohistochemical analysis of COX-2 expression displayed considerable heterogeneity in staining intensity and percentage of positive cells between and within individual PDAC cases. In cases with heterogeneous COX-2 expression within a lesion, the average immunoscore for such a case was counted. Using both monoclonal and polyclonal antibodies, the PDAC cells showed diffuse cytoplasmic patterns of expression. Expression of COX-2 (Figure 1), examined using monoclonal anti-COX-2 antibody, was revealed in 66 cases (80.5%); 27 tumors (32.9%) expressed COX-2 at 1+ level, 39 at 2+ level (47.6%), and 16 cases (19.5%) were COX-2 negative (in 3 samples, a sufficient amount of neoplastic tissue was not available for IH analysis, and analysis of COX-2 expression using monoclonal antibody was not performed). Results of immunohistochemical analysis of COX-2 expression by polyclonal antibody were retrieved from our previous study^[38] and are included in Table 1 [28 tumors (32.9%) expressed COX-2 at 1+ level, 31 at 2+ level (36.5%), and 26 cases (30.6%) were COX-2 negative].

The median overall survival (OS) in the study population was 1.3 years. There was no significant difference between OS in males and females (median OS 1.1 years

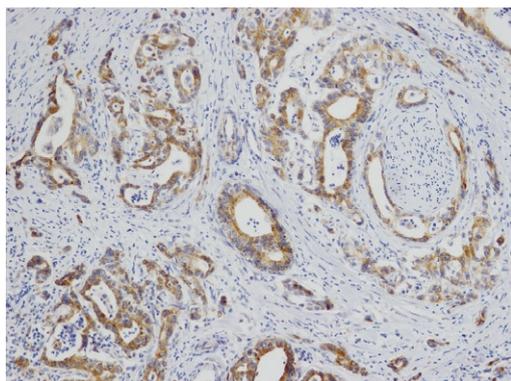

Figure 1 Overexpression of cyclooxygenase-2 (COX-2) in pancreatic invasive ductal adenocarcinoma with displayed perineural spreading of the tumor (COX-2 immunohistochemistry, original magnification, $\times 100$).

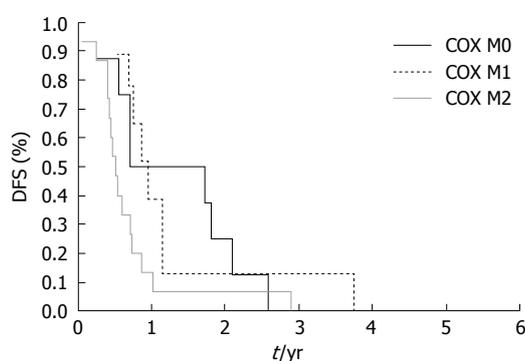

Figure 2 Kaplan-Meier disease free survival (DFS) curves for patients with resectable pancreatic cancer stratified by the level of COX-2 expression examined using monoclonal antibody. High expressors of COX-2 (2+, COX M2) had significantly lower survival curve than low expressors of COX-2 (1+, COX M1) or COX-2 negative cases (0, COX M0), $P = 0.019$.

in males *vs* 1.3 years in females; $P = 0.143$). Regarding nodal (N) status, N1 status was associated with shorter median OS (1.0 year in N1 group *vs* 1.5 years in N0 group; $P = 0.102$). Median OS for patients with adjuvant therapy was 1.4 years, and for patients without adjuvant therapy 1.3 years. The median disease free survival (DFS) for patients with adjuvant therapy was 0.8 years, and for patients without adjuvant therapy 0.7 years. Differences did not reach statistical significance.

No correlations between the levels of COX-2 expression (using both monoclonal and polyclonal antibodies) and the histological grade, T or nodal status were revealed.

In the Kaplan-Meier analysis, no significant correlations were found between the levels of COX-2 expression and OS (again using both polyclonal and monoclonal antibodies). However, trends to longer median OS were found in COX-2 negative cases (1.4 years in COX-2 negative *vs* 1.3 years in low expressors *vs* 1.0 in high expressors) using monoclonal antibody.

Correlating the levels of COX-2 expression and DFS; using polyclonal antibodies, trends to longer median DFS were found in COX-2 negative cases (1 year in COX-2 negative *vs* 0.7 years in low expressors *vs* 0.5 years in high expressors), but these values were not significant ($P = 0.211$); using monoclonal antibody, a statistically signifi-

cant correlation was found between COX-2 expression levels and DFS. Significantly longer DFS was revealed in COX-2 negative cases (median DFS 1.2 years in COX-2 negative *vs* 0.9 year in low expressors *vs* 0.5 year in high expressors, $P = 0.019$) (Figure 2).

Low histological grade showed a strong association with a longer OS ($P < 0.001$). Median OS for patients with grade 3 tumors was 0.7 years *vs* 1.6 years for grade 2 and 1.8 years for grade 1. Correlation of survival and T status revealed a shorter OS in T3 tumors, but the results reached only marginal statistical significance ($P = 0.070$). In a multivariate Cox proportional hazards regression model, histological grade (G), T, and nodal status remained valuable predictors of a worse survival with borderline significance for T [hazards ratio (HR) = 4.18 for G (if G = 3, $P < 0.001$); HR = 1.64 for T (if T = 3, $P = 0.065$); HR = 2.53 for N (if N = 1, $P = 0.006$)]. Higher grade, T or N status was associated with a worse OS.

DISCUSSION

Immunohistochemistry has become an integral part of histopathological diagnosis and can also provide important data to predict clinical course of the disease and potential therapeutic responsiveness. Thus, a validation of usefulness of different immunoprofiles and methodological approaches in predictive oncopathology is necessary. Based on a PubMed search, there are 7 papers^[33-39] reporting the correlations between COX-2 expression and selected clinicopathological parameters, including survival rates, in pancreatic cancer. The possible role of the COX-2 expression profile used as a prognostic factor for pancreatic ductal adenocarcinomas is largely discussed. Five studies did not show any trends or statistically significant correlations between COX-2 expression and survival rates^[35-39]. Our previous study^[38] also did not show significant correlations between these parameters, although trends to longer DFS in COX-2 negative cases were demonstrated. Recently, Matsubayashi *et al*^[34] reported that the COX-2 expression in patients with pancreatic ductal adenocarcinoma undergoing a potentially curative pancreaticoduodenectomy is predictive of survival, independent of other known prognostic markers, particularly in cancers ≥ 3 cm. These results were supported by Juuti *et al*^[33] who reported the expression of COX-2 to be associated with poor outcome for pancreatic ductal adenocarcinoma, which was independent of tumor stage, grade, or age in multivariate analysis. Moreover, these results were obtained, even if not only surgically resectable pancreatic cancers were included for analysis. Both Matsubayashi *et al*^[34] and Juuti *et al*^[33], who showed the significant correlation between COX-2 expression and clinical outcome, worked with mouse antihuman monoclonal antibodies. A discussion about the possible role of the selected antibody has been initiated. Antigenic blocking experiments showed higher sensitivity but lower specificity of polyclonal antibodies when compared with monoclonal antibodies^[40]. The presented comparative analysis only partially supported the possible prognostic role of COX-2 expression. Results retrieved from our previous study^[38], in which rabbit polyclonal antibody was

used, were completed with results obtained by examination of COX-2 expression using the same mouse antihuman monoclonal antibody that was used in the studies of Juuti *et al.*^[33] and Matsubayashi *et al.*^[34]. Using the monoclonal antibody, a significantly shorter DFS was found in patients with COX-2 positive tumors. Trends to shorter DFS in COX-2 expressors were only reported using the polyclonal antibody^[38]. No significant results were obtained regarding OS; the only trends to longer OS were demonstrated in COX-2 negative cases using monoclonal antibody. Our results do not sufficiently support the findings of Juuti and Matsubayashi, even when the standardized protocols for immunohistochemical evaluation of COX-2 expression, which should be preventive of known technical and interpretative pitfalls in immunohistochemistry, were used. Except for the mentioned type of antibody, the main factors potentially affecting immunohistochemical staining are the tissue processing, especially the type and length of fixation, and antigen retrieval. All tissues included in the study were routinely fixed in 10% neutral buffered formalin for 24 h, and antigen retrieval was performed using a standardized protocol. To avoid the misinterpretation of results, especially unspecific immunostaining, systems of positive (both external and internal) and negative controls were used in each run. Based on our results, COX-2 expression does not seem to represent a valuable independent prognostic factor, even if using the monoclonal antibody brought statistically significant results when correlating DFS and COX-2 expression levels and when trends to longer median OS were also demonstrated.

Correlating the COX-2 expression with the level of tumor differentiation, no significant relationship was revealed between the level of COX-2 expression and the histological grade of the pancreatic cancer independently of the antibody used. These findings are in agreement with previous studies^[23,35,41]. Merati *et al.*^[36] described increased expression of COX-2 in well differentiated ductal adenocarcinomas, but this trend was not observed in our study group, and the proposed role of COX-2 in carcinogenesis of pancreatic cancer remains puzzling.

The routinely used grading of the histological differentiation of tumors and evaluation of T and N status were proven to represent efficient prognostic factors. Higher grade of the tumor and N1 status were significantly associated with a shorter survival in patients with resectable pancreatic cancer. T3 status was associated with shorter survival only with marginal significance.

In conclusion, based on these presented results and the previously published data, an immunohistochemical assessment of COX-2 expression is not superior to the conventional prognostic factors such as tumor histological grade, stage, and nodal status. The possible role of COX-2 in potential targeted therapy and chemoprevention of pancreatic cancer using COX-2 inhibitors remain as unanswered questions and need further evaluation.

incidence of pancreatic cancer almost equals the mortality rate and the five-year survival rate does not reach 5%. Mediators of inflammatory pathways are known to play an important role in carcinogenesis and represent a key link between chronic inflammation and cancer.

Research frontiers

Cyclooxygenase-2 (COX-2) represents a key modulatory molecule in inflammation and carcinogenesis. COX-2 is known to have multiple tumorigenic effects. Increased expression of COX-2 has been observed in a variety of tumors including pancreatic cancer. In the literature, the prognostic significance of COX-2 expression including the role of antibody used for an evaluation of COX-2 expression profile have been discussed.

Innovations and breakthroughs

Recent reports have highlighted the role of COX-2 in carcinogenesis of pancreatic cancer and COX-2 has been suggested as a potential therapeutic target. This study confirmed the relationship of COX-2 to biological processes involved in pancreatic cancer, but its potential usefulness as a prognostic marker was not demonstrated.

Applications

The level of COX-2 expression does not seem to be a valuable independent prognostic factor, even if a significantly longer disease free survival and trends to longer overall survival were demonstrated in COX-2 negative cases using monoclonal antibodies. Immunohistochemical assessment of COX-2 expression is not superior to the conventional prognostic factors such as grade, stage and nodal status.

Terminology

COX-1 and COX-2 represent enzymes which are involved in the conversion of arachidonic acid to prostaglandins. COX-1 is expressed in many tissues under physiological conditions, while COX-2 is not constitutively expressed and several studies have suggested its positive role in regulation of growth and angiogenesis as well as inhibition of apoptosis in cancer.

Peer review

In this paper, Hermanova *et al* analyzed by immunohistochemistry COX-2 in pancreatic adenocarcinoma tissue samples. They concluded that the COX-2 expression does not seem to represent a valuable independent prognostic factor and is not superior to the conventional prognostic factors. Concerning the general view of the manuscript, it is characterized by a well done internal structure and acceptable quality of language. The data are clearly described and the statistical analysis seems to be correct.

Abstract

AIM: To report the incidence of non-small-bowel bleeding pathologies encountered during double-balloon enteroscopy (DBE) procedures and to analyse their significance.

METHODS: A retrospective study of a prospective DBE database conducted in a tertiary-referral center was conducted. A total of 179 patients with obscure gastrointestinal bleeding (OGIB) referred for DBE from June 2004 to November 2008 were analysed looking for the incidence of non-small-bowel lesions (NSBLs; all and newly diagnosed) encountered during DBE.

RESULTS: There were 228 (150 antegrade and 78 retrograde) DBE procedures performed in 179 patients. The mean number of DBE procedures was 1.27 per patient. The mean age (SD) of the patients was 62 ± 16 years old. There were 94 females (52.5%). The positive yield for a bleeding lesion was 65.9%. Of the 179 patients, 44 (24.6%) had NSBLs (19 of them had dual pathology with small-bowel lesions and NSBLs); 27 (15.1%) had lesions not detected by previous endoscopies. The most common type of missed lesions were vascular lesions.

Non-small-bowel lesions encountered during double-balloon enteroscopy performed for obscure gastrointestinal bleeding. *World J Gastroenterol* 2010; 16(15): 1885-1889 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i15/1885.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i15.1885>

INTRODUCTION

Obscure gastrointestinal bleeding (OGIB) accounts for approximately 5% of all patients with gastrointestinal (GI) bleeding^[1], and in approximately 75% of these patients, lesions can be found in the small bowel^[2-4].

Double balloon enteroscopy (DBE) was introduced by Hironori Yamamoto in 2001^[5] and in the same year, the United States Food and Drug Administration approved the use of capsule endoscopy (CE)^[6]. With the advent of CE and DBE, the management of OGIB has been revolutionised^[7]. Mid-GI bleeding, previously considered almost inaccessible, is now effectively diagnosed and treated by a combination of CE and DBE as ambulatory procedures.

Often non-small-bowel lesions (NSBLs) are identified

during the search for pathology in the small bowel. This was a commonly reported phenomenon in push enteroscopy studies^[8,9] and has been re-confirmed in CE studies, showing an incidence of NSBL of between 6.4%^[10] and 38.8%^[11]. The only DBE series looking at NSBL in OGIB reported a missed rate of 24.3%^[12]; however, most of these patients had no prior CE. Our study investigated the incidence and clinical relevance of NSBL encountered during DBE performed for OGIB in patients who had prior CE and standard endoscopies.

MATERIALS AND METHODS

Study protocol

This is a single-center retrospective study in a tertiary referral teaching hospital in Sydney, Australia, conducted between June 2004 and November 2008. One endoscopist with experience in DBE and in therapeutic endoscopy performed the DBEs, with trainee registrars assisting with the outer tube. DBE was performed using the Fujinon enteroscope (Fujinon EN-450T5, Fujinon Corp., Saitama, Japan). DBE was performed *via* the antegrade (oral) or retrograde (anal) route, and the intention was to perform a targeted approach with the DBE. The approach was determined by the endoscopist, based on the time a lesion was seen in relation to the total small-bowel transit time on the CE study. If the lesion was within the proximal two thirds of the small bowel, then an antegrade DBE was used.

The DBE was performed with the patient either conscious or under deep sedation with a combination of intravenous midazolam (Pfizer, Bentley, Australia), fentanyl (Mayne Pharma Ltd., Mulgrave, Australia), and propofol (Fresofol 1%, Pharmatel Fresenius Kabi Pty Ltd, Hornby, Australia) administered by the assistant or attending anaesthetist. The preparation for the procedures included a fasting period of 8 h before the oral procedure and a routine sodium picosulphate-based bowel preparation (Picoprep, Pharmatel Fresenius Kabi Pty Ltd., Hornby, Australia), or sodium phosphate-based preparations (Fleet, Ferring Pharmaceuticals, Gordon, Australia) with a clear fluid diet the day before the procedure for the anal approach. The DBE technique was as previously described by the innovator H Yamamoto^[5].

A failed retrograde DBE was defined as failure to insert the tip of the scope beyond the terminal ileum (approximately 20cm beyond the ileocaecal valve), as previously defined by Fry *et al*^[12]. The antegrade DBE was considered to be a failure if the endoscopist failed to pass the duodeno-jejunal flexure.

Patients

All patients were referred by their specialist gastroenterologists or gastrointestinal surgeons to our tertiary referral service. All patients included in the study had OGIB as defined by the American Gastroenterological Association (AGA) criteria^[13]. Thus, all patients had their initial investigations (EGD and colonoscopy) performed by their

referring gastroenterologists within 6 mo of their CE. Information on patient demographics, previous investigations (endoscopic and radiological), findings and intervention with DBE, limitations of insertion, complication rates, and follow-up after therapy were all retrieved. Ethics board approval was obtained before data collection.

Patients were excluded if they had no prior CE, if the procedure could not be completed due to poor bowel preparation not allowing progress through the colon, procedures performed for colonic indications, sedation failure and technical/equipment failure.

NSBLs were defined as bleeding lesions proximal to the papilla of Vater or distal to the ileocecal valve (i.e. within reach of conventional upper and lower endoscopes). Small-bowel lesions (SBLs) were defined as bleeding lesions that lie between papilla of Vater and ileocaecal valve. Bleeding lesions were defined as lesions that definitely or probably explain the patient's bleeding or anaemia, such as active bleeding lesions, lesions with recent evidence of bleeding, or healed/healing lesions likely to have recently bled. Red marks and classical telangiectatic angioectasia were considered bleeding lesions whereas red spots were not.

Statistical analysis

The statistical software package SPSS for Windows Version 14 (SPSS Inc., Chicago, Ill) was used to analyse the data. mean \pm SD was used to summarise data for continuous variables, whereas percentages were used for categorical variables.

RESULTS

Demographics

We identified 179 patients with OGIB who were referred for DBE. Two hundred and twenty eight DBE procedures (150 antegrade; 78 retrograde) were performed. Twenty seven patients had both antegrade and retrograde procedures. The mean number of DBE procedures was 1.27 per patient. The mean age (SD) of the patients was 62 \pm 16 years. There were 94 females (52.5%).

Findings

DBE found a bleeding lesion in 118 (65.9%) patients and the distribution of bleeding lesions is summarised in Table 1. Ninety-three out of the total 179 patients (51.9%) had a positive finding localised to SBLs, with the most common being angioectasia ($n = 64$), followed by tumours/polyps ($n = 13$), and small bowel ulcers ($n = 11$) (Table 2). NSBLs were found in 44 (24.6%) patients (Table 3). Nineteen (10.6%) patients had dual bleeding pathologies in both the small bowel and outside the small bowel. Six (3.4%) were inconclusive due to failed procedures and all of them were of the retrograde group. Normal examinations were seen in 55 (30.7%) patients.

A total of 46 NSBLs were found in 44 patients. The majority of these 46 NSBLs were of vascular origin ($n = 27$), and the others were of peptic ($n = 13$) and neoplastic

Table 1 Findings by DBE performed for OGIB and anatomical distribution of bleeding lesions *n* (%)

Findings and distributions	Subjects
Positive for bleeding lesions	118 (65.9)
Small bowel only	74 (41.3)
Non-small bowel only	25 (14.0)
Small bowel and non-small bowel	19 (10.6)
Negative findings/normal	55 (30.7)
Inconclusive (failure of procedure)	6 (3.4)
Total	179 (100.0)

DBE: Double balloon enteroscopy; OGIB: Obscure gastrointestinal bleeding.

Table 2 Small-bowel bleeding lesions found in the study cohort

Small-bowel lesions	<i>n</i>
Angioectasia	64

Bleeding diverticula	2
Meckel's diverticulum	1
Stricture	1
Total	94 ^a

^aNinety-four small bowel bleeding lesions were found in 93 patients. Nineteen patients also had NSBLs. NSBLs: Non-small-bowel lesions.

(*n* = 6) origins. Thirty-four of the lesions were found in the upper GIT; whereas 12 of the others were in the lower GIT. Of the 44 patients who had NSBL, 27 (15.1% from the total cohort) of their lesions were newly diagnosed during DBE, despite their prior investigations. These included angioectasia (*n* = 12), hiatus hernia with Cameron's erosions (*n* = 3), gastric ulcers (*n* = 2), and others (Table 3).

Interventions

Endoscopic interventions were performed in 96/118 (81.4%) patients who had positive bleeding lesions; 80 patients had therapeutic interventions (argon plasma coagulation in 75 and polypectomy in five), 14 patients had diagnostic biopsy, and two patients had tattoo placement for targeted surgery. Nineteen patients required medical treatment (18 were given proton pump inhibitors, one received chemotherapy for lymphoma), 11 patients were referred for surgery (eight neoplastic tumours, two bleeds that failed to be controlled endoscopically, and one Meckel's diverticulum).

Among the 44 patients who had NSBLs, endoscopic interventions were given in 23 patients; 20 of them had argon plasma coagulation and three had biopsies. Twenty one patients required medical treatments (18 required proton pump inhibitors and three were given treatment for variceal control). One patient had surgical resection for cecal carcinoma.

DISCUSSION

management of obscure GI bleeding was published in January 2000^[14] and revised in 2007^[13] following the availability of CE and DBE. The revised guidelines included CE as a pivotal investigation in OGIB. Depending of the findings on CE, DBE plays a key role in delivering targeted therapy or additional diagnostic clarification. One key element in the revised recommendations is for the inclusion of a repeat EGD and colonoscopy. The main point of contention is the timing of repeat procedures, as data is limited and hence the optimal timing of repeat procedures remains unclear.

Missed NSBLs have been a problem previously recorded in many published series. The literature for push enteroscopy has shown missed NSBL to account for up to 64.0% of all positive findings^[8]. In another push enteroscopy series, missed upper GIT lesions accounted for 10.2% of 233 patients who had OGIB^[9]. This issue has continued into the CE data, with several reports now showing missed NSBL in the order of 6.4%^[10] to 38.8%^[11]. Not surprisingly, Fry *et al.*^[12] in their DBE series reported the missed NSBL rate to be 24.3%; however, in that series CE was not available for all of their patients. In our cohort, NSBLs were detected in 24.6% of patients, a number strikingly similar to Fry *et al.*^[12]. However, all our patients had prior CE. In such circumstances, it stands to reason that CE would have identified some missed lesions and our figure should have been lower than that of Fry *et al.*^[12]. There was one clear explanation

for this. Not all NSBLs in our series were in fact completely missed. A significant number of these NSBLs were suspected or known by the referring doctors. However, referrals were made to exclude dual pathology (SBL and NSBL). Excluding those NSBLs that were known by previous investigations, the true missed rate for NSBL in our cohort was actually 15.1%.

There are several reasons to explain why lesions could be missed on conventional endoscopies. Lesions such as Dieulafoy's can be very difficult to diagnose as they can "resolve" by the time patients have their endoscopy. Often small-bowel bleeding can be caused by similar types of lesions and hence are dependent on the "timing" of DBE. This is best illustrated in study by Pennazio *et al*^[15], in which the group of patients with ongoing overt bleeding had a 92.3% positive yield on CE when compared to groups with previous overt bleeding (12.9%) and guaiac-positive stool/iron deficiency anaemia (44.2%). If DBE could be performed during active bleeding then similar diagnostic rates with the addition of therapy should be achieved, limited only by the inferior total enteroscopy rates of DBE (77.5%^[16] in the hands of experts).

Lesions such as Cameron's erosions also depend on the timing of endoscopy to confirm them as the bleeding source. Often, gastroenterologists referred such patients to our service with a high index of suspicion for Cameron's lesions but with no successful endoscopic timing. Hypovolemia and anaemia could cause lesions to look less obvious and this is particularly the case with small angioectasia, and could account for some missed lesions. Inadequate endoscopic examination also remains an issue. Despite the ease of EGD, careful examination for small lesions placed in awkward or in blind spots should be considered, and a more diligent and thorough examination is warranted in patients with OGIB. Likewise, an excellent colon preparation is required with a careful mucosal examination to exclude small mucosal bleeding points.

Missed lesions are highly relevant in the management of OGIB. Hartmann *et al*^[17] studied 47 patients who had OGIB and were subjected to CE and intraoperative enteroscopy. Despite the accurate diagnosis from total small bowel examination and curative endoscopic and surgical treatments, on a mean follow up of 346 d, 25.5% of the patients had a re-bleed, and 19.1% of them required further interventions or blood transfusion. This suggests that despite the gold standard diagnostic and therapeutic approaches (in this case CE and IOE), many patients continue to bleed. Missed lesions could play a key role in these patients. In some series of patients with OGIB and a negative CE who continue to bleed, a repeat CE can find a lesion in up to 75% of patients^[18]. Hence, patients who re-bleed need repeat examination of their entire GI tract to look for missed lesions.

In our cohort, 19 patients with NSBL had dual bleeding pathologies with both NSBL and SBL involvement. This suggests that if a significant NSBL is found during DBE, the small bowel examination should be completed, as approximately half of these patients will

also have a significant small bowel finding. Conversely, if a definite bleeding site is found in the small bowel, then careful examination for NSBL is still warranted, even when no suspicion exists for NSBL due to the high true missed rate in our cohort of 15.1%.

The low diagnostic rates in our cohort reflect some real issues in managing patients with OGIB. Not all findings at CE are relevant and often the role of DBE is to exclude a lesion. One recurrent and classic situation is folds of bowel that appear like a polyp or a submucosal lesion. In addition, flecks of transported blood or mucous on the bowel surface could be mistaken as angioectasia or ulcers. Several studies, including our previous work^[19], found that many CE findings are false positives.

We recognised the limitation of this study as being a retrospective series. It was difficult to classify all lesions into bleeding and non-bleeding lesions. We had to include a group of lesions as probable bleeders due to the size, appearance, history, and behaviour of the lesions. For instance, large polyps, extensive ulcerative disease, and malignant-looking lesions were considered probable bleeders, even though no blood or altered blood was detected on endoscopy. Likewise, diverticular disease might be considered a bleeder or non-bleeder based on their number and appearance.

In conclusion, NSBLs are a common finding during DBE, despite prior endoscopic examinations. Importantly, 15.1% of patients had unsuspected findings and hence careful examination of the entire GI tract is essential in all patients.

COMMENTS

Background

The problem of "missed" lesions seen at subsequent endoscopic examinations has been well documented in patients with obscure gastrointestinal bleeding (OGIB). The exact degree of this problem in the new era of capsule endoscopy and double-balloon enteroscopy remains unclear.

Research frontiers

The degree of the problem, the type of lesions missed, and the timing of repeat endoscopic examinations require further evaluation.

Innovations and breakthroughs

This paper shows that in a tertiary referral practice, the rate of missed lesions can be as high as 1 in 4 patients and thus highlights the relevance of repeat examinations in patients with ongoing OGIB.

Applications

In patients with ongoing OGIB without a definite finding on endoscopic evaluation, repeat procedures are worthwhile.

Terminology

OGIB is defined as bleeding with a negative endoscopy and colonoscopy.

Peer review

This paper is well written and provides new information on missed sites of bleeding within reach of conventional endoscopy and colonoscopy following capsule and regular endoscopy. The value of double balloon enteroscopy is also highlighted in diagnostic and therapeutic terms.

Abstract

AIM: To examine the coexistence of metachronous and synchronous cancer in branch duct intraductal papillary mucinous neoplasms of the pancreas (IPMN).

METHODS: We reviewed the records of 145 patients with branch duct IPMN between January 1991 and April 2008 and assessed the relationship between IPMN and intra- or extra-pancreatic carcinoma and the outcome of IPMN.

RESULTS: The mean observation period was 55.9 ± 45.3 mo. Among the 145 patients, the frequency of extra-pancreatic cancer was 29.0%. The frequency of gastric cancer, colon cancer, breast cancer, and pancreatic cancer were 25.5%, 15.7%, 13.7%, and 9.8%, respectively. Twenty (13.8%) of the patients died. The cause of death was extra-pancreatic carcinoma in 40%,

pancreatic cancer in 25%, IPMN *per se* in 20%, and benign disease in 15% of the patients.

CONCLUSION: The prognosis for IPMN depends not on the IPMN *per se*, but on the presence of intra- or extra-pancreatic cancer.

INTRODUCTION

Intraductal papillary mucinous neoplasm of the pancreas (IPMN) shows a wide spectrum of histological presentations, ranging from adenoma with mild atypia to adenocarcinoma, and was first described by Ohashi *et al*^[1] in 1980. IPMN is divided into two types, the main duct type and the branch duct type. In general, branch duct IPMN develops slowly and has a comparatively good prognosis. However, in several studies, it became evident that IPMN is a disease that very frequently coexists with cancer. Therefore, the prognosis of IPMN is more closely related to the coexisting disease than to IPMN

per se^[2-8]. In the present study, the prognostic significance of the coexistence of metachronous and synchronous cancer in branch duct IPMN was investigated.

MATERIALS AND METHODS

The subjects were 145 patients with branch duct IPMN, including 33 resected and 112 non-resected cases, between January 1991 and April 2008, who had been periodically followed-up to date. The ratio of males to females was 79:66, the mean age was 66.3 ± 10.2 years (range: 29-89 years), and the mean observation period was 55.9 ± 45.3 mo (range: 1-217 mo). We classified IPMN into the main duct type without multi-locular dilatation of the branch duct, and the branch duct type. The Institutional Review Board of Tokyo Medical University reviewed and approved the entire study.

Indication of surgery for branch type IPMN

In our department, we consider that surgery for the branch type IPMN is indicated when the diameter of the cyst is 30 mm or more, the diameter of the mural nodule is 10 mm or more, and cytology findings of the pure pancreatic juice reveal suspected malignancy.

Strategy for branch type IPMN

For regular follow-up, we performed hematological tests, including those for tumor markers (carbohydrate antigen 19-9, and carcinoembryonic antigen) and pancreatic enzymes (amylase, lipase, and elastase-1), and several types of imaging (ultrasonography, endoscopic ultrasonography, computed tomography, or magnetic resonance cholangiopancreatography) every 6 to 12 mo.

Clinicopathological assessment of branch type IPMN

We assessed the clinicopathological findings as outlined below. (1) The relationship between IPMN and intra- or extra-pancreatic cancer; and (2) Prognosis of IPMN.

Statistical analysis

Normally distributed data are presented as mean \pm SD. Significance was analyzed by the χ^2 test or Fisher's exact probability test, and Aspin-Welch's *t*-test. Statistically significant differences were denoted by $P < 0.05$. Statistical analysis was performed using Stat Mate III (ATMS Co Ltd, Tokyo, Japan).

RESULTS

The resected patients had significantly greater mean cyst diameter, diameter of the main pancreatic duct, and height of node protrusion compared to those of non-resected patients ($P < 0.05$, $P < 0.01$, and $P < 0.01$, respectively, Table 1).

The relationship between IPMN and intra or extra-pancreatic cancer

There was no statistically significant difference regarding

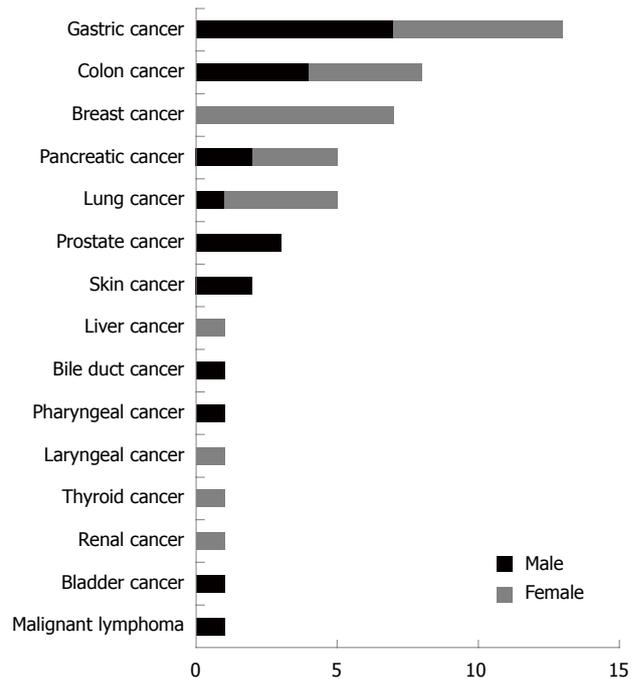

Figure 1 Details of intra- or extra-pancreatic cancers in patients with intraductal papillary mucinous neoplasms of the pancreas (IPMN).

pancreatic cancer, and cancer was detected in 15.7% (8/51) during follow-up for IPMN.

Prognosis of IPMN, and clinicopathological findings in fatal cases of IPMN

Of the 145 patients with IPMN, 13.8% (20/145) died. As shown in Figure 2, the cause of death was extra-pancreatic cancer in 40% (8/20), pancreatic cancer in 25% (5/20), IPMN *per se* in 20% (4/20), and benign disease in 15% (3/20) of the patients. In particular, the cause of death of resected and non-resected cases is shown in Figure 2B and C.

The clinicopathological findings in four fatal cases of IPMN are shown in Table 4. The ratio of men to women was 3:1, the mean age was 64.5 years, two patients underwent surgery immediately after detection, and both had invasive adenocarcinoma accompanying IPMN. In one of the resected patients, the cyst diameter was 35.0 mm and the height of node protrusion was 19 mm. However, lymph node metastasis was observed post-operatively and the patient died of cancer 14 mo later. The other patient was found to have a nodular lesion with a diameter of 26.6 mm and pancreatic cancer was diagnosed. The patient underwent surgery, but hepatic metastasis occurred post-operatively and she died of cancer eight mo later. Of the

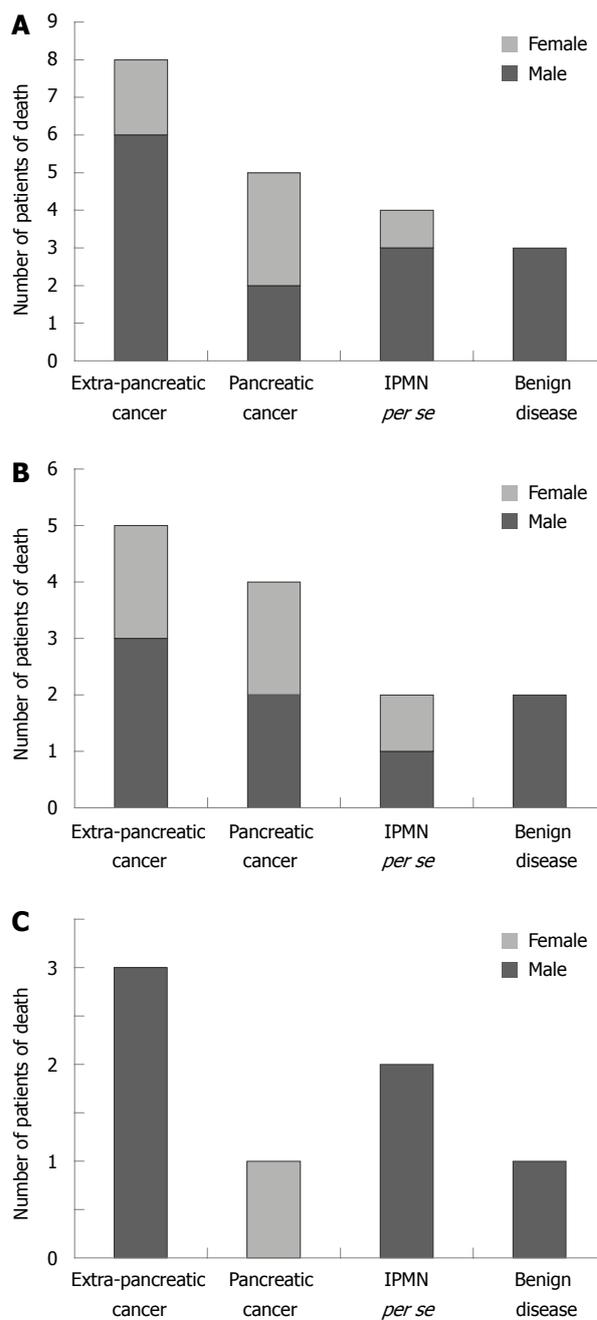

Figure 2 Number of patients of death. A: In patients with IPMN; B: In patients with resected IPMN; C: In patients with non-resected IPMN.

patients that died of cancer due to IPMN, two refused surgery and were therefore under observation only. They died

at 37 and 112 mo, respectively, after detection. One non-resected patient initially had a 60 mm cyst and a 10 mm height mural nodule. When the patient died 37 mo later, the diameter of the cyst was 90 mm and the height of the mural nodule was 30 mm. The other non-resected patient initially had a cyst 20 mm in diameter with no mural nodule protrusion and when the patient died 112 mo later, the cyst had become a nodular lesion with a diameter of 64 mm.

DISCUSSION

We set out to determine the prognostic factors affecting cases of IPMN accompanied by cancer. In the present study, it became evident that cases complicated with metachronous and synchronous cancers in branch-type IPMN are quite common. Other studies that closely investigated such patients reported frequencies of extra-pancreatic cancer of 23.6%-46.8% and of a total of 864 IPMN patients, 32.9% (284/864) had extra-pancreatic cancer, which is almost the same as the subjects in the present study, where the frequency was 29.0% (42/145)^[2-10] (Table 5). In addition, the most frequently occurring complications were gastric cancer and colon cancer, which

was the same as in this study (Table 6).

On the other hand, other studies reported pancreatic cancer occurring in 3.8 to 9.2% of IPMN cases^[6,11,12]. In our study it was 3.5% (5/145), which was slightly lower. In general, the etiology of second primary tumors is complex, involving multiple factors such as: (1) shared risk factors for the primary and secondary tumors, (2) host susceptibility to the development of specific tumors, (3) altered immunity as a result of the primary tumor and/or treatment, and (4) treatment with cytotoxic agents (radiotherapy and chemotherapy)^[3]. In the present study, there was no clearly significant difference between cases complicated with other organ cancers and those without such complications in terms of cyst diameter, diameter of the main pancreatic duct, and presence or absence of mural nodules. This demonstrated that these data cannot be used as indices in the discovery of intra or extra-pancreatic cancer. Thus, further investigations, including follow-up studies, are necessary.

In the present study, most cases of IPMN were diagnosed after extra-pancreatic cancer was diagnosed. However, there are also reports stating that the time of IPMN diagnosis is unrelated to the onset of extra-pancreatic cancer^[3,5].

The follow-up period and imaging modality for follow-up vary according to reports, and no consensus has been obtained. In this study, no case of pancreatic cancer occurred during follow-up. However, several researchers have reported pancreatic cancer after diagnosis of IPMN^[6,11-15]. These findings demonstrate that periodic follow-up is necessary, even after IPMN is diagnosed.

The 5-year survival of patients with IPMN that undergo resection was reported to be for 36%-66%, even among those with invasive cancer. Thus, longer survival than that for pancreatic cancer can be expected^[16-20]. According to our data, 25% of deaths were due to pancreatic cancer, while 40% were due to cancer of other organs. On the other hand, the follow-up periods of two patients who refused surgery and opted for conservative treatment, but who then died due to IPMN, were 37 and 112 m, which was relatively long. Our data demonstrated that to determine the prognosis for IPMN, intra- or extra-pancreatic cancer is the key factor, rather than the IPMN *per se*.

In conclusion, to decide on the prognosis for IPMN, the presence of intra- or extra-pancreatic cancer is the main prognostic factor, rather than IPMN *per se*. Therefore,

there is no fixed algorithm regarding the follow-up period or methodology, but in all cases, close follow-up, especially for the development of cancer, is very important.

COMMENTS

Background

Several investigators have suggested that the prognosis of the intraductal papillary mucinous neoplasms of the pancreas (IPMN) is more closely related to coexisting diseases than IPMN *per se*.

Research frontiers

In reports on studies that closely investigated such patients, the frequency of extra-pancreatic cancer was 23.6%-46.8% in a total of 864 IPMN patients, and 32.9% (284/864) had extra-pancreatic cancer, which corresponds well with the data from the subjects in the present study, where the frequency was 29.0% (42/145). On the other hand, many studies reported pancreatic cancer to occur in 3.8% to 9.2% of IPMN cases.

Applications

It appears to be important to determine the presence of intra- or extra-pancreatic cancer when examining the patients with IPMN.

Terminology

IPMN including branch duct type and main pancreatic duct type, have high risk for intra- or extra-pancreatic cancer, leading to death of patients.

Abstract

AIM: To clarify the gender differences about the clinical features and risk factors of low-dose aspirin (LDA) (81-100 mg daily)-associated peptic ulcer in Japanese patients.

METHODS: There were 453 patients under treatment with LDA (298 males, 155 females) who underwent esophagogastroduodenoscopy at the Department of Gastroenterology and Hepatology of Hiratsuka City Hospital between January 2003 and December 2007. They had kept taking the LDA or started treatment

during the study period and kept taking LDA during the whole period of observation. Of these, 119 patients (87 males, 32 females) were diagnosed as having LDA-associated peptic ulcer. We examined the clinical factors associated with LDA-associated peptic ulcer in both sexes.

RESULTS: A history of peptic ulcer was found to be the risk factor for LDA-associated peptic ulcer common to both sexes. In female patients, age greater than 70 years (prevalence ORs 8.441, 95% CI: 1.797-33.649, $P = 0.0069$) was found to be another significant risk factor, and the time to diagnosis as having LDA-associated peptic ulcer by endoscopy was significantly shorter than that in the male patients ($P = 0.0050$).

CONCLUSION: We demonstrated gender differences about the clinical features and risk factors of LDA-associated peptic ulcer. Special attention should be paid to aged female patients taking LDA.

INTRODUCTION

Low-dose aspirin (LDA) is one of the main agents used for the prevention of thromboembolic vascular events, and has the advantages of both low cost and a prolonged duration of antiplatelet action^[1]; however, it is associated with a doubling of the risk of gastrointestinal bleeding, even at doses as low as 75 mg daily^[2,3]. The gender differences in the clinical manifestations of LDA-associated gastroduodenal mucosal injury have not been well studied. The aim of this study was to clarify the clinical features and risk factors of LDA-associated gastroduodenal mucosal injury in both sexes.

MATERIALS AND METHODS

Patients

There were 453 patients under treatment with LDA (298 males; median age, 71 years; age range, 43-93 years and 155 females; median age, 73 years; age range, 47-95 years) who underwent esophagogastroduodenoscopy (EGD) at the Department of Gastroenterology and Hepatology of Hiratsuka City Hospital between January 2003 and December 2007. The study was conducted in accordance with the Declaration of Helsinki and the study protocol was approved by the Ethics Committee of Hiratsuka City Hospital. The exclusion criteria were: patients who were taking LDA for less than 7 d, patients who had been previously diagnosed or treated for LDA-associated gastroduodenal mucosal injury in the past, patients with gastric or duodenal cancer, history of gastric or esophageal surgery and any current active cancer. Detailed information about the drug treatment and other risk factors were obtained from the medical records and also from interviews with the patients when they underwent medical examination. Concomitant use of anti-ulcer drugs (proton-pump inhibitors (PPIs), Histamine type 2 receptor antagonists (H2RAs), muco-protective agents, anticoagulants and/or antiplatelets and antithrombotic agents was defined as starting with LDA or taken for more than 4 wk before receiving endoscopy.

Endoscopic assessments

Endoscopic examinations were performed in each patient. Only ulcers with whitish exudate that were over 5 mm in size^[4] and had perceptible depth were included in the determination of the ulcer, with ulcer scars being excluded.

Helicobacter pylori infection status

The patients diagnosed to have ulcer were checked for *Helicobacter pylori* (*H. pylori*) infection using the *H. pylori* serum antibody assay, urea breath test, rapid urease test and *H. pylori* culture of two biopsy specimens obtained from the gastric body and antrum. If one of the tests was positive, the patient was labeled as *H. pylori*-positive, and if more than two of the tests were negative, the patient was labeled as *H. pylori*-negative.

Table 1 Clinical characteristics of patients taking LDA enrolled in the present study

	Patients with ulcer (n = 119)	Patients without ulcer (n = 334)	P-value

¹Forty-six patients presented with melena and/or hematemesis and bleeding source in the stomach or duodenum identified by endoscopy and were excluded from GI symptoms in this analysis. LDA: Low-dose aspirin; GI: Gastrointestinal; NS: Not significant.

Statistical analysis

Statistical evaluation was carried out using Fisher's exact test, *t*-test or Mann-Whitney *U*-test and these variables were also evaluated by multivariate logistic regression model using a Wald statistic forward stepwise selection. The level of significance was set at $P < 0.05$. Statistical analyses were performed with Stat View software (SAS Institute, Cary, NC).

RESULTS

The baseline characteristics of the study population

The 453 patients under treatment with LDA who underwent EGD were included in this investigation. The baseline characteristics of the study population are summarized in Table 1. One hundred and nineteen (26.3%, 87 males, 32 females) of the 453 patients receiving LDA were diagnosed as having LDA-associated peptic ulcer, consisting of 92 patients with LDA-associated gastric ulcer (71 males, 21 females), 20 patients with duodenal ulcer (14 males, 6 females) and 7 patients with gastric and duodenal ulcers (2 males, 5 females).

The age of female patients with ulcer was greater than that of without ulcer ($P = 0.0338$). The most common indication for LDA was secondary prevention of ischemic heart disease (62.3%, 282/453). There were no significant differences in the distribution of underlying diseases between patients with ulcer and without ulcer ($P = 0.8380$). There were no significant differences in the presence of the gastrointestinal (GI) symptoms, defined as abdominal pain, nausea, reflux symptoms and/or the indigestion

Table 2 Univariate analysis to identify factors predictive of LDA-associated gastroduodenal ulcer in male and female patients

Factor	Male patients (n = 299)			Female patients (n = 155)		
	Patients with ulcer (n = 87)	Patients without ulcer (n = 211)	P-value	Patients with ulcer (n = 32)	Patients without ulcer (n = 123)	P-value

Smoking	22	36	NS	1	8	NS

PPIs: Proton-pump inhibitors; H2RAs: Histamine type 2 receptor antagonists; NSAIDs: Nonsteroidal anti-inflammatory drugs.

Table 3 Age-stratified prevalence of LDA-associated peptic ulcer in males and females

Age (yr)	Patients with ulcer (n = 119) (M/F)	Patients without ulcer (n = 334) (M/F)
40-49	2/0	4/3
50-59	15/2	20/7
60-69	24/2	64/28
70-79	33/17	94/55
80-89	10/11	26/27
90-	2/1	3/3

syndrome, between the patients with ulcer and without ulcer ($P = 0.0761$). Forty-six patients presented with melena and/or hematemesis and bleeding source in the stomach or duodenum identified by endoscopy were excluded from GI symptoms in this analysis. Moreover, even in patients with peptic ulcer, about half were asymptomatic.

Univariate analyses to identify predicted factors of LDA-associated gastroduodenal ulcer in both sexes were shown in Table 2. A history of peptic ulcer was found to be the only significant risk factor common to both sexes (male, $P = 0.0109$, female $P = 0.0030$), and age greater than 70 years was another risk factor in female patients ($P = 0.0443$). As shown in Table 3, there were no significant differences in the prevalence of LDA-associated peptic ulcer among age brackets in either sex (male, $P = 0.3137$, female $P = 0.3612$).

***H. pylori* infection status**

The *H. pylori* infection status was determined in 69 patients (58.0%, 69/119), but remained unknown in the remaining 50 patients who were therefore not included in the statistical analysis of this parameter. Of the 69 patients, 62.3% (43/69) were *H. pylori*-positive [gastric ulcer, 69.1% (38/55); duodenal ulcer, 25.0% (2/8); gastric and duodenal ulcer, 50.0% (3/6)] and 26 (37.7%) were *H. pylori*-negative. There were no significant differences in the *H. pylori* infection rate between both sexes [male: 66.7% (30/45), female: 54.2% (13/24)] ($P = 0.4344$). The

Table 4 Duration of LDA administration until diagnosis as having LDA-associated peptic ulcer in 106 patients

Month	Male (n = 78)	Female (n = 28)
-1	3	3
1-11	15	6
12-23	6	6
24-35	10	5
36-47	11	4
48-59	5	0
60-71	5	2
72-	23	2
Mean (min-max)	42 (1-223)	25.5 (1-130)

H. pylori infection rate was significantly lower in patients with LDA-associated ulcer as compared with that in patients with non-LDA-associated ulcer [including other nonsteroidal anti-inflammatory drugs (NSAIDs) associated ulcer] (77.0%, 419/544) diagnosed in the same study period (data are not shown in Tables) ($P = 0.0112$).

Time to diagnosis as having LDA-associated peptic ulcer by endoscopy

As shown in Table 4, we investigated the time from the start of LDA administration to the diagnosis as having LDA-associated peptic ulcer by endoscopy in 106 of the 119 patients (89.1%). LDA-associated peptic ulcer was diagnosed within the first month in 6 cases (5.7%) within the first 12 mo in 28 cases (26.4%), and within 5 years in 74 cases (69.8%). In female patients, the duration was significantly shorter than in male patients ($P = 0.0050$) (male: mean 42.0 mo; range, 1-223 mo, female: mean, 25.5 mo; range, 1-130 mo). The incidence of LDA-associated peptic ulcer seemed almost constant and did not decrease with time, at least over the follow-up period of 72 mo in this study.

Multivariate analysis to identify the risk factors of LDA-associated peptic ulcer in both sexes

Table 5 shows the results of multivariate analyses to identify the risk factors of LDA-associated peptic ulcer

Table 5 Multivariate analysis to identify risk factors of LDA-associated gastroduodenal ulcer in male and female patients

Factor	Odds ratio	95% CI	P-value
Male patients (n = 211)			
PPIs	0.069	0.009-0.555	0.0120
H2RAs	0.498	0.256-0.967	0.0396
History of peptic ulcer	3.745	1.734-8.088	0.0008
Female patients (n = 123)			
H2RAs	0.255	0.077-0.839	0.0245
History of peptic ulcer	6.439	1.874-22.131	0.0031
Age ≥ 70 yr	8.441	1.797-33.649	0.0069

Odds ratio: Prevalence odds ratio.

in both sexes. In male patients, a history of peptic ulcer (prevalence ORs 3.745, 95% CI: 1.734-8.088, $P = 0.0008$) was found to be associated with an increase in the risk, and a history of PPIs (prevalence ORs 0.069, 95% CI: 0.009-0.555, $P = 0.0120$) and/or H2RAs (prevalence ORs 0.498, 95% CI: 0.256-0.967, $P = 0.0396$) use was found to be associated with a decrease in the risk. In female patients, a history of peptic ulcer (prevalence ORs 6.439, 95% CI: 1.874-22.131, $P = 0.0031$) and age greater than 70 years (prevalence ORs 8.441, 95% CI: 1.797-33.649, $P = 0.0069$) were associated with an increase in the risk. Statistical analysis with respect to the use of PPIs could not be performed in female patients, because there was no female patient taking PPIs who was diagnosed as having LDA-associated peptic ulcer.

DISCUSSION

The present study demonstrated gender differences in the clinical features of LDA-associated gastroduodenal ulcer in Japanese patients. Previous reports have indicated age greater than 65 years, previous history of peptic ulcer^[4,5], use of other NSAIDs^[6] and *H. pylori* infection^[7] as some of the risk factors of LDA-associated peptic ulcer, and the concomitant use of antisecretory drugs as a factor reducing the risk of LDA-associated peptic ulcer^[5,8,9]. In this study, a history of peptic ulcer was found to be the risk factor of LDA-associated peptic ulcer common to both sexes. In female patients, advanced age or aging was found to be another significant factor. In elderly patients, gastric mucosal defenses are impaired because of the reduced mucus and bicarbonate secretion, and also the significant decrease in gastric mucosal perfusion. The reduced gastric mucosal defenses coupled with a reduced gastric prostaglandin biosynthesis may account for the higher susceptibility of the mucosa to damage-inducing agents^[10]. In general, female subjects are at a relatively reduced risk of developing gastric ulcers^[11]. In animal experimental models, female sex hormones have been demonstrated to show significant antiulcer activity and to promote healing of drug-associated ulcers (aspirin, indomethacin)^[12,13]. Estrogen has also been reported to reduce the incidence of *H. pylori*-associated gastric mucosal injuries, despite having no effect on the *H. pylori* infection status. Female sex hormones may exert a protective effect against LDA-

associated mucosal injury. In female patients of advanced age, the gradual decrease in the serum levels of female sex hormones after menopause and with advancing age, coupled with the reduced gastric mucosal defenses may be responsible for the increase in the risk of LDA-associated peptic ulcer.

In addition, time from the start of LDA until the diagnosis of LDA-associated peptic ulcer by endoscopy was shorter in the female patients. This gender difference, akin to the significantly higher relative risk and short time-to-onset of alcohol-related liver disease in women as compared to men for any given level of alcohol intake^[14], is yet to be well elucidated. The incidence of peptic ulcer seemed almost constant and does not decrease with time, at least over the follow-up period of 72 mo in this study (Table 3). It has been suggested that NSAID-associated gastrointestinal bleeding occurs mainly within the first few weeks of treatment^[15], which is a shorter period than that reported in LDA users. We should recognize that LDA-associated peptic ulcer may not occur for several years; therefore, it is important to continue antisecretory therapy, especially in high-risk patients. Future prospective cohort studies are needed to confirm this assumption.

COMMENTS

Background

The gender differences in the clinical manifestations of low-dose aspirin (LDA)-associated gastroduodenal mucosal injury have not been well-studied.

Research frontiers

The authors hypothesized that there were gender differences in clinical features of LDA-associated peptic ulcer, and it might be useful to identify the risk factors of LDA associated ulcer in both sexes.

Innovations and breakthroughs

In female patients, age greater than 70 years was found to be a significant risk factor of LDA associated peptic ulcer in addition to a history of peptic ulcer, and the time to diagnosis as having LDA-associated peptic ulcer by endoscopy was significantly shorter than that in the male patients.

Applications

By understanding the gender differences in clinical features of LDA-associated ulcer, this study may represent a future strategy for the prevention of LDA-associated peptic ulcer.

Terminology

Special attention should be paid to aged female patients taking LDA. People should also recognize that LDA-associated peptic ulcer may not occur for several years; therefore, it is important to continue antisecretory therapy, especially in high-risk patients.

Peer review

This study is adequately designed and performed. It means a contribution in a topic of high relevance.

Abstract

AIM: To investigate the procedure, feasibility and effects of laparoscope-assisted continuous circulatory hyperthermic intraperitoneal perfusion chemotherapy (CHIPC) in treatment of malignant ascites induced by peritoneal carcinomatosis from gastric cancers.

METHODS: From August 2006 to March 2008, the laparoscopic approach was used to perform CHIPC on 16 patients with malignant ascites induced by gastric cancer or postoperative intraperitoneal seeding. Each patient underwent CHIPC three times after laparoscope-assisted perfusion catheters placing. The first session was completed in operative room under general anesthesia, 5% glucose solution was selected as perfusion liquid, and 1500 mg 5-fluorouracil (5-FU) and 200 mg oxaliplatin were added in the perfusion solution. The second and

third sessions were performed in intensive care unit, 0.9% sodium chloride solution was selected as perfusion liquid, and 1500 mg 5-FU was added in the perfusion solution alone. CHIPC was performed for 90 min at a velocity of 450-600 mL/min and an inflow temperature of $43 \pm 0.2^\circ\text{C}$.

RESULTS: The intraoperative course was uneventful in all cases, and the mean operative period for laparoscope-assisted perfusion catheters placing was 80 min for each case. No postoperative deaths or complications related to laparoscope-assisted CHIPC occurred in this study. Clinically complete remission of ascites and related symptoms were achieved in 14 patients, and partial remission was achieved in 2 patients. During the follow-up, 13 patients died 2-9 mo after CHIPC, with a median survival time of 5 mo. Two patients with partial remission suffered from port site seeding and tumor metastasis, and died 2 and 3 mo after treatment. Three patients who are still alive today survived 4, 6 and 7 mo, respectively. The Karnofsky marks of patients (50-90) increased significantly ($P < 0.01$) and the general status improved after CHIPC. Thus satisfactory clinical efficacy has been achieved in these patients treated by laparoscopic CHIPC.

CONCLUSION: Laparoscope-assisted CHIPC is a safe, feasible and effective procedure in the treatment of debilitating malignant ascites induced by unresectable gastric cancers.

INTRODUCTION

Malignant ascites are a common complication induced mainly by advanced ovarian cancer and also by gastrointestinal cancers (e.g. gastric cancer, colorectal cancer, and liver cancer). Once vast malignant ascites occur in patients with advanced gastric carcinoma or postoperative peritoneal seeding, disseminated seeding metastasis can be observed. Patients would lose the opportunity to undergo surgery, and nothing can be done except treating the pyloric obstruction or other complications. In addition, the prognosis is extremely poor and the survival time is generally as low as less than 2 mo^[1].

In recent years, continuous circulatory hyperthermic intraperitoneal perfusion chemotherapy (CHIPC) has appeared as a new auxiliary chemotherapy for abdominal malignant tumors. Preliminary clinical efficacy has been achieved in the prevention and treatment of malignant tumor metastasis^[2-4].

Currently, laparoscope-assisted CHIPC has been used clinically to treat malignant ascites in a few medical institutions in the United States, France and Italy. In comparison with traditional CHIPC, laparoscope-assisted CHIPC has a good clinical profile and carries the benefits of definitive palliation of ascites with a minimal invasion, fewer traumas, less pain, shorter recovery time and more stable efficacy, thus avoiding the abdominal laparotomy and large incision necessary in patients with unresectable tumors^[5-8]. However, little information related to the facilities, therapeutic temperature, velocity of drug perfusion or complications involved in laparoscope-assisted CHIPC has been available. This limits the widespread use of laparoscope-assisted CHIPC in clinical chemotherapy. Therefore, in this study, we present a detailed report on the use of laparoscope-assisted CHIPC in treatment of patients with malignant ascites induced by advanced gastric cancers.

MATERIALS AND METHODS

Inclusion criteria and clinical data

This protocol was approved by Cancer Hospital of Guangzhou Medical College. From August 2006 to March 2008, 16 patients with malignant ascites induced by advanced gastric cancers were treated *via* laparoscope-assisted CHIPC.

The diagnosis of primary gastric cancer complicated by malignant ascites was established and existence of peritoneal diffusive seeding was verified by laparoscopic examination. Thus these patients were not well suited for the tumor resection. They had no serious cardiopul-

monary diseases. Informed consent of CHIPC and laparoscopic surgery was obtained from all the patients.

As shown in Table 1, of the 16 patients in this study, there were 7 men and 9 women aged 43-74 years (median age, 56 years). Karnofsky (KPS) marks ranged from 40 to 70 points and the course of disease ranged from 5-30 d (15 d on average). There were 7 primary cases of gastric cancer and 9 cases of postoperative gastric cancer, which were diagnosed by laparotomy, gastric fiberoptic endoscopy, serum tumor markers (CEA and CA199) and ascite cytology. Ultrasonic B and laparoscopic examinations displayed 4000-9000 mL seroperitoneum in all the patients. Five patients had obvious abdominal distention, abdominal pain and oliguria or anuria with high intraperitoneal pressure caused by ascites, and no apparent palliation was found after repeated abdominal puncture drainage, 11 patients had numerous free cancer cells within the ascites, 2 cases presented obvious bloody ascites, and 1 case presented chyle-like ascites.

Laparoscopic examination and chemotherapeutic catheter placement

After endotracheal anesthesia, a transverse cut (10 mm long) was performed at the belly, 5 mm below the umbilicus. The seroperitoneum was extracted as completely as possible; artificial pneumoperitoneum was established *via* an open procedure with a pressure of 13 mmHg (1 mmHg = 0.133 kPa); a 10-mm Trocar was inserted into the abdominal cavity *via* the working port. Thereafter, the laparoscope (10 mm and 30°) was inserted *via* the 10 mm Trocar to examine the abdominal viscera and tumors. The site, size and clinical stages of tumors were examined laparoscopically. Patients with peritoneal diffusive seeding and unresectable tumors were advised to receive laparoscope-assisted CHIPC.

In the process of laparoscope-assisted CHIPC, three new ports were prepared under the guidance of a laparoscope. On the right side, the second and third ports (both 10 mm long) were prepared at the cross-point of the mid-clavicular line and transverse surfaces, with two finger spaces above and below the umbilicus, respectively. On the left side, the fourth port (10 mm long) was prepared at the cross-point of the mid-clavicular line and transverse surface, with two finger spaces below the umbilicus. Thereafter, under the guidance of laparoscope, a 10 mm Trocar was inserted into the abdominal cavity *via* the working port. Two perfusion catheters were placed in the right superior abdominal cavity *via* the third and fourth working ports, respectively. One drainage catheter was placed in the Douglas' cavity of the lowest place in the pelvic cavity *via* the second working port. Then, the laparoscope was placed in the inferior abdomen and the Trocar was inserted. Subsequently, the laparoscope was pulled out, and the perfusion catheter was placed in the Douglas' cavity of the lowest place in the pelvic cavity under the guidance of the Trocar.

CHIPC procedures

CHIPC was performed by our self-developed "BR TRG

CHIPC: Circulatory hyperthermic intraperitoneal perfusion chemotherapy; GC: Gastric cancer; PGC: Postoperative gastric cancer; GSB: Gastroscopic biopsy; PP: Postoperative pathology; MAC: Mucinous adenocarcinoma; M-LDAC: Medium-low differentiated adenocarcinoma; SRCC: Signet ring cell cancer.

II type high-precision hyperthermic perfusion intraperitoneal treatment system” (authorized by two patents from China: Intraperitoneal Hyperthermic Perfusion Treatment System with patent number ZL2006200613779 and Continuous Intraperitoneal Hyperthermic Perfusion Treatment Apparatus with patent number ZL2006200613764) with precise $\pm 0.2^\circ\text{C}$ temperature control, $\pm 5\%$ flow control accuracy, and an automatic cooling function.

Patients completed the first session of CHIPC in the operating room under general anesthesia. The second and third sessions were performed in the intensive care unit on the first and second day after the operation. At the first session, 5-fluorine (1500 mg) and oxaliplatin (200 mg) were added into the 5% glucose solution (4500-6000 mL) as perfusion liquid. Then CHIPC was performed for 90 min with a velocity of 450-600 mL/min and an inflow temperature of $43 \pm 0.2^\circ\text{C}$.

At the second and third sessions, pethidine hydrochloride (75 mg) and promethazine hydrochloride (25 mg) were administered by intramuscular injection less than 10 min before CHIPC. Propofol (3-8 mL/h, iv) as an anesthetic agent with a continuous vein pump. The dose was continuously adjusted according to patient status. The temperature and duration of CHIPC were the same as for the first session; 5-fluorine (1500 mg) was added to the 0.9% saline solution (4500-6000 mL) as perfusion liquid. When the third session of CHIPC was completed, the intra-abdominal perfusate and ascites were drained out. Two perfusion catheters were then pulled out, and a drainage catheter was remained most frequently in the body.

Evaluation and determination of efficacy

Two weeks later, malignant ascites were collected for the last time; the remained drainage catheter was withdrawn; and ultrasonic B reexamination was performed to evaluate ascite remission status. Thereafter, ultrasonic B or computed tomography (CT) was performed for follow-up, at least once a month. Ascite status and tumor progression

were assessed. Karnofsky marks were used to evaluate ascite remission and patient quality of life before CHIPC and one and two weeks after the last CHIPC, respectively. All data were statistically analyzed using SPSS13.0 statistical software.

According to the modified WHO criteria of efficacy assessment in malignant tumors^[1], clinical efficacy was divided into three grades: (1) complete remission (CR): ascites are completely absorbed after treatment sustained over 4 wk; (2) partial remission (PR): ascites are reduced by 50% and sustained over 4 wk; and (3) no consequence (NC): ascites reduced no obvious or increased after treatment.

RESULTS

Clinical efficacy

The intraoperative course was uneventful in all cases; mean operative period for laparoscope-assisted perfusion catheters placing was 80 min; no postoperative deaths or complications related to the laparoscope-assisted CHIPC procedure occurred in this study. After the first laparoscope-assisted CHIPC, the daily amount of ascite outflow was 100-300 mL. After the first day, ascite outflow gradually decreased. A week later, daily outflow was 0-30 mL. During the period from two weeks after laparoscope-assisted CHIPC to the end of follow-up, clinical CR of ascites and related symptoms were achieved in 14 of the 16 treated patients (90.5%), and PR was achieved in 2 patients (9.5%). Thus the objective remission rate (ORR = CR + PR) was 100%. The Karnofsky mark indicating patient quality of life was 50-90, which was increased significantly in comparison with before laparoscope-assisted CHIPC ($P < 0.01$).

Before laparoscope-assisted CHIPC, free cancer cells were found in the ascites of 11 patients (Figure 1A). However, free cancer cells degenerated and necrotized after the first CHIPC (Figure 1B). No intact free cancer cells were found in ascites after the second laparoscope-assisted CHIPC, but degenerated and necrotized cancer cells were

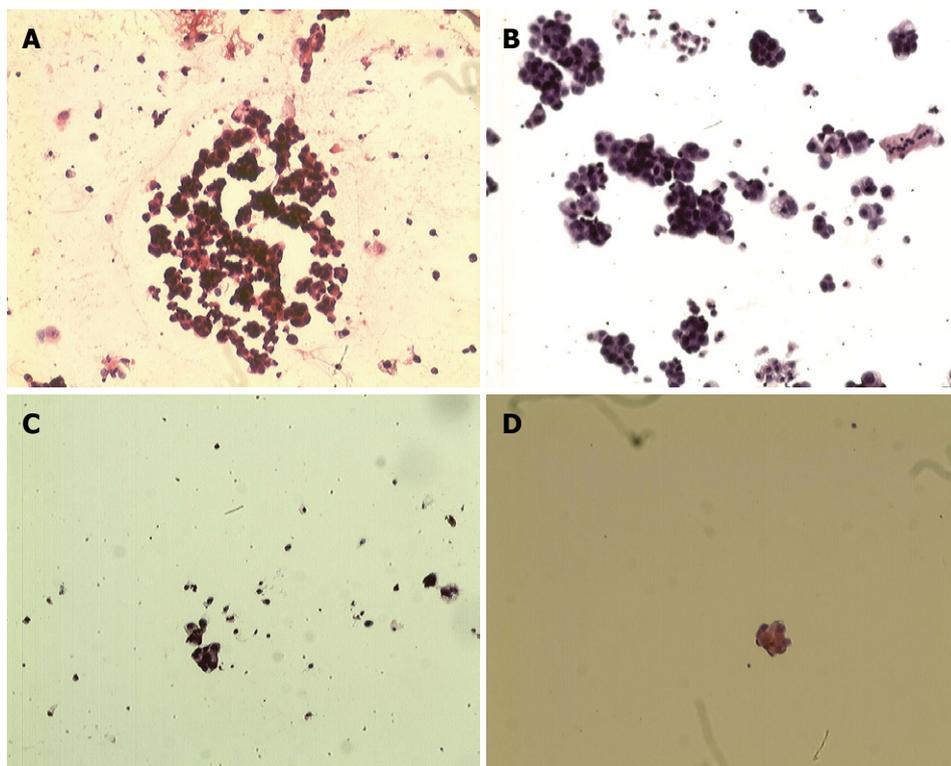

Figure 1 Cancer cells ascites. A: Numerous free cancer cells were found in ascites before circulatory hyperthermic intraperitoneal perfusion chemotherapy (CHIPC) (HE, $\times 100$); B: Intact free cancer cells in ascites clearly reduced in number, and some degenerated and necrotized after the first CHIPC (HE, $\times 100$); C: No intact free cancer cells but rather degenerated and necrotized cells were found in ascites after the second CHIPC; D: No free cancer cells were found in ascites after the third CHIPC.

observed (Figure 1C). No intact free cancer cells were found in the abdomen after the third CHIPC (Figure 1D). In addition, bloody ascites in two cases and chyle-like ascites in 1 case turned clear after the first laparoscope-assisted CHIPC. In addition, the general status of patients improved after the third laparoscope-assisted CHIPC. Mental status, appetite and body weight improved, and symptoms of anemia were obviously alleviated. Thus, satisfactory initial clinical efficacy has been achieved in these patients treated by laparoscope-assisted CHIPC.

Side effects

In the course of laparoscope-assisted CHIPC, patients had no obviously abnormal vital signs except for transient fever, abdominal distension and bellyache. Dynamic re-examination in the anterior, median and posterior phases of laparoscope-assisted CHIPC revealed no anomalies in hepatorenal functions. Bone marrow suppression of I - II degrees was observed in three cases and slight gastrointestinal reaction in one case; and symptoms were remitted after symptomatic treatment. In addition, there were no complications, such as abdominal incision infection or adhesive ileus, after the laparoscope-assisted CHIPC operation.

Follow-up and prognosis

Clinical efficacies of laparoscope-assisted CHIPC in patients with gastric cancer complicated by malignant ascites are summarized in Table 2. All patients had complete follow-up data. During the follow-up (2-9 mo), 13 patients survived from 2 to 9 mo with a median survival time of 5 mo. The causes of death were intestinal obstruction (7 cases), gastrointestinal bleeding (3 cases), or cachexia (3 cases). Two patients with partial remission suffered from port-site seeding of the tumor and died within 2 and 3 mo

after treatment, respectively. Three patients still alive today survived 4, 6 and 7 mo, respectively. Five patients failed in resection of the primary lesions in the re-laparotomy, and cecal fistula or ileal fistula was made in 4 patients for treatment of intestinal obstruction induced by tumor infiltration. The diagramed survival curves are shown in Figure 2.

DISCUSSION

Malignant ascites induced by malignant tumors in the abdominal cavity (e.g. ovarian cancer, gastric cancer, colorectal cancer, and other intra-abdominal cavity) are a common complication of intraperitoneal malignant tumors. The prognosis is extremely poor and the survival time is very short^[1]. Gastric cancer is one of the most common intraperitoneal malignant tumors complicated by malignant ascites. Patients with gastric cancer complicated by malignant ascites suffer mostly from the rapid increase in ascites in addition to the clinical symptoms, vital signs and cachexia of primary diseases. However, diuretic treatment is not effective; single-puncture drainage of ascites leads to rapid re-growth; and multiple puncture drainage of ascites can cause severe complications such as hypoalbuminemia and hydrogen electrolyte disturbance. The ascites cause abdominal distention, abdominal pain and oliguria or anuria, which strongly impact the quality of life and render clinical treatment difficult. Therefore, suppressing or eliminating the rapid growth of ascites has great significance in the comprehensive treatment of patients with advanced gastric carcinoma or postoperative celiac diffusive seeding^[1].

In recent years, CHIPC has appeared as a new auxiliary chemotherapy for intraperitoneal malignant tumors. Hyperthermic chemotherapeutic liquid at large doses fa-

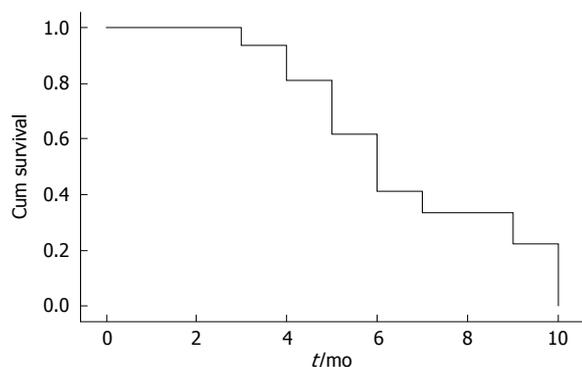

Figure 2 Diagrammed survival curves of patients undergoing laparoscopic CHIPC in gastric cancer complicated by malignant ascites.

cilitates a full and effective reach of the drugs to the tiny celiac carcinoma metastases. Perfusion chemotherapy affects mechanical removal of intra-abdominal free cancer cells. During the perfusion, chemotherapeutic drugs are locally administered to the abdominal cavity, which leads to a high, constant and sustained local drug concentration. However, fewer drugs enter into the systemic circulation, which reduces the systemic side-effects. Therefore, CHIPC has obvious advantages in comparison with simple intraperitoneal chemotherapy in the treatment of malignant ascites. Preliminary efficacy has been achieved in the prevention and treatment of the peritoneal seeding of malignant tumors^[5-8].

In the process of laparoscope-assisted CHIPC, the site, size and clinical stages of tumors are laparoscopically examined. Patients with peritoneal diffusive seeding and unresectable tumors are advised to undergo laparoscope-assisted CHIPC. Laparoscope-assisted CHIPC integrates the benefits of a definitive palliation of ascites with a minimal invasion, which leads to fewer traumas, less pain, shorter recovery time and solid efficacy, thus avoiding the abdominal laparotomy and large incision necessary in patients with unresectable tumors. There-

fore, laparoscope-assisted CHIPC is a potential therapy for malignant ascites^[9-12].

Ferron *et al.*^[13] performed laparoscope-assisted CHIPC on five adult pigs in France. Trocar was placed in the four celiac corners; omental total resection was performed. The final Trocar below the umbilicus was positioned using Dapdics, which is helpful in operating upon the ansa intestinalis. The abdominal cavity was filled with hot saline for 30 min at 43°C. As a result, the liquid was well distributed in the intra-abdomen with the appropriate temperature, and no surgical complications occurred. Therefore, the authors suggest that laparoscope-assisted CHIPC is safe and feasible for chemotherapy of malignant ascites.

Gesson-Paute *et al.*^[14] performed laparoscope-assisted CHIPC on ten adult pigs to investigate the changes in pharmacokinetics. In the experiment, perfusion and drainage catheters were laparoscopically placed in the upper and lower abdominal quadrants. In control animals, drainage catheters were placed laparotomically. CHIPC was performed with perfusion liquid containing oxaliplatin (460 mg/m²) for 30 min at 41-43°C. The perfusion liquid was sampled every minute to determine the drug concentration. The results showed that the operation was performed smoothly without complications. Drug absorption rate was 41.5% in the experimental group but 33.4% in the control. This difference was not statistically significant ($P = 0.0543$, $n = 5$). The half-life of oxaliplatin in laparoscope-assisted CHIPC was significantly shorter than that in laparotomic CHIPC (37.5 min *vs* 59.3 min, $P = 0.02$), which indicates that the adsorption of oxaliplatin in laparotomic CHIPC is significantly faster than that in laparotomic CHIPC, leading to increased clinical efficacy. In addition, the celiac drug kinetic curvature for laparoscopic and laparotomic CHIPC was 16.3 *vs* 28.1, $P = 0.02$, respectively, which reflects intraperitoneal barrier penetration of oxaliplatin. Therefore, the authors believed that laparoscope-assisted CHIPC-associated pharmacokinetics elucidate intraperitoneal drug adsorption and support the viewpoint that laparoscope-assisted CHIPC is safe, with robust clinical efficacy.

Facchiano *et al.*^[15] treated five patients with malignant ascites after palliative resection of gastric cancer by laparoscope-assisted CHIPC in a hospital affiliated to the Paris University. Celiac perfusion and drainage catheters were laparoscopically placed in the upper and lower abdominal quadrants, and laparoscope-assisted CHIPC was performed with perfusion liquid containing mitomycin plus platinum for 60-90 min at an inflow temperature of 45°C. The results showed that the operation went on smoothly without related complications for a mean 181 min; malignant ascites were eliminated in all 5 cases. The authors suggest that laparoscope-assisted CHIPC in patients with malignant ascites after palliative resection of gastric cancer is safe and feasible, with robust clinical effect.

Garofalo *et al.*^[16] performed laparoscope-assisted CHIPC on 14 cases of malignant ascites and five cases of gastric cancer, three cases of colorectal cancer, three cases of ovarian cancer, two cases of breast cancer and one case of intraperitoneal pseudomyxoma, respectively. Laparoscope-assisted CHIPC was performed with chemotherapeutic drugs (e.g. carboplatin, cisplatin and mitomycin according to the primary tumor type) for 90 min at inflow temperature of 42°C. Four drainage catheters were laparoscopically placed in the upper and lower abdominal quadrants and were pulled out after perfusion. The results indicated that malignant ascites had been well controlled in all 14 cases, and postoperative CT scanning confirmed pelvic effusion in one case. The authors conclude that laparoscope-assisted CHIPC is safe and efficient for chemotherapy of patients who suffer from advanced malignant tumors complicated by ascites and peritoneal seeding and who are not suited for cytoreductive surgery. However, the prerequisites are surgeon's experience with laparoscopic tumor staging and patient's capacity to undergo laparoscope-assisted CHIPC.

Knutsen *et al.*^[17] performed laparoscope-assisted CHIPC on five patients who underwent laparotomic cytoreductive surgery three to eight weeks earlier. The primary diseases included adenocarcinoma of the cecum in one case, appendiceal adenocarcinoma in three cases and gallbladder adenocarcinoma in one case. The inflow temperature was 42.1°C and outflow temperature was 40.5°C. After the operation, one patient exhibited port-site seeding, one patient died of tumor progression, and three patients survived without tumor progression and enjoyed a normal quality of life within four months after laparoscope-assisted CHIPC. The author suggests that laparoscope-assisted CHIPC after laparotomic cytoreductive surgery can guarantee the constant velocity of perfusion and maintain a stable intra-abdominal temperature.

In the process of CHIPC, drainage tubes tend to be plugged up by the great omentum or intestinal canals, so unobstructed drainage is the key to successful CHIPC. Through the long-term observation of clinical practice, we have mastered reliable means to place laparoscope-assisted CHIPC tubes and prevent jamming of the drainage tube. Drainage tubes which pass through the perforations of the right upper quadrant or left upper quadrant are placed in the lowest pelvic cavity (Douglas' cavity), and perfusion tubes are placed in the abdominal

hepatorenal recess and the splenic recess through the perforations of the right lower quadrant or left lower quadrant, respectively. When undergoing laparoscope-assisted CHIPC, the patient is placed in the supine or head-high-foot-low (15°) positions. After the abdominal cavity is full of liquid, drainage tubes are open to drain the liquid, with help of the body position. The great omentum and intestinal canals are difficult to position within the pelvic cavity and therefore unlikely to plug up the drainage tube, thus unobstructed circulatory perfusion is needed. If pelvic drainage tubes are plugged up, smooth drainage can be ensured by changing infusion tube from the right upper quadrant (hepatorenal recess) into drainage tube to the lower quadrant (Douglas' cavity) and changing the patient's position from head low to supine position. In this study, all the patients suffered from gastric cancer-induced malignant ascites and their great omentums were all excised or contracted into clumps. The abdominal cavity volume was big enough to ensure smooth drainage; there was no failure in the drainage tube jam in laparoscope-assisted CHIPC.

We have successfully developed a High Precision Intraperitoneal Hyperthermic Perfusion Treatment system with independent intellectual property rights. In this study, we used this machine for laparoscope-assisted CHIPC to treat 16 patients with malignant ascites induced by peritoneal carcinomatosis from gastric cancers. All patients with ascites have remitted which indicates a 100% effective rate as reported by other authors^[15,17]. Bloody ascites in two cases and chyle-like malignant ascites in one case turned clear very quickly after the first laparoscope-assisted CHIPC. The median survival time was 5 mo, which is prolonged as compared with the traditional therapy, and other reports as well^[16,17]. General status, mental status, appetite and body weight improved, symptoms of anemia were alleviated, and initial clinical efficacy was satisfactory in the patients. All these results imply that laparoscope-assisted CHIPC has good clinical efficacy.

In addition, our clinical observations indicate that the primary tumors remain or even that peritoneal seeding foci are aggravated after laparoscope-assisted CHIPC. However, the symptoms associated with malignant ascites decreased or disappeared completely and ultrasonic B examination has not revealed ascite recurrence. The theory of this system remains to be elucidated. At the same time, bloody and chylous ascites became clear very quickly after laparoscope-assisted CHIPC, a process which also requires further studies.

Port-site seeding is a frequent problem for laparoscopic doctors. Patients who undergo laparoscope-assisted CHIPC have many free cancer cells in the abdominal cavity and more severe port-site seeding. Two patients with port-site seeding are included in this study and exhibited only partial remission after laparoscope-assisted CHIPC, which indicates poor clinical efficacy. However, this study includes only a limited number of cases, and the influence of laparoscope-assisted CHIPC on the quality of life and long-term survival of patients requires further researches.

In conclusion, laparoscope-assisted continuous circulatory intraperitoneal hyperthermic perfusion chemotherapy

(CHIPC) in gastric cancer complicated by malignant ascites guarantees the uniform velocity of perfusion liquid, maintains the stable intra-abdominal temperature, facilitates a full and effective reach of the drugs to the celiac cancers, and has advantages such as minimal invasion, less pain and short recovery time. These factors contribute to achieving a good clinical efficacy, including improved quality of life and prolonged survival. Therefore, laparoscope-assisted CHIPC is safe and feasible for a widespread clinical use.

COMMENTS

Background

Malignant ascites is a common complication of advanced peritoneal malignant tumors, and treatment of this malady is very difficult clinically. Continuous circulatory hyperthermic intraperitoneal perfusion chemotherapy (CHIPC) has achieved satisfactory therapeutic effects in treatment of malignant ascites.

Research frontiers

Laparoscope-assisted CHIPC integrates the benefits of definitive palliation of gastric cancer complicated by malignant ascites with fewer traumas, less pain, shorter recovery time and more stable efficacy, thus avoiding the abdominal laparotomy and large incision necessary in patients with unrespectable tumors.

Innovations and breakthroughs

Laparoscope-assisted CHIPC is a safe, feasible and effective procedure to treat debilitating malignant ascites induced by unresectable intraperitoneal carcinomatosis of gastric cancers.

Applications

Laparoscope-assisted CHIPC for gastric cancer complicated by malignant ascites has advantages such as minimal invasion, less pain and short recovery time. These factors contribute to achieving a good clinical efficacy, including improved quality of life and prolonged survival.

Terminology

CHIPC is a novel adjuvant therapy for intra-abdominal malignancies. High-doses of warm chemotherapy liquid are administered intra-abdominally so that chemotherapy drugs can have a full contact with the tumor metastases. Chemotherapeutic agents administered into the abdominal cavity have a higher, constant, and persistent drug concentration but less drugs entering the circulatory system, and few systemic toxic side effects.

Peer review

The scientific and innovative contents as well as readability of this paper can reflect the advanced levels of the clinical research in gastroenterology both at home and abroad.

Abstract

AIM: To evaluate the induction of remission and maintenance effects of probiotics for ulcerative colitis.

METHODS: Information was retrieved from MEDLINE, EMBASE, and the Cochrane Controlled Trials Register. The induction of remission and promotion of maintenance were compared between probiotics treatment and non-probiotics treatment in ulcerative colitis.

RESULTS: Thirteen randomized controlled studies met the selection criteria. Seven studies evaluated the remission rate, and eight studies estimated the recurrence rate; two studies evaluated both remission and recurrence rates. Compared with the non-probiotics group, the remission rate for ulcerative colitis patients who received probiotics was 1.35 (95% CI: 0.98-1.85). Compared with the placebo group, the remission rate of ulcerative colitis who received probiotics was 2.00 (95% CI: 1.35-2.96). During the course of treatment, in patients who received probiotics for less than 12 mo compared with the group treated by non-probiotics, the remission rate of ulcerative colitis was 1.36 (95% CI: 1.07-1.73). Compared with the non-probiotics

group, the recurrence rate of ulcerative colitis patients who received probiotics was 0.69 (95% CI: 2.47-1.01). In the mild to moderate group who received probiotics, compared to the group who did not receive probiotics, the recurrence rate was 0.25 (95% CI: 0.12-0.51). The group who received *Bifidobacterium bifidum* treatment had a recurrence rate of 0.25 (95% CI: 0.12-0.50) compared with the non-probiotics group.

CONCLUSION: Probiotic treatment was more effective than placebo in maintaining remission in ulcerative colitis.

INTRODUCTION

Inflammatory bowel disease is a chronic recurrent disease, which mainly consists of ulcerative colitis and Crohn's disease, and whose causes are as yet unclear. It is still assumed that inflammatory bowel disease is caused by integrative factors, such as genetic susceptibility, an imbalance between gastrointestinal probiotics and pathogens, an impairment of intestinal epithelial cells, and

host immune dysfunctions. Many clinical and research studies have indicated that intestinal flora dysbacteriosis contributes to the pathogenesis of ulcerative colitis. Probiotics are non-pathogenic beneficial flora, which have important effects on maintaining the balance of intestinal flora^[1]. Probiotics can adjust the metabolic activity of the intestinal flora and their components by preventing bacterial overgrowth and by maintaining the integrity of the intestinal mucosal barrier, thereby adjusting and stabilizing the intestinal environment^[2,3].

Inducing remission and preventing recurrence and complications are the primary goals of inflammatory bowel disease treatment^[4]. Many ulcerative colitis patients experience a short period of remission after induction but then must be treated by surgery after recurrent attacks. Postoperative pouchitis is always caused by the reduction of *Lactobacillus lactis* and *Bifidobacterium*. Many studies have discussed the positive effects of probiotics for treating stomach and intestine diseases, including ulcerative colitis^[5-7]. However, the sample size has been relatively small, such that there is no definitive evidence as to whether probiotics are helpful. Thus, this paper systematically evaluates probiotics' curative effects for treating ulcerative colitis based on existing random control trials.

MATERIALS AND METHODS

Retrieval strategy

Data was retrieved from the databases: We searched the data from MEDLINE (1966 to August 2009), EMBASE (1980 to August 2009), and the Cochrane Controlled Trials Register (1995 to August 2009). The keywords were used below: probiotics, inflammatory bowel disease, ulcerative colitis, *Escherichia coli*, *Lactobacillus*, *Bifidobacterium*, and yeasts. Language was limited to studies published in English. Moreover, abstracts presented at main international gastrointestinal disease meetings (including Digestive Disease Week of the American Gastroenterological Association, the World Congress of Gastroenterology) for the past five years were analyzed by joint manual retrieval. The retrieval results were reviewed by two evaluators, and a third person was consulted if the two evaluators' opinions were different.

Selection criteria: All the random control experiments that compared probiotics with ulcerative colitis treatment medicine or placebo were collected, including abstracts and full texts. The selection criteria were as follows: (1) adult and pediatric studies were included; (2) the experiments compared the curative effect of probiotics with standard therapy for ulcerative colitis or placebo; (3) all were random control tests; (4) abstracts and meeting presentations were selected; and (5) patients had a definite diagnosis of ulcerative colitis using definite diagnosis standards. Reviews and case reports were excluded.

Data retrieval and quality assessment

Two researchers selected the papers after reading the titles, abstracts, and full texts. They evaluated the quality of each

selected paper and retrieved the data. If they had different opinions, a third researcher helped them to determine the applicability of the paper in question. The quality of the methods used by the selected random control experiments was assessed by the Cochrane Reviewer Handbook 5.0 random control experiment quality assessment standard. The following methods were evaluated: (1) Random method: random method right, random method not described, random method error; (2) Allocation concealment: concealment method right, concealment method not described, concealment method error, concealment method not used; (3) Blind method: whether the evaluator was blinded to the conditions of the experiment; and (4) Whether lost or exit: if there are lost or exit conditions, the reasons are indicated clearly or not, and whether intention-to-treat analysis was used. According to these four quality criteria, all answers that were "right or enough", where the possibilities for bias are the least; the assessment was level "A". If one or more criteria were not described, it means that the assessment was partially satisfied. In this condition, there is a possibility of relative bias, and the assessment was designated as level "B". If one or more criteria were erroneous or not used, there was a high possibility of relative bias, and the assessment was designated as level "C".

Statistical analysis

The relative risk and 95% confidence interval (95% CI) was calculated based on the data. Statistical analysis was performed with Cochrane Collaboration's Revman 5.0. Heterogeneity analyses were performed on the experimental results. If there was obvious heterogeneity, the random effects model was chosen, if not, the fixed effects model was chosen.

Whether there was publication bias could be observed by an inverted funnel plot, and the bias level was assessed by the formula:

$$\sum_{j=1}^m \ln(\hat{OR}_j) = 0$$

$$m = \left[\frac{k \ln(\hat{OR})}{1.96} \right]^2 \bar{\omega} / k - k$$

Where k is the number of selected papers; m is the least unpublished number of reports that yield a combined effect size with no statistical significance; $\bar{\omega}$ is the average weight of k published reports (reciprocal of variance); and $\ln(\hat{OR})$ is the estimate value logarithm of the combined effect size.

RESULTS

A total of 286 papers were retrieved. After a thorough screening of the titles, abstracts, or full texts and excluding reviews, uncontrolled tests, and basic research, 13 papers were ultimately selected^[5-11] (Figure 1). One of the 13 papers was published as an abstract, 12 of were published as full text; seven of them evaluated the remission rate, eight papers assessed the recurrence rate, and two papers evaluated both the remission rate and recurrence rate. The span of the research or the duration of

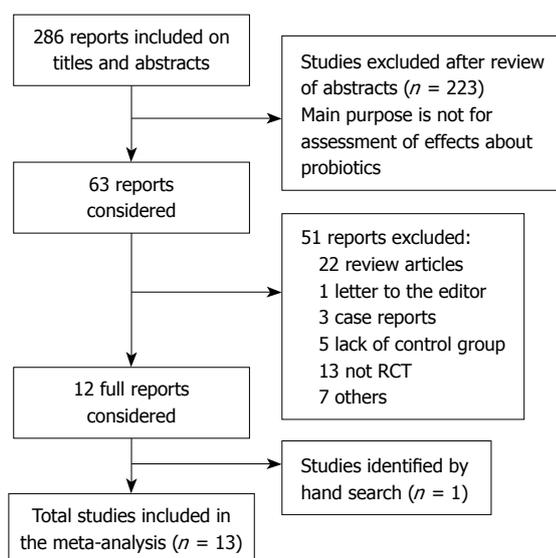

Figure 1 Study selection process. A flowchart was present in this figure and the flowchart summarizes the selection of studies including numbers and reasons of studies excluded.

the follow-up visits was 1 to 12 mo. All the papers were published in English. The general conditions of the selected research are shown in Table 1^[8-20].

Quality assessment of selected papers

The quality assessment of the 13 selected papers is shown in Table 2. Three reports were level A, eight were level B, and two papers were level C.

Induction of remission of ulcerative colitis by probiotics

Seven reports evaluated the remission rate, which involved a total of 399 patients. Among the 399 patients, probiotics were used as an auxiliary therapy in 219 patients, and 180 patients were treated by standard therapy or placebo. Comparing the probiotics auxiliary therapy group with non-probiotics auxiliary therapy group, the remission rates were not significantly different (remission rate: 1.35, 95% CI: 0.98-1.85, $P = 0.07$), but there was an obvious heterogeneity in the results ($P = 0.02$, $I^2 = 62\%$). The total remission rate of the probiotics auxiliary therapy group was 68.2%, and for the non-probiotics auxiliary therapy group it was 60.4% (Figure 2A).

Sub-group analysis

Due to the heterogeneity of the total remission rate, sub-groups were analyzed based on the severity of disease, placebo or not, different kinds of probiotics, and the span of probiotics therapy. The selected reports were first separated into a mild to middle subgroup and an active

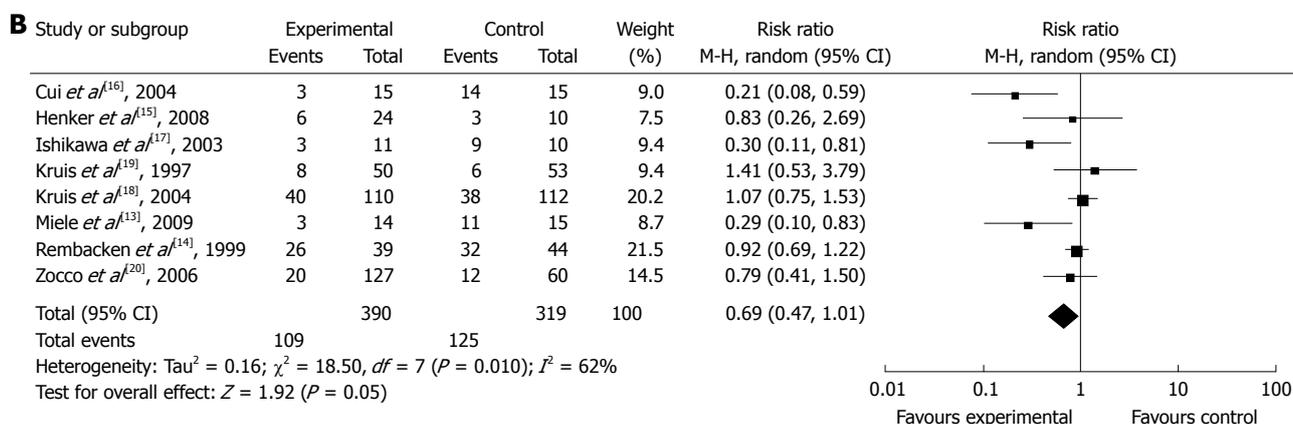

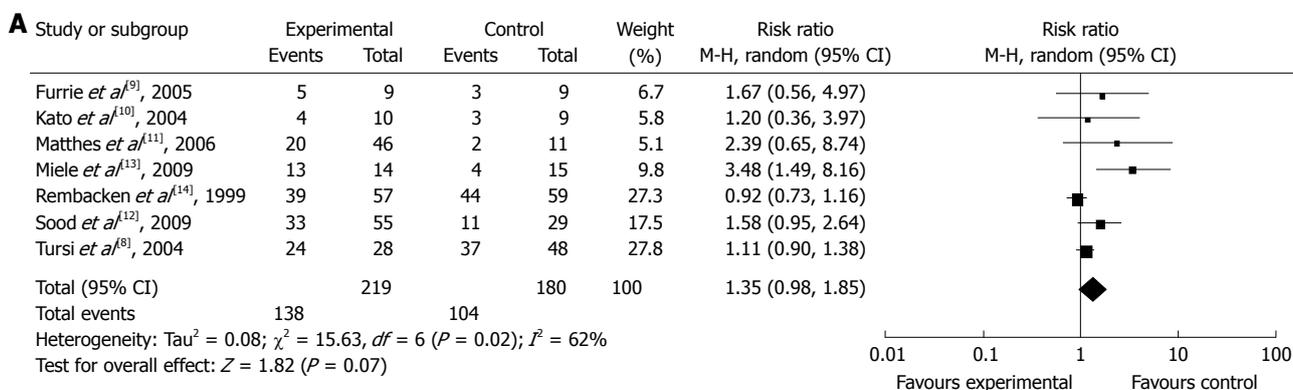

Figure 2 Remission rate (A) and relapse rate (B) of probiotic group vs control group.

phase subgroup. The remission rate of the mild to middle sub-group was 1.64 (95% CI: 0.98-2.72) and heterogeneity was obvious ($P = 0.02$, $I^2 = 66\%$). The remission rate for the active phase subgroup was 0.97 (95% CI: 0.77-1.22), and heterogeneity existed ($P = 0.28$, $I^2 = 13\%$). Secondly, the selected reports were divided into a placebo controlled sub-group and a non-placebo controlled sub-group. The remission rates of these two sub-groups were 2.00 (95% CI: 1.35-2.96) and 1.00 (95% CI: 0.85-1.18), respectively. The remission rate of the probiotics auxiliary therapy sub-group was significantly better than the placebo sub-group, and there were obvious heterogeneities in these two sub-groups ($P = 0.46$, $I^2 = 0\%$). The selected reports were then separated into a VSL#3 subgroup, an *E. coli* subgroup, and a *Bifidobacterium longum* subgroup. The remission rate of the VSL#3 subgroup was 1.66 (95% CI: 0.87-3.15), and heterogeneity was obvious ($P = 0.006$, $I^2 = 80\%$). The remission rate of the *E. coli* subgroup was 1.02 (95% CI: 0.80-1.30), and heterogeneity was obvious ($P = 0.12$, $I^2 = 59\%$). The remission rate of the *Bifidobacterium longum* subgroup was 1.43 (95% CI: 0.64-3.19), and heterogeneity was not apparent ($P = 0.69$, $I^2 = 0\%$). Finally, the selected research was divided into groups that received treatment for at least 12 mo or less than 12 mo, based on the course of treatment. The remission rate for the 12 mo sub-group was 1.69 (95% CI: 0.43-6.67), and heterogeneity was not apparent ($P = 0.002$, $I^2 = 90\%$). The remission rate of the sub-group that received treatment for less than 12 mo was 1.36 (95% CI: 1.07-1.73). In the subgroup that received treatment for less than 12 mo and was treated by probiotics auxiliary therapy, the remission rate was obviously better than the control group, and heterogeneity existed ($P = 0.33$, $I^2 = 14\%$).

Sensitivity analysis

Seven reports evaluated the remission rate. In one of the studies, the patients were treated by probiotic enema formulations but not by humatin, so this research was excluded. Sensitivity analysis indicated that the total remission rate was 1.30 (95% CI: 0.94-1.78), and that the statistical heterogeneity was significant ($P = 0.02$, $I^2 = 63\%$). There was no significant differences in the remission rates between the groups that received probiotics or non-probiotics.

Effect of probiotics on the recurrence rate in maintenance treatment of ulcerative colitis

Eight reports assessed the recurrence rate, which involved a total of 709 patients, 390 of them used probiotics for maintenance treatment, and 319 patients used control medicine or a placebo. There was a significant difference between the total recurrence rates between the probiotics maintenance therapy group and placebo maintenance therapy group (recurrence rate: 0.69, 95% CI: 0.47-1.01, $P = 0.05$). The total recurrence rate for the probiotics maintenance therapy group was 27.9%, while the recurrence of the control group was 39.2%. The heterogeneity of the total recurrence rate was found to be significant by meta-analysis ($P = 0.01$, $I^2 = 62\%$).

Subgroup analysis

Due to the significant heterogeneity of the total recurrence rate, it was necessary to analyze the subgroups to explain and/or reduce the heterogeneity. The selected studies were first divided into an active phase subgroup, a remission stage subgroup, and a mild to middle subgroup. The remission rate of the active phase subgroup was 0.48 (95% CI: 0.10-2.26) with obvious heterogeneity ($P = 0.003$, $I^2 = 89\%$). The remission rate of the remission stage subgroup was 1.01 (95% CI: 0.14-0.61) without heterogeneity ($P = 0.96$, $I^2 = 0\%$). The recurrence rate of the probiotics therapy group was much lower than the non-probiotics therapy group. The selected research was then separated into a placebo control subgroup and a non-placebo control subgroup. The remission rate of the placebo control sub-group was 0.25 (95% CI: 0.12-0.51) without obvious heterogeneity ($P = 0.68$, $I^2 = 0\%$). The non-placebo control subgroup's remission rate was 0.92 (95% CI: 0.75-1.14) with visible heterogeneity ($P = 0.26$, $I^2 = 24\%$), which was obviously higher than the placebo control sub-group. The remission rate of the probiotics therapy group was not significantly different from the non-placebo control sub-group.

The selected research was then grouped into an *E. coli* subgroup, a *Bifidobacterium* subgroup, and a VSL#3 *Lactobacillus* subgroup. The remission rate of the *E. coli* subgroup was 1.02 (95% CI: 0.81-1.29), and there was no obvious heterogeneity ($P = 0.76$, $I^2 = 0\%$). The remission rate of the *Bifidobacterium* subgroup was 0.25 (95% CI: 0.12-0.51) without visible heterogeneity ($P = 0.63$, $I^2 = 0\%$). The VSL#3 *Lactobacillus* subgroup remission rate was 0.59 (95% CI: 0.35-1.01) with significant heterogeneity ($P = 0.11$, $I^2 = 60\%$). Finally, the selected studies were divided into patients that had received treatment for 12 mo and those that had received treatment for less than 12 mo. The remission rate of the 12 mo subgroup was 0.83 (95% CI: 0.68-1.03) with significant heterogeneity ($P = 0.07$, $I^2 = 51\%$), while the remission rate of the group that had received treatment for less than 12 mo was 0.55 (95% CI: 0.09-3.51) with significant heterogeneity ($P = 0.009$, $I^2 = 85\%$) (Figure 2B).

Publication bias assessment

The publication bias could not only be qualitatively analyzed using a funnel plot to observe whether a bias existed, but we could also quantitatively count the bias level using a formula to determine the extent of the publication bias.

Quantification of publication bias: In the above analysis concerning probiotic treatment and its effect on the remission rate and recurrence rate of ulcerative colitis, the publication bias was analyzed quantitatively; however, quantification of the publication bias requires positive results, thus the total recurrence rate of ulcerative colitis affected by probiotics only was assessed.

To compare the recurrence rate between the probiotics group and non-probiotics group, the values used were as follows: $\ln(R) = -0.3711$, $W = 101.59$, $m = 8 \times (0.3711/1.96)^2 \times (101.59/8) - 8 = 21$. The result showed

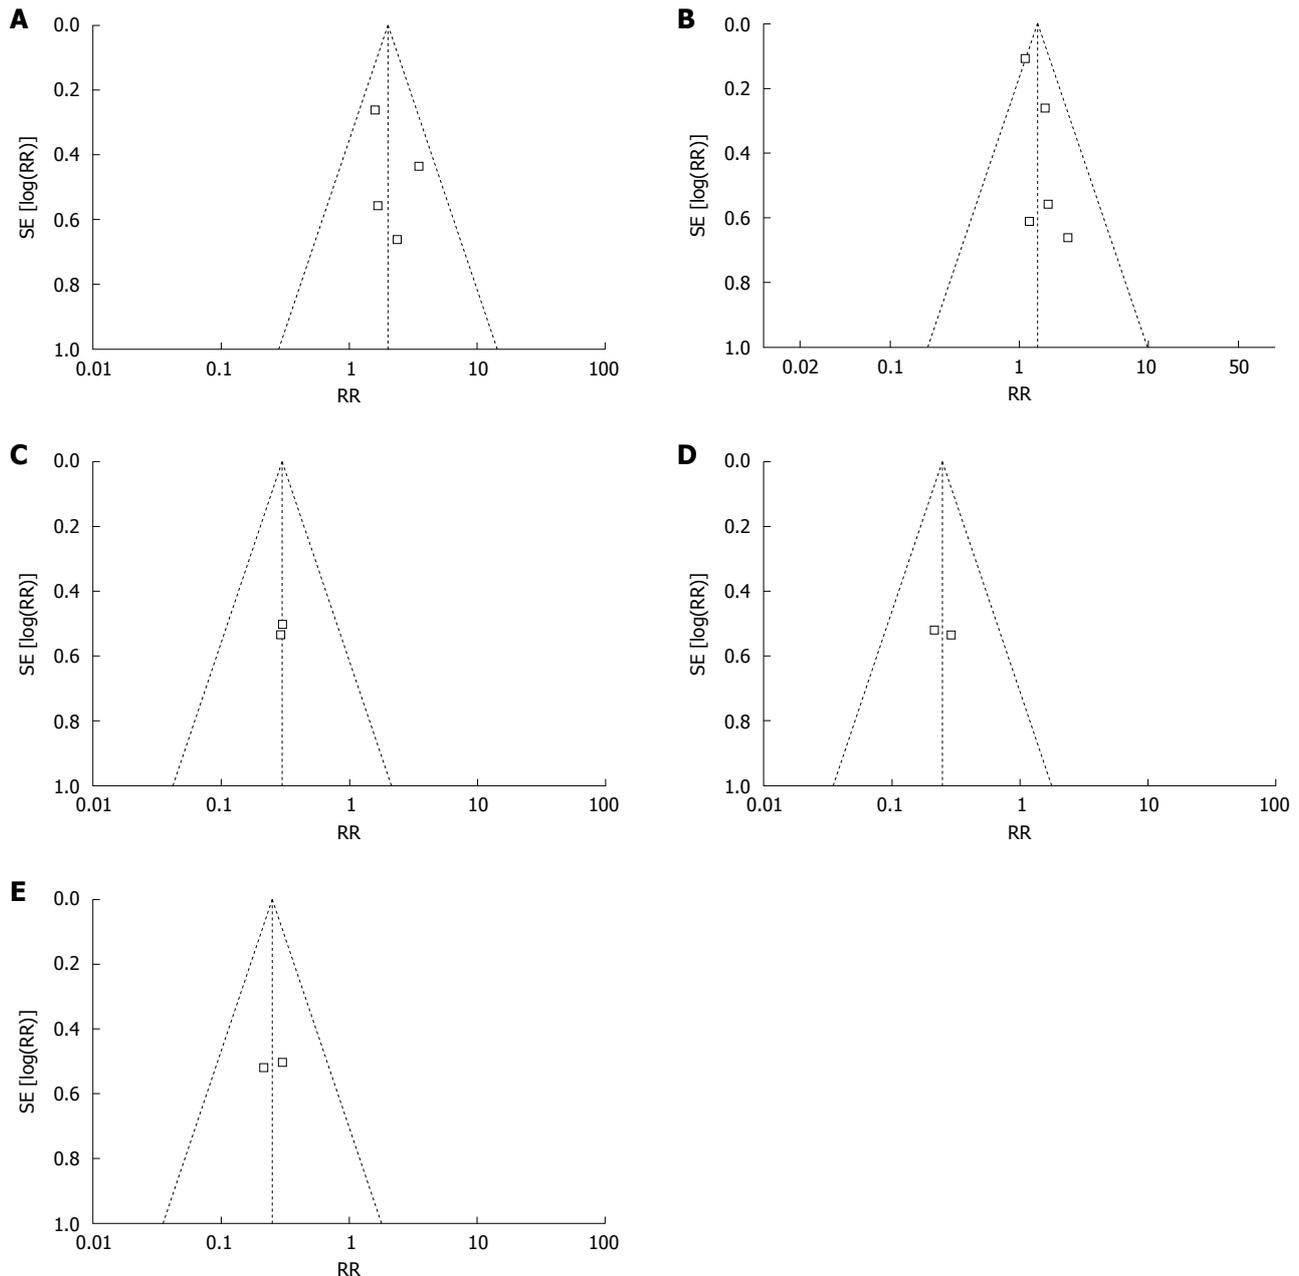

Figure 3 Inverted funnel plot analysis of the relative of remission rate. A: Inverted funnel plot analysis of the relative of remission rate between probiotics group and placebo group; B: Less than 12 mo group: Inverted funnel plot analysis of the relative of remission rate between probiotics group and non-probiotics group; C: Mild and middle UC group: Inverted funnel plot analysis of the relative of remission rate between probiotics group and non-probiotics group; D: Inverted funnel plot analysis of the relative of remission rate between probiotics group and placebo group; E: Inverted funnel plot analysis of the relative of remission rate between *Bifidobacterium longum* therapy group and non-probiotics therapy group.

the analysis results could not be reversed unless 21 non-statistically significant papers were added. This indicated that publication bias had little effect on the results in the analysis of recurrence rate of probiotics group and non-probiotics group. Therefore, the results were reliable.

Qualitative evaluation of publication bias: Inverted funnel plot analysis can analyze the results from a fixed effect model. Figure 3 shows that the inverted funnel plot had an uneven distribution and apparent asymmetry. This meant that in the patients who were treated for less than 12 mo, there was a publication bias in the relative of re-

mission rate between the probiotics group and the non-probiotics group. The inverted funnel plots that were symmetrical indicated that there was no visible publication bias.

DISCUSSION

This study shows that using probiotics provides no additional benefit in inducing remission of ulcerative colitis, but probiotics auxiliary therapy is much better than non-probiotics therapy for maintenance therapy. Research has discussed the various effects of probiotics as an ulcerative colitis therapy. The mechanism of probiotics in ulcerative

colitis therapy mainly involves the following: (1) to prevent pathogen infiltration by restraining bacterial adherence and bacteria translocation, or to produce anti-bacterial substances that inhibit pathogenic bacteria; (2) to improve the intestinal mucosal barrier function, and the permeability and stability of the mucosal barrier; and (3) to regulate the mucosal immune response. Probiotics cause modifications of the mucosal immune response, improve activities of macrophages and NK cells, stimulate the production of antibodies, regulate the nuclear factor- κ B (NF- κ B) pathway, induce the apoptosis of T cells, and reduce the secretion of proinflammatory factors^[21]. However, most of the studies on the effects of probiotics in ulcerative colitis therapy were performed *in vitro* or in animal models. Although probiotic effects are closely related to applied clinical conditions, there are some disputes between the results from basic research and clinical research. In addition, the inconsistency of research baselines has also caused disagreement among clinical researchers.

Although this study shows that using probiotics provides no additional benefit in the induction of remission for ulcerative colitis, there was a visible heterogeneity in the total remission rate. This effect might be related to the different methods used by the selected papers, such as the kinds of probiotics used, the treatment time, the types of ulcerative colitis, medication compliance of patients, whether patients were treated by antibiotics simultaneously, difference of the control groups, the analysis of the results, and the sample size. Some research shows that there are significantly different effects yielded by different kinds of bacteria and yeasts used as therapies^[22,23]. Subgroup analysis demonstrated that the probiotics group was more likely to be in remission than the placebo group of patients with ulcerative colitis. In the subgroup that received treatment for less than 12 mo, the remission rate of the probiotics group was obviously higher than the non-probiotics group. The results suggested that probiotics auxiliary therapy could be used as another choice to induce the remission of ulcerative colitis, which has a better remission effect than the non-probiotics therapy group after 1 year. Some research has shown that the protective effects of probiotics act during the initial stage of ulcerative colitis impairment, but not during the refractory period. This result still needs to be confirmed using additional random control tests.

In the maintenance therapy stage, the probiotics auxiliary therapy was obviously better than non-probiotic therapy; that is, the recurrence rate of probiotics auxiliary therapy group was significantly lower than non-probiotics therapy group during the maintenance therapy stage, and this difference was heterogeneous. Subgroup analysis showed that the effect of probiotic maintenance therapy was obviously better than non-probiotic therapy in the mild to middle subgroup, placebo subgroup, and *Bifidobacterium* subgroup, and this difference was statistically significant. The results demonstrated that probiotics auxiliary therapy was more suitable in ulcerative colitis patients. Compared with standard treatments, such as 5-ASA or mesalazine, the effect of probiotics auxiliary therapy was

not significantly different, but was obviously better than placebo therapy. The recurrence rate of the *Bifidobacterium* group was much lower than the non-probiotics therapy group, and the difference was statistically significant.

The main advantage of probiotics therapy is that it does not affect the regeneration of normal mucosa during active therapy^[23]. To overcome gastrointestinal tract infections, probiotics must be non-pathogenic and resistant to antibiotics. In addition, probiotics can resist stomach acid, bile, and antibiotics and can modify immune processes to destroy invading microorganisms^[24].

In this meta-analysis, the evaluation criteria of the results were not totally consistent. To a certain extent, this condition added to the heterogeneity of the systemic review.

In conclusion, whether the use of probiotics is better than non-probiotics therapy during the remission induction stage and maintenance stage of ulcerative colitis still needs further clinical trials, including variations of bacterial species, applied dosage, treatment timing, and the course of treatment.

COMMENTS

Background

Ulcerative colitis is a chronic recurrent colon disease whose pathogenesis is not clear. Whether probiotics should be used in treatment remains in dispute. This paper compares the effects of probiotics and drug treatment of ulcerative colitis or placebo in remission induction and maintenance of ulcerative colitis.

Research frontiers

Many studies indicated probiotics have positive effects in treating gastrointestinal diseases, including ulcerative colitis. However, the data comes from small sample studies and does not provide enough evidence of probiotics' advantage.

Innovations and breakthroughs

Thirteen randomized controlled experiments with relatively larger sample sizes, systematically evaluated the probiotics' remission induction and maintenance effects in treating ulcerative colitis.

Applications

Through meta-analysis, probiotics should be considered as an auxiliary medicine in the remission induction stage and maintenance stage of ulcerative colitis.

Peer review

This is a meta-analysis of the effect of probiotics on ulcerative colitis, which might provide some useful information. It is a nice, well-conducted study.

Abstract

AIM: To study the differential expression of proteins between natural taurine treated hepatic stellate cells and controls, and investigate the underlying regulatory mechanism of natural taurine in inhibiting hepatic fibrosis.

METHODS: A proteomic strategy combining two-dimensional gel electrophoresis and ultra-performance liquid chromatography-electrospray ionization-tandem mass spectrometry (UPLC-ESI-MS/MS) was used to study the differential expression of proteins and Western blotting was used to validate the results. Gene ontology (GO) method was utilized to analyze the functional enrichment of differentially expressed proteins. Flow cytometry was performed to compare the apoptosis rate between taurine-treated and untreated hepatic stellate cells (HSCs).

RESULTS: Nineteen differentially expressed proteins (11 up-regulated and 8 down-regulated) were identified

by 2D/MS, and the expression profiles of GLO1 and ANXA1 were validated by Western blotting. GO analysis found that these differentially expressed proteins were enriched within biological processes such as "cellular apoptosis", "oxidation reaction" and "metabolic process" in clusters. Flow cytometric analysis showed that taurine-treated HSCs had a significantly increased apoptosis rate when compared with the control group.

CONCLUSION: Natural taurine can promote HSC apoptosis so as to inhibit hepatic fibrosis.

INTRODUCTION

Hepatic fibrosis (HF) is the excessive accumulation of extracellular matrix (ECM) through which the liver repairs injury^[1,2]. HF occurs in most types of chronic liver diseases due to various causes, and approximately 25%-40% of HF cases may ultimately progress to hepatic cirrhosis or even hepatocellular carcinoma. Therefore, prevention of the initiation of HF and interference with or reversal

of the fibrotic process is important for controlling the development of chronic liver diseases, which has become one of the research focuses in China and other countries^[3,4].

Hepatic stellate cells (HSCs) are nonparenchymal cells found in the perisinusoidal space of the liver also known as the space of Disse^[5]. HSCs contribute significantly to the occurrence of HF because activated HSCs have been found to secrete a great amount of ECM when migrating, proliferating and synthesizing in the injured site of the liver^[6,7]. It is generally believed that reversal of the fibrotic process is difficult once HSCs are activated. Some studies, however, have shown that HF may be inhibited to a certain extent by reducing the number of HSCs *via* apoptosis induction^[8,9].

Taurine, or 2-aminoethanesulfonic acid (C₂H₇NO₃S), is an important anti-injury substance in the body^[10]. Taurine has a protective effect on various types of liver injury^[11,12] and may mitigate HF by inhibiting the deposition of ECM^[13]. The antifibrotic mechanism of taurine may involve its inhibition of the activation and proliferation of HSCs^[9,14]. Because the molecular mechanism of taurine-mediated antifibrotic activity has not been fully unveiled and is little studied, it is imperative to use “omics” methods to systematically investigate the molecular mechanism by which taurine inhibits HF.

Therefore, in the present study, we analyzed the differential expression of proteins between taurine-treated HSCs and controls using two-dimensional electrophoresis (2-DE), ultra-performance liquid chromatography-electrospray ionization-tandem mass spectrometry (UPLC-ESI-MS/MS) and bioinformatics method to identify proteins associated with the inhibition of HF by taurine. Moreover, we aimed to understand better the molecular mechanism underlying taurine's protection against HF and thereby provide new targets for the management of HF and drug development.

MATERIALS AND METHODS

Materials

Human HSCs (LX-2) were purchased from XiangYa Central Experiment Laboratory, Central South University, Changsha, Hunan Province, China. Natural taurine was provided by Yuanlong Pearl Co. Ltd., Beihai, Guangxi Zhuang Autonomous Region, China. Acrylamide, bisacrylamide, glycine and HRP-ECL luminescent substrate were purchased from Sigma (USA). Immobilized pH gradient (IPG) strips (immobiline™ DryStrip, pH3-10, nonlinear, 18 cm) and image analysis software (ImageMaster 2D platinum) were purchased from Amersham Pharmacia. Bradford protein assay kit was provided by Beyotime Institute of Biotechnology (China). Primary and secondary antibodies were purchased from Santacruz; Annexin V apoptosis assay kit, from Nan Jing KeyGen Biotech Co., Ltd. (China); vertical electrophoresis apparatus and Trans-Blot system, from Bio-Rad (USA); Epics XL II flow cytometer, from Beckman Coulter (USA); inverted light microscope, from Olym-

pus (Japan); IPGphor IEF System and ImageScanner, from Amersham Pharmacia. Vertical slab electrophoresis apparatus (PROTEAN II xi Cell) was bought from Bio-Rad (USA) and UPLC-ESI-MS/MS system was provided by Micromass (UK).

Methods

Incubation and treatment of HSCs (LX-2): The cells were incubated in DMEM containing 100 U/mL penicillin, 100 U/mL streptomycin and 10% fetal bovine serum at 37°C, 50 mL/L CO₂ and saturated humidity. The medium was replaced every other day. When the cell density achieved 80%-90%, trypsin was used for digestion and the cell concentration was adjusted to be 1 × 10⁵/mL. The supernatant was discarded and then reaction was maintained for 48 h after the addition of 2% DMEM containing 40 mmol/L taurine. HSCs were randomized equally to receive treatment with or without taurine.

Protein extraction and quantification: The cells were collected after centrifugation and washed in PBS twice. After 10 μL of RNAase and 10 μL of DNAase, were added respectively, the solution was placed in ice bath at 4°C for 20 min and then centrifuged at 14000 × *g* for 30 min and the supernatant was collected. Protein quantification was performed by the Bradford method. In the same way, 1 μL of the sample was collected and 99 μL of water was added followed by supplementation with 1 mL of Bradford working solution. After shaking for 5 min, measurement was conducted. The absorbance of the test sample was measured at 595 nm.

2-DE: The first-dimension isoelectric focusing (IEF) electrophoresis was performed on an IPGphor IEF System. Proteins were centrifuged for 2 min before loading. A loading amount of 150 μg was dissolved in rehydration solution containing 8 mol/L urea, 0.02% Chaps, 0.02 mol/L dithiothreitol (DTT) and 0.05% IPG buffer and then 800 μL of cover fluid was added. The focused gel strips were equilibrated twice in sodium dodecyl sulfate (SDS) equilibration buffer (1.5 mol/L tris-Cl, pH 8.8, 50 mmol/L, 30% Glycerol, 6 mol/L Urea, 2% SDS, Bromophenol blue trace) and rotated on a shaking table for 15 min × 2. The first equilibration buffer was supplemented with 20 mmol/L DTT and the second equilibration buffer was added with 100 mmol/L iodoacetamide. Gel strips were taken out and then the vertical second-dimension sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) was run on a PROTEIN II xi Cell system. Polyacrylamide gels (13%) were used for separation. Electrophoresis was run at a constant current of 40 mA for 40 min and at 60 mA for 5 h until the bromophenol blue front reached the bottom of the gel. Rapid silver staining was performed in accordance with the manufacturer's manual. Gels were stained with 0.1% Coomassie brilliant blue R350 at 100°C for 10 min and then de-stained in 10% acetic acid overnight.

Gel image analysis: Stained 2-DE gels were scanned in transmission scan mode using an Image-scanner™. Then,

matching of protein spots and differential expression analyses between the treatment group and the control group were performed using ImageMaster 2D Platinum 5.0 software.

Mass spectrometry and database query: In-gel digestion was done for 19 differentially expressed protein spots whose concentrations met the requirement of mass spectrometry (MS). In-gel digested products were analyzed by UPLC-ESI-MS/MS (Micromass Company). The mass spectral data obtained after processing with the data analysis software PLGS v2.3 were used to search through the NCBI database with a MS/MS ion strategy using Mascot software (<http://www.matrixscience.co.uk>). The search parameters included trypsin digestion, M oxidation and iodoacetamide alkylation (variable modifications), and 1 missed cleavage. The mass error tolerance in both the MS and MSMS data was 0.2-Da.

GO functional analysis: GO is a stratified tree structure for analysis of gene and protein functions^[15]. We used the BinGO plugin in the Cytoscape platform to analyze functions of 19 differentially expressed proteins, with special focus on the enrichment of these proteins in biological process^[16,17]. Then, we classified the significantly enriched GO terms according to functional similarity. Finally, we visualized the significantly enriched GO terms and their parent/child items in a tree structure in the Cytoscape platform and indicated the classification of the GO terms in the diagram.

Apoptosis detection: HSCs were incubated in the presence of 40 mmol/L taurine for 48 h, washed in PBS twice and then re-suspended in 100 μ L of buffer containing calcium ion. After this, staining was carried out for 20-30 min by adding 5 μ L of Annexin V-FITC dye and then for 5 min by supplementation with 5 μ L of PI dye. The cell concentration was adjusted to be about 1×10^5 /mL by adding a proper amount of calcium ion-containing buffer. The cells were detected on a flow cytometer within 1 h, with the excitation wavelength and the emission wavelength of 488 nm and 530 nm, respectively. The experiment was repeated in triplicate for each sample.

Western blotting: Total proteins in HSCs were extracted as described in the section of protein extraction and quantification, quantified by the Bradford method, isolated by SDS-PAGE and then transferred onto a nitrocellulose membrane with a Trans-Blot SD apparatus. The membrane was blocked in a blocking buffer (TBST solution containing 5% skim milk) at room temperature (RT) for 2 h. Primary antibodies were added at a dilution of 1:500 and the membrane facing down was incubated at RT for 1 h with slight shaking. After incubation with primary antibodies, the membrane was washed and incubated at RT for 1 h with mild shaking in the presence of horseradish peroxidase (HRP) conjugated goat anti-

mouse secondary antibodies (1:5000). After this, the membrane was washed. *Visualization of protein bands* was achieved by the chemiluminescence method and the films were developed and fixed. GAPDH was used as an internal reference. The experiment was repeated in quadruple for each protein.

Statistical analysis

Data were expressed as mean \pm SD. Difference in the relative content of differentially expressed protein spots was analyzed by *t* test for statistical significance ($P < 0.05$) and *t* test was also performed to determine whether treatment with taurine caused a statistically significant change in apoptosis of HSCs ($P < 0.05$). Hypergeometric test was used to test the enrichment of GO terms. A multiple testing procedure controlling false discovery rate (FDR) was performed as described by Benjamini and Hochberg, with the threshold for enrichment significance set to be $FDR < 0.01$ ^[18]. All statistics were performed on R software.

RESULTS

2-DE and image analysis

Under the same experimental conditions, the 2-DE experiment was repeated 3 times separately for 2 groups of protein samples. Three pieces of parallel gels with high resolution and good reproducibility were obtained for each group. The mean number of protein spots from 3 pieces of gels was 745 ± 32 in the taurine treatment group *vs* 748 ± 25 in the control group, with a match rate of 86.08% between groups. Six hundred and forty-three differential protein spots were screened from both groups. Of these protein spots, 19 spots (11 up-regulated and 8 down-regulated) showed more than three-fold differential expression (Figure 1) following treatment with taurine. Figure 2 is a local amplification of 4 pairs of up-regulated or down-regulated protein spots, which clearly demonstrates changes in protein expression between taurine-treated HSCs and controls.

Identification of differentially expressed proteins by UPLC-ESI-MS/MS

Identification by UPLC-ESI-MS/MS was performed for the 19 differentially expressed proteins following in-gel digestion and peptide extraction. The resulting peptide fragments were used to search through the NCBI database using Mascot software and these 19 differentially expressed proteins were successfully identified (ions scores > 38 , $P < 0.05$). Table 1 summarizes the code, name, relative molecular weight, isoelectric point and peptide fragment coverage for the differentially expressed proteins. The most significantly up-regulated expression was observed in GLO1, a glyoxylase capable of catalyzing and forming lactoylglutathione, which has been reported to be linked to inflammatory reactions and tumors^[19,20]. In contrast, AKR1A1, an aldehyde reductase important for both glucose metabolism and oxidative reactions^[21], showed the most markedly down-regulated expression.

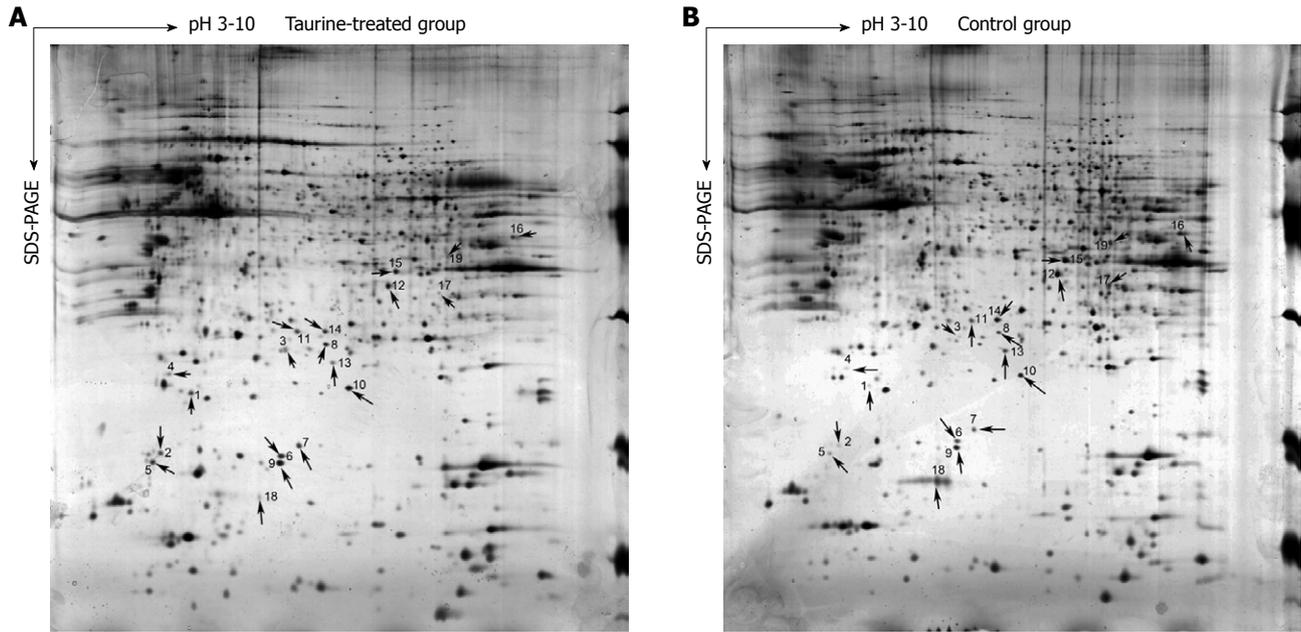

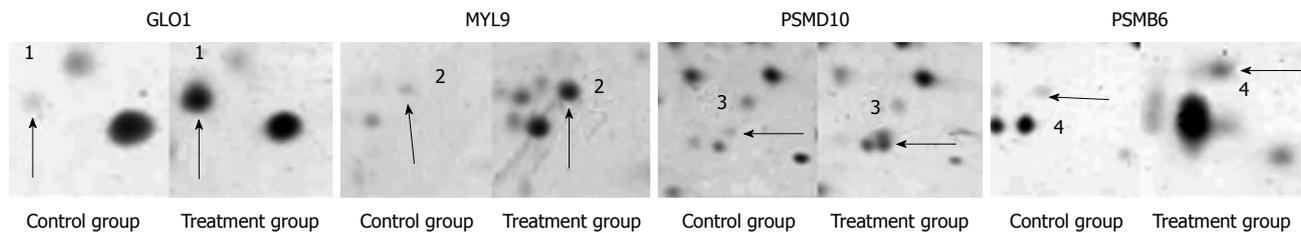

Figure 1 Two-dimensional gel electrophoresis (2-DE) images of taurine-treated hepatic stellate cells (HSCs) and controls. A: Taurine-treated group; B: Control group. In both images, transverse arrows represent isoelectric focusing and longitudinal ones represent sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE).

Up-regulated proteins

Down-regulated proteins

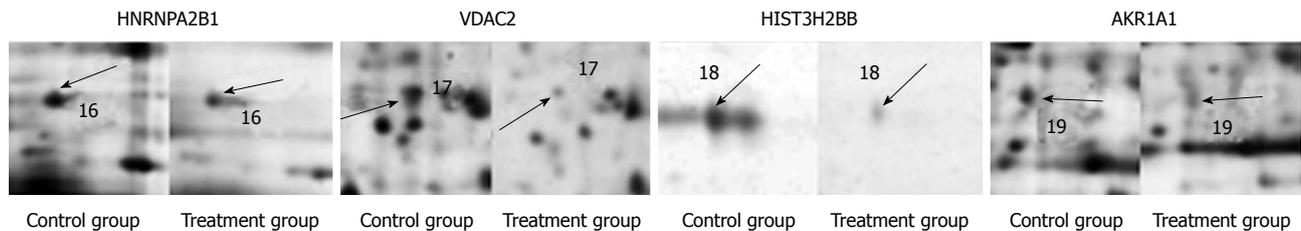

Figure 2 Local amplification of some differentially expressed protein spots (arrows). Up-regulated: GLO1, MYL9, PSMD10 and PSMB6, and down-regulated: HNRNPA2B1, VDAC2, HIST3H2BB and AKR1A1.

Validation of differentially expressed proteins by Western blotting

Among the differentially expressed proteins identified successfully by mass spectrometry, the protein GLO1 and ANXA1 were selected and subjected to Western blotting detection. Taurine treatment caused a significantly up-regulated expression of GLO1 and ANXA1 in HSCs (Figure 3). These expression profiles were completely consistent with the locally amplified 2-D electrophoretogram in Figure 2. Therefore, Western blotting detection of the differentially expressed proteins confirmed the reliability and validity of the proteomic high throughput experiments.

GO functional analysis of differentially expressed proteins

We entered the names of the differentially expressed proteins into the BinGO plugin in the Cytoscape platform to perform GO functional enrichment analysis, with special focus on the changes in the biological process of HSCs after taurine treatment. Table 2 lists 9 significantly enriched GO terms and relevant proteins identified after screening with a threshold of FDR < 0.01. Functional categorization of the GO terms revealed that these differentially expressed proteins were enriched within biological processes such as “cellular apoptosis”, “oxidation reaction” and “metabolic process” in clusters. Figure 4 provides

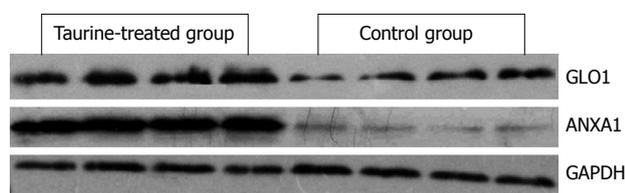

Figure 3 Results of validation by Western blotting for differentially expressed proteins. GAPDH was used as an internal reference. The experiment was repeated 4 times for each protein. Four columns in the right side represent the control group and the other 4 columns in the left side are from the taurine-treated group.

a visualized network of the 9 significantly enriched GO terms and their parent/children items. We can see that Cluster 1, 2 and 3 correspond to the category of “cellular apoptosis”, “oxidation reaction” and “metabolic process” in Table 2, respectively. The consistency between these two dimensions suggests an important role of these biological processes in taurine-treated HSCs.

Results of apoptosis detection

To further confirm the functional findings from proteome data, we detected apoptosis of HSCs treated with or without taurine. Figure 5 shows that taurine treatment resulted in a significant increase in the apoptosis rate of HSCs ($13.6\% \pm 3.3\%$ vs $4.65\% \pm 1.1\%$ in the control group, $P < 0.05$). Thus, proteome data and results of apoptosis detection

consistently suggest that taurine may have an inhibitory effect on HF by promoting HSC apoptosis.

DISCUSSION

In the present study, we employed a proteomics strategy combining 2-DE and UPLC-ESI-MS/MS to investigate difference in protein expression between natural taurine-treated and untreated HSCs. Nineteen differentially expressed proteins (11 up-regulated and 8 down-regulated) were identified. The protein GLO1 and ANXA1 were then selected and subjected to validation by Western blotting, yielding expression profiles in full agreement with results obtained by 2-DE. GO functional analysis showed that these differentially expressed proteins were enriched within biological processes - “cellular apoptosis”, “oxidation reaction” and “metabolic process” in clusters. Flow cytometric analysis showed that taurine-treated HSCs had a significantly increased apoptosis rate compared with the control group. Our comparative proteomic analysis revealed that taurine may inhibit HF by promoting HSC apoptosis.

The apoptotic mechanism of HSCs is complex where various apoptotic pathways are not only inter-independent but also interconnected. For instance, the iron chelator deferoxamine, which may increase the activity of caspase 3 when inducing the release of mitochondrial cytochrome C (cyt-c), induces HSC apoptosis *via* both the mitoch-

Table 2 Functional categorization of differentially expressed proteins

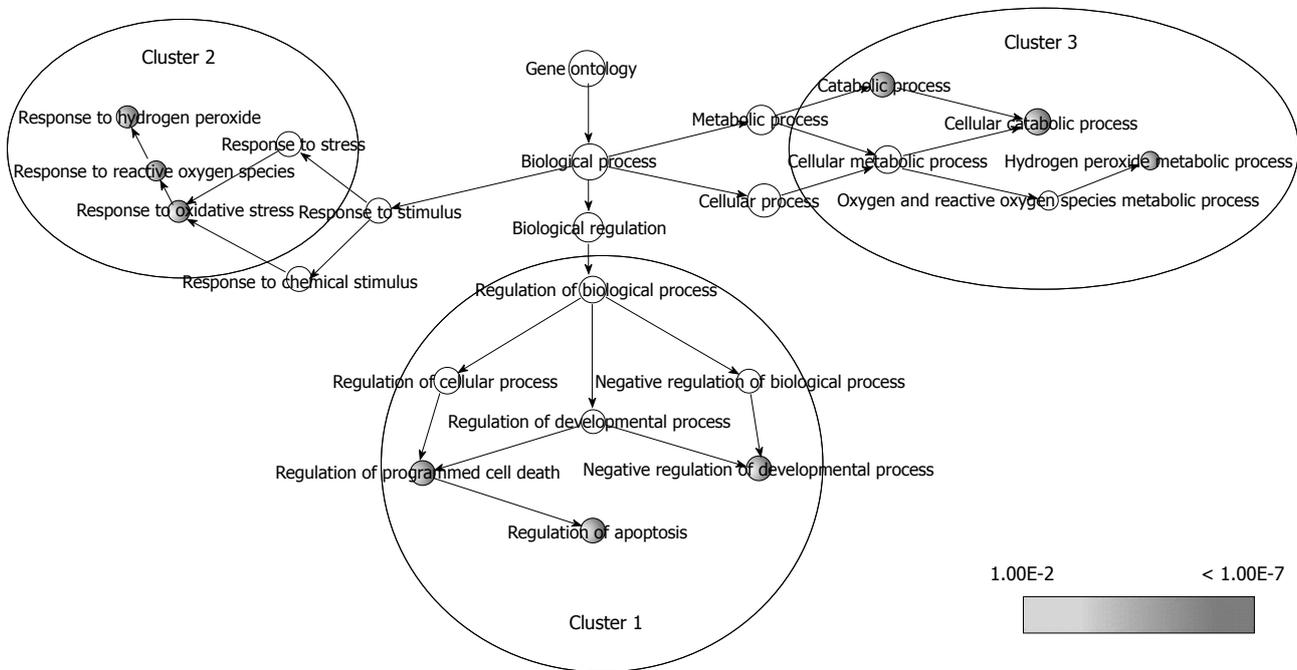

Figure 4 Network diagram of functional categorization of differentially expressed proteins. The categories in this tree structure fully correspond to the 3 categories in Table 2 and the depth of color ranging from light to dark gray indicates the significance level of FDR in Table 2. Gray nodes represent significantly enriched GO terms and white nodes signify GO terms that have a parent/child relationship with gray nodes. Connecting lines between nodes construct a directional hierarchy of the GO terms.

ondrial pathway and the death receptor pathway^[22]. Our previous study has also found that natural taurine may regulate the TGF-β1/smad signaling pathway and has an activity against HF^[23]. To date, however, the molecular mechanism and relevant pathways responsible for taurine’s ability to promote HSC apoptosis have not been well understood. During confirmation of this phenomenon, we found differential expression of proteins including TPT1, ANXA1, HSPB1, GLO1, PRDX2 and SOD1 in taurine-treated HSCs, which was tightly associated with cellular apoptosis. Therefore, we presume that TPT1, ANXA1, HSPB1, GLO1, PRDX2 and SOD1 are important proteins in the taurine-mediated pathway of HSC

apoptosis. These proteins may play a role in classical apoptotic pathways. Or they may constitute, on their own, a specific apoptotic pathway for HSCs by interacting with each other and regulating other proteins. We need to analyze taurine-mediated HSC apoptosis based on findings. Our another previous work has shown that natural taurine may protect mitochondria in HF rats by regulating liver lipid peroxidation, indicating an anti-HF effect^[24]. Functional analysis of the differentially expressed protein demonstrated the ability of taurine to regulate oxidation reaction in HSCs. In fact, oxidation-related biological processes, such as reactive oxygen species (ROS) in Table 2, are closely associated with apoptosis induction^[25]. Among

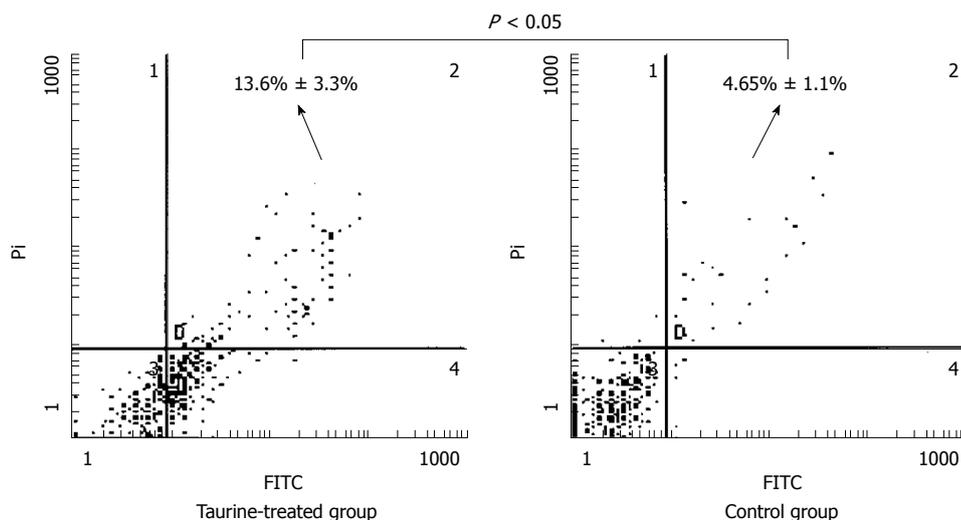

Figure 5 Apoptosis profiles of HSCs treated or untreated with taurine. The experiment was repeated 3 times for each sample (*t* test, $P < 0.05$). Cell count in the second quadrant was used to calculate the apoptosis rate.

the proteins involved in oxidation reaction, some may be engaged in HSC apoptosis as well (SOD1), and some belong to the same protein family (PRDX3 and PRDX2). Moreover, the hydrogen peroxide metabolic process listed in Table 2 is actually one of the basic steps of oxidation reaction^[26,27] and this metabolism-related process also involves SOD1 and PRDX3. Thus, it is possible that, in the interconnected process of HSC apoptosis, SOD1 and PRDX3 play a critical mechanism-specific role. For the reasons given above, we presume that natural taurine may facilitate the release of cyt-c from mitochondria and then promote HSC apoptosis by directly or indirectly inducing activation of caspase *via* ROS^[25,28] and that SOD1 and PRDX3 are two significant functional proteins in the process.

The hepatic parenchyma consists of parenchymal liver cells (PLCs) including hepatocytes and non-parenchymal liver cells (NPLCs) associated with sinusoids including HSCs. It has been demonstrated that the activation of HSCs is the key issue in the pathogenesis of HF^[7]. Changes of hepatocytes proliferation may stimulate hepatocyte interaction with HSCs possibly *via* cell adhesion molecules leading to HSC activation and HSC clustering^[29,30]. It is obvious that HSCs is the most important HF target cell line in the liver, however, HSC-HSC and hepatocyte-HSC cell adhesion may play a combined role in HF. Therefore, study of the activation and apoptosis of HSC can extensively survey the possible pathological mechanisms of HF, but further investigations on animal models or clinical patients *in vivo* will obtain more exact results for HF in living organisms.

Taurine can either be synthesized chemically or extracted from natural sources. However, natural taurine is more superior to synthetic taurine in promoting HSC apoptosis^[31]. The advantage and innovativeness of our present study are reflected in the selection of natural taurine for investigation of its mechanism in regulating HSC apoptosis. In addition, since no studies using proteomic high throughput technologies to investigate the inhibition of HF by taurine have been published in China and other countries, our findings are useful for

future systematic studies on biological mechanism.

Life is a vast and complex dynamic network system and the therapeutic mechanism of drug treatment mimics an integrated modulatory chain effect involving a variety of pathways in regulating biological networks^[32]. The present study, which systematically investigated how natural taurine may regulate HF-associated biological networks, will help to cast a new light on the action mechanism and targets of taurine.

ACKNOWLEDGMENTS

We sincerely thank Dr. Xing-Yi Hang for his assistance in data analysis and manuscript revision.

COMMENTS

Background

Hepatic fibrosis (HF) occurs in most types of chronic liver diseases and approximately 25%-40% of HF cases may ultimately progress to hepatic cirrhosis. Hepatic stellate cells (HSCs) contribute significantly to the occurrence of HF and the activation of HSC is the key issue in the pathogenesis of HF. It is expected that HSCs are targets for pharmacological or molecular interventions for the treatment of HF.

Research frontiers

Taurine is a kind of important anti-injury substance in the body. Taurine has a protective effect on various types of liver injury. It has been clear that the antifibrotic mechanism of taurine may involve its inhibition of the activation and proliferation of HSCs. However, the molecular mechanism of taurine-mediated antifibrotic activity is largely unknown. Now the research hotspot is to unveil the underlying regulatory mechanisms and accumulate data for drug development.

Innovations and breakthroughs

In the present study, the authors analyzed the differential expression of proteins between taurine-treated HSCs and controls by comparative proteomics technologies. It is the first investigation to study the natural taurine mediated protection effects against HF. Nineteen differentially expressed proteins were identified and functional analysis provided confident evidence of HSC apoptosis promotion by taurine treatment.

Applications

The study results are very helpful to understand better the molecular mechanism underlying taurine's protection against HF and thereby provide new targets for the management of HF and drug development.

Peer review

The authors investigated the effect of taurine on the HSCs by proteomic analysis. They identified 19 differently expressed proteins belonging to the

biological process of apoptosis, cellular oxidation and metabolic processes. They also found an increased rate of apoptosis in taurine exposed cells. Overall, this work is of interest in relation to taurine induced protection in HF and in the underlying alterations in specific proteins in HSC.

INTRODUCTION

The association of cystic fibrosis (CF) and Crohn's disease (CD) is well known, but, to date, there are very few cases in the literature of patients suffering from mucoviscidosis who have required treatment with infliximab.

CF is the most common life-threatening autosomal recessive disease in Caucasian children; it has an incidence of 1 case in every 2500 children born alive^[1]. CF involves an anomalous function of the exocrine glands, caused by a mutation of a gene (cystic fibrosis transmembrane conductance regulator, *CFTR*) located on chromosome 7, which codes for a protein involved in ion transport through the cell membrane^[1]. More than 1000 mutations of *CFTR* have been identified, the most common of which is ΔF 508, found in 50% of CF patients. Pulmonary complications are the most common causes of mortality, but the presenting symptoms are very often linked to gastrointestinal and pancreatic biliary diseases. These are mainly caused by the unusual viscosity of the secretions in hollow organs and in the ducts of solid organs^[1].

Meconium ileus, intussusception, appendicitis, rectal prolapse, gastro-esophageal reflux, CD and fibrosing colonopathy are the gastrointestinal diseases observed in patients suffering from CF^[1,2].

CD is a chronic inflammatory bowel disease which may be localized throughout the gastrointestinal tract. The association between CD and CF is known; there are reports of a prevalence of CD in patients suffering from CF 17 times higher than in controls^[3].

CD in patients suffering from CF is, therefore, not an exceptional event; the use of an immunosuppressant such as infliximab in patients suffering from CF may, however, be considered as uncommon, as seen in the lack of data available in the literature. Probably, underlying this lack of

Abstract

The association of cystic fibrosis and Crohn's disease (CD) is well known, but to date, there are very few cases in the literature of patients suffering from mucoviscidosis who have required treatment with infliximab. We report the case of a 23-year-old patient suffering from cystic fibrosis and severe CD treated successfully with infliximab without any infective complications or worsening of the pulmonary disease and with a long term (2 years) complete remission.

data is the fear that the immunosuppressive properties of such a biological treatment would be contraindicated by the characteristic infections in CF, especially of the lung.

We report the case of a 23-year-old patient suffering from CF and severe CD who was treated successfully with infliximab and who is in long term remission.

CASE REPORT

This is a report of the case of a 23-year-old female suffering from CF who, from the age of 16 years, started having recurrent abdominal pain associated with weight loss. She was regularly followed up by a centre for CF.

At the age of 14 years, she underwent explorative laparotomy with appendectomy for suspected acute abdomen. The operation was complicated by the appearance of a cutaneous fistula at the site of the surgical wound. Because of persistence of symptoms associated with severe deterioration of nutritional condition, she was sent to our centre. A low digestive endoscopy carried out at our unit showed a condition of acute pancolitis compatible with chronic inflammatory bowel disease. The histological examination of the multiple biopsies taken confirmed the suspected diagnosis of CD.

An induction treatment cycle with prednisone, full dose for 4 wk, with mesalazine and metronidazole was initiated. Having obtained clinical and endoscopic histological remission, we reduced the prednisone dose, stopped metronidazole and continued maintenance treatment with mesalazine. The patient continued treatment with mesalazine alone with good clinical progress for about four years during which she did not come to us for check-ups but preferred to go to the hospital in her city of residence.

In 2003, she underwent emergency laparotomy at another centre following the appearance of acute abdomen. Surgery showed a pericolic abscess collection in the cecum and ascending colon; she was then subjected to ileocecal resection and ileotransverse colonic anastomosis. At two months following the surgery, the girl was treated with steroids, azathioprine and mesalazine for severe flare-up of disease. She continued with low dose steroid treatment (5-10 mg/d) for about two years; treatment with azathioprine was suspended owing to poor efficacy and was replaced with methotrexate (MTX).

During this period of time the patient presented stable respiratory function (spirometry, clinical outcome of exacerbation), but she developed chronic *Pseudomonas aeruginosa* airway infection. Therefore, ciprofloxacin or trimethoprim sulfamethoxazole or doxycycline was administered for 2 wk twice every 3 mo.

In August 2006, the patient returned to us spontaneously following recurrent episodes of abdominal pain and considerable weight loss (about 10 kg in the previous 2 mo). An ileocolonoscopy carried out under sedoanalgesia showed hyperacute disease of the sigmoid-rectum (Figure 1A and B). Multiple "tags" were present in the anal site with a big "knife-cut" lesion at the level of the posterior commissure. The histological examination confirmed a severe reactivation of her disease. The

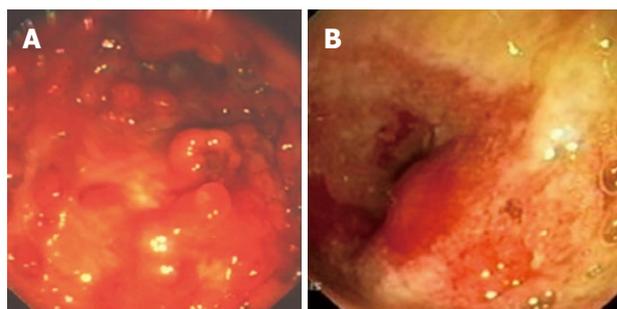

Figure 1 ileocolonoscopy findings. A: Multiple inflammatory pseudopolyps; B: Hyperacute Crohn's disease of the sigmoid-rectum.

CD activity index (CDAI) was 390. Index values of 150 and below are associated with quiescent or non-active disease (i.e. "remission"); values over 150 are indicative of active disease, and over 450, extremely severe disease^[4]. Total parenteral nutrition was therefore started with complete suspension of fractionated feeding by oral administration and medical treatment was resumed (cortisone, metronidazole as antibiotic and mesalazine as anti-inflammatory).

Due to the steroid therapy, fasting blood glucose pathologically increased (320 mg/dL) and therefore subcutaneous insulin therapy was started with an improvement of glucose intolerance.

Endoscopic histological examination performed after a short time (4 wk), showed only modest improvement of the lesions found earlier during the endoscopic examination, despite improvement of the general condition.

Because of the severity of the lesions, particularly of the anus, and after informing the patient and the pneumologists, we decided to start a biological treatment cycle with infliximab in addition to treatment with azathioprine (AZA) (2.5 mg/kg per day) in a single administration in the morning, associated with antibiotic treatment with 3rd generation cephalosporin and glycopeptide. The infusions of infliximab can be superimposed with this treatment regime, which is used in our centre, with an initial treatment at 0, 2, and 6 wk, followed by a maintenance phase with infusions every 8 wk.

At the discontinuation of steroids, insulin therapy was no longer necessary.

After the first three intravenous infusions of infliximab, endoscopic examination showed complete regression of anal lesions and distinct improvement of the lesions of the sigmoid rectum, with healing appearance of the mucosa and no continuous lesions up to the ileocolic anastomosis.

The appearance of the ileum, explored to about 40 cm, was within acceptable limits. Nine months after beginning the treatment and after 7 infusions of infliximab, the patient showed distinct improvement in her general condition and body weight increased by 13 kg.

Twelve months after commencement of the treatment, condition continues to be optimal and there has been no complication involving infection in the lung or septic episodes. The working of the lungs was kept stable during

Figure 2 Endoscopic remission.

the course of treatment with infliximab (forced expiratory volume in 1 s (FEV1) 85% in April 2006 and FEV1 80% in July 2007), without any pulmonary exacerbations.

Suspension of the biological treatment was therefore programmed after the 10th infusion, while treatment with AZA and mesalazine as maintenance continued. Since the last infliximab infusion two years have passed and a complete remission of CD has been maintained both clinically and endoscopically (Figure 2).

DISCUSSION

This report deals with the case of a patient suffering from CF who, at the age of 16 years, was diagnosed as suffering from CD. The literature reports frequent cases of CD during the course of CF. The prevalence is about 17 times greater than that of controls^[3]; this shows that there is a pathogenic relationship between the two diseases. The etiopathogenesis has not yet been identified but a number of mechanisms have been proposed, the most probable of which is an altered immune response to a chronic infection^[4]. Furthermore, patients who are carriers of the ΔF 508 mutation seem to have an increased risk of developing gastrointestinal problems^[5].

The literature contains case reports of diagnosis of CD in patients suffering from CF who complain of long periods of abdominal pain and most of all, loss of weight, in spite of appropriate nutritional and therapeutic support^[6,7]. As in the case of our patient, protracted gastrointestinal symptoms and lack of response to basic treatment make it necessary to conduct instrumental examinations, in particular endoscopic examinations such as gastroscopy and colonoscopy, associated with perendoscopic biopsies, which allow a differential diagnosis between CD and fibrosing colonopathy^[7,8]. This has led, in the last few years, to an increase in the diagnosis of CD during the course of CF^[7], which was not suspected in the past. The aim of treatment during the course of CD is to induce and maintain remission of the disease. Corticosteroids have demonstrated a high efficiency in inducing clinical remission in patients with moderate to severe forms of disease^[9,10]. In order to maintain the remission and to reduce the risk of dependence on corticosteroids, there is general agreement regarding the early introduction of im-

munosuppressants such as AZA, MTX, 6 mercaptopurine (MP) and also infliximab^[11-13]. In the case of our patient, given the modest clinical and endoscopic response after one month of treatment with steroids, this therapeutic opportunity was also discussed with the pneumologists. Biological treatment with infliximab associated with AZA was therefore started, because of the presence of significant anal lesions, although the literature currently contains few case reports of patients suffering from CF treated with infliximab. However, numerous studies have shown the efficacy of infliximab in inducing or maintaining remission of disease in adults suffering from CD who have moderate-severe forms, with perianal localization or with fistulizing forms^[9,10,14-17]. In patients with CF the presence of bronchiectasis and colonization with *Pseudomonas*, as in our patient, would normally represent a relative contraindication to the administration of infliximab, but numerous studies of bronchoalveolar lavage fluid from patients with CF have shown a high concentration of inflammatory mediators such as tumor necrosis factor α (TNF α)^[18]. Indeed, drugs such as azithromycin ameliorate lung function in cystic fibrosis patients while also reducing the levels of TNF α ^[19].

In our experience with this patient, we observed a significant clinical improvement even after the first dose. This improvement was endorsed by the resolving of endoscopic and histological lesions, as is also reported in the literature^[9,20,21]. The association of infliximab with AZA was justified by the fact that concurrent treatment with AZA, 6 MP or MTX may be helpful in maintaining the clinical response to infliximab, reducing the amount of circulating antibodies directed towards the latter; which are thought to be responsible for some cases of non response^[22-25].

As shown in the literature^[18,19], as well as in the case of our patient, the moment a treatment focused for CD was introduced, although not free of risks, a distinct improvement of the general condition was observed with weight increase of about 13 kg. After over 12 mo of treatment with infliximab and AZA, no pulmonary complication which would have compelled suspension of treatment was observed. In addition, the literature shows that no severe adverse events have occurred and that there was no reported increase in the prevalence of respiratory tract infections during infliximab administration in patients with chronic obstructive pulmonary disease^[26].

The main questions arising from treatment with infliximab in this patient were, firstly, the possibility that the biological treatment could increase susceptibility to infections by opportunistic pathogens given the concurrent basic lung disease, since patients with cystic fibrosis already spontaneously suffer from such infections. Moreover, the infections most frequently reported during infliximab infusions are respiratory tract infections and urinary tract infections (35% infliximab-treated patients vs 25% placebo recipients)^[27].

Secondly, given the excellent clinical, endoscopic, and histological progress of the patient, there was doubt regarding the best moment for suspension of the drug,

especially taking into consideration the possibility of causing allergies or reduced efficacy in case of re-treatment because of the possible presence of antibodies against infliximab^[9,22,23,25,28,29].

As regards the first challenge, the constant cover with antibiotic treatment was found to be effective in keeping the lung disease under control, as it did not worsen but rather remained stable as is shown by the spirometry tests taken during the course of immunosuppressive treatment.

As regards suspension of treatment, in the absence of precise bibliographic guidance, we believed that it was appropriate to suspend treatment in accordance with previously reported data after a period of not less than one year^[30].

Abstract

Abdominal wall defects and incisional hernias represent a challenging problem. In particular, when a synthetic mesh is applied to contaminated wounds, its removal is required in 50%-90% of cases. Biosynthetic meshes are the newest tool available to surgeons and they could have a role in ventral hernia repair in a potentially contaminated field. We describe the use of a sheet of bovine pericardium graft in the reconstruction of abdominal wall defect in two patients. Bovine pericardium graft was placed in the retrorectus space and secured to the anterior abdominal wall using polypropylene sutures in a tension-free manner. We experienced no evidence of recurrence at 4 and 5 years follow-up.

INTRODUCTION

Abdominal wall defects and incisional hernias represent a challenging problem. The risk of developing an incisional hernia after a midline laparotomy is up to 11%^[1]. The size of the abdominal wall defect and the potential presence of contamination of the site can complicate this commonly performed surgical repair. Several techniques have been adopted over time. Primary repairs often lead to unacceptable high tension, and their recurrence rate has been reported as high as 12%-50%^[1,2]. In patients whose fascial defect is significant, mesh repair is preferable in order to obtain a tension-free abdominal wall closure. In the latter case, the recurrence rates are reported between 3% and 24%^[2-4]. According to the literature, the use of prosthetic mesh reduces the recurrence rate but is also associated with serious complications in 10%-15% of cases. Some of these complications, such as infection, fistula and skin erosion, often lead to mesh removal^[4]. In particular, when

a synthetic mesh is applied to contaminated wounds, its removal is required in 50%-90% of the cases^[5]. Strength, flexibility, host tissue compatibility and ability to avoid infections should characterize an ideal mesh. Many synthetic and biological mesh tissues have been proposed over time but no single material, nor newer biosynthetic mesh, has fulfilled these requirements and gained universal acceptance. We present two cases in which biological meshes were used successfully in contaminated fields.

CASE REPORT

Case 1

A 62-year-old white woman presented to the General Surgery and Senology Unit of our University with a 6-mo history of abdominal pain after right hemicolectomy for carcinoma through a midline laparotomy at another institution. Her medical history was also significant for obesity, hypertension and coronary artery disease. She stated that pain occurred soon after the surgical procedure, together with random fever. Six months later, she developed an abdominal wall abscess that spontaneously drained externally through a small incisional hernia in the right-upper abdomen, and formed a persistently draining sinus. Following this, she underwent incisional hernia repair with pre-peritoneal prolene mesh placement. After 4 mo, she developed a small fistula again (Figure 1A), therefore, she was admitted to our division for further care. On physical examination, we observed a well-healed midline incision with mild tenderness along the incision itself. Computed tomography (CT) of the abdomen showed a multiloculated collection around the mesh, which measured approximately 12 cm × 15 cm. A course of antibiotic therapy (imipenem) was initiated before bacterial cultures were obtained. The first culture was positive for *Staphylococcus aureus* and *Pseudomonas aeruginosa*. The second, after 1 wk of appropriate antibiotic administration, remained negative for any microorganism.

We scheduled the patient for exploration and mesh removal. We entered the abdominal cavity through her previous midline laparotomy. The cavity was then exposed and the fluid collection aspirated along with debris. The inflammatory process extended to the periosteum of the tenth rib. Removal of the mesh from the anterior abdominal wall required extensive and tedious dissection. The abdomen was entered and all adhesions to abdominal organs (bowel and omentum) were removed. We noticed an anomaly of the rib profile, therefore, after further investigation, we discovered a bone fracture with surrounding tissue rearrangement. We excised the rib for histological examination and it was consistent with osteomyelitis (Figure 1B and C). After removal of the contracted mesh, we created skin flaps and re-positioned the posterior rectus sheath. We placed a sheet of bovine pericardium graft (Tutomes[®]; Tutogen Medical, Germany) in the retrorectus space and secured the mesh in a tension-free manner to the abdominal wall, using polypropylene sutures. The anterior rectus sheath was then

re-positioned with Vicryl, and the skin was closed with staples (Figure 1D). The patient had no significant postoperative complications, and she was discharged on postoperative day 6. We performed CT at 5 mo after surgery, which showed no seroma and excellent remodeling of the host tissue. There was no clinical evidence of recurrence at her 5-year follow-up visit.

Case 2

A 69-year-old man with a previous history of left hemicolectomy for diverticular disease underwent elective incisional hernia repair with intraperitoneal polytetrafluoroethylene (PTFE) mesh placement 8 mo later. Postoperatively, the patient developed a persistent infected seroma, which was unresponsive to antibiotic treatment. The patient underwent surgery again to drain the collection, debride the area, and substitute the contracted Goretex mesh with a polypropylene mesh in the retrorectus space. This attempt proved unsuccessful and led to abscess formation after only 1 mo. The patient was scheduled for elective removal of the polypropylene mesh. After removal of the contracted mesh (Figure 2A-C), the posterior rectus sheath was re-positioned to the midline, and a sheet of bovine pericardium mesh (Tutomes[®]) was implanted in the retrorectus space and secured to the anterior abdominal wall using polypropylene sutures in a tension-free manner. The anterior abdominal wall was then re-positioned with Vicryl interrupted sutures and the skin was closed with staples (Figure 2D). The patient had no significant postoperative complications, and he was discharged on postoperative day 3. At his 4-year follow-up visit, there was no evidence of recurrence.

DISCUSSION

Treatment of incisional hernias

Incisional hernias are still a challenging problem for the surgeon. Their primary repair leads to high recurrence rates (up to 50%) because of the tension created and myocutaneous flap necrosis^[1,2].

Many techniques have been proposed over time to reduce tension, such as relaxing incisions, and compartment release. Unfortunately, the results are far from being optimal^[6,7]. Furthermore, large, full-thickness, abdominal wall defects secondary to wide resection of malignant tumors, traumatic injuries, or congenital abnormalities, cannot be closed primarily. The use of prosthetic meshes has then become necessary. Along with the traditional open techniques of mesh implantation, the more recent laparoscopic approach has gained popularity because of the decrease in wound infection, recurrence rates and recovery time.

Unfortunately the intrinsic property of tissue ingrowth of the prosthetic meshes currently used, such as polypropylene, polyester and PTFE, is also the cause of unwanted adhesions, chronic sinus (2%-6%), fistula formation (0%-2%) and wound infections (2%-17%)^[8]. Other potential complications of synthetic meshes in-

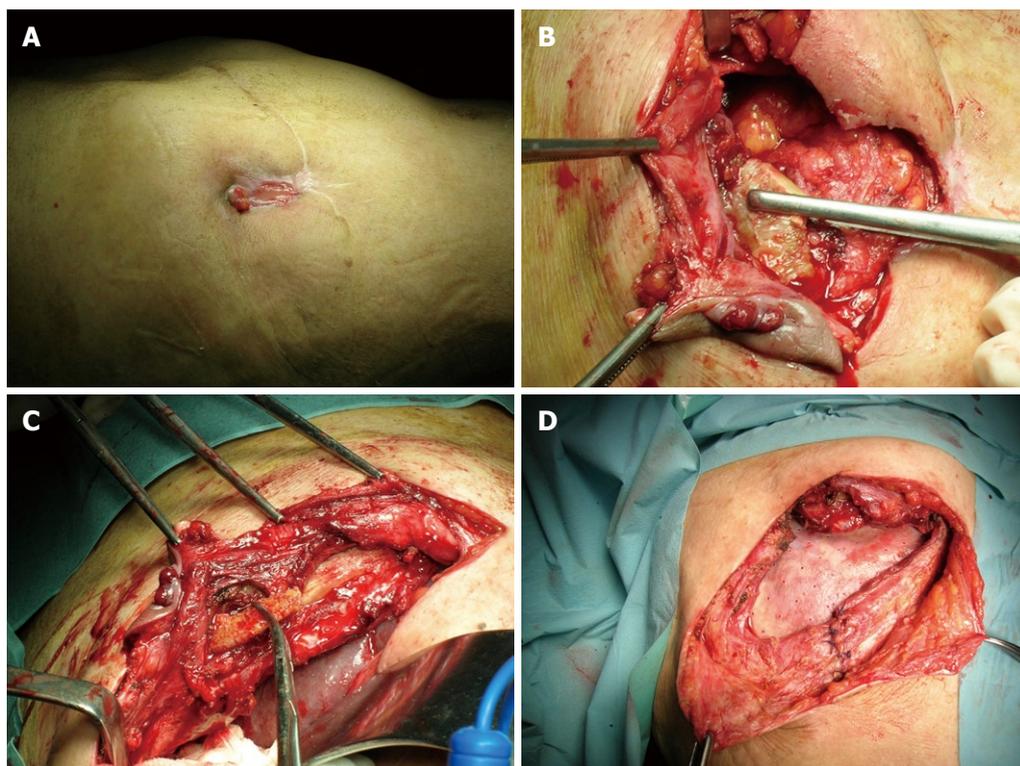

Figure 1 Case 1. A: Abdominal wall with subcutaneous fistula; B: Rib anomaly; C: Bone fracture with tissue rearrangement; D: Sheet of bovine pericardium mesh; anterior rectus sheath re-positioned with Vicryl.

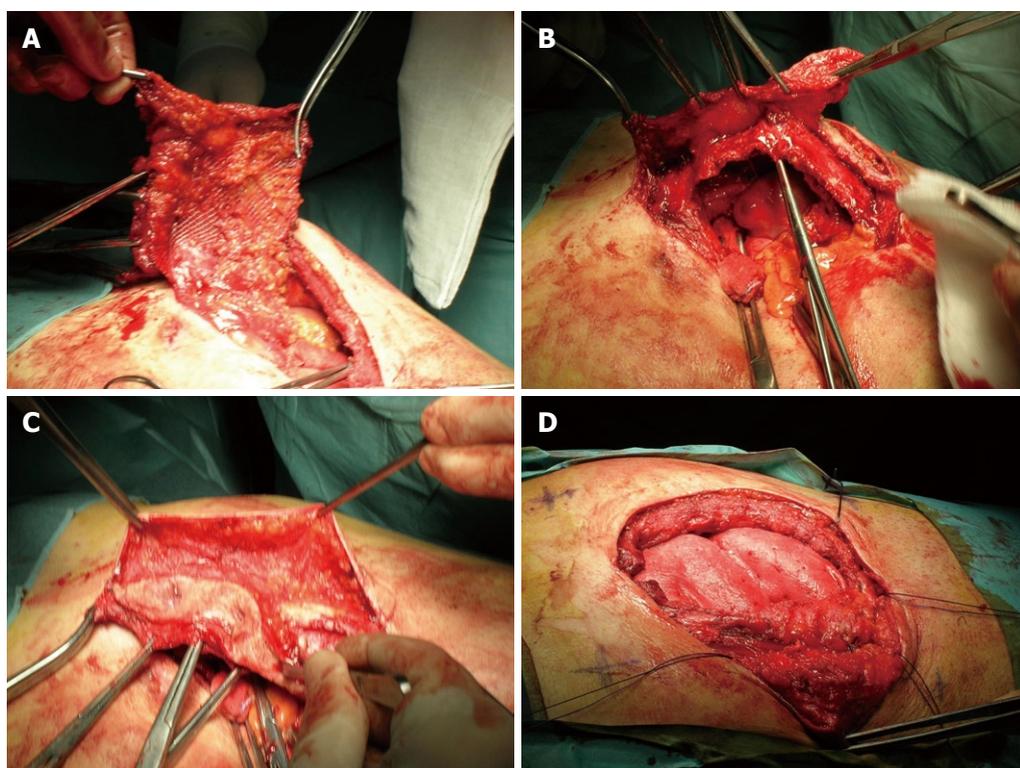

Figure 2 Case 2. A-C: Preexisting contracted mesh; D: Sheet of bovine pericardium mesh in the retrorectus space.

clude mesh contraction, migration, folding of the edges with visceral contact, recurrence, inflammation, seroma, and chronic pain due to inflammatory response and/or

nerve entrapment. As a result, complications are common following ventral hernia repair, and occur in 5%-30% of laparoscopic cases and 27%-34% after open cases^[9].

Table 1 Classification of biological grafts

Species of origin	Allogenic	Xenogenic	
Type of collagen matrix	Dermis	Intestinal submucosa	Bovine pericardium
Decellularization process	Yes	Yes	Yes (TUTOMESH®)
Cross-linking	Yes	No	No
Sterilization method	Salt solution, patented non-denaturing agents		H ₂ O ₂ , NaOH, γ irradiation
Storage (need for refrigeration)	Yes	No	No
Rehydration requirement	Yes	No	No

Contaminated abdominal wall defect: role of biological prostheses

Even more challenging is the repair of complex contaminated abdominal wall defects, since no ideal operative technique or material for fascial reconstruction is currently available. The fear of fibrosis, erosions, infection and fistulas with the commonly used prosthetic meshes, has led engineers and surgeons to investigate alternative materials in order to achieve tension-free repair in a single-stage operation, even in highly contaminated fields. Bio-synthetic grafts seem to offer a solution to this challenging problem. Their concept is to provide a collagen and other extracellular matrix scaffold, in which the host fibroblasts can create angiogenesis and deposit new collagen. The non-synthetic nature of these products allows them to be more resistant to infections. Several biological grafts are available on the market. Their classification is based on the species of origin (allogenic, xenogenic), type of collagen matrix utilized (dermis, pericardium, intestinal submucosa), decellularization process, presence or absence of cross-linking, storage requirements (need for refrigeration or not), and the need for rehydration (Table 1).

Bovine pericardium (TUTOMESH®) is a cadaveric bovine pericardium surgical mesh that is processed by solvent dehydration followed by gamma irradiation. It has no risk for transmission of viruses or prions. The graft consists of collagenous connective tissue with three-dimensional intertwined fibers, it has multidirectional mechanical strength, and can be implanted regardless of the direction of the graft. Collagenous connective tissue with multidirectional fibers retains the mechanical strength and elasticity of the native tissue, while providing the basic structure to support replacement by new endogenous tissue (known as remodeling). It is indicated for use in general, gynecological, cardiac and plastic surgery, such as repair of pericardial structures, soft tissue deficiencies, rectal and vaginal prolapse, and hernias (including diaphragmatic, femoral, incisional, inguinal, lumbar, paracolostomy, and umbilical hernias), gastric banding, muscle flap reinforcement, and reconstruction of the pelvic floor.

A bioprosthesis derived from human acellular dermal matrix (Alloderm®; Lifecell Corporation, Brachburg, NJ, USA) has been used as a tissue substitute for skin

grafting over the past 20 years, but its use for abdominal wall reconstruction is relatively recent. At present, there are not enough data or long-term reports to establish universal consensus for its use over other bioprotheses, but it is the material with the most published literature. Some authors have described concerns about the laxity of the material and its ability to stretch over time, with the development of eventration or pseudo-recurrences^[9].

Another available product is derived from porcine dermal collagen (Permacol™; Tissue Science Laboratories plc, Covington, GA, USA). It is a flexible acellular cross-linked porcine dermal collagen that is approved by the US Food and Drug Administration for use as a tissue substitute. It has been used in the United Kingdom since 1998. In addition to its three-dimensional collagen architecture that is similar to human dermis, it supports fibroblast infiltration and neovascularization. As a result of its manufacturing peculiarity of cross-linking, its remodeling process is delayed in the host tissue, which provides additional strength, but also possible incomplete remodeling. The porcine dermal collagen graft is easy to handle and has demonstrated comparable tensile strength to polypropylene. Integration into host tissue and neovascularization allow for antibiotic diffusion and in turn, greater resistance to infections, as in other similar biological grafts^[10].

Surgical techniques: overview

Four types of incisional hernia repair with mesh have been commonly described.

In the inlay technique, the fascial defect cannot be approximated, so the prosthetic material is secured to the edges of the fascia to achieve abdominal wall closure. The onlay technique places the mesh above a primary fascial closure. The more recently described sublay technique (Rives Stoppa repair) applies the concepts of a tension-free technique in which the prosthetic mesh is secured in the retrorectus space after closure of the posterior rectus sheath/peritoneum. The aim is to prevent contact between the mesh and abdominal viscera. The coverage of the mesh provided by the muscle decreases the complications related to the mesh proximity to the subcutaneous tissue (seroma, wound infection)^[11,12]. Finally, with the advent of meshes designed with an anti-adhesive barrier on one side, the mesh position has been moved one layer deeper, into the peritoneal cavity; the so-called intraperitoneal technique. In the latter, the mesh is secured to the abdominal wall with stitches, staples or tacks, and this is commonly performed laparoscopically.

Review of the literature

The data available on biological mesh implants for ventral hernia repair are very recent, and mostly in the form of case series. Lindermann *et al.*^[13] have published their experience using bovine pericardium graft in 37 incisional and two parastomal hernias. They have described four recurrences in the incisional group treated with the inlay technique (fascial defect cannot be approximated). They have suggested that the high elasticity of the mesh during the

remodeling phase could be the likely cause of recurrence. Post *et al*^[14], in their series of 13 successful incisional hernias with sublay bovine pericardium, have described one case in which the mesh had to be re-attached after it had pulled off the suture line during a coughing spell. No infection, pain, foreign body feeling or recurrence was seen. Parker *et al*^[10] have reported their experience using Permacol in nine patients affected by complicated abdominal defects with either a contaminated wound or a history of a hernia mesh infection. In all cases, the mesh was placed in the retromuscular underlay position, and in spite of the presence of active infection or gross contamination, no infectious complications occurred. Baghai *et al*^[15] have evaluated 20 biological mesh implants in 17 patients who required recurrent ventral hernia repair following synthetic mesh explantation due to infection. Different biological grafts were utilized in the study (including porcine intestinal submucosa, human and porcine dermis). Also, all the implants were carried out with an open technique in the inlay, onlay or retrorectus position. All the patients treated with the inlay or onlay technique ($n = 17$) experienced wound infection and/or dehiscence within 2 wk of surgery. The three remaining biological implants, placed in the retrorectus space with closure of the anterior fascia, were successful with no infection, dehiscence or recurrences at 6 mo follow-up. Therefore, Baghai *et al*^[15] have suggested that biological mesh implants are not effective when used with an inlay or onlay technique. According to these preliminary results, the mesh position, regardless of the type of biological mesh composition and texture, may play a key role in the incidence of hernia recurrence. Patients whose defect is corrected by a bridging technique (inlay technique) seem to have an increased tendency to develop eventration and a higher recurrence rate, compared with those whose defect is reinforced after fascia closure (sublay technique)^[9]. According to some authors, the use of biological meshes in a bridging manner (inlay technique) provides only a temporary means for restoration of abdominal wall integrity in highly contaminated fields, which leads to future implantation of a more durable prosthesis to reestablish the integrity of the abdominal wall. Conversely, when the biological mesh is used to reinforce a primary fascia closure (sublay or underlay technique), the rate of recurrence seems comparable with other prosthesis^[16,17]. In the setting of a contaminated wound, delayed closure has been proposed to prevent a closed environment infection and limit recurrence, but its routine use has not gained wide support^[18].

Choice of biological prosthesis

The scarcity of literature comparing the different types of biological grafts precludes an evidenced-based decision about which one to use. Therefore, we have to decide according to the characteristics of the grafts to choose the appropriate product.

Permacol is available in larger sizes than cadaveric graft (up to 18 cm × 28 cm), it is less expensive than human cadaveric dermal graft, and does not require rehy-

dration before being placed^[10].

Bovine pericardium meshes have been used safely even for the repair of inguinal or paraesophageal hernias, in which the constant movement of structures is a risk factor for recurrence^[19]. In our opinion, one of the main advantages of bovine pericardium graft resides in the relative lack of elastin compared to dermal products (both allogenic and xenogenic). This, in turn, results in a higher ratio of mature collagen/elastin at the end of the remodeling, possibly minimizing eventration and pseudo-recurrence^[9]. Also, these products are easy to handle, do not require refrigeration, have a long shelf life, and can be used immediately after opening without long rehydration processes. Finally, they tend to be less expensive than their human tissue counterparts. However, further studies with larger numbers of patients and longer follow-up are required to guide better the right choice of material^[9,20].

In conclusion, complex reconstruction of the abdominal wall can be challenging. Biosynthetic meshes are the newest tool available in the surgeon's armamentarium and they could have a role in ventral hernia repair in clean and contaminated fields. Their use is based on the concept of providing a collagen and extracellular matrix scaffold in which the host fibroblasts can create angiogenesis and deposit new collagen. In reviewing our results, the bovine pericardium as a xenogenic implant is a useful alternative to allogenic materials in incisional hernia repair. Further experience and longer follow-up is necessary to determine the results of bioprosthesis when used for abdominal wall reconstruction.

INTRODUCTION

Gastric adenomyoma (AM) is a rare, benign tumor, characteristically composed of glands and cysts, lined by columnar, flattened epithelia and a prominent smooth muscle stroma. The entity was first described by Magnus-Alsleben^[1] in 1903. Patients with gastric AM may be asymptomatic, or have nonspecific gastrointestinal symptoms such as epigastric pain, vomiting^[2-5]. We describe, herein, an extremely rare case of gastric AM presenting as melena.

CASE REPORT

A 68-year-old man was referred to our hospital with a 1-week history of melena. He had no remarkable past medical history and alcohol consumption or history of smoking or drugs. Upon hospitalization, physical examination, routine laboratory parameters and tumor markers including carcinoembryonic antigen, cancer antigen 19-9, and alpha fetoprotein were normal, except for markers of hypochromic anemia including hemoglobin 89 g/L (normal range: 120-160 g/L), hematocrit 28.6% (normal range: 40%-50%), mean corpuscular hemoglobin concentration 311 g/L (normal range: 320-360 g/L), serum ferritin 8.31 µg/L (normal range: 21.81-274.66 µg/L).

Abdominal computed tomography (CT) scanning showed a heterogeneous mass in the gastric antrum. Tumor tissue was slightly enhanced after injection of a

Abstract

Gastric adenomyoma (AM) is a rare benign tumor characterized by gland-like structures embedded within a smooth muscle stroma. We report a case of a 68-year-old man with gastric AM admitted to our hospital for melena. Endoscopic examination revealed a gastric mass of about 4 cm in diameter, located in the antrum. Histologic examination of the excised specimen showed irregularly arranged glands and interlacing smooth muscle bundles surrounding the glandular elements. Although gastric AM is rare, it should be considered in differential diagnosis of extramucosal gastric tumor.

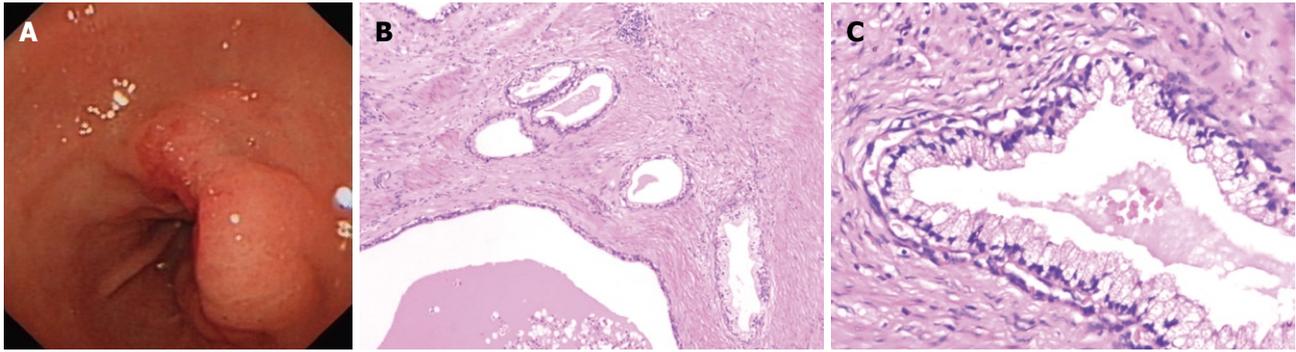

Figure 1 Gastric adenomyoma. A: Upper gastrointestinal (GI) endoscopy showing an irregular lesion with central ulcer in the gastric antrum; B: Microscopy showing several glands and cyst surrounded by smooth muscle (HE, $\times 50$); C: High-power view showing glands lined by columnar mucinous epithelium (HE, $\times 200$).

contrast medium. Neither further invasion beyond the gastric wall, nor visible metastatic lesions in the liver or enlarged lymph nodes were observed.

Endoscopic examination revealed an ulcerated mass of about 4 cm in diameter, located on the lesser curvature and posterior wall of the gastric antrum, with the duodenum partly involved (Figure 1A). The esophagus and the remaining parts of stomach were normal. Histopathological examination of mass biopsies showed several dilated glands with mild atypia in an inflamed stroma and necrosis. A decision was made to proceed with surgery in order to relieve the symptoms. As frozen sections revealed the possibility of a gastric AM, a distal subtotal gastrectomy was performed. Postoperative recovery was uneventful.

Macroscopic examination revealed a 50 mm \times 43 mm \times 23 mm ulcerated mass with sharp margins and a greyish-white cut surface. It was solid and cystic with clear, mucinous fluid in the lumens. The cysts ranged up to 8 mm. Microscopic examination showed that the tumor was located mainly in submucosa and muscularis propria of the stomach, composed of glands and cysts surrounded by bundles of smooth muscle tissue (Figure 1B). Epithelial cells lining the glands and cysts were columnar and flattened mucinous cells (Figure 1C). Cellular stratification was minimal and nuclei were basally located with only slight atypia. Mitotic activity was absent. Complete sectioning of this mass failed to demonstrate exocrine or endocrine pancreatic structures. Accumulations of inflammatory mononuclear cells were noted near the glands.

DISCUSSION

AM of the gastrointestinal tract is rare, most frequently observed in the duodenum, gall bladder and stomach. Most cases of gastric AM occur in adults with no symptom or have nonspecific gastrointestinal symptoms. Scarcely clinical manifestations such as localized peritonitis have been reported^[6]. To the best of our knowledge, this is the first case of gastric AM presented with melena. We ascribe the hemorrhage to mucosal ulcer.

In spite of the availability of newer diagnostic techniques, including CT and endoscopic ultrasonography^[7], it is still difficult to diagnose gastric AM before operation.

Endoscopic examination cannot differentiate gastric AM from other extramucosal lesions, such as gastrointestinal stromal tumor, lipoma, neurilemmoma, hemangioma, gastrointestinal autonomic nerve tumor, carcinoid, lymphoma or even gastric carcinoma. In the majority of cases, endoscopic biopsies are superficial and fail to obtain representative tumor tissue. Therefore, frozen section is very helpful to establish the intraoperative diagnosis and to avoid unnecessary extensive operations. In the present case, two biopsies were not diagnostic, frozen section revealed the possibility of gastric AM.

Histologically, gastric AM should be differentiated from high-grade adenocarcinoma and gastritis cystica profunda. Gastric adenocarcinoma associated with gastric AM has been reported^[8]. The common features that favor an adenocarcinoma are epithelial atypia, mitotic figures, and fibrous stromal reaction. Gastritis cystica profunda (GCP) is characterized by elongation of gastric foveola with hyperplasia and cystic dilatation of gastric glands, extending into the gastric submucosal layer. The absence of smooth muscle bundles around the cysts helps to differentiate GCP from AM.

Based on the similarities of epithelial component of AM to pancreatic ducts, several authors consider gastric AM as a variant of ectopic pancreas without exocrine or endocrine components^[9,10]. Yamagiwa *et al*^[11] divided ectopic pancreas into type I (with all elements of normal pancreatic tissues), type II (with pancreatic tissues but no islets), and type III (with pancreatic ducts only). Gastric AM represents type III. However, Takeyama *et al*^[6] considered AM as a hamartoma based on the disordered proliferation of smooth muscle.

In summary, although gastric AM is rare, it should be always considered in the differential diagnosis of extramucosal gastric lesions. Despite the development of modern diagnostic techniques, its diagnosis remains challenging. If in doubt, frozen section can help to avoid unnecessary radical operation.

Abstract

We have read with interest the paper published in issue 2, volume 16 of *World Journal of Gastroenterology* 2010 by Nakamura *et al*, demonstrating that the antioxidant resveratrol (RVT) enhances hepatitis C virus (HCV) replication, consequently, they conclude that RVT is not a suitable antioxidant therapy for HCV chronic infection. The data raise some concern regarding the use of complementary and alternative medicine since the most frequent supplements taken by these patients are antioxidants or agents that may be beneficial for different chronic liver diseases. A recent study by Vidali *et al* on oxidative stress and steatosis in the progression of chronic hepatitis C concludes that oxidative stress and insulin resistance contribute to steatosis, thus accelerating the progression of fibrosis. We are particularly interested in investigating how the oxidative and nitrosative stress mechanisms are involved in the pathogenesis of different chronic liver diseases.

TO THE EDITOR

We read with interest the paper by Nakamura *et al*^[1] demonstrating that the antioxidant resveratrol (RVT) enhances the hepatitis C virus (HCV) replication, consequently, they conclude that RVT is not a suitable antioxidant therapy for HCV chronic infection. The data raise some concern regarding the use of complementary and alternative medicine since the most frequent supplements taken by these patients are antioxidants or agents that may be beneficial for different chronic liver diseases. A recent study by Vidali *et al*^[2] on oxidative stress and steatosis in the progression of chronic hepatitis C (CHC) concludes that oxidative stress and insulin resistance contribute to steatosis, thus accelerating the progression of fibrosis. They speculate that therapeutic regimens including anti-oxidant agents could be of clinical relevance in CHC patients infected with genotype non-3, according to their own results^[2]. There is evidence that antioxidant therapies may ameliorate the necro-inflammatory activity in CHC patients^[3].

We are particularly interested in investigating how the oxidative and nitrosative stress mechanisms are involved in the pathogenesis of different chronic liver diseases^[4]. Based on this rationale, we would like to support the hypothesis that antioxidant compounds might be proven beneficial for acute and chronic liver diseases. According to ours and other author experience, nitric oxide (NO)

has deleterious consequences in the presence of reactive oxygen species, since peroxynitrites are formed. NO participates in the pathophysiology of viral (chronic hepatitis B and CHC) and autoimmune (primary biliary cirrhosis and autoimmune hepatitis) liver diseases^[5,6], as well as in acute liver allograft rejection^[7]. Moreover, NO contributes to liver ischemia-reperfusion injury and inhibition of inducible nitric oxide synthase (iNOS) shows beneficial effects^[8]. Consistently, we found that N-acetyl-cysteine (NAC) modulates the expression of iNOS in human hepatocytes stimulated by proinflammatory cytokines^[9]. The effect occurs by blocking the activation of the iNOS promoter, and is associated with modulation of NF- κ B activity, a central transcription factor for induction of iNOS expression. The biological phenomenon might well be the basis of the therapeutic effects of NAC on chronic liver diseases different from those caused by acetaminophen intoxication.

Further insights into the hepatoprotective mechanisms of antioxidants might be learnt by analysing the glutathione precursor S-adenosyl-methionine (SAME) actions. Administration of SAME to patients with alcoholic liver cirrhosis showed beneficial effects^[10]. Its possible mechanisms of action include: (1) acting as a methyl donor compound and contributing to restoration of mitochondrial glutathione content, which is necessary to counterbalance the oxidant environment in cirrhotic liver, and (2) attenuating the hepatic production of NO, through the modulation of nitric oxide synthase-2. SAME exerts these effects by accelerating re-synthesis of inhibitor κ B alpha and blunting the activation of nuclear factor κ B, thereby reducing the transactivation of NO synthase-2 promoter^[11].

Taking all these data together, abundant evidence suggests that antioxidants can effectively attenuate the oxidative and nitrosative stress in liver injury, ultimately improving inflammation and fibrosis progression. It is worth testing these drugs in future clinical trials including CHC patients, mainly those who present negative predictive factors of sustained virological response to standard antiviral regimens. However, controversies raise from the results of the study by Nakamura *et al*^[1] promoting the possible need of investigations on the effects of different antioxidants on HCV replication before its use as a supplement in treatment of CHC patients.

Meetings

Events Calendar 2010

January 25-26
 Tamilnadu, India
 International Conference on Medical Negligence and Litigation in Medical Practice

January 25-29
 Waikoloa, HI, United States
 Selected Topics in Internal Medicine

January 26-27
 Dubai, United Arab Emirates
 2nd Middle East Gastroenterology Conference

January 28-30
 Hong Kong, China
 The 1st International Congress on Abdominal Obesity

February 11-13
 Fort Lauderdale, FL, United States
 21th Annual International Colorectal Disease Symposium

February 26-28
 Carolina, United States
 First Symposium of GI Oncology at The Caribbean

March 04-06
 Bethesda, MD, United States
 8th International Symposium on Targeted Anticancer Therapies

March 05-07
 Peshawar, Pakistan
 26th Pakistan Society of Gastroenterology & Endoscopy Meeting

March 09-12
 Brussels, Belgium
 30th International Symposium on Intensive Care and Emergency Medicine

March 12-14
 Bhubaneswar, India
 18th Annual Meeting of Indian National Association for Study of the Liver

March 23-26
 Cairo, Egypt
 14th Pan Arab Conference on Diabetes PACD14

March 25-28
 Beijing, China
 The 20th Conference of the Asian

Pacific Association for the Study of the Liver

March 27-28
 San Diego, California, United States
 25th Annual New Treatments in Chronic Liver Disease

April 07-09
 Dubai, United Arab Emirates
 The 6th Emirates Gastroenterology and Hepatology Conference, EGHC 2010

April 14-17
 Landover, Maryland, United States
 12th World Congress of Endoscopic Surgery

April 14-18
 Vienna, Austria
 The International Liver Congress™ 2010

April 28-May 01
 Dubrovnik, Croatia
 3rd Central European Congress of surgery and the 5th Croatian Congress of Surgery

May 01-05
 New Orleans, LA, United States
 Digestive Disease Week Annual Meeting

May 06-08
 Munich, Germany
 The Power of Programming: International Conference on Developmental Origins of Health and Disease

May 15-19
 Minneapolis, MN, United States
 American Society of Colon and Rectal Surgeons Annual Meeting

June 04-06
 Chicago, IL, United States
 American Society of Clinical Oncologists Annual Meeting

June 09-12
 Singapore, Singapore
 13th International Conference on Emergency Medicine

June 14
 Kosice, Slovakia
 Gastro-intestinal Models in the Research of Probiotics and Prebiotics-Scientific Symposium

June 16-19
 Hong Kong, China
 ILTS: International Liver Transplantation Society ILTS Annual International Congress

June 20-23
 Mannheim, Germany
 16th World Congress for Bronchoesophagology-WCBE

June 25-29
 Orlando, FL, United States
 70th ADA Diabetes Scientific Sessions

August 28-31
 Boston, Massachusetts, United States
 10th OESO World Congress on Diseases of the Oesophagus 2010

September 10-12
 Montreal, Canada
 International Liver Association's Fourth Annual Conference

September 11-12
 La Jolla, CA, United States
 New Advances in Inflammatory Bowel Disease

September 12-15
 Boston, MA, United States
 ICAAC: Interscience Conference on Antimicrobial Agents and Chemotherapy Annual Meeting

September 16-18
 Prague, Czech Republic
 Prague Hepatology Meeting 2010

September 23-26
 Prague, Czech Republic
 The 1st World Congress on Controversies in Gastroenterology & Liver Diseases

October 07-09
 Belgrade, Serbia
 The 7th Biannual International Symposium of Society of Coloproctology

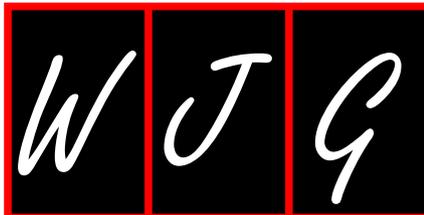

October 15-20
 San Antonio, TX, United States
 ACG 2010: American College of Gastroenterology Annual Scientific Meeting

October 23-27
 Barcelona, Spain
 18th United European Gastroenterology Week

October 29-November 02
 Boston, Massachusetts, United States
 The Liver Meeting® 2010--AASLD's 61st Annual Meeting

November 13-14
 San Francisco, CA, United States
 Case-Based Approach to the Management of Inflammatory Bowel Disease

December 02-04
 San Francisco, CA, United States
 The Medical Management of HIV/AIDS

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systematically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Instructions to authors

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 $\mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG,

WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China

E-mail: wjg@wjgnet.com

<http://www.wjgnet.com>

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekaAlert/AAAS (<http://www.eurekaalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

ACKNOWLEDGMENTS I Acknowledgments to reviewers of *World Journal of Gastroenterology*

APPENDIX I Meetings
I-IV Instructions to authors

AIM AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

FLYLEAF I-VII Editorial Board

EDITORS FOR THIS ISSUE

Responsible Assistant Editor: *Xiao-Fang Liu*
Responsible Electronic Editor: *Wen-Hua Ma*
Proofing Editor-in-Chief: *Lian-Sheng Ma*

Responsible Science Editor: *Lin Tian*
Proofing Editorial Office Director: *Jian-Xia Cheng*

Abstract

Celiac disease (CD) is a permanent auto-immune enteropathy, triggered in genetically predisposed individuals by the ingestion of dietary gluten. Gluten is the alcohol-soluble protein component of the cereals wheat, rye and barley. CD is a multifactorial condition, originating from the interplay of genetic and environmental factors. The necessary environmental trigger is gluten, while the genetic predisposition has been identified in the major histocompatibility complex region on chromosome 6p21, with over 90% of CD patients expressing HLA DQ2 and the remaining celiac patients express DQ8. The fact that only about 4% of DQ2/8-positive individuals exposed to gluten develop CD, has led to the recognition that other genetic and environmental factors are also necessary. In the last few years, several epidemiological studies have suggested that the timing of the introduction of gluten, as well as the pattern of breastfeeding, may play an important role in the

INTRODUCTION

Celiac disease (CD) is a permanent auto-immune enteropathy, triggered in genetically predisposed individuals by the ingestion of dietary gluten. Gluten is the alcohol-soluble protein component of the cereals wheat, rye and barley. It is composed of 2 major protein fractions: glutenin and gliadin; most of the toxic activity exerted by gluten in CD is due to gliadin.

CD is an increasingly recognized condition; its true prevalence is, however, difficult to ascertain, because many (arguably the majority) of affected people are asymptomatic or show mild symptoms and signs^[1,2].

CD is a multifactorial condition, originating from the interplay of genetic and environmental factors. The necessary environmental trigger is gluten, while the genetic predisposition has been identified in the major his-

tocompatibility complex region on chromosome 6p21, with over 90% of CD patients expressing HLA DQ2 (DQA1*05/DQB1*02) or in the trans position in HLA-DR5/DR-7 heterozygous patients. The remaining celiac patients express DQ8 (DQA1*0301/DQB1*0302). While these haplotypes confer the highest genetic risk for CD, the fact that only about 4% of DQ2/8 positive individuals exposed to gluten develop CD, has led to the recognition that other genetic factors are also necessary^[3]. In the last few years, significant advances have been made leading to the identification of 6 regions that harbor genes controlling immune responses in relevant biological pathways. So far, 7 additional candidate genes have been uncovered that are considered as plausible contributors to the development of CD^[4,5].

In the last few years, several epidemiological studies have suggested that the timing of the introduction of gluten into the diet, as well as the pattern of breastfeeding, may play an important role in the subsequent development of CD.

THE ROLE OF GLUTEN-WHEN

The attractive hypothesis that the age at first introduction of gluten in predisposed individuals could influence the onset of CD relies upon the fact that at some point in time during development, humans appear to lose their ability to develop oral tolerance to newly introduced antigens^[6]. On the other hand, early introduction of solid foods (i.e. before the intestinal immune system reaches a certain level of maturation) may lead to development of intolerance^[7].

In reality, the results of most older studies had suggested that the age at first introduction of gluten would not affect the development of CD, while it would modify the onset of symptoms^[8].

A decrease of the incidence of biopsy-proven CD following a change in weaning practices was first reported at the end of 1970s among the pediatric population of West Somerset, England^[9]. The authors noticed that the incidence of CD declined from 1:1228 to 1:4168 following the recommendations to avoid both the addition of cereals to bottle feeds and the introduction of gluten before 4 mo of age. The cohort of children considered in this study was quite small and it was a retrospective analysis; additionally, the overall incidence of CD reported appears markedly low compared to the present knowledge of the epidemiology of CD. In spite of these limitations, that work gave the first support to the role of age at first exposure to gluten in the development of CD.

Much stronger epidemiological evidence about the role of timing of solid introduction on the development of CD came from a recent 10-year observational study that investigated the age at first introduction (before 3 mo of age, between 3 and 7 mo and at 7 mo or later) of gluten-containing cereals in a group of 1560 children at risk of CD or type 1 diabetes (positivity to

HLA-DR3, -DR4 or a first-degree relative with type 1 diabetes) in relation to the subsequent risk of developing CD autoimmunity (CDA)^[10]. CDA was defined as positive tissue transglutaminase antibody (tTG Ab) on 2 or more consecutive visits or a positive tTG Ab and a small bowel biopsy consistent with CD. The results, generated as part of a larger effort within the so-called DAISY project, showed that, out of 51 children who developed CDA, those exposed to gluten in the first 3 mo of age had a 5-fold increased risk of CDA compared to those exposed at 4 to 6 mo [hazard ratio (HR), 5.17; 95% confidence interval (CI): 1.44-18.57]; and those who received gluten for the first time at 7 mo of age or after showed a slightly increased hazard ratio compared with those exposed at 4-6 mo (HR, 1.87; 95% CI: 0.97-3.60). These results seem to confirm the existence of a “window” period, during which the first exposure to gluten should occur in order to minimize the risk of subsequent development of CD. Perhaps the biggest limitation of the DAISY study is the lack of data on the amount of gluten ingested. Although the authors speculated that the children that received gluten after 7 mo consumed a higher amount of gluten on its introduction, this remains speculative.

THE ROLE OF GLUTEN-HOW MUCH

The epidemic of CD among Swedish children observed in the mid 80s suggests that the amount of gluten ingested during weaning can play a pivotal role in the development of CD. After 1982, Sweden experienced a quite unique epidemic of CD in children under 2 years of age, with the annual incidence increasing 4-fold to 200-240 cases/100 000 inhabitants per year, followed from 1995 by a sharp decline to the previous level of 50-60 cases^[11,12]. Such a trend was not observed in nearby countries (i.e. Denmark and England), where, in contrast, a decline in the incidence of CD was noticed in the same period. This epidemic pattern was later related to new dietetic guidelines (later changed for this reason) that resulted in gluten being introduced to infants after they had been weaned from the breast, and in addition (due to concomitant, unrelated reasons) larger amounts of gluten were also given at that time.

To make the story even more complex, came the observation from analysis of the data of the Swedish CD epidemic, that the overall prevalence of CD diagnosed by serological screening (EMA) was not different in the group of children born in 1996-1997 compared with those born in 1992-1993^[13]. This finding indicated that the amount of gluten introduced during weaning might affect the development of symptomatic CD, but does not protect the children from being affected by sub-clinical or silent forms of the disease.

Finally, follow-up studies of that same cohort of children born during the epidemic^[14] showed that the increased risk of developing CD carries on with time, as the prevalence of this condition in 12-year-old children

(thus born during the epidemic) has been reported to be as high as 3%^[14].

The regional differences in the epidemiology of CD in India also give support to the hypothesis that the amount of gluten plays an important role in the onset of CD. CD is reported frequently in high wheat-consuming states in Northern India and quite rarely in the Southern States, where rice is the staple food^[15].

THE ROLE OF BREASTFEEDING

The protective effect of breastfeeding on the development of food allergy has been long suspected. Indeed, the majority of the studies on the specific protective effect of breastfeeding on the development of CD, although having very different methodologies and population selection, found a negative correlation between the duration of breastfeeding and the development of CD^[16-18]. A rigorous meta-analysis reviewed all the observational epidemiological studies dealing with the effect of breastfeeding on development of CD and found that children being breastfed at the time of gluten introduction had a 52% reduction in risk of developing CD, compared to their peers who were not breastfed at the time of gluten introduction [pooled odds ratio (OR), 0.48; 95% CI: 0.40-0.59]^[19].

The same author proceeded to estimate how many cases of CD could be prevented in the UK by assuming higher rates of breastfeeding, to conclude that if all babies were breastfed at the time of gluten introduction, this would result in the prevention of more than 2500 cases of CD per year^[20]!

The observation of the Swedish experience also gave some clues about the protective role of breastfeeding on CD. The Swedish children that were breastfed at the first exposure to gluten, even with high amounts, showed a lower risk of developing CD than those who were formula fed (OR, 0.59; 95% CI: 0.42-0.83), and the risk was reduced further if they continued to be breastfed afterwards (OR, 0.36; 95% CI: 0.26-0.51)^[21,22].

Surprisingly, the data generated in the context of the DAISY project previously mentioned^[8] did not provide evidence on the protective role of prolonged breastfeeding. The authors themselves pointed out this discrepancy, ascribing it to the different methodology - the DAISY study was prospective and focused on high risk children, whereas all the previous studies were retrospective and included the general pediatric population.

In spite of all the evidence outlined, some crucial issues remain unanswered: (1) Does breastfeeding at the first exposure to gluten offer a permanent protection against CD or does it only delay its appearance? (2) Are those children breastfed during the introduction of gluten more likely to develop extraintestinal (“atypical”) CD? A series of 162 celiac children enrolled at the University of Chicago showed that children breastfed at the time of gluten introduction were just as likely to develop intestinal as extra-intestinal symptoms, whereas children

who were not breastfed when weaned with gluten had a much higher chance of showing intestinal symptoms^[6]; and (3) What is the mechanism underlying the protective role of breastfeeding towards the development of CD? Presently one can only speculate on 4 possible ways: (a) breast milk contains substances with immunomodulatory activity on the intestinal mucosa, within the idiotypic network; (b) children that are breastfed at gluten introduction during weaning receive lower amounts of gluten, even on a pro/kg body weight basis; (c) breastfeeding prevents gastrointestinal infections, a known contributing factor in the pathogenesis of CD; or (d) the absence of possible multiple contemporary associations with other solids and nutrients.

ESPGHAN RECOMMENDATIONS

On the basis of the above described epidemiological data, the European Society for Paediatric Gastroenterology, Hepatology and Nutrition (ESPGHAN) Committee recommended avoidance of both early (< 4 mo) and late (> 7 mo) introduction of gluten and introduction of small amounts of gluten gradually while the child is still breastfed^[23]. This temporary window allows the possibility of modulating the mucosal immune response, with progressively decreasing breastfeeding and maturation of the gastro-intestinal system^[22].

CONCLUSION

There remain several open questions about the role of early feeding practices on the development of CD, including the role of additional genetic factors, the type of gluten introduced, and, certainly not least, the role played by the microbiota. It appears that celiac children, even in remission, have a composition of microflora that differs from healthy controls^[24]. It is likely that CD may be the end result of an intricate interplay by all of these factors. The challenge is for us to tease out their roles and understand the specific mechanisms that ultimately lead to CD, in order to achieve the ambitious goal of its prevention.

Abstract

Insulin resistance is one of the pathological features in patients with hepatitis C virus (HCV) infection. Generally, persistence of insulin resistance leads to an increase in the risk of life-threatening complications such as cardiovascular diseases. However, these complications are not major causes of death in patients with HCV-associated insulin resistance. Indeed, insulin resistance plays a crucial role in the development of various complications and events associated with HCV infection. Mounting evidence indicates that HCV-associated insulin resistance may cause (1) hepatic steatosis; (2) resistance to anti-viral treatment; (3) hepatic fibrosis and esophageal varices; (4) hepatocarcinogenesis and proliferation of hepatocellular carcinoma; and (5) extrahepatic manifestations. Thus, HCV-associated insulin resistance is a therapeutic target at any stage of HCV infection. Although the risk of insulin resistance in HCV-infected patients has been

documented, therapeutic guidelines for preventing the distinctive complications of HCV-associated insulin resistance have not yet been established. In addition, mechanisms for the development of HCV-associated insulin resistance differ from lifestyle-associated insulin resistance. In order to ameliorate HCV-associated insulin resistance and its complications, the efficacy of the following interventions is discussed: a late evening snack, coffee consumption, dietary iron restriction, phlebotomy, and zinc supplements. Little is known regarding the effect of anti-diabetic agents on HCV infection, however, a possible association between use of exogenous insulin or a sulfonylurea agent and the development of HCC has recently been reported. On the other hand, insulin-sensitizing agents are reported to improve sustained virologic response rates. In this review, we summarize distinctive complications of, and therapeutic strategies for, HCV-associated insulin resistance. Furthermore, we discuss supplementation with branched-chain amino acids as a unique insulin-sensitizing strategy for patients with HCV-associated insulin resistance.

INTRODUCTION

Insulin resistance is frequently seen in patients with

hepatitis C virus (HCV) infection^[1,2]. Although in the general population, lack of exercise and overeating are major causes of insulin resistance, in patients with HCV infection, hepatic inflammation, activated inflammatory cytokines, and HCV-induced impairments of insulin and lipid signaling molecules are also important factors for the development of insulin resistance^[3-14]. Therefore, the prevalence of insulin resistance is higher in patients with HCV infection compared to that in the general population and patients with other hepatobiliary disorders^[6,15].

Generally, insulin resistance results in the development of type 2 diabetes mellitus and increases the risk of life-threatening complications such as cardiovascular diseases, renal failure, and infections. However, these complications are not major causes of death in cirrhotic patients with insulin resistance^[16]. On the other hand, the development of intrahepatic complications, including hepatocellular carcinoma (HCC), is known to be associated with insulin resistance^[17-21]. Insulin resistance is also reported to be involved in the development of extrahepatic manifestations of HCV infection including gastric cancer^[22-24].

Reduction of fasting blood glucose and hemoglobin A1c (HbA1c) is a well-established therapeutic strategy for prevention of complications in diabetic patients^[25,26]. However, in patients with chronic liver diseases, fasting blood glucose and HbA1c are not always available for evaluation of glucose metabolism because of decreased hepatic glycogen content^[27] and increased turnover of hemoglobin^[28]. Furthermore, an association between the use of exogenous insulin or sulfonylurea agents and the development of HCC has recently been reported^[29,30]. Although therapeutic guidelines for inhibiting the distinctive complications of HCV-associated insulin resistance are not yet available, amelioration of insulin resistance is considered to inhibit complications and improve prognosis. Here, we summarize treatments that could reduce HCV-associated insulin resistance.

In this review, we summarize distinctive complications of, and therapeutic strategies for, HCV-associated insulin resistance. In addition, we discuss the merits of branched-chain amino acid (BCAA) supplementation as a unique insulin-sensitizing strategy for patients with HCV-associated insulin resistance.

DISTINCTIVE COMPLICATIONS OF HCV-ASSOCIATED INSULIN RESISTANCE

Complications of HCV-associated insulin resistance are different from those of lifestyle-associated insulin resistance^[16]. Cardiovascular diseases are major causes of death in patients with lifestyle-associated insulin resistance^[31]. However, these complications are not major causes of death in patients with HCV-associated insulin resistance^[16]. In contrast, HCV-associated insulin resistance is involved in the development of various complications associated with HCV infection. Here, we summarize events associated with insulin resistance that are distinctive complications of HCV-associated insulin resistance (Figure 1).

Hepatic steatosis

Hepatic steatosis is commonly observed^[32,33] and is an independent risk factor for disease progression in patients with HCV infection^[34]. Various mechanisms are operative in the development of hepatic steatosis. HCV core protein induces production of reactive oxygen species and lipid peroxidation^[35]. HCV core protein also regulates secretion of very low-density lipoprotein, triglycerides, and apolipoprotein B through regulation of fatty acid synthase, microsomal triglyceride transport protein, peroxisome proliferator-activated receptor γ (PPAR γ), and sterol regulatory element binding protein-1c^[9,36-38]. Thus, HCV itself is directly involved in the development of hepatic steatosis. In addition, insulin is an anabolic hormone and promotes hepatic lipogenesis through activation of hydroxymethylglutaryl-CoA reductase and acetyl-CoA carboxylase^[39]. In addition, insulin inhibits lipolysis through regulation of phosphodiesterase type 3B^[19]. In HCV core gene transgenic mice, the development of insulin resistance precedes the development of hepatic steatosis, suggesting that insulin resistance may induce hepatic steatosis^[8,40]. However, hepatic steatosis could also cause insulin resistance^[41,42], and therefore, the initial step in HCV-related metabolic disorders remains unclear in patients with HCV infection.

Resistance to anti-viral treatment

Insulin resistance is associated with a poor response to anti-viral treatment in patients with HCV genotype 1, 2, and 3 infections^[10,43-46]. Although the reason for an association between insulin resistance and resistance to anti-viral treatment is largely unknown, the following are possibilities. Insulin resistance is known to increase hepatic lipid synthesis^[47]. Since the lipid droplet is an important organelle for HCV replication^[48], accumulation of hepatic lipid droplets may increase HCV replication and result in poor responses to anti-viral treatment, even in patients with HCV genotype 2 and 3^[45].

Alternatively, HCV core protein is reported to up-regulate suppressor of cytokine signaling (SOCS) 3^[6,49-52], which acts as an adaptor to facilitate the ubiquitination of signaling proteins, leading to subsequent proteasomal degradation of SOCS3^[19]. HCV core protein-induced SOCS3 upregulation promotes proteasomal degradation of insulin receptor substrate (IRS) 1 and IRS2, resulting in the development of insulin resistance in patients with HCV infection^[6,19,44]. Simultaneously, SOCS3 is also known to inhibit interferon-alpha-induced expression of the anti-viral proteins 2',5'-oligoadenylate synthetase and myxovirus resistance A through inactivation of Janus kinase, a signal transducer and activator of the transcription pathway^[49]. Thus, SOCS3 seems to be a key molecule for a cross-talk between insulin resistance and resistance in patients with HCV infection. In fact, hepatic expression of SOCS3 has predictive value for the outcome of anti-viral therapy in patients with HCV infection^[53,54].

Hepatic fibrosis and esophageal varices

Insulin resistance is closely associated with progression

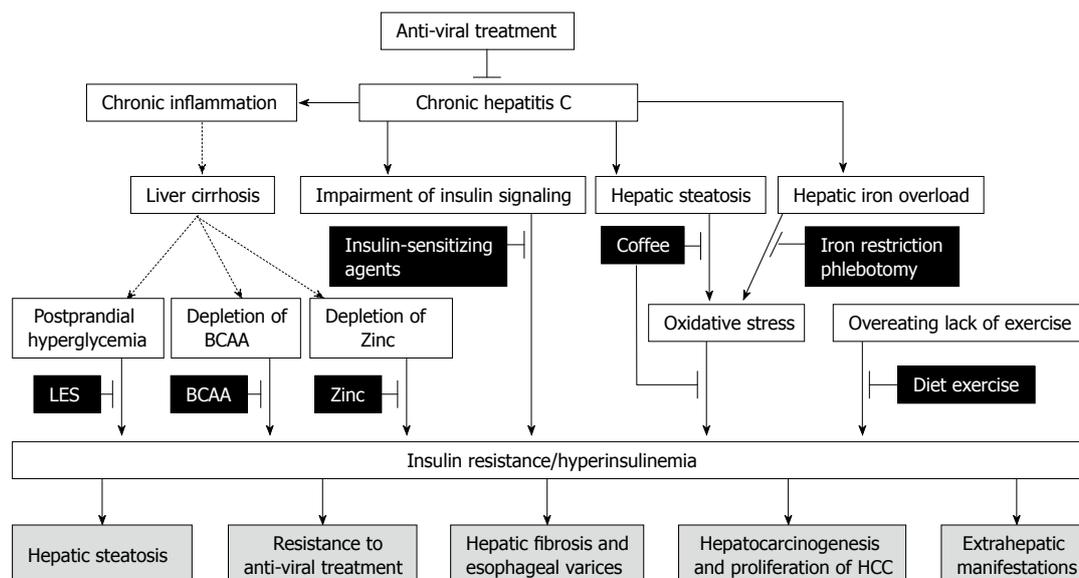

Figure 1 Pathogenic mechanisms and therapeutic strategies for hepatitis C virus (HCV)-associated insulin resistance. Black squares indicate therapeutic strategies for HCV-associated insulin resistance. Proper diet, exercise, iron restriction, phlebotomy, and coffee intake are recommended to any stage of liver disease. In cirrhotic patients, a late evening snack (LES), branched-chain amino acid (BCAA) supplementation, and a zinc supplement are also recommended. Insulin-sensitizing agents can be used in patients with chronic hepatitis C, however, the agents are not always recommended for patients with liver cirrhosis because of severe adverse effects.

of hepatic fibrosis in patients with HCV infection^[6,11,55]. The hepatocyte is known to degrade circulating insulin, and, therefore, hepatic fibrosis may reduce insulin clearance, resulting in increased serum insulin levels regardless of the presence of insulin resistance^[56]. However, insulin resistance is seen in early stages of chronic hepatitis C^[6]. Furthermore, even in patients that have received a liver transplantation for HCV-related liver cirrhosis, insulin resistance is a risk factor for rapid progression of hepatic fibrosis^[57]. These findings suggest that insulin resistance promotes hepatic fibrosis. Insulin resistance may directly affect hepatic stellate cells and increase connective tissue growth factor (CTGF), which causes production of extracellular matrix^[58]. Alternatively, insulin resistance-induced hepatic lipid accumulation may increase oxidative stress, resulting in progression of hepatic fibrosis^[32].

Insulin resistance is also a risk factor for esophageal varices in cirrhotic patients with HCV infection^[59]. As the hepatic fibrosis is correlated with the development of esophageal varices, insulin resistance may be associated with the development of esophageal varices through progression of hepatic fibrosis^[60]. In addition, insulin modulates the endothelial synthesis of nitric oxide and endothelin^[61], regulators of sinusoidal blood flow^[62]. Thus, insulin-induced hepatic fibrosis and vasoconstriction may be possible mechanisms for the development of esophageal varices.

Hepatocarcinogenesis and proliferation of HCC

Liver cirrhosis, aging, and being a male are well-known risk factors for the development of HCC in patients with HCV infection^[18,63]. In addition, insulin resistance is now recognized as an independent risk factor for the devel-

opment of HCC worldwide^[18,63]. Diabetes is reported as the only independent risk factor for HCC in patients with chronic hepatitis C^[21]. Moreover, development of diabetes-related HCC is reported to be independent of viral hepatitis and alcoholism^[64]. These findings suggest that insulin resistance has direct effects on hepatocarcinogenesis. Although precise mechanisms for this effect remain unclear, the following explanations may be put forward. Insulin resistance causes lipid accumulation^[19]. Visceral adiposity results in changes in serum adipocytokine levels, including reduction of adiponectin, which suppresses effects for hepatocarcinogenesis^[65]. Hepatic lipid accumulation also increases oxidative stress, which may be responsible for the development of HCC^[18,63]. Besides these possibilities, insulin has a mitogenic effect^[19,30], suggesting that insulin may be directly linked to hepatocarcinogenesis^[19].

Insulin resistance may be associated not only with hepatocarcinogenesis, but also with proliferation of HCC. We have examined the significance of insulin resistance on the prognosis in patients with HCV-associated HCC and found that insulin resistance is an independent risk factor for poor prognosis^[20]. As no significant difference was seen in disease-free survival between patients with and without insulin resistance, these findings indicate that insulin resistance accelerates the proliferation of HCC^[20]. In good accordance with our results, Saito *et al.*^[66] reported that reduction of serum insulin levels by continuous infusion of octreotide significantly suppressed proliferation of HCC. Although the mechanisms for insulin-induced proliferation of HCC remain obscure, insulin exerts growth-promoting activity through activation of a mitogen-activated protein kinase pathway^[19]. In addition, overexpression of transducing molecules for insulin signaling, IRS1^[67] and IRS2^[68],

and downregulation of suppressing molecules for insulin signaling, phosphatase and tensin homologue^[69], and SH2 domain-containing inositol phosphatase-2^[20] occur in HCC. Thus, HCC may be sensitive to insulin stimulation.

Extrahepatic manifestations

HCV causes extrahepatic manifestations including mixed cryoglobulinemia, Sjögren's syndrome, and non-Hodgkin lymphoma, oral lichen planus, oral squamous cell carcinoma, and malignancies other than HCC^[22-24,70-73]. In patients with extrahepatic manifestations of HCV, fasting insulin levels and homeostasis model assessment for insulin resistance are significantly higher than for patients without extrahepatic manifestations^[22]. Among various extrahepatic manifestations, insulin resistance is associated with oral lichen planus^[23], oral squamous cell carcinoma^[24], and multiple primary cancers including gastric cancer^[24]. Although reasons for this association remain unclear, a high prevalence of precancerous lesions and cancers are seen in patients with type 2 diabetes mellitus^[74,75], suggesting that insulin resistance or hyperinsulinemia may enhance carcinogenic activities.

DISTINCTIVE THERAPEUTIC STRATEGY FOR HCV-ASSOCIATED INSULIN RESISTANCE

Despite awareness of the increased risk of insulin resistance, therapeutic guidelines to inhibit distinctive complications of HCV-associated insulin resistance have not yet been established. HCV itself has a significant impact on the development of insulin resistance, and eradication of HCV improves insulin resistance^[44,46,76]. Thus, anti-viral therapy is a fundamental therapeutic strategy for patients with HCV infection. In addition, amelioration of insulin resistance is considered to inhibit complications and improve prognosis. Here, we summarize treatments which could improve HCV-associated insulin resistance as therapeutic strategies (Figure 1).

Late evening snack

Proper diet and exercise are fundamental for patients with lifestyle-associated insulin resistance as well as patients with HCV-associated insulin resistance^[77-80]. As a nutritional treatment for liver cirrhosis, divided energy intake (4 to 6 meals/d) has been recommended^[77,79]. As postprandial hyperglycemia is characteristic of HCV-associated insulin resistance^[77-80], a decrease in energy intake per meal reduces postprandial hyperglycemia and hyperinsulinemia. In particular, a late evening snack is reported not only to improve glucose intolerance^[81-84], but also to suppress hepatocarcinogenesis in cirrhotic patients^[85].

Coffee consumption

Coffee consumption reduces the risk of elevated serum alanine aminotransferase activity^[86], hepatic fibrosis^[87], and disease progression in chronic hepatitis C^[88]. Coffee

consumption also reduces the risk of HCC independent of HCC etiology^[89]. Caffeine is metabolized by hepatic cytochrome P450 1A2 into 3 metabolites, the dimethylxanthines paraxanthine, theobromine, and theophylline. Of these metabolites, theophylline inhibits transforming growth factor- β -stimulated CTGF expression through PPAR γ and Smad 2/3-dependent pathways. Since CTGF and transforming growth factor- β are important factors associated with progression of hepatic fibrosis and hepatocarcinogenesis, a metabolite of caffeine, theophylline, may have an inhibitory effect on the development of complications associated with HCV infection. In addition, coffee has significant effects on glucose metabolism^[90]. In an animal experiment, the insulin-sensitizing effects of coffee have been demonstrated^[91]. Similarly, in a human study, coffee consumption reduced fasting glucose and insulin levels^[90,92]. Although the mechanisms for the coffee-induced insulin-sensitizing effect remain unclear, some possibilities exist. Chlorogenic acids, a constituent of coffee, inhibits hepatic glucose-6-phosphate translocation^[90,93], limits glucose absorption from the gut by inhibiting Na⁺-dependent transport^[94], and increases the secretion of glucose regulating hormone, glucagon-like peptide (GLP)-1, from the gut^[90,95,96]. These findings suggest that a constituent of coffee, chlorogenic acid, directly ameliorates HCV-associated insulin resistance. Furthermore, coffee modulates lipid metabolism^[97,98] and lowers body weight^[90], indicating that coffee may suppress the lipid-induced increase in oxidative stress and ameliorates HCV-associated insulin resistance.

Phlebotomy

Hepatic iron overload produces oxidative stress and is a factor responsible for the development of HCV-associated insulin resistance^[4,99-101]. Although the pathogenesis of hepatic iron overload remains unclear, recent studies showed that iron-regulating molecules are modulated by HCV infection. Hepcidin is a negative regulator of duodenal iron absorption and macrophage iron release^[100] and decreased hepatic expression of hepcidin is seen in both HCV polyprotein transgenic mice^[102] and patients with HCV infection^[103-105]. In addition, upregulation of hepatic expression of transferrin receptor 2, a mediator of iron uptake, is responsible for hepatic iron overload^[106].

In order to reduce hepatic iron deposition, dietary iron restriction and phlebotomy are effective. Dietary iron restriction (less than 7 mg/d) decreases serum alanine aminotransferase levels in patients with HCV infection^[107]. Phlebotomy reduces oxidative stress as well as insulin resistance in patients with HCV infection^[101,108,109]. A long-term combination treatment with phlebotomy and dietary iron restriction reduces the risk of development of HCC in patients with HCV infection^[110].

Supplementation of zinc

Zinc plays a crucial role in the metabolism of protein, carbohydrate, lipid, nucleic acid, and ammonia^[111-113]. In fact, zinc supplementation improves glucose disposal in patients

with cirrhosis^[114]. Zinc also inhibits hepatic inflammation^[115] and hepatic fibrosis^[116]. More recently, zinc supplementation was shown to lower the cumulative incidence of HCC in patients with HCV infection^[117]. It is unclear whether these inhibitory effects of zinc on progression of liver disease are mediated by amelioration of insulin resistance. However, zinc participates in the synthesis, storage and secretion of insulin^[118] and regulates the binding ability of insulin to bind to its receptor^[113]. As the serum zinc level is decreased in patients with HCV infection^[115,117], supplementation of zinc could be a therapeutic option.

Anti-diabetic agents

Exogenous insulin and sulfonylurea agents: Anti-diabetic agents are effective for decreasing plasma glucose and HbA1c levels, leading to prevention of diabetes mellitus-associated complications including cardiovascular diseases^[119,120]. However, it has never been determined whether anti-diabetic agents prevent complications or improve prognosis in patients with HCV infection. Use of exogenous insulin or sulfonylurea agents may worsen hyperinsulinemia. In fact, we, along with others, recently reported an association between exogenous insulin or sulphonylurea treatment and the development of HCC in patients with HCV infection^[29,30,121]. Use of exogenous insulin is also reported to be associated with the development of colon cancer^[122] and other malignancies^[123]. Although a causal relationship between exogenous insulin and the development of HCC remains controversial^[124], the reduction of serum insulin levels is a first line therapeutic strategy for insulin resistance^[125-128].

Insulin-sensitizing agents: Insulin resistance is associated with a poor response to anti-viral treatment in patients with HCV infection^[10,43-46]. Amelioration of insulin resistance may improve the response to anti-viral treatment. However, the impact of insulin-sensitizing agents, biguanides and thiazolidinediones, on sustained virologic response (SVR) rates has not yet been established. Recently, metformin, a biguanide agent, has been reported to ameliorate HCV-associated insulin resistance, and increase the SVR rate in HCV genotype 1 infected patients with normalization of homeostasis model assessment for insulin resistance at week 24 of therapy^[129]. Pioglitazone, a thiazolidinedione agent, has also been reported to ameliorate insulin resistance and increase SVR rates in patients with HCV genotype 4 infection^[130]. Although the insulin-sensitizing mechanisms of metformin and pioglitazone are different, both agents are known to upregulate IRS^[131,132], which is the molecule responsible for HCV-associated insulin resistance^[3,6,50], and to improve HCV-associated insulin resistance. Because both agents have severe adverse effects, neither is recommended for patients with liver cirrhosis. Biguanides predispose cirrhotic patients to lactic acidosis^[133]. Thiazolidinediones cause overproduction of hydrogen peroxide leading to severe hepatotoxicity^[134]. Thus, further validation for safety is required.

Dipeptidyl peptidase IV (DPPIV) inhibitor is a new

therapeutic agent^[135] and its clinical efficacy in type 2 diabetes has been shown^[136]. Although no study has examined the effect of DPPIV inhibitor on HCV-associated insulin resistance, we found that activation of DPPIV is a factor responsible for HCV-associated insulin resistance^[27]. Thus, a DPPIV inhibitor may be suited for ameliorating HCV-associated insulin resistance.

BCAA supplementation, a possible insulin-sensitizing agent

BCAA are constituents of proteins and are required for protein synthesis^[19,78,137,138]. In addition, BCAA are reported to modulate glucose metabolism. Leucine and isoleucine induce glucose transporter 1 and 4 translocation to the plasma membrane of muscle cells and improve glucose metabolism in a carbon tetrachloride-induced cirrhotic rat model^[139]. In addition, leucine enhances the insulin-induced activation of the Akt/mammalian target of the rapamycin pathway in adipocytes of db/db mice^[140]. Moreover, isoleucine increases hepatic phosphatidylinositol 3-kinase activity and improves insulin resistance in Zucker fa/fa rats, a model of severe insulin resistance^[141]. Recently, knockout of the mitochondrial BCAA aminotransferase gene in mice, in which results in elevated plasma BCAA levels, was found to ameliorate insulin resistance^[142]. Thus, BCAA improve insulin signaling in various animal models *via* several pathways. In good agreement with these results in animals, in human studies, we have recently shown that BCAA-enriched supplementation reduces insulin resistance in patients with HCV infection^[143,144]. In a multicenter, randomized, controlled trial, BCAA supplementation led to a reduction in the risk of HCC in cirrhotic patients^[145]. This suppressive effect on hepatocarcinogenesis was more evident in obese patients with HCV infection^[145]. Both obesity and HCV induce the development of insulin resistance. Thus, BCAA may improve insulin resistance and subsequently inhibit insulin resistance-induced hepatocarcinogenesis^[19,145].

CONCLUSION

In this review, we summarize the distinctive complications of, and therapeutic strategies for, HCV-associated insulin resistance. Although cardiovascular diseases, renal failure, and infections are well-known complications of lifestyle-associated insulin resistance, these complications are not major causes of death in cirrhotic patients with insulin resistance. HCV-associated insulin resistance rather causes (1) hepatic steatosis, (2) resistance to anti-viral treatment, (3) hepatic fibrosis and esophageal varices, (4) hepatocarcinogenesis and proliferation of HCC, and (5) extrahepatic manifestations. These complications are life-threatening, and therapeutic strategies for HCV-associated insulin resistance have to be considered on the basis of its pathogenic mechanisms.

Pathogenic mechanisms for HCV-associated insulin resistance differ from those for lifestyle-associated insulin resistance. Postprandial hyperglycemia, lipid-induced oxi-

ductive stress, hepatic iron overload, and depletion of zinc are responsible for the development of HCV-associated insulin resistance. Therefore, a late evening snack, coffee consumption, dietary iron restriction, phlebotomy, and supplementation of zinc are recommended therapeutic strategies. No clinical guidelines for the use of anti-diabetic agents are available for patients with HCV-associated insulin resistance. However, use of exogenous insulin or sulphonylurea may increase the risk for HCC. On the other hand, insulin-sensitizing agents may improve the SVR rate of anti-viral treatment. In addition, BCAA supplementation has an insulin-sensitizing effect as well as a suppressive effect on hepatocarcinogenesis. Thus, in order to ameliorate HCV-associated insulin resistance, various therapeutic approaches are required.

Abstract

AIM: To understand how interactions between hepatitis C virus (HCV) and the host's immune system might lead to viral persistence or effective elimination of HCV.

METHODS: Nucleotides 3519-3935 of the non-structural 3 (NS3) region were amplified by using reverse transcription polymerase chain reaction (PCR). PCR products of the HCV NS3 regions were integrated into a PCR[®] T7TOPO[®] TA vector and then sequenced in both directions using an automated DNA sequencer. Relative major histocompatibility complex binding levels of wild-type and variant peptides were performed by fluorescence polarization-based peptide competition assays. Peptides with wild type and variant sequences of NS3 were synthesized locally using F-moc chemistry

and purified by high-performance liquid chromatography. Specific cytotoxic T lymphocytes (CTLs) clones toward HCV NS3 wild-type peptides were generated through limiting dilution cloning. The CTL clones specifically recognizing HCV NS3 wild-type peptides were tested by tetramer staining and flow cytometry. Cytolytic activity of CTL clones was measured using target cells labeled with the fluorescence enhancing ligand, DELFIA EutDA.

RESULTS: The pattern of natural variants within three human leukocyte antigen (HLA)-A2-restricted NS3 epitopes has been examined in one patient with chronic HCV infection at 12, 28 and 63 mo post-infection. Results obtained may provide convincing evidence of immune selection pressure for all epitopes investigated. Statistical analysis of the extensive sequence variation found within these NS3 epitopes favors a Darwinian selection model of variant viruses. Mutations within the epitopes coincided with the decline of CTL responses, and peptide-binding studies suggested a significant impact of the mutation on T cell recognition rather than peptide presentation by HLA molecules. While most variants were either not recognized or elicited low responses, such could antagonize CTL responses to target cells pulsed with wild-type peptides.

CONCLUSION: Cross-recognition of CTL epitopes from wild-type and naturally-occurring HCV variants may lead to impaired immune responses and ultimately contribute to viral persistence.

INTRODUCTION

Hepatitis C virus (HCV) is one of the leading causes of chronic liver disease^[1] arising from persistent infection that lasts decades despite evidence of humoral and cellular immune responses^[2]. Chronic infection occurs in up to 85% of patients^[3]. The mechanisms responsible for high rates of HCV persistence are unknown, but are thought to involve a complex interplay between the host immune system and viral diversity^[4], which may lead to viral escape through the mutation of epitopes recognized as targets of the immune response^[4,5]. The combination of a very high rate of HCV replication, estimated at 10^{12} virions per day^[6], and an RNA-dependent RNA polymerase that lacks proofreading ability^[7] sets the stage for Darwinian selection of variant or mutant viruses *via* pressure mediated by humoral and cellular immune responses^[8].

Selective pressure appears to be applied by all elements of the immune response including antibody-producing B-cells and both CD4⁺ and CD8⁺ T cells. Such persistence of HCV infection has been particularly associated with mutations in epitopes encompassed within the hypervariable region 1 of HCV envelope glycoprotein 2, recognized by both antibodies and CD4⁺ helper T cells^[9,10]. Studying a class II restricted immunodominant epitope within the non-structural 3 (NS3) protein region of HCV, we have identified a highly significant variation that correlated with escape from CD4⁺ T cell responses^[11-14]. Other sequence variations in epitopes recognized by CD8⁺ cytotoxic T lymphocytes (CTLs) have been identified in chimpanzees^[4,15] and humans^[16-22] with chronic HCV infections.

CTLs recognize peptide fragments of cellular or viral proteins in the form of short peptides comprising 8-11 amino acids presented in association with major histocompatibility complex (MHC) class I molecules on the surface of infected cells^[23-27]. These peptides are usually derived from intracellular viral protein pools and associated in the lumen of the endoplasmic reticulum with MHC class I molecules, after which the MHC-peptide complex is transported to the cell surface and recognized by a specific T cell receptor (TCR) located on the surface of the CD8⁺ killer T cell.

Variation within a viral epitope can lead to a total or partial loss of functional recognition by CTL. Substitutions occurring at key anchor residues may alter peptide affinity for MHC class I molecules and thereby interfere with antigen presentation and effector T-cell mediated clearance of infected cells. Other variations, primarily in solvent-accessible residues, may abrogate TCR recogni-

tion altogether or alter it in such a way that critical activation signals are not transmitted to the cytotoxic T cells resulting in attenuated responses or even anergy^[10,16-18]. Examples of attenuated responses have also been found with HIV and HBV^[28-32]. It is thought that by antagonizing T-cell responses to native epitopes, viruses expressing mutant epitopes might aid in the survival of infected cells producing wild-type viruses, which would otherwise be recognized and destroyed by CTL. Although parts of this issue have been examined in chronic HCV infection^[15-18,33], unresolved questions remain, including whether naturally occurring variants antagonize CTL responses to wild-type epitopes that are found within the same host. To address this, viral sequences were examined by assessing CTL activity in three epitopes that were previously identified by Koziel *et al.*^[34]. Comprising amino acids 1073-1081, 1131-1139, and 1169-1177, these 9-mer epitopes are restricted by human leukocyte antigen (HLA)-A*02 and recognized by specific CTL clones. Initially, we examined epitope heterogeneity in the viral sequences from an A*02-positive patient applying polymerase chain reaction (PCR) technology. This was followed by the synthesis of peptides corresponding to observed variations in these epitopes and subsequently used to sensitize A*02-expressing target cells. Results illustrate allele-specific viral evolution and escape from a dominant CD8⁺ CTL response. While most variants were either not recognized or elicited low responses, such could antagonize CTL responses to target cells pulsed with wild-type peptides. The ability to interfere with CTL function was independent of the ability of variant peptides to bind MHC molecules. Overall, we view this study as a bridge to understanding how interactions between HCV and the host's immune system might lead to viral persistence or effective elimination of HCV.

MATERIALS AND METHODS

Human subjects

Peripheral blood samples were collected from a patient B3019 with chronic HCV at approximately 12 mo (B3019.1), 28 mo (B3019.3), and 63 mo (B3019.5) after infection. This patient never received any therapeutic intervention during the 5 years chronic HCV infection. The presence of HCV-specific antibodies and HCV RNA in the patient's serum was determined as described previously^[11]. Blood was collected in acid citrate dextrose anticoagulant, centrifuged at $400 \times g$ for 15 min, and divided into plasma and buffy coat fractions. After isolation of peripheral blood mononuclear cells (PBMC) over Lymphocyte Separation Medium (Organon/Teknika), plasma and PBMC were stored at -70°C or in liquid nitrogen, respectively.

Amplification of the HCV NS3 region using reverse transcription PCR

Total HCV genomic RNA was isolated from 140 μL of B3019.1, 3019.3 and 3019.5 sera using the QIAamp[®] Viral RNA Mini Kit (QIAGEN, Inc.). The cDNA

was synthesized using reverse transcriptase (RT) from Moloney's murine leukemia virus and random hexadecoxynucleotide primers (Invitrogen). HCV cDNA was then amplified using nested primer sets ("outer" sense prime: 5'-GGCCTCCTAGGGTGTATAATCACC-3'; "outer" antisense primer: 5'-GAGGAGTTGTCCGTGAACAC-3'; "inner" sense primer: 5'-CAGATCGTGTCAACTGCTAC-3'; "inner" antisense primer 5'-CCA-CAGGGATAAAGTCCACC-3') specific for nucleotides 3519-3935 of the NS3 region. Primers were created based on the previously reported HCV sequence from genotypes 1a, (isolate H77), which generated a final PCR product of 417 bp.

Initial PCR was performed using the outer primer set starting with heat-activation of the ProofStart DNA Polymerase at 95°C for 5 min, followed by 35 cycles of denaturation at 94°C for 30 s, annealing at 55°C for 30 s and extension at 72°C for 1 min. A final extension step at 72°C for 10 min was introduced to increase the pool of full-length products. Two microliters of the first amplification product was transferred into the second nested PCR reaction mixture containing the "inner" primer pair. The second round of amplification was performed for 35 cycles under equal conditions. For all PCR amplifications, ProofStart DNA Polymerase (QIAGEN) with proofreading capabilities was used. PCR products were analyzed on a 1.5% agarose gel stained with ethidium bromide. As described elsewhere^[35], all measures were taken to avoid contamination of PCR samples.

As a control strategy for polymerase errors, two different experimental approaches were applied. In a first experiment, the plasmid pT7 TOPO-TA/NS3 from the Hutchinson strain (1a) of HCV^[36] was diluted to 10⁻¹⁴ g/mL and amplified using the same PCR procedure described above. In an alternative experiment, reverse transcription PCR (RT-PCR) was used to amplify an RNA template derived from the pT7 TOPO-TA/NS3 plasmid. The RNA template was obtained utilizing a T7 RNA polymerase (USB) according to the supplier's instructions. The resulting transcript was treated with DNase I for 15 min at room temperature and RNA was extracted using the QIAamp[®] Viral RNA Mini Kit (QIAGEN, Inc.). Reverse transcription and amplification of this control RNA was carried out as described above.

Cloning and sequencing

PCR products of the HCV NS3 regions were integrated into a PCR[®] T7TOPO[®] TA vector (Invitrogen, Carlsbad, CA). Ligations and transformations were executed according to the manufacturer's instructions. Recombinant clones were then screened for positive PCR product integration by using a PCR amplification procedure detecting HCV NS3 inserted fragments. Plasmid DNAs with confirmed inserts were purified with QIAprep[®] spin miniprep kit (QIAGEN, Inc.) according to the standard protocol from Qiagen and further analyzed. Thirty independent clones for each sample of B3019.1, B3019.3 and B3019.5, as well as 23 and 17 independent clones

for each control strategy, respectively, were sequenced in both directions using an automated DNA sequencer (373A, Applied Biosystems). The sequencing results were analyzed using GCG SeqWeb package (V2.0.2). The polymerase error rate under applied conditions was calculated as [(No. of sporadic changes)/[(No. of clones) × (sequence length) × (PCR cycles)] as described by Smith *et al.*^[37].

Peptide synthesis

Peptides with wild type and variant sequences of NS3 1073-1081, NS3 1131-1139 and NS3 1169-1177 were synthesized locally using F-moc chemistry and purified by high-performance liquid chromatography (HPLC). Peptide powder was dissolved in a drop of DMSO and adjusted to approximately 1 mg/mL with RPMI 1640 tissue culture medium before being used to stimulate PBMC in CTL cloning, cytotoxicity and antagonist assays. For the competition assay procedure, the FITC-labeled peptide was commercially synthesized by Synpep (Dublin, CA) using solid-phase strategies and purified with reverse-phase HPLC. For this procedure, NS3 peptides were originally dissolved in 100% DMSO at a concentration of 10 mmol/L. Subsequent dilutions were done in 1 × bovine γ globulin in PBS (BGG/PBS; 0.5 mg/mL; 0.05%; Sigma; St. Louis, MO).

Fluorescence polarization-based peptide competition assay

To determine relative MHC binding levels of wild-type and variant peptides, fluorescence polarization (FP)-based peptide competition assays were performed as described^[38,39]. Initially, the four components of the binding reaction (competitor peptide, tracer, sHLA and β 2m) were prepared as concentrates. The fluorescent-labeled tracer peptide (pFITC P5), ALMDKVL-K(FITC)-V, and the sHLA-A*0201 component of the reaction were diluted to appropriate 8 × and 2 × solutions, respectively. The β 2m component (Fitzgerald Industries International; Concord, MA) was prepared as an 8 × mix and always added in a 2 × molar excess of the used sHLA concentration. Each competitor peptide was prepared at various dilutions and added as 4 × solutions. For all preparations, 1 × BGG/PBS was used as buffer. Next, each individual well of a black 96-well LJL HE PS microplate (Molecular Devices) was loaded with 5 μ L of the prepared 8 × β 2m, 10 μ L of each competitor solution, and 5 μ L of 8 × pFITC. To start the peptide exchange procedure, the 2 × sHLA mixes was activated by incubating at 53°C for 15 min before adding 20 μ L to the previously loaded wells reaching a final volume of 40 μ L. All reagents were added to the wells of the microtiter plate sequentially using manual pipettors. The plates were then read at room temperature using an Analyst AD (Molecular Devices; Sunnyvale, CA) until no further increase in polarization was observed indicating that equilibrium was reached (24-48 h). Data analysis was performed using the software package Prism (GraphPad), by direct fit to the

appropriate models by computer-aided, nonlinear regression analysis.

CTL cloning

Specific CTL clones toward HCV NS3 wild-type peptides 1073-1081 (wt1073), 1131-1139 (wt1131) and 1169 (wt1169) were generated. Briefly, PBMCs were thawed, diluted rapidly at 4°C, washed twice by centrifugation at $400 \times g$ for 10 min, resuspended and plated into wells of 96 well flat bottom plates (200 μ L) at a density of 2×10^6 cells/mL. Cells were then stimulated individually with wild-type NS3 peptides 10 nmol/L at 37°C in a 5% CO₂ incubator. After 7 d of incubation, 20 U/mL rhIL-2 (ENDOGEN) was added to the cultures. On day 14, cells were screened for the ability to lyse target cells pulsed with NS3 wild-type peptide. Functional cells were further subcloned by limiting dilution (at cell densities of 10, 3, 1 and 0.3 cells/well) in 96 well round bottom plates which contained 10^5 irradiated, autologous PBMCs, 20 U/mL rhIL2, and 10 nmol/L HCV NS3 wild-type peptide. Positive clones were further expanded and re-stimulated in 24-well plates with 10^5 irradiated (3000 rad) autologous PBMCs, in the presence of 10 nmol/L wild-type peptide and 20 U/mL rhIL-2 in RPMI 1640 medium supplemented with 25 mmol/L HEPES buffer, 2.0 mmol/L L-glutamine, 50 U/mL penicillin, and 100 mg/mL streptomycin, 5.0 mg/mL gentamicin, 10 U/mL sodium heparin, 1.0 mmol/L sodium-pyruvate, and 10% pooled AB human serum (complete RPMI-10 AB). Finally, cells were tested for cytolytic recognition of B-LCL targets pulsed separately with wild-type peptides. 14 d after the last stimulation, specific CTL clones were maintained in a long term culture in T-25 flasks by re-stimulating 2×10^6 cells every 2 wk with 1×10^6 irradiated (3000 rad) allogeneic PBMC feeders and 50 U/mL rIL-2 in complete RPMI-10 AB media. Not immediately used clones were frozen in liquid nitrogen for later usage.

Tetramer staining and flow cytometry

The CTL clones specifically recognizing HCV NS3 wild-type peptides were washed with 10% FCS in PBS followed by staining with the HCV NS3 1073-1081 peptide MHC class I tetramer complexes as described previously^[40]. The following antibodies and tetramer complexes were used: Anti-CD8-FITC, anti-mouse IgG FITC (Pharmingen, San Diego, CA, USA), HLA-A*02-restricted HIV p17 epitope tetramer PE, HLA-A*02-restricted HCV NS3 1073-1081 tetramer PE. Specific CTL clones were incubated with the antibodies and tetramer reagents for 45 min at room temperature in the dark, then washed with $1 \times$ PBS and resuspended in 500 μ L of $1 \times$ PBS. Samples were analyzed on a FACScan flow cytometer (Becton-Dickinson, Mountain View, CA, USA). The data were analyzed by WinMDI 2.8 software, kindly provided by Dr. Joel Trotter. Both the HCV NS3 1073-1081 peptide-MHC class I tetramer complex and the negative control tetramer complex HIV p17 peptide SLYNTVATL were made by the NIAID tet-

ramer Facility, Emory University Vaccine Center (Emory University, Atlanta, GA, USA).

Cytotoxicity assay

Cytolytic activity of CTL clones was measured using target cells labeled with the fluorescence enhancing ligand, DELFIA EuTDA (Perkin-Elmer Life Sciences, Norwalk, CT) according to the manufacturer's instructions. As target cells, the HLA-A*02 positive Epstein-Barr virus (EBV) transformed B-cell line (L.B3019) was labeled with DELFIA BATDA reagents at 37°C for 20 min, washed three times, and incubated with the indicated concentration of peptide for 1 h. After three additional washes, effector cells were added at various concentrations and incubated for 2 h in 96-well round-bottom plates (5000 target cells per well) at 37°C in 5% CO₂. After centrifugation at $500 \times g$ for 5 min, 20 μ L of supernatant was transferred to corresponding wells of a flat bottom plate and 200 μ L of europium solution was added. Fluorescence was measured using a Wallace Victor2 Multilabel Counter (Perkin-Elmer Life Sciences). Percent specific release was calculated according to the following formula: Percent specific lysis = $100 \times [(experimental\ release - spontaneous\ release)/(maximum\ release - spontaneous\ release)]$. Results were reported as the means of duplicate wells.

Antagonist assay

To measure the ability of each variant peptide to antagonize CTL responsiveness against wild-type peptide, an antagonist assay was performed using the method described by Jameson *et al.*^[41] under slightly modified conditions. Briefly, target cells were labeled with DELFIA BATDA reagents at 37°C for 20 min, washed three times with RPMI 1640 medium, and then pulsed for 1 h with 10 nmol/L wild-type peptide. After removal of the wild-type peptide by another wash step ($3 \times$), the cells were pulsed a second time using varying concentrations of variant or control peptide for another hour. After a final wash step, specific CTL effector cells were added at various concentrations and incubated for 2 h. After incubation, the cytolytic activity of CTL was measured as described above. Percent inhibition of lysis was calculated as $\{\% \text{ inhibition} = 100 \times [(A-B)/A]\}$ where A is the percent specific lysis in the absence and B is the percent lysis in the presence of the variant peptide under investigation. Each point represents the mean of duplicate wells.

RESULTS

Mutations in the HCV NS3 region

The majority of RNA viruses produce RNA polymerases that lack proofreading activity, and thus introduce mutations into the viral genome. In the presence of immune selection pressure exerted by CTLs against wild-type virus, this genomic diversity could facilitate preferential expansion of mutant progeny encoding altered

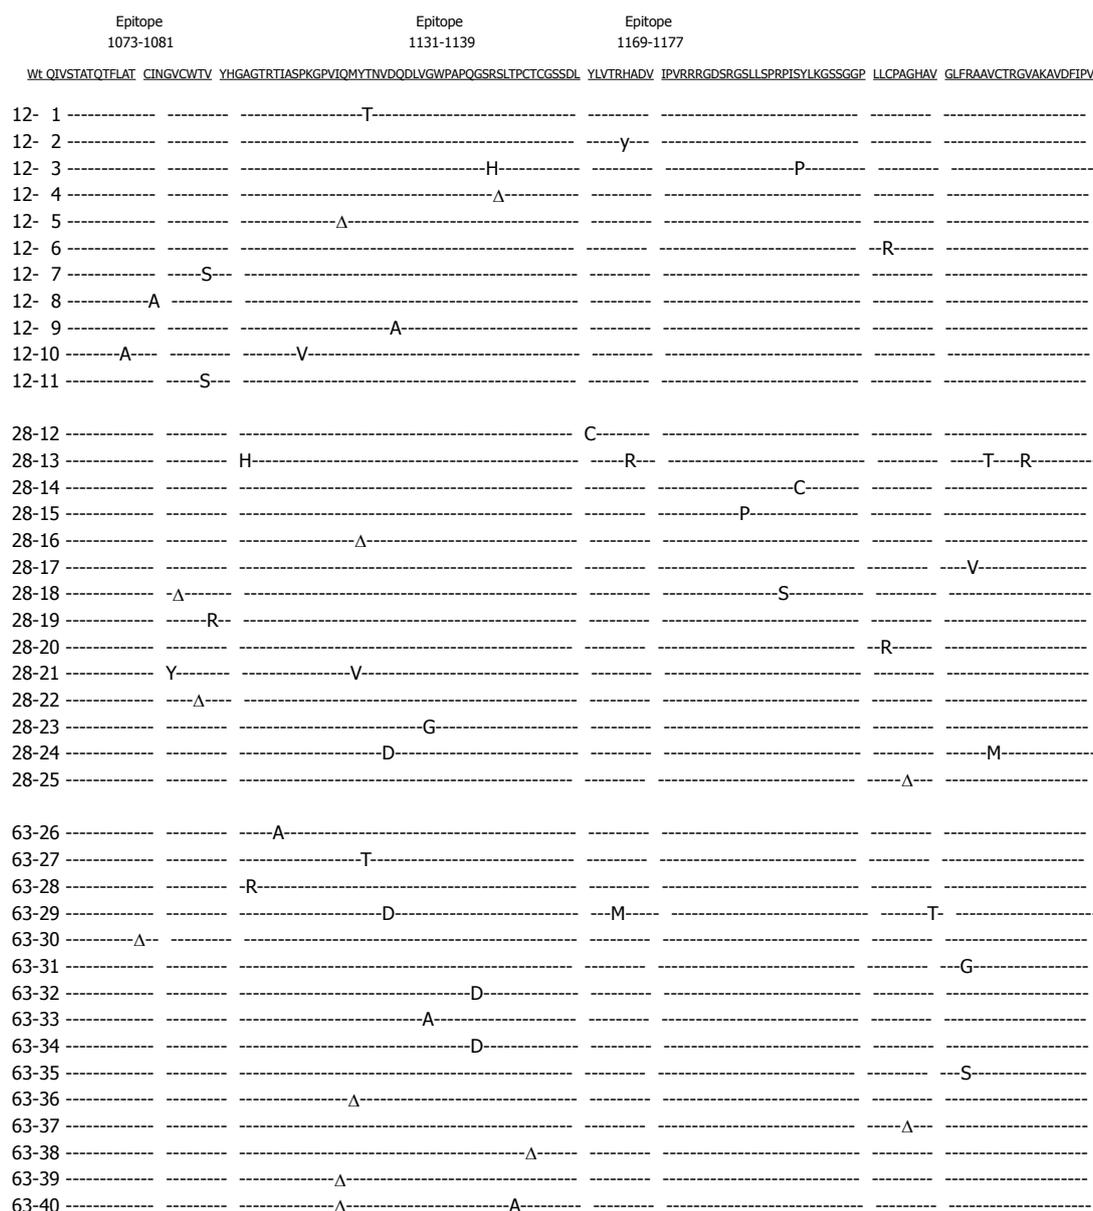

Figure 1 Summary of sequence changes detected over time within the hepatitis C virus (HCV) non-structural 3 (NS3) fragment of a single patient. HCV RNA extracted from patient sera at months 12, 28 and 63 was amplified by reverse transcription polymerase chain reaction (RT-PCR). A panel of molecular clones spanning the NS3 fragment was aligned with the wild-type consensus sequence which is shown on top (underlined). From a total of 51 nucleotide substitutions found, 39 were nonsynonymous, causing amino acid alterations (capital letters). The amplified NS3 fragment encompasses epitopes NS3 1073-1081, 1131-1139 and 1169-1177. Dashed lines indicate identity to the consensus sequences, whereas positions of synonymous mutations not causing amino acid alterations are marked with the greek delta sign (Δ).

epitopes that evade recognition by effector T cells. To monitor HCV genetic diversity within a fragment of the NS3 region, three different sera samples of a single subject with chronic HCV, collected at approximately 12, 28, and 63 mo after infection, were investigated by sequence analysis. In particular, the region 1060-1198 was selected for analysis because of the inclusion of previously identified HLA-A*02 restricted epitopes comprising amino acids 1073-1081, 1131-1139, and 1169-1177. An overall sequence comparison to the wild-type sequence revealed a set of 40 out of 90 individually sequenced clones (44.4%) carrying one or more mutations (Table 1). Within the 40 alternative sequences, a total of 51 nucleo-

tide substitutions were detected of which 12 (23.5%) were synonymous (SYN) silent mutations and 39 (76.5%) were nonsynonymous (NSY) mutations, respectively, leading to specific amino acid alterations within this NS3 fragment (Figure 1). The frequency of sporadic substitutions was calculated as 1.9×10^{-5} according to the formula described by Smith *et al*^[37]. Furthermore, the frequency of mutations observed at 3 different time points of disease progression for the same patient was not significantly different.

To determine if observed mutations are consistent with a positive Darwinian selection model as described in other reports^[13,14,20], we compared the ratios of NSY/

Table 1 Mutations in the HCV NS3 region

Sample	Month 12	Month 28	Month 63	Total
No. of clones tested	30	30	30	90
Clones with mutations	11	14	15	40
Total mutations	13	20	18	51
SYN mutations	2	4	6	12
NSY mutations	11	16	12	39

SYN: Synonymous; NSY: Nonsynonymous; HCV: Hepatitis C virus; NS3: Non-structural 3.

SYN mutation for the NS3 fragment covering amino acid 1060-1198. As defined earlier for positive Darwinian selection, the rate of NSY substitution usually exceeds the SYN substitution rate and heterogeneity increases more quickly, whereas at sites subject to negative selection, the NSY/SYN ratio is < 1 and the heterogeneity will be much lower^[37,42]. Among the total 51 nucleotide substitutions, 18 occurred in the first codon position, 18 at the second and 15 at the third position. According to the methods used by Nei *et al.*^[43] and Wang *et al.*^[14], theoretical values for SYN and NSY mutations were calculated as 11.7 and 39.3, respectively, which closely match our observed values of 12 for SYN and 39 for NSY. The total NSY/SYN ratio was 3.3, which is consistent with the positive Darwinian selection theory. Furthermore, we also compared our observed mutation values from different sections of the amplified region within NS3 with theoretical values for NSY mutations (Table 2). As seen in Figure 2, we found a significantly higher frequency of NSY mutations for section 1070-1119, 1130-1139, 1150-1159 and 1170-1189, earlier described as variable regions and also harboring the known HLA-A*02 epitopes. As expected, these findings are in contrast to the frequencies found within the so-called conservative regions covering sections 1060-1069 and 1120-1129 and showing a much lower mutation rate. It is notable that the 10-fold higher mutation rate within the epitope region 1073-1081, 1131-1139 and 1169-1177 compared to the conservative regions, with a NSY/SYN ratio of 2.8, suggests a high level of positive selective pressure on these immunogenic regions. No mutations were found in sections 1140-1149, 1160-1169 and 1190-1198 potentially carrying sequences not under immunological pressure within this patient. Variants do not seem to accumulate within CTL epitopes and most NSY are transient.

To ensure that the observed mutations were not due to nucleotide misincorporations introduced by the RT or polymerase during the amplification reaction, two control experiments were carried out: In the first experiment, 0.01 pg of a known NS3 plasmid template was subjected to PCR amplification in the usual two step protocol and subcloned. Sequence analysis of 23 independent clones showed absolute identity compared to the parental clone. In a second experiment, 0.01 pg of the same NS3 plasmid template was linearized and *in vitro* transcribed with T7 RNA polymerase. Limiting amounts of the RNA transcript was subjected to the

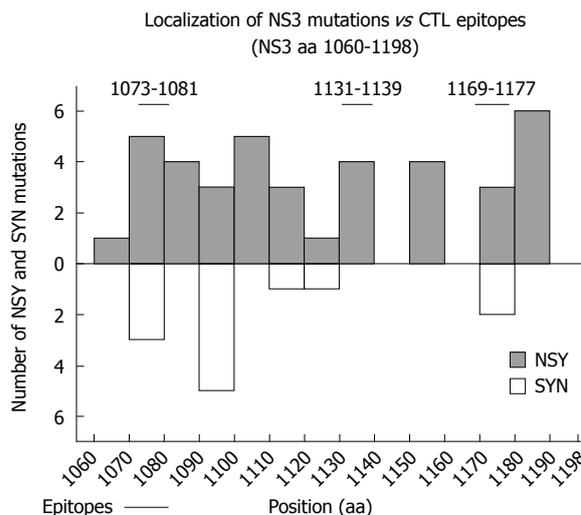

Figure 2 Localization of NS3 mutations in the proximity of three cytotoxic T lymphocyte (CTL) epitopes. Sequence alterations within the NS3 region between amino acid (aa) 1060-1198 are graphically visualized. Nonsynonymous (top) and synonymous (bottom) mutations are shown separately. NS3 CTL epitope regions 1073-1081, 1131-1139 and 1169-1177 are indicated.

complete RT-PCR amplification procedure, and the amplified product was subcloned and sequenced. Out of 17 independent clones sequenced, only one demonstrated a single nucleotide change. An error rate of 2.02×10^{-6} was calculated according to the formula described by Smith *et al.*^[37] and found to be well in line with the Pfu DNA polymerase error rate reported by others^[44,45]. Conclusively, these findings not only highlight the fidelity of the polymerase used for our viral genome amplification procedure, but also confirm the necessity of utilizing proofreading DNA polymerases to prevent false interpretation of mutations in genetic diversity studies of RNA viruses. Taken together, our results suggest that the mutations identified by our approach primarily represent naturally occurring mutations in the HCV RNA genome, rather than artificial PCR errors.

In addition, particular attention was given to the analysis of sequence changes encompassing epitopes recognized by CTL responses^[34]. Changes that emerged within stretches of sequence containing CTL epitopes are shown in Figure 1. As seen, sequence data from the epitopes defined within the NS3 region clearly reveal evolution in these target regions. By month 63 after transmission, bulk sequence data from the single targeted regions illustrates the development of mixed viral populations while still maintaining the original dominant sequence. Complete replacement of the initial virus population with viruses bearing nonsynonymous sequence changes within one or more epitope-containing regions could not be observed. For epitope CINGVCWTV (1073-1081), three mutations developed at residues 1, 6 and 7, whereas 4 different mutations were noted within epitope YLVTRHADV (1131-1139) with changes at residues 1, 4, and 6. Only 2 alterations were observed for epitope LLCPAGHAV at residues 3 and 8, which may indicate a less immunologically pressured epitope. These

Table 2 Nonsynonymous and synonymous mutations in different regions of HCV NS3

¹Epitope region. Expected sporadic mutations = $ER \times L \times Nc \times N \times P/Ns$, where ER = error rate of polymerases (2.02×10^{-6}), L: Nucleotide length of compared region; Nc: Number of PCR cycles; N: Number of clones sequenced; P: Proportion of sporadic mutations expected to produce amino acid substitutions (2/3), Ns: Number of sample (1) according to Smith *et al.*^[37] (1997). PCR: Polymerase chain reaction; NS: No significant.

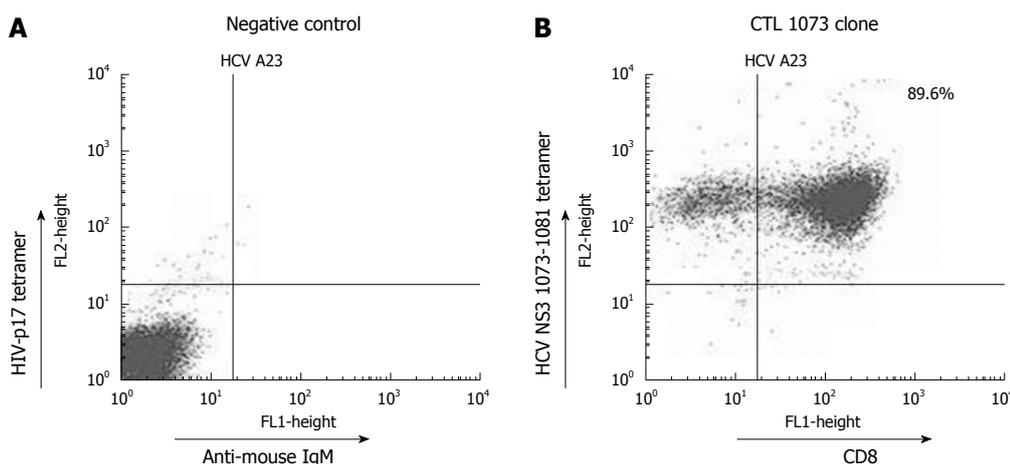

Figure 3 HCV NS3 1073-1081 tetramer staining using a CTL clone specific for wt1073. A: As a negative control, CTL clone 1073 was stained with the HIV-p17 tetramer reagent and anti-mouse IgM FITC. As expected, no cell shift was observed; B: The same CTL clone was stained with the HCV NS3 1073-1081 tetramer and anti-CD8⁺-FITC. A positive HCV NS3 1073-1081 tetramer staining is shown with tetramer/CD8⁺ cells located in the upper right quadrant. The origin of cells seen in the upper left quadrant could not be identified and need further investigation. All staining experiments were repeated three times with similar results. Identical results were obtained with HCV NS3 1073-1081 tetramer staining using other CTL clones for wt1073 (data not shown).

numbers are small, but consistent with the possibility of CTL-mediated selection.

Cytotoxicity of wt-specific CTL clones against various natural epitope variants

Next, we examined the phenotypic effects of these changes upon CTL recognition. For this reason, we initially produced CTL clones specifically recognizing target cells pulsed with wild-type peptides. CTL clone 1073 was generated recognizing MHC complexes loaded with wt1073, whereas CTL 1131 and CTL1169 were made to bind complexes harboring wt1131 and wt1169, respectively. Their specificity was confirmed in a separate set of experiments, where CTL clones were stained with

MHC class I tetramers loaded with the corresponding HCV NS3 wild-type peptide. Figure 3 shows the result for the CTL clone 1073.3 containing tetramer positive CD8⁺ cells in the upper-right quadrant. Additional staining experiments were performed using clones 1073.2 and 1073.4 with similar outcome (data not shown).

Subsequently, the cytolytic activity of these CTL clones was determined by incubating them with target cells pulsed with either variant or wild type peptides as reference. Results obtained for CTL 1073 (Figure 4A) showed a more than 80% cytolytic activity, confirming the capability of this CTL clone to recognize wild-type peptide wt1073 presented by the HLA-A*02 positive EBV transformed target B-cell line (LB3019). In all instances,

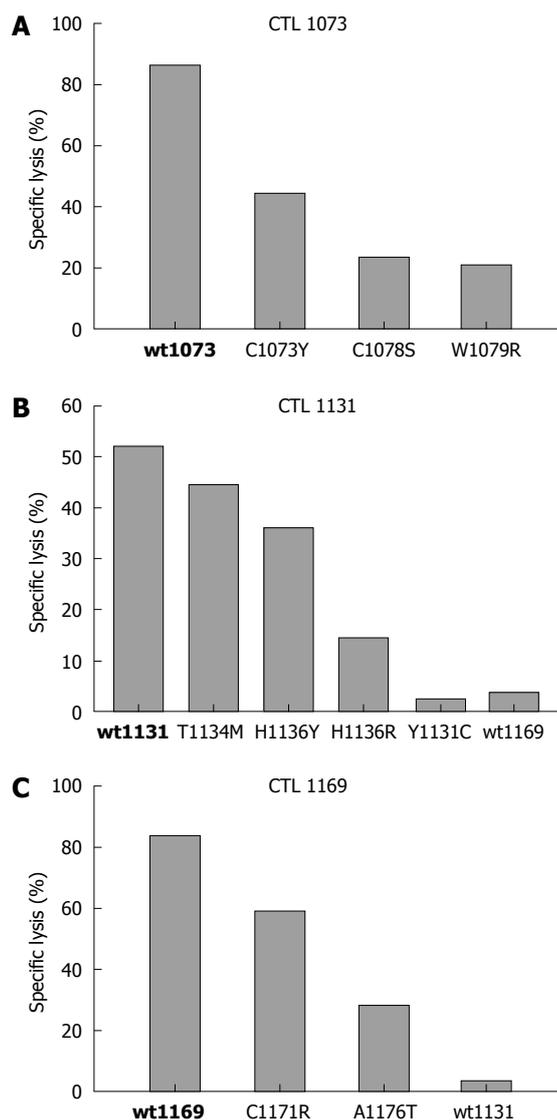

Figure 4 Effect of amino acid changes on epitope-specific CD8⁺ CTL responses. The relative ability of synthetic peptides corresponding to the indicated wild type (**bold**) and variant epitope sequences to sensitize autologous target cell lines for lysis by CTL clone 1073 specific for wt1073 (A), clone 1131 specific for wt1131 (B) and clone 1169 specific for wt1169 peptide (C) was determined using *in vitro* cytotoxicity assays. The results shown are the specific lysis (%) of target cells incubated with each wild type (**bold**) and variant peptide at a concentration of 10 nmol/L. As expected, the highest cytotoxicity was found against wild-type peptides followed by various degrees of lysis for epitope variants. Target cells used in these assays were prepared from the B cell line (L.B3019) with an effector to target ratio of 20:1.

the amino acid changes found within this epitope region (1073-1081) showed reduced ability of the variant peptides to sensitize target cells for CTL lysis. Changes from cysteine (C) to serine (S) at position 6 and tryptophan (W) to arginine (R) at position 7 were found to be more effective than changes from a cysteine (C) to tyrosine (Y) at position 1 thus showing only a 50% reduction of specific lysis. Similar results were found for the epitope region 1169-1177 using CTL1169 (Figure 4C). The cytolytic activity for the parental peptide wt1169 again was over 80%. Variant C1171R, containing an amino acid change from cysteine (C) to an arginine (R) at position 3 could

still be recognized with a 60% lytic activity, whereas only a minor activity level was noted for A1176T, showing a change from alanine (A) to threonine (T) at position 8. The control experiment using unrelated wild-type peptide wt1131 did not produce any cytolytic response confirming the specificity of CTL recognition. Finally, CTL clone 1131 (covering epitope region 1131-1139) (Figure 4B) was also, as expected, able to sensitize target cells for CTL lysis when using the wt peptide (wt1131). Target cells loaded with variant peptide T1134M and H1136Y with mutations at position 4 [threonine (T) to methionine (M)] and position 6 [histidine (H) to tyrosine (Y)], respectively, seemed nearly unaffected, showing only minor loss of cytolytic activity compared to the wild-type response, suggesting that the mutations seen in these particular cases did not abolish CTL recognition. In contrast, CTL 1131 completely failed to respond to variant peptide Y1131C and showed only minor lytic activity using target cells loaded with peptide H1136R harboring an amino acid substitution at position 6 [histidine (H) to arginine (R)]. This result suggests that the mutations within variant peptide Y1131C from a tyrosine (Y) to a cysteine (C) at position 1 was highly efficient to abrogate CTL recognition in contrast to the observation made for CTL 1073, where the opposite mutation at the same position from a cysteine (C) to tyrosine (Y) had much less impact on the lytic capability of the CTL clone. Overall, a decrease in specific lysis could be demonstrated for the majority of variant peptides compared to wild-type responses indicating that most of our identified HCV NS3 epitope variants were able to escape or lower specific CTL recognition to various degrees.

Impact of variant peptides on MHC class I binding

To investigate directly whether these amino acid changes within the variant peptides were due to impairment of peptide binding to MHC and/or to alteration of recognition of the peptide-MHC complex by T cells, we performed a series of peptide binding assays to determine if our identified viral peptide epitope variants lost their capacity to form stable class I major histocompatibility complexes compared to their wild-type counterpart. After peptides representing putative escape variants were synthesized, binding affinities of both wild-type and variant peptide epitopes were assessed using serial dilutions of the peptides in FP-based peptide competition assays utilizing soluble HLA (sHLA)-A*0201 molecules as the binding entity. Each peptide tested generated its own binding isotherm from which IC₅₀ values were extracted. Figure 5A-C present multiple reaction curves obtained from the competition experiments, whereas Table 3 summarizes assessed IC₅₀ values for the peptides along with their exact amino acid sequences. Using previously obtained results^[39], we used other assay systems as guidelines to define an FP-based classification system, where peptides with an FP-based IC₅₀ value of 5000 nmol/L and lower were considered high affinity binding, 5000-50 000 nmol/L IC₅₀ values were considered medium-affinity binding, 50 000-1 000 000 nmol/L

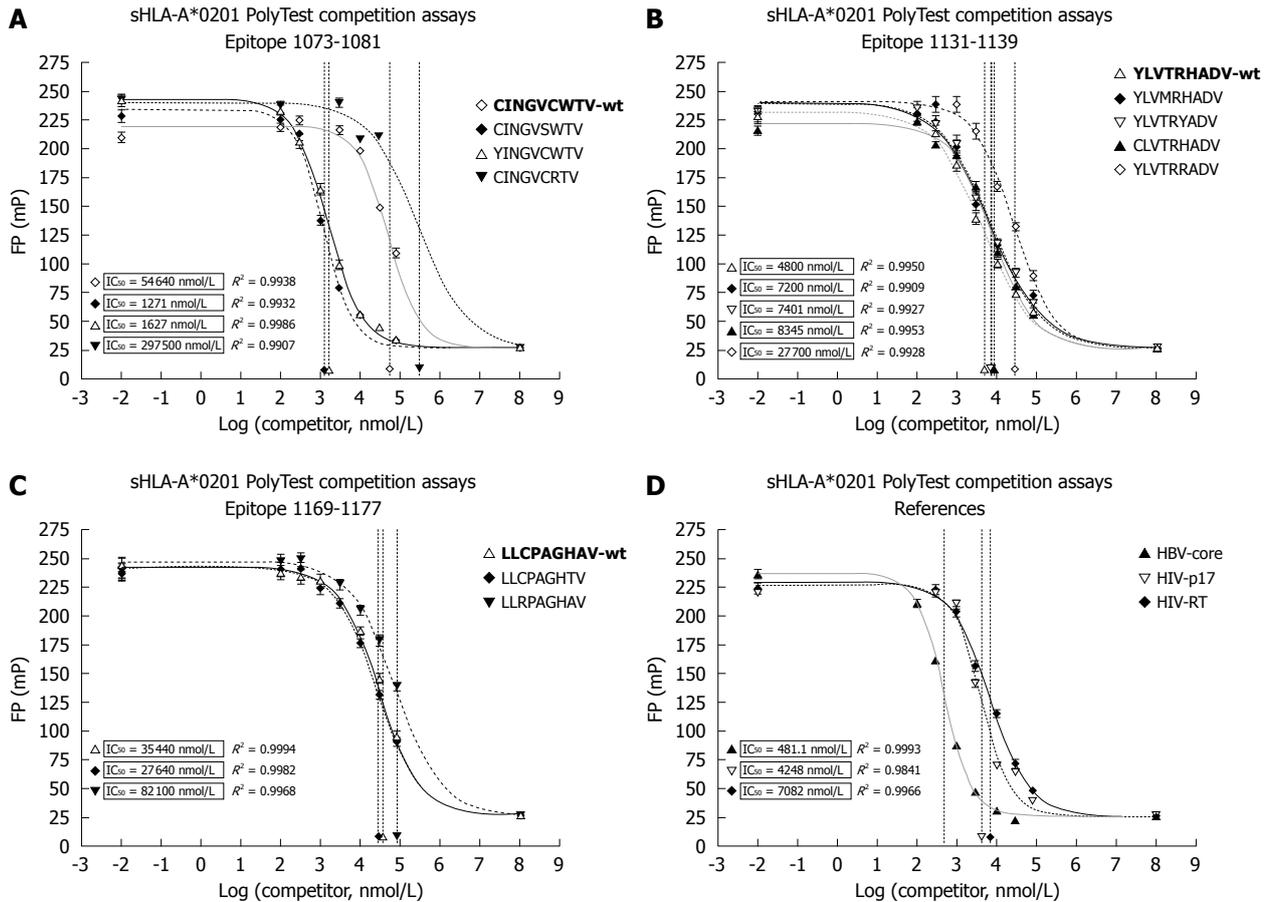

Figure 5 Soluble human leukocyte antigen (HLA)-A*0201 competition assays determining the binding capacity (IC_{50}) of natural HCV epitope variants. The affinity of three wild type HCV peptide epitopes (bold) wt1073 (A), wt1131 (B), wt1169 (C) derived from three locations within the NS3 region and their variants C1073Y, C1078S and W1079R (A), Y1131C, T1134M, H 1136Y and H1136R (B), C1171R and A1176T (C) was determined. Control peptides HBV-Core, HIV-p17 and HIV-reverse transcriptase (RT) were included to provide reference values to other viral systems. Their affinities are presented in graph (D). For each experiment, 8 serial dilutions (100 nmol/L-80 μ mol/L) of the unlabeled viral peptide were used to compete against a FITC-labeled tracer peptide. After reaching equilibrium, IC_{50} values for all peptides were determined by fitting the data to a dose-response model using the software Prism. R^2 values indicate the goodness of fit.

¹Means of two experiments. Variant substitutions are expressed in underlined letters.

IC_{50} values were judged low-affinity binding, and IC_{50} values above 1 mmol/L were regarded as no binders. Additionally, low affinity binders were further subdi-

vided into a low (50 000-350 000 nmol/L) and very low affinity category (350 000-1 000 000 nmol/L). To provide better correlation between peptide binding affinity and

immunogenicity, binding results from peptides known for their ability to induce potent and specific CTL responses were presented (Figure 5A). Among our viral controls, the HBV-derived epitope FLPSDFFPSV was found to display very high affinity values. As one of the more referenced peptides found in literature, FLPSDFFPSV is known for high affinity binding to A*0201^[46-48] as well as for inducing potent CTL responses^[49]. Additional controls were the peptides SLYNTVATL and ILKEPVGHV, two other well-studied HIV-derived CTL epitopes^[50-52].

According to our FP-based classification system, wild-type peptides wt1131 and wt1169 were found to be of high and medium affinity, respectively, matching with the high cytolytic activity level of these CTL clones (Figure 4B and C). Somewhat unexpected was the low affinity binding observed for wild-type peptide wt1073, showing a very high cytolytic response when used in combination with CTL clone 1073 (Figure 4A). However, it has to be noted that this wild-type peptide has two cysteine residues within its sequence, allowing for disulfide bond formation. Potentially, this characteristic could lead to a reduced availability of intact peptides during the assay procedure directly affecting IC₅₀ determination, ultimately causing an underestimation of its binding capacity. As the two variant peptides within this group, C1078S and C1073Y, have only a single cysteine in their sequence and demonstrate very high affinity thus strongly supporting our hypothesis of a cys-cys interference.

In reviewing the binding results found for each variant peptide, none of the amino acid changes identified within each epitope region abolished peptide binding. Motif analysis of these variants showed that none of the anchor positions (defined at position 2 and 9 for nonameric peptides and critical for high affinity A*0201-related binding) contained any amino acid alterations, consistent with an escape mechanism affecting mainly peptide regions responsible for TCR recognition rather than MHC binding. More specifically, variants T1134M, H1136Y and Y1131C covering epitope 1131-1139 remained in close affinity range of the wild-type peptide indicating that mutations at positions 1, 4, and 6 had practically no effect on their binding capacity. An exception within this epitope region is variant peptide H1136R, whose binding capacity dropped 5.8 fold compared to the wild-type peptide probably caused by the introduction of a positive charge derived from the arginine (R) residue replacing the original histidine (H) residue at position 6. Similar observations were made in variant peptides W1079R and C1171R, in which the introduction of an arginine (R) at position 7 and 3 resulted in a more dramatic decrease in affinity. W1079R shifted to a 5.4 and C1171R to a 2.3 fold lower binding capacity. It is noteworthy that variant W1079R, like parental peptide Wt1073, possesses a disulfide bond potentially causing interference in binding thus also causing an underestimation of its binding capacity. Nevertheless, these arginine substituted variant peptides were still able

to bind A*0201. Interestingly, in some cases such as C1078S, C1073Y and A1176T, the binding capacity actually increased compared to the wild-type peptide.

CTL antagonism

Because peptide variants of class I -restricted epitopes potentially could antagonize naturally occurring epitopes^[31], we explored this possibility by using different ratios of variant to wild-type peptide concentrations (V:W). In these antagonist assays, target cells were pre-pulsed with wt1073 (Figure 6A), wt1131 (Figure 6B) or wt1169 (Figure 6C) peptides for 1 h and pulsed a second time after excessive washing with variant or control peptide for another hour. Notably, results showed that all of the specific clones were antagonized by their corresponding variant peptides generally providing inhibition values above 35% for the V:W ratio 1:1 (Figure 6). This observation is in good agreement with the obtained IC₅₀ data suggesting that all variant peptides are capable of binding HLA-A*0201. In more detail, NS3 variant peptides C1073Y, C1078S and W1079R behaved as strong antagonists for CTL 1073 and inhibited lysis of target cells at all three ratios tested (Figure 6A). An exception is variant peptide W1079R, which could not significantly inhibit the lysis of target cells at the low V:W ratio 0.1:1. This is most likely due to its much lower affinity compared to the other variant peptides within this epitope region. However, the fact that W1079R performed well as antagonist above the 1:1 ratio supports our earlier concern of reduced activity within the peptide binding assay which seems not to influence this cell-based antagonist assay. Equal results were obtained for variant peptides Y1131C, T1134M, H1136R and H1136Y testing antagonistic effects using CTL 1131 (Figure 6B). However, because of an insufficient amount of cell material obtained for CTL clone 1131, experiments were only conducted at a single V:W ratio of 1:1. Nevertheless, all of the variant peptides acted as antagonists for this CTL with highest inhibition of target lysis seen for H1136Y (92%), followed by Y1131C (68%), H1136R (47%), and T1134M (37%). The low inhibition results obtained for T1134M was somewhat unexpected considering its much higher binding capacity and cytotoxicity compared to the other variants within this group. This observation seems to indicate the presence of other factors involved to successfully antagonize CTL responses within this experimental setup such as peptide stability towards degradation and also uptake and transport mechanisms of the target cell potentially influencing peptide availability within the cell. Furthermore, both variant peptides C1171R and A1176T also demonstrated strong capabilities to antagonize CTL 1169 responses as shown in Figure 6C. Moreover, it was found that control peptide wt1131 (specific to CTL clone 1131), with high HLA-A*0201 binding affinity, was unable to inhibit CTL recognition of the wild-type peptides for CTL 1073 and 1169, respectively (Figure 6A and C). A similar result was obtained for wt1169 together with CTL 1131, suggesting that those natural variant peptides do not

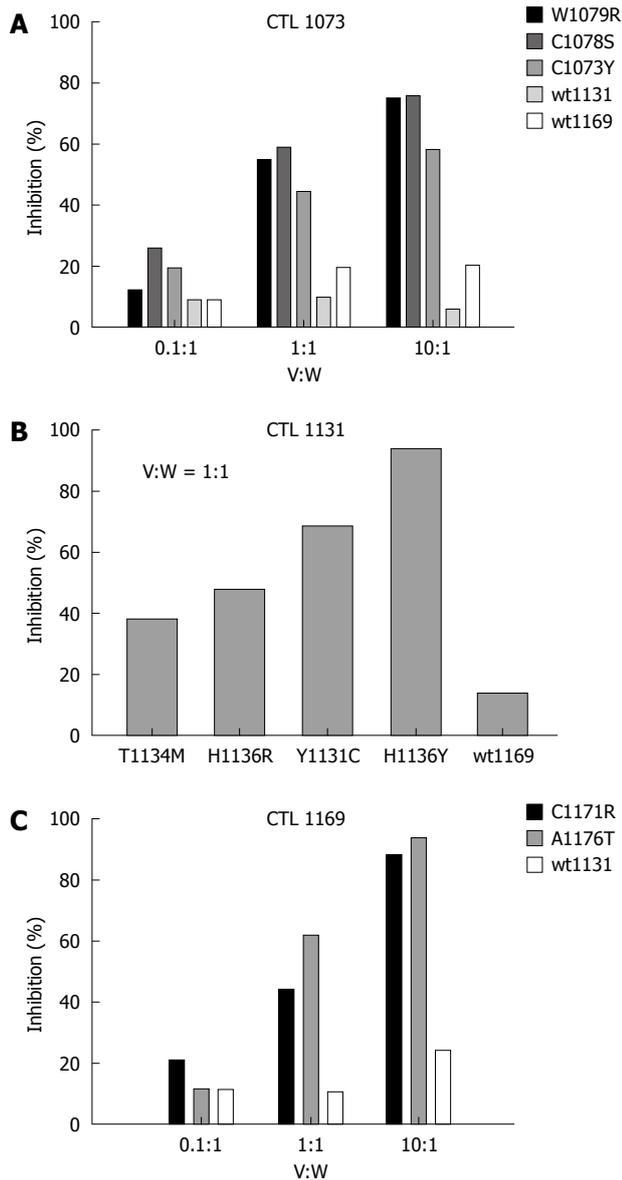

Figure 6 Antagonistic effect of NS3 peptide variants inhibiting specific cytolytic activity of specific CTL clones. A detailed inhibition profile is shown for CTL clones 1073 (A) and 1169 (C) in which target cells were pre-pulsed with 10 nmol/L of wild-type peptide, and then incubated at indicated ratios of variant to wild-type peptide concentrations (V:W). Wild-type peptides wt1131 and wt1169 were used as negative controls for experiments using CTL clone 1073, where only a single control (wt1131) was used for tests involving CTL clone 1169. Both data sets were determined at effector to target ratios of 20:1. Because of lack of material, a more simplified profile is shown for CTL clone 1131 (B) testing only a V:W ratio of 1:1 with wt1169 as negative control. All experiments were performed in duplicates.

simply exert their inhibitory activity by competing with wild-type peptides for HLA binding as recently described for hepatitis B epitopes by Bertoletti *et al*^[28].

DISCUSSION

In recent years, there has been an increasing interest in HCV vaccine approaches that elicit CTL, which recognize and eliminate cells infected with HCV. Unlike antibodies, effective CTL responses can be directed against epitopes

derived from any viral protein, raising the possibility that CTLs can be targeted to regions that are more conserved than the viral envelope. Current vaccine modalities can elicit potent CTL responses against multiple viral epitopes. Indeed, many lines of evidence indicate that cell-mediated immunity plays a major role in restraining HCV infections. Several studies have suggested an association between certain MHC class I and class II alleles in the control of viral replication. Strong HCV-specific CD4⁺ and CD8⁺ T cell responses against multiple viral epitopes have been associated with clearance of HCV during acute infection^[1,15,53-60], and thought to be important contributors to protective immunity^[58,61,62]. A typical example of replication control by CTL was recently presented for HIV, showing antibody-mediated depletion of CD8⁺ cells in infected macaques, which resulted in dramatically increased virus loads in both acute and chronic infections^[63-65]. However, despite the presence of specific CD8⁺ CTL responses, more than 80% of individuals develop a persistent HCV infection. Although there is increasing evidence for the importance of HCV-specific T cell responses in the resolution of HCV infection, reasons for the failure of the immune system to eradicate the virus are less clear^[66]. Functional impairment of the antigen-specific CTL responses has been observed by several investigators and is thought to be possible reasons for viral persistence despite measurable T cell responses in HCV^[66-69]. Under normal circumstances CD8⁺ T-cells contribute to the control of viral infections by recognizing peptides of viral proteins presented by MHC class I molecules on infected cells. If HCV peptides are presented to the immune system, why does the virus persist? One potential explanation for this phenomenon is that HCV seems to accumulate mutations in both its structural and NS proteins^[36,70], and escape mutants may emerge under the presence of immune selection pressure exerted by CTLs against wild-type virus. Despite the importance of the CTL epitope viral mutation for immune evasion, in HCV infection many highly targeted epitopes have a low mutation frequency. Epitopes such as HLA-A2 restricted NS3 1073-1081 are consistently targeted by CD8⁺ T cells, but amino acid mutations facilitating immune evasion are rarely observed^[16,71]. Since the NS3 protein shares both protease and NTPase-dependent helicase functions, it has been proposed that mutations in these epitopes may be lethal to the virus^[72]. Additionally, another study indicates that CTL escape mutations emerging early in infection are not necessarily stable, but are eventually replaced with variants that achieve a balance between immune evasion and fitness for replication^[73].

CTLs contribute to the control of viral infections by recognizing peptides of viral proteins presented by MHC class I molecules on infected cells. Some viruses have developed strategies to evade recognition by CTL and one of these strategies involves antigenic variation in CTL epitopes. The emergence of CD8⁺ escape variants has been demonstrated in numerous other viral infections chronically infecting their host like HBV, HIV, or SIV^[74-78]. In HCV infection, a strong association between viral persistence and the development of escape mutations has

been demonstrated in the chimpanzee model^[4,15,62]. In this study, animals with persistent infections developed mutations in multiple regions of the viral genome encoding known epitopes and were largely confined to the MHC class I restriction element expressed by these animals. Further, such mutations correlated with abrogated CTL function. In addition to studies in acute hepatitis, other sequence variations in epitopes recognized by CD8⁺ CTLs have been identified in humans with chronic HCV infections^[16-20,22]. By focusing on single MHC class I alleles, Tsai *et al.*^[18] observed variant epitope sequences with CTL antagonist activity within an A*02-restricted HCV E1 epitope in two patients who developed chronic infections, whereas Timm *et al.*^[20] described the development of CTL responses against a single HLA-B*08-restricted epitope within the NS3. Furthermore, Ray *et al.*^[22] used the unique approach of comparing the sequences of viruses from 22 humans with chronic hepatitis C with the sequence of the single common virus. The expression of HLA-B*07, HLA-B*35, or HLA-B*37 alleles were found to be linked to the presence of mutations in epitopes presented by these alleles, indicating a likely role for CTL-mediated pressure in driving viral evolution. All these manuscripts constitute a critical mass of evidence for CTL mutations in MHC class I-restricted epitopes of HCV, which may play an important role in evasion of the antiviral CTL response. CTL activities *in vivo* may be impacted by cross-recognition with HCV-related or unrelated epitope sequences found in humans. For example, there exists partial sequence homology between the NS3 1131-1139 and NS4 1585-1593 epitopes and between NS 1073-1081 epitope and influenza-A neuraminidase, a common human pathogen.

Study of viral evolution throughout the course of HCV infection has hence proved extremely difficult in the past. Much effort has therefore recently been directed to the monitoring of HCV evolution. Such analyses allow definitive assessment of changes within the viral genome, which are critical in determining the role of immune selection pressure in viral evolution. Since the high rate of chronicity after acute HCV infection is difficult to explain in the presence of a multi-specific CTL response^[18], we sought to identify mechanisms favoring viral persistence. As noted earlier, we have previously described an immunodominant T-cell epitope restricted by HLA-DR15 in HCV NS3, NS3 358-375, for which epitope variants evolve through immune selection and stimulate not only attenuated levels of proliferation and IL-2 production, but also higher levels of type 2 cytokines^[13,79]. We reasoned that if CD8⁺ CTL exerts selection pressure on the virus, then the frequency of amino acid replacement should be higher in class I MHC restricted epitopes as well, potentially altering the outcome of infection by preventing or delaying clearance of infected hepatocytes by T lymphocytes and thus contribute to persistent HCV infection.

In order to identify escape mutations in a single patient with chronic infection, we monitored the genetic diversity

in a region of the HCV NS3 protein that contains HLA-A*02-restricted CTL epitopes, NS3 1073-1081^[34,54,80], NS3 1131-1139^[81,82], and NS3 1169-1177^[60,83]. Sequence analysis presented extensive variations in this region along with significant substitutions in segments encoding the class I restricted epitopes. Furthermore, results showed that the ratio of nonsynonymous base substitution (which changed the amino acid encoded) to synonymous base substitution (which left encoded amino acids unchanged) in these NS3 epitopes was 10-fold higher than in flanking sequences. This is comparable with our previous observations and consistent with the model for a positive Darwinian selection pressure expected for immune-mediated selection of escape variants at the epitope level^[13,14,21]. Genetic variation is inherent to all RNA viruses but has been best characterized for HIV-1, which is the result of a high number of errors made by the RT enzyme^[84], the absence of an RT proofreading mechanism during replication^[85,86], the fast turnover of virions in HIV infected individuals^[87-89] and selective immunological pressure from the host. Since HCV replication is directed by an error-prone RNA-dependent RNA polymerase encoded by the viral *NS5b* gene, which due to its propensity to introduce mutations into the viral genome, seems to provide the same selective advantage enjoyed by HIV, facilitating preferential expansion of the mutant progeny that potentially evade immune recognition. As a result, the virus population in an infected patient does not consist of a single uniform sequence but rather a distribution of different variants or quasispecies. The generation of new antigenic variants that escape the current immunological attack may lead to a persistent infection that culminates in the development of chronic infections. However, the massive heterogeneity observed in the worldwide epidemic of HIV-1 originated from a rapid viral turnover in HIV infected individuals, and seems to be much less extensive in chronic HCV infected individuals where the initial highly homogeneous virus population changes with much slower kinetics towards a mixed viral population.

Indeed, this process of immune evasion through mutation that characterizes infection with HCV viruses is a substantial barrier to the development of successful vaccines and therapeutic interventions based on manipulation of the T cell response. From this perspective, it is essential to gain a more integrated picture of the controlling influences that underlie the complex relationship between HCV and CD8⁺ T cell immunity. Due to the observed viral evolution in the NS3 region, we hypothesized that the newly discovered variant sequences may resemble mutations capable of escaping from the original CTL response against the wt epitope. For this reason, we examined the relationship between cloned CTL responses and variant viral peptide sequences derived from the three NS3 epitopes. In total, 5 out of the 9 CTL responses studied here were not recognized by specific CTL and another four variant peptides dramatically reduced the cytolytic activity of CTL. Nonetheless, comparison of features of CTL suggested that both

quantitative and qualitative factors may play a role in determining the pressure exerted by individual epitope-specific CTL responses on *in vivo* viral replication. Considering that HLA-A*02 represents the most frequent allele in the Northern American population with a gene frequency of 27.2% in Caucasians, 23.0% in Hispanics, 22% in Natives and 12.3% in African Americans^[90], we assume that, in the absence of reversion, certain variants can be expected to be present at least in some HLA-A*02-negative subjects with chronic infection. Another factor that likely has an important impact on the extent and kinetics of viral escape from epitope-specific CTL responses is the cost of escape to intrinsic viral fitness. Several papers^[91,92] provide examples of high costs to intrinsic viral fitness preventing a lasting impact on overall viral evolution of particular epitopes. If CTL escape constitutes a common and significant means of immune evasion in HCV infection, vaccination strategies should be designed to elicit a response that will have the minimal chance of being escaped after infection. One way in which escape can be reduced is by induction of a T cell response that exerts balanced pressure against multiple viral epitopes (e.g. composed of multiple epitope-specific responses of similar magnitude and efficacy). A vaccine-generated host immune response that attacks the primary viral strain and subsequent mutants that arise during replication would possibly circumvent persistence through elimination or drive viral evolution towards defective mutants with high fitness cost and which lack the ability to infect new host cells or replicate in infected cells.

With respect to cellular immune responses, mutations can have effects other than loss of binding to MHC or TCR molecules. Studies in HLA class I restricted systems have demonstrated that altered peptide ligands (APLs) may antagonize the immune response or lead to antigen-specific anergy not only in CTL responses to HCV^[10,16-18] but also to the inhibition of CTL responses to native antigens in other viral systems^[28,31,32,93,94]. Based on our previous work with the class II restricted epitope NS3 358-375^[13,14], we were interested to know whether class I restricted variant epitopes for NS3 could also act as APLs and thus antagonize CTL function. Indeed, most variant peptides for each of the three CTL epitopes were capable of acting as antagonists and suppressed CTL recognition of wild-type peptide epitopes. For some of the variant peptides, inhibition was detectable at antagonist concentrations as low as 1 nmol/L, which is similar to physiological levels of natural peptides within infected cells according to Christinck *et al.*^[95]. Thus, it is interesting to speculate that escape and antagonism may together serve to blunt the CTL response to multiple HCV epitopes. Ultimately, antagonism may play an important role in the persistence of HCV and other viral infections, where mutant viruses harboring antagonist APL epitopes may aid in the survival of wild-type viruses which otherwise would be recognized and destroyed by CTL. Furthermore, these observations are likely due to TCR

antagonism as opposed to MHC blockade, which is supported by the fact that experiments using wild-type control peptides with high HLA-A*02 binding affinity failed to show inhibition of CTL recognition of targets pulsed with a CTL corresponding wild-type peptide. This represents a different mechanism than that reported earlier by Bertoletti *et al.*^[28]. In terms of the practical implications of this phenomenon, reported antagonism of T lymphocyte activity in a vaccine study is of particular concern because the antagonism was identified in a patient that became infected following vaccination^[96]; antagonism may therefore represent a potential mechanism for vaccine failure and requires further careful consideration.

Overall, our data are correlative and it is important to emphasize that the coexistence of virus encoding wild type and variant epitopes does not prove that such are selected for by *in vivo* CTL responses. In the absence of a convenient animal model for HCV infection, the causal relationship between blunted CTL responses and a variant viral peptide sequence in HCV infection cannot be tested directly^[97,98]. Nonetheless, the presence of variant peptides that are not recognized by or are able to antagonize specific CTL in the same patient is consistent with the notion that CTL pressure on a mutable virus such as HCV can result in the selection of escape or APL variants, similar to proposals by others with respect to HCV^[16,18] and other viral infections^[31,74]. The fact that all variant peptides in the NS3 1073-1081 epitope were able to antagonize two CTL clones specific for the wild-type sequence suggests that immune selection for variants, if it exists, may be very strong. In line with this is the fact that similar results were obtained with variant peptides located in epitopes NS3 1131-1139 and NS3 1169-1177 although clones were differentially susceptible to the inhibitory activity of certain variant peptides. Alternatively, if such variants arise from quasispecies variations present in the initial inoculum, they would need to be maintained without sacrificing viral fitness in a significant way. This raises a question, currently unanswered, as to whether mutation of the HCV genome recapitulates quasispecies diversity within a single patient. To our knowledge this has not been investigated, but the answer would have important ramifications for understanding the immuno-pathogenesis of an HCV infection.

In summary, the findings presented here illuminate the potential mechanisms that underlie observed patterns of mutational immune escape. Analyses of MHC binding data suggest that amino acid substitutions in the bound peptide preferably impact TCR recognition, rather than MHC binding, as a consequence of continuous shifts in antigen topography that exemplify adaptive viral evolution to the individual host environment. In addition, the ability of naturally occurring variant forms to antagonize CTL clones, as suggested within this study, is increasingly recognized in chronic infections of other viruses. In this light, persistence of HCV seems to be facilitated by viral evolution not only enabling the escape from prominent CTL responses but also through antagonistic effects triggered by

viral variants. It can be imagined that various variant peptides, which were found to have similar binding affinities to the MHC, compete against the wild type and therefore help to maintain wild-type virus by lowering the number of wild-type peptides to be recognized by patient CTLs. In any event, simultaneous analysis of the viral nucleotide sequence and the CTL response to multiple CTL epitopes in the same individual is needed to determine the potential contribution of CTL escape variants to HCV persistence. Information on heterogeneity in a single carrier seems very important in understanding immunopathogenic processes that may be influenced by viral genomic changes; such goes beyond a simple paradigm of viral escape from strong and multi-specific CTL responses against various immunodominant epitopes and should be considered as a potential determinant of HCV persistence. However, variants do not seem to accumulate within CTL epitopes but occur in early infection. Other minor species may be present but not detected and/or arise at time points other than those examined. We suggested that HCV escape mutants occurring are transient, but are eventually replaced with variants/or wild type that may seek a balance between avoiding recognition by host immune cells and reducing fitness for replication. Ultimately, viral mutants that escape immune recognition are a formidable challenge to the design of an effective HCV vaccine.

COMMENTS

Background

The mechanisms responsible for high rates of hepatitis C virus (HCV) persistence are unknown, but may involve viral escape through the mutation of epitopes recognized as targets of the immune response. It is thought that by antagonizing T-cell responses to native epitopes, viruses expressing mutant epitopes might aid in the survival of infected cells producing wild-type viruses, which would otherwise be recognized and destroyed by cytotoxic T lymphocytes (CTLs). Although parts of this issue have been examined in chronic HCV infection unresolved questions remain, including whether naturally occurring variants antagonize CTL responses to wild-type epitopes that are found within the same host.

Research frontiers

Variation within a viral epitope can lead to a total or partial loss of functional recognition by CTL. Substitutions occurring at key anchor residues may alter peptide affinity for major histocompatibility complex (MHC) class I molecules and thereby interfere with antigen presentation and effector T-cell mediated clearance of infected cells. Overall, the authors' study showed the way to understanding how interactions between HCV and the host's immune system might lead to viral persistence or effective elimination of HCV.

Innovations and breakthroughs

Mutations in MHC class I-restricted HCV epitopes that affect T-cell receptor recognition by CD8⁺ CTLs have also been correlated with the severity and persistence of HCV infection. The authors examined viral evolution in three immunodominant HLA-A*02-restricted NS3 epitopes in a patient chronically infected with HCV. Results obtained provide convincing evidence of immune selection pressure for all epitopes investigated. Mutations within the epitopes coincided with the decline of CTL responses, and peptide-binding studies suggested a significant impact of the mutation on T cell recognition. Results illustrate allele-specific viral evolution and escape from a dominant CD8⁺ CTL response.

Peer review

The authors have examined the pattern of natural variants within three HLA-A2-restricted NS3 epitopes in one patient with chronic HCV infection at 12, 28 and 63 mo post-infection.

Abstract

AIM: To gain molecular insights into the action of the histone deacetylase inhibitor (HDACI) trichostatin-A (TSA) in pancreatic cancer (PC) cells.

METHODS: Three PC cell lines, BxPC-3, AsPC-1 and CAPAN-1, were treated with various concentrations of TSA for defined periods of time. DNA synthesis was assessed by measuring the incorporation of 5-bromo-2'-deoxyuridine. Gene expression at the level of mRNA was quantified by real-time polymerase chain reaction. Expression and phosphorylation of proteins was monitored by immunoblotting, applying an infrared imaging technology. To study the role of p38 MAP kinase, the specific enzyme inhibitor SB202190 and an inactive control substance, SB202474, were employed.

RESULTS: TSA most efficiently inhibited BrdU incorporation in BxPC-3 cells, while CAPAN-1 cells displayed the lowest and AsPC-1 cells an intermediate sensitivity. The biological response of the cell lines correlated with the increase of histone H3 acetylation after TSA application. In BxPC-3 cells (which are wild-type for *KRAS*), TSA strongly inhibited phosphorylation of ERK 1/2 and AKT.

In contrast, activities of ERK and AKT in AsPC-1 and CAPAN-1 cells (both expressing oncogenic *KRAS*) were not or were only modestly affected by TSA treatment. In all three cell lines, but most pronounced in BxPC-3 cells, TSA exposure induced an activation of the MAP kinase p38. Inhibition of p38 by SB202190 slightly but significantly diminished the antiproliferative effect of TSA in BxPC-3 cells. Interestingly, only BxPC-3 cells responded to TSA treatment by a significant increase of the mRNA levels of *bax*, a pro-apoptotic member of the *BCL* gene family. Finally, in BxPC-3 and AsPC-1 cells, but not in the cell line CAPAN-1, significantly higher levels of the cell cycle inhibitor protein p21^{Waf1} were observed after TSA application.

CONCLUSION: The biological effect of TSA in PC cells correlates with the increase of acetyl-H3, p21^{Waf1}, phospho-p38 and *bax* levels, and the decrease of phospho-ERK 1/2 and phospho-AKT.

Molecular determinants of the antitumor effects of trichostatin A in pancreatic cancer cells. *World J Gastroenterol* 2010; 16(16): 1970-1978 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i16/1970.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i16.1970>

INTRODUCTION

Pancreatic cancer (PC) constitutes the fourth to fifth leading cause of cancer deaths in Western countries. Despite many scientific efforts in recent years, PC still has

the worst survival rate (< 5%) of all common human tumors^[1,2], and therapeutic progress has been very slow. Important reasons for this dissatisfying situation include the lack of markers for early diagnosis, and the limited efficiency of radio- and chemotherapy.

In the development of ductal adenocarcinoma, the most common form of PC, accumulation of somatic gene mutations in pancreatic progenitor cells plays a key role^[3]. For example, oncogenic mutations of the *KRAS* gene are detectable in approximately 90% of pancreatic adenocarcinomas. Other frequent genetic alterations in PC include loss or inactivation of the anti-oncogenes *p53*, *p16/CDKN2A* and *DPC4*^[3].

While the essential contribution of somatic gene mutations is well established, recent studies have implicated epigenetic alterations in pancreatic carcinogenesis as well^[4]. Thus, several genes with tumor suppressor properties, such as *p16/CDKN2A* (if not genetically inactivated)^[5], *p57^{KIP2}/CDKN1C*^[6] and *BNIP3*^[7], were shown to frequently undergo epigenetic promoter silencing by aberrant methylation of CpG islands. Hypomethylation of CpG's, in contrast, has been described for several genes overexpressed in PC, including *claudin4*, *S100A4*, and *prostate stem cell antigen*^[8].

Besides promoter methylation, histone modification by acetylation and further post-translational modifications represents a key principle of epigenetic regulation. Histone acetylation is associated with a repressed chromatin state, and tightly controlled by two classes of enzymes, histone acetyltransferases and histone deacetylases^[9-11]. Inhibitors of histone deacetylases (HDACI) display anti-cancer activities and are, therefore, of growing clinical interest^[12]. With respect to PC, recent experimental studies have suggested that HDACI may efficiently inhibit growth and induce apoptosis even of drug resistant cell lines^[13-15]. Furthermore, a synergistic action with classic cytostatic drugs, such as gemcitabine, has been demonstrated^[16-18]. We have recently shown that HDACI also exert antifibrotic efficiency by inhibiting functions of pancreatic stellate cells^[19]. Since fibrosis is considered a progression factor of PC, this "side effect" might enhance antitumor activities of these drugs.

The molecular targets of HDACI in PC are incompletely characterized. Although expression of cell-cycle inhibitors (e.g. p21^{Waf1}/CDKN1A^[14,17]) and modulation of pro-apoptotic pathways^[13,15,17] have been implicated in HDACI action, the molecular determinants of HDACI efficacy or ineffectiveness are currently unclear. Here, we have chosen three human PC cell lines that differ in their biological sensitivity to the HDACI trichostatin A (TSA) for a comparison of TSA effects at the molecular level. We have focussed on pathways that are considered to be important both for PC cell growth/survival as well as HDACI action. By this approach, we have identified molecular correlates of TSA effectiveness in PC cells.

MATERIALS AND METHODS

Materials

Media and supplements for cell culture were obtained from Biochrom (Berlin, Germany), the 5-bromo-2'-deoxyuridine

(BrdU) labelling and detection enzyme-linked immunosorbent assay kit from Roche Diagnostics (Mannheim, Germany), and SB202190 and SB202474 from Merck Chemicals/Calbiochem (Darmstadt, Germany). TRI reagents and all chemicals used for reverse transcription and TaqmanTM real-time polymerase chain reaction (PCR) were from Applied Biosystems (Foster City, CA, USA). PVDF membrane was supplied by Millipore (Schwalbach, Germany), anti-p21^{Waf1} immunoglobulin (mouse monoclonal) by Becton Dickinson Biosciences Pharmingen (Heidelberg, Germany), the other primary antibodies (all raised in rabbits) by New England BioLabs (Frankfurt, Germany), and Odyssey[®] blocking buffer, stripping buffer and secondary antibodies for immunoblotting by LI-COR (Bad Homburg, Germany). Tissue culture dishes (Corning plasticware), standard laboratory chemicals and TSA were from Sigma-Aldrich (St. Louis, MO, USA). The HDACI was dissolved in ethanol and stored at -20°C as a stock solution (3.3×10^{-3} mol/L).

Cell culture

All cells used in this study represent human pancreatic carcinoma cell lines. CAPAN-1 cells were grown in IMDM supplemented with 17% foetal calf serum (FCS) and 10 mL/L non-essential amino acids (dilution of a $100 \times$ stock solution). BxPC-3 cells were cultured in RPMI with 10% FCS. The culture medium for AsPC-1 cells was DMEM containing 10% FCS. All culture media were supplemented with 10^5 U/L penicillin and 100 mg/L streptomycin. The cell lines were grown at 37°C in a 5% CO₂ humidified atmosphere. When reaching subconfluency, the cells were harvested by trypsinization, and recultured according to the experimental requirements.

Quantification of DNA synthesis

DNA synthesis was assessed by measuring incorporation of BrdU into newly synthesized molecules. Therefore, PC cells growing in 96-well plates were pretreated with drugs as indicated. 24 h after drug application, BrdU labelling was initiated by adding labelling solution at a final concentration of 1×10^{-5} mol/L (in the culture medium). After an overnight incubation, labelling was stopped, and BrdU uptake was measured according to the manufacturer's instructions.

Immunoblotting

Cells were harvested by medium aspiration and addition of boiling lysis buffer^[20] directly to the cell monolayer. Cellular proteins received from equal numbers of cells were separated by SDS-polyacrylamide gel electrophoresis (10%-12% gels, depending on the experimental requirements) and transferred onto PVDF membrane by semi-dry blotting. After blotting, the filters were blocked and processed by incubation with the indicated primary antibody as previously described^[20,21]. The secondary antibody was IRDye[®] 800CW conjugated goat anti-mouse IgG and goat anti-rabbit IgG, respectively. All immunoblots were scanned at a wavelength of 800 nm, using an Odyssey[®]

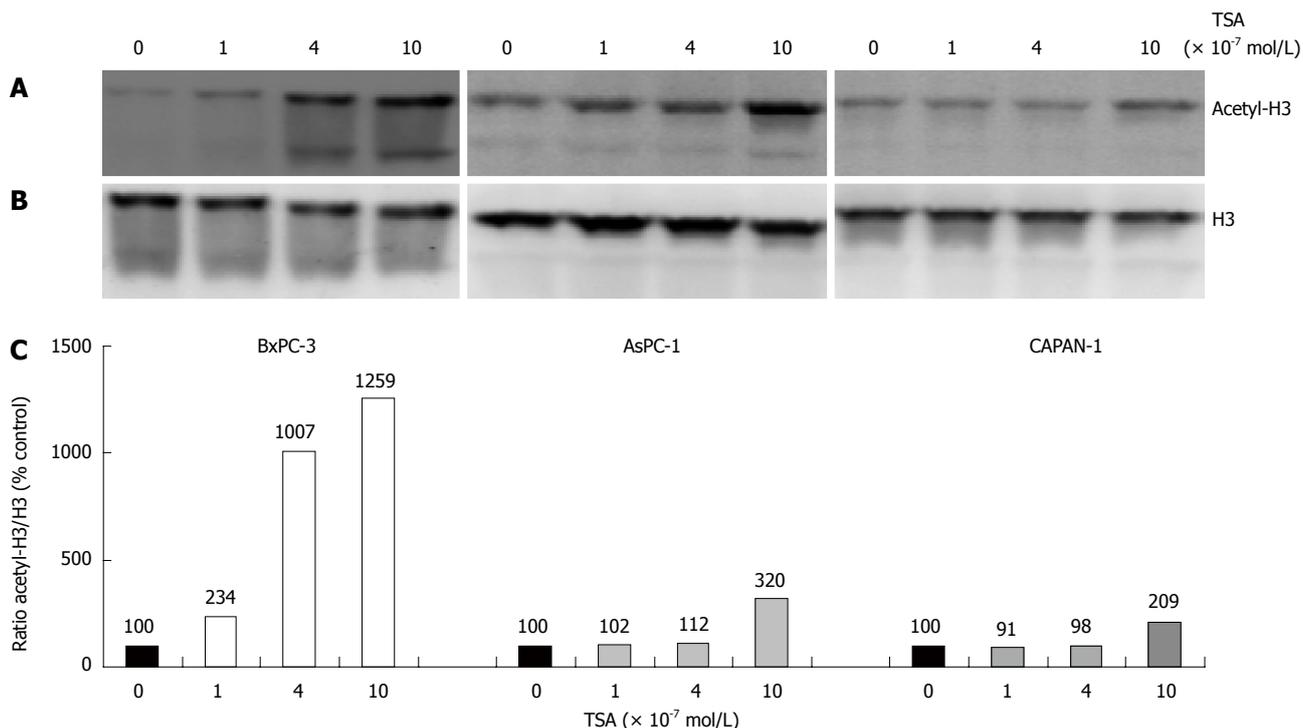

Figure 1 Enhancement of histone H3 acetylation by trichostatin-A (TSA). The indicated pancreatic cancer (PC) cell lines were treated with various concentrations of TSA for 24 h. A: Histone H3 acetylation was analyzed by immunoblotting; B: Reprobing of the blot with an anti-H3 protein-specific antibody revealed no systematic differences of the histone H3 amount among the samples; C: Acetyl-histone H3 levels were further investigated using image analysis software and related to the histone H3 protein level. Therefore, acetyl-histone H3 and H3 protein signal intensities were determined, and the ratio acetyl-histone H3/H3 protein was calculated. A ratio of 100% corresponds to control cells cultured without TSA. The data shown are representative of three independent experiments.

Infrared Imaging System. Signal intensities were quantified by means of the Odyssey[®] software version 3.0. Prior to reprobing with additional primary antibodies, the blots were treated with stripping buffer according to the instructions of the manufacturer.

Quantitative reverse transcriptase-PCR using real-time TaqMan™ technology

The pancreatic cancer cell lines were challenged with TSA as indicated. Afterwards, total RNA was isolated with TRI reagent according to the manufacturer's instructions. The RNA was reverse transcribed into cDNA by means of TaqMan™ Reverse Transcription Reagents and random hexamer priming. Relative quantification of target cDNA levels by real-time PCR was performed in an ABI Prism 7000 sequence detection system (Applied Biosystems) using TaqMan™ Universal PCR Master Mix and the following Assay-on-Demand™ human gene-specific fluorescently labelled TaqMan™ MGB probes: Hs00180269_m1 (bax), Hs00355782_m1 (p21^{Waf1}), and Hs99999905_m1 [glyceraldehyde-3-phosphate dehydrogenase (GAPDH), used as house-keeping control gene]. Following the guidelines of the manufacturer, PCR was performed under the following conditions: 95°C for 10 min, 50 cycles of 15 s at 95°C, 1 min at 60°C. The reactions were run at least in duplicate, and repeated 6 times with independent samples. Relative expression of each mRNA compared with GAPDH was calculated according to the equation $\Delta Ct = Ct_{\text{target}} - Ct_{\text{GAPDH}}$. The relative amount of target mRNA in

control cells and samples treated with drugs as indicated was expressed as $2^{-(\Delta\Delta Ct)}$, where $\Delta\Delta Ct_{\text{treatment}} = \Delta Ct_{\text{sample}} - \Delta Ct_{\text{control}}$.

Statistical analysis

Results are expressed as mean \pm SE for the indicated number of separate cultures per experimental protocol. Statistical significance was analyzed using the indicated statistical test. $P < 0.05$ was considered to be statistically significant.

RESULTS

TSA enhances histone acetylation in PC cell lines

In initial experiments, we compared the effects of TSA on the acetylation of histone H3 in the three different pancreatic cancer cell lines used in this study (Figure 1). In all cell lines, a dose-dependent increase of H3 acetylation was observed, suggesting an inhibition of histone deacetylase activity. The effect of TSA was stronger in BxPC-3 cells than in the other two cell lines, and AsPC-1 cells were somewhat more sensitive to TSA treatment than CAPAN-1 cells. The functional consequences of TSA action were investigated in subsequent experiments.

TSA inhibits DNA synthesis of pancreatic cancer cells

TSA significantly inhibited the incorporation of BrdU into newly synthesized DNA in all cell lines tested, but with remarkably different efficiency (Figure 2): While BxPC-3 cells showed a significant response at a TSA con-

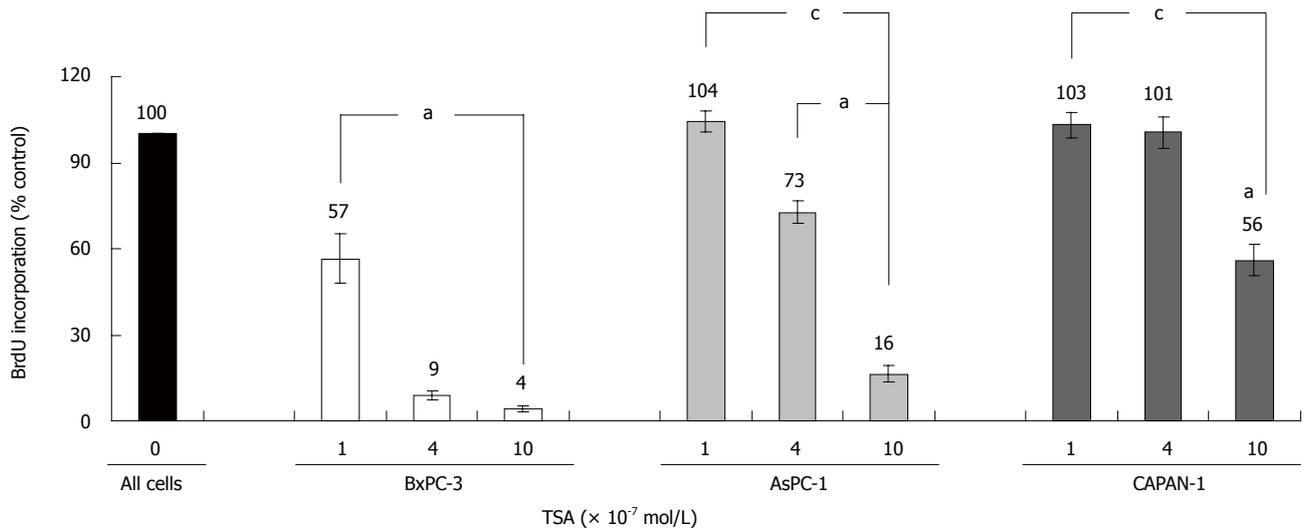

Figure 2 Effects of TSA on the BrdU incorporation of PC cell lines. BxPC-3, AsPC-1 and CAPAN-1 cells were treated with TSA as indicated for 24 h, before DNA synthesis was assessed with the BrdU incorporation assay. 100% BrdU incorporation corresponds to cells cultured without TSA. Data are presented as mean \pm SE ($n = 6$ separate cultures); $^aP < 0.05$ vs control cultures, $^cP < 0.05$ vs BxPC-3 cells (Wilcoxon's rank sum test).

centration of 1×10^{-7} mol/L, 10 times higher doses were required to reduce the DNA synthesis of CAPAN-1 cells. AsPC-1 cells displayed an intermediate sensitivity. Furthermore, at any concentration tested, BrdU incorporation was significantly stronger inhibited in BxPC-3 cells than in the other two cell lines. Action of HDACI has previously been linked to the suppression of cell proliferation and induction of apoptosis^[13-15], and diminished incorporation of BrdU might be an indicator of both. Although a differentiation between these processes was not our main focus, we noticed that at TSA concentrations up to 4×10^{-7} mol/L the rate of cell death did not increase in any cell line over a treatment period of 48 h (data not shown).

Effects of TSA at the level of signal transduction

In the next experiments, the molecular basis of the different TSA responsiveness of our PC cell lines was studied. Therefore, we chose the approach to focus on intracellular proteins that have previously been implicated both in HDACI action and stimulation/inhibition of PC cell growth. As shown in Figure 3, a cell line-specific pattern of the TSA response was observed.

In BxPC-3 cells, but not in the other two cell lines, treatment with TSA at 10×10^{-7} mol/L significantly diminished phosphorylation of the kinases ERK 1 and 2, which are key elements of the Ras-Raf-MEK-ERK pathway^[22] (Figure 3A, panel 1 and 2, and Figure 3B). Furthermore, only in BxPC-3 cells TSA at 10×10^{-7} mol/L almost completely blocked phosphorylation of AKT (Figure 3A, panel 3 and 4, and Figure 3C), which acts downstream of the phosphatidylinositol (PI) 3-kinase^[23]. A further evaluation of the PI 3-kinase/AKT pathway revealed that its best-characterized negative regulator, the PI 3-kinase phosphatase PTEN^[23], was expressed and phosphorylated in all three cell lines in a TSA-independent manner (Figure 3A, panel 5 and 6; quantification data not shown). These data suggest that PTEN was not involved in the mediation of

TSA effects on AKT.

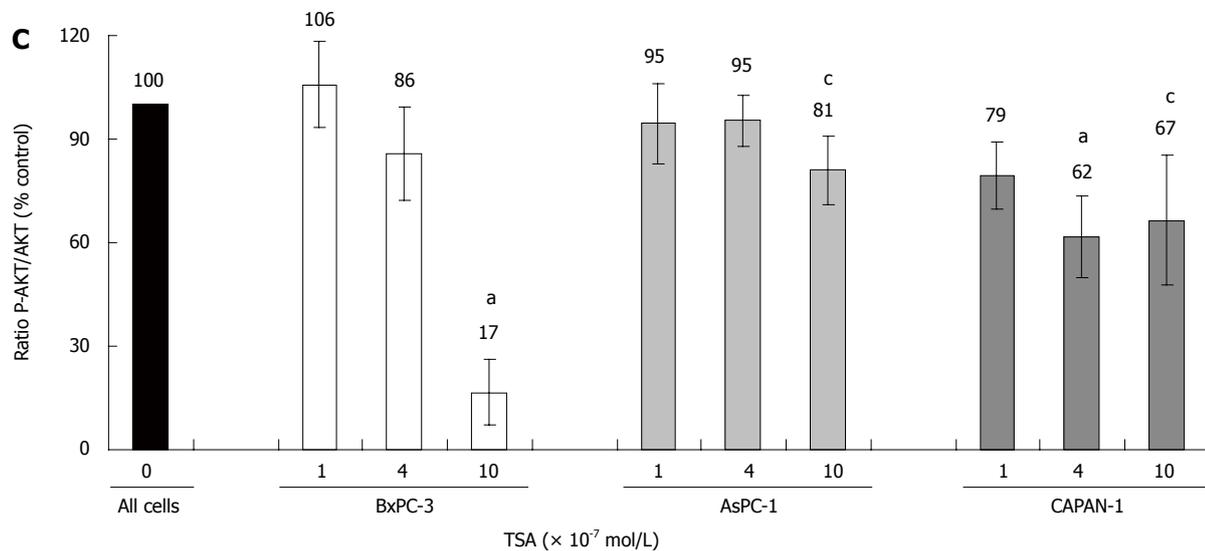

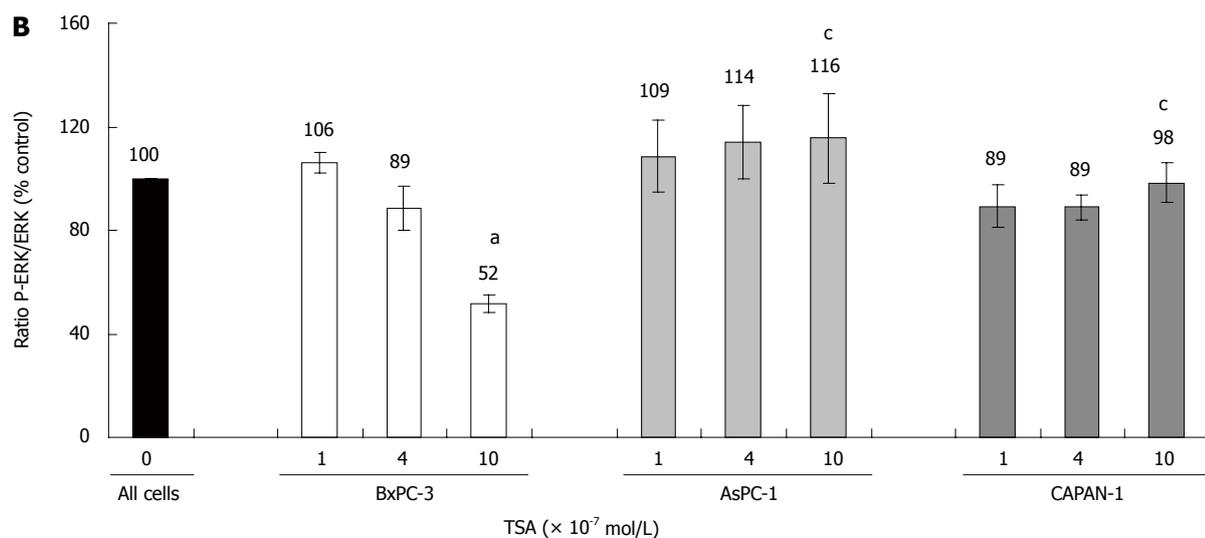

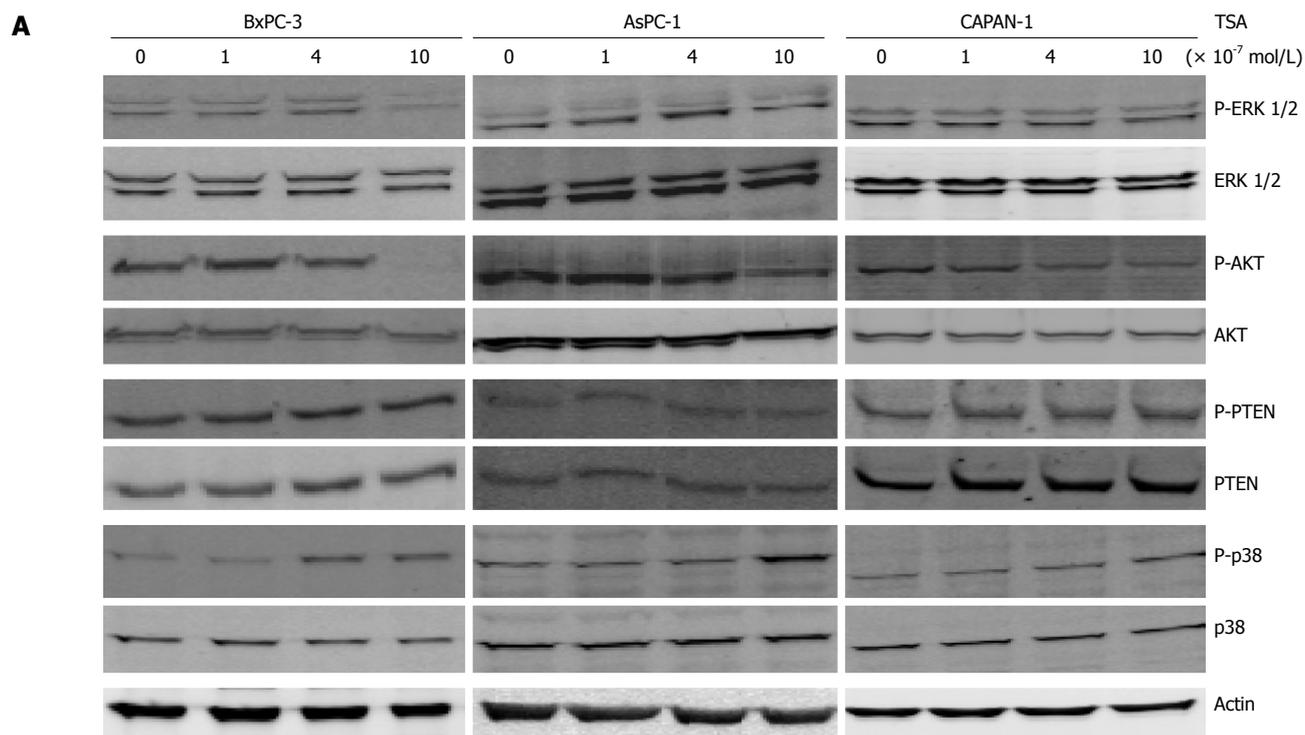

Finally, we studied how TSA treatment affected phosphorylation of the MAP kinase p38, which like ERK plays a profound role in tumorigenesis^[24]. Here, in all three cell lines a dose-dependent enhancement of phosphorylation was observed (Figure 3A, panel 7 and 8, and Figure 3D). The effect was most pronounced in BxPC-3, followed by AsPC-1 and CAPAN-1 cells.

Effects of p38 MAP kinase inhibition on DNA synthesis of PC cells

To study the biological consequences of p38 MAP kinase activation by TSA, the specific inhibitor SB202190 and an inactive control substance, SB202474, were employed. In the absence of TSA, incubation of BxPC-3 cells with the drugs did not significantly affect BrdU incorporation. In the presence of TSA, BrdU incorporation of SB202190-treated BxPC-3 cells exceeded the one of cells exposed to SB202474 (Figure 4). Although the difference was small, it reached statistical significance. In AsPC-1 and CAPAN-1 cells, SB202190 had no effect on the incorporation of BrdU; independent of the presence or absence of TSA (data not shown). The data therefore suggest a (limited) contribution of p38 MAP kinase to the inhibition of DNA synthesis by TSA selectively in BxPC-3 cells; the cell line which had also shown the strongest TSA-dependent increase of p38 MAP kinase phosphorylation (Figure 3D).

Expression of TSA target genes in PC cell lines

Various HDACI target genes identified so far have been linked to the induction of cell cycle arrest or apoptosis. We chose two of the best-studied candidate genes, *BAX* and *p21^{Waf1}* (CDKN1A, Cip1), to compare the effects of TSA on gene expression in the three PC cell lines. *BAX*, a pro-apoptotic member of the *BCL* gene family^[25], and the cell-cycle inhibitor gene *p21^{Waf1}* were found to be ex-

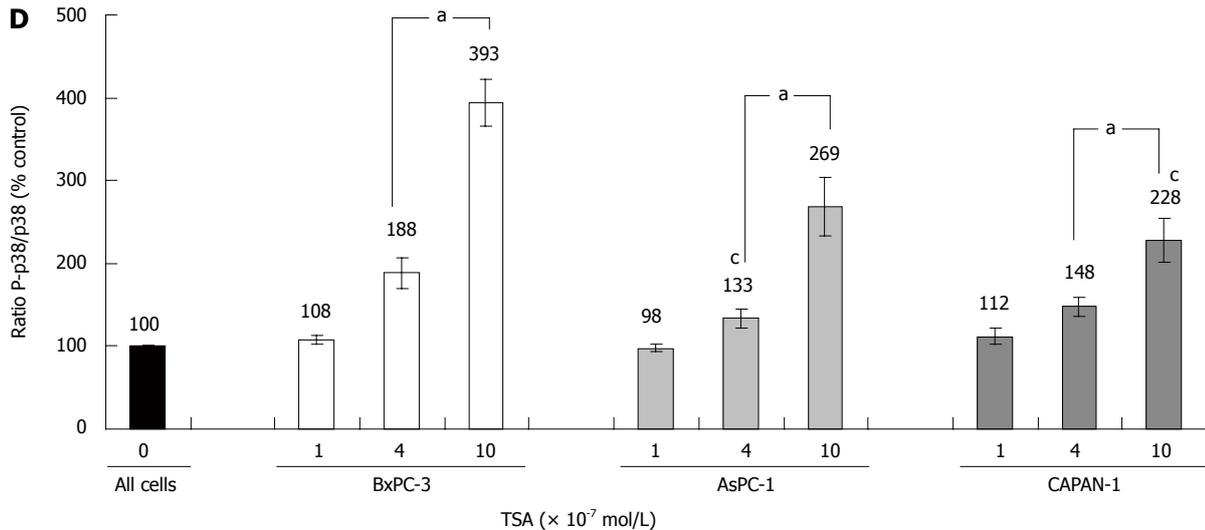

Figure 3 Expression and phosphorylation of signal transduction proteins in TSA-treated PC cell lines. BxPC-3, AsPC-1 and CAPAN-1 cells were treated with TSA at concentrations up to 10×10^{-7} mol/L for 24 h. A: Expression and phosphorylation of the indicated proteins was analyzed by immunoblotting. Phospho-proteins were detected first, followed by a reprobing of the blots with anti-protein specific antibodies. Actin was used as a housekeeping control protein; B-D: Fluorescence signal intensities of phospho (P) proteins and total proteins were quantified using Odyssey[®] software version 3.0. Subsequently, the ratios phospho-ERK/ERK protein (B), phospho-AKT/AKT protein (C) and phospho-p38/p38 protein (D) were determined. A ratio of 100% corresponds to control cells cultured without TSA. Data of 8 independent experiments were used to calculate mean values and SE; ^a $P < 0.05$ vs control cultures, ^c $P < 0.05$ vs BxPC-3 cells (Wilcoxon's rank sum test).

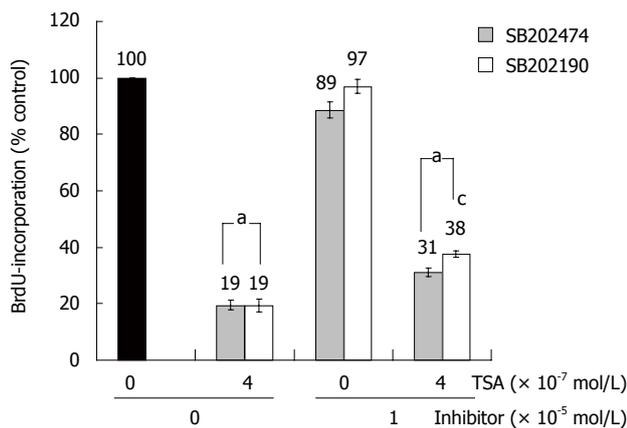

Figure 4 SB202190 diminished inhibition of BrdU incorporation by TSA in BxPC-3 cells. The cells were treated with TSA, SB202190 and SB202474 at the indicated concentrations for 24 h, before DNA synthesis was assessed with the BrdU incorporation assay. 100% BrdU incorporation corresponds to untreated cells. Data are presented as mean \pm SE ($n = 16$ separate cultures); ^a $P < 0.05$ vs control cultures, ^c $P < 0.05$ vs SB202474-treated cells (identical concentration of TSA) (Wilcoxon's rank sum test).

pressed in all cell lines (Figure 5A and B). In TSA-treated BxPC-3 cells, a significant increase of bax mRNA levels was observed, whereas AsPC-1 cells displayed a non-significant tendency towards higher bax mRNA levels, only. Surprisingly, CAPAN-1 cells responded to TSA application by a dose-dependent, significant decrease of bax mRNA expression (Figure 5A).

Treatment of BxPC-3 and AsPC-1 cells with TSA caused a strong increase of p21^{Waf1} mRNA expression, while in CAPAN-1 cells this effect was less pronounced (Figure 5B). Similar results were obtained at the level of p21^{Waf1} protein expression (Figure 5C). Here, in CAPAN-1 cells the TSA effect did not reach statistical significance.

DISCUSSION

The molecular targets of HDACI in PC cells have been studied by several groups in recent years. The results suggest that inhibitors of cell-cycle progression, such as p21^{Waf1}/CDKN1A, and regulators of cell survival/death are involved in the mediation of antiproliferative and pro-apoptotic effects of HDACI^[13-15,17]. The molecular basis of variations in the biological efficiency of HDACI in different PC cells, however, has not been systematically studied so far. It is also largely unknown how precisely the increase of histone acetylation is linked to the biological and molecular effects of HDACI described above. To address these questions, we chose an experimental model system of three PC cell lines that differ significantly in their biological responsiveness to the HDACI trichostatin A. BxPC-3 cells, which displayed the strongest increase of histone H3 acetylation and decrease of DNA synthesis, were the only wild-type *KRAS* cells in this study. Interestingly, only BxPC-3 cells also showed a significant inhibition of ERK 1/2 and AKT phosphorylation in response to TSA treatment. Both ERK 1/2 (through Raf-1 and MEK) and AKT (through PI 3-kinase) are downstream of *KRAS*^[26]. We therefore hypothesize that oncogenic *KRAS* mutations may reduce, but not abolish, TSA efficiency by preventing an inhibition of AKT and ERK 1/2 signalling.

Although BxPC-3 cells were most sensitive to TSA treatment, DNA synthesis of CAPAN-1 and AsPC-1 cells could also be reduced by the drug. In CAPAN-1 cells, however, a significant effect was achieved at the high TSA concentration of 1×10^{-6} mol/L only. Searching for further molecular explanations of these phenomena, we found that CAPAN-1 cells showed the weakest increase of acetyl-histone H3, p21^{Waf1} and phospho-p38 levels. Furthermore, an unexpected decrease of bax mRNA expres-

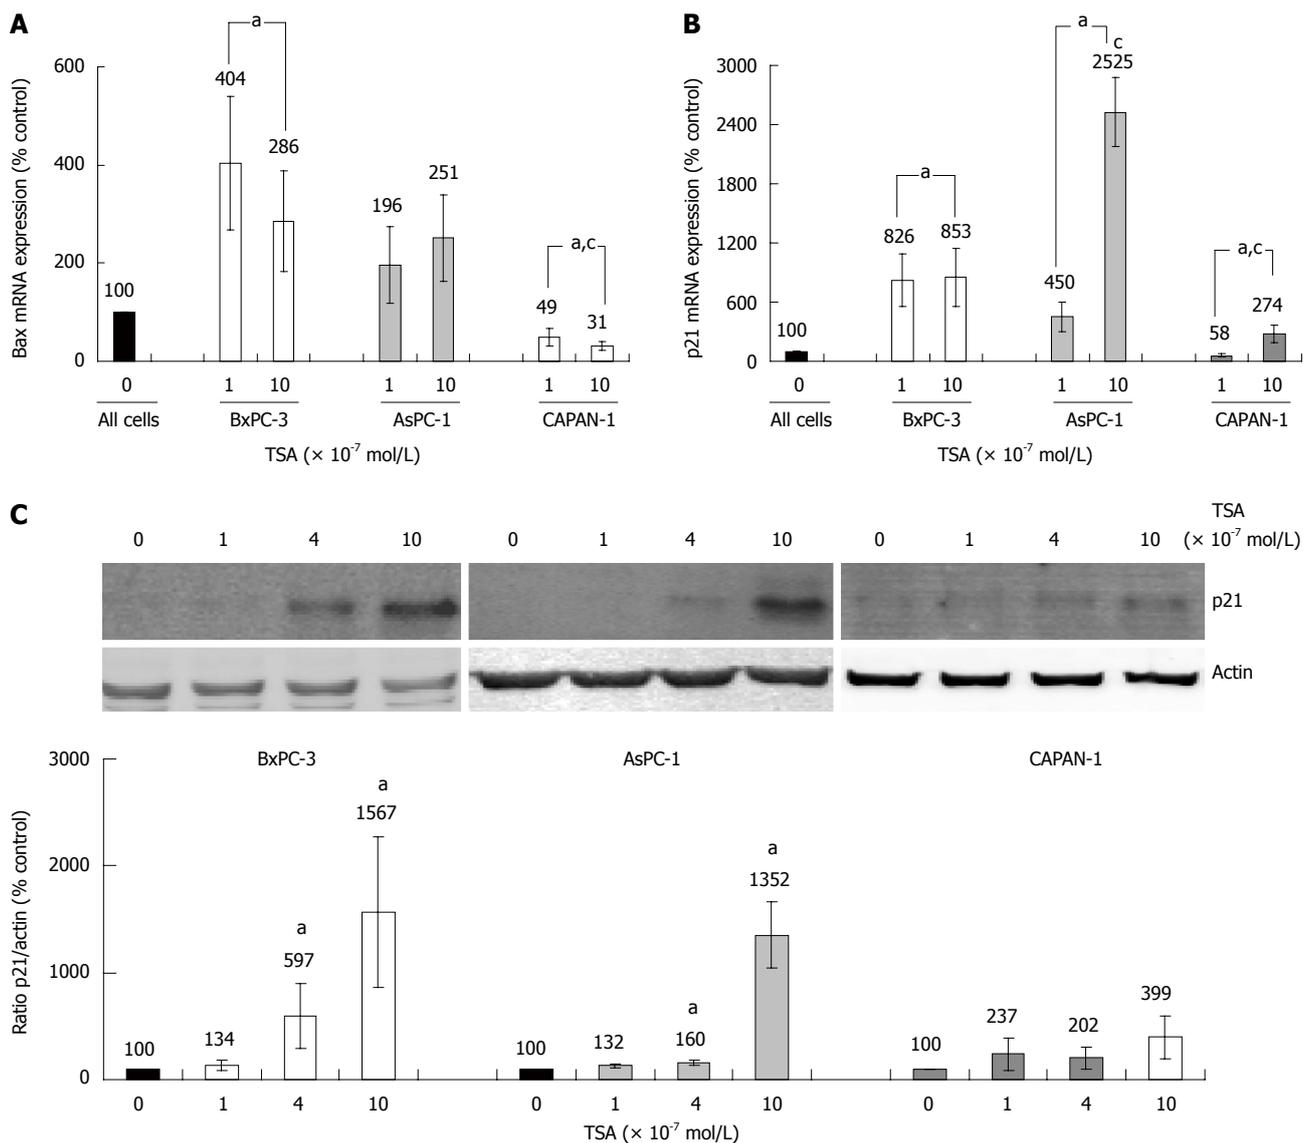

Figure 5 Effects of TSA on BAX and p21^{Waf1} expression in PC cell lines. A, B: The cell lines were incubated with TSA for 8 h as indicated. The mRNA expression of Bax (A), p21^{Waf1} (B) and the housekeeping gene GAPDH (A and B) was analyzed by real time PCR, and relative amounts of target mRNA were determined. 100% mRNA expression of each gene corresponds to cells cultured without TSA. Data of ≥ 6 independent experiments were used to calculate mean values and SE; ^a $P < 0.05$ vs control cultures, ^c $P < 0.05$ vs BxPC-3 cells (Mann-Whitney test); C: BxPC-3, AsPC-1 and CAPAN-1 cells were treated with TSA at concentrations up to 10×10^{-7} mol/L for 24 h. Expression of the p21^{Waf1} protein and actin (housekeeping control protein) was analyzed by immunoblotting. Fluorescence signal intensities of p21^{Waf1} and actin were quantified, and the ratio p21^{Waf1}/actin was determined. A ratio of 100% corresponds to control cells cultured without TSA. Data of 8 independent experiments were used to calculate mean values and SE; ^a $P < 0.05$ vs control cultures, ^c $P < 0.05$ vs BxPC-3 cells (Wilcoxon's rank sum test).

ssion was observed in these cells.

Taken together, our data suggest that the biological efficiency of TSA in the different PC cell lines correlates with the increase of histone H3 acetylation, p21^{Waf1} expression and p38 MAP kinase phosphorylation, and the decrease of ERK 1/2 and AKT phosphorylation. Using a specific inhibitor of p38, we also obtained evidence for a direct involvement of this kinase in the mediation of the antiproliferative effect of TSA in the cell line BxPC-3. Along these lines, the efficiency of TSA in PC cells might be restricted by antagonistic effects of other factors, such as oncogenic KRAS, on intracellular pathways that are critical for HDAC1 action.

Considering established crosstalks between growth-reg-

ulatory pathways, we hypothesize that the diverse molecular effects of TSA observed in this study are, at least in part, causally related. Specifically, we suggest direct links between modulation of MAP kinase (ERK, p38) signalling by the drug and induction of p21^{Waf1} expression, since activation of p38 and inhibition of ERK phosphorylation have previously been shown to enhance p21^{Waf1} promoter activation in other contexts^[27-29]. Furthermore, AKT has been implicated in functional inactivation of p21^{Waf1} through the phosphorylation of the protein, resulting in its cytoplasmic localization^[30]. While cellular localization of p21^{Waf1} was not investigated in this study, we observed an inverse correlation between p21^{Waf1} expression and AKT activity.

A detailed knowledge of the molecular mechanisms

of TSA action is essential to understand what determines the HDACi sensitivity and resistance of tumors. Our data encourage further studies in the field of pancreatic cancer, where novel therapeutic approaches are particularly needed.

COMMENTS

Background

Pancreatic cancer has the worst prognosis of all common human tumors, indicating an urgent need for novel therapeutic approaches. Histone deacetylase inhibitors, such as trichostatin-A (TSA) or the clinically available drug SAHA, display anti-cancer activities *in vitro* and *in vivo*. They are therefore under experimental investigation for the treatment of different human malignancies. Histone deacetylase inhibitor (HDACi) act as epigenetic regulators by increasing histone acetylation, which is associated with a repressed chromatin state.

Research frontiers

While the immediate targets of HDACi action are clear, the precise molecular links between histone protein acetylation and suppression of cancer cell growth remain to be established. In most types of cancer cells, inhibitors of cell cycle progression and regulators of cell survival/apoptosis are important mediators of HDACi effects. However, a systematic overview of the underlying molecular mechanisms is missing. Thus, it is currently unknown which genes and proteins critically determine the efficacy or ineffectiveness of HDACi in pancreatic cancer (PC) cells.

Innovations and breakthroughs

The results of this study provide molecular insights into HDACi action in pancreatic cancer cells. The data suggest that the biological efficiency of TSA in different PC cell lines, indicated by the inhibition of DNA synthesis, correlates with the increase of histone H3 acetylation, but also both with genetic alterations and specific effects at the level of intracellular signal transfer as well as gene expression. In detail, expression of wild-type *KRAS*, a strong increase of *bax*, $p21^{Waf1}$ and phospho-p38 levels, and a diminished phosphorylation of ERK 1/2 and AKT were found to be associated with a high biological efficiency of the drug. The authors hypothesize that PC cells differ in their biological sensitivity to TSA, since not all tumor cells exhibit the full range of molecular targets required for an effective HDACi action.

Applications

The results of this study open an avenue for the further investigation of the molecular determinants of HDACi action in PC cells. An improved understanding of HDACi effects at the molecular level may ultimately lead to the establishment of markers predicting the HDACi sensitivity or resistance of tumors.

Terminology

Pancreatic cancer is a malignancy of the pancreas with poor prognosis that typically displays the histological features of a ductal adenocarcinoma. HDACi, including trichostatin A, are substances that increase histone acetylation by inhibiting the activity of histone deacetylases. MAP kinases (such as ERK 1/2 and p38), PTEN and AKT are intracellular proteins that are involved in the intracellular transfer of receptor-derived signals regulating e.g. cell growth and survival. $p21^{Waf1}$ belongs to a family of proteins that prevent cells from entering the S-phase of the cell cycle, while *bax* is an inductor of apoptotic cell death.

Peer review

It is an interesting and well written manuscript, and a scientifically sound modest extension of what is known regarding histone deacetylase inhibitors and cancer.

Abstract

AIM: To evaluate the value of the hepatitis B virus (HBV) replication mouse model with regard to several aspects of the study of HBV biology.

METHODS: To evaluate the HBV replication mouse model in detecting the efficacy of anti-HBV agents, the interferon inducer polyinosinic-polytidylin acid (polyIC) and nucleotide analogues adefovir and entecavir were administered to mice injected with wild type pHBV4.1, and the inhibiting effect of these agents on HBV DNA replication was evaluated. To identify the model's value in a replication ability study of HBV drug-resistant mutants and a HBx-minus mutant, telbivudine resistance mutants (rtM204I, ayw subtype), adefovir resistance mutants (rtA181V + rtN236T, ayw subtype) and HBx-minus mutants were injected respectively, and their corresponding HBV DNA replication intermediates in mouse liver were assessed.

RESULTS: Compared with the wild type HBV replication mouse model without antiviral agent treatment, the HBV DNA replication intermediates of the polyIC-treated group were decreased 1-fold; while in the entecavir- and adefovir-treated groups, the levels of HBV DNA replication intermediates were inhibited 13.6-fold and 1.4-fold, respectively. For the mouse models injected with telbivudine resistance mutant, adefovir resistance mutant and HBx-minus mutant, HBV DNA replication intermediates could still be detected, but the levels of HBV DNA replication intermediates of these mutants decreased 4.5-fold, 5.6-fold and 2.9-fold respectively, compared with the mouse model with wild type HBV plasmid.

CONCLUSION: The HBV replication mouse model we established was a useful and convenient tool to detect the efficacy of antiviral agents and to study the replication ability of HBV mutants *in vivo*.

INTRODUCTION

Hepatitis B virus (HBV) is an enveloped hepatotropic DNA virus associated with significant morbidity and mor-

tality. Globally, at least 2 billion people or one third of the world population have been infected with HBV, over 378 million people (or 6% of the world population) are chronic carriers, and approximately 620000 people die each year from acute and chronic sequelae secondary to HBV infection^[1]. As the pathogenic mechanisms of HBV remain to be elucidated, molecular biological studies for HBV are still required. Present options to treat chronic HBV infection are restricted to the use of interferon and nucleoside analogues; interferon was the first drug approved for the treatment of HBV although the response rates were not high and there were some side effects^[2,3]. The recent development of nucleoside analogues to treat HBV infection has accelerated with the characterization of the molecular mechanism of HBV replication. Nucleoside analogues interfere with the viral reverse transcriptase and thus inhibit viral replication^[4]. However, the development of drug resistance is a major limitation to long-term effectiveness of antiviral agents. Therefore, the current treatment is not ideal in clinical studies and it is necessary to develop new anti-HBV therapeutic options for chronic hepatitis B patients^[5]. Understanding the mechanisms of drug resistance mutants is also important for designing new agents and devising strategies to manage and prevent the development of antiviral drug resistance^[6-8].

As the host range of HBV is limited to humans and primates, most *in vivo* studies about the mechanism of HBV replication and HBV-associated liver diseases, and about the selection of anti-HBV drugs, have been performed by using HBV transgenic mice^[9-12]. However, the acquisition of transgenic mice is very time-consuming and laborious, needing expensive microinjection equipment and complicated technologies. It is costly and inconvenient to establish HBV transgenic mice with every mutant^[13]. Thus, the availability of a small model which can be easily established to study the *in vivo* efficacy of new antiviral drugs and mechanisms of HBV virulence would help to develop new options to control HBV replication. In our lab, a simple and convenient immunocompetent mouse model for HBV replication has been established by using a hydrodynamic-based procedure^[14].

As our mouse model is a transient HBV transfection model with viral replication and expression lasting for 10 d and peaking at day 3 and day 4 after transfection, whether this HBV replication mouse model can meet the applicable requirement and be used in studies about HBV is unclear. The present study was performed to identify these issues by utilizing the HBV replication mouse model to evaluate the effect of polyIC and nucleoside analogues on HBV replication and to investigate the replication ability of drug-resistant HBV mutants and an HBx-minus mutant^[15].

MATERIALS AND METHODS

Plasmids

Wild type pHBV4.1 is an HBV replication competent plasmid which contains 1.3 copies of the HBV genome (subtype ayw)^[16,17]; the telbivudine resistance mutant named as pLdT is a plasmid at which the residue rt204

ATG (M, Methionine) is changed into ATT (I, Isoleucine); the adefovir resistance mutant named as pADV2 is a plasmid at which the residue rt181 GCT (A, Alanine) is changed into GTT (V, Valine) and the residue rt236 AAC (N, Asparagine) is changed into ACC (T, Threonine). Both mutants were derived from wild type pHBV4.1 by site-directed mutagenesis (QuikChange mutagenesis kit, Stratagene) according to the manufacturer's instructions and were confirmed by sequencing. The plasmid payw1.2 is a replication competent construct that contains 1.2 copies of the wild type HBV genome (subtype ayw). The HBx-minus mutant payw*7, which contains an ochre termination signal (CAA to UAA) after codon 7 (at codon 8) in the HBx ORF and lacks the expression of HBx, was derived from payw1.2 by site-directed mutagenesis^[18,19].

Animals

Balb/c male mice (6-8 wk old) at specific pathogen-free (SPF) level, weighing 18-20 g, were purchased from the Huaxi Laboratory Animal Center of Sichuan University, China. All mice drank tap water and were fed rat chow *ad libitum* and were kept within a 12 h light-dark cycle at constant temperature and humidity. All mice were cared for in compliance with institutional guidelines. For establishment of the mouse model, the mice were injected with 10 µg HBV plasmid DNA in 2 mL phosphate-buffered saline (PBS) *via* the tail vein within 5-8 s^[20].

Study procedure

To evaluate the HBV replication mouse model in screening the efficacy of antiviral drugs *in vivo*, polyinosinic-polytidylin acid (polyIC) (Sigma USA) and nucleoside analogues adefovir (GlaxoSmithKline) and entecavir (Bristol-Myers Squibb) were administered by injection or oral gavage and their inhibiting efficacies on HBV replication (wild type HBV) were assessed. Twenty-four hours after the HBV replication mouse model was established, 200 µg polyIC in 200 µL PBS was given three times at 24 h intervals, and 200 µL PBS was used as a control. Twenty-four hours after hydrodynamic injection with pHBV4.1 plasmid, the nucleoside analogue-treated groups were administered adefovir by oral gavage at a dose of 1.5 mg/kg per day, and entecavir at a dose of 0.075 mg/kg per day in a medication course lasting 3 d, while the PBS group was used as a control. On the third day, the mice were sacrificed 4-6 h after the oral gavage. For each group there were at least 3 mice in parallel.

To identify the value of the HBV replication mouse model for assessing replication ability of HBV mutant strains, the drug-resistance mutants pLdT (rtM204I, ayw subtype) and pADV2 (rtA181V + rtN236T, ayw subtype) as well as HBx-minus mutant payw*7 were injected respectively. Three days after injection, all mice were sacrificed and samples of liver tissue and blood were collected.

Liver tissue was collected and frozen in liquid nitrogen. Blood samples were processed for collection of serum and stored at -20°C until assayed. The corresponding HBV DNA replication intermediates in liver were assessed as follows.

Detection of hepatitis B surface antigen and hepatitis B e antigen by enzyme-linked immunosorbent assay:

Hepatitis B e antigen (HBeAg) and hepatitis B surface antigen (HBsAg) qualitative analysis was performed with 50 μ L mouse serum by using enzyme-linked immunosorbent assay (ELISA). HBeAg and HBsAg detection kits (Shanghai Shiye Kehua Company, China) were used respectively, according to the manufacturer's instructions, and samples were considered positive at $A_{450} \geq 2.1$.

Detection of HBV DNA replication intermediates by Southern blotting:

The frozen liver tissue was mechanically pulverized in liquid nitrogen and HBV DNA replicative intermediates were isolated as described previously^[21]. One hundred and twenty micrograms of liver tissue powder was lysed in 0.6 mL of 100 mmol/L Tris hydrochloride (pH 8.0) and 2 mL/L NP40. The supernatant was adjusted to 6.75 mmol/L magnesium acetate plus 200 μ g DNaseI/mL, and incubated for 1 h at 37°C. The supernatant was readjusted to 10 mmol/L ethylenediaminetetraacetic acid (EDTA), 8 g/L sodium lauryl sulfate, 100 mmol/L NaCl and 1.6 mg pronase/mL, and was incubated for an additional 1 h at 37°C. The supernatant was extracted twice with phenol/chloroform, precipitated with 0.7 volume of isopropanol, and resuspended in 30 μ L of 10 mmol/L Tris hydrochloride (pH 8.0) and 1 mmol/L EDTA. DNA Southern blotting hybridization analysis was performed with 30 μ L viral replication intermediates, as previously described. Filters were probed with digoxigenin-labeled (Roche Applied Science) HBV ayw genomic DNA to detect HBV sequences. The level of HBV DNA replicative intermediates was calculated by the Quantity One software according to the manufacturer's instructions.

RESULTS

The effect of polyIC on HBV replication

PolyIC is a strong inducer of internal interferon and its efficacy on HBV replication *in vivo* was studied. As shown in Figure 1A and B, the level of HBV DNA replication intermediates in liver tissue of the polyIC-treated group was inhibited by about one-fold, as compared with that of the PBS-treated group. This result suggested that polyIC injection decreased the level of viral replication in the liver.

The effect of nucleoside analogues on HBV replication

To investigate whether the HBV replication mouse model can be used in the selection of anti-HBV agents, we used this model to test the effect of entecavir and adefovir, two of the approved nucleotide analogues for chronic hepatitis B, on HBV replication. Figure 2A and B show the levels of HBV DNA replication intermediates in liver tissue of the mouse model. Compared with the PBS-treated group, the HBV DNA replication intermediate levels in the entecavir-treated group and the adefovir-treated group were inhibited by around 13.6-fold and 1.4-fold, respectively. In contrast to these results, it appeared that both nucleo-

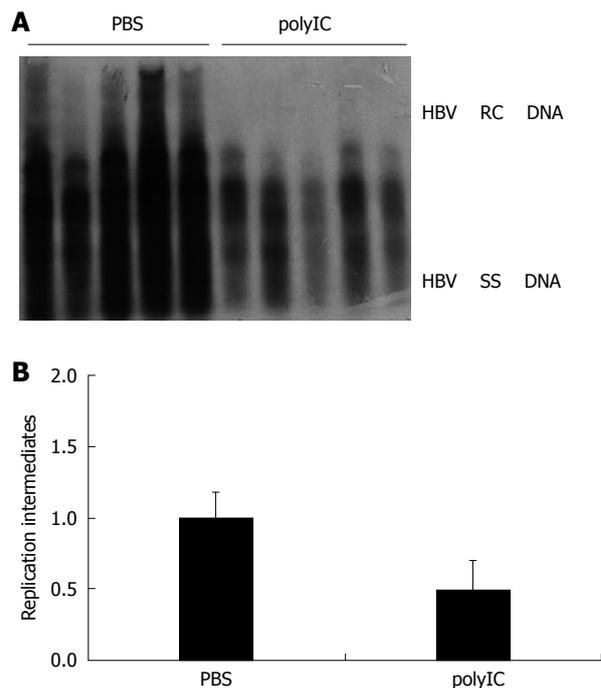

Figure 1 Evaluation of the effect of polyIC on hepatitis B virus (HBV) replication using the HBV replication mouse model. A: The effect of polyIC on HBV DNA replication intermediates in mouse model. After hydrodynamic transfection, mice were treated with phosphate-buffered saline (PBS) (control) or polyIC; B: The relative intensity of HBV DNA replication intermediates of the mouse model for PBS group and polyIC group which inhibited the HBV replication by about one fold. The levels of HBV DNA replication intermediates in PBS-treated group were set to 1, and the relative levels of polyIC-treated group were calculated accordingly.

side analogues did not influence the expression of HBV-associated antigens, as the HBeAg and HBsAg were both positive in the serum of the mouse model after nucleoside analogue treatment for 3 d.

Replication ability of drug-resistant HBV mutants

To investigate whether our HBV replication mouse model can be used in studies about replication ability of drug-resistant HBV mutants, the mouse model was used to study the replication ability of two drug-resistant HBV variants: an adefovir resistance mutant and a telbivudine resistance mutant. The HBV DNA replication ability of both drug-resistant HBV mutants decreased by a large amount compared with the wild type control mouse group. HBV DNA replication in the telbivudine resistance mutant pLdT (rtM204I) was decreased about 4.5-fold and in the adefovir resistance mutant pADV2 (rtA181V + N236T) was decreased about 5.6-fold, compared with the wild type mice (Figure 3A-D). This result suggested that these mutations in the drug-resistant HBV mutants could result in the decline of replication ability. However, the HBsAg and HBeAg were both positive in the serum of the mouse model as compared with the wild type control.

Replication ability of HBx-minus mutant

In order to evaluate whether the HBV replication mouse model can be used in the study of the mechanism by which HBV replicates, we utilized this model to identify

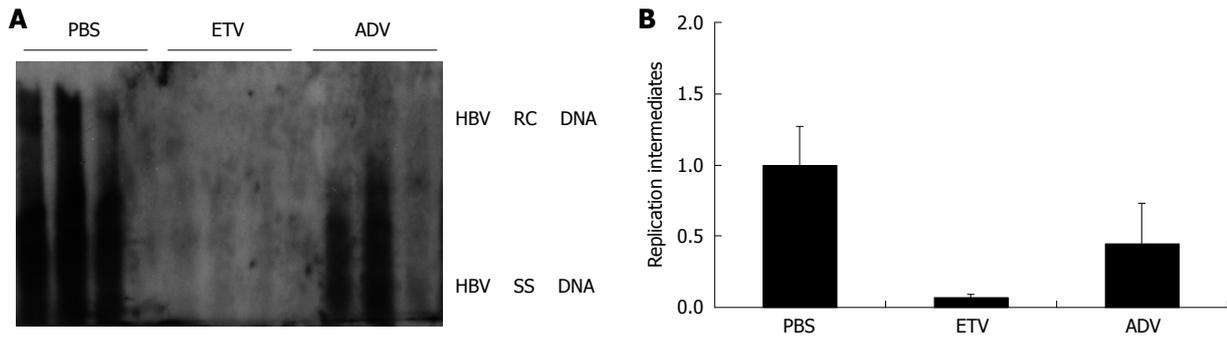

Figure 2 Evaluation of the effect of nucleoside analogues entecavir (ETV) and adefovir (ADV) on HBV replication using the HBV replication mouse model. After hydrodynamic transfection, mice were administered by oral gavage with two different nucleoside analogues: entecavir at a dose of 0.075 mg/kg per day and adefovir at a dose of 1.5 mg/kg per day for 3 d. A: HBV DNA replication intermediates in the mouse model treated with PBS (control), entecavir and adefovir, respectively; B: The relative levels of HBV DNA replication intermediates in the mouse model among different groups treated with PBS (control), entecavir and adefovir, respectively. The levels of HBV DNA replication intermediates in PBS treated group were set to 1, and the relative levels of treated groups were calculated accordingly.

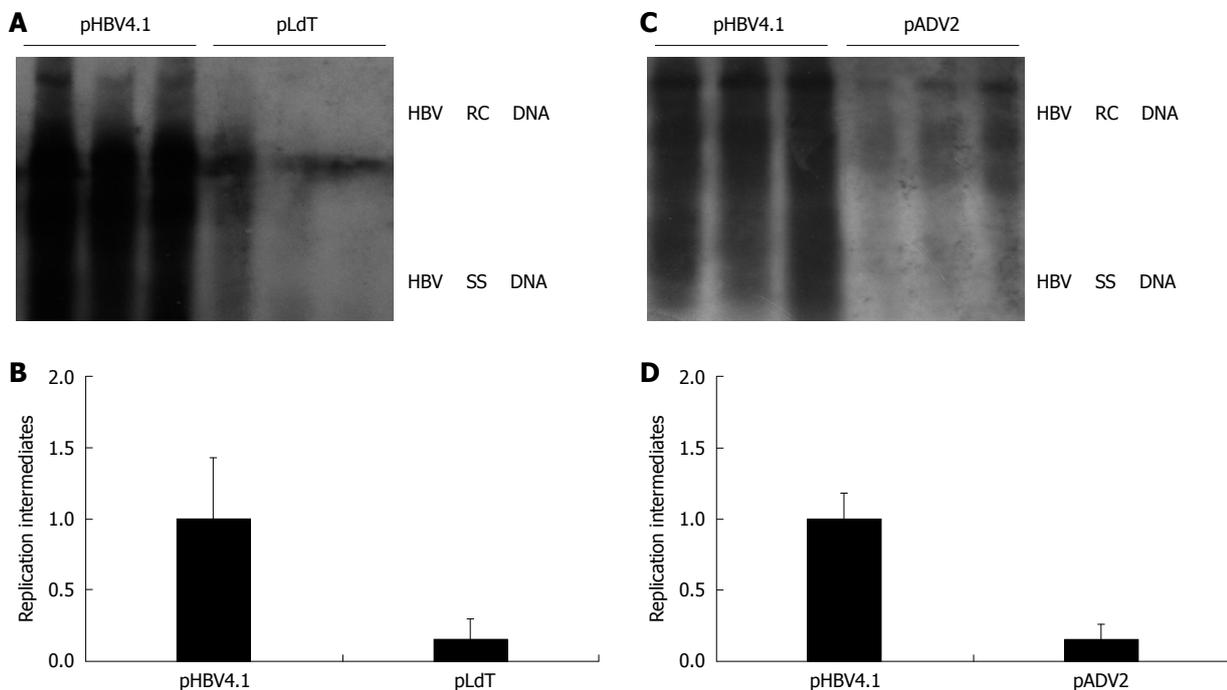

Figure 3 Assessment of HBV replication ability of drug-resistant HBV mutants using the HBV replication mouse model. The levels of HBV DNA replication intermediates in wild type group were set to 1, and the relative levels of mutant groups were calculated accordingly. A, B: The HBV DNA replication intermediates and relative intensity between wild type injected with pHBV4.1 and telbivudine resistance mutant injected with pLdT (rtM204I); C, D: The HBV DNA replication intermediates and relative intensity between wild type injected with pHBV4.1 and adefovir resistance mutant injected with pADV2 (rtA181V + N236T).

the role of the HBx-minus mutant in HBV replication. Plasmids of wild type and HBx-minus mutant were transferred into Balb/c mice, respectively. The levels of HBV DNA replication intermediates from these two constructs were compared (Figure 4A). In both wild type and HBx-minus mutant groups HBV DNA replicated in this mouse model, which suggested that both plasmids had ability to replicate *in vivo*. However, the levels of HBV DNA replication intermediates of the HBx-minus mutant were decreased by nearly 2.9-fold compared with the payw1.2 control in this mouse model (Figure 4B).

DISCUSSION

The development of animal models for HBV infection is

crucial for understanding viral replication, disease pathogenesis, and selecting candidate drugs for the treatment of HBV infection^[22]. However, the narrow range of hosts for the virus has limited the availability of animal models. Chimpanzees are susceptible to HBV infection, but experiments with chimpanzees are limited by cost, availability and ethical considerations. Hepadnaviruses such as ground squirrel hepatitis virus, woodchuck hepatitis virus and duck HBV have offered opportunities to investigate some mechanisms of viral pathogenesis, but these hepadnaviruses have some differences to HBV in terms of genome structure, transcription and replication regulation. Therefore, they cannot serve as a substitute for research into HBV^[23]. Recently, much attention has been paid to HBV transgenic mice, especially HBV

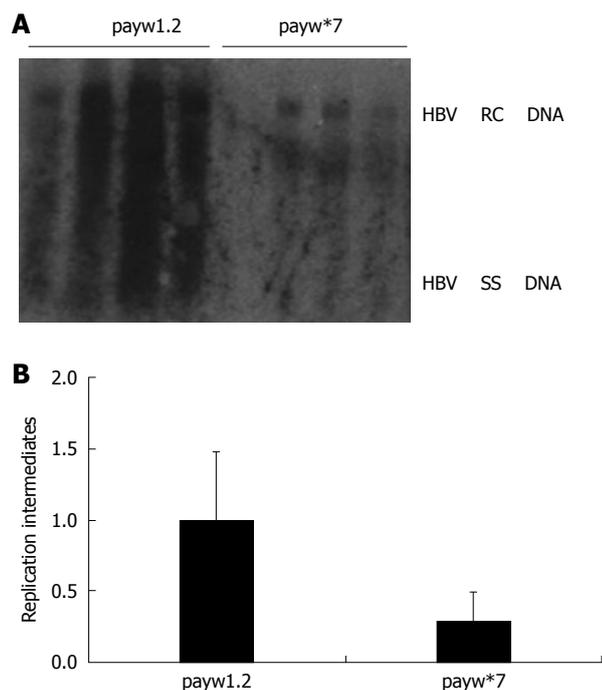

Figure 4 Assessment of HBV replication ability of HBx-minus mutant using the HBV replication mouse model. A: The levels of HBV DNA replication intermediates between wild group injected with payw1.2 and HBx-minus mutant group injected with payw*7; B: The relative intensity of HBV DNA replication intermediates between wild group injected with payw1.2 and HBx-minus mutant group injected with payw*7. The levels of HBV DNA replication intermediates were reported to the levels of the mice injected with payw1.2, which were set at 1.

replication-competent transgenic mice with 1.3 copies of HBV genome. These transgenic mice have provided information on pathogenesis and virus replication and are widely used in studies of HBV. However, a plasmid needs to be transferred into a male pronucleus, then injected embryos are implanted into pseudopregnant females and live births tested for transgene, before transgenic mice can be cultivated; this process requires a great deal of time, cost and labor^[24,25]. Furthermore, in HBV transgenic mice all viral RNA is synthesized from a chromosomally integrated copy of the virus, whereas no cccDNA, the natural template of viral transcription *in vivo*, is produced^[26,27]. By using a hydrodynamic-based procedure, our laboratory has established a rapid and convenient mouse model with a high level of HBV replication. In this study, this mouse model was used to evaluate the inhibitory effect of some anti-HBV agents on HBV replication, the replication ability of HBV-resistant mutants and the effect of HBx on HBV replication; the results shown above suggesting that this model can be used for studies of HBV biology.

The principal treatments for chronic hepatitis B include the use of interferon and nucleoside analogues. PolyIC is a strong inducer of internal α/β interferon which could inhibit the HBV replication. In our study, it was shown that after treating the animal models with polyIC, the level of HBV replication decreased; there were at least 3 mice in parallel for each group to ensure the reliability and accuracy of results. The effect of polyIC injections on HBV replication in these mice was less than that in HBV trans-

genic mice reported previously^[28] but supportive of the suggestion that an inhibitory effect of α/β interferon can be achieved in this mouse model. Similarly, we found that entecavir and adefovir, two of the approved nucleoside analogue treatments for chronic hepatitis B in the clinic, could also inhibit HBV replication in this mouse model. Furthermore, there are different inhibition levels according to the two different drugs as entecavir showed greater effects than adefovir in our study; this corresponds with the clinical report that entecavir has the greatest inhibitory effect on HBV^[29]. These results demonstrate that this animal model can be used to study existing and potential therapeutic approaches directed against HBV.

Long-term treatment of HBV with nucleoside analogues is associated with the emergence of resistant virus strains. The rate of development of lamivudine resistance increases progressively during treatment with rates of 20% to 25% reported annually and approaching more than 80% after 4 to 5 years of therapy^[30,31]. The resistance rate to adefovir is 2% at 2 years and 29% at 5 years. It was previously demonstrated that the HBV mutation resistant to adefovir is the rtA181V + N236T^[32-34], which was associated with a 5 to 10 fold decrease in sensitivity to adefovir and a moderately reduced replication capacity observed in *in vitro* assays^[35-37]. The viral mutant resistant to telbivudine is the rtM204I mutation. It has been reported that the presence of resistant variants is one of the factors that causes severe liver damage and even fulminant liver failure, while the mechanisms remain unclear^[38-40]. Therefore, the biological properties and mechanisms by which HBV-resistant variants cause deteriorated liver function need to be explored, and the effective agents against these variants need to be selected^[41]. If HBV transgenic mice are used, it is very impractical to construct transgenic mice with every mutant. In contrast, it was demonstrated that the properties of HBV-resistant variants could be tested in a convenient HBV replication mouse model. Our results suggest that the mutations in drug-resistant HBV mutants could affect the replication process and result in the decline of replication ability but that they do not affect the transcription process and the expression of HBsAg and HBeAg. This could be because mutations may cause allosteric changes in the catalytic region of polymerase and affect the enzyme function but the transcription of viral messenger RNA which is translated into viral proteins is not affected. Thus, this mouse model of HBV replication will greatly facilitate studies about HBV drug-resistant mutants.

To understand the mechanism of HBV transcription, replication and pathogenesis, it has been necessary to mutate the HBV genome and then survey the transcription, replication and expression levels of viral mutants. In this way, the function of different HBV genome sequences can be understood. However, this research would be very time-consuming, costly and laborious if HBV transgenic mice are used. In the present study, the results were consistent with previous observations in HBV transgenic mice and cell culture as mentioned above, suggesting that this mouse model could be used in functional studies about HBV and that this model of HBV replication will

also provide a useful tool for mechanism studies of HBV.

From these data we can draw the conclusion that this rapid and convenient model of HBV replication affords new opportunities and can be applied widely to many aspects of the study of HBV such as selection of antiviral candidates against HBV, the properties of drug-resistant variants, and the studies of HBV replication mechanisms. Furthermore, the model is reliable and simple for the study of HBV genomic function, and especially for investigating the mechanisms involved in HBV replication through the mutating HBV genome and for selection of new agents against HBV mutants.

ACKNOWLEDGMENTS

We are grateful to Alan McLachlan (The Scripps Research Institute, La Jolla, CA, USA) for plasmid pHBV4.1.

COMMENTS

Background

More than 378 million people are chronic carriers of hepatitis B virus (HBV), and approximately 620 000 people die each year related to HBV infection. The lack of convenient and reliable animal models has hindered progress in HBV research. Recently, the authors have established a simple HBV replication mouse model using hydrodynamic tail vein injection of HBV replication competent plasmid (pHBV4.1) into Balb/c mice.

Research frontiers

An HBV mouse model established by using a hydrodynamic *in vivo* transfection method is useful and convenient. Chronic HBV mouse models have been established by using immunodeficient mice. With the progress of tissue engineering and transgenic technology, some liver cell humanized transgenic mice for studying human HBV have also been constructed.

Innovations and breakthroughs

In this study using an HBV replication model, the authors found that the *in vivo* ability of HBV DNA replication of drug-resistant HBV mutants decreased greatly, while the HBsAg and HbeAg were both positive in the serum compared with the wild type. It was further discovered that the lack of HBx also decreased the ability of HBV DNA replication *in vivo*. The authors demonstrated that the properties of HBV mutant variants could be tested in this convenient HBV replication mouse model without constructing transgenic mice.

Applications

The HBV replication mouse model established in this study is a rapid and convenient tool to detect the efficacy of antiviral agents and to study the replication ability of HBV mutants *in vivo*.

Peer review

The work done by Gao *et al* has a great value and the studied issue is applicable. It includes HBV gene expression and replication by HBV plasmids, which were delivered to the mouse liver by hydrodynamic injection. Development of methods that allow an efficient expression of exogenous genes in animals would provide tools for gene function studies, treatment of diseases and for obtaining gene products.

METHODS: Two hundred and ninety-eight patients with advanced esophageal cancer underwent esophagectomy between 1997 and 2006. One hundred and ninety patients (63.8%) were treated with neoadjuvant CRT prior to resection. A total of 986 metastatic LNs were examined. Survival of the patients was analyzed according to intra- and extra-capsular LNI.

RESULTS: Five-year survival rate was 22.5% for the entire patient population. Patients with extracapsular LNI had a 5-year survival rate of 16.7%, which was comparable to the 15.8% in patients with infiltrated nodes of the celiac trunk (pM1lymph). In contrast to patients treated with surgery alone, neoadjuvant therapy resulted in significantly ($P = 0.001$) more patients with pN0/M0 (51.6% vs 25.0%). In 17.6% of the patients with surgery alone vs 16.8% with neoadjuvant CRT, extracapsular LNI was detected. Neoadjuvant therapy does not reduce the occurrence of extracapsular LNI.

CONCLUSION: Extracapsular LNI is an independent negative prognostic factor not influenced by neoadjuvant CRT. In a revised staging system for esophageal cancer, extracapsular LNI should be considered.

Abstract

AIM: To assess the effects of neoadjuvant chemoradiotherapy (CRT) on the presence of extracapsular lymph node involvement (LNI) and its prognostic value in patients with resected esophageal cancer.

2010; 16(16): 1986-1992 Available from: URL: <http://www.wjg-net.com/1007-9327/full/v16/i16/1986.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i16.1986>

INTRODUCTION

Surgery remains the treatment of choice for most localized esophageal cancers. However, despite complete tumor resection and extensive lymphadenectomy, systemic and local recurrence is common, and the 5-year survival rate is 15%-39%^[1]. There is increasing evidence to include combined neoadjuvant chemoradiotherapy (CRT) as an alternative to surgical resection alone, to improve survival for locoregional esophageal cancer. The aim of combining neoadjuvant chemotherapy and radiotherapy is to reduce the tumor size and maximize local control. A meta-analysis from GebSKI *et al*^[2] that included data from 10 neoadjuvant CRT trials of 1209 patients has shown an absolute overall survival benefit of 13% when compared with surgery alone. This result prompted some investigators to consider neoadjuvant treatment as the standard of care in esophageal cancer^[3].

Regarding prognostic factors for esophageal cancer treated with neoadjuvant CRT, histomorphological tumor regression and the extent of lymphatic dissemination are among the most important predictors for survival in gastrointestinal malignancies^[4,5]. More recently, attention has been paid to the prognostic value of extracapsular lymph node involvement (LNI) in patients with gastrointestinal malignancies. Extracapsular LNI is the extension of cancer cells through the nodal capsule into the perinodal fatty tissue: a common phenomenon in gastrointestinal cancer patients^[6]. Its presence identifies a subgroup of patients with a significantly worse long-term survival.

However, the effects of neoadjuvant therapy on the presence of extracapsular LNI and its prognostic relevance are unclear because to date, most studies have not included patients undergoing such therapy.

The aim of this study was to assess the prevalence as well as the prognostic impact of extracapsular LNI in patients with resected esophageal cancer who were treated with neoadjuvant CRT.

MATERIALS AND METHODS

Patients

Four hundred and thirty-six patients with esophageal cancer were treated in the Department of Surgery between January 1, 1997 and December 31, 2006. Two hundred and ninety-eight patients had locally advanced tumors with cT3-4. The histological distribution was 155 (52.0%) squamous cell carcinoma and 143 (48%) adenocarcinoma. One hundred and ninety of these patients were treated with neoadjuvant CRT prior to resection. The reasons for primary surgical resection

were exclusion criteria for chemoradiation, such as age, comorbidity, and lack of patient consent. Relevant patient characteristics are summarized in Table 1. Written informed consent was obtained from all patients in this study.

Staging

TNM staging was performed according to the criteria of the International Union Against Cancer^[7]. Clinical staging was based on results from barium swallow examination, endoscopic ultrasound, and computed tomography (CT) of the chest and abdomen (4-mm sections). Endoscopy and endoscopic ultrasound were performed by two experienced examiners for all patients.

Surgical resection and CRT regimen

Surgical treatment of choice was subtotal *en bloc* esophagectomy using a right transthoracic approach including two-field lymphadenectomy of mediastinal and abdominal LNs. The specimens were removed *en bloc* including the LNs. To ensure primary tumor integrity, the LNs were dissected partially in the operating theater and partially by pathologists according to a standardized protocol. The examined LNs were documented according to the sixth edition of the TNM classification^[7]. The median number of examined LNs was 28 (4-74).

Standard reconstruction for patients receiving trans-

thoracic esophagectomy was done by stomach interposition with high intrathoracic esophagogastronomy^{18,91}.

One hundred and ninety patients received preoperative CRT according to a standardized protocol, which is described in detail elsewhere⁵¹. Locally advanced tumors (cT3-4) were included unless documented systemic metastases or bronchoscopically proven invasion of the tracheobronchial tree was present. Patients with cT2 tumors were offered this treatment protocol when CT showed a tumor mass compatible with a T3 category, while endoscopic ultrasound showed complete invasion of the muscularis propria without clear invasion of the adventitia (so-called near T3 categories). Cisplatin (20 mg/m² per day) was administered as a short-term infusion on days 1-5 and 5-fluorouracil (1000 mg/m² per day) as a continuous infusion over 24 h on days 1-5. Radiotherapy was administered by linear accelerators with 10-15-MV photons. Radiotherapy was simulated to encompass the tumor volume with 5-cm cephalo-caudal margins and 2-cm radial margins, and treatment ports were designed to include enlarged regional nodes based on CT evaluation and endoscopic ultrasound. Radiation was delivered in daily fractions of 1.8 Gy with a total dose of 36 Gy using a multiple field technique. Surgical resection was performed 4-5 wk following completion of CRT, after clinical restaging. If there was evidence for tumor progression, patients underwent definitive CRT without surgery.

Histopathology

Histopathological examination of all resected specimens consisted of thorough evaluations of tumor stage, residual tumor (R) category, grading, and number of examined and involved LNs. The specimens were fixed in 5% formaldehyde and embedded in paraffin. The LNs were counted and a series of sections from each node was selected and stained with hematoxylin and eosin, as well as periodic acid-Schiff. All dissected LNs were microscopically analyzed for metastatic disease.

Extracapsular LNI was defined as metastatic cancer extending through the nodal capsule into the perinodal fatty tissue. Examination of the LNs was performed by two experienced pathologists (S.E.B. and U.D.). Deposits of metastatic cancer cells without a recognizable LN were considered as extracapsular LNI, unless these deposits were associated with perineural and/or had vessel involvement. In cases of desmoplastic reactions resulting in difficulty in identifying the preexisting LN capsule, an imaginary line representing the original capsule was drawn to facilitate this interpretation (see also Lagarde *et al*¹¹⁰).

The ratio of the number of involved to examined regional LNs was termed the lymph node ratio. According to the sixth edition of the TNM classification for tumors of the lower esophagus, metastasis in the celiac lymph node group (LNG 9) is classified as M1a, and in other non-regional locations, as M1b¹⁷¹. After neoadjuvant therapy, the pathological assessment is difficult because of potential tumor regression. For this reason, such clas-

sification is identified with the prefix “y” to indicate that it does not have the same reliability as the pTNM classification after surgery alone¹¹¹.

Statistical analysis

Beginning in 1997, data were collected prospectively according to a standardized protocol. Analysis of the data was performed retrospectively. The median, with the lower quartile and upper quartile, was used for descriptive statistics. χ^2 statistics were calculated for factor frequencies, with a significance level of $P < 0.05$.

The median follow-up time for the study patients was calculated using the time between surgical procedure and the end of follow-up for censored data; for deceased patients until December 31, 2007¹⁴. The median follow-up time was 4.1 years (range: 0.5-10.5 years). All living patients had follow-up of > 1 year.

Kaplan-Meier plots were used to describe survival distribution¹²². The log-rank test was used to evaluate survival differences¹³³. For multiple comparisons, the Holm-Sidak method was used. In addition, 95% CI for the different survival curves was calculated. Postoperative mortality was included in the calculation of prognosis. The 30-d postoperative mortality was 3.4%. The multivariate analysis of survival used Cox regression analysis to identify independent prognostic variables. The level of significance was set at $P < 0.05$.

All statistical analyses were performed using SPSS for Windows version 15.0. For graphic presentation of the results, Sigma-Plot version 8.0 was used.

RESULTS

Two hundred and ninety-eight patients with locally advanced esophageal cancer were included in this study. The median age of the patients was 61.0 years (range: 22-82 years). Neoadjuvant CRT was administered to 190 of the 298 patients (63.8%). The demographics and the established prognostic factors for the patients are shown in Tables 1 and 2.

A total of 8376 LNs (median 28; range: 4-74) were resected. All positive LNs ($n = 986$) were reexamined for the presence of extracapsular LNI. Tumor growth beyond the LN capsule was detected in a total of 351 lymph nodes.

Age, sex and differentiation grade were comparable between the patients with and without extracapsular LNI. The number of LNs with extracapsular involvement was significantly ($P < 0.001$) correlated with the number of positive nodes (data not shown). Extracapsular LNI was seen more often when the numbers of resected and identified nodes, the numbers of positive nodes, and the lymph node ratios were higher.

To analyze the effect of neoadjuvant CRT on the prevalence of extracapsular LNI, patients with and without neoadjuvant therapy were compared. 190 patients received neoadjuvant therapy, and 108 underwent surgery alone (Tables 2 and 3).

LNI: Lymph node involvement; Caps (-): Without extracapsular LNI; Caps (+): With extracapsular LNI.

The 5-year survival rate was 22.5% for the entire patient population. LN-negative patients had a 5-year survival rate of 34%. Intracapsular LNI decreased the 5-year survival rate to 20%. Detection of extracapsular LNI resulted in a 5-year survival rate of 7% ($P < 0.001$). The resection plane (R0 resection vs R1/2 resection) also proved to be an independent prognostic parameter ($P < 0.001$) in univariate analysis.

In the group with the neoadjuvant regimen, we observed a decrease in distant metastases (pM1 lymph + pM1 organ). Neoadjuvant therapy also resulted in a significant ($P = 0.001$) increase of patients with pN0/M0 (51.6%), compared with surgery alone (25%) (Table 3). After neoadjuvant therapy, there was also a survival benefit for patients with negative LNs. However, this was not significant compared to surgery alone (Table 2).

Neoadjuvant therapy did not reduce the occurrence of extracapsular LNI. In 19/108 patients (17.6%) with surgery alone vs 32/190 patients (16.8%) with neoadjuvant CRT, extracapsular LNI was detected (Table 3, Figure 1).

All LNs with extracapsular involvement were within the radiation field. We did not detect a difference between patients treated with neoadjuvant CRT and those who were resected primarily.

Univariate and multivariate analysis (Table 4) revealed that pN, pM category, extracapsular LNI, and radicality of the resection plane were all significant prognostic parameters for esophageal cancer.

DISCUSSION

The presence and extent of lymphatic dissemination are among the most important predictors for survival in gastrointestinal malignancies^[14,15]. More recently, attention has been paid to the presence of extracapsular LNI, which identifies a subgroup of patients with significantly worse long-term survival^[16,10,16,17]. For breast cancer,

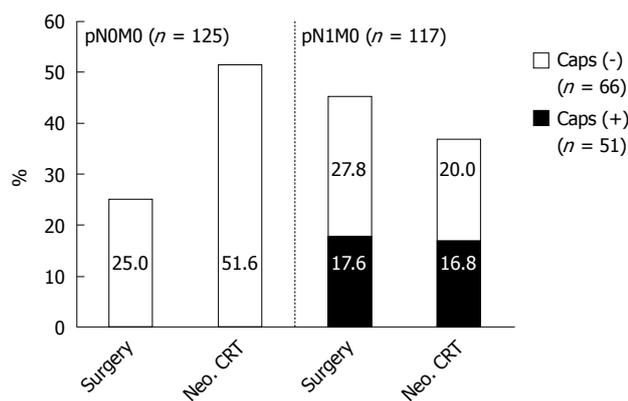

Figure 1 Extent of lymph node (LN) metastases and extracapsular LN involvement (LNI), comparing surgery alone with neoadjuvant chemoradiotherapy (CRT) and surgery. pN0/M0: Neoadjuvant CRT resulted in an increase of patients with pN0/M0 compared to surgery alone ($P = 0.001$); pN1/M0: Neoadjuvant CRT did not reduce extracapsular LNI. Caps (-): Without extracapsular LNI; Caps (+): With extracapsular LNI; Neo.: Neoadjuvant.

extracapsular spread is such an important factor that it has been appended to the TNM classification as a specific subcategory^[18].

In a recently published systematic review on the significance of extracapsular LNI in gastrointestinal malignancies, Wind and coauthors have identified seven papers that discuss the impact of extracapsular LNI in esophageal cancer^[6,10,17,19,23]. In general, these studies applied variable inclusion and exclusion criteria with respect to the type and stage of tumors and the use of (neo)adjuvant therapies. Only three studies from Tachikawa *et al.*^[23], Lerut *et al.*^[17], and Lagarde *et al.*^[10] have provided some detailed information on the prognostic value of the number of LNs with extracapsular involvement.

Due to the heterogeneity of the design of the existing studies, the effect of preoperative CRT on the presence and extent of extracapsular LNI is unclear.

In the present study, we demonstrated that extracapsular LNI was an independent prognostic parameter for esophageal cancer. Lerut *et al.*^[17], and Lagarde *et al.*^[10] have analyzed relatively uniform groups of patients with adenocarcinoma of the esophagus and have found a similar result. Also, for patients with squamous cell carcinoma, Tachikawa *et al.*^[23] have concluded that prognosis is significantly worse when extracapsular disease is confirmed. However, Tachikawa *et al.*^[23] analyzed a non-homogeneous cohort of patients with squamous cell carcinoma, treated with surgery and different chemotherapeutic regimens or no adjuvant therapy.

The present study comprised a consecutive series of 298 patients with adenocarcinoma and squamous cell carcinoma of the esophagus. There was a significant correlation between the number of positive nodes resected and the number with extracapsular involvement. The greater the number of positive LNs, the higher the number with extracapsular involvement. These results underline the findings of Lerut *et al.*^[17] and Lagarde *et al.*^[10], that extracapsular LNI is an independent prognostic parameter for esophageal cancer.

pN1 (-): pN1 category without extracapsular LNI; pN1 (+): pN1 category with extracapsular LNI.

To explain the aggressiveness of tumors with extracapsular LNI, investigators have discussed the ability of cancer cells not only to spread into an LN, but also to invade through the node capsule in an immunologically hostile environment^[24,25]. The prognostic relevance of this extracapsular spread is heightened by the fact that patients with only one positive node have significantly worse survival rates if tumor involvement extends beyond the LN capsule^[10]. As a result of this, several authors have proposed designing a new or revised staging system for esophageal cancer that includes the presence and extent of extracapsular LNI as an additional parameter^[15,26]. For breast cancer, the occurrence of extracapsular LNI is such an important factor that it has been added to the TNM classification as a specified subcategory^[18].

There is increasing evidence to support neoadjuvant CRT for treatment of esophageal cancer. A meta-analysis published by GebSKI *et al.*^[2] has shown significant survival benefits from preoperative CRT for patients with esophageal cancer. However, until now, the effects of such a neoadjuvant regimen on the presence of extracapsular LNI in esophageal cancer have not been analyzed.

The present study is believed to be the first, in which a relatively uniform group of patients with esophageal carcinoma was evaluated to determine the extent to which neoadjuvant CRT influences the presence of extracapsular LNI. We compared the data from patients receiving neoadjuvant therapy with those from patients treated with primary esophagectomy. This comparison showed some selection bias. However, although patients who were excluded from neoadjuvant CRT might have been older or have had greater comorbidity, the preoperative staging for both groups was the same.

In accordance with earlier reports from our group, neoadjuvant therapy resulted in a significant increase of patients with pN0/M0 compared to those having surgery alone^[5]. Mariette *et al.*^[27] also recently have reported a

significant decrease of LN metastases after neoadjuvant CRT. Approximately 13% of patients develop tumor progression under neoadjuvant CRT^[5]. To ease comparison between patients treated with surgery alone *vs* those receiving preoperative CRT, patients with progressive disease (i.e. pM1 lymph + pM1 organ) were excluded from our calculations of extracapsular LNI.

Regarding extracapsular LNI, neoadjuvant therapy did not reduce its occurrence. Extracapsular LNI was detected in 19 patients (17.6%) with surgery alone *vs* 32 (16.8%) with neoadjuvant CRT.

This observation demonstrates that extracapsular LNI reflects highly aggressive biological behavior of the primary tumor, which is not influenced by neoadjuvant CRT in a multimodal treatment setting. An issue that remains unresolved is the optimal radiation dosage for neoadjuvant CRT. In a review by Geh *et al*^[28], a dose-response relationship between increasing radiotherapy, 5-FU and cisplatin doses, and pathological complete response (pCR) was reported. In contrast, increasing radiotherapy treatment time and increasing median age reduced the probability of pCR. However, low dosage of radiation reduced the risk of postoperative morbidity and mortality. Our study protocol, with 36 Gy, 5-FU and cisplatin is in the median range of published protocols^[2,28]. The advantage of our current study is that all patients were treated with the same protocol regardless of histological tumor type, so that varying therapies could not affect the results.

Due to lack of evidence, the accuracy of the 6th UICC/TNM classification is suboptimal, especially when the extent of lymphadenectomy and the effects of neoadjuvant therapy are ignored^[7,29]. There is no doubt that the ratio of positive LNs and the extent of extracapsular LNI have a significant impact on prognosis^[10,17,27,30]. Nothing is known about the effects of neoadjuvant therapy on the extent and prognostic role of extracapsular LNI. By clarifying this issue, whether neoadjuvant treatment influences the spread of extracapsular LNI, the request for a revised staging system for esophageal cancer must be supported^[29,31].

Extracapsular LNI identifies a subgroup of esophageal cancer patients with significantly worse long-term survival rates. The present study provides evidence to suggest that neoadjuvant CRT does not influence the occurrence of extracapsular LNI. This hypothesis has to be proven in a real prospective study.

Extracapsular LNI is an independent negative prognostic factor that reflects particularly aggressive biological behavior of tumors and has valuable prognostic potential. Therefore, in a revised staging system for esophageal cancer, extracapsular LNI should be taken into account as a negative prognostic factor.

about the effects of neoadjuvant chemoradiotherapy (CRT) on the presence of extracapsular lymph node involvement (LNI) and its prognostic value in patients with resected esophageal cancer. To clarify this issue might help to set up novel treatment strategies and lead to more individualized therapeutic strategies with better survival.

Research frontiers

In the present study, the authors describe, perhaps for the first time, the impact of neoadjuvant CRT on the presence of LNs with extracapsular tumor spread in esophageal cancer. The study demonstrates that extracapsular LNI is not influenced by neoadjuvant CRT.

Innovations and breakthroughs

The present study is believed to be the first in which a relatively uniform group of patients with esophageal cancer was evaluated to determine the extent to which neoadjuvant CRT influences the presence of extracapsular LNI.

Applications

Detection of extracapsular LNI might identify a subgroup of esophageal cancer patients with significantly worse long-term survival rates, who do not benefit from neoadjuvant CRT.

Terminology

Extracapsular LNI is defined as extension of cancer cells through the nodal capsule into the perinodal fatty tissue.

Peer review

This was an interesting study in a reasonably large population, with a novel aspect of the importance of extracapsular LNI in patients receiving neoadjuvant CRT for esophageal cancer.

Abstract

AIM: To assess and correlate the lipid content of various organs in obese subjects and in persons with a normal body weight.

METHODS: Magnetic resonance spectroscopy and a previously validated gradient echo magnetic resonance imaging method with Dixon's two point technique were used in this study to quantify fat in liver, pancreas as well as kidney.

RESULTS: In 36 volunteers with body mass index (BMI) ranging from 20.0 to 42.9 kg/m², the median fat content of liver, pancreas and kidney was 2.3% (interquartile range: 0.2%-7.8%), 2.7% (1.0%-6.5%) and 0.7% (0.1%-1.4%), respectively. BMI and subcutaneous fat correlated significantly with liver and pancreas fat content. We show for the first time the significant correlation of liver and pancreas fat content in healthy

controls ($r = 0.43$, $P < 0.01$). These observations are related to body weight as measured by BMI and the amount of subcutaneous fat. Kidney fat content is very low and correlates with none of the other fat depots.

CONCLUSION: Renal lipid accumulation, unlike the coupled accumulations of fat in liver and pancreas, is not observed in obese subjects. Unlike suggestions made in previous studies, renal lipid accumulation appears not to be involved in the pathogenesis of renal disease in humans.

INTRODUCTION

Storage of fat within the peritoneal cavity (visceral fat) and within other tissues (ectopic fat) rather than in subcutaneous adipocytes, is accompanied by adverse metabolic and lipotoxic effects^[1,2]. Both visceral fat^[1] and liver fat^[3] are known for secreting numerous atherogenic factors into the blood system, e.g. lipids and inflammatory cytokines, predisposing to cardiovascular diseases, one of which is atherosclerotic renovascular disease (ARVD)^[4,5]. It has been hypothesized that in obesity and metabolic syndrome, ectopic fat causes lipotoxic damage to organs^[4,5], e.g. liver (steatohepatitis and cirrhosis)^[6], pancreas (β -cell

dysfunction)^[7] and lipotoxicity of the kidney^[4].

Whereas liver steatosis has been quantified in dozens of magnetic resonance imaging (MRI) studies, and pancreatic lipomatosis^[8-10] and muscle fattening^[8-11] in some, quantitative documentation of the content of fat in human kidneys *in situ* appears to be lacking entirely. In rats, however, steatosis of the kidney was recently associated with an alteration in renal acidification^[12]. In that study, the fat accumulated in the renal cortex, as shown quantitatively by enzymatic triglyceride measurement and qualitatively by oil red O staining^[12]. This fits the notion that, within the cortex, the proximal tubule is vulnerable to lipid accumulation due to its role in the reabsorption of free fatty acids bearing albumin^[13,14].

The most accurate, and therefore preferable, method for quantifying hepatic fat content is metabolic MRI, i.e. multivoxel magnetic resonance spectroscopy (MRS)^[15-17]. Other MRI methods are less reproducible or have systematic errors. In a previously published comparison of subjects examined by MRS and by a Dixon-based dual-echo breath hold gradient echo method, we found strong correlation between the liver fat content according to both methods and concluded that MRI can be used for quantifying fat content, provided that the small systematic overestimation of fat content at the lower end range is corrected for^[17]. The comparison is now extended to 36 volunteers, varying from lean to obese, with application of the Dixon-based MRI fat quantification method to pancreas and kidney as well as liver. Only the liver was additionally examined by MRS. Our approach was to apply the equation converting the liver MRI fat values to the MRS values, to the pancreas and kidney MRI values. Additional MRS examinations of pancreas and kidney would have made the total MRI examination times too lengthy. Furthermore, reliable MRS of the renal cortex, a thin layer of tissue sandwiched between the peripheral fat and the fatty core of the kidney, is technically not feasible.

High hepatic lipid content is common in obese subjects who are otherwise healthy, i.e. overweight persons not suffering from metabolic disease^[15]. In this study we examined 36 volunteers with a wide range of body mass index (BMI) values, using previously validated MRI methods to quantify the fat content of liver, pancreas as well as kidney. The purpose was to quantify the lipid content of these organs in obese subjects and in persons with a normal body weight. Our hypothesis was that in obese persons the lipid content of liver, pancreas and kidney would be higher than in thin persons. Our comparatively large study was also intended to assess possible relationships between the fat content in different organs.

MATERIALS AND METHODS

Thirty-six adult volunteers were recruited by advertisement to undergo abdominal MRI and liver MRS. These volunteers had a BMI ranging from 20.0 to 42.9 kg/m² with a mean value of 27.5 kg/m² and were average in that they were neither profound exercisers nor sedentary. Eight

out of 36 subjects were obese, i.e. they had BMI values exceeding a value of 30. Two-thirds of the participants were men; the median age was 39 years (range: 22-64 years). Everyone was interviewed to assess the status of his health and cases of any disease, including diabetes, were excluded. All volunteers gave informed consent. The studies were approved by the medical ethics committee.

Magnetic resonance studies

MRI and MRS studies took place in one measurement session, using a 1.5 Tesla whole-body scanner (MAGNETOM Avanto; Siemens Medical Solutions, Erlangen, Germany) equipped with gradients of up to 40 mTm⁻¹ (maximal slew rate = 200 mT m⁻¹/ms) and a six-channel spine array coil. Subjects were in the supine position. In both MRI and MRS a large flex coil placed over the liver was used simultaneously with the spine array coil as receiver. T₁-weighted gradient echo images were recorded to assess the anatomy of liver, kidneys and pancreas.

Dixon's two point MRI technique

Breath-hold T₁-weighted gradient echo MR images, a dual flip angle adaptation of the wide spread gradient-recalled echo MRI method based on Dixon's two point technique^[18], were acquired with 6 mm slice thickness, section gap 0 mm, matrix 256 × 160 and a repetition time (TR) of 155 ms, and TEs of 2.4 ms (OP) and 4.8 ms (IP). Flip angles of 20° and 70° were used to generate intermediate-weighted and T₁-weighted images, respectively. Images were corrected for T₂* decay: $S_{corrected} = S e^{(\tau/T_2^*)}$, where τ is the echo time difference between IP and OP images, and S represents the signal intensity in a defined region of interest (ROI)^[19]. Under these conditions $\tau = 2.4$ ms combined with $T_2^* = 19.44$, calculated from the mean spectral line width of the water peak in human liver measured by MRS in the 36 volunteers (details are given in a next paragraph), gave a correction factor of 1.13 for S_{ip} relative to S_{op}.

The algorithm used for estimating fat content, modified to prevent occasional mix-ups of water and fat signals^[17], consists of: (a) adjustment for T₂* relaxation as described above, (b) calculation of the apparent fat content using the following equation %fat = (S_{ip} - S_{op})/2S_{ip} × 100% (equation 1) for both intermediate- or hydrogen density-weighted, (%fat_{Hwt} at 20° flip angle) and T₁-weighted (%fat_{T1wt} at 70° flip angle) image pairs, (c) if fat_{Hwt} AND %fat_{T1wt} ≤ 20%, then %fat = MIN [%fat_{Hwt}, %fat_{T1wt}], if fat_{Hwt} AND %fat_{T1wt} > 20% and %fat_{Hwt} ≤ %fat_{T1wt}, then %fat = %fat_{Hwt}, otherwise, %fat = 100% - %fat_{Hwt}, where AND is a logical operator, and MIN (*a*, *b*) is a mathematical operator computing the minimum value between *a* and *b*. A T₂* of 19.4 ms for liver tissue was adopted from the results of a previous study^[17] for correcting S_{ip} in the above mentioned MRI algorithm. This value was used for correcting all MRI fat content figures in Table 1.

CSI), point resolved spectroscopy (PRESS) with a repetition time (TR) of 5000 ms and an echo time (TE) of 30 ms, was performed using a field of view of $16 \times 16 \text{ cm}^2$ and a volume of interest of $5 \times 8 \times 4 \text{ cm}^3$ positioned inside the liver (Figure 1C)^[20]. The CSI measurement lasted $16 \times 16 \times 5 = 1280 \text{ s}$ or approximately 21 min. Shimming was automated and water suppression was not applied in order to be able to calculate the fat-water ratio distributions in the liver directly^[17]. At the used TR of 5 s, T_1 saturation of the water and fat signals is negligible, that is $\text{TR} > 5T_1$ ^[21], and at the used TE of 30 ms the correction applied to our data to compensate for the fact that the fat signal has a longer T_2 (78 ms) than water (60 ms) was 12.2%^[22]. In our MRS method respiratory compensation was not applied as this was previously shown not to affect the quality and composition of our liver spectra^[17].

The liver MRS data were co-registered to the MR images in the liver by using the coordinates of the anterior right (AR) and posterior left (PL) at the same height position as regional checkpoints. The kidney and pancreas MRI fat contents were derived from a single slice centered on the organ involved. Figure 1 shows the regions of interest for kidney (a), pancreas and liver tissue (b) and the matching liver MRS spectral map (c) for one of the volunteers examined. In the analysis of kidney data the results for left and right kidney volumes of interest containing medulla and renal column tissue were averaged. MRS measurements of the renal cortex and pancreas were not performed because, apart from measurement time considerations, accurate quantification of small tissue volumes adjacent to the fatty tissue surrounding these organs is impossible.

The thickness of the layer of subcutaneous fat was measured at the two most left and right points on the same MRI slice to obtain a measure of the amount of subcutaneous fat tissue (Figure 1A). A more precise method^[23] was not feasible in our study, as the MRI field of view was often too small to depict the entire abdominal body cross section.

The pancreas measurements were confined to the tail (cauda) because that tended to be easier to depict than caput and corpus (Figure 1B). The difference be-

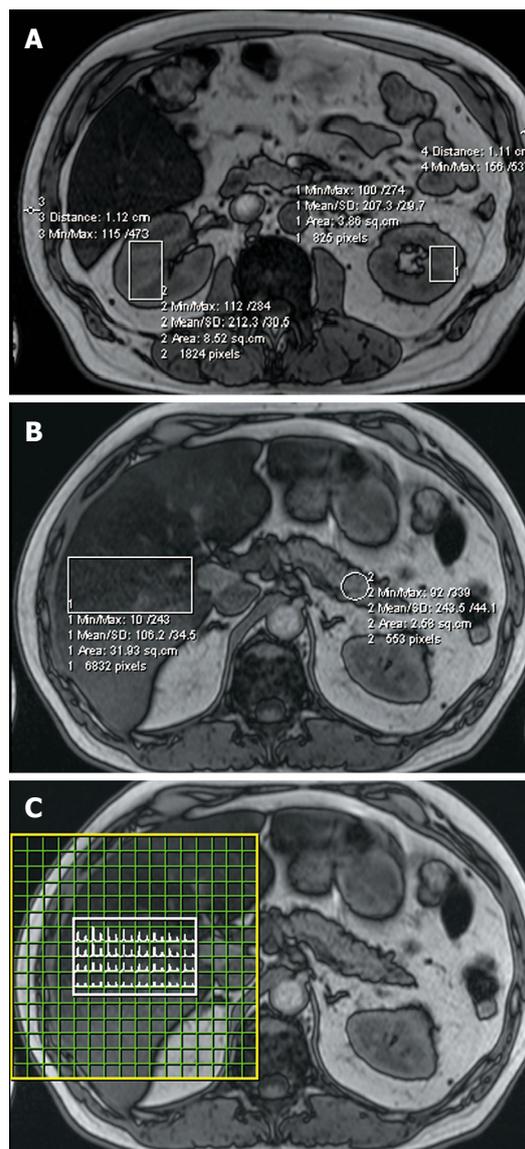

Figure 1 Regions of interest on magnetic resonance imaging (MRI) (OP series with 70° pulse angle and TE = 2.4 ms) and the corresponding magnetic resonance spectroscopy (MRS). A: Kidney and subcutaneous tissue measurement; B: Liver and pancreas; C: Liver MRS spectral map, showing an array of water and fat peaks.

tween the liver fat content according to MRS, the gold standard^[17], and liver fat content according to MRI was used to correct all MRI content figures determined in this study (kidney, liver, pancreas). This approach is reasonable because with the combined use of the flex and spine array as receiver MRI coils, the B1 field in the positions corresponding with the locations of these organs did not show significant differences. In other words, the outcome of phantom experiments gave us reason to expect that equivalent Dixon's two point technique MRI signal intensities in liver, pancreas and kidney should correspond to the same fat content.

Statistical analysis

The distributions of the obtained fat contents were not

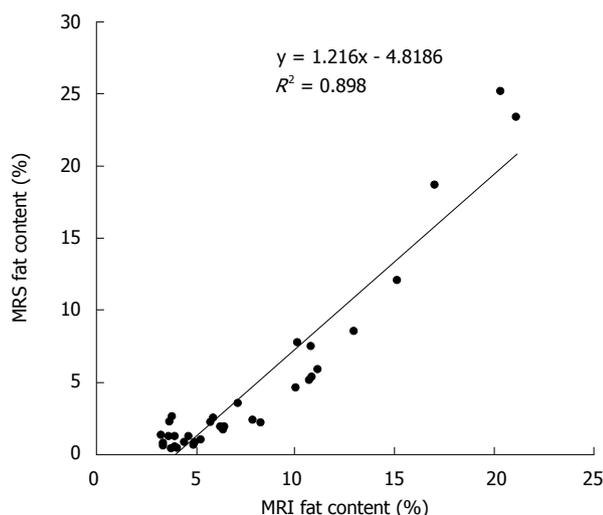

Figure 2 Liver fat content according to MRS plotted against the fat content of the same volume of interest according to MRI.

normal, thus non-parametric correlations were calculated using Spearman's correlation coefficients (with 2-tailed testing of significance).

RESULTS

MRI correction

Mean liver fat content according to MRS was 3.2% lower than that according to MRI (4.4% *vs* 7.6%). The linear correlation between liver fat content according to MRI and MRS is shown in Figure 2 ($r = 0.95$, $P < 0.0001$). The obtained slope ($y = 1.216x - 4.82$) was used to correct all MRI-determined tissue fat contents.

MRI fat measurements

After correction for this systematic overestimation, which is inherent to the MRI method^[13], calculated fat content of liver, pancreas and kidney was 2.3% (interquartile range: 0.2%-7.8%), 2.7% (1.0%-6.5%) and 0.7% (0.1%-1.4%), respectively. For the kidney fat measurements the variance between subjects was lower (interquartile range: 1.8%) than in liver (7.6%) and pancreas (5.5%). Illustrated by Figure 3 is the observation that, compared with the normal body weight subjects, the subgroup of obese subjects tended to have comparatively high fat in the liver (median 4.57% *vs* 1.11%), slight elevation in the pancreas (3.60% *vs* 2.26%) and equally low fat contents in the kidney (1.35 *vs* 0.64). The interquartile ranges for these organs in obese and normal weight persons showed great overlap and were of comparable magnitude, i.e. 2.93-7.70 (0.18-7.76), 2.32-8.88 (0.62-5.45) and 0.61-1.49 (0.10-1.17), respectively. Table 1 shows that BMI, a measure of overall fat deposits in the human body, correlated significantly with the amount of subcutaneous fat ($r = 0.77$, $P < 0.01$), liver fat content ($r = 0.52$, $P < 0.01$) and pancreas fat content ($r = 0.35$, $P < 0.05$). The amount of subcutaneous fat also correlated significantly with liver fat content and pancreas fat content ($r = 0.45$ and $r = 0.44$, respectively;

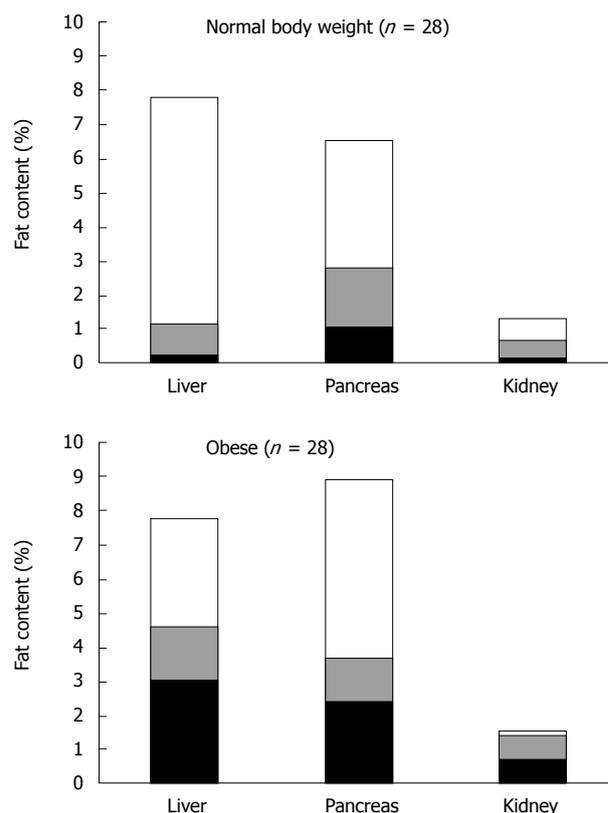

Figure 3 Tissue fat content, median values and interquartile ranges, according to MRI (i.e. after correction by MRS) for subjects with normal body weight and for obese subjects.

$P < 0.01$). Liver and pancreas fat contents were significantly correlated ($r = 0.43$, $P < 0.01$). Kidney fat content was comparatively low, showed little intersubject variation and correlated with none of the other fat depots.

DISCUSSION

These healthy volunteers, who varied in body weight from lean to obese, had kidney fat contents that were comparatively low and showed little variation between subjects. The kidney fat content correlated with none of the other fat depots, indicating that in otherwise healthy subjects obesity does not affect kidney fat content. In other words, renal lipid accumulation, unlike the accumulation of fat in liver and pancreas, is not observed in obese healthy subjects.

In this study, we used a previously validated gradient echo MRI method^[17] for determining the fat content in liver pancreas and kidney. In our liver measurements we compared the MR spectroscopy results in the thirty-six volunteers with the MRI liver content results to refine the correction equation needed to adapt the MRI method for quantitative use. Specifically, we determined the coefficient of correlation between the two-point Dixon-based MRI method and the MRS results in liver and used the result to correct all MRI data for systematic overestimation at the lower end range, a phenomenon also observed by others^[24] and most probably related to Rician noise

distribution-related overestimation of the magnitude images of weak fat signals. Thus we have used our liver data for correcting all MRI data based on the assumption that the MRI method works out the same for liver and other organs (pancreas, kidney). This is the best one can do, considering that (1) MRS examinations of small fat embedded organs are inaccurate; and that (2) it is not an option to collect tissue biopsies from healthy volunteers. Furthermore, as stated in Materials and Methods, control experiments had made sure that with the radiofrequency coils used, the MRI signal intensities in positions corresponding with those of liver, pancreas and kidney corresponded to the same fat contents.

Renal lipotoxicity and its role in the pathogenesis of renal disease are not fully understood^[4,5]. It has been assumed that renal disease progression is promoted by the accumulation of lipids in the kidneys, a phenomenon in which triglyceride-rich lipoproteins, free fatty acids and their metabolites, and albumin-loaded free fatty acids appear to be involved. Quantitative documentation of the content of fat in human kidneys *in situ* appears not to exist, so we cannot compare our MRI-determined kidney fat content figures to literature data. In a bovine growth hormone transgenic mouse line, kidney triglycerides, while lower than those found in liver, recently showed a similar trend of reduced levels as compared with non-transgenic littermate controls showing overall fat mass increases^[25]. Furthermore, in rats, steatosis of the kidney was recently associated with an alteration in renal acidification^[12]. The fat accumulated in the renal cortex, as shown quantitatively by enzymatic triglyceride measurement and qualitatively by oil red O staining^[12]. This fits the notion that, within the cortex, the proximal tubule is vulnerable to lipid accumulation due to its role in the reabsorption of free fatty acids bearing albumin^[13,14]. Our result in humans, with regard to the finding of very low fat content (up to 2%) in the cortex of kidneys of both lean and obese individuals, is not in line with the findings of the above experimental studies.

Our observation of significant correlation between liver and pancreas fat content according to MRI ($r = 0.43$, $P < 0.01$) is also in disagreement with a recent study involving a smaller number of volunteers than we included here (17 *vs* 36)^[10], and with another small study ($n = 15$) in which the existence of significant correlation between liver and pancreas fat content is not mentioned^[8]. The small scale of both earlier studies in humans probably explains their failure to demonstrate the correlation between the fat content in liver and pancreas. The presence of such a correlation does fit a previous demonstration that obese nondiabetic subjects have increased fat in the pancreas^[8]. It is also in line with a notion that lipomatosis of the pancreas reflects early events in the pathogenesis of diabetes^[9], confirming what has been shown in numerous publications dealing with the fattening of the liver.

The significant correlations of BMI with both liver and pancreas fat content in this study are in agreement with a previous report^[8]. Why would obese subjects tend to accumulate fat in liver and pancreas and not

in the kidney, despite the observation that obesity and the metabolic syndrome are involved with initiation of chronic kidney disease^[4]? It seems that due to specific requirements, such as albumin loading needed to facilitate the uptake of fat into kidney tissue, obese but otherwise healthy subjects do not accumulate fat in the kidneys.

In conclusion, this is the first demonstration of the use of an MRI method for determining kidney fat content. Observed for the first time are significantly correlated liver and pancreas fat contents in (otherwise) healthy persons varying in body weight from lean to obese. These observations are related to body weight as measured by BMI and the amount of subcutaneous fat. The amount of fat in the kidney in obese persons is small and not related to the amount of body fat or the fat content of liver and pancreas. We have thus shown that in obesity, the first step in the pathogenesis of renal disease, lipid is not accumulated in the kidney. Therefore, the role of lipid accumulation in the pathogenesis of renal disease, diabetes and metabolic disease in humans should be reconsidered. That is not to say that fat metabolites, rather than the triglyceride levels detected here by MRI, may have profound effects. In future studies we propose to examine patients suffering from the above illnesses in order to validate our current hypothesis that the lipid content is always low in the kidneys.

COMMENTS

Background

Worldwide obesity is on the rise and so are diseases associated with accumulation of fat in various organs.

Research frontiers

This is the first study providing quantitative fat content data for human liver, pancreas and kidney *in situ*.

Innovations and breakthroughs

Shown here for the first time is significant correlation of the liver and pancreas fat contents in persons with body weights varying between thin and obese.

Applications

This study shows that magnetic resonance imaging can be used to study metabolic disease noninvasively. The fat content of multiple organs can thus be quantified and correlated.

Terminology

The fat content of human tissues can be quantified by using magnetic resonance imaging methods to quantify and compare the signals of water and fat. The fat content of human tissues is typically expressed as fat/(water+fat).

Peer review

The study assessed renal lipid accumulation, as well as fat accumulation in the liver and pancreas of a series of volunteers varying in body weight from thin to obese. Results confirmed the correlation between liver and subcutaneous fat content as well as showing the absence of fat storage in the kidney. The latter is the real novel finding of the study.

Abstract

AIM: To investigate and compare efficacy and differences in the nutritional status evaluation of gastroenterology patients by application of two methods: subjective global assessment (SGA) and nutritional risk index (NRI).

METHODS: The investigation was performed on 299 hospitalized patients, aged 18-84 years (average life span 55.57 ± 12.84), with different gastrointe-

stinal pathology, admitted to the Department of Gastroenterohepatology, Clinical and Hospital Center "Bezanijska Kosa" during a period of 180 d. All the patients, after being informed in detail about the study and signing a written consent, underwent nutritional status analysis, which included two different nutritional indices: SGA and NRI, anthropometric parameters, bioelectrical impedance analysis, and biochemical markers, within 24 h of admission.

RESULTS: In our sample of 299 hospitalized patients, global malnutrition prevalence upon admission varied from 45.7% as assessed by the SGA to 63.9% by NRI. Two applied methods required different parameters for an adequate approach: glucose level (5.68 ± 1.06 mmol/L vs 4.83 ± 1.14 mmol/L, $F = 10.63$, $P = 0.001$); body mass index (26.03 ± 4.53 kg/m² vs 18.17 ± 1.52 kg/m², $F = 58.36$, $P < 0.001$); total body water (42.62 ± 7.98 kg vs 36.22 ± 9.32 kg, $F = 7.95$, $P = 0.005$); basal metabolic rate (1625.14 ± 304.91 kcal vs 1344.62 ± 219.08 kcal, $F = 9.06$, $P = 0.003$) were very important for SGA, and lymphocyte count was relevant for NRI: $25.56\% \pm 8.94\%$ vs $21.77\% \pm 10.08\%$, $F = 11.55$, $P = 0.001$. The number of malnourished patients rose with the length of hospital stay according to both nutritional indices. The discriminative function analysis (DFA) delineated the following parameters as important for prediction of nutritional status according to SGA assessment: concentration of albumins, level of proteins, SGA score and body weight. The DFA extracted MAMC, glucose level and NRI scores were variables of importance for the prediction of whether admitted patients would be classified as well or malnourished.

CONCLUSION: SGA showed higher sensitivity to predictor factors. Assessment of nutritional status requires a multidimensional approach, which includes different clinical indices and various nutritional parameters.

INTRODUCTION

Many methods of assessment of nutritional status have been developed to identify malnourished patients or the risk for malnutrition. Most of them, such as subjective global assessment (SGA), Malnutrition Universal Screening Tool, Mini Nutritional Assessment, Nutritional Risk screening-NRS 2002, dealt with multiple components: medical history, dietary intake, amount of weight loss, biochemical variables, and anthropometric measurements^[1-3]. SGA is a clinical assessment index which appeared to be the most widely used and applied in a variety of patient populations, especially in surgical, oncology patients and subjects with chronic renal disease^[1,4-6]. The nutritional risk index (NRI), developed by Veterans Affairs Total Potential Nutrition Cooperative Study Group, is an objective screening nutritional tool and has predictive potential to identify patients who become nutritionally depleted during hospitalization or are at increased risk for disease complications^[7]. There is divided opinion about “gold standard” techniques for determining a patient’s nutritional status: some authors are of the opinion that SGA is more sensitive to any biochemical markers or anthropometric measurements alone and is the best predictor for hospital-related outcome than other nutritional indices^[8-11], while others considers that NRI must reflect real risk for malnutrition independent of severity of disease^[12,13].

In the present study we attempted to investigate differences in baseline nutritional parameters in patients with different digestive diseases and disorders and intended to estimate degrees of concordance between two applied nutritional assessment methods, SGA and NRI. Also, we aimed to evaluate parameters which significantly influence the nutritional state.

MATERIALS AND METHODS

The investigation was performed on 299 hospitalized patients, aged 18-84 years (average life span 55.57 ± 12.84), with different gastrointestinal pathologies, admitted to the Department of Gastroenterohepatology, Clinical and

Hospital Center “Bezanijska Kosa” during a period of 180 d. Patients with the following diagnosis: gastritis/oesophagitis, inflammatory bowel disease, peptic ulcer disease, functional bowel disorders, chronic pancreatitis, decompensate chronic liver disease, compensate chronic liver disease, autoimmune hepatitis, were classified as the benign group, while individuals with gastric, colorectal and pancreatic cancer were classified as the malignant group. The patients included in the study met the following criteria: subjects older than 18 years, metabolic and clinical stability, stable state of consciousness, absence of any kind of morphological or abnormalities of extremities. Exclusion criteria for all subjects were edema, major cardio-respiratory resuscitation, severe hyperhydration in patients with liver cirrhosis, estimated by clinical and ultrasound examination.

Nutritional measurements

All the patients, after being informed in detail about the study and signing a written consent, underwent nutritional status analysis upon admission, using 2 different nutritional indices: SGA and NRI, anthropometric parameters, bioelectrical impedance analysis (BIA), and biochemical markers. All measurements were performed within 24 h of admission. The SGA^[14] is a clinical nutritional index, which involved a standardized questionnaire consisting of dietary intake change, recent body weight changes, gastrointestinal symptoms, functional capacity, and physical signs of malnutrition (loss of subcutaneous fat or muscle mass, oedema, ascites). The standardized questionnaire was performed by a previously trained investigator, gastroenterologist (Filipović BF). Patients were classified into to three different groups: well-nourished (SGA-A), moderately malnourished (SGA-B) and severely malnourished (SGA-C). The NRI^[15] was computed by equation, which included concentration of albumin and the ratio of actual to usual weight: $NRI = (1.519 \times \text{serum albumin (g/L)} + 0.417 \times (\text{present weight/usual weight} \times 100))$. NRI score higher than 100 indicates that the patient is at no risk, a score of 97.5 to 100 indicates low risk, a score of 83.5 to 97.5 indicates medium risk, and a score lower than 83.5 indicates high risk. In order to perform appropriate statistical analysis we merged all malnourished individuals into one group. The usual weight was defined as a stable weight over the last six months before admission. The standard laboratory tests were analyzed: complete blood count, concentration of albumin, total protein, cholesterol, C-reactive protein (CRP) and glucose level. The lymphocyte count was calculated from the total blood cell count, and the differential white blood cell count was obtained by an automated analyzer. Anthropometric variables were determined: body weight and height, triceps skin fold thickness, mid-arm and waist circumferences. Body height was measured to the nearest 0.5 cm with a stadiometer and body weight was measured with mechanical scales. Triceps skin fold thickness was measured with a skin caliper on the posterior upper arm, midway between the acromion and olecranon process. A skin fold

¹ $\chi^2 = 46.24$, DF = 1, $P < 0.001$; ²Cochran's κ index = 0.367; $P < 0.001$. SGA: Subjective global assessment; NRI: Nutritional risk index.

thickness of 5 to 8 mm was determined as borderline fat stores, and of 3 mm or less as severe depletion. Mid-arm circumference was measured with non-stretch measuring tape, midway between the acromion and olecranon of the non-dominant arm, and 15 cm or less was an indicator of severe depletion of muscle mass. Both parameters were used to compute mid-arm muscle circumference (cm) according to the formula, as reported by Frisanchio^[16]: mid-arm circumference (cm) - [triceps skin fold thickness (mm) \times 0.3412], as an estimate of muscle mass or lean tissue stores. Bioelectrical impedance was performed using a single frequency (50 kHz) Bioelectrical Impedance Analyzer, standard platform-based electrode system, model TANI-TA BC-418MA (TANITA CORPORATION, Tokyo, Japan). This analyzer has a Goal Setter function which calculates the amount of fat mass to be lost in order to achieve a selected target. All measurements were performed in the morning within 24 h of admission. Patients had fasted overnight. Patients were told to stand barefoot on the platform-based electrode system with both feet and to grip two electrodes with both hands. The following parameters were by default revealed by the built-in software: body mass index (BMI), basal metabolic rate (BMR), body fat mass (FM), fat free mass (FFM), total muscle mass (MM), total body water (TBW), impedance of whole body (IWH). Resistance was directly measured in Ohms at 50 kHz, 550 mA using BIA. "Impedance/index", which is defined as body height squared divided by resistance, was determined. The length of hospital stay was actual number of hospitalization days and was recorded retrospectively from the Hospital Administration. The study was approved by the Ethical Committee, Clinical and Hospital Center Bežanijska Kosa.

Statistical analysis

Statistical analysis was performed with a commercially available statistical software program (SPSS 13.0, Inc, Chicago IL, US). As well as the usual methods of descriptive statistics (mean, standard deviation- SD), we tested and obtained differences by Student *t* test for independent samples. Entire testing was performed at a 95% probability level. Concordance between the two assessment methods was analyzed by Cochran's κ (k) index. The value of κ index varies from 0 to 1: a value < 0.00

Table 2 Differences in laboratory values of obtained parameters according to the applied nutritional scores (mean \pm SD)

Parameters (serum)	Well	Malnourished	Significance <i>t</i> test
SGA assessment	<i>n</i> = 163	<i>n</i> = 136	
Glucose (mmol/L)	5.68 \pm 1.06	4.83 \pm 1.14	$F = 10.63$, $P = 0.001$
Cholesterol (mmol/L)	5.52 \pm 0.96	3.54 \pm 0.79	$F = 10.61$, $P = 0.001$
C reactive protein (mg/L)	12.42 \pm 16.48	22.08 \pm 18.46	$F = 11.44$, $P = 0.001$

Lymphocyte count (%)	25.56 \pm 8.94	21.77 \pm 10.08	$F = 11.55$, $P = 0.001$
Cholesterol (mmol/L)	5.25 \pm 1.04	4.27 \pm 1.35	$F = 8.27$, $P < 0.05$
C reactive protein (mg/L)	11.25 \pm 8.86	19.97 \pm 20.93	$F = 6.48$, $P < 0.05$

Degrees of freedom = 297; NS: Not significant.

indicates less than chance, 0.00-0.20 poor, 0.21-0.40 fair, 0.41-0.60 moderate, 0.61-0.80 substantial and 0.81-1.00 almost perfect concordance. The predictive potential of analyzed parameters was evaluated by the analysis of discriminant function.

RESULTS

Prevalence

In our sample of 299 hospitalized patients in the gastroenterohepatology department the frequency of any degree of malnutrition at admission varied from 45.7% as assessed by the SGA to 63.9% by NRI (Table 1). No significant differences were obtained in gender distribution of malnutrition (χ^2 for SGA = 1.05, DF = 1, $P > 0.05$; χ^2 for NRI = 2.63, DF = 1, $P > 0.05$). Age did not significantly differ between well-nourished and malnourished patients ($F = 0.53$, DF = 1, $P > 0.05$). A degree of corroboration between the two screening methods for assessment nutritive status, SGA and NRI, was revealed as fair concordance (Table 1).

Nutritional parameters

The mean values and SD of the laboratory, anthropometric characteristics and parameters of bioelectrical impedance analysis according to both applied nutritional methods were shown on Tables 2, 3 and 4. Moreover, the number of malnourished patients rose with the length of hospital stay according to both nutritional indices (Table 5). The discriminative function analysis (DFA) delineated the following parameters as important for prediction of nutritional status according to SGA assessment: concentration of albumins, level of proteins, SGA score and body weight. The DFA extracted MAMC, glucose level and NRI scores as the variables of importance for the prediction to whether admitted patients will be classified as well or malnourished (Table 6). The correctness of the equations was emphasized by the accuracy test computed from the examined group (93.7% and 100%).

DISCUSSION

In this paper, the authors intended to estimate the adequacy of nutritional assessments comparing two of the most often used methods: SGA and NRI. The prevalence of malnutrition in hospitalized patients was reported to vary between 20% and 60%. Higher prevalence has been revealed in the elderly and in patients with malignant diseases^[17-20]. In our investigation the overall prevalence of malnutrition was significantly higher by NRI assessment methods (63.9%) than SGA nutritional score (45.7%). Observed differences in prevalence of malnutrition between indices could be the result of different scoring systems. The problem appears with the classification of the mildly malnourished, who, according to SGA, are adequately classified, while NRI assigns them to the group of moderately malnourished^[21]. Schneider and Hebuterne^[22] claimed that nutritional clinical indices are more sensitive and more accurate compared with a single nutritive parameter. The nutritional parameters used to determine malnutrition varied in different studies. Most authors revealed that levels of serum albumin and cholesterol decreased in malnourished individuals and this result indicated that hypoalbuminemia and low levels of cholesterol could be

a predictor of risk for malnutrition, rather than a parameter for identifying and quantifying nutritional status^[23-26]. However, some authors suggested that serum albumin and body mass index are overestimated factors in the malnutrition assessment^[27]. Our results sustained this opinion, at least considering albumins. In our clinical study cholesterol in lower concentrations correlated with poor nutritional status, according to both applied nutritional indices. Scalfi *et al.*^[28] have claimed that impedance-index was decreased in malnourished patients and several studies have demonstrated that BIA is strictly associated with fat free mass and total body water in healthy subjects and

in patients. Nevertheless, it is still debated whether and for what purpose BIA can be used in the evaluation of body composition changes^[29,33]. Furthermore, our investigation showed that the impedance-index is significantly lower in malnourished patients when compared with other examinees.

Apparently, two applied methods requiring different parameters are needed for an adequate approach: glucose level, body mass index, total body water, basal metabolic rate are very important for SGA, and lymphocyte count is relevant for NRI. Results of several studies have suggested moderate to perfect concordance between the SGA and the NRI or between SGA and the mini nutritional assessment^[13,34]. Some authors reported poor overlapping levels between the same assessment methods^[21]. SGA has some limitations in evaluating nutritional status. First, the SGA is a clinical index which consists of subjective parameters to determine malnutrition. Second, the SGA failed to recognize the group of patients with mild degrees of malnutrition and some cases of malnutrition, particularly early and acute malnutrition. In prospective studies, SGA was demonstrated to be a good predictor of complications related with poor nutritional state^[22,35,36]. On the other hand, the combination of serum albumin and weight loss, as presented in the NRI, would reflect nutritional risk and indicate severity of illness and adverse outcome^[2,12]. According to our results, malnourished patients had a longer hospital stay than well-nourished patients, applying results from both nutritive techniques. Discriminant function analysis has outlined some nutritive variables such as concentrations of serum albumins, level of total protein, SGA score and body weight according to the SGA nutritional assessment method, while different nutritional parameters (MAMC, glucose level and NRI score) by the NRI assessment method have been extracted as predictors of whether individuals will be classified as well or malnourished.

In conclusion, SGA showed higher sensitivity to predictor factors, although the sensitivity of NRI methods was also very high. Assessment of the nutritional status requires a multidimensional approach, which includes different clinical indices and various nutritional parameters.

COMMENTS

Background

Many methods of assessment of nutritional status have been developed to identify malnourished patients or risk for malnutrition. Most of them such as subjective global assessment (SGA), Malnutrition Universal Screening Tool, Mini Nutritional Assessment, Nutritional Risk screening-NRS 2002-dealt with multiple components: medical history, dietary intake, amount of weight loss, biochemical variables, and anthropometric measurements.

Research frontiers

In the authors' investigation overall prevalence of malnutrition was significantly higher by nutritional risk index (NRI) assessment methods (63.9%) than SGA nutritional score (45.7%). The corroboration between the two methods, was, according to Cochran's κ index = 0.367, which could be interpreted as fair concordance.

Innovations and breakthroughs

The discriminative function analysis extracted MAMC, glucose level and NRI scores as the variables of importance for the prediction to whether admitted patients will be classified as well or malnourished. The correctness of the equa-

tions was emphasized by the accuracy test computed from the examined group (93.7% and 100%).

Applications

SGA showed higher sensitivity to predictor factors, although the sensitivity of NRI was also very high. Assessment of the nutritional status requires a multidimensional approach, which includes different clinical indices and various nutritional parameters.

Terminology

The SGA is a clinical nutritional index, which involved a standardized questionnaire consisting of dietary intake change, recent body weight changes, gastrointestinal symptoms, functional capacity, and physical signs of malnutrition (loss of subcutaneous fat or muscle mass, oedema, ascites). The NRI was computed by equation, which included concentration of albumin and the ratio of actual to usual weight: $NRI = [1.519 \times \text{serum albumin (g/L)} + 0.417 \times (\text{present weight/usual weight} \times 100)]$. The bioelectrical impedance analysis is a software based electrode platform variant system for the evaluation of the parameters of nutritional status.

Peer review

The authors have compared the two nutritional indices currently in use-SGA and NRI- for their efficacies in delineating malnutritional cases. The study has been conducted with a large number of patients. The data generated for comparison seems appropriate and suggests the corroboration between two screening methods for assessment of nutritional status.

Abstract

AIM: To investigate the presence of mixed infection and discrepancy between hepatitis C virus (HCV) genotypes in plasma, peripheral blood mononuclear cells (PBMCs), and liver biopsy specimens.

METHODS: From September 2008 up to April 2009, 133 patients with chronic hepatitis C referred to Firouzgar Hospital for initiation of an antiviral therapy were recruited in the study. Five milliliters of peripheral blood was collected from each patient and liver biopsy was performed in those who gave consent or had indications. HCV genotyping was done using INNO-LiPA™ HCV II in serum, PBMCs, and liver biopsy specimens and then confirmed by sequencing of 5'-UTR fragments.

RESULTS: The mean age of patients was 30.3 ± 17.1 years. Multiple transfusion was seen in 124 (93.2%) of

patients. Multiple HCV genotypes were found in 3 (2.3%) of 133 plasma samples, 9 (6.8%) of 133 PBMC samples, and 8 (18.2%) of 44 liver biopsy specimens. It is notable that the different genotypes found in PBMCs were not the same as those found in plasma and liver biopsy specimens.

CONCLUSION: Our study shows that a significant proportion of patients with chronic hepatitis C are affected by multiple HCV genotypes which may not be detectable only in serum of patients.

INTRODUCTION

Hepatitis C virus (HCV) is an enveloped positive-stranded RNA virus of the family Flaviviridae and genus Hepacivirus that causes both acute and chronic hepatitis^[1-3]. HCV is a major health problem affecting 170 million people worldwide^[4]. It is estimated that chronic HCV infection is responsible for approximately 250 000 to 350 000 deaths per year, mainly related to decompensation of cirrhosis, end-stage liver disease, and hepatocellular carcinoma^[5].

Phylogenetic analysis of HCV sequences resulted in a nomenclature that recognizes distinct virus types and subtypes^[6]. Six large groups of viral genotypes^[7-12], in addition to over 70 different subtypes (termed a, b, c, *etc.*) are distributed worldwide^[6,13]. The HCV genotypes should be systematically determined before treatment, as it determines the indication, the duration of treatment, the dose of ribavirin and the virological monitoring procedure^[14].

The HCV is considered as essentially hepatotropic^[15], but virus sequences have also been found in other important extrahepatic sites, including peripheral blood mononuclear cells (PBMCs), the central nervous system, and bone marrow from chronically-infected patients^[16-19].

HCV replicates through a negative-strand intermediary. Although hepatocytes are the primary sites for HCV replication, there is evidence of negative-strand HCV RNA in PBMCs. The HCV genomic sequences present in PBMCs have been found to differ from those found in serum and the liver biopsy specimens^[20-24]. Detection of HCV RNA in extrahepatic reservoirs has important implications for transmission, disease progression, and effective treatment^[25]. Furthermore, the PBMC compartment may be a privileged site for HCV, which is able to reinitiate viral replication after termination of HCV treatment when conditions again become more favorable. Re-infection of HCV after orthotopic liver transplantation has postulated that extrahepatic sites are suitable for HCV replication^[26]. Thus, even if clearance of HCV from hepatocytes is achieved by treatment, re-infection from extrahepatic sites, such as the PBMC compartment, may occur^[27].

The purpose of the present study is to determine the presence and frequency of different HCV genotypes in plasma, PBMC, and liver biopsy specimens of chronically infected patients.

MATERIALS AND METHODS

Patients

In this cross-sectional study, 133 consecutive patients with established chronic hepatitis C referred to Firouzgar Hospital from September 2008 to July 2009 were enrolled. Informed consents were obtained from the patients, and the study was approved by the local ethics committee of GI and Liver Disease Research centre (GILDRC) of Iran University of Medical Sciences.

Inclusion criteria were positive anti-HCV antibodies along with positive plasma HCV RNA. Also none of the included patients had been treated for HCV previously.

Collection and preparation of samples

About 5 mL of peripheral blood were collected from each patient into EDTA-containing vacutainer tubes. Plasma was stored at -70°C until analysis. PBMCs were isolated from EDTA-treated blood by centrifugation over density gradient (Lymphoprep, Oslo, Norway). PBMCs were then washed three times with phosphate-buffered saline (pH = 7.4), counted and stored at -70°C for later detection. Some of the patients who gave consent underwent a liver biopsy for diagnostic purpose. Liver biopsy specimens were di-

vided into 2 portions: one used for histological diagnosis, and the second was submerged into RNALater (Ambion Inc., Austin, TX) and stored at -70°C for HCV genotyping. Samples of serum and PBMCs were collected from all patients on the same day the liver biopsy was performed.

Isolation of RNA from serum, PBMCs, and liver

RNA was extracted from 140 µL of plasma by using the QIAamp Viral RNA Extraction kit (Qiagen GmbH, Hilden, Germany), from a pellet of approximately $3-5 \times 10^6$ PBMCs using the RNA Virus Mini Extraction Kit (Invitex GmbH, Germany), and from approximately 2 mm³ of liver biopsy specimens using the DNA/RNA Virus Mini Extraction Kit (Invitex GmbH, Germany), according to the manufacturer's instructions.

HCV genotyping

RNA was isolated from plasma, PBMC, and liver biopsy specimens as described above. 5'-untranslated region (5'-UTR) genotyping was done using a standard methodology with the INNO-LiPA™ HCV II kit (Innogenetics, Ghent, Belgium) according to the manufacturer's instructions. Briefly, the 5'-UTR is amplified with biotinylated primers. Biotin-labeled PCR products are reverse hybridized to specific probes attached to nitrocellulose strips and then incubated with a chromogen. Developing results in a purple precipitate that forms a line on the strip. The HCV type is deduced on the basis of the patterns of hybridizing bands, using the line probe assay interpretation chart^[28].

INNO-LiPA™ HCV II genotyping has also been confirmed by sequencing of 5'-UTR fragments. The HCV 5'-UTR was amplified from total RNA isolated from plasma, PBMC, and liver biopsy specimens of 10 randomly selected patients by reverse transcriptase-PCR as described previously^[29]. The 211-bp 5'-UTR PCR products were sequenced by dye termination method using the ABI 3130 XL sequencer. The sequencing results were compared with other sequences posited in gene bank by Blast software.

Statistical analysis

Data analysis was done by SPSS software version 16.0, using descriptive statistical indexes such as mean and standard deviation (SD), 95% confidence interval (CI) and *t* test. *P* value less than 0.05 was considered statistically significant.

RESULTS

One hundred and thirty three patients with established chronic hepatitis C were recruited in this study. Multiple blood transfusion was the most important related risk factor found in 124 (93.2%) of patients, 87 (65.4%) with thalassemia and 37 (27.8%) with hemophilia. The source of infection was unknown in 9 (6.8%) patients. The mean age of patients was 30.3 ± 17.1 years. Out of 133 patients, 100 (75.2%) were male. The mean viral load of all of the patients was $6.3 \times 10^5 \pm 7.8 \times 10^5$ (range from 45000 to 5.59×10^6). Out of 133 patients, 44 patients gave consent to undergo liver biopsy. Genotype 1a was the most fre-

quent genotype in serum (63.9%), PBMCs (61.0%), and in liver biopsy specimens (54.5%). HCV genotypes in serum, PBMCs, and liver biopsy specimens of all patients were similar except for 20 patients (15%).

The complete data of these patients have been summarized in Table 1. As shown in Table 2, more than one HCV genotype has been found in some patients, as 3 (2.3%) patients had different HCV genotypes in their serum samples. In 9 (6.8%) patients, different HCV genotypes were found in PBMCs. In 8 (18.2%) patients (who were not exactly same as the 9 patients with different HCV genotypes in PBMCs) multiple HCV genotypes were found in liver biopsy specimens. The INNO-LiPA™ HCV II genotyping was confirmed with sequencing of the 5'-UTR. A 100% correlation was demonstrated between INNO-LiPA™ HCV II genotyping and sequencing of the 5'-UTR.

DISCUSSION

The present study was performed on 133 chronically

HCV infected patients to evaluate the prevalence of potential mixed HCV infection in their plasma, PBMCs, and liver biopsy specimens. In 15% of these patients different HCV genotypes were found in these compartments. Multiple HCV genotypes were detected in 3 (2.3%) of 133 plasma, 9 (6.8%) of 133 PBMC, and 8 (18.2%) of 44 liver biopsy specimens.

Mixed infection is infection of an individual with two or more distinct HCV genotypes. Mixed viral infection is of great clinical importance as it may result in more severe disease, unresponsiveness to antiviral therapy or recurrence after the completion of antiviral therapy course^[30].

In our study, various HCV genotypes presented in PBMCs were different from those found in plasma or liver biopsy specimens (Table 1). It means that PBMCs may present some divergent types, which are not detectable in liver biopsy specimens. It reinforces the previous proposed theories in which PBMCs have been known as an extrahepatic replication site for HCV^[17,25,26,31-34].

It is suggested that infection with one HCV type doesn't make a barrier to acquisition of other genotypes, therefore multiple exposures to HCV especially in potential risk groups, might lead to several episodes of re-infection and to the establishment of mixed infection in some patients. It is also well known that super infection with a new HCV strain leads to suppression of one virus under the detection limit of PCR while the other one prevails as under antiviral therapy, the displaced strain may become viremic again and may alter the outcome of therapy^[30,35-39].

In our study the prevalence of mixed HCV infection was estimated about 2.3% in plasma, 6.8% in PBMC, and 18.2% in liver biopsy specimens of chronically infected patients with HCV. Mixed infection with two HCV genotypes have been detected in 1% of HCV-positive patients,

using type-specific primers^[40,41]. Also figures of 1.6% to 31% have been reported in multi-transfused hemophiliacs^[42,43].

Our study demonstrated that a significant proportion of HCV infected patients have divergent HCV genotypes in their PBMCs and liver biopsy specimens which were not detectable in their plasma.

In the present study we used INNO-LiPA™ HCV II genotyping which is currently the most applied method and has more sensitivity than RFLP. One of the problems of INNO-LiPA™ HCV II is that it may underestimate the actual rate of mixed infection^[9,30,44]. According to this, the true prevalence of mixed infection may be higher than estimated in this study.

The second shortcoming is that only 44 of our patients had indication or gave consent to undergo liver biopsy, however, 18.2% of them had multiple HCV genotypes which is a significant proportion of the total. It indicates that hepatocytes are the main reservoirs for HCV. On the other hand since performance of liver biopsy is not possible for all patients, we suggest the assessment of PBMCs as another HCV reservoir for detection of HCV mixed infection^[26,34,45].

In conclusion, our study shows that patients with hemophilia and thalassemia are from the most high risk groups in whom mixed infection is relatively common. On the other hand failure to treatment and relapse of infection is also frequent in these groups. So it seems that considering the plasma genotype as the target genotype for scheduling of an anti HCV therapy may be one of the factors that leads to the failure of treatment. HCV genotyping in PBMCs or liver biopsy specimens might be beneficial.

COMMENTS

Background

Relapse and failure of antiviral therapy have been frequently seen in patients with chronic hepatitis C especially in those who are on multiple blood transfusions.

Research frontiers

It has been suggested that infection with multiple hepatitis C virus (HCV) genotypes in patients affected by chronic HCV infection might result in frequent relapse after antiviral therapy.

Innovations and breakthroughs

The authors found that a significant proportion of patients with chronic HCV infection, especially who are on chronic blood transfusion, might present more than one HCV genotype in their serum, hepatocytes and peripheral blood mononuclear cells (PBMCs). It is notable that detected HCV genotypes in serum may be different from those found in PBMCs or hepatocytes.

Applications

According to the above findings the authors suggest HCV genotyping in hepatocytes and PBMCs along with serum of patients. This may result in choosing a more appropriate antiviral therapy in these patients.

Peer review

This is a well written manuscript and it addresses a relevant topic of multiple HCV infections/superinfection/humoral protection and others. Moreover, the material itself is of some value.

Abstract

AIM: To investigate the changes in renal function at 12-24 mo in patients following sodium phosphate (NaP) preparation for screening colonoscopy.

METHODS: We carried out a retrospective study on the results from patients who received health check-up services as part of an employer-provided wellness program performed between August 2006 and May 2008 and who were followed up for 12-24 mo. Prior to screening colonoscopy, 224 patients underwent bowel cleansing

with NaP (NaP group) and 113 patients with polyethylene glycol (PEG group). The control group comprised 672 age-matched patients. We compared the changes in the creatinine levels and the glomerular filtration rates (GFRs) from baseline to 12-24 mo between the NaP, PEG, and control groups using two-way repeated measured analysis of variance. In addition, multivariate linear regression analysis was performed to assess the risk factors for a decreased GFR.

RESULTS: The baseline mean serum creatinine level in the NaP, PEG, and control groups was 1.12 ± 0.15 , 1.12 ± 0.16 , and 1.12 ± 0.15 mg/dL, which increased to 1.15 ± 0.15 , 1.15 ± 0.18 , and 1.15 ± 0.15 mg/dL, respectively, after 12-24 mo. The baseline mean GFR in the NaP, PEG, and control groups was 69.0 ± 7.7 , 68.9 ± 8.0 , and 69.6 ± 6.7 mL/min per 1.73 m^2 , which decreased to 66.5 ± 7.8 , 66.5 ± 8.3 , and 67.4 ± 6.4 mL/min per 1.73 m^2 , respectively, after 12-24 mo. The changes in serum creatinine levels and GFRs were not significantly between the NaP, PEG, and control groups ($P = 0.992$ and $P = 0.233$, respectively). Using multivariate linear regression analysis, only the baseline GFR was associated with the change in GFR ($P < 0.001$). Indeed, the bowel preparations were not associated with the change in GFR ($P = 0.297$).

CONCLUSION: NaP bowel preparation in subjects with normal renal function was not associated with renal injury, and NaP can thus be used safely for screening colonoscopy.

INTRODUCTION

A bowel cleansing preparation is an essential prerequisite for safe, efficient, and accurate colonoscopy^[1]. Oral sodium phosphate (NaP) and polyethylene glycol (PEG) are the most widely used bowel cleansing agents before colonoscopy. Because small-volume NaP is better tolerated than 4-L PEG, NaP is more effective in bowel cleansing than PEG for bowel preparation^[2,3].

However, with the widespread use of NaP for bowel preparation, case reports and case series have suggested a possible association between the use of NaP and acute kidney injury, particularly in those patients with potentially compromised renal phosphate handling capacity^[4-8]. Several studies have reported an association between NaP exposure and incident kidney injury^[9-14]. Indeed, the findings have been mixed, with some studies reporting a strong association^[11,12,14] and other studies reporting a non-significant trend toward better kidney outcomes after NaP^[9,10,13] compared with other purgatives.

However, the populations evaluated in previous studies had considerable heterogeneity with a variety of indications for colonoscopy and differing health status. The comparisons for renal functional changes have been performed between 2 groups (i.e. NaP *vs* PEG or NaP *vs* healthy control). Furthermore, analyses of Asian populations have been limited.

Given the large number of patients exposed to NaP annually, clarification of this association is essential from clinical and public health perspectives. We analyzed the results of health screening services as part of an employer-provided wellness program. The primary end points were the changes in creatinine levels and glomerular filtration rates (GFRs) between 12 and 24 mo after NaP bowel preparation for screening colonoscopy, and the results were compared with those of patients who received PEG or no bowel preparation agents during the same study period.

MATERIALS AND METHODS

The Healthcare Center of Konkuk University Medical Center provides medical screening programs to individuals employed at corporations that offer medical screening services annually or biannually as part of their corporate wellness plans. According to the policy of the company, colonoscopy screening may or may not be provided as part of the screening program. Examination data have been recorded electronically in a centralized digital medical record system. The Konkuk University Medical Center Institutional Review Board approved the study protocol.

We retrospectively analyzed cohort data of the health

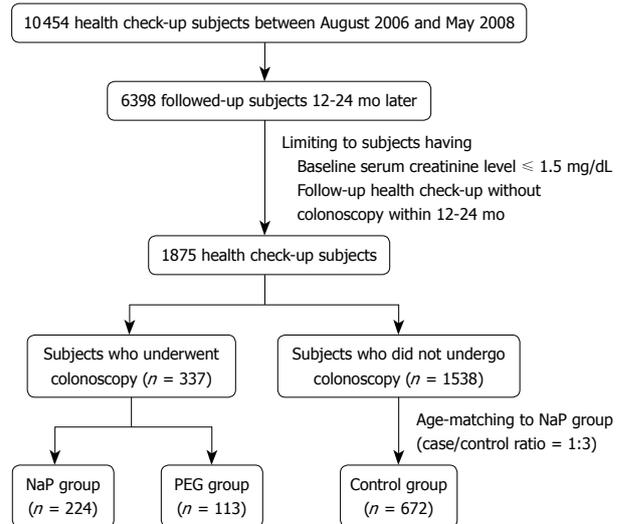

Figure 1 Flow diagram for selection of case and control subjects. NaP: Sodium phosphate; PEG: Polyethylene glycol.

screening program in subjects with normal creatinine levels who had undergone a health check-up between August 2005 and May 2008 and follow-up evaluations 12-24 mo later. During this period, 10 454 patients had health check-ups in the Healthcare Center of Konkuk University Medical Center. Of these, 6398 were followed up 12-24 mo later. Two hundred and twenty-four subjects underwent bowel cleansing with NaP for colonoscopy during the initial health check-up and had a follow-up health check-up without a colonoscopy (NaP group). One hundred and thirteen subjects took PEG for colonoscopy preparation and had a follow-up health check-up without a colonoscopy (PEG group). Of 1538 patients who had undergone health check-ups without colonoscopy and follow-up health check-ups without colonoscopy during the same period, 672 subjects, age-matched with the NaP group, were randomly selected as the control group. Figure 1 shows the flow diagram for selection of NaP, PEG, and control subjects.

The patients received written information about the medical screening program and a standard questionnaire, which included questions regarding personal medical history, such as hypertension and diabetes mellitus. Telephone interviews were conducted to ensure that the examinees who called to make an appointment were asymptomatic (i.e. no recent changes in bowel habits, lower abdominal pain, or visible rectal bleeding). Persons with symptoms were urged to seek medical care.

An oral NaP solution (Fleet[®]; Unimed Pharm. Inc., Seoul, Korea) or PEG (Colyte 4L[®]; Taejun Pharm. Co. Ltd., Seoul, Korea) was used for bowel preparation. Our center used PEG as a purgative for all subjects who underwent colonoscopy until July 2006 and then changed to NaP, except for those patients who had previous renal problems, heart failure, liver cirrhosis, or were > 65 years of age, because of better patient tolerance and cost-effectiveness. The dosing of NaP was as follows. Only liquid foods were consumed on the day of bowel preparation. Two doses of oral NaP solution (45 mL) were

Table 2 Comparison of the creatinine level and glomerular filtration rate (GFR) among NaP, PEG and control groups (mean ± SD)

Evaluation time	Creatinine level (mg/dL)				GFR (mL/min per 1.73 m ²)			
	NaP group	PEG group	Control group	<i>P</i>	NaP group	PEG group	Control group	<i>P</i>
Baseline	1.12 ± 0.15	1.12 ± 0.16	1.12 ± 0.15	0.985	69.03 ± 7.74	68.91 ± 7.95	69.57 ± 6.67	0.467
Follow-up 12-24 mo later	1.15 ± 0.15	1.15 ± 0.18	1.15 ± 0.15	0.928	66.46 ± 7.78	66.47 ± 8.26	67.42 ± 6.39	0.118

given at least 10-12 h apart. Each dose was taken with at least 250 mL of liquid, followed by an additional fluid intake of at least 1 L. The second dose was taken in the same manner and at least 3 h before the procedure. The dosing of PEG was as follows: No solid food was consumed for at least 2 h prior to ingestion of the solution. PEG (240 mL every 10 min) was consumed until the rectal output was clear or 4 L had been consumed. The colonoscopy was performed 4-6 h after bowel cleansing.

Age, race, gender, and clinical data sufficient to calculate an abbreviated Modification of Diet in Renal Disease Study Group (MDRD) glomerular filtration rate (GFR) were collected. The creatinine level on the day of the health check-up was recorded as the patient's baseline renal function. The creatinine concentration at the follow-up health check-up 12-24 mo later was recorded. The GFR was calculated using the abbreviated MDRD formula: $GFR (mL/min \text{ per } 1.73 \text{ m}^2) = 186 \times (\text{serum creatinine})^{-1.154} \times (\text{age})^{-0.203} \times 0.742$ (if female).

Serum creatinine and GFR at the initial health check-up were considered the baseline levels and at the follow-up health check-up at 12-24 mo were considered the follow-up level. In the current study, we excluded subjects with a baseline creatinine level > 1.5 mg/dL or chronic renal disease.

Statistical analysis

Continuous variables are expressed as the mean ± SD, while categorical variables are presented as absolute values and percentages. A one-way analysis of variance (ANOVA) was used to examine the differences among the characteristics at baseline of the NaP, PEG, and control groups. The changes in the creatinine levels and GFRs between the NaP, PEG, and control groups were compared using the Student *t*-test. The changes in the creatinine levels and GFRs between baseline and follow-up among the PEG, NaP and control groups were compared using two-way repeated measures ANOVA. The data for the NaP, PEG

and control groups were included in a multivariate linear regression analysis to assess the relationship of the baseline creatinine level, group, age, gender, medication for hypertension, medication for diabetes mellitus, body mass index (BMI), and baseline phosphate level to the decline in renal function. A categorical "group effect" variable was defined to specify whether the patient was in the NaP, PEG, and control groups and was used in the multivariate regression model. For each variable, the odds ratio (OR) and 95% confidence interval (CI) were reported. A two-tailed *P*-value < 0.05 was considered statistically significant, and all analyses were performed with SPSS (version 12.0K; SPSS Inc., Chicago, IL, USA).

RESULTS

The baseline characteristics of subjects in each group are outlined in Table 1. The mean age of the PEG group, 51.1 ± 10.5 years, was significantly older than in the NaP and control groups (46.9 ± 8.6 years). Although there was a smaller proportion of subjects with diabetes mellitus in the NaP group compared with the PEG or control groups, there was no statistically significant difference among the groups. The phosphate level was significantly higher in the NaP group compared with the PEG and control groups on the day of the baseline health check-up.

Table 2 illustrates the changes in renal function between the groups. There was no significant difference between the baseline and follow-up levels of mean creatinine levels and the calculated MDRD GFR between groups. The baseline creatinine level for the NaP group ranged from 0.5-1.5 mg/dL (mean, 1.12 ± 0.15 mg/dL), with a calculated MDRD GFR ranging from 35 to 143 mL/min per 1.73 m² (mean, 69.03 ± 7.74 mL/min per 1.73 m²). Serum creatinine at 12-24 mo follow-up ranged from 0.4-3.0 mg/dL (mean, 1.01 ± 0.15 mg/dL), and GFR was 22-175 mL/min per 1.73 m² (mean, 66.46 ± 7.78 mL/min per 1.73 m²). There was no significant difference in the

changes in serum creatinine between the NaP and PEG group ($P = 0.980$) or the NaP and control group ($P = 0.173$). No significant difference was not found in the changes in GFR between the NaP and PEG group ($P = 0.764$) or the NaP and control group ($P = 0.143$). In addition, although creatinine level and GFR deterioration occurred at the 12-24 mo interval, there was no significant difference in the changes in creatinine levels and GFRs between the NaP, PEG, and control groups ($P = 0.992$ and $P = 0.233$, respectively; Figure 2).

To further identify the variables involved in the deterioration of renal function in patients who were exposed to the NaP preparation, we applied a linear regression model with the dependent variables (change in creatinine and GFR from baseline to 12-24 mo) and the following independent variables: age, creatinine or GFR at baseline, hypertension, diabetes, BMI, and serum phosphate. No significant risk factor for changes in serum creatinine (Table 3) was found. The NaP bowel preparation also was not associated with the creatinine change ($P = 0.366$). On the other hand, results of multivariate linear regression analysis indicated that the GFR change was only associated with the baseline GFR ($P < 0.001$). Based on the multiple linear regression model in Table 3, when all other variables remained constant, the change in GFR decreased by 0.14 units for every 1-unit increase in GFR at baseline. The NaP bowel preparation was not associated with the GFR change ($P = 0.269$). However, the model was used to select the significant variables for the change in the GFR rather than predicting the change in the GFR level since the R^2 value was low.

DISCUSSION

The demand for colonoscopy has steadily increased, with improved colorectal cancer screening uptake^[15]. Most patients undergoing colonoscopy receive NaP- or PEG-based purgatives. Multiple studies have shown that NaP is better tolerated and more cost-effective, and at least as efficacious as PEG^[2,3]. In a meta-analysis that compared NaP with PEG for bowel preparation in 25 randomized studies, the occurrence of serious adverse events with oral NaP was zero^[16,17]. Thus, there may be a reason to preferentially use NaP.

However, recent case reports and case series have suggested a possible association between NaP and acute kidney injury^[4-8,18], termed acute phosphate nephropathy. These cases presented to their medical care providers with impaired renal function and elevated serum creatinine levels from a few days up to a few weeks after ingestion of NaP. All of these patients had histopathologic evidence of phosphate nephropathy. Although the mechanism by which NaP may cause renal injury is unknown, acute phosphate nephropathy is characterized histologically by deposition of calcium phosphate crystals in tubular epithelial cells and lumens, interstitial inflammation and fibrosis, and evidence of tubular cell apoptosis^[6]. In many reported cases, the serum creatinine levels have remained increased long after disease recognition, leading some investigators to conclude that NaP may be an under-recognized cause of chronic kidney disease^[18].

The present study examined changes in renal functions in patients who had received oral NaP as a colon cleansing

Table 4 Description of the design, demographic characteristics, and effect estimate in previous studies

	Design	Population	Race (%)	Control	Timing of Follow-up	Association between NaP exposure and incident kidney injury
Abaskharoun <i>et al</i> ^[9]	RC	Any patients who had outpatient CFS	Not reported	PEG	3 mo-9 yr	No

agent before colonoscopy and compared the changes with a group who received PEG or did not receive any purgatives. If a potent association existed, use of NaP would be inadvisable. If a weak, but significant, association existed, the risk of NaP must be weighed against such potential benefits as improved visualization of bowel mucosa and perhaps increased willingness of patients to undergo colonoscopy. If no association exists, NaP may be used without reservation. In this study, during the 12 to 24 mo follow-up, the changes in serum creatinine and MDRD GFRs were similar between the NaP, PEG, and control groups.

A number of previous controlled human studies have reported an association between NaP exposure and incident kidney injury^[9-14]. Table 4 summarizes the design, demographic characteristics, and effect estimates across previous studies^[9-14]. Unfortunately, it is impossible to determine whether an association between NaP and deterioration of renal function exists because of interstudy heterogeneity^[19].

Previous studies, except one study by Hurst *et al*^[11], enrolled any colonoscopy recipients^[9,10,12-14]. Inpatient colonoscopy recipients are more likely to have an underlying disease and more likely to develop kidney injury compared with asymptomatic healthy persons. In addition, because serum assays were not routinely used in previous studies, the authors had to derive this information by retrospectively identifying those patients whose conditions required the measurement of serum creatinine levels before and after bowel preparation. Therefore, the previous study population was not representative of all patients who received a bowel preparation for colonoscopy, especially for the purpose of screening colonoscopy. On the other hand, our participants had scheduled serum assays and colonoscopies as a part of health check-up services for an employer-provided wellness program, and this examination served the employees annually or biannually. Thus, all of our participants were an asymptomatic and relatively healthy homogenous group. In addition, studies in Asian subjects have been very rare, and our analysis could be relevant for this population.

Another noteworthy point is the role of the control group. Some studies considered PEG-treated controls^[9,11,13,14], whereas other studies also included any non-NaP bowel purgative^[10,12]. Because there is negligible systemic absorption of PEG^[20] and experimental data have not shown kidney lesions, even after prolonged daily exposure^[21], the PEG-treated group is a reasonable control for the NaP-treated group. However, because there was no recognizable possibility of purgative-induced renal impairment, such as volume depletion or patient condition necessitating PEG instead of NaP (renal impairment, heart failure, hepatic dysfunction, electrolyte imbalance, acute colitis, or inflammatory bowel disease), the subjects who were not exposed to PEG or NaP were also an appropriate control. In our study, both control groups were used and we found no significant differences in renal functional deterioration in the NaP group compared with either control group.

Lastly, the follow-up timing was important to compare the renal functional deterioration because purgative-induced volume depletion (expected to be greater with NaP, which is hyperosmolar, than with PEG, which is iso-osmolar) may have impaired renal function early after exposure without causing irreparable kidney damage. However, previous studies, apart from that of Abaskharoun *et al*^[9], followed the serum creatinine level up to 12 mo^[10-14]. Although the choice of a 12-24 mo follow-up interval was not based on firm evidence, we believe that it was a reasonable choice because the resultant kidney injury may take longer than 12 mo to become clinically manifest, and NaP exposure might result in a transient rise in serum creatinine^[18].

Our multivariate analysis identified that baseline renal function was an independent predictor of deterioration in renal function. This is a well-established risk factor for renal disease^[22]. On the other hand, in our multivariate analysis, the deterioration of GFR was not associated with NaP use or the serum phosphate level. A typical bowel preparation regimen for colonoscopy using NaP contains 5-10 times the usual daily intake of inorganic phosphate, and studies have shown a significant increase in serum phosphate levels^[23-25].

Hyperphosphatemia has been shown to predispose to acute kidney injury in rat models^[26], and an analogy to tumor lysis syndrome suggests a similar effect in humans. In addition, data from rat models suggest that hyperphosphatemia causes progressive deterioration in kidney function^[27,28]. An experimental model suggested that hyperphosphatemia resulted in calcium phosphate deposition in tubular cells and lumens, with subsequent apoptosis of tubular epithelial cells and interstitial fibrosis, consistent with histologic findings from case reports of acute phosphate nephropathy^[6,18]. Differences in predisposition to NaP-related kidney injury may result from allelic variations in sodium phosphate transporters or factors influencing their expression and cellular trafficking^[28].

With respect to exposure misclassification, our patients lacked data on nephrotoxic medications, including renin angiotensin system inhibitors, diuretics, non-steroidal anti-inflammatories, and radio-contrast material. There was unavoidable selection bias involving patients who received PEG because of our purgative selection. Thus, the presumably high-risk population was a lower proportion of the NaP group compared with the PEG group.

In conclusion, the changes in renal function in patients who used NaP was similar to healthy controls or PEG-treated patients. Further studies are warranted to validate and generalize our findings. Nonetheless, careful attention must be taken with patient selection, especially in patients with impaired renal function, and appropriate dosing of oral NaP (45 mL dose taken twice daily, 6-12 h apart) to prevent renal toxicity. Adequate hydration (at least 2-3 L of clear fluid throughout the cleansing period) is important during colon cleansing with oral NaP.

COMMENTS

Background

Case reports and case series have suggested a potential association between use of oral sodium phosphate (NaP) bowel preparations and kidney injury. Given the large numbers of patients exposed to NaP and the large and increasing incidence of chronic kidney disease, this association is of great public health importance.

Research frontiers

In the past year, a number of controlled human studies have evaluated the association between NaP exposure and incident kidney injury. However, results of these studies have been mixed, because considerable heterogeneity among population, control, and timing of follow-up.

Innovations and breakthroughs

As a potential risk of NaP is suggested, it is unethical to evaluate the association between NaP exposure and incident kidney injury using a prospective, randomized, controlled study. Thus, the selection of the study population is most important to reduce bias. Unlike previous studies, the present study evaluated the results from routine health check-ups for an employer-provided wellness program. Thus, although the analyses were retrospective, the selection bias was small and follow-up timing was consistent compared with previous studies. In addition, the changes in creatinine level and glomerular filtration rates (GFRs) in the NaP-treated group were compared not only to the polyethylene glycol-treated group, but also the healthy control group who did not use any purgatives.

Applications

Bowel preparation with oral NaP in patients who have normal renal function seems safe and effective; however, adequate hydration must be maintained before and after colonoscopy. To optimize safety, other agents should be considered in patients with increased serum creatinine or decreased GFR at baseline and in those predisposed to nephropathy.

Peer review

The study by Seol *et al* has been designed to answer a relevant clinical question: is the bowel cleaning NaP-prep safe in general population? Although retrospective, due to the large sample size and adequate control population, the study clearly reassures on this issue.

Abstract

AIM: To assess the risk factors and the efficacy of medications of patients with gastric and duodenal ulcers among Chinese patients in Taiwan.

METHODS: Patients with peptic ulcers, diagnosed by upper endoscopy, were retrospectively collected between January 2008 and December 2008. The differences were compared.

RESULTS: Among all 448 cases, 254 (56.6%) and 194 (43.4%) patients had gastric ulcers and duodenal ulcers respectively. Patients with gastric ulcers were younger than those with duodenal ulcers. Although more men existed, there was a female predominance in middle-aged cases. Patients with duodenal ulcers had a higher rate of *Helicobacter pylori* (*H. pylori*) infection (62.4% vs 43.3%, $P = 0.001$), and those with gastric ulcers owned a significantly higher amount of aspirin and nonsteroidal anti-inflammatory drug (NSAID) use (7.5% vs 1.5%, 6.7% vs 2.1%, $P = 0.001$). Tobacco smoking and alcohol drinking had no different impact between these two groups. Proton-pump inhibitors and H₂-receptor antagonists (H₂RA) were

effective, but significantly less so in cases with duodenal ulcers receiving H₂RAs, or in those with *H. pylori* infection and a history of NSAID use.

CONCLUSION: Patients with gastric ulcers had lower *H. pylori* infection but more aspirin or NSAID use. Antisecretory therapy was ineffective in gastric ulcers underwent H₂RA treatment, and cases combined *H. pylori* infection and NSAID use.

INTRODUCTION

Peptic ulcer disease develops when the protective mechanisms of the gastrointestinal mucosa, such as mucus and bicarbonate secretion, are overwhelmed by the damaging effects of gastric acid and pepsin^[1]. Peptic ulcers occur mainly in the stomach (gastric ulcer) or proximal duodenum (duodenal ulcer), and they continue to be a common disease that causes a substantial socioeconomic burden and negatively impacts on quality of life.

Helicobacter pylori (*H. pylori*) infection was originally identified as the main cause of peptic ulcers. As the prevalence of *H. pylori* infection has declined in western

countries, gastric ulcer has become more commonly associated with the use of nonsteroidal anti-inflammatory drugs (NSAID) and aspirin^[2]. Tobacco smoking and alcohol drinking were also meaningful risk factors for peptic ulcer disease^[3].

Effective pharmacologic suppression of gastric acid secretion began with the introduction of H₂-receptor antagonists (H₂RA) in the 1970s, which greatly improved clinical outcomes. The development of proton-pump inhibitors (PPI) further improved inhibition of gastric acid secretion, and ensured very high healing rates for duodenal and gastric ulcers^[4]. The aim of this study was to compare the association of *H. pylori* infection, NSAID and aspirin use, tobacco smoking and alcohol drinking with gastric and duodenal ulcers, and further assess the efficacy of therapeutic medications in the patients with peptic ulcer disease.

MATERIALS AND METHODS

Data from the medical records of consecutive patients with peptic ulcers, diagnosed by open-access transoral upper endoscopy in our hospital, a 1155-bed academic urban tertiary-care center, were retrospectively analyzed between January 2008 and December 2008. Exclusion criteria were as follows: (1) cirrhosis with varices or portal hypertensive gastropathy, (2) combined other structural gastrointestinal disorders, such as gastroesophageal reflux disease, esophageal or gastric malignancy, (3) prior gastric surgery, (4) use of chronic anti-acid medication, such as PPI or H₂RA, for more than 2 mo prior to enrollment, and (5) combined gastroduodenal ulcers so undistinguished clearly.

Written informed consent for upper endoscopy was obtained from all patients before the procedure. Medications taken longer than 3 mo prior to the enrollment, including aspirin or other NSAID, were recorded. Aspirin and NSAID were recorded separately due to discrepant doses of these drugs. All cases underwent rapid urease test (CLO test, Delta West, Bentley, Australia) for *H. pylori* status from antral biopsy.

Patients were assigned to the gastric ulcer group or the duodenal ulcer group according to the locations of peptic ulcers, which were confirmed by experienced gastroenterologists. The definition of peptic ulcers was mucosal break of stomach or duodenum over 3 mm in diameter, or more than 10 gastric or duodenal erosions. The patients with *H. pylori* infection underwent standard eradication therapy, including oral PPI 40 mg, amoxicillin 2 g and Klaricid 1 g a day for one week. All patients enrolled in the study received PPI (omeprazole 20 mg, lansoprazole 30 mg, pantoprazole 40 mg once per day) or H₂RA (ranitidine 150 mg, cimetidine 400 mg twice a day). The efficacy of therapeutic medications was defined as ulcer healing and negative rapid urease test evaluated by repeated endoscopy pulse antral biopsy at our outpatient clinic 3 mo following initial endoscopy. Patients who received aspirin were also given PPI or H₂RA, and those who received NSAID were shifted to Coxibs in addition to standard PPI or H₂RA use.

Statistical analysis

Data are expressed as standard derivation of mean for each of the measured parameters. Gender, *H. pylori* infection, and combined medication are expressed as a percentage of the total patient number. Statistical comparisons were made using Pearson's χ^2 test to compare the effects of gender, *H. pylori* infection, tobacco smoking, alcohol drinking, combined medications, and risk factors. *t* test was used to compare the mean ages of patients, and Fisher's exact test was applied to evaluate the therapeutic efficacy of cases with aspirin or NSAID use. A *P* value below 0.05 was considered statistically significant.

RESULTS

Among all consecutive patients who received open-access upper endoscopy between January and December 2008, there were 448 cases enrolled in our study and the characteristic of them were displayed in Table 1. Among these patients, 254 patients (56.6%) had isolated gastric ulcers and 194 patients (43.4%) had isolated duodenal ulcers. Comparing the chronic medication use of patients with gastric ulcers and duodenal ulcers, more patients with gastric ulcers took aspirin and NSAID than did those with duodenal ulcers (7.5% *vs* 1.5%, 6.7% *vs* 2.1%, respectively), and the difference was significant (*P* = 0.001).

Most of the patients with gastric ulcers were in the fifth decade of life, whereas most patients with duodenal ulcers were in the sixth decade, as shown in Figure 1. There were more male patients than female patients in both groups, and a similar gender ratio existed between these two groups. The ratio of gender according to age distribution is shown in Figure 2. More female cases were noted in the 50-60-year-old patients with gastric ulcers and the 60-70-year-old patients with duodenal ulcers. Male predominance was noted

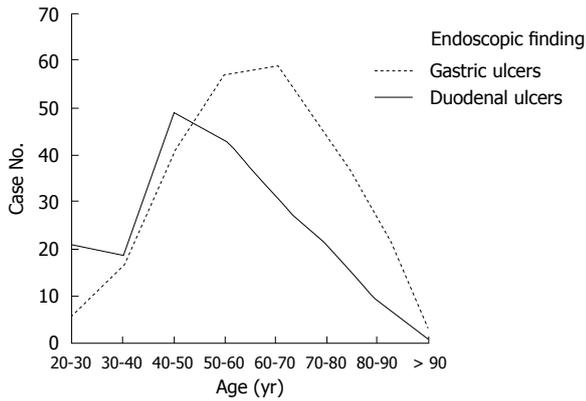

Figure 1 Age distribution of the two groups of patients.

in both the younger and older gastric ulcer and duodenal ulcer patients.

The rate of *H. pylori* infection, shown in Table 1, was significantly higher in the patients with duodenal ulcers than in those with gastric ulcers (62.4% vs 43.3%, $P = 0.001$). Similarly, more patients with duodenal ulcers smoked tobacco and drank alcohol than those with gastric ulcers (16% vs 14.2%, 11.3% vs 8.3%, respectively), but these differences in our study were insignificant ($P = 0.595$ and 0.274).

There was a similar proportion of patients in each of the two groups with positive *H. pylori* infection according to age distribution, as shown in Figure 2. The lowest rate was noted in gastric ulcer patients in the second and ninth decades of life, and the highest rate was found in duodenal ulcer patients in the ninth decade of life. However, the numbers in these groups were very small.

In regard to the impact of therapeutic efficacy on *H. pylori* infection, all had effective eradication proven by negative secondary rapid urease test. As illustrated in Table 2, the results revealed there were similar rates of peptic ulcer healing among patients with and without *H. pylori* infection in both groups who underwent eradication

Table 3 The impact of therapeutic efficacy according to co-mediations and ulcer location of patients *n* (%)

Co-medications	Therapeutic efficacy		Total	P-value
	Ulcer healed	Ulcer unhealed		
None				
Positive <i>H. pylori</i> infection	159 (75.7)	51 (24.3)	210	0.370 ^a
Negative <i>H. pylori</i> infection	140 (71.8)	55 (28.2)	195	
ASP				
Positive <i>H. pylori</i> infection	8 (80)	2 (20)	10	0.195 ^b
Negative <i>H. pylori</i> infection	12 (100)	0	12	
NSAID				
Positive <i>H. pylori</i> infection	6 (60)	4 (40)	10	0.035 ^b
Negative <i>H. pylori</i> infection	11 (100)	0	11

therapy. There was no significant difference between the efficacy of PPI and H2RA among patients with duodenal ulcers (78.2% vs 72.3%, $P = 0.430$). On the contrary, PPI was significantly more effective than H2RA in patients with gastric ulcers (79.4% vs 62.9%, $P = 0.007$).

As shown in Table 3, the therapeutic efficacy of PPI and H2RA was compared among patients who used aspirin or NSAIDs regularly or took no medicine. In regard to the combined influence of *H. pylori* infection and chronic aspirin or NSAID use in patients with peptic ulcer disease, there was a lower rate of response to therapeutic medicine, especially in the cases taking NSAID (60% vs 100%, $P = 0.035$).

DISCUSSION

Peptic ulcer disease is associated with gastric hypersecretion, a physiological imbalance between antagonistic gastric hormones, cholinergic hypersensitivity, psychological stress, tobacco smoking, alcohol consumption, or use of aspirin and NSAID. Duodenal ulcer is essentially an *H. pylori*-related disease and is caused mainly by an increase in acid and pepsin load^[5]. Gastric ulcer in Western countries is most commonly associated with NSAID ingestion or *H. pylori* infection. As the prevalence of *H. pylori* infection has declined in western countries, gastric ulcer has become more commonly associated with the use of NSAID and aspirin^[6].

The prevalence of peptic ulcers in developed countries has been declining for several decades owing to improvements in sanitation and a reduced rate of *H. pylori* acquisition^[7]. Recently, a study in Taiwan reported incidences of gastric and duodenal ulcer diseases decreased 42%-48% and 41%-71%, respectively, in a 10-year period^[8]. The birth cohorts with the highest risk of developing gastric ulcer were born 10-20 years before those with the highest risk for duodenal ulcer in all European countries, the USA, Australia and Japan^[9]. Our results were similar, although our study was not population-based.

Previous studies have shown that male gender is an independent risk factor for peptic ulcer disease in populations in the USA, Japan and Norway^[10-12]. Our results documented male predominance in both the patients

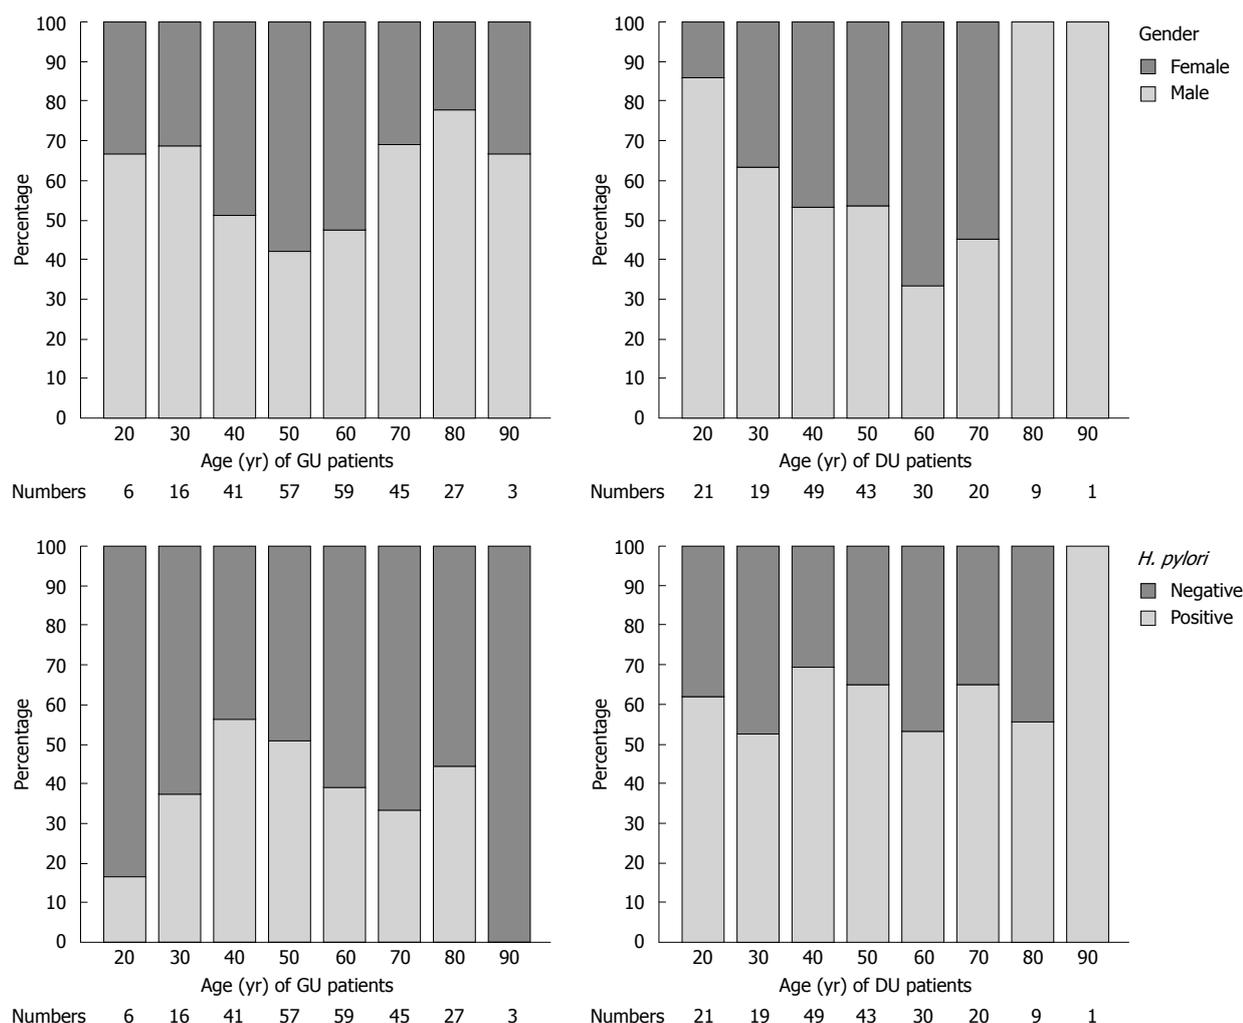

Figure 2 The ratio of gender and *Helicobacter pylori* (*H. pylori*) infection according to age distribution of the two groups of patients. GU: Gastric ulcer; DU: Duodenal ulcer.

with gastric ulcers and in those with duodenal ulcers. Interestingly, we also found there was relative female predominance in middle-aged patients, although no previous studies had similar findings. The reason may be that middle-aged women are more likely to seek medical treatment than men in the same age group.

Previous studies had documented tobacco smoking and alcohol drinking as firm risk factors for peptic ulcer disease^[3,5], however, no available data focused on the different impacts of these factors in achieving gastric ulcers and duodenal ulcers. Our study found similar influences of these two groups, implying the excellent benefit of quitting tobacco smoking and alcohol drinking in patients with peptic ulcer disease, regardless of the location of the ulcers.

During the 1980s, *H. pylori* infection was found in more than 90% of patients with duodenal ulcers, and around 70% of patients with gastric ulcers^[13]. An increased prevalence correlates with lower educational levels, income, and other socioeconomic factors^[14]. A recent study reported a seroprevalence of *H. pylori* infection in 56.4% of patients with duodenal ulcers and a lower rate in those with gastric ulcers^[3]. Similarly, our patients had

a lower prevalence of *H. pylori* infection than previously expected, with a rate of 42.9% in cases with gastric ulcers, and 62.4% in those with duodenal ulcers. The result may be due to improvements in hygiene, and it emphasizes the fact that eradication therapy should not be initiated without prior verification of the infection.

On the contrary, aspirin and NSAID significantly increase the risk of adverse gastric or duodenal ulcers and complications, especially bleeding^[3]. Gastric ulcers are strongly linked to NSAIDs, and this was confirmed by the positive relationship between aspirin or NSAID use and gastric ulcers in our study. *H. pylori* infection and NSAID have additive or synergistic effects on adverse gastrointestinal outcomes: *H. pylori* damages through direct pathogenic mechanisms, and NSAID causes disruption of mucosal defensive mechanisms indirectly^[2]. Our study did not include this conclusion because there were too few cases with *H. pylori* infection taking aspirin or NSAID to be analyzed sufficiently.

In regard to the patients with peptic ulcer disease owing to *H. pylori* infection, studies indicate that eradication of infection not only heals peptic ulcers, but also reduces the ulcer recurrence rate^[15]. Maintenance treatment should

be continued with PPI use following *H. pylori* eradication in all patients to prevent ulcer recurrence or complications^[16]. Standard dose PPI treatment should be prescribed for 4 wk in patients with duodenal ulcers and for 8 wk in patients with gastric ulcers^[17].

The results of our study revealed an adequate ulcer healing rate in patients with gastric or duodenal ulcers who received antisecretory therapy, PPI or H2RA, whether they had *H. pylori* infection or not, and whether they were taking aspirin and other NSAID or not. There were two subgroups of patients with a significantly poor therapeutic response: patients with gastric ulcers who underwent H2RA treatment (62.9%), and patients with both *H. pylori* infection and NSAID use who accepted antisecretory therapy (60%).

One previous study noted that pantoprazole was more effective than ranitidine in the treatment of duodenal ulcers, providing not only symptom remission but also faster ulcer healing^[18]. Another study reported *H. pylori* infection and NSAID use synergistically increase the risk of peptic ulcers and ulcer bleeding^[19]. These results implied that PPI, at least in duodenal ulcers, is more effective than H2RA, and prolonged antisecretory therapy may be necessary in the treatment of peptic ulcers caused by *H. pylori* infection and NSAID use. One recent study among a Japanese population also mentioned that it is desirable to administer antiulcer agents to patients with risk factors, such as *H. pylori* infection, when taking NSAID^[20].

There were some limitations in our study. Firstly, our study, a form of referral-based endoscopy, as opposed to a population-based survey, was less representative of the general population due to selection bias. Secondly, we only recorded the recent use of NSAID. There is a possibility that some patients were unaware that they were taking NSAIDs. Besides, the kinds of NSAID and PPI were heterogeneous. Thirdly, only an incomplete previous history of peptic ulcer disease or *H. pylori* infection was available to be analyzed. Furthermore, previous *H. pylori* eradication was not listed in the exclusion criteria of this study, and the *H. pylori* infection rate may be an underestimation. Lastly, major limitations of this study included the retrospective study design and the lack of randomization. Although the duration of this study was designed to be as long as one year, it is possible that there were unmeasured differences among these subgroups.

In the present study, Chinese patients in Taiwan with peptic ulcers had different characteristics. The patients with gastric ulcers were older, had a lower ratio of *H. pylori* infection and a greater association with aspirin or NSAID use, compared with those with duodenal ulcers. Antisecretory therapy was very effective in patients with peptic ulcer disease, except cases with gastric ulcers who underwent H2RA treatment, and those who had combined *H. pylori* infection and NSAID use and accepted antisecretory therapy.

COMMENTS

Background

Peptic ulcer disease is associated with *Helicobacter pylori* (*H. pylori*) infection, aspirin and nonsteroidal anti-inflammatory drug (NSAID) use, tobacco smoking

and alcohol drinking. Effective pharmacological therapy includes H2-receptor antagonist (H2RA) and proton-pump inhibitor (PPI).

Research frontiers

Although risk factors and therapeutic efficacy are well known in Western countries, the information in the Chinese population is relatively rare. The aim of this study was to assess the risk factors and the efficacy of medications of patients with gastric and duodenal ulcers among Chinese patients in Taiwan.

Innovations and breakthroughs

The authors' result found that Chinese patients in Taiwan with gastric ulcers were older, had a lower ratio of *H. pylori* infection and a greater association with aspirin or NSAID use compared with those with duodenal ulcers. Antisecretory therapy was very effective against peptic ulcers, except in cases with gastric ulcers who underwent H2RA treatment, and those with combined *H. pylori* infection and NSAID use who accepted antisecretory therapy.

Applications

Maintenance treatment should be continued with PPI use, following *H. pylori* eradication, in all patients to prevent ulcer recurrence or complications, especially in cases who used NSAID.

Peer review

The study compares a group of gastric ulcer patients with a group of duodenal ulcer patients in terms of demographic characteristics, certain risk factors, and response to treatment. It is of moderate importance with minimal novelty.

Abstract

AIM: To investigate the efficacy of acellular dermal matrix (ADM) for intestinal elongation in animal models.

METHODS: Japanese white big-ear rabbits ($n = 9$) and Wuzhishan miniature pigs ($n = 5$) were used in the study. Home-made and commercial ADM materials were used as grafts, respectively. A 3-cm long graft was interposed in continuity with the small bowel and a side-to-side anastomosis, distal to the graft about 3-4 cm, was performed. The animals were sacrificed at 2 wk, 4 wk, 8 wk and 3 mo after surgery and the histological changes were evaluated under light microscope and electron microscope.

RESULTS: The animals survived after the operation with no evidence of peritonitis and sepsis. Severe ad-

hesions were found between the graft and surrounding intestine. The grafts were completely absorbed within postoperative two or three months except one. Histological observation showed inflammation in the grafts with fibrinoid necroses, infiltration of a large amount of neutrophils and leukomonocytes, and the degree varied in different stages. The neointestine with well-formed structures was not observed in the study.

CONCLUSION: It is not suitable to use acellular dermal matrix alone as a scaffold for the intestinal elongation in animal models.

INTRODUCTION

Short bowel syndrome (SBS) is defined as a spectrum of small intestinal dysfunction for a major portion of small intestines being resected and the patients need chronic total parenteral nutrition (TPN) in lifetime. However, a long-term use of TPN is associated with significant

morbidity and mortality^[1-3], such as system infection and progressive cholestatic liver disease and many patients could not afford the high cost of the nutrition support. Several bowel elongation procedures were successful in increasing the absorptive surface area, but these methods were not widely applied for serious complications. Small intestinal transplantation may be a valid option, but the result is unsatisfactory for immunologic problems.

Recently, acellular biomaterials have received extensive attentions, including acellular dermal matrix (ADM). ADM provides a biologic scaffold that allows native cellular ingrowth and tissue remodeling. In this study, we applied the ADM as scaffold for the mucosal growth and intestinal elongation in animal models.

MATERIALS AND METHODS

Animal

Japanese white big-ear rabbits ($n = 9$, body weight 2.0-2.2 kg) and Wuzhishan miniature pigs ($n = 5$, body weight 41-44 kg) were used in the study. Animal care and use complied with the institutional regulations established and approved by the Animal Care and Use Committee of the Capital Medical University for Animal Research Program. All the animals were housed in individual cages under standard laboratory conditions and fed animal chow and water *ad libitum*.

Preparation of ADM

A Japanese white big-ear rabbit and a Wuzhishan miniature pig were used as the donors, respectively. Segments of the small intestine were harvested and cut into 5-cm lengths. The grafts were sterilized in 75% ethanol, rinsed in saline solution, and stored at 4°C in a Penicillin-Streptomycin solution until use. The dermis was acellularized in accordance with the method reported previously by Takami *et al.*^[4]. In brief, the segment of the small intestine was treated with 0.25% Trypsin (Roche corp.) at 4°C for 24 h to remove the epidermis and other cellular components from the dermal matrix. Subsequently, the dermal matrix was incubated in buffered 0.5% Triton X-100 (Sigma-Aldrich Corp.) for 24 h at 37°C. An oscillator was used during these procedures. Dispase-Triton ADM was then extensively washed with phosphate buffered solution (PBS) and stored in PBS at 4°C until use (Figure 1). All solutions were treated with filter sterilization.

Surgical procedures

Surgical procedures were performed under general anesthesia with 3% Pentobarbital (25 mg/kg). All the Japanese white big-ear rabbits (group A) and two Wuzhishan miniature pigs (group B) were transplanted with the allograft materials respectively, and the other two pigs (group C) with the human acellular dermal matrix (HADM, Ruinuo[®], Qingyuanweiye Bio-Tissue Engineering Ltd, Beijing, China).

A laparotomy in the right lower abdominal quadrant

was performed, and the small bowel was transected in the middle portion. A graft (3 cm long) was interposed in continuity with the small bowel using interrupted end-to-end two layers anastomosis (muscularis-serosa layer and full-thickness layer) with 1-0 nonabsorbable sutures. Then a side-to-side anastomosis, distal to the graft about 3-4 cm (Figure 2), was performed. The defect of the mesentery was repaired to avoid entocoele. All the viscera were laid back to the abdominal cavity. The abdominal wall was closed with running suture, while the skin with interrupted suture. In the group of HADM, the graft was sewn at the edges with sutures to construct a tube, and then the same operation was repeated as mentioned above.

All the animals were maintained on a liquid diet and water for 48 h and then on a full diet. Two rabbits were sacrificed at 2, 4 and 8 wk, respectively after surgery. The study endpoint was 3 mo after the operation. Pathologic specimens including the anastomotic site were fixed in formalin, embedded in paraffin, and processed routinely for light microscopy. Histological changes were evaluated under light microscope and transmission electron microscope.

RESULTS

The animals survived after the operation with no evidence of peritonitis or sepsis. All the rabbits had gradual weight loss from median 2.1 to 1.8 kg and the survival after the operation was no longer than 8 wk, while the body weight of pigs increased from median 42 to 51 kg which were executed at 3 mo after the surgery according to the scheme.

In group A, severe adhesions were found between the graft and surrounding intestine. There was almost no blood supply in the grafts and the lumens were full of dry stool or pus at 2 and 4 wk after surgery. At the 8th postoperative week, the grafts totally disappeared, similar to group B and one pig in group C and there were only two blind-ended pouches. The other one in group C seemed to be the most successful one considering the small intestinal continuity was restorative. But the graft shrank from 3 to 0.2 cm and became a narrow-ring without flexibility (Figure 3).

Histological observation showed acute inflammation in the tissue during the first two weeks. In the first week, there were focal fibrinoid necroses and infiltration of a large amount of neutrophils and leukomonocytes (Figure 4A and B). In the second week, there was a further development of the inflammation. The fibrinoid necroses and cell infiltration became dispersed and inflammatory exudates of neutrophils and pus cells could be seen (Figure 4C and D). At the same time, a lot of micrangiums and fibroblasts appeared in the scaffold. By the 4th postoperative week, the infiltration of leukocytes and leukomonocytes mitigated. No well-formed structure could be seen and all the layers were contorted in the narrow-ring of group C (Figure 5). The thickening serosa and infiltration of a small amount of leukocytes and leukomonocytes could be discovered. Immunocytochemical stain with smooth muscle actin showed smooth muscle cells in the narrow-ring of ADM with disordered structure.

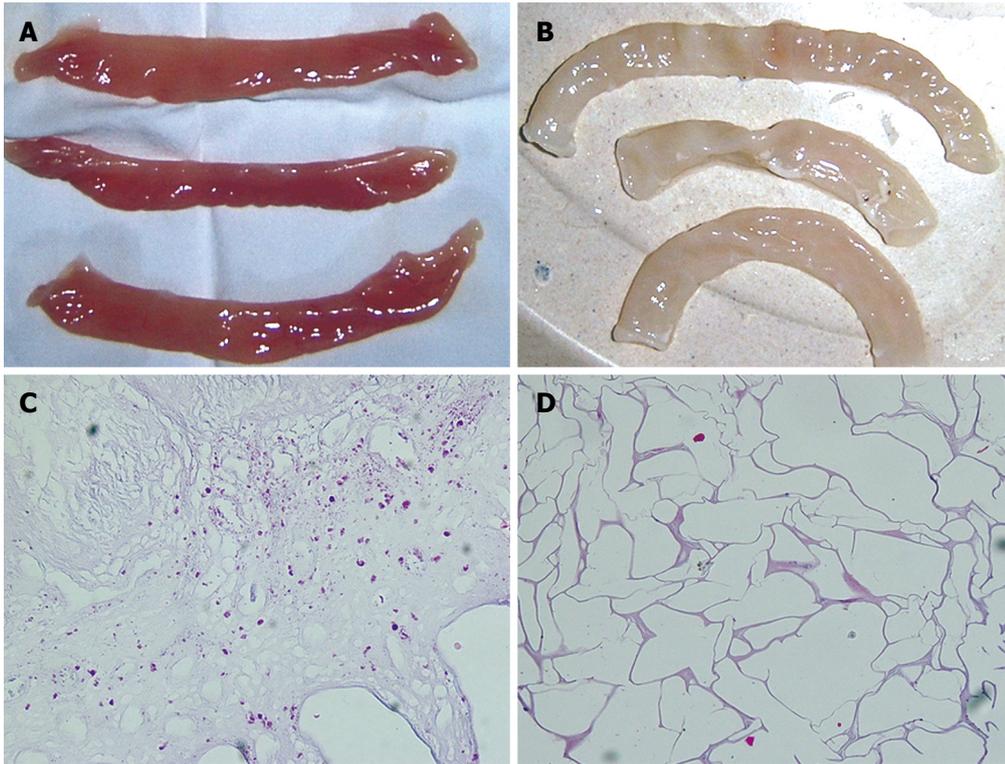

Figure 1 Acellular dermal matrix. A: Segments of the small intestine; B: Segments of acellular dermal matrix; C, D: Hematoxylin and eosin–stained histological photomicrography showed that all the cellular elements of the small intestine have been removed (C: × 100, D: × 400)

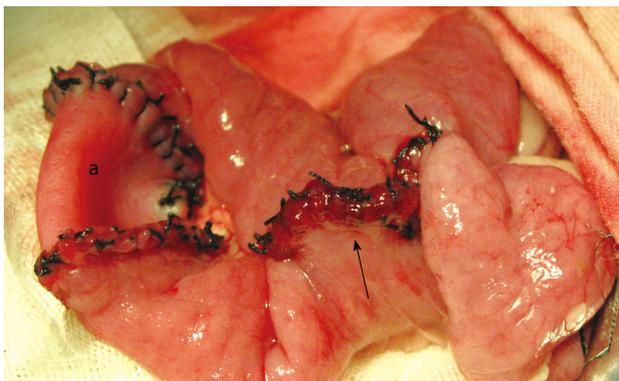

Figure 2 Surgical procedures. a: ADM; arrow: Side-to-side anastomosis.

DISCUSSION

Several surgical procedures have been used to improve the SBS^[5,6]: (1) to decrease transit time of the bowel content by creation of intestinal valves or interposition of bowel segments; (2) to increase mucosal surface area; and (3) to increase the bowel length or to transplant the bowel. Objective assessment of these surgical techniques was deficient due to a relatively small number of patients. The small intestine transplantation is becoming a less morbid therapy in recent years, but it remains complicated and is limited due to the donor availability.

ADM is a dermal biomaterial in which all of the cellular elements have been removed. The biologic properties of ADM, including its ability to support tissue regeneration repopulation with fibroblasts, revascularization, new collagen deposition and eventual absorption and replacement with native tissue permit its use in tissue reconstruc-

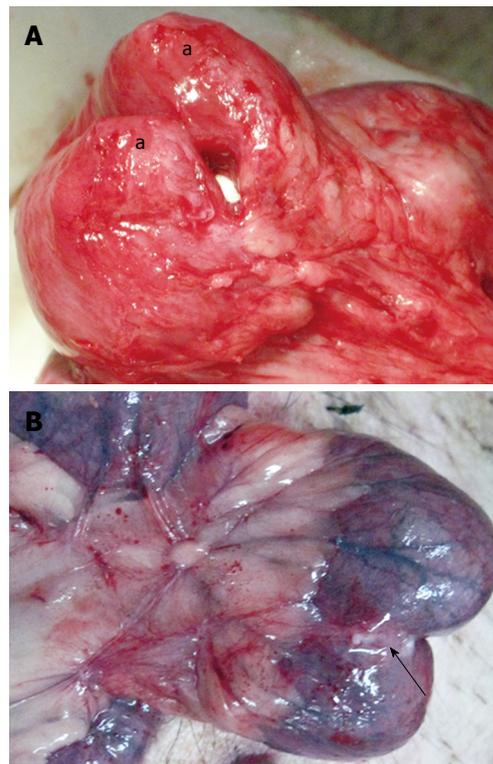

Figure 3 Postoperative gross specimen. A: ADM has been absorbed completely (a: Blind-ended pouch); B: The graft was shrinking (arrow: The ADM material).

tion. Now ADM has been used successfully in repairing the defect or damaged tissues and organs both in preclinical animal studies and in clinical applications^[7-11], such as burn surgery, herniorrhaphy, urethroplasty, pelvic floor

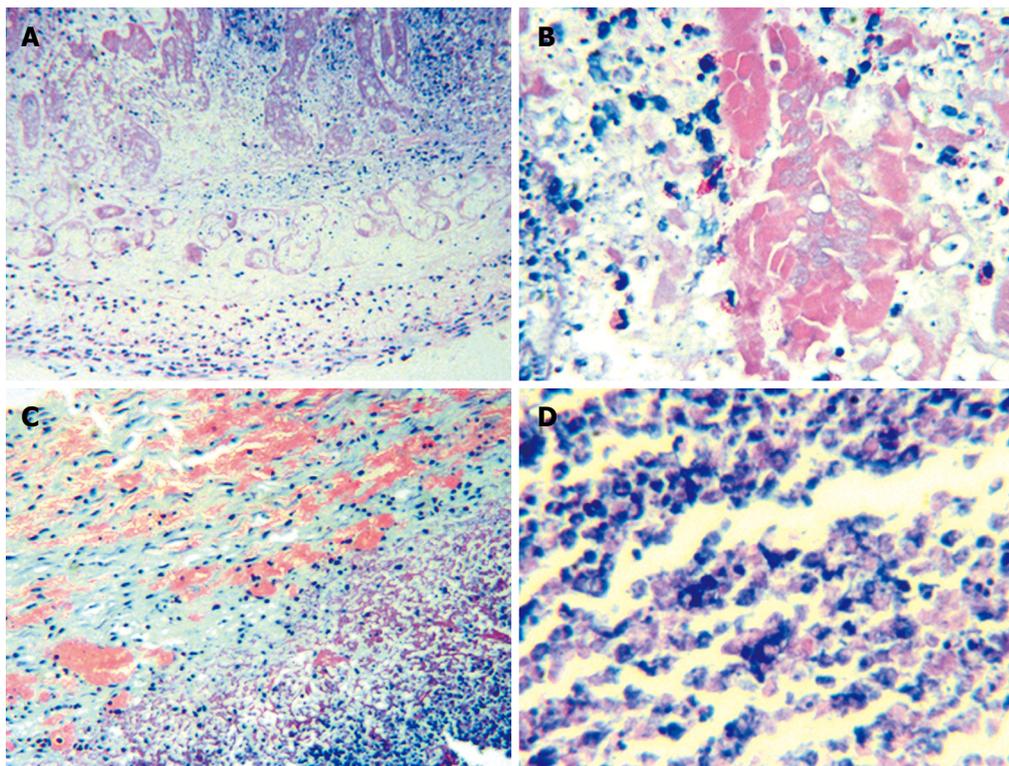

Figure 4 Histological photomicrography of postoperative ADM. Focal fibrinoid necroses and infiltration of a large amount of neutrophils and leukomonocytes in the first week (HE stain, A: $\times 100$, B: $\times 400$); a further development of the inflammation in the second week (HE stain, C: $\times 100$, D: $\times 400$).

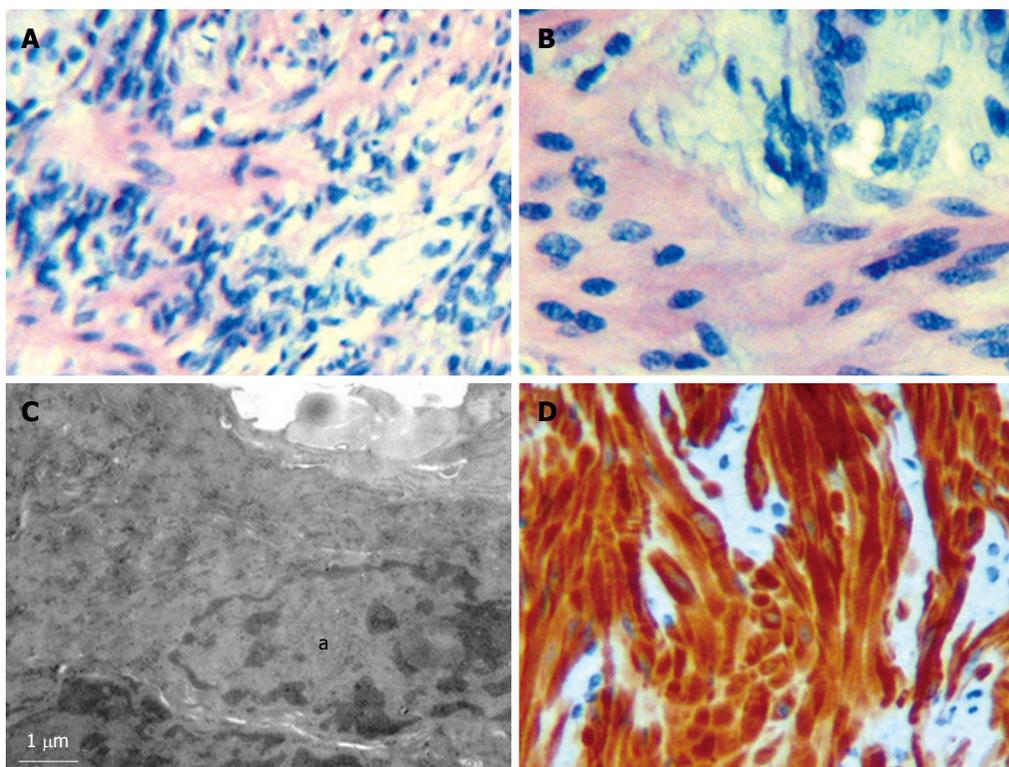

Figure 5 Structures of the ADM were contorted in the narrow-ring. A: $\times 100$; B: $\times 200$; C: Transmission electron microscopy, $\times 20000$; a: Fibroblast; D: Immunocytochemical stain with smooth muscle actin showed smooth muscle cells in the narrow-ring.

reconstruction, contaminated abdominal wall defects and fistula.

We supposed that the ADM can be used as a scaffold for tissue regeneration with the normal morphology of the mucosa, submucosa, muscle and serosa layers. An *in vivo* study in dog models showed that an extracellular matrix (ECM) plus autologous muscle could facilitate the

reconstruction of the esophagus with near normal biomechanical properties and structure^[12]. Pahari *et al*^[13] used the acellular human dermis in the form of tubular scaffolds for intestinal elongation. Intact mucosa with well-formed crypts was evident at 6 mo after operation^[13].

But it did not develop like what we had designed in the study. The grafts were almost completely absorbed

in two or three months. Pus could be seen in the lumens of ADM and histological examination showed the inflammatory exudates of neutrophils and pus cells. Thus, the ADM might be a source of infection in this study, though we have tested that the ADM can be used in contaminated wound for its resistance to infection^[14]. Inadequate blood supply and the rapid absorption were the most likely reasons. All the ADM depends on the blood infiltrating from the two anastomotic ends and the supply was very limited comparing with the granulation tissue of the wound surface. Immunocytochemical stain with smooth muscle actin showed smooth muscle cells in the narrow-ring at 3 mo after surgery, which is an exciting event and consistent with our previous study^[14].

The biggest challenge of bowel tissue engineering is the recovery of peristaltic activity of the regenerated bowel, which needs both smooth muscle and reinnervation of the regenerated bowel. It seemed that there was no evidence of innervations of the neointestine to date. Even the neointestine had well-formed structures, the dysmotile segment may become dilated, resulting in fecal stasis, bacterial overgrowth and malabsorption.

Our conclusion is different from some of the previous studies. We have made several reviews of the whole procedure, but no obvious errors could be found. Even if there were some problems in the process of preparation of the ADM, which was more elaborate, group C (HADM, Ruinuo[®]) had the same result. So we believe that the result is reliable. Though ADM has been successfully used to repair and reconstruct the tissue defects in many fields, it seemed that the single use of ADM is not suitable to the intestinal elongation in the present study and there is a long way to go before the ADM can be used for intestinal elongation.

COMMENTS

Background

Short bowel syndrome (SBS) has puzzled surgeons for a long time. Though some treatments have been reported, the effects are unsatisfactory. In recent years, acellular dermal matrix (ADM) has been used in many fields to provide a biologic scaffold for tissue regeneration or scarless healing, and few studies for SBS have been performed, and the results are uncertain.

Research frontiers

There are only few studies about ADM used for intestinal elongation. This study was designed to use both the home-made and commercial ADM materials. At the same time, different species were transplanted with the allograft materials. All of these can improve the credibility of this research.

Innovations and breakthroughs

This study was designed according to the previous work, but it showed different results. The authors gave some possible reasons, which were worthy of in-depth studies.

Applications

ADM may be used for intestinal elongation, but some reforms are necessary in its future application.

Terminology

ADM is a new material that all of the cellular elements have been removed. The kind of material has special biologic properties, including support of tissue regeneration with concomitant revascularization and repopulation with fibroblasts, new collagen deposition, absorption and replacement with native tissues.

Peer review

The treatment of short bowel syndrome has always been a challenge for the surgeons and any serious work regarding this issue will be very important for surgeons and patients. The aim of this work was to evaluate the efficacy of acellular dermal matrix for intestinal elongation, which has been well designed and performed.

Abstract

AIM: To determine the antiviral mechanism or target of oxymatrine against hepatitis B virus (HBV).

METHODS: HepG2.2.15 cells were incubated with culture medium containing 500 µg/mL of oxymatrine for 2 and 5 d. The surface antigen of HBV (HBsAg) and e antigen of HBV (HBeAg) in supernatant were determined by ELISA. HBV DNA in supernatant, and intracellular covalently closed circular DNA (cccDNA), relaxed circular DNA (rcDNA) and pregenomic RNA (pgRNA) were quantified by specific real-time polymerase chain reaction (PCR) or reverse transcription (RT)-PCR.

RESULTS: Treatment with oxymatrine for 2 d and 5 d reduced the production of HBV by the cell line, as

indicated by the decline of HBsAg (22.67%, $t = 5.439$, $P = 0.0322$ and 22.39%, $t = 5.376$, $P = 0.0329$, respectively), HBeAg (55.34%, $t = 9.859$, $P = 0.0101$ and 43.97%, $t = 14.080$, $P = 0.0050$) and HBV DNA (40.75%, $t = 4.570$, $P = 0.0447$ and 75.32%, $t = 14.460$, $P = 0.0047$) in the supernatant. Intracellular cccDNA was also markedly reduced by 63.98% ($t = 6.152$, $P = 0.0254$) and 80.83% ($t = 10.270$, $P = 0.0093$), and intracellular rcDNA by 34.35% ($t = 4.776$, $P = 0.0413$) and 39.24% ($t = 10.050$, $P = 0.0097$). In contrast, intracellular pgRNA increased by 6.90-fold ($t = 8.941$, $P = 0.0123$) and 3.18-fold ($t = 7.432$, $P = 0.0176$) after 500 µg/mL of oxymatrine treatment for 2 d and 5 d, respectively.

CONCLUSION: Oxymatrine may inhibit the replication of HBV by interfering with the process of packaging pgRNA into the nucleocapsid, or inhibiting the activity of the viral DNA polymerase.

INTRODUCTION

Despite efficient vaccines, chronic hepatitis B virus (HBV)

infection remains a major public health problem, which involves more than 350 million people in the world^[1]. Antiviral agents play a key role in the treatment of chronic hepatitis B infection by inhibiting the replication of the virus, and delaying or preventing progression to cirrhosis, hepatocellular carcinoma and death. Interferon- α (IFN- α) has been shown to be effective in suppressing HBV replication and inducing remission of liver disease^[2]. Its principal antiviral mechanism has been thought to include both a direct antiviral effect and an immunomodulatory effect^[3-5]. However, its efficacy is limited to a small percentage of highly selected patients and is often associated with adverse effects such as flu-like symptoms, fatigue, leucopenia, depression, anorexia, hair loss, *etc.*^[2]. Nucleoside analogues such as lamivudine, adefovir dipivoxil and entecavir could competitively inhibit the activity of HBV DNA polymerase or terminate the elongation of newly synthesized DNA chain by incorporation, and demonstrated potent anti-HBV efficacy *in vitro* and *in vivo*^[2]. However, nucleoside analogues are also limited to certain adult patients, and related adverse effects such as renal tubular dysfunction by adefovir have also been reported^[2]. In addition, viral mutation may induce drug resistance to nucleotide analogues and relapse of hepatitis B^[2].

In China, many herbs or their derivatives have also been widely used in the treatment of viral hepatitis and associated complications such as liver cirrhosis and liver failure^[6,7]. Oxymatrine, a type of alkaloid extracted from the herb *Sophora alopecuroides* L.^[8], had shown a promising anti-HBV effect in a HBV-transfected cell line, in a HBV transgenic mice model and in patients with chronic hepatitis B^[9-11]. Oxymatrine had also been found to be capable of relieving hepatic fibrosis or severe injury independently^[12-14]. It has been approved for the treatment of hepatitis B by the State Food and Drug Administration of China, and is listed as one of the recommended anti-HBV agents in the Guideline for Prevention and Treatment of Chronic Hepatitis B jointly proposed by the Chinese Society of Hepatology and the Chinese Society of Infectious Diseases^[15]. Unfortunately, unlike IFN- α or antiviral nucleoside analogues, little is known about the exact mechanism or target of oxymatrine against HBV.

The replication cycle of the hepadnavirus involves a pathway by reverse transcription of an RNA intermediate^[16], during which several important replicative intermediates are generated, including covalently closed circular DNA (cccDNA), pregenomic RNA (pgRNA) and progeny virus relaxed circular DNA (rcDNA), and the viral particle is secreted outside after maturation^[17]. The antiviral agents usually target one or more specific sites of the HBV replication cycle. It can be reasoned that any intervention or interruption in the replication cycle of HBV will result in the fluctuation or alteration of the product occurring in the specific site, which will in turn provide clues to illuminate the target of antiviral agents. In this paper, we investigated the effect of oxymatrine on the replication cycle in the HepG2.2.15 cell line, and explored the possible antiviral target of oxymatrine.

MATERIALS AND METHODS

Compounds

Oxymatrine was provided by Jiangsu Chia-tai Tianqing Pharmaceutical Co. Ltd, China, the purity of which had been determined to be greater than 99% by high-performance liquid chromatography. The compound powder was stored at room temperature in light-resistant containers, and stock solutions were prepared when required by dissolving reagents in dimethyl sulfoxide to a concentration of 200 mg/mL and stored at -4°C.

Cell line

The HepG2.2.15 cell line, which could support persistent replication of HBV and produce intact HBV particles^[18], was provided by the Molecular Viral Laboratory of Fudan University with permission from the Mount Sinai Medical Center, NY, USA. It was maintained with Dulbecco's Modified Eagle Medium (Gibco-BRL, Grand Island, NY, USA) supplemented with 10% (vol/vol) heat-inactivated fetal bovine serum (Gibco-BRL, Grand Island, NY, USA), 380 μ g/mL G418 (Gibco-BRL, Grand Island, NY, USA) 125 μ g/mL penicillin and 50 μ g/mL streptomycin at 37°C in a humidified incubator containing 50 mL/L CO₂. Then cells were harvested from the flask by treating the monolayer with 0.25% trypsin (Gibco-BRL, Grand Island, NY, USA) and 1 mmol/L EDTA, and resuspended in culture medium for further use.

Cytotoxicity

HepG2.2.15 cells were inoculated on a 96-well culture microplate (Costar, Corning Inc., NY, USA) at a density of 2×10^4 /mL (200 μ L for each well). After incubating for 48 h, supernatant was substituted by fresh culture medium containing serial 1:2 dilutions of oxymatrine, varying from 8000 μ g/mL to 62.5 μ g/mL (triplicates for each concentration), and was refreshed every other day. After treatment for 6 d, cytotoxicity of oxymatrine was determined by a MTT assay as previously described in detail^[19].

Treatment of HepG2.2.15 cells with oxymatrine

HepG2.2.15 cells were inoculated in 12 flasks (75-cm², NUNC, Roskilde, Denmark) at a density of 2×10^5 /mL (12 mL for each flask). Forty-eight hours after cell inoculation, HBV DNA could be easily detected in the culture medium. Then the culture medium was removed, and fresh culture media containing 500 μ g/mL of oxymatrine were added, while the normal control group was refreshed with new culture media. At different times (2 d and 5 d) after treatment, supernatant from 3 flasks of each group were collected independently for determination of HBV surface antigen (HBsAg), HBV e antigen (HBeAg), and HBV DNA, and cells were harvested by trypsin digestion and washed 3 times with phosphate buffered solution (PBS, pH 7.3). Then cells were counted and different numbers of cells were used to determine different HBV replicative intermediates: 1×10^6 cells for cccDNA, 3×10^6 cells for

HBV: Hepatitis B virus; cccDNA: Covalently closed circular DNA; rcDNA: Relaxed circular DNA; pgRNA: Pregenomic RNA; MGB: Minor grooving binder; PCR: Polymerase chain reaction; RT-PCR: Reverse transcription polymerase chain reaction.

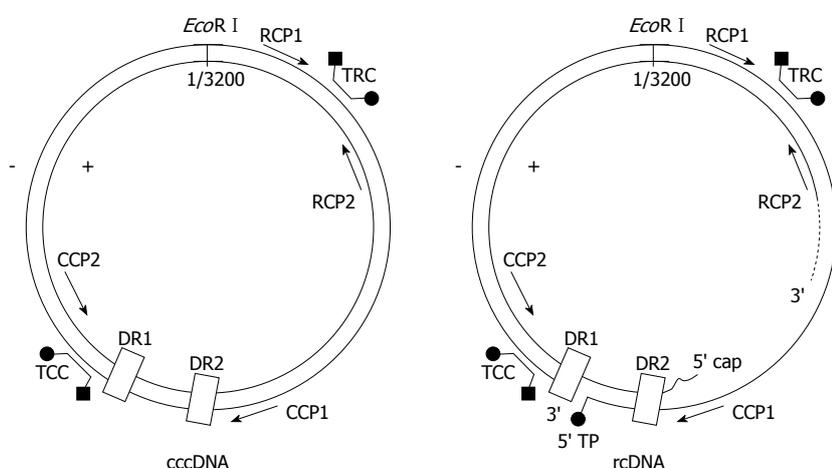

Figure 1 Schematic diagram of intracellular covalently closed circular DNA (cccDNA), relaxed circular DNA (rcDNA) and design of PCR primers and probes. When rcDNA is detected by primer set CCP1 and CCP2, new strand extension priming by CCP1 or CCP2 will cease at the site of the nick in the minus strand or gap in the plus strand, respectively, and no PCR product is generated. Therefore primer set CCP1 and CCP2 will preferentially amplify cccDNA and not (or to a lesser extent) rcDNA. Primer set RCP1 and RCP2 can amplify both cccDNA and rcDNA.

pgRNA and another 1×10^6 cells for rcDNA. At each interval, those unharvested flasks continued to be incubated with fresh culture media containing the same amount of antiviral agent as before.

Determination of HBsAg, HBeAg and HBV DNA in supernatant

Supernatant from each flask was collected at different times after oxymatrine treatment and stored at -20°C until measurement. HBsAg and HBeAg were simultaneously detected by ELISA kits (Sino-America Biotechnology Co. Ltd, Shanghai, China) according to the manufacturer’s instruction. HBV DNA in the supernatant was purified with QIAamp DNA Mini Kit (QIAGEN Inc., Chatsworth, CA, USA) following the manufacturer’s instruction, and then was determined by real-time fluorescent PCR with primer RCP1/RCP2 and Taqman® minor grooving binder (MGB) probe DRC, targeting the S open reading frame (ORF) of HBV genome (Figure 1 and Table 1).

Real-time fluorescent PCR was performed on the ABI prism 7000 Sequence Detection System (Applied Biosystems Inc., USA) with following PCR cycling parameters: 2 min at 50°C for uracil N-glycosylase incubation, 10 min at 95°C for Hotstart Taq DNA polymerase activation, followed by 40 cycles of denaturation for 30 s at 95°C and annealing for 60 s at 60°C. The reaction system consisted

of 0.5 μL of sense primer (25 μmol/L), 0.5 μL of anti-sense primer (25 μmol/L), 1.25 μL of Taqman MGB probe (10 μmol/L), 25 μL of Taqman® Universal PCR master mix (2 × concentration, P/N 4304437, Applied Biosystems Incorporation, USA), 5 μL of template, supplemented with double-distilled water to a final volume 50 μL. Uniform real-time PCR system and cycling mode were utilized in the determination of cccDNA, total HBV DNA and cDNA because different prime sets and probes were designed based on the same principle for Taqman® real-time PCR technology.

Purification and quantification of intracellular cccDNA

Since HBV cccDNA is structurally similar to plasmid, intracellular cccDNA was extracted from cells by an alkali lysis procedure with Plasmid Mini Kit (QIAGEN Inc., Chatsworth, CA, USA), which would remove most of cellular chromosomal DNA and non-supercoiled rcDNA. Purified cccDNA was dissolved in 50 μL TE buffer (10 mmol/L, pH 8.0), and 10 μL product was further treated with Plasmid-Safe™ ATP-Dependent DNase (PSAD, Epicentre Technologies, Madison, WI, USA) to remove any remaining rcDNA, single-stranded virus DNA and cellular chromosomal DNA. Briefly, DNA was digested with 10 U PSAD for 1 h at 37°C in the presence of 1 × buffer (33 mmol/L Tris-acetate pH 7.8, 66 mmol/L

potassium acetate, 10 mmol/L magnesium acetate and 0.5 mmol/L DTT) and 1 mmol/L ATP, followed by incubation in 70°C water for 30 min to inactivate PSAD. Intracellular cccDNA was quantified by selective fluorescent PCR with primer set spanning DR1 and DR2 region, which had been documented to be capable of amplifying cccDNA more efficiently than rcDNA (10⁴:1)^[20,21]. Design of the primer set CCP1 and CCP2, and the Taqman[®] MGB probe DCC was demonstrated in Figure 1 and Table 1. The mean level of cccDNA pool of each cell at different times was calculated according to total cccDNA and the number of cells for cccDNA extraction (1 × 10⁶).

Isolation of intracellular core particles and determination of viral DNA

Cytoplasmic core particles in HepG2.2.15 cells were isolated as described with modification^[22]. Briefly, cells were incubated at 37°C with 1 mL of lysis buffer (1 mmol/L EDTA, 0.1% Nonidet P-40, 50 mmol/L NaCl, 8% sucrose) for 10 min, then nuclei and other insoluble materials were removed by centrifugation at 15000 r/min for 2 min. Supernatants were treated with 10 U RQ1 DNase (Promega) and 0.1 µg of RNase A (Sigma) at 37°C for 15 min, then 1/4 volume of polyethylene glycol 8000 (PEG 8000, Amresco) solution (10% PEG 8000, 0.6 mol/L NaCl) were added, followed by incubation at 4°C for 30 min and centrifugation at 15000 r/min for 10 min. Pellets containing core particles were re-suspended in 500 µL of digestion buffer (50 mmol/L Tris, 10 mmol/L EDTA, 150 mmol/L NaCl, 1% sodium dodecyl sulfate, 0.5 mg/mL proteinase K, pH 8.0) and were incubated at 50°C for 2 h. Nucleic acids were extracted with phenol:chloroform (25:24) and then with chloroform:isoamylol (24:1), and were precipitated from the aqueous fraction with ethanol, dissolved in TE buffer (10 mmol/L Tris hydrochloride, 1 mmol/L EDTA, pH 8.5). Viral DNA in core particles was quantified by real-time fluorescent quantitative PCR with primer RCP1/RCP2 and Taqman MGB probe TRC (Figure 1 and Table 1). The mean viral DNA in core particles of each cell was calculated in the same way as cccDNA.

Extraction of total RNA and analysis of intracellular pgRNA

Total RNAs were extracted from cells with Total RNA Miniprep System (Viogene, Sunnyvale, CA, USA) and dissolved in 50 µL RNase-Free ddH₂O, and 10 µL product was treated with 8 U RQ1 DNase to eliminate DNA contamination from virus or cells. Then cDNAs were synthesized by reverse transcription with SuperScript[™] III First-Strand Synthesis System for RT-PCR (Invitrogen Corp., San Diego, CA, USA) according to the manufacturer’s instruction.

Because HBV mRNAs of different lengths (3.5, 2.4, 2.1 and 0.7 kb) are transcribed from the same cccDNA template, and ORFs overlap with each other in various regions (Figure 2), it is crucial to find a specific target region for RT-PCR in order to discriminate pgRNA from other mRNAs. In addition to its role in viral DNA replication, the pgRNA is also a bicistronic mRNA that encodes C

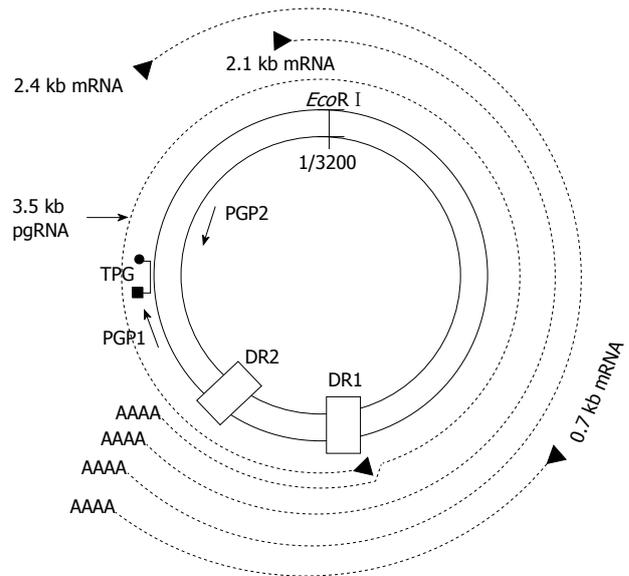

Figure 2 Schematic diagram of HBV mRNAs and design of PCR primer and probe for determining pregenomic RNA (pgRNA). Four kinds of HBV mRNAs are transcribed from the same cccDNA template and overlap with each other in various regions (dashed lines, dark triangle indicating the initiate site of transcription). The largest mRNA, 3.5 kb pgRNA, encodes both core protein and DNA polymerase of HBV. The promoter region of the DNA polymerase gene, which does not exist in the other 3 smaller mRNAs, was selected as the amplifying target for determining pgRNA by real-time RT-PCR with primer PGP1, PGP2 and Taqman MGB probe TPG.

and P proteins^[22,23], which contain an approximate 1010 bp nucleotide sequence (nt1838-2850, from the end of X ORF to the origin of S ORF) not existing in the other 3 smaller mRNAs (Figure 2). The primer set PGP1/PGP2 and Taqman MGB probe TPG targeting this region was designed to detect pgRNA (Table 1 and Figure 2). Results of RNA extraction and RT-PCR were normalized with the housekeeping gene β-actin as control^[24]. The β-actin cDNA of each sample was determined simultaneously by real-time PCR with primer BAP1/BAP2 and Taqman MGB probe TBA (designed on the basis of M10277 β-actin gene sequence). The mean expression level of β-actin in HepG2.2.15 was assumed to be similar to that in human tissues, namely, 5320 copies per cell^[25].

Statistical analysis

All results were expressed as mean ± SD. Data from the treatment group and normal control group were analyzed by the Student unpaired *t* test using statistical software SPSS 10.0. Differences were considered statistically significant at *P* < 0.05.

RESULTS

Cytotoxicity of oxymatrine to HepG2.2.15 cells

Cytotoxicity to HepG2.2.15 cells was determined with fresh culture medium containing serial 1:2 dilutions of oxymatrine. The survival percentage of HepG2.2.15 cells under different concentrations of oxymatrine is shown in Figure 3. The mean half toxic concentration (TC₅₀) of oxymatrine was 1219.66 µg/mL, calculated by the Reed-

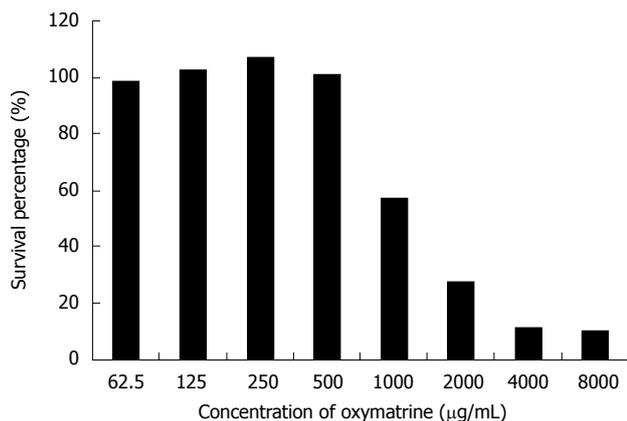

Figure 3 Survival of HepG2.2.15 cells after oxymatrine treatment. Two days after being inoculated, cells were incubated with different concentrations of oxymatrine for 6 d, and then the percent survival of cells was determined by MTT assay. The cytotoxicity experiment was repeated twice.

Muench formula^[26]. In further experiments, the effect of 500 µg/mL of oxymatrine (approximately equal to the largest nontoxic concentration) on the replication cycle of HBV was analyzed *in vitro*.

Effect of oxymatrine on secretion of HBsAg and HBeAg in HepG2.2.15 cell line

As shown in Figure 4, oxymatrine could inhibit secretion of HBsAg and HBeAg by HepG2.2.15 cells. After treatment with oxymatrine for 2 d and 5 d, the mean optical density at a wavelength of 450 nm (A_{450}) was 0.096 ± 0.011 and 0.175 ± 0.016 , respectively, when HBsAg in the supernatant was determined by microplate reader (Model 550, Bio-Rad), and decreased by 22.67% ($t = 5.439, P = 0.0322$) and 22.39% ($t = 5.376, P = 0.0329$) compared to the normal control ($A_{450} = 0.124 \pm 0.018$ and $A_{450} = 0.226 \pm 0.022$, respectively). The A_{450} of HBeAg in the supernatant after treatment for 2 d and 5 d was 0.259 ± 0.031 and 0.713 ± 0.031 , respectively, which indicated that secretion of HBeAg was reduced by 55.34% ($t = 9.859, P = 0.0101$) and 43.97% ($t = 14.080, P = 0.0050$) compared to the normal control ($A_{450} = 0.580 \pm 0.034$ and $A_{450} = 1.269 \pm 0.052$, respectively). Of note was that the reduction in HBeAg was at least twice that of HBsAg.

Effect of oxymatrine on production of virions in the supernatant

Since each virion contains only one copy of the genome, production of hepatitis B virions in the supernatant could be measured by quantification of supernatant HBV DNA. As demonstrated in Figure 5A, treating HepG2.2.15 cells with oxymatrine resulted in a significant reduction in hepatitis B virions in the supernatant. After treatment with 500 µg/mL oxymatrine for 2 d and 5 d, the level of HBV DNA in the supernatant was $(5.69 \pm 0.86) \times 10^4$ and $(7.86 \pm 0.99) \times 10^4$ copies/mL, respectively, while in the normal control the mean level was $(9.60 \pm 2.98) \times 10^4$ and $(31.85 \pm 4.74) \times 10^4$ copies/mL, respectively. In another words, production of virions was reduced by 40.75% ($t = 4.570,$

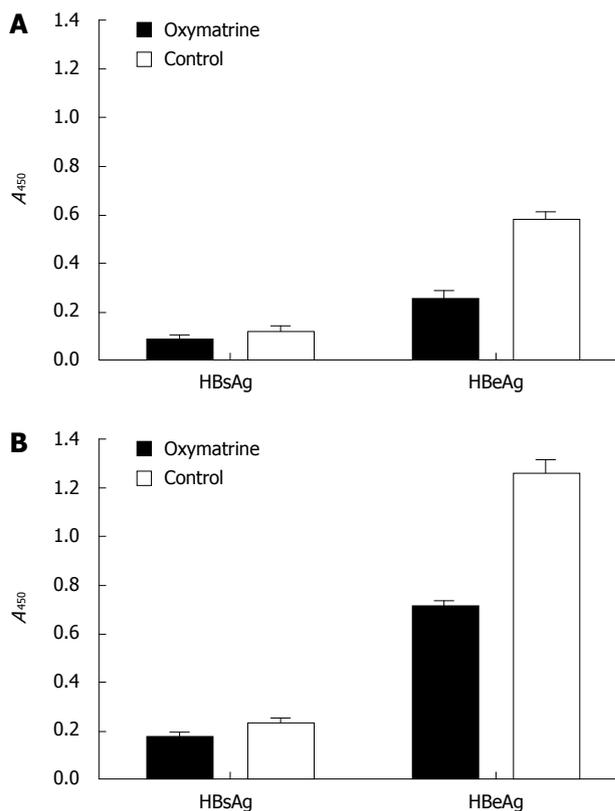

Figure 4 Effect of oxymatrine on the secretion of HBsAg and HBeAg in the HepG2.2.15 cell line. A: After treatment with oxymatrine for 2 d, HBsAg in the supernatant decreased by 22.67% compared to normal control, and HBeAg by 55.43%; B: After treatment with oxymatrine for 5 d, HBsAg in the supernatant decreased by 22.39% compared to normal control, and HBeAg by 43.97%.

$P = 0.0447$) and 75.32 % ($t = 14.460, P = 0.0047$), at 2 d and 5 d, respectively.

Effect of oxymatrine on the formation of intracellular HBV cccDNA pool

At different times after oxymatrine treatment, the HBV cccDNA pool in HepG2.2.15 cells diminished significantly compared with the normal control group (Figure 5B). After treatment for 2 d and 5 d, the size of the intracellular HBV cccDNA pool was downregulated to 0.75 ± 0.16 and 3.50 ± 0.26 copies per cell, respectively. The decrease was 63.98% ($t = 6.152, P = 0.0254$) and 80.83% ($t = 10.270, P = 0.0093$), respectively, after incubation with oxymatrine, compared with normal controls (2.09 ± 0.23 and 18.26 ± 3.43 copies per cell, respectively).

Effect of oxymatrine on viral DNA synthesis in the intracellular core particles

The effect of oxymatrine on the intracellular production of progeny viruses was indirectly measured by determination of HBV DNA in the intracellular core particles. As shown in Figure 5C, treatment with oxymatrine could lower the level of viral DNA in core particles isolated from HepG2.2.15 cells. After oxymatrine treatment for 2 d and 5 d, viral DNA in core particles was reduced to 144.95 ± 48.78 and 302.32 ± 36.36 copies per cell, respectively,

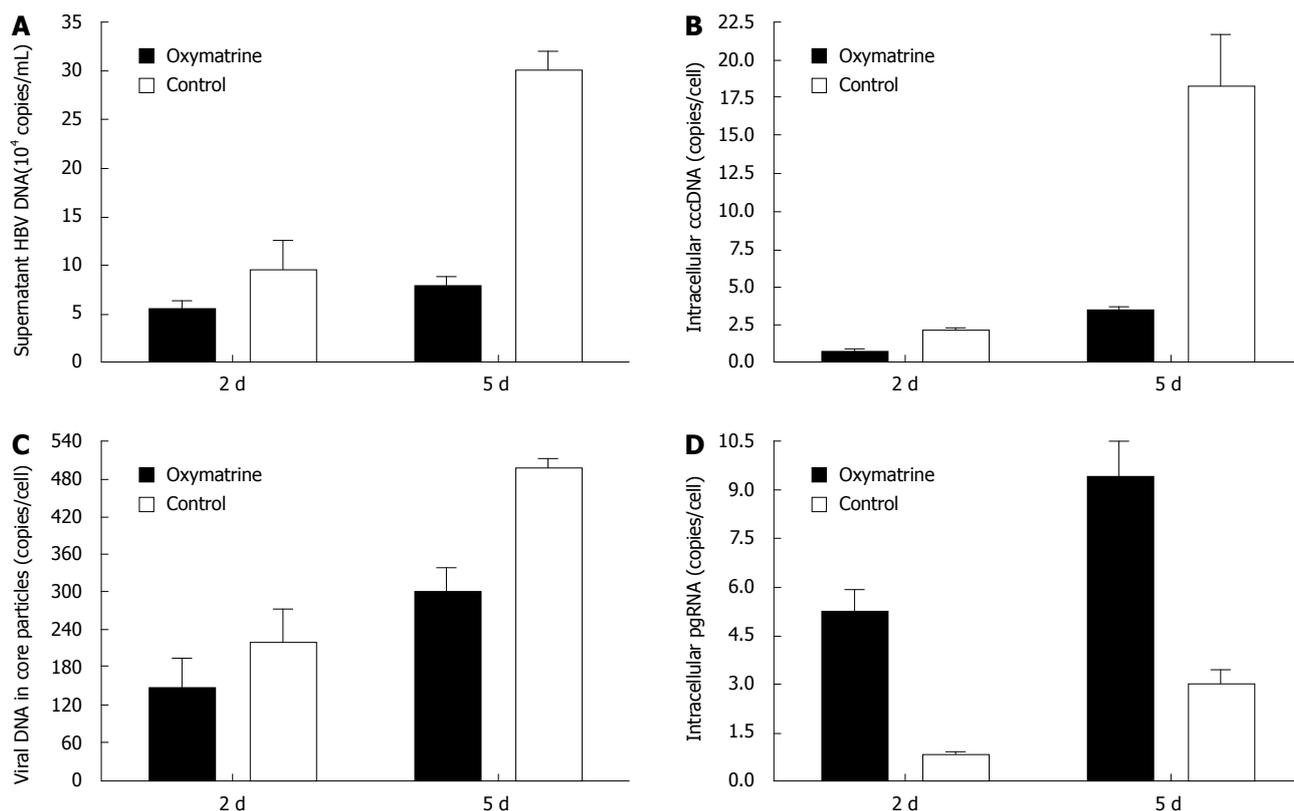

Figure 5 Effect of oxymatrine on the replication of HBV in HepG2.2.15 cell line after treatment for 2 d and 5 d. Compared to normal control, treatment with oxymatrine for 2 d and 5 d resulted in: (A) a decrease in HBV DNA in the supernatant by 40.75% and 75.32%, respectively; (B) a reduction in the intracellular HBV cccDNA pool by 63.98% and 80.83%; and (C) a reduction in viral DNA in the intracellular core particles by 34.35% and 39.24%. However, intracellular pgRNA increased by 6.90-fold and 3.18-fold (D).

which was 34.35% ($t = 4.776, P = 0.0413$) and 39.24% ($t = 10.050, P = 0.0097$) lower than that of normal controls (220.79 ± 51.73 and 497.57 ± 16.15 copies per cell, respectively). It could be noted that the reduction of viral DNA in core particles was not as great as that of the intracellular HBV cccDNA pool and HBV DNA in the supernatant after treatment with oxymatrine either for 2 or 5 d. In addition, the HBV cccDNA pool was significantly lower than that of viral DNA in core particles. After treatment with oxymatrine for 2 d and 5 d, the level of viral DNA in core particles was 193.27-fold and 86.38-fold the size of the cccDNA pool, respectively. For the normal control, it was 105.64-fold and 27.25-fold, respectively.

Effect of oxymatrine on intracellular HBV pgRNA

Unlike the other 2 replicative intermediates, the level of intracellular HBV pgRNA was upregulated after oxymatrine incubation, as shown in Figure 5D. With oxymatrine treatment for 2 d and 5 d, intracellular pgRNA accumulated to 5.25 ± 0.69 and 9.43 ± 1.13 copies per cell, respectively, which was 6.90-fold ($t = 8.941, P = 0.0123$) and 3.18-fold ($t = 7.432, P = 0.0176$) to that of normal control (0.76 ± 0.16 and 2.97 ± 0.48 copies per cell, respectively).

DISCUSSION

Because of the lack of a convenient and economic ani-

mal model with persistent HBV infection, the effect of oxymatrine on the replication cycle of HBV was investigated in the HepG2.2.15 cell line, which was established by transfecting a hepatoblastoma cell line (HepG2) with plasmids containing four 5'→3' tandem copies of the HBV genome, and could produce 42 nm Dane particles and more 22 nm spherical or filamentous particles^[18]. The cell line could support the full replication cycle HBV, as evidenced by identification of replicative intermediates or products including cccDNA, HBV-specific polyadenylated RNAs (pgRNA, 2.5 kb RNA and 2.1 kb RNA), and incomplete double- and single-stranded forms of the HBV genome, none of which were necessarily dependent on the chromosomally-integrated HBV DNA^[27]. In addition, HBV virions produced by the cell line were rich in endogenous polymerase activity^[27] and could induce hepatitis in chimpanzees^[28]. Therefore, the cell line is an appropriate model for identifying the molecular events in intracellular viral replication cycle as well as secretion of HBV particles.

As indicated by our results, secretion of HBsAg and HBeAg from HepG2.2.15 cells could be inhibited after incubation with oxymatrine for 2 d and 5 d. Of note was that secretion of HBeAg was reduced more than that of HBsAg after oxymatrine treatment either for 2 d (22.67% vs 55.43%) or 5 d (22.39% vs 43.97%). A discrepancy between the reductions in HBsAg and HBeAg has also

been observed by other researchers^[9,29]. HBsAg is encoded by S ORF of the viral genome, and is organized into spherical or filamentous HBsAg particles outside infected cells without a viral genome, which typically outnumber virions by 1000:1 to 10 000:1^[30]. Thus, expression of HBsAg can be independent of the replication of HBV. HBeAg is translated from the same template as core protein and polymerase, pgRNA, which is also the template for synthesis of progeny virus. In contrast to HBsAg, although HBeAg plays no role in viral assembly and its function is not clear^[30], expression and secretion of HBeAg were found to be associated with active replication of HBV^[31]. Therefore, inhibition of HBV replication would inevitably reduce the secretion of HBeAg while it may not affect or have a smaller effect on the secretion of HBsAg, as evident by the difference between the reductions in HBsAg and HBeAg by oxymatrine.

Consistent with previous research *in vitro*^[9,19,29], definite inhibition by oxymatrine of the replication of HBV was observed in our investigation. As far as we know, this was the first time that the effect of oxymatrine on production of virions in the supernatant and intracellular synthesis of the viral genome was simultaneously investigated. After treatment with oxymatrine for 2 d and 5 d, production of virions in the supernatant was reduced by 40.75% and 75.32%, while viral DNA synthesis in intracellular core particles was 34.35% and 39.24% lower than that of normal control. It appeared that extracellular viral DNA was more likely to be reduced by oxymatrine than intracellular viral synthesis. A similar effect has also been observed in cell lines treated with lamivudine or clevudine^[32], and in patients with chronic hepatitis B who were under antiviral therapy with adefovir or entecavir^[33,34]. A possible explanation for this may be that competitive inhibition of activity of HBV DNA polymerase or premature chain termination by these antiviral agents may result in predominant immature viral particles containing only intact or non-intact single-stranded viral DNA, which could not be discriminated from mature virions containing relaxed circular double-stranded DNA by routine PCR or fluorescent PCR. Therefore, the reduction in mature virions may not be intrinsically reflected in the determination of viral DNA in core particles by PCR. In contrast, because only mature virions could be secreted outside infected cells^[16], reduced intracellular production of mature virions could be more sensitively identified by detection of supernatant HBV DNA in cell lines or serum HBV DNA *in vivo*.

The effect of oxymatrine on intracellular HBV cccDNA was also first reported in this research. HBV cccDNA is the first replicative intermediate generated after HBV entering into hepatocytes, which indicates the origination of intracellular HBV replication and successful establishment of HBV infection^[17]. Reductions varying from 0.8 log₁₀ to 2.8 log₁₀ in the intrahepatic cccDNA have been reported in patients receiving mono- or combined antiviral therapy with IFN- α or nucleos(t)ide analogues for 48 wk^[33-35], and persistence of cccDNA in the nuclei of hepatocytes after withdrawal of antiviral agents was be-

lieved to be primarily responsible for the reoccurrence of hepatitis B^[36]. Therefore, the effect on nuclear cccDNA was an indispensable index when evaluating an anti-HBV agent, and a predictor of a sustained antiviral response to therapy^[37]. In our research, a marked decline in the intracellular cccDNA pool was observed after oxymatrine treatment for 2 d and 5 d (63.98% and 80.83%, respectively). The conversion of viral genome into cccDNA did not depend on viral polymerase activity^[20], and formation of the nuclear cccDNA pool in the nuclei of hepatocytes had been shown to be mainly dependent on recycling of cytoplasmic mature progeny virions into nuclei of hepatocytes^[38,39]. Therefore, the reduction in the cccDNA pool induced by oxymatrine may be attributed to reduction in cytoplasmic mature virions rather than direct inhibition of the conversion of rcDNA into cccDNA. It should be noted that, in contrast to hepatocytes in the liver, HepG2.2.15 cells are actively dividing, and whether cccDNA can survive cell division or not is still unknown^[40]. The reduction in the cccDNA pool should not be attributed to cell proliferation, because the survival of HepG2.2.15 cells incubated with 500 μ g/mL oxymatrine was found to be approximately 100% in the cytotoxicity experiment (Figure 2), and the cell proliferation rate after oxymatrine treatment was not significantly different to that of normal control when assessed by the total number of cells acquired from flasks at each time (data not shown).

Interestingly, although significantly lower than that of the normal control group ($P < 0.05$), the cccDNA pool after oxymatrine continued to expand slowly (from 0.75 copies per cell to 3.50 copies per cell). This was probably because production of virions in the cytoplasm was not completely inhibited, and more cytoplasmic rcDNAs were recycled into the nucleus instead of being secreted out so as to compensate for the loss of the cccDNA pool and maintain intracellular infection. The "wisdom" of HBV to maintain an intracellular existence by conserving cccDNA could be corroborated by other facts. It has been reported that even in chimpanzees or patients with sustained clearance of serum HBsAg and negative serum HBV DNA, residual cccDNA could still be detected in their hepatocytes^[41,42].

In our research, a special strategy was taken to determine intracellular cccDNA, which integrated extraction by alkali lysis, purification with Plasmid-Safe™ ATP-dependent DNase (PSAD) and quantitative real-time PCR with selective primer set. Because HBV cccDNA is similar to plasmid in spatial structure and physicochemical characteristics, a procedure for purification of plasmid DNA with a kit based on alkali lysis was adopted, which would irreversibly denature double-stranded DNA species (including HBV DNA integrated into the cellular chromosome and viral rcDNA) that were not covalently closed^[43,44]. PSAD can selectively hydrolyze linear double-stranded (ds) DNA to deoxynucleotides at slightly alkaline pH, and with a lower efficiency, hydrolyzes linear and closed circular single-stranded DNA. We had observed that overnight incubation of total chromosomal DNA from 20 mg of

liver tissues with 10 U PSAD could digest it to an invisible level in agarose electrophoresis, and approximately 1 log₁₀ reduction was observed by real-time PCR when HBV genome with 10⁸ to 10⁶ hepatitis B virions was treated with 10 U PSAD for 1 h (data not shown). PSAD was also frequently used by other researchers^[21,32,33,35] to minimize the background rcDNA before detection of cccDNA with selective PCR, which would preferentially amplify cccDNA rather than rcDNA (10⁴:1)^[20,21].

After oxymatrine incubation for 2 d and 5 d, intracellular pgRNA increased by 6.90-fold and 3.18-fold, respectively. It seemed a little incomprehensible why pgRNA accumulated distinctively in spite of a decline in the cccDNA pool and reduction of DNA synthesis in core particles. Two possible targets in the intracellular replication cycle of HBV interference by oxymatrine might account for such result. First, the packaging process of pgRNA into the protein nucleocapsid was interrupted by oxymatrine, and pgRNA accumulated in the nucleus or cytoplasm of hepatocytes, which resulted in further reduction of DNA synthesis in core particles and then nuclear cccDNA. Second, pgRNA was packaged into nucleocapsid as normal, but the activity of virus DNA polymerase was suppressed by oxymatrine. It is well known that accompanying extension of viral minus-strand DNA by reverse transcription with pgRNA as template (catalyzed by reverse transcriptase activity of HBV polymerase), pgRNA is degraded synchronously from pgRNA/minus-strand DNA hybrids by the RNase H activity of viral polymerase^[17,45]. Therefore, suppression of viral DNA polymerase would lead to reduction of rcDNA and cccDNA and less pgRNA degradation compared to the normal control group. This hypothesis could be evidenced by the phenomena discovered by other investigators, who reported that duck HBV reverse transcriptase expressed by a recombinant P vector would suppress viral pregenomic RNA accumulation by 3-4-fold in an LMH cell line^[24]. Whether the packaging process of pgRNA or viral DNA polymerase was the exact antiviral target of oxymatrine remains to be further investigated.

Very few investigations had studied the effect of antiviral agents on intracellular HBV RNAs as far as we know. In HBV-transgenic mice, animals treated with adefovir resulted in a significant reduction in serum and intrahepatic HBV DNA, but mean relative intrahepatic HBV RNA (log₁₀ pg/μg ± SD), seemed to be a little higher than that of saline-control animals (5.8 ± 2.5 *vs* 4.7 ± 2.4) after treatment, although the difference was not statistically significant^[46]. In the same research, animals treated with lamivudine had a significant reduction in serum HBV DNA, and slight but insignificant reduction in intracellular HBV DNA, and HBV RNA seemed to be even higher than that of saline-control animals (7.0 ± 1.4 *vs* 4.7 ± 2.4) although the difference was also statistically significant. It should be noted that the author did not clarify which fragment of HBV DNA had been chosen as a probe for detecting HBV RNA by Northern blot, so it was hard to know which of the 4 HBV mRNAs (3.5 kb,

2.4 kb, 2.1 kb and 0.07 kb) may contribute to the alteration of HBV RNA in the result. Other nucleoside analogues, such as 5-fluoro-2',3'-dideoxy-3'-thiacytidine (5-FSddC), failed to affect intrahepatic HBV-specific RNAs (3.5 kb, 2.5 kb and 2.1 kb) when detected by Northern blot, although they reduced intracellular viral DNAs (rcDNA and single-stranded DNA) in a dose-dependent manner^[47].

In conclusion, our research demonstrated an inhibitory effect of oxymatrine on the replication cycle of HBV, which may be attributed to interference with the process of packaging pgRNA into the nucleocapsid, or inhibiting the activity of the viral DNA polymerase. The independent effect of oxymatrine on these 2 targets remains to be studied further. In addition, comparative analysis of the chemical or spatial structure between oxymatrine and nucleoside analogues may help illuminate the antiviral mechanism of oxymatrine.

COMMENTS

Background

It is the consensus that anti-hepatitis B virus (HBV) therapy plays a decisive role in slowing disease progress, prolonging the survival, and improving the prognosis of patients with chronic hepatitis B. Anti-HBV agents now available include interferon-α and several nucleos(t)ide analogues. Although many patients have benefited from them, the adverse effect of interferon-α, virus-resistance to nucleos(t)ide analogues as well as the high cost of these agents have limited their utilization. Therefore, it is very necessary to screen for more cost-effective antiviral agents.

Research frontiers

China has unique resources for screening for candidate anti-HBV drugs in traditional medicine. In this area, most researchers work hard to find new derivatives or mono-components from various Chinese herbs to test their anti-HBV effect *in vitro* or *in vivo*. However, not enough importance has been attached to identification of the antiviral mechanism of the agents that seem to have promising anti-HBV activity.

Innovations and breakthroughs

Oxymatrine is a type of alkaloid extracted from the herb *Sophora alopecuroides* L. Prior research concerning oxymatrine involved determining its anti-HBV effect in cell lines, in animals and in double-blind, randomized, multicenter clinical trials. Some researchers had observed its effect in relieving hepatic fibrosis or severe liver injury. Unfortunately, no research had tried to explore the exact antiviral target of oxymatrine, and little was known about the mechanism of oxymatrine against HBV until now, which is a major obstacle to its marketing. In this paper, the authors reported the effect of oxymatrine on the main steps of the HBV replication cycle. The change in different replicative intermediates after oxymatrine incubation was documented and analyzed for the first time. Based on the results, the authors proposed that oxymatrine may inhibit the replication of HBV by interfering with the process of packaging pregenomic RNA (pgRNA) into the nucleocapsid, or inhibiting the activity of the viral DNA polymerase.

Applications

Although the authors have not confirmed the exact target of oxymatrine in inhibiting the replication of HBV in this article, the preliminary results proposed 2 candidate targets for further research.

Peer review

In this paper, the effect of oxymatrine on the replication cycle in the HepG2.2.15 cell line was investigated, and the possible antiviral targets of oxymatrine were explored. The inhibitory effect of oxymatrine on the replication cycle of HBV, interfering with the process of packaging pgRNA into the nucleocapsid, or inhibiting the activity of the viral DNA polymerase were demonstrated.

Abstract

AIM: To analyze the value of computed tomography (CT) volume measurements for evaluation of the survival rate of unresectable hepatocellular carcinoma (HCC) patients after transcatheter arterial chemoembolization (TACE).

METHODS: One hundred and sixty-six unresectable HCC patients after TACE were involved in this retrospective study. Hepatic CT scan was performed for all patients before and 4 wk to 2 mo after TACE to define the morphologic features of HCC including its largest diameter, volume, product of the greatest axial dimension, tumor to liver volume ratio (TTLVR), and tumor shrinkage ratio. Clinical variables used in the study included gender, age, pattern of tumor growth, number of lesions, Child-Pugh classification of liver function, repeated TACE times, pre- or post-treatment α -fetoprotein (AFP) level, portal vein cancerous thrombus, tumor me-

tastasis, degree of lipiodol retention within the tumor, and percutaneous ethanol injection. The correlation between survival time and clinical variables of patients or lesions was analyzed by combining morphologic features with the corresponding clinical and general data as input. A Cox proportional hazard model was used to analyze prognostic factors. The Kaplan-Meier method was used to calculate the cumulative survival time. Influence of the parameters on prognosis was analyzed by the log-rank test.

RESULTS: The overall 6, 12, 24, 36 and 60 mo cumulative survival rates were 78.92%, 49.85%, 23.82%, 15.60% and 8.92%, respectively. The median survival time was 12 mo. Univariate and multivariate analysis showed that only 4 parameters were the independent prognostic factors including TTLVR ($\chi^2 = 14.328$, $P < 0.001$), portal vein cancerous thrombus ($\chi^2 = 5.643$, $P = 0.018$), repeated TACE times ($\chi^2 = 8.746$, $P = 0.003$), and post-treatment serum AFP level ($\chi^2 = 5.416$, $P = 0.020$). When the TTLVR value was less than 70%, the survival time was inversely correlated with the TTLVR value.

CONCLUSION: CT volume measurement technique can predict the prognosis of unresectable HCC patients after TACE.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies in Africa and Asia, especially in China and Japan. The tumor is often already large in size when it is diagnosed, and the prognosis of HCC patients, especially those with unresectable lesions tends to be poor. The median survival time of untreated HCC patients is less than 6 mo from its diagnosis^[1,2]. The treatment of HCC is very challenging. The outcome of resection and liver transplantation is good. However, they are only suitable for less than 15% of patients. Although many treatment modalities for HCC are available, transcatheter arterial chemoembolization (TACE) has been shown to be the most effective procedure for unresectable HCC^[3]. Patients receiving TACE often demonstrate a remarkable embolization effect and consequently have a higher cumulative survival rate^[4].

Advances in computed tomography (CT) technology can quantify volumetric tumor burden due to its volumetric data acquisition and image processing^[5-8]. Compared with uni- and bi-dimensional measurement techniques, volumetric quantification can result in a different assessment result^[9-11].

The largest tumor diameter, product of the greatest axial dimension, and several volume measurements show a congruence with the actual volume when the measured lesion is a sphere, an ellipsoid, or a cube. However, these measurements may have significant differences if the tumor has an irregular shape^[12,13]. Three-dimensional (3D) measurements have advantages for the assessment of irregular masses, because they compensate for actual tumor shape rather than assume it to be a sphere, an ellipsoid, or a cube^[6,14]. Spiral CT theoretically offers advantages in terms of accuracy and reproducibility over 3D measurements^[14,15]. In follow-up studies, 3D measurements enable the evaluation of changes in the diameter of a neoplasm, and offer a more complete evaluation of changes in tumor size over time.

It has been reported that TACE in combination with cytostatic drugs (doxorubicin, cisplatin, mitomycin C) for treatment of HCC patients can reduce vital tumor tissue and prolong survival time^[1,3,4,16]. When an indication for palliative TACE is established, strict guidelines based on the condition of patients and tumor stage must be followed. In this study, we retrospectively reviewed the morphologic CT data about lesions in 166 unresectable HCC patients after TACE. The correlation between morphological variables and survival rate was also intensively investigated.

MATERIALS AND METHODS

Clinical data and variables

Segmental lipiodol-TACE was performed for 166 HCC patients (143 men, 23 women) at the age of 51 ± 12 years (range: 21-78 years) in February 1999 to August 2006. HCC was diagnosed based either on percutaneous liver needle biopsy (112 patients) or on imaging and clinical examination (54 patients). This retrospective study was approved by our institution's research ethics board. Informed consent was obtained from all patients. Cirrhosis was classified according to the Child-Pugh system. Child-Pugh grades A and B were found in 148 and 18 patients, respectively.

The morphologic features of HCC, including its largest diameter, product of the greatest axial dimensions, tumor volume (TV), tumor to liver volume ratio (TTLVR) and tumor shrinkage ratio (TSR) post-treatment, were evaluated for their correlation with treatment outcome. In addition, other study variables influencing treatment outcome were analyzed, including gender, age, pattern of tumor growth, number of lesions, Child-Pugh classification of liver function, repeated TACE times, pre-treatment or post-treatment serum α -fetoprotein (AFP) levels, portal vein cancerous thrombus, tumor metastasis, degree of lipiodol retention within the tumor, and percutaneous ethanol injection (PEI). A total of 17 variables were analyzed in the study.

Criteria for inclusion or exclusion of TACE

TACE was performed for HCC patients to control their local tumor growth and prolong their survival time. All patients undergoing TACE had contraindications for liver resection judged by a multidisciplinary team composed of hepatic surgeons, radiologists, hepatologists, and oncologists. The inclusion criteria for unresectable HCC include disease multifocality, early vascular invasion, decompensated liver disease, or poor performance status. To simplify the study, those whose main trunk of the portal vein was completely obstructed by a tumor thrombus or those who underwent surgical resection after TACE, were excluded from the study.

TACE procedures

Transcatheter hepatic segmental arterial chemoembolization using lipiodol mixed with anticancer drugs, including 40-60 mg adriamycin, 50-100 mg cisplatin (CDDP) or 10-20 mg mitomycin C (MMC) and a mixture of 2-30 mL iodized oil (lipiodol, André Guerbet, Aulnay-sous-bois, France), was carried out followed by injection of gel-foam particles. The mixture of lipiodol and anticancer drugs was super selectively infused into hepatic arteries supplying the tumor-bearing segment or subsegment until the lipiodol was densely accumulated in the tumor and tumor-bearing area. The arteries were then embolized with gelatin sponge particles. The volume of injected lipiodol in each patient was 2-30 mL depending on the

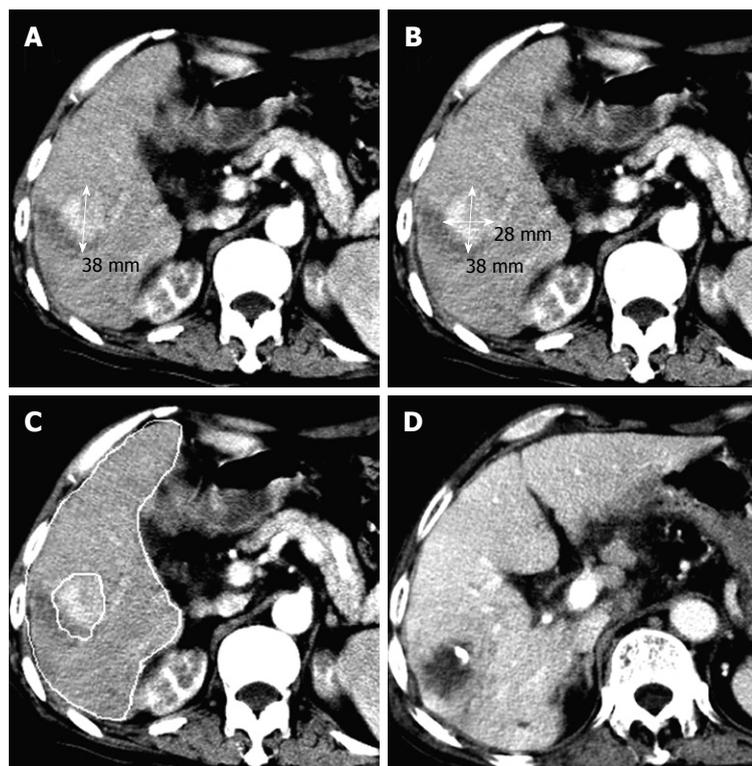

Figure 1 Transverse computed tomography (CT) scans showing a mononodular pattern of hepatocellular carcinoma (HCC) in the right posterior lobe of liver and an observed survival time of 33 mo in a 76-year-old man with a tumor volume of 55.64 cm³ and a tumor to liver volume ratio (TTLVR) of 5.16%. A and B: Arterial phase contrast-enhanced CT scan showing a high density nodule in the right lobe of liver before the first transcatheter arterial chemoembolization (TACE) procedure, while one-dimensional measurement showing the largest tumor diameter (3.8 cm), and two-dimensional measurement showing the tumor product of the greatest axial dimension (10.64 cm²); C: Contrast-enhanced CT scan showing hepatic and lesion volumetric measurements before the TACE procedure; D: Follow-up CT scan displaying complete tumor necrosis 44 d after the first TACE procedure.

tumor size, vascularity, and fluoroscopic findings^[4].

Tumor markers and CT/MR images were detected during the follow-up after TACE. TACE procedure was repeated if any residual tumor was detected after 4 wk. TACE was performed 1-7 times (1 time for 60, 2 times for 57, and ≥ 3 times for 49 patients) in the study, and the mean repetition frequency was 2.12 times. Of the 166 patients, 9 were treated with PEI after TACE.

CT scanning and measurement techniques

CT scanning was performed for patients using a helix-spiral CT scanner (Somatom Plus 4, Siemens, Germany) before treatment. Pre- and post-contrast enhanced images of the liver of all patients were obtained. Contrast medium (Omnipaque, 300 mgI/mL, Schering, Germany) was administered by intravenous bolus injection into a cubital vein during the arterial phase (volume = 100 mL, flow rate = 2-4 mL/s, scan delay time = 25 s), portal venous phase (scan delay time = 60 s) or venous phase (scan delay time = 90 s)^[16,17]. Biphasic and triphasic CT scans were performed for 76 and 90 patients, respectively.

CT scan and tumor measurements were performed using three measurement techniques during follow-up. Uni-dimensional measurement (Figures 1A and 2A) and product of the greatest axial dimension (Figures 1B and 2B) were obtained as previously described^[2]. TV was measured by manually delineating (with a computer mouse) its contours on all sections, followed by calculating the lesion area with computer software (Figures 1C and 2C) as previously described^[7,8,16,18]. Nonenhanced (Figure 2D) and contrast-enhanced CT (Figure 1D) were performed again within 4 wk to 2 mo (44 \pm 8 d) after TACE during the

follow-up. Volumetric CT evaluation included analysis of TV, liver volume, TTLVR, and TSR. The TTLVR value was less than 25% ($n = 74$), less than 50% ($n = 48$), less than 70% ($n = 38$), and 70% or over ($n = 8$)^[15], respectively. The TSR value was greater than 50% reduction in TV ($n = 33$), greater than 25% reduction in TV ($n = 64$), 0%-25% reduction in TV ($n = 27$), and disease progression ($n = 42$), respectively, after treatment. The retention of lipiodol within tumor tissue was classified into four types according to the lipiodol accumulation pattern observed after lipiodol-TACE^[19]: type I = homogeneous ($n = 38$), type II = defective (defect is found in lipiodol accumulation in the main tumor, $n = 44$), type III = inhomogeneous (inhomogeneous lipiodol accumulation was observed in the main tumor, $n = 53$), and type IV = only slight accumulation ($n = 31$).

Statistical analysis

Statistical analysis was performed using SPSS11.5. Survival time from the commencement of treatment was analyzed using the Kaplan-Meier method. The influence of parameters on prognosis was evaluated by log-rank test. The influence of clinical variables on prognosis was evaluated by univariate analysis. When the result was statistically significant, multivariate regression analysis according to the Cox proportional hazard model was used to analyze the factors influencing the prognosis to avoid any confounding interaction between them. The largest tumor diameter, product of the greatest axial dimensions, and TV/TTLVR represented the 1D, 2D, and 3D measurements, respectively. Correlations between tumor size, each of the three different measurements, and survival time were analyzed

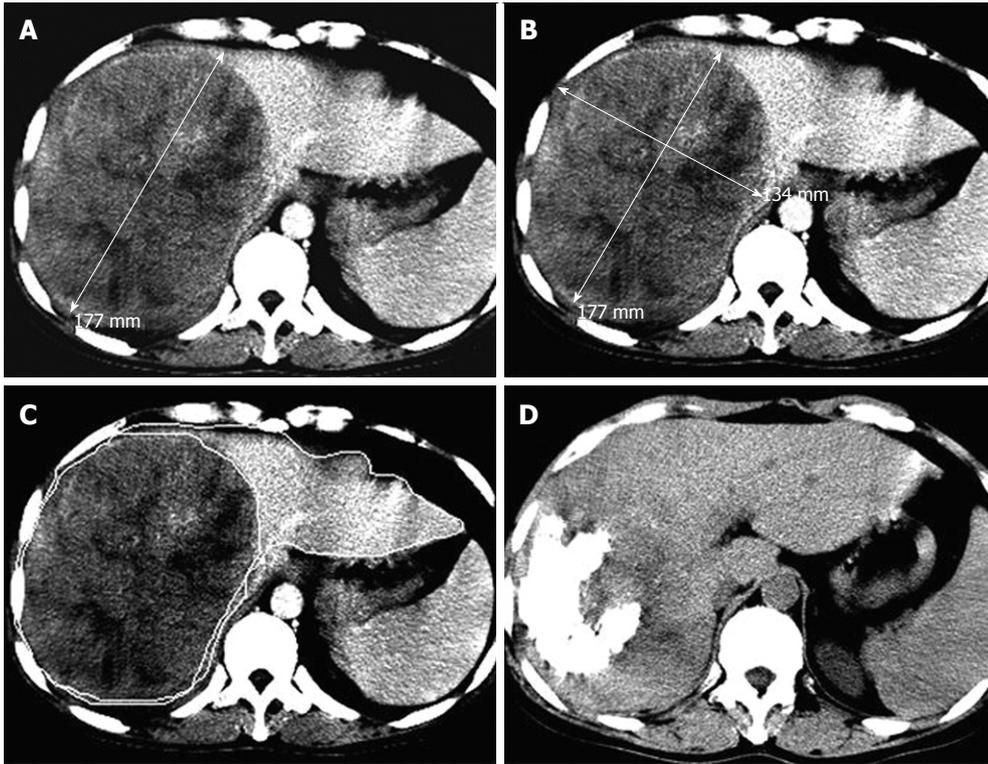

Figure 2 Transverse CT scans showing a massive pattern of HCC in the right lobe of a 46-year-old man with a tumor volume of 1936.70 cm³, a TTLVR of 67.52%, and a survival time of 6 mo. A and B: Arterial phase contrast-enhanced CT scan showing a high density tumor in the right lobe of liver before the first TACE procedure, while one-dimensional measurement showing the largest tumor diameter (17.7 cm) and two-dimensional measurement showing the tumor product of the greatest axial dimension (237.18 cm²); C: Contrast-enhanced CT scan showing hepatic lesion volumetric measurements before TACE; D: Nonenhanced CT follow-up scan showing lipiodol retention of grade III and a reduced tumor size 60 d after the first TACE procedure.

using the Spearman coefficient of correlation. $P < 0.05$ was considered statistically significant.

RESULTS

General features

The formed mass was divided into nodular type ($n = 39$), and massive type ($n = 127$) on the basis of imaging examination^[20]. Multiple lesions were identified in 31 patients and a mono-nodular pattern was detected in 135 patients. Portal vein cancerous thrombus was classified into four subgroups according to location: bilateral or trunk ($n = 20$), right branch ($n = 20$), left branch ($n = 6$), and no cancerous thrombus ($n = 119$). The serum AFP levels (< 20 ng/mL) were normal in 100 patients and elevated in 66 patients (≥ 20 ng/mL) before TACE. The patients with elevated AFP levels were monitored in 4 wk to 2 mo after TACE. The AFP level was decreased in 38 patients and increased in 28 patients after TACE. Tumor metastasis was divided into intrahepatic metastasis ($n = 24$), extrahepatic metastasis ($n = 6$), lymphoid node metastasis ($n = 13$), and no metastasis ($n = 123$).

Measurement data

The mean liver volume was 1621.39 ± 637.83 cm³ (range: 637.38-3514.73 cm³). The TV was 6 to 2432 cm³ with a mean of 590.13 ± 608.08 cm³ and a median of

384.26 cm³. The TTLVR was $30.54\% \pm 21.69\%$ (range: 0.44%-85%) with a median of 26.62%. The largest tumor diameter was 2.0-22 cm with a mean diameter of 9.47 ± 4.00 cm and a median diameter of 9.1 cm. The tumor product of the greatest axial dimension was 2.64-264 cm² with a mean of 79.76 ± 56.46 cm² and a median of 65.85 cm².

Cox proportional hazard model analysis

The survival time was analyzed using the Kaplan-Meier method. The overall results obtained by log-rank test are shown in Figure 3. The 6 mo-, 1-, 2-, 3-, and 5-year cumulative survival rates of patients after TACE were 78.92%, 49.85%, 23.82%, 15.60% and 8.92%, respectively. The median and mean survival time was 12 ± 1 mo and 20 ± 2 mo, respectively.

Univariate analysis showed that 13 parameters were the significant prognostic factors, including pattern of tumor growth, Child-Pugh's classification of liver function, repeated TACE times, post-treatment AFP level, portal vein cancerous thrombus, tumor metastasis, largest tumor diameter, tumor product of the greatest axial dimension, TV, TTLVR, TSR, degree of lipiodol retention within the tumor, and PEI (Table 1). Since these variables are related to each other, multivariate Cox regression analysis was performed using the significant variables identified in the univariate analysis model. Finally, 4 variables including

Method: Forward stepwise (likelihood ratio).

TTLVR, portal vein cancerous thrombus, repeated TACE times and post-treatment AFP level that entered the model could not be removed (Table 2).

In this study, the survival time was inversely correlated with the TTLVR values. The higher the TTLVR value was, the shorter the survival rate would be. The mean and median survival time was 28 and 18 mo, respectively, in 74 patients with their TTLVR less than 25%. Those whose TTLVR was 25%-50% and 50%-70% had a shorter mean and median survival time. Patients whose TTLVR was $\geq 70\%$ usually had a poor prognosis even after TACE. The survival time of 8 patients whose TTLVR was $\geq 70\%$ was no more than 6 mo after TACE, indicating that TTLVR is a significant factor influencing

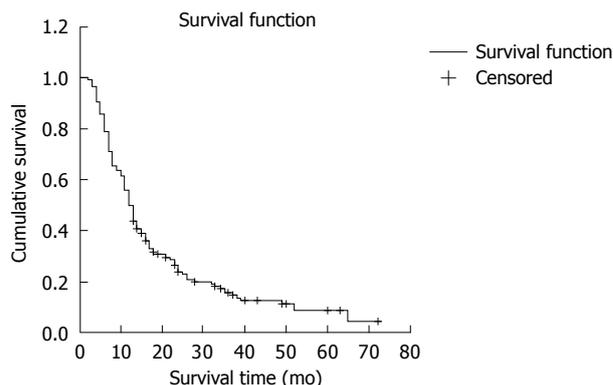

Figure 3 Cumulative survival time of 166 HCC patients after TACE. The 6 mo- 1-, 2-, 3-, and 5-year cumulative survival rates were 78.92%, 49.85%, 23.82%, 15.60% and 8.92%, respectively, in HCC patients after TACE.

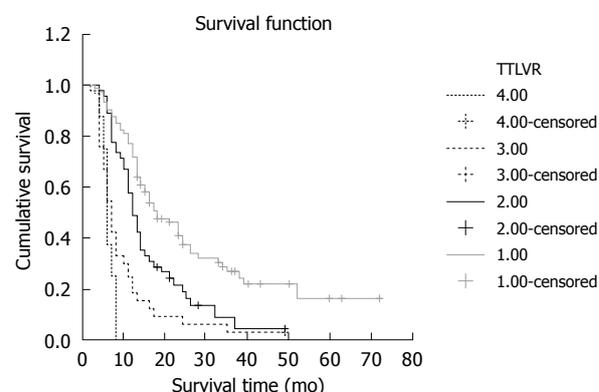

Figure 4 Reverse correlation between survival time and TTLVR values. The TTLVR value was 0%-25%, 25%-50%, 50%-70%, and 70%, respectively.

the cumulative survival rate of HCC patients after TACE ($\chi^2 = 14.328, P < 0.001$). Furthermore, TTLVR is a risk factor affecting the outcome of treatment because of a positive B value. The mean, median and cumulative survival rates of patients are shown in Figure 4 and Table 3.

Univariate analysis showed that the influence of tumor size measured with different methods including TV, TTLVR, largest tumor diameter, and tumor product of the greatest axial dimensions was significant on prognosis of HCC patients and their correlations are listed in Table 4.

DISCUSSION

It was reported that the median survival time of untreated HCC patients is less than 6 mo from its diagnosis^[2]. However, it was 12 mo after TACE in our study, indicating that TACE is an effective treatment modality for HCC, a finding in agreement with the reported data^[4].

Selection of optimal CT tumor measurement methods is still a challenge in treatment of HCC patients. Tumor size is widely considered a good indication for choosing an appropriate treatment modality for HCC patients, although it is difficult to accurately determine the lesion volume. In 1979, the World Health Organiza-

Table 3 Cumulative survival ratios of different TTLVR subgroups

Subgroup	Cumulative survival rate (%)					Median survival (mo)	Mean survival (mo)
	6 mo	12 mo	24 mo	36 mo	60 mo		
0%-25%	90.54	77.03	37.68	26.56	16.30	18	28
25%-50%	88.89	48.89	18.72	8.92	4.04	12	16
50%-70%	54.55	18.18	6.06	3.03	0.00	7	10
≥ 70%	37.50	0.00	0.00	0.00	0.00	6	6

Significant differences in survival were recognized for cumulative survival ratios of different TTLVR subgroups by log rank test: 0%-25% vs 25%-50% ($\chi^2 = 9.1$, $P = 0.003$), 0%-25% vs 50%-70% ($\chi^2 = 33.71$, $P < 0.001$), 0%-25% vs ≥ 70% ($\chi^2 = 38.98$, $P < 0.001$), 25%-50% vs 50%-70% ($\chi^2 = 9.08$, $P = 0.003$), 25%-50% vs ≥ 70% ($\chi^2 = 22.91$, $P < 0.001$), 50%-70% vs ≥ 70% ($\chi^2 = 1.71$, $P = 0.19$).

Table 4 Correlations between largest tumor diameter, tumor product of the greatest axial dimension, TV, and TTLVR

Parameter	Tumor largest diameter	Tumor product of diameters	TV
TTLVR	0.836	0.842	0.897
Tumor largest diameter		0.976	0.916
Tumor product of diameters			0.928

Largest tumor diameter vs TTLVR ($r = 0.836$, $P < 0.001$), tumor product of the greatest axial dimension vs TTLVR ($r = 0.842$, $P < 0.001$), TV vs TTLVR ($r = 0.897$, $P < 0.001$), largest tumor diameter vs tumor product of the greatest axial dimension ($r = 0.976$, $P < 0.001$), largest tumor diameter vs TV ($r = 0.916$, $P < 0.001$), tumor product of the greatest axial dimension vs TV ($r = 0.928$, $P < 0.001$).

tion (WHO) established the guidelines for tumor response to treatment. According to the WHO guidelines, the maximum diameter in the transverse plane and the largest perpendicular diameter of a tumor, measured on the same image, are multiplied to yield a cross product^[9]. In 1994, the European Organization for Research and Treatment in Oncology, the National Cancer Institute of the United States, and the National Cancer Institute of Canada Clinical Trials Group reviewed the tumor measurement techniques in view of the advances in imaging technologies. The revised response evaluation criteria in solid tumors guidelines advocate that uni-dimensional measurement (largest diameter in the transverse plane) can be used alone to quantify tumor burden^[6].

Tumor diameter, cross-sectional area or TV can be used to measure the size of tumors with a perfect sphere shape for the classification of their responses to TACE or other treatments. Unfortunately, since most tumors have an irregular geometry the size of tumors estimated with each parameter is usually significant different^[21]. Prasad *et al.*^[9] showed that 37 patients with secondary liver tumors responded to treatment with uni-dimensional and bi-dimensional techniques. However, tumor burden measured with TV gave a different response to treatment compared with uni-dimensional or bi-dimensional technique in a considerable proportion of patients, suggesting that methods to obtain directly TV are very important in treatment of HCC with an irregular geometry.

Advances in medical imaging have provided new means to assess tumor with volumetric imaging technologies such as helical CT and magnetic resonance imag-

ing, both of which allow physicians to accurately quantify tumor burden and to efficiently evaluate the outcomes of treatment^[5,9,16,22,23]. In our study, 3D measurements of HCC were made in patients with HCC using helical CT images. It has been shown that CT measurements of TV can provide a more sensitive assessment of tumor change than qualitative evaluation using linear methods^[24,25]. Moreover, changes in TV may be correlated with the prognosis of HCC patients^[25,26].

To our knowledge, only one study^[16] is available on the survival time of HCC patients after TACE. However, no studies are available on the correlation between tumor size measurements of unresectable HCC and survival time of HCC patients after TACE. In this study, we investigated not only the correlation between any variable and survival time, but also the correlation between multiple variables and survival data with confounding interaction effects taken into account.

In this study, univariate Cox regression analysis showed that there was an almost complete agreement between treatment response and TTLVR, TV, largest tumor diameter and tumor product of the greatest axial dimensions in 166 HCC patients after TACE ($P < 0.001$). However, multivariable Cox regression analysis demonstrated that TTLVR was the only significant factor for the prognosis of HCC patients after TACE, suggesting that TTLVR may be more important for evaluating the prognosis of HCC patients than either a simple volumetric measurement or a linear measurement after TACE. Moreover, a volumetric measurement would not only overcome the difficulties in estimating the size of lesions that are confluent and irregular in shape, but also permit the measurement of overall tumor burden in an organ. Kim *et al.*^[27] have shown the significance of TTLVR for prognosis of HCC patients compared with other treatment modalities. Using a multivariate Cox hazard model, they investigated the prognostic factors for 119 HCC patients after liver transplantation, and showed that the TV ratio greater than 10% can be used as an independent prognostic factor.

It is worth noting that some studies have shown that the survival time is not always associated with the size of tumors detected at the time of treatment with TACE^[2,28]. In some cases, volumetric tumor measurement for evaluating therapeutic response can not show any advantages over uni-dimensional and bi-dimensional measurements^[10,12]. To some extent, the difference is

thought to be due to the fact that the patients in these studies had different clinical characteristics. For instance, Sohaib *et al.*^[10] studied only nodal masses, which tend to have regular ovoid structures. Furthermore, TTLVR was not investigated in such studies.

Our study also showed a strong correlation between survival time and frequency of repeated TACE, which is consistent with the findings in other studies^[3,29,30]. The mean survival time of patients undergoing ≥ 2 times of TACE was significantly longer than that of those undergoing TACE once. The reason why repeated TACE can prolong the survival time of these patients is that additional embolization can make up for the incomplete effect of previous treatment, indicating that repeated TACE in treatment of HCC is very important for prolonging the survival time of patients^[30].

It has been shown that portal vein cancerous thrombosis is associated with the survival time of HCC patients after TACE^[26,30,31], which is consistent with the findings in our study. Portal vein cancerous thrombosis is an important factor for predicting survival time, as univariate or multivariable Cox regression analysis in our study has shown that it is statistically significant. Independent of initial values, a lower serum AFP level after TACE is another useful post-procedural predictor^[29,32], which usually implies that a favorable tumor response occurs.

In conclusion, volumetric CT technique can be reasonably used to measure tumor burden in an organ. TTLVR is a significant prognostic factor influencing the survival time of HCC patients after TACE. Compared with uni-dimensional and bi-dimensional criteria for evaluating the response of unresectable HCC to TACE, the volumetric measurement technique gives favorable results.

However, there are some limitations in our study. First, some bias may have occurred in this retrospective study due to the lack of complete clinical data. Second, the TV measurement technique relies on a mostly manual operation. Tracing individual tumor margins with mouse is time consuming and the results may have some variations if performed by different observers^[33]. Moreover, the software for accurate TV estimation must be installed and used^[9]. In the future, advances in post-processing of images may allow for automatic lesion contouring and TV calculation, leaving the radiologist the simple task of refining the outlined tumor contours^[12]. Using these techniques can further improve the reproducibility of volume measurements and allow precise measurement of tumor burden in an organ.

The authors thank Professor Pang FM for his helpful advice on the statistical analysis.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is one of the most common malignancies

in Asia and Africa. Transcatheter arterial chemoembolization (TACE) has been shown to be one of the most effective procedures for the treatment of unresectable HCC. Since quantification of tumor size with computed tomography (CT) is usually used to assess the prognosis of HCC patients after TACE, it is very important to measure the accurate tumor size. Many studies have shown that uni-dimensional or bi-dimensional measurements can be employed to evaluate the prognosis of HCC patients after TACE. However, it can not always achieve a satisfactory prognosis.

Research frontiers

Three-dimensional measurement has advantages over uni- and bi-dimensional measurements for the assessment of irregular masses. Spiral CT offers theoretical advantages in terms of the accuracy and reproducibility of three-dimensional measurements. Previous studies have shown that CT-based three-dimensional measurement provides a more sensitive assessment of tumor change than qualitative evaluation with linear methods. However, CT-based three-dimensional volumetric measurement for prognostic evaluation of unresectable HCC after TACE has not been systematically addressed. In this study, the authors demonstrate that a volumetric CT technique can predict the prognosis of unresectable HCC patients after TACE.

Innovations and breakthroughs

Previous studies evaluated the survival time of HCC patients after TACE on the basis of tumor to liver volume ratio (TTLVR) values, but multivariable Cox regression analysis was not done. In this study, the authors investigated not only the correlation between multiple variables and survival data, but also took the confounding interaction between these factors. Furthermore, this study showed that volumetric quantification might result in a more favorable assessment than uni-dimensional and bi-dimensional techniques.

Applications

The results of this study suggest that a volumetric CT technique can reasonably predict the prognosis of unresectable HCC patients after TACE.

Terminology

TTLVR: A measurement value for tumor burden in the liver. It may be a significant prognostic factor influencing the survival time of HCC patients after TACE.

Peer review

The authors studied the prognostic significance of CT volumetric measurements in HCC patients after TACE. This work states that simple response evaluation criteria in solid tumors and WHO criteria are insufficient for the adequate evaluation of HCC lesions after treatment. Furthermore, this study revealed that TTLVR might result in a more favorable assessment than uni-dimensional and bi-dimensional measurement techniques. The results are interesting and useful for readers.

affected by loss of heterozygosity (LOH) and their clinical implications.

METHODS: Four hundred and forty single nucleotide polymorphisms (SNPs) located at 49 genes around D4S2964 were selected from the National Center for Biotechnology Information website for the SNPs microarray fabrication. LOH of SNPs markers in 112 cases of hepatocellular carcinoma (HCC) tissues and paired adjacent liver tissues were investigated by the SNPs microarray. The correlation between allelic losses with clinicopathological features and overall survival was analyzed.

RESULTS: A fine map of LOH of SNPs in genes around D4S2964 was plotted. The average frequency of LOH in genes was 0.39. A correlation between cirrhosis and the FAL index (fractional allelic loss) was found ($P = 0.0202$). Larger tumor size was found to be significantly associated with LOH in genes ADP-ribosyltransferase 3 (ART3), nucleoporin 54 kDa (NUP54), scavenger receptor class B, member 2 (SCARB2) and coiled-coil domain containing 158 (CCDC158) ($P = 0.043$, $P = 0.019$, $P = 0.001$, $P = 0.037$, respectively). Kaplan-Meier analysis showed that patients with LOH in ARD1 homolog B (ARD1B) and septin 11 (SEPT11) had a significantly lower survival rate than those with retention ($P = 0.021$ and $P = 0.004$, respectively). A Cox regression model suggested that LOH in ARD1B and SEPT11, respectively, were predictors of the overall survival in HCC ($P = 0.006$ and $P = 0.026$, respectively).

CONCLUSION: LOH in genes around D4S2964 may play an important role in HCC development and progression. LOH in ARD1B and SEPT11 could serve as novel prognostic predictors in HCC patients.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most prevalent cancers and the third leading cause of cancer mortality worldwide^[1]. It has been ranked the second leading cause of cancer death in China since the 1990s^[2]. HCC incidence and mortality rates continue to increase, particularly among middle-aged black, Hispanic, and white men in the United States^[3]. The main causes of HCC are hepatitis B and C virus (HBV and HCV) infection, dietary exposure to aflatoxin B1 and high-level alcohol consumption^[4]. Although many risk factors are known, the molecular mechanisms of carcinogenesis and progression of HCC have not been well elucidated.

Loss of heterozygosity (LOH) at microsatellite markers has been reported in nearly all types of human cancers. LOH regions found in a significant portion of tumors are thought to embody tumor suppressor genes (TSG). However, hundreds of LOH regions remain to be explored for the presence of TSGs. LOH in HCC is frequently detected in many chromosome regions, including 1p, 4q, 8p, 9p, 10q, 11p, 13q, 16q, 17p and 22q^[5-10]. Allelic losses in some of the regions were correlated to clinicopathologic features and HCC progression^[11]. An association between LOH and poor prognosis was also implicated in some studies^[9,12].

In our previous study, we performed a genome-wide LOH analysis in HCC with 382 microsatellite (MS) markers, and found that LOH frequency of D4S2964 located at 4q21 in HCC was as high as 50% and correlated with HBV infection^[5]. A high frequency of LOH in HCC at the D4S2964 locus was also observed by Nishimura *et al.*^[13]. The high frequency of LOH at D4S2964 was only found in HCC. Those results strongly suggest the presence of TSGs specifically for human HCC in this region. Because of the low density of the microsatellite markers, it is very difficult to use these markers for TSG identification. In the present study, we took advantage of the National Center for Biotechnology Information (NCBI) single nucleotide polymorphism (SNP) database and designed a novel strategy to gain deeper insight into the D4S2964 locus and to determine genes that may be involved in hepatocarcinogenesis. We

included all 49 genes located within 4 Mb upstream and downstream of the D4S2964 locus, and selected 440 SNPs from the 49 genes with an average of 9 SNPs in each gene from the NCBI website. With the microarray consisting of probes for all the 440 SNPs, we detected LOH in 112 HCC cases paired with non-cancerous liver tissues and analyzed the correlation between the LOH affected genes and clinical features. Our study provided important clues for the identification of candidate TSGs in the LOH affected region and their clinical implication.

MATERIALS AND METHODS

Patients and tissue specimens

All 112 HCC patients, 94 males and 18 females with an age range of 13 to 72 years (median, 45.5 years), underwent surgical resection at the Department of Hepatobiliary Oncology, Sun Yat-sen University Cancer Center between 2004 and 2007. All of the tumors removed from these patients were confirmed as HCC by pathological examination. None of the patients had received any other therapies such as chemoembolization or chemotherapy before surgery. The follow-up time for these patients ranged from 1 to 58 mo with a median follow-up time of 36 mo. Most (96 of 112, 85.7%) of the patients were HBsAg positive. This study was approved by the Committee for the Conduct of Human Research of the Sun Yat-Sen University Cancer Center. Informed consent was obtained from each patient.

Primary liver carcinoma and matched non-tumor liver tissues were obtained from 112 patients when they underwent hepatectomy. Both tumors and corresponding adjacent non-tumor tissues (not less than 2 cm away from the HCC) were sampled. The fresh tissues were immediately immersed in RNAlater (Ambion, Inc., USA) after surgical resection, stored at 4°C overnight to allow thorough penetration of the RNase inhibitor, and then frozen at -80°C until use. After total RNA extraction using TRIzol reagent (Invitrogen, USA), DNA in the interphase and phenol phase from the initial homogenate was isolated according to the manufacturer's instructions.

SNP genotyping by microarray

Forty-nine genes located within approximately 8 Mb (from 77 to 85 Mb on the long arm of chromosome 4) and flanking the D4S2964 locus were included in the study. A total of 440 SNP markers with a heterozygosity greater than 0.10 were selected from the NCBI SNP database (<http://www.ncbi.nlm.nih.gov/snp>). The SNPs were located either within or 5 kb upstream/downstream of the 49 corresponding genes. On average, 9 SNPs (2-14) were selected for each gene. The average distance between adjacent markers for each gene was 7.8 kb and ranged from 0.2 to 111 kb. The polymorphic sites of the SNPs were all transition variations (A/G-C/T) to facilitate microarray analysis by two fluorescent colors.

The high-throughput SNP microarray genotyping system described by Wang *et al.*^[14] was used with minor modifications. The microarray was printed using a SmartArrayTM.

136 printer and scanned by a LuxScan™-10K Scanner (both devices are products of CapitalBio Inc., Beijing, China). Genotype call for each SNP was determined by a computer program called “AccuTyping2b”^[15] based on two color signal intensities. If the log ratio of the two color (Cy5 and Cy3) intensities for a SNP was between -3.3 and 3.3, the SNP genotype was considered as heterozygous (C/T). If the log ratio was greater than 3.3 or less than -3.3, the genotype was assigned as homozygous, C/C and T/T, respectively.

LOH analysis and DNA sequencing validation

In the present study, LOH was defined as the SNP that was homozygous in tumor tissue and heterozygous in the corresponding non-tumor tissue. If any one of the SNPs in a gene had LOH, the gene was assigned as LOH. The FAL index (fractional allelic loss) for individual cases was defined as the ratio of the number of SNPs showing LOH to the total number of informative SNPs in a tumor patient; it reflects the degree of LOH of the tumor^[16].

In order to confirm the genotypes and LOH of SNPs, DNA sequences containing these SNPs were amplified separately using the same condition as described above for multiplex PCR, and the PCR products were sent to Invitrogen (Guangzhou, China) for DNA sequencing.

Statistical analysis

The χ^2 -test, Fisher's exact test and Mann-Whitney *U* test were used to analyze the correlations between clinicopathological features and the FAL index or LOH index. The overall survival curves were estimated using the Kaplan-Meier analysis. The log-rank test was used to evaluate the statistical significance of the differences. The prognostic significance of each clinicopathologic characteristic was determined using univariate Cox regression analysis. Parameters that were significantly related to survival rate in the univariate analysis were entered into the multivariate analysis. With a Cox proportional hazard model, multivariate analysis was carried out to identify the prognostic significance of clinicopathologic variables. A forward stepwise selection with the likelihood ratio criterion or an enter mode was used to identify the variables in the Cox model whenever appropriate. The SPSS version 15.0 software package and Graph-Pad Prism were used for statistical analysis.

RESULTS

SNP genotyping by microarray and validation by DNA sequencing

A total of 13 322 SNP genotypes were determined as informative (heterozygous) in non-tumor liver tissues. The heterozygosity rate was 0.27 [13322/(440*112)]. Typical microarray images for SNP genotyping of the tumor and corresponding non-tumor tissue in one patient are shown in Figure 1A and B. Twenty-five informative genotypes for six SNPs, rs17352824, rs2280101, rs3733329, rs6828114, rs6845080, and rs9307811 in 10 pairs of

tumor/non-tumor tissues were validated by the sequence analysis. Typical results are shown in Figure 1C and D. The concordant rate of SNP genotypes from microarray and DNA sequencing was 96% (24/25). The inconsistent genotype was rs6845080 in a non-tumor tissue, in which the genotype by microarray was determined as C/T heterozygote, whereas that from DNA sequencing was C/C homozygote.

LOH detection in the 112 HCC cases

Among the 440 SNPs selected in the study, 22 were shown to be non-informative in all cases, and were excluded from the data analysis. Of the 13 322 informative genotypes, 2553 (19.2%) showed LOH in tumor tissues. The results from LOH analysis for the 418 SNPs in the 49 genes in the 112 HCC patients are summarized in Figure 2. The FAL values for the 112 cases ranged from 0 to 0.769. All genes had at least one SNP affected by LOH in at least two patients. The fraction of the 112 cases with at least one SNP affected by LOH for each gene ranged from 0.227 (the *FGF5* gene) to 0.643 (the *PPEF2* gene) with an average of 0.382. However, for some genes, such as *CXCL10* and *CXCL11*, the number of HCC patients with informative SNPs was very small, and therefore the fractions may have fluctuated in a rather wide range. The genes statistically shown to be associated with clinical features had > 30 informative cases.

Association between clinicopathological features and LOH

In order to elucidate the possible clinical significance of sample FAL indices, the 112 cases were divided into two groups according to the median FAL value and a χ^2 analysis was performed. Results showed a significant correlation between FAL and cirrhosis but not with gender, age, serum α -fetoprotein (AFP) concentration, HBsAg

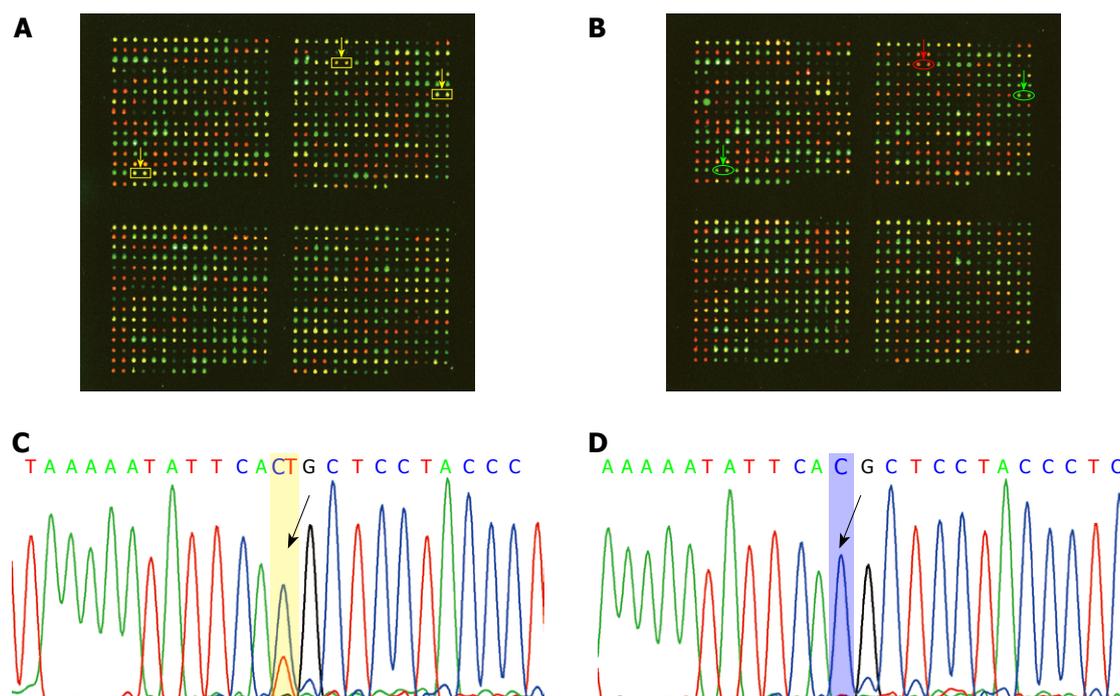

Figure 1 Representative case showing loss of heterozygosity. A: Informative normal adjacent tissue in SNP array. Yellow arrow shows the SNP loci with heterozygous genotype; B: Corresponding tumor tissue in SNP array. Red (or green) arrow shows the corresponding SNP loci with homozygous genotype; C: Informative normal adjacent tissue in DNA sequencing. Arrow shows the SNP loci with heterozygous genotype; D: Corresponding tumor tissue in DNA sequencing. Arrow shows the corresponding SNP loci with homozygous genotype.

status, tumor stage, tumor size, or recurrence (Table 1). The Mann-Whitney U test also revealed that HCCs with cirrhosis had significantly higher FAL indices than those without cirrhosis ($P = 0.020$, Figure 3).

Furthermore, we analyzed the correlation between LOH in genes and clinical features, including serum AFP concentration, HBsAg status, HBeAg status, tumor size, tumor stage, cirrhosis, recurrence and metastasis. The results are summarized in Table 2. Larger tumor size was found to be significantly associated with LOH in genes ADP-ribosyltransferase 3 (ART3), nucleoporin 54 kDa (NUP54), scavenger receptor class B, member 2 (SCARB2) and coiled-coil domain containing 158 (CCDC158) ($P = 0.043$, $P = 0.019$, $P = 0.001$, $P = 0.037$, respectively, Table 2), which are tandemly located. LOH in two genes, septin 11 (SEPT11) and chemokine (C-X-C motif) ligand 13 (CXCL13) was detected more frequently in HCC patients who were HBeAg-negative than in those who were HBeAg-positive ($P = 0.041$, $P = 0.024$, respectively, Table 2). However, LOH in cyclin I (CCNI) and SEC31 homolog A (SEC31A) were also more frequently detected in HBsAg-positive HCC patients than in HBsAg-negative patients ($P = 0.037$, $P = 0.013$ respectively, Table 2). The patients with LOH in ARD1 homolog B (ARD1B) showed a higher serum HBV-DNA level and a higher recurrence rate than those not affected by LOH in the gene ($P = 0.049$, $P = 0.046$, respectively, Table 2). LOH in genes helicase, POLQ-like (HELQ) and 1-acylglycerol-3-phosphate O-acyltransferase 9 (AGPAT9) was also found to be related with cirrhosis status ($P = 0.006$, $P = 0.033$, respectively, Table 2).

Correlation between LOH in genes ARD1B and SEPT11 and survival rate of HCC patients

Using the Kaplan-Meier curve, we showed that LOH in genes ARD1B and SEPT11 was a significant prognostic factor for poor overall survival rate in HCC patients. Patients with LOH in genes ARD1B and SEPT11 had a significantly lower survival rate than those without LOH in these genes ($P = 0.021$, $P = 0.004$, respectively, Figure 4).

Univariate and multivariate analyses of prognostic variables in HCC patients

Univariate and multivariate Cox regression models were performed to identify the variables of potential prognostic significance in all patients with HCC. The difference in predicting the prognosis was assessed by examining the ratio hazard and P value for each variable. Univariate Cox regression analysis showed that LOH in ARD1B and/or SEPT11 was significantly associated with overall survival rate (Table 3). Univariate Cox regression analysis also indicated that clinical variables including tumor size, recurrence, number of nodules and serum AFP were significantly associated with overall survival rate. Multivariate analysis with an enter mode was performed for LOH in ARD1B or in SEPT11, tumor size, recurrence, number of nodules, and serum AFP with overall survival rate. Results showed that LOH in ARD1B or in SEPT11 and number of nodules were predictors of the overall survival rate in HCC patients ($P = 0.006$, $P = 0.001$; and $P = 0.026$, $P = 0.005$, respectively, Table 4). LOH in ARD1B, LOH in SEPT11, tumor size, recurrence, number of nodules, and serum AFP altogether were analyzed with multivariate Cox regression model using

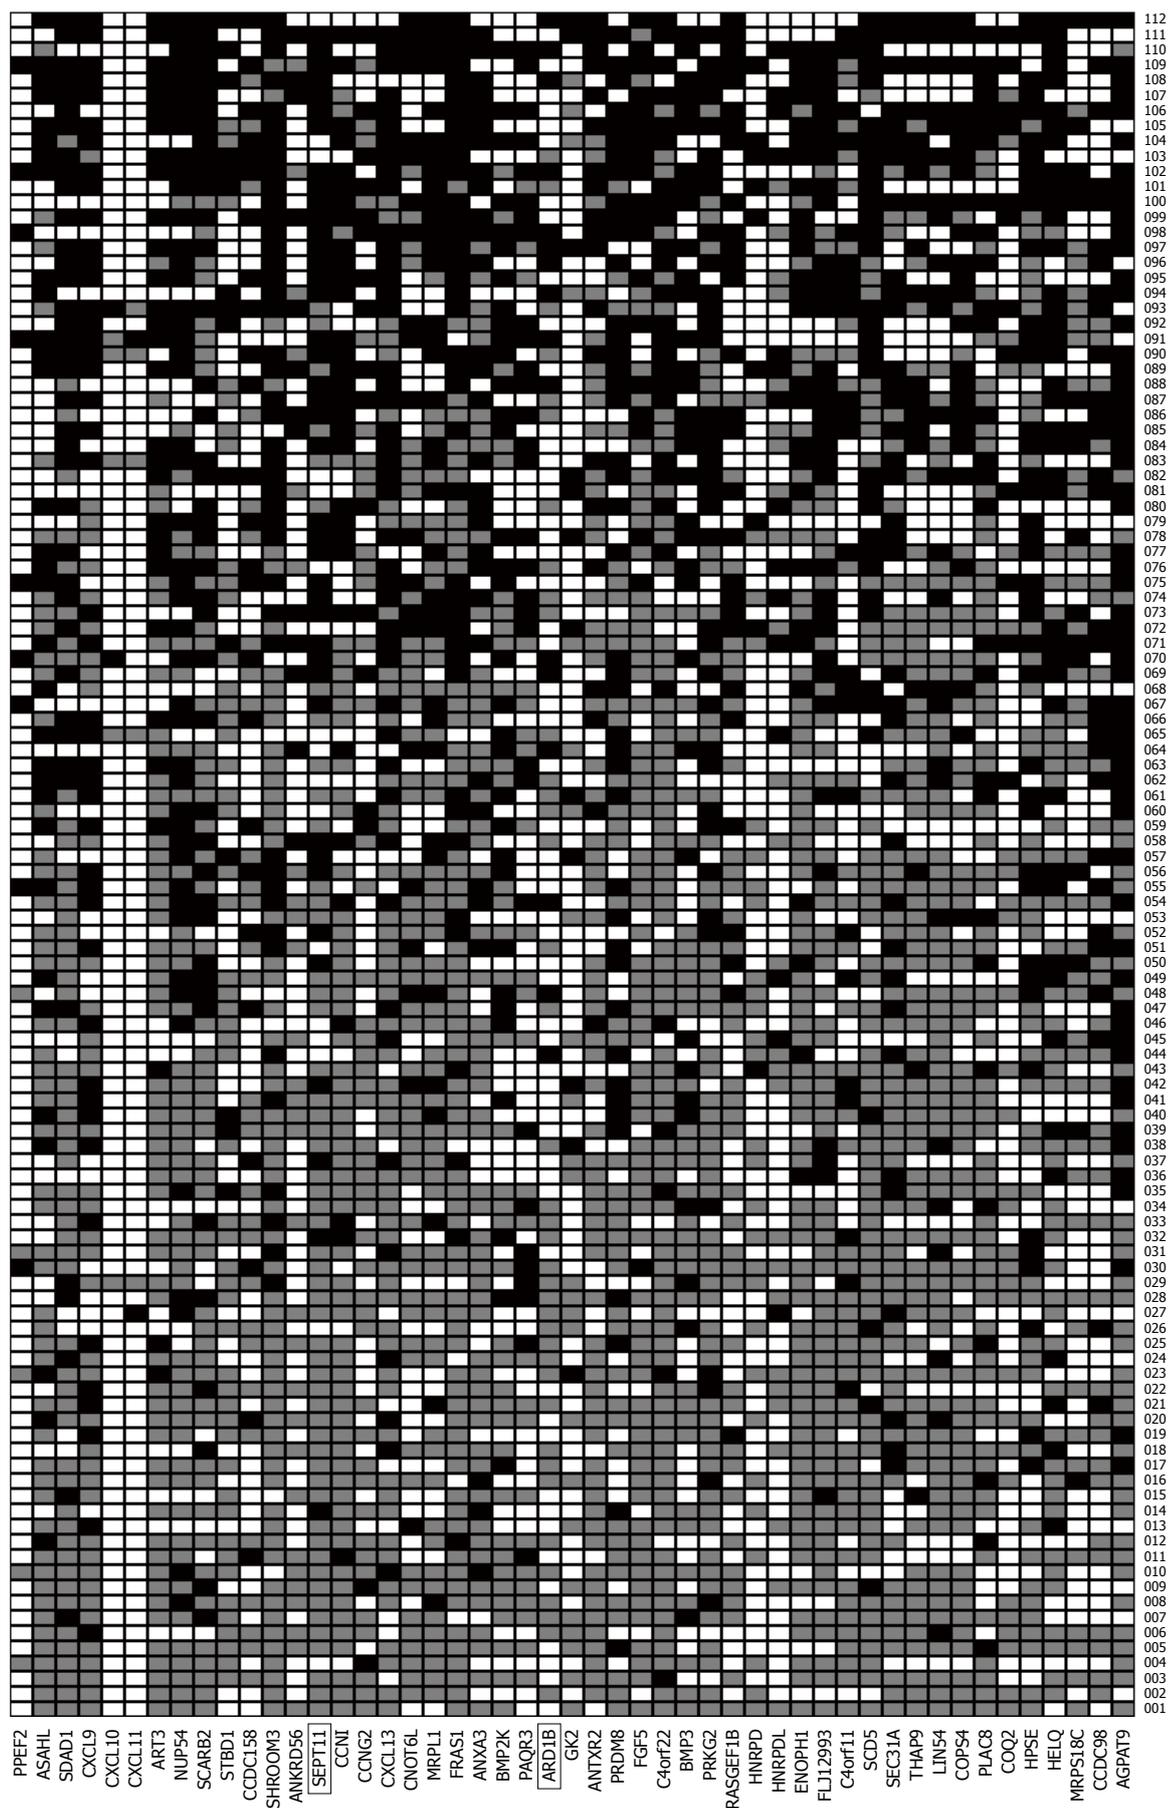

Figure 2 Summary of LOH analysis results. Case numbers are indicated in the right column. Gene names are listed in the bottom row, in the order of physical position from 77 Mb to 84 Mb (left to right). Gray boxes: Retention; White boxes: Noninformative; Black boxes: LOH.

several human cancers, including esophageal adenocarcinoma, cervical cancer, head and neck squamous cell carcinoma, oral squamous cell carcinomas, malignant mesothelioma, small-cell lung cancer and HCC^[17-27]. However, allelic losses on 4q occurred more frequently in HCC than in all other cancers and was found to be correlated with elevated α -fetoprotein production and *p53* gene mutations^[17,26]. Many important genes encoding albumin, alcohol dehydrogenase (ADH3), fibrinogen and UDP-glucuronyltransferase, which are predominantly expressed in the liver, are located on chromosome 4q. Genes on the long arm of this chromosome including protein tyrosine phosphatase, non-receptor type 13 (PTPN13), nucleosome assembly protein 1-like 5 (NAP1L5), and PR domain containing 5 (PRDM5), were documented as potential TSGs^[28-30]. However, a large number of loci with high LOH frequency found in HCC have not been explored. Therefore, it is postulated that chromosome 4q should contain other unknown TSGs.

In the present study, based on our previous study and those by other researchers^[5,13], we detected LOH in 49 genes around the D4S2964 locus by a custom microarray consisting of 440 SNPs. The average distance between these SNPs in the genes was 7.8 kb. To our knowledge, this is the first time LOH has been detected in such a way. The high-density markers in genes would display

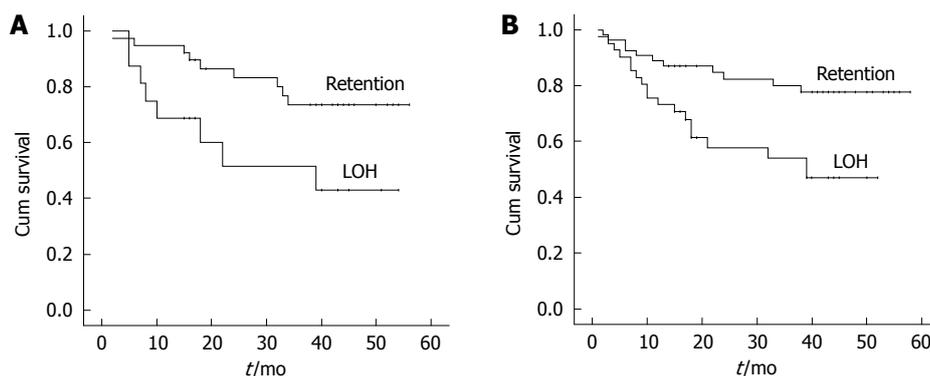

Figure 4 The association of loss of heterozygosity (LOH) in gene ARD1 homolog B (ARD1B) and septin 11 (SEPT11) with the postoperative survival of patients. A: Kaplan-Meier overall survival plot based on LOH in ARD1B (log-rank test, $P = 0.021$); B: Kaplan-Meier overall survival plot based on LOH in SEPT11 (log-rank test, $P = 0.004$).

more detailed and smaller LOH regions in single genes, and compensate for the weakness of SNP markers with much less informativeness than microsatellite markers.

Then we analyzed the correlations between allelic losses and clinicopathological features. The results showed that HCC patients with cirrhosis had significantly higher FAL indices (Table 1, Figure 3) and higher LOH fraction in HELQ and AGPAT9 (Table 2) than those without cirrhosis. These results showed that patients with or without cirrhosis can be discriminated by the FAL index and LOH in genes HELQ and AGPAT9. Cirrhosis is a definite, established risk factor for HCC. In patients with cirrhosis, cirrhotic livers with high liver cell proliferative activity have a higher risk of developing cancer^[31]. Higher LOH on several microsatellite markers on chromosome 16 and chromosome 17 was reported to be related to cirrhosis status in HCC patients^[32]. In our previous study, LOH was found in non-cancerous liver tissues with cirrhosis caused by chronic viral hepatitis B (data not published). Therefore, some LOH may be involved in hepatocarcinogenesis. Furthermore, the analysis revealed a correlation between larger tumor size and LOH in genes ART3, NUP54, SCARB2 and CCDC158 (Table 2). Interestingly, these genes are located in a cluster in the same chromosomal region. Therefore, further analysis of this region may lead to identification of new TSGs. The data also suggested that LOH in genes SEPT11, CXCL13, CCNI, SEC31A and ARD1B were correlated with HBV infectious status (Table 2). HBV infection in humans has been recognized as one of the main risk factors for liver cirrhosis and HCC. How-

ever, the molecular mechanism underlying HBV infection is still unclear. Our results may provide insight into the understanding of HBV-related HCC.

Most importantly, we found that LOH in genes ARD1B and SEPT11 were significantly correlated with poor overall survival in HCC patients (Figure 4). Univariate and multivariate Cox regression models further revealed that LOH in genes ARD1B and SEPT11 were significant prognostic factors for poor overall survival. However, when LOH in ARD1B, LOH in SEPT11, and clinical features altogether were analyzed by a multivariate Cox regression model, only LOH in ARD1B, not LOH in SEPT11, and the number of nodules were prognostic predictors of HCC (Table 4).

The ARD1B gene encodes a human protein with 81% sequence identity to ARD1 homolog A (ARD1A), which encodes the human protein N- α -acetyltransferase. Compared to lower organisms which only have one ARD, ARD1B potentially complements the functions of ARD1A, adding more flexibility and complexity to protein N- α -acetylation in human cells^[33]. Although the biological function of ARD1B in cancer remains unclear, it is recognized that the N-terminal acetylation of proteins influences multiple processes such as the cell cycle, heat-shock resistance, mating, sporulation, and telomeric silencing. However, RNAi-mediated knockdown of ARD1A and N (α)-acetyltransferase 15, NatA auxiliary subunit (NATH) induced apoptosis in human cell lines^[34]. Immunohistochemical analysis showed that ARD1A protein was expressed extensively in several cancer tissues

including glandular carcinoma and squamous cancer^[35]. It is proposed that ARD1A or the ARD1A-NATH complex could be drug targets in cancer treatment^[36]. Homologous to ARD1A, ARD1B is probably a functional protein in cancer development and/or progression. Although further study of ARD1B in cancer is necessary, our data suggest that LOH in ARD1B is a prognostic predictor of HCC and ARD1B is a potential TSG.

COMMENTS

Background

High frequency of loss of heterozygosity (LOH) at locus D4S2964 was previously reported in hepatocellular carcinoma (HCC) by this research group and was confirmed by another group in Japan. The aim of this study was to investigate genes around the locus D4S2964 affected by LOH using a customized single nucleotide polymorphisms (SNP) microarray and their clinical implications.

Research frontiers

In HCC and nearly all other cancers, there are still a lot of important LOH regions which need to be explored with regard to what genes are involved in carcinogenesis and their biological and clinical implications. In general, LOH regions are thought to embody tumor suppressor genes (TSG), which are able to inhibit the development and progression of cancer.

Innovations and breakthroughs

This study reported LOH in genes at the D4S2964 locus that are proposed to be involved in the development and progression of HCC. With the SNP microarray, the authors showed that LOH in ARD1 homolog B (ARD1B) is an independent prognostic predictor of HCC and LOH in other genes correlated with tumor size, cirrhosis, hepatitis B virus infection, recurrence and metastasis.

Applications

These results provide novel and valuable information on LOH at the D4S2964 locus in HCC and provide clues for identifying TSGs related to HCC. In addition, this study proposes a new strategy to gain deeper insight into LOH regions existing in various cancers.

Terminology

Loss of heterozygosity (LOH): In a heterozygote, the loss of one of the two alleles at one or more loci in a cell lineage or cancer cell population due to chromosome loss, deletion, or mitotic cross-over.

Peer review

The study has been well conducted, including a reasonable series of paired samples from patients with HCC. Experimental procedures and statistics are correct. The results reported provide novel and valuable information that may contribute to our understanding and management of HCC.

Abstract

AIM: To investigate the prognostic impact of metastatic lymph node ratio (rN) on gastric cancer after curative distal gastrectomy.

METHODS: A total of 634 gastric cancer patients who underwent curative resection (R0) of lymph nodes at distal gastrectomy in 1995-2004. Correlations between positive nodes and retrieved nodes, between rN and retrieved nodes, and between rN and negative lymph node (LN) count were analyzed respectively. Prognostic factors were identified by univariate and multivariate analyses. Staging accuracy of the pN category (5th UICC/TNM system) and the rN category was compared according to the survival rates of patients. A linear regression model was used to identify the relation between rN and 5-year survival rate of the patients.

RESULTS: The number of dissected LNs was related with metastatic LNs but not related with rN. Cox regression analysis showed that depth of invasion, pN and rN category were the independent predictors of survival ($P < 0.05$). There was a significant difference in survival

between LN stages classified by the rN category or by the pN category ($P < 0.05$). However, no significant difference was found in survival rate between LN stages classified by the pN category or by the rN category ($P > 0.05$). Linear regression model showed a significant linear correlation between rN and the 5-year survival rate of gastric cancer patients ($\beta = 0.862, P < 0.001$). Pearson's correlation test revealed that negative LN count was negatively correlated with rN ($P < 0.001$).

CONCLUSION: rN category is a better prognostic tool than the 5th UICC pN category for gastric cancer patients after curative distal gastrectomy. Increased negative LN count can reduce rN and improve the survival rate of gastric cancer patients.

INTRODUCTION

Gastric cancer, a common malignancy worldwide, is the

second most common cause of cancer-related death^[1]. Despite recent advances in multimodality treatment and targeted therapy, complete resection remains the only curative treatment modality. Lymph node metastasis is one of the most important prognostic factors for gastric cancer^[2-4], and accurate categorization of lymph node metastasis or optimization of pN category is critical for decision making of its subsequent therapies after surgery. Compared with total gastrectomy, distal gastrectomy is one of the most important operative procedures for gastric cancer, which can decrease postoperative morbidity and mortality and improve the postoperative life quality and nutrition condition of gastric cancer patients^[5-8]. Although there are some studies on the prognostic significance of rN in gastric cancer^[9-11], few relevant researches are available on gastric cancer after curative distal gastrectomy. Therefore, the aim of this retrospective study was to evaluate the prognostic value of metastatic lymph node ratio (rN) for gastric cancer after curative distal gastrectomy.

MATERIALS AND METHODS

Between January 1995 and November 2004, 1289 patients diagnosed as primary gastric cancer were treated with curative resection at Department of Oncology, Fujian Medical University Union Hospital (Fuzhou, China). Of the 1289 patients, 709 underwent distal gastrectomy, 75 were excluded from the study for T4 lesions in order to avoid data heterogeneity due to more extensive resections and higher positive margins. Finally, 634 patients were enrolled in this study. Curative surgery was defined as complete tumor removal with no macroscopic residual tumor, no invasion of carcinoma cells in the margin, and no evidence of distant metastasis. Clinical and histopathologic data about each patient were classified according to the Japanese Classification of Gastric Carcinoma (JCGC)^[12]. Lymph nodes were meticulously dissected from the *en bloc* specimens, and the dissected lymph nodes were classified by surgeons who reviewed the excised specimens after surgery based on the JCGC. Based on the 5th edition of UICC/TNM system^[13], pN category was defined as pN0 with no metastatic lymph nodes, pN1 with 1-6 metastatic lymph nodes, pN2 with 7-15 metastatic lymph nodes, and pN3 with > 15 metastatic lymph nodes, respectively. rN intervals were determined using the best cut-off approach and the survival rate of patients (log-rank statistic) was considered a dependent variable. The best-fit cut-off values of rN intervals were rN0: 0%, rN1: 1%-20%, rN2: 21%-50%, and rN3: > 50%, respectively. The patients were followed up by trained investigators through e-mail, telephone, visiting patients or recording the consultations of patients at the outpatient clinic. The survival time was the time when diagnosis was made to the last contact, or to the date of death, or to the date when the survival information was collected. All surviving patients were followed up for more than 5 years. The median follow-up time of

the entire cohort was 62.0 mo (range 1-172 mo). A total of 591 patients were followed up, accounting for 93.2%.

Statistical analysis

Pearson's correlation coefficient (*r*) was used to study the relations between positive nodes and retrieved nodes, between rN and retrieved nodes, and between rN and negative LN count. Survival rate was calculated with the Kaplan-Meier method. Cox proportional hazard model was used in multivariate analysis, with a backward elimination model for all covariates. A linear regression model was established to correlate rN with survival based on Kaplan-Meier 5-year survival estimates at each rN interval, using 5% of rN interval as an independent variable. *P* < 0.05 was considered statistically significant. All statistical analyses were performed using the statistical package for social science (SPSS) version 13.0 for Windows.

RESULTS

Clinicopathological parameters of patients

The clinicopathological parameters of patients are summarized in Table 1. There were 467 males and 167 females at the age of 22-87 years (56.1 ± 12.1 years). The tumor diameter was 4.3 ± 1.7 cm. Gastric cancer was found at the lower third (L), lower and middle third (LM),

and middle third (M) of stomach in 521, 41, and 71 patients, respectively. Based on the Japanese Classification of Gastric Carcinoma^[12], 118 were at stage pT1, 174 at stage pT2, and 342 at pT3, respectively. As far as the histological grades were concerned, 140 were differentiated and 494 were undifferentiated. Lymph node metastasis was observed in 439 patients (69.2%). Based on the 5th UICC/TNM pN category^[13], 195 patients (30.8%) were classified as pN0, 232 (36.6%) as pN1, 156 (24.6%) as pN2 and 51 (8.0%) as pN3, respectively. Using the rN category, 195 patients (30.8%) were classified as rN0, 172 (27.1%) as rN1, 156 (24.6%) as rN2, and 111 (17.5%) as rN3, respectively. The median of total LN number was 23 (range 5-61, mean 23.1 ± 8.6) in each patient.

Correlation between LN metastasis and retrieved nodes

Pearson's correlation test showed that the number of metastatic lymph nodes was significantly related with that of retrieved nodes ($r = 0.252$, $P < 0.001$, Figure 1A), but the rN was not related with the number of retrieved nodes ($r = -0.075$, $P > 0.05$, Figure 1B).

Univariate and multivariate survival analysis

The 5-year survival rate of the entire cohort was 57.6%. The clinicopathological variables tested in univariate analysis are shown in Table 2. The factors influencing the 5-year survival rate were tumor diameter ($P = 0.036$), pathology types ($P = 0.003$), depth of invasion ($P < 0.001$), pN category ($P < 0.001$) and rN category ($P < 0.001$). The covariates of gender ($P = 0.991$), age ($P = 0.423$), tumor location ($P = 0.058$) and digestive tract construction ($P = 0.064$) had no significant influence on the survival rate. Multiple survival rates were calculated with the Cox's proportional hazard regression model. In order to confirm the influence of rN, the prognostic factors including tumor diameter, pathology types, depth of invasion and pN category except for rN category in univariate analysis were analyzed by stepwise regression. As a result, two independent prognostic parameters, namely depth of invasion ($P < 0.001$) and pN category ($P < 0.001$), were obtained. When rN category was included in the Cox's regression, the two independent prognostic parameters were also obtained. The risk ratios and their 95% confident interval are listed in Table 3.

Comparison of survival rates between subsets of patients in either LN classification

The subgroups of patients, defined by the pN category, were discriminated with rN category. A significant difference was observed in survival rates between LN stages classified by the rN category or by the pN category ($P < 0.05$, Table 4), whereas no significant difference was found in survival rates between LN stages classified by the pN category or by the rN category (Table 5).

Projected rN impact on overall survival rate

The linear regression model demonstrated that the regression equation of assumed linearity was $y = -0.814x + 74.4$ ($\beta = 0.862$, $P < 0.001$). The regression line of this

Figure 1 Pearson's correlation tests. calculated rN effect on the 5-year survival rate is shown in Figure 2. The hypothetical baseline 5-year survival rate (based on the y-intercept, i.e. 0% rN) was 74.4%. When rN was increased 10%, the calculated 5-year survival rate was decreased by 8.14%.

Correlation analysis between rN and negative LN count

Pearson's correlation test showed that the negative LN

in clinical practice, especially when adjuvant treatment is considered. Metastasis to lymph nodes is considered the main prognostic factor for gastric cancer patients who undergo radical resection. In 1997, the International Union against Cancer (UICC) proposed that the category of lymph node involvement should be classified according to the number of metastatic lymph nodes. It has been reported that the category based on the number of metastatic lymph nodes is more sensitive than that based on the location of metastatic lymph nodes in prognostic eval-

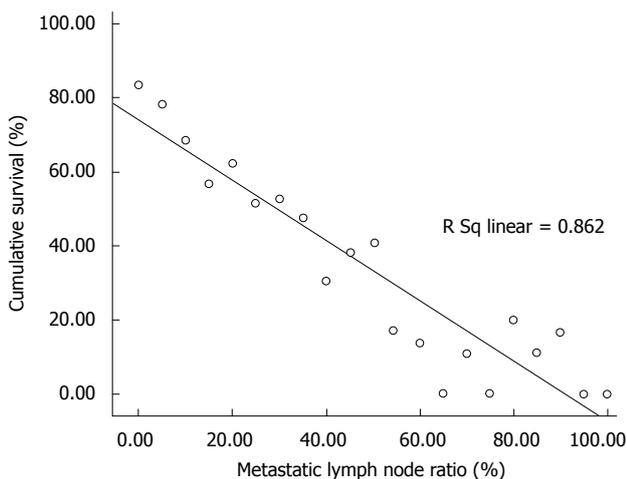

Figure 2 Regression line of rN impact on the 5-year survival rate.

count was negatively correlated with rN ($r = 0.684$, $P < 0.001$, Figure 1C).

DISCUSSION

Accurate staging of gastric cancer is of great importance

uation of gastric cancer^[14-16]. However, the UICC/TNM classification (5th edition) only recommended that 15 or more lymph nodes should be examined for the accurate staging of gastric cancer. From the statistical viewpoint, the number of metastatic lymph nodes increases in proportion to the number of dissected nodes, suggesting that pN category can be influenced by the extent of lymphadenectomy. In addition, the pN category may be changed by adding or reducing one positive lymph node, suggesting that gastric cancer classified as N1 after limited lymph node dissection may be classified as N2 or N3 after extensive lymphadenectomy. This phenomenon is the so-called stage migration^[17,18]. Sun *et al*^[19] reviewed 2159 gastric cancer patients who underwent gastrectomy with a curative intent, and found that there is a closed linear correlation between the number of retrieved LNs and the number of metastatic nodes, while there is no correlation between rN and the number of retrieved nodes, which is consistent with the results of our present study, suggesting that patients with identical rN, even with a different number of detected metastatic nodes, will have a similar outcome, and that rN category is superior to the 5th UICC/TNM classification in terms of minimizing stage migration.

Fukuda *et al*^[20] compared the pN category of the UICC/TNM in 1997 with a classification based on the metastatic lymph node ratio in patients who underwent R0 resection using the regression analysis, and identified that the metastatic lymph node ratio is the most important prognostic factor for gastric cancer. The results of univariable and multivariable analyses of potential prognostic factors in this study showed that the rN category was one of the independent prognostic parameters. Kunisaki *et al*^[21] analyzed 1472 early gastric cancer patients undergone curative gastrectomy, and found that rN can identify subsets of patients with a significantly different survival rate within UICC/TNM pN1, pN2 and pN3 categories, suggesting that the outcome of patients with the same number of metastatic nodes, or with a larger number of retrieved LNs, is unfavorable. In the present study, however, a significant difference was observed in survival rates between lymph-node stages classified by the rN category or by the UICC pN category, but no significant difference was found in survival rates between lymph-node stages classified by the UICC pN category or by the rN category, indicating that the UICC/TNM classification can demonstrate stage migration and heterogeneous stratification for disease-specific survival. However, the metastatic lymph node ratio showed less stage migration and homogenous stratification in this study. The N category is currently defined by the number of positive nodes, but routine H&E staining may not exactly reflect the prognosis of lymph node metastasis due to lymph node micro-metastasis^[22-25]. Therefore, the rN category may give more accurate prognostic information on nodal involvement than the current pN category of TNM, thus having a great impact on the selection of patients who may benefit from the adjuvant treatment.

A study from Italy^[11] showed that the number of metastatic lymph nodes is significantly related with rN, and that the more the number of metastatic lymph nodes is, the

higher the rN will be, indicating that gastric cancer patients with a higher rN have a greater risk of death after surgery and a shorter survival time. In this study, when the rN was increased 10%, the calculated 5-year survival rate was decreased by 8.14%, whereas when the rN was decreased 10%, the calculated 5-year survival rate was increased by 8.14%, suggesting that the long-term survival can be improved by reducing rN. Moreover, Person's correlation test showed that rN was negatively correlated with the negative LN count ($P < 0.001$), indicating that removal of more negative lymph nodes can reduce rN.

In conclusion, increased negative LN count can reduce rN, thus improving the long-term survival of patients with gastric cancer after curative distal gastrectomy.

COMMENTS

Background

Distal gastrectomy is one of the most important operative procedures for gastric cancer. Although the staging system of gastric cancer has been refined step by step, staging techniques never stop updating. So far, few studies are available on the relative contribution of metastatic lymph node (LN) ratio to the prognostic evaluation of gastric cancer after curative distal gastrectomy.

Research frontiers

Some researches have shown that metastatic lymph node ratio (rN) is an excellent predictor for the survival rate of patients with colon cancer, pancreatic cancer, breast cancer and other carcinomas. Some related studies on gastric cancer have also found the potential effect of rN on prognostic evaluation, but no consensus on stratification cutoffs, especially lack of data on gastric cancer after curative distal gastrectomy.

Innovations and breakthroughs

The authors investigated the validity of metastatic LN ratio as a prognostic factor by retrospectively reviewing 634 gastric cancer patients who underwent curative resection (R0) with distal gastrectomy in 1995-2004. The relation between rN and survival was discovered.

Applications

Metastatic LN ratio can provide accurate information on LN metastasis and lymphadenectomy for gastric cancer after curative distal gastrectomy. Moreover, the rN category is an important prognostic factor and increment of negative LN count can reduce rN, thus improving the survival rate of gastric cancer patients.

Peer review

This is an interesting study about the prognostic value of metastatic lymph node ratio (MLR) for 634 gastric cancer patients who underwent curative subtotal gastrectomies at a single institute. The study was well designed.

Abstract

To the best of our knowledge, this is the first report of the application of hemostatic forceps in active gastrointestinal (GI) bleeding that is not related to endoscopic submucosal dissection. An 86-year-old woman with chronic intake of low-dose aspirin had a Dieulafoy's lesion of the third duodenal portion. Bleeding control with epinephrine injection was unsuccessful. A 60-year-old man presented with a bleeding ulcer in the duodenal bulb. Ten days after combined endotherapy, he had recurrent bleeding from two minimal lesions in the same location. A 66-year-old woman under combined antithrombotic treatment was referred to us for chronic GI bleeding of unexplained origin. Endoscopy revealed active diverticular bleeding in the second duodenal portion. A 61-year-old woman underwent endoscopic mucosal resection of superficial gastric adenocarcinoma, which was complicated with immediate bleeding. In all cases, the blood was washed out using a water-jet-equipped, single-channel gastroscope with a large working channel. The bleeding points were pinched and retracted with hemostatic forceps. Monopolar electrocoagulation was performed using an electro-surgical current generator. Hemostasis was achieved. No complications occurred. In conclusion, hemostatic forceps may be an effective as well as safe alternative approach for active GI bleeding of various origins.

INTRODUCTION

Therapeutic endoscopy has greatly reduced the indications for urgent surgery in cases of gastrointestinal (GI) bleeding. Despite several advances in endoscopic technology, hemostasis can be technically challenging. In addition, the risk of rebleeding, which is associated with high mortality, cannot be eliminated^[1].

Hemostatic forceps is commonly included in the essential accessories for performing endoscopic submucosal dissection (ESD)^[2]. Therefore, we assumed that it could be also applicable in the treatment of active GI bleeding that is not related to ESD.

CASE REPORT

Case 1

An 86-year-old woman was admitted for melena. She had a medical history of ischemic heart disease and chronic intake of low-dose aspirin. She was intravenously administered omeprazole (8 mg/h). Her endoscopic findings were suggestive of a Dieulafoy's lesion that was located in the third duodenal portion at the level of the genu inferius. An initial attempt at bleeding control with injection of epinephrine solution at a dose of 25 mL proved

to be unsuccessful. At that point, the decision was made to use a hemostatic forceps (Coagrasper, FD-410LR; Olympus, Tokyo, Japan). The blood was washed out using a water-jet-equipped, single-channel gastroscope (GIF1T 140; Olympus), with a large working channel (diameter: 3.8 mm), and the hemostatic forceps was advanced through it. The bleeding point was gently grasped and retracted with the hemostatic forceps (Figure 1A). At that point, monopolar electrocoagulation was delivered using an electrosurgical current generator (ICC 200; ERBE, Tübingen, Germany) with forced mode at a setting of 60 W (Figure 1B). The coagulation effect was evaluated by washing out the blood again. The whole hemostatic procedure was carried out with success within 5 min. The bleeding point had to be grasped twice. The total duration of complete coagulation with this setting was about 1 min. The patient tolerated the procedure well. She had no perforation or rebleeding.

Case 2

A 60-year-old man presented with ulcer bleeding in the duodenal bulb. He was managed with injections of epinephrine solution in combination with the placement of two hemoclips (QuickClip II, standard size; Olympus) and intravenous administration of omeprazole (8 mg/h). However, during the next 10 d, he developed recurrent bleeding. A repeat endoscopy demonstrated two simultaneously oozing, bleeding, minimal lesions in the ulcer area. The endoclips remained attached to the site of application. Although high doses of epinephrine solution (60 mL) were injected again, they failed to achieve hemostasis. After that, a VIO 200 ERBE generator was set to soft coagulation mode (Effect 5, 80 W) to coagulate the bleeding lesions with hemostatic forceps. The same endoscope and technique were used (Figure 2). As it was difficult to keep the endoscope stable in the retro pyloric bulb, coagulation was also delivered by applying the tip of the unopened hemostatic forceps to the bleeding points. Prompt and effective hemostasis was achieved without any further episodes of bleeding. Following an uneventful recovery, the patient was discharged home a few days later.

Case 3

A 66-year-old woman was referred to our Endoscopy Unit for chronic GI bleeding of unexplained origin. She was receiving combined antithrombotic treatment with low-dose aspirin and clopidogrel for advanced cardiovascular disease. She was also receiving omeprazole for ulcer prevention. On upper endoscopy, she had signs of active diverticular bleeding of the second duodenal portion. She underwent endoscopic hemostasis by using an ERBE VIO 200 generator with either soft coagulation mode (Effect 5, 80 W) or forced mode (60 W), as well as hemostatic forceps, which grasped and retracted the bleeding point. The procedure was well tolerated and resulted in bleeding control. No late-onset complications were observed.

Case 4

A 61-year-old woman was diagnosed with depressed-

type IIc superficial adenocarcinoma in the stomach, with a diameter of approximately 1.5 cm. Cap-assisted endoscopic mucosal resection (EMR) of her neoplastic lesion was complicated with immediate bleeding. Coagulation of the spurting bleeding vessels using an ERBE VIO 200 generator (soft mode, Effect 5, 50 W) and hemostatic forceps allowed us to complete successfully the EMR procedure (Figure 3). The patient was treated with omeprazole 20 mg *bid*. She did not experience any further complications. She was discharged home within 48 h.

DISCUSSION

Several techniques or devices have been used for the endoscopic control of active GI bleeding. The widely available endoscopic hemostatic options include injection techniques such as epinephrine or sclerosant, ablative ones such as heater probe or argon plasma coagulation (APC), and mechanical methods such as endoclips or endoscopic banding^[1]. In several ulcer bleeding cases, combination endoscopic treatment with epinephrine injection and thermal coagulation or endoclippping has been recommended to achieve better outcomes^[3]. Bleeding control of a Dieulafoy's lesion may require hemostasis with multiple endoscopic treatment methods, whereas clinical experience with endotherapy of duodenal intradiverticular bleeding is limited to a small number of cases^[4,5].

GI bleeding is a major complication of endoscopic surgery. Minor bleeding during ESD can be managed with coagulation using an electrosurgical knife. When that fails, conventional endoscopic means such as hemoclips or APC can be applied^[6]. However, endoclippping may pose several difficulties in the completion of the dissection procedure^[7].

A hemostatic forceps is a valuable tool for performing safely ESD procedures, which are usually demanding^[8]. Its intraoperative use is extended from the coagulation of actively bleeding or oozing vessels to the pre-coagulation of visible, exposed vessels on the artificial ulcer. It does not only aim at facilitating an ESD procedure, so as to continue the endoscopic intervention safely, but also to prevent delayed bleeding as a late-onset complication^[9].

In our small study, a hemostatic forceps was used in the endoscopic management of GI bleeding that was unrelated to ESD. To the best of our knowledge, this is the first report of its application beyond ESD in the English-language literature. Our initial experience demonstrated that monopolar coagulation using a hemostatic forceps as: (1) a second-line therapeutic approach during the same hemostatic procedure; (2) second-line retreatment of two simultaneously bleeding sources after recent combined endotherapy with other modalities; and (3) first-line treatment of a non-iatrogenic bleeding lesion or an EMR-induced lesion, was effective as well as devoid of any post-procedural complications.

Although omeprazole was introduced prior to endotherapy in all our cases, the clinical efficacy of proton pump inhibitors (PPIs) in acute bleeding is a matter of debate. They can reduce the severity of endoscopic signs

Figure 1 Endoscopic images. A: The bleeding point is pinched with a hemostatic forceps; B: Coagulation delivery at the retracted bleeding point.

Figure 2 An opened hemostatic forceps while washing out the blood after coagulation.

Figure 3 Coagulating the bleeding vessels during cap-assisted endoscopic mucosal resection (EMR).

of recent bleeding and the need for endotherapy, but they have not provided a clear benefit in terms of rebleeding, mortality or the need for surgery^[10]. In addition, the administration of PPIs prior to ESD does not seem necessary for the prevention of postoperative bleeding^[11]. However, they can prevent delayed bleeding more effectively than H₂-receptor antagonists^[12]. Moreover, epinephrine was initially injected in two cases. Epinephrine alone can provide initial hemostasis of 80%-100% in bleeding ulcers, but recurrent bleeding rates range from 6% to 36%. Similar to ulcers, it may only provide temporary hemostasis of bleeding of Dieulafoy's lesions^[13].

Although that hemostatic tools appears to be a reasonable alternative option for the endoscopic treatment of various bleeding lesions, a few practical and technical issues should be taken into consideration before encouraging endoscopists to use it for non-variceal, actively bleeding cases, to achieve definitive hemostasis. To date, the clinical experience of its hemostatic applications has not extended further than those interventionists that perform ESD procedures. However, it is conceivable that excessive coagulation with it might result in delayed perforation. Therefore, one should be aware of the mode of use of a hemostatic forceps, to avoid any complications. The bleeding point should be precisely pinched, retracted and coagulated with a minimal contact area for a minimum time^[7]. In difficult cases, it is also possible to achieve prompt tissue coagulation with the simple contact of an unopened hemostatic forceps, as shown in our second case. However, by pinch-

ing an artery, its use seems more advantageous than other endoscopic techniques, such as APC, for avoiding unnecessary maneuvers and providing accurate hemostasis. To facilitate capture, a hemostatic forceps can be also rotated.

Several experts in ESD procedures usually coagulate the blood vessels using a hemostatic forceps in soft mode^[7,9,14-20]. Others use the coagulation mode of the knife for hemostasis^[21,22]. In our endoscopy unit, we generally use an ERBE VIO 200 generator in soft mode (Effect 5, 50, 80 or 100 W) for a hemostatic forceps. However, an ICC 200 generator, which can be set to soft or forced mode, is the only available option for emergency cases. This is the reason why that was used for the coagulation of the Dieulafoy's lesion and the duodenal intradiverticular bleeding. In the case of the Dieulafoy's lesion, the field was blood-filled and large amounts of water were required to clear it. It took us a long time to grasp the spurting lesion twice and coagulate it with the forced mode to complete the hemostatic procedure. Despite the prolonged duration of coagulation, the bleeding was controlled with no early or delayed-onset complications. It seems doubtful if the use of soft coagulation would be effective in achieving hemostasis. In the case of the large bleeding diverticulum in the second duodenal portion, which was not easily accessible, we continued the coagulation using the forced mode (60 W), because the hemostatic effect of the soft mode with 80 W current was not rapid enough. Although there might be a higher risk of excess tissue injury from thermocoagulation

in thin-walled duodenal diverticula, an endoclip-induced perforation has been reported as the only complication of endotherapy of diverticular bleeding in a recent case series^[5]. Possible explanations include the sharp tip of the hemoclip and excessive air inflation during therapeutic endoscopy^[23].

In conclusion, our case series supports the potential value of the application of a hemostatic forceps in active GI bleeding of various origins. It suggests that it seems to be a reliable and safe therapeutic tool even for those cases of bleeding that are unrelated to ESD, which are difficult to treat with other endoscopic means, although more cases need to be studied before any firm conclusions can be made. Proper techniques and settings should be followed to avoid any procedure-related complications.

Abstract

Management of acute pancreatitis in pregnancy is based on expert opinion only, due to geographic and ethnic variations. Nonbiliary causes should be sought as they are associated with worse outcomes. Alcohol as a cause of acute pancreatitis is not rare. Hemoconcentration as a marker of fluid deficit and severity should be predicted with caution and fluid resuscitation should be done carefully by closely monitoring the central venous pressure, cardiac and respiratory system. Hypercalcemia of hyperparathyroidism may be falsely lowered due to hypoalbuminemia or suppressed by magnesium tocolysis.

TO THE EDITOR

We read with interest the article "Acute pancreatitis in

pregnancy" by Pitchumoni *et al*^[1] in December 7, 2009 issue of *World Journal of Gastroenterology*. We agree that recommendation for management of acute pancreatitis is based on expert opinion only, due to geographic and ethnic variations. There are few points which need to be added regarding hyperlipidemic and alcoholic pancreatitis, as well as hemoconcentration as a marker of severity, analgesics and antibiotics dosage in pregnancy.

Nonbiliary causes of acute pancreatitis should be sought as they are associated with worse outcomes. Alcohol as a cause of acute pancreatitis is not rare. Eddly *et al*^[2] studied 89 cases of acute pancreatitis among 305 101 deliveries, and found that alcohol is an etiological factor associated with increased rates of recurrence, 12.3% of patients are in preterm delivery and pseudocyst, and 43% of patients are in the third trimester of pregnancy, 37% of women are nulliparous and 64% have one or more children. The average maternal age at presentation is 26.2 years and higher in patients with alcoholic pancreatitis.

Hyperlipidemic pancreatitis patients account for 4%-6% of all acute pancreatitis patients and have a poor outcome^[3]. Omega-3 fatty acids may prevent recurrent hypertriglyceridemia during pregnancy^[4].

During pregnancy, the maternal blood volume is increased progressively till the 30th wk of gestation, which is 50% greater than normal^[5]. This volume expansion is due to the effects of steroid hormones and elevated plasma levels of aldosterone and renin leading to dilution of red blood cells. So the hemoglobin level for hemoconcentration as a marker of fluid deficit and severity should be predicted with caution and fluid resuscitation should be done carefully by closely monitoring the central venous pressure, cardiac and respiratory system.

Meperidine and fentanyl are the preferred analgesic during pregnancy^[6]. In case of necrotizing pancreatitis, antimicrobial therapy with imipenem/cilastin is often started in view of its high morbidity. The pharmacokinetics of imipenem will change during pregnancy with a larger volume of distribution and faster total clearance from plasma^[7]. The dose adjustment during pregnancy should be considered.

The diagnosis of acute pancreatitis may be com-

plicated during pregnancy due to a mild physiological elevation of amylase, and magnetic resonance cholangio-pancreatography helps to detect acute pancreatitis and its complications^[8]. Very uncommonly, disseminated intravascular coagulation (DIC) can occur in acute pancreatitis. Tang *et al*^[9] studied 103 patients with acute pancreatitis during pregnancy, and found that 1 out of 3 patients with DIC would die in the third trimester of pregnancy.

A comprehensive search for causes should be taken even when the cause of pancreatitis is obscure. It has been reported that triglyceride level declines with bowel rest and hydration, and hypercalcemia of hyperparathyroidism may be falsely lowered due to hypoalbuminemia or suppressed by magnesium tocolysis^[10]. γ -glutamyl transpeptidase (GGTP) levels either are unchanged or fall slightly during gestation. An elevated GGTP level can help us to evaluate the history of alcohol use during pregnancy as patients might not be coming forth, due to stigmata associated with it^[11].

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systematically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Published by

Beijing Baishideng BioMed Scientific Co., Ltd.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Instructions to authors

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P* < 0.05, ^b*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, ^c*P* < 0.05 and ^d*P* < 0.01 are used. A third series of *P* values can be expressed as ^e*P* < 0.05 and ^f*P* < 0.01. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG,

WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
