ABOUT COVER Neumann H, Neurath MF, Mudter J. New endoscopic approaches in IBD.
World J Gastroenterol 2011; 17(1): 63-68
<http://www.wjgnet.com/1007-9327/full/v17/i1/63.htm>

AIM AND SCOPE *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.
The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

Peroral cholangioscopy was first described in 1970s and has recently gained popularity. Peroral cholangioscopy is appealing to therapeutic endoscopists because a direct intraluminal view of the biliary duct system offers possibilities for diagnosis and interventions beyond that which other imaging or endoscopic modalities can provide. As the image quality of cholangioscopies improves, so too does their diagnostic capability, and as their durability and maneuverability increases, so too does their potential use for therapeutic applications. This editorial is intended to provide a brief review of recent developments in peroral cholangioscopy and current indications for its use.

Parsi MA. Peroral cholangioscopy in the new millennium. *World J Gastroenterol* 2011; 17(1): 1-6 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i1/1.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i1.1>

INTRODUCTION

Diseases of the biliary system are frequently encountered in clinical practice^[1]. An examination of the bile ducts is often required for the appropriate diagnosis and management of patients with biliary diseases. The dramatic technical advances of flexible endoscopy during the last four decades have resulted in endoscopic retrograde cholangiopancreatography (ERCP) being used as a primary method of diagnosing and treating many biliary diseases^[1]. In the United States alone, approximately half a million ERCP procedures are performed annually. ERCP can demonstrate the anatomy of the biliary tract and reveal anatomical abnormalities, strictures and intraductal filling defects. However, this technique does not always differentiate the biological nature of bile duct lesions and can fail to determine their intraluminal extension. Furthermore, it is unable to provide information about biliary mucosal lesions that do not project into the biliary lumen. Peroral cholangioscopy as an adjunct to ERCP is a promising procedure that provides direct visualization of the biliary tree. It has been shown to have value in treating difficult-to-remove biliary stones^[2], assessing indeterminate biliary strictures^[3], and distinguishing between different intraductal lesions of the biliary tree^[4]. In recent years, cholangioscopy has gained popularity in the United States and is being performed in increasing numbers not only in academic institutions and large tertiary care referral centers, but also in smaller hospitals and private practices. In this paper, clinical applications of peroral cholangioscopy and its role in diagnosis and management of biliary disorders are reviewed.

HISTORICAL PERSPECTIVES

The first peroral cholangioscopy was performed in 1975

Table 1 Comparison of currently available single and dual operator cholangioscopies

	Endoscopists needed	Image quality	Tip deflection	Simultaneous irrigation and instrumentation	Fragility
Single operator (SpyGlass)	One	Moderate - good	4 way (up/down, left/right)	Yes	No ¹
Dual operator					
Fiberoptic cholangioscopies	Two	Moderate - good	2 way (up/down)	No	Yes
Video cholangioscopies	Two	Excellent	2 way (up/down)	No	Yes

¹All components of the spyglass system are single-use with the exception of the spyprobe (the light and image conveyor of the system) which is multi-use. The spyprobe is fragile and has to be handled with care.

Figure 1 Cholangioscopic view of normal intrahepatic biliary mucosa (image by a prototype video cholangioscope, CHF type Y0002, Olympus Corporation, Tokyo, Japan).

using a prototype cholangioscope that was thin enough to pass through the accessory channel of a duodenoscope^[5]. The concept of passing a thinner endoscope through a larger one later became known as the “mother-baby” or “mother-daughter” concept. Even today, almost all cholangioscopy systems are based on this concept. The initial prototype cholangioscope had poor image quality, no instrumentation or irrigation capability, and no tip deflection. Despite all its shortcomings, it proved that peroral cholangioscopy is feasible. In the mid-1980s second generation cholangioscopes were introduced^[5]. These cholangioscopes had added tip deflection and an accessory channel that could be used either for irrigation or instrumentation. In the late 1990s and early in the new millennium, advances in imaging technology led to the introduction of video cholangioscopies with improved image quality that enabled satisfactory views of the biliary mucosa (Figure 1). Addition of narrow band imaging (NBI) capability led to further improvements in detection of abnormal vascularization of biliary mucosa, which is of importance for diagnosis of certain biliary malignancies^[6]. The first semi-disposable single-operator cholangioscopy system was developed in 2005 and made it possible for a single endoscopist to operate both the baby and mother endoscopes.

SINGLE AND DUAL OPERATOR CHOLANGIOSCOPY SYSTEMS

In cholangioscopy, the terms “single operator” and “dual

operator” refer to the number of endoscopists required to perform the procedure. As a general rule, dual operator cholangioscopy systems require two endoscopists, while single operator cholangioscopy systems require only one endoscopist for performance. There are, however, reports of use of dual operator cholangioscopy systems by a single operator with the help of appropriate accessory equipment^[7].

Currently, most cholangioscopy systems are dual operator. Dual operator cholangioscopies of varying length, diameter and image quality are available. Most dual operator cholangioscopies have fiberoptic image quality. There is limited commercial availability of video cholangioscopies with enhanced image quality. At present, all video cholangioscopies with NBI capability are prototypes and not commercially available.

The only single operator cholangioscopy system currently available is the SpyGlass direct visualization system (Boston Scientific, Natick, MA, USA). This system is fiberoptic-based and has single and multi-use components.

Some of the advantages and disadvantages of the currently available single and dual operator cholangioscopies are summarized in Table 1.

CLINICAL APPLICATIONS

Several clinical applications for peroral cholangioscopy have been described. With expanded use, additional indications are expected to be reported. Clinical applications of cholangioscopy can be divided into common, uncommon and rare applications. Common applications include stone therapy and diagnosis of indeterminate biliary strictures. Uncommon applications include guidewire placement during ERCP, assessment of post-liver-transplantation biliary strictures, and evaluation of indeterminate intraductal filling defects or irregularities of the bile duct wall seen on imaging studies such as computed tomography (CT), magnetic resonance imaging (MRI), endoscopic ultrasound (EUS) or ERCP. Rare applications include staging and ablation of biliary neoplasms, investigation of recurrent pancreatitis, and evaluation of hemobilia.

Common applications

Currently, most peroral cholangioscopy procedures are performed for two indications: biliary stones and indeterminate biliary strictures.

Table 2 Common factors associated with failed biliary stone removal during endoscopic retrograde cholangiopancreatography

Patient factors
Abnormal anatomy
Prior surgery
Extremely J-shaped stomach
Large hernias
Malrotations
Unstable or difficult endoscope position
Short duodenal bulb
Abnormal anatomy
Long duodenoscope position
Bile duct abnormalities
Presence of ductal strictures
Severely dilated ducts
Stone factors
Size
Large size
Location
Intrahepatic
Cystic duct
Proximal to strictures
Impacted stones

Biliary stones

Difficult to remove stones: Gallstone disease or cholelithiasis continues to be a major health problem throughout the world, and affects 10%-20% of the Caucasian population^[8-13]. It has been estimated that 15%-20% of patients with gallstone disease also have stones in their bile ducts (choledocholithiasis)^[13]. Stones in the bile ducts have to be removed because of their potential to cause jaundice, cholangitis, and pancreatitis^[14-16]. This is accomplished in close to 95% of the cases during ERCP by conventional methods such as sphincterotomy with or without sphincter dilatation, use of extraction balloons or retrieval baskets, mechanical lithotripsy, or a combination of these methods^[17]. At times, however, stone extraction by standard methods is not possible. There are a number of reasons as to why some stones cannot be removed by conventional means; some of the most common of which are presented in Table 2.

A variety of methods have been devised for endoscopic extraction of stones that are not removable by conventional means during ERCP. As a general rule, these methods involve using shock waves to crush or fragment the stones inside the bile duct, with subsequent removal of the fragments (Figure 2). The shock waves for fragmentation of biliary stones are usually generated using electric spark (electrohydraulic lithotripsy) or laser light (laser lithotripsy). Probes that pass through the accessory channels of cholangioscopes for laser or electrohydraulic lithotripsy are commercially available. Although use of these probes through an extraction balloon under fluoroscopic guidance has been reported^[18,19], in our institution, we use them under direct visualization by utilizing a cholangioscope. These probes have to be precisely positioned on the stone to increase effectiveness and reduce complications. Direct visualization ensures that the shock waves

**Figure 2** Cholangioscopic views of a bile duct stone prior to (A) and after (B) electrohydraulic lithotripsy. The lithotripsy probe is visible in the left lower corner of (B).

are aimed at the stone and not the bile duct wall, because shock waves delivered to the bile duct wall can cause bleeding and perforation. Direct visualization by cholangioscopy also allows distinction between stone fragments, air bubbles or blood clots, which can be indistinguishable on contrast cholangiography^[20].

Laser or electrohydraulic lithotripsy has been used for fragmentation and subsequent extraction of difficult to remove stones for many years, and both techniques have been shown to be safe and effective^[21,22]. In a recent multicenter study, cholangioscopy-guided laser or electrohydraulic lithotripsy were effective in > 90% of the cases^[2].

There are currently no randomized studies that have compared the effectiveness of laser and electrohydraulic lithotripsy for fragmentation and subsequent extraction of difficult-to-remove biliary stones.

Missed stones: Cholangioscopy allows detection of stones that might have been missed during cholangiography. Small stones can be “drowned” in contrast and be missed, and larger stones can block a duct, thus preventing passage of contrast, and evade detection during ERCP (Figure 3). In a study of patients with primary sclerosing cholangitis, stones were not detectable on cholangiography in seven of 23 patients (30%)^[23]. In a more recent multicenter study, stones were missed in 29% of patients who presented for ERCP for different indications. In that study, ERCP was immediately followed by peroral cholangioscopy, which led to detection of the stones^[24].

Figure 3 Cholangioscopic view of a small stone surrounded by contrast in an intrahepatic duct. The stone was missed during endoscopic retrograde cholangiopancreatography (image by Spyglass Direct Visualization System, Boston Scientific, Natick, USA).

Indeterminate biliary strictures

Biliary strictures can be benign or malignant. Accurate diagnosis of biliary strictures is essential for treatment planning and the correct choice of treatment, such as surgical resection or endoscopic stenting. However, differentiation of malignant from benign ductal lesions remains a challenge^[25]. Brush cytology during ERCP or fine needle aspiration by EUS has become the preferred initial method of pursuing a diagnosis in many patients with pancreatobiliary malignancies^[25,27]. These techniques allow easy and convenient sampling and have a low complication rate^[25,27,28]. The diagnostic specificity of biliary brush cytology or fine needle aspiration is very high and few false-positive diagnoses have been reported^[25,29]. The major limitation of these techniques has been the relatively modest diagnostic sensitivity, ranging from 10% to 50% in most series^[25,29].

There have been attempts to improve the sensitivity of brush cytology obtained during ERCP. Physical changes to the brushing device itself, such as use of longer and stiffer brushes, have not been shown to improve sensitivity^[30]. Balloon dilatation of strictures, to expose underlying tissue, prior to obtaining brush samples has been tried but not shown to be of any benefit^[31]. Mutation analysis of the cells obtained by brushing does not seem to improve diagnostic accuracy^[32], and DNA methylation analysis of ERCP brush specimens has shown only small benefit^[25].

It has been suggested that peroral cholangioscopy can improve diagnosis of indeterminate biliary strictures by visualization of the mucosa at the site of the stricture, and by targeted biopsy.

Visualization of the mucosa at the site of the stricture: It is well known that the presence of irregularly dilated and tortuous blood vessels (so-called tumor vessels) due to neovascularization at the site of pancreatic or biliary strictures is indicative of malignancy^[33]. Tumor vessels can be detected by direct visualization using a cholangioscope. Intraductal nodules or masses can also be indicative of malignancy and be easily detected by cholangioscopy. However, tumor vessels and intraductal masses can be ap-

preciated only in a fraction of malignant strictures; probably those with more advanced disease. Certain types of cholangiocarcinoma involve submucosal layers of the bile duct wall and cannot be detected by cholangioscopy, which visualizes the superficial layers. Biliary strictures caused by extraluminal compression, such as those associated with pancreatic cancer, cannot be detected by cholangioscopy, unless at later stages when the tumor has infiltrated and penetrated the bile duct wall.

Studies to assess the value of stricture visualization by cholangioscopy have reported high sensitivity for detection of malignant lesions^[4,34]. The reported sensitivity in some of these studies has approached 100%^[4]. In these studies, however, the criteria used for labeling a stricture as malignant have been somewhat lax. As an example, irregular biliary mucosa has been used to label a stricture as malignant. It is well known that irregular biliary mucosa on cholangioscopy can also be seen in benign lesions such as primary sclerosing cholangitis, or chronic inflammation associated with choledocholithiasis or recurrent cholangitis^[35]. Therefore, the high sensitivity in such studies is often achieved at the cost of lower specificity. This is alarming, because false-positive results can have a devastating impact on the affected patients' lives.

Although, undoubtedly, direct visualization of indeterminate biliary strictures can aid in their diagnosis, the true value of peroral cholangioscopy for this purpose has not been vigorously studied.

Targeted biopsy: Targeted biopsy is defined as biopsy of the sites that are clearly affected by disease under direct visualization. Theoretically, targeted biopsy should improve cancer detection rate in malignant biliary strictures by allowing sampling of the sites that appear suspicious. In a recent multicenter study that assessed the role of cholangioscopy-guided targeted biopsy for diagnosis of indeterminate biliary strictures, initial observations suggested a large improvement in sensitivity^[3]. However, later observations at conclusion of the study have indicated a somewhat more modest benefit^[24]. Well-designed studies are needed to assess better the value of cholangioscopy-guided targeted biopsy for evaluation of indeterminate biliary strictures.

Uncommon applications: In our institution, 10%-20% of peroral cholangioscopy procedures are performed for indications other than stone disease and stricture diagnosis. Some of these indications are discussed below.

Characterization of indeterminate intraductal lesions or filling defects

Increased use of imaging studies such as CT, MRI and EUS has led to an increase in incidental findings such as intraductal biliary lesions or filling defects. Although, most often these findings are real, they can also be due to artifacts.

Direct visualization of the intraluminal biliary tree is the most appropriate way to investigate further the nature of these findings. Cholangioscopy has been shown to be effective for this purpose^[4,36].

Assessing post-liver-transplantation anastomotic strictures

Various refinements in surgical techniques and postoperative and immunosuppressive management have reduced the incidence of complications after liver transplantation. Biliary complications, however, continue to be a significant cause of morbidity after liver transplantation^[37,38].

In selected cases, cholangioscopy can prove beneficial in diagnosis and treatment of biliary complications after liver transplantation. In a study of 20 liver transplant patients, cholangioscopy helped diagnose ischemia, ulcerations, scar tissue, intraductal clots, and retained suture material, which otherwise might have been missed by ERCP alone^[39]. The role of cholangioscopy in assessment of anastomotic strictures after liver transplantation is evolving.

Assistance in guidewire placement

ERCP has attained a primary role in the treatment of biliary strictures and biliary stones. Success of ERCP in these cases, however, depends on the ability to traverse the stricture or the stone with a guidewire that is then used to direct instruments such as dilating balloons or lithotripsy baskets^[40]. In the vast majority of cases, this is accomplished easily. With severe strictures or impacted stones, however, it can represent a time-consuming challenge, and in some studies, a failure rate of up to 20% has been reported^[41]. In such cases, cholangioscopy can facilitate guidewire placement and prevent more invasive procedures such as transhepatic access or surgery. Several studies have highlighted the value of cholangioscopy in such instances^[40,42].

Rare applications: We define rare applications as those responsible for $\leq 1\%$ of our peroral cholangioscopy volume. For obvious reasons, these indications have been reported only in one or two case reports and no studies have assessed the true value of peroral cholangioscopy in these settings.

Evaluation of recurrent pancreatitis

Peroral cholangioscopy was used in a 62-year-old post-cholecystectomy patient with recurrent acute pancreatitis of undetermined etiology. It revealed a T-tube remnant in the cystic duct stump, which served as a nidus for biliary sludge and stone formation. The T-tube remnant had evaded detection by ERCP, CT and magnetic resonance cholangiopancreatography. Removal of the T-tube remnant prevented further episodes of pancreatitis^[43].

Determination of source of bleeding in hemobilia

A 54-year-old man was reported to have bleeding from arteriovenous malformations of the bile duct, which was detected by peroral cholangioscopy, with subsequent successful treatment by endovascular intervention^[44]. In another study, the cause of hemobilia in a 57-year-old man could not be identified by ERCP, CT or angiography. Peroral cholangioscopy revealed multiple biliary ulcers. Biopsies were consistent with cytomegalovirus cholangiopathy that responded to antiviral therapy, with subsequent cessation of bleeding^[45].

Staging and ablation of biliary neoplasms

Peroral cholangioscopy was used in a 78-year-old man to determine the extent of a biliary neoplasm. Use of a video cholangioscope with NBI capability allowed precise determination of the margins of the lesion. Successful ablation of the neoplasm with brachytherapy was confirmed by repeat peroral cholangioscopy at 1 mo follow-up^[46].

CONCLUSION

Recent advances such as introduction of a single operator cholangioscopy system or video cholangioscopies with high image quality have led to renewed interest in cholangioscopy, with subsequent expanded use. Currently, the most common indications for cholangioscopy are stone therapy and evaluation of indeterminate biliary strictures. Several other clinical applications have been described. As this technology is gaining more popularity and use, other indications are certain to be described.

FROM THE EDITOR

Angiogenesis plays a critical role in tumor growth and metastasis. Most of the digestive cancers depend strictly on the development of an adequate blood supply in the form of neovascularization, which has a pivotal role in primary tumor growth and the development of metastasis. Thus, new blood vessels formed inside the tumor are usually highly permeable and provide a route for cancer cells to enter blood circulation^[1]. Tumor vascularization has been attracting a lot of attention in recent years due to possible implications in semi-quantitative diagnosis, as well as in prognosis stratification and targeted treatment^[2]. There are several ways traditionally proposed for investigation of tumor vascularization, but all these methods have several methodological flaws, including artifacts induced by air or fat [contrast-enhanced transabdominal ultrasound (US)], reduced resolution [contrast-enhanced computer tomography (CT)] or invasiveness (angiography or surgery)^[3].

Categorizing the patients through mini-invasive procedures, before chemotherapy or surgery, is of crucial importance. This has implications for the appropriate design of clinical trials, but also for the improvement of the decision making process, by selecting the tumors that are most likely to respond to treatment. Recently developed angiogenesis inhibitors represent a highly attractive target for tumor therapy, since they theoretically offer the hope of long-term control of tumor progression^[4]. Several anti-angiogenic inhibitors were recently developed

Abstract

Angiogenesis has a critical role in primary tumor growth and the development of metastases. Several angiogenesis inhibitors were recently developed, being a very attractive target for digestive tumor therapy. However, individualized therapy should not only be based on the pre-treatment imaging evaluation, but also on sensitive monitoring of microvascular changes during treatment. State-of-the-art imaging techniques have the potential to visualize and characterize angiogenesis, although the technology and methodologies employed are recent and need further validation. The aim of this series of reviews was to analyze and enhance current knowledge and future perspectives about the real-time assessment of angiogenesis in digestive cancers, used for the longitudinal monitoring of the effects of chemo-radiotherapy (including anti-angiogenic therapies), as well as for the precise targeting of drugs through molecular-based drug-delivery systems.

Key words: Angiogenesis; Digestive cancers; Chemo-radiotherapy

and have already been proven to be effective in clinical trials: bevacizumab (recombinant humanized anti-VEGF monoclonal antibody), cetuximab (anti-EGFR monoclonal antibody), erlotinib (tyrosine-kinase inhibitor), *etc*^[5]. Even though anti-angiogenic treatments are an established anti-cancer therapy, several mechanisms of tumor evasion and refractoriness have been described after inhibition of a single pro-angiogenic pathway, due to compensatory upregulation of different angiogenic pathways^[6]. Tailoring the anti-angiogenesis therapy as a function of the pre-operative imaging evaluation would be the next step, with a consequent decrease of toxicity, as well as an increase of median progression-free survival. Furthermore, these procedures would possibly allow a sensitive monitoring of microvascular changes caused by chemoradiotherapy or other ablative treatments. The ultimate goal would be to achieve an early diagnosis where the “angiogenic switch” could be delayed and tumor evasion mechanisms could be prevented, in order to induce a dormant state, while transforming cancer into a chronic disease^[7].

The main objectives of our series of reviews include the discussion of several advanced imaging techniques, complementary used for the real-time assessment of angiogenesis in digestive cancers. The advanced imaging techniques discussed will include several “red-flag” endoscopic techniques used for the depiction of minute changes in the vessel pattern of preneoplastic and neoplastic lesions (tri-modal imaging including autofluorescence imaging, zoom endoscopy and narrow band imaging)^[8]. Utility of Doppler-optical coherence tomography (D-OCT) for the depiction and quantification of low-velocity, low-volume blood flow will also be reviewed^[9]. These techniques will be supplemented by the presentation of confocal laser endomicroscopy and the potential applications of this breakthrough technique for the in-vivo assessment of vascularization based on the use of specific vascular contrast agents^[10]. Targeted contrast-enhanced ultrasound and its role in the depiction of angiogenesis, as well as ultrasound-directed drug delivery and the physics behind sonoporation will also be discussed^[11]. A comprehensive discussion will focus also on the use of contrast-enhanced endoscopic ultrasound (including specific harmonic imaging)^[12]. Current and future hybrid imaging techniques like real-time virtual sonography (a combination of US/EUS with CT/magnetic resonance imaging) will also be briefly described^[13]. Lastly, molecular imaging perspectives and new developments of targeted

contrast agents will be critically analyzed^[14].

The aim of this series of reviews will be to analyze and enhance the current knowledge and future perspectives of the *in-vivo*, real-time assessment of angiogenesis in digestive cancers, used for the longitudinal monitoring of the effects of chemo-radiotherapy (including anti-angiogenic therapies), as well as for the precise targeting of drugs through molecular based drug-delivery systems.

Abstract

It is well known that angiogenesis is critical in the transition from premalignant to malignant lesions. Consequently, early detection and diagnosis based on morphological changes to the microvessels are crucial. In the last few years, new imaging techniques which utilize the properties of light-tissue interaction have been developed to increase early diagnosis of gastrointestinal (GI) tract neoplasia. We analyzed several "red-flag" endoscopic techniques used to enhance visualization of the vascular pattern of preneoplastic and neoplastic lesions (e.g. trimodal imaging including autofluorescence imaging, magnifying endoscopy and narrow band imaging). These new endoscopic techniques provide better visualization of mucosal microsurface structure and microvascular architecture and may enhance the diagnosis and characterization of mucosal lesions in the GI tract. In the near future, it is expected that trimodal imaging endoscopy will be practiced as a standard endoscopy technique as it is quick, safe and accurate for making a precise diagnosis of gastrointestinal pathology, with an emphasis on the diagnosis of early GI tract cancers. Further large-scale randomized controlled trials comparing these modalities in different patient subpopulations

INTRODUCTION

It is well known that angiogenesis is critical in the transition from premalignant to malignant lesions. Consequently, early detection and diagnosis based on morphologic changes to the microvessels are crucial. Conventional endoscopic diagnosis using white light is based on subtle morphological changes such as superficially elevated, flat, or depressed lesions and minimal changes in color. However, these findings are difficult to recognize, especially for inexperienced endoscopists. As a result, the diagnosis may be inaccurate or a superficial cancer in the gastrointestinal (GI) tract may be overlooked.

New imaging techniques which utilize the properties of light-tissue interaction have recently been developed to enhance early diagnosis of GI tract neoplasia. Endoscopic autofluorescence imaging (AFI) produces real-time pseudocolor images based on the detection of natural tissue fluorescence generated from endogenous fluorophores (collagen, nicotinamide, adenine dinucleotide, flavin and

porphyrins) through emission induced by excitation light. The system can visualize lesions, including malignancies, by differences in tissue fluorescence properties and can reveal early stage cancers not detectable by conventional white light endoscopy (WLE)^[1,2]. Magnifying endoscopy with narrow band imaging (ME-NBI) represents a real-time endoscopic imaging technique which enhances visualization of the surface texture and the vascular network of the mucosa with the aim of improving tissue characterization and differentiation^[3].

AUTOFLUORESCENCE IMAGING

The principle of autofluorescence diagnosis is based on the interaction between light with a specific wavelength and tissue fluorophores. When tissues are exposed to short wavelength light, endogenous fluorophores (collagen, nicotinamide, adenine dinucleotide, flavin and porphyrins) are excited, leading to the emission of fluorescent light of a longer wavelength (i.e. autofluorescence)^[4]. Normal, inflamed and neoplastic tissue have different autofluorescence characteristics that may thus enable their differentiation. Thus, normal tissue is pseudocolored as green, blood vessels as dark green, while hypertrophic fundic mucosa of the stomach and dysplastic/neoplastic areas appear as magenta. During AFI, a suspected neoplasia (AFI-positive lesion) is defined as any area that is different in color from the surrounding mucosa, and which has a defined circumferential margin^[5].

Autofluorescence is abnormal in neoplastic tissues due to several mechanisms: (1) increase in the nuclear-cytoplasmic ratio, which consequently determines decreased autofluorescence as nuclei show no autofluorescence as compared with cytoplasm; (2) loss of collagen, submucosal collagen is the strongest fluorophore which disappears due to thickening of the mucosa; and (3) neovascularization, inducing increased hemoglobin concentration which absorbs autofluorescence light^[6].

Several published studies showed an increased sensitivity for the detection of high-grade dysplasia and early cancer in the GI tract when autofluorescence techniques were used^[1,2,5-9]. Kara *et al.*^[7] showed the effectiveness of AFI in identifying high-grade dysplasia and early cancer in patients with Barrett's esophagus. Compared with WLE and random 4-quadrant biopsies, AFI increased the detection of high-grade dysplasia and esophageal adenocarcinoma by an additional 6 out of 60 patients, representing an increase of 10%, from 23% to 33%. False-positive lesions were determined by the presence of acute inflammation. On the other hand, Kara *et al.*^[8] showed that fluorescence imaging with light-induced fluorescence endoscopy (LIFE) using a fiber-optic endoscope was no better than standard WLE for the detection of high-grade dysplasia and early cancer in a randomized crossover study of patients with Barrett's esophagus. Another study tested the diagnostic performance of AFI for early gastric neoplasms, thus Ohkawa *et al.*^[9] concluded that LIFE is highly sensitive (sensitivity 96.4%) but not very specific (specificity 49.1%), since 50.9% of benign lesions were also identified

as having abnormal fluorescence images. Using the latest technology incorporated in AFI systems, Kato *et al.*^[5] obtained similar results, with approximately 25% of superficial elevated neoplasia diagnosed only by AFI and missed by WLE. In principle, a superficial elevated neoplasm of a similar hue to the surrounding mucosa might be overlooked during WLE, but it can be revealed by AFI if the elevated neoplasm appears as magenta within a normal looking green mucosa (Figures 1-4).

While all these studies demonstrate the vast potential of AFI to target premalignant lesions (high grade dysplasia) and early cancers, they also reveal important limitations of this technique and set-up directions for future improvement. The large number of false-positive results with a consequent low positive predictive value implies a potential benefit from adjunct methods such as ME-NBI, optical-coherence tomography (OCT) or confocal laser endomicroscopy (CLE)^[10] which would provide greater detection specificity. The use of trimodal imaging endoscopy that includes WLE, AFI and ME-NBI incorporated in one endoscopy system might improve diagnostic accuracy for high-grade dysplasia and early cancer^[11-13]. ME-NBI is currently considered the technique of choice for improvement of diagnostic accuracy because it reduces the high rate of false-positive results associated with WLE and AFI. Autofluorescence consists primarily of visible light, resulting in images limited essentially to the mucosal surface. Consequently, the development of infrared techniques may provide greater tissue penetration, obtaining images with greater contrast between lesions and their surrounding regions, and allowing the visualization of vascularization in deeper lesions, including the submucosa. Some studies reported that infrared endoscopy is capable of detecting abnormal submucosal vascularization in tumor lesions, with retention of indocyanine green being correlated with the size of the submucosal vascular bed^[14-18]. There is also a direct correlation between the presence of infrared fluorescence and the number of submucosal vessels. With the development of tumor invasion, there is a tendency for more abnormal blood vessels to be formed, further accompanied by an increase in fluorescence^[18].

NARROW BAND IMAGING

Narrow band imaging (NBI) is an optical image technology that enhances structural mucosal patterns (pit-pattern), as well as mucosal/submucosal vessels, by employing the characteristics of the light spectrum. The technology consists of placing narrow bandpass filters in front of a conventional white-light source to obtain tissue illumination at selected narrow wavelength bands. Currently available NBI systems use 2 narrow band filters that provide tissue illumination in the blue (415 nm) and green (540 nm) spectrum of light. The superficial penetrating wavelength of 415 nm corresponds to the main peak on the absorption spectrum of hemoglobin, while the deeper penetrating wavelength of 540 nm corresponds to a secondary hemoglobin absorption peak. Capillaries in the superficial mucosal layer are emphasized by the 415 nm light and are

Figure 1 Normal esophageal mucosa. A: Normal vascular pattern above the gastroesophageal (GE) junction visualized in white light endoscopy; B: Autofluorescence imaging of the normal mucosa and vascular pattern above the GE junction; C: Magnifying endoscopy with narrow band imaging depicting the submucosal vessels in cyan and intrapapillary capillary loops in brown.

Figure 2 Esophageal squamous cell carcinoma invading the gastroesophageal junction. A: Elevated irregular mucosa with abnormal vascular pattern, difficult to see in white light endoscopy in retroflexion, immediately below the gastroesophageal junction; B: Autofluorescence imaging showing the lesion extension in magenta, with surrounding green normal mucosa; C: Magnifying endoscopy with narrow band imaging showing irregular, thick and distorted mucosal vessels characteristic for tumor angiogenesis.

Figure 3 Early gastric adenocarcinoma at the level of the gastric angle. A: Irregular ulcer visualized in white light endoscopy (WLE); B: Autofluorescence imaging showing in magenta the neoplastic margins and a larger lesion extension, as compared with WLE; C: Magnifying endoscopy with narrow band imaging showing a modified pit pattern, with irregular and distorted vascular pattern in the center suggesting high-grade dysplasia/early cancer, and with villous pits and light blue crest sign in the margins suggesting intestinal metaplasia.

displayed in brown, whereas deeper mucosal and submucosal vessels are made visible by the 540 nm light and are displayed in cyan (Figures 1-4). NBI performance is certainly maximized when it is combined with magnification (ME-NBI)^[3,19]. This technique improves the morphological analysis of epithelial crests of the mucosa and enables

a more precise analysis of the abnormal surface architecture (pit-pattern) of neoplastic lesions. However, the most important contribution is represented by the clear visualization of the vascular network in the mucosa, being especially useful in evaluation of the abnormal neoangiogenesis process in high-grade dysplasia/early cancer^[20].

Figure 4 Gastric polyp with moderate dysplasia. A: White light endoscopy showing a 10 mm gastric polyp; B: Autofluorescence imaging with magenta areas on the surface of the polyp, surrounded by green normal mucosa; C: Magnifying endoscopy with narrow band imaging showing a modified pit pattern of the mucosa with an increased number of capillaries.

It was previously recognized that the morphological changes of an intrapapillary capillary loop (IPCL) might represent a new option for early diagnosis of squamous cell carcinoma in the esophagus^[21,22]. However, evaluation of IPCLs under white light observation requires high levels of proficiency and is usually not possible during the usual clinical workup. By using the magnifying scope, the normal appearance of the IPCL is identified as red dots. NBI enables a more vivid observation of the IPCLs, increasing diagnostic accuracy, especially for inexperienced endoscopists (Figure 1C)^[23]. Branching vessels which are located relatively deeper in the wall layers are observed in cyan, while IPCLs which are located in a more superficial layer, are observed as brown loops (brown dots).

Changes in the IPCL pattern include dilatation, tortuosity and/or caliber change of individual IPCL or multiple IPCLs of various shapes. According to the degree of change, these are classified into five types^[23,24]: type I is associated with normal epithelium and IPCLs are observed as smooth running small-diameter capillary vessels; type II involves minimal dilatation and elongation of IPCLs, and is often equivalent to regenerative tissue or inflammation; type III assumes minimal changes in IPCLs and corresponds to borderline lesions which potentially include esophagitis and low-grade intraepithelial neoplasia; in type IV, 3 of the 4 abnormal IPCLs patterns are present and correspond to high-grade intraepithelial neoplasia; finally, type V includes all 4 abnormal IPCLs characteristics and signifies the presence of cancer. Type V is subdivided in four types, type V-1, V-2, V-3 to V_N which reflect cancer infiltration depth. In type V-1, IPCLs demonstrate characteristic changes, dilatation, meandering, irregular caliber and variable form, and corresponds to m1 lesions (carcinoma *in situ*). As it advances to m2 and m3, destruction of IPCL advances gradually and these changes are further extended into the submucosa. Thus, in type V_N, which is characteristic of sm deep invasive carcinoma, new tumor vessels appear, around 10 times larger than the irregular vessels which appear in IPCLs type V-3 (Figure 2C)^[23,24].

ME-NBI is very useful for identifying superficial squamous cell carcinoma in the head and neck region. Muto *et al*^[25,26] reported that visualization of abnormal

microvessel architecture in cancerous lesions is significantly improved by NBI as compared with WLE. This finding is clinically significant because no cases of superficial cancer in the oropharynx or hypopharynx were previously reported before the advent of NBI.

Most of the studies using NBI were designed to evaluate the mucosal pattern and capillary network of patients with Barrett's esophagus, knowing that during WLE it is difficult to identify dysplastic and early neoplastic changes. In all these studies, the accuracy of the diagnosis was higher for NBI as compared with WLE^[27-34]. NBI with magnifying endoscopy thus enables visualization of the details of the mucosal surface and capillary networks without using dyes. Regular villous/gyrus-forming mucosal patterns, as well as flat mucosa with long branching blood vessels are highly predictive for specialized intestinal metaplasia without dysplasia. Irregular/disrupted mucosal pattern, an irregular vascular pattern and abnormal blood vessels are associated with high-grade intraepithelial neoplasia or early cancer. Abnormal vascularity was defined as dilated, corkscrew vessels with increased vascularity and an abnormal, nonuniform branching pattern (Figure 2C)^[27,28]. All high-grade intraepithelial neoplasia have at least one abnormality, and 85% have two or more abnormalities^[27]. Goda *et al*^[29] reported that the addition of capillary pattern to fine mucosal patterns improved the diagnostic value of ME-NBI for detecting specialized intestinal metaplasia and superficial adenocarcinoma.

In a recent study, Singh *et al*^[30] validated a simplified classification of the various morphologic patterns visualized in Barrett's esophagus in four easily distinguishable types: A, round pits with regular microvasculature (columnar mucosa without intestinal mucosa); B, villous/ridge pits with regular microvasculature (intestinal metaplasia); C, absent pits with regular microvasculature (intestinal metaplasia); D, distorted pits with irregular microvasculature (high-grade intraepithelial neoplasia). This classification showed reproducibility and repeatability, both by experienced endoscopists and for those unfamiliar with NBI, suggesting a rapid learning curve. Therefore, ME-NBI allows all endoscopists to perform targeted biopsies for specialized intestinal metaplasia and high-grade intraepi-

thelial neoplasia with a high rate of success^[30-34].

There is no evidence to prove the clinical usefulness of NBI during non-magnifying endoscopic observation for detecting abnormal pathology within the stomach and the duodenum. From a technical point of view, the mucosal image by non-magnification observation with NBI is too dark and noisy for meaningful investigation, because the lumen of the stomach is large^[35]. Feasibility studies showed the potential of NBI with magnification to identify gastric intestinal metaplasia^[36], predict the histologic subtypes of early gastric cancer^[37], and improve margin delineation of gastric cancer for endoscopic mucosal resection^[38]. Uedo *et al.*^[36] reported that a distinctive finding called light blue crests is a good indicator of histological intestinal metaplasia, which is a well-known risk factor for the development of differentiated-type gastric cancer. NBI observation of a light blue crest, defined as a fine blue-white line on the crests of the epithelial surface or gyri, correlated with the histologic diagnosis of intestinal metaplasia with 89% sensitivity and 93% specificity. The light blue crest was frequently observed in the mucosa surrounding differentiated-type early gastric cancers, and it demarcated the extent of the tumors (Figure 3C).

In a study involving 165 patients with depressed-type early gastric cancers, Nakayoshi *et al.*^[37] reported that ME-NBI is not sufficient to replace conventional histology, but is capable of predicting the histological characteristics of gastric cancer. They classified the abnormal microvascular pattern into two types. In the case of differentiated-type depressed early gastric cancer, a relatively regular fine network pattern was more likely to be observed, while for the undifferentiated-type, a irregular, twisting, or corkscrew pattern was more likely to be observed, representing a relatively low density of microvessels. However, ME-NBI may not be sufficient to replace conventional histology, but it may allow improved differentiation between benign and malignant minute lesions and may be useful for diagnosing the extent of cancerous infiltration.

MULTIBAND IMAGING

Multiband imaging (MBI) represents a digital image processing technique that enhances the appearance of mucosal surface structures by using selected wavelengths of light in reconstructed virtual images. MBI technology uses a software-driven image-processing algorithm that is based on spectral estimation methods. A standard image captured by a color charge-coupled device video endoscope is sent to a spectral estimation matrix processing circuit contained in the video processor. Here, reflectance spectra of corresponding pixels that make up the conventional image are mathematically estimated. From these spectra, it is feasible to reconstruct a virtual image of a single wavelength. Three such single-wavelength images can be selected and assigned to the red, green and blue monitor inputs, respectively, to display a composite color-enhanced MBI image in real-time^[9]. There are very few published data thus far on the efficacy of MBI for detection or differentiation of GI tract lesions, although the technique

seems to be superior to WLE, noninvasive and may more easily detect lesions without dye, during both routine and detailed examinations^[39,40].

In conclusion, these new endoscopic techniques provide better visualization of mucosal surface microstructure and microvascular architecture and may enhance the diagnosis and characterization of mucosal lesions in the GI tract. In the near future, trimodal imaging endoscopy, which combines WLE, AFI and ME-NBI, is expected to be practiced as a standard endoscopy technique as it is quick, safe and accurate for making a precise diagnosis of GI pathology. Although there is compelling evidence that these new techniques are superior to conventional endoscopy, current clinical guidelines are still limited. Further large-scale randomized controlled trials comparing these modalities in different patient subpopulations are, of course, warranted before their endorsement in the routine practice of GI endoscopy.

INTRODUCTION

Optical coherence tomography (OCT) is a relatively new method in medical imaging, with first attempts being recorded at the beginning of the last decade^[1]. Based on the analyses of light interference properties generated by a low-coherence source (low-coherence interference), OCT is a noninvasive, high-resolution method. With a resolution in the range of 10-15 μm for standard OCT and up to 1-5 μm if special sources are used^[2,3], this method offers cross-section imaging of the sample with a penetration depth of 2-3 mm. Depending on the OCT configuration, Doppler capabilities are also available in order to provide both structural and functional analyses. With the first application in the field of ophthalmology^[4], promising OCT systems have recently been developed for other fields of medicine including cardiology^[5-7], dermatology^[8] and gastroenterology^[9].

Angiogenesis describes the formation of new vessels from preexisting vasculature under physiological and pathological conditions. Tumor neo-angiogenesis is a fundamental step for solid tumor growth and for metastasis, because it results in spread and development of the network of capillaries from existing blood vessels that are capable of providing the necessary oxygen and nutrients. The process is mediated by various stimulatory and inhibi-

Abstract

Optical coherence tomography (OCT) is a noninvasive, high-resolution, high-potential imaging method that has recently been introduced into medical investigations. A growing number of studies have used this technique in the field of gastroenterology in order to assist classical analyses. Lately, 3D-imaging and Doppler capabilities have been developed in different configurations, which make this type of investigation more attractive. This paper reviews the principles and characteristics of OCT and Doppler-OCT in connection with analyses of the detection of normal and pathological structures, and with the possibility to investigate angiogenesis in the gastrointestinal tract.

Key words: Optical coherence tomography; Doppler; Gastrointestinal tract; Gastrointestinal cancer; Angiogenesis

tory factors^[10], including cytokines (hormone-like peptides and low-molecular-weight albumins) and growth factors. These factors activate different enzymes (proteases, collagenases, gelatinases and heparinases) that degrade the extracellular matrix and proteins of the basal membrane, thus generating the proliferation and migration of endothelial cells. One of the main triggers of neo-angiogenesis is the secretion of the vascular endothelial growth factor (VEGF)/vascular permeability family of factors^[11,12]. VEGFs are cytokines that have many effects on vascular endothelium, and these multifunctional effects can contribute to angiogenic responses^[11].

The influence of these angiogenic factors is included in different mathematical models, using different living tissue or artificial tissue models such as chick embryo chorioallantoic membrane (CAM) or porous biomaterials^[13-15], in order to describe both the vascular network growth and flow modeling. The purpose of these studies was either to develop understanding of the angiogenesis mechanism or to describe the possibility of direct drug delivery and monitoring of the effects at the level of tumor blood vessels.

Evaluation of angiogenesis thus represents an important step for tumor assessment, especially because of the advent of angiogenesis inhibitors that are already established as anticancer agents. Consequently, to study such a complex process requires multiple correlated investigations that can assess and quantify low-velocity, low-volume blood flow. High-resolution functional imaging methods like 3D-OCT and/or Doppler-OCT could prove to be of considerable importance, especially for the real-time assessment of tumor microvascular flow.

OCT

For the sake of clarity and to associate the physics of the method with its medical applications, a short description of the OCT and Doppler-OCT principles, together with specific characteristics of the experimental system, are provided. Detailed description of the physical principles and mathematical equations that govern the method have been provided by several other papers^[16-20].

Basically, an OCT device provides an analysis similar to B-mode ultrasound investigation^[18]. The main difference is that, instead of using an ultrasound beam, OCT uses low-coherence light, which is provided by a source with emission in the infrared range, typically between 700 and 1500 nm, depending on the optical properties of the target^[21]. In the case of OCT measurements, direct analyses of the reflected intensity is not possible, because of using light, contrary to the case of ultrasound investigation, for which the image obtained is a direct mapping process of the reflected intensity from the target. This is due to the large difference between the velocity of the ultrasound beam and that of the light. Instead, in a standard OCT experiment (Figure 1), the infrared radiation is directed towards an interferometric set-up, where it is split into two beams: one used as reference and directed to a moving mirror, and the other is sent towards the

Figure 1 Scheme of a standard optical coherence tomography set-up based on a Michelson interferometer.

sample. After reflection, the sample and reference beams are mixed together, which produces the physical process of interference. Interference occurs only as long as they remain coherent, and the properties of the interference pattern are used as input signal for the imaging process. It should be emphasized that the characteristics of the OCT method are directly related to the properties of the light source used, with the optical characteristics of the sample and with the set-up type.

Based on the above-mentioned factors, advantages and disadvantages of OCT analysis in comparison with ultrasound investigation can be summarized as follows. (1) The main advantage of OCT analysis is higher resolution; 3-15 μm is possible^[2,3]. This is explained by the conditions for the interference process; to produce interference, two beams should be coherent. The light source is partially coherent, which means that coherence of the source is finite, and consequently, the two waves emitted by the source are coherent as long as they are not apart by more than a coherence length of the source. This means that the (optical) length of the reference and sample arm should not differ by more than the coherence length of the source; otherwise the two waves travelling back and forth along these arms do not interfere with each other. It also means that, by controlling the moving mirror in the reference arm (i.e. controlling the length of the reference arm), one has the possibility to control the depth in the sample, from where the reflected signal is received and analyzed (axial resolution); (2) Special mention should be made about the fact that, in an OCT experiment, no connection between the lateral and axial resolution of the measurements exists (in lateral resolution, both control and shape of the beam are playing a major role)^[18,20]. Axial resolution can be estimated using the formula^[16,18]: $\xi_z = [(2 \ln 2)/\pi][\lambda_0^2/\Delta\lambda]$ (eq. 1), where λ_0 is the central wavelength and $\Delta\lambda$ is the bandwidth, with the assumption that the incoming beam has a Gaussian shape and it travels through the air; nevertheless, in many practical set-ups, the radiation is travelling through optical fibers; (3) Infrared radiation (low-energy photons) is used and the source also has low power (mW range), therefore, this method is completely noninvasive; and (4) A major disadvantage compared to ultrasound as-

Figure 2 Scheme of Fourier domain-optical coherence tomography set-up.

assessment is the low penetration depth (2–3 mm, depending on the wavelength and optical properties of the analyzed sample^[21,22]), due to the high dispersion and absorption coefficient for the visible-infrared light in biological tissues. Nevertheless, in order to perform analyses that require only millimeter-range penetration depth (different types of mucosa investigation, surface blood microvessels), OCT investigations provide a valuable tool.

As mentioned above, a few parameters (properties of the light source, optical characteristics of the sample, and set-up type) determine the OCT experiments. There are several different set-up configurations for an OCT device used for medical investigations^[16–20]. These include time domain OCT (TD-OCT), Fourier domain OCT (FD-OCT), and swept source OCT (SS-OCT). FD-OCT and SS-OCT are usually grouped together under the name of spectral domain OCT.

TD-OCT was one of the first methods used and it involves a set-up similar to the well-known Michelson interferometer (Figure 1), which has the moving mirror in one arm and the sample in the other. It uses a broad-band light source^[23] and it works similar to the above description. The produced interferogram is measured by a single detector as a function of time delay between the light travelling back and forth along the two arms^[17]. The axial resolution depends on the coherence length of the source^[16,17], and can be given by the equation above (eq. 1). The main disadvantage of this OCT set-up is that it involves mechanical moving parts (moving mirror) that make it difficult to achieve the high scanning rate necessary for *in vivo* 2D and 3D investigations.

FD-OCT uses a charge coupled device or an array photodetector for registering the signal from the interfering light, instead of using a moving mirror and a single detector^[17,18]. A dispersive element (grating or spectrometer) is introduced in the set-up (Figure 2), which projects on to the detector a distribution of the intensity as a function of wavelength. A Fourier transform of the registered

signal provides the back-scattering signal from the sample as a function of time (practically as a function of penetration depth^[16–18]). The main disadvantage in this case is the presence of motion artefacts^[16,19,24].

SS-OCT is similar to FD-OCT but, instead of using a dispersive element to select different wavelengths and an array detector for analyses of the signal, it has a swept source (tunable laser) and a single detector^[17,18,25].

Both FD-OCT and SS-OCT allow direct access to the whole spectrum within one measurement, which offers high sensitivity and imaging resolution, together with high scan rates, which make possible 2D and 3D investigations or fast Doppler measurements^[18,22].

Of these three basic schemes, polarization sensitive detection or phase-sensitive detection can be added in order to improve the imaging process^[16,17].

Doppler-OCT basically estimates the shift in frequency of the laser beam (laser Doppler velocimetry) when the process of the scattering takes place on a moving element^[18,26,27]. As a result of the fact that OCT does not measure directly the reflected intensity, but an interference signal, special mathematical methods are required in order to analyze the received signal; methods which depend on the OCT set-up type^[18]. An important detail is represented by the fact that, if laminar flow is assumed^[20,28], then transversal measurements (in the range of $\pm 15^\circ$) are possible in order to visualize the blood vessels under the sample surface.

The system we have used in our measurements is an SS-OCT from THORLABS (OCS1300SS; Munich, Germany) (Figure 3). The source is a swept laser (55 kHz) with a central wavelength of 1325 nm and an average power of 12 mW. The system is capable of 2D and 3D scans (with an A-scan rate of 55 KHz), with an axial resolution of 12 μm and a lateral resolution of 15 μm . Optical power on the sample is 5 mW. A Doppler module is also available. The system has an image acquisition rate of 50 frames/s.

CLINICAL APPLICATIONS

The possibility offered by the OCT system to deliver near histopathological resolution images makes this method a valuable tool for assessing the gastrointestinal tract. The possibility to investigate tumor structures with high resolution, without performing a classical biopsy, has become very attractive, especially in situations when harvesting biopsy is difficult to realize, or is very hazardous^[9]. Several authors have investigated gastrointestinal cancers by OCT but, due to the late development of Doppler capabilities, few have performed investigations of the angiogenesis process. Generally, to date, most of the studies have evaluated the structural (architectural) changes in the digestive mucosa under pathological conditions, and have identified the correct OCT layer structure inside normal/pathological tissue.

Early studies using OCT techniques have focused on the structure and characteristics of the gastrointestinal tract layers, in order to distinguish between different conditions^[29–32] and patterns, in an attempt to develop computer-assisted diagnostic methods. Also, a lot of interest

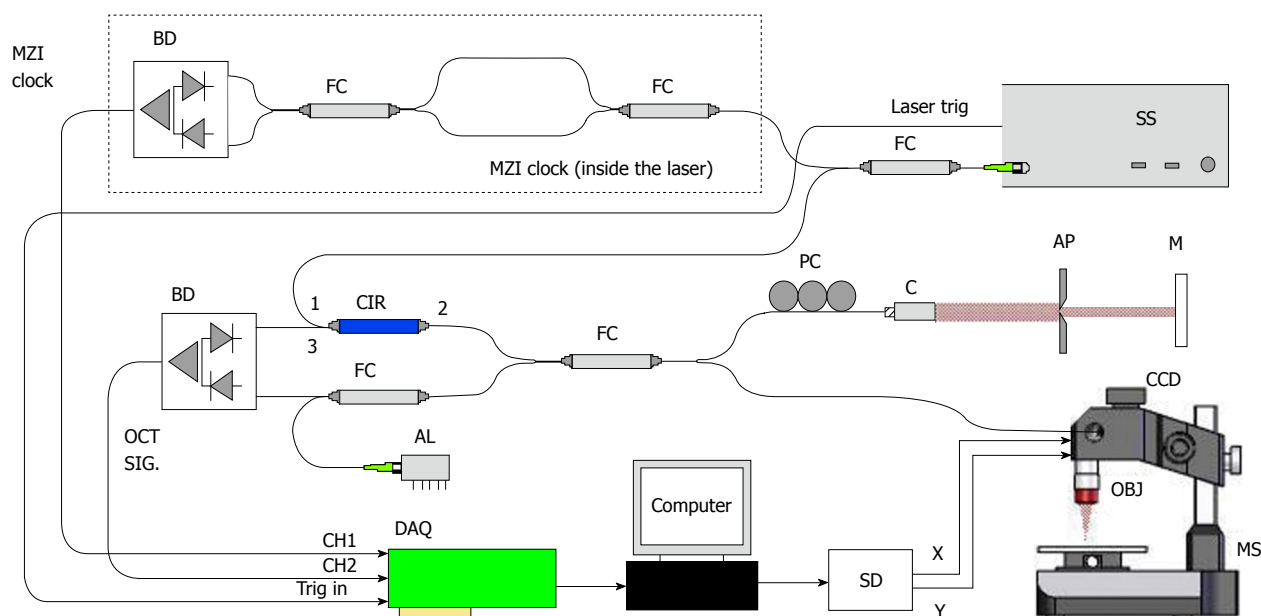

Figure 3 Set-up for OCS1300SS (courtesy of Thorlabs). OCT: Optical coherence tomography; SS: Swept source.

has been directed towards the development of the OCT systems (e.g. new sources, fast acquisition rates, different types of catheters, and modeling of the involved physical processes) for the purpose of management during *in vivo* investigations^[29,31,33]. For example, it has been shown that the structure of the esophageal wall (i.e. squamous epithelium, lamina propria, muscularis mucosa, submucosa, and muscularis propria), as well as the stomach layers (i.e. glandular epithelium, muscularis mucosa, submucosa, and muscularis propria) can be assessed by OCT in order to diagnose pathological aspects^[32].

Recently^[34], ultra-high resolution investigations have been performed in gastric tissues. Based on a higher resolution than standard OCT (10 μm), these studies have demonstrated that computer-aided image analysis is possible, even for detection of different grades of dysplasia^[34,35]. Furthermore, it has been shown that OCT imaging using a standard resolution OCT system with a catheter, which acquires a linear longitudinal plane at a rate of 2/s, can identify specialized intestinal metaplasia at the squamo-columnar junction, with an accuracy close to that of endoscopy^[36]. A pertinent review of OCT in the gastrointestinal tract (esophagus, stomach, small intestine and colon) has been carried out^[37] for normal and pathological (pre-neoplastic tissue, dysplasia and neoplasia) tissues, specifying the detected characteristics. For bile and pancreatic ducts, OCT has also been shown to be a valid tool^[38,39] that allows analysis of near histopathological resolution. The lower gastrointestinal tract has been subjected to OCT investigations^[40] in correlation with histology. Colon cancer was initially studied on mouse models, which have shown that OCT is capable of distinguishing between characteristics of the mucosa (i.e. thickening of the mucosal layer and loss of visibility of tissue boundary lines^[41]), even before adenoma arises. Recently, 3D-OCT investigation of the colon has been performed^[42], in order

to illustrate the differences in pathology. A pilot study on six volunteers was performed, which made possible the observation of clear differences between normal glandular epithelium, normal squamous epithelium and chronic inflammation from ulcerative colitis.

From the point of view of gastrointestinal tract mapping, most of the studies have involved the upper tract (esophagus, with emphasis on Barrett's esophagus), where studies and imaging analysis are the most advanced^[9,20,43,44] and can assist classic endoscopy. A more challenging task is the stomach, where low resolution and penetration depths are observed^[9,20]. In contrast, the colon is a region where images with good investigative potential have been recorded^[9,18,31].

The Doppler-OCT technique was developed later than standard OCT, and only a few studies have been published^[27,45-48]. Most of the expectations for this method were initially to detect and analyze mucosal and submucosal microvascularization. Position (e.g. lamina propria and submucosa) and size (small vessel $\leq 100 \mu\text{m}$, medium vessels $\leq 400 \mu\text{m}$, and large vessels $\geq 400 \mu\text{m}$) of the blood vessels could be detected^[48] in different parts of the gastrointestinal tract. Nevertheless, for the clinical translation of Doppler-OCT into a standard medical investigation, patterns and different characteristics of the microvascularization should be identified and used to produce computer-aided diagnostic procedures. There are not many sources that provide values for physical parameters of biological tissues, e.g. (refractive index, dispersion coefficient); values which are necessary for physical and mathematical modelling, and research should be directed towards such measurements.

We have conducted our early experiments on biopsies (Figure 4A and B) and in a chick embryo CAM model (Figures 5 and 6), where human biopsy implants (xenografts) were placed. The images clearly showed the pos-

Figure 4 2-D (A) and 3-D (B) optical coherence tomography images of gastric tissue biopsy with visualization of normal components of the parietal layers.

Figure 5 Macroscopic view of a chick embryo chorioallantoic membrane with human gastric tumor implant.

Figure 6 Doppler-optical coherence tomography imaging of a chick embryo chorioallantoic membrane (2 mm × 2 mm) showing capillary activity (arrows) near a human gastric tumor implant.

sibility to identify the microvascularization around the implant zone and the detection of blood flow. It seems that

parameters that characterize the capillary network, such as density, flux and diameter, are accessible to the imaging process, and in addition with other characteristics provided by OCT (i.e. architectural distortion, presence of submucosal glands, and alteration of the layer structure^[9,20]), they can be useful to describe the angiogenesis process.

CONCLUSION

Even though, at present, OCT investigations in gastroenterology are not able alone to provide adequate results (most of the published studies report accuracy and positive predictive values lower than endoscopy), it is worth developing combination of classical endoscopy and OCT techniques to harness the advantages of both. Also, given the large number of medical studies that use these types of devices, as well as recent technical improvements to the systems, it is clear that OCT methods are very promising. At the same time, acquisition of Doppler 3-D images could prove very valuable for the quantitative description of the angiogenesis process, due to the high resolution of this method and the fact that the results can be correlated with structural and functional properties of the samples.

Abstract

Gastrointestinal cancers represent a major cause of morbidity and mortality, with incomplete response to chemotherapy in the advanced stages and poor prognosis. Angiogenesis plays a crucial part in tumor growth and metastasis, with most gastrointestinal cancers depending strictly on the development of a new and de-

INTRODUCTION

Confocal laser endomicroscopy (CLE) is an emerging technology which allows *in vivo* imaging of cellular and subcellular details of the gut mucosa and vessels during ongoing endoscopy. With real-time microscopic analysis of the mucosal layer at high resolution, an immediate di-

agnosis is possible for different diseases and types of tissues. A magnification of about $1000\times$ enables evaluation of the epithelial cells, connective tissue and changes in vascular patterns. By using intravenously administered fluorescein sodium, images of vessel architecture are readily available, and early recognition of vascular changes in the gastrointestinal (GI) neoplasia is possible^[1]. Furthermore, if real-time diagnosis cannot be obtained, the same technique allows targeted sampling of relevant areas ("smart biopsies") with fewer specimens sent to the pathologist but with significantly higher diagnostic yield compared to random biopsies^[2].

The potential role of CLE has been explored in different pathologic conditions of the GI tract, the possibility of diagnosing premalignant and malignant lesions of the GI tract being particularly important considering the prognostic implications. Gastroenterologists have shown significant interest in this technique, looking for further potential applications in molecular imaging.

Cancers of the digestive tract nowadays represent a major cause of morbidity and mortality. Tumor growth and metastatic potential are strictly dependent on the development of a new and devoted capillary network, which will supply oxygen and nutrients to the newly formed tumor and will allow malignant cells to access the systemic circulation^[3]. Following intravenous administration of contrast agent, CLE allows *in vivo* real-time visualization of the tumor vasculature which is structurally and functionally altered by comparison with the pre-existing vessel network. Furthermore, pre-clinical trials have shown that quantitative characterization of microvessels *in vivo* is possible with confocal mini probes and the additional image processing software^[4]. Such analysis of the microvascular architecture is fundamental for early detection of neoplastic transformation and assessment of the tumor's metastatic potential. The complex, multistep process of neovascularization is the consequence of a dynamic balance between pro- and anti-angiogenic factors^[5]. Targeting markers of angiogenesis, such as vascular endothelial growth factor (VEGF) and epidermal growth factor receptor (EGFR), in association with endomicroscopic examination, as a future challenge, will add to the morphological aspect functional analysis of the neoplastic process. First steps towards such molecular endomicroscopic imaging have been made by recent studies on animal models.

PRINCIPLES AND TECHNIQUE

The newly developed endomicroscope integrates a miniature confocal microscope into the distal tip of a conventional endoscope enabling simultaneous standard video imaging and confocal microscopy of the mucosal layer. During CLE, an argon ion laser delivers an excitation beam of 488 nm wavelength at the surface of the tissue allowing targeted endomicroscopic images to be captured^[6]. By placing the distal tip of the endomicroscope in intimate contact with the mucosa, multiple grayscale optical sections are recorded at different depths within a range of 0-250 μm . The optical slices are parallel with

the mucosal surface with a 7 μm thickness and a lateral resolution of 0.7 μm , the field of view being $475\ \mu\text{m} \times 475\ \mu\text{m}$ ^[7,8].

Apart from this dedicated endomicroscope, CLE can be performed with a miniprobe. This stand-alone confocal probe can be passed through the working channel of most endoscopes for examination of both the upper and the lower digestive tract. The entire probe-based endomicroscopy system consists of a flexible catheter probe representing a bundle of optical fibers linked to a micro-objective, a laser scanning unit (excitation wavelength 488 nm) and control and acquisition software. A range of mini probes were designed with various optical parameters for different endoscopic procedures^[8,9]. The advanced image processing software allows real-time sequence display for an immediate morphologic diagnosis and also post-procedural analysis and editing. It enables vessel detection and quantitative microvascular measurements, features that make the system suitable for angiogenesis studies^[4].

Contrast agents

High-resolution confocal imaging is achieved by using an exogenous fluorescence technique. Of the potentially suitable contrast agents in humans, the most commonly used are intravenous fluorescein sodium (10%) and topically applied acriflavine (0.2%)^[10]. Acriflavine hydrochloride passes the cell membrane and strongly labels acidic constituents, providing clear visualization of the nuclei and cytoplasm, but only in the superficial layers of the mucosa (0-100 μm). Thus, it is particularly important in depicting intraepithelial neoplasia and cancer of the GI tract^[11]. Fluorescein is a slightly acidic, hydrophilic dye with nonspecific staining properties. Within seconds of intravenous administration it strongly binds to serum albumin and makes the vascular pattern easily detectable. The remaining unbound dye diffuses across the capillaries and, by entering the tissue, it highlights the extracellular matrix^[10,11].

With increasing interest by gastroenterologists in molecular imaging, novel fluorescent contrast agents have been developed targeting disease-specific biomarkers. These include labeled peptides which are easy to deliver to the target structure due to their low molecular weight, but they have variable affinity^[12]. A heptapeptide conjugated with fluorescein has been topically administered for specific *in vivo* imaging of human colorectal neoplasia^[13]. Fluorescently labeled antibodies, on the other hand, are highly selective, binding to their defined target, but may induce immune reactions. Already approved therapeutic antibodies could be labeled for imaging tumors, thus deciding the choice of targeted chemotherapy and potentially predicting the response to treatment^[12]. CLE was able to accurately classify human xenograft tumors in mice and human tissue specimens based on their EGFR expression using fluorescently labeled antibodies against EGFR^[14]. Anti-VEGF antibodies were also used as fluorescent contrast agents for *in vivo* molecular imaging in animal models^[15]. Extensive pharmacokinetic and safety studies are needed to define clinical applications for these molecular probes.

Figure 1 Esophageal surface epithelium visualized using intravenous fluorescein. A: Capillary loops (arrows) of the esophageal papillae; B: Dilatation of intercellular spaces and increased vasculature off the papillae in reflux esophagitis; C: Presence of cylindrical epithelial cells and goblet cells (arrows) in the distal esophagus suggesting Barrett's epithelium.

CLINICAL APPLICATIONS IN GI CANCERS

The spectrum of potential indications for CLE is broad and includes pathology of both the upper and lower GI tract, most importantly screening and surveillance for cancer based on the cellular and vascular changes. Microscopic imaging of the mucosa is performed after previous detection by standard or optically enhanced endoscopy (autofluorescence imaging, narrow band imaging, i-scan, *etc.*) of “areas of interest”^[10].

Esophagus

The normal endomicroscopic view of the esophageal surface includes polygonal cells within the non-keratinized squamous epithelium and the regular capillary loops of the esophageal papillae directed towards the luminal surface (Figure 1A)^[7,11].

In patients with gastroesophageal reflux disease (Figure 1B), Barrett's epithelium is a well defined premalignant condition associated with adenocarcinoma of the lower esophagus. Although the main diagnostic feature of Barrett's esophagus is the presence of goblet cells, easily detectable with CLE, the vascular pattern, highlighted by fluorescein staining, can also be considered. The subepithelial capillaries are still regular in shape beneath a

specialized columnar epithelium (Figure 1C)^[7]. Significant alterations of the capillary loops are notable in neoplastic tissue with irregular, dilated vessels of increased permeability recognized in the lamina propria due to the brighter signal intensity. Thus CLE is able to detect early neoplastic transformation based on changes in the vascular architecture^[1,16]. In the progression of cancers associated with Barrett's esophagus, angiogenesis represents an essential step. Confocal endomicroscopy can detect this newly developed vascular network and also it enables quantitative measurements such as microvessel density (MVD). Becker *et al.*^[17] evaluated confocal microscopy images acquired from 20 patients, which showed that, in neoplastic Barrett's esophagus, MVD was significantly higher compared to benign conditions.

Stomach

In imaging the stomach, confocal diagnostic criteria have been established in clinical studies for normal gastric mucosa (Figure 2A) as well as for chronic gastritis with intestinal metaplasia (Figure 2B) and cancer by correlation with histopathological examination as the gold standard^[18-22]. While most of these studies classified lesions based mainly on the changes in cells and pit patterns, Liu *et al.*^[23] described endomicroscopic aspects of vascular architecture

Figure 3 Confocal laser endomicroscopy of the normal colon using intravenous fluorescein. A: Normal aspect of colonic mucosa showing regular architecture of crypts and capillaries of lamina propria (arrows); B: Dark shadows in the lumen of the vessels representing the red blood cells (arrows).

Figure 4 Confocal laser endomicroscopy of the colon using intravenous fluorescein. A: Colon carcinoma with total disorganization of cell architecture, invasion and destruction of the vessels with leakage of fluorescein (arrows); B: Severe inflammatory changes in ulcerative colitis with cellular infiltrate causing an increase in the distance between crypts and excessive vascularity (arrows).

in both normal and malignant mucosa of the upper GI tract. Contrast enhanced CLE (fluorescein sodium 10%, 5 mL) highlights the vascular network of the normal gastric mucosa revealing different aspects between parts of the stomach. The subepithelial capillaries of the gastric body show a honeycomb-like pattern surrounding the gastric pits while in the antrum they are typically coil-shaped. Differentiated early gastric cancer appears to be hypervascular with tortuous, dilated vessels, irregular in shape and size (Figure 2C). In contrast, a hypovascular aspect was described for undifferentiated cancer with isolated, short branch vessels that did not interconnect. In one case report, probe-based endomicroscopy made it possible to diagnose angiodysplasia as a cause of chronic anemia by real-time imaging of a dilated blood vessel with moving red blood cells^[24], adding proof to CLE's feasibility for vascular imaging.

Colon

Clinical trials have delineated potential applications for endomicroscopic examination of the colon. Following intravenous administration of fluorescein the capillaries of the normal colonic mucosa are clearly visualized in the deeper layers of the lamina propria as bright structures (Figure 3A) with moving dark shadows in the lumen representing

the red blood cells which are not labeled by fluorescein (Figure 3B). This network of capillaries circumscribing the regular round mucosal glands results in a typical honeycomb pattern in CLE sequences^[6,11]. In the proximal colon the vasculature appears more dense than in the distal colon, an aspect which correlates with the physiological profile of water absorption along the large intestine^[25].

Confocal patterns based on changes in vessel and crypt architecture have been defined to differentiate among neoplastic and non-neoplastic tissue^[26,27]. In contrast to the regular vascular pattern of the normal mucosa, in colonic cancer the vessels are dilated, distorted with little or no orientation to the adjacent tissue. Increased permeability of the new tumoral vessels is proved by fluorescein passing from the lumen into the interstice which appears intensely bright (Figure 4A)^[11,26]. Colon cancer, with 655 000 deaths worldwide per year, is the second leading cause of cancer-related death in the Western world^[28]. In order to improve the prognosis, colorectal cancer should be detected in the early stages or even precursor stages, when it is possible to cure the selected cases by immediate endoscopic resection. Flat lesions are difficult to detect using standard endoscopic methods and conventional colonoscopy has a significant false-negative rate for intraepithelial neoplasia. CLE is able to predict intraepithelial neoplasia with high

accuracy (99.1%) based on the morphological changes in vascularization mentioned above and the irregular cell architecture^[27].

Precursor neoplastic lesions are also detected by endomicroscopic examination, such as adenomatous polyps, the most important risk factor for colon cancer^[29]. They can be diagnosed microscopically *in situ* with high accuracy, taking into account the altered vascular pattern and also the lack of epithelial surface maturation, crypt budding, and loss of cell polarity^[30].

Patients with inflammatory bowel diseases (IBD), both ulcerative colitis (UC) and Crohn's disease (CD) have a higher risk of developing colorectal cancer as a result of persistent inflammation of the colon. In long-standing ulcerative colitis, CLE is a feasible solution for detecting neoplastic changes in suspect areas. When preceded by a wide-field examination technique, such as chromoendoscopy, CLE has been shown to increase the diagnostic yield of intraepithelial neoplasia while reducing the number of biopsy samples^[31,32]. Inflammatory changes are also depicted by endomicroscopic examination. Increased vasculature of the mucosa (Figure 4B) together with the chronic inflammatory infiltrate result in an enlarged distance between crypts, which show different shapes and sizes^[11].

A recent published study aimed to evaluate the role of CLE in the assessment of inflammatory activity in UC^[33]. On CLE images microvascular alterations and fluorescein leakage as well as crypt architecture were analyzed, and showed good correlation with the histological findings.

While the reported studies have considered mainly descriptive features of the vascular architecture for diagnosis purposes, quantitative measurements of the normal and tumoral vessels could be possible by translating results from preclinical research on small animal models to clinical trials. Laemmel *et al.*^[4] demonstrated in a murine model that is possible to make *in vivo* microvascular observation with a miniprobe confocal fluorescence microscope. They used fluorescein-isothiocyanate-labeled dextran (FITC-dextran) or FITC-albumin injected intra-arterially for clear visualization of the microvascular network. Confocal microscopy enabled observations and measurements usually provided by intravital microscopy: functional capillary density, capillary permeability, vasoconstriction and dilation effects in a minimally invasive procedure. Thus, confocal microscopy has shown potential in the field of microcirculation that should be explored for clinical translation.

IMMUNOENDOSCOPY

The association of endomicroscopic examination with tagged markers of inflammation and proliferation represents an evolutionary leap in GI endoscopy. Thus "immunoendoscopy" aims at the detection and characterization of lesions based on the molecular changes found in inflammation and neoplasia, with potential major impact on current diagnostic and therapeutic algorithms. The exogenous contrast agents for molecular imaging include

fluorescently labeled antibodies and peptides which directly bind to their targets, and "smart" probes with tumor-specific activation^[12].

Goetz *et al.*^[34] approached *in vivo* molecular imaging in a study of human inflammatory and neoplastic diseases in rodent models. They aimed to evaluate a newly developed, handheld confocal miniprobe for *in vivo* subsurface morphological, functional and molecular imaging. Octreotate was labeled with 5-carboxyfluorescein for targeted imaging of somatostatin receptors. After systemic application of developed tracer, neuroendocrine tumors and somatostatin-receptor-expressing pancreatic islet cells were visualized with excellent correlation with immunohistochemistry.

In a pilot *in vivo* human study, a phage library was screened to isolate a peptide that specifically bound colonic dysplasia. The identified heptapeptide sequence was then synthesized and conjugated with fluorescein for use in patients undergoing colonoscopy. After its topical administration, endomicroscopic examination visualized preferential binding of the labeled peptide to dysplastic colonocytes over normal mucosa with high sensitivity and specificity (81% and 82%, respectively), although the molecular target of the sequence was unknown^[13].

With constant interest in understanding angiogenesis and recent advances in antiangiogenic therapies for oncologic patients came the need for imaging this complex process *in vivo*. Targeting angiogenic regulators has been already performed on animal models with promising results for future clinical trials.

One trial evaluated the feasibility of CLE for real-time molecular imaging of EGFR expression, an already established therapeutic target for colorectal cancer^[14]. EGFR is overexpressed in many tumors, playing a central role in proliferation, angiogenesis, invasion, and metastasis^[35,36]. In this trial it was possible to visualize and differentiate EGFR expression patterns in human xenograft tumors in mice with a handheld CLE probe after injection of fluorescently labeled antibodies. Additionally, topical application of fluorescently labeled antibodies provided adequate contrast, enabling distinction of neoplastic from non-neoplastic human colorectal tissue samples based on their EGFR expression^[14]. The same team specifically targeted VEGF for imaging its expression in murine tumors, human xenografts and human tissue samples of colorectal cancer^[15]. VEGF has been intensely studied in basic and clinical research and is already a therapeutic target in metastatic colorectal cancer^[5]. CLE images showed a VEGF-specific signal which correlated well with immunohistochemistry. These studies provide evidence that "immunoendoscopy" is feasible, and results from basic research could be technically translated into clinical practice. *In vivo* molecular imaging could enable selection of patients who would benefit from targeted therapies and could monitor the response to treatment.

Chick embryo chorioallantoic membrane (CAM) is a very convenient experimental model for studying angiogenesis of grafted tumors^[37]. The feasibility of gastric and

Figure 5 Confocal laser microscopy of the chick embryo chorioallantoic membrane. A: Chick normal chorioallantoic membrane with visualization of large vessels (arrowheads), medium vessels (arrows) and circulating nucleated erythrocytes; B: Fragment of viable human colon cancer tissue (arrows) implanted on chick embryo chorioallantoic membrane.

colonic biopsy implantation, both normal and neoplastic, on the chick CAM for the study of angiogenesis was recently demonstrated^[38]. Fragments of human gastric and colonic mucosa were obtained through endoscopic biopsy, immersed in saline and implanted within 60 min on the chick CAM. Next, the implanted tissue fragments were examined using the confocal laser microscope after previous intravascular administration of 10% fluorescein. Confocal microscopic examination managed to identify both the initial vascularization (Figure 5A) and the newly formed vessels of the grafted tissue (Figure 5B), including intravascular blood flow, representing a starting point for future immunoendoscopy studies in humans, with great therapeutic implications for angiogenic inhibitors.

In conclusion, CLE has led GI endoscopy into a new era. CLE is certainly no longer considered just another endoscopic technique, but a crucial and revolutionary imaging method for real-time assessment of changes in the vascularization pattern of GI structures. Furthermore, *in vivo* molecular imaging, combining CLE with targeted staining, will have a significant impact on both basic research and clinical practice.

Abstract

Ultrasonic imaging is becoming the most popular medical imaging modality, owing to the low price per examination and its safety. However, blood is a poor scatterer of ultrasound waves at clinical diagnostic transmit frequencies. For perfusion imaging, markers have been designed to enhance the contrast in B-mode imaging. These so-called ultrasound contrast agents consist of microscopically small gas bubbles encapsulated in biodegradable shells. In this review, the physical principles of ultrasound contrast agent microbubble behavior and their adjustment for drug delivery including sonoporation are described. Furthermore, an outline of clinical imaging applications of contrast-enhanced ultrasound is given. It is a challenging task to quantify and predict which bubble phenomenon occurs under which acoustic condition, and how these phenomena may be utilized in

ultrasonic imaging. Aided by high-speed photography, our improved understanding of encapsulated microbubble behavior will lead to more sophisticated detection and delivery techniques. More sophisticated methods use quantitative approaches to measure the amount and the time course of bolus or reperfusion curves, and have shown great promise in revealing effective tumor responses to anti-angiogenic drugs in humans before tumor shrinkage occurs. These are beginning to be accepted into clinical practice. In the long term, targeted microbubbles for molecular imaging and eventually for directed anti-tumor therapy are expected to be tested.

INTRODUCTION

Advanced medical imaging has a strong impact on research and clinical decision-making in real-time assessment of angiogenesis in digestive cancers. Ultrasonic imaging is becoming the most popular medical imaging modality, owing to the low price per examination^[1] and its safety^[2]. A B-mode ultrasound scan shows contrasted regions from transitions in acoustic impedance, i.e. transitions in tissue type, in the form of brighter pixels. However, blood is a poor scatterer of ultrasound waves at clinical diagnostic transmit frequencies, which lie between 1 and 40 MHz. For perfusion imaging, markers have been designed to en-

hance the contrast in B-mode imaging. These so-called ultrasound contrast agents consist of microscopically small gas bubbles encapsulated in biodegradable shells.

Contrast-enhanced ultrasound (CEUS) represents a significant advancement in the evaluation of angiogenesis in digestive cancers. In particular, in the study of focal liver lesions, CEUS has been widely used for detection and characterization of malignancy. The unique feature of CEUS of non-invasive assessment in real-time liver perfusion throughout the vascular phases has led to a great improvement in diagnostic accuracy of ultrasound, but also in guidance and evaluation of responses to therapy. Currently, CEUS is part of the state-of-the-art diagnostic work-up of focal liver lesions, resulting in safe and cost-effective patient management.

In this review, the physical principles of ultrasound contrast agent microbubble behavior and adjustments for drug delivery, including sonoporation, are described. Furthermore, an outline of clinical imaging applications of CEUS is given.

Ultrasound

The sound that humans can perceive lies within the frequency range 20 Hz–20 kHz. Ultrasound is by definition all sound higher than 20 kHz. The ultrasound frequencies utilized in medical imaging are mainly in the range 1–40 MHz. Such high frequencies cannot be transmitted through air but can be transmitted satisfactorily through solid or fluid materials. An ultrasonic transducer serves a dual function as both transmitter and receiver of ultrasound. A signal generated by an ultrasonic transducer typically consists of a pulse of a few μ s with a certain center frequency. Part of this signal propagates through target tissue, part is reflected by macroscopic tissue structures, part is absorbed by tissue, and part is scattered by structures in the tissue smaller than the acoustic wavelength. Only a small portion of the transmitted acoustic energy is received by the transducer, but this portion is used to build an ultrasonic image. The received signal is the superposition of specular reflections at tissue boundaries and echoes from tissue backscattering^[3]. Current real-time 2-dimensional imaging capabilities are in excess of 30 frames per second^[4]. Contemporary imaging techniques have been summarized by Wells^[5].

The quality of a B-mode scan is expressed by the contrast-to-noise ratio, which is defined as the absolute difference of the signal-to-noise ratio in the target tissue and the signal-to-noise ratio in the surrounding tissue^[4].

On clinical ultrasound devices, the intensity of the ultrasonic field is generally adjusted with a switch for the mechanical index (MI) instead of the acoustic amplitude. The MI depends on the maximum value of peak negative pressure and the centre frequency of the ultrasound field^[6]. For $MI < 0.3$, the acoustic amplitude is considered low. For $0.3 < MI < 0.7$, there is a possibility of minor damage to neonatal lung or intestine^[6]. These are considered moderate acoustic amplitudes. For $MI > 0.7$, there is a risk of cavitation if an ultrasound contrast agent

containing gas microspheres is being used, and there is a theoretical risk of cavitation without the presence of ultrasound contrast agents^[6]. The risk increases with MI values above this threshold^[6]. These are considered high acoustic amplitudes^[7]. In commercial scanners, the MI has been limited to 1.9 for medical imaging^[8]. Figure 1 shows examples of B-mode scans recorded at different MI. At higher MI, the contrast-to-noise ratio increases.

Microbubble physics

The density and compressibility parameters of blood cells hardly differ from those of plasma. Therefore, blood cells are poor scatterers in the clinical diagnostic frequency range^[9]. Since imaging blood flow and measuring organ perfusion are desirable for diagnostic purposes, markers should be added to the blood to differentiate between blood and other tissue types. Such markers must have resonance frequencies in the medical ultrasonic range. Figure 2 shows the resonance frequencies of free and encapsulated gas microbubbles as a function of their equilibrium radius. The resonance frequencies of encapsulated microbubbles lie slightly higher than those of free gas bubbles^[10,11], but clearly well within the clinical diagnostic range, too. Based on their acoustic properties, microbubbles are well suited as an ultrasound contrast agent.

The pressure inside a bubble must be higher than the ambient pressure^[12]. This difference is generally referred to as the surface pressure. The smaller the bubble, the higher is the surface pressure. Since fluids are forced to flow from a location with a higher pressure to a location with a lower pressure, a bubble cannot exist in true equilibrium. For example, a free air bubble with a 6 μ m diameter dissolves within 100 ms^[13]. To prevent quick dissolution, ultrasound contrast agent microbubbles contain low-solubility gas, such as SF₆ or C₃F₈^[14]. The encapsulating shells are made of biodegradable materials, such as phospholipids or albumin^[15]. With mean diameters below 6 μ m, these microbubbles are small enough to pass through the lung capillaries. Detailed overviews of the compositions of the ultrasound contrast agents used most in imaging research have been given by Postema *et al.*^[3], Sboros^[16] and Tinkov *et al.*^[17]. In this section, we classify ultrasound contrast agents into only 4 categories, based on the presence of an encapsulating shell and its thickness, similar to Tinkov *et al.*^[17].

A bubble in a low-amplitude sound field can be considered a forced damped harmonic oscillator^[18,19] and its oscillating behavior can, as a result, be modeled as a mass-spring-dashpot system^[20]. The spherically symmetric oscillating behavior of ultrasound contrast agent microbubbles has been described with models based on the Rayleigh-Plesset equation^[21], modified for the presence of an encapsulating shell^[22–32]. Generally, the presence of blood has a relatively small effect on bubble dynamics^[33]. To give an indication of the vast amount of existing models: Qin *et al.*^[34] defined 16 separate dynamic bubble model classes. The reason for the high number of existing models is the fact that most physical properties of en-

Figure 2 Resonance frequencies of free (unencapsulated) (solid line) and lipid-encapsulated (dotted line) microbubbles as a function of equilibrium radius.

capsulated microbubbles cannot actually be measured, so that pseudo-material properties have to be chosen when predicting ultrasound contrast agent microbubble behavior. Examples of such pseudo-material properties are shell elasticity parameters and shell friction parameters. At low-amplitude driving pressures, an ultrasound contrast agent microbubble oscillates linearly, i.e. the bubble excursion is proportional to the instantaneous pressure. However, at high-amplitude driving pressures, it oscillates nonlinearly. Figure 3 demonstrates the oscillation behavior of 2 contrast microbubbles subjected to continuous sine pressure waves with low, moderate, and high amplitudes. Both bubbles oscillate linearly at $MI = 0.01$. With increasing driving amplitude, asymmetries in radial excursion and expansion time rise, especially for the bigger bubble, which is closer to the resonance size. At $MI = 0.8$, both bubbles expand to a factor of the initial size, followed by a rapid collapse of the smaller bubble. The bigger bubble demonstrates collapse at $MI = 0.18$ and higher.

A dynamic bubble generates an acoustic signal that depends on the fluid displacement by the bubble as a func-

tion of time. Detection strategies have been developed to discriminate acoustic signal-generated by ultrasound contrast agent microbubbles from other acoustic signals such as specular reflections and tissue scattering. These strategies are the reason that CEUS is suitable for the detection of blood. The 10 most common detection strategies include coded excitation, harmonic power Doppler, phase inversion and power modulation^[34,35]. All single-pulse and multi-pulse imaging detection strategies make use of the nonlinear behavior of microbubbles^[34,35].

Other types of nonlinear behavior than asymmetric oscillations are discussed below.

If a bubble with a negligible shell collapses near a free or a solid boundary, the retardation of the liquid near the boundary may cause bubble asymmetry. This asymmetry causes differences in acceleration on the bubble surface. During further collapse, a funnel-shaped jet may protrude through the bubble, shooting liquid to the boundary^[36]. Such jets have been observed in high-speed observations of ultrasound contrast agent microbubbles^[37-40]. Empirical relations exist between the collapsing bubble radius, the jet length, and the pressure at the tip of jets^[41-43]. It has been speculated whether microbubble jetting can be applied for ultrasound-guided drug delivery^[38,39,42].

During the collapse phase, a bubble may fragment into a number of smaller bubbles^[44]. Fragmentation has been observed with contrast agents with thin elastic shells. The number of fragments into which a contrast microbubble breaks up has been associated with asymmetric oscillations^[40,45]. Fragmentation can be predicted from the moment when the kinetic energy of the bubble surpasses its surface energy^[27]. Bubble fragmentation costs energy, but the subsequent coalescence of bubble fragments generates enough acoustic energy to be detected^[27].

Thick-shelled microbubbles have demonstrated sonic cracking during a high-amplitude ultrasonic cycle^[46,47]. The

Figure 3 Simulated radius-time curves (radius R normalized with equilibrium radius R_0 , time t normalized with period T_0) of ultrasound contrast microbubbles with $0.55\ \mu\text{m}$ (left column) and $2.3\ \mu\text{m}$ (right column) equilibrium radii, respectively, modeled with a conservative Rayleigh-Plesset equation^[3], using a conservative shell stiffness parameter^[48]. The modeled ultrasound field was a continuous sine wave with a frequency of 0.5 MHz and acoustic amplitudes corresponding to (top-bottom) mechanical index = 0.01, 0.10, 0.18, 0.35, and 0.80, similar to the experiments by Karshafian *et al.*^[92].

increased pressure difference between inside and outside of the microbubble during the expansion phase of the wave^[48] causes the shell to be stretched until it surpasses a critical deformation^[49], resulting in its mechanical cracking. The

released bubble has an expansion amplitude much higher than an encapsulated bubble of identical size. Therefore, the acoustic signal from an ultrasound contrast agent after gas release differs from that of the same contrast agent be-

fore gas release, until the released gas has dissolved^[50].

After a disruptive ultrasonic burst, the disappearance of microbubble fragments or released gas can be traced with low-amplitude ultrasound, as well as the wash-in rate of fresh contrast agent^[51]. Hence, the efficiency of the disruptive burst can be measured.

Bubble translation in the direction of the sound field is caused by a primary radiation force resulting from a pressure gradient across the bubble surface^[52]. The translation is maximal in the contraction phase of the oscillating microbubble. Making use of this phenomenon, ultrasound contrast agent microbubbles can be forced to move farther away from the transducer, towards vessel walls^[53-61], increasing the success rate of targeting to a boundary.

In a standing sound wave field^[62], bubbles can aggregate to clusters ultimately a quarter of the acoustic wavelength apart^[61]. The formation of ultrasound contrast agent microbubble clusters and the ultrasonic pushing of these clusters towards a vessel wall have been recently observed using high-speed photography^[61].

The occurrence of the above-mentioned phenomena is influenced by (1) the ultrasonic parameters: transmit frequency, acoustic amplitude, pulse length, pulse repetition rate and transmit phase; (2) the ultrasound contrast agent composition: the composition of the shell, the bubble sizes, the size distribution and the gas; and (3) the physical properties of the medium: viscosity, surface tension, saturation.

Figure 4 gives an overview of the nonlinear phenomena that have been observed with ultrasound contrast agents, the type of ultrasound contrast agent in which they have occurred, and the minimum acoustic regime required.

Molecular imaging

Dayton *et al.*^[35] defined molecular imaging as the non-invasive application of an imaging modality to discern changes in physiology on a molecular level^[12]. Although ultrasound contrast agents were intended for perfusion imaging, they

have proven useful in molecular imaging as well, after modification of the microbubble shell. Dayton *et al.*^[35] discerned 2 targeting strategies: active targeting, in which a ligand specific for the molecular target, and passive targeting, in which the physiochemical properties of the agent are used to achieve retention at the target site^[12]. Molecular imaging and targeting have been reviewed elsewhere in depth^[35,63]. In summary, the main applications include the detection of angiogenesis, inflammation, plaques and thrombi^[8,12,17].

Drug delivery

It has been proven by numerous groups, that the cellular uptake of drugs and genes is increased, when the region of interest is under sonication, and even more so when a contrast agent is present^[12,64-91]. This increased uptake has been attributed to the formation of transient porosities in the cell membrane, which are big enough for the transport of drugs into the cell. The transient permeabilization and resealing of a cell membrane is called sonoporation^[64]. The sonoporation-induced cellular uptake of markers with molecular weights between 10 kDa and 3 MDa has been reported in several studies^[17,74,92]. Schlicher *et al.*^[93] showed that ultrasound-induced cavitation facilitated cellular uptake of macromolecules with diameters up to 56 nm. Even solid spheres with a 100 nm diameter have been successfully delivered with the aid of sonoporation^[82]. This implies that drug size is not a limiting factor for intracellular delivery^[92]. However, the pore opening times can be so short that, if the drug is to be effectively internalized, it should be released close to the cell membrane when poration occurs^[94].

There are 2 hypotheses for explaining the sonoporation phenomenon, the first being microbubble oscillations near a cell membrane, the second being microbubble jetting through the cell membrane. Based on modeling, high-speed photography, and recent cellular uptake measurements, we concluded that microbubble jetting behavior can be excluded as the dominant sonoporation

mechanism^[7]. The influence of microbubble disruption, i.e. fragmentation or sonic cracking, on sonoporation will have to be further investigated^[7]. Without the presence of an agent, it has been assumed that sonoporation is caused by bubbles, which have been generated in the transducer focus as a result of inertial cavitation^[95,96].

Instead of just facilitating the transient opening up of cell membranes, a microbubble might also act as the vehicle itself to carry a drug or gene load to a perfused region of interest, in which case the load has to be released with the assistance of ultrasound. Apart from mixing ultrasound contrast agent with a therapeutic agent, several schemes have been proposed to combine microbubbles with a therapeutic load^[97]. Tinkov *et al.*^[17] discriminated the following 7 microbubble structure classes for drug delivery: (1) attachment to the outer shell surface; (2) intercalation between monolayer phospholipids; (3) incorporation in a layer of oil; (4) formation of complexes with smaller particles (secondary carriers); (5) physical encapsulation in a polymer layer and coating with biocompatible material; (6) surface loading of protein-shelled microbubbles; and (7) entire volume loading of protein-shelled microbubbles. The drugs are to be released at the site of interest during insonication^[98], presumably by disrupting the microbubble shell. It has been demonstrated *in vitro*, that higher doses of DNA were delivered during ultrasound insonication when the DNA was loaded on albumin-encapsulated microbubbles than when unloaded microbubbles were mixed with plasmid DNA^[67]. Amounts of DNA loading on microbubbles have been between 0.002 (pg/ μm^3)^[99] and 2.4 (pg/ μm^3)^[17,67].

Instead of attaching a drug to the capsule, therapeutic compounds in the gas phase might be encapsulated with thick shells, to keep them from dissolving. At the region of interest, the shell should be cracked with ultrasound, releasing the gaseous content^[46,47,100,101]. However, only a few therapeutic compounds exist in the gaseous phase, e.g. nitric oxide^[48] and several gaseous anesthetics.

A therapeutic agent inside the microbubble shell may react with the shell and dampen the bubble oscillations. Therefore, it might be more suitable to have the therapeutic agent in the core of the microbubble, separated from the shell by a gaseous layer. Incorporating a liquid drop containing drugs or genes inside an ultrasound contrast agent microbubble, however, is technically challenging^[102]. As opposed to bubbles, antibubbles consist of a liquid core encapsulated by gas^[103]. Such a droplet inside a bubble may be generated with the jetting phenomenon: the collapse of a bubble near a free surface produces a liquid jet^[104], which may break up into one or several droplets^[105]. Another option would be to stabilize the liquid core by means of a biodegradable skeleton attached to the microbubble shell.

It has been noted, that, if microbubbles can create pores, it is also possible to create severe cell and tissue damage^[106]. There is an inverse correlation between cell permeability and cell viability^[92,107-109], i.e. not all cell membrane pores are temporary. This indicates that sonoporation is

just a transitory membrane damage in the surviving cell^[92]. Cell lysis results from irreversible mechanical cell membrane damage^[110], which allows the intracellular content to leak out^[64]. Only recently, ultrasound-induced apoptosis has been observed with cancer cells *in vitro*^[110,111], and also in the presence of an ultrasound contrast agent^[112]. Apart from situations where lysis is desired (sonolysis)^[113], ultrasonic settings should be chosen such that cell lysis is minimal. Side effects observed are capillary rupture, hemorrhage, and dye extravasation^[106]. These side effects, however, have been associated with relatively high microbubble concentrations, long ultrasonic pulse lengths, and high acoustic intensities^[106].

CLINICAL IMAGING APPLICATIONS

Liver

Ultrasonography is the most commonly used imaging modality worldwide for diseases of the liver. However, it has limited sensitivity in the detection of small tumor nodules. In addition, ultrasonographic findings are often nonspecific, as images of benign and malignant liver lesions overlap considerably. The introduction of microbubble contrast agents and the development of contrast-specific techniques have opened new prospects in liver ultrasonography. The advent of second-generation agents that enable continuous real-time contrast-enhanced imaging has been instrumental in improving the acceptance and reproducibility of the examination. With the publication of guidelines for the use of contrast agents in liver ultrasonography by the European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB)^[114,115], CEUS is now routinely used in clinical practice.

As opposed to contrast media used with computed tomography (CT) and magnetic resonance (MR) imaging, ultrasound contrast agents can visualize the capillary net of the examined tissue, because CEUS is considerably more sensitive to very small amounts of contrast agent, even to single bubbles. Furthermore, because sonography is a dynamic method that is performed in real time, additional information about tissue perfusion can be deduced from the influx and washout of the contrast media, thus facilitating the differential diagnosis of tumors. In addition, signals from the microbubbles enable the visualization of slow flow in microscopic vessels without Doppler-related artifacts. Various software packages have been developed to enable quantification of changes in contrast intensity and to provide additional objective information over the entire course of the contrast examination.

Microbubbles enable dynamic imaging of tumor angiogenesis. This approach is now routinely used for diagnosis, particularly for the detection and characterization of various liver tumors.

The most common malignancy of the liver is metastases. Hepatic metastasis is a sign of advanced tumor stage, and curative treatment is only possible in a very small number of patients. When the objective is cure, liver resection is the most effective therapy, but several ablation

Figure 5 B-mode image of a metastasis from a colon cancer to the liver appearing hyperechoic with a dark halo.

Figure 6 Contrast-enhanced ultrasound B-mode image of a colon cancer metastasis (same as in Figure 5) in the arterial phase showing marked hyperenhancement in the right panel. Note also the dark centre of the tumor, indicating a necrotic portion of the metastasis.

techniques have evolved. For directed tumor therapy, accurate imaging of the number and distribution of the metastases is required. On grey-scale ultrasound images, metastases may appear as hypo-, iso- or hyperechoic lesions, and some of them have a halo (Figure 5). Unenhanced ultrasonography achieves a sensitivity between 45% and 80% in detecting liver metastases^[116,117]. Not surprisingly, this compares unfavorably with the results of studies with contrast-enhanced CT and MR. However, the application of an intravascular ultrasound contrast agent during transcutaneous ultrasonography of the liver improves detection of metastases significantly^[118-120].

After injection, 3 phases of contrast enhancement can be differentiated: the arterial phase, in which the contrast agent reaches the liver first *via* the hepatic artery; the portal phase, where the contrast agent has passed circulation and spreads through the liver in the portal branches; and the late or parenchymal phase, in which the agent slowly distributes within the entire liver parenchyma. Metastases show characteristic features in all 3 phases after contrast agent injection. Differentiation of hypervascular from hypovascular metastases is achieved perfectly by real-time imaging during the arterial phase: hypervascular metastases, e.g. from malignant melanoma, thyroid carcinoma, or neuroendocrine carcinoma, appear as hyperenhancing, usually with a typical rim enhancement of varying size (Figure 6). In contrast, hypovascular metastases le-

Figure 7 Contrast-enhanced ultrasound B-mode image of a colon cancer metastasis (same as in Figure 5) in the sinusoidal (late) phase, showing marked hypoenhancement in the right panel.

sions, e.g. from colorectal carcinoma (great variability) or bronchogenic carcinoma, may appear as hypoenhancing lesions in the arterial phase. Large metastases may have inhomogeneous enhancement because of necrosis, as shown in Figure 6. At the beginning of the portal phase, the enhancement fades and the entire lesion becomes increasingly hypoechoic. In the late phase, both hypovascular and hypervascular metastases invariably appear as dark defects, whereas the enhancement persists in the normal liver parenchyma (Figure 7). During this phase, the lesions are usually particularly well defined, often with sharp punched-out borders. Both portal venous and late-phase imaging markedly increase the contrast between the enhancing normal liver and the nonenhancing metastases and thus improve detection, particularly of small lesions, i.e. < 1 cm in diameter. The improved detection obtained by the use of ultrasound contrast agents allows for the implementation of CEUS for the follow-up of patients undergoing surgery and chemotherapy, to assess the efficacy of antineoplastic treatment^[121-124]. To determine the utility of CEUS as a prognostic tool for metastatic renal cell carcinoma patients receiving sunitinib, Lassau and co-workers studied 38 patients receiving 50 mg/d sunitinib^[125]. They found that time to peak intensity and slope of the wash-in curve were significantly associated with disease-free survival; time to peak intensity was also significantly associated with overall survival^[125]. Furthermore, they concluded that CEUS is a useful tool for predicting early efficacy of sunitinib in metastatic renal cell carcinoma patients^[125].

Hepatocellular carcinoma

Hepatocellular carcinoma (HCC) is the second common malignant liver tumor and the most common primary liver cancer, usually occurring as a complication of chronic liver disease and most often arising in a cirrhotic liver. The accurate and early diagnosis of HCC is essential for treatment of the affected patients. Surgical resection, liver transplantation, percutaneous alcohol ablation and radio-frequency ablation are potentially curative therapies. On grey-scale sonography, HCCs may be hypoechoic (26%), hyperechoic (13%) or have mixed (61%) echogenicity depending on the size of the tumor, the fat content, the degree of differentiation and the scarring of necrosis^[126].

Figure 8 B-mode image of hepatocellular carcinoma with well-demarcated margins and a perilesional halo.

Figure 9 Color Doppler in hepatocellular carcinoma reveals a basket pattern around the tumor, illustrating the anatomy of the arterial tumor supply.

Figure 10 Contrast-enhanced ultrasound allows for visualization of the arteriogram of hepatocellular carcinoma in the early arterial phase. The feeding vessel is visible on the tumor right side. Typically there is initial peripheral enhancement before the centripetal influx to the center of the tumor.

HCCs with well-demarcated margins, perilesional halos or a hypoechoic pattern have a greater rate of detection by ultrasonography (Figure 8). Controversially, infiltrative or iso-hyperechoic HCCs without peripheral halos, as well as HCCs with internal septa or posterior echo enhancement, are harder to detect, with lower reported sensitivities. The use of Doppler in HCC can sometimes reveal a basket pattern around the tumor, depicting the anatomy of the arterial tumor supply (Figure 9).

When CEUS is applied, HCCs are typically characterized by hypervascularity in the arterial phase. Using real-

Figure 11 The portal phase of hepatocellular carcinoma. Because of high circulation velocity within hepatocellular carcinoma, there is relatively rapid washout, often starting in the portal phase.

Figure 12 The sinusoidal (late) phase of hepatocellular carcinoma is shown. Typically, hepatocellular carcinoma is hypovascular (hypoechoic) during the late phase of perfusion confirming the malignant nature of the tumor.

time evaluation with low MI, early and usually intense arterial enhancement is identified and in most cases a feeding artery is clearly visible. Tumor vessels, often appearing with a basket-like pattern, tend to enhance in a centripetal fashion extending from the periphery to the centre of the tumor (Figure 10). Arterial enhancement may be inhomogeneous, because the tumor contains septa, regions of different tissue differentiation and shunting among the neo-formed vessels, and sometimes necrosis^[127]. Because of the high circulation velocity within HCC, there is relatively rapid nodular washout, often starting in the portal phase (Figure 11). Typically, HCC is hypovascular (hypoechoic) during the late phase of perfusion (Figure 12). At the same time, normal liver parenchyma increases the echogenicity and homogeneity because of portal venous enhancement.

Surveillance of patients at risk of developing HCC is based on ultrasound examinations performed at either 6 or 12 mo intervals. Early detection of HCC in patients with cirrhosis is a clinical challenge, since the different entities that are involved in the multi-step process of hepatocarcinogenesis, such as low-grade and high-grade dysplastic nodule, share common ultrasonic features. However, CEUS allows for reliable detection of arterial angiogenesis associated with a malignant transformation. When whole lesion enhancement or mosaic enhancement in the arterial phase with an enhancement defect in the portal phase was regarded as a positive finding of HCC, a sensitivity of 92% and a specificity of 87% were found^[128]. It has been shown that the ability of CEUS to diagnose HCC cur-

Figure 13 Ductal adenocarcinoma (between arrows) of the pancreas showing poor enhancement in the arterial phase. The same is true for the late venous phase.

rently approaches that of optimized multi-detector CT or dynamic MR imaging protocols^[129-136]. The use of CEUS to characterize nodular lesions in cirrhosis have been recommended by the clinical practice guidelines issued by the European Federation of Societies for Ultrasound in Medicine and Biology and the American Association for the Study of Liver Diseases^[115].

Pancreas

The pancreas, lying deep to the stomach and duodenum, is among the most inaccessible organs in the body for visualization with ultrasonography. Hence, confirmation of pancreatic disease has remained a great challenge in clinical imaging. However, transabdominal ultrasonography has developed to be a useful tool in the differential diagnosis of pancreatic tumors because the technique is inexpensive, easy to perform, and widely available. Nevertheless, only after the introduction of second-generation contrast media^[3], has transabdominal sonography yielded results comparable to those of other diagnostic modalities. CEUS can be used to improve detection of pancreatic lesions or to characterize pancreatic lesions already visible with ultrasonography. Furthermore, the staging of some pancreatic lesions can be improved by the use of contrast media. However, there is an important difference between a pancreatic CEUS study and the well-established liver CEUS study: the blood supply of the pancreas is entirely arterial and the enhancement of the gland begins almost together with the aortic enhancement. With CEUS the enhancement reaches its peak between 15 and 20 s after injection of the ultrasound contrast agent. Accordingly, pancreatic tissue enhancement is earlier and shorter than that of the liver because of the absence of a venous blood supply such as the portal vein in the liver. After a marked parenchymal enhancement in the early contrast-enhanced arterial phase, there is a progressive washout of contrast medium with gradual loss of echogenicity.

Ductal adenocarcinoma is the most frequent tumor of the pancreas, comprising between 80% and 90% of all tumors of the exocrine pancreas. Ultrasonographic findings typically are a hypoechoic lesion with ill-defined margins, often with spicules and tending to alter the gland contour^[137-139]. Characteristically, ductal adenocarcinoma

Figure 14 Neuroendocrine tumour (arrow) shows a rapid intense enhancement in the early arterial phase of contrast-enhanced ultrasound examination.

shows poor enhancement in all CEUS phases (Figure 13). On the contrary, neuroendocrine tumors (NETs) appear hypervascular in CEUS imaging. Imaging is important for the differentiation between NETs and ductal adenocarcinoma in selecting the correct therapeutic strategy and determining prognosis. With color- and power-Doppler ultrasonography a spotted pattern can sometimes be observed inside endocrine tumors^[140]. However, Doppler signals are not always detected because of the small size of the lesion or of the tumor vascular network. Typically, NETs show a rapid intense enhancement in the early contrast-enhanced phases (Figure 14), with the exception of possible necrotic intralesional areas.

Gastrointestinal tract

Colon cancer is one of the world's most common malignancies. The main therapy is surgical resection. To diagnose colon cancer, endoscopy is the preferred method, but in many places around the world, X-ray is still used. Using ultrasonography, the normal gastrointestinal (GI) wall is visualized as a layered structure consisting of 5 to 9 layers, depending on transmitted frequency^[141-143]. When digestive cancers develop, the wall layers become blurred, wall thickness is increased, and the ultrasound appearance of the GI wall resembles a kidney, i.e. pseudo-kidney sign or target lesion. However, CEUS does not yet have a place in the work-up of patients with suspected colonic cancer.

In oncology, early evaluation of targeted treatment response with functional imaging is of major importance. Dynamic CEUS is now recognized as a functional imaging technique able to evaluate new antiangiogenic drugs targeting cancers in the abdomen. This therapy evaluation is based on analysis of the curve of signal intensity over time after injection of ultrasound contrast agents (Figure 15). Novel quantification software allows for objective quantification of tumor perfusion parameters including maximum intensity of enhancement, mean transit time, time to peak, and wash-in slope coefficient. CEUS allows for early prediction of tumor response to treatment based on changes in vascularity, before morphological changes become apparent^[144]. Lassau and co-workers evaluated CEUS with perfusion software as a predictor of early tumor response to imatinib (Glivec) in c-kit-positive gas-

Figure 15 Analysis of time intensity curves after injection of contrast agents depicting a pancreatic carcinoma (same as Figure 13). The green curve depicts the normal pancreatic perfusion whereas the red curve illustrates the hypoenhancing malignancy.

trointestinal stromal tumors (GISTs)^[145]. They studied 59 tumors with metastases or a recurrence from a GIST prospectively and found that initial contrast uptake at day 1 was predictive of the future response^[145]. A strong correlation was found between the decline in tumor contrast uptake at days 7 and 14 and tumor response^[145]. They concluded that CEUS is a non-invasive imaging technique that allows the early prediction of tumor response in c-kit-positive GISTs treated with Glivec^[145].

Tumor growth is dependent on both endothelial and tumor cells. One question is whether changes in tumor vasculature are implicated in tumor tissue degeneration during antiangiogenic therapies. In a study using CEUS, it was shown that tumor cells abruptly became necrotic following antivascular therapy, whereas untreated tumors were protected from degeneration by a significant blood supply^[146]. Because antiangiogenic therapies inhibit the growth of new tumor-associated blood vessels, as well as prune newly formed vasculature, they would be expected to reduce the supply of oxygen and thus increase tumor hypoxia. Franco and co-workers used DC101, an anti-vascular endothelial growth factor receptor 2 antibody to study tumor hypoxia^[147]. Using ultrasonography, they observed consistent reductions in microvascular density, blood flow, and perfusion^[147]. The increase in tumor hypoxia was evident within 5 d and remained so throughout the entire course of treatment^[147]. These results suggest that sustained hypoxia and impairment of vascular function can be 2 consistent consequences of antiangiogenic drug treatment.

Concluding remarks

It is a challenging task to quantify and predict which bubble phenomenon occurs under which acoustic condition, and how these may be utilized in ultrasonic imaging. Aided by high-speed photography, our improved understanding of encapsulated microbubble behavior will lead to more sophisticated detection and delivery techniques.

More sophisticated methods use quantitative approaches to measure the amount and the time course of bolus or reperfusion curves and have shown great promise in revealing an effective tumor response to anti-angiogenic

drugs in humans before tumor shrinkage occurs. These are beginning to be accepted into clinical practice. In the long term, targeted microbubbles for molecular imaging and eventually for directed anti-tumor therapy are expected to be developed.

In principle, in any perfused region that can be reached by ultrasound, ultrasound-directed drug delivery could be performed. However, since the ultrasonic fields used with diagnostic ultrasound scanners differ greatly per organ targeted, some regions will be far from ideal. The ultrasonic frequencies transmitted in endoscopy are much higher than the resonance frequencies of conventional ultrasound contrast agents. Therefore, for such applications, smaller carriers will have to be developed for ultrasound-directed drug delivery.

In conclusion, combining ultrasound contrast agents with therapeutic substances may lead to simple and economic methods of treatment with fewer side effects, using conventional ultrasound scanners. Ultrasound-directed drug delivery has great potential in the treatment of malignancies in the digestive system.

various pancreatic malignancies. The sensitivity of power Doppler sonography to depict tumor neovascularization can be increased by contrast agents. Contrast-enhanced harmonic imaging is a useful aid in identifying the tumor vasculature and studying pancreatic microperfusion. In the future, these techniques could potentially be used to quantify tumor perfusion, to assess and monitor the efficacy of antiangiogenic agents, to assist targeted drug delivery and allow molecular imaging.

Abstract

Contrast agents are increasingly being used to characterize the vasculature in an organ of interest, to better delineate benign from malignant pathology and to aid in staging and directing therapeutic procedures. We review the mechanisms of action of first, second and third generation contrast agents and their use in various endoscopic procedures in the gastrointestinal tract. Various applications of contrast-enhanced endoscopic ultrasonography include differentiating benign from malignant mediastinal lymphadenopathy, assessment of depth of invasion of esophageal, gastric and gall bladder cancers and visualization of the portal venous system and esophageal varices. In addition, contrast agents can be used to differentiate pancreatic lesions. The use of color Doppler further increases the ability to diagnose and differentiate

CONTRAST-ENHANCED ENDOSCOPIC ULTRASONOGRAPHY

The use of intravenous contrast agents in ultrasonography was first utilized in echocardiography to enhance imaging of cardiac chambers and great vessels^[1]. Since then, they have been used in transabdominal ultrasonography and more recently in endoscopic ultrasonography (EUS). Use of contrast agents in EUS has been shown to improve the characterization of the vasculature inside the organ of interest, to better delineate benign from malignant pathology^[2-8], to aid in staging and directing therapeutic procedures and thereby to determine prognosis.

CONTRAST AGENTS

Contrast agents are made of gas-filled microbubbles encapsulated by a phospholipid or albumin shell. They are categorized into first, second and third generation based on their capability for transpulmonary passage and their half-life in the human body. Commonly used first generation agents include Albunex, Levovist and Echovist. Second generation agents include SonoVue, Sonazoid, and Optison among others^[9,10]. The only third generation agent currently available is Echogen, capable of phase-shift from liquid to gas form once it attains body temperature^[11]. Contrast agents in use today are relatively safe and have demonstrated no severe, long-lasting adverse effects in humans (Table 1)^[12,13].

MECHANISMS OF ACTION

Contrast agents were specifically developed to image vascularity and vessel patterns, especially for small volume and slow velocity blood flow. This is highly important in tumors, where angiogenesis completely alters the vascular structure. The principle of ultrasound contrast agents is that they create multiple small interfaces with high echogenicity, a process best achieved by gaseous microbubbles, surrounded by a shell used to increase stability^[14]. Microbubbles are very good backscatters, effectively reflecting the ultrasound waves. However, the microbubbles respond and oscillate to sound pressure in a non-linear fashion, with an asymmetrical diameter induced by ultrasound pressure. The diameter is variable between 2 and 10 μm , about the size of red blood cells. Consequently, they do not leave the vascular system (blood pool contrast agents). The ultrasound contrast agents are administered through intravenous bolus injection, in a large arm vein. Second-generation contrast agents are those passing through the lungs, allowing contrast enhancement of the entire vascular system.

Contrast agents were used initially as Doppler signal enhancers, including in contrast-enhanced EUS examinations (CE-EUS). Both color Doppler and power Doppler can be used, especially for regions with very low flow volumes, where the unenhanced signal is too weak or the signal-noise ratio is too poor (Figures 1 and 2). Although the contrast agent selectively enhances the useful signal to the detriment of the noise, the main disadvantage of these techniques is the presence of artifacts. Both tissue motion (flash) artifacts and blooming artifacts appear and impede the examinations. Flash artifacts are specific to the Doppler mode, appearing as color signals caused by tissue motion, being most commonly seen in hypoechoic areas, induced by cardiac or respiratory motion^[15]. Blooming artifacts appear as a consequence of the high amplification of the backscattered signal, which saturates the receiver and causes smearing of the color signal. They appear immediately after the wash-in phase and disappear when the concentration of contrast is lower^[16]. The introduction of second generation contrast agents made it possible to

Figure 1 Contrast enhanced endoscopic ultrasonography exam of lung adenocarcinoma. A: Non-enhanced power Doppler image of a lung adenocarcinoma visualized in the aorto-pulmonary window from the mid-esophagus, with discrete Doppler signals in the periphery of the mass and embedding of a large branch of the left pulmonary artery; B: Same tumor visualized after contrast-enhancement with SonoVue, with a better depiction of the vascular peripheral signals and the possibility of quantification of the vascular index. The relationship to the aorta and pulmonary artery is clearly depicted.

enhance B-mode and contrast-harmonic imaging for improved visualization (Figure 3)^[17,18].

CLINICAL USES OF CE-EUS

Differentiating benign from malignant mediastinal lymphadenopathy

EUS-guided fine-needle aspiration (FNA) represents the current “gold-standard” for the diagnosis of malignant mediastinal lymphadenopathy^[19,20], and is further improved by localized cytopathologic assessment of the specimens^[21]. Nonetheless, EUS-FNA carries the risk of mediastinitis if inflammatory nodes are aspirated, contamination and tumor seeding. However, studies have not been consistent in their findings^[6,22]. CE-EUS may offer a non-invasive method to increase the specificity of diagnosis of benign lymph nodes, and aid in targeting aspiration of only high-yield lymph nodes.

Differentiating benign from malignant lymph nodes using appearance and type (arterial, venous) of vascularity may not be reliable since non-lymphomatous cancer cells invade lymph nodes heterogeneously^[23]. Currently, CE-EUS cannot replace EUS-guided FNA in confirming malignant mediastinal lymph nodes. The combination of CE-EUS and EUS-FNA will possibly improve diagnostic accuracy.

Table 1 Intravenous contrast agents, their composition and manufacturers^[10,13]

Contrast agent	Composition	Manufacturer
First generation		
Albunex	5% human albumin with stabilized microbubbles	Mallinckrodt
Echovist (SHU 454)	Standardized microbubbles with galactose shell	Schering
Levovist (SHU 508)	Stabilized, standardized microbubbles with galactose, 0.1% palmitic acid shell	Schering
Myomap	Albumin shell	Quadrant
Quantison	Albumin shell	Quadrant
Sonavist	Cyanoacrylate shell	Schering
Sonazoid	C ₄ F ₁₀ with lipid stabilizer shell	GE healthcare
Second generation		
Definity/luminity	C ₃ F ₈ with lipid stabilizer shell	Bristol-myers squibb medical imaging
Imagent-imavist	C ₆ H ₁₄ with lipid stabilizer shell	Alliance
Optison	C ₃ F ₈ with denatured human albumin shell	GE healthcare
Bisphere/cardiophere	Poly lactide-coglycolide shell with albumin overcoat	-
SonoVue (BR1, Bracco, Italy)	SF ₆ gas with lipid stabilizer shell	Bracco
AI700/imagify	C ₄ F ₁₀ gas core stabilized with polymer shell	Acusphere
Third generation		
Echogen	Dodecafluoropentane (DDEFP) liquid in phase shift colloid emulsion	Sonus pharmaceuticals

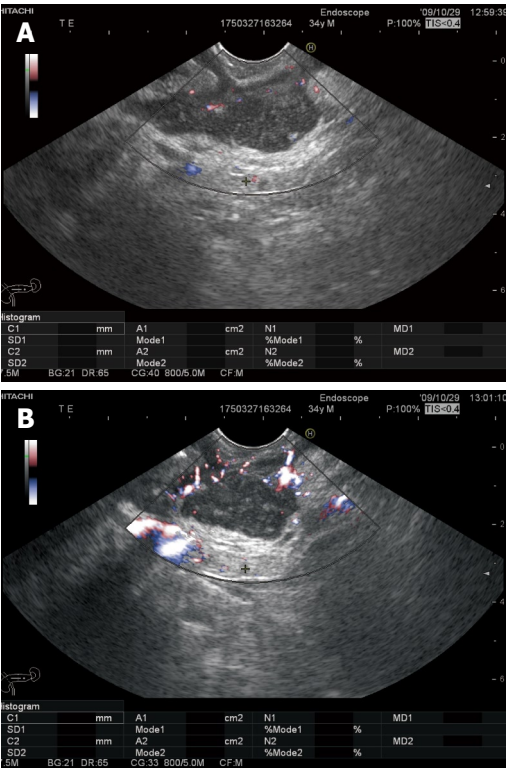

Figure 2 Contrast enhanced endoscopic ultrasonography of pancreatic cancer. A: Pancreatic head adenocarcinoma visualized in bidirectional non-enhanced power Doppler mode; B: Contrast-enhancement with SonoVue indicates a hypovascular mass with increased collateral circulation.

Esophageal and gastric cancer

EUS can provide cross-sectional imaging of the wall of the gastrointestinal tract, and determine the depth of invasion of cancers. The normal esophageal and gastric walls consist of five layers on EUS images with enhancement of the third and fifth layers (submucosa and subserosa, respectively). Esophageal cancers are not enhanced with CE-EUS because of their relative avascularity^[8]. In gastric cancer, assessment of the depth of invasion can be im-

Figure 3 Contrast-enhanced (SonoVue) harmonic endoscopic ultrasound imaging showing a small (12 mm) hypovascular adenocarcinoma in the head of the pancreas. The tumor tissue did not enhance in the early arterial phase, nor in the late venous phase, as compared to the surrounding pancreatic parenchyma.

proved with CE-EUS, especially for depressed, endophytic cancers. Use of CE-EUS improves the overall accuracy of assessment of depth of invasion of gastric carcinoma from 70% to 90%. Active ulcers and scars in both malignant and non-malignant lesions are not enhanced post-contrast. This has been attributed to the nature of vascularity (linear convergence) and foci of fibrosis. Gastric myogenic tumors appear as hypoechoic masses linked to the fourth layer on EUS^[8]. Hirooka *et al*^[24] demonstrated that poorly differentiated gastric carcinomas were enhanced by infusion of Albunex whereas well differentiated ones were not. However, prediction of histologic type of gastric carcinoma by the nature of the enhancement has been inconsistent.

Gallbladder diseases

CE-EUS has the potential to differentiate gallbladder lesions and assess the depth of tumor infiltration in gallbladder carcinomas^[5]. It can differentiate chronic cholecystitis and cholesterol polyps from infiltrating and exophytic gallbladder cancer, respectively, since the three-layer structure

remains intact in the benign conditions. Majority of gallbladder adenocarcinomas enhance with EUS on administration of Alburnex^[5], unlike other gallbladder diseases including adenosquamous carcinoma cholesterol polyps and chronic cholecystitis^[5,24]. CE-EUS is also able to clearly differentiate the depth of invasion in the gallbladder wall from T1b from T1a, improving accuracy over standard EUS^[5].

Pancreatic diseases

First generation: CE-EUS has been used in pancreatic cancer to demarcate vascular landmarks, detect vascular obliteration by a thrombus or tumor, and examine microvascular blood flow to organs and lesions.

Alburnex was the earliest contrast agent used to enhance EUS images. Hirooka *et al.*^[24] demonstrated that peripheral injection of Alburnex can enhance B-mode images of pancreatic pathology during high-frequency EUS. Enhancement was marked in cases of pancreatic islet cell tumors. Pancreatic ductal cell carcinomas remained unenhanced compared to the surrounding normal parenchyma and fibrosis thereby making boundaries clearer^[24]. Administration of contrast also improved the capability for differential diagnosis of lesions identified by B-mode EUS^[25].

A study by the same authors in 1998 demonstrated similar findings with 100% image enhancement (at 12 Hz) using Alburnex in islet cell carcinomas and serous cystadenomas, 80% enhancement in mucin-producing tumors, and 75% in chronic pancreatitis. Also, no enhancement was noted with ductal cell carcinomas and pancreatic pseudocysts, consistent with hypovascularity. Differences in vascularity as demonstrated on angiography paralleled the enhancement patterns during CE-EUS, except in 20% and 25% of cases with mucin-producing tumors and chronic pancreatitis, respectively. In addition, they demonstrated that areas of normal parenchyma and fibrosis around a lesion can be enhanced, demarcating the boundaries. This could lead to accurate pre-operative staging and planning of surgical resection lines, in the case of mucinous tumors involving the main pancreatic duct^[4].

The authors propose that enhancement after Alburnex may be related, at least in part, to the nature of microcirculation and vascular permeability of the lesion, which determine the concentration of contrast agent within the lesion. This could account for the less predictive pattern of angiography with sonographic enhancement^[4]. Concentric bile duct wall thickening on intraductal ultrasonography with strong enhancement after administration of Levovist was seen in patients with autoimmune pancreatitis with a reduction in enhancement after steroid therapy likely indicating resolution of inflammation^[26].

Second generation: Using an experimental second generation microbubble contrast agent, Wong *et al.*^[27] demonstrated hypoechogenicity in normal pancreatic tissue after a bolus but not with continuous infusion. This could be related to a greater intravascular density of contrast material with bolus injection compared to a continuous infu-

sion. A decreased echo signal from the pancreatic parenchyma after contrast injection may be due to an increased signal from the pancreatic interface with adjacent structures^[27]. Whether this will have a clinically useful application remains to be determined. Certainly, lesions that are enhanced with contrast will be more easily distinguished from the surrounding normal pancreas.

CE-EUS reveals the characteristic vascularity and can diagnose and follow up intraductal papillary mucinous neoplasms (IPMN) of the pancreas. Enlargement or enhancement of a mural nodule accurately indicated the presence of atypical malignant epithelium and determined the need for surgical resection^[28]. Mural nodules were classified into four types based on morphology during EUS, before and after contrast: Type 1 (low papillary type), Type 2 (polypoid type), Type 3 (villous type) and Type 4 (invasive type with a blurred hypoechoic area between lesion and parenchyma). When IPMNs with Type 3/4 were diagnosed as malignant, accuracy was higher^[29].

The use of CE-EUS has also been used to differentiate between mass-forming chronic pancreatitis and pancreatic cancer. Focal lesions can be seen in alcohol and autoimmune pancreatitis, with presentation similar to that of pancreatic cancer. CE-EUS produces a “parenchymographic” enhancement (i.e. isovascular to pancreatic parenchyma) in inflammatory benign masses and shows an inverse correlation with the degree of fibrosis within the mass, the duration of the inflammatory process and the enhancement with contrast infusion. Ductal carcinomas exhibit complete absence or a low level of enhancement due to greater fibrosis within the tumor^[30,31].

Color Doppler

Combining B-mode EUS with CE-Doppler ultrasound improves the visualization of the vascularity of a pancreatic lesion, with malignant ductal adenocarcinoma demonstrating low flow and a relatively avascular pattern. Bhutani *et al.*^[32] described enhancement of color Doppler signals from the celiac artery, superior mesenteric artery, and portal vein during EUS in a swine model after administration of Levovist. This effect was easily appreciated without the need for complex quantitative measurements. No visually obvious enhancement was evident in vessels such as the aorta that already had a pronounced unenhanced color Doppler signal^[32]. Using Optison (FS069), Becker *et al.*^[33] demonstrated that the sensitivity and specificity of echo-enhanced color-Doppler EUS are comparable with the cytopathology results. Ueno *et al.*^[34] differentiated islet cell tumors and ductal cell cancer with color-Doppler EUS. Islet cell tumors had marked hypervascularization whereas patients with adenocarcinoma had vascularity only around the tumor. These results have been confirmed by several other investigators. Hypovascularity as a sign of malignancy in CE-EUS can provide 92% sensitivity and 100% specificity (89%-100%)^[2]. Using CE-Doppler EUS, hypovascularized malignant ductal adenocarcinoma and hypervascularized benign tumor entities, mostly neuroendocrine tumors, and serous microcystic adenomas of the pancreas

can be easily differentiated. This is of pivotal importance since serous microcystic adenomas can be observed due to low growth potential, and neuroendocrine tumors may be enucleated or otherwise and less radically resected compared to ductal adenocarcinoma.

Power Doppler

Unenhanced power Doppler ultrasonography is unable to provide tumor differentiation, as a previous study showed a very low specificity (77%) of unenhanced power Doppler EUS^[35]. Although other factors like the presence of peripancreatic collaterals, might improve the specificity, this was not confirmed in larger studies. It is possible to misdiagnose necrotic pancreatitis as ductal adenocarcinoma and also to find inflammation surrounding ductal adenocarcinomas. Indeed, the presence of power Doppler inside the inflammatory masses is variable as a function of inflammation and necrosis, thus complicating the differential diagnosis^[35].

The sensitivity of power Doppler sonography to depict tumor neovascularization can be increased by contrast agents. In an animal model of pancreatic vascular disruption using 50% ethanol plus purified carbon particle solution, standard EUS demonstrated hypoechogenicity in the ethanol treated area. With injection of Definity, power Doppler EUS revealed marked contrast enhancement of normal pancreatic parenchyma from the ethanol-treated area^[36]. Several studies using CE-EUS with power Doppler scanning also demonstrated an improvement in discrimination of pancreatic cancer from chronic pancreatitis^[33,37,38] and may also help to localize small benign tumors such as insulinomas^[7].

Hocke *et al.*^[38], using pulsed Doppler analysis with CE-Doppler EUS, demonstrated an improvement in the differentiation between chronic pancreatitis and malignancy. They used specific criteria to define malignancy: lack of vascularization before injection of SonoVue, irregular appearance of arterial vessels over a short distance post-injection, and absence of detection of venous vessels in the lesion^[38]. In contrast to the technique described by Becker *et al.*^[33], Hocke *et al.*^[38] combined the analysis of the detected vessels with pulsed wave Doppler analysis. They concluded that the use of second generation contrast agents with low mechanical index techniques will possibly allow real-time imaging with or without three-dimensional reconstructions in EUS imaging.

With CE power Doppler sonography, the signal intensity from flowing blood is lower compared to that of moving solid tissue structures. Harmonic imaging was specifically developed to overcome these obstacles, since tissue particles have fewer harmonic waves than intravascular microbubbles, thus avoiding flash and blooming artifacts^[35].

Harmonic imaging

CE harmonic imaging techniques are currently available for EUS, as a result of the improvement in transducer technology. Thus, the use of adequate broadband transducers that can detect harmonic signals was recently

been reported^[17,25]. A pilot study previously described an experimental technique with low mechanical index, which allowed differentiation between chronic pancreatitis and pancreatic cancer, based on tissue microperfusion characteristics^[17]. Another feasibility study demonstrated both parenchymal perfusion and microvasculature in the pancreas^[25]. Both intermittent homogeneous parenchymal perfusion images and real-time continuous images of finely branching vessels of the pancreas were obtained with a mechanical index of 0.4. Although the initial study included a small number of patients with pancreatic lesions, it seemed that tumor characterization was possible based on the vascular or perfusion pattern. Thus, pancreatic carcinomas had absent or heterogeneous perfusion images in the intermittent mode, while the vessels were visualized as irregular “network like” structures in real-time mode. Both neuroendocrine tumors and chronic pseudotumoral pancreatitis were homogenous and iso- or hyper-vascular. Several other research groups are testing the feasibility of CE-EUS^[39-41]. CE-EUS with low mechanical index (0.4) was tested in 25 patients, after peripheral injection of SonoVue^[39]. The method seemed feasible for differentiating adenocarcinoma from other focal mass lesions, being proposed as the method of choice to establish the management of patients when EUS-FNA is non-contributive. Harmonic imaging has also been used with CE-EUS after peripheral injection of Sonazoid in two settings, WPI (wide-band pulse inversion harmonic) and EXPHD (extended pure harmonic detection)^[40]. The change in echo-intensity was evaluated. Ductal carcinomas, IPMTs, chronic pancreatitis and endocrine tumors demonstrate varied echo-intensities after infusion of contrast agent. CE harmonic EUS can be a useful aid in identifying tumor vasculature, especially that of pancreatic masses^[41].

Esophageal varices and portal hypertension

B-mode EUS can detect grade II varices or larger. After administration of Levovist, flow signals can become evident beneath the third echogenic layer of the esophageal wall and help visualize perforating veins and periesophageal vessels^[42]. EUS-guided portal vein angiography by using CO₂ as a contrast agent, has been evaluated in a porcine model. This is less viscous, making it easier to inject through small-caliber needles, minimizing damage to the vascular wall compared with iodinated contrast (Table 2)^[43].

FUTURE PERSPECTIVES

Tumor blood flow was previously linked in several studies with both metastasis potential and poor prognosis. A clear correlation was also proven between microvessel density, different angiogenic factors [e.g. vascular endothelial growth factor (VEGF)] and the tumors with definite vascular signals demonstrated by CE ultrasound^[44]. Quantification of tumor perfusion has been proven feasible for the early assessment and monitoring of the efficacy of antiangiogenic agents in quantitative terms based on changes in vascularity, before morphological changes become apparent^[45].

The feasibility of new technologies using CE ultrasound with microbubbles targeted to VEGF receptor type 2 are currently being tested^[46-48]. Several applications of molecular imaging and targeted ultrasound therapy can also be envisioned in the near future, including determination of the detailed physical processes behind sonoporation (increased uptake of drugs inside the cell through transient porositities in the cell membrane in the presence of contrast agents).

In this context, the development of CE-EUS will be clearly beneficial for targeted ultrasound imaging and ultrasound-assisted drug-delivery applications in gastrointestinal tract tumors, as well as other tumors accessible by EUS (pancreatic and lung tumors, *etc.*).

INTRODUCTION

Conventional cross-sectional imaging techniques [ultrasound, computed tomography (CT), magnetic resonance (MR), etc.] have important roles in noninvasive diagnosis, and in tumor treatment strategies. The techniques employed have different working principles, consequently complementing each other with respect to the information obtained. The combination (fusion) of two imaging techniques was developed in recent years, defining the so-called "hybrid techniques" or "fusion imaging". Combinations of anatomical imaging techniques (ultrasound with CT or MR imaging), as well as associations between anatomical (CT or MR imaging) and molecular (SPECT or PET) imaging modalities are currently used in clinical practice.

TECHNICAL ISSUES

One example of fusion imaging is real-time virtual sonography (RVS), a technique that enables the display of an ultrasound B mode image and CT or MR images in real-time^[1]. The system includes a magnetic positioning sensor fixed on the convex-shaped probe of the ultrasound scanner, for the creation of images with identical cross-

Abstract

Visualization of tumor angiogenesis can facilitate non-invasive evaluation of tumor vascular characteristics to supplement the conventional diagnostic imaging goals of depicting tumor location, size, and morphology. Hybrid imaging techniques combine anatomic [ultrasound, computed tomography (CT), and/or magnetic resonance imaging (MRI)] and molecular (single photon emission CT and positron emission tomography) imaging modalities. One example is real-time virtual sonography, which combines ultrasound (grayscale, colour Doppler, or dynamic contrast harmonic imaging) with contrast-enhanced CT/MRI. The benefits of fusion imaging include an increased diagnostic confidence, direct comparison of the lesions using different imaging modalities, more precise monitoring of interventional procedures, and reduced radiation exposure.

Figure 1 The probe and the magnetic sensor are assembled with careful attention to the positions of the orientation marks.

Figure 2 The left liver lobe ultrasound and computed tomography images are visualized at the same time in real-time virtual sonography.

Figure 3 A 65-year-old male patient with liver metastases. The workstation monitor displays the ultrasound and computed tomography images in real-time.

sections in real-time. This is done according to the position and the angle of the probe in relation to previously acquired CT and MR volume data. To be compatible with the RVS module, CT examination must meet certain requirements: (1) the volume data must be archived in the DICOM format; (2) the slice thickness should be 3 mm or less and image reconstruction the same; and (3) the CT scan area must include the xiphoid process.

To display virtual images, it is necessary to transfer the CT or MR data to the ultrasound machine^[2]. The magnetic positioning sensor unit is carefully assembled, based on the position of orientation marks. It uses a distal attachment, which helps install the magnetic positioning sensor on the probe, as shown in Figure 1. The magnetic sensor detects the changes in location, direction, and rotation of the probe during normal ultrasound scanning of the patient. The transmitter (the instrument that produces the magnetic waves) for the magnetic positioning sensor unit is installed on the left flank of the patient. Using a probe equipped with the magnetic sensor, a sagittal section of the left hepatic lobe is then captured (Figure 2). The xiphoid process is usually chosen as a reference anatomical point. In case of a mismatch between the ultrasound and the virtual image (CT or MR), it is possible to readjust and correct the mismatch during the exam. The adjustment is made possible by freezing the CT/MR images on a section with clearly visible anatomical landmarks, for

example the portal vein bifurcation or the right kidney in a longitudinal view, followed by identification of a similar ultrasound image and continuation of examination^[3]. The workstation monitor displays two images: the ultrasound real-time image and the virtual reconstructed CT/MR image (Figure 3).

CLILINICAL APPLICATIONS

The founding principles of combining the ultrasound image and the CT/MR images were based on several observations. In recent years, frequent imaging investigations led to the discovery of small focal liver lesions, which can be treated locally by ultrasound-guided radiofrequency ablation (RFA) or other ablation techniques. However, ultrasound exams are cannot always identify isoechoic tumors, tumors recurring locally in areas treated with lipiodol following transarterial chemoembolization (TACE), or tumors recurring in areas treated previously by RFA or percutaneous ethanol injection (PEI) procedures^[4]. In addition, in ultrasound examinations, there are a few dead angles and it is difficult to examine the whole liver, especially in obese patients. Nodules that are poorly identified on ultrasound are clearly visible on CT/MR. However, interventional treatment is easier to perform under ultrasound-guidance, while the exposure to increased doses of radiation is also avoided. Thus, real-time virtual sonogra-

Figure 4 Real-time virtual sonography of liver nodules with simultaneous display of the contrast-enhanced magnetic resonance section and ultrasound images. 2D (A), Power Doppler (B), and contrast enhanced ultrasound (C) vs the reconstructed corresponding image.

phy combines the imaging advantages of both techniques. Several studies have already proved the feasibility of the RVS module, especially for percutaneous RFA of poorly visible or unidentifiable focal liver lesions during B-mode sonography^[5-7].

The RVS module is compatible with B-mode (Figure 4A), color Doppler imaging (CDI) mode (Figure 4B), and dynamic contrast harmonic imaging (D-CHI) mode (Figure 4C)^[8]. Therefore, RVS might have important clinical applications in the assessment of tumor angiogenesis. Hepatocellular carcinoma, a hypervascular tumor mainly supplied by hepatic arteries, shows a typical pattern in contrast-enhanced ultrasound: arterial hypervascularization (Figure 5A) with washout in the portal venous during the late phase (Figure 5B)^[9]. Real-time virtual ultrasound can reveal the contrast-enhanced ultrasound image in a similar way to contrast-enhanced CT/MR, although the

Figure 5 Single hepatocellular carcinoma (3 cm) nodule in a cirrhotic patient. In real-time virtual ultrasonography, after contrast agent injection, a progressive and intense enhancement is observed in the arterial phase (A), followed by wash-out in the tardive phase (B), on contrast-enhanced ultrasound, versus corresponding contrast-enhanced magnetic resonance images.

Figure 6 Real-time virtual sonography showing multiple metastases, better depicted on contrast-enhanced computed tomography as compared with ultrasound. A nodule in nodule aspect is visualized with excellent correlation on both contrast-enhanced magnetic resonance and real-time ultrasound.

mechanism of action is clearly different^[8]. Likewise, liver metastases that are poorly visible in 2D ultrasound can also be discovered in real-time virtual ultrasound, especially if contrast-enhancement is used (Figure 6). Although, the combined use of contrast-enhanced images has not yet been described in terms of accuracy for the positive and differential diagnosis of small focal liver lesions, RVS might combine the advantages of both methods (ultrasound and CT/MR).

For oncological patients, the tumor response to che-

motherapy is conventionally assessed by RECIST and WHO size criteria, obtained during CT/MR follow-up^[10]. Anti-angiogenic treatments induce lesion necrosis with no change in volume of the initial tumor; therefore, the use of size criteria appear inappropriate. Several studies have shown that the use of microbubble contrast agents can detect changes in vascularization, by calculation of maximal perfusion parameters, such as peak intensity, time to peak intensity, area under the curve, and slope coefficient of wash-in^[11-14]. Thus, the simultaneous use of real-time virtual sonography with dynamic contrast-enhanced ultrasound can be also employed. The method might allow the quantification of tumor perfusion for early assessment and quantitative monitoring of the efficacy of antiangiogenic agents, based on changes in vascularity, even before morphological changes become apparent^[10].

LIMITS

RVS cannot be used in patients if CT/MR is contraindicated (patients with known contrast medium allergies, renal failure, or metallic implants). Another limitation of RVS is that the technique does not always show the best synchronization between ultrasound and CT/MR images, although the discrepancy can be adjusted with careful visualization of neighboring portal and hepatic veins in most cases^[8]. The use of the RVS module does prolong the examination time; therefore, the clinical impact, in terms of improved decision making, should be further assessed. The technique adds the costs of CT/MR to the costs of the contrast-enhanced ultrasound exam; thus the cost-effectiveness of this approach must be evaluated in future studies^[15].

CONCLUSION

In conclusion, hybrid ultrasound imaging techniques now play a pivotal role in diagnosis, staging, and follow-up during treatment. During local ablation of focal liver lesions hybrid ultrasound imaging allows better control of the procedure and less radiation exposure.

Abstract

Recent advancements in the endoscopic imaging of Barrett's esophagus can be used to probe a wide range of optical properties that are altered with neoplastic progression. This review summarizes relevant changes in optical properties as well as imaging approaches that measures those changes. Wide-field imaging approaches include narrow-band imaging that measures changes in light scattering and absorption, and autofluorescence imaging that measure changes in endogenous fluorophores. High-resolution imaging approaches include optical coherence tomography, endocytoscopy, confocal microendoscopy, and high-resolution microendoscopy. These technologies, some coupled with an appropriate contrast agent, can measure differences in glandular morphology, nuclear morphology, or vascular alterations associated with neoplasia. Advances in targeted contrast agents are further discussed. Studies that have explored these technologies are highlighted; as are the advantages and limitations of each.

BACKGROUND

The incidence of esophageal adenocarcinoma (EAC) is rapidly increasing; over the last 40 years, the incidence rate of EAC has risen by over 300% in the United States^[1]. This is of particular concern because the overall 5-year survival rate for patients diagnosed with EAC is only 12%^[2]. Although detecting and treating esophageal neoplasia at an early stage has been reported to increase 5-year survival to rates as high as 81%^[3], current methods of early detection have significant limitations. As a result, more than 60% of patients with EAC are diagnosed at a late stage, after local, regional, or distant metastases have occurred^[4].

EAC arises primarily in patients with Barrett's esophagus (BE)^[5,6], which is a highly prevalent condition in which the squamous epithelium of the esophagus is replaced by intestinal metaplasia (IM) near the gastroesophageal (GE) junction^[7-9]. Because of this increased risk, patients with BE undergo regular surveillance endoscopy at designated intervals in an attempt to identify neoplastic lesions at an early stage^[10,11]. Surveillance involves endoscopic examination with random four-quadrant biopsies

taken every 1-2 cm along the BE segment^[10].

Despite surveillance efforts, routine biopsy protocols have been shown to miss up to 57% of neoplastic lesions in patients with BE^[12]. This is largely due to the fact that dysplasia or neoplasia may be focal, flat and endoscopically indistinguishable from non-neoplastic epithelium on routine white-light endoscopy (WLE). The ability to delineate better superficial mucosal changes associated with early neoplasia at a macroscopic level, and subsequently, identify the subcellular changes associated with neoplastic progression would greatly enhance the yield and efficacy of current surveillance practices.

CHANGES IN OPTICAL PROPERTIES

In a standard WLE examination, the endoscopist views white light reflected from the surface of the esophagus; although visual examination of reflected white light can identify some changes in tissue morphology associated with neoplasia, it does not exploit the full range of changes in tissue optical properties that are associated with dysplasia and cancer. Neoplasia alters the light absorption and scattering properties of esophageal tissue^[13,14]; in addition, neoplasia is associated with changes in the autofluorescence properties of esophageal tissue^[13,15-17].

A number of new endoscopic approaches have been developed to more effectively probe neoplasia-related changes in optical properties to improve visualization of early neoplastic lesions. For example, the color of illumination light can be optimized to probe better changes in tissue absorption and/or scattering. Autofluorescence endoscopy can be used to image changes in tissue fluorescence that are associated with neoplasia. Moreover, improving spatial resolution of endoscopic imaging can help reveal changes in cellular architecture and morphology associated with neoplasia. Finally, optically active contrast agents can be used to improve further image contrast and probe specific molecular and morphologic features of neoplastic tissue that may not be associated with changes in native optical properties.

Here, we first review changes in the optical properties of esophageal tissue associated with neoplasia, and then outline new endoscopic imaging approaches to use these changes to improve early detection of esophageal neoplasia. Finally, we discuss the use of targeted contrast agents to expand the range of molecular changes that can be imaged *in vivo*.

Neoplasia-associated changes in tissue light scattering and absorption

Light attenuation in esophageal tissue is governed by a combination of absorption and scattering. In the visible region of the spectrum, the primary source of light absorption in esophageal tissue is hemoglobin. Esophageal neoplasia is associated with increased angiogenesis^[18], and endoscopic imaging approaches to enhance vascular contrast may improve early detection^[19,20]. Oxyhemoglobin has absorption peaks at 420, 542, and 577 nm^[13]; examining the tissue at these illumination wavelengths can enhance

vascular contrast, with vasculature appearing visibly darker than the surrounding tissue due to the increase in light absorption^[21]. Neovascularization is an important quantifiable tool for distinguishing neoplasia from non-neoplastic Barrett's epithelium. Irregular angiogenesis occurs within the lamina propria at various levels of the mucosal layer in high-grade dysplasia (HGD) and cancer. These features have been verified by analysis of microvessels and overexpression of relevant markers such as vascular endothelial growth factor and CD34, which results in a statistically significant difference between the microvessel density in BE versus HGD and cancer^[19,20].

Light scattering in tissue is a result of spatial fluctuations in the refractive index. In general, the scattering of stroma is significantly greater than that of the epithelium and is the dominant source of reflected white light from intact tissue. Neoplasia is associated with a small decrease in stromal scattering that is attributed to degradation in collagen fibers, possibly due to proteases secreted by pre-neoplastic epithelial cells^[18,22,23]. The attenuation of light in tissue is wavelength dependent, with longer red wavelengths able to penetrate more deeply than shorter blue wavelengths. Thus, tuning the illumination wavelength provides some ability to control penetration depth, and highlight vascular contrast.

Neoplasia-associated changes in tissue autofluorescence

Some endogenous constituents of esophageal tissue can reemit absorbed light in the form of fluorescence. Endogenous fluorophores are found in both the epithelium and the stroma of esophageal tissue, and fluorescence imaging provides a way to monitor changes in the concentration and composition of these fluorophores. When esophageal tissue undergoes malignant transformation, endogenous fluorophores undergo alterations^[24-26], which can be probed *via* autofluorescence imaging (AFI), to detect abnormalities that may not be visible during standard WLE. Tuning the excitation wavelength provides a way to selectively probe various fluorophores that can then be quantified by measuring light intensity at specific emission wavelengths^[26].

The primary fluorophores within the epithelium include mitochondrial NADH and FAD found in epithelial cells. Epithelial cells show cytoplasmic autofluorescence attributed to NADH using UV excitation wavelengths (330-370 nm) and FAD using green excitation wavelengths (510-550 nm)^[27,28]. Levels of mitochondrial NADH^[15] and mitochondrial FAD increase due to dysplastic changes in the epithelium^[29,30].

Stromal fluorescence of esophageal tissue is predominantly associated with covalent collagen crosslinks, which are characterized by relatively high autofluorescence intensity across a broad range of UV, blue, and green excitation wavelengths^[16]. Esophageal neoplasia is associated with a loss of stromal autofluorescence, which has been attributed to a decrease in collagen crosslinking^[18,22,23]. Finally, invasive esophageal cancers are often associated with porphyrin fluorescence, with maximal excitation near 400 nm and emission in the red spectral region^[13,31,32].

Table 1 Advantages and disadvantages of optical technologies for identification of neoplasia in Barrett's esophagus

Technology	Advantages	Disadvantages	Stage of clinical translation
Standard WLE	Capable of scanning wide area, widely available outside of tertiary care centers, no exogenous contrast	Limited sensitivity and specificity	Commercially available
High-definition WLE	Capable of scanning wide area, increased image contrast, no exogenous contrast	Performance evaluated in moderate-sized studies	Commercially available
AFI	Capable of scanning wide area, consistently high sensitivity, no exogenous contrast	High rate of false positives, performance evaluated only in small pilot studies	Commercially available
NBI	Capable of scanning wide area, consistently high sensitivity, no exogenous contrast	Performance evaluated in small pilot studies	Commercially available
OCT	Resolves subsurface structure, no exogenous contrast	Technology still under development	Clinical studies
Endocytoscopy	Histology-like imaging, high specificity	Low sensitivity, limited field of view, requires exogenous contrast	Commercially available
CME	Nuclear morphology can be viewed, high sensitivity and specificity	Limited field of view, high cost, uses IV exogenous contrast	Commercially available
High-resolution microendoscopy	Some nuclear morphology can be viewed, lower cost, adaptable to any endoscope	Limited field of view, requires exogenous contrast, technology still in development	Clinical studies

AFI: Autofluorescence imaging; OCT: Optical coherence tomography; CME: Confocal microendoscopy; WLE: White-light endoscopy; NBI: Narrow-band imaging.

High-resolution imaging

The spatial resolution of optical imaging is governed by diffraction, and with visible wavelengths of light, subcellular resolution imaging is possible. Typically, standard endoscopic imaging approaches do not achieve diffraction-limited resolution, however, recent advances in high-resolution imaging techniques such as optical coherence tomography (OCT), endocytoscopy, and endomicroscopy afford the ability to image with subcellular resolution. Such approaches are often termed "optical biopsy", because they allow visualization of glandular and cellular alterations associated with neoplasia. Optical contrast in high-resolution imaging is governed by the same alterations in tissue absorption, scattering and fluorescence described above. In addition, optically active contrast agents are often used to increase contrast for high-resolution imaging.

IN VIVO ASSESSMENT OF IMAGING TECHNOLOGIES

In the past decade, advances in imaging technologies have enabled gastroenterologists to optically image Barrett's-associated neoplasia with better contrast *in vivo*. The development of wide-field imaging technologies affords clinicians a macroscopic view of the tissue, serving as a "red-flag technique" for relevant abnormalities. High-resolution technologies assess microscopic features of the tissue and, if coupled with an ideal source of contrast, may measure biochemical, molecular, and vascular changes. Table 1 summarizes a number of different optical technologies currently under investigation, describes the advantages and disadvantages of each, and describes which stage they have reached in terms of clinical translation. Table 2 summarizes the accuracy of the technologies that have been translated to clinical use and have been used in large clinical trials.

Narrow-band imaging

Narrow-band imaging (NBI) is a wide-field imaging technology that takes advantage of changes in light scat-

Table 2 Summary of performance of emerging optical technologies

Type of detection	Study size	Sensitivity, specificity
AFI	60 patients, 116 images	91%, 43% ^[36]
NBI	63 patients, 175 images	94%, 76% ^[33]
	51 patients, 204 images	100%, 98% ^[34]
	21 patients, 75 images	89%, 95% ^[38]
High-resolution imaging (1-15 μ m resolution)		
OCT	33 patients, 314 images	68%, 82% ^[43]
	55 patients, 177 images	83%, 75% ^[58]
Endocytoscopy	16 patients, 166 images	56%, 68% (425 \times)
		42%, 83% (1125 \times) ^[47]
Confocal imaging	63 patients, 433 images	93%, 98% ^[48]
	38 patients, 296 images	75%, 90% ^[50]

AFI: Autofluorescence imaging; OCT: Optical coherence tomography; NBI: Narrow-band imaging.

tering and absorption in neoplastic tissue. Systems that implement NBI illuminate tissue with one or more narrow-band wavelength ranges corresponding to hemoglobin absorption peaks. Reflected light in these bandwidths is recombined to create a digital image with enhanced vascular contrast. This approach can also enhance visualization of villous mucosal patterns due to lining of vessels in mucosal folds^[21]. An example is shown in Figure 1.

For example, one NBI system combines information from three wavelength ranges: 400-430 nm (blue), 530-550 nm (green), and 600-620 nm (red). Higher relative intensity from the blue region is used to enhance surface level vasculature associated with neoplasia, due to its shallow penetration depth. In a 63 patient study using this approach, researchers in Amsterdam used features such as mucosal morphology and vascular contrast to determine grade of disease. The presence and regularity of these patterns were found to be essential for image evaluation. Out of the 175 areas, 52 were used as training material for endoscopists and the remaining 123 were used as a validation set. In the validation set, 94% of HGD images were

Figure 1 Endoscopic images from an area positive for esophageal adenocarcinoma. Abnormal areas (arrow) can be seen in the high-resolution white light image (A), and the narrow-band image (B) [Copyright (2008), with permission from Elsevier]^[36]; in the narrow-band image, the irregular mucosal morphology is visible (arrow); an abnormal area (arrow) can be seen in the autofluorescence image (C) where areas with loss of fluorescence are indicated as purple regions in the pseudo-colored overlay [Copyright (2005), with permission from Elsevier]^[36].

noted to show irregular or disrupted villous/gyrus mucosal pattern, and 85% were noted to show irregular vascular patterns. Using these features and others, they developed a multi-step hierarchical classification system based on mucosal morphology, including features such as type and regularity of mucosal patterns, regularity of vasculature patterns, and presence and type of abnormal blood vessels. Using this multistep evaluation, they determined the overall sensitivity and specificity to be 94% and 76%, respectively^[33]. Similarly promising performance was also obtained using the same NBI system in a 51 patient study by Sharma and colleagues; sensitivity and specificity for detection of HGD were 100% and 99%, respectively^[34].

Of continued debate, however, is the question of how NBI compares to high-definition white-light endoscopy (HD-WLE) using the current generation of endoscopes. This new generation of endoscopes offers markedly higher pixel densities and high-definition images that result in increased contrast in villous mucosal patterns, and a marked improvement in resolution^[35,36] over standard WLE^[37]. In a study with 65 patients, Wolfsen and colleagues, using a narrow-band system in which only two of the shorter wavelength ranges associated with hemoglobin were used, observed that the combination of HD-WLE and NBI did find higher grades of dysplasia in 18% of the study patients, using fewer biopsies than for standard endoscopy. They also observed that out of five of the cases in which HGD or EAC was detected, three were detected by HD-WLE as well. Although results favored NBI, the study was not designed to determine the efficacy of one modality over the other^[38]. Another study by Curvers and colleagues has observed that, while expert endoscopists preferred the image contrast provided by NBI, this did not improve overall interobserver agreement or accuracy when compared to HD-WLE^[39,40]. Larger studies are needed to determine which is the more accurate technique.

AFI

AFI can also increase contrast between non-neoplastic and neoplastic sites, as a result of the loss of autofluorescence associated with esophageal neoplasia. Typically, tissue auto-

fluorescence is excited in the blue region (395–475 nm) and fluorescence emission is collected at longer wavelengths (> 490 nm) to detect changes in fluorophores associated with malignant transformation. Because the intensity of autofluorescence can be low, this technique requires the use of highly sensitive CCDs to collect the autofluorescence signal. In recent systems, reflected light is also collected through a second CCD. Co-registered images can be used to compensate for changes in fluorescence intensity associated with variations in illumination and distance from the tip of the endoscope to the tissue, thereby further enhancing autofluorescence contrast. The resulting effect is pseudo-colored purple to highlight neoplastic lesions^[36,37]. An example is shown in Figure 1.

In a recent 60 patient study using a standard endoscope with an added AFI component, Kara was able to detect HGD in 22 patients, 14 of which were detected with AFI and WLE, and six of which were detected using AFI alone; thereby increasing the detection rate from 23% to 33% using AFI. Only one of the patients was diagnosed using four-quadrant biopsies alone^[36]. Results suggest that AFI may aid in the detection of additional HGD sites; however, it may not exclude the need for the standard four-quadrant biopsies. Sensitivity and specificity based on the 116 samples used for this study were 91% and 43%, respectively. Although no patient was diagnosed without AFI and four-quadrant biopsies, they cite a high rate of false positives using AFI alone, due in part to the loss of autofluorescence associated with acute inflammation^[36].

Although individually these enhanced endoscopic technologies have shown success, the high rate of false positives is a major drawback. To address this limitation, a combination of modalities is being explored to utilize the benefits of each; potentially increasing the accuracy of detection at the point of surveillance. Kara and colleagues have conducted a 20 patient pilot study in which HD-WLE and AFI were used initially to locate suspicious lesions. Once the lesions were identified, an NBI scope was introduced for detailed inspection of vascular and mucosal patterns. They found that 40% of the HGD lesions were discovered with AFI alone. However, the false-positive rate of

Figure 2 Optical coherence tomography images of intestinal metaplasia (A), and of neoplasia (C, E) are shown with corresponding histological images shown below [Copyright (2006), with permission from Elsevier]^[43], dilated glands (C) and increased surface reflectivity (E) can be seen in the optical coherence tomography images of neoplastic tissue, corresponding histopathology is shown (B, D, F). Scale bars, 500 μm .

the modality was 40% and the positive predictive value was 60%. Following NBI inspection, the false-positive rate was reduced to 10%, which achieved a positive predictive value of 85%^[41]. A more recent study with one scope containing both modalities achieved similar results. In that study, AFI was able to detect more lesions than high-resolution WLE alone, however, the false-positive rate remained a high 81%; following detailed inspection with NBI the rate was reduced to 26%^[42]. In both cases however, random four-quadrant biopsies detected additional lesions that the optical modalities did not identify, which indicates the need for further development of these and other technologies.

High-resolution imaging

Wide-field imaging techniques, such as AFI and NBI, were developed to measure large surface areas of gastrointestinal tissue. More recently, high-resolution systems have been developed to achieve near diffraction-limited imaging from small fields of view. Four primary approaches have been pursued to increase spatial resolution. OCT can image esophageal tissue with 10–15 μm resolution and a penetration depth of 1–2 mm. Endocytoscopy can image surface level esophageal tissue with up to 1–2 μm resolution using the highest magnification setting. Confocal microscopy can image esophageal tissue with 1–2 μm spatial resolution with a penetration depth of 300–400 μm . High-resolution microendoscopy can image surface level esophageal tissue with 4–5 μm spatial resolution. Recent clinical studies with these modalities highlight the benefits and limitations of high-resolution imaging.

OCT uses variations in the time it takes light to be reflected from structures beneath the tissue surface to image

sub-surface tissue structures as seen in Figure 2, in a manner analogous to ultrasound imaging. In a 55 patient study, researchers have determined that OCT could differentiate HGD and EAC from BE with a sensitivity of 83% and a specificity of 75%^[43]. An advantage of OCT is that it relies on endogenous differences in light scattering to generate image contrast. OCT may be a particularly useful tool in the detection and surveillance of sub-squamous BE because of its relatively greater depth of penetration^[44]. However, the technology is still under development^[45] and further clinical studies are needed to assess performance in a wide variety of clinical settings.

Endocytoscopy uses a probe that is passed through the instrumentation channel of an endoscope to image with subcellular resolution. Essentially, high-resolution epi-reflectance microscopy is used with methylene blue contrast to highlight relevant nuclear features (Figure 3A and B). Although models vary, there are generally two types each with different magnifications settings; one at 450 \times where the field of view can be as wide as 300 μm \times 300 μm , and a higher magnification setting of 1125 \times where a field of view as small as 120 μm \times 120 μm is made visible^[46]. A large study evaluating 166 sites in 16 patients with endocytoscopy by Pohl and colleagues reported a sensitivity and specificity of 42% and 83%, respectively^[47]. Although high specificity was encouraging, they did emphasize the need for an initial wide-field surveillance technique to identify suspicious areas. This technology is certainly promising; however, larger studies need to be performed.

Confocal microendoscopy (CME) images subsurface tissue structure with high resolution by using a spatial filter to reduce the background signal produced by scat-

Figure 3 Images representing intestinal metaplasia and neoplasia collected using endocytoscopy (A, B) [Copyright (2007), with permission from Thieme]^[47], confocal microendoscopy (C, D) [Copyright (2006), with permission from Elsevier]^[48], and high-resolution microendoscopy (E, F) [Copyright (2008), with permission from Elsevier]^[51]. Typically applied methylene blue is used in endocytoscopy to highlight nuclear changes (A, B); In metaplasia (A), nuclei appear organized and regular; this is in stark contrast to neoplasia (B) where nuclei appear pleomorphic. Both images were taken using 1125 × magnification. Confocal images were taken using intravenous fluorescein to enhance contrast of subepithelial capillaries (C, D); for intestinal metaplasia (C), confocal microendoscopy allows visualization of mucin-containing goblet cells (white arrow); For Barrett's-associated neoplasia (B), cells are irregularly oriented (white arrow) and malignant invasion of the lamina propria can be seen (yellow arrow). Confocal images are 500 μm × 500 μm . High-resolution microendoscopy uses proflavine for contrast enhancement, highlighting changes in glandular and nuclear patterns (E, F). High-resolution images are 750 μm in diameter.

tered out-of-focus light, which produces images with 1-2 μm spatial resolution. Although CME images can be generated either in reflectance or fluorescence mode, in the context of esophageal imaging, fluorescence CME has been primarily used. Since tissue autofluorescence is weak, typically fluorescent contrast agents are used to generate image contrast in CME. Kiesslich and researchers conducted a 63 patient study in Germany using an endoscope that incorporated standard WLE and confocal microscopy; fluorescein (10% w/v) was administered intravenously to generate vascular contrast. Subepithelial capillaries located in the upper and deeper layers of the lamina propria were identified due to fluorescein con-

trast. Leakage of fluorescein due to irregular capillary formation indicated neoplastic areas (Figure 3C and D). Indeed, due to these irregularities, neoplasia could be detected with a sensitivity and specificity of 94% and 98% respectively^[48]. In a prospective, randomized, double-blind, controlled, crossover study with 39 patients using the same system, CME with targeted biopsy was shown to not only be accurate, but to nearly double the diagnostic yield of collected biopsies. In examining the biopsies identified by standard four-quadrant biopsies and the biopsies identified by CME, there was no statistically significant difference in detection of neoplasia between the two techniques^[49]. However, although accuracy and

diagnostic yield is impressive, the high cost may limit this technology to tertiary care centers.

A fiber-bundle, probe-based confocal system that can be passed through the instrument channel of any standard endoscope was used in a 38 patient study by Pohl and other researchers. A major benefit of this technology is its adaptability to existing endoscopes. This system also requires exogenous contrast; fluorescein was administered intravenously. The sensitivity and specificity of the two study endoscopists were 75% and 89% and 75% and 91%, respectively. They concluded that the confocal fiber probe showed a high negative predictive value for detecting unapparent neoplasia in BE; however, sensitivity was not ideal^[50].

An alternative approach to high-resolution fluorescence imaging uses a coherent fiber bundle placed in direct contact with the surface of tissue labeled with fluorescent dyes to yield high resolution images that reveal subcellular structure (Figure 3E and F)^[51]. This low-cost alternative to confocal imaging may be suited for community-wide surveillance outside of tertiary care centers. In a small pilot study of nine patients, with topical proflavine for contrast enhancement of cell nuclei, researchers achieved a sensitivity and specificity of 87% and 85% using fluorescence microendoscopy^[52].

Contrast enhancement

As optical imaging technology continues to advance, the concurrent development of appropriate contrast agents that target biomarkers of neoplasia is crucial. Two general classes of optical contrast agents have been explored to improve image contrast: vital dyes and targeted contrast agents. Absorbing or fluorescent dyes that have an affinity for specific tissue constituents have often been used to improve the ability to visualize specific features associated with neoplasia. Often referred to as vital dyes, these stains can help delineate features such as angiogenesis, leaky vasculature, and cell morphology. In contrast, targeted contrast agents use a high affinity probe molecule to target a specific molecular biomarker associated with neoplasia^[53]. The probe molecule must be coupled to an optically active component, such as a fluorescent dye or scattering nanoparticle. Here, we briefly review the utility of both types of contrast agents for improved detection of esophageal neoplasia.

Vital dyes can be utilized to delineate better morphological changes associated with epithelial neoplasia. For example, the absorptive dye methylene blue localizes primarily in nuclei and can enhance visualization of nuclei when coupled with appropriate high-resolution instrumentation. Using an endocytoscope, nuclear characteristics associated with neoplasia such as homogeneity, nuclear-to-cytoplasmic ratio, and organization can be resolved. However, since methylene blue dye is known to induce oxidative damage of DNA when exposed to white light illumination^[54], the risks of the contrast agent need to be weighed against the benefits to determine potential use.

Fluorescent vital dyes may be advantageous due to the lack of interference with standard endoscopy. Fluorescein

is a dye that is administered intravenously, thus enhancing the view of vasculature in epithelial tissue. When coupled with confocal imaging, subsurface vasculature can be seen. The illumination and collection wavelengths of commercially available confocal systems correspond to fluorescein excitation (about 490 nm) and emission (about 520 nm)^[48,50]. Acriflavine is another vital fluorescent dye that can be seen using similar excitation (about 450 nm) and emission (about 510 nm) wavelengths. Acriflavine stains cell nuclei, highlighting nuclear characteristics such as size, shape, and spacing, and has been used previously *in vivo* for gastrointestinal imaging^[55].

Targeted contrast agents serve as beacons that signal specific molecular events associated with pre-cancer formation. The benefit of targeted agents is the potential to achieve a high signal to background ratio by virtue of selective binding to a molecular target. Lu and researchers used a phage display library with about 2.8×10^9 unique sequences to select a cancer-specific peptide. The library was biopanned against three cultured human esophageal cell types: adenocarcinoma, metaplasia, and normal, to identify a peptide with specificity for the adenocarcinoma cell line. They used the selected peptide labeled with FITC to image Barrett's-associated neoplasia *in vivo*. The agent was topically applied and imaged with a concurrently developed prototype fluorescence endoscope. Initial results showed a significant increase in binding to Barrett's-associated neoplasia over Barrett's alone when imaged with wide-field fluorescence imaging (Figure 4)^[56]. In a different study, Hsiung and colleagues fluorescently labeled a high-affinity heptapeptide sequence selected with similar phage display techniques for the colon, and were able to differentiate dysplastic from non-dysplastic colonic crypts using confocal imaging^[57]. In both of these cases, the topically applied contrast agent was incubated *in vivo* for a short period of time before the unbound agent was washed off to reduce non-specific signals. Although the excitation and emission wavelengths of these agents correspond well with commercially available confocal endoscopes, another important advantage demonstrated by these studies is the ability to image these agents with both wide-field fluorescence and CME.

DISCUSSION

Recent advances in imaging technologies afford visualization of endogenous optical alterations associated with gastrointestinal neoplasia. NBI shows contrast associated with light absorption due to hemoglobin. High sensitivity and specificity is cited in studies using this technology, however some indicate that there is no significant difference between contrast associated with NBI imaging and HD-WLE, which is becoming increasingly available. AFI measures the signal decrease associated with loss of stromal collagen fluorescence and increased fluorescence associated with porphyrin. Various studies evaluating AFI have cited high sensitivity, but a high rate of false positives. The combination of NBI and AFI may afford better sensitivity and specificity rates; NBI has shown to reduce

Figure 4 *In vivo* localization of contrast agent localized to a neoplasia region visualized using wide-field fluorescence endoscopy. White light endoscopic image (A) shows no evidence of lesion; topical administration of peptide-targeted fluorescent dye reveals neoplastic area (B) [Copyright (2008), with permission from IOS Press]^[56]; targeted neoplastic crypts seen with fluorescence microscopy (C), and corresponding histology (D) [Copyright (2010), with permission from Elsevier]^[59].

the number of false positives identified by AFI from 81% to 26%^[42].

High-resolution imaging will also play a major role in improving detection, affording clinicians an “optical biopsy” of epithelial tissue. Confocal imaging allows for optical sectioning of up to 250 μm deep, and coupled with vital dyes such as fluorescein, allows evaluation of vascular regularity. High sensitivity and specificity have been cited; however, high cost and the limited field of view remain concerns. Endocytoscopy allows for histology-like reflectance imaging where nuclei appear dark blue due to methylene blue contrast. The technology achieves high specificity; however, the dye has been shown to interfere with white light imaging and image quality has been an issue. When combined with wide-field imaging techniques, high-resolution technologies may reduce false-positive rates if coupled with the appropriate contrast agent.

Unfortunately, despite all the advances in optical imaging methods, there are still lesions that are only detected by standard four-quadrant biopsies. Improvements in contrast agents are also needed to facilitate early detection. A number of contrast agents are commercially available; primarily vital dyes such as fluorescein and methylene blue. However, recent *in vivo* testing of optically labeled high-affinity peptide and heptapeptide sequences has paved the way for molecule-specific contrast agents for gastrointestinal neoplasia^[56,57]. Although advances have translated the use of vital dyes and contrast agents *in vivo*, there are still many unanswered questions regarding their ultimate clinical role. What will be the ideal mechanism of delivery?

How will the development of *in vivo* imaging technologies accommodate the use of new contrast agents? Finally, will the addition of contrast agents create a multifaceted platform that can improve overall accuracy of surveillance?

Although these new imaging technologies may be appropriate for tertiary care centers, additional considerations are necessary as these technologies are disseminated more widely. A potential solution may be a lower cost technology such as the high-resolution microscope, or an adaptable technology such as the confocal miniprobe with topically applied contrast agents; both of which have been cited to achieve reasonably high sensitivity and specificity. Objective, quantitative algorithms will also be important because clinicians outside of tertiary care clinics may not be as familiar with optical characteristics of abnormal lesions detected with new technologies. Various groups have begun work in this area; however, larger trials need to be conducted to determine effectiveness^[52,58].

At this point, larger studies are needed to test the combination of multi-scale, multi-modal technologies against the current surveillance standard, and to test whether the use of contrast agent is advantageous. This multifaceted optical approach has the potential to improve surveillance in BE; once validated, it has the potential to be utilized for surveillance of neoplasia along the gastrointestinal tract and can be further developed for screening.

Abstract

Recent advances in endoscopic imaging techniques have revolutionized the diagnostic approach of patients with inflammatory bowel disease (IBD). New, emerging endoscopic imaging techniques visualized a plethora of new mucosal details even at the cellular and subcellular level. This review offers an overview about new endoscopic techniques, including chromoendoscopy, magnification endoscopy, spectroscopy, confocal laser endomicroscopy and endocytoscopy in the face of IBD.

INTRODUCTION

Patients with long standing ulcerative colitis and Crohn's disease are at an increased risk for the development of intraepithelial neoplasia (formerly known as dysplasia) and colorectal neoplasia. Therefore, surveillance endoscopy is mandatory in these patients. Nevertheless, standard white light endoscopy with multiple random biopsies may miss a quantum of lesions^[1].

During the last ten years, a variety of new endoscopic techniques were introduced to improve diagnosis and patient outcome in inflammatory bowel disease (IBD). Traditionally, standard white light endoscopy only allows the investigation of the mucosal surface and surrounding blood vessels at low magnification (Figure 1). To overcome these limitations, new endoscopic imaging techniques were developed providing a more detailed view of the mucosa. Emerging endoscopic imaging techniques include chromoendoscopy and magnification endoscopy. Additionally, new endoscopic devices now allow real time *in vivo* histology during ongoing endoscopy.

This review describes the concept of advanced endoscopic imaging techniques in IBD.

CHROMOENDOSCOPY

Chromoendoscopy uses different staining techniques to enhance the mucosal detail and submucosal vascular pattern, thereby improving the detection of pathological lesions and enabling a more precise diagnosis. Currently, chromoendoscopy is distinguished in dye-based and dyeless imaging techniques.

The basic principle of dye-based chromoendoscopy (DBC) is the use of biocompatible dye agents (Figure 2). Dyes include absorptive (methylene blue 0.1%-0.5%, cresyl violet 0.2%) and contrast agents (indigo carmine

Figure 1 High-resolution standard white light endoscopic image of active Crohn's disease. Endoscopy shows ulcerations, mucosal edema and erythema.

Figure 2 Chromoendoscopy with indigo carmine. A better distinction of mucosal changes in long standing ulcerative colitis (A) and pit pattern analysis of suspicious lesions (B).

0.2%-0.4%). DBC yields an additional diagnostic value with a 3-4 higher detection rate of intraepithelial neoplasia^[2,3]. However, dye-based chromoendoscopy has some potential limitations. There are additional costs for the equipment needed for dye spraying, it is a time consuming procedure, the dye does not always coat the surface evenly and it does not allow for a detailed analysis of the subepithelial capillary network, which is an important feature in the early diagnosis of gastrointestinal neoplasia.

Therefore, dye-less chromoendoscopy (DLC; also called virtual chromoendoscopy) has been developed (Figure 3). DLC includes narrow band imaging (NBI; Olympus, Tokyo, Japan), Fujinon intelligent color enhancement (FICE; Fujinon, Tokyo, Japan) and i-Scan (Pentax, Tokyo, Japan).

Figure 3 Virtual chromoendoscopy using the Fujinon intelligent color enhancement-system. A: Shows standard white light endoscopic image; B-D: Illustrate different Fujinon intelligent color enhancement settings to improve mucosal detail.

NBI is based on optical filters within the light source of the endoscope which narrow the bandwidth of spectral transmittance such that the blood vessels are enhanced and thus seen more easily.

FICE and i-Scan are based on the same physical prin-

Figure 4 High-magnification endoscopy of ileum mucosa in patient with Crohn's disease without activity. Villi are clearly visualized.

circle as NBI, but due to a computed spectral estimation technology, they are not dependent on the presence of optical filters inside of the video endoscope. In contrast to NBI, FICE and i-Scan use an endoscopic image from the video processor and reconstruct virtual images in real time by increasing the intensity of narrowed blue light to a maximum and by decreasing narrowed red light and green light to a minimum resulting in an improved contrast of the capillary patterns and enhancement of the mucosal surface.

One recent study evaluated magnifying colonoscopy with NBI for the diagnosis of intraepithelial neoplasia in ulcerative colitis. It was found that the tortuous pattern determined by NBI colonoscopy may be a clue for the identification of dysplasia during surveillance for ulcerative colitis^[4]. Another study included 50 patients with longstanding ulcerative colitis and reported on a moderate accuracy (sensitivity 75%, specificity 81%) for the NBI diagnosis of intraepithelial neoplasia^[5]. Additionally, NBI colonoscopy may be of value for determining the grade of inflammation in patients with quiescent ulcerative colitis^[6].

Very recently, it was shown that FICE could not improve the detection or delineation of ulcers and erosions due to Crohn's disease^[7]. Nevertheless, these preliminary data have to be proven in larger prospective trials.

One recent published study tested the efficacy of high definition endoscopy alone compared to i-Scan or chromoendoscopy with methylene blue (0.1%) in screening for colorectal cancer^[8]. It was found that both i-Scan and chromoendoscopy identified more lesions compared to high definition endoscopy alone. Additionally, i-Scan was able to predict neoplasia as precisely as chromoendoscopy.

MAGNIFICATION ENDOSCOPY

Magnification endoscopy (also called zoom endoscopy) utilizes a movable lens to vary the degree of magnification up to 150-fold (Figure 4). By staining the entire colon with methylene blue, it has been shown that chromoendoscopy combined with magnification endoscopy has the potential to improve targeting biopsy examination in patients with long-standing colitis and facilitate early detection of intraepithelial neoplasia and colorectal cancer^[2]. In the chro-

moendoscopy arm a significantly better correlation was found between the endoscopic assessment of degree ($P = 0.0002$) and extent ($P < 0.0001$) of colonic inflammation and the histopathologic findings compared with the conventional colonoscopy group. Additionally, more targeted biopsies were possible, and significantly more intraepithelial neoplasia were detected in the chromoendoscopy group ($P = 0.003$).

These data were confirmed by Hurlstone and colleagues^[3]. In a prospective study, 162 patients with longstanding ulcerative colitis underwent total colonoscopy. After detection of subtle mucosal changes intravital staining with indigo carmine was used. Subsequently, the macroscopic type and the staining pattern were defined. Chromoendoscopy with magnification and targeted biopsies significantly increased diagnostic yield for intraepithelial neoplasia and the number of flat neoplastic changes as opposed to conventional colonoscopy.

The largest prospective study to date comparing conventional endoscopy with magnification endoscopy enrolled 300 patients with ulcerative colitis^[9]. Magnification imaging was significantly better than conventional colonoscopy for predicting disease extent *in vivo* ($P < 0.0001$). The authors concluded that high-magnification imaging provides a sensitive and specific *in vivo* "virtual biopsy" in ulcerative colitis. High-accuracy optical biopsy could limit the number of biopsies required, with significant cost savings for pathology services.

SPECTROSCOPY

Spectroscopy includes several optical techniques, including fluorescence-, reflectance-, light scattering spectroscopy and optical coherence tomography. Spectroscopy depends on the wavelength of the light source and on tissue characteristics. Based on differences between the spectra of light that is backscattered between cells, different spectra can be identified that are specific for various diseases such as ischemia, inflammation, and malignancy^[10].

One study assessed fluorescence endoscopy for the detection of intraepithelial neoplasia in ulcerative colitis by taking optical guided biopsies. By using 5-aminolevulinic acid as an exogenous fluorophore agent, sensitivity

Figure 5 Confocal laser endomicroscopy using either the integrated system (iCLE, A) or the probe-based system (pCLE, B) visualizes dilated microvessels, leakage and disturbed crypt architecture in active ulcerative colitis.

and specificity for dysplastic lesions was 100% and 62%, respectively^[11]. Very recently, the detection of invisible flat intraepithelial neoplasia with protoporphyrin IX fluorescence was compared to standard 4-quadrant biopsies^[12]. Flat intraepithelial neoplasia was detected in 7% of patients by standard white light 4-quadrant biopsies and in 24% of patients using fluorescence-guided endoscopy ($P = 0.02$). Sensitivity and specificity for differentiating patients with and without dysplasia were 100% and 81%, respectively. Additionally, dysplastic and non-dysplastic mucosa could be discriminated with a sensitivity and specificity of 73% and 81%, respectively.

CONFOCAL LASER ENDOMICROSCOPY

In 2004, confocal laser endomicroscopy was introduced, allowing real time *in vivo* histology of 1000-fold magnification during ongoing endoscopy^[13]. Currently, two FDA approved devices are available (Figure 5). One is integrated into the distal tip of a high resolution endoscope (iCLE; Pentax, Tokyo, Japan), one represents a stand-alone probe which is capable of passage through the working channel of most standard endoscopes (pCLE; Cellvizio, Mauna Kea Technologies, Paris, France). A blue laser light source delivers an excitation wavelength of 488 nm and returning light is detected at > 505 nm. Endomicroscopy requires the application of fluorescence agents, either systemically (fluorescein) or topically (e.g. acriflavine, cresyl violet)^[14].

While endomicroscopy only covers a limited field of view within the mucosa, pan-endomicroscopy of the whole gastrointestinal tract is not feasible. Therefore, macroscopic visualization of suspected areas is necessary before performing targeted endomicroscopy.

To date, different studies have addressed the utility of endomicroscopy for the *in vivo* diagnosis of IBD associated mucosal changes.

To compare endomicroscopic imaging of inflamed and non-inflamed rectal mucosa in patients with ulcerative colitis, Watanabe *et al.*^[15] enrolled 17 patients with ulcerative colitis and 14 controls. Confocal images were compared to standard histopathology. Endomicroscopy was able to visualize crypt architecture, capillaries and inflammatory cells, providing equivalent information to histopathology.

Recently, a new classification of inflammation activity in ulcerative colitis using endomicroscopy was proposed^[16], including crypt architecture and microvascular alterations. In this study, endomicroscopy was reliable for real-time assessment of inflammation activity in ulcerative colitis showing good correlations with histological results (Spearman's rho, both $P < 0.001$).

Our group addressed the utility of endomicroscopy for the *in vivo* evaluation of Crohn's disease associated changes. Using the pCLE system, endomicroscopy was able to diagnose Crohn's disease associated changes with high accuracy. Furthermore, pCLE could detect residual macroscopic non-visible mucosal inflammation as precisely as histology (κ values 0.8, unpublished data).

Current guidelines recommend a large number of biopsy specimens during surveillance colonoscopy in ulcerative colitis. Nevertheless, flat lesions still may be missed. In a trial of longstanding ulcerative colitis, chromoendoscopy was used to unmask lesions for endomicroscopy and compared with standard white light endoscopy with random biopsies^[17]. Chromoendoscopy in combination with endomicroscopy detected 4.75-fold more neoplasia compared to conventional colonoscopy ($P = 0.005$). Additionally, 50% fewer biopsy specimens were required ($P = 0.008$). The presence of neoplastic changes could be predicted with high sensitivity, specificity and accuracy (94.7%, 98.3%, 97.8%, respectively).

One recent study prospectively evaluated the clinical applicability and predictive power of endomicroscopy for the *in vivo* differentiation of dysplasia-associated lesion mass (DALM) or adenoma-like mass (ALM)^[18]. Accuracy of endomicroscopy was 97% and an excellent agreement between endomicroscopy and histopathological diagnosis was found ($\kappa = 0.91$).

ENDOCYTOSCOPY

Endocytoscopy (Olympus, Tokyo, Japan) is a new imaging technique, enabling microscopic imaging of the mucosal layer of the gut at a magnification up to 1400-fold (Figure 6). Endocytoscopy is based on a contact light microscope which enables real-time visualization of cellular structures of the superficial epithelial layer in a plane parallel to the

Figure 6 Endocytoscopy enables visualization of different cytological and architectural features, including size, arrangement, and density of cells.

mucosal surface. Currently, systems integrated into the distal tip of an endoscope (iEC) and probe-based (pEC) systems are available. Probe-based systems consist of handheld miniproboscopes, which are capable of being inserted through the accessory channel of a standard endoscope. The device provides ultra high magnification imaging at $\times 570$ (pEC), $\times 580$ (iEC) or $\times 1400$ (pEC) on a 19-inch monitor from an optical sampling site of about 0.5 mm in diameter. Endocytoscopy requires preparation of the mucosal layer with absorptive contrast agents like methylene blue or toluidine blue^[19].

Recently, endocytoscopy has been established as a useful tool to examine mucosal surfaces^[20-23]. Different studies suggest the potential of endocytoscopy for the *in vivo* evaluation of duodenal mucosa in celiac disease^[21]. Furthermore, endocytoscopy was able to detect tissue abnormalities in normal mucosa surrounding colorectal cancer and to identify neoplasia in aberrant crypt foci^[22]. Additionally, endocytoscopy was shown to distinguish neoplastic from non-neoplastic lesions, and also to differentiate invasive colon cancer from adenoma^[23,24].

Currently, data on endocytoscopy for *in vivo* diagnosis of IBD are still lacking. Nevertheless, this new imaging technique is a promising development allowing surface magnification at cellular and subcellular resolution.

CAPSULE ENDOSCOPY

In order to evaluate the small intestine capsule endoscopy (CE) was introduced. Currently two CE systems are available. One is distributed by Given Imaging (Norcross, Ga), and one by Olympus (Tokyo, Japan). The capsule is passively propelled through the intestine by peristalsis while transmitting color images of the intestine^[25].

CE is useful for the evaluation of the small intestine in patients in whom the diagnosis of Crohn's disease is elusive^[26]. Due to the danger of capsule retention in patients with established Crohn's disease, a patency capsule is available which is self-dissolved approximately 30 h after ingestion. In addition, balloon-guided endoscopy could be used to remove impacted capsules^[27]. Dubcenco and coworkers studied CE findings in patients with established and suspected small-intestine Crohn's disease and correlated the findings with radiologic, endoscopic and histologic

findings. Final diagnosis of active small-intestine Crohn's disease was made in 74% of patients. In addition, CE yielded a sensitivity and specificity of 89.6% and 100%, respectively, and a positive predictive value and a negative predictive value of 100% and 76.9%, respectively^[28]. Furthermore, CE was shown to be superior compared to push enteroscopy and enteroclysis^[29].

CONCLUSION

Modern endoscopy has revolutionized the diagnosis and management of patients with IBD. The newly developed endoscopic devices offer features that allow more and more mucosal and submucosal details to be seen. According to high magnification and respective reduced field of view, prior assessment of suspicious lesions is mandatory. Chromoendoscopy, using either vital or virtual staining techniques unmasks circumscribed lesions and confocal laser endomicroscopy or endocytoscopy can then be used to predict intraepithelial neoplasia with high accuracy. Nevertheless, the assessment of these new endoscopic imaging modalities in clinical practice still warrants further investigation. In addition, currently there is no reimbursement for advanced endoscopic imaging methods including endomicroscopy, endocytoscopy and spectroscopy. Therefore, endoscopy with multiple random biopsies remains the gold standard for surveillance in patients with IBD.

Abstract

AIM: To develop lymph node metastasis (LNM)-associated biomarkers for colorectal cancer (CRC) using quantitative proteome analysis.

METHODS: Differences in protein expression between primary CRC with LNM (LNM CRC) and without LNM (non-LNM CRC) were assessed using methyl esterification stable isotope labeling coupled with 2D liquid chromatography followed by tandem mass spectrometry (2D-LC-MS/MS). The relationship to clinicopatholog-

ical parameters and prognosis of candidate biomarkers was examined using an independent sample set.

RESULTS: Forty-three proteins were found to be differentially expressed by at least 2.5-fold in two types of CRC. S100A4 was significantly upregulated in LNM CRC compared with non-LNM CRC, which was confirmed by Western blotting, immunohistochemistry and real-time quantitative polymerase chain reaction. Further immunohistochemistry on another 112 CRC cases showed that overexpression of S100A4 frequently existed in LNM CRC compared with non-LNM CRC ($P < 0.001$). Overexpression of S100A4 was significantly associated with LNM ($P < 0.001$), advanced TNM stage ($P < 0.001$), increased 5-year recurrence rate ($P < 0.001$) and decreased 5-year overall survival rate ($P < 0.001$). Univariate and multivariate analyses indicated that S100A4 expression was an independent prognostic factor for recurrence and survival of CRC patients ($P < 0.05$).

CONCLUSION: S100A4 might serve as a powerful biomarker for LNM and a prognostic factor in CRC.

INTRODUCTION

Colorectal cancer (CRC) is the third most prevalent human cancer worldwide, with 1 million estimated new cases annually, of which, about 50% die^[1]. CRC frequently migrates through the lymphatic route, depositing tumor cells into local lymph nodes, namely lymph node metastasis (LNM). The status of the local lymph nodes delivers crucial information concerning cancer staging, prognosis, and clinical decision making, on the understanding that the existence of LNM notably reduces the chance of CRC survival^[2]. Unfortunately, the mechanisms related to LNM remain poorly understood at present because LNM is a complicated process that involves cancer cell detachment from the primary tumor, migration, invasion, adhesion and implantation in the new environment. A variety of dysregulated molecules play a significant role in this highly sophisticated process^[3,4]. Therefore, LNM-related investigations have attracted much attention.

Clinicopathological features such as poorly differentiated cancer, depth of wall penetration, lymphovascular invasion, and tumor size are considered to be associated with CRC with LNM (LNM CRC)^[5,6]; however, these characteristics are still insufficient to predict the existence of LNM. In order to improve the diagnosis and prognosis of CRC, there is an urgent need to identify specific tumor molecular markers to recognize patients with LNM, which can define a subset of CRC patients who could benefit from rational management.

It is presently in progress to develop new strategies for the identification of cancer-related molecular markers. Proteomics, the emerging technology that examines the overall characteristics of the expressed proteins, has identified many differential proteins associated with tumor development and progression in various diseases^[7-10]. The recent development of proteomic technology, which presents better sensitivity than conventional gel-based strategies - coupling stable isotope labeling with liquid chromatography followed by tandem mass spectrometry (LC-MS/MS) - introduces a powerful approach to accurate qualitative and quantitative proteomic analysis of clinical samples, as successfully applied to research on difference cancers^[11-14]. This procedure can provide new opportunities to develop biomarkers associated with LNM for CRC.

In the present study, we employed the combination of methyl esterification stable isotope labeling and 2D-LC-MS/MS to perform an accurate quantitative analysis. A total of 43 proteins were identified that were differently expressed by at least 2.5-fold, including S100A4, which was significantly upregulated in LNM CRC compared with non-LNM CRC. S100A4 was recently reported in association with LNM in several studies that attracted our interest^[15-17]. Meanwhile, there have been a limited number of similar studies on the association of S100A4 with CRC. As a result, we focused our attention on S100A4. After confirmation by Western blotting, immunohistochemistry and real-time quantitative polymerase chain reaction (PCR), we further investigated the relationship between S100A4 expression and the lymph node metastatic phe-

notype of CRC, and determined its prognostic value on another independent set of 112 CRC cases.

MATERIALS AND METHODS

Patients and samples

A total of 144 colorectal carcinoma samples were collected after obtaining informed consent in our hospital (Fudan University Shanghai Cancer Center, Shanghai, China). None of the patients received chemotherapy or radiotherapy before surgery. Resected specimens were reviewed by two senior pathologists according to the criteria described in the American Joint Committee on Cancer Cancer Staging Manual (6th edition, 2002)^[18]. For the screening and confirmation study, 32 primary CRC tissue samples that were obtained from patients who underwent curative resection in 2009 were collected and divided into two groups of LNM CRC and non-LNM CRC, with 16 cases in each group. The number of lymph nodes retrieved was not less than 12 in the non-LNM CRC. None of them had distant metastasis. The fresh colorectal tumor tissues were obtained immediately after surgery, washed twice with chilled phosphate buffered saline (PBS), immediately stored in liquid nitrogen and at -80°C in our tissue bank until further use. The detailed clinical data of these patients is provided in Table 1. For the S100A4 expression study, paraffin-embedded tissues in another independent set of 112 primary CRC samples between January and August 2004 were used for immunohistochemistry assessment. Ethical approval was obtained from the Cancer Center Research Ethics Committee.

Sample preparation, methyl esterification stable isotope labeling and 2D-LC-MS/MS

Frozen samples were crushed to powder in liquid nitrogen, and dissolved in lysis buffer [7 mol/L urea, 2 mol/L thiourea, 100 mmol/L DTT and 1 × protease inhibitor cocktail (Roche, Penzberg, Germany)] by continuous vortex at 4°C for 1 h. After centrifugation at 15000 r/min for 45 min at 4°C, equal amounts of each sample from LNM CRC and non-LNM CRC groups were pooled together. One hundred micrograms of proteins from each sample pool were reduced with 10 mmol/L dithiothreitol (60 min, 56°C) and alkylated with 12 mmol/L iodoacetamide in darkness (45 min, 37°C), followed by digestion with 1:20 (w/w) ratio of trypsin (Promega, Madison, WI, USA) overnight at 37°C. The lyophilized peptides from LNM CRC sample were tagged with d0-methanolic HCl, whereas those from non-LNM CRC samples were labeled with d3-methanolic HCl (Sigma-Aldrich, St. Louis, MO, USA) as previously described^[13,19]. Briefly, 100 µL of d0-methanolic HCl or d3-methanolic HCl (created by dropwise addition of 160 µL acetyl chloride with stirring to 1 mL d0-methanol or d3-methanol) was added to the corresponding sample. The reaction was allowed to proceed for 2 h at room temperature. After lyophilization and re-dissolving in 100 µL 5% acetonitrile in 0.1% formic acid, the two peptides were mixed, followed by desalination using Sep-Pak Vac C18 (Waters, Milford, MA, USA).

LNM: Lymph node metastasis; CRC: Colorectal cancer.

They were lyophilized again and re-dissolved in 40 μ L of the above-mentioned solution. Subsequently, the resultant sample was separated by a 2D microcapillary HPLC system, followed by MS/MS analysis using an LTQ Orbitrap (Thermo Fisher, San Jose, CA, USA). LC solvent gradients were controlled by the chameleon 6.5 (Dionex, Amsterdam, The Netherlands). The MS scan was operated in the data-dependent mode to switch automatically between MS and MS/MS acquisition. Fragment ion selection was based on ion intensity (above 10 counts) and charge state (+2, +3).

Data analysis

Bioworks 3.3.1 was used to generate the peaklists of all acquired MS/MS spectra, which were then automatically searched against the International Protein Index human protein sequence database, version 3.43 using SEQUEST (University of Washington, licensed to Thermo Fisher), with a 95% confidence level. Except for 57 Da reductive alkylation modification on Cys, static modifications were set on Asp, Glu, C-terminal (+14 Da and +17 Da for light and heavy isotope labeling, respectively). The mass tolerance of the peptides and fragment ions was 10 ppm and 1.0 Da, respectively. The identified peptides were further ana-

lyzed with two computer software programs, PeptideProphet and ProteinProphet. PeptideProphet with a probability score of 0.9 and ProteinProphet with a probability score of 0.95 were used to ensure an overall false-positive rate below 0.005. Quantification of the ratio of each protein was achieved using the Xpress program. Proteins with expression fold change > 2.5, $P < 0.05$ were defined as differentially expressed proteins.

Western blotting

The same protein samples for screening were used for Western blotting. Briefly, 30- μ g protein samples from each case were separated by 10% SDS-PAGE and subsequently transferred to PVDF membranes. The membranes were incubated with rabbit polyclonal antibody against S100A4 (1:1000 dilution; Abcam, Cambridge, UK) and then incubated with a horseradish-peroxidase-conjugated secondary antibody (1:100 dilution; Proteintech, Chicago, IL, USA). β -actin was detected simultaneously as a loading control (anti- β -actin, 1:1000 dilution; Kangchen, Beijing, China). All blots were visualized using an ECL detection system (Amersham, Arlington Heights, IL, USA) and quantitated by densitometry using an LAS-3000 imager.

Immunohistochemistry

S100A4 expression was examined immunohistochemically using paraffin-embedded tissues. In brief, 4- μ m-thick tissue sections were heated in 6.5 mmol/L citrate buffer (pH 6.0) at 100°C for 28 min, and incubated with antibody against S100A4 (1:200 dilution). Immunostaining was performed employing the DAKO En-Vision System (Dako Diagnostics, Zug, Switzerland). In the negative control group, PBS was used instead of primary antibody. S100A4 expression was scored by two independent experienced pathologists. Each sample was graded according to the intensity and extent of staining as described previously^[11]. The intensity of staining was scored as 0 (no staining), 1 (weak staining), and 2 (strong staining). The extent of staining was based on the percentage of positive tumor cells: 0 (no staining), 1 (1%-25%), 2 (26%-50%), 3 (51%-75%), and 4 (76%-100%). The final score was assessed by summarizing the results of intensity and extent of staining. The case was considered negative if the final score was 0 or 1 (-) or 2 or 3 (\pm), and positive if the score was 4 or 5 (+) or 6 or 7 (++). In most cases, the two reviewers provided consistent results. Any inconsistencies were resolved by discussion to achieve a consensus score.

Real-time quantitative PCR

Total tissue RNA was extracted using the Rneasy Mini Kit (Qiagen, Valencia, CA, USA). Real-time quantitative PCR analysis was performed according to the manufacturer's instructions (the Quant SYBR Green PCR Kit, TIAN-GEN BIOTECH, Beijing, China). β -actin was applied as an internal control. The primers for β -actin (205 bp) were 5'-TGACGTGGACATCCGCAAAG-3' (sense) and 5'-CTGGAAGGTGGACAGCGAGG-3' (antisense). The primers for S100A4 (185 bp) were 5'-GCCCTGGATGT-

¹Protein ratio represents the abundance ratio between lymph node metastasis group and non-lymph node metastasis group. LNM: Lymph node metastasis; CRC: Colorectal cancer.

GATGGTGT-3' (sense) and 5'-TCGTTGTCCCTGTT-GCTGTC-3' (antisense). Each assay was done in triplicate, and the average was calculated. For relative quantification, $2^{-\Delta\Delta C_t}$ was calculated and used as an indication of the relative expression levels.

Statistical analysis

The Student *t* test was used to evaluate the differences in S100A4 expression between LNM CRC and non-LNM CRC. The χ^2 test was used to assess the relationships between S100A4 expression and clinicopathological factors. The cumulative recurrence and survival probability were

estimated using the Kaplan-Meier method, and differences were calculated by log-rank test. Prognostic factors were determined using Cox regression analysis. The recurrence-free and overall survival times were calculated from the first resection of the primary tumor to first evidence of recurrence or to death from any cause, respectively. The diagnosis of recurrence was based on the typical features presented on computed tomography/magnetic resonance imaging and elevated serum carcinoembryonic antigen. All *P* values were two-sided, and *P* < 0.05 was considered to be significant. Statistical analyses were performed using SPSS 13.0 software.

RESULTS

Quantitative proteome analysis with methyl esterification stable isotope labeling combined with 2D-LC-MS/MS

To perform accurate quantitative analysis, we compared the protein expression profiles between LNM CRC and non-LNM CRC using methyl esterification stable isotope labeling combined with 2D-LC-MS/MS. The quantitative differential expression of 644 proteins was identified, after calibration with β -casein. Significantly, 43 of these (6.7%) proteins were displayed differentially (at least 2.5-fold) in LNM CRC compared with non-LNM CRC. Among these 43 proteins, 28 were found to be upregulated in LNM CRC (Table 2), and 15 were downregulated (Table 2). The identification of S100A4 significantly upregulated in LNM CRC is shown in Figure 1 as an example. These differentially expressed proteins formed the possible protein profiles associated with LNM in CRC.

Confirmation of S100A4 expression by Western blotting, immunohistochemistry and real-time quantitative PCR

We extended the experiments to confirm the differential expression of S100A4 in the same samples described above.

Thirty micrograms of total proteins from LNM CRC and non-LNM CRC were analyzed *via* Western blotting. The expression of S100A4 was dramatically higher in LNM CRC compared with non-LNM CRC ($P < 0.001$). A representative Western blotting result is presented in Figure 2A.

To confirm upregulation of S100A4 at the protein level, we used immunohistochemistry to evaluate S100A4 expression *in situ*. In normal mucosa, there was no immunoreactivity in cells. In non-LNM CRC, there was weak staining in cancer cells. In LNM CRC, there was notable brown staining in both primary and matched metastatic lymph node cancer cells. Positive staining was present mainly in the cytoplasm and/or nucleus of cancer cells (Figure 2B).

Real-time quantitative PCR revealed that S100A4 mRNA level was higher in LNM CRC than in non-LNM CRC ($P < 0.001$, Figure 2C), which is consistent with the trend at the protein level.

Association of S100A4 expression with clinicopathological features and postoperative prognosis of CRC patients

To detect the relationship between S100A4 expression and clinicopathological features and whether S100A4 could be a prognostic factor in predicting clinical outcomes of CRC patients, we evaluated S100A4 expression in an additional archived 112 CRC samples. In the group of 53 LNM CRC samples, 83% were positive for S100A4 expression, whereas 16.9% of the 59 non-LNM CRC samples had positive expression.

After division of these patients into S100A4-positive and S100A4-negative groups, statistical analysis revealed that positive expression of S100A4 was significantly associated with LNM, and advanced TNM stage ($P < 0.001$).

Table 3 Relationships of S100A4 expression with clinicopathological factors in colorectal cancer

Clinicopathological factors	n	S100A4 expression		P value ¹
		Negative	Positive

¹Statistical analysis was estimated with χ^2 test, and $P < 0.05$ was considered statistically significant; ²Grading of differentiation status and TNM classification for colorectal cancer were based on the American Joint Committee on Cancer Cancer Staging Manual (6th edition, 2002). The tumors were classified into two groups: well differentiated (grades I and II) and poorly differentiated (grades III and IV).

However, no significant correlations were observed between S100A4 expression and other clinicopathological parameters of sex, age, tumor size, tumor differentiation and tumor location (Table 3).

Furthermore, we found that patients with S100A4-positive CRC had significantly poorer prognosis than those with S100A4-negative CRC. The 5-year cumulative recurrence rate was significantly higher in patients with S100A4-positive CRC than in the S100A4-negative group ($P < 0.001$, Figure 3A). The 5-year cumulative survival rate in patients with S100A4-positive CRC was much lower than in those with S100A4-negative CRC ($P < 0.001$, Figure 3B). Univariate analyses revealed that LNM, TNM stage and S100A4 expression were associated with recurrence and overall survival. In multivariate analysis, LNM, TNM stage and S100A4 expression were also independent prognostic factors of recurrence and overall survival ($P < 0.05$, Table 4).

DISCUSSION

Metastasis remains one of the major challenges in management of CRC patients. LNM is the most common form of metastasis in CRC. To develop LNM-associated biomarkers for CRC, we employed the quantitative proteomic strategy of methyl esterification stable isotope

Figure 1 Identification of quantitatively dysregulated expression of S100A4. A: Quantification of S100A4 through the isotopically labeled fragment ion signals of the peptide "TDEAAFQK". The areas under the monoisotopic peaks represent the relative abundance of peptides, light [lymph node metastasis (LNM)]/heavy (non-LNM) = 3.04:1; B: Identification of the peptide "TDEAAFQK" from S100A4 by MS/MS.

labeling coupled with 2D-LC-MS/MS. A total of 644 proteins were identified, including 43 that were differentially expressed by at least 2.5-fold between LNM CRC and non-LNM CRC. We found many of the 43 proteins that possibly participate in the biological processes associated with tumor metastasis, such as cell motility and adhesion, migration, and signal transduction.

Among the upregulated proteins, annexin A2, one of the calcium- and phospholipid-binding proteins, has been widely reported in various cancers with the regulation of cell growth, motility, invasion and signaling pathways^[20]. The increase in caveolin-1 performs the functions of signal transduction, cell transformation and anti-apoptotic activity^[21]. Moreover, caveolin-1 has been found to be overexpressed in several multidrug-resistant cancer cell lines^[22,23]. In addition, some downregulated proteins identified in our study have also been observed to possess similar biological effects, including galectin-3-binding protein^[24] and cyclin-G-associated kinase^[25].

Previously, Pei *et al.*^[26] have carried out a proteomic study on 10 CRC samples using conventional 2D electrophoresis coupled with MALDI-TOF-MS, and have reported a pattern of four differentially expressed proteins potentially associated with LNM. In contrast, our results revealed up to 43 proteins that were differentially

expressed by at least 2.5-fold. Annexin A2 and glutathione S-transferase P1 both correlated with LNM in our study and that of Pei *et al.* Heat shock protein-27 and liver fatty acid binding protein (L-FABP) were found to correlate with LNM by Pei *et al.*, but not in our study, whereas 41 proteins identified in our study were not listed by Pei *et al.* This discordance is probably due to the different clinical background of the samples included in the studies, and the different proteomic strategies used. It is required to analyze systemically and integrate all the complementary data from various institutions into a common databank to elucidate exactly the molecular background of CRC. In addition, Pang *et al.*^[27] have identified and confirmed six differentially expressed proteins (e- fatty acid binding protein 5, methylcrotonoyl Coenzyme A carboxylase 2, pyrophosphatase 2, synaptotagmin-like protein 2, Ezrin, and smooth muscle protein) that are associated with LNM in prostate cancer by DIGE-based proteome analysis. However, there was no concordance between the results in that study and our study, which is probably mainly due to the different cancers and proteomic approaches included.

Recently, several studies have shown that S100A4 is an important factor relevant to progression and prognosis in various human cancers, such as thyroid^[28], breast^[29], pancreatic^[30], bladder^[31], gastric^[17] and colorectal^[32] cancer.

Figure 2 Confirmation of the overexpression of S100A4 in colorectal cancer. A: Western blotting analysis for S100A4 expression in colorectal cancer (CRC) specimens. β -actin was used as the internal loading control. The histogram shows the relative expression levels of S100A4 in non-LNM (16 cases) and lymph node metastasis (LNM) (16 cases) groups. Data represent the mean \pm SE ($P < 0.001$, Student *t* test); B: Immunohistochemical study of S100A4 distribution and expression in CRC specimens at 20×10 magnification. a: There was no immunoreactivity in the normal mucosa; b: Weak staining in cancer cells in the non-LNM group; c: Strong staining in cancer cells in the LNM group; d: Marked metastatic lymph nodes (arrow); C: mRNA level of S100A4 via real-time quantitative polymerase chain reaction. S100A4 was consistently increased in the LNM group (16 cases) compared with non-LNM group (16 cases). The mRNA level was normalized to that of β -actin. Data represent the mean \pm SE ($P < 0.001$, Student *t* test).

In particular, several studies have revealed that overexpression of S100A4 strongly indicates the presence of LNM^[15-17], which agrees with our original study aim. However, similar investigations have been limited between S100A4 expression and LNM in CRC. In view of the above reasons, S100A4, one of the significantly upregulated proteins identified in LNM CRC compared with non-

LNM CRC, which has been confirmed at the protein and mRNA levels, attracted our attention and interest.

S100A4, also known as 18A2/mts1, CAPL, PEL-98, 42A, p9Ka, and metastasin, belongs to the S100 superfamily of calcium-binding proteins^[33]. S100A4-mediated calcium signaling plays a major role in crucial biological functions that influence various aspects of cell physiology,

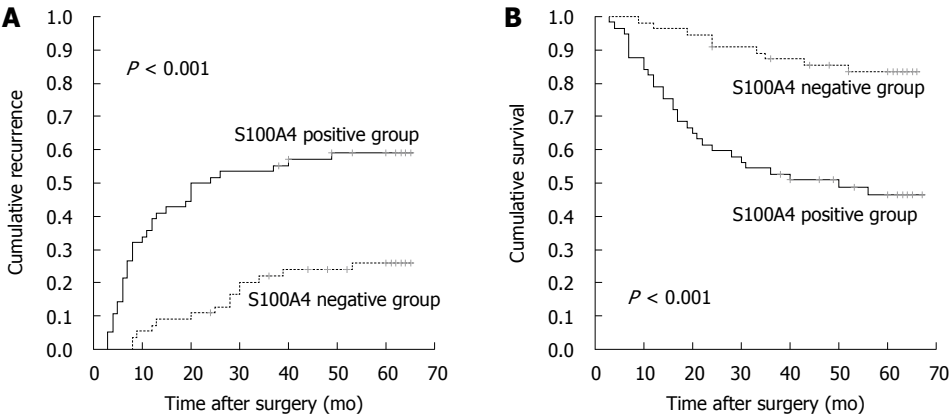

Figure 3 Overexpression of S100A4 correlated with poor prognosis in 112 colorectal cancer patients. A: Cumulative recurrence between the S100A4-positive and S100A4-negative groups ($P < 0.001$, log-rank test); B: Cumulative survival between the S100A4-positive and S100A4-negative groups ($P < 0.001$, log-rank test).

HR: Hazard ratio; CI: Confidence interval.

including proliferation and apoptosis, and differentiation and morphogenesis. It is also significantly involved in cell adhesion and motility, and cancer invasion and metastasis^[34,35]. A large body of evidence suggests that S100A4 is involved in cell metastatic phenotype by modulating the cytoskeletal dynamics, cadherin/catenin complex cytoskeletal linkage, CD44/cytoskeletal linkage, and extracellular-matrix-associated proteolytic enzyme. Furthermore, S100A4 can participate in the activation of the matrix metalloproteinase/tissue inhibitor of metalloproteinase system and angiogenic factor vascular endothelial growth factor, which in turn can lead to tumor neovascularization^[36,37].

To study further the relationship between S100A4 expression and the LNM phenotype of CRC, and determine whether S100A4 could be a prognostic factor in predicting clinical outcomes of CRC patients, we examined an additional 112 archived CRC samples for S100A4 expression. We found that the elevation in S100A4 expression level was significantly correlated with LNM and advanced TNM stage, which suggests that S100A4 plays an important part in the progression of CRC from a localized to lymph node metastatic disease. In addition, patients with S100A4-positive CRC had an increasing risk of recurrence and significantly reduced overall survival. Univariate and

multivariate analyses indicated that S100A4 expression is a powerful independent prognostic factor for recurrence and overall survival in CRC, which indicates the considerable prognostic value of S100A4 expression.

In conclusion, our current study employed a quantitative proteome analysis to profile the differently expressed proteins associated with LNM in CRC. S100A4 was identified and confirmed to be significantly overexpressed in LNM CRC. Further evaluation in an independent sample set has suggested that S100A4 acts as a powerful biomarker for LNM and prognosis in CRC. However, many questions remain to be answered with respect to the cellular function of S100A4 and how it exerts its influence on metastatic progression, with further investigations on our part in progress. We also identified a number of proteins besides S100A4 that might provide a more profound insight into the mechanism of LNM in CRC and merit further research.

COMMENTS

Background

Colorectal cancer (CRC) is one of the most prevalent cancers worldwide, and it is estimated that half of the patients die from cancer annually. Lymph node metastasis (LNM) is the most common form of metastasis although the mechanism is largely unknown. Studies on metastasis of CRC were performed in order to improve the diagnosis and prognosis.

Research frontiers

LNM is a complicated process that involves a variety of dysregulated molecules playing a significant role. Increasingly, it has become a hot research topic to employ proteome analysis to identify proteins associated with tumor development and progression in various diseases.

Innovations and breakthroughs

To date, there has been a limited number of studies regarding specific tumor molecular markers associated with LNM in CRC. In this study, the authors employed more sensitive proteome analysis than conventional strategies to identify a set of differently expressed proteins associated with LNM. Furthermore, the authors confirmed the significant correlation between overexpression of S100A4 and LNM, advanced TNM stage, increased recurrence rate and decreased overall survival rate.

Applications

By identifying the protein S100A4 as being associated with LNM, the authors evaluated the biological features and prognosis in CRC, which could improve our understanding of CRC, and provide a scientific basis for the application of S100A4 inhibitors in the treatment of CRC.

Terminology

Proteome: all proteins that derive from the genome of cells, a tissue or an organism. It is a dynamic collection that reflects both the intrinsic genetic information of the cell and the impact of its immediate environment. Compared with gene analysis, proteome analysis can provide a more accurate view of the biological status and be expected to be more useful for evaluating, for example, disease development, progression and response to treatment.

Peer review

The authors performed also an extensive proteomics analysis, and identified 43 proteins that were differentially regulated in metastatic cancer, including 16 proteins that were upregulated even more than S100A4. The results indicate that overexpression of S100A4 could be used as biomarker for LNM in CRC. However, none of the latter candidate biomarkers were further examined in terms of prognostic value.

Abstract

AIM: To investigate the expression profile of miRNA in esophageal squamous cell carcinoma (ESCC).

METHODS: The expression profile of miRNA in ESCC tissues was analyzed by miRNA microarray. The expression levels of miR-143 and miR-145 in 86 ESCC patients were determined by real-time polymerase chain reaction (PCR) using TaqMan assay. The mobility effect was estimated by wound-healing using esophageal carcinoma cells transfected with miRNA expression plasmids.

RESULTS: A set of miRNAs was found to be deregulated in the ESCC tissues, and the expression levels of miR-143 and -145 were significantly decreased in most of the ESCC tissues examined. Both miR-143 and miR-145 expression correlated with tumor inva-

sion depth. The transfection of human esophageal carcinoma cells with miR-143 and miR-145 expression plasmids resulted in a greater inhibition of cell mobility, however, the protein level of the previously reported target of miR-145, *FSCN1*, did not show any significant downregulation.

CONCLUSION: These findings suggest that the deregulation of miRNAs plays an important role in the progression of ESCC. Both miR-143 and miR-145 might act as anti-oncomirs common to ESCC.

INTRODUCTION

MicroRNAs (miRNAs) are an endogenous conserved class of non-coding 20-22 nt small RNAs that regulate gene expression at post-transcriptional level by mainly binding to 3'-UTR of target mRNAs, leading to mRNA degradation or translation inhibition^[1]. Many miRNAs show sequence and function conservation between distantly related organisms, suggesting that this class of small RNAs is an integral part of essential cellular processes^[2]. It was predicted that about 30% of human genes are

regulated by miRNAs^[3]. miRNAs regulate a variety of biological processes, including developmental timing, signal transduction, cell growth, and cell death^[4]. The importance of microRNA in cancer is highlighted by the observation that about 50% of miRNAs are located in cancer-associated genomic regions or fragile sites, which are frequently amplified or deleted in tumorigenesis^[5]. Moreover, accumulated evidence shows that miRNAs are aberrantly expressed in various cancers, suggesting that they play a vital role as a novel class of oncogenes or tumor suppressor genes, depending on the targets they regulate^[6]. Recent reports demonstrate a role for miRNA expression in disease progression and outcome^[7].

Esophageal carcinoma is one of the most lethal malignancies in China and other Asian areas, with a significant low 5-year survival rate after curative surgery^[8,9]. There are two major histologic types of esophageal cancer: esophageal squamous cell carcinoma (ESCC) and esophageal adenocarcinoma. To date, many studies focusing on miRNA expression profiles in Barrett's esophagus and esophageal adenocarcinoma have been reported^[10]. Yang *et al.*^[11] identified 11 miRNAs showing statistically significant differences between the different progression stages of esophageal adenocarcinoma. Nevertheless, there is still little information available on specific miRNA expression patterns and their roles in ESCC. Feber *et al.*^[12] identified a set of differentially expressed miRNAs that could distinguish different esophageal tissue types and also discriminate malignant from normal esophageal tissue, including adenocarcinoma, squamous cell carcinoma, Barrett's esophagus and high-grade dysplasia. These data suggest that miRNA expression profiling is now a promising method to identify key miRNAs which play important roles in esophageal carcinogenesis.

Chaoshan Area in China is the main coastal area and has a high ESCC morbidity rate^[13]. The specific geographical environment and dietary habits of the population may characterize some of the specific features of ESCC in this area, which might also be reflected in the miRNA expression profile in ESCC tissues. To develop novel diagnostic and therapeutic targets for esophageal squamous cell cancer, we first investigated the expression profile of miRNA in three pairs of clinical ESCC samples and confirmed the differences in expression of relevant miRNAs using real-time quantitative reverse transcription-polymerase chain reaction (qRT-PCR) in 86 pairs of ESCC samples. The associations between miRNA expression and clinicopathological features were analyzed. Furthermore, we tried to identify the targets of these differentially expressed miRNAs.

MATERIALS AND METHODS

Cell lines

Human ESCC cell lines EC8712, KYSE150, EC109, EC18, SHEEC, KYSE180, KYSE70, and KYSE140 were cultured in 199 or DMEM medium (Invitrogen, Carlsbad, CA, USA) plus 10% newly born calf serum.

Specimen collection

ESCC tissues and matched normal tissues were obtained from surgical specimens immediately after resection from patients undergoing primary surgical treatment of esophageal carcinoma from Oct 2007 to Dec 2008 in the Department of Tumor Surgery of Shantou Central Hospital, China. No patient had received preoperative irradiation or chemotherapy. The samples were flash frozen in liquid nitrogen and stored at -80°C until RNA extraction. Among these samples, three were used for microRNA microarray analysis and 86 were using for qRT-PCR analysis. Tumor specimens underwent histological examination by a pathologist to confirm the diagnosis, verify the presence of tumor, select those samples with at least 75% tumor tissue, and establish the pathological stage. Clinical and pathological information was extracted from the patients' medical charts and pathology reports. The clinical data used for qRT-PCR analysis are shown in Table 1. Written consent for tissue donation (for research purposes) was obtained from the patients before tissue collection and the protocol was approved by the Institutional Review Board of Shantou Central Hospital.

miRNA microarray

RNA labeling and hybridization were completed by KangChen Bio-tech Inc. (Shanghai, China) according to

the manufacturer's instructions. Briefly, total RNA from three pairs of esophageal carcinoma and matched normal tissues were isolated using Trizol (Invitrogen, USA) and purified using the RNeasy mini kit (QIAGEN, Germany). The concentration and quality of total RNA were measured by NanoDrop ND-1000 at 260 and 280 nm (A260/280) and confirmed by gel electrophoresis. Each RNA sample from three pairs of ESCC was separately labeled using the miRCURY Hy3/Hy5 labeling kit and hybridized on the six miRCURYTM locked nucleic acid (LNA) array version 11.0 (Exiqon, Denmark), which contains probes for 1700 mature miRNAs. Scans were quantified using GenePix software (Molecular Devices). The data were exported to Microsoft Excel worksheets, log₂ transformed, normalized using global Lowess (Locally Weighted Scatter plot Smoothing) regression algorithm (MIDAS, TIGR Microarray Data Analysis System), which we previously found to produce the best within-slide normalization to minimize the intensity-dependent differences between the dyes. Replicated spots on the same slide were averaged by obtaining a median ratio of replicated spots. Between slides normalization was performed by scale normalization to reduce between-slide variability. Only those with a greater than 2-fold increase or 2-fold decrease in expression in two samples were considered significantly changed. Samples were clustered according to their miRNA profile using Cluster 3.0 and shown using Treeview.

miRNA real-time RT-PCR quantification

qRT-PCR analysis of miRNA expression was carried out using TaqMan MicroRNA Assay kits according to the manufacturer's protocol (Applied Biosystems, USA). Briefly, total RNA was extracted using TRIzol Reagent (Invitrogen, USA) from clinical samples and ESCC cell lines. cDNAs were synthesized from total RNA using gene-specific primers. Reverse transcriptase reactions contained 10 ng RNA samples, 50 nmol/L stem-loop RT primer, 1 × RT buffer, 0.25 mmol/L each of the dNTPs, 3.33 U/μL MultiScribe reverse transcriptase and 0.25 U/μL RNase inhibitor. The 15 μL reactions were incubated for 30 min at 16°C, 30 min at 42°C, 5 min at 85°C, and then held at 4°C. The 20 μL PCR reaction included 1.33 μL RT product, 1 × TaqMan Universal PCR master mix and 1 μL primers and probe mix of the TaqMan MicroRNA Assay kit. Reactions were incubated in a 96-well optical plate at 95°C for 10 min, followed by 40 cycles at 95°C for 15 s and 60°C for 1 min. PCR reactions were run on a 7500 Real Time PCR machine (Applied Biosystems) and analyzed using 7500 System SDS software.

U6 small nuclear RNA was used as an internal control to normalize RNA input. The Ct value is defined as the fractional cycle number at which the fluorescence passes the fixed threshold. The fold change was calculated using the 2^{-ΔΔCt} method, presented as the fold-expression change in tumors relative to their corresponding normal tissues after normalization to the endogenous control. All experiments were carried out in triplicate.

Plasmid construction

Human genomic fragments of miR-145 and miR-143 pre-

cursors with flanking about 200 bp were amplified by PCR using human genomic DNA as a template. PCR primers were designed as follows: miR143 forward: 5'-AAGCT-TAAGGTCAAGGTTTGGTCCT-3'; miR143 reverse: 5'-CTCGAGTGCTAAGATGGACACACTGG-3'; miR145 forward: 5'-AAGCTTCAGAGGGTTTCCGGTACTT-3'; miR-145 reverse: 5'-CTCGAGAGCCTCACAGGGAT-GTTATG-3'. The PCR products were cloned into the pDNA3.0 vector and named pcDNA-miR145 and pcDNA-miR143, respectively.

Transfection

Approximately 2 × 10⁵ of KYSE150 and KYSE180 cells were seeded and cultured in 6-well plates, respectively. For each well, 2.0 μg of plasmids were added to 100 μL Opti-MEM medium and 10 μL of Superfect (QIAGEN, Germany). The mixture was added to the cells and incubated for 2 h before replacing the medium. Stable clones were generated by selection in complete culture medium containing 400 mg/L of G418.

In vitro wound-healing assay

KYSE150 and KYSE180 cells were seeded in a 6-well dish, and incubated overnight yielding a confluent monolayer for wounding. Wound healing was performed using a tip with a flat point. An image was taken at different time points in each visual field at 50 ×.

miRNA target prediction

TargetScan (release 5.1, <http://www.targetscan.org/>) was used to analyze potential target genes for the deregulated microRNAs.

Western blotting

Total cell lysates were prepared in RIPA buffer [50 mmol/L TrisHCl, pH 8.0, 150 mmol/L NaCl, 1% (vol/vol) Nonidet P-40, 0.5% (wt/vol) sodium desoxycholate, 0.1% (wt/vol) SDS] containing the complete protease inhibitor cocktail. Western blotting analysis was performed as described with the following primary antibodies: monoclonal mouse anti-fascin (DAKO, Denmark) and mouse anti-β-actin (Sigma, MO, USA). Experiments were repeated in triplicate.

Statistical analysis

Statistical differences between tumor and normal tissue were evaluated using the paired *t*-test. Statistical differences between clinicopathologic parameters and miRNA fold change were evaluated using ANOVA. The correlation coefficients of miR-143 and miR-145 were calculated using the Spearman correlation. *P* values less than 0.05 were considered statistically significant. All calculations were performed using Statistical Program for Social Sciences (SPSS) software 13.0 (SPSS Inc., Chicago, IL, USA).

RESULTS

Patient characteristics

The group specimen used for qRT-PCR was obtained

from 62 males and 24 females and their details are shown in Table 1. The average age of these patients was 54 years and ranged from 40 to 75 years. Fifty-seven patients (66.3%) had tumors smaller than 5 cm, and 29 (33.7%) had tumors greater than 5 cm. Lymph node metastases were observed in 38.4% of the patients ($n = 33$), while the remaining patients had no lymph node metastases. Of these patients, 4 (4.7%) of 86 were diagnosed at invasion T1, 18 (20.9%) at invasion T2 and 64 (74.4%) at invasion T3. Histological type was ulcerative in 49 cases, medullary in 24 cases, fungating in 10 cases and 3 cases were unidentified. Seventy-four cases were well differentiated (I + II) and 12 cases were poorly differentiated. Taken together, the numbers diagnosed in the four clinical stages were 3, 49, 4 and 30, respectively. After two years of follow-up, the overall survival rate of the 86 ESCC patients was as high as 84.9% with only 13 deaths reported. The impact of the expression of miRNAs on patient survival will be analyzed in a future study.

Differential expression of miRNAs found in ESCC

Using miRNA microarray, we then identified the miRNAs that were differentially expressed in tumor and non-tumor samples. Only miRNAs that were altered by at least 2-fold in at least two of the samples were considered significant candidates. Using these strict criteria, we identified 33 upregulated miRNAs and 40 downregulated miRNAs between normal and cancer tissues. Heat maps depict the relative expression level of mature miRNAs indicated by microarray analyses of the samples from three patients (Figure 1). This showed that the changes from two chips in each clinical case were consistent.

In accordance with previous reports^[12,14], miR-21 was observed to be the most upregulated miRNA with an average 24.4-fold change. miR-203 was the most downregulated with an average 4.3-fold change. miR-203, miR-99a and miR-100 were also found to be downregulated in this study. With the exception of these, several miRNAs such as miR-143 and miR-145 were found to be changed in esophageal squamous cell carcinoma (Figure 1). On average miR-143 was downregulated 4.3-fold, while miR-145 was downregulated 3.2-fold. miR-25 was only detected in one chip and was upregulated 2.3-fold. However, a previous report of significant differential expression of miRNAs in ESCC^[12,14-16], including miR-106b, -103, -107, -34b, -139 and -129, did not show significant changes in our study. All raw and normalized miRNA expression data are available from GEO publicly accessible server (<http://www.ncbi.nlm.nih.gov/geo/>) with the accession number: GSE23142.

Downregulation of miR-143 and miR-145 in ESCC

To confirm our microarray data and to determine the clinical significance of deregulated expression of miRNAs in esophageal carcinoma, we evaluated the expression of two cancer-associated miRNAs, miR-143 and miR-145, in 86 clinical samples of esophageal carcinoma and their matched normal tissues using qRT-PCR. These microR-

Figure 1 miRNAs are deregulated in esophageal squamous cell carcinoma as detected by microRNA microarray. Three pairs of esophageal carcinoma and normal tissue matches were analyzed by miRCURY LNA™ microRNA Arrays v.11.0. Each RNA sample was dye-swap labeled. Unsupervised hierarchical cluster analysis of miRNA expression in three esophageal carcinoma patients. Rows: miRNAs; columns: cases. The analysis showed that two chips in each case were consistent. For each miRNA, red represents higher expression and blue represents lower expression than the average expression. S1, sample 1; S2, sample 2; S3, sample 3.

NAs were chosen as they had previously been shown to be differentially expressed in various tumors. U6 RNA expression did not differ significantly between tumor and non-tumor tissue in our study population (data not shown). As shown in Figure 2, the expression level of miR-145 was significantly downregulated in ESCC compared to matched normal tissues ($P = 0.001$), and no statistically significant difference in miR-143 expression between the two groups was observed ($P = 0.436$).

Using the $2^{-\Delta\Delta Ct}$ method and a 2-fold change criterion, the qRT-PCR results showed that the expression of miR-143 was downregulated in 47.7% (41/86) and miR-145 was downregulated in 61.6% (53/86) of the clinical samples of esophageal carcinoma (Figure 3). The qRT-PCR results showed good consistency with the microRNA microarray results. In order to investigate the

^b $P < 0.01$.

clinical values of miR-143 and miR-145, we analyzed the relationships between the expression levels of these two miRNAs in cancer tissues and clinicopathological factors of patients with esophageal carcinoma. The mean fold changes of miRNAs in esophageal carcinoma samples and their possible connections with cancer are presented in Table 2. Significant correlations between miR-143 and miR-145 levels in the primary tumors and tumor invasion were observed ($P = 0.000$ and $P = 0.001$, respectively, Figure 4). Furthermore, the co-expression of miR-143 and miR-145 was analyzed with the Spearman correction and showed a value of 0.967 ($P = 0.000$).

miR-143 and miR-145 inhibit cell mobility

The expression levels of miR-143 and miR-145 were significantly downregulated in ESCC cell lines (Figure 5A). Following transfection with pcDNA-miR143 and pcDNA-miR145, the expression levels of these two microRNAs were significantly increased (Figure 5B). In the wound-healing assays, the distance KYSE150 and KYSE180 stably transfected cells moved in a wounded cell monolayer on plastic was determined, together with pcDNA transfected cells which were used as controls. The results showed that the cells transfected with

Figure 2 Differential expression of miR-143 (A) and miR-145 (B) in esophageal squamous cell carcinoma compared to normal tissue. Each value represents the relative expression using the 2- Δ Ct method with U6 RNA as an endogenous control. miR-145 is significantly deregulated in esophageal carcinoma patients ($P = 0.001$).

miR-145 and miR-143 migrated very small distances and were unable to achieve wound closure (Figure 5C and D, respectively). For stably transfected KYSE150 cells, 89% of the wounds containing the control cells (16/18 visual fields) were closed or were healing, while only 58% of the miR-143 transfectant (7/12 visual fields) and 18% of the miR-145 transfectant (3/17 visual fields) were healing. For stably transfected KYSE180 cells, the percentage of healing in the control, miR-143 transfectant and miR-145 transfectant was 50% (6/12), 42% (5/12) and 0% (0/6), respectively.

miRNA target prediction and identification

Since miR-143 and miR-145 can inhibit the mobility of esophageal carcinoma cells, we tried to identify their targets that related to cell mobility. Recently, *FSCN1* has been proved to be a target of miR-145 both in the esophageal squamous cell lines TE2 and TE13 and in bladder cancer^[17,18]. However, our results showed that the protein level of *FSCN1* did not significantly change in the miR-143 and miR-145 stable expressing KYSE150 and KYSE180 cells, respectively (Figure 6A and B). Using TargetScan, we found that the 3'-UTR of *FSCN1* contained hundreds of miRNA binding sites, especially four conserved binding sites for miR-145 and two non-conserved

Table 3 miR-143 and miR-145 predicted targets related to cell mobility

Predicted targets	Functions
miR-143	
LASP1 (LIM and SH3 protein 1)	Functions as an actin-binding protein and possibly in cytoskeletal organization
RICTOR (RPTOR independent companion of MTOR, complex 2)	Functions upstream of Rho GTPases to regulate the actin cytoskeleton
ARHGAP26 (Rho GTPase activating protein 26)	Regulates the organization of the actin-cytoskeleton
EPB41 [erythrocyte membrane protein band 4.1 (elliptocytosis 1, RH-linked)]	Together with spectrin and actin, constitute the red cell membrane cytoskeletal network.
MYO3A (myosin III A)	Belongs to the myosin superfamily, an actin-dependent motor protein
MARCKS (myristoylated alanine-rich protein kinase C substrate)	An actin filament crosslinking protein involved in cell motility
SVIL (supervillin)	Tightly associated with both actin filaments and plasma membranes
miR-145	
ARF6 (ADP-ribosylation factor 6)	Regulates vesicular trafficking, remodeling of membrane lipids, and signaling pathways that lead to actin remodeling.
ABLIM2 (actin binding LIM protein family, member 2)	Bound strongly to F-actin, localized to actin stress fibers
ADD3 [adducin 3 (γ)]	Involved in assembly of the spectrin-actin network in erythrocytes and at sites of cell-cell contact in epithelial tissues
CAPZB (c apping protein (actin filament) muscle Z-line, β)	Regulates growth of the actin filament by capping the barbed end of growing actin filaments.
ELMO1 (engulfment and cell motility 1)	Mediates cytoskeletal rearrangements during phagocytosis of apoptotic cells and cell motility
PHACTR2 (phosphatase and actin regulator 2)	Coprecipitated with both PP1 and actin
TMOD1 (tropomodulin 1)	Inhibits depolymerization and elongation of the pointed end of actin filaments

Figure 3 Downregulation of miR-143 and miR-145 in esophageal squamous cell carcinoma. Using the $2^{-\Delta\Delta Ct}$ method, those with a greater than 2-fold change were considered significant. The expression of miR-143 was downregulated in 48.9% (46/94) and miR-145 was downregulated in 60.6% (57/94) clinical samples of esophageal carcinoma.

binding sites for miR-143 (Figure 7). Moreover, we also found other predicted targets of miR-143 and miR-145 that related to cell mobility using TargetScan (Table 3).

DISCUSSION

Accumulated studies have indicated that microRNAs,

Figure 4 Associations between the expression of miR-143 and miR-145 and clinicopathologic features. The expression of both miR-143 and miR-145 were significantly associated with esophageal squamous cell carcinoma tumor invasion ($P = 0.000$ and $P = 0.001$, respectively).

posttranscriptional modulators of gene expression, are involved in the initiation and progression of various malignancies. Many studies have demonstrated that some human miRNAs are consistently deregulated in human

Figure 5 miR-143 and miR-145 inhibited esophageal squamous cell carcinoma cell mobility. A: The expression levels of miR-143 and miR-145 in esophageal squamous cell carcinoma (ESCC) cell lines. Using normal tissue as the control, both miRNAs were significantly downregulated in ESCC cell lines; B: The increased expression of miR-143 and miR-145 following stable transfection. Quantitative reverse transcription-polymerase chain reaction demonstrated a significant increase in the expression levels of miR-143 and miR-145 in KYSE150 and KYSE180 cells transfected with the respective expression plasmids compared with the levels in control cells ($P < 0.01$); C, D: The increased expression of miR-143 and miR-145 inhibited the mobility of both KYSE150 and KYSE180 cells. The miRNA stably transfected cells were seeded in a 6-well plate, streaks were made using a tip when the cells were grown to almost confluence 24 h later. Streaks were photographed at different intervals at 50 \times . This showed that upregulation of miR-143 and miR-145 can prevent ESCC cell wound healing. These findings are shown in (C) and (D).

cancer, suggesting a role for these genes in tumorigene-

sis^[19]. A comparison between human cancers and adjacent

In this study, our miRNA microarray results partially agree with Feber's and Guo's findings, including miR-21 and miR-203, miR-99a and miR-100, respectively, which further support the robustness of our results. With the exception of deregulated miRNAs identified in Feber's and Guo's reports, we also found common differentially expressed miRNAs as reported recently by Ogawa *et al.*^[16], including the upregulation of miR-21 and the downregulation of miR-133b and miR-145. Nevertheless, this is the

A number of reports have shown that miR-143 and miR-145 are downregulated in various cancer cells, including colorectal cancer, nasopharyngeal carcinoma, lung cancer and B-cell malignancies^[20-23]. To our knowledge, we have performed the largest study to date which assesses the potential diagnostic and prognostic utility of

miRNAs in esophageal squamous cell cancer. Consistent with the aforementioned previous reports, our miRNA microarray and qRT-PCR results revealed that miR-143 and miR-145 were under-expressed in most esophageal carcinoma specimens, compared with matched normal tissue samples. These results imply that these two miRNAs might serve as novel diagnostic and therapeutic targets for esophageal squamous cell cancer.

However, the pathobiological significance of aberrant miRNA expression in human esophageal squamous cell carcinoma has not been well documented. In this study, we found that both miR-143 and miR-145 correlated with tumor invasion. This suggested that both of these miRNAs might be associated with esophageal carcinoma progression. To date, little information is available on the correlations between miR-143 and miR-145 and the clinicopathologic features of other tumors. It was reported that there was no relationship between miR-143 and miR-145 expression and other clinicopathological features, except that miR-145 expression was related to cancer site following the analysis of 98 primary colorectal cancer specimens^[20]. Slaby *et al.*^[24] also found that colorectal cancer tumors larger than 50 mm in maximum diameter were characterized by low expression of miR-143 and miR-145. Clapé *et al.*^[25] showed that miR-143 expression levels were inversely correlated with advanced stages of prostate cancer. Therefore, the roles of miR-143 and miR-145 in esophageal squamous cell carcinoma progression remain to be revealed.

Xin *et al.*^[20] showed that miR-143 and miR-145 selectively target genes that regulate the actin cytoskeleton in smooth muscle cells, which is intimately coupled to cell migration. Migration of esophageal squamous carcinoma cells was consistently reduced by over-expression of miR-143 and miR-145 in our wound-healing experiments. It has been reported that *FSCN1* is a target of miR-145 both in bladder cancer and esophageal carcinoma^[17,18]. However, no significant downregulation of *FSCN1* protein was found in ESCC KYSE150 and KYSE180 cells, while the expression of miR-143 and miR-145 was rescued. This controversial result may be due to the specificity of these cell lines. Using TargetScan, we also found other predicted targets of miR-143 and miR-145 related to cell mobility, such as *LASP1* and *ARF6*. These results implied that *FSCN1* could be regulated by other miRNAs in ESCC cell lines except the TE series^[16]. The targets of miR-143 and miR-145 in KYSE150 and KYSE180 cells remain to be identified.

Interestingly, the chromosome loci of both miR-143 and miR-145 are very close to each other within approximately 2 kb on 5q32, which led us to speculate that both precursors originate from the same primary transcript. In our study, we found that these two miRNAs were highly co-expressed in 86 esophageal tumors, with Spearman correlation coefficients of 0.967 ($P = 0.000$). This indicated that miR-143 and miR-145 might be regulated by the same factor(s) and generated from the same primary transcript (pri-miRNAs). However, various results have suggested that there may be different mechanisms for the transcriptional regulation of this locus. miR-143 and

miR-145 could be transcribed individually and co-transcribed. Zhang *et al.*^[27] demonstrated that miR-143 is transcribed by nuclear factor κ B, and the expression levels of miR-143 were dramatically increased in metastatic HBV-HCC and HCC patients. Xu *et al.*^[28] found that the 1.5 kb sequence upstream of miR-145 has an intrinsic promoter activity, and such activity is repressed by OCT4, which is one of the targets of miR-145. Cordes *et al.*^[29] also found that miR-143 and miR-145 were direct transcriptional targets of the serum response factors, myocardin and Nkx2-5, in multipotent murine cardiac progenitors. The transcription regulation of miR-143/-145 seems to be tissue-specific.

In summary, we report that miRNAs were deregulated and miR-143 and miR-145 were downregulated in ESCC. Furthermore, rescued expression of miR-143 and miR-145 can inhibit cell mobility. This study provides the first evidence for the anti-oncogenic activity of miR-143 and miR-145 in the development of esophageal squamous cell cancer. Targets of these two miRNAs remain to be defined. These results indicate that miRNAs may eventually constitute useful biomarkers as well as therapeutic targets.

COMMENTS

Background

MicroRNAs (miRNAs) regulate gene expression by mainly binding to the 3'-UTR of target mRNAs, leading to mRNA degradation or translation inhibition. miRNAs are aberrantly expressed in various cancers, suggesting that they play a vital role as a novel class of oncogenes or tumor suppressor genes, depending on the targets they regulate.

Research frontiers

Esophageal squamous cell carcinoma is one of the most lethal malignancies in China. Many studies have reported the miRNA expression profiles in Barrett's esophagus and esophageal adenocarcinoma. In this study, the authors report the expression profile of miRNA in esophageal squamous cell carcinoma (ESCC) and investigate the expression and functions of miR-143 and miR-145 in ESCC.

Innovations and breakthroughs

Some human miRNAs are consistently deregulated in human cancer, suggesting a role for these genes in tumorigenesis. A set of miRNAs was found to be deregulated in ESCC and the expression levels of miR-143 and miR-145 were significantly decreased in most of the ESCC tissues examined. The authors performed the largest study to date which assessed the potential diagnostic and prognostic utility of miRNAs in ESCC. It is the first study to show that both miR-143 and miR-145 were correlated with tumor invasion depth. The anti-oncogenic role of miR-143 and miR-145 was demonstrated as significant cell mobility inhibition.

Applications

This study provides the first evidence of the anti-oncogenic activity of miR-143 and miR-145 in the development of ESCC. These results indicated that miRNAs may eventually constitute useful biomarkers as well as therapeutic targets.

Peer review

Many miRNAs are found deregulated in ESCC tissue and miR-143 and -145 are significantly decreased in ESCC. Both miR-143 and miR-145 correlated with tumor invasion depth. This study provides the evidence for an anti-oncogenic activity of miR-143 and miR-145 in the development of ESCC and may develop to be useful biomarkers or therapeutic targets in ESCC. It's an excellent study.

Abstract

AIM: To examine the relationship between the trends in food consumption and gastric cancer morbidity in Poland.

METHODS: The study was based on gastric cancer incidence rates and consumption of vegetables, fruit, vitamin C and salt in Poland between 1960 and 2006. Food consumption data were derived from the national food balance sheets or household budget surveys. Spearman correlation coefficients were used to estimate the relationship between the variables.

RESULTS: A negative correlation was found between vegetables (-0.70 both for men and women; $P < 0.0001$), fruit (-0.65 and -0.66; $P < 0.0001$) and vitamin C (-0.75 and -0.74; $P < 0.0001$) consumption and stomach cancer incidence rates. The same applied to the availability

INTRODUCTION

Gastric cancer ranks fourth in morbidity and second in mortality for malignant cancers worldwide^[1]. However, in numerous countries, in particular in economically developed ones, gastric cancer morbidity within the past few decades has reduced significantly. Several epidemiological studies have shown that this phenomenon is most probably related to favorable changes in dietary pattern in the developed countries, that is, mostly to increased consumption of fresh fruit and vegetables, and decreased consumption of salt-preserved food^[2] and greater availability of refrigerators^[3]. It is assumed that lower gastric cancer morbidity rates are also related to lower prevalence of *Helicobacter pylori* (*H. pylori*) infection, which is considered as an essential factor for the development of a majority of gastric cancers^[4,5]. In these countries, prevalence of

H. pylori infections affects 20%-40% of the population.

Against this background, Poland seems to be a particular case. Despite the fact that, according to national epidemiological studies, the percentage of people infected with *H. pylori* is unusually high and amounts to 73% of the total population and 85%-95% of those aged > 25 years^[6], in 2006, gastric cancer morbidity rate was twofold lower compared to that in 1960^[7,8].

What was the reason for such a significant decrease in morbidity rate, taking such widespread dissemination of *H. pylori* as a major carcinogen into consideration? This intriguing phenomenon might be most probably assigned to specific changes in dietary pattern, as in the case of western countries.

Data that reflect average food consumption per capita in Poland in 1950-2006 show that this period was highly diversified with regard to dietary trends^[9-11]. In relation to the above, the two following periods can be distinguished: 1950-1989 and 1990-2006. Within the first period, consumption of products of animal origin (meat and meat products, animal fat, milk and dairy products, butter, fish and eggs) as well as sugar and sugar products showed a growing trend. At the same time, consumption of cereals and potatoes had decreased. Growth of vegetable consumption had come to an end in the 1950s and 1960s. Fruit consumption was low, particularly compared to other countries, due to frequent fluctuations in crops and limited fruit import, which was insufficient to mitigate the effect of such fluctuations.

Within the second period, a reversal in these trends was noticeable, particularly in relation to consumption of butter and other animal fats, red meat as well as milk and dairy products. This period was also characterized by a significant increase in fruit consumption and, despite no increasing trend, also in relatively high vegetable consumption^[9-11].

The above-mentioned favorable phenomena are considered to have brought about a significant improvement in the health situation in Poland. It can be assumed that positive changes in diet have influenced the decline in overall mortality seen since 1992, and stabilization of total malignant cancer mortality as well as a significant decrease in morbidity.

MATERIALS AND METHODS

Data on gastric cancer incidence rates were derived from the National Cancer Registry administered by the Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology in Warsaw^[7,8]. They showed standardized gastric cancer incidence rates for men and women covering individual years between 1960 and 2006, excepting 1984, 1986, 1997 and 1998, for which no such data were available; in the case of the missing data for 1997-1998, the physicians' strike was the main contributing reason.

The source of information on the dietary pattern in the same time period was the database that was established and maintained for several decades by the National Food and Nutrition Institute^[9-11]. This database covers both

published and unpublished data derived from the national food balance sheets and shows major food quantities available for consumption per capita/year. They are converted into energy and nutrients with the use of a set of nutrient conversion factors developed at the institute and based on the national food composition tables^[12]. The resultant estimates show energy and nutrient amounts derived from food and available for consumption per capita/d.

In Poland, no data on average consumption of table salt per capita over the long term are available. Such data are available only for the period before World War II^[13]. After the war, this practice has not been continued. Data on salt consumption re-appeared, however, in 1998. They show average monthly consumption of salt per capita in households, which participated in budget surveys, carried out on annual basis using a sampling method that allowed for generalization of the results to all households in the country^[14]; these data were used for the analyses in the present study.

The features of the data on food quantities available for consumption and the derived estimates of the amounts of energy and nutrients made them particularly useful in the analysis of the trends over time, and to compare them with the trends in the health situation. In such a way, they were utilized in the present study. The study was focused on identification and measurement of the relationship between gastric cancer incidence rates and variables related to dietary pattern represented by the consumption of fruit, vegetables, vitamin C and kitchen salt. A trend in the equipment of Polish households with refrigerators was taken into consideration also as an important factor that affected perishable food quality and protected against nutrient loss.

Spearman's rank correlation coefficients (r_s) were estimated as a measure of the relationship between stomach cancer incidence rates and selected parameters.

RESULTS

Gastric cancer has a much higher incidence among men than women. In a base year of our analysis, i.e. 1960, the standardized rate for men amounted to 25.1/100 000, which exceeded twice the incidence rate for women (10.4/100 000)^[7]. For men, this rate reached a maximum level in 1970 and was 38% higher compared to 1960. In the same year, the maximum morbidity level was observed among women also; the rate was 39% higher than in 1960. The following years brought a decline in morbidity, and in 2006, the rates for men and women were approximately two times lower compared to the base year^[8].

Due to the fact that gastric cancer is one of two major types of cancer for which the risk is commonly agreed to be modified mainly by food and nutrition^[15], correlations between morbidity rates and consumption of certain food products and nutrients, which had both a positive and negative impact on this type of cancer, were analyzed. Due to reliable evidence that diets rich in fruit and vegetables protect against gastric cancer, these groups of products were analyzed first.

Figure 1 Fruit consumption and gastric cancer morbidity in 1960-2006.

Figure 2 Correlation between fruit consumption and gastric cancer morbidity. Spearman's rank correlation coefficient (r_s) for men: $r_s = -0.65$ ($P < 0.001$), and for women: $r_s = -0.66$ ($P < 0.001$).

At the beginning of the 1960s, fruit was of minor importance in the average dietary pattern in our country, which resulted from low domestic production levels and no imports (Figure 1)^[10]. In the following years, the role of fruit has been gradually increased due to its greater availability. A particular improvement has been observed within the past 12 years, i.e. after initiation of political, economic and social transformation, accompanied by an increase in domestic fruit production and import^[9,11]. Also, changes in retail price relations between fruit and other food products have stimulated consumer demand for fruit and this has had a great impact.

Spearman's rank correlation coefficient, which covered fruit consumption in 1960-2006 and gastric cancer morbidity in the same period, showed a high correlation between the increase in fruit consumption and decrease in morbidity rate (Figure 2).

Vegetables traditionally have been more prominent than fruit in the dietary pattern in Poland, which has resulted from their greater availability and, in consequence,

lower prices. Consumption of this group of products, similarly to fruit, has been subject to a growing trend, and in 2006 was almost 30% higher compared to 1960 (Figure 3)^[9-11].

Estimate of the Spearman's rank correlation coefficient showed a very high correlation between the trend in vegetable consumption and gastric cancer morbidity (Figure 4).

Increased consumption of both food groups resulted in the growth of vitamin C content in the diet, despite a reduction in potato consumption: total vitamin C content grew from approximate 100 mg/d in 1960 to 124 mg in 2006, and a rise in the proportion contributed by fruit and vegetables was noted (Figure 5)^[9-11]. Calculations made for the purposes of this study showed a very high correlation between increased vitamin C intake and decreased gastric cancer morbidity (Figure 6).

Reliable evidence that confirmed that storing food in refrigerators protects against gastric cancer^[15-17] has focused attention on the trend in their availability in Polish

Figure 3 Vegetables consumption and gastric cancer morbidity in 1960-2006.

Figure 4 Correlation between vegetable consumption and gastric cancer morbidity. Spearman's rank correlation coefficient (r_s) for men: $r_s = -0.70$ ($P < 0.001$), and for women: $r_s = -0.70$ ($P < 0.001$).

Figure 6 Correlation between vitamin C intake and gastric cancer morbidity. Spearman's rank correlation coefficient (r_s) for men: $r_s = -0.75$ ($P < 0.001$), and for women $r_s = -0.74$ ($P < 0.001$).

Figure 7 Equipment of households with refrigerators and gastric cancer morbidity in 1960-2006.

households. This equipment has become popular relatively late in our country. In 1960, there were only an average of 1.8 refrigerators per 100 households, which contrasts with western countries (Figure 7). The above situation has also related to the availability of refrigerators in the retail and catering trades.

Up to 1970, the number of refrigerators increased to approximate 37 per 100 households, although still only about one-third of the total number of households. Only at the beginning of the 1980s were > 90% of households equipped with refrigerators.

Estimates made for the purposes of this study demonstrated a very high correlation between the equipment of households with refrigerators and gastric cancer morbidity (Figure 8).

It has been proven that diets with high salt content have an unfavorable effect on gastric cancer. Consumption of table salt in 1929 amounted to 9.9 kg per capita (27 g/d), and decreased to 8.4 kg in 1938 (23 g/d). Despite the decrease,

this amount was still very high, which resulted mainly from its common usage as a preserving agent, which in turn, was determined by insufficient development of commercial food processing. Slow progress in this area in the early years after World War II allows us to assume that salt consumption was maintained at the same very high level observed in the pre-war period, and then decreased. According to the results of household budget surveys, table salt consumption in 2006 amounted to 0.25 kg/mo per person, that is, 3 kg/year (8.2 g/d)^[14]. This is almost threefold lower compared to consumption in 1938, but the fact that data from food balance sheets and budget surveys are not fully comparable should be mentioned. Despite this reservation, the decrease in salt consumption is unquestionable.

Data on total sodium chloride consumption, including both table salt and salt contained in food products (calculated on the basis of sodium content) showed that between 1999 and 2006, this consumption decreased significantly (Figure 9). At the same time, similar to previous

Figure 8 Correlation between equipment of households with refrigerators and gastric cancer morbidity. Spearman's rank correlation coefficient (r_s) for men: $r_s = -0.77$ ($P < 0.001$), and for women: $r_s = -0.80$ ($P < 0.001$).

Figure 9 Total salt consumption and gastric cancer morbidity in 1999-2006. Kitchen salt and salt calculated from sodium content in food products.

Figure 10 Correlation between total salt consumption and gastric cancer morbidity. Spearman's rank correlation coefficient (r_s) for men: $r_s = 0.97$ ($P < 0.001$), and for women: $r_s = 0.99$ ($P < 0.001$). Kitchen salt and salt calculated from sodium content in food products.

years, a regular decrease in gastric cancer morbidity has been recorded, both for men and women. Calculations

made for the purposes of this study demonstrated almost full correlation between the analyzed factors (Figure 10).

DISCUSSION

Our results enabled us to conclude that dietary factors have had a significant impact on gastric cancer risk in Poland. Their importance was underlined by the very high decrease in gastric cancer morbidity rate within the past few decades, despite a significant prevalence of *H. pylori* infection (73% of total population and 85-95% of adults aged > 25 years)^[6] and smoking, which are important, commonly accepted factors that increase gastric cancer risk.

Infection with *H. pylori* (first-class carcinogen) is considered to be an essential factor for initiation of a series of inflammatory lesions in gastric mucous membrane, from chronic superficial inflammation to pre-cancer lesions (atrophic inflammation, metaplasia, dysplasia), from which gastric cancer may develop^[18,19]. Gastric cancer grows as a result of complex interactions between genetic factors, virulence of *H. pylori* and environmental factors (dietary pattern, smoking). Our study shows that nutritional factors probably constitute one of the most important elements in these complex interactions.

For many years vitamin C has been considered as a significant factor for decreasing the risk of gastric cancer morbidity. As some studies have demonstrated, high concentrations of this vitamin in gastric juice and gastric mucous membrane can establish unfavorable conditions for development of *H. pylori* in the stomach, and its administration in high doses can even lead to eradication of this bacterium^[20]. It has been proven that vitamin C reduces growth of bacteria in culture, and the activity of urease produced by these bacteria^[21]. This enzyme enables *H. pylori* to survive in the acid environment of gastric juice, because it alkalizes the microenvironment by decomposition of urea to ammonium and carbon dioxide. However, it should be emphasized that the most important mechanism by which vitamin C can reduce the carcinogenic effect of *H. pylori* infection is destruction of free oxygen radicals that are produced in great amounts during infection^[22]. They damage the genetic material of gastric epithelial cells, which leads to mutations.

It can be assumed that increased vitamin C intake reduces the deficiency in vitamin C in smokers. Smoking, similar to *H. pylori* infection, results in lower concentration of vitamin C in gastric juice. This decrease is greater in smokers infected with *H. pylori* compared with non-smokers^[21]. An increase in consumption of fruit, vegetables and fruit juices could reduce the risk of gastric cancer development in smokers.

The impact of vitamin C on the decreased concentration of N-nitro compounds in the stomach in patients with chronic atrophic gastritis might also be significant^[23,24]. A previous study has proven that vitamin C has the ability to slow down the nitrosation process, which results in the presence of nitrosamines in the stomach; compounds that have a mutagenic effect and are considered as carcinogens^[25]. *In vitro* and *in vivo* tests have shown that ascorbic acid is the strongest inhibitor of this process^[26]. It reacts with nitrites to produce nitrogen oxides. It oxidizes itself to dehydroascorbic acid, which reduces the nitrosation reaction; details of which remain unknown. In addition,

ascorbic acid reduces transformation of nitrates to nitrites, which are direct substrates for nitrosamine production. The above is of significant importance in *H. pylori* infection, because, in the course of such infection, there is a significant increase in the concentration of nitrous compounds that are the source for nitrosamine production.

We found a very high correlation between decrease in gastric cancer morbidity and increase in dietary vitamin C content, which was related to growing consumption of fruit and vegetables. The purpose of many studies has been to examine the association between fruit and vegetable consumption and the incidence of gastric cancer. In a prospective study of Swedish women and men, consumption of vegetables was inversely associated with risk of gastric cancer after controlling for potential confounders^[27]. However, no significant association was observed between fruit consumption and gastric cancer risk. In a Canadian study that evaluated associations between dietary patterns and incident gastric cancer risk, dietary patterns characterized by increased consumption of fruit and vegetables were associated with lower risk^[28]. The association between vegetables and fruit consumption and gastric cancer risk was investigated in the Japan Public Health Center-based Prospective Study^[29]. That study suggested that vegetable and fruit intake, even in low amounts, was associated with a lower risk of stomach cancer. In contrast, a different Japanese study (Japan Collaborative Cohort Study) found no association between stomach cancer mortality and consumption of fruit and vegetables^[30]. The Netherlands Cohort Study found evidence for an inverse association between stomach cancer and the consumption of vegetables and fruit, however, it became weaker and non-significant in multivariate analysis^[31].

The nested case-control EPIC study is one of the largest prospective analyses of the association of nutrition with cancer. That study found no association between total vegetable intake or specific groups of vegetables and gastric cancer risk, except for the intestinal type, for which a negative association was found for total vegetable intake. There was no evidence of any association between fresh fruit intake and gastric cancer risk^[32]. Within the EPIC cohort, dietary vitamin C also showed no significant association with gastric cancer risk at any level of intake^[33].

In Poland, decreased salt consumption within the past few decades has probably also contributed to the decrease in gastric cancer morbidity. High concentrations of sodium chloride in the stomach facilitate damage and inflammation of mucous membranes, which leads to development of atrophic lesions, which are pre-cancerous lesions^[34]. A high-salt diet is considered to alter the viscosity of the protective mucous barrier and facilitate exposure to carcinogenic factors such as nitrates. Some information suggests that high salt intake in some way facilitates colonization with *H. pylori*^[35,36]. However, other studies have suggested that high salt intake *per se* does not promote *H. pylori* infection^[37].

According to the WCRF/AICR report, any effect of salt on stomach cancer is principally the result of regular consumption of salted or salt-preserved food, rather than salt as such^[15]. Some studies have investigated only salt added in cooking or at the table, but this is usually a small

proportion of total salt consumption. The results from such studies are liable to produce different conclusions. For example in the Netherlands Cohort Study, an inverse association was found between stomach cancer and salt added to hot meals^[38].

However many studies have confirmed the association between salt and/or salty food intake and the risk of stomach cancer. In a case-control study in Lithuania, a higher risk of gastric cancer was found in subjects who added salt to prepared meals or those who liked salty food^[39]. In a cohort study conducted in a rural area of Japan, the frequent intake of highly salted food remained as a significant risk factor for gastric cancer mortality^[40].

It is not entirely clear whether high salt intake and *H. pylori* infection are independent or interdependent risk factors. In a prospective study of a Japanese population, the effect of high salt intake on gastric carcinogenesis was strong in subjects who had atrophic gastritis and *H. pylori* infection^[37]. A study of 67 Chinese rural counties has suggested an interaction between high salt consumption and *H. pylori* infection^[41]. The significant correlation between *H. pylori* prevalence and stomach cancer mortality was only observed in counties with high levels of urinary sodium, and the significant correlation between urinary sodium and stomach cancer mortality only existed in counties with high *H. pylori* prevalence. In a case-control study in Korea, subjects with positive *H. pylori* infection and a high salt preference had a 10-fold higher risk of early gastric cancer than those without *H. pylori* infection and a low salt preference^[42].

In light of the above-mentioned results, the observed decrease in gastric cancer morbidity in Poland could be explained by the fact that, in the years when salt consumption was very high, the impact of *H. pylori* infection on carcinogenesis was significantly higher compared to the time in which dietary salt content was lower. Another factor that could have influenced the decrease in gastric cancer morbidity in Poland could be improvement in food storage, which has resulted from better equipment of households with refrigerators. This method of food storage protects fruit and vegetables against loss of vitamin C. It also prevents growth of microorganisms that can reduce nitrates contained in food products to nitrites.

The WCRF/AICR report has concluded that there is convincing evidence that use of refrigeration indirectly protects against gastric cancer^[15]. Some surveys have shown a significant association between the use of refrigeration and reduced risk of gastric cancer. According to a case-control study conducted in Northern Italy, 5% of all gastric cancer cases were attributable to less than 30 years use of an electric refrigerator^[16]. In a case-control study in Germany, the use of a refrigerator at home for ≥ 30 years compared to ≤ 24 years showed an inverse relationship with stomach cancer risk^[17]. However, in the Netherlands Cohort Study, no association was observed for duration of refrigerator use^[38]. Similarly, in a Polish case-control study, no association was found between stomach cancer risk and long-term refrigerator use^[43].

To summarize, our study shows that the effect of certain nutritional factors (increase in fruit and vegetable

consumption and related increase in dietary vitamin C and decrease in salt consumption) within the past few decades could have had a positive preventive impact on gastric cancer. The preventive effect probably depends on recognized and well-documented mechanisms reducing the risk of carcinogenesis, and perhaps on still unknown mechanisms. The prevention might also occur in populations that are exposed to other, strong, unfavorable environmental factors (carcinogens), such as *H. pylori* or smoking. Our results constitute a crucial argument for aiming to improve diet in the population through nutritional education, food production and mass catering.

COMMENTS

Background

In many countries, gastric cancer morbidity within the past few decades has reduced significantly. This phenomenon is most probably related to favorable changes in the dietary pattern in developed countries; mostly to increased consumption of fresh fruit and vegetables and decreased consumption of salt-preserved food. Lower gastric cancer morbidity is also related to lower prevalence of *Helicobacter pylori* (*H. pylori*) infection, which is considered to be essential for development of the majority of gastric cancer cases. However, Poland seems to be a particular case. Despite the fact that the percentage of people infected with *H. pylori* is unusually high, in 2006, gastric cancer morbidity rate was twofold lower compared to that in 1960.

Research frontiers

Gastric cancer ranks fourth in morbidity and second in mortality among malignant cancers worldwide. Despite the decline in incidence of this cancer, it is important to investigate the factors that could decrease or increase the risk of the disease. In this study, the relationship between diet and gastric cancer morbidity during the past few decades in Poland was evaluated.

Innovations and breakthroughs

The relationship between diet and cancer morbidity is mainly based on the results of case-control studies or prospective cohort studies. The present study was conducted using national data on diet that were derived from food balance sheets or household budget surveys.

Applications

The results suggest a positive influence of increased fruit and vegetable consumption, and related increase in dietary vitamin C content and reduced salt consumption, on the decline in gastric cancer morbidity. These results could be useful in preparation of dietary guidelines for cancer prevention.

Terminology

Metaplasia is the reversible replacement of one differentiated cell type with another mature differentiated cell type. Dysplasia is an expansion of immature cells, with a decrease in the number and location of mature cells. Urease is an enzyme that catalyzes the hydrolysis of urea into carbon dioxide and ammonia. Nitrosation is a process of converting organic compounds into nitroso derivatives.

Peer review

The manuscript is well written and underlines in an exhaustive manner the cause of the decline in gastric cancer incidence in Poland.

Abstract

AIM: To compare diverse endoscopic interventions in the management of occluded uncovered self-expanding metal stents (SEMSs) that had been placed for palliative treatment of unresectable malignant biliary obstruction.

METHODS: A retrospective review was undertaken

in 4 tertiary endoscopic centers to determine optimal management of different types of occluded SEMSs. The technical success of performed treatment in occluded SEMSs, the patency of the stent, the need for re-intervention and the financial costs of each treatment were analyzed.

RESULTS: Fifty four patients were included in the analysis; 21 received Hanaro, 19 Wallstent and 14 Flexus. For the relief of obstruction, a plastic stent was inserted in 24 patients, a second SEMS in 25 and mechanical cleaning was performed in 5 patients. The overall median second patency rates between second SEMSs and plastic stents did not differ (133 d for SEMSs vs 106 d for plastic stents; $P = 0.856$). Similarly, no difference was found between the overall survival of SEMS and plastic stent groups, and no procedure-related complications occurred. Incremental cost analysis showed that successive plastic stenting was a cost-saving strategy at least in Greece.

CONCLUSION: Insertion of uncovered SEMSs or plastic stents is a safe and effective treatment for occluded uncovered SEMSs; insertion of plastic stents appears to be the most cost-effective strategy.

management of occluded biliary uncovered metal stents: A multicenter experience. *World J Gastroenterol* 2011; 17(1): 98-104 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i1/98.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i1.98>

INTRODUCTION

The treatment of choice for patients with unresectable malignant biliary obstructions with survival time beyond 6 mo, is the insertion of self-expanding metal stents (SEMSs), either endoscopically or percutaneously^[1-4]. The main advantages of SEMSs over plastic stents in the palliation of malignant biliary strictures are their longer patency, greater complication-free survival, and cost-effectiveness, despite the initial cost; stent patency is critical because it significantly affects patient survival^[5-7]. However, despite their large lumen, SEMSs are prone to occlusion by tissue ingrowth or overgrowth and biliary sludge/debris^[8,9], resulting in recurrent jaundice or cholangitis; unlike plastic stents, the major disadvantage of SEMSs is the difficulty with repositioning or extraction once deployed^[10]. In contrast, plastic stents are less expensive and easier to remove or to change, although they have a shorter duration of patency and a higher risk of clogging and dislocation^[11]. There are currently limited data comparing the efficacy of different treatment options and reporting on the follow-up of SEMS occlusion; only 3 studies^[12-14] described the management of occluded Wallstents and one with different types of SEMSs^[15]. As SEMSs with different characteristics are more frequently used worldwide, we anticipate that occluded SEMSs of different types will be more commonly encountered in current clinical practice. Since experience and consensus regarding the optimal management of occlusion of different types of SEMSs is lacking, such data would be useful in clinical decisions. In this respect, in countries (e.g. Greece) where endoscopic retrograde cholangiopancreatography (ERCP) costs are very low compared to those with SEMSs, initial endoscopic retrograde biliary drainage by a plastic stent appears to be less expensive.

We conducted this study to compare diverse endoscopic interventions, but with significant cost difference, in the management of different types of occluded SEMSs by 4 tertiary level centers over a 10-year period.

MATERIALS AND METHODS

A retrospective study was performed between September 1999 and December 2008 in 4 tertiary endoscopic centers in Northern ($n = 3$) and Central ($n = 1$) Greece, in patients undergoing therapeutic ERCP for unresectable malignant distal biliary obstruction. Medical records were reviewed to determine the management and clinical course until death of patients with occluded SEMSs or the end of the study period (cut-off date, January 31, 2009). Additional information was also obtained by phone contact with the patients' referring physicians or relatives. The study was approved by the institutional re-

view boards of all participating hospitals.

We identified patients through the endoscopy database. Age, sex, indication for first SEMS placement, information from outpatient visits, diagnostic tests, interventions and treatments that patients underwent at the 4 centers were reviewed. Three types of uncovered SEMS had been used. The Wallstent (Boston Scientific, USA) original SEMS is considered the industry standard. It consists of a braided stainless steel mesh with soft barbed ends, is available in 40, 60 and 80 mm lengths, and 8 or 10 mm diameter, and costs 2200 Euros. The Flexus (formerly Mometherm and Luminex) (ConMed, USA) is a highly flexible nitinol stent with flared ends. The stent is made from a laser-cut single piece of nitinol, a nickel-titanium alloy that provides a high degree of flexibility, and the interstices of the lattice work are large enough to permit cannulation and, after dilatation, placement of another stent in "Y" configuration for palliation of hilar strictures and costs 1950 Euros. The Hanaro (MI Tech, Korea) is also made of nitinol and costs 1650 Euros. The interstices of the lattice are larger compared to those of a Wallstent and similar to those of the Flexus stent.

Stent occlusion was diagnosed when a patient developed symptoms and/or signs of cholangitis (fever, right upper quadrant tenderness, and/or a ≥ 2 -fold increase in bilirubin concentration above baseline at the post endoscopic retrograde biliary drainage period) or when bilirubin concentration increased ≥ 2 -fold above baseline after endoscopic retrograde biliary drainage, even without cholangitis symptoms and/or signs or an imaging study confirming biliary obstruction recurrence. The reason for stent occlusion was classified as predominantly tumor ingrowth, tumor proximal or distal overgrowth or obstruction from sludge/debris. Tumor ingrowth and proximal overgrowth were identified when cholangiography showed a stricture within the stent (Figure 1A) or a new stricture proximal to the stent, respectively. Distal overgrowth was diagnosed by direct endoscopic visualization (Figure 1B). Occlusion from debris or sludge was diagnosed when cholangiography showed filling defects within the lumen of the stent and cleaning of the stent produced passage of debris/sludge confirmed endoscopically. Management of occluded SEMSs included insertion of either an additional uncovered SEMS (Figure 1C and D) or a 10 Fr plastic stent (length 7, 9 or 10 cm) (Figure 1E) within the first or mechanical cleaning of the occluded SEMS. Mechanical cleaning was accomplished by flushing the obstructed SEMS with normal saline solution and repetitive passage of an inflated stone extraction balloon through the SEMS. Successful endoscopic management of stent occlusion was defined as a significant decrease in bilirubin level after the procedure and/or resolution of cholangitis or imaging improvement. First stent patency was defined as the time (in days) elapsed from the initial stent placement to the first occlusion that required one of the aforementioned interventions (placement of a second SEMS, plastic stent or mechanical cleaning). Second stent patency was defined as the time (in days) elapsed from the intervention to resolve the first occlusion to the first subsequent intervention or patient death with a

Figure 1 The reasons for stent occlusion (A, B) and the management of occluded self-expanding metal stents (C-E). A: Cholangiogram showing self-expanding metal stent (SEMS) occlusion by tumor ingrowth (arrow); B: Endoscopic view showing the distal end of a SEMS completely occluded by tumor overgrowth; C: Insertion of a new SEMS within the distally occluded stent; D: The second SEMS (arrows) was placed to resolve the occlusion by tumor overgrowth; E: Plastic biliary stent (arrowheads) passed through the occluded SEMS (arrows) that had been placed for palliation of pancreatic carcinoma.

patent stent. Overall second stent patency was defined as the time until a second SEMS became obstructed or the patient died with a patent SEMS, or, in the case of plastic stents, the time until no further stent exchanges could be performed or the patient died with a patent stent. For each treatment strategy to resolve the first SEMS obstruction (new SEMS, plastic stent or mechanical cleaning) we retrospectively counted the total amount of stents of either type used until the patient's death and calculated the cost per patient.

The incremental cost per patient (excluding the cost of the initial SEMS) was calculated by multiplying the number of stents of each type used by their price adding the cost of a balloon catheter (160 Euros) for each mechanical cleaning procedure, 70 Euros for daily hospital charges and cost of hospitalization because of cholangitis until the endpoint, and 150 Euros for each ERCP, according to the financial policy of the Greek National Health System.

Statistical analysis

The analysis was performed using the statistical program Statistical Package for Social Sciences (SPSS, version 13.0, Chicago, IL, USA). The estimation of patient survival and stent patency in the various groups of the study was performed using the Kaplan-Meier method, supplemented by the log-rank test used for comparisons of groups in relation to their survival and the duration of patency of the stents.

For the purpose of statistical data analysis the χ^2 test,

Fisher's exact test, the Mann-Whitney *U* test and the Kruskal-Wallis test were used. For comparisons between groups the Bonferroni adjusted *P*-value was used. Significance was set at $P < 0.025$.

RESULTS

Between September 1999 and December 2008, 219 patients with distal unresectable biliary obstruction received uncovered SEMSs of 3 different types, at 4 tertiary endoscopy centers. Hanaro stents were used in 74, Wallstents in 81 and Flexus stents in 64 patients. Sixty-three (28.8%) patients who underwent an ERCP because of SEMS (Hanaro 26, Wallstent 20 and Flexus 17) occlusion as determined by an increasing serum bilirubin level and/or an imaging study confirming recurrence of biliary obstruction were identified. Nine patients were excluded from the study because data were incomplete for analysis. There were 54 patients, 31 male, 23 female; median age 71 (range, 54-86 years) who were followed up until death and were included in the analysis. Of the 54 uncovered SEMSs that were occluded, 21 were Hanaro, 19 Wallstent and 14 Flexus stents (Table 1). Indications for SEMSs insertion were: pancreatic carcinoma in 28, cholangiocarcinoma in 10, papillary cancer in 8, metastatic lymphadenopathy in 7 and hepatocellular carcinoma in 1 case (Table 1). Hepatic metastases were present in 6 patients with metastatic lymphadenopathy (Table 1). The cause of first SEMS occlusion was ingrowth in 35 patients (64.8%), overgrowth

SEMS: Self-expanding metal stent.

in 14 patients (25.9%) and sludge/debris in 5 patients (9.3%) (Table 1). There was no difference in the etiology of occlusion between the 3 types of SEMS ($P = 0.773$) (Table 1). The first occlusion presented as cholangitis in 31 (57.4%) and painless jaundice in 23 (42.6%) patients, without any significant difference between the 3 types of SEMS ($P = 0.116$) (Table 1). A plastic stent had been placed before SEMS insertion in 9 patients (Table 1). The overall median (range) duration of the first SEMS patency was 242.5 (74-754) d. More specifically, for Hanaro stents the patency period was 248 (74-582) d, for Wallstents 176 (98-754) d, and for Flexus stents 228.5 (178-398) d, with

no significant difference between them ($P = 0.936$) (Table 1 and Figure 2A).

The outcomes and financial costs of interventions in the course of treatment of first SEMS occlusion are summarized in Table 2. From the 25 patients managed by a second SEMS insertion, 17 (68%) died after a median 116 (62-227) d without requiring further intervention, but 8 (32%) patients presented with re-occluded stents after a median 144 (26-331) d (Table 2). Those with re-occluded stents were treated with either plastic stent insertion (5 patients) or mechanical cleaning (3 patients) and 9 plastic stents were required in total (Table 2). From the 24

Figure 2 Patency of different stent (A-C) and survival after first self-expanding metal stent occlusion (D). A: Patency of 3 self-expanding metal stent (SEMS) until first occlusion; B: Patency of second SEMS vs overall plastic stent patency; C: Patency of second SEMS vs first plastic stent; D: Survival after first SEMS occlusion.

patients managed by plastic stent insertion, 13 patients (54.2%) died after a median 84 (40-179) d without requiring further intervention but 11 (45.8%) patients presented with re-occluded stents after a median 91 (60-74) d and were treated with plastic stent exchanges as many times as required, resulting in the insertion of 20 additional plastic stents (Table 2). In 2 patients, both with papillary tumors, stent exchange was unsuccessful on the third and fourth ERCP due to duodenal invasion by the tumor. They refused further intervention and died. Of the 5 patients who were treated by mechanical cleaning alone, only one (20%) required no further interventions and died 39 d later, while the other 4 (80%) presented with a second obstruction after a median 112 (21-180) d, treated by plastic stent insertion in 3 patients and SEMS insertion in one (Table 2). Two patients required an additional plastic stent. Overall, 31 patients (57.4%) required no further interventions until their death after a median 97 (39-227) d and 23 patients (42.6%) presented with a second obstruction after a median 96 (21-331) d (Table 2).

Apart from cholangitis, other complications including post-endoscopic retrograde biliary drainage bleeding, cholecystitis, pancreatitis or stent migration were not observed and there was no complication-related mortality.

Median overall patency of the second SEMS was 133 (range, 26-331) d and for successive plastic stenting 106 (range, 39-645) d ($P = 0.856$) (Figure 2B). However, when compared with the patency of the first plastic stent, which

was 88 (range, 40-179) d, the patency of the second SEMS was significantly longer ($P < 0.001$) (Figure 2C). Survival after the first occlusion was 142 (range, 39-870) d: 106 (range, 40-645) d for plastic stent placement, 177 (range, 60-870) d for a second SEMS, and 210 (range, 39-870) d for mechanical cleaning ($P = 0.180$) (Figure 2D).

Overall, the average cost was 1685 (380-3620) Euros per patient: 2170 (1870-3620) Euros per patient for insertion of a second SEMS at initial obstruction, 590 (380-2550) Euros per patient for insertion of a plastic stent at the same setting and 1020 (380-2550) Euros per patient treated by mechanical cleaning ($P < 0.001$) (Table 2).

DISCUSSION

Although endoscopic biliary stenting is accepted as the treatment of choice in patients with inoperable malignant biliary obstruction, and has been associated with reduced morbidity and short hospital stay, the major problem faced after endoscopic stent insertion is stent occlusion. Relative data on the optimal management of occluded SEMSs, are very limited to case reports and small retrospective studies^[12-15]. Our retrospective multicenter series includes the largest number of patients with occluded SEMSs managed endoscopically and is the second study to include different types of occluded SEMSs, thereby better depicting the daily practice worldwide. The initial occlusion rate of SEMSs in our series was 28.8%, consistent with that

of previous studies^[12,13]. Moreover, the occlusion rate was similar between the 3 types of SEMS (Hanaro 35.1%, Wallstent 24.7%, Flexus 26.6%), irrespective of the different design and material. The major cause of SEMSs occlusion was tumor ingrowth (64.8%), confirming the previous observations^[12-15]. This is thought to have been secondary to the growth of tumors within the interstices of the uncovered SEMSs. It is interesting that the rate of ingrowth was similar among the 3 types of SEMS (Hanaro 76.2%, Wallstent 63.2%, Flexus 50%) despite the larger interstices of mesh in Hanaro and Flexus stents.

Our finding that mechanical cleaning of sludge/debris is an ineffective treatment for occluded SEMSs, presenting with high re-occlusion rates in a short time (median: 94 d, range: 21-180) is compatible with other series^[12-14]. Notably, sludge is accrued because the stent surface allows for the adherence of proteins, glycoproteins, or bacteria and the bile flow is insufficient to clean the surface; stent clogging may be caused by microbiological adhesion and biliary stasis. In this regard, treatment with antibiotics and/or ursodeoxycholic acid to prevent clogging of biliary stents in patients with malignant stricture of the biliary tract, however, cannot be recommended routinely on the basis of the existing randomized clinical trials^[16].

Placement of either a second SEMS, independent of its type, or a plastic stent inside the occluded SEMS, was equally effective in resolving the jaundice or the symptoms of cholangitis, in accordance with other series^[12-15,17]. We found that the overall stent patency between second SEMSs and plastic stents for resolution of the first obstruction was not statistically different (133 d *vs* 106 d, $P = 0.856$) (Figure 2B). However, the patency of the second SEMS was significantly longer than that of the first plastic stent [133 (26-331) d *vs* 88 (40-179) d, $P < 0.001$] (Figure 2C), confirming the previous series. There was no difference on second SEMS patency between the 3 types of SEMS [Hanaro 144 (range, 42-331) d, Wallstent 97 (range, 26-243) days, Flexus 133 (range, 92-184) d] ($P = 0.943$). SEMS patency before the first occlusion was not predictive of the duration of the patency of the SEMS placed within the initial stent. This is in contrast to the observation of Katsinelos *et al*^[11] of a positive correlation between the patency of the first Wallstent and the period of patency of the second Wallstent, but in accordance with Bueno *et al*^[3] and Rogart *et al*^[13] studies.

Kaplan-Meier analysis in our study revealed that survival of patients with a second SEMSs was similar to that with plastic stents (Figure 2D). Interestingly, patients who underwent a second SEMS placement had fewer subsequent interventions compared with patients who had plastic stents inserted, but the difference was not statistically significant ($P = 0.33$).

Several studies^[3-10,12-15] have attempted to address the cost-effective management of occluded SEMS for malignant biliary obstruction. In our series, incremental cost analysis showed that the most cost-effective method appeared to be plastic stent insertion ($P < 0.001$) unlike the previous studies^[3,12,13], but similar to the study by Abraham *et al*^[11]. However, based on the special characteristics of

our health system, our financial analysis is disproportionately influenced by the direct cost of stents, either SEMS or plastic, over the cost of ERCPs and the indirect cost of hospitalizations related to stent occlusion. Therefore, the cost-effectiveness data from our study may not apply directly to countries with different health systems.

Our study has limitations similar to those of prior studies, with retrospective analysis and a relatively small number of patients having a variety of causes for SEMS placement and expected survival. Because the subjects were not randomly allocated, firm conclusions cannot be drawn until a prospective randomized and stratified study in larger numbers confirms our findings. However, data from such a study are unlikely to be available in the near future.

In conclusion, our findings support the use of plastic stents as the main intervention in patients with occluded SEMSs despite the increased number of subsequent ERCPs, because it is cost-effective, especially in health systems where the cost of expendables markedly exceeds that of the medical services.

COMMENTS

Background

Self-expandable metal stents (SEMSs) remain the treatment of choice for patients with unresectable malignant biliary stricture and survival time beyond 6 mo. However, despite their large lumen, they are prone to occlusion. The reported experience on the management of occluded SEMSs of different types is limited.

Research frontiers

Experience and consensus on the optimal management of occlusion of different types of SEMSs, which are used more frequently worldwide is lacking. However, such data are useful in clinical decisions about the treatment of occluded biliary uncovered SEMSs.

Innovations and breakthroughs

The present retrospective multicenter study investigated the diverse endoscopic interventions in the management of different types of occluded SEMSs. The findings support the use of a cost-effective plastic stent as the main intervention in patients with occluded uncovered SEMSs.

Applications

These findings are of potential financial importance especially in healthy systems where the cost of SEMSs markedly exceeds the medical service costs.

Terminology

Uncovered SEMSs are occluded by tissue ingrowth or overgrowth and biliary sludge/debris, resulting in recurrent jaundice or cholangitis.

Peer review

In this good retrospective study, the authors found that a cheap plastic biliary stent was as good as an expensive SEMS for the treatment of occluded SEMSs.

Abstract

AIM: To evaluate the effects of ginger on gastric motility and emptying, abdominal symptoms, and hormones that influence motility in dyspepsia.

METHODS: Eleven patients with functional dyspepsia were studied twice in a randomized double-blind manner. After an 8-h fast, the patients ingested three capsules that contained ginger (total 1.2 g) or placebo, followed after 1 h by 500 mL low-nutrient soup. Antral area, fundus area and diameter, and the frequency of antral contractions were measured using ultrasound at frequent intervals, and the gastric half-emptying time was calculated from the change in antral area. Gastrointestinal sensations and appetite were scored using

visual analog questionnaires, and blood was taken for measurement of plasma glucagon-like peptide-1 (GLP-1), motilin and ghrelin concentrations, at intervals throughout the study.

RESULTS: Gastric emptying was more rapid after ginger than placebo [median (range) half-emptying time 12.3 (8.5-17.0) min after ginger, 16.1 (8.3-22.6) min after placebo, $P \leq 0.05$]. There was a trend for more antral contractions ($P = 0.06$), but fundus dimensions and gastrointestinal symptoms did not differ, nor did serum concentrations of GLP-1, motilin and ghrelin.

CONCLUSION: Ginger stimulated gastric emptying and antral contractions in patients with functional dyspepsia, but had no impact on gastrointestinal symptoms or gut peptides.

Effect of ginger on gastric motility and symptoms of functional dyspepsia. *World J Gastroenterol* 2011; 17(1): 105-110 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i1/105.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i1.105>

INTRODUCTION

Functional dyspepsia is a clinical syndrome that is characterized by chronic or recurrent upper abdominal pain or discomfort in the absence of underlying organic disease

that can explain the symptoms^[1]. Pharmacological therapy for patients with functional dyspepsia remains unsatisfactory^[2]. The results of controlled trials have generally been disappointing, and only small benefits relative to placebo have been found with histamine H₂-receptor antagonists^[3], proton-pump inhibitors^[4], and *Helicobacter pylori* eradication^[5]. In addition to poor efficacy, pharmacological agents (e.g. cisapride) are associated with a risk of adverse effects.

Herbal medicine might be an attractive alternative based on the perception of its natural approach and low risk of adverse effects. However, the lack of standardization of herbal ingredients has limited the number of rigorous clinical studies available.

Ginger (*Zingiber officinale*) has been used to treat a number of medical conditions, including those affecting the digestive tract^[6,7], such as dyspepsia, flatulence, nausea and abdominal pain. However, the mechanisms responsible for its beneficial effects are not well understood. Yamahara *et al.*^[8] and Micklefield *et al.*^[9] have reported that gastrointestinal motility is enhanced by ginger and its active constituents, but they did not measure gastric emptying. We previously have shown that ginger increases the frequency of antral contractions and accelerates gastric emptying of a low-nutrient liquid in healthy volunteers^[10].

There have been few studies on the effects of ginger in patients with functional dyspepsia. We hypothesized that acceleration of gastric emptying in patients with functional dyspepsia might be accompanied by a reduction in upper gastrointestinal symptoms, and that its action on gastric motility could be mediated *via* increased secretion of ghrelin^[11] or motilin^[12], or by suppression of glucagon-like peptide-1 (GLP-1)^[13].

MATERIALS AND METHODS

Patients

Eleven patients diagnosed with functional dyspepsia on the basis of Rome III criteria were invited to take part. Patients had persistent or recurrent upper abdominal pain or discomfort, which was characterized by the presence of one or more of early satiety, postprandial fullness, bloating, and nausea. Symptoms had been present for at least 6 wk within the preceding 6 mo, without an identifiable structural or biochemical abnormality to which they could be attributed^[1]. Symptoms of retrosternal pain, burning, and regurgitation were considered features of gastroesophageal reflux disease, rather than of functional dyspepsia. Therefore, patients who had predominantly reflux-related symptoms were excluded. Patients were screened by physical examination, laboratory tests (blood picture, fasting glucose, and liver-function tests), abdominal ultrasonography, and upper gastrointestinal endoscopy to exclude other causes of dyspepsia, and none was taking any medication known to affect gastric motility.

Each subject was studied on two afternoons, separated by at least 7 d, in double-blind randomized order. Following a fast of 8 h for solids and liquids, the patients ingested three capsules that contained a total of 1.2 g ginger root powder (Ginger Root; Nature's Way Products

Inc., Springville, UT, USA), or three identical placebo capsules that contained starch, together with 50 mL water. One hour later, they consumed 500 mL chicken and corn soup (United Kanboo, Taipei, Taiwan), which contained 118.6 kcal (2.6 g protein, 2.6 g fat, 21.2 g carbohydrate). The soup was boiled and subsequently cooled to 37°, and was consumed over 5 min ($t = -5$ to 0 min). All patients underwent trans-abdominal ultrasound to measure antral area, fundic area and diameter^[14], and antral contractions at intervals using an Aloka SSD-2000 CL Ultrasound Machine (Aloka, Tokyo, Japan) with a 3.5-MHz annular array probe. Antral contractions were defined as > 50% change in antral area compared to the relaxed area ($\Delta A/A$)^[15], and their frequency as the number of contractions during 5-min periods beginning at 5, 30, 60 and 120 min after soup ingestion. A questionnaire with visual analogue scales (VASs)^[16] for symptoms pain, nausea, abdominal discomfort, bloating and abdominal fullness, was administered at 10-min intervals between $t = -10$ and 90 min. Grading was made on a 100-mm unmarked line between "no symptoms" at one end and "excruciating symptoms" at the other. Venous blood was sampled at $t = -10$, 30, 60 and 90 min for measurement of blood glucose and plasma peptides. Blood glucose concentrations were determined immediately using a portable blood glucose meter (MediSense Companion 2 meter; MediSense Inc., Waltham, MA, USA). The accuracy of this method has been confirmed using the hexokinase technique^[17]. The remainder of the samples was collected into ice-chilled EDTA-treated tubes that contained 400 KIU/mL aprotinin. Plasma was separated and samples stored at -70°C for subsequent analysis of GLP-1, ghrelin and motilin concentrations, using ELISA. Ghrelin was measured by a commercial ELISA kit (Phoenix Pharmaceuticals Inc., Burlingame, CA, USA); intra- and interassay coefficients of variation (CV) were < 5% and < 9%, respectively; motilin and GLP-1 were also measured by a commercial ELISA kit from Phoenix Pharmaceuticals.

Statistical analysis

Gastric half-emptying time (T₅₀) was defined as the time for antral area to decrease to half the maximum increase above baseline, and was calculated by linear interpolation between time points^[10]. The values on the two study days were compared using the Wilcoxon signed rank test. Antral area, fundic area and diameter, frequency of antral contractions and gastrointestinal sensation scores were compared using repeated measures ANOVA. Results are shown as median and range for T₅₀, and mean \pm SD for other variables. $P < 0.05$ was considered significant.

RESULTS

All subjects tolerated the study well.

Antral area and gastric emptying

Gastric emptying was more rapid after ginger than placebo [T₅₀: 12.3 (8.5-17.0) min *vs* 16.1 (8.3-22.6) min, P

Figure 1 Antral area after ginger and placebo in patients with functional dyspepsia who consumed 500 mL low-nutrient soup between -5 and 0 min. Gastric emptying was more rapid after ginger than with placebo [T50: 12.3 (8.5-17.0) min vs 16.1 (8.3-22.6) min, $P \leq 0.05$]. There was a trend for smaller antral area after ginger ($P = 0.13$); data are means \pm SE, $n = 11$.

Figure 2 Frequency of antral contractions after ginger and placebo in patients with functional dyspepsia. There was a trend for a higher frequency of antral contractions after ginger ($P = 0.06$). Data are means \pm SE, $n = 11$.

≤ 0.05]. There was a trend for smaller antral area after ginger, although this did not reach statistical significance ($P = 0.13$) (Figure 1).

Antral contractions

There was a trend for more antral contractions after ginger compared to placebo ($P = 0.06$) (Figure 2).

Figure 3 Fundus area and diameter in patients with functional dyspepsia. There was no difference in either measure between ginger and placebo. Data are means \pm SE, $n = 11$.

Fundic area and diameter

Fundus dimensions did not differ between the two study days (Figure 3).

Gastrointestinal sensations

Soup ingestion was associated with increased fullness and bloating, and decreased hunger and appetite scores, but without any difference between ginger and placebo. There were no significant changes in nausea or abdominal discomfort from baseline, or any differences in these sensations between study days (Figure 4).

Gastrointestinal peptide concentrations

There were no differences in plasma concentrations of motilin, ghrelin, or GLP-1 between the two study days (Figure 5).

DISCUSSION

In this study, we demonstrated that ginger increased the rate of gastric emptying in patients with functional dyspepsia when compared to placebo, and that this was associated with a trend for an increased frequency of gastric antral contractions, but no change in dimensions of the fundus. This was consistent with our previous study in healthy volunteers^[10]. Despite more rapid emptying, ginger

Figure 4 Visual analogue scale scores for gastrointestinal symptoms after ginger and placebo in patients with functional dyspepsia who consumed 500 mL low-nutrient soup between -5 and 0 min. There was no difference in any sensation between the two study days. Data are means \pm SE, $n = 11$.

had no effect on gastrointestinal symptom scores in our patients.

About 40% of patients with functional dyspepsia have abnormally delayed gastric emptying^[18], and prokinetic medications have often been used in the treatment of this condition^[19]. We did not select our dyspeptic patients on the basis of delayed gastric emptying, and as a group, their rate of gastric emptying was comparable to the healthy volunteers that we had studied previously using the same technique^[10]. It is possible that ginger could have improved symptoms in a more selected group of patients who had delayed emptying, and in particular, those with an abnormally wide antrum, a feature that has been associated particularly with bloating^[20].

It is also possible that the lack of symptomatic improvement with ginger was related to the low-nutrient nature of the soup meal. Although this meal was associated with increases in fullness and bloating, the changes were modest. A meal with a higher caloric load, particularly one that contained more lipid^[21], might have provoked more symptoms, from which it would be possible to demonstrate an improvement with ginger. Similarly, although we used the same dose of ginger as Lien *et al.*^[22], who reported a reduction in nausea induced by circularvection, our subjects reported low ratings for nausea throughout the study, thus, it would be difficult to demonstrate an effect of ginger if one existed. Stadelmann *et al.*^[23] have reported that a combination of peppermint oil and ginger extract

Figure 5 Plasma concentrations of glucagon-like peptide-1, motilin and ghrelin in patients with functional dyspepsia. There was no difference in the concentrations of any hormone between the ginger and placebo groups. Data are means \pm SE, $n = 11$. GLP-1: Glucagon-like peptide-1.

for 4 wk improved gastrointestinal symptom scores when compared to placebo, but the relative contribution of each active agent is unclear.

The mechanism by which ginger could enhance antral contractions and gastric emptying is not clear. We could not demonstrate any modulation of gut-derived hormones that are known to affect gastric motility, including motilin, ghrelin or GLP-1. It would be of interest to examine whether ginger affects the plasma concentrations or the actions of cholecystokinin, because this hormone is reported to be elevated in patients with functional dyspep-

sia^[21]. Abdel-Aziz *et al*^[24] have reported the potential for ginger to act on the 5-HT₃ receptor ion-channel complex, by binding the serotonin binding site, and Shibata *et al*^[25] have reported that a component of Dai-Kenchu-Tou (which contains ginger) stimulated gastric motility through cholinergic and 5-HT₃ receptors in dogs. The limitation of this study is that our observation was limited to 90 min of gastric emptying, and a single dose of ginger would not have been adequate for treatment of dyspepsia symptoms in patients with functional dyspepsia, especially as this disease is chronic and recurrent. Therefore, it is difficult to draw any clear conclusion. Further proper clinical trials of several weeks' treatment with ginger capsules seem to be necessary before starting trials in subgroups of patients with functional dyspepsia.

In summary, we confirmed that the acceleration of gastric emptying by ginger that we initially demonstrated in healthy volunteers extended to patients with functional dyspepsia. Further studies could be indicated in specific subgroups of patients (e.g. those with predominant bloating or nausea, or those with known delayed gastric emptying), to determine whether this can be a useful therapeutic approach.

COMMENTS

Background

Pharmacological therapy for patients with functional dyspepsia remains unsatisfactory. There have been few studies on the effects of ginger in patients with functional dyspepsia.

Research frontiers

Ginger (*Zingiber officinale*) has been used to treat a number of medical conditions, including those that affect the digestive tract. In this study, the authors demonstrated that the effect of ginger could be a potential mechanism for mediating gastric motility.

Innovations and breakthroughs

The authors had previously shown that ginger increases the frequency of antral contractions and accelerates gastric emptying of a low-nutrient liquid in healthy volunteers. However, the actual effect of ginger on patients with functional dyspepsia is still unknown, and this is believed to be the first study to explore this issue. Furthermore, current *in vivo* studies suggest that ginger is an effective therapy for patients with functional dyspepsia.

Applications

By understanding how ginger works on gastric motility, this study might represent a future strategy for therapeutic intervention in patients with delayed gastric emptying.

Terminology

The acceleration of gastric emptying by ginger that we initially demonstrated in healthy volunteers extends to patients with functional dyspepsia.

Peer review

Overall, this preliminary study of 11 patients with functional dyspepsia seems well designed. The data were appropriately analyzed and indicate that ginger has an impact on symptoms and gastric emptying. A large study needs to be undertaken to demonstrate its efficacy convincingly.

ferred mice, protection against CCl₄-induced liver injury was reflected by significantly decreased serum ALT, AST, MDA and TNF- α levels compared to those in control mice ($P < 0.01$ to 0.05 in a dose-dependent manner). Histological observations also revealed that hepatocyte necrosis, hemorrhage, vacuolar change and hydropic degeneration were apparent in mice after CCl₄ administration. In contrast, the damage was markedly attenuated in the Kal gene-transferred mice. The expression of hepatic fibrogenesis marker transforming growth factor- β 1 was also reduced in the pKal transferred mice.

CONCLUSION: Intramuscular electrotransfer of plasmid pKal which was formulated with PLG significantly alleviated the CCl₄-induced oxidative stress and inflammatory response, and reduced the liver damage in a mouse model.

Abstract

AIM: To investigate the effect of transgenic expression of kallistatin (Kal) on carbon tetrachloride (CCl₄)-induced liver injury by intramuscular (im) electrotransfer of a Kal-encoding plasmid formulated with poly-L-glutamate (PLG).

METHODS: The pKal plasmid encoding Kal gene was formulated with PLG and electrotransferred into mice skeletal muscle before the administration of CCl₄. The expression level of Kal was measured. The serum biomarker levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), malonyldialdehyde (MDA), and tumor necrosis factor (TNF)- α were monitored. The extent of CCl₄-induced liver injury was analyzed histopathologically.

RESULTS: The transgene of Kal was sufficiently expressed after an im injection of plasmid formulated with PLG followed by electroporation. In the Kal gene-trans-

INTRODUCTION

Gene therapy refers to a therapeutic approach by introduction and expression of genetic material in particular cells

or tissues. Over the past two decades, great efforts and abundant resources have been invested into the development of an effective, safe and relatively long-lasting gene therapy strategy. Great success has been made recently so that gene therapy was elected as one of the breakthroughs of 2009 by Science^[1]. In order to achieve the goal of therapy, a carrier, or “vector”, is the key required to deliver the genetic material into the target cells. Whilst exciting progress in the development of gene therapy have been made, a safe and efficient method of gene delivery has been elusive thus far. Initially, a number of viral vectors were chosen, owing to their high efficiency in gene transfer. Unfortunately, they also bring added risks to the patients, even though their virulence was genetically disabled. Non-viral vectors avoid the risks. However, lower transferring efficiency has limited their clinical use thus far. To boost efficacy of non-viral gene therapies several delivery methods have been under investigation. Electro-gene therapy is one of the most efficient non-viral approaches for gene therapy^[2-4]. It has already been considered a safe method because naked DNA is not immunogenic and plasmid DNA does not have the risk of insertional mutagenesis^[5]. Moreover, DNA electrotransfer can be accomplished using devices that have already been used on human cancer patients to deliver cytotoxic molecules such as bleomycin and cisplatin to solid tumors by electrochemotherapy^[6,7]. Thus all elements are available for safe and widespread use of this efficient technology and for implementing the use of genes for medical purposes^[8]. To further improve the transfer efficiency, plasmids were formulated in poly-L-glutamate (PLG) prior to intramuscular (im) injection and electroporation. Such a combined approach significantly elevated transgene expression in myofibers^[9].

Kallistatin (Kal) that belongs to the serine protease inhibitor family is widely expressed in organs such as the liver, kidneys, and blood vessels. Previous studies have demonstrated kallistatin to be a potent anti-inflammatory agent. Kallistatin administration by gene delivery attenuates oxidative stress, apoptosis, inflammation, and organ damage in animal models^[10-13]. These findings indicate that kallistatin may play an important role as an antioxidant in maintaining oxidative balance and preventing oxidative endothelial and tissue injury.

Oxidative stress is a state of redox imbalance caused by increased reactive oxygen species (ROS) generation and decreased antioxidant capacity. Administration of carbon tetrachloride (CCl₄) is an established experimental model of severe toxic liver injury involving generation of oxidative stress and is frequently used for the screening of anti-hepatotoxic and/or hepatoprotective activities of drugs^[14]. Antioxidants and anti-inflammatory agents can play a role in liver protection by scavenging active oxygen and free radicals and neutralizing lipid peroxides.

In the present study, we first investigated the feasibility of improving the expression of the transgene after introducing the PLG formulated plasmid into mouse skeletal muscle by electroporation, then investigated the therapeutic efficacy of Kal expression in the circulation on CCl₄-induced liver injury. After CCl₄ had been injected into mice to induce liver injury, evaluations of liver marker

enzymes, the extent of oxidative stress and liver histology were performed, revealing that elevated levels of human Kal were effective in alleviating oxidative stress and protecting liver against CCl₄-induced liver damage.

MATERIALS AND METHODS

Materials

Sodium salt of PLG (15-50 kDa) was purchased from Stsien Co (Nanjing, China); EndoFree plasmid Giga kit was purchased from Qiagen GmbH (Hilden, Germany); DNA Delivery Device was purchased from TERESA Healthcare Sci-Tech Company (Shanghai, China); reporter lysis buffer and β -galactosidase enzyme assay system was purchased from Promega (Madison, USA); BCA Protein Assay Kit was purchased from Pierce (Rockford, USA); Quantikine kit was purchased from R&D Systems Inc (Minneapolis, USA).

Experimental animals

Balb/c mice (6- to 8-wk-old females, Slaccas Company, Shanghai) were used throughout this study. The animals were maintained on a 12/12 h day/night cycle at room temperature 18-24°C. Food and water were provided *ad libitum*. The Animal Studies Ethics Committee of Huaqiao University approved all the experiments reported here.

Plasmid DNA

The expression plasmid pLac encoding β -galactosidase under the control of the cytomegalovirus immediate-early promoter, and the pKal under the control of the same promoter and driving a coding sequence for the human Kal, were constructed as reported previously^[15] and kept in our laboratory. The integrity of the sequence was determined by DNA sequencing. Plasmids were transformed and expanded into *E. coli* strain JM-109 and purified with the EndoFree plasmid Giga kit in accordance with the supplier's protocol. DNA was dissolved in Endofree TE buffer and kept frozen in aliquots at a concentration of 2 mg/mL.

Formulation of plasmid DNA

Formulation was made by mixing the plasmid DNA with the sodium salt of PLG before adjusting the NaCl concentration to 0.15 mol/L with a 5 mol/L stock solution. The plasmid and polymers were allowed to incubate at room temperature for 15 min prior to adding NaCl for tonicity adjustment. The pH of the formulation was adjusted using dilute hydrochloric acid or sodium hydroxide to 7.0. Sterility of the formulation was achieved by sterile filtration through sterile 0.22 μ m pore size filters, and was injected immediately after preparation.

Im injection

Mice were anesthetized by intraperitoneal (ip) injection of pentobarbital sodium at a dose of 30 mg/kg body weight. The plasmid was injected directly into the tibialis anterior (TA) muscles of the mice using a 500 μ L syringe. The injected volumes were 50 μ L for each side of the TA muscles.

In vivo electroporation

Two minutes after the im injection of plasmid DNA, an electrical field was applied to the area around the injection. Two silver needle electrodes were inserted 3 mm apart into the TA muscles and 6 electric pulses were applied using the TERESA DNA delivery device. The electric pulses were 50 ms in duration at a voltage of 60 V.

β-galactosidase assay

The TA muscles treated with plasmid pLac were excised at different time points post delivery, and were analyzed for β-galactosidase expression. The samples were collected immediately after euthanizing the animals. The samples were frozen by keeping in liquid nitrogen and then stored at -70°C until further use. These samples were weighed, minced into small pieces and homogenized with reporter lysis buffer using a homogenizer. The tissue homogenate was then centrifuged at 15000 g and 4°C for 15 min and the clear supernatant was separated for further analysis. The β-galactosidase activity was measured using the β-galactosidase enzyme assay system. The total protein content of the samples was measured with the BCA protein assay kit. Finally, the enzyme activity in the samples was expressed as milliunits/mg of protein.

CCl₄ treatment

The mice were divided into the following groups: (1) control; (2) CCl₄; (3) pLac (50 μg) + CCl₄; (4) pKal (100 μg) + CCl₄; (5) pKal (50 μg) + CCl₄; and (6) pKal (25 μg) + CCl₄. Each group was composed of 8 mice. CCl₄ was dissolved in corn oil vehicle (1:1, v/v). The mice received a single ip injection with the CCl₄ preparation at a dose of 0.8 mL/kg body weight to induce liver injury 6 d after plasmid administration. Control mice received an ip injection of an equal volume of corn oil alone. The mice were sacrificed and the blood samples were collected *via* the inferior vena cava 24 h after CCl₄ treatment. The livers were sampled immediately afterwards.

Measurement of serum biomarker levels

The serum concentration of kallistatin and tumor necrosis factor (TNF)-α were measured with the Quantikine Immunoassay kit following the manufacturer's instructions. Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities were measured using a Hitachi 7020 biochemical analyzer. Lipid peroxidation was detected by measuring the serum level of malonyldialdehyde (MDA) spectrophotometrically, the end product derived from the breakdown of polyunsaturated fatty acids and related esters, with the classical thiobarbituric acid method^[16].

Histological analysis

The excised liver was fixed in buffered formalin, embedded in paraffin, cut into 5 μm-thick sections, and examined with hematoxylin eosin (HE) staining. Pathology was scored in a blinded manner by a trained pathologist by counting the number of necrotic or inflammatory foci per microscopic field^[17]. Five fields were checked at 200 × magnification as follows: 0 (absent), 1 (< 2foci), 2

(2-4 foci), and 3 (> 4 foci). The inflammatory response and muscle damage arising from plasmid injection and electroporation was evaluated by analysis of HE-stained slides of TA muscles.

Immunohistochemical analysis

After deparaffinization in xylene and rehydration in graded ethanols, endogenous peroxidase activity of the paraffin-embedded slides was blocked by incubation with 3% hydrogen peroxide (H₂O₂) at 37°C for 10 min. The slides were then treated twice in a microwave oven for 5 min in citrate buffer (pH 6.0) at high power to retrieve antigens. After blocking with goat serum at 37°C for 30 min, the specimens were incubated with the rabbit polyclonal antibodies (primary antibody) against transforming growth factor (TGF)-β1 overnight at 4°C, followed by incubation with biotinylated anti-rabbit antibody at 37°C for 30 min and then horseradish peroxidase conjugated streptavidin at 37°C for 10 min. The slides were stained using 3,3'-diaminobenzidine-H₂O₂, counterstained with hematoxylin, and examined under a light microscope.

Statistical analysis

Data are given as means ± SD. Analysis of variance was performed to test the significance; *P*-values were considered significant when less than 0.05.

RESULTS

Transgene expression

The transgene expression in the TA muscle was enhanced by the PLG formulation (Figure 1). The expression of β-galactosidase in the animals that received plasmid formulated in 6 mg/mL PLG reached its peak level at 5 d post-delivery and was 5-fold higher than that in the mice who received naked plasmid. Thus PLG could enhance the expression of an electroporated plasmid injected im in muscles.

The electroporation of an increasing dose of plasmid pKal (25-100 μg) into TA muscle led to a dose-dependent increase in human Kal plasma concentration, detected on the 7th day after plasmid injection (Figure 2). The level of serum Kal in the 50 μg group was almost 2-fold higher than that in the 25 μg group, but was only slightly lower than in the 100 μg group, suggesting there was a saturation of expression such that the relationship of plasmid dose and transgene expression level was not linear.

Protective effects on CCl₄-induced liver damage

The mice induced with a single dose of CCl₄ developed hepatic damage as compared with the normal control group (*P* < 0.01), as shown by marked changes in ALT and AST activities in the serum (Table 1). Injection of pKal resulted in a significant reduction in ALT and AST activities with each of the 3 doses compared with the CCl₄ alone group (*P* < 0.01-0.05).

Effects on serum TNF-α level

TNF-α is one of the pro-inflammatory cytokines which

Figure 1 Time-course study of the effect of the poly-L-glutamate formulation on transgene expression of pLac in the tibialis anterior muscle after electroporation transfer. The plasmids were transferred with (square) and without (triangle) poly-L-glutamate (PLG) formulation. The values shown are mean \pm SD, $n = 8$.

Figure 2 Dose-dependent kallistatin concentrations in the serum responded to intramuscular electrotransfer of a plasmid pKal in poly-L-glutamate formulation. The values shown are mean \pm SD, $n = 8$. Kal: Kallistatin.

are early mediators of tissue damage and repair. Mouse serum TNF- α concentration was measured to evaluate the influence of Kal on CCl₄-induced inflammatory responses (Table 1). CCl₄ exposure markedly stimulated TNF- α releasing in comparison with the control group ($P < 0.01$). The serum TNF- α levels in the 3 pKal + CCl₄ groups were significantly lower than that in the CCl₄ group ($P < 0.01-0.05$) in a dose-dependent manner. These results clearly suggested that the CCl₄-induced inflammatory response could be suppressed by pretreatment with pKal.

Effects on hepatic oxidative stress

The generation of ROS and increase of hepatic lipid peroxidation are important features of chronic liver diseases. To examine the effects of Kal on hepatic oxidative stress, liver tissue was homogenized to determine the hepatic MDA level 24 h after CCl₄ administration (Table 1). MDA is the end product of lipid peroxidation; its level indirectly reflects the degree of oxidative stress. The hepatic MDA concentration in the group treated with CCl₄ was only significantly higher than in the control group ($P < 0.01$). The 3 pKal pretreatment groups significantly attenuated the elevated MDA compared with CCl₄ and pLac + CCl₄ groups ($P < 0.01-0.05$).

Table 1 Serum biomarker levels affected by transgene of kallistatin on carbon tetrachloride-induced liver injury ($n = 8$, mean \pm SD)

Group	ALT (U/L)	AST (U/L)	MDA (nmol/mg protein)	TNF- α (pg/mL)
Control	37 \pm 7	48 \pm 7	0.46 \pm 0.10	2.9 \pm 2.1
CCl ₄	134 \pm 26 ^b	183 \pm 20 ^b	1.15 \pm 0.29 ^b	28.1 \pm 11.8 ^b
pLac + CCl ₄	123 \pm 18 ^b	181 \pm 28 ^b	1.07 \pm 0.33 ^b	28.8 \pm 9.4 ^b
pKal (100 μ g) + CCl ₄	95 \pm 24 ^d	121 \pm 35 ^d	0.48 \pm 0.27 ^d	12.4 \pm 4.0 ^d
pKal (50 μ g) + CCl ₄	98 \pm 28 ^c	143 \pm 37 ^c	0.65 \pm 0.25 ^d	14.5 \pm 3.5 ^d
pKal (25 μ g) + CCl ₄	101 \pm 32 ^c	151 \pm 37 ^c	0.82 \pm 0.21 ^c	17.3 \pm 4.8 ^c

^b $P < 0.01$ vs control group; ^c $P < 0.05$, ^d $P < 0.01$ vs CCl₄ group. ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; MDA: Malonyldialdehyde; TNF: Tumor necrosis factor; CCl₄: Carbon tetrachloride.

Histological analysis

To analyze the extent of liver injury, liver sections were stained with hematoxylin and eosin (Figure 3). No apparent damage was found in the liver sections from the control mice (Figure 3A). In contrast, extensive damage was detected in the sections from CCl₄ and pLac + CCl₄ groups (Figure 3B and C). Hepatocyte necrosis was the predominant histopathologic lesion, and the affected livers displayed hemorrhage, vacuolar change, hydropic degeneration of hepatocytes and infiltration of inflammatory cells. All these lesions in the pKal + CCl₄ groups were significantly attenuated (Figure 3D-G).

Immunohistochemical detection of TGF- β 1

In liver tissue from the control group, the expression of TGF- β 1 was negative in liver cells and weakly positive in stromal cells of the portal area (Figure 4A). In the CCl₄ and pLac + CCl₄ groups, the expression of TGF- β 1 was strongly positive in the cytoplasm of both hepatic parenchymal cells and stromal cells (Figure 4B and C). Compared with the CCl₄ group, the expression of TGF- β 1 was significantly reduced in the pKal treatment groups (Figure 4D-F).

Treatment-associated muscle damage

The safety of plasmid injection and electroporation was evaluated by im injection of 50 μ g pLac followed by electroporation. Fifty μ L saline injections were used as a control. The injected TA muscles were harvested on day 7, fixed, dehydrated, and analyzed by HE staining. The representative images of the muscle samples in various groups are shown in Figure 5. The treatment induced low inflammatory responses at the injection site. No necrosis was observed for any of the groups.

DISCUSSION

The transfer ability of the recombinant plasmid can be improved by the combination of proper formulation, im injection, and electroporation. To improve the efficacy and reproducibility of plasmid delivery, protective, interactive, non-condensing polymers and non-ionic block co-polymers, consisting of ethylene oxide and propylene

oxide monomers, have been developed^[18,19]. Both systems have increased distribution of DNA within the muscle tissue and augmented transgene expression compared with DNA in saline. Negatively charged polymers, such as PLG, could also improve the expression of genes delivered by im injection and electroporation, and elevated levels of secreted gene products in multiple *in vivo* models have been reported^[18,20]. Although the mechanism by which PLG enhances transgene expression is unknown, based on our data we concur with other authors' findings that the formulation of PLG can (1) disperse plasmids throughout the electrical field at the time of electroporation; (2) protect plasmids from nuclease degradation; and (3) facilitate intracellular uptake and trafficking of transcriptional active plasmid in muscle cells^[9].

The technique of electroporation has been used for nearly 30 years as a means of introducing DNA into cells *in vitro*, and is now widely used for transfection of plasmids into different tissues *in vivo*. More recently, electroporation has been used for the treatment of cutaneous and

subcutaneous tumors in humans and its safety was proved clinically^[21]. Our results also showed that electroporation treatment-associated muscle damage was minimal. These experiences have paved the way for the clinical use of gene electroporation in humans. The DNA electroporation is reaching the clinical stage as several clinical trials to transfer genes in tumors and in muscle are ongoing^[22,23].

Using an intramuscular electrotransfer method, we demonstrated that the PLG formulation of pKal provided a satisfactory expression level of Kal. The expressed Kal possesses antioxidant properties and the secreted Kal could contribute to protection of liver against CCl₄-induced damage in a mouse model, as indicated by both histological observation and biochemical evaluation. The Kal gene-transferred mice demonstrated a significant reduction in the level of serum peroxidation marker MDA, with a concomitant improvement in the activities of the hepatic antioxidative defense system. This suggests that Kal is able to protect against hepatic cellular membrane oxidative damage *via* a free radical scavenging property.

Figure 4 Immunohistological analysis of transforming growth factor- β 1 (brown) in the mice livers treated with carbon tetrachloride. A: Control; B: Carbon tetrachloride (CCl₄); C: pLac + CCl₄; D: pKal (100 μ g) + CCl₄; E: pKal (50 μ g) + CCl₄; F: pKal (25 μ g) + CCl₄.

Figure 5 Inflammatory response and muscle damage arising from plasmid injection and electroporation. A: Saline; B: pLac.

Our results also exhibited the anti-inflammatory activity of Kal. TNF- α is a proinflammatory cytokine produced predominantly by macrophages and plays a key role in the host defense response to injury and infection. The expression of Kal in the circulation inhibited the increase in TNF- α production from Kupffer cells following CCl₄ injection, due to its anti-inflammatory activity.

The efficiency of most protein drugs, whose half-life *in vivo* is generally shorter than chemical drugs, markedly depends on their plasma kinetics. Taking the advantages of gene transfer, a steady-state therapeutic level of the recombinant protein in the circulation could be maintained for a long time. This is especially important in the treatment of chronic disease or the prevention of disease. Our results showed that the constant expression level of Kal in the pKal group with the lowest dosage was already sufficient to prevent CCl₄-induced liver damage. These data provided compelling and mechanistic evidences for the importance of Kal in regulation of liver injury.

TGF- β 1 in the liver is secreted by hepatocytes, Kupffer cells, stellate cells (HSC), endothelial cells and infiltrating mononuclear cells, and plays a pivotal role in hepatic fibrogenesis. Among many inflammatory cytokines involved in liver fibrosis, TGF- β 1 appears to be the most important, because (1) there is higher TGF- β 1 expression in activated HSC; (2) TGF- β 1 has potency in upregulating extracellular matrix expression; (3) there is higher expression of TGF- β receptors on HSC; and (4) TGF- β 1 increases the expression of tissue inhibitor of metalloproteinases-1. Therefore, many antifibrosis strategies focus on reducing the secretion of TGF- β 1 and blocking the TGF- β signal transduction pathway to reduce TGF- β 1-induced HSC proliferation. Our results clearly demonstrated the inhibitory effect of Kal expression on the hepatic TGF- β 1 level in an experimental animal model of liver damage induced by CCl₄.

In conclusion, the data of this study provided the evidence that the combination of PLG formulation, im injection and electroporation of plasmid encoding the Kal gene is an effective gene therapeutic method in a CCl₄-induced liver damage model. The beneficial effects of this technique to reduce the expression of TGF- β 1 also make

it a promising strategy for the treatment of hepatic fibrosis in the future.

COMMENTS

Background

Acute and chronic hepatic injuries cause high morbidity and mortality worldwide. Although the pathogenesis is not fully understood, it is clear that reactive oxygen species play a key function in the pathological changes in the liver. Kallistatin is a member of the serine proteinase inhibitor superfamily and was shown to have pleiotropic effects, including anti-oxidative stress, anti-inflammation and angiogenesis. Studies show it can attenuate oxidative stress, apoptosis, inflammation, and organ damage. However, the short half-life of kallistatin protein *in vivo* limits its efficiency. In contrast, long-term transgene expression can be achieved by gene therapy.

Research frontiers

Gene therapy has already proven to be a novel and promise modality in reducing liver injury, but is still in its infancy, and ideal gene delivery systems for gene transfer with high and prolonged gene expression, as well as less cytotoxicity or immunogenicity remain to be developed. Viral vectors are so far the most efficient tools for delivery of genes into mammalian cells. Drawbacks such as cost, immunogenicity, and difficulties in manufacture have shifted the interest towards nonviral vectors. However, the low efficiency of gene transfer hampers the development of nonviral vectors severely.

Innovations and breakthroughs

In order to boost the efficacy of non-viral gene therapy delivery, DNA electrotransfer technology was applied and the plasmid formulation was also optimized. The kallistatin expression *in vivo* was increased greatly; the animal model showed that the gene therapy strategy was effective in alleviating oxidative stress and protecting the liver against carbon tetrachloride (CCl₄)-induced liver damage.

Applications

Although additional studies are necessary to translate this technology into clinical trials in humans, the results provide a rationale to develop new pharmacological strategies in the clinical management of patients with acute and chronic liver injury.

Terminology

Electro-gene therapy: a method involving injection of a naked plasmid encoding a marker gene or a therapeutic gene, followed by *in vivo* electroporation, where short electrical pulses are applied to the injected tissue. The gene expression of the injected plasmid was reported to increase more than 100-fold.

Peer review

The paper described the improvement of the intramuscular electrotransfer of a kallistatin-encoding plasmid by using poly-L-glutamate in plasmid formulation. The ensuing increased presence of kallistatin in plasma protected those transfected mice from the hepatotoxic effects of a single dosage of CCl₄. In general, results are sound and their interpretation is correct.

Abstract

AIM: To identify the risk factors and three single nucleotide polymorphisms (SNPs) of *NOD2/CARD15* gene in inflammatory bowel disease (IBD) of the population in Zhejiang, China.

METHODS: A case-control study was conducted using recall questionnaire to collect data on demographic, socioeconomic, lifestyle characteristics and dietary behaviors from 136 determined IBD patients and 136 paired healthy controls. COX regression method was used to screen the statistically significant risk factors for IBD. The polymorphisms of *NOD2/CARD15* gene *Arg702Trp*, *Gly908Arg* and *Leu1007fsinsC* were genotyped and further compared between 60 patients with IBD and 60 healthy controls by polymerase chain reaction and restriction fragment length polymorphism.

RESULTS: IBD occurred primarily in young and middle-aged people. The mean age for IBD patients was 42.6 years. The ratio of males to females was 1.23:1. COX regression indicated a higher statistical significance in milk, fried food and stress compared with the other postulated risk factors for IBD. None of the pa-

Wang ZW, Ji F, Teng WJ, Yuan XG, Ye XM. Risk factors and gene polymorphisms of inflammatory bowel disease in population of Zhejiang, China. *World J Gastroenterol* 2011; 17(1): 118-122 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i1/118.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i1.118>

INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC) are the two main types of idiopathic inflammatory bowel disease (IBD) whose etiology is multifactorial and still vague. Currently, the development of IBD is considered to have a close relationship with immunology, genetics, environment and infection. The incidence of IBD in Western populations increased during the past few decades with an estimated incidence of 0.35%-1.00% for CD and 0.10%-1.00% for UC^[1]. *NOD2/CARD15* is the first verified predisposing gene of CD where three *NOD2* variants *Arg702Trp*, *Gly908Arg* and *Leu1007fsinsC* were found to be associated with CD in the Caucasian populations^[2,3]. Nevertheless, these single nucleotide polymorphisms

(SNPs) were not found to predispose to CD in Japanese and Hong Kong populations^[4,5], leaving controversies on their exact role in CD. The number of patients with IBD has been increasing in China, but only a few studies have investigated the risk factors in IBD. Moreover, association between *NOD2* gene and the development of IBD has seldom been evaluated in the Chinese population^[6]. Therefore, the purpose of this study was to identify the risk factors by case-control studies and determine whether the *NOD2* variants are associated with IBD in the population of Zhejiang, China.

MATERIALS AND METHODS

Subjects

One hundred and thirty six patients with IBD and 136 age and sex-matched healthy controls were recruited from the First Affiliated Hospital of Zhejiang University, Jinhua Central Hospital, Ningbo Medical Treatment Center, Lihuili Hospital and Taizhou Hospital of Zhejiang Province between January 2005 and December 2008. The age of IBD patients (84 UC and 52 CD) ranged from 18 to 85 years. Written informed consent was obtained from all the cases and controls. Blood samples were collected from 60 patients (32 UC and 28 CD) and 60 healthy controls randomly. IBD was diagnosed based on the clinical, radiographic, endoscopic and histologic criteria.

Questionnaire

Each subject received a questionnaire to obtain demographic data. The questionnaire also contained items specifically related to IBD: education background, heredity, occupation condition (occupation classification and stress), habitat condition during the past 5 years (drinking water and toilet), infection, appendectomy, measles, oral contraceptive use, estrogen replacement, dietary habits (vegetarian diet or carnivorous diet), smoking history, tea drinking, and alcohol, milk, fried food and spicy food intake. All questionnaires were checked for completeness, and doubtful responses from both patients and healthy controls were confirmed upon return of the questionnaire.

Genotyping

DNA was isolated from peripheral blood using the Genomic DNA Isolation Kit (Sangon, Shanghai, China). All polymerase chain reaction (PCR) assays were performed in a 25 μ L volume reaction. Three single nucleotide polymorphisms (SNPs) of *NOD2/CARD15* gene were amplified by specific primers (Table 1)^[7] under the following conditions: an initial denaturation at 95°C for 5 min, followed by 35 cycles of denaturing at 94°C for 20 s, annealing at 60°C (*Arg702Trp*), 55°C (*Gly908Arg*) or 58°C (*Leu1007fsinsC*) for 30 s and extension at 72°C for 1 min, and final incubation at 72°C for 7 min. PCR products were electrophoresed in a 2% agarose gel and visualized by ethidium bromide staining.

Genotyping for *Arg702Trp*, *Gly908Arg* and *Leu1007fsinsC* was performed using polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP):

Table 1 The primers for *NOD2/CARD15* gene

SNPs	Primers	Length of products (bp)
<i>Arg702Trp</i>	Forward 5'-CTTCCTG-GCAGGGCTGTGTC3' Reverse 5'-CATGCAC-GCTCTTGGCCTCAC3'	176
<i>Gly908Arg</i>	Forward 5'-AAGTCTGTAAT-GTAAAGCCAC3' Reverse 5'-CCCAGCTCCTCCCTCTTC3'	380

SNPs: Single nucleotide polymorphisms.

a 10 μ L aliquot of the product was digested with an appropriate restriction enzyme. The tubes were incubated at 37°C for 4 h, and then transferred to 65°C for 20 min. After digestion, fragment sizes for carriers of the polymorphic alleles decreased, resulting in the presence of different fragments (Table 2). Products were electrophoresed in a 15% polyacrylamide gel and visualized by silver nitrate staining.

Statistical analysis

Semi-quantitative data were analyzed using COX regression to calculate relative risk (RR) and their 95% confidence interval. Frequencies and susceptibilities of mutations among CD, UC and controls were compared based on χ^2 or Fisher exact test. All data were analyzed in SPSS (version 13.0), where *P* value of 0.05 or less was considered statistically significant in all cases.

RESULTS

A total of 272 subjects were enrolled in the study who all completed the questionnaires. The mean age for IBD patients was 42.6 years and the ratio of males to females was 1.23:1. The result showed that milk, fried food intake and stress were risk factors for IBD in both univariate and multivariate logistic regression analysis (Tables 3 and 4). The number of cases of infection, appendectomy, oral contraceptive use, and estrogen replacement was too small for statistical analysis, so the data of these variables were not shown in the tables.

Electropherogram of the amplified DNA fragments is shown in Figure 1. PCR-PFLP analyses showed that *Arg702Trp*, *Gly908Arg* and *Leu1007fsinsC* alleles of 60 IBD patients and 60 healthy controls were all wild type. None of the patients with IBD and healthy controls had heterozygous or homozygous SNPs variants.

DISCUSSION

The etiology and pathogenesis of IBD have been and continue to be intensely investigated. Accumulating evi-

dences strongly suggest that it is mediated immunologically and that the inflammatory process is influenced by environmental and host factors. In this study, we found a higher prevalence of IBD in young and middle-aged people which may be associated with the strong gastrointestinal immune function and intense immune response. The prevalence of CD was higher in males (36 cases) than in females (16 cases), but the prevalence of UC was similar among males (39 cases) and females (45 cases), which is consistent with other studies.

Many environmental factors may be involved in the pathogenesis of IBD, including: dietary habits, cigarette smoking, appendectomy, oral contraceptive use, infection and so on. However, the epidemiologic evidence for an etiologic role of these potential risk factors in IBD is inconsistent. In this study, there was a strong evidence for an increased risk of developing IBD associated with stress, milk intake and fried food. Stress increases gut muscle tone and intestinal transit time. Several studies reported that people with functional gastrointestinal disorders had significantly more behavioral and emotional symptoms than

**Figure 1** Amplified fragments of *NOD2/CARD15* gene. M: DNA marker; A: Amplified fragment of Arg702Trp; B: Amplified fragment of Leu1007fsinsC; C: Amplified fragment of Gly908Arg; D: Negative control.

healthy people^[8]. UC patients are most likely to experience the problems like mood and anxiety^[9]. Some hormones released during stress (e.g. corticotrophin-releasing factor) can promote intestinal inflammation and alter visceral sensitivity when released locally in the gut^[10]. Epidemiological studies showed that the prevalence of IBD varies among populations. The immigrants had a different incidence of IBD within a generation. It has been suggested that different food antigens play a significant role. The present study confirms an increased risk of developing IBD associated with milk intake. IgE-mediated allergy to cow's milk proteins is common in the children and adults who experience repeated gastrointestinal symptoms, and often is the first manifestation of food allergy. Cow's milk protein allergy may induce the abnormal immune response of digestive tract that increases the relative risk of IBD. In epidemio-

logic studies, high-temperature cooking methods have been associated with the formation of carcinogenic substances such as heterocyclic amines, acrylamide and polycyclic aromatic hydrocarbons^[11]. These products have been associated with endothelial dysfunction and inappropriate immune responses, which results in the development of IBD and intestinal cancer.

Cigarette smoking that has been reported as a risk factor for IBD in many studies might even have beneficial effects on the course of UC, but exacerbates the course of CD. The potential mechanisms involved in this dual relationship may include the effects of nicotine administration on inflammatory cytokine, changes in blood flow and gut permeability^[12]. In this study, cigarette smoking was not significantly associated with the development of IBD. Studies showed that IBD patients were more likely to be white collar and urban residents with high educational background. Infection and oral contraceptive use were considered to increase the risk of developing IBD, whereas vegetarian diet, tea drinking, spicy food intake and appendectomy decreased the risk. In this study, no significant association was found between these factors and IBD.

Monozygotic twin concordance, familial predisposition, and segregation analyses have shown that genetic factors confer susceptibility to IBD. *NOD2/CARD15* gene locates on chromosome 16q12, encoding a member of the Apat-1/Ced-4 superfamily of apoptosis regulator that is expressed in monocytes. *NOD2/CARD15* gene is involved in the recognition of lipopolysaccharide and subsequent activation of necrosis factor- κ B, and disturbs the activation of the innate immune system by bacterial antigens. *NOD2/CARD15* gene mutation or deletion induces the abnormal innate immune response, which is important for immunological protection against intestinal microbes and may contribute to the development of IBD. Increased *CARD15* was detected in mononuclear and epithelial cells of colon in CD patients^[13,14]. Hugot *et al.*^[2] showed that a frame shift variant and two missense variants were associated with CD. This result is in accordance with the studies in different populations^[3,7]. In our study, common *NOD2* variants associated with increased susceptibility to CD in Caucasian populations were not verified in the Zhejiang population. It is conceivable that the *NOD2* variants present in Caucasian patients are rare or nonexistent in the Zhejiang population and not detected in our limited population sample. Our results are in agreement with those studies in Asian patients^[4,5]. This diversity of linkage analyses may arise from the heterogeneity of the disease and differences in genetic background of the population studied.

Human epidemiologic studies combine both parts of the typical risk assessment process into a single study by assessing the degree of exposure and the association with the risk of disease in a single study. The present study supports that intestinal environmental and genetic factors are vital for the pathogenesis of IBD. However, the heterogeneity among the small number of studies limited the ability to draw conclusions. Further studies using a larger cohort of patients with IBD are warranted to identify the risk factors and gene susceptibility to IBD.

COMMENTS

Background

Crohn's disease (CD) and ulcerative colitis (UC) are the two main types of idiopathic inflammatory bowel disease (IBD) whose etiology is multifactorial and still vague. The development of IBD is considered to be closely related to immunology, genetics, environment and infection. *NOD2/CARD15* is the first verified predisposing gene of CD in the Caucasian populations.

Research frontiers

The etiology and pathogenesis of IBD have been and continue to be intensely investigated. Three *NOD2* variants *Arg702Trp*, *Gly908Arg* and *Leu1007fsinsC* were found to be associated with CD in the Caucasian populations, but not in Japanese and Hong Kong populations. In this study, the authors identified the risk factors by case-control study and determined whether the *NOD2* variants are associated with IBD in China's Zhejiang population.

Innovations and breakthroughs

Only a few studies have investigated the risk factors of IBD in China. Moreover, the association between *NOD2* gene and the development of IBD has seldom been evaluated in the Chinese population. This study demonstrated that milk, fried food and stress are associated with increased risk of IBD, and the common variants in *NOD2/CARD15* gene are not associated with IBD in the Zhejiang population.

Applications

NOD2 variants present in Caucasian patients may be rare or nonexistent in the Zhejiang population. Milk, fried food and stress are the potential risk factors for IBD.

Terminology

NOD2/CARD15 gene locates on chromosome 16q12, encoding a member of the Apat-1/Ced-4 superfamily of apoptosis regulator that is expressed in monocytes. *NOD2/CARD15* gene is involved in the recognition of lipopolysaccharide and subsequent activation of necrosis factor- κ B, and disturbs the activation of the innate immune system by bacterial antigens. *NOD2/CARD15* gene mutation or deletion can induce the abnormal innate immune response.

Peer review

This is an interesting paper looking at 136 IBD patients and paired healthy controls from the Zhejiang population comparing risk factors, and SNP analysis of *NOD2/CARD15* in 60 patients and paired controls. No patients had variants in the *NOD2/CARD15* gene by the methods used. Milk, fried food and stress were cited as potential risk factors. This work adds to the existing literature on *NOD2*, and supports the finding of lack of association with IBD in oriental populations.

Abstract

AIM: To compare the long-term outcome of percutaneous vs surgical radiofrequency ablation (RFA) for hepatocellular carcinoma (HCC) in dangerous locations.

METHODS: One hundred and sixty-two patients with HCC in dangerous locations treated with percutaneous or surgical RFA were enrolled in this study. The patients were divided into percutaneous RFA group and surgical RFA group. After the patients were regularly followed up for a long time, their curative rate, hospital stay time, postoperative complications and 5-year local tumor progression were compared and analyzed.

RESULTS: No significant difference was observed in curative rate between the two groups (91.3% vs 96.8%, $P = 0.841$). The hospital stay time was longer

and more analgesics were required while the incidence of bile duct injury and RFA-related hemorrhage was lower in surgical RFA group than in percutaneous RFA group ($P < 0.05$). The local progression rate of HCC in dangerous locations was significantly lower in surgical RFA group than in percutaneous RFA group ($P = 0.05$). The relative risk of local tumor progression was 14.315 in percutaneous RFA group.

CONCLUSION: The incidence of severe postoperative complications and local tumor progression is lower after surgical RFA than after percutaneous RFA.

INTRODUCTION

Hepatocellular carcinoma (HCC) is currently the fifth most common malignant neoplasm in the world^[1], causing more than 500 000 deaths every year^[2]. HCC is prevalent in Asia and Africa and its incidence has steadily increased in European and American populations^[3,4]. Theoretically, the best treatment of HCC is orthotopic liver transplantation (OLT) which provides the opportunity for its cure^[5], but the scarcity of donors limits this treatment.

In the last two decades, local ablative therapy has become a safe and effective procedure for small HCC, of which radiofrequency ablation (RFA) is considered the most promising one^[6]. It was reported that RFA for small HCC provides a comparable survival time and local tumor control after surgical resection^[7,8], and may also be used as a bridge therapy for liver transplantation^[9-11]. RFA is minimally invasive with a lower complication rate and a shorter hospital stay time than hepatectomy^[12,13].

Although the indication of RFA is much wider than that of surgical resection for HCC, tumors in some circumstances are reported^[14-18] not quite suitable for RFA, such as a central nodule near the porta hepatis due to the risk of injuring major bile ducts, a nodule near large vessels due to a heat sink effect-induced incomplete ablation, a peripheral nodule near extrahepatic organs due to the risk of alimentary tract perforation or pleural effusion caused by heat injury.

In our institute, tumor location is not simply regarded as a contraindication of RFA. This retrospective study was designed to compare the long-term outcome of percutaneous and surgical RFA for HCC in these so-called dangerous locations. To the best of our knowledge, it is the first study comparing the efficacy of surgical and percutaneous RFA for HCC in dangerous locations of the liver.

MATERIALS AND METHODS

Diagnostic criteria

Diagnosis of HCC was made according to the diagnostic criteria for HCC recommended by the European Association for the Study of the Liver^[19], which was based on ultrasound-guided biopsy, or the concordant classical dynamic radiological features of HCC in two radiologic techniques, or one radiologic technique showing typical features of HCC together with an elevated α fetoprotein (AFP) level over 400 ng/mL.

Definition

Tumor in dangerous locations^[18] was defined as a lesion (\leq 0.5 cm in diameter) near large vessels such as a primary or secondary branch of the portal vein, the base of hepatic veins, or the inferior vena cava (IVC), or as a lesion (less than 0.5 cm in diameter) near extrahepatic organs measured on radiological images.

A curative treatment^[19] was defined as no residual viable tumor tissue within the treatment zone confirmed by a 4-wk-afterward-performed spiral triphasic enhanced CT after a complete ablation of the lesion assessed by intraoperative ultrasonography (IOUS).

Local tumor progression^[20] was defined as the appearance of viable tumor tissue that was contiguous with the area completely ablated during follow-up.

Inclusion criteria and enrollment

In our institute, a curative RFA is usually expected for patients conforming to the Milan criteria for liver transplantation. The inclusion criteria in this study included patients with a confirmed diagnosis of HCC or a solitary HCC (\leq

5 cm in diameter) or up to 3 nodules ($<$ 3 cm in diameter), liver function of Child-Pugh class A or B, a prothrombin time of less than 5 s, a HBV-DNA-PCR quantitation of less than 10^5 copies/mL, but without extrahepatic metastasis or obvious vascular invasion, previous or simultaneous malignancies or evident bleeding tendency (a platelet count $> 50 \times 10^9$ /L or correctable by transfusion, no previous treatment of HCC, and those suitable and willing to be treated with RFA).

The study was performed according to the guidelines of the Helsinki Declaration. A written informed consent was obtained from each patient before intervention. Between February 2003 and February 2007, RFA was performed for 794 consecutive HCC patients in West China Hospital. Of these patients, 513 were diagnosed as primary HCC, 484 of them met the inclusion criteria. Of these 484 patients, 162 had at least one nodule in dangerous locations.

Follow-up

Patients were followed up at a three month interval after treatment. Abdominal ultrasonography and helical computer tomography (CT), serum AFP measurement and liver function tests were performed during each visit. When intrahepatic recurrence was suspected, spiral CT or magnetic resonance imaging (MRI) was performed. When extrahepatic metastases were suspected, thoracic CT and bone scintigraphy were performed. Local tumor progression was specifically noticed as the endpoint in this study.

Statistical analysis

Differences in the surgical and percutaneous RFA groups were analyzed by the unpaired *t* test for continuous variables and by the χ^2 test or continuity correction method for categorical variables. Local tumor progression curves were plotted with the Kaplan-Meier method and compared by the log-rank test. Relative prognostic significance of the variables in predicting local tumor progression was assessed with univariate and multivariate Cox proportional hazards regression models. All variables with their $P < 0.05$ by univariate comparison were subjected to multivariate analysis. Results of multivariate analysis were presented as relative risk (RR) with corresponding 95% confidence intervals (CI). Statistical analysis was performed using the SPSS 13.0 statistical software (SPSS Company, Chicago, Illinois, USA). All statistical tests were two-sided and differences were considered when $P < 0.05$.

RFA procedure

Equipments: All RFA procedures were performed on an inpatient basis by surgeons from the Department of Hepato-biliary-pancreatic Surgery using a commercially available system (Radionics, Cool-Tip System, Burlington, MA, USA), single/clustered needle electrode(s) with a 2 cm or 3 cm exposed tip and ultrasound guidance (Vivid4, GE, USA; iU22, Philips, USA). Clustered electrodes were used systematically for lesions ($>$ 3 cm in diameter).

Percutaneous RFA: General anesthesia was employed, 2-4 grounding pads were attached to the thighs of pa-

tients and the electrode was inserted into the lesion according to a route assessment via ultrasound. The needle tip was inserted to the bottom of the tumor (i.e. the most distal border from the skin puncture site) in the first session to avoid gas formation between non-ablated lesion and ultrasound transducer. At the time of subsequent RFA sessions, the electrode position was determined via IOUS scrutiny. The ablation subsequence was always from “bottom” to “top” to provide a clear, real-time ultrasound image. The electrode was inserted at different sites and overlapping ablations were performed until the entire lesion was ablated as determined by IOUS.

Assessment of ablation: After measurement of the baseline impedance, generator output power was gradually increased from 80 W to 200 W, with a peristaltic pump infusing cold saline into the electrode lumen to maintain the tip temperature below 20°C. The timer was usually set to 12 min for each session. Impedance was synchronously monitored with the system. Session in the same site was repeated until the impedance increased at least 10 Ohms over baseline and became stable. The electrode was heated to 90-100°C before it was drawn back in order to eliminate seeding cancer cells and prevent bleeding. Treatment was continued until complete ablation features were achieved in IOUS.

RFA in dangerous locations

Percutaneous RFA: The route of electrode insertion should be carefully considered on ultrasound scrutiny. When the tumor was in segment VII, close to the diaphragm, the electrode was inserted through the right pleural cavity of patients. Saline was infused into the right pleural cavity to compress the right lobe of the lung, then the electrode reached the target under the ultrasound-guidance and percutaneous RFA was achieved through an artificial serothorax. A thoracic close drainage was needed for 2 d after therapy.

Surgical RFA: A right subcostal incision with a midline extension was chosen. Extensive dissociation of the liver was usually performed from the ligaments and adhesions to other organs, such stomach, colon or kidneys and large vessels. The route of surgical RFA was assessed by IOUS on the liver surface. The distance between the tumor and other vulnerable organs or vessels could be enlarged when the operator rotated the liver.

Ablation timing: The time of RFA was usually irregular in the dangerous locations, RFA was stopped as soon as the ultrasound detected microbubbles generated by RFA reaching the distal border of the assumed area. An experienced operator managed most injuries to adjacent organs and structures as well as the heat sink effect from large vessels with RFA.

Assessment of response

Response was assessed according to the modified European Association for the Study of the Liver criteria^[19].

Table 1 Demographic parameters of patients undergoing percutaneous and surgical radiofrequency ablation

Parameters	Patients undergoing percutaneous RFA (n = 63)	Patients undergoing surgical RFA (n = 93)	P value

Non-hepatitis B virus (HBV) & hepatitis C virus (HCV): Patients who were negative for HBV and HCV antibody but not for anti-HBs. RFA: Radiofrequency ablation; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; AFP: α fetoprotein; TB: Total bilirubin; PLT: Platelet; PT: Prothrombin time; ALB: Albumin.

Spiral triphasic enhanced CT was performed one month after RFA. Residual viable tumor was diagnosed if an enhanced area was noted within the treatment zone. If RFA was repeated, another CT was performed four weeks later to assess the response to RFA. If residual viable tissue of the tumor still existed, RFA was considered a failure and the patient was treated with transcatheter hepatic arterial chemoembolization (TACE).

Potential conflict of interest

This study did not receive any support from industry or private corporations.

RESULTS

Of the 482 patients, 162 had at least one nodule in the dangerous locations (156 had a lesion and 6 had 2 lesions in the dangerous locations) and 320 had HCC in the ordinary location. Of the 162 patients with HCC in dangerous locations, 34 had their diagnosis made by biopsy and 128 were diagnosed non-invasively, 69 received percutaneous RFA and 93 underwent surgical RFA. The demographic parameters of patients who underwent percutaneous and surgical RFA are listed in Table 1. A significant difference was found in HBV/HCV-infection and serum AFP level ($P < 0.05$). The tumor locations and adjacent vessels and organs in patients who underwent percutaneous and surgical RFA are shown in Table 2. The mean follow-up time of patients who underwent percutaneous and surgical RFA was 28.4 ± 14.7 mo (range 3-81 mo) and 31.6 ± 24.1 mo

$P = 0.640$ by Pearson χ^2 test for segment location and $P = 0.054$ by Pearson χ^2 test for adjacent vessels or organs. Lesion between segments was registered at the major location. *n*: Lesion number; RFA: Radiofrequency ablation; PH: Porta hepatis; RHV: Right hepatic vein; MHV: Middle hepatic vein; LHV: Left hepatic vein; IVC: Inferior vena cava; GB: Gall bladder.

(range 6–78 mo), respectively ($P > 0.05$). Censored patients included 17 out of the 69 patients who underwent percutaneous RFA and 22 out of the 93 patients who underwent surgical RFA ($P = 0.885$).

Patients who underwent percutaneous RFA

Eighty-nine lesions were found in 69 patients who underwent percutaneous RFA (Table 1). The mean treatment session was 2.0 ± 1.2 /lesion for the 78 nodules (≤ 3 cm in diameter) and 3.4 ± 0.8 /lesion for the 7 nodules (larger than 3 cm but smaller than 5 cm in diameter). Of the 89 lesions, 73 nodules were found in the dangerous locations, the mean tumor size was 1.7 ± 1.1 cm, and the mean treatment session was 3.7 ± 2.1 /lesion. The complete RFA rate was 98.6% (68/69) assessed intraoperatively, and the curative rate was 91.3% (63/69) assessed by CT 4 wk thereafter. The RFA failure rate was 4.3% (3/69). Two patients failed to achieve a curative outcome after 2 times of percutaneous RFA. The last patient had one nodule (1 cm in diameter) in 2 tumors very close to the pericardium. RFA was aborted due to the concern of malpositioning the electrode byIOUS. These three patients were later treated with TACE.

Patients who underwent surgical RFA

One hundred and eight lesions were found in 93 patients who underwent surgical RFA (Table 1). The mean treatment session was 1.2 ± 0.5 /lesion for the 85 nodules (≤ 3 cm in diameter) and 2.8 ± 0.9 /lesion for the 23 nodules

Table 3 Major complications of radiofrequency ablation

Classification of complications	Percutaneous RFA (<i>n</i> = 69)	Surgical RFA (<i>n</i> = 93)	<i>P</i> value
Grade I			
Analgesics requirement	17	58	0.000
Fever above 38.5°C	23	45	0.055
Grade II			
Ascites	4	11	0.190
Persistent jaundice	2	0	0.315

Bile duct injury	5	1	0.040
Procedure-related hemorrhage	6	1	0.018
Malignant seeding	2	0	0.315

RFA: Radiofrequency ablation.

(larger than 3 cm but smaller than 5 cm in diameter). The mean tumor size and mean treatment session were 1.8 ± 1.0 cm and 2.9 ± 2.0 /lesion, respectively, for the 95 nodules in the dangerous locations. The complete RFA rate was 100% (93/93) assessed intraoperatively, and the curative rate was 96.8% (90/93) assessed by CT 4 wk afterward. The RFA failure rate was 1.1% (1/93). A nodule (4 cm in diameter) in a patient who failed to RFA compressed the right hepatic duct. To avoid the bile duct injury, a stent was inserted into the compressed bile duct, and ethanol was injected into the adjacent tumor border to the bile duct before RFA. Unfortunately, bile fistula still occurred on day 25 after operation, and CT showed an incomplete ablation of the tumor. A T-tube drainage was placed *via* laparotomy later. Tumor encroaching on the right hepatic duct wall was highly suspected, and treated with palliative therapy due to poor liver function.

Hospital stay time and mortality of patients, and complications of RFA

The hospital stay time of HCC patients was significantly longer after surgical RFA than after percutaneous RFA (6.1 ± 3.1 d *vs* 3.5 ± 2.9 d, $P < 0.001$).

No patient died within 30 d after surgical and percutaneous RFA with a mortality of 0%.

According to the accorcion severity grading system of surgical complications^[21], the complications of percutaneous and surgical RFA are shown in Table 3. The number of patients requiring analgesics was significantly greater after surgical RFA than after percutaneous RFA ($P < 0.001$). However, the incidence of bile duct injury and RFA-related hemorrhage was higher in patients after percutaneous RFA than after surgical RFA ($P = 0.05$).

Local tumor progression

During the 5-year study period after treatment, the local

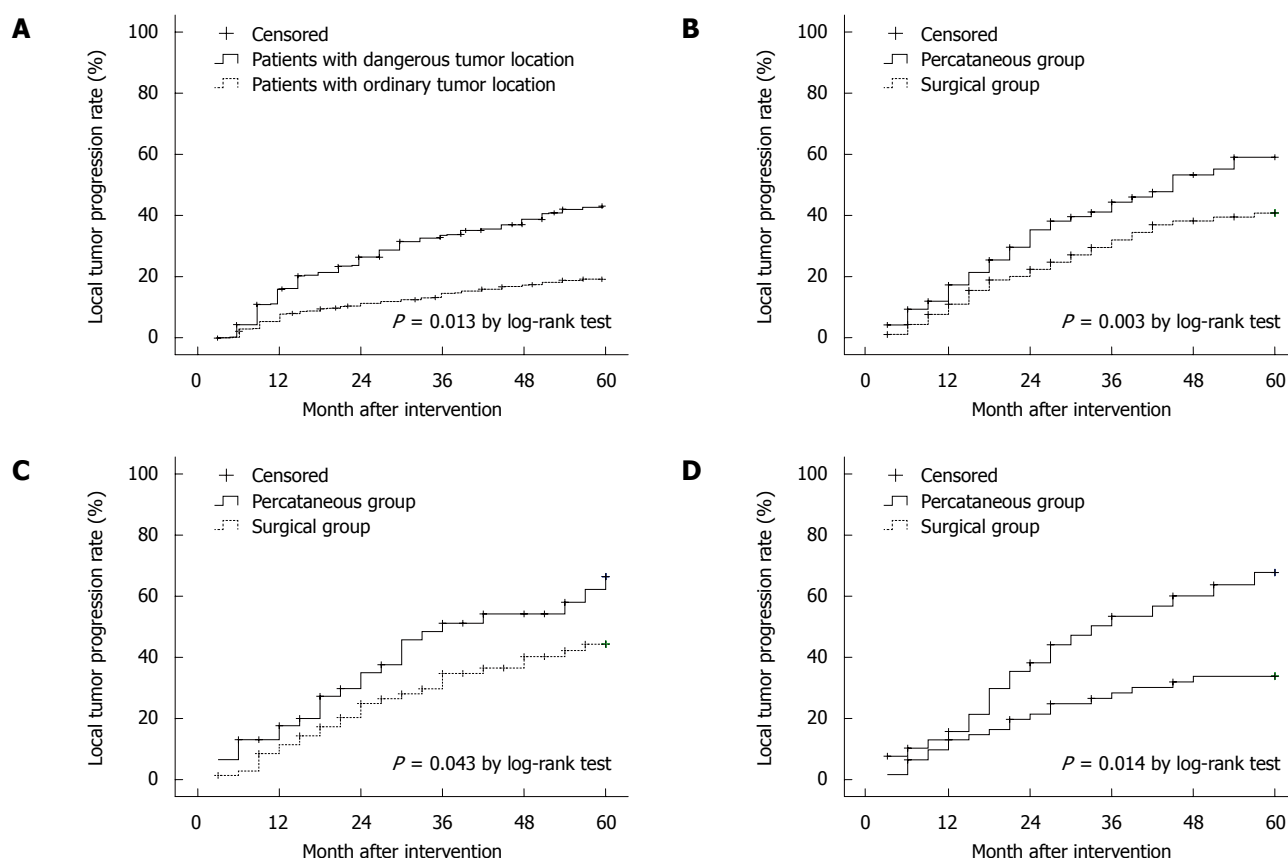

Figure 1 Local tumor progression in patients with hepatocellular carcinoma at common and dangerous locations (A), and hepatocellular carcinoma (B), cirrhosis (C), solitary hepatocellular carcinoma with its diameter ≥ 3 cm (D) after percutaneous and surgical radiofrequency ablation.

tumor progression was observed in 75 (46.3%) out of the 162 patients with HCC in the dangerous locations and in 71 (22.2%) out of the 320 patients with HCC in the general locations. The local tumor progression was more severe in patients with HCC in the dangerous locations than in those with HCC in the general locations ($P < 0.015$, Figure 1A).

Of the 162 patients with HCC in the dangerous locations, 69 and 93 were treated with percutaneous RFA and surgical RFA, respectively. Local tumor progression was observed in 40 out of the 69 patients with HCC after percutaneous RFA and in 35 out of the 93 patients after surgical RFA. The 1-, 2-, 3-, 4-, 5-year local tumor progression rate was 17.4%, 36.2%, 46.4%, 53.6%, 57.6%, respectively, for patients after percutaneous RFA, and 9.9%, 21.5%, 30.1%, 35.5%, 37.6%, respectively, for those after surgical RFA. The local tumor progression was more severe in patients after percutaneous RFA than after surgical RFA ($P < 0.003$, Figure 1B).

Forty-six out of the 63 cirrhotic patients underwent percutaneous RFA and 71 out of the 93 cirrhotic patients underwent surgical RFA (Table 1). The local tumor progression was more severe in patients after percutaneous RFA than after surgical RFA ($P < 0.05$, Figure 1C).

Thirty-nine out of the 69 patients with solitary HCC (≤ 3 cm in diameter) underwent percutaneous RFA and 62 out of the 93 patients with HCC underwent surgical RFA (Table 1). The local tumor progression was more

severe in patients after percutaneous RFA than after surgical RFA ($P < 0.05$, Figure 1D).

Univariate analysis revealed that 5 out of the 10 variables (RFA approach, Child-Pugh class, total bilirubin level, serum AFP level and tumor size) were related to local tumor progression. Multivariate Cox proportional hazards regression analysis showed that percutaneous RFA, total bilirubin level > 10 ng/L and tumor size > 3 cm were the related risk factors for HCC. The corresponding relative risks were 14.315 (95% CI: 4.857-25.412), 8.124 (95% CI: 2.325-101.587), and 11.741 (95% CI: 3.754-21.665), respectively (Table 4).

DISCUSSION

One important advantage of RFA for liver tumors is micro-invasive when compared with partial hepatectomy^[12,13,22-25]. Some institutes have reported RFA on an out-patients basis^[26]. However, even though the morbidity of malignant seeding in the needle tract is low, it is hard to avoid^[27,28]. Moreover, hemorrhage after the electrode is drawn out appears undetectable in a short time by ultrasonography.

In this study, the hospital stay time of patients with HCC was significantly longer with more analgesics required after surgical RFA than after percutaneous RFA. Surgical RFA seemed more invasive than percutaneous RFA. However, the incidence of more severe complica-

Table 4 Univariate and multivariate analysis of relative risks for local tumor progression

Variable	Univariate analysis	Multivariate analysis	
	P value	Relative risk (95% CI)	P value
Percutaneous vs surgical RFA	0.000	14.315 (4.857-25.412)	0.000

tions, such as bile duct injury and procedure-related hemorrhage, was lower in patients after surgical RFA than after percutaneous RFA.

It was reported that a lesion in dangerous locations of the liver is treated with artificial hydrothorax and ascites to achieve percutaneous RFA^[18]. A curative RFA was achieved with artificial hydrothorax in 3 patients in this study. However, artificial ascites was not applied when HCC near extrahepatic organs was treated, because the local ascites was not always capable of dividing a safety zone, the fluidity of liquid made the ascites lack of tension to support a safety zone, membrane adhesions unusually existed between organs and liver, the lesion was often located very close to the surface of the liver when the artificial ascites was needed, and ascites decreased the temperature at the outer part of the lesion when RFA was performed. Thus viable tumor cells could survive.

Compared with surgical RFA, IIOUS of percutaneous RFA is indirect (through abdominal wall), and the choice of route to the lesion is restricted. Injury of important structures, such as bile ducts or extrahepatic organs, should be avoided and RFA should eliminate the viable tumor cells in the assumed area as complete as possible. RFA should be stopped as soon as the ultrasonography shows microbubbles generated by RFA reaching the assumed distal border. In this study, the mean session for each lesion in the dangerous locations was 3.7 ± 2.1 /lesion in percutaneous RFA group and 2.9 ± 2.0 /lesion in surgical RFA group. The patients undergoing percutaneous RFA needed significantly more sessions than those undergoing surgical RFA to ablate a lesion ($P < 0.05$). The effect of percutaneous RFA mainly depends on the experience of operators. On the contrary, surgical RFA may provide a direct ultrasonography monitoring the liver surface, even a visual contact during the procedure. A mobilized liver could offer more choices of route for the electrode and a reliable safety zone in extrahepatic organs or IVC. Thus more attention should be paid to tumor elimination, even the routine impedance-dependent assessment technique can be applied in some surgical RFA procedures and in evaluation by IIOUS, which may be more accurate than that used in percutaneous RFA procedures

and can at least in part explain why more severe local tumor progression was found in patients after percutaneous RFA than after surgical RFA.

This study has the following limitations. First, it was a retrospective study and therefore had inherent defects due to the nature of the method. Second, the rate of censor patients was relatively high in patients undergoing percutaneous and surgical RFA. Third, physicians with diverse experiences might achieve different outcomes of percutaneous RFA. Finally, there was a significant difference in proportion of HBV/HCV-infection and serum AFP level between the patients who underwent surgical or percutaneous RFA.

In conclusion, surgical RFA seems more invasive than percutaneous RFA and the incidence of severe postoperative complications and local tumor progression is lower after surgical RFA than after percutaneous RFA for HCC in dangerous locations.

COMMENTS

Background

The efficacy of radiofrequency ablation (RFA) on hepatocellular carcinoma (HCC) has been debated for a long time. Whether RFA is effective against HCC both in dangerous location and in common location remains controversial.

Research frontiers

The corona of micro-invasion makes lots of colleagues concentrate on percutaneous RFA. Although laparoscopic RFA has been applied recently in some major institutes, laparoscopic ultrasonography needs a long time to be evaluated. Surgical RFA seems more suitable to be employed in most hospitals when difficult circumstances are encountered.

Innovations and breakthroughs

This study was a retrospective study assessing the value of surgical and percutaneous RFA for local or regional HCC in difficult anatomical positions with a large number of patients and a long follow-up time.

Applications

This study may help clinicians to choose RFA when encountering HCC in difficult anatomical positions.

Terminology

Tumor in the dangerous location is defined as a lesion (≤ 0.5 cm in diameter) near large vessels, such as a primary or secondary branch of the portal vein, the base of hepatic veins, or the inferior vena cava (IVC), or a lesion near extrahepatic organs (less than 0.5 cm in diameter) measured on radiological images.

Peer review

This article is a multinational collaborative study, assessing the value of percu-

taneous vs surgical RFA for local or regional HCC in difficult anatomical positions. It is a very interesting and clinically useful study with a large number of patients who were followed up for a long time, thus permitting evaluation of the final outcome of respective treatment modalities.

Abstract

Duplication cyst of the stomach with a pseudostratified columnar ciliated epithelium is extremely rare. We describe two cases of these cysts, with emphasis on their immunophenotype and embryogenesis. The first patient was a 29-year-old man who presented with cramping abdominal pain in his left lower quadrant. The second patient was a 26-year-old woman who had a history, over several years, of chronic epigastric abdominal pain radiating to her back. Both lesions were surgically removed. They showed the same histomorphology. The cysts were lined by a pseudostratified respiratory epithelium with ciliated cells. The first cyst was connected to the stomach, while the second cyst was not connected. Both cysts expressed thyroid transcription factor-1 (TTF-1) and surfactant. In this report, we explore the possible embryogenesis of these lesions in the light of TTF-1 and surfactant expression.

INTRODUCTION

A gastrointestinal duplication is defined as a spherical hollow structure with a smooth muscle coat, lined by a mucous membrane, and attached to any part of the gastrointestinal tract, from the base of the tongue to the anus. However, foregut duplication cyst of the stomach is rare^[1,2]. Foregut duplications may or may not communicate with the gastrointestinal tract, and are usually diagnosed at a young age^[2]. There have been relatively few case reports describing this entity^[3-12]. Adenocarcinoma has been reported in four cases of gastric duplication cyst, but not in cysts that have a ciliated epithelium^[13-16]. Controversy exists concerning the embryological origin of these anomalies^[11,17,18]. Here, we present two cases of gastric ciliated duplication cyst with emphasis on immunophenotype and embryogenesis.

CASE REPORT

Case 1

Case history: The patient was a 29-year-old Caucasian man who presented to his local emergency department for evaluation of acute abdominal pain. The pain started in the lower abdomen and then localized to the left lower quadrant. He had mild nausea, but no vomiting. He had a history of gastroesophageal reflux disease. Physical examination was notable only for left lower quadrant tenderness to palpation. A computed tomography scan (CT-scan) of the abdomen and pelvis was performed and revealed a

Figure 1 A computed tomography scan of the abdomen and pelvis was performed utilizing intravenous and oral contrast. A 4 cm × 5 cm cystic mass (arrow) appears along the greater curvature of the stomach adjacent to the spleen.

mass at the greater curvature of the stomach (Figure 1). An esophagogastroduodenoscopy was performed, revealing a submucosal mass in the fundus of the stomach, approximately 2 cm from the gastroesophageal junction (Figure 2), which was soft on compression. Endoscopic ultrasound revealed a cystic mass in the submucosa of the fundus of the stomach. The imaging and endoscopic findings were most consistent with a gastric duplication cyst. To secure the diagnosis and prevent possible malignant degeneration, the patient was advised to undergo a partial gastrectomy.

Pathological findings: Macroscopically, a sack-like lesion (8.5 cm × 5.5 cm × 4.8 cm) was found with a smooth capsulated wall. The inner wall was also smooth. Microscopically, the cyst was lined by an antrum-type gastric mucosa and a respiratory epithelium with ciliated cells (Figure 3A and B). No intestinal-type epithelium was present. The outside layer consisted of a circular and a longitudinal muscle wall, with a myenteric plexus. The gastric epithelium immunophenotype was cytokeratin 20+, MUC5a/c+, cytokeratin 7+, MUC1-, MUC2-, CDX-2-, TTF-1-, and surfactant-, while the ciliated epithelium had the following immunophenotype: cytokeratin 20-, MUC5a/c-, cytokeratin 7+, MUC1-, MUC2-, CDX-2-, TTF-1+, and surfactant+ (Figure 3C-F).

Case 2

Case history: The patient was a 26-year-old woman with history of chronic epigastric pain for eight years following her first childbirth. The pain was intermittent, and colicky, without identifiable aggravating factors. More recently, the pain had become severe in intensity and required narcotics for relief. The pain was not associated with nausea, vomiting, abdominal distention, fevers, or chills. She admitted to a normal appetite, but had had an unintentional 50-pound weight loss over the last year. She underwent an esophagogastroduodenoscopy, which revealed a normal esophagus, a small hiatal hernia, and diffuse moderate inflammation of the stomach. A CT-scan of the abdomen revealed a cystic mass near the gastroesophageal junction along the lesser curvature of the stomach, which extended to the

Figure 2 Retroflexed endoscopic view of a gastric mass arising in the fundus (arrow). Overlying rugae are effaced, suggestive of a submucosal process.

superior margin of the pancreas and abutted the liver and inferior vena cava (Figure 4). The mass was nonenhancing and cystic in appearance. The primary suspicion was that this represented a congenital gastrointestinal duplication cyst. A partial gastrectomy was performed for further evaluation and treatment.

Pathological findings: Macroscopically, the cyst was an ovoid-shaped structure (5 cm × 2.2 cm × 2 cm). The external surface was covered with tan, shiny serosa. The cystic cavity was filled with a tan-white mucoid material. The cyst inner surface was unremarkable, tan, and smooth. Microscopically, the cyst was lined by a respiratory epithelium with ciliated cells (Figure 5A and B). No intestinal-type epithelium was present. The outside layer consisted of a circular and a longitudinal muscle wall, with a myenteric plexus. The epithelium had the following immunophenotype: cytokeratin 20-, MUC5a/c-, cytokeratin 7+, MUC1-, MUC2-, CDX-2, TTF-1+, and surfactant+ (Figure 5C and D).

DISCUSSION

Gastrointestinal duplication can occur in any region of the gastrointestinal tract; however, a foregut duplication cyst of the stomach is rare. The stomach is the site of only 24% of all alimentary tract duplication cysts, which is the least common site after the ileum, esophagus, and colon. Of reported gastric duplication cysts, most occur in females, with 80% presenting in patients younger than 12 years of age. They are characteristically located on the distal greater curvature, and the majority are cystic and non-communicating. Histologically, they are usually lined with a typical gastric mucosa^[15]. As in the present two cases, a ciliated pseudostratified epithelium has been reported^[3-12].

We present two foregut duplication cysts of the stomach, one connected and one separated, in a 29-year old woman and a 26-year old man, respectively. These two cases showed distinct morphological and immunoprofile findings. Both cysts were lined with pseudostratified ciliated epithelia, and expressed TTF-1 and surfactant.

The pathogenesis of alimentary tract duplications is

Figure 3 Case 1. A: Hematoxylin and eosin stain of gastric/ciliated epithelium (4 ×); B: High power view of the ciliated epithelium (40 ×); C: CK20 showing staining in the surface gastric epithelium, but not in the ciliated epithelium (10 ×); D: MUC5a/c staining showing positive expression in the gastric epithelium but not in the ciliated epithelium (10 ×); E: Thyroid transcription factor-1 nuclear staining in the ciliated epithelium only (10 ×); F: Surfactant staining in the ciliated epithelium only (10 ×).

Figure 4 Case 2. Computed tomography-scan of the abdomen and pelvis with intravenous and oral contrast showing a non-enhancing cystic structure (arrow) abutting the lesser curvature of the stomach and liver along the ligamentum venosum.

Figure 5 Case 2. A, B: Hematoxylin and eosin staining of pseudostratified ciliated epithelium (A: 4 ×, B: 40 ×); C: Thyroid transcription factor-1 nuclear staining in the ciliated epithelium (10 ×); D: Surfactant staining in the ciliated epithelium (10 ×).

controversial. There has been no suggestion of an explanation based on embryological development^[17]. However, others have suggested theory of embryological origin from supernumerary foregut buds^[11]. Others have proposed that abnormal recanalization after the solid epithelial stage of embryonic bowel development is the underlying cause of these lesions^[18].

We found that these cysts are lined with a ciliated pseudostratified epithelium and express TTF-1 and surfactant. These two factors are involved in lung embryogenesis. These findings might partially explain the embryogenesis of these lesions. When the embryo is approximately four weeks old, the respiratory diverticulum appears along the ventral wall of the pharyngeal gut. The esophagotracheal septum gradually partitions this diverticulum from the dorsal part of the foregut. In this manner, the foregut divides into the ventral portion, the respiratory primordium, and a dorsal portion, which becomes the esophagus and stomach^[19]. The middle branch of the tracheal trifurcation is grossly and histologically identical to the other two branches of the trifurcation, including expression of TTF1, which become the lungs^[20]. Early in the development of the esophagus, it is lined by a pseudostratified columnar epithelium. This is a characteristic of the respiratory epithelium, but the mucosa of the esophagus apparently undergoes subsequent metaplasia and squamous differentiation^[1,8]. Based on the presence of the ciliated epithelium, we propose that a branch coming off the trifurcation gives rise to the duplication cyst. Later, the cyst either remains connected to the esophagus/stomach or becomes separated.

TTF-1 is a homeobox transcription factor whose expression in the developing foregut is specifically limited to the respiratory tract^[21-23]. It is particularly important for normal lung development^[24-28]. TTF-1 enhances branching morphogenesis of embryonic lung explants *in vitro*^[29]. A *TTF-1* knockout mouse developed no distal lung parenchyma^[30]. Furthermore, TTF-1 is thought to be important for terminal respiratory epithelial cytodifferentiation. It has the capacity to regulate expression of surfactant proteins, A, B, and C, as well as the Clara cell secretory protein, all markers of respiratory cell specific differentiation^[25,26,28,31-33]. Thus, the presence of TTF-1 and surfactant expression is a function of lung differentiation. The presence of these two factors in the described cysts might explain why these cysts maintain their phenotype of a respiratory epithelium with no squamous metaplasia. As with tracheo-esophageal fistulae^[20], TTF-1 might have lost its normal patterning role in the developing lung, preventing induction of branching morphogenesis in the duplication cyst. The nonbranching pattern of growth of the duplication cyst might be attributable to local mesenchymal-epithelial interactions that override TTF-1 patterning activity.

In conclusion, gastric duplication cysts are rare, and their origin remains uncertain. The two cases presented here, and the resulting histological findings, suggest a novel origin. In both cases, the cysts are lined with a pseudostratified respiratory epithelium with ciliated cells, which express TTF-1 and surfactant. This suggests an origin from

the respiratory diverticulum, which arises from the ventral foregut and could also explain why these cysts do or do not maintain their connection to the gastrointestinal tract.

Abstract

A 37-year old male presented with an acute abdomen suggestive of an appendiceal perforation. Urgent laparotomy showed a duplicated appendix with one of the lumens involved with appendicitis and a focal peri-appendicular abscess while the other lumen had a localized appendiceal cancer. Recognition of congenital intestinal duplications in adults is important to avoid serious clinical consequences.

TO THE EDITOR

An article recently published in the *World Journal of Gas-*

troenterology concerned a duplicated vermiform appendix in an adult^[1]. The authors emphasized the need for surgical intervention to avoid any future complication, in particular, the disconcerting possibility of malignant degeneration within the duplication^[2,3]. Duplication of the appendix, fortunately, is distinctly rare, reportedly occurring in only 1/25 000 patients (0.04%) operated on for acute appendicitis^[4]. Clinical features may depend on the type of appendiceal duplication as a number of variants have been described, specifically, type A with incomplete duplication and a common base (so-called bifid appendix), and types B or C, both forms having complete duplication with independent bases^[5,6].

We had a similar, but unusual experience in a 37-year old adult male in August 1996. He presented with an acute abdomen thought to be a perforated appendix. An urgent laparotomy showed a type A duplicated or bifid appendix with an acute appendicitis involving only one lumen associated with a focal periappendiceal abscess and localized peritonitis. The other lumen showed a well-differentiated carcinoma extending into, but not through the muscularis propria. No vascular or lymphatic invasion was identified. Imaging studies and carcinoembryonic antigen testing were negative. Two weeks later, a further ileocecal resection was done. The resected intestine and 17 mesenteric lymph nodes showed no malignancy. Family history revealed that his father had synchronous mucinous colon cancers at the age of 45 years and his brother was diagnosed with colon cancer at the age of 26 years. A paternal uncle died of colon cancer at the age of 35 years. No other congenital abnormalities were recognized and there was no known contact with a toxic or noxious agent *in utero*. Colonoscopy screening at the ages of 20, 24 and 30 years was completed in other centers because of his family history of colon cancer and no abnormalities were detected. A colonoscopy in November 1996 in our hospital revealed no other abnormalities, similar to colonoscopies in 2000, 2005 and 2010. Because of his family history, genetic evaluation to exclude a HNPCC was negative including gene testing for MLH1 and MSH2.

Carcinoma in the intestinal tract developing with co-existent duplication has been rarely reported and appears

limited to only a small number of cases^[3,7]. Appendiceal cancer has been associated with a duplication thought to represent a Meckel's diverticulum^[8] as well as in a single prior report of a duplicated appendix^[9]. While this presentation may also mimic colon cancer^[10], missing a second duplicated appendix in this setting could lead to serious clinical consequences. In the present case, appendiceal duplication was fortunately recognized and an early stage carcinoma was successfully resected.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclu-

sion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Baishideng Publishing Group Co., Limited

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organizations]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit on-

line. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review.

Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use

Instructions to authors

uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of P values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date,

volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 $24.5 \mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Instructions to authors

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interac-

tions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

World Journal of *Gastroenterology*

World J Gastroenterol 2011 January 14; 17(2): 137-272

Editorial Board

2010-2013

The *World Journal of Gastroenterology* Editorial Board consists of 1144 members, representing a team of worldwide experts in gastroenterology and hepatology. They are from 60 countries, including Albania (1), Argentina (8), Australia (29), Austria (14), Belgium (12), Brazil (10), Brunei Darussalam (1), Bulgaria (2), Canada (20), Chile (3), China (69), Colombia (1), Croatia (2), Cuba (1), Czech (4), Denmark (8), Ecuador (1), Egypt (2), Estonia (2), Finland (8), France (24), Germany (75), Greece (14), Hungary (10), India (26), Iran (6), Ireland (7), Israel (12), Italy (101), Japan (112), Jordan (1), Kuwait (1), Lebanon (3), Lithuania (2), Malaysia (1), Mexico (10), Moldova (1), Netherlands (29), New Zealand (2), Norway (11), Pakistan (2), Poland (11), Portugal (4), Romania (3), Russia (1), Saudi Arabia (3), Serbia (3), Singapore (10), South Africa (2), South Korea (32), Spain (38), Sweden (18), Switzerland (11), Thailand (1), Trinidad and Tobago (1), Turkey (24), United Arab Emirates (2), United Kingdom (82), United States (249), and Uruguay (1).

Contents

Weekly Volume 17 Number 2 January 14, 2011

EDITORIAL

- 137 Pathologic pancreatic endocrine cell hyperplasia

Ouyang D, Dhall D, Yu R

TOPIC HIGHLIGHT

- 144 Quality of life in patients with esophageal stenting for the palliation of malignant dysphagia

Diamantis G, Scarpa M, Bocus P, Realdon S, Castoro C, Ancona E, Battaglia G

ORIGINAL ARTICLE

- 151 Connective tissue growth factor reacts as an IL-6/STAT3-regulated hepatic negative acute phase protein

Gressner OA, Peredniene I, Gressner AM

- 164 Switching-on of serotonergic calcium signaling in activated hepatic stellate cells

Park KS, Sin PJ, Lee DH, Cha SK, Kim MJ, Kim NH, Baik SK, Jeong SW, Kong ID

- 174 Systematic review on the surgical treatment for T1 gallbladder cancer

Lee SE, Jang JY, Lim CS, Kang MJ, Kim SW

- 181 LY294002 potentiates the anti-cancer effect of oxaliplatin for gastric cancer *via* death receptor pathway

Liu J, Fu XQ, Zhou W, Yu HG, Yu JP, Luo HS

BRIEF ARTICLE

- 191 Percutaneous endoscopic gastrostomy and gastro-oesophageal reflux in neurologically impaired children

Thomson M, Rao P, Rawat D, Wenzl TG

- 197 Polymorphisms in NF- κ B, PXR, LXR, PPAR γ and risk of inflammatory bowel disease

Andersen V, Christensen J, Ernst A, Jacobsen BA, Tjønneland A, Krarup HB, Vogel U

- 207 Acute diverticulitis in younger patients: Any rationale for a different approach?

Faria GR, Almeida AB, Moreira H, Pinto-de-Sousa J, Correia-da-Silva P, Pimenta AP

- 213 Hemolysis results in impaired intestinal microcirculation and intestinal epithelial cell injury

Hanssen SJ, Lubbers T, Hodin CM, Prinzen FW, Buurman WA, Jacobs MJ

- 219 Angiogenic markers endoglin and vascular endothelial growth factor in gastroenteropancreatic neuroendocrine tumors
Kuiper P, Hawinkels LJAC, de Jonge-Muller ESM, Biemond I, Lamers CBHW, Verspaget HW
- 226 Evaluation of small bowel blood flow in healthy subjects receiving low-dose aspirin
Nishida U, Kato M, Nishida M, Kamada G, Yoshida T, Ono S, Shimizu Y, Asaka M
- 231 ¹⁸F-fluorodeoxyglucose positron emission tomography in the diagnosis of small pancreatic cancer
Okano K, Kakinoki K, Akamoto S, Hagiike M, Usuki H, Yamamoto Y, Nishiyama Y, Suzuki Y
- 236 Seroprevalence of anti-HAV among patients with chronic viral liver disease
Cho HC, Paik SW, Kim YJ, Choi MS, Lee JH, Koh KC, Yoo BC, Son HJ, Kim SW
- 242 Magnesium citrate with a single dose of sodium phosphate for colonoscopy bowel preparation
Choi YS, Suh JP, Kim JK, Lee IT, Youk EG, Lee DS, Kim DS, Lee DH
- 249 Risk factors for hilar cholangiocarcinoma: A case-control study in China
Cai WK, Sima H, Chen BD, Yang GS
- 254 Effects of penethyclidine hydrochloride in small intestinal damage caused by limb ischemia-reperfusion
Zhang Y, Leng YF, Xue X, Zhang Y, Wang T, Kang YQ
- 260 CYP1A1 Ile462Val polymorphism contributes to colorectal cancer risk: A meta-analysis
Jin JQ, Hu YY, Niu YM, Yang GL, Wu YY, Leng WD, Xia LY

CASE REPORT

- 267 Splenic infarction associated with sorafenib use in a hepatocellular carcinoma patient
Kim SO, Han SY, Baek YH, Lee SW, Han JS, Kim BG, Cho JH, Nam KJ

LETTERS TO THE EDITOR

- 271 Potential efficacy of ginger as a natural supplement for nonalcoholic fatty liver disease
Sahebkar A

ACKNOWLEDGMENTS I Acknowledgments to reviewers of *World Journal of Gastroenterology*

APPENDIX I Meetings
I-VI Instructions to authors

ABOUT COVER Park KS, Sin PJ, Lee DH, Cha SK, Kim MJ, Kim NH, Baik SK, Jeong SW, Kong ID.
Switching-on of serotonergic calcium signaling in activated hepatic stellate cells.
World J Gastroenterol 2011; 17(2): 164-173
<http://www.wjgnet.com/1007-9327/full/v17/i2/164.htm>

AIM AND SCOPE *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.
The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

FLYLEAF I-VII Editorial Board

Abstract

Pathologic hyperplasia of various pancreatic endocrine cells is rare but has been long known. β cell hyperplasia contributes to persistent hyperinsulinemic hypoglycemia of infancy, which is commonly caused by mutations in the islet ATP-sensitive potassium channel, and to non-insulinoma pancreatogenous hypoglycemia in adults, which may or may not be associated with bariatric surgery. α cell hyperplasia may cause glucagonoma syndrome or induce pancreatic neuroendocrine tumors. An inactivating mutation of the glucagon receptor causes α cell hyperplasia and asymptomatic hyperglucagonemia. Pancreatic polypeptide cell hyperplasia has been described without a clearly-characterized clinical syndrome and hyperplasia of other endocrine cells inside the pancreas has not been reported to our knowledge. Based on morphological evidence, the main pathogenetic mechanism for pancreatic endocrine cell hyperplasia is increased endocrine cell neogenesis from exocrine ductal epithelium. Pancreatic endocrine cell hyperplasia should be considered in the diagnosis and management of hypoglycemia, elevated islet hormone levels, and pancreatic neuroendocrine tumors. Further studies of pathologic pancreatic endocrine cell hyperplasia will

INTRODUCTION

The pancreas, a key regulator of nutrient digestion, absorption, and utilization, can be divided into two major components, the endocrine and exocrine pancreas. The endocrine pancreas consists of five distinct cell types, α , β , δ , ϵ , and pancreatic polypeptide (PP) cells, that produce glucagon, insulin, somatostatin, ghrelin, and PP, respectively^[1-3]. The pancreatic endocrine cells may give rise to distinct neuroendocrine tumors such as insulinoma, gastrinoma, glucagonoma, VIPoma, and non-functioning tumors^[4-6]. In contrast, pancreatic endocrine cell hyperplasia as a group of diseases is a relatively unexplored area. From the 1960s to the present day, there have been various reports regarding pancreatic endocrine cell hyperplasia. Much of the literature has focused on β cell hyperplasia in particular, but hyperplasia of other pancreatic endocrine cells has also been described, some in great detail. In this review we summarize the body of literature on pathologic pancreatic endocrine cell hyperplasia.

Hyperplasia refers to an increased number of a certain type of cells in a given organ or tissue than is ordinarily observed. Mechanisms regulating pancreatic endocrine cell

number include proliferation (division of existing cells), apoptosis (controlled cell death), and neogenesis (differentiation of endocrine cells from the exocrine epithelium), and abnormalities in each could result in hyperplasia^[7-9]. The diagnostic criteria of pancreatic endocrine cell hyperplasia are not universally agreed upon. Rindi *et al.*^[10] defines pancreatic endocrine cell hyperplasia as an expansion of the endocrine cell mass to more than 2% (in adults) or 10% (in infants) of the total pancreas mass. As it is impractical to do detailed pancreatic morphometry in a clinical specimen, the diagnosis of pancreatic endocrine cell hyperplasia is often subjective. Most would regard an islet size large than 250 μm in diameter and an increase in islet numbers as evidence of pancreatic endocrine cell hyperplasia^[11-14].

Pancreatic endocrine cell hyperplasia can be non-specific and involve most or all types of islet cells or specific and involve predominantly one cell type. Non-specific, focal endocrine hyperplasia and microadenoma are not uncommon incidental pathological findings in the pancreas; if carefully screened, up to 10% of adults harbor these lesions at autopsy^[15]. In those patients, all types of pancreatic endocrine cells could be focally hyperplastic. Most of those lesions probably do not indicate clinical significance. Diffuse pancreatic endocrine cell hyperplasia and microadenoma are a feature of multiple endocrine neoplasia type 1 (MEN1), and to a less extent, von Hippel-Lindau (VHL) disease^[16-19]. All types of endocrine cells can be hyperplastic, but β and α cells are more often so, probably because these cells are normally more numerous than other types. In this article, we will focus on diffuse and specific pancreatic endocrine cell hyperplasia as a group of diseases. We define it pathologically as an overwhelming increase in islet size and/or number in all the pancreatic sections examined so that it is reasonable to assume that the remaining pancreas or unexamined pancreas blocks should exhibit similar changes. Moreover, the hyperplastic endocrine cells should be mainly limited to one type of islet cells which have apparently similar cell lineage supported by consistent hormone production profile and other cellular markers. Finally we will only discuss the literature on pathologic pancreatic endocrine cell hyperplasia in humans.

β CELL HYPERPLASIA

The pancreatic β cells are the only source of insulin, the hormone that decreases blood glucose levels by increasing glucose uptake and decreasing hepatic glucose output. Physiological hyperplasia of β cells is commonly seen in patients with insulin resistance and early-stage type 2 diabetes, and is intensely studied for diabetes treatment^[20,21]. Except for postprandial hypoglycemia, we are not aware of any reports that physiological β cell hyperplasia causes clinical syndromes^[22,23]. The physiological β cell hyperplasia appears to be tightly regulated and has not been reported to give rise to pancreatic neuroendocrine tumors. We thus consider it part of insulin resistance syndromes and will not address it further in this article.

Admittedly, pathologic β cell hyperplasia is a controversial term in both infants and adults in the absence of endocrine tumor syndromes. Although β cell hyperplasia has been recorded in non-insulinoma hyperinsulinemic hypoglycemia, it is rather moderate in most cases and may be even non-existent in some cases^[24]. “Nesidioblastosis” has been used by some authors to denote the same pathologic changes^[25-28]. The term nesidioblastosis was coined in the first half of the 20th century initially to describe islet neogenesis from pancreatic ductal epithelium in neonates with hyperinsulinemic hypoglycemia^[29]. β cell hyperplasia and hypertrophy often accompany nesidioblastosis^[24,30-32]. Although islet neogenesis is also observed in normal infants, by the 1970s, nesidioblastosis was used to describe all forms of persistent congenital hyperinsulinism in infants, whether the hyperinsulinemic states were associated with hyperplasia or not^[25,26]. In recent years, nesidioblastosis has also been used to describe acquired hyperinsulinism with β cell hyperplasia in adults^[27,28]. As the use of this term is not consistent, we use nesidioblastosis strictly as a morphological term in describing any endocrine cells (not limited to β cells) budding from the ductal epithelium and use “persistent hyperinsulinemic hypoglycemia of infancy (PHHI)” to describe the various forms of similar such diseases in neonates or infants and “non-insulinoma pancreatogenous hypoglycemia (NIPH)” to describe hypoglycemia syndromes without evidence of insulinoma in adults^[24,30-41]. Both PHHI and NIPH are associated with pathologic β cell hyperplasia in most cases.

Clinically characterized by hyperinsulinemic hypoglycemia in infants and neonates, PHHI is not a single disease entity but a group of related diseases^[33-35]. In the majority of patients, insulinoma is not identified but the pancreas exhibits focal or diffuse β cell abnormalities commonly associated with genetic mutations affecting β cells^[35,42]. In about a third of cases, focal β cell hypertrophy and hyperplasia is observed^[33,34]. The endocrine cells are arranged in huge islet-like structures separated by acinar cells or connective tissue, and some harbor large nuclei. The endocrine cell proliferation rate is generally increased. All types of endocrine cells are represented in the islet-like structures with normal spatial distribution. The percentage of β cells is higher (70%-90%) than normal (50%). The diffuse form is found in about two-thirds of cases. Although the β cell mass is only mildly increased compared with normal control, islet size varies and some islets are very large while others are poorly defined and irregularly shaped small endocrine cell clusters. As in the focal form, all types of endocrine cells are represented in the islet-like structures with normal spatial distribution, and some endocrine cells have large hyperchromatic nuclei. The endocrine cell proliferation rate, however, is not increased in the diffuse form^[43]. Clinically it is important to differentiate the focal from the diffuse form as partial pancreatectomy is sufficient for the former while near-total or total pancreatectomy is required for the latter. There is a correlation between the underlying genetic abnormalities and the pancreas pathology. The focal hypertrophy and

hyperplasia is associated with a paternally inherited ATP-sensitive potassium channel defect with loss of maternal heterozygosity on the 11p chromosome, and is thus sporadic^[35,42]. The diffuse form is most commonly associated with traditional mutations leading to defects in the same potassium channel, and can be either sporadic or familial. It is still unclear how the genetic abnormalities lead to the unique islet structure and β cell morphology.

In adults, NIPH is a rare cause of hyperinsulinemic hypoglycemia^[36-41]. NIPH is characterized by mostly postprandial hypoglycemia rather than fasting hypoglycemia which is usually seen in patients with insulinoma^[38-40]. This syndrome is distinguished from reactive hypoglycemia in that in some patients, the development of severe neuroglycopenic symptoms including diplopia, dysarthria, confusion, disorientation, and even convulsions and coma, may occur in addition to adrenergic symptoms that predominate in reactive hypoglycemia^[22,23,38-40]. This syndrome is also distinguished from PHHI in that these patients do not have mutations of the KIR6.2 (KCNJ11) and SUR1 (ABCC8) genes, which encode the subunits of the pancreatic ATP-sensitive potassium channel^[38]. Evidence of β cell hyperplasia is present in every patient studied^[36-41]. The islets exhibit normal structure but diffusely are more numerous and larger than those in normal control, and nesidioblastosis is pervasive. All types of islet cells are normally distributed throughout the islets but the predominant cell type is the β cell. Partial pancreatectomy often resolves hypoglycemia^[36-41]. The association of NIPH and bariatric surgery is controversial. Hypoglycemia after bariatric surgery is common and is mostly caused by dumping syndrome^[44,45]. In a minority of patients, hypoglycemia is associated with hyperinsulinemia and can only be controlled by partial pancreatectomy^[44,46]. It was initially reported that the endocrine pancreas essentially exhibits the same changes as described above for patients without a history of obesity and bariatric surgery^[44,46]; later studies, however, failed to demonstrate β cell hyperplasia when obese patients without bariatric surgery were used as controls^[47]. Thus bariatric surgery may not by itself cause β cell hyperplasia.

In summary, pathologic β cell hyperplasia causes

hypoglycemia and requires pancreatectomy in most patients. Pancreatic neuroendocrine tumor pathogenesis is a concern but has not been observed clinically. Increased neogenesis (morphologically as nesidioblastosis) appears to be the main mechanism responsible for β cell hyperplasia. The etiology of β cell hyperplasia commonly is mutations in the ATP-sensitive potassium channel in infants; in adults, it is still unknown but is probably related to unknown genetic changes. Further study of β cell hyperplasia will undoubtedly provide insights into fundamental β cell biology and suggest novel therapies for diabetes.

α CELL HYPERPLASIA

Although much research has focused on β cell hyperplasia, α cell hyperplasia also occurs and recent studies have shed light on its mechanism. The α cells are the second most common cells in an islet^[1-3]. The first case of diffuse α cell hyperplasia and hyperglucagonemia was published more than 40 years ago in a 69-year-old man with hyperparathyroidism and calcific pancreatitis^[48]. The cause of α cell hyperplasia and hyperglucagonemia in that case was not clear but the pancreatitis may have contributed to α cell hyperplasia or the patient may have had multiple endocrine neoplasia type 1 which encompasses primary hyperparathyroidism and pancreatic endocrine cell hyperplasia^[16,17]. To our knowledge, nine more cases of α cell hyperplasia have been reported afterwards (Table 1)^[49-54]. Glucagon levels were elevated in all cases where they were measured. The ethnicity of patients included Asian, Iranian, or presumably Caucasians. Both female and male patients were affected and all patients were adults aged from 25 to 74; none had a family history of endocrine tumors. Only one patient presented with typical glucagonoma syndrome in the form of necrolytic migratory erythema, deep vein thrombosis, and weight loss, and the other eight patients presented with non-specific symptoms in whom hyperglucagonemia was identified during the work-up for possible pancreatic neuroendocrine tumors.

Regardless whether the α cell hyperplasia is associated with glucagonoma syndrome, its morphology is remarkably similar in all cases^[49-54]. We have performed detailed

histological studies on the α cell hyperplasia of our patient (Figure 1)^[53]. In this patient's pancreas, hyperplastic islets were innumerable and classic nesidioblastosis was commonly seen. Most of these hyperplastic islets (60%-80%) contain endocrine cells positive for glucagon but negative for insulin, but smaller, normal-looking islets exhibit normal insulin and glucagon hormonal expression. Accompanying the α cell hyperplasia, there are a 4-cm non-functioning pancreatic neuroendocrine tumor and multiple microadenomas. Henopp *et al*^[54] further note that it is difficult to distinguish microglucagonomas from hyperplastic islets in α cell hyperplasia, and in some very large islets (> 300-500 μ m), there appears to be an imperceptible transition from α cell hyperplasia to microglucagonoma. Thus the morphological studies suggest that α cell hyperplasia gives rise to glucagonoma and other pancreatic endocrine tumors.

The pathogenesis of α cell hyperplasia has been elucidated in our patient^[55]. As the patient has extremely elevated glucagon levels but without glucagonoma syndrome, which resembles the phenotype of mice without a glucagon receptor^[56,57], we sequenced the patient's glucagon receptor gene and identified a novel homozygous inactivating P86S mutation^[55]. When tested *in vitro*, the P86S mutant glucagon receptor exhibits partial cytoplasmic

localization and decreased glucagon binding. Compared with the wild-type glucagon receptor, the P86S mutant produces less cAMP under physiological concentrations of glucagon. The hyperplastic α cells in our patient also produce glucagon-like peptide 1 and PP, suggesting immature, more embryonic traits. We believe that our patient has a novel disease which we term "Mahvash disease" because it has a distinct etiology (inactivating glucagon receptor mutation), pathology (α cell hyperplasia), and clinical syndrome (hyperglucagonemia and pancreatic neuroendocrine tumors).

Thus clinically, there appear to be at least two types of α cell hyperplasia, functional and reactive. Functional α cell hyperplasia is analogous to adult β cell hyperplasia (which produces non-insulinoma pancreatogenous hyperinsulinemic hypoglycemia, NIPH) and produces non-glucagonoma hyperglucagonemic glucagonoma syndrome. Partial or total pancreatectomy may be a logical treatment. Currently only one case of functional α cell hyperplasia is known^[54]. Our case and possibly a few others represent reactive α cell hyperplasia (equivalent to Mahvash disease) which produces hyperglucagonemia as a result of inactivated glucagon signaling and consequently does not cause glucagonoma syndrome^[49-54]. The clinical significance of reactive α cell hyperplasia is pancreatic neuroendocrine tumors so that clinical, laboratory, and imaging surveillance are required to identify those tumors early. Once identified, these tumors should be treated as a regular pancreatic neuroendocrine tumor.

PP CELL HYPERPLASIA

PP-producing cells represent about 10% of endocrine cells in an islet^[1-3]. The PP cells often take up a peripheral position, mixed with α and δ cells. The physiologic effects of PP are not very clear but include inhibiting gallbladder contraction and pancreatic enzyme secretion and decreasing appetite and food intake^[58,59]. PP cell hyperplasia was first described in 1980 and a total of eight cases of diffuse PP cell hyperplasia have been reported to our knowledge (Table 2)^[60-65]. As in α cell hyperplasia, both sexes were affected and patients were aged from 37 to 76 years; all

patients were without a family history of endocrine tumors. Watery diarrhea was a common symptom and four of the eight patients had simultaneous or a history of gastrinoma and Zollinger-Ellison syndrome. The clinical significance of PP cell hyperplasia and elevated PP levels remain relatively unknown. It is not clear if PP cell hyperplasia indeed causes elevated PP levels. First of all, there does not appear to be a direct relationship between the number of PP cells in the pancreas and the serum levels of circulating PP^[66]. In addition, PP levels were unknown in most patients and were measured in only two of the eight patients; in one of these two patients, the PP levels were comparable to those in asymptomatic patients with pancreatic neuroendocrine tumors. Lastly, the association of PP cell hyperplasia and gastrinoma may confound the clinical presentations of PP cell hyperplasia as diarrhea is a common symptom of gastrinoma. Thus far, a clinical syndrome of elevated PP levels cannot be established and it is not clear whether PP cell hyperplasia causes watery diarrhea. PP cell hyperplasia has also been found to be positive on somatostatin receptor scintigraphy, an imaging modality used to visualize neuroendocrine tumors^[65].

The histology of PP cell hyperplasia is very similar to that of α or β cell hyperplasia but the hyperplastic cells are PP cells^[60-65]. There are numerous PP cell clusters, some of which are very large and dysplastic. The PP cells are the predominant cells found inside or outside the islets. Extensive PP cell neogenesis is inferred from the evident nesidioblastosis. While the association with gastrinoma suggests that it may be secondary to gastrinoma, the etiology of PP cell hyperplasia remains elusive.

HYPERPLASIA OF OTHER PANCREATIC ENDOCRINE CELLS

Somatostatin is secreted by the δ cells of the islets. Islet somatostatin probably plays a paracrine role in inhibiting insulin and glucagon secretion from the neighboring β and α cells^[67]. Somatostatin cell hyperplasia inside the pancreas appears to be extremely rare and only one case of focal δ cell hyperplasia has been reported which is in association with pancreatic cancer^[68]. Hyperplasia of gastrin cells inside the pancreas has not been reported. We could not identify any literature on hyperplasia of ghrelin cells or vasoactive intestinal peptide cells either inside the pancreas or in other organs.

PANCREATIC ENDOCRINE CELL HYPERPLASIA AND PATHOGENESIS OF NEUROENDOCRINE TUMORS

It is not clear if pancreatic endocrine cell hyperplasia represents precursor lesions for pancreatic neuroendocrine tumors^[69,70]. Diffuse endocrine cell hyperplasia, dysplasia, and microadenoma are present in the pancreas of patients with MEN1 and VHL, and are indeed considered as pre-

cursor lesions^[16-19]. The hyperplastic pancreatic endocrine cells in patients with MEN1 and in mice with a heterozygous *menin* mutation are polyclonal and retain the normal *menin* allele, indicating that deletion of one copy of *menin* causes pancreatic endocrine cell to proliferate without tumorigenesis^[71,72]. Loss of heterogeneity (LOH) of the *menin* locus is present in adenomas as small as 0.3 mm in diameter, demonstrating that these microadenomas are true tumors according to Knudson's two-hit hypothesis of tumor development^[73]. Interestingly, the exact pattern of LOH is different between microadenomas, suggesting that these microadenomas arise independently from the hyperplastic background^[71,72]. As only a select number of clinical adenomas eventually develop while there are numerous microadenomas, additional mutations have to accrue to form larger and clinically significant pancreatic neuroendocrine tumors (PNETs). There have been no reports of similar precursor lesions for sporadic PNETs. Endocrine hyperplasia, dysplasia, and microadenoma, however, are not uncommon findings in the pancreas^[27]. It is not known if these lesions are monoclonal. Although most of these lesions probably do not indicate clinical significance, they could represent precursor lesions giving rise to sporadic PNETs, since all clinical PNETs have to pass through a microadenoma stage during their growth^[73]. It is thus plausible that PNETs develop from precursor (pre-malignant) lesions such as hyperplasia and microadenoma in familial PNET syndromes and at least partly in sporadic cases such as the patient we describe with α cell hyperplasia and pancreatic neuroendocrine tumors^[53]. The key question of what additional genetic changes are needed to transform a microadenoma to a clinical PNET remains unanswered.

CONCLUSION

Pathologic pancreatic endocrine cell hyperplasia is a distinct group of diseases with various clinical, histological, and etiological features. β cell hyperplasia in adults causes non-insulinoma pancreatogenous hypoglycemia and probably contributes to persistent hyperinsulinemic hypoglycemia in infants. α cell hyperplasia causes glucagonoma syndrome or pancreatic neuroendocrine tumors. The main pathogenetic mechanism for pancreatic endocrine cell hyperplasia is increased endocrine cell neogenesis rather than proliferation of existing cells. The etiology has only been elucidated in some patients with demonstration of mutations of relevant genes regulating pancreatic endocrine cell phenotype. Although rare, this group of diseases does affect a significant number of patients and should be considered in the diagnosis and management hypoglycemia, elevated islet hormone levels, and pancreatic neuroendocrine tumors. Moreover, as the pancreatic endocrine cells are critical in regulating glucose metabolism and their hyperplasia may result in tumorigenesis, further studies of pathologic pancreatic endocrine cell hyperplasia will likely yield insights into the pathogenesis and treatment of diabetes and pancreatic neuroendocrine tumors.

or palliative intervention. To date, only a few published studies can be found on Medline examining HRQoL in patients with advanced EC treated with SEMS implantation. The aim of this study was to review the impact on HRQoL of SEMS implantation as palliative treatment in patients with EC. All Medline articles regarding HRQoL in patients with advanced EC, particularly those related to SEMS, were reviewed. In most studies, relief of dysphagia was the only aspect of HRQoL being measured and SEMS implantation was compared with other palliative treatments such as brachytherapy and laser therapy. SEMS insertion provides a swift palliation of dysphagia compared to brachytherapy and no evidence was found to suggest that stent implantation is different to laser treatment in terms of improving dysphagia, recurrent dysphagia and better HRQoL, although SEMS insertion has a better technical success rate and also reduces the number of repeat interventions.

INTRODUCTION

Esophageal cancer (EC) is a devastating disease with an incidence that is rising more rapidly in the Western world than that of any other cancer^[1]. Despite advances in therapy, more than 50% of patients have incurable disease at the time of presentation and only 5%-10% of patients survive 5 years later^[2]. The incidence rates of EC are highly variable across geographic areas. Whereas rates are relatively low in many parts of the world, exceptionally high incidence rates have been reported from some regions of China. Moderate to high incidence rates have been reported from other areas or populations, including parts of Central Asia, South Africa, South America, northern France, and among African-Americans in the United States^[3,4]. A marked change in the male to female ratio of age-adjusted incidence rates has also been observed^[5].

Squamous cell carcinoma is the predominant histologic type of EC in the world^[4]. Nevertheless, a shift in proportion of EC type from SCC to adenocarcinoma (AC) has been reported to have occurred in Western countries, notably from the 1970s in the United States and from the 1980s and early 1990s in some European countries^[6-8]. The reason for this shift is not clear, but it may be related to several factors, including transitions in lifestyle and diet, being overweight, and declining rates of *Helicobacter pylori* infection in the Western world^[7,9]. In Europe, while incidence of SCC has remained stable or declined during the past few decades, the incidence of esophageal AC has been rising. This increase has been more prominent in Northern Europe, notably in the United Kingdom and Ireland, but smaller increases have also been reported from other parts of the continent^[7,8].

Most ECs are diagnosed at an advanced stage and in patients with co-morbidity. This precludes curative treatment and makes palliative treatment a more realistic option for most of these patients^[10]. Dysphagia is the predominant symptom in more than 70% of patients with EC^[11]. Several management options have been developed in recent years to palliate malignant dysphagia. These include mechanical measures such as endoluminal stenting or surgery and antineoplastic methods such as external beam radiation, brachytherapy, chemotherapy, chemoradiotherapy, laser treatment, photodynamic therapy or ablation using injection of alcohol or chemotherapeutic agents. The optimum management of dysphagia caused by advanced primary EC is not established although continued progress has been made in recent years to achieve this goal^[10,12,13]. However, palliation remains an important aspect of treatment, with goals of relieving dysphagia, reducing the risk of aspiration, maintaining a patent orogastric pathway and nutritional status and improving the quality of life.

Esophageal intubation for the palliation of dysphagia from malignant esophageal obstruction has been practiced for over a hundred years. In 1959, Celestin^[14] described the palliation of esophageal malignancy with a plastic endoprosthesis introduced at laparotomy. In the 1970s,

Atkinson *et al*^[15] introduced an endoscopically inserted plastic prosthesis, with a more reduced complication rate. Plastic stents have been superseded by the newer range of metallic self-expanding stents that are safer and easier to place^[14-22]. The first description of the endoscopic placement of an expanding metallic spiral stent was made by Frimberger^[23] in 1983. Nevertheless, some series report little difference in the degree of palliation from dysphagia between plastic and metal stents^[14,24], although the complication rates with metallic stents are significantly lower.

However, the use of self-expanding metal stents (SEMS) is not without problems. Stent migration, incomplete expansion of the stent and tumour ingrowth and overgrowth may require further intervention for recurrent dysphagia. Insertion of stents beyond the gastro-esophageal junction has been observed to result in acid reflux^[25,26]. More recently, developments in SEMS design have resulted in the increasing use of anti-reflux SEMS^[27,28] and retrievable SEMS^[29]. Although SEMS insertion is now reported to be the most common palliative method for treating dysphagia in EC^[30], there is a paucity of evidence regarding its effectiveness in improving the quality of life and nutritional status of the patients.

The aim of this study was to review the impact on health-related quality of life (HRQoL) of SEMS implantation as palliative treatment in patients with EC. A text word literature review was performed using the PubMed and Medline databases. Although this was not a systematic review, the search terms used were as follows: esophageal AND cancer OR carcinoma AND quality of life OR HRQoL OR health-related quality of life OR patient reported outcome AND self-expandable metal stents OR esophageal stents. The reference lists of identified articles were searched for further relevant publications. Two researchers (Diamantis G and Scarpa M) independently selected the studies, limited to clinical studies published between January 1980 to July 2010 and in the English language. Unpublished data and data published in abstract form only were excluded, because these were unlikely to contain sufficient methodologic information to allow valid conclusions to be made. Whenever there was discordance regarding study inclusion the two researchers negotiated an agreement.

HRQOL AS MEASURE OF OUTCOME AFTER TREATMENT OF EC

Defining HRQoL is a complex matter and a universally accepted definition does not exist. Usually, the term quality of life (QoL) and, more specifically, HRQoL, refers to a multidimensional construct which encompasses patients' perceptions of both negative and positive aspects in at least 4 dimensions: physical, emotional and social functions, as well as disease and treatment-related symptoms^[31]. More recently, the assessment of other dimensions of QoL (e.g. spiritual well-being or sexual function) has received more attention. QoL data provide direct measures of benefit as perceived by the patients and may be

Table 1 Examples of quality of life questionnaires used to assess quality of life in patients with esophageal cancer

Category	Type of questionnaire	Advantages	Disadvantages
Generic	SF-36	Good psychometric properties	
	EQ-5D	Reliable	Limited number of domains
Cancer-specific	Spitzer QoL index	Brief and easy to complete	Limited number of domains
	EORTC QLQ C30	Fully validated The most widely used specific instrument Clinical significance assessed	Ceiling effect Site-specific modules may add to patient burden
EC-specific	HAD scale	Well validated and widely used with RSCL	Only assesses anxiety and depression
	EORTC QLQ-OES18	Fully validated	Needs to be used with QLQ-C30
	EORTC QLQ-STO22	Fully validated	Limited supporting psychometric data
	FACT-E	Provides overall summary score	

Modified from Conroy *et al*^[55]. SF-36: Medical Outcomes Study 36-Item Short Form Health Survey; HAD: Hospital Anxiety and Depression; QoL: Quality of life; EORTC QLQ: European Organization for Research and Treatment QoL Questionnaire; FACT: Functional Assessment of Cancer Therapy.

useful for helping them clarify their treatment preferences. The data are also intended to help physicians' decisions by allowing them to understand patients' experiences of treatment, and there is evidence that QoL data may have prognostic value, especially in metastatic disease.

Questionnaires are the most frequently used tools to measure QoL. Multitudes of HRQoL instruments have been described providing adequate coverage of the basic HRQoL dimensions (i.e. physical, functional, social, and emotional function). As the patients represent the most appropriate source of information for their own QoL, the patient self-report is the usual means of assessing QoL. There is no consensus as to which instruments are more appropriate. However, not all QoL instruments have been shown to have acceptable psychometric properties such as reliability, validity and responsiveness. These tools can be classified into 3 main categories: generic instruments, symptom-focused questionnaires and cancer-specific instruments (Table 1).

Esophagectomy, of all elective or emergency surgical oncology procedures performed, is currently one of the most highly rated for morbidity and mortality. Mortality rates vary between 1% and 8% and major morbidity occurs in almost 50% of the patients undergoing resection^[32,33]. The impact of surgery on QoL has been investigated in several prospective studies using validated reliable questionnaires^[34-36]. These investigations generally showed that early in the postoperative phase most aspects of QoL significantly deteriorate. Probably the only aspect of QoL that does not dramatically deteriorate after surgery is emotional function^[34-37]. Several studies have shown that scores for emotional function remain stable after surgery and this may represent patients' relief that the procedure is over, despite the slow physical recovery. Dysphagia scores are generally improved or stable after surgery and patients report fewer problems swallowing solid and soft foods than before the operation. Relief of dysphagia, however, is replaced with other symptoms such as anorexia, change in taste, nausea and diarrhea. The combined impact of multiple symptoms and general deterioration in key aspects of well-being leads to reduced overall QoL scores, but these

gradually recover within 9 mo. Although longitudinal studies show QoL recovery after surgery, one of the difficulties with interpreting these studies relates to missing data due to attrition. The 1-year survival rate after esophagectomy is about 65%; therefore, most papers reporting a recovery of QoL only include data from patients who are alive and sufficiently well to complete questionnaires.

Safieddine *et al*^[38] suggested that although combined modality therapy (chemotherapy/radiation therapy/surgical intervention) is arduous and prolonged, its effect on HRQoL in patients with operable EC is transient, since HRQoL scores return to baseline levels after induction and before surgical intervention. Similarly, surgical intervention has a significant effect on HRQoL because FACT-E scores (Functional Assessment of Cancer Therapy-Esophageal; a validated tool to measure the effect of treatment on functional, social, physical, and emotional well-being that incorporates the EC subscale and allows for a systematic evaluation of QoL specifically in the context of EC) decrease significantly 1 mo after surgical intervention but again return to baseline levels within 3 mo of surgical intervention. Significantly greater increases in FACT-E scores were observed in patients who were still alive 1 year after surgical intervention with or without disease but were observed to decrease in those who died within 1 year of surgical intervention. These researchers had similar findings in patients after esophagectomy who had not been treated with induction chemoradiotherapy.

HRQOL AFTER SEMS IMPLANTATION IN PATIENTS WITH INOPERABLE EC

Since their introduction in the early 1990s^[39,40], SEMS have virtually supplanted not only conventional prostheses but also most forms of ablative therapy in the palliation of malignant dysphagia^[41,42]. The reasons for this range from perceived to real benefits. The latter include smaller delivery systems (precluding the need for excessive dilation), ability to curve around acute angulations, and the larger internal diameter of most SEMS compared with conventional prostheses. The perceived, as opposed to proved,

Table 2 Characteristics of conventional and anti-reflux mechanism self-expanding metal stents

	Material	Length	Inner diameter	Constrainability	Foreshortening	Anti-reflux mechanism
Conventional SEMS						
Ultraflex	Nitinol	10 cm (7 cm CS)	18 mm with 23 mm PF	Braided nylon wire	20% to 40%	
	Polyurethane sheath	12 cm (9 cm CS) 15 cm (12 cm CS)	23 mm with 28 mm PF	Not reconstrainable when partially deployed		
Z stent	Stainless steel	8, 10, 12, 14 cm	18 mm with 25 mm PF and DF	Polyethylene sheath	None	
	Polyurethane covering			Reconstrainable when partially deployed		
Wallstent	Elgiloy	10 cm (8 cm CS)	20 mm with 23 mm PF and DF	Polyethylene sheath	Up to 28%	
	Polyurethane sheath	15 cm (13 cm CS)		Reconstrainable when partially deployed		
SEMS with an anti-reflux mechanism						
Dua Z-stent						Polyurethane sleeve (collapses with gastric pressure)
DO stent						Tricuspid valve
Fer-X-Ella stent						Stainless steel with polyethylene covering and windsock type valve

Modified from Sreedharan *et al*^[56]. SEMS: Self-expanding metal stents; CS: Covered segment; PF: Proximal flare; DF: Distal flare.

benefits have been heavily touted by the manufacturers and include more precise placement (contradictory data because of prosthesis foreshortening in many of the SEMS), fewer long-term complications, and long-term survival advantages. In the 20 years since their introduction, both the SEMS themselves and their delivery systems have undergone multiple modifications. As such, most SEMS have evolved from an uncovered to a covered form, diameters of the prostheses have often been increased, and attempts have been made to minimize migration, gastroesophageal reflux, and tissue ingrowth (Table 2). Although it is safer and easier to place expandable stents, they are not devoid of complications. The major complications include stent migration, stent block, bleeding, and perforation, while the minor ones are foreign body sensation, regurgitation, and chest pain. The main complication of metal stents is distal migration, with an incidence rate ranging between 10% and 30%^[43]. It is more commonly (50%) seen when covered endoprosthesis are used to treat distal esophageal lesions involving the gastroesophageal junction^[44,45]. Stents can become blocked either due to tumor ingrowth through the stent mesh (17%-36%) or tumor overgrowth (10%)^[46,47].

As mentioned in the introduction, the primary aim of treatment in patients with inoperable EC is to relieve dysphagia with minimal morbidity and mortality, and thus improve their QoL. Implantation of a SEMS has become established as a treatment modality for the palliation of malignant dysphagia. SEMS relieves dysphagia rapidly and improves the nutritional status. However, in most studies, relief of dysphagia is the only aspect of HRQoL being measured, although physical, mental and social functioning and other EC-specific aspects of HRQoL are additional important outcome measures, as explained before.

A randomized clinical trial comparing SEMS with plastic endoprosthesis published in 2002 by O'Donnell *et al*^[48]

included 50 patients suffering from dysphagia due to an inoperable EC, and measured QoL using EORTC QLQ-30, a multi-dimensional cancer-specific QoL questionnaire and an EC specific questionnaire (EORTC OES-24), allowing QoL to be measured over 26 components relating to cancer in general and EC in particular. Although the authors found no statistical significance in any of the 26 components, 21 of the 26 components showed a trend towards the metal group, five were neutral and none favored plastic stents.

Shenfine *et al*^[49] in a randomized controlled trial regarding the cost-effectiveness of palliative therapies for patients with inoperable EC studied QoL in detail using four different questionnaires including Spitzer QoL index, Karnofsky performance scale, Euroqol EQ-5D and EORTC QLQ-30. They also used proxy and self-administered questionnaires. These authors reported differences in the baseline quality of life index favoring the non-SEMS group and went on to report 1 and 6 wk QoL data for the different treatment groups. Mean QoL index for the SEMS group at 6 wk was significantly lower than for the QoL index at baseline for the same group. The authors concluded that decreased QoL in the SEMS group at 6 wk, although not statistically significant, reflected the presence of pain following the intervention; the effect of pain on quality of life may have significant implications for treatment with SEMS.

Bergquist *et al*^[50], in their randomized controlled clinical trial published in 2005, compared endoluminal brachytherapy with endoscopic stent placement for newly diagnosed patients with advanced EC or gastroesophageal junction cancer, with a primary outcome being the detailed evaluation of HRQoL. Sixty-five patients eligible for the study were enrolled; 34 were randomized to stent treatment and 31 to brachytherapy. The authors assessed dysphagia improvement as a part of disease-specific HRQoL question-

Table 3 Quality of life results after self-expanding metal stents placement for malignant dysphagia

Madhusudhan <i>et al</i> ^[54]	2009	Prospective study	QoL after palliative stenting in patients with inoperable EC	EORTC QLQ-C30 EORTC QLQ-OES 18	Palliative stenting using SEMS resulted in significant improvement in all scales of QoL

QoL: Quality of life; HRQoL: Health-related quality of life; EC: Esophageal cancer; SEMS: Self-expanding metal stents.

naire EORTC OES-23 and found a statistically significant improvement in dysphagia grade, ability to swallow saliva, choking and coughing compared to baseline scores. There was no improvement in these outcomes for patients treated with brachytherapy. In an interim inter-group analysis at 1 mo a significant improvement in dysphagia scale favored the SEMS group. At 3 mo, some of the dysphagia-related parameters continued to show clinical improvement in the SEMS group but these did not achieve statistical significance. In the brachytherapy group, clinically significant improvements were noted in some of the parameters related to dysphagia at 3 mo and these were maintained at 6 mo. However, these data did not achieve statistical significance. General health QoL was measured using the EORTC QLQ-30 scale. In the stent group all functional scales and single symptom scales deteriorated compared to mean scores at inclusion. The largest deterioration was found for social function, followed by pain, role function and insomnia. In the brachytherapy group, a clinically relevant deterioration was found for most variables on the function and single symptom scales with physical function, global QoL and pain scales reaching statistical significance.

The same type of comparison between these two types of palliative procedures, brachytherapy and stent placement, in patients with advanced EC was published from Homs *et al*^[51] who prospectively compared generic and disease-specific HRQoL between single dose brachy-

therapy and SEMS placement. Treatment with single dose brachytherapy gave better overall scores on HRQoL scales compared with stent placement for the palliation of EC. Major improvements were seen on the dysphagia and eating scales of the disease-specific EORTC OES-23, in contrast to other scales of this disease-specific measure which remained almost stable during follow-up. In addition, pain levels remained stable or slightly increased during follow-up, indicating that adequate pain management during follow-up is important.

In a randomized trial carried out at the Western General Hospital in Edinburgh (United Kingdom)^[52], patients presenting with advanced inoperable EC were randomized to palliative therapy by endoscopic thermal ablation (34 patients) or insertion of a SEMS (31 patients), assessing HRQoL. The authors evaluated cancer-specific and EC-specific questionnaires (EORTC QLQ-30 and OES 24) along with a generic questionnaire (SF-36) and a psychometric questionnaire (HAD Scale). The baseline QoL data were reported to be similar in the two groups. However, at 1 mo the SEMS group was significantly worse in parameters of physical function, physical health, pain and emotional health. Results of the cancer-specific questionnaires were reported to be significantly worse in the SEMS group for fatigue, emotional, cognitive and social function and troublesome taste. No differences were noted in dysphagia, deglutition and eating scores.

Several randomized studies comparing different types

of SEMS have been published over the last 10 years but only a few of them have assessed HRQoL as an outcome. Siersema *et al*^[53] performed a prospective, randomized study comparing the Ultraflex stent, the Flamingo Wallstent, and the Gianturco-Z stent in 100 consecutive patients with dysphagia caused by EC or carcinoma of the gastric cardia. All patients were evaluated before stent placement and at 4-wk intervals until death. The authors used the WHO performance status in addition to the dysphagia score to evaluate QoL. The mean WHO performance status before and at 4 wk after stent placement was not different among the 3 patient groups.

Madhusudhan *et al*^[54] in their prospective study assessed the QoL using EORTC QLQ-C30 (version 3) and EORTC QLQ-OES 18 questionnaires before stenting, and at 1, 4, and 8 wk following placement of the stent. The results showed significant improvement following stenting. The general health scale and function scores increased significantly. Most symptom scores, except pain, showed improvement. The pain score deteriorated at 1 wk, as initial expansion of SEMS following its placement led to an increase in pain sensation. Over a period of 2 mo, the pain scores decreased to baseline values. The financial strain scores also showed a significant improvement.

The QoL results after SEMS placement for malignant dysphagia are displayed in Table 3.

CONCLUSION

The prime objective of palliative treatment in patients with inoperable esophageal or gastro-esophageal junctional cancers is to achieve adequate improvement in dysphagia and QoL in a short span of time with a reduced need for additional interventions. In summary, the above analysis confirms that SEMS insertion provides a swift palliation of dysphagia compared to brachytherapy. However, this difference gradually diminishes over time and, in the long run, brachytherapy appears to provide better dysphagia improvement and improved disease-specific QoL scores along with better general health-related QoL scores in these gradually deteriorating patients. On the other hand, no evidence was found to suggest that stent implantation is any better than laser treatment in terms of improving dysphagia, recurrent dysphagia or in yielding a better QoL. Nevertheless, SEMS insertion has a better technical success rate and also reduces the number of repeat interventions. Finally, QoL seems to be similar between different types of conventional SEMS.

Abstract

AIM: To investigate the mechanisms involved in a possible modulator role of interleukin (IL)-6 signalling on CYR61-CTGF-NOV (CCN) 2/connective tissue growth factor (CTGF) expression in hepatocytes (PC) and to look for a relation between serum concentrations of these two parameters in patients with acute inflammation.

METHODS: Expression of CCN2/CTGF, p-STAT3, p-Smad 3/1 and p-Smad2 was examined in primary freshly isolated rat or cryo-preserved human PC exposed to various stimuli by Western blotting, electrophoretic mobility shift assay (EMSA), reporter-gene-assays and reverse-transcriptase polymerase chain reaction.

RESULTS: IL-6 strongly down-regulated CCN2/CTGF protein and mRNA expression in PC, enhanceable by extracellular presence of the soluble IL-6 receptor gp80, and supported by an inverse relation between IL-6 and CCN2/CTGF concentrations in patients' sera. The inhi-

bition of TGF β 1 driven CCN2/CTGF expression by IL-6 did not involve a modulation of Smad2 (and Smad1/3) signalling. However, the STAT3 SH2 domain binding peptide, a selective inhibitor of STAT3 DNA binding activity, counteracted the inhibitory effect of IL-6 on CCN2/CTGF expression much more pronounced than pyrrolidine-dithiocarbamate, an inhibitor primarily of STAT3 phosphorylation. An EMSA confirmed STAT3 binding to the proposed proximal STAT binding site in the *CCN2/CTGF* promoter.

CONCLUSION: CCN2/CTGF is identified as a hepatocellular negative acute phase protein which is down-regulated by IL-6 *via* the STAT3 pathway through interaction on the DNA binding level.

INTRODUCTION

Fibrogenic restructuring of the liver is commonly caused by chronic inflammatory processes. Upon perpetuation of the initial inflammatory attack, a rapid synthesis of several proteins, which is stimulated by cytokines such as tumor necrosis factor (TNF)- α , interleukin (IL)-1, and particularly IL-6, takes place in order to restore homeostasis.

This process is widely known as the hepatocellular acute phase reaction upon the initial tissue injury, infection or inflammation^[1].

CYR61-CTGF-NOV (CCN) 2/connective tissue growth factor (CTGF), a member of the CCN superfamily of secreted, cysteine-rich glycoproteins, has been implicated in the pathogenesis of hepatic fibrosis and is currently suggested to be an important downstream amplifier of the effects of the profibrogenic master cytokine transforming growth factor (TGF)- β ^[2,3]. Its molecular mechanism of action is still not known in detail, but it very likely strengthens the binding of TGF β 1 to its cognate receptors^[4]. Its crucial role in fibrogenesis is documented by strong up-regulation in fibrotic liver tissue^[5-7], and even more importantly by recent studies, in which knock-down of CCN2/CTGF by siRNA lead to substantial attenuation of experimental liver fibrosis^[8,9]. Recently, we were among the first to identify that hepatocytes (PC) substantially synthesize CCN2/CTGF in cell culture and in injured liver, and that CCN2/CTGF is sensitively up-regulated by TGF β 1^[10-12].

IL-6, originally identified as a B cell differentiation factor in 1981^[13] is a pleiotropic cytokine, which is in the liver mostly synthesized by hepatic macrophages (Kupffer cells) or CD4+ T-helper (Th) cells^[14-16]. IL-6 signals through a cell-surface type I cytokine receptor complex consisting of the ligand-binding IL-6R α chain (gp80, CD126), and the signal-transducing component gp130, which is the common signal transducer for several cytokines including leukemia inhibitory factor (LIF), oncostatin M, or IL-11, and which is almost ubiquitously expressed in most tissues^[17]. In contrast, the expression of gp80 is restricted to certain cells such as PC, neutrophils, monocytes/macrophages and some lymphocytes. However, naturally occurring soluble IL-6R together with IL-6 can stimulate cells lacking gp80 receptor part, a process termed trans-signalling^[18]. As IL-6 interacts with its receptor gp80, it triggers the gp130 and IL-6R proteins to form a complex, thus activating the receptor. These complexes bring together the intracellular regions of gp130 to initiate a signal transduction cascade through certain transcription factors, Janus kinases (JAKs) and Signal Transducers and Activators of Transcription (STATs), but may also lead to an activation of MAP-kinase (MAPK) and phosphoinositide 3-kinase (PI3K) signalling cascades^[19].

In the present study, we investigated the anti-fibrogenic effect of IL-6 comparing with the effect of other selected cytokines (IL-12, IL-2) on CCN2/CTGF. The down-regulating effect of IFN- γ on CCN2/CTGF in hepatocytes and hepatic stellate cells was already shown by others^[11,20]. On the other hand, the up-regulation of IL-6 induced by CCN2/CTGF was shown in pancreatic stellate cells^[21].

Earlier reports by van Gool *et al.*^[22] gave evidence that the stereotypical rat acute phase reactant α 2-macroglobulin acts as an inhibitor of experimental hepatitis; however, the impact of this or other acute phase proteins such as IL-6 on CCN2/CTGF production in PC and the molecular basis of CCN2/CTGF involvement in the acute phase reaction are yet unknown.

We therefore investigated the mechanisms involved in

a possible modulator role of IL-6 signalling on CCN2/CTGF expression in rat and human PC and looked for a possible association between serum concentrations of these two parameters in patients with acute inflammation. Our findings propose that CCN2/CTGF serves as a hepatocellular negative acute phase protein which is down-regulated by IL-6 *via* the STAT3 pathway.

MATERIALS AND METHODS

Reagents

Cytokines or soluble cytokine receptors: rrIL-6 (506-RL), IL-2, IL-12, rhTGF β 1 (240-B) and rhsgp130 (228-GP) were all from R&D Systems (Minneapolis, MN); rhsgp80 was prepared as described by Weiergräber *et al.*^[23] and kindly provided by the Department of Biochemistry, University Hospital of RWTH Aachen, Germany. rhIL-6 (1131567) was from Roche (Mannheim, Germany). STAT3 inhibitors: PDTC was from Sigma-Aldrich (St. Louis, MO); cell permeable STAT3 inhibitor peptide (PY*³LKTK, Cat. No. 573096) was from Calbiochem (Darmstadt, Germany). Specific MAP Kinase inhibitors used in this study were: PD98059 (Cat. No. 513000), SB203580 (Cat. No. 559398), and UO126 (Cat. No. 662005) were all from Calbiochem (Darmstadt, Germany), Edelfosine (PKI-ET18) was from Biaffin (Kassel, Germany).

Antibodies for Western blotting: rabbit anti-Smad3 (ab28379) and chicken anti- α 1-AT (ab14226) (Abcam, Cambridge, UK); goat anti-CTGF/CCN2 (L-20, sc-14939) (Santa Cruz, CA); rabbit anti-p-Smad3 (Ser423/425)/p-Smad1 (Ser463/465) (#9514), rabbit anti-p-Smad2 (Ser465/467) (#3101), rabbit anti-Smad2 (#3102), rabbit anti-phospho-STAT3 (Tyr705) (#9145) and mouse anti-STAT3 (#9139) (Cell Signalling/New England Biolabs, Ipswich, MA); mouse anti- β -actin (AC-15, Cat. No. 5441, Sigma-Aldrich).

Animals

Adult male Sprague-Dawley rats (body weight 180 to 220 g, between 0.5 and 0.8 years of age) had free access to a standard laboratory chow diet and normal tap water throughout the experimental period. All animals received care and treatment in compliance with the German Animal Protection Act, which is in accordance with the German Research Council's criteria.

Isolation and culture of rat hepatocytes

Primary rat PC were isolated from male Sprague-Dawley rats by the two-step collagenase method of Seglen^[24] modified as described before^[25]. Cell culture was performed under serum-free conditions as previously described^[10]. Supplementation of the culture medium with rrIL-6, rhTGF β 1 or STAT3 inhibitors was performed as described in the respective figure legends.

Western blotting analysis

Preparations of cytoplasmic cell extracts, determination of protein concentrations, and Western blotting analysis were performed exactly as previously described^[11,26]. Den-

sitometric quantification of the blot results was done with the Lumi-Imager (Roche, Mannheim, Germany) and the LumiAnalyst 3.0 Software (Roche).

Reverse-transcriptase polymerase chain reaction for rat *CCN2/CTGF*

Total cellular RNA was extracted with the Qiagen RNeasy Mini purification kit (Qiagen, Hilden, Germany). cDNA was reverse-transcribed using the First-Strand cDNA synthesis kit III (Invitrogen, Karlsruhe, Germany). Reverse-transcriptase polymerase chain reaction (RT-PCR) was performed using the Geneamp 9700 Thermocycler PCR System (Applied Biosystems, Germany) and the following primers: *rCCN2/CTGF* (forward: 5'-CGTCCATGCTGCACAGG-3'; reverse: 5'-CAAGTTTGAGCTTTCTGG-3') as previously described^[3]. The size of the amplified fragment was 144 bp.

Electrophoretic mobility shift assay

Nuclear extracts of rat PC treated with rrIL-6 (10 µg/L, 30 min), were prepared and the electrophoretic mobility shift assay (EMSA) performed slightly modified from that previously described^[27]. In brief, for EMSA, 3.4 µg of total nuclear protein were used for each lane. The oligonucleotide sequence used to assess the two proposed STAT binding sites in the *CCN2/CTGF* promoter (proximal: -418 to -415 bp, distal: -384 to -381 bp)^[28] was 5'-AGGAATTCCTGCTGTTTGCCTCTTCAGCTACCTACTTCCT-3'. The mutated proximal STAT binding site (mt, proximal) was analyzed using the following oligonucleotide sequence: 5'-AAGAATTCCTGCTGTTTGCCTCTTCAGCTACCTACTTCCT-3'. The oligonucleotide sequence of the probe reflective of the mutant distal putative STAT binding site (mt, distal) was: 5'-AGGAATTCCTGCTGTTTGCCTCTTCAGCTACCTACTTCTT-3'. All oligos were synthesized by MWG Biotech (Ebersberg, Germany). The synthetic oligonucleotides were labeled using a T4 polynucleotide kinase (DNA 5'-End Labeling Kit; Promega, Mannheim, Germany) and [γ -³²P]ATP (Perkin Elmer, Rodgau-Jügesheim, Germany). Following incubation of the radiolabeled probes with nuclear extracts, protein-DNA complexes were resolved on a NOVEX 6% retardation gel (Invitrogen) and detected using a Typhoon 9410 Phosphor-Imager (Amersham Biosciences, Freiburg, Germany).

Generation of recombinant *CCN2/CTGF* reporter adenovirus (Ad-hCTGF-Luc)

For generation of the reporter adenovirus Ad-hCTGF-Luc, the approximately 2.5-kbp *Cla* I fragment of vector pGL3-Basic-hCTGF-Luc^[12] harbouring a fusion of human *CCN2/CTGF* gene promoter and the luciferase reporter gene was cloned into the *Cla* I site of vector pΔE1sp1A^[29] resulting in the generation of pΔE1sp1A-hCTGF-Luc. The integrity of cloning boundaries was verified by restriction analysis and sequencing with the flanking primers 5'-GCGTAACCGAGTAAGAATTTG-3' and 5'-GGC-GACCATCAATGCTGGAG-3' that were obtained from MWG-Biotech AG (Ebersberg, Germany).

The integration of the reporter cassette from pΔE1-

sp1A-hCTGF-Luc into the adenoviral backbone vector pJM17^[30] was performed by *in vitro* homologous recombination in the human embryo kidney cell line 293 using a protocol described before^[31]. Successful generation of recombinant viral particles was visualized by viral foci formation. After total infection, the viral particles were released from cells by three rounds of a freeze-thaw cycle and separated from cell debris by centrifugation at 3000 r/min for 10 min. To generate high titer viral stocks, 293 cells were re-infected at a multiplicity of infection (MOI) of 1 and grown for 3-4 d. Amplified viruses were harvested, concentrated through standard CsCl gradient centrifugation and subsequently purified using the BD Adeno-X™ Purification Filter system (BD Biosciences, Clontech, Palo Alto, CA) according to the manufacturer's instructions.

Luciferase gene reporter assay

Cells were cultured in black 96 well plates and infected with 1×10^8 virions/mL of Ad-hCTGF-luc reporter virus. After specific treatment, the luciferase activity was measured as described previously^[3].

Culture of primary human hepatocytes

Primary human hepatocytes from a 15-year-old female donor of Caucasian origin with history of traumatic head injury (BD Gentest™ Cryopreserved Human Hepatocytes, Cat. No. 454551, Lot. No. 208, BD Bioscience, Franklin Lakes, NJ) were cultured according to the distributor's instructions. Primary human hepatocytes were stored in liquid nitrogen vapor until ready and were gradually thawed for further use^[32]. Cell purification was performed using Cryopreserved Hepatocytes Purification Kit (Cat. No. 454500, BD Bioscience). The viability of the final cell suspension, checked by trypan blue exclusion, was around 70% and cell recovery was $9-11 \times 10^6$ cells/vial. For the induction assay, primary human hepatocytes were seeded in ISOMs Seeding Media supplemented with 5% FCS, 2 mmol/L L-glutamine, penicillin (100 kIU/L), streptomycin (100 g/L) (all from BioWhittaker Europe) and ascorbic acid (50 mg/L, Merck Biochemicals, Darmstadt, Germany) on type I collagen coated plastic dishes (BD Bioscience) with a density of 19×10^4 cells/cm² and cultured in a humidified atmosphere (37°C, 5% CO₂). The first change of medium was performed with HepatoStim medium (Cat. No. 355056, BD Bioscience) supplemented with L-glutamine, penicillin and streptomycin as described above and rhEGF (Cat. No. 354052, BD Bioscience) 4 h after seeding. The cells were incubated for another 24 h until the medium was changed and supplemented with the indicated concentrations of rhIL-6, gp80 and gp130 for further 24 and 48 h as described in the respective figure legends.

Patients

Patients admitted to the hospital with different severity of an acute phase reaction [$n = 36$; mean age 47 years, range 1-86 years; 27 males (age 8-86 years) and 9 females (age 1-54 years)] having serum IL-6 concentrations routinely determined as part of their disease-related diag-

nostics, were included in the study. Patients were divided into two groups according to their serum IL-6 concentrations: Group 1 - IL-6 < 100 ng/L [$n = 21$; mean age 54 years, range 20-74 years; 18 males (age 18-74 years) and 3 females (age 14-37 years)]; Group 2 - IL-6 > 100 ng/L [$n = 15$; mean age 42 years, range 1-86 years; 9 males (age 8-86 years) and 6 females (age 1-54 years)]. Peripheral venous blood samples were taken in the morning (6 to 8 AM) upon admission to the hospital. Serum was separated at 4000 *g* 30 to 60 min after clot-retraction and stored at -80°C. At the time of blood sample collection, the patients did not suffer from liver fibrosis or renal insufficiency, as indicated by normal serum activities of ALT, AST, gamma-GT (GGT), and creatinine concentrations, respectively. All blood samples were used anonymously.

Determination of human serum IL-6 and CCN2/CTGF concentrations

Quantitative determination of human IL-6 was performed using a chemiluminescence assay on the Immulite 2000 autoanalyzer (Siemens Medical Healthcare, Erlangen Germany). Serum levels of the CCN2/CTGF were determined in replicates using a human CCN2/CTGF sandwich enzyme-linked immunosorbent assay provided by DRG, Mountainside, NJ, USA (Cat. No. 090731). CCN2/CTGF protein standards were obtained from BioVendor, Heidelberg, Germany (Cat. No. RD172035100).

Statistical analysis

For statistical analysis, SPSS 16.0 (SPSS, Chicago, IL) was used, applying two-tailed unpaired Student's *t* tests with a *P* value for significance set at least at 0.05. The correlations between variables were analyzed with the Pearson correlation tests. Values of *P* < 0.05 were considered statistically significant.

RESULTS

IL-6 inhibits CCN2/CTGF expression in cultured rat hepatocytes

We tested the effects of cytokines produced by liver residing immunocompetent cells on CCN2/CTGF expression in PC (Figure 1). Application of rrIL-6 (as representative of the IL-6 family of interleukins) strikingly reduced hepatocellular CCN2/CTGF protein expression in a dose dependent manner as seen in Western blotting analysis (Figure 1A) and also inhibited the transcriptional activation of the pGL3-hCTGF-luc reporter (Figure 1B). This finding is supported by the observation that rrIL-6 suppressed mRNA level of CCN2/CTGF in PC (Figure 1C). The difference in the intensity of reduction in Western blotting analysis and reporter gene assay may be explained by the fact that consistent reduction of CCN2/CTGF *de novo* synthesis, as seen by the moderate reduction of CCN2/CTGF promoter activity, eventually results in a strong reduction of overall availability of CCN2/CTGF within the cell, as seen by an even stronger decrease of CCN2/CTGF protein expression in Western blotting

analysis. As expected the stimulation with IL-6 induced synthesis of α 1-antitrypsin, an acute phase protein in cultured rat PC (Figure 1D).

In contrast, treatment with IL-2 (as representative of the common γ chain family of interleukins), and IL-12 (as representative of the IL-12 family of interleukins), showed no change in either CCN2/CTGF protein expression (Figure 1E) or transcriptional activation of the pGL3-hCTGF-luc reporter gene (unpublished data) in cultured PC.

TGF β 1 fails to induce CCN2/CTGF expression in cells pretreated with IL-6

As previously reported^[12] rhTGF β 1 induced CCN2/CTGF protein expression in PC (Figure 2). Based on this, we tested whether rrIL-6 was able to reduce not just spontaneous, but also TGF β 1-driven CCN2/CTGF protein expression. Indeed TGF β 1 largely failed to induce CCN2/CTGF expression in cells pretreated with different dosages of rrIL-6 (Figure 2A), an observation particularly prominent at earlier time points (2, 4 h) (Figure 2B). The inhibition of TGF β 1 driven CCN2/CTGF expression by rrIL-6 did not involve a modulation of TGF β 1 induced Smad signaling as rrIL-6 had no negative effect on phosphorylation of both Smad-2 and -3 proteins (Figure 2C). However, the observed immediate suppression of CCN2/CTGF synthesis, already within the first 2 h after stimulation with IL-6, suggests a direct interaction between IL-6 induced STAT3 signalling and transcriptional activation of the CCN2/CTGF promoter.

Complexation of IL-6 and sgp80 enhances the inhibitory effect of this cytokine on CCN2/CTGF protein expression in primary human hepatocytes

In order to avoid possible species specific phenomena, we therefore used primary human hepatocytes for ongoing studies in this direction. Our aim was to investigate whether the enhancing effect of sgp80 on IL-6 signaling, as previously described by Rose-John *et al.*^[18] for other cellular systems, was also transferrable to IL-6 dependent repression of hepatocellular CCN2/CTGF protein expression.

As observed in rat PC, application of rhIL-6 strikingly reduced CCN2/CTGF protein expression in primary human hepatocytes cultured for another 24 h and 48 h after stimulation (Figure 3A and B). This effect was enhanced by pre-incubation of IL-6 with sgp80 and attenuated by co-incubation with recombinant human soluble gp130 (sgp130) complexing with IL-6, and sgp80 (Figure 3B). As expected, synthesis of classical acute phase proteins such as α 1-AT and C-reactive protein (CRP) was increased in both cell fraction (Figure 3A and B) and conditioned culture medium of primary human hepatocytes following pre-incubation of IL-6 with sgp80 (Figure 3C and D).

Inhibition of STAT3 counteracts the IL-6 induced suppression of CCN2/CTGF expression in cultured rat hepatocytes

To study the mechanism of IL-6 induced suppression of

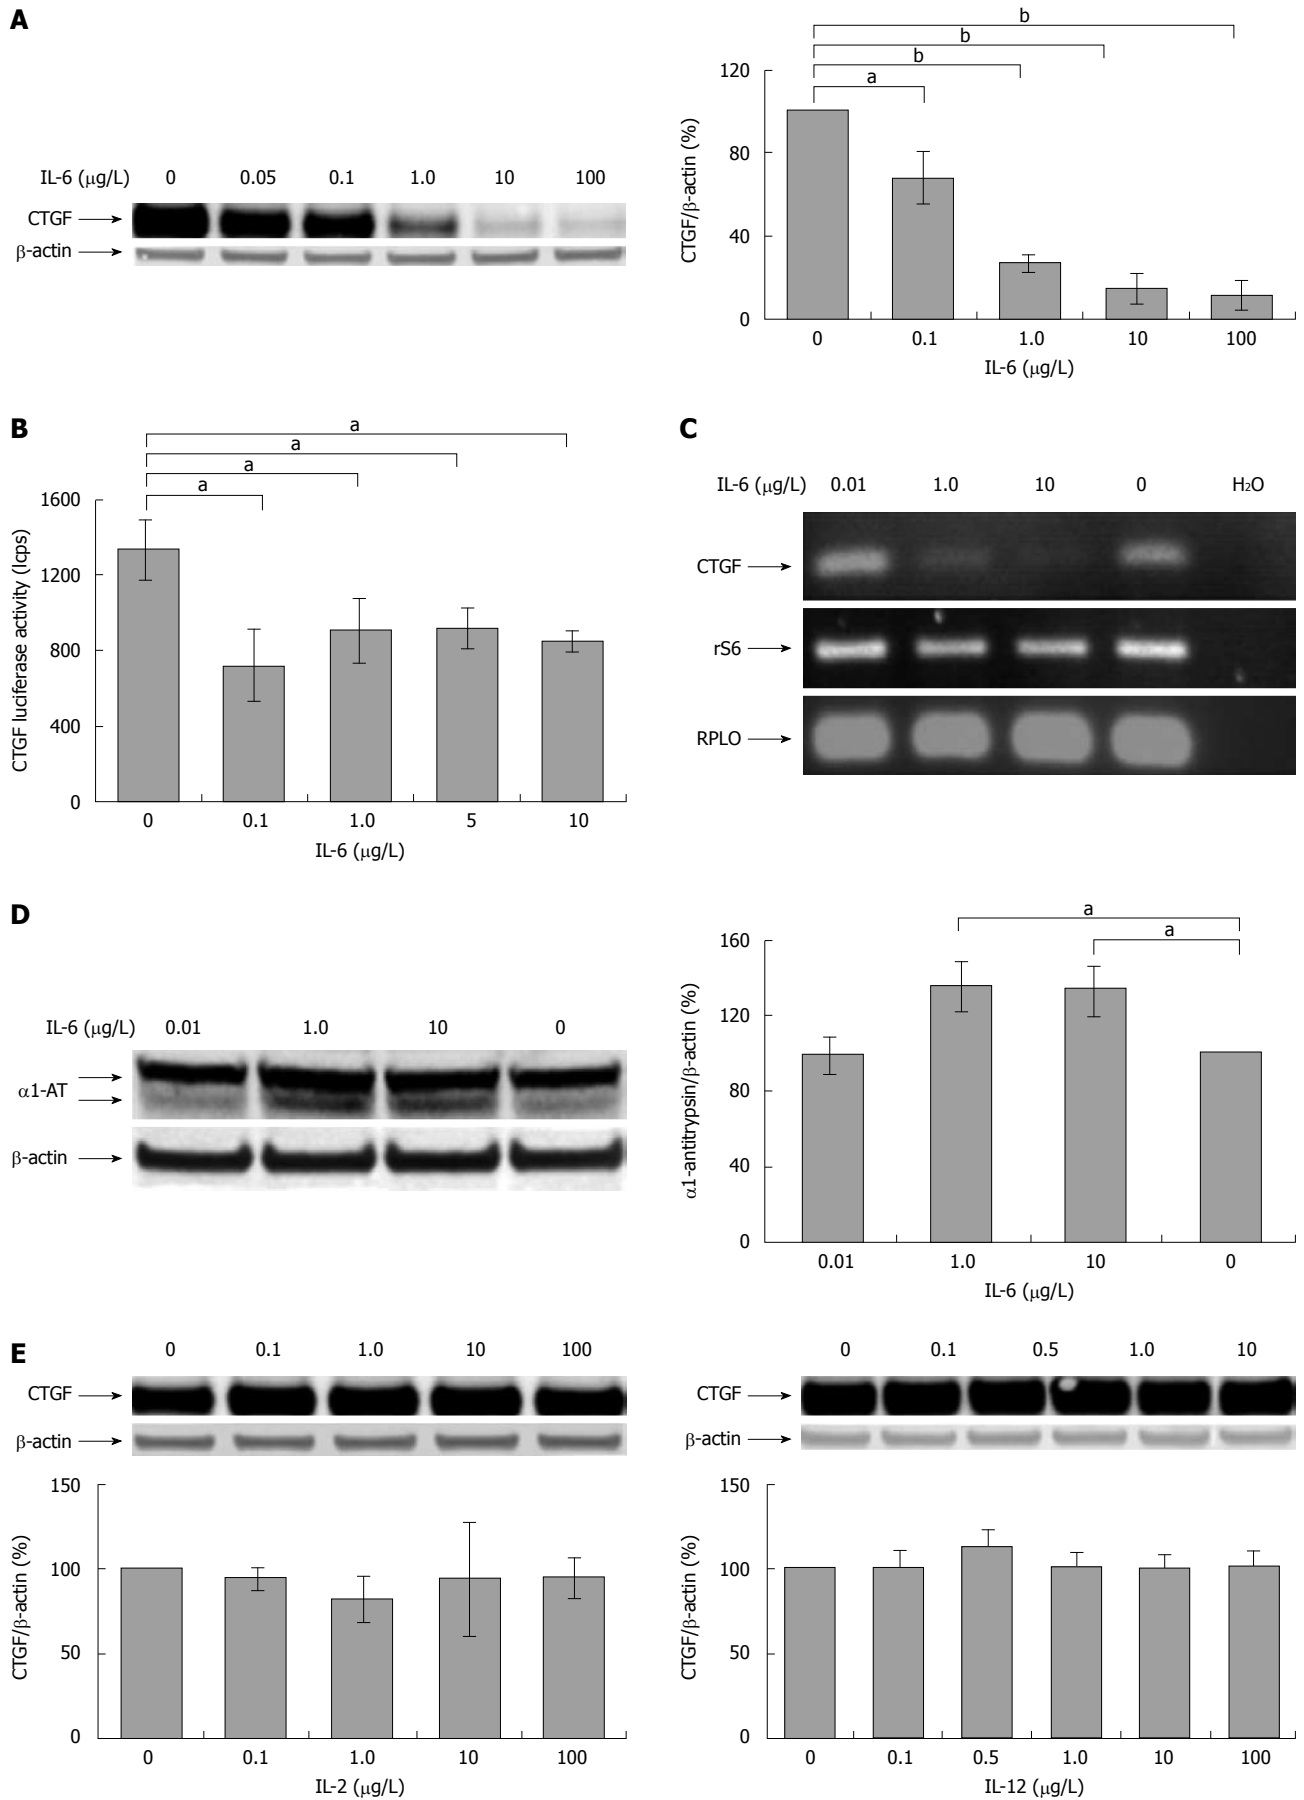

Figure 1 Interleukin-6 inhibits CYR61/CTGF/NOV 2/connective tissue growth factor expression in cultured rat hepatocytes. A: Western blotting of CYR61-CTGF-NOV (CCN) 2/connective tissue growth factor (CTGF) of rat hepatocytes (PC) cultured for 24 h under serum-free conditions with or without addition of indicated concen-

trations of rr interleukin (rrIL)-6. β -actin served as loading control. A representative blot is shown. Blots were quantified relative to β -actin using the Lumi Imager System. Quantifications represent the mean \pm SD of 3 independent cultures. $^aP < 0.05$, $^bP < 0.0001$ vs untreated control; B: CCN2/CTGF reporter gene activation. Rat PC were cultured in serum-free medium for 24 h and transfected with Ad-hCTGF-Luc then subjected to the indicated concentrations of rrIL-6 16 h after transfection and cultured for another 24 h before harvest. Mean values (\pm SD from 3 cultures) are shown. $^aP < 0.05$ vs untreated control; C: Reverse-transcriptase polymerase chain reaction (RT-PCR) of CCN2/CTGF of rat PC. Rat PC were cultured in serum-free medium and treated with rrIL-6 at indicated concentrations for 24 h. RT-PCR was performed using primers for rat CCN2/CTGF as described in Materials and Methods. rS6 and RPLO served as internal control. A representative experiment of 3 independent cultures is shown; D: Western blotting of α 1-AT of rat PC cultured for 24 h under serum-free conditions with or without addition of indicated concentrations of rrIL-6. A representative blot is shown. Blots were quantified as described in (A). $^aP < 0.05$ vs untreated control; E: Western blottings of CCN2/CTGF of PC cultured for 24 h in serum-free medium with or without addition of indicated concentrations of IL-2 or IL-12. β -actin served as loading control. Representative blots of 3 independent experiments are shown. Blots were quantified as described in (A).

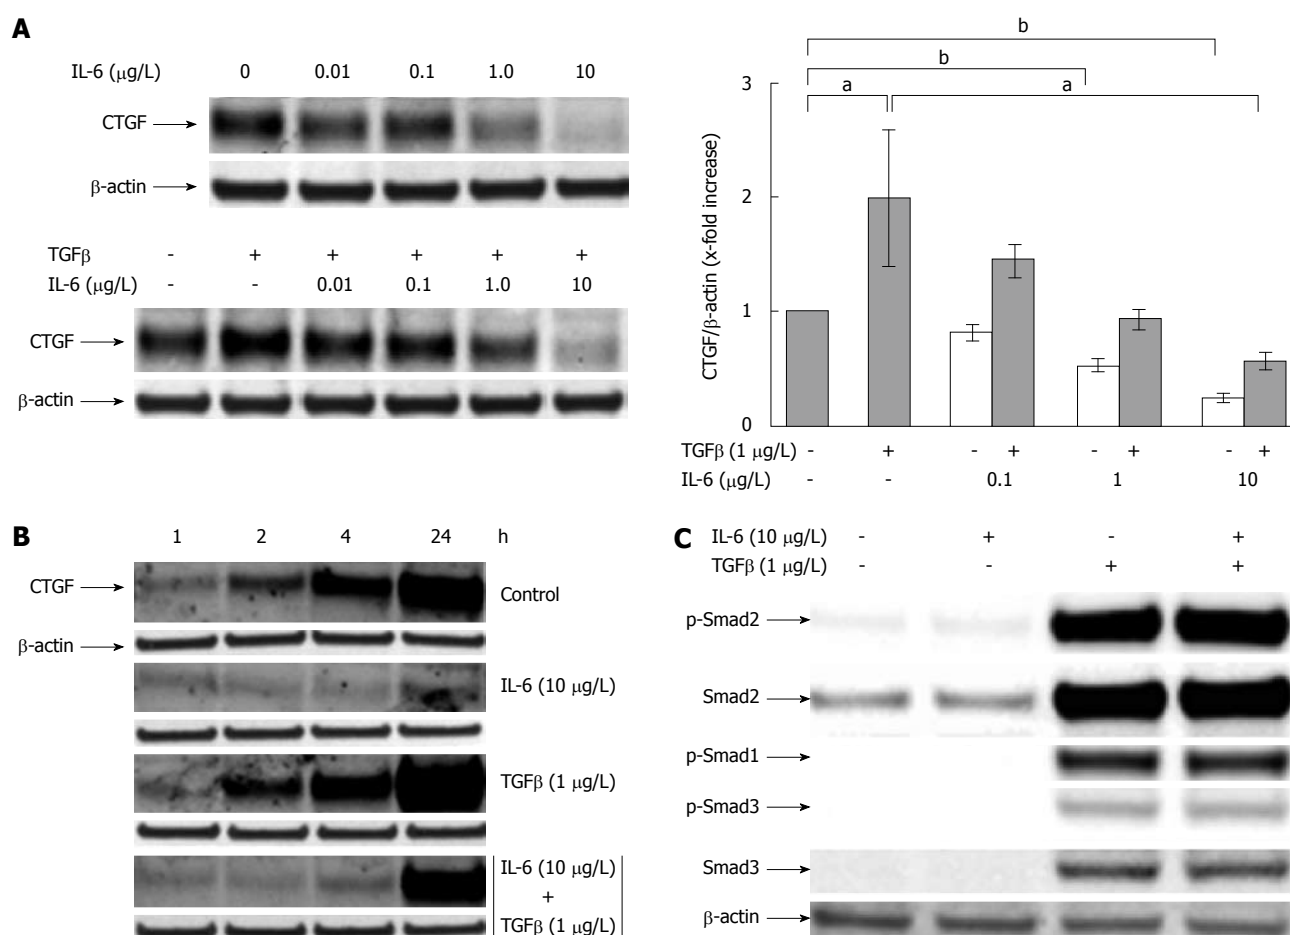

Figure 2 Interleukin-6 acts as an inhibitor of transforming growth factor β 1 induced CYR61/CTGF/NOV 2/connective tissue growth factor protein expression in cultured rat hepatocytes. A: Western blottings of CYR61/CTGF/NOV (CCN) 2/connective tissue growth factor (CTGF) of rat hepatocytes (PC) cultured under serum-free conditions with or without addition of rr interleukin (rrIL)-6 at indicated concentrations 30 min prior addition of rhTGF β 1 (1 μ g/L). The cell culture only with IL-6 at indicated concentrations served as internal control. Cells were harvested after another 24 h. β -actin served as loading control. Representative blots are shown. Blots were quantified relative to β -actin using the Lumi Imager System. Quantifications represent the mean \pm SD of 3 independent cultures. $^aP < 0.05$, $^bP < 0.0001$ vs untreated control; B: Western blottings of CCN2/CTGF of rat PC cultured as stated in (A) under serum-free conditions with or without addition of rrIL-6 (10 μ g/L) 30 min prior addition of rhTGF β 1 (1 μ g/L) where indicated. The cells were harvested after 1, 2, 4 and 24 h. β -actin served as loading control. A representative blot of 3 independent experiments is shown; C: Western blottings of phosphorylated and total Smad2 and Smad3, the latter antibody cross-reacting with Smad1. Rat PC were cultured for 24 h under serum-free conditions with or without addition of rh transforming growth factor (TGF) β 1 (1 μ g/L) and indicated concentrations of rrIL-6. Representative blots are shown.

CCN2/CTGF, the signal transduction pathway known to mediate IL-6 specific effects to the nucleus was interrupted at different levels using specific inhibitors (Figure 4). Inhibition of MAP-kinase signaling by the specific inhibitors (PD98059, SB203580, and UO126) did not abrogate the inhibitory effects of IL-6 on hepatocellular CCN2/CTGF synthesis (Figure 4A). Also, blocking of phosphatidylinositol phospholipase C signaling by administration

of edelfosine did not interfere with IL-6 signaling to the CCN2/CTGF promoter (Figure 4A).

However, exposure of cells to rrIL-6 leads to an activation of the JAK/STAT3 pathway by inducing STAT3 phosphorylation in primary rat PC^[33]. PC were pre-treated with pyrrolidine dithiocarbamate (PDTC) for 2 h and subsequently stimulated with rrIL-6. PDTC was previously proven to primarily impair STAT3 phosphorylation in

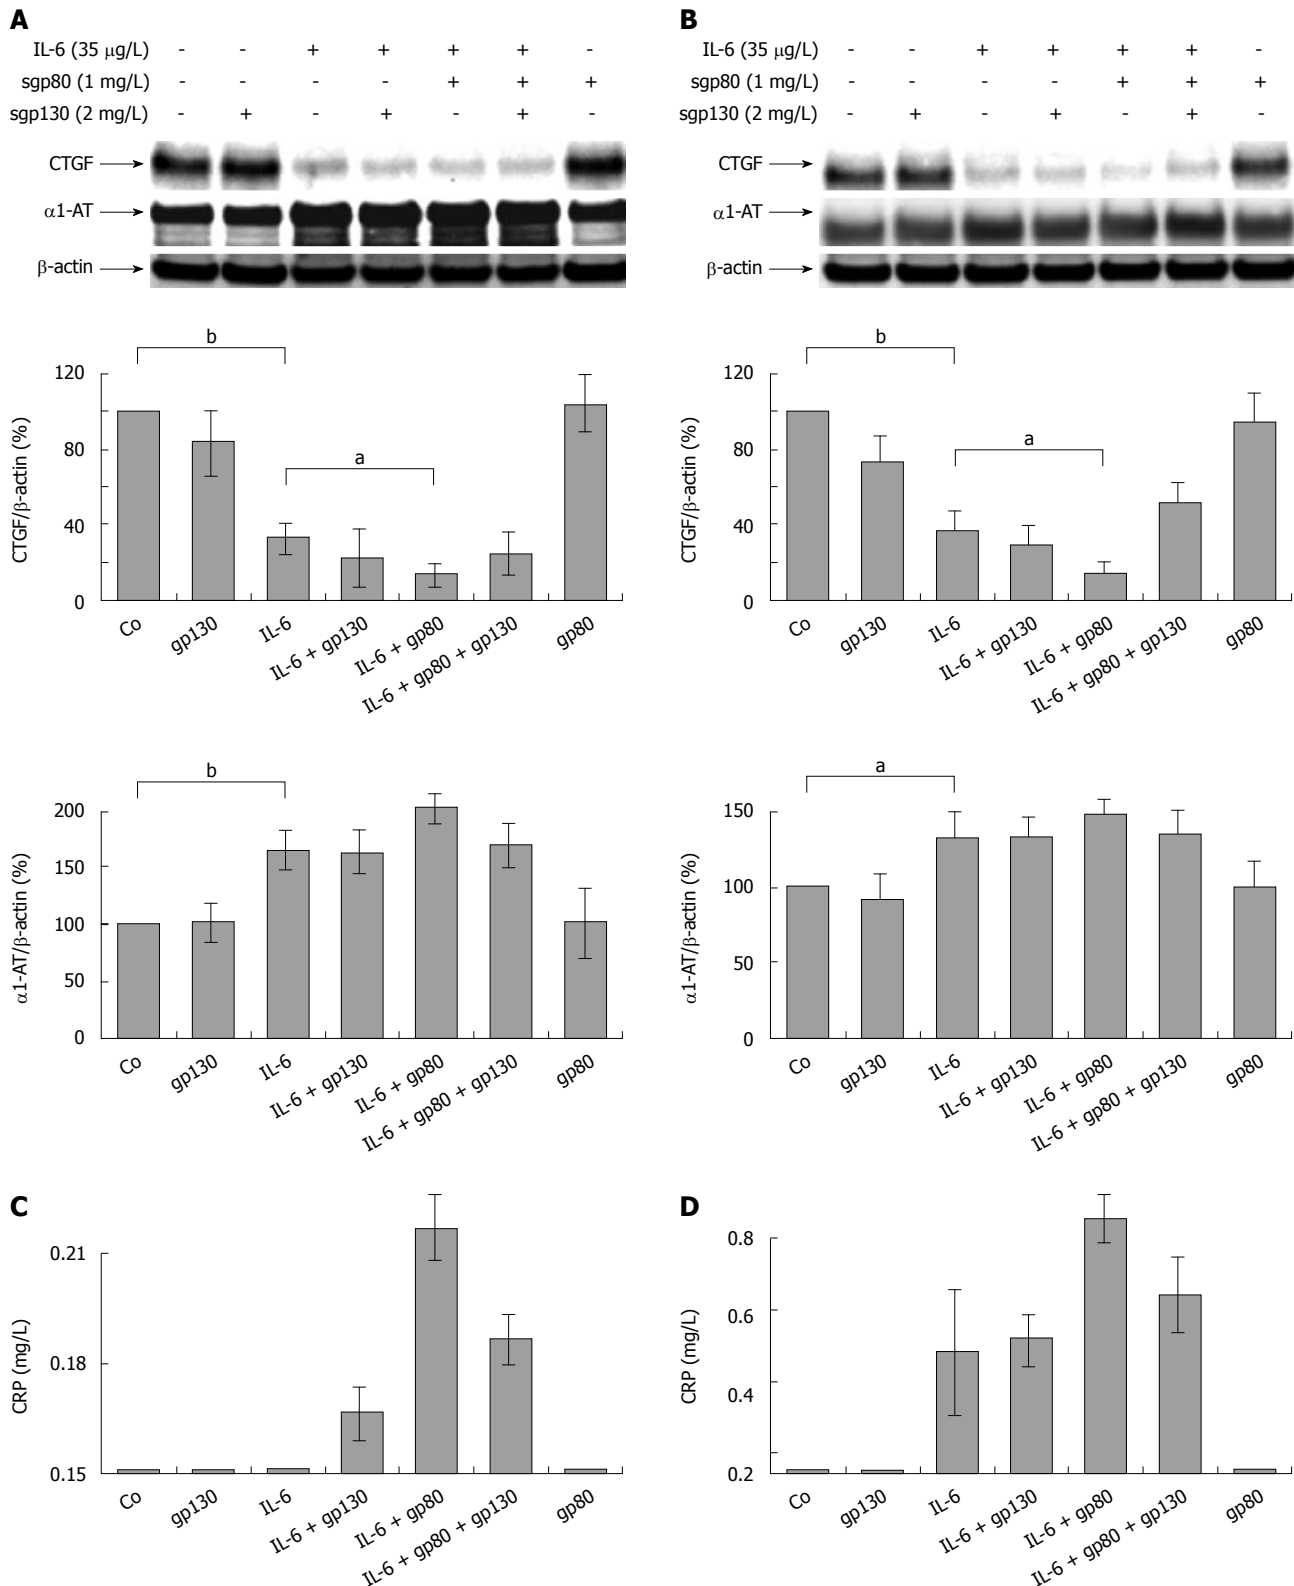

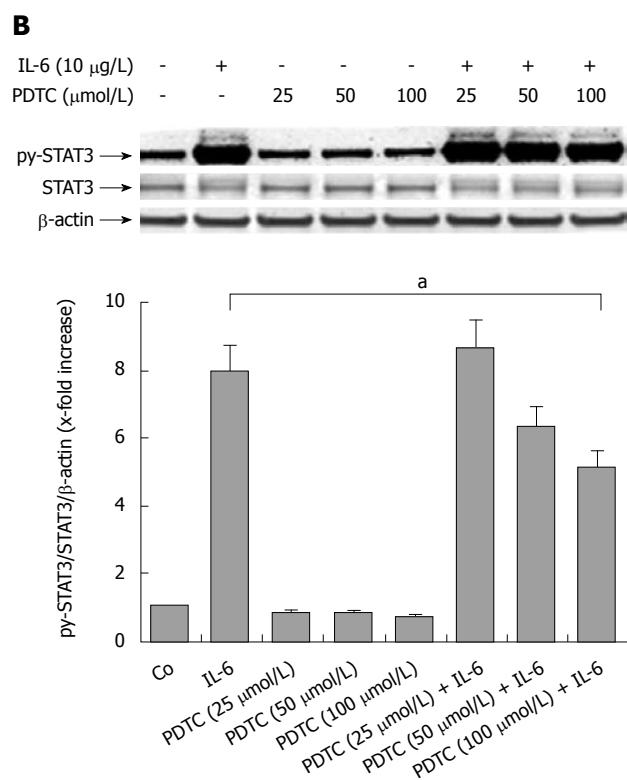

Figure 3 Soluble gp80 receptor enhances the inhibitory effect of interleukin-6 on hepatocellular CYR61/CTGF/NOV 2/connective tissue growth factor expression in primary human hepatocytes. A: Western blottings of CYR61/CTGF/NOV (CCN) 2/Connective tissue growth factor (CTGF) and α 1-AT of primary human hepatocytes cultured under serum-free conditions for 24 h and stimulated with rh interleukin (rhIL)-6 (35 µg/L), soluble gp80 receptor (sgp80, 1 mg/L) and soluble gp130 receptor (sgp130, 2 mg/L) or a complex of both. Cells were harvested after 24 h. β -actin served as loading control. Blots were quantified relative to β -actin using the Lumi Imager System. Representative blots are shown. ^a $P < 0.005$, ^b $P < 0.0001$ vs untreated or IL-6 treated control; B: Primary human hepatocytes were cultured and stimulated as described in (A). Cells were harvested after 48 h. β -actin served as loading control. Blots were quantified as described in (A). Representative blots are shown. ^a $P < 0.005$, ^b $P < 0.0001$ vs untreated or IL-6 treated control; C, D: Ultrasensitive C-reactive Protein as determined using a particle enhanced ultra sensitive assay on the Siemens BN2 nephelometer in supernatants from primary human hepatocytes cultures harvested after 24 h (C) and 48 h (D). The baseline indicates the lower detection limit of the assay at 0.15 mg/L.

Cells were harvested after 30 min. β -actin served as loading control. Representative blots of 3 independent cultures are shown. Blots were quantified relative to β -actin using the Lumi Imager System. Quantifications represent the mean \pm SD of 3 independent cultures. $^aP < 0.05$ vs IL-6 treated (PDTC untreated) control; C: Western blottings of CCN2/CTGF of rat PC cultured under serum-free conditions with or without addition of PDTC at indicated concentrations 2 h prior addition of rrIL-6 (10 μ g/L). Cells were harvested after another 2 h. β -actin served as loading control. A representative blot out of 3 is shown. Blots were quantified as described in (A). $^bP < 0.0001$ vs IL-6 treated (PDTC untreated) control; D: Western blottings of PY-STAT3 and STAT3 of rat PC cultured under serum-free conditions with or without addition of PY*LKTK at indicated concentrations 1 h prior addition of rrIL-6 (20 μ g/L). Cells were harvested after another 30 min. β -actin served as loading control. Blots were quantified relative to β -actin using the Lumi Imager System. A representative blot out of 3 is shown. $^bP < 0.0001$; E: Western blottings of CCN2/CTGF of rat PC cultured under serum-free conditions with or without addition of PY*LKTK at indicated concentrations 1 h prior addition of rrIL-6 (20 μ g/L). Cells were harvested after another 24 h. β -actin served as loading control. Blots were quantified relative to β -actin using the Lumi Imager System. A representative blot out of 3 is shown. $^aP < 0.005$, $^bP < 0.0001$; F: EMSA using nuclear lysates of PC treated with rrIL-6 (10 μ g/L; 30 min) and 32P-labeled double-stranded oligonucleotide probes containing the two proposed wild-type (wt) STAT binding sites as well as the mutated (mt) proximal and distal STAT binding sites in the CTGF promoter. Lane 1: Labeled probe containing both proposed STAT binding sites; lane 2: Nuclear extract and labeled probe containing both proposed STAT binding sites (wt); lane 3: Nuclear extract, labeled probe and 100-fold molar excess of unlabeled probe containing both proposed STAT binding sites (wt); lane 4: Labeled mutated (mt, proximal) probe; lane 5: Nuclear extract and labeled mutated (mt, proximal) probe; lane 6: Nuclear extract, labeled mutated (mt, proximal) probe and 100-fold molar excess of unlabeled mutated (mt, proximal) probe; lane 7: Labeled mutated (mt, distal) probe; lane 8: Nuclear extract and labeled mutated (mt, distal) probe; lane 9: Nuclear extract, labeled mutated (mt, distal) probe and 100-fold molar excess of unlabeled mutated (mt, distal) probe. The following specific activities were determined using scintillation counting: wt double strand oligonucleotide, 5.23×10^7 cpm/ μ g DNA; mt proximal oligonucleotide, 3.70×10^7 cpm/ μ g DNA; mt distal oligonucleotide, 3.73×10^7 cpm/ μ g DNA. The activities put on the gel were: wt double strand oligonucleotide, 33090 cpm; mt proximal oligonucleotide, 45 844 cpm; mt distal oligonucleotide, 31 556 cpm.

PC^[34]. The extent of the phosphorylation of the tyrosine residue (PY705) of STAT3, important for STAT3 dimerization and DNA binding activities, was analyzed by Western blotting analysis using a phospho-specific antibody in cells treated with rrIL-6 for up to 30 min. PDTC reduced STAT3 phosphorylation in a dose dependent manner (Figure 4B), while CCN2/CTGF protein expression, reduced by rrIL-6, could be restored up to 80%-90% of the untreated control 2 h after pre-application of PDTC (Figure 4C). One hour pre-incubation of rat hepatocytes with the cell permeable STAT3 SH2 domain binding peptide (PY*LKTK), known to be a highly selective inhibitor of STAT3 DNA binding activity^[35], in contrast to PDTC, did not impair STAT3 (PY705) phosphorylation, as expected (Figure 4D), but had a strong counteracting effect on IL-6 induced inhibition of CCN2/CTGF expression (Figure 4E). These results suggest that IL-6 mediates its repressive effect on CCN2/CTGF synthesis *via* direct interaction of activated (phosphorylated) STAT3 with the CCN2/CTGF promoter. An EMSA demonstrated that the synthetic double-stranded oligonucleotide containing the two putative STAT binding sites forms a major protein-DNA complex with nuclear extracts from rat PC treated with 10 μ g/L rrIL-6 (Figure 4F; wt, labeled). Whereas application of a mutated proximal binding site (Figure 4F; mt proximal, labeled) did affect binding of STAT3 to the CTGF promoter sequence, the mutated distal binding site (Figure 4F;

mt distal, labeled) did not. These findings suggest that the distal binding site has a lower affinity for STAT3 than the proximal site.

Inverse association between IL-6 and CCN2/CTGF serum concentrations in patients with different severity of an acute phase reaction

All the findings discussed above were based exclusively on results of *in vitro* experiments. However, results obtained from *in vitro* studies are frequently not directly transferable to the *in vivo* situation. Therefore, we investigated serum concentrations of CCN2/CTGF and IL-6 in Caucasian patients with different extent of an acute phase reaction, hypothesizing that a change in serum concentrations of IL-6 influences CCN2/CTGF serum concentrations in the respective patients.

In order to further corroborate this hypothesis, we clustered sepsis patients into two groups with defined ranges of IL-6 serum concentrations [2-99 ng/L (< 100 ng/L), 104-6100 ng/L (> 100 ng/L)], and compared CCN2/CTGF serum concentrations between both groups (Figure 5A). Results impressively demonstrate an inverse association between IL-6 and CCN2/CTGF serum concentrations with highly significant differences ($P < 0.0001$) between patients with low IL-6 concentrations and those with IL-6 concentrations > 100 ng/L. Data are shown in Tables 1-3.

Table 1 Mean and 95% CI for mean (in braces) of serum concentrations of interleukin-6 and connective tissue growth factor in two groups of patients with different severity of an acute phase reaction

	IL-6 (ng/L)	CTGF (μg/L)
Group 1: IL-6 < 100 ng/L (n = 21)	36 (1.7-54.3)	880.7 (344.0-1417.4)
Group 2: IL-6 ≥ 100 ng/L (n = 15)	1028.3 (46.6-2010.0)	391.2 (109.2-673.3)

IL-6: Interleukin-6; CTGF: Connective tissue growth factor.

Table 2 One sample statistics

	n	Mean CTGF (μg/L)	Std. deviation	Std. error mean
IL-6 < 100	21	851.18	900.50	196.51
IL-6 ≥ 100	15	391.23	509.36	131.52

IL-6: Interleukin-6; CTGF: Connective tissue growth factor.

Table 3 One-sample test

Test value = 0				
t		Mean difference CTGF (μg/L)	95% CI of the difference	
			Lower	Upper
IL-6 < 100	4.332	851.18	441.27	1261.08
IL-6 ≥ 100	2.975	391.23	109.15	673.30

IL-6: Interleukin-6; CTGF: Connective tissue growth factor.

We next observed the longitudinal development of CCN2/CTGF and IL-6 serum concentrations in one representative individual patient over a time period of 22 d. Figure 5B demonstrates an inverse relation between IL-6 and CCN2/CTGF concentrations, suggesting an indirect response of serum CCN2/CTGF concentrations to the individual's acute phase status.

DISCUSSION

It is firmly established that the fibrogenic process in the liver is prominently regulated by TGFβ1^[36-38]. However, TGFβ1 has not only multiple profibrogenic, but also immunosuppressive effects^[39-41]. *Vice-versa*, immunosuppressive agents, such as glucocorticoids, are capable of enhancing TGFβ1 induced target gene expression, in particular of CCN2/CTGF, in rat PC^[42]. We and others have previously reported that PC substantially synthesize CCN2/CTGF during culture and in injured liver, that CCN2/CTGF is sensitively up-regulated by TGFβ1^[10,11] in a Smad2 dependent mechanism and that PC are likely to be the major cellular source of CCN2/CTGF in the liver^[12]. In turn, CCN2/CTGF acts as a downstream sensitizer of TGFβ1 actions in PC^[3].

Inflammation and injury to tissue results in a variety of local and systemic events. However, although the local

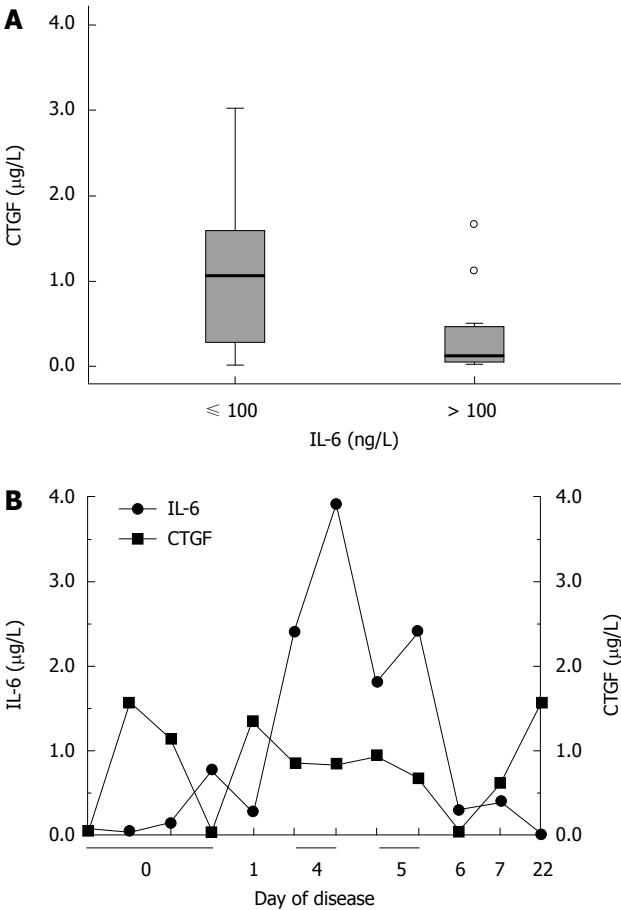

Figure 5 Inverse relation of interleukin-6 and CYR61/CTGF/NOV 2/connective tissue growth factor serum concentrations in patients with different severity of an acute phase reaction. A: Patients (n = 36) were categorized according to their interleukin (IL)-6 serum concentrations. Corresponding CYR61/CTGF/NOV (CCN) 2/connective tissue growth factor (CTGF) concentrations were significantly lower in patients with high IL-6 serum concentrations (IL-6 > 100 ng/L, n = 15) compared to those with low IL-6 serum concentrations (IL-6 ≤ 100 ng/L, n = 21). Box plot are displayed, where the dotted line indicates the median per group, the box represents 50% of the values, and horizontal lines show minimum and maximum values of the calculated non-outlier values; open circles indicate outlier values; B: Longitudinal development of CCN2/CTGF and IL-6 serum concentrations in one representative individual patient (20 years old, male) over a time period of 22 d.

events of edema formation and cellular infiltration have received considerably more attention, the systemic response to inflammation is no less profound. The particular systemic event which forms the substance of this communication is the change in the circulating levels of plasma proteins which occurs after inflammatory injury, and the manner in which these changes in plasma concentration are controlled by changes in the rate of synthesis. The changes which occur are regulated at the liver by alteration of the rate of synthesis of the individual protein^[43,44].

In this study, we provide evidence that IL-6 strongly down-regulates spontaneous as well as TGFβ1-induced CCN2/CTGF protein and mRNA expression in PC, an effect enhanced by the extracellular presence of the soluble IL-6 receptor gp80. These data were confirmed by an inverse relation between IL-6 and CCN2/CTGF serum concentration in patients with different extent of

Figure 6 A simplified and schematic overview of the proposed interplay of interleukin-6 and tissue growth factor $\beta 1$ on the regulation of CTGF/NOV 2/connective tissue growth factor expression in hepatocytes and its relevance for inflammation, host defence and fibrogenesis in chronic liver disease. CTGF: Connective tissue growth factor; IL-6: Interleukin-6; TGF: Transforming growth factor.

an acute phase reaction. The inhibition of TGF $\beta 1$ driven CCN2/CTGF expression by IL-6 did not involve modulation of TGF $\beta 1$ induced Smad2 (and Smad1/3), as well as MAP-kinase or phosphoinositide 3-kinase signaling, but required activation of the STAT3 pathway. Furthermore, the difference between the potency of pyrrolidine dithiocarbamate (PDTC), an inhibitor primarily of STAT3 phosphorylation, and PY**LKTK*, a highly selective inhibitor of STAT3 DNA binding activity, as counteractors of IL-6 induced repression of CCN2/CTGF expression in PC imply that downregulation of CCN2/CTGF synthesis by IL-6 is mediated through direct interaction of activated (phosphorylated) STAT3 with the CCN2/CTGF promoter.

In the 600 bp fragment upstream of the transcription start site in the CCN2/CTGF promoter sequence putative STAT binding sites have been described (proximal: -418 to -415 bp, distal: -384 to -381 bp)^[28], but their functional relevance has not been verified yet. The immediate suppression of CCN2/CTGF synthesis within the first 30 min after stimulation with IL-6, suggest a direct interaction between IL-6 induced STAT3 signalling and transcriptional activation of the CCN2/CTGF promoter, a hypothesis herein confirmed by EMSA showing that the distal binding site seems to have a lower affinity for STAT3 than the proximal one.

Based on these results, it may be suggested that CCN2/CTGF belongs to the family of negative acute-phase-reactants, displaying a decrease of synthesis during the acute inflammatory process. Several negative acute-phase-proteins have been identified so far, e.g. albumin, transferrin, transthyretin and transcortin^[45]. But apart from transcortin, whose reduced bioavailability results in decreased glucocorticoid binding and, thus, in an enhancement of the inflammatory response, little is known of the biological function of these proteins.

Earlier studies by van Gool *et al.*^[46,47] investigated the clinical significance of the depressed acute-phase reaction in 14 patients with acute hepatitis B, and found that the acute-phase-reactant $\alpha 2$ -macroglobulin ($\alpha 2M$) was negatively correlated to the subsequent course of hepatitis, and

to the duration of the illness. This was most likely due to inflammatory inhibiting effects of $\alpha 2M$.

Therefore, it may be suggested that the observed down-regulation of negative acute-phase-proteins should have similar effects on the pathogenesis of liver fibrosis as does the upregulation of acute-phase-proteins, i.e. attenuation of the inflammatory state through an enhancement of immune stimulation, decreased tissue injury, and, thus, in an retardation of the fibrogenic process. The opposite effects may be observed in conditions of immune suppression. In other terms, CCN2/CTGF would *per se* act as an immunosuppressive and profibrogenic which is antagonized by the acute-phase-reaction as an unspecific immune response. On the contrary, recent results of Karger *et al.*^[22] show that CCN2/CTGF induces IL-6 gene expression in pancreatic stellate cells, thus, in turn, enhancing the local inflammatory reactions in the pancreas. Little is known of the immunomodulatory capacities of CCN2/CTGF, but its crucial role in fibrogenesis is documented by strong upregulation in fibrotic liver tissue^[5,6,48] and even more importantly by recent studies in which knock-down of CCN2/CTGF by siRNA leads to substantial attenuation of experimental liver fibrosis^[8,9].

In summary, our results of an inhibitory effect of IL-6 on hepatocellular CCN2/CTGF expression suggest a role of CCN2/CTGF as “negative” acute-phase-protein, whose decreased synthesis during the acute-phase-reaction results in an, at least temporary, interruption of (TGF $\beta 1$ mediated) immune suppression and fibrogenesis, amplified by CCN2/CTGF (Figure 6). However, for an appropriate assessment of this phenomenon, a detailed understanding of a possible immunomodulatory role of CCN2/CTGF is needed. Our results hopefully initiate further studies in this direction.

COMMENTS

Background

Hepatocytes (PC) are a major cellular source of connective tissue growth factor (CCN2/CTGF), a downstream amplifier of profibrogenic transforming growth factor (TGF)- $\beta 1$. Earlier reports identified the rat acute phase reactant $\alpha 2$ -macroglobulin ($\alpha 2M$) as an inhibitor of experimental hepatitis and fibrosis; however, the impact of acute phase reaction initiating interleukins such as interleukin (IL)-6 on CCN2/CTGF synthesis in PC is still unknown. This paper investigates the mechanisms involved in a possible modulator role of IL-6 signalling on CCN2/CTGF expression in PC and looks for a possible relation between serum concentrations of these two parameters in patients with acute inflammation.

Research frontiers

CTGF=CCN2, one of six members of cysteine-rich, secreted, heparin-binding proteins with a modular structure, is widely recognized as an important player in hepatic and non-hepatic fibrogenic pathways. Its expression is strongly increased in fibrotic tissues and TGF- β , the profibrogenic master cytokine, is a strong stimulator of CTGF synthesis in hepatocytes, biliary epithelial cells and

stellate cells. Functional activity as a mediator of fibre-fibre, fibre-matrix and matrix-matrix interactions, as an enhancer of profibrogenic TGF- β and several secondary effects owing to TGF- β enhancement, and as a down-modulator of the bioactivity of bone morphogenetic protein-7 have been shown or at least proposed. Consequently, knockdown of CTGF considerably attenuates experimental liver fibrosis. The spill-over of CTGF from the liver into the blood stream proposes this protein as a non-invasive reporter of TGF- β bioactivity in this organ. Indeed, it was shown that CTGF levels in sera correlate significantly with fibrogenic activity.

Innovations and breakthroughs

Fibrogenic restructuring of the liver is commonly caused by chronic inflammatory processes. Upon perpetuation of the initial inflammatory attack, a rapid synthesis of several proteins, which is stimulated by cytokines such as tumor necrosis factor (TNF)- α , IL-1, and particularly IL-6, takes place in order to restore homeostasis. This process is widely known as the hepatocellular acute phase reaction upon the initial tissue injury, infection or inflammation CTGF has been implicated in the pathogenesis of hepatic fibrosis and is currently suggested to be an important downstream amplifier of the effects of the profibrogenic master cytokine TGF- β which explains why experimental knockdown of CTGF considerably attenuates experimental liver fibrosis. Earlier reports gave evidence that the stereotypical rat acute phase reactant α 2M acts as an inhibitor of experimental hepatitis; however, the impact of this or other acute phase proteins such as IL-6 on CCN2/CTGF production in PC and the molecular basis of CCN2/CTGF involvement in the acute phase reaction was long unknown, thereby launching the present study, whose results identify CTGF as a hepatic negative acute phase protein.

Applications

The results of the present study, showing an inhibitory effect of IL-6 on hepatocellular CCN2/CTGF expression, suggest a role of CCN2/CTGF as "negative" acute-phase-protein, whose decreased synthesis during the acute-phase-reaction results in an, at least temporary, interruption of (TGF β 1 mediated) immune suppression and fibrogenesis, amplified by CCN2/CTGF. However, for an appropriate assessment of this phenomenon, a detailed understanding of a possible immunomodulatory role of CCN2/CTGF is needed. The results hopefully initiate further studies in this direction.

Terminology

Acute Phase Reaction: The term acute phase response summarizes the endocrine or metabolic changes observed in an organism, either locally or systemically, a short time after injuries or the onset of infections, immunological reactions, and inflammatory processes. The acute phase reaction is initiated and mediated by a number of cytokines with inflammatory activities secreted by a variety of cell types (i.e. granulocytes, monocytes, lymphocytes, etc.) in response to the inflammatory stimuli. **Acute Phase Protein:** Acute-phase proteins are a class of proteins whose plasma concentrations increase (positive acute-phase proteins) or decrease (negative acute-phase proteins) during the acute phase reaction. **CTGF=CCN2:** CTGF is a 38 kDa, cysteine-rich, secreted peptide and a classical downstream target of TGF- β . Among the many functions of the CTGF gene family are embryogenesis, wound healing and regulation of extracellular matrix production. **Liver Fibrosis:** Hepatic fibrosis is overly exuberant wound healing in which excessive connective tissue builds up in the liver. The extracellular matrix is either overproduced, degraded deficiently, or both. The trigger is chronic injury, especially if there is an inflammatory component. **TGF- β :** TGF- β is a multifunctional cytokine that regulates tissue morphogenesis and differentiation through effects on cell proliferation, differentiation, apoptosis, and extracellular matrix production. TGF- β has been implicated as a "master switch" in induction of fibrosis in many tissues including the liver.

Peer review

This work identifies CTGF as a hepatocellular negative acute phase protein which is down-regulated by IL-6 via the STAT3 pathway through interaction on the DNA binding level. The paper is well written, the biochemical documentation excellent, and the results clearly show a significant implication of CTGF in the inflammatory response of the liver.

Abstract

AIM: To investigate serotonergic Ca^{2+} signaling and the expression of 5-hydroxytryptamine (5-HT) receptors, as well as Ca^{2+} transporting proteins, in hepatic stellate cells (HSCs).

METHODS: The intracellular Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) of isolated rat HSCs was measured with a fluorescence microscopic imaging system. Quantitative PCR was per-

formed to determine the transcriptional levels of 5-HT receptors and endoplasmic reticulum (ER) proteins involved in Ca^{2+} storage and release in cultured rat HSCs.

RESULTS: Distinct from quiescent cells, activated HSCs exhibited $[\text{Ca}^{2+}]_i$ transients following treatment with 5-HT, which was abolished by U-73122, a phospholipase C inhibitor. Upregulation of 5-HT_{2A} and 5-HT_{2B} receptors, but not 5-HT₃, was prominent during trans-differentiation of HSCs. Pretreatment with ritanserin, a 5-HT₂ antagonist, inhibited $[\text{Ca}^{2+}]_i$ changes upon application of 5-HT. Expression of type 1 inositol-5'-triphosphate receptor and type 2 sarcoplasmic/endoplasmic reticulum Ca^{2+} ATPase were also increased during activation of HSCs and serve as the major isoforms for ER Ca^{2+} storage and release in activated HSCs. Ca^{2+} binding chaperone proteins of the ER, including calreticulin, calnexin and calsequestrin, were up-regulated following activation of HSCs.

CONCLUSION: The appearance of 5-HT-induced $[\text{Ca}^{2+}]_i$ response accompanied by upregulation of metabotropic 5-HT₂ receptors and Ca^{2+} transporting/chaperone ER proteins may participate in the activating process of HSCs.

INTRODUCTION

Hepatic stellate cells (HSCs), also known as “Ito cells” or “fat-storing cells”, localize between hepatocytes and sinusoids (space of Disse) in mammalian livers. In their healthy state, HSCs control retinoid homeostasis, sinusoidal blood flow, macromolecule transport, and potentially act as antigen-presenting cells in the liver^[1,2]. However, in response to hepatic injury, HSCs undergo gross morphological and functional changes, transforming to a myofibroblast-like phenotype in a process called “activation” or “trans-differentiation”^[3,4]. Manifestations of activated HSCs include: (1) the expression of contractile cytoskeletal proteins such as α -smooth muscle actin (α -SMA)^[5,6]; (2) enhanced extracellular matrix synthesis^[7,8]; (3) increased cell size and proliferation^[9]; (4) decreased size of lipid droplets^[8,10]; and (5) well developed endoplasmic reticulum (ER), Golgi bodies, and compacted microfilaments^[11,12]. In particular, the deposition of cross-linked collagen during the activation process may result in cirrhotic changes accompanied by life-threatening hepatic dysfunction.

Serotonin [5-hydroxytryptamine (5-HT)] is a neurotransmitter that also acts as a multifunctional hormone in various tissues^[13], where it modulates proliferation and differentiation of muscle, neurons, and mammary glands^[14-16]. Serotonin released from platelets at sites of injury plays an important role in liver regeneration and fibrosis^[17]. It has been reported that patients with cirrhosis of the liver and portal hypertension have increased plasma serotonin levels^[18]. The expression levels of 5-HT_{2A} and 5-HT_{2B} are increased in the liver after hepatectomy as well as in activated HSCs^[2,17]. Moreover, 5-HT₂ receptor antagonists suppress cell proliferation and expression of key fibrogenic factors in activated HSCs^[2,19]. Among the mammalian 5-HT receptors (5-HT₁ to 5-HT₇), the 5-HT₂ receptor family is coupled to the G_{q/11} protein and increases intracellular Ca²⁺ concentration ([Ca²⁺]_i) mobilized from ER reservoirs^[20].

As the major intracellular calcium storage site, the ER possesses various kinds of calcium regulatory proteins that participate in: (1) pumping Ca²⁺ into the ER lumen, such as the sarcoplasmic/endoplasmic reticulum Ca²⁺ ATPase (SERCA); (2) releasing Ca²⁺ into the cytosol, such as IP₃ or ryanodine receptors; and (3) buffering Ca²⁺, such as calreticulin and calnexin, which are also known as chaperones. ER Ca²⁺ homeostasis is maintained by a balance between Ca²⁺ release and replenishment^[21]. The free Ca²⁺ concentration in the ER ([Ca²⁺]_{ER}) ranges from 60-400 μ mol/L, and disturbances in [Ca²⁺]_{ER} homeostasis can affect many of the functions of the ER including protein synthesis, secretion^[22], protein folding^[23], and sensitivity of cells to apoptosis^[24]. Further, [Ca²⁺]_{ER} homeostasis might be critically required for the activation process of HSCs in order to

keep up with accelerated protein synthesis. However, until now, the compensatory changes in ER protein expression involved in Ca²⁺ homeostasis and chaperone function have not been clearly elucidated.

[Ca²⁺]_i may be important for the activation of HSCs, primarily because [Ca²⁺]_i regulates the transcription of genes critical for cell function^[25], and secondly because contractile elements such as α -SMA respond sensitively to [Ca²⁺]_i^[26]. We hypothesized that serotonin, acting as an autocrine or paracrine mediator, can elicit a Ca²⁺ signal, and this signal might be involved in the activation of HSCs. Moreover, there may be an alteration in the ER function of HSCs such as Ca²⁺ release and protein folding. In this study, we isolated and cultured rat HSCs on plastic dishes *in vitro*, which has been widely accepted as an appropriate model for the study of activated HSCs^[8,27]. Appearance of [Ca²⁺]_i transients induced by 5-HT and the upregulation of 5-HT₂ receptors and ER proteins were observed during HSC activation. These observed changes may participate in an activation signal as well as adaptive changes during the trans-differentiation of HSCs.

MATERIALS AND METHODS

Isolation of rat HSCs

HSCs were isolated from male Sprague-Dawley rats (150-250 g) by means of a collagenase/pronase perfusion and Nycodenz-gradient centrifugation, as previously described^[28,29]. HSCs were cultured with DMEM containing fetal bovine serum (10%) and antibiotics-antimycotics (Invitrogen, Carlsbad, CA, USA) in a humidified incubator (5% CO₂, 37°C). The purity of HSCs was > 95% as assessed by their typical microscopic morphology and positive immunocytochemical staining for desmin at 24 to 48 h after seeding.

Quantitative reverse transcription-polymerase chain reaction analysis

Total cellular RNA was isolated and purified from HSCs at different culture periods, and reverse transcription (RT) was performed with random hexamers. Quantitative real time PCR using SYBR Green PCR Master mix (Applied Biosystems, Foster City, CA, USA) was performed on an ABI PRISM 7900HT Sequence Detection System (Applied Biosystems). Sequence specific oligonucleotide primers for the genes of interest were designed based on rat sequences deposited in the GenBank database (Tables 1 and 2), and the amplification program included the activation of AmpliTaq Gold at 95°C for 10 min, followed by 45 cycles of a two-step PCR reaction with denaturation at 95°C for 15 s and annealing/extension at 60°C for 1 min. The constitutively expressed housekeeping gene glyceraldehydes-3-phosphate dehydrogenase (GAPDH) was selected as an endogenous control to correct for potential variation in RNA loading and efficiency of amplification reactions.

Fluorescent [Ca²⁺]_i measurement

HSCs at 3 d or 2 wk after isolation were seeded on glass

5-HT: 5-hydroxytryptamine.

coverslips and loaded with fura-2/AM (5 μ mol/L) in a dark room for 30 to 60 min at room temperature. Dye-loaded cells were then washed and transferred to a perfusion chamber on a fluorescence microscope (IX-70, Olympus, Tokyo, Japan). The HSCs were alternately excited at 340 and 380 nm by a monochromatic light source (LAMDA DG-4; Sutter, Novato, CA, USA), and fluorescence images were captured at 510 nm with an intensified CCD camera (Cascade; Roper, Duluth, GA, USA). Images were analyzed using the Metafluor 6.1 software package (Universal Imaging Corporation, Downingtown, PA, USA).

Immunocytochemistry

HSCs cultured on coverslips were fixed in 4% paraformaldehyde and immunocytochemical staining was performed using an antibody for α -SMA (Sigma Chemical Co., St Louis, MO, USA). After incubating with a biotinylated secondary antibody, an avidin-conjugated peroxidase complex was added to the slides and 3-amino-9-ethylcarbazole (AEC) was used as the chromogen.

Electrophysiology

Whole-cell membrane currents were recorded using the gramicidin-perforated patch-clamp technique as described

previously^[28]. All experiments were performed at room temperature (20–24°C). The internal solution for the perforated patch clamp contained (in mmol/L): 140 KCl, 5 EGTA, 10 HEPES, 0.5 CaCl₂, 5 NaCl, and gramicidin (50 μ g/mL) (pH 7.2). The external solution contained (in mmol/L): 135 NaCl, 5.4 KCl, 1.8 CaCl₂, 1 MgCl₂, 5 HEPES, and 10 glucose (pH 7.4).

Statistical analysis

Quantitative data are expressed as the mean \pm SE. Statistical comparisons were made by the two-tailed Student's *t*-test and ANOVA. Differences with *P* < 0.05 were considered to be significant. PCR from each cDNA sample was done in triplicate and *n* indicates the number of experiments. For quantitative comparisons, the expression level of each gene was normalized to that of GAPDH and presented as relative expression ratio (target/GAPDH) by applying the formula $2^{-\Delta\Delta Ct[30]}$.

RESULTS

Serotonergic signaling and receptor expression during HSC activation

We isolated HSCs using density gradient-based separation with Nycodenz. Most of the harvested cells (> 95%)

5-HT: 5-hydroxytryptamine; SERCA: Sarcoplasmic/endoplasmic reticulum Ca²⁺ ATPase; α -SMA: α -smooth muscle actin; RyR: Ryanodine receptor; TGF: Transforming growth factor.

exhibited positive intra-cytoplasmic staining for desmin and glial fibrillary acidic proteins (GFAP). Expression of HSC trans-differentiation markers was tested at 1 d, 1 wk and 2 wk after isolation. In activated HSCs (2 wk after isolation), bundles of α -SMA were clearly observed as cytoskeletal fibers in immunocytochemical staining (Figure 1A), which was not evident in quiescent cells. In a voltage-clamp mode, nimodipine (10 μ mol/L)-sensitive L-type Ca²⁺ currents were recorded only for activated

HSCs (Figure 1C). The expression level of α -SMA and the L-type Ca²⁺ channel (Cav1.2) were proportional to the activation period elicited by culturing cells on plastic dishes (Figure 1B and D). Transforming growth factor- β 1 (TGF- β 1), an abundant isoform of TGF in both normal and cirrhotic liver, is known as the main profibrogenic cytokine^[31]. We observed that the type I receptor for TGF- β 1 (T β -RI) was also upregulated during activation (Figure 1E), while the expression of 28S RNA as well as

Figure 1 Expression of α -smooth muscle actin, L-type calcium channels and type 1 transforming growth factor- β receptors in activated rat hepatic stellate cells. A: Immunocytochemical staining for α -smooth muscle actin (α -SMA) was performed on hepatic stellate cells (HSCs) cultured for 1 wk; C: Whole cell Ca^{2+} currents in a voltage-clamp mode were recorded from 2 wk-cultured HSCs, and were completely blocked by nimodipine (10 $\mu\text{mol/L}$); Changes in the transcript levels of α -SMA (B), the $\alpha_1\text{c}$ subunit of the L-type Ca^{2+} channel (Cav1.2) (D), the type 1 receptor of transforming growth factor- β (T β -RI) (E), and 28S RNA (F) during HSC culturing (1 d, 1 wk and 2 wk) were measured by quantitative real-time reverse transcription-polymerase chain reaction analysis. Expression levels were normalized to glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and expressed as a relative expression ratio (target/GAPDH). Data are presented as the mean \pm SE ($n = 3$).

GAPDH was not changed during the activation process of HSCs (Figure 1F).

Serotonergic signaling has been suggested as a candidate for triggering activation of HSCs^[2,17]. We focused on $[\text{Ca}^{2+}]_i$ signaling in HSCs, which has been emphasized by previous work as having an important role in the activation process^[26,32]. As shown in Figure 2A and B, strong $[\text{Ca}^{2+}]_i$ transients followed by a slow plateau increase were recorded in response to 5-HT (10 $\mu\text{mol/L}$) application only from most of the activated HSCs (2 wk after isolation; 81 cells out of 92 cells), but not from quiescent cells (3 d after isolation; 0 out of 11 cells). The 5-HT-induced $[\text{Ca}^{2+}]_i$ increase was dose-dependent in activated HSCs (Figure 2C). Consistent with a previous report^[33], ATP also evoked $[\text{Ca}^{2+}]_i$ transients in activated HSCs while acetylcholine did not (Figure 3).

Among the 5-HT receptors, 5-HT₂ is known to release Ca^{2+} from the ER while 5-HT₃ acts as a ligand-gated cation channel^[20]. We estimated the steady-state mRNA levels of 5-HT receptor isotypes (5-HT₁ to 5-HT₇) using reverse transcription-polymerase chain reaction (RT-PCR) and found that the 5-HT_{2A} and 5-HT_{2B} receptors, but not 5-HT₃, were abundantly transcribed (Figure 2D). Consistent with the observed changes in $[\text{Ca}^{2+}]_i$, the expression of 5-HT_{2A} was increased by about 17-fold after 2 wk of isolation (5-HT_{2A}/GAPDH; from 0.004 at 1 d to 0.067 at 2 wk). 5-HT_{2B} was also found to be upregulated in activated HSCs (from 0.003 to 0.008) using quantitative RT-PCR (Figure 2E).

It has been recognized that 5-HT₂ receptors are coupled with the G_{q/11}-phospholipase C pathway. Figure 4A and B show that the 5-HT-induced $[\text{Ca}^{2+}]_i$ changes were abolished

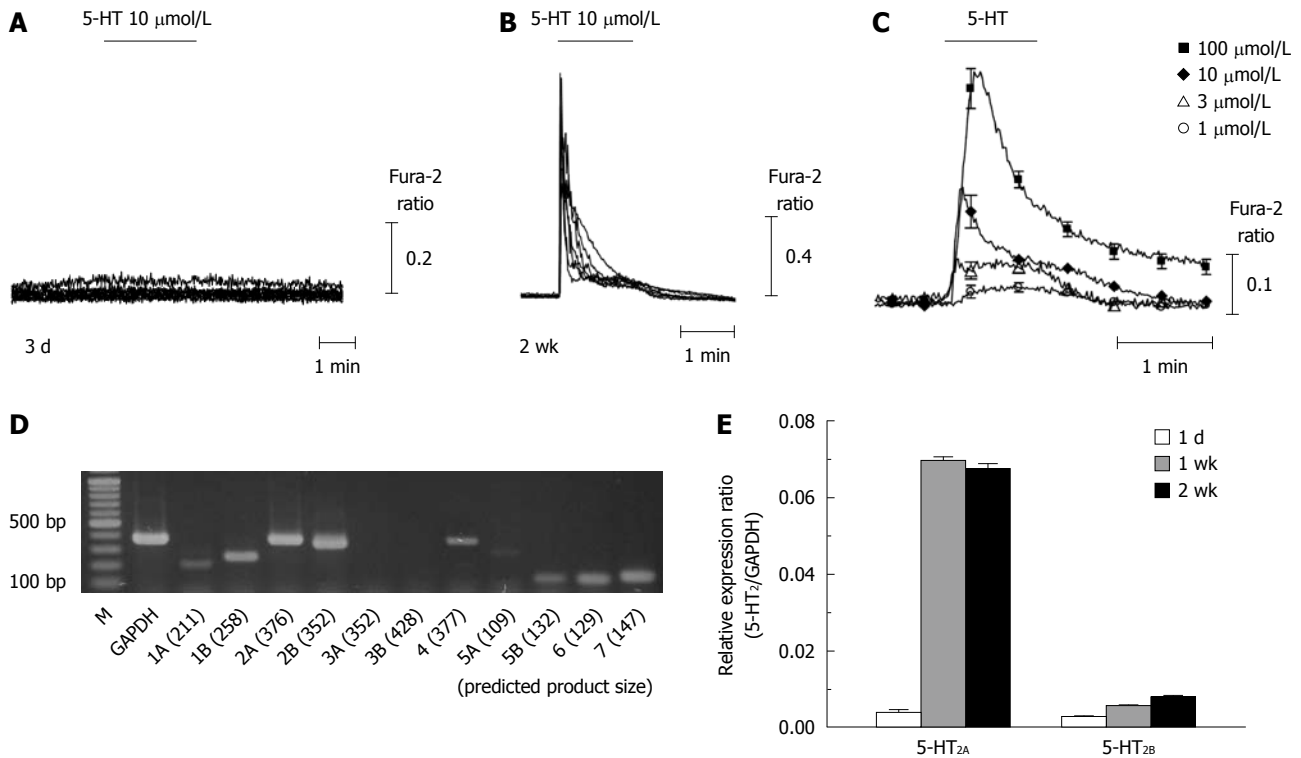

Figure 2 5-hydroxytryptamine-induced intracellular Ca^{2+} concentration changes and the expression of 5-hydroxytryptamine₂ receptors in quiescent and activated hepatic stellate cells. A, B: 5-hydroxytryptamine (5-HT)-induced intracellular Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) transients were recorded from hepatic stellate cells (HSCs) at 3 d (A) and 2 wk (B) after isolation; C: Averages of $[\text{Ca}^{2+}]_i$ changes (from 13-40 cells/each trace) in response to 5-HT (1-100 $\mu\text{mol/L}$) application to 2 wk-cultured HSCs are shown; D: Steady-state mRNA levels of the 5-HT receptor isotypes in 2 wk-cultured HSCs were compared using reverse transcription-polymerase chain reaction (RT-PCR); E: Using quantitative RT-PCR, the transcriptional changes in 5-HT₂ receptors among 1 d-, 1 wk- and 2 wk-cultured HSCs were compared. Expression levels were normalized to GAPDH and expressed as a relative expression ratio (target/GAPDH, $n = 3$). Data are presented as the mean \pm SE.

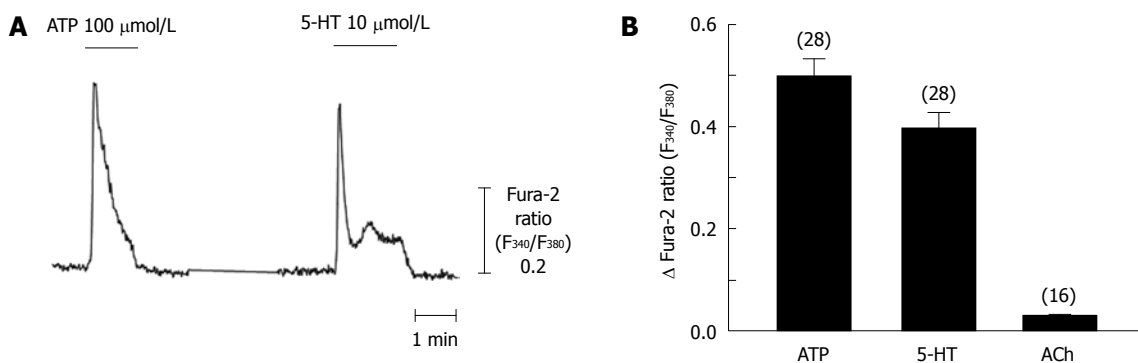

Figure 3 Comparison of intracellular Ca^{2+} concentration responses to various metabotropic receptor agonists in activated hepatic stellate cells. Intracellular Ca^{2+} concentration changes following application of ATP (100 $\mu\text{mol/L}$), 5-hydroxytryptamine (5-HT) (10 $\mu\text{mol/L}$), or acetylcholine (ACh, 10 $\mu\text{mol/L}$) were measured in 2 wk-cultured hepatic stellate cells ($n = 3-6$, 16-28 cells). Data are presented as the mean \pm SE.

by pretreatment with 1 $\mu\text{mol/L}$ U73122, a phospholipase C inhibitor (0.05 ± 0.05 peak changes of Fura-2 ratio from 0.66 ± 0.12 , $n = 13$). We also observed that $[\text{Ca}^{2+}]_i$ transients induced by 5-HT were not altered in extracellular Ca^{2+} -free conditions (data not shown). These results suggest that 5-HT activates phospholipase C to produce IP_3 , which induces Ca^{2+} release from ER in activated HSCs. To confirm the receptor subtype, we tested blocking effects of a universal 5-HT₂ antagonist, ritanserin, which does not discriminate among 5HT₂ isotypes. 5-HT-induced $[\text{Ca}^{2+}]_i$ responses were attenuated by pretreatment

with 10 $\mu\text{mol/L}$ ritanserin by 46.3% (0.34 ± 0.08 from 0.89 ± 0.10 , $n = 11$).

Upregulation of calcium transporting and binding proteins in the ER

In mammalian cells, there are three major subtypes of the sarcoplasmic/endoplasmic reticulum Ca^{2+} ATPase (SERCA1, 2, and 3) which pump Ca^{2+} into the ER lumen. We observed SERCA2 to be the dominant subtype in HSCs. SERCA2, especially SERCA2b, is considered to be a house-keeping protein expressed constitutively

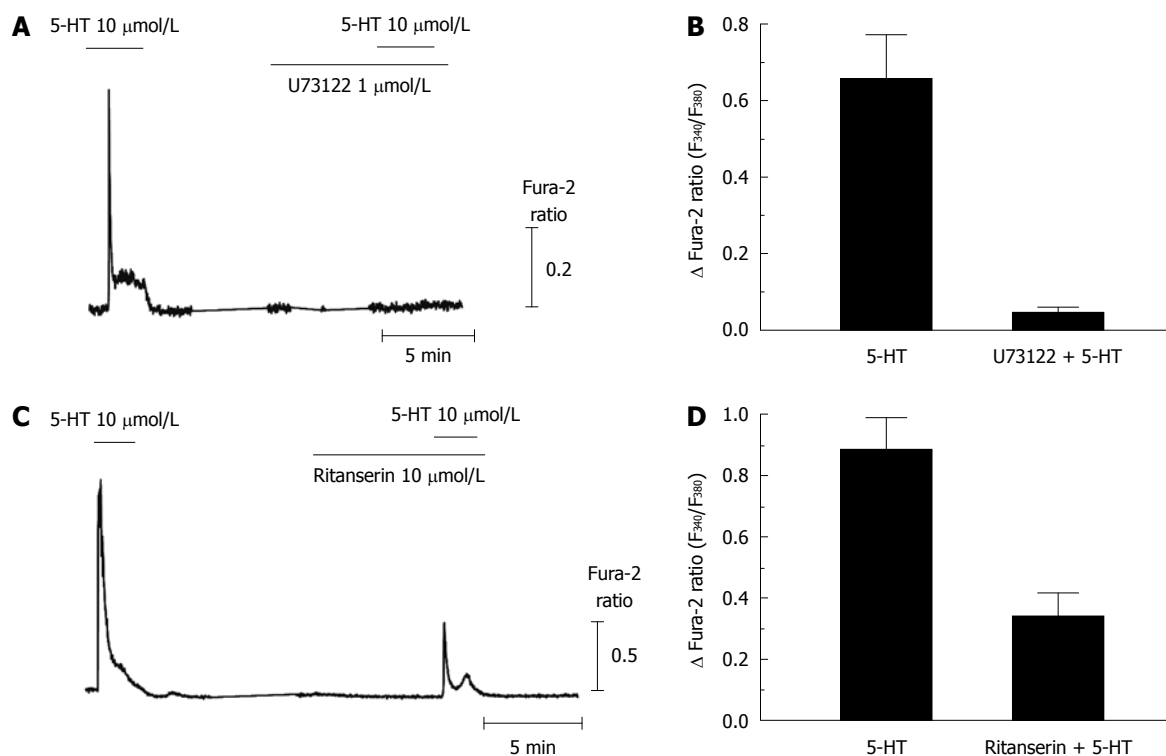

Figure 4 5-hydroxytryptamine-induced intracellular Ca^{2+} concentration transients via metabotropic 5-hydroxytryptamine₂ receptor in activated hepatic stellate cells. A, B: 5-hydroxytryptamine (5-HT)-induced intracellular Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) transients were completely abolished by pretreatment with U73122 (1 $\mu\text{mol/L}$), a phospholipase C blocker ($n = 3$, 11 cells); C, D: Ritanserin (10 $\mu\text{mol/L}$), a 5-HT₂ antagonist, inhibited the $[\text{Ca}^{2+}]_i$ responses to 5-HT in activated hepatic stellate cells (2 wk-cultured cells; $n = 3$, 13 cells). Data are presented as the mean \pm SE.

in most kinds of cells; however, in HSCs, the expression of SERCA2 tends to increase during activation. Specifically, the relative expression ratio of SERCA2 (SERCA2/GAPDH) at 1 d after isolation was 0.058, and increased to 0.106 after 1 wk in culture and 0.164 after 2 wk in culture *in vitro* (Figure 5A). The expression of SERCA3 was also increased during culture (SERCA3/GAPDH; 0.4×10^{-3} at 1 d and 6.9×10^{-3} at 2 wk).

Among the three isoforms (types 1 through 3) of the IP_3 receptor, the type 1 IP_3 receptor was the main subtype expressed in activated HSCs. We observed that the expression of the type 1 IP_3 receptor increased by about 7-fold ($\text{IP}_3\text{R 1/GAPDH} = 0.037$) after 1 wk of culture, and 20-fold (0.100) after 2 wk of culture compared to (0.005) levels 1 d after isolation (Figure 5B). In contrast, the expression level of ryanodine receptors, which are a family of Ca^{2+} -releasing channel proteins expressed in the ER, either did not change or was decreased during the activation of HSCs (Figure 5C).

We investigated whether Ca^{2+} binding chaperones of the ER could be up-regulated following the activation process of HSCs. There were similar increases in the expression levels of calreticulin (calreticulin/GAPDH; from 0.204 at 1 d to 0.655 at 2 wk), calnexin (calnexin/GAPDH; from 0.240 at 1 d to 0.750 at 2 wk), and calsequestrin in HSCs. In the case of calsequestrin, the expression level in HSCs at 1 d after isolation was undetectable, but was markedly increased (calsequestrin/GAPDH; 0.217) after 2 wk of culturing (Figure 5D).

DISCUSSION

Trans-differentiation of HSCs is accompanied by marked increases in protein synthesis, including collagen, elastin, and glycoproteins^[7]. It is well known that Ca^{2+} homeostasis in the ER is critical for the synthesis, folding, and secretion of protein^[22,23]. In HSCs, the depletion of ER Ca^{2+} stores inhibits protein synthesis and increases intracellular degradation of collagen^[34]. Maintaining a high Ca^{2+} gradient across the ER membrane (around 1000-fold) is accomplished by active Ca^{2+} transport by SERCAs. Among the three different isoforms of SERCAs, SERCA2 is considered to be a house-keeping protein expressed in the ER of most cell types, including HSCs^[34]. We observed that SERCA2 was the main isotype in quiescent and activated HSCs (Figure 5A). During activation, the expression of SERCA2 (and also SERCA3) was increased, which likely helped to maintain appropriate ER Ca^{2+} concentrations.

Chaperone proteins in the ER facilitate the folding of newly synthesized proteins and glycoproteins. In particular, calreticulin and calnexin are important chaperones involved in a “quality control” system for protein synthesis^[35]. In addition, these chaperones act as Ca^{2+} binding proteins in the ER. Overexpression of calreticulin increases the total amount of Ca^{2+} in intracellular stores, whereas calreticulin-deficient cells have reduced ER Ca^{2+} storage capacity^[36]. Impaired collagen synthesis has been observed in cells derived from mice possessing genetic defects in ER chaperone proteins^[37]. In this study, we observed for

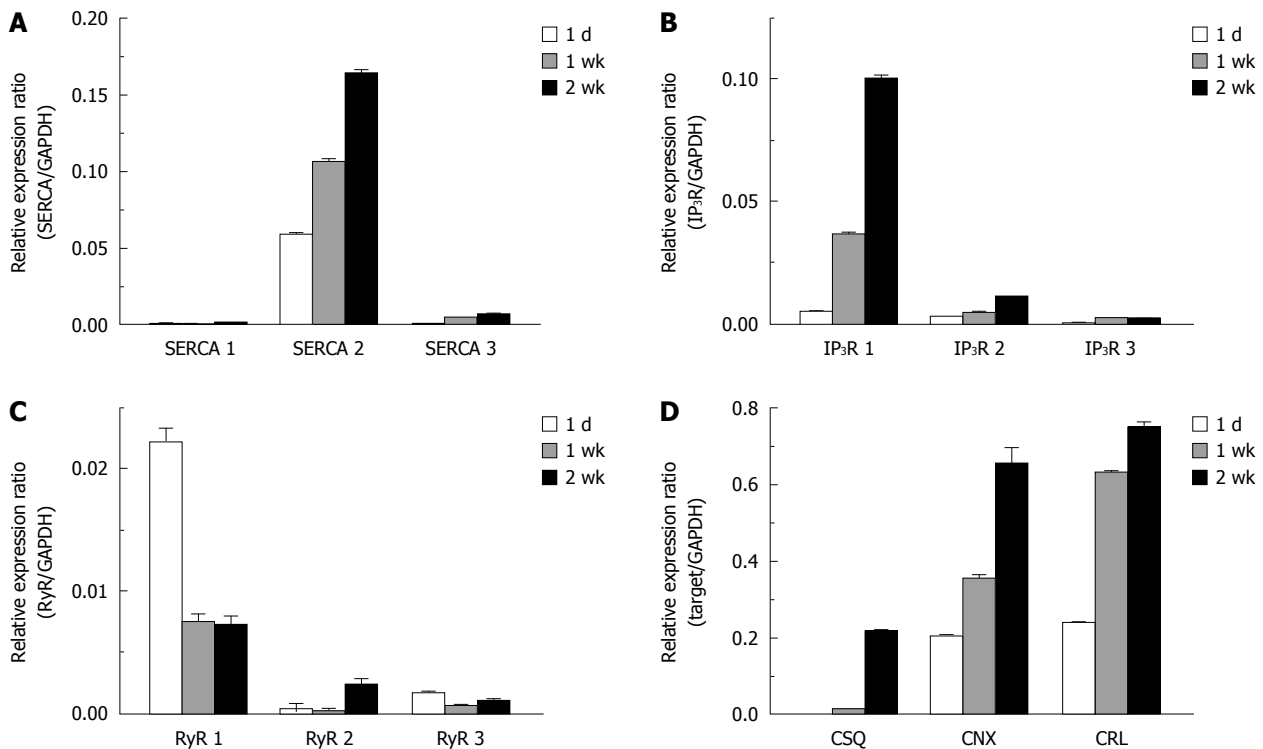

Figure 5 Up-regulation of endoplasmic reticulum Ca²⁺ transporting and binding proteins in activated hepatic stellate cells. Changes in the expression level of 3 isoforms of the sarcoplasmic/endoplasmic reticulum Ca²⁺ ATPase (SERCA) (A), inositol triphosphate receptor (IP₃R) (B), ryanodine receptor (RyR) (C) and Ca²⁺ binding chaperones (D) during the culture periods (1 d, 1 wk and 2 wk) were measured by quantitative real-time reverse transcription-polymerase chain reaction analysis. Expression levels were normalized to GAPDH and expressed as a relative expression ratio (target/GAPDH). Data are presented as the mean \pm SE ($n = 3$). CSQ: Calsequestrin, CNX: Calnexin, and CRL: Calreticulin.

the first time that the expression of ER Ca²⁺ binding proteins was markedly increased during the activation process of HSCs, which might be an important adaptive change for trans-differentiation.

Upon stimulation from the extracellular space, ER Ca²⁺ is the main source for releasing Ca²⁺ and is responsible for enabling biologic signaling mediated by Ca²⁺. In addition, Ca²⁺ release from the ER stimulates store-operated Ca²⁺ entry into the cytosol, which eventually increases the refilling of the ER Ca²⁺ reservoir. It has been shown that cytosolic Ca²⁺ signaling is important for proliferation and differentiation of HSCs^[25]. Similar to myofibroblast-like cells, activated HSCs can have a contractile response to [Ca²⁺]_i changes, which may increase vascular resistance leading to portal hypertension *in vivo*^[32]. During trans-differentiation, the expression of L-type calcium channels increases, which may contribute to cytosolic Ca²⁺ signaling in HSCs^[26,38]. In the present study, we observed that 5-HT increased [Ca²⁺]_i only in activated HSCs *via* a serotonergic receptor. Until now, 5-HT-induced [Ca²⁺]_i changes have not been reported in HSCs. Physiologic concentrations of 5-HT in plasma are known to be less than 100 nmol/L, but those in cirrhotic patients are significantly elevated (3-4 fold) compared to controls^[39]. Moreover, intrahepatic neighboring cells secrete 5-HT to act as an autocrine/paracrine regulator^[40]. Thus, we hypothesize that local 5-HT concentration close to the releasing cells might be higher than the plasma level and repetitive exposure may

have additive effects on [Ca²⁺]_i-mediated changes in the process of HSC activation.

We observed that 5-HT elicited a [Ca²⁺]_i response *via* the metabotropic 5-HT₂ receptor in activated HSCs. This was demonstrated by the findings that 5-HT-induced [Ca²⁺]_i transients were (1) completely blocked by a PLC inhibitor; (2) not altered by nominally Ca²⁺ free conditions; and (3) reduced by a 5-HT₂ blocker. 5-HT_{2A} is known to mediate mitogenic effects in fibroblasts^[41], while 5-HT_{2B} is involved in the development of the heart and enteric nervous system^[42]. However, we did not discriminate whether the 5-HT_{2A} and/or 5-HT_{2B} receptor mediated the serotonergic Ca²⁺ signaling in activated HSCs. We also observed that the type I IP₃ receptor (IP₃R 1) is the main isoform expressed in activated HSCs, which is consistent with a recent report by Kruglov *et al.*^[32]. The expression level of IP₃R 1 was increased during the activation process (Figure 5B).

Various ligands for G_{q/11}-coupled metabotropic receptors could be important extracellular stimuli, as they generate IP₃ by activating phospholipase-C. Interestingly, it has been reported that the expression of the P2Y metabotropic purinoceptor (P2Y6) is rapidly upregulated following activation of HSCs, with a similar increase in ATP-induced [Ca²⁺]_i transients^[33]. The same study also reported that extracellular UDP increases the transcription of procollagen in activated HSCs *via* activation of the P2Y receptor, and this effect is partially inhibited by a P2Y receptor blocker. These results add further support to the

hypothesis that Ca^{2+} signaling released from ER stores is associated with HSCs undergoing the process of activation. We also observed that ATP increased $[\text{Ca}^{2+}]_i$, which might be mediated by the metabotropic P2Y receptor (Figure 3). However, acetylcholine did not induce calcium changes, indicating that muscarinic acetylcholine receptors do not functionally exist in activated HSCs, even in the presence of machinery for ER Ca^{2+} release.

In this study, we observed the pronounced increase in serotonergic $[\text{Ca}^{2+}]_i$ response related to the upregulation of metabotropic 5-HT₂ receptors, type 1 inositol-5'-triphosphate receptor, type 2 sarcoplasmic/endoplasmic reticulum Ca^{2+} ATPase, and Ca^{2+} binding ER chaperone proteins following trans-differentiation of HSCs. These changes may be involved in the pathophysiologic (pro-fibrotic) process of rat HSCs as well as being a compensatory mechanism for maintaining ER Ca^{2+} homeostasis and protein synthesis/maturation. Switching on and off of the serotonergic signaling pathway might be implicated in potential treatment for portal hypertension. Yet, the biological relevance of a 5-HT-induced $[\text{Ca}^{2+}]_i$ transient in HSCs remains to be clarified. Moreover, it is not obvious whether simply switching-off this serotonergic signaling is an ideal target for developing treatments for liver cirrhosis. While there is evidence to suggest that 5-HT₂ antagonists reduce proliferation and increase cell death of isolated HSCs^[2,19], a recent study found that fibrotic changes induced by CCl₄ are not ameliorated by a 5-HT₂ antagonist^[29,43]. Further studies to elucidate the detailed role of serotonergic signaling in HSCs are needed in order to develop therapeutic approaches to hepatic fibrosis.

COMMENTS

Background

Hepatic stellate cells (HSCs) are known to initiate hepatic fibrosis by trans-differentiating into myofibroblast-like cells. Changes in intracellular Ca^{2+} concentration ($[\text{Ca}^{2+}]_i$) have been suggested as a stimulus for the activation of HSCs.

Research frontiers

Recent data showed that activated HSCs responded to 5-hydroxytryptamine (5-HT) in a profibrogenic manner, which can be suppressed by 5-HT₂ antagonists. In this study, the authors demonstrated that 5-HT generated $[\text{Ca}^{2+}]_i$ transients released from endoplasmic reticulum (ER) in trans-differentiated HSCs, which was consistent with the upregulation of 5-HT₂ receptors.

Innovations and breakthroughs

Serotonergic $[\text{Ca}^{2+}]_i$ signaling has not been reported in HSCs, until now. It is also a novel finding that the expression of ER Ca^{2+} binding proteins was markedly increased during the activation process of HSCs.

Applications

The identification of $[\text{Ca}^{2+}]_i$ signaling and the expressional changes of Ca^{2+} handling proteins in the process of HSC activation could help us to understand the pathophysiology and develop therapeutic approaches to hepatic fibrosis.

Terminology

IP₃ receptor and sarcoplasmic/endoplasmic reticulum Ca^{2+} ATPase are ER proteins involved in Ca^{2+} release from, and refilling into, ER. Calsequestrin, calnexin, and calreticulin are ER Ca^{2+} binding chaperone proteins. Upregulation of all these proteins is important not only for $[\text{Ca}^{2+}]_i$ signaling but also for maintaining ER Ca^{2+} levels needed for protein synthesis/maturation.

Peer review

The manuscript by Park *et al* reports the results of investigations on the serotonergic Ca^{2+} signaling, and the expression of 5-HT receptors and Ca^{2+} transporting proteins in rat HSCs. By employing reverse transcription-polymerase chain reac-

tion, and fluorescent (fura-2) and electrophysiological techniques, as well as immunocytochemistry, the authors conclude that the increase in serotonergic $[\text{Ca}^{2+}]_i$ responses accompanied by the upregulation in 5-HT₂ receptors and Ca-transport proteins attests to their role in HSC activation. It is worthy of publication.

Eight patients (1.1%) with T1a GB cancer and 52 patients (9.3%) with T1b GB cancer died of recurrent GB cancer ($P < 0.01$).

CONCLUSION: Simple cholecystectomy represents the adequate treatment of T1a GB cancer. There is no definite evidence that extended cholecystectomy is advantageous over simple cholecystectomy for T1b GB cancer.

Abstract

AIM: To evaluate the efficacy of simple and extended cholecystectomy for mucosa (T1a) or muscularis (T1b) gallbladder (GB) cancer.

METHODS: Original studies on simple and extended cholecystectomy for T1a or T1b GB cancer were searched from MEDLINE (PubMed), Cochrane Library, EMBase, and CancerLit using the search terms of GB, cancer/carcinoma/tumor/neoplasm.

RESULTS: Twenty-nine out of the 2312 potentially relevant publications met the eligibility criteria. Of the 1266 patients with GB cancer included in the publications, 706 (55.8%) and 560 (44.2%) had T1a and T1b GB cancer, respectively. Simple cholecystectomy for T1a and T1b GB cancer was performed in 590 (83.6%) and 375 (67.0%) patients, respectively ($P < 0.01$). In most series, the treatment of choice was simple cholecystectomy for T1a GB cancer patients with a 5-year survival rate of 100%. Lymph node metastasis was detected in 10.9% of the T1b GB cancer patients and in 1.8% of the T1a GB cancer patients, respectively ($P < 0.01$).

INTRODUCTION

Gallbladder (GB) cancer confined to mucosa (T1a) or muscularis (T1b) is classified as an early cancer. Because of the high prevalence of advanced stage GB cancer at presentation, early GB cancer has been less studied among all GB cancers. However, on the basis of studies performed on GB cancer, less than 10% are early GB cancers and the proportion is growing because they tend to be diagnosed after laparoscopic cholecystectomy.

Most authors would agree that T1a GB cancer is a local disease and simple cholecystectomy represents its adequate treatment, provided that the resection margin is not involved. It was reported that the incidence of lymph node metastasis of GB cancer is less than 5%^[1-9].

Recurrent GB cancer has been reported only in the form of case reports^[2-4,10-12] and the 5-year survival rate of most GB cancer patients is approaching 100%^[1,3,13-21]. Particularly, laparoscopic cholecystectomy is believed to be the adequate treatment of T1a GB cancer^[4,12,14,16-20,22,23]. Although port site recurrence^[24] and possible tumor seeding caused by pneumoperitoneum^[25] are concerned, few cases have been reported^[10,24].

It has been argued that T1b GB cancer may have spread regionally or systematically at presentation. Therefore, whether T1b GB cancer should be treated with simple cholecystectomy or extended cholecystectomy still remains debatable. Some authors believe that T1b GB cancer should be considered simply as a local disease with the following reasons. First, lymphovascular and perineural invasion and lymph node metastasis are rarely found in patients with pT1b GB cancer^[26]. Second, the outcome of patients with pT1b GB cancer in terms of survival after simple cholecystectomy is excellent and similar to that of patients with pT1a GB cancer when the resection margins are not invaded^[10,17]. Third, extended cholecystectomy does not increase the long-term survival rate of patients with pT1b GB cancer^[15,17]. Fourth, no difference has been observed in survival rates between patients who underwent subsequent laparotomy with additional resection and those who did not^[7,15,17]. On the other hand, others believe that lymphovascular and perineural invasion and lymph node metastasis are more frequently found in patients with pT1b GB cancer^[11,13,14], and pT1b GB cancer recurs more frequently than pT1a GB cancer^[7,11,18]. Extended cholecystectomy increases the long-term survival rate of patients with pT1b GB cancer^[5,11,27].

Few early GB cancer cases are available and randomized trials are difficult to conduct for the assessment of appropriate surgical procedures. Therefore, a pooled systematic analysis of the efficacy of each surgical procedure for early GB cancer is essential to establish the appropriate management of T1a and T1b GB cancer. This study was to evaluate the efficacy of simple and extended cholecystectomy for T1a or T1b GB cancer.

MATERIALS AND METHODS

Search strategy

Original studies on surgery for T1 GB cancer were searched from MEDLINE (PubMed, 1966-2008), Cochrane Library (1996-2008), EMBase (1970-2008), and CancerLit (1970-2008) using the search terms of GB, cancer/carcinoma/tumor/neoplasm.

Selection criteria

Of the identified studies, only publications in the English language were included. Selection was confined to peer-reviewed articles. Unpublished data, abstracts, case reports and case series containing less than 5 patients were excluded. Studies in which the T stage was inadequately assessed and diagnosis was other than adenocarcinoma were excluded. All surgical studies on histologically proven

T1a and T1b GB cancer were included. T1a and T1b GB cancer was defined as a cancer confined to the mucosa to muscularis, respectively. Only studies describing surgical intervention (simple cholecystectomy or extended cholecystectomy, *etc.*) for T1a and T1b GB cancer were included. Only the most recent publications were included when the selected articles included the same or overlapping data in multiple publications.

Data extraction

Two authors (Lee SE and Kang MJ) reviewed each article and performed data extraction independently according to the predefined inclusion criteria. General information pertaining to the study design, patient number and follow-up length were recorded. Types of intervention were classified into simple cholecystectomy and extended cholecystectomy, respectively. Because the extent of extended cholecystectomy varied in each article, we defined it as cholecystectomy, regional lymph node dissection, liver resection beyond wedge resection and/or resection of other organs, respectively. The overall 5-year survival rate of patients with GB cancer was defined as the primary outcome. Secondary outcomes included mortality, morbidity, and recurrence of GB cancer. The extracted data were then cross-checked by the two authors to eliminate the discrepancy.

Statistical analysis

Data are presented as median (range) unless otherwise stated. Interpretative analyses were performed based on pooled as opposed to individuals. Since patient data could not account for censored, missing or incomplete follow-up, survival analyses could not be conducted based on these data.

RESULTS

Search results

Overall, the search identified 2312 potentially relevant publications. After the titles and abstracts were reviewed, 252 publications were potentially eligible and full text reviews were conducted. Finally, 29 studies^[1,3-22,24,26-32] that specifically assessed the surgical outcomes of patients with T1a and T1b GB cancer met the eligible criteria (Figure 1). There were no randomized studies and all studies were retrospective in nature. Furthermore, the majority of studies involved a small number of patients (median 15, range 5-89) except for nation-wide surveys^[1,5,7,16] (Table 1).

Characteristics of the study population

Twenty-nine publications included 1266 patients with T1 GB cancer. Of these 1266 patients, 706 (55.8%) and 560 patients (44.2%) had T1a and T1b GB cancer, respectively.

Types of surgical intervention

The operative procedures performed in the 1266 patients are summarized in Table 2. Simple cholecystectomy for T1a and T1b GB cancer was performed in 590 (83.6%) and 375 (67.0%) patients, respectively ($P < 0.01$). Ex-

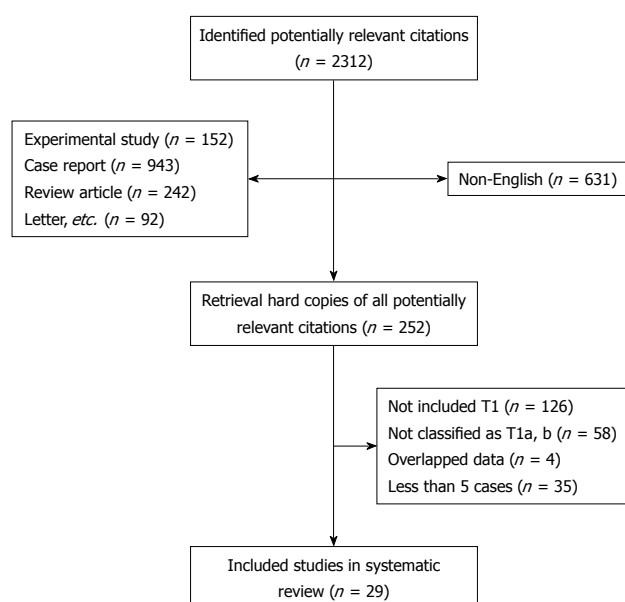

Figure 1 Flowchart of included articles.

tended cholecystectomy for T1a and T1b GB cancer was performed in 110 (15.6%) and 168 (30.0%) patients, respectively ($P < 0.01$).

Postoperative morbidity and mortality

Five articles (17.2%)^[1,3,15,16,24] discussed the postoperative morbidity related to the operative procedure. Complications occurred in 11 patients (11/52, 21.2%) following simple cholecystectomy, and in 21 patients (21/75, 28%) after extended cholecystectomy. Five postoperative deaths (1.0%)^[1,24] occurred after simple cholecystectomy and the causes of death included acute myocardial infarction and pulmonary embolism. Seven postoperative deaths (1.5%)^[1,10,11,24] occurred after extended cholecystectomy. Three patients died of co-morbidities of the disease, two patients died of hemorrhage, one patient died of peritonitis and one died of liver failure.

Lymph node metastasis

Of the 29 reviewed articles, information on lymph node metastasis was available from 17 publications (58.6%)^[3,5-7,10,11,13-18,24,26-28,31] (Table 3). Lymph node metastasis was found in 1.8% and 10.9% of T1a and T1b GB cancer patients, respectively ($P < 0.01$). Of the 17 publications, only 5 included lymph node metastasis cases^[3,5,13,15,17] (Table 4).

Recurrence

Information pertaining GB cancer recurrence was available from 26 out of 29 articles (89.76%)^[1,3,5-8,10-13,15-22,24,26-30,32].

Kim <i>et al</i> ^[17]	0/10	1/9 (11.1)	2.250	1.342-3.771
Ogura <i>et al</i> ^[13]	5/201 (2.5)	25/165 (15.2)	7.000	2.616-18.733

Eight patients (1.1%) with T1a GB cancer^[3,4,10-12,18,26] and 52 patients (9.3%) with T1b GB cancer^[4-7,11,12,17-19,27,32] died of recurrent GB cancer ($P < 0.01$). The studies reporting recurrent GB cancer are listed in Table 5. Cases of T1a GB cancer recurrence and the recurrence pattern of T1b GB cancer are summarized in Tables 6 and 7, respectively.

Survival rate

Twenty-one publications^[1,3,5-11,13-21,27,30,32] described the 5-year survival rate of GB cancer patients. The 5-year survival rate of patients with T1a and T1b GB cancer is 45%-100% and 37.5%-100%, respectively (Table 8).

Only 6 publications^[5,6,11,15,17,27] compared the survival rates of patients after simple cholecystectomy or extended cholecystectomy. No significant difference was observed in the survival rate of patients with T1a GB cancer after different operative procedures. However, 3 publications^[5,11,27] showed a significantly longer survival time of patients with T1b GB cancer after extended cholecystectomy (Table 9).

Outcome of patients after laparoscopic cholecystectomy and open cholecystectomy

Only two studies^[4,12] compared the survival rates of patients with T1 GB cancer after laparoscopic cholecystectomy and open cholecystectomy. No significant difference

was observed in the survival rate of patients after the two operative procedures. However, it must be emphasized that the total number of patients included was small. In addition, 6 studies^[17-20,22,30] evaluated the safety of laparoscopic cholecystectomy on the basis of recurrent GB cancer and survival rate of GB cancer patients, showing a low recurrence rate and a high survival rate (Table 10). Meta-analysis could not be performed because no studies reported the hazard ratio for overall survival rate according to the surgical procedure.

DISCUSSION

This review evaluated the surgical outcomes of patients with T1 GB cancer. The evidence was of low quality, because it was obtained from the reviewed articles, and most studies were case series. No study was controlled, and all reviewed articles were retrospective in nature. Furthermore, such studies usually involved a small number

of patients, making it difficult to draw a statistically sound conclusion. The inclusion of heterogeneous groups of patients who underwent surgery at different centers by different specialists also made interpretation of results challenging. However, the relatively low incidence of this condition makes it impractical to conduct adequately powered randomized controlled trials to compare different surgical and/or nonsurgical interventions. Therefore, a systematic review of evidence despite a lower scientific level was needed.

Simple cholecystectomy for T1a GB cancer was performed in 84% of patients. Of these patients, 46% underwent laparoscopic cholecystectomy. Lymph node metastasis was found only in 1.8% GB cancer patients with a recurrence rate of 1.1%. Because 50% of the recurrence occurred in the common bile duct, pathological confirmation of cystic duct margin would be important. If cystic duct margin was proved to be positive for GB cancer,

resection of the common bile duct should be performed. Although the 5-year survival rate of patients with T1a GB cancer was 45%-100%, the publications^[1,11,32] showing a low survival rate did clarify that most deaths were not related to GB cancer. The remaining publications reported a 5-year survival rate of over 90%, indicating that simple cholecystectomy is the adequate surgical treatment of T1a GB cancer. In particular, recent reports^[17-20,30] showed a 100% 5-year survival rate of patients with GB cancer following laparoscopic cholecystectomy, indicating that laparoscopic cholecystectomy is a safe procedure for GB cancer. However, because a report^[10] on peritoneal seeding due to GB perforation during laparoscopic cholecystectomy and a report^[4] on port site recurrence following laparoscopic cholecystectomy, careful dissection to avoid perforation of GB should be performed and GB should be retrieved using a plastic bag.

Simple cholecystectomy and extended cholecystectomy for T1b GB cancer were performed in 67% and 30% patients, respectively. More patients with T1b GB cancer underwent extended cholecystectomy ($P < 0.01$). Despite a lack of evidence, many authors agreed that aggressive approach would be needed for T1b GB cancer. This review validated the rationale behind this approach to a certain extent. Lymph node metastasis of T1b GB cancer was 11%, which was significantly higher than that (2%) of T1a GB cancer ($P < 0.01$). The publications^[3,5,13,15,17] reporting lymph node metastasis of T1a and T1b GB cancer showed that the incidence of lymph node metastasis of T1b GB cancer is 1.3-7 times higher than that of T1a GB cancer (Table 4). The recurrence rate of T1b GB cancer was 9%, which was significantly higher than that (1%) of T1a GB cancer ($P < 0.01$). The publications^[3-7,10-12,17,18,26,27,29,32] reporting the recurrence rate of T1a and T1b GB cancer showed that the recurrence rate of T1b GB cancer is 1.3-24 times higher than that of T1a GB cancer (Table 7). In addition, the recurrence rate of GB cancer was higher after simple cholecystectomy than after extended cholecystectomy (12.5% *vs* 2.7%, $P < 0.01$). Although the recurrence sites were not available in 50% of the cases reviewed, no patient showed loco-regional recurrence after extended cholecystectomy in the remaining cases. The 5-year survival rate of patients with T1b GB cancer was 37.5%-100%. Studies^[1,5,11,15,27] showing a 5-year survival rate of less than 50% discussed simple cholecystectomy cases. Of these publications, 3^[5,11,27] showed a significantly higher survival rate after extended cholecystectomy than after simple cholecystectomy. However, the total number of patients included was too small to comment on statistical significance. Except for these studies, the rest showed a 5-year survival rate of over 80% for patients with GB cancer irrespective of surgical procedure. Although there was no definite evidence that extended cholecystectomy was advantageous over simple cholecystectomy in this review, regional lymph node dissection should be included in any surgical procedure for T1b GB cancer considering that the lymph node metastasis rate was relatively high. Although the recurrence rate of GB cancer was high and the survival rate of GB cancer

patients was low after simple cholecystectomy, extended cholecystectomy was recommended for T1b GB cancer in several guidelines^[33,34]. In view of the inconclusive results obtained from this review, multicenter prospective studies should be performed to clarify the surgical strategy for T1b GB cancer.

In conclusion, T1 GB cancer should be treated based on the outcomes of this review. Simple cholecystectomy for T1a GB cancer is the adequate treatment and laparoscopic cholecystectomy is a safe procedure for T1b GB cancer, provided the port site recurrence is considered. Careful dissection should be conducted considering that the peritoneal seeding is associated with bile spillage. Resection margin of cystic duct should be confirmed histopathologically with possible common bile duct resection in mind. There is no definite evidence that extended cholecystectomy is advantageous over simple cholecystectomy for T1b GB cancer. Because lymph node metastasis is considerable, regional lymphadenectomy should be performed for the treatment and staging of GB cancer.

COMMENTS

Background

Most authors agree that mucosa (T1a) gallbladder (GB) cancer is a local disease and simple cholecystectomy represents its adequate treatment provided that the resection margin is not involved. It has been argued that muscularis (T1b) GB cancers may have spread regionally or systematically at presentation. Therefore, whether T1b cancers should be treated with simple cholecystectomy or extended cholecystectomy still remains debatable.

Research frontiers

Few early GB cancer cases are available and randomized trials are difficult to conduct for the assessment of appropriate surgical procedures. Therefore, a pooled systematic analysis of the efficacy of each surgical procedure for early GB cancer is essential to establish the appropriate management of T1a and T1b GB cancer.

Innovations and breakthroughs

Original published studies on surgery for T1 GB cancer were searched from MEDLINE (PubMed, 1966-2008), Cochrane Library (1996-2008), EMBase (1970-2008), and CancerLit (1970-2008).

Applications

Simple cholecystectomy for T1a GB cancer is its adequate treatment and laparoscopic cholecystectomy is safe procedure for T1b GB cancer provided the port site recurrence is considered. There is no definite evidence that extended cholecystectomy is advantageous over simple cholecystectomy for T1b GB cancer.

Terminology

GB cancer confined to T1a or T1b is as an early cancer.

Peer review

This review evaluated the surgical outcomes of T1 GB cancer. The evidence is of low quality, because it was obtained from the reviewed articles, and most studies were case series. No study was controlled and all reviewed articles were retrospective in nature. Furthermore, such studies usually involved a small number of patients, making it difficult to draw a statistically sound conclusion. The inclusion of heterogeneous groups of patients who underwent surgery at different centers by different specialists also made interpretation of results challenging. However, the relatively low incidence of GB cancer makes it impractical to conduct adequately powered randomized controlled trials comparing different surgical and/or nonsurgical interventions. Therefore, systematic review of evidence despite a lower scientific level is needed.

tion and cell apoptosis *in vitro*, and increased tumor growth inhibition and cell death in the tumor mass *in vivo*. In MKN45 and AGS cells, oxaliplatin treatment promoted both protein kinase B (Akt) and NFκB activation, while pretreatment with LY294002 significantly attenuated oxaliplatin-induced Akt activity and NFκB binding. LY294002 promoted oxaliplatin-induced Fas ligand (FasL) expression, Fas-associated death domain protein recruitment, caspase-8, Bid, and caspase-3 activation, and the short form of cellular caspase-8/FLICE-inhibitory protein (c-FLIPs) inhibition. *In vivo*, LY294002 inhibited oxaliplatin-induced activation of Akt and NFκB, and increased oxaliplatin-induced expression of FasL, inhibition of c-FLIPs, and activation of caspase-8, Bid, and caspase-3.

CONCLUSION: Combination of oxaliplatin and LY294002 was therapeutically promising for gastric cancer treatment. The enhanced sensitivity of the combined treatment was associated with the activation of the death receptor pathway.

Abstract

AIM: To examine the effects of combined treatment of oxaliplatin and phosphatidylinositol 3'-kinase inhibitor, 2-(4-morpholinyl)-8-phenyl-4H-1-benzopyran-4-one (LY294002) for gastric cancer.

METHODS: Cell viability was evaluated by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay. Apoptotic cells were detected by flow cytometric analysis and terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling assay. Western blotting and immuno-precipitation were used to examine protein expression and recruitment, respectively. Nuclear factor κB (NFκB) binding activities were investigated using electrophoretic mobility shift assay. Nude mice were used to investigate tumor growth.

RESULTS: Treatment with combined oxaliplatin and LY294002 resulted in increased cell growth inhibi-

LY294002 potentiates the anti-cancer effect of oxaliplatin for gastric cancer *via* death receptor pathway. *World J Gastroenterol* 2011; 17(2): 181-190 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i2/181.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i2.181>

INTRODUCTION

Gastric cancer is the second leading cause of cancer death in the world and the top lethal cancer in Asia^[1]. The management of gastric cancer is usually a multi-approach involving surgery, chemotherapy, and radiotherapy. Approximately half of gastric cancer patients present with non-operable tumors^[2]. As such, besides surgical resection, chemotherapy is the main adjuvant treatment for postoperative and advanced gastric cancer^[2]. Combined chemotherapy regimens are currently accepted as the first-line treatment for this disease^[3].

Oxaliplatin, a third-generation platinum coordination complex of the 1,2-diaminocyclohexane families, generates covalent adducts between platinum and two adjacent guanines or guanine and adenine in cell DNA, which leads to disruption of DNA replication and transcription^[4,5]. Oxaliplatin was shown to be effective in the treatment of advanced gastric cancer when combined with 5-fluorouracil and leucovorin, and has also been used in adjuvant chemotherapy for gastric cancer. Despite the improvement in the efficacy of chemotherapeutic drugs used in the treatment of metastatic gastric cancer, the response rates in the advanced diseases are approximately 47.9% for the most effective drug combinations, and the vast majority of patients relapse, with a median survival of only 11.2 mo^[6]. Recently, the combination of chemotherapy and a targeted therapeutic agent was shown to be promising for the treatment of advanced gastric cancer.

Several studies have reported that protein kinase B (Akt) is a key molecule for protecting cells from apoptosis, likely due to phosphorylation and inactivation of a variety of key pro-apoptotic targets. The Akt-mediated survival-signaling pathway is an attractive target for cancer chemotherapy^[7-10]. In gastric cancer, over expression and activation of Akt have also been detected, and anomalous expression of Akt induces cell survival^[7,11]. In addition, inhibition of Akt activity stimulates apoptosis and enhances the sensitivity of gastric cancer to chemotherapy in a variety of mammalian cells^[12-14].

In the present study, we examined the role of 2-(4-morpholinyl)-8-phenyl-4H-1-benzopyran-4-one (LY294002) in augmenting the anti-cancer effects of oxaliplatin in gastric cancer. We found that LY294002 sensitizes gastric cancer cells to oxaliplatin in both *in vitro* and *in vivo* studies. Furthermore, the death receptor pathway was involved in regulating Akt-mediated apoptosis in response to chemotherapy in gastric cancer.

MATERIALS AND METHODS

Cell culture

Human gastric carcinoma cell lines MKN45 and AGS were obtained from the Cell Bank of Shanghai Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences. All the cell lines were cultured in RPMI 1640 medium (GIBCO, NY, USA) supplemented with heat-inactivated 10% fetal bovine serum (FBS), 10 U/mL penicillin,

and 10 µg/mL streptomycin in a humidified atmosphere containing 5% CO₂ and 95% air at 37°C.

Antibodies and reagents

Phosphatidylinositol 3'-kinase (PI3K) inhibitor (LY294002) and oxaliplatin were purchased from Alexis Biochemicals (San Diego, CA, USA). The primary antibodies against human Akt1, phosphorylated Akt at Ser⁴⁷³ (phospho-AktSer⁴⁷³), phospho-AktThr³⁰⁸ (Cell Signaling Technology, Beverly, MA, USA), short form of cellular caspase-8/FLICE-inhibitory protein (c-FLIPs), long form of c-FLIP (c-FLIP_L), Fas ligand (FasL), Fas, Fas-associated death domain protein (FADD), caspase-8, caspase-3, Bid, nuclear factor κB (NFκB)-p65 and actin (Santa Cruz Biotechnology, Santa Cruz, CA, USA) were used in Western blotting. The primary antibodies against human phospho-AktSer⁴⁷³, NFκB-p65, FasL, active caspase-8, t-Bid, c-FLIPs, and active caspase-3 (Cell Signaling Technology, Beverly, MA, USA) were used in immunohistochemistry.

Cell transfection

FasL siRNA was purchased from Santa Cruz Biotechnology. MKN45 and AGS cells were transiently transfected with FasL siRNA using Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA) according to the manufacturers' instructions. FasL expression was detected by Western blotting.

3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay

Cells (4×10^3 cells/well) were plated in 96-well plates in 100 µL of RPMI 1640 without FBS, and incubated for 24 h. Various concentrations (0-4 µmol/L) of the anticancer drugs were added to the culture medium. The viability of cells was evaluated by a 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay according to the manufacturers' specifications (Roche Applied Science, Indianapolis, IN, USA). Briefly, MTT was added at a concentration of 500 mg/L, and cells were incubated for 4 h at 37°C. The absorbance readings of each well were determined using a computer-controlled microtiter plate reader at 570 nm wavelength. The percentage cell survival was defined as the relative absorbance of untreated vs treated cells.

Apoptosis analysis

Cells were treated with various concentrations (0-20 µmol/L) of anticancer drugs and suspended at chosen time points (24 h). Next, 2×10^6 cells were centrifuged and washed twice with ice-cold phosphate-buffered saline. Apoptotic cells were detected by flow cytometry using Annexin V-Fluorescein and propidium iodide (Molecular Probes, Invitrogen, Eugene, OR, USA).

Western blotting and immunoprecipitation

Cells were lysed in ice-cold lysis buffer (25 mmol/L Tris/HCl, pH 7.6, 150 mmol/L NaCl, 5 mmol/L EDTA, 1 mmol/L Na₃VO₄, 50 mmol/L β-glycerophosphate, 10 mmol/L

NaF, 1% Triton X-100, and 0.5 mmol/L phenylmethyl sulfonylfluoride) containing a protease inhibitor cocktail (Roche Diagnostics Ltd., Mannheim, Germany). Protein concentration was determined by Protein Assay (Bio-Rad laboratories, Hercules, California, USA). Western blotting was performed and subjected to the standard protocol. Total cellular proteins (40 µg protein) were separated on SDS-PAGE, and transferred to nitrocellulose membranes (Bio-Rad laboratories). Anti-actin antibody was used to ascertain equal loading of protein. Specific antibodies diluted in TBS-T containing 5% nonfat milk were used to detect indicated proteins. The appropriate horseradish peroxidase (HRP) conjugated secondary antibodies were used at 1:3000 for all antibodies. Positive antibody reactions were detected with the enhanced chemoluminescence system and Hyperfilm X-ray film.

For immunoprecipitation of the Fas death-inducing signaling complex (DISC), cells were lysed and the lysate (300 mg protein/sample) was incubated with 0.4 mg anti-Fas antibody overnight at 4°C. Immunoprecipitates were separated by 10% SDS-PAGE and immunoblotted with anti-FADD.

Electrophoretic mobility shift assay

NFκB binding assays were performed using nuclear extracts and biotin-labeled NFκB oligonucleotides (Panomics, Fremont, CA, USA). Electrophoretic mobility shift assay (EMSA) was performed using an EMSA Gel-Shift Kit. For EMSA, an equal amount of nuclear extracts was incubated for 30 min with an NFκB-specific 32P-labeled oligonucleotide and binding mix as described previously^[15]. Samples were electrophoresed at 100 V and 4°C, transferred to Biotodyne nylon membranes (Pierce Biotechnology, Rockford, IL, USA), and then cross-linked in an ultraviolet cross-linker (Stratagene Inc., La Jolla, CA, USA). Protein gels were visualized using streptavidin-HRP followed by chemiluminescence detection. The nucleotide sequence of biotin-labeled NFκB was 5'-AGCTATGTGGGTTTTCCTCATGAGC-3'.

In vivo assay for tumor growth

MKN45 (5×10^6) was implanted subcutaneously into the flank of nude mice (6 in each group, male BALB/c nu/nu, 4-6 wk of age) (Institute of Materia Medica, CAS, Shanghai, China). When the tumors were 100-150 mm³ in size, oxaliplatin (1.3 mg/kg) and/or LY294002 (25 mg/kg) were injected into the intraperitoneal space every four days. Tumor growth was monitored by measuring tumor volume, which was calculated by the formula: $V \text{ (mm}^3\text{)} = \text{width}^2 \text{ (mm}^2\text{)} \times \text{length (mm)}/2$. The mice were sacrificed 6 wk later, and tumors were harvested and evaluated with hematoxylin and eosin and terminal deoxynucleotidyl transferase-mediated dUTP nick end-labeling (TUNEL) assay. The expression of phospho-AktSer⁴⁷³, p65 subunit of NFκB (NFκB-p65), and several proteins in the death receptor pathway was examined by immunohistochemistry as described previously^[16].

TUNEL assay

To detect apoptotic cells in tumor tissue sections, an *in situ* apoptosis detection kit (Roche Diagnostics) was used. Tumor sections were incubated with proteinase K, rinsed with ddH₂O, dewaxed with dimethylbenzene, and rehydrated with gradient ethanol. A 3% H₂O₂ solution was used to block endogenous peroxidase. After incubation with equilibration buffer and terminal deoxynucleotidyl transferase enzyme, sections were incubated with antidigoxigenin-peroxidase conjugate. Peroxidase activity in each section was shown by diaminobenzidine. Finally, sections were counterstained with hematoxylin. Positive cells were identified and counted (three random fields per slide) under light microscope (Carl Zeiss, Thornwood, NY, USA).

Statistical analysis

All data were expressed as mean ± SD. Comparisons of the difference of mean values were assessed using Student's two-tailed *t* test. Differences were considered statistically significant for $P < 0.05$ and $P < 0.01$. All means were calculated from at least three independent experiments.

RESULTS

LY294002 increased oxaliplatin-induced cell proliferation inhibition and apoptosis in gastric cancer cells

MKN45 and AGS cells were treated with various doses of oxaliplatin (0, 0.25, 1, 4 µmol/L for cell growth inhibition, and 0, 5, 10, 20 µmol/L for cell apoptosis) for 24 h with or without the pretreatment of LY294002 (25 µmol/L). Cell growth inhibition was evaluated by MTT assay. Apoptotic cells were investigated by flow cytometry. LY294002 significantly increased oxaliplatin-induced growth inhibition (In MKN45, oxaliplatin *vs* oxaliplatin + LY294002: $3.2\% \pm 0.1\%$ *vs* $4.1\% \pm 0.1\%$, $P > 0.05$, $6.7\% \pm 1.1\%$ *vs* $11.5\% \pm 1.3\%$, $P < 0.05$, $12.5\% \pm 1.3\%$ *vs* $29.7\% \pm 1.7\%$, $P < 0.01$, and $13.7\% \pm 3.1\%$ *vs* $29.8\% \pm 3.3\%$, $P < 0.01$; in AGS, $6.6\% \pm 0.1\%$ *vs* $7.1\% \pm 0.2\%$, $P > 0.05$, $8.4\% \pm 1.4\%$ *vs* $14.3\% \pm 1.2\%$, $P < 0.05$, $16.5\% \pm 2.5\%$ *vs* $41.1\% \pm 3.8\%$, $P < 0.01$, and $18.4\% \pm 2.1\%$ *vs* $35.3\% \pm 4.3\%$, $P < 0.01$) and apoptosis (in MKN45, oxaliplatin *vs* oxaliplatin + LY294002: $1.7\% \pm 0.1\%$ *vs* $2.6\% \pm 0.3\%$, $P > 0.05$, $14.3\% \pm 3.4\%$ *vs* $26.3\% \pm 4.3\%$, $P < 0.05$, $28.0\% \pm 4.7\%$ *vs* $44.2\% \pm 5.12\%$, $P < 0.01$, and $41.4\% \pm 4.7\%$ *vs* $63.1\% \pm 9.3\%$, $P < 0.01$; in AGS, $3.2\% \pm 0.1\%$ *vs* $4.1\% \pm 1.2\%$, $P > 0.05$, $13.4\% \pm 3.8\%$ *vs* $22.7\% \pm 3.5\%$, $P < 0.05$, $26.6\% \pm 4.1\%$ *vs* $42.5\% \pm 4.8\%$, $P < 0.01$, and $40.9\% \pm 5.9\%$ *vs* $69.8\% \pm 6.5\%$, $P < 0.01$) (Figure 1).

LY294002 inhibited basal and oxaliplatin-induced phosphorylation of Akt and NFκB/DNA binding activities

MKN45 and AGS cells were treated with oxaliplatin (20 µmol/L) and LY294002 (25 µmol/L) used singly or in combination for 24 h. For combined treatment, pretreatment of LY294002 was followed by oxaliplatin. Oxaliplatin induced an increase in the phosphorylation of Akt (Ser⁴⁷³) in MK45 and AGS cells. LY294002 significantly

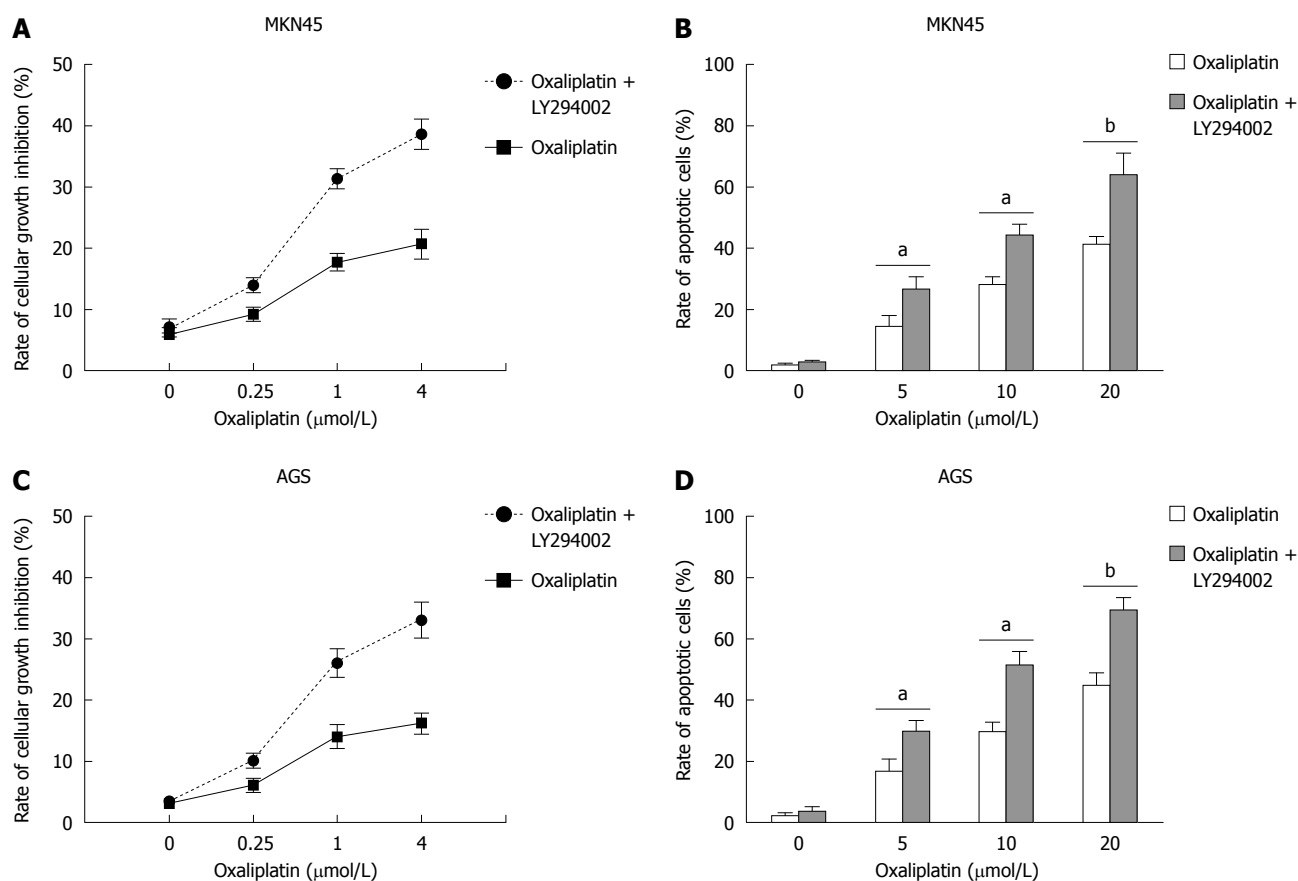

Figure 1 LY294002 increased oxaliplatin-induced cell proliferation and apoptosis in gastric cancer cells. MKN45 and AGS cells were treated with various doses of oxaliplatin (0-20 μmol/L) for 24 h with or without LY294002 pretreatment (25 μmol/L). A, C: Cell growth inhibitory rates were evaluated by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay; B, D: Apoptosis of cells was investigated by flow cytometry. LY294002 significantly increased oxaliplatin-induced growth inhibition and apoptosis. ^a $P < 0.05$, ^b $P < 0.01$ vs oxaliplatin alone.

reduced oxaliplatin-induced phosphorylation of Akt (Ser⁴⁷³) (Figure 2A and B). Oxaliplatin and LY294002 did not modulate the phosphorylation of Akt at Thr308 (data not shown). NFκB activity in MKN45 and AGS cells was examined using EMSA. Oxaliplatin stimulated NFκB/DNA binding activity in MKN45 and AGS cells (Figure 2C and D). When oxaliplatin was combined with LY294002, NFκB/DNA binding activity was decreased.

Effects of oxaliplatin, LY294002, or combination in recruitment of FADD, expression of FasL and c-FLIPs, and activation of caspase-8, Bid and caspase-3

Several molecules of the death receptor pathway were investigated using Western blotting. In MKN45 and AGS cells, oxaliplatin increased FasL expression, recruited FADD, and activated caspase-8, caspase-3, and Bid cleavage (t-Bid formation) (Figure 3). LY294002 significantly promoted the oxaliplatin-induced changes. Oxaliplatin reduced the c-FLIPs, while LY294002 enhanced this effect of oxaliplatin. Oxaliplatin and LY294002 did not modulate the expression of the c-FLIP_L (data not shown).

FasL siRNA attenuated oxaliplatin-, LY294002-, or combination-induced cell apoptosis

To further investigate whether LY294002 promoted oxali-

platin-induced apoptosis through the death receptor pathway, MKN45 and AGS cells transfected with FasL siRNA were treated with oxaliplatin, LY294002, or a combination of both. FasL expression was inhibited by FasL siRNA in MKN45 and AGS cells (Figure 4A). FasL silencing decreased LY294002- (in MKN45, LY294002 *vs* LY294002 + FasL siRNA: $10.5\% \pm 1.3\%$ *vs* $4.1\% \pm 0.6\%$, $P < 0.05$; in AGS, $14.6\% \pm 0.7\%$ *vs* $4.0\% \pm 0.7\%$, $P < 0.05$), oxaliplatin- (in MKN45, oxaliplatin *vs* oxaliplatin + FasL siRNA: $39.4\% \pm 3.6\%$ *vs* $10.7\% \pm 3.9\%$, $P < 0.01$; in AGS, $45.1\% \pm 4.1\%$ *vs* $11.8\% \pm 2.8\%$, $P < 0.01$), or combination- (in MKN45, combination *vs* combination + FasL siRNA: $55.7\% \pm 7.6\%$ *vs* $15.4\% \pm 2.4\%$, $P < 0.01$; in AGS, $63.4\% \pm 5.8\%$ *vs* $18.6\% \pm 4.5\%$, $P < 0.01$) induced cell apoptosis (Figure 4B).

Effects of oxaliplatin, LY294002, or combination on tumor growth and apoptosis in vivo

Four experimental groups were examined: (1) control group; (2) LY294002 group; (3) oxaliplatin group; and (4) combined oxaliplatin and LY294002 therapy group. Tumor growth curves were plotted to compare differences in anti-tumor efficiency in the course of the experiments (Figure 5A). TUNEL assay was performed to detect apoptotic cells in tumor tissue sections (Figure 5B).

Figure 2 LY294002 inhibited basal and oxaliplatin-induced phosphorylation of Akt and nuclear factor κ B/DNA binding activities. MKN45 and AGS cells were incubated with oxaliplatin (20 μ mol/L) or LY294002 (25 μ mol/L) used singly or in combination for 24 h. A, B: Oxaliplatin enhanced the phosphorylation of Akt (Ser⁴⁷³, but not Thr308), while LY294002 inhibited the induction of Akt activity in MKN45 and AGS cells; C, D: Oxaliplatin increased nuclear factor κ B (NF κ B)/DNA binding activity, while LY294002 inhibited the induction of NF κ B/DNA binding activity.

Figure 3 Effects of oxaliplatin, LY294002, or combination on recruitment of Fas-associated death domain protein, expression of Fas ligand and short form of cellular caspase-8/FLICE-inhibitory protein, and activation of caspase-8, Bid, and caspase-3. A-D: In MKN45 and AGS cells, oxaliplatin led to increased Fas ligand (FasL) expression, Fas-associated death domain protein (FADD) recruitment, caspase-8 and caspase-3 activation, and Bid cleavage (t-Bid formation). LY294002 significantly promoted these oxaliplatin-induced changes. Oxaliplatin reduced short form of cellular caspase-8/FLICE-inhibitory protein (c-FLIP_s) expression, while LY294002 enhanced this effect of oxaliplatin. Oxaliplatin and LY294002 did not modulate long form of cellular caspase-8/FLICE-inhibitory protein expression (data not shown). IP: Immunoprecipitation; WB: Western blotting.

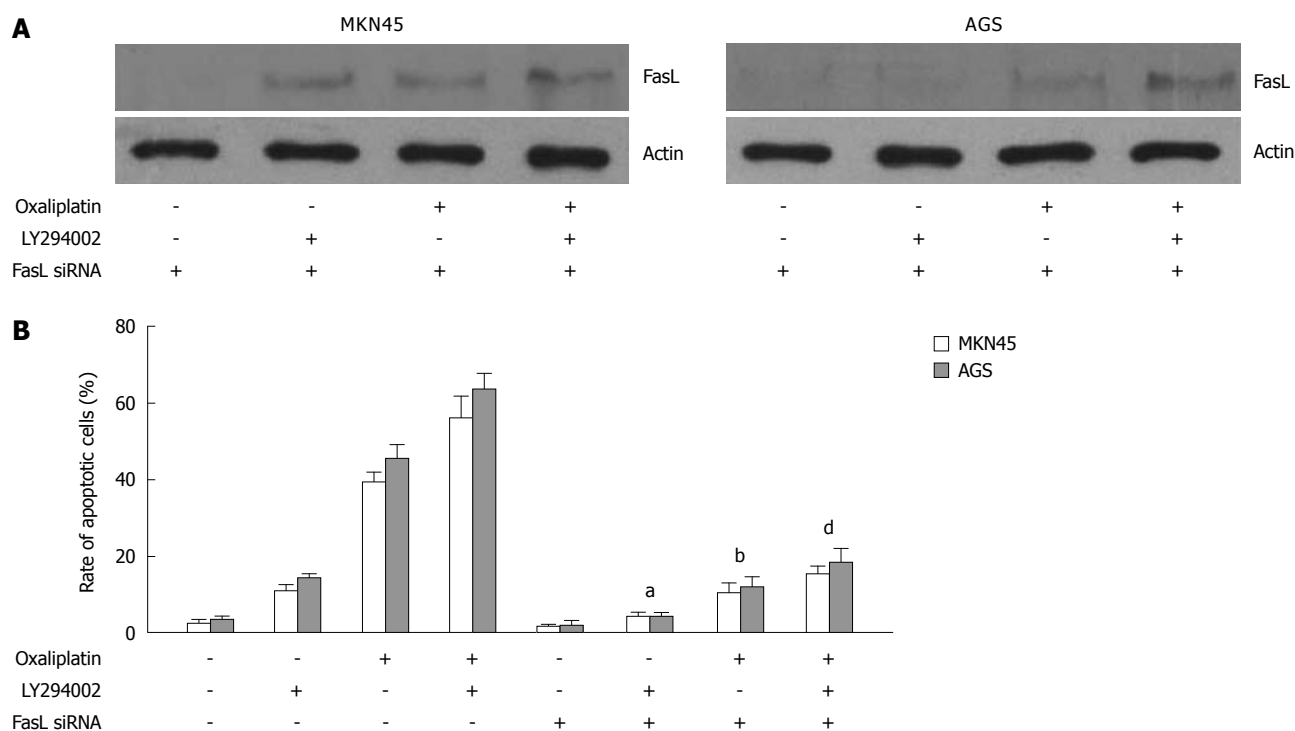

Figure 4 Fas ligand siRNA attenuated oxaliplatin-, LY294002-, or combination-induced cell apoptosis. A: Fas ligand (FasL) expression was inhibited by FasL siRNA in MKN45 and AGS cells; B: FasL silencing decreased oxaliplatin-, LY294002-, or combination-induced cell apoptosis. ^a $P < 0.05$ vs LY294002 treatment; ^b $P < 0.01$ vs oxaliplatin treatment; ^d $P < 0.01$ vs combination of oxaliplatin and LY294002.

At the end of 6 wk, tumor volume in combined oxaliplatin and LY294002 therapy group was greatly reduced compared with oxaliplatin group ($763 \pm 155 \text{ mm}^3$ vs $1789 \pm 233 \text{ mm}^3$, $P < 0.01$). Oxaliplatin combined with LY294002 significantly enhanced cell death in the tumor mass *via* apoptosis when compared with oxaliplatin treatment alone.

Immunohistochemical analysis was performed to evaluate the expression of death receptor pathway molecules (Figure 5C). LY294002 inhibited oxaliplatin-induced activation of Akt and NF κ B, and increased oxaliplatin-induced expression of FasL, inhibition of c-FLIPs, and activation of caspase-8, Bid and caspase-3.

DISCUSSION

Oxaliplatin is a diaminocyclohexane platinum anti-cancer agent. Although oxaliplatin produces DNA crosslinking similar to those of cisplatin^[17], cisplatin-resistant cells generally remain sensitive to oxaliplatin^[18]. Furthermore, oxaliplatin induces fewer complications compared with other platinum derivatives such as cisplatin and carboplatin that induce nephrotoxicity^[19] and myelosuppression^[20], respectively. Recently, oxaliplatin was shown to be effective in the treatment of advanced gastric cancer when combined with 5-fluorouracil and leucovorin, and has also been used in adjuvant chemotherapy for gastric cancer. However, despite the improvement in the efficacy of chemotherapeutic drugs used in the treatment of metastatic gastric cancer, the response rate and relative 5-year survival rate in the advanced disease remain low^[21].

The PI3K/Akt signaling pathway plays a critical role in cell cycling, cell growth, protein translation, and suppression of apoptosis by Akt-mediated phosphorylation^[22-24], and also promotes tumor growth, survival, and aggressiveness^[25,26]. In gastric cancer, several studies have reported that the majority of patients exhibit increased expression and activation of Akt^[11,27]. Over expression of phosphorylated Akt was associated with poor overall survival, disease-free survival, and high tumor recurrence in gastric cancer patients^[28]. In gastric carcinoma cell lines, phosphorylation of Akt is required for cell growth and survival^[28]. Thus, blocking the constitutively active PI3K/Akt signaling pathway may provide a novel strategy for targeted cancer therapy.

In this study, the specific PI3K inhibitor LY294002 promoted oxaliplatin-induced growth inhibition and cell apoptosis in MKN45 and AGS cells, suggesting that LY294002 enhanced the chemotherapeutic sensitivity to oxaliplatin in gastric cancer cells. Previous *in vitro* and *in vivo* studies demonstrated that activation of the PI3K pathway was associated with the therapeutic efficacy of several chemotherapeutic agents including 5-FU, paclitaxel, cisplatin, irinotecan, and doxorubicin^[29-32], while activation of the PI3K pathway induced chemoresistance in cancer cells. To explore the possible mechanisms of LY294002 in sensitizing gastric cancer cells to oxaliplatin, we examined the phosphorylation levels of Akt in oxaliplatin treated MKN45 and AGS cells. We found increased expression of phosphorylated Akt at Ser⁴⁷³ after treatment with oxaliplatin in MKN45 and AGS cells, which is in agreement with a previous study in cholangiocarcinoma cells^[33]. LY294002

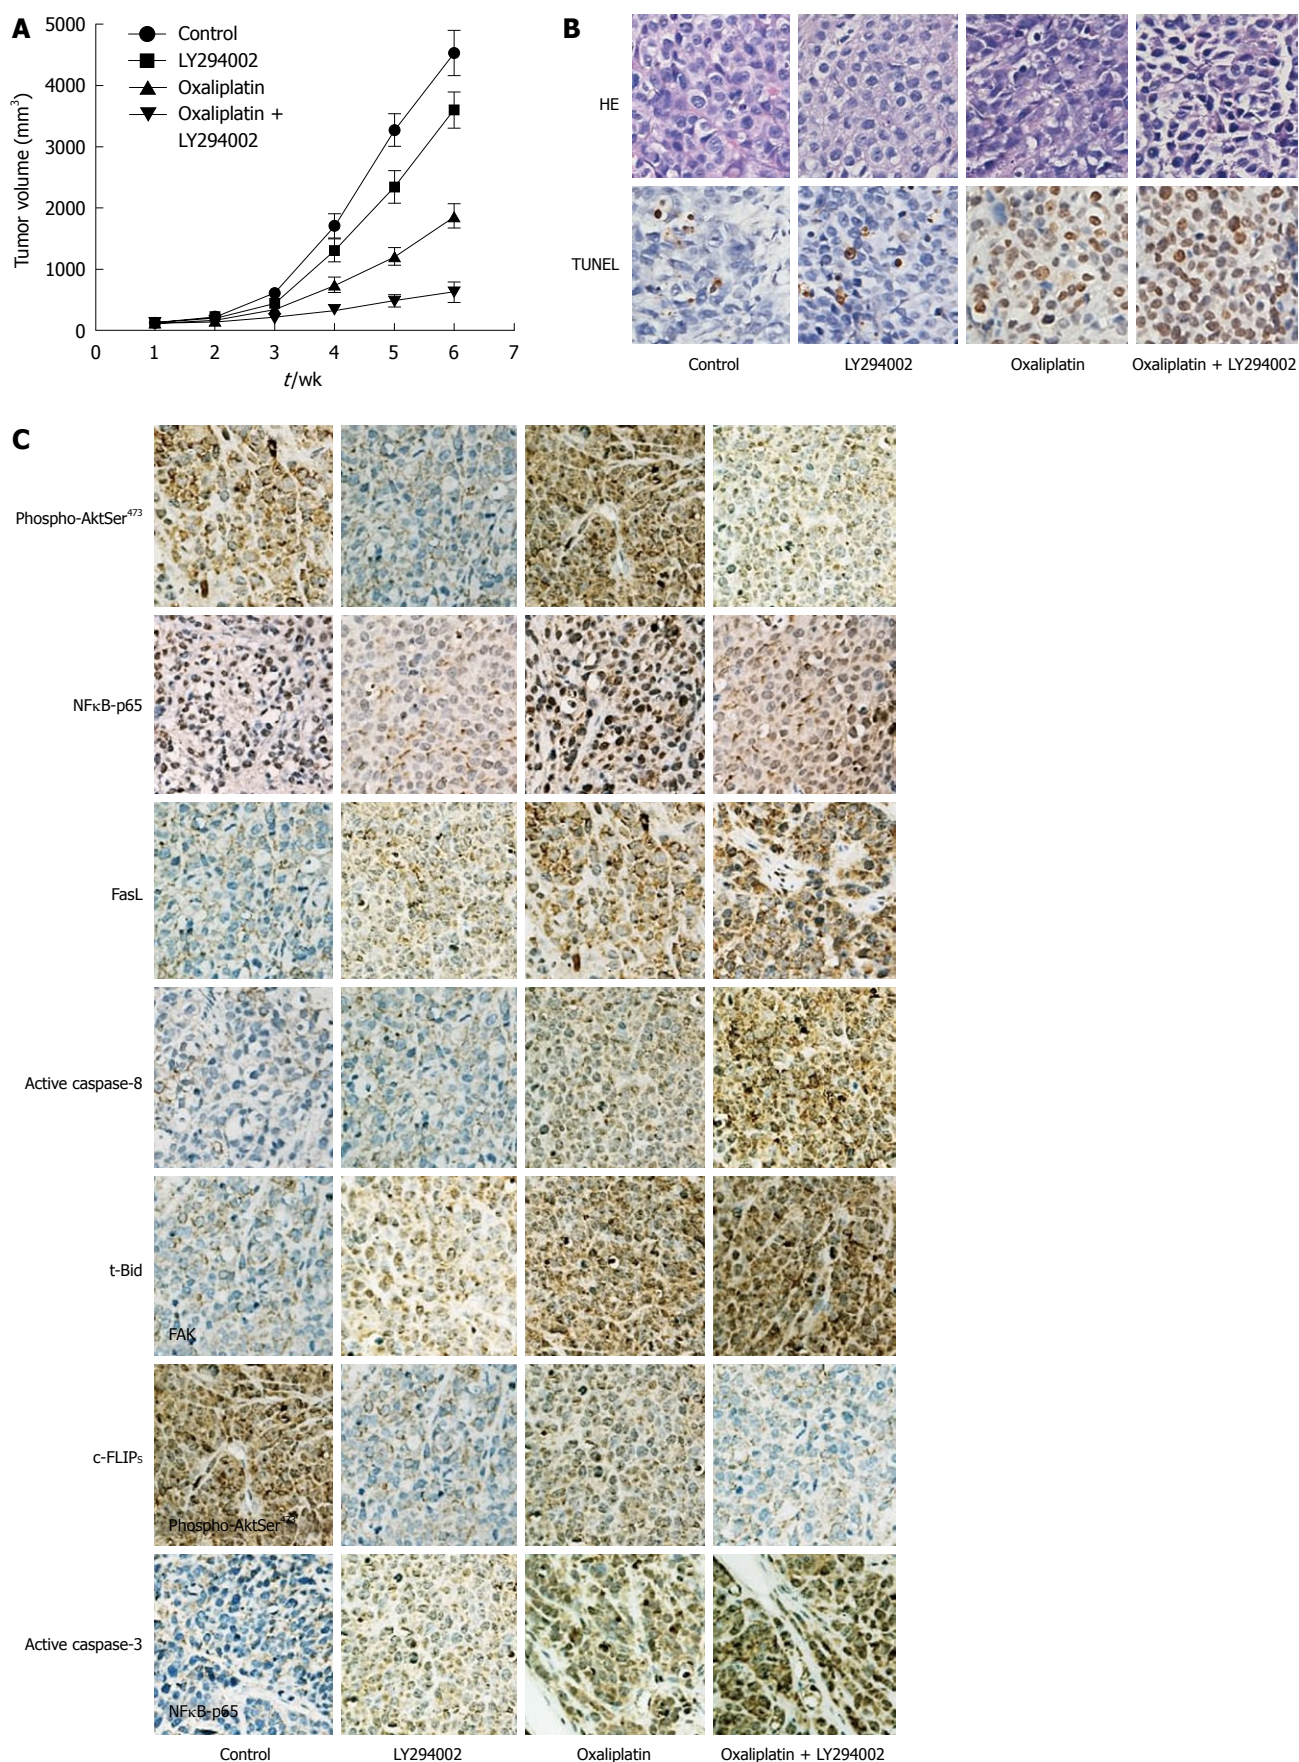

Figure 5 Effects of oxaliplatin, LY294002, or combination on *in vivo* tumor growth and apoptosis. A: Tumor volumes of nude mice in each group are presented. Each time point represents the mean tumor volume for each group; B: Detection of apoptotic cells in tumor tissue was performed by transferase-mediated dUTP nick end labeling (TUNEL) assay; C: The expression of phospho-AktSer⁴⁷³, nuclear factor κ B (NF κ B)-p65, Fas ligand (FasL), short form of cellular caspase-8/FLICE-inhibitory protein (c-FLIPs), Bid, caspase-8, and caspase-3 was investigated by immunohistochemical analysis.

blocked basal and oxaliplatin-induced phosphorylation of Akt, and resulted in an increased apoptotic rate compared with oxaliplatin alone, suggesting that Akt phosphorylation might regulate oxaliplatin resistance in gastric cancer cells. The significant increase in oxaliplatin-induced cytotoxicity in gastric cancer pretreated with LY294002 indicates that the resistance of gastric cancer cells to chemotherapeutic agents can be modulated.

NF κ B plays an important role in suppression of apoptosis. Akt phosphorylates I κ B (NF κ B inhibitor) kinases, leading to degradation of I κ B, as well as NF κ B activation^[34]. Although many studies strongly support the anti-apoptotic role of NF κ B, there are some evidences that NF κ B can induce apoptosis^[35-37]. In the present study, oxaliplatin enhanced NF κ B/DNA binding activity, while LY294002 blocked anticancer drug-induced activation of NF κ B. These data indicate that activation of Akt/NF κ B in gastric cancer cells may be a key mechanism in inhibiting oxaliplatin-induced apoptosis. It is possible that additional components of the PI3K/Akt pathway may be involved in the chemoresistance of gastric cancer cells.

To further define the role of LY294002 in the regulation of oxaliplatin-induced apoptosis, we examined expression of molecular markers of the death receptor-signaling pathway. LY294002 dramatically increased oxaliplatin-induced FasL expression, FADD redistribution into membrane lipid rafts, caspase-8 and caspase-3 activation, and Bid cleavage in MKN45 and AGS cells. Next, we down-regulated FasL using FasL siRNA in LY294002-, oxaliplatin-, or combination-treated MKN45 and AGS cells. Oxaliplatin, LY294002, or combination treatment-induced apoptosis was attenuated by FasL silencing, suggesting that the death receptor pathway might be involved in the cell apoptosis induced by oxaliplatin or LY294002 in gastric cancer cells. However, the precise mechanism whereby oxaliplatin or LY294002 induces FasL expression remains unknown.

Apoptosis mediated by Fas is regulated by c-FLIP expression^[38]. There are two isoforms of c-FLIP: the full-length c-FLIP_L and c-FLIP_S^[39,40]. c-FLIP_S is considered solely anti-apoptotic and confers resistance to receptor-mediated apoptosis by blocking proteolytic activation of caspase-8 at the Fas DISC, while c-FLIP_L exhibits dual roles^[41,42]. Additionally, c-FLIP_S and c-FLIP_L are differently regulated^[43-45]. The PI3K pathway is an important regulator of c-FLIP_S, but not c-FLIP_L, expression in human gastric cancer cells^[45]. In this study, oxaliplatin-induced apoptotic death was accompanied by suppression of c-FLIP_S in MKN45 and AGS cells. Compared with oxaliplatin alone, combination of oxaliplatin and LY294002 produced enhanced down-regulation of c-FLIP_S. c-FLIP_L expression was not significantly changed by treatment with LY294002 or oxaliplatin. These findings indicate that the anti-apoptotic function of c-FLIP_S may be more potent than that of c-FLIP_L in oxaliplatin-induced apoptosis, and that Akt is involved in regulation of c-FLIP_S in human gastric cancer cells.

We also examined the effects of the combined treatment of oxaliplatin and LY294002 in an *in vivo* xeno-

graft model. LY294002 significantly increased oxaliplatin-induced tumor growth and cell death in the tumor mass *via* apoptosis. Moreover, altered expression levels of FasL, Bid, caspase-8, caspase-3, and c-FLIP_S were found in the tumor xenograft. These data suggest that combination of oxaliplatin and LY294002 elicited a strong antitumor effect in gastric cancer *in vivo*, and that the death receptor pathway might mediate the additive cytotoxicity of oxaliplatin and LY294002.

In summary, we present a novel therapeutic approach for treatment of gastric cancer using the combined oxaliplatin and the PI3K/Akt inhibitor LY294002, that may be mediated, at least in part, by modification of the death receptor pathway.

COMMENTS

Background

Gastric cancer remains a leading cause of cancer death worldwide. Besides surgical resection, chemotherapy is important treatment for gastric cancers. Despite the improvement in the efficacy of chemotherapeutic drugs, the response rates and the median survival remain low.

Research frontiers

Traditional cancer therapy predominantly utilizes cytotoxic chemotherapeutic agents. The cytotoxic events are affected mainly through disruption of various aspects of DNA synthesis and repair or disturbance of mitosis, processes which are common to all dividing cells. For this reason, most chemotherapeutic agents are often accompanied with substantial adverse effects. Target-protein-based cancer therapy has become available in clinical practice. Phosphatidylinositol 3-kinase (PI3K) inhibitors have potential to target specific pathways involved in tumor cell growth.

Innovations and breakthroughs

The PI3K/Akt pathway has been shown to be involved in the chemoresistance of gastric cancer. In both *in vitro* and *in vivo* studies, the targeted inhibition of PI3K/Akt results in increased oxaliplatin-induced apoptosis and inhibition of cellular proliferation of gastric cancer. Furthermore, the activation of the death receptor pathway may be an important mechanism by which PI3K/Akt inhibition is involved in oxaliplatin-induced apoptosis.

Applications

By understanding how LY294002 enhances the therapeutic effect of oxaliplatin in gastric cancer cells, this study provides information about the potential therapeutic intervention in patients with gastric adenocarcinoma.

Terminology

Oxaliplatin: A third-generation platinum coordination complex of the 1,2-diaminocyclohexane families, generates covalent adducts between platinum and two adjacent guanines or guanine and adenine in cell DNA. LY294002: 2-(4-morpholinyl)-8-phenyl-4H-1-benzopyran-4-one, a specific inhibitor of PI3K.

Peer review

This is a well-written report on the synergistic anti-tumor effects of the combined treatment with oxaliplatin and LY294002 in gastric cancer cells. The data and results are straight-forward and clearly support the conclusion that targeting PI3K/Akt results in increased oxaliplatin-induced apoptosis and inhibition of cellular proliferation of gastric cancer.

Abstract

AIM: To investigate the effects of percutaneous endoscopic gastrostomy (PEG) feeding on gastro-oesophageal reflux (GOR) in a group of these children using combined intraluminal pH and multiple intraluminal impedance (pH/MII).

METHODS: Ten neurologically impaired children underwent 12 h combined pH/MII procedures at least 1 d before and at least 12 d after PEG placement.

METHODS: Prior to PEG placement (pre-PEG) a total of 183 GOR episodes were detected, 156 (85.2%) were non-acidic. After PEG placement (post-PEG) a total of 355 episodes were detected, 182 (51.3%) were non-acidic. The total number of distal acid reflux events statistically significantly increased post-PEG placement (pre-PEG total 27, post-PEG total 173, $P = 0.028$) and the

mean distal pH decreased by 1.1 units. The distal reflux index therefore also significantly increased post-PEG [pre-PEG 0.25 (0-2), post-PEG 2.95 (0-40)]. Average proximal pH was lower post-PEG but the within subject difference was not statistically significant ($P = 0.058$). Median number of non-acid GOR, average reflux height, total acid clearance time and total bolus clearance time were all lower pre-PEG, but not statistically significant.

CONCLUSION: PEG placement increases GOR episodes in neurologically impaired children.

INTRODUCTION

The enteric nervous system contains more neurones than the spinal cord^[1]. Insults to the central nervous system therefore may result in dysfunction of the gastro-intes-

tinal tract such as oro-motor dysfunction, rumination, gastro-oesophageal reflux (GOR), delayed gastric emptying and constipation. All these problems may contribute to feeding difficulties and ultimately sub-optimal nutrition in neurologically impaired children. In children with severe oro-motor dysfunction calorie supplementation of oral feeds is often not successful and adjunctive methods are required in order to achieve adequate nutrient intake. The long-term use of a fine bore nasogastric tube (NGT), though most widely used, has several limitations. These include nasal discomfort, laryngeal irritation and penetration, recurrent pulmonary aspiration, tube blockage, tube displacement, oral aversion and possibly impedance of the progressive maturation of the oral feeding pattern from sucking to chewing^[2]. Percutaneous endoscopic gastrostomy (PEG) technique has become increasingly popular for the provision of nutrition in disabled children^[3] and there are a variety of commercially available devices of variable lengths and calibres that are suitable even in young children^[4].

Several studies have demonstrated the clinical advantages to patients fed *via* PEG when compared with other feeding techniques^[5,6]. Randomised comparisons of feeding in patients with dysphagia secondary to neurological impairment, demonstrated that PEG-fed children achieved better weight gain than those fed *via* NGT^[7,8]. Post-operative follow up however, is essential to monitor weight gain and the development of GOR^[9]. Indeed nutritional rehabilitation using a feeding gastrostomy of disabled children is associated with increased mortality and morbidity secondary to GOR^[10].

Oesophageal pH monitoring is regarded as the investigation of first choice in children with unusual presentations of GOR disease (GORD), such as apnoea and recurrent respiratory disease^[11-14]. However pH measurements cannot detect GOR in the pH range 4.0-7.0 due to the proximity to the physiological oesophageal pH^[15-17] and thus misses many episodes of postprandial reflux in young infants and intragastrically fed children due to neutralisation of gastric contents by milk formula for 1-2 h after a meal. Therefore the term acid (pH < 4) and/or non-acid (pH ≥ 4) GOR should be preferred over the term GOR. Because GOR-associated symptoms are not necessarily confined to acid GOR, a pH-independent technique, known as multiple intraluminal impedance (MII) has been established^[18-21], which detects a typical decrease of electrical impedance (resistance) during the passage of a bolus through a measuring segment. The use of multiple segments along a catheter allows the analysis of movement, direction and height attained by the bolus, making it possible to distinguish antegrade and retrograde bolus movement. Simultaneous use of integrated pH sensors can help determine the pH of the reflux episodes as well.

The aim of this study was to measure GOR in neurologically impaired children before and after insertion of a PEG using the combined pH/MI procedure.

MATERIALS AND METHODS

The study included 10 neurologically impaired patients (5 male, 5 female), nine being diagnosed with cerebral palsy and one with Down's syndrome. All had severe feeding difficulties requiring long-term nutritional support and were admitted to the Centre for Paediatric Gastroenterology, Royal Free Hospital, London, UK for insertion of a PEG. Patients underwent a daytime 12-h impedance procedure for detection of acid and non-acid GOR before (Pre-PEG) and after (Post-PEG) PEG placement.

Pre- and Post-PEG study

Patients were of median age 4.9 years (range 0.5-16.8 years). Impedance procedure took place 1-79 d (median 1.5 d) prior to PEG placement. All patients were bolus fed of which four patients were fed orally and six were fed *via* NGT during the study.

Patients were of median age 5.3 years (range 0.8-17 years). The impedance procedure took place 12-384 d (median 55 d) after PEG placement, and this represented a pragmatic compromise dependent on parental instruction. All patients were receiving bolus feeds *via* their PEG during the study.

Patients were on the same medication during the pre- and post-PEG impedance procedure; eight were not on any medication influencing gastric pH or motility, one was on omeprazole and cisapride, and one was on ranitidine and Gaviscon®. There was no change in the parent/carer subjective impression of potential reflux-related events or symptoms and no change in the frequency of diagnosis of chest aspiration or infection.

The study protocol was approved by the Royal Free NHS Trust Ethical Review Committee. On the initial visit to the clinic informed consent was obtained from the parent or guardian.

An MII catheter (outer diameter 2 mm) with two pH-sensitive antimony electrodes and seven impedance electrodes (PRZ-062B00013, Sandhill Scientific, Inc., Colorado, USA) was used. Changes in intra-oesophageal impedance were measured along this catheter. The impedance was measured between seven adjacent electrodes (15 mm apart), thus enabling readings to be obtained from 6 impedance channels (6 adjacent electrode pairings). The catheter was passed transnasally and positioned by a height-derived formula^[22] with total measuring segments reaching from approximately 1.5 cm above the lower oesophageal sphincter (channel 6) to the upper oesophagus (channel 1). The pH sensors were situated at the level of channel 6, approximately 2 cm above the gastro-oesophageal junction, and at the level of channel 1. The catheter was connected to a Windows 98 personal computer, *via* voltage transducers (Z-Box) that continuously recorded impedance and pH events (Sandhill Scientific, Inc). Impedance and pH signals were sampled at a rate of 50 Hz per channel, as compared to 0.25 Hz in conventional pH-metry. Impedance and pH recordings were made for 12 h.

All impedance recordings were visually analysed for

the typical MII pattern of GOR. This was defined as any retrograde-passing bolus detected by channel 4 with a duration of more than 5 s. The reflux index was calculated for both proximal and distal pH sensors by (percentage of time < pH 4.0/total study duration). The clearance time for a liquid bolus may differ from the time taken for the acid environment to neutralise at the pH sensors. Thus the height reached by each bolus, as well as the volume- and acidity-clearance, was registered for each MII-defined GOR episode. Mean values for all episodes were calculated for each patient. As data from children ($n = 10$) in pre- and post-PEG groups was not normally distributed, medians are reported for between-group comparisons, and non-parametric tests (Wilcoxon Rank Sum) used in statistical analyses. *A priori* variables selected for comparison were: reflux index (proximal and distal pH), total reflux events, acid-reflux events, non-acid reflux events, bolus height, bolus clearance time and acid clearance time.

RESULTS

Prior to PEG placement a total of 183 reflux events were detected by the combined pH/II procedure. 156 (85.2%) were non-acidic and 27 (14.8%) were acidic. Post PEG placement a total of 355 reflux events were detected, of which 182 (51.3%) were non acid and 173 (48.7%) were acidic.

The total number of reflux events and acid reflux events were significantly lower before PEG placement ($P = 0.047$ and $P = 0.028$, respectively) (Table 1). Individual measurements are detailed in Tables 2 and 3. The average minimum distal pH was lower by 1.1 pH units post-PEG placement ($P = 0.05$) and the distal reflux index was significantly higher, but still within normal limits after the procedure [$P = 0.032$, reflux index (RI) 0.25% pre-PEG and 2.95% post-PEG].

The percentage of the GOR events reaching the uppermost impedance channel (channel 1) i.e. the pharyngeal space, pre-PEG placement was 56%. Post-procedure this increased significantly to 82%.

The median number of non-acid reflux events per hour, average reflux height, total distal and proximal acid clearance time and total bolus clearance time were all lower pre-PEG placement, but were not significantly different.

The average minimum proximal pH was also lower post-PEG placement but again, this was not statistically significant.

Nutritional improvement occurred between the pre- and post-PEG insertion with a median weight gain of 2.53 kg (range 0.8–7.24 kg).

Table 1 summarises the main results before and after PEG placement.

DISCUSSION

We describe the effect of PEG placement on GOR events

Table 1 Summary of pH and multiple intraluminal impedance results before and after percutaneous endoscopic gastrostomy placement

Parameter	Pre-PEG	Post-PEG	P-value
Total GOR events	183	355	
Median	17.50	39.50	0.047
Range	2-54	3-63	
Total number of GOR events reaching uppermost channel 1	103	290	
Median	9.00	27.00	0.022
Range	1-29	1-55	
Total non-acid GOR events	156	182	
Median	13.00	18.00	0.610
Range	2-49	3-38	
Total acid GOR events	27	173	
Median	1.00	13.00	0.028

GOR: Gastro-oesophageal reflux; PEG: Percutaneous endoscopic gastrostomy.

in neurologically impaired children with feeding difficulties by using a combined pH and intraluminal impedance measurement.

The use of combined pH and impedance allows detection of both acid ($\text{pH} < 4$) and non-acid ($\text{pH} \geq 4$) GOR episodes, as well as the height of the refluxate and the total acid clearance time. In our study 183 reflux events were detected by MII pre-PEG insertion, of which 85.2% were non-acid and would therefore have been undetected using the “gold standard” pH-metry. The total number of GOR episodes more than doubled after PEG insertion. Furthermore, the average distal oesophageal pH was significantly lower after PEG placement. This is clinically relevant as we have shown that an acid reflux event takes longer to clear than a non-acid bolus. Skopnik *et al*^[17] in a study of 17 infants using MII, detected that 90% of GOR episodes were non-acid and therefore undetectable by conventional pH-metry.

Table 2 Individual results of pH and multiple intraluminal impedance results before percutaneous endoscopic gastrostomy placement

Patient	Total GOR	Total GOR/h	Total non-acid GOR	Total non-acid GOR/h	Total acid GOR	Total acid GOR/h	Prox RI (%)	Dist RI (%)	Reflux events reaching ch 1
1	24	2.00	24	2.00	0	0.00	0.0	0.0	18
2	54	4.50	49	4.08	5	0.42	0.2	0.4	29
3	18	1.50	13	1.08	5	0.42	0.1	2.2	6
4	7	0.58	6	0.50	1	0.08	0.3	0.1	6
5	23	1.92	22	1.83	1	0.08	0.2	0.5	14
6	3	0.25	2	0.17	1	0.08	0.0	0.1	1
7	19	1.58	19	1.58	0	0.00	0.0	0.0	9

10	21	1.8	14	1.17	7	0.58	1.5	2.7	20

"Ch 1" refers to the most proximal impedance measurement and was located in the pharynx or most proximal 3 cm of oesophagus. GOR: Gastro-oesophageal reflux; RI: Reflux index.

Likewise, Wenzl *et al*^[23] showed in 50 patients that only 14.9% of MII-determined reflux episodes were acidic, whilst non-acidic reflux events have clearly been temporally associated with unexplained respiratory phenomena^[24].

The diagnosis of GOR is more difficult in children with neurological impairment as the characteristic features may be absent. Although GOR may cause pain manifesting as restlessness, abnormal movements or food refusal, these symptoms may be subtle and frequently go undetected in the disabled child. Any operative procedure is a major undertaking with potential complications, particularly in an undernourished child who has recurrent respiratory infections and may have postural deformities. Therefore accurate assessment of GORD and careful patient selection is even more important in these children before PEG insertion, particularly as patients with moderate to severe GOR are already considered unsuitable for the procedure. For this reason, operative gastrostomies are frequently performed in conjunction with a fundoplication in those children with refractory or severe GOR. It has been previously reported^[24] that neurologically impaired children may have a reduction in the lower oesophageal sphincter (LOS) pressure, which may predispose not only to GOR, but

also to recurrent respiratory infections. This concept was supported by Wenzl *et al*^[25] who, in a study evaluating the link between reflux and respiratory phenomena in 22 infants, reported 78% of the reflux episodes causing apnoea to be non-acidic. Changes in gastric motility and lower oesophageal sphincter pressure following gastrostomy tube placement may also account for the observation that clinically significant GOR is detected in 75% of children after insertion of a gastrostomy tube^[9]. Therefore the increase in GOR events entering the pharyngeal space from 56% to 82% after the placement of a PEG may have significant clinical implications, suggesting an increased risk of aspiration pneumonia in this vulnerable cohort of children.

None of the patients selected for this study had an abnormal reflux index prior to PEG-placement. Although the post-procedure median reflux index still remained < 4%, the more than 10 fold increase in RI following the procedure suggests that less careful selection of patients for such an intervention may lead to a profound deterioration in GOR. In fact three patients had a RI > 4% post procedure. The detected increase in distal reflux index and total number of acid GOR events, along with the increased height of refluxate is likely to be the result of disordered gastric motility, and hence the delayed

emptying, that arises from the anchoring of the gastric wall to the abdominal wall by the PEG.

Mollitt *et al.*^[9] observed that, while a gastrostomy tube can greatly improve nutritional status and facilitate care of the neurologically disabled child, postoperative follow-up for the development of GOR was essential. Rehabilitation of nutrition in children with neurological impairment can be associated with an increase in mortality and morbidity secondary to GOR. MII has potentially significant implications in the diagnosis, patient selection and follow-up of neurologically impaired, gastrostomy-fed children who have an increase risk of developing GOR. Indeed, for the first time we are now able to accurately and objectively undertake a physiologically appropriate assessment of GOR which is of particular clinical significance in children with neurological impairment. A more accurate assessment of the pathophysiology of GORD and disturbed gastro-oesophageal motility may allow us to study the effects of treatment modalities such as feed thickeners, proton pump inhibitors and prokinetic agents, which may subsequently improve the efficacy of our therapeutic approach in this complex subgroup of children.

The placement of a PEG in neurologically compromised children needs careful consideration in view of the presented findings. The number and severity of GOR events are likely to increase after the procedure and may lead to significant morbidity in this group of children.

COMMENTS

Background

Percutaneous endoscopic gastrostomy (PEG) technique or "non surgical opening in the stomach" has become increasingly popular for the provision of nutrition in disabled children particularly as several studies have demonstrated that PEG-fed children achieved better weight gain than those fed via a tube in their stomach via the nose (Nasogastric tubes). However, nutritional rehabilitation using a feeding gastrostomy of disabled children is associated with increased mortality and morbidity secondary to gastro-oesophageal reflux (GOR). So far, pH studies were helpful in diagnosing "acid reflux" in these children. However pH measurements cannot detect non acid reflux GOR due to the proximity to the physiological oesophageal pH and hence a pH-independent technique, known as multiple intraluminal impedance (MII) has been established.

Research frontiers

The aim of this study was to measure GOR in neurologically impaired children before and after insertion of a PEG using the combined pH/MI procedure.

Innovations and breakthroughs

For the first time the authors were now able to accurately and objectively undertake a physiologically appropriate assessment of acid and non-acid GOR.

Applications

Using combined pH/MI testing the authors could undertake a physiologically appropriate assessment of gastroesophageal reflux which is of particular clinical significance in children with neurological impairment

Terminology

MI is a technique which detects a typical decrease of electrical impedance (resistance) during the passage of a bolus through a measuring segment. The use of multiple segments along a catheter allows the analysis of movement, direction and height attained of the bolus, making it possible to distinguish antegrade and retrograde bolus movement.

Peer review

This is a nice contribution. Subjects were bolus fed during the day of their pH/MI. It is well written paper, with a clear message that PEG feeds in this paediatric subpopulation aggravate or promote reflux.

1801282) and C1431T (rs 3856806); pregnane X receptor (PXR) (NR1I2) *PXR* A-24381C (rs1523127), C8055T (2276707), and A7635G (rs 6785049); and liver X receptor (LXR) (NR1H2) *LXR* T-rs1405655-C and T-rs2695121-C were assessed in a Danish case-control study of 327 Crohn's disease patients, 495 ulcerative colitis (UC) patients, and 779 healthy controls. Odds ratio (OR) and 95% CI were estimated by logistic regression models.

RESULTS: The *PXR* A7635G variant, the *PPAR γ* Pro12Ala and *LXR* T-rs2695121-C homozygous variant genotypes were associated with risk of UC (OR: 1.31, 95% CI: 1.03-1.66, $P = 0.03$, OR: 2.30, 95% CI: 1.04-5.08, $P = 0.04$, and OR: 1.41, 95% CI: 1.00-1.98, $P = 0.05$, respectively) compared to the corresponding homozygous wild-type genotypes. Among never smokers, *PXR* A7635G and the *LXR* T-rs1405655-C and T-rs2695121-C variant genotypes were associated with risk of IBD (OR: 1.41, 95% CI: 1.05-1.91, $P = 0.02$, OR: 1.63, 95% CI: 1.21-2.20, $P = 0.001$, and OR: 2.02, 95% CI: 1.36-2.99, $P = 0.0005$, respectively) compared to the respective homozygous variant genotypes. *PXR* A7635G (rs6785049) variant genotype was associated with a higher risk of UC diagnosis before the age of 40 years and with a higher risk of extensive disease (OR: 1.34, 95% CI: 1.03-1.75 and OR: 2.49, 95% CI: 1.24-5.03, respectively).

CONCLUSION: Common *PXR* and *LXR* polymorphisms may contribute to risk of IBD, especially among never smokers.

INTRODUCTION

Chronic inflammatory bowel diseases (IBDs), ulcerative colitis (UC), and Crohn's disease (CD) are complex diseases that result from the interaction of numerous genetic and environmental factors^[1,2]. Recent studies have increased dramatically the number of genes known to be involved in IBD^[3-7]. However, the contribution of *NOD2* gene polymorphisms to IBD etiology in populations of Northern Europe is relatively small^[8-10], which has heightened interest in resolving the genetic determinants of IBD in these countries.

The rising incidence of IBD in the West suggests that environmental factors play a major role in its pathogenesis. The intestinal lumen contains a vast array of different substances that may interact with the host, such as dietary factors, microbial components, and environmental pollutants. Many of these stimuli interact with the transcription factor nuclear factor (NF)- κ B *via* activation of Toll-like receptors (TLRs) such as TLR4^[11,12]. Nuclear receptors are intracellular transcription factors that are activated by ligands^[13], which constitute a link between environmental factors and the regulation of many cellular processes, including inflammation^[14-16]. Thus, genetic variation in certain transcription factors may modify the regulation of relevant environmental factors and the associated risk of IBD.

Activation of NF- κ B leads to the induction of pro-inflammatory signal cascades^[13,17] and the resolution of intestinal inflammation^[18-20]. Studies on animal models of colitis^[21,22] and IBD patients^[23,24] suggest that impaired NF- κ B function leads to IBD. A polymorphism that involves deletion of four nucleotides in the NF- κ B promoter region, named -94ATTG ins/del, has been associated with attenuated promoter activity in luciferase reporter studies^[25]. The variant allele has been investigated as an IBD risk gene, but the results of these studies have been inconsistent^[24-31].

Activation of the nuclear receptors peroxisome proliferator-activated receptor (PPAR) γ , pregnane X receptor (PXR), and liver X receptor (LXR) leads to transcriptional regulation of pro-inflammatory target genes^[14,32,33] and inhibition of NF- κ B activity^[15,16,34,35], which results in a decrease in inflammation.

Studies of animal colitis models^[36-38] and IBD patients^[39] have suggested that impaired PPAR γ expression may confer IBD. The PPAR γ Pro12Ala variant allele is in tight linkage with the PPAR γ C1431T variant allele^[40], and the Pro to Ala substitution results in decreased transcriptional activation of target genes^[41]. Studies on the associa-

tion of the PPAR γ C1431T and Pro12Ala polymorphisms with a risk for IBD have demonstrated varying results^[42-44].

Loss of PXR function has been associated with intestinal inflammation in animal studies^[15], and low levels of PXR expression have been found in the intestine of UC patients^[45]. The PXR A7635G (rs6785049) homozygous variant genotypes and PXR C8055T (rs2276707) variant genotypes have been associated with a pronounced induction of a PXR target gene, *CYP3A4*, after treatment with rifampin^[46]. However, studies of PXR polymorphisms in relation to the risk for IBD have been inconsistent^[47-50].

Loss of LXR function compromised innate immunity in an animal model, which was attenuated after LXR administration^[14]. The LXR tag polymorphisms in intron 7 rs1405655 and intron 2 rs2695121 have been previously investigated as candidate gene targets involved in Alzheimer's disease^[51-53].

Tobacco smoke is a source of many exogenous compounds and induces inflammation^[54]. Moreover, smoking differentially affects the risk of CD and UC^[55], and the underlying mechanisms behind these effects are poorly understood^[56].

Accordingly, altered responses of NF- κ B, PPAR γ , PXR, and LXR to environmental pathogens may be involved in susceptibility to IBD. Hence, genetic variations in the transcription factors may modify the inflammatory response to environmental stimuli and affect the risk for IBD.

In the present study, we determined the allele and haplotype frequencies of polymorphisms in the genes that encode the transcription factors NF- κ B (*NFKB1*) -94ins/del (rs28362491); PPAR γ (*PPARG*) Pro12Ala (rs 1801282) and C1431T (rs 3856806); PXR (*NR1I2*) A-24381C (rs1523127), C8055T (rs2276707-T), and A7635G (rs 6785049); and LXR β (*NR1H2*) T-rs1405655-C and T-rs2695121-C. These polymorphisms were investigated together with the smoking status in a Danish cohort of 327 patients with CD, 495 patients with UC, and 779 healthy controls.

MATERIALS AND METHODS

Ethics

All subjects received written and oral information and provided written informed consent. The study was performed in accordance with the Declaration of Helsinki and was approved by the local Scientific Ethical Committees (VN2003/124).

Patients and controls

Diagnosis of CD or UC was based on clinical, radiological, endoscopic and histological examinations (infectious and other cases of IBD were excluded)^[56-58]. Patients were recruited from Viborg, Aalborg, and Herning Regional Hospitals from January 2004 to March 2005. Healthy blood donors recruited from Viborg Hospital served as controls. All subjects were Caucasian and older than 18 years of age. Data on the extent of the disease (CD: L1, L2, L3, UC: E1, E2, E3), family history, surgical treatment, advanced

medical treatment, age at diagnosis (under or over 40 years of age), and information on smoking habits at the time of diagnosis (patients) and at study entry (healthy controls) were collected.

Genotyping

Functional single nucleotide polymorphisms (SNPs) were selected based on the literature, except in the case of LXR with tag SNPs selected based on previous disease association^[51-53] because there were no available data on the functional effects. DNA was extracted from EDTA-stabilized peripheral blood samples from all patients and healthy controls using either a PureGene (Gentra Systems, Minneapolis, MN, USA) or Wizard Genomic (Promega, Madison, WI, USA) DNA purification kit, according to the manufacturers' recommendations.

Genotypes were determined by Taqman allelic discrimination (ABI 7500/7900HT, Applied Biosystems). DNA (20 ng) was analyzed in volumes of 4 μ L. Samples from cases and sub-cohort members were mixed during genotyping, and laboratory staff were blinded to the case or control status during analysis. Known genotype controls were included in each run. To confirm reproducibility, 10% of the samples were genotyped again. The genotypes exhibited 100 % identity.

NF κ B (NFKB1) ATTG ins/del (rs28362491) and PPAR γ (PPARG) Pro12Ala were genotyped as previously described^[59] and^[60], respectively). PPAR γ (PPARG) C1431T^[61], PXR (NR1I2) A-24381C (rs1523127), C8055T (rs2276707), and A7635G (rs6785049); and LXR- β (NR1H2) T-rs1405655C and T-rs2695121C were assessed using developed assays (Applied Biosystems).

Statistical analysis

Logistic regression was utilized to analyze the relationship between the investigated polymorphisms and IBD. The statistical analysis included only subjects with all necessary information available. Age was entered linearly in the model after verifying these data using a linear spline^[62]. Subgroup analyses were performed on polymorphisms in relation to the extent of the disease (CD: L1, L2, L3, UC: E1, E2, E3), family history, surgical treatment, advanced medical treatment, and age at diagnosis (above or below 40 years of age) for all cases. The haplotypes were inferred manually as described previously^[63].

Power analysis

The Genetic Power Calculator for case-control was utilized for power analysis of discrete traits^[64]. This study had greater than 80% power to detect a dominant effect with an odds ratio (OR) of 1.5 in either CD or UC, or 1.4 if CD and UC were combined.

RESULTS

Study population description

Characteristics of the Danish IBD patients and controls are shown in Table 1. Current smoking was more common among CD than UC patients, with incidences of

Disease location was classified according to the WGO Montreal classification. Statistical analyses included subjects for whom all information was available. ¹Azathioprine, 6-mercaptopurine, tumor necrosis factor inhibitors, or methotrexate; ²5-aminosalicylic acid, prednisolone. CD: Crohn's disease; UC: Ulcerative colitis.

51% and 17%, respectively. The genotype distributions among the controls did not deviate from Hardy-Weinberg equilibrium. The variant allele frequencies of the studied polymorphisms are shown in Table 2.

Associations between polymorphisms and disease phenotypes

The association between genotypes and the disease risk was analyzed separately for CD and UC (Table 3). The PXR A7635G (rs6785049) variant genotypes, PPAR γ Pro12Ala homozygous variant, and LXR T-rs2695121-C homozygous genotypes were associated with a higher risk of UC, as compared to the homozygous wild-type genotype (OR: 1.31, 95% CI: 1.03-1.66, *P* = 0.03, OR: 2.30, 95% CI: 1.04-5.08, *P* = 0.04, and OR: 2.41, 95% CI: 1.00-1.98, *P* = 0.05, respectively). No association was found between risk of CD and any genotype. Furthermore, no association was found between NF κ B -94 ins/del or PPAR γ C1431T polymorphisms and disease risk (Table 3).

Interaction between gene polymorphisms and smoking

The association between genotypes and disease risk was analyzed for current smokers, previous smokers, and never smokers. There was no interaction between smoking

status and gene polymorphisms in relation to the risk of CD or UC (data not shown). In general, there was an association between smoking status and the risk of CD and UC. The OR for risk of CD was high among smokers and low among former smokers, regardless of genotype status. In contrast, the OR for UC was high among former smokers and low among current smokers, regardless of genotype.

The ORs for associations between genotypes and the risk of CD, UC and combined IBD among individuals that had never smoked are shown in Table 4. The ORs were analyzed separately for CD and UC and for the combined groups to describe the risk of IBD because there was no heterogeneity between the two groups. The PXR A7635G (rs6785049) and LXR T-rs1405655-C and T-rs2695121-C variant genotypes were associated with a higher risk for IBD, as compared to the homozygous wild-type genotypes (OR: 1.41, 95% CI: 1.05-1.91, $P = 0.02$ and OR: 1.63, 95% CI: 1.21-2.20, $P = 0.001$, OR: 2.02, 95% CI: 1.36-2.99, $P = 0.0005$, respectively).

Haplotype analysis

Haplotype analysis among the healthy controls demonstrated that the PXR C8055T variant genotype was more frequent in carriers of the PXR A7635G variant allele than among carriers of the A7635G wild-type, which indicated that these two polymorphisms were linked. Moreover, the presence of the A-24381C variant allele seemed to be independent of the PXR C8055T and A7635G genotypes. No significant association of PXR haplotypes and disease risk

was determined (data not shown). Tables 5 and 6 show the minor allele frequencies of the PXR polymorphisms compared to those in other studies, and published associations between PXR polymorphisms and risk of IBD^[47-59].

Haplotype analysis in the healthy controls demonstrated that carriage of the LXR rs1405655 C variant allele was linked to the presence of the LXR rs2695121 C variant allele. Carriage of the LXR rs1405655 C allele in this instance did not add to the risk of IBD, compared to carriage of only the rs2695121 C allele. The OR for the association between the LXR haplotype that encompassed the T-rs2695121-C and the T-rs1405655-C variant allele was 1.17, 95% CI: 1.00-1.36 and 1.23, 95% CI: 1.00-1.52, compared to the compound wild-type haplotype, respectively (data not shown).

Haplotype analysis was not performed for the closely linked PPAR γ Pro12Ala and C1431T polymorphisms.

Subgroup analysis

Subgroup analysis revealed that the PXR A7635G (rs6785049) variant genotype was associated with a higher risk of UC diagnosis before the age of 40 years and with a higher risk of extensive disease (OR: 1.34, 95% CI: 1.03-1.75 and OR: 2.49, 95% CI: 1.24-5.03, respectively), and the LXR T-rs2695121-C variant genotype was associated with a higher risk of advanced medical treatment for UC (OR: 1.80, 95% CI: 1.08-2.99) as compared to the homozygous wild-type genotype (data not shown).

DISCUSSION

In the present case-control study of 822 IBD patients (327 CD and 495 UC) and 773 healthy controls, we determined that PXR and LXR variant allele carriers were at higher risk of UC than the homozygous wild-type carriers, and that the association was strongest among individuals that had never smoked and those with severe UC. An association between PPAR γ Pro12Ala and the risk of UC was determined based on only a few subjects. No associations were determined between gene polymorphisms and risk for CD or UC among previous or current smokers. Furthermore, no associations were found between the NF- κ B gene polymorphism and risk of CD or UC. The association between LXR C-rs1405655-T and T-rs2695121-C variant genotypes and the risk of IBD among individuals that had never smoked withstood Bonferroni correction for multiple testing, whereas the other associations were not validated by these analyses. The strengths and weaknesses of the present study must be considered^[65]. For instance, one strength of the present study is the well-characterized study subjects with information that included smoking status. There are various methods used to determine the control group with associated advantages and disadvantages^[66]. In this study, the control group consisted of blood donors, who were not a random sample of the population. However, confounding data is not a likely explanation of the association because both cases and controls were not aware of their genotypes, and geno-

Statistical analyses included subjects for whom all information was available. ¹Adjusted for age, sex and smoking status. NF- κ B: Nuclear factor κ B; PPAR γ : Peroxisome proliferator-activated receptor γ ; CD: Crohn's disease; UC: Ulcerative colitis; OR: Odds ratio; PXR: Pregnane X receptor; LXR: Liver X receptor.

typing was performed blindly. Furthermore, stratification could theoretically result in the determined associations. However, this possibility is considered unlikely because the cohort was recruited from an area of Denmark with a homogeneous population^[67]. Minor allele frequencies of *PXR* polymorphisms in the present study and in other published studies on Caucasian populations are shown in Table 5. The allele frequencies of the present study did not deviate from previously determined frequencies^[47,49,50]. Therefore, heterogeneity or stratification in the control group is not a likely explanation for the determined associations in our study (Table 5).

The present study included 1600 participants, and power analysis determined that this study had more than 80% power to detect a dominant effect with an OR of 1.5 in relation to either CD or UC, and 1.4 when CD and UC were combined. Moreover, genetic determinants may be stronger among patients with extensive development of

the disease^[68,69] and disease onset at a younger age. However, the obtained results cannot be excluded as false positive.

An association of the *NF- κ B* -94 ins/del with UC, CD, or IBD was not determined in the present study. The variant allele has been associated with a risk of UC in a study that used the family-based association test and the transmission disequilibrium test in 131 IBD pedigrees with UC offspring, which was replicated in a second set of 258 UC and 653 healthy controls with an OR for the combined studies of 1.57 (1.14-2.16)^[25]. This study was further replicated in a small study of 127 UC patients and 155 healthy controls^[26], whereas larger studies have not indicated any association between the polymorphism and IBD^[27-29], UC^[30,31], or CD^[24]. Our results are in accordance with the latter studies^[27-31].

In the present study, a statistically significant (although modest) association was determined between the homozygous *PPAR γ* Pro12Ala variant genotype and an increased

Rs3814055 and rs1523127 are closely linked.

risk of IBD. This result cannot be excluded as random because of the small sample size. In a combined Dutch and Chinese study, the PPAR γ C1431T variant allele was associated with UC in the Chinese study group but not in the Dutch study group, and no associations were indicated with CD^[42]. No associations between PPAR γ Pro12Ala polymorphism and UC^[43] or CD^[44] have been demonstrated in two small studies. Therefore, these collective studies

have not yielded consistent data that supported involvement of PPAR γ in IBD.

PXR A7635G (rs6785049) variant allele carriers were at a higher risk of UC and IBD than homozygous wild-type carriers were. Furthermore, risk was highest among individuals that had never smoked. Table 6 shows the results of published association studies of PXR polymorphisms in IBD. The risk allele is indicated for positive

associations, whereas a null result is indicated as “neg” in Table 6. These results were inconsistent. No association was determined between the PXR A-24381C (rs1523127) polymorphism and IBD in the present study or in a previous Scottish study^[49]. In contrast, Irish and Spanish studies have indicated opposite associations between IBD and the closely linked PXR C-25385T (rs3814055) polymorphism^[47,50]. Furthermore, the A7635G (rs6785049) variant genotype was found to be associated with risk for UC in the present study, whereas this allele was indicated to be protective for IBD in the Irish study^[47]. Collectively, these results suggest that variable linkage disequilibrium between the investigated and biologically functional SNPs, and population heterogeneity may contribute to the inconsistent results.

Low levels of PXR were expressed in the intestine of UC patients, and high PXR activity ameliorated colitis in an animal IBD model^[70]. Thus, impaired PXR function may fail to suppress NF- κ B-induced intestinal inflammation^[13,71]. Moreover, attenuated activation of PXR target genes, such as the xenobiotic transporters *MDR1* (ABCB1) and *MRP2* (ABCC2), may lead to a less proficient epithelial barrier. Several lines of evidence support the role of impaired xenobiotic transport in IBD, including the development of colitis in *mdr1a*-deficient mice^[72], low *MDR1* expression levels in UC patients^[73], and a meta-analysis that indicated an association between an *MDR1* (ABCB1) polymorphism and the risk of UC^[74]. Therefore, impaired PXR function may lead to less effective induction of *MDR1* and export of harmful substances that originate from bacteria, diet, and pollutants.

The present investigation yielded strong associations between the LXR T-rs2695121-C homozygous variant allele and the risk of UC, and between both of the studied LXR variants and the risk of IBD among individuals that had never smoked. Haplotype analysis suggested a strong linkage between the two polymorphisms, and that carriage of the LXR T-rs1405655-C variant genotype coupled to the other LXR polymorphism does not add to the risk of IBD, compared to carriage of only the LXR T-rs2695121-C variant genotype. These polymorphisms have only been previously investigated in relation to Alzheimer’s disease^[53]. LXR seems to have anti-inflammatory properties, and LXR represses a set of inflammatory genes after activation by bacterial components or cytokines^[32]. Furthermore, LXR has been recently demon-

strated to upregulate xenobiotic transport proteins, such as *MDR1* (ABCB1)^[75] and *MRP2* (ABCC2)^[76]. Therefore, our results suggest the involvement of LXR in UC etiology.

Finally, the present study suggested that the associations between the PXR A7635G (rs6785049) and both of the studied LXR variant genotypes and UC were stronger among never smokers than among previous or current smokers. Therefore, the impact of the PXR and LXR gene polymorphisms on population disease risk may be larger in population with low frequencies of smokers than in those with many smokers. None of the associations indicated in the previously mentioned studies were adjusted for smoking status. Therefore, differences in relevant exposure may have contributed to the inconsistent results. We have previously found that inclusion of smoking status may be essential for evaluation of genetic predisposition to IBD (unpublished data, V. Andersen), and the present study is in accordance with our former study. Moreover, recently, passive smoking has been suggested to confer risk of IBD in children^[77,78].

Tobacco smoke contains > 3000 different chemical substances that have an impact on many biological pathways in relation to IBD^[55]. However, no interaction between smoking status and the studied polymorphisms was determined in the present study. Tobacco smoke suppresses NF- κ B activation in blood mononuclear cells^[58], and a similar mechanism may occur in the intestine.

In summary, the present study of 1600 individuals suggests that PXR and LXR are implicated in determining individual susceptibility to UC in the Danish high-incidence population. Furthermore, the conferred risk seems to be strongest among individuals that have never smoked. Clearly, further research is necessary to assess the overall role of inborn variants in PXR and LXR on UC susceptibility and the underlying biological mechanisms in relation to IBD etiology. Our results suggest that inclusion of smoking status may be essential for the evaluation of the role of genetic predisposition to IBD.

COMMENTS

Background

Environmental and genetic factors are involved in the etiology of the chronic inflammatory bowel diseases (IBDs), ulcerative colitis (UC), and Crohn’s disease. Furthermore, gene-environment interactions may result from variants in genes involved in the handling of environmental factors.

Research frontiers

The rising incidence of IBD in the West suggests that environmental factors play a major role in its pathogenesis. Nuclear receptors are intracellular transcription factors that constitute a link between environmental factors and the regulation of many cellular processes, including inflammation. In this study, the authors demonstrated that genetic variants in the nuclear receptors pregnane X receptor (PXR) and liver X receptor (LXR) may confer risk of UC. Furthermore, the conferred risk seems to be strongest among individuals that have never smoked.

Innovations and breakthroughs

Recent reports have highlighted the importance of genetic variations in the etiology in IBD. This study explores the contribution of genetic variations in nuclear factors to risk of IBD. This is the first study to suggest that LXR may confer risk of UC, and moreover, add to our knowledge of risk of UC associated with PXR variants. Next, this study substantiated the authors' previous findings that inclusion of smoking status may be essential for the evaluation of the role of genetic predisposition to IBDs.

Applications

By understanding the genetic contribution to risk of IBDs, this study adds further to our knowledge about the biological pathways that lead to disease, which is considered a prerequisite for development of new molecular targets for treatment.

Terminology

PXR, LXR and peroxisome proliferator-activated receptor γ (PPAR γ) are nuclear receptors, i.e. sensors of the environment, because they are activated by the binding of various compounds termed ligands, and next, in similarity with nuclear factor (NF)- κ B, they are transcription factors, i.e. they regulate transcription of their target genes. Thereby, nuclear factors may constitute a link between environmental factors and the regulation of inflammation.

Peer review

The authors examined the contribution of genetic variants in the nuclear receptors PXR, LXR and PPAR γ and the transcription factor NF- κ B to the risk of IBDs. The study revealed that variants in genes that coded for PXR and LXR confer risk of UC, especially among never smokers. Furthermore, the study demonstrates that inclusion of smoking status may be essential for the evaluation of the role of genetic predisposition to IBDs.

Abstract

AIM: To compare the natural history and course of acute diverticulitis in a younger age group with an older population and to evaluate whether younger patients should be managed differently.

METHODS: This study was a retrospective review of 157 patients treated with acute diverticulitis between January 1, 2004 and December 31, 2007. Diverticulitis was stratified according to the Hinchey classification. Patients were divided into 2 populations: group A \leq 50 years ($n = 31$); group B > 50 years ($n = 126$). Mean patient follow-up was 15 mo.

RESULTS: The median age was 60 years. A significantly higher proportion of patients in group B presented with complicated diverticulitis (36.5% vs 12.9%, $P = 0.01$). Recurrence was more frequent in group A

(25.8% vs 11.1%, $P = 0.03$) and the mean time-to-recurrence was shorter (12 mo vs 28 mo, $P = 0.26$). The most severe recurrent episodes of acute diverticulitis were classified as Hinchey stage I and none of the patients required emergency surgery. In multivariate analysis, only age ($P = 0.024$) was identified as an independent prognostic factor for recurrence.

CONCLUSION: Based on the results of this study, we recommend that diverticulitis management should be based on the severity of the disease and not on the age of the patient.

INTRODUCTION

Diverticulosis of the colon is an acquired condition that results from herniation of the mucosa through defects in the muscular layer. Epidemiological and anatomic studies have revealed that diverticular formation of the colon occurs primarily in industrialized and Westernized countries^[1,2]. The true incidence of diverticulosis is difficult

to measure because most individuals are asymptomatic. It is believed that approximately 60% of individuals over the age of 60, living in Westernized countries, will develop colonic diverticula^[3]. Postmortem studies revealed that the disorder is rare prior to the fourth decade, but increases progressively, so that at age 80 approximately 65% of patients will have diverticula of the colon^[4,5]. Several epidemiological studies have demonstrated an association between diverticulosis and diets low in dietary fibers and high in refined carbohydrates^[6-9].

Most patients with colonic diverticula remain asymptomatic; only 10%-25% will develop diverticulitis and 1% will actually require surgery^[1,3,10,11]. The clinical presentation of acute diverticulitis varies widely from mild inflammation to full-blown perforation and peritonitis. In most patients however, the clinical presentation of diverticulitis is mild and medical treatment will achieve successful management of the acute episode^[12].

When treated medically, the risk of recurrent diverticulitis ranges from 7% to 45%^[13-15], with most recurrences (90%) occurring in the first 5 years^[13-16]. The fact that the severity of recurrent attacks is usually considered to be higher than the first episode^[13] has been questioned by several authors^[16-21].

In recent years, there has been conflicting information regarding the incidence and natural history of diverticulitis in younger patients (aged 50 years or younger). While earlier studies found that the incidence ranged between 2% and 7%^[22-26], more recent studies reported a higher incidence ranging between 18% and 34%^[17,27]. The natural course and outcome of diverticulitis in the younger patient has also been a matter of discussion. While earlier studies reported a more severe course with a higher rate of complications and recurrent episodes in younger patients with diverticulitis^[7,8,22,25,28], some recent reports suggested a milder course, not different from that observed in older patients^[12,19,21,27]. The aim of this retrospective study was to compare the natural history and the course of acute diverticulitis in a younger age group with that of an older population. Our purpose was to evaluate whether younger patients should be treated according to the same criteria as their older counterparts.

MATERIALS AND METHODS

One hundred fifty seven consecutive patients aged 24-93 years (median, 60 years) with documented acute sigmoid diverticulitis were treated at the University Hospital São João at Porto, with a catchment area of roughly 1 million patients, between 2004 and 2007.

For the patients diagnosed with diverticulitis, who had prior attacks, the clinical, radiological and analytical data of the first episode was retrieved and analyzed. Patients were stratified for age, according to the age at first episode.

The diagnosis of acute diverticulitis was based on lower abdominal pain (usually on the left side), fever and an increase in serum inflammatory parameters. Emergency surgical treatment was undertaken in patients with diffuse peritonitis or septic shock. Patients not undergoing emer-

gency surgery had an abdominal computed tomography (CT) scan and only those with characteristic findings were included in this study. CT scan findings were classified as uncomplicated (localized colonic wall thickening and/or infiltration of pericolic fat) or complicated (pericolic or abdominal abscess, localized or free extra luminal air or contrast, bowel obstruction, and fistula formation). The severity of complicated diverticulitis was graded according to Hinchey's criteria^[29]. Stage I patients had small or confined pericolic abscesses, Stage II patients had larger pelvic or distant intra-abdominal abscesses, Stage III patients had purulent diverticulitis and in Stage IV patients had fecal peritonitis.

After resolution of acute inflammation, all patients who had no previous endoscopic diagnosis of diverticular disease underwent elective colonoscopy to confirm the presence of colonic diverticula and to rule out the presence of other diseases, such as cancer or inflammatory bowel disease.

The patients were stratified into 2 groups, according to age at first acute episode: group A included patients aged 50 years or younger ($n = 31$) and group B included patients older than 50 years ($n = 126$).

Demographic (age, gender, ethnicity), clinical (presentation signs and symptoms, endoscopic findings), laboratory [white blood cell count and C-reactive protein (CRP) measurements] and radiological (CT scan) features were analyzed and compared between the 2 groups.

Emergency surgery was undertaken if patients had diffuse peritonitis, septic shock, or if the clinical course did not improve after 48-72 h of conservative medical management. In some patients, elective surgery was performed after resolution of the acute episode and all of these had bowel preparation and primary anastomosis. CT-guided percutaneous drainage was performed in patients with abscesses larger than 4 cm in diameter.

Follow-up (range, 6-54 mo; median, 15 mo) was available for 98% of the population and completed in June 2008.

Recurrence of diverticulitis was diagnosed if the patient presented with similar symptoms and clinical findings, confirmed by laboratory and radiological investigations. The rate and severity of recurrences was compared between both groups, as well as the need of emergency or elective surgery after an episode of recurrent diverticulitis.

For statistical analysis, the program SPSS (version 15.0 for Mac) was used. The differences in the distribution of cases according to several parameters being analyzed were compared by χ^2 test for categorical variables and the Student *t*-test for continuous variables. Multivariate analysis was performed using the logistic regression method in order to identify independent factors associated with recurrence. $P < 0.05$ were considered significant.

RESULTS

The median age of the 157 patients with acute sigmoid diverticulitis was 60 years (range, 24-93 years). The mean age of patients in group A was 40 years (median, 41 years)

Table 1 Clinical and laboratory features of the 2 groups of patients according to age *n* (%)

	Group A (≤ 50 yr)	Group B (> 50 yr)	<i>P</i>
Signs and symptoms			
Abdominal pain	30 (96.7)	117 (92.8)	NS
Fever	9 (29.0)	30 (23.8)	NS
Acute abdomen	10 (32.3)	30 (23.8)	NS
Vomiting	5 (16.1)	26 (20.6)	NS
Constipation	3 (9.7)	23 (18.2)	NS
Diarrhea	2 (6.4)	13 (10.3)	NS
Laboratory			
Leucocytosis ($> 11 \times 10^9$)	24 (82.7)	67 (55.8)	0.01
Mean WBC count ($\times 10^9$)	15.0	13.1	0.01
Mean CRP (mg/dL)	151.5	133.5	0.005

Group A (*n* = 31) and Group B (*n* = 126). WBC: White blood cell; CRP: C-reactive protein.

and for group B was 65 years (median, 62 years). Sixty-eight patients (43.3%) were male and 89 (56.7%) were female (M/F: 0.76/1). Thirty-one patients (19.7%) were 50 years old or younger. There was a striking male predominance in the younger age group (group A) with a male:female ratio of 1.8:1. The older age group (group B) showed a female predominance with a male:female ratio of 0.61:1. The difference between both groups according to gender was significant (*P* = 0.008).

The most common symptom present on admission was left lower quadrant abdominal pain, which was observed in 147 (93.6%) patients. No significant differences were observed between groups A and B regarding the symptoms and signs most commonly observed in acute episodes (Table 1).

In this series, younger patients had a significantly higher percentage of leucocytosis (82.7% *vs* 55.8%, *P* = 0.01) than patients older than 50 years. The mean value of leucocytosis was significantly higher in patients of group A (*P* = 0.012) as well as the mean value of CRP elevation (*P* = 0.005) (Table 1).

One hundred and seven patients (68.2%) had a mild course of diverticulitis with no complications. Fifty patients (31.8%) had a more severe and complicated course. The most common complications were abdominal abscesses, which were observed in 33 cases (21.0%). Five patients required guided percutaneous drainage of abdominal abscesses. These resolved in all patients with no need for further urgent surgery. There were 17 patients (10.8%) who developed free perforation and all underwent emergency surgery (Table 2). No patient died during hospitalization.

One hundred and forty seven patients underwent an abdominal CT scan. Ten patients presented with diffuse peritonitis and septic shock, and underwent emergency surgery without further radiological investigation. In these cases, diagnosis of complicated diverticulitis was done intraoperatively.

A significantly lower proportion of patients of group A presented with complicated diverticulitis, compared to patients of group B (12.9% *vs* 36.5%, *P* = 0.01), namely

Table 2 Severity of disease (Hinchey classification) and surgical treatment of the 2 groups according to age *n* (%)

Elective surgery	4 (16.1)	5 (4.0)	0.07

Table 3 Recurrence and severity of recurrent disease in the 2 groups according to age *n* (%)

	Group A (≤ 50 yr)	Group B (> 50 yr)	<i>P</i>
Disease recurrence			0.03
Non recurrent	23 (74.2)	112 (88.9)	
Recurrent	8 (25.8)	14 (11.1)	
Severity of recurrence			0.10
Non complicated	6 (75)	10 (71)	
Complicated (Grade I)	2 (25)	4 (29)	

Table 4 Multivariate analysis of recurrence factors in patients with diverticulitis

Factor	Binary regression logistics	
	Exp (B)	<i>P</i>
Male gender	1.13	0.827
Age ≤ 50 yr	0.26	0.024
White blood cell count ($\times 10^9$)	0.99	0.830
Severity index	1.08	0.798

abdominal abscesses (Hinchey stages I / II, 9.7% *vs* 23.8%) and free perforation (Hinchey stages III / IV, 3.2% *vs* 12.7%) (*P* = 0.04) (Table 2).

A significantly lower proportion of patients of group A underwent an emergency operation after the first episode of acute diverticulitis (3.2% *vs* 14.3%, *P* = 0.026) (Table 2). Seventeen patients undergoing emergency surgery had free perforation with diffuse peritonitis, and 2 patients had pericolonic abscesses.

A significantly higher proportion of patients of group A developed recurrence of diverticulitis (25.8% *vs* 11.1%, *P* = 0.03) (Table 3). The mean interval between the primary episode and the recurrent disease was 12 mo (range, 1-40 mo; median, 4 mo) in group A and 28 mo (range, 1-150 mo; median, 6 mo) in group B (*P* = 0.26). No significant differences were observed between the 2 groups regarding the severity of recurrent episodes (*P* = 0.1) (Table 3). The most severe recurrent episodes of acute diverticulitis were classified as Hinchey stage I and none of the patients required emergency surgery.

In multivariate analysis of this series, age (*P* = 0.024) was identified as an independent prognostic factor of recurrence of acute diverticulitis (Table 4).

Figure 1 Flowchart of the clinical evolution of the patients with acute diverticulitis in our series.

DISCUSSION

For many years, diverticulosis was considered an old patient's disease with an incidence of 5% in patients younger than 50 years of age^[13]. Recently, the incidence of diverticulosis in younger patients has increased and has been reported to range from 18% to 34%^[17,19,21,27]. In our study, 19.7% of patients with diverticulitis were aged 50 years or younger.

We report a male predominance in younger patients with acute diverticulitis, which is in agreement with previous studies^[19,30].

Patients presenting with clinical signs, symptoms and laboratory findings suggesting acute diverticulitis underwent a CT scan of the abdomen at initial presentation. Abdominal CT is the diagnostic test of choice in acute diverticulitis. It has high sensitivity (approximately 93%-97%) and specificity approaching 100% for the diagnosis^[31,32]. It is the best method for grading the severity of inflammation, and it also enables the classification of diverticulitis into complicated or uncomplicated disease^[12,33].

In the present series, 17 patients (10.8%) with diffuse peritonitis and septic shock underwent emergency surgery. This observation is in agreement with other reports suggesting that 10% of patients admitted with acute diverticulitis will require surgical treatment during the same admission^[34].

The clinical course and severity of diverticulitis in younger patients have not yet been clearly defined. The most appropriate management of patients whose acute

diverticulitis resolves after medical treatment is still controversial. Diverticulitis in younger patients has been reported to have a more aggressive course or to require emergency surgery more frequently than in older patients^[7,8,13,21,24,28,35-37]. As such, it has been argued that all patients younger than 50 should undergo elective colon resection after an initial episode of acute diverticulitis, with the intention to prevent a recurrent attack, which could present with perforation and require a stoma^[11,17,36,37]. However, other studies published in the last decade failed to support this conclusion and suggest that the course of diverticulitis in younger patients is not as aggressive as once thought^[12,19,27,38-41]. These studies reported a course of disease in younger patients not different from the older age group and with a similar rate of complications. Our study found that complicated episodes of acute diverticulitis were significantly less frequent in younger patients, suggesting that diverticulitis in younger patients does not have a more aggressive course.

In our study, younger patients were significantly more prone to recurrent episodes, despite the relatively short follow-up period. Our data is consistent with earlier studies that reported a higher recurrence rate of diverticulitis among younger patients^[21,30].

The most appropriate timing for elective surgery following an episode of acute diverticulitis remains controversial. Parks first described medical management of diverticulitis in 1969^[13]. He stated that mortality rate for each subsequent attack of diverticulitis increased from 4.7% during the first admission to 7.8% during each subsequent

episode. He also reported that diverticulitis was less likely to respond to medical therapy as the number of acute episodes increased. Some retrospective studies suggested that the number of recurrences is associated with an increased need for a subsequent emergency surgical procedure^[19]. It was suggested^[42] that the likelihood of emergency surgery is increased by a factor of at least 2 with each subsequent hospitalization for diverticulitis. Thereafter, the American Society of Colon and Rectal Surgeons published a practice guideline for uncomplicated diverticulitis, which recommended definitive surgical treatment after 2 episodes of diverticulitis^[11] based on the data provided by Parks. In recent years, this finding has been questioned and in its most recent guidelines, the American Society of Colon and Rectal Surgeons, no longer considers the number of attacks as a definite indication for surgery^[41].

In this study, we have observed that in the subgroup of 18 patients, which developed acute recurrence after non-operative treatment (Figure 1), only 5 (27.8%) had complicated findings on CT scan, classified as Hinchey stage I. All patients that developed acute recurrence were successfully treated nonoperatively. These results suggest that recurrence is not associated with an increased rate of either complications or less successful medical management, and are in agreement with several recent publications that have questioned the practice of surgical resection after 2 attacks, as well as after complicated disease^[16-21,43,44].

According to our data, the great majority of younger patients (87.1%) had uncomplicated diverticulitis according to the CT scan criteria. Twenty-five of the younger patients (81%), after a first episode of uncomplicated diverticulitis, did not require surgery during follow-up. Although a significant amount of these patients developed recurrent episodes (24.0%), only one developed a recurrence with a pericolic abscess (Hinchey stage I) and none required emergency surgery. This data suggests that younger patients with uncomplicated diverticulitis may be managed safely without an operation after an initial episode of diverticulitis, which is in agreement with other recent reports^[45]. Three patients of group A (< 50 years old) with complicated diverticulitis did not require surgery during follow-up (Figure 1). One patient developed a non-complicated recurrence and none required an emergency operation. Although this may suggest that complicated diverticulitis may also be managed without an operation, the number of patients was too small to allow for any recommendation. These results are in agreement with another recent report^[46].

In conclusion, our study shows that acute diverticulitis is a mild disease with a low complication rate. In younger patients, there is a male predominance and the disease tends to be less severe than in the older age group, in spite of the higher recurrence rate. According to our results, the clinical course of uncomplicated acute diverticulitis is similar both in younger and older patients. Therefore the same guidelines should be used in the treatment of both groups of patients. The number of younger patients with complicated diverticulitis evaluated in this study was small but, should our results be confirmed in larger or even pro-

spective studies, it seems reasonable to recommend the adoption of a similar strategy in both age groups.

COMMENTS

Background

The management of patients with diverticular disease after resolution of an attack of acute diverticulitis, has been a matter of debate by colon and rectal surgeons. The reports of a more severe and virulent disease in younger patients has been questioned by several authors and although the incidence has increased in the last decades, these patients are increasingly managed conservatively.

Research frontiers

To compare the natural history and the course of acute diverticulitis in a younger age group with an older population and to evaluate whether younger patients should be managed differently.

Innovations and breakthroughs

In this retrospective study, the patients younger than 50 years at first presentation of diverticulitis had less severe disease but a higher recurrence rate (25.8% vs 11.1%). All the patients with recurrent disease were managed with conservative treatment and for the majority of patients, the most severe attack of diverticulitis was the first. On multivariate analysis, age was the only factor predictive of recurrence.

Applications

Based on the results of this study, the authors recommend that diverticulitis management should be based on the severity of the disease and not on the age of the patient.

Peer review

Overall this is a good observational study, with interesting conclusions. Its strength is that all patients had computed tomography-documented episodes of diverticulitis and good follow-up.

hemoglobin (FHb) on intestinal microcirculation and intestinal epithelial injury in a rat model.

METHODS: To induce elevated intravascular circulating FHb, male Sprague-Dawley rats received water or FHb infusion. Microcirculatory changes in jejunum, ileum and colon were evaluated using fluorescent microspheres. Intestinal injury was quantified as plasmatic release of ileal lipid binding protein (iLBP) and verified by histological analysis of the ileum.

RESULTS: Water and FHb infusions resulted, when compared with saline infusion, in reduced intestinal microcirculation (after 30 min $P < 0.05$, or better; after 60 min FHb infusion $P < 0.05$ for jejunum and colon). Circulating FHb levels correlated significantly with release of iLBP (Spearman $r = 0.72$, $P = 0.0011$). Epithelial cell injury of the villi was histologically observed after water and FHb infusions.

CONCLUSION: This study shows that circulating FHb leads to a reduction in intestinal microcirculatory blood flow with marked injury to intestinal epithelial cells. These data support the hypothesis that circulating FHb contributes to the development of intestinal injury.

Abstract

AIM: To study the effect of circulating cell-free oxy-

INTRODUCTION

Gastrointestinal complications following cardiovascular surgery are feared, as these complications are associated with high patient morbidity and mortality rates^[1-4]. The proposed pathophysiological mechanisms underlying intestinal complications include: (1) Ischemia/reperfusion and hypoperfusion injury as a result of redistribution of blood flow and increased oxygen demand; (2) Inflammatory mediated endothelial dysfunction and priming; and (3) Increased mesenteric vascular resistance^[5-7].

It is widely accepted that cardiovascular surgery is associated with considerable injury to red blood cells resulting in hemolysis. The use of extracorporeal circulation, donor blood transfusion and cell salvage devices inevitably leads to increased circulating levels of the hemolytic product cell-free oxyhemoglobin (FHb)^[8-10]. Such circulating FHb has been reported to scavenge endothelial nitric oxide (NO) in chronic hemolytic diseases, potentially perturbing microcirculatory blood flow which may result in organ injury and/or organ dysfunction^[11,12]. The effect of hemolysis on intestinal microcirculation and gut wall integrity remains unclear. We hypothesized that intravascular FHb compromises intestinal blood flow and consequently induces intestinal epithelial cell injury.

The present study aimed to evaluate intestinal blood flow and intestinal epithelial cell injury due to elevated circulating FHb levels. An animal model was developed with FHb plasma levels similar to those found during cardiovascular surgery. The influence of circulating FHb on intestinal microcirculation was studied using fluorescent microspheres and intestinal injury was evaluated both biochemically and histopathologically.

MATERIALS AND METHODS

Animals

The Animal Ethics Committee of the Maastricht University Medical Center approved the study. Male Sprague-Dawley rats, 450-500 g (Charles River Laboratories, Maastricht, The Netherlands) were housed under controlled conditions of temperature and humidity. Prior to the experiments, rats were fed standard rodent chow *ad libitum* and had free access to water.

Generation and measurement of FHb

To generate FHb-containing solution for infusion, heparinized blood was obtained from rats through aortic puncture 1 d prior to intervention. Red blood cells were isolated by centrifugation ($2750 \times g$, 15 min at 4°C). Supernatant and buffy-coat were carefully discarded and the remaining red blood cells were washed thrice in fresh sterile saline (1:3 v/v). Hemolysis was induced by freeze-thaw cycles. To remove all red blood cell membranes the solution was ultra-centrifuged ($20000 \times g$, 30 min at 4°C) and filtered (0.2 µm, Schleicher and Schuell, Dassel, Germany). Final FHb concentration was adjusted with sterile saline to 300 µmol/L. FHb concentration for infusion, as well as plasma values, were measured by derivative spectrophotometry^[13].

Figure 1 The effect of saline, water or free oxyhemoglobin infusion on mean arterial pressure and free oxyhemoglobin levels. During the study period the mean arterial pressure (MAP) (left Y-axis) remained unchanged in all interventional groups. Plasma free oxyhemoglobin (FHb) levels (right Y-axis) were significantly elevated in the group with water infusion and in the group with FHb infusion after 15 min and onwards. ^b $P < 0.01$, ^d $P < 0.001$.

Experimental design

After induction with 4% isoflurane, anesthesia was maintained at 2% during the whole study protocol. To calculate mean arterial pressure (MAP) a cannule (polyethylene tubing, PE-10) was placed in the left femoral artery and connected to an external pressure transducer (Uniflow®; Baxter, Utrecht, The Netherlands). Microspheres were infused *via* a cannule (PE-10, 11 cm) that was placed in the aortic arch *via* the right femoral artery. The left femoral vein was used to infuse saline, water or FHb.

Three groups ($n = 6$ per group) were included in the study. To induce intravascular hemolysis and yield circulating FHb, the first group received sterile pyrogen-free water infusion (prime 0.6 mL/100 g BW, continuous infusion of 2 mL/100 g BW per hour); the second group received FHb infusion (prime 0.65 mL/100 g BW, continuous infusion 1.3 mL/100 g BW per hour). The control group received saline infusion in the same volume as the water infusion group.

Assessment of microcirculatory blood flow using microspheres

To evaluate the intestinal microcirculatory blood flow pre-infusion, and after 15, 30 and 60 min, fluorescent microspheres with different colors were used (yellow, lemon, orange or persimmon; diameter 15 µm, 1×10^6 microspheres/mL; Dye-Trak®, Triton Technology, San Diego, CA). Infusion of microspheres (0.25-0.3 mL) and calculation of organ blood flow were performed as described previously^[14].

Evaluation of intestinal injury

To evaluate enterocyte damage, the release of intestinal ileal lipid binding protein (iLBP) was measured. For iLBP assessment, arterial blood samples (600 µL) were collected before infusion and after 15, 30 and 60 min of infusion. ILBP was measured in plasma by an Enzyme Linked Immuno Sorbent Assay (ELISA, detection limit 1.28 ng/mL), kindly provided by Hycult biotechnology (Hbt, Uden, The Netherlands).

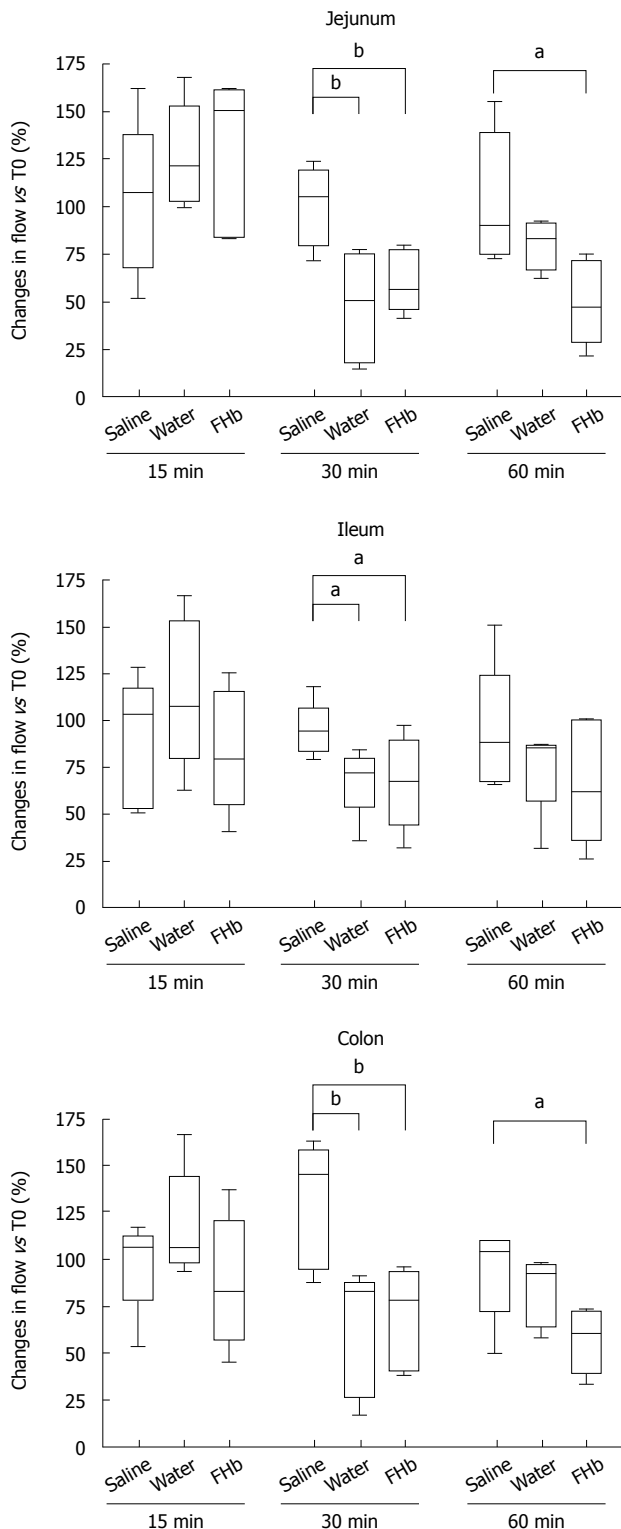

Figure 2 Decreased intestinal microcirculatory blood flow after water and free oxyhemoglobin infusion. The gut was divided into three sections: jejunum, ileum and colon. Basal flow was set at 100% for all groups at T0. In both the water infusion group as well as in the free oxyhemoglobin (Fhb) infusion group the microcirculation decreased. After infusion of saline, the microcirculatory blood flow remained around 100% throughout the study. Changes in time in microcirculatory blood flow are presented at T15, T30 and T60 and compared with the saline infusion group. ^a $P < 0.05$, ^b $P < 0.01$.

After sacrifice, ileum tissue samples were fixed in neutral buffered formaldehyde and embedded in paraffin

Figure 3 Hemolysis is associated with intestinal injury. The infusion of water and free oxyhemoglobin (Fhb) led to a rapid and significant release of ileal lipid binding protein (iLBP), a cytosolic protein mainly present in the ileum and expressed in mature enterocytes. ^a $P < 0.05$, ^b $P < 0.001$.

wax. For morphological evaluation, deparaffinized 3 μ m sections were either stained with hematoxylin and eosin or anti-iLBP, using a polyclonal rabbit anti-mouse iLBP (cross-reactive with rat, Hbt, Uden, The Netherlands) and a biotinylated polyclonal antibody swine anti-rabbit, a streptavidin-biotin system (Dako, Glostrup, Denmark), and visualized by applying 3-amino-9-ethylcarbazole (AEC, Sigma, St. Louis, MO). A Nikon eclipse E800 microscope with a Nikon digital camera DXM1200F was used to capture images.

Statistical analysis

To test for differences in plasma levels of Fhb and iLBP, two-way analysis of variance with Bonferroni post-tests was used. To test for differences between changes in microcirculatory blood flow, two-tailed unpaired t -test was used. To evaluate an association between plasma Fhb and plasmatic iLBP release, Spearman correlation analysis for nonparametric data was used on area under the curve (AUC) between Fhb and iLBP for each individual subject of every group.

RESULTS

Hemolysis, Fhb and MAP

Plasma levels of Fhb before intervention were comparable between all groups (Figure 1). Water and Fhb infusions resulted in significantly elevated plasma levels of Fhb [peak values 29.6 (8.9) μ mol/L and 32.6 (2.7) μ mol/L, respectively, $P < 0.001$]. These levels are comparable to those found in patients during cardiovascular surgery in our University Medical Center, whereas infusion of saline did not result in elevated plasma Fhb levels. Infusion of either solution did not lead to changes in MAP.

Changes in intestinal microcirculation during hemolysis

The microcirculation was evaluated in the jejunum, ileum and colon (Figure 2). Whereas after 15 min of infusion no differences in blood flow occurred, at 30 min a significant decrease in microcirculatory blood flow of the

Figure 4 Histological and immunohistochemical evaluation of intestinal injury. Histological evaluation of the ileum was performed using HE staining (A, C and E, $\times 100$). When compared to the saline group (A, B), water (C, D) and free oxyhemoglobin (FHB) (E, F) infusions led to the development of subepithelial spaces (asterisks) in the villi. In support of the findings of plasmatic release of ileal lipid binding protein (iLBP), immunohistochemical analysis of the ileum shows cytosolic staining for iLBP in the epithelial cells of the upper part of the villi (B, $\times 200$). Leaking of iLBP in the subepithelial spaces (arrows) indicates intestinal epithelial cell injury after water or FHB infusion (D, F, $\times 200$). Insets show 400 \times magnification of selected areas where staining of iLBP can be seen outside the intestinal epithelial cellular membrane, indicating epithelial cellular injury (D, F).

jejunum, ileum and colon was seen, when compared to the saline group ($P < 0.05$ or better). After 60 min, the jejunal and colonic microcirculation was still significantly reduced in the FHB infusion group (jejunum and colon: FHB *vs* saline infusion, $P < 0.05$). These data indicate a deleterious effect of FHB on intestinal microcirculatory blood flow.

Intestinal injury during elevated circulating FHB levels

Release of iLBP: iLBP levels before infusion were comparable in all groups (Figure 3). Interestingly, at the time of reduced microcirculatory blood flow, at 30 and 60 min, plasma iLBP levels were significantly elevated in both the water and FHB infusion groups (peak values 20.6 (4.4) ng/mL and 16.1 (2.5) ng/mL, respectively). Moreo-

ver, the AUC for plasma FHB levels correlated significantly with the AUC for iLBP release ($r = 0.72$, $P = 0.0011$), indicating a strong association between hemolysis and intestinal injury.

Histological analysis for intestinal injury

Histological analysis (Figure 4) showed subepithelial spaces and injury at the tip of the villi in both the water infusion and FHB infusion groups, but not in the saline infusion group. Immunohistochemical staining of the ileum showed subepithelial spaces positive for iLBP in both the water and FHB infusion groups, indicating that iLBP had leaked from epithelial cells. No staining was observed in control sections (data not shown). These data indicate epithelial cell injury of the gut.

DISCUSSION

Taken together, these data show that elevated plasma levels of circulating FHB, as occurs during intravascular hemolysis, decrease intestinal microcirculation and result in intestinal injury, as demonstrated by the release of iLBP and confirmed immunohistochemically.

Our animal model was designed after a canine model developed by Minneci *et al.*^[11] to study the effects of water infusion-induced intravascular hemolysis on NO bioavailability and hemodynamic variables serving as a model for chronic hemolysis, such as occurs in sickle-cell anemia. Our infusion protocol was adjusted in order to attain plasma FHB levels comparable to those found during cardiovascular surgery in our university medical center (Figure 1)^[8]. The observed decreased microcirculatory blood flow at 30 min (Figure 2) suggests a rapid exhaustion of FHB scavenger proteins (haptoglobin, CD 163)^[15]. The reduction in microcirculatory blood flow was less pronounced after 60 min in both the water and FHB infusion groups. This might be explained by the gradual upregulation of heme-catabolizing enzymes (HO-1, biliverdin reductase)^[16,17] or enhanced NO-generating systems (NOS I, II and III)^[18,19], through either enhancement of FHB clearance or counteraction of the deleterious effects of FHB, respectively.

Intestinal damage, assessed by intestinal fatty acid-binding proteins such as iLBP (Figure 3), has been reported previously in cardiovascular surgical patients^[2,5]. To the authors' best knowledge, so far no studies have been performed to evaluate a possible correlation between FHB and gastrointestinal injury in clinical or experimental studies. Recently, we have shown that intestinal epithelial cell injury occurring during and after major cardiovascular surgery is associated with a systemic inflammatory response^[20]. It is tempting to speculate that FHB plays a role in the development of intestinal and also renal injury in such patients, where levels of circulating FHB are found comparable or even higher than those reached in this study^[20,21]. Acute gastrointestinal complications after cardiovascular surgery are known to result in a complicated postoperative period and are associated with high mortality rates. In a current study, we show that the concentrations of plasma FHB and urine N-acetyl glucosaminidase (NAG) levels increase during extracorporeal bypass-assisted cardiovascular surgery, which indicates that hemolysis and tubular epithelial injury have occurred. Interestingly, we have found that the total release of plasma FHB is independently correlated with urine NAG, which in turn is independently associated with the postoperative increase in serum creatinine^[21] used as a marker for acute kidney injury.

Taken together, our data suggest that circulating FHB is not only a health risk in chronic diseases such as sickle-cell anemia, thalassemia and malaria, but also may be a cause for concern in patients subject to extracorporeal circulation, blood transfusion and cell salvage devices resulting in substantial acute hemolysis. Therefore, circulating FHB levels should be closely monitored in clinical practice

when treating these patients, who are at risk of developing gastrointestinal complications. Future studies are needed to develop means to counteract the deleterious effects of circulating FHB.

COMMENTS

Background

Gastrointestinal complications after cardiovascular surgery are feared, while their pathophysiology is often unclear. Cardiovascular surgery is associated with considerable injury to red blood cells, resulting in hemolysis with concomitant release of cell-free hemoglobin. Recently, studies in patients experiencing elevated levels of cell-free hemoglobin have shown a disturbed microcirculatory blood flow.

Research frontiers

Hemolysis is not uncommon during cardiovascular surgery, resulting in elevated circulating levels of cell-free hemoglobin. The effect of hemolysis on intestinal microcirculation and gut wall integrity is unclear, so far. In this study, the authors demonstrate that hemolysis decreases intestinal microcirculatory blood flow, and that hemolysis, in particular the release of cell-free hemoglobin, is associated with intestinal damage.

Innovations and breakthroughs

Recent studies have emphasized the deleterious effects of hemolysis on microcirculatory blood flow and possible induction of organ injury. Moreover, the release of cell-free hemoglobin appears to play a pivotal role through its interference with vascular endothelial nitric oxide. This is the first study to show a decreased intestinal microcirculatory blood flow during elevated levels of circulating cell-free hemoglobin, resulting in intestinal damage. Moreover, a strong correlation between elevated circulating cell-free hemoglobin and intestinal injury is revealed.

Applications

By identifying hemolysis, and in particular the release of cell-free hemoglobin, as a potential initiator of intestinal damage, future studies can now address its specific role in the pathophysiology of gastrointestinal complications in the clinical setting of cardiovascular surgery. Furthermore, studies evaluating therapy options focussed on counteracting the deleterious effects of cell-free hemoglobin are needed.

Terminology

Intravascular hemolysis results in elevated levels of circulating cell-free hemoglobin. Due to its nitric oxide scavenging properties (nitric oxide being the most potent endothelial vasodilator known), the intravascular release of cell-free hemoglobin consequently might result in decreased tissue microcirculation and cause tissue damage. In this study, intestinal injury was measured by evaluating release of ileal lipid binding protein, a protein expressed mainly in the ileum, in mature enterocytes only.

Peer review

The study examined the effects of free hemoglobin and H₂O infusion on artery pressure, intestinal blood flow, and ileal lipid binding protein release in rats, and found that both factors can induce intestinal epithelial injury. The topic is interesting, study is well designed and carefully carried out, manuscript is well written, and results are convincing.

four-fold higher tissue levels of endoglin and VEGF were seen in tumors compared to associated normal tissue. This increased endoglin tissue expression in tumors was significantly related to tumor size ($P < 0.01$), presence of metastases ($P = 0.04$), and a more advanced tumor stage ($P = 0.02$), whereas expression of VEGF was not.

CONCLUSION: We suggest that endoglin is a potential marker to indicate and predict metastases, which might be useful in the post-resection therapeutic approach of patients with GEP-NETs.

Abstract

AIM: To investigate the expression and potential prognostic role of vascular endothelial growth factor (VEGF) and endoglin in gastroenteropancreatic neuroendocrine tumors (GEP-NETs).

METHODS: Microvessel density (MVD) in GEP-NETs was evaluated using endoglin and CD31 immunohistochemistry. In addition, tissue levels of endoglin and VEGF were determined in homogenates by ELISA.

RESULTS: Endoglin was highly expressed on tumor endothelial cells. CD31 MVD in GEP-NETs was significantly higher compared to endoglin MVD ($P < 0.01$). Two- to

INTRODUCTION

Gastroenteropancreatic neuroendocrine tumors (GEP-NETs), including gastrointestinal carcinoids and pancreatic neuroendocrine tumors (PNETs), comprise a very heterogeneous group of neoplasia, with respect to tumor biology, histocytology and prognosis^[1]. Despite

a slow-growing nature, they are primarily malignant^[2]. Angiogenesis, the formation of new blood vessels from the existing vascular bed, is a crucial process in tumor progression. When tumors reach a size of 1–2 mm, they become dependent on neovascularization, not only to provide them with nutrients and oxygen, but also as an exit route for metabolic waste products, further growth of the primary tumor, and eventually, metastatic spread^[3]. One of the key factors in angiogenesis is vascular endothelial growth factor (VEGF), which has numerous effects on endothelial cells (ECs), including induction of migration and differentiation^[4]. Several studies have addressed the prognostic implications of VEGF in patients with GEP-NETs, and trials investigating the action of the anti-VEGF antibody bevacizumab in patients with GEP-NETs are ongoing^[5,6].

Another important growth factor, with a pivotal role in angiogenesis is transforming growth factor (TGF)- β 1, a multifunctional cytokine that is involved in numerous physiological and pathological processes^[7]. Endoglin (CD105) is a co-receptor for TGF- β 1. As a result of its principal expression on ECs of newly formed blood vessels, several studies have suggested that endoglin is a specific marker of neovascularization in various cancer types^[8–10]. In pancreatic carcinomas, high endoglin microvessel density (MVD) has been found to be related to shorter survival, and therefore, is suggested to be a prognostic marker^[11]. In colorectal cancer, the vessel count by positive endoglin staining is able to identify patients at high risk of metastases^[12].

In the present study, we assessed the tissue expression and levels of two key players in the process of angiogenesis, namely endoglin and VEGF, to assess their potential clinical implications in patients with GEP-NETs.

MATERIALS AND METHODS

Patients

After surgical removal, tumor tissues were collected at the Department of Gastroenterology, Leiden University Medical Centre (LUMC), Leiden, and either frozen at -80°C for protein extraction and/or embedded in paraffin for immunohistochemical staining.

Sixty-eight homogenates (27 tumor samples and 41 normal samples) of 27 patients were available for the determination of tissue levels of endoglin. For the measurement of VEGF levels, one tumor sample was exhausted, therefore, the total number of tumor samples comprised 26. For CD31 and endoglin immunostaining, 50 and 49 samples, respectively, of 39 patients, were available. For most patients, but not all, both homogenates and paraffin slides were available. In total, 41 patients with GEP-NETs were included. GEP-NETs comprised PNETs and gastrointestinal neuroendocrine tumors, which were also referred to as carcinoids.

Clinicopathological information was obtained by evaluation of patients' medical files and pathology reports, when available. According to the classification of the World Health Organization for GEP-NETs, tumors were

categorized into well-differentiated neuroendocrine tumor (NET), well-differentiated neuroendocrine carcinoma (NEC), or poorly differentiated NEC^[13]. From some patients, the WHO classification was not assessable due to lack of specified classification. All studies were performed according to the guidelines of the LUMC medical ethics committee, in compliance with the Helsinki Declaration.

Immunohistochemistry

Immunohistochemistry was performed as follows. Tissues were fixed in formalin, embedded in paraffin, and cut into 5- μm sections. After deparaffinization and rehydration, endogenous peroxidases were blocked in methanol containing 0.3% H_2O_2 (Merck, Darmstadt, Germany). Antigen retrieval was performed by boiling in 0.01 mol/L citrate buffer, pH 6.0, for 10 min. Slides were incubated overnight at room temperature (RT) with primary antibodies: biotinylated goat anti-human endoglin (1:200; R&D Systems Europe, Abingdon, UK), or mouse monoclonal anti-CD31 (1:400; Dako, Glostrup, Denmark) diluted in PBS with 1% bovine serum albumin (BSA), as described previously^[14]. Immunodetection was performed with a biotinylated goat anti-mouse antibody (for CD31) and horseradish peroxidase (HRP)-streptavidin complex (both Dako) for 30 min at RT. Staining was visualized using 0.05% 3,3'-diaminobenzidine (Sigma, Darmstadt, Germany) that contained 0.0038% H_2O_2 . Colon carcinomas were used as positive controls. Negative controls were included by omitting the primary antibodies. Representative photomicrographs were taken with an Olympus BX-51TF microscope equipped with a DP23-3-5 camera.

The endoglin and CD31 MVD in the tumor-bearing area were quantified by computerized analysis. Four representative tumor areas for either endoglin or CD31 were selected and photographed at $100\times$ magnification. Images were binarized and the extent of staining was quantified using ImageJ 1.43u (National Institutes of Health, Bethesda, MD, USA). Finally, the average MVD out of four photographs was taken. The microvessel quantification was performed blinded, that is, without knowledge of patients or tumor characteristics, and expressed as the number of pixels per field $\times 1000$.

Quantitative human endoglin and VEGF determinations in tissue samples

Tissues were homogenized and protein concentrations were determined according to Lowry *et al.*^[14,15]. Endoglin levels were determined in tissue homogenates, using a commercially available quantitative immunoassay (ELISA) for human endoglin, performed according to the manufacturer's instructions (R&D Systems), as described before^[14]. VEGF tissue levels were determined using a commercially available duoset (R&D Systems) as described before^[16].

Statistical analysis

Statistical analysis was performed using SPSS version 16 and GraphPad Prism version 5. Unpaired *t* test and one-

way ANOVA were used to compare mean levels of endoglin and VEGF between various data sets. Orthogonal regression analysis and Pearson's correlation (*r*) were used to explore the relationship between two variables. Survival curves were plotted using the method of Kaplan and Meier. Results are reported as mean ± SE. A *P* value of < 0.05 was considered statistically significant.

RESULTS

Overall, 41 patients with NETs were included (Table 1), of which, the majority were female. Most patients (28/41) had a solitary primary tumor, while 13/41 patient had multiple primaries. Primary tumors of 23/41 patients were localized in the pancreas, 5/41 in the duodenum, 10/41 in the small bowel, 1/41 in the appendix, 1/41 in the sigmoid, and in one patient, the exact primary tumor location was unknown. Functional tumors were mainly insulinomas (42.1%) and gastrinomas (52.6%). Tumor size was significantly different between the groups (*P* = 0.01), with a smaller tumor size for functional PNETs. Metastases were seen in the majority of patients, with an almost equal distribution of lymph node or liver location. Angio-invasion was present in only 18.3% of the tumors.

Endoglin and VEGF tissue levels were measured in 27

Figure 1 Orthogonal regression analysis of endoglin tissue levels and tumor size (*n* = 26) in 17 patients. (In one patient, information about tumor size was missing, so this patient was not included in this analysis). Increasing endoglin levels in tumors were significantly correlated with greater tumor size.

tumor samples from 18 patients with GEP-NETs. Endoglin and VEGF levels were significantly increased in tumors compared to (associated) normal tissues (Table 2). However, among the various types of GEP-NETs, both endoglin and VEGF levels were comparable. Metastatic tumors showed significantly higher endoglin levels compared to those in primary lesions. VEGF levels were also increased in metastases, although not significantly. Furthermore, well-differentiated NECs showed significantly higher endoglin levels compared to well-differentiated NETs. Again, this difference in VEGF levels was not statistically significant, although levels in well-differentiated NECs were also increased. Of particular interest, we observed that primary tumor tissues of patients who had developed lymph node or liver metastases displayed significantly higher endoglin levels than from those without metastases. Neither endoglin nor VEGF levels were significantly related to other clinicopathological parameters, including patients' age, sex, hormonal status (i.e. functional or non-functional) of the PNETs, or the presence of angio-invasion. Endoglin tissue levels, but not tissue levels of VEGF, were found to increase with tumor size (Figure 1). Finally, endoglin tumor levels showed no significant correlation with VEGF tumor levels (*r* = 0.11 with *P* = 0.59).

The immunohistochemical expression of endoglin and CD31 was analyzed in 39 patients with GEP-NETs. All tumors showed expression for CD31 and endoglin on intratumor vascular ECs. Endoglin expression was mainly observed on ECs of small tumor-associated blood vessels, whereas its expression in normal, non-tumorous tissue was weak or negative, in contrast to CD31 staining (Figure 2). The CD31 MVD was found to be significantly higher than the endoglin MVD in 73% of the tumor samples (*P* < 0.01). No significant differences in endoglin and CD31 MVD were observed between carcinoids and PNETs (Table 3). Furthermore, endoglin and CD31 MVD were not significantly related to clinicopathological parameters such as patients' age, sex, tumor size, functionality, and angio-invasion.

Endoglin and CD31 MVD were significantly corre-

lated with endoglin tumor levels; $r = 0.64$ with $P < 0.01$ (Figure 3) and $r = 0.58$ with $P < 0.01$, respectively. VEGF tumor levels were not correlated with endoglin MVD ($r = 0.28$ with $P = 0.25$), but were borderline significantly correlated with CD31 MVD ($r = 0.43$ with $P = 0.07$).

To evaluate the prognostic potential of endoglin and VEGF tissue levels, Kaplan-Meier survival analysis was performed (Figure 4) by dividing the patients into two groups (i.e. low vs high) using the mean value of endoglin and VEGF tumor levels (Table 2). Both endoglin and VEGF tissue levels were not significantly related to patient survival. Furthermore, patients were divided into two groups based on the MVD of endoglin and CD31. Both

parameters were not significantly correlated with overall survival of these patients.

DISCUSSION

In this study, we observed that the expression of the angiogenic cell marker endoglin was related to tumor size, aggressiveness and metastatic potential in patients with GEP-NETs, whereas expression of another key player in angiogenesis, namely VEGF, was not.

In general, GEP-NETs are highly vascularized. In recent years, it has become clear that angiogenesis has important effects on tumor progression in several cancers,

Figure 2 Immunostaining of endoglin and CD31 on peritumoral and intratumoral vessels in gastroenteropancreatic neuroendocrine tumors. A: Endoglin staining was limited to angiogenic vessels, whereas CD31 stained both old and new blood vessels in tumor tissue. Magnification 100 ×; B: Representative endoglin staining in a pancreatic neuroendocrine tumor and a gastrointestinal carcinoid metastasis (small bowel mesentery). Magnification 100 ×. Inserts show a higher magnification at 200 ×.

Figure 3 Correlation analysis of the endoglin microvessel density and endoglin tissue levels in tumors ($n = 17$). Endoglin MVD was significantly correlated with tumor levels of endoglin.

and the therapeutic role of angiogenesis inhibitors in the treatment of cancers is increasing^[17,18]. In this study, we investigated whether endoglin and VEGF were related to any clinicopathological characteristics of GEP-NETs, and evaluated their potential prognostic implications.

By immunohistochemistry, we observed high endoglin expression on vascular ECs in tumor tissues of GEP-NETs. In contrast to CD31, immunopositivity of endog-

lin was mainly observed on newly formed blood vessels, which indicates that endoglin is more representative of tumor neovascularization than the pan-endothelial marker CD31.

Furthermore, we found that endoglin tissue levels were significantly higher in tumors compared to normal tissues. We observed that increased endoglin expression was indicative of metastatic disease. Endoglin levels were higher in metastases compared to primary tumors, and primary tumors with metastases showed higher endoglin levels compared to tumors without metastases. Additionally, endoglin levels were increased in well-differentiated NECs compared to well-differentiated NETs, and higher endoglin levels were related to larger tumor size in patients with GEP-NETs. In several cancers, the extent of tumor angiogenesis was shown to reflect their potency to become invasive and form metastases^[19,20]. Our data indicate that tissue endoglin can serve as a potential assessment marker for tumor aggressiveness (i.e. NEC *vs* NET) and the presence of metastases following tumor resection. In the context of anticancer therapy, anti-endoglin treatment might provide a new effective anti-angiogenic strategy for GEP-NETs, but more research is needed. However, several promising *in vivo* and *in vitro* studies using anti-endoglin antibodies for anti-cancer treatment have recently been published^[21].

In the present study, we did not evaluate the immuno-

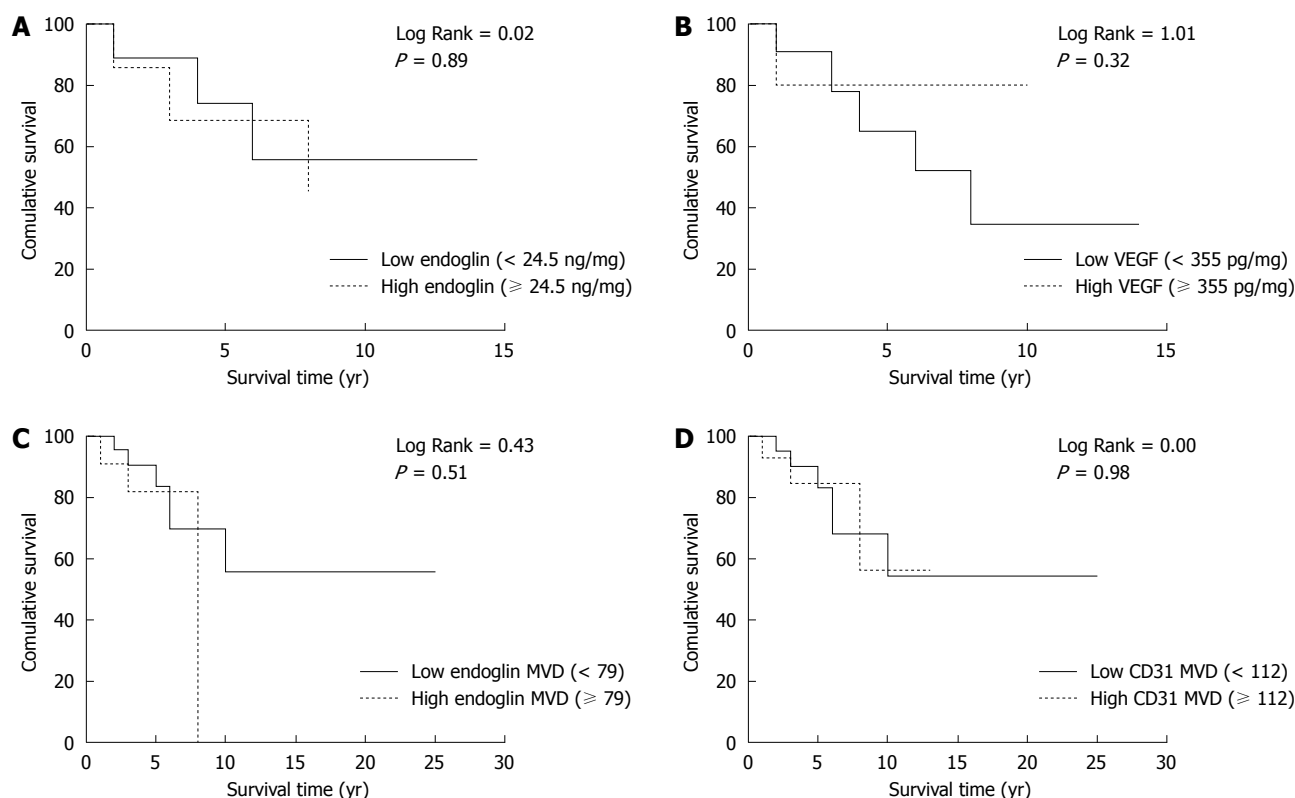

Figure 4 Kaplan-Meier survival analysis for endoglin tumor levels (A), vascular endothelial growth factor tumor levels (B), endoglin microvessel density (C) and CD31 microvessel density (D). Patients were divided into two groups based on mean tumor levels (A and B) or mean microvessel density (MVD) scores (C and D). None of the parameters showed a significant correlation with patient survival. VEGF: Vascular endothelial growth factor.

histochemical expression of VEGF. High immunoeexpression of VEGF on GEP-NETs has already been shown by others, but opposing results regarding the prognostic role of VEGF in these tumors have been reported. Takahashi *et al.*^[22] found no correlation of VEGF-A immunoeexpression with growth of blood vessels, hematogenous spread or tumor growth in pancreatic endocrine tumors. In contrast, Zhang *et al.*^[23] have revealed that strong expression of VEGF was associated with increased angiogenesis and poor prognosis in patients with GEP-NETs. However, we determined tissue VEGF expression in GEP-NETs and found that VEGF tissue levels showed a similar pattern to endoglin, but were not significantly related to any clinicopathological parameter. Therefore, we assume that, although VEGF is most likely to be involved in the process of neoplastic blood vessel formation in GEP-NETs, this key mediator of angiogenesis is not the appropriate prognostic marker in these tumors. In contrast, our data suggest that endoglin can function as a predictive marker for the development of metastases in GEP-NETs. Endoglin is a co-receptor for TGF- β 1. Among the various members of the TGF- β family, TGF- β 1 is mostly involved in cancer, and has been shown to stimulate angiogenesis^[24]. Endoglin is an important modulator of the TGF- β response; particularly in tumor pathogenesis^[25]. In another study by our group, strongly increased tissue levels of endoglin were observed in colorectal cancer, whereas premalignant lesions displayed endoglin levels comparable to those in normal tissues, which supports the pivotal role of endoglin in tumor progression^[14].

The fact that neither endoglin nor VEGF levels were associated with patient survival might be due to the relatively good prognosis of the patients. Gastrointestinal carcinoids show a 5-year survival rate of about 70%, whereas PNETs have a reported 5-year survival rate ranging from 25% to 100%, even in the case of (unresectable) liver metastases^[26,27]. In our study cohort, 10/18 patients in whom endoglin or VEGF levels were determined were still alive at the end of the study (median survival 8 years), which makes it unlikely to use one of these parameters as a predictor of outcome or survival marker. However, our data support a role for endoglin in identifying patients with GEP-NETs at risk for metastasis.

It is worth reiterating that the current study involved a relatively small number of patients. Nevertheless, GEP-NETs are a rare disease with a low incidence, which leads to general scarcity of patients and samples. However, we believe that the significant differences observed here are representative and illustrate the differential expression pattern of endoglin and VEGF among GEP-NETs.

In conclusion, we suggest that endoglin is a potential marker to predict present and future metastases, which might help to optimize the therapeutic approach in patients with GEP-NETs.

COMMENTS

Background

Angiogenesis is required for tumor growth and progression and development of metastases. Vascular endothelial growth factor (VEGF) and endoglin both

play an important role in angiogenesis. Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) are rare and heterogeneous. Although markers for GEP-NETs exist, sensitive and specific markers that indicate tumor growth and behavior are lacking.

Research frontiers

The aim of the present study was to evaluate the expression and potential prognostic role of VEGF and endoglin in GEP-NETs.

Innovations and breakthroughs

From other studies it is already known that GEP-NETs are highly vascularized tumors. Although several studies have investigated the immunohistochemical expression VEGF in GEP-NETs, VEGF tissue levels or endoglin expression have not been studied in these tumors before. Therefore, this study is believed to be the first to investigate tissue expression and levels of VEGF and endoglin in GEP-NETs, to determine the clinical impact of these angiogenic factors in patients with GEP-NETs.

Applications

Based on our findings, we suggest that endoglin is a potential marker to indicate the presence of metastases in GEP-NETs. By demonstrating that increased endoglin expression on tumors is related to tumor aggressiveness (including grade of differentiation, size and presence of metastases), this study could present a future target for post-resection therapeutic intervention in the treatment of patients with GEP-NETs.

Terminology

Angiogenesis is the process of new blood vessel formation. This process is induced by several growth factors, including VEGF, and transforming growth factor (TGF)- β 1. Endoglin is a co-receptor for TGF- β 1 and a marker for angiogenic endothelial cells.

Peer review

This is a well-written paper that describes a study that evaluated the expression and potential prognostic role of VEGF and endoglin in a small sample of GEP-NETs patients, and is of considerable interest.

Abstract

AIM: To investigate the relationship between low-dose aspirin-induced small bowel mucosal damage and blood flow, and the effect of rebamipide.

METHODS: Ten healthy volunteers were enrolled in this study. The subjects were divided into two groups: a placebo group given low-dose aspirin plus placebo and a rebamipide group given low-dose aspirin plus rebamipide for a period of 14 d. Capsule endoscopy and contrast-enhanced ultrasonography were performed before and after administration of drugs. Areas under the curves and peak value of time-intensity curve were calculated.

RESULTS: Absolute differences in areas under the curves were -1102.5 (95% CI: -1980.3 to -224.7, P

INTRODUCTION

There have been several reports recently on the incidence of small bowel complications induced by non-steroidal anti-inflammatory drugs (NSAIDs)^[1,2]. However, there have been few investigations of low-dose acetylsalicylic acid (ASA)-induced small bowel damage. Endo *et al*^[3] reported that small bowel pathology was observed in 80%

of 10 healthy subjects after 2 wk with low-dose ASA but that there was no significant difference in mucosal break in subjects who used low-dose ASA and those who did not (with ASA: 30%, without: 0%). Smecuol *et al*^[4] reported that 3 cases of erosion and 1 case of bleeding were observed in 4 of 20 healthy subjects, and these cases were thought to have been caused by increase in permeation of the small intestinal mucosa (increased sucrose urinary excretion: 107.0 mg; range, 22.9–411.3, $P < 0.05$). These results indicated that mucosal breaks caused by taking low-dose ASA occurred not only in the upper gastrointestinal tract (GI) but also in the lower GI tract. However, the cause of small bowel injury is not clear.

Bjarnason *et al*^[5] reported that NSAIDs-induced small intestinal damage is caused by a lack of mucosal prostaglandins, decrease in blood flow, induction of nitric oxide and increased permeability. There are several key words for this hypothesis and we should investigate them, such as permeability, blood flow, free radicals, nitric oxide, and inflammation.

There are various techniques for measurement of blood flow in organs. Nishida *et al*^[6] reported that measurement of liver blood flow by using contrast-enhanced ultrasonography (CE-US) was useful for diagnosis of pancreatic carcinoma, and there have been some reports on evaluation of gastric blood flow using CE-US^[7,8].

We focused on blood flow in the small bowel as a possible cause of ASA-derived small bowel complications. There is no therapeutic strategy for the prevention of these complications. We wanted to investigate a candidate drug. Rebamipide is an anti-ulcer drug^[9]. Its actions include increasing endogenous prostaglandin^[10], scavenging free radicals, suppressing permeability, and elevating blood flow in the stomach^[11]. In this study, we investigated the relationship between low-dose ASA-induced small bowel mucosal damage and small bowel blood flow, and we also evaluated the preventive effect of rebamipide against small bowel damage and the effect of rebamipide on blood flow.

MATERIALS AND METHODS

This study was approved by the Ethics Committee of Hokkaido University Hospital. Written informed consent was given by all participants.

Inclusion and exclusion criteria

Inclusion criteria were absence of upper and lower GI injuries, such as erosion, ulcer, and bleeding on endoscopy. The subjects enrolled in this study were aged from 20 to 50 years. Subjects who were taking some drugs were excluded.

Study design

All of the participants in this study were healthy. A randomized, double-blind, cross-over, placebo-controlled trial using rebamipide was performed.

The study design is shown in Figure 1. The subjects were divided into two groups: a placebo group with low-

dose ASA (100 mg once daily) plus placebo (three times daily) and a rebamipide group with low-dose ASA (100 mg once daily) plus rebamipide (100 mg three times daily). The first period lasted 14 d. After a wash-out period of more than 14 d and the second period lasted a further 14 d. All subjects underwent capsule endoscopies and CE-US before and after each administration period.

The placebo was prepared by Yamanami Pharmacy. Rebamipide (100 mg) and the placebo were each contained in a soft colored capsule.

Randomization

Subjects were recruited for the treatment sequences in a random fashion according to a randomization schedule for the treatment period. A randomization number that was associated with a specific treatment, either rebamipide or placebo, was assigned to each subject. Randomized numbers were generated by the SAS program.

Capsule endoscopy

We used the Given video capsule system (PillCam®, Given Imaging Ltd., Yoqneam, Israel) in this study. The capsule endoscopy procedure and methodology for the review of images were conducted as previously described. All video images were analyzed by skilled reviewers (Nishida U and Kato M) who remained blinded to the subjects' treatment protocol. All images were saved for final comprehensive analysis upon completion of post-treatment capsule endoscopies.

Contrast-enhanced ultrasonography

The longitudinal view of the small bowel was imaged in the left upper abdomen. Baseline CE-US and contrast-enhanced CE-US were performed with a 7.5 MHz center frequency linear transducer using an ultrasound unit SSA-790A (AplioXG™, Toshiba Medical Systems Co., Otawara, Japan). The imaging mode was pulse subtraction. Prior to CE-US, 20 mg of scopolamine butylbromide was injected intravenously to suppress peristalsis. Perflubutane microbubbles (Sonazoid; GE Healthcare), a lyophilized preparation reconstituted for injection, were injected intravenously at a concentration of 0.015 mL/kg. Ten seconds after contrast medium injection, enhanced signals from blood flow in the small intestinal wall were captured until 45 s on cine clips equipped with the ultrasound unit. Regions of interests of fixed sizes were placed in the mucosal area of the small bowel at three regions (Figure 2). A time intensity curve (TIC) of blood flow enhancement signal in the small bowel was plotted from recorded ultrasonographic images using ImageLab software, which was developed by C++ software dedicated to CE-US images obtained by AplioXG. Area under the curve (AUC) and TIC peak value (maximum intensity) were calculated from the TIC. These values were used to estimate small bowel blood flow inside the mucosal layer.

Evaluation

The primary end point was evaluation of the change of

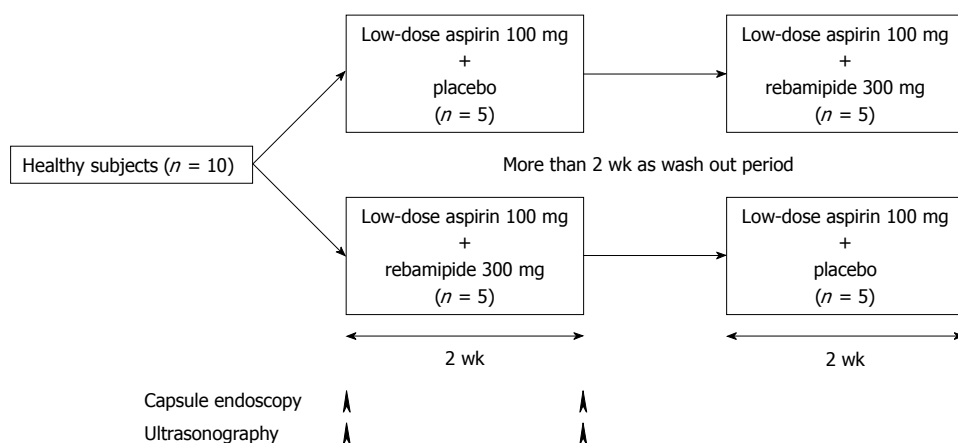

Figure 1 Study design. A randomized placebo-controlled double-blinded cross-over study was performed using rebamipide. Capsule endoscopy and contrast-enhanced ultrasonography were performed before and after administration of drugs.

Figure 2 Image of contrast-enhanced ultrasonography. Regions of interests (ROI) were placed in the mucosal area of the small bowel at three regions. A time intensity curve of blood flow enhancement signal was plotted from recorded ultrasonographic images.

low-dose ASA-induced small bowel blood flow. Blood flow was measured by CE-US. TIC for blood flow in the small bowel was plotted from recorded CE-US images with Image Lab software. The secondary end point was evaluation of the preventive effect of rebamipide with low-dose ASA-related small bowel damages such as erosion, erythema, and petechiae.

In this study, a mucosal break of the small bowel was defined as erosion, ulcer, bleeding or perforation.

Safety assessment

Symptoms and other adverse events were recorded through this study period. If these events occurred, they were treated appropriately.

Statistical analysis

The primary end point was to evaluate changes in small bowel blood flow. Blood flow was estimated by AUC and TIC. They were analyzed by absolute differences between before and after each administration periods. They were evaluated by 95% confidential intervals. The secondary end point was to evaluate the preventive ef-

fect of rebamipide. Preventive effect was evaluated using small bowel mucosal injuries and subject numbers that got mucosal breaks. Small bowel injuries (ulcer, erosion and erythema) were described by mean \pm SD. They were analyzed by Fischer's exact test. Findings of $P < 0.05$ were considered significant. Statistical analyses were performed using SAS[®] version 8.2 (SAS Institute, Cary, NC).

RESULTS

Subjects

Ten males were enrolled in this study. The mean age of the subjects was 29 ± 5 years. Two subjects were infected with *Helicobacter pylori*.

Evaluation of blood flow

The values of AUC in the placebo group and rebamipide group were 464.2 ± 381.8 and 1414.1 ± 1340.3 , respectively. The absolute difference is shown in Table 1. In the placebo group, there was a significant difference in the values of AUC before and after taking ASA (difference: -1102.5 , 95% CI: -1980.3 to -224.7 , $P = 0.0194$). The difference in the rebamipide group, -152.7 , was not statistically significant (95% CI: -1604.2 to 641.6 , $P = 0.8172$).

Peak values of the TIC in the placebo group and the rebamipide group were 226.2 ± 251.4 and 402.5 ± 283.9 , respectively. In the placebo group, the difference in the peak values of TIC before and after taking ASA was -148.0 (95% CI: -269.4 to -26.2 , $P = 0.0225$), which was statistically significant. The difference in the rebamipide group, 28.3 , was not statistically significant (95% CI: -269.0 to 325.6 , $P = 0.8343$). The differences are shown in Table 1.

Small intestinal injuries

Changes in the numbers of erosions, petechiae and erythemas are shown in Table 2. Differences in the numbers of erosions, petechiae and erythemas in the placebo group were 0.5 ± 1.0 , 10.1 ± 53.6 and -1.0 ± 2.3 , respectively, and those in the rebamipide group were 0.0 ± 0.0 , -8.6 ± 15.4 and -0.6 ± 1.0 , respectively.

Table 1 The evaluation of area under the curve and time intensity curve by ultrasonography before and after taking low-dose aspirin ($n = 10$)

	Placebo			Rebamipide		
	A.D.	95% CI	P-value	A.D.	95% CI	P-value
AUC	-1102.5	-1980.3 to -224.7	0.0194	-152.7	-1604.2-641.6	0.8172
TIC	-148.0	-269.4 to -26.2	0.0225	28.3	-269.0-325.6	0.8343

A.D.: Absolute differences; AUC: Area under the curve, TIC: Time intensity curve.

Table 2 The evaluation of the preventive effect of rebamipide on low-dose aspirin-induced worsened small bowel injury compared with placebo (mean \pm SD)

	Placebo	Rebamipide
Erosion	0.5 \pm 2.7	0.0 \pm 0.0
Petechiae	10.1 \pm 53.6	-8.6 \pm 15.4
Erythema	-1.0 \pm 2.3	-0.6 \pm 1.0

Table 3 Number of subjects with small intestinal mucosal breaks

	Placebo	Rebamipide
Mucosal breaks	2	0

No ulcer, bleeding or perforation was observed. There were 2 cases of mucosal break in the placebo group but no cases in the rebamipide group (Table 3). Two cases of erosions were localized in the ileum region (Figure 3).

Safety assessment

No adverse events were observed throughout the study period.

DISCUSSION

In the present study, treatment with low-dose ASA resulted in a decrease in small bowel blood flow, with changes in AUC of -1102.5 (95% CI: -1980.3 to -224.7, $P = 0.0194$) and peak value of TIC of -148.0 (95% CI: -269.4 to -26.2, $P = 0.0225$) (Table 1). Low-dose ASA also caused small bowel damage. Treatment with ASA induced small bowel erosion in 2 cases and increased petechiae (Tables 2 and 3). These results indicated that low-dose ASA-induced small bowel injury is correlated with decreasing small bowel blood flow. Bjarnason *et al*^[5] proposed a cascade as the mechanism of NSAIDs-induced small bowel injury: NSAIDs induce a decrease in prostaglandin, the decrease in prostaglandin leads to a decrease in small bowel blood flow, and the decrease in small bowel blood flow leads to an increase in small bowel inflammation and injury. In another pathway, increasing permeability also leads to small bowel injury. Our results support their hypothesis; blood flow was one of the mechanisms of NSAIDs-related small bowel injury. However, small bowel damage was slight in our subjects. This might be due to the short-term use of ASA and the fact that the subjects were young and healthy.

**Figure 3** Image of capsule endoscopy. Low-dose aspirin induced mucosal breaks such as denuded areas and erosions were detected in the placebo group. A: Denuded area; B: Erosion.

Moreover, most patients who take low-dose ASA are chronic users, and decrease in small bowel blood flow may continue for a long time. Therefore, long-term observation of small bowel blood flow is needed.

On the other hand, low-dose ASA-induced small bowel erosions in the placebo group and the rebamipide group were 20% and 0%, respectively.

Small bowel blood flow did not decrease in the rebamipide group; changes in the AUC and TIC were -152.7 and 28.3 (not statistically significant). Kim *et al*^[11] reported that rebamipide did not decrease upper GI blood flow compared with placebo in healthy subjects taking ibuprofen. Our results suggested that rebamipide prevents a decrease in lower GI blood flow as well as a decrease in upper GI blood flow.

Recently, there have been three reports on the usefulness of drugs for low-dose ASA and NSAIDs-induced small bowel complications. Fujimori *et al*^[12] reported that misoprostol, a prostaglandin analogue, prevented

diclofenac-induced small bowel complications in healthy subjects. Niwa *et al.*^[13] reported that rebamipide prevented diclofenac-induced small bowel injury in healthy subjects. Shiotani *et al.*^[14] reported that geranylgeranylacetone (GGA: Teprenone) did not prevent low-dose ASA-induced small bowel damage. These drugs are cytoprotective drugs for gastric ulcer and gastritis. A proton pump inhibitor is useful for upper GI tract. However, it is not effective for the lower GI tract because of a lack of acid secretion. Further investigation is therefore needed to establish a novel therapeutic strategy for chemical-induced lower GI complications. These three reports may suggest that tentative drug for small bowel is needed to have the action for increasing prostaglandin as mechanism.

The number of subjects in our study was small. A study using a larger number of subjects is needed. Recently several mechanisms of ASA-induced small bowel complications were treated. But we explained only blood flow one of these several mechanisms. As the future study, we will need to examine relationship among several actions and functions.

In conclusion, low-dose ASA-induced decrease in small bowel blood flow is correlated with small-bowel mucosal injury. Rebamipide does not decrease small bowel blood flow.

COMMENTS

Background

Low-dose aspirin has been widely used for prevention of cardiovascular and cerebrovascular events. Several studies have shown that mucosal breaks caused by taking low-dose aspirin occurred not only in the upper gastrointestinal tract but also in the lower gastrointestinal tract.

Research frontiers

However the cause of small bowel injury is not clear. One of the mechanisms of drug-induced small bowel damage is decrease in blood flow. In this study, the authors investigated the relationship between low-dose aspirin-induced small bowel mucosal damage and blood flow using video capsule endoscopy and contrast-enhanced ultrasonography, and the authors also evaluated the effect of rebamipide on blood flow.

Innovations and breakthroughs

Recent reports have highlighted the mechanisms of aspirin-induced small bowel damage, and the prevention and treatment of aspirin-induced small bowel damage. This is the first study to report that short-term administration of low-dose aspirin is associated with small bowel injuries and blood flow. And rebamipide does not decrease small bowel blood flow.

Applications

This study may represent a future strategy for therapeutic intervention in the treatment of patients with low-dose aspirin-induced small bowel mucosal damage.

Terminology

Rebamipide is an anti-ulcer drug. Its actions include for increasing endogenous prostaglandin, scavenging free radicals, suppressing permeability, and elevating blood flow in the stomach. In this study contrast-enhanced ultrasonography were performed with a 7.5 MHz center frequency linear transducer using an ultrasound unit SSA-790A. The imaging mode was pulse subtraction.

Peer review

This study focuses on the evaluation of small bowel blood flow in healthy subjects with low-dose aspirin (a randomized placebo-controlled double-blinded cross-over study using video capsule endoscopy and contrast-enhanced ultrasonography). Low-dose acetylsalicylic acid-induced decrease in small bowel blood flow is correlated with small-bowel mucosal injury. The collected experiences are interesting

and may represent a future strategy for treatment of patients with drug-induced small bowel mucosal damage.

Abstract

AIM: To investigate the role of ¹⁸F-fluorodeoxyglucose positron emission tomography (FDG-PET) in the diagnosis of small pancreatic cancer.

METHODS: This study involved 31 patients with proven invasive ductal cancer of the pancreas. The patients were divided into 3 groups according to the maximum diameter of the tumor: TS1 (maximum tumor size ≤ 2.0 cm), TS2 (> 2.0 cm and ≤ 4.0 cm) or TS3-4 (> 4.0 cm). The relationships between the TS and various diagnostic tools, including FDG-PET with dual time point evaluation, were analyzed.

RESULTS: The tumors ranged from 1.3 to 11.0 cm in diameter. Thirty of the 31 patients (97%) had a positive FDG-PET study. There were 5 patients classified as TS1, 15 as TS2 and 11 as TS3-4. The sensitivity of FDG-PET, computed tomography (CT) and magnetic resonance

imaging (MRI) were 100%, 40%, 0% in TS1, 93%, 93%, 89% in TS2 and 100%, 100%, 100% in TS3-4. The sensitivity of FDG-PET was significantly higher in comparison to CT and MRI in patients with TS1 ($P < 0.032$). The mean standardized uptake values (SUVs) did not show a significant difference in relation to the TS (TS1: 5.8 ± 4.5 , TS2: 5.7 ± 2.2 , TS3-4: 8.2 ± 3.9), respectively. All the TS1 tumors (from 13 to 20 mm) showed higher SUVs in FDG-PET with dual time point evaluation in the delayed phase compared with the early phase, which suggested the lesions were malignant.

CONCLUSION: These results indicate that FDG-PET with dual time point evaluation is a useful modality for the detection of small pancreatic cancers with a diameter of less than 20 mm.

INTRODUCTION

Pancreatic cancer is the 5th leading cause of cancer-related mortality in Japan, with an estimated 20 000 deaths attributable to the disease^[1,2]. The annual mortality rate closely

approximates the annual incidence, thereby reflecting a generally short survival time associated with pancreatic cancer, which is generally less than 1 year. Cancer of the pancreas has the shortest median survival time out of all cancer types in a stage for stage basis. Early diagnosis is the most important factor for improving the overall survival and quality of life in patients with pancreatic cancer.

Recently, positron emission tomography (PET) has demonstrated superiority to computed tomography (CT), ultrasonography (US), and endoscopic US (EUS) in its sensitivity and specificity in diagnosing pancreatic cancer^[3-6]. Furthermore, the metabolic activity of the tumor may be of prognostic significance. We have been reported the efficacy of delayed additional ¹⁸F-fluorodeoxyglucose PET (FDG-PET) imaging in the differential diagnosis of malignant from benign lesions in patients who are suspected of having pancreatic cancer^[7]. Furthermore, the detection rate of liver metastases smaller than 1 cm in diameter from pancreatic cancer was only 33% on early image and 58% on delayed image^[7]. However, the role of dual time point FDG-PET in the diagnosis of small pancreatic cancers has yet to be established.

Therefore, the present study investigated whether small cancers of the pancreas could be accurately diagnosed by FDG-PET with dual time point evaluation.

MATERIALS AND METHODS

Patients

Thirty-one patients with pancreatic carcinoma suspected on the basis of conventional radiological studies (22 males and 9 females; mean age, 65 years; age range, 44-82 years) and who underwent FDG-PET between 2003 and 2007 were retrospectively selected. Patients were excluded from this study if they had poorly controlled diabetes mellitus (presenting with blood glucose level > 200 mg/dL prior to PET imaging). Conventional radiological staging was performed by means of CT or magnetic resonance imaging (MRI). The location of the cancer was in the head of the pancreas in 17 patients and in the body and tail in 14 patients. Twelve of the 31 cancers were diagnosed to be unresectable, and 19 patients eventually underwent surgery with a curative intention, although the cancer turned out to be unresectable in 7 because of intraoperative findings.

Methods

The patients were divided into 3 groups according to the maximum diameter of the tumor: TS1 (maximum size ≤ 2.0 cm), TS2 (> 2.0 cm and ≤ 4.0 cm) or TS3-4 (> 4.0 cm) as indicated by the classification system of the Japan Pancreas Society. FDG-PET was analyzed semi-quantitatively using the standardized uptake values (SUVs). The sensitivity of diagnosing pancreatic cancer was examined for FDG-PET, CT, MRI and the serum levels of carcinoembryonic antigen (CEA) and carbohydrate antigen 19-9 (CA19-9) with regard to the size of the tumor. The details of SUVs, the histological findings and correlation of CT findings were evaluated in patients with TS1 pan-

creatic cancer. This study was performed retrospectively by collecting and analyzing data from the patient records.

FDG-PET

The FDG-PET images were acquired with a PET machine (Siemens EXACT HR+, CTI, Knoxville, TN, USA). The patients were required to fast for at least 4 h before PET imaging. The emission images were acquired (early image) 1 h after the intravenous administration of 5 mCi of FDG. Delayed PET emission images of the upper abdomen were acquired at 2 h after administration of ¹⁸F-FDG, using 2 or 3 bed positions with a 3-min acquisition at each^[7]. This acquisition was immediately followed by a transmission scan of the same transverse planes, using a 2-min acquisition at each bed position. The early and delayed PET images were reviewed independently and consecutively by 2 radiologists with extensive experience in FDG-PET imaging. PET images were compared with the corresponding CT and/or MRI images for accurate anatomical identification of the tumor. The findings were considered to be positive when both radiologists strongly suspected malignant disease. In addition, the images were analyzed semi-quantitatively using the SUV, as reported elsewhere. Briefly, for semi-quantitative analysis, a region of interest was placed over the entire FDG-avid lesion including the largest amount of radioactivity using the transverse PET image. The SUV was calculated as: $SUV = (\text{activity in region of interest in mCi}) / (\text{injected dose in mCi} / \text{weight in kg})$.

CT

CT studies were performed with a multidetector row CT scanner (Aquilion, Toshiba, Tokyo, Japan). Helical images of the abdomen were routinely obtained and reconstructed with 5 mm thickness. After pre-contrast CT scans, arterial dominant phase images of dynamic CT were obtained starting 40 s after the beginning of the intravenous bolus injection (3 mL/s) of 100 mL of iodized contrast medium at 350 mg/mL. The pancreatic phase and the late phase (near equilibrium phase) were also obtained, starting at 60 and 180 s after injection, respectively. The CT images were interpreted independently and consecutively by 2 radiologists with extensive experience of more than 10 years in CT scanning. The findings of the CT scans were considered positive when both radiologists strongly suspected malignant disease due to a discrete low-attenuation mass within the pancreas.

MRI

Two 1.5 T superconducting units, Signa Advantage (General Electric, Milwaukee, WI, USA, USA) and Visart (Toshiba, Tokyo, Japan), were used for MRI. T1-weighted gradient-echo imaging; FS-T2-weighted turbo SE imaging and heavily T2-weighted turbo SE images were acquired in the order of scan after initial T1-weighted localizing images were obtained in the coronal and trans-axial directions.

Statistical analysis

The χ^2 test was employed for a statistical comparison of

Table 1 Clinicopathological profiles of the 31 patients

	mean \pm SD (range) or <i>n</i> (%)
Age (yr)	65 \pm 9 (44-82)
Gender (M:F)	22:9

Head	17 (55)
Body	11 (35)
Tail	3 (10)
Maximum tumor diameter (cm)	3.8 \pm 2.0 (1.3-11.0)
SUV	6.5 \pm 3.3 (2.5-15.8)

SUV: Standardized uptake value.

Table 2 Correlations between tumor size and sensitivity of positron emission tomography, computed tomography, magnetic resonance imaging or tumor markers

TS (cm)	<i>n</i>	PET (%)	CT (%)	MRI (%)	CEA (%)	CA19-9 (%)
TS1 (≤ 2)	5	100 ^a	40	0	0	40
TS2 ($> 2, \leq 4$)	15	93	93	89	20	73
TS3-4 (> 4)	11	100	100	100	73	91

TS: Tumor size; PET: Positron emission tomography; CT: Computed tomography; MRI: Magnetic resonance imaging; CEA: Carcinoembryonic antigen; CA19-9: Carbohydrate antigen 19-9. ^a*P* = 0.002 *vs* MRI or CEA, *P* = 0.038 *vs* CT or CA19-9.

the sensitivity of FDG-PET, CT, MRI, CEA and CA19-9. The Student *t* test was used to compare the values of the SUV between the groups. All statistical analyses were performed using SPSS software (SPSS, Chicago, USA). A *P* value < 0.05 was considered to be statistically significant.

RESULTS

Table 1 shows the clinicopathological profiles of the 31 patients. The sensitivity of FDG-PET, CT, MRI, the serum levels of CEA and CA19-9 were 100%, 40%, 0%, 0%, 40% in TS1, 93%, 93%, 89%, 20%, 73% in TS2 and 100%, 100%, 100%, 73%, 91% in TS3-4 (Table 2). The sensitivity of PET for detecting TS1, TS2, and TS3 tumors was 100%, 93%, and 100%, respectively. The sensitivity of FDG-PET was significantly higher in comparison to CT, MRI and the serum levels of CEA and CA19-9 in the patients with TS1 (*P* = 0.002 *vs* MRI or CEA, *P* = 0.038 *vs* CT or CA19-9).

Although the sensitivity was higher for larger tumors, the SUV was not significantly associated with the TS factor. The mean SUV did not show a significant difference in relation to the TS (TS1: 5.8 ± 4.5 , TS2: 5.7 ± 2.2 , TS3-4: 8.2 ± 3.9), respectively. The diagnosis of pancreatic adenocarcinoma was histologically confirmed in all patients with TS1 cancer (Table 3). The tumor was well differentiated in 4 patients and poorly differentiated in one patient. The tumor diameter ranged from 13 to 20 mm. All the TS1 tumors showed higher SUVs in the delayed phase compared with that in the early phase. The SUV pattern suggested the small lesions were malignant tumors.

Table 3 Characteristics of TS1 pancreas cancer

	Age (yr)	Gender	Size (mm)	Tumor differentiation	SUV early	SUV delayed
1	77	F	13	Poor	3.59	4.16
2	77	M	20	Well	5.53	7.10
3	82	F	20	Well	2.74	3.14
4	68	M	18	Well	2.87	3.06
5	81	M	20	Well	12.79	13.78

Poor: Poorly differentiated adenocarcinoma; Well: Well differentiated adenocarcinoma; SUV: Standardized uptake value; SUV early: Value at 1 h after iv ¹⁸F-fluorodeoxyglucose; SUV delayed: Value at 2 h.

Figure 1 Positron emission tomography images of a 68-year-old male with TS1 pancreatic cancer. A: Whole body positron emission tomography image shows apparent increased uptake of ¹⁸F-fluorodeoxyglucose in the tumor (arrow, delayed point standardized uptake value, 3.06); B: Axial computed tomography image with contrast enhancement shows small low-density mass in the pancreas body (arrow); C: The histological findings (HE staining) of the pancreas revealed invasive ductal cancer in the body of the pancreas with a diameter of 18 mm.

Representative images of one patient (case 4 in Table 3) with TS1 pancreas cancer are shown in Figure 1. A 68-year-old male was transferred to our hospital for evaluation and further management of diabetes mellitus. A whole body FDG-PET image shows apparent increased uptake in the tumor (delayed point SUV, 3.06) (Figure 1A). An axial CT image with contrast enhancement shows a small low-density mass in the pancreas body (Figure 1B). The histological findings (HE staining) of the pancreas revealed invasive ductal cancer in the body of pancreas with a diameter of 18 mm (Figure 1C).

DISCUSSION

The usefulness of FDG-PET in diagnosing distant disease from advanced pancreatic cancer has been previously reported, although the poor spatial resolution of FDG-PET is known to limit the local staging of pancreatic cancer^[3]. CT is better suited to demonstrate the relationship of the tumor, adjacent organs, and vascular structure in advanced pancreatic cancer, but it is rela-

tively insensitive for detecting pancreatic cancers < 2 cm in size^[8-11]. Although the sensitivity of contrast-enhanced helical CT in the detection of pancreatic carcinoma is reported to vary from 76% to 92%, the sensitivity declines to 58% to 67% for tumors smaller than 2 cm^[8-10,12]. The sensitivity of EUS or MRI has been reported to be the same or slightly better in comparison to that of CT^[13,14].

Patients with small pancreatic carcinoma have no typical symptoms, which make it very difficult to detect. In contrast to the inherent limitations of this anatomic imaging modality, functional imaging using FDG PET appears to represent a significant advance in the detection of small pancreatic cancers < 2 cm in size. Seo *et al.*^[15] reported the effectiveness of FDG-PET for the detection of small pancreatic cancers with a sensitivity of 81% for tumors smaller than 2 cm. Although there have been a few reports indicating the value of FDG-PET in the diagnosis of small pancreatic cancer, the efficacy of dual phase FDG-PET in small pancreatic cancer has not been fully evaluated.

Dual time point FDG-PET is a more reliable method than single time point FDG-PET for differentiating pancreatic cancer from a mass identified to be chronic pancreatitis. In addition, delayed PET imaging is also helpful for identifying more lesions in patients with pancreatic cancer^[7]. Dual time point evaluation is routinely performed in our institution for patients with pancreatic cancer. There were 5 tumors smaller than 2 cm in the current series, and the sensitivity of FDG-PET for the detection of these tumors was 100%, although there was no tumor smaller than 1 cm. A dual time point evaluation may help to increase the sensitivity in the diagnosis of small pancreatic cancer.

The increased uptake of FDG due to the enhanced glucose metabolism of cancer cells is a sensitive marker of tumor viability or biological behavior. The SUV is an independent prognostic factor in various malignant tumors. Sperti *et al.*^[16] demonstrated that a high SUV (> 4.0) was associated with shorter survival. Maemura *et al.*^[17] reported that pancreatic tumors with distant metastases showed significantly higher SUV levels than tumors without metastases. The present study showed the SUVs of pancreatic cancer did not differ significantly in relation to tumor size. The results indicate that FDG-PET may, therefore be useful even in patients with small pancreatic cancers that can not be visualized by either CT or other modalities. The present study did not provide data on the specificity because there were no benign lesions. In our previous study^[7], the specificity of FDG-PET for detection of pancreatic cancer was 65%. Benign lesions such as chronic pancreatitis and autoimmune-related pancreatitis can also accumulate FDG and result in false-positive interpretations of PET studies. Further studies including benign lesions are required to clarify the diagnostic accuracy of FDG-PET.

The routine use of PET is not believed to be cost-effective and thus has not been accepted as a standard screening examination for small pancreatic cancer. Although the etiology of pancreatic cancer has not yet been completely elucidated, several factors are thought to be associated with cancer^[18-21]. Smoking is a consistently iden-

tified environmental risk factor which doubles the risk of pancreatic cancer^[19,20]. Dietary factors, such as high energy intake, cholesterol, and high meat consumption are known to increase the risk. Long-standing diabetes, chronic pancreatitis and certain hereditary conditions can affect the risk of developing pancreatic cancer. FDG-PET screening is therefore recommended if the patients are elderly and have been identified to be at risk for pancreatic cancer. FDG-PET screening for the detection of pancreatic cancers should therefore be considered for patients with chronic pancreatitis, because such patients are 16 times more likely to develop pancreatic cancer than healthy controls. Dual time point FDG-PET is a reliable method for differentiating pancreatic cancer from a mass identified to be chronic pancreatitis^[22]. However, there is a limitation in our study. This study was performed by a PET scanner. The coregistration of CT and PET images or integrated PET/CT devices may help to improve some diagnostic problems. Further evolution of PET scanner technology, including the PET/CT hybrid scanner, should provide superior diagnostic performance.

These results indicate that FDG-PET is a useful modality for the detection of small pancreatic cancers with a diameter of less than 20 mm. However, this study was limited due to the small population of patients. As a result, further prospective studies with PET/CT involving a larger population of patients should therefore be conducted to substantiate the results of this study.

COMMENTS

Background

Early diagnosis is the most important factor for improving the overall survival and quality of life in patients with pancreatic cancer. Positron emission tomography (PET) has demonstrated superiority to computed tomography (CT), ultrasonography (US), and endoscopic US (EUS) in its sensitivity and specificity in diagnosing pancreas cancer.

Research frontiers

Delayed additional ¹⁸F-fluorodeoxyglucose PET (FDG-PET) imaging is a useful method in differential diagnosis of malignant from benign lesions. However, the role of dual time point FDG-PET in the diagnosis of small pancreatic cancers has yet to be established.

Innovations and breakthroughs

The usefulness of FDG-PET in diagnosing distant disease from advanced pancreatic cancer has previously been reported, although the poor spatial resolution of FDG-PET is known to limit the local staging of pancreatic cancer. This is the first study to describe the usefulness of dual time point FDG-PET in detection of small pancreatic cancers with a diameter of less than 20 mm.

Applications

The ability to diagnose the early stage of pancreas cancer can be improved by using the dual time point FDG-PET in combination with CT, US and EUS. Early diagnosis is the most important factor for improving the overall survival and quality of life in patients with pancreatic cancer.

Terminology

Dual time point FDG-PET: FDG, a glucose analog, is taken up by high-glucose-using cells such as brain, kidney, and cancer cells, where phosphorylation prevents the glucose from being released intact. FDG-PET can be used for diagnosis, staging, and monitoring treatment of cancers. PET scans detect the areas with increased glucose uptake. The standardized uptake value of FDG is measured from two sequential time points.

Peer review

This article is a retrospective analysis concerning a diagnostic value of PET for small pancreatic cancer. It is well-written but there are several issues to be resolved.

RESULTS: The overall prevalence of IgG anti-HAV was 86.61% (854/986) in patients with chronic liver disease and was 88.13% (869/986) in age- and gender-matched patients from the Center for Health Promotion. The anti-HAV prevalence was 80.04% (405/506) in patients with chronic hepatitis B, 86.96% (20/23) in patients with chronic hepatitis C, 93.78% (422/450) in patients with HBV related liver cirrhosis, and 100% (7/7) in patients with HCV related liver cirrhosis. The anti-HAV prevalence according to the decade of age was as follows: 20s (6.67%), 30s (50.86%), 40s (92.29%), 50s (97.77%), and 60s (100%). The anti-HAV prevalence was significantly higher in patients older than 40 years compared with that in patients younger than 40 years of age. Multivariable analysis showed that age \geq 40 years, female gender and metropolitan cities as the place of residence were independent risk factors for IgG anti-HAV seropositivity.

CONCLUSION: Most Korean patients with chronic liver disease and who are above 40 years of age have already been exposed to hepatitis A virus.

Abstract

AIM: To investigate the current seroprevalence of hepatitis A virus (HAV) antibodies in patients with chronic viral liver disease in Korea. We also tried to identify the factors affecting the prevalence of HAV antibodies.

METHODS: We performed an analysis of the clinical records of 986 patients (mean age: 49 ± 9 years, 714 males/272 females) with chronic hepatitis B virus (HBV) or hepatitis C virus (HCV) infection who had undergone HAV antibody testing between January 2008 and December 2009.

INTRODUCTION

Hepatitis A virus (HAV) is an epidemiologically important virus with a worldwide distribution and causes acute hepatitis in humans. This virus has been responsible for numerous disease outbreaks resulting from close personal contact or sexual contact^[1-3], contaminated food or water^[3-7], injection drug use^[8,9] and other modes of transmission^[8,10].

The pattern of this disease includes infection during early childhood followed by life-long immunity^[11]. When acquired in childhood, HAV is a very benign disease, over 70% of patients are asymptomatic and fulminant liver failure is extremely rare^[12,13]. When the infection occurs in adulthood, a much more prolonged course is seen and the rate of jaundice and fulminant liver failure is much higher^[12-14].

During recent decades, due to improvements in sanitation and hygiene, the age of infection by this virus has shifted from early childhood to adolescence or even later^[11,15,16]. Although the overall case-fatality rate of acute HAV among persons of all ages is only 0.01%-0.3%^[17-19], it is higher (1.8%) among adults who are 50 years of age or older^[19]. More importantly, acute HAV superinfection causes severe liver disease, acute liver failure and even higher mortality rates in patients with underlying chronic liver disease (CLD). Numerous studies have identified CLD as a risk factor for fulminant hepatitis and death from acute HAV infection^[7,20-29].

The aim of this study was to investigate the current seroprevalence of HAV antibodies (anti-HAV) in patients with chronic viral liver disease in South Korea. We also tried to determine the age-specific seroprevalence in these patients to assess whether vaccination against HAV is necessary in all patients who have underlying viral liver diseases, and to determine the factors that affect IgG anti-HAV seropositivity.

MATERIALS AND METHODS

Study design, population, and collection of data

We identified a total of 986 patients with chronic viral liver disease who had undergone HAV antibody testing between June 2008 and December 2009 at the Samsung Medical Center, Seoul, South Korea. The inclusion criteria consisted of hepatitis B virus (HBV) surface antigen (HBsAg) positivity or hepatitis C virus (HCV) antibodies (anti-HCV) and HCV RNA positivity in more than two tests for at least 6 mo. Patients with human immunodeficiency virus infection and a past medical history of HAV vaccination were excluded from this study.

The status of underlying liver disease was classified into chronic hepatitis and liver cirrhosis (LC). The diagnosis of LC was made if any one of the following findings was met: (1) compatible intraoperative gross findings or histologically compatible findings; (2) evidence of portal hypertension in patients with liver disease; and (3) compatible radiologic findings and platelet counts less than $100 \times 10^9/L$.

During the same period, 986 age- and gender-matched patients from the Center for Health Promotion were selected as the control group by one-to-one matching, and the study was statistically powered at 89%. There was no loss of subjects in the case group. Patients from the Center for Health Promotion who tested positive for HBsAg or anti-HCV and had a medical history of liver disease were excluded.

Laboratory procedures

Commercially available immunoassays (Anti-HAV IgG IRMA kit, North Institute of Biological Technology, Beijing, China; ARCHITECT HBsAg assay, Abbott Laboratories, Sligo, Ireland; ADVIA Centaur HCV assay, Siemens Healthcare Diagnostics, Los Angeles, CA, USA) were used to detect IgG anti-HAV, HBsAg and anti-HCV, respectively. The HCV RNA was amplified by RNA PCR and hybridization methods (COBAS® AmpliCor HCV test version 2.0, Roche Molecular Systems, Branchburg, NJ, USA, lower limit of detection 50 IU/mL).

Statistical analysis

The Cochran-Armitage trend test was used to assess the association between age and seropositivity rate for anti-HAV. McNemar's test was used to compare the seropositivity rate for anti-HAV between patients with CLD and patients from the Center for Health Promotion. Categorical variables were compared with the χ^2 test. Binary logistic regression analysis was used to determine the relationship between the variables and seropositivity for anti-HAV.

P values < 0.05 were considered statistically significant and Bonferroni's method was used to correct for inflated type I error due to multiple testing. All the statistical analyses were run on SPSS version 15.0 (SPSS Inc., Chicago, IL, USA).

Ethical considerations

The institutional review board of Samsung Medical Center approved this retrospective study.

RESULTS

Patient demographics

The patient characteristics are detailed in Table 1. The mean age of the patients was 49 years (range: 20-80 years) and the vast majority of patients were over 40 years old (84%). A male preponderance (72.41%) was observed and the vast majority of patients had chronic viral hepatitis B (51.32%) and HBV related LC (45.64%). A relatively large proportion of the patients were from Seoul, the capital of South Korea (39.45%). The overall prevalence of IgG anti-HAV in patients with CLD was 86.61% (854/986).

The prevalence of IgG anti-HAV according to age

When the study participants were classified by decade of age into five groups, from 20s to more than 60 years old, the anti-HAV seroprevalence was 6.67% and 50.86% in

the patients in their 20s and 30s, respectively. The positivity rate for anti-HAV in the patients in their 40s, 50s and 60s was 92.29%, 97.77% and 100%, respectively. The prevalence of IgG anti-HAV in patients with CLD, and as divided by 5-year age intervals, is shown in Figure 1A. The seropositivity rate for anti-HAV increased gradually as age increased ($P < 0.001$). The anti-HAV prevalence was significantly higher in patients older than 40 years compared

with those patients younger than 40 years of age (94.95% *vs* 33.58%, respectively, $P < 0.001$).

The prevalence of IgG anti-HAV according to age in the age- and gender-matched patients from the Center for Health Promotion is shown in Figure 1B. The overall prevalence of anti-HAV was 88.13% (869/986) and the seropositivity rate for anti-HAV increased gradually as age increased ($P < 0.001$). There was no significant difference in the anti-HAV seroprevalence between patients with CLD and those from the Center for Health Promotion ($P = 0.141$).

The prevalence of IgG anti-HAV according to the etiology and status of liver disease

The overall prevalence of anti-HAV was 86.51% in the 956 patients with chronic HBV infection, and it was 90% in the 30 patients with chronic HCV infection. There was no statistically significant difference in seropositivity for anti-HAV between the patients with HBV infection and those with HCV infection ($P = 0.582$). For the HBsAg-positive patients, the anti-HAV prevalence in each group divided by the decade of age increased gradually as age increased, which was similar for all the patients (Table 2).

The prevalence of IgG anti-HAV according to the status of CLD is shown in Figure 2. The anti-HAV seroprevalence was 80.04% (405/506) in patients with chronic hepatitis B, 86.96% (20/23) in patients with chronic hepatitis C, 93.78% (422/450) in patients with HBV related LC and 100% (7/7) in patients with HCV related LC.

Factors affecting the seropositivity of IgG anti-HAV

The anti-HAV prevalence according to gender, the status of liver disease and place of residence is shown in Table 3. Anti-HAV was more frequently detected in female patients (90.07%) than in male patients (85.29%, $P = 0.049$). As for the status of liver disease, anti-HAV antibody was more frequently detected in patients with LC (93.87%) than in those with chronic hepatitis (80.34%, $P < 0.001$). As for the place of residence, anti-HAV antibody was less frequently detected among patients who lived in Seoul or Gyeonggi-do (79.95%-87.96%) than among those living in metropolitan cities or other provinces (92.38%-95.05%, $P < 0.001$).

Multivariable analysis of the factors for anti-HAV seropositivity is shown in Table 4. Age ≥ 40 years ($P < 0.001$), female gender ($P = 0.014$) and metropolitan cities as the place of residence ($P = 0.012$) were independent risk factors for IgG anti-HAV seropositivity.

DISCUSSION

The epidemiological pattern of HAV infection is cur-

rently changing in many developing countries. An improved socioeconomic status, more sanitary conditions and better hygiene practices have reduced the incidence of HAV infection, and the age-specific HAV seroprevalence in the general population has steadily decreased. The decrease in HAV infection in young adults has resulted in a reduction in individuals with protective antibody and increased hepatitis A in the adult population. In Korea, symptomatic hepatitis A has been gradually increasing since the mid-1990s, with a tendency toward an increase in the mean age and disease severity^[30-35].

A number of studies have suggested that the clinical course of HAV infection is more severe in patients with CLD^[7,20-29]. Mortality in patients with HBsAg was found to be significantly higher than that in patients without HBsAg in an outbreak of HAV infection in Shanghai^[23], and an analysis of HAV associated deaths in the United States revealed a higher rate of fatality in HBV carriers than in patients without HBV^[24]. Moreover, patients with HCV infection were reported to experience HAV associated fulminant hepatic failure more often than those patients without CLD. In a prospective cohort study of adults with HCV infection, Vento *et al*^[31] reported that 41.2% of patients with acute HAV superinfection developed acute liver failure and 35.3% died.

In our study, the overall seroprevalence of IgG anti-HAV in the 986 Korean patients with chronic viral liver disease was 86.61%. When the study participants were classified by the decade of age, the anti-HAV seroprevalence was 6.67%, 50.86%, 92.29%, 97.77% and 100% in patients in their 20s, 30s, 40s, 50s and 60s, respectively. These results are consistent with recent Korean studies^[28,29]. The anti-HAV prevalence was significantly higher in patients older than 40 years compared with those younger than 40 years of age (94.95% *vs* 33.58%, respectively). These data indicate that most patients with chronic viral liver diseases and who are above 40 years of age have already been exposed to HAV infection, and have naturally acquired immunity against HAV. Hence, vaccination against HAV should be considered in young anti-HAV-negative patients.

In the present study, we expected the seroprevalence of anti-HAV to be higher in patients with CLD than in those from the Center for Health Promotion, considering the relatively low socioeconomic status of the CLD patients. However, there was no statistically significant difference in anti-HAV seroprevalence between the two groups (86.61% *vs* 88.13%, respectively, $P = 0.141$). This finding may indicate that the immune response to HAV infection is not altered by chronic infection with either HBV or HCV. This result is also consistent with the results of the multivariable analysis in our study.

As shown in the multivariable analysis and Figure 1A, patient age was the most important factor for determining the seropositivity rate of IgG anti-HAV. Although anti-HAV was more frequently detected in patients with LC than in those with chronic viral hepatitis (93.87% *vs* 80.34%, respectively), this was probably attributable to age when considering the results of the multivariable analysis.

Female patients had a relatively higher rate of HAV seropositivity. This finding might be explained by the fact that female subjects in Korea have a larger number of social and household contacts and so probably have more exposure to HAV. We also observed significant differences among the places of residence. The lowest seroprevalence was observed in Seoul, the largest and most urbanized city in Korea, and the highest was in the provinces, with a more rural way of life. Such differences in seroprevalence might well be attributed to the vast variations in living conditions.

The current study has a couple of limitations. First, this is a retrospective study and the available epidemiological data on HAV infection is limited. Socioeconomic characteristics, including the educational level, salary, the number of siblings, the type of residence, the water supply, *etc.*, were not included in this study. Although multivariable analysis of the seropositivity of anti-HAV was carried out with relatively limited variables, the results in the present study may not be applicable to all patients with CLD. Second, although the current study included a large number of CLD patients, it was performed at a single medical center. Therefore, the patients may not be representative of the whole population of Korea. We also used data from the Center for Health Promotion and these patients may not be representative of the general Korean population without CLD when considering the fact that patients with a relatively higher level of socioeconomic status visit the Center for Health Promotion.

In conclusion, the overall prevalence of IgG anti-HAV in Korean patients with chronic viral liver disease was 86.61%, and most patients who are above 40 years of age have already been exposed to HAV. Therefore, vaccination against HAV should be considered, particularly for young anti-HAV-negative patients with chronic liver disease.

COMMENTS

Background

An improved socioeconomic status, more sanitary conditions and better hygiene practices have reduced the incidence of hepatitis A virus (HAV) infection. In Korea, symptomatic hepatitis A has been gradually increasing since the mid-1990s, with a tendency toward an increase in the mean age and disease severity. Acute HAV superinfection causes severe liver disease, acute liver failure and even higher mortality rates in patients with underlying chronic liver disease.

Research frontiers

Identifying the current seroprevalence of HAV antibodies in patients with chronic viral liver disease would be valuable for establishing appropriate vaccination guidelines for patients with chronic liver disease.

Innovations and breakthroughs

Recent studies reported a rapid epidemiological shift in HAV infection. In this study, the authors evaluated seroprevalence of IgG anti-HAV in patients with chronic liver disease using large population based data, and investigated the age-specific seroprevalence and the factors that affect IgG anti-HAV seropositivity.

Applications

There has been an apparent epidemiological shift in HAV seroprevalence in patients with chronic liver disease. Most patients who are above 40 years of age have already been exposed to HAV. Therefore, vaccination against HAV should be considered, particularly for young anti-HAV-negative patients with chronic liver disease.

Abstract

AIM: To evaluate the efficacy and acceptability of magnesium citrate and a single dose of oral sodium phosphate (45 mL) solution for morning colonoscopy bowel preparation.

METHODS: A total of 159 patients were randomly assigned to receive two split doses of 90 mg of sodium phosphate (Group I, $n = 79$) or magnesium citrate (250 mL, the day before the procedure) followed by 45 mL of sodium phosphate (the day of procedure, Group II, $n = 80$). The quality of bowel cleansing and the acceptability of each regimen were compared, including the satisfaction, taste, willing to repeat and adverse effects of each regimen.

RESULTS: The quality of bowel cleansing of Group II was as good as that of Group I (An Aronchick scale score of good or excellent: 70.9% vs 81.0%, respectively, $P = 0.34$; the Ottawa system score: 4.4 ± 2.6 vs 3.8 ± 3.0 , respectively, $P = 0.76$). There was no statistically

significant difference between both groups with regard to acceptability, including the satisfaction, taste and willingness to repeat the regimen. A significantly greater number of older patients (over 65 years old) in Group II graded the overall satisfaction as satisfactory (48.1% vs 78.1%, respectively; Group I vs Group II, $P = 0.01$). There were no significant adverse reactions.

CONCLUSION: Magnesium citrate and a single dose of sodium phosphate was as effective and tolerable as the conventional sodium phosphate regimen and is a satisfactory option.

INTRODUCTION

The worldwide introduction of screening colonoscopy programs has led to a dramatic increase in the number of colonoscopies. Despite the development of techniques and instruments, the difficulties in bowel preparation for a complete colonoscopic examination still remain a challenge to the physician and the examinee. These difficulties may result in significant noncompliance and thus subop-

timal preparation, which subsequently may lead to missed lesions^[1], an increased procedure time and the need for repeat colonoscopy^[2], as well as reluctance to undergo follow-up examinations.

Sodium phosphate is a low-volume laxative, and it is known to be superior to 4l polyethylene glycol (PEG) solution, both for acceptability by the patient and for the quality of bowel cleansing^[3-6]. However, a significant proportion of patients complain that its bad taste is unacceptable and there are adverse reactions such as nausea, vomiting and headache. Moreover, more potential adverse reactions associated with hyperphosphatemia may theoretically develop under any conditions that increase absorption or decreased elimination of phosphate^[7]. Unfortunately, poor compliance with the instructions about the dosage or interval of oral sodium phosphate and undetected chronic illness, particularly in the elderly, may result in a higher possibility of unexpected adverse events. Recent reports of renal failure associated with sodium phosphate have raised increasing concerns^[8-12] in spite of some reports demonstrating its safety in a series of clinical trials^[13,14].

In this study, we wanted to find a better and easier preparation regimen for a complete colonoscopic examination. We have experienced that the usual bowel preparation for sigmoidoscopy in our hospital using magnesium citrate the day before the procedure scheduled in the next morning was able to debulk the colon of solid fecal material without much patient discomfort. Therefore, we hypothesized that taking magnesium citrate the day before the procedure and then taking a single dose of sodium phosphate (45 mL) on the day of procedure would be as effective a regimen as the conventional two doses of sodium phosphate and more tolerable for morning colonoscopy.

MATERIALS AND METHODS

Study design, patient enrollment and the end outcomes

This was a prospective, randomized, endoscopist-blinded, controlled study. All consecutive patients referred to the Outpatient Department of Gastroenterology and Surgery at Daehang Hospital (Seoul, Korea) between September 2009 and December 2009 for colonoscopy in the morning were enrolled in this clinical study. The exclusion criteria were as follows: ileus or suspected bowel obstruction, significant gastroparesis or gastric outlet obstruction, the presence of serious medical conditions such as severe cardiac, renal, hepatic or metabolic diseases, pregnancy, lactation and a history of prior colon or rectal surgery. Written informed consent was obtained from each patient. No patient refused to participate. The primary end outcomes in this study were the efficacy of bowel preparation according to the Aronchick scale and the Ottawa Bowel Preparation Scale (OBPS), the patients' tolerance, the overall satisfaction, the taste and the willingness to repeat the same preparation regimen, if necessary. The sec-

ondary end outcomes included assessment of the OBPS components (i.e. the right vs middle vs left colon, and the fluid score) and a subgroup assessment according to age, gender, a prior bowel cleansing regimen and so forth.

Colon bowel preparation

A total of 159 patients were randomly assigned to receive two split doses of 90 mg of oral sodium phosphate (Group I, $n = 79$) or 250 mL of magnesium citrate (magnesium carbonate 4.3 g and anhydrous citric acid 7.8 g/100 mL) (the day before the procedure) and this was followed by 45 mL of sodium phosphate (the day of the procedure, Group II, $n = 80$). Group I ingested a single dose (45 mL) of sodium phosphate starting at 8:00 PM on the day before the procedure and then they ingested the remaining 45 mL of sodium phosphate at 5:00 AM on the day of colonoscopy. Group II ingested magnesium citrate (one bottle; 250 mL) at 8:00 PM on the preceding day and a single dose (45 mL) of sodium phosphate at 5:00 AM on the procedure day. Both groups took one tablet of bisacodyl as pretreatment 30 min before each laxative on the day before the procedure. All the patients who had taken oral sodium phosphate were instructed to drink an additional 1-1.5 L of water. Both groups had a thick liquid diet for dinner on the day before the procedure, and they took nothing further by mouth after 6:00 PM. All the colonoscopy procedures were performed between 8:30 AM and 11:30 AM. The quality of bowel cleansing, the tolerability, the satisfaction, the willing to repeat the procedure and the adverse effects of each regimen were compared.

Evaluation of bowel preparation

Efficacy of bowel cleansing: The endoscopists, who were blinded to the form of preparation, performed the colonoscopy exams. To standardize and minimize interobserver variation, we had a meeting before the start of this study and an investigator gave a standardized explanation for assessing the quality of bowel preparation during the meeting. A poster with endoscopic photos that demonstrated the scoring system was placed in each endoscopy room as a reminder. The endoscopists were also requested to take pictures of each colon segment before cleansing the segments with saline during the procedure.

Bowel cleansing was assessed at the end of the colonoscopy using the OBPS and the Aronchick scale. The OBPS has a potential score ranging from 0 (excellent preparation, no fluid) to 14 (inadequate in all segments with a large amount of fluid) (Table 1). The Aronchick scale was as follows: excellent (a small volume of clear liquid or greater than 95% of the surface was seen); good (a large volume of clear liquid covering 5% to 25% of the surface but greater than 90% of the surface was seen); fair (some semisolid stool that could be suctioned or washed away but greater than 90% of the surface was seen); and poor (semisolid stool that could not be suctioned or washed away and less than 90% of the surface was seen).

There were ten colonoscopists who performed colonos-

Table 1 Summary of the scoring system for the Ottawa Bowel Preparation Scale

Cleanliness
Excellent (0): mucosal detail clearly visible. If fluid present, it is clear. Almost no stool residue
Good (1): some turbid fluid or stool residue but mucosal detail still visible. Washing and suctioning not necessary
Fair (2): turbid fluid or stool residue obscuring mucosal detail and contour. However, mucosal detail becomes visible with suctioning. Washing not necessary
Poor (3): presence of stool obscuring mucosal detail and contour. However, with suctioning and washing, a reasonable view is obtained
Inadequate (4): solid stool obscuring mucosal detail and contour despite aggressive washing and suctioning
Fluid: small (0), moderate (1), large (2)

PEG: Polyethylene glycol; NS: Not significant.

copies in this study. All the colonoscopists were experts who had experienced at least 1000 cases of colonoscopy after their gastrointestinal or coloproctologic fellowship. To check the interobserver variation for rating the efficacy of bowel preparation, all the colonoscopy pictures were reviewed by two experienced endoscopists (Choi YS and Suh JP) who were blinded to the preparation methods.

Patient acceptability

All the patients completed a questionnaire before colonoscopy. It was used to assess the past medical history, compliance, discomfort symptoms during preparation and the overall satisfaction. The investigated symptoms were nausea or vomiting (present = 1, absent = 0), abdominal pain or discomfort (present = 1, none = 0) and abdominal distension (present = 1, none = 0). The overall satisfaction with the preparation was rated on a 3 scale (satisfactory, fair and unsatisfactory). The willingness to repeat the same preparation method in the future, if necessary, was also evaluated with a “yes” or “no” question.

Statistical analysis

All the continuous variables are presented as means and standard deviations or as medians and ranges, as appropriate. The χ^2 test was used for comparisons between categorical variables and Student's *t* test was used for com-

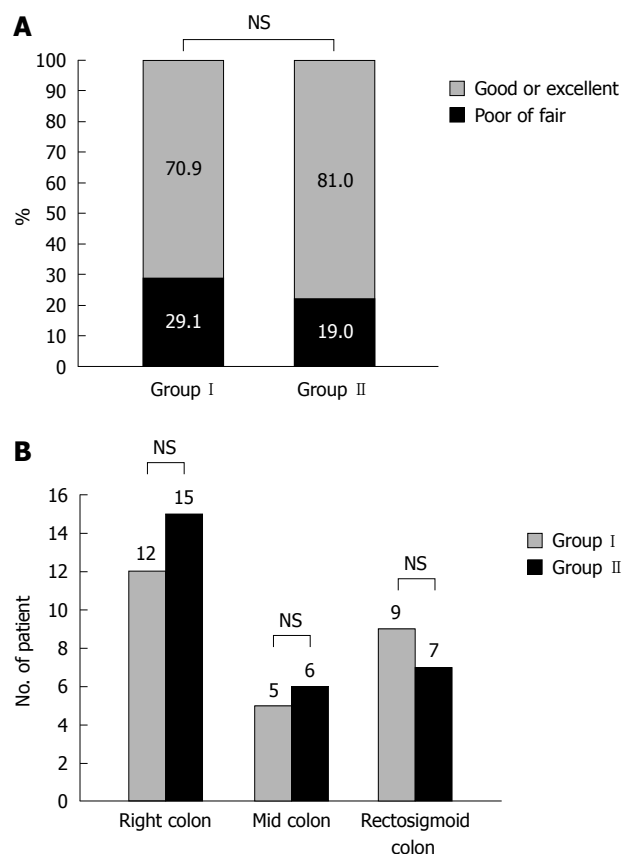

Figure 1 Quality of bowel cleansing. A: Quality of bowel cleansing. The patients are graded as good or excellent quality vs fair or poor quality with the conventional sodium phosphate regimen (Group I) or the magnesium citrate and a single dose sodium phosphate regimen (Group II); B: Segmental quality of bowel cleansing. The patients are scored with colon segment grades of poor or inadequate with the conventional sodium phosphate regimen (Group I) or the magnesium citrate and a single dose sodium phosphate regimen (Group II). NS: Not significant.

parisons between continuous variables. *P* values less than 0.05 were regarded as statistically significant.

RESULTS

Baseline characteristics

A total of 180 consecutive patients were enrolled and randomized into two groups (90 patients in each group). Twenty-one patients were excluded because the procedure was postponed or canceled. Finally, 159 patients were included in the analysis. There was no significant difference in the baseline characteristics between both groups (Table 2). In all cases, cecal intubation was successful. There were no serious complications or adverse events immediately after the procedure.

Assessment of the quality of bowel cleansing

There was no significant difference in bowel cleansing quality as evaluated by the Aronchick scale between both bowel preparation regimens. Group I had 56 satisfactory preparations (defined as excellent or good) of 79 (70.9%) compared with 62 of 80 (81.0%) for Group II (*P* = 0.34) (Figure 1A).

Figure 2 Patient acceptability. A: For overall satisfaction, 65.8% in Group I and 82.0% in Group II replied that they were “satisfied” or it was “fair”; B: For assessing taste, the percentage of patients who responded “good or tolerable” was not significantly different between Group I (69.6%) and Group II (73.4%); C: For the willingness to repeat the regimen, the percentage of patients who responded “yes” was not significantly different between Group I (83.5%) and Group II (80.8%). NS: Not significant.

When bowel preparation was assessed by the Ottawa scale, the preparation quality was not significantly different as well (Table 3). The mean score was not significantly different between both groups for the right colon ($P = 0.54$), the mid colon ($P = 0.47$), the rectosigmoid colon ($P = 0.97$) or the total amount of fluid ($P = 0.48$). In both groups, the patients with colon segment grades of poor or inadequate were 12 (15.2%) *vs* 15 (18.8%), 5 (6.3%) *vs* 6 (8.0%) and 9 (11.4%) *vs* 7 (9.0%) for the right colon, the mid colon and the rectosigmoid colon, respectively (Figure 1B).

Table 3 Efficacy of bowel cleansing by Ottawa scoring system (mean \pm SD)

Variables	Group I (n = 79)	Group II (n = 73)	P value
Right colon	1.4 \pm 1.1	1.3 \pm 1.1	NS
Mid colon	1.0 \pm 0.9	0.8 \pm 0.9	NS
Rectosigmoid colon	1.3 \pm 0.9	1.2 \pm 1.0	NS
Fluid present	0.7 \pm 0.6	0.4 \pm 0.6	NS
Overall score	4.4 \pm 2.6	3.8 \pm 3.0	NS

NS: Not significant.

Figure 3 Overall satisfaction with bowel preparation in the elderly (> 65 years). 48.1% in Group I and 78.1% in Group II replied that they were “satisfied” or it was “fair” ($P = 0.017$).

There was no significant difference of the segmental bowel preparation quality either.

Assessment of patient acceptability (overall satisfaction, taste and willing to repeat)

The percentage of patients with symptoms such as abdominal distension with the two preparation regimens was 23% *vs* 34%, respectively, nausea or vomiting 45% *vs* 41%, respectively, and abdominal pain 15% *vs* 13%, respectively.

When patients were asked whether they were satisfied with the bowel preparation regimen, 65.8% (52 of 79) in Group I and 82.0% (62 of 80) in Group II replied that they were “satisfied” or it was “fair” (Figure 2A). When patients were asked how the laxatives tasted, the patients who responded “good or tolerable” were not significantly different between Group I (69.6%) *vs* Group II (73.4%) (Figure 2B). When patients were asked whether they were willing to repeat the same preparation regimen if necessary, the percentage of patients who responded “yes” was not significantly different between Group I (83.5%) *vs* Group II (80.8%) (Figure 2C).

Subgroup assessment of the bowel cleansing quality and patient acceptability

When the patients over 65 years old were asked whether they were satisfied with the bowel preparation regimen, 48.1% (13 of 27) in group I and 78.1% (25 of 32) in group II replied that they were “satisfied” or it was “fair” ($P = 0.017$) (Figure 3). The question about taste and will-

ingness to repeat revealed no significant differences between both groups.

When only the patients who had previously undergone colonoscopy and had taken PEG or oral sodium phosphate were asked about patient acceptability, the prior sodium phosphate users generally had a preference for this new regimen rather than the new PEG users concerning overall satisfaction (80.0% *vs* 64.3%, respectively, $P = 0.26$), taste tolerance (80% *vs* 71.4%, respectively, $P = 0.52$) and willing to repeat (90.0% *vs* 61.3%, respectively, $P = 0.04$).

DISCUSSION

The early detection of colonic neoplasm *via* colonoscopy and its removal by polypectomy is popular and increasing, yet many people avoid screening colonoscopy because they fear the preparation required for colonoscopy. The two most commonly-used regimens for colonoscopic bowel preparation are currently a large volume of osmotically balanced PEG solution and a small volume of an osmotically active agent, oral sodium phosphate. Four liters of PEG solution is known to be safe and effective, but poorly tolerated. In contrast, sodium phosphate is known to be well-tolerated and as effective as PEG solution. Oral sodium phosphate has been shown to be very safe in a large series of clinical trials^[13,14]. Its administration is known to be associated with only an asymptomatic, mild increase in serum phosphate (mean increase: 3 mg/dL) and a minimal decrease in serum calcium (mean decrease: 0.3 mg/L); these changes are readily reversible^[10]. Clinically significant adverse reactions, including severe hyperphosphatemia, hypocalcemia, seizure, tetany, hypovolaemia and acute renal failure are thought to be extremely rare, with a reported incidence of 1.44 per million patients^[10,15]. Under normal conditions, phosphate is absorbed in the small intestine and eliminated by the kidney as calcium phosphate^[15]. The conventional dosage of oral phosphate for bowel cleansing is one bottle (45 mL) the evening before the procedure and another bottle the next morning. Any condition that can increase absorption or decrease elimination of phosphate such as repeated dosing, dehydration, the use of diuretics and ACE inhibitor, or a preexisting illness that may impair phosphate homeostasis, for example, hyperparathyroidism, renal insufficiency or delayed intestinal transit can be a risk factor. Indeed, fatal cases have been observed among the patients with a history of renal dysfunction^[16-18], ischemic colitis^[17], cirrhosis^[18] and in elderly patients with normal renal function^[19,20]. The maximum safe dose of sodium phosphate is 90 mL^[21]. Several studies on the adverse effects of high doses of sodium phosphate have suggested that these high doses should be avoided^[13-15]. If the recommended dose of 60 g (90 mL) is surpassed, or if the interval between doses is < 5 h, severe hyperphosphatemia could develop^[10,15,18,22,23]. Fine *et al*^[24] have found that the mortality rate was 33%, and that the risk of death was high if the serum phosphate level increased beyond 32.69 mg/dL (10.56 mmol/L). Most of the deaths reported in the lit-

erature have been caused by arrhythmia or heart attack associated with electrolyte changes and dehydration^[25]. Therefore, adequate fluid intake is necessary. Markowitz *et al*^[10] has suggested that patients must be encouraged to drink eight cups of fluids (1920 mL) and Rex *et al*^[2] have promoted taking 3.6 L of clear fluids. However, it was reported that the standard dose of sodium phosphate could induce the development of hyperphosphatemia even in low-risk and well-hydrated patients^[7].

In this study, we attempted to debulk the colon of solid fecal material with magnesium citrate at first and thereby decrease the volume of oral sodium phosphate required for bowel cleansing without compromising the quality of the bowel preparation. Rather, we achieved superior overall satisfaction in the elderly patients who were pretreated with magnesium citrate. It is practically significant to find that this new regimen is better tolerated by elderly patients since the potential for complications associated with bowel preparation may be relatively increased in elderly patients due to poor compliance with the recommended fluid intake. In addition, elderly patients have a greater possibility of having an underlying chronic illness that may be undetected. Therefore, we think a lower volume of sodium phosphate can be safer and better suited for everybody. The patients who had previously taken two doses of sodium phosphate for bowel preparation had a tendency to prefer this new regimen rather than the PEG solution, suggesting that this regimen can be an alternative option for the intolerant patients.

We found that overall rates of adequate bowel cleansing in both groups were relatively high (Group I, 70.9% and Group II, 81%), which suggested that bisacodyl as pretreatment and procedure time scheduled for the morning had influenced the overall quality of bowel cleansing. Both regimens were scheduled for morning because afternoon colonoscopies have higher failure rates than morning colonoscopies, and the suggested scheduling of all outpatient colonoscopies is preferentially in the morning to avoid suboptimal procedures^[26]. The dosing time of magnesium citrate was determined as 9 h before taking the oral sodium phosphate. In a previous study that used magnesium citrate as pretreatment to decrease the volume of PEG solution, magnesium citrate was taken at 1-2 h before ingesting 2 L of PEG solution^[27,28]. However, we expect that a 9 h time interval would be optimal, with reference to the usual interval time for the split-dosed PEG solution regimen or the oral sodium phosphate regimen.

Our study has several limitations. First, the safety profiles, including electrolytes, hemoglobin and the BUN/creatinine change, were not evaluated to prove the safety advantages of this new regimen compared to the conventional sodium phosphate regimen, although the volume of sodium phosphate was reduced by half. Second, we excluded the patients with medical conditions that are currently contraindicated for conventional sodium phosphate use such as heart failure, cirrhosis, renal disease, very old age patients or those taking diuretics or ACE inhibitors and so forth. Thus, the findings in our study need to be

confirmed in a large study with various groups of patients. Third, there were ten colonoscopists involved in this study. Although all the endoscopists were trained in using the scale with photographs illustrating each point on the OBPS, and the degree of agreement was acceptable according to a κ coefficient of greater than 0.4, the study could have been more powerful if all the colonoscopies had been performed by a single colonoscopist. Fourth, there was a discrepancy between “better” overall satisfaction and a “similar” propensity of willingness to repeat the bowel preparation regimen among the elderly patients. Further tailored evaluation of a large group of elderly patients is needed to verify this.

As mentioned above, the use of the conventional dose of sodium phosphate is theoretically limited for patients with any condition that can increase the absorption or decrease the elimination of phosphate. If we think a lower volume of sodium phosphate might be safer, then this must be verified in individual cases since the mechanism of an adverse reaction to sodium phosphate and its risk factors has not been fully discovered. Further evaluation of the safety profile is mandatory.

In conclusion, a regimen of magnesium citrate and a single dose of oral sodium phosphate was as effective as the conventional two doses of sodium phosphate, and our new regimen was well tolerated. Therefore, this regimen could be a good option to routinely prepare for morning colonoscopy.

COMMENTS

Background

Oral sodium phosphate is a hyperosmolar, low-volume laxative for colonoscopy bowel preparation, and it is known to be as effective as polyethylene glycol solution. It is generally better tolerated, but the bad taste and uncomfortable abdominal symptoms such as nausea and vomiting frequently lead to poor compliance with the oral sodium phosphate regimen, and all this can subsequently cause incomplete bowel cleansing. Moreover, potential adverse reactions associated with hyperphosphatemia may develop.

Innovations and breakthroughs

This is the first clinical study to evaluate the efficacy and tolerability of magnesium citrate and a single dose of oral sodium phosphate for bowel preparation prior to morning colonoscopy. The findings demonstrated this modified regimen, in which the volume of sodium phosphate was reduced by half was as effective and tolerable as the conventional sodium phosphate regimen.

Applications

The study results suggest that magnesium citrate and a single dose of oral sodium phosphate can be an effective and satisfactory option to routinely prepare for morning colonoscopy.

Terminology

Magnesium citrate acts as an osmotic laxative which is often used for bowel preparation

Peer review

In this well designed paper the author has proposed a combination of magnesium citrate the day before the procedure and sodium phosphate early in the morning of the day of the procedure, associated with one tablet of bisacodyl as compared to standard cleansing using two doses of sodium phosphate, with one tablet of bisacodyl. The paper is interesting and the design is adequate, as are the results and comments.

Abstract

AIM: To study the association between hilar cholangiocarcinoma (HC) and pre-existing medical conditions.

METHODS: Three hundred and thirteen HC patients admitted to the Eastern Hepatobiliary Surgery Hospital (Shanghai, China) in 2000-2005 and 608 healthy controls were enrolled in this study. Association between HC and pre-existing medical conditions was studied with their adjusted odds ratio (OR) calculated by logistic regression analysis.

RESULTS: The prevalence of choledocholithiasis (adjusted OR = 2.704, $P = 0.039$), hepatolithiasis (adjusted OR = 3.278, $P = 0.018$), cholecystolithiasis (adjusted OR = 4.499, $P < 0.0001$), cholecystectomy (adjusted OR = 7.012, $P = 0.004$), biliary ascariasis (adjusted OR = 7.188, $P = 0.001$), liver fluke (adjusted OR = 10.088, $P = 0.042$) and liver schistosomiasis (adjusted OR = 9.913, $P = 0.001$) was higher in HC patients than in healthy controls.

CONCLUSION: Biliary tract stone disease (choledocholithiasis, hepatolithiasis, cholecystolithiasis) and parasitic

INTRODUCTION

Hilar cholangiocarcinoma (HC) is a rare and highly malignant cancer of the bile duct, accounting for less than 2% of all human malignancies. Although the entire biliary tree is a potential risk, tumors involving the biliary confluence or the right or left hepatic ducts are most common, accounting for 40%-60% of all tumors. Its etiology remains poorly understood and its incidence has been increasing in China. The long-term prognosis of HC is poor due to its early metastasis. Complete resection has been recognized as the most effective therapy for HC. However, surgical management still remains a major challenge because of its location close to the portal vein, hepatic artery, and liver parenchyma. So far, most studies have been focused on the risk factors for intrahepatic cholangiocarcinoma (ICC)^[1-3], while few studies on the risk factors for HC are available^[4]. Due to the increasing incidence and poor long-term prognosis of HC, it is extremely important to evaluate the risk factors for HC in order to decrease its incidence.

MATERIALS AND METHODS

Study population

Three hundred and thirteen HC patients who received surgical dissection at the Eastern Hepatobiliary Surgery Hospital of the Second Military Medical University (Shanghai, China) from January 2000 to December 2005 were included in this study. HC was diagnosed by pathological examination of samples taken from HC patients. Those who were diagnosed as HC but did not undergo surgery were excluded from the study.

Controls

Six hundred and eight healthy individuals who visited the Eastern hepatobiliary Surgery Hospital of the Second Military Medical University for a routine checkup served as controls and were matched to the HC patients for sex and age (± 4 years). Moreover, the years of search were matched in HC patients and controls for risk factors to minimize their difference.

Several potential risk factors for HC were studied and divided into 3 broad categories: biliary tract condition and operation, infectious diseases, and miscellaneous potential risk factors. Biliary tract condition and operation included choledocholithiasis, hepatolithiasis, cholecystolithiasis, primary sclerosing cholangitis (PSC), parasitic liver disease and cholecystectomy. Infectious diseases included hepatitis B virus (HBV) and hepatitis C virus (HCV) infection. Miscellaneous potential risk factors included alcoholic liver disease, type II diabetes mellitus, smoking and ulcerative colitis.

Statistical analysis

Prevalence of HC and potential risk factors for HC were compared in HC patients and controls. χ^2 test or Fisher's exact test was used for categorical variables, and *t* test was used for discrete variables.

Variables with a *P* value < 0.05 were considered statistically significant. Odds ratio (OR) and 95% CI of each risk factor for HC were computed as estimate of the relative risk by unconditional logistic regression analysis, using the maximum-likelihood estimate.

RESULTS

Demographic and baseline parameters of patients and controls

A total of 313 patients (194 men and 119 women with male-to-female ratio of 1.63:1) diagnosed as HC were enrolled in the present study. Their mean age was 56.64 ± 10.585 years (range 32-80 years). Most HC developed during the fourth to sixth decade, and reached the peak at the age of 55 years (Figure 1).

The distribution of HC in controls and HC patients according to their age and gender is shown in Table 1. No significant difference was found in gender and mean age between HC patients and controls, suggesting that the pairing is effective.

Figure 1 Distribution of age and sex in patients with hilar cholangiocarcinoma admitted to the Eastern Hepatobiliary Surgery Hospital (Shanghai, China) during 2000-2005.

Table 1 Demographic characteristics of patients with hilar cholangiocarcinoma and control subjects

Variable	HC patients (<i>n</i> = 313)	Controls (<i>n</i> = 608)	<i>P</i>
Mean age	56.64 ± 10.585	55.58 ± 10.792	0.895

Female	119	228	

HC: Hilar cholangiocarcinoma.

Risk factors

The risk factors were divided into 3 categories: biliary tract condition and operation, infectious diseases and other risk factors. In biliary tract condition and operation, the prevalence of choledocholithiasis, hepatolithiasis cholecystolithiasis, cholecystectomy, biliary ascariasis, liver schistosomiasis and liver fluke was higher in HC patients than in controls (*P* < 0.05), while no significant difference was found in the prevalence of PSC between HC patients and controls. In infectious diseases, the prevalence of HBV infection was 7.3% in HC patients and 6.3% in controls (*P* = 0.526), the prevalence of HCV infection was 1.0% in HC patients and 2.1% in controls (*P* = 0.151). In other risk factors, the prevalence of ulcerative colitis (UC), alcoholic liver disease, type II diabetes mellitus and smoking was 0.3%, 0.6%, 5.4% and 22%, respectively, in HC patients, and 0.0%, 0.3%, 6.1% and 20.0%, respectively, in controls.

The distribution of risk factors in each category is summarized in Table 2.

Multiple logistic regression analysis

Logistic regression model was used to adjust the demographics (age, sex), and the adjusted OR and 95% CI for the different risk factors were calculated. Multivariate analysis showed that choledocholithiasis, hepatolithiasis, cholecystolithiasis, cholecystectomy, biliary ascariasis, liver fluke and liver schistosomiasis were the risk factors for HC, while HBV infection, HCV infection, PSC, UC, alco-

holic liver disease, type II diabetes mellitus and smoking were not the significant risk factors for HC (Table 3).

DISCUSSION

In this case-control study, the risk factors for HC were examined in Chinese population, including choledocholithiasis, hepatolithiasis, cholecystolithiasis, cholecystectomy, biliary ascariasis, liver fluke and liver schistosomiasis. Although HBV and HCV infection have been reported to be intimately associated with intrahepatic cholangiocarcinoma (ICC)^[1,2], they were not demonstrated to be significantly associated with HC in our study. In addition, PSC, UC, alcoholic liver disease, type II diabetes mellitus and smoking were not significantly related to HC.

The prevalence of biliary tract stone disease (hepatolithiasis, cholecystolithiasis and choledocholithiasis) and cholecystectomy was higher in HC patients than in controls. Hepatolithiasis is more frequently seen in East Asian countries than in Western countries, and represents a high-risk factor for ICC due to inflammation and epithelial proliferation^[3]. In parallel, extrahepatic lithiasis may promote chronic inflammatory changes in extrahepatic bile ducts, thus increasing the risk of developing extrahepatic cholangiocarcinoma (ECC), which can explain why choledocholithiasis increases the risk of developing HC. However, the reasons why hepatolithiasis increases the risk of developing HC are less clear. It was reported that cholecystolithiasis is a risk factor for ECC according to its ecological and epidemiological evidence, and the incidence of HC is decreased 10 or more years after cholecystectomy for cholecystolithiasis^[5,6]. In our study, the prevalence of both cholecystolithiasis and cholecystectomy was higher in HC patients than in controls. Cholecystectomy was

Table 3 Risk factors for hilar cholangiocarcinoma and their *P* value, odds ratio and 95% CI

Risk factors	<i>P</i>	OR	95% CI	
			Lower	Upper
Choledocholithiasis	0.039	2.704	1.054	6.941
Hepatolithiasis	0.018	3.278	1.226	8.766
Cholecystolithiasis	< 0.0001	4.499	2.990	6.769
Cholecystectomy	0.004	7.012	1.895	25.954
Biliary ascariasis	0.001	7.188	2.245	23.015
Liver fluke	0.042	10.088	1.085	93.775
Liver schistosomiasis	0.001	9.913	2.702	36.369

OR: Odds ratio.

not a risk factor for HC because the majority of surgical procedures (76%) were performed within a year prior to tumor diagnosis, which is consistent with the findings in a recent US case-control study^[7].

Chronic infectious liver diseases, such as HBV and HCV infection, were not significantly associated with HC in our study. The prevalence of HBV and HCV infection was 7.3% and 1.0%, respectively, in HC patients, and 6.3% and 2.1%, respectively, in controls. The prevalence of HBV is rather high in China, and HBV is strongly associated with hepatocellular carcinoma (HCC). Moreover, the HBV genome has been detected not only in infected hepatocytes but also in bile duct epithelial, endothelial, and smooth muscle cells^[8]. It has been shown that HBV is also an independent risk factor for ICC in Chinese population^[9]. In the present study, HBV was not associated with HC, which is, however, not consistent with the reported findings in China^[10], suggesting that HBV is related to ECC. It was reported that HCV can also damage the bile duct epithelial cells, thus leading to a range of proliferative, inflammatory, and generative changes^[11]. Recent studies from Korea, Japan and Italy showed that HCV is associated with cholangiocarcinoma^[12-14]. A population-based case-control study in US^[6] showed that HCV is associated with ICC, but not with ECC. This study also showed that HCV was not a risk factor for HC. Although both HBV and HCV can be detected in hepatic bile ducts, most studies demonstrated that they are related only to intrahepatic bile duct carcinoma^[15,16]. The detailed mechanism still needs further investigation.

It has been shown that parasitic liver disease is related with cholangiocarcinoma^[17-19]. In the present study, biliary ascariasis, liver fluke (*Clonorchis sinensis*) and liver schistosomiasis were significantly associated with HC in Chinese population. Ascariasis is endemic in China and 4.8% cases had a history of biliary ascariasis in our study. *Ascaris* invasion into the bile duct may cause biliary colic, pyogenic cholangitis, pancreatitis and septicemia. A residual dead worm may destroy the biliary epithelial cells, resulting in fibrosis or nidi that may form stones. It was reported that ova and fragments of *ascaris* can serve as for stone formation^[20] and choledocholithiasis is a risk factor for HC. The bile duct damage induced by *ascaris*,

worm and stone formation may play an important role in genesis and development of cholangiocarcinoma. *Clonorchis sinensis* infestation is common in East Asia countries, including China, Korea, and Far East Russia, where the local inhabitants are used to eat raw fish or shrimp^[21]. In our study, 4 patients were infected with *Clonorchis sinensis* and had a history of eating fresh fish and shrimp. An epidemiological study from Thailand suggested that liver fluke (*opisthorchis viverrini*) is associated with cholangiocarcinoma^[22]. A hospital-based case control study in Korea also revealed that *Clonorchis sinensis* is strongly associated with cholangiocarcinoma^[23]. Schistosomiasis is the second most common parasitic infection worldwide after malaria. *Schistosomiasis Japonica*, occurring in Japan and China, may be a risk factor and an independent adverse prognostic factor for HCC^[24,25]. Besides, it has been shown that schistosomiasis *Japonica* is a risk factor for HC in Egyptian^[4]. Our study also confirmed that schistosomiasis *Japonica* was associated with HC in Chinese population. Carcinogenesis occurs in patients with parasitic infection, because the existence of parasites within the host induces chronic inflammation^[26,27]. Phagocytes release reactive oxygen and nitrogen species in patients with chronic inflammation are potential to damage DNA, proteins and cell membranes, modulate enzyme activities and gene expression, thus promoting carcinogenesis^[28-30].

In the Western world, the most common risk factor for HC is PSC^[31,32], an inflammatory disease of the bile duct, which is in turn closely associated with UC. The prevalence of UC in patients with PSC is 70%-100%^[33-35]. It was reported that the lifetime risk of developing cholangiocarcinoma in patients with PSC is 10%-15%^[36]. Parker *et al*^[37] described the association between UC and cholangiocarcinoma in 1954. Converse *et al*^[38] in 1971 found that the incidence of HC is higher in patients with PSC than in those with UC. The prevalence of PSC and UC is higher in Western world than in Asia^[39]. No epidemiological investigation of PSC and UC is available in China. In our study, PSC was diagnosed in 2 patients and UC in 1 patient. However, no PSC or UC was observed in controls.

It was reported that alcoholic liver disease and type II diabetes mellitus are related to extrahepatic cholangiocarcinoma in US population^[40]. However, our study demonstrated that they were not significantly associated with HC in Chinese population.

Our study had two potential limitations. One is that clinical records were used as the source for risk factor information, and the other is that most patients and controls came from certain geographic regions, which may omit some risk factors prevalent in other regions of China.

In summary, cholecystolithiasis, hepatolithiasis, choledocholithiasis, biliary ascariasis, liver fluke and liver schistosomiasis are the risk factors for HC, while PSC and UC are the suspected risk factors for HC in China. Further study is needed to explore the role of these risk factors in the development of HC.

COMMENTS

Background

Although several risk factors are associated with the development of hilar cholangiocarcinoma (HC), such as primary sclerosing cholangitis (PSC), liver fluke or biliary tract stone disease, the risk factors for HC in Chinese patients have not been fully studied.

Research frontiers

The etiology of cholangiocarcinoma has been well studied, and several risk factors for HC have been documented. Chronic infectious liver diseases, such as hepatitis B virus (HBV) and hepatitis C virus (HCV) infection, have been fully investigated in recent studies and are considered as the important risk factors for cholangiocarcinoma.

Innovations and breakthroughs

In this study, neither HBV infection nor HCV infection was associated with HC in Chinese population, which is not consistent with previous studies. PSC and ulcerative colitis were not the risk factors for HC possibly due to their low incidence in Chinese population. In addition to liver fluke, biliary ascariasis and liver schistosomiasis are also the risk factors for HC, which have not been reported in previous studies.

Applications

HC is a rare malignant disease with a poor prognosis. The findings in this study may contribute to its control.

Peer review

The authors investigated the potential risk factors associated with HC, and demonstrated that biliary tract stone and parasitic liver disease are the risk factor for HC, which may contribute to its control.

Abstract

AIM: To investigate the protective effect of penehyclidine hydrochloride post-conditioning in the damage to the barrier function of the small intestinal mucosa caused by limb ischemia-reperfusion (LIR) injury.

METHODS: Male Wistar rats were randomly divided into three groups (36 rats each): the sham-operation group (group S), lower limb ischemia-reperfusion group (group LIR), and penehyclidine hydrochloride post-conditioning group (group PHC). Each group was divided into subgroups ($n = 6$ in each group) according to ischemic-reperfusion time, i.e. immediately 0 h (T_1), 1 h (T_2), 3 h (T_3), 6 h (T_4), 12 h (T_5), and 24 h (T_6). Bilateral hind-limb ischemia was induced by rubber band application proximal to the level of the greater trochanter for 3 h. In group PHC, 0.15 mg/kg of penehyclidine hydrochloride was injected into the tail vein immediately after 3 h of bilateral hind-limb ischemia. The designated rats were sacrificed at different time-points of reperfusion; diamine oxidase (DAO), superoxide dismutase (SOD) activity, myeloperoxidase (MPO) of small intestinal tissue, plasma endotoxin, DAO, tumor necrosis factor- α

(TNF- α), and interleukin (IL)-10 in serum were detected in the rats.

RESULTS: The pathological changes in the small intestine were observed under light microscope. The levels of MPO, endotoxin, serum DAO, and IL-10 at T_1 - T_6 , and TNF- α level at T_1 - T_4 increased in groups LIR and PHC ($P < 0.05$) compared with those in group S, but tissue DAO and SOD activity at T_1 - T_6 decreased ($P < 0.05$). In group PHC, the tissue DAO and SOD activity at T_2 - T_6 , and IL-10 at T_2 - T_5 increased to higher levels than those in group LIR ($P < 0.05$); however, the levels of MPO, endotoxin, and DAO in the blood at T_2 - T_6 , and TNF- α at T_2 and T_4 decreased ($P < 0.05$).

CONCLUSION: Penehyclidine hydrochloride post-conditioning may reduce the permeability of the small intestines after LIR. Its protection mechanisms may be related to inhibiting oxygen free radicals and inflammatory cytokines for organ damage.

INTRODUCTION

Limb ischemia-reperfusion (LIR) injury has been observed

in atherosclerosis, thrombosis or injury to the great vessels in the extremities, severe crushing injury and surgery^[1-3]. It can lead to limb edema, skeletal muscle dysfunction, and necrosis, and may further result in the dysfunction and structural damage to other organs such as the heart, lungs, brain, small intestines, and so on^[4,5]. Therefore, protection against ischemia-reperfusion injury has become an important focus of research in clinical work.

In recent years, many narcotics have been used to reduce the damage caused by ischemia-reperfusion^[6-8]. The new anti-cholinergic drug penehyclidine hydrochloride (PHC), reported to have protective effects against organ injury^[9-11], was developed by the Institute of Pharmacology and Toxicology in China (Academy of Military Medical Sciences) to minimise side effects harmful to the cardiovascular system^[12,13]. To date, no reports on the protective effects of PHC against LIR in the small intestines have been published. In this study, the serum and small intestinal tissue diamine oxidase (DAO), plasma endotoxin (reflecting the barrier function of the small intestinal mucosa), superoxide dismutase (SOD), and myeloperoxidase (MPO) activity of the small intestinal tissue, as well as serum tumor necrosis factor- α (TNF- α) and interleukin (IL)-10 levels (reflecting damage to the small intestine) were examined in rats.

MATERIALS AND METHODS

Experimental animals

One hundred and eight healthy 6-mo-old male Wistar rats weighing 220-250 g were provided by the Medical Experimental Animal Center of the Gansu College of Traditional Chinese Medicine, China. The rats were randomly divided into 3 groups: the sham-operation group (group S), limb ischemia-reperfusion group (group LIR), and penehyclidine hydrochloride post-conditioning group (group PHC). Each group was divided into sub-groups ($n = 6$ in each group) according to ischemic-reperfusion time, i.e. immediately (T_1), 1 h (T_2), 3 h (T_3), 6 h (T_4), 12 h (T_5), and 24 h (T_6).

Animal model

The LIR model was established as follows: the rats were fasted 12 h preoperatively with unlimited drinking water; and exposed to 2% isoflurane until the loss of righting reflex, and fixed onto a sit-board on the operating table. The posterior limbs of the rats were ligated with elastic rubber bands above the greater trochanter to completely block the blood flow. Group S was anesthetized, but did not undergo ligation. Group LIR was ligated until complete ischemia of the lower limbs, and released after 3 h to restore blood flow to the posterior limbs; reperfusion was conducted for 1, 3, 6, 12, and 24 h. In group PHC, the rubber band was released after 3 h of ischemia, and then 0.15 mg/kg PHC was injected into the tail veins, followed by reperfusion for 1, 3, 6, 12 and 24 h. After the reperfusion at pre-set time points (T_1 - T_6), the rats were sacrificed under deep isoflurane anaesthesia. All experiments were conducted according to the protocols approved by the Lanzhou University Animal Care and Use Committee.

About 5 mL of blood was drawn from the inferior vena cava of the rats. The blood was centrifuged at 3000 r/min for 15 min to separate the serum, which was stored at -20°C for further target detection. The small intestines of the rats were quickly removed up to 5 cm from the ileocecal valve and washed three times with normal saline. Then, 0.5 g of the small intestines were ground into tissue homogenate in a glass homogeniser; after centrifugation at 3500 r/min for 20 min, the resultant supernatant was diluted into a 10% solution with normal saline and stored at -20°C for further target detection. The remaining small intestines were fixed in 10% formalin, embedded in paraffin, stained with hematoxylin and eosin, sectioned, and observed for pathological changes under optical microscope.

Evaluation of changes in the barrier function of the small intestinal mucosa

The rat small intestinal tissue and serum DAO were detected using a spectrophotometer with an automatic biochemical analyser (OLYMPUS-AU5400; kit provided by the Nanjing Jiancheng Bioengineering Institute, China). Plasma endotoxin was measured using a quantitative chromogenic substrate assay (Xiamen TAL Experimental Plant Co., Ltd.).

Evaluation of damage mechanism in the small intestine

SOD and MPO activities in the rat small intestinal tissue were measured by colorimetry (Nanjing Jiancheng Bioengineering Institute). Serum TNF- α and IL-10 were measured by enzyme-linked immunosorbent assay (Wuhan Boster Biological Technology, Ltd., China).

Statistical analysis

All data were reported as mean \pm SD. Statistical significance was determined by one-way analysis of variance using SPSS version 17.0 for Windows (SPSS Inc., Chicago, IL, USA).

RESULTS

Rat small intestinal pathological changes

The small intestinal microstructure of the group S rats were normal: the villi were lined with normal epithelial cells, the interstitium was congestion-free, and gland morphology was normal. The small intestinal tissue of the group LIR rats had obvious pathological changes: the villi were malpositioned, atrophied, and shorter and thicker; loose interstitial edema with lymphocytic infiltration was observed, and lymph node follicles and submucosal lymphatic vessels were filled with lymphocytes. The small intestinal microstructure of the group PHC had certain pathologic changes that were less pronounced than in the group LIR.

Changes in the barrier function of the small intestinal mucosa

DAO is an enzyme synthesised primarily in gastrointestinal mucosal cells. The intestinal tissue and serum levels of DAO have been used as an indicator of the integrity and functional mass of the intestinal mucosa^[14,15]. When intes-

Figure 1 Changes of intestinal tissue diamine oxidase, serum diamine oxidase and plasma endotoxin in rats. S group: Sham-operation group; LIR group: Lower limb ischemia-reperfusion group; PHC group: Penheyclidine hydrochloride post-conditioning group. DAO: Diamine oxidase.

tinal mucosal integrity was disrupted during shock, burns, abdominal aortic surgery, liver disease, ischemia-reperfusion injury, and so on, an increase in intestinal permeability and translocation of bacteria endotoxin, and plasma endotoxin as well, was observed^[16,17]. In the groups LIR and PHC, serum DAO and plasma endotoxin levels at all preset time-points of reperfusion (T₁-T₆) increased compared with the group S ($P < 0.05$), whereas the tissue DAO content decreased ($P < 0.05$). Compared with the T₂-T₆ of group LIR, the tissue DAO activity of group PHC increased ($P < 0.05$), whereas the serum DAO activity and plasma endotoxin concentration were decreased ($P < 0.05$).

The tissue and serum DAO activity and plasma endotoxin concentration reached its peak ($P < 0.05$) (Figure 1) compared with other preset time-points of reperfusion at T₄ in the groups LIR and PHC.

Changes of certain factors in damage mechanism in the small intestine

In the groups LIR and PHC, the MPO activity of the small intestinal tissue and serum IL-10 at T₁-T₆, and serum TNF- α at T₁-T₄ were higher than those in the group S ($P < 0.05$), whereas the tissue SOD activity at T₁-T₆ was lower ($P < 0.05$). In group PHC, the tissue SOD activity at T₂-T₆ and serum IL-10 at T₂-T₅ were significantly higher than those in group LIR ($P < 0.05$); however, the tissue MPO activity at T₂-T₆ and serum TNF- α at T₂ and T₄ decreased ($P < 0.05$). In the groups LIR and PHC, the tissue SOD and MPO activities reached their peak at T₄ ($P < 0.05$) while TNF- α reached its peak at T₂ ($P < 0.05$). Thereafter, TNF- α gradually decreased, and even decreased at T₅ and T₆ in group S ($P \geq 0.05$); IL-10 at T₃ exhibited the highest concentration ($P < 0.05$) even at T₄-T₅, and the serum IL-10 also maintained a relatively high concentration (Figure 2).

DISCUSSION

The gastrointestinal tract in ischemia-reperfusion injury is of interest, not only because its functions are damaged, but also it is a potential factor of multiple organ dysfunction syndrome (MODS) associated with reperfusion injury^[18,19]. When the intestinal barrier is injured, the gut endotoxins may enter into the extraintestinal tissues and produce free radicals and cytokines that potentiate the development of MODS^[20-22]. In the group LIR, at different reperfusion time points, the small intestinal mucosa had varying degrees of injury, including neutrophil and lymphocyte infiltration, as well as small intestinal epithelial cell degeneration, necrosis, or even sloughing off. This result shows that LIR injury induces injury to the small intestinal mucosa. Meanwhile, the small intestinal tissue DAO activity in the group LIR was lower than in the group S; however, the activity of serum DAO and the plasma endotoxin were significantly higher than in the group S, indicating that the mucous membrane barrier of the rat small intestines was destroyed and gut permeability changed, leading to the absorption of gut cavity endotoxin and small intestinal tissue DAO into the blood stream.

LIR injury leading to permeability changes in intestinal mucosal reperfusion injury may be closely related to the production of excessive oxygen free radicals and inflammatory cytokines^[19,20,23,24]. Oxygenated free radicals appear to play a prominent role in mediating the damage associated with gastrointestinal diseases. The production of reactive oxygen metabolites in ischemia-reperfusion involves oxidases found in resident phagocytic cells, as well as microvascular and mucosal epithelial cells^[25]. SOD is a key enzyme that eliminates free radicals by converting superoxide anions into hydrogen peroxide, which is

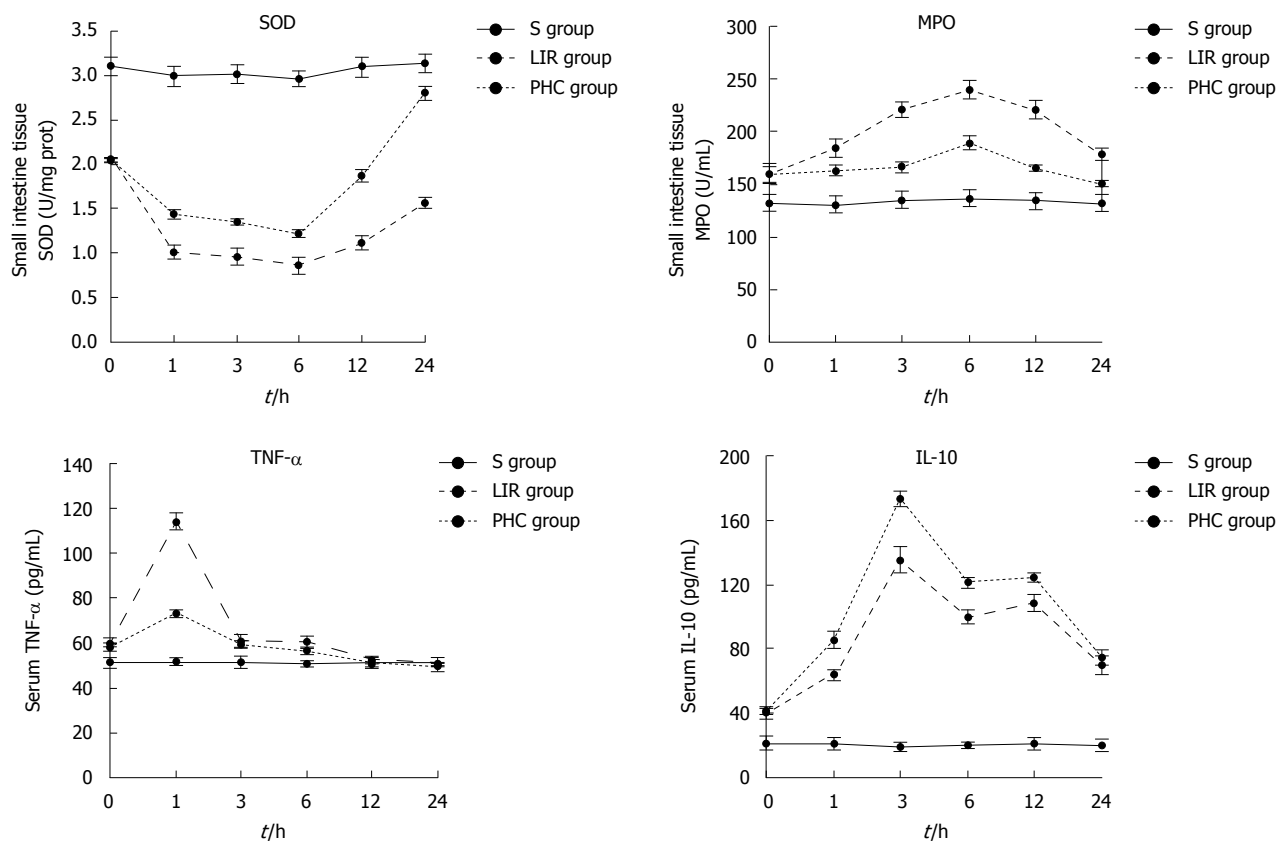

Figure 2 Changes of intestinal tissue superoxide dismutase, intestinal tissue myeloperoxidase, serum tumor necrosis factor- α and interleukin-10 in rats. S group: Sham-operation group; LIR group: Lower limb ischemia-reperfusion group; PHC group: Penehyclidine hydrochloride post-conditioning group. SOD: Superoxide dismutase; MPO: Myeloperoxidase; TNF- α : Tumor necrosis factor- α ; IL-10: Interleukin-10.

then removed by glutathione peroxidase and catalase. A high amount of oxygen free radicals is generated during ischemia followed by reperfusion, which leads to excessive consumption of SOD^[26]. MPO, on the other hand, is released upon activation to catalyse the formation of oxidants, which can lead to tissue damage during chronic inflammation, and serves as a major enzymatic catalyst of lipid peroxidation at inflammation sites^[27]. In this paper, the small intestinal tissue SOD activity of the group LIR during reperfusion was lower than that of the group S, but higher than that of MPO. This shows that an increase in oxygen free radicals and lipid peroxidation occurs, resulting in changes in the pathophysiology of the small intestinal mucosa, causing mucosal epithelial damage, edema, and activation of inflammatory immune cells.

Ischemia and reperfusion injury are associated with the coordinated activation of a series of cytokines and adhesion molecules^[27-29]. When the intestinal damage releases a large amount of inflammatory cytokines, including rapidly produced TNF- α , inflammatory cells accumulate and intestinal inflammatory damage occurs. IL-10 modulates pro-inflammatory cytokine production and tissue injury following ischemia-reperfusion injury^[30]. A study showed that the exogenous administration of IL-10 reduced the systemic inflammatory response in a rodent model of intestinal reperfusion injury, an effect associated with the inhibition of cytokine production and neutrophil accumulation^[31]. Being anti-inflammatory, the release of IL-10

can modulate pro-inflammatory cytokine production and reperfusion-associated tissue injuries^[32]. This experiment also suggested that IL-10 may inhibit the role of TNF- α .

PHC mainly blocks muscarinic acetylcholine receptors, which shows a wide range of biological activities, including antioxidation, cytoprotective activity, and so on. PHC can inhibit lung vascular leak, inflammation and p38MAPK activation, signalling a potential role in lipopolysaccharide and alleviation of lung injuries by inhibiting apoptosis in lung tissue cells^[9]. Wang *et al.*^[10] found that PHC attenuated the acute lung injury induced by endotoxin involving the nuclear factor- κ B (NF- κ B) pathway. The inhibition of NF- κ B activation in intestinal epithelial cells prevented the increase in systemic TNF- α concentrations after intestinal ischemia and reperfusion^[33]. In this study, PHC post-conditioning significantly reduced the pathological damage to the small intestine with lower limb ischemia-reperfusion injury. Although this damage was inevitable, the small intestinal injury in the group PHC was less severe than that in the group LIR. PHC post-conditioning increased SOD activity and reduced MPO activity, thereby reducing oxygen free radicals to diminish tissue damage. PHC post-conditioning can effectively lower the blood levels of DAO, endotoxin and TNF- α , which disrupt the effects of the organisation. PHC post-conditioning can also promote the production of anti-inflammatory factor IL-10, which inhibits TNF- α and reduces inflammatory cell accumulation in the local organization.

In conclusion, PHC post-conditioning can improve small intestinal mucosal injury induced by lower limb ischemia-reperfusion. It increases SOD activity to scavenge oxygen free radicals, reduces the production of inflammatory cytokine TNF- α , and increases the production of anti-inflammatory factor IL-10. The protective action of PHC post-conditioning on ischemia-reperfusion injury may be controlled by various mechanisms, which should be explored by further investigations.

ACKNOWLEDGMENTS

We would like to thank Dr. Gen Chen from Lanzhou University for providing the laboratory facilities.

COMMENTS

Background

Limb ischemia-reperfusion (LIR) injury can not only lead to damage of limb itself and other organs such as the heart, lungs, brain, small intestines and so on, but also may further trigger a systemic inflammatory response and multiple organ dysfunction mainly induced by dysfunction and structural damage of intestines. Penahyclidine hydrochloride (PHC) is a new anticholinergic drug with antimuscarinic, antinicotinic activities, retained potent central and peripheral anticholinergic activities. Although PHC has protective effects against septic shock and organ injury, the effects of PHC post-conditioning against LIR in the damage of the small intestines remains unknown.

Research frontiers

Damage of the gastrointestinal tract in ischaemia-reperfusion injury is of interest because it functions not only as a target organ but also as a potential effector of the multiple organ dysfunction associated with reperfusion injury. The authors used PHC post-conditioning to protect the damage to the barrier function of the small intestinal mucosa caused by LIR injury, because PHC post-conditioning can significantly inhibit the production of tumor necrosis factor- α (TNF- α), suppress excessive expression of inducible nitric oxide synthase, counteract lipid peroxidation and increase superoxide dismutase (SOD) level.

Innovations and breakthroughs

The authors aimed to investigate the protective effect of PHC post-conditioning in the damage to the barrier dysfunction of the small intestine caused by LIR injury. The results indicate that PHC post-conditioning may reduce the permeability of the small intestines after LIR. Its protection mechanisms may be related to inhibiting oxygen free radicals and inflammatory cytokines for organ damage.

Applications

Although additional studies are necessary to confirm this effect in humans, the authors found the protective effect of PHC in the clinical management of patients with limb ischemia-reperfusion. PHC used in surgical operation might reduce the damage of small intestine from limb ischemia-reperfusion injury.

Terminology

PHC is a new anti-cholinergic drug, selectively blocking M1, M3 receptors and N receptor. Compared with other anticholinergics, the notable advantage of PHC is that it does not accelerate heart rate, and it can improve microcirculation, inhibit lipid peroxidation, attenuate the release of lysosome, and depress microvascular permeability.

Peer review

This manuscript demonstrated that PHC post-conditioning can improve small intestinal mucosal injury induced by lower limb ischemia-reperfusion. It increases SOD activity to scavenge oxygen free radicals, reduces the production of inflammatory cytokine TNF- α , and increases the production of anti-inflammatory factor interleukin-10.

Abstract

AIM: To study the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk by meta-analysis.

METHODS: A meta-analysis was performed to investigate the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk by reviewing the related studies until September 2010. Data were extracted and analyzed. Crude odds ratio (OR) with 95% confidence interval (CI) was used to assess the strength of relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk.

RESULTS: Thirteen published case-control studies including 5336 cases and 6226 controls were acquired. The pooled OR with 95% CI indicated that CYP1A1 Ile462Val polymorphism was significantly related with colorectal cancer risk (Val/Val vs Ile/Ile: OR = 1.47,

INTRODUCTION

Colorectal cancer, one of the most prevalent cancers worldwide, ranks fourth in frequency in men and third in women^[1]. In recent years, the incidence of colorectal cancer has increased in most countries but its prognosis is still poor. A number of researches have shown that colorectal cancer is possibly related with tobacco and alcohol con-

sumption as well as other environmental sources^[2-4]. It has been shown that inter-individual differences including single nucleotide polymorphism (SNP) may influence human susceptibility to colorectal cancer^[5,6].

Metabolic enzymes including phase I and phase II enzymes are involved in activation and detoxification of xenobiotics, which play an important role in the pathogenesis of colorectal cancer^[7]. Cytochrome P450, including family 1, subfamily A, polypeptide 1 (CYP1A1), is one of the phase I enzymes, metabolizing a large number of endogenous and exogenous substances, such as polycyclic aromatic hydrocarbons, heterocyclic amines, aromatic amines, and N-nitrosamines^[8,9]. Thus, CYP1A1 plays an important role in human susceptibility to colorectal cancer due to various exogenous factors.

Non-synonymous SNP (rs1048943) leads to amino acid change in exon 7 of CYP1A1 from Ile to Val (nucleotides A-G) at codon 462, which may alter the protein activity and the human susceptibility to colorectal cancer. Since the first study on the relation between colorectal cancer and CYP1A1 Ile462Val polymorphism conducted by Sivaraman *et al*^[10] in 1994, a large number of epidemiological studies on the relation between colorectal cancer and CYP1A1 Ile462Val polymorphism have been conducted, but their conclusions are different or even contradictory. In this study, a meta-analysis of the published case-control studies was performed to assess the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk.

MATERIALS AND METHODS

Search strategy

Studies on the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk were search from PubMed from 1994 to September 2010 using the key words "CYP1A1", "colorectal cancer", "colon cancer", "rectum cancer", and "polymorphism". Related studies were also searched from the references of original papers or reviews. All studies were selected according to the following criteria: only case-control studies on the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk, sufficient published data for estimating odds ratio (OR) with 95% confidence interval (CI), and selection of the largest or most recent studies when several publications reporting the same or overlapping data^[11]. Only the data published in 2007 were selected from two studies by Kiss *et al*^[12,13] who reported overlapping data in Hungarians. Finally, 13 case-control studies including 5336 patients with colorectal cancer and 6226 controls were enrolled in our meta-analysis.

Data extraction

Two investigators independently extracted the following data from the included publications, including name of the first author, publication data, country origin, source of control, racial descent of the study population, genotyping method, number of different genotypes, and Hardy-Weinberg equilibrium (HWE) in controls.

Statistical analysis

Crude OR with 95% CI was computed to assess the strength of relation between CYP1A1 Ile462Val polymorphisms and colorectal cancer risk. Codominant model (Val/Val *vs* Ile/Ile, Ile/Val *vs* Ile/Ile), dominant model [(Val/Val + Ile/Val) *vs* Ile/Ile] and recessive model [Val/Val *vs* (Ile/Val + Ile/Ile)] were evaluated. Subgroup statistical analysis of the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk in Asians and Europeans was performed. Heterogeneity assumption was checked by chi-square based Q-test^[14]. Pooled OR estimation of each study was calculated with the random-effect model (DerSimonian and Laird method) when $P < 0.10$ ^[15]. Otherwise, the fixed-effect model (Mantel-Haenszel method) was selected^[16]. The publication bias was evaluated with the funnel plot and linear regression asymmetry test as previously described^[17]. Statistical analysis was performed using the STATA version 9.2 (Stata Corporation, College Station, TX) and Review Manager (version 4.2, Oxford, England), using two-sided *P*-values.

RESULTS

Study characteristics

Thirteen published case-control studies including 5336 patients with colorectal cancer and 6226 controls met the inclusion criteria for the meta-analysis^[10,13,18-27]. The distribution of studies in different populations is listed in Table 1. The minor allele frequency of Val in controls ranged from 0.030 in Europeans^[22] to 0.255 in Asians^[23]. Genotyping methods included polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP), allele-specific PCR, TaqMan, MassARRAY system, microarray system, and APEX. The distribution of genotypes in controls of all studies was in agreement with HWE except for two studies^[19,20].

Meta-analysis

The results of meta-analysis and heterogeneity test are shown in Table 2. The colorectal cancer risk was significantly higher in individuals carrying the Val/Val genotype than in those carrying the Ile/Ile genotype (OR = 1.47, 95% CI: 1.16-1.86, $P = 0.002$, $P_{\text{heterogeneity}} = 0.44$, Figure 1A). The dominant and recessive models also showed that colorectal cancer risk was significantly related with the CYP1A1 Ile462Val polymorphism [(Val/Val + Ile/Val) *vs* Ile/Ile: OR = 1.33, 95% CI: 1.01-1.75, $P = 0.04$, $P_{\text{heterogeneity}} < 0.01$, Figure 1B; Val/Val *vs* (Ile/Val + Ile/Ile): OR = 1.49, 95% CI: 1.18-1.88, $P = 0.0009$, $P_{\text{heterogeneity}} = 0.77$, Figure 1C] in the total population. Subgroup race analysis showed that the CYP1A1 Ile462Val polymorphism was significantly related with colorectal cancer risk in Europeans [Ile/Val *vs* Ile/Ile: OR = 1.22, 95% CI: 1.05-1.42, $P = 0.008$, $P_{\text{heterogeneity}} = 0.25$; (Val/Val + Ile/Val) *vs* Ile/Ile: OR = 1.24, 95% CI: 1.07-1.43, $P = 0.004$, $P_{\text{heterogeneity}} = 0.24$] and in Asians [Val/Val *vs* Ile/Ile: OR = 1.40, 95% CI: 1.07-1.82, $P = 0.01$, $P_{\text{heterogeneity}} = 0.23$; Val/Val *vs* (Ile/Val + Ile/Ile): OR = 1.46, 95% CI: 1.12-1.89, $P = 0.005$, $P_{\text{heterogeneity}} = 0.24$].

	Asian	0.98	0.96-1.13	0.17
Val/Val vs (Ile/Val + Ile/Ile)	Total	1.49	1.18-1.88	0.77
	European	1.39	0.80-2.41	0.94
	Asian	1.46	1.12-1.89	0.24

¹Estimates for random effects. P_h: Test for heterogeneity; CYP1A1: Cytochrome P450, including family 1, subfamily A, polypeptide 1; OR: Odds ratio; CI: Confidence interval.

Publication bias

Funnel plot and Egger's test were used to estimate the publication bias of studies. The funnel plots seemed symmetrical in all models (Val/Val vs Ile/Ile: $P = 0.17$, (Val/Val + Ile/Val) vs Ile/Ile: $P = 0.17$, Val/Val vs (Ile/Val + Ile/Ile): $P = 0.39$, Figure 2). No publication bias concerning the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk was detected.

DISCUSSION

CYP1A1, a phase I enzyme encoded by the CYP1A1 gene, has been mapped to chromosome 15q24.1. The CYP group of enzymes is involved in metabolic activation and detoxification of tobacco-derived carcinogen and other xenobiotics. It has been shown that alcohol intake and cigarette smoking are two important risk factors for colorectal cancer^[20,25,27]. Reactive intermediates can bind to DNA when they are activated, resulting in adducts that cause mutations if not repaired, thereby initiating carcinogenesis^[28]. Meanwhile, valine for isoleucine transition at codon 462 can lead to genetic disequilibrium from adenine to guanine mutation. It has been shown that CYP1A1 Ile462Val polymorphism can increase the activity of enzymes and activation of carcinogens may increase the risk of colorectal cancer^[29,30]. At the same time, CYP1A1 Ile462Val polymorphisms in genotypes show considerable variations in their activities in different diseases and ethnics, as the variant Val, exhibiting an elevated breast cancer risk in Caucasian^[31], is a risk factor for esophageal cancer in Asians but not in Caucasians^[32]. However, Ile/Val polymorphism is not related with the increased risk of prostate cancer^[33].

The first study, published in 1994^[10], did not reveal the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer. To date, no consensus conclusion is

available on the relation of CYP1A1 Ile462Val polymorphism and colorectal cancer. Pereira Serafim *et al*^[25] demonstrated that the risk of colorectal cancer is 5-fold higher in Brazilians with the Val genotype (OR = 5.14, 95% CI: 3.15-10.80). Sachse *et al*^[19] reported that the risk of colorectal cancer is about 2-fold higher in Europeans with the homozygous Val allele (OR = 2.15, 95% CI: 1.36-3.41). Kiss *et al*^[13] and Yeh *et al*^[23] also reported that the risk of colorectal cancer is similar to those reported by Pereira Serafim *et al*^[25] and Sachse *et al*^[19] in Hungarians and Asians with

the Val genotype. However, other studies from USA and Europe showed that colorectal cancer risk is not significantly related with CYP1A1 Ile462Val polymorphism^[10,18,20-22,24,26,27], but positively related with Val allele and smoking (OR = 2.5, 95% CI: 1.3-4.8) in Europeans^[20]. The present meta-analysis of 13 eligible case-control studies including 5336 cases and 6226 controls showed that CYP1A1 Ile462Val polymorphism could contribute to colorectal cancer risk. The stratified analysis according to the ethnicity revealed that CYP1A1 Ile462Val polymorphism was positively related with colorectal cancer risk both in Asians and in Europeans. However, no report is available on the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk in Africans. On the other hand, gender factor may change the risk of colorectal cancer sometimes. It was reported that the colorectal cancer risk is 3.1-fold higher in Chinese women with CYP1A1 Val/Val and XRCC3 Thr/Thr genotypes than in those with CYP1A1 Ile and XRCC3 Met alleles^[23], suggesting that CYP1A1 Ile462Val polymorphism may be an important risk factor for colorectal cancer.

Heterogeneity is another problem found in our meta-analysis. A significant heterogeneity was observed in Ile/Val vs Ile/Ile and (Val/Val + Ile/Val) vs Ile/Ile. However, subgroup ethnicity analysis showed that the heterogeneity was removed apparently, indicating that the genetic background and environment are different in different ethnicities.

Several limitations in our meta-analysis need to be addressed. First, the results were obtained based on the unadjusted estimates and lacked of original data about the eligible studies, thus limiting the evaluation of effects of gene-gene and gene-environment interactions on the pathogenesis of colorectal cancer. Second, other single nucleotide polymorphisms of CYP1A1 were identified, but no linkage disequilibrium and haplotype analysis of these polymorphisms was performed. Third, the real relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk might have been influenced since the sample size was relatively small in this analysis, thus a further analysis of the relation between CYP1A1 polymorphism and colorectal cancer should be performed.

In conclusion, CYP1A1 Ile462Val polymorphism may contribute to colorectal cancer risk. Further study is needed with a large-scale case-control sample to validate the identified risk in our current meta-analysis, and potential gene-gene and gene-environment interactions should be taken into account when the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk is further studied.

COMMENTS

Background

Colorectal cancer is one of the most prevalent malignances worldwide. CYP1A1 is one of the phase I enzymes. Ile to Val transition has been supposed as a risk factor for colorectal cancer. A large number of studies on the association between CYP1A1 and colorectal cancer risk have been conducted, but their conclusions are different or even contradictory.

Research frontiers

Many studies indicate that CYP1A1 Ile462Val polymorphism plays an important role in pathogenesis of esophageal cancer in Asians and breast cancer in Caucasians. However, the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk remains controversial and no meta-analysis has been conducted.

Innovations and breakthroughs

This meta-analysis systemically assessed the relation between CYP1A1 Ile462Val polymorphism and colorectal cancer risk, showing that the Val allele may be a risk factor for colorectal cancer in both Europeans and Asians.

Applications

The results of meta-analysis in this study show that the CYP1A1 Ile462Val polymorphism contributes the human susceptibility to colorectal cancer in both Europeans and Asians, which may help us to make early prevention and treatment of colorectal cancer.

Peer review

This is an interesting meta-analysis of the association between CYP1A1 Ile462Val polymorphism and colorectal cancer risk. The authors carefully reviewed the literature and collected the original data. The methods they used in meta-analysis are proper.

INTRODUCTION

Sorafenib (Nexavar[®], Bayer) is an oral vascular endothelial growth factor receptor (VEGFR) tyrosine kinase inhibitor (TKI) that has been approved by the United States Food and Drug Administration for the treatment of hepatocellular carcinoma (HCC). Many studies regarding the adverse effects of this drug have been reported, which include hand-foot skin reaction, diarrhea, anorexia, asthenia, alopecia, weight loss, hypertension and arterial thromboembolism. The rate of arterial thromboembolic events following the use of sorafenib has been reported to be about 3.8%^[1]. However, most cases have been cardiac or cerebrovascular events. There have been no clinical reports of splenic infarction associated with sorafenib, to date. We report a patient who developed a spontaneous infarction of the spleen after treatment with sorafenib used for the treatment of HCC.

CASE REPORT

A 69-year-old female with a history of HCC presented to

Abstract

Sorafenib, a multitargeted tyrosine kinase inhibitor, has been shown to improve survival in patients with advanced hepatocellular carcinoma (HCC). As the clinical use of sorafenib increases, many adverse effects have been reported, such as hand-foot skin reaction, diarrhea, anorexia, asthenia, alopecia, weight loss, hypertension and arterial thromboembolism. However, there are no prior reports of splenic infarction as an adverse effect of sorafenib. Here, a case of splenic infarction in a patient with HCC who was treated with sorafenib is reported. The patient had no other predisposing factors to explain the splenic infarction except for the administration of sorafenib. The splenic infarction improved after sorafenib was discontinued; however, the HCC progressed.

Figure 1 Contrast-enhanced abdominal computed tomography. A wedge-shaped hypodense lesion in the spleen is consistent with splenic infarction (arrow). Hepatic artery catheter is seen in hepatic artery as artifact.

the gastrointestinal department with left upper quadrant (LUQ) discomfort. The patient was previously treated with percutaneous ethanol injection therapy (PEIT) for primary HCC in 1999, and subsequently transarterial chemoembolization (TACE) for local recurrent HCC in 2008 and 2009. Recently, two cycles of hepatic arterial infusion (HAI) chemotherapy with FUDR (0.3 mg/kg) and sorafenib (400 mg *po bid*) were provided for intrahepatic metastases. Initially, this combination chemotherapy was started the day after an HAI catheter was inserted. During these treatments, intermittent abdominal pain and itching of both palms were observed. At that time, endoscopic findings showed acute gastromucosal lesions; therefore, treatment with sucralfate and a proton pump inhibitor was started. The abdominal pain improved. However, after several days other characteristics of abdominal discomfort returned. The patient reported a sudden onset of dull, left-sided upper quadrant abdominal pain. The patient stopped her medications including sorafenib and the symptoms gradually improved.

A physical examination was unremarkable except for mild LUQ tenderness. The laboratory investigations including complete blood counts, electrolytes, liver and kidney function tests were all within normal limits. EKG, chest X-ray and cardiac enzymes were also within normal range. An abdominal computed tomography (CT) scan showed a wedge-shaped opacity in the spleen suggestive of an acute infarction (Figure 1). Further evaluations were performed to determine the possible cause of the spontaneous splenic infarction such as infectious endocarditis, atrial fibrillation, hematologic disorders, autoimmune disease or other possible infectious diseases. Additional laboratory tests of the peripheral blood smear, i.e. protein C and S, antithrombin III, lipid profile, homocysteine and autoantibodies including antinuclear antibody, antineutrophil cytoplasmic antibodies (ANCA), rheumatoid factor, antiphospholipid antibodies, and complement levels, were not specific. Tumor markers of α -fetoprotein (316.18 ng/mL) and PIVKA-II (393 mAU/mL) were elevated. Although she had underlying liver cirrhosis, the absence of encephalopathy and ascites, and the normal prothrombin

Figure 2 Follow up abdominal computed tomography (1 mo). New hypodense lesion has developed in upper level of the spleen (arrow).

time and albumin resulted in a Child-Pugh A functional class. The 2D echocardiogram and venous Doppler were unremarkable.

During the evaluation, the patient continued HAI chemotherapy with FUDR according to schedule without sorafenib. At discharge, sorafenib was administered again, because the symptoms had gradually improved; however, a few days later, the sorafenib was discontinued due to a second attack of LUQ pain. One month later, the follow up CT scan showed another wedge-shaped lesion in the spleen without aggravation of the HCC (Figure 2). The follow up laboratory data showed no significant changes, including for platelet count. Intra-arterial chemotherapy without sorafenib was provided. One month later, a CT scan showed diminished infarction size in the spleen; however, the HCC progressed (Figure 3).

DISCUSSION

The vascular endothelial growth factors (VEGFs) play a critical role in angiogenesis and stimulate endothelial cell proliferation, migration and tube formation^[2]. Sorafenib was developed because of its anti-angiogenic action in inhibiting tyrosine kinase of the VEGF receptor; it has been shown to improve the clinical outcome of patients with HCC in a large phase III trial^[3]. The side effects associated with this agent are mostly mild to moderate. Rash, exfoliative dermatitis, hand-foot skin reaction, diarrhea and fatigue are the most common adverse events, occurring in 33%-38% of patients^[4]. However, unexpected toxicities have also been reported, including thrombotic events^[5]. Most of the adverse events are downstream effects of the suppression of VEGF signaling in endothelial cells of normal organs. The thrombotic events are also associated with anti-VEGF effects. VEGF not only stimulates endothelial cell proliferation, but also promotes endothelial cell survival and helps maintain vascular integrity. Inhibition of VEGF could thereby diminish the regenerative capacity of endothelial cells and cause abnormalities that expose pro-coagulant phospholipids of the luminal plasma membrane or underlying matrix, leading to thrombosis^[6]. In addition, VEGF increases production of NO and

Figure 3 Contrast-enhanced computed tomography scan in arterial phase at the time of diagnosis of initial splenic infarction (A) and 2 mo later (B). A: When splenic infarction was diagnosed, an approximately 4 cm x 4 cm sized hepatocellular carcinoma (HCC) (arrow) was shown in S6; B: Two months later, the size of HCC was enlarged to 5 cm x 5 cm (arrow) and an intrahepatic metastatic nodule was also seen (arrowhead) beside main mass.

prostacyclin, and inhibits proliferation of vascular smooth muscle cells. Reduction in NO and prostacyclin, after inhibition of VEGF signaling, may predispose to thromboembolic events^[7]. Moreover, VEGF inhibition may also increase the risk of thrombosis by increasing the hematocrit and blood viscosity *via* overproduction of erythropoietin^[8]. Other concurrent pathological findings in a patient might also play a central role. There are some reports of anti-VEGF agent-related thromboembolic events such as myocardial infarction and cerebrovascular accidents. To date, thrombotic risks with intravenous bevacizumab have been studied extensively, in contrast to oral VEGFR TKIs where data on arterial events have not yet been evaluated. Recently, Choueiri *et al.*^[9] reported the relative risk of arterial thrombotic events with bevacizumab and a VEGFR TKI (sorafenib or sunitinib); a two-fold and three-fold increase was reported, respectively. This risk did not depend on the type of malignancy.

In a meta-analysis of bevacizumab-treated patients, the major underlying risk factors of arterial thrombotic events were advanced age, hypertension, diabetes, and a prior history of thrombotic events. The treatment duration for the incidence of thrombotic events was within the first 3 mo of therapy; however, the data regarding the occurrence of the events, during the course of the trial, were frequently not reported^[10]. In the case reported here, the patient was of advanced age but had no predisposing factors. The

thromboembolic event was a splenic infarction with the clinical symptom of LUQ pain. The symptoms developed 2 mo after administration of sorafenib. Most prior reports of TKI-associated arterial thrombotic events have shown myocardial infarctions and/or cerebrovascular accidents; a splenic artery infarction has not been previously reported. Possible causes of splenic infarction were investigated. The physical examination, laboratory findings, imaging studies and other drug history did not suggest any other possible causes except for the sorafenib administration. Although the patient had a history of other therapeutic procedures such as PEIT, TACE, and HAI chemotherapy, the last TACE was administered 16 mo previously and the HAI chemotherapy was continued without LUQ pain. The HAI catheter was inserted at the correct hepatic arterial level, and the distal end was connected to the port at the right femoral artery. Anatomically this should not contribute to occlusion of the splenic artery. Furthermore, the patient tolerated HAI chemotherapy without the sorafenib. The time interval from the initial administration of sorafenib to onset of LUQ pain, and the fact that discontinuing sorafenib was associated with resolution of symptoms, suggested that the sorafenib was the cause of the acute splenic infarction. Two months later, the follow up CT scan showed improvement of the splenic lesion; however, the HCC had progressed.

In this case, discontinuing sorafenib resolved the splenic infarction, however, at the expense of the HCC. Perhaps if the sorafenib had been continued with other pain medications and anticoagulants, the outcome would have been better. The use of low-dose aspirin for the prophylaxis of arterial thromboembolic events in high-risk patients is supported by an extensive body of literature^[11] and is recommended as the standard of care^[12]. Therefore, if a patient has a good response to sorafenib, it might be better to continue the sorafenib with the addition of low-dose aspirin to prevent events such as a splenic infarction, which is not life threatening.

Abstract

Nonalcoholic fatty liver disease (NAFLD) is one of the most common liver diseases and its prevalence is likely to reach epidemic proportions. According to the "two-stage hypothesis" proposed for the pathophysiology of NAFLD, insulin resistance, oxidative stress and pro-inflammatory cytokines are among the key promoters of the disease. Here, ginger has been hypothesized to prevent NAFLD or blunt its progression *via* several mechanisms, such as sensitizing insulin effects, activating peroxisome proliferator-activated receptor γ which induces adiponectin and down-regulates pro-inflammatory cytokines, changing the balance between adiponectin and tumor necrosis factor- α in favor of adiponectin, promoting considerable antioxidant effects and antidyslipidemic properties, and reducing hepatic triglyceride content which can prevent steatosis. The aforementioned mechanisms imply that ginger possesses interesting potentials for serving as a natural supplement for the prevention and treatment of NAFLD. Therefore, conducting trials to explore its benefits in clinical practice is greatly recommended.

TO THE EDITOR

Nonalcoholic fatty liver disease (NAFLD), one of the most common liver diseases, is growing fast into an epidemic problem in Western countries. NAFLD, covering a wide spectrum of hepatic conditions from simple steatosis to nonalcoholic steatohepatitis (NASH), may lead to more severe disorders such as cirrhosis and hepatocellular carcinoma. The pathophysiology of NAFLD has been conceptualized to be a two-stage process, consisting of fat accumulation in hepatocytes and consequent hepatic steatosis in the first stage, and hepatic injury or NASH in the second stage. Insulin resistance plays a central role in both stages of NAFLD pathogenesis while oxidative stress and pro-inflammatory cytokines [in particular tumor necrosis factor (TNF)- α] are among the important promoters of the second stage.

Ginger (underground rhizomes of *Zingiber officinale*) is a famous spice which has been used for centuries as a medicinal plant in different traditional medicine systems. The therapeutic effects of ginger have also been validated by modern research, rendering it as a potential medication for a variety of disorders. Gingerols and shogaols represent the predominant pungent constituents of ginger responsible for many of its medicinal properties. Herewith, it is hypoth-

esized that ginger might be applied as a potential natural medicine that could counteract the biochemical abnormalities involving the pathogenesis of NAFLD as follows.

Insulin resistance is a common feature in patients with NAFLD and NASH. Regarding the key role of insulin resistance and resulting hyperinsulinemia in hepatic triglyceride accumulation, insulin sensitizing is an important therapeutic mechanism against NAFLD. A previous preliminary study reported that the insulin sensitivity to adipocytes could be improved using ginger, with gingerol as its active component for this effect^[1].

It is considered that peroxisome proliferator-activated receptors α (PPAR α) and γ (PPAR γ) can influence hepatic triglyceride accumulation and thereby pathogenesis of NAFLD. It was reported that PPAR γ can improve insulin sensitivity and decrease the flux of fatty acids into liver^[2]. Moreover, PPAR γ activation is associated with other beneficial effects such as induction of adiponectin expression and secretion, and down-regulation of the expression of pro-inflammatory cytokines including TNF- α . Hence, PPAR γ agonists have been hypothesized to be of therapeutic importance in NAFLD^[2]. Noteworthy, ginger's 6-shogaol has been reported to be a significant agonist of PPAR γ in adipocytes^[3].

Previous studies showed that both TNF- α and adiponectin play an important role in the development of hepatic steatosis and in its progression to NASH^[4,5]. These cytokines have conflicting activities and antagonize each other's production and effects. While adiponectin has several protective effects against NAFLD such as improvement of insulin resistance and reduction of fat accumulation in hepatocytes. TNF- α antagonizes these effects and promotes hepatic steatosis. Therefore, down-regulation of TNF- α may be a potential approach to the treatment of NAFLD and amelioration of liver damage. Ginger is deemed to be effective for this purpose as several previous studies have shown that ginger extract and its bioactive constituents can decrease the TNF- α expression^[6,7]. Moreover, it has been found that both 6-gingerol and 6-shogaol can significantly inhibit TNF- α mediated down-regulation of adiponectin expression^[5].

Along with cytokines, oxidative stress also plays an important role in the second stage of NAFLD, mediating the progression of hepatic steatosis to NASH. Therefore, antioxidants such as vitamin E have gained therapeutic application in the treatment of NAFLD. In addition to the other benefits mentioned, ginger possesses considerable antioxidant properties including radical scavenging activity and inhibitory effect on lipid peroxidation, which can be ascribed to the presence of polyphenols such as gingerol and curcumin in this plant^[8]. Besides, ginger protects the liver against hepatotoxic agents by enhancing the hepatic antioxidant activity^[9,10].

Triglyceride accumulation in hepatocytes is the hallmark of NAFLD. There is evidence that ginger can reduce hepatic triglyceride content, induce LDL receptor and down-regulate HMG-COA expression in the liver^[11].

Moreover, ginger extract has been reported to exert its anti-hyperlipidemic effects by decreasing serum levels of total cholesterol, LDL-C and triglycerides and increasing HDL-C^[12]. Thus, supplementation with ginger might be effective in the prevention of steatosis and control of dyslipidemia which is a risk factor for NAFLD^[10].

In spite of the aforementioned interesting potentials of ginger, the efficacy of this wonderful spice has not been sufficiently investigated in relation to NAFLD. Given the long reputation of ginger as a medicinal herb and dietary spice with a good safety, tolerability and low price, future clinical trials are warranted to identify its efficacy as a multifunctional adjunctive therapy for NAFLD.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclu-

sion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organizations]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit on-

line. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review.

Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use

Instructions to authors

uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of P values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, ▲, △, etc., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date,

volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 $24.5 \mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Instructions to authors

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interac-

tions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

The lack of an effective medical treatment for gastroparesis has pushed the research of new techniques of gastric electrical stimulation (GES) for nearly half a century of experimentation with a large variety of electrical stimuli delivered to the gastric wall of animals and patients with gastroparesis. Three principal methods are currently available: gastric low-frequency/high-energy GES with long pulse stimulation, high-frequency/low-energy GES with short pulse stimulation and neural sequential GES. The first method aims to reset a regular slow wave rhythm, but has variable effects on contractions and requires devices with large and heavy batteries unsuitable for implantation. High-frequency/low-energy GES, although inadequate to restore a normal gastric electro-mechanical activity, improves dyspeptic symptoms, such as nausea and vomiting, giving patients a better quality of life together with a more satisfactory nutritional status and is suitable for implantation. Unfortunately, the numerous clinical studies using this type of GES, with the exception of two, were not controlled and there is a need for definitive verification of the effectiveness of this technique to justify the cost and the risks of this procedure. The last method, which is neural sequential GES, consists of a microprocessor-controlled sequential activation of a series of annular electrodes along the distal two thirds of the stomach and is able to

induce propagated contractions causing forceful emptying of the gastric content. The latter method is the most promising, but has been used only in animals and needs to be tested in patients with gastroparesis before it is regarded as a solution for this disease.

INTRODUCTION

Gastroparesis is a chronic disorder characterized by a severe functional delay in gastric emptying (GE), which not only causes distressing symptoms, such as upper abdominal discomfort or pain, a sense of epigastric fullness after meals, early satiety, nausea, and vomiting, but may also lead to nutritional depletion requiring enteral or parenteral nutrition. The treatment of this condition represents a clinical challenge and is one of the most disappointing areas in medicine. The current available medical therapy is represented, by dietary modifications and administration of prokinetic agents, such as domperidone, metoclopramide and derivatives, cholinomimetics, such as neostigmine, macrolides, such as clarithromycin, erythromycin, and "motilides" and, more recently, the 5HT₄ selective agonists, such as prucalopride^[1], while cisapride has been withdrawn from most markets due to its dangerous side effects which

affect the heart. However, some patients with gastroparesis can not undergo chronic treatment with prokinetic drugs, due to the occurrence of severe side-effects, such as nervous disturbances caused by metoclopramide, hyperprolactinemia due to domperidone, and antibiotic activity with erythromycin. In addition, tachyphylaxis may occur with some drugs, such as domperidone and erythromycin, and refractoriness to prokinetic agents is observed in a significant number of patients. The intrapyloric endoscopic injection of botulinum toxin seems to relieve the symptoms of gastroparesis^[2,3]. However, a preliminary controlled double-blind study apparently failed to confirm previous results with regard to symptoms, although showed a significant improvement in solid GE^[4]. If all of these treatments are unsuccessful and nutrition “per os” is insufficient, patients must undergo enteral nutrition. Surgical jejunostomy performed by laparoscopy and percutaneous endoscopic jejunostomy are indicated for patients with refractory gastroparesis unable to maintain sufficient nutrition “per os”, in order to provide nutrients, fluids and medications^[5], on condition that there are no motor disturbances of the intestine, such as pseudo-obstruction. If enteral nutrition is not possible, the patient is usually referred to the surgeon for partial or even subtotal gastrectomy with Roux en Y reconstruction^[6]. If gastric resection is risky, or refused by the patient, or does not resolve the nutritional problems, the patient must undergo permanent enteral or parenteral nutrition. No alternative to surgery and chronic artificial nutrition was imaginable until 1963, when investigators hoped that gastric electrical stimulation was a new way to cure ileus^[7]. Following cardiac stimulation with a pacemaker, these authors thought that it would be sufficient to deliver an electrical stimulus to the gut wall to restore an efficient contraction. However, this simple idea turned out to be more difficult than expected and remained a dream for decades, because the electrical activity, that governs the motor function of the stomach, is much more complex than that of the heart.

The present paper presents a critical overview of various methods of gastric electrical stimulation used in animals and humans aiming to restore efficient gastric motor function and improve dyspeptic symptoms in gastroparesis.

GASTRIC MYOELECTRICAL ACTIVITY

To understand the mechanism of gastric electrical stimulation it is necessary to know what gastric myoelectrical activity is. This consists of an uninterrupted sequence of electrical potential variations called “slow waves”, that spring out continuously, at a frequency of about 3/min in man, from a small zone of the proximal gastric corpus near the great curvature (pacemaker area), and propagate distally along the gastric wall toward the pylorus in the form of incomplete depolarization-repolarization annular bands. When the depolarization reaches a determined threshold, the smooth muscle cell membrane depolarizes completely with consequent contraction and another kind of electrical activity, called “spike potentials”, appears superim-

Figure 1 Gastric myoelectric and pressure activities recorded with an intraluminal electromyographic and manometric technique from the gastric antrum of a healthy subject during a period of absence of pressure waves (top tracing) and a period of contractile activity (bottom tracing). Note the slow waves of normal morphology and the frequency of 3 cycles/min that in correspondence with the contractions are followed by bursts of spikes^[6]. EMG: Gastric myoelectric; Pn: Pneumogram; P: Pressure.

posed on the second part of the slow wave^[8,9] (Figure 1). The origin of slow waves lies in the interstitial cells of Cajal type I (ICC), a series of highly ramified cells located between the longitudinal and circular muscle coats, making close contacts with the Auerbach plexus and the smooth muscle cells of both layers mediating the cholinergic excitatory and nitrergic inhibitory inputs^[10]. These cells, also called myoneural, have the property of automatically generating and transmitting to smooth muscle cells, the slow waves with an intrinsic frequency decreasing caudally^[10,11]. The absence of ICC is associated to the absence of coordinated slow waves^[12] and depletion of these cells in pathologic conditions, such as diabetic gastroparesis, may interrupt the propagation of both spontaneous and artificially paced slow waves^[13].

Hence, the orad area generates the most frequent slow wave activity and functions as a pacemaker. Slow waves initiated at proximal areas migrate caudally and “capture” (“entrain”) contiguous distal areas of less frequent intrinsic activity, driving them at their own rate (“coupling”). The slow waves propagate from one cell to another through special contacts in the cell membrane called “nexuses”, which provide a pathway of low electrical resistance regulated by the neuro-humoral control system. From these data one can understand the complexity of gastric myoelectrical activity and the importance of its role in gastric motor function. It represents the end point of the motility control system, on which neurocrine, endocrine and paracrine systems operate, and, as it establishes frequency, direction and propagation velocity of peristaltic waves, it may be considered the indispensable condition (“conditio sine qua non”) of any coordinated motor activity of the stomach^[14].

In gastroparesis, there are more or less severe alterations in gastric myoelectrical activity^[15], which may be record-

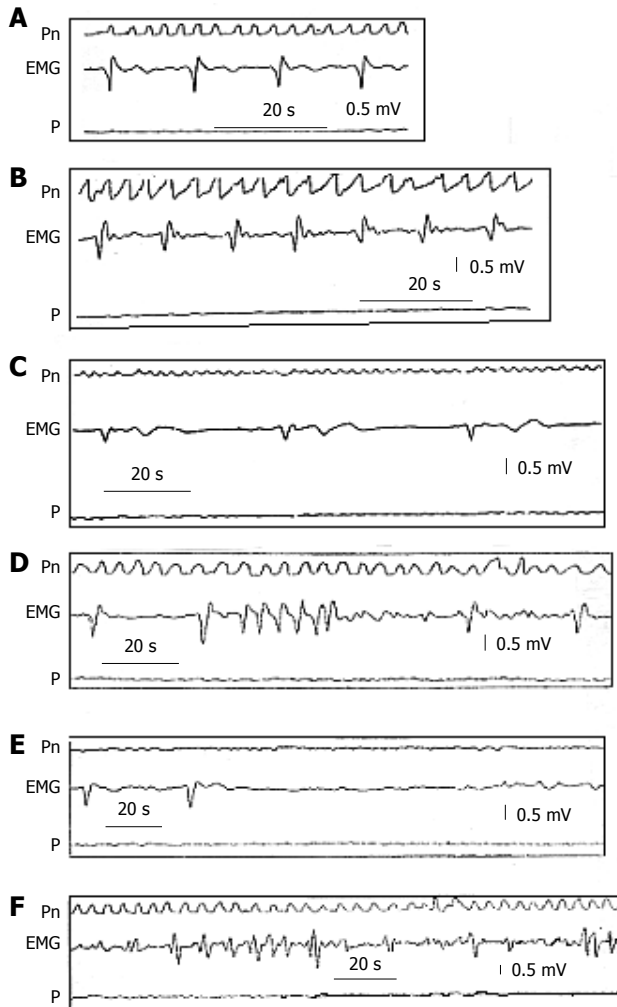

Figure 2 Electrogastrographic alterations. Series of alterations in the gastric myoelectric activity recorded with an electromyographic and manometric technique from the gastric antrum of patients with severe gastroparesis in confront with (A) normal myoelectric activity recorded in a healthy subject showing slow waves of normal morphology and frequency of 3 cycles/min. B: Tachygastric; C: Bradygastric; D: Run of high frequency tachygastric; E: Bradyarrhythmia; F: Complete disorganization of myoelectric activity ("gastric fibrillation"). Note that all these alterations are associated with absence of gastric contractions^[1]. EMG: Gastric myoelectric; Pn: Pneumogram; P: Pressure.

ed with intraluminal, serosal and cutaneous electrodes^[16,17]. The electrogastrographic alterations consist of various kinds of arrhythmias (Figure 2), very similar to those observed on the electrocardiogram in some cardiac diseases, such as tachygastric, tachyarrhythmia, bradyarrhythmia, asystolia (electrical silence), and gastric fibrillation^[16]. The latter is a complete disorganization of gastric electrical activity due to impairment of coupling and propagation of gastric slow waves. All these alterations result in a lack of propagated gastric contractions with a more or less severe delay in GE. However, it is also possible that, despite a regular slow wave rhythm, the gastric wall is unable to contract (electro-mechanical dissociation), because of alterations in the smooth muscle cell contractile system activation and operation.

It is paramount to remember that the motility structures of the gastric wall, such as the smooth muscle cell contractile system, interstitial cells of Cajal pacemaker

network, enteric neurons (motor, sensory, integratory) and afferent and efferent fibres connected with the CNS, work using a depolarization-repolarization mechanism. An electrical stimulus delivered to the gastric wall may influence the electrical activity of these structures with consequent modifications of their function and its effect depends on the characteristics of excitability of the target tissues and on the stimulus parameters.

GASTRIC ELECTRICAL STIMULATION

Gastric electrical stimulation (GES) consists of the delivery of electrical stimuli by means of electrodes implanted in the musculature of the gastric wall which are connected to a stimulator device in order to restore effective gastric contractions with normal GE and improve the symptoms of refractory gastroparesis.

Since the 1960s, many investigators have tried to re-establish normal gastric myoelectrical activity to generate coordinated peristaltic activity in patients with refractory gastroparesis^[18]. They used a large variety of electrical stimuli differing in pulse width, amplitude and frequency with diverse approaches and various results. It is the difference in frequency of the electrical stimuli from 3-4 cycles/min (cpm) to 50 cycles/s (Hz), which is mainly responsible for the different effects on the target structures of the gut wall.

Two principal types of GES are available: (1) Low-frequency/high-energy GES with long pulse stimulation, the frequency of which is just above that of the native slow wave with a pulse duration in the order of some tenths of a second; and (2) High-frequency/low-energy GES with short pulse stimulation, the frequency of which is markedly above that of the native slow wave with a pulse duration less than one thousandth of a second, delivered singly or in bursts of various length.

Low-frequency/high-energy GES with long pulse (gastric electrical pacing)

The electrical stimulus likely activates the interstitial cells of Cajal and/or muscle cells directly without involving intramural cholinergic nerves, because the administration of atropine does not block the appearance of electrical-ly-induced slow waves^[19].

This stimulation is called low-frequency/high-energy GES, because the frequency is slightly above that of the slow wave and its request for energy is high, due to prolonged delivery of a pulse current, for which it is also called "long pulse stimulation". It may be properly defined as "gastric electrical pacing" (GEP), as it refers to electrical stimuli which are aimed to induce propagated slow waves that replace the spontaneous waves.

If a pulse stimulus with a constant current of 2-4 mA lasting 30-500 ms is given to the gastric wall during a non-refractory period, an extra slow wave is induced, which propagates along the gastric wall both in oral and aboral directions, depending on the site of stimulation^[20,21]. When a series of stimuli is given, a series of slow waves is induced (entrainment) only if the stimulus frequency is

Figure 3 Normalization of ectopic tachygastria with low-frequency/high-energy gastric electrical stimulation [pacing frequency: 3.2 cycles/min (cpm), pulse width: 300 ms, amplitude: 4 mA] in a patient with gastroparesis. The pacing was carried out in the proximal corpus and the recording electrodes were in the mid gastric corpus (S_2) and in the gastric antrum (S_4). Before pacing a slow wave of about 3.5 cpm was recorded at S_2 (A) and tachyarrhythmias at S_4 (B), whereas the pacing with a frequency of 3.2 cpm entrained gastric slow waves at S_2 (C) and S_4 (D)^[44].

slightly above that of the intrinsic frequency, but not more than 4.7 cpm in man^[18,20,22] (Figure 3). The entrainment, however, is not sufficient to re-establish a propagated contraction in all cases and consequently to improve GE, especially if the neuromuscular structures are severely damaged^[20]. In fact, GEP in dogs following stimulation of 100-300 ms duration, 5-7 cpm frequency and 2-4 mA amplitude was able to entrain slow waves, even after an artificial gastroparesis induced by the association of vagotomy and glucagon, but the effect on gastric contraction and GE was obtained only in some cases^[18,23-27]. However, in patients with gastroparesis, GEP performed by means of an external device and transcutaneous electrodes fixed in the proximal corpus, with a frequency of 3-3.3 cpm, an amplitude of 2-4 mA and a pulse duration of 30-300 ms, was able to induce a regular rhythm in most patients, and in some cases restored efficient contractions, accelerated GE and improved symptoms^[28-32].

In conclusion, besides these limitations this kind of extrinsic pacing may re-establish a normal frequency of slow wave activity in gastric dysrhythmias, but does not guarantee the appearance of true contractions and consequent improvement in GE, especially in conditions of severe gastric atony, and has little effect on vomiting. Unfortunately, long duration pulses require high energy which must be provided by batteries too heavy and large to be implanted in a patient for long-term treatment.

High-frequency/low-energy GES with short pulse (gastric neuro-stimulation)

This type of stimulation is called “high-frequency GES” (HF-GES), because the frequency of the stimulation is well above the intrinsic frequency, and is also called

Figure 4 Type of electrical stimulation used by the Enterra system. Short bursts of short duration rectangular pulses (330 μ s each) with amplitude of 4 mA were given at a frequency of 14 Hz in each burst. Bursts in turn lasted 0.1 s and were delivered every 5 s^[39].

“high-frequency/low-energy” GES, because it requires a low quantity of energy, and, being short the length of pulse, is also called “short pulse stimulation”.

If a series of stimuli of 2-5 mA amplitude is delivered to the gastric wall with a frequency higher than 4.8 cpm cycles/min at 2-5 mA, no slow waves are induced, because the frequency stimulus is above the “maximum driven frequency” of the stomach. The native slow wave continues to spread with its own frequency and slight modifications, while the effects on contractions and GE are variable^[27,33-38]. Stimulation may be performed with a single pulse of constant current^[35] of short duration (approximately 300 μ s) or by a couple of pulses of 300 μ s at 70 μ s intervals^[34] or by a burst of pulses of high frequency (up to 50 Hz)^[33] and variable length. As the power consumption is low, this system does not require unwieldy batteries and allows the implantation of a portable device.

The type of HF-GES most used is performed with an implantable stimulator called Enterra (Medtronic, Minneapolis, MN, USA). It delivers electrical stimuli consisting of couples of pulses with a frequency of 14 Hz, amplitude 5 mA, duration 330 μ s, which are delivered for 0.1 s at a frequency of 12 cpm^[39] (Figure 4). The electrodes are positioned *via* laparotomy or laparoscopy in the musculature of the gastric corpus, whereas the pulse generator is inserted in a subcutaneous pocket^[34,40,41]. This method of stimulation is approved by the USA Food and Drug Administration (FDA) within certain limits on humanitarian grounds and in a few selected centres of research with the approval of the Institutional Review Board, to be used in patients with diabetic or idiopathic refractory gastroparesis, but has not been authorized by NICE in the UK. Moreover, some centres in the USA have discontinued the implantation of this device, because of few benefits to patients in terms of cost and risks.

With regard to the effects of HF-GES on gastric electro-mechanical activity, the slow waves remain practically unchanged^[19,24,26,27,35,37,38], whereas the effects on contractions are contradictory^[19,26,27,37]. This may be due to the fact that none of these investigators considered the possible spontaneous occurrence of activity fronts of the migrating motor complex that may increase the motility index casually in correspondence with the period of stimulation. GE was found to be unchanged, worsened or improved, sometimes after months or years of stimulation^[26,34,35,38,42-51]. However, these studies were not controlled and in some cases the patients continued to take

prokinetic drugs during the period of stimulation^[35,38]. Some investigators solved the problem of little effect on GE by adding a pyloroplasty to GES obtaining an obvious improvement in GE^[52]. Other investigators devised a dual stimulation protocol alternating pulses of short duration (0.3 ms) with pulses of long duration (500 ms) every 10 s with the aim of obtaining not only an antiemetic effect, but also to correct dysrhythmias and improve GE^[53]. In conclusion, the effect of HF-GES on slow waves and contractions is absent or at least dubious, while there is a slight and inconstant effect on GE.

With regard to the effects of HF-GES on symptoms of gastroparesis, the first uncontrolled trials from a small number of centres reported significant and prolonged gastric symptoms improvement in both diabetic and idiopathic gastroparesis with about 80% reduction in nausea and vomiting^[34,46,54-59]. One further study^[48] from three regional centres regarding 214 patients carrying the device for an average of 4 years, reported a continued improvement of at least one of the gastroparesis symptoms in 50% to 92% of patients. However, no symptom score and quality of life measurements at baseline and at follow-up were carried out with respect to a control group of 25 non-implanted patients. In addition, no survival benefits were observed in implanted patients with respect to non-implanted patients.

The major fault in all these studies was the absence of a double-blind randomized crossover design, with the exception of one complete study^[60] and one abstract^[61]. In the first study which included the Enterra system, 33 patients (17 diabetic and 16 idiopathic) were randomized to ON and OFF stimulation for 1 mo periods in a double-blind crossover design, followed by a non-blinded ON period of 6-12 mo. With regard to the results there were, however, as noted in a follow-up "Letter to the Editor"^[62], discrepancies between the initial submission to the USA FDA, where a decrease in vomiting frequency was reported without significant differences between the ON and OFF periods, and the subsequent publication in *Gastroenterology*, where a reduction in vomiting frequency was observed in diabetic patients during the ON period and not during the OFF period. The decrease in vomiting frequency continued during the uncontrolled phase of stimulation, confirming the results of other studies^[58], but no significant decreases in postprandial fullness, early satiety, pain and bloating were observed. Due to these limited results, the authors announced in a reply to the previously reported "Letter to the Editor"^[62], that a new controlled double-blind multicentre trial of GES with Enterra was underway.

The results of a new prospective multicentric double-blind randomized controlled crossover study with Enterra was presented at the DDW of 2010^[61] on the effects observed in 32 patients with idiopathic gastroparesis. After 6 wk of stimulation, a double-blind randomized consecutive 3-mo crossover period with the device ON or OFF was followed by an unblinded ON period up to 12 mo after implantation. However, during the crossover period there was a non-significant reduction in weekly vomiting frequency with a median of 9.8 episodes during the OFF

period vs 6.4 during the ON period. At one year after implantation, symptoms and quality of life were significantly improved as well as GE at 2 h, but not at 4 h.

In patients treated with this system the decrease in vomiting was associated with an improvement in some nutritional parameters, such as body weight and serum albumin, and with a decrease in necessity for parenteral or enteral nutrition. In addition, the need for visits and hospitalization and the use of prokinetic and antiemetic drugs were significantly decreased, whereas in diabetic gastroparesis the glycaemic control was improved, as well as the health-related quality of life^[34,46,49,50,56,57,60]. A comparison between medical therapy for gastroparesis and the necessity for health care resources was determined, however, this was carried out only in one study with a very small randomized control group and without a detailed indication of the drugs and doses used^[55].

Other studies on the effect of GES were performed in other types of patients with gastroparesis, such as those who underwent a partial gastric resection with or without Roux en Y gastric bypass and those who underwent esophagectomy or heart-lung and kidney-pancreas transplant procedures^[42,63,64], who reported a decrease in symptoms for long periods of time. However, the energy requirement for successful stimulation was higher in patients with postsurgical gastroparesis with respect to any other type of gastroparesis^[65].

The major problem with this procedure is the scarce responsiveness which may occur in patients with prominent bloating or pain^[58], and in idiopathic with respect to diabetic gastroparesis^[58,60]. Also, patients with interstitial cell of Cajal loss showed little response to HF-GES^[66]. The possible causes of a poor response may lie in the incorrect positioning of electrodes and in opiate use at the time of implantation which may blunt the response to stimulation^[58]. Consequently, some investigators suggest an intraoperative endoscopic ultrasound to confirm the correct positioning of the electrodes within the gastric muscle layer^[67]. To test the response before the implantation of a permanent stimulatory device, other investigators placed percutaneous stimulating electrodes at the time of gastrostomy or used a PEG technique^[68]. Self anchoring percutaneous electrodes have been used^[69,70], which may allow prolonged stimulation up to 2 mo^[71]. Other investigators propose to adjust the stimulation parameters using hand-held programming devices to increase the voltage or pulse frequency.

Another important problem of the Enterra system is the complications that may take place in up to 20% of patients, such as infections, migration and erosion of the stimulating device^[34,60], stomach wall perforation, pain due to adhesive bands from pacing wires to the abdominal wall^[72], dislodgment, breakage and erosion of leads into small bowel^[73], and stomach wall perforation and intestinal obstruction. All these complications require another surgical intervention and are sometimes lethal^[46].

The mechanism of action of this type of HF-GES is unknown. In fact, symptom improvement is not due to an entrainment of slow waves, or to a correction of underlying slow wave dysrhythmias^[56,74], or to an improvement in

GE. The improvement in symptoms was associated with a decrease in gastric retention at 4 h in rare cases^[43], whereas in the majority of cases there was a discrepancy between the improvement in symptoms and the disappointing results on gastric motor function. A decrease in vomiting with the Enterra system was also observed in patients with hereditary intestinal pseudo-obstruction or with simple functional dyspepsia^[70,75], as well as in patients with nausea and vomiting regardless of GE rates^[74,76]. These results indicate the existence of a mechanism independent of GE improvement. The fact that in a couple of controlled studies^[60,61] a similar improvement in symptoms occurred during the crossover double-blind ON and OFF stimulation, suggests that this mechanism could be a placebo effect or that the surgery itself on the stomach and abdominal wall may have given rise to some kind of afferent stimuli that decreased the sensation of nausea and vomiting. In addition, a spontaneous improvement in gastric motility and dyspeptic symptoms cannot be excluded, as this was noted in patients with postviral gastroparesis and in patients with intractable diabetic and idiopathic gastroparesis under tube feeding, who resumed spontaneously with oral feeding^[5,77,78]. No significant effect on the blood levels of gut hormones with gastrokinetic activity, such as motilin, gastrin, neurotensin and pancreatic polypeptide was observed. Other investigators took into consideration modifications in sympathetic-vagal activity, adrenergic and cholinergic functions^[79,80] or modulation of thoracic spinal neurons activity^[81], as well as that of the paraventricular nucleus of the hypothalamus^[82] and that of the thalamus, which were found on PET to be activated in gastroparetic patients by gastric stimulation^[80]. However, the hypothesis that the device acts through vagal pathways^[54,83] was disproved by the fact that HF-GES also works well in patients with vagotomy^[42]. Symptom improvement is possibly due to an action on afferents fibres^[84] which inhibit the vomiting centre or influence symptom perception in the brain or promote fundic relaxation through nonvagal nitrergic pathways^[38,85-87]. In fact, experiments with a gastric barostat showed that HF-GES decreases sensitivity to gastric distension and enhances gastric accommodation to a meal in patients with severe idiopathic gastroparesis^[85]. As to why this kind of GES improves nausea and vomiting remains an enigma.

Neural sequential GES is another type of high-frequency GES

The application of a train of electrical square waves with a duration of a few ms and a frequency > 50 Hz with an amplitude of 8-16 V for 4-16 s invokes a contraction of the gut wall at the site of the electrodes. This type of electrical stimulation induces a release of acetylcholine from the intramural cholinergic fibres, which in turn stimulates muscle cell contraction. In fact, its effect is prevented by the previous administration of atropine^[88] and for this reason is called "neural GES"^[89]. This contraction, however, does not propagate spontaneously, but either circumferentially and aborally^[90]. To have a contraction involving a circular band of gastric musculature it is necessary to use

Figure 5 Characteristics of one sequential gastric pacing stimulation protocol in dogs are shown from the proximal (1) to the distal (4) electrodes, that were positioned along the gastric corpus and antrum at 4 cm interval. Four second duration pulse trains with an amplitude of 14 V and a frequency of 50 Hz were delivered in synchronized fashion with a 4 s lag between adjacent stimulus sites^[89].

a circular chain of electrodes, and to have a propagated contraction it is necessary to employ a series of these electrodes encircling both the corpus and the antrum, activating them sequentially ("neural sequential GES")^[88]. The spontaneous slow wave is overwhelmed by these electronically co-ordinated contractions. This system has the advantage of working both when spontaneous waves show a regular rhythm, but are unable to induce efficient pressure waves, and when slow waves are arrhythmic, uncoupled, completely disorganised and not responding to low-frequency pacing.

Mintchev *et al*^[89,91] with the aid of a series of 4-6 ring electrodes placed in the corpus and antrum of dogs, sequentially activated by a microprocessor (Figure 5), was able to induce strong propagated contractions, that increased GE of both liquids and solids. The effectiveness of this type of GES was also demonstrated in a gastroparetic patient at the time of laparotomy^[89]. Acute and chronic canine studies confirmed the feasibility of this microprocessor-controlled stimulation method with an implantable multichannel stimulator^[92], which may be externally controlled with radiofrequency^[93,94].

However, before initiating studies in patients with gastroparesis, chronic experiments in animal models are necessary with an implantable device to evaluate not only the long-term efficiency of this method and the possible incidence of surgical complications, but also to assess the pathophysiologic influence of electrical current pulses on neuromuscular structures of the gastric wall and the effects of the strong antral contractions in the management of gastric content. In fact, one must bear in mind the motor function of the pylorus and duodenum when antral contractions occur. If the pylorus remains open during stimulation, the strong artificial contractions may cause a rapid GE of food particles with consequent risk of maldigestion and dumping syndrome, as suggested by Hasler^[95], because the "intestinal brake" is lacking. In addition, if there is a non-propulsive motor disorder of the small intestine, an accumulation of material in the intestinal lumen may take place, which may give rise to a func-

Figure 6 Two ambulatory 24-h gastroduodenal recordings (A and B) carried out on two separate days in a patient with apparently refractory gastroparesis by means of a probe with 5 miniaturized electronic pressure transducers, 5 cm apart: one in the corpus (C), two in the antrum (A1 and A2) and two in the duodenum (D1 and D2). On the first day (A) the recording was carried out without drug administration and on the second day (B) with clarithromycin (CLA) administration. A: On the first day, the postprandial gastric motor activity was very low and only three activity fronts of the Migrating Motor Complex were observed, two during the night and one early in the morning; B: On the second day, the oral administration of clarithromycin 30 min before lunch was followed about 3 h later by a burst of powerful peristaltic contractions starting in the stomach and progressing in the duodenum, followed by two others bursts at about 80 min intervals. The oral administration of clarithromycin 30 min before dinner induced after about 2.4 h a series of six bursts of powerful peristaltic waves in the stomach and duodenum at 80-100 min intervals^[103].

tional obstruction. If the pylorus does not open, as may happen in patients with diabetic gastroparesis^[96], strong artificial contractions could accumulate the gastric content against the closed pylorus with consequent abnormal antral distension and possible occurrence of pain.

Finally, we are not sure that the normalization of GE will be accompanied by the disappearance of dyspeptic symptoms, if there is visceral hypersensitivity, as happens in patients with dyspepsia despite normal GE^[97]. However, we believe that the problem of gastric stasis is crucial in gastroparesis and should be corrected in any case. In fact, besides the severe consequences on symptoms and nutrition and the negative effect on the glycaemic control of diabetes, it may cause “*per se*” gastric damage, such as gastritis (which may be erosive in diabetics), phytobezoars^[98] with possible ulceration, obstruction and gastric perforation and pharmacobezoars comprised of medications^[99].

From these considerations we believe that an in-depth experimentation of neural sequential GES in various pathophysiological conditions associated with gastroparesis is mandatory.

COMMENT AND CONCLUSION

Many investigators have been engaged in resolving the problem of gastric electrical stimulation in the last half century with different approaches and various outcomes.

Low-frequency/high-energy GES, known as gastric electrical pacing with long pulse stimulation, is able to induce a regular rhythm, restore efficient contractions, and improve GE and symptoms in some cases of gastroparesis, but requires a high quantity of electrical current, which can only be provided by a device too large and heavy to be implanted and for this reason is not suitable for clinical

studies. However, with the progress in electronic miniaturization and in the potency of batteries this method may be considered again in the future.

High-frequency/low-energy GES with short pulse stimulation, such as the Enterra system, although it does not significantly modify slow wave and motor activity and does not consistently resolve the problem of delayed GE^[34,46,60], shows, however, a good effect on nausea and vomiting with slight but significant improvement in nutritional depletion and health-related quality of life^[34,48,57,100]. However, the possibility of spontaneous improvement or a placebo effect cannot be ruled out for sure and there are many considerations regarding the clinical use of this type of GES.

First, one must keep in mind that up to 20% of patients develop more or less severe complications, sometimes lethal, related to implantation of the device^[46].

Second, 13% of patients are non-responders^[60], especially those with idiopathic gastroparesis, and the improvement in nausea and vomiting may be temporary in 50% of patients^[58] and does not include other dyspeptic symptoms, such as epigastric pain, which is an important disabling symptom compelling the patient to continue analgesic therapy^[101].

Third, the benefit in nutritional parameters is low, as the average body weight increases were from 0.9 kg^[46] to 8.4%^[34] a year.

Fourth, when an improvement is obtained, this may not be any better than that obtained by a pyloric injection of botulinum toxin, which avoids the need for surgery in up to 2/3 of patients referred to the surgeon for GES^[102]. Moreover, an aggressive drug treatment in suitable doses, taking care to recognize and avoid pseudo-refractoriness to these drugs, may spare implantation of GES. In fact,

in most of the studies examined, including those claiming the superiority of GES over medical therapy^[55,56], there was a generic statement of refractoriness to prokinetic and antiemetic drugs without specifying the kind of drugs and dosages. None of the studies considered pseudo-refractoriness due to faulty bioavailability of the drug, which may take place when it is orally administered at the usual time interval of 30 min before meals. We performed a gastroduodenal 24 h-manometric examination in a gastroparetic patient with apparent refractoriness to prokinetics and demonstrated that the drug administered 30 min before a meal took about 3 h to stimulate gastric motility (Figure 6)^[103]. Gastric contractions were almost absent during this time, while the meal stagnated in the stomach causing dyspeptic symptoms. One should remember that in these patients about 80% of the gastric content is still in the stomach 2 h after ingestion^[60], and that the prokinetic pill also takes this time to reach the intestine to be absorbed and stimulate gastric motility. Therefore, we decided to administer the prokinetic pill more than 2 h before meals to this patient and obtained a marked improvement in dyspeptic symptoms associated with an improvement in GE and a progressive gain in body weight^[103].

Fifth, among the considerations that dissuade exposing a patient with intractable gastroparesis to the Enterra system outside of a rigorous placebo-controlled study, there is also the high cost of the procedure which exceeds USD 20000 and the existence of some limitations, such as the necessity to avoid certain metal detecting security devices and magnetic resonance imaging.

With these considerations in mind, it is advisable to discontinue the use of this type of gastric stimulator for gastroparesis outside properly designed double-blind controlled studies, because it is a costly and risky procedure that does not resolve the principal problem of gastroparesis, that is GE delay, and only improves vomiting without significantly influencing other dyspeptic symptoms, such as epigastric fullness, satiety, anorexia and epigastric pain.

Sequential neural GES, which is able to induce propagated gastric contractions with consequent acceleration of GE, is the most promising method, as it affects the core of the problem of gastroparesis which is gastric stasis, rather than just mitigate the symptoms. However, there is still much research to be carried out, since to date, this method has been used only on animals and one patient with gastroparesis^[89,91], therefore it is necessary to use this type of GES in different pathophysiologic conditions of gastroparesis. The hope is that electronic technology could make possible an easily implantable device for humans, able to modulate contractile activity following physiologic necessities. Under these circumstances, GES will become able to treat gastroparesis, whereas to date none of the current technologies has been demonstrated unequivocally to consistently accelerate GE and improve all symptoms in patients with gastroparesis.

Abstract

Hepatitis B surface antigen (HBsAg) is produced and secreted through a complex mechanism that is still not fully understood. In clinical fields, HBsAg has long served as a qualitative diagnostic marker for hepatitis B virus infection. Notably, advances have been made in the development of quantitative HBsAg assays, which have allowed viral replication monitoring, and there is an opportunity to make maximal use of quantitative HBsAg to elucidate its role in clinical fields. Yet, it needs to be underscored that a further understanding of HBsAg, not only from clinical point of view but also from a virologic point of view, would enable us to deepen our insights, so that we could more widely expand and apply its utility. It is also important to be familiar with HBsAg variants and their clinical consequences in terms of immune escape mutants, issues resulting from overlap with corresponding mutation in the *P* gene, and detection problems for the HBsAg variants. In this article, we review current concepts and issues on the quantification

INTRODUCTION

Hepatitis B virus (HBV) causes a wide range of clinical consequences, from acute and chronic infection to cirrhosis and hepatocellular carcinoma, and represents a global public health problem^[1,2]. Historically, HBV dates to 1967 when an unknown antigen in Australia was recognized to be associated with hepatitis type B, which was later referred to as the hepatitis B surface antigen (HBsAg)^[3]. Since then, HBsAg has served as a qualitative diagnostic marker for HBV infection. Notably, advances have been made in the development of quantitative HBsAg assays, which have allowed viral replication monitoring. A number of clinical studies have evaluated the clinical utility of HBsAg and suggested its potential roles. Yet, it needs to be underscored that a further understanding of HBsAg, not only from a clinical point of view but also from a virologic point of view, would enable us to deepen our insights, so that we could more widely expand and apply its utility. Therefore, in this article, we review current concepts and issues on the quantification of HBsAg titers

(qHBsAg) with respect to their biologic nature, method principles, and clinically relevant topics.

STRUCTURE AND MOLECULAR VIROLOGY OF HBsAg

Components of the viral structure

HBV belongs to *Hepadnaviridae* and is composed of the envelope, core, DNA genome, and viral polymerase. It has a circular form of partially double-stranded DNA and is approximately 3200 nucleotides in length^[4,5]. A 42-45 nm long HBV spherical form (Dane particle), which is the full virion with infectivity, can be visualized (Figure 1) under electron microscopy. It has two-layered shells. The outer shell is the envelope protein referred to as hepatitis B surface (HBs) protein, which is further divided into small, middle, and large HBs proteins (SHBs, MHBs and LHBs proteins, respectively), and the inner shell is a core protein referred to as the hepatitis B core protein in which viral polymerase and the HBV genome is enclosed. In addition to the abovementioned full virion, smaller non-infectious subviral particles are present in the serum; 17-25 nm spherical particles, mainly composed of SHBs protein, constitute the most abundant form, which is as much as 10000-fold in excess of the full infectious virion^[4,6]. Filamentous (or tubular) particles are another form, with a 20 nm diameter and variable length, and are composed of SHBs, MHBs, and the LHBs protein. The form of the HBV particles appears to be determined by the proportion of LHBs protein^[7]. All three forms can be detected in serum with commercial assays and are collectively referred to as HBsAg.

Synthesis and secretion

HBV has four distinct open reading frames (ORFs) that encode the envelope, core, polymerase, and X proteins. ORF S has three internal AUG codons encoding the SHBs, MHBs, and LHBs proteins, which correspond to the S, preS2 + S, and preS1 + preS2 + S domains, respectively (Figure 2). These proteins have a common carboxyl end but different amino ends^[8].

Like all other proteins, mRNA transcription is the first event to occur. Two 2.1 kb mRNAs for the M/SHBs proteins and a 2.4 kb mRNA for the LHBs protein are formed, and take a separate pathway from viral replication. Diverse transcription factors are involved and act on promoters, enhancers, and other regulatory elements, such as the glucocorticoid responsive element^[9,10]. LHBs and M/SHBs expression are thought to be independently regulated with different promoters; a typical TATA box is present in the LHBs promotor (S promotor I, SPI), whereas the TATA-less promotor, which usually has multiple initiation sites, is associated with the M/SHBs promotor, thus accounting for synthesis of distinct proteins from one mRNA. In patients with active viral replication, the protein expression pattern shows a predominance of the M/SHBs protein in contrast to a predominance of the LHBs protein in inactive carriers^[11]. After transcription, protein synthesis and glycosylation follows at the endoplasmic reticulum (ER) membrane resulting in a 226

Figure 1 Schematic model of hepatitis B surface antigen structure. Three forms of hepatitis B surface (HBs) antigen (Dane particle, filamentous particle, and spherical particle) are visualized in serum by electron microscopy. These are composed of small, middle, and large hepatitis B surface proteins. LHBs: Large HBs proteins; MHBs: Middle HBs proteins; SHBs: Small HBs proteins.

Figure 2 Schematic presentation of the S/preS1/preS2 gene, RNA transcripts, and translational products. Opening reading frame S has three internal AUG codons. Transcription to produce the 2.1 kb and 2.4 kb mRNAs first occurs after translation into small hepatitis B surface proteins (SHBs), middle hepatitis B surface proteins (MHBs), and large hepatitis B surface proteins (LHBs) ensues with different promoters.

amino acid SHBs protein, the MHBs protein with an additional 55 amino acids, and the LHBs protein with an additional 108-119 amino acids. Although the LHBs mRNA includes the M/SHBs sequence, it does not translate into the M/SHBs protein, and the ratio between the MHBs and SHBs protein is controlled by a complex mechanism, which is not fully understood^[12]. To form a full virion, a mixture of HBs proteins in a well-balanced ratio is utilized to envelop core particles in which SHBs and LHBs protein are indispensable^[13]. The virion is transported to the cell membrane through vesicles, and several conditions must be satisfied for successful secretion, because excess SHBs protein is required, whereas excess LHBs protein prevents secretion and causes dilatation of the ER with a ground-glass appearance^[14-16].

Function

The primary function of the HBs protein as a virologic structure is to enclose the viral components. It also plays a major role in cell membrane attachment to initiate the infection process. Several studies have confirmed the idea that the peptide in the preS1 domain is essential in this process, showing that it specifically binds to the human liver plasma membrane and can be inhibited by a monoclonal antibody^[17,18]. However, participation of the SHBs protein in attachment has also been suggested following identification of hepatocyte-bound endonexin II, which

specifically binds the SHBs protein^[19]. Additionally, from the host perspective, the HBs protein has the major antigenic components, including the *a* determinant, which is important for host-activated immunity. However, from a virologic perspective, it is postulated that excess HBs protein may divert such neutralizing antibody immune function away from the infectious virion^[20].

QUANTITATIVE HBsAg ASSAYS

Methods to detect HBsAg were first described in the 1970s using radioimmunoassays and enzyme immunoassays^[21,22]. Since then, various diagnostic techniques have been developed, which are mostly confined to qualitatively diagnose HBV in clinical practice. Recently, quantitative assay of HBsAg has been developed, and two commercially available assays will be briefly introduced here.

The Architect HBsAg QT (Abbott Diagnostic, Wiesbaden, Germany) is a chemiluminescent microparticle immunoassay, which is currently the method most widely used in clinical studies^[23]. The Architect HBsAg QT assay is a two-step immunoassay with flexible assay protocols, referred to as Chemiflex, for quantitatively determining human serum and plasma HBsAg concentrations. In the first step, the sample and hepatitis B surface antigen antibody (anti-HBs) coated with paramagnetic microparticles are combined. HBsAg present in the sample binds to the anti-HBs coated microparticles. After washing, acridinium-labeled anti-HBs conjugate is added. Following another wash cycle, pre-trigger and trigger solutions are added to the reaction mixture. The resulting chemiluminescent reaction is measured as relative light units (RLUs). A direct relationship exists between the amount of HBsAg in the sample and the RLUs detected by the Architect Immunoassay System optics. The Architect HBsAg is a fully automated system and can detect as low as 0.2 ng/mL of HBsAg with a dynamic range of 0.05-250.0 IU/mL^[24].

Elecsys HBsAg II (Roche Diagnostics, Indianapolis, IN, USA) is another method for quantitatively determining HBsAg^[25]. In the first incubation step, the antigen in the sample reacts with two biotinylated monoclonal HBsAg-specific antibodies and a monoclonal/polyclonal (sheep) HBsAg-specific antibody, labeled with a ruthenium complex, to form a sandwich complex. In the second step, streptavidin-coated microparticles are added, and the complex binds to the solid phase *via* interaction with biotin and streptavidin. The results are reported as a cutoff index (signal sample/cutoff), and the sample is considered reactive if the index is greater than 1.0.

CLINICAL APPLICATION OF QUANTITATIVE HBsAg

Correlation with serum HBV DNA

Although measuring serum HBV DNA is the gold standard for monitoring viral load, it is relatively expensive and not yet readily available in some areas. By contrast, the technique for detecting qHBsAg is fairly easy and inexpensive, and the primary aim of initial clinical studies

was to determine the relationship between qHBsAg and serum HBV DNA (Table 1). In 2004, Deguchi *et al.*^[23] first reported the clinical significance of a high qHBsAg in patients who were hepatitis B e antigen (HBeAg) positive as opposed to those with an antibody positive to the hepatitis B e antigen (anti-HBe), and that qHBsAg correlated well with the serum HBV DNA level ($r = 0.862$). Although there are some contradicting results on whether qHBsAg is correlated with serum HBV DNA^[26,27], it seems that they are correlated based on a number of studies^[28-33]. Further studies are required to investigate the possibility of using qHBsAg as an aid, if not an alternative, for HBV DNA.

Correlation with covalently closed circular DNA

An important qHBsAg issue is its association with covalently closed circular DNA (cccDNA). cccDNA is a minichromosome and acts as a viral template and replenishing pool for maintaining a chronic HBV infection^[34]. Therefore, it is essential to understand the biology of cccDNA when considering HBV therapy. However, to examine cccDNA, an invasive procedure is required, and qHBsAg has been suggested as a surrogate marker for cccDNA. Werle-Lapostolle *et al.*^[29] reported a significant decrease in cccDNA, qHBsAg, and serum HBV DNA with adefovir (ADV) therapy, and that there was a strong correlation between cccDNA and other variables. This observation was supported by subsequent studies; Wurstthorn *et al.*^[35] and Chan *et al.*^[36] also showed that cccDNA was significantly correlated with qHBsAg, suggesting that serial monitoring of qHBsAg might act as an additional marker to evaluate treatment response during antiviral therapy.

Prediction of response to antiviral therapy

After the accumulation of data confirming that qHBsAg can be utilized as a viral monitor, qHBsAg has been evaluated as a predictor of virologic response. In a study by Chan *et al.*^[36] the sensitivity, specificity, and positive and negative predictive values for sustained virologic response (SVR) in patients treated with pegylated interferon (Peg-IFN) + lamivudine (LAM) were 86%, 56%, 43%, and 92%, respectively, with baseline qHBsAg concentrations less than 10000 IU/mL. According to the data of Manesis *et al.*^[31] achieving the complete elimination of HBsAg would probably require 10.6 years of effective LAM therapy or 5.4 years of a sustained response to interferon. Recently, the clinical usefulness of on-treatment qHBsAg in patients treated with Peg-IFN ± LAM has been suggested in both HBeAg positive and negative patients; a decline in qHBsAg of > 1 log IU/mL or specifically 0.5 and 1.0 log IU/mL at weeks 12 and 24, respectively, had high predictive value for SVR, and on-treatment HBsAg levels could be used as an early predictor of durable off-treatment response to Peg-IFN-based therapy^[32,33,37]. Of note is a long-term study by Marcellin *et al.*^[38] in which 35% of patients who had qHBsAg < 1500 IU/mL at week 12 eventually cleared the HBsAg by 4 years post-treatment, which supports the clinical utility of qHBsAg. Furthermore, qHBsAg was superior to cccDNA and serum HBV DNA for predicting SVR in patients undergoing Peg-IFN-based therapy with receiver

Table 1 Recent clinical studies with quantification of hepatitis B surface antigen titers in hepatitis B virus infection

Author	Antiviral therapy	Correlation	Prediction	Clinical results
Deguchi <i>et al</i> ^[23]	-	HBV DNA	-	qHBsAg is higher in HBeAg(+)
Chen <i>et al</i> ^[28]	-	HBV DNA	-	qHBsAg is higher in HBeAg(+) and high HBV DNA levels, whereas qHBsAg is low in low HBV DNA level CHB
Werle-Lapostolle <i>et al</i> ^[29]	ADV	cccDNA, HBV DNA	-	HBsAg and cccDNA decrease with ADV
Kohmoto <i>et al</i> ^[30]	LAM	HBV DNA	-	qHBsAg is helpful for early detection of drug resistant strains
Wursthorn <i>et al</i> ^[35]	Peg-IFN + ADV	cccDNA	-	Peg-IFN + ADV decreases cccDNA and HBsAg, which are well correlated
Chan <i>et al</i> ^[36]	Peg-IFN + LAM	cccDNA	Low baseline qHBsAg can predict SVR	Peg-IFN + LAM decreases cccDNA and HBsAg, which are well correlated
Manesis <i>et al</i> ^[31]	IFN vs LAM	HBV DNA	Low baseline qHBsAg can predict SVR	IFN induces sharper decrease in qHBsAg than LAM
Wiegand <i>et al</i> ^[27]	FAM ± LAM	HBV DNA (not correlated)	Decline of qHBsAg can predict HBsAg loss	2 log drop to below 100 IU/mL is associated with HBsAg clearance
Moucari <i>et al</i> ^[32]	Peg-IFN	HBV DNA	Early qHBsAg drop can predict SVR	qHBsAg may be useful to optimize Peg-IFN therapy
Brunetto <i>et al</i> ^[33]	Peg-IFN ± LAM vs LAM	HBV DNA	On-treatment qHBsAg decline can predict sustained HBsAg loss	qHBsAg < 10 IU/mL at week 48 and 1 log decline predict sustained HBsAg clearance to optimize treatment strategy
Lau <i>et al</i> ^[37]	Peg-IFN ± LAM	-	On-treatment qHBsAg can be used as an early predictor of SVR	In HBeAg(+) patients, qHBsAg reduction through weeks 12, 24 and 48 were higher in patients with HBeAg seroconversion
Marcellin <i>et al</i> ^[38]	Peg-IFN ± LAM	-	qHBsAg at week 12 can predict long-term HBsAg clearance	35% of patients who had qHBsAg < 1500 IU/mL at week 12 cleared up HBsAg by 4 yr post-treatment
Lu <i>et al</i> ^[39]	Peg-IFN ± LAM	cccDNA	qHBsAg was superior to cccDNA and serum HBV DNA in predicting SVR	Area under ROC curve with qHBsAg, cccDNA and HBV DNA was 0.769, 0.734, and 0.714, respectively, for predicting SVR
Brunetto <i>et al</i> ^[65]	Peg-IFN ± LAM	-	On-treatment qHBsAg can be used as an early predictor of SVR	On-treatment decline in HBsAg appears to be genotype dependent. Genotype B patients showed the most rapid and pronounced decline
Hou <i>et al</i> ^[66]	Peg-IFN vs LAM	-	-	Peg-IFN was superior to ADV in HBeAg seroconversion and qHBsAg decline in LAM-resistant patients

HBV: Hepatitis B virus; HBsAg: Hepatitis B surface antigen; qHBsAg: Quantification of HBsAg titers; HBeAg: Hepatitis B e antigen; CHB: chronic hepatitis B; ADV: Adefovir; LAM: Lamivudine; Peg-IFN: Pegylated interferon; cccDNA: Covalently closed circular DNA; FAM: Famciclovir; SVR: Sustained virologic response; ROC: Receiver operating characteristic.

operating characteristic (ROC) curves of 0.769, 0.734, and 0.714, respectively^[39].

MOLECULAR HBsAg VARIANTS

Much of our understanding of the biologic nature of the HBs protein has been gathered from various mutation and truncated protein experimental models^[40,41], and it is worthwhile to address the relevance and consequences of HBsAg variants from a clinical point of view. Besides the lack of HBV proof-reading capacity^[42], the development of an HBsAg mutation can be attributed to immune pressure from extensive vaccination programs, injections of hepatitis B immunoglobulin (HBIG) following liver transplantation, and the overlap with a mutation in the corresponding *P* gene.

Immune escape mutants

Since the introduction of an extensive vaccination program, concerns about HBsAg variants have increased after an HBV infection occurred in infants who had received an HBV vaccination and who had mounted an adequate anti-HBs response. This was presumed to be caused by immune selection pressure, because the HBsAg *a* determinant is the major epitope for HBV vaccination^[43,44]. Changes in the amino acids within the *a* determinant, particularly between 137-147, disable surface antigen domain

recognition by neutralizing antibodies. Of importance is the G145R mutant, because it is the most common and is replication competent with stability^[45]. In a Taiwanese epidemiological study, it was reported that the prevalence of the *a* determinant mutation had increased from 7.8% to 28.1%, after 15 years of a universal vaccination program^[46]. Fortunately, in the following years, neither the percentage increase nor any significantly adverse events with an outbreak of HBV infection actually occurred; thus, a mass vaccination program is continuing with adequate justification^[47].

In addition to the extensive vaccination program, the wide use of HBIG following liver transplantation adds selection pressure to HBV. Ten of 20 patients who developed recurrent HBV infection despite hepatitis B immunoglobulin prophylaxis had amino acid substitutions involving the *a* determinant, which were mostly absent in pretransplantation clones^[48].

Overlap and mutation in the *P* gene

A mutation in the *P* gene from prolonged oral nucleos(t)ide therapy can cause an altered sequence in the corresponding *S* gene due to overlap of the two genes^[49], which is summarized in Table 2^[50]. The nucleotide at rt204 in the *P* gene is associated with resistance to LAM, telbivudine (LdT), and entecavir (ETV), and the rtM204V/I mutation typically results in a sI195M, sW196S, sW196L or a termi-

Table 2 Mutations in viral polymerase gene induced by oral antiviral agents and corresponding changes in hepatitis B surface antigen

Polymerase domain	Mutation in polymerase	Oral antiviral agents	Corresponding change in HBsAg
B	rtI169T	ETV	sF161H/L

¹Stop codon. Modified from reference^[50]. HBsAg: Hepatitis B surface antigen; ETV: Entecavir; LAM: Lamivudine; LdT: Telbivudine; ADV: Adefovir; TFV: Tenofovir.

nal codon in the overlapping *S* gene^[50]. In previous studies, LAM selected HBsAg mutants with reduced anti-HBs binding capacity, and secretion of HBsAg was prevented with a mutant strain due to the stop codon^[51,52]. rtI181 is another important site that confers resistance to ADV and/or LAM/LdT. Recently, Warner and Locarnini demonstrated that rtA181T caused a secretory defect and had a negative effect on secretion of the wild-type HBV virion because of a concomitant change in the envelope protein at sW172^[53]. Similarly, ETV-associated rtI169T/sF161L leads to a decrease in HBsAg immunoreactivity^[54].

The clinical significance of overlap and a common mutational substitution in the *S* and *P* gene was further extended by Kamili *et al.*^[55] who demonstrated a successful experimental infection with the rtV173L, rtL180M, and rtM204V HBV mutants that resulted in sE164D and sI195M despite high anti-HBs levels in chimpanzees^[55]. Furthermore, the possibility of a *vice versa* phenomenon with respect to an extensive vaccination program might be postulated in that HBsAg mutants from selection pressure might harbor the corresponding *P* gene mutation, resulting in primary resistance to antiviral agents and therapy failure with these agents.

Detection and variants of HBsAg

As described above, an HBsAg mutation leads to diverse effects, such as decreased secretion and reduced binding capacity to anti-HBs. Of note is that not only a mutation in the *a* determinant but also in the *S* promoter or a deletion in the preS region can cause such effects^[56,57]. These effects may hamper the diagnostic performance of commercial assays, and several reports have pointed to the

problem of not being able to detect HBV with an *a* determinant mutation^[58,59].

An occult HBV infection is defined as the persistence of the HBV genome in HBsAg negative individuals, and one of the explanations for occult HBV infection is a mutation in HBsAg and undetectability by available assays^[60]. Both the Architect HBsAg QT and Elecsys HBsAg II seem to reliably detect HBsAg mutants with high sensitivity and specificity^[24,25,61]. However, further studies are needed to validate such detection ability, because new or complex combinations of mutations can arise in this era of antiviral agents and extensive vaccination.

FUTURE PERSPECTIVES

Despite progress on qHBsAg, a number of unanswered questions still remain. Precise control mechanisms for HBsAg production in HBV are poorly understood. A discrepancy between qHBsAg and serum HBV DNA exists, although a correlation has been documented. Further research on the virologic nature of HBV could answer these two questions. Meanwhile, the role of qHBsAg in the clinical field is being actively investigated, especially as a predictor to virologic response. Of particular interest is the potential role of qHBsAg for defining the end point of oral antiviral therapy. Current American Association for the Study of Liver Diseases and European Association for the Study of the Liver guidelines with respect to an end point for therapy are unsatisfactory, because reversion to HBeAg positivity does occur after terminating therapy, and the loss of HBsAg is infrequently encountered^[62,63]. In this regard, qHBsAg might be particularly helpful in patients with undetectable HBV DNA, even with a highly sensitive polymerase chain reaction assay^[64]. In contrast to undetectable HBV DNA, which provides no further information for the virologic responders, HBsAg is continuously shed and detected and, based on the observations of previous studies, qHBsAg with serial monitoring in patients with undetectable HBV DNA may be utilized to determine the end point of therapy and validate the durability of antiviral agents.

CONCLUSION

HBsAg is produced and secreted through a complex mechanism that is still not fully understood. Nevertheless, quantification of serum HBsAg is currently available and there is an opportunity to make maximal use of qHBsAg to elucidate its role in clinical fields. However, a deep understanding of the virology is necessary, and it is also important to be familiar with HBsAg variants and their clinical consequences in terms of immune escape mutants, issues resulting from overlap with corresponding mutation in the *P* gene, and detection problems for the HBsAg variants. Unanswered questions need to be resolved through further qHBsAg research.

Genomic and genetic alterations influence the progression of gastric cancer. *World J Gastroenterol* 2011; 17(3): 290-299 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i3/290.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i3.290>

Abstract

Gastric cancer is one of the leading causes of cancer-related deaths worldwide, although the incidence has gradually decreased in many Western countries. Two main gastric cancer histotypes, intestinal and diffuse, are recognised. Although most of the described genetic alterations have been observed in both types, different genetic pathways have been hypothesized. Genetic and epigenetic events, including 1q loss of heterozygosity (LOH), microsatellite instability and hypermethylation, have mostly been reported in intestinal-type gastric carcinoma and its precursor lesions, whereas 17p LOH, mutation or loss of E-cadherin are more often implicated in the development of diffuse-type gastric cancer.

INTRODUCTION

Gastric cancer is one of the leading causes of cancer-related deaths worldwide, although the incidence has gradually decreased in many Western countries^[1]. Several attempts to classify gastric cancer have been made over the past decades. Most successful, and widely used, is the classification by Lauren, which, by microscopic morphology alone, distinguishes two main cancer pathogeneses, diffuse and intestinal subtypes, which clearly appear as dissimilar clinical and epidemiological entities. Although most of the genetic alterations that have been reported are observed in both intestinal and diffuse gastric cancers, it has become apparent that these two tumor types result from different genetic pathways^[2] (Table 1).

Microsatellite instability and *p53* mutation, reduced

p27 expression, cyclin E overexpression and 6.0-kb transcripts of the *c-met* gene are involved in malignant transformation from precancerous lesions to intestinal-type gastric cancer. In addition, *DCC* loss, *APC* mutations, 1q loss of heterozygosity (LOH), *p27* loss, reduced expression of tumor growth factor (TGF)- β type I receptor and *HER2* gene amplification are frequently associated with an advanced stage of intestinal-type gastric carcinoma. In contrast, LOH at chromosome 17p (*p53*) and mutation or loss of E-cadherin are more often implicated in the development of diffuse-type gastric cancer, while loss of *p27* and gene amplification of *K-sam* and *c-met* lead to disease progression and metastatic spread.

The two types of gastric carcinoma organize different patterns of interplay between neoplastic and stromal cells through the growth factor/cytokine receptor system, which has a critical role in cell growth, apoptosis, morphogenesis, angiogenesis and metastasis. Other genetic factors, such as DNA polymorphism and genetic instability, may also be implicated in the two distinct major genetic pathways of gastric carcinogenesis.

GENOMIC INSTABILITY

Two phenotypes of genomic instability are generally recognized in gastric cancer: the phenotype associated with microsatellite instability (MSI) and that which is associated with chromosomal instability (CIN). These phenotypes are not necessarily independent and may even overlap in some cases^[3].

MSI

MSI is a common feature of gastric cancer due to a deficit in the DNA mismatch repair system and derives from the presence of spontaneous DNA replication errors in simple repetitive sequences^[4]. A standard panel of microsatellite markers, including mononucleotide (*BAT26* and *BAT25*) and dinucleotide (*D2S123*, *D5S346* and *D17S250*) repeats, has been recommended and guidelines for MSI testing (Bethesda Guidelines) have been drawn up^[5]. Using the reference panel, three levels of MSI can be identified: high-level MSI (MSI-H), low-level MSI (MSI-L) and microsatellite stable (MSS). Recently, it has been established that mononucleotide repeats are instrumental in detecting MSI-H tumors because of their high sensitivity and specificity, and MSI-L has been defined as instability limited to dinucleotide loci^[6]. After the adoption of the Bethesda panel, MSI-H phenotype was reported in a range of 5%-50% of all gastric carcinomas with significant differences in various ethnic groups. MSI-H appears to be a phenotypical marker of an underlying cellular defect involving DNA mismatch repair (MMR). Functional inactivation by mutations or epigenetic mechanisms of MMR genes, including *hMLH1* and *hMSH2*, is responsible for the MSI-H phenotype in gastric cancer. Abnormal loss of protein expression of either *hMLH1* or *hMSH2* has been observed in MSI-H gastric carcinomas^[7]. In particular, altered expression of *hMLH1* has been associated with gene inactivation by promoter hypermethylation.

MSI-H gastric carcinomas follow a molecular pathway of tumor progression, characterized by the presence of multiple frameshift mutations affecting mononucleotide tracts within genes involved in cancer-related molecular networks which control cellular homeostasis at different levels. MSI-related mutations occur in many genes at variable frequencies^[4]. Genes regulating cell-cycle and apoptotic signaling are frequently targeted in MSI-H gastric carcinomas and include *TGF β R2*, *IGF1R*, *TCF4*, *RIZ*, *BAX*, *CASPASE5*, *FAS*, *BCL10* and *APAF1*^[8]. Moreover, genes involved in genomic integrity maintenance, i.e. *hMSH6*, *hMSH3*, *MED1*, *RAD50*, *BLM*, *ATR* and *MRE11*, are also frequently altered in MSI-H tumors^[9]. Several studies indicate that, in most MSI-H gastric cancers, multiple target genes are simultaneously mutated and multiple hits impact on different genes in the same pathway^[10]. In contrast, gastric carcinomas with MSS and MSI-L exhibit predominant *p53* mutations^[7].

As compared with MSS or MSI-L, gastric carcinomas with MSI-H show a significantly higher frequency of antral location, intestinal subtype, a lower incidence of lymph node metastasis and improved survival^[8,11-15].

CIN

CIN is a feature of various tumors, including gastric cancer, commonly associated with chromosomal aberrations responsible for major modifications of DNA content, i.e. changes in chromosome copy number, and also high-level LOH, gene deletions and/or amplifications^[16,17]. All these alterations may lead to oncogene activation and/or tumor suppressor gene inactivation. As with other tumors, aneuploidy is generally considered an unfavorable prognostic factor^[18-21], though contrasting results have been reported^[22-25].

High CIN levels have also been associated with a shorter survival in gastric cancer patients^[26] and high LOH frequencies have been identified at several chromosome arms, including 1p, 3p, 4p, 5q, 7p, 8p, 8q, 9p, 12p, 13q, 17p, 18q, 20q and 22q^[27-29].

The allelotype of gastric carcinoma is similar to that of colorectal and esophageal cancers, suggesting the presence of a common genetic pathway for tumor development. Some of these chromosomal segments include genes which are strongly implicated in carcinogenesis, such as the *p53* gene on chromosome 17, *DCC*, *DPC4* and *SMAD2* genes on chromosome 18, and *APC* and *MCC* genes on chromosome 5. Several studies have found that tumors with LOH at chromosome 5q, 18q or 17p had a poorer prognosis than tumors that did not show LOH at these sites^[30,31].

EPIGENETIC INSTABILITY

Epigenetic changes, such as aberrant methylation of CpG islands in promoter regions, are commonly detected in human cancers and can permanently inactivate tumor-suppressor genes and affect important pathways of cell cycle regulation and proliferation. The methylation of CpG islands may be considered a third molecular phenotype of

Table 1 Molecular genetic changes in gastric cancer

	Abnormalities	Intestinal phenotype (%)	Diffuse phenotype (%)	Local progression	Distant metastasis	Prognosis	Prolonged survival	Ref.
Microsatellite instability	Mutation, hypermethylation, reduced expression	20-30	0-10	No	NA	Good	Yes	[8,11]
Tyrosine kinases								
HER2/neu	Amplification/overexpression	10-15	0	Yes	Yes	Poor	No	[57-59]
RUNX3	Hemizygous deletion/hypermethylation/loss of expression	15-45	40-80	Yes	Yes	Poor	No	[62-64]
FHIT	Loss of protein expression (LOH, MSI)	35-65	20-80	Yes	Yes	Poor	No	[65,66]
NM23	Downregulation	3-25	30-70	Yes	Yes	Poor	Discordant results	[73,75]
VEGF	Overexpression	65	35-45	Yes	Yes	Poor	No	[77-79]
HIF-1 α	Overexpression	25-60	45-60	Discordant results	NA	NA	Discordant results	[80-82]
COX2	Overexpression	60-70	30-70	Yes	Yes	Discordant results	No	[77,83,84]
SPARC	Overexpression	70-80	25-55	Discordant results	Yes	Poor	No	[85-87]
p53	LOH/mutation/hypermethylation/overexpression	20-40	20-40	Yes	Yes	No correlation	No	[88-91]
p21	Loss	60		Yes	Yes	Poor	No	[92-94]
p27	Reduced expression	50		Yes	Yes	Poor	No	[95-97]
bcl2	LOH/overexpression	40	0	No	No	Good	Yes	[98]
BAX	Reduced expression	10	5	NA	Yes	Poor	No	[99]
pRb	Reduced expression	60	50	NA	NA	Poor	No	[1,92]
c-myc	Overexpression	45	10	Possible	Possible	Poor	No	[101-104]

Tumor-associated proteases								[115-117]
PAI-1	Overexpression	45-75	35-50	Yes	Yes	Poor	No	
uPAR	Overexpression	40-75	30-50	Yes	NA	Poor	No	
uPA	Overexpression	65	30	Yes	NA	Poor	No	

FHIT: Fragile histidine triad; LOH: Loss of heterozygosity; MSI: Microsatellite instability; VEGF: Vascular endothelial growth factor; HIF-1 α : Hypoxia inducible factor-1 α ; COX2: Cyclooxygenase-2; SPARC: Secreted protein acidic and rich in cysteine; PRL-3: Phosphatase regenerating liver 3; PAI-1: Plasminogen activator inhibitor type 1; uPA: Urokinase-type plasminogen activator; u-PAR: u-PA receptor; NA: Not available.

gastric cancer and the tumor-related genes more commonly methylated are *APC*, *CDH1*, *MHL1*, *CDKN2A*, *CDKN2B* and *RUNX3*. It has also been widely reported that *CDKN2A*, *CDH1* and *MLH1* are more frequently inactivated by promoter methylation rather than by mutations^[32].

A series of individual methylated genes has been related to prognosis in gastric cancer. Methylation of tumor-suppressor genes, such as *CDH1*^[33], *DKK3*^[34], *PTEN*^[35] and *MGMT*^[36], of putative tumor-suppressor genes, such as *TFPI2*^[37] and *CACNA2D3*^[38], and of other tumor-related genes, such as *PCDH10*^[39] and *SOX2*^[40], has been associated with shorter disease-free and/or overall survival.

The combined use of *APC* and *CDH1* methylation markers has identified a subgroup of patients with worse prognosis^[41]. Conversely, methylation of single genes has been associated with a better prognosis in some cases. Patients showing methylation of *APC*^[42], the M1 region of *MAL* promoter^[43] and cyclooxygenase-2 (*COX2*)^[44] showed prolonged survival, compared to patients without methylation of these genes.

As with colorectal cancer, the CpG island methylator phenotype (CIMP), characterized by concurrent promoter hypermethylation of multiple genes, has also been described in gastric cancer^[45,46] and it has been shown to correlate with hypermethylation of other known cancer-related genes, such as *p16*, *bMLH1* and *THBS-1*^[45,47]. Furthermore, the CIMP status is associated with clinically useful information and patients with negative CIMP methylation have significantly shorter survival than those with high CIMP methylation^[46,48].

ALTERATIONS OF GENES INVOLVED IN MOLECULAR PATHWAYS

Genetic and genomic variations occurring in genes and molecules that participate in proliferation, invasion and metastasis (e.g. growth factors and their receptors, signal transducers, cell-cycle and apoptosis regulators, cell adhesion molecules, DNA repair genes and matrix metallo-

proteinases) may influence the prognosis of patients with gastric cancer.

Tyrosine kinases

Amplification of some tyrosine kinases (c-met, K-sam and HER2/neu) is associated with human gastric cancer progression. Alternatively, spliced transcripts and enhanced protein expression levels for some of these tyrosine kinases are correlated with the clinical outcome of gastric cancer patients^[49].

The oncogene *c-met*, encoding for the hepatocyte growth factor receptor, is preferentially amplified in diffuse-type tumors and has been described to be well correlated with stage and prognosis^[50,51]. Overexpression of c-met has also been shown to be associated with lower survival probability^[52,53].

K-sam oncogene, a member of the fibroblast growth factor receptor family, is more frequently activated in diffuse-type tumors^[2]. Overexpression of K-sam occurs in approximately 32% of diffuse-type gastric cancers, and the prognosis of K-sam-positive patients is poorer than that of K-sam-negative patients^[54].

The HER2 protein (HER2/neu or ErbB-2) is a glycoprotein with tyrosine kinase activity, homologous to the epidermal growth factor receptor. HER2 is codified by a gene located on chromosome 17q21 and does not bind to any known ligand. Some studies demonstrated that overexpression of c-erbB2 is selectively found in intestinal tumors and may serve as a prognostic marker for tumor invasion and lymph node metastasis. Overexpression of HER2 protein in gastric cancer has been reported to range from 7.4% to 38%^[55-57]. The prognostic value of HER2 expression and/or amplification has been widely investigated with controversial findings. Although most available studies indicate that the overexpression of HER2 is an independent prognostic factor associated with a shorter disease-free^[58] and overall survival^[57-59], some studies failed to confirm its prognostic role on multivariate analysis^[51] or to find a correlation between HER2 overexpression and survival parameters^[56,60]. Also associated with poor survival is the presence of HER2 amplification^[61].

RUNX3

RUNX3, a gene that codifies for a member of the runt domain-containing family of transcription factors, frequently shows loss of expression due to hemizygous deletion and hypermethylation in gastric cancer. This gene, generally expressed in only 45%-50% of gastric cancer patients^[62,63], positively regulates the expression of BIM and p21, and negatively regulates vascular endothelial growth factor (VEGF), thus affecting apoptosis, cell growth arrest and angiogenesis. The loss or substantial decrease of *RUNX3* protein expression in gastric cancer has been significantly associated with shorter survival^[62,64].

FHIT

The fragile histidine triad gene (*FHIT*) encodes a diadenosine 5',5'''-P1,P3-triphosphate hydrolase and is generally inactivated by deletion or methylation in several

tumors, including gastric cancer. The absence of *FHIT* protein has been shown to correlate with higher tumor stage and histological grade^[64], as well as with poor overall survival^[65,66].

NM23

The *NM23* gene maps to chromosome 17q21 and encodes the nucleoside diphosphate kinase A, a member of the NDP kinase family. *NM23* expression is reduced in metastatic melanoma and breast cancer cell lines^[67]. Transfection into cell lines affects invasion, motility, colonization, differentiation and liver metastasis^[68]. Decreased expression of *NM23-H1*, the human homologue, is found in advanced stages of human cancer^[69,70].

The expression of the putative metastasis-suppressor gene *NM23* in gastric carcinoma is controversial. In several studies, expression of *NM23* has been shown to be inversely correlated with the metastatic potential of gastric cancer^[71,72] and with prolonged overall survival^[73]. The results of other studies, however, suggest that *NM23* is not a metastasis suppressor gene and does not show correlation with metastasis^[74,75].

VEGF

VEGF is a pro-angiogenic factor, frequently overexpressed in tumors. Mutations of *p53*, which under physiological conditions downregulates VEGF, may be responsible for its overexpression^[76].

A correlation of the expression of VEGF with lymph node and liver metastasis has been described^[77] and patients with VEGF-positive tumors have a rather worse prognosis than those with VEGF-negative tumors^[78,79].

HIF-1 α

The hypoxia inducible factor, *HIF-1 α* , is a transcription factor that plays an essential role in cellular and systemic homeostatic responses to hypoxia. The prognostic role of *HIF-1 α* expression in gastric cancer patients is controversial: high levels have been associated with a shorter overall survival^[80], but also with no difference in survival parameters^[81]. However, its upregulation (high *HIF-1 α* mRNA or protein levels) has been found to be positively correlated with VEGF^[82] or *p53*^[80] protein expression in gastric cancer patients, and overall survival of patients with high mRNA levels of *HIF-1 α* and VEGF, as well as of *HIF-1 α* and *p53*, was shorter compared to patients with different features.

COX2

COX2 is one of the key isoenzymes in the production of prostaglandins, and is thought to be involved in carcinogenesis. Some studies indicate that *COX2* may play a role in the development of gastric cancer, and its overexpression is associated with nodal metastasis, tumor invasion and differentiation, implicating a poor prognosis^[77,83,84].

SPARC

The secreted protein acidic and rich in cysteine (SPARC or osteonectin) is a member of a family of matricellular

proteins that modulates cell-matrix interactions and cell function without participating in the structural scaffolding of the extracellular matrix. Since SPARC alters membrane permeability, cell shape, proliferation, migration and attachment, it may play a role in angiogenesis. It has been reported that its overexpression correlates with distant metastasis and poor prognosis^[85-87]. It is not clear whether SPARC overexpression is a useful marker in the prediction of lymph node metastasis development^[85].

p53

The p53 protein plays a fundamental role in cell growth and division. The function of the *p53* gene is more frequently altered due to LOH and mutation than to DNA methylation. Mutations of *p53* are present in about 40% of early and advanced, well-differentiated gastric cancers^[88]. A lower incidence of *p53* mutations has been shown in young patients compared to older patients^[89].

p53 can be investigated by immunohistochemical techniques, bearing in mind that the half-life of the p53 mutant protein is prolonged. Cells carrying the p53 mutant protein can be stained with antibodies against p53, whereas cells carrying normal p53 are negative. Sequencing of the gene after screening can also be performed in order to determine the mutation location within the gene^[90].

Overexpression of p53 often occurs in the early stages of intestinal-type tumors, and there is no significant difference between early and advanced cancers. In contrast, p53 abnormalities are not often seen in the early stages of diffuse-type tumors, but tend to occur as the disease progresses^[91].

p21

p53 cell cycle regulatory function is mediated by different effectors. One of these is a cyclin-dependant kinase inhibitor (CDK I), the p21 protein. The cell cycle check points are controlled by a cascade of phosphorylation. Protein kinases such as cyclin-dependent kinases are activated by cyclins and inhibited by CDK I, although p21 is up-regulated not only through a p53 pathway, but also through a TGF β RII pathway.

Levels of p21 expression could indicate the absence of a functional p53 protein in neoplastic cells. It has been reported that the survival of gastric cancer patients with p21-positive tumors is significantly longer than that of patients with p21-negative tumors^[92]. The expression of p21 is usually assessed in combination with p53 status and contributes to predicting the clinical outcome of gastric cancer patients^[93,94].

p27

It has been suggested that the cyclin-dependent inhibitor p27, which controls the transition from G1 to S in the cell cycle, has prognostic relevance in gastric cancer. Reduced p27 expression is detected in approximately 40%-50% of gastric cancers^[28]. Some studies have shown that tumors with a low expression of p27 protein are poorly differentiated and at an advanced stage^[95,96]. However, some authors have found no difference in overall survival of gastric can-

cer patients whether with high or low p27 expression^[97]. p53, p21 and p27 have also been analyzed in combination, confirming their role as prognostic markers^[91].

BCL2

BCL2 and *p53* are closely linked in the regulation of apoptosis. LOH at the *BCL2* locus is frequently observed in gastric cancer. The overexpression of *BCL2* may have a role in the development of gastric cancers. It has been shown that *BCL2* overexpression reduces cellular proliferative activity and correlates with a less aggressive biological behavior of the tumor. The prognostic role of *BCL2* on its own or in association with p53 has not yet been elucidated^[98].

BAX

BAX gene encodes a protein belonging to the BCL family members. Negative *BAX* protein expression has been associated with de-differentiation, lymph node metastasis and shorter survival, suggesting that *BAX* status may play a role in the development and differentiation of gastric cancer and tumor progression^[99].

pRb

pRb encodes a protein that is a negative regulator of the cell cycle. Poor prognosis of gastric cancer patients with low levels of pRb expression has been reported^[92,100].

c-myc

c-myc gene encodes a multifunctional, nuclear phosphoprotein that plays a role in cell cycle progression, apoptosis and cellular transformation. It functions as a transcription factor that regulates transcription of specific target genes. The c-myc protein has been shown to be significantly enhanced in well-differentiated gastric cancer^[101] and associated with a poor prognosis^[102]. Although c-myc is a short-lived protein in normal cells, its stability is increased in transformed cells through several mechanisms. One of these has recently been identified in the overexpression of a human oncoprotein, the cancerous inhibitor of protein phosphate 2A (CIP2A) that stabilizes c-myc^[103]. Interestingly, the expression of CIP2A has been associated with reduced overall survival in gastric cancer patients^[104].

Cyclin E

Cyclin E overexpression correlates with invasiveness and proliferation and may be a marker of tumor aggressiveness. Although somatic mutations of the cell cycle inhibitor *p16^{MTS}* are rare, its reduced expression is associated with depth of invasion and metastatic potential in both diffuse- and intestinal-type gastric carcinomas. However, recent data show that the survival of gastric cancer patients with cyclin E-positive tumors is not significantly shorter than that of negative patients^[92].

E-cadherin

Cell adhesion molecules are implicated in human carcinogenesis. Cadherin is a superfamily of calcium-mediated membrane glycoproteins, forming one of the four classes of adhesion molecules. E-cadherin, one of the members

of the transmembrane glycoprotein family expressed by epithelial tissues, not only acts as a cell adhesion molecule, but also plays an important role in growth development and carcinogenesis. The intact function of E-cadherin is crucial for the establishment and maintenance of epithelial tissue polarity and structural integrity. Around 25%-40% of hereditary diffuse gastric cancers are caused by heterozygous E-cadherin. The inactivation of the second allele occurs by mutation and methylation events, and this results in the complete inactivation of the protein^[105]. Reduced expression of E-cadherin correlates with infiltrative and metastatic ability in gastric cancer^[33] and the gene encoding E-cadherin, *CDH1*, was among the first to be considered as an invasion suppressor gene. Patients with E-cadherin-positive gastric cancers showed statistically significant prolonged 3- and 5-year survival rates, compared to patients with E-cadherin-negative tumors^[33,106].

It has been shown that serum soluble E-cadherin is increased in several non-neoplastic diseases and also in various cancers, including gastric tumors. E-cadherin may be a potentially useful prognostic marker and high levels of soluble E-cadherin correlate with the depth of tumor invasion, as well as inoperability^[107]. In addition, levels higher than 10000 ng/mL predict a survival of less than 3 years in more than 90% of patients^[108].

The Wnt-frizzled- β -catenin signaling pathway is frequently activated in gastric carcinoma (e.g. upregulation of *Wnt* gene expression or of genes for Wnt ligand receptors, upregulation of *RAC1* and inactivation of *APC*), leading to poor differentiation and increased tumor invasiveness^[109].

MUC1

Mucins are high-molecular weight glycoproteins containing oligosaccharides. These glycoproteins constitute the major components of the mucus that protects the gastric epithelium. Overexpression of mucin 1 (MUC1) has been linked to poor prognosis in gastric cancer patients^[65,110].

It has been reported that MUC1 may accelerate tumor invasion by the impairment of E-cadherin^[111]. The combined expression of MUC1 and E-cadherin shows that survival for gastric cancer patients with abnormal E-cadherin/MUC-positive expression was shorter than for patients with other expression patterns^[106].

PRL-3

The phosphatase regenerating liver 3 (*PRL-3*) gene encodes a protein belonging to a class of prenylated protein tyrosine phosphatases. These proteins are cell signaling molecules with a regulatory role in several cellular processes. The prognostic role of PRL-3 in solid tumors, including gastric cancer, has been recently reviewed by Bessette *et al.*^[112]. High expression of PRL-3 has been associated with several unfavorable clinical parameters, such as tumor size, depth of invasion, lymphatic invasion, advanced stage and shorter overall survival. Successive studies have confirmed these findings^[113,114].

Tumor-associated proteases

Tumor-associated proteases and their inhibitors play a

central role in tumor invasion and metastasis. The positive correlation of histological data with the urokinase-type plasminogen activator (uPA) and the plasminogen activator inhibitor type I (PAI-1) has been reported. Moreover, the independent prognostic impact of both uPA and PAI-1 on the survival of gastric cancer patients has been demonstrated. Elevated uPA and PAI-1 levels have been shown to be associated with shorter survival^[115,116]. A trend towards poor prognosis has also been observed in patients with high expression of the u-PA receptor (u-PA-R)^[113] and the uPA system may therefore be a target for novel therapeutic agents.

The prognostic role of some uPA genotypes has recently been investigated and an association was demonstrated between the exon 6 C/T polymorphism with invasive phenotype, but not with susceptibility or survival^[117].

CONCLUSION

Gastric carcinomas are histologically and genetically heterogeneous and are influenced by gene-environment interactions resulting in the activation of multiple molecular pathways. The molecular subtypes of gastric cancer include three main groups of tumors characterized by either the CIN, the MSI or the CIMP pathways. Currently, it is not clear whether or in what way knowledge of these subtypes of gastric carcinomas is of use in clinical practice, with regard to predicting specific pathways with mutational and regulatory alterations that may interfere with targeted therapies.

METHODS: We developed a stable S3-green fluorescence protein (GFP) cell line that replicated the GFP-tagged HCV sub-genomic RNA derived from a highly efficient JFH1 virus. S3-GFP replicon cell line was injected subcutaneously into γ -irradiated SCID mice. We showed that the S3-GFP replicon cell line formed human HCC xenografts in SCID mice. Cells were isolated from subcutaneous tumors and then serially passaged multiple times in SCID mice by culturing in growth medium supplemented with G-418. The mouse-adapted S3-GFP replicon cells were implanted subcutaneously and also into the liver of SCID mice *via* intrasplenic infusion to study the replication of HCV in the HCC xenografts. The tumor model was validated for antiviral testing after intraperitoneal injection of interferon- α (IFN- α).

RESULTS: A highly tumorigenic S3-GFP replicon cell line was developed that formed subcutaneous tumors within 2 wk and diffuse liver metastasis within 4 wk in SCID mice. Replication of HCV in the subcutaneous and liver tumors was confirmed by cell colony assay, detection of the viral RNA by ribonuclease protection assay and real-time quantitative reverse transcription polymerase chain reaction. High-level replication of HCV sub-genomic RNA in the tumor could be visualized by GFP expression using fluorescence microscopy. IFN- α cleared HCV RNA replication in the subcutaneous tumors within 2 wk and 4 wk in the liver tumor model.

CONCLUSION: A non-infectious mouse model allows us to study replication of HCV in subcutaneous and metastatic liver tumors. Clearance of HCV by IFN- α supports use of this model to test other anti-HCV drugs.

INTRODUCTION

Hepatitis C virus (HCV) is the most common blood-borne infection that affects the liver. The majority of individuals infected with HCV end up with a chronic disease in which the virus replicates in the liver for a long period of time. There are approximately 170 million people currently infected with HCV worldwide^[1,2]. The incidence of new HCV infections each year is increasing in developing nations due to blood transfusion from unscreened donors, which makes HCV a significant worldwide public health problem. The standard treatment option for chronic HCV infection is combination of pegylated interferon- α (IFN- α) with ribavirin^[3]. However, the majority of chronic HCV patients do not clear the virus infection with this treatment, and these individuals remain at high risk for developing cirrhosis and liver cancer. There is no effective treatment available for liver cirrhosis and cancer, so the development of alternative therapeutic strategies using a small animal model system to cure chronic HCV infection is crucial.

Development of novel antiviral therapies that target the multiple steps in the HCV life cycle, including viral genome replication, assembly, and infection is now possible due to the availability of the infectious, full-length HCV cell culture systems. A number of antiviral strategies have been developed during the past 2 years, including small molecules, anti-sense oligonucleotides, siRNA, ribozymes, and recombinant antibodies that have been designed to inhibit HCV replication in cell culture models^[4,5]. Progress in the targeted delivery of these antiviral molecules to inhibit viral replication in the liver is hampered due to the lack of a small animal model for HCV infection. The development of an animal model for HCV infection has been difficult due to the fact that the virus has limited host tropism and can infect only humans and chimpanzees^[6,7]. The chimpanzee is the only natural animal model for studying HCV infection^[8]. The chimpanzee model has been used in the past to study many aspects of HCV pathobiology and infectivity using cloned viral genomes, and it remains an important animal model. However, it is a difficult and expensive animal model that cannot be used to optimize experiments that deal with the liver-targeted delivery of intracellular treatment approaches such

as siRNA or antibodies. Therefore, a small animal model for HCV infection is required to test different experimental therapies developed using HCV cell culture systems. Rodents are the preferred animal models for testing gene delivery experiments because of their size, low cost and short gestation period. Previously, researchers have developed mouse models for HCV infection using transgenic technology or direct transfection of HCV RNA into the liver^[9]. Transgenic mice are not models for HCV infection or antiviral testing because of stable integration of HCV cDNA into the mouse chromosome. It will be difficult to differentiate the viral RNA replication from the HCV RNA produced due to cellular transcription in the transgenic animal models. There has been limited success using this transgenic approach because mouse hepatocytes do not support HCV RNA replication or infection^[9,10].

To overcome this limitation, four different mouse models have been developed to study experimental HCV infection *in vivo*: the immunotolerized rat model^[11], the Trimer mouse model^[12], the uPA/SCID mouse model^[13-15], and the Fah^{-/-} Rag^{-/-} IL-2^{-/-} mouse model^[16]. The rat model for HCV infection has been developed using immunotolerized rat embryos that can allow transplantation of human hepatoma cell lines that can be infected with HCV. These models have been used to study the complete life cycle of HCV infection, and antiviral testing. In the latter three models, researchers have used highly specialized mouse strains that support transplantation of human hepatocytes into the mouse liver. These models appear to be highly relevant animal models for HCV infection. A number of investigators have been using these models to infect chimeric mice with HCV or hepatitis B virus^[13-16]. However, these models are relatively complicated to use because they require specialized surgical skills, special strains of mice, use of human hepatocytes, as well as HCV-infected serum samples. Recently, a xenograft mouse tumor model for HCV infection has been described that utilizes the mouse-adapted replicon cell line that contains the luciferase reporter^[17,18]. The replication of HCV RNA has been measured in the mouse liver and subcutaneous tumor xenograft using a whole-body real-time imaging system. This model has been used to evaluate the antiviral properties of IFN- α and protease inhibitors. There is a lot of interest in this mouse model because it is less expensive, non-infectious, and can be easily adapted to any research laboratory.

We describe here a mouse model for studying the replication of the JFH1 sub-genomic clone of HCV in subcutaneous and liver tumors using a green fluorescence protein (GFP)-labeled sub-genomic replicon in the Huh-7 cell line. The development of a mouse-adapted GFP-labeled replicon cell line, combined with the highly efficient JFH1 virus facilitates high-level replication of the HCV in subcutaneous and liver tumors of laboratory mice with a partially suppressed immune system. We have developed a mouse-adapted HCC cell clone that replicates sub-genomic HCV RNA and forms HCC xenografts in SCID mice. We show that replication of HCV in the subcutaneous and liver tumors can be assayed using several biochemical

methods by looking at GFP expression and evaluating the antiviral effects on HCV by cell colony assay, ribonuclease protection assay, and real-time quantitative reverse transcription polymerase chain reaction (RT-qPCR). We showed that IFN- α successfully inhibited replication of HCV RNA in the HCC xenograft, which indicates that the model can be used to test the efficacy of different antiviral strategies that target the HCV replication cycle.

MATERIALS AND METHODS

Animals

Female SCID/bg and NOD/SCID γ mice 6-8 wk old were obtained from Charles River Laboratories (Wilmington, MA, USA) and Jackson laboratory (Bar Harbor, ME, USA), respectively. The mice were maintained in sterile conditions in a pathogen-free environment at the Department of Comparative Medicine, Tulane University Health Sciences Center. All animal experiments were carried out after receiving approval from the Institutional Animal Care and Use Committee (IACUC), Tulane University Health Sciences Center. All the SCID mice were γ -irradiated at 3 Gy (approximately 3.2 min) 1 d prior to cell transplantation. SCID/bg mice were used for subcutaneous tumor xenografts and NOD/SCID mice were used for liver tumor development. Throughout every experiment, we carefully checked the mice for their well-being, body condition and movement. All of the mice were weighed every alternate day to check for weight loss. A drop in their body weight was considered as an indication of sickness. After surgery, the mice were kept in separate sterile cages and observed carefully until they fully recovered.

Mouse-adapted replicon cell lines

We developed a stable Huh-7 cell line (S3-GFP) that replicated the HCV-GFP sub-genomic RNA of the JFH1 clone. The replicon cell line expressed a high level of GFP that could be visualized directly under a fluorescence microscope. We previously have shown that IFN- α inhibits replication of HCV in the S3-GFP cell line in a dose-dependent manner^[19]. One million GFP-replicon cells were implanted subcutaneously into the right and left flank of SCID/bg mice. Mice were followed for the development of tumors. When the tumors reached 10 mm in size, they were harvested in a sterile Petri dish. Cells were dissociated by collagen digestion and separated by low-speed (500 rev/min) centrifugation. The cell pellet was resuspended in RBC lysis buffer (eBioscience, San Diego, CA, USA) for 15 min; cells were centrifuged and the cell pellet was resuspended in DMEM with 10% FBS supplemented with G-418 (1 mg/mL). The cells were cultured and expression of GFP in the Huh-7 cells was examined over time under a fluorescence microscope. When most of the Huh-7 cells in the culture showed GFP expression, they were harvested and injected into SCID mice for tumor development. The *in vivo* passaging experiments were repeated several times until > 50% of the cells in the subcutaneous tumor were GFP-positive.

Intrasplenic infusion of mouse-adapted replicon cells

Intrasplenic infusion of replicon cells was performed using a previously described procedure^[20]. NOD/SCID γ mice were anesthetized with isoflurane under a laminar flow cabin. The surgical area was shaved and swabbed with betadine scrub. A small incision was made in the left flank in order to expose the spleen and carry out the cell injection. The spleen was accessed with a small forceps, and 10^6 replicon cells were injected into the inferior splenic pole; a monofilament suture was placed across the spleen at the site of injection to reduce spillage of cells into the abdominal cavity. The peritoneal wall and skin were separately closed using a monofilament suture and staples, respectively. After 3, 4, 5 and 6 wk, the animals were euthanized by CO₂ inhalation and their livers were removed. Part of the liver was fixed in 10% buffered saline for 72 h, processed, and embedded in paraffin. Tissue blocks were made for histological analysis after hematoxylin and eosin staining. The remaining part of the liver tissue was frozen in OCT compound for GFP expression analysis.

IFN treatment

IFN- α 2b (Intron A; Schering-Plough, NJ, USA) was diluted in PBS at a concentration of 150 IU/ μ L and stored at -70°C. Both the subcutaneous and liver tumor models were validated by intraperitoneal injection of 100 μ L IFN- α solution (total 15000 IU/mouse) three times weekly. A group of five mice was used to test the IFN antiviral effect in the subcutaneous and liver tumor models.

Histology and immunocytochemistry

The growth of HCC xenografts in the SCID mice was examined by hematoxylin and eosin staining of fixed and paraffin-embedded mouse tumor and liver specimens. Five-micrometer sections were cut from each tissue block, mounted on a glass slide, and dried over night at room temperature. All of the sections were deparaffinized in xylene, rehydrated by dipping in a graded alcohol series, and washed in PBS. To demonstrate the implantation of replicon cells in the liver, the tissue sections were stained with an antibody against human serum albumin (Dako, Carpinteria, CA, USA). The immunoreactivity of the albumin antibody was detected using the ABC detection kit using a standard laboratory protocol. To demonstrate expression of GFP in the subcutaneous and liver tumors, frozen sections were prepared. The sections were washed in PBS and stained with Hoechst dye (H33342, Calbiochem, Germany). Expression of GFP in the HCC xenograft was observed using a fluorescence microscope (Olympus) using a standard procedure^[19].

Cell colony assay

To study the replication of HCV sub-genomic RNA in the HCC xenografts, the liver was digested with collagenase and viable S3-GFP replicon cells were obtained by low-speed centrifugation. The cell pellet was suspended in 5 mL RBC lysis buffer (eBiosciences) for 15 min. The

viable tumor cells (S3-GFP) were cultured in DMEM supplemented with G-418 (1 mg/mL). Huh-7 cells that supported HCV RNA replication after IFN treatment were selected. The number of cell colonies formed in each cell culture dish was counted after Giemsa staining (Sigma, St. Louis, MO, USA).

RPA

Total RNA was isolated from the subcutaneous tumor by the GITC method and subjected to RPA for the detection of genomic positive-strand HCV RNA, using an antisense RNA probe that targeted the 5' untranslated region (UTR). For the RPA, 25 µg total RNA was mixed with a negative-strand RNA probe that targeted the 5'-UTR of HCV (10⁶ cpm) in a 10-µL hybridization solution, denatured for 3 min at 95°C, and hybridized overnight at 50°C. RNase digestion was performed in 200 µL RNase digestion buffer (10 mmol/L Tris, pH 7.5, 5 mmol/L EDTA and 0.3 mol/L NaCl) that contained RNaseA/T1 cocktail at 1:100 dilutions (Ambion, Austin, TX, USA) for about 1 h at 37°C. It was then treated with 2.5 µL 25% SDS and 10 µL proteinase K (20 mg/mL) for 15 min. Samples were extracted with phenol:chloroform and precipitated with absolute ethanol. The pellet was suspended in 16 µL gel loading buffer, heat denatured, and separated on a 6% TBE-urea gel (Invitrogen, Carlsbad, CA, USA). The gel was dried and exposed to X-ray film (Kodak Bio-max-XAR, Rochester, NY, USA). To detect JFH1-HCV mRNA in the transfected cells, we prepared a plasmid construct called pCR-II-2a (Invitrogen), which contained the sequence of 79-297 nt of the 5'-UTR sequence of the JFH1 clone (pCR-II NT-218). This plasmid was linearized with the *Xba*I restriction enzyme. T7 RNA polymerase was used to prepare a negative-strand RNA probe for detection of positive-strand HCV RNA. The same amounts of the RNA extracts were subjected to RPA for GAPDH mRNA. We used a linearized pTRI-GAPDH-human antisense control template to prepare a probe to detect GAPDH mRNA using Sp6 RNA polymerase (Ambion). The appearance of a 218-nt fragment in the RPA indicated the presence of HCV positive-strand RNA.

RT-nested PCR and Southern blot analysis

To detect HCV RNA in the liver tumors, total RNA was isolated from the liver tissues by the GITC method^[21]. cDNA synthesis for HCV positive-strand RNA was carried out using 1 µg total cellular RNA, an outer antisense primer and avian myoblastosis virus (AMV) reverse transcriptase (Promega, Madison, WI, USA). Amplification of the cDNA was performed in 50 µL reaction mixture that contained 250 ng outer sense primer and *Taq* DNA polymerase. The first PCR product was amplified by another round of PCR using outer and inner sets of primers, as described previously^[21]. The HCV PCR products were further subjected to Southern blot analysis by using a positive-sense HCV-specific ³²P-labeled oligoprobe. One microgram of total cellular RNA was used to amplify albumin mRNA levels by RT-PCR. The sequence of primer

and probe used in these experiments has been described previously^[21].

Real-time RT-qPCR

Real time RT-qPCR was performed to quantify HCV RNA levels in the infected cell culture using a published protocol^[22]. The 243-bp HCV DNA was amplified from the RNA extract by RT-PCR using the outer sense primer 5'-GCAGAAAGCGCCTAGCCATGGCGT-3' (67-90) and outer antisense primer 5'-CTCGCAAGCGCCCTATCAGGCAGT-3' (287-310). cDNA synthesis was performed from positive-strand HCV RNA using an outer antisense primer that targeted the highly conserved 5'-UTR region of HCV in a 20-µL volume. Two micrograms of total cellular RNA were mixed with 1 µL outer antisense primer (200 ng/µL), denatured at 65°C for 10 min, and annealed at room temperature. AMV reverse transcriptase (10 U) (Promega) was added and incubated at 42°C for 60 min in the presence of 50 mmol/L Tris, pH 8.3, 50 mmol/L EDTA, 500 nmol/L dNTP, 250 nmol/L spermidine, and 40 U RNasin (Promega). cDNA was stored at -20°C until use. SYBR Green real-time PCR amplification was performed in a 20-µL volume that contained 10 µL SYBR Green ER qPCR SuperMix, 1 µL (250 ng/µL) of sense and antisense primer with 4 µL cDNA and 4 µL distilled water. All samples were run in triplicate. The amplification was carried out using the standard program recommended by Bio-Rad Laboratories that included: a first cycle at 50°C for 2 min, 95°C for 8 min, and an additional 50 cycles in which each cycle consisted of a denaturation step at 95°C for 10 s, and annealing and extension steps at 60°C for 30 s. At the end of the amplification cycles, melting temperature analysis was performed by a slow increase in temperature (0.1°C/s) up to 95°C. Amplification, data acquisition, and analysis were performed on CFX96 Real Time instrument (Bio-Rad Laboratories) using CFX manager software (Bio-Rad Laboratories).

RESULTS

HCC xenografts formed subcutaneously support HCV replication

We prepared a chimeric clone of the sub-genomic HCV of JFH1 2a virus by fusing it with GFP in a frame with one of the non-structural proteins of HCV (NS5A). Huh-7 replicon cells that replicated the HCV-GFP sub-genomic RNA emitted a green fluorescent signal when exposed to a specific wavelength of light. This allowed direct visualization of HCV RNA replication. These replicon cells were cultured for > 1 year and were found to have stably maintained GFP expression with > 60%-80% of cells positive by flow analysis. We have shown that IFN-α inhibits replication of HCV RNA and inhibits GFP expression in a dose-dependent manner in the replicon cells^[19]. With this GFP-based replicon cell line, we sought to establish an HCC xenograft in SCID mice using the mouse-adapted replicon cells as described previously^[18]. The experimental steps involved in generating the *in vivo*

Figure 1 Summary of overall experimental plan to generate a mouse-adapted hepatitis C virus-green fluorescence protein replicon cell line. A chimeric replicon clone was prepared by inserting the green fluorescence protein (GFP) coding sequences with the NS5A sequences of the hepatitis C virus (HCV) sub-genomic clone. Huh-7 cells were transfected with a transcribed sub-genomic HCV-RNA replicon. A stable Huh-7 cell line with replicating HCV GFP chimera RNA (S3-GFP replicon) was developed. The replicon cell line was implanted in SCID mice for tumor development. Subcutaneous tumor that developed in SCID mice was collected and cells with replicating HCV-GFP were selected by culture in growth medium that contained G-418 (1 mg/mL). The *in vivo* adaptation process was repeated to generate a mouse-adapted S3-GFP replicon cell line that demonstrated 50% GFP expression in subcutaneous tumors.

adapted GFP replicon cells are summarized in Figure 1. S3-GFP replicon cells were injected subcutaneously into the right and left flank of SCID mice after γ irradiation. Tumors were harvested when they were 10 mm in size and cells were isolated and cultured in selection medium. After the first passage, we found that expression of GFP in the replicon cells was very faint and only a few cells (< 10%) showed bright GFP positivity. The sub-genomic HCV RNA has a neomycin gene selection marker that allows the selection of tumor cells that support HCV replication. Therefore, replicon cells were cultured with medium that contained G-418, to select for increased intracellular GFP expression. After 1 wk, a high level of GFP expression was seen in most of the cells in culture. This experiment suggested that *in vivo* tolerance occurred at the cellular level as well as at the level of intracellular virus replication in the replicon cells. We were able to select a homogeneous population of Huh-7 cells with stable GFP expression after the first passage in SCID mice. To obtain a GFP replicon cell line with increased growth and replication capacity, *in vivo* passaging experiments were repeated three additional times. Figure 2 suggests that *in vivo* passaging of replicon cells allowed for the selection of replicon cells with increased replicative ability. The expression of GFP in the frozen tumor sections was examined under a fluorescence microscope after nuclear staining. The levels of viral RNA replication in the subcutaneously formed HCC xenografts were very high and GFP expression was observed in most of the replicon cells (Figure 2). We generated a highly adapted GFP replicon cell line (S-3GFP/*in vivo*) that formed a HCC xenograft in SCID/bg mice within 2 wk.

HCC xenografts in the liver support HCV replication

It is important to develop an HCC xenograft in the liver because HCV replicates in the liver of the human host. Furthermore, a liver tumor model is needed to assess and optimize the targeted delivery of antiviral therapy. We wanted to determine whether the mouse-adapted replicon cells that formed a subcutaneous tumor could also form HCC in NOD/SCID mouse liver. The Huh-7 cells were infused into the liver by intrasplenic injection, and examined for liver tumor development at weekly intervals. The growth of mouse-adapted Huh-7 cells in the liver was slow compared to the subcutaneous model, and took almost 4 wk to reveal diffuse HCC nodules throughout the liver (Figure 3C and D). Normal mouse liver and histology are shown in Figure 3A and B. To examine whether HCV replication in liver tumors occurred at a similar level as that seen in the subcutaneous model, frozen sections of the liver tumors were examined for GFP expression. To our surprise, the level of HCV RNA replication was low in the liver tumor, and we could not see a very high level of GFP expression in the HCC xenografts formed in the SCID mouse liver. The loss of GFP expression was not due to an alteration in the open reading frame of GFP in the sub-genomic HCV RNA, because we could recover HCV GFP RNA levels when cells were isolated from the xenografts and cultured in medium supplemented with G-418. The negative GFP expression was due to the low level of HCV replication in the liver tumors. These results suggested that the liver microenvironment significantly suppressed HCV RNA replication compared to that in the subcutaneously formed tumors. We then examined whether these HCV GFP replicon cells needed to adapt to the liver microenvironment to support high-level replication of HCV. The mouse-adapted GFP replicon cells were therefore adapted to the liver microenvironment by another three passages. At each passage, we could recover HCV GFP expression in culture, which suggested that HCV RNA replication in the liver tumors was not completely lost. We then examined whether GFP expression could be seen in the HCC xenografts formed in the mouse liver, using the cells that had undergone three passages. We were able to see GFP expression in tumor nodules in the liver after three passages (Figure 3E and F). The replication of HCV RNA in the liver tumors was also confirmed by cell colony assay after culturing tumor cells in medium that contained G-418 (1 mg/mL). The replicon cells derived from the liver tumors formed G-418-resistant cell clones, which suggested that HCV replication occurred within the HCC xenografts in SCID mice. Liver tumor supporting HCV RNA replication was confirmed by RT-nested PCR followed by Southern blot analysis. These results suggest that we have developed a mouse-adapted S3-GFP replicon cell line that forms liver tumor after splenic injection. The level of HCV RNA in the liver tumor was determined by real time RT-qPCR that was in the range of 10^4 copies/ μ g of total cellular RNA. The subcutaneous tumor tissue showed a mean titer of 10^5 copies/ μ g of total cellular RNA. There is one log reduction in the HCV RNA titer in

Figure 2 Intracellular expression of hepatitis C virus-green fluorescence protein in the subcutaneous tumor of SCID mice. Mice were injected subcutaneously with 10^6 hepatitis C virus-green fluorescence protein (GFP) replicon cells. Tumor growth was monitored on a weekly basis. A: Tumorigenicity of Huh-7 replicon cells in γ -irradiated SCID mice; B: Expression of GFP in tumor cells during the *in vivo* passage. The number of GFP positive cells was low ($< 10\%$) after the first passage. There was a gradual increase in GFP expression in the subcutaneous tumors after each passage. After four passages, the number of GFP-positive cells increased significantly ($> 50\%$).

Figure 3 Human hepatocellular carcinoma xenograft in SCID/NOD mouse liver. A: Gross appearance of normal mouse liver with distended gall bladder; B: Light microscopic appearance of normal liver stained with hematoxylin and eosin ($4 \times$ magnification). The portal tracts are shown by single arrows and the central veins are marked with double arrows; C: Gross appearance of mouse liver with metastatic nodules of hepatocellular carcinoma (HCC). Note the distended white-tan areas of metastasis and infarction in the mouse liver (single arrows); D: Microscopic metastasis of HCC diffusely infiltrating the liver through the portal venous system (single arrows). Note the areas of infarction secondary to the tumor emboli in the portal vein (double arrow). Human hepatocytes can be easily discriminated from the mouse hepatocytes by their size and pale color; E: Expression of hepatitis C virus-green fluorescence protein (GFP) fusion protein in the S3-GFP liver tumors in the mouse; F: Hematoxylin and eosin staining (frozen section) of HCC tumor in the mouse liver at 4 wk after intrasplenic infusion of S3-GFP replicon cells.

the HCC tumor formed subcutaneously *vs* those formed in the liver (Figure 4). The HCV RNA titer in the liver tumor model is comparable to that found in chronically infected human liver tissue^[23]. We hypothesize that this might be due to the fact that there are differences in the innate immune pressure on HCV RNA replication in the peripheral compared with internal organs such as the liver.

There is evidence to support our observations that the liver has its own innate immune system that might suppress replication of HCV^[24-26].

IFN- α inhibits HCV replication in the HCC xenograft formed subcutaneously

To investigate the ability of IFN- α to inhibit HCV RNA

Figure 4 Comparison of hepatitis C virus RNA level between hepatocellular carcinoma xenografts formed subcutaneously and in the liver. RNA extract was prepared using the GITC method. The hepatitis C virus (HCV) RNA level was measured by real-time polymerase chain reaction using 1 μ g total RNA isolated from the tumor samples, and mentioned as log copies/ μ g RNA. HCV RNA levels were 10-fold higher in the tumors formed subcutaneously compared to those that were formed in the liver. The titer of HCV in the liver tumor model was comparable to that in the infected human liver.

replication in the subcutaneous HCC xenografts, the mice at 2 wk post-implantation were treated with IFN- α at 15000 IU/mice three times weekly. The mice were sacrificed at different time points after initiation of IFN- α treatment and the tissues were processed for HCV expression. IFN treatment decreased GFP expression in a time-dependent manner, with > 50% decrease in GFP expression after 1 wk (Figure 5B and E), with complete inhibition after 2 wk (Figure 5C and F). The untreated sections showed expression of GFP (Figure 5A and D). To show that the hepatocytes that support HCV replication are human hepatoma cells, immunostaining of HCC cells was performed using an antibody to human serum albumin. The results presented in Figure 5G-I clearly showed that the HCC xenografts were positive for human albumin. The level of albumin expression did not change due to IFN- α treatment. To ensure that IFN- α treatment inhibited viral RNA replication and reduced the level of HCV RNA in the HCC xenografts, total RNA was extracted from the tumor samples and processed for RPA. The results of this analysis are shown in Figure 6, which indicated that HCC xenografts in SCID mice supported a high level of HCV RNA replication, and the levels of HCV RNA in the tumors were completely inhibited after 2 wk of IFN- α treatment. The results shown in Figure 6A and B suggested that HCV RNA level in the subcutaneous HCC tumors increased from 18 to 28 d after tumor development. IFN treatment successfully inhibited virus replication within the tumors and the HCV-RNA titer decreased significantly after 2 wk of treatment, and remained below the limits of detection at 4 wk. We examined the possibility that IFN- α treatment could have an effect on tumor growth, which could have affected the measured HCV RNA levels in the tumors. The tumor size and histology of IFN- α -treated and untreated animals were compared (Figure 7). We did not notice any difference in the tumor growth or histology between the treated and untreated

animals. The dose of IFN- α treatment used in the *in vivo* experiments only inhibited HCV RNA replication, but did not inhibit the tumor growth. Taken together, these results indicated that HCC xenografts that formed subcutaneously in the SCID mice supported a high level of HCV RNA replication, and that IFN- α directly inhibited HCV replication in the tumors. All mice were doing well throughout the IFN- α treatment experiment and their body weight did not change significantly. Mice tolerated the IFN- α treatment well.

IFN- α completely inhibits replication of HCV 2a sub-genomic RNA in the HCC xenograft in mouse liver

We demonstrated the usefulness of this model by evaluating whether HCV replication in the liver tumor model could be inhibited by IFN- α . Mice were treated with intraperitoneal injection of IFN- α three times weekly at 15000 IU/mouse, starting at 4 wk after S3-GFP transplantation. Control animals received saline injections at similar time intervals. At different treatment intervals, mice were sacrificed and liver tissue was collected. The ability of IFN- α to inhibit HCV replication was confirmed by four independent assays. First, hepatocytes were isolated from the liver and cultured in the presence of growth medium that contained G-418 (1 mg/mL). The number of S3-GFP replicon cell colonies in the plate was compared to assess the antiviral effects of IFN- α against HCV replication in the xenograft tumors. Figure 8A shows that 4 wk IFN- α treatment successfully inhibited replication of HCV in the liver tumors. Second, the intracellular HCV RNA in the tumors tissue was examined by using RT-nested PCR and Southern blot analysis that targeted the highly conserved 5'-UTR region of the HCV genome. We showed that HCV RNA was detectable in the liver tumors of untreated mice over 5 wk, by RT-nested PCR and Southern blot analysis. IFN- α treatment completely inhibited HCV RNA replication in the liver tumors and remained undetectable at 4 and 5 wk, using the highly sensitive RT-nested PCR and Southern blot analysis (Figure 8B). IFN- α treatment did not alter the cellular albumin RNA levels. Third, expression of GFP in the liver tumors after IFN- α treatment was negative after 4 wk (Figure 8C). Fourth, the level of HCV RNA in the treated and untreated tumor samples was assessed by real-time PCR. The results of this analysis suggested that HCV levels decreased significantly in the tumors and remained below the detection limit after 4 wk of IFN- α treatment (Figure 8D). These data clearly showed that IFN- α inhibited HCV RNA replication in the liver tumor model and there was a significant difference in the level of HCV replication in the liver tumors between the untreated and IFN- α -treated mice. To demonstrate that the decrease in the HCV RNA replication after IFN- α treatment was not due to the direct effect of IFN on tumor growth in these HCC xenografts, histological examination of liver tumor in IFN- α -treated and untreated animals was performed. The histological pictures shown in Figure 9 indicate that there was no evidence of cellular necrosis in the tissue

Figure 5 Interferon- α inhibits hepatitis C virus-green fluorescence protein expression in human hepatocellular xenografts formed subcutaneously in SCID mice. Mouse-adapted replicon cells were injected subcutaneously into SCID mice, which then developed visible tumors after 2 wk. The mice were injected intraperitoneally with a total dose of 15 000 IU interferon- α (IFN- α) in 100- μ L volumes, three times weekly. Tumors were harvested after 1 and 2 wk of IFN treatment and examined for green fluorescence protein (GFP) expression and viral RNA by RPA and real-time polymerase chain reaction. A, D: Expression of GFP in the frozen sections of hepatocellular carcinoma (HCC) xenografts before IFN- α treatment; B, E: Expression of GFP 1 wk after IFN-treatment; C, F: Expression of GFP after 2 wk IFN-treatment. The middle panel shows DAPI staining of the nucleus. IFN inhibited hepatitis C virus RNA replication and GFP expression in the liver tumors at 7 and 14 d; G-I: Intracytoplasmic expression of human albumin in the HCC xenografts formed by subcutaneous injection of *in vivo* adapted Huh-7 replicon cells.

Figure 6 Intracellular hepatitis C virus RNA levels in subcutaneous tumors. A: RPA measuring intracellular hepatitis C virus (HCV) RNA levels in hepatocellular xenografts formed subcutaneously. There was a gradual increase in HCV RNA levels in the subcutaneous tumors at 3, 7 and 14 d post-tumor development. Two weeks of interferon (IFN) treatment completely inhibited HCV RNA replication in the subcutaneous tumors, as demonstrated by a negative RPA signal at 14 d of IFN- α treatment; B: Real-time reverse transcription polymerase chain reaction showing HCV RNA levels in the subcutaneous tumors before and after IFN- α treatment. IFN treatment decreased HCV RNA levels in the tumors, which remained below the detection limits after 2 wk.

sections of mice that received IFN- α treatment. These results indicated that the reduction of HCV RNA levels

in the tumor was due to a specific antiviral mechanism of IFN- α .

Figure 7 Interferon treatment has no effect of tumor growth in SCID/bg mice. A, B: Histology of tumor sections of experimental mice before (A) and after (B) 2 wk of interferon- α (IFN- α) treatment showed no evidence of tumor cell necrosis or apoptosis (10 \times magnification); C: Kinetics of tumor growth between two groups of mice during IFN- α treatment. The mean tumor volume remained the same between these two groups of mice.

DISCUSSION

Cell culture and animal models are required for the development of novel experimental therapies for chronic HCV infection. A number of antiviral strategies have been developed that inhibit HCV replication in cell culture systems^[4,5]. The successful use of different therapeutic agents to inhibit chronic HCV infection requires further validation using an easily accessible small animal model. Our laboratory has developed multiple siRNA targets in the 5'-UTR region of the HCV genome, and has shown that intracellular delivery of these siRNAs can completely degrade HCV RNA in cell culture^[27]. We have also developed recombinant antibodies targeted to the viral NS3 helicase, and have shown that intracellular expression of these antibodies inhibits viral helicase activity and virus replication in a cell culture model^[28]. The next step of this research is to test the effectiveness of these different antiviral strategies that target inhibition of viral replication, using an animal model system. Therefore, development of a small animal model for HCV infection was essential to optimize targeted, hepatic delivery of siRNA and recombinant antibodies. Mice and other rodents are not susceptible to natural HCV infection, thus, there are several alternative approaches that have been employed during the past few years to replicate HCV infection using mouse models. The advantages and disadvantages of these models to study HCV infection in mouse models are discussed.

The most promising small animal model for studying HCV infection is now the human liver chimeric mouse. The principle of developing this mouse model is based on the availability of specific mouse strains in which human hepatocytes can be efficiently transplanted into the mouse liver. Two specific mouse strains are currently being used for development of the humanized mouse liver. One is the SCID-Alb/uPA mouse and the other is the Fah^{-/-} Rag^{-/-} IL-2^{-/-} mouse. Both mouse strains have high liver regeneration capacity due to their liver injury and support a high degree of human hepatocyte transplantation. The humanized mouse liver has been shown to have normal hepatic architecture and support HCV replication after natural infection. The studies conducted by Mercer *et al.*^[13] and Tateno *et al.*^[29] have used a mouse strain called SCID-Alb/uPA. Using this mouse strain, Mercer *et al.*^[13] have shown that the humanized mouse liver contains > 50% human hepatocytes, and Tateno *et al.*^[29] have shown that humanized mouse liver contains > 92% human hepatocytes. The Alb/uPA transgenic mouse strain shows severe hepatotoxicity due to overexpression of the urokinase plasminogen (*uPA*) gene in hepatocytes, which leads to continuous liver regeneration. Human hepatocytes that lack this transgene preferentially survive after transplantation and are stably maintained in this mouse liver. This mouse strain has been crossed with an immunodeficient mouse (SCID or Rag2) to generate the SCID-Alb/uPA mouse strain that tolerates transplantation of human hepa-

Figure 8 Antiviral effect of interferon- α in the liver tumor model. S3-green fluorescence protein (GFP) cells were implanted in the liver of NOD/SCID mice by intrasplenic injection. After 3 wk, interferon- α (IFN- α) treatment was started. The time shown represents the weeks after IFN treatment. A: Colony assay of viable tumor cells isolated from the liver tumor model at different time points with or without IFN- α treatment. Tumor cells isolated from the entire mouse liver were cultured in the medium that contained 1 mg/mL G-418. The replicon cells with hepatitis C virus (HCV) survived the treatment and formed cell colonies. Left panel: there was an increase in the number of cell colonies between 4 and 5 wk. Right panel: IFN- α treatment completely inhibited HCV replication and cell colony formation at 4 wk; B: RT-nested polymerase chain reaction (PCR) and Southern blot analysis for HCV and albumin in the RNA extracts of the liver tumor. Left panel shows the results without treatment. Right panel shows IFN- α treatment; C: Expression of HCV-GFP in the liver tumors before and after IFN treatment. IFN treatment after 4 wk completely inhibited HCV-GFP expression in the S3-GFP tumors in the SCID mouse liver; D: Real-time reverse transcription PCR (RT-PCR) showed that the levels of HCV in the liver tumor remained undetected after 4 wk of IFN- α treatment. The dotted line indicates the limit of detection for real time RT-PCR assay.

tocytes well. Human hepatocytes can be successfully transplanted into the SCID-Alb/uPA mice within 1 or 2 wk after birth. Several studies have now successfully used this model to replicate HCV infection and have tested several antiviral molecules, including IFN- α and protease inhibitors. The study conducted by Bissig *et al*^[16] has used Fah^{-/-} Rag2^{-/-} IL-2^{-/-} mice and has shown that the humanized mouse liver contains > 80% human hepatocytes. This mouse strain lacks fumaryl acetoacetate, which is an enzyme that is required for tyrosine amino acid metabolism. Mice that lack this enzyme show severe hepatotoxicity due to accumulation of toxic metabolites. This mouse strain has been bred with Rag2^{-/-} IL-2^{-/-} mice to generate an immunodeficient mouse strain that supports transplantation of adult human hepatocytes. Recently, Bissig *et al*^[16] have used this mouse model to replicate HCV infection from cell culture and from the serum of chronically infected patients. They also have shown that pegylated IFN- α and Debio 025 (cyclophilin inhibitor) inhibit HCV replication in this chimeric mouse model. The investigators have

shown that these chimeric mice sustain viral replication for > 6 mo, without any substantial side effects. There is no doubt that these chimeric mouse models are extremely challenging technically, complicated to use, and expensive. Despite the technical challenges, these models hold promise for studying the long-term effect of HCV infection on the development of liver fibrosis and cancer.

We described here an HCC xenograft mouse model in which human tumor cells were implanted in the liver of an immunodeficient mouse. This model is relatively simple compared to the human liver chimeric mouse model. This model can be used for experimental verification of the efficacy of targeted antiviral therapies against HCV. The model utilizes SCID/bg and NOD/SCID mice with a partially suppressed innate immune system (natural killer cell response) and adaptive immune system (both B- and T-cell mediated response)^[30]. In an earlier study, Zhu *et al*^[18] have performed similar experiments to generate a mouse-adapted HCV Con-1 replicon cell line using the SCID/bg mice. The *in vivo* adaptation of HCV is not possible using

Figure 9 Histological evaluation of liver sections after hematoxylin and eosin staining that indicates that interferon- α treatment did not cause any tumor necrosis or reduce the size of tumor nodules in the SCID mice liver. The upper panel shows the untreated mouse liver sections after 2-5 wk of tumor development. The black arrows indicate the hepatocellular carcinoma (HCC) tumor in the mouse liver. Similarly, the lower panel shows the interferon- α -treated mouse liver sections with HCC tumor at different time points (10 \times magnification).

this approach due to the low-level replication capacity of the HCV Con-1 replicon clone. The authors had to re-engineer the sub-genomic clone with reinsertion of HCV sub-genomic RNA with a highly efficient internal ribosome entry site, and a highly adapted mutation in the non-structural gene, to sustain high-level replication of HCV RNA within the tumor. They have successfully measured HCV replication in this mouse model by measuring luciferase activity using non-invasive whole-body imaging. They have shown that IFN- α and protease inhibitor BILN-2061 reduce HCV RNA replication in the subcutaneous and liver tumor models. The authors have not shown whether these treatments lead to complete clearance of HCV in these tumors models. Another study by Guévin *et al*^[31] also has demonstrated that full-length HCV replication can be achieved in HCC tumor xenografts formed subcutaneously using immunodeficient mouse strains. The authors have made mouse-adapted Huh-7 cells by multiple passages in SCID mice. The authors have shown that the xenograft tumors in the SCID mouse produce infectious virus particles. The infectious virus produced in the xenograft tumors can be serially passaged in SCID mice. The authors have shown that IFN- α and protease inhibitor BILN-2061 inhibit replication of the cell culture HCV cc strain JFH1 in the mouse model.

The mouse model described here differs in some aspects compared to the two previously described tumor xenograft models. We realized that high-level replication of HCV in the SCID mouse liver might be possible by using the highly efficient JFH1 clone. We used the JFH1 virus clone that replicated at a much higher level in the HCC xenografts formed in the SCID mice. The GFP-labeled replicon cell line showed that replication of HCV occurred in the HCC tumors, and could be determined by

direct examination under fluorescence microscopy. The replicon cell line is similar to chronically infected human hepatocytes, except that these cells do not produce the infectious virus, which makes this animal model safer to use. We have used a number of biochemical methods (colony assay, RPA, real-time RT-PCR and RT-nested PCR and Southern blot analysis) that quantitatively evaluate HCV replication in the subcutaneous tumors in an accurate manner. If necessary, this model can also be adapted using a luciferase-based, mouse-adapted HCV replicon cell line so that the whole-body imaging technique can be used to monitor HCV replication in the mouse model. The diffuse metastasis of HCC throughout the liver lobes after intrasplenic infusion of replicon cells mimics *in vivo* distribution of chronically infected hepatocytes in human liver. We demonstrated replication of HCV RNA in multiple HCC nodules in the portal tracts of the SCID mice livers. This liver tumor model developed by intrasplenic injection of replicon cells provides a better assessment of the biodistribution and pharmacokinetics of IFN- α when compared to direct injection of replicon cells to the liver, where HCC tumors are formed only in selected areas of the organ. We noticed that the level of HCV replication in the liver tumor model was 10-fold lower when compared to that in the subcutaneous model. This could be due to the innate antiviral pressure against HCV between the peripheral organ and liver microenvironment. The dynamics of viral RNA replication in the liver tumor model are comparable to those of chronically infected human liver. As a practical validation of this mouse model, we showed that IFN- α treatment inhibited HCV RNA replication and abolished GFP expression in the subcutaneous HCC xenografts within 2 wk, which suggests that the mouse model can be used to test the success of other antiviral

strategies against HCV. We showed that IFN- α completely inhibited viral replication in the liver tumor model, and HCV RNA in liver tumors was undetectable by using a highly sensitive RT-nested PCR. The sensitivity of this RT-nested PCR assay was found to be in the range of 1-10 copies of HCV RNA^[32]. Using this mouse model, we showed that IFN- α administration completely eliminated HCV sub-genomic RNA replication, which supports the practical use of this animal model to test other antiviral strategies against the background of a growing tumor. This mouse model, therefore, can be used practically to optimize methods for targeted delivery of siRNA and recombinant antibodies that are designed to inhibit HCV replication in tumor xenografts in the mouse liver.

The SCID mouse model described here can be adapted to any research laboratory because it is relatively simple, safe and less expensive, thus allowing it to be used in large numbers for testing. This mouse model can be utilized to establish the success of targeted liver delivery methods of a variety of antiviral strategies within a short period of time. *In vivo* experiments that address the toxicity of different antiviral approaches with this animal model can be tested using a large number of mice to achieve statistical power of significance. This model deals with non-infectious HCV and does not depend on the use of donated or harvested human hepatocytes or infected serum samples. We have also developed *in vivo* adapted Huh-7 cells by elimination of HCV replicon replication. Tumor xenografts that use this Huh-7 cell line in SCID mice can be used to study the infectivity of JFH1 virus and other relevant clinical HCV strains. This will allow us to test the efficacy of neutralizing monoclonal antibodies directed against the HCV envelope protein. There are also some limitations in the tumor xenograft mouse models for HCV that are described here. For example, this model cannot be used for investigation of immunopathogenesis of chronic HCV infection or vaccine development because the SCID mice have defective B- and T-cell responses. Nevertheless, this animal model will be useful for antiviral evaluation and testing the potential of intracellular delivery of siRNA and recombinant antibodies that are directed at inhibition of HCV replication in the liver.

We thank Jeanne Frois and Mallory Schexnayder for critically reading the manuscript. The authors thank Takaji Wakita for providing the JFH-1 and pSGR clone. The authors thank Mathew Burrow for assisting us during the experiments with tumor implantation.

COMMENTS

Background

Hepatitis C virus (HCV) is the most common blood-borne infection that affects the liver. Several antiviral strategies have been developed during the past 2 years, including small molecules, antisense oligonucleotides, siRNA, ribozymes, and recombinant antibodies that are designed to inhibit HCV replication in cell culture models. A small animal model for HCV is required to test different experimental therapies developed using HCV cell culture systems.

Research frontiers

Development of a small animal model for studying HCV infection has been difficult because the virus only infects humans and chimpanzees. The only available animal model is a chimeric humanized mouse model. This model is very costly, technically very challenging, and very expensive. The authors developed an hepatocellular carcinoma (HCC) xenograft tumor model in SCID mice using a replicon cell line that replicates highly efficient JFH1 virus. The replicon cells were transfected with a green fluorescent protein (GFP)-tagged HCV sub-genomic clone so that the antiviral effect could be observed by GFP expression. The replication of HCV could be inhibited by interferon- α (IFN- α), which indicates that the model can be used for antiviral screening. The HCC xenograft mouse model is less expensive, non-infectious, and can be easily adapted to any research laboratory.

Innovations and breakthroughs

The authors developed an S3-GFP replicon Huh-7 cell line that was highly adapted to mice and formed human HCC xenografts in SCID mice. We showed that HCV replicated in the HCC xenografts formed subcutaneously and in the liver. The antiviral effect of IFN- α showed clearance of HCV in this mouse model.

Applications

This model can be used to optimize methods for liver-targeted delivery of several antiviral strategies against HCV replication.

Abstract

AIM: To investigate the role of octreotide on cellular proliferation and apoptosis of human hepatoma (HepG2) cells.

METHODS: We studied cellular proliferation, apoptosis and the possible internal caspase-mediated apoptosis pathway involved, after treatment of HepG2 carcinoma cells with octreotide in comparison with the apoptosis caused by tumor necrosis factor- α (TNF- α). Activities of caspase-3, caspase-9, caspase-8 and caspase-2 were studied, while apoptosis was investigated through detection of DNA fragmentation and through identification of apoptotic cells with the annexin-V/propidium iodide flow cytometric method.

RESULTS: After an initial increase in HepG2 cellular proliferation, a significant inhibition was observed with

10^{-8} mol/L octreotide, while TNF- α dose-dependently decreased proliferation. Early and late apoptosis was significantly increased with both substances. Octreotide significantly increased caspase-3, caspase-8 and caspase-2 activity. TNF- α significantly increased only caspase-2. Cellular proliferation was decreased after treatment with octreotide or TNF- α alone but, in contrast to TNF- α , octreotide decreased proliferation only at concentrations of 10^{-8} mol/L, while lower concentrations increased proliferation.

CONCLUSION: Our findings are suggestive of caspase-mediated signaling pathways of octreotide antitumor activity in HepG2 cells, and indicate that measurements of serum octreotide levels may be important, at least in clinical trials, to verify optimal therapeutic drug concentrations.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common malignancy in the world and is estimated to cause approximately half a million deaths annually^[1]. There are striking differences in the incidence of HCC related to

age, gender, race, and geographic region, with hepatitis C virus (HCV) infection acquired 2-4 decades previously explaining at least half of the observed increase in HCC^[2]. The survival rates remain generally dismal (median 8 mo)^[2]. Undoubtedly, the best available treatment for all liver tumors is complete surgical resection. However, the synthetic somatostatin analogue octreotide has been found effective in inhibiting tumor growth in a variety of experimental models^[3,4]. Octreotide did not influence hepatic or portal blood flow, although significantly increased reticuloendothelial system activity^[5,7]. Apart from stimulation of the reticuloendothelial system, octreotide may have other mechanisms of action, to inhibit the growth of hepatic tumors. One of the mechanisms suggested may be a direct antiproliferative effect, through receptor-mediated growth inhibition^[8]. *In vitro* studies have shown that octreotide demonstrates high affinity binding towards somatostatin receptors sstr2, sstr3 and sstr5, while no binding affinity is found towards receptors sstr1 and sstr4^[9-11]. It has been reported that octreotide inhibits the proliferation and induces apoptosis of different HCC cell lines *in vitro*^[12-18]. The mechanisms of apoptosis induction however are not well understood.

Tumor necrosis factor- α (TNF- α) is a well established as a means of apoptosis induction in a variety of cell types through specific responsive receptors, but other cells require transcriptional arrest^[19]. Hepatoma cells treated with TNF- α and cycloheximide (CHX) undergo apoptosis, which is preceded by a strong activation of c-jun N-terminal kinase^[20]. The human HCC cell line, SMMC-7721, was insensitive to TNF- α cytotoxicity, but quickly underwent apoptosis in the presence of TNF- α and CHX^[21].

Apoptosis is a complex process characterized by caspase activation, cell shrinkage, chromatin condensation and internucleosomal DNA fragmentation^[22-25]. Caspases are cysteine-containing aspartic acid-specific proteases and all have similar site-specific proteolytic activity. Caspases are divided into 3 distinct groups based on their substrate specificities. Group I (YVADase) includes caspase-1, -4 and -5 which are involved in cytokine production. Group II (DEVDase) caspases, e.g. caspase-3 and -7 are the main effector caspases during apoptosis. These are cleaved by group III (IETDase) caspases (e.g. caspase-6, -8, -9 or -10) early in the onset of apoptosis^[26]. Upon activation, group II caspases act on various cell proteins^[26]. Most, but not all, events in apoptosis appear to require a caspase-mediated proteolytic step^[25].

Octreotide has been clinically used for treatment of HCC, with conflicting results. Both increased survival^[27,28] and no effect^[29,30] have been reported. Although negative studies have been criticized^[31], the mechanisms by which octreotide may act have not been adequately clarified. Apoptosis may be a fundamental mechanism. In this study, we examined the effect of octreotide on cellular proliferation, apoptosis and caspase activation in HepG2 HCC cells. The model of TNF- α -induced apoptosis was chosen for comparison with octreotide in a study of the biological behavior of caspases, after treatment of HepG2 cells with octreotide.

MATERIALS AND METHODS

Octreotide was from Novartis (Basel, Switzerland) and was used at concentrations of 10^{-10} mol/L to 10^{-7} mol/L, to identify the optimal concentration for inhibition of cell proliferation. Incubations with TNF- α (R&D Systems, Minneapolis, USA) were made at concentrations from 0.1 to 100 ng/mL (0.1, 1, 10, 20, 100 ng/mL). According to the proliferation curve, the suitable concentrations for further experiments were 10^{-8} mol/L for octreotide and 20 ng/mL for TNF- α . These concentrations were used for all further combinations and measurements of apoptotic features.

Cell culture and incubation conditions

The HepG2 cell line is a human hepatocyte carcinoma cell line derived from a well-differentiated human hepatoblastoma and was purchased from the European Collection of Cell Cultures (ECACC, Porton Down, UK). HepG2 cells are maintained in continuous culture in our laboratory in RPMI supplemented with 10% fetal bovine serum (FBS, Gibco, Paisley, UK), at 37°C and in an atmosphere of 5% CO₂. For experiments, HepG2 cells were seeded in 24-well plates at a density of 2×10^4 /cm². Twenty four hours before the experiment, they were cultured in fresh medium without FBS, and then treated with different concentrations and combinations of all substances. Incubations were made at 37°C in 5% CO₂. Supernatants were collected and stored in -80°C, while cell extracts were used for measurements of caspase activity. Control medium was complete media with 10% FBS. HepG2 cells cultured in control medium are referred to as control cells.

Proliferation assays

For measurement of growth inhibition, the sulforhodamine B colorimetric assay (SRB Assay; Biotium Inc., Hayward, CA, USA) was used, as previously described^[32,33]. HepG2 cells were plated in 96-well plates, at an initial density of 5×10^3 cells, with 200 μ L medium per well. All substances were added to cultures 1 d after seeding, in order to obtain best attachment of the cells at the beginning of the experiments. Cells were grown for a total of 6 d, with a change of medium and substances on the third day after treatment. Measurements were made as described in the original protocol. Briefly, 50 μ L of 50% trichloroacetic acid were placed into the 200 μ L medium and plates were stored at 4°C for 30 min. After washing 5 times with deionized water, plates were left to dry for 24 h at room temperature. Then, 70 μ L of 0.4% sulforhodamine B in 1% acetic acid were placed in every well and left at room temperature for 20 min. Before air drying for a second time, plates were washed 5 times with 1% acetic acid. At the end of the procedure, 200 μ L of unbuffered Tris-base solution (pH 10.5) were added to each well and measurements were made at 490 nm, subtracting the background at 620 nm. The mean of the optical densities of 8 different controls was considered to be 100% and all other values were expressed as a percentage of the controls.

Detection of apoptosis

DNA fragmentation: For detection of apoptosis, a sandwich, one step, colorimetric enzyme-linked immunosorbent assay, the Cell Death Detection ELISA Plus kit (Roche Diagnostics, Mannheim, Germany) was used. The assay allows for the specific determination of histone-complexed DNA fragments (mono and oligonucleosomes) from the cytoplasm of cells, after the induction of apoptosis. Briefly, after induction of apoptosis and 24-h incubation, the cells were pelleted by centrifugation (200 *g*, 10 min) and the supernatants (containing DNA from necrotic cells that leaked through the membrane during incubation) were discarded. Cells were resuspended and incubated for 30 min in lysis buffer. After lysis, intact nuclei were pelleted by centrifugation. Aliquots of the supernatants were transferred to a streptavidin-coated well of a microtiter plate with 2 monoclonal antibodies, antihistone (biotin-labeled) and anti-DNA (peroxidase-conjugated), so that nucleosomes in the supernatant created antibody-nucleosome complexes, which were continuously bound to the microtiter plate by the streptavidin. All samples were then incubated with peroxidase substrate and absorbance was measured at 405 nm. The mean of the optical densities of 8 different controls was considered to be 100% and all other values were expressed as a percentage of the controls.

Annexin-V/propidium iodide staining: For better evaluation of apoptotic features, the modified Annexin-V Apoptosis Detection Kit (BioVision, Mountain View, CA, US) was used, which is based on the observation that soon after initiation of apoptosis, cells translocate the membrane phosphatidylserine (PS) from the inner face of the plasma membrane to the cell surface, but they also shrink, increasing their side scatter (SS) and reducing their forward scatter (FS) characteristics. Once on the cell surface, PS can be easily detected by staining with a fluorescent conjugate of Annexin-V, that has a high affinity for PS. Cells that have bound Annexin-V-fluorescein isothiocyanate (FITC) (early apoptotic) show green staining in the plasma membrane, while cells that have lost membrane integrity will show red staining [propidium iodide (PI)] throughout the nucleus and a halo of green staining (FITC) on the cell surface (late apoptotic or necrotic cells).

After treatment and 24-h incubation in 24-well plates, adherent HepG2 cells were gently trypsinized and washed once with serum-containing medium. Then, 1.5×10^5 cells were collected by centrifugation (98 *g*, 5 min) and resuspended in 300 μ L of $1 \times$ Binding Buffer. After gentle pipetting to resuspend the cell pellets, 3 μ L of Annexin-V-FITC and 3 μ L of 50 μ g/mL PI, were added, followed by a 5-min incubation at room temperature in the dark. Annexin-V-FITC binding was analyzed by flow cytometry (Epics Elite) (Ex = 488 nm; Em = 530 nm) using a FITC signal detector and PI staining by the phycoerythrin emission signal detector. Debris was excluded by scatter gating (forward *vs* side). At least 10000 events were counted for each sample.

Caspase activity

The activities of caspase-3, caspase-9, caspase-8 and caspase-2 were measured. For the evaluation of caspase activity, colorimetric activity assay kits (Chemicon, Temecula, CA, USA) were used. The assays are based on spectrophotometric detection of the chromophore *p*-nitroaniline (*p*NA) after cleavage from the labeled substrate DEVD-*p*NA (caspase-3), LEHD-*p*NA (caspase-9), IETD-*p*NA (caspase-8) and VDVAD-*p*NA (caspase-2), respectively. Briefly, after treatment and 24-h incubation, supernatants were collected and cells were resuspended in 250 μ L of chilled lysis buffer and incubated on ice for at least 10 min. After centrifugation (5 min, 10000 *g*), supernatants (cytosolic extracts) were transferred to a fresh tube and placed on ice. The protein concentration for each sample set was assayed with BIORAD Protein assay (BIORAD, Munchen, Germany)^[34]. Samples were incubated for 2-3 h at 37°C and measured at 405 nm, as indicated. The absorbance of *p*NA from every sample was compared with the uninduced controls and values were expressed as μ mol/L of *p*NA per microgram of cytosolic protein (μ mol/L per microgram).

Statistics

Statistical analysis was performed using Microsoft Excel 2007 and Instat software (GraphPad software inc., San Diego, California, USA). Results are expressed as mean \pm standard error of the mean (SE). The Kolmogorov and Smirnov test was used to check the Gaussian distribution of data. Statistical comparisons were performed using one-way analysis of variance with Tukey's *post hoc* comparisons. The non parametric Kruskal-Wallis test was used instead if Bartlett's test indicated a significant difference between standard deviations. $P < 0.05$ was considered statistically significant.

RESULTS

Effect of octreotide on HepG2 proliferation

Octreotide caused an initial increase in HepG2 proliferation ($165.2\% \pm 6.2\%$ and $127\% \pm 3\%$ with octreotide 10^{-10} mol/L and 10^{-9} mol/L, respectively) followed by a significant inhibition at a concentration of 10^{-8} mol/L (concentration expected in the blood of patients receiving treatment), reducing cellular proliferation to $77.5\% \pm 1.9\%$ of control (Figure 1). No difference was observed at a concentration of 10^{-7} mol/L ($108.3\% \pm 3.8\%$).

The effect of TNF- α was also examined, at concentrations from 0.1 ng/mL to 100 ng/mL. At the low concentrations of 0.1 and 1 ng/mL, TNF- α had no significant effect on the proliferation of HepG2 cells ($96.9\% \pm 5\%$ and $90.6\% \pm 4.5\%$, respectively), after 6 d of incubation. A marked inhibitory effect was detected with 10, 20 and 100 ng/mL TNF- α , which reduced cellular proliferation to $69.4\% \pm 4\%$, $69.6\% \pm 2.3\%$ and $61.4\% \pm 1.7\%$ of control, respectively (Figure 2). However, because TNF- α at a concentration of 20 ng/mL had the optimum inhibitory effect in another HCC cell line (SMMC-7721 cells)^[19], this concentration was selected for further experiments.

Figure 1 Octreotide at a concentration of 10^{-8} mol/L had a statistically significant inhibitory effect on cellular proliferation of HepG2 hepatocellular carcinoma cells, compared to untreated cells. Lower concentrations caused an initial increase in proliferation. The results represent the mean of 8 different experiments \pm SE ($^bP < 0.01$, $^dP < 0.001$). NS: Not significant.

Figure 2 Tumor necrosis factor- α at concentrations of 10, 20 and 100 ng/mL had a statistically significant inhibitory effect on cellular proliferation of HepG2 cells, compared to untreated cells. The results represent the mean of 8 different experiments \pm SE ($^dP < 0.001$). TNF- α : Tumor necrosis factor- α .

Effect of octreotide on HepG2 apoptosis

Apoptosis was detected based on determination of histone-complexed DNA fragments (mono and oligonucleosomes) from the cytoplasm of apoptotic cells. Similar non significant detection of DNA fragmentation was noted after 24-h treatment of HepG2 cells with either octreotide or TNF- α ($115.2\% \pm 6.95\%$ and $115.2\% \pm 8.17\%$, respectively) (Figure 3).

Necrotic cells should be visualized as double positive cells of large dimensions, as they rapidly lose membrane integrity and swelling occurs before destruction, or as fractured membranes of low FS and SS, PI only positive or double positive, but in the place where debris is usually detected and excluded. We also observed that all double positive cells had very small dimensions (data not shown), although they were still intact. We considered double positive cells as cells that followed the apoptotic rather than the necrotic procedure, having increased their SS and decreased their FS characteristics, but still retaining relatively small dimensions. That was the reason why we followed

Figure 3 Detection of DNA fragmentation revealed a non significant increase in DNA fragments, after 24-h treatment with octreotide or tumor necrosis factor- α ($n = 8$). TNF- α : Tumor necrosis factor- α ; NS: Not significant.

a specific gating strategy for analysis. Octreotide caused a significant increase in early apoptosis ($7.2\% \pm 1.4\%$, $P < 0.01$, Annexin-V positive cells) and a highly significant increase in late apoptosis ($15.3\% \pm 2.7\%$, $P < 0.001$, Annexin-V/PI double positive cells). TNF- α significantly increased early ($12.5\% \pm 1.4\%$, $P < 0.001$) and more so late apoptosis ($26.4\% \pm 4\%$, $P < 0.001$, Figure 4). All comparisons were made with untreated HepG2 cells used as control cells ($0.5\% \pm 0.3\%$ and $2 \pm 0.3\%$ for early and late apoptosis, respectively) (Figure 4).

Effect of octreotide on caspase activity in HepG2 cells

Caspase-3 activity was significantly increased after treatment of HepG2 cells with octreotide (4.71 ± 0.81 $\mu\text{mol/L}$ per microgram protein, $P < 0.01$) alone, while after TNF- α only, a non significant increase was found (3.28 ± 0.55 $\mu\text{mol/L}$ per microgram protein), compared with uninduced cells (1.87 ± 0.24 $\mu\text{mol/L}$ per microgram protein) (Figure 5). A small but not significant increase in caspase-9 activity was detected after treatment of HepG2 cells with TNF- α (2.44 ± 0.33 $\mu\text{mol/L}$ per microgram protein) or octreotide alone (2.42 ± 0.77 $\mu\text{mol/L}$ per microgram protein) (Figure 5), compared to uninduced cells (1.56 ± 0.21 $\mu\text{mol/L}$ per microgram protein). TNF- α caused a non significant increase in caspase-8 activity (0.9 ± 0.18 $\mu\text{mol/L}$ per microgram protein) compared with control cells (0.51 ± 0.06 $\mu\text{mol/L}$ per microgram protein) (Figure 5). However, octreotide caused a significant increase (1.3 ± 0.1 $\mu\text{mol/L}$ per microgram protein, $P < 0.01$). TNF- α and octreotide caused a significant increase in caspase-2 activity (1.73 ± 0.17 $\mu\text{mol/L}$ per microgram protein and 1.7 ± 0.18 $\mu\text{mol/L}$ per microgram protein, respectively, $P < 0.001$), compared with control cells (0.8 ± 0.09 $\mu\text{mol/L}$ per microgram protein) (Figure 5).

DISCUSSION

Clinical studies of non-neuroendocrine tumors demonstrate that octreotide can inhibit the growth of a variety of tumors, either directly, through binding on the sstrs of tumor cells, or indirectly, through an immunomodulatory or an antiangiogenic effect^[35-37]. Several reports indicate that

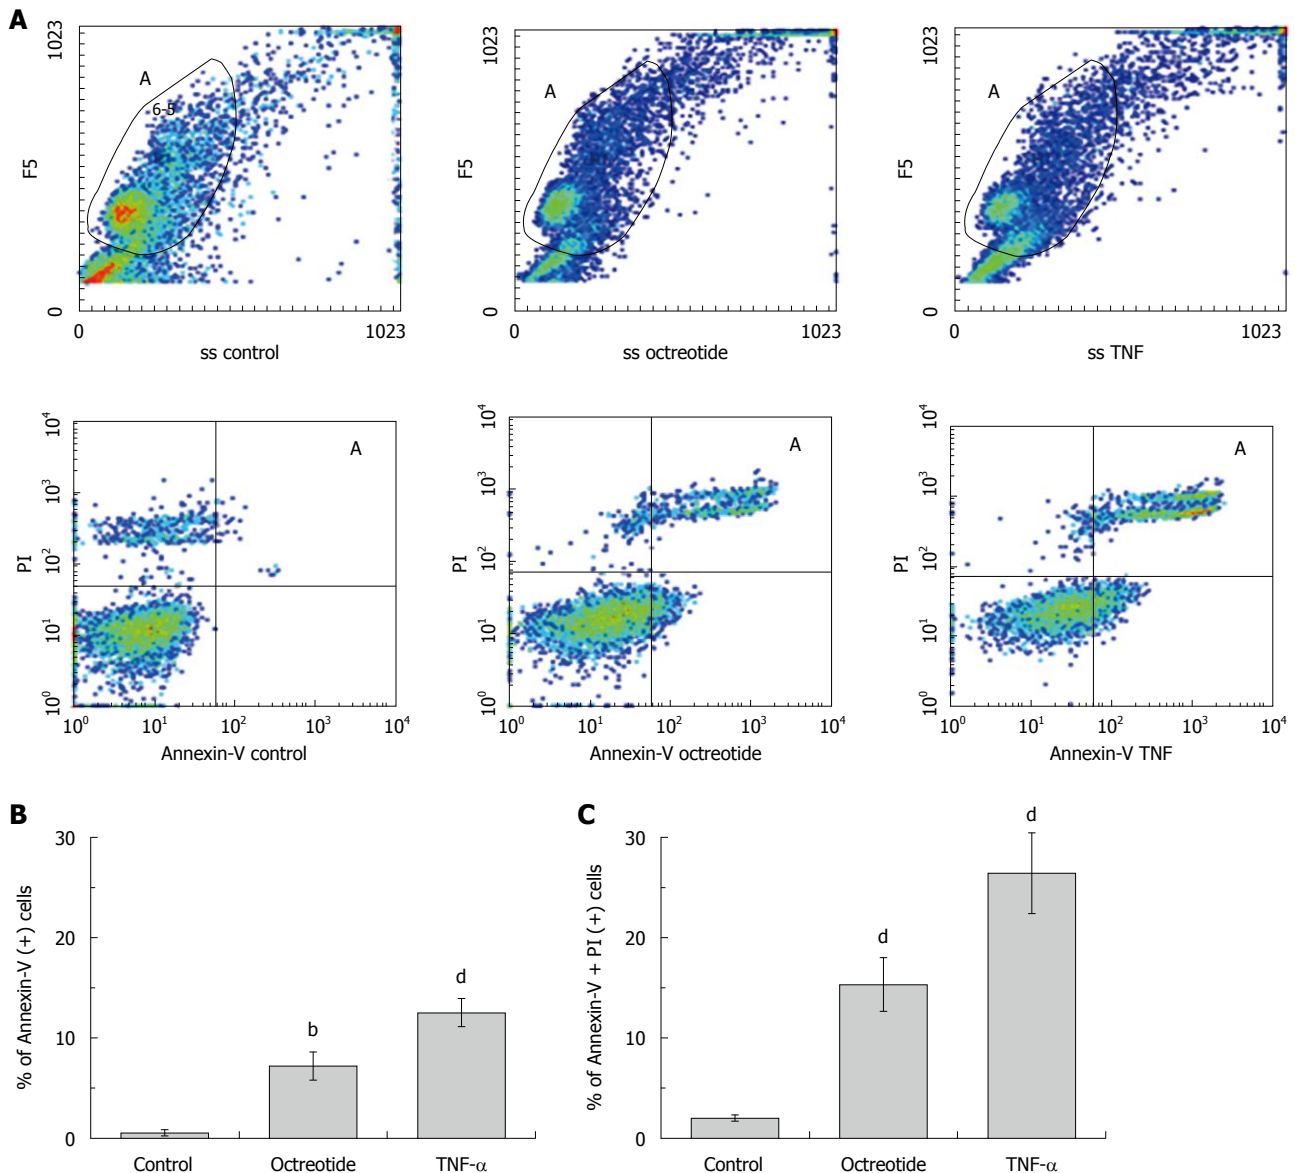

Figure 4 The apoptotic effect of octreotide and tumor necrosis factor- α alone is shown. A: Octreotide and tumor necrosis factor- α (TNF- α) significantly increased early (Annexin-V only positive, right lower quadrant) and more so late apoptotic cells [Annexin-V and propidium iodide (PI) positive, right upper quadrant]. Every sample was analyzed with the same gating strategy (Gate A) to exclude debris and non-specific binding of Annexin-V, while control refers to uninduced HepG2 cells; B: Annexin-V positive cells; C: Annexin-V/PI positive cells. B and C: Mean of 8 different experiments \pm SE ($^bP < 0.01$, $^dP < 0.001$).

octreotide inhibits the proliferation and induces apoptosis of HCC cells *in vitro*^[12-18]. In this study we confirmed that octreotide inhibits HepG2 proliferation^[12,15,18], but only at a concentration of 10^{-8} mol/L, although an initial increase at lower concentrations was observed.

In contrast to these findings, there are also reports that proliferation of HCC cells or hepatic stellate cells is not affected by octreotide^[38,39]. In the study of Reynaert *et al*^[39], shorter periods of culture compared to ours were used, while activation of sstrs was achieved with individual synthetic agonists, therefore a possible combined effect of concomitant receptor activation may have been missed. Similarly, clinical trials have demonstrated a survival benefit of patients with inoperable HCC treated with octreotide^[27,28], but also negative studies have been published^[29,30] and recently criticized^[31]. Interestingly, in our study, lower concentrations of octreotide increase proliferation and

this is possibly an additional reason for divergent results in both clinical trials and *in vitro* studies of octreotide in HCC. Our findings also indicate that measurements of serum octreotide levels may be important, at least in clinical trials, to verify optimal therapeutic drug concentrations.

Octreotide binds mainly to sstr2, sstr3 and sstr5^[40], the presence of which has been recently documented in HepG2 cells^[12,41]. The antiproliferative effect of octreotide is thought to be mediated by sstr2^[42] and sstr5^[43]. Even when a significant amount of sstr2 binding in cellular membranes is not evident, it is possible that octreotide is internalized either along with sstr2 or alone as reported by Dournaud *et al*^[44] and Hornick *et al*^[45]. Recently a desensitization of sstr2 has been reported after short term incubation of an HCC cell line with octreotide, which is probably reversed after long term incubation^[46]. We have previously reported an IC₅₀ of 1.25 nmol/L for the

Figure 5 Caspase-2 (A), -3 (B), -8 (C) and -9 (D) activities, after treatment of HepG2 cells with 10^{-8} mol/L octreotide and 20 ng/mL tumor necrosis factor- α , compared to untreated cells. The results represent the mean of 10 different experiments \pm SE ($^bP < 0.01$, $^dP < 0.001$). TNF- α : Tumor necrosis factor- α ; NS: Not significant.

antiproliferative effect of octreotide for HepG2 cells^[41] which is within the range of IC_{50} for sstr2 but it is lower from the IC_{50} reported for sstr5. In the case of sstr5, it is possible that a biological effect can be achieved without activation of the total number of receptors.

The antiproliferative effect of octreotide may be due to either cell necrosis or cell apoptosis^[47]. Therefore, we investigated the apoptotic effect of octreotide, particularly in association with caspase activation, comparing this effect with the well-described pathways of TNF- α -mediated apoptosis. The machinery of apoptosis includes death receptors, adaptor proteins and proteolytic enzymes (caspases). Death receptors belong to the tumor necrosis factor receptor gene superfamily. Among these receptors, TNF receptor-1 (TNFR1) and Fas (CD95) are the most extensively characterized, and both are abundantly expressed in liver^[20,48]. TNF- α at 20 ng/mL induced apoptosis in human hepatoma cell line SMMC-7721 *in vitro*, which was exacerbated by the hypoxanthine-xanthine oxidase system and CHX, but alleviated by superoxide dismutase, suggesting that TNF- α -induced apoptosis may be due to oxidative stress^[49]. The SMMC-7721 cell line was insensitive to TNF- α cytotoxicity and underwent apoptosis quickly in the presence of TNF- α and CHX^[21]. In accordance with this study, the optimal concentration of TNF- α was also found to be 20 ng/mL for HepG2 cells in our study.

Our findings with flow cytometry showed that both octreotide and TNF- α induced a significant early and late apoptosis of HepG2 cells. DNA fragmentation measurements also demonstrated a non significant induction

of apoptosis. This possibly means that flow cytometry is a more sensitive method for quantification of apoptosis.

The mechanism by which octreotide induces apoptosis is not well understood. Changes in sstr expression because of downregulation or possible heterodimerization^[27,50] of a receptor, together with changes in the expression of regulatory proteins required for correct trafficking of specific sstr subtypes, could affect the direct antitumor effect of octreotide, which has been previously demonstrated in models expressing sstr2^[51,52]. Mediated by sstr2, octreotide upregulates tumor necrosis factor-related apoptosis-inducing ligand (TRAIL), death receptor 4 (DR4) and TNFR1, and down-regulates Bcl-2, which results in apoptosis^[53]. Mediated by sstr3, octreotide upregulates p53^[47] or induces Bcl-2-associated protein Bax^[47,54] and acidic endonuclease, resulting in apoptosis. In addition to these mechanisms, in this study we demonstrated a direct effect of octreotide on caspase activation. The effect of octreotide on caspase-mediated apoptosis, is limited to caspase-3 activation, as the main effector caspase supportive of apoptosis and it was detected in primary pheochromocytoma cells^[55], in radiation-induced intestinal damage^[56] and in activated lymphocytes^[57]. Interestingly, decreased caspase-3 mRNA expression in Kupffer cells also indicates a possible additional beneficial effect of octreotide in HCC, through an antiapoptotic effect on Kupffer cells^[58].

We suggest a caspase-mediated apoptotic pathway after treatment of HCC cells with octreotide, where, unlike TNF- α induced apoptosis, 3 out of 4 caspases tested were significantly increased. The activation of all caspases

indicates a possible mitochondria-dependent apoptotic pathway. In contrast, findings from TNF- α -induced apoptosis possibly indicate a different pathway.

A TNF- α -mediated pathway is reported to activate caspase-8, which promotes cleavage of various downstream caspases, including caspases-3, -6 and -7. Caspase-8 can also cleave the Bcl-2 homologue Bid to reveal an active truncated Bid fragment inducing cell death through a mitochondrial pathway^[59-62]. However in our study, caspase-8, caspase-3 and caspase-9 were all increased by TNF- α , but this was not statistically significant. Furthermore, caspase-2 was significantly increased by TNF- α , a finding not reported before. In a previous study, we presented a TNF- α -induced increase of caspase-2, but this increase did not reach the statistical significance^[63]. In the present study, with an increased number of experiments, we found a significant increase in caspase-2 by TNF- α in HepG2 cells. This may be related to inefficient cleavage of Bid, so that all caspases can be significantly activated^[59].

Caspase-2 seems to play critical and specific roles in programmed cell death^[64]. It has been difficult to assign caspase-2 to the effector or initiator caspase groups. Cytokine-induced and stress-induced apoptosis act through conceptually similar pathways in which mitochondria are amplifiers of caspase activity rather than initiators of caspase activation^[65]. In our study, caspase-2 appeared to be activated independent of significant (octreotide) or non-significant (TNF- α) activation of the mitochondria-mediated pathway. This may have been the result of intracellular events (such as pH or stress) or feedback activation by effector caspases (such as caspase-3).

Thus, our findings suggest that in HepG2 cells octreotide probably causes apoptosis by a mitochondrial apoptosis pathway, sequentially implicating caspase-8, -2, -9 and -3, although further experiments are required to define the exact initiator pathway. TNF- α on the other hand seems to induce caspase-2 activation, possibly mediated through oxidative stress, as suggested before^[65]. The non-significant activation of the extrinsic pathway (caspase-8) or of the intrinsic pathway (caspase-9), perhaps due to inefficient Bid cleavage, is maybe the cause of the resistance observed in previous studies and of the eliminated TNF- α -mediated apoptotic effects observed in our study.

In summary, our results support the induction of a caspase-mediated apoptotic pathway by octreotide in HCC cells, implicating both the receptor-mediated and the mitochondrial-apoptotic pathway. The correlation of specific apoptotic, caspase-mediated pathways, with the expression of sstrs in HCC cells needs more investigation to better define and clarify the intracellular mechanisms of the antiproliferative effects of octreotide.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is the fifth most common malignancy in the world and is estimated to cause approximately half a million deaths annually. Undoubtedly, the best available treatment for all liver tumors is complete surgical resection. However, the synthetic somatostatin analogue octreotide has been found effective in inhibiting tumor growth in a variety of experimental models.

Research frontiers

Apart from stimulation of reticuloendothelial system, octreotide may have other mechanisms of action, to inhibit the growth of hepatic tumors. It has been reported that octreotide inhibits the proliferation and induces apoptosis of different HCC cell lines *in vitro*. The mechanisms of apoptosis induction however are not well understood.

Innovations and breakthroughs

Several reports indicate that octreotide inhibits the proliferation and induces apoptosis of HCC cells *in vitro*. In this study, the authors confirmed that octreotide inhibited HepG2 proliferation at a concentration of 10^{-8} mol/L. Interestingly, lower concentrations of octreotide increased proliferation and this is possibly an additional reason for divergent results in both clinical trials and *in vitro* studies of octreotide in HCC. Also, their results support the induction of a caspase-mediated apoptotic pathway by octreotide in HepG2 cells, implicating both a receptor-mediated and mitochondrial-apoptotic pathway.

Applications

The findings of the present study indicate that measurements of serum octreotide levels may be important, at least in clinical trials, to verify optimal therapeutic drug concentrations. Also, based on the recently documented presence of sstr2, sstr3 and sstr5 in HepG2 cells, the need for further correlation of specific apoptotic, caspase-mediated pathways, with the expression of somatostatin receptors in HCC cells, is highlighted, to better define and clarify the intracellular mechanisms of the antiproliferative effects of octreotide.

Peer review

The authors evaluated the role of octreotide on cellular proliferation and apoptosis of HepG2 cells. Their results support the induction of a caspase-mediated apoptotic pathway by octreotide in HepG2 cells, implicating both a receptor-mediated and a mitochondrial-apoptotic pathway. They, also, indicated that measurements of serum octreotide levels may be important, at least in clinical trials, to verify optimal therapeutic drug concentrations.

Abstract

AIM: To investigate the role of heme oxygenase-1 (HO-1) in pathogenesis of experimental hepatorenal syndrome (HRS).

METHODS: Rats were divided into liver cirrhotic group, zinc protoporphyrin IX (ZnPP) treatment group, cobalt protoporphyrin (CoPP) treatment group and sham group. Biliary cirrhosis was established by bile duct ligation in the first three groups. Rats in the ZnPP and CoPP treatment groups received intraperitoneal injection of ZnPP and CoPP, respectively, 24 h before sample collection. Expression of HO-1 mRNA in kidney was detected by reverse-transcription polymerase chain reaction, while protein expression was determined by immunohistochemical analysis. Hematoxylin and eosin staining was performed to observe liver cirrhosis and renal structure. Renal artery blood flow, mean arterial pressure and portal vein pressure, 24 h total urinary volume, serum and urine sodium concentrations, and creatinine clearance rate (Ccr) were also measured.

RESULTS: The HO-1 mRNA and protein expression levels in kidney, 24 h total urinary volume, renal artery blood flow, serum and urine sodium concentration and Ccr were lower in cirrhotic group than in sham group ($P < 0.05$). However, they were significantly lower in ZnPP treatment group than in cirrhotic group and significantly higher in CoPP treatment group than in cirrhotic group ($P < 0.05$).

CONCLUSION: Low HO-1 expression level in kidney is an important factor for experimental HRS.

INTRODUCTION

Renal dysfunction is very common in patients with advanced liver disease or cirrhosis. Its severity ranges from electrolyte-balance disturbances and water retention to hepatorenal syndrome (HRS)^[1], which is a unique form of renal failure associated with liver cirrhosis or portal hypertension^[2]. Although HRS represents a functional form and sometimes a reversible form of renal failure without significant changes in renal histology during the course of decompensated cirrhosis^[3,4], it is a poor prognostic indica-

tor for patients with liver cirrhosis, who show an increased risk of morbidity and mortality^[2,3]. So far, no effective strategies are available for the treatment or prevention of HRS. Instead, patients are usually managed by maintaining their adequate hemodynamic status and intravascular volume. A better understanding of the pathophysiological mechanism underlying HRS helps to guide its treatment.

It is currently believed that marked renal vasoconstriction and predominant peripheral arterial vasodilation play a critical role in the pathogenesis of HRS^[5-7]. Previous studies have shown that nitric oxide (NO), a potent vasodilator, plays an important role in the development of hyperdynamic syndrome and peripheral vasodilation during cirrhosis^[8]. Increased NO level and synthetase activity in patients with liver cirrhosis have adverse effects on the functions of renal tubules and glomeruli^[9], and inhibition of NO synthetase prevents the development of renal failure in an animal model of HRS^[10,11]. Carbon monoxide (CO), a byproduct of heme oxygenase-1 (HO-1), shares many characteristics with NO. Endogenous CO is an activator of soluble guanylate cyclase and relaxes vascular smooth muscle in a cGMP-dependent or a cGMP-independent manner^[12,13]. Studies have shown that the HO-1/CO system plays an important role in the control of vascular tone and that inhibition of HO-1 blocks vasodilation induced by heme^[12-14]. HO-1 is also involved in the prevention of renal failure after renal ischemia^[15] or glycerol-induced acute renal injury in rats^[16].

Metalloporphyrins constitute a class of compounds in which the central iron of heme is replaced by other metals such as cobalt and zinc^[17]. These metalloporphyrins inhibit or induce HO-1. This study was to evaluate the expression of HO-1 in kidneys of rats with experimental HRS and the functional role of HO-1 in the pathogenesis of HRS by manipulating its activity *via* intraperitoneal injection of either zinc protoporphyrin IX (ZnPP), a specific HO-1 enzyme inhibitor, or cobalt protoporphyrin (CoPP), a specific HO-1 enzyme inducer.

MATERIALS AND METHODS

Animals

Healthy male Sprague Dawley rats, weighing 200-220 g, were obtained from the Laboratory Animal Center of Dalian Medical University.

Reagents

ZnPP and CoPP (Sigma, St Louis, MO, USA) were dissolved in 0.2 mol/L of NaOH, adjusted to a pH of 7.4 and diluted in 0.85% NaCl with a final concentration of 1 mg/mL as previously described^[18]. Rabbit anti-mouse HO-1 antibody (Boster Biological Technology, Wuhan, China), anti-rabbit IgG (MaxVision™2, Maixin Biotechnology, Fuzhou, China), TaKaRa RNA polymerase chain reaction (PCR) kit (AMV) Version 3.0 (TaKaRa Biotechnology, Dalian, China) were used in the study.

Animal model and grouping

The rats were randomly divided into sham group ($n = 8$),

cirrhotic group ($n = 10$), ZnPP treatment group ($n = 9$) and CoPP treatment group ($n = 8$). They were well fed and housed for 3 d before any experimental protocols. Biliary cirrhosis was induced by bile duct ligation (BDL)^[19,20] in rats of the cirrhotic group, ZnPP and CoPP treatment groups. The surgical procedures were approved by the Animal Care and Use Committee of Dalian Medical University. Laparotomy was performed under anesthesia with ether. The bile duct was isolated and double-ligated with a 3-0 silk suture. The abdominal wall and skin were closed with a 4-0 silk suture, and the antibiotic benzathine benzylpenicillin powder was sprinkled over the closed incision. The rats were continuously fed and housed for a further 4-wk period after surgery, and samples were collected. Rats in sham group underwent laparotomy with the bile duct isolated but not ligated. Rats in ZnPP and CoPP treatment groups received an intraperitoneal injection with ZnPP^[21] or CoPP (30 mg/kg body weight) once, 24 h before sample collection. Rats in the 4 groups were housed in metabolic cages for the last 24 h, and urine was collected to measure its volume and the sodium and creatinine (Cre) levels.

Sample collection

Four weeks after surgery, the rats were anesthetized with ether and their portal vein, right carotid artery, and renal artery were isolated. Renal artery blood flow was measured by ultrasound (LOGIQ7, GE, USA). A catheter, connected to a pressure transducer (BL-420F biological experimental system, Chengdu Technology and Market Co. Ltd., China), was placed in the carotid artery for measurement of mean arterial pressure (MAP), then 1 mL of arterial blood was collected in a heparinized syringe through an arterial catheter to measure carboxyhemoglobin (COHb) using a RapidLab 1245 blood gas analyzer (Siemens, USA), as an index for the CO level in arterial blood. The catheter was placed in the portal vein to measure portal vein pressure (PVP). Then, 4 mL of blood was collected from the rats to measure serum levels of bilirubin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), Cre and sodium with a Hitachi 7600-110 automatic biochemical analyzer (Hitachi Co., Tokyo, Japan). Urine levels of Cre and sodium were also measured using this machine. The Cre clearance rate (Ccr) was calculated as urine Cre \times urine volume/serum Cre. The left kidney and one liver lobe were excised, some of their tissues were fixed in a 10% neutral formalin solution and embedded in paraffin, while the remaining tissues were preserved at -80°C for PCR.

Reverse-transcription PCR analysis

Total RNA was extracted from kidneys following a standard guanidinium phenol-chloroform extraction protocol. The quantity of RNA was determined by measuring the optical density at 260 nm ($A_{260 \text{ nm}} = 1$ for 40 $\mu\text{g/mL}$ RNA), and the purity of RNA was assessed by determining the ratio of the optical density obtained at 260 and 280 nm (pure RNA: $A_{260 \text{ nm}}/A_{280 \text{ nm}} = 2.0$) using a Shimadzu UV-1206 spectrophotometer (Shimadzu, Japan). The primer sequences for HO-1 are 5'-ACTTTCAGAAAGGGTCAGGTGTCC-3' (forward) and 5'-TTGAGCAGGAAGGCGGTCTTAG-3'

Table 1 Effect of bile duct ligation and cobalt protoporphyrin or zinc protoporphyrin IX treatment on serum and urine levels of creatinine and sodium, and creatinine clearance rate (mean \pm SD, $n = 8-10$ per group)

	Sham group	Cirrhosis group	CoPP group	ZnPP group
Serum Cre ($\mu\text{mol/L}$)	30.4 \pm 1.81	36.3 \pm 6.27 ^a	33.5 \pm 5.98	45.3 \pm 8.92 ^c
Urine Cre ($\mu\text{mol/L}$)	7.18 \pm 1.15	8.08 \pm 2.50	4.49 \pm 1.51	6.31 \pm 1.20
Serum sodium (mmol/L)	142.86 \pm 3.44	138.75 \pm 0.96 ^a	142.64 \pm 5.43 ^c	136.57 \pm 1.40 ^c
Urine sodium (mmol/L)	91.50 \pm 12.12	71.33 \pm 10.07 ^a	109.15 \pm 64.93	66.25 \pm 11.8

AST (IU/L)	156.8 \pm 18.28	237.2 \pm 95.13 ^a	467.14 \pm 222.28 ^c	209.11 \pm 65.77

^a $P < 0.05$ vs sham group; ^c $P < 0.05$ vs cirrhotic group. CoPP: Cobalt protoporphyrin; ZnPP: Zinc protoporphyrin IX; Cre: Creatinine; Ccr: Creatinine clearance rate; AST: Aspartate aminotransferase.

(reverse) and the product size is 524 bp, while the primer sequences for β -actin are 5'-GGAGTCAACGGATT-TGGT-3' (forward), 5'-GTGATGGGATTTCCATTG-3' (reverse) and the product size is 226 bp. An aliquot of each mixture was used for reverse-transcription (RT)-PCR amplification using reagents purchased from Takara Bio Inc (Dalian, China). PCR products were separated by 2.5% agarose gel electrophoresis. The product bands were photographed and the density of each product band was quantified. The results were expressed as the ratio of the band density for HO-1 mRNA to that of β -actin mRNA.

Immunohistochemical analysis

Kidney and liver tissues were fixed in a 10% neutral formalin solution and embedded in paraffin wax and cut into sections. Some sections were routinely stained with HE while the other sections underwent deparaffinization, rehydration and inactivation, and were incubated with rabbit-anti-mouse HO-1 monoclonal antibody (1:50) at room temperature for 60 min, and then with secondary antibody (MaxVisionTM2) at room temperature for 15 min. The sections were mounted after staining. The primary antibody was replaced by phosphate-buffered saline to serve as a negative control. Five high-power microscopic fields were randomly chosen per slide and the yellow material in cytoplasm was considered to represent a HO-1-positive cell. Cell staining was assigned to 4 scores: 4 = > 75% positive cells, 3 = 50%-75% positive cells, 2 = 25%-50% positive cells, and 1 = < 25% positive cells. Cell staining intensity was scored based on its color as follows: 0 = no staining, 1 = faint yellow, 2 = light brown, and 3 = dark brown^[22]. The final score was defined as staining intensity \times percentage of positive cells. The mean score of five fields was used to compare the four groups.

Statistical analysis

Data analysis was performed using the SPSS 10.0 software (Chicago, IL, USA). Analysis of variance or Wilcoxon statistical methods were used to determine statistical significance. All measurements in this study were expressed as mean \pm SD. $P < 0.05$ was considered statistically significant.

RESULTS

Biochemical examination

The serum level of AST in biliary cirrhotic group was

237.2 \pm 95.13 IU/L, which was significantly higher than that (156.8 \pm 18.28 IU/L) in sham group ($P < 0.05$). The serum level of Cre was significantly higher and the Ccr was significantly lower in biliary cirrhotic group than in sham group ($P < 0.05$). The serum Cre level was significantly higher in ZnPP treatment group ($P < 0.05$) and slightly lower in CoPP treatment group than in cirrhotic group ($P > 0.05$). The serum and urine sodium levels were significantly lower in cirrhotic group than in sham group ($P < 0.05$). The serum sodium concentration was significantly lower in ZnPP treatment group and significantly higher in CoPP treatment group than in cirrhotic group ($P < 0.05$, Table 1).

Hemodynamic parameters and arterial blood gas levels

The PVP was significantly higher and the MAP was significantly lower in cirrhotic group than in sham group ($P < 0.01$). However, no significant difference was found in PVP and MAP in ZnPP and CoPP treatment groups compared with cirrhotic group. The COHb level in arterial blood was significantly higher in cirrhotic group than in sham group ($P < 0.05$) while significantly lower in ZnPP treatment group and significantly higher in CoPP treatment group than in cirrhotic group ($P < 0.05$). The renal artery blood flow was significantly lower in cirrhotic group than in sham group ($P < 0.01$), while significantly lower in ZnPP treatment group and significantly higher in CoPP treatment group than in cirrhotic group ($P < 0.05$). Furthermore, the 24 h urine volume was significantly smaller in cirrhotic group than in sham group ($P < 0.05$), while significantly smaller in ZnPP treatment group and significantly larger in CoPP treatment group than in cirrhotic group ($P < 0.05$, Table 2).

Histopathological analysis of liver and kidney in cirrhotic and sham rats

Liver and kidney tissue samples from cirrhotic and sham rats were stained with HE to examine the histopathological changes. The bridging necrosis of hepatic cells was observed in livers of rats 4 wk after BDL, particularly in portal areas, nodular regeneration of hepatocytes, collapse, and disorganization of the hepatic lobular structure, numerous lymphocytes infiltrating the portal area and around the central vein, and the formation of pseudolobules surrounded by fibrous septa. In contrast, except for vascular dilation and congestion of the mesenchyme, no

RABF (mL/min \cdot 100 g)	3.89 \pm 0.09	3.58 \pm 0.04 ^b	3.76 \pm 0.06 ^c	3.50 \pm 0.08 ^c
Urine (mL/24 h)	15.00 \pm 2.23	10.93 \pm 1.92 ^a	13.5 \pm 1.10 ^c	8.50 \pm 1.10 ^c

^a $P < 0.05$, ^b $P < 0.01$ vs sham group; ^c $P < 0.05$ vs cirrhosis group. CoPP: Cobalt protoporphyrin; ZnPP: Zinc protoporphyrin IX; PVP: Portal vein pressure; MAP: Mean arterial pressure; COHb: Carboxyhemoglobin; RABF: Renal arterial blood flow.

Figure 1 Representative photomicrographs of rats in cirrhotic and sham groups (magnification 200 \times , HE staining). A: Normal liver structure; B: Liver cirrhosis; C: Normal kidney structure; D: Renal structure in cirrhotic group.

obvious pathological changes were observed in kidneys of cirrhotic group compared with sham group (Figure 1).

Renal HO-1 mRNA expression level

RT-PCR showed that the expression level of HO-1 mRNA in kidney was significantly lower in cirrhotic group than in sham group ($P < 0.01$). Furthermore, renal HO-1 mRNA expression was significantly decreased in ZnPP treatment group ($P < 0.05$) and significantly higher in CoPP treatment group than in cirrhotic group ($P < 0.05$) (Figure 2).

Immunohistochemical detection of HO-1 protein in kidney and liver

To localize the HO-1 protein expression in kidneys, immunohistochemistry was performed using specimens from the four groups. The HO-1 protein was mainly expressed in the distal renal tubules, which is similar to reported

findings^[23] (Figure 3). The intensity and percentage of cells expressing HO-1 protein in kidney were also detected. Mild staining was observed in renal tissue samples from sham group, with a score of 1.21 ± 0.33 . The HO-1 score was 0.79 ± 0.25 in cirrhotic group, which was significantly lower than that in sham group ($P < 0.01$). The HO-1 score (0.21 ± 0.25) was lower in ZnPP treatment group and higher in CoPP treatment group (2.46 ± 0.46) than in cirrhotic group ($P < 0.05$). The staining intensity and percentage of cells expressing HO-1 protein were also evaluated in liver of cirrhotic and sham groups. Unlike the HO-1 protein expression in kidney, the mean hepatic HO-1 score was significantly higher in cirrhotic group than in sham group (4.63 ± 0.74 vs 0.63 ± 0.52 , $P < 0.01$).

DISCUSSION

Renal dysfunction is very common in patients with ad-

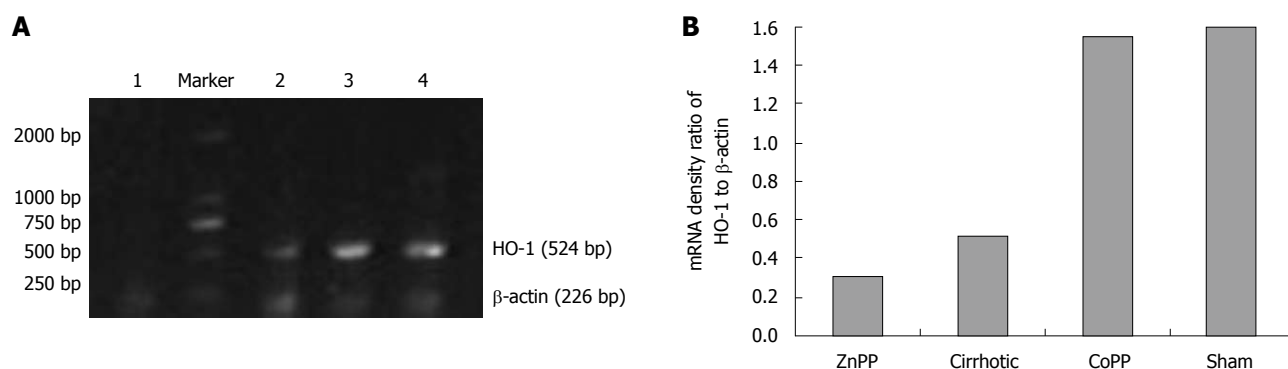

Figure 2 Expression of heme oxygenase-1 mRNA in kidney. A: Representative reverse-transcription polymerase chain reaction data showing the heme oxygenase-1 (HO-1) mRNA expression levels in kidneys from zinc protoporphyrin IX (ZnPP) treatment group (lane 1), cirrhotic group (lane 2), cobalt protoporphyrin (CoPP) treatment group (lane 3), and sham group (lane 4); B: Quantitative data showing the ratio of band density of the corresponding HO-1 mRNA to that of β-actin mRNA.

Immunohistochemical staining of renal heme oxygenase-1 (HO-1) protein in rats of sham group (A), cirrhotic group (B), zinc protoporphyrin IX (ZnPP) treatment group (C), cobalt protoporphyrin (CoPP) treatment group (D), and immunohistochemical staining of hepatic HO-1 protein in rats of sham group (E) and cirrhotic group (F) in the upper part (magnification 200 ×), and quantitative scoring (G) of immunohistochemical staining of renal HO-1 protein expression in each group in the lower part.

vanced cirrhosis, and its severity varies from electrolyte-balance disturbances and water retention to HRS. HRS is considered a functional renal failure because no structural damage has been observed in kidney, and can be reversed in some cases^[4]. However, it carries a worse prognosis of patients with cirrhosis and increases their risk of mortal-

ity^[2,3]. It has been reported that the annual incidence of HRS in patients with liver cirrhosis and ascites is about 8%^[24]. Typical features of HRS include oliguria, hyponatremia, azotemia, and hyponatruiria. Although the pathophysiological mechanism underlying HRS is still incompletely understood, marked renal vasoconstriction in the presence

of splanchnic and systemic vasodilation may play an important role, and may thus reduce the renal arterial blood flow and the glomerular filtration rate, resulting in oliguria and an increased serum Cre concentration^[6-8]. Studies have shown that the HO-1/CO system plays an important role in the control of vascular tone and that inhibition of HO-1 blocks vasodilation induced by heme^[12-14]. In addition, HO-1 is also involved in the prevention of renal failure after renal ischemia^[15] or glycerol-induced acute renal injury in rats^[16]. In this study, the relation between expression of HO-1 in kidney and renal arterial blood flow and renal function was investigated in cirrhotic rats.

To evaluate the hepatic, renal, and systemic changes in rats 4 wk after BDL, the MAP, PVP, COHb in arterial blood, serum levels of AST and ALT, Cre and sodium, urine sodium and Cre were measured. The changes in hepatic and renal histology were also examined, and the expression levels of HO-1 mRNA and protein in liver and kidney were evaluated. The Ccr level was also measured as an index of glomerular filtration rate and renal function. The serum level of AST was significantly higher in cirrhotic group than in sham group, indicating that BDL causes marked liver injury, with liver cirrhosis confirmed with HE staining of liver specimens. In addition, the MAP level was significantly lower in BDL rats than in time-matched sham rats, indicating that a hyperdynamic state occurs. Furthermore, the PVP was significantly higher in BDL rats than in time-matched sham rats, indicating that portal hypertension exists. Oliguria, hyponatremia, hyponatremia, increased Cre concentrations and decreased Ccr were also observed in BDL rats. All these findings show that experimental HRS was established in BDL rats. Accompanied with the decreased renal arterial blood flow and renal function, the HO-1 mRNA and protein levels in kidney of rats were significantly lower in cirrhotic group than in sham group, indicating that production of CO is decreased in kidney, because CO is mainly generated by degrading heme due to HO. HO has constitutive and inducible isoforms^[25,26]. HO-1, a 32-kDa inducible protein^[27], catalyzes the rate-limiting step in oxidative degradation of heme to biliverdin, releasing equimolar amounts of CO and iron^[26]. The HO-1/CO system plays a vital role in many activities, including anti-oxidative stress, anti-inflammation, inhibition of cellular proliferation, and regulation of cytokine expression. CO, a gaseous messenger similar to NO, can activate soluble guanylate cyclase leading to production of cGMP^[28] which mediates various physiological functions^[29] including vasodilation^[30]. CO can also relax vascular smooth muscle in a cGMP-independent manner^[12,13]. HO-1 activity is the primary source of circulating CO^[31], and HO-1 contributes to vasodilation mainly through HO-1-derived CO^[32]. Thus, the declined HO-1 expression in kidney may be responsible for a decrease in vasodilation. In addition, oxidants can cause localized renal vasoconstriction^[33]. Thus, the antioxidant action of HO-1 and its products can preserve renal arterial blood flow. Decreased HO-1 expression in kidney of BDL rats impairs their ability to buffer locally produced oxidants, thus leading to decreased renal arterial blood flow and deteriorated renal function.

Surprisingly, the COHb level was significantly higher

in cirrhotic group than in sham group, suggesting that there is more CO in circulation, since it is predominately bound to hemoglobin in the form of COHb^[34]. This large amount of CO may be produced by increased HO-1 expression in other organs, such as liver, because the HO-1 expression level in liver was higher in cirrhotic group than in sham group. Thus, we speculate that the decreased HO-1 expression in kidney and suppression of locally produced CO contribute to the decreased renal arterial blood flow and renal dysfunction in cirrhotic rats.

To evaluate the functional consequences of HO-1 changes, BDL rats were treated with either ZnPP or CoPP. The PVP and MAP were measured to evaluate systemic effects of ZnPP and CoPP treatment, renal arterial blood flow, 24 h total urinary volume, serum and urine levels of sodium and Cre were also measured to evaluate the effects of ZnPP and CoPP on HRS. The expression level of HO-1 mRNA and protein in kidney was lower in ZnPP treatment group and higher in CoPP treatment group than in cirrhotic group, without obvious changes in PVP and MAP, while the renal arterial blood flow was significantly lower and the renal function was more severely impaired in ZnPP treatment group than in cirrhotic group, as demonstrated by the decreased 24 h total urinary volume, Ccr, and serum level of sodium. In contrast, the renal arterial blood flow and 24 h total urinary volume were higher in CoPP treatment group than in cirrhotic group. However, unlike ZnPP treatment, CoPP treatment did not significantly affect serum Cre or Ccr compared with cirrhotic group. Nevertheless, increasing the treatment time or the CoPP dose may have elicited the different results in our study. Because ZnPP or CoPP treatment did not significantly affect MAP or PVP, changes in renal artery vascular tone were not considered to represent systemic vascular effects of HO-1 inhibition or HO-1 induction.

In conclusion, renal HO-1 expression, renal arterial blood flow, Ccr, 24 h total urinary volume, serum and urine sodium concentrations are lower in cirrhotic rats than in sham rats. Inhibition of renal HO-1 activity decreases renal arterial blood flow and aggravates renal dysfunction in rats with HRS. Meanwhile, activation of renal HO-1 activity had the opposite effects. Taken together, decreased HO-1 expression in kidney plays an important role in the pathogenesis of experimental HRS.

COMMENTS

Background

Renal dysfunction is very common in patients with advanced cirrhosis, and its severity ranges from electrolyte-balance disturbances and water retention to hepatorenal syndrome (HRS). HRS is a poor prognostic indicator for patients with liver cirrhosis, and can increase its morbidity and mortality in such patients. At present, the pathophysiological mechanism underlying HRS is still incompletely understood.

Research frontiers

Intense renal vasoconstriction in combination with peripheral arterial vasodilation plays an important role in occurrence of HRS. Studies have shown that the heme oxygenase-1 (HO-1)/carbon monoxide system is a crucial component in regulation of vascular tone and that inhibition of HO-1 blocks vasodilation induced by heme. HO-1 is also central to the prevention of renal failure after renal ischemia or glycerol-induced acute renal injury in rats. In this study, we in-

vestigated the expression of HO-1 in the kidney of experimental rats with HRS and evaluated the functional role of HO-1 in the pathogenesis of HRS.

Innovations and breakthroughs

The characteristics of HRS became evident in rats 4 wk after bile duct ligation (BDL), including reduced creatinine clearance rate and fluid retention, without changes in renal histology. The decreased renal arterial blood flow and renal function were accompanied with decreased renal expression of HO-1 at mRNA and protein levels. To evaluate the functional consequences of the changes in HO-1 expression, the authors treated BDL rats with either zinc protoporphyrin IX (ZnPP), a specific HO-1 inhibitor or cobalt protoporphyrin (CoPP), a HO-1 inducer. ZnPP treatment significantly reduced the renal arterial blood flow and further worsened the renal function, while CoPP treatment had the opposite effects. The relation between HO-1 and renal arterial blood flow and renal function was systematically evaluated by treating BDL rats with ZnPP and CoPP.

Applications

The mechanisms underlying renal dysfunction in patients with advanced liver disease or cirrhosis are complicated and remain incompletely understood. However, the findings in this study indicate that decreased renal HO-1 expression plays an important role in the pathogenesis of experimental HRS.

Terminology

HRS, a progressive renal failure that occurs in patients with chronic liver disease and advanced hepatic failure in the absence of any apparent clinical cause for renal insufficiency, corresponds to a functional alteration without histological changes in renal tissue. HO-1 is heme oxygenase-1, a rate-limiting enzyme that is also known as heat shock protein 32, and can be induced by CoPP and inhibited by ZnPP *in vivo*.

Peer review

This paper, written in rather good English, is quite important and interesting, which shows that decreased HO-1 expression in the kidney plays an important role in the pathogenesis of experimental HRS, as it demonstrated that the renal HO-1 expression, renal arterial blood flow, creatinine clearance rate, 24 h total urinary volume, serum and urine sodium concentrations were lower in cirrhotic rats than in sham rats, thus inhibition of renal HO-1 activity decreases renal arterial blood flow and aggravates renal dysfunction in rats with HRS.

Abstract

AIM: To investigate Glyoxalase I and fructosamine-3-kinase (FN3K) activity in red blood cells from patients with colorectal adenomas and cancer.

METHODS: Thirty three consecutive subjects with one or more histologically confirmed colorectal adenomatous polyps, 16 colorectal cancer patients and a group of 11 control subjects with normal colonoscopy were included in the study. Glyoxalase I and FN3K activities were measured in red blood cells using a spectrophotometric and radiometric assay, respectively.

RESULTS: A significant reduction in both Glyoxalase I and FN3K activity was detected in patients with tumors compared to patients with adenomas and the controls. Erythrocyte Glyoxalase I activity in colorectal cancer was approximately 6 times lower than that detected in patients with adenoma (0.022 ± 0.01 mmol/min per milliliter vs 0.128 ± 0.19 mmol/min per milliliter of red

blood cells, $P = 0.003$, Tukey's test). FN3K activity in red blood cells from patients with colon cancer was approximately 2 times lower than that detected in adenoma patients (19.55 ± 6.4 pmol/min per milliliter vs 38.6 ± 31.7 pmol/min per milliliter of red blood cells, $P = 0.04$, Tukey's test).

CONCLUSION: These findings suggest that deglycating enzymes may be involved in the malignant transformation of colon mucosa.

INTRODUCTION

The enzymatic defense against glycation involves enzymatic activities, such as the glyoxalase system, amadoriase and fructosamine 3 kinase, which suppress the formation of glycation adducts and repair sites of early glycation^[1].

Glyoxalase I together with Glyoxalase II constitutes the glyoxalase system, a ubiquitous detoxification pathway which protects against cellular damage caused by potent cytotoxic metabolites, such as methylglyoxal. Methylglyoxal is a physiological substrate, derived from glycolysis, via degradation of triose phosphate intermediates, lipid peroxidation, and fragmentation of glycated proteins^[2].

As a highly reactive metabolite, methylglyoxal has a strong ability to cross-link with protein amino groups to form stable products called advanced glycation end products, and to attack guanine residues of DNA leading to DNA glycation^[3]. The cytotoxicity of methylglyoxal is due to its mutagenic and antiproliferative properties and to its ability to trigger apoptosis^[4], *via* oxidative signaling^[5]. Experimental evidence shows that the glyoxalase system is involved in the regulation of cellular growth^[6,7]. Altered expression of this system is involved in several human disorders, including cancer^[8-11]. Over-expression of Glyoxalase I is associated with clinical multidrug resistance in tumors of high incidence and mortality, such as carcinomas of the lung, breast and prostate and Glyoxalase I inhibitors provide effective therapy for these tumors^[1,12].

Fructosamine-3-kinase (FN3K) is an intracellular deglycating enzyme that phosphorylates fructosamines on the third carbon of their deoxyfructose moiety. The fructosamine 3-phosphates so formed are unstable and their spontaneous decomposition leads to the regeneration of the free amine^[13,14]. This enzyme seems to catalyze a repair mechanism offering selective cell advantage.

We previously evaluated *FN3K* gene expression in colorectal cancer patients, and showed that *FN3K* gene expression was significantly lower in colon cancer tissue than in the corresponding surrounding normal mucosa^[15]. Moreover, we found that *FN3K* activity is particularly downregulated in tumors located on the left side of the colon^[16].

The adenoma-carcinoma sequence in the colon represents one of the most characterized models of human tumor progression. The transition from normal to malignant phenotype implies the activation of pathways that underlie aberrant clone expansion^[17].

Alterations of metabolic pathways, such as changes in the balance between glycation and enzymatic anti-glycation defense, are considered to be crucial for sustaining tumor development^[18]. The risk of colorectal adenoma increases with serum levels of fructosamine^[19]. The decline in expression of deglycating enzymes may be the key to increased protein glycation in the tumor phenotype.

In this study, we evaluated the levels of Glyoxalase I and *FN3K* activity in red blood cells from patients with colorectal adenomas and cancer.

MATERIALS AND METHODS

Subjects

The study included thirty three consecutive subjects (18 males and 15 females, mean age 67.6 ± 11.7 years) with one or more histologically confirmed colorectal adenomatous polyps removed after complete endoscopy, and sixteen colorectal cancer patients (6 males and 10 females, mean age 68.1 ± 6.4 years) undergoing colon surgery. A group of eleven control subjects (6 males and 5 females, mean age 45 ± 5.8 years) with normal colonoscopy, performed in the same endoscopy unit during the same period, was also included.

Written informed consent was obtained from all the participants.

Measurement

Anthropometric measurements were obtained by the participants wearing scrub suits without shoes. Body weight was measured using a calibrated scale (Detecto; model 437). Standing height was measured with a vertical metal ruler. Body mass index (BMI) was calculated as weight in kilograms divided by the square of the height in meters (kg/m^2).

Ficoll-Paque separation

Participants were fasted for 12 h prior to examination. Blood samples taken from the subjects by venous puncture were collected in tubes containing EthyleneDiamineTetraacetic Acid (K-EDTA) anticoagulant or a serum separator gel. Blood serum was shipped to the central laboratory for routine analyses. For *in vitro* isolation of erythrocytes, blood samples with K-EDTA were quickly layered on the Ficoll-Paque solution and centrifuged at 400 *g* for 40 min at 20°C. The lymphocytes and plasma were then removed and the erythrocytes were recovered from the bottom layer and washed with 4-volumes of phosphate-buffered saline. Isolated red blood cells were stored at -80°C until assayed. All the analyses were performed within 6 mo.

Glyoxalase I activity assay

Glyoxalase I enzymatic activity was measured in frozen erythrocytes, according to the method described by Thornalley^[20] with minor modifications. The frozen red blood cell pellet was lysed with 1 mL of 10 mmol/L TRIS-HCl, pH = 7.8, 1 mmol/L DTT, 1 $\mu\text{g}/\text{mL}$ leupeptin and was well mixed. The samples were centrifuged for 10 min at 2000 *g* and the supernatant was used for the enzymatic activity assay. Aliquots of 50 μL of supernatant were incubated with 100 μL of reaction mix containing 7.9 mmol/L methylglyoxal, 1 mmol/L glutathione, 14.6 mmol/L magnesium sulfate and 182 mmol/L imidazole HCl, pH = 7.0. The activity of Glyoxalase I was determined by monitoring the increase in absorbance at 240 nm due to the formation of *S*-D-lactoylglutathione for 2 min at 25°C. One unit of activity was defined as the formation of 1 mmol of *S*-D-lactoylglutathione/min per milliliter of blood red cells.

Fructosamine-3 kinase activity assay

FN3K enzymatic activity was measured in frozen erythrocytes lysed with 1 mL of 10 mmol/L TRIS-HCl, pH = 7.8, 1 mmol/L DTT and 1 $\mu\text{g}/\text{mL}$ leupeptin. The samples were centrifuged for 10 min at 2000 *g* and 50 μL of supernatant were incubated with 100 μL of reaction mix [5 mmol/L glucose, 10 mmol/L Tris-HCl (pH 7.8), 1 mmol/L DTT, 1 $\mu\text{g}/\text{mL}$ leupeptin, and 2 mmol/L D-[1-¹⁴C]-glucose (49.5 mCi/mmol) for 40 min at 37°C.

Subsequently, 30 μL aliquots of the samples were spotted on cation-exchange papers (P81; Whatman), which were washed three times with ice-cold 75 mmol/L H_3PO_4 and then once with alcohol and once with acetone. After drying, the papers were counted for radioactivity in the presence of a scintillant. *FN3K* activity was expressed as picomoles of incorporated D-[1-¹⁴C]-glucose/min per milliliter of red blood cells. Parallel samples were as-

sayed to evaluate total and non-specific radioactivity. The enzyme activity assay was validated using samples in the presence of the FN3K inhibitor, 1-deoxy-1-morpholino-fructose.

Statistical analysis

The mean and standard deviation were calculated for each group. Groups were compared using one-way analysis of variance and Tukey's Multiple Comparison test. Differences in the means were considered statistically significant if the *P*-value was < 0.05. Analysis of covariance was used to model, controlling for glycemia, a potential variable confounder.

RESULTS

The clinical characteristics of all subjects studied are shown in Table 1. There was a weak increase in glycemia levels from the controls to the adenoma and cancer patients. No difference in mean BMI values between the groups was observed.

Table 2 summarizes the data for Glyoxalase I and FN3K activity levels detected in red blood cells from controls, adenoma and tumor-bearing patients.

There was a significant reduction in Glyoxalase I activity in red blood cells from patients with tumor compared to controls, and a trend in decreasing activity from controls to adenoma and cancer patients. Erythrocyte Glyoxalase I activity in colorectal cancer was about 6 times lower than that detected in patients with adenoma (0.022 ± 0.01 mmol/min per milliliter *vs* 0.128 ± 0.19 mmol/min per milliliter of red blood cells, *P* = 0.003, Tukey's test). A significant reduction in FN3K activity levels in erythrocytes from colon cancer patients with respect to controls and adenoma patients was also observed. FN3K activity in the red blood cells of patients with colon cancer was approximately 2 times lower than that detected in adenoma patients (19.55 ± 6.4 pmol/min per milliliter *vs* 38.6 ± 31.7 pmol/min per milliliter of red blood cells, *P* = 0.04, Tukey's test).

The differences in enzymatic activities among the control, adenoma and cancer groups were controlled for fasting glycemia using analysis of covariance. The absolute value of association did not decrease; there was only an increase in standard error of the coefficients and consequently a decrease in the *P*-value of the null hypothesis. In any case, the inverse association of both enzymes with cancer was still statistically significant (two tails, *P* < 0.05).

DISCUSSION

This study provides evidence of a role for the deglycating enzymes, Glyoxalase I and FN3K, in colorectal cancer development. The trend of decreased Glyoxalase I activity from the controls to adenoma and cancer patients strengthens the association between this deglycating enzyme and colon cancer, and suggests that its decrease in activity can support the evolution of the malignant process.

The glyoxalase system has received considerable atten-

tion regarding its possible relationship with cancer. In an animal model of carcinogenesis, an appreciable decrease in rat liver glyoxalase activity was found after the development of hepatoma^[21]. Some authors also showed that glyoxalase activity in the blood of tumor-bearing animals was much lower than glyoxalase activity in the blood of normal animals^[22]. The presence of Glyoxalase I gene polymorphism, which may result in a decrease in glyoxalase activity, increases breast cancer risk^[23]. This gene polymorphism seems to have a role not only in the development of breast cancer, but also in the progression of neoplasia^[23].

Recently, a significant reduction in *FN3K* gene expression was detected in colorectal cancer with respect to normal pair-matched tissue^[15,16], suggesting that decreased FN3K expression is related to the malignant phenotype.

This study also suggests that there are functional modifications of FN3K in colon cancer development, since reduced FN3K activity is detectable in the progression from adenoma to cancer.

Epidemiological studies clearly indicate that the risk of several types of cancer (including pancreas, liver, breast, colorectal, and urinary tract) is increased in diabetic patients^[24,25]. Higher levels of serum glucose were present in our patients with colon cancer compared to those with adenoma and the controls. The inverse association of both enzymes with cancer was maintained after controlling for fasting glycemia. However, we doubt the necessity to control for glycemia, because it may be part of the causal chain between the enzymes and the neoplasia, as an intermediate variable. Hyperglycemia may correlate with the development of adenoma and invasive colon cancer^[26], and non-enzymatic glycation is one of the principal

mechanisms by which hyperglycemia contributes to cellular damage^[27].

The enzymatic defense against glycation suppresses damage to biological macromolecules, if this defense in normal physiological states is at a low level, cellular injury occurs. Glycation proteins with associated functional impairment of repair enzymes has a critical role in the activation of pathways of cellular transformation^[18,28].

The findings of this study provide evidence that deglycating enzymes may be involved in increasing the risk of precancerous lesions and malignant transformation of colon mucosa.

Further studies on a large cohort of patients with colorectal cancer will be designed to translate our findings into clinical practice, allowing the development of a fast and accurate blood test to diagnose colorectal cancer at different stages.

COMMENTS

Background

Protein glycation is a spontaneous reaction involving reducing sugars with the amino groups of proteins. In this reaction the ϵ -amino group of lysine condenses with the carbonyl of a sugar to form a Schiff's base, which then slowly undergoes an Amadori rearrangement to become a ketoamine or, if the reacting sugar is glucose, fructosamines. The fate of fructosamines is to continue to react slowly until they become "advanced glycation end products" which are thought to play a role in the pathophysiology of several human disorders, including cancer. Protein glycation contributes to the morbidity and mortality of diseases which have a major social impact (diabetes, heart disease and endstage renal disease) and is suspected to contribute to other diseases (Alzheimer's disease, arthritis and ageing). It is now recognized that there is an enzymatic defense against glycation - a group of enzymes which suppress the physiological levels of potent glycating agents and repair glycated proteins, such as Glyoxalase I and fructosamine-3-kinase.

Research frontiers

Alterations of metabolic pathways, such as changes in the balance between glycation and enzymatic anti-glycation defense, are considered to be crucial in the activation of pathways of cellular transformation. This study identifies molecular targets which can be used not only for colorectal cancer diagnosis, but also for its prevention and treatment.

Innovations and breakthroughs

The study of circulating levels of deglycating enzymes in red blood cells from patients with colorectal cancer is certainly an innovation that might help to diagnose colorectal cancer using a fast and partially invasive method.

Applications

Further studies on a large cohort of patients with colorectal cancer will be designed to translate our findings into clinical practice, allowing the development of a fast and accurate blood test to diagnose colorectal cancer at different stages.

Peer review

This is a nicely presented concise research study on the assessment of Glyoxalase I and fructosamine-3-kinase activity in red blood cells from colorectal cancer patients. The experimentation is well performed. A clinical relevant experimental group of cancer and healthy patients are investigated in this study. Statistical methods are careful chosen and resulted in significant clinical relevant observations. The study of deglycating enzymes in red blood cells may be translate in clinical practice by the development of a fast accurate test to diagnose colorectal cancer in different stages.

Abstract

AIM: To compare the effect of calcium and cholecalciferol alone and along with additional sodium fluoride or ibandronate on bone mineral density (BMD) and fractures in patients with Crohn's disease (CD).

METHODS: Patients ($n = 148$) with reduced BMD (T-score < -1) were randomized to receive cholecalciferol (1000 IU) and calcium citrate (800 mg) daily alone (group A, $n = 32$) or along with additional sodium fluoride (25 mg *bid*) (group B, $n = 62$) or additional ibandronate (1 mg *iv*/3-monthly) (group C, $n = 54$). Dual energy X-ray absorptiometry of the lumbar spine (L1-L4) and proximal right femur and X-rays of the spine were performed at baseline and after 1.0, 2.25 and 3.5 years. Fracture-assessment included visual reading of X-rays and quantitative morphometry of vertebral bodies (T4-L4).

RESULTS: One hundred and twenty three (83.1%) patients completed the first year for intention-to-treat (ITT) analysis. Ninety two (62.2%) patients completed the second year and 71 (47.8%) the third year available for per-protocol (PP) analysis. With a significant increase in T-score of the lumbar spine by $+0.28 \pm 0.35$ [95% confidence interval (CI): 0.162-0.460, $P < 0.01$], $+0.33 \pm 0.49$ (95% CI: 0.109-0.558, $P < 0.01$), $+0.43 \pm 0.47$ (95% CI: 0.147-0.708, $P < 0.01$) in group A, $+0.22 \pm 0.33$ (95% CI: 0.125-0.321, $P < 0.01$); $+0.47 \pm 0.60$ (95% CI: 0.262-0.676, $P < 0.01$), $+0.51 \pm 0.44$ (95% CI: 0.338-0.682, $P < 0.01$) in group B and $+0.22 \pm 0.38$ (95% CI: 0.111-0.329, $P < 0.01$), $+0.36 \pm 0.53$ (95% CI: 0.147-0.578, $P < 0.01$), $+0.41 \pm 0.48$ (95% CI: 0.238-0.576, $P < 0.01$) in group C, respectively, during the 1.0, 2.25 and 3.5 year periods (PP analysis), no treatment regimen was superior in any in- or between-group analyses. In the ITT analysis, similar results in all in- and between-group analyses with a significant in-group but non-significant between-group increase in T-score of the lumbar spine by 0.38 ± 0.46 (group A, $P < 0.01$), 0.37 ± 0.50 (group B, $P < 0.01$) and 0.35 ± 0.49 (group C, $P < 0.01$) was observed. Follow-up in ITT analysis was still 2.65 years. One vertebral fracture in the sodium fluoride group was detected. Study medication was safe and well tolerated.

CONCLUSION: Additional sodium fluoride or ibandronate had no benefit over calcium and cholecalciferol alone in managing reduced BMD in CD.

INTRODUCTION

Inflammatory bowel disease (IBD) patients are at risk of reduced bone mineral density (BMD), especially in Crohn's disease (CD)^[1-5]. Genetic, endocrine, metabolic and nutritional factors contribute to CD-associated osteoporosis, and inflammation *per se* may exert an important risk since inflammatory mediators such as the pro-inflammatory cytokines tumour necrosis factor (TNF)- α , interleukin (IL)-1 β or IL-6 and other TNF-related cytokines such as receptor activator of nuclear factor κ B (RANK) and its ligand, RANKL or osteoprotegerin, are directly involved in the disease process^[6-13].

The prevalence of a reduced BMD in IBD patients is up to 38% with some 15% suffering from osteoporosis^[1-5,7]. Thus, of approximately 300 000 patients with IBD in Germany^[14], up to 45 000 may have an increased fracture risk. The high prevalence of up to 21.7% in osteoporosis-related vertebral fractures is of clinical relevance^[1,2,15-18].

Different strategies to improve BMD and to prevent osteoporosis-related fractures have been examined. Hormone replacement therapy (HRT) and bisphosphonates are established in postmenopausal osteoporosis and bisphosphonates in steroid-induced osteoporosis^[19-21]. In particular, the efficacy of bisphosphonates has received special interest in large clinical trials^[22-24]. Bisphosphonates have reduced the fracture risk considerably in patients with postmenopausal osteoporosis^[25,26]. Sodium fluoride can also increase BMD but its efficacy in reducing fractures remains controversial^[27-29].

To this day, few studies have evaluated the management of reduced BMD in IBD patients. Calcium and vitamin D administration can inhibit the rate of bone loss^[30]. HRT is an effective treatment to prevent bone loss in postmenopausal women with CD^[31]. In a previous study, we demonstrated the efficacy of sodium fluoride in increasing BMD in CD patients^[32]. Other studies reported a significant increase in BMD with the administration of iv pamidronate (30 mg every 3 mo)^[33], alendronate (10 mg/d)^[34] or etidronate periodically (400 mg orally for 14 d)^[35]. However, the primary end-point in all studies was BMD and only small cohorts with limited follow-up were investigated; the prevalence and incidence of vertebral fractures was not evaluated.

Our aim was to assess the effectiveness of cholecalciferol and calcium alone or with additional sodium fluoride or ibandronate in a larger CD patient population and longer follow-up period. The primary endpoint was to assess the efficacy of the 3 therapeutic approaches to improve BMD (in-group change). Secondary endpoints were

to compare the 3 therapies for the best improvement in BMD (between-group change), fracture rate and safety.

MATERIALS AND METHODS

Patients

The 148 randomized outpatients had a diagnosis of CD based on histological, endoscopic, radiological or clinical criteria and a reduced BMD of the lumbar spine: T-score < -1, i.e. osteopenia according to World Health Organization (WHO) criteria as published in 1994^[36]. Disease-related data on previous and current state of health were recorded using a standardized questionnaire throughout the study including adverse effects and serious adverse effects reporting. Disease activity was estimated using the CD activity index (CDAI)^[37]. Cumulative lifetime steroid-dose was estimated and expressed in grams of prednisolone equivalent. Nutritional status was assessed by body mass index (BMI). Exclusion criteria included: age < 18 years, chronic renal insufficiency (creatinine > 1.5 mg/dL), known primary hypo- or hyperparathyroidism, untreated thyroid disease, and any known medication, e.g. previous treatment with either sodium fluoride or bisphosphonates, or a condition affecting BMD other than glucocorticoid therapy. None of the patients was pregnant and female patients planning pregnancy were excluded.

Ethics

The study was approved by the Ethics Committee of the University of Ulm/Germany, and conducted in accordance with the 1975 Helsinki Declaration, as revised in 1983. All participants gave written informed consent before inclusion.

Protocol, assignment and masking

Patients were randomized to treatment group A, B or C, taking study medication as follows: (1) 1000 IU cholecalciferol (Vigantolekten®, Merck, Darmstadt, Germany) and 800 mg calcium citrate (Calcitrat®, Merckle, Ulm, Germany) daily (group A); (2) additional 25 mg of slow-release sodium fluoride (Nafril®, Merckle, Ulm, Germany) *bid* (group B); and (3) additional ibandronate 1 mg iv 3-monthly (Bondronat®, Roche, Basle, Switzerland) (group C). A random 1:2 allocation sequence, basic cholecalciferol and calcium (A) and additional sodium fluoride or additional ibandronate (B or C), was computer-generated and the sequences were concealed until intervention was assigned. Baseline examination included dual energy X-ray absorptiometry (DXA) of the spine and femur and plain radiographic imaging of the thoracic and lumbar spine in 2 planes. Follow-up examinations were conducted at 3-mo intervals. In group B, sodium fluoride was taken daily for 12 mo, followed by a 3-mo fluoride-free period. The second and third 12-mo cycle started at month 15 and 30. Follow-up DXA and plain radiography of the spine were performed after 12, 27 and 42 mo, i.e. 1.0, 2.25 and 3.5 years. With the last patient in study in June 2005, this patient completed the 3.5-year study period in January 2009 (last patient out).

Figure 1 CONSORT diagram.

Bone densitometry

BMD of the spine (L1-L4) was assessed by DXA (Hologic QDR1000, Hologic Inc., Waltham/MA). At the proximal right femur, 4 sites (femoral neck, trochanter and intertrochanteric area, Ward's triangle) were measured; an average (total femur) was obtained from the first 3 sites. Average BMD values for L1-L4 and total femur were used for calculations. The manufacturer supplied the normal values. BMD was expressed as absolute values (g/cm^2) and as number of standard deviations from the peak bone mass of a young adult gender-matched reference population (T-score). According to the WHO recommendation for postmenopausal women as published in 1994, reduced BMD was defined as a T-score < -1.0 ^[36]. Patients with e.g. major sclerosis of the aorta, osteophytes and scoliosis on X-rays precluding accurate measurements of lumbar BMD by DXA were excluded.

Quantitative morphometry

Morphometric methods have been developed for standardized assessment of vertebral deformities in studies of spinal osteoporosis^[38]. The use of a fixed percentage reduction in vertebral height is the simplest and most practical method to study vertebral deformities^[39]. In this study, visual reading of X-rays and the quantitative morphometry (QM) of the vertebral bodies were standardized according to criteria of the European Vertebral Osteoporosis Study^[40]; only the threshold value was set from 25% to 20%. QM was performed using 6-point digitization to calculate the anterior (Ha), mid (Hm), and posterior (Hp)

height of the vertebral bodies T4-L4 (Figure 1). A vertebra was classified deformed if at least one ratio (Ha/Hp, Hm/Hp, Hp/Hp-up and Hp/Hp-low) was below the threshold value. For every vertebra considered deformed quantitatively, a radiological differential diagnosis was performed for the etiology, distinguishing osteoporotic, degenerative, traumatic and other reasons. Differential diagnosis prevents overestimation of prevalent osteoporotic fractures due to deformations of other etiology, since 45.9% and 30.9% of spinal deformities in men and women are reported to be of non-osteoporotic origin^[41].

Laboratory testing

A patient's hematocrit was determined for the calculation of the CDAI, and other inflammation-related parameters [leukocytes, platelets, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)] were obtained. Regarding bone metabolism, we focused on calcium phosphate homeostasis and investigated calcium and phosphate as well as the 25(OH)- and 1,25(OH)₂-vitamin-D₃ serum levels and parathyroid hormone. All laboratory tests were performed in the DIN EN ISO 15189:2007 accredited "Zentrale Einrichtung Klinische Chemie" of the University Hospital of Ulm, Germany. Laboratory technology and standard values can be checked at <http://www.uniklinik-ulm.de/index.php?id=1159>.

Statistical analysis

Results are presented as mean \pm SD. Qualitative variables were expressed as frequencies and percentage. The Mann-

Whitney rank sum test was used to test the effect of each therapy on BMD and biochemical markers after 12, 27 and 42 mo compared to baseline. The Student *t*-test for unpaired observations was used to compare between-group differences. Intention-to-treat (ITT) analysis was performed for all patients with at least one DXA during follow-up. Two-tailed tests for significance were used in the statistical analyses and $P \leq 0.05$ was considered significant. The Statistical Package SAS V6.11 was used for analysis.

RESULTS

Participant flow and follow-up

The CONSORT diagram shows the number of patients randomly assigned and receiving intended treatment, the patient flow through each year of the study, the number completing the study protocol, and the number analyzed for the primary outcome (Figure 1). One hundred and forty-eight patients with a T-score < -1.0 were ITT analysis, 92 (62.2%) completed the 27-mo and 71 (47.8%) the 42-mo study period and were available for per-protocol (PP) analysis. Reasons for withdrawal were failure to attend follow-up [48 patients (32.4%)] and personal reasons [27 patients (18.2%), withdrawal of written informed consent ($n = 7$), referred to primary care ($n = 10$), moving house ($n = 7$), unknown ($n = 3$)]. One patient was excluded due to a malignancy (testicular cancer), retrospectively present before randomization; he recovered completely.

Baseline characteristics

Baseline characteristics of the patients are given in Table 1. With a 1:2 random allocation to treatment groups, group A was smaller compared to group B or C. BMD was slightly but non significantly higher in group A. Patients in group A were a little younger than in group B ($P = 0.3$) and C ($P = 0.06$). No further differences in baseline characteristics were observed.

BMD of the spine, in-group change

In group A, BMD of the spine increased continually during the 1.0, 2.25 and 3.5-year study period (Table 2, Figure 2). In group B, lumbar BMD increased during the 1.0 and 2.25-year period, and in the third year, a further but non significant increase was observed (Table 2, Figure 2). In group C, BMD of the spine increased continually during the 1.0, 2.25 and 3.5-year period, again with the greatest increases in the first and second year (Table 2, Figure 2).

BMD of the spine, compared between-groups

Comparing the increase in lumbar spine BMD of the groups A, B and C at 1.0, 2.25 and 3.5 years, no group revealed superior results. There was no difference for group B receiving added sodium fluoride or for group C receiving added ibandronate in comparison with group A receiving only cholecalciferol and calcium citrate nor was there a significant difference in the comparison of groups B and C at any time in the 3.5-year study period (Table 2, Figure 2).

¹Intention to treat (ITT) analysis. BMI: Body mass index; CDAI: Crohn's disease activity index; BMD: Bone mineral density.

BMD of the femur, in-group change and compared between-groups

There was no significant change in femur BMD in any of the 3 groups during the entire follow-up period, and no significant differences between groups A, B and C at 1.0, 2.25 and 3.5-year follow-up in the change in femur BMD (data not shown).

BMD of the spine (ITT)

A pre-planned ITT analysis was performed. As in PP analysis, comparing the increase in BMD in in- and between-group A, B and C analysis, cholecalciferol and calcium alone did not perform any worse than with additional sodium fluoride or ibandronate, and no group revealed superior results (Table 3, Figure 3) Mean observation time in the ITT analysis was 2.65 years.

Prevalence and incidence of vertebral fractures

For assessment of prevalent fractures and fracture incidence, the ITT population was analyzed, i.e. 123 (83.1%) patients who completed at least the first 12-mo follow-up. The duration of follow-up did not differ significantly for the treatment groups A, B and C. At baseline, a total of 56 vertebral fractures was seen in 29 (23.6%) of 123 patients,

^b*P* < 0.01. BMD: Bone mineral density.

Clinical course of the underlying CD and change in BMD

Seventy (57%) of the 123 patients who completed at least the first 12-mo study period were treated with systemic glucocorticoids at least once during the study, as reported in the standardized questionnaire completed at every follow-up examination at 3-mo intervals. Change in spine and femur BMD did not differ from the change observed in patients who had not received any systemic steroids (data not shown). While a slight increase in BMI and an improvement in CDAI was observed during the study period with no significant differences in and between the 3 treatment groups, the increase in BMI and the decrease in CDAI again did not correlate with the change in spine and femur BMD in all patients (data not shown).

Laboratory markers and change in BMD

No significant difference in inflammation parameters (leukocytes, platelets, ESR, CRP) were obtained in and between the groups A, B and C. Focusing on calcium-phosphate-homeostasis we investigated calcium and phosphate as well as the 25(OH)- and 1,25(OH)₂-vitamin-D₃ serum levels

Table 4 Prevalence and incidence of vertebral fractures

BMD: Bone mineral density.

and parathyroid hormone. Only 25(OH)-vitamin-D₃ serum levels increased significantly in all 3 groups over time, but no change was seen in the other calcium phosphate homeostasis parameters investigated. No correlation of any serum levels of any parameter of calcium phosphate homeostasis with BMD or change in the BMD of the spine or femur could be observed (data not shown).

Adverse events

Adverse events (AEs) were reported in the standardized questionnaire used throughout the study at every 3-mo follow-up examination. AEs occurred in 35 patients (9 in group A; 14 in group B; 12 in group C). Most AEs were related to worsening of CD (28 patients), with 15 patients who had a bowel resection during study follow-up. One patient in the ibandronate group had to be withdrawn due to pregnancy (Figure 1). Study medication was generally well tolerated. Seven patients reported undigested calcium citrate and 2 undigested sodium fluoride pills in their feces. Six patients reported minor and completely reversible bone pain (< 2 h) or flu-like symptoms after intravenous infusion of ibandronate, manageable with acetaminophen if needed.

DISCUSSION

This is one of the most extended studies in the management of reduced BMD in CD. In our randomized study, we compared the effectiveness of cholecalciferol and calcium supplementation alone or along with additional sodium fluoride or additional ibandronate. More than 140 CD patients with reduced BMD (T-score < -1) were included in this study with a maximum follow-up of 3.5 years. In this young CD patient setting, increases in BMD were similar in all in- and between-treatment-group analyses, calcium and cholecalciferol supplementation not only prevented further bone loss but increased lumbar BMD and the effect was not increased further by addition of sodium fluoride or ibandronate. Regarding the prevention of fractures, the overall fracture rate in this study was too small to demonstrate between-group differences.

There were a number of limitations with the design of our study that could affect the interpretation of results. First, the study was not placebo-controlled nor blinded, and the dropout rate was high particularly after the first year. For ethical reasons we decided not to deny a basic

therapeutic regimen with cholecalciferol and calcium to any patient with reduced BMD. Unfortunately, it is a flaw of the study design that there was therefore no placebo or simple observation arm. Also, by using a blinded study comparing an oral *vs* iv administered study drug, a single tertiary outpatient clinic such as ours doing an investigator initiated trial as large as this would just be overworked. The dropout rate after the first year and only about 50% of patients completing the study reflects again the setting of our tertiary outpatient clinic where patients usually only show up if a primary or secondary health care center refer them for special reasons and problems. To manage this and to avoid misleading results we did the pre-planned ITT analysis, and found no difference in the results compared to PP analysis in in- and between-group analyses and with a mean observation time of 2.65 years, which was still longer than any follow-up in the CD patient setting before.

Oral treatment of osteoporosis with bisphosphonates relies on compliance and the absorption is low, probably especially in CD patients. When we planned this study, ibandronate was the only bisphosphonate to be administered safely as an iv bolus injection, and therefore offered an interesting alternative suitable for outpatient treatment^[42]. At that time, data of a study investigating 3-monthly iv injections of ibandronate in the treatment of postmenopausal osteoporosis were published, and treatment was reported to be safe and effective with a dose of 1 mg^[43]. This is why we had a 1 mg ibandronate 3-monthly iv intervention arm in our study. A recent meta-analysis pooled data from 4 phase III clinical trials to assess the relationship between ibandronate dose, changes in BMD, and rates of fractures. Lumbar spine BMD increased with increasing ibandronate dose and the incidence of fractures decreased as lumbar BMD increased. The pooled data pointed out the effectiveness of ibandronate to increase BMD and decrease fracture rate^[44]. In our predominantly young CD patient setting, the increase in lumbar BMD with 1 mg 3-monthly iv dosing equaled the efficacy of ibandronate for the treatment of postmenopausal osteoporosis, and the overall increase in BMD in our CD patient setting was as good as with higher doses in postmenopausal osteoporosis^[43,44].

When we planned this study, the discussion whether sodium fluoride can not only increase BMD but also prevent fractures was still open, and based on our pilot study we decided to have again a sodium fluoride intervention

arm. Here, the increase in lumbar BMD was somewhat less than in our pilot studies^[32,45]. In both, serum fluoride at 0, 6 and 12 mo was in the effective range of 0.095–0.19 mg/L^[46]. Nevertheless, the difference was most probably due to the lower sodium fluoride dose in the present study (50 mg *vs* 75 mg) which we chose based on an investigation using the same 50 mg dose and slow-release formula in postmenopausal women reporting an increase in BMD of 4%–5% per year^[27]. There remains little information available on sodium fluoride and fracture rate and therefore the efficacy of sodium fluoride in preventing fractures remains controversial^[27,28]. Nevertheless, Rubin has reported the efficacy of slow-release sodium fluoride in the prevention of vertebral fractures in postmenopausal osteoporosis^[29]. In our study, only one incident vertebral fracture was diagnosed in the sodium fluoride group. With the scientific interest focused on bisphosphonates, this question will be left open and up to now, sodium fluoride is not approved for the treatment of osteoporosis, if any, in most countries..

To this day, some other studies have evaluated the management of osteoporosis in CD, most using bisphosphonates. The primary end-point in all these studies was BMD and none reported the prevalence and incidence of fractures. Haderslev *et al*^[34] examined in a 12-mo double-blind, randomized, placebo-controlled trial the effect of 10 mg alendronate daily and reported a significant increase in lumbar BMD compared to placebo. Bartram *et al*^[33] reported an increase in BMD within 1 year with either a daily dose of 500 mg calcium and 400 IU vitamin D alone or with 3-monthly infusions of 30 mg pamidronate. The gain in BMD was a little more pronounced in the pamidronate group. Siffledeen *et al*^[35] reported a randomized trial of etidronate (400 mg orally) or not for 14 d and 500 mg calcium and 400 IU vitamin D for 76 d. This cycle was repeated 8 times. BMD significantly increased in both the etidronate- and the non-etidronate-treated groups.

Only a minority of recently diagnosed IBD patients had optimal serum 25-hydroxyvitamin-D₃ levels and serum 25-hydroxyvitamin-D₃ was positively correlated with baseline BMD of the lumbar spine, total hip, and total body, in a study by Leslie *et al*^[15]. Therefore, optimization of vitamin D may play an important role in preventing IBD-related bone disease^[13]. Vogelsang *et al*^[30] prevented BMD loss in CD patients by long-term vitamin D supplementation. Increases in BMD were especially prevalent among patients who had normal serum levels of 25-hydroxyvitamin-D₃ (68%), whereas increases occurred in only 18% of patients with low serum levels of 25-hydroxyvitamin-D₃.

Our study in CD patients with reduced BMD (T-score < -1, i.e. osteopenia according to WHO criteria as published in 1994^[36]) confirmed for the first time that the safe and well tolerated cholecalciferol and calcium supplementation alone not only prevented further bone loss but increased BMD of the lumbar spine for the better. Additional sodium fluoride or ibandronate had no benefit over cholecalciferol and calcium alone in managing reduced BMD. CD patients may take cholecalciferol and calcium first, and only add optional bisphosphonates, first and foremost in

patients with reduced BMD and prevalent fractures, taking into account all the data on bisphosphonates and fracture rate in postmenopausal osteoporosis which we still do not have for CD. Our results support the common clinical practice reported with the implementation of the American College of Gastroenterology and American Gastroenterology Association osteoporosis screening guidelines in inflammatory bowel disease^[47], with specific therapies based on DXA findings initiated in 69% of patients: oral calcium and vitamin D supplementation in 69% and bisphosphonates in 20%^[48].

COMMENTS

Background

Reduced bone mineral density (BMD) commonly affects patients with Crohn's disease (CD). Many facts link the 2 states together. With reduced BMD, the fracture risk increases.

Research frontiers

In postmenopausal women, therapy for reduced BMD is well established, but not in CD. In postmenopausal women, the standard of care is bisphosphonates. In CD, this question is still open. In this study, the authors test the effectiveness and safety of basic cholecalciferol and calcium supplementation alone or along with oral sodium fluoride or intravenous ibandronate to improve BMD compared to baseline.

Innovations and breakthroughs

In this study, sodium fluoride or ibandronate had no added benefit over basic cholecalciferol and calcium supplementation alone in increasing BMD in patients with CD and reduced BMD at baseline. One vertebral fracture in the sodium fluoride group was not sufficient to suggest a difference between groups. The study medication was safe and well tolerated.

Applications

In CD patients with reduced BMD, cholecalciferol and calcium supplementation is common clinical practice. Our data support this approach to improve bone BMD in CD patients.

Abstract

AIM: To assess the absolute number of T-regulatory cells (Tregs; CD4⁺CD25⁺Foxp3⁺) in the peripheral blood of gastric and colorectal cancer patients.

METHODS: We enrolled 70 cancer patients (33 gastric cancer, 37 colorectal cancer) and 17 healthy volunteers. The CD3⁺CD4⁺ lymphocytes and CD4⁺CD25⁺Foxp3⁺ Tregs in the peripheral blood were analyzed with flow cytometry. The absolute numbers of Tregs were calculated based on the CD4⁺CD25⁺Foxp3⁺ cells percent-

age of CD3⁺CD4⁺ cells and the absolute numbers of CD3⁺CD4⁺ cells per microliter.

RESULTS: The mean number of CD4⁺CD25⁺Foxp3⁺ cells per microliter in colorectal cancer patients was 15.7 (SD: 21.8), for gastric cancer patients 12.2 (SD: 14.3), and for controls 17.5 (SD: 11.4). The absolute number of Tregs was significantly lower in gastric cancer patients than in controls ($P = 0.026$). There was no statistically significant difference for gastric *vs* colorectal cancer or colorectal cancer *vs* controls. The absolute number of Tregs was also significantly depressed in N⁺ *vs* N⁻ cancer patients [22.0 (27.7) *vs* 10.1 (9.0), $P = 0.013$], and in the subgroup of gastric cancer patients [30.3 (27.6) *vs* 9.6 (8.0), $P = 0.003$]. No statistical difference was observed in the proportion of Tregs in the CD4⁺ population between the groups.

CONCLUSION: The absolute number of Tregs in peripheral blood of gastric cancer but not colorectal cancer patients was significantly decreased in comparison with that in healthy controls.

INTRODUCTION

There is evidence that regulatory T lymphocytes Tregs might be important for immunotolerance to self- and allo-antigens^[1]. Activity of these cells is one of the mechanisms of immune evasion by tumors, which inhibits the antitumor activity of effector cells. They also suppress the antigen-presenting function of dendritic cells and the activity of natural killer cells^[2,3]. Tregs are the subset of CD4⁺ cells that express high levels of the interleukin-2 receptor α chain CD25. Therefore, Tregs are described as CD4⁺CD25⁺ cells. However, the value of CD25 as a specific marker is limited, because it is also expressed on activated CD4⁺ cells. Recent studies have shown that Foxp3, a member of the transcription factor family, represents a specific marker for Tregs^[4]. However, Foxp3 is a nuclear protein and it is impossible to use it for isolation of cells. Many previous studies on Tregs in neoplastic diseases that were performed before the discovery of Foxp3 used CD4⁺CD25⁺ subpopulation as an equivalent to Tregs. Recently, flow cytometric detection of CD4⁺CD25⁺Foxp3⁺ in human cancer studies has been described^[5]. The main outcome from studies in human cancer is the increase in the proportion of Tregs/CD4⁺ cells among tumor-infiltrating lymphocytes (TILs), metastatic lymph nodes and peripheral blood^[6]. The increase in Tregs was in some studies a prognostic factor of poor survival. However, these data are not uniform for all types and locations of tumors^[7-9].

The aim of our study was to assess the absolute number of Tregs (CD4⁺CD25⁺Foxp3⁺) in the peripheral blood of gastric and colorectal cancer patients.

MATERIALS AND METHODS

The study consisted of 70 patients (33 gastric cancer and 37 colorectal cancer) treated in a single institution between 2006 and 2009. All these patients had histologically confirmed disease. The median age was 68 years (range: 32-82 years). There were 42 male and 28 female patients. All these patients underwent laparotomy. The details of clinicopathological characteristics are summarized in Table 1.

None of the patients received chemotherapy, radiotherapy, immunotherapy or other form of therapy that influenced the immune system. Patients had no history of autoimmune disease or recent infection.

The blood of 17 healthy volunteers was tested as controls. The control group consisted of 10 men and seven women with a mean age of 42 years (range: 25-52 years).

The study was approved by the Ethical Committee of Jagiellonian University.

Blood samples were collected prior to any interventional procedure in sterile EDTA vacutainers. Peripheral blood samples (100 μ L) obtained from cancer patients were incubated in TruCount tubes (BD Biosciences, San Jose, CA, USA) with a monoclonal antibody cocktail: FITC-conjugated anti-CD3 and PE-conjugated anti-CD4 (5 μ L; BD Biosciences) for 30 min at 4°C. The samples were treated with 400 μ L FACS Lysing Solution (BD Biosciences), and after erythrocyte lysis, 10000 CD3⁺CD4⁺

cells along with beads were acquired on a FACSCanto flow cytometer and analyzed with FACSDiva Software (BD Biosciences). The absolute numbers of CD3⁺CD4⁺ lymphocytes in samples were calculated on a basis of bead and lymphocyte counts. Tregs (CD4⁺CD25⁺Foxp3⁺) were stained in 200 μ L EDTA peripheral blood samples using the Human Regulatory T Cell Staining Kit (eBiosciences, UK), according to manufacturer's instructions, and acquired on the flow cytometer. The absolute numbers of Tregs were calculated based on the CD4⁺CD25⁺Foxp3⁺ cells percentage of CD3⁺CD4⁺ cells and the absolute numbers of CD3⁺CD4⁺ cells per microliter.

Statistical analysis

All quantitative variables were described as mean (SD). The Mann-Whitney *U* test and the χ^2 test were used when appropriate to compare distribution of individual variables between groups. *P* < 0.05 was considered statistically significant. Statistical analysis was performed using SPSS version 14 software (SPSS Inc., Chicago, IL, USA).

RESULTS

Absolute number of CD4⁺CD25⁺Foxp3⁺ cells in peripheral blood

The mean number of CD4⁺CD25⁺Foxp3⁺ cells per microliter in colorectal cancer patients was 15.7 (21.8), for gastric cancer patients 12.2 (14.3) and for controls 17.5 (11.4) (Figure 1).

The difference between colorectal cancer patients and the control group was not significant (*P* = 0.079). There was a significant difference between the gastric cancer patients and the control group (*P* = 0.026). The difference between the gastric cancer and colorectal cancer patients was not significant.

The absolute number of CD4⁺CD25⁺Foxp3⁺ cells did not differ according to sex in either the colorectal or gastric

Figure 1 The absolute number of CD4⁺CD25⁺Foxp3⁺ cells in peripheral blood of colorectal and gastric cancer patients and controls.

cancer patients. Patients aged ≤ 65 years and > 65 years had similar results for both cancer types (Table 2). The analysis of TNM stage revealed that, for more advanced-stage cancer, Treg count was lower but the difference was not significant.

In colorectal cancer patients, Treg absolute count was not related to tumor grade, lymph node status or distant metastases. There was also no difference between gastric cancer subgroups according to Lauren's histological classification. In gastric cancer patients, the number of CD4⁺CD25⁺Foxp3⁺ cells was significantly lower in peripheral blood of N⁺ patients (*P* = 0.003). For the pooled group of patients (gastric and colorectal cancer), this difference was also significant (*P* = 0.013). There was no difference between M⁻ and M⁺ gastric cancer patients for absolute number of Tregs, or in the entire group of cancer patients.

Ratio of CD4⁺CD25⁺Foxp3⁺ cells/CD4⁺ cells in peripheral blood

The CD4⁺CD25⁺Foxp3⁺/CD4⁺ lymphocyte ratio did not show any differences between N⁺ and N⁻ and M⁺ and M⁻

patients for both types of cancer. This proportion was not related to sex or age (Table 3). There was no difference between stages I / II and III / IV for either type of cancer, nor in the pooled group of cancer patients.

DISCUSSION

The prevalence of Tregs in various compartments in patients with tumors has been described as a potential prognostic factor. Tregs have been found in TILs (primary and metastatic tumors), in metastatic lymph nodes, malignant ascites, pleural effusion, and peripheral blood^[6,10]. The prognostic significance of these findings is not uniform. Moreover, the impact of Tregs has been reported as their density in tumor stroma, proportion of TILs, Tregs/CD4 ratio, Tregs/CD3 ratio, or Tregs/CD8 ratio^[11-14]. Mostly, the proportion of CD25⁺Foxp3⁺ cells among CD4⁺ TILs has been analyzed.

Most of these studies were retrospective and based on the immunohistochemical examination of paraffin-embedded, previously collected specimens. On the other hand, peripheral blood is easily accessible and enables repeated measurements prior to surgery or in the follow-up period. Therefore, it is important to establish the pattern of Tregs in peripheral blood of patients with various tumors. However, the number of Tregs in peripheral blood changes less markedly than in TILs^[11].

The present study was a pilot study, therefore, assessment of the number of cells was performed preoperatively only. The results of the assessment in the early post-operative period would probably be influenced by the pro-inflammatory and anti-inflammatory post-injury reactions. This might change the lymphocyte subpopulations. Our present results can form a background for subsequent studies on Tregs in the preoperative period and follow-up of cancer patients.

¹Mann-Whitney *U* test. The Tregs/CD4⁺ ratio in healthy volunteers group was 2.1%, and this was equal to that observed in gastric cancer patients.

In our study, the absolute number of CD25⁺Foxp3⁺ cells in peripheral blood did not differ between gastric and colorectal cancer patients. There was no difference between sex and age groups. Some authors have described increased prevalence of Tregs among T-lymphocyte populations in elderly patients^[15]. Others have not observed this tendency^[16]. There is also no clear evidence in the literature that the Tregs population is sex-related.

The absolute number of Tregs was significantly lower in gastric cancer patients than in controls. This is probably in contrast with other studies in gastric cancer patients, however, it is impossible to compare these results directly. The main problem is the difference in description of Tregs. Some early studies have analyzed the population of CD4⁺CD25⁺ cells, others CD4⁺CD25^{high} cells, and more recently, CD4⁺CD25⁺Foxp3⁺ lymphocytes^[12,13,17-20]. Most probably this is not the last word in the identification of functionally active Tregs. Even if these populations have a common core, they are not identical. Moreover, the technical process of identification can vary and bias the final result.

In colorectal cancer patients, the absolute number of Tregs in peripheral blood did not differ from that in healthy controls. There are not sufficient data to compare this result with other studies, because the main colorectal cancer studies have concentrated on prevalence of Tregs among TILs^[12,13,21]. The pattern of Tregs localization and its correlation with tumor stage and prognosis also differs between gastric and colorectal cancer. The high prevalence of Tregs in colorectal cancer has been reported as a positive factor, contrary to gastric cancer for which it has been reported as a negative factor^[7,8,11,13,22]. The reason for these differences might also be related to the different results observed in gastric and colorectal cancer patients in our study. However, the regulatory mechanisms of Treg maturation, activation and distribution are not fully under-

stood. Therefore, we could not clarify the observed differences between the results in gastric and colorectal cancer.

We found that N⁺ gastric cancer patients had significantly lower absolute counts of Tregs in peripheral blood than had N⁻ patients.

Our study included 25 node-positive patients and this probably influenced the mean Treg count in the whole group. Several studies have revealed an increase in Tregs in metastatic lymph nodes in gastric and esophageal cancer^[23]. Our study might have demonstrated Treg migration to the metastatic lymph nodes and accumulation in the peritumoral infiltrate in more advanced tumors. There is some evidence that, in gastric cancer, Tregs might migrate to the tumor microenvironment *via* a chemokine-mediated mechanism^[24].

The increase in Tregs among TILs has also been observed in colorectal cancer patients^[25], but we did not observe a significant drop in peripheral blood Tregs in node-positive colorectal cancer patients. However, for the pooled N⁺ *vs* N⁻ group, the difference was significant. The lack of difference between M⁻ and M⁺ patients supports the hypothesis that the peripheral Tregs population does not change significantly during metastasis formation. The increase in CD4⁺CD25^{high} to CD4⁺ cell ratio in comparison to that in healthy donors has been described in metastatic cancer^[26]. However, the absolute numbers of Tregs in these populations have not been reported.

In our study, the number of patients was < 40 for each cancer type. These relatively small numbers preclude statistical analysis of Tregs counts at single TNM stages. Therefore, we performed our analysis on I / II *vs* III / IV stages. The absolute number of Tregs was lower in the more advanced group, but the difference did not reach statistical significance.

The proportion of Tregs to CD4⁺ cells was 2.18% for colorectal cancer and 2.01% for gastric cancer patients.

This value is located between that reported in the literature of 4%-6% for gastrointestinal cancer and 1%-3% for the healthy population^[27]. However, the calculated percentages of Tregs (of CD4 or of CD3) or proportions of Tregs/CD8 is influenced by at least two variables. It should be considered that subpopulations of lymphocytes can change during tumor progression^[28]. Therefore, the ratio and absolute numbers should be included.

In conclusion, our study was focused on the peripheral blood Tregs as a potential marker of disease, which was relatively easy to measure during the pretreatment and follow-up periods. The absolute number of Tregs in the peripheral blood of gastric cancer patients was significantly decreased in comparison to that in the healthy controls. This phenomenon was even strongly expressed in patients with lymph node metastasis. This was not observed in colorectal cancer patients. Our findings suggest that the population of Tregs in peripheral blood does not simply mimic stromal Tregs. Further studies on larger groups of patients are necessary to evaluate the Treg population in cancer patients.

COMMENTS

Background

The prevalence of T regulatory lymphocytes (Tregs) in various cancers has been described as a prognostic factor. The assessment of the absolute number of Tregs (CD4⁺CD25⁺Foxp3⁺) in the peripheral blood of gastric and colorectal cancer patients can be used to monitor disease during treatment.

Research frontiers

Our study was focused on peripheral blood Tregs as a potential disease marker, which was relatively easy to measure during pretreatment and follow-up periods. The prevalence of Tregs in various compartments in patients with tumors has been described as a potential prognostic factor. Tregs have been found in tumor-infiltrated tissues and fluids, but the prognostic significance of these findings is not uniform. The impact of Tregs has been reported as their density in tumor stroma or the proportion of Tregs among tumor-infiltrating lymphocytes (TILs), Tregs/CD4 ratio, Tregs/CD3 ratio, or Tregs/CD8 ratio. However, overall, the proportion of CD25⁺Foxp3⁺ cells amongst CD4⁺ TILs is analyzed.

Innovations and breakthroughs

Many studies of Tregs as a prognostic factor have been retrospective and based on immunohistochemical examination of paraffin-embedded, previously collected specimens. On the other hand, peripheral blood is easily accessible and enables repeated measurements prior to surgery or in the follow-up period. Therefore, it is important to establish the pattern of Tregs in peripheral blood of patients with various tumors.

Applications

In utilizing peripheral blood Tregs as a potential disease marker, this study demonstrates a way of improving the assessment and management of patients with gastric cancer.

Peer review

The authors assessed the absolute number of Tregs (CD4⁺CD25⁺Foxp3⁺) in the peripheral blood of gastric and colorectal cancer patients. The absolute numbers of Tregs were calculated based on the CD4⁺CD25⁺Foxp3⁺ cells percentage of CD3⁺CD4⁺ cells and the absolute numbers of CD3⁺CD4⁺ cells per microliter. The absolute number of Tregs in the peripheral blood of gastric cancer patients was significantly decreased in comparison to the healthy controls. This phenomenon was even strongly expressed in patients with lymph node metastasis, but not observed in colorectal cancer patients. The findings suggest that the population of Tregs in peripheral blood does not simply mimic stromal Tregs. Further studies on larger groups of patients are necessary to evaluate the Treg population in the blood of cancer patients.

Abstract

AIM: To investigate whether differences in the rapidity of a positive result for *Helicobacter pylori* can save resources, by comparing two commercially available urease kits.

METHODS: One hundred and eighty-five adults (130 outpatients, 55 inpatients) undergoing gastroscopy were entered prospectively. Patients were divided into two groups: Group 1 (if they were not on PPIs, antibiotics, H₂A, bismuth or sucralfate for up to 14 d prior to the endoscopy) and Group 2 (if they were on, or had been on, any of the above medication in the previous 14 d). At endoscopy two sets of biopsies, taken in random order, were placed in the wells of the *Campylobacter*-like organism (CLO) test (Kimberly-Clark, Utah, USA) and the Quick test (Biohit Plc, Helsinki, Finland). Five additional gastric biopsies were taken for histology/Giemsa and immunohistochemical study. The two urease test slides

were read at 2 min, 30 min, 2 h and 24 h. Sensitivity and specificity at 24 h were determined.

RESULTS: At 24 h, for all patients, there was no difference in sensitivity (100% vs 97.5%), specificity (99.3%), positive (97.5%) and negative predictive values (100% vs 99.3%) between the CLO and Quick tests, respectively. There was a positive result at 30 min in 17/41 (41.5%) CLO tests, and in 28/40 (70%) Quick tests, $P = 0.05$. Quick test enabled the prescription of eradication therapy before discharge in all 28/40 patients. Only 12 (30%) follow-up appointments were needed. If the CLO test had been used alone, only 17 (41.5%) prescriptions would have been possible prior to discharge and 24 (58%) follow-up appointments would be needed ($P = 0.001$). Of 2000 gastroscopies performed annually at our unit, a saving of 123 follow-up appointments (total: 8856 Euros or 11808 USD) would be achieved if we switched to the Quick test.

CONCLUSION: Direct comparison of locally available urease test kits is worthwhile, since the appropriate choice results in a significant saving of resources. Local costs and follow-up protocols will determine the magnitude of these savings.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is a spiral-shaped gram-negative bacterium which was identified in 1979^[1]. It produces urease in abundance, the activity of which, through the production of ammonia, together with the bacterium's motility and ability to adhere to the gastric mucosa, enables its survival in the acid environment of the stomach. *H. pylori* is a causative agent for chronic active gastritis, peptic ulcer disease, gastric cancer and mucosa associated lymphoid tissue lymphoma^[2]. It has also been shown to be associated with extragastric diseases, such as iron deficiency anemia and idiopathic thrombocytopenic purpura^[3-5].

Non-invasive methods of *H. pylori* detection include serum antibody detection, fecal antigen tests^[6] and the urea breath test^[7]. Invasive methods of *H. pylori* detection require endoscopy in order to obtain gastric tissue for histologic determination, bacterial culture or for use in urease detection kits.

Urease detection kits are inexpensive and easy to use. Biopsies from the gastric mucosa are placed in a well containing a yellow colored agar gel which contains urea and a pH indicator. Urease cleaves urea liberating ammonia, which is alkaline turning the agar color red, so indicating the presence of a urea-producing organism. The test enables the determination of the *H. pylori* status of the patient within 24 h, with a substantial proportion giving a positive result within a few hours^[8]. This represents a clear advantage over the costly and labor-intensive method of histological examination with special stain.

The aims of our study were to: (1) evaluate the sensitivity and specificity of two commercially available urease detection kits; (2) compare the time interval required for each kit to give a positive result; and (3) determine whether any differences would expedite patient management and save resources, by enabling treatment to be prescribed before patients are discharged from the endoscopy unit, thus avoiding a follow-up appointment.

MATERIALS AND METHODS

The study protocol was approved by the Hospital Ethics Committee. Patients over the age of 18 years referred for upper gastrointestinal endoscopy, in whom *H. pylori* detection was indicated, were enrolled prospectively, after written informed consent was obtained. Before gastroscopy, patients were asked whether they were, or had been in the previous 14 d, on treatment with proton pump inhibitors (PPIs), histamine type 2 receptor antagonists (H₂A), antibiotics, bismuth, or sucralfate. Patients not on PPIs, antibiotics, H₂A, bismuth or sucralfate for up to 14 d prior to the endoscopy, for the purpose of analysis were subsequently assigned to Group 1 and patients who were on, or had been on any of the above medication in the previous 14 d were assigned to Group 2. Patients on anticoagulants or with known prolonged international normalized ratio (INR), activated partial thromboplastin time (aPTT), or platelet count below 100 000/mL were excluded. Gastroscopy was performed routinely under light intravenous

sedation and local anesthetic spray to the oropharynx.

The two urease detection kits used for comparison in this study were (1) the *campylobacter*-like organism (CLO) test Rapid Urease Test (Kimberly-Clark, Utah, USA), the gel of which contains urea United States Pharmacopeia (29 mg/mL), phenol red (a pH indicator), buffers and a bacteriostatic agent to prevent the growth of contaminating urease-positive organisms and (2) the *H. pylori* Quick test (Biohit Plc, Helsinki, Finland).

Both kits were kept at room temperature for at least 10 min prior to endoscopy. At endoscopy, two biopsy specimens, one from the antrum and one from the body (mid greater curve) of the stomach^[7] were obtained for each urease test, each pair \leq 1 cm apart. Each tissue pair was embedded in the same gel-containing well of the kits under investigation. Samples for the two urease tests were taken in a random order (sealed envelope). In each instance, following the biopsies for the urease tests, three biopsies from the antrum and two from the body of the stomach were obtained (within 1 cm of the previous biopsies) for histology/Giemsa and immunohistochemical staining. For each set of biopsies a new disposable spiked forceps with fenestrated cup was used (cup diameter 2.5 mm, Wilson Cook Medical Inc., Winston-Salem, NC, USA). The exact time of the placement of the biopsies in the urease test wells was recorded and the wells inspected for color change at 2 min, 30 min, 2 h and 24 h. The test was assigned positive when there was a color change of at least 2 mm radius of red cloud around the biopsy specimen, or complete color change of the yellow well to red or magenta.

Patients were discharged after 30-45 min post-endoscopy. Where a positive result was obtained, *H. pylori* eradication therapy was prescribed prior to discharge. The number of prescriptions issued before discharge was recorded. Patients not issued a prescription prior to discharge were given follow-up appointments for the result of the urease test and prescription of eradication therapy, where indicated. The financial burden of these extra appointments was calculated from data supplied by the accounts department of our hospital, comprising estimated administrative costs and cost of medical time.

Histology

The gastric mucosa tissue was fixed by a routine fixation system and was embedded in paraffin blocks. A series of three to four thick sections of each block were used for routine stains (hematoxylin/eosin-Giemsa) and immunohistochemistry. Immunohistochemical evaluation was performed as follows: de-paraffined sections of all blocks were pretreated in citrate buffer, pH 6.0 for 10-20 min followed by cooling at room temperature for 20 min. The primary antibody was then added (polyclonal rabbit anti-*H. pylori* serum at 1:250 dilution; Thermo Fischer Scientific, Runcorn, Cheshire, UK) and incubated for 30 min at room temperature. To detect antibody, a visualization system with diaminobenzene was used. Giemsa and immunostained slides were examined independently by two experienced histopathologists (Filippidis T and Leontara V)

Table 1 Sensitivity, specificity and predictive values for *Campylobacter*-like organism test and Quick test (all patients)

Test (at 24 h)	True positive	True negative	Total
CLO test			
Positive	40	1	41
Negative	0	144	144
Quick test			
Positive	39	1	40
Negative	1	144	145

Campylobacter-like organism (CLO) test: sensitivity 100% [95% confidence interval (CI): 91.24-100], specificity 99.3% (95% CI: 96.2-99.88), positive predictive value (PPV) 97.6% (95% CI: 87.4-99.57), negative predictive value (NPV) 100% (95% CI: 97.4-100); Quick test: sensitivity 97.5% (95% CI: 87.12-99.56), specificity 99.3% (95% CI: 96.2-99.88), PPV 97.5% (95% CI: 87.12-99.56), NPV 99.3% (95% CI: 96.2-99.88).

who were blind to the urease test results, using light microscopy; first separately and then their results were compared. Any differences were resolved by discussion between the two histopathologists. A true positive test was determined when any two of the four tests (CLO test, Quick test, Giemsa stain, immunohistochemical stain) were positive.

Statistical analysis

The sensitivity, specificity, positive and negative predictive values of the urease tests were determined for the overall number of the patients and separately for the group of patients not on PPIs, antibiotics, H₂A, bismuth or sucralfate for up to 14 d prior to the endoscopy (Group 1) and for the group of patients who were on, or had been on any of the above medication in the previous 14 d (Group 2).

Statistical comparison of the two urease tests was by the student *t*-test for two dependent proportions, χ^2 test and the McNemar test. A statistically significant difference in the comparison of the two kits was considered when *P* value was ≤ 0.05 . Confidence intervals (CI) were determined at the 95% level.

RESULTS

Sensitivity and specificity of CLO test and Quick test at 24 h - all patients

Between April and October 2007, 185 adult patients (101 male, 84 female); age range 18-82, mean 49 years, were entered into the study. One hundred and thirty were outpatients (70%) and 55 (30%) inpatients. The overall results were as follows.

CLO test was positive at 24 h in 41 cases (22%) and negative in 144 cases (78%). Quick test was positive at 24 h in 40 cases (22%) and negative in 145 cases (78%). Histology/Giemsa/immunohistochemistry was positive for *H. pylori* in 44 cases (23.8%).

For all 185 patients, the sensitivity, specificity, positive (PPV) and negative predictive value (NPV) for the CLO test and Quick test were similar (Table 1). The concordance of the CLO test and Quick test for a positive result was 95% and for a negative result was 98%.

Table 2 Sensitivity, specificity and predictive values of the *Campylobacter*-like organism and Quick tests in Group 1

Test (at 24 h)	True positive	True negative	Total
CLO test			
Positive	26	0	26
Negative	0	79	79
Quick test			
Positive	25	0	25
Negative	1	79	80

Campylobacter-like organism (CLO) test: sensitivity 100% [95% confidence interval (CI): 87.13-100], specificity 100% (95% CI: 95.36-100), positive predictive value (PPV) 100% (95% CI: 87.13-100), negative predictive value (NPV) 100% (95% CI: 95.36-100); Quick test: sensitivity 96.1% (95% CI: 81.11-99.32), specificity 100% (95% CI: 95.36-100), PPV 100% (95% CI: 86.68-100), NPV 98.7% (95% CI: 93.25-99.78).

Table 3 Sensitivity, specificity and predictive values of the *Campylobacter*-like organism and Quick tests in Group 2

Test (at 24 h)	True positive	True negative	Total
CLO test			
Positive	14	1	15
Negative	0	65	65
Quick test			
Positive	14	1	15
Negative	0	65	65

Campylobacter-like organism (CLO) test: sensitivity 100% [95% confidence interval (CI): 78.47-100], specificity 98.5% (95% CI: 91.9-99.73), positive predictive value (PPV) 93.3% (95% CI: 70.18-98.81), negative predictive value (NPV) 100% (95% CI: 94.42-100); Quick test: sensitivity 100% (95% CI: 78.47-100), specificity 98.5% (95% CI: 91.9-99.73), PPV 93.3% (95% CI: 70.18-98.81), NPV 100% (95% CI: 94.42-100).

Comparison of CLO and Quick test for patients on or off antisecretory drugs or antibiotics

Of the total 185 patients, Group 1 comprised 105 patients of whom 31 (29%) were inpatients. Group 2 comprised 80 patients of whom 24 (30%) were inpatients. None had been on bismuth or sucralfate. At 24 h, sensitivity, specificity, PPV and NPV was the same for the two kits, both for Group 1 and Group 2 (Tables 2 and 3).

Table 4 displays separately the results of the two urease test kits for Group 1 and 2. At 30 min, taking the CLO test and Quick test together, a total of 33 out of 51 tests were positive in Group 1, as compared to only 12 out of 30 in Group 2 (*P* = 0.03). At 2 h, there was no statistically significant difference between Group 1 and Group 2 (*P* = 0.11). In Group 1, 13 out of 26 CLO tests and 20 out of 25 Quick tests were positive at 30 min (*P* = 0.02), with no difference at 2 h. There was no statistically significant difference in the rapidity of the two urease tests at 30 min and 2 h in Group 2 (*P* = 0.13, *P* = 0.14, respectively).

Comparison of rapidity of a positive result for the CLO and Quick tests

The number of positive CLO and Quick tests for all patients at 2 min, 30 min, 2 h and 24 h is shown in Table 5. Of a total of 40 positive Quick tests at 24 h, only 12 re-

Table 4 Number of patients with a positive *Campylobacter*-like organism and Quick test at 2 min, 30 min, 2 h, 24 h for Groups 1 and 2

Time	Group 1		Group 2	
	CLO test	Quick test	CLO test	Quick test
2 min	2	5	0	3
30 min	13 ^a	20 ^a	4	8
2 h	23	25	11	14
24 h	26	25	15	15

^a*P* = 0.02. CLO test: *Campylobacter*-like organism test.**Table 5** Number of patients with a positive *Campylobacter*-like organism and Quick test at 2 min, 30 min, 2 h, 24 h (all patients)

Time	CLO test	Quick test	<i>P</i> -value
2 min	2	8	0.03
30 min	17	28	0.05
2 h	34	39	0.28
24 h	41	40	0.45

CLO test: *Campylobacter*-like organism test.

mained negative at 30 min (30%), whereas 24 of a total of 41 positive CLO tests at 24 h (58%) remained negative at 30 min (*P* = 0.001). This enabled the prescription of *H. pylori* eradication therapy before departure from the endoscopy unit for 28/40 patients with a positive Quick test at 30 min and only 12 (30%) follow-up appointments were given.

Estimation of differences in financial costs and resources

Based on the above results if the CLO test had been used alone, only 17 (41.5%) prescriptions would have been possible (*P* = 0.05) prior to discharge and 24 (58%) follow-up appointments would be needed (*P* = 0.001). The additional financial cost of each of the additional 12 follow-up appointments at our hospital, for consultation and the prescription of eradication therapy, would be 17 Euros in administrative costs and 55 Euros in medical time (total: 72 Euros or 96 USD).

At our unit, just over 2000 gastroscopies are performed annually. Given our observed overall prevalence of *H. pylori* colonization of 41/185 (22%), we can expect 440 *H. pylori*-positive cases each year. Extrapolating from the data we present here on a difference of 28% in negative results at 30 min (58% CLO negative at 30 min *vs* 30% Quick negative), if the Quick test was used in preference to the CLO test, a saving of 123 follow-up appointments (total: 8856 Euros or 11 808 USD) would be achieved at our unit each year.

DISCUSSION

The diagnosis of *H. pylori* infection relies on various testing methods, with the gold standard being histology/

staining^[9]. Urease testing can provide rapid testing in the endoscopy suite, or in the hours following, but does not provide a gold standard assessment of infection.

We selected the CLO test and the Quick test for comparison because they were available locally. We considered that comparison of a greater number of urease test kits would not be justified due to the excessive number of gastric biopsies that this would entail.

Our results indicate, by using two biopsies placed in the same well, that there is no difference in the overall performance of the CLO test and Quick test at 24 h, with sensitivity at 100% and 97.5%, and specificity at 99%, respectively. There was, however, a significant difference in the rapidity of a positive test, in favor of the Quick test, which resulted in a significantly greater number of prescriptions issued prior to discharge at 30-45 min than would have been the case if the CLO test had been used alone.

Previous studies using similar methods also reported the sensitivity of the urease detection kits to be over 90%^[10-12]. Goh *et al*^[11] compared the HUITAI rapid urease test to histology and culture for *H. pylori* detection. Two biopsy specimens were used (antrum and body of stomach), as in our study. The sensitivity and specificity of the kits were 98.2% and 99%, respectively. In another study by Wong *et al*^[12], the PyloriTek kit was evaluated using as gold standard histology and an in-house rapid urease test. In this study, only one biopsy from the antrum was used yielding 96.3% sensitivity and 97.9% specificity, and the benefit of the addition of a corpus biopsy was found to be marginal^[12].

The results from the comparison of the reaction time of Groups 1 and 2 (Table 4) indicate that in patients with recent intake of antisecretory drugs or antibiotics the positivity of both urease tests is delayed at 30 min, although the final result at 24 h is not influenced. These findings are in agreement with those of van Keeken *et al*^[10]. On the other hand, a decrease in sensitivity, in addition to delayed positivity, was reported by Prince *et al*^[13], whilst Midolo *et al*^[14] reported that false positive tests when acid suppression therapy is in use occur only after 24 h of incubation. The mechanism by which these medications interfere with the results is thought to be either by directly inhibiting *H. pylori* urease, or by changing the *H. pylori* colonization pattern^[13].

There have been a number of previous comparisons of the speed of urease test kits: van Keeken *et al*^[10] compared the accuracy and reaction time of a new dry rapid urease test, the GUT test, with the CLO test, culture and histology. The urease test was found reliable to read 60-120 min after endoscopy. Said *et al*^[15] compared the accuracy and reaction time of a urease test, the Pronto Dry, with the CLO test and histology. A positive reaction time was achieved at 30 min, similar to the present study. In the study by Goh *et al*^[11], the rapidity of the HUITAI rapid urease test was also examined. The median positive reaction time was 1.0 min (25%-75% inter-quartile range: 1.0-3.0 min); more rapid than that observed in the present study^[11]. However, no data were given concerning the rapidity of the HUITAI test and its possible impact on resources. Caution should be exercised when

comparing studies of urease test reaction times in different populations, such as the European and Far Eastern. A crucial determinant of the rapidity of a positive urease test is the bacterial load present in the gastric biopsies. This may be higher in the Far East^[16].

In our study, there was a significant difference in the rapidity of a positive urease result at 2 and 30 min after placement of the biopsies in the test wells (Table 5), in favor of the Quick test. As a result, we were able to prescribe *H. pylori* eradication therapy before discharge from the endoscopy unit in a significantly higher number of patients (so obviating the need for follow-up visit for the prescription of eradication therapy) than would have been the case if the CLO test had been used alone. The prevalence of *H. pylori* infection of 22% observed in our study is consistent with the 19% reported in a recent seroepidemiological study of Hellenic Navy recruits^[17]. This rate is much lower than that reported in studies of the previous decade and is thought to be due to an improvement in lifestyle and socioeconomic status, in line with observations in other developed countries^[16-18].

On the basis of our results we calculated that there would be a substantial annual saving in medical and administrative time as well as financial cost, if we adopted the Quick test in preference to the CLO test. In busier endoscopy units or areas of higher *H. pylori* prevalence, the benefit would be higher. Precise financial savings for each endoscopy unit would need to be calculated according to the outpatient follow-up protocol and to local costs. These vary widely between countries and institutions. Where the practice of endoscopy units is to delegate the reading of the urease test and prescription of eradication therapy to other providers, the cost saving would be transferred to the latter.

We conclude that in selecting from locally available urease test kits, direct comparison of the rapidity of a positive result is worthwhile because the appropriate choice of kit would result in a significant saving of resources.

COMMENTS

Background

Helicobacter pylori (*H. pylori*), is a urease (enzyme) producing organism responsible for chronic active gastritis, peptic ulcer disease, gastric cancer and mucosa associated lymphoid tissue lymphoma. One method of rapid detection is by the use of urease detection kits which are inexpensive and easy to use. These kits consist of a well containing a yellow colored agar gel; during gastroscopy, biopsies from the gastric mucosa are placed in the well. The presence of *H. pylori* will turn the agar color red, so indicating the presence of *H. pylori*. The test enables the determination of the *H. pylori* status of the patient within 24 h, and therefore the prescription of eradication therapy.

Research frontiers

According to the literature many urease detection kits have been studied for their sensitivity and specificity as well as for their rapidity. In this article, the authors emphasize the impact of the rapidity of the test on the financial and administrative costs.

Innovations and breakthroughs

The preferential use of a rapid urease test kit results in substantial annual savings in medical and administrative time as well as in financial cost.

Applications

Direct comparison of locally available commercial urease tests is worthwhile because it may lead to saving of resources.

Peer review

The diagnosis of *H. pylori* infection relies on various testing methods, with the gold standard being histology/staining. Urease testing can provide rapid testing in the endoscopy suite, or in the hours following, but does not provide a gold standard assessment of infection.

Abstract

AIM: To examine the effect of increasing dietary zinc (Zn) intake and the lack of metallothionein (MT) expression on activity of small intestinal disaccharidases.

METHODS: MT- I and II knockout (MT^{-/-}) and wild-type (MT^{+/+}) female mice at 3.5 wk of age were randomly fed with a diet containing 2 (2 Zn), 15 (15 Zn) or 50 (50 Zn) mg Zn/kg ($n = 8/\text{group/genotype}$) for 5 wk. Small intestinal segments (duodenum, jejunum and ileum) were collected and either fixed in 10% formalin for histological analysis or snap frozen in liquid nitrogen for sucrase, lactase and maltase activity analyses.

RESULTS: Plasma Zn was significantly ($P < 0.05$) lower (33%) in MT^{-/-} compared with MT^{+/+} mice fed the 2 Zn diet. Villus height and crypt depth were increased by approximately 15% in MT^{+/+} mice compared with MT^{-/-} mice. Duodenal disaccharidase activities were significantly higher in MT^{+/+} compared with MT^{-/-} mice particularly in those fed the 2 Zn diet. For the 50 Zn diet, jejunal sucrase and lactase activities were significantly higher in MT^{-/-} (13313 ± 2314 ; 4107 ± 364 $\mu\text{mol glucose/well/min/g tissue}$, respectively) compared with MT^{+/+} mice (7054 ± 608 ; 1818 ± 174). Similarly, ileal lactase activities were higher in MT^{-/-} (1480 ± 192) compared with MT^{+/+} (629 ± 353) mice particularly those fed the 2 Zn diet.

CONCLUSION: Increasing dietary Zn has little effect on disaccharidases activity in MT wild-type mice. The presence of MT may enhance morphological and functional development of the gut.

INTRODUCTION

Gastrointestinal function is characterized by growth, structural and functional changes of the crypts and villi, macro-

molecular absorption capacity and alteration in the activity of the small intestinal brush-border disaccharidases^[1]. It is well documented that weaning is associated with marked changes in the histology and biochemistry of the small intestine, and such changes include increased cell proliferation and differentiation^[2] and altered activity of the brush border disaccharidases, lactase and sucrase^[1]. These changes are often used as indicators of small intestinal maturity and development following the consumption of a solid diet.

The brush border disaccharidases, lactase and sucrase, are considered accurate markers of enterocyte maturity and functional capacity^[3]. It is well documented that dietary modification is correlated with significant changes in the histology and biochemistry of the small intestine^[4]. Furthermore, pigs fed an inorganic zinc (Zn) diet and weaned pigs from sows fed an inorganic Zn diet compared with those fed the control diet had improved gut morphology^[5,6]. In addition, Zn deficiency has been shown to reduce villous dimensions and increase villous density in the small intestine; however after a short period of Zn supplementation, villous density basal width and the maximum height of individual villi returned to normal^[7]. Duff and Ettarh^[8] demonstrated that Zn-fed mice produced more crypt cells in the distal part of small intestine compared with controls. Furthermore, it has been shown that weanling rats fed a semi-purified Zn-deficient diet have significantly lower levels of sucrase, maltase, lactase, leucine aminopeptidase, and alkaline phosphatase compared with rats fed a control or high Zn diet^[9,10].

Zn is an essential nutrient required for cell growth, differentiation, and survival, and its deficiency causes growth retardation, immunodeficiency, and other health problems^[11]. Therefore, Zn homeostasis must be tightly controlled in individual cells. The transcellular uptake of Zn occurs in the distal duodenum and proximal jejunum^[12-15] from the brush border membrane. The mechanisms of exogenous zinc uptake have not yet been entirely elucidated, although both saturable and nonsaturable processes are involved^[16]. Zn has been shown to be a potent inducer of its endogenous binding protein, metallothionein (MT)^[17,18], a low molecular weight, intracellular cysteine-rich, metal-binding protein that consists of 4 isoforms (MT-1 to MT-4), with MT-1 and MT-2 being the most widely expressed isoforms^[19]. MT is found mainly in the liver, kidneys, intestine and pancreas^[17]. MT synthesis is induced by a number of metals, cytokines and stress hormones as well as by a wide range of chemicals, many of which act indirectly *via* a stress or inflammatory response^[20,21].

Metal regulation of MT genes has been covered in several recent reviews^[22,23]. Briefly, the binding of Zn to the metal transcription factor-1 allows the protein to bind to metal response elements in the promoter region which, in turn, initiates MT-gene transcription. Functions of MT include protection from cell apoptosis, promotion of cell proliferation and differentiation, regulation of Zn pools in circulation and in cells, scavenging of free radicals and protection against toxicity of heavy metals^[17-19]. We hy-

pothesized that an increase in dietary Zn and a lack of MT-1 and MT-2 expression will alter small intestinal disaccharidases activity. Thus the aims of the present study were to investigate the effects of various concentrations of dietary Zn intake (2, 15, or 50 mg Zn/kg diet) and the lack of MT-1 and MT-2 expression on small intestinal morphology and activity of disaccharidases in mice. This is applicable to the young infant starting complementary feeding whether dietary Zn may aid in nutrient absorption.

MATERIALS AND METHODS

Animals

Twenty four MT wild-type (MT+/+) C57BL/6 mice were obtained from the University of Adelaide (Adelaide, South Australia) and 24 MT-1 and 2 null (MT-/-) mice were obtained from a breeding colony at the Children, Youth and Women's Health Service Animal Care Facility (North Adelaide, South Australia). MT-/- (mixed genetic background of OLA129 and C57BL6 strains) mice were F3 derivatives of the interbreeding of normal C57BL6 mice^[24].

At 3 wk old, mice were randomly allocated to be fed with either a 2, 15 or 50 mg Zn/kg diet (2 Zn, 15 Zn and 50 Zn) for 5 wk ($n = 8/\text{group/genotype}$) and body weight was recorded weekly. Mice were fed a casein-based diet^[25] supplemented with ZnSO₄ to 2, 15 or 50 mg Zn/kg. The casein-based diet contained (g/kg): cornflour starch, 514; casein, 180; sucrose, 152; wheat bran, 50; peanut oil, 50; D,L-methionine, 2.5; choline chloride, 1 and codliver oil, 4.4. The mineral profile (g/kg diet) was: KH₂PO₄, 17.155; CaCO₃, 14.645; NaCl, 12.530; MgSO₄ · 7H₂O, 4.99; FeC₆H₅O₇ · 5H₂O, 0.296; CaPO₄, 0.170; MnSO₄ · 4H₂O, 0.080; CuSO₄, 0.123; KI, 0.00025; (NH₄)₆Mo₇ · O₂₄ · 4H₂O, 0.00125; Na₂SeO₃, 0.00005. The vitamin profile (mg/kg diet) was: thiamine HCl, 70; riboflavin, 30; niacin (nicotinic acid), 50; pantothenic acid, 150; pyridoxal HCl, 15; hydroxycobalamin, 0.02; inositol, 400; p-aminobenzoic acid, 50; folic acid, 10; biotin, 0.4 and glucose, 225. For the purpose of this study we chose the 15 mg Zn/kg diet as the normal (control) diet and the 2 and 50 mg Zn/kg diet as the low and high Zn diet respectively. The Zn diets were given to the animals *ad libitum* and the Zn content of the diets was validated by atomic absorption spectrophotometry using a Perkin-Elmer 3030 (Überlingen, Germany).

Tissue collection

At the end of the experimental period, all mice were CO₂ asphyxiated and blood was withdrawn by cardiac puncture. The mice were then killed by cervical dislocation. The liver and gut were excised and the pancreas and mesentery removed. The gut was separated into stomach, small intestine, cecum and colon. The contents of the small intestine were flushed thoroughly with saline. The small intestine was then divided into the duodenum, from the gastro-duodenal junction to the ligament of Treitz, and into two segments of equal length comprising the jejunum, and ileum. A 4 cm segment of the duodenum, jejunum and ileum were excised for histological assess-

ment and disaccharidase activity analysis, respectively. The protocol adhered to the Australian Code of Practice for the Care and Use of Animals for Scientific Purposes and approval was obtained from the Animal Care and Ethics Committee of the Women's and Children's Hospital (South Australia).

Plasma Zn

Blood samples were placed in lithium heparin tubes to obtain plasma, which was stored at -20°C until analysis. Plasma samples were diluted (1:2) in 10% trichloroacetic acid (Sigma-Aldrich, Sydney Australia) and were analyzed for Zn concentration ($\mu\text{mol/L}$) by atomic absorption spectrophotometry using a Perkin-Elmer 3030 (Perkin-Elmer Pty Ltd, Uberlingen, Germany).

Histological assessment

Small intestinal segments of 2 cm were removed and fixed in 10% formalin overnight, processed and embedded in paraffin wax (cross section), from which 4 μm -thick small intestinal sections were cut using the RM2235 microtome (Leica, Germany) and mounted onto glass slides. Sections were dewaxed and stained with Lillie-Mayer's hematoxylin and eosin and coverslipped. On each section, approximately 40 crypt depths and villi heights (expressed as μm) were measured using the Eclipse50i light microscope (Nikon, Japan) and Image ProPlus 5.0 package (Media Cybernetics, USA).

Disaccharidase assays

Disaccharidase activities in intestinal segments were assessed using a microplate modification of the Dahlqvist^[26] assay in duplicates. Gut segments were homogenized in 10 mmol/L phosphate-buffered saline by Ultra-TurraxT25 homogenizer (Janke and Kunkel, Germany). Homogenates were centrifuged at 3500 rpm at 4°C for 10 min. The supernatant was then aliquoted and snap-frozen at -80°C for subsequent sucrase, maltase and lactase activity assays. Glucose standards (0, 1.25, 2.5, 5, 10, 20, 30 and 40 nmol/L) were prepared. Samples were diluted 1:20, 1:50 and 1:100 with 50 mmol/L phosphate buffer and then pipetted onto a 96-well plate. A solution of 0.2 mol/L sucrose, lactose or 0.004 mol/L maltose was added (50 μL /well) and the plate incubated at 37°C for 30 min. Tris-glucose oxidase was added to all wells and incubated at 37°C for another 30 min. Absorbance was determined using a Tecan spectrophotometer (Sunrise, Austria) set at 490 nm wavelength. Disaccharidase activities were analyzed using Table-Curve (Systat Software, USA) and results were expressed as μmol glucose/well/min/g of tissue.

Statistical analysis

Histological analysis data were not normally distributed therefore data were log transformed and are presented as geometric mean \pm SE of the mean. Disaccharidase activity data are expressed as mean \pm SE of the mean. All data were analyzed using two-way analysis of variance followed by Tukey's *post-hoc* test (SigmaStats3.0). The significance level was determined as $P < 0.05$.

Figure 1 Comparison of plasma zinc (mean \pm SE of the mean) of MT+/+ and MT-/- mice fed the 2, 15 and 50 mg/kg Zn diet for 5 wk ($n = 8/\text{group/genotype}$). ^a $P < 0.05$ vs MT+/+ mice fed the 2 mg/kg Zn diet. MT: Metallothionein.

RESULTS

Body weight and plasma Zn

There were no differences in body weights of both MT+/+ and MT-/- mice between the dietary Zn groups (data not shown). There were no differences in plasma Zn levels between MT+/+ and MT-/- mice when fed the 15 Zn or 50 Zn diet. However, there was a significant ($P < 0.05$) decrease (33%) in plasma Zn in MT-/- mice fed the 2 Zn diet compared with MT+/+ counterparts (Figure 1). There was an apparent trend of an increase in plasma Zn levels as the dietary Zn levels increased in MT-/- mice. Whereas in MT+/+ mice this was more tightly controlled with no difference in plasma Zn with increasing dietary Zn.

Small intestinal weight and length

An increase in dietary Zn did not change small intestinal weight between MT+/+ and MT-/- mice. However, there was a significant ($P < 0.05$) difference in small intestinal weight in MT-/- mice fed 2 Zn (0.74 ± 0.04 g) and 50 Zn (0.70 ± 0.03 g) compared with those fed the 15 Zn (0.59 ± 0.02 g). Interestingly, MT-/- mice had a significantly ($P < 0.05$) longer small intestine compared with MT+/+ mice, in particular in mice with the 2 Zn (29.8 ± 0.8 cm *vs* 25.7 ± 0.9 cm, respectively) and 50 Zn diets (29.1 ± 0.6 cm *vs* 26.8 ± 0.6 cm, respectively).

Villus height and crypt depth

Histological analysis (Tables 1 and 2) of the small intestine in MT+/+ and MT-/- mice showed that increasing dietary Zn concentrations did not alter villus height and crypt depth ($P > 0.05$). Differences in ileal villus height were insignificant irrespective of genotypes and dietary groups (Table 1). However, shorter villi were observed in the duodenum and jejunum of MT-/- mice fed with 15 Zn and/or 50 Zn diet(s) compared with MT+/+ mice (Table 1). Crypt depth was also significantly shorter in the duodenum (all dietary groups), jejunum (15 Zn and 50 Zn) and ileum (2 Zn) in MT-/- mice ($P < 0.05$) (Table 2).

Disaccharidase activities

MT-/- mice fed the 2 Zn diet had a significantly reduced

Table 1 Villus height (μm) in MT+/+ and MT-/- mice fed the 2, 15 or 50 mg/kg Zn diet for 5 wk

^a $P < 0.05$ vs MT-/- mice. Data are expressed as mean \pm SE of the mean ($n = 8$ /diet/genotype). MT: Metallothionein.

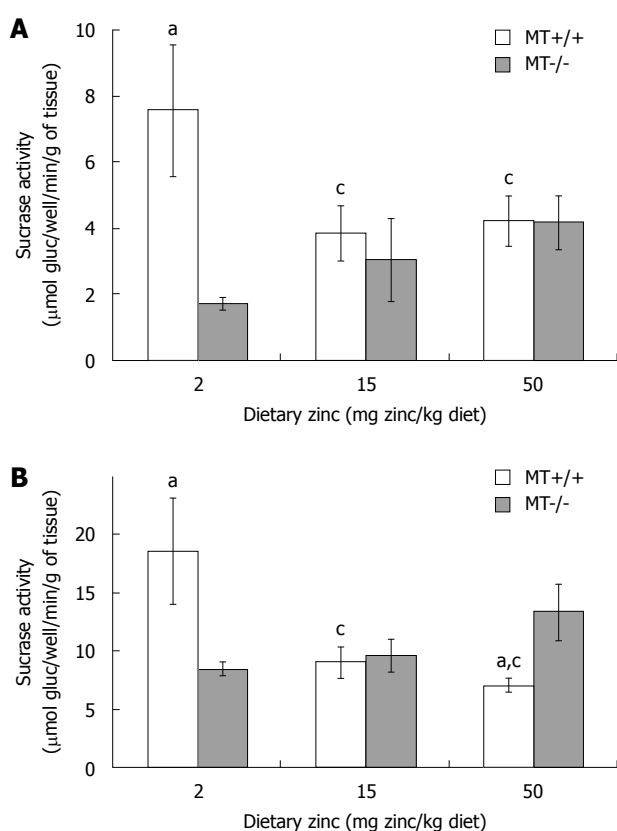

Figure 2 Comparison of sucrase activity in the duodenum (A) and jejunum (B) of MT+/+ and MT-/- mice fed the 2, 15 and 50 mg/kg Zn diet for 5 wk ($n = 8$ /group/genotype). ^a $P < 0.05$ vs MT-/- mice fed the 2 or 50 mg/kg Zn diet, respectively; ^c $P < 0.05$ vs MT+/+ mice fed the 2 mg/kg Zn diet. MT: Metallothionein.

duodenal and jejunal sucrase activity compared with MT+/+ mice (Figure 2). Interestingly, sucrase levels were significantly lowered in the jejunum of MT+/+ mice receiving 15 Zn and 50 Zn (by 12%) compared with 2 Zn (Figure 2B). MT+/+ mice fed with 50 Zn also showed a lower activity in the jejunum compared with MT-/- mice. Results in both figures showed a trend of a decrease in sucrase activity in MT+/+ mice and an increase in MT-/- mice as dietary Zn concentration increased ($P < 0.05$). No significant differences were obtained for the ileum regardless of dietary Zn and genotypes ($P > 0.05$).

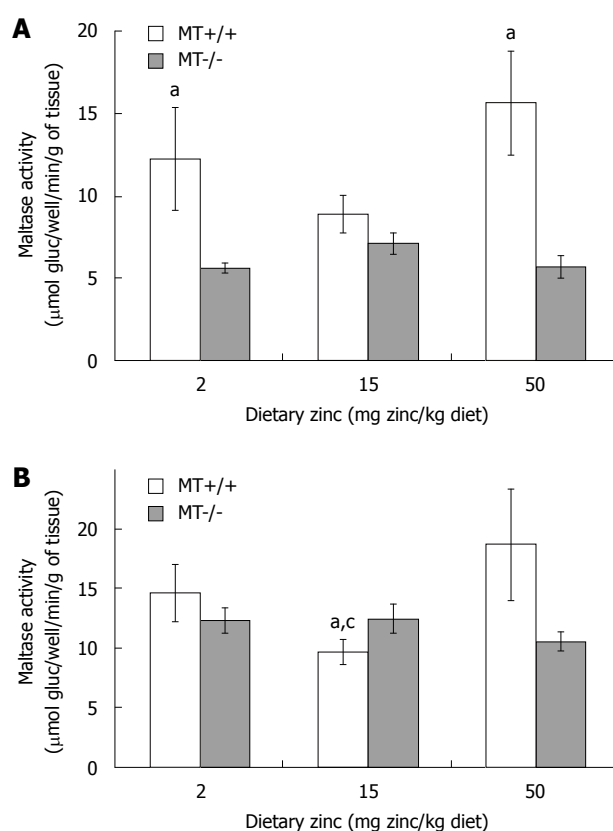

Figure 3 Comparison of maltase activity in the duodenum (A) and jejunum (B) of MT+/+ and MT-/- mice fed the 2, 15 and 50 mg/kg Zn diet for 5 wk ($n = 8$ /group/genotype). ^a $P < 0.05$ vs MT-/- mice fed the 2, 15 or 50 mg/kg Zn diet, respectively; ^c $P < 0.05$ vs MT+/+ mice fed the 50 mg/kg Zn diet. MT: Metallothionein.

Duodenal maltase activity of MT+/+ mice fed with 2 Zn and 50 Zn was 37% and 47% higher, respectively, than that of MT-/- mice receiving same levels of dietary Zn (Figure 3A). When dietary Zn intake was increased from 15 Zn to 50 Zn, MT+/+ mice exhibited a marked increase in jejunal maltase activity (Figure 3B). Significant differences were also observed between MT+/+ and MT-/- mice receiving 15 Zn ($P < 0.05$). No differences were seen in ileal maltase activity regardless of dietary Zn and genotypes ($P > 0.05$).

In MT+/+ mice, there was a trend of a decrease in

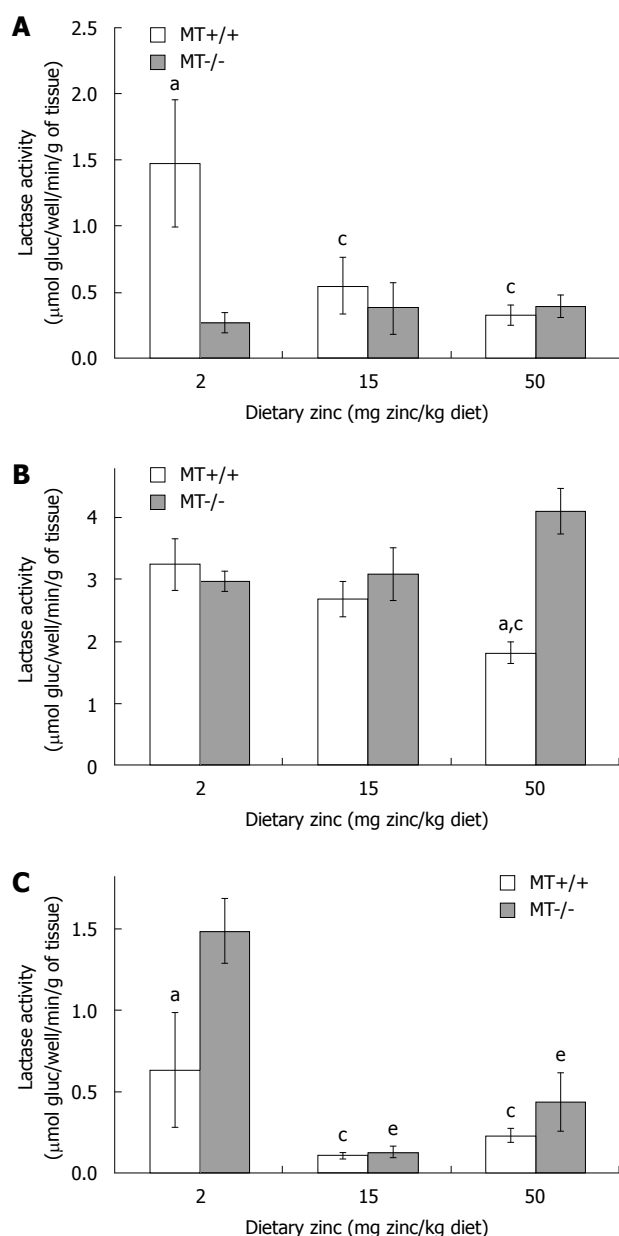

Figure 4 Comparison of lactase activity in the duodenum (A), jejunum (B) and ileum (C) of MT+/+ and MT-/- mice fed the 2, 15 and 50 mg/kg Zn diet for 5 wk ($n = 8/\text{group/genotype}$). ^a $P < 0.05$ vs MT-/- mice fed the 2 or 50 mg/kg Zn diet; ^c $P < 0.05$ vs MT+/+ mice fed the 2 mg/kg Zn diet; ^e $P < 0.05$ vs MT-/- mice fed the 2 mg/kg Zn diet. MT: Metallothionein.

lactase activity when the dietary Zn levels increased in different regions of the small intestine (Figure 4A-C). For example, MT+/+ mice receiving 50 Zn showed 28% reduction ($P < 0.05$) in jejunal lactase activity compared with the 2 Zn group (Figure 4B). Interestingly, in MT-/- mice, while the increase in dietary Zn levels did not appear to alter the lactase activity in the duodenum (Figure 4A) and in the jejunum (Figure 4B), the ileal activity was significantly lower in the 15 Zn and 50 Zn groups by 84% and 55%, respectively, compared with MT-/- mice fed with 2 Zn (Figure 4C). Genotype comparisons showed that, in MT-/- mice, the lactase activity in the duodenum was significantly lower when fed the low Zn diet (2 Zn, Figure 4A), but was significantly higher ($P < 0.05$) in the jejunum

when fed the high Zn diet (50 Zn, Figure 4B) and in the ileum when fed the low Zn diet (2 Zn, Figure 4C), compared with their MT+/+ counterparts.

DISCUSSION

The development profile of disaccharidase activity in rodents seems to be well correlated with the transition from milk to solid food consumption^[1]. Although it has been reported that dietary modification is associated with altered activity of the brush border disaccharidases^[6,8,27], the influence of dietary Zn levels and the interaction of dietary Zn with its endogenous binding protein MT on small intestinal maturation has been unclear. Thus, in the present study, we examined the effect of increasing dietary Zn concentration and the role of MT-1 and 2 gene knockout on morphological changes and disaccharidase levels in weanling mice. To our knowledge, this is the first study to assess Zn supplementation on small intestinal morphology in wild-type and MT-1 and 2 null mice.

The measurements of villus height and crypt depth provide an indication of the maturity and functional capacity of small intestinal enterocytes. In the present study, although we have shown that increasing dietary Zn intake did not appear to significantly increase growth of the small intestine morphologically, as demonstrated in the histological analysis of villus height and crypt depth, the MT+/+ mice fed the high Zn diet had a higher villus height in most of the regions of the small bowel. This is consistent with a previous study^[6], showing villus height in the jejunum of sows fed Zn was greater than those fed the control diet. Similar trends were observed in other studies showing that, although not significant, pigs supplemented with Zn tend to have an increased villus height: crypt depth ratio in the jejunum and higher goblet cell counts in the ileum^[5,28]. It has been speculated that the differences in the intestinal morphology of pigs are being masked because of deterioration in the mucosa immediately after weaning, a common phenomenon in weaning pigs. However, growth performance was improved by the addition of ZnO which responded linearly to incremental doses of Zn^[28]. In our current study, we further showed that the presence of MT markedly increases villus height and crypt depth in the small intestine, in particular in mice fed a high dietary Zn, and that crypt depth is generally greater in the wild-type mice than the null mice, suggesting the importance of MT- I and II in supporting optimal intestinal growth in response to dietary Zn supply.

Considering the role of Zn as a coenzyme for more than 300 enzymes particularly in RNA-DNA synthesis and cell proliferation^[11], these improvements in intestinal morphology may be explained by the beneficial effects of Zn on cell proliferation, differentiation, and protein synthesis^[29]. This is supported by the trend of increase in plasma Zn with increasing dietary Zn in the present study and is consistent with our previous study^[30]. In contrast, Zn deficiency has been shown to cause villus atrophy, elevated levels of mucosal cell apoptosis, ulceration, inflammation as well as reduction in crypts proliferation^[8].

Furthermore, it has been reported that Zn deficiency may impair carbohydrate digestion, as reflected in decreased disaccharidase activities, and may contribute to poor nutrition^[10]. The results of these findings suggest that dietary addition of Zn in the normal diet of mice is vital for small intestinal mucosal integrity as well as improved small intestinal morphology.

In general, intestinal disaccharidase activities are lower in MT^{-/-} compared with MT^{+/+} mice particularly at the low dietary Zn concentration (except for jejunal sucrase and lactase activity in the ileum), indicating that the combination of low dietary Zn and the lack of MT expression have a negative impact on the activity of disaccharidases in the small intestine. MT is a binding protein that regulates the quantity of Zn absorbed by binding Zn within the mucosal cells, thereby regulating its transfer across the basolateral membrane into the circulation and deposition in the liver^[17,31]. We have shown that MT^{-/-} mice accumulate less Zn^[25], whereas transgenic mice accumulate more^[19]. This is consistent with our data where MT^{-/-} mice have lowered plasma Zn compared with MT^{+/+} mice, in particular with low dietary Zn intake, suggesting that the presence of MT- I and II plays a role in maintaining Zn homeostasis at low dietary Zn intake. It is possible that the low Zn status may be a contributing factor to decreased levels of disaccharidase activities in MT^{-/-} mice. This is consistent with other studies^[7,9,10,32] which reported that Zn deficiency causes marked reductions in intestinal mucosal protein content and disaccharidase activity. Furthermore, MT has been shown to have metallo-regulatory functions in cellular growth and differentiation^[33], and the lack of MT- I and MT- II expression may also be another contributing factor to the lower levels of disaccharidase activities in MT^{-/-} mice.

Interestingly, increasing dietary Zn in the diet did not have a significant increase on intestinal disaccharidase activity in the wild-type mice. This is consistent with previous studies^[7,34] where Zn supplementation has little or no effect on brush border disaccharidases. We have shown that increasing the dietary Zn concentration to 50 mg Zn/kg diet increases maltase activity only. It is possible that the highest dietary Zn concentration in the present study may be too low to induce disaccharidase activity.

MT has long been implicated in the regulation of absorption and excretion of Zn by the intestine^[31,35] and the presence of MT has been shown to restrict Zn absorption at high Zn concentrations^[12]. It has been argued that MT limits Zn absorption by sequestering it in the intestinal wall, thereby transiently reducing its absorption and favoring Zn transfer back into the gut lumen^[12,14]. Furthermore, it has been shown that at high Zn concentration, MT^{-/-} mice absorb Zn more readily and retain more Zn in the intestinal wall compared to MT-transgenic mice^[36]. The high Zn intakes may explain why MT^{-/-} mice have significantly greater jejunal sucrase and lactase activities than MT^{+/+} mice by inducing small intestinal disaccharidase activities. These adaptive mechanisms play a central role in nutrient processing and absorption which maintain normal homeostasis in these mice. This is also consistent with

MT^{-/-} mice having a heavier and longer small intestine, an adaptive mechanism to absorb more Zn to maintain Zn homeostasis when dietary Zn is high. These changes in intestinal disaccharidase activity in response to the interaction of dietary Zn and endogenous MT remain to be investigated. It is possible that intestinal disaccharidase activity and MT expression may not be related. To our knowledge this is the first study to report intestinal brush border enzyme activities in MT^{-/-} mice. Thus, the role of MT in the expression of disaccharidase activities, particularly in MT^{-/-} mice, warrants further investigation.

In conclusion, limiting the level of dietary Zn in the diet does not affect the activity of small intestinal brush border disaccharidases in wild-type mice. However, the presence of MT enhances the morphological and functional development of the gastrointestinal tract. Thus, simple Zn supplementation may be insufficient to drive growth and development of the small intestine. In light of the present findings, future studies investigating the close interaction between Zn and MT on gut maturation and development are warranted.

COMMENTS

Background

The development of brush border enzymes and gut maturation is associated with complementary feeding. However, it is unclear whether the activity of the brush border disaccharidases is influenced by dietary zinc levels and the presence of the endogenous binding protein metallothionein.

Research frontiers

The role of metallothionein on gut maturation and development, in particular, in small intestinal morphology and brush border enzymes is an important area of research in the future.

Innovations and breakthroughs

The present study demonstrated that the presence of metallothionein, a zinc binding protein, may have a positive impact on villous morphology and digestive and absorptive function of the small intestine.

Applications

Future studies investigating the role of different levels of metallothionein in the gut on small intestinal morphology and the activities of brush border enzymes which may elucidate the underlying mechanism of metallothionein in altering intestinal physiology, villous architecture, and enzyme activities.

Terminology

Disaccharidases - enzymes located on the brush border and which are essential for digestion and absorption.

Peer review

Tran *et al* report on a basic research study in metallothionein wild-type and knockout mice testing the influence of different amounts of alimentary zinc on small intestinal disaccharidases. The paper is well written and the point is clearly made.

biliary cystadenoma in 8 patients and cystadenocarcinoma in 1 patient. All symptoms resolved after surgery. There has been no recurrence during a median (range) 31 (7-72) mo of follow up.

CONCLUSION: In spite of the improvement in imaging modalities and increasing recognition of biliary cystadenoma and cystadenocarcinoma, accurate preoperative diagnosis may be difficult. Complete surgical removal (liver resection or enucleation) of these lesions yields satisfying long-term results.

Abstract

AIM: To investigate the eligible management of the cystic neoplasms of the liver.

METHODS: The charts of 9 patients who underwent surgery for intrahepatic biliary cystic liver neoplasms between 2003 and 2008 were reviewed retrospectively. Informed consent was obtained from the patients and approval was obtained from the designated review board of the institution.

RESULTS: All patients were female with a median (range) age of 49 (27-60 years). The most frequent symptom was abdominal pain in 6 of the patients. Four patients had undergone previous laparotomy (with other diagnoses) which resulted in incomplete surgery or recurrences. Liver resection ($n = 6$) or enucleation ($n = 3$) was performed. The final diagnosis was intrahepatic

INTRODUCTION

The first account of an intrahepatic biliary cystadenoma (IHBCA) was published in 1887 and the first resection was performed in 1892^[1]. The tumor was redefined by Edmondson in 1958 as a multilocular lesion with an ovarian-like stroma^[2]. However, in subsequent years, unilocular cystadenomas as well as cystadenomas without an ovarian-like stroma have been reported. Only 38 cases could be included in an extensive review in 1977^[3]. With

the widespread availability of modern imaging techniques and developments in safe liver surgery, the number of reported cases increased to approximately 150 by 1994 (approximately 100 patients in the 1994 review by Devaney *et al.*^[2], and other earlier papers^[4-6] not included in the review).

Biliary cystadenocarcinoma was first described in 1943^[7]; a review published in 1998 included 113 patients^[8]. Devaney *et al.*^[2] proposed three subsets of cystadenocarcinoma based on the pathology material submitted to their institutional laboratories for primary diagnosis or consultation: (1) cystadenocarcinoma originating from a benign cystadenoma with ovarian-like stroma (occurs exclusively in women); (2) *de novo* cystadenocarcinoma occurring almost only in men; and (3) cystadenocarcinoma that occurs in women but does not contain an ovarian-like stroma.

The long list of possibilities in the differential diagnosis includes simple cysts, parasitic cysts, degenerated metastatic tumors, mucin-producing metastatic tumors, congenital cystic dilation, cystic hemangioma, lymphangioma, hepatic foregut cyst, mesenchymal hamartoma and teratoma^[2,9-11]. Imaging techniques are the primary diagnostic tools. However, the relative scarcity of the cystadenomas and cystadenocarcinomas diagnosed by different techniques and reported over a longer period than a century renders making definite statements on pathognomonic findings difficult. Also, the high frequency of simple cysts in patients older than 40 years of age (14%-24% depending on age) greatly complicates the problem in patients with unilocular cystadenomas^[12]. It is possible that some IHBCAs are misdiagnosed as simple liver cysts.

IHBCA is a premalignant lesion; intrahepatic biliary cystadenocarcinoma (IHBCAC) cannot be reliably differentiated from IHBCA by imaging or preoperative aspiration cytology. Therefore both types of lesion should be excised^[4,10,11,13-17].

In this article, we communicate our institutional experience on IHBCA and IHBCAC and review the related surgical literature.

MATERIALS AND METHODS

The charts of patients examined for cystic liver lesions between 2003 and 2008 were studied retrospectively.

The diagnosis of IHBCA was made by radiologic criteria (ultrasonography with computed tomography or magnetic resonance imaging). Important radiologic features were^[18-23]: (1) Presence of a multilocular or unilocular mass with a well-defined capsule; and (2) Presence of one or more of the following structures exhibiting contrast enhancement: papillary projections, internal septations with nodular areas, wall thickness irregularities and mural nodules.

Because the necessity and utility of performing cyst fluid aspiration for tumor marker [carcinoembryonic antigen (CEA), carbohydrate antigen 19-9 (CA 19-9)] measurements and cytologic examination have been controversial issues until recently, the decisions in individual patients were left to the discretion of the attending surgeon.

Surgical intervention was performed if radiologic findings suggested an IHBCA or IHBCAC. All specimens were sent for histopathological examination. Frozen section was performed after enucleation procedures without any diagnosis of malignancy.

All patients were followed by computed tomography for possible recurrences every 6 mo in the first two post-operative years and then annually.

RESULTS

In the study period, 210 patients with cystic liver lesions were examined at our unit; 168 patients had parasitic cysts; 33 of the 42 nonparasitic cystic lesions were simple hepatic cysts. The final diagnoses in the remaining patients were IHBCA ($n = 8$) and IHBCAC ($n = 1$). These nine patients were all female with a median (range) age of 49 (27-60) years.

The most common symptom was abdominal pain observed in 6 patients. Three patients were asymptomatic; cystic liver masses had been discovered incidentally during radiological examinations for other purposes.

Four patients had undergone previous laparotomy (with other diagnoses) which resulted in incomplete surgery or recurrences. Two of these patients were operated on with the preoperative diagnosis of cystic echinococcal disease (one at our hospital). At surgery, the cystic lesions were misdiagnosed as simple liver cysts and unroofing was performed. However, histopathologic examination showed IHBCA in one and IHBCAC in the other. The remnant tumors in both patients were resected with appropriate surgical margins. Another patient was operated on with the diagnosis of echinococcal cyst at another hospital in the third month of her pregnancy. Operative findings did not confirm the preoperative diagnosis; a partial resection was performed and the histopathological diagnosis was IHBCA. In the course of the pregnancy, the size of the remnant cystic lesion increased from 12 to 27 cm in diameter. After a successful delivery, she was referred to our institution for hepatic surgery. A 58 year-old woman was operated on for cholecystolithiasis at another hospital; however, there was a suspicion of a malignant cystic lesion in segment V of the liver, the operation was stopped and she was referred to our hospital.

None of the patients had clinical or biochemical findings of cholestasis. Serum CEA levels were within normal range in all patients; serum CA 19-9 levels were within the normal range in 7 patients (including the single patient with IHBCAC) and were increased in 2 other patients (99 and 77 U/mL respectively; range 0-34 U/mL).

Preoperative percutaneous cyst fluid aspiration was performed in 4 patients. CA 19-9 levels were markedly increased in all samples (above 10000 U/mL; normal range for serum: 0-34 U/mL) and CEA levels were increased in 2 (15 and 18 ng/mL, respectively; normal range for serum: 0-4 ng/mL). Cyst fluid samples for postoperative examination were obtained intraoperatively in 4 other patients; both CA 19-9 (10000 U/mL and 379 U/mL) and CEA (27 U/mL and 651 U/mL respectively) were increased in 2 patients and within normal range in the other 2.

CEA and CA 19-9 measurement was not performed in the patient with cystadenocarcinoma.

Cytologic examination results were nondiagnostic, including the single patient with cystadenocarcinoma.

Preoperative evaluation of the period is the same as hepatobiliary operation's. The operative technique was determined according to the location of tumor in the liver and proximity to major vascular structures. Six patients were treated by hepatic resection: 4 by major hepatectomies (1 by right hepatic lobectomy, 1 by left hepatectomy, 1 by left lateral sectionectomy, and 1 by central bisegmentectomy) and 2 by nonanatomic resections. In 3 patients, the tumor was removed by enucleation. Enucleation was performed as in hemangiomas as described by Alper *et al*^[24]. Frozen section was performed routinely after enucleation procedure and no invasive malignancy was diagnosed in these 3 patients. Therefore, no additional hepatic resection was performed.

Perioperative findings, length of the operation time and blood loss were uneventful in 9 patients.

There was no major complication and mortality.

Histopathologic examination revealed IHBCA in 8 patients and IHBCAC in 1. An ovarian-like mesenchymal stroma was observed in 8 patients including the patient with IHBCAC.

All patients were followed up for median (range) 31 (7-72) mo without recurrence.

DISCUSSION

Although the incidence of IHBCA and IHBCAC has been reported to be less than 5% of all hepatic cystic lesions^[25], this figure, which is quoted in other papers^[11,26] should be interpreted with caution since the frequency of simple cysts in patients older than 40 years of age varies between 14% and 24%^[12]. The true incidences of both lesions are probably much lower since the largest surgical series reported includes 34 IHBCAs^[13] and 6 IHBCACs^[6]. The controversy in the literature stems from the lack of established criteria for preoperative diagnosis especially in the case of unilocular IHBCAs^[4,10,27].

In spite of the improvements in imaging techniques, the differential diagnosis of simple hepatic cysts and IHBCAs is still problematic. In a Cleveland Clinic series, 10 of 18 patients underwent incorrect and unnecessary procedures such as percutaneous aspiration, ethanol injection, unroofing and omentoplasty^[16]. In 1 of the patients in the present series, a patient with right upper abdominal quadrant pain was diagnosed as having cholecystolithiasis and a simple hepatic cyst in segment V of the liver. However, during surgery, the surgeon suspected the possibility of a cystic tumor and terminated the operation. Although radiologic features such as papillary projections, internal septations with nodular areas, wall thickness irregularities and mural nodules suggest the possibility of a IHBCA^[28,29], all of these except papillary projections may be observed in simple cysts as well albeit at a lower frequency^[29].

Liver echinococcal cysts pose another diagnostic problem in endemic countries^[30]. In our series, 3 cases under-

went inappropriate initial procedures with the misdiagnosis of hydatid disease. Although that absence of a germinative membrane and daughter cysts may have alerted the surgeons intraoperatively, their lack of experience precluded further interventions in the first operation. In 1 of these patients, the incidental observation of the natural history of an IHBCA under the hormonal milieu of pregnancy is interesting. The patient underwent unroofing of a 12 cm cyst at the 3rd month of pregnancy; the lesion size increased to 27 cm in a matter of 6 mo. This is in accordance with the female hormone-dependency of these lesions, previous observations in pregnant patients^[11,25,31-34] and possible association with oral contraceptive use^[34].

Although serum levels of CA19-9 and CEA may be increased in some patients^[26,27,35-37], this is not a universal finding^[10]. In the present series serum CA 19-9 levels were high in 2 patients (the single patient with IHBCAC not among them); all serum CEA levels were within the normal range.

Levels of cystic fluid CA 19-9 have been proposed "as a diagnostic help in liver cysts of unknown nature"^[38] and some centers incorporated cyst fluid tumor marker (CA19-9 and CEA) measurements into their management algorithm^[13]. However, definite diagnostic criteria for CA19-9 and CEA levels have not been established because the published data were largely limited to the reports on increased levels in small numbers of IHBCA patients without statistically robust comparison with levels in simple cysts. Consequently, the same problem occurred in the differentiation of IHBCAs and IHBCACs^[26,35,36,38-40].

In the widely cited important contribution by Koffron *et al*^[13], the cyst fluid CEA and CA 19-9 levels of 22 IHBCA patients were compared with the levels in 4 patients with simple cysts and 4 patients with polycystic liver disease. All 8 control cases had normal levels; in contrast CA19-9 was markedly increased in all IHBCA patients; there were mild to marked increases in CEA levels as well^[13]. This paper was given serious consideration by some of our attending physicians who experienced dilemmas in some patients. For example, a 75-year-old woman underwent complete aspiration of two hepatic cysts in the right lobe; the CA 19-9 levels were above 10000 U/mL whereas CEA levels were within the normal range. The presumptive diagnosis at that time was an IHBCA; surgery was not offered due to the comorbid illnesses. That she has not had a recurrence for 2.5 years suggests that the lesions might be simple cysts rather than cystadenomas and an operation would have been unnecessary.

Two important papers published in 2009 shed more light to this issue. Waanders *et al*^[41] conducted cyst fluid CA 19-9 measurements in 109 polycystic liver disease patients and 24 simple cyst patients and detected "extremely high" levels in both groups. Although the absence of pathologic confirmation is a potential weakness in interpretation (i.e. some of the patients may have had unilocular cystadenomas), the universally increased levels in all 24 patients are strong evidence for increased levels in simple cysts. Although the number of patients in the other paper^[29] is smaller (14 patients with hepatic simple cysts), a major

strength is that all patients had pathologically confirmed diagnoses. Both normal and dramatically increased CA 19-9 and CEA levels were detected in simple cyst patients; there were no significant differences between the simple cyst patients ($n = 14$) and IHBCA patients ($n = 17$). These recent data suggest that cyst fluid tumor marker levels do not provide additional information in patients with suspected IHBCA.

Cyst fluid cytology has not been found to be useful in the differentiation of IHBCA and IHBCAC^[33,42] because demonstration of malignant cells is rare, i.e. a negative cytology result will give a false sense of security. Needle biopsy of papillary projections or mural nodules may be more useful for this purpose^[13]; however this is generally unnecessary since there is a surgical indication for IHBCA and definite preoperative diagnosis of IHBCAC is not strictly required^[8]. Since there is a risk of tumor cell implantation due to the aspiration procedure^[42], routine aspiration of hepatic cystic lesions should be avoided.

There is a general consensus that an IHBCA should be removed completely either by enucleation or liver resection because lesser procedures are associated with recurrence rates as high as 90%^[4,40,43,44]. Satisfactory results with enucleation using the dissection plane between tumor and liver tissue have been reported^[4,13,45]. Enucleation, which allows maximum preservation of hepatic parenchyma, is an appropriate procedure for benign lesions. One concern is that the IHBCA may harbor a malignancy which may be missed by preoperative imaging. In such instances, enucleation would be inappropriate even in patients with noninvasive carcinoma^[2]; therefore hepatectomy with negative surgical margins is preferred. Although frozen section examination may sometimes yield a false-negative result for cancer^[42], it is still wise to perform it on samples from solid parts of enucleated tumors^[13] because resection of the adjacent parenchyma may be conducted in patients with carcinoma. Some groups advocate routine resection for these lesions^[27]. Left hepatectomy was performed in this series for the only patient with IHBCAC in whom the tumor was located at median and lateral sections. Two patients with lesions in lateral and 1 patient in posterior sections were treated by enucleation. Frozen section was performed after enucleations and no invasive malignancy was detected. Major hepatectomies had to be performed in 3 IHBCA patients with lesions very close to vascular structures. Nonanatomic resections were carried out in 2 cases.

In conclusion, with the improvement and widespread availability of radiologic modalities, cystic biliary liver neoplasms are being detected more frequently. However, the differential diagnosis from simple cysts and in endemic countries, from echinococcal cysts, is still challenging. Although there are no pathognomonic findings except for papillary projections (not present in many cases), radiological imaging finding such solid parts, papillary projections and septation or mural nodules in cystic lesion are the basis of preoperative diagnosis. Cyst fluid examination with cytology and CEA and CA 19-9 level measurement do not provide additional information. Partial resections are inappropriate. The treatment of choice is total exci-

sion either enucleation of IHBCAs and formal resection for IHBCACs and suspicious lesions.

COMMENTS

Background

Biliary cystadenomas and cystadenocarcinomas are both rare neoplasms of the biliary system. They may be easily misdiagnosed and operated on as simple cysts or hydatid cysts. Inappropriate drainage and unroofing operations result in recurrences. Reliable preoperative differentiation of the premalignant form-cystadenoma- and the malignant form cystadenocarcinoma is difficult except in obviously invasive lesions.

Research frontiers

Contrary to the previous popular opinion, recent data suggest that cyst fluid tumor marker levels do not provide additional information in patients with suspected intrahepatic biliary cystadenoma. Also, cyst fluid cytology has not been found to be useful in the differentiation of intrahepatic biliary cystadenoma and intrahepatic biliary cystadenocarcinoma, because demonstration of malignant cells is rare, i.e. a negative cytology result will give a false sense of security. Reliable techniques should be developed for reliable preoperative differential diagnosis of simple hepatic cysts, biliary cystadenomas and cystadenocarcinomas.

Innovations and breakthroughs

Surgical removal of the whole cyst with negative resection margins is recommended by many authors in order to avoid recurrences. In some cases, this is impossible because of the proximity to the vascular structures and importantly, aggressive surgery is unnecessary for a benign lesion. In three patients, the authors performed enucleation due to proximity to the vascular structures; frozen section revealed no malignancy. These patients have experienced no recurrence.

Applications

The treatment of choice is total excision; either enucleation of intrahepatic biliary cystadenomas and formal resection for intrahepatic biliary cystadenocarcinomas and suspicious lesions. Frozen section should be routine after enucleation.

Peer review

It's an interesting review of a very rare neoplasm of the biliary system.

CONCLUSION: This series supports the concept of delayed single-stage open pancreatic necrosectomy for IPN. Advances in critical care, antibiotics and interventional radiology have played complementary role in improving the outcomes.

Abstract

AIM: To analyze outcomes of delayed single-stage necrosectomy after early conservative management of patients with infected pancreatic necrosis (IPN) associated with severe acute pancreatitis (SAP).

METHODS: Between January 1998 and December 2009, data from patients with SAP who developed IPN and were managed by pancreatic necrosectomy were analyzed.

RESULTS: Fifty-nine of 61 pancreatic necrosectomies were performed by open surgery and 2 laparoscopically. In 55 patients, single-stage necrosectomy could be performed (90.2%). Patients underwent surgery at a median of 29 d (range 13-46 d) after diagnosis of acute pancreatitis. Sepsis and multiple organ failure accounted for the 9.8% mortality rate. Pancreatic fistulae (50.8%) predominantly accounted for the morbidity. The median hospital stay was 23 d, and the median interval for return to regular activities was 110 d.

INTRODUCTION

Severe acute pancreatitis (SAP) is a disease with high morbidity and mortality^[1,2]. In the absence of specific effective therapy, management revolves around supportive care^[3,4].

While the overall reported mortality of acute pancreatitis (AP) varies between 5% and 12%^[2,5], SAP, which comprises around 10%-20% of AP, continues to have a high mortality rate of around 25%^[6,7] due to organ failure and sepsis arising from infected pancreatic necrosis (IPN).

Management of IPN has been widely studied over the last few decades^[6,8-20]. Data on indications, timing and technique of debridement for IPN are varied. However, while recent reports reflect the common theme of delayed surgery in IPN^[21], the ideal debridement technique continues to be debated^[6,12,15].

Reports regarding minimally invasive surgery for IPN are now being published^[22-25]. Thus, if we are to develop

evidence-based guidelines for the management of IPN, rather than comparing outcomes with the relatively higher mortality encountered in some reports published a few decades ago, a more balanced comparison should particularly include results from larger series, and include some of the more recent series in which surgery for IPN has been complemented by advances in critical care, interventional radiology and broader spectrum antibiotics.

We have been performing open necrosectomy in a uniform manner for the last 10 years with conventional abdominal drainage without post-operative peritoneal lavage.

The purpose of our study was to analyze the feasibility and outcome of performing open necrosectomy for IPN in a delayed fashion.

MATERIALS AND METHODS

During the time period between January 1998 and December 2009, patients with SAP who developed IPN and were referred to the authors' center for surgical management were analyzed for this report.

At admission, patients were scored for severity, based on the APACHE II scoring system^[1,26], and were managed with resuscitation and intensive (supportive) care strategies. SAP was defined clinically by the presence of associated organ failure and/or local complications such as necrosis, abscess, or pseudocyst^[27]. In addition, the patients were also defined as having SAP if the APACHE II score was ≥ 9 .
