Abstract

Peritoneal adhesions represent an important clinical challenge in gastrointestinal surgery. Peritoneal adhesions are a consequence of peritoneal irritation by infection or surgical trauma, and may be considered as the pathological part of healing following any peritoneal injury, particularly due to abdominal surgery. The balance between fibrin deposition and degradation is critical in determining normal peritoneal healing or adhesion formation. Postoperative peritoneal adhesions are a major cause of morbidity resulting in multiple complications, many of which may manifest several years after the initial surgical procedure. In addition to acute small bowel obstruction, peritoneal adhesions may cause pelvic or abdominal pain, and infertility. In this paper, the authors reviewed the epidemiology, pathogenesis and various prevention strategies of adhesion formation, using Medline and PubMed search. Several preventive agents against postoperative peritoneal adhesions have been investigated. Their role aims in activating fibrinolysis, hampering coagulation, diminishing the inflammatory response, inhibiting collagen synthesis or creating a barrier between adjacent wound surfaces. Their results are encouraging but most of them are contradictory and achieved mostly in animal model. Until additional findings from future clinical researches, only a meticulous surgery can be recommended to reduce unnecessary morbidity and mortality rates from these untoward effects of surgery. In the current state of knowledge, pre-clinical or clinical studies are still necessary to evaluate the effectiveness of the several proposed prevention strategies of postoperative peritoneal adhesions.

INTRODUCTION

Peritoneal adhesions represent an important clinical challenge in gastrointestinal surgery. Peritoneal adhesions are a consequence of peritoneal irritation by infection or surgical trauma. They are a major cause of morbidity, resulting in multiple complications, many of which may manifest several years after the initial surgical procedure[1,2].

Development of peritoneal adhesions has been studied extensively, but to date, there has been no definitive strategy to prevent their formation, as controversies concerning the effectiveness of available preventive agents still exist. In addition, most of the available clinical literature concern gynecological patients; for patients undergoing general and/or abdominal surgery, no recommendations or guidelines exist[3]. The aim of this review is to present the epidemiology, pathogenesis and various prevention strategies of adhesion formation. We performed a literature search for this review in Medline and PubMed, using the key words: "adhesions", "intraperitoneal adhesions", "intra-abdominal adhesions", "adhesion reduction", "adhesion prevention", "adhesion formation", "adhesion pathophysiology". We also reviewed the reference lists in all articles retrieved in the search, as well as those of major texts regarding peritoneal adhesion formation. Both clinical and experimental studies upon adhesion formation were retained. There was no restriction regarding publication language.

Definition, epidemiology and consequences of peritoneal adhesions

Peritoneal adhesions are pathological bonds usually between omentum, loops of bowel and the abdominal wall. These bonds may be a thin film of connective tissue, a thick fibrous bridge containing blood vessels and nerve tissue, or a direct contact between two organ surfaces[4]. According to their etiology, peritoneal adhesions may be classified as congenital or acquired, which can be postinflammatory or postoperative (the most frequent)[5]. Among postoperative adhesion formation, three processes may be distinguished: *adhesion formation* (adhesions formed at operative sites); *de novo adhesion formation* (adhesions formed at non-operative sites); and *adhesion reformation* (adhesions formed after the lysis of previous adhesions)[6] . Diamond *et al*[7] have distinguished type 1 and type 2 formation of postoperative peritoneal adhesions. Type 1 or *de novo* adhesion formation concerns adhesions formed at sites that did not have previous adhesions, including type 1A (no previous operative procedure at the site of adhesions) and type 1B (previous operative procedures at the site of adhesions). Type 2 involves adhesion reformation, with two separate subtypes: type 2A (no operative procedure at the site of adhesions besides adhesiolysis) and type 2B (other operative procedures at the site of adhesions besides adhesiolysis)[7].

Peritoneal adhesions are mostly induced by surgical procedures in the peritoneal cavity, and their prevalence after major abdominal procedures has been evaluated at 63%-97%[8,9]. Overall, approximately one-third of patients who underwent open abdominal or pelvic surgery were readmitted an average of two times over the subsequent 10 years for conditions directly or possibly related to adhesions, or for further surgery that could potentially be complicated by adhesions; > 20% of all such readmissions occurred during the first year after initial surgery, and 4.5% of readmissions were for adhesive small bowel obstruction (ASBO)[1,10-13]. Colorectal surgery has proved to be the most important type of surgery that may cause intra-abdominal adhesions[14]. This surgery has the highest total number of inpatient episodes, inpatient days, operating time, theater time, and costs due to peritoneal adhesion-related intestinal obstruction[14]. Among open gynecological procedures, ovarian surgery had the highest rate of readmissions directly related to adhesions (7.5/100 initial operations)[13].

Small bowel obstructions (SBO) is the most common complication of peritoneal adhesions[1,2,8,9]. At Westminster Hospital (London, United Kingdom), intestinal obstruction accounted for 0.9% of all admissions, 3.3% of major laparotomies, and 28.8% of cases of large or SBO over 24 years[5]. A 1992 British survey has reported an annual total of 12 000-14 400 cases of adhesive intestinal obstruction. Barmparas *et al*[15] have studied the incidence and risk factors for ASBO following laparotomy. The overall incidence of ASBO was 4.6% and the risk of ASBO was highly influenced by the type of procedure, with ileal pouch-anal anastomosis being associated with the highest incidence of SBO[15]. In 1988 in the United States, admissions for adhesiolysis accounted for nearly 950 000 d of inpatient care[5]. All these studies have demonstrated that ASBO is a significant health issue both in the developed and developing world. However, ASBO risk factors, such as the type of past surgical procedure, the site of adhesions, as well as the timing and recurrence rate of adhesive obstruction, remain unpredictable or poorly understood[5].

In addition to ASBO, peritoneal adhesions may cause pelvic or abdominal pain, and infertility[1,2,16]. Peritoneal adhesions may also prolong the time needed to gain access to the abdominal cavity at subsequent surgery[17,18], and may increase the risk of bowel injury during subsequent surgery[19]. Controversy remains on the role of peritoneal adhesions on abdominal pain. Adhesions have been implicated as a significant cause of chronic pelvic pain, and their surgical lysis has been proposed as the therapeutic modality of choice[20,21]. However, chronic pelvic pain is one of most common gynecological complaints and yet remains an enigma. A comparison of chronic pelvic pain patients and asymptomatic infertility patients has not revealed a significant difference in the density or the location of adhesions[22]. Thus, it is possible that a common mechanism for pelvic pain exists and that adhesions are only associated features. Bradykinin, histamine and other autocoids are able to stimulate pain receptors. For Rapkin *et al*[22], these findings question the role of pelvic adhesions as a cause of chronic pelvic pain. According to other authors, although adhesions are thought to cause pain indirectly by restricting organ motion, thus stretching and pulling smooth muscle of adjacent viscera or the abdominal wall, adhesions themselves are capable of generating pain stimuli. Sulaiman *et al*[23] have studied the distribution, location, size and type of nerve fibers present in human peritoneal adhesions, associated or not with chronic pelvic pain. They have found that nerve fibers,

identified histologically, ultrastructurally, and immunohistochemically, were present in all examined peritoneal adhesions. Furthermore, fibers expressing the sensory neuronal markers calcitonin gene-related protein and substance P were present in all adhesions irrespective of reports of chronic abdominopelvic pain. That study has suggested that these structures may be capable of conducting pain after appropriate stimulation, and peritoneal adhesions are implicated as a cause of chronic abdominopelvic pain. In addition, many patients are relieved of their symptoms after adhesiolysis[23].

As consequence, peritoneal adhesions have a significant economic impact. Their direct costs in Sweden can be estimated to be $13 million annually[24]. It has been estimated that in the United States, there are 117 hospitalizations for adhesion-related problems per 100 000 people, and the total cost for hospital and surgical expenditure is about $1.3 billion[25]. In some European countries, the direct medical costs for adhesion-related problems are more than the surgical expenditure for gastric cancer and almost as much as for rectal cancer[3,26,27]. Indeed, postoperative adhesions have a profound economic impact, including the surgical procedure itself, hospitalization, recuperation and lost productivity[25]. During 1988, excluding patient and indirect costs, hospitalization in the United States, accounting for 948 727 d of inpatient care, was responsible for an estimated $1179.9 million in expenditure, of which $925 million was associated with hospital costs and $254.9 million with surgeons' fees[25]. The study of Ray *et al*[28] has demonstrated substantial costs associated with surgical procedures and hospitalization for adhesiolysis. During 1996, the total annual cost of adhesions management exceeded $2 billion, excluding recuperation and lost productivity[28]. Hospitalization for adhesiolysis alone cost > $700 million. Furthermore, > 300 000 patients are estimated to undergo surgery to treat adhesion-induced SBO in the United States annually[25]. Thus, developing effective strategies for adhesion prevention may help to reduce adhesions management costs and unnecessary morbidity and mortality rates.

Postoperative peritoneal adhesion pathophysiology

The first peritoneal adhesions were described at postmortem examination of a patient with peritoneal tuberculosis in 1836. To explain this finding, it was suggested in 1849 that coagulated lymphatic vessels may turn into fibrinous adhesions[29,30]. Until now, the exact pathophysiology of peritoneal adhesions has remained elusive. Despite many clinical and experimental studies, peritoneal adhesions pathophysiology remains controversial.

Aside from the normal peritoneal regeneration, the process of postoperative peritoneal adhesion formation may be considered as the pathological part of healing following any peritoneal injury, particularly due to abdominal surgery[5,31]. The balance between fibrin deposition and degradation is crucial in determining normal peritoneal healing or adhesion formation. If fibrin is completely degraded, normal peritoneal healing may occur. In contrast, incompletely degraded fibrin may serve as a scaffold for fibroblasts and capillary in growth to form peritoneal adhesions.

Peritoneal injury, due to surgery, infection or irritation, initiates inflammation with fibrinous exudate and fibrin formation[32]. Fibrin results from coagulation cascade activation that is activated in the peritoneal cavity, resulting in the formation of thrombin that triggers conversion of fibrinogen into fibrin. However, owing to activation of the fibrinolytic system, any intra-abdominal fibrin deposits must be lysed. After abdominal surgery, however, the equilibrium between coagulation and fibrinolysis is disturbed, in favor of the coagulation system. Thus, fibrin forms deposits are a matrix for ingrowth of fibrocollagenous tissue. Indeed, fibroblasts invade the fibrin matrix and the extracellular matrix (ECM) is produced and deposited. This ECM can still be completely degraded by the proenzymes of matrix metalloprotease (MMP), leading to normal healing. However, if this process is inhibited by tissue inhibitors of MMPs, peritoneal adhesions may be formed[33]. Generally, if fibrinolysis does not occur within 5-7 d of the peritoneal injury, the temporary fibrin matrix persists and gradually becomes organized with collagen-secreting fibroblasts. This process leads to peritoneal adhesion formation[34,35] and growth of new blood vessels mediated by angiogenic factors[13].

Activation of the fibrinolytic system results in the conversion of plasminogen into plasmin that is highly effective in the degradation of fibrin into fibrin degradation products. Tissue-type plasminogen activator (tPA) and urokinase-type plasminogen (uPA) are both plasminogen activators. They are expressed in endothelial cells, mesothelial cells and macrophages. tPA, a serine protease, is the main plasminogen activator and has a high affinity for fibrin. It binds to a specific receptor, which exposes a strong plasminogen-binding site on the surface of the fibrin molecule. Therefore, in the presence of fibrin, the activation rate of plasminogen is strikingly enhanced, whereas in the absence of fibrin, tPA is a poor activator of plasminogen[36,37]. This results in higher plasminogen activation at the sites where it is required, whereas systemic activation is prevented. In the peritoneal cavity, tPA is responsible for 95% of plasminogen-activating activity[38]. uPA is equally effective in the degradation of fibrin[39], but its much lower affinity for fibrin results in a significantly lower plasminogen-activating activity. Besides activation of plasminogen, uPA may play an important role in tissue remodeling[40].

Plasminogen activation is hampered by plasminogen-activating inhibitor (PAI)-1 and 2 throughformation of inactive complexes. The most potent inhibitor of tPA and uPA is the glycoprotein PAI-1. PAI-2 is less effective in counteracting plasminogen activators. It probably plays a role in peritoneal tissue repair[41]. Both PA-1 and PAI-2 are produced by endothelial cells, mesothelial cells, monocytes, macrophages and fibroblasts. Other plasminogen activator inhibitors have been identified: PAI-3 and protease nexin 1. Several protease inhibitors, such as

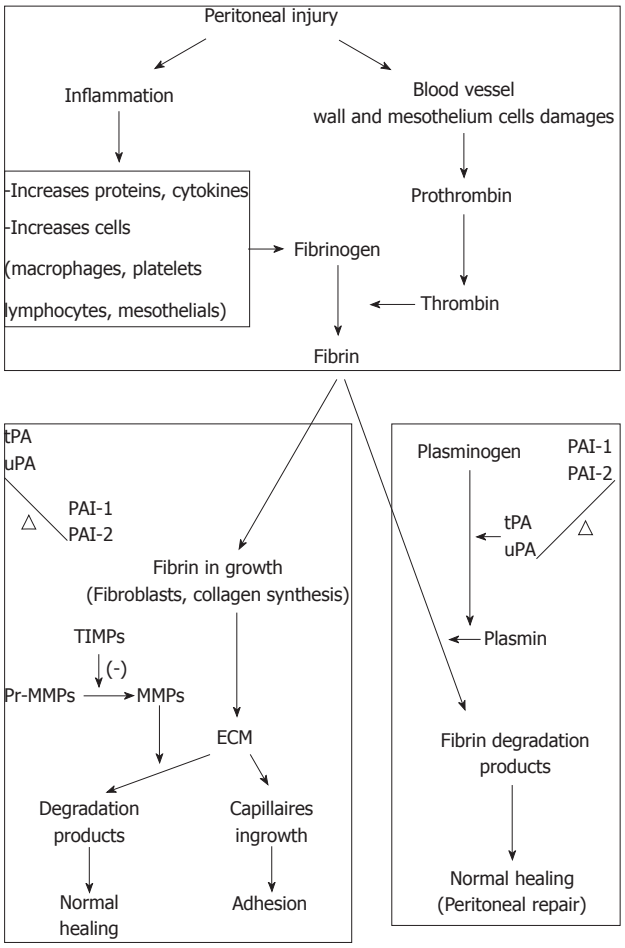

Figure 1 Balance between plasminogen activators and plasminogen inhibitors. TIMP: Tissue inhibitors of metalloproteinases; MMP: Matrix metalloprotease; ECM: Extracellular matrix; tPA: Tissue-type plasminogen activator; uPA: Urokinase-type plasminogen; PAI: Plasminogen-activating inhibitor.

α2-macroglobulin, α1-antitrypsin and α2-antiplasmin, inhibit plasmin directly. However, their roles in peritoneal fibrinolysis are not well defined[42]. The balance between plasminogen activators and plasminogen inhibitors is crucial in determining normal healing or adhesion formation (Figure 1). Therefore, PAI-1 is considered to be an important factor in the development of adhesions and high PAI concentrations are found in adhesions and peritoneal tissue of patients with extensive adhesions[43,44].

Prevention

Several preventive agents against postoperative peritoneal adhesions have been investigated. Their roles are in activating fibrinolysis, hampering coagulation, diminishing the inflammatory response, inhibiting collagen synthesis, or creating a barrier between adjacent wound surfaces. These prevention strategies can be grouped into four categories: general principles, surgical techniques, mechanical barriers, and chemical agents[3].

General principles and surgical techniques: Some basic principles should be respected during all abdominal surgical procedures. These principles are close to the "Halstedian principles" (W.S. Halsted 1852-1922), the first surgeon who recognized the importance of these measures[45]. Peritoneal damage should be avoided by careful tissue handling, meticulous hemostasis, continuous irrigation and avoiding unnecessary drying, ineffective use of foreign bodies, and suturing or clamping of tissue. The use of fine and biocompatible suture materials, atraumatic instruments and starch-free gloves is also recommended. Starched gloves are a significant risk factor for postoperative adhesions. Several experimental studies have shown that the use of starch-powdered gloves during laparotomy is associated with an increased risk of extensive postoperative peritoneal adhesions[46]. Foreign bodies most frequently found in postoperative adhesions are: surface powders from surgical gloves; lint from packs, drapes, or gowns; wood fibers from disposable paper items; and suture materials. However, recent data have suggested that, in the absence of an additional peritoneal injury, foreign bodies are an infrequent cause of adhesion induction[9,47]. Ordonez *et al*[48] have evaluated the effect of training on postoperative adhesion formation in a rabbit model. The training effect was evaluated by duration of surgery and amount of bleeding. This study has shown that there is a significant effect of experience on duration of surgery. With experience, duration of surgery progressively decreases, and postoperative adhesions also decrease in extent, tenacity, type and total score. According to these findings, surgical training and the respect of some basic principles ("Halstedian principles") are important for adhesion prevention.

Some intraoperative techniques, such as avoiding unnecessary peritoneal dissection or avoiding closure of the peritoneum, should be applied. Many experimental studies have shown that non-closure of the peritoneum is associated with decreased peritoneal adhesion formation[49-51]. However, some studies have reported no difference[52,53] or even decreased peritoneal adhesion[54] with peritoneal closure. However, grafting or suturing peritoneal defects may increase peritoneal ischemia, devascularization, and necrosis, predisposing the site to decreased fibrinolytic activity and increased adhesion formation[55].

Furthermore, surgical trauma should be reduced as much as possible. The surgical approach (open *vs* laparoscopic) could play an important role in the development of adhesions. In most abdominal procedures, the laparoscopic approach is associated with a significantly lower incidence of postoperative peritoneal adhesions or adhesion-related re-admissions. Brokelman *et al*[56] have shown in a prospective trial that there is no difference in tPA antigen, tPA-activity, uPA antigen, or PAI-1 antigen concentrations in peritoneal biopsies taken at the beginning compared to the end of the laparoscopic procedure, irrespective of the intra-abdominal pressure or light activity. In contrast, some studies have reported no difference between both surgical approaches. A role for CO_2 pneumoperitoneum in adhesion formation after laparoscopic surgery has been reported[48,57].

During laparoscopic surgery, CO_2 pneumoperitoneum by itself has a real impact on abdominal adhesions. It has

been demonstrated that adhesion formation increases with the duration of CO_2 pneumoperitoneum and insufflation pressure[48,57]. Indeed, prolonged laparoscopic surgery requires long duration and large volume gas insufflations, which raise concerns about the adverse effects of prolonged gas insufflations[58]. The standard CO_2 used in current laparoscopic practice is cold dry CO_2, which is not physiological to the normal conditions of the peritoneal cavity[57]. Many studies have shown that short-duration laparoscopy, < 3 h, with cold dry CO_2 insufflation can cause peritoneal alterations and result in numerous detrimental outcomes, including postoperative peritoneal adhesion formation[48,58]. The benefits of heated humidified CO_2 insufflation (37 ℃ and 95% relative humidity, physiological conditions) have been reported to include less hypothermia, less postoperative pains, shortened recovery room stay, better convalescence, less tumor spread and growth[48,58], and less adhesion formation[35]. Furthermore, Molinas *et al*[59] have demonstrated that CO_2 pneumoperitoneum increases postoperative peritoneal adhesions in a time- and pressure-dependent relationship, and that this increase is reduced by the addition of 2%-4% oxygen, suggesting peritoneal hypoxia as the driving mechanism. It supposes that when fibrinolytic activity decreases, the process of adhesion formation does not depend anymore on the surgical approach, but evolves on its own account.

Mechanical barriers: Liquid or solid mechanical barriers may prevent postoperative peritoneal adhesion formation by keeping peritoneal surfaces separate during the 5-7 d required for peritoneal re-epithelialization. They prevent contact between the damaged serosal surfaces for the first few critical days. An ideal barrier should be biodegradable, safe, non-inflammatory, non-immunogenic, persist during the critical re- mesothelialization phase, stay in place without sutures or staples, remain active in the presence of blood, and be rapidly and easily applied[60,61]. Also, it should not interfere with healing, promote infection, or cause adhesions. Barriers are currently considered the most useful adjuncts that may reduce postoperative peritoneal adhesion formation. Various solid or fluid barrier agents have been tested experimentally and in clinical trials.

Liquids such as crystalloids, dextran, hyaluronic acid, cross-linked hyaluronic acid and icodextrin have been used to prevent adhesion. They separate injured surfaces by "hydroflatation" but their effectiveness is controversial. Crystalloids, such as saline and Ringer's lactate, are used in large amounts but they are rapidly absorbed. The most commonly used hypertonic solution was 32% dextran 70, but it was abandoned because of serious complications[61]. Other liquid barriers that have the advantage of a longer residence time in the abdominal cavity, such as hyaluronic acid (Sepracoat®, Genzyme Corporation, Cambridge, MA, United States), cross-linked hyaluronic acid (Intergel® Hyalobarrier gel; Baxter, Pisa, Italy), and icodextrin (Adept®, Baxter Healthcare Corporation, Deerfield, IL, United States) have shown promising results in experimental and clinical studies[61]. Brown *et al*[62] have demonstrated that Adept is a safe and effective adhesion reduction agent in laparoscopy.

There are non-absorbable and bio-absorbable films, gels or solid membranes. The most commonly used mechanical barriers are oxidized regenerated cellulose (Interceed®; Johnson & Johnson Medical, Arlington, TX, United States), expanded polytetrafluoroethylene (Preclude Peritoneal Membrane®; W.L. Gore and Associates Inc., Flagstaff, AZ, United States), hyaluronic acid-carboxymethylcellulose (Seprafilm®; Genzyme Biosurgery, Cambridge, MA, United States) and polyethylenglycol (SprayGel®; Confluent Surgical Inc., Waltham, MA, United States). Preclude is non-degradable and requires a second operation for removal. The most extensively studied bioabsorbable films are Seprafilm and Interceed. Seprafilm is absorbed within 7 d and excreted from the body within 28 d[63,64]. Prospective randomized controlled trials have shown the efficacy of Seprafilm in reducing the incidence and extent of postoperative adhesions[65-68]. However, Seprafilm may cause a significant impairment of anastomoses, and should not be applied to anastomosis cases[69]. Other experimental studies have demonstrated that covering lesions of the parietal peritoneum with microsurgically applied autologous peritoneal transplants can completely prevent severe peritoneal adhesion formation. However, the advantage of a synthetic barrier is that the material does not need to be obtained surgically and can be cut to size outside of the abdomen and then applied without sutures[70].

Chemical agents: Chemical agents generally prevent the organization of the persisting fibrin, by fibroblastic proliferation inhibition. Many agents are used to inhibit this proliferation such as, non-steroidal anti-inflammatory drugs (NSAIDs), corticosteroids, calcium channel blockers, histamine antagonists, antibiotics, fibrinolytic agents, anticoagulants, antioxidants, hormones, vitamins, colchicines and selective immunosuppressors[60].

NSAIDs reduce peritoneal adhesions in some animal models by prostaglandin and thromboxane synthesis inhibition[9]. They decrease vascular permeability, plasmin inhibitors, platelet aggregation, and coagulation and also enhance macrophage function[9]. Rodgers *et al*[71] have shown that postoperative administration of anti-inflammatory drugs to the site of injury reduced the formation of postoperative adhesions in two animal models. A rat model has been used to investigate the efficacy of nimesulide, a selective cyclooxygenase-2 inhibitor, in the prevention of adhesion formation. This study has shown that preoperative intramuscular or postoperative intraperitoneal administration of nimesulide to the site of injury reduced the formation of postoperative adhesion in this rat model[72]. Generally, some anti-inflammatory drugs may be effective in preventing adhesions, but there is no clinical significant evidence from any published study to recommend their use in humans for this purpose, and several side effects still have to be ascertained[73].

Corticosteroid therapy reduces vascular permeability

and liberation of cytokines and chemotactic factors and has reduced peritoneal adhesion formation in some animal models[70]. However, corticosteroids have side effects, such as immunosuppression and delayed wound healing[60,74]. Kirdak *et al*[75] have investigated the effectiveness of different doses of methylprednisolone in preventing experimentally induced peritoneal adhesions in rats. They have found that there was no difference in the effectiveness of different methylprednisolone doses, administered topically, in preventing peritoneal adhesion formation, and furthermore, steroids did not prevent peritoneal adhesion development[75].

In animal models, these hormones may prevent adhesion formation, but some studies have not confirmed this effectiveness in humans[74]. Progesterone has been reported to have an anti-inflammatory as well as immunosuppressive effect, and may prevent adhesion formation[73]. However, Confino *et al*[76] have shown that there was no significant difference overall in the incidence of adhesion formation between progesterone-treated and control rabbits. They have revealed a beneficial effect of progesterone in the reduction of only minor adhesion formation formed after minor peritoneal damage[76]. Furthermore, it has been shown that neither estrogen nor gonadotropin-releasing hormone prevented adhesion formation, but there were fewer adhesions formed in estrogen-treated than untreated animals[77].

The use of anticoagulants to prevent the formation of peritoneal adhesions has been enthusiastically reported in the literature[78]. Many molecules have been used, such as heparin or dicumarol, which prevents adhesion by increasing the fibrinolysis due to serine esterase activity[79]. Heparin is the most widely investigated anticoagulant used for prevention of adhesions. However, its efficacy in reducing adhesion formation whether administered alone or in combination with interceed barrier has not been demonstrated in clinical trials[78].

Fibrinolytic agents such as recombinant tPA, when applied locally, have reduced adhesions in animal models[73]. However, these fibrinolytic agents may cause hemorrhagic complications[73]. Three different drugs, tPA (Actilyse®; Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany), fondaparinux (Arixtra®; GlaxoSmithKline, France), and activated drotrecogin alfa (Xigris®; Elli Lilly and Co., DSM Pharmaceuticals, Inc. Greenville, NC, United States), which affect the coagulation process at various stages, have been studied for their effectiveness in preventing intraperitoneal adhesion formation in rats[80]. All three agents were effective in preventing adhesions when compared to the control group. Nevertheless, activated drotrecogin alfa seemed the most effective except when considering clinical applicability, in which case fondaparinux seemed to offer the greatest advantage[80]. However, further studies have suggested that all these approaches may have only limited success, impeded lack of safety, efficacy and many adverse effects without eliminating the problem of postoperative peritoneal adhesion formation[81,82].

Some antibiotics are commonly used for prophylaxis against postoperative infections and adhesion formation. Less peritoneal infection may lead to less peritoneal adhesion formation. Linezolid (Zyvox®; Pfizer, New York, NY, United States) has been found to reduce intraperitoneal adhesion formation in a rat uterine horn model[83]. However, other studies have shown that intra-abdominal application itself causes adhesion formation[73]. Sortini *et al*[84] have shown that antibiotics led to greater adhesion formation by Zühlke score as compared to saline, whereas no difference was observed between antiseptics and saline. Indeed, antibiotics in intraperitoneal irrigation solutions have been demonstrated to increase peritoneal adhesion formation in rat models, and thus, are not recommended as a single agent for adhesion prevention[79].

Vitamin E is the most studied vitamin in adhesion prevention. *In vitro* studies have demonstrated that vitamin E has antioxidant, anti-inflammatory, anticoagulant and antifibroblastic effects, and decreases collagen production. It has been found to be effective for reducing adhesion formation by some authors[85]. Corrales *et al*[86] have shown that vitamin E, administered intraperitoneally, is as effective as carboxymethylcellulose membrane in preventing postoperative adhesions. By contrast, the same effect has not been achieved after intramuscular administration[87]. A significant difference has been found between intraperitoneal and intramuscular vitamin E administration[87]. Thus, intraperitoneal administration of vitamin E might be recommended to prevent adhesion formation. However, according to our literature review, there have been no human studies that have recommended the use of vitamin E for postoperative adhesion prevention.

One study has been carried out to elucidate the effects of different concentrations of methylene blue on the process of peritoneal adhesion formation and to define its minimum dose that can effectively prevent the formation of such adhesions in a rat model[88]. It could be concluded that 1% methylene blue had the best anti-adhesion potential[88]. If methylene blue prevents peritoneal adhesions, it can cause significant impairment of anastomotic bursting pressure during the early phase of the wound healing process by its transient inhibitory effect on the nitric oxide pathway[89].

Adhesions are a result of the inflammatory response to tissue injury in the peritoneal space. Although the mechanism is unclear, local anesthetics are reported to have some anti-inflammatory effects, as shown in some animal studies[90]. These anti-inflammatory effects are related to the inhibition of neutrophils. It has also been shown that local anesthetics activate the fibrinolytic system, reduce factor Ⅷ, plasminogen and α2-antiplasmin concentration, and inhibit platelet aggregation[91,92]. Thus, besides the accelerative effect of a mixture of 2.5% lidocaine and 2.5% prilocaine in the wound healing process, some studies have demonstrated that intraperitoneal lidocaine and prilocaine inhibit the formation of postoperative peritoneal adhesions without compromising wound healing in a bacterial peritonitis rat model[93].

Hepatocyte growth factor (HGF) can inhibit collagen deposition and has fibrinolytic capacity[94,95]. Liu *et al*[96] have demonstrated that local application of recombinant adenovirus carrying the *HGF* gene reduced adhesion formation in a rat model. Other studies have investigated the use of gene therapy to manage postoperative adhesions. Smad7, a protein that occupies a strategic position in fibrinogenesis, inhibits transforming growth factor-β and has the potential to attenuate postoperative adhesion. Guo *et al*[97] have investigated in an experimental model the therapeutic potential of exogenous Smad7 to prevent fibrinogenesis in postoperative intra-abdominal adhesion. In this rat model, ultrasound-microbubble-mediated Smad7 transfection significantly decreased the incidence and severity of peritoneal adhesions, but the use of targeted gene therapy as a preventive agent against ASBO still needs extensive evaluation before any clinical trial.

CONCLUSION

Postoperative peritoneal adhesions are a major health problem with a significant economic impact. Fibrinolysis seems to be a key factor in determining the pathogenesis of adhesion formation and in its prevention. Several studies on this problem have been conducted. Their results are encouraging, but most of them are contradictory and have been conducted in animal models. Until additional findings from future clinical studies, only meticulous surgery can be recommended to reduce unnecessary morbidity and mortality rates from these untoward effects of surgery. In the current state of knowledge, preclinical or clinical studies are still necessary to evaluate the effectiveness of the several proposed prevention strategies for postoperative peritoneal adhesions.

Abstract

Chronic radiation proctopathy occurs in 5%-20% of patients following pelvic radiotherapy. Although many cases resolve spontaneously, some lead to chronic symptoms including diarrhea, tenesmus, urgency and persistent rectal bleeding with iron deficiency anemia requiring blood transfusions. Treatments for chronic radiation proctitis remain unsatisfactory and the basis of evidence for various therapies is generally insufficient. There are very few controlled or prospective trials, and comparisons between therapies are limited because of different evaluation methods. Medical treatments, including formalin, topical sucralfate, 5-amino salicylic acid enemas, and short chain fatty acids have been used with limited success. Surgical management is associated with high morbidity and mortality. Endoscopic therapy using modalities such as the heater probe, neodymium:yttrium-aluminium-garnet laser, potassium titanyl phosphate laser and bipolar electrocoagulation has been reported to be of some benefit, but with frequent complications. Argon plasma coagulation is touted to be the preferred endoscopic therapy due to its efficacy and safety profile. Newer methods of endoscopic ablation such as radiofrequency ablation and cryotherapy have been recently described which may afford broader areas of treatment per application, with lower rate of complications. This review will focus on endoscopic ablation therapies, including such newer modalities, for chronic radiation proctitis.

Key words: Chronic; Radiation proctitis; Endoscopic; Argon plasma coagulation; Radiofrequency; Cryoablation

INTRODUCTION

Chronic radiation proctopathy (CRP) is a troublesome complication occurring in 5%-20% of patients following pelvic radiotherapy for carcinoma of the prostate, rectum, urinary bladder, cervix, uterus and testes[1-6]. Radiation-induced mucosal damage results in endothelial dysfunction, microvascular injury with intimal fibrosis, and fibrin thrombi of small arteries and arterioles leading to ischemia, fibrosis and the development of neovascular lesions[1,2]. CRP resolves spontaneously in many cases, but in some can lead to persistent rectal bleeding and iron deficiency anemia requiring blood transfusion[3]. Other symptoms of CRP include diarrhea, mucoid discharge, urgency, tenesmus, rectal pain and fecal incontinence. These symptoms interfere with daily activities and have an adverse effect on quality of life[4]. Treatment for CRP remains unsatisfactory. Medical measures, including formalin application[5], topical sucralfate[6], 5-amino salicylic acid enemas[7], short chain fatty acids[8] and antioxidants

such as vitamin E[9] and pentoxifylline[10] have been used with limited success. Surgical management is associated with high morbidity and mortality[11].

The basis of evidence for the therapy of CRP is generally insufficient. There are very few high-quality trials and comparisons between therapies are limited because of different evaluation methods. Most data are from case series of a single treatment from a single center. Therefore, a degree of pragmatism needs to be shown on the basis of these data and local availability of therapy. Sucralfate enemas seem to be the best available "medical" therapy and are safe and well tolerated. Additional use of oral metronidazole may enhance this effect[12]. Steroid enemas may have some effect, but are less well tolerated and probably have lower efficacy. Formalin therapy is effective in up to 48% of patients with CRP[13,14]. However, high rates of complications have been reported including rectal pain, incontinence, diarrhea, formalin-induced colitis, anal and rectal strictures, rectal ulcerations, and rectal perforation[13,14]. Also, the technique of application, concentration of formalin and the success rates reported in different studies highly vary[15]. The duration of effect based largely on anecdotal reports remains unclear, but appears to be around 3 mo[15]. Another described therapeutic modality is hyperbaric oxygen therapy, which is purported to have an angiogenic effect and stimulate collagen formation and re-epithelialization[16]. Aural barotrauma is the most common side effect reported, although it appears to be largely transient and minor[15,17]. The equipment needed is expensive and not readily available. Thus, at the present time, it is not a practical means of treating CRP outside of specialized centers and is usually reserved for cases refractory to more readily available forms of therapy.

The goal of endoscopic treatments of CRP is to achieve control of bleeding. Attaining this goal improves the patient's quality of life by reducing the need for iron replacement, blood transfusion and hospital admissions, resolving symptoms of anemia, and symptoms of hematochezia. Endoscopic therapy using modalities such as the heater probe[18], neodymium:yttrium-aluminium-garnet (Nd:YAG) laser[19,20], potassium titanyl phosphate (KTP) laser[21] and bipolar electrocoagulation[22] has been reported to be of some benefit, but at the expense of a high level of complications[23]. Of ablative therapies, thermal methods seem to be effective and safe. Simple heater probe treatment or argon plasma coagulation (APC) is the preferred method for their better safety profile. Intra-rectal formalin seems to be effective, but possibly has a higher rate of complications[14]. Newer methods of endoscopic ablation such as radiofrequency ablation and cryotherapy have been recently described which may afford broader areas of treatment per application. This review shall focus on endoscopic ablation therapies used in management of CRP.

CONTACT PROBE THERAPY: HEATER AND BIPOLAR PROBE

The heater probe has a teflon-coated heating element at its tip that delivers standardized energy over set times. Bipolar electrocautery probe has a pair of electrodes at its tip through which current is passed using the tissue for conduction[24]. Both devices are contact probes, making them useful for directed therapy in the setting of active bleeding. The disadvantage is char formation on the tip of the probe, leading to decreased treatment efficiency and requiring repeated cleaning. Fuentes *et al*[25] treated 8 patients with the heater probe for rectal bleeding, which required one to four treatment sessions for complete cessation or significant reduction in bleeding. In a randomized prospective trial by Jensen *et al*[18], a total of 21 patients were treated either by a heater probe (n = 9) or a bipolar electrocoagulation probe (n = 12). A mean of four sessions were required for either probe. In the 12 mo of endoscopic treatment *vs* 12 mo medical therapy, the severe bleeding episodes diminished significantly for the bipolar probe (75% *vs* 33%) and heater probe (67% *vs* 11%). No side effects were reported in any of the studies using these modalities (Table 1).

LASER THERAPY

Nd:YAG

Nd:YAG laser was one of the first endoscopic laser modalities used in the treatment of CRP. Leuchter *et al*[26] reported successful treatment of rectal hemorrhage in a patient after four applications. The laser uses a 1.06 nm wavelength and penetrates to a depth of up to 5 mm[27]. Nd:YAG laser has a low affinity for hemoglobin and H_2O but is well absorbed by tissue protein, thus making it ideal for deeper vessel coagulation[28]. Initially, a setting of 40 W and pulse duration of 1/2 s maximum is used with the tip at approximately less than 1 cm from the mucosal surface. The desired effect in treating telangiectasias is attained with the formation of white coagulum. The study by Barbatzos *et al*[20] involved nine patients who underwent a mean of three treatments. There were no complications, and bleeding was decreased to occasional spotting. Ventrucci *et al*[29] also reported successful treatment in nine patients. The median number of treatments required per patient was three to achieve cessation of bleeding in four patients and occasional spotting in four others. One patient still required transfusions at completion of the study. Transmural necrosis, fibrosis, stricture formation and recto-vaginal fistula are some of the complications reported with use of Nd:YAG. Nd:YAG use for CRP has declined because of its cost, the need to aim directly at telangiectasias, and the possibility of severe endoscopic damage if the laser strikes the endoscope in retroflexion (Table 2).

Potassium titanyl phosphate

The KTP laser uses the beam from the Nd:YAG laser that is passed through a KTP crystal, reducing the wavelength by half (532 nm)[30]. At this wavelength, the energy is absorbed by hemoglobin and the depth of penetration is more shallow (1-2 mm) compared to Nd:YAG. This affinity for hemoglobin permits selective coagulation, thus making it quite useful in the treatment of superficial vascular lesions. The use of KTP for CRP has been limited. Taylor *et al*[21] treated 26 patients with bleeding secondary

Table 1 Literature on contact probe therapy use in chronic radiation proctopathy

Authors	Modality	*n*	No. of treatment	Power settings	Response rate	Duration of study	Side effects

to CRP using 4-10 W and a median of two sessions. They reported a symptomatic improvement in 65% patients, while there was no change in seven (30%) and there was an increase in hematochezia in one (5%). No perforations or fistula formation were reported in the study.

Argon laser

The argon laser is functionally similar to KTP with similar wavelength, resulting in tissue heat penetration of 1-2 mm depth, and is also useful in superficial blood vessel photocoagulation. O'Conner[31] treated five patients using the argon laser at 1.5 W and reported cessation of bleeding after two to four treatment sessions with no complications. Buchi and Dixon[32] treated three patients successfully, with only one patient reporting cramps. Similarly, Taylor *et al*[33] reported control of bleeding achieved after a median of three sessions in 14 patients. Power was set between 3.5 and 8 W with a flow rate of 1.5-2.5 mL/s and no complication was encountered.

ARGON PLASMA COAGULATION

Laser therapy for hemorrhagic CRP was largely supplanted by argon plasma coagulation (APC), which is less expensive, easier, safer and more widely available. This involves the application of bipolar diathermy current using inert argon gas as a conducting medium, delivered *via* a through-the-scope catheter. Unlike traditional bipolar devices, the current jumps from the probe to the target lesion, with the arc being broken once the tissue is desiccated. The theoretical advantage is a uniform, more predictable and limited depth of coagulation (0.5-3 mm)[34], to minimize the risks of perforation, stenosis and fistulization. APC can be applied axially and radially, allowing tangential coagulation of lesions around rectal bends[35-37]. Also, the APC generator is mobile and can be used quickly and at any place or time[35-37]. Given all these benefits, APC has rapidly become the preferred, first-line endoscopic therapy for hemorrhagic CRP (Table 3).

Most studies on the use of APC in the management of CRP have demonstrated benefit (Table 3). APC ameliorates rectal bleeding associated with mild to moderate hemorrhagic CRP in 80%-90% of cases, and improves symptoms of diarrhea, urgency and tenesmus in 60%-75% of cases[38-41]. Ten studies also reported an increase in the mean hemoglobin levels after APC in almost all patients after the treatment, suggesting the effective control of rectal bleeding. Cumulative average increase in mean hemoglobin levels is around 2.26 gm% (range, 1.1-3.8 gm%). Relief of blood transfusion dependency has also been reported in almost all patients treated with APC (57 of 60 patients, 95%) in one series (Table 3).

However, APC has inherent limitations especially in very severe, extensive CRP, e.g., with greater than half of the rectal surface area involved or with fresh surface bleeding[38,41,42]. More diffuse lesions usually require repeated applications per session and multiple treatment sessions (ranging from one to five sessions). A few studies report up to 8 sessions needed to achieve complete resolution of symptoms, endoscopic disappearance of all telangiectasias, and complete cessation of bleeding[41,43]. The mean number of sessions per patient reported varies from 1 to 3.6 with a calculated overall cumulative mean of 2.13 sessions per patient (calculated median: 2) (Table 3). Mean interval between sessions usually ranges from 4 to 8 wk. Follow-up ranges from 1 to 48 mo with a mean of 3-31 mo across different studies (calculated overall mean: 15 mo). Recurrent proctopathy has been reported

to respond to additional rounds of APC therapy[44,45].

Patients on anticoagulants or aspirin demonstrate higher recurrence[46]. Kaassis *et al*[44] found that patients who were receiving anticoagulation therapy may require more APC sessions, but can achieve an equivalent clinical response as those who are not on anticoagulation. Rectosigmoid lesions are also more difficult to treat due to the tortuosity that often accompanies radiation injury in this region. When rectal lesions are very distant from the anus, application of APC with a rigid probe through an operating sigmoidoscope may be easier than through a flexible endoscope. Lesions located immediately above the dentate line in the upper part of the anal canal are also difficult to treat. These may require retroflexion of the scope with higher risk of rectal scarring, limited mobility of the endoscope, and greater patient discomfort. One technique described by Coriat *et al*[47], using a transparent cap attached to the tip of the colonoscope, allowed better visualization of low rectal lesions and of the upper part of the anal canal without retroflexion and proper distance for effective and safe APC delivery. Notwithstanding, APC may be avoided in the presence of radiation-induced rectal strictures and fistulae, which may worsen as the treated area heals.

Overall, the reported complication rate with APC has been variable (Table 3). Canard *et al*[48] reported an overall morbidity of 47%: post-treatment pain in 20% and severe complications in 3 (10%), including a patient with severe bleeding, extensive necrosis of lower part of the rectum, and perforation. Alfadhli *et al*[14] and Swan *et al*[49] reported complications in 30%-35%. On the other hand, the experiences of Villavincencio *et al*[50] were better, with a 19% incidence of both short-term (such as tenesmus, anismus) and long-term (including diarrhea, rectal pain) complications. The commonest procedure-related complication reported is anal or rectal pain with or without tenesmus, which is most likely to occur following treatment near the dentate line[50,51], and usually resolves spontaneously within few days or with standard analgesics[45,48,50,51]. Abdominal bloating and cramping, and vagal symptoms related to colonic distension have also been reported. One potential drawback of using APC is the possibility of excessive luminal distention from the rapid instillation of argon gas that occurs during treatment. It is recommended that, when possible, a two-channel endoscope should be used so that the insufflated argon gas can be removed periodically during the procedure[52]. Several authors have reported colonic explosion [1 of 56 (1.8%)[46] to 3 of 27 (11.1%)[53]] with or without perforation (Table 3) when the bowel has not been formally cleansed, and adequate colonic lavage is therefore a mandatory requirement[38,46,53,54]. Rare complications reported include arteriovenous fistula, urinary retention and necrosis of lower part of the rectum. Although life-threatening gas embolism has been reported during bronchoscopic application of APC, no such complication has been reported during gastrointestinal endoscopic application[55].

Rectal ulcers are common following APC treatment. Severe ulceration may result in "painting" of the rectal wall. Therefore, brief pulse treatment of targeted lesions is recommended[50]. Ravizza *et al*[51] reported asymptomatic rectal ulcers in 14 (52%) of 27 patients, a frequency that is relatively high in comparison with the reported overall frequency of about 3%-16% (Table 3) in other series, despite similar gas flow rate and power settings compared to the other studies. Furthermore, this data may underestimate the true frequency of rectal ulcer, as 41% of the patients in this study did not undergo endoscopy after the last APC session. However, no strictures were observed after ulcer healing[51]. Rectal ulcers developing during APC can be considered a consequence of thermal injury to already damaged and vascularly compromised tissue that is thus more fragile and has poorer healing[56]. Incidence of ulcers may be affected by the flow rate of the argon gas and power settings, the method of application, the interval between sessions, and the number of sessions subsequent to ulcer development which may delay ulcer healing due to repeated thermal injury[51]. The fact that rectal ulcers are not clinically troublesome means they should not be considered an absolute contraindication to APC, nor do they necessarily require any additional endoscopic follow-up[51].

Compared to ulcers, the occurrence of strictures is less common. The frequency of this complication varies among different studies, many studies describing no occurrence of rectal strictures while few studies reporting such complication in 2%[49]-13.3%[40] (Table 3). A review of literature by Ravizza *et al*[51] reported 9 cases of asymptomatic rectal strictures in 207 treated patients, with an overall frequency of 4.3%. However, given the fact that most of the rectal strictures are asymptomatic, their true incidence is difficult to estimate and theoretically would be higher than reported by several studies.

The studies involving APC are not uniform in method. The power settings range from 30 to 60 W (median 40-50 W), with an argon flow rate from 0.8 to 2 L/min (median 1.5-2 L/min) (Table 3). Lower power settings have been subscribed for lower complication rate and decreased number of treatment sessions required for complete coagulation, with almost all complications occurring at power settings above 45 W[48]. Duration of burn and power settings have also been correlated with depth of injury to the muscularis propria in swine colon[57]. Thus lower power settings appear to cause less injury while coagulating just as well as at higher settings. Unfortunately, most of the studies do not report the success of individual settings. Only few studies have compared APC at different settings. One small study of 42 patients compared 50 and 60 W therapies, but reported no statistical difference between the two[58]. Ravizza *et al*[51] found a higher rate of rectal ulceration with higher settings; 59% with flow of 3 L/min and a power of 60 W compared to 40% with a 2 L/min flow and a power of 40 W, albeit without statistical significance ($P = 0.4$) in the limited study.

No prospective comparative trials of the APC with other endoscopically directed treatment modalities exist, nor is there any experience on the role of adjuvant medical therapy such as the use of steroids, sucralfate or 5-aminosalicylic acid enemas between APC sessions. Most importantly, there are no control or crossover studies.

However, in many of the studies involving APC, most of the patients had unsuccessful results with medical therapy before undergoing APC. For example, in the study by Ravizza *et al*[51], 17 of their 27 patients had been treated unsuccessfully with corticosteroid or salicylate enemas. Tjandra *et al*[41,43] also found APC to be effective in 11 patients with CRP refractory to formalin therapy. Similarly in the study by Villavicencio *et al*[50], 12 of their 21 patients had been treated unsuccessfully with various pharmacologic agents including oral and rectal mesalamine, and rectal corticosteroids. Other forms of endoscopic treatment (laser photocoagulation, multicolor coagulation) had been performed in 5 of their patients, all failed in achieving control of bleeding[50]. In a study by Zinicola *et al*[42], 6 (42.8%) patients had previously failed treatment with steroid enemas or 5-aminosalicylic acid enemas. In a recent study by Swan *et al*[49], 16 patients who failed in previous treatments for CRP all responded to endoscopic APC therapy. Alfadhli *et al*[14] retrospectively compared the APC with topical formalin, and found APC to be more effective (79% *vs* 27% responders) and safer (14.3% *vs* 81.8% adverse effects) than topical formalin in controlling hematochezia. The rate of single-session APC responders (63.6%) was almost double that of the formalin-treated group (33.3%)[14].

RADIOFREQUENCY ABLATION

Radiofrequency ablation (RFA) with the BARRx Halo90 system has achieved superficial and broad fields of ablation in the esophagus[59,60] suggesting that similar benefits could be achieved in the colon and rectum. Zhou *et al*[61] have reported successful use of RFA with the BARRx Halo90 system in treating three patients with lower gastrointestinal bleeding from CRP, including two who failed in conventional therapy. In all cases, the procedure was well tolerated and hemostasis was effectively achieved after 1 or 2 RFA sessions. Re-epithelialization by neosquamous mucosa was observed over areas of prior hemorrhage above the prior dentate line. No stricturing or ulceration was seen on follow-up up to 19 mo after RFA treatment. In this report, real-time *in vivo* endoscopic optical coherence tomography (EOCT) was also used to assess the treatment efficacy. EOCT could visualize epithelialization and subsurface tissue microvasculature before and after treatment, demonstrating its potential for follow-up assessment of endoscopic therapies and directing areas for retreatment, without the need for excisional biopsy. This is particularly important for patients with radiation proctitis since biopsy is relatively contraindicated due to the high risk of rebleeding.

Several benefits of RFA have been found compared with other endoscopic treatments for radiation proctitis. These include squamous re-epithelialization seen after RFA with prevention of rebleeding and the relative lack of stricturing and ulceration that is seen often after other thermal ablative procedures. The tightly spaced bipolar array of the RFA catheter limits the radiofrequency energy penetration, restricting the RFA treatment to the superficial mucosa, thereby avoiding deep tissue injury in relatively ischemic mucosa and resulting in post-treatment ulceration and structuring, as commonly noted following conventional endoscopic therapies. Finally, RFA allows much broader areas of tissue to be treated simultaneously compared to the point-by-point approach required with heater or bipolar probes[18,22], or APC[44,62]. As with APC, the unit is mobile and can be used in different rooms of an endoscopic suite. The BARRx unit also delivers a consistent amount of energy to the surface using well-defined and reproducible ramp-up of energy. This minimizes the possibility of operator-dependence and over-treatment that may lead to perforations or ulcerations.

Nikfarjam *et al*[63] recently reported another case with extensive CRP that had continued bleeding despite APC. The HALO90 radiofrequency system was used for treating regions of proctitis at an energy density of 12 J/cm^2. At monthly intervals, over 3 mo, RFA was performed with a mean of 7 regions ablated at a time. The mean treatment time was 29 min. There was no significant bleeding after the first treatment session. The patient was symptom free at 6 mo follow-up with minimal evidence of residual mucosal abnormalities

CRYOABLATION

Cryoablation, similar to APC, is a noncontact method of therapeutic tissue destruction *via* application of extreme cold temperatures to a targeted area. Cryoablation has the benefit of uniform treatment of larger surface areas and ease of targeted application. Cryoablation works through immediate and delayed effects. Delayed effects are related to induction of ischemic necrosis.

Kantsevoy *et al*[64] reported the successful use of experimental endoscopic cryotherapy in patients with radiation proctitis, as a part of a pilot study that was conducted to evaluate the safety and efficacy of endoscopic cryotherapy for bleeding mucosal vascular lesions. They used a Prototype Ⅱ device to spray nitrous oxide through the accessory channel of an upper endoscope[65]. Complete cessation of bleeding was achieved in all 7 (100%) patients who underwent cryoablation therapy for radiation proctitis. A major advantage of the cryotherapy technique identified was the ability to treat large areas of mucosa relatively quickly. The only adverse effect reported was transient abdominal pain with spontaneous resolution in one out of a total of 26 patients treated for various gastrointestinal mucosal bleeding lesions.

Shaib *et al*[66] reported the first case of mucosal healing and symptomatic resolution of radiation proctitis using low-pressure cryoablation (CryoSpray, CSA Medical) in a patient who previously did not respond to medical therapy with steroid suppositories. Cryoablation was performed using a liquid nitrogen spray injected through the cryoablation catheter passed through an endoscopic channel. A total of four 10-s applications were used for each area of proctitis. During cryoablation, a decompression tube was placed in the rectum to prevent over-insufflation. No adverse effects after cryoablation were seen. Hemoglobin was reported to increase from 9.4 g/dL to 11.7 g/dL over the 15-wk follow-up period with

sigmoidoscopic resolution.

Battish *et al*[67] also reported similar results in small case series of 2 patients with established radiation proctitis who underwent cryoablation using liquid nitrogen (CryoSpray). Each patient underwent 4 applications of 10 s each with complete resolution of mucosal bleeding and telangiectasias on follow-up endoscopy. The only post-procedure adverse effect reported was transient abdominal distention in one patient.

Most recently, Hou *et al*[68] reported a prospective case series of 10 patients with hemorrhagic CRP with a mean follow-up of 3.3 mo. All patients underwent a single endoscopic session of cryotherapy, consisting of three 5-s applications per involved area of mucosa, performed with a 9F cryoablation catheter (formerly CryMed, now CSA Medical)[68]. Endoscopic improvement was reported in 70% of patients, with an overall 37% decrease in rectal telangiectasia density from a mean of 2.7 to 1.7 ($P = 0.02$). Symptomatic improvement was observed in 80% of patients with an overall 51% reduction in Radiation Proctitis Severity Assessment Scale score from a mean of 27.7 to 13.6 ($P = 0.009$)[68]. Severe complication included one (10%) patient with cecal perforation secondary to over-insufflation likely caused by a failure of the decompression tube. Subsequently, the protocol was adapted to reduce treatment duration and perform full colonoscopy after treatment for colonic decompression. One case (10%) of rectal ulcer was also reported[68].

Reports using cryoablation for CRP remain experimental and anecdotal. These early case reports support the use of cryoablation therapy in management of CRP. However, there has been no prospective study comparing cryoablation with other treatment modalities such as APC, with regards to efficacy, side effects and durability of results. Larger studies or case series are required to confirm the utility or superiority of cryoablation.

The current commercially available cryotherapy apparatus is less mobile and somewhat more cumbersome than most APC and the BARRX units, and requires maintaining a supply of liquid nitrogen which lasts approximately 2 wk in the current holding tank. Thus treatments for incidental findings, particularly in a lower volume endoscopy unit, may be more difficult. In our view, a major advantage of cryotherapy over the other heat-generating ablative methods is that colonic lavage to minimize the possibility of gas ignition is not necessary. However, drawing from the animal studies, the depth of tissue destruction may be deeper by CSA cryotherapy than that achieved by BARRx radiofrequency ablation, and it is unclear whether this could lead to greater strictures, abscess and fistulas, or whether cryotherapy is inherently less prone to such complications. Moreover, the rapidly expanding gas would require adequate venting which may be more difficult for lesions higher in the sigmoid colon.

CONCLUSION

Endoscopic therapies have become the treatment of choice in patients with troublesome bleeding due to CRP, and may be used in conjunction with medical therapies. The ability to safely treat these patients in an outpatient setting is extremely attractive. Endoscopic therapy has proven successful in stopping bleeding from CRP, in addition to providing symptomatic relief by reducing urgency, tenesmus, and the frequency of hematochezia and transfusion requirements. Initially, endoscopists had used the heater and bipolar probes[9,10], then the neodymium/yttrium aluminum garnet[11,12] and potassium titanyl phosphate lasers[13,14], which were each effective. Formalin administration through a rigid scope also proved effective[15,16]. The use of APC by endoscopy has become an attractive treatment option, because it is a noncontact approach that is efficient, effective, relatively safe and well tolerated.

While focal ablative tools such as lasers, contact probes and APC may be helpful when bleeding occurs from limited number of identifiable ectatic vessels, a larger field of arteriovenous malformations (AVMs) or oozing may be more difficult to control. Moreover, poor healing and subsequent ulcerations can exacerbate bleeding in this CRP field, which is vascularly compromised. Therefore methods allowing for broader field of treatment such as formalin instillation, or the newer methods of RFA and cryotherapy may be theoretically advantageous in this setting. In particular, the unexpected finding of neosquamous epithelialization with RFA may have further advantages in preventing rebleed.

Future comparison of these treatment modalities would be enhanced using the uniquely-suited EOCT as an imaging tool, since this allows broad areas of scan with subsurface near-microscopic visualization for vessel features and density.

Present evidence for endoscopic therapy of CRP remains largely anecdotal, and future studies to demonstrate efficacy need to adopt a standard scoring system for CRP. Denton *et al*[16] suggested possible scoring systems and outcome measures (including quality-of-life scores) that seem sensible in this disease. Adoption of such scoring system may allow better comparison of different studies and different modes of treatment. Moreover, bleeding from CRP often resolves spontaneously, and there needs to be larger randomized controlled studies for the treatment of CRP. Given such limitations and differences in availability of equipment and expertise, it is difficult to recommend a truly evidence-based algorithm for management of CRP. However, we recommend a trial of medical therapy such as sucralfate enemas with oral metronidazole for mild cases. Severe cases, particularly hemorrhagic CRP and those refractory to medical treatment, should be promptly offered endoscopic therapy. Currently, APC is the preferred first-line endoscopic modality given the vast experience and availability. Refractory cases should be referred to centers for hyperbaric oxygen therapy or centers performing newer endoscopic therapies such as radiofrequency and cryoablation, which may become the standard of care in the future particularly for more extensive lesions.

Abstract

AIM: To investigate the biological role of alpha fetoprotein (AFP) and its clinical significance in carcinogenesis of hepatocellular carcinoma (HCC).

METHODS: Clinical analysis of HCC patients and immunohistochemical examination were conducted to evaluate the relationship between serum AFP level and patient mortality. Confocal microscopy, Western blotting, dimethylthiahzolyl-2,5-diphenyl-tetrazolium bromide, Cell Counting Kit-8 assays and flow cytometry were performed to explore the possible mechanism.

RESULTS: Among the 160 HCC patients enrolled in this study, 130 patients survived 2 years (81.25%), with a survival rate of 86.8% in AFP < 2 0 μg/L group, 88.9% in AFP 20-250 μg/L group, and 69.6% in AFP > 250 μg/L group, demonstrating a higher mortality rate in HCC patients with higher AFP levels. Surgical treatment was beneficial only in patients with low AFP levels. The mortality rate of HCC patients with high AFP levels who were treated surgically was apparently higher than those treated with conservative management. The results of immunohistochemistry showed that AFP and AFP receptor were merely expressed in tissues of HCC patients with positive serum AFP. Consistently, *in vitro* analysis showed that AFP and AFPS were expressed in HepG2 but not in HLE cells. AFP showed a capability to promote cell growth, and this was more apparent in HepG2 cells, in which the proliferation was increased by 3.5 folds. Cell cycle analysis showed that the percentage of HepG2 cells in S phase after exposure to AFP was modestly increased.

CONCLUSION: HCC patients with higher AFP levels show a higher mortality rate, which appears to be attributable to the growth promoting properties of AFP.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most frequent neoplasm worldwide, and accounts for 5.6% of all human cancers[1-3]. HCC in China has an increasing incidence, and it has become the second most frequent cause of estimated cancer-related death in the country[4]. Approximately 75%-80% of primary liver cancers are attributable to persistent viral infections with hepatitis B virus (HBV) or hepatitis C virus (HCV)[5]. HBV is the major etiologic factor of HCC in China[6]. Alpha fetoprotein (AFP) has served as a useful biomarker for diagnosis of HCC since the 1970s, when most patients with HCC were diagnosed at an advanced stage and had clinical symptoms. Serum levels of AFP above the reference value of 10 μg/L occur in approximately 75% of HCC cases[7]. Although AFP has a relatively low specificity in some patients with chronic non-neoplastic liver diseases, and it is non-diagnostic in some cases of small HCCs, AFP is still viewed as an important biomarker for the diagnosis of HCC[5,8,9].

AFP is an oncofetal protein normally produced in the fetal liver and yolk sac, and it is undetectable or found in trace amounts only in adults. In addition to its use in clinical diagnosis of liver cancer, the biological and pathophysiological functions of AFP have generated considerable interest. There has been compelling progress in these areas, particularly in regard to the role of this protein in cell growth and apoptosis. A recent study showed that cytoplasmic AFP may function as a regulator by interacting with phosphatase and tensin homolog deleted on chromosome ten protein and stimulating cell growth through the PI3K/AKT signal pathway[10]. Moreover, AFP co-localizes and interacts with retinoic acid receptors-β (RAR-β) in the cytoplasm, and plays a role in inhibiting translocation of RAR-β into the nucleus *via* competitive binding to RAR-β with all trans retinoic acid (ATRA)[11,12]. Thus, cytoplasmic AFP serves as an inhibitor in the retinoic acid-retinoic acid receptor signaling pathway and is most likely at least in part responsible for retinoid resistance in tumor chemotherapy[10]. By counteracting the effect of AFP, it may be possible to increase the sensitivity of tumor cells to ATRA. AFP also interacts with caspase-3 in the cytoplasm and blocks onward transmission of signaling from caspase-8[13]. Knockdown of AFP increases the sensitivity of hepatoma cells to tumor necrosis factor-related apoptosis inducing ligand (TRAIL) and thereby triggers caspase-3 signaling. Therefore, it is possible that the combination of *AFP* gene silencing together with ATRA/TRAIL treatment will enhance the chemotherapeutic efficiency of these agents.

AFP therefore should be regarded not only as a marker for diagnosis of HCC, but also as a factor involved in ontogenetic and oncogenic growth. AFP receptors have been identified in various cell lines and tissues[14-20], and these receptors have been isolated and characterized[21-23]. Moreover, the intracellular events triggered by the binding of AFP to its receptor are being studied[24-27]. High mortality rates and poor clinical outcome are typically observed in patients with primary liver cancer as well as in other AFP-producing cancers. However, the relationship of AFP and its receptor with the mortality and patient outcome has not been fully clarified. Thus, understanding of the mechanism underlying this phenomenon may benefit the development of new clinical therapeutic strategies.

In the current study, we retrospectively analyzed the relationship between serum AFP levels and the mortality in 160 HCC patients and examined the *in vitro* effects of AFP on cell growth in order to support the assumption that elevated AFP is a significant risk factor in HCC mortality due to its capability of promoting growth of tumor cells.

MATERIALS AND METHODS

Subjects

One hundred and sixty HCC patients hospitalized in Beijing You'an Hospital between January 2006 and June 2009 were recruited to this study and the relationship between serum AFP levels and mortality was retrospectively assessed. In each case, a preliminary diagnosis of HCC was made based on the guidelines for clinical diagnosis and staging of primary HCC published by the Chinese Society of Liver Cancer (2001), fulfilling at least one of the following criteria[28]: (1) a hepatic space-occupying lesion with serum AFP ⩾ 400 μg/L; (2) serum AFP < 400 μg/L but with a new hepatic space-occupying lesion, with arterial phase enhancement on computed tomography or magnetic resonance imaging. All the patients selected were confirmed by histopathological evaluation. Patient demographics and clinicopathological data are summarized in Table 1. The AFP cut-off value used in this study has been proved to be sensitive and specific, and defined by receiver operator characteristic curve as described before[29]. This study protocol (2006-LINSHEN-3) was approved by the Ethical Committee of Beijing You'an Hospital, Capital Medical University. Informed consent was obtained from all patients.

Of the 160 HCC patients, 88 underwent surgical resection and 72 were treated conservatively with only heteropathy. All the patients were followed up for 2 years at an interval of 6 mo. The survival rates of the patients with surgical and non-surgical management were retrospectively analyzed.

Immunohistochemistry

Immunohistochemical staining was performed on 4-μm formalin-fixed, paraffin-embedded tissue blocks. Tissue sections were deparaffinized and rehydrated, and heat-induced epitope retrieval was carried out in a 10 mmol/L citrate buffer (pH 6.0). After endogenous peroxidase was

blocked with 3% H_2O_2, sections were incubated with primary antibodies against AFP (Santa Cruze Inc., United States, sc-8399) and AFPR (Santa Cruze Inc., United States, sc-51751) overnight at 4 ℃. A biotin-free horseradish peroxidase-labeled secondary antibody (Zhongshan Golden Bridge, Beijing, China) was used for 60 min at room temperature. Coloration was performed with 3,3'-diaminobenzidin.

Cell lines

HepG2 cells, an AFP-producing HCC cell line, were cultured in Dulbecco's modified eagle media (DMEM) supplemented with 10% fetal calf serum (FCS). The HLE hepatoma cell line, which is an AFP non-producer showed no detectable amount of AFP, and was maintained in DMEM medium supplemented with 10% FCS.

Western blotting

Western blotting was performed for analysis of expression of AFP and AFP receptor (AFPR) in HepG2 and HLE cells as previously described[30]. Briefly, cell lysate (40 μg) from each sample was subjected to 10% sodium dodecyl sulfate-Polyacrylamide gel electrophoresis. Electrophoretic transfer of proteins from gels onto nitrocellulose membranes (Amersham, United Kingdom) was carried out in transblotting cells. Membranes were blocked by immersing in 5% nonfat milk (w/v)/PBS for 1 h, and then incubated with anti-AFP, AFPR and β-actin mAbs (Santa Cruz Biotech Inc, United States) at room temperature for 2 h. After rinsing with PBS/0.1% Tween-20, membranes were incubated with horseradish peroxidase-conjugated goat anti-mouse (Zhongshan Boil Tech Co, Beijing) IgG secondary Ab. Immunocomplexes were visualized by incubation of the filters with the Enhanced Chemiluninescence kit (Zhongshan Boil Tech Co, Beijing) and exposure of X-ray film.

Intracellular localization of AFP and AFPR

Localization of AFP and AFPR in HepG 2 and HLE cells was analyzed with confocal microscopy as previously described[13]. Mouse anti-human AFP and mouse anti-human AFPR antibodies were purchased from Santa Cruz Biotech Inc, United States. Secondary goat anti-mouse IgG antibodies conjugated with rhodamine (Tetramethylrhodamineisothiocyanate) were purchased from Jackson Immun Res Lab, Inc, United States. Images of HepG 2 and HLE cells were captured with a confocal laser microscope (Leica TCS-NT SP2, Germany).

Determination of viability

To assess the effect of AFP on cell proliferation, the dimethylthiahzolyl-2,5-diphenyl-tetrazolium bromide (MTT) colorimetric assay and analysis were performed with the Cell Counting Kit (CCK)-8 (Dojindo Laboratories, Kumamoto, Japan) as described previously[31]. The CCK-8 assay was used to verify the effect of AFP seen with the MTT assay[32]. Briefly, 5×10^3 HepG 2 and human lens epithelial (HLE) cells were pipetted into 96-well microplates with various concentrations of AFP (0, 0.01, 0.1, 1, 10 and 100 mg/L) for the MTT assay, and were further subdivided into 0, 50, 100, 200 and 400 μg/L concentrations for both the MTT and CCK-8 assays. The absorbencies were measured at a wavelength of 570 nm for MTT assay and 450 nm for CCK-8 assay on a Universal Microplate Reader (EL × 800). The percentage of cell proliferation for each treatment was calculated as % cell proliferation = [(A_{570} or 450sample-background)/(A_{570} or 450 control-background)] × 100%.

Cell cycle analysis

Cell cycle measurement was performed by flow cytometry of DNA following propidium iodide (PI) staining[33]. Briefly, HepG 2 and HLE cells were cultured in serum-free medium for 12 h to arrest the cell cycle. The supernatant was then replaced by fresh medium containing 10% FCS and cells were transferred into 6-well plates (3×10^5 cells/ well). Cells were then treated with AFP (400 μg/L) for 24 h and stained by addition of 10 mg/mL PI at a final concentration of 50 mg/L. DNA content was analyzed with a FACScan-420 flow cytometer (Becton-Dickinso) as described previously. The distribution of cells in different cell cycle stages was determined according to the DNA content.

Statistical analysis

All data were statistically analyzed using χ^2 test and the t test and SPSS16 software, and expressed as mean ± SD.

RESULTS

Relationship between serum AFP level and mortality of HCC patients

HCC patient survival was analyzed retrospectively. Table 2 shows the relationship between the serum AFP level and mortality among three groups of HCC patients. There were no significant differences in mortality among these groups in the first 6 mo of evaluation. However, after one year, a higher mortality rate was observed in the high AFP group (> 250 μg/L) as shown in Table 2. The mortality rate in these groups of patients showed a direct correlation with serum AFP level. At the end of 2 years, 130/160 (81.25%) patients were alive with a survival rate of 86.8% in AFP < 20 μg/L group, 88.9% in AFP 20-250 μg/L group, and 69.6% in AFP > 250 μg/L group. These results demonstrate that the HCC patients with AFP levels higher than 250 μg/L had a higher mortality rate.

Further analysis showed that the overall survival rate (88.9%, 48/54) in HCC patients with lower AFP levels (AFP < 20 μg/L and 20-250 μg/L) who were treated surgically, was apparently higher than in those with high AFP levels in both groups treated surgically (61.8%, 13/21) ($P < 0.05$) and nonsurgically (80.0%, 40/50) at 24 mo ($P < 0.05$) (Figure 1A). There were no significant differences in the survival rates between patients managed surgically and conservatively in the two groups with lower

AFP levels. It is noteworthy that the survival rates of HCC patients with high AFP levels (> 250 μg/L) treated surgically (61.8%, 13/21) were lower than those treated conservatively (86.4%, 19/22) at 24 mo (P < 0.05). This suggests that surgical management confers survival benefit to HCC patients with lower AFP levels, but may be detrimental to the clinical course of HCC patients with AFP levels higher than 250 μg/L.

Expression of AFP and AFPR in liver tissues of HCC patients

We performed immunohistochemistry to confirm the existence of AFP/AFPR in tumor tissues of HCC patients. As shown in Figure 1B, neither normal liver tissues nor negative serum AFP showed any detectable AFP and AFPR. Interestingly, AFPR was expressed in AFP positive tissues but not in AFP negative tissues. The co-expression of AFPR and AFP in HCC patients indicated the functional relationship between these two proteins. Specific stronger staining of AFP and AFPR appeared in the cytosol and membrane, but not in the nucleus of tumor cells (Figure 1B). AFPR was not detected in fibrocytes surrounding the tumor cells. There was no qualitative relationship between serum AFP levels and the AFPR levels. In HCC patients with low serum AFP levels, immunohistochemistry still exhibited stronger AFPR staining. It is thus far unknown whether there is a clinical significance associated with expression of AFPR. Further clinical studies are needed to explore and establish the importance of AFPR in occurrence and progression of HCC.

Confirmation of existence of AFP and AFPR in HepG2 and HLE cells

To further evaluate the role of AFP in cell growth, cultured HepG2 and HLE hepatoma cell lines were used. Data from Western blotting showed that both AFP and AFPR were expressed in HepG2 but not in HLE cells (Figure 2A). Morphologic images under confocal microscope further confirmed that AFP and AFPR were present and scattered throughout the cytoplasm in HepG2 cells (Figure 2B and C). Although variable expressions

of AFP in different cell lines have been reported previously, there has been no data regarding the presence and distribution of AFPR. It is of interest to note that AFPR is present only in cells with AFP. Consistent with the immunohistochemical observations noted above, HepG2 cells produced both AFP and AFPR, while HLE cells produced neither of these proteins. This suggests the possibility of co-transcription and functional interrelation of these molecules.

Effect of AFP on cell proliferation

To verify the effect of AFP on tumor growth, MTT and CCK-8 cell proliferation assays were performed. The MTT assay showed that the maximum effect of AFP in promoting growth of both HepG2 and HLE cells was achieved at a 24 h incubation, and the most effective AFP dosage was about 1 mg/L (Figure 3A). More significantly proliferative effect was found in HepG2 cells, which showed a 3.5-fold increase in proliferation as compared with HLE cells at an AFP concentration of 1 mg/L. HepG2 cells are AFP and AFPR producing cells, and these cells showed a higher sensitivity in their response to AFP. When the AFP concentration range was limited to 0-400 μg/L, dose-dependent growth was observed in both cell lines (Figure 3C), however, HepG2 cells showed greater proliferation, similar to that shown in Figure 3A and B. The CCK-8 assay was used to further confirm the results obtained with MTT using AFP at a concentration range of 0-400 μg/L, which demonstrated a similar trend of growth (Figure 3D).

Cell cycle analysis

Flow cytometry was used to examine the effect of AFP on the cell cycle. Separation of cells in G0/G1, S phase and G2/M was based upon linear fluorescence intensity after staining with PI. Representative profiles are shown in Figure 4. The large initial peak (left) represents cells in G0/G1, the intervening area represents cells in S phase, and the final tail/small peak (right) represents cells in G2/M. These results showed that when HepG2 cells were exposed to AFP (400 μg/L), the percentage of cells in S phase was modestly increased (19.4%, P < 0.01) (Figure 4A and B). In contrast to HepG2 cells, the profile of the cell cycle in HLE cells did not show any significant change (Figure 4C and D).

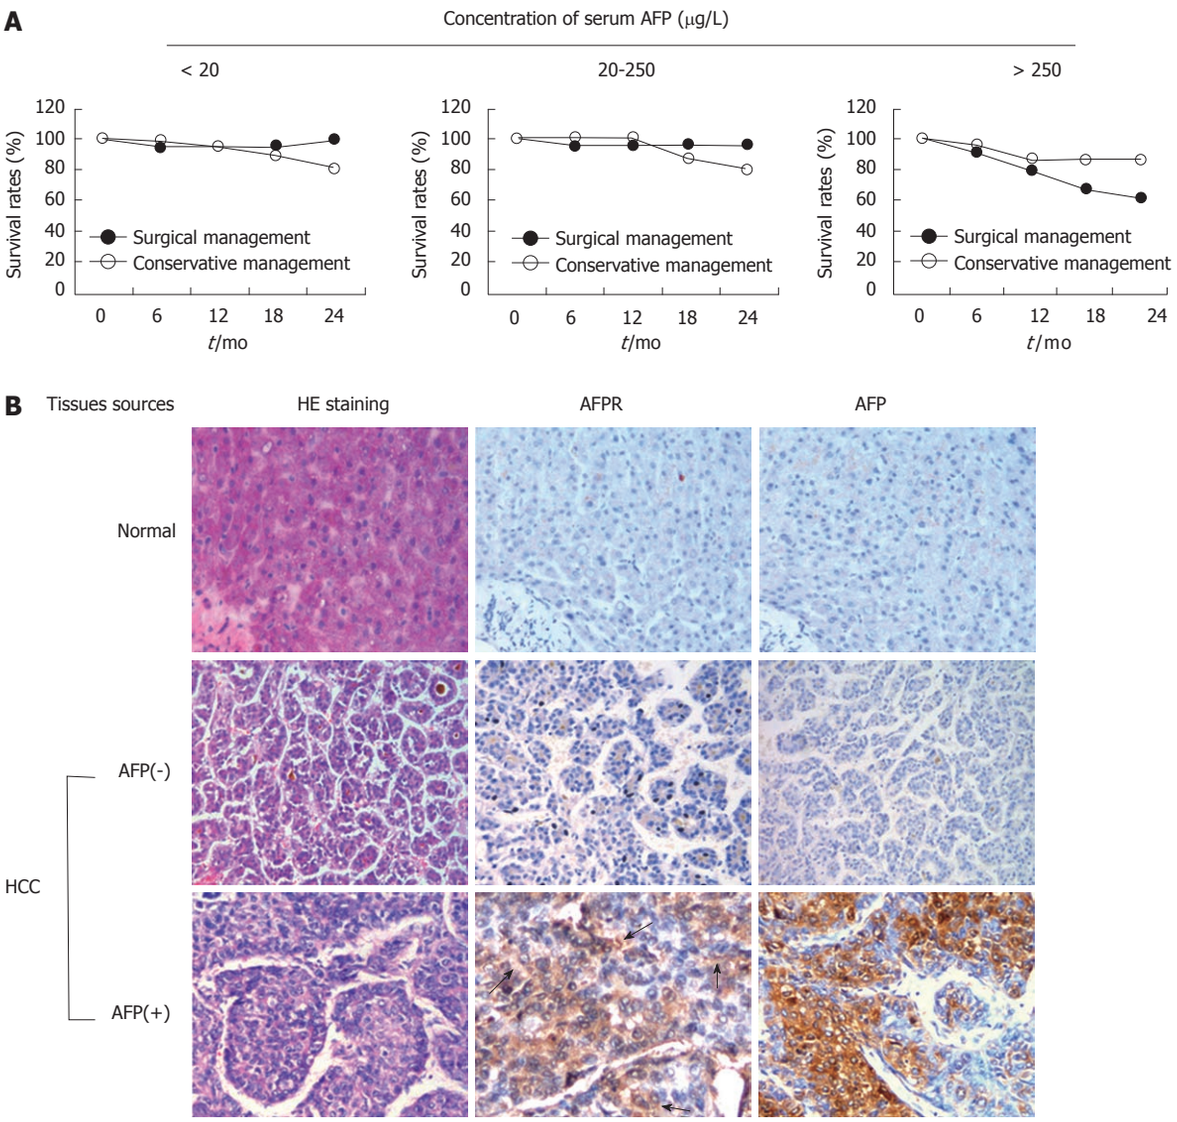

Figure 1 Survival rates of hepatocellular carcinoma patients and expression of alpha fetoprotein and alpha fetoprotein receptor in tumor tissues. A: Comparison of survival rates in hepatocellular carcinoma (HCC) patients with various alpha fetoprotein (AFP) levels who were treated surgically or non-surgically. Serum AFP levels of these HCC patients were divided into three groups: < 20 μg/L, 20-250 μg/L and > 250 μg/L; B: Immunohistochemical analysis of AFP and AFP receptor (AFPR) expressions in HCC tumor tissues. Membranous expression of AFPR is indicated with arrows. HE: Hematoxylin-eosin staining; AFP: Alpha fetoprotein; AFPR: Alpha fetoprotein receptor; HCC: Hepatocellular carcinoma.

DISCUSSION

HCC is one of the most common cancers worldwide, with a high mortality and prevalence rate in some countries, including China. Clinical studies have shown a potential relationship between AFP level and progression of HCC, and AFP may be used as a marker for monitoring treatment response in HCC patients[34-36]. As demonstrated in the retrospective analysis of 160 HCC patients in this study, patient mortality was apparently related to AFP levels. Patients with lower AFP levels (< 250 μg/L) showed a higher survival rate. Moreover, although surgical treatment has long been considered to be the primary therapeutic option for HCC[37], in this study surgery conferred survival advantage only in patients with lower AFP levels (< 250 μg/L). Surgical intervention in this study was associated with acceleration of death in patients with higher AFP levels (> 250 μg/L). These results may play a pathological role in carcinogenesis and progression of HCC.

There is extensive evidence showing that AFP is functionally an embryonic and fetal carrier/transport molecule for a multitude of ligands including fatty acids, bilirubin, heavy metals, steroids, retinoids, drugs, dyes and antibiotics[38]. However, the biological and pathophysiological roles of AFP associated with the occurrence and high mortality of HCC are still under study[22,39]. Silencing AFP expression by knockdown of its gene may play a role in growth arrest and apoptosis in human HCC cells[10,11,13,40]. Although AFP is widely used as a marker for diagnosis of HCC, some basic researches imply that AFP may be applicable in the treatment and prognostic monitoring of HCC patients[27,33]. Nevertheless, clinical observations supporting the biological role of AFP is still far from sufficient and additional data remains to be accumulated and evaluated.

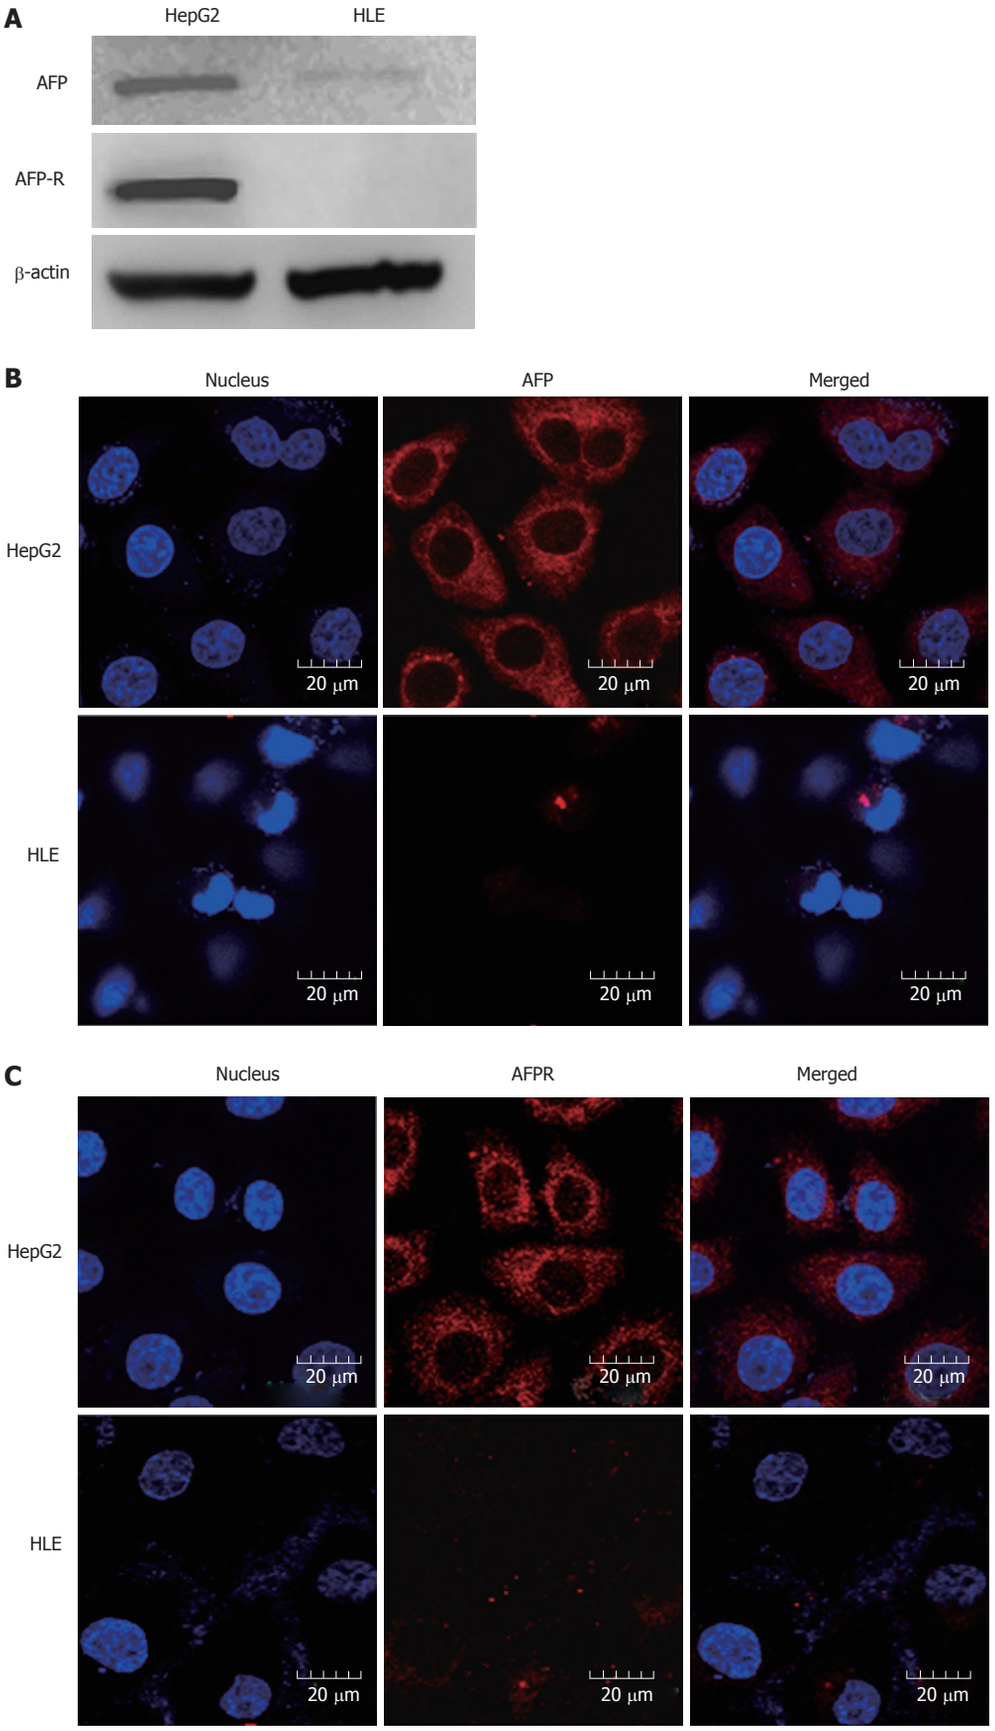

Figure 2 Expression of alpha fetoprotein and alpha fetoprotein receptor in HepG2 and HLE cells. A: Western blotting; B and C: Confocal microscopy. The immunoblots and images captured by cofocal microscopy are representative of experiments that were repeated at least three times. AFP: Alpha fetoprotein; AFPR: Alpha fetoprotein receptor.

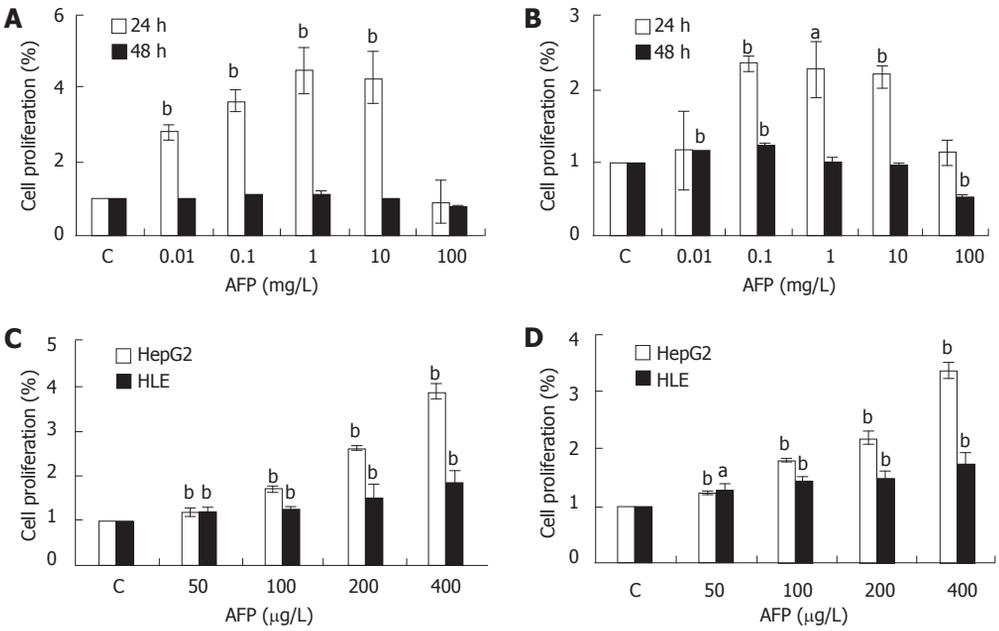

Figure 3 Effects of alpha fetoprotein in proliferation of HepG2 and HLE cells. Different concentrations (0, 0.01, 0.1, 1, 10 and 100 mg/L) of alpha fetoprotein (AFP) were tested in cell culture. The proliferation of HepG2 (A) and HLE (B) cells was evaluated with the dimethylthiahzolyl-2,5-diphenyl-tetrazolium bromide (MTT) assay at 24 and 48 h. HepG2 and HLE cells were further tested with 0, 50, 100, 200 and 400 μg/L AFP and proliferation was evaluated by MTT (C) and a cell counting kit (cck)-8 assay (D) at 24 h. The differences in proliferation between HepG2 and HLE cells were statistically analyzed with SPSS16 software. Data are representative of experiments that were repeated three times and are presented as mean ± SD for 6-9 samples.

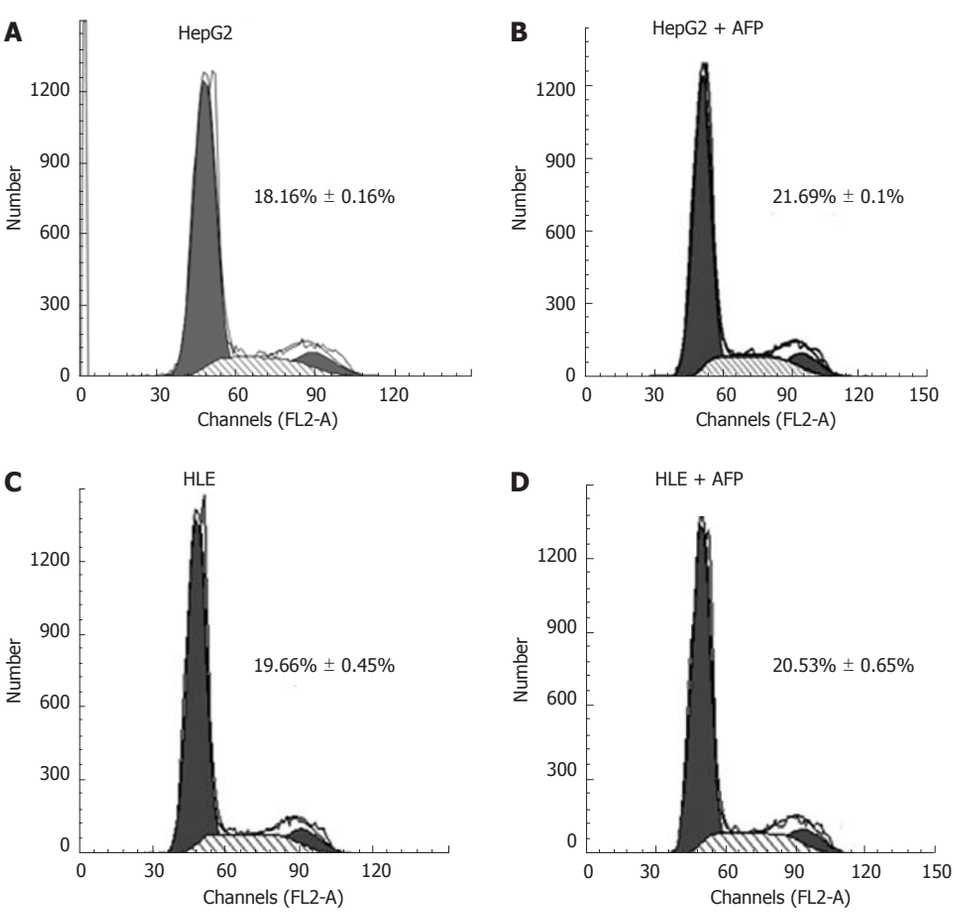

Figure 4 Effects of alpha fetoprotein on cell cycle progression of HepG2 and HLE cells. The distribution of cells in different cell cycle phases was determined according to DNA content. The data are representative of 3 independent experiments. Each panel represents a different treatment group. A: HepG2 cells without treatment; B: HepG2 cells treated with 400 μg/L alpha fetoprotein (AFP) for 24 h; C: HLE cells without treatment; D: HLE cells treated with 400 μg/L AFP for 24 h. In each panel, the number represents cell percentage in S phase. Data are presented as mean ± SD of 3 samples. AFP: Alpha fetoprotein.

The significance of AFPR in cell proliferation is of particular concern. However, until recently there has been little work involving AFPR in its clinical relation to HCC. Given the fact that AFP and its receptor are co-expressed in serum AFP positive but not in AFP negative tissues or cells as shown in this study, it is conceivable that cells expressing AFPR are more sensitive to AFP, thereby exhibiting greater proliferation and an associated increase in the proportion of cells in S phase. It has been inferred that AFP is secreted from hepatoma cells and acted on these cells through an autocrine mechanism. However, this does not occur in AFP negative tissues or cells as shown in this study. It is of particular interest that observations in HCC patients were consistent with findings from laboratory research, in that about one-third of HCC patients had similar AFP levels to healthy subjects, leading to a low mortality[41]. Thus, based on these results and findings in cultured cell assays, the intrinsic mechanism underlying the role of AFP in the mortality of HCC patients might be implicated.

Taken together, these results emphasize the significance and importance of serum AFP level in HCC patient survival. It appears that AFP is not simply a marker for diagnosis, it is also a growth factor in tumor progression. This concept of the function of AFP is consistent with the observations in this study in that HCC patients with higher serum AFP levels appear to have a higher mortality. Incorporation of serum AFP level into the criteria for evaluating prognosis and determining therapeutic options in HCC patients will likely be of significant benefit in patient management. Nonetheless, further clinical studies are needed to confirm this conclusion.

COMMENTS

Background

Although alpha fetoprotein (AFP) has been used as a serum marker for the clinical diagnosis of hepatocellular carcinoma (HCC), the biological role of this molecule in relation to its clinical significance is still unclear. The goal of this study is to evaluate the relationship between elevated serum AFP levels and survival of HCC patients and possible underlying mechanisms.

Research frontiers

AFP is an oncofetal protein and widely used as a marker in clinical diagnosis of HCC. In the last decade, compelling progress has been made in the two related research areas. First, AFP excreted into the circulation is able to promote cell growth and has been defined as a growth regulator in ontogenic growth and tumor progression. Second, it was recently demonstrated that intracellular AFP may function as a signal molecule through binding key proteins involved in growth or apoptosis signal pathways.

Innovations and breakthroughs

This study showed that AFP and AFPR were merely expressed in tissues of HCC patients with positive serum AFP. HCC patients with higher AFP levels had a higher mortality rate, which appears to be attributable to the growth promoting properties of AFP.

Applications

The findings in this study emphasize the significance and importance of serum AFP level in HCC patient survival. It appears that AFP is not simply a marker for diagnosis, it is also a growth factor in tumor progression. Incorporation of serum AFP level into the criteria for evaluating prognosis and determining therapeutic options in HCC patients may significantly benefit the management of HCC patients.

Peer review

This is an interesting study which underlines the importance of AFP in hepatocellular carcinoma. The paper is well written. This is another study which shows that AFP must play a key role in the decision making in operative treatment for HCC patients. A prospective study with comparable groups of HCC patients (size and number of tumor nodules, differentiation, clinical parameters of patients) either with low or high AFP would be ideal in the future.

Abstract

AIM: To study the relationship between the *cyclooxygenase (COX)-2* gene and the proliferation and apoptosis of esophageal squamous carcinoma EC109 cells.

METHODS: The techniques of RNA interference (RNAi) and cell transfection, as well as the levels of oncogenicity in nude mice, were used to study the role of COX-2 in the esophageal squamous carcinoma cell (ESCC) line EC109. Following RNAi and transfection, Western blotting analysis was used to determine the expression of the COX-2 protein. The 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT) reduction assay was used to evaluate cell growth, and flow cytometry was used to detect cell apoptosis.

RESULTS: Western blotting analysis demonstrated that *COX-2* expression was significantly reduced in EC109 cells treated with *COX-2*-specific short interfering RNA (siRNA) but was increased in EC109 cells transfected with *COX-2*. Furthermore, *COX-2* siRNA treatment inhibited cell proliferation ($P < 0.01$) and induced apoptosis in EC109 cells, as determined by an MTT assay and by flow cytometry, respectively. In contrast, transfected *COX-2* led to increased cell proliferation ($P < 0.05$) and decreased apoptosis in EC109 cells. In addition, combination treatment of cells with *COX-2* siRNA and aspirin had a synergistic effect ($P < 0.01$). For experiments measuring tumorigenicity, xenograft tumors of a greater volume and weight were found in the *COX-2* group compared with other groups ($P < 0.05$). A large dose of aspirin inhibited tumor growth in nude mice effectively ($P < 0.05$), and the rate of tumor suppression was 51.8% in the high-dose aspirin group.

CONCLUSION: *COX-2* plays a very critical role in ESCC carcinogenesis, and *COX-2* siRNA combined with aspirin has the potential to be an anticancer therapy for the treatment of ESCC.

INTRODUCTION

Esophageal carcinoma is a common malignant neoplasm worldwide with high fatality rates[1]. This condition can be classified as esophageal squamous cell carcinoma (ESCC) or esophageal adenocarcinoma. Cancers arising from esophageal tissue, especially ESCC, have high incidence rates in China. Despite surgical treatment and chemotherapy, the prognosis of ESCC had until recently been very poor. Thus, early identification and effective treatment are highly desirable for an improved prognosis.

Cyclooxygenase is an enzyme responsible for the synthesis of prostaglandins, and it has two isoforms, COX-1 and COX-2. COX-1 is a constitutive enzyme and is found in most mammalian cells. COX-2, on the other hand, is undetectable in most normal tissues but can be induced by tumor-promoting agents, growth factors and inflammation.

To date, many studies have shown *COX-2* to play a very important role in carcinogenesis. *COX-2* has been reported to be over-expressed in many malignant tumors, such as those in breast, lung, stomach, colon and pancreatic cancer[2-6], and levels of *COX-2* expression are associated with poor prognosis of some cancers[7]. Non-steroidal anti-inflammatory drugs (NSAIDs) and *COX-2* inhibitors have been shown to effectively suppress tumor development[8]. For instance, recent studies have indicated that the regular use of aspirin can reduce the risk of esophageal cancer by as much as 90%[9,10]. Due to the inhibitory effect of aspirin on COX activity, we hypothesized that *COX-2* is involved in the development of esophageal cancer.

In fact, the association between *COX-2* and ESCC has previously been examined. In these studies, the common findings were that *COX-2* was over-expressed in ESCC and that it contributed to carcinogenesis. However, the molecular mechanism by which *COX-2* promotes carcinogenesis in squamous cells remained unclear.

Previous research has shown that the mechanisms behind *COX-2* gene expression differed by cell type and the cell growth conditions. The pleiotropic effects of COX-2 on carcinogenesis include increased cellular proliferation, inhibition of apoptosis, increased angiogenesis, impaired cell adhesion and increased invasion of malignant cells[11-13].

In the present study, we have delineated the effects of increased or decreased levels of *COX-2* on human ESCC proliferation and apoptosis. Specifically, we have investigated the effect of *COX-2* overexpression on ESCC cell proliferation and apoptosis. We have also analyzed the effects of aspirin, a nonspecific *COX-2* inhibitor and the specific depletion of COX-2 by short interfering RNA (siRNA) in ESCC. The results showed that *COX-2* overexpression induced antiapoptotic activity and promoted tumorigenesis, while the inhibition of COX-2 effectively suppressed the proliferation of cancer cells and tumorigenesis in nude mice.

A recent study by Yang GZ *et al*[14] found that *COX-2* expression was upregulated during an early stage of ESCC, especially in more fully differentiated carcinomas. Therefore, the inhibition of *COX-2* by RNAi or aspirin treatment could be an effective strategy for the prevention and treatment of early stages of ESCC.

MATERIALS AND METHODS

Cell lines

EC109 is a cell line that was derived from a patient with a well-differentiated ESCC, and the line was obtained from the Cancer Institute at the Chinese Academy of Medical Sciences. EC109 cells were maintained in RPMI 1640 culture medium (Invitrogen, United States) supplemented with 10% fetal calf serum, 1% penicillin/streptomycin and 2% L-glutamine. The cells were grown in a humidified 37 ℃ incubator with 5% CO_2. They were fed every 3 d with complete medium and were subcultured when confluent.

Construction of hCOX-2 expression vectors and transient transfections

The modified pOSML-PGHS-2 plasmid, kindly provided by Dr. Smith WL (University of Michigan, United States), contains the full-length *hCOX-2* gene. After the sequence of full-length *hCOX-2* cDNA had been confirmed by sequence analysis, *COX-2* cDNA (approximately 1.9 kb) was cloned into the pcDNA3.1/V5HisA expression vector. One day before transfection, EC109 cells were seeded at 2.5 × 10^5/plate in 6 cm dishes in RPMI 1640 antibiotic-free medium containing 10% fetal bovine serum (FBS) until they were 80%-90% confluent. After 24 h, 800 μL of RPMI 1640 medium without FBS or antibiotics was added to each well, and the cells were transfected with either the *COX-2* expression plasmid (pcDNA3.1V5HisA/*hCOX-2*) or with an empty control vector (pcDNA3.1V5HisA) using Lipofectamine™2000 (Invitrogene, Carlsbad, CA) according to the manufacturer's protocol. In brief, 5 μg of *COX-2* plasmid DNA was diluted in serum- and antibiotic-free RPMI 1640 medium to a total volume of 100 μL. In addition, 5 μL of Lipofectamine™2000 was diluted with serum- and antibiotic-free RPMI 1640 medium to a total volume of 100 μL. The diluted plasmid DNA was combined with the diluted Lipofectamine™2000. Following incubation for 20 min at room temperature, 200 μL of the mixture was added to each well, and the cells were incubated at 37 ℃ in a CO_2 incubator for 5 h. The RPMI 1640 medium containing 10% FBS was changed after 5 h, and the cells were incubated for an additional 24 h at 37℃ in a CO_2 incubator. For the combined treatment of *COX-2* transfection and aspirin, 8 mmol/L aspirin was added 24 h after the *COX-2* plasmid (pcDNA3.1V5HisA/*hCOX-2*) was transfected into the EC109 cells, and the cells were treated with aspirin for 48 h.

COX-2 siRNA synthesis and transfection

COX-2 siRNA was synthesized by GeneChem (Shanghai, China). The *COX-2*-specific siRNA was designed to target positions 293-311 (5'-CUGCUCAACACCGGAAU-

UUtt-3') of the *COX-2* transcript (GenBank Accession No: NM_000963). We also used a scrambled siRNA as a negative control. This negative control had no significant homology to any known human, mouse or rat gene sequence (non-silencing-FITC: 5'-UUCUCCGAACGUGUCACGUtt-3'). EC109 cells were plated in 6-well plates at 2×10^5 cells per well, and RPMI 1640 medium without antibiotics was added to each well. After 24 h, the cells were grown to reach 40%-50% confluence and were transfected with *COX-2* siRNA using the Lipofectamine ™2000 reagent according to the manufacturer's instructions. The original stock of siRNA was resuspended in siRNA suspension buffer provided by the manufacturer. From this stock (20 μmol/L), 15 μL was diluted with 250 μL of Opti-MEM, and 5 μL Lipofectamine™2000 was diluted with 250 μL of Opti-MEM. After 5 min at room temperature, these were combined and incubated for 20 min. The siRNA-Lipofectamine complexes were then added to the plated cells and mixed gently. The cells were incubated at 37 ℃ in a humidified atmosphere of 5% CO_2 for 84 h. For combination treatment of *COX-2* siRNA with aspirin (Sigma, United States), 8 mmol/L aspirin was added 48 h after the *COX-2* siRNA was transfected into the EC109 cells, and the cells were treated with aspirin for 36 h.

Western blotting

Cells were harvested and lysed in lysis buffer, and Western blotting analysis was performed using conventional protocols. Briefly, the protein concentration of the extracts was determined using a bicinchoninic acid kit (Pierce, United States) with bovine serum albumin as the standard. Total protein samples (30 μg) were loaded and separated by 10% SDS-PAGE gels and then transferred to protran nitrocellulose membranes (Whatman, United Kingdom). The membranes were incubated with an anti-COX-2 antibody (1:200; Santa Cruz, United States) and, after extensive washing, a horseradish peroxidase-conjugated goat anti-rabbit IgG antibody (1:2000; Santa Cruz) for 1 h at room temperature. The signal was detected by chemiluminescence using an ECL Detection Kit (Amersham, United States). The membranes that were probed for *COX-2* were re-probed for β-actin (1:10 000; Santa Cruz, United States) to normalize for loading and/or quantification errors and to allow for the direct comparison of protein expression. The bands were quantified using a Gel EDAS analysis system (Cold Spring United States Corporation) and Gel-Pro Analyzer 3.1 software (Media Cybernetics, United States).

3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide assay

To evaluate the effects of COX-2 overexpression and aspirin treatment on the proliferation of the EC109 cells, the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay was used. In brief, EC109 cells were seeded in 96-well plates at a density of 2×10^5 cells/well and cultured for 24 h. The cells were then transfected with the *COX-2* expression plasmid (pcDNA3.1V5HisA/hCOX-2) or the empty control vector (pcDNA3.1V5HisA) for 72 h. At 24 h post-transfection, the co-treated cells were treated with aspirin (8 mmol/L) for an additional 48 h. Then, 20 μL of 5 mg/mL MTT solution (Gibco, Grand Island, United States) was added to 200 μL of the media in each well. After an additional incubation for 4 h, the media was discarded, and 150 μL of DMSO was added to each well to dissolve the formazan crystals. The optical density at 492 nm was read using an automated microplate reader. The experiments were conducted in triplicate, and the results are shown as the mean ± standard deviation (SD) of three independent experiments.

Detection of the rate of apoptosis by flow cytometry

To determine the effects of *COX-2* overexpression and aspirin treatment on apoptosis, EC109 cells were transfected with either an empty control vector, *hCOX-2* cDNA alone or with *hCOX-2* cDNA plus aspirin treatment. The cells were collected by centrifugation at 200 *g* for 5 min and stained with propidium iodide (PI; R&D Company, Minneapolis, United States). The pellets were washed twice with ice-cold phosphate-buffered saline (PBS), fixed overnight at 4 ℃ in 70% ethanol and stored at -20 ℃. The pellets were washed twice with PBS, and the cells were incubated with 5 μg/mL PI and 50 μg/mL RNase A in PBS for 1 h at room temperature in the dark. Flow cytometry was conducted using a FACSCalibur flow cytometer (BectonDickson, Mountain View, CA). Ten thousand events were collected per sample, and the cells were analyzed for the rate of apoptosis using CELLQUEST software. This experiment was performed in triplicate.

Tumorigenicity in nude mice

To generate stably transfected cell lines, cells transfected with pcDNA3.1V5HisA/*hCOX-2* as well as cells transfected with the empty control vector (pcDNA3.1V5HisA) were selected with 500 μg/mL G418. After 30 d of selection with G418, a G418-resistant stably transfected cell line was created. EC109 parent cells and stably transfected cells were trypsinized and collected. The cell viability was > 95% as determined by trypan blue staining. Cells (4×10^6) in 0.1 mL PBS were inoculated subcutaneously onto the backs of 4- to 6-wk-old male BALB/c nude mice (five per group). Male BALB/c nu/nu mice weighing (15.24 ± 0.57) g were purchased from the Experimental Animal Center at the Chinese Academy of Medical Sciences and Peking Union Medical College. The mice were housed under sterile conditions. For mice given the combination of *COX-2* transfection and aspirin treatment, a high dose (0.315 mg/dL^{-1}) or a low dose (0.016 mg/dL^{-1}) of aspirin was orally administrated once per day starting one day before the inoculation of *COX-2*-transfected EC109 cells. The aspirin administered to experimental animals was provided by the Bayer Animal Health Company. The tumor size was monitored weekly

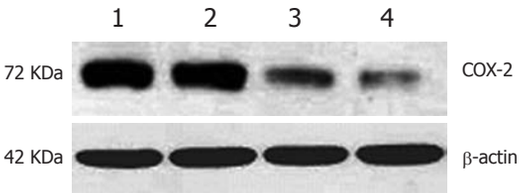

Figure 1 Western blotting for cyclooxygenase-2 protein expression after transfection of EC109 cells. 1: Parental cells; 2: *hCOX-2*-transfected cells; 3: Vector control cells; 4: Cells treated with aspirin for 48 h after transfection with *hCOX-2*.

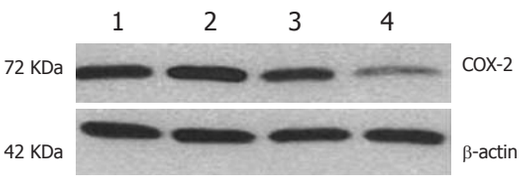

Figure 2 Western blotting for cyclooxygenase-2 protein expression after RNA interference treatment of EC109 cells. 1: Parental cells; 2: Negative control siRNA; 3: *Cyclooxygenase-2 (COX-2)* short interfering RNA (siRNA); 4: Cells treated with aspirin for 48 h after transfection with *COX-2* siRNA.

using calipers, and the tumor volume was calculated using the following formula: volume = 0.5 × length × width[2]. At the end of 4 wk, all the mice were sacrificed and their weight was recorded. The tumors were excised and kept in 4% formalin for immunohistochemical analysis. The percentage of cells expressing nuclear Ki67 was used for the assessment of cellular proliferation rate. The nuclear Ki67 expression and the nuclear COX-2 protein expression was detected by immunohistochemistry. The Ki67 and COX-2 antibodies for immunohistochemistry were purchased from the Fuzhou Mai Xin Company (Fuzhou, China). PV6001 Kits were purchased from Zhong Shan Golden Bridge Biological Technology (Beijing, China). All procedures using animal experimentation were approved by the local animal research authorities, and animal care was conducted in accordance with institutional guidelines.

Statistical analysis

Statistical analysis was performed using SPSS statistical software (SPSS 11.0, United States). The differences between the groups were assessed using the analysis of variance test. The results were considered statistically significant when the *P* value was < 0.05 or < 0.01.

RESULTS

Expression of COX-2 in EC109 cells transfected with pcDNA3.1V5HisA/hCOX-2 and treated with aspirin

The expression of *COX-2* was evaluated in EC109 cells transfected with either the pcDNA3.1V5HisA/*hCOX-2* or pcDNA3.1V5HisA vector. For the combined treatment group, 8 mmol/L aspirin was added to the cell culture 24 h after transfection with the *COX-2* plasmid (pcDNA3.1V5HisA/*hCOX-2*) for a period of 48 h. COX-2 protein expression was evaluated by Western blotting analysis. In comparison to the parent cell line or the control vector transfectants, a slight increase in *COX-2* expression was observed in the *COX-2*-transfected EC109 cells. However, the expression of *COX-2* was suppressed after aspirin was added to the *COX-2*-transfected EC109 cells. For Western blotting analysis, the *COX-2* expression was normalized to β-actin expression by band intensity (Figure 1).

Inhibition of COX-2 protein expression by RNAi and/or aspirin treatment

Given the importance of *COX-2* in ESCC carcinogenesis, we used an *in vitro* experimental model that used ESCC cell lines to determine whether *COX-2*-specific siRNA was able to downregulate *COX-2* expression. From a panel of ESCC cell lines, we choose a well-differentiated line (EC109) that had a moderate level of *COX-2* expression. The effect of *COX-2* siRNA treatment on protein expression was assessed by Western blotting analysis. As shown in Figure 2, *COX-2* expression was reduced in EC109 cells 84 h after transfection with the *COX-2* siRNA (100 nmol/L), while the negative control siRNA had no effect on the expression of *COX-2*. *COX-2* expression was normalized to β-actin expression by band intensity. *COX-2* expression was significantly further decreased in the EC109 cells transfected with *COX-2* siRNA for 36 h and also in the EC109 cells treated with aspirin for 48 h (Figure 2). These results suggest that the co-administration of aspirin and siRNA had a synergistic effect on the inhibition of *COX-2* gene expression.

COX-2 overexpression and aspirin treatment increase EC109 cellular proliferation

The MTT assay was conducted to elucidate the effects of *COX-2* transfection and aspirin treatment on EC109 cell proliferation. The values are expressed as the mean ± SD of three independent experiments. The results from this assay indicated that *COX-2* transfection led to a marked increase in cell proliferation at 72 h (Figure 3). Statistical analysis found that cell proliferation was significantly increased in *COX-2*-transfected EC109 cells ($P < 0.05$). However, there was no significant increase in the proliferation of cells transfected with the empty vector, as compared to parent cells. Furthermore, cell proliferation was not significantly affected by the administration of aspirin

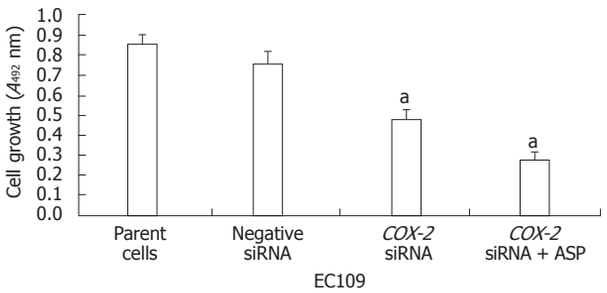

Figure 4 Inhibition of cell proliferation in EC109 cells by short interfering RNA and aspirin treatment (n = 3, mean ± SD). $^{a}P < 0.01$. siRNA: Short interfering RNA; ASP: Aspirin.

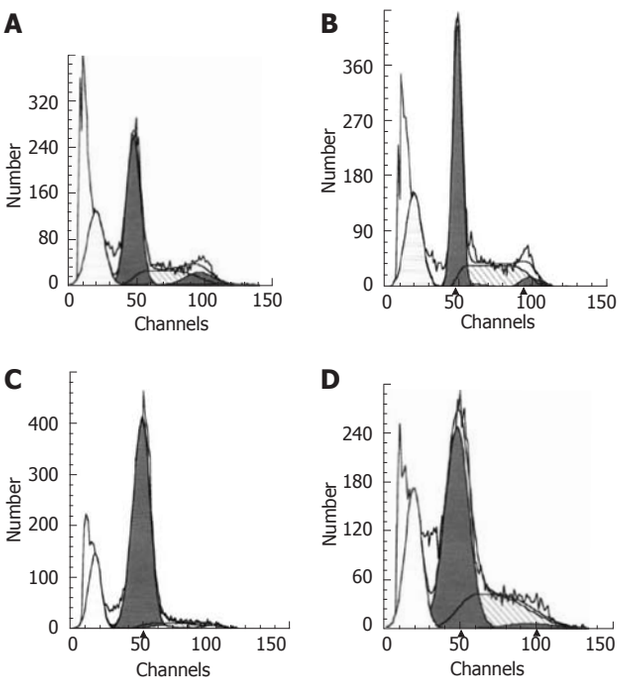

Figure 5 *hCOX-2* transfection and aspirin treatment induces apoptosis in EC109 cells. A: Parental cells; B: Samples transfected with the control pcDNA3.1V5HisA vector; C: Samples transfected with the *cyclooxygenase-2*-expressing plasmid pcDNA3.1V5HisA/hCOX-2; D: Samples transfected with the pcDNA3.1V5HisA/hCOX-2 plasmid for 24 h and treated with aspirin for an additional 48 h.

to *COX-2*-transfected cells as compared with control cells (Figure 3). These data demonstrate that cell proliferation was increased following *COX-2*-transfection in EC109 cells and decreased upon co-administration of aspirin. Therefore, the expression of *COX-2* was important for proliferation in EC109 cells. Moreover, *COX-2* overexpression by transfection promoted cell proliferation, and the inhibition of *COX-2* expression by aspirin treatment inhibited cell proliferation in EC109 cells.

COX-2 RNAi and aspirin treatment reduce EC109 cellular proliferation

To elucidate the effects of the siRNA and aspirin treatments on EC109 cell proliferation, the MTT assay was used, and cell proliferation was determined by counting the numbers of viable cells. The values are expressed as the mean ± SD of three independent experiments. There was no significant reduction in the number of viable EC109 cells at 24 h post-treatment. However, at 48 h, we detected a significant decrease in the number of viable cells. Furthermore, *COX-2* siRNA treatment resulted in a significant inhibition of cell proliferation in the EC109 cells ($P < 0.01$) at 84 h post-transfection (Figure 4). The proliferation was not affected by treatment with the control siRNA. Additionally, the treatment of siRNA-transfected cells with aspirin further increased the inhibition of cell proliferation ($P < 0.01$, Figure 4). These data demonstrate that *COX-2* expression is important for proliferation in EC109 cells and that the inhibition of *COX-2* by siRNA alone or combined with aspirin treatment can inhibit the proliferation of EC109 cells.

COX-2 overexpression and aspirin treatment reduce the rate of apoptosis in EC109 cells

To determine the effect of *COX-2* transfection and aspirin treatment on apoptosis in esophageal cancer EC109 cells, flow cytometry was performed on PI-stained cells. The results showed that EC109 cells transfected with *hCOX-2* were resistant to apoptosis. Comparing to the rate of apoptosis that was 28.7% in parent cells group and 26.96% in empty vector transfected cells group, the rate of apoptosis was decreased to 17.75% in COX-2-transfected EC109 cells (Figure 5). Apoptosis was not significantly influenced by transfection with the empty vector control. However, the rate of apoptosis increased to 24.97% when the transfected EC109 cells were treated with aspirin (Figure 5). These data indicate that apoptosis in EC109 cells was affected by *COX-2* transfection and aspirin treatment.

COX-2 RNAi and aspirin increase the rate of EC109 cellular apoptosis

To determine the effect of siRNA and aspirin treatment on the rate of apoptosis in EC109 cells, treated cells were labeled with PI and analyzed by flow cytometry. The inhibition of *COX-2* by siRNA alone or with aspirin treatment resulted in a significant decrease in the growth of the EC109 cells due to the induction of apoptosis. Apoptosis was not significantly influenced by treatment with the negative control siRNA. Comparing to the rate of apoptosis that was 1.35% in parent cells group and 1.72% in negative control siRNA-treated cells group respectively, the rate of apoptosis was increased to 4.33% in siRNA-treated EC109 cells (Figure 6) and was further increased to 11.66% when EC109 cells were treated with both the COX-2-specific siRNA and aspirin (Figure 6). These data indicate that the COX-2-specific siRNA alone or in combination with aspirin treatment induced the apoptosis of EC109 cells.

Tumorigenicity in nude mice

***COX-2* overexpression increases tumor growth:** Human *COX-2* cDNA was cloned into the pcDNA3.1V5HisA vector, which was stably transfected into the EC109 cells.

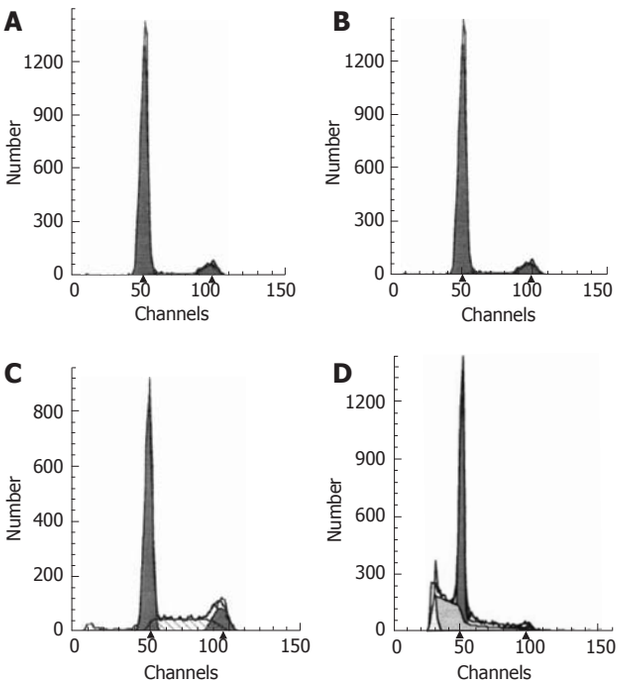

Figure 6 Short interfering RNA-mediated *cyclooxygenase-2* knockdown with aspirin treatment induces apoptosis in EC109 cells. A: Parental cells; B: Samples treated with the negative control short interfering RNA (siRNA); C: Samples treated with *cyclooxygenase-2 (COX-2)* siRNA; D: Samples treated with COX-2 siRNA for 48 h and treated with aspirin for an additional 36 h.

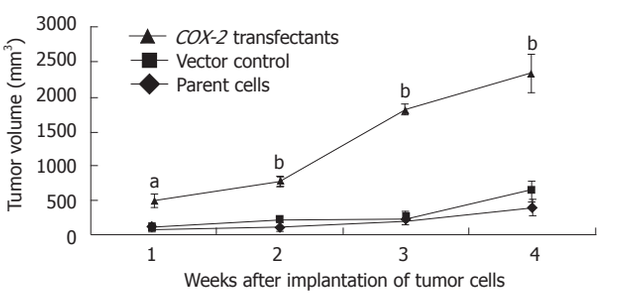

Figure 7 Effect of cyclooxygenase-2 on tumor growth in the nude mouse xenograft tumor model (n = 15, mean ± SD). $^{a}P < 0.05$, $^{b}P < 0.01$. COX-2: Cyclooxygenase-2.

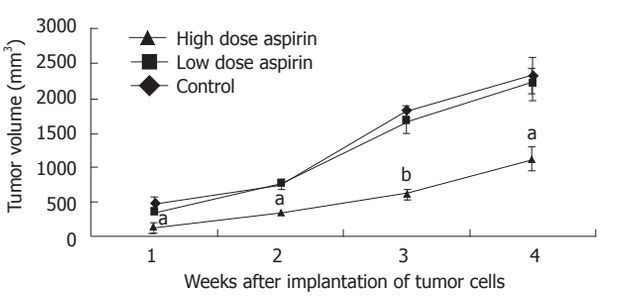

Figure 8 Effect of aspirin on tumor growth in the nude mouse xenograft tumor model (n = 15, mean ± SD). $^{a}P < 0.05$, $^{b}P < 0.01$.

To assess changes in cell biology after gene transfection, cell proliferation was measured by an MTT assay. *COX-2*-transfected cells appeared to have a markedly different growth pattern, as compared to the EC109 parent cells or the vector control-transfected cells (Figure 3). To investigate the role of *COX-2* in tumorigenicity, tumor progression was evaluated in nude mice. Following selection, G418-resistant stably transfected cells were inoculated into nude mice. The first xenografted tumor was found 3 d after the implantation of *COX-2*-transfected tumor cells, and tumor sizes were measured weekly. Four weeks after cell transfer, tumors established by EC109 parent cells or vector control (pcDNA3.1V5HisA) cells produced tumors of 393.43 mm^3 ± 118.48 mm^3 and 634.50 mm^3 ± 159.29 mm^3, respectively, while tumors from *COX-2*-transfected (pcDNA3.1V5HisA/*hCOX-2*) cells produced markedly larger tumors that were 2344.49 mm^3 ± 273.52 mm^3 in volume ($P < 0.01$ or $P < 0.05$, Figure 7). When mice were sacrificed at 28 d post-transfer, the EC109 parent cells and vector control cells had produced tumors that were 0.67 g ± 0.15 g and 0.89 g ± 0.29 g, respectively, while *COX-2*-transfected cells had produced larger tumors that were 2.58 g ± 0.26 g in weight ($P < 0.05$). Data are expressed as the mean ± SD of five independent samples (n = 15). These data show that *COX-2* gene expression increased tumor growth.

Aspirin treatment reduces tumor growth: Aspirin, an inhibitor of *COX-2*, was administered to nude mice starting one day before the implantation of *COX-2*-stably transfected EC109 cells. At day 28 after implantation, a high dose of aspirin (0.315 mg/dL^{-1}, once per day) had significantly reduced tumor volume ($P < 0.01$ or $P < 0.05$) and tumor weight ($P < 0.05$) in this xenograft model (Figure 8). However, there was no significant difference in tumor volume between the low-dose aspirin (0.016 mg/dL^{-1}, once per day) and control group. Date are expressed as the mean ± SD of five independent samples (n = 15). The tumor inhibition rate for the high-dose aspirin group was 51.80%, and the tumor inhibition rate for the low-dose aspirin group was 5.98%. No digestive hemorrhages or ulcers were found in the mice. Therefore, large doses of aspirin effectively inhibited the growth of these xenografted tumors in nude mice.

Evaluation of Ki67 immunostaining in cancer xenografts: The expression of Ki-67 protein is strictly associated with cell proliferation, which makes Ki-67 expression a biomarker and a strong predictor of cancer. We mainly observed Ki-67 protein expression in the nuclei of xenografted tumor cells (Figure 9). Immunohistochemical sections stained for Ki-67 were quantified with a computer-aided image analysis machine using the association between high gray-scale density and tumor cell proliferation. The quantification of staining intensity demonstrated that cell proliferation in tumor xenografts from cells transfected with *COX-2* was greater than in tumors from parent cells and vector control-transfected cells.

DISCUSSION

A large body of evidence suggests that *COX-2*-overexpressing cancer cells may possess a survival advantage that

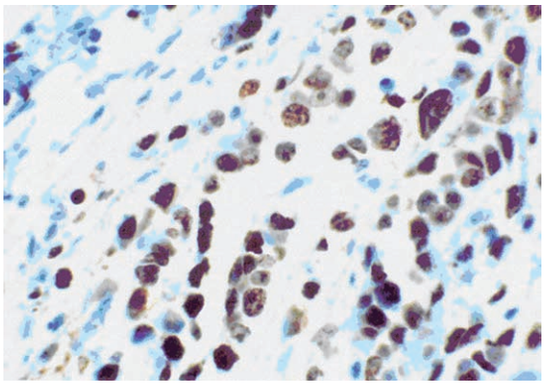

Figure 9 Ki-67 expression in the nuclei of cells in xenograft tumors from pcDNA3.1V5HisA/hCOX-2-transfected EC109 cells at 400 x magnification.

facilitates tumor development and progression[15,16]. In our study, RNAi was used as a potent tool to inhibit *COX-2* gene expression levels in human ESCC. *COX-2* RNAi resulted in significant suppression of cellular proliferation in EC109 cells. This result, together with the observation that aspirin treatment inhibited the growth of the EC109 cells, indicates that *COX-2* activity may be directly associated with proliferation in EC109 cells. To further investigate the role of *COX-2* in ESCC carcinogenesis, EC109 cells were transfected with recombinant *COX-2*-expressing vectors to establish stably transfected cell lines. The increased COX-2 protein expression observed in transfected cells suggests that *COX-2* transfection effectively increases *COX-2* levels and leads to the increased proliferation of these cells.

Other studies have found an association between *COX-2* overexpression and the antiapoptotic signature of cancer[17-19]. In this study, an antiapoptotic effect was observed in *COX-2*-transfected cells. Considering the proapoptotic effect of aspirin, our results suggest that *COX-2* overexpression contributed to the antiapoptotic signature of the EC109 cells. Furthermore, *COX-2* RNAi promoted apoptosis in these cells. Our data suggest that *COX-2*-specific siRNA treatment combined with the administration of aspirin is a promising treatment option for *COX-2*-expressing ESCCs. *COX-2* overexpression-mediated upregulation of the antiapoptotic protein Bcl-2 has been proposed to be a mechanism that leads to the antiapoptotic signature of cancer cells[20].

In light of these results obtained from *in vitro* experiments, we hypothesized that *COX-2* cDNA would enhance the *in vivo* tumorigenesis of EC109 cells. As expected, nude mice transfected with *COX-2* showed faster tumor growth and larger tumors, which is in contrast to mice transfected with the parental cell line or the vector control cells. Furthermore, the immunohistochemical data support these findings, as Ki-67, a marker of cell proliferation, was found at increased levels in the *COX-2*-tranfected tumor xenografts. In addition, the suppression of *COX-2* expression by high-dose aspirin treatment effectively attenuated the oncogenesis of EC109 cells *in vivo*.

Although transfection of *COX-2* into EC109 cells resulted in increased cellular proliferation, stronger antiapoptotic activity and enhanced tumorigenesis *in vivo,* the EC109 cell line itself had endogenous *COX-2* expression. Therefore, we deduce that *COX-2* function is correlated with the amount of its expression and enzyme activity.

NSAID-mediated growth inhibition of tumor cells involves COX-prostaglandin E_2 (PGE_2)-dependent and COX-PGE_2-independent pathways[21]. In COX-PGE_2-dependent pathways, COX-2 inhibitors suppress carcinogenesis *via* the inhibition of COX-2-derived PGE_2, which promotes cell proliferation and immunosuppression[22]. The elevated levels PGE_2 in *COX-2*-overexpressing cells are related to the metastatic potential of the cancer cells, which can be reduced in a dose-dependent manner by COX inhibitors[12]. Furthermore, the COX-2 enzyme itself can promote cancer development and progression[23]. In COX-PGE_2-independent pathways, the mechanism by which COX-2 inhibitors suppress carcinogenesis involves the reduced activation of Akt, inhibition of nuclear factor-κB activation, downregulation of the antiapoptotic protein Bcl-XL, inhibition of peroxisome proliferator-activated receptor (PPAR)-δ, activation of PPAR-γ and the activation of caspase family members. One or more of these COX-PGE_2-independent effects could contribute to the proapoptotic and antiproliferative effects of NSAID treatment[24]. The hypophosphorylation of the retinoblastoma tumor suppressor protein as well as the downregulation of multiple proliferation-promoting cyclins and cyclin-dependent kinases induced by NSAIDs has been reported in colon carcinoma cells[23]. The extent of the use of COX-PGE_2-dependent or -independent pathways following NSAID treatment may depend on the cell type.

Gene therapy and RNAi are the most exciting and promising technologies in biomedicine today. The goal of gene therapy is to introduce genetic material (DNA or RNA) encoding a protein, which is missing or defective, into a patient's cells or tissues. RNAi is the sequence-specific post-transcriptional silencing of gene expression mediated by small double-stranded RNA molecules. RNAi has become an exceptionally powerful method to inhibit the expression and function of disease-causing genes, and it performs better than all similar techniques previously tested in gene therapy. However, the use of RNAi is still in its infancy, and the safety of the delivery system and tissue-targeting and the potential for adverse effects or lifelong RNAi persistence should still be considered before RNAi becomes a feasible and safe therapy for patients. In fact, RNAi-mediated gene therapy remains the single most promising biomedical strategy for knocking down expression of the *COX-2* gene in human ESCC, and we believe that the successful clinical implementation of RNAi gene therapy and its eventual translation into clinical benefits are merely a question of time.

In this study, no gastric mucosal hemorrhages were found in mice, even after administration of large doses of aspirin. However, the gastric mucosa of nude mice is different from human gastric mucosa. In patients, larger

doses of aspirin can increase the risk of bleeding, including bleeding ulcers, and combined therapy with RNAi can allow for lower doses of aspirin. The risk for bleeding tends to decrease as the dose of aspirin is decreased. Further long-term animal experiments may be required to test the effectiveness of *COX-2* inhibitors and RNAi in the treatment of ESCC.

In conclusion, our present study has indicated that *COX-2* plays a crucial role in the carcinogenesis of human ESCC by increasing cell proliferation and resistance to apoptosis and subsequently enhancing tumorigenesis *in vivo*. These results suggest that *COX-2* may be a new gene target for ESCC treatment and that inhibition of *COX-2* expression by RNAi and aspirin treatment may serve as an early and effective prevention and treatment of early-stage, *COX-2*-expressing ESCC.

COMMENTS

Background

Esophageal cancer can be divided into two major groups including esophageal squamous cell carcinoma (ESCC) and esophageal adenocarcinoma. Epidemiological studies indicate that ESCC is the dominant form in Asian countries, especially China, Japan and Korea. Some studies have shown that *COX-2* is overexpressed in ESCC and contributes to carcinogenesis. However, the molecular mechanisms by which *COX-2* promotes carcinogenesis in squamous cells remain unclear. Given the high fatality rate and the rapidly increasing incidence of ESCC, the definition of the role of *COX-2* in the pathogenesis and therapy of this cancer is highly desirable.

Research frontiers

In this study, RNAi was used as a potential tool to inhibit *COX-2* gene expression in human ESCC. *COX-2* RNA interference (RNAi) significantly suppressed the proliferation of EC109 cells in a manner similar to treatment with aspirin, a non-specific COX inhibitor. Moreover, *COX-2* transfection effectively increased COX-2 levels and increased the proliferation of EC109 cells. These results indicate that COX-2 may be directly associated with the proliferation of EC109 cells. Considering the proapoptotic effects of aspirin, our results favor the view that *COX-2* overexpression contributes to the acquisition of antiapoptotic activity in EC109 cells. Moreover, *COX-2* RNAi treatment was able to promote apoptosis. *COX-2* short interfering RNA (siRNA) combined with aspirin has the potential to be an effective anticancer therapy for the treatment of ESCC. Furthermore, the tumorigenicity assay in nude mice revealed a faster tumor growth and larger xenograft tumor size in the *COX-2*-transfected cell group. Alternatively, the suppression of *COX-2* expression by high-dose aspirin treatment effectively attenuated the oncogenesis of EC109 cells *in vivo*.

Innovations and breakthroughs

In the past few years, RNAi has become an important research tool to study and manipulate a particular gene and its function. Furthermore, the use of siRNA as a potent and specific inhibitor of a specific target gene provides a new therapeutic approach for many incurable diseases, particularly cancer. In addition, aspirin may boost the effectiveness of chemotherapy in the treatment of cancers. This is the first study to report that *COX-2* siRNA combined with aspirin treatment has the potential to be an effective anticancer therapy for ESCC.

Applications

Gene therapy and RNAi are the most exciting and promising technologies in biomedicine today. RNAi is an exceptionally powerful method to inhibit the expression and the function of disease-causing genes, and it has out-performed all similar methodologies previously tested in gene therapy. The data presented here suggest that the use of *COX-2*-specific siRNA combined with aspirin is a promising treatment for *COX-2*-expressing ESCCs. The present research believes that the successful clinical implementation of this combination therapy is merely a question of time.

Terminology

Non-steroidal antiinflammatory drug (NSAID): NSAIDs block the COX enzymes and reduce the levels of prostaglandins throughout the body. NSAIDs are used primarily to treat inflammation, mild to moderate pain, and fever. Aspirin is a unique NSAID.

Peer review

The authors aimed to study the relationship between the *COX-2* gene and the proliferation and apoptosis of esophageal squamous carcinoma EC109 cells. They have demonstrated that *COX-2* expression was significantly reduced in EC109 cells treated with *COX-2*-specific siRNA but was increased in cells transfected with *COX-2*. They have concluded that COX-2 plays a critical role in ESCC carcinogenesis, and that *COX-2* siRNA combination treatment with aspirin has the potential to be an effective anticancer therapy for ESCC. Overall, the manuscript is very interesting and adds to the body of literature on the positive effects of aspirin in carcinogenesis. It is also very well written and the conclusions are supported by the data.

Abstract

AIM: To compare histological endpoint assessment using noninvasive alternatives to biopsy during treatment in a chronic hepatitis C virus (HCV) cohort.

METHODS: Patients with chronic HCV were randomized to receive interferon-based therapy for 24 (genotypes 2/3) or 48 (genotype 1) wk. FibroSURE™ (FS) was assessed at baseline and at week-12 post-treatment follow-up. Baseline biopsy for METAVIR was assessed by a single pathologist. FibroScan® transient elastography (TE) was performed during treatment in a patient subset.

RESULTS: Two thousand and sixty patients (n = 253 in Asia) were classified as METAVIR F0-1 (n = 1682) or F2-4 (n = 378). For F2-4, FS (n = 2055) had sensitivity and specificity of 0.87 and 0.61, respectively, with area under the receiver-operating curve of 0.82; corresponding values for TE (n = 214) and combined FS/TE (n = 209) were 0.77, 0.88 and 0.88, and 0.93, 0.68 and 0.88. Overall FS/TE agreement for F2-4 was 71% (κ = 0.41) and higher in Asians *vs* non-Asians (κ = 0.86 *vs* 0.35; $P < 0.001$). Combined FS/TE had 97% accuracy in Asians (n = 33). Baseline FS (0.38 *vs* 0.51, $P < 0.001$) and TE (8.0 kPa *vs* 11.9 kPa, P = 0.006) scores were lower in patients with sustained virological response than in nonresponders, and were maintained through follow-up.

CONCLUSION: FS and TE may reliably differentiate mild from moderate-advanced disease, with a potential for high diagnostic accuracy in Asians with chronic HCV.

INTRODUCTION

Complications of chronic hepatitis C virus (HCV) infection occur as a consequence of progressive liver fibrosis, leading to cirrhosis, liver failure, and hepatocellular carcinoma. Histological assessment of liver injury and fibrosis is important for making treatment decisions, as well as for predicting prognosis and therapeutic outcome, in chronic liver disease[1]. Liver biopsy is, however, an invasive procedure, limited by issues relating to sampling, cost and morbidity, and only provides a static measure of fibrosis[2]. Accurate noninvasive methods of monitoring changes in fibrosis would be helpful in following the natural history of the disease and monitoring potential antifibrotic responses to antiviral or other treatment modalities. The past decade has seen the development of several noninvasive predictive indices for hepatic fibrosis based on direct and indirect serum markers, as well as imaging modalities to measure liver stiffness, such as transient elastography (TE) (FibroScan®, Echosens, Paris, France)[3]. Serum HCV FibroSURE™ (FS) (Laboratory Corporation of America, Raritan, NJ, United States) combines α_2-macroglobulin, haptoglobin, γ-glutamyl transpeptidase, apolipoprotein A_1, alanine transaminase, and total bilirubin into a proprietary algorithm for fibrosis and inflammatory activity[4]. Both noninvasive modalities have been extensively evaluated in viral hepatitis and other chronic liver diseases[5]. The combination of serum tests, such as FS or FibroMeters, and TE appears to improve the cross-sectional diagnostic accuracy for advanced-stage disease in chronic HCV[6,7]. The French Haute Autorité de Santé has approved FS and TE as first-line tests to detect cirrhosis in chronic HCV[8]. Few studies, however, have determined the utility of either biomarkers or TE to accurately follow longitudinal changes in fibrosis both during and after antiviral therapy to better define long-term histological outcomes in chronic HCV[9-12]. Although there are emerging studies of TE in Asian patients with chronic liver disease (mostly due to chronic hepatitis B virus), no studies have evaluated the utility of both FS and TE in Asian patients with chronic HCV[13,14].

The aims of the present study were to: (1) compare the diagnostic utility of FS and TE for fibrosis at baseline in treatment-naïve patients with chronic HCV; (2) determine concurrent changes in both FS and TE with virological responses during and after albinterferon alfa-2b (albIFN) combination therapy; and (3) evaluate the performance of these noninvasive tests for the detection of significant fibrosis in an Asian cohort.

MATERIALS AND METHODS

Study population

Adult patients with chronic HCV genotype (Gt) 1 or 2/3 (n = 2225) who had not previously received interferon (IFN)-α therapy were enrolled in two global phase Ⅲ studies of albIFN conducted at 136 centers worldwide between December 2006 and October 2008 (ClinicalTrials. gov nos. NCT00402428 and NCT00411385)[15,16]. Patients were excluded if they had decompensated liver disease or other causes of chronic liver disease, including co-infection with hepatitis B virus or human immunodeficiency virus; a significant co-existing medical condition; Gilbert's disease; or alcohol or drug dependence. Patients were randomized in a 1:1:1 ratio to one of three open-label treatment groups: albIFN 900 or 1200 μg every 2 wk, or PEGinterferon alfa-2a (PEGASYS®, Hoffmann-La Roche Inc., Nutley, NJ) 180 μg once weekly. All patients also received oral ribavirin (RIBASPHERE®, 3 Rivers Pharmaceuticals®, Warrendale, PA, United States) 800 mg/d (Gt 2/3) or 1000-1200 mg/d (Gt 1) in two divided doses. Treatment duration was 24 (Gt 2/3) or 48 (Gt 1) wk, with follow-up at week 48 or 72, respectively, for sustained virological response (SVR) assessment. Patients with detectable HCV RNA at post-treatment week-12 follow-up were determined to be nonresponders (NRs) and were not required to complete final follow-up at post-treatment week 24. Serum HCV-RNA levels were measured by real-time polymerase chain reaction assay (COBAS® Ampliprep/COBAS® Taqman® HCV Test, Hoffman-La Roche): limit of detection was 15 IU/mL and lower limit of quantitation 43 IU/mL.

All patients provided written informed consent and the institutional review boards of all participating centers approved the studies, which were performed in accordance with the Helsinki Declaration of 1975. The authors accept full responsibility for the accuracy of the whole content, including findings, citations, and references contained in this manuscript.

Procedures for fibrosis assessment

Pretreatment liver biopsies were available in 2060 patients, and evaluated for METAVIR fibrosis stage and

Table 1 Baseline patient demographics *n* (%)

ALT: Alanine transaminase; BMI: Body mass index; SD: Standard deviation; TE: Transient elastography; ULN: Upper limit of normal.

activity grade by a single pathologist (Torbenson M) who was blinded to study assignments or results. Adequate biopsy quality was based on assessment by the pathologist of specimens ⩾ 15 mm in length and/or including ⩾ 6 portal tracts. The METAVIR scoring system classifies fibrosis on a five-point scale: F0 = no fibrosis; F1 = portal fibrosis without septa; F2 = few septa; F3 = numerous septa without cirrhosis; and F4 = cirrhosis; necro-inflammatory activity is graded on a 4-point scale: A0 = none; A1 = mild; A2 = moderate; and A3 = severe[17].

Fasting serum samples were frozen at -70 ℃ within 2 h of collection. Assessment with FibroSURE, a commercial serum marker panel assay, was performed independently, with blinding of clinical and pathologic assessments at a central laboratory (Laboratory Corporation of America), at baseline and 12 wk after the end of treatment. The TE measurements were obtained using FibroScan at baseline, weeks 12, 24 and 48, and 12 wk after the end of treatment in patients with HCV Gt 1, and weeks 12, 24 and 36 with Gt 2/3, at 40 study sites as part of a protocol-specified substudy. Results of TE with ⩾10 acquisitions, a success rate ⩾ 60%, and an interquartile range < 30% of the median value were considered valid measurements, as per manufacturer's recommendation and prior studies[3,18,19].

Statistical analysis

Patient demographic and clinical laboratory characteristics were descriptively summarized, and reported as mean ± SD and range. All tests were two-sided, and statistical significance was assessed at the 0.05 level. Performance characteristics differentiating mild (F0-1) from moderate-severe (F2-4) fibrosis at baseline were determined for FS. Performance of this assay for F2-4 was determined by area under the receiver-operating characteristic curve (AUROC) using the DeLong method[20]. Values for AUROC were standardized relative to a uniform prevalence distribution, and an adjusted AUROC was calculated to account for spectrum bias, using the difference between the mean stage of advanced fibrosis minus the mean stage of nonadvanced fibrosis[21]. The FS modality provides a continuous regression index with a corresponding predicted individual fibrosis stage[22]. An FS index < 0.32 was used for stage F0-1. For two-stage predictive indices with FS for F0-1, F1-2, and F3-4, the midpoint index value was used as a threshold for assignment of stage for analysis. The TE cut-off values were chosen *via* AUROC analysis as the point at which sensitivity and specificity were maximized. Recommended thresholds for TE in chronic HCV of > 7 kPa and > 12.5 kPa for F2 and F4, respectively, were also assessed[6]. For assessing the utility of combined FS and TE, prediction was based on a logistic-regression model containing both indices, as well as their pairwise interaction. The measure of agreement chosen was Cohen's κ. Differences between continuous variables were assessed by Student's *t* test, assuming unequal variance. All statistical analyses were performed using SAS® 9.2 (SAS Institute, Cary, NC).

RESULTS

Patient demographics

Baseline biopsy (mean length 17 mm ± 9 mm) results were available from 2060 patients with chronic HCV. Patients were mostly men (58.1%) and caucasian (77.6%), with a mean age of 45.2 ± 11.4 years and a prevalence of significant fibrosis of 18.3% (Table 1).

Baseline FibroSURE performance

Results for FS and biopsy were available in 2055 patients. For stages F2-4, FS had a sensitivity of 0.87, a specificity of 0.61, and an AUROC of 0.82 [95% confidence interval (CI) 0.80-0.84, Figure 1]; the corresponding adjusted AUROC relative to a uniform prevalence distribution was 0.84. For F4, sensitivity was 0.63, specificity was 0.85, and AUROC was 0.83 (95% CI 0.79-0.86). The misclassification rate for FS was 34% (*n* = 703/2055), and most of these patients (93%; *n* = 653) were false-positive F2-4 (Figure 2). For biopsy specimens > 15 mm and F2-4 (46.0%; *n* = 948/2055), sensitivity was 0.86, specificity was 0.61, and AUROC was 0.83 (95% CI 0.80-0.86). The FS misclassification rate, however, remained 34% in these patients with longer biopsy specimens. For biopsies > 15 mm and F4, sensitivity was 0.67, specificity was 0.84, and AUROC was 0.86 (95% CI 0.81-0.91). For moderate-severe necro-inflammatory activity of A2-3, sensitivity and specificity were both 0.66, and AUROC was 0.71 (95% CI 0.69-0.73).

Baseline TE

Results of TE and biopsy were available in 214 patients. For stage F2, TE > 10.1 kPa had a sensitivity of 0.77, a specificity of 0.88, an AUROC of 0.88 (95% CI 0.82-0.93),

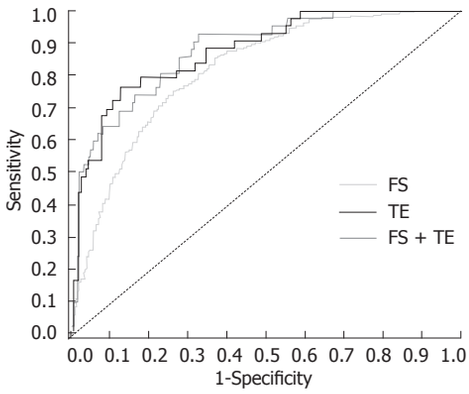

Figure 1 Baseline area-under-the-receiver-operating-curve analysis for stages F2-4 for FibroSURE and transient elastography. Of the overall cohort with baseline biopsy (n = 2060), FibroSURE (FS) was available in 2055 patients, transient elastography (TE) in 214, and both FS and TE in 209. Area-under-the-receiver-operating-curve values for stages F2-4 were 0.82 for FS, 0.88 for TE, and 0.88 for FS + TE. Differences between FS and TE were not significant. FS: FibroSURE; TE: Transient elastography.

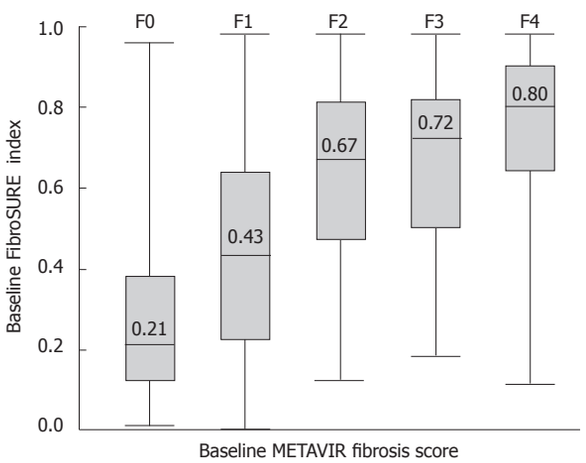

Figure 2 Boxplot distribution of FibroSURE index scores in all patients at baseline (n = 2055). Box parameters represent 25th and 75th percentile index scores for each fibrosis stage; median index values are shown within box, and upper and lower range limits are represented by vertical lines.

and an adjusted AUROC of 0.88 (Figure 1). For F4, TE > 11.7 kPa had a sensitivity of 0.94, a specificity of 0.88, and an AUROC of 0.93 (95% CI 0.88-0.98). The misclassification rate for TE was 14% (n = 31), with approximately two-thirds of these patients (68%; n = 21) classified as false-positive F2-4. For F2-4 with biopsy specimens > 15 mm (39.3%, n = 84; F2-4 prevalence 22.6%, n = 19), sensitivity was 0.63, specificity was 0.91, and AUROC was 0.83 (95% CI 0.72-0.93).

Performance characteristics of TE, using a previously recommended threshold of > 7 kPa for stages F2-4[6], indicated a higher sensitivity and lower specificity of 0.88 and 0.65, respectively, with a lower overall accuracy of 0.70. For stage F4 at a TE threshold of > 12.5 kPa, sensitivity was lower at 0.72, but with a similar specificity of 0.89.

Baseline comparison of combined FibroSURE and TE

Both FS and TE results were available in 209 patients before therapy. For this subset, prediction of stages F2-4 using FS and TE in combination had a sensitivity of 0.93, a specificity of 0.68, an AUROC of 0.88 (95% CI 0.82-0.94), and an adjusted AUROC of 0.88 (Figure 1). Agreement between FS and TE, however, for F2-4 was 0.71 (95% CI 0.65-0.77), with a Cohen's κ of 0.41 (95% CI 0.30-0.52). Among 61 patients with nonconcordance for FS and TE, 88% (n = 54) were F2-4 by FS and F0-1 by TE; biopsy indicated mild-stage disease in most of these 54 patients [F0-1 in 88.9% (n = 48); F2-4 in 11.1% (n = 6)]. Conversely, only seven of the 61 patients were F0-1 by FS and F2-4 by TE; four of these patients were F0-1 by biopsy.

For the 148 patients with agreement between FS and TE, 68% (n = 101) were stages F0-1 and 32% (n = 47) were F2-4 by both noninvasive tests. Biopsy results, however, indicated agreement with both FS and TE in 86% (n = 128), with 3% and 11% misclassified by both noninvasive tests as F0-1 and F2-4, respectively. Biopsies were > 15 mm in 56 of the patients for which there was agreement between FS and TE, and concordance results for the noninvasive tests were compared with the biopsy results: there was a slight reduction in the proportion of patients misclassified by the combination of FS and TE (from 14.0% to 10.7%), although the sample size was relatively small. Agreement between FS and TE for stage F4 increased to 0.85 (95% CI 0.80-0.90; κ = 0.53), and compared with biopsy, misclassification rates (biopsy < F4) for both FS and TE were 7.3%, with all cases being false positives.

Changes in transient elastography during therapy

Results for TE were available in a subset of 217 patients who completed treatment (HCV Gt 1, n = 122; Gt 2/3, n = 95). Mean TE scores were lower at baseline in patients who achieved an SVR compared with NRs (8.0 *vs* 11.9 kPa; P = 0.006). Further multivariate modeling showed no association with Gt, race, or body mass index, but significant increases in liver stiffness in older patients (P < 0.001) and men (P = 0.03). In addition, TE scores were higher in patients with METAVIR grades 2-3 inflammatory activity score at baseline (11.8 *vs* 7.3; P < 0.001), with further minimal declines in TE measurements during therapy for patients with an SVR and NRs. The difference at baseline remained significant only at week 12 (P = 0.03) and lost significance at later on-treatment time points (Figure 3). At the follow-up visit, overall mean changes in TE from baseline were -1.3 kPa (P < 0.001) and -2.7 (P = 0.04) for patients with an SVR and NRs, respectively, reflecting declines to levels that remained different (6.9 *vs* 10.1; P = 0.049). There was no correlation between changes in TE and alanine transaminase during or after therapy.

Changes in FibroSURE after antiviral therapy

Baseline FS scores were available in 2082 patients (HCV Gt 1, n = 1200; Gt 2/3, n = 882), with 1731 also available at post-treatment follow-up. Patients who achieved an SVR (n = 1305) had lower mean baseline FS fibrosis index scores compared with NRs (n = 777; 0.38 *vs* 0.51;

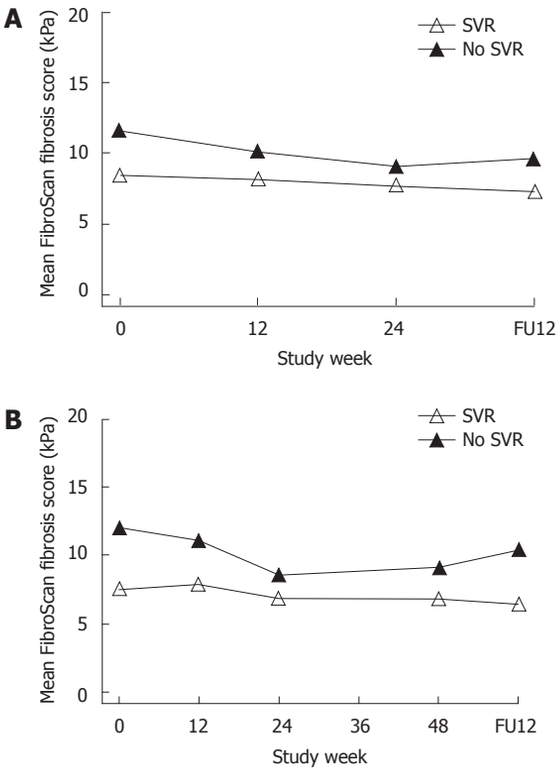

Figure 3 Changes in transient elastography with therapy according to sustained virological response. Mean FibroScan fibrosis scores over time by sustained virological response status in patients with hepatitis C virus (A) genotypes 2/3 and (B) genotype 1. FU: Follow-up.

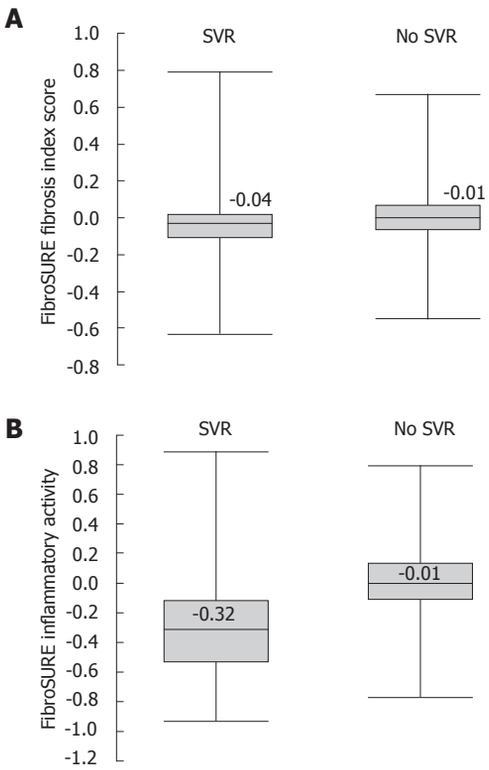

Figure 4 Changes in FibroSURE with therapy according to sustained virological response. Changes in FibroSURE (A) fibrosis index and (B) inflammatory index at 12 wk post-treatment compared with baseline values by sustained virological response status.

Table 2 Performance of FibroSURE and transient elastography in patients from Asia *vs* non-Asian regions

Test	Region (*n*)	F2-4 (%)	Sens	Spec	PPV (%)	NPV (%)	Accuracy (%)	AUROC
FS	Asia (253)	24.9	0.90	0.60	42.9	95.0	67.6	0.83
	NAR (1802)	17.4	0.86	0.61	31.9	95.4	65.5	0.82
TE	Asia (33)	24.2	0.88	0.92	77.8	95.8	90.9	0.92
	NAR (181)	19.3	0.77	0.87	58.7	94.1	85.1	0.87
FS + TE	Asia (33)	24.2	0.88	1.00	100.0	96.2	97.0	0.97
	NAR (176)	19.3	0.91	0.68	40.8	97.0	72.7	0.88

AUROC: Area under the receiver operating curve; FS: FibroSURE; NAR: Non-Asian region; NPV: Negative predictive value; PPV: Positive predictive value; Sens: Sensitivity; Spec: Specificity; TE: Transient elastography.

$P < 0.001$). Baseline FS necro-inflammatory activity scores were not significantly lower in patients with an SVR (0.45 *vs* 0.47; $P = 0.06$). At post-treatment follow-up week 12, there was a significant reduction in FS fibrosis scores from baseline in patients with an SVR compared with NRs (Δ = -0.06 *vs* 0.0; $P < 0.001$; Figure 4). As expected with a biochemical response that accompanies viral clearance, there was a significant reduction in FS necro-inflammatory activity scores in patients with an SVR compared with NRs following antiviral therapy (Δ = -0.35 *vs* -0.02, $P < 0.001$) (Figure 4).

FibroSURE and transient elastography in Asian patients

There were 253 Asian patients with a baseline biopsy (mean length 13.5 ± 8.4 mm), classified as stages F0-1 in 75% (n = 190) and F2-F4 in 26% (n = 63). For F2-4 with FS (n = 253), sensitivity was 0.90, specificity was 0.60, and AUROC was 0.83. These results were comparable to those in patients from a non-Asian region (NAR; n = 1802), with a sensitivity of 0.86, a specificity of 0.61, and an AUROC of 0.82 (Table 2). In comparison to FS, TE had a similar sensitivity (0.88), but a higher specificity (0.92) and AUROC (0.92, $P = 0.11$); however, there were only 33 Asian patients with available TE. There was no difference in F2-4 prevalence between Asian patients with available TE (25%) and FS (24%). Despite the small cohort, TE results for F2-4 in Asian patients were comparable to those in NAR patients (n = 181, AUROC 0.92 *vs* 0.87, $P = 0.35$).

For patients with both noninvasive tests available (Asian, n = 33; NAR, n = 176), agreement between FS and TE for stages F2-4 was higher in Asian than in NAR patients [94%

(κ = 0.86) *vs* 67% (κ = 0.35); $P < 0.001$]. The combination of FS and TE improved the accuracy for F2-4 in both Asian (97.0%) and NAR patients (72.7%), with AUROC values of 0.97 and 0.88, respectively (Table 2).

Most patients from the Asian region with available FS or TE achieved an SVR (85%; $n = 216$) and thus comparisons with NRs were not feasible. Baseline FS fibrosis scores, however, were higher in Asian than in NAR patients with an SVR (0.45 *vs* 0.36; $P < 0.001$), likely reflecting differences in F2-4 prevalence between the two study populations. Changes in FS fibrosis scores at week-12 follow-up were also comparable between Asian and NAR patients with an SVR (Δ = -0.04 *vs* -0.06; $P = 0.09$). In addition, mean TE measurements were comparable at baseline between Asian and NAR patients with an SVR (8.8 *vs* 7.8 kPa; $P = 0.56$), with no significant differences in changes at week 12 (-0.14 kPa *vs* -0.25 kPa, $P = 0.91$) or after therapy (-1.4 kPa *vs* -1.3 kPa, $P = 0.98$).

DISCUSSION

This large prospective cohort study in patients with chronic HCV provides validation of the diagnostic utility of serum markers and TE in relation to biopsy and IFN-based therapy. Few studies have addressed longitudinal changes in either serum markers or TE with therapy and, importantly, the present global study also provides the first evaluation of both noninvasive tests in patients from the Asia-Pacific region with chronic HCV. One limitation of this study was that TE data could only be obtained at 40 non-US study sites, as this device is not yet approved for use in the United States. Despite the limited cohort size for TE ($n = 214$) compared with FS ($n = 2055$), in accordance with prior observations, the overall results of this study indicate that both FS and TE have potential utility in the detection of moderate-severe-stage disease. However, the performance characteristics of these noninvasive tests (particularly TE) may be somewhat better for exclusion of cirrhosis[6,23]. For stages F2-4, FS and TE were effective in both Asian and NAR patients, but the agreement and accuracy of combined FS and TE were higher in the limited cohort of Asian patients with both tests ($n = 33$). Changes in FS and TE in relation to SVR were similar for both Asian and NAR patients.

This study shows that both pretreatment TE ($n = 217$) and FS ($n = 2082$) scores were lower in patients who achieved an SVR than in NRs, and that these differences were maintained through week 12 of therapy. Multivariate modeling indicated that older age and male sex (both predictive of lower virological responses in chronic HCV) were also independently associated with higher TE measurements at baseline. Other smaller studies, however, have failed to demonstrate similar baseline associations. A recent study from France evaluated TE and FS in 112 patients with chronic HCV receiving antiviral therapy, but did not include baseline biopsy or evaluation during therapy[11]. That study did not find any significant differences at baseline between patients with an SVR and NRs. Another study assessed TE alone before and after therapy in a Japanese chronic HCV cohort of 145 patients, and noted no differences at baseline between patients with an SVR and NRs[12]. Similar findings from another small French cohort evaluating TE alone have also been reported[24]. A recent meta-analysis of longitudinal studies in viral hepatitis indicated that both FS and TE could estimate treatment effect on fibrosis progression, although TE appeared to have early variability on treatment due to possible changes in necro-inflammatory activity[25]. The present study suggests that FS and TE could provide useful adjunctive information for the prediction of virological response prior to IFN-based therapy for chronic HCV. These noninvasive tests, however, likely reflect baseline differences in inflammatory response, but could complement established host-viral predictors of virological response to IFN-based therapy, such as HCV-RNA levels, viral Gt, race, and host *IL28B* polymorphism[26,27].

At follow-up, both FS and TE declined in patients who achieved an SVR. This is in accordance with prior observations that successful treatment with a biochemical response was associated with a decline in serum fibrosis marker indices or TE measurements in patients with chronic HCV[9-12,28,29]. A limitation of this study is that post-treatment biopsies were not required as part of these two clinical registration trials, which would have allowed for correlation between the observed declines in noninvasive test scores and changes in fibrosis or necro-inflammation. TE measurements may vary significantly with immune-mediated inflammatory responses in patients with chronic hepatitis B virus[30]. In contrast to other studies in patients with chronic HCV[6], however, this study also demonstrated a significant association between TE and histological necro-inflammatory activity at baseline. This association may have implications for establishing TE thresholds for different fibrosis stages in chronic HCV and may also explain the decline in liver stiffness measurements in patients with an established SVR in the present cohort. In this study, 80% of patients had no or mild fibrosis (stages F0-1) prior to treatment and thus were incapable of achieving a significant regression in fibrosis.

Both Asian and NAR cohorts demonstrated comparable performance characteristics for FS and TE. The observed accuracy and specificity for prediction of stages F2-4 in Asians, however, was higher in the small TE cohort. The combination of FS and TE in Asian patients resulted in a high accuracy for prediction of F2-4, with no false-positive results. Thus, biopsies for staging F2-4 could have been avoided in almost all Asian patients in this small cohort of 33 patients. There was excellent agreement between FS and TE in Asian patients, and this may partly relate to a slightly higher prevalence of advanced-stage disease and lower body mass index in the Asian cohort. Furthermore, increased waist circumference appears to be a common reason for failure of TE in European cohorts[19]. Although there are potential issues in obtaining adequate TE measurements in Asian patients

due to a narrow intercostal space, this was not a limiting factor in the present study[13]. Thus, the combination of FS and TE in Asian patients with chronic HCV merits further evaluation.

One of the strengths of this study is that sample collections were standardized per protocol for the two phase Ⅲ clinical trials, laboratory assessments were performed centrally, and all biopsies were evaluated by a single experienced liver histopathologist. Standardization significantly reduced the heterogeneity observed in prior studies comparing results across different geographic populations[23]. Biopsy sampling and observer error, however, are inherent limitations to the development and validation of all fibrosis biomarkers[31]. The experience of the pathologist may be more important than biopsy characteristics[32]. Furthermore, prior studies have indicated that the accuracy of liver biopsy (and noninvasive tests) is dependent on sample size[9,33-35]. In contrast to these prior observations, no significant change in the diagnostic accuracy of FS for stages F2-4 in > 900 patients with biopsies > 15 mm was found in the present study. Of note, TE accuracy for F2-4 appeared to decline in > 80 patients with this optimal biopsy length, although only 19 with biopsy F2-4 were in this cohort.

Prior studies have suggested that noninvasive performance indices for stages F2-4 and F4 are improved using sequential algorithms of FS and TE[6], or aspartate aminotransferase-to-platelet ratio index and FS[36]. In the present study, the F2-4 results for combined FS and TE indicated a comparable AUROC and agreement (0.88 and 71%, respectively) to those observed in a recent study from France in 302 patients with chronic HCV (0.91 and 72%, respectively) with a higher prevalence of advanced-stage disease[37]. Although discordance rates between sequential FS and TE with biopsy were not reported in the French study, prior data from that cohort indicated 84% concordance between biopsy and FS/TE agreement. This observation is similar to the 86% agreement noted in the present study; however, in contrast to the French cohort, cases of discordance between biopsy and FS/TE agreement were due to false positives with the noninvasive tests. In practical terms, agreement between FS and TE regarding prediction of F2-4 in the present study cohort could have avoided 71% of biopsies, although 10% of patients would still have been misclassified as having significant fibrosis. The discordance rate between FS and TE was 29%, with biopsy and TE agreement in most of the cases that appeared to have mild-stage disease. As expected, misclassification rates and discordance between FS and TE with biopsy were significantly reduced for prediction of F4.

With a broader range of available therapeutic options for patients with chronic HCV in the future, noninvasive measures that can accurately exclude advanced-stage disease will likely assume a more significant clinical role in the treatment decision process. Recent mathematical modeling indicates that a perfect biomarker of stages F2-4 may not exceed an AUROC of 0.9[38], and thus various issues regarding biopsy sampling error and noninvasive test discordance should be individualized when using these tests to predict a threshold of F2 in clinical practice. The observed heterogeneity among studies (including the present one) for optimized TE cutoffs indicates that a range of liver stiffness measurements for each fibrosis threshold in patients with chronic HCV may be more appropriate[39]. Standardization of AUROC curves or other methods to reduce effects of spectrum bias in disease prevalence allows for comparison of FS across studies, including selected cohorts within studies, but not for TE due to variable optimal thresholds[21]. No significant differences between observed and standardized AUROC values were found in the present study for either noninvasive measure.

In summary, this study demonstrates that a combination of serum and imaging noninvasive tests can be used for prediction of at least moderate-stage disease in a global cohort of patients with chronic HCV, including the potential of higher accuracy for the combination of FS and TE in Asian patients. Furthermore, some baseline differences in index values for both FS and TE were dependent on virological response and merit further evaluation in the context of IFN-based therapy.

COMMENTS

Background

Liver biopsy is an invasive procedure associated with significant costs and risk of complications. Noninvasive alternatives to biopsy for the determination of fibrosis stage include serum [FibroSURE (FS)] or imaging-based [transient elastography (TE) FibroScan] tests. The combination of these two modalities appears to have a good predictive value for excluding cirrhosis. Fibrosis is a predictor of virological response to chronic hepatitis C virus (HCV) therapy, and noninvasive tests may also be useful in this regard. Test values may vary with antiviral therapy for chronic HCV, perhaps due to changes in hepatic inflammation or with body habitus. Few studies have evaluated the utility of both these noninvasive modalities in patients with chronic HCV during interferon-based therapy, and there are limited data for these tests in Asian patients, particularly in comparison with non-Asian cohorts.

Research frontiers

Both FS and TE are validated measures for the noninvasive assessment of fibrosis. One important research issue is the determination of their utility in following changes in fibrosis or inflammation, e.g., as part of the natural history of disease or during and after antiviral therapy.

Innovations and breakthroughs

In this study, both FS and TE demonstrated good potential utility in the detection of moderate-severe-stage disease, but the performance characteristics of these noninvasive tests (particularly TE) may be somewhat better for exclusion of cirrhosis. Agreement between these tests and their accuracy for predicting disease stage may be higher in Asian than in non-Asian patients with chronic HCV. Patients that achieved a sustained virological response with interferon therapy appeared to have lower noninvasive test values at baseline.

Applications

Both FS and TE appear to have good clinical utility in predicting moderate-severe fibrosis prior to therapy, in both Asian and non-Asian patients with chronic HCV. Lower index scores at baseline may signify a better chance of responding to antiviral therapy.

Terminology

FS comprises a combination of simple biochemical blood tests that predict fibrosis. TE is an ultrasound-based imaging method to measure liver stiffness, which also predicts fibrosis.

Peer review

The authors investigated FS *vs* Fibroscan in treatment-naive patients with HCV. This article is unique and interesting.

Abstract

AIM: To investigate the potential benefit of Fujinon intelligent chromo endoscopy (FICE)-assisted small bowel capsule endoscopy (SBCE) for detection and characterization of small bowel lesions in patients with obscure gastroenterology bleeding (OGIB).

METHODS: The SBCE examinations (Pillcam SB2, Given Imaging Ltd) were retrospectively analyzed by two GI fellows (observers) with and without FICE enhancement. Randomization was such that a fellow did not assess the same examination with and without FICE enhancement. The senior consultant described findings as P0, P1 and P2 lesions (non-pathological, intermediate bleed potential, high bleed potential), which were considered as reference findings. Main outcome measurements: Inter-observer correlation was calculated using kappa statistics. Sensitivity and specificity for P2 lesions was calculated for FICE and white light SBCE.

RESULTS: In 60 patients, the intra-class kappa correlations between the observers and reference findings were 0.88 and 0.92 (P2), 0.61 and 0.79 (P1), for SBCE using FICE and white light, respectively. Overall 157 lesions were diagnosed using FICE as compared to 114 with white light SBCE ($P = 0.15$). For P2 lesions, the sensitivity was 94% vs 97% and specificity was 95% *vs* 96% for FICE and white light, respectively. Five (P2 lesions) out of 55 arterio-venous malformations could be better characterized by FICE as compared to white light SBCE. Significantly more P0 lesions were diagnosed when FICE was used as compared to white light (39 *vs* 8, $P < 0.001$).

CONCLUSION: FICE was not better than white light for diagnosing and characterizing significant lesions on SBCE for OGIB. FICE detected significantly more non-pathological lesions. Nevertheless, some vascular lesions could be more accurately characterized with FICE as compared to white light SBCE.

INTRODUCTION

Obscure gastroenterology (GI) bleeding (OGIB) is defined as bleeding of unknown origin that persists or recurs after a negative initial or primary endoscopy (colonoscopy or upper endoscopy) result[1]. OGIB is frequently caused by a lesion in the small bowel[2]. Small bowel capsule endoscopy (SBCE), which allows the non-invasive visualization of mucosa throughout the entire small bowel, has revolutionized the exploration of small bowel diseases, and particularly the evaluation of OGIB[3]. Several studies showed that a SBCE is highly effective in detecting small-bowel lesions, with an overall diagnostic yield superior to that of push enteroscopy or radiological imaging, and comparable to double balloon enteroscopy (DBE)[4-7]. In addition, the SBCE procedure is technically easy and well tolerated, and carries a low risk of complications[6]. SBCE is the first-line examination in OGIB after a negative upper and lower gastrointestinal endoscopy[8].

The Fujinon intelligent chromo endoscopy (FICE) system is a new, virtual chromoendoscopy technique that enhances mucosal visibility, wherein the bandwidth of the conventional endoscopic image is narrowed down arithmetically using computerized spectral estimation technology[9]. Pohl *et al*[10,11] have previously demonstrated that FICE is comparable to conventional chromoendoscopy for surveillance of Barrett's esophagitis and detection of colonic polyps. There are limited data regarding use of FICE for small bowel lesions. In a recent case series of 17 patients, Neumann *et al*[12] used DBE with FICE technology and demonstrated a benefit in characterizing angiodysplasias, in delineating the submucosal capillary network, and in the detection of small bowel polyps.

The positive yield of capsule endoscopy for evaluation of OGIB is around 60%. This value further decreases if the examination is delayed after the index bleed[6]. The addition of FICE technology to SBCE may improve the diagnostic yield.

The objective of our study was to assess the value of a FICE equipped small bowel (SB) capsule for evaluation of obscure GI bleeding and for the detection and characterization of SB lesions.

MATERIALS AND METHODS

This study was conducted in the endoscopy unit of a tertiary care referral centre and teaching hospital. Sixty consecutive SBCE examinations (Pillcam SB2; Given Imaging Ltd, Israel), which were performed for OGIB, were chosen for the study. These examinations were performed to analyze either obscure-overt or obscure-occult GI bleeding in the preceding year. All included patients had received a polyethylene glycol-based bowel preparation before the examination and were given metoclopramide (10 mg) as a prokinetic before swallowing the capsule. These examinations were already analyzed under white light only by the senior consultant, who has more than eight years experience in conducting capsule endoscopy and enteroscopy. Two GI fellows with similar experience (70 procedures) in conducting capsule endoscopy (observers 1 and 2) analyzed the examinations with and without FICE enhancement using Rapid Reader (Version 6: Given Imaging Ltd, Israel); their experience was considered as reaching a minimum threshold number to assess competency. The fellows were allowed to use the speed of their choice for reading. Randomization was such that a fellow did not assess the same examination with and without FICE enhancement. In practice, fellow 1 read the videos 1 to 30 without FICE and the following videos (31 to 60) with FICE, and vice-versa for fellow 2. The entire examination was conducted either under white light or FICE technology. Rapid Reader (Version 6) provides three channels for FICE technology (Table 1)[13]. Channel 1 was used for examination with FICE by both fellows, as the wavelength settings for red, green and blue light were found to be most suited to small bowel evaluation. This was determined by the consultant and the observers after a pilot study of 15 patients. No historical data for the patients were made available to the observers. The analysis was conducted by the GI fellows on the department's central computer. Individual findings were password protected. The boundary between the jejunum and the ileum was fixed empirically as the half time of the capsule small-bowel passage time. Both fellows used the common structured terminology as per the Given Capsule Endoscopy working group[14]. Both fellows were blinded to the findings (white light) of the senior consultant, which were taken as the reference. The senior consultant analyzed the results based on his reference findings. All findings were labeled as P0, P1 and P2 lesions (non-pathological, intermediate bleed potential-superficial erosions, red spots-or high potential bleed potential-hemorrhagic erosions, ulcer, arterio-venous malformations, or tumor) by the senior consultant[15]. Each time a lesion was seen in the FICE mode and not with white light, it was re-evaluated by the senior consultant. Comparison was performed for the detection of SB lesions, as well for characterization, i.e. vascular pattern, of a lesion that was considered as an arterio-venous malformation or a tumor as a Gastrointestinal stromal tumor (GIST) or an adenocarcinoma.

Institutional review board approval has been obtained from the local Ethical Committee for this retrospective study.

Table 1 Wavelengths in nm (Fujinon intelligent chromo endoscopy)[13]

	Red	Green	Blue
FICE channel 1	595	540	535
FICE channel 2	420	520	530
FICE channel 3	595	570	415

FICE: Fujinon intelligent chromo endoscopy.

Table 2 Number of lesions (P0, P1, P2) detected by the two observers and the senior consultant, respectively

	Observer 1	Observer 2	Consultant (reference findings)
Total	117	154	131
P0	20	27	15
P1	37	55	41
P2	60	72	75

Statistics analysis

Inter-observer correlation was calculated by using kappa statistics. A kappa value of 1 was considered perfect agreement and 0 was considered no agreement at all. Sensitivity and specificity for P2 lesions was calculated for FICE and white light SBCE. SPSS software [version 16, (SPSS Inc, Chicago, IL)] was used for the analysis. Statistical analysis of categorical values was conducted using the Fischer's exact test. Significance was accepted at a value of $P < 0$ .05.

RESULTS

Visualization of the entire small bowel was achieved in 56 patients; in the remaining four, the capsule reached the terminal ileum. All patients had excellent bowel preparation. In these 60 patients, observers 1 & 2 detected 117 [P0 (20), P1 (37), P2 (60)] and 154 [P0 (27), P1 (55), P2 (72)] lesions, respectively, as compared to 131 [P0 (15), P1 (41), P2 (75)] by the senior consultant (Table 2). The commonest P2 lesions were arterio-venous malformations (n = 43), followed by small bowel ulcerations (n = 27), small bowel tumors (GIST n = 2; adenocarcinoma n = 1), and Dieulafoy's lesions (n = 2). Intra-class correlation for P1 and P2 lesions was calculated as 0.69 and 0.89 respectively. Intra-class kappa correlations between the observers and reference findings were 0.88 (P2), 0.61 (P1) for SBCE using FICE, and 0.92 (P2), 0.79 (P1) for SBCE with white light respectively. Overall 153 lesions were diagnosed by the two observers with SBCE using FICE as compared to 118 by SBCE with white light (P = 0.15). Considering the senior consultant's findings as the gold standard, for P2 lesions, the sensitivity was 94% (0.87-1.02) *vs* 97% (0.92-1.02) and specificity was 95% (0.87-1.03) *vs* 96% (0.86-1.04) for FICE and white light respectively. In 5/55 arterio-venous malformations, analysis of SBCE with FICE did not help in detection, but did result in better characterization of these P2 lesions as compared to analysis with white light (Figures 1-3). The mean duration for analyzing SBCE with FICE was longer than when white light was used (75 min *vs* 55 min). Significantly more P0 lesions were diagnosed by the 2 observers when FICE was used as compared to white light (39 *vs* 8, $P < 0.01$) (Table 3).

DISCUSSION

Capsule endoscopy has become a cornerstone in the non-invasive evaluation of OGIB. The high diagnostic yield of intestinal SBCE has been proven in several studies, and ranges from 55% to 81%[4-7,16,17]. The rate of rebleeding in patients with OGIB and negative SBCE is significantly lower (4.6%) compared with those with a positive SBCE (48%)[18].

The FICE system is based on a computed spectral estimation technology that processes the reflected photons to reconstruct virtual images with a choice of different wavelengths. This leads to enhancement of the tissue microvasculature as a result of the differential optical absorption of light by hemoglobin in the mucosa. These abnormal areas can be defined by magnification[9,19,20].

Ours is the first study in the literature that has used the potential advantages of FICE to assist the detection and characterization of OGIB lesions by capsule endoscopy and using the new Rapid Reader 6 (Given Imaging Ltd, Israel). Our study suggests that addition of FICE technology does not help in identifying clinically significant lesions during analysis of SBCE. This contrasts with existing data on FICE. Ringold *et al*[21] described two cases in which high-contrast imaging with FICE improved the visibility of normal mucosal vessels and aided in the detection of vascular ectasias that were not easily seen by routine double-balloon enteroscopy. Similarly, improved detection rates for arterio-venous malformations and adenomatous polyps were noted by Neumann *et al*[12] with FICE aided enteroscopy in a series of 17 patients. Recently, Imagawa *et al*[22] reported that FICE may improve visibility of small bowel lesions that were detected under white light by video capsule. This series is not really comparable, in that 75 out of the 145 lesions were tumors. Moreover, the authors of the study did not report the detection rate or characterization of the lesions. Interestingly, they observed that setting 1 of the FICE system was the best one for improving visibility, confirming our selection of channel 1 as the most effective.

Arterio-venous malformations were also the predominant lesions in our study. Despite this, the number of lesions detected by FICE and white light capsule endoscopy were similar. In fact, FICE detected significantly more non-pathological (P0) lesions as compared to white light. There was similar concordance for FICE and white light SBCE for pathological lesions (P2) in our study. The mean duration for analyzing SBCE with FICE was longer than when white light was used, thus diminishing the appeal of FICE for SBCE.

There are a few reasons for the limited effectiveness of SBCE with FICE for identifying lesions in our study. All patients had excellent bowel preparation; hence, there was better visualization by white light alone. This is supported by a recent meta-analysis that showed that small-bowel purgative preparation (polyethylene glycol solution or sodium phosphate) improves the diagnostic yield of the examination[23]. We also found that white reflections tend to increase during the FICE mode, potentially interfering with the image quality. This may be particularly important for clearly discerning ulcerated lesions and may result in their erroneous reporting. In addition, channel 1

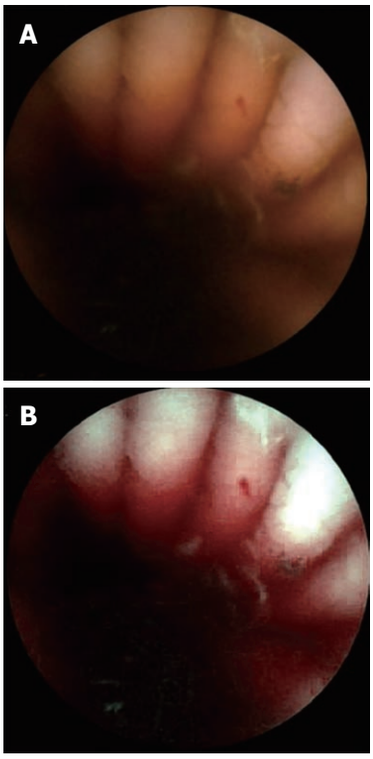

Figure 1 A non-pathological lesion (P0) with Fujinon intelligent chromo endoscopy.

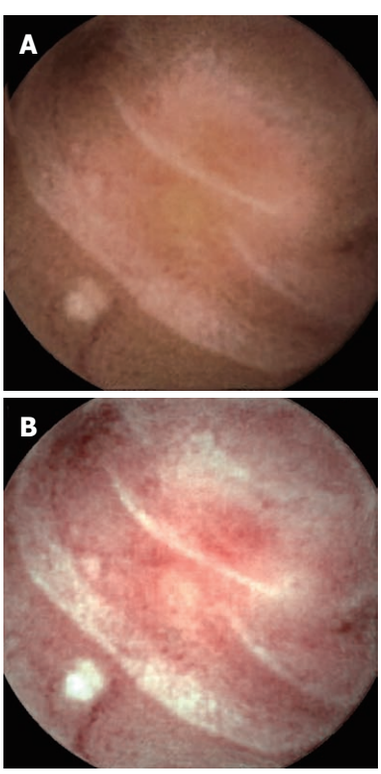

Figure 2 A non-pathological lesion (P1) with Fujinon intelligent chromo endoscopy.

of FICE had a prominent red hue; hence, small red spots and prominent folds appeared as angio-ectasias when

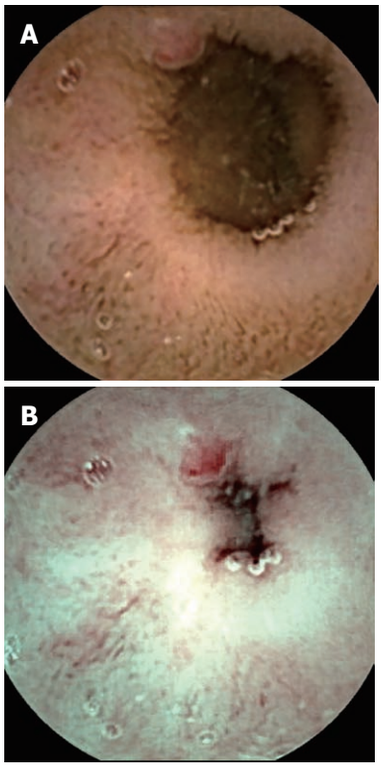

Figure 3 Vascular lesion (P2) with white light and Fujinon intelligent chromo endoscopy.

FICE was used. Several lymphangectasias, floating clots, and prominent veins were also found amongst the P0 lesions diagnosed by SBCE when FICE was used, thus reducing its utility.

We found that assessment of SBCE with FICE to be somewhat useful in the better characterization of vascular lesions. Arborization of the vascular network in the case of arterio-venous malformations was better assessed by FICE as compared to white light in 5 patients during this study, making their detection easier.

The strong points of the study were the use of the central workstation computer for capsule analysis, thereby enabling use of similar settings, image resolution and password protection of the reference and observers' findings. The common structured terminology, as per the Given Capsule Endoscopy working group, was used by both observers[14].

A first limitation of our study was the analysis of retrospective data and the relatively small patient numbers. A longer prospective study with patient follow up may be required to confirm our findings.

A second limitation is the absence of a reference standard for defining the SB lesions. Obviously, in several patients, lesions were confirmed by enteroscopy, biopsies, radiology, or surgical specimens, but not for all. The absence of a well-defined standard reference is a common problem in studies assessing the diagnostic yield of capsule endoscopy.

In conclusion, this is the first study to assess the ability of a FICE-equipped video capsule for detecting and

Table 3 Number of small bowel findings (patients) described by the two observers when using either white light or Fujinon intelligent chromo endoscopy compared to the senior consultant (white light)

	White light (two observers)	FICE (two observers)	*P* value (FICE *vs* WL for observers 1 and 2)	White light (senior consultant)
P0 (no patients)	8 (8)	39 (24)	< 0.01	15 (10)
P1 (no patients)	43 (33)	49 (32)	0.30	41 (29)
P2 (no patients)	67 (38)	65 (37)	1.00	75 (40)

FICE: Fujinon intelligent chromo endoscopy; WL: White light.

characterizing SB lesions in cases of OGIB. SBCE with FICE technology did not improve diagnostic yield, but did detect more P0 lesions. FICE may improve the characterization of vascular lesions in a limited number of cases. Further improvements in software technology for FICE may be required to enhance its clinical application in capsule endoscopy for OGIB.

In our study, FICE-assisted SBCE analysis was not better than white light for diagnosing and characterizing significant lesions in the evaluation of OGIB. FICE detected significantly more non-pathological lesions; however, some vascular lesions could be more easily characterized on FICE as compared to white light SBCE.

COMMENTS

Background

Obscure gastroenterology bleeding (OGIB) is frequently caused by a lesion in the small bowel. Capsule endoscopy that allows visualization of the small bowel is now recognized as the first step procedure in case of OGIB. Arteriovenous malformations are the most frequent lesions that are responsible for OGIB. Quality of the video images, as well as the experience of the reader, are mandatory for providing accurate results.

Research frontiers

The goals of video capsule endoscopy are the detection of lesions and their characterization. The reader is invited to qualify the lesion as clinically significant or not. This is important for defining further therapeutic strategy. Improvement of image quality may improve the diagnostic yield.

Innovations and breakthroughs

The Fujinon intelligent chromo endoscopy (FICE) system is a new, virtual chromoendoscopy technique that has been designed to enhance visibility of lesions. This technique, which is used for conventional endoscopy, has been adapted for video capsule endoscopy (given imaging). In this retrospective study, FICE did not improve the detection of small bowel lesions in comparison with the white light, but did allow better characterization of some vascular lesions.

Applications

FICE technology is now available in clinical practice. Its use should be reserved for the better characterization of lesions that were detected by white light. Some prospective studies should be performed for confirming the present data.

Terminology

OGIB is defined as digestive bleeding of unknown origin that persists or recurs after a negative endoscopy work-up. Video capsule endoscopy is a non-invasive method allowing a complete investigation of the small bowel. FICE is a new chromoendoscopic tool that has been designed for enhancing visibility of lesions in comparison to white light.

Peer review

This interesting study is well conducted and the results and conclusions are of practical application.

Abstract

AIM: To compare the reliability of gastritis staging systems in ranking gastritis-associated cancer risk in a large series of consecutive patients.

METHODS: Gastric mucosal atrophy is the precancerous condition in which intestinal-type gastric cancer (GC) most frequently develops. The operative link for gastritis assessment (OLGA) staging system ranks the GC risk according to both the topography and the severity of gastric atrophy (as assessed histologically on the basis of the Sydney protocol for gastric mucosal biopsy). Both cross-sectional and long-term follow-up trials have consistently associated OLGA stages Ⅲ-Ⅳ with a higher risk of GC. A recently-proposed modification of the OLGA staging system (OLGIM) basically incorporates the OLGA frame, but replaces the atrophy score with an assessment of intestinal metaplasia (IM) alone. A series of 4552 consecutive biopsy sets (2007-2009) was retrieved and reassessed according to both the OLGA and the OLGIM staging systems. A set of at least 5 biopsy samples was available for all the cases considered.

RESULTS: In 4460 of 4552 cases (98.0%), both the high-risk stages (Ⅲ + Ⅳ) and the low-risk stages (0 + Ⅰ + Ⅱ) were assessed applying the OLGA and OLGIM criteria. Among the 243 OLGA high-risk stages, 14 (5.8%) were down-staged to a low risk using OLGIM. The 67 (1.5%) incidentally-found neoplastic lesions (intraepithelial or invasive) were consistently associated with high-risk stages, as assessed by both OLGA and OLGIM ($P < 0.001$ for both). Two of 34 intestinal-type GCs coexisting with a high-risk OLGA stage (stage Ⅲ) were associated with a low-risk OLGIM stage (stage Ⅱ).

CONCLUSION: Gastritis staging systems (both OLGA and OLGIM) convey prognostically important information on the gastritis-associated cancer risk. Because of its clinical impact, the stage of gastritis should be included as a conclusive message in the gastritis histology report. Since it focuses on IM alone, OLGIM staging is less sensitive than OLGA staging in the identification of patients at high risk of gastric cancer.

INTRODUCTION

Gastric mucosal atrophy is by far the greatest risk factor for non-hereditary, intestinal-type distal gastric cancer (GC)[1]. The gold standard for atrophy assessment is histology, but non-invasive tests (mainly pepsinogen serology) are also applied for this purpose[1-3].

According to the current international literature, atrophy is defined as the "loss of appropriate glands". This definition covers both the "loss" of native glands (replaced by fibrosis) and the metaplastic replacement of the appropriate (native) glands due to antral intestinalization, corpus antralization [i.e., spasmolytic polypeptide-expressing metaplasia (SPEM)] and/or intestinalization[2].

Consistent evidence correlates the extent/topography of atrophy with the risk of GC, and it is on these grounds that a system for staging gastritis [the operative link for gastritis assessment (OLGA) staging system] was proposed[4]. Gastritis stages (0 to Ⅳ) express increasing extents of atrophy, as assessed histologically on antral and corpus biopsies. In different epidemiological settings, both cross-sectional and long-term follow-up studies have consistently allocated a small minority of gastritis patients to stages Ⅲ-Ⅳ, associating only this population with a significantly higher GC risk (high-risk OLGA stages)[3,5-10]. OLGA stages Ⅲ-Ⅳ have also been consistently associated with molecular tissue markers of high-risk gastritis[11,12]. These correlations potentially support the advisability of endoscopic follow-up for such high-stage patients.

A significant correlation has been demonstrated between high-risk OLGA stages and pepsinogen serology; this correlation between organic and functional disease supports the rationale for implementing serology in GC secondary prevention programs[5].

A recently-proposed modification of the OLGA staging system (OLGIM)[10] basically incorporates the same staging frame, but replaces the "global" score for atrophy (in its different phenotypic variants) with the histological assessment of intestinal metaplasia (IM) alone. The rationale behind the OLGIM proposal lies in the fact that IM is easier to assess histologically than the "global" spectrum of the atrophic lesions (as in the OLGA approach).

This study compares the OLGA and OLGIM staging systems in the assessment of gastritis-associated gastric cancer risk (i.e., stages 0- Ⅰ-Ⅱ = low-risk stages *vs* Stages Ⅲ-Ⅳ = high-risk stages).

MATERIALS AND METHODS

Patients

All gastric biopsy sets recorded between January 2007 and December 2009 were retrieved from the archives of the Surgical Pathology and Cytopathology Unit at the Department of Diagnostic Medical Sciences and Special Therapies of Padova University. Case recruitment did not distinguish between initial or follow-up endoscopies; all the patients considered were natives of the Veneto region and underwent endoscopy at the same institution (Padova Teaching Hospital). The institute's ethical regulations on research conducted on human tissues were followed.

For all the cases considered, a set of at least 5 biopsy samples was available (2 samples from the antral mucosa, 1 from the mucosa of the incisura angularis, and 2 from the anterior and posterior walls of the oxyntic stomach). In accordance with the biopsy sampling protocol, additional specimens had been obtained from any focal lesions. Details were always available regarding the site of the biopsy.

For the purposes of the study, pediatric patients (under 18 years old), patients with a history of autoimmune gastritis, and those who had undergone esophageal or gastric surgery, esophagogastric endomucosal resection or submucosal dissection were excluded.

Original slides or serial sections (4-6 microns thick) obtained from archival paraffin-embedded tissue samples [hematoxylin and eosin, Alcian- Blue and Periodic Acid Schiff stain and Giemsa for *Helicobacter pylori* (*H. pylori*)] were histologically re-considered.

Histology

Three trained gastroenterology pathologists (Fassan M, Pizzi M and Rugge M), blinded to any endoscopic or clinical information, jointly examined all the histology specimens and reached a consensus on the score for each of the histological variables considered. For OLGA staging purposes, atrophy was defined as the loss of appropriate glands with or without epithelial metaplasia (i.e., IM in antral and/or oxyntic biopsy samples; pseudo-pyloric metaplasia in oxyntic biopsy samples)[2]. Glandular atrophy was scored according to the recommendations in the OLGA staging tutorial[4,13]. For OLGIM staging purposes, only IM was considered and scored according to the recommendations of the OLGIM proposers[10]. The inter-observer consistency in assessing the two staging systems was tested by means of *K* statistics in a randomly selected series of 100 cases and was ranked as "excellent" (k coefficient = 0.75 and 0.77 for OLGA and OLGIM, respectively).

Any incidentally-found neoplastic lesions were histologically assessed according to internationally validated criteria[14,15]. Within the spectrum of gastric intra-epithelial neoplasia (IEN), the categories considered were: low-grade

Table 1 Demographic and pathological features of the study population

	Total	Stage 0		Stage Ⅰ		Stage Ⅱ		Stage Ⅲ		Stage Ⅳ

[1]Including low- and high-grade intraepithelial neoplasia and invasive gastric cancers. SD: Standard deviation; M: Males; F: Females; *Hp*: *Helicobacter pylori*; OLGA: Operative link for gastritis assessment; OLGIM: Operative link on intestinal metaplasia assessment.

IEN (LG-IEN) and high-grade IEN (HG-IEN). The inter-observer consistency in assessing IEN lesions was tested by means of *K* statistics in a randomly selected series of 35 IEN/gastric cancer cases and was ranked as "fair to good" (k coefficient = 0.66). Gastric cancer was diagnosed in the presence of neoplastic epithelia infiltrating the lamina propria.

Statistical analysis

The strength of the association between the stage of gastritis and the demographic and pathological features was calculated using Wilcoxon's signed rank test (W), and the modified Kruskal-Wallis nonparametric test for trend (KW), as appropriate. The inter-observer consistency in classifying atrophic and IEN lesions was tested in two series of 100 and 35 randomly-selected biopsy sets, respectively, calculated as the overall proportion of agreement (the number of total paired observations in which the same result was obtained), and tested using Fleiss's kappa statistic[16]. Stata software (Stata Corporation, College Station, TX) was used for all the calculations. A P value < 0.05 was considered significant.

RESULTS

Overall, 4552 consecutive biopsy sets were considered. The male/female ratio was 1/1.18, and the patients' mean age was 55.1 years (median 57.0, range 20-89). For the males, the mean age was 55.0 years (range 20-88), while for the females it was 55.1 years (range 20-89).

Overall, 2967 biopsy sets (65.2%) showed no atrophic changes (i.e., stage 0 gastritis according to both OLGA & OLGIM) and the prevalence of the low-risk stages was 94.7% and 95.0% according to OLGA and OLGIM, respectively (Table 1).

In all, there were 67/4552 (1.5%) incidentally-found neoplastic lesions (either intraepithelial or invasive), including: 21 cases of LG-IEN; 6 cases of HG-IEN; 40 cases of GC (6 cases of diffuse-type proximal GC; 34 of intestinal-type distal GC). The M/F ratio among the neoplastic patients was 1.03/1 and their mean age (67.8 years; median 68; range 45-86) was significantly higher than that of the non-neoplastic patients (mean 54.8 years; median 57 years; range 20-89) (W; $P < 0.001$).

H. pylori was assessed histologically in 1698 patients (37.3%). Its prevalence among the neoplastic cases was 26 (38.8%), disregarding any previous eradication therapies. However, this study only focuses on the neoplastic risk associated with the stage of gastritis, without any specific reference to, or speculation about, the impact of the etiology on the morphogenesis of the gastric disease.

For 4460 out of 4552 cases (97.98%), low-risk stages (0 + Ⅰ + Ⅱ) and high-risk stages (Ⅲ + Ⅳ) were staged consistently using either OLGA or OLGIM criteria (Figure 1). For the 92 (2.0%) cases staged inconsistently, 14 were considered as low-risk using the OLGIM criteria and as high-risk according to OLGA. No cases staged as high-risk by OLGIM were down-staged when the OLGA criteria were applied.

The number of patients with high-risk stages (Ⅲ-Ⅳ) was 243 according to OLGA and 229 according to OLGIM, i.e., among the 243 OLGA high-risk stages, 16 (6.6%) were down-staged by OLGIM; in particular, 14 OLGA stages Ⅲ and Ⅳ were classified as stage Ⅱ according to OLGIM.

In all, 67 intraepithelial (i.e., non-invasive) or invasive neoplastic lesions were detected. All the 27 intraepithelial neoplasia coexisted with intestinalized glands. Among the 40 cases of invasive adenocarcinoma, 6 (15%) were located in the cranial stomach and histologically featured a solid/diffuse-type GC; the other 34 (85%) were cases of intestinal-type GC. After distinguishing between low- and high-risk stages, a significant association emerged between stages Ⅲ-Ⅳ and both intraepithelial and invasive neoplasia according to both the staging systems [W; $P < 0.001$ for both (Table 1)].

Fifty-nine of 67 (88.1%) and 57/67 (85.1%) intraepithelial or invasive neoplastic lesions were associated with high-risk OLGA and OLGIM stages, respectively. Six gastric cancers were detected in cases classified as OLGA/OLGIM low-risk gastritis: all 6 were diffuse-type gastric cancers (Figure 2). Two intestinal-type GCs coexisting with OLGA stage Ⅲ were associated with OLGIM stage Ⅱ gastritis (Figures 2 and 3).

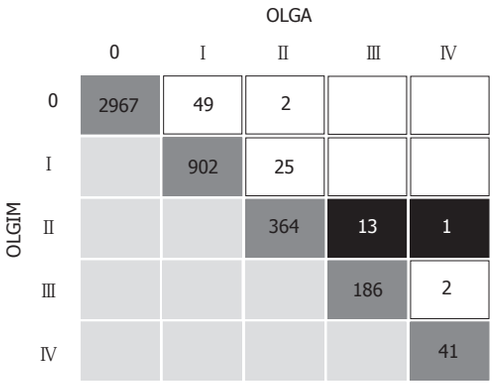

Figure 1 Distribution of patients by the two considered staging systems (operative link for gastritis assessment *vs* operative link on intestinal metaplasia). OLGA: Operative link for gastritis assessment; OLGIM: Operative link on intestinal metaplasia.

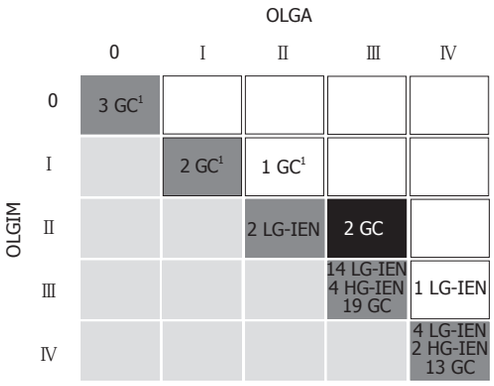

Figure 2 Distribution of preneoplastic/neoplastic lesions in the two considered staging-systems (i.e., operative link for gastritis assessment (OLGA)] and operative link on intestinal metaplasia assessment stages (OLGIM)]. [1]Diffuse-type (signet ring) gastric cancer. GC: Gastric cancer; LG-IEN: Low-grade intraepithelial neoplasia; HG-IEN: High-grade intraepithelial neoplasia.

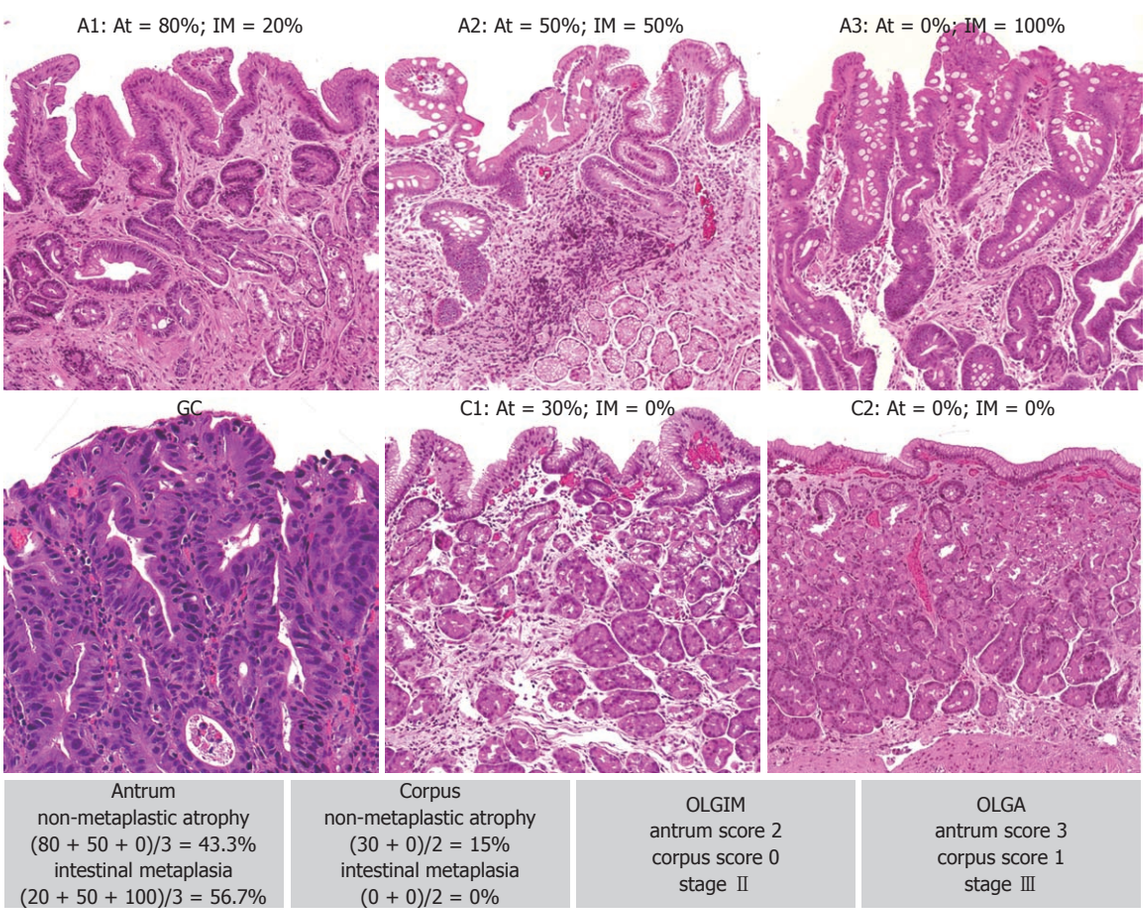

Figure 3 One of two gastric cancers developing in operative link for gastritis assessment stage Ⅲ, but the operative link for gastritis assessment stage Ⅱ, gastric mucosa. Representative images of 6 biopsy samples (3 from the mucosecreting/antral compartment, 1 from the lesion, and 2 from the oxyntic/corpus compartment) labeled according to site of origin (A: antral/angular; GC: gastric cancer; C: corpus), showing the percentages of atrophic/metaplastic lesions and the consequent operative link for gastritis assessment/operative link on intestinal metaplasia assessment stages.

DISCUSSION

Gastric cancer is still a health priority in Western Europe and it represents an epidemiological emergency in Eastern Europe, Central and Eastern Asia, and some South American regions[17-26].

Gastric mucosal atrophy is generally considered the "cancerization field" in which GC develops. Based on such a rationale, and incorporating the experience gained with the Sydney system[27], the OLGA staging system ranks the gastritis-associated cancer risk according to both the topography and the extent of gastric mucosa atrophy[2,4-6,26-28].

As regards topography, extensive biopsy sampling protocols (such as the one applied in the Houston experience) potentially increase the prognostic reliability of any staging system and they should be theoretically preferred. In line with the Sydney system[27], however, both OLGA and OLGIM systems require a (minimum) set of 5 biopsy samples for gastritis staging, which should strike a good compromise between the priority of obtaining a representative biopsy set and the operative limits of daily clinical practice[27].

The OLGIM proposal replaces the "global" atrophy score with a semiquantitative assessment of intestinal metaplasia (extent and site); according to its proposers, such a strategy should considerably increase the inter-observer agreement - an undeniable advantage[29,30].

In the present series of more than four thousand consecutive cases, 98% of stage Ⅲ-Ⅳ gastritis were consistently staged by applying either OLGA or OLGIM. The finding that patients' ages increase with higher stages further supports the clinico-biological plausibility of both systems.

It is worth noting that two intestinal-type GCs (both coexisting with OLGA stage Ⅲ gastritis) were found associated with OLGIM-Ⅱ gastritis (i.e., low-risk atrophic gastritis). In fact, by focusing on IM alone, OLGIM is less sensitive in identifying high-risk gastritis, and this may result in the down-staging of patients who should be offered follow-up[29,30]. Comparative studies involving non-GI (i.e., specialist) pathologists are needed to test which system (OLGA or OLGIM) provides more accurate results in relation to the time and effort spent on the histology assessment.

In his seminal work on gastric carcinogenesis, Pelayo Correa described mucosal atrophy as a cardinal step in the biological pathway that may eventually progress to gastric adenocarcinoma[31]. The current definition of gastric mucosal atrophy includes two different phenotypes: (1) loss (shrinkage or disappearance) of glands, which are replaced by fibrotic expansion of the lamina propria; and (2) metaplastic replacement of native glands by intestinalized and/or pseudopyloric glands (corpus antralization or SPEM). Focusing on IM alone excludes pseudopyloric metaplasia (i.e., SPEM) from the spectrum of atrophy, although it has recently been found increasingly important in gastric carcinogenesis (through transdifferentiation from mature chief cells following parietal cell loss)[32-34].

Lastly, considering IM alone carries the risk of us losing the correlation between gastric atrophy (as assessed by gastric serology, and PgI in particular) and its organic counterpart (resulting from the concurrence of the different phenotypes of gastric atrophy)[35-38].

In conclusion, gastritis staging effectively conveys an unequivocal message regarding the gastritis-associated cancer risk and may point to follow-up strategies tailored to a patient-specific clinico-pathological situation. This priority supports the inclusion of staging in gastritis histology reports and the demand for further efforts to improve the reproducibility of any staging criteria - bearing in mind that "easier" does not necessarily mean "better"!

COMMENTS

Background

Despite its declining incidence, gastric cancer is still the second cause of cancer-related death worldwide. Gastric atrophy is by far the main risk factor for non-hereditary, intestinal-type distal gastric cancer. Consistent evidence relates the extent and topography of atrophy to the gastric cancer risk.

Research frontiers

Building on current knowledge of the biology of gastritis, an international group of gastroenterologists and pathologists has proposed a system for reporting gastritis in terms of stage [the operative link for gastritis assessment (OLGA) staging system]. The OLGA staging system basically ranks gastric cancer risk according to the extent/topography of gastric atrophy. A recently proposed modification of the OLGA, called the OLGIM staging system, basically incorporates the OLGA frame, but considers intestinal metaplasia alone, instead of the global atrophy score.

Innovations and breakthroughs

In a large series of consecutive retrospective cases, the present study compares the reliability of the OLGA *vs* the operative link on intestinal metaplasia assessment (OLGIM) systems in ranking gastritis-associated cancer risk. Both staging systems stratify gastritis patients in different cancer risk classes, providing a clinico-biological rationale for a patient-tailored clinico-endoscopic follow-up. OLGIM staging, however, includes cases of gastritis at high risk of gastric neoplasia in its low-risk stage Ⅱ.

Applications

Gastritis staging conveys information on the clinico-pathological outcome of gastritis that is relevant to patient management, leading to an adequate patient stratification according to different cancer risks.

Terminology

OLGA is the acronym for "operative link for gastritis assessment", an innovative gastritis staging system proposed by an international group of gastroenterologists and pathologists that basically ranks the gastric cancer risk according to the extent and severity of gastric atrophy. OLGIM is the acronym for "operative link on intestinal metaplasia assessment", a modification of the OLGA staging system, which basically adopts the OLGA staging frame, but replaces the global atrophy score with an assessment of intestinal metaplasia alone.

Peer review

The authors compared the reliability of histological gastritis staging systems, OLGA and OLGIM, in ranking gastritis-associated cancer risk in a large series of consecutive cases. They concluded that both staging systems provide prognostically useful information on the gastritis-associated cancer risk even if OLGIM is less sensitive.

Abstract

AIM: To compare long-term results of gastric cancer patients undergoing laparoscopic and open gastrectomy in a single unit.

METHODS: From February 2000 to September 2004, all patients with adenocarcinoma of the stomach were assessed to entry in this longitudinal prospective non-randomized trial. Primary endpoint was cancer-related survival and secondary endpoints were overall survival, evaluation of surgical complications and mortality.

RESULTS: Fifty-eight patients were enrolled. Forty-seven patients were followed-up (range 11-103, median 38 mo). Four patients were lost at follow up. Twenty-two patients underwent a laparoscopic gastric surgery (LGS) and 25 had a standard open procedure (OGS). No statistical difference was found between the two groups in terms of 5 years cancer-related mortality rate (50% *vs* 52%, $P = 1$), and 5 years overall mortality rate (54.5% *vs* 56%, $P = 1$). Accordingly, cancer-related and overall survival probability by Kaplan-Meier method showed comparable results ($P = 0.81$ and $P = 0.83$, respectively). We found no differences in surgical complications in the 2 groups. There was no conversion to open surgery in this series.

CONCLUSION: LGS is as effective as OGS in the management of advanced gastric cancer. However LGS cannot be recommended routinely over OGS for the treatment of advanced gastric cancer.

Key words: Advanced gastric cancer; Laparoscopy; Laparoscopic cancer surgery; Long-term outcomes; Survival

INTRODUCTION

Radical surgical resection of the stomach and regional lymph nodes dissection is still the mainstream of the treatment of advanced gastric cancer (AGC). In 1994 Kitano *et al*[1] reported the first laparoscopic gastric resection and Billroth reconstruction in a patient with early gastric cancer (EGC). Laparoscopic gastric surgery (LGS) has been shown to improve short-term results and quality of life, compared to standard techniques[2,3,4] and has become an acceptable alternative approach in the management of

EGC especially in Japan and Korea[5,6,7]. The experience of laparoscopic gastric surgery in the western world is smaller because most of the gastric cancers are seen in an advanced stage and LGS is not considered an acceptable alternative to standard open surgery as yet. Little is known about long-term results and tumour recurrence after laparoscopic gastrectomy in AGC and most of the reported series are small[8].

However, the National Institute for Clinical Excellence in the United Kingdom has recently published an overview on interventional procedures regarding LGS[9]. LGS emerges as a feasible and oncologically secure procedure with several benefits.

Until large and well-conducted trials are undertaken also in the west and also including patients with AGC, case-control studies and preliminary data are important to guide the necessary acceptance to LGS.

LGS has been performed by our group since 1999. We herein report our 5 years results of a consecutive series of patients who have undergone LGS or standard open gastric surgery mostly for AGC over a four year period (February 2000-September 2004) and followed-up accordingly. The aim of this study was to evaluate long-term results of laparoscopy-assisted gastrectomy compared to open standard procedures in terms of overall and cancer-related survival probabilities.

MATERIALS AND METHODS

Between February 2000 and September 2004 all patients with preoperative diagnosis of non-metastatic gastric adenocarcinoma seen at our institution were evaluated to enter in this longitudinal prospective non-randomized trial. All patients underwent diagnostic work-up according to a standard protocol [endoscopy with biopsy, total-body computed tomography (CT) scan, endoscopic ultrasound (EUS) in selected patients]. Eligible patients were assigned either to laparoscopic or open procedure at the multidisciplinary cancer meeting, after the preoperative staging, solely on the basis of the availability of an upper gastrointestinal surgeon with experience in advanced laparoscopic surgery and accordingly to patients' preference. Demographics and preoperative clinical data analyzed included gender, age, body mass index (BMI), the American Association of Anaesthetists (ASA) score, pathological tumor-node-metastasis (pTNM) stage, tumour location, histological differentiation. Patients were stratified into 3 groups (proximal, distal, intermediate) according to tumour location.

The eligibility criteria were: histological diagnosis of gastric cancer at any stage ($\geqslant$ 1b), tumour location below the cardias and above the pylorus, pre-operative work-up indicating a surgical resection with an aim to perform R0 gastrectomy. Exclusion criteria were: age < 18 or > 75 years, BMI > 32, ASA score > 3, previous gastric surgery, presence of lynitis plastica, para-aortic lymph-nodes involvement, systemic metastases, contraindications to laparoscopy (severe cardiovascular disease, large abdominal wall or diaphragmatic hernias, *etc*). There was no selection bias during the enrollment process and inclusion criteria were the same for both groups.

Fifty-eight consecutive patients were enrolled in the study. Data from 47 patients who underwent open gastric surgery (OGS, $n = 25$) or LGS ($n = 22$) and then entered our oncologic follow-up (FU) protocol were included. Of this group of patients 91.5% had an AGC and underwent a D2 lymph nodes dissection. Four patients (8.5%) had a tumour in stage 1b and had a dissection of regional nodes (D1) + group β. The type of surgical resection and lymph nodes dissection were the same in both groups according to tumour location and disease stage. OGS required a midline xipho-umbilicus or a bilateral sub costal access. LGS was performed using a 3 ports plus liver retractor technique; at the end of the procedure the first port access was enlarged up to 5 cm to retrieve the specimen and to complete the already stapled esophago-jejunum side-to side anastomoses, if required. The same preoperative and postoperative care was provided to both groups. Adjuvant therapy, where appropriate, was similar for all patients. Patients were followed-up in the outpatient setting until cancer-related death or to the endpoint of the study, September 30, 2009. Follow-up schedule included history, clinical examination, blood tests and tumour markers every 6 mo. Upper gastrointestinal endoscopy was performed twice a year for the first 2 years then as clinically indicated. Total body CT scan was performed at 6 mo from surgery and then annually. Positron emission tomography (PET)-CT was indicated in selected cases.

Primary endpoints of the study were cancer related survival rate and disease-free interval. Secondary endpoints were overall survival rate and evaluation of number of harvested lymph nodes. Cancer related survival represents the number of patients alive at the end of the follow-up period (5 years). Disease free interval represents the period of time in which the patients were free of disease during the follow-up period.

All data were collected on a Microsoft® Excel spreadsheet and derived retrospectively from the database. Results were expressed as median and range of observed values. Statistical analyses were obtained with SPSS 17.0. Qualitative data were compared using Fisher's exact test or Pearson's χ^2 test; quantitative data showing a normal distribution were compared using a paired *t* test. Survival rates were assessed by Kaplan-Meier method and analyzed by the log-rank test. Regardless of the statistical analysis used, $P < 0.05$ was considered statistically significant.

RESULTS

Eighty-three patients with diagnosis of gastric cancer were referred to our unit from February 2000 to September 2004. Of these patients, 58 were eligible to enter the study. Eight patients were excluded thereafter because of distant nodal involvement, liver metastases or peritoneal carcinosis found intra-operatively. Three patients died within 90 d of surgery, one in the OGS group from complications related to surgery and one in each group due to pre-surgical co-morbidity. Ac-

Table 1 Clinical characteristics of patients

	LGS (n = 22)	OGS (n = 25)	P value
Median age, yr (range)	67 (38-75)	68 (54-75)	0.07
Gender (M/F)	13/9	13/12	0.4
BMI, kg/m^2 (range)	23 (18-25)	22 (18-26)	0.9
ASA score, median (range)	2 (0-3)	2 (0-3)	0.3
0	5 (23%)	2 (8%)	
1	3 (14%)	8 (32%)	
2	10 (45%)	10 (40%)	
3	4 (18%)	5 (20%)	
Tumor location (%)			0.9
Upper	5 (23%)	6 (24%)	
Middle	7 (32%)	7 (28%)	
Lower	10 (45%)	12 (48%)	
Lauren histology (%)			0.7
Intestinal	12 (54%)	12 (48%)	
Diffuse	10 (46%)	13 (52%)	
pTNM [1997] (%)			0.6
I b	2 (9%)	2 (8%)	
II	9 (41%)	13 (52%)	
IIIa/b	10 (45%)	7 (28%)	
IV	1 (5%)	3 (12%)	

LGS: Laparoscopic gastric surgery; OGS: Open gastric surgery; M/F: Male/Female; BMI: Body mass index; ASA: The American Association of Anaesthetists; pTNM: Pathological tumor-node-metastasis.

cording to this trial purpose, these cases were not included in the analysis of long-term results. Four patients were lost at follow-up (8.5%), two in the LGS group and 2 in the OGS group (P = 1). The median follow up was 38 mo (range 11-103) in the whole series, 39 mo in the LGS group (range 12-100) and 38 mo in the OGS group (range 11-103; P = 0.7).

Among the 47 patients left for the purpose of the study (26 males and 21 females; median age 68, range 38-75), 22 underwent LGS (46.8%) and 25 had a standard OGS (53.2%). According to tumour location and intraoperative findings, 12 patients had a total gastrectomy (5 LGS, 7 OGS) and 25 a sub-total gastrectomy (13 LGS, 13 OGS). No conversion from laparoscopic to open surgery occurred in the LGS group.

There were no significant differences between the two groups with respect to demographics and preoperative data considered, type of resection, type of lymphadenectomy and number of harvested lymph nodes. The characteristics of the study population and the type of surgical procedures are summarized in Tables 1 and 2 respectively.

A radical D2 lymph node dissection was performed in all 43 cases (91% in LGS and 92% in OGS) with a preoperative stage of T $\geqslant$ 2 or for any N+. Two patients in the LGS group (9%) and 2 in the OGS group (8%) had a preoperative T1\N0 diagnosis confirmed by EUS and underwent D1 + β lymphadenectomy according to our institution practice guidelines. The numbers of harvested lymph-nodes was 29 ± 7 in the LGS group and 30 ± 9 in the OGS group, thus showing no differences between the two techniques (P = 0.46). Three patients (1 in LGS, 4.5% and 2 in OGS, 8%) were found intra-operatively to have tumour invasion of the adjacent organs underwent an additional procedure, namely liver wedge resection, splenectomy and transverse colon resection.

Table 2 Operative findings

	LGS (n = 22)	OGS (n = 25)	P value
Type of gastric resection (%)			0.7
Subtotal	17 (77%)	18 (72%)	
Total	5 (23%)	7 (28%)	
Reconstruction (%)			0.6
Billroth 2	3 (14%)	2 (8%)	
Roux-en-Y	19 (86%)	23 (92%)	
Lymphadenectomy (%)			1
D1	2 (9%)	2 (8%)	
D2	20 (91%)	23 (92%)	
Lymph-nodes retrived	29 ± 7	30 ± 9	0.5

LGS: Laparoscopic gastric surgery; OGS: Open gastric surgery.

In the whole study group, 24 patients (51%) died of tumour recurrence. In the LGS group recurrence was observed in 11 patients (50%), the median disease free interval was 28 mo (range 12-60) and the median survival 39 mo (range 12-60). There was no port-site recurrence. In the OGS group recurrence was observed in 13 patients (52%) after a median of 26 mo (range 10-60) (P = 0.69). Median survival of the OGS group was 38 mo (range 11-60) (P = 0.73). There was no difference in the type of recurrence in the 2 study groups. Loco-regional recurrence (defined as tumor found by TC or TC-PET involving nodes or peritoneum in the region of the previous gastrectomy, including nodes around porta hepatis) or carcinosis occurred in 6 patients, liver metastases and jaundice in 12 patients and diffuse/systemic metastases in 6 patients

Cancer related mortality rate was comparable between the two groups (P = 1).

There was no difference in overall survival rate between the two groups (P = 0.9). Twelve patients (54.5%) in the LGS group and 14 patients (56%) in the OGS group died for any cause during the surveillance period.

Cancer related survival and overall survival (Figures 1 and 2, respectively) show similar Kaplan-Meier curves (P = 0.81 and 0.83, respectively) for OGS and LGS patients. Survival analyses are shown in Table 3.

DISCUSSION

Oncologically adequate surgical resection is the only therapeutic modality that offers curability in patients with gastric cancer.

According to our institution policy and current international guidelines the operation of choice for gastric cancer is a total or subtotal gastrectomy, depending on tumour location, with D2 dissection in advanced gastric cancer and with D1 ± β lymphadenectomy in non infiltrating tumours.

This paper reports a consecutive series of gastrectomies for cancer performed in a single unit over a 4-year period. The number of patients included in this report is small and come after a short learning curve experience but represents the first sensible group of patients who

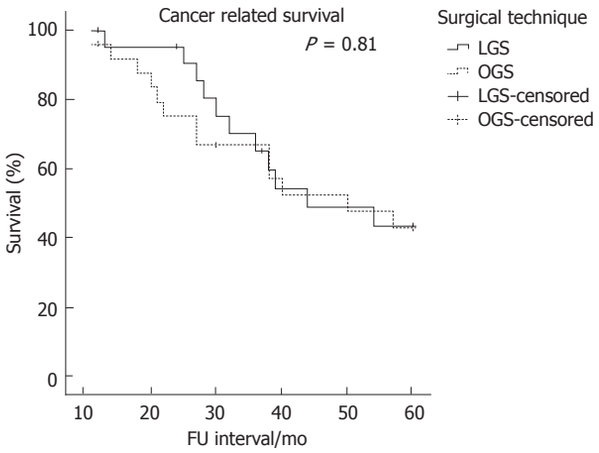

Figure 1 Kaplan-Meier estimates of cancer related survival. LGS: Laparoscopic gastric surgery; OGS: Open gastric surgery; FU: Follow up.

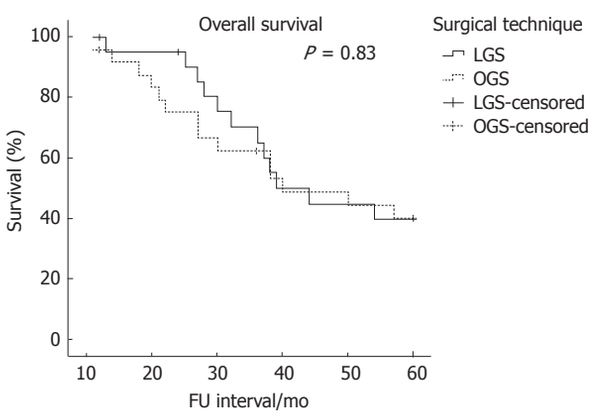

Figure 2 Kaplan-Meier estimates of overall survival. LGS: Laparoscopic gastric surgery; OGS: Open gastric surgery; FU: Follow up.

has completed follow-up so far. Almost half of the procedures were performed laparoscopically and the patients were not randomly assigned to one or the other procedure nor selected on the basis of pre-operative criteria such as tumour extension, BMI or other. However, to have a comparable number of patients, the 2 procedures were alternated whenever possible and this may well represent a sensible bias in the present series. Furthermore patients in the laparoscopic group were slightly younger than those operated with an open approach ($P = 0.07$); this is possibly related to an undesired selection bias based on patients' wishes.

Since the first report of laparoscopic gastric resection for cancer[1], various institutions around the world routinely perform LGS. However the vast majority of this experience comes from Asian medical institutions and is limited to the treatment of EGC. The standard lymphadenectomy for EGC is limited to the regional lymph nodes and even though LGS has been reported more difficult than OGS, from the 8th questionnaire survey of endoscopic surgery in Japan that recently examined 4799 cases of laparoscopic assisted distal gastrectomy, it appears clear that LGS is a safe procedure with an extremely low surgical mortality[10].

Table 3 Tumour recurrence and survival analyses

	LGS (n = 22)	OGS (n = 25)	P value
Overall 5 yr mortality rate	12 (54.5%)	14 (56%)	1
Cancer-related 5 yr mortality rate	11 (50%)	13 (52%)	1
FU (5 yr) accomplishment	20 (91%)	23 (92%)	1
Type of recurrence			0.9
Port-site M	0 (0%)		
Locoregional/carcinosis	2 (18%)	4 (31%)	
Hepatic M	6 (55%)	6 (46%)	
Distant M	3 (27%)	3 (23%)	
Median survival, mo (range)	39 (12-60)	38 (11-60)	0.7
Disease free interval, mo (range)	28 (12-60)	26 (10-60)	0.6

LGS: Laparoscopic gastric surgery; OGS: Open gastric surgery; FU: Follow up.

Table 4 Survival analyses by Kaplan-Meier method

	AGC + T1b (n = 47)	AGC (n = 43)
Cancer related survival probability analyses (P)	0.81	0.92
Overall survival probability analyses (P)	0.83	0.92

AGC: Advanced gastric cancer.

If the feasibility and safety of LGS in the treatment of EGC has been proven, it is also true that several reports have shown the efficacy of LGS in the cure of EGC with results comparable to those of an OGS series[11,12].

On the other hand, the role of LGS in the treatment of AGC is still controversial and many doubts remain about its safety and oncological efficacy. However it has to be said that many case series have been recently published showing adequate resection margins and lymph nodes retrieval for LGS in AGC whilst long term results still lack of comfortable numbers[13-16].

We hereby report our 5 years follow-up of a consecutive series of patients undergoing laparoscopic *vs* OGS, mostly with AGC. More precisely over 90% of the patients recruited for this study underwent surgery for AGC whilst four patients (2 from each group) were in stage 1b. The survival curves were re-analyzed after the exclusion of this subgroup of patients but no differences were found ($P = 0.9$) as shown in Table 4.

We demonstrate the technical feasibility of a radical lymph nodes dissection; a complete D2 dissection was always possible when appropriate, and the number of lymph-nodes dissected in all the cases of tumour > T1 complied with the Western (harvested N > 25) criteria of R0 resection for AGC. Also, no significant differences were found between the 2 groups (mean lymph nodes: LGS 29 *vs* OGS 30). Moreover the Kaplan-Meier survival curves show similar results when survival of the LGS group is compared to that of the OGS group (5 years cancer related survival 50% for LGS and 48% for OGS, $P = 0.81$).

Laparoscopic surgery may offer some advantages in

oncologic patients: less surgical stress, less blood loss and complications, better cellular immunity and cytokine release pattern[7,8,17,18].

Given the little data regarding gastric cancer and considering the characteristics of these patients (fragile, elderly, often malnourished and immune-compromised) and the specific biology of the tumour itself (subserosal cancer with transcoelomic metastatic capacity), at the moment we can only speculate that LGS could potentially offer a better outcome over OGS. This preliminary experience hasn't changed our clinical practice. However, currently we don't offer LGS to patients with known metastatic nodes to the lymph-nodes of the second level.

A large, multicenter and randomized trial should be designed to document long term benefit of LGS in the treatment of AGC according to tumour-stage (TNM) or preoperative evaluation such as age, co-morbidity, neo-adjuvant therapy.

In conclusion, LGS seems to be as effective as OGS in the treatment of advanced gastric cancer considering the long-term survival probabilities. However, given the lack of strong evidence on a large study population and the technical expertise required to complete a R0 laparoscopic gastrectomy, the authors cannot endorse LGS over OGS for the treatment of advanced gastric cancer outside clinical trials in specialized centres.

COMMENTS

Background

Gastric cancer is one of the leading causes of death for solid tumours worldwide. Surgical resection is the only hope of cure. Laparoscopic gastric resection is accepted as an alternative method of cure for early gastric cancer, especially in Asia. Its role in the treatment of advanced gastric cancer is a matter of debate.

Research frontiers

Laparoscopic surgery in cancers of the digestive tract (colon) has been demonstrated to bring some advantages, including a possible role in reducing recurrence. The authors looked at the role of laparoscopic gastric resection for advanced gastric cancer and showed that even this technically demanding procedure is safe and feasible in expert hands and that the long term results are equivalent to those of standard open surgery.

Innovations and breakthroughs

In this paper a case-control study was undertaken. Laparoscopic gastrectomy is compared to open surgery. This is one of the few papers with a long term follow-up of a consecutive series of patients with advanced gastric cancer undergoing laparoscopic surgical resection. It shows a good surgical result and reinforced the known advantages of gastrointestinal laparoscopic surgery. Case-control studies are important to guide surgical practice in cancer management.

Applications

This study could represent a step forward in minimally invasive surgery of the upper digestive tract. The long term results show that laparoscopic gastric resection is an oncologically adequate procedure that can be carried out with acceptable morbidity and mortality.

Peer review

This manuscript provides a single center comparison between laparoscopic and open gastrectomy, finding no significant difference in surgical resectability or oncologic outcomes. Overall, it is well written.

Abstract

AIM: To formulate a noninvasive index predictive of severity of liver fibrosis and activity in chronic hepatitis C.

METHODS: This cross sectional study was conducted on polymerase chain reaction positive, treatment naïve patients. Fibrosis was staged on a five point scale from F0-F4 and activity was graded on a four point scale from A0-A3, according to the METAVIR system. Patients were divided into two overall severity groups, minimal disease (< F2 and < A2) and significant disease (≥ F2 or ≥ A2). Eleven markers were measured in blood. Statistically, the primary outcome variable was identification of minimal and significant overall disease. Indices were formulated using β regression values of different combinations of nine statistically significant factors. Diagnostic performance of these indices was assessed through receiver-operating characteristic curve analysis.

RESULTS: A total of 98 patients were included and of these 46 had an overall clinically significant disease. Our final six marker index, Liverscore for Hepatitis C, consisted of age, alanine transaminase, gamma-glutamyl transpeptidase, apolipoprotein A-1, alpha-2 macroglobulin and hyaluronic acid. The area under the curve was found to be 0.813. On a 0-1 scale, negative predictive value at a cutoff level of ≤ 0.40 was 83%, while positive predictive value at ≥ 0.80 remained 89%. Altogether, 61% of the patients had these discriminative scores.

CONCLUSION: This index is discriminative of minimal and significant overall liver disease in a majority of chronic hepatitis C patients and can help in clinical decision making.

Key words: Chronic hepatitis C; Staging and grading; Liver fibrosis and activity; Noninvasive assessment; Liverscore

INTRODUCTION

Chronic hepatitis C (CHC) induces injury and inflammation of the liver, which appears to be responsible for

the associated fibrogenesis[1]. Morbidity and mortality in CHC is associated with the development of cirrhosis and its complications. The rate of fibrosis progression varies markedly from person to person and over time. The risk of developing cirrhosis varies from 10% to 20% over a period of 20 years[2]. Treatment of CHC is complex, costly, and associated with side effects that are difficult to accept in a population that is predominantly asymptomatic. Furthermore, about half of the patients with genotype 1, and slightly lesser than that in other genotypes, fail to respond to anti-viral therapy[3,4].

Treatment decisions are recommended to be individualized on the basis of severity of the liver disease, treatment response rates, co-morbid conditions and the readiness of the patient for treatment[5]. Therefore, assessment of the fibrosis stage and rapidity of progression of fibrosis (necro-inflammation) may help in determining the prognosis and the need of therapy in an individual patient. A prevalence peak of advanced fibrosis and cirrhosis in CHC patients is expected during this decade. Thus, increasing numbers of patients will require assessment. Furthermore, with the development of anti-fibrotic therapies, there will be a need for regular and more frequent monitoring[6].

In underdeveloped countries like Pakistan, with a high prevalence of disease and resource constrains[7,8], it seems unrealistic to offer treatment to all patients. There is a need to identify patient categories to rationalize the need for therapy. For patients showing minimal disease, treatment may be deferred with follow up for disease progression. Treatment may be offered to patients with progressive disease or else, safer, better tolerated, and more cost effective therapy will become available.

Liver biopsy is the current tool for the assessment of liver disease; nonetheless it is an invasive procedure and may be associated with complications. Moreover, the biopsy facility is not available in remote areas and is not always possible[9]. Alternative strategies are being actively evaluated, such as imaging and non-invasive biochemical monitoring of liver disease. Some of the biochemical markers, especially panels of multiple markers in the form of indices are promising, and may reduce the number of liver biopsies for assessment of liver disease[10]. The purpose of this study was to evaluate the predictive value of noninvasive biomarkers for the diagnosis of overall liver disease categories in CHC.

MATERIALS AND METHODS

This was a cross sectional study to determine the diagnostic accuracy of noninvasive biomarkers, conducted at Ziauddin University Hospital, Karachi, Pakistan from June 2006 to July 2010. The study was approved by Ethics Review Committee of the university. Treatment naïve polymerase chain reaction proven CHC patients, of 20 to 60 years of age, were included in the study. Patients with HBV co-infection and diabetes mellitus were excluded. Patients with history of other chronic inflammatory conditions, alcohol intake, and blood disorders requiring frequent blood transfusions were also excluded. A questionnaire was completed for every patient to document possible variables, such as demographic factors, and to rule out causes of exclusion. Written informed consent was obtained from each patient.

Liver biopsy

A percutaneous liver biopsy was performed with a 16-18 gauge modified Menghini aspiration needle (Surecu® TSK, Japan). Tissue was formalin fixed, paraffin-embedded, and processed for light microscopic examination. Along with standard hematoxylin and eosin staining, slides were also stained with connective tissue stains. Only liver biopsy specimens of more than 10 mm length and having not less than five portal tracts were included in the study[11]. Biopsy specimens with evident pathology, but without identification of the correct number of portal tracts, were also included. Histological features of the liver biopsy specimens were analyzed according to the METAVIR group scoring system[11,12], by one pathologist (Jamal Q), without any knowledge of the clinical or biochemical data. Every specimen was staged for fibrosis on a five-point scale; F0 = no fibrosis; F1 = portal fibrosis without septa; F2 = portal fibrosis with rare septa; F3 = numerous septa without cirrhosis; and F4 = cirrhosis. There is an element of subjectivity in classifying patients in different stages, especially in biopsy specimens, because of the majority of hepatic lobules being partial. However, we considered any fibrosis beyond portal tracts as significant (F2). Fibrosis was considered F3 when 50% or more portal tracts showed fibrous septa extending beyond the portal tracts. Necroinflammatory lesions were graded on a four point scale on the basis of an algorithm based on the severity of focal lobular necro-inflammation and piecemeal necrosis; A0 = no histological activity, A1 = mild activity, A2 = moderate activity, and A3 = severe activity[11].

On the basis of fibrosis stage and necro-inflammatory grade patients were divided into two overall severity groups; minimal disease $\leqslant$ F2 and $<$ A2 and significant disease $\geqslant$ F2 or $\geqslant$ A2[13].

Biochemical markers

Chemical analysis was carried out for alanine transaminase (ALT), gamma-glutamyl transpeptidase (GGT), alkaline phosphatase (ALP), total and direct bilirubin, apolipoprotein A-1 (Apo A-1), haptoglobin, alpha-2 macroglobulin (A2M), hyaluronic acid (HA), hydroxyproline (HYP) and proline.

The ALT assay was performed by an International Federation of Clinical Chemistry standardized ultraviolet enzymatic method, GGT was assayed by an enzymatic colorimetric method, the ALP assay was performed by a colorimetric method and total and direct bilirubin assays were performed according to the method described by Jendrassik and Grof. All enzymatic activities were measured at 37 ℃. All the above assays were performed using reagents from Roche Diagnostics®. A2M and haptoglobin assays were performed by an immuno-turbidimetric method using polyclonal rabbit anti-human antibodies (DakoCytomation Denmark Code. Nos. Q0102 &

[1]Significant disease, A2, 3 or F2-4. Minimal disease, A0, 1 and F0, 1, Results are shown as mean ± SD or *n* (%). ALT: Alanine transaminase; ALP: Alkaline phosphatase; GGT: Gamma-glutamyl transpeptidase; A2M: Alpha-2 macroglobulin; Apo-A1: Apolipoprotein A-1.

Q0330). The Apo-A1 assay was also performed immune-turbidimetrically, using reagents from Randox® UK (Cat. No. LP2989). HA was measured by an enzyme-linked binding protein microplate assay (Corgenix® Inc. United States). HYP and proline assays were carried out by high performance liquid chromatography (HPLC), using a method as described by Lange and Mályusz[14]. A HPLC unit LC-20AT was used with ultraviolet-visible spectroscopy photodiode array detector (SPD-M20A) and system controller, CBM-20A, all from Shimadzu Corporation Japan. A 6 mmID × 15 cm, C_{18} (Shim-pack CLC-ODS Japan) chromatography column was used.

Statistical analysis

Statistical analysis was performed using SPSS version 17.0 (Chicago, IL). A χ^2 test was used to compare the qualitative and independent *t* test was used to compare the quantitative variables. A *P* value of less than 0.05 was considered statistically significant.

The primary outcome for statistical analysis was identification of the patients with minimal and significant disease. The factors identified in the univariate analysis were subjected to logistic regression. Keeping overall disease as binary variable, β regression coefficients of the factors were obtained to generate the indices. The diagnostic value of these indices was compared by calculating the area under receiver operating characteristic (AUROC) curve. The best suited 6 marker index, chosen for final analysis, was transformed into a standardized scale ranging from 0-1 through percent ranking as liverscore for hepatitis C.

Through ROC curve analysis, the diagnostic value of the Liverscore at various cutoff points was assessed by calculating sensitivity, specificity, and positive and negative predictive values, for overall disease.

RESULTS

Initially 104 CHC patients were enrolled. Six patients were excluded; the biopsy specimens of four patients had less than five portal tracts, one biopsy showed a granuloma, and assays for three biochemical markers could not be performed in one patient.

Baseline characteristics

Table 1 shows the baseline characteristics of 98 patients, 52 (53%) patients were male (Male: Female = 1.15:1). The mean age was 36.0 ± 10.6 years. On liver biopsy, 26 (27%) patients had an activity grade of A2-3 and 42 (43%) had F2-4 fibrosis stages. Except for 4 patients, all the patients with A2 or A3 activity on liver biopsy also had F2-4 fibrosis. The major determinant of overall significant disease category was thus found to be the stage of the disease. In aggregate, 46 (47%) patients were classified as having clinically significant overall disease (A2-3 or F2-4).

Univariate analysis

The demographic and biochemical variables were compared for their association with different overall disease categories (Table 2). The mean age of patients with significant disease was significantly higher (39.6 ± 11.4 year *vs* 32.9 ± 8.7 year, $P = 0.002$), while gender distribution was not different between significant and minimal disease groups ($P = 0.15$). The mean total and direct bilirubin levels were significantly higher in the significant disease group ($P = 0.04$ for both). The mean ALT level was significantly higher in significant disease group than the minimal disease group ($P = 0.002$), but the mean difference of ALP level was statistically insignificant between the two groups ($P = 0.78$). Mean GGT was significantly higher in the significant disease group ($P < 0.001$). Mean difference of haptoglobin was not statistically significant according to overall disease categories ($P = 0.99$). The mean of A2M was significantly higher as in the significant disease group ($P = 0.002$), but mean Apo-A1 was significantly lower in the significant disease group ($P = 0.002$). The mean hydroxyproline was also significantly lower in the significant disease group ($P = 0.03$), while proline was not statistically different in minimal and significant

disease (P = 0.27). Mean hyaluronic acid was significantly higher in the significant disease group (P = 0.001).

Formulation and assessment of indices

In the univriate analysis, nine variables were identified as significantly associated with two groups of overall significant disease. These included age of the patient, bilirubin total and direct, ALT, GGT, A2M, Apo-A1, HYP and HA. As bilirubin total and direct were highly correlated (r = 0.85), we included bilirubin total only. Although gender was not significantly associated with histological categories, we included it in some indices to see if it improved their performance. Various combinations of the factors identified in the univariate analysis, were assessed by logistic regression. By keeping the overall disease categories as a binary variable, β regression coefficients of the factors were obtained to generate indices. The diagnostic value of these indices was assessed by an area under ROC (AUROC) curve. In the nine marker index, age, gender, bilirubin total, ALT, GGT, A2M, Apo-A1, HYP and HA were included. Bilirubin total was excluded in the eight marker index. Gender and HYP were excluded in the seven marker index. Gender, total bilirubin, and HYP were excluded in the six marker index. AUROC (±SE) was found to be 0.831 (0.05) for both the nine and eight marker indices and 0.813 (0.05) for both the seven and six marker indices. Although indices having HYP as a component i.e., the nine and eight marker indices performed slightly better, we excluded these indices because the difference was marginal and measurement of HYP is expensive and is not available in routine clinical laboratories. The AUROC was similar for seven and six marker indices.

Finally, we selected a six marker index formulated from beta regression values keeping overall disease category as a binary variable. The formula used to generate this index is given below (with ALT and GGT expressed as U/L, A2M as G/L, Apo A1 as mg/dL and HA as ng/mL).

Six marker index = -1.578 + 0.018 (age) + 0.023 (ALT) + 0.021 (GGT) + 0.152 (A2M) - 0.015 (Apo A1) + 0.014 (HA)

The obtained scores were converted to a standardized index ranging from 0-1 through percent ranking as Liverscore for Hepatitis C (Table 3).

The ROC curve showing the sensitivity and specificity for overall disease categories is shown in Figure 1, with an AUROC (± SE) of 0.813 (0.05). The specificity, sensitivity, positive predictive value (PPV) and negative predictive value (NPV) were calculated at different levels. Important cutoff points are shown in Table 4. Negative predictive value of Liverscore for Hepatitis C at a cutoff level of 0.30 was 84%. Six out of 31 patients who were below this cutoff were wrongly diagnosed (false nega-

0.30	89	48	58	84
0.40	85	62	64	83
0.70	54	90	82	70
0.80	39	96	89	65

Positive predictive value and negative predictive value were calculated for a prevalence of 0.45, all the values are expressed as percentages. PPV: Positive predictive value; NPV: Negative predictive value.

tives). All patients had F2 fibrosis and minimal activity. At a cutoff point of 0.40, NPV remained at 83%. Seven out of 40 patients below this cutoff were false negatives, again all had F2 fibrosis. For the positive predictive value, to identify the presence of significant fibrosis, cutoff levels of $\geqslant 0.70$ and $\geqslant 0.80$ were compared, and had 82% and 89% positive predictive values, respectively. Out of 29 patients with a score of 0.70 and above, five were false positives, all with F1 fibrosis. At a cutoff point of 0.80, two patients out of 20 in this study were false positives. Again both had F1 fibrosis.

Thus, a liverscore for hepatitis C of 0.40 or below reliably excludes the presence of significant disease and a score of 0.80 and above confirms the presence of significant disease.

DISCUSSION

The rate of fibrosis progression in CHC patients varies markedly from person to person, and only a minority suffers from long term complications[2]. The current use of liver biopsy for the assessment of liver histology has many drawbacks. Noninvasive assessment of liver histology has been the focus of research for many years. Isolated markers of liver cell injury and fibrosis have not proved to be sufficiently reliable for clinical use[15]. Development of indices consisting of multiple markers is now being focused to distinguish between minimal and clinically significant fibrosis categories.

Our final index, liverscore for hepatitis C, consisted of six markers, ALT, GGT, A2M, Apo-A1, hyaluronic acid and age of the patient. AUROC with this index was found to be 0.813 for overall disease. This index was also evaluated for fibrosis stage and activity grade separately, with clinically acceptable diagnostic performance (data not shown). The negative predictive value of Liverscore for Hepatitis C at a cutoff level of $\leqslant 0.40$ was 83%. All the patients (7/40) diagnosed as false negatives had F2 fibrosis and minimal activity. For the positive predictive value, a cutoff level $\geqslant 0.80$ was found suitable, with a PPV of 89%. At this cutoff, two patients out of 20 were false positives, both had F1 fibrosis. The diagnostic performance of this index in terms of AUROC is comparable to other similar indices reported in the literature.

Forns' index[16] consists of age of the patient, GGT, cholesterol, and platelets. AUROC was 0.86 in the formulation and 0.81 in the validation group. Using the cut off score of < 4.2, presence of significant fibrosis could be excluded in 36% (125/351) patients, with a NPV of 96% in the formulation group. The majority of the patients in this cohort had genotype 1. This index includes cholesterol, which is metabolized differently in genotype 3; it has been suggested[17] that this index might not perform well in patients having genotype 3, the most common genotype affecting the Pakistani population[18].

AST to platelet ratio index (APRI) is a very simple and widely validated index that amplifies the opposing effects of liver fibrosis on AST and platelet counts[19]. The AUROC curve of APRI for prediction of significant fibrosis remained 0.80 in training and 0.88 in the validation set. In one study from Pakistan[20], it showed an AUROC of 0.82 for significant fibrosis. At a cutoff point of < 0.5, the authors could exclude the presence of significant fibrosis in 36% (43/120) patients, with an NPV of 78%. Our index performed slightly better than this at a cutoff point of $\leqslant 0.40$, with the exclusion of 41% patients and an NPV of 83%. Our index has a better NPV and these scores were present in 41% (40/98) patients. This has a clinical advantage of identifying patients that can safely be deferred for urgent treatment.

Patented Fibrotest® for fibrosis consists of age and gender of the patient, GGT, total bilirubin, haptoglobin, A2M and Apo A-1. In addition, the same authors have also reported Actitest® for necroinflammation, which includes ALT in addition to Fibrotest® biomarkers[13]. This is the most widely validated noninvasive marker and is in clinical use. The AUROC for the identification of liver fibrosis was 0.84 and 0.87 for the formulation and validation group, respectively. The PPV of this index was excellent (> 90% certainty of presence of F2, F3 or F4) for scores ranging from 0.60 to 1.00 (34% of all patients). This index could exclude the presence of significant fibrosis in 12% of patients, with a high negative predictive value (100% certainty of absence of F2, F3 or F4) for scores ranging from zero to 0.10. This high accuracy of Fibrotest was not uniform in different populations. A study carried out by Rossi et al., in the Australian population demonstrated, a PPV of 78% at a Fibrotest® score of > 0.6 and an NPV of 85% at < 0.1[21]. We included all the components of Fibrotest® in our initial analysis; however, haptoglobin and gender of the patients were not discriminative of minimal and clinically significant disease in our cohort of patients in univariate analysis. Thus, these were not included in the final index.

Hepascore consists of age and gender of the patient, bilirubin, A2M and HA. For significant fibrosis, it showed an AUROC of 0.85 and 0.82 in the training and validation groups, respectively. A score of $\geqslant 0.5$ was 92% specific and 67% sensitive in the training set and 89% specific and 63% sensitive in the validation group. At this cutoff it provided high PPVs of 87% and 88% in the training and validation set, respectively[22]. Authors have not reported negative predictive values for significant fibrosis. We have all the data required for the calculation of Hepascore and will evaluate the performance of this score in our patients.

All the above mentioned scores either predict fibrosis or activity. One advantage of our index is its prediction for overall disease, which includes both fibrosis stage and activity grade. Both these histopathological categories are important for prognosis and making treatment decisions[23]. Furthermore, the majority of the previous indices have been reported in populations infected predominantly with HCV genotype 1. Evidence points towards the possibility that HCV genotype 3 associated CHC is a metabolically different disease[24]. Our index

might perform better in genotype 3 patients, because it is formulated in a population predominantly infected with this genotype[18].

All the factors included in our index are available and easily programmable on automated instruments in routine clinical laboratories. Furthermore, factors included in the Liverscore for Hepatitis C have physiological rationale.

Gamma-glutamyl transpeptidase is synthesized by the liver cells, its synthesis increases with fibrosis. The mechanisms for this increase could be the stimulation of GGT synthesis by epidermal growth factor during fibrogenesis[25]. ALT is synthesized by hepatocytes and its release into serum is related to liver cell injury[26]. The synthesis of A2M increases during stellate cell activation in the course of fibrogenesis, and its serum concentration increases with fibrosis[27]. In liver fibrosis, Apo A-1 release from the hepatocytes is hampered by the collagen fibers decreasing its serum levels[28]. Hyaluronic acid is a nonsulfated glycosaminoglycan and is major component of extracellular matrix. Among the direct markers of liver fibrosis, HA has been most extensively studied in CHC. It increases in the liver during fibrogenesis and is released into the systemic circulation during remodeling. Recent indices consisting of HA in combination with indirect markers have shown promising results[22].

Some of the markers we evaluated were not helpful in differentiating minimal from significant disease. Total and direct bilirubin were significantly associated with different histological categories, but were highly correlated (r = 0.85). Direct bilirubin was therefore excluded. Total bilirubin was included in the seven marker index, but its exclusion did not affect the diagnostic value and was thus excluded from the final index. Serum levels of ALP are known to be raised in both alcoholic and non-alcoholic liver disease with advanced histological changes. In addition, ALP has shown a discriminative value for advanced fibrosis and cirrhosis previously[29]. It was also associated with mild and advanced fibrosis categories in our study, but not for overall disease, the primary outcome in our study, thus, we did not include ALP in our index. HYP and proline are amino acids present in collagen in large quantities. The HYP content of liver biopsies is found to increase with advancing stage of fibrosis[30]. The evidence that fibrosis is a dynamic two way process with fibrosis and its degradation occurring simultaneously, prompted us to include these amino acids as products of collagen degradation in our panel of biomarkers. We expected their high levels in serum because of the greater amount of collagen undergoing remodeling in advanced stages. We found no association of these amino acids of collagen degradation with severity of liver fibrosis or necroinflammatory activity. HYP, however, was statistically associated with overall disease category, but actually decreased. In the only study we could find, predictive value of these amino acids in sera of CHC patients was evaluated for advanced (F3 and 4) and mild (F0, 1 and 2) fibrosis[31]. Proline was not significantly different between the two groups, while HYP was found to be increased with advanced fibrosis, but showed a low (0.525) area under ROC curve. We found no study comparing these amino acids in minimal and significant fibrosis or overall disease. The evidence that their serum levels do not increase with increasing fibrosis might be explained by slower fibrosis degradation in advanced fibrosis. It has been shown that accumulation of fibrosis is the net effect of increased fibrogenesis and its decreased degradation[32].

One limitation of our study was that we could not validate our results in a different cohort of patients. This was not possible because of the smaller number of patients recruited in our study. We recommend an independent study for the validation of our index.

In conclusion, a liverscore for hepatitis C of 0.40 or below excludes the presence of significant disease. Thus, it can reliably exclude around 41% of CHC patients that do not require an urgent treatment. A score of 0.80 and above confirms the presence of significant disease. Using these cutoff values, the severity of the liver disease can reliably be predicted in around 61% of the CHC patients.

COMMENTS

Background

Chronic hepatitis C (CHC) is a leading cause of liver fibrosis and its complications, such as cirrhosis and hepatocellular carcinoma. On the other hand, the disease progresses slowly and may even remain non progressive in many patients. Thus, assessment of severity of liver fibrosis and activity guides prognosis and treatment decisions. Liver biopsy, the current gold standard for monitoring liver histology, is associated with complications and is not possible in all patients.

Research frontiers

Noninvasive assessment of liver histology has been a focus of research for many years. The majority of these noninvasive indices have been developed in western populations with predominantly hepatitis C virus (HCV) genotype 1. The research hotspot is to develop a noninvasive index in our population with a predominantly HCV genotype 3.

Innovations and breakthroughs

The noninvasive index score of 0.40 or below (on a scale of 0-1) excludes the presence of significant liver disease and a score of 0.80 and above confirms the presence of significant disease reliably. With these cutoff points, this index was discriminative for minimal and significant overall disease in 61% of our patients.

Applications

The development of a convenient monitoring tool will allow physicians to make evidence based clinical decisions and closely monitor disease progression.

Terminology

Activity grade is a measure of necroinflammation in liver tissue. Higher grades are related to rapid disease progression. Fibrosis stage is a measure of the amount of fibrosis in the liver. Overall disease is regarded as minimal when both grade and stage are < 2 and is significant when either of the grade or stage is ⩾ 2. Significant disease is an indication for institution of antiviral treatment when liver histology is known.

Peer review

This cross sectional study was conducted on polymerase chain reaction positive, treatment naïve patients to formulate a noninvasive index predictive of severity of liver fibrosis and activity in CHC. This study represents an attempt to accomplish such a goal by determining the diagnostic accuracy of a group of noninvasive biomarkers in the assessment of liver fibrosis.

Abstract

AIM: To compare the presentation and impact on quality of life of gastroesophageal reflux disease (GERD) in old and young age groups.

METHODS: Data from adult patients with GERD diagnosed by endoscopic and symptomic characteristics were collected between January and November 2009. Exclusion criteria included combined peptic ulcers, malignancy, prior surgery, antacid medication for more than 2 mo, and pregnancy. Enrolled patients were assigned to the elderly group if they were 65 years or older, or the younger group if they were under 65 years. They had completed the GERD impact scale, the Chinese GERD questionnaire, and the SF-36 questionnaire. Data from other cases without endoscopic findings or symptoms were collected and these subjects comprised the control group in our study.

RESULTS: There were 111 patients with GERD and 44 normal cases: 78 (70.3%) and 33 patients (29.7%) were in the younger and elderly groups, respectively. There were more female patients (60.3%) in the younger group, and more males (72.7%) in the elderly group. The younger cases had more severe and frequent typical symptoms than the elderly patients. Significantly more impairment of daily activities was noted in the younger patients compared with the elderly group, except for physical functioning.

CONCLUSION: Elderly patients with GERD were predominantly male with rare presentation of typical symptoms, and had less impaired quality of life compared with younger patients in a Chinese population.

Key words: Gastroesophageal reflux disease; Quality of life; Age factors

INTRODUCTION

Gastroesophageal reflux disease (GERD) is a chronic disease which has a considerable, impact on the everyday lives of affected individuals, and interferes with physical activity, impairs social functioning, disturbs sleep and reduces productivity at work[1]. The prevalence of the disease increases with age[2,3], and advanced age has been identified as a significant risk factor for relapse of esophagitis[4,5]. Furthermore, elderly patients present less frequently with the typical symptoms of heartburn, acid regurgitation, and abdominal or chest pain, which are quite different from those of young subjects[6,7]. Several previous studies assessed clinical symptoms and quality of life of GERD patients using the GERD impact scale[8], Chinese GERD questionnaire (GERDQ)[9], and the Short Form 36 (SF-36) questionnaire[10,11]. However, to date, no studies have been conducted to compare the quality of life of young and old patients with GERD. The aim of this study was to compare the presentation and impact on quality of life of GERD in younger and elderly patients in a Chinese population.

MATERIALS AND METHODS

Data from consecutive patients with GERD in our hospital were collected between January 2009 and November 2009. All patients underwent an open-access transoral upper gastrointestinal endoscopy, and those who were diagnosed with erosive esophagitis, or had typical symptoms, were considered for inclusion in the study. Exclusion criteria were as follows: (1) GERD combined with other structural gastrointestinal disorders, such as peptic ulcer disease, esophageal or gastric malignancy; (2) prior gastric surgery; (3) use of chronic antacid medication, such as proton pump inhibitors or H2-receptor antagonists, for more than 2 mo prior to enrollment; and (4) pregnancy.

The enrolled patients were assigned to the younger group if they were under the age of 65 years; patients 65 years and over were assigned to the elderly group. All cases were asked to complete the GERD impact scale, the Chinese GERDQ, and the SF-36 questionnaire (Chinese version), and results were compared between the two groups. Data from other cases without endoscopic findings of erosive esophagitis or symptoms related with GERD were collected and these subjects served as the control group in our study. All study participants completed the SF-36 questionnaire, a widely used health survey.

Data are expressed as mean ± SD deviation for each of the measured parameters. A P value below 0.05 was considered statistically significant. Statistical comparisons were made using Pearson's χ^2 test, or Fisher's exact test, to compare the effects of gender and endoscopic or clinical reflux esophagitis severity, and the independent Student t test was used to analyze scores of each scale and questionnaire.

Table 1 Characteristics and endoscopic symptoms in younger and elderly cases with gastroesophageal reflux disease

Variable	Younger group (n = 78, 70.3%)		Elderly group (n = 33, 29.7%)		
	n (%)	mean ± SD	n (%)	mean ± SD	P value
Mean age (yr)		37.73 ± 10.17		72.94 ± 9.58	
Symptom duration (yr)		2.82 ± 3.92		2.50 ± 2.99	0.384[1]
Gender					0.001[2]
M	31 (39.7)		24 (72.7)		
F	47 (60.3)		9 (27.3)		
Endoscopic reflux esophagitis severity					
NERD	15 (19.2)		0		0.001[3]
L.A. Grade A	50 (64.1)		16 (48.5)		
L.A. Grade B	8 (10.3)		8 (34.2)		
L.A. Grade C	5 (6.4)		6 (18.2)		
L.A. Grade D	0		3 (9.1)		

[1]Pearson's χ^2 test, [2]Independent t test, [3]Fisher's exact test. F: Females; M: Males; L.A.: Los Angeles classification; SD: standard derivation; NERD: Non erosive reflux disease.

RESULTS

Among all enrolled consecutive patients between January and November 2009, there were 111 with GERD and 44 normal cases. Patients' characteristics and endoscopic reflux esophagitis severity are shown in Table 1. Among the patients with GERD, there were 78 patients (70.3%) in the younger group and 33 cases (29.7%) in the elderly group. A similar duration of symptoms was noted between the younger cases (mean 2.82 years) and the elderly cases (mean 2.50 years). Comparing the gender of each group, there were significantly more female patients (60.3%) in the younger group, and more male patients (72.7%) in the elderly group. The elderly patients had greater endoscopic disease severity than the younger patients, based on the Los Angeles classification.

The presentation of the younger and elderly patients with GERD in our study are summarized in Table 2, which show the results of the GERD impact scale. As shown in Table 2, the young cases had a higher prevalence of typical symptoms than the elderly patients, including burning (48.7% *vs* 15.2%, P = 0.005), pain in chest (64.3% *vs* 33.3%, P = 0.001), regurgitation of food (79.5% *vs* 54.6%, P = 0.058), hoarseness (73.1% *vs* 39.4%, P = 0.010) and chronic conditions related to heartburn (44.8% *vs* 33.3%, P = 0.708).

The quality of life results in the two groups measured by the GERD impact scale are shown in Table 3, and the SF-36 questionnaire results are shown in Table 4 and Figure 1. As shown in Table 3, significantly impaired activities of daily living, including sleep disturbance (52.6% *vs* 18.2%, P = 0.004), feeding and drinking problems (64.1% *vs* 12.1%, P = 0.001), and impact on social activites (43.6%

Mental health	54.77 ± 16.18	66.18 ± 15.10	0.001

All were analyzed by independent *t* test.

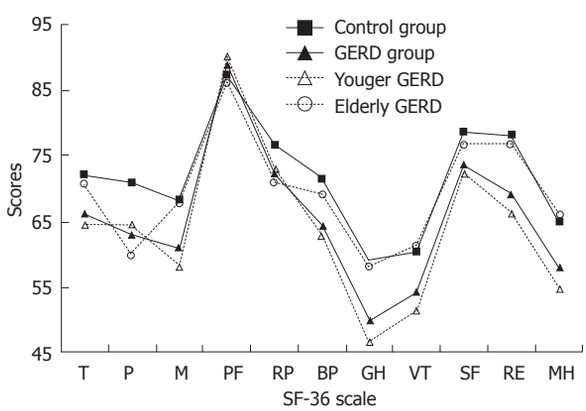

Figure 1 Scores of SF36 questionnaire among the control cases, and younger and elderly cases with gastroesophageal reflux disease. T: Total SF36 scores; P: Total physical health scores; M: Total metal health scores; RP: Role-physical; RF: Physical functioning; BP: Bodily pain; GH: General perception; VT: Vitality; MH: Mental health; SF: Social functioning; RE: Role-emotional; GERD: Gastroesophageal reflux disease.

as shown in Table 3, younger patients had higher scores than elderly patients in the items of physical functioning (mean 90.26 *vs* 86.39, $P = 0.342$), role-physical limitations (mean 72.76 *vs* 71.21, $P = 0.853$), and total physcial health status (mean 64.54 *vs* 60.03, $P = 0.240$). In contrast, younger patients had lower scores than elderly patients for the following items: bodily pain (mean 62.70 *vs* 69.18, $P = 0.089$), general perception of health (mean 46.47 *vs* 58.09, $P = 0.005$), vitality (mean 51.22 *vs* 61.36, $P = 0.013$), social functioning (mean 72.18 *vs* 76.76, $P = 0.263$), emotional limitations (mean 66.24 *vs* 76.82, $P = 0.203$), mental health status (mean 54.77 *vs* 66.18, $P = 0.001$), total mental health status (mean 58.15 *vs* 67.76, $P = 0.011$), and total health status (mean 64.58 *vs* 70.73, $P = 0.106$).

DISCUSSION

GERD is a chronic disease that tends to relapse and develop complications[12], and it is reported to be more severe and to have a higher incidence of severe complica-

tions in older *vs* younger patients[4,13,14]. Moreover, clinical features of GERD in old patients are quite different from those of younger adult subjects, with the elderly presenting less frequently with the typical symptoms of heartburn, acid regurgitation, and pain[15]. Our study findings showed similar results in that most typical symptoms of GERD occurred in the younger patients, but occurred more rarely in the older subjects. The only exception in our study was that acid regurgitation was more frequent in older patients than in young ones, but this difference was non-significant. Hence, the typical esophageal symptoms of GERD, such as heartburn, are unreliable markers when diagnosing this disease in elderly patients[16].

Interestingly, the symptom of hoarseness, which is often considered an extraesophageal symptom of GERD[17], was also more frequently noted in the younger patients. Our results demonstrated that the younger patients with GERD not only had more typical esophageal symptoms but also more extraesophageal symptoms than in the elderly group. Furthermore, a previous study reported roughly one-third of elderly patients may have none of the symptoms usually associated with GERD[6]. It has been suggested that old patients may display symptoms in a different manner compared with young patients.

Patients with GERD may present with a broad range of troublesome symptoms that can damage the quality of their daily lives[18,19]. The negative effects of GERD are dependent on the frequency and severity of symptoms rather than the presence of esophagitis. Studies conducted in Sweden's general population, which assessed the impact of the severity and frequency of GERD symptoms showed that even symptoms rated as mild are associated with a clinically meaningful reduction in wellbeing[20]. A German study determined that patients with symptoms of GERD had substantially impaired physical and psychosocial aspects of wellbeing compared with the general population, and felt restricted as a result of food and drink problems, disturbed sleep, and impaired vitality and emotional wellbeing[18]. A Chinese study reported that the largest decrements in quality of life scores among all subscales in subjects with GERD symptoms were related to bodily pain and role limitations[21]. Another study found that patients with GERD reported more impairment due to pain but less impairment with regard to physical and role functioning[11]. Our study yielded similar results, namely, that patients with GERD reported impaired quality of life in all dimensions, except physical functioning, compared with quality of life in the normal population.

The quality of life findings revealed slightly lower physical scores in elderly patients with GERD. It is possible that the increased disability or frailty associated with aging may account for the lower physical functioning. In addition, compared with elderly patients, significantly impaired mental health and vitality in the younger GERD patients was found in our study. That is, severity and frequency of symptoms of GERD were associated with impaired quality of life. This finding is consistent with the results of a previous study which showed both severity and perceived discomfort of symptoms were valid markers of the degree of quality of life impairment[22,23].

There were some limitations in our study. Firstly, some personal matters and other co-morbidity of diseases, which tend to influence quality of life, such as psychiatric factors[24], central obesity[25], chronic heart failure, and chronic obstructive pulmonary disease or asthma[26] were not considered. These might have led to scoring bias in the questionnaire. Secondly, overlap of GERD with inflmmatory bowel syndrome and functional dyspepsia should be considered. The overlaps were common and might worsen scores of questionnaries in our study according to a previous report[27]. Thirdly, our study design was hospital-based. Further research should include representative samples from the general population to confirm these results.

In conclusion, in the present study, elderly and younger adult patients with GERD in a Chinese population had different characteristics. Elderly GERD patients were predominantly male, rarely presented with typical GERD symptoms and their quality of life was less impaired compared with younger GERD patients.

COMMENTS

Background

Gastroesophageal reflux disease (GERD) is a chronic disease which has an impact on the everyday lives of affected individuals. The prevalence of the disease increases with age, but elderly patients present less frequently with typical symptoms of heartburn and acid regurgitation, which are quite different from symptoms of young subjects.

Research frontiers

Several previous studies assessed clinical symptoms and quality of life of GERD patients using the questionnaire. However, to date, no studies have been conducted to compare the quality of life of young and old patients with GERD. The aim of this study was to compare the presentation and impact of quality of life in younger and elderly GERD patients in a Chinese population.

Innovations and breakthroughs

The study found more female patients in the younger group, and more males in the elderly group. The younger cases had more severe and frequent typical symptoms than the elderly patients. Significantly impaired daily activities were noted in the younger patients compared with the elderly group, except for physical functioning.

Applications

The diagnostic features of GERD should be determined in the elderly, since these patients have rare presentations of typical symptoms, and less impaired quality of life compared with younger cases in a Chinese population.

Peer review

It's an interesting and important manuscript in which the vluable index based on patient has been shown.

Abstract

AIM: To evaluate the effect of hands-on training of gastroenterology fellows in gastric polypectomy using an *ex vivo* simulator.

METHODS: Eight gastroenterology fellows at Mackay Memorial Hospital, Taipei were evaluated in gastric polypectomy techniques using a pig stomach with artificial polyps created by a rubber band ligation device. The performance of four second year (year-2) fellows who had undergone one year of clinical training was compared with that of four first year (year-1) fellows both before and after a 4-h workshop using the *ex vivo* simulator. The workshop allowed for hands-on training in the removal of multiple artificial polyps and the placement of hemoclips at the excision site. Evaluation included observation of technical skills, procedure time, and the fellows' confidence scale.

RESULTS: One week after the workshop, the year-1 fellows were re-evaluated and had significantly improved mean performance scores (from 17.9 ± 1.8 to 22.5 ± 0.7), confidence scale (from 4.5 ± 1.0 to 7.8 ± 0.5) and procedure time (from 615.0 ± 57.4 s to 357.5 ± 85.0 s) compared with their baseline performance. After 4 h of training using the *ex vivo* simulator, the skills of the year-1 fellows were statistically similar to those of the year-2 fellows.

CONCLUSION: Use of this *ex vivo* simulator significantly improved the endoscopic gastric polypectomy skills of gastroenterology fellows who had not had previous clinical training in gastric polypectomy.

Key words: *Ex vivo*; Animal tissue model; Hands-on training; Pig stomach; Polypectomy

INTRODUCTION

Interventional endoscopy continues to advance, requiring that endoscopists obtain practical training in skills needed for therapeutic intervention. This has traditionally been accomplished by having trainees perform endoscopy on patients under close supervision. However, the use of animal models is a safe way to practice the techniques used in therapeutic endoscopy[1]. Since the mid-1990s, an *ex vivo* porcine-tissue simulator has been widely used in many hands-on training programs. It has been shown to facilitate skill in a variety of endoscopic procedures, such as hemostasis for arterial or variceal bleeding[2,3]. It is also useful in training trainers for endoscopy programs[4].

Endoscopic polypectomy is one such skill that must be acquired, including removal of gastric polyps incidentally discovered during endoscopic evaluations. Hyperplastic polyps are by far the most common histologic type of gastric polyp, occurring most commonly in the antrum[5]. When such polyps are larger than 1 cm, the risk of neoplastic transformation increases. Therefore, endoscopic polypectomy may be necessary both for accurate diagnosis and as definitive treatment[6,7]. Larger polyps, however, may be more difficult for inexperienced endoscopists to manage, as are those in more challenging locations. Fellows in gastroenterology training programs need to become familiar with the practical skills required, both in removing the polyp and closing the resulting mucosal defect[8].

We developed a method to simulate artificial polyps in an *ex vivo* pig-stomach model for use in our gastroenterology fellowship training program. As far as we are aware, this novel approach has not previously been described. We designed this study to evaluate this model in training gastroenterology fellows.

MATERIALS AND METHODS

The study group comprised eight gastroenterology fellows at Mackay Memorial Hospital, Taipei, Taiwan, four in the second year (year-2) and four in the first year (year-1) of subspecialty training. Year-2 fellows had already learned to perform endoscopic gastric polypectomy in patients under the supervision of an experienced supervisor certified by the Digestive Endoscopic Society of Taiwan. Year-1 fellows were certified in diagnostic endoscopy after one year of training but had no prior experience performing gastric polypectomy, although they had assisted other endoscopists in placing hemoclips. None of the eight fellows had ever used an *ex vivo* pig-stomach simulator prior to this study. One instructor conducted workshop training, and two reviewers evaluated the fellows' skill in performing polypectomy. The instructor and reviewers each had more than 10 years' experience in interventional endoscopy and were certified as instructors by the Digestive Endoscopic Society of Taiwan.

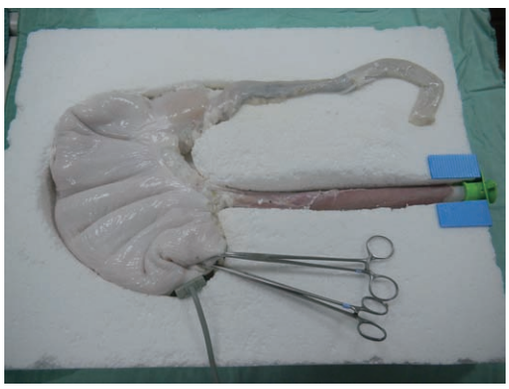

Figure 1 ***Ex vivo*** **porcine organ package including esophagus, stomach and duodenum in a handmade simulator shell.**

The *ex vivo* pig-stomach simulator was a modified version of the compactEASIE model[2,3]. Fresh pig stomachs, including short segments of the lower esophagus and duodenum, were purchased from a slaughterhouse early in the morning of the day they were to be used and were stored in cool saline until preparation. For the simulator, the stomach was placed in a hand-made container composed of layered polystyrene boards cut so as to accommodate the esophagus, stomach, and duodenum (Figure 1). It was irrigated copiously with tap water until clean. Defects in the viscera were closed using appropriately sized Kelly forceps. A flexible overtube (Sumitoma Corp, Tokyo, Japan) with an air-tight valve was inserted into the short segment of the lower esophagus and a plastic band placed to seal the space between the overtube and esophagus. The distal end of the small bowel was closed with Kelly forceps for a good air-tight effect. An electronic-conduction pad was placed between the stomach and the polystyrene board, and an electrosurgical generator (VIO 200D; ERBE Corp., Tuebingen, Germany) with standard settings was used.

The instructor created simulated gastric polyps by using a pneumatically-activated esophageal variceal ligation device (MD-48709; Sumitoma Corp, Tokyo, Japan). For the skills assessment portion of the study, a polyp was created in the cardia in essentially the same location for each fellow being evaluated (Figure 2A). The endoscope (GIF Q230; Olympus Optical Co. Ltd, Tokyo, Japan) and other equipment (polypectomy snare: SD-8P-1; Olympus Optical Co. Ltd, Tokyo, Japan; hemoclip applicator: HX-100 LR; Olympus Optical Co. Ltd, Tokyo, Japan) were retired from clinical use and all used exclusively in animals at the time of the study. The Institutional Review Board at Mackay Memorial Hospital approved this training project.

Polypectomy techniques

Fellows were assessed for their ability to set up the equipment, to remove the entire polyp safely and to close the mucosal defect so as to prevent hemorrhage or perfora-

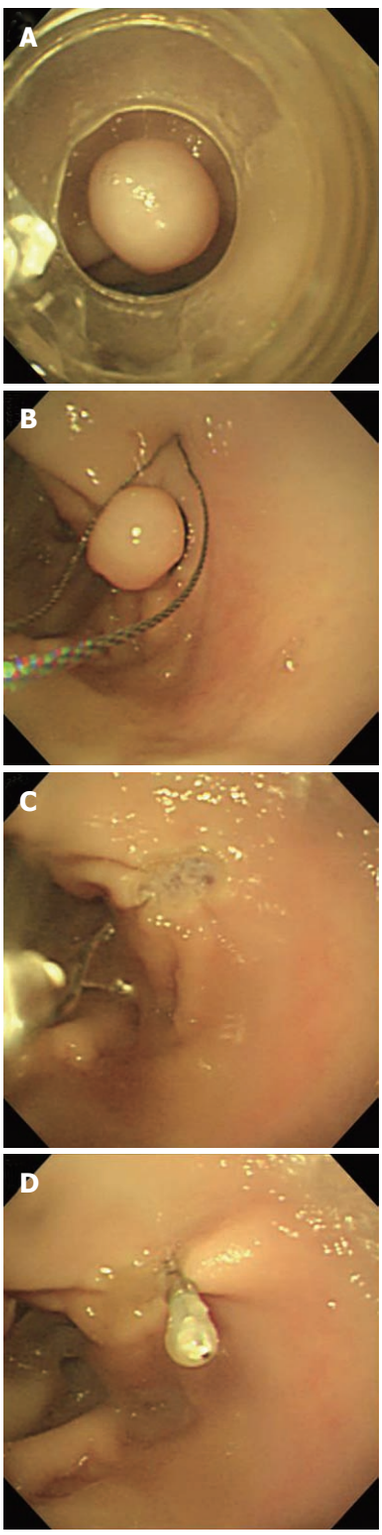

Figure 2 Use of the simulator for evaluation. A: One approximate 8-mm gastric polyp artificially created with a rubber band ligation device in the porcine stomach cardia; B: Snare being advanced to encircle the polyp; C: Successful removal of the entire lesion; D: Application of a hemoclip.

tion. They were required to advance the snare to encircle the target tissue and then transect the polyp with an electrosurgical cutting device attached to the snare. They then had to ensure closure of the mucosal defect by placing hemoclips, which required understanding of how to load the clips, and also direct an assistant in proper placement (Figure 2B-D).

Figure 3 Use of the simulator for training: several artificial polyps placed in different position in the porcine stomach. Use of a multiband ligation device reduced the time required to load rubber bands, allowing efficient creation of multiple artificial polyps.

Workshop training

Following a baseline skills assessment, the four year-1 fellows attended a 4-h workshop led by one instructor, with an assistant to handle the instruments. There was an initial 1-h lecture about gastric polypectomy, followed by the instructor demonstrating the procedure for 1 h, including proper techniques, equipment settings, and communication with the assistant. The final 2 h involved hands-on practice by the fellows (30 min each). For this session, multiple gastric polyps were artificially created ahead of time in various locations within the porcine stomach using a preloaded multiband esophageal variceal ligation device (Speedband Superview Super 7; Microvasive, MA, United States). This allowed each fellow to practice removing a number of simulated polyps for training (Figure 3). While one fellow was practicing, the other three acted as observers and benefitted by hearing the instructions, feedback, and correction of technical errors given to the others.

Outcome measures

Skills assessments were all conducted by two reviewers who had not conducted the training session, and again with an assistant for the actual procedure. All eight fellows were assessed at baseline. A second evaluation was conducted for year-1 fellows a week after they had attended the workshop. Before each evaluation, fellows indicated on a 10-point visual analogue scale their own degree of confidence in performing the procedure. The reviewers met before each evaluation session to standardize the evaluation criteria. Each independently completed a standard assessment checklist for each fellow. The time to complete the procedure was recorded. The standard rating score was based on a 5-point score (1-5 from poor to excellent) for each of 5 items: (1) setting up and testing the equipment; (2) issuing correct instructions to the

[1]Year-2 fellow assessment *vs* year-1 fellow initial assessment; unpaired *t* test; [2]year-2 fellow assessment *vs* year-1 fellow final assessment; unpaired *t* test; [3]year-1 fellow initial assessment *vs* year-1 fellow final assessment; paired *t* test.

assistant; (3) proper localization of the polyp; (4) removal of the polyp with minimal tissue injury; and (5) successful application of the hemoclips. The scores for each item were summed for the final performance score.

Statistical analysis

The primary aim was to assess changes in performance score, procedure time, and confidence among the year-1 fellows before and after workshop training. This was done by using paired *t* tests. The results for the year-1 fellows at both baseline and again after training were also compared with those of the year-2 fellows, using unpaired *t* tests. Date was analyzed using SPSS 11.0 (SPSS Inc, Chicago, Ill). Results were considered to be statistically significant if the *P* value was < 0.05.

RESULTS

Baseline fellow characteristics and skills

Year-1 and -2 fellows were of comparable age and academic background. Year-2 fellows had done about twice as many diagnostic endoscopies as the year-1 fellows. At baseline assessment, year-2 fellows had a significantly higher mean performance score (21.1 ± 0.9 *vs* 17.9 ± 1.8), confidence scale (7.8 ± 0.5 *vs* 4.5 ±1.0), and shorter procedure time (377.5 ± 156.3 s *vs* 615.0 ± 57.4 s) than year-1 fellows.

Assessment of learning progress in year-1 fellows

One week after the workshop using the *ex vivo* simulator, the year-1 fellows were re-evaluated and had significantly improved mean performance scores (from 17.9 ± 1.8 to 22.5 ± 0.7), confidence scale (from 4.5 ± 1.0 to 7.8 ± 0.5) and procedure time (from 615.0 ± 57.4 s to 357.5 ± 85.0 s) compared with their baseline performance. The significantly improved scores were attributed to doing a better job of setting up the equipment and in communicating with the assistant (Table 1). There were no significant differences between the final assessments for the year-1 fellows and those of the year-2 fellows.

DISCUSSION

Our study demonstrated the feasibility of using the *ex vivo* pig stomach with artificially created polyps to improve the practical skills of gastroenterology fellows learning the techniques of gastric polypectomy. In theory, this should minimize risks to patients, as the fellows can practice the necessary maneuvers on the *ex vivo* model.

The most important advantage of the method we devised is the ease with which artificial polyps can be created. A previously described method is to lift the mucosa with surgical forceps and ligate the base with a suture[9]. However, using the multiband esophageal variceal ligator to raise the tissue and band allows rapid creation of multiple polyps in different locations within the stomach and allows the fellows to practice on a variety of lesions such as they might encounter clinically. Reducing the time required to prepare the model makes it more user-friendly. The entire setup is relatively inexpensive and easily portable.

Practicing with the *ex vivo* simulator has several other advantages over traditional clinical training in which an instructor supervises the trainee who performs the procedure in an actual patient. Clinical endoscopy may be a prolonged and difficult procedure in some patients. If the patient is unstable, the instructor may have to take over the procedure. Even if able to carry out the entire procedure themselves, fellows may feel less free to ask questions or receive feedback in the clinical setting. Also, unlike polyps of the colon, gastric polyps are relatively uncommon, with an incidence of less than 2%[10,11]. This means that in the course of subspecialty training, a fellow is unlikely to have many opportunities to perform gastric polypectomy under supervision. The four year-2 fellows we assessed had performed only a mean of 5 gastric polypectomies, with only one having the chance to do two such procedures in the second year of training.

A satisfactory outcome for gastric polypectomy requires expertise in multiple skills, including preparation of the electrosurgical cutting device and accessories, in addition to the endoscopic techniques such as proper snaring, stretching the polyp away from the intact mucosa, safe cutting and finally application of hemoclips to close the mucosal defect. Knowing that so many skills are required puts additional pressure on trainees, especially the first few times they perform the procedure. When they have to do so in a real patient, lack of confidence may increase the risk of technical errors and unpredictable outcomes[12]. Our year-1 fellows had considerable improvement in the confidence scale from a mean score of 4.5 ± 1.0 before training to 7.8 ± 0.5 after using the simulator in the work-

shop. They were able to practice the procedure a number of times without fear of injuring a patient. This contention is supported by the fact that their performance scores did appear to improve after the training.

As noted above, the most obvious improvement after the workshop was in setting up the equipment and communicating with the assistant. The educational experience in this workshop transcends a "simulation experience" because it also involves lectures, student-student interaction, and interaction with a faculty member which are all in a non-simulated environment. Of course this exposure would be in addition to a formal teaching setting with mentoring, and this by no means will or can replace that. While the mean score for hemoclip application improved from baseline (2.6 ± 0.5 to 3.6 ± 0.9), it did not reach 4 points. This experience is similar to that noted by Hochberger *et al*[1] when they first designed the compactEASIE model. This particular technique involves more intricate maneuvers and several steps, increasing the opportunities to make mistakes. It thus appears the application of hemoclips may require more training sessions for the fellows to achieve competency, which is all the more reason for ensuring that a good simulator is available. Familiarity with loading of the device, delivery, and deployment may enhance safe and successful application[13].

The expense of conducting a hands-on workshop may be a limiting factor for some training programs. Our 4-h workshop cost about US $350 overall using our hand-made simulator, endoscopes and accessories retired from clinical practice and pig stomachs. Because this workshop was a project of our Clinical Skills Training Center, the instructor, reviewers and assistants were all volunteers, and no facility fee was needed. The Olympus GIF Q230 endoscopes, polypectomy snare, and hemoclip device were retired from our clinical service and cost almost nothing to use. The hemoclips and rubber band ligation cost US $300. The price of one hand-made simulator was US $35 and pig stomachs were US $15 each. We therefore believe this hand-made *ex-vivo* porcine-stomach simulator could be used by most institutions without requiring a huge capital outlay.

Our study had a number of limitations. Firstly, this was an in-house project; we didn't recruit fellows from other sites therefore had a very small sample, precluding rigorous statistical analysis. The performance evaluations by the two reviewers were unblinded. Because we didn't invite outside experts as reviewers, there may have been observational bias. Evaluation with a video recording of the entire procedure is an alternative blinded method, but this approach can't adequately assess the equipment setup process or communication with the assistant. Secondary, we presume it's a very realistic simulator to represent the task of gastric polypectomy no matter the size of polyp, techniques or procedures time and it is easily transferable to clinical care. Whether those results will translate into better clinical performance of polypectomy as the year-1 fellows continue on into the second year of training remains to be seen. A number of factors may possibly result in incomplete transfer of simulator-acquired skills to the real world[14], including differences between the training environment and the clinic, anxiety and stress of learners[15]. Conducting such a study on a larger scale with an appropriate sample size and assessment of the clinical data is therefore still necessary.

Our pilot study demonstrates the feasibility of using the *ex vivo* pig stomach with artificially created polyps to improve the practical skills of gastroenterology fellows learning the techniques of gastric polypectomy. The workshop allowed the year-1 fellows to improve their skills nearly to the level of those acquired by year-2 fellows who were trained clinically. In theory, this should minimize risks to patients, as the fellows can practice the necessary maneuvers on the *ex vivo* model. We believe this is a simple and cost-effective way to train gastroenterology fellows in endoscopic polypectomy and regard this program as preceding training in more complicated polypectomy once competent in standard removal of small and pediculated lesions.

ACKNOWLEDGMENTS

The authors thank Wang MS, research nurse and colleagues in the Clinical Skills Training Center for the preparing the *ex vivo* porcine model and providing technical assistance.

COMMENTS

Background

Since the mid-1990s, an ex vivo porcine-tissue simulator had been widely used in many hands-on training programs. It has been shown to facilitate skill in a variety of endoscopic procedures.

Research frontiers

Endoscopic polypectomy is one such skill that must be acquired, including removal of gastric polyps incidentally discovered during endoscopic evaluations. The authors developed a method to simulate artificial polyps in an *ex vivo* pig-stomach model for use in their gastroenterology fellowship training program.

Innovations and breakthroughs

The most important advantage of the method the authors devised is the ease with which artificial polyps can be created. Using the multiband esophageal variceal ligator to raise the tissue and band it allows rapid creation of multiple polyps in different locations within the stomach.

Applications

Reducing the time required to prepare the model makes it more user-friendly. The entire setup is relatively inexpensive and easily portable.

Peer review

The authors should be congratulated in their efforts on this manuscript. Though the number of fellows is small, the differences and improvements were profound. The educational experience herein transcends a "simulation experience" because it also involves lectures, student-student interaction, and interaction with a faculty member - all in a non-simulated environment. The topic is timely. It would be a benefit if this improvement could be tied to a clinical parameter to remove doubt that all that occurred was improving performance in a simulation experience.

Abstract

AIM: To analyze the clinicopathologic features and the prognosis of primary intestinal lymphoma.

METHODS: Patients were included in the study based on standard diagnostic criteria for primary gastrointestinal lymphoma, and were treated at Sun Yat-sen University Cancer Centre between 1993 and 2008.

RESULTS: The study comprised 81 adults. The most common site was the ileocaecal region. Twenty-two point two percent patients had low-grade B-cell lymphoma. Fifty-one point nine percent patients had high-grade B-cell lymphoma and 25.9% patients had T-cell lymphoma. Most patients had localized disease. There were more patients and more early stage diseases in the latter period, and the origin sites changed. The majority of patients received the combined treatment, and about 20% patients only received nonsurgical therapy. The wverall survival and event-free survival rates after 5 years were 71.6% and 60.9% respectively. The multivariate analysis revealed that small intestine and ileocaecal region localization, B-cell phenotype, and normal lactate dehydrogenase were independent prognostic factors for better patient survival. Surgery based treatment did not improve the survival rate.

CONCLUSION: Refined stratification of the patients according to the prognostic variables may allow individualized treatment. Conservative treatment may be an optimal therapeutic modality for selected patients.

INTRODUCTION

In the recent years, the incidence of non-Hodgkin's lymphoma (NHL) has increased worldwide, especially for primary extranodal lymphoma (ENL). Primary gastrointestinal lymphoma (PGIL) is the commonest ENL, which accounts for 30%-45% of ENL. Gastric lymphoma is the most frequent (55%-70%), followed by intestinal lymphoma (20%-35%), and colorectal lymphoma (5%-10%)[1].

Due to a lack of characteristic symptoms and a low

incidence rate, primary intestinal lymphoma (PIL) is easily misdiagnosed until serious complications occur, such as perforation and ileus. Furthermore, the optimal treatment for PIL remains controversial, and the prognosis is unsatisfactory. Although during the past two decades, the diagnosis and treatment of PGIL has changed tremendously, results from studies of gastric lymphoma are controversial regarding the benefit of surgical resection[2-4]. However, a large-scale prospective investigation of PIL is difficult due to its low incidence and complicated histologic subtypes.

Numerous retrospective studies report the PGIL in European countries[5-7], but there were no large-sample studies from Asia in this decade besides Japan[8]. Our study consisted of 81 Chinese patients with PIL who were diagnosed and treated at Sun Yat-sen University Cancer Centre between 1993 and 2008. It was a single center study, which retrospectively analyzed the clinical features, anatomic and histologic distribution, time trends and the prognosis of the PIL in Chinese patients.

MATERIALS AND METHODS

Patients

This study consisted of 81 adult Chinese patients with PIL who were diagnosed and treated at Sun Yat-sen University Cancer Centre between 1993 and 2008. Patients were included in the study based on standard diagnostic criteria for PGIL; patients had to present gastrointestinal (GI) symptoms or predominant lesions in the GI tract[9]. The patients who presented with second malignancies, had missing confirmation of histologic subtype, or had no follow-up information were excluded from the study.

The diagnostic workup included: details of the patients' history and physical examination with inspection of Waldeyer's ring, blood cell count, serum chemistry, chest radiographs, abdominal ultrasound, computed tomography (CT) scan of the chest and abdomen, bone marrow aspiration or biopsy, and endoscopy examination with multiple biopsy. Endoscopic ultrasound and positron emission tomography (PET)/CT were carried out when available.

The histologic specimens were obtained by endoscopic biopsy or surgery. These specimens were stained routinely with hematoxylin and eosin. Immunohistochemical staining for CD3 and CD20 was performed on all 81 specimens. In some selected cases, additional staining and polymerase chain reaction-based amplifications of genes for immunoglobulin heavy chain or T-cell receptor gamma chain were done. All slides were reviewed separately by two pathologists and a common consensus was reached in all cases. Histologic classification was done according to WHO criteria[10].

Patients were then staged according to the Ann Arbor system with modifications[11].

Treatment and response

The treatment modalities included surgical resection, conservative treatment (chemotherapy and radiotherapy), and the combined treatment. The main first line chemotherapy were four to six cycles of cyclophosphamide (CHOP) 750 mg/m^2, doxorubicin 50 mg/m^2, and vincristine 1.4 mg/m^2 (maximum, 2mg) each on day 1, plus prednisone 100 mg on days 1 to 5) or RCHOP (rituximab 375 mg/m^2 on day 0, plus CHOP). The regimen of cyclophosphamide, vincristine, doxorubicin, high-dose methotrexate (CODOX-M), alternating with ifosfamide, etoposide and high-dose cytarabine (IVAC), were used for patients with Burkitt's lymphoma[12].

International Workshop Criteria was used for response evaluation. Therapeutic response after the initial treatment was designated as complete remission (CR), partial remission, stable disease, or progression of disease.

Follow up and statistical analysis

Overall survival (OS) was defined as the time from diagnosis to the date of death for any reason or to the last follow-up. Event-free survival (EFS) was measured from the date of diagnosis to the date that event occurred. Events included disease progression, relapse and patient death for any reason.

The statistical differences were evaluated using the Student's *t*-test, Mann-Whitney *U* test (rank sum test) and the χ^2 test. Survival curves were calculated according to the Kaplan-Meier method, and the value was compared using the log rank test. All variables that influenced the prognosis ($P < 0.10$) were put into a multivariate analysis using the Cox proportional hazards model. Differences were considered significant if the *P*-value was < 0.05. All statistical analyses were performed using the Statistical Software Package for the Social Sciences version 17.0 (SPSS 17.0).

RESULTS

Patient clinical features

From January 1993 to December 2008, 81 patients with PIL were recruited for the study. The patients had a mean age of 46 years (range, 18-75 years) and comprised of 58 men and 23 women.

The clinical symptoms of PIL were unspecific. Pain was the main diagnostic symptom in most cases (75.3%), followed by hematochezia (25.9%) and diarrhea (16.9%). Palpable mass, constipation and loss of appetite were less common symptoms. Perforation was scarce (7.4%). "B" symptoms occurred in 42.0% patients.

Most patients had localized disease. Sixty-six (81.5%) patients had Stage Ⅰ~Ⅱ disease and 15 (18.5%) had Stage Ⅲ~Ⅳ disease. Most patients (75.3%) received the combined treatment, while about one fifth of patients only received nonsurgical therapy. The clinical features are shown in Table 1.

Sites of origin

The origins of PIL were confirmed by surgery, endoscopy, or CT. They were subdivided as follows: (1) duodenum; (2) jejunum; (3) ileum; (4) ileocaecal region; (5)

Table 1 Clinicopathologic features *n* (%)

colon; (6) rectum; and (7) multiple sites. The ileocaecal region was defined as involvement of terminal ileum, cecum, appendix and or lower part of ascending colon. The most common site of PIL was the ileocaecal region (38.3%), followed by the colon (24.7%) and 13.6% small intestine (Table 2).

Histologic subtypes

PIL are heterogeneous diseases. In the current study, B cell NHL and T-cell NHL were both classified into five common subtypes. The B cell subtypes, arranged by order, were: diffuse large B-cell lymphoma (DLBCL) 35 (43.2%), marginal zone B-cell lymphoma 15 (18.5%), Burkitt and Burkitt-like lymphoma 4 (4.9%), follicular lymphoma 3 (3.7%), and mantle cell lymphoma 3 (3.7%). The ranks of the T cell subtypes were: enteropathy-type T cell lymphoma 7 (8.6%), peripheral T-cell lymphoma, not otherwise specified 5 (6.2%), uncertain subtype 5 (6.2%), anaplastic 3 (3.7%), and NK/T 1 (1.2%). All types of intestinal lymphoma showed broadly similar patterns in both sexes, apart from marginal zone lymphoma (MALT) which was predominant in women (9 in 23, 39.1%) (Table 3).

Time trends of intestinal lymphoma

The study was divided into two 8 year periods due to the use of Rituximab after 2000. Twenty-seven (33.3%) patients belonged to Period A, and 54 (66.7%) to Period B. Over these two periods, the average age of patients didn' t change (43.9 years *vs* 47.2 years, $P = 0.454$). The sites of origin were different ($P = 0.0469$), whereas the histology differences were not significant ($P = 0.4975$). More patients were in the early stage in period B ($P < 0.0001$), however the treatment and response did not change significantly ($P = 0.686$ *vs* $P = 0.6842$, respectively).

Treatment and prognosis

The follow-up after the diagnosis ranged from 18 to 183 mo (mean, 72 mo). The OS and EFS rates after 5 years were 71.6% and 60.9% respectively. Prognostic factors on univariate analysis were shown in Table 4.

Female patients showed a better OS, but EFS did not different between two groups. The sites of origin were prognostic (Figure 1). EFS in different sites were significantly changed ($P = 0.025$), and OS in the small intestine and ileocaecal region were significantly longer compared with rectum and multiple sites ($P = 0.016$). Histologic subtype was prognostic for EFS and OS ($P = 0.002$ and $P < 0.001$, respectively). B cell phenotype had a better prognosis than T cell phenotype (Figure 2). Patients who had perforation showed a poorer EFS and OS than those did not perforate. In the normal lactate dehydrogenase (LDH) group, EFS and OS were significantly better compared with the elevated LDH group ($P = 0.010$ *vs* $P = 0.034$, respectively) (Figure 3).

We could not detect any significant influence of age, stage, bulky disease, B symptom, treatment or time trend in EFS and OS of the PIL.

Cox multivariate analysis revealed that small intestine and ileocaecal region localization, B-cell phenotype, and normal LDH were independent prognostic factors for better OS and EFS (Table 5).

We also did prognostic analyses for the subgroups of B-cell lymphomas. Kaplan-Meier curves showed the sur-

Table 4 Prognostic factors on univariate analysis[1]

Characteristics	*n* = 81	5-year EFS	*P* value	5-year OS	*P* value

[1]Assessed by the log-rank test. EFS: Event-free survival; OS: Overall survival; LDH: Lactate dehydrogenase.

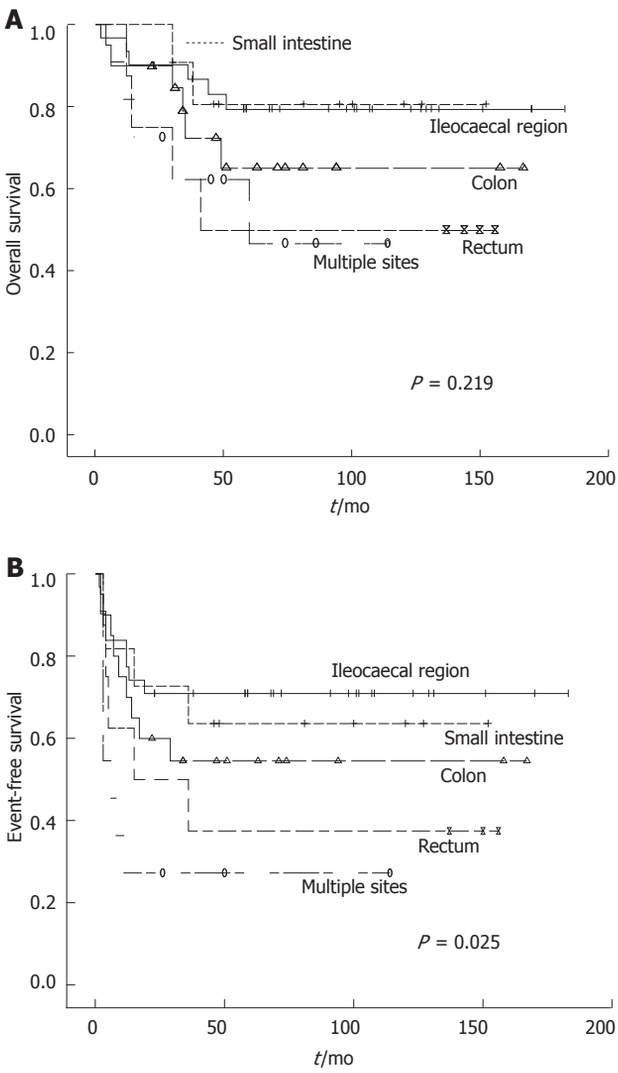

Figure 1 The survival curves stratified by the five groups according to anatomic site of origin. A: Overall survival among five groups (P = 0.219). Small intestine and ileocecal region *vs* rectum and multiple sites (P = 0.016); B: Event-free survival among five groups (P = 0.025).

vival of follicular lymphoma was better than MALT and DLBCL, and Burkitt lymphoma was the worst. However, the *P* values were not significant.

Cox multivariate analysis revealed that normal LDH were protective factors for better EFS (P = 0.007), and the gender and sites of origin were independent prognostic factors (P = 0.037 and P = 0.05, respectively). More specifically, females had better OS, and small intestine and ileocaecal region had better prognosis than rectum and multiple sites. We could not detect any significant influence of pathology, age, stage, bulky disease or treatment in B cell PIL (Table 6).

Numbers of T-cell lymphoma were too small for subanalyses. The small number of patients made it difficult to get an accurate analysis.

DISCUSSION

There are many publications about the epidemiology and clinical features of PIL. Only a few of the publications recruited more than 80 PIL patients[1,6,8], however, all of them were published before 2003. Except for a report on PGIL in Chinese patients which recruited 184 intestinal patients in 1995 from Hong Kong[13], there was no relative large-sample report from mainland China. Due to the differences in living habits and environment effects between Hong Kong and mainland China, it was necessary to analyze the epidemiology and prognosis of PIL in mainland China.

PIL is a male predominant disease, and male:female ratio was 2.5:1. In our series, we found that the age of the patients (median age = 46 and mean age = 46) were younger than the other reports[5,6,8,13-15].

The ileocaecal region was the most common site, with a frequency of 38.3%. Unlike the other reports[5,8,13,16], the colorectal involvement was more frequent. The rates of primary sites varied considerably in the other publications, especially noticeable for the rates of the ileocaecal region. The data ranged from 9.5% to 38.3% in our re-

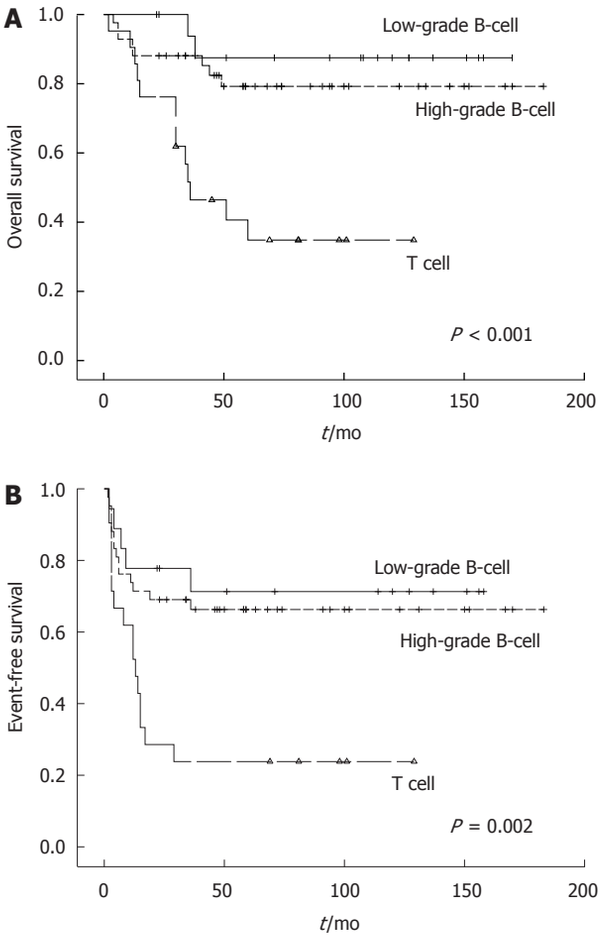

Figure 2 The survival curves stratified by the three histologic subgroups. A: Overall survival among the three groups ($P < 0.001$); B: Event-free survival among the three groups ($P = 0.002$).

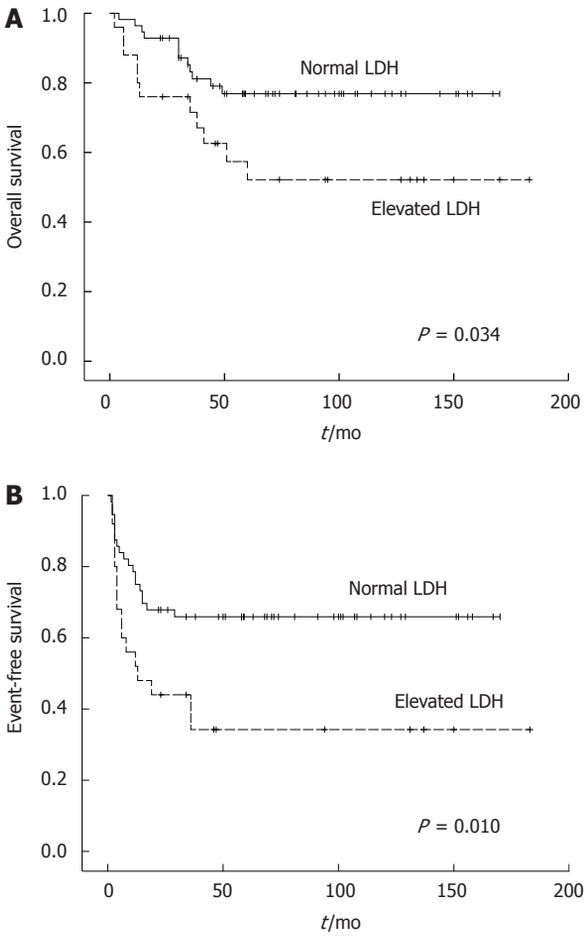

Figure 3 The survival curves stratified by the two groups according to lactate dehydrogenase levels. A: Overall survival between the two groups ($P = 0.034$); B: Event-free survival between the two groups ($P = 0.010$). LDH: Lactate dehydrogenase.

port[16]. We considered that the main reason for the difference was probably the precise definition of the ileocaecal region, which was missing in most reports. We believe it is important to distinguish it as a separate site, because our data show a significantly better prognosis for this region.

High-grade B cell lymphoma was the most common subtype in all the patients. This was followed by T cell lymphoma, which is apparently more than in Europe[5,6]. In our opinion, the reason for this is due to the higher ratio of T cell lymphoma in the NHL in China than European countries. Two publications reported T cell lymphoma only comprised 5% and 20.6% of the primary intestinal lymphoma in Chinese patients[17,18]. The difference between the reported series is difficult to interpret. Geographic variations in the prevalence of viral or bacterial infection, celiac disease, diet or other environmental factors may be the cause of the difference. However, the most likely reason may be due to these other studies having too small a sample size.

Our data confirmed the rising trend of PIL over the past 16 years in China, which was similar to reports from the United States[19] and Europe[6]. Furthermore, the number of patients with early stages or multiple sites has also increased. Advances in diagnostic procedures have led to an improvement in the accuracy in the diagnosis of lymphoma. However, an actual increase in the incidence of intestinal lymphoma should also be considered. Increasing exposure or susceptibility to risk factors, such as *H. pylori* infection, excessive protein or fat in the diet, and environmental pollution also may have contributed to this increase[6,20].

Most of the patients received combined treatment including surgery and chemotherapy with or without radiotherapy, 69.1% patients reached CR. The OS and EFS rates after 5 years were 71.6% and 60.9%, respectively. This was similar to the other reports[5,8].

Multivariate analysis revealed that small intestine and ileocaecal region localization, B-cell phenotype, and normal LDH were independent prognostic factors for better OS and EFS. Female gender[21] and no perforation indicated better OS in univariate analysis, but not significantly in multivariate analysis.

We also did prognostic analyses for the subgroups of B-cell lymphomas. The pathology subtypes of the B-cell lymphomas were not significant prognostic factors. Perhaps the small number of subtypes made it difficult to get an accurate analysis.

Stage and age were prognostic factors in many reports[2,22-25], and the size of the mass were also mentioned,

but we found no find significant effect. Other factors reported to have contributed to survival included surgical resection and a good performance status[3].

We found surgery based treatment and radical surgery did not improve the survival rate. This fact raised the question of whether surgery is really necessary. Usually, the diagnostic difficulties, as well as the high rate of initial complications, led to primary resection of PIL in most patients. However, the efficacy of this procedure has not been evaluated so far. Furthermore, we observed complete remissions of PIL in patients receiving only conservative therapy[8,26,27].

It is clear that there was no benefit from lymph node clearance in lymphoma patients, which makes a case against extended surgical procedures. Surgery is still controversial as first-line therapy in patients with early stages of gastric lymphoma. Our findings indicate that patients with a clear diagnosis, better prognostic factors, and without initial complications should consider the conservative approach so that they may have a better quality of life. However, emergency operation is required when treatment related complications occur, such as perforation, ileus or bleeding.

PIL are heterogeneous diseases. In our point of view, the different prognostic factors and controversial treatment may be caused by the different constitution of these sub-types, ignoring racial and environment factors. Thus, further randomized prospective studies with a large number of patients are essential for this to be established.

COMMENTS

Background

In recent years, the incidence of primary extranodal lymphoma has increased, and gastrointestinal lymphomas are the most frequent subtype. However, the optimal treatment for primary intestinal lymphoma (PIL) remains controversial.

Research frontiers

Numerous retrospective studies reported primary gastrointestinal lymphoma in Europe, but there were no large-sample studies from China. The optimal treatment for PIL remains controversial, and the prognostic data for patients with PIL remain to be elucidated.

Innovations and breakthroughs

This study analyzed the clinical feature, anatomic and histologic distribution, time trends, treatment responses and the prognosis of primary intestinal lymphoma in Chinese patients. The authors found surgery based treatment and radical surgery did not improve the survival rate. The fact raised the question of whether surgery is really necessary. The findings indicate that patients with a clear diagnosis, better prognostic factors, and without initial complications should consider the conservative approach, so that they may have a better quality of life.

Applications

Refined stratification of patients with PIL, according to the prognostic variables, may allow individualized treatment. Conservative treatment may be an optimal therapeutic modality for selected patients.

Terminology

PIL: Primary intestinal lymphoma; marginal zone lymphoma, mantle cell lymphoma, diffuse large B-cell lymphoma, enteropathy-type T cell lymphoma and peripheral T-cell lymphoma, not otherwise specified *et al* are histologic types of non-Hodgkin's lymphoma.

Peer review

This is an interesting manuscript on primary gastrointestinal-lymphoma in China. The authors analyzed the clinicopathologic features of PIL with special reference to time trends. They determined the prognostic factors for intestinal lymphoma and evaluated the influence of therapeutic modalities on the prognosis. The results showed that conservative treatment might be an optimal therapeutic modality for selected patients with PIL.

Abstract

Adjuvant chemotherapy by S-1 following gastrectomy is considered standard treatment in Japan. Analysis of follow-up data have proved the efficacy of S-1 administration, and that hematological adverse events were relatively rare. Pyrimidine anti-metabolites, including S-1, have shown relatively lower risks for secondary hematological malignancies in comparison to alkylating agents and topoisomerase-Ⅱ inhibitors. We here report a case of therapy-related leukemia after S-1 administration. A patient who had received S-1as the sole adjuvant chemotherapy was diagnosed with acute erythroid leukemia. To the best of our knowledge, our patient represents the first report of S-1 induced acute leukemia.

Key words: S-1; Secondary leukemia; Acute erythroid Leukemia; Gastric cancer

INTRODUCTION

S-1 (tegafur + gimeracil + osteracil) oral administration for long periods has been widely used in East Asia as an adjuvant chemotherapy and for a advanced gastric cancer with little caution regarding the development of secondary malignancy[1]. The Adjuvant Chemotherapy Trial of S-1 for Gastric Cancer (ACTS-GC), a randomized study comparing S-1 adjuvant therapy with surgery only proved the efficacy of S-1adjuvant therapy. In the ACTS-GC study, hematological adverse events of grade 3 or 4 were relatively rare[2].

Therapy-related leukemia (TRL) may be separated into two types. The first type which usually develops 3-6 years after chemotherapy with alkylating agents, is usually preceded by a preleukemic phase. It is associated with specific unbalanced cytogenetic aberrations mostly involving chromosome 5 or 7, with an acute myeloid leukemia (AML) and invariably carries a poor prognosis. The second type is found in patients treated with topoisomerase Ⅱ inhibitors, and lacks a preleukemic phase. Rather, it often develops after a short latency, and presents with

cytogenetic rearrangements specific to *de novo* AML, such as t(8;21), inv(16), t(15;17) or often with a balanced translocation between 11q23 and other chromosomes, primarily t(6;11), t(9;11) and t(11;19)[3-5].

Although alkylating agents and topoisomerase Ⅱ inhibitors are well known as drugs that are related to the development of therapy-related leukemia, pyrimidine antimetabolites, including S-1, have been thought to be rarely associated with the development of leukemia[6]. In fact, therapy related acute leukemia by the sole administration of pyrimidine antimetabolites is very rare. Therapy-related leukemia induced by S-1 has not yet been reported. A recent study, however, revealed that pyrimidine antimetabolites could cause damage to DNA[7].

CASE REPORT

We report a 67-year-old male who developed acute erythroid leukemia after adjuvant chemotherapy using S-1 following distal gastrectomy (D2 resection) for primary gastric cancer (T2N1M0 stage Ⅱ, poorly differentiated adenocarcinoma non-solid type). Peripheral blood analysis showed no abnormalities before chemotherapy.

Ten courses of chemotherapy S-1 (120 mg/d) were orally administered between April 2008 and July 2009. He had not received any other chemotherapeutic agents. In August 2009, peripheral blood analysis demonstrated mild anemia and leukocytopenia. He was referred to our department for further examination. Peripheral blood analysis showed anemia (Hb9.0 g/dL), leukocytopenia (1840/μL) and thrombocytopenia (101 000/mL). Bone marrow aspiration revealed hypercellular marrow with 57.1% of the erythroblasts showing megaloblastic morphologic changes. Blast comprised 38.0% of non-erythroid cells.

Bone marrow pictures revealed morphologically dysplastic nuclei and cytoplasm in all three hematopoietic cell lineages. The patient was diagnosed with acute erythroid leukemia, according to the WHO classification. Immunophenotypical analysis by flowcytometry demonstrated that the leukemic cells were CD 4- CD13+, CD33dim, CD34+, CD56+, CD117+, MPO-/+, TdT- and HLA-DR+. Chromosomal analysis showed 45, XY, del(5q), inv(12)(p13;q13), -17, -17, add (22)(q13), +marl[7]/47, sl, +10, +11, +22, add (22)[4]48, sdl1, +8[2]/46, XY[3].

The patient was initially treated with idarubicin and Ara-C, but failed to achieve complete remission and was subsequently administered an alternative induction chemotherapy regimen [G-CSF + Fludarabine + Ara-C + Mitoxantrone (FLAGM)]. Treatment with salvage chemotherapy failed to induce remission. She died after 3 mo from diagnosis from sepsis and liver failure.

DISCUSSION

The introduction of adjuvant chemotherapy after successful surgical or radiotherapeutic eradication of cancers has been considered to improve relapse-free survival. However, treatment-related malignancy has emerged as a serious complication. The accumulation of genetic aberrations induced by anti-cancer agents in hematopoietic stem cells ultimately leads to myelodysplastic syndrome (MDS)/AML[8]. On the other hand, oral administration of pyrimidine anti-metabolites for long periods has been widely used in Japan as an adjuvant chemotherapy with little caution regarding the development of secondary malignancy.

Abe *et al*[9] reported a case of tegafur-induced AML who developed AML 8 years after starting tegafur (Table 1). This patient showed del(5) chromosomal change, as in our case. Other patients Table 1 were also administrated a large amount of pyrimidine anti-metabolites; in all of them it took at least 24 mo to develop AML. Our patient developed AML after a cumulative S-1 dose of 33.6g only 13 mo after starting S-1.

Acute erythroid leukemia accounts for less than 5% of all leukemia cases. The incidence for leukemia among 65-to-69-year-old males in Japan is $18.9/10^5$ per year[12]. We estimate that the possibility of the coincidence of two malignancies would not be very high given this data. However, the patient's leukocytes might have had an abnormal gene that did not present phenotypically before, and S-1 administration might have caused a further gene mutation that caused the leukemia.

S-1 is a combination preparation consisting of tegafur, gimeracil [5-chloro-2,4-dihydroxypyridine (CDHP)] and oteracil potassium (Oxo) in a molar ratio of 1:0.4:1. CDHP reversibly inhibits the function of dihydropyrimidine dehydrogenase (DPD), which mediates the rate-limiting process of 5-‰Fluorouracil (5-FU) elimination, thereby increasing the plasma concentration of 5-FU. UFT is another combination preparation consisting of tegafur and uracil in a molar ratio of 1:4. Although uracil, like CDHP, inhibits DPD, its inhibitory potency is far weaker than that of CDHP[13]. The content of tegafur in UFT is also 3-to 5-fold higher than that in S-1. Therefore, a short time duration and a small cumulative dose of S-1 could still induce secondary leukemia as in our case. Two cases of S-1 -induced chronic myeloid leukemia (CML) have been reported. The cumulative doses of S-1 were only 41.5 g and 92.5 g, respectively[14]. The present case should serve as a cogent warning that even a relatively short period of S-1 intake may result in the development of lethal leukemia.

Therapy-related leukemias are often refractory to conventional treatment and are associated with poor survival, with a few exceptions such as acute promyelocytic leukemia. As recently reviewed by Pedersen-Bjergaard *et al*[15], survival after post -transplant t-MDS/AML is estimated to be 6 mo.

Manola *et al*[16] reported that t(12;12)(p13;q13) constitutes a disruption of the *ETV6*(*TEL*) gene. The 12p13 region is genetically unstable and fragile, with subsequent translocations and insertions into other chromosomes[17]. It has been reported that multiple chromosome breaks in this region are likely to have been induced through

chemo/radiotherapy or mutagens, and are associated with a subgroup of patients with extremely bad prognoses. Although the 12p13 region is considered genetically unstable, t(12;12)(p13;q12~q13) is a rare cytogenetic abnormality. Only one case of therapy-related acute leukemia with t(12;12)(p13;q13) has been reported[16].

Our case suggests that therapy-related leukemia may develop after exposure to pyrimidine anti-metabolites. Thus, S-1 may induce TRL even when used for shorter durations and at lower cumulative doses than other pyrimidine anti-metabolites. Adjuvant chemotherapy by S-1 is a standard therapy for locally advanced gastric cancer in Japan, and is often used in China and Singapore as well. Therefore, more caution should be taken against the possibility of t-MDS/AML caused by S-1 in these countries.

Abstract

Autoimmune pancreatitis (AIP) is a rare form of pancreatitis characterized by prominent lymphocyte infiltration and pancreatic fibrosis resulting in organ dysfunction. The pathogenesis and pathology of AIP remain unknown. A 64-year-old Chinese man presented with symptoms and signs of bile duct obstruction diffuse enlargement of the head of pancreas, elevated IgG levels, and negative autoimmune antibody responses. A pylorus-preserving pancreatoduodenectomy was performed and a pancreatic tumor was suspected. However, periductal lymphoplasmacytic infiltration and fibrosis were found in the head of pancreas and nearby organs instead of tumor cells. Four months after surgery, the patient was readmitted because of reoccurrence of severe jaundice and sustained abdominal distension. Prednisone 30 mg/d was administered orally as an AIP was suspected. One and a half months later, the symptoms of the patient disappeared, and globulin, aminotransferase and bilirubin levels decreased significantly. Over a 9-mo follow-up period, the dose of prednisone was gradually decreased to 10 mg/d and the patient remained in good condition. We further demonstrated dominant CD3+/CD8+ populations, CD20+ cells and a few CD4+ cells in the pancreatic parenchyma, duodenum and gallbladder wall by immunohistochemical assay. This AIP case presented with significant CD8+ T lymphocyte infiltration in the pancreas and extra-pancreatic lesions, indicating that this cell population may be more important in mediating AIP pathogenesis than previously known and that AIP might be a poorly defined autoimmune disease with heterogeneous pathogenesis.

INTRODUCTION

Autoimmune pancreatitis (AIP) is a rare form of pancre-

atitis characterized by prominent lymphocyte infiltration and pancreatic fibrosis resulting in organ dysfunction[1]. This disease has been mainly reported in Japan and Europe with an estimated incidence of 4%-6% among chronic pancreatitis patients[2,3]. In China, only a few AIP cases have been reported even though approximately 5% of chronic pancreatitis cases resulted from autoimmune-associated responses[4]. To date, the pathogenesis and pathology of AIP remain undefined. Previously, CD4+ T lymphocytes were thought to be critical (relative to CD8+ T lymphocytes) in mediating AIP pathogenesis[5-7]. However, the case of AIP described herein demonstrated a significant CD8+ infiltration and an absence of CD4+ T lymphocytes in the pancreas and surrounding organs, including the duodenum.

CASE REPORT

A 64-year-old Chinese man was admitted to the West China Hospital on May 8, 2004 with a history of 1-mo abdominal distension and 3-d jaundice. He was examined with blood biochemical tests, including direct bilirubin (DB, 114.71 μmol/L), indirect bilirubin (IB, 44.9 μmol/L), alanine amino transferase (ALT, 70 IU/L), aspartate amino transferase (AST, 51 IU/L), globulin (45.8 g/L) and fasting plasma glucose (FPG, 6.1 mmol/L) (Figure 1). Computed tomography (CT) showed a 3 cm × 3 cm mass at the head of the pancreas suspected to be a pancreatic tumor. Therefore, a pylorus-preserving pancreatoduodenectomy was performed on May 11 and a 3 cm × 3 cm mass was identified at the head of the sclerified pancreas, with cholestatic changes in the liver and gallbladder hydrop with dilation of the common bile duct (1.5-2 cm; the normal range is 0.3-0.8 cm). Pathological examination showed chronic inflammation with fibrosis in the pancreatic and common bile ducts as well as moderate to severe epithelial dysplasia (Figure 2). Adenoepithelial hyperplasia but not tumor cells were found in the pancreatic parenchyma. The patient was discharged 2 wk after surgery when jaundice symptoms abated.

Four months later on September 13, 2004, the patient was readmitted to the West China Hospital due to a recurrence of severe jaundice and sustained abdominal distension. No obvious abnormal findings were identified following physical examination other than jaundice in the skin and sclera. Blood biochemical results (Figure 1) demonstrated the levels of DB at 91.5 μmol/L, IB at 37.7 μmol/L, ALT at 41 IU/L, AST at 59 IU/L, globulin at 60.4 g/L, FPG at 4.3 mmol/L, immunoglobulin gamma (IgG) at 47.2 g/L, IgA > 3000 mg/L and C-reactive protein at 14.3 mg/L. Detections of anti-nuclear antibodies, anti-double strand DNA antibodies (anti-dsDNA), anti-Smith antibodies, anti-Sjogren syndrome A antibodies, anti-Sjogren syndrome B antibodies, anti-Jo-1 antibodies, anti-mitochondrial M2 antibodies, anti-liver-kidney microsome antibodies, anti-liver cytosol antibody type 1 and anti-soluble liver antigen antibodies were all negative. Magnetic resonance cholangiopancreatography

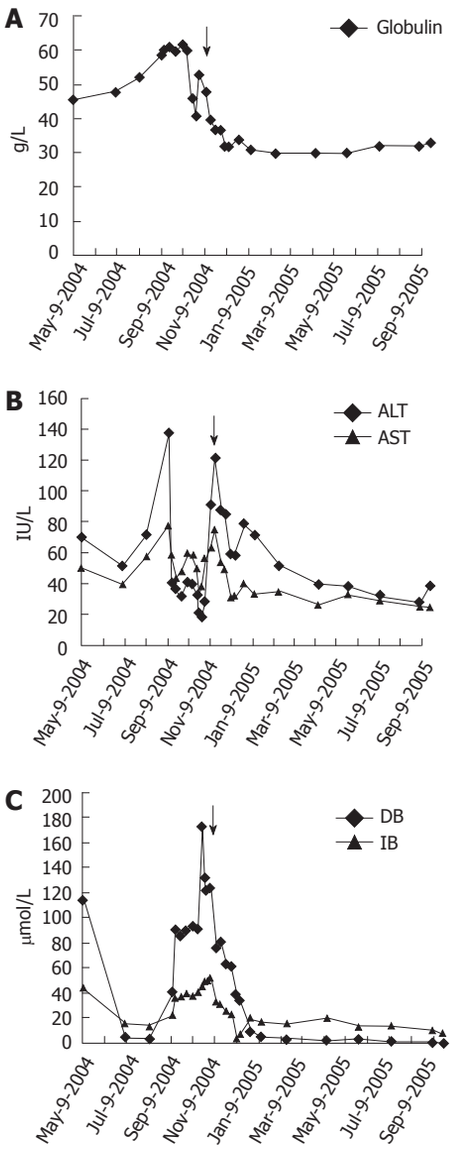

Figure 1 Blood biochemical analyses. Pre- and post-prednisone treatment levels of (A) immunoglobulin, (B) aminotransferase and (C) bilirubin. The black arrow indicates the start of prednisone treatment. ALT: Alanine amino transferase; AST: Aspartate amino transferase; DB: Direct bilirubin; IB: Indirect bilirubin.

showed a dilated intrahepatic biliary duct and a thickened and asperous wall of the common bile duct.

Based on the hypergammaglobulinemia and elevated IgG levels observed, this patient was suspected to have pancreatitis of autoimmune origin. Prednisone 30 mg/d was administered orally beginning on November 2, 2005. One and a half months later, the patient was discharged from the hospital after the jaundice and abdominal distension disappeared and the globulin (Figure 1A), aminotransferase (Figure 1B) and bilirubin (Figure 1C) levels decreased significantly. Over a 9-mo follow-up period, the dose of prednisone was gradually decreased to 10 mg/d and the patient remained in good condition without the presentation of either jaundice or abdominal distention and his globulin (Figure 1A), aminotransferase (Figure 1B) and bilirubin (Figure 1C) levels were within the nor-

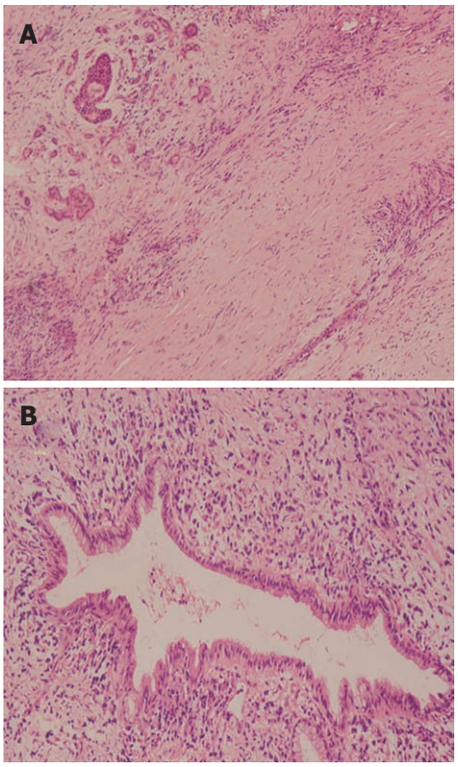

Figure 2 Characterization of pathological changes. The head of the pancreas was examined following Hematoxylin and eosin staining, demonstrating (A) pancreatic ductal atrophy and lymphocytic infiltration with fibrotic proliferation and (B) periductal infiltration of lymphocytes.

mal range.

To further characterize the pathogenesis of AIP in this case, histopathologic and immunohistochemical analyses were carried out to determine the CD3, CD4, CD8 and CD20 positive profiles in paraffin sections taken from the head of the pancreas, duodenum and gallbladder. Hematoxylin and eosin staining of the head of pancreas showed ductal atrophy and periductal lymphocytic infiltration with fibrotic proliferation (Figure 2), and high levels of CD3+ cells were identified in the periductal region of the head of the pancreas (Figure 3A), duodenal villi (Figure 3B) and the gallbladder wall (Figure 3C). Interestingly, CD4+ cells were present at low levels in the specimens from the head of the pancreas (Figure 3D), duodenum (Figure 3E) and the gallbladder wall (Figure 3F). Parallel to the CD3 expression levels, CD8+ cells were detected at high levels in the periductal region of the head of the pancreas (Figure 3G), duodenal villi (Figure 3H) and the gallbladder wall (Figure 3I). The CD20 was expressed at low levels in the periductal region of the head of the pancreas (Figure 3J) and focally expressed in the duodenal villi (Figure 3K). No CD20 expression was detected in the gallbladder wall (Figure 3L).

DISCUSSION

AIP, also described as chronic pancreatitis of autoimmune origin, is clinically similar in presentation to pancreatic carcinoma. AIP patients may undergo pancreatoduodenectomy as a consequence of treatment. It is reported that 2.5%-11% of the patients diagnosed with pancreatic malignancy actually had a benign pancreatic disorder confirmed by pathological examination after surgery[7] and 9.9% of the patients underwent pancreatoduodenectomy following a diagnosis of pancreatitis, 38% of them were reported to be caused by autoimmune responses[8,9].

AIP is characterized by an irregular narrowing of the main pancreatic duct, massive lymphoplasmacytic inflammation of the pancreatic parenchyma, hypergammaglobulinemia and a fair response to glucocorticoid treatment[10]. The case presented in this report was mainly characterized by symptoms and signs of bile duct obstruction, diffuse enlargement of the head of pancreas, elevated IgG levels, negative autoimmune antibody responses and periductal lymphoplasmacytic infiltration and fibrosis. After a strict treatment regimen of prednisone, the patient recovered quickly and his globulin, aminotransferase, and bilirubin levels returned to normal for more than half a year. In our case, AIP was diagnosed based on the criteria established by the Japan Pancreas Society[2,11].

AIP presentation has recently been divided into either subtype type 1 or 2[12-14]. In Asia, type 1 AIP presents at a higher frequency and is also referred to as lymphoplasmacytic sclerosing pancreatitis or AIP without granulocyte epithelial lesions (GELs). Type 2 AIP is referred to as idiopathic duct-centric pancreatitis or AIP with GELs. The case presented here with periductal lymphoplasmacytic infiltration (without granulocytes), fibrotic proliferation and pancreatic ductal atrophy is consistent with the histopathological features of type 1 AIP[13,15,16].

It was previously reported that infiltrating cells in AIP cases predominantly consisted of CD4+ T lymphocytes with few detectable CD8+ T lymphocytes and B lymphocytes[2,7]. T helper imbalance (Th1 *vs* Th2) is believed to be associated with the initiation of AIP[17] and elevated Th1 responses were reported in both pancreatic and extra-pancreatic lesions in AIP patients[18,19]. CD4+CD25+ regulatory T lymphocytes have also been demonstrated to contribute significantly to the pathology of AIP-associated lesions compared to lesions resulting from other pancreatic disorders[6,19]. In animal AIP disease models, administration of amylase-sensitized CD4+ T lymphocytes elicited autoimmune pancreatitis, suggesting that CD4+ T lymphocytes may be the most important components in mediating disease pathogenesis[20]. This observation is supported by the cases presenting with a reduced number of infiltrating CD4+ T lymphocytes in AIP lesions.

In contrast, our case presented with infiltrating CD8+ T (primarily cytotoxic T lymphocytes) instead of CD4+ T lymphocytes in both pancreatic and extra-pancreatic lesions. Since CD4+ T helper lymphocyte is believe to be indispensable in mediating various types of immune responses, we hypothesize that CD4+ T lymphocytes may have originally infiltrated these tissues and then recruited more CD8+ T lymphocytes functioning as effector cells of AIP pathogenesis. These data demonstrated that the presence of CD8+ T lymphocytes in AIP lesions may be

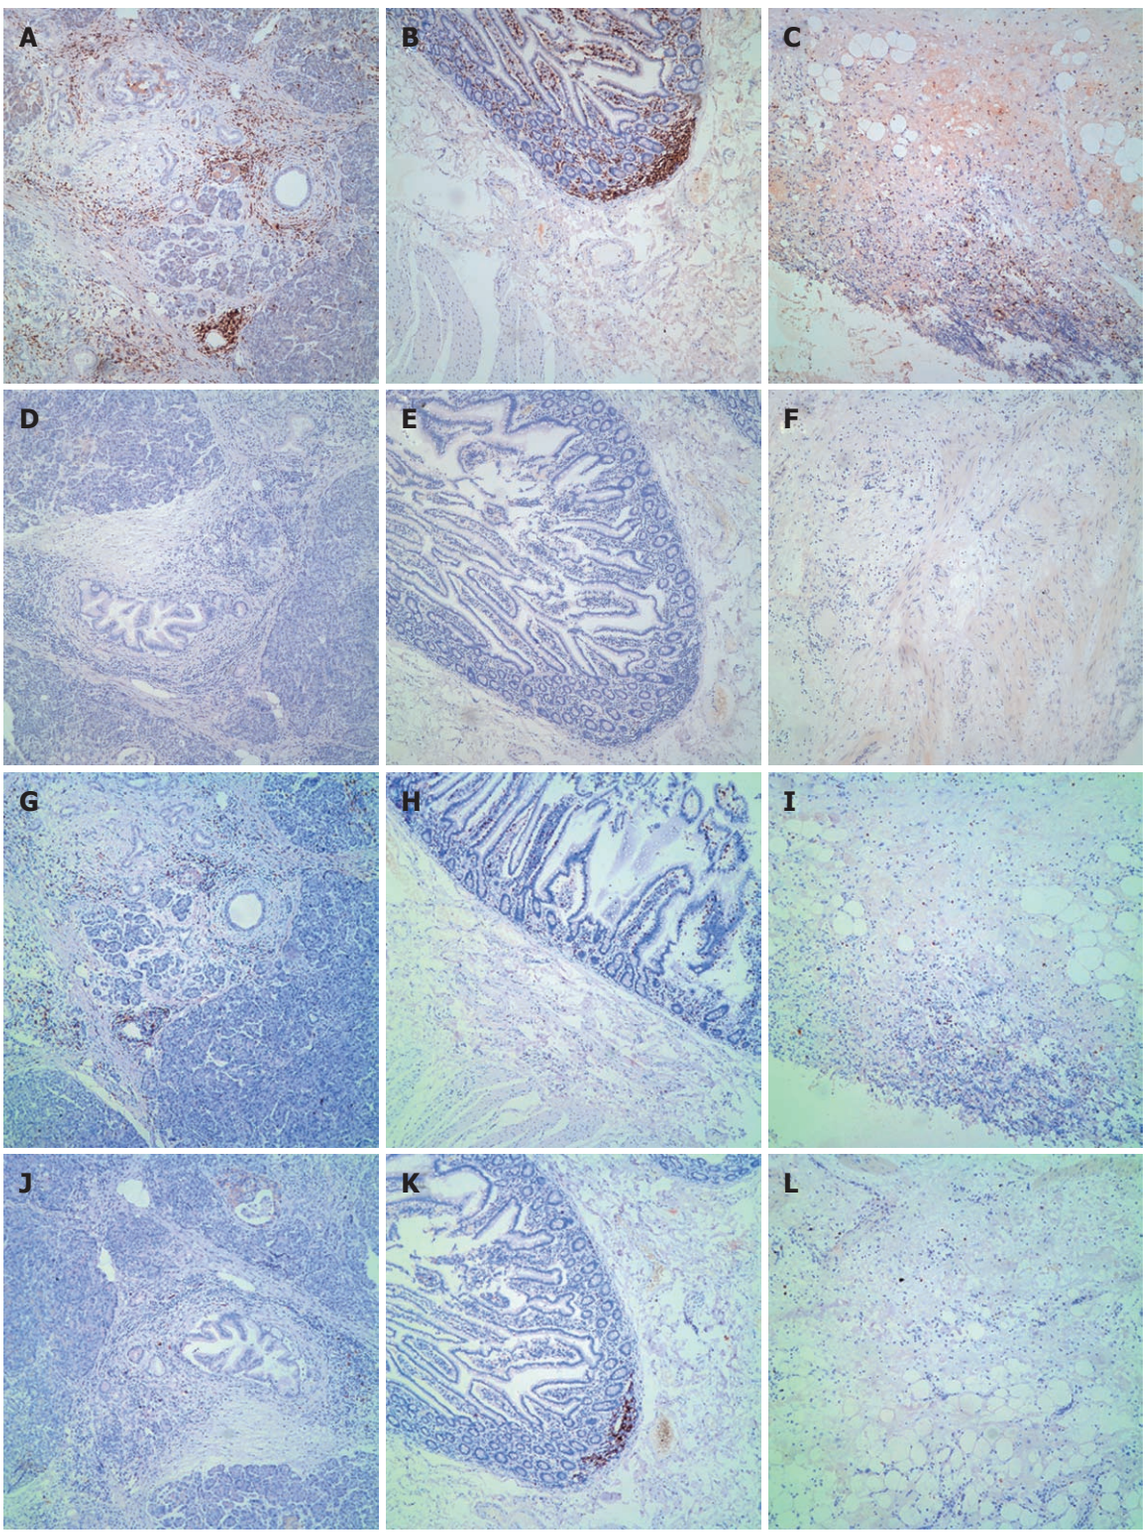

Figure 3 Immunohistochemical characterization. The head of the pancreas, duodenum and the wall of the gallbladder were examined for the presence of CD3+, CD4+, CD8+ and CD20+ cells; magnification × 100. A: CD3+ lymphocyte infiltration in the periductal region of the head of the pancreas; B: CD3+ lymphocyte infiltration and their focal concentration in duodenal villi; C: CD3+ lymphocyte infiltration in the wall of the gallbladder; D: CD4+ lymphocytes infiltration in the head of the pancreas; E: CD4+ lymphocyte infiltration in the duodenum; F: CD4+ lymphocyte infiltration in the gallbladder; G: CD8+ lymphocyte infiltration in the periductal region of the head of the pancreas; H: CD8+ lymphocyte infiltration in the duodenal villi; I: CD8+ lymphocyte infiltration in the wall of the gallbladder; J: CD20+ lymphocyte infiltration in the periductal region of the head of the pancreas; K: Focal CD20+ lymphocyte infiltration in duodenal villi; L: CD20+ lymphocyte infiltration in the wall of the gallbladder.

more important than previously thought and that elicitation of AIP may have heterogeneous origins. A limitation in these observations is that they have only been reported in a single case, more investigations about the role of

CD8+ T lymphocytes are required to further understand the pathogenesis of AIP.

In summary, we identified a significant number of CD8+ T lymphocytes infiltrating in both pancreatic and extra-pancreatic AIP lesions, instead of CD4+ T lymphocytes as commonly expected. It suggests that AIP might possess heterogeneous autoimmune origins.

ACKNOWLEDGMENTS

We want to thank the pathologists from the Department of Pathology, West China Hospital, Sichuan University, for their hard work in the immunohistochemistry. We also thank the physicians and surgeons from West China Hospital, Sichuan University for taking care of the patients and helping collect the data.

Abstract

The aim of this study was to investigate an association between the development of cholangiocarcinoma (CCA) and the *ABO* variant *rs505922* (known to increase pancreatic cancer risk) in a large cohort of European individuals with CCA. In total, 180 individuals with CCA and 350 CCA-free controls were included. The *ABO* variant *rs505922* was genotyped using a polymerase chain reaction-based assay. Association between this single nucleotide polymorphism (SNP) and CCA was tested in contingency tables. Neither allele distributions nor association tests and regression analysis provided evidence for an increased risk of CCA among carriers of the *ABO* variant (all $P > 0.05$). Nevertheless, we documented a deviation from Hardy-Weinberg equilibrium in the entire CCA cohort ($P = 0.028$) and for patients with intrahepatic ($P = 0.037$) but not extrahepatic tumor localization ($P > 0.05$). The association tests did not provide evidence for a prominent role of the investigated SNP in the genetic risk of CCA. However, Hardy-Weinberg disequilibrium in the entire cohort and the intrahepatic CCA subgroup warrants future studies investigating a potential CCA risk modulation by individual blood groups.

Key words: *ABO*; Biliary tract cancer; Blood groups; Genetic risk; Single nucleotide polymorphism

Krawczyk M, Mihalache F, Höblinger A, Acalovschi M, Lammert F, Zimmer V. Pancreatic cancer risk variant *ABO rs505922* in patients with cholangiocarcinoma. *World J Gastroenterol* 2011; 17(41): 4640-4642 Available from: URL: http://www.wjgnet.com/1007-9327/full/v17/i41/4640.htm DOI: http://dx.doi.org/10.3748/wjg.v17.i41.4640

TO THE EDITOR

We were very interested to read the recent report by Greer *et al*[1], which further substantiates the association between an individual's blood group and the risk of pancreatic cancer. In line with previous data, Greer *et al*[2] demonstrate that individuals with blood group O have a lower risk of pancreatic cancer relative to blood groups A or B. These serological data are consistent with results from a large genome-wide association study comprising 2457 patients with pancreatic cancer, whereby the common variant *rs505922* (C > T) in the *ABO* locus was identified as a genetic risk factor for this malignancy. Interestingly, the [TT] genotype, which proved to be protective against pancreatic malignancy, is in complete linkage disequilibrium

Table 1 Allele and genotype distribution and association tests

ABO rs505922 allele/genotype	Counts of alleles/genotypes	
	Controls (2N = 700)	Cases (2N = 360)
C	246 (0.35)	124 (0.34)
T	454 (0.65)	236 (0.66)
CC	50 (0.14)	28 (0.16)
CT	146 (0.42)	68 (0.38)
TT	154 (0.44)	84 (0.46)
Association test	χ^2	*P*
Allele frequency difference test	0.05	0.82
Armitrage's trend test	0.05	0.83
OR statistics	OR	95% CI
[T]↔[C]	1.03	0.79-1.35
[TT]↔[CC]	0.94	0.57-1.66
[TT]↔[CT + CC]	1.11	0.78-1.60

Patients with cholangiocarcinoma are defined as cases, the [C] allele represents the assumed cholangiocarcinoma risk allele. CI: Confidence interval; OR: Odds ratio.

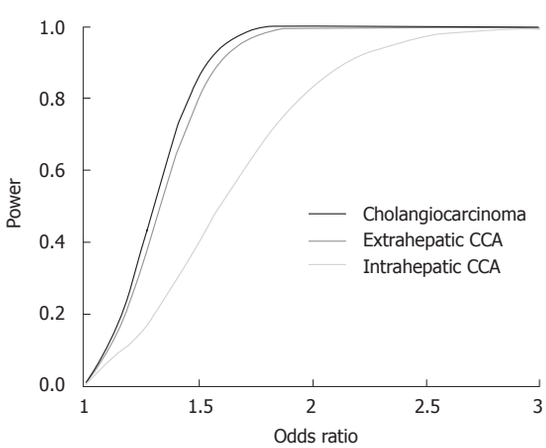

Figure 1 Statistical power as a function of the effect size (odds ratio) in the cholangiocarcinoma cohort (black) and in extra- and intrahepatic cholangiocarcinoma subgroups (dark grey and grey, respectively) (α set at 0.05). CCA: Cholangiocarcinoma.

(r^2 = 1.0) with blood group O. Conversely, the [C] allele is present in individuals with blood groups A, B or AB.

Cholangiocarcinoma (CCA) albeit uncommon, represents the second most prevalent primary liver cancer, and is globally increasing in incidence[3]. As with pancreatic cancer, CCA is usually diagnosed in the late stages with locally advanced or metastatic disease, and is therefore characterized by poor prognosis. Hence, the identification of genetic variants contributing to CCA development is warranted, to further elucidate the pathobiological mechanisms modulating disease risk, and to assist with the development of novel screening strategies for detecting patients at risk of biliary malignancy. Many low-risk variants have been postulated to confer an increased risk for cancers, including CCA[4]. Indeed, our previous study demonstrated the genetic risk of CCA to be modulated by heterozygosity for the *alpha1-antitrypsin* Z allele[5].

In the current study, we therefore specifically assessed the potential role of blood groups in CCA risk using a single nucleotide polymorphism (SNP)-based approach in a large European CCA cohort consisting of 180 individuals with CCA and 350 CCA-free controls. The details of this cohort are described in our previous study[5]. With regards to our methodology, the intronic variant *rs505922* was genotyped with a 99% success rate, using a polymerase chain reaction-based assay with 5'-nuclease and fluorescence detection (Taqman, Applied Biosystems, Foster City, CA, United States). The consistency of our genotyping results with the Hardy-Weinberg equilibrium (HEW) was verified by exact tests (http://ihg2.helmholtz-muenchen.de/cgi-bin/hw/hwa1.pl). An association between the *ABO* variant and biliary cancer was tested in contingency tables (genotypes, Armitrage's trend test; alleles, χ^2 test) and by regression analysis using SPSS software (version 18.0).

Table 1 summarises the genotyping results. The frequency of [TT] individuals (known to carry blood group O) is consistent with the distributions reported in European populations (http://www.bloodbook.com/world-abo.html). As shown in Table 1, allele distributions did not differ significantly between cases and controls (P > 0.05). The association tests [common odds ratio (OR) = 1.01, P = 0.83)] and regression analysis (OR for the [TT] variant = 1.11, P = 0.56) did not provide evidence for the involvement of the *ABO* variant in CCA. Similarly, subsequent exploratory data analysis stratifying cases according to gender and intra- *vs* extrahepatic tumour localisation yielded no significant association between *rs505922* and CCA (all P > 0.05). Interestingly, we detected a departure from HWE in patients with CCA (P = 0.028) and in the subgroup of cases with intrahepatic CCA (P = 0.037), but not in cases with extrahepatic disease (P > 0.05). Although the SNP was not associated with CCA in the above statistical tests, the presence of Hardy-Weinberg disequilibrium might however, be indicative of a possible association, since the assumption of no selection implies that the gene is not associated with the disease[6]. Confirmed consistency with HWE in the much larger control cohort and 100% consistent results in re-genotyped cancer individuals (n = 20) argue against genotyping errors as a reason for departure from HWE in the cancer group. However, the exploratory data analysis in the current study may be underpowered due to the limited sample size of the intrahepatic CCA subgroup (n = 40) (Figure 1). Of note, recent data from an Italian hospital-based cancer registry report a non-significant underrepresentation of serological blood group 0 in a chimeric cancer subgroup referred to as "*liver and intrahepatic bile ducts*" (36% *vs* 46 %; P = 0.015; n = 78)[7].

In conclusion, the blood group polymorphism investigated in this study does not appear to alter the general risk of developing CCA. Furthermore, due to the relatively small number of patients with intrahepatic CCA, departure from HWE should be interpreted with caution. Nevertheless, further dedicated studies exploring the possible functional role of *ABO* blood types in cholangiocarcinogenesis in selected groups of patients (i.e., with

intrahepatic CCA) may provide further insight into the pathobiological mechanisms that enhance the risk of this malignancy.

ACKNOWLEDGMENTS

The authors gratefully acknowledge Caroline S Stokes (Saarland University Hospital, Homburg) for her expertise and help during the preparation of this manuscript.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions
Manuscripts should be submitted through the Online Submission

System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be

used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-8538-1893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

The gut microbiota plays a role in promoting and maintaining inflammation in inflammatory bowel diseases (IBD), hence the rationale for the use of antibiotics in the treatment of those disorders. Antibiotics, however, may induce untoward effects, especially during long-term therapy. Rifaximin α polymer is an antibacterial agent that is virtually unabsorbed after oral administration and is devoid of systemic side effects. Rifaximin has provided promising results in inducing remission of Crohn's disease (up to 69% in open studies and significantly higher rates than placebo in double blind trials) and ulcerative colitis (76% in open studies and significantly higher rates than placebo in controlled studies) and might also have a role in maintaining remission of ulcerative colitis and pouchitis. The potential therapeutic activity of rifaximin in IBD deserves to be further investigated and confirmed in larger, controlled studies. The optimal dosage still needs to be better defined.

Key words: Antibiotics; Gut microbiota; Inflammatory bowel disease; Rifaximin

INTRODUCTION

The etiology of inflammatory bowel diseases (IBD) still remains obscure. Genetic, immunological, environmental, and psychological factors can all play a role in the pathophysiology of both ulcerative colitis and Crohn's disease.

The gut microbiota is now recognized as a further important factor involved in promoting and/or maintaining the inflammatory process typical for IBD[1-3].

The concentration of intestinal bacteria in IBD patients is higher than normal, gradually increasing with the severity of the disease[1]. A breakdown in the qualitative balance between protective and harmful bacteria (dysbiosis) has also been proposed as a potential mechanism[2].

Indeed, in Crohn's disease, an increased presence of *Campylobacter concisus*[4] and *E. Coli*[5], as well as a substantial decrease in the amount of the anti-inflammatory commensal *Faecalibacterium prausnitzii*[5,6], has been reported.

On the other hand, it has been suggested that *Fusobacterium varium* can promote the development of ulcerative colitis[7].

The above data constitute a good rationale for the use of antibiotics in IBD[8].

Various meta-analyses have demonstrated that antibiotics such as metronidazole, ciprofloxacin, clofazimine and antibiotic combinations can be successfully employed in the treatment of Crohn's disease[9-11], ulcerative colitis[12] and pouchitis[13].

However, prolonged administration of antibiotics is accompanied by systemic adverse effects.

Rifaximin α-polymer, a rifampicin derivative, is a

locally acting antibacterial agent that is virtually unabsorbed after oral administration, is mostly excreted as unchanged drug in the stools in the course of intestinal disorders, and is thus devoid of systemic side effects.

It exhibits a broad-spectrum activity against enteric bacteria and a lack of clinically relevant acquired resistance[14-16]. Currently approved in the United States for the treatment of travellers' diarrhea, rifaximin is being used in a variety of gastrointestinal disorders, such as small intestine bacterial overgrowth, colonic diverticular disease, *Clostridium difficile* infection, as well as in the treatment of portal systemic encephalopathy[16,17].

In particular, rifaximin has been shown to modulate the colonic microbiota of patients with Crohn's disease by increasing the concentration of *Bifidobacteria* and *Faecalibacterium prausnitzii*[18].

In addition, experimental studies have shown that the drug can reduce the development of trinitrobenzene sulfonic acid-induced colitis and accelerate healing by preventing bacterial translocation[19], as well as exerting anti-inflammatory activities by increasing the expression of pregnane-X-receptor and by antagonizing the effects of tumor necrosis factor -α on intestinal epithelial cells[20,21].

The possible therapeutic role of rifaximin in the treatment of IBD has been repeatedly investigated in recent years.

RIFAXIMIN AND CROHN'S DISEASE

Further to an open-label study where rifaximin 200 mg tid administered for 16 wk to 29 patients with active Crohn's disease reduced Crohn's disease activity index (CDAI) score by more than 40% and induced clinical remission in 59% of cases[22], and a recent retrospective analysis of the charts of 68 patients receiving adjunctive therapy with rifaximin (mean dose 600 mg/d for 16 wk) showing remission in up to 70% of cases[23], two controlled studies were carried out.

A multicenter, double-blind, placebo controlled trial including 83 patients with mild-to-moderate Crohn's disease[24] found that monotherapy with rifaximin 800 mg bid for 12 wk was superior to placebo in promoting clinical remission (CDAI < 150), which was observed in 52% of cases compared with 33% in the placebo group. The difference in remission rates, however, was statistically significant ($P = 0.032$) only between the subgroups of patients with baseline values of C reactive protein above the upper normal limit.

A recent, international, multicenter, randomised study enrolling 402 patients from 55 centers in Europe and Israel demonstrated that an extended intestinal release formulation of rifaximin 400 mg in daily doses of 400-1200 mg bid for 12 wk was significantly superior to placebo in inducing remission (as defined as a CDAI < 150).

The best results were observed at the dose of 800 mg bid (remission rate 62.2% *vs* 42.6% in the placebo group: $P = 0.005$) and the effects were maintained during a subsequent 12-wk follow-up without treatment[25].

RIFAXIMIN AND ULCERATIVE COLITIS

In an open-label study, 30 patients with a mild-to-moderate flare-up of ulcerative colitis during maintenance treatment with mesalazine, and in whom steroid treatment was not advisable because of a history of poor tolerability, rifaximin 400 mg bid was added for four weeks[26]. Clinical remission was obtained in 76.6% of cases.

On the other hand, a group of 28 patients refractory to steroid therapy received an adjunct therapy with either rifaximin 400 mg bid or placebo for 10 d, in a double blind fashion. In the rifaximin group clinical improvement was observed in 64.3% of patients, who showed a significant reduction in stool frequency ($P < 0.02$), rectal bleeding ($P < 0.05$) and sigmoidoscopic score ($P < 0.05$) compared with placebo[27].

A small pilot experience on six mesalazine-intolerant patients with ulcerative colitis, who were in remission after a course of oral steroids, employed a combination of rifaximin 400 mg + the probiotic agent *Saccharomyces boulardii* 500 mg as a maintenance treatment for three months. At the end of the treatment period, all patients were still in clinical remission, which suggests that this therapeutic combination can be useful in preventing early relapses of ulcerative colitis[28].

Rifaximin, in doses ranging from 200 to 1800 mg/d, was also assessed as a maintenance therapy in 51 patients who had undergone restorative proctocolectomy and ileal pouch-anal anastomosis for ulcerative colitis, affected by antibiotic-dependent pouchitis[29]. At 3 mo, remission was maintained in 65% of patients. 79% of these patients were still in remission at 6 mo, 58% at 12 mo and 6% at 24 mo.

A combination of rifaximin 1000 mg bid and ciprofloxacin 500 mg bid for 15 d had been previously found capable of promoting either improvement (55.5%) or remission (33.3%) in eighteen patients with chronic active pouchitis[30].

CONCLUSION

The role of the gut microbiota in the development and maintenance of inflammation in IBD provides the rationale for the use of antibiotics in the medical treatment of both Crohn's disease and ulcerative colitis. Systemic antibiotics, such as ciprofloxacin and/or metronidazole, are commonly employed with good results, but possible side effects limit their use, especially for prolonged periods.

On the other hand, rifaximin α polymer, thanks to its negligible intestinal absorption, represents a safer and more attractive alternative. Both in open and in controlled studies, rifaximin, either in monotherapy or as an adjunctive treatment, was found to provide satisfactory results when administered for up to 12 wk (Table 1).

In a preliminary experience in children with IBD, rifaximin induced encouraging results and proved to be well tolerated[31].

Abstract

Non-steroidal anti-inflammatory drug (NSAID)-induced small bowel injury is a topic that deserves attention since the advent of capsule endoscopy and balloon enteroscopy. NSAID enteropathy is common and is mostly asymptomatic. However, massive bleeding, stricture, or perforation may occur. The pathogenesis of small intestine injury by NSAIDs is complex and different from that of the upper gastrointestinal tract. No drug has yet been developed that can completely prevent or treat NSAID enteropathy. Therefore, a long-term randomized study in chronic NSAID users is needed.

INTRODUCTION

Non-steroidal anti-inflammatory drugs (NSAIDs) are some of the most commonly used pharmaceuticals worldwide. They are used for prevention and treatment of inflammatory diseases, arthritis, collagen diseases, pain, fever, and ischemic cerebrovascular disorders because of their anti-inflammatory, analgesic, antipyretic, and anti-platelet functions. In recent years, it has also been reported that they are effective for the prevention of colorectal cancer[1].

NSAIDs function by inhibiting cyclooxygenase (COX), the enzyme responsible for synthesis of prostaglandin. However, there are side effects with the use of NSAID-based therapy. The most common side effects are disorders of the digestive tract mucosa[2]. In addition to upper gastrointestinal complications, such as gastric and duodenal ulcers, complications in the small intestine and colon can occur, which cause bleeding, perforation, stricture, and chronic problems, such as iron deficiency anemia and protein loss[3].

The adverse effects of NSAIDs on the gastrointestinal tract are often unrelated to abdominal symptoms. In patients with suspected gastrointestinal bleeding, but who are not found to have bleeding lesions on gastroscopy and colonoscopy, NSAID-induced small intestine ulcerative lesions should be suspected[4]. The use of

NSAIDs has recently increased; therefore, increased awareness of the gastrointestinal side effects is needed. However, effective prevention and treatment of the side effects of NSAIDs in the small intestine have not yet been determined. In this manuscript, we review the studies conducted to date on the prevention and treatment of small intestine damage caused by NSAIDs.

EPIDEMIOLOGY

Until recently, gastrointestinal injury by NSAIDs was studied mainly in upper gastrointestinal organs, such as the stomach and duodenum, but there have been few studies on the small intestine. Among chronic NSAID users, up to 25% suffer from upper gastrointestinal ulcers, while bleeding or perforation occurs in 2%-4%[5].

Upper gastrointestinal complications in the stomach or duodenum are relatively easy to examine by endoscopy and upper gastrointestinal series, whereas it is more difficult to observe complications of the small intestine and determine the prevalence of injuries to this organ[6]. However, according to autopsy results published by Allison *et al*[2] in 1992, small intestinal ulcers were found in 0.6% of patients who did not take NSAIDs, whereas they were found in 8.4% of individuals taking NSAIDs. In more than 70% of arthritis patients receiving NSAID therapy for more than three months, intestinal inflammation accompanied by bleeding and protein loss was induced; even after the therapy ended, and these symptoms could persist longer than 16 mo[7]. Iron deficiency anemia due to blood loss in the small intestine was found in 41% of rheumatoid arthritis patients taking NSAIDs[1].

According to a recent study, gross damage was observed in 68% of volunteers who were administered 75 mg of diclofenac for 2 wk[8]. Another report found that macroscopic injury occurred in 80% of patients who took low doses of aspirin for 2 wk[9]. NSAID-related damage mainly occurred in the distal small bowel and colon, most commonly in the ileocecal region[10].

PATHOGENESIS

Administering NSAID increases intestinal permeability within 12 h and inflammation in the small intestine within 10 d[10]. The mechanism underlying small intestine injury by NSAIDs, unlike complications of the upper gastrointestinal tract, has not been elucidated because of the presence of intestinal bacteria in the small intestine and other complicating factors. The results of studies on the mechanism of injury by NSAIDs are still not sufficient, but can be summarized as combined systemic and local effects.

Currently, this has been described as a "three hit hypothesis"[3]. First, the phospholipids in cell surface membrane are damaged by direct injury by the NSAID, and damage to mitochondria within the cells subsequently occurs. Damage to mitochondria cause a reduction of energy generation within the cells (uncoupling of oxidative phosphorylation), release of intracellular calcium, and generation of free radicals. This leads to a decrease of integration between the cells and increased permeability of the small intestine. Through the increased intestinal permeability, various materials such as bile acids, food, intestinal bacteria, and proteolytic enzymes damage the weakened intestinal barrier and secondary inflammation occurs by the activation of neutrophils[3].

In experimental studies, Gram-negative bacteria invade the mucous membrane and activate Toll-like receptors, which are the receptors for Gram-negative bacterial lipopolysaccharide (LPS). It was reported that Toll-like receptors stimulate the inflammatory response and play an important role in small intestine damage[11,12].

If intestinal bacteria secrete endotoxins, intestinal bacterial translocation can occur. That is, LPS originating from endotoxins can spread to other places in addition to the intestine. LPS increases the expression of inducible nitric oxide synthase (iNOS) and iNOS leads to the production of peroxynitrite, the cytotoxic moiety from nitric oxide (NO) and superoxide. Ampicillin and metronidazole inactivate LPS and reduce iNOS expression[13].

Enterohepatic circulation plays an important role in gut injury. If NSAIDs do not enter the enterohepatic circulation, they will not damage the small intestine. For example, sundilac or aspirin, which do not enter the enterohepatic circulation, are less toxic to the small intestine[14]. However, if the intestine is continuously exposed to the drugs in the bloodstream *via* the enterohepatic circulation, damage may occur[14].

NSAIDs are conjugated to acryl glucuronides in the liver and excreted through the canalicular membrance of hepatocytes into bile[15]. Electrophilic NSAID-acyl glucuronides contact the brush border proteins of the enterocyte, causing the uptake of the NSAID into the cell. Acyl glucuronide also plays a role in the transport of NSAIDs to the target site-the distal part of jejunum/ileum. However, the role of acyl glucuronides in NSAID enteropathy is not yet clear.

There are two types of COX: COX-1 and COX-2. Prostaglandins derived from COX-1 are considered to be important for maintaining intestinal mucosa homeostasis. Previously, it was found that COX-1 had "housekeeping" characteristics, and inhibition of this factor reduced blood circulation in the mucosa and increased intestinal permeability, thereby causing injury to the gastrointestinal tract. Inhibition of COX-2 is not associated with gastrointestinal damage[16]. However, in a recently study using an animal model, intestinal mucosa damage occurred when both COX-1 and COX-2 were inhibited[17]. This finding suggests that COX-2 acts as immunomodulator and is involved in the healing process of inflammation. Thus, there could be an immunological mechanism whereby the inhibition of COX-2 causes gastrointestinal damage[3].

Heme oxygenase-1 (HO-1) is the rate-limiting en-

zyme in heme catabolism, and the upregulation of HO-1 produces anti-inflammatory or anti-oxidative effects. HO-1 is thought to be involved in the inhibition of small intestinal damage associated with NSAID. Pretreatment with an HO-1 inhibitor, SnPP (tin-protoporphyrin Ⅸ), exacerbates damage to the small intestine by indomethacin. Lansoprazole ameliorates small intestine ulcers induced by indomethacin through the upregulation of HO-1[18].

DIAGNOSIS

In the past, the documentation of NSAID-induced enteropathy was based on the measurement of small intestine permeability and an analysis of indicators of inflammation, such as fecal calprotectin. In recent years, intestinal mucosa have been able to be viewed directly by capsule endoscopy and enteroscopy[19,20].

For diagnosis, there should be a history of NSAID use, no history of antimicrobial agent use, and no bacterial growth in the stool or tissue cultures. There should be no vasculitis or granuloma in tissue specimens, and, after stopping an NSAID, clinical symptoms and the lesions found by endoscopy should disappear.

Intestinal permeability test

The intestinal permeability test, which examines damage to the intestinal barrier, is primarily used to measure the amount of an orally administered test reagent that is discharged in the urine[21]. Within 12 h after NSAID therapy, increased intestinal permeability can be observed. The material that is used for an intestinal permeability test is rarely absorbed into the normal intestinal barrier, but its absorption increases in damaged intestinal barrier, after which it is transported into the bloodstream and excreted in urine. Most of the material used for this test is excreted in urine within a certain time and is not metabolized *in vivo*[1]. The probes used in intestinal permeability tests include polyethylene glycol, cellobiose, sugars (such as lactulose and mannitol), and radionuclides, such as chromium-51-labeled ethylenediaminetetraacetic acid (^{51}Cr-EDTA). Of these, ^{51}Cr-EDTA is the most widely-used for measuring the damage by NSAIDs. It is not degraded by intestinal bacteria, reflects some of the colon permeability, and is used in a relatively simple assay. Increased intestinal permeability is observed in about 50%-70% of long-term NSAID users. Although the clinical usefulness of the intestinal permeability test is low, it has been used in a clinical study that observed the effects of food or drugs on the inhibition of intestinal damage caused by NSAIDs[1,6].

Measurement of intestinal inflammation

Intestinal inflammation by NSAIDs can be measured by scintigraphy using ^{111}Indium-labeled neutrophils[21]. In 50%-70% of individual taking NSAIDs for more than six months, labeled white cells were found to accumulate in the terminal ileum 20 h after administration, and a slight increase of inflammation was observed compared to patients with inflammatory bowel disease (IBD). This can be measured up to 16 mo after the patient has stopped taking the drug. However, this method is very expensive and it is difficult to apply in clinical tests. The detection of calprotectin in feces is used for detecting intestinal inflammation caused by NSAIDs, and inflammation is found in 44%-70% of long-term NSAID users. Excretion of ^{111}Indium in the stool is proportional to fecal calprotectin. However, it is also increased in individuals with IBD and colon cancer, unlike the intestinal permeability test, and has the disadvantage of low specificity for NSAID enteropathy[3,6].

Endoscopy

The recently introduced wireless capsule endoscopy and double-balloon enteroscopy can diagnose lesions, such as inflammation, erosions, and ulcers and complications including bleeding and stenosis, which are caused by NSAIDs[20]. In particular, capsule endoscopy, which is a non-invasive examination, is very useful. It can diagnose small bowel lesions in 70% of NSAID users and shows a high correlation with the fecal calprotectin test in measuring intestinal inflammation. Erosions or ulcers, which are the endoscopic findings of NSAID-induced enteropathy, can be caused by many factors besides NSAIDs, and histological examination cannot determine the cause of these lesions. Diseases for differential diagnosis include infection, IBD, ischemia, radiation enteritis, vasculitides, and drugs such as potassium chloride (KCl). The history of NSAID use, biopsy, and improvement of clinical symptoms after stopping the drug use are required for diagnosis. A diaphragm-like stricture is a characteristic finding, which is a secondary scar reaction of ulcer injury, and has non-inflammatory mucosa. There are usually multiple strictures occurring in the mid-intestine, ileum, and colon[22]. Maiden *et al*[19] classified the findings of capsule endoscopy into five groups: reddened folds, the denuded area, red spots, mucosal breaks, and blood. Graham[7] divided capsule endoscopy findings into red spots, small erosions, large erosions, and ulcers. In contrast, double-balloon enteroscopy has the advantages of directly treating bleeding lesions and the ability to perform histological examinations; however, it is a time-consuming and an invasive test[23]. Unfortunately, both tests incur relatively high costs, so their use is limited.

CLINICAL MANIFESTATION

In 60%-70% of NSAID-induced enteropathy, it is subclinical. This disorder displays nonspecific symptoms, such as iron deficiency anemia, gastrointestinal bleeding, hypoalbuminemia, vitamin B12 or bile acid malabsorption, diarrhea, and acute abdominal pain. Complications such as massive bleeding, stricture, and perforation may occur. These complications are rare, but can be fatal[6].

Gastrointestinal bleeding

Small intestinal injury caused by NSAIDs, even when not severe, can cause persistent bleeding and iron deficiency anemia. In patients with NSAID enteropathy, the sites of inflammation and bleeding are identical when measured by scintigraphy using ^{111}Indium-labeled neutrophils to observe intestinal inflammation, and technetium-99 m labeled red blood cell scintigraphy to show bleeding. In patients taking NSAIDs for rheumatoid arthritis who had severe anemia but no bleeding lesions observed by gastroscopy and colonoscopy, small intestinal ulcers have been observed in 47% when enteroscopy was performed. Generally, there is 2-10 mL of daily blood loss[4,6,24]. Apparent acute gastrointestinal bleeding is relatively rare and is caused by ulcers and erosions.

Protein loss

Protein loss in inflamed intestinal mucosa caused by the prolonged use of NSAID leads to hypoalbuminemia[1,3,6,24,25]. Previously, the loss of protein was thought to be secondary to bleeding, but it may occur without anemia. A gross bleeding lesion may not be found in the intestine of patients with enteropathy accompanied by loss of protein[24]. Nowadays, it is thought that protein loss associated with enteropathy can occur without lesions, such as inflammation, erosions, or ulcers.

Perforation and obstruction

Perforation associated with NSAID use is an uncommon complication that has a risk similar to that of bleeding. A case of perforation in a patient treated with high doses of indomethacin was reported[6,24].

Chronic ulcers caused by NSAID result in fibrosis and diaphragm-like strictures. Multiple diaphragm-like septa of 1-4 mm-thickness form in the middle part of the small intestine. If the intestinal lumen is narrowed, obstruction of the small intestine occurs in 17% of patients with NSAID-induced small intestinal ulcers[6]. This is associated with the drug dosage and duration, and accompanied by diarrhea, weight loss, iron deficiency anemia, and protein loss[24].

PREVENTION AND TREATMENT

There is still no proven method of preventing or curing small intestine damage due to NSAIDs. The simplest method is to stop taking the drugs. NSAIDs in prodrug and enteric-coated forms, and ones with controlled release have been developed, but they do not inhibit damage to the small intestine. In addition, H2-blocking agents and sucralfate that have effects on upper gastrointestinal complications are not useful for treating or preventing NSAID-related small intestinal damage, and the effect of proton pump inhibitors (PPI) has not yet been proven[26].

COX-2 selective inhibitor

The development of COX-2 selective inhibitors was expected to significantly reduce gastrointestinal complications caused by NSAIDs. COX-2 selective inhibitor reduced NSAID-associated upper gastrointestinal complications, but the effect on complications of the small intestine has yet to be proven. Currently, short-term treatment with COX-2 selective inhibitors has shown no effect on small intestinal permeability[27]. There have been some reports that symptoms of enteropathy are not observed in patients treated for short periods of time with COX-2 selective inhibitors[27-30]. However, it was also reported that the symptoms of patients treated with COX-2 inhibitors for more than three months were no different to those of patients treated with traditional NSAIDs[31,32]. An underlying reason for this observation is that selective COX-2 inhibitors also have some inhibitory effects on COX-1, and COX-2 has a role in the regulation of mucosal blood flow in some tissues. In addition, COX-2 inhibition increases leukocyte adherence without changes in the bloodstream. COX-2 may have an anti-inflammatory role in the vasculature, and COX-2 selective inhibitor has the disadvantage of adverse cardiovascular side effects.

NO, hydrogen sulfide-releasing NSAID, and zinc-NSAID

It has been reported that COX inhibiting NO donator, hydrogen sulfide-releasing NSAID, and zinc-NSAID prevent NSAID-induced gastrointestinal damage by vasodilation, anti-inflammation, and some cytoprotective actions[33]. Exogenous NO plays a role in maintaining mucosal integrity in the gastrointestinal tract by modulating mucosal blood flow and mucus secretion. Combining an NO donor drug with naproxen or aspirin provides protection from damage by NSAID[34]. Hydrogen sulfide has vasodilation, anti-oxidant, and anti-inflammatory effects[35,36].

Metronidazole

Metronidazole is an antibiotics used to treat anaerobic pathogen infections. When administered (800 mg/d), this drug decreases intestinal inflammation and blood loss caused by NSAID, but does not affect intestinal permeability[37]. Microbes sensitive to metronidazole are major neutrophil chemoattractants in NSAID enteropathy. However, other antibiotics except metronidazole are not effective for treating small intestinal damage caused by NSAIDs. The impact of metronidazole is not achieved by the effect on intestinal bacteria but by the inhibition of oxidative phosphorylation in the mitochondria of the intestinal cells[3].

Sulfasalazine

Sulfasalazine reduces NSAID-induced inflammation and blood loss[38]. The beneficial effect of sulfasalazine on rheumatoid arthritis seems to be due to the sulphapyridine moiety not to its 5-aminosalicylic acid moiety[39]. However, its role is unclear in NSAID-related enteropathy. It is useful in the ileitis of ankylosing spondylitis or for treating long-term NSAID users with rheumatoid

arthritis[38,39]. However, additional research is needed.

Rebamipide

Rebamipide increases mucus and stimulates the production of prostaglandin[40]. It also has anti-inflammatory properties. Rebamipide is a free radical scavenger and produces its effects by inhibiting superoxide production and suppressing myeloperoxidase activity[41]. Therefore, rebamipide can be expected to have an effect on intestinal inflammation. In a recent study, rebamipide prevented diclofenac-induced small bowel injury compared to a placebo[42].

Lansoprazole

Lansoprazole prevents the indomethacin-induced small bowel injury by upregulating HO-1, which has anti-inflammatory and anti-oxidative effects. This compound shows a broader PPI role in addition to its acid production suppression[18].

Goldstein *et al*[30] divided healthy volunteers into the three groups: a celecoxib group, a naproxen plus omeprazole group, and control group, and performed capsule endoscopy. Small bowel lesions were found in 16%, 55% and 7% of the individuals in each group, respectively. This indicates that small bowel lesions cannot be prevented with omeprazole. In other words, in the sites unaffected by gastric acid secretion, such as the small intestine, the increased mucosal protective effect of lansoprazole is more important.

Misoprostol

Misoprostol is a synthetic prostaglandin (PGE1) analog. It has a mucosal protective effect and effectively suppresses NSAID gastrointestinal side effects[43]. However, there is conflicting evidence for its effect on small bowel complications. In one report, misoprostol inhibited NSAID-associated intestinal permeability changes and showed a significant effect on enteropathy[44,45]. It was also found to be effective for treating enteropathy induced by low doses of aspirin[12]. However, misoprostol showed no significant effect on intestinal permeability in patients administered indomethacin in randomized controlled trials[46]. In this study, however, low doses of misoprostol were given for only one week, so additional research to verify these results is required. Misoprostol also has common side effects such as diarrhea, abdominal pain, headache, and constipation[3,6].

Eupatilin

Song *et al*[47] reported that eupatilin protects cultured feline ileal smooth muscle cells against cell damage caused by indomethacin. These protective functions are apparently due to eupatilin-mediated HO-1 induction through extracellular signal-regulated kinase and NF-E2-related factor-2 signal. Therefore, eupatilin is expected to lower the risk of complications such as ulcers, bleeding, and obstruction through its mucosal protective actions in chronic NASID users, but more systematic research is necessary.

Nutritional intervention

A period of time is needed for the prophylactic use of a drug; therefore, it would be better to use foods such as pharmaconutrients, which have relatively low pharmacological risks compared with drugs that have many side effects. Recombinant human lactoferrin has bactericidal, anti-inflammatory, and antioxidant activities, and can be taken orally as a supplement[48]. Commercial fish protein hydrolysate is a fermented fish product that is beneficial for the intestine[49]. Both recombinant human lactoferrin and fish hydrolysate reduce NSAID-associated intestinal permeability compared to a placebo.

Glutamine is a non-essential amino acid and used as energy sources of intestinal mucosa cells. It has been reported that after short-term administration of NSAIDs, glutamine is effective for the prevention of increased intestinal mucosa permeability[50]. In bovine colostrum, there are plenty of growth factors, such as insulin-like growth factor, various immunoglobulins, and antimicrobial peptides. Administration of bovine colostrum with glutamine is effective in reducing gut injury and transbacterial location caused by short-term administration of NSAIDs[51-53].

Other drugs

It was reported that the 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitor fluvastatin has antioxidative activity and suppresses the formation of ileal ulcers caused by NSAIDs in rats[54]. Other HMG-CoA reductase inhibitors, pravastatin and atrovastatin, did not show these effects[54]. In addition, it was reported that the immunosuppressive drug tacrolimus (FK506) prevents small bowel ulcers caused by indomethacin in rats. This may be due to inhibition of iNOS induction by tacrolimus[55].

CONCLUSION

As capsule endoscopy and enteroscopy have recently become more widely used, NSAID-induced small intestinal damage has emerged as a clinically important issue. To reduce the risk of complications, such as ulcers, bleeding, and obstruction, in chronic NASID users, many researches have attempted to treat and prevent these disorders. To this end, metronidazole, sulfasalazine, COX-2 inhibitors, misoprostol, rebamipide, human lactoferrin, and fish protein hydrolate, have been examined, but there are currently no results of long-term administration. Thus, methods to effectively treat and prevent small bowel injury caused by NSAIDs are still lacking. Therefore, a long-term randomized study in chronic NSAID users is needed. In addition, careful monitoring and special attention for the indications of NSAIDs are required to avoid this disorder in individuals taking NSAIDs.

Abstract

Rapid advances in imaging technology have improved the detection, characterization and staging of colorectal liver metastases. Multi-modality imaging approach is usually the more useful in diagnosis colorectal liver metastases. It is well established that hepatic resection improves the long-term prognosis of many patients with liver metastases. However, incomplete resection does not prolong survival, so knowledge of the exact extent of intra-hepatic disease is crucially important in determining patient management and outcome. The diagnosis of liver metastases relies first and totally on imaging to decide which patients may be surgical candidates. This review will discuss the imaging options and their appropriate indications. Imaging and evaluating of colorectal liver metastases (CRLM) have been performed with contrast-enhanced ultrasound, multidetector computed tomography, magnetic resonance imaging (MRI) with extra-cellular contrast media and liver-specific contrast media MRI, and positron emission tomography/computed tomography. This review will concentrate on the imaging approach of CRLM, and also discuss certain characteristics of some liver lesions. We aim to highlight the advantages of each imaging technique, as well as underscoring potential pitfalls and limitations.

Key words: Liver metastasis; Colorectal cancer; Imaging-modality; Diagnosis

INTRODUCTION

Metastatic disease to the liver is a very common clinical situation in oncology. The liver is one of the most common sites of metastatic spread of epithelial cancers, second only to regional lymph nodes. Colorectal cancer is one of a few malignant tumors in which the presence of limited synchronous liver metastases or metachronous metastases need surgical resection[1]. Colorectal liver metastases (CRLMs) develop during the course of colorectal cancer in up to 50%-70% of patients[1-3]. Metastases are confined to the liver in 30%-40% of patients at the time of detection and are potentially resectable in about 20%-30% of the cases[4,5]. Hepatic resection is the only potentially curative treatment for these colorectal liver metastases and in selected groups, the 5-year median survival has been reported to be up to 30% (range 15%-67%)[5]. Patients with untreated but potentially resectable metastases show a median survival of 8 mo and the 5-year survival rate

of these patients is less than 5%[6,7]. Eligibility for surgical treatment requires strict criteria. Besides an adequate clinical condition, all liver lesions have to be completely resectable. The diagnosis of liver metastases relies first and totally on imaging to decide which patients may be surgical candidates. Thus, the imaging technique able to demonstrate the exact number, regional distribution, size of metastases and the volume of the remaining liver is crucial to determine resectability.

In many centers, imaging and evaluating of CRLM have been performed with contrast-enhanced ultrasound (CEUS), multi-detector computed tomography (MDCT), magnetic resonance imaging (MRI) with extra-cellular contrast media and liver-specific contrast media MRI, and positron emission tomography/computed tomography (PET/CT). This review will concentrate on the imaging approach of CRLM, and also discuss certain characteristics of some liver lesions. We aim to highlight the advantages of each imaging technique, as well as underscoring potential pitfalls and limitations.

IMAGING MODALITY PERFORMANCE

CEUS

The development of CEUS has dramatically increased the potential of sonography in the assessment of focal liver lesions. The use of contrast agents allows perfusion mapping of focal lesions, thus enabling characterization of focal lesions. Bernatik *et al*[8] investigated the diagnostic yield of CEUS *vs* helical CT in the detection of liver metastases (no histological diagnosis), CEUS showed 97% of lesions seen by CT.

Although CEUS is widely used to assess the liver, it has some limitations: it needs considerable operator expertise and often reveals equivocal results in patients with (chemotherapy-induced) fatty infiltration of the liver. Due to the limitations in the visualization of segmental distribution and 3D-shape of metastases, it is limited in the preoperative assessment of patients with colorectal liver metastases.

MDCT

Nowadays MDCT is the mainstay of staging and follow-up of these patients, because it provides good coverage of the liver and the complete abdomen and the chest in one session. MDCT scanner has the capability for high-resolution studies with sub-millimetre slice thickness resulting in isotropic pixel sizes, which enable images to be reformatted in various planes that still have the same resolution as the axial images. This may improve detection of small lesions. High-resolution scans with maximum intensity technique and volumetric three-dimensional rendering enable accurate segmental localization and delineation of tumour[9]. Vascular reconstruction enables the demonstration of the hepatic arterial and portal venous anatomy obviating the need for conventional angiography in surgical planning of tumour resection[10]. Volumetric measurement of tumour size and normal liver is also more accurate[11].

How many scans are necessary for a CT examination of the liver? In patients with colorectal cancer, liver metastases are calcified in 11% at initial presentation[12]. These lesions with calcification are much better seen on unenhanced scans than on portal-venous phase scans. Small CRLM often are hyperattenuating during the hepatic arterial phase whereas larger lesions will often show a hyperattenuating rim during the hepatic arterial phase and a hypoattenuating centre representing diminished vascularity and/or tumour necrosis[13], and larger lesions usually are detected as hypoattenuating lesions during the portal venous phase[14]. However the vascularity and therefore enhancement characteristics can be widely variable for reasons that are poorly understood[15-17].

Meijerink *et al*[18] concluded 50 patients suspected of CRLM, they found adding rigid-body co-registered subtraction CT images to a conventional 4-phase CT protocol for pre-operative detection and characterization of CRLM seems of no value. Wicherts *et al*[19] found Arterial and equilibrium phase have no incremental value compared to hepatic venous phase CT in the detection of CRLM. Venous phase is still the most significant timing to detect liver metastases.

Several studies have assessed the value of using thin slices to improve detection of small metastases. Two point five mm or 3.75 mm thick slices were significantly superior to 5, 7.5 and 10 mm thick slices[20,21]. When the slice thickness is decreased to 1 mm, no further improvement in lesion detection is seen, but there is a considerable increase in image noise with subsequent degradation of image quality[22].Therefore a slice thickness of 2-4 mm is recommended for axial viewing.

Although MDCT is the modality of choice for staging colorectal cancer, up to 25% of liver metastases may still be missed[23,24]. Extra care has to be taken for patients with contrast allergies or with renal impairment.

CT with arterioportography

In CT with arterioportography (CTAP), CT scanning of the liver is performed during contrast agent injection into either the superior mesenteric artery or splenic artery *via* a percutaneously placed catheter. It provides maximum tumor-to-liver contrast by enhancing the liver parenchyma alone as in the portal phase and depicts tumor deposits as areas of perfusion defects. This is based on the fact that metastases are almost exclusively fed *via* the hepatic artery. CTAP was usually reserved for imaging candidates prior to surgical hepatic resection as it provided an accurate segmental localization of liver metastases and excellent depiction of liver vasculature. This invasive technique is less routinely performed with the advent of MDCT and MRI with liver-specific contrast agents, which are as accurate in lesion detection but with much lower false positive rates[25].

MRI

The standard MRI protocol should always include un-

enhanced T1- and T2-weighted and contrast-enhanced pulse sequences. In liver MR imaging a set of T1-weighted in-phase and opposed-phase gradient-recalled echo gradient-recalled echo images is acquired to assess the parenchyma for the presence of fatty infiltration or focal sparing of diffuse fatty infiltration. For T2-weighted imaging, the turbo-spin echo (TSE) or the fast spin echo with fat suppression are preferred over the single-shot TSE pulse sequences. In addition, heavily T2-weighted pulse sequences with a time of echo of approximately 160-180 ms may help in differentiation between solid [metastasis, hepatocellular carcinoma (HCC), *etc.*] and non-solid lesions (e.g., haemangioma, cyst)[26,27].

After the acquisition of unenhanced pulse sequences, contrast-enhanced pulse sequences are always obtained. Nowadays, two different groups of MR contrast agents for liver imaging are available: first, the non-specific gadolinium chelates and second the liver-specific MR contrast agents. The latter group can be divided into two subgroups, the hepato-biliary contrast agents, and the reticulo-endothelial (or Kupffer cell) contrast agents.

NON-SPECIFIC GADOLINIUM CHELATES

The liver and liver-lesion enhancement patterns obtained with non-specific gadolinium chelates (extracellular contrast agents) are similar to those obtained with iodinated contrast agents used in CT. Several agents with similar properties are on the market, including gadopentetate dimeglumine (Schering, Berlin, Germany), Gd-DTPA-BMA (GE Healthcare, Oslo, Norway), Gd-DOTA (Guerbet, Aulnay-sous-Bois, France), and Gado-teridol (Bracco, Milan, Italy).

Extracellular gadolinium chelates are used extensively for liver MRI. Following intravenous injection of a gadolinium-based agent, typically three phases of contrast enhancement are imaged: the arterial, portal venous phase and the equilibrium phase. During the arterial phase, most of the liver does not enhance as the majority of the liver's blood supply is *via* the portal vein. Enhancement patterns of liver lesions are similar to those demonstrated on CEUS and contrast-enhanced CT. The equilibrium phase or delayed phase is useful for helping with lesion differentiation (e.g., haemangioma *vs* metastasis). In addition, washout of contrast from HCC and peripheral or heterogeneous washout from liver metastases are characteristic findings on delayed imaging[28,29].

LIVER-SPECIFIC CONTRAST AGENTS

Hepatobiliary agents

Hepatobiliary agents represent a heterogeneous group of paramagnetic molecules of which a fraction is taken up by hepatocytes and excreted into the bile. Mangafodipir trisodium (Teslascan®, GE Healthcare) is taken up by hepatocytes and results in signal intensity increase on T1-weighted images (a so-called "T1 enhancer")[30], and a fraction is also taken up by the pancreas, which has been used for pancreatic MR imaging[31,32]. Focal non-hepatocellular lesions (i.e., metastases) do not enhance post-contrast, resulting in improved lesion conspicuity Mangafodipir-enhanced MRI has been show to be superior to unenhanced MRI and helical CT for detection of liver metastases[1,32,33].

Gd-BOPTA (Multihance®, Bracco) is a liver-targeted paramagnetic contrast agent and unlike conventional Gadolinium chelates, has almost two-fold greater T1 relaxivity which improves image contrast and detection of liver lesions, due to its high T1-relaxing effect and hepatocyte binding capability[34].

Gd-EOB-DTPA (Primovist®, Schering) and Gd-BOPTA are hybrid contrast agents, which carry a lipophilic ligand[35]. After intravenous bolus injection these agents show biphasic liver enhancement with a rapid T1 enhancement of the liver similar to that seen with non-specific extracellular gadolinium agents. Then hepatic signal intensity continues to rise for 20-40 min (Gd-EOB-DTPA) and 60-90 min (Gd-BOPTA), reaching a plateau after about 2 h because of hepatocytic uptake. This results in increasing contrast between liver and non-hepatocellular tumors[36].

Reticuloendothelial agents

All reticuloendothelial system (RES) agents are superparamagnetic iron oxide-based contrast agents (SPIO). SPIO particles are taken up by RES cells (so-called Kupffer cells) of normal liver parenchyma, as also by macrophages of the spleen and lymph nodes. They shorten T2 and T2* relaxation times in the liver tissue, and resulting in a loss of signal intensity in normal liver parenchyma. Despite of this, malignant liver lesions do not have a substantial number of RES cells and appear as hyperintense lesions with distinct borders in contrast to the hypointense liver parenchyma after application of SPIO on T2-weighted MR images[37,38] .

There are some published studies comparing some methods reporting varying sensitivity. Some have reported that SPIO-enhanced MRI has better diagnostic efficacy for liver lesions over that of Gadolinium-enhanced MRI, Gd-BOPTA-enhanced MRI and dynamic CT imaging with high sensitivity values[39-41]. Another study has claimed equal sensitivity between SPIO-enhanced MRI and Gd-BOPTA-enhanced MRI in the delayed hepatocyte phase for the detection of LMs[42,43]. Mainenti *et al*[44] found Gd- and SPIO-enhanced MRI had equal performance and were shown to perform significantly better than the other modalities on a per lesion basis. These data were similar to previous studies comparing Gd- and SPIO-enhanced MRI each other[4,39] or with MDCT[39,45] or PET/CT[46]. Based on Zech *et al*[47] experience and the existing literature, imaging using Gd-EOB-DTPA-enhanced MR can be expected to be superior to the using standard gadolinium chelates or to spiral CT, especially for the differential diagnosis of hypervascular lesions.

Blyth *et al*[48] suggest that MRI is a highly sensitive method of pre-operative imaging of colorectal liver me-

tastases and should be considered the "gold standard". Except contraindications to MRI include pacemakers, implantable cardiac defibrillators, cochlear implants and metallic orbital foreign bodies, MR imaging is still limited in the anatomic coverage, although the recent introduction of multi-channel MR coils with wider coverage and the moving-table MR technique has re-established the "competitiveness" of MR with MDCT with regard to patient throughput. One of the advantages of MR in liver imaging is the better soft tissue contrast, which reveals better characterization of focal liver lesions in question. The development of a liver-specific MR contrast agent has further improved the diagnostic yield of MRI in lesion detection and characterization.

PET/CT

The recent introduction of PET/CT hybrid scanners enables seamless and accurate fusion of the high resolution anatomic localisation of CT with the functional data of FDG-PET. A combination of FDG-PET and CT scanning characteristics seems promising, and integrated PET/CT is becoming more widely available, although the exact clinical value and efficacy is not yet fully established. Due to restricted availability, high cost and an additional radiation exposure, PET/CT should be used in selected patients where the diagnosis is not clear following conventional diagnostic modalities.

TRUE ACCURACY OF IMAGING AND FUTURE DEVELOPMENTS

Twenty to twenty-five percent of patients with known solid malignant tumors have hepatic metastases at the time of diagnosis. The incidence of solid benign liver tumors is around 20%[49], thus in patients with known malignancy, 20%-25% of lesions under 2 cm are benign[50]. The most frequent benign lesion is hemangioma with a prevalence of 7%-21%, followed by focal nodular hyperplasia with a prevalence of up to 3%; other benign lesions are far rarer[28,49].

In two studies showed that 24%[39] and 18%[51] of lesions 1 cm or smaller were not detected by any imaging technique. Which imaging modality is the best model in detection of CRLM? The issue of when to use which imaging method is still not solved. The answer likely depends on local equipment, availability, and operator expertise.

Contrast-enhanced intra-operative US (CE-IOUS) is considered the gold standard thereby achieving universal usage and should arguably be considered the final diagnostic procedure[52-55]. Several studies have shown that IOUS still has a higher sensitivity and specificity than the noninvasive techniques, such as helical CT and MRI[54,56-58]. However, there have been few studies on CE-IOUS in literature and CE-IOUS is not widely used among hepatic surgeons.

CT liver imaging offers increased sensitivity and may also able to assess extrahepatic disease but is inferior to MRI scanning in direct comparisons[59-62].

CTAP is considered by many to be the "gold standard" for hepatic imaging but it is an invasive technique with a high (up to 15%) false-positive rate[60].

Hekimoglu *et al*[37] could detect lesions CRLM over 1 cm by all the 3 imaging modalities including SPIO-enhanced MRI, GbD-enhanced dynamic MRI and dynamic CT imaging also with a high sensitivity. However, only SPIO-enhanced MRI detected LMs less than 1 cm with 100% sensitivity which has not been reported until today. So, He therefore, recommend SPIO-enhanced MRI for patients with colorectal carcinoma with suspected small sized LMs. MRI provides a sensitive, non-invasive method of assessing liver lesions and direct comparison between CTAP and MRI shows that MRI is better at identifying and characterising liver lesions[63-65].

Kinkel *et al*[66] performed a meta-analysis including papers published between 1985 and 2000 and concluded that, at equivalent specificity, PET/CT is more sensitive than US, CT and MRI for the detection of hepatic metastases from gastro-esophageal and colo-rectal cancers. Subsequently Bipat *et al*[4] performed a meta analysis including papers published between 1990 and 2003 and concluded that PET/CT is the most sensitive diagnostic tool for the detection of hepatic metastases from colo-rectal cancer on a per patient basis, but not on a per lesion basis. Mainenti *et al*[44] found PET/CT shows a trend to perform better than the other modalities in the identification of patients with CRLM.

The combination of PET and CT is a perfect solution. On theoretical grounds, it is preferable to combine PET with (functional) MRI, for better soft tissue evaluation with a relatively low radiation burden. An excellent example of the application of PET/MRI fusion is accurate delineation of malignant lesions in the liver, to allow optimally guided locoregional therapeutic intervention[67]. It is expected that integrated PET/MRI scanners will become clinically available in the next few years.

Clearly, continuing improvements in imaging are allowing metastases to be identified at an earlier stage but a different approach is needed to improve the detection of metastases smaller. A multi-modality strategy is recommended since no single modality can accurately detect all colorectal liver metastases[68].

Abstract

This study is aimed to assess the long-term health-related quality of life (HRQL) of patients after esophagectomy for esophageal cancer in comparison with established norms, and to evaluate changes in HRQL during the different stages of follow-up after esophageal resection. A systematic review was performed by searching medical databases (Medline, Embase and the Cochrane Library) for potentially relevant studies that appeared between January 1975 and March 2011. Studies were included if they addressed the question of HRQL after esophageal resection for esophageal cancer. Two researchers independently performed the study selection, data extraction and analysis processes. Twenty-one observational studies were included with a total of 1282 (12-355) patients. Five studies were performed with short form-36 (SF-36) and 16 with European Organization for Research and Treatment of Cancer (EORTC) QLQ C30 (14 of them also utilized the disease-specific OES18 or its previous version OES24). The analysis of long-term generic HRQL with SF-36 showed pooled scores for physical, role and social function after esophagectomy similar to United States norms, but lower pooled scores for physical function, vitality and general health perception. The analysis of HRQL conducted using the Global EORTC C30 global scale during a 6-mo follow-up showed that global scale and physical function were better at the baseline. The symptom scales indicated worsened fatigue, dyspnea and diarrhea 6 mo after esophagectomy. In contrast, however, emotional function had significantly improved after 6 mo. In conclusion, short- and long-term HRQL is deeply affected after esophagectomy for cancer. The impairment of physical function may be a long-term consequence of esophagectomy involving either the respiratory system or the alimentary tract. The short- and long-term improvement in the emotional function of patients who have undergone successful operations may be attributed to the impression that they have survived a near-death experience.

INTRODUCTION

Esophageal cancer is an increasingly common cancer with a poor prognosis. During recent decades, the incidence of esophageal cancer has risen steadily, and it is now the fastest rising solid tumor in most Western countries. Moreover, moderate to high incidence rates have been reported in other areas, including parts of China, Central Asia, South and East Africa, South America, Northern France, and the United States among African-Americans[1]. Despite recent improvements in diagnosis, surgical treatment and (neo)-adjuvant therapy, the prognosis of patients with esophageal cancer remains poor, with overall 5-year survival rates of only 5%-15%[1,2]. Esophagectomy is the standard treatment for those patients who present with resectable esophageal cancer[3-5], but it offers a limited (25%-35%) chance of cure[5,6] and is associated with a considerable risk of serious complications[4,5,7]. Therefore, the use of chemotherapy or radiotherapy in combination with surgery has been tested. Nevertheless, meta-analyses of randomized trials of neoadjuvant chemotherapy and chemoradiation followed by surgery and surgery alone for patients with esophageal carcinoma showed only minor survival advantages[8,9]. Only patients with a complete pathologic response to neoadjuvant therapy enjoy a significantly better chance of survival, whereas non-responders have a worse prognosis than patients undergoing surgery alone[10,11].

For a long time, morbidity and mortality represented the main (and often the only) outcome measure that could be used to evaluate esophagectomy for esophageal cancer. The morbidity and mortality rates associated with the procedure and the poor patient survival rate left almost no space for further consideration. However, in recent years, along with the increase in the success of the therapy, health-related quality of life (HRQL) has generally become accepted as an important outcome parameter, along with long-term survival, mortality, and complication rates. In fact, knowledge of risk factors for poor postoperative HRQL may be relevant to clinical decision making. Moreover, these findings may be used to inform patients of the long-term consequences of surgery. On this basis, the aim of this systematic review was to analyze quality of life after curative surgery for esophageal cancer.

INCLUSION AND EXCLUSION CRITERIA

Since we expected to find only observational studies, the checklist proposed by Meta-analysis of Observational Studies in Epidemiology group 38 was used as a guideline to perform this systematic review[12]. We defined observational studies as reports that used data from existing databases, cross-sectional studies, case series, case-control studies, or studies with a historical control or a cohort design.

Studies were eligible for inclusion if they reported on a series of patients who underwent esophagectomy because of esophageal cancer and if post-operative quality of life was described and analyzed in the "material and methods" and "results" sections. Studies reporting on a mix of esophageal adenocarcinoma and squamous cell cancer patients were included. In contrast, those reporting on malignancies other than esophageal adenocarcinoma or squamous cell cancer were excluded. All studies eligible for inclusion in this systematic review also had to present detailed information on the methods used to assess quality of life and on when the questionnaire was administered. Studies that analyzed HRQL using questionnaires other than short form-36 (SF-36), European Organization for Research and Treatment of Cancer (EORTC) QLQ C30 and OES18/24 and those that only presented their results graphically were excluded. When studies were discovered to report (partially) similar patient data, only the most recent and complete data sets were considered.

SEARCH STRATEGY

Four medical databases were used in this research: Medline (January 1978 to March 2011), the Cochrane Database of Systematic Reviews, the Cochrane Central Register of Controlled Trials and Embase. These databases were searched with the help of a clinical librarian. The keywords and medical subject headings used were "esophageal cancer", "esophagectomy" and "quality of life", as indicated in Figure 1. Only clinical studies written in English were selected. A manual cross-reference search of the eligible papers was performed to identify additional relevant articles. Based on the initial search results, two researchers (Scarpa M and Valente S) independently selected the studies that matched the inclusion criteria. Data quoted as unpublished and data from abstracts were not used. Any disagreements between the two researchers regarding which studies should be included were resolved through discussion.

DATA EXTRACTION

Data were extracted only from original articles using a preformatted sheet with a set of pre-defined parameters: demographic data, histologic type, cancer stage, cancer site, type of surgery (two-way or three-way esophagectomy), type of reconstruction (esophagogastroplasty or esophagocoloplasty), neoadjuvant or adjuvant therapy, timing of follow-up and HRQL data gathering, type of questionnaire used, item and total results.

OUTCOME MEASURE: QUALITY OF LIFE INSTRUMENTS

Studies were included if at least one of the following validated quality of life instruments was used: the EORTC-QLQ-C30, the EORTC-QLQ-OES18 or 24, or the SF-36. A summary of these questionnaires appears below.

The EORTC-QLQ-C30 questionnaire was developed by the Quality of Life division of EORTC. This 30-item questionnaire explores the generic quality of life of patients affected by oncologic diseases. It is a self-report

instrument that includes five functional scales (physical, role, emotional, social and cognitive), three symptom scales (fatigue, nausea and vomiting, and pain), a global health status scale and six single items (dyspnea, insomnia, appetite loss, constipation, diarrhea, and financial difficulties)[13]. The EORTC-QLQ-OES-18 and 24 are two extra modules that are used specifically for esophageal cancer. These questionnaires consist of 18 questions (or 24 in the previous version) assessing dysphagia, deglutition, abdominal/gastrointestinal symptoms, eating difficulties, pain, and emotional problems related to esophageal cancer and to the side effects of chemotherapy/radiotherapy[14]. The SF-36 consists of 36 items within 8 dimensions: psychological functioning, role limitations due to physical problems, pain, general health perceptions, energy/vitality, social functioning, and role limitations due to emotional problems and mental health[15].

STATISTICS

A clinical statistician was consulted to assess the accuracy of our analysis. The Review Manager 4.2 software (The Cochrane Collaboration, Copenhagen: Nordic Cochrane Centre, 2003) was used to process the data and conduct the analysis. For studies presenting HRQL results obtained from patients who had undergone the same treatment regimen and been presented with the same questionnaire at the same point in time with respect to their surgery, a meta-analysis of the HRQL scores was attempted. The results were presented as weighted mean differences [95% confidence interval (CI)]. Based on previous research, a difference of at least 10 mean score points between time points or comparison groups was considered clinically relevant, whereas a difference of 5-10 was considered weak[16]. $P < 0.05$ was considered to indicate that the results were significant.

STUDY SELECTION

The studies selected are shown in Figure 2. The initial search yielded 380 articles, of which 349 did not meet the criteria for inclusion. Based on their titles, 286 papers were excluded because they clearly covered a variety of unsuitable topics. Forty-four articles were then excluded on the basis of their abstracts; these were case reports and review articles without original data or articles on forms of neoplasm other than esophageal carcinoma. Of the 50 candidate papers, an additional 29 were then excluded, of which 10 were not focused on quality of life after esophagectomy for esophageal carcinoma[14,17-25], 10 presented their results only in a graphical format[26-35], 7 used quality of life questionnaires other than the SF36, QLQ C30 or OES24/18[36-42] and 2 reported data from the same dataset as other studies[43,44]. Although they reported the same dataset, three studies from the Karolinska Institute of Stockholm were included in the review because they analyzed different aspects of HRQL after esophagectomy[45,46]. However, the patients included in these studies were counted only once in all totals.

The 21 studies included in the analysis were all published between 1995 and 2010 and are listed according

Table 1 Studies characteristics: Aims of the studies and timing of health-related quality of life recording

Sudy	Study aim	Timing post op HRQL measures

Rosmolen *et al*[51]	Comparison between HRQL after endoscopical ablation and esophagectomy for early Barrett's neoplasms	A single assessment at 24 (17–35) mo

The 21 studies included in the analysis are listed according their aim and then chronologically. HRQL: Health-related quality of life; HGD: High grade dysplasia; CT-RT: Chemotherapy-radiotherapy; op: Operative; po: Post-operative.

their aim and then chronologically in Tables 1 and 2. Five studies were performed using SF36 and 16 using EORTC QLQ C30 (14 of them also utilized the disease-specific OES18 or the previous version, the OES24). Nine studies were observational cross-sectional studies and twelve were prospective ones. Patients were enrolled consecutively in 17 of them. Generic and disease-specific questionnaires were both used in 18 studies, and the HRQL was the primary focus for 15 of them. Five were population-based studies.

Study characteristics

There were 21 observational studies analyzed, and these studies included data for a total of 1282 patients. The number of patients ranged from 12 to 355 per study. The follow-up duration after esophagectomy, as reported in the articles, was between 4 and 63 mo. The range of mean ages reported by the different papers was 59 to 69 years. The indication for surgery was esophageal adenocarcinoma in 835 patients and squamous cell carcinoma in 395. However, in the series by Schneider *et al*[48], 5 out of 17 patients were operated on for esophageal perforation. Hendrick *et al*[49], Moraca *et al*[50] and Rosmolen *et al*[51] included 35, 24 and 7 patients, respectively, who underwent esophagectomy because of high-grade dysplasia. The characteristics of the patients included in each study are described in Table 3.

Long term generic HRQL after esophagectomy vs healthy subjects

Five studies analyzed the long-term generic HRQL of 246 patients using the SF-36 questionnaire (median follow-up range: 36-64 mo)[49,50,52-54]. The studies by Moraca *et al*[50] and Cense *et al*[52] were not used for the meta-analysis because the SF-36 scores in the first were not reported in a standard, comparable manner and because all patients reported on in the second underwent esophagocoloplasty. The studies by Hendrick *et al*[49], De Boer *et al*[53] and McLarty *et al*[54] were sufficiently homogenous, and thus, a meta-analysis of their results was attempted. The pooled scores for physical function, physical role, and social function after esophagectomy were similar to sex- and age-matched United States norms, whereas the pooled scores for physical function, vitality and general health perception were lower than the relevant norms ($P = 0.005$, $P < 0.001$ and $P = 0.006$, respectively). In contrast, scores for bodily pain and mental health in long-term survivors after esophagectomy were higher than the relevant norms ($P = 0.08$ and $P = 0.02$, respectively). The significant weighted mean differences that emerged based on the comparison between the long-term generic HRQL of patients who had undergone esophagectomy and that of healthy subjects are shown in Figure 3.

Generic and disease specific HRQL after neoadjuvant therapy and esophagectomy

Three studies analyzed generic and disease-specific HRQL for 255 patients using the QLC-30 and OES-18 questionnaires at different stages in the follow-up timeline (baseline, 3, 6, 9 and 12 mo) after neoadjuvant therapy and esophagectomy[55-57]. Reynolds *et al*[55] and Avery *et al*[56] compared the HRQL of patients who had undergone neoadjuvant therapy with that of patients who had un-

dergone esophagectomy alone. Based on these studies, data for the patients who had undergone neoadjuvant therapy and esophagectomy were identified. Data from the study by Reynolds *et al*[55] were uploaded for meta-analysis, but could not be used because the standard deviation values were missing. The baseline scores were compared to scores obtained after a 6-mo follow-up. The EORTC- QLQ-C30 global scale results tended to be better at the baseline than at the 6-mo follow-up ($P = 0.08$), and physical function was also better at the baseline ($P < 0.001$). Likewise, the symptom scales showed worsened fatigue, dyspnea and diarrhea 6 mo after the procedure ($P < 0.001$, $P < 0.001$ and $P < 0.001$, respectively). In contrast, emotional function had significantly improved after 6 mo ($P < 0.001$). The significant weighted mean difference results associated with the comparison between the baseline HRQL figures and the figures achieved 6 mo after neoadjuvant therapy and esophagectomy are shown in Figure 4.

Generic and disease specific HRQL after minimally invasive esophagectomy

Two studies prospectively analyzed the generic and disease-specific HRQL of 255 patients using the EORTC-QLQ-C-30 and OES-18 questionnaires at different points on the follow-up timeline (baseline, 3, 6, 9 and 12 mo) after minimally invasive esophagectomy[58,59]. The surgical techniques used in the two studies were similar and included thoracoscopic esophageal mobilization and mediastinal lymphadenectomy, followed by laparoscopic gastric mobilization and resection, and abdominal lymph-

adenectomy. Wang *et al*[59] compared the HRQL results achieved after minimally invasive esophagectomy with those achieved after open esophagectomy, and the study by Parameswaran *et al*[58] was an uncontrolled prospective study. Therefore, the baseline scores were compared to scores obtained during a 6-mo follow-up. Social function, cognitive function, emotional function and dysphagia proved to be significantly improved during the 6-mo follow-up ($P < 0.001$, $P < 0.001$, $P < 0.001$ and $P < 0.001$, respectively). In contrast, physical function was better at the baseline ($P < 0.001$), and role function tended to appear worse at the 6-mo follow-up point. The significant weighted mean difference results associated with the comparison between the baseline HRQL figures and the figures from 6 mo after neoadjuvant therapy and esophagectomy are shown in Figure 5.

Predictors of generic and disease specific HRQL after esophagectomy

Three articles from the Karolinska Institute, Stockholm specifically investigated predictors of generic and disease-specific HRQL after esophagectomy for cancer by analyzing the data from the Swedish Esophageal and Cardia Cancer register, which had conducted a nationwide, prospective, population-based study of how esophageal surgery-related factors had influenced quality of life 6 mo after surgery[45-47]. Although they reported information from the same dataset, these studies were all included in the review because they analyzed different aspects of HRQL after esophagectomy. The first study, by Viklund *et al*[45], included 100 patients and indicated that surgery-related complications were the main predictor of reduced global quality of life 6 mo after surgery. Except for anastomotic strictures, each of the predefined complications (e.g., anastomotic leakage, infections, cardiopulmonary complications, and operative technical complications) contributed to a decrease in quality-of-life scores. Rutegard *et al*[46], using a larger study population, showed that extensive surgery (characterized as using the transthoracic approach, extensive lymphadenectomy, and wider resection margins and as being of a longer duration) was not associated with worse HRQL measures than less extensive operations. Moreover, they observed that the severity of dysphagia was similar in patients who had handsewn and stapled anastomoses. Technical surgical complications were confirmed to have a deleterious effect on several aspects of HRQL. Finally, the same group concluded that no clinically relevant differences in terms of generic and disease-specific HRQL were found to be correlated with differences in the volume of surgeries conducted at hospitals (low volume: 0-9 operations/year; high volume: > 9 operations/year) or by particular surgeons (low volume: 0-6 operations/year; high-volume: > 6 operations/year)[47].

Long-term generic and disease-specific HRQL after esophagectomy

Data from the articles that analyzed long-term generic and disease-specific HRQL after esophagectomy were collected, but their clinical heterogeneity was so high that it was impossible to pool them. Four studies analyzed the generic HRQL of 152 (18-87) patients using the QLC-30 questionnaire and evaluated disease-specific HRQL using the OES-18 questionnaire in conducting long-term follow-up[60-63]. Fagevik *et al*[60] evaluated 18 patients 2 years after thoraco-abdominal esophageal resection and observed that, 2 years after surgery, respiratory function was significantly lower than it was prior to surgery, as was physical performance. In contrast, HQRL was comparable to age- and sex-matched population norms for most other functions. After 2 years, diarrhea, dyspnea, appetite loss and fatigue were still clinically significant. Similarly, Lagergren *et al*[61] analyzed 47 patients who had survived for at least 3 years after esophagectomy for a malignant disease. In these long-term survivors, most HRQL items had returned to preoperative levels by the 3-year assessment; however, their scores for physical function, breathlessness, diarrhea, and reflux remained significantly worse than at the baseline. Nevertheless, patients reported significantly better emotional function 3 years after surgery than before treatment. Djärv *et al*[62] reported the results for a cohort of 87 patients who had survived for at least 3 years after esophagectomy for cancer, using data from the prospective Swedish nationwide population study. As in other studies, these patients reported significantly more problems with fatigue, diarrhea, appetite loss, nausea and

vomiting than did those in the reference population, and they also reported significantly poorer role and social function. Finally, Courrech Staal *et al*[63] compared the generic and disease-specific HRQL of 36 patients with esophagectomy (who had or had not received neoadjuvant therapy) after a median follow-up of 54 mo with the data for a reference sample of patients with esophageal cancer (1031 patients) and with that of the general population (7802 subjects). These long-term survivors reported better health-related quality of life than the reference sample of patients with esophageal cancer, even if their HRQL appeared lower than that of the reference sample of individuals from the general population[63].

PECULIAR ASPECTS OF HRQL AFTER ESOPHAGECTOMY

Data from the four articles that analyzed peculiar aspects of HRQL after esophagectomy were collected, but although the EORTC questionnaires were used, the level of clinical heterogeneity was so high that it was impossible to pool them[48,51,64,65]. In 1995, in one of the first studies focused on HRQL, Blazeby *et al*[64] observed that patients treated using esophagectomy reported significantly better physical, emotional, cognitive, and global health scores than did those who had received palliative treatment. These patients also had significantly worse pain, fatigue, appetite loss, constipation, and dysphagia. Ariga *et al*[65] performed a prospective direct comparison of outcomes after treatment in patients with resectable esophageal cancer who had received definitive chemoradiation and those who had undergone surgery alone. They surveyed HRQL in patients who had survived more than 2 years using a cross-sectional approach, and concluded that the HRQL of patients who had definitive chemoradiation and that of patients who had undergone surgery alone were similar. Diarrhea, appetite loss and eating problem scores were worse in patients who had undergone surgery alone than in those who had undergone chemoradiation[65]. Moreover, Schneider *et al*[48] compared the HRQL of those patients who had undergone elective and emergency esophagectomy with those who had undergone collar reconstruction. They observed a temporary decrease in postoperative HRQL in both groups and a return to preoperative values during the follow-up except for physical functioning, which remained decreased in patients who had undergone elective esophagectomy for cancer. Finally, Rosmolen *et al*[51] compared HRQL and fear of cancer among 81 patients who had undergone endoscopic treatment and 27 patients who had undergone surgery for early Barrett's neoplasia. They observed that patients in the surgery group reported significantly more eating problems and reflux symptoms on the EORTC-OES18 questionnaire, whereas endoscopy patients reported more fear of recurrence than surgery patients. They concluded that preserving the esophagus after endoscopy, which is preferable from a clinical perspective, may induce fear of cancer recurrence[51].

CONCLUSION

Esophageal cancer is an increasingly common cancer with a poor prognosis. Esophagectomy is the standard treatment for those patients who present with resectable esophageal cancer[3-5], but it still offers a limited (25%-35%) chance of cure[5,6] and is associated with considerable risk of serious complications[4,5,7]. For a long time, morbidity and mortality represented the main, and often the only, outcome measures that could be used to evaluate esophagectomy for esophageal cancer. The morbidity and mortality rates associated with the procedure and the patients' poor survival rates due to the aggressive nature of the disease left almost no space for further analysis. However, in recent decades, along with the increased success of the therapy, HRQL has become an important outcome parameter in addition to survival, mortality, and complication rates[67]. In fact, postoperative HRQL can yield information that is relevant for clinical decision-making and help to inform patients about the long-term consequences of surgery. With that in mind, this systematic review was designed to collect and analyze data reflecting patterns in HRQL after curative surgery for esophageal cancer.

Twenty-one studies published between 1995 and 2011 were included in this analysis. One limitation of this review is the clinical heterogeneity of the studies included. To increase homogeneity, only studies performed using SF36 or with EORTC-QLQ-C30 and OES18 (or the pre-

vious version, OES24) were included. Nevertheless, virtually every study used a different surgical approach and a different means of comparison, and they also did not present exact data. Furthermore, data for the recruited patients were collected during a range of intervals after surgery. Therefore, it was very difficult and sometimes impossible to obtain sufficiently homogeneous data to recalculate the statistical analyses or perform a meaningful meta-analysis. For example, 5 studies analyzed long-term generic HRQL after esophagectomy in comparison with that of healthy subjects using SF-36 questionnaires distributed at roughly comparable intervals after esophagectomy[49,50,52-54] but two studies could not be used for the meta-analysis, one because the SF-36 scores were not reported in a standard or comparable way and the other because all patients underwent esophagocoloplasty[50,52].

On the other hand, the remaining three studies were sufficiently homogenous, and thus, a meta-analysis of their results was attempted[49,53,54]. In these three studies, the pooled scores for physical, role, and social function after esophagectomy were similar to sex- and age-matched United States norms. In contrast, in a group of patients with similar follow-up, Djärv *et al*[62] and Courrech *et al*[63] observed significantly poorer role and social function. Differences between the HRQL measurement tools (SF36 and QLQ C30) may have created this difference in the results, and cross-cultural differences among the different groups of patients may also have been a factor. Health-related quality of life may vary from one population to another according to differences in cultural heritage, value systems, family structure, medical systems, values and norms related to illness-related communication, and other factors[67].

In the three studies that analyzed long-term generic HRQL after esophagectomy *vs* in healthy subjects, the pooled physical function, vitality and general health perception scores were lower than the sex- and age-matched norms[49,53,54]. Similarly, in patients alive at 3 years analyzed using the EORTC-QLQ-C30 and OES18, Djärv *et al*[62] and Courrech *et al*[63] reported encountering significantly more problems with fatigue, diarrhea, appetite loss, nausea and vomiting than in the reference population. Moreover, Lagergren *et al*[61] and Fagevik *et al*[60] observed that scores for physical function, breathlessness, diarrhea, and reflux were significantly worse than at the baseline. Finally, also in the three studies that prospectively analyzed generic and disease-specific HRQL using QLC-30 and OES-18 questionnaires after neoadjuvant therapy and esophagectomy, the EORTC C30 global scale results tended to be worse 6 mo after esophagectomy, as were physical function, fatigue, dyspnea and diarrhea[55-57]. Physical function impairment is a long-term consequence of esophagectomy that can involve either the respiratory system (which can be impaired by the thoracotomy sequelae) or the alimentary tract (which can be affected by accelerated transit and functional sequelae).

In contrast, in the three studies that compared HRQL after esophagectomy to that of healthy subjects using SF-36, bodily pain and mental health in long-term survivors after esophagectomy was higher than normal[49,53,54]. Similarly, in the three studies that prospectively analyzed generic and disease-specific HRQL using QLC-30 and OES-18 questionnaires after neoadjuvant therapy and esophagectomy, emotional function was significantly better at the time of the 6-mo follow up[55-57]. Moreover, Lagergren *et al*[61] observed that long-term survivors reported significantly better emotional function even 3 years after surgery. The short- and long-term improvement in emotional function in patients successfully operated on for esophageal cancer may be attributed to their sensation of having been quite close to death and having survived. In our opinion, this experience is different to that of having survived a car accident because of the duration, which can give patients sufficient time to experience the challenge in a positive way. On the other hand, it should be noted that this improved emotional function was observed in survivors.

Several studies analyzed a specific aspect of HRQL after esophagectomy. Two studies prospectively analyzed generic and disease-specific HRQL after minimally invasive esophagectomy[58,59]. The surgical techniques reported on in both studies were similar, and thus, it was possible to compare the results. The results were similar to those report by larger studies performed with group of patients who had undergone open esophagectomy, in that these patients experienced significantly improved social function, cognitive function, emotional function and dysphagia. However, physical function worsened 6 mo after esophagectomy[58,59]. In their direct comparison, Wang *et al*[59] concluded that global quality of life and physical functioning were better in the minimally invasive group than in the open surgery group. Additional larger studies should explore the exact benefit of minimally invasive esophagectomy in terms of HRQL.

Data from a Swedish nationwide, prospective, population-based study were used in three studies by the Karolinska Institute, Stockholm that investigated the most important predictors of HRQL after surgery for esophageal cancer using data from 6 mo after surgery[45-47]. Unexpectedly, extensive surgery, as used in the transthoracic approach, was not associated with lower HRQL than less invasive operations[46]. No clinically relevant differences in generic or disease-specific HRQL were observed based on the volume of procedures done at hospitals[47]. Age, sex, and body mass index showed no association with HRQL 6 mo after surgery, but patients with comorbidity, tumors in a more advanced stage (Ⅲ to Ⅳ), or tumors located in the middle or upper esophagus exhibited an increased risk of poor HRQL. Moreover, the occurrence of surgery-related complications was the main predictor of reduced postoperative HRQL[45,47]. Except for anastomotic strictures, each of the predefined complications (e.g., anastomotic leakage, infections, cardiopulmonary complications, and operative technical complications) decreased the patients' HRQL scores. In patients with non-neoplastic diseases such as Crohn's disease or ulcerative

colitis, postoperative complications did not seem to have a long-term effect on HRQL[68,69], so the reasons why patients submitted to esophagectomy can experience postoperative complications that can heavily affect HRQL must be different. Firstly, a 6-mo follow-up period may be not sufficiently long enough, as the problems caused by the complications may be still ongoing. Secondly, the different type of surgery that implies usually has thoracotomy play a direct role. In fact, the complications of a thoracotomy may have direct implications for dyspnea, fatigue and pain.

Some articles analyzed more peculiar aspects of HRQL after esophagectomy[48,64,65]. The observation that patients who received palliative treatment had significantly worse pain, fatigue, appetite loss, constipation, and dysphagia might be expected[64]. In contrast, the results presented by Ariga *et al*[65] are much less expected. They observed that patients with squamous cell carcinoma who underwent definitive chemoradiation had similar general HRQL scores and lower diarrhea, appetite loss and eating problem scores than those who had undergone surgery alone[65]. These results could be mainly attributed to the effect of the loss of function of the stomach transposed in the thorax. Schneider *et al*[48] observed the persistence of decreased physical functioning in patients who had undergone elective esophagectomy for cancer, as compared to patients who had undergone emergency esophagectomy for benign conditions. The conclusions of this study may suggest that the long-term impairment of physical functioning could be due more to the cancer itself or to radiation/chemotherapy than to esophagectomy. Finally, the analysis of the HRQL after endoscopic treatment and surgery for early Barrett's neoplasia showed that conservative, non-definitive treatments such as endoscopic ablation may cause more fear of recurrence than more invasive but definitive treatments, such as esophagectomy[51]. Fear of cancer recurrence may negatively impact HRQL, and proper counseling may be advisable when patients elect such options[51].

In conclusion, short- and long-term generic and disease-specific HRQL is deeply affected by esophagectomy for cancer. The impairment of physical function may be a long-term consequence of esophagectomy and can involve either the respiratory system (which can be impaired by the thoracotomy sequelae) or the alimentary tract (which can be affected by accelerated transit and functional sequelae). The short- and long-term improvement in the emotional function of patients who have been successfully operated on may be attributed to their impression of having survived a near-death experience.

Abstract

AIM: To determine the apoptosis pathway in residual viable hepatocellular carcinoma (HCC) tissues following transarterial embolization (TAE).

METHODS: Ten patients with HCC who received surgical resection after TAE were enrolled in the study group, and 24 patients with HCC who received surgical resection only served as the control group. In the study group, we measured the changes in tumor size and α fetoprotein (AFP) levels after TAE. All tissue samples were taken from the residual tumors. The expression of various apoptotic proteins was evaluated *via* immunoblotting procedures. The results were analyzed using a Student's *t* test.

RESULTS: Tumor size and the AFP level decreased by 46.2% and 55.3% after TAE, respectively. There was no significant difference detected for the Bcl-2/Bax ratio or the cleaved caspase-9 expression levels in either group. However, extrinsic apoptopic pathway-related expression of Fas and cleaved caspase-8 expression were significantly higher in the study group than in the control group ($P < 0.05$). In addition, cleaved caspase-3 expression in the study group was higher (1.62-fold) than in control group ($P < 0.05$).

CONCLUSION: TAE is an effective palliative therapy that decreases tumor size and AFP levels *via* an increase in extrinsic apoptosis pathway in patients with unresectable HCC.

Key words: Apoptosis; Hepatocellular carcinoma; Transarterial embolization

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant cancers in the world[1,2]. Generally, HCC is induced by chronic liver injury such as liver cirrhosis. The chronic injury leads to a change in the cellular properties of the liver and curtails the delivery of blood throughout the liver. Subsequently, this pathological change leads to a reduction in blood circulation throughout the liver and accompanying hypoxia. The increased cellularity associated with the highly proliferative tumor cells also induces local hypoxia inside the actual HCC[3]. Hypoxia can stimulate angiogenesis to support tumor growth by inducing angiogenic factors[3,4]. Many people with advanced HCC have tumors that are unresectable by the time of disease diagnosis. Transarterial embolization (TAE) appears to be as effective as transarterial chemoembolization (TACE) and plays a major role in the treatment of patients with advanced HCC[5,6]. However, the exact molecular changes and apoptotic pathway activity of cancerous tissues following embolization still needs to be elucidated.

Several studies have reported that TACE inhibits tumor angiogenesis and induces tumor cell apoptosis. Other studies have found that TACE stimulates tumor angiogenesis and increases the proliferative activity of the tumor cells due to anoxic stress-related Bcl-2 overexpression[7,8]. Unfortunately, most previous papers neglected to examine the counter factor of apoptotic protein (Bax) expression in residual viable cancerous tissues following TAE in HCC patients. We examined the expression of apoptotic proteins in the specimens taken from both groups (surgical resection only and surgery after TAE) of HCC patients. To determine whether the intrinsic or extrinsic apoptotic pathways were involved, we examined the Bcl-2/Bax ratio (anti-apoptosis protein/an inducer of apoptosis), cleaved caspase-9, Fas, cleaved caspase-8 and cleaved caspase-3 expression levels.

To our knowledge, this is the first report to study the apoptotic pathway in the residual viable cancerous tissues of HCC patients following TAE. A better understanding of the molecular changes and apoptotic pathways associated with HCC will aid in the development of more effective future therapies.

MATERIALS AND METHODS

Patients and tissue samples

From January 2006 to December 2009, we enrolled 10 patients (6 men and 4 women; average age, 53.6 years) with HCC as a study group. All 10 patients received TAE with 95% alcohol and Gelform due to poor liver function and relative high initial risks for operation. The study group patients then underwent hepatic resection three weeks after the TAE. During the same period, we enrolled 24 patients (16 men and 8 women; average age, 54.4 years) who only received surgical resection for HCC as a control group. All liver tumor tissues were stored at -80 ℃ for immunoblotting (including Bcl-2/Bax ratio, cleaved caspase-9, Fas, cleaved caspase-8 and cleaved caspase-3) or fixed in formalin for immunohistochemical (IHC) staining (including caspase-9, caspase-8 and cleaved caspase-3). Simultaneously, we measured the changes in tumor size and α fetoprotein (AFP) in the study group after TAE. The specimens were removed only after written informed consent was obtained from the patients. This study was approved by the Institute Ethics Committee of Taichung Armed Forces General Hospital.

Antibodies

Nine types of primary antibodies were used in the present study: (1) Bcl-2, a mouse monoclonal antibody (sc-7382, Santa Cruz, Santa Cruz, CA, United States; dilution 1:500 for immunoblotting); (2) Bax, a mouse monoclonal antibody (sc-7480, Santa Cruz; dilution 1:200 for immunoblotting); (3,4) caspase-9, two rabbit polyclonal antibodies for immunoblotting (No. 9502, Cell Signaling, Beverly, MA, United States; dilution 1:1000) and IHC staining (sc-8355, Santa Cruz; dilution 1:100); (5) Fas, a rabbit polyclonal antibody (sc-7886, Santa Cruz; dilution 1:400 for immunoblotting); (6,7) caspase-8, a mouse monoclonal antibody for immunoblotting (No. 9746, Cell Signaling; dilution 1:1500) and a goat polyclonal antibody (sc-6134, Santa Cruz; dilution 1:50 for IHC staining); (8) cleaved caspase-3, a rabbit monoclonal antibody (No. 9664, Cell Signaling; dilution 1:1000 and 1:50 for immunoblotting and IHC staining, respectively); and (9) β-actin, a mouse monoclonal antibody (No. 8226, Abcam, Cambridge, MA, United States; dilution 1:8000 for immunoblotting). The secondary antibodies used were horseradish peroxidase (HRP)-conjugated goat anti-mouse IgG (No. 0031430, Pierce, Hercules, CA, United States; for detection of Bcl-2, Bax, caspase-8 and β-actin) and goat anti-rabbit IgG (No. 0031460, Pierce; for detection of caspase-9, Fas and cleaved caspase-3) for immunoblotting or a commercial kit (PicTure™; Zymed, South San Francisco, CA, United States) for IHC staining.

Immunoblotting

The immunoblotting method was modified from our previous studies[9,10]. In brief, aliquots containing 100 μg of sample supernatants were added to the sample buffer and heated at 95 ℃ for 5 min. After electrophoresis and transformation, blots (polyvinylidene fluoride membranes; Millipore, Bedford, MA, United States) were preincubated in phosphate buffer saline with 0.05% Tween 20 (PBST) buffer containing 5% (wt/vol) nonfat dried milk to minimize non-specific binding. According to the manufacturer's manual, Bcl-2, Bax, cleaved caspase-9, Fas, cleaved caspase-8, cleaved caspase-3 and β-actin antibodies should bind to proteins with molecular weights of about 26, 23, 35-37, 48, 43, 17-19 and 44 kDa, respective-

ly. The blots were cut into upper and lower parts at feasible sites for the incubations. The blots were incubated with the primary antibodies diluted in 1% bovine serum albumin and 0.05% sodium azide in PBST. The blots were then incubated with HRP-conjugated secondary antibody diluted in PBST. The blots were developed using a SuperSignal West Pico Detection Kit (No. 34082, Pierce). After development, the immunoblots were scanned and imported as TIFF files. All immunoreactive bands were analyzed using MCID software version 7.0 (Imaging Research, Ontario, Canada). The results were converted to numerical values to compare the relative protein abundance of the immunoreactive bands.

Immunohistochemical staining

The immunohistochemical (IHC) staining method used was modified from our previous study[9]. In brief, the sections were stained with primary antibody (caspase-9, caspase-8 or cleaved caspase-3) or PBS (negative control) before being analyzed with the commercial kit. The sections were observed under light microscope (model BX50; Olympus, Tokyo, Japan), and the micrographs were reviewed.

Statistical analysis

All data were analyzed using the Student's *t* test with $P < 0.05$ being considered statistically significantly different. Values were expressed as the mean ± SE.

RESULTS

The tumor size and AFP levels decreased by about 46.2% and 55.3%, respectively, following TAE (Table 1). The Bcl-2/Bax ratio and cleaved caspase-9 expression levels, both indicative of the intrinsic apoptosis pathway, demonstrated no statistical differences between the groups ($P > 0.05$; Figures 1 and 2A; Table 2). However, the expression levels of Fas and cleaved caspase-8, both involved in the extrinsic apoptosis pathway, were significantly higher in the study group ($P < 0.05$; Figure 2C and D; Table 2). Cleaved caspase-3 expression in the study group was also higher than in the control group ($P < 0.05$; Figure 2B; Table 2). Representative sections from study group patients (Figure 3A-D) and control group patients (Figure 3E-H) for IHC staining (caspase-9, caspase-8 and cleaved caspase-3) supported the immunoblotting results.

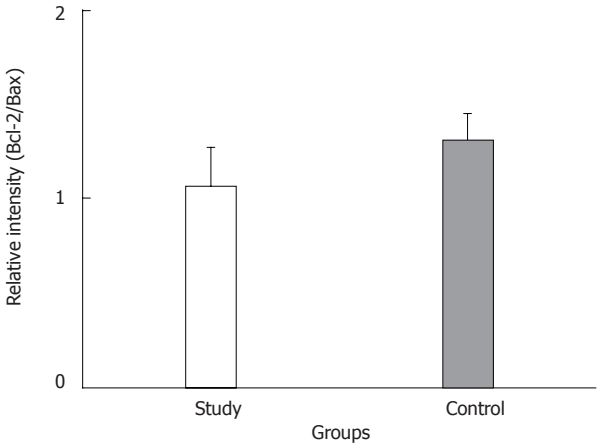

Figure 1 Relative intensity (ratio) of protein abundance of Bcl-2 to Bax in the study and control groups. Study: HCC post-TAE; Control: HCC. HCC: Hepatocellular carcinoma; TAE: Transarterial embolization.

These findings demonstrated that the decreased tumor size and AFP levels in HCC patients following TAE resulted from increased activity of the extrinsic apoptosis pathway.

DISCUSSION

HCC is one of the most common and lethal malignant tumors worldwide. The late diagnosis and advanced underlying liver cirrhosis responsible for HCC generally makes complete resection non-viable. TACE is one of the most validated treatments for unresectable HCC in patients with preserved liver function[11-13]. Several studies have reported that TACE inhibits tumor angiogenesis and induces tumor cell apoptosis[7,14]. Conversely, other studies indicate that TACE stimulates tumor angiogenesis and increases proliferative activity of the tumor cells due to hypoxic stress-induced Bcl-2 overexpression[7,8]. Hypoxia enhances proliferation, angiogenesis, metastasis, chemoresistance and radioresistance to suppress differentiation and apoptosis of HCC[15]. Therefore, combining therapies that induce and target hypoxia may be beneficial to HCC patients. TAE appears to be as effective as TACE in improving survival rates of cirrhotic HCC patients[5,6,16]. TAE allows local tumor response to reach 88%, and in addition, bleeding control can be increased

from 83% to 100%[17,18]. However, there have been no further studies investigating the molecular changes and apoptotic pathways of residual viable HCC tissues following TAE.

Apoptosis, in multicellular organisms, plays an important role in development and tissue homeostasis[19-21]. The two major mechanisms of cell death are referred to as the intrinsic and extrinsic pathways. The intrinsic (or mitochondrial) pathway is induced by cellular stress, which involves Bcl-2, Bax, mitochondrial outer-membrane permeability and caspase-9 protein. The extrinsic (or death receptor) pathway is induced by specific ligands that engage death receptors, which generally involves Fas and the binding and activation of caspase-8 protein[22-24]. In the human apoptotic pathway cascade, 14 caspases (cysteinyl aspartate-specific proteinases) have been discovered to date[25,26]. Among them, caspase-3 is considered the most crucial executioner protease, as it is essential for apoptotic death in mammalian cells[27].

In this study, tumor size and AFP level were decreased by 46.2% and 55.3% following TAE, respectively. There was no significant difference of Bcl-2/Bax ratio and cleaved caspase-9 expression in either group. However, the expression levels of Fas and cleaved caspase-8, both involved in the extrinsic pathway, were significantly higher in the study group than in control group. In addition, increased cleaved caspase-3 expression was also observed in the TAE group (1.62-fold over the control group level). These findings demonstrate increased apoptosis through the extrinsic pathway in HCC patients following TAE. Previous studies had not examined the expression of proliferative and apoptotic proteins (Bcl-2

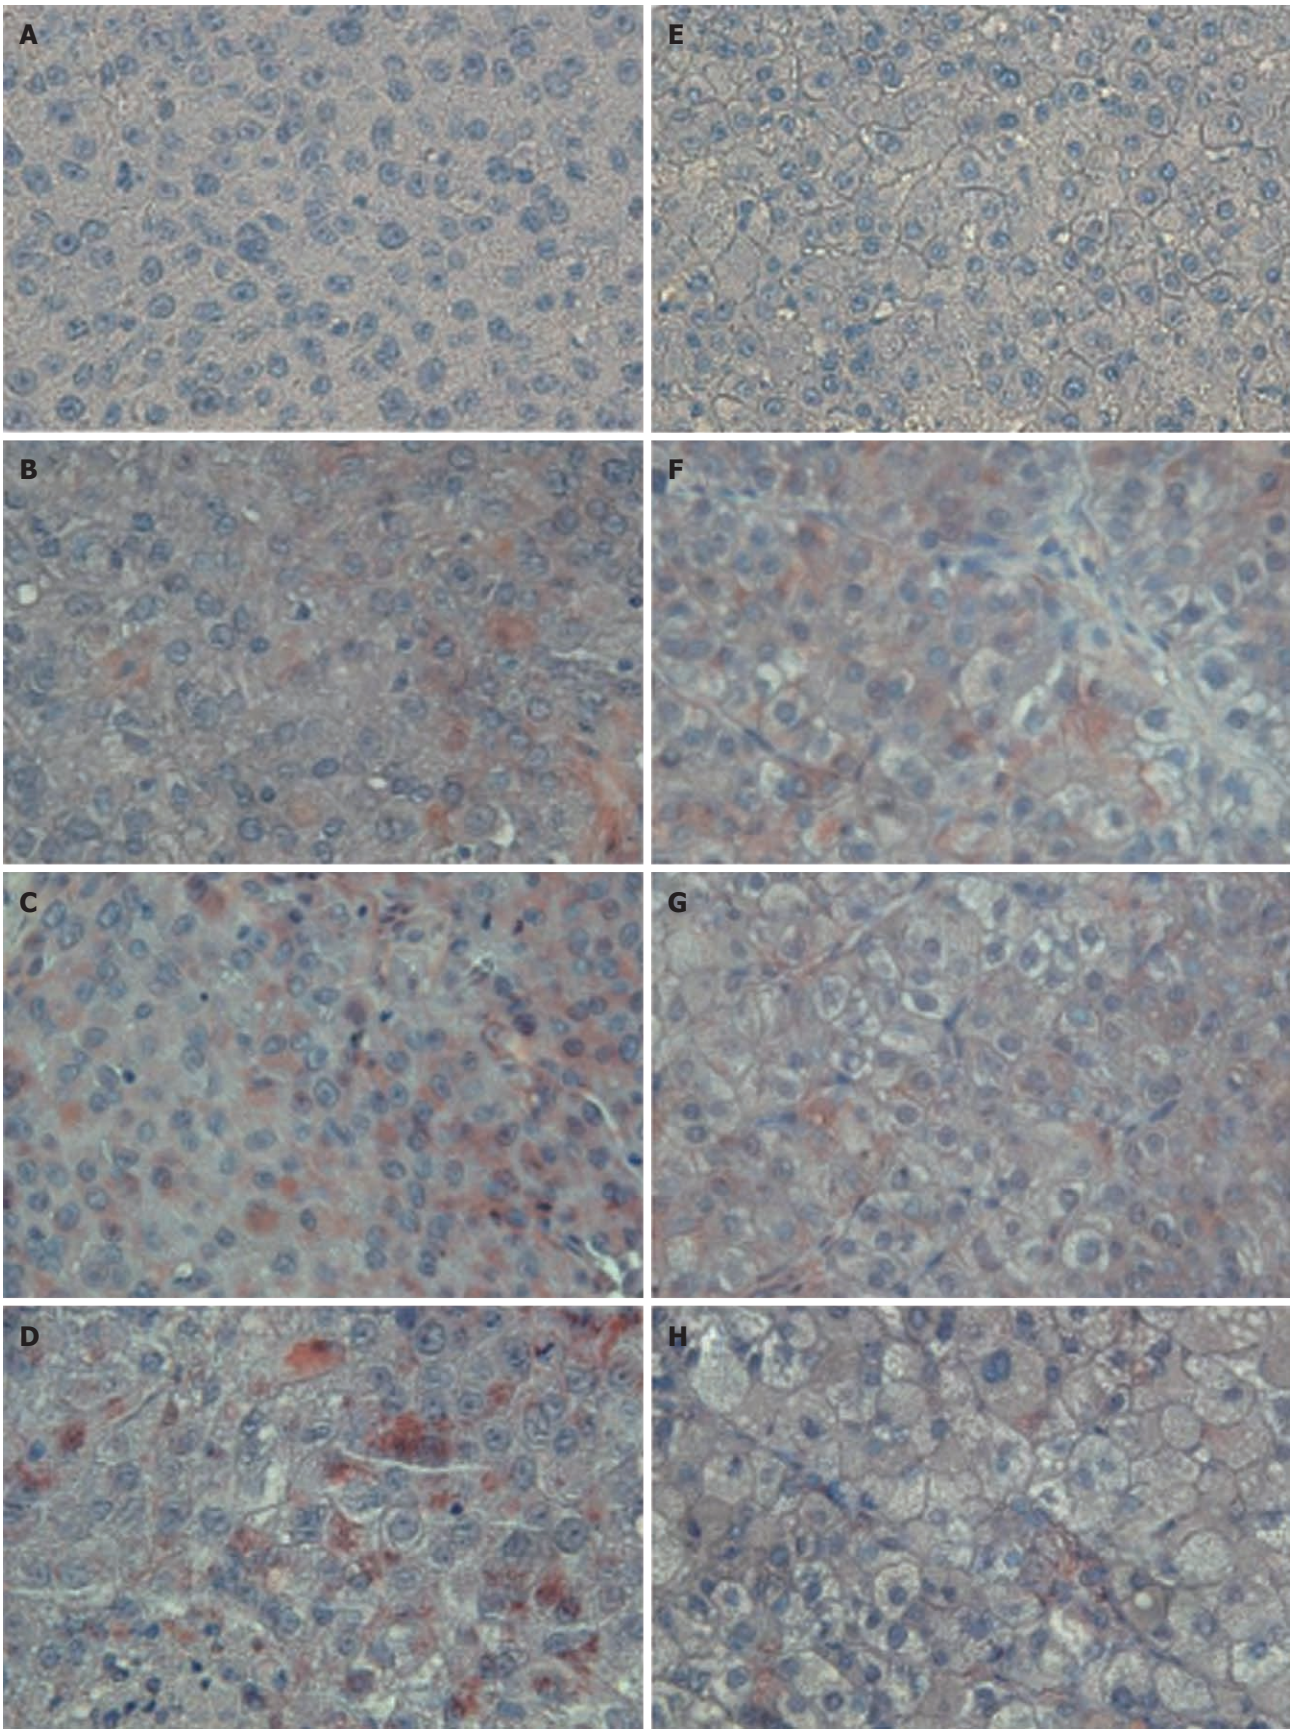

Figure 3 Representative sections of patients from the study (A-D) and control (E-H) groups after hematoxylin staining (negative control, A and E), caspase-9 immunostaining (B and F), caspase-8 immunostaining (C and G) or cleaved caspase-3 immunostaining (D and H). Study: HCC post-TAE; Control: HCC. Higher immunoreactivity of caspase-8 and cleaved caspase-3 stain was observed in the study group than in the control group. and Bax) in residual viable HCC tissues simultaneously.

In conclusion, our data indicate that TAE is an effective palliative therapy that decreases tumor size and AFP levels *via* increasing the extrinsic apoptosis pathway in patients with unresectable HCC. Thus, it would be of interest to investigate whether increasing the expression of extrinsic apoptotic proteins could provide more effective treatment for patients with HCC.

COMMENTS

Background

Transarterial embolization (TAE) plays a major role in the treatment of patients with unresectable hepatocellular carcinoma (HCC). However, the apoptotic pathway of residual viable HCC tissues following TAE remains unclear. Elucidating the apoptosis pathway associated with residual viable HCC following a TAE procedure should aid in the development of more effective therapies in the future.

Research frontiers

To evaluate potential therapeutic effects, the authors examined the changes in tumor size and α fetoprotein (AFP) levels following TAE. There are two major mechanisms of cell death, and the intrinsic and extrinsic pathways. The intrinsic (or mitochondrial) pathway is induced by cellular stress, which involves Bcl-2, Bax and caspase-9 protein. The extrinsic (or death receptor) pathway is induced by specific ligands that engage death receptors, which involves Fas and the binding and activation of caspase-8 protein. Caspase-3 is considered as the crucial executioner protease because it is essential for apoptotic death in mammalian cells. All of these apoptotic proteins were examined during this study.

Innovations and breakthroughs

This is the first report to study the apoptotic pathway in the residual viable cancerous tissues of patients with HCC following TAE. A better understanding of the molecular changes in and apoptotic pathways of HCC should lead to the development of more efficacious therapies in the future.

Applications

TAE is an effective therapy for decreasing tumor size and AFP levels *via* increasing the extrinsic pathway apoptosis in patients with unresectable HCC. Thus, it would be of interest to investigate whether further increasing the expression of extrinsic apoptotic proteins could provide more effective treatment for patients with HCC.

Peer review

This is a study showing different expression of apoptotic proteins in residual viable HCC tissues in patients subjected to TAE or not. The authors demonstrated that in TAE group there is a significant increase of apoptosis through extrinsic pathway.

Abstract

AIM: To evaluate the accuracy of two non-invasive tests in a population of Alaska Native persons. High rates of *Helicobacter pylori* (*H. pylori*) infection, *H. pylori* treatment failure, and gastric cancer in this population necessitate documentation of infection status at multiple time points over a patient's life.

METHODS: In 280 patients undergoing endoscopy, *H. pylori* was diagnosed by culture, histology, rapid urease test, ^{13}C urea breath test (UBT), and immunoglobulin G antibodies to *H. pylori* in serum. The performances of ^{13}C-UBT and antibody test were compared to a gold standard defined by a positive *H. pylori* test by culture or, in case of a negative culture result, by positive histology and a positive rapid urease test.

RESULTS: The sensitivity and specificity of the ^{13}C-UBT were 93% and 88%, respectively, relative to the gold standard. The antibody test had an equivalent sensitivity of 93% with a reduced specificity of 68%. The false positive results for the antibody test were associated with previous treatment for an *H. pylori* infection [relative risk (RR) = 2.8]. High levels of antibodies to *H. pylori* were associated with chronic gastritis and male gender, while high scores in the ^{13}C-UBT test were associated with older age and with the *H. pylori* bacteria load on histological examination (RR = 4.4).

CONCLUSION: The ^{13}C-UBT outperformed the antibody test for *H. pylori* and could be used when a non-invasive test is clinically necessary to document treatment outcome or when monitoring for reinfection.

Key words: Urea breath test; Antibody test; Sensitivity; Specificity

INTRODUCTION

Helicobacter pylori (*H. pylori*) infection has been associated with peptic ulcer disease, gastric cancer, and acute gastritis[1]. Alaska Native persons have a high seroprevalence of *H. pylori* (75% all ages)[2], along with high rates of gastric cancer[3]. In rural Alaska, *H. pylori* seroprevalence is as high as 69% by the ages of 5-9 years and 87% among 7-11 year olds, as measured by the urea breath test (UBT)[4]. These findings have led to research investigations on *H. pylori* treatment outcome, reinfection rates after treatment, and the association of *H. pylori* infection with anemia in this population[4-8]. In Alaska, antimicrobial resistance rates in *H. pylori* are as high as 63% for metronidazole, 31% for clarithromycin, and 9% for levofloxacin[5,9,10]. Along with high levels of antimicrobial resistance, treatment failure rates approaching 30% in urban Alaska and 45% in rural Alaska have been demonstrated. The rate of *H. pylori* reinfection in Alaskan adults after two years was 14.5%[6]. In rural Alaskan children, aged 7 to 11 years, the reinfection rate exceeded 50% 32 mo after documented successful treatment[11]. Tests are needed after esophagogastroduodenoscopy (EGD) to document cure and continued infection-free status because of high rates of treatment failure and reinfection for *H. pylori*. Tests dependent on an EGD are not feasible for sequential follow-up or for longitudinal research studies. In rural and remote study populations, EGD testing is not available. Additionally, the cost and invasiveness of an EGD make *H. pylori* tests that are dependent upon them impractical in some settings.

This investigation was conducted as part of an Alaskan *H. pylori* reinfection study in which we enrolled persons scheduled for EGD over a three year period, treated them for *H. pylori*, and then followed them for two years with the ^{13}C-UBT test. As part of a secondary objective, we enrolled persons both positive and negative for *H. pylori* infection who were undergoing EGD for clinical indications. We aimed to determine the accuracy of non-invasive *H. pylori* tests compared to the invasive gold standard tests, based on samples obtained during EGD. The non-invasive tests that were considered in this evaluation were the ^{13}C-UBT and the detection of immunoglobulin G (IgG) antibodies to *H. pylori* (anti-HP) in serum. The invasive tests evaluated in this study were culture, histology and rapid urease test [campylobacter-like organism (CLO) test®]. We also sought to determine if the performance of the ^{13}C-UBT and the antibody assay could be improved through use of different cut-off points. Additionally, we examined whether the quantitative level of anti-HP or the ^{13}C-UBT were associated with clinical characteristics of the *H. pylori* infection, such as the presence of a peptic ulcer and the severity of gastritis, in this Alaskan population.

MATERIALS AND METHODS

Patients

Persons ⩾ 18 years of age undergoing EGD for clinical indications at the Alaska Native Medical Center (ANMC) in Anchorage, Alaska gave their consent to participate in an *H. pylori* reinfection study between September 1998 and December 2000. A description of this study cohort has been previously published[6]. From this cohort, we conducted a cross-sectional analysis to determine the sensitivity and specificity of five tests for *H. pylori*: serology, culture, CLO test® (Ballard Medical Products, Draper, UT, United States), histology and ^{13}C urea breath test (BreathTek™ UBT; Meretek Diagnostics Inc., Lafayette, CO, United States). The result of the breath test is measured as the delta over baseline (DOB), which is the difference between the ratio $^{13}CO_2/^{12}CO_2$ after and before consumption of a Pranactin-Citric solution containing ^{13}C-urea. The participants were recruited prior to EGD; therefore, the cohort consisted of persons both positive and negative for *H. pylori*. Upon enrollment, a medical chart review was performed at ANMC to determine the participants' history of: peptic ulcer disease, previous EGD procedures, and previous treatment for an *H. pylori* infection. Endoscopic findings documented during EGD included location and type of ulcer and presence of antral and fundal gastritis.

This study was approved by the Centers for Disease Control and Prevention Institution Review Board (IRB), the Alaska Area IRB of the Indian Health Service, the Southcentral Foundation Board, as well as the Alaska Native Tribal Health Consortium Board of Directors. Written informed consent was obtained from all participants.

Laboratory methods

At the time of EGD (initial enrollment), blood was drawn and a ^{13}C-UBT test was administered. Sera were tested for *H. pylori*-specific IgG by an in-house enzyme-linked immunosorbent assay (ELISA), as described previously[7]. Sera were negative if the optical density (OD) was ⩽ 0.3, positive if ⩾ 0.5, and indeterminate if in between. In-house ELISA cut-offs were determined using 254 sera collected from a previous study[7].

All participants had up to three gastric biopsy specimens taken for testing for *H. pylori* from the antrum and the fundus of the stomach. One biopsy was taken, as per the manufacturer's instructions for the CLO test®, for the detection of urease. Biopsies were stained with Diff-Quik® (Mercedes Medical, Sarasota, FL, United States) stain, for identification of *H. pylori*, and with hematoxylin and eosin stain for histological evaluation. A research pathologist examined both histological slides for the presence of intestinal metaplasia, acute and chronic gastritis, and the amount of *H. pylori* present, according to the Updated Sydney System[12]. The final one or two biopsies were used to culture *H. pylori*. Cultures were incubated at 37 ℃, 12% CO_2, and 98% humidity for up to 10 d. Isolates were identified as *H. pylori* on the basis of positive catalase, oxidase, and urease reactions, typical colony morphology, and curved gram-negative bacilli on gram-stained smears.

Table 1 Characteristics of 280 patients enrolled in Anchorage, Alaska undergoing esophagogastroduodenoscopy during 1999 and 2000

Characteristic	% (*n*)
Mean age (min, max)	48 yr (19, 88)
Sex (female)	66% (184)
Medical chart review	
History of peptic ulcer disease	19% (53)
Previous EGD	32% (90)
Previously treated for *H. pylori*	23% (63)
Endoscopist evaluation during EGD	
Moderate-severe gastritis	41% (115)
Mild-no gastritis	59% (165)
Ulcer	9% (25)

EGD: Esophagogastroduodenoscopy; *H. pylori*: *Helicobacter pylori*.

Table 2 Percent positive for *Helicobacter pylori* by test type among 280 patients enrolled in Anchorage, Alaska for an *Helicobacter pylori* reinfection study, 1999-2000

Test type		% *H. pylori* positive (*n*/*N*)
Histology	Antrum	49% (135/278)
	Fundus	46% (124/271)
	Combined	50% (140/280)

[1]Rapid urease test, Ballard Medical Products. [2]A positive culture or in the case of a negative culture, a positive histology result and a positive campylobacter-like organism (CLO) test®. [13]C urea breath test (UBT)[3], Breath-Tek™, Meretek Diagnostics Inc. *H. pylori*: *Helicobacter pylori*; Anti-HP IgG: Antibodies to *H. pylori* immunoglobulin G.

Statistical analysis

The gold standard used to compare test accuracies was a positive result by culture or in the case of a negative culture, a positive result by both histology and CLO test®. Test accuracy was the number of true positives plus true negatives divided by the total sample size. The manufacturer's recommended cut-off (DOB ≥ 2.4) for the ^{13}C-UBT test was used for definition of a positive *H. pylori* result for analysis.

RESULTS

The characteristics of the 280 patients who underwent EGD are shown in Table 1. The mean age of participants was 48 years and 66% were female. Of the 280 participants, 155 (55%) were positive by the ^{13}C-UBT test (Table 2). Ninety-two persons tested positive for anti-HP IgG (OD value ≥ 0.5), 168 persons tested negative (OD value ≤ 0.3), and 20 were indeterminate. If persons with indeterminate results by the antibody test are considered negative for *H. pylori* infection, then 60% of the entire 280 persons were positive by serology (Table 2). However, if those with indeterminate results were removed, then 65% were positive for *H. pylori* antibodies (Table 2). Of the 280 participants, 50%, 51% and 49% of persons were positive for *H. pylori* by histology, culture and CLO test®, respectively. Using the gold standard of either a positive culture, or a positive result of both histology and CLO test®, 53% (149/280) of persons were positive for *H. pylori*.

The performance of the non-invasive tests in comparison to the invasive tests and the gold standard are shown in Table 3. The sensitivity of the ^{13}C-UBT test in relationship to invasive tests and the gold standard ranged from 93% to 97%. The specificity was somewhat lower, and ranged from 78% to 88% when compared against invasive tests and the gold standard. The accuracy of the ^{13}C-UBT test ranged from 86% to 90%. The sensitivity of the serological assay (detection of anti-HP) in relation to the invasive tests and the gold standard was between 92% and 93%, and the specificity ranged from 58% to 68%. The concordance of anti-HP and ^{13}C-UBT was 81%. For the two invasive tests of histology and culture, there was concordance on 89% of persons. Finally, the CLO test® had a concordance of 90% and 92% with respect to histology and culture, respectively.

The sensitivity and specificity of the anti-HP assay presented in Table 3 were calculated with the indeterminate (0.3 ≤ anti-HP OD < 0.5) results removed. The overall accuracy of the anti-HP assay against the gold standard was 81.5%. Of 118 persons negative for *H. pylori* by the gold standard, 32% (n = 38) were positive by anti-HP (representing the false positives) and 68% (n = 80) were negative by anti-HP. In these 118 persons, 55% (21/38) of persons positive by anti-HP had a previous treatment for *H. pylori* documented in their medical record compared to 20% (16/80) of persons negative for anti-HP [relative risk (RR) = 2.8, 95% CI: 1.6-4.7]. In these 118 persons, the magnitude of the anti-HP OD was positively associated with previous treatment for *H. pylori* (P < 0.0001, Figure 1). Persons with an anti-HP OD ≥ 0.8 were 4.9 times (95% CI: 2.1-11.7) more likely to have had a previous treatment for *H. pylori* than persons with an anti-HP OD < 0.15.

The receiver operating curves for the quantitative anti-HP OD measurements against the gold standard are shown in Figure 2, with indeterminate results included (n = 280). The accuracy of the serological assay was between 78%-80% for cut-off points between anti-HP OD values of 0.3 and 0.7. The accuracy of the serological test diminishes using cut-off points above an anti-HP OD value of 0.7. The sensitivity and specificity of the anti-HP assay at a cut-off point of 0.3 are 94% and 61%, respectively. At a higher cut-off point of 0.7, the specificity of the test improves to 82%, but the sensitivity decreases from 94% to 76%. At no cut-off point does the accuracy of the anti-HP assay exceed 80% when the indeterminate results are included. The optimal cut-off point when including the indeterminate results was an

[1]Antibodies to *Helicobacter pylori* (*H. pylori*) immunoglobulin G optical density (anti-HP IgG OD) was associated with male gender [$P < 0.0001$, odds ratio (OR) = 6.2] and chronic gastritis ($P = 0.003$, OR = 5.8) on multivariate analysis. [2]Delta over baseline (DOB) from ^{13}C urea breath test (UBT) test was associated with numerous *H. pylori* ($P = 0.0005$, OR = 3.6) and older age ($P = 0.01$, OR = 2.5) on multivariate analysis.

anti-HP OD value of 0.5, which resulted in a test accuracy of 79.6%. A high anti-HP OD among persons positive for *H. pylori* by the gold standard was associated with male gender and chronic gastritis on histological examination (Table 4). The association with chronic gastritis was stronger in the antral specimen ($P = 0.02$) than the fundal specimen ($P = 0.25$).

The overall accuracy of the ^{13}C-UBT test against the gold standard was 91%, with an area under the curve value of 0.97 (Figure 2). The accuracy of the ^{13}C-UBT test was above 90% for all values in between a DOB of 2.0 and 4.0 and was highest, at 93%, between 2.8 and 3.0. Using a lower value of 2.0 as the cut-off point (91% accuracy) resulted in false negative and positive rates of 5% and 12%, whereas use of a higher value of 4.0 (90% accuracy) resulted in false negative and positive rates of 15% and 5%, respectively. The ^{13}C-UBT had a specificity and positive predictive value of 100% for cut-offs ⩾ 7.0 DOB. Additionally, among persons positive for *H. pylori* by the gold standard, a high ^{13}C-UBT DOB was associated with the number of *H. pylori* organisms seen on histological slides and age ⩾ 50 years (Table 4). Persons with a ^{13}C-UBT ⩾ 9 DOB were 4.4 (95% CI: 1.7-11.3) times more likely to have a large number of *H. pylori* bacteria on histological examination than persons with a ^{13}C-UBT < 9 DOB (Figure 3).

DISCUSSION

Our study provides important information about the accuracy of five tests commonly used in clinical practice for the diagnosis of *H. pylori* infection. Clinicians have a

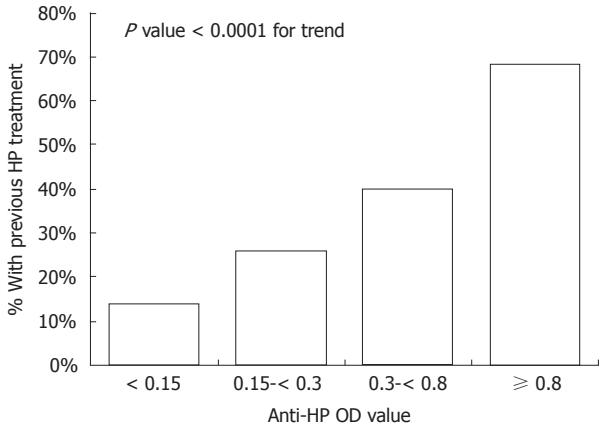

Figure 1 Among persons negative for *Helicobacter pylori* by the gold standard, the percentage of persons with a documented previous treatment for *Helicobacter pylori* according to the antibodies to *Helicobacter pylori* immunoglobulin G optical density (*n* = 118). HP: *Helicobacter polori*; OD: Optical density.

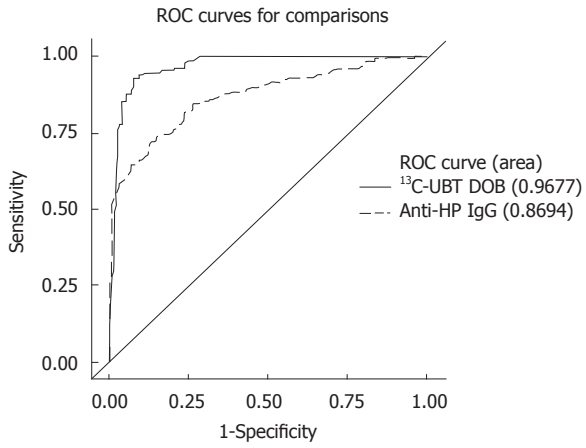

Figure 2 The receiver operating characteristic curves for anti-*Helicobacter pylori* level (serological test) and ^{13}C urea breath test delta over baseline *vs* the gold standard for *Helicobacter pylori* infection in a group of 280 Alaskans undergoing esophagogastroduodenoscopy. Gold standard was a positive *Helicobacter pylori* test by culture or, in the case of a negative culture result, a positive histology result and a positive campylobacter-like organism test. ROC: Receiver operating characteristic; UBT: Urea breath test; DOB: Delta over baseline; HP: *Helicobacter polori*; IgG: Immunoglobulin G.

variety of tests to choose from to diagnose *H. pylori* infection in patients with abdominal symptoms. The data comparing the sensitivity, specificity, and accuracy of each test are incomplete and can be confusing to clinicians. We evaluated the performance of *H. pylori* tests in a population of Alaskan native adults with a high prevalence of *H. pylori* infection (53% using the gold standard). The ^{13}C-UBT test accurately diagnosed 91% of persons relative to our gold standard, whereas the serological assay had a reduced accuracy of 81%. Our study suggests that in populations with high rates of sequelae from *H. pylori* (gastric cancer, duodenal ulcer disease), as well as high *H. pylori* treatment failure rates, and high reinfection rates after treatment, the ^{13}C-UBT test may be the best non-invasive test option available for longitudinal evaluation of *H. pylori* infection.

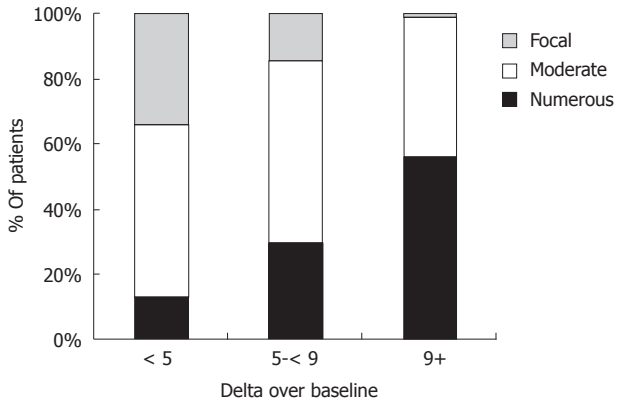

Figure 3 The amount of *Helicobacter pylori* (numerous, moderate, focal) on histological examination according to the delta over baseline value for the ^{13}C urea breath test among *Helicobacter pylori* positive persons (*n* = 149).

The antibody assay had low specificity and positive predictive value because this test can be positive in persons with a previous successfully treated *H. pylori* infection and in those with a current active infection. In this study population of urban Alaska Native adults evaluated by EGD, over 1 in 5 persons were found to have had a treatment for *H. pylori* documented in their medical records prior to entering the study. We found some persons who were negative by the gold standard tests for active infection, among whom we were able to document that the presence of anti-HP IgG was associated with previous treatment for *H. pylori*. Indeed in this group, persons with a high level anti-HP IgG were close to five times more likely to have been previously treated for *H. pylori* compared to those with low levels of anti-HP. Previously published data from this study found that the mean anti-HP IgG level was 0.64 OD units (above the assay's positive breakpoint) two years after documented successful treatment for *H. pylori*[7], demonstrating that anti-HP antibodies persist long after eradication. The antibody assay may still be suitable in treatment naïve populations in epidemiological investigations aimed at establishing baseline estimates of *H. pylori* prevalence. However, for the clinical purpose of identifying persons with active *H. pylori* infection, the antibody test has limited utility, because persons recovered from *H. pylori* infection might be mistakenly identified as harboring an active infection. In populations with a high prevalence of, and treatment for *H. pylori* infection, this assay is not optimal for use in a "test and treat" strategy in patients with dyspeptic symptoms. Patients identified by elevated antibody levels who are not actively infected may unnecessarily receive additional treatment for *H. pylori*.

We found that the anti-HP OD ⩾ 1.1 was associated with male gender and chronic gastritis as determined by histological evaluation. The finding of an association with gastritis has been documented in other studies[13-16]. Sheu *et al*[13] found the titer level of *H. pylori* to be associated with antral gastritis but not presence of ulcer,

similar to our study. In contrast, Chen *et al*[17] did not find an association with antral gastritis when restricting the analysis to *H. pylori* positive persons, an analysis similar to ours. Although the serological assay is less accurate in predicting active *H. pylori* infection in this Alaska Native population, high levels of anti-HP IgG increased the odds by 4-fold that chronic gastritis will be diagnosed by histology. The lower anti-HP level found in women could be attributable to inadvertent treatment of the *H. pylori* infection in the use of metronidazole for treating vaginal infections in women. Indeed, in this study group, women had higher levels of metronidazole use[8], and higher levels of metronidazole use were associated with lower anti-HP levels (CDC unpublished data).

With a sensitivity and specificity of 93% and 97%, respectively, using the manufacturer's recommended cut-off point, the ^{13}C-UBT provided the best non-invasive test for documentation of infection-free status. The accuracy of the test in our population compares well with performance of the UBT (both ^{13}C-UBT and ^{14}C-UBT) in other studies[18-20], and is in contrast to a recent study that found much lower specificity in Spain[21]. In our study, we found that the accuracy of the ^{13}C-UBT was > 90% with cut-off points between 2.0 and 4.0 DOB, similar to findings in other reports[22]. Additionally, we found that the DOB value was positively associated with the amount of *H. pylori* present on histological examination. Persons with very high DOB values were over four times more likely to have a high concentration of *H. pylori* bacteria than persons with low DOB values, an association documented elsewhere[23-25]. The association between the concentration of *H. pylori* organisms on histology and other pathological outcomes (gastritis, intestinal metaplasia), as well as treatment outcome, is being investigated further.

In summary, in a population in the United States with a high background prevalence of *H. pylori*, we found that the ^{13}C-UBT test outperforms the serological assay in the detection of active *H. pylori* infection. The ^{13}C-UBT avoids the problem associated with the serological test of incorrectly identifying persons who have recovered from *H. pylori* as having active infection. For clinical purposes, in persons with gastrointestinal symptoms in whom an EGD procedure is not planned, the ^{13}C-UBT appears to be useful to rule out or confirm *H. pylori* infection, and to test for a cure in persons who have been treated for *H. pylori* infection.

The authors would like to thank Catherine Dentinger, Marilyn Getty, Jim Gove, Cindy Hamlin and Susan Seidel for patient recruitment.

COMMENTS

Background

High rates of *Helicobacter pylori* (*H. pylori*) infection and antimicrobial resistance have been documented in Alaska Native persons. High infection pressure and antimicrobial resistance have led to elevated rates of treatment failure of and reinfection with *H. pylori*. Non-invasive tests, not dependent on an esophagogastroduodenoscopy (EGD), are necessary to document cure and continued infection-free status.

Research frontiers

The performances of five tests [^{13}C urea breath test (UBT), detection of immunoglobulin G (IgG) antibodies to *H. pylori* in serum, culture, histology and rapid urease test] that are commonly used in clinical practice for *H. pylori* were evaluated in 280 patients undergoing EGD at the Alaska Native Medical Center in Anchorage, Alaska.

Innovations and breakthroughs

The overall accuracy for diagnosing *H. pylori* infection was 91% for the ^{13}C-UBT test and 81% for the antibody assay. False positive results for the antibody assay were associated with previous successful treatment of *H. pylori* infection. A high antibody level was associated with histological gastritis. An elevated level for the ^{13}C-UBT test was associated with a high bacterial load of *H. pylori* on histological examination.

Applications

In a population with a high background rate of *H. pylori* infection, the authors found the ^{13}C-UBT to be the most clinically useful noninvasive test for the diagnosis and follow-up of patients with gastrointestinal symptoms.

Terminology

The result of the ^{13}C-UBT test is measured as the delta over baseline, which is the difference between the ratio $^{13}CO_2/^{12}CO_2$ after and before the consumption of a Pranactin-Citric solution containing ^{13}C-urea. Test accuracy was the number of true positives plus true negatives divided by the total sample size.

Peer review

This study is a well-done population study for the evaluation of the accuracy of two non-invasive tests (^{13}C-UBT) and the detection of IgG antibodies to *H. pylori* in serum) in a population of Alaska Native persons with high prevalence of *H. pylori* infection.

Abstract

AIM: To investigate the effectiveness of low-volume plus ascorbic acid [polyethylene glycol plus ascorbic acid (PEG + Asc)] and high-volume plus simethicone [polyethylene glycol plus simethicone (PEG + Sim)] bowel preparations.

METHODS: A total of one hundred and forty-four outpatients (76 males), aged from 20 to 84 years (median age 59.5 years), who attended our Department, were divided into two groups, age and sex matched, and underwent colonoscopy. Two questionnaires, one for patients reporting acceptability and the other for endoscopists evaluating bowel cleansing effectiveness according to validated scales, were completed. Indications, timing of examination and endoscopical findings were recorded. Biopsy forceps were used as a measuring tool in order to determine polyp endoscopic size estimation. Difficulty in completing the preparation was rated in a 5-point Likert scale (1 = easy to 5 = unable). Adverse experiences (fullness, cramps, nausea, vomiting, abdominal pain, headache and insomnia), number of evacuations and types of activities performed during preparation (walking or resting in bed) were also investigated.

RESULTS: Seventy-two patients were selected for each group. The two groups were age and sex matched as well as being comparable in terms of medical history and drug therapies taken. Fourteen patients dropped out from the trial because they did not complete the preparation procedure. Ratings of global bowel cleansing examinations were considered to be adequate in 91% of PEG + Asc and 88% of PEG + Sim patients. Residual Stool Score indicated similar levels of amount and consistency of residual stool; there was a significant difference in the percentage of bowel wall visualization in favour of PEG + Sim patients. In the PEG + Sim group, 12 adenomas $\leqslant$ 10 mm diameter (5/left colon + 7/right colon) *vs* 9 (8/left colon + 1/right colon) in the PEG + Asc group were diagnosed. Visualization of small lesions seems to be one of the primary advantages of the PEG + Sim preparation.

CONCLUSION: PEG + Asc is a good alternative solution as a bowel preparation but more improvements are necessary in order to achieve the target of a perfect preparation.

Key words: Bowel preparation; Polyethylene glycol; Ascorbic acid; Colonoscopy; Simethicone

INTRODUCTION

Colorectal cancer (CRC) is one of the most common cancers diagnosed in Western countries and it is the major cause of cancer-associated morbidity and mortality[1]. The increased demand for colonoscopy can be attributed to widespread CRC screening and surveillance[2,3]. A screening procedure, to be effective, must ensure high sensitivity and it must be both safe and tolerable in order to warrant adequate compliance in asymptomatic individuals[4].

Colonoscopy has been accepted as the gold standard for colon exploration and is considered the most effective method for assessing colonic lesions. In fact, this procedure performed in asymptomatic individuals $\geqslant$ 50 years old with no history of CRC or adenomas, and in younger high-risk patients[1,5], permits an early detection of CRC.

Several specific pre-procedure quality indicators were selected in 2006 by the American Society for Gastrointestinal Endoscopy (ASGE)/American College of Gastroenterology (ACG) taskforce on quality in endoscopy with the aim of establishing competence in colonoscopy performance. They are: (1) appropriate indication; (2) informed consent obtained; (3) use of recommended surveillance intervals; (4) use of recommended ulcerative colitis and Crohn's colitis surveillance; and (5) patient preparation[5].

An inadequate preparation can be costly in terms of missed lesions, increased risk of complications, time required for procedure, and need for repeated colonoscopies[5,6]. Moreover, patient compliance to the preparation process is often poor[7] and it remains a deterrent for patients in whom colonoscopy is required[8]. Independent predictors of an inadequate colon preparation include a later colonoscopy starting time, failure to follow preparation instructions, inpatient status, indication of constipation, use of tricyclic antidepressants, male gender, and a history of cirrhosis, stroke, or dementia[9].

The ideal colon cleansing for diagnostic and surgical procedures would reliably empty the colon of fecal material, have no effect on the gross or microscopic appearance of the colon, require a short period for ingestion and evacuation, cause no discomfort and produce no significant shifts of fluids or electrolytes[10-13]. Moreover, the cleansing regimen should be simple and suitable for inpatients and outpatients. Nowadays, available methods do not completely meet these criteria, and problems with patient compliance, safety, and adequacy of cleansing prompt continued investigation for alternative forms of cleansing.

Polyethylene glycol (PEG)-based gut lavage is an isosmotic solution that passes through the bowel without absorption or secretion. PEG has been safely used in patients with serum electrolyte imbalances, advanced hepatic dysfunction, acute and chronic renal failure and congestive heart failure[14,15]. PEG does not alter the histological features of colonic mucosa and may be used in patients suspected of having inflammatory bowel disease without obscuring the diagnostic capabilities of colonoscopy or biopsy analysis. Several PEG lavage solutions have added simethicone which is an oral antifoaming agent that decreases bloating, abdominal discomfort and abdominal pain by promoting the clearance of excessive gas along the gastrointestinal tract by reducing the surface tension of air bubbles. This combination is safe and effective (significant fluid and electrolyte shifts are avoided) but requires the consumption of large volumes of fluid in order to achieve a cathartic effect[16]. Nowadays, a low-volume PEG oral solution for colon cleansing that combines PEG with electrolytes plus ascorbic acid and sodium sulphate is gaining popularity over large volume oral lavage solutions[17]. The megadose of ascorbic acid that is not completely absorbed remains in the colonic lumen where it exerts an osmotic effect so a smaller quantity of PEG is required.

The aim of our randomized trial was to compare the PEG + ascorbic acid and sodium sulphate preparation (MoviPrep®; Norgine BV; PEG + Asc) with a PEG + simethicone preparation (Selg®-Esse 1000, Promefarm Srl, IT; PEG + Sim) in terms of cleansing effectiveness, patient compliance, physical tolerability, endoscopic findings and costs.

MATERIALS AND METHODS

A total of one hundred and forty-four outpatients (76 males), aged from 20 to 84 years (median age 59.5 years), who attended our Department of Surgical Sciences of "Sapienza" University of Rome over the period May 2009 to October 2010 and who underwent elective colonoscopy for routine clinical indications were randomized. Patients were 1:1 randomized to receive the commercially available bowel cleansing regimens: (1) 2 L of PEG + ASC (MoviPrep®; Norgine BV); and (2) 4 L of PEG + Sim (Selg®-Esse 1000, Promefarm Srl, IT). A computer-generated randomization chart was used to determine allocation. Allocation was concealed with an opaque envelope. The envelope was opened when the patient met the inclusion criteria and provided informed consent. Exclusion criteria were as follows: hospitalized patients, allergy or hypersensitivity to any constituent of both lavage solutions, and inability to fill in a questionnaire. Patient demographics, mean time of examination, indications and colonoscopy findings are shown in Table 1.

Written instructions on how to prepare and ingest the bowel preparation solution (Table 2) and dietary advice, randomly alternating between PEG + Asc and PEG + Sim, were given and explained by the endosco-

Table 2 Colonoscopy preparation schedules

PEG + Asc	2 L from 6:00 to 8:00 PM (250 mL every 15 min) plus 500 mL of clear fluid for every L of solution, evening before colonoscopy Each liter of PEG + Asc (MoviPrep®) contains 100 g macrogol 3350, 7.5 g sodium sulfate, 2.7 g sodium chloride, 1 g potassium chloride, 4.7 g ascorbic acid, 5.9 g sodium ascorbate, and lemon flavoring
PEG + Sim	2 L from 3:00 to 5:00 PM and 2 L from 6:00 to 8:00 PM (250 mL every 15 min), evening before colonoscopy Each liter of PEG + Sim (Selg®-Esse 1000) contains 58.3 g macrogol 4000, 0.08 g simethicone, 5.68 g sodium sulfate, 1.68 g sodium bicarbonate, 1.46 g sodium chloride and 0.74 g potassium chloride and mandarin aroma

A low-fiber diet (mainly the avoidance of fruits and vegetables) was recommended for three days before the endoscopy to all subjects and, the day before, they were advised to have regular breakfast, a light lunch and only clear liquids for dinner. PEG + Asc: Polyethylene glycol plus ascorbic acid; PEG + Sim: Polyethylene glycol plus simethicone.

pists or paramedical staff at the time of exam scheduling. The coordinator told all patients not to reveal to the physicians performing the colonoscopy which preparation they had taken. An informed consent form was obtained from each study subject.

Upon arrival at the endoscopy suite, patients filled in a questionnaire and were interviewed about their compliance to the assigned bowel preparation method (Appendix A). Feasibility of instructions and willingness to retake the exam in the future if needed was recorded. Difficulty in completing the preparation was rated in a 5-point Likert scale (1 = easy to 5 = unable). Adverse

Table 3 Colonoscopy preparation assessments

Aronchick scale	
1 Excellent	Small volume of clear liquid or greater than 95% of surface seen
2 Good	Large volume of clear liquid covering 5% to 25% of surface but greater than 90% of surface seen
3 Fair	Some semi-solid stool that could be suctioned or washed away but greater than 90% of surface seen
4 Poor	Semi-solid stool that could not be suctioned or washed away and less than 90% of surface seen
5 Inadequate	Repreparation needed
Residual stool score (total in sum of three score)	
Amount of residual stool	0 = none 1 = small 2 = moderate 3 = large
Consistency of residual stool	0 = none 1 = clear liquid 2 = colored liquid 3 = stool particles 4 = semi-solid stool 5 = solid stool
Percent bowel wall visualized	0 ⩾ 75% 1 = 50%-75% 2 = 25%-49% 3 ⩽ 25%

experiences (fullness, cramps, nausea, vomiting, abdominal pain, headache and insomnia), number of evacuations and types of activities performed during preparation (walking or resting in bed) were also investigated. The exams, performed by experienced endoscopists, were scheduled between 8:30 AM and 2:00 PM. Standard colonoscopies (EVIS EXERA Ⅱ video colonoscope CF-Q165I®, Olympus Europa Holding GmbH) were used for colonoscopic examinations. A minimum 6-min withdrawal time was spent. After the procedure, endoscopists filled in a questionnaire in order to evaluate the global bowel cleansing score with an Aronchick scale, as indicated in Table 3[18].

A Residual Stool Score (Table 3), based on the amount and consistency of residual stool and on the percent of bowel wall visualization[19,20], was recorded for each of five colon segments: cecum, right colon, transverse colon, left colon/sigmoid, and rectum. The three component scores from each colon segment were averaged and then summed to calculate a total residual stool score for each subject (range 0-11 for total score, 0 = best). Overall, colon cleansing efficacy was considered adequate if the ranking was 1-3 Aronchick scale score. Indications, timing of examination and endoscopical findings were recorded. Biopsy forceps were used as a measuring tool in order to determine polyp endoscopic size estimation.

χ^2 test including Yates' continuity correction was used as appropriate. A significant difference was considered when the P value was $\leqslant 0.05$. All analyses were performed using GraphPad InStat version 2.04a.

PEG + Asc: Polyethylene glycol plus ascorbic acid; PEG + Sim: Polyethylene glycol plus simethicone.

RESULTS

Seventy-two patients were selected for the PEG + Asc group and seventy-two for the PEG + Sim group. The two groups were age and sex matched as well as comparable in terms of medical history and drug therapies taken. Fourteen patients dropped out from the trial because they did not complete the preparation procedure (Table 4). Among these patients, some were unable to complete their preparations because of nausea (13 patients) and others because of vomiting. There were no significant differences in reported side effects between the PEG + Asc and the PEG + Sim groups. The most common reported side effects were nausea and vomiting (Tables 4 and 5). In 14 cases, endoscopists were unable to achieve cecal intubation: 6 patients due to lack of bowel cleansing, 6 due to a poor tolerance and 2 patients because of the presence of a malignant stricture (both in the PEG + Asc group). Rating global bowel cleansing using the Aronchick scale (Table 6): examinations were considered to be adequate in 91% of PEG + Asc and 88% of PEG + Sim patients. Residual Stool Score indicated similar levels of amount and consistency of residual stool; there was a significant difference in the percentage of bowel wall visualization in favour of PEG + Sim patients (Figure 1).

Table 6 Overall gut cleansing and cecal intubation performed

Overall gut cleansing	PEG + Asc	PEG + Sim
No. of patients	69	61
Aronchick 1	8/5	17/16
Aronchick 2	29/27	13/12
Aronchick 3	26/26	24/24
Aronchick 4	5/2	5/5
Aronchick 5	1/0	2/0

PEG + Asc: Polyethylene glycol plus ascorbic acid; PEG + Sim: Polyethylene glycol plus simethicone.

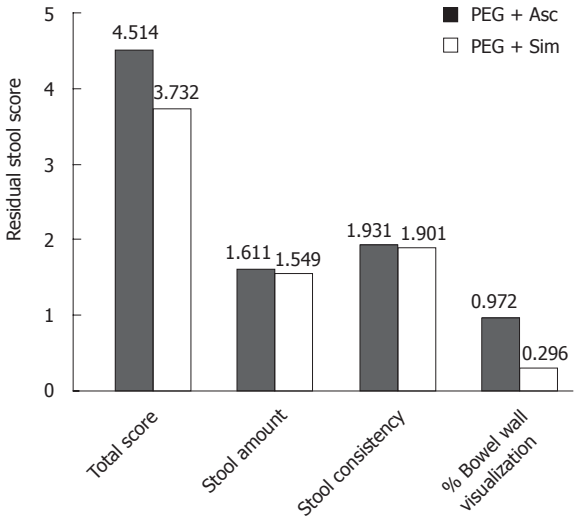

Figure 1 Residual stool score. A lower score indicates better bowel cleansing. Subjects in the PEG + Sim group demonstrated significantly lower scores for percentage of colon visualization. PEG + Asc: Polyethylene glycol plus ascorbic acid; PEG + Sim: Polyethylene glycol plus simethicone.

In the PEG + Sim group, 12 adenomas ⩽ 10 mm in diameter (5/left colon + 7/right colon) *vs* 9 (8/left colon + 1/right colon) in the PEG + Asc group were diagnosed (Figure 2). Furthermore, in the PEG + Sim group, 12 adenomas ⩽ 5 mm in diameter *vs* 5 (left colon only) in the PEG + Asc group were diagnosed.

The average time of examination was about 22 min. Moreover, the median timing of colonoscopy was longer in negative tests (24 min, range 20-40) than in colonoscopies with polyp diagnosis (19 min, range 18-25). In patients with a score of 4 or 5 on the Aronchick scale of bowel preparation, the average time for colonoscopy completion was approximately 27 min. The average number of bowel movements obtained during the preparation did not appear to be related to the degree of cleanliness achieved, with 13 movements for 1 or 2 Aronchick scale, 11 movements for 3 Aronchick scale and 11 movements for 4 or 5 Aronchick scale score. Conversely, the presence of clear liquid at the time of the last evacuation is a reliable parameter of effective colonic cleansing. In fact, 93% of patients who achieved a 1, 2 or 3 Aronchick scale score reported the presence of clear liquids during the last evacuation, while patients with 4 or 5 Aronchick scale score reported this in only

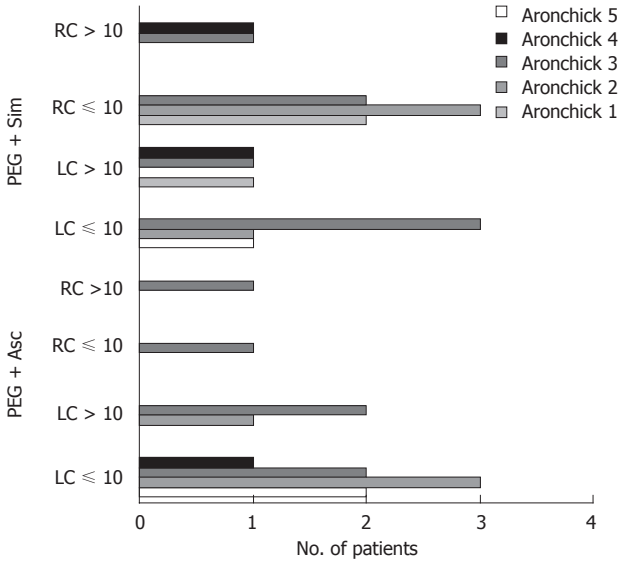

Figure 2 Patients with at least one newly diagnosed polyp in relation to the level of cleanliness achieved (LC = Left colon; RC = Right colon). PEG + Asc: Polyethylene glycol plus ascorbic acid; **PEG + Sim: Polyethylene glycol** plus simethicone.

Table 7 Patient questionnaire findings by preparation group tolerability

Question	PEG + Asc	PEG + Sim
Clear liquid at the time of the last evacuation		
Yes	51	62
No	21	10
Is this the first time you took a preparation for colonoscopy?		
Yes	33	43
No	39	29
Discomfort:		
None	18	28
Slightest	32	36
Moderate	17	6
Severe	5	2
How much would you be prepared to repeat this preparation for colonoscopy?		
A little	18	15
Fairly	32	42
Much	15	11
I would never repeat	7	4

40% of cases. Sixty-three percent of the subjects taking PEG + Sim and 39% of the subjects taking PEG + Asc ($P = 0.005$) reported that they would rather try another preparation for a future colonoscopy. Other patient questionnaire findings rated by preparation group tolerability are reported in Table 7.

DISCUSSION

Currently, the most significant disadvantage of performing colonoscopies is the need for adequate bowel preparation and poor bowel preparation impacts on the efficiency of colonoscopy[21]. Moreover, the major obstacle preventing a large scale implementation of CRC screening is the low level of patient compliance[21], and patient compliance is limited because of embarrassment[20,21], the bowel preparation procedure[8] and the fear of pain and discomfort associated with the examination[22-24].

Cleansing methods for colonoscopy have evolved by attempting to achieve a high efficiency together with a high patient compliance. A consensus of the American Society for Gastrointestinal Endoscopy, the American Society of Colon and Rectal Surgeons and the Society of American Gastrointestinal and Endoscopic Surgeons, indicated that PEG is the gold standard for colonoscopic bowel preparation (Grade IA), and aqueous sodium phosphate (NaP) is an alternative regimen to PEG solutions (Grade IA)[24].

Several meta-analyses on the available bowel preparations have favored NaP, concluding that it was effective and better tolerated by patients than PEG solutions[25-28]. However, the disadvantages of NaP are the associated side effects. Significant changes in serum electrolyte levels[29], even in patients without renal failure, have prompted recommendations for serum electrolyte evaluation prior to the administration of sodium phosphate[30,31]. On the other hand, osmotically balanced electrolyte lavage solutions (PEG-ELS, SF-ELS) offer safe and effective cleansing[22-24,32-34] but volume related discomfort and adverse experiences have decreased the percentage of patients completing the pre-examination preparation. This is mainly due to the large volumes of fluid required for bowel preparation, the unpleasant taste and an increase in the incidence of side effects[15]. In order to bypass volume and taste problems, a PEG electrolyte lavage solution containing ascorbic acid was developed. This low-volume formulation has satisfied many of our requirements. In fact, in our study the subjects enrolled were outpatients, and it was not possible to carry out a complete clinical history and serum electrolyte evaluation. Thus, one of our major considerations was patient safety in colonic preparation, which is well documented for PEG solutions.

To help ensure compliance, the paramedical staff explained to the patient in detail the instructions containing the correct procedures to follow, with special attention paid to explaining the importance of additional fluid consumption with this procedure. Patients were then asked if they completely understood the procedure they had to follow.

Our study has limitations, such as number of patients, single center, lack of a practice calibration on the bowel preparation scoring system for all physicians involved before the study, and full-dose *vs* split-dose regimen comparisons. However, some conclusions on efficacy of bowel wall cleansing, adenoma detection rate and patient compliance can be made.

Bowel cleansing can be evaluated using different scoring systems such as the Aronchick[18], the Ottawa[35] and the Boston scale[36]. In our study, we decided to use the Aronchick scale assisted by a residual stool score to evaluate effectiveness, as previously adopted by Bala-

ban *et al*[19] and Harenwood *et al*[20]. Our data on the bowel cleansing evaluation showed similar levels in both groups, that in most cases was found to be "excellent-fair" (Aronchick 1-3) allowing cecal intubation in 90% of cases. However, we noted better colonic wall visualization in the PEG + Sim group, probably due to the effect of the simethicone.

Only a small number of studies have compared the adenoma detection rate to the quality of bowel preparation[6,37,38]. Froehlich *et al*[6] and Harewood *et al*[37], however, demonstrated that a better bowel preparation led to a higher rate of colon lesion detection, enhancing the ability to discern smaller lesions and thus improved the thoroughness of colonoscopy. In our trial, only 3 out of 30 polyps (Aronchick 4 only) were diagnosed in the presence of inadequate bowel preparation and two of them were > 10 mm in diameter. Thus, we focused on the diagnosis of adenoma in relation to the degree of colonic preparation, paying attention to adenomas ⩽ 10 mm or 5 mm and their distribution. Indeed, while there is no significant difference in total adenoma detection rates between groups, looking at the number of adenomas ⩽ 10 mm and ⩽ 5 mm in diameter and their distribution, there was significant evidence of a greater number of microadenomas diagnosed in favor of the PEG + SIM group. This result reinforces our observations that PEG + Sim has a better ability to clean the colon wall as represented by the residual stool score. Although the impact of detection and removal of micro-adenomas on CRC incidence or mortality is debated, this parameter, which is strongly influenced by the quality of bowel preparation, could be objectively representative of the view of the intestinal wall.

However, since colonoscopy is the best screening test for CRC, we cannot underestimate the importance of patient compliance which directly affects its acceptance and distribution. We must therefore consider whether it is more important to have a highly effective or highly popular test and search for a compromise. So, from the aspect of patient compliance, the majority of patients in both groups completed the bowel preparation in the specified schedule (96% for PEG + Asc and 85% for PEG + Sim). Both groups contained patients who reported side effects and did not finish the pre-procedure preparation. However, this occurred predominantly in the PEG + Sim group, although colonoscopy was still able to be performed and it did not affect the results of the bowel cleansing score. Thus, in this study, the inability to completely drink the PEG + Sim solution (75% of the total was always drunk) did not significantly reduce the effectiveness of the pre-procedure preparation. It is difficult to say the same for the PEG + Asc group considering the small number of patients with adverse events (n = 3). However, our data have shown, in agreement with Ell *et al*[16], that the PEG + Asc formulation was more acceptable to patients and a greater number of them finished the recommended dose.

In conclusion, we agree that PEG + Asc is a good alternative solution, in particular addressing patient compliance, but some improvements seem to be necessary in order to achieve the target of a perfect preparation. One area could be the visualization of small lesions. This seems to be one of the primary advantages of the PEG + Sim solution. Based on the data, the low-volume preparation represents a valid alternative to high-volume preparations, especially with regard to patient compliance. However, improvements are needed to reduce the side effects in both types of preparation and further studies should be carried out, giving the patient the choice of preparation to be taken.

COMMENTS

Background

Colonoscopy has been accepted as the gold standard for colon exploration and is considered the most effective method for assessing colonic lesions. An inadequate preparation can be costly in terms of missed lesions, increased risk of complications, time required for procedure and need for repeated colonoscopies.

Research frontiers

A bowel cleansing regimen should be simple and suitable for inpatients and outpatients. Nowadays, available methods do not completely meet these criteria, and problems with patient compliance, safety, and adequacy of cleansing prompt continued investigation for alternative forms of cleansing.

Innovations and breakthroughs

Our randomized trial compared the polyethylene glycol plus ascorbic acid (PEG + Asc) and sodium sulphate preparation with a polyethylene glycol plus simethicone (PEG + Sim) preparation in terms of cleansing effectiveness, patient compliance, physical tolerability, endoscopic findings and adenoma detection rate.

Applications

The low-volume preparation represents a valid alternative to high-volume preparations, especially with regard to patient compliance. On the other hand, the optimal visualization of colonic wall seems to be one of the primary advantages of the PEG + Sim solution. Through this study, the authors suggest different preparation regimens for different indications.

Peer review

This randomized trial compared the polyethylene glycol plus ascorbic acid and sodium sulphate preparation (MoviPrep®; Norgine BV, PEG + Asc) with a polyethylene glycol plus simethicone preparation (Selg®-Esse 1000, Promefarm Srl, IT, PEG + Sim) in terms of cleansing effectiveness, patient compliance, physical tolerability, endoscopical finding. Bowel preparation is a specific quality indicator and it is a critical point in clinical practice.

Abstract

AIM: To evaluate the management of pancreaticopleural fistulas involving early endoscopic instrumentation of the pancreatic duct.

METHODS: Eight patients with a spontaneous pancreaticopleural fistula underwent endoscopic retrograde cholangiopancreatography (ERCP) with an intention to stent the site of a ductal disruption as the primary treatment. Imaging features and management were evaluated retrospectively and compared with outcome.

RESULTS: In one case, the stent bridged the site of a ductal disruption. The fistula in this patient closed within 3 wk. The main pancreatic duct in this case appeared normal, except for a leak located in the body of the pancreas. In another patient, the papilla of Vater could not be found and cannulation of the pancreatic duct failed. This patient underwent surgical treatment. In the remaining 6 cases, it was impossible to insert a stent into the main pancreatic duct properly so as to cover the site of leakage or traverse a stenosis situated downstream to the fistula. The placement of the stent failed because intraductal stones (n = 2) and ductal strictures (n = 2) precluded its passage or the stent was too short to reach the fistula located in the distal part of the pancreas (n = 2). In 3 out of these 6 patients, the pancreaticopleural fistula closed on further medical treatment. In these cases, the main pancreatic duct was normal or only mildly dilated, and there was a leakage at the body/tail of the pancreas. In one of these 3 patients, additional percutaneous drainage of the peripancreatic fluid collections allowed better control of the leakage and facilitated resolution of the fistula. The remaining 3 patients had a tight stenosis of the main pancreatic duct resistible to dilatation and the stent could not be inserted across the stenosis. Subsequent conservative treatment proved unsuccessful in these patients. After a failed therapeutic ERCP, 3 patients in our series developed superinfection of the pleural or peripancreatic fluid collections. Four out of 8 patients in our series required subsequent surgery due to a failed non-operative treatment. Distal pancreatectomy with splenectomy was performed in 3 cases. In one case, only external drainage of the pancreatic pseudocyst was done because of diffuse peripancreatic inflammatory infiltration precluding safe dissection. There were no perioperative mortalities. There was no recurrence of a pancreaticopleural fistula in any of the patients.

CONCLUSION: Optimal management of pancreaticopleural fistulas requires appropriate patient selection that should be based on the underlying pancreatic duct abnormalities.

INTRODUCTION

The pancreaticopleural fistula is a rare type of internal pancreatic fistula. Although the precise incidence is unknown, pancreaticopleural fistulas are reported to occur in approximately 0.4% of patients with pancreatitis[1]. These fistulas are most commonly associated with alcoholic chronic pancreatitis[1-3]. The pancreaticopleural fistula results from a disruption of a major pancreatic duct usually due to an underlying pancreatic disease. A ductal disruption on the anterior surface of the pancreas usually leads to pancreatic ascites, whereas the posterior ductal leakage might result in thoracic fluid collections. The pancreatic juice spreads retroperitoneally through the paths of least resistance, commonly through the aortic or esophageal hiatus.

The management of pancreaticopleural fistulas remains controversial. The timing of surgical and endoscopic intervention for a pancreaticopleural fistula is disputable. There are no definitive criteria that would allow accurate prediction which patients are likely to benefit from medical treatment and which patients should be offered early surgical intervention. Medical therapy of pancreaticopleural fistulas fails in 59%-69% of cases[1,3,4]. Additionally, unsuccessful conservative treatment is associated with an increased rate of complications[3,5]. Recently, endoscopic instrumentation has become the preferred treatment in pancreaticopleural fistulas and an apparently high rate of fistula resolution has been reported in the literature[4,6]. In light of these observations we used endoscopic retrograde cholangiopancreatography (ERCP) with stenting of the pancreatic duct as an initial treatment in patients with a pancreaticopleural fistula.

In this article we present our experience in the management of patients with pancreaticopleural fistulas who initially underwent endoscopic therapy.

MATERIALS AND METHODS

Patients

Between January 2000 and February 2010, 10 patients with a spontaneous pancreaticopleural fistula presented to our department. Two patients who received primary surgical treatment for a pancreaticopleural fistula due to the surgeon's preference were excluded from the study. The patient group consisted of 7 males and 1 female. The mean age of the patients was 48 years (range: 34-63 years).

Methods

The pancreaticopleural fistula was defined as a pleural effusion with amylase content above 1000 IU/L and protein level above 3.0 g/dL. The fistulous tract was additionally demonstrated with computed tomography (CT), magnetic resonance cholangiopancreatography (MRCP) or ERCP in all the cases.

Medical records were reviewed retrospectively for each patient. The clinical manifestations, underlying pancreatic pathology, imaging appearance and management of the pancreaticopleural fistula were evaluated. Early response to therapy and long-term outcome were assessed.

We used ERCP with an intention to stent the main pancreatic duct as an initial treatment. ERCP was performed as early as possible after the recognition of amylase-rich pleural effusion. ERCP was carried out by the interventional endoscopists skilled in therapeutic endoscopy with several years of experience in pancreatic procedures. Failure of endoscopic treatment was deemed an indication to operative intervention. Our medical management of pancreaticopleural fistulas included diet restriction and enteral or parenteral nutrition. Enteral feeding was delivered through a feeding tube inserted endoscopically or under fluoroscopic guidance into the proximal jejunum. Somatostatin analogs were administered in selected patients. Medical treatment before the trial of ERCP was not used uniformly, but most patients received it following the endoscopic procedure. The pleural effusion was drained in the patients with severe dyspnea or infected fluid. The details of conservative treatment are summarized in Table 1.

Time to fistula healing was calculated from the date of the initial ERCP till the day of normalization of amylase level in the pleural fluid or disappearance of pleural effusion on a chest X-ray or ultrasound.

Statistical analysis

Descriptive statistics were used including mean and range.

RESULTS

The pancreaticopleural fistula was most commonly a complication of underlying chronic pancreatitis or a late consequence of acute pancreatitis. Chronic pancreatitis had been symptomatic for a period between 2 mo and 10 years. In one case, a pancreaticopleural fistula developed in a patient who had a longitudinal pancreaticojejunostomy (a modified Puestow procedure) for chronic pancreatitis 10 mo earlier. All the patients presented with a thoracic symptomatology and most patients had left-sided pleural effusion. The diagnosis was established by means of thoracentesis in each case showing a high amylase level in the pleural fluid sample. The demographic and clinical characteristics of the patients with a pancreaticopleural fistula are summarized in Table 2.

The fistulous tract was additionally visible in CT in 6 cases, in ERCP in 5 cases and in MRCP in 2 cases (Figures 1-3). Imaging investigations revealed peripancreatic fluid collections in all patients. These collections were located along the fistulous tract that dissected into the mediastinum through the esophageal or aortic hiatus

Figure 1 Computed tomography scan demonstrates left pleural effusion and a fluid collection extending through the esophageal hiatus that corresponds to a pancreaticopleural fistula (arrow).

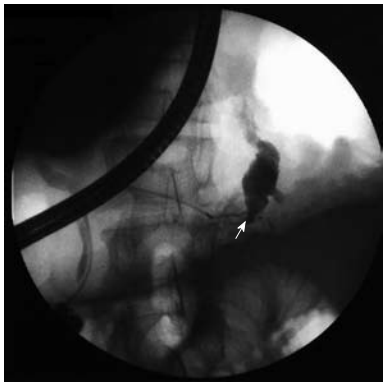

Figure 2 Endoscopic retrograde cholangiopancreatography shows a ductal leakage (arrow) in the tail of the pancreas with the contrast spreading into the chest.

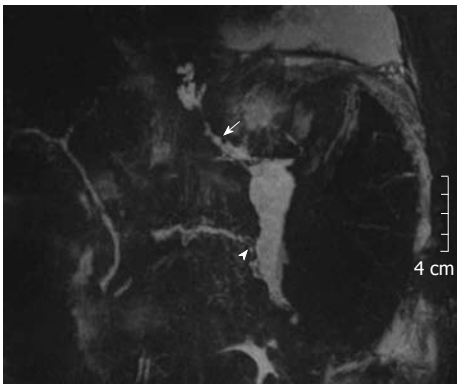

Figure 3 Magnetic resonance cholangiopancreatography demostrates a pancreaticopleural fistula (arrow) extending from a ductal disruption (arrowhead) at the tail of the pancreas into the chest. A ductal blockage in the body of the pancreas precluded evaluation of the anatomy of the upstream duct in endoscopic retrograde cholangiopancreatography.

(Figure 1). The pancreas was usually of normal size with features of chronic pancreatitis. The imaging findings in the patients with a pancreaticopleural fistula are shown in Table 3.

ERCP with an intention to insert a stent so as to bridge the site of leak was performed as early as possible after the recognition of amylase-rich pleural effusion. In only one case, the stent bridged the site of leakage. The fistula in this patient closed within 3 wk following the procedure. The main pancreatic duct in this case appeared normal, except for a leak located in the body of the pancreas. In another patient, the papilla of Vater could not be found and cannulation failed. This patient underwent surgical

treatment. In the remaining 6 cases, it was impossible to insert a stent into the main pancreatic duct properly so as to cover the site of leakage or traverse a stenosis situated downstream to the fistula. The placement of the stent failed because intraductal stones (n = 2) and ductal strictures (n = 2) precluded its passage or the stent was too short to reach the fistula located in the distal part of the pancreas (n = 2). In 3 out of these 6 patients, the pancreaticopleural fistula closed on further medical treatment. In these cases, the main pancreatic duct was normal or only mildly dilated, and there was a leakage at the body/tail of the pancreas. In one of these 3 patients, additional percutaneous drainage of the peripancreatic fluid collections allowed better control of the leakage and facilitated resolution of the fistula. This patient had two ductal disruptions in the body/tail of the pancreas and otherwise a normal main pancreatic duct. The stent was inserted so that it bridged the proximal ductal leak, but could

not cover the second site of leakage which still supplied the fistula. The remaining 3 patients had a tight stenosis of the main pancreatic duct resistible to dilatation and the stent could not be inserted across the stenosis. Subsequent conservative treatment proved unsuccessful in these patients.

After a failed ERCP, 3 patients in our series developed superinfection of the pleural or peripancreatic fluid collections. Moreover, one of these patients developed a pancreaticobronchial fistula manifesting as left lobar pneumonia probably due to a prolonged chest tube drainage. The details of endoscopic treatment are summarized in Table 4.

Half of the patients in our series required surgical intervention after an unsuccessful attempt of endoscopic treatment. Distal pancreatectomy with splenectomy was performed in two cases. The patient after the Puestow operation underwent distal pancreatectomy with an end-to-end pancreaticojejunostomy. In one case, only external drainage of the pancreatic pseudocyst was done because of diffuse peripancreatic inflammatory infiltration. There were no perioperative mortalities. Postoperatively, two patients developed a pancreaticocutaneous fistula which closed spontaneously in one case and after the placement of an additional endoscopic stent in the other case.

The median follow-up was 13.5 mo (range: 5 mo-10 years). There were no recurrences of the pancreaticopleural fistula in any of the patients. The only patient in our series successfully managed with endoscopic treatment alone underwent a pancreaticoduodenectomy 2 years later for intractable abdominal pain due to underlying chronic pancreatitis.

DISCUSSION

The diagnosis of a pancreaticopleural fistula is established when an amylase-rich fluid is drained on thoracentesis. There is not any established threshold of amylase level that is diagnostic of a pancreaticopleural fistula. We arbitrarily defined the pancreaticopleural fistula as a pleural effusion with an amylase content above 1000 IU/L. However, pleural effusions due to a pancreaticopleural fistula commonly show amylase level of many thousand units[1].

It is essential to evaluate the ductal anatomy and pancreatic morphology before planning further management. ERCP and MRCP are the commonly used modalities in the assessment of pancreatic fistulas. We discourage the use of ERCP as a first-line tool for confirmation of a pancreaticopleural fistula because of considerable risk of introducing infection. MRCP seems to be a better choice for the visualization of a pancreaticopleural fistula. This method enables recognition and outlining of both a fistula and the anatomy of the pancreatic ducts. Moreover, MRCP is a non-invasive study without the risk of superinfection or acute pancreatitis. It has been shown that MRCP detects pancreatic duct abnormalities and calculi with a similar accuracy to ERCP[7]. In contrast to ERCP, this study has the advantage of demonstrating the pancreatic duct upstream to the site of a complete obstruction, as it was the case in one of our patients. MRCP was helpful in the diagnosis of pancreaticopleural fistula in 80% of the cases, while ERCP and CT were useful in 78% and 47% respectively[2].

The role of conservative treatment and the timing of surgical or endoscopic intervention for a pancreaticopleural fistula is disputable. A 2-3-wk trial of medical therapy is traditionally recommended[1,5]. Failure of conservative treatment is considered an indication for endoscopic or surgical intervention. The success rate in resolution of a pancreaticopleural fistula on medical therapy alone has been reported to be of 31%-65%[1-3]. However, conservative treatment requires prolonged hospitalization and is costly. Moreover, failed medical treatment results in a higher rate of complications and significantly longer hospital stay[3]. In a series reported by Lipsett *et al*[5], 80% of deaths during non-operative management of internal pancreatic fistulas occurred in patients who had been treated conservatively for over 3 wk. Furthermore, pleural effusions left undrained for a long period might lead to the formation of lung entrapment, sequestrated pleural fluid collections or a pancreaticobronchial fistula. Therefore, the potential risks of prolonged medical treatment should always be weighted against the morbidity and mortality associated with operative treatment. The appropriate patient selection according to the ductal morphology visualized in MRCP might spare these 2-3 wk of conservative treatment in the cases with a poor chance of spontaneous fistula closure. In our series, only the fistulas that developed in patients with fairly normal pancreatic ducts responded well to medical treatment.

ERCP was initially used as a diagnostic tool. Nowadays, various therapeutic procedures can be performed at the time of ERCP. The armamentarium of interventional endoscopists includes pancreatic sphincterotomy, ductal stenting, nasopancreatic drainage and lithotripsy. Saeed *et al*[8] were first to report resolution of a pancreaticopleural fistula after endoscopic stenting of the pancreatic duct. Since then, there have been published multiple reports of successful closure of pancreaticopleural fistulas after endoscopic instrumentation of the pancreatic duct[4,6,9-12]. Nevertheless, endoscopic techniques carry the risk of serious complications such as acute pancreatitis, bleeding, perforation or septic complications. The complication rate of pancreatic endotherapy varies considerably and ranges from 7% to 25%[13-15]. Moreover, pancreatic endotherapy is technically demanding and requires substantial experience to avoid potentially life-threatening complications. Therefore, careful selection of patients is essential before endoscopic therapy is recommended.

We reviewed the management of pancreaticopleural fistulas based on the case reports and case series published between 1993 and 2009. Our search of the literature provided 30 cases of pancreaticopleural fistulas with adequately described ductal anatomy in ERCP and endoscopic treatment. Eight cases were treated medically following only a diagnostic ERCP. Most of these pa-

tients received total parenteral nutrition and a pancreatic enzyme inhibitor or somatostatin analog. Four out of the 8 pancreaticopleural fistulas healed on conservative treatment alone. The main pancreatic duct was normal or irregular without any obvious stricture in two of these cases and there was a ductal stenosis with a leak in the pancreatic tail in the remaining two cases. ERCP in all the 4 fistulas resistant to medical treatment revealed a downstream stricture of the pancreatic duct. Twenty cases were treated successfully with endoscopic instrumentation such as stent insertion (n = 16) or nasopancreatic drainage (n = 4). Sixteen out of 20 fistulas were located in the head or body of the pancreas. In 11 cases, there was only a ductal disruption without any significant stenosis of the main pancreatic duct. These patients were treated with a stent or nasopancreatic catheter placed across the site of leakage. In the remaining 9 cases, there was a concomitant ductal stricture that could be dilated and stented, although the stent or nasopancreatic catheter did not bridge the site of a ductal disruption in two cases. Another two patients underwent endoscopic instrumentation combined with extracorporeal lithotripsy due to intraductal stones. The reports of the pancreaticopleural fistulas after unsuccessful endotherapy did not provide adequate descriptions of the pancreatic duct anatomy.

The success rate of therapeutic endoscopy in pancreaticopleural fistulas is varied. Khan *et al*[6] successfully treated all 5 of their patients with a pancreaticopleural fistula by means of intraductal stenting. Similarly, Pai *et al*[14] reported a 96.4% success rate of endotherapy in the treatment of internal pancreatic fistulas, including 13 pancreaticopleural fistulas. However, most ductal disruptions in this series were located in the head and body of the pancreas (64.2%) and no leakage at the time of ERCP was found in 28.6% cases. Such proximal ductal disruptions are, however, more easily managed endoscopically. Varadarajulu *et al*[13] reported only a 55% success rate in resolution of the pancreatic duct disruption using a transpapillary stenting technique, although placement of a stent was possible in 95% of patients. However, it is noteworthy that 92% of the ductal disruptions that closed were in the cases where the stent bridged the site of leakage. In the remaining cases, the stent was put only close to the site of disruption (2%) or just across the ampulla (6%). In a series published by O'Toole *et al*[16] endotherapy used in internal pancreatic fistulas was successful in a third of their patients and there was a similar rate of both failed ductal cannulations and unsuccessful endoscopic treatment. Kaman *et al*[17] attempted placement of nasopancreatic drainage in six patients with an internal pancreatic fistula, but it failed in four patients due to ductal pathology. In their series, the fistula closed in only one patient. Similarly, endotherapy alone proved successful in just one case also in our series, and a partial success was seen in another patient. On the other hand, in some case series therapeutic endoscopy was not possible in most patients because of failed cannulation or stenting of the main pancreatic duct[18]. The duration of stent or nasopancreatic drainage is unknown, but most ductal disruptions resolve with a median time of 4-6 wk[14,15].

The majority of the pancreaticopleural fistulas that closed after endotherapy had a stent inserted so that it bridged the site of disruption. Shah *et al*[19] reported resolution of a pancreaticopleural fistula after exchange of a stent for a longer one that could bridge the site of disruption. Initial trial of a stent inserted only up to the site of disruption was unsuccessful in this case. It follows that a stent not only decreases the ductal pressure, but also plays a certain mechanical role in sealing the leakage. Decreasing ductal pressure may not be sufficient for resolution of a ductal disruption and coverage of the leak with a stent is required in some cases.

In our series, unsuccessful endotherapy resulted from the inability to cannulate the ampulla and failure to stent across the site of leakage or a downstream stenosis within the main pancreatic duct. The appropriate placement of a pancreatic stent for the treatment of a pancreaticopleural fistula requires coverage of the site of leakage or stenting across a stricture situated downstream to the fistula. Otherwise, endotherapy has to be considered unsuccessful and operative treatment should be performed early to prevent septic complications. In this series, the stent could not be inserted properly into the pancreatic duct because the papilla of Vater was not found (n = 1), intraductal stones (n = 2) and ductal strictures (n = 2) precluded passage of a stent or the stent was too short to reach the fistula located in the distal part of the pancreas (n = 2). In 3 out of these patients, the fistula closed on further medical treatment. In these cases, the main pancreatic duct was normal or only mildly dilated, except for a leakage located at the body/tail of the pancreas, what suggests a fairly good outflow of the pancreatic juice into the duodenum. In one of these 3 patients, additional percutaneous drainage of the peripancreatic fluid collections allowed better control of the leakage and facilitated resolution of the fistula. Therefore, the patients with a normal or mildly dilated main pancreatic duct without any downstream stenosis can receive a trial of conservative treatment, especially when the leakage is located in the pancreatic tail. The fistulas originating from the tail of the pancreas are usually low-output and more prone to spontaneous resolution. Endotherapy used in this patient group might further promote resolution of the fistula if a stent is inserted across the site of leakage. The patients with a downstream stricture or a fistula located in the head and body of the pancreas should preferably undergo endotherapy. However, a high rate of failure can be expected because of intraductal stones and strictures inherent to chronic pancreatitis that are often hard to dilatate due to severe fibrosis. In our series, the 3 patients with a tight stenosis of the main pancreatic duct could not be properly stented and conservative treatment used after ERCP was unsuccessful. After a failed ERCP, 3 patients in our series developed superinfection of the pleural or peripancreatic fluid collections. The pancreaticopleural fistula usually has a tortuous fistulous tract

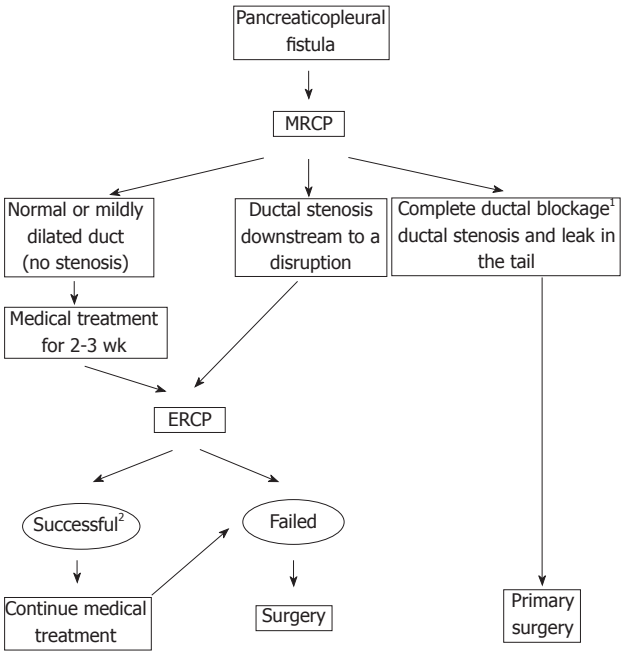

Figure 4 The algorithm for the treatment of pancreaticopleural fistulas. [1]Complete ductal blockage due to stones may be approached with endoscopic or extracorporeal lithotripsy. [2]Successful endotherapy: The stent inserted across the site of a ductal disruption or traverses a ductal stricture. MRCP: Magnetic resonance cholangiopancreatography; ERCP: Endoscopic retrograde cholangiopancreatography.

that connects with complex intraabdominal or thoracic fluid collections what renders them especially susceptible to infection. The patients after a failed ERCP should be treated operatively soon after the endoscopic procedure, preferably within the following 24-48 h. Any longer delay might lead to serious septic complications such as intraabdominal abscess or pleural empyema and continued medical treatment usually fails. On the other hand, infected peripancreatic fluid collections after a failed therapeutic ERCP further complicate surgical dissection and sometimes external drainage is all that can be done in such a situation. Antibiotic prophylaxis might prevent some septic complications after ERCP. However, prophylactic antibiotics were not used in our series.

Before the era of therapeutic endoscopy, surgery was frequently used as a primary treatment in patients with pancreaticopleural fistulas. Nowadays, surgery is often seen as a treatment of the last resort and used only after failure of medical and endoscopic therapy. However, a delay in the definitive treatment of the cases having a poor chance of healing without surgical intervention might result in increased morbidity and mortality. On the other hand, pancreatic operations performed for a pancreaticopleural fistula have now acceptably low morbidity and mortality rates in the high-volume centers[18,20]. Moreover, early operative treatment is recommended in the institutions where there are no endoscopists experienced in the treatment of pancreatic diseases. Primary and early surgical treatment of pancreaticopleural fistulas might prove cost- and time-saving in appropriately selected patients and prevent life-threatening complications due to a failed ERCP, repeated thoracenteses or prolonged pleural drainage. In our series, 4 patients underwent surgical treatment after a failed endotherapy. Two of these patients had uncomplicated postoperative course. The other 2 patients developed a pancreaticocutaneous fistula. In contrast to internal pancreatic fistulas, the external fistulas can be managed conservatively for a long time because of a low risk of septic complications, and they often heal spontaneously.

The pancreaticopleural fistulas usually occur in patients with chronic pancreatitis. Even though endotherapy may be initially successful, progression of the disease often leads to subsequent complications that frequently require surgical intervention. Therefore, surgical treatment might prove more effective for a longterm amelioration of the symptoms. In our series, one patient needed pancreatic resection because of intractable pain syndrome, although endotherapy had allowed resolution of the pancreaticopleural fistula 2 years earlier.

In conclusion, the choice of primary management in patients with pancreaticopleural fistulas should be tailored to the pancreatic ductal abnormalities. The patients with a normal or mildly dilated pancreatic duct without a downstream stenosis visualized on MRCP are optimally managed with a trial of medical treatment, especially when the leakage is located in the pancreatic tail. Ductal disruptions in the head and body of the pancreas and presence of a ductal stricture favor endoscopic treatment as a first-line therapy. Early surgical intervention is recommended whenever a stent cannot bridge the site of a ductal disruption or there is a downstream ductal stricture which can not be stented. Complete ductal obstruction anywhere along the main pancreatic duct or both a stricture and leakage within the pancreatic tail favor primary surgical treatment due to a poor chance of appropriate endoscopic stent placement. We propose an algorithm for the optimal management of pancreaticopleural fistulas (Figure 4).

COMMENTS

Background

The pancreaticopleural fistula is a rare type of internal pancreatic fistula. These fistulas are most commonly associated with alcoholic chronic pancreatitis and result from a disruption of a major pancreatic duct. The management options in pancreaticopleural fistulas include conservative treatment and endoscopic or surgical intervention.

Research frontiers

The management of pancreaticopleural fistulas remains controversial. The timing of surgical and endoscopic intervention for a pancreaticopleural fistula is still disputable. There are no definitive criteria that would allow accurate prediction which patients are likely to benefit from medical treatment and which patients should be offered early surgical or endoscopic intervention. In the study, the role of early therapeutic endoscopy with stenting of the pancreatic duct was evaluated in regard to the pancreatic ductal anatomy.

Innovations and breakthroughs

Endoscopic retrograde cholangiopancreatography with therapeutic intervention has recently become the preferred treatment in pancreaticopleural fistulas and an apparently high rate of fistula resolution has been reported in the literature. This study suggests that the choice of primary management in patients with pancreaticopleural fistulas should be tailored to the pancreatic ductal abnormalities.

Applications

The management of patients with pancreaticopleural fistulas can be improved with appropriate patient selection based on the pancreatic duct abnormalities. This selection is essential for the optimal treatment of pancreaticopleural fistula with low morbidity rate.

Peer review

The paper addresses the important issues in management of pancreaticopleural fistulas.

Abstract

AIM: To describe the socio-demographic features, etiology, and risk factors for Budd-Chiari syndrome (BCS) in Egyptian patients.

METHODS: Ninety-four Egyptian patients with confirmed primary Budd-Chiari syndrome were presented to the Budd-Chiari Study Group (BCSG) and admitted to the Tropical Medicine Department of Ain Shams University Hospital (Cairo, Egypt). Complete clinical evaluation and laboratory investigations, including a thrombophilia workup and full radiological assessment, were performed to determine underlying disease etiologies.

RESULTS: BCS was chronic in 79.8% of patients, acute or subacute in 19.1%, and fulminant in 1.1%. Factor V Leiden mutation (FVLM) was the most common etiological cause of disease (53.1%), followed by mutation of the gene encoding methylene tetrahydrofolate reductase (MTHFR) (51.6%). Current or recent hormonal treatment was documented in 15.5% of females, and BCS associated with pregnancy was present in 17.2% of females. Etiology could not be determined in 8.5% of patients. Males had significantly higher rates of MTHFR gene mutation and Behçet's disease, and females had significantly higher rates of secondary antiphospholipid antibody syndrome. A highly significant positive relationship was evident between the presence of Behçet's disease and inferior vena caval occlusion, either alone or combined with occlusion of the hepatic veins ($P < 0.0001$).

CONCLUSION: FVLM is the most common disease etiology and MTHFR the second most common in Egyptian BCS patients. BCS etiology tends to vary with geographic region.

Key words: Budd-Chiari syndrome; Epidemiological aspects; Etiology; Factor V Leiden mutation; Methylene tetrahydrofolate reductase gene mutation

INTRODUCTION

Budd-Chiari syndrome (BCS) is a rare, but potentially life-threatening, hepatic disorder caused by obstruction of hepatic venous outflow at any level from the hepatic venules to the right atrium[1]. The exact prevalence of BCS is unknown, but has been estimated as 1 per 100 000 of the general population worldwide[2], with a higher prevalence being evident in developing countries such as China, India, Nepal, and South Africa[3]. BCS affects all races, usually during the third or fourth decade of life, and is more common in females[4]. The etiology of BCS can be classified as either primary, attributable to intrinsic intraluminal thrombosis or development of venous webs; or secondary, caused by intraluminal invasion by a parasite or a malignant tumor, or extraluminal compression by an abscess, cyst, or solid tumor[5].

At least one hereditary or acquired procoagulative disorder is present in 74% of BCS patients; intravascular thrombosis, mostly encountered in patients with primary myeloproliferative disorders (MPD), is the most common etiological factor[4]. Polycythemia vera is present in 10%-40% of BCS patients, whereas essential thrombocythemia and myelofibrosis are less common[6]. Hepatic vein thrombosis occurs in up to 12% of patients with paroxysmal nocturnal hemoglobinuria (PNH); this is the leading cause of mortality from BCS[7]. As many as 30% of BCS patients carry a Factor V Leiden mutation (FVLM); such a mutation is present in the majority of pregnancy- or oral contraceptive-related instances of hepatic vein thrombosis[8]. Patients with BCS may show nonspecifically decreased levels of Protein C, Protein S, and antithrombin, attributable to impaired hepatic synthesis, but levels less than 20% of normal suggest the presence of an inherited deficiency[9].

BCS is less common in western countries, but primary membranous obstruction of the inferior vena cava (IVC) is the most common cause of BCS in South Africa and Asia[10]. No underlying etiology can be identified in about 5% of BCS patients. Recent research has suggested that endothelial dysfunction and decreased fibrinolytic activity contribute to idiopathic instances of BCS[1].

The aim of the present epidemiological study was to describe the socio-demographic features, etiology, and risk factors for BCS in Egyptian patients.

MATERIALS AND METHODS

Study design and sampling

The present descriptive study enrolled 94 consecutive Egyptian patients between April 2009 and February 2011. Each patient was confirmed to have primary BCS, were introduced to the Budd-Chiari Study Group (BCSG), and then admitted to the Tropical Medicine Department of Ain Shams University Hospital (Cairo, Egypt). All patients provided written informed consent to participate in the study. Complete histories and clinical examinations were recorded for all patients.

Laboratory investigations included a complete blood count, a liver profile, and a coagulation profile. A thrombophilia workup, performed to determine the underlying etiology of BCS, included measurement of anticardiolipin antibodies, lupus anticoagulant, antinuclear antibodies, protein C, protein S, and antithrombin Ⅲ; and flow cytometry quantitating CD55 and CD59 levels to diagnose PNH. The possible presence of a FVLM was assessed in 64 patients, whereas the statuses of prothrombin and methylene tetrahydrofolate reductase (MTHFR) gene mutations were evaluated in 60 patients. *JAK2* mutational status was assessed, and/or a bone marrow biopsy exploring the possible presence of a myeloproliferative disorder was performed, in 62 patients.

Radiological assessment using abdominal Duplex ultrasonography (US) was performed to assess the patency of all of the hepatic veins (HVs), the portal vein, and the IVC. Abdominal magnetic resonance (MR) imaging, MR venography, or multislice computed tomography, was performed to confirm all diagnoses and to assess vascular anatomy.

Statistical analysis

Analysis of variance was used to compare the mean values of laboratory parameters. Multiple comparisons were performed using the least significant difference post-hoc test and results are presented as means and standard deviations (SDs). Non-parametric data were analyzed using the Kruskal-Wallis test and are presented as medians with interquartile ranges (IQRs). The chi-squared test and Fisher's exact test were used to test for differences among variables; the results are presented as percentages with corresponding *P* values. The unpaired Student's *t* test was used to test for differences in mean values of laboratory parameters between males and females, and the results are presented as means with SDs. Non-parametric data were analyzed using the Mann-Whitney *U* test and data are presented as medians with IQRs. Spearman's correlation coefficient was used to test the strength of associations between variables. All data were analyzed using SPSS version 15. A *P* value less than 0.05 was considered significant (S); a *P* value less than 0.01 was highly significant (HS); and a *P* value less than 0.001 was very highly significant (VHS).

RESULTS

We enrolled 94 Egyptian patients with BCS. There were 58 females (61.7%, mean age: 28.88 ± 9.08 years) and 36 males (38.3%, mean age: 28.64 ± 8.35 years). A total of 34 patients (36.2%) were from Cairo, 39 (41.5%) from the Delta, and 21 (22.3%) from Upper Egypt. A total of 75 patients (79.8%) had chronic BCS, 18 (19.1%) acute or subacute BCS, and 1 (1.1%) fulminant BCS. By the Child-Pugh classification, 30 patients (32%) were class A, 33 (35%) class B, and 31 (33%) class C.

Table 1 summarizes the clinical manifestations of our 94 patients. The most common symptoms were ab-

Sig: Significance; NS: Not significant; S: Significant; HS: Highly significant; VHS: Very highly significant; PC: Protein C; PS: Protein S; AT: Antithrombin; FVLM: Factor V Leiden mutation; PGM: Prothrombin gene mutation; MTHFR: Methylene tetrahydrofolate reductase; *JAK2*: Janus tyrosine kinase-2; MPD: Myeloproliferative disorder; APA: Antiphospholipid antibody syndrome; PNH: Paroxysmal nocturnal hemoglobinuria.

MTHFR gene mutation and Behçet's disease, whereas females had a significantly higher rate of secondary antiphospholipid syndrome (APA).

Table 4 summarizes the Duplex US findings. A total of 74.5% of all patients had HV occlusion, 3.2% IVC occlusion, and 17% both HV and IVC occlusion. PV thrombosis was present in 5.3% of patients. Figure 1 shows a representative color Doppler US of a patient with a dilated congested left HV and significant stenosis at the junction thereof with the IVC. Figure 2 is a representative B-mode sonograph showing occlusion of all hepatic veins, a slit-like IVC, and a markedly enlarged caudate lobe.

Table 5 summarizes the relationship between BCS etiology and radiological data. A highly significant positive relationship was evident between the presence of Behçet's disease and IVC occlusion, either isolated or combined with occlusion of the hepatic veins ($P < 0.0001$). No other significant relationship was evident between any etiological factor and radiological data.

DISCUSSION

Our current epidemiological study of 94 Egyptian patients with confirmed diagnoses of primary BCS describes the socio-demographic features, etiology, and risk factors for BCS. Previous reports found that BCS affects all races, usually during the third or fourth decade of life, and is slightly more common in females[4]. More females than males (61.7% *vs* 38.3%) were present in our population and mean patient age at the time of first visit was 28.64 ± 8.35 years for males and 28.88 ± 9.08 years for females.

Figure 1 Representative color Doppler ultrasonograph showing a dilated congested left hepatic vein with significant stenosis at the junction thereof with the inferior vena cava.

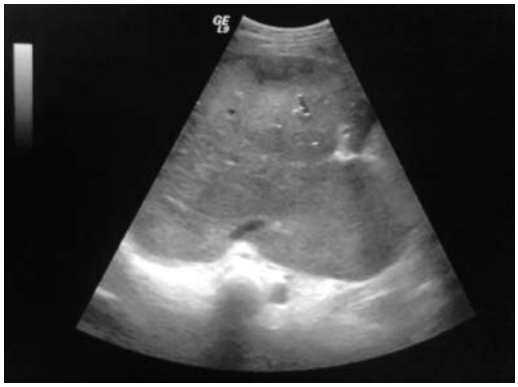

Figure 2 Representative B-mode sonograph showing occlusion of all hepatic veins, a slit-like inferior vena cava and a markedly enlarged caudate lobe.

BCS patients from different geographic regions tend to show distinct disease etiologies. In particular, thromboses are more common in western BCS patients, whereas development of venous webs is more frequent in Eastern and Japanese BCS patients[11]. Recent studies have shown that primary BCS should be regarded as a multifactorial disease, and that co-occurrence of several prothrombotic disorders leads to thrombosis at this uncommon location. A previous study found that several prothrombotic conditions were evident in at least 35% of BCS patients[12]. Thus, in the workup of such patients, identification of a single etiology should not indicate that additional etiologies should not be sought[1]. A previous study by Uskudar *et al*[13] in Turkey identified at least one etiological factor in 72% of patients, two in 18.6%, and three in 1.3%. In our present study of Egyptian patients, we identified at least one etiological factor in 48.9% of patients, two in 30.9%, three in 8.5%, and four in 3.2%.

Table 6 shows the prevalence rates of the major causal factors of primary BCS as reported in the current study and in that of Valla, conducted in 2009[1] and based on the work of Primignani *et al*[12,14], Patel *et al*[15], Colaizzo *et al*[16], and Kiladjian *et al*[17]. In the current study, FVLM was the most common cause of disease (53.1% of patients); 37.5% of patients were FVLM heterozygotes and 15.6% FVLM homozygotes. Similarly, a study in India by Mohanty *et al*[11] found that FVLM was the most common etiology of BCS (26% of patients). Identification of FVLM as a risk factor for venous thrombosis was a major advance in understanding the pathogenesis of BCS[8]; the possible presence of FVLM should be routinely investigated when BCS is diagnosed[11].

Table 4 Duplex ultrasound findings in patients with Budd-Chiari syndrome (n = 94)

Ultrasound finding		Patients n (%)
Hepatomegaly		78 (83)
Splenomegaly		48 (51.1)

	Isolated IVC	3 (3.2)
	Associated PV thrombosis	5 (5.3)

HV: Hepatic vein; RHV: Right hepatic vein; LHV: Left hepatic vein; MHV: Middle hepatic vein; PV: Portal vein; IVC: Inferior vena cava.

MTHFR gene mutation was the second most common etiology of BCS in the current study, evident in 51.6% of patients, of whom 38.3% were heterozygotes and 13.3% homozygotes. A previous study in China by Li *et al*[18] found that the prevalence of the MTHFR 677/T genotype in BCS patients was 45.12%, a figure similar to ours. Valla[19] reported that the *G20210A* prothrombin gene mutation (PGM), another recently discovered inherited marker, was less common in BCS patients than the other prothrombotic mutations mentioned above. In the present study, very few patients had a PGM (3.3% heterozygous, 1.7% homozygous).

MPD is the leading cause of BCS in western countries, foun d in 20%-53% of patients. Polycythemia vera was reported in 10%-40% of patients, whereas essential thrombocythemia and myelofibrosis were less common[6]. In the current study, we identified MPD in 29% of patients, of whom 28.5% had overt disease and 71.5% were of occult status. We confirmed the presence of such disorders by identification of the *JAK2 V617F* mutation. A recent study reported that clusters of dystrophic megakaryocytes evident in bone marrow biopsy samples were specific for MPD[20]. In our current study, a *JAK2* mutation was present in 29% of patients; this figure was lower than that previously reported by Colaizzo *et al*[21] (34.4%), Spivak[22] (40%), and Patel *et al*[15] (58.5%). These discrepancies may be attributable to the use of different DNA sources (peripheral blood granulocytes in

our present study and bone marrow films in the work of Patel *et al*[15]) or to differences in patient populations.

APA syndrome was one of the major causes of BCS in the current study, being present in 28.7% of patients; 17% with primary APA and 11.7% with APA secondary to systemic lupus erythematosus (SLE). A previous report found that 3%-17% of patients with venous thrombosis showed measureable levels of antiphospholipid antibodies[23]. In the current study, we were surprised to find Behçet's disease in 12.8% of our patients. This disease is common in certain countries, and Uskudar *et al*[13] reported that the disease was present in 9% of Turkish patients with BCS. Thus, we suggest that patients with BCS should always be screened for Behçet's disease. Such a diagnosis can be difficult, even in male patients from countries where the disease is endemic; use of the diagnostic criteria of the International Study Group of Behçet's Disease may be helpful[24].

The prevalence of primary deficiencies in Protein C, Protein S, and Antithrombin Ⅲ in BCS patients is difficult to determine, for several reasons. Firstly, the liver synthesizes these inhibitors of coagulation, and liver dysfunction related to BCS thus induces non-specific falls in the plasma levels of the inhibitors. Secondly, diagnosis of any primary deficiency is based on measurement of plasma protein level, because most mutations in the relevant genes are unique, rendering diagnosis using molecular biology techniques alone difficult. Finally, complete family screening is recommended to differentiate between inherited and false instances of deficiencies in Proteins C and S, but this is usually impractical. Thus, the question of whether a primary deficiency in the expression of one of the proteins mentioned above exists will remain unanswered in most instances[19]. However, a level below 20% of the normal value suggests the presence of an inherited deficiency[2]. In the present study, we identified deficiencies in Antithrombin Ⅲ, Protein C, or Protein S in 4.3%, 1.1%, and 4.3% of our patients, respectively. Mohanty *et al*[11] studied BCS patients in India, and found deficiencies in Antithrombin Ⅲ, Protein C, and Protein S in 3.8%, 13.2%, and 5.7% of patients, respectively. Uskudar *et al*[13] worked with BCS patients in Turkey, and reported deficiencies in Antithrombin Ⅲ, Protein C, and Protein S in 3%, 9%, and 7% of patients, respectively.

A previous study found that hepatic vein (HV) thrombosis occurred in up to 12% of patients with PNH; this is the leading cause of mortality in BCS patients[7]. In the present study, PNH was documented in 2.1% of patients, similar to what was previously reported by Valla[2] (2%). Membranous obstruction of the IVC is the most

common cause of BCS in South Africa and Asia, but is less common in western countries, where the condition is thought to be a consequence of IVC thrombosis[10]. One of the most striking results of the present study was that development of IVC venous webs was not responsible for any instance of BCS. In contrast, Uskudar *et al*[13] reported that venous webs were one of the most common etiological factors of BCS in Turkey.

Analysis of the relationship between gender and BCS etiology indicated that females were more likely to have secondary APA syndrome than males (17.2% *vs* 2.8%), but that males were more likely to have MTHFR gene mutations (71.5% *vs* 41%) and also had significantly higher rates of Behçet's disease (30.6% *vs* 1.7%). We also found that potential risk factors for BCS included previous thrombosis elsewhere in the body (27.5%), recent pregnancy (17.2% of females), and hormonal therapy (15.5% of females). Each of our BCS patients on hormonal therapy or with pregnancy-related BCS displayed an additional etiological factor. Thus, many women with BCS who are pregnant or users of oral contraceptives appear to have additional thrombophilic conditions[25].

In the present study, we found isolated HV involvement in 74.5% of patients, isolated IVC involvement in 3.2%, and combined HV and IVC occlusion in 17%. In a previous study of 237 patients with BCS, Darwish Murad *et al*[26] reported obstruction of the HV, the IVC, and both veins, in 62%, 7%, and 31% of patients, respectively. The high rate of IVC thrombosis found in the cited study was associated with the high prevalence of Behçet's disease. These findings were similar to those of the Turkish study by Uskudar *et al*[13], who reported HV involvement in 77% of patients and IVC involvement in 53%. Together, the results indicate that the etiology of BCS may be related to the site of obstruction.

Previous studies have indicated that the site of the lesion varies among patients of different countries. In particular, IVC involvement is more common in Nepal, South Africa, China, India, and Japan, whereas HV involvement is more common in the west[4]. In the current study, we assessed the extent of association between BCS etiology and the anatomical site of thrombosis as revealed using different imaging modalities. Our results indicate a significant association between the presence of Behçet's disease and the anatomical site of thrombosis. In particular, Behçet's disease was diagnosed in 12 patients, 9 (75%) with combined IVC and HV thrombosis, 2 (16.7%) with isolated HV thrombosis, and 1 (8.3%) with isolated IVC thrombosis. These results are similar to those reported by Bayraktar *et al*[27], who found that 85.7% of Behçet's disease patients had combined IVC and HV thrombosis and 14.2% had isolated HV thrombosis.

An increasing number of studies support the concept that thrombosis is site-specific, depending on the underlying prothrombotic disorder[28]. For example, MPD is more common in BCS patients than in those with portal vein thrombosis; Factor V Leiden mutation is more strongly associated with BCS than is portal vein thrombosis; and the *G20210A* prothrombin gene mutation is more strongly associated with portal vein thrombosis than is BCS. Further site-specificity may be in play within the hepatic venous outflow tract per se. Indeed, the FVLM appears to be particularly common in patients with IVC obstruction[8] and the use of oral contraceptives, or pregnancy, is specifically associated with hepatic vein involvement[29].

In conclusion, our study of Egyptian BCS patients indicated that FVLM was the most common etiology, MTHFR the second most common, and that BCS commonly occurs during the third decade of life and is more prevalent in females. Comparison of our data with those of previous studies indicates that BCS patients from different geographic regions tend to differ in terms of etiology.

COMMENTS

Background

Budd-Chiari syndrome (BCS) results from hepatic venous outflow obstruction at any level, from the hepatic venules to the right atrium, and is estimated to affect every 1 out of 100 000 subjects in the general population worldwide. BCS affects all races, usually during the third or fourth decade of life, and is slightly more common in females.

Research frontiers

BCS patients from different geographic regions tend to vary in terms of disease etiology. Previous reports have indicated that thromboses are more common in the West and venous webs more frequent in the East and Japan. In the present study of Egyptian patients, the authors demonstrate that Factor V Leiden mutation (FVLM) was the most common etiology, methylene tetrahydrofolate reductase gene mutation the second most common, and that the disease was of multiple etiologies in 42.6% of patients.

Innovations and breakthroughs

This is the first epidemiological study to examine the socio-demographic features, etiology and risk for development of BCS in Egyptian patients.

Applications

In the workup for determining the etiology of BCS, identification of a single cause should not preclude investigation of additional contributing factors. The presence of an underlying hypercoagulable state should be investigated in all patients.

Terminology

FVLM is the most common cause of inherited thrombophilia. The mutated factor Va is resistant to degradation by protein C, a natural anticoagulant. The rise in the level of undegraded factor Va over time increases the risk of uncontrolled thrombin and thrombus formation. Methylene tetrahydrofolate reductase is an enzyme active in re-methylation of homocysteine. Deficiencies in the enzyme cause hyperhomocysteinemia; this condition compromises the functions of the anticoagulant and fibrinolytic systems.

Peer review

The authors investigated the epidemiology of Budd-Chiari syndrome in Egyptian patients. The results indicate that BCS is most common during the third decade of life and is more often diagnosed in females than in males. In Egyptian patients, FVLM was the most common etiology, methylene tetrahydrofolate reductase gene mutation the second most common, and multiple etiologies were present in 42.6% of patients. Thus, in workup for determination of the etiology of BCS, identification of a single cause should not preclude investigation of additional relevant factors. The presence of an underlying hypercoagulable state should be investigated in all BCS patients. The present study provides valuable new information on BCS.

Abstract

AIM: To identify differentially expressed microRNAs (miRNAs) in human colon cancer stem cells (SW1116csc) and study their function in SW1116csc proliferation.

METHODS: SW1116csc were isolated from the human colon cancer cell line, SW1116 and cultured in serum-free medium. A miRNA microarray was used to detect differential expression profiles of miRNAs in SW1116csc and SW1116 cells. Real-time quantitative polymerase chain reaction (PCR) was performed to verify the differential expression of candidate miRNAs obtained from the microarray. Target mRNAs of differentially expressed miRNAs were predicted with target prediction tools. miRNA expression plasmids were transfected into SW1116csc using Lipofectamine 2000 reagent. Cell proliferation curves were generated with trypan blue staining, and the colony formation rate of transfected cells was measured with the soft agar colony formation assay. Expression of target mRNAs and proteins from differentially expressed miRNAs were detected using reverse transcription (RT)-PCR and western blotting.

RESULTS: Compared with expression in SW1116 cells, 35 miRNAs (including hsa-miR-192, hsa-miR-29b, hsa-miR-215, hsa-miR-194, hsa-miR-33a and hsa-miR-32) were upregulated more than 1.5-fold, and 11 miRNAs (including hsa-miR-93, hsa-miR-1231, hsa-miRPlus-F1080, hsa-miR-524-3p, hsa-miR-886-3p and hsa-miR-561) were downregulated in SW1116csc. The miRNA microarray results were further validated with quantitative RT-PCR. miR-93 was downregulated, and its predicted mRNA targets included BAMBI, CCND2, CDKN1A, HDAC8, KIF23, MAP3K9, MAP3K11, MYCN, PPARD, TLE4 and ZDHHC1. Overexpressed miR-93 significantly inhibited cell proliferation and colony formation by SW1116csc. Furthermore, miR-93 negatively regulated the mRNA and protein levels of HDAC8 and TLE4.

CONCLUSION: Some miRNAs were differentially expressed during differentiation of SW1116csc into SW1116 cells. miR-93 may inhibit SW1116csc proliferation and colony formation.

INTRODUCTION

Cancer stem cells (CSC) are a sub-population of cancer cells that possess characteristics associated with normal

stem cells, such as self renewal and the ability to differentiate into multiple cell types. CSCs are tumorigenic, in contrast to most cancer cells, which are thought to be non-tumorigenic. The CSC hypothesis infers that if CSCs were eliminated, the tumor would simply regress due to differentiation and cell death. Since the identification and characterization of CSCs in hematological malignancies, an increasing number of studies have described CSCs in solid tumors such as ovarian[1], colon[2], lung[3], breast[4], liver[5], melanoma[6] and pancreatic[7] tumors, raising the possibility that the CSC hypothesis applies to most neoplastic systems. CSCs are the most critical tumor cell type because they are capable of self renewing, differentiating, and maintaining tumor growth and heterogeneity, and thus play an important role in tumorigenesis and therapeutics.

MicroRNAs (miRNAs) are small noncoding RNAs that posttranscriptionally regulate gene expression. Mature miRNAs can specifically bind to 3' untranslated regions of target cellular mRNA, in turn triggering mRNA degradation or inhibition of translation[8]. To date, thousands of miRNAs have been identified in the human genome, where they act as key regulators of a wide variety of biological processes including development, cell differentiation, apoptosis, metabolism, and signal transduction[9]. Consequently, abnormal patterns of miRNAs have been found in various human diseases, most notably cancer[10]. Recent findings indicate that alterations in the expression of several miRNAs are present in human cancers, suggesting potential roles in carcinogenesis[11]. Expression of some miRNAs, such as let-7 in human lung cancers[12], the miR-15a/miR-16-1 cluster in chronic lymphocytic leukemia[13], and neighboring miR-143/miR-145 in colorectal neoplasia and breast cancer[14,15], is reduced, suggesting potential tumor suppressor activity. In contrast, other miRNAs, such as the miR-17-92 cluster in human B-cell lymphomas[16] and miR-155/BIC in Hodgkin lymphoma[17], are overexpressed, suggesting oncogenic potential.

miRNAs are emerging as important regulators of cellular differentiation and proliferation and have been implicated in the etiology of a variety of cancers. However, the role of miRNAs in human colon cancer stem cells remains poorly understood. In this study, we screened and identified differential miRNA expression profiles in colon cancer stem cells using a miRNA microarray and studied the function of differentially expressed miRNAs in the proliferation of colon cancer stem cells.

MATERIALS AND METHODS

Cell culture

The human colon cancer cell line (SW1116) was purchased from Cell Bank, Shanghai Institute of Life Science, Chinese Academy of Sciences and maintained in RPMI-1640 medium (Invitrogen, Carlsbad, CA, United States) supplemented with 10% fetal bovine serum (Gibco BRL, United States), penicillin G (1×10^5 U/L), and streptomycin (100 mg/L) in a 50 mL/L CO_2 atmosphere at 37 ℃. SW1116csc (Figure 1) were isolated previously[18] and maintained in serum-free DMEM/F12 medium supplemented with human recombinant epidermal growth factor (20 μg/L; Invitrogen), human recombinant basic fibroblast growth factor (20 μg/L; Invitrogen), L-glutamine (2 mmol/L), insulin (4 U/L), penicillin G (1×10^5 U/L), and streptomycin (100 mg/L).

Microarray experiments

Total RNA was extracted from SW1116csc and SW1116 cells using Trizol reagent (Invitrogen). The quantity was measured on a spectrophotometer (Ultraspec 2000, Pharmacia Biotech), and the integrity of the RNA was checked on a 1% agarose gel. Low-molecular-weight RNA (< 200 nt) was separated from the total RNA using mirVana miRNA purification columns (Ambion, Austin, TX, United States) for miRCURY™ array microarray (v.13.0) (Exiqon) analysis according to the manufacturer's protocol, which uses the LNA probe to detect miRNA expression. LNA is a high-affinity RNA analog with a bicyclic furanose unit locked in an RNA-mimicking sugar conformation, which results in unprecedented hybridization affinity toward complementary single-stranded RNA molecules. This makes LNA-modified DNA probes ideally suited for RNA targeting. Microarray images were analyzed using an Axon GenePix 4000B microarray scanner (Molecular Devices), and GenePix pro V6.0 (Molecular Devices) was used to read the raw intensity of the image. Average values of the replicate spots of each miRNA were background subtracted, normalized, and subjected to further analysis. Normalization was performed using the signal of U6 snRNA on the chip, and the cutoff value was set to 1000.

Real-time quantitative reverse transcription polymerase chain reaction

For polymerase chain reaction (PCR) of miRNAs, cDNA synthesis was performed with 100 ng total RNA using a SuperScript Ⅲ Reverse Transcriptase kit (Invitrogen) according to the manufacturer's protocol. The sequences of primers and probes specific for individual miRNAs and the U6 RNA internal control are shown in Table 1. PCR consisted of denaturation at 95 ℃ followed by 40 cycles of 95 ℃ for 15 s, 60 ℃ for 30 s, and 72 ℃ for 3 s. Thermal cycling and fluorescent monitoring were performed on an ABI 7700 sequence analyzer (PE Biosystems). Relative expression (RE) of the sample gene was calculated using the ΔΔCT method using the formula RE = 2ΔΔCT where CT = PCR cycle in which the sample fluorescent intensity exceeds that of background, ΔCT sample = CT sample - CT U6 sample, ΔCT control = CT control - CT U6 control, and ΔΔCT = ΔCT sample - ΔCT control.

miRNA target prediction

A list of potential miRNA targets was created by combining predicted targets from the mirBase, TargetScan, miRanda, and PicTar target prediction algorithms. Po-

tential targets were chosen based on gene function, the number of predicted target sites, and target prediction by multiple algorithms.

Plasmid constructs and transfection

The human miR-93 precursor (CUGGGGGCUC-CAAAGUGCUGUUCGUGCAGGUAGUGUGAU-UACCCAACCUACUGCUGAGCUAG CACUUCCC-GAGCCCCCGG) was reverse-transcribed and cloned into pSilencer 4.1 (Ambion). The correct plasmid was named pS-miR-93, and the control plasmid (pS-Neg) consisted of a scrambled sequence (Ambion). The sequence of the pS-miR-93 plasmid was confirmed with DNA sequencing. SW1116csc were seeded at 1×10^5 cells/well in a 12-well plate (BD Bioscience). After 48 h, the cells were transfected with 1 μg/well of pS-miR-93 or pS-Neg using 4 μL Lipofectamine 2000 reagent (Invitrogen) per well according to the manufacturer's protocol. After 24 h, cells were harvested, and total mRNAs and proteins were extracted.

Cell proliferation assay

SW1116csc and pS-miR-93-transfected SW1116csc (SWt) cells were seeded at a density of 1×10^4 in 35-mm Petri dishes. Cultured cells stained with trypan blue were observed and counted in triplicate over 6 wk.

Colony formation in soft agar

Cells were disassociated, suspended in medium containing 0.3% agar and 10% serum, and plated onto a bottom layer containing 0.6% agar. The cells were plated at a density of 3×10^4 cells/6-cm dish, and the number of colonies > 0.5 mm in diameter was counted 14 d later.

RT-PCR

Total RNA was extracted, and cDNA was synthesized as above. PCR was performed in a 50-μL volume containing 1 μL Taq DNA polymerase (Hua Mei Co.), 5 μL 10 × buffer, 1 μL dNTPs (10 mmol/L), 2 μL primers (10 μmol/L), and 1 μL cDNA (0.1 μg/μL). Amplification was performed in a thermal cycler (Perkin-Elmer Co., United States). The PCR products were analyzed and photographed with a gel documentation system (FR-200, Shanghai Fu Ri Bio Co.). For HDAC8, the forward primer used was F: 5'-TGGGCAGTCGCT-GGT-3', and the reverse primer was R: 5'-GTGGCT-GGGCAGTCATAA-3' (product size: 285 bp). For TLE4, F: 5'-ACTCCCACTGCTGTGCAAG-3', R: 5'-GTTTCTGGCACAATGCACAG-3' (194 bp). For glyceraldehyde-3-phosphate dehydrogenase (GAPDH), F: 5'-TTGGTATCGTGGAAGGACTCA-3', R: 5'-TGTCATCATATTTGGCAGGTT-3' (270 bp). RT-PCR primers were synthesized by Shanghai Sangon Co.

Western blotting

Cell extracts were prepared in lysis buffer (20 mmol/L Tris-HCl, pH 7.5, 0.1% Triton X-100, 0.5% sodium deoxycholate, 1 mmol/L phenylmethylsulfonyl fluoride, 10 μg/mL aprotinin, and 10 μg/mL leupeptin) and centrifuged at 12 000 × *g* at 4 ℃. The total protein concentration was measured using a BCA assay. Cellular extracts containing 50 μg total proteins were subjected to 10% SDS-PAGE and transferred electrophoretically to polyvinylidene difluoride membranes (Invitrogen). Blots were probed at 4 ℃ overnight with primary antibodies in 5% milk/TBST. The antibodies for western blotting were HDAC8, TLE4 and GAPDH (Santa Cruz Biotechnology, Santa Cruz, CA).

Statistical analysis

All data are presented as the mean ± SE. SPSS for Windows (version 15.0, SPSS Inc., United States) was used for statistical analysis. P values < 0.05 were considered statistically significant.

RESULTS

miRNA expression profiling with miRNA microarray

We used an miRNA microarray to evaluate miRNA expression profiles of colon cancer stem cells (SW1116csc) and differentiated colon cancer cells (SW1116). Analysis of data derived from the miRCURY™ array microarray indicated that compared with SW1116 cells, there were 46 differentially expressed miRNAs in SW1116csc. Among them, 35 miRNAs (including hsa-miR-192, hsa-miR-29b, hsa-miR-215, hsa-miR-194, hsa-miR-33a and hsa-miR-32) were overexpressed more than 1.5-fold and 11 miRNAs (including hsa-miR-93, hsa-miR-1231, hsa-miRPlus-F1080, hsa-miR-524-3p, hsa-miR-886-3p and hsa-miR-561) were downregulated (Table 2). Expression of miR-93 in SW1116csc was decreased by 16.7 times, and we chose this miRNA for further study.

Validation of microarray results using quantitative PCR

To validate our microarray results, we performed quantitative PCR with some of the miRNAs that were differentially expressed in SW1116csc according to the microarray data. We selected miR-93, miR-1231, miR-32, miR-33a, miR-194, miR-215, miR-29b and miR-192 for quantitative PCR. The quantitative PCR results indicated that the expression of miR-93 and miR-1231 was decreased, whereas the expression of miR-32, miR-33a, miR-194, miR-215, miR-29b and miR-192 was significantly increased in SW1116csc cells (Figure 2). The quantitative PCR result was in agreement with that of the microarray.

Prediction of miR-93 target gene

By combining predicted targets generated with the mirBase, TargetScan, miRanda and PicTar target prediction algorithms, potential targets of miR-93 were chosen. The stem relevant mRNA targets included BAMBI, CCND2, CDKN1A, HDAC8, KIF23, MAP3K9, MAP3K11, MYCN, PPARD, TLE4, and ZDHHC1.

Inhibition of cell proliferation and colony formation of SW1116csc by pS-miR-93 transfection

We tested for differences in the proliferation rate between SW1116csc, pS-Neg-transfected SW1116csc (SWcon), and pS-miR-93-transfected SW1116csc (SWt). The cells were examined from week 1 to week 7 after seeding. As shown in Figure 3, there was a difference in the growth rate between SWcon and SWt cells. SWt cells grew slowly and showed growth inhibition after week 3. The self-renewing capacity of SWt cells was also examined with the colony formation assay. When plated at a density of 100 cells/well, SW1116csc and SWcon cells generated a greater mean number of tumor spheres (72.3 ± 4.2 and 64.5 ± 3.6, respectively) than did SWt cells (19.6 ± 2.1) (Figure 4).

Overexpression of miR-93 reduces the mRNA and protein levels of HDAC8 and TLE4

To provide additional evidence for the role of miR-93 in inhibition of SW1116csc proliferation and colony formation, we examined the effect of miR-93 on the expression of HDAC8 and TLE4. As shown in Figure 5, miR-93 mimics significantly attenuated the mRNA and protein levels of HDAC8 and TLE4.

DISCUSSION

Mature functional miRNAs of approximately 22 nucleo-

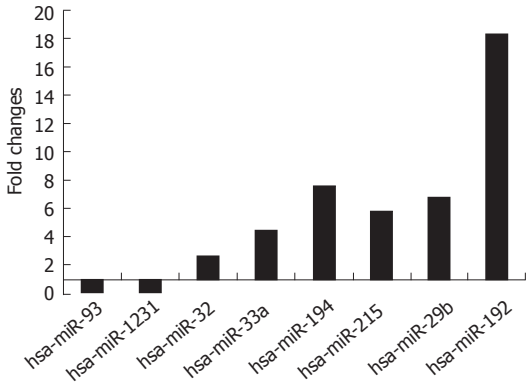

Figure 2 Expression levels of select miRNAs in SW1116csc as measured with quantitative reverse transcription polymerase chain reaction.

tides that are generated from long primary miRNA transcripts control gene expression at the posttranscriptional level by degrading or repressing target mRNAs. Some miRNAs aberrantly expressed in cancer have been well documented[19,20]. These miRNAs regulate the expression of signaling molecules such as cytokines, growth factors, transcription factors, and proapoptotic and antiapoptotic molecules. Recently, miRNAs were found to play a role in the differentiation of stem cells. Proper regulation of differentiation of stem cells is crucial to normal development and the avoidance of cancer[21]. However, the differential expression of miRNAs in human colon cancer

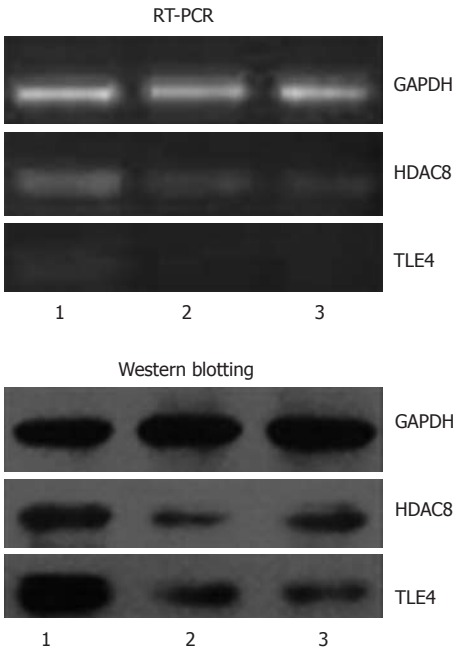

Figure 5 Expression of HDAC8 and TLE4 mRNA and protein in SW1116csc, SW1116 cells and SWt cells. 1: SW1116csc; 2: SW1116 cells; 3: SWt cells. stem cells has not been addressed.

Here we analyzed the differential expression of miRNAs in human colon cancer stem cells and differentiated colon cancer cells. We identified 46 differentially expressed miRNAs in SW1116csc. We observed miRNAs that were upregulated and others that were downregulated. The miR-93 expression level was significantly lower in SW1116csc than in SW1116 cells, indicating that miR-93 may be involved in the development or replication of colon CSCs.

One of the key characteristics of stem cells is their ability to divide for long periods of time when most other cells are quiescent[22]. Because the function of miR-93 in colon CSCs was unknown, we identified the biological effects of miR-93 on colon CSCs when its expression in these cells was upregulated by examining the role of miR-93 on cellular growth and proliferation of transfected SW1116csc. Overexpression of miR-93 consistently inhibited cell proliferation and colony formation of SW1116csc. To the best of our knowledge, this study is the first to demonstrate the differential expression of miRNAs in colon CSCs and the effect of miR-93 on colon CSCs. However, the underlying mechanisms of these effects are not completely understood. Using miRNA target prediction tools and RT-PCR, we found that inhibition of overexpressed miR-93 probably affects cell proliferation and colony formation of colon cancer stem cells by targeting HDAC8 and TLE4.

Histone deacetylase (HDAC) enzymes are a family of proteins with complex, multifunctional roles *in vivo*, including transcriptional regulation, regulation of tubulin

and cytoskeletal function, control of cardiac cell growth, regulation of thymocyte development, and facilitation of DNA repair[23]. HDAC enzymes function in part to control the acetylation state of nucleosomal histones, thereby regulating transcription. More recently, however, it has been shown that HDAC enzymes have many non-histone acetylation targets as well, including tubulin, heat-shock proteins, and a variety of transcription factors such as p53 and NF-kB subunit p65[24,25].

HDAC8 is a newly identified HDAC that was cloned and characterized in 2000. It is a novel marker of smooth muscle differentiation and is expressed at low levels in normal white blood cells but overexpressed in some malignant hematological cell lines[26]. cDNA microarray analysis suggests that there is differential expression of HDAC8 between mammary tumors and normal lactating mammary glands and that it may play a key regulatory role in mammary gland tumorigenesis[27]. Here we found that the expression level of HDAC8 in human colon cancer cells was high. Thus, accumulating data increase our understanding of the role of abnormally elevated HDAC8 activity in the pathogenesis of tumors.

Groucho (Gro) or Transducin-like Enhancer of Split (TLE) proteins constitute a family of highly conserved cofactors for transcription. They act as non-DNA-binding corepressors and are recruited to promoters *via* interaction with a DNA binding partner. Gro corepressor proteins interact with multiple transcription factors and thus affect different signaling pathways[28]. They contact histones and recruit HDACs, thereby altering local chromatin structure. Gro corepressor proteins confer repressing functions on binding partners with an activating potential[29].

The Gro/TLE family of corepressors interacts with at least five families of transcription factors and plays critical roles in Drosophila and vertebrate development. During B-lymphocyte differentiation, TLEs mediate the repressive effect of Pax5 *via* recruitment by Pu.1, limiting alternative cell fates[30]. However, the ability of Gro/TLEs to interact with other signaling pathways suggests a potentially broader role for Gro/TLEs in both normal and malignant hematopoiesis. Members of the Gro/TLE family of corepressors bind to all known Tcf/LEF complexes and act as inhibitors of Wnt/β-catenin signaling[31,32], a pathway implicated in expansion and self-renewal of the hematopoietic stem cell compartment[33]. Similarly, Gro/TLEs inhibit NF-κB signaling[34], a pathway constitutively activated in acute myeloblastic leukemia and thought to play an important role in hematopoietic cell proliferation, survival, and chemoresistance. *Gro/TLE* gene family members are also key effectors of Notch signaling, a pathway implicated in HSC fate determination and self-renewal[35]. The high expression of TLE4 in human colon CSCs indicates interactions with Wnt, NF-κB, or Notch signaling and suggests that TLE4 may be involved in the proliferation and differentiation of colon CSCs.

In summary, our study suggests that during the course of colon CSC differentiation towards colon cancer cells, some miRNAs are differentially expressed. miR-93 is one of the miRNAs that was downregulated, and overexpressed miR-93 significantly inhibited cell proliferation and colony formation by colon CSCs. Furthermore, overexpression of miR-93 negatively regulated mRNA and protein expression of HDAC8 and TLE4. The inhibition of cell proliferation by miR-93 in colon CSCs may occur by targeting HDAC8 and TLE4.

COMMENTS

Background

The cancer stem cell (CSC) hypothesis is currently at the center of a rapidly evolving field, involving a change of perspective on the development and treatment of cancers. However, research has been hampered by the lack of distinct molecular markers of CSCs.

Research frontiers

Since the identification and characterization of CSCs in hematological malignancies, an increasing number of studies have described CSCs in solid tumors such as ovarian, colon, lung, breast, liver, melanoma and pancreatic tumors, suggesting that the CSC hypothesis applies to most neoplastic systems.

Innovations and breakthroughs

Previously isolated SW1116csc were compared with SW1116 cells. The authors identified 35 miRNAs that were upregulated and 11 miRNAs that were downregulated in SW1116csc. Overexpressed miR-93 significantly inhibited cell proliferation and colony formation of SW1116csc. Furthermore, miR-93 negatively regulated the mRNA and protein expression levels of HDAC8 and TLE4.

Applications

The study of CSCs has important implications for future cancer treatment and therapies. The CSC hypothesis states that if the CSCs were eliminated, the tumor would simply regress due to differentiation and cell death. By selectively targeting CSCs, it may be possible to treat patients with aggressive, non-resectable tumors and prevent the tumor from metastasizing.

Terminology

CSCs are a sub-population of cancer cells that possess characteristics associated with normal stem cells, such as self renewal and the ability to differentiate into multiple cell types. CSCs are tumorigenic, in contrast to most cancer cells, which are thought to be non-tumorigenic. CSCs persist in tumors as a distinct population and cause relapse and metastasis by giving rise to new tumors.

Peer review

The authors presented an original work about colon CSCs and identified a potentially new pathway that could be targeted for colon cancer management.

Abstract

AIM: To evaluate the clinical significance of CpG island methylator phenotype (CIMP) in plasma and its association with hepatocellular carcinoma (HCC) progress.

METHODS: CIMP status of 108 HCC patients was analyzed using a methylation marker panel in tumor tissues and plasma with methylation-specific polymerase chain reaction. Fifteen samples of non-neoplastic liver tissues and 60 of plasma from healthy persons were examined simultaneously. Examined genes included *APC, WIF-1, RUNX-3, DLC-1, SFRP-1, DKK* and *E-cad*.

RESULTS: The frequencies of high-level methylation in HCC tissue and plasma were at least 15% for the seven genes: *APC*, 48/108, 44.44% in tissue and 26/108, 24.07% in plasma; *WIF-1*, 53/108, 49.07% in tissue and 35/108, 32.41% in plasma; *RUNX-3*, 52/108, 48.14% in tissue and 42/108, 38.89% in plasma; *DLC-1*, 38/108, 35.18% in tissue and 23/108, 21.30% in plasma; *SFRP-1*, 40/108, 37.04% in tissue and 31/108, 28.7% in plasma; *DKK*, 39/108, 36.1% in tissue and 25/108, 23.14% in plasma; and *E-cad*, 37/108, 34.3% in tissue and 18/108, 16.67% in plasma. CIMP+ ($\geqslant$ 3 methylated genes) was detected in 68 (60.2%) tumor tissue samples and 62 (57.4%) plasma samples. CIMP was not detected in non-neoplastic liver tissues or plasma of healthy persons. CIMP status in tumor tissues differed significantly in gender, hepatitis B surface antigen, alpha-fetoprotein, and tumor-node-metastasis stage ($P < 0.05$). Similar results were obtained with plasma samples ($P < 0.05$). There was no difference in CIMP status in age, presence of hepatitis C virus antibody, cirrhosis, number of nodes, number of tumors, tumor size, or Edmondson-Steiner stage. A one-year follow-up found that the metastatic rate and recurrence rate in the CIMP+ group were significantly higher than in the CIMP- group as assessed with plasma samples ($P < 0.05$).

CONCLUSION: Plasma DNA can be a reliable sample source for CIMP analysis. CIMP in plasma may serve as a molecular marker of late-stage and poor-prognosis HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer in the world[1] and one of the leading causes of cancer-related death[2] because of late-stage diagnosis, lack of effective therapy, and easy recurrence[3]. Despite much progress in diagnostic and treatment strategies for HCC, recurrence and metastasis remain the main factors affecting patient survival. The 5-year survival rate is between 35% and 41% after resection[4,5] and between 47% and 61% after liver transplantation[6]. In general, prognosis remains poor, thus identification of useful molecular prognostic markers is necessary.

DNA methylation is an enzyme-mediated chemical modification that usually occurs in cytosine-guanine dinucleotide-rich areas (CpG islands) in the promoter region of genes. Aberrant promoter hypermethylation is an important mechanism leading to loss of gene function in tumors[7] including HCC[8,9]. The methylation pattern of multiple genes can provide useful information on global epigenetic alterations[10]. The hypermethylated subtype in tumors, called the CpG island methylator phenotype (CIMP) in which multiple genes are concurrently methylated, is a novel marker of tumor progression[11,12]. Methylation of CpG islands in the promoters of many tumor suppressor genes effectively silences those genes[13]. These epigenetic alterations may be important early events in carcinogenesis and may also be potential biomarkers for early detection[14]. CIMP is an important mechanism in HCC development and may serve as a molecular marker of late-stage HCC with poor prognosis[15]. Tumor tissue is the current gold standard to detect methylation in HCC[16]. However, not all patients' tissue samples can be used, but blood plasma samples are readily available from all patients.

Because determining the methylation status of single genes has limited prognostic value[17], CIMP has been reported as a promising predictive biomarker in many human cancers[17-19]. Many studies have investigated the relationship between CIMP and HCC prognosis[15,20], but these studies used tumor tissue as a research tool. These studies only examined the patients who underwent hepatic resection or liver puncture. Promoter methylation in breast cancer can be detected in the circulating plasma DNA[21]. The usefulness of future DNA methylation studies will be greatly enhanced if the efficacy is equivalent by using plasma and tumor tissues (Iyer *et al*[22], 2010). In this study, we analyzed the CIMP status of 108 HCC patients based on a methylation marker panel. Examined genes included *APC*, *WIF-1*, *RUNX-3*, *DLC-1*, *SFRP-1*, *DKK* and *E-cad*. These genes were selected because they have been found to be frequently methylated in HCC and other malignancies. The aim of our current study was to evaluate the clinical significance of CIMP in plasma DNA and its association with prognosis in HCC.

MATERIALS AND METHODS

Patients and specimens

Between 2008 and 2010, 108 paired samples of primary HCC and corresponding non-neoplastic liver tissues and plasma from Chinese patients were collected during surgical resection at the Nantong Tumor Hospital. Samples from 60 healthy persons were used as matched controls. The controls had no self-reported history of cancer and were frequently matched to age (± 5 years), gender, and residential area. After resection, tissue specimens were immediately frozen in liquid nitrogen and stored at -70 ℃. Patients consisted of 85 men and 23 women, ranging in age from 32 to 74 (52.48 ± 7.56) years. Questionnaire data and blood samples were also collected from all patients and controls. After centrifugation, separated plasma samples were stored at -70 ℃. The diagnosis of HCC was confirmed by pathological examination or elevation of alpha-fetoprotein (AFP, > 400 g/L) combined with imaging examinations including magnetic resonance imaging (MRI) and/or computerized tomography (CT). Tumor-node-metastasis (TNM) stage was classified according to the 6th edition TNM classification of the American Joint Committee on Cancer (Greene *et al*, 2002). Fifteen samples of noncancerous liver tissues were obtained from patients with liver hemangioma. Eighty-six patients had cirrhosis, 84 patients were positive for hepatitis B surface antigen (HBsAg), and 19 patients were positive for hepatitis C virus antibody (anti-HCV). Written informed consent was obtained from each patient, and the study protocol was approved by the local ethics committee.

DNA extraction and sodium bisulfite

DNA from both plasma (200 μL per column) and tissue samples was treated with proteinase K and then extracted with phenol-chloroform according to the manufacturer's instructions (Shanghai ShineGene Molecular Biotech, Inc., Shanghai, China) and stored at -20 ℃. A final elution volume of 50 μL was collected. The extracted DNA was treated with sodium bisulfite using an EZ DNA-methylation™ kit (Zymo Research, Orange, CA, United States) to convert all unmethylated cytosines to uracils. Bisulfite-modified DNA was resuspended in 10 μL elution buffer and stored at -20 ℃ until methylation-specific polymerase chain reaction (MSP).

MSP

MSP was used to determine the methylation status of CpG islands in genes after bisulfate treatment[23,24]. The methylation status of the promoters of *APC*, *WIF-1*, *RUNX-3*, *DLC-1*, *SFRP-1*, *DKK* and *E-cad* was determined with a two-step MSP protocol that consists of amplification and detection. Polymerase chain reaction (PCR) products were analyzed on 2% agarose gels, stained with ethidium bromide, and visualized with ultraviolet illumina-

tion. All experiments were performed in duplicate. Table 1 lists the primer sequences.

Follow-up

Patients were followed up for one year. The last follow-up was on September 8, 2010. None of the patients received chemotherapy prior to surgery. The median follow-up time was 5 mo (range, 3-12 mo). Patients were given a physical examination, abdominal ultrasonography, and chest X-ray, and serum was collected and tested for AFP. During the first year, local recurrence and distant metastasis were monitored every 3 mo with CT and/or MRI. Only 98 of the 108 patients were completely followed up. Twenty-one patients (19.44%) were found to have HCC recurrence; these patients all had AFP levels >20 μg/L, and CT examination revealed a clear image of the liver cancer. These 21 patients appeared to have different degrees of multicentric new lesions of the liver, including multiple nodules, apparent mass, the portal vein, hepatic vein thrombosis and sub-lesions. Twenty-four (22.2%) patients had HCC metastasis. According to their clinicopathological characteristics, formation of portal vein tumor thromboses, and dissemination into lymph nodes, 18 patients showed liver metastasis, four patients had bone metastasis, and two patients had brain metastasis. Forty-four (40.74%) patients died of cancer-related causes. Fifty-four patients were still alive at the time of the last follow-up.

RUNX3	52[1]	42	4	0	0	52.47

[1]χ^2 test comparing the frequencies of gene methylation between tumor and non-neoplastic samples, $P < 0.05$.

Statistical analysis

The SPSS 13.0 software package (SPSS, Inc., Chicago, IL, United States) was used for all statistical analyses. Values for the clinical and biological characteristics of patients were expressed as means ± SD. Comparison was done with Student's t test. A χ^2 test or Fisher's exact test was used to compare the incidence of methylation. All P values presented are two-sided, and a P value of less than 0.05 was considered statistically significant.

RESULTS

Clinical data

Median tumor size was 6.0 cm (range, 1.2-19.4 cm). According to the Edmondson-Steiner classification system, 7 cases were classified as grade Ⅰ, 55 cases were grade Ⅱ, 43 cases were grade Ⅲ, and 3 cases were grade Ⅳ. According to the 6th edition TNM classification of the American Joint Committee on Cancer (Greene *et al*, 2002), 51 cases were classified as grade Ⅰ, 20 cases were grade Ⅱ and 37 cases were grade Ⅲ.

Methylation of tumor-associated genes in HCC

We examined the methylation status of seven tumor-associated genes (*APC*, *WIF-1*, *RUNX-3*, *DLC-1*, *SFRP-1*, *DKK*, *E-cad*) in tissue and plasma samples from HCC patients and controls. The results are summarized in Table 2. No methylation was detected in the promoters of these genes in normal tissues or control plasma. Table 2 shows that methylation was more frequent in HCC than in adjacent non-neoplastic liver tissue and normal liver tissues for all seven genes. The same results were observed for plasma (Table 2). Methylation at any level was detected in one or more of the genes in 99 (91.67%) of 108 cases. The frequencies of high-level methylation in HCC tissue and plasma were at least 15% for the seven genes, including 44.44% for *APC*, 49.07% for *WIF-1*, 48.14% for *RUNX3*, 35.18% for *DLC-1*, 37.04% for *SFRP-1*, 36.1% for *DKK*, and 34.3% for *E-cad* in tissue. In plas-

ma, the frequencies were 24.07% for *APC*, 32.41% for *WIF-1*, 38.89% for *RUNX3*, 21.30% for *DLC-1*, 28.7% for *SFRP-1*, 23.14% for *DKK* and 16.67% for *E-cad*.

Concordance of data obtained from plasma and tissue samples

The frequencies of promoter methylation in tissue and plasma samples for the seven tumor-associated genes were as follows: *APC*, 48/108, 44.44% in tissue and 26/108, 24.07% in plasma; *WIF-1*, 53/108, 49.07% in tissue and 35/108, 32.41% in plasma; *RUNX3*, 52/108, 48.14% in tissue and 42/108, 38.89% in plasma; *DLC-1*, 38/108, 35.18% in tissue and 23/108, 21.30% in plasma; *SFRP-1*, 40/108, 37.04% in tissue and 31/108, 28.7% in plasma; *DKK*, 39/108, 36.1% in tissue and 25/108, 23.14% in plasma; and *E-cad*, 37/108, 34.3% in tissue and 18/108, 16.67% in plasma. We observed significant concordance of promoter methylation between plasma and tissue samples for all seven genes.

CIMP in HCC

According to the criteria in a related study[25], the CIMP status of each of our 108 HCC samples was classified as CIMP+ (with ⩾ 3 methylated genes) or CIMP- (with two or fewer methylated genes). In this study, because of a cutoff value of 3, the average number of methylated genes was 2.8 in tumor tissue and 2.0 in plasma. Regarding tumor tissues, 65 cases of HCC (60.2%) were classified as CIMP+, and 43 (39.8%) cases were classified as CIMP-. When plasma was examined, 62 cases of HCC (57.4%) were classified as CIMP+, and 46 cases (42.6%) were classified as CIMP-. No CIMP+ samples were from non-neoplastic tissues or healthy controls.

Relationship between CIMP and clinicopathological characteristics

We analyzed the relationship between CIMP and clinicopathological characteristics including age, gender, HBsAg, anti-HCV, serum AFP level, liver cirrhosis, number of nodes, tumor size, number of tumors, Edmondson-Steiner grading, and TNM stage. In tumor tissues, we found significant differences between CIMP and gender, HBsAg, AFP, and TNM stage ($P < 0.05$ for all; Table 3). The same result was obtained with plasma samples, including differences between CIMP and gender, HBsAg, AFP, and TNM stage ($P < 0.05$ for all; Table 3). There were no differences between CIMP status and age, anti-HCV, cirrhosis, number of nodes, number of tumors, tumor size, or Edmondson-Steiner stage.

Prognostic significance of CIMP in HCC

Follow-up for up to one year found that the rates of metastasis differed significantly between the CIMP+ and CIMP- groups when tumor tissue ($P < 0.05$) and plasma were examined ($P < 0.05$). CIMP+ tumors appeared to frequently undergo metastasis. The recurrence rates were significantly higher in the CIMP+ group compared with the CIMP- group when both tumor tissue and plasma were examined ($P < 0.05$ for both). Survival rates differed significantly between the CIMP+ and CIMP- groups ($P < 0.05$ for both; Table 4).

DISCUSSION

Little is known about the many risk factors that are likely to affect the metastasis and recurrence of HCC. The development and progression of HCC is a multistep process, and the basic molecular pathway of HCC development remains largely unknown. Abnormal gene expression may be an early event in tumorigenesis and a potential biomarker for early detection[14]. Recurrence, which is frequent after surgical resection, and metastasis are the main factors affecting the long-term prognosis of HCC patients. Currently, predicting the development and guiding the treatment for HCC are generally based on clinical characteristics and/or the stage of HCC[26].

Table 4 Relationship between CpG island methylator phenotype and prognosis of hepatocellular carcinomas after a one-year follow-up ($n = 98$)

Prognosis	CIMP+		CIMP-		χ^{21}	χ^{22}
	Tumor	Plasma	Tumor	Plasma		
Metastasis						
Yes	22[a]	19[a]	2	5	11.032	5.762
No	40	38	34	36		
Recurrence						
Yes	18[a]	17[a]	3	4	5.796	4.257
No	44	40	33	37		
Survival						
Yes	26[a]	23[a]	24	27	5.574	4.621
No	36	32	12	16		

[1]Indicates χ^2 test comparing the prognosis between CIMP+ and CIMP- in tumor tissues; [2]Indicates the comparison in the plasma. [a]$P < 0.05$. CIMP: CpG island methylator phenotype.

However, genetic and epigenetic changes can also be used as indicators of cancer progression and/or markers. Epigenetic processes, in particular, abnormal methylation of CpG islands in HCC, may play a crucial role in cancer development[27,28]. In our study, we examined the methylation status of seven tumor-associated genes (*APC*, *WIF-1*, *RUNX-3*, *DLC-1*, *SFRP-1*, *DKK* and *E-cad*) on the basis of their biological significance in tissue and plasma in HCC and controls. We observed no methylation in the promoters of these genes in normal tissues and control plasma. The frequencies of high-level methylation in HCC tissue and plasma were at least 15% for these seven genes. The results showed that examining the methylation status of multiple genes may aid the diagnosis of early HCC. In this study, we also found that promoter methylation in plasma DNA was highly specific for certain cancer-related genes and that results for plasma were similar to those for tissue samples. There was good concordance in DNA methylation between plasma and tumor tissues in HCC.

CIMP+ tumors tend to occur in older patients with colorectal cancer, and this phenotype is overrepresented in proximal colon cancer tumors[29]. In esophageal adenocarcinoma, CIMP is associated with poor prognosis[30]. CIMP is also associated with environmental factors and serum AFP levels in HCC[31,32]. Many studies have investigated the relationship between CIMP and HCC prognosis[15,20]. However, these studies used tumor tissue samples, thereby limiting the applicability of the research. In our study, we found that CIMP in tumor tissues as well as plasma was associated with metastasis and recurrence of HCC. The presence of CIMP+ tumors indicates the likelihood of metastasis and recurrence in HCC. Thus, CIMP may play an important role in the pathogenesis, metastasis, and recurrence of HCC. Methylation may silence the genes associated with suppression of metastasis and recurrence. We also observed that there were no CIMP+ samples from corresponding non-neoplastic tissues and healthy controls, consistent with the known importance of methylation in cancer development. Our study also shows that promoter methylation in plasma DNA was highly specific and was seen in both plasma and tissue samples. Therefore, CIMP detection in plasma rather than tumor tissues may be used as a reliable source for predicting the prognosis of patients with HCC.

It has been shown that methylation of genes associated with tumors and CIMP is intimately involved in the early process of carcinogenesis and tumor progression[13]. We found that CIMP is a common phenomenon in HCC. Thus, CIMP may ultimately offer a new tool for predicting patients' clinical outcomes.

CIMP that is associated with tumors seems to have distinct epidemiology, histology, and molecular features[20].

The functional significance of methylation of tumor-associated genes in HCC may be that this process initiates progressive inactivation of these genes[15]. CIMP may be useful for stratifying the prognosis of patients with TNM stage I HCC and for identifying patients who are at higher risk for recurrence[20]. In our study, the presence of CIMP+ tumors indicates a poor prognosis in HCC. Thus, CIMP detection may determine the prognosis of patients with HCC. Furthermore, our study shows that promoter methylation in plasma DNA was highly specific and plasma and tissue samples yielded similar results. Therefore, CIMP detection in plasma, rather than tumor tissues, may be used as a reliable index for predicting the course of patients with HCC. Limitations of this study are that the results were based on a relatively small sample of patients, and the number of cancer-related genes we examined was small. Furthermore, the length of follow-up was only one year. Thus, in the future, a larger-scale multi-gene study that includes an extended follow-up period is needed to confirm our results.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is the the fifth most common malignant cancer in the world, for later diagnosis, lack of effient therapy and easy recurrence. Despite a lot of progress in diagnostic and treatment strategies for HCC, recurrence and metastasis are still the main factors affecting the long-term prognosis for patients. In general, prognosis is still poor, and identification of useful molecular prognostic markers is required.

Research frontiers

DNA methylation is an enzyme-induced chemical modificationthat usually occurs in cytosine-guanine dinucleotide-rich areas (CpG islands) in the gene promoter regions. Aberrant promoter hypermethylation is an important mechanism for loss of gene function in tumors including HCC. The methylation pattern of multiple genes can provide useful information and an overall picture of epigenetic alterations. The hypermethylated subtype in tumors, called the CpG island methylator phenotype (CIMP), where multiplegenes are concurrently methylated, is a novel marker for tumor for progression. CIMP is an important mechanism in hepatocellular carcinoma development and could serve as a molecular marker of late stage and poorly prognostic HCC development.

Innovations and breakthroughs

Many studies have investigated the relationship between CIMP and prognosis associated with HCC, and also made many admirable achievements. However, these studies based on tumor tissue as a research object. These patients were only confined to patients with hepatic resection or liver puncture and part of the patients would be missed. Plasma DNA can be reliable for testing methylation profile in hepatocellular carcinoma patients. The productivity level of future DNA methylation studies will be greatly enhanced if the efficacy of using plasma is

equivalent to tumor tissue.In this study, the authors analysed the CIMP status of HCC patients based on a methylation marker panel. Associated genes include the *APC*, *WIF-1*, *RUNX3*, *DLC-1*, *SFRP-1*, *DAPK* and *E-cad*. These genes were selected because they have been found to be methylated frequently in HCC and other malignancies. The aim of the present study was to evaluate the clinical significance of CIMP in plasma associated with prognosis in HCC.

Applications

In this study, the authors found that plasma DNA could be used as a reliable resource and replace tumor tissue for CIMP research. This results also suggested that CIMP in plasma could serve as a molecular marker of late stage and poorly prognostic HCC.

Terminology

Epigenetic changes: Heritable changes in gene structure that without changing the gene sequence. CpG islands: CpG rich areas located in the promoter regions of many genes. CpG island methylation: The addition of a methyl group to a cytosine residue that lies next to guanine within CpG dinucleotides. CIMP: The hypermethylated subtype in tumors, called the CIMP, where multiplegenes are concurrently methylated.

Peer review

This article is new and clinically informative in that it has firstly reported that the CIMP in plasma is associated with the presence of HCC.

Abstract

AIM: To investigate the effects of laparoscopic hepatectomy for the treatment of hepatocellular carcinoma (HCC).

METHODS: From 2006 to January 2011, laparoscopic hepatectomies were performed on 30 cases of HCC at Northern Jiangsu People's Hospital. During this same time period, 30 patients elected to undergo conventional open hepatectomy over laparoscopic hepatectomy at the time of informed consent. The degree of invasiveness and outcomes of laparoscopic hepatectomy compared to open hepatectomy for HCC were evaluated.

RESULTS: Both groups presented with similar blood loss amounts, operating times and complications. Patients in the laparoscopic hepatectomy group started walking and eating significantly earlier than those in the open hepatectomy group, and these more rapid recoveries allowed for shorter hospitalizations. There were no significant differences between procedures in survival rate.

CONCLUSION: Laparoscopic hepatectomy is beneficial for patient quality of life if the indications are appropriately based on preoperative liver function and the location and size of the HCC.

Key words: Laparoscopy; Hepatocellular carcinoma; Liver resection; Liver lobectomy

INTRODUCTION

Laparoscopic resection of liver tumors was first reported in 1993[1]. It was initially adopted to treat peripheral, benign tumors that were amenable to non-anatomical wedge resection. The relatively slow development of laparoscopic liver resection compared to other subspecialties of laparoscopic surgery can be attributed to several reasons. First, some technical maneuvers that are frequently applied in open liver resection, such as organ mobilization, control of vascular inflow, and hanging

maneuvers, are difficult to reproduce in the laparoscopic setting. Difficulty in controlling hemorrhage, especially when profuse bleeding arises from the inferior vena cava or occurs deep in the liver parenchyma, is another major concern. Risk of gas embolism secondary to pneumoperitoneum can lead to dire consequences. In addition, increased risks of postoperative bile leakage and bleeding and uncertain long-term oncological outcomes concomitant with the resection of malignant tumors are obstacles that have undermined the development of laparoscopic hepatectomy[2].

With advancements in surgical instruments and increasing experience in laparoscopic treatment for benign liver diseases, there has been a growing interest in its application for hepatocellular carcinoma (HCC). We have actively performed laparoscopic hepatectomies for hepatic tumors, particularly for HCCs, since 2000. Recent experience has persuaded us that there are great potential benefits of laparoscopic hepatectomy; however, few reports exist regarding the usefulness, morbidity, and mortality of laparoscopic hepatectomy for HCC[3]. In this study, we addressed the indications, evaluated the degree of invasiveness, and analyzed the outcomes of laparoscopic hepatectomy for HCC based on our 5 years of experience.

MATERIALS AND METHODS

Patients

From 2006 to January 2011, laparoscopic hepatectomies were performed on 30 cases of HCC: 29 Child class A and one Child class B. Hepatitis B and hepatitis C viruses were positively noted in 24 and three cases, respectively. Twenty-three patients had chronic hepatitis, and 25 had liver cirrhosis. The localization of HCC by Couinaud's classification was as follows: segment Ⅰ, eight patients; segments Ⅱ and Ⅲ, ten patients; segment Ⅳ, four patients; segment Ⅴ, six patients; and segment Ⅵ, two patients.

During this same time period, 30 patients elected to undergo conventional open hepatectomy over laparoscopic hepatectomy at the time of informed consent. Twenty-eight cases (left lateral segmentectomy, 10; partial hepatectomy, 20) were retrospectively selected by the same criteria: the tumor was solid, was located in the left lateral or lower segment, and was < 10 cm in size. All operations were performed by the authors. The patients undergoing laparoscopic hepatectomy were compared to patients who underwent open hepatectomy with respect to operation time, blood loss, and blood chemistry. For statistical analysis, Student's *t* test, Kaplan-Meier method (for survival rates), and log-rank test were used. $P < 0.05$ was considered statistically significant.

Surgical procedure

The technique of laparoscopic hepatectomy has been described elsewhere[4]. Briefly, patients received general anesthesia according to the same protocol. Each patient's position and trocar placement were determined based on the location of the tumor. Laparoscopic hepatectomies were performed with the four- or five-trocar technique. Exploration of the extent of the tumor and its relationship with the vascular anatomy and other tumors in the liver was performed using intraoperative ultrasonography. In laparoscopic hepatectomy, there is the possibility of a CO_2 embolism by pneumoperitoneum during transection of the liver parenchyma and vessels[5]. Therefore, the pneumoperitoneum was shifted using abdominal wall lifting, particularly during liver parenchymal transection. The line of the intended liver parenchymal transection was marked on the liver surface using diathermy or microwaves. After the liver was punctured using a microwave scalpel along the line of the transection, it was irradiated with microwaves (average power 75 W) for a 30-s interval. Ultrasonic dissection of the liver was performed using an ultrasonic surgical system. The branched vessels were clipped and transected. In recent cases, laparoscopic coagulating shears were actively employed, and an endoscopic linear stapler was applied for liver transection if the tumor was pedunculated. In addition, the use of an endolinear stapler allowed surgeons to achieve rapid dissection and transection of Glisson's sheath and the hepatic veins in a left lateral segmentectomy. The resected liver was maneuvered into a plastic bag. Extraction of the undivided specimen was performed in all patients through the slightly enlarged trocar incision, which enabled histological review.

Table 1 Clinicopathological features

RESULTS

Demographic data of the clinicopathological features in the open and laparoscopic hepatectomy groups are shown in Table 1. There were no differences in any of the preoperative background variables between the two groups, including tumor size.

All laparoscopic hepatectomies were successful, and there were no notable differences in operating times compared with open hepatectomy (Table 2). Postoperatively, the peak values of total bilirubin and alanine aminotransferase did not differ significantly between

Table 2 Clinicopathological features

the two groups. The patients started walking and eating significantly earlier in the laparoscopic hepatectomy group, and recovered more rapidly, which consequently allowed for shorter hospitalization. The laparoscopic hepatectomy group had a 13.3% complication rate, and the open hepatectomy group had a complication rate of 10%. However, this difference did not reach statistical significance (Table 2). Three patients in the laparoscopic hepatectomy group suffered bile leakage from the transected liver surface and recovered after drainage for 3 d. There were no hospital deaths in either group.

No recurrences related to laparoscopy, such as peritoneal dissemination and port-site recurrences, were observed. There were no significant differences in the survival rates between procedures, although more clinical cases and longer follow-up periods are needed to reach definitive conclusions. The 5-year survival rates for open and laparoscopic hepatectomy groups were 53.3% and 50%, respectively (Figure 1, $P > 0.05$).

DISCUSSION

Laparoscopic surgery for liver resection is a highly specialized field because the liver has unique anatomical features that present technical obstacles for surgery, such as difficulties in the control of bleeding and the potential for bile leakage from the intrahepatic vessels. However, important technological developments and improved endoscopic procedures have been established. Equipment modifications, such as intraoperative ultrasonography, ultrasonic dissection, microwave coagulators, and argon beam coagulators, and the introduction of endoscopic linear staplers and laparoscopic coagulation shears have been recognized for their efficacy in liver surgery. These advances have led to a higher frequency of laparoscopic partial hepatectomies performed in recent years. There have been reports of laparoscopic right and left lobectomy[6-9]. The future direction of laparoscopic liver resection is the use of surgical robotic systems[1,10,11]. Liver resection with the use of the Da Vinci robotic system has been reported[5]. The potential advantages of using robots include the visualization of high-quality 3D images and tremor filtering. The EndoWrist robotic instrument is even able to perform a 360-degree range of motion. However, the advantages of employing robotic systems must be balanced with the high cost of surgery, lack of training schemes, and difficulty of conversion to open surgery. Nonetheless, the use of surgical robots is expected to become more common in the treatment of both benign and malignant liver tumors in the foreseeable future.

The treatment of HCC and, more specifically, the indications for hepatectomy, are very limited. Nonsurgical ablation therapy, an alternative method to surgery, has been advocated by some because it yields improved quality of life, which has subsequently provoked controversy over curability[12]. However, the Liver Cancer Study Group of Japan has reported that patients who underwent hepatic resection had a higher survival rate than a nonsurgical treatment group, even for small-sized HCCs[13]. Under these circumstances, laparoscopic hepatectomy represents an intermediate option between ablation therapy and conventional hepatectomy; ablation therapy is less invasive than surgical resection, but laparoscopic hepatectomy is superior in its ability to resect the tumor completely and in allowing optimal pathological evaluation from the resected specimen. Although laparoscopic surgery is less invasive than standard hepatectomy, laparoscopic hepatectomy is inferior to open hepatectomy in terms of anatomical resection. Laparoscopic systematic resection is currently contraindicated because of its technical difficulties, except in the case of left lateral segmentectomy. A recent report has demonstrated the safety associated with more limited blood loss for laparoscopic left lateral segmentectomies in a case–control study[14].

Laparoscopic liver resection is a safe and feasible treatment option for HCC, even in cirrhotic liver[15]. However, converting to a new surgical method does not mean that the old surgical method was a failure. With advances in surgical techniques and instruments, laparoscopic liver

resection has been performed more frequently, even for tumors in difficult anatomical locations. Nonetheless, oncological clearance should not be jeopardized in exchange for the postoperative benefits of laparoscopic surgery. Laparoscopic liver resection offers advantages over open resection in terms of ambulation, oral intake and hospital stay. These more rapid recoveries allow for shorter hospitalization, which is reflected in reduced cost and better patient quality of life. The equivalent 5-year survival rates that are observed with laparoscopy promote this approach as a promising avenue of research for the resection of HCCs; however, further evaluation is required.

COMMENTS

Background

With the development of laparoscopic instruments and parenchymal transection devices and an improved understanding of the vascular anatomy of the liver, it is now widely accepted that laparoscopy will be used increasingly in liver surgery.

Research frontiers

The underlying intent of laparoscopic surgery for hepatocellular carcinoma is to provide curative resection while minimizing complications. In this study, the authors demonstrated that laparoscopic hepatectomy avoids some of the disadvantages of open hepatectomy and is beneficial for quality of life, as a minimally invasive procedure. There were no significant differences in the survival rates between procedures.

Innovations and breakthroughs

This paper describes a retrospective evaluation of a cohort of patients who underwent laparoscopic hepatectomy at a single center. A good clinical outcome depended on the reasonable choice of indication, suitable parenchymal transection devices, and sufficient experience in hepatic resection and laparoscopy.

Applications

Laparoscopic hepatectomy can be performed in selected patients.

Peer review

This is a comparative observational study on laparoscopic liver resection for cancer. Its publication seems important in a time of intense and controversial discussion about the use of laparoscopy for liver cancer.

Abstract

Composite colorectal carcinomas are rare. There are a modest number of cases in the medical literature, with even fewer cases describing composite carcinoma with neuroendocrine and squamous components. There are to our knowledge no reports of composite carcinoma molecular alterations. We present a case of composite carcinoma of the splenic flexure in a 33 year-old Caucasian male to investigate the presence and prognostic significance of molecular alterations in rare colonic carcinoma subtypes. Formalin-fixed paraffin-embedded (FFPE) tissue was hematoxylin and eosin- and mucicarmine-stained according to protocol, and immuno-stained with cytokeratin (CK)7, CK20, CDX2, AE1/AE3, chromogranin-A and synaptophysin. DNA was extracted from FFPE tissues and molecular analyses were performed according to lab-developed methods, followed by capillary electrophoresis. Hematoxylin and eosin staining showed admixed neuroendocrine and keratinized squamous cells. Positive nuclear CDX2 expression confirmed intestinal derivation. CK7 and CK20 were negative. Neuroendocrine cells stained positively for synaptophysin and AE1/AE3 and negatively for chromogranin and mucicarmine. Hepatic metastases showed a similar immunohistochemical profile. Molecular analysis revealed a G13D *KRAS* mutation. *BRAF* mutational testing was negative and microsatellite instability was not detected. The patient had rapid disease progression on chemotherapy and died 60 d after presentation. Although the G13D *KRAS* mutation normally predicts an intermediate outcome, the aggressive tumor behavior suggests other modifying factors in rare types of colonic carcinomas.

Key words: Composite carcinoma; Neuroendocrine; Squamous; *KRAS*; *BRAF*; Microsatellite instability

INTRODUCTION

Composite carcinomas are composed of at least two different intermingled malignant cell types. Such tumors have been documented in numerous gastrointestinal organs[1-4]. The usual composite carcinoma contains

adenocarcinoma and neuroendocrine components; however, spindle cell, osteoid metaplasia, squamous, and pleomorphic patterns have been identified[5]. Although up to 20% of colonic adenocarcinomas contain neuroendocrine cells, these have not been shown to influence prognosis[5]. When rendering a diagnosis of composite carcinoma, it is recommended that tumors contain a neuroendocrine component comprising at least one-third to one-half of the tumor[5].

The behavior of composite carcinomas is variable. In some cases, tumor behavior is similar to adenocarcinoma[5]; however, some case reports show progression to death within months[6]. The follow-up interval is not known in all of these cases. In some composite carcinomas, metastatic disease is solely from the neuroendocrine component[7], while others have shown composite metastases[8].

Primary squamous carcinoma of the colon occurs in one out of every 2000-4000 colorectal carcinomas[9]. Diagnostic criteria include the exclusion of metastases from other organs, the absence of a squamous fistula tract, the absence of concurrent anal squamous carcinoma, and the presence of squamous features on histologic examination[10]. The most frequent sites of primary squamous carcinoma of the colon are the proximal colon and rectum. Patients usually present during the fifth decade of life and more than 15% have distant metastases at presentation[11]. The average survival after diagnosis is 30 mo and the 5-year survival is approximately 30%[11]. Surgical resection remains the mainstay of therapy, and cisplatin and 5-fluorouracil are commonly used chemotherapeutic agents[12]. Squamous carcinomas with small cell or undifferentiated features have a very poor prognosis[13].

Tumor microsatellite instability (MSI) and *KRAS* and *BRAF* mutations have prognostic and predictive significance in colorectal adenocarcinomas, but little is known regarding these findings in the rarer subtypes of colorectal carcinomas such as high grade neuroendocrine carcinoma or squamous cell carcinoma. Microsatellite instability is found in 10-15% of sporadic colorectal carcinomas. MSI-H patients typically have proximal tumors with an overall more favorable outcome compared to tumors with microsatellite-instability. *BRAF* mutations, of which greater than 90% are V600E, occur in 70% of sporadic MSI cases and in 10%-15% of microsatellite-stable cases[14]. *KRAS* mutations are found in 30%-50% of colorectal carcinomas. The G12D, G12V and G13D mutations are the most common *KRAS* mutations, in order of decreasing frequency[15]. In particular, the G12V mutation is an independent risk factor for a 30% increase in relapse or death[16], while the G13D mutation predicts an intermediate outcome between two broad groups of cases; those with *BRAF*, G12D and G12V mutations and those with MSI-H with concurrent G13D mutations[15]. To our knowledge molecular alterations have not been characterized in composite carcinomas of the colon with neuroendocrine and squamous components. This case report describes an aggressive and fatal tumor in an unusual gastrointestinal location in an unusual age demographic, with a G13D *KRAS* mutation.

CASE REPORT

A 33 year-old Caucasian male veteran presented to the Nashville Veterans Affairs Medical Center with a 3-wk history of anorexia, dry heaves, bloating, mid-epigastric pain, and night sweats. The patient's past medical history is unremarkable except for an esophageal stricture treated with endoscopic dilatation, and gastroesophageal reflux disease treated with proton pump inhibitors. On examination, the abdomen was mildly distended with no palpable mass. Laboratory studies revealed a leukocytosis (white blood cell 18 600/μL) and a creatinine of 1.19 mg/dL (to convert to millimoles per liter, multiply by 0.0555), indicating renal impairment due to spontaneous tumor lysis. Alkaline phosphatase was 929 U/L, and aspartate aminotransferase and alanine aminotransferase were 221 and 93 U/L. A carcinoembryonic antigen level was not obtained. Right upper quadrant ultrasound revealed a multinodular liver, and non-contrast computed tomography of the chest, abdomen and pelvis showed descending colon wall thickening with enlarged mesenteric lymph nodes, and an enlarged liver with innumerable coalescing lesions measuring 2-4 cm. No other masses were identified.

The patient underwent percutaneous liver biopsy and endoscopic biopsy of the circumferential and nearly obstructing colonic lesion. Initial Hematoxylin and Eosin (HE) sections of the colonic and hepatic biopsies showed a metastatic, predominantly neuroendocrine tumor which positively stained for CDX2, AE1/AE3 and synaptophysin and negatively stained for cytokeratin (CK)7, CK20 and chromogranin-A. There was extensive necrosis and mitotic activity. The patient began cisplatin and etoposide chemotherapy; however interval computed tomography showed enlarging hepatic metastases. The patient underwent emergent sleeve resection with colonic diversion for obstruction. Final histopathologic staging showed a ypT3ypN2ypM1 composite carcinoma, which was grossly white-tan with slight lobulations. HE sections showed submucosal keratinizing squamous cells admixed with neuroendocrine cells (Figure 1). There was extensive necrosis and mitotic activity. The immunohistochemical profile was similar to the initial biopsies (Figures 2 and 3). Mucicarmine staining in several sections confirmed the absence of mucin production. Lymphovascular invasion was composed of neuroendocrine cells, and four of seven lymph nodes were involved by both tumor components. There was no associated squamous metaplasia or fistula. The patient's functional and clinical status declined, and therapy was shifted to palliative. The patient died at home, 60 d after initial presentation. An autopsy was not performed. Post-mortem molecular analyses on the surgical resection specimen demonstrated the tumor was microsatellite-stable, was negative for the V600E *BRAF* mutation, and harbored a G13D *KRAS* mutation (Figure 4).

MATERIALS AND METHODS

Biopsy and surgical sections were formalin-fixed, paraffin-embedded, and HE stained according to standard protocol. CK7, CK20, CDX2, AE1/AE3, chromogranin-A and synaptophysin immunostains were run on Leica BondMax instruments (Bannockburn, IL) as follows: primary antibody incubation for 15 min, post-primary (proprietary, Leica) for 8 min, polymer (proprietary, Leica) for 8 min, peroxidase block for 5 min, DAB chromogen for 10 min, and hematoxylin counterstain for 10 min. CK7 additionally uses Epitope Retrieval Solution 1 (proprietary, Leica) for 10 min. Mucicarmine staining was performed according to standard protocol. For molecular analyses, DNA was extracted from three 10-micron thick tissue sections representing tumor or normal tissue, respectively, using the QIAquick PCR Purification Kit (QIAGEN, Valencia, CA) following prior tissue lysis and treatment with proteinase K.

MSI analysis

Five ng of normal and tumor DNA were amplified using multiplex polymerase chain reaction (PCR) containing fluorescently labeled primers for 5 mononucleotide markers corresponding to NR-21, BAT-26, BAT-25, NR-24, MONO-27 and 2 pentanucleotide markers for identity confirmation (Promega, Madison WI). The assay was performed according the instructions listed by the manufacturer, amplicons were subjected to capillary electrophoresis using an ABI 3130xl, and the results were analyzed using GeneMapper v3.7 software.

BRAF analysis

Five ng of tumor DNA was analyzed for the common *BRAF* mutation V600E using a lab developed allele-specific (AS) PCR assay for this mutation. The AS PCR assay uses a common forward primer (5'-TGTTTTCCTTTACTTACTACACCTCAGA-3') and two reverse primers (5'-CAGTGGAAAAATAGCCTCAATTCT-3' and 5'-ACCCACTCCATCGAGATTTCT-3'), each tagged with a different fluorochrome to produce an internal control amplicon and, if present, a V600E (c.1799T > A) mutation-specific amplicon. Amplicons were separated using capillary electrophoresis on an ABI 3130xl and the results were analyzed using GeneMapper v3.7 software.

KRAS analysis

Ten ng of tumor DNA was analyzed for common *KRAS* mutations using allele specific PCR and previously described primers for the detection of mutations G12A, G12C, G12D, G12R, G12S, G12V, G13C and G13D[17]. In addition to the fluorescent tagged mutation specific primer, each of the eight PCR reactions also contained a previously described common wild type reverse primer to produce a mutation-specific amplicon of 176, 179 or

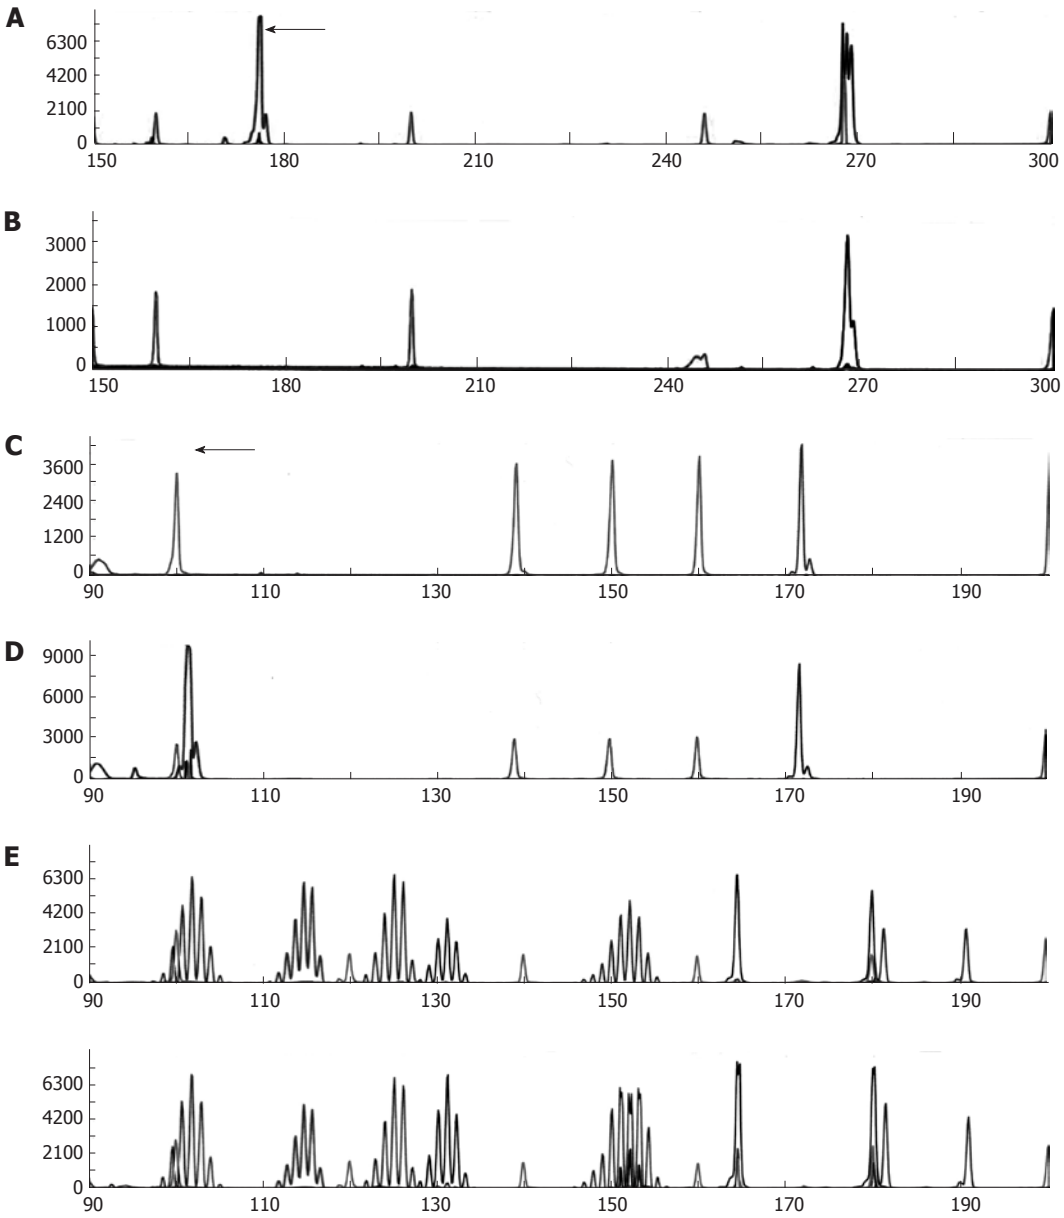

Figure 4 Molecular analysis. A, B: *KRAS* mutation analysis; A: The peak at 176 bp (arrow) corresponds to the G13D mutation; B: Absent peak in the G12D mutation analysis (internal size standards at 160, 200, 248 and 300 bp; internal control amplicon peak at 267 bp for A and B); C, D: *BRAF* V600E mutation analysis; C: The tumor is negative for the *BRAF* V600E mutation as shown by the absence of a peak at 101 bp (arrow); D: *BRAF* V400E positive control with peak at 101 bp (internal size standards at 100, 140, 150, 160 and 200 bp; internal control amplicon peak at 171 bp for C and D); E: Microsatellite instability testing demonstrates a microsatellite-stable tumor, top; normal tissue, bottom (internal size standards at 120, 140, 160 and 200 bp).

180 base pairs in length depending on the location and mutation present[18]. To confirm the amplification efficiency of the DNA, a third, lab-developed wild-type forward primer (5'-GTGTATTAACCTTATGTGTGACATG-3') was included to yield a wild type amplicon of 267 base pairs in length. Amplification conditions included a 5 min denaturation at 95 ℃ followed by 40 cycles of 95 ℃ for 30 s, 60 ℃ for 2 min and 72 ℃ for 2 min. The PCR assay concluded with a final extension phase of 10 min at 72 ℃. PCR products were separated using capillary electrophoresis on an ABI 3130xl, and the results were analyzed using GeneMapper v3.7 software.

DISCUSSION

This case report highlights a rare subtype of colorectal carcinoma with unusual features, including early age of onset and location at the splenic flexure. Additionally, this case documents molecular alterations which have not previously been documented in composite carcinomas with squamous and neuroendocrine features.

Most composite carcinomas are neuroendocrine and adenomatous, while this case showed squamous, rather than adenomatous, differentiation. While squamous carcinomas typically arise in the proximal colon and rectum when patients are in the fifth decade of life[11], this case

describes a 33 year-old with a lesion at the splenic flexure. Furthermore, the tumor was entirely submucosal and intramural, with no mucosal involvement, raising the possibility of a distant metastasis from an unidentified primary tumor. A computerized tomography scan of the chest, abdomen, and pelvis failed to demonstrate any other mass which could have potentially metastasized. The tumor was CDX2 positive, confirming lower gastrointestinal origin.

Due to the young age of the patient, aggressive nature of the tumor, and unusual histology, we performed molecular analyses of well-known genetic alterations in colorectal carcinoma which have prognostic and predictive significance. We anticipated that the tumor was microsatellite-stable, as it did not have mucinous or medullary histology or prominent tumor-infiltrating lymphocytes. As *BRAF* mutations are the least common of the alterations analyzed, we also anticipated this would be negative. Due to the patient's rapid progression, it was possible that the tumor harbored a *KRAS* mutation. The G13D mutation we identified would have excluded the patient from treatment with cetuximab or panitumumab. Current literature suggests this mutation results in an intermediate prognosis; however, this patient's clinical course was representative of a mutation with a very poor outcome. Given that the majority of colorectal carcinomas are adenocarcinomas, it is possible that rarer colorectal carcinoma histologic subtypes with similar genetic alterations may not have similar clinical courses as adenocarcinomas. The presence of other genetic alterations or modifier genes in these histologic subtypes remains to be determined. This study demonstrates prognostic and predictive value of molecular alterations is not uniform across tumor subtypes and further information is needed before such results drive therapeutic decision-making in cases of rare tumors.

In summary, we present a rare case of metastatic composite colorectal carcinoma containing squamous and neuroendocrine components. The young age of presentation and location within the colon are unusual. The tumor harbored a G13D *KRAS* mutation, with more aggressive behavior than expected from such a mutation.

Abstract

The authors present the clinical case of an 87-year-old Caucasian male admitted to the emergency room with hematemesis. He had a history of intermittent dysphagia during the previous month. Endoscopic evaluation revealed an eccentric, soft esophageal lesion located 25-35 cm from the incisors, which appeared as a protrusion of the esophagus wall, with active bleeding. Biopsies were acquired. Tissue evaluation was compatible with a melanoma. After excluding other sites of primary neoplasm, the definitive diagnosis of Primary Malignant Melanoma of the Esophagus (PMME) was made. The patient developed a hospital-acquired respiratory infection and died before tumor-directed treatment could begin. Primary malignant melanoma represents only 0.1% to 0.2% of all esophageal malignant tumors. Risk factors for PMME are not defined. A higher incidence of PMME has been described in Japan. Dysphagia, predominantly for solids, is the most frequent symptom at presentation. Retrosternal or epigastric discomfort or pain, melena or hematemesis have also been described. The characteristic endoscopic finding of PMME is as a polypoid lesion, with variable size, usually pigmented. The neoplasm occurs in the lower two-thirds of the esophagus in 86% of cases. PMME metastasizes *via* hematogenic and lymphatic pathways. At diagnosis, 50% of the patients present with distant metastases to the liver, the mediastinum, the lungs and the brain. When possible, surgery (curative or palliative), is the preferential method of treatment. There are some reports in the literature where chemotherapy, chemohormonotherapy, radiotherapy and immunotherapy, with or without surgery, were used with variable efficacy. The prognosis is poor; the mean survival after surgery is less than 15 mo.

INTRODUCTION

Primary malignant melanoma of the esophagus (PMME) is a rare neoplasm. Only 0.1% to 0.2% of all esophageal malignant tumors are attributed to PMME and only 0.5% of all noncutaneous melanomas are found in the esophagus[1].

Although PMME was first reported in 1906[2] and confirmed with histological evidence in 1952[3], the diagnosis remained controversial until 1963 when the

presence of benign melanocytes within the esophageal mucosa was demonstrated[4]. This observation was confirmed later in two other studies[5,6].

Risk factors are not yet defined but esophageal melanosis has been indicated as predisposing factor[6-8].

PMME is more common in men between de 6th and 7th decades[1,9,10]. Cases have been described at young ages[11,12]. A higher incidence has been described in Japan[1,9].

Symptoms are usually present for less than 3 mo. Dysphagia is the most frequent complain at presentation but retrosternal or epigastric discomfort or pain are also common. Hematemesis or melena are less frequent[1].

A polypoid, pigmented lesion in the lower two-thirds of the esophagus is the typical endoscopic finding[10]. Less frequently they are non-pigmented, but melanin can be identified in histological examination in a large proportion of those cases[1,9,13], and the true incidence of amelanotic melanoma of the esophagus is less than 2%[14].

Thoracic and abdominal computed tomography (CT), barium swallow examination and endoscopic ultrasonography are useful as staging methods[15-18].

Most PMME are diagnosed at advances stages of the disease[10]. Although there is not a formal recommendation, surgery is the preferential method of treatment but the prognosis remains poor.

The authors present a case of PMME and review the literature.

CASE REPORT

An 87-year-old Caucasian male, without relevant or previously known health problems, was brought to our emergency room with hematemesis. He had a history of intermittent dysphagia during the previous month. After hemodynamic stabilization, an upper gastrointestinal endoscopy was performed revealing an eccentric, soft lesion located 25-35 cm from the incisors, which appeared as a protrusion of the esophagus wall, with active bleeding and numerous clots. A CT scan was performed to characterize the nature of the lesion. The CT identified a solid enhancing mass with soft tissue attenuation, extending above the aortic arch and without any imaging signs of aortic invasion (Figure 1). No apparent pulmonary, hepatic or mediastinal nodes or adenopathies were identified. After excluding the possibilities of an aortic aneurysm or aorto-esophageal fistula, an upper gastrointestinal endoscopy was repeated with endoscopic hemostasis, administering 10 mL of adrenaline (1:10 000). The next day an endoscopic review was performed (Figure 2) and biopsies were acquired. Histological examination revealed "tissue infiltrated with crowded cells, most of them without visible cytoplasm (when visible, it contained a brown pigment that stained black with Fontana Masson technique) and hyperchromatic, rounded nuclei" (Figure 3A). Immunohistochemical findings included positive vimentin, protein S-100 and HMB-45 staining and negative keratins (MNF, LP 34, CAM 5.2) and LCA (Figure 3B). The patient was observed by the dermatology and ophthalmology departments and no suspicious skin, eye or anal lesions were found; the diagnosis of primary esophageal melanoma was made. During his hospital stay, the patient developed a hospital-acquired respiratory infection. The patient died after 35 d, before tumor-directed treatment could begin.

Figure 1 Coronal reformat of a contrast-enhanced chest computed tomography demonstrates a solid enhancing mass with soft tissue attenuation in the middle third of the esophagus (arrow) causing obstruction and proximal dilatation. The distal third of the esophagus (arrowheads) is unremarkable.

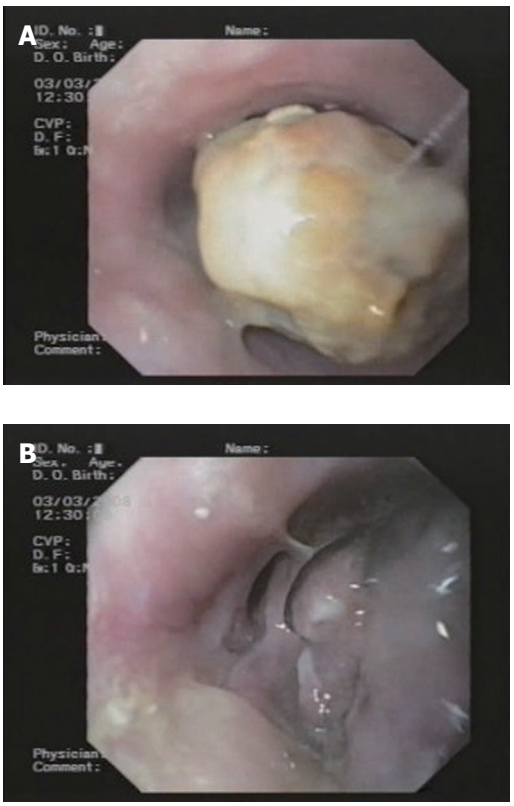

Figure 2 Upper gastrointestinal endoscopy of the patient. A: Soft polypoid tumor protruding to the esophageal lumen, located 25cm to 35cm from the incisors; B: A closer view of the lesion shows that tumor surface is darker than esophageal mucosa due to its melanin content.

DISCUSSION

Primary malignant melanoma of the esophagus is a rare

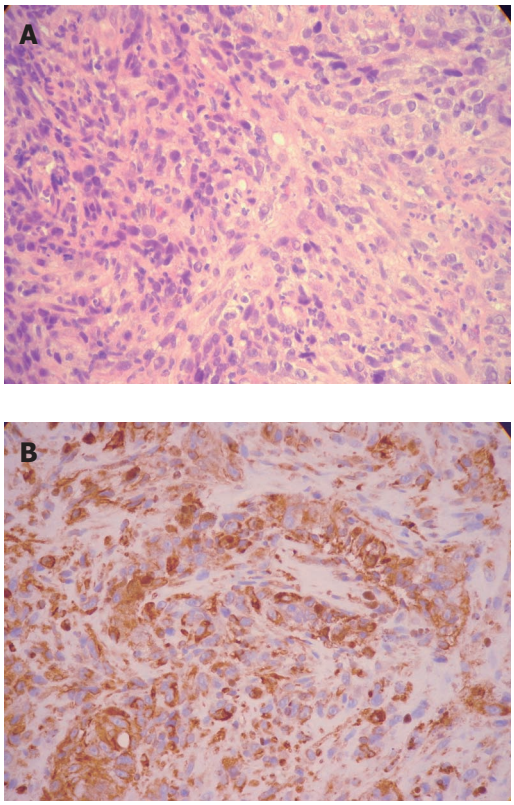

Figure 3 Histopathological findings. A: Hematoxylin and eosin staining discloses crowded rounded or elongated cells within distinct cytoplasm and hyperchromatic nuclei (magnification, x 100); B: Immunohistochemical study for HMB45 (anti-melanoma protein mAb). The positive reaction (brown cytoplasmic reaction) supports the diagnosis of malignant melanoma (magnification, x 100).

neoplasm and represents 0.1% to 0.2% of all esophageal malignant tumors and 0.5% of all noncutaneous melanomas[1].

The first to report a case of PMME was Bauer in 1906[2]. In 1952, Garfinkle and Cahan were the first to confirm the diagnosis with histological evidence[3]. The diagnosis remained controversial until 1963 when la Pava *et al*[4] demonstrated the presence of benign melanocytes within the esophageal mucosa in 4 of 100 autopsy specimens. Later, Tateishi *et al*[5] (1974) and Ohashi *et al*[6] (1990) confirmed this observation and demonstrated that 2.5 % to 8% of the general population has typical melanocytes within the esophageal mucosa[4-6].

The origin of melanocytes of the esophagus remains unclear. Two hypotheses are proposed: (1) migration of melanoblasts from the neural crest; and (2) pluripotent immature cells migrate to the esophagus and then differentiate into melanocytes[1,5].

Risk factors are not yet defined. No association between tobacco or alcohol consumption appears to exist. Melanosis, a benign condition defined as an increased number of melanocytes within the basal layer and an increased quantity of melanin in these melanocytes, has been indicated as a predisposing factor and it has been described in association with or preceding PMME[6,7]. In 2007, Oshiro *et al*[8] described a case of an esophageal melanotic lesion found incidentally during upper gastrointestinal endoscopy that after 19 mo of follow-up underwent malignant transformation.

PMME occurs predominantly in males between the ages of 50-70 years old[1,9,10]. One pediatric case has been reported[11] as well as another in a young adult[12]. A higher incidence of PMME has been described in Japan[1,9] and a greater number of esophageal melanocytes have been observed in this population[6].

Dysphagia, predominantly for solids, is the most frequent symptom at presentation (79.8% of all cases[1]). Retrosternal or epigastric discomfort or pain appears in 33.1% of the cases[1]. Occasionally, melena or hematemesis are reported, as occurred in our case. Symptoms are typically present for less than 3 mo[1]. The reported size of the tumors at diagnosis and the short duration of symptoms demonstrate that this is a rapidly growing neoplasm.

The characteristic endoscopic finding of PMME is as a polypoid lesion, with variable size, usually pigmented. The neoplasm occurs in the lower two-thirds of the esophagus in 86% of cases[10]. They are non-pigmented in 10%-25% of cases but melanin can be identified at histological examination in some of them[1,9,13]. The true incidence of amelanotic melanoma is less than 2%[14]. PMME should be included in the differential diagnosis list of all polypoid tumors found during endoscopic evaluation of the esophagus. Other possible diagnoses are leiomyoma, lipoma, fibroma, neurofibroma, some epidermoid carcinomas, sarcoma, small cell carcinoma, carcinosarcoma and metastatic melanoma.

Thoracic and abdominal CT allows lesion visualization and staging. Barium swallow examination can show a bulky, polypoid intraluminal filling defect[15]. Endoscopic ultrasonography as a staging method has been used in a few cases but the results were coincident with those obtained in histological examination of the resected specimens[16-18].

Diagnostic criteria have been developed by Allen and Spitz[19] and include a typical histologic pattern of melanoma and the presence of melanin granules within the tumor cells; origin from squamous epithelium with junctional activity; junctional activity with melanotic cells in the adjacent epithelium. Histological examination of specimens obtained by endoscopic biopsies are often misdiagnosed and described as poorly differentiated carcinoma, especially when the melanoma cells contain few or no melanin granules (in the series of Sabanathan[1] only 54% of cases were diagnosed preoperatively as malignant melanoma). More recently, immunohistochemical staining with S-100 or anti-melanoma protein mAb (HBM-45) allows accurate identification of this kind of tumor.

PMME metastasizes *via* hematogenic and lymphatic pathways. At diagnosis, about 50% of patients present distant metastases to the liver (31%), the mediastinum (29%), the lungs (18%) and the brain (13%)[10].

Treatment should be individualized for each patient. The choice should be based on tumor size and location, presence or absence of metastases, age and comorbidities of the patient.

When possible, surgery (curative or palliative), is the

preferential method of treatment. Radical resection with great margins is recommended as this tumor has a widespread intramucosal component. Survival after radical resection is 14.18 mo and after limited local excision is only 9 mo[1].

Adjuvant or neoadjuvant chemotherapy or chemohormonotherapy are not globally beneficial. However, some authors have described sporadic successful cases using these therapies. A frequently utilized course, similarly to that used in cutaneous melanoma, includes dacarbazine, nimustin and vincristine. Two cases with at least 7 years survival have been described[20,21]. In 2004, Uetsuka *et al*[20] described a case using dacarbazine, nimustine, cisplatin and tamoxifen before and after surgery and interferon-β monthly only after surgery. In 2007, Kawada *et al*[21] described a case using chemotherapy (dacarbazine, nimustine and vincristine) and local endoscopic injection of interferon-β before and after surgery.

Radiotherapy can be effective but should be reserved for PMME with metastatic illness, patients with high surgical risk or for those who refuse a surgical approach[9]. When used as neoadjuvant or adjuvant therapy of radical surgery, a 16.72 mo survival was achieved[1].

Khoury-Helou *et al*[22] described a 9-year survival in the case of a patient who underwent surgery followed by chemotherapy (5-fluorouracile and cisplatin) and radiotherapy (40Gy) after identification of a ganglionar metastasis.

Immunotherapy using autologous monocyte-derived dendritic cells pulsed with the epitope peptides of melanoma-associated antigens (MAGE-1, MAGE-3), in association with passive immunotherapy with lymphokine-activated killer cells, is an alternative proposed for adjuvant treatment[23].

Intraluminal brachytherapy in association with photoablation with Nd: YAG laser has also been used as an alternative treatment for a patient with surgical contraindications[24]. Another option for palliative treatment is esophageal stent implantation[25].

The prognosis is poor; the mean survival after surgery is less than 15 mo[9,10]. At least 7 patients have survived 5 or more years; they were all submitted to total esophagectomy but only three of them were submitted to some kind of adjuvant treatment[20,22,26-30].

Eighty-five percent of PMME patients die of disseminated disease[1].

Our patient died of a fatal hospital-acquired infection and therefore was not submitted to any tumor-directed therapy. PMME represents a rare condition, especially in western countries. Clinicians should be aware of PMME when considering the differential diagnosis of an esophageal polypoid lesion. The prognosis is poor and treatment should be promptly initiated, yet there is no formal recommendation on this subject.

Abstract

Confocal laser endomicroscopy is a novel imaging technology, which allows real-time visualization and interpretation of microscopic details in live tissues. Although several potential uses have been identified for this technology, no data are available regarding its real-world uses. We report the results of an email-based survey of experts in North America regarding their use of the technology.

Key words: Confocal laser endomicroscopy; Expert opinion

TO THE EDITOR

Confocal laser endomicroscopy (CLE) is a novel tool which allows real-time *in vivo* visualization of histological details in the setting of endoscopy[1]. Since the first description of use of an endoscope-based system in humans in 2004, the technology has been studied for several indications. These include use to identify Barrett esophagus, *in vivo* gastric cancer, gastric intestinal metaplasia, celiac disease, colorectal polyps, ulcerative colitis surveillance, graft-*vs*-host disease, biliary tract strictures, pancreatic cysts, and use in association with endoscopic mucosal resection[2]. In a recent issue of this journal, Gheonea *et al*[3] reviewed data regarding its use in studying vascularization patterns of gastrointestinal malignancies. Despite this expanding list of potential applications, no data are available regarding the indications for which the technology is currently used in real-world settings.

While preparing a departmental presentation on CLE, we contacted gastroenterologists who were listed as using probe-based CLE (pCLE) in North America in an effort to identify expert opinion regarding current and potential clinical applications. Users were identified from the website of Mauna Kea Technologies[4]. All users were contacted on September 4, 2010 by email and were posed a single open-ended question requesting their personal views on current applications and real-world utility of pCLE. No questionnaire was used. Data were abstracted from responses and were analyzed.

Fifty-one gastroenterologists across 31 institutions were listed as using pCLE. Email addresses were gleaned for 43 physicians from 23 institutions by searching hospital or university websites or accessing publications where the practitioner was the corresponding author. Of 43 emails sent, 4 were returned as undeliverable, leaving 39/51 (76.5%) who were assumed to be contacted suc-

cessfully. Among 39, responses were obtained from 30 (76.9%). An analysis of the email response times of contacted experts has been published separately[5].

The most frequently cited uses for pCLE among current practitioners of the technology were as follows: Barrett esophagus (21/30; 70%); indeterminate biliary strictures (14; 46.7%); use in conjunction with endoscopic mucosal resection (13; 43.3%); colon polyps (12; 40%); ulcerative colitis surveillance (9; 30%); gastric intestinal metaplasia (4; 13.3%); molecular imaging (2; 6.7%); and neuroendocrine hyperplasia (1; 3.3%). Needle-based CLE was cited as a potential application by four (13.3%). Six responses (20%) listed no potential applications. Twelve respondents (40%) described the technology as "experimental" or as a "research tool", and an additional seven (23.3%) described its use as currently "not ready for practice" or "undetermined".

Our study sheds light on physician practices and opinions regarding the current clinical utility of pCLE. Our data show that while many of the respondents believed pCLE had several potential applications, a majority (63%) felt that the technology was not yet ready for primetime. Cost of the equipment, need to learn a new technology, a learning curve associated with the technology, uncertain reimbursement, and potentially increased time spent for certain applications are some reasons which may slow the adoption of this new technology in community gastroenterology practices. In the face of an increasing array of uses, we believe there is a need for an analysis of the cost-effectiveness of the technology, and for an expert consensus on indications for which its use would be best-suited.

World J Gastroenterol 2011 November 14; 17(42): I-VI
ISSN 1007-9327 (print) ISSN 2219-2840 (online)

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions
Manuscripts should be submitted through the Online Submission

System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be

used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Hepatocellular carcinoma (HCC) is one of the most frequent neoplasms worldwide and in most cases it is associated with chronic liver disease. Liver transplantation (LT) is potentially the optimal treatment for those patients with HCC who have a poor functional hepatic reserve due to their underlying chronic liver disease. However, due to the limited availability of donors, only those patients whose oncologic profile is favorable can be considered for LT. Despite the careful selection of candidates based on strict rules, 10 to 20% of liver transplant recipients who have HCC in the native cirrhotic liver develop tumor recurrence after transplantation. The selection criteria presently employed to minimize the risk of recurrence are based on gross tumor characteristics defined by imaging techniques; unfortunately, the accuracy of imaging is far from being optimal. Furthermore, microscopic tumor features that are strictly linked with prognosis can not be assessed prior to transplantation. Pre-transplantation tumor downstaging may allow transplantation in patients initially outside the selection criteria and seems to improve the prognosis; it also provides information on tumor biology. The main peculiarity of the transplantation setting, when this is compared with other modalities of treatment, is the need for pharmacological immunosuppression: this is based on drugs that have been demonstrated to increase the risk of tumor development. As HCC is an aggressive malignancy, immunosuppression has to be handled carefully in patients who have HCC at the time of transplantation and new categories of immunosuppressive agents should be considered. Adjuvant chemotherapy following transplantation has failed to show any significant advantage. The aim of the present study is to review the possible strategies to avoid recurrence of HCC after liver transplantation based on the current clinical evidence and the more recent developments and to discuss possible future directions.

Key words: Chemotherapy; Hepatocellular carcinoma; Immunosuppression; Liver transplantation; Tumor recurrence

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most frequent neoplasms worldwide with more than 500 000 new cases diagnosed each year. In more than 90% of cases, HCC is associated with chronic liver disease, par-

ticularly disease caused by hepatitis B (HBV) or hepatitis C (HCV) viral infection[1].

Resective surgery of HCC with curative intent has two main limitations: the impaired functional reserve of the liver in the presence of cirrhosis often contraindicates surgery, while the persistence of the underlying chronic liver disease leads to recurrence of the tumor within the liver in more than 50% of cases in the long-term[2]. Furthermore, liver cirrhosis is by itself a progressive condition that substantially limits life expectancy.

For these reasons, liver transplantation (LT) theoretically represents the ideal treatment of HCC on cirrhosis as it removes both the tumor and the underlying condition that results in HCC.

However, the initial experience with LT for HCC in the eighties was discouraging, as recurrence rates of more than 50% were reported in many series; the indication for LT in the presence of HCC was therefore questioned[3-5].

In 1995, Mazzaferro *et al*[6] published the results of a prospective study where he demonstrated that, by adopting strict selection criteria with regard to the size and number of tumor nodules, it was possible to achieve a satisfactory long-term recurrence-free survival after LT. The criteria established in that study, known as the "Milan criteria" have from then on been the basis for the selection of patients with HCC on cirrhosis for transplantation. Currently, HCC on cirrhosis represents one of the main indications for LT: according to the report of the United Network for Organ Sharing (UNOS), in 2008, 17.5% of 6069 recipients of a liver graft from a deceased donor were HCC carriers, while 10 616 LTs have been performed up to 2009 in Europe on HCC patients according to the data of the European Liver Transplant Registry (ELTR).

Although in absolute terms the present results of LT for HCC are outstanding, considering that we are dealing with a highly aggressive tumor, 10% to 20% of recipients still develop tumor recurrence. This failure rate is of particular relevance in the transplantation field where great effort is made not to waste precious and rare resources such as liver grafts[7,8].

The purpose of the present review is to analyze possible strategies to avoid HCC recurrence following LT.

PATIENT SELECTION

Although they provide excellent results, the selection criteria introduced by Mazzaferro result in the exclusion of a great number of possible LT candidates whose tumor slightly exceeds the limits. In addition, in the original article the Milan criteria were verified by pathology of the explanted liver, while in the clinical setting HCC is staged by imaging techniques. The accuracy of imaging in preoperative staging is far from optimal and ranges between 14% and 80%[9-12] (Table 1).

Since 1996, attention has been focused on the possibility of recruiting a larger number of LT candidates whose tumor is beyond the Milan criteria but still within a safety zone in terms of likelihood of recurrence. Several proposals for revision of the Milan criteria have been made over the years, the most popular of which are summarized in Table 2[6,9,13,14]. The latest of these proposals is from Mazzaferro *et al*[14] and is known as the "up-to-seven" rule: the sum of the number of tumor nodule(s) and the maximum diameter of the nodule(s) must not exceed the value of seven.

A system has also been developed to predict the survival probability of a LT candidate with HCC as a function of size and number of tumor nodules; using freely accessible software it is possible to calculate the probability of survival linked to given tumor features. This software, called the Metroticket Calculator takes into account another parameter, the presence of microvascular tumor invasion (MVI) that has been shown to be intimately related to the biology of the tumor[15]. The importance of MVI as a determinant of recurrence has been known for years; histological grading has also been associated with tumor recurrence in several reports[16-17]. Unfortunately, MVI and histological grading can not be precisely assessed prior to transplantation; percutaneous biopsy of the tumor nodule can miss the area of the tumor where MVI is present or may fall in an area of the nodule were the tumor is more differentiated. In fact, grading varies within the same nodule and is eventually defined by the area were the highest degree of undifferentiation is found[18].

The main bias of all the selection systems currently in use is that they are based on the gross pathological features of the tumor. Apart from the difficulty of cor-

Table 1 Accuracy of imaging techniques in the pre-transplant staging of hepatocellular carcinoma

Mazzaferro V, 2009, multicenter study	1556	No. of HCC nodules + maximum diameter (cm) ≤ 7	71% (5-yr overall) if MVI absent

pts: Patients; RF: Recurrence-free; HCC: Hepatocellular carcinoma; MVI: Microvascular tumor invasion.

rectly staging the tumor at imaging, size and number of nodules are not always related to the effective biology of the tumor. Esnaola showed that MVI is certainly more frequent in multiple and large tumors; however, 53% of patients with multiple nodules and 50% of patients with nodules larger than 4 cm in diameter did not display MVI at histology[19]. Jonas *et al*[20] has recently proposed an index based on DNA cytometry in tumor tissue that can establish the relative risk of recurrence; unfortunately, this index can not be evaluated prior to transplantation. Fiorentino *et al*[21] a few years ago demonstrated that biological markers such as membrane expression of E-cadherin and β-catenin, and nuclear expression of β-catenin were predictors of prognosis. These markers could be assessed on preoperative biopsy; however, the value of these markers has never been tested prospectively.

Serum alpha fetoprotein level at the time of LT is also linked to prognosis[22-24]; however, it is not considered in the more widely used selection systems for LT candidates.

PRE-TRANSPLANT DOWNSTAGING

Neo-adjuvant therapy prior to LT has been proposed mainly to slow the progression of HCC while the patient is on the waiting list, to avoid drop-out[25]. Other authors have proposed downstaging, within the Milan criteria, of tumors that were initially beyond the criteria, thus allowing transplantation[26,27]. Among the possible techniques used to downstage HCC, the most widely used is transarterial chemoembolization (TACE), followed by radiofrequency ablation (RFA)[28]. In 2008, Yao *et al*[29] reported the results of a prospective trial of downstaging that included 61 patients originally outside the Milan criteria; in the majority of cases, TACE was used for downstaging however, some patients were also treated with RFA or surgical resection. No tumor recurrences were observed at a median follow-up of 25 mo in the 35 patients who underwent LT following downstaging. There is some evidence that response to downstaging can be used as a prognostic factor to select patients with best prognosis after LT; in particular, it has been observed that the degree of tumor necrosis after TACE is linked to prognosis[30,31].

ADJUVANT CHEMOTHERAPY

Adjuvant chemotherapy has historically failed to show any advantage after resection of HCC[32]. In the setting of liver transplantation, the first relevant report on adjuvant chemotherapy was published by Olthoff and colleagues in 1995; a series of 25 LT recipients with HCC received intravenous fluorouracil, doxorubicin, and cisplatin for 6 mo after LT. Many of these patients had tumors well beyond the Milan criteria, 6 patients did not complete the treatment because of severe side-effects and a 3-year tumor-free survival of 46% was reported; the authors concluded that this result was satisfactory when compared to that achieved in an historical series of 17 patients transplanted between 1984 and 1988 whose tumor-free survival was worse[33].

In 2002, Roayaie published the results of a prospective study carried out on 43 patients who had tumors larger than 5 cm in diameter at the time of LT and were administered 6 cycles of systemic doxorubicin after surgery. In 11 of these 42 patients, adjuvant treatment was discontinued, mainly due to side-effects; recurrence-free survival was 48%[34].

In more recent years, two different prospective randomized trials showed no significant advantage of adjuvant therapy with systemic doxorubicin administered after LT[35,36].

Another recent report on adjuvant therapy with cisplatinum and adriamycin on a series of 12 LT recipients with poor prognostic factors again failed to show any advantage[37].

Although promising preliminary results have been reported with the use of targeted molecular drugs such as sorafenib in advanced HCC, the use of these agents in the transplantation field has not yet been assessed[38].

PHARMACOLOGICAL IMMUNOSUPPRESSION

Some 20 years ago, Yokoyama *et al*[39] from the Pittsburgh group noticed that the doubling time of HCCs that recurred after LT was significantly shorter than that observed in HCCs that arose in non-transplanted patients. The authors concluded that the accelerated growth rate of HCC in LT recipients was due to pharmacological immunosuppression.

Indirect evidence of a favoring effect of immunosuppression on tumor genesis comes from the observation that the incidence of malignancies is significantly higher in organ recipients than in the general population[40].

The cornerstone of pharmacological immunosuppression in organ transplantation is represented by the calcineurin inhibitors (CNIs), namely cyclosporine and tacrolimus. These agents affect T-cell recognition of alloantigen and signal transduction *via* the calcium-dependent calcineurin pathway. Besides inhibiting interleukin (IL)-2 expression, they increase transforming growth factor (TGF)-β 1, a potent inhibitor of IL-2-stimulated T-cell proliferation; unfortunately, TGF-β 1 depresses the natural killer cell-mediated anti-tumor immune response, and is implicated in the development of the metastatic process[41-43].

A study published in the Lancet by Dantal *et al*[44] in 1998, showed that there was a significant relationship between the dosage of cyclosporine administered to kidney transplant recipients and the development of posttransplant *de novo* malignancies, while Freise *et al*[45] demonstrated in an animal model that cyclosporine has an adverse effect on recurrence of hepatoma after liver transplantation.

In 2002, the group of Bologna first demonstrated that there was a direct relationship between the cumulative dosage of cyclosporine administered in the first year

after LT and HCC recurrence-free survival: the higher the dosage of cyclosporine given, the lower the recurrence-free survival[46]. This observation was confirmed by a subsequent study from the same group, where exposure to cyclosporine was shown to be an independent determinant of recurrence-free survival[47]. A later report published in 2008, showed that both tacrolimus and cyclosporine exposure were independently associated with HCC recurrence together with MVI and tumor histological grading[48].

A newer category of immunosuppressant drugs called m-TOR (mammalian target of rapamycin) inhibitors have raised a high degree of interest. These drugs are associated with strong immunosuppressant activity, due to the blocking of IL-2 stimulation of lymphocyte proliferation, and have a potential anti-cancer effect which has been demonstrated in the experimental setting. The anti-cancer effect is mainly related to the impairment of vascular endothelial growth factor (VEGF) production and the blockage of VEGF-induced vascular endothelial cell stimulation[41]. Several reports are available in the literature that seem to indicate that m-TOR inhibitors have some efficacy in reducing the incidence of *de novo* malignancies, or even arresting the progression of aggressive neoplasms after organ transplantation[49-56].

In the clinical setting, m-TOR inhibitors, namely sirolimus and everolimus, have been initially tested in association with CNIs to reduce renal damage associated with the use of these latter agents.

However, a report by Knetemann *et al*[57] published in 2004, showed that by minimizing the use of CNIs through the use of m-TOR inhibitors it was possible to achieve a satisfactory disease-free survival when transplanting patients whose HCC was beyond the Milan criteria.

Since then several centers have employed m-TOR inhibitors in patients with HCC; unfortunately, this has been done outside controlled multicentric trials.

Few reports have compared the results of LT for HCC in patients under CNIs-based immunosuppression to those observed under m-Tor inhibitor-based immunosuppression. The first of these reports comes from Bologna: in a matched case-control study where the clinical and pathological risk factors were identical in the two groups, the 3-year recurrence-free survival was 30% higher in patients who received sirolimus as part of their immunosuppressive schedule than in those who remained on standard treatment based on tacrolimus[58].

Some confirmation of this finding has been provided by Toso *et al*[59], who analyzed the Scientific Registry of Transplant Recipients in the United States to ascertain whether survival after LT in HCC patients was influenced by type of immunosuppression: the author concluded that sirolimus-based maintenance therapy was associated with improved survival.

CONCLUSION

Of the possible strategies to avoid tumor recurrence after LT in HCC patients, the careful selection of candidates based on macroscopic tumor findings is a cornerstone that seems to have been exploited to the maximum. Thus, better characterization of tumor biology is necessary; the main problem in this field is outlining markers assessable on tumor biopsy.

While there is no evidence of the efficacy of adjuvant chemotherapy, more research on immunosuppressive agents is warranted. It is reasonable to suggest that CNIs should be administered at their effective minimum in HCC LT recipients. Although definitive evidence is not yet available, there are enough data to support the use of m-TOR inhibitors in association with CNIs for immunosuppression, or when the risk of tumor recurrence is high, due to the presence of poor prognostic factors, as the main immunosuppressants in a CNI-sparing regimen.

Further prospective studies on large numbers of patients are warranted to confirm the efficacy of this strategy and to quantify the extent of the possible gain in terms of recurrence-free survival.

Abstract

Pancreatic metastases are rare, with a reported incidence varying from 1.6% to 11% in autopsy studies of patients with advanced malignancy. In clinical series, the frequency of pancreatic metastases ranges from 2% to 5% of all pancreatic malignant tumors. However, the pancreas is an elective site for metastases from carcinoma of the kidney and this peculiarity has been reported by several studies. The epidemiology, clinical presentation, and treatment of pancreatic metastases from renal cell carcinoma are known from single-institution case reports and literature reviews. There is currently very limited experience with the surgical resection of isolated pancreatic metastasis, and the role of surgery in the management of these patients has not been clearly defined. In fact, for many years pancreatic resections were associated with high rates of morbidity and mortality, and metastatic disease to the pancreas was considered to be a terminal-stage condition. More recently, a significant reduction in the operative risk following major pancreatic surgery has been demonstrated, thus extending the indication for these operations to patients with metastatic disease.

Key words: Pancreatic metastases; Renal cell carcinoma; Pancreatic surgery; Prognostic factors; Therapeutic approach; Radiological findings

INTRODUCTION

Renal cell carcinoma (RCC) remains an important cause of cancer death in the United States, with an estimated 58 240 new cases and approximately 13 040 deaths in 2010[1].

The natural history of RCC is characterized by a high 5-year survival (up to 95%) when the tumor is limited to the kidney (stage 1)[2-4]. Among patients with RCC, 20% to 30% have metastases at presentation, and up to 40%-50% will develop widespread metastatic disease after nephrectomy. The 5-year survival rate is < 10%-15% once metastases have spread[5,6].

Pancreatic metastases are rare, with a reported incidence varying from 1.6% to 11% in autopsy studies of patients with advanced malignancy[7,8]. In clinical series, the frequency of pancreatic metastases ranges from 2% to 5% of all pancreatic malignant tumors[9-12].

The tumors that metastasize most commonly to the pancreas are RCC, lung cancer (adenocarcinoma and non-small cell lung carcinoma), lobular breast carcinoma, and colorectal adenocarcinoma, followed by melanoma, soft-tissue sarcoma (leiomyosarcoma), and a large number of other neoplasms[7,8,13-19].

However, the pancreas is an elective site for metastases from carcinoma of the kidney and this peculiarity has been reported by several studies[11,19-27]. Pancreatic metastases from RCC are frequently the only metastatic site and they typically occur a long time after nephrectomy[20,23,26].

MECHANISM OF DISEASE

According to Sellner *et al*[23], local lymphogenous or local venous spread through abnormal lymphatic or venous communications between the RCC and the pancreas[11,21,28] cannot play an important role, because this would fail to explain the lack of relationship between the site of isolated pancreatic metastases and the side affected by the primary tumor: i.e., the left or right kidney. The localization anywhere in the pancreas irrespective of the site of the RCC argues, instead, in favor of a hematogenous systemic spread. However, a systemic spread would not explain the discrepancy between the relative frequency of multiple pancreatic metastases and the absence of metastases to other organs. The most likely explanation for this unique behavior of isolated pancreatic metastases would seem to lie in the special biology of the tumor. Tumor cells apparently have a high affinity for the parenchyma of the pancreas and only there do they find the conditions they need to mature to manifest metastases. The high affinity of some renal cancer cells for the parenchyma of the pancreas is supported by some reports[23] of metachronous late metastases which again occurred solely in the residual pancreas[11,22]. The results of basic research, which is slowly unraveling the local biochemical mechanisms that underlie the development of metastases, are promising, so it is hoped that the biochemical causes of the unique spreading pattern of some RCC will perhaps be understood one day[29].

CLINICAL CHARACTERISTICS

As with primary pancreatic cancer, the early signs and symptoms of isolated pancreatic metastases are often non-specific and subtle. Isolated pancreatic metastases are often found with routine surveillance imaging for primary lesions or as an incidental finding on imaging done for an unrelated indication.

Pancreatic metastasis of RCC generally occurs in the seventh decade of life and is usually asymptomatic[14,15,30], although cases of abdominal pain, gastrointestinal bleeding caused by duodenal involvement, weight loss, jaundice, and pancreatitis due to pancreatic duct obstruction have been described[14,15,26,31].

Most of the studies reviewed report mean time intervals greater than 10 years, and a period as long as 32.7 years has been described[12,19,21-24,26,32]. In fact, renal carcinoma is the primary tumor that metastasizes to the pancreas following the greatest disease-free interval. This singular feature of RCC makes long-term follow-up essential in these patients.

Multiple lesions throughout the pancreatic gland have been more frequently detected in patients with RCC than in those with other primary tumors. Other single-center series reported similar frequencies of multifocality with respect to pancreatic RCC metastases, ranging from 20% to 45%[12,22,23,26,27,33,34]. In the review by Sellner *et al*[23], multiple lesions occurred in 39% of the 187 patients. This issue has important clinical implications: surgical treatment of patients with suspected pancreatic metastases from RCC must take into account the high probability that the patient will have more than one pancreatic lesion.

In a recent review by Masetti *et al*[35], univariate survival analyses conducted in a subgroup of patients with RCC metastases (n = 157), with a median follow-up of 24 mo (range 1 to 134 mo), showed that the factors associated with worse survival were symptoms at diagnosis, and a disease-free interval less than 2 years in patients with metachronous lesions.

RADIOLOGICAL FINDINGS

Computed tomography and magnetic resonance imaging

The diagnosis of pancreatic metastasis is usually made on radiological or endoscopic criteria, since most patients do not present related symptoms.

The disparity in prognosis and management of patients with primary and secondary pancreatic tumors, as well as the fact that in very selected cases a radical surgical resection can be considered as treatment of pancreatic metastases and achieve prolonged survival, underline the importance of detection and characterization of these lesions by computed tomography (CT) and magnetic resonance imaging (MRI)[9,24,36].

Identifying the sites and extent of the metastatic lesions within the pancreas helps determine the feasibility and extent of pancreatic surgery.

There is comparatively little difficulty in identifying large lesions within the pancreas when using a standard CT technique because they typically deform the contour of the pancreas. Small lesions, however, may be easily missed. The CT evaluation should be performed with

a multidetector CT, a high rate of intravenous contrast media injection (3-5 mL/s) and scanning during the arterial (20 s delay) and portal (50-60 s delay) phases. The MR evaluation should be performed with a 1.5 or 3 T scanner with T1 and T2 weighted sequences, without and with contrast media injection at dynamic acquisition in arterial, portal and venous phases.

The growing use of imaging techniques, in particular of CT in the periodic follow-up of oncological patients, allows earlier detection of small pancreatic metastases, and in most cases the oncological background and existence of previous follow-up permit a correct diagnosis. Moreover, in controversial cases, CT can also be considered as an important tool in providing guidance to biopsy in order to obtain a definitive diagnosis[9,10,36,37].

Imaging features of metastatic pancreatic tumors point to their primary origin and the enhancement pattern reflects the vascular perfusion of the lesions. RCC metastases are usually hypervascular and consequently show intense homogeneous contrast enhancement in the arterial phase, greater than normal pancreatic parenchyma, and a tendency to pass undetected in more delayed post-contrast phases, since the difference in density between the mass and the normal pancreatic gland decreases.

In lesions larger than 1.5 cm, rim enhancement with hypodense central areas of necrosis may be seen.

Pancreatic metastases do not appear to show a predilection for a particular part of the pancreas[37,38]. Three types of metastatic involvement of the pancreas have been described in the literature. The most common type of all metastases and in particular of RCC metastases, reported in 50%-73% of cases, is that of a solitary, localized, well-defined mass. A second pattern of multiple pancreatic lesions has been reported in 5%-10% of cases, and a third pattern of diffuse metastatic infiltration causing generalized enlargement of the organ in 15%-44% of cases[9,30,39,40].

Other features described in this type of lesion are calcifications, ductal and biliary obstruction, vascular extension, and cystic degeneration, although these findings are quite non-specific.

On MRI, pancreatic lesions typically appear hypointense, compared with normal gland tissue on unenhanced T1 weighted images, both with and without fat saturation. Following intravenous contrast media injection, homogeneous enhancement is typically demonstrated in smaller lesions and rim enhancement in larger ones. On T2 weighted images, the lesions are slightly heterogeneous and moderately hyperintense. Hypointense nodules are sometimes visible on T2 weighted images, especially in the diffusely enlarged type. Diffusion weighted imaging was recently included in the standard MRI protocol; metastatic lesions typically also show a hyperintensity signal in sequences with high b-values (700-1000).

When hypervascular pancreatic lesions are depicted on contrast-enhanced CT and MRI, differentiation from a primary pancreatic endocrine tumor might be difficult. The other differential diagnoses include metastasis of hypervascular neoplasm, intrapancreatic accessory spleen and vascular lesions, such as arteriovenous fistulas or aneurysms of the splenic artery[10,19,22,32,41]. In most cases, the oncological background and existence of previous follow-up of the neoplastic disease allows a correct diagnosis, and in controversial cases a CT-guided biopsy can be performed.

Endoscopic ultrasonography

The development of imaging technology has improved the detection and differentiation of small lesions but difficulties remain. Pancreatic lesions are commonly undetected at an early stage since the symptoms of small pancreatic lesions are frequently vague and non-specific.

Endoscopic ultrasonography (EUS) is a highly sensitive diagnostic method for detection of pancreatic lesions, especially small lesions.

Pancreatic metastases appear as solid intraparenchymal space-occupying lesions with an internal structure that is much more hypoechoic than the normal pancreatic tissue, or isoechoic. These lesions are homogeneous, round, well circumscribed and associated with enhancement through transmission of the ultrasonic beam[36,42,43].

At Power Doppler or Color Doppler evaluation and with ultrasound contrast agent (CE-EUS), metastatic pancreatic tumors from renal cell carcinomas are hypervascular (hypervascular enhancement compared with the surrounding pancreatic tissue).

F-18 fluorodeoxyglucose positron emission tomography

There is no firm consensus regarding the role of this technique in pancreatic cancer and especially in metastases from RCC.

Fluorodeoxyglucose Positron Emission Tomography (FDG-PET) has not been extensively studied for the evaluation of distant metastases from RCC. Reported studies of FDG-PET in metastatic RCC have involved few patients, and most series have compared the results of FDG-PET with clinical outcome determined by follow-up with conventional anatomic radiological techniques; moreover, pathologic confirmation of metastatic disease, if performed, was usually combined with radiological follow-up for reporting results.

In a study reported by Ramdave *et al*[44], FDG-PET identified distant metastases from RCC in six out of six patients evaluated for possible metastatic disease. Presence of metastatic disease was confirmed by pathology (fine-needle aspiration cytology) in only one of these six patients. In the same study, FDG-PET detected unsuspected metastatic disease not seen on CT in two of 17 patients evaluated for primary RCC. Metastatic disease was confirmed by biopsy at laparotomy in only one of these cases. In another study by Brouwers *et al*[45], among 20 RCC patients with 112 distant metastatic lesions evaluated by FDG scintigraphy and followed clinically, FDG-PET detected 69% (77 of 112) of the metastatic lesions. Of these, 32 lesions had not been detected by routine imaging modalities.

Table 1 Studies of renal cell cancer that include more than five patients

Ref.	Yr	*n*	5-yr survival	Median survival

Konstantinidis *et al*[62]	2010	20	61%	8.7 yr

NR: Data not reported. Survival data is from the time of resection of the pancreatic metastasis, not from diagnosis of the primary tumor.

Using FDG-PET for restaging 36 patients with advanced RCC, Safaei *et al*[46] demonstrated a sensitivity and specificity of 87% and 100%, respectively.

Majhail *et al*[47] calculated the sensitivity, specificity, positive predictive value, and negative predictive value of FDG-PET for detection of distant metastases from RCC. They observed the sensitivity of FDG-PET to be 63.6%; however, in the same work the authors noted that FDG-PET was more sensitive for imaging larger lesions (sensitivity was 83.3% for lesions > 1.5 cm and 92.9% for lesions > 2.0 cm in size). Again, true-positive lesions were larger in size (mean size, 2.2 cm) compared with false-negative lesions (mean size, 1.0 cm).

Overall, FDG-PET scintigraphy is not a very sensitive imaging modality for the evaluation of metastatic RCC and may not adequately characterize small metastatic lesions. However, positive FDG-PET is predictive for the presence of RCC in imaged lesions, may complement anatomic radiological imaging modalities, and may alleviate the need for a biopsy in selected situations. A negative FDG-PET, however, does not rule out active malignancy.

PET could be used in early assessment of the response to chemotherapy, radiotherapy or both modalities. Indeed, the ability to predict therapeutic response early during a course of treatment is important since prognosis is poor, lifespan is limited and toxicity in non-responding patients is not acceptable.

OUTCOME OF SURGERY

Resection of liver, lung, and brain metastases has proven to be effective in the treatment of several types of tumors. The strongest evidence in favor of this practice exists for colorectal cancer, in which the resection of liver metastases has been shown to prolong patient survival and to improve the quality of life[16]. Moreover, study results published in the literature suggest that the resection of metastases from other types of tumors can improve patient outcome[48-50].

Although pancreatic surgery is considered one of the most technically demanding and challenging surgical disciplines, steady improvements in surgical techniques and advances in perioperative supportive care, based on a modern interdisciplinary approach that includes anesthesiology, oncology, radiology, nutritional science, and nursing, has reduced mortality to less than 5% in high-volume centers.

Standardized pancreatic resection adapted to the location of the tumor, in terms of partial pancreaticoduodenectomy, distal pancreatectomy, and total pancreatectomy, is generally recommended for the management of isolated pancreatic metastases. Because of the high recurrence rate[20], atypical local resection is confined to some exceptional cases.

Treatment recommendations for multiple pancreatic metastases vary. Whereas some advise total pancreatectomy, others[51-53] critically reject surgery on the assumption that multiple pancreatic metastases signal incipient fatal disseminated metastatic disease.

A few isolated articles describing small series of patients who underwent surgery for pancreatic metastatic disease have recently been published, reporting encouraging results[10,14,54].

We have identified 18 studies addressing pancreatic metastasectomy for RCC with five or more patients[10-12,14,15,22,27,35,54-63]. Survival results from these studies are listed in Table 1. Of the 12 studies that included long-term survival data, seven (58.3%) reported 5-year survival rates from the time of the pancreatic metastasectomy higher than 80%.

OUTCOME WITHOUT RADICAL RESECTION

In the case of unresectable disease, surgical or endoscopic palliation in association with chemotherapy can improve the quality of life but not survival, even if, in rare cases of renal cell metastases, an improved survival has been reported after palliative surgery[34,64].

In the series described by Zerbi *et al*[12], 13 patients who did not undergo resection, because of locally advanced disease or due to the presence of extrapancreatic disease, all received immunotherapy with interferon (IFN) α as first-line treatment; 6 patients underwent other therapies (interleukin-2 in 3 cases, thalidomide in 1 case, radiotherapy in 1 case, bone marrow transplantation in 1 case). The median survival was 27 mo (range 17.5 to 50.2 mo).

In this group of patients who did not undergo surgical resection, 2- and 5-year survival rates were 59% and 47%, respectively.

Table 2 Prognostic factors for risk group stratification model[70]

Factors for risk group	Poor prognostic category and factors
Factor	Category
Time from diagnosis to study entry	< 12 mo
Hemoglobin	Below lower limit of reference range
Lactate dehydrogenase	> 1.5 x upper limit of reference range
Corrected serum calcium	> 10.0 mg/dL
Previous radiotherapy	Yes
No. of metastatic sites	⩾ 2
Risk Group	No. of factors
Favorable	Zero or one
Intermediate	Two
Poor	Three or more

Patients are stratified into three groups depending on the number of poor prognostic factors found, as follows: favorable risk group, patients with zero or one poor prognostic factor; intermediate risk group, presence of two poor prognostic factors; poor risk group, presence of three or more poor prognostic factors.

PROGNOSTIC FACTORS

No prospective randomized or case-controlled studies have been performed to evaluate the role of surgical resection. In addition, many of the existing retrospective studies are limited because of the small number of patients who were treated for prolonged periods of time.

The pooled data from the 18 studies in Table 1 do not contain adequate detail to assess features for the prediction of outcome in the context of pancreatic metastasectomy for RCC. However, analyzing the three largest series reported in the literature it can be seen firstly that in their series of 21 patients who underwent pancreatic metastasectomy for RCC, Reddy *et al*[54] reported that tumor size greater than 4 cm ($P = 0.13$) and perineural invasion ($P = 0.26$) were not associated with significant differences in outcome, whereas lymph node involvement (hazard ratio 24.1, $P = 0.01$) and vascular invasion (hazard ratio 20.4, $P = 0.007$) were each associated with worse overall survival. The median survival was 4.8 years (range 0.35 to 18.3 years). Metachronous RCC had a similar survival to synchronous lesions ($P = 0.98$).

Zerbi *et al*[12] addressed the question of whether or not pancreatic metastasectomy changes the progression of RCC. They assessed a non-matched control group of patients with non-operatively managed pancreatic RCC metastasis. In this study, 13 out of 36 patients with pancreatic RCC were not offered surgery on the basis of functional status or extent of disease. These 13 patients were the control group, and their outcome was compared with outcomes for patients undergoing pancreatic metastasectomy. For the entire cohort, the median survival was 27 mo (range 0.6 to 222 mo) and 5-year survival was 47%. Patients who had tumors resected had a 5-year survival of 88% compared with 47% for the non-operative group ($P = 0.026$), suggesting a benefit of pancreatic metastasectomy.

On the other hand, in their series of 20 patients with pancreatic metastases from RCC, Konstantinidis *et al*[62] reported that, on univariate analysis, the number of metastatic nodules (solitary *vs* multiple, $P = 0.87$), the size of metastases (greater or smaller than median of 3 cm, $P = 0.78$), the location of the metastases ($P = 0.72$), or an R1 resection ($P = 0.62$) had no prognostic significance for overall survival. Hemoglobin values below the lower level of the reference range also did not predict worse outcome ($P = 0.99$). Patients had median and mean follow-up of 36.8 and 38.1 mo, respectively (range 0.5 to 143 mo). Their median survival from the time of metastasectomy was 8.7 years (range 1.3 to 12 years) and 5-year actuarial survival was 61%.

However, the treatment of pancreatic metastases from RCC remains controversial because of the relatively low frequency of this localization and the complex natural history of RCC, ranging from cases with a long disease-free interval to others with early development of widespread metastases[65].

To predict the behavior of disease in patients with metastatic RCC, several prognostic models have recently been developed[66-68]. In particular, Motzer *et al*[68,69] from Memorial Sloan-Kettering Cancer Center (MSKCC) proposed categorizing patients with metastatic RCC into one of three classes by using a model with five prognostic factors. This prognostic score was recently validated and modified by a study from the Cleveland Clinic Foundation group[70](Table 2).

CHEMOTHERAPY

Since RCC is highly resistant to chemotherapy, interleukin-2 or IFN α have been widely used as first-line treatment of metastatic disease. These agents have limited efficacy and are associated with considerable toxic effects. Response rates with these cytokines were low (5% to 20%), the median overall survival was approximately 12 mo, and the overall survival rate at 5 years was less than 10%[71-75].

Several molecularly targeted therapies have recently shown substantial clinical efficacy in patients with advanced RCC, in particular the multitargeted tyrosine kinase inhibitors (such as sunitinib and sorafenib), anti-vascular endothelial growth factor (VEGF) antibody (such as bevacizumab), and mammalian target of rapamycin (mTOR) pathway inhibitors (such as everolimus and temsirolimus). The treatment regimen is based on the MSKCC risk stratification, on the type of the tumor (clear cell renal carcinoma or not clear cell renal carcinoma), and on the previous treatment (cytokines or multitargeted therapy). Sunitinib is chosen as first-line therapy in patients with favorable or intermediate prognosis. Two phase 2 trials on sunitinib in patients treated with cytokines as first-line therapy showed that the objective response rates (as assessed by investigators and by an independent review) were 34%-40%, better than with INF α[76,77].

The subsequent randomized phase 3 trial enrolled 750 patients. There were 375 patients in the sunitinib group and 372 in the IFN group. The median progression-free survival (PFS) was 11 mo for patients in the sunitinib group and 5 mo for patients in the IFN group

Table 3 Therapeutic algorithm

Patients with clear cell renal carcinoma		First-line therapy	Second-line therapy
Without previous treatment	Prognostic grade: favorable or intermediate prognosis	Sunitinib or Bevacizumab + interferon α	IL-2 high dose or clinical trial
	Prognostic grade: poor	Temsirolimus	Sunitinib or clinical trial
With previous treatment	With cytokines	Sorafenib	Sunitinib
	With multitargeted therapy	Everolimus	Tyrosine kinase inhibitor or clinical trial
Patients with not clear cell renal carcinoma		Temsirolimus	Sunitinib or sorafenib

($P < 0.001$), with a 58% reduction in the risk of progression. Sunitinib also improved the objective response rates (47% *vs* 12%)[78]. Patients with this prognostic grade can also be treated with bevacizumab plus IFN. In the first phase 2 trials, bevacizumab improved PFS with respect to placebo (4.8 mo *vs* 2.5 mo)[79].

The AVOREN study[80], a randomized phase 3 trial, enrolled 649 patients with 327 patients on IFN plus bevacizumab and 322 patients on IFN plus placebo. Bevacizumab plus IFN showed better PFS (median 10.2 mo *vs* 5.4 mo; $P = 0.0001$) and response rate (31% *vs* 13%). The mortality risk fell by about 14%. An American phase 3 trial (CALGB 90206)[81] confirmed the good results of bevacizumab.

In patients with poor prognosis, temsirolimus is the first option. A phase 3 trial[82] compared 3 therapeutic regimens, temsirolimus *vs* IFN *vs* the combination of these 2 agents. Temsirolimus alone improved both PFS and overall survival (OS), with a reduction of the mortality risk (14%). It is also the first choice in patients with not clear cell renal carcinoma.

Sorafenib showed superiority as a second-line therapy over placebo in terms of PFS and OS in patients treated with cytokines. The TARGET study[83], a phase 3 trial, randomized 903 patients; there were 451 patients in the sorafenib group and 452 in the placebo group. The median overall survival was 19.3 mo for patients in the sorafenib group and 15.9 mo for patients in the placebo group ($P = 0.02$). PFS was also significantly prolonged with sorafenib treatment (5.5 mo *vs* 2.8 mo; $P < 0.001$), with a 49% reduction in the risk of progression. Significantly more patients in the sorafenib group than in the placebo group had partial responses or stable disease ($P < 0.001$).

In patients treated previously with multitargeted therapy, everolimus can be the first choice. A phase 3 trial compared everolimus *vs* placebo in patients treated with sorafenib and/or sunitinib. Everolimus doubled the PFS compared with placebo (4 mo *vs* 1.9 mo) and decreased the risk of recurrence.

Based on all the clinical trials, we can summarize all the evidence in a therapeutic algorithm (Table 3). In the future, personalized treatments will be prescribed according not only to clinical criteria, but also to biological and molecular factors such as for breast and colorectal cancer.

RADIOTHERAPY

Pancreatic metastases are commonly treated with surgical resection. However, such a resection cannot always be performed safely, especially in elderly patients or those with diabetes mellitus. Pancreatic metastases of RCC may be treated successfully with radiation therapy (RT).

In the literature there is only one case report of four patients[84]. These patients presented with multiple pancreatic metastases of RCC and were treated with RT combined with IFN α. Radiotherapy was delivered at 2 Gy/fraction, up to 50 Gy in 25 fractions, with three-dimensional conformal radiation therapy technique and 10 MV photon beams from linear accelerators.

In three patients, stable local disease persisted for an average time of 33.6 mo (range11 to 69 mo) after RT. In one patient, a partial response was obtained, lasting 25 mo after RT.

The European Association of Urology guidelines recommend RT for the treatment of brain and bone lesions to induce symptomatic relief of metastases from RCC. To our knowledge, there are no other previous reports of radiotherapy for pancreatic metastases of RCC.

In patients with pancreatic metastases of RCC, surgical resection with or without systemic treatment, such as cytokine therapy or antiangiogenic therapy, should be considered if complete resection is possible.

On the other hand, systemic treatment with or without RT to induce symptomatic relief and to prevent disease progression can be considered for high-risk patients, such as those with a poor performance status, diabetes mellitus, and older age.

ALTERNATIVE APPROACHES

Treatment options for unresectable pancreatic metastases of RCC are limited and new therapeutic measures should be advocated. Radiofrequency ablation (RFA) is a local ablative method that can destroy the tumor by thermal coagulation and protein denaturation. RFA has been used successfully in the treatment of unresectable solid tumors in the liver, lung, kidney, brain, breast, prostate, bone, adrenal glands and spleen[85-92]. Application of RFA to the pancreas presents potential problems related to anatomical considerations and particular properties of the pancreatic parenchyma. The risk of inadvertent thermal injury to the distal common bile duct, duodenum, transverse colon and portal vein is considerable with RFA. In addition, thermal injury to normal pancreatic tissue may cause acute necrotizing pancreatitis, pancreatic fistula or pancreatic ascites[93-101].

Elias *et al*[94] reported two cases of multiple pancreatic metastases from RCC treated by RFA. Both patients manifested acute necrotizing pancreatitis with massive destruction of normal pancreatic parenchyma.

Hadjicostas *et al*[96], based on results obtained in four patients, concluded that RFA seems to be a feasible, potentially safe and promising option in patients with advanced and non-resectable pancreatic cancer. Girelli *et al*[102], based on results obtained in 50 patients, showed that RFA of

locally advanced pancreatic cancer is feasible and relatively well tolerated, with a 24% complication rate.

Postoperative observation (clinical surveillance, laboratory tests and imaging studies) is mandatory because of the potential for major or minor, early or later complications. The most frequent complications encountered in the earlier postoperative period (within 1 wk) are fluid collection, pancreatic fistula, duodenal perforation and vascular damage. At later times, digestive or abdominal bleeding, infections or abscesses are more common. Severe acute pancreatitis is a rare complication[96]: in Girelli's[102] study, there was only one case, and none were reported in Wu's study[101]. Major complications are frequently present with RFA of pancreatic head tumors, mainly owing to the closeness of the duodenum. These lesions are more difficult to treat, as reported previously[101].

While waiting for other studies to clarify its role, RFA should be performed in high-volume centers by an experienced surgical team devoted to pancreatic surgery.

CONCLUSION

Thus, as suggested by Zerbi *et al*[12], a high index of suspicion is necessary for all patients with a history of RCC, and they should be monitored lifelong to allow the early detection of recurrence.

Because of the possibility of substantial morbidity after pancreatic resection and the questionable benefit of metastasectomy in some patients, pancreatic metastasectomy should be offered only after a thoughtful and systematic selection process. Ideally, this process would involve a multidisciplinary team that includes a medical oncologist and an experienced pancreatic surgeon. Once the decision is made to proceed with resection, evidence suggests that the procedure should be performed at a high-volume center[103,104]. In agreement with Reddy *et al*[54], we suggest the following criteria for the selection of patients for pancreatic metastasectomy: primary cancer type that is associated with successful outcome, control of the primary cancer site, isolated metastases, resectability of the metastasis, and patient fitness to tolerate pancreatectomy.

Prospective studies would better address the role of surgical therapy in pancreatic metastasectomy. However, because of the rarity of these lesions, such a trial can only be performed in a multi-institutional setting and possibly only for RCC metastases because of their high relative incidence compared with other cancers.

Abstract

Various mucin-producing neoplasms originate in different abdominal and pelvic organs. Mucinous neoplasms differ from non-mucinous neoplasms because of the differences in clinical outcome and imaging appearance. Mucinous carcinoma, in which at least 50% of the tumor is composed of large pools of extracellular mucin and columns of malignant cells, is associated with a worse prognosis. Signet ring cell carcinoma is characterized by large intracytoplasmic mucin vacuoles that expand in the malignant cells with the nucleus displaced to the periphery. Its prognosis is also generally poor. In contrast, intraductal papillary mucinous neoplasm of the bile duct and pancreas, which is characterized by proliferation of ductal epithelium and variable mucin production, has a better prognosis than other malignancies in the pancreaticobiliary tree. Imaging modalities play a critical role in differentiating mucinous from non-mucinous neoplasms. Due to high water content, mucin has a similar appearance to water on ultrasound (US), computed tomography (CT), and magnetic resonance imaging, except when thick and proteinaceous, and then it tends to be hypoechoic with fine internal echoes or have complex echogenicity on US, hyperdense on CT, and hyperintense on T1- and hypointense on T2-weighted images, compared to water. Therefore, knowledge of characteristic mucin imaging features is helpful to diagnose various mucin-producing neoplastic conditions and to facilitate appropriate treatment.

Key words: Mucin; Neoplasm; Ultrasound; Computed tomography; Magnetic resonance; Abdomen and pelvis

INTRODUCTION

Mucinous carcinoma is a histological subtype of tumor in which at least 50% of the tumor is composed of large pools of extracellular mucin and columns of malignant cells. Although less frequent than non-mucinous carcinoma, mucinous carcinoma is associated with a worse prognosis, because it is more frequently diagnosed in the advanced stage and is associated with more frequent local recurrence, serosal invasion, lymphatic and vascular invasion, lymph node metastasis, and distant metastasis[1,2]. Signet ring cell carcinoma is composed of signet ring cells that have a vacuolated cytoplasm containing abundant intracellular mucin and a nucleus displaced to the periphery. The prognosis for signet ring cell carcinoma is generally poor, although its prognosis is still controversial[3,4]. Intraductal papillary mucinous neoplasm (IPMN) is an uncommon neoplasm arising from the bile duct and pancreas, which is characterized by a proliferation of ductal epithelium associated with ductal dilatation and variable mucin production. Distinguishing IPMN from other tumors is essential because IPMN has a better prognosis than other malignancies in the pancreaticobiliary tree[5,6].

Careful distinction of mucinous and non-mucinous tumors is important, as the clinical outcome of these entities may somewhat differ. Because abundant mucin within the tumor is the hallmark of mucinous neoplasms, mucin-producing neoplasms typically show some distinct imaging features. Therefore, familiarity with the critical imaging features of mucin-producing neoplasms in the abdomen and pelvis may facilitate an accurate diagnosis and treatment.

In this article, we classify mucin-producing neoplasms in the abdomen and pelvis into four types according to characteristic morphological features: unilocular or multilocular cystic neoplasms lining mucin-secreting epithelium that contain mucinous fluid; tumors characterized by intraluminal proliferation of mucinous neoplastic transformation of epithelium lining pancreaticobiliary ducts, which are arranged in a papillary pattern and typically produce and accumulate mucin; tumors composed of neoplastic epithelium containing intracellular mucin associated with little or no extracellular mucin; and tumors composed of abundant extracellular mucin due to mucin-secreting neoplastic epithelium. On the basis of these four types, we discuss and illustrate the clinical significance and imaging features of mucin-producing neoplasms in the abdomen and pelvis.

BASIC CONCEPTS

Mucin is a high-molecular-weight glycoprotein containing oligosaccharides attached to the mucin core protein, and is the major component of mucus lining the surface of glandular epithelium as a viscoelastic gel. Mucin is expressed by various epithelial mucosal cells, which exist in the respiratory, digestive, and urogenital tracts, and secretory epithelial surfaces of specialized organs such as the liver, pancreas, gallbladder, kidneys, salivary glands, lacrimal glands, and eyes. Mucin has a central role in maintaining homeostasis and promoting cell survival in a variety of conditions. Because the outermost area of a typical epithelial surface consists of secreted gel-forming mucin, mucin lubricates and forms a barrier that protects the mucosal epithelium from potentially noxious intraluminal substances such as air, food, enzymes, acidic pH, salt, bacteria, and viruses. Additionally, mucin gels capture and hold biologically active molecules that may incite inflammatory, repair, or healing processes following their release[7,8].

Cancer cells, especially adenocarcinomas, express aberrant forms or amounts of mucins that arise as a consequence of the deregulation of mucin core protein expression. Mucins in cancer cells contribute to carcinogenesis and tumor invasion by simultaneously disrupting existing interactions and establishing new ones. These tumors produce variable amounts of intracellular and/or extracellular mucins[9].

Mucus is composed of 95% water and 5% high-molecular-weight glycoprotein. Due to its high water content, mucin usually appears anechoic on ultrasound (US), and has computed tomography (CT) attenuation and magnetic resonance (MR) signal intensity similar to those of water. However, the imaging appearance of mucin varies depending on water and protein concentrations. Concentrated mucin increases US echogenicity, which may appear hypoechoic with fine internal echoes or in a complex echogenic pattern. Concentrated mucin also has CT attenuation values above that of water, as well as high signal intensity on T1-weighted images and low signal intensity on T2-weighted images due to shortening of both the T1 and T2 relaxation times[10]. Knowledge of these characteristic mucin imaging features is helpful to diagnose various mucin-producing neoplastic conditions and to avoid pitfalls.

MUCIN-PRODUCING NEOPLASTIC CONDITIONS

Well-circumscribed cystic neoplasms lining mucin-secreting epithelium and containing mucinous fluid

Mucinous cystic neoplasm of the pancreas: A mucinous cystic neoplasm (MCN) is lined by mucin-producing columnar epithelium. This tumor is characterized by an ovarian-like stromal component, which is essential for diagnosing MCN of the pancreas. MCN of the pancreas

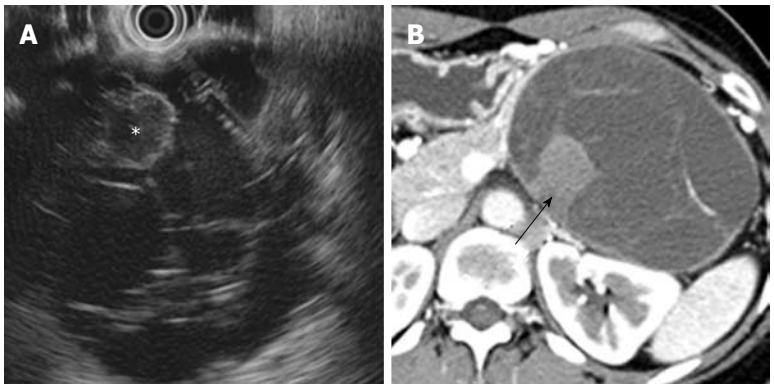

Figure 1 Mucinous cystadenoma of the pancreas in a 40-year-old woman. A: Endoscopic ultrasound image shows a complex multiloculated cystic mass in the pancreatic tail. Note a hyperechoic locule (asterisk) within the cystic tumor; B: Contrast-enhanced CT image shows a well-circumscribed multiloculated mass in the tail of the pancreas with enhancement of thin internal septa and the peripheral wall. Note a highly attenuated locule (arrow) within the cystic tumor. CT: Computed tomography.

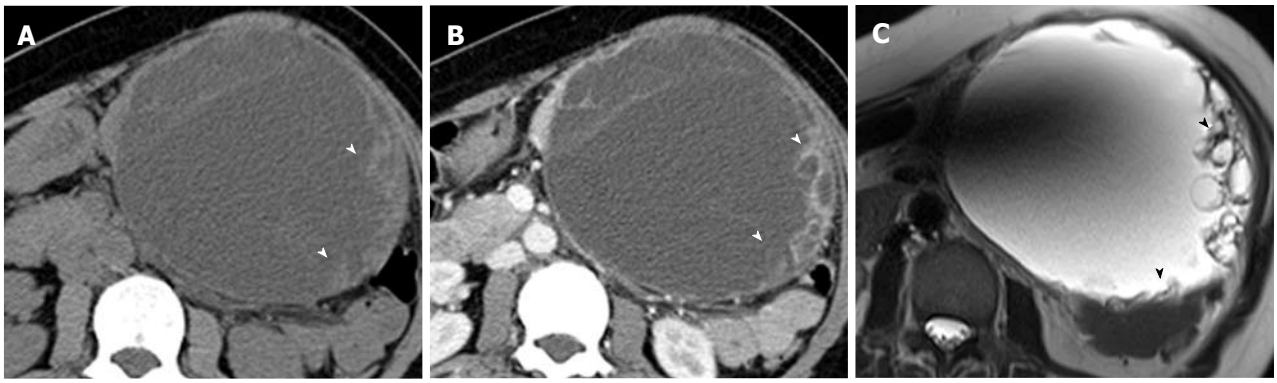

Figure 2 Mucinous cystadenocarcinoma of the pancreas in a 44-year-old woman. A, B: Non-enhanced (A) and contrast-enhanced (B) CT images show a well-circumscribed multi-septated cystic mass with enhancing soft tissue components (arrowheads) in the tail of the pancreas; C: T2-weighted MR image shows a large multilocular cystic mass with high signal intensity and peripheral soft tissue components with low signal intensity (arrowheads) in the pancreatic tail. CT: Computed tomography; MR: Magnetic resonance.

shares both clinical and pathological characteristics with biliary and ovarian mucinous tumors[11]. MCN occurs predominantly in middle-aged women, typically in the body or tail of the pancreas. Although a spectrum of MCNs from benign (mucinous cystadenoma) to malignant (mucinous cystadenocarcinoma) occurs, MCNs should always be resected because they are all potentially malignant[11].

On cross-sectional imaging, a MCN appears as a well-capsulated, unilocular, or multilocular septated cystic lesion (Figures 1 and 2). The tumor is round to oval with a smooth external margin, and the wall of the cyst is typically thick with delayed enhancement[11,12]. Peripheral calcification is seen in 10%-25% of cases and is an important characteristic of MCN that can be used to distinguish it from serous cystadenoma, which tends to have central calcification[11]. A MCN generally does not communicate with the pancreatic duct, unlike an IPMN-P. When rarely present, such a communication is due to fistula formation between the MCN and the pancreatic duct[13]. Different attenuations or signal intensities may be noted within the cystic cavity, depending on whether mucoid or hemorrhagic fluid is present. The presence of an internal enhancing soft tissue component is indicative of mucinous cystadenocarcinoma (Figure 2)[11,14].

Biliary cystadenoma and cystadenocarcinoma: Biliary cystadenomas and cystadenocarcinomas are rare tumors arising in the bile duct epithelium as multilocular cystic masses containing carcinoembryonic antigen-rich mucinous fluid. They are generally intrahepatic (85%) and occur more frequently in middle-aged women. These tumors are similar to mucinous cystic tumors that arise in the pancreas and ovary and are further subdivided into those with ovarian stroma and those without ovarian stroma. The presence of ovarian stroma may be a favorable prognostic sign. However, gross or imaging features cannot distinguish tumors with ovarian stroma from those without ovarian stroma[15,16].

The CT appearance of a biliary cystadenoma and cystadenocarcinoma includes a solitary cystic mass with a well-defined thick fibrous capsule, mural nodules, internal septa, and, rarely, capsular calcification. These appear as a multilocular cystic mass with variable signal intensities on both T1- and T2-weighted images depending on the

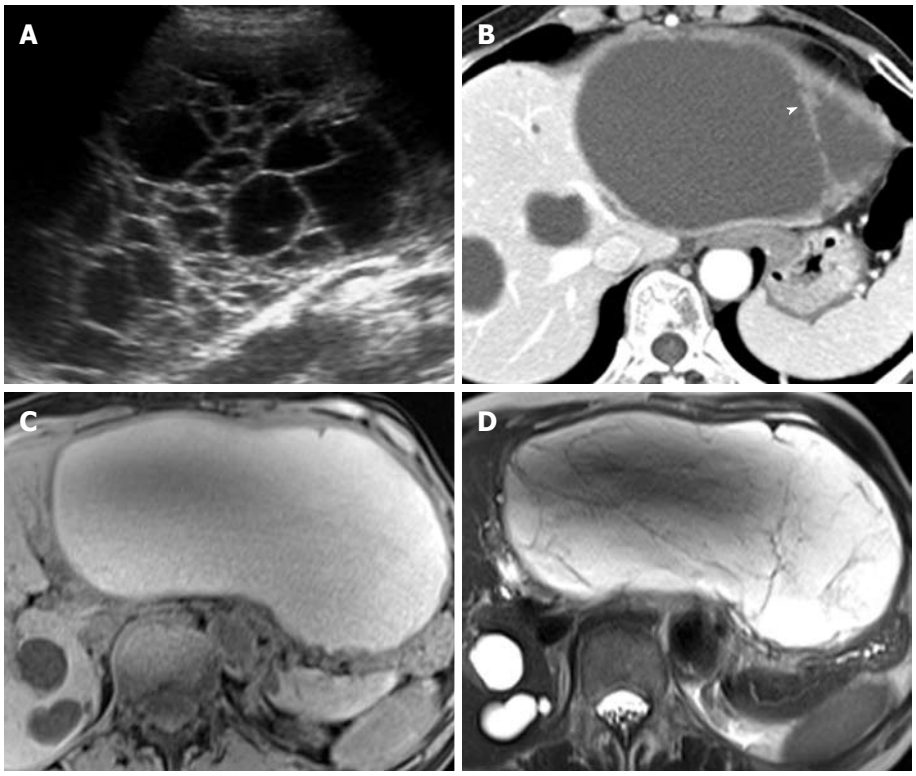

Figure 3 Biliary cystadenoma in the liver of a 55-year-old woman. A: Ultrasound image shows a multiseptated cystic mass in the liver; B: Contrast-enhanced CT image shows a well-circumscribed cystic liver mass, which has similar attenuation to that of hepatic cysts. Note the internal septa with nodular thickening (arrowhead); C, D: T1- (C) and T2-weighted (D) MR images show a multiseptated cystic mass with hyperintensity. CT: Computed tomography; MR: Magnetic resonance.

presence of mucin, hemorrhage content, or solid components (Figure 3)[17]. Internal nodularity and septation have been associated with a biliary cystadenocarcinoma, whereas septation without nodularity is associated with a biliary cystadenoma. However, these findings overlap between benign and malignant forms. Because both a biliary cystadenoma and cystadenocarcinoma are treated with total surgical excision, distinguishing these two diseases may be of little practical importance[15,16].

Biliary cystadenomas and cystadenocarcinomas morphologically resemble a cystic variant of an intrahepatic intraductal papillary neoplasm of the bile duct (IPN-B). Distinguishing these two diseases may be possible on images in which the cystic IPN-B is communicating with the intrahepatic bile ducts and the downstream bile duct is dilated due to excessive mucin, whereas biliary cystadenomas and cystadenocarcinomas do not communicate with the bile duct, and mucin is confined to the cystic mass[18].

Mucinous cystic tumors of the ovary: Mucinous cystic tumors of the ovary are the second most common type of ovarian epithelial tumor. They can be classified as adenomas, borderline malignancies, or adenocarcinomas, according to the histopathological degree of malignancy. A mucinous cystadenoma is composed of a single layer of columnar cells with abundant intracellular mucin and small basilar nuclei in the cysts. A mucinous borderline tumor is a noninvasive epithelial tumor characterized by cytologic atypia without stromal invasion. A mucinous cystadenocarcinoma has an irregular glandular structure and papillae with obvious stromal invasion[19].

On MR imaging, a mucinous cystic tumor typically appears as a large multilocular cystic mass. The loculi show variable signal intensity on both T1- and T2-weighted images (so-called "stained glass" appearance), depending on the viscosity of the materials present, such as mucin, blood products, or debris (Figures 4, 5 and 6). A unilocular cystic appearance is rare for mucinous cystic tumors. A solid component, thick septa, and a thick and irregular wall are suggestive of a malignant epithelial ovarian tumor (Figure 6)[20,21].

A primary intestinal mucinous carcinoma, most commonly from the appendix or colon, can metastasize to the ovary. Metastases to ovary are much more common than an ovarian cystadenocarcinoma. A metastatic carcinoma is often bilateral, whereas a mucinous cystadenocarcinoma is usually unilateral. However, mucinous cystadenocarcinomas mimic metastases to the ovary from a primary mucinous carcinoma on MR imaging[20,21].

The gross and radiological appearances of mucinous borderline tumors usually do not reliably distinguish them from cystadenomas or even some cystadenocarcinomas. The most frequent MR feature of mucinous borderline tumors is a predominantly cystic lesion with varying cyst and septal wall thickness. Mucinous borderline tumors and cystadenocarcinomas tend to have greater numbers of loculi on MR imaging than cystadenomas, which can be explained by more active mitosis in mucinous bor-

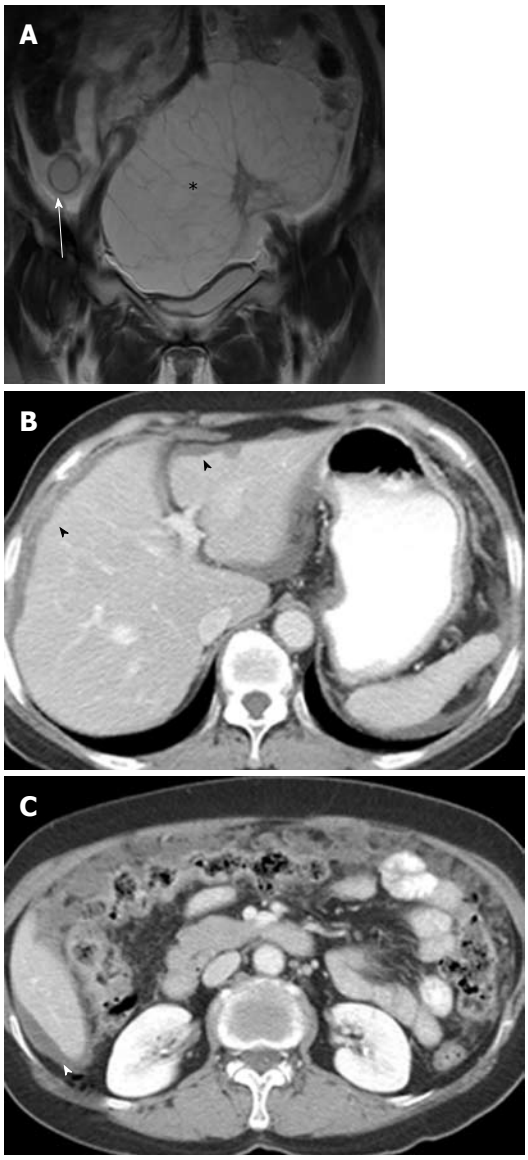

Figure 4 Coexistence of a mucinous cystadenoma of the appendix and ovary in a 63-year-old woman. A: Coronal T2-weighted MR image shows a well-defined cystic mass with hyperintensity in the appendix (arrow) and a multiloculated cystic mass in the left ovary (asterisk); B, C: Contrast-enhanced CT images show low-attenuation mucinous deposits in the peritoneal cavity and scalloping of the liver margin (arrowheads), suggestive of pseudomyxoma peritonei. CT: Computed tomography; MR: Magnetic resonance.

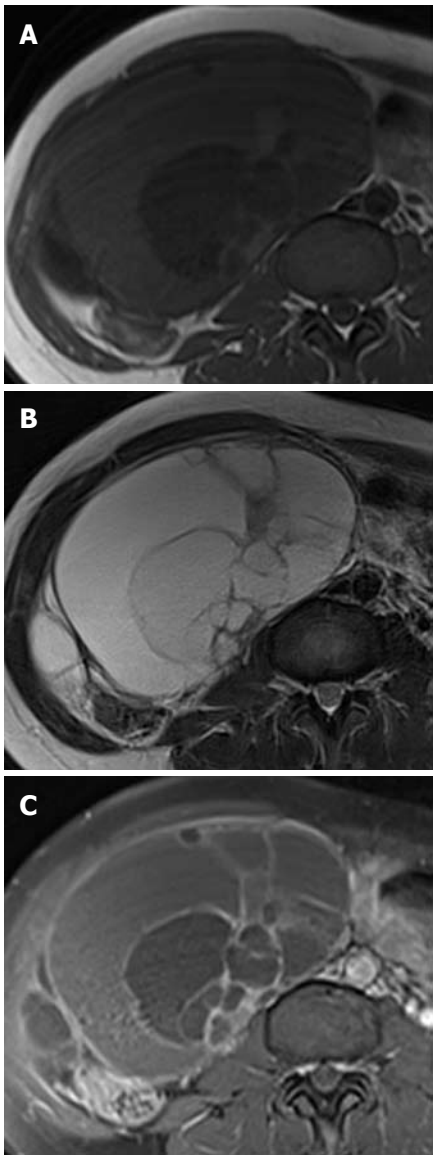

Figure 5 Mucinous borderline tumor of the right ovary in a 41-year-old woman. A, B: T1- (A) and T2-weighted (B) MR images show a cystic mass with large numbers of loculi with varying signal intensity in the right ovary; C: Contrast-enhanced fat-saturated T1-weighted MR image shows the enhancement of multiple internal septa and wall in the cystic mass. MR: Magnetic resonance.

derline tumors and cystadenocarcinomas, resulting in production of larger numbers of glands and loculi (Figures 5 and 6). Both mucinous cystadenocarcinomas and borderline tumors show a solid portion on MR imaging, which is pathologically composed of densely aggregated fine numerous loculi or diffuse tumor cell proliferation. However, the solid portion of a mucinous cystadenocarcinoma is larger and more commonly seen than in a borderline tumor. Pelvic organ invasion, implants, and lymphadenopathy may be helpful ancillary findings suggestive of malignancy[22,23].

Mucocele of the appendix: Mucocele is a descriptive term for a mucinous distension of the appendiceal lumen, regardless of the underlying pathology. A mucocele is quite rare, with a prevalence of 0.2%-0.3% among appendectomies and 8% of all appendiceal tumors. A mucocele can be caused by a variety of nonneoplastic, benign neoplastic, and malignant conditions. However, most mucoceles are associated with neoplastic epithelium. A mucinous cystadenoma is the most common type, representing 63%-84% of mucoceles. A mucinous cystadenoma is based on villous adenomatous changes in the mucin-rich epithelium, which produce marked intraluminal dilatation by mucin reaching up to 6 cm. An appendiceal perforation occurs in up to 20% of cases, with mucinous spillage into the periappendiceal area or onto the serosal surface, which leads to pseudomyxoma

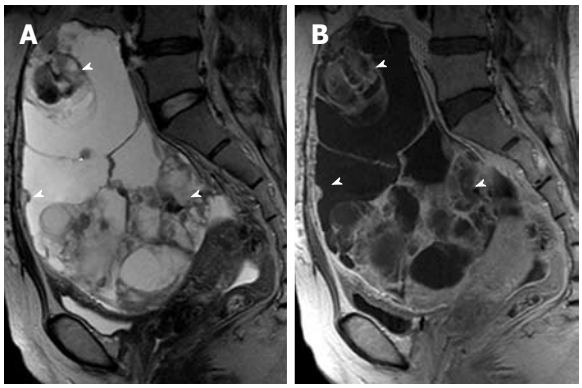

Figure 6 Mucinous cystadenocarcinoma of the left ovary in a 47-year-old woman. A: Sagittal T2-weighted MR image shows a huge multilocular ovarian cystic mass with multiple hypointense solid components (arrowheads); B: Sagittal contrast-enhanced T1-weighted MR image shows an ovarian cystic mass with enhancement of internal septa and solid components (arrowheads). MR: Magnetic resonance.

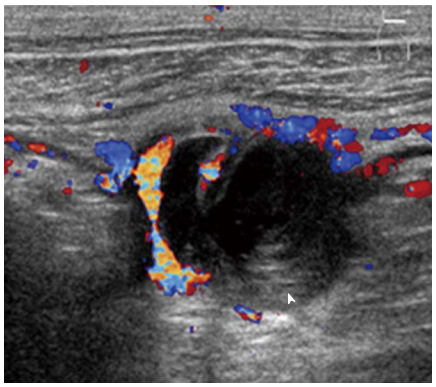

Figure 7 Mucocele of the appendix in a 54-year-old man. Ultrasound image shows an anechoic round mass in the appendix with echogenic layers (arrowhead) (the so-called "onion-skin" sign).

peritonei (PMP) and a possibly fatal outcome. A mucinous cystadenocarcinoma is less common than a cystadenoma, accounting for 11%-20% of cases. The presence of stromal invasion by neoplastic cells is indicative of an adenocarcinoma[24,25].

Imaging plays an important role when evaluating appendiceal mucocele. US usually reveals a unilocular, ovoid, anechoic mass in the region of the appendix. Internal echogenicity varies depending on the acoustic interfaces produced by the mucin, including hypoechoic masses with fine internal echoes and complex echogenic masses with acoustic enhancement. Concentric and echogenic layers within the cystic mass (the so-called "onion skin" sign) are specific for mucocele of the appendix (Figure 7). The reason for the layered appearance on US is unclear; nevertheless, it may be explained by a fluctuation in mucin secretion into the cavity along with the gradual absorption of water or by a fluctuation in the degree of excretion blockage from the cavity[24,26]. CT is the imaging modality of choice because CT depicts tissue characteristics, the anatomical relationship between the cystic mass

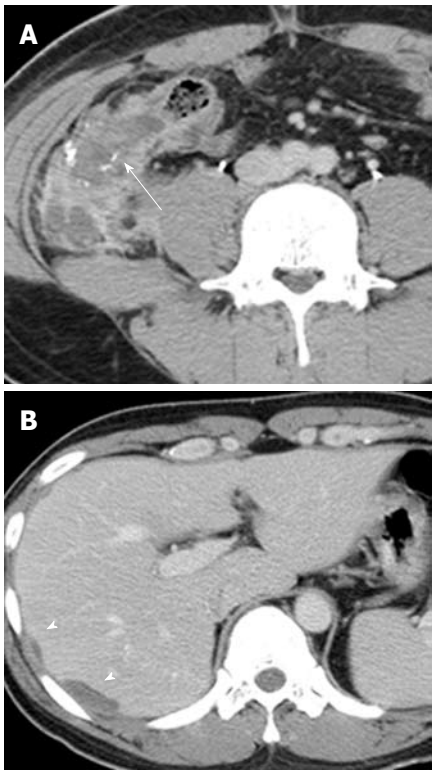

Figure 8 Mucinous cystadenocarcinoma of the appendix in a 26-year-old man. A: Contrast-enhanced CT image shows a complex hypoattenuating mass with enhancing solid portions and punctate calcifications in the appendix (arrow); B: Contrast-enhanced CT image of the upper abdomen shows loculations of fluid scalloping on the liver surface (arrowheads), providing evidence of a mass effect. CT: Computed tomography.

and cecum, and helps rule out or confirm the diagnosis. On CT, a mucocele appears as a round or tubular cystic mass with thin and enhancing walls, which is contiguous with the base of the cecum. Curvilinear mural calcification is sometimes seen in less than 50% of cases, which is suggestive of a mucocele. A mucocele is hyperintense on T2-weighted image and variably hypointense or isointense on T1-weighted image, depending on the mucin concentration (Figure 4). The presence of enhancing nodular lesions raises the possibility of a mucinous cystadenocarcinoma (Figure 8). Identifying a normal right ovary in women is also crucial to exclude a cystic ovarian neoplasm or tubo-ovarian abscess[24,25,27].

Since mucoceles usually present as a chronic noninfectious process, most are relatively asymptomatic. However, their presenting symptoms sometimes mimic acute appendicitis. The differential diagnosis between a mucocele with secondary appendicitis and appendicitis without a mucocele is important because surgical management may be altered according to the presence or absence of mucocele. CT features such as cystic dilatation of the appendix, a luminal diameter greater than 1.5 cm, and mural calcification suggest a mucocele coexisting with acute appendicitis, although there is some overlap with the diagnosis of acute appendicitis without a mucocele[28].

The treatment of choice is surgical excision, and the

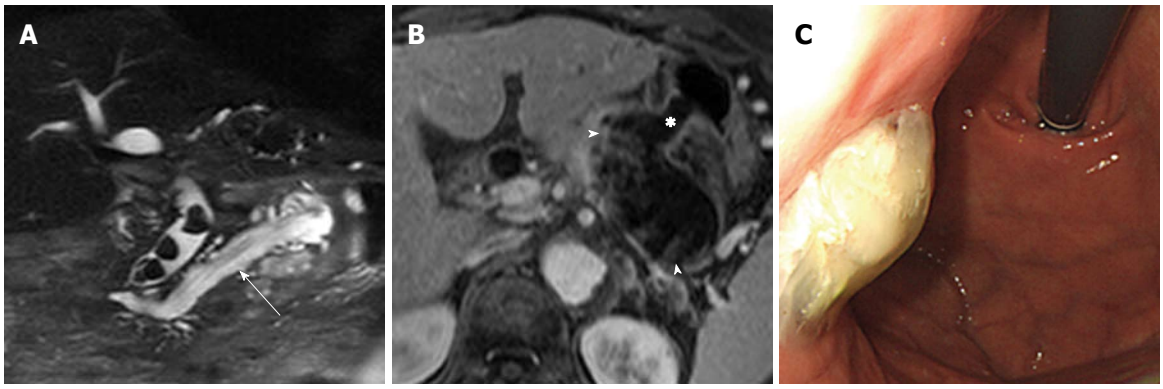

Figure 9 Intraductal papillary mucinous neoplasm of the pancreas in an 80-year-old woman. A: Coronal T2-weighted RARE MR image shows cord-like hypointense mucin in the dilated main pancreatic duct (arrow). Note multiple stones in the dilated common bile duct; B: Axial contrast-enhanced fat-saturated T1-weighted MR image demonstrates a fistula (asterisk) between the dilated main pancreatic duct and the stomach. Note mural nodules (arrowheads) within the dilated main pancreatic duct, which strongly suggest a malignant Intraductal papillary mucinous neoplasm; C: Endoscopy image reveals mucin leaking from the papilla. RARE: True rapid acquisition with relaxation enhancement; MR: Magnetic resonance.

type of surgery performed is related to the size and the histological contents of the mucocele. A full abdominal exploration is advised during surgery, because a mucocele can be associated with other tumors, particularly colonic adenocarcinoma and ovarian tumors[26].

Tumors that produce and accumulate mucin in the pancreaticobiliary tract

Intraductal papillary mucinous neoplasm of the pancreas: IPMN-P, known as one of the mucin-producing pancreatic tumors, is an uncommon pancreatic neoplasm with characteristic histology and distinctive clinicobiological behavior. It is characterized by an intraductal proliferation of mucinous cells arranged in a papillary pattern. Excessive mucin secretion in the ducts by this proliferation ultimately leads to cystic dilatation of the major duct, the second duct, or both, depending on the tumor location. Abundant mucin production is usually observed in most cases of IPMN-P. The clinical symptoms and signs of IPMN-P are due to impaired outflow of pancreatic juice, which is induced by the hypersecretion of mucin[5,29].

IPMN-P occurs most frequently in men, and the mean age at the time of diagnosis is approximately 60 years. It is most commonly located in the head or uncinate process of the pancreas. IPMN-P has a low potential for malignancy, and it has a better prognosis than other pancreatic malignancies because of slow growth rates, rare parenchymal invasion, low rates of metastatic spread, and low recurrence after resection[5,29].

Characteristic endoscopic retrograde cholangiopancreatography findings of IPMN-P include communication between a cystic lesion in the branch duct and the main pancreatic duct, intraluminal filling defects of the pancreatic duct due to the presence of mucin or a mass, and the depiction of a patulous papilla with mucin extrusion from the orifice of the papilla. CT or MR findings of IPMN-P include grapelike clustered cystic lesions reflecting focal dilatation of the branch ducts, diffuse dilatation of the main pancreatic duct, mural nodules, bulging papilla, and communication of branch duct-type IPMN with the main pancreatic duct. Although the diagnosis of malignancy in IPMN is often difficult, even with recent advanced MR techniques, several indirect findings can suggest the presence of malignancy, including the presence of mural nodules, thick septa, septal calcification, and a main pancreatic duct dilated to greater than 10 mm in diameter (Figure 9)[5].

Papillary neoplasm of the bile duct: A papillary neoplasm of the bile duct is an intraductal tumor with numerous minute frondlike papillary projections. In approximately one-third of cases, tumors produce abundant viscous mucin, resulting in intermittent and incomplete obstruction of the segmental or lobar bile ducts or the entire biliary tree. A papillary neoplasm of the bile ducts arises from the mucosa and slowly spreads along its luminal surface. Only in the late stage does it invade the bile duct, and thus prognosis is relatively favorable[6,30].

Considering the shared biliary tract and pancreatic origin, the two systems may have similar pathological features. Thus, IPN-B is the biliary counterpart of IPMN-P. In both organs, these neoplasms arise within the duct system and show a predominantly intraductal growth pattern, commonly an overproduction of mucin, and an association with invasive adenocarcinoma[30].

Based on the gross appearance of the intraductal tumors, IPN-B may be classified as an intraductal polypoid tumor, a cast-like growing tumor, a mucosal spreading growth, a cystic variant, or a floating tumor[31]. Thus, variable imaging appearances of IPN-B include an intraductal polypoid mass within a localized ductal dilatation, diffuse and marked duct ectasia with a visibly enhanced papillary mass or masses, intraductal cast-like lesions within a mildly dilated duct, diffuse and marked duct ectasia without a visible mass, or a floating tumor. The friable part of the papillary tumor may slough off and be seen in imaging as a floating tumor within the bile duct, which can be radiologically confused with a bile duct stone[32,33].

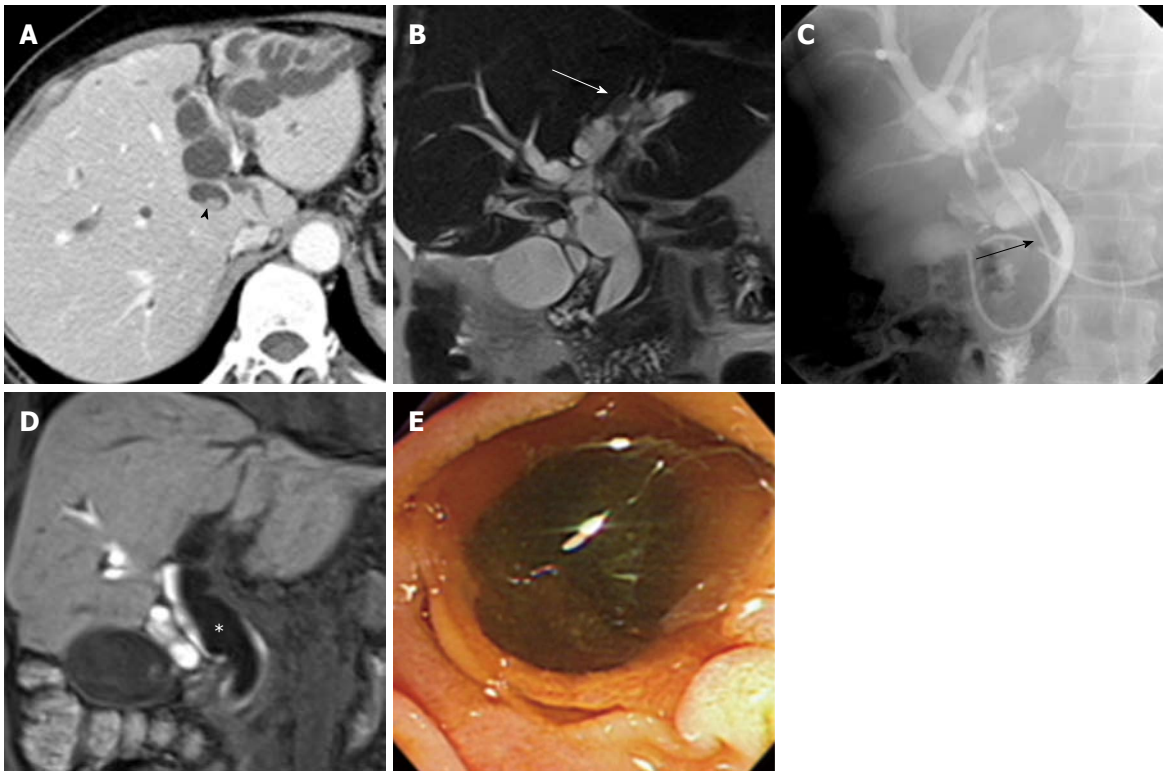

Figure 10 Intraductal papillary mucinous neoplasm of the bile duct in a 58-year-old woman. A: Contrast-enhanced CT image shows severe dilatation of the left intrahepatic ducts without visible intraductal mass. Note a small stone in the dilated intrahepatic duct (arrowhead); B: Coronal T2-weighted RARE MR image shows dilatation of the intrahepatic and extrahepatic ducts. Note the hypointense intraductal mass (arrow) in the left intrahepatic duct; C: Endoscopic retrograde cholangiogram image shows a filling defect (arrow) within the marked dilated extrahepatic bile duct, due to mucin; D: Coronal gadoxetic acid-enhanced T1-weighted MR image obtained at 60 min post-injection shows contrast-filled bile duct with an elongated, low signal intensity lesion (asterisk), which represents mucin; E: Endoscopy image reveals mucin leaking from the papilla. CT: Computed tomography; RARE: True rapid acquisition with relaxation enhancement; MR: Magnetic resonance.

CT and MR images may fail to detect mucin itself because the attenuation or signal intensity of mucin is usually similar to that of bile. A large amount of mucin can be suggested by indirect CT and MR findings, including disproportionate and severe dilatation of the bile ducts proximal or even distal to the tumor, hepatic parenchymal atrophy in the affected lobe or segments, and bulging of the papilla (Figure 10). This usually occurs in IPN-B with mucosal spreading growth without forming tangible masses, and can be explained by the production of excessive amounts of mucin and a longstanding increased ductal pressure on the adjacent hepatic parenchyma due to the partial obstruction[34].

Moreover, in our experience, mucin appears as an elongated and amorphous filling defect within an enhanced bile duct on gadobenate dimeglumine-enhanced or gadoxetic acid-enhanced MR imaging, similar to that of direct cholangiographic findings (Figure 10). The filling defect due to mucin could be confused with other intraluminal filling defects, such as a stone, blood clot, or mass. T2-weighted images can be helpful to distinguish hyperintense mucin from other intraluminal filling defects that usually appear as a signal void, or as hypointense or isointense[35].

Papillary neoplasm of the gallbladder: Mucin-producing carcinoma of the gallbladder is rare, and occurs mostly in older women. Mucin-producing carcinoma of the gallbladder histologically includes two different types: well-differentiated papillary adenocarcinoma and mucinous carcinoma. Well-differentiated adenocarcinoma (particularly papillary adenocarcinoma) usually presents as a papillary growth pattern and can produce mucin in the gallbladder lumen. A well-differentiated papillary adenocarcinoma is potentially less invasive due to its tendency toward intraluminal growth. At cross-sectional imaging, it appears as a papillary protrusion in an enlarged gallbladder[36].

Tumors composed of neoplastic epithelium containing intracellular mucin associated with little or no extracellular mucin

Signet ring cell carcinoma: Signet ring cell carcinoma is characterized by large intracytoplasmic mucin vacuoles that expand in the malignant cells and push the nucleus to the periphery, creating a "signet ring" configuration. When ⩾ 50% of the tumor is composed of cells of this type, it is classified as a signet ring cell carcinoma. More than 96% of all signet ring cell carcinomas arise in the stomach, with the rest arising in other primary organs including the rectum, colon, gallbladder, pancreas, bladder, and breast[3,4].

Signet ring cell carcinomas usually produce minimal mucosal alterations in the gastrointestinal tract, but signet

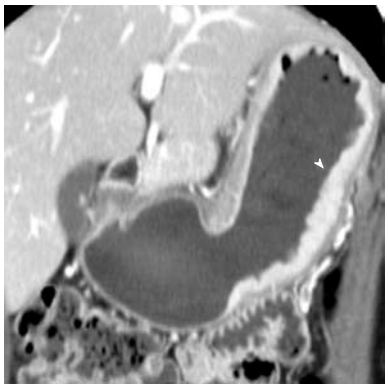

Figure 11 Signet ring cell carcinoma of the stomach in a 45-year-old woman. Coronal reformatted contrast-enhanced CT image shows diffuse gastric wall thickening with strong enhancement (arrowhead) along the lesser and greater curvature of the stomach. CT: Computed tomography.

ring cells diffusely infiltrate throughout the bowel wall and often incite a marked desmoplastic reaction in the submucosa and muscularis propria, which produces the classic pathological features of primary scirrhous carcinoma, also known as the linitis plastic type[3,4].

Gastric signet ring cell carcinoma accounts for 5%-15% of all gastric cancers, and occurs at a higher frequency in females and young patients. The prognosis of gastric signet ring cell carcinoma remains controversial. However, signet ring cell histology is generally considered a poor prognostic factor in gastric carcinoma[3]. Hyperenhancement of the involved stomach wall compared with liver attenuation on portal venous phases of contrast-enhanced CT and a predominantly thickened layer of the gastric wall are more commonly found in gastric signet ring cell carcinoma than in non-signet ring cell carcinoma (Figure 11). Hyperenhancement of the gastric lesion may correspond to intermingled loose and immature fibrosis or neovascularized signet ring cells[37].

Colorectal signet ring cell carcinoma is rare, ranging from 0.1% to 2.4% of all colorectal carcinomas. Most are localized exclusively in the rectum. This carcinoma commonly occurs in younger patients and also has a high rate of spread to the lymph nodes, ovaries, or peritoneal surface. Distant hematogenous metastasis to the liver or lung is uncommon. The most common and characteristic CT features of this tumor are a long segment of concentric wall thickening and a target appearance (Figure 12)[38]. Imaging findings of colorectal signet ring cell carcinoma are similar to those of metastatic linitis plastica originating from a primary tumor, such as breast, gastric, or bladder cancers. Metastatic linitis plastica appears as a malignant target sign consisting of thickened inner (mucosa and submucosa) and outer (serosa) layers and a relatively thin hypoattenuated middle layer (muscularis propria), or bowel wall thickening with homogeneous attenuation. In contrast, a benign target sign can be caused by submucosal edema, inflammatory infiltration, or hemorrhage and thus appears as a prominent hypoattenuating middle layer (submucosa) and thin hyperattenuating inner (mucosa) and outer layer (muscularis propria and serosa)[39].

Figure 12 Signet ring cell carcinoma of the rectum in a 42-year-old man. A, B: Axial (A) and coronal reformatted (B) contrast-enhanced CT images show concentric wall thickening with malignant target sign (arrowheads in A, arrow in B) in the rectum; C: Photomicrograph image (original magnification, × 200; HE stain) shows multiple signet ring cells. CT: Computed tomography; HE: Hematoxylin and eosin.

Tumors composed of abundant extracellular mucin due to mucin-secreting neoplastic epithelium

Mucinous adenocarcinoma of the gastrointestinal tract: Adenocarcinomas in various organs can produce and secrete extracellular mucin. This extracellular mucinous material may be so copious that the malignant cells appear to float within a gelatinous pool. Mucinous carcinoma is diagnosed when extracellular mucin within the tumor is retained by more than 50% of the cells[1,2].

Mucinous carcinoma of the gastrointestinal tract is a rare subtype of adenocarcinoma that usually occurs in the stomach and colorectum. Mucinous carcinomas in

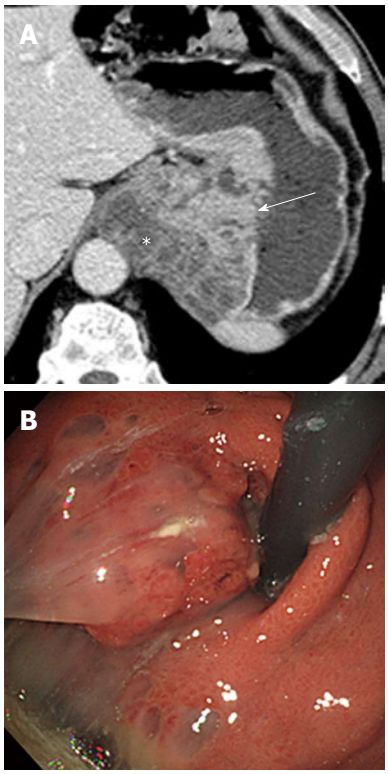

Figure 13 Mucinous carcinoma of the stomach in a 62-year-old woman. A: Contrast-enhanced CT image shows a large mass lesion in the gastric cardia containing abundant mucin pools (asterisk) and enhanced solid portions (arrow); B: Endoscopy image shows jellylike mucin leaking from the gastric mass. CT: Computed tomography.

the gastrointestinal tract have worse prognosis than non-mucinous carcinomas, because they are more frequently diagnosed in the advanced stage and are associated with deeper cancer depth, higher incidence of lymph node metastasis, lymphatic and venous permeation, and peritoneal dissemination[1,2].

Gastric mucinous carcinoma represents approximately 3% of all gastric cancers. Most gastric carcinomas are detected by endoscopy combined with biopsy. However, it is often difficult to diagnose mucinous carcinoma by biopsy because most mucinous gastric carcinomas are located predominantly in the submucosa and the frequency of mucosal involvement is somewhat low. Therefore, an accurate preoperative diagnosis of mucinous carcinomas in the gastrointestinal tract by CT or MR is important. The most common CT appearance for a gastric mucinous carcinoma is a diffuse wall thickening greater than 1 cm with preserved layering enhancement (Figure 13). A thickened hypoattenuating middle or outer layer corresponds to abundant mucin pools located in the submucosa or deeper layers, and the thin enhancing inner layer corresponds to the overlying normal mucosal layer with or without the exception of focal cancer infiltration. Miliary and punctate calcifications within the mucin pool are present and are thought to be diagnostic for mucinous adenocarcinoma[40].

Colorectal mucinous carcinoma varies from 5% to 15%

Figure 14 Mucinous adenocarcinoma of the cecum in a 69-year-old man. Contrast-enhanced CT image shows a huge eccentric hypoattenuating mass with poor enhancement of the solid portion of the cecum (asterisk). The mass has invaded the retroperitoneum (arrow). CT: Computed tomography.

of all colorectal carcinomas. Mucinous carcinoma most frequently occurs in the rectosigmoid or ascending colon. CT features indicating mucinous-type colorectal cancer include marked eccentric bowel wall thickening greater than 2 cm, heterogeneous contrast enhancement of the tumor with poor enhancement of the solid portion, a large area of hypoattenuation, and intramural calcification (Figure 14). On MR imaging, a colorectal mucinous carcinoma appears with very high signal intensity on T2-weighted images as a manifestation of the presence of extracellular mucin (Figure 15). Intratumoral congestion, abscess, necrosis and mural edema or entrapped fluids also appear with high signal intensity on T2-weighted images. A mucin tumor can be distinguished from a mimic because the tumor mucin pool may be enhanced, whereas others are not enhanced[41,42]. The enhancement pattern can be a peripheral, heterogeneous, or lacelike enhancement, corresponding to the enhancing mesh-like internal structure formed by the cells, cord, and vessels that line the pools of extracellular mucin[42].

Perianal mucinous adenocarcinoma: A perianal mucinous adenocarcinoma is a rare clinical condition that represents approximately 3% to 11% of all perianal carcinomas. Although their etiology is debatable, mucinous adenocarcinomas may originate from chronic anal fistulas, abscesses, anal glands, or intestinal duplications. This carcinoma is usually diagnosed at an advanced stage and the overall prognosis is poor[43]. CT findings suggesting a perianal mucinous adenocarcinoma include a multilocular cystic mass with peripheral calcification around the anus. It is well established that MR imaging plays an important role when evaluating a perianal mucinous carcinoma-associated fistula in ano. MR features indicating a perianal mucinous adenocarcinoma include masses filled with markedly hyperintense content on T2-weighted images, enhancing solid components, mesh-like internal enhancement, a fistula between the mass and the anus, contrast enhancement of peripheral structures or peritumoral areas, and regional areas of lymph node enlargement. A sol-

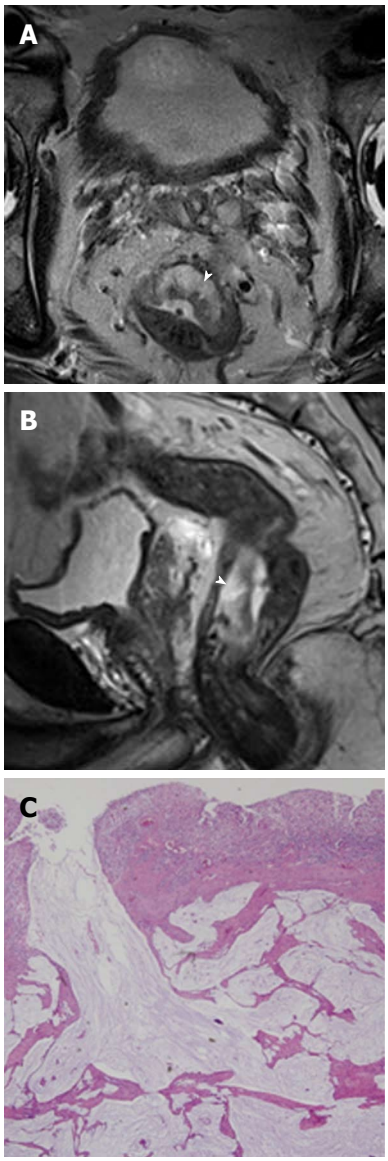

Figure 15 Mucinous adenocarcinoma of the rectum in a 63-year-old man. A, B: Axial (A) and coronal (B) T2-weighted MR images show an area of hyperintense mucin pools (arrowhead) in the rectal mass; C: Photomicrograph image (original magnification, × 40; HE stain) shows large pools of extracellular mucin and tumor cells. MR: Magnetic resonance; HE: Hematoxylin and eosin.

Figure 16 Perianal mucinous adenocarcinoma in a 41-year-old man. A: Sagittal T2-weighted MR image shows a hyperintense mass (arrowheads) in the perianal area; B: Sagittal contrast-enhanced T1-weighted MR image shows mesh-like internal enhancement (arrowheads) within the mass; C: Photomicrograph image (original magnification, × 100; HE stain) shows large pools of extracellular mucin and tumor cells. MR: Magnetic resonance; HE: Hematoxylin and eosin.

id enhancing component and mesh-like enhancement can be a clue to distinguish mucinous adenocarcinomas from abscesses associated with a fistula in ano (Figure 16)[43].

Urachal mucinous carcinoma: Urachal carcinoma is a rare neoplasm arising from the urachal remnant. Although a normal urachus is commonly lined by transitional epithelium, most urachal cancer is adenocarcinoma (90%), which is caused by metaplasia of the urachal mucosa into columnar epithelium followed by a malignant transformation. Approximately 70% of urachal carcinomas are mucinous adenocarcinomas which contain variable amounts of extracellular mucin. Although the prognosis for urachal carcinoma is slightly better than that of nonurachal adenocarcinoma, its prognosis is generally poor because this tumor arises in a clinically silent anatomical location and is generally discovered only after local invasion or metastatic disease. A characteristic CT feature of urachal carcinoma is a midline supravesical solid and partly cystic mass due to mucin produced by the tumors (Figure 17). Psammomatous calcification may occur in 50%-70% of cases. Extension of a urachal carcinoma along the Retzius space helps distinguish it from other vesical carcinomas. T2-weighted images are helpful for detecting the area of the mucin pool within the tumor[44].

Adenoma malignum: Adenoma malignum, also known as a minimal deviation adenocarcinoma, is a rare subtype of

Figure 17 Intraperitoneal spread of mucinous adenocarcinoma of the urachus (also called peritoneal mucinous carcinomatosis) in a 57-year-old man. A: Contrast-enhanced CT image shows a midline supravesical mass with heterogeneous attenuation. Within the mass are scattered low-attenuation areas (arrowheads), which represent mucin; B: Contrast-enhanced CT image of the upper abdomen shows low-attenuation mucinous ascites scalloping the liver margin. Note the right pleural effusion (asterisk) and diffuse nodular thickening of the peritoneum (arrowheads). CT: Computed tomography; MR: Magnetic resonance.

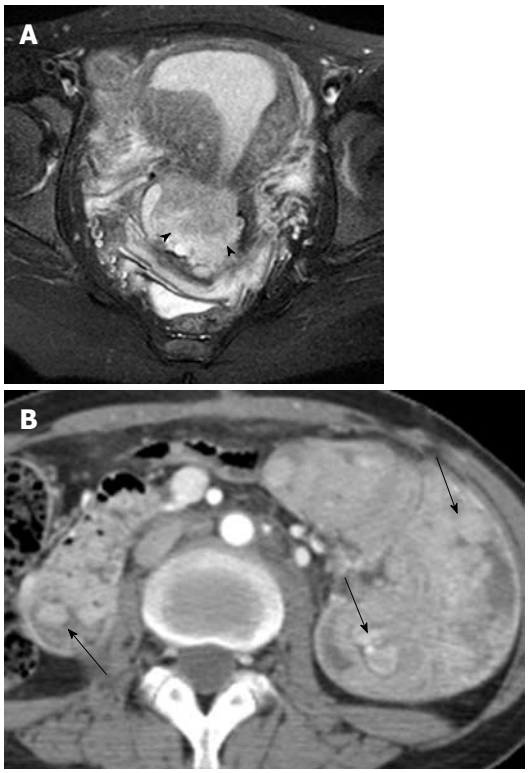

Figure 18 Adenoma malignum of the cervix in a 30-year-old woman with Peutz-Jeghers syndrome. A: Axial T2-weighted MR image shows a multicystic lesion with a solid component (arrowheads) in the uterine cervix; B: Contrast-enhanced CT image shows multiple polyps (arrows) in the duodenum and small bowel causing intussusceptions. CT: Computed tomography; MR: Magnetic resonance.

mucinous adenocarcinoma, representing about 3% of all cervical adenocarcinomas. Adenoma malignum is often associated with Peutz-Jeghers syndrome and mucinous tumors of the ovary. Despite the presence of well-differentiated histopathological features, the prognosis is unfavorable because of early dissemination into the peritoneal cavity and early distant metastasis[45].

On MR imaging, adenoma malignum is characterized by a multicystic lesion, demonstrating very high signal intensity on T2-weighted images, with some solid enhancing components in the deep cervical stroma (Figure 18). However, these MR findings are often confused with those of some other pseudoneoplastic lesions such as deep nabothian cysts, florid endocervical hyperplasia, or papillary endocervicitis, because some portions of these pseudoneoplastic cervical lesions are thickened or accompanied by solid components with enhancement, reflecting the inflammatory process in the cervix stroma or congestion of the small vessels[45].

Mucinous carcinoma of the gallbladder: Mucinous carcinoma of the gallbladder has a massive mucus pool within the carcinoma tissue, tends to growth invasively, and is associated with a poor prognosis. A mucinous carcinoma appears as a focal multilocular hypodense lesion with rim-like enhancement on contrast-enhanced CT. A hyperechoic mass on US and a near-water density on non-enhanced CT pathologically reflect a tumor containing a massive mucin pool with fibrous septa (Figure 19). Calcification within the tumor is often seen. Movable spotty and hyperechoic debris on US or movable filling defects on cholangiography inside the gallbladder lumen or biliary tree, which reflect hypersecretion of mucin, are helpful for diagnosing a mucin-producing carcinoma of the gallbladder. Dilatation of the cystic duct, intrahepatic ducts, or common bile duct is sometimes seen[36].

Mucinous type of cholangiocarcinoma: Mucinous carcinoma is the rarest histological type of cholangiocarcinoma. Mucinous carcinoma appears as an extremely hypodense mass with marginal or septal enhancement on contrast-enhanced CT, and as an extremely hypointense and hyperintense mass on T1- and T2-weighted images, respectively. Its radiological characteristics reflect large mucinous lakes throughout the tumor without mucin excretion into the bile duct[46].

PSEUDOMYXOMA PERITONEI

PMP is an uncommon clinical condition characterized by

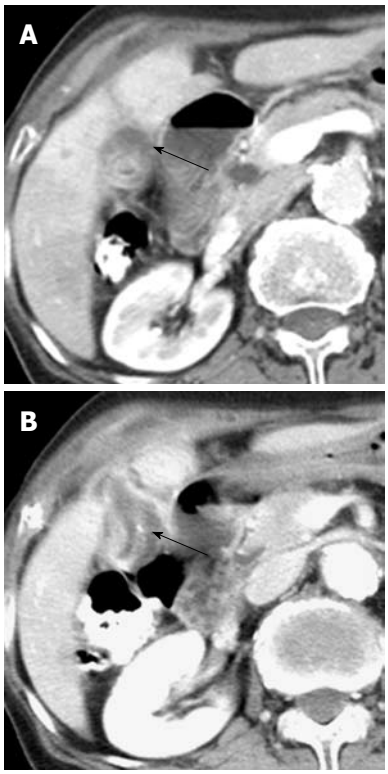

Figure 19 Mucinous carcinoma of the gallbladder in a 77-year-old woman. A: Contrast-enhanced CT image shows localized wall thickening (arrow) in the body of the gallbladder containing a suspicious mucin pool; B: Contrast-enhanced CT image inferior to (A) shows a punctate calcification and localized wall thickening (arrow) in a mildly distended gallbladder. CT: Computed tomography.

accumulation of copious gelatinous materials throughout the peritoneal cavity. It is found in one of 5000 laparotomies, and occurs more commonly in women than men. PMP occurs when mucin-producing lesions rupture into the peritoneal cavity. PMP due to rupture of an appendiceal mucocele is the most common. Mucinous tumors arising from the ovary, gastrointestinal tract, pancreas, and urachus may also cause PMP. However, its origin may not be clear due to extensive organ involvement. Coexistence of mucinous tumors of the appendix and ovary are frequently observed in most women with PMP (Figure 4). Although relationship of PMP to other tumors continues to be controversial, ovarian tumors may represent a secondary deposit from appendiceal tumors[47]. Although most pseudomyxomas are in the peritoneal cavity, they may occur in the retroperitoneum. Pseudomyxoma retroperitonei is caused by rupture of a retrocecal appendiceal mucocele into the retroperitoneal space and fixation of the lesion to the posterior abdominal wall[48].

PMP may be classified into three clinicopathological categories: disseminated peritoneal adenomucinosis (DPAM), peritoneal mucinous carcinomatosis (PMCA), and PMCA with features intermediate between DPAM and PMCA or with discordant features. DPAM is characterized by peritoneal lesions composed of abundant extracellular mucin containing scant mucinous epithelium with little cytologic atypia or mitotic activity, whereas PMCA is characterized by peritoneal lesions composed of more abundant mucinous epithelium with the architectural and cytologic features of carcinoma. Because DPAM is histologically benign, its prognosis is better than that of PMCA[49].

On CT, PMP appears as ascites with attenuation slightly higher than water. It initially accumulates at sites of relative stasis such as the pouch of Douglas/rectovesical pouch, the right and left subphrenic space, or the surface of the liver and spleen. Septa, curvilinear or amorphous calcification, areas of soft tissue attenuation due to solid elements within mucinous material, or compressed mesentery are seen more commonly within PMP as the volume of disease increases. Scalloping of the visceral surface, particularly the liver, is the diagnostic feature that distinguishes mucinous from simple ascites (Figures 4, 8 and 17). Although CT findings of DPAM and PMCA overlap considerably, PMCA tends to be more frequently accompanied by coexistent pleural masses or effusion, lymphadenopathy, and diffuse peritoneal infiltration such as omental cakes (Figure 17)[49].

CONCLUSION

Various mucin-producing neoplasms originate in different abdominal and pelvic organs. Distinguishing mucinous from non-mucinous tumors is important because of the differences in clinical outcome. Imaging modalities play a critical role in differentiating these two entities. Due to high water content, mucin has a similar appearance to water on both CT and MR imaging, except when thick and proteinaceous, and then it tends to be hyperdense compared to water and hyperintense on T1- and hypointense on T2-weighted images. A correct diagnosis of mucin-producing neoplasms is possible when these imaging features are identified on cross-sectional imaging. Because imaging features of mucin can have a similar appearance to water in both CT and MR imaging, the differentiation of mucinous from non-mucinous neoplastic conditions *via* only imaging features of mucin is sometimes problematic. In addition, further studies with appropriate quantitative and statistical analyses are required to confirm whether these imaging findings can be helpful in the correct diagnosis of mucin-producing neoplasms. However, the imaging appearance of mucin-producing neoplasms differs somewhat depending on the organ of origin; additional information about the distinctive imaging features of mucin-producing neoplasms according to tumor location may also facilitate accurate diagnosis and treatment.

Abstract

AIM: To examine the activation of the Nalp3 inflammasome and its downstream targets following lipopolysaccharide (LPS)-induced stimulation in the liver.

METHODS: Six-to-eight-week-old C57BL/6 chow fed mice were injected intraperitoneally with 0.5 μg/g bodyweight LPS and sacrificed 2, 4, 6, 18 or 24 h later. LPS-induced liver damage was confirmed by a biochemical assay to detect alanine aminotransferase (ALT) levels. To determine if LPS stimulation in the liver led to activation of the inflammasome, real-time quantitative polymerase chain reaction was used to evaluate the mRNA expression of components of the Nalp3 inflammasome. Enzyme-linked immunosorbent assays were used to determine the protein expression levels of several downstream targets of the Nalp3 inflammasome, including caspase-1 and two cytokine targets of caspase-1, interleukin (IL)-1β and IL-18.

RESULTS: We found that LPS injection resulted in liver damage as indicated by elevated ALT levels. This was associated with a significant increase in both mRNA and protein levels of the proinflammatory cytokine tumor necrosis factor (TNF)-α in the liver, as well as increased levels of TNFs in serum. We showed that LPS stimulation led to upregulation of mRNA levels in the liver for all the receptor components of the inflammasome, including Nalp3, Nalp1, pannexin-1 and the adaptor molecule apoptosis-associated speck-like, caspase recruitment domain-domain containing protein. We also found increased levels of mRNA and protein for caspase-1, a downstream target of the inflammasome. In addition, LPS challenge led to increased levels of both mRNA and protein in the liver for two cytokine targets of caspase-1, IL-1β and IL-18. Interestingly, substantial baseline expression of pre-IL-1β and pre-IL-18 was found in the liver. Inflammasome and caspase-1 activation was indicated by the significant increase in the active forms of IL-1β and IL-18 after LPS stimulation.

CONCLUSION: Our results show that the Nalp3 inflammasome is upregulated and activated in the liver in response to LPS stimulation.

INTRODUCTION

The endotoxin lipopolysaccharide (LPS), a component of Gram-negative bacteria, plays an important role in

acute liver injury as well as chronic liver diseases including fatty liver associated with either alcohol consumption or metabolic syndrome and obesity[1,2]. LPS has also been implicated in insulin resistance as well as in steatohepatitis in non-alcoholic fatty liver disease[3-5]. Increasing evidence suggests that gut-derived LPS through the gut-liver axis affects the extent of liver damage in many different types of inflammatory liver diseases[6]. LPS is a prototypical ligand for the pattern recognition receptor (PRR), Toll-like receptor 4 (TLR4). TLR4 induces downstream signaling *via* the MyD88 adapter molecule and induces production of proinflammatory cytokines through activation of the regulatory factor nuclear factor (NF)-κB[6]. In the liver, TLR4 is expressed in both parenchymal and immune cells, thereby providing potential for LPS-induced activation[7].

Studies have shown that the Nalp3 inflammasome is activated by both pattern associated molecular patterns (PAMPs), including LPS and bacterial RNA, and danger-associated molecular patterns (DAMPs)[8,9]. The Nalp3 inflammasome is a caspase-1 activating multiprotein complex, which has been implicated in numerous inflammatory processes and human diseases including gout, pseudogout, contact hypersensitivity, and most recently Alzheimer's disease[10,11]. Furthermore, mutations in the *Nalp3* gene that lead to gain-of-function mutations, result in several hereditary syndromes including: Muckle-Wells syndrome, familial cold autoinflammatory syndrome, and chronic infantile neurological cutaneous and articular syndrome[12].

In response to stimulation by either DAMPs or PAMPs, Nalp3 interacts with pro-caspase-1 through the adaptor molecule [apoptosis-associated speck-like, caspase recruitment domain (CARD)-domain containing protein (ASC)] to form the inflammasome, which leads to activation of caspase-1. Active caspase-1, previously known as interleukin (IL)-1β converting enzyme, a heterodimer of p20 and p10 subunits, is the central effector protein of the inflammasome complex and promotes the cleavage of pro-IL-1β, pro-IL-18 and pro-IL-33 to their biologically active, mature forms[13]. In addition, active caspase-1 has been shown to cleave other substances, such as caspase-7 and sterol regulatory element-binding proteins, therefore playing a pivotal role in cell death and survival[14].

The mRNA levels of the components the Nalp3 inflammasome are expressed in the eye, heart and lung in response to LPS stimulation[15]. Although mRNA levels of IL-1β have also been shown to increase in the liver in response to LPS stimulation, the role of the Nalp3 inflammasome in the liver in response to LPS stimulation has not been determined[16]. In the liver, the Nalp3 inflammasome is upregulated upon acetaminophen-induced toxicity[17] and the contribution of Nalp3 has been described in *Propionibacterium acnes* and LPS-induced acute liver injury[18]; however, a role for Nalp3 in other liver conditions has not been identified.

Although the role of the proinflammatory cytokine, tumor necrosis factor (TNF)α, has been extensively studied in both alcoholic and non-alcoholic fatty liver disease, the role of IL-1β and the inflammasome has yet to be explored. LPS plays an important role in liver disease; elevated LPS levels are detected in the portal and systemic blood of patients with alcoholic and non-alcoholic fatty liver disease[19,20]. Furthermore, there is increased sensitivity to LPS in both alcoholic liver disease and fatty liver disease[21]. Here, we examined if LPS induce the Nalp3 inflammasome in the liver. In this study, we showed that LPS stimulation led to induction of the components of the Nalp3 inflammasome at both the mRNA and protein level in the liver and this is associated with increased IL-1β production.

MATERIALS AND METHODS

Mice

Six-to-eight-week-old wild-type C57BL/6 chow fed mice received intraperitoneal injections of 0.5 μg/g LPS in PBS (Sigma, St Louis, MO, United States) (three mice per group) for 2, 4, 6, 18 and 24 h. Serum was separated from whole blood and stored at -80 ℃. Liver samples were snap frozen in liquid nitrogen or stored in RNAlater (Qiagen Sciences, Germantown, MD, United States) for RNA extraction. All animals received proper care in agreement with animal protocols at the University of Massachusetts Medical School Institutional Animal Use and Care Committee.

Biochemical alanine aminotransferase assay

Serum alanine aminotransferase (ALT) was determined using a kinetic method (DTEK LLC, Bensalem, PA, United States).

RNA analysis

RNA was purified from livers using the RNeasy kit (Qiagen Sciences) and on-column DNA digestion. cDNA was transcribed with the Reverse Transcription System (Promega, Madison, WI, United States). Real-time quantitative polymerase chain reaction (qPCR) was performed using iCycler (Bio-Rad Laboratories, Hercules, CA, United States) as described previously[22]. Primer sequences are shown in Table 1.

Cytokine enzyme-linked immunosorbent assay measurements

Whole cell lysates were extracted from liver tissue as previously described[22]. These lysates were assayed for mature IL-1β (R and D Systems, Minneapolis, MN, United States), TNF-α, total IL-18, and total IL-1β (BD Biosciences, United States). Serum was also assayed for mature IL-1β (R and D Systems).

Statistical analysis

Statistical significance was determined using Student's *t*

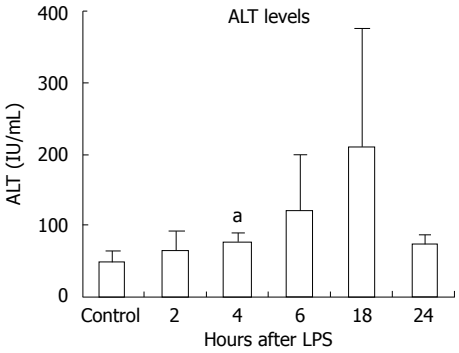

Figure 1 Lipopolysaccharide stimulation results in liver damage. C57BL/6 wild-type chow-fed mice (three per group) were injected intraperitoneally with lipopolysaccharide (LPS) for 2, 4, 6, 18 or 24 h. Serum was separated from whole blood and analyzed for alanine aminotransferase (ALT), which was significantly increased after 4 h of LPS stimulation. Mean ± SD are shown. $^{a}P < 0.01$.

test (two-tailed distribution). Data are presented as mean ± SE and were considered significant at $P < 0.05$. ALT statistical significance was determined using the non-parametric Kruskal-Wallis test followed by the Mann-Whitney test.

RESULTS

LPS induces liver injury and inflammatory cytokines

Gut-derived LPS plays a role in several inflammatory liver diseases[6]. To evaluate the effects of LPS on the liver, we injected wild-type mice with LPS for 2, 4, 6, 18 or 24 h and monitored ALT levels to evaluate liver injury. We found increased ALT levels in sera from mice injected with LPS at the 4-18-h time points, reaching statistically significant levels at 4 h, indicating LPS-induced liver damage (Figure 1).

It has been shown that LPS-induced signaling through TLR4 results in production of proinflammatory cytokines, one of which, TNF-α, has been linked to liver damage[23,24]. We identified significant elevation in liver TNF-α mRNA expression at all time points after LPS stimulation compared to the unstimulated controls (Figure 2A). TNF-α protein levels were undetectable in liver tissue from unstimulated controls but were significantly increased at all time points after LPS stimulation with a maximal increase at 2 h (Figure 2B).

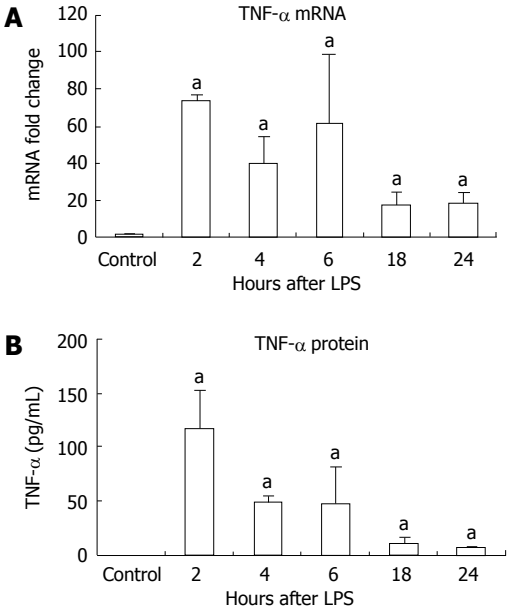

Figure 2 Inflammation in the liver is seen after lipopolysaccharide stimulation. A: Tumor necrosis factor (TNF)-α mRNA in liver tissue was significantly increased at all time points after lipopolysaccharide (LPS) stimulation. TNF-α mRNA was analyzed by real-time quantitative polymerase chain reaction and normalized to 18S. The values are shown as a fold change to the non-stimulated LPS control; B: Similarly, TNF-α protein was significantly elevated in liver tissue following LPS stimulation as detected by enzyme-linked immunosorbent assay. Protein levels were normalized to total protein concentration in each tissue sample. Mean ± SD are shown. $n = 3$ for each group (except at 4 h LPS stimulation, where $n = 2$ due to an outlier), $^{a}P < 0.01$.

LPS upregulates mRNA expression of Nalp3 inflammasome components

For complete function, the inflammasome requires expression of its various components including Nalp3, ASC (the adapter molecule), and caspase-1[8,10]. We investigated the mRNA levels of the different types of inflammasomes, including the Nalp1 and Nlrc4 inflammasomes. Our examination revealed a significant increase in liver mRNA of *Nalp3* after ≥ 4 h LPS stimulation, with a peak at 6 h (Figure 3A). Upregulation of the inflammasome was not limited to *Nalp3*, and there was a significant increase in *Nalp1* (sevenfold) and *Nlrc4* (3.5-fold) mRNA at 24 h compared to the unstimulated controls ($P < 0.01$, $P = 0.04$, respectively, data not shown). We also analyzed the mRNA of other components of the inflammasome including the pyrin and CARD-domain-containing adaptor ASC; caspase-1, an inflammatory caspase; and pannexin-1, a hemi-channel that is recruited upon activation of the P2X7 receptor and is a necessary component for inflammasome activation[25]. The mRNA levels of *ASC* gradually increased at each time point after LPS stimulation (Figure 3B), whereas caspase-1 levels peaked at 6 h and pannexin-1 mRNA levels peaked at 6 h (Figure 3C and D).

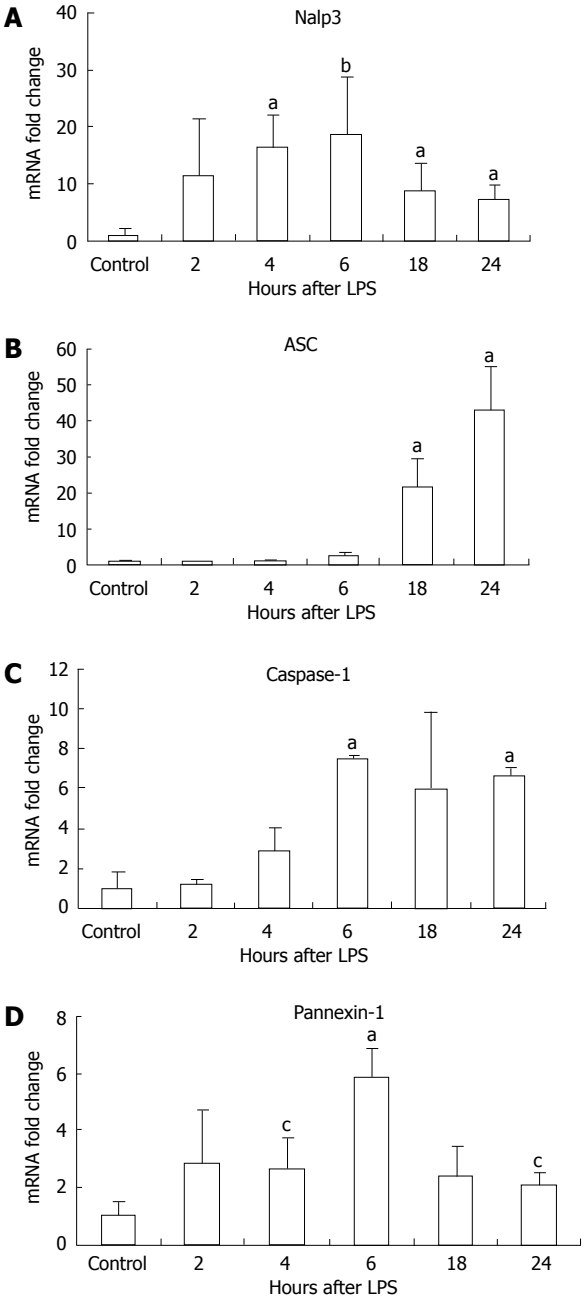

Figure 3 Lipopolysaccharide stimulation increased Nalp3 inflammasome mRNA expression in liver tissue. Liver RNA analysis of Nalp3 (A), apoptosis-associated speck-like, caspase recruitment domain-domain containing protein (ASC) (B), caspase-1 (C) and pannexin-1 (D) were analyzed by real-time quantitative polymerase chain reaction. The values were normalized to 18S and are shown as a fold increase to the non-lipopolysaccharide (LPS) stimulated control. Mean ± SD are shown. $n = 3$ per group, $^{a}P < 0.01$, $^{b}P < 0.03$, $^{c}P < 0.05$.

Activation of the inflammasome results in increased levels of total IL-18, total IL-1β, and mature IL-1β

LPS stimulation has been shown to increase levels of pro-IL-1β transcripts[26]. However, production of the biologically active *IL-1β* and IL-18 requires the mature caspase-1 to cleave the precursor forms into their mature forms[27]. First, we evaluated mRNA levels of *IL-1β* and *IL-18* and found that *IL-1β* mRNA levels were significantly increased at all time points post-LPS stimulation

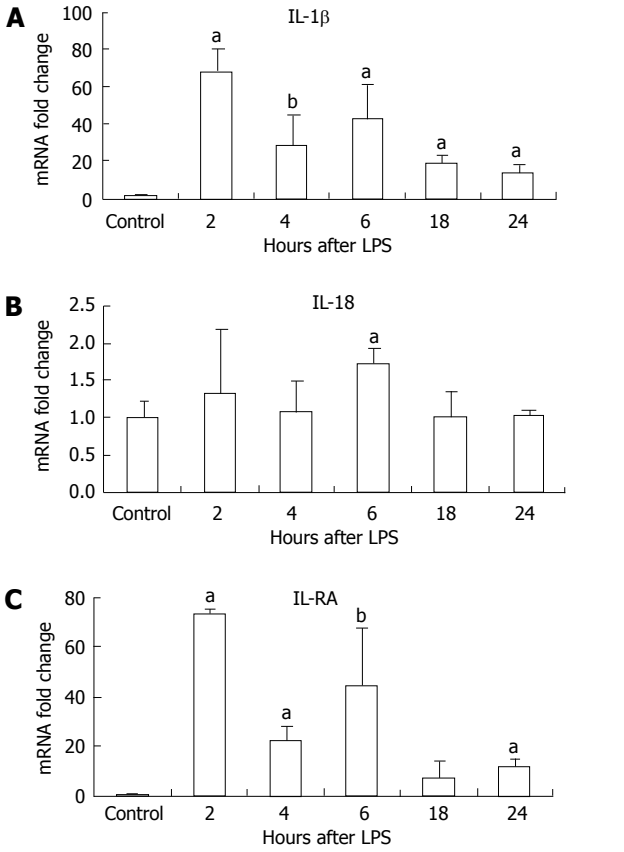

Figure 4 Lipopolysaccharide stimulation increased interleukin (IL)-1β and IL-18 mRNA, and IL-1RA transcription in the liver. Liver mRNA levels of IL-1β (A), IL-18 (B) and IL-1RA (C) were analyzed by real-time quantitative polymerase chain reaction and normalized to 18S. Mean ± SD are shown. $n = 3$ per group [except at 2 h lipopolysaccharide (LPS) stimulation, where $n = 2$ due to outlier], $^{a}P < 0.01$, $^{b}P < 0.03$.

peaking at 2 h (Figure 4A). Induction of *IL-18* mRNA by LPS was modest but reached statistical significance at the 6-h time point (Figure 4B). There was also induction of the mRNA for the IL-1 receptor antagonist after LPS stimulation in the liver (Figure 4C).

We sought to determine whether the increase in mRNA correlated with increased protein production for IL-1β and IL-18. We found basal expression of pro-IL-1β protein in the livers of unstimulated control mice and this was significantly upregulated at 2 h after LPS stimulation (Figure 5A). More importantly, we observed a significant increase in mature IL-1β protein in liver tissue at all time points post-LPS stimulation compared to the controls, in which no mature IL-1β was detected (Figure 5B). Consistent with inflammasome activation, we found increased serum IL-1β levels in mice after stimulation with LPS for 2 and 6 h (Figure 5C). Investigation of IL-18, which is also cleaved by caspase-1, revealed a significant increase in total IL-18 in the liver at all time points following LPS injection (Figure 5D).

DISCUSSION

Although many molecules and compounds activate the

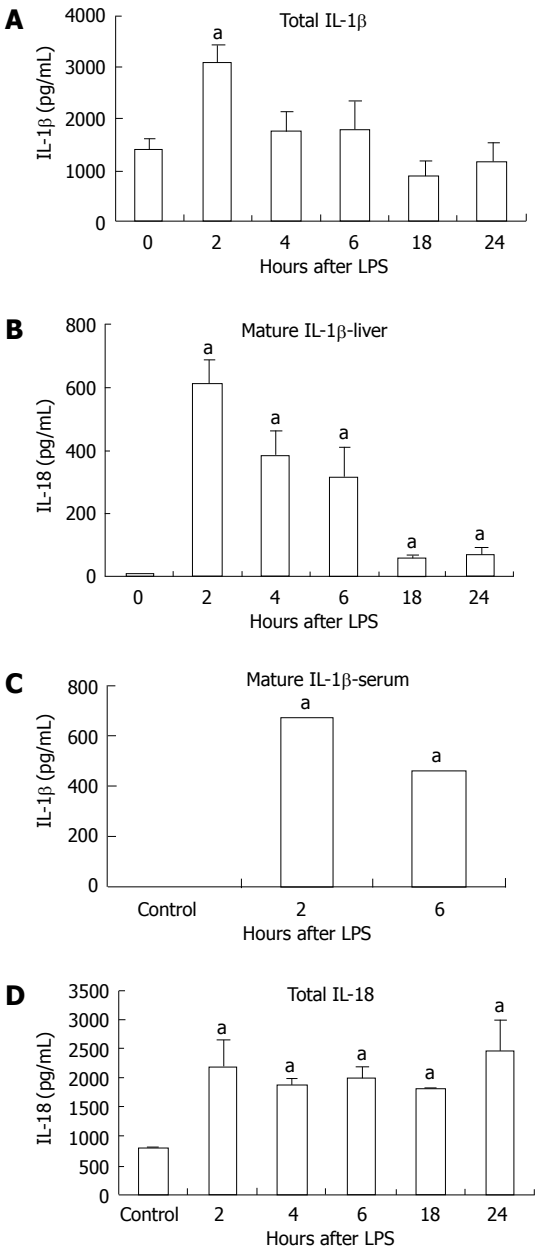

Figure 5 Lipopolysaccharide increased interleukin-1β and interleukin-18 protein. Protein level was detected in liver tissue by enzyme-linked immunosorbent assay for total-interleukin (IL)-1β (pro-IL-1β and cleaved IL-1β) (A), cleaved IL-1β in the liver tissue (B),cleaved IL-1β in the serum (C) and total IL-18 (pro-IL-18 and cleaved IL-18) (D) in liver tissue. The values shown are the fold change compared to non-Lipopolysaccharide (LPS) stimulated control. Protein levels were normalized to total protein concentrations in each tissue sample. Mean ± SD are shown. $n = 3$ per group (except at 2 h LPS stimulation, where $n = 2$ due to an outlier), $^{a}P < 0.01$.

Nalp3 inflammasome both *in vitro* and *in vivo*[8], the role of Nalp3 inflammasome in a healthy liver following LPS stimulation has not been determined. Our novel findings demonstrate upregulation of the Nalp3 inflammasome in the liver in response to LPS stimulation, both at the mRNA and protein levels. We also show for the first time that the components of the inflammasome pathway, including ASC and caspase-1, are upregulated in the liver after LPS challenge and this results in functional activation of the inflammasome and caspase-1, indicated by IL-1β and IL-18 secretion.

LPS is recognized by TLR4, which induces an intracellular signaling cascade leading to activation of NF-κB, as well as the production of pro-IL-1β and pro-IL-18[28]. Previous studies have suggested that signaling through the TLRs alone is insufficient to generate the production of mature IL-1β and IL-18, and that a second signal is needed that leads to ionic perturbation[29]. These perturbations may include ATP signaling through the P2X7 channel, leading to changes in intracellular potassium concentrations and membrane perturbations. The physiological importance of ATP in IL-1β secretion is unclear and the second signal that leads to cleavage of pro-IL-1β in the liver is still under investigation[30]. *In vitro* studies have shown that a second signal is needed in addition to LPS to obtain cleavage of pro-IL-1β[31]. It is possible that a DAMP released by injured cells could act as the second signal. *In vivo* studies, however, have shown that LPS alone is sufficient to increase cleavage of IL-1β and IL-18[31]. Our novel data demonstrate that, after *in vivo* LPS challenge, the inflammasome is activated in the liver and this results in increased inflammasome function and IL-1β secretion. We found that LPS stimulation not only increased *IL-1β* mRNA levels and the expression of pro-IL-1β protein, but it significantly increased the levels of the 18-kDa form of mature IL-1β in the liver. Secretion of mature IL-1β also resulted in elevated IL-1β in the serum. Interestingly, we found significant levels of pro-IL-1β protein expressed in the liver without exogenous stimulation. This suggests that the exogenous LPS probably provided the second signal for IL-1β production. The mechanisms for the presence of pro-IL-1β protein in the liver remain to be determined, however, one possibility is stimulation *via* PAMPs, such as LPS, which are being constantly supplied by the gut through the portal vein to the liver[6].

Cleavage of pro-IL-1β is mediated by activated caspase-1; consistent with this, we found increased levels of IL-1β protein in the serum after LPS challenge. The other target of the caspase-1 complex and inflammasome activation is IL-18. Consistent with LPS-induced inflammasome and caspase-1 activation, we found an increase in IL-18 mRNA and total IL-18 levels in the liver. Due to limitations of the detection assay, we could not distinguish between the mature form of IL-18 and pro-IL-18, but the increase in total IL-18 after LPS stimulation was most likely due to an increase in both.

We found elevated basal levels of pro-IL-1β in the liver, and pro-IL-1β was further increased by LPS with the highest levels at 2 h following stimulation. It is likely that LPS-induced inflammasome activation can cleave the pre-existing pro-IL-1β to the mature form by caspase-1. In addition to activation of the Nalp3 inflammasome, our data suggests that other types of caspase-1-activating inflammasomes, Nalp1 and Nlrc4, may also play a role in caspase-1 activation and subsequent IL-1β cleavage in the liver. Our data showed that both *Nalp1* and *Nlrc4* mRNA

levels were upregulated in the liver following LPS stimulation. This suggests that other inflammasome-activating signals lead to full activation in the liver.

The contribution of the Nalp3 inflammasome to inflammation in the liver in response to LPS stimulation may have implications for several different liver diseases. Increased gut-derived LPS has been shown to contribute to liver inflammation in alcoholic and non-alcoholic fatty liver diseases, as well as other forms of liver damage such as hepatitis C virus infection[32]. In healthy subjects, the liver plays a central role in elimination of gut-derived endotoxins and other pathogens to maintain immune homeostasis[33]. Thus, it is tempting to speculate that gut-derived ligands of TLRs constantly entering the liver could contribute to the high basal expression of pro-IL-1β found in the liver in our experiments. The high basal expression of pro-IL-1β represents the first step of inflammasome activation, and this appears to provide a pre-activated state where even single LPS stimulation can result in inflammasome activation, as seen in the liver after *in vivo* LPS challenge in our experiments. The specific role of Nalp3 and the inflammasome remains to be evaluated in different types of liver diseases where inflammation is related to LPS and other pathogen-derived or endogenous danger signals.

COMMENTS

Background

The endotoxin lipopolysaccharide (LPS) is a component of Gram-negative bacteria, and plays an important role in both acute liver injury as well as chronic liver diseases, including fatty liver associated with either alcohol consumption or metabolic syndrome and obesity. Several pathogen-associated molecular patterns, including LPS, induce inflammasome activation, an intracellular multiprotein complex leading to release of inflammatory cytokines and cell death.

Research frontiers

Inflammasomes are required for effective clearance of several viral and bacterial pathogens. In addition, inflammasomes have been reported to play a major role in several diseases with sterile inflammation such as gout, Alzheimer's disease, atherosclerosis and type 2 diabetes. Here, the authors show the contribution of the Nalp3 inflammasome to LPS-induced inflammation in the liver.

Innovations and breakthroughs

Recently, the contribution of the Nalp3 inflammasome to *Propionibacterium acnes* plus LPS-induced acute liver injury has been described. Here, authors show the increased expression and role of the inflammasome in healthy liver following LPS stimulation.

Applications

The contribution of the Nalp3 inflammasome to inflammation in the liver in response to LPS stimulation may have implications for several liver diseases, including alcoholic and non-alcoholic fatty liver disease, as well as hepatitis C virus infection where the role of gut-derived endotoxin has been shown previously. A better understanding of the pathological mechanism may help future attempts to develop effective therapy.

Terminology

Nalp3, also called cryporin is a nucleotide oligomerization domain-like receptor that forms one of the most characterized inflammasome complexes.

Peer review

This is a well done study that examines the role of the inflammasome in the liver following LPS exposure.

Abstract

AIM: To investigate the utility of Beclin-1 and LC3, two autophagy-related proteins, in predicting the cetuximab efficacy in advanced colorectal cancer (ACRC).

METHODS: The data of 85 patients with ACRC treated at the Sun Yat-sen University Cancer Center from March 1, 2005 to December 31, 2008 were studied, including 45 cases treated with cetuximab-containing chemotherapy and 40 cases treated with non-cetuximab-containing chemotherapy. Beclin-1 and LC3 expression was evaluated by immunohistochemistry, and KRAS status was evaluated by polymerase chain reaction.

RESULTS: Beclin-1 and LC3 expression in ACRC was significantly correlated (r = 0.44, P < 0.01); however, LC3 was more highly expressed in cancerous tissues than in normal tissues (Z = -2.63, P < 0.01). In the cetuximab-containing chemotherapy group, patients with low LC3 expression had higher objective response rates (ORRs) than those with high LC3 expression (52.9% *vs* 17.9%, P = 0.01), and patients with low Beclin-1 expression had a longer median progression-free survival (PFS) than their counterparts with higher Beclin-1 expression (9.0 mo *vs* 3.0 mo, P = 0.01). However, neither of these predictive relationships was detected in the group treated with non-cetuximab-containing chemotherapy. Patients with wild-type KRAS had higher ORRs (42.3% *vs* 9.1%, P = 0.049) and disease control rates (DCRs) (73.1% *vs* 36.4%, P = 0.035), and longer median PFS (5.5 mo *vs* 2.5 mo, P = 0.02) than those with mutant KRAS in the cetuximab-containing chemotherapy group. Neither Beclin-1 (P = 0.52) nor LC3 (P = 0.32) expression was significantly correlated with KRAS status.

CONCLUSION: Patients with low Beclin-1 expression had a longer PFS than those with high Beclin-1 expression, and patients with low LC3 expression had a higher ORR in ACRC patients treated with cetuximab-containing chemotherapy.

Key words: Beclin-1; Cetuximab; Colorectal neoplasms; Drug therapy; LC3

INTRODUCTION

Colorectal cancer (CRC) is one of the most common cancers worldwide. Although therapeutic strategies have improved in recent years, the fact that 25% of patients present with advanced colorectal cancer (ACRC) at diagnosis and an additional 25% eventually progress to this stage makes it especially challenging to treat. Both the Irinotecan-based[1] and Oxaliplatin-based regimens[2] have achieved a median overall survival of 20 mo in these patients; however, further improvement has been difficult due to their serious adverse cytotoxic events. The introduction of cetuximab, a monoclonal antibody targeting epidermal growth factor receptor (EGFR), to standard chemotherapy has increased the median overall survival to 24 mo in the patients with chemotherapy-naïve or refractory ACRC[3,4]. Beneficial effects were also observed in Chinese patients with ACRC[5,6]. Although wild-type KRAS is the precondition recommended by national comprehensive cancer network (NCCN) guidelines for the administration of cetuximab to patients with ACRC, at least half of the patients[7,8] with wild-type KRAS do not benefit from this drug. Thus, it is vital to identify new predictive markers for cetuximab efficacy.

Autophagy is a catabolic process involving the degradation of a cell's own unnecessary, injured, or aged proteins and organelles and the subsequent recycling of degraded products to maintain survival. However, excessive autophagy leads to cell death, characterized by the presence of autophagic vacuoles[9]. In addition to the physiological role of autophagy, this process is also involved in many pathological conditions, including myopathy, neuronal degeneration, infectious disease, and cancer[10]. Since autophagy was first observed in yeast, more than 20 autophagy-related genes (*Atg*) have been identified[11], many of which are conserved in mammals. As an autophagosomal orthologue of yeast Atg8, microtubule-associated protein 1 light chain 3 (LC3), including LC3-Ⅰ and LC3-Ⅱ, plays a crucial role in autophagosome formation. In particular, LC3-Ⅱ is a specific marker of the autophagic process since it directly correlates with the number of autophagosomes[12]. Additionally, Beclin-1 is an essential modifier of the autophagic process and has been implicated in tumor development, including breast, ovarian, and prostate tumors in humans, which have allelic loss of Beclin-1[13]. Combined with other biochemical factors, Beclin-1 can be used to monitor autophagy[13].

It was reported in the journal cancer cell that autophagic death appears in colon cancer cells when the protein level of EGFR is decreased as a result of transient transfection with EGFR siRNA. Moreover, it was found that autophagic death was independent of EGFR tyrosine kinase activity, but depended on SGLT-1, a new pathway downstream of EGFR that controls the glucose metabolism essential for cell life[14]. In a previous study, our group also found that the SGLT-1 expression level was related to the clinical stage of CRC[15]. Cetuximab, a chimeric monoclonal antibody targeted against the extracellular domain of EGFR, may have a similar effect as EGFR siRNA, such that it also simultaneously induces autophagic death by the SGLT-1 pathway and apoptosis by the inhibition of a tyrosine kinase pathway in colon cancer cells. Until now, the relationship between the efficacy of cetuximab and autophagy in colorectal cancerous tissues was uncertain. To clarify this issue, we investigated autophagy activity by assaying the expression of Beclin-1 and LC3 in colorectal cancerous tissues, determined the correlation between Beclin-1 and LC3 expression and the efficacy of cetuximab in patients with ACRC, and evaluated the association between KRAS status and the expression of Beclin-1 and LC3.

MATERIALS AND METHODS

Patients

Eighty-five ACRC patients with definitive pathological diagnoses, paraffin-embedded pathology specimens and complete clinicopathologic information who received papillary chemotherapy in the Sun Yat-Sen University Cancer Center from March 1, 2005, to December 31, 2008, were enrolled in this study. Two study arms were used. The first arm included 45 patients who received cetuximab-containing chemotherapy. The other arm of 45 patients was selected randomly from the ACRC patients who had received papillary chemotherapy without cetuximab. Five patients in the second arm were excluded because their paraffin-embedded specimen blocks were not available. Thus, only 40 cases were ultimately entered. These patients had local relapse or distant metastasis when they began papillary chemotherapy with or without cetuximab. Some had stage Ⅱ or Ⅲ cancer at the initial visit. Cancer cell-free surgical margins obtained from 28 CRC patients were used as controls.

Immunohistochemical staining for Beclin-1 and LC3

The formalin-fixed, paraffin-embedded pathology specimens of 85 CRC tissue samples and 28 normal colorectal tissue samples were all successfully examined. The diagnosis was microscopically confirmed by a pathologist. All hematoxylin-eosin stained specimens from the 85 CRC cases contained cancerous tissues, whereas all 28 control samples were cancer free. Five-micrometer sections were cut from the paraffin blocks and placed on glass slides. The slides were dried in an incubator at 60 ℃ for 60 min, deparaffinized in xylene, and then rehydrated in an ethanol series. After washing in water, antigen retrieval with citrate buffer was performed at high temperature and pressure. The sections were cooled for 20 min, washed twice with Phosphate buffered solution (PBS) for 5 min each, and then incubated in serum for 10 min. The primary antibody, either Beclin-1 (1:100) or LC3 (1:400) (Beclin-1 from Cell Signal, United States; LC3 from Novus Biologicals, United States), was diluted in 1% PBS and incubated for 45 min after the serum was tipped. The slides were then washed twice with PBS and incubated with the anti-rabbit secondary antibody (Invitrogen, United States) for 30 min. After an additional two washes in PBS, the slides were incubated with di-

Table 1 Comparison of baseline clinicopathological characteristics between cetuximab-containing chemotherapy group and non-cetuximab-containing group *n* (%)

aminobenzidine (DAB, Invitrogen, United States) for 10 min to visualize immunolabeling. After washing, the sections were counterstained with hematoxylin (Invitrogen, United States). Squamous cell cancer of the cervix and neurons from the cerebral cortex were used as positive controls for Beclin-1 and LC3, respectively, according to the manufacturer's instructions for each antibody. PBS was used as the negative control instead of the primary antibody on each slide for both Beclin-1 and LC3.

Hscore assessment

This method of assigning an histological score (Hscore) has been previously described[16,17]. Two independent pathologists with no knowledge of the clinical data scored all immunohistochemical staining of Beclin-1 and LC3, according to the staining intensity and the percentage of positively stained tumor cells. Staining intensities were classified into 4 grades: 0 (pale yellow or no staining), 1 (yellow), 2 (deep yellow) and 3 (brown). The percentage of positively stained tumor cells was scored in 4 grades: 0 (0%-10%), 1 (10%-25%), 2 (25%-50%) and 3 (50%-100%). The intensity and percentage of positively stained tumor cells were scored after counting at least 10 high-power fields at 400 ×. Mean Hscores were calculated as follows: [(Intensity reader 1 × Percentage reader 1) + (Intensity reader 2 × Percentage reader 2)]/2.

Polymerase chain reaction analysis of KRAS mutation

Six sections (5-μm thick) from the formalin-fixed, paraffin-embedded blocks were used for genomic DNA extraction using the QIAamp DNA Paraffin-Embedded Tissue Kit (QIAGEN) according to the manufacturer's instructions. The quality and concentration of the extracted DNA were determined by ultraviolet spectrophotometry. DNA quality was analyzed using a polymerase chain reaction (PCR) reaction (20 μL) that contained 10 μL master mix, 0.15 μL glyceraldehyde-3-phosphate dehydrogenase (GAPDH)-F, 0.15 μL GAPDH-R, 7.7 μL ddH_2O and 2 μL DNA. Products were visualized by electrophoresis on a 2% agarose gel. KRAS mutations were detected by a PCR (25 μL) composed of 12.5 μL PCR mix, 0.5 μL Primer A, 0.5 μL Primer B, 0.3 μL Probe 1 [FAM (carboxyfluorescein, blue) maker], 0.6 μL Probe 2 [VIC (Aequoria Victoria, green) maker], 8.1 μL ddH_2O and 2.5 μL DNA. The KRAS primers are as follows[18]: forward, 5'-AAGGCCTGCTGAAAATGAC-3'; and reverse, 5'-TGGTCCTGCACCAGTAATATG-3'. Samples for the control assay with a cycle threshold (Ct) below 35 were considered positive, whereas samples with Ct ⩾ 38 were scored as negative (wild-type).

Statistical analysis

All statistics were calculated using SPSS for Windows, version 17.0. Nonparametric tests were used to compare the expression of Beclin-1 and LC3 between colorectal cancerous tissues and normal tissues. Correlations of Beclin-1 and LC3 Hscore with KRAS status were assessed by Spearman's correlation analysis. The Chi-square test was used to compare the baseline characteristics of the cetuximab-containing chemotherapy and the non-cetuximab-containing chemotherapy, and analyze the influence of Beclin-1 and LC3 expression on the objective response rates (ORR) and disease control rates (DCR) of the two groups. Kaplan-Meier curves and Cox regression models were used as univariate and multivariate analysis tools, respectively, to evaluate progression-free survival (PFS) and overall survival (OS). Significance was defined as $P \leqslant 0.05$. All *P* values were two-sided.

PFS was calculated as the time lapsed between the date of treatment and the date of relapse or progressive disease. Patients with no signs of relapse were censored at the time of last follow-up or death. OS was calculated from the day of diagnosis until death or the last follow-up.

RESULTS

Baseline characteristics of the 85 patients with ACRC, including gender, age, primary clinical stage, tumor site, family history of tumor and histological grade, are listed in Table 1. All clinicopathologic characteristics of the patients receiving cetuximab-containing chemotherapy or non-cetuximab-containing chemotherapy were equivalent. By the time of the final follow-up (December 1, 2010), 57 patients had died, 27 were alive [performance status (PS) ⩽ 1 in 20 patients, PS = 2 in five patients, and PS = 3 in two patients], and one patient was lost to follow-up during a median follow-up time of 34.0 mo (2.0-137.0 mo).

Expression of Beclin-1 and LC3 in CRC tissues

The expression of Beclin-1 and LC3 was successfully evaluated in all 85 CRC tissues and 28 normal colorectal

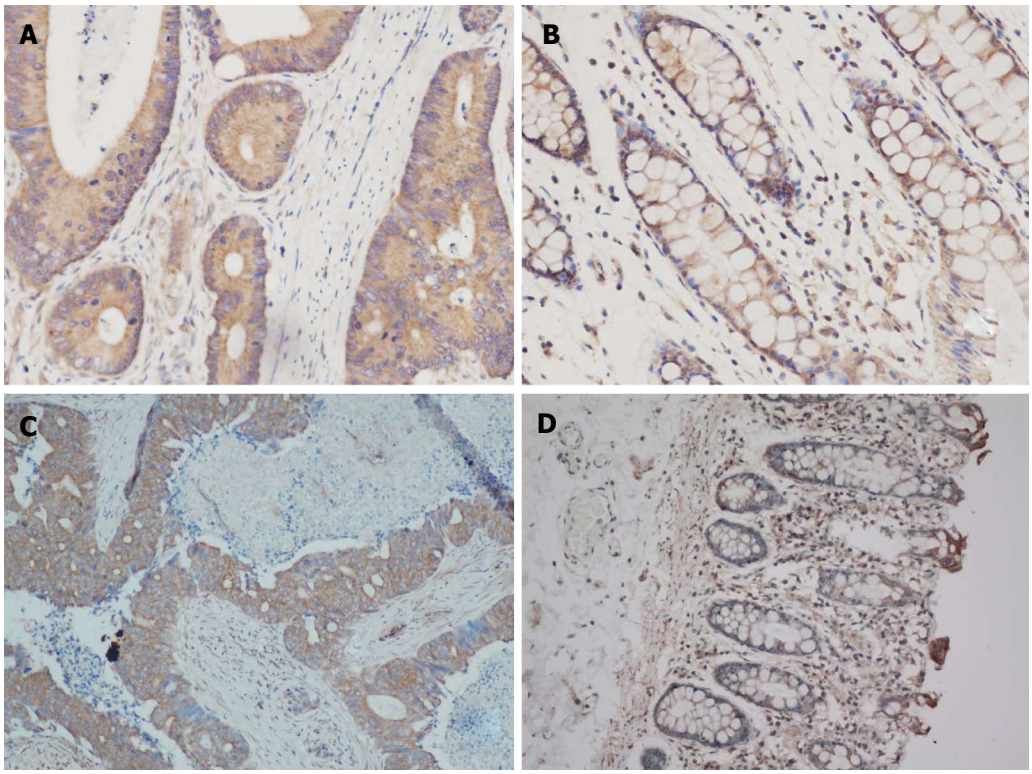

Figure 1 Immunohistochemical photomicrographs of Beclin-1 and LC-3 in colorectal cancer tissues and colorectal normal tissues (200 ×). A, B: Beclin-1 displayed strongest cytoplasm staining in colorectal cancer (CRC) tissues and weak positive staining in normal tissues: C, D: LC3 displayed intense granular staining of the cytoplasm in CRC tissues but absent in normal tissues.

K-M test was used to compare the expression of Beclin-1 or LC3 between CRC tissues and colorectal normal tissues. *P* value ≤ 0.05 was considered statistically significant. CRC: Colorectal cancer.

tissues. The Hscore consisting of seven grades was used to assess the tumor tissue. The expression of Beclin-1 and LC3 in cancerous and normal tissues is shown in Figure 1. The Hscore of LC3 expression in cancerous tissues was higher than that in normal tissues ($P < 0.01$), while Beclin-1 expression was not significantly different ($P = 0.35$) (Table 2).

Association of Beclin-1 and LC3 expression and KRAS status with efficacy of cetuximab-containing chemotherapy

Expression of Beclin-1 and LC3 correlated with short-term efficacy: For the 45 patients who had ever received cetuximab-containing chemotherapy, the Chi-square test was used to analyze the different ORRs and DCRs of the regimen, in patients with tumors exhibiting low or high Beclin-1 and LC3 expression (Table 3). The patients with low LC3 expression had a higher ORR than those with high LC3 expression (52.9% *vs* 17.9%, $P = 0.01$). Beclin-1 expression had no influence on ORR (26.7% *vs* 33.3%, $P = 0.65$). Neither Beclin-1 (80.0% *vs* 56.7%, $P = 0.12$) nor LC3 (76.5% *vs* 57.2%, $P = 0.19$) expression affected the DCR. In this whole group, the median PFS was 3.0 mo. The median PFS of the patients with low and high Beclin-1 expression was 9.0 mo and 3.0 mo, respectively ($P = 0.01$) (Figure 2). The median PFS of the patients with low and high LC3 expression was 3.0 mo and 4.0 mo, respectively ($P = 0.62$).

Association between KRAS status and short-term efficacy: Among the 45 patients treated with cetuximab-containing chemotherapy, 37 patients were successfully tested for *KRAS* gene mutations. The *KRAS* mutation rate in CRC patients was 29.7% (11/37). The *KRAS* mutations were all in codon 12. Nine cases had the G12D mutation (12 GGT→GAT, Gly→Asp), one case had the G12C mutation (12 GGT→TGT, Gly→Cys), and one case had the G12S mutation (12 GGT→AGT, Gly→Ser). The patients with wild-type KRAS had higher ORR (42.3% *vs* 9.1%, $P = 0.049$), DCR (73.1% *vs* 36.4%, $P = 0.035$) and PFS (5.5 mo *vs* 2.5 mo, $P = 0.02$) than those with *KRAS* mutations (Table 4 and Figure 3).

Effects of KRAS, Beclin-1 and LC3 on OS: The median OS in this study cohort was 40.0 mo. The most common potential factors affecting OS, including gender, age, primary clinical stage, tumor site, family history of tumor, histological grade, the expression of Beclin-1, LC3 and KRAS status, were analyzed as shown in Table 5. Only clinical stage ($P < 0.01$) and histological differentiation ($P = 0.049$) were found to be predictive factors of OS by univariate analysis. When the clinical stage, histological differentiation, Beclin-1 expression, LC3 expression, Hscore and KRAS status were subjected to multivariate analysis, only TNM stage retained its prognostic value ($P < 0.01$) (Table 6). Only 37 cases were included in the COX regression model because the KRAS status of eight cases was not tested successfully.

Correlation of Beclin-1 and LC3 expression and KRAS status: Spearman's correlation analysis revealed that Beclin-1 and LC3 expression levels in CRC exhibited a correlation coefficient of 0.44 ($P < 0.01$). However, neither Beclin-1 nor LC3 expression was related to KRAS status ($P = 0.52$ and $P = 0.32$, respectively).

Association of Beclin-1 and LC3 expression with efficacy of non-cetuximab-containing chemotherapy

For patients treated with non-cetuximab-containing chemotherapy, the ORRs and DCRs of the first-line chemotherapy were compared among patients exhibiting low and high expression of Beclin-1 and LC3. Neither Beclin-1 expression (ORR = 42.9% and 36.8%, $P = 0.70$; DCR = 85.7% and 84.2%, $P = 0.89$ in low and high Beclin-1 expression groups, respectively) nor LC3 expression (ORR = 43.7% and 37.5%, $P = 0.69$; DCR = 81.2% and 87.5%, $P = 0.59$ in the low and high LC3 expression groups, respectively) affected the ORR or DCR (Table 3). In addition, neither low nor high Beclin-1 or LC3 expression influenced PFS (7.0 mo *vs* 7.0 mo, $P = 0.29$; 7.0 mo *vs* 7.0 mo, $P = 0.60$) in this group, which had a median PFS of 7.0 mo. In addition, no significant associations were found between OS and Beclin-1 (33.0 mo *vs* 24.5 mo, $P = 0.67$) or LC3 expression (33.0 mo *vs* 29.0 mo, $P = 0.84$).

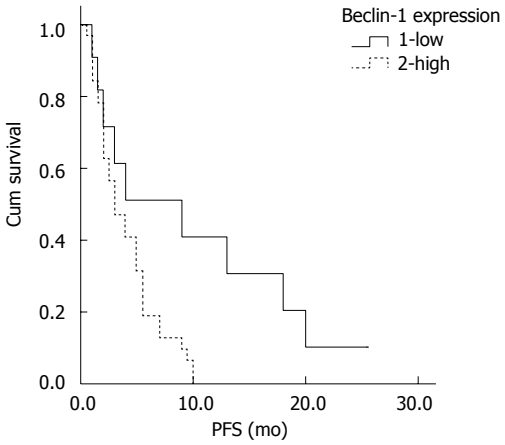

Figure 2 Progression-free survival of advanced colorectal cancer patients with low and high Beclin-1 expression in cetuximab-containing chemotherapy group. The median PFS of the patients with low and high Beclin-1 expression (a low expression defined as immuhistochemistry score < 6.0 and a high expression defined as immuhistochemistry score ⩾ 6.0.) was 9.0 mo and 3.0 mo respectively ($P = 0.01$). PFS: Progression-free survival.

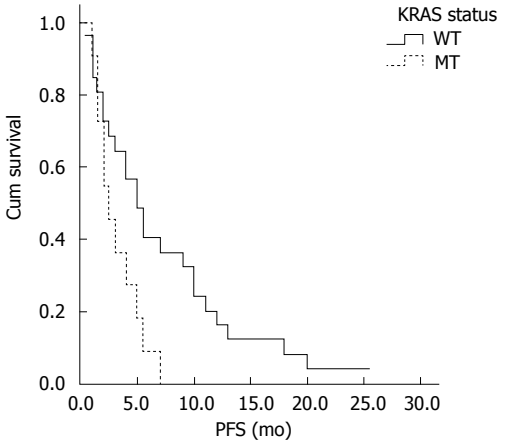

Figure 3 Progression-free survival of advanced colorectal cancer patients with KRAS wild type and patients with KRAS mutation treated by cetuximab-containing chemotherapy. Thirty-seven of 45 patients were successfully tested *KRAS* gene in cetuximab-containing chemotherapy group, the median PFS of patients with KRAS wild type was significantly higher than that of patients with KRAS mutation (5.0 mo and 2.5 mo, respectively, $P = 0.02$). PFS: Progression-free survival.

Thirty-seven of 45 cases were included in COX regression model because the KRAS status of 8 patients was not available. B: Regression coefficient; SE: Standard Error; OR: Odds ratio; CI: Confidence Interval.

DISCUSSION

The expression of Beclin-1 and LC3 was evaluated in 85 patients with ACRC. Forty-five of those patients had been treated with cetuximab-containing chemotherapy, and 40 patients received non-cetuximab-containing chemotherapy at the Sun Yat-Sen University Cancer Center. The two treatment groups were merged because the baseline characteristics with potential prognostic influence, including gender, age, primary clinical stage, tumor site, family history and histological grade, were equivalent. Levels of Beclin-1 and LC3 in ACRC tissues were significantly correlated ($P < 0.01$); however, only LC3 was more highly expressed in cancerous tissues than in normal tissues ($P < 0.01$). The reason for the expression heterogeneity of these two autophagy-related proteins could be the followings: (1) mutations in Belcin-1 are rarely present in gastrointestinal cancers[19,20], such that Beclin-1 expression is predicted to be almost identical in colorectal cancerous tissues and normal tissues; or (2) autophagy might be induced by factors other than Beclin-1, e.g., SGLT1[14], such that LC3 overexpression, usually considered a hallmark of autophagy, might not always occur in conjunction with Belcin-1 overexpression[21]. Indeed, the status of Beclin-1 expression in colorectal cancer had not been satisfactorily evaluated before the present work. One study investigating 103 colorectal and 60 gastric carcinoma tissues by immunohistochemistry indicated increased expression of Beclin-1 in malignant gastrointestinal epithelial tissues compared with normal mucosal epithelial tissues[22]. However, decreased mRNA and protein levels of Beclin-1 in colorectal cancerous tissues were also reported in China[20]. Although immunohistochemical detection of LC3 cannot distinguish LC3-Ⅰ and LC3-Ⅱ, it can still serve as an indicator of autophagic activity since LC3-Ⅱ is a dominant form of LC3[23]. The present study demonstrated that most colorectal cancerous tissues had higher levels of LC3 expression than most normal colorectal tissues, which generally exhibited low levels of LC3 (Table 2). This finding was supported by the results of a study involving 163 gastrointestinal cancer patients in whom LC3 was differentially expressed in the cytoplasm of cancer cells, but not in noncancerous epithelial cells[24]. Based on these findings, we speculate that normal cells exhibit a basal level of autophagy in order to maintain cellular homeostasis. Furthermore, increased autophagy in colorectal cancer cells may also play a crucial role in tumor survival; this finding was consistent with previous studies[25,26].

We also found that the patients with low LC3 expression had higher ORRs than those with high LC3 expression ($P = 0.01$) in the cetuximab-containing chemotherapy group; however, LC3 did not correlate with ORR in the non-cetuximab-containing chemotherapy group. Furthermore, the median PFS of patients with low and high Beclin-1 expressions was significantly different ($P = 0.01$) in the cetuximab-containing chemotherapy group; however, Beclin-1 expression could not predict PFS in the non-cetuximab-containing chemotherapy group. In summary, neither LC3 nor Beclin-1 correlated with treatment outcome in the non-cetuximab-containing chemotherapy group, but low expression of each protein correlated with good outcomes, based on ORR or median PFS, in the cetuximab-containing chemotherapy group. These data indicates that low autophagy levels are strongly correlated with good efficacy of cetuximab. To our knowledge, this is the first report that is based on clinical data. Our findings are in accordance with the idea that autophagy protects colon cancer cells from the apoptotic effects of cetuximab[27,28].

We also determined whether Beclin-1 and/or LC3,

two autophagy-related proteins, were as useful as *KRAS* gene mutations[3] in predicting the efficacy of cetuximab-containing regimens in ACRC. *KRAS* gene status is considered the gold standard to predict cetuximab efficacy in patients with ACRC. Cetuximab was specially designed to block the tyrosine kinase pathway in which KRAS is involved, and induce apoptosis; however, autophagy, another pathway downstream of EGFR, was also recently found to be influenced by cetuximab[27,28]. Consistent with other studies[7,29,30], our results showed that patients with wild-type KRAS had higher ORRs and DCRs and longer median PFS. We then attempted to predict the cetuximab treatment outcome by combining KRAS status with Beclin-1 and LC3 expression levels; however, this was not possible because neither of the autophagy-related proteins was correlated with KRAS status. Additionally, we found that KRAS status was a more powerful biomarker than either Beclin-1 or LC3 for predicting the efficacy of cetuximab-containing chemotherapy in ACRC. Although the OS of subgroups with low LC3 expression, low Beclin-1 expression and wild-type KRAS was longer than that of their counterparts with high LC3 expression, high Beclin-1 expression and mutant KRAS (Table 5), none of the three biomarkers was powerful enough to predict the OS of the ACRC patients treated with cetuximab by univariate or multivariate analysis. More importantly, the autophagy-related proteins, Beclin-1 and LC3, predicted drug efficacy independent of KRAS status, possibly because the autophagic pathway is distinct from the tyrosine kinase pathway that regulates KRAS. Panitumumab, an entirely human monoclonal antibody specific to EGFR, was also reported to affect colon cancer cell proliferation independent of KRAS mutation status, possibly through the induction of autophagy[31]. Though the nature of autophagy's involvement in a cell's response to cytotoxic chemotherapy or cetuximab treatment has been controversial, our findings imply that autophagy makes a mild to moderate contribution to the anti-tumor effects of cetuximab, but it is not as critical as KRAS. We believe that the autophagy could be used to enhance and/or predict cetuximab efficacy.

Obviously, the heterogeneity of Beclin-1 and LC3 expression and their limited ability to predict the efficacy of cetuximab may restrict their utility. The findings discussed herein may be associated with our small patient sample. Beclin-1 is only an autophagy modifier, and varying levels of this protein do not always indicate the presence or absence of autophagy; however, LC3 expression is a hallmark of autophagy initiation.

Based on our data, we conclude that low levels of autophagy were associated with high anti-tumor activity of cetuximab-containing chemotherapy because patients with low LC3 expression exhibited higher ORRs. Similarly, patients with tumors expressing low levels of Beclin-1 had longer median PFS. Wild-type KRAS was strongly correlated with good outcomes in terms of ORR, DCR and PFS. Importantly, Beclin-1 and LC3 expression predicted cetuximab treatment outcomes while they were not related to the KRAS status, indicating that autophagy might offer another potential avenue to enhance and/or predict cetuximab efficacy in patients with ACRC.

ACKNOWLEDGMENTS

We want to thank Professor Xiao-Feng Zhu and Professor Jian-Yong Shao for their help in this study.

COMMENTS

Background

At least half of the advanced colorectal cancer (ACRC) patients with wild-type KRAS do not benefit from cetuximab. Thus, it is vital to identify new predictive markers for cetuximab efficacy. Autophagic death occurred in colon cancer cells when epidermal growth factor receptor (EGFR) was blocked with EGFR siRNA. Both of cetuximab and EGFR siRNA targeted the extracellular domain of EGFR, which indicates that autophagy may be involved in cetuximab antitumor activity and predict cetuximab efficacy in patients with ACRC. LC3 plays a crucial role in autophagosome formation and Beclin-1 is an essential modifier of the autophagic process, so LC3 and Beclin-1 can be used to monitor autophagy.

Research frontiers

Autophagy protects colon cancer cells from the apoptotic effects of cetuximab, however, Panitumumab, another antibody specific to EGFR, was also reported to affect colon cancer cell proliferation independent of KRAS mutation status, possibly through the induction of autophagy. What the exact role autophagy plays in ACRC and whether autophagic markers, such as Beclin-1 and LC3, can predict efficacy of cetuximab, are still unknown.

Innovations and breakthroughs

Based on clinical data, this study found for the first time that low levels of autophagy were associated with high anti-tumor activity of cetuximab-containing chemotherapy in ACRC patients.

Applications

The study results suggest that autophagy might offer another potential avenue to enhance and/or predict cetuximab efficacy in patients with ACRC.

Terminology

Autophagy: A catabolic process involving the degradation of the cells to maintain survival, but excessive autophagy leads to cell death. In recent years, it has been found that autophagy is involved in cancer process and treatment; Microtubule-associated protein 1 light chain 3 (LC3): It includes LC3-Ⅰ and LC3-Ⅱ, and plays a crucial role in autophagosome formation; Beclin-1: An essential modifier of the autophagic process and being implicated in tumor development.

Peer review

It is an interesting article and authors have done extensive work and written well with important figures and tables.

Abstract

AIM: To evaluate clinical validity of the compression anastomosis ring (CAR™ 27) anastomosis in left-sided colonic resection.

METHODS: A non-randomized prospective data collection was performed for patients undergoing an elective left-sided colon resection, followed by an anastomosis using the CAR™ 27 between November 2009 and January 2011. Eligibility criteria of the use of the CAR™ 27 were anastomoses between the colon and at or above the intraperitoneal rectum. The primary short-term clinical endpoint, rate of anastomotic leakage, and other clinical outcomes, including intra- and postoperative complications, length of operation time and hospital stay, and the ring elimination time were evaluated.

RESULTS: A total of 79 patients (male, 43; median age, 64 years) underwent an elective left-sided colon resection, followed by an anastomosis using the CAR™ 27. Colectomy was performed laparoscopically in 70 patients, in whom two patients converted to open procedure (2.9%). There was no surgical mortality. As an intraoperative complication, total disruption of the anastomosis occurred by premature enforced tension on the proximal segment of the anastomosis in one patient. The ring was removed and another new CAR™ 27 anastomosis was constructed. One patient with sigmoid colon cancer showed postoperative anastomotic leakage after 6 d postoperatively and temporary diverting ileostomy was performed. Exact date of expulsion of the ring could not be recorded because most patients were not aware that the ring had been expelled. No patients manifested clinical symptoms of anastomotic stricture.

CONCLUSION: Short-term evaluation of the CAR™ 27 anastomosis in elective left colectomy suggested it to be a safe and efficacious alternative to the standard hand-sewn or stapling technique.

Key words: Compression anastomosis; Colon; Anastomotic leakage; CAR™ 27

INTRODUCTION

A well-vascularized tension-free anastomosis is of paramount importance for successful colorectal surgery and the hand-sewn or stapling technique is currently the most common surgical standard for restoration of bowel continuity. However, both techniques inevitably leave foreign materials within tissue, evoking an inflammatory reaction, thus potentially resulting in a number of anastomosis-related adverse effects. In particular, permanent presence of metallic foreign material after stapled anastomosis often contributes to the reduced size of the anastomotic lumen, and may be responsible for frequent postoperative stricture[1].

Anastomotic leakage still remains a serious problem associated with substantial morbidity and mortality. Although considerable variations are seen among surgeons, an overall clinically apparent anastomotic leakage proximal to the peritoneal reflection of the rectum ranges in frequency from 3.4% to 6%[2,3]. For anterior resection of the rectum, clinical leakage rate is known to be higher-between 2.9% and 15.3%[4-6]. In particular, not only increasing surgical morbidity and mortality, this complication may be associated with worse survival and higher recurrence after curative resection of colorectal cancer[7,8]. These drawbacks associated with conventional anastomotic techniques naturally lead surgeons to investigate a more ideal concept of the anastomosis. As an alternative to the end-to-end circular stapling device, a novel compression anastomosis ring (CAR™ 27; NiTi Surgical Solutions, Netanya, Israel) was introduced recently. It is made of shape-memory alloy of nickel-titanium (Nitinol), which is temperature dependent. Because this device is staple-free, there is no puncturing injury of the bowel wall, no risk of anastomotic bleeding, and it does not leave any permanent foreign material within the body. Within 6 to 11 d, the entire device together with the necrotized tissue detaches and is naturally eliminated from the body during bowel movements, leaving a wide and patent sutureless end-to-end anstomosis[9].

The aims of the current study were to present early clinical experience of the CAR™ 27 device in colorectal or colocolic end-to-end anastomosis after left-sided colon resection, and to evaluate the safety, efficacy, and technical feasibility of the device.

MATERIALS AND METHODS

Patients

A non-randomized prospective data collection was performed for patients undergoing an elective left-sided colon resection, followed by an anastomosis using the CAR™ 27 for various left-colonic etiologies. Eligibility criteria of the use of the CAR™ 27 were anastomoses between the colon and at or above the intraperitoneal rectum. The surgical procedures were performed by a single surgeon (HJ Choi). Between November 2009 and January 2011, a total of 79 anastomoses were constructed by use of the CAR™ 27. Preoperatively, patients were informed of the method of bowel anastomosis. Data on patient demographics, surgical indications, operative procedure, perioperative course, and outcome were recorded prospectively on data sheets. The primary short-term clinical endpoint was the rate of anastomotic leakage, and other clinical outcomes, including intra- and postoperative complications, length of operation time and hospital stay, and the ring elimination time were recorded. No postoperative radiologic contrast study was performed routinely, and anastomotic leakage was diagnosed clinically.

Figure 1 NiTi compression anastomosis ring (CAR™ 27). It consists of firing device, ring loader, polyethylene anvil, and nitinol ring (Courtesy of NiTi™ Surgical Solutions, Netanya, Israel).

Description and use of the CAR™ 27

Nitinol is a temperature-dependent shape memory alloy of nickel-titanium because it expands and flexes when cooled, but resumes its shape and size when it returns to its normal temperature[10]. Nitinol leaf springs are used in the CAR™ 27 to maintain a continuous pressure at the anastomosis independent of the thickness of tissue within the anastomosis. By cooling the ring in cold saline for about 30 s, the nitinol leaf springs flatten within the ring. When an anastomosis is created, the ring can accommodate to the different thicknesses of tissue within the anastomosis[11]. At body temperature, the nitinol leaf springs begin to return to their original shape, which closes the gap gradually until the trapped tissue becomes necrotic. As a result, healthy tissue connects the bowel ends at the ring's outer perimeter to restore the bowel continuity.

The CAR™ 27 instrument consists of two main components, a main firing device and detachable compression elements (Figure 1). Compression elements are composed of a polyethylene anvil ring and a nitinol leaf spring-containing metal ring. Its use is similar to that of current curved circular staplers and it was manipulated according to the manufacturer's instructions. In brief, the detachable anvil ring was inserted into the proximal bowel lumen and secured by a purse-string suture, when an anastomosis was ready after colon resection. After immersing the mounted ring with its loader in cold saline for several minutes, the ring was loaded to the distal end of the firing device. The firing device was then inserted transanally up to the stapled end of the colon or upper rectum. A thin trocar shaft emerged from the instrument to pierce the distal stapled end and was assembled to the shaft of the detachable anvil head by sliding one into the other. To deploy the CAR™ 27 from the housing onto

the tissue, the operating knob was rotated until it could not be turned any further and the indicator line was visible, and the cutting trigger and the cutting handle were squeezed simultaneously. When fired, the device holds the two ends of tissue together with circumferentially placed barbed points, which penetrate through the tissue, holding it to the polyethylene anvil ring. After firing, the cutting trigger and the cutting handle were released and the instrument was withdrawn by pulling gently out of the rectum and anus. Because this device is temperature-dependent, warm saline was instilled around the anastomosis immediately after firing for quicker and securer return to its pre-deformed shape. Completeness of the anastomosis was confirmed by an air-leak test.

RESULTS

A total of 79 patients (male, 43) underwent an elective left-sided colon resection, followed by an anastomosis using the CAR™ 27. Patient demographics and primary diagnoses for a colectomy are shown in Table 1. Patients ranged in age from 30 to 82 (median, 64). The majority of patients (95%) received left-sided colon surgery for neoplastic etiologies. Surgical and pathologic data are shown in Table 2. Laparoscopic colectomy was performed in 70 patients, in whom two patients who underwent a laparoscopic anterior resection for sigmoid colon cancer were converted to open procedure (2.9%); one for bulky tumor with uterine adhesions and the other for physiologic adhesions with marginal artery injury. Combined procedures were performed in 5 patients [2, total abdominal hysterectomy (TAH) and bilateral salpingo-oophorectomy; 1, video-assisted thoracic surgery (VATS) wedge pneumonectomy; 1, cholecystectomy; 1, TAH]. Table 3 shows intra- and postoperative complications. There was no surgical mortality. There was an intraoperative complication associated with immature manipulation of the CAR™ 27 anastomosis. This 67-year old male received a laparoscopic anterior resection for sigmoid colon cancer. Immediately after deployment of the CAR™ 27 by firing, the proximal segment of the anastomosis was pulled upward to check perfectness of the anastomosis and the proximal side of the anastomosis was stripped off circumferentially. To solve this intraoperative problem, the device was dismantled and another new CAR™ 27 anastomosis was constructed. Premature enforced tension over the anastomosis with the CAR™ 27 still in the cold temperature might be a factor. One patient with sigmoid colon cancer showed anastomotic leakage after 6 d postoperatively. This 33-year-old female received a second laparoscopic exploration, and primary suture closure of the anastomotic defect (with the CAR™ 27 left) and temporary diverting ileostomy were performed. Postoperatively, all patients were informed that the ring would be expelled with bowel movement within 14 d after surgery. Practically, the exact date of expulsion of the ring could not be recorded because most patients were not aware that the ring had been expelled with stool. In the patient who received a diverting ileostomy for anastomotic leakage, the ring was not expelled and retained within the colon until 9 d after an ileostomy closure (Figure 2). Postoperatively, no patient manifested clinical symptoms suggestive of anastomotic stricture. Colonoscopy at 6-month follow-up showed a wide and patent anastomosis constructed by the CAR™ 27 (Figure 3).

DISCUSSION

As a secure anastomosis is the crucial step for success-

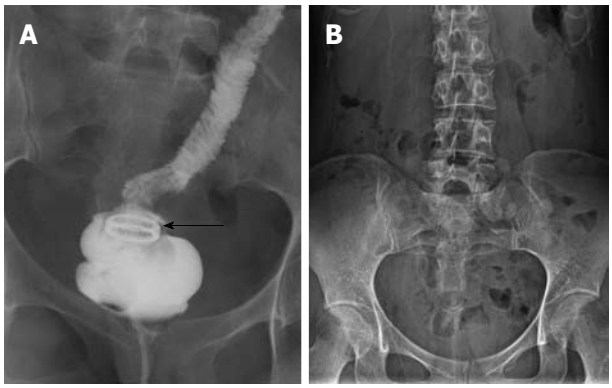

Figure 2 Abdominal radiographs of the patient complicated by anastomotic leakage. A: Gastrografin study showed complete healing of the anastomotic leakage with the ring (arrow) retained at the anastomosis a week before ileostomy takedown; B: The ring was eliminated from the body spontaneously and was no longer seen on the radiograph nine days after the ileostomy closure.

ful colorectal surgery, search for the ideal concept of the anastomosis has been the subject of surgical interest since the 19th century. The goal has been to devise an innovative method to eliminate the risk of anastomosis-associated leakage. The concept of compression anastomosis is that two bowel ends are compressed together by a sutureless device, preventing leakage and facilitating the natural healing process in the compressed region. The idea of compression anastomosis was first devised by Denan who developed two metal rings kept in position by a spring in a canine model in 1826. In 1892, Murphy[12] introduced "Murphy's button," which consisted of a pair of metal rings that compressed circular segments of intestine, leading to tissue necrosis. But it was not popular in clinical use because of too tight compression that led to peripheral ischemia and premature necrosis. It took another 100 years for a new compression anastomosis device to be put into wide use. In 1985, Hardy *et al*[13] developed a biofragmentable anastomosis ring (Valtrac™ BAR; Covidien, Mansfield, MA, United States) which is made of absorbable polyglycolic acid and radiopaque barium sulfate. To prevent tissue ischemia and to accommodate tissue thickness, margins of two identical rings are scalloped in shape and three gap-widths in the closed position (1.5, 2.0 and 2.5 mm) are available. A number of studies, including prospective randomized trials confirmed that the Valtrac™ BAR was a safe and reliable compression anastomotic device in both elective and emergency surgery[14-17]; however, intraoperative problems have been reported, including failure of purse-string sutures, inappropriate selection of the size of the Valtrac™ BAR with partial or full-thickness tear of the bowel wall, and failure of snap or shattering of the device[16,17].

Stepping forward, a novel compression anastomotic device made of nitinol (Nickel Titanium Naval Ordinance Laboratory), a shape memory alloy of nickel-titanium was introduced recently. Nitinol has two physical properties: temperature-dependent shape memory and super-elasticity. When cooled down, it has lower mechanical properties and becomes pliable, and then it becomes stable and returns to its pre-deformed shape at room temperature[10]. Super-elastic leaf springs made of nickel-titanium alloy are used in the NiTi CAR™ 27 in order to maintain a continuous pressure at the anastomosis independent of the thickness of tissue within the anastomosis[11]. The reparative healing process outside the ring produces an intact anastomosis before detachment and expulsion of the ring, leaving no foreign material within the body. The safety of this device has been demonstrated in animal studies[9,18]. Compared to other compression devices clinically, distinctive theoretical merits of the Nitinol are that it can accommodate different thickness around the circumference of the anastomosis and that it provides a constant, continuous, and uniform pressure over the pressed tissue along its compressing perimeter[19]. The CAR™ 27 was approved by the US Food and Drug Administration (FDA) for the use in intestinal anastomoses in August, 2006 and by the Korea FDA in May, 2009.

Clinical experiences with use of the CAR™ 27 in colonic anastomoses are still very scarce. Preliminary results of a phase Ⅱ, prospective, clinical trial by D'Hoore *et al*[20] were promising. In 10 patients who underwent high anterior resection or left colectomy, no anastomotic leakage occurred, and only three patients noticed passage of the ring through the anal canal. A recent prospective multicenter study comparing CAR™ 27 anastomosis (10 patients) with stapled anastomosis (13 patients) also demonstrated that the safety and efficacy of colorectal anastomosis using the CAR™ 27 in human was comparable to standard stapled anastomosis[19]. This study was first human multicenter trial but the sample size was too small to draw definite conclusions. The most recent non-randomized, prospective pilot study of the CAR™ 27 device in 23 patients undergoing a left-sided colectomy experienced an anastomotic leakage in one patient (4.3%) and stricture in two (8.6%)[21]. The current study has the largest sample size ever presented, demonstrating clinical safety relevant to CAR™ 27 anastomosis in both laparo-

scopic and open left-sided colectomies. A systemic review (Cochrane Database) of nine studies involving 1233 patients (622 stapled and 611 hand-sewn) found that overall rate of clinical leaks was 6.3% and 7.1%, respectively[22]. Valtrac™ BAR instead of staples is a standard method of intraperitoneal colonic anastomosis in open surgery in our practice to minimize anastomotic stricture. The overall rate of anastomotic leak after the Valtrac™ BAR colonic anastomosis in our series (632 patients) was 0.6%[23]. Compared to these results, leakage in one patient (1.3%) in this study implies that CAR™ 27 anastomosis is as safe and efficacious as conventional hand-sewn or stapling anastomosis. In addition, it is financially superior to end-to-end (EEA) stapling device (around $324 *vs* $360).

Issues associated with the CAR™ 27 anastomosis may deserve mentioning. Our experience of an intraoperative total anastomotic disruption associated with premature enforced tension over the anastomosis might reflect learning-curve error. Since this experience, it is our technical policy to leave the CAR™ 27 anastomosis soaked in warm saline for a few minutes, allowing the ring to recover to body temperature. Tulchinsky *et al*[19] recommended digital removal of the ring when it is not expelled spontaneously in a diverted patient. This seems to be an unnecessary maneuver. Moreover, in higher anastomosis from the anus, manual removal is not possible and forced instrumental removal of the retained ring may be rather harmful. Although the ring was not expelled and retained during the diversion in the leaked patient in this study, there were no problems associated with the retained ring during the diversion (134 d), and it expelled spontaneously after the ileostomy closure. In this sense, no specific maneuver is necessary and restoration of fecal stream after takedown of the diversion would be enough to eliminate the ring exteriorly.

To date, the clinical indication for the CAR™ 27 anastomosis is restricted to high level anastomoses at or above the anterior resection and it is not indicated in low rectal or anal anastomoses. Considering its superior technologic properties, anastomosis using the CAR™ 27 appears to be able to be performed safely in low anterior resection of the rectum. In addition, further prospective large-scale studies might be imperative to determine if the CAR™ 27 anasomosis can be constructed safely in diseased bowel such as Crohn's colitis, and if it can be performed liberally in emergency surgery.

In conclusion, short-term evaluation of the CAR™ 27 anastomosis in patients undergoing laparoscopic or open elective left colectomy proved to be a safe and efficacious alternative to the standard hand-sewn or stapling technique. Along with its technical superiorities, a prospective large-scale clinical trial would confirm the validity of the CAR™ 27 in diverse clinical settings.

COMMENTS

Background

A secure anastomosis is a crucial step for successful colorectal surgery and the hand-sewn or stapling technique is currently the most common surgical standard method of anastomosis. However, both techniques inevitably leave foreign materials within tissue, evoking an inflammatory reaction, thus potentially resulting in a number of anastomosis-related adverse effects.

Research frontiers

To overcome safety limits in hand-sewn and stapled techniques, the concept of compression anastomosis is introduced. A novel compression anastomotic device (CAR™ 27), made of a shape memory alloy of nickel-titanium, has two peculiar physical properties: temperature-dependent shape memory and superelasticity.

Innovations and breakthroughs

This is the largest study to evaluate the safety, efficacy, and technical feasibility of the CAR™ 27 anastomosis in left-sided colon resection. Short-term evaluation of the CAR™ 27 anastomosis in elective left colectomy is a safe and efficacious alternative to the standard hand-sewn or stapling technique. Among 79 patients, only one (1.3%) was complicated by anastomotic leakage in one patient, and it is financially superior to stapling device.

Applications

The study results suggest that the CAR™ 27 anastomosis can be applied both in laparoscopic and open left colectomy with safety. Despite encouraging results, clinical indication of the CAR™ 27 is, to date, limited to intraperitoneal anastomosis, and it is not indicated in low rectal or anal anastomoses. Considering its superior technologic properties, one of promising indications would be its use after a low anterior resection of the rectum. In addition, the potential expansion of its indications to patients with inflammatory bowel disease or with impaired healing for reasons such as radiation awaits further prospective clinical evaluations.

Terminology

Temperature-dependent shape memory of the device is the property that it has lower mechanical properties and becomes supple when cooled down, and then it becomes stable and returns to its pre-deformed shape at room temperature.

Peer review

This is a well written paper on the use of the compression anastomosis ring in left-sided colonic anastomosis and the results are comparable to stapled anastomosis.

Abstract

AIM: To evaluate the value of ABC (D) stratification [combination of serum pepsinogen and *Helicobacter pylori* (*H. pylori*) antibody] of patients with gastric cancer.

METHODS: Ninety-five consecutive patients with gastric cancer were enrolled into the study. The serum pepsinogen Ⅰ (PG Ⅰ)/pepsinogen Ⅱ (PG Ⅱ) and *H. pylori* antibody levels were measured. Patients were classified into five groups of ABC (D) stratification according to their serological status. Endoscopic findings of atrophic gastritis and histological differentiation were also analyzed in relation to the ABC (D) stratification.

RESULTS: The mean patient age was (67.9 ± 8.9) years. Three patients (3.2%) were classified into group A, 7 patients (7.4%) into group A′, 27 patients (28.4%) into group B, 54 patients (56.8%) into group C, and 4 patients (4.2%) into group D, respectively. There were only three cases in group A when the patients taking acid proton pump inhibitors and those who had undergone eradication therapy for *H. pylori* (group A′) were excluded. These three cases had mucosal atrophy in the grey zone according to the diagnostic manual of ABC (D) stratification. Histologically, the mean age of the patients with well differentiated adenocarcinoma was significantly higher than that of the patients with poorly differentiated adenocarcinoma ($P < 0.05$). There were no differences in the pattern of atrophy in the endoscopies between the well differentiated and poorly differentiated groups.

CONCLUSION: ABC (D) stratification is a good method for screening patients with gastric cancers. Endoscopy is needed for grey zone cases to check the extent of mucosal atrophy.

Key words: Gastric cancer; *Helicobacter pylori*; Pepsinogen; ABC (D) stratification; Cancer screening

INTRODUCTION

Gastric cancer remains the second leading cause of can-

cer death in Japan, although its mortality has continued to decrease for decades[1]. Screening systems or methods to detect early gastric cancers have contributed to the decrease in gastric cancer deaths[2,3]. Mass screening for gastric cancer by X-ray examination was introduced in the 1960s and has been epidemiologically confirmed to be effective for reducing gastric cancer mortality[2,3]. However, the decreases in efficiency have been thought to result from the decreased coverage rates and a tendency for the same participants to undergo gastric cancer screening repeatedly. Therefore, a more effective screening system, focusing on high-risk patients, is needed.

Helicobacter pylori (*H. pylori*) infection and subsequent atrophic gastritis have been regarded as risk factors for gastric cancer[4-6]. The combination of serum pepsinogen (PG) and *H. pylori* antibody [ABC (D) stratification] has been suggested to serve as a useful predictive marker for patients with gastric cancers[4-6]. This combination of serum markers would represent a much simpler and less invasive method than endoscopy, and therefore, would be suitable for a large general population. A large scale study by Ohata *et al*[4] reported that the combination of serum PG and anti-*H. pylori* antibody provide a good method for predicting the development of gastric cancer. Mizuno *et al*[6] also reported the usefulness of this screening method in a population-based cohort study.

However, the studies concerning the use of ABC (D) stratification only focused on patients with no disease or an unknown disease status. Analyses of the ABC (D) stratification of patients with confirmed gastric cancer are lacking. The aim of this study was to evaluate the ABC (D) stratification so as to provide information that might be useful for screening patients with gastric cancers.

MATERIALS AND METHODS

Patients and study design

Ninety-five consecutive patients with gastric cancer were enrolled in the study. All patients were diagnosed as having gastric cancer at Shirakawa Clinic (Maebashi, Japan) between November 2007 and October 2009. IgG antibodies to *H. pylori* and the levels of pepsinogen I (PG I) and II (PG II) were measured and classified by ABC (D) stratification. Group A consisted of patients with normal PG and *H. pylori* antibody (-); group B had normal PG and *H. pylori* (+); group C had atrophic PG and *H. pylori* (+); and group D had atrophic PG and *H. pylori* (-). Group A' included patients with normal PG who were *H. pylori* (-) after *H. pylori* eradication therapy or who were being treated with proton pump inhibitors.

A data collection sheet was designed to obtain the relevant clinical information about the patients for review. All of the patients provided written informed consent before receiving the examination. Olympus XQ260 or N260 (Olympus Optical Co, Tokyo, Japan) instrument was used for endoscopic examination. When gastric cancer was suspected by routine endoscopy, chromoendoscopy with indigo carmine and a biopsy were performed. All cases were histologically confirmed to have gastric cancer. According to the endoscopic gastric mucosal findings, the patients were classified into three categories: those without atrophy, those with close-type atrophy, and those with open-type atrophy[7].

Serological tests and definition of ABC (D) stratification

H. pylori infection was determined by enzyme-linked immunosorbent assay (ELISA) kits (E-plate EIKEN *H. pylori*, Eiken Chemical Co., Ltd., Tokyo, Japan). Subjects with $\geqslant$ 10 U/mL were classified as having *H. pylori* infection. Those with < 10 U/mL were regarded as being *H. pylori* negative. The sensitivity and specificity of this assay for *H. pylori* infection were 100% and 93.8%, respectively. The levels of PG I and PG II were measured using the E-plate EIKEN Pepsinogen I and the E-plate EIKEN Pepsinogen II (Eiken Chemical Co., Ltd., Tokyo, Japan), respectively. Atrophic gastritis was diagnosed according to the serum PG I and PG II criteria proposed by Miki and others[8-10]. Briefly, the serum PG status was defined as atrophic when the criteria of both serum PG I level $\leqslant$ 70 ng/mL and a PG I /PG II ratio $\leqslant$ 3.0 were simultaneously fulfilled. All other cases were classified as normal. These criteria have a sensitivity of 70.5% and a specificity of 97%.

Statistical analysis

Differences between the groups were analyzed by Fischer's exact probability test and Mann-Whitney's *U* test when a significant difference was obtained by the Kruskal-Wallis test. A *P* value less than 0.05 was considered to be significant.

RESULTS

Patient characteristics

Ninety-five patients were diagnosed as having gastric cancer at our institution between November 2007 and October 2009. The mean age of the patients was (67.9 ± 8.9) years (range, 38-83, median 69). There were 72 male and 23 females. According to ABC (D) stratification, there were 3 (3.2%) patients in group A, 7 patients (7.4%) in group A', 27 (28.4%) in group B, 54 (56.8%) in group C, and 4 (4.2%) in group D, respectively (Table 1). There were no significant differences in the mean age, sex ratio, location of the tumor, macroscopic findings or histological type among the five groups. According to endoscopic findings, two cases (2.1%) had no atrophy, 21 (22.1%) had closed-type atrophy, and 72 (75.8%) had open-type atrophy. The relationship between ABC (D) stratification and the endoscopic atrophic border are shown in Table 2. There were no significant differences in the endoscopic atrophic border pattern among the five groups. There were 35 patients with closed-type or open-type atrophy in the PG negative group.

Table 2 Relationship between ABC (D) stratification and endoscopic atrophic border in patients with gastric cancers

	Endoscopic atrophic border			
ABC (D) stratification	Non	Closed type	Open type	Total
A: *H. pylori* (-) PG (-)	1	3	6	10 (10.6%)
B: *H. pylori* (+) PG (-)	1	7	19	27 (28.4%)
C: *H. pylori* (+) PG (+)	0	10	44	54 (56.8%)
D: *H. pylori* (-) PG (+)	0	1	3	4 (4.2%)
Total	2 (2.1%)	21 (22.1%)	72 (75.8%)	95 (100%)

H. pylori: *Helicobacter pylori*; PG: Pepsinogen; Non: No atrophic change.

in groups A-D. Figure 1A shows a 70-year-old male with *H. pylori* (-) and PG (-). However, open- type atrophy was found in endoscopy. He should have been classified into group D because of the extent of mucosal atrophy. The PG Ⅰ level was low (28.5 ng/mL), although PG was negative based on the PG Ⅰ/PG Ⅱ ratio (3.9). Figure 1A' shows a 48-year-old female with *H. pylori* (-) and PG (-). She had no atrophy in the endoscopic findings. This case received post-eradiation therapy for *H. pylori*. The patient was *H. pylori* negative with the titer of the *H. pylori* antibody under 10 U/mL. However, the antibody titer was 7.6 U/mL, so she was not completely *H. pylori* negative. Figure 1B shows a 72-year-old male with *H. pylori* (+) and PG (-). He had closed-type atrophy in the endoscopic findings. Figure 1C shows a 71-year-old male with *H. pylori* (+) and PG (+). This case was positive for both *H. pylori* and PG. He had open-type atrophy in the endoscopic examinations. Figure 1D presents a 69-year-old male with *H. pylori* (-) and PG (+). He had open-type atrophy in endoscopy. Because of the progression of mucosal atrophy, we concluded that this patient was likely negative for *H. pylori* because the organism cannot live in the atrophic mucosa.

Gastric cancers arising from group A and group A'

A summary of the patients with gastric cancer arising from group A and group A' is shown in Table 3. Among 10 patients, there was one case without atrophy, 3 cases of closed-type atrophy, and 6 cases of open-type atrophy. There were only 3 (3.2%) cases in group A when the patients in group A' (who was taking acid proton pump inhibitors and/or had received eradication therapy for *H. pylori*) were excluded. These 3 cases had mucosal atrophy and were classified into the grey zone pattern based on the diagnostic manual of ABC (D) stratification. Eight of the 10 patients were classified into group A or A' because their serum PG Ⅰ/PG Ⅱ ratio was greater than 3. The serum PG Ⅰ levels of the 8 patients were ≤ 70 ng/mL.

Histological analysis

Histologically, there were 76 (80.0%) cases of well or moderately differentiated adenocarcinomas (well differentiated group) (Table 4). There were 19 (20.0%) cases of poorly differentiated adenocarcinomas or signet ring cell carcinomas (poorly differentiated group). The mean age of the patients in the well differentiated group [(70.2 ± 5.8) years] was significantly higher than that of the poorly differentiated group [(61.4 ± 12.9) years, $P < 0.05$]. There were no differences in the sex ratio or the pattern of atrophy in endoscopy between the well differentiated group and the poorly differentiated group. The proportion of group C patients tended to be higher in the well differentiated group, although it did not reach statistical significance. It was supposed that the patients with well differentiated adenocarcinomas would shift from group B to C as they aged.

The relationship between ABC (D) stratification and the endoscopic atrophic border according to the histological differentiation is shown in Tables 5 and 6. There were no differences in the distribution of the endoscopic atrophic border between the well differentiated and poorly differentiated groups.

DISCUSSION

A screening program with an upper gastrointestinal series has been confirmed to be effective for reducing mortality from gastric cancer in Japan[2,3]. Since the X-ray with photofluorography was first introduced in the 1960s, it has played a key role in gastric cancer screening[11,12]. However, the existing program by the X-ray was introduced prior to the discovery of *H. pylori* and documentation of its carcinogenicity. Only approximately 13% of the target population participated in the program[13]. Given these drawbacks, it is necessary to establish an effective screening system, focusing on high-risk status such as *H. pylori* infection and atrophic gastritis. The combined use of

serum anti-*H. pylori* antibodies and PG measurement has been reported to be a useful screening method for gastric cancers[4], and several recent reports have confirmed the usefulness of this screening method[5,6]. However, most of these reports targeted the general population during routine health check-ups. The ABC (D) stratification of patients who have already been diagnosed with gastric cancer has not been sufficiently investigated. In this study, we evaluated the ABC (D) stratification of patients with confirmed gastric cancers.

Rapid progress has been made in the studies on stomach carcinogenesis since the discovery of *H. pylori*. The relationship between atrophic gastritis and gastric cancer has been confirmed epidemiologically. Uemura *et al*[14] reported that only *H. pylori*-infected subjects developed gastric cancer among a group of patients with organic or functional gastroduodenal disorders. Fukase *et al*[15] reported a randomized controlled trial in which *H. pylori* eradication contributed to the reduction of metachronous gastric cancer after endoscopic resection of early gastric cancer. Not surprisingly, the combination of *H. pylori* infection determined by serum anti-*H. pylori* antibodies and atrophic gastritis determined by serum PG levels is promising for diagnosing gastric cancer[4-6].

Mizuno *et al*[6] reported that the atrophy-positive *H. pylori*-positive group (group C in ABC (D) stratification system) had a moderately high hazard ratio of 11.23, while the atrophy-positive *H. pylori*-negative group (group D) had a markedly higher hazard ratio of 14.81. These two groups are therefore considered the most appropriate candidates for gastric cancer screening. It is well known that anti-*H. pylori* antibody production may be reduced when atrophy progresses because *H. pylori* does not survive very well in the intestinal metaplasia mucosa[6]. As group D represents the status of severe atrophic gastritis with marked intestinal metaplasia, it is the highest-risk group for developing gastric cancer. In addition, the atrophy-negative *H. pylori*-positive group (group B) had a relatively high hazard ratio of 4.20[6]. This group represents the status of *H. pylori*-induced active gastritis without extensive atrophy, which is thought to be one of the factors that contribute to the diffuse-type gastric cancer. As diffuse-type gastric cancer grows and invades faster than the intestinal type, this group is considered to be a candidate for a gastric cancer screening program. In this study, there were only 3 cases in group A when group A' patients were excluded. Seven patients in group A' were receiving proton pump inhibitor therapy or had previously been treated for eradicating *H. pylori* infection. As a result, precise medical interviews, such as prescription of proton pump inhibitors and a past history of *H. pylori* eradication are needed. Three group A cases had mucosal atrophy upon endoscopic examination. Based on this mucosal atrophy, these cases should be classified into group D. The pepsinogen levels of these patients are shown in Table 3. In this study, the serum PG status was defined as atrophic when the criteria of both serum PG I level $\leqslant$ 70 ng/mL and a PG I /PG II ratio $\leqslant$ 3.0 were simultaneously fulfilled. These criteria have a sensitivity of 70.5% and a specificity of 97%[16]. The serum PG I levels of the 3 group A cases were all $\leqslant$ 70 ng/mL. They were classified into normal PG because they had a PG I /PG II ratio > 3.0. This indicates that special attention should be paid to avoiding false negative cases of atrophic gastritis. None of the gastric cancer patients in our study were both *H. pylori* (-) and without atrophic gastritis. Ohata *et al*[4] reported a study with a cohort of 4655 healthy asymptomatic subjects (average age,

49 years) who were followed up for a mean period of 7.7 years. No cancer developed in the *H. pylori* (-)/normal PG group during their study period[4].

Graham and Asaka[17] proposed an eradication program for gastric cancer. Under their proposal, all adults would receive non-invasive testing for *H. pylori* infection and atrophic gastritis. All *H. pylori* infected patients would have confirmed *H. pylori* eradication[17]. Those with atrophic gastritis would be considered for further evaluation and possible surveillance[17]. The cases that were *H. pylori* (-) and had no atrophy would be excluded from the follow-up program. However, additional attention should be paid to mucosal atrophy, because the sensitivity of PG only 70.5%. Since the ultrathin transnasal endoscopy can be used for health check-ups, gastric cancer screening with ABC (D) stratification in combination with endoscopy may represent a useful screening system. In conclusion, our findings suggest that a combination screening for the *H. pylori* antibody titer and serum PG status may therefore be useful for predicting the development of gastric cancer. However, additional attention should be paid to avoiding false negatives for the patients who are taking acid proton pump inhibitors and those who have received prior eradication therapy for *H. pylori*. Endoscopy is needed for grey zone cases to accurately determine the mucosal atrophy status.

COMMENTS

Background

Gastric cancer remains the second leading cause of cancer death in Japan, although its mortality has continued to decrease for decades. Screening systems or methods to detect early gastric cancers have contributed to the decrease in gastric cancer deaths. The combination of serum pepsinogen (PG) and *Helicobacter pylori* (*H. pylori*) antibody [ABC (D) stratification] can serve as a useful predictive marker for diagnosing patients with gastric cancers.

Research frontiers

Recent studies concerning the use of ABC (D) stratification have focused on pa-

tients with either no disease or an unknown disease. There have so far been few analyses of ABC (D) stratification of patients confirmed to have gastric cancer.

Innovations and breakthroughs

ABC (D) stratification may be useful for predicting the development of gastric cancer. However, additional attention should be paid to avoiding false negatives for patients who are taking acid proton pump inhibitors and those who have received prior eradication therapy for *H. pylori*. Endoscopy is needed to evaluate grey zone cases to accurately determine the mucosal atrophy status.

Applications

Combination screening for the *H. pylori* antibody titer and serum PG status [ABC (D) stratification] is a good method for screening patients with gastric cancers.

Terminology

ABC (D) stratification is a screening method for patients with gastric cancer using a combination of the *H. pylori* antibody titer and serum PG status.

Peer review

This manuscript describes the evaluation of ABC (D) stratification in a group of patients confirmed to have gastric cancer. The authors found that ABC (D) stratification correlated closely with the disease status, but noted possible false negatives due to the fact that some patients have previously received treatments aimed at eradicating *H. pylori*. Overall, the study is well designed and the analysis approach is sound. Although the findings were somewhat expected based on previous studies, the study does provide further support for the use of the ABC (D) stratification system. The findings of this study would therefore be of interest to other researchers in this field if published.

Abstract

AIM: To evaluate the effect of autoclaved diet on the jejunum neurons of the myenteric plexus of rats during their growth.

METHODS: The experimental groups were made up of rats going through weaning whose mothers received either an autoclaved or a non-autoclaved diet during gestation and lactation, and rats that were fed the same diet as their mothers during the post-weaning period. In order to measure the neurons' body profile and to quantify the number of neurons per area, preparations were stained by the nicotinamide adenine dinucleotide-diaphorase method.

RESULTS: No significant changes were observed in rats' body weight or in the number of neurons regardless of the diet used ($P > 0.05$). There was a decrease in the jejunum-ileum length in rats treated with an autoclaved diet ($P < 0.05$). An increase in the neuronal cross-sectional area was seen in rats that had received the autoclaved diet, an effect that was significant for animals undergoing weaning. In addition, all observed factors showed significant differences when related to the age of the animals.

CONCLUSION: The autoclaved diet did not alter the quantity of neurons, but increased their cell body area, suggesting changes similar to those observed in protein deficiency.

Key words: Myenteric neurons; Jejunum; Morphometry; Diet; Autoclaving

INTRODUCTION

The nutritional makeup of the diet provided to laboratory animals and the procedures used for its preparation, storage, and sterilization must be evaluated not only to ensure the proper development of the animal, but also to avoid contamination with pathogenic microorganisms[1-3].

Animal facilities have traditionally used the recommended autoclaving conditions of 120 ℃ for 15 min to sterilize commercial diet, as this is an easy, safe and low cost process[4]. However, this exposure to high temperature may compromise the components of the ration, destroying vitamins and proteins and affecting the nutritional value of the diet[2,4,5].

Proteins may become more chemically reactive after autoclaving, leading to their degeneration or even to reaction with other substances, and compromising their digestibility, functionality and nutritional value[4,6].

These characteristics have been evaluated through the KOH protein solubility test, which has been shown to be a good indicator of the reduction of the amount of protein in feed[6-9].

It is known that animal tissues are not homogeneously affected by protein deficiency[10]. Thus, tissues that show low rates of metabolism or cell renewal are later compromised[11]. Different conditions of protein malnutrition have been shown to cause changes in the amount and size of neurons in the myenteric plexus of the segment of the gastrointestinal tract of rats of different ages[12-18]. The results indicated that factors such as nutritional quality of the diet and animal age might interfere with functional morphology of the myenteric plexus, resulting in impairment of the function of the digestive system and, consequently, the performance of the animal.

For these reasons, in addition to the concern of maintaining the composition of the diet provided to laboratory animals, the integrity of nervous system elements that control the activities of the digestive system, such as the myenteric plexus, is important for animal nutrition and production, since a structural impairment of this plexus in animals with some type of protein deficiency should not be ignored.

Thus, considering the key role of the jejunum (and consequently the myenteric plexus) in the process of nutrient absorption[19], and the practice of autoclaving for diet sterilization in the care of laboratory animals, the myenteric neurons of the jejunum of rats fed autoclaved rations during pre- and post-weaning periods were qualitatively and quantitatively evaluated.

MATERIALS AND METHODS

Animals and diet

Four female Wistar rats from the central animal facility of the Maringa State University, were housed separately in polypropylene boxes equipped with an automatic feeder and drinker, kept in a temperature-controlled (22 ℃) and photoperiod regulated room (12 h of light and 12 h of darkness). They received commercial water and food for rats (Nuvilab® CR1-Nuvital) ad libitum. After an adaptation period of one week, the animals were impregnated and divided into two groups, where two females made part of the control group (CG) and were maintained with a non-autoclaved diet (ND) with a soluble protein level of approximately 80.85% in KOH[20] (Figure 1). The remaining two females integrated into the experimental group (EG) and were fed with the same diet, except that the diet was autoclaved (120 ℃ for 15 min), leading to protein levels around 47.36% [autoclaved diet (AD)]. The composition of the diet is shown in Table 1.

At birth, the offspring of each female were equalized to five young males, which were divided into the following groups according to diet and periods of life: (1) CG21, 21-day-old animals whose mothers were maintained with ND during pregnancy and nursing; (2) EG21, 21-day-old animals whose mothers were maintained with AD during pregnancy and nursing; (3) CG70, animals whose mothers were maintained with AD during pregnancy and nursing and were then maintained with the same diet until 70 d of age; and (4) EG70, animals whose mothers received AD during pregnancy and nursing and were then maintained with the same diet until 70 d of age.

After weighing, the animals were euthanized by cervical dislocation and laparotomized in order to remove the jejunum.

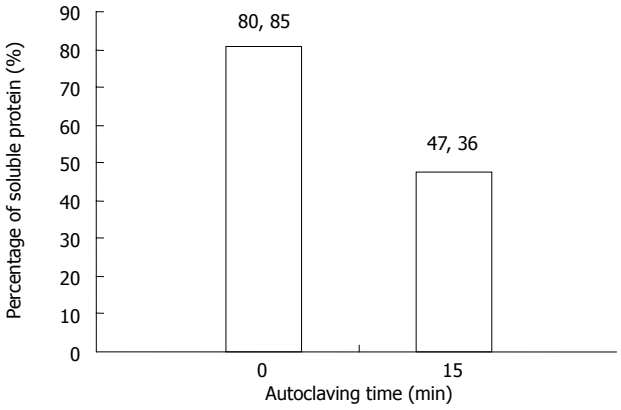

Figure 1 Percentage levels of soluble protein in KOH found in commercial diet according to the autoclaving time.

Table 2 Animals fed with an autoclaved diet (EG21 and EG7) compared to animals in the CG21 and CG70

Group	Body weight (g)	No. of neurons	Cell body area (μm^2)
CG21	46.8 ± 1.6[1]	1061.0 ± 50.72[1]	230.0 ± 10.9[1]
EG21	47.2 ± 1.7[1]	1168.0 ± 71.42[1]	282.1 ± 7.0[2]
CG70	237.4 ± 10.3[2]	881.4 ± 38.96[2]	347.4 ± 13.4[3]
EG70	252.4 ± 11.1[2]	969.4 ± 82.03[2]	377.4 ± 22.0[3]

Average and standard deviation of body weight (g), number of neurons and cell body area of reactive NADH-diaphorase myenteric neurons present in 8.96 mm2 of prepared membrane of the jejunum of rats during weaning periods (21 d), whose mothers received non-autoclaved rations (CG21) and autoclaved rations (EG21) during periods of pregnancy and nursing and of rats during post-weaning periods (70 d) fed with autoclaved feed (CG70) and non-autoclaved feed (EG70). Average followed by different numerals 1, 2, 3 in the same column differ ($P < 0.05$) by the Kruskal-Wallis test.

Nicotinamide adenine dinucleotide-diaphorase histochemical technique

The jejunum was initially washed in Krebs solution, ligated with cotton threads at its extremities and its lumen was filled with a syringe needle until slightly distended. After incubation in Krebs solution at room temperature for 15-30 min, the specimens were transferred to a permeabilizing agent (0.3% Triton-X in Krebs solution) for 60 s and then submitted to three 10 min washes in Krebs solution.

The specimens were then incubated for 60 min at 20 min in 20 mL of a medium containing 0.5 mg/mL nitro blue tetrazolium (Sigma-Aldrich) in distilled water (5 mL), 0.1 mol/L sodium phosphate buffer (5 mL, pH 7.3), distilled water (10 mL) and 0.5 mg/mL β-nicotinamide adenine dinucleotide (reduced form)[21].

The reaction was stopped by immersion in 10% buffered formalin solution in which the viscera were fixed (24 h minimum). Fragments of each jejunum about 1 cm in length were opened longitudinally. The mucosal and submucosal layers of these fragments were removed and the specimens were thoroughly washed in distilled water. Finally, whole-mount preparations were laid in glycerol on a microscope slide and sealed with Entellan (Merck KGaA, Darmstadt, Germany).

Morphoquantitative analysis

The neuronal density and the profile areas of the nerve cell bodies were measured by examining the whole-mount preparations under a binocular microscope at 400x magnification. For each specimen, all neurons present in 40 microscopic fields (0.224 mm^2 each) were counted (total area of 8.96 mm^2). The profiles of 80 random nerve cell perikarya from each specimen were obtained on a semiautomatic device for morphometry analysis (Image pro Plus, 3.01). The data were expressed as means ± SD and compared by Kruskal-Wallis test. The level of significance was set at $P < 0.05$.

Bioethics

All experimental procedures were reviewed and approved by the Bioethics Committee of the School of Medicine and Veterinary of the University of São Paulo.

RESULTS

The animals fed with an autoclaved diet (EG21 and EG70) showed an increase in body weight of 0.83% and 6.3%, respectively, compared to animals in the CG21 and CG70 (Table 2). However, there was no statistically significant difference ($P > 0.05$) when comparing groups of same age (21 d and 70 d).

Through the nicotinamide adenine dinucleotide (NADH)-diaphorase reaction, it was verified that the myenteric plexus was organized in elongated ganglia containing neurons of different sizes in all studied groups. These ganglia were scattered and arranged in parallel in the same direction as the muscle bundles of the circular layer of the muscular coat of jejunum.

The number of myenteric neurons present in 8.96 mm^2 of jejunum differed between the 21- and 70-day-old animals, with lower amounts present in the 70-day-old animals ($P < 0.05$) (Table 2). However, when comparing the same age groups, (CG21 and EG21; CG70 and EG70), the number of neurons was shown to not change after use of autoclaved diet. Animals from the EG21 and EG70 groups showed an increase of 9.2% and 9% in the number of neurons when compared with the CG21 and CG70 groups, respectively, but this increase did not reach statistical significance ($P > 0.05$).

The area of the neuron cell bodies ranged from 105.1 μm^2 to 553.9 μm^2 in the CG21 group and from 101.1 μm^2 to 640.7 μm^2 in the EG21 group. In the CG70 group, the dimensions ranged from 95.2 μm^2 to 713.2 μm^2 and from 97.3 μm^2 to 843 μm^2 in the EG70 group.

The average size of myenteric neurons was smaller ($P < 0.05$) for younger animals (CG21 and EG21) compared to the 70-day-old animals (CG70 and EG70). The neurons from the CG70 and EG70 groups showed an increase in their average area of around 51% and 33.8%, respectively, when compared to their control groups (CG21 and EG21) (Table 2).

Statistically, it was found that the average area of the neuronal cell body differed between animals from the CG21 and EG21 groups ($P < 0.05$), with higher values for animals from EG21, whose mothers received an autoclaved diet during pregnancy and nursing (Table 2). Although it was verified that neurons in the CG70 group showed a cell body average area smaller than that observed in EG70, the differences in this parameter between the two groups were not significant ($P > 0.05$) (Table 2).

DISCUSSION

After autoclaving, the quality of the protein was altered in the diet sterilization procedure, reducing the usable protein content and indicating that animals in the EG21 and EG70 groups received feed with a lower protein quality than those in their respective control groups

(CG21 and CG70).

Regardless of whether the diet was autoclaved, animals gained body weight during the experiments because of the natural growth and development from birth to adulthood. Although not statistically significant ($P > 0.05$), animals in the EG21 and EG70 groups had weight gain 0.85% and 6.3% higher than their respective controls (CG21 and CG70). In contrast, studies that examined rats of various ages and during different periods of protein malnutrition reported a decrease in body weight[13-17,22,23]. These differences are justifiable since the autoclaving temperature of the feed used in this study does not significantly alter the performance of rats in pre- or post-weaning periods. The compromise in animal performance is seen after autoclaving feed at temperatures higher than those used in our study[9]. Thus, the change in protein quality of the autoclaved ration given to animals in this study was not sufficient to influence a significant variation in animals' body weight.

The reactive NADH-diaphorase myenteric neurons of the jejunum were organized predominantly in a dispersed ganglion distributed parallel to the direction of muscles fibers of circular layers of the muscular coat, as described for the myenteric plexus of rats[24].

In the quantitative analysis, although animals from the experimental groups (EG21 and EG70) had respective increases of 9.2% and 9% in the quantity of neurons compared to their controls (CG21 and CG70), the number of myenteric neurons present in 8.96 mm^2 of jejunum in animals that were fed with an autoclaved diet did not change, since the average amount of neurons observed did not differ ($P > 0.05$) among animals from the CG21 (1061 ± 50.72) and EG21 (881.4 ± 38.96) groups, and even among animals from CG70 (881.4 ± 38.96) and EG70 (969.4 ± 82.03).

On the other hand, the number of myenteric neurons present in 8.96 mm^2 of jejunum differed ($P < 0.05$) among 21- and 70-day-old animals, with lower values seen in 70-day-old animals. The decrease of 16.9% among the 21-day-old animals and 17% among 70-day-old animals indicates that the quantity of neurons was not influenced by the provided diet. It is believed that the numbers of neurons does not decrease, but increases during the animals' growth period, and the observed decreases are only related to the greater dispersion of neurons in the organ[24,25].

In the morphometric analysis, we verified that the average area of cell body of reactive NADH-diaphorase myenteric neurons varied and differed ($P < 0.05$) during nursing and post-weaning periods. In general, the cell body area of neurons increased in animals from the CG70 (347.4 ± 13.4 μm^2) and EG70 (377.4 ± 22 μm^2) groups when compared to animals from the CG21 (230 ± 10.9 μm^2) and EG21 (282.1 ± 7.0 μm^2) groups, respectively.

However, animals that received an autoclaved diet (EG21) during pregnancy and lactation had a significant increase in neuron cell body area (22.65%) ($P < 0.05$) during the suckling period. On the other hand, there was an increase of 8.65% in the cell body area of neurons for animals from the EG70 group compared to animals from the CG70 group, but this effect was not statistically significant. These data suggest an effect of autoclaved diet on the area of myenteric neurons during the suckling period, which is different from the effect shown in the other study[15], which observed a small reduction in the size of neurons in the myenteric plexus under severe protein restriction.

Thus, an increase in the area of the cell body of myenteric neurons could be a response to nutritional deficiency associated with exposure time or the level of this deficiency. The increase in cell body area was mainly seen in animals from the EG21 group, whose mothers received an autoclaved diet during the pregnancy and lactation period, and this could be a neuronal response in order to remedy possible deficiencies. Neurons can increase metabolic activities to compensate for the decrease in protein quality of the ration, but our results could indicate neurons' lower ability to achieve maximum expected development during the growth process.

The increase in neuronal size during animal growth is expected[24]. However, the fact that the neurons of animals that received an autoclaved diet during the post-weaning period had a growth level of 33.8% (lower than the 51.5% seen in CG70 animals) may suggest that an autoclaved diet causes a nutritional deficiency that inhibits the normal development of neurons during the post-weaning period. However, tests must be conducted to confirm this assumption.

Based on the solubility analysis of the protein in animal feed in KOH, it was found that the protein solubility level was 47.36% after autoclaving and 80.85% before autoclaving, indicating a decrease in the protein digestibility of 33.49%[8]. This means that the autoclaved diet had a usable protein level of 10.52% compared to the 17.97% of non-autoclaved diet, which falls below the 15% suggested by the National Research Council (NRC)[26] for rats undergoing pregnancy, lactation and growth.

Despite the low level of usable protein in the autoclaved diet (10.52%), it is still higher than the 8% used in some studies examining protein deficiency[14,16,17,22]. However, as the NRC[26] establishes a minimum protein level of 15% for rats during reproduction, pregnancy, lactation and growth periods and a level of 5% for maintenance phase, autoclaving the feed decreases the quality of the protein and may have interfered in neuronal development. This fact is corroborated by the size of neuronal cell bodies of animals that did not receive an autoclaved diet and those that did. Thus, although autoclaving the feed is more desirable, based on cost and safety, than other sterilization processes[4], its use must be considered when the objective of the research is to evaluate the nervous system.

In summary, the use of an autoclaved diet during pregnancy, lactation and post-weaning does not alter the quantity of reactive NADH-diaphorase myenteric neurons in the jejunum but does interfere with the increase

in cell body area of neurons, preventing the neuron cell body from reaching a size similar to that observed using a non-autoclaved diet, suggesting a lower metabolic activity for those neurons.

ACKNOWLEDGMENTS

The authors would like to thank Dr. Lilian J Oliveira and Dr. Janaina M Monteiro for their support with the laboratory procedures.

COMMENTS

Background

Neurons morphological characteristics influence their functional performance. Most of these characteristics develop early in neuron development, and therefore may be influenced by external factors such as nutritional quality, which must be well known and controlled.

Research frontiers

The exposure to high temperature may compromise the components of the ration, destroying vitamins and proteins and affecting the nutritional value of the diet. It occurs during the autoclaving process, altering the expected performance of the provided diet.

Innovations and breakthroughs

Recent studies indicate that factors such as nutritional quality of the ration and animal age may interfere with the morphofunctional aspects of the myenteric plexus compromising digestive system function, and consequently the animal's performance.

Applications

Changes in the nutritional values of autoclaved diets may be considered to correct possible tissue loss during animal growth and development.

Terminology

The identification of myenteric neurons by the nicotinamide adenine dinucleotide (NADH)-diaphorase histochemical technique occurs through formation of formazan granules from an artificial electron acceptor (nitro blue tetrazolium), allowing the evaluation of respiratory activity of neurons, which provides evidence of their metabolic activity.

Peer review

This manuscript is an interesting article in an attempt to evaluate the effect of autoclaved diet on the jejunum neurons of the myenteric plexus of rats during their growth phase. The results suggest that changes similar to those observed for protein deficiency occur in rats that have been fed with an autoclaved diet, but that this occurs to a lesser degree than for true protein deficiency.

Abstract

AIM: To investigate the appropriate time for combination therapy in HBeAg positive chronic hepatitis B (CHB) patients with decompensated cirrhosis.

METHODS: Thirty HBeAg positive CHB patients with decompensated cirrhosis were enrolled in the study. All of the patients were given 48 wk combination therapy with lamivudine (LAM) and adefovir dipivoxil (ADV). Briefly, 10 patients were given the *de novo* combination therapy with LAM and ADV, whereas the other 20 patients received ADV in addition to LAM after hepatitis B virus (HBV) genetic mutation.

RESULTS: Serum alanine aminotransferase and total bilirubin were both improved in the two groups at 4, 12, 24 and 48 wk after treatment. Serum albumin was also improved at 24 and 48 wk after combination therapy in both groups. The serum HBV DNA level was still detectable in every patient in the two groups at 4 and 12 wk after combination treatment. However, in the *de novo* combination group, serum HBV DNA levels in 4 (40%) and 9 (90%) patients was decreased to below 1×10^3 copies/mL at 24 and 48 wk after the combination treatment, respectively. In parallel, serum HBV DNA levels in 2 (20%) and 8 (40%) patients in the add-on combination group became undetectable at 24 and 48 wk after combination treatment, respectively. Furthermore, 6 (60%) patients in the *de novo* combination group achieved HBeAg seroconversion after 48 wk treatment, whereas only 4 (20%) patients in the add-on combination group achieved seroconversion. Child-Pugh score of patients in the *de novo* combination group was better than that of patients in the add-on combination group after 48 wk treatment. Moreover, patients in the *de novo* combination group had a significantly decreased serum creatinine level and elevated red blood cell counts.

CONCLUSION: *De novo* combination therapy with LAM and ADV was better than add-on combination therapy in terms of Child-Pugh score, virus inhibition and renal function.

INTRODUCTION

Hepatitis B virus (HBV) is prevalent world-widely. World Health Origination estimates that approximately 400 million people are chronic HBV carriers around the world[1]. Chronic hepatitis B (CHB) is a leading cause of hepatic cirrhosis and hepatocellular carcinoma (HCC)[1]. Once cirrhosis develops, mortality is high in untreated patients. The 5 years mortality rate of CHB patients with decompensated cirrhosis is 86%[2]. Therefore, it is necessary to develop an effective therapy for those decompensated cirrhosis patients infected with chronic HBV.

The treatment for decompensated cirrhotic patients aims to delay the occurrence of HCC. Recommended therapy options are nucleos(t)ide analogues, such as lamivudine (LAM), adefovir dipivoxil (ADV) and entecavir (ETV). Previous studies showed that LAM is effective in cirrhotic patients infected with chronic HBV[3,4]. However, the clinical benefit of LAM is limited by the emergence of resistant mutant strains[5,6]. Recently, ADV has been strongly considered as a rescue therapeutic agent to resistant mutants[7,8]. Several studies showed that combination therapy with LAM and ADV is better than ADV monotherapy in LAM-resistant patients infected with HBV[7,9,10]. However, it remains unclear how to start the combination therapy in HBeAg positive patients with decompensated cirrhosis secondary to hepatitis B. In the present study, we aimed to evaluate the better combination therapy in HBeAg positive patients with decompensated cirrhosis secondary to hepatitis B.

MATERIALS AND METHODS

Patients

Adult patients who had CHB with decompensated cirrhosis and HBeAg positive were enrolled in the study from January 2008 to June 2010 in Peking University First Hospital and Shijiazhuang Fifth Hospital. The criteria for diagnosis of hepatitis were those which appear in the guidelines for prevention and treatment of CHB in China[11]. The diagnosis of decompensated cirrhosis was based on clinical, laboratory, previous histological, ultrasonographic and radiological signs of cirrhosis with at least one sign of liver decompensation (ascites, variceal bleeding, hepatic encephalopathy, non-obstructive jaundice). Patients co-infected with hepatitis A virus, hepatitis C virus, hepatitis D virus, hepatitis E virus, or human immunodeficiency virus and with alcoholic cirrhosis, autoimmune hepatitis, hepatorenal syndrome, HCC or severe heart, brain, renal diseases were excluded from the study. All of the patients were both HBV DNA and HBeAg positive. A total of 30 patients were enrolled in the study. Child-Pugh score was used to assess the clinical status of every patient[12]. Sixteen patients were at B stage (mean score: 8.4), and the other 14 patients were at C stage (mean score: 11.1).

Treatment of patients

All of the patients were given LAM (100 mg/d QO, GSK, Suzhou, China) at the beginning of treatment. Ten of them were then given ADV 10 mg/d (QO, GSK, Suzhou, China) over the following 2 wk (*de novo* combination arm), while the other 20 patients received ADV 10 mg/d in addition to LAM after HBV genetic YMDD mutation (add-on combination arm). The duration of combination treatment was 48 wk for both arms.

Biochemical and virological analysis

Peripheral blood was taken from all of the patients in the morning with fasting for at least 8 h. HBsAg, HBsAg antibody (anti-HBs), HBeAg, HBeAg antibody (anti-HBe) and HBcAg antibody (anti-HBc) were detected by AxSYM MEI kits (Abbott Laboratories, United States). Serum HBV DNA level was measured by quantitative polymerase chain reaction (PCR) (Daan Gene Co., LTD of Sun Yan-sen University, Guangzhou, China) at certain time points (week 0, 4, 12, 24 and 48) during treatment. The detection limit of HBV DNA was 1×10^3 copies/mL.

Routine biochemical and hematological tests were performed at the participating centers using automated techniques at certain time points (week 0, 4, 12, 24 and 48) during treatment. Child-Pugh score was also assessed simultaneously.

Statistical analysis

Data were expressed as arithmetic mean ± SD, median (range), or frequency and percentage when appropriate. Student *t* test was used to analyze the normally distributed quantitative variables between the two study groups. Mann-Whitney rank sum test was used to analyze the skewed data. All tests were two tailed, and *P* value less than 0.05 was considered statistically significant. All statistical calculations were done using the SPSS 16.0 (Statistical Package for the Social Science; SPSS Inc., Chicago, IL, United States) statistical software.

RESULTS

Baseline characteristics

A total of 30 patients were enrolled in the study, including 17 males (56.7%) with a median age of 42 years (40-49 years). Data showed that serum alanine aminotransferase (ALT), total bilirubin (TBIL) and albumin (ALB) levels at baseline in the *de novo* combination patients were significantly lower than those in the add-on combination patients. However, mean serum HBV DNA level and Child-Pugh score were not different between the two groups. Table 1 shows the baseline characteristics of the study population.

Virological response

The percentage of patients with undetectable HBV DNA in the *de novo* combination group was 0, 0, 40% and 90% at 4, 12, 24 and 48 wk after the treatment, respectively. However, it was 0, 0, 20% and 40% at each time point in the add-on combination group, respectively. Figure 1 shows that the percentage of patients

Table 1 Characteristics of patients at baseline, median (min-max)

Characteristic	*De novo* combination group (n = 10)	Add-on combination group (n = 20)	P value
Age (yr)	45.6 ± 8.2	45.2 ± 8.2	0.89
Gender (males,%)	6 (60%)	11 (55%)	1
Height (m)	1.7 ± 0.7	1.7 ± 0.9	0.58
Weight (kg)	68.9 ± 9.7	67.3 ± 10.5	0.69
BMI (kg/m^2)	23.8 ± 1.8	23.7 ± 1.6	0.88
HBV DNA levels (log_{10}, copies/mL)	6.23 ± 0.91	6.43 ± 0.95	0.58
Serum ALT (IU/L)	124 (82-156)	283 (187-321)	0
Serum TBIL (μmol/L)	49.5 (23-72)	73.5 (49.0-99.6)	0.001
Serum ALB (g/L)	29.75 (25.40-34.00)	26.65 (23.00-32.00)	0.021
Child-Pugh score	11 (9-13)	11 (9-13)	0.809
Red blood cell counts (× 10^{12}/L)	3.6 (3.0-4.5)	3.3 (1.9-5.0)	0.234
HB (g/L)	106 (90-120)	97 (75-115)	0.059
White blood cell counts (× 10^9/L)	3.85 (2.70-6.80)	3.75 (1.90-6.00)	0.657
Blood PLT count (× 10^9/L)	96 (76-150)	96 (50-112)	0.657
Serum BUN (mmol/L)	6.05 (3.70-8.10)	4.35 (1.90-8.50)	0.139
Serum Cr (μmol/L)	99.5 (77.0-145.0)	77.0 (40.0-156.0)	0.024

BMI: Body mass index; HBV: Hepatitis B virus; ALT: Alanine aminotransferase; TBIL: Total bilirubin; ALB: Albumin; HB: Hemoglobin; PLT: Platelet; BUN: Blood urine nitrogen; Cr: Creatinine.

with undetectable HBV DNA was significantly different between the two groups after the 48 wk treatment (P = 0.017). Moreover, no patient in the two groups showed detectable virological resistance during the 48 wk combination treatment.

Biochemical response

We showed that ALT, TBIL and ALB of patients were decreased in the two groups after treatment. Furthermore, 6 (60%) patients in the *de novo* combination group achieved HBeAg seroconversion, whereas only 4 (20%) patients in the add-on combination group achieved seroconversion (P = 0.045).

Child-Pugh score at baseline was not statistically different in the two groups. Table 2 shows that Child-Pugh score in the *de novo* combination group was significantly lower than that in the add-on combination group after the 48 wk treatment.

Hematological changes and renal function

Red blood cell counts and hemoglobin levels in the 2 groups showed no difference at baseline. However, red blood cell counts and hemoglobin in the *de novo* combination group were higher than those in the add-on combination group at 24 and 48 wk after treatment. White blood cell counts and platelet (PLT) level showed no difference between the two groups at baseline and during the treatment period.

Moreover, serum blood urine nitrogen (BUN) level was not different between the two groups at baseline and during treatment. Serum creatinine (Cr) at baseline in the *de novo* combination group was significantly higher than

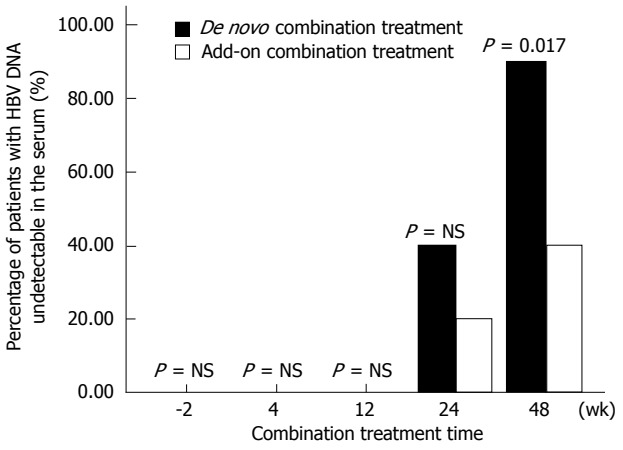

Figure 1 The percentage of decompensated cirrhotic chronic hepatitis B patients with undetectable hepatitis B virus (HBV) DNA in the serum of the two groups during the treatment period. NS: Not signifcant.

that in the add-on combination group. However, serum Cr level in the 2 groups was not significantly different after treatment (Table 3).

Side effects

Both *de novo* combination treatment and add-on combination treatment were well tolerated. No patient in either group discontinued the drug during the period.

In the *de novo* combination group, serum BUN level of two patients was slightly increased, two patients had slight diarrhea, and one patient had nausea. In parallel, in the add-on combination group, serum BUN level of two patients was slightly increased, two patients had nausea, one patient had slight diarrhea, and one patient had upper gastrointestinal hemorrhage. All these symptoms disappeared after relevant management.

DISCUSSION

In this retrospective study, we compared *de novo* combination therapy with add-on combination therapy in HBeAg positive and decompensated cirrhosis patients infected with HBV. The percentage of patients with undetectable HBV DNA was 40% (4/10) and 20% (4/20) in the *de novo* combination and add-on combination groups at 24 wk after treatment, respectively. However, this difference between two groups was not statistically different. The percentage of patients with undetectable HBV DNA in the *de novo* combination group (9/10, 90%) was significantly higher than that in the add-on combination group (8/20, 40%) at 48 wk after treatment. We, for the first time, compared *de novo* combination treatment with add-on combination treatment in cirrhotic decompensated patients secondary to hepatitis B. Some researchers compared LAM and ADV combination therapy with ADV monotherapy after LAM-induced viral genetic resistance. They showed that LAM and ADV combination therapy is a more effective treatment to get a virological response and has lower genetic resistance than ADV monothera-

py[7-9]. However, the efficiency of LAM and ADV combination therapy in treatment naïve patients with decompensated cirrhosis remains unclear. In the present study, we showed that *de novo* combination therapy was more effective than add-on combination therapy in terms of virological response and HBeAg seroconversion. No patient achieved virological resistance during combination treatment in both two groups.

It is known that HBeAg seroconversion is accompanied by biochemical and histological regression of liver disease[13,14]. Our data showed that the percentage of HBeAg seroconversion in the *de novo* combination group (6/10, 60%) was significantly higher than that in the add-on combination group (4/20, 20%).

Due to its simplicity in clinical practice, Child-Pugh score has been widely applied as the prognostic marker in patients with decompensated cirrhosis[15,16]. Child-Pugh score is one of the risk factors for assessing patients with decompensated cirrhosis[17]. In this study, Child-Pugh score of all patients was significantly decreased in the two groups after 24 and 48 wk combination treatment. Child-Pugh score at baseline was not different between the two groups. However, the score in the *de novo* combination group was superior to that in the add-on combination group after 48 wk treatment. LAM and ADV combination therapy could improve clinical symptoms in patients with decompensated cirrhosis. But, *de novo* combination therapy was more effective in improving hepatic function than LAM and ADV combination therapy after genetic resistance.

ALT, TBIL and ALB of the patients were different at baseline between the two groups. However, these three parameters were all significantly decreased in the two groups during the treatment period. LAM and ADV combination therapy was an effective way to produce a biochemical response in CHB patients with decompensated cirrhosis.

It has been reported that ADV decreases renal function[18]. In our study, serum Cr and BUN levels of all patients were not increased during the treatment period. However, serum Cr level in the *de novo* combination group was significantly higher than that in the add-on combination group (104.0 ± 23.5 *vs* 83.0 ± 29.4, $P < 0.05$) at baseline. But serum Cr in the two groups was not dif-

ferent after the 48 wk treatment. Our data showed LAM and ADV combination therapy did not affect renal function during the treatment period. The *de novo* combination therapy could improve serum Cr level in the decompensated cirrhosis patients infected with chronic HBV.

Taken together, a higher percentage of patients with undetectable HBV DNA and HBeAg seroconversion was obtained from the *de novo* combination group than from the add-on combination group. Moreover, Child-Pugh score in patients with the *de novo* combination therapy was better than that in patients with the add-on combination therapy after 48 wk treatment. Therefore, HBeAg positive decompensated cirrhotic patients infected with chronic HBV should receive LAM and ADV combination therapy at the beginning of antiviral treatment.

In the present study, we have several shortcomings as follows. First, the number of subjects was small because the number of patients treated with *de novo* combination therapy was limited in China. Second, the period of the combination treatment was not long enough. Therefore, a larger number of subjects and longer treatment duration are required in our future study.

COMMENTS

Background

The mortality rate of chronic hepatitis B patients with decompensated cirrhosis is very high. Recommended therapy options are nucleos(t)ide analogues. But, the combination treatment option with nucleos(t)ide analogues for HBeAg positive patients with decompensated cirrhosis secondary to hepatitis B is not very clear.

Research frontiers

Combination therapy with lamivudine (LAM) and adefovir dipivoxil (ADV) is better than ADV monotherapy in LAM-resistant patients infected with hepatitis B virus. But in HBeAg positive patients with decompensated cirrhosis secondary to hepatitis B, it remains unclear whether combination treatment at the beginning of therapy is better than add-on combination therapy. In this study, the authors demonstrate that *de novo* combination therapy is more effective than add-on combination therapy with LAM and ADV in HBeAg positive patients with decompensated cirrhosis secondary to hepatitis B.

Innovations and breakthroughs

Some research showed that LAM and ADV combination therapy is more effective as a means to get a virological response and has lower genetic resistance than ADV monotherapy after LAM-induced viral genetic resistance. However, the efficiency of LAM and ADV combination therapy in naïve patients with decompensated cirrhosis is unclear. For the first time, this study compared *de novo* combination treatment with add-on combination treatment in the cirrhotic decompensated patients secondary to hepatitis B.

Applications

By understanding that *de novo* combination therapy is more effective than add-on combination therapy, this study may represent a future strategy in the treatment of HBeAg positive patients with decompensated cirrhosis secondary to chronic hepatitis B.

Terminology

De novo combination treatment means combination treatment with two or more drugs from the beginning of the treatment. Child-Pugh score is a system to assess the disease stage for decompensated cirrhotic patients.

Peer review

In this study, the authors have made an attempt to determine the effective time frame for combined therapy used in HBeAg positive chronic hepatitis B patients with decompensated cirrhosis. Though the study is limited to only 30 patients, it is novel and contributes a substantial amount of knowledge to the field.

Abstract

AIM: To evaluate the impacts of *Schistosoma japonicum* (*S. japonicum*) ova on the tight junction barriers in a trinitrobenzenesulfonic acid (TNBS)-induced colitis model.

METHODS: Balb/c mice were randomly divided into three groups: control group; $TNBS^+ova^-$ group and $TNBS^+ova^+$ group. TNBS was used intracolonic to induce colitis and mice of the $TNBS^+ova^+$ group were pre-exposed to *S. japonicum* ova as a prophylactic intervention. Colon inflammation was quantified using following variables: mouse mortality, weight loss, colon extent and microscopic inflammation score. Serum expression of tumor necrosis factor-α and interferon-γ were assessed to evaluate the systemic inflammatory response. NOD2 and its mRNA were also tested. Bacterial translocations were tested by culturing blood and several tissues. ZO-1 and occludin were chosen as the representations of tight junction proteins. Both the proteins and mRNA were assessed.

RESULTS: Ova pre-treatment contributed to the relief of colitis and decreased the mortality of the models. NOD2 expression was significantly downregulated when pretreated with the ova. The TNBS injection caused a significant downregulation of ZO-1 and occludin mRNA together with their proteins in the colon; ova pre-exposure reversed these alterations. Treatment with *S. japonicum* ova in the colitis model caused lower intestinal bacterial translocation frequency.

CONCLUSION: *S. japonicum* ova can maintain epithelial barrier function through increasing tight junction proteins, thus causing less exposure of NOD2 to the luminal antigens which may activate a series of inflammatory factors and induce colitis.

Key words: Crohn's disease; *Schistosoma japonicum* ova; Tight junction protein; ZO-1; Occludin

INTRODUCTION

Crohn's disease (CD) is a chronic inflammatory disorder of the gastrointestinal tract. Although the etiology is multifactorial and remains incompletely understood, inflammation, immunity, genetic and environmental factors have been suggested to predispose to CD[1]. Despite the multiple mechanisms that have been investigated

hitherto, proinflammatory cytokines play the most important role since they are the ultimate pathway that leads to the colitis. Therapies targeting these proinflammatory cytokines have been extensively investigated and shown to be effective both in animal experiments and clinical trials[2-3].

In addition, CD patients demonstrate increased intestinal bacterial translocation (IBT), which may be due to the increased intestinal pericellular permeability, reflecting the decreased epithelial barrier function[4]. The tight junctions (TJs), which form the pericellular barrier, are thought to be the primary determinant of mucosal permeability in the presence of an intact epithelium[5]. Impaired TJs lead to an increase of exposure of intestinal bacteria to submucosal pattern pathogen recognition receptors (PPRRs), such as toll-like receptors (TLRs) and nucleotide-binding-oligomerization domains (NODs). NOD2 has been found to exert antibacterial activity limiting survival of enteric bacteria after invasion[6-7]. As one of the main responsible genes, NOD2 and its protein have been found to be upregulated in CD patients[8].

It is well established that helminthes can protect mice from experimental colitis[9-11]. We have also demonstrated in our former study that freeze-killed *Schistosoma japonicum* (*S. japonicum*) ova could relieve the colon inflammation and prevent IBT in a trinitrobenzenesulfonic acid (TNBS)-induced model by upregulating Th2-type cytokine and downregulating TLR4 mRNA expression[12]. In the present study, we further investigate the influence of *S. japonicum* ova on TNBS-induced colitis in mice and whether *S. japonicum* ova prevent IBT by upregulating tight junction proteins. Since TLR4, one of the main extracellular receptors of enteric antigens, has been found to be upregulated in TNBS-induced colitis which was blocked by the pretreatment of *S. japonicum* ova[12], we further discuss here whether NOD2, one of the main intracellular receptors, has the same ability.

MATERIALS AND METHODS

Animals

Ninety Balb/c mice (Animal Center of Shanghai Laboratory, Chinese Academy of Science) were randomly divided into 3 groups. Twenty mice from the control group received an intra-colonic injection of 0.5 mL saline on day 15. Forty mice from the $TNBS^+ova^-$ group received an intra-colonic injection of 0.5 mL TNBS (Sigma) on day 15. Thirty mice from the $TNBS^+ova^+$ group received intra-peritoneal injections of 10 000 freeze-killed *S. japonicum* ova (Zhejiang Academy of Medical Science) on day 1 and day 11, and were challenged with TNBS on day 15. The surviving mice were sacrificed on day 22. Serum expression of tumor necrosis factor (TNF)-α and interferon (IFN)-γ were detected. Ten animals from each group were randomly selected and the full-length colon from these animals was isolated and evaluated.

Another 30 mice were grouped according to the former methods and were sacrificed on day 16. Blood, liver, spleen and mesenteric lymph nodes (MLN) were cultured and the identification of bacteria was completed using VITEK-32 Auto Microbiotic System (bioMérieux).

GAPDH sense	5′-GGTGAAGGTCGGTGTGAACG -3′	233
GAPDH antisense	5′-CTCGCTCCTGGAAGATGGTG-3′	

GAPDH: Glyceraldehyde phosphate dehydrogenase.

Evaluations of the colonic inflammation

Mice were weighed daily and the numbers of surviving mice were recorded. The extents of colon were assessed in the sacrificed mice. The proximal 1.0 cm of the colonic segment was used for histology. The segment was fixed in 4% formaldehyde and embedded in paraffin. Morphometric analysis was performed on haematoxylin-eosin-stained 4 μm transverse sections. The microscopic slides were reviewed by two histologists blinded to the groups. The extent of damage and colonic inflammation was assessed using a modification of the histopathological grading system of Macpherson and Pfeiffer[13].

Enzyme linked immunosorbent assay for serum IFN-γ and TNF-α

Mouse serum was assembled for enzyme linked immunosorbent assay (ELISA). ELISA was performed according to the manufacturer of the kits instructions. TNF-α ELISA kit was a product of Sigma Co. IFN-γ ELISA kits were purchased from Jingmei biotech.

Realtime-PCR analysis

Colons were removed, washed in phosphate buffered solution, and then flash frozen in liquid nitrogen. Total RNA was extracted using Trizol reagent (TAKARA) according to the manufacturer's protocol. RNA was treated with DNase (TAKARA) and was converted to cDNA using a reverse transcription kit as described by the manufacturer (INVITROGEN). Primers for PCR (INVITROGEN) were listed in Table 1. The parameters for PCR amplification were as follows: 95 ℃: 10" × 1 cycle, 95 ℃: 5"→60 ℃ 20"→55 ℃ 20" × 40 cycles. The concentration of each sample was calculated from the threshold cycle (Ct). The fluorescent products were detected by LightCycle system (BIO-RAD IQ5) before the completion of each cycle.

Western blotting analysis

The colons were lysed and homogenized in ice-cold RIPA lysis buffer (Beyotime, Jiangsu, China). Proteins were loaded onto each well of SDS-polyacrylamide Ready

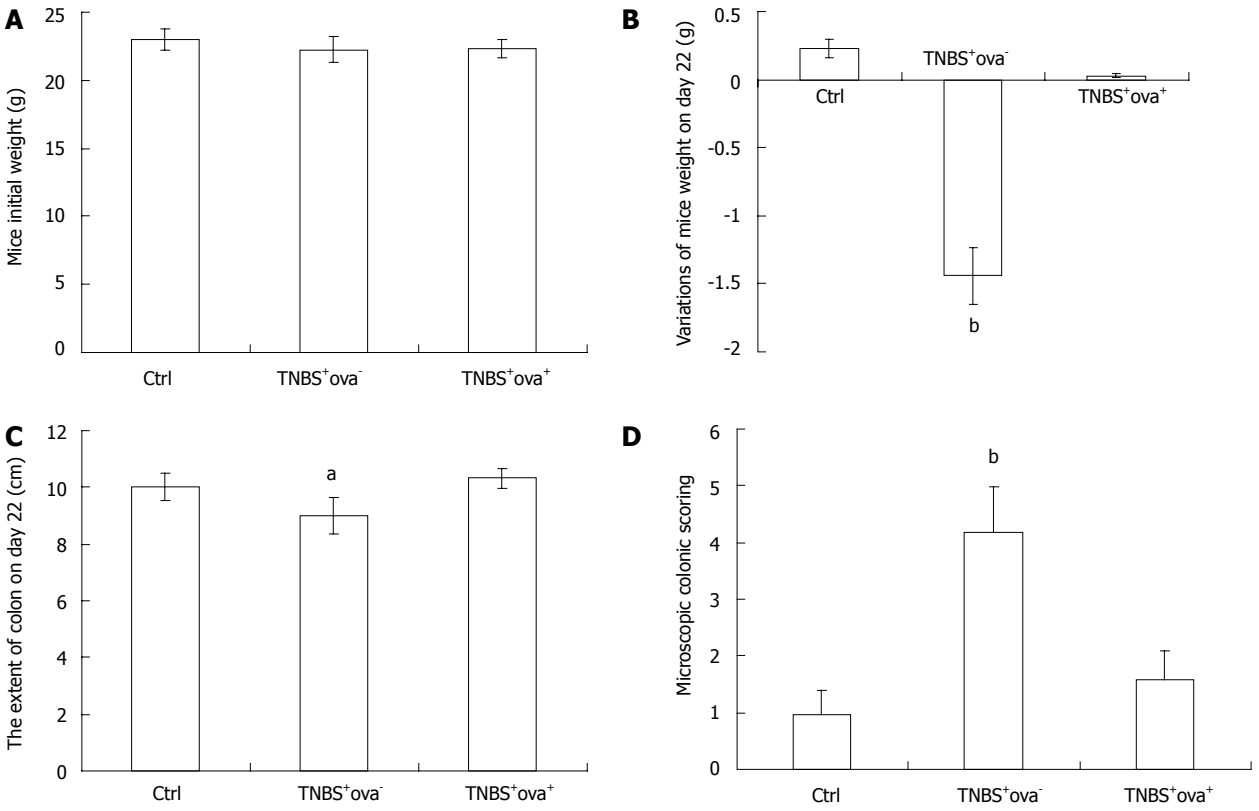

Figure 1 The evaluations of colitis. The initial weight of each group (A) and variations of weight (B), colon extent (C) and microscopic colonic scoring (D) on day 22. Data are presented as mean ± SD. $n = 10$, $^{a}P < 0.05$ *vs* the other two groups; $^{b}P < 0.01$ *vs* the other two groups. TNBS: Trinitrobenzenesulfonic acid.

Gels (BioRad, Hercules) for electrophoresis. Proteins were transferred onto a nitrocellulose membrane (BioRad, Hercules) by electroblotting. The membrane was washed and blocked with 5% milk in Tris-buffered saline with 0.05% Tween-20, and incubated overnight with specific primary antibody at 4 ℃. Rabbit anti-mouse-Occludin-mAb (2 μg/mL, ZYMED), rabbit anti-mouse-ZO-1-mAb (3 μg/mL, Abcam) and rat anti-mouse-NOD2-mAb (eBioscience) were used as the primary antibodies. HRP-conjugated goat anti-rabbit-IgG (1:1000, Santa Cruz) was employed as the secondary antibody. Membranes were washed and the assessed proteins were detected using an enhanced chemiluminescence reagent (Amersham Biosciences). Relative intensity of the bands was quantified using Leica image analysis software (Alphaln notech).

Assessment of bacterial translocation

Blood, liver, spleen and MLN were removed under sterile conditions. Blood was plated onto sheep's blood agar and tissues were slit and cultured with sterile broth at 36 ℃ for 24 h. The limpid medium was then incubated for another 6 d. Each turbid medium was considered as positive regardless of its incubation time. The positive medium was plated onto sheep's blood agar and eosin-methylene blue (EMB) agar. The blood agar and EMB agar were purchased from Shanghai Reagent Providing and Research Center for Diarrhea Disease Control. Cultures were incubated at 37 ℃ for 3 d. Any bacterial growth in the broth or on the agar plates was identified with standard microbiological methods on VITEK-32 Auto Microbic System.

Data analysis

All data were analyzed using SPSS 14.0 and are presented as means ± SD. Nonparametric data were analyzed by Kruskal-Wallis test with Mann-Whitney *U* post-hoc test. Parametric data were analyzed by 2-way ANOVA with SNK post-hoc test. The *P* value was considered significant if less than 0.05.

RESULTS

Mice common appearance and mortality

Exposure to schistosome eggs reproducibly ameliorated TNBS colitis in treated mice. Mice of the TNBS^{+}ova^{+} group presented with inapparent bloody stools, weight loss and activity reduction. The extent of the colon was shortened in TNBS-induced models and this was reversed in the ova-treated group (Figure 1). Nothing abnormal was found in the control group. During the first week after intra-colonic injection of TNBS, the mortality of each group was as follows: control group 0/20 (0%), TNBS^{+}ova^{-} group 20/40 (50%), TNBS^{+}ova^{+} group 6/30 (20%) ($P < 0.05$ between each group).

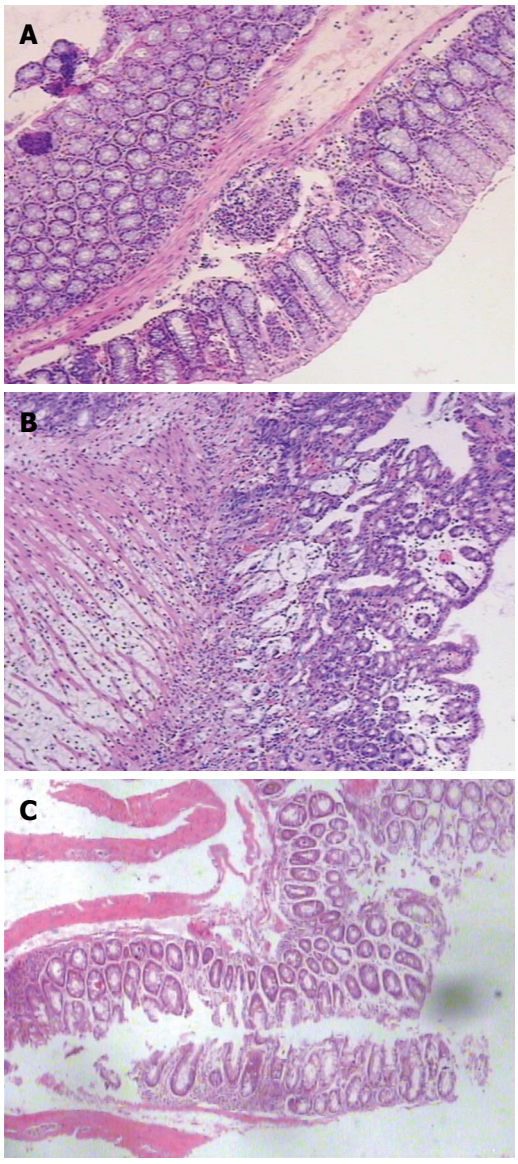

Figure 2 The histology of the colon in different group of mice (HE, × 10). Rare inflammation was found in controls (A). Transmural chronic inflammation was observed in TNBS-induced colitis (B). The inflammation was significantly relieved in schistosome ova treated mice (C). HE: Hematoxylin and eosin; TNBS: Trinitrobenzenesulfonic acid.

Microscopic inflammation score

No microscopic damage was found in the colon of control animals (Figure 2A). Compared with the colon of control mice, TNBS induced a distortion of colonic mucosal architecture and an inflammatory infiltration throughout the whole colonic wall. The inflammation was characterized by hyperaemia and edema of mucosa which led to thickening of the colonic wall, ulcer formation, folliculus lymphatics hyperplasia, and transmural chronic inflammatory cell infiltration (Figure 2B). Treatment with *S japonicum* ova tended to relieve the inflammation with infiltration of only a few inflammatory cells (Figure 2C). The histology score also showed a significant relief of colon inflammation in $TNBS^+ova^+$ group compared with the $TNBS^+ova^-$ group (Figure 1).

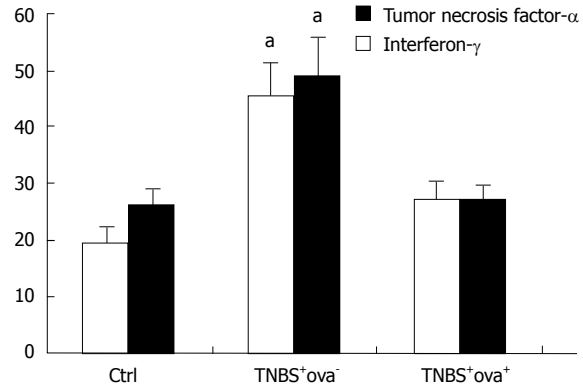

Figure 3 The serum levels of tumor necrosis factor-α (white bar) and interferon-γ (black bar). Data are presented as mean ± SD. There were 20 animals in the control group and the $TNBS^+ova^-$ group and 24 in the $TNBS^+ova^+$ group. $^aP < 0.05$ *vs* the other two groups. TNBS: Trinitrobenzenesulfonic acid.

Measurement of inflammatory factors in serum

We also surveyed the expression of inflammatory factors in the serum to further evaluate the inflammatory reaction in the different groups. As shown in Figure 3, a highly increased expression of TNF-α and IFN-γ was detected in the $TNBS^+ova^-$ group. In the $TNBS^+ova^-$ group, the expression of TNF-α was significantly higher than that of the control group and the $TNBS^+ova^-$ group. IFN-γ expression was downregulated in the $TNBS^+ova^+$ group compared with $TNBS^+ova^-$ group ($P < 0.05$).

The expression of NOD2 and its mRNA in the colon

Since NOD2 is one of the most important pattern pathogen recognition receptors which could induce a large quantity of inflammatory factors such as TNF-α and IFN-γ when inappropriately activated, we further studied the variations of NOD2 and its mRNA in the colon to verifying whether the NOD2 pathway was influenced during TNBS-induced colitis and whether it can be reversed by *S. japonicum* ova.

As shown in Figure 4, TNBS injection caused a distinct increase of NOD2 in the colon as compared with control mice. However, when mice were pretreated with *S. japonicum* ova, NOD2 expression was much lower in spite of the TNBS effect. Similar effects were also found in NOD2 mRNA expression among the three groups (Figure 5).

The evaluation of the intestinal barrier function

To further understand the cause of the over-activation of NOD2, we used IBT frequency to evaluate the intestinal barrier function. Bacterial identification showed the translocated bacteria were predominantly opportunistic pathogens especially *Escherichia coli*, *Bacillus proteus*, *Klebsiellas*, *Pseudomonas fluorescens*, *Pseudomonas pyocyanea* and enterococci were also found in several mice. IBT was more common in the $TNBS^+ova^-$ group. After exposure to *S japonicum* ova, the frequency of IBT to MLN, blood, liver and spleen was obviously reduced (Table 2).

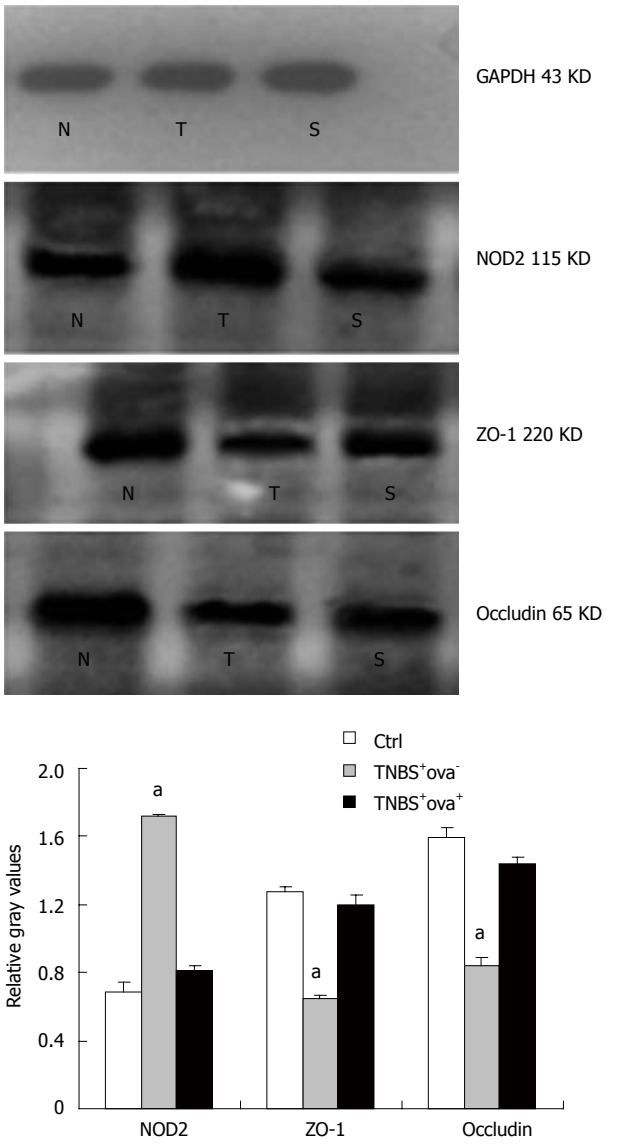

Figure 4 Effect of *Schistosoma japonicum* ova on the expression of NOD2, ZO-1 and occludin (Western blotting). White bar represents the control group (N), grey bar represents the TNBS$^+$ova$^-$ group (T), black bar represents the TNBS$^+$ova$^+$ group (S). Data are presented as mean ± SE. n = 10. $^aP < 0.05$ *vs* the other two groups. NOD2: Nucleotide-binding-oligomerization domain 2; TNBS: Trinitrobenzenesulfonic acid; GAPDH: Glyceraldehyde phosphate dehydrogenase.

The expressions of ZO-1, occludin and their mRNAs in the colon

In order to gain further insight into the mechanism of intestinal barrier function alteration, we detected the tight junction proteins that constitute the main frame of the barrier. The *ZO-1* and occludin expression levels were reduced in the TNBS$^+$ova$^-$ group compared with the normal controls. Egg pre-exposure produced a significant elevation in the expression of these tight junction proteins in the experimental induced models (Figure 4). *ZO-1* and occludin mRNA was examined using realtime-PCR. Similar to the study of the proteins, ZO-1 and occludin mRNA expression was obviously downregulated in the TNBS$^+$ova$^-$ group compared with the controls. Egg pretreatment led to a dramatic upregulation of these genes (Figure 6).

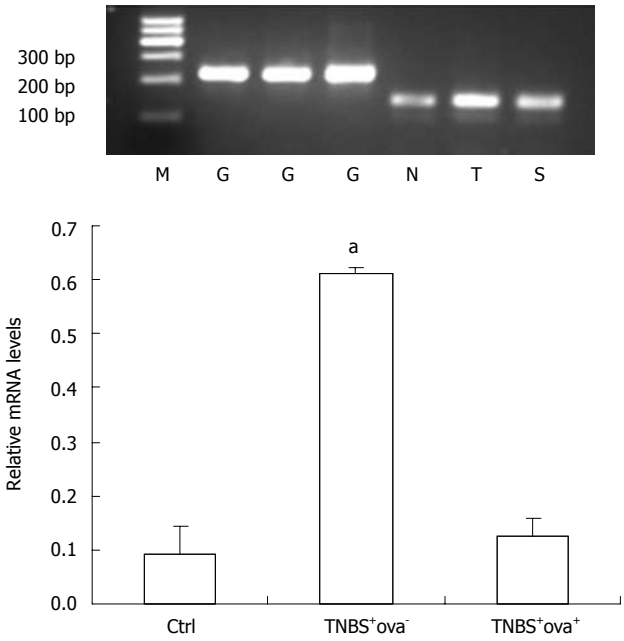

Figure 5 Effect of *Schistosoma japonicum* ova on the expression of *NOD2* mRNA (Realtime-PCR). M: Marker; G: GAPDH; N: Control group; T: TNBS$^+$ova$^-$ group; S: TNBS$^+$ova$^+$ group. Data are presented as mean ± SE. n = 10. $^aP < 0.05$ *vs* the other two groups. GAPDH: Glyceraldehyde phosphate dehydrogenase; TNBS: Trinitrobenzenesulfonic acid.

Table 2 Culture of blood, mesenteric lymph nodes, liver and spleen

	No. of mice	MLN	Blood	Liver	Spleen
Control	10	1/10	0/10	0/10	0/10
TNBS$^+$ova$^-$	10	8/10	10/10	9/10	5/10
TNBS$^+$ova$^+$	10	1/10^a	3/10^a	2/10^a	1/10^a

$^aP < 0.05$ compared with the TNBS group. MLN: Mesenteric lymph nodes; TNBS: Trinitrobenzenesulfonic acid.

DISCUSSION

CD is a disease more prevalent in developed countries where the sanitary conditions are better. Scientists believe that intestinal hygiene might be a risk factor of CD and helminthes have been thought to be beneficial to CD[9-11]. Elliot *et al*[9] found that pretreating mice with *Schistosoma mansoni* ova could relieve TNBS-induce colitis. We have also demonstrated in our previous study that *S. japonicum* ova pretreatment could prevent experimental colitis in mice by a mechanism of Th2-polarizing stimuli[12]. Summers *et al*[9] reported a safe and effective result from their short-term study of live *Trichuris suis* ova therapy in 29 patients with CD. Croese *et al*[11] also established a potential role of *Necator americanus* in the remission of autoimmune disease, including CD.

In the present study, we also found an obvious inflammatory reaction both in the colon and the blood.

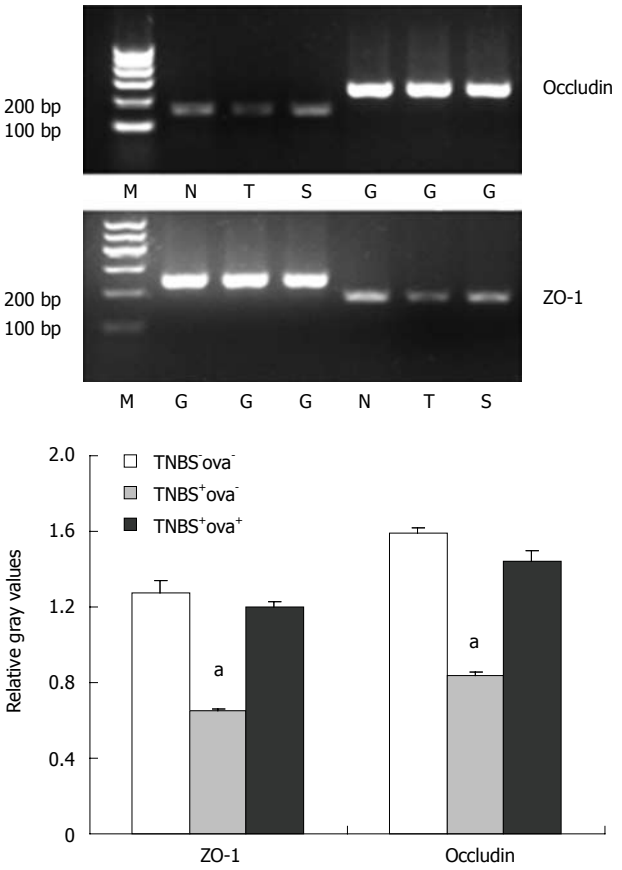

Figure 6 Effect of *Schistosoma japonicum* ova on the expression of *ZO-1* and occludin mRNA (Realtime-PCR). White bar represents the control group (N), grey bar represents the TNBS$^+$ova$^-$ group (T), black bar represents the TNBS$^+$ova$^+$ group (S). M: Marker; G: GAPDH. Data are presented as mean ± SE. n = 10. $^aP < 0.05$ *vs* the other two groups. GAPDH: Glyceraldehyde phosphate dehydrogenase. TNBS: Trinitrobenzenesulfonic acid.

The innate immune system plays an important role in the production of these inflammatory factors. Among varieties of the PPRRs, TLRs and NODs are the most important in antigen recognition. In our former study we demonstrated that TLR4 expression was elevated after the mice were injected with TNBS and was downregulated in the ova group[12]. *NOD2/CARD15*, famous as the first predisposing gene of CD, codes a cytosolic protein which provides a second line of innate immune defense within IECs and adjacent immune cells, expanding immune surveillance beyond membrane-associated TLRs[14]. Thus we assume that the ova might also decrease the production of the inflammatory cytokines through downregulating NOD2 expression in a direct or indirect pattern. We detected the expression of *NOD2* mRNA using realtime-PCR. The results showed that in the TNBS$^+$ova$^-$ group, the *NOD2* mRNA was increased and the ova pre-exposure significantly downregulated *NOD2* mRNA expression. We suppose that the ova relieved colitis and suppressed the inflammatory reaction partially because of the downregulation of PPRRs which might be inappropriately activated and thus produced large quantities of inflammatory cytokines.

The intestinal epithelial barrier also plays an important role in the onset and progression of CD. Increased IBT to the MLN, liver, blood and spleen was found in the present study. We supposed it might be due to the increased intestinal pericellular permeability, which was usually caused by impaired intestinal barrier function. The intestinal barrier function was maintained by a series of epithelial TJs, protecting the body from pathogens and other toxic luminal substances. Transmembrane proteins (such as occludin, tricellulin, claudins and junctional adhesion molecule) interact with cytoplasmic peripheral membrane proteins (such as ZO-1, ZO-2, ZO-3 and cingulin), and thus constitute the frames of TJs[15].

An obvious downregulation of ZO-1 and occludin was found in the present study using Western blotting, which could be prevented by pre-exposure to the *S. japonicum* ova. We further tested the expression of ZO-1 and occludin mRNA and the outcome was consistent with the protein study.

Inflammatory mediators such as cytokines, toxins and reactive oxygen species contributed to the impairment of TJs[16-20]. The best-studied cytokine that causes barrier dysfunction due to epithelial tight junction regulation is TNF-α. Poritz *et al*[19] incubated MDCK cells with different concentrations of TNF-α and found the fragmentation staining of ZO-1, suggesting a disruption of the TJs. They also found that claudin-1 expression was decreased along with an increasing concentration of TNF-α. It was demonstrated that the TNF-α-induced TJs impairment was mediated by NF-κB activation in Caco-2 cells[19]. Treatment of T84 cells with IFN-γ also caused a dose- and time-dependent increase in monolayer permeability. Examination of specific proteins associated with TJs by immunoblotting and confocal microscopy revealed changes in the localization and expression levels of the tight junction proteins after exposing the cells to IFN-γ. Specifically, they found that IFN-γ treatment resulted in an almost total loss of ZO-1[20].

Impaired barrier function leads to the exposure of submucosal immunocytes to luminal antigens and initiates the innate immune reaction. TLRs and NODs are PPRRs that are expressed by intestinal epithelial cells and submucosal immunocytes. The inappropriate activation of TLRs and NODs may cause the over-reaction of the immune system and overproduction of cytokines (such as IFN-γ and TNF-α), leading to the formation of CD. We assume that treating mice with *S. japonicum* ova might cut down the impairment of the intestinal epithelial barrier through protecting the TJs, thus preventing the activation of PPRRs and downregulating inflammatory mediators like TNF-α and IFN-γ, leading to the remission of colitis.

Despite various therapeutic measures against CD, even the most experienced clinician might have problems with treatment of many cases, especially those with complications. Helminthes might be beneficial in CD. The clarification of this mechanism contributes to finding out the key effective component, which may be a novel potential way of treating CD.

COMMENTS

Background

Crohn's disease (CD) is more prevalent in developed countries where sanitary conditions are better. Scientists have found that helminthes can protect mice from experimental colitis. The intestinal epithelial barrier plays an important role in the onset and progress of CD. Tight junctions (TJs), which form the pericellular barrier, are thought to be the primary determinant of mucosal permeability in the presence of an intact epithelium. The impaired TJs lead to an increase of exposure of intestine bacteria to submucosal proteins, like nucleotide-binding-oligomerization domains (NODs). Nucleotide-binding-oligomerization domain 2 (NOD2) has been found to exert antibacterial activity limiting survival of enteric bacteria after invasion. As one of the main responsible genes, NOD2 and its protein have been found to be upregulated in CD patients.

Research frontiers

TJs could be affected by a large amount of factors, such as cytokines, toxins and reactive oxygens. Many proteins and signal transduction systems participate in the regulation of TJs such as Rho/Ras-GTPases. Recently, it was reported that Notch-1 plays an important role in maintaining epithelial barrier function and promoting tight junction protein expression.

Innovations and breakthroughs

Till now various studies have proved that helminthes and their eggs do favor the relief of colitis both in experimental models and in some small scale clinical trials, but the rationale of how this works remains unknown. It was usually thought that helminthes might relieve colonic inflammation by a T cell immunity balance adjustment. Zhang and his co-workers investigated the impact of *S. japonicum* ova on trinitrobenzenesulfonic acid (TNBS)-induced colitis from a new point of view. They found that helminthes and their eggs might protect the intestine from inflammation by increasing the TJs and protecting the intestinal barrier function.

Applications

Despite various therapeutic measures against CD, even the most experienced clinician might have problems with treatment of many cases, especially those with complications. Helminthes and their eggs might be beneficial to treatment of CD. The clarification of this mechanism contributes to finding out the key effective component, which may be a novel potential method for treating CD.

Terminology

Intestinal bacterial translocation: The bacteria in the intestine migrate to the peripheral circulation and other organs (liver, spleen, *etc.*) through the portal vein due to the increased intestinal permeability; NOD2: One of the pattern pathogen recognition receptors which exists in the cytoplasm and recognize muramyl dipeptide of the bacteria. NOD2 is also the first predisposing gene of CD; Tight junctions: tight junctions form a network of close contacts between membranes of adjacent cells. They control the pericellular transport of ions, water, and solutes, and in addition they constitute a fence separating apical and basolateral membrane proteins.

Peer review

The paper is an intriguing and well designed paper which addresses a relevant issue.

Abstract

AIM: To investigate the clinicopathologic features of bile duct tumor thrombus (BDTT) occurrence after treatment of primary small hepatocellular carcinoma (sHCC).

METHODS: A total of 423 patients with primary sHCC admitted to our hospital underwent surgical resection or local ablation. During follow-up, only six patients were hospitalized due to obstructive jaundice, which occurred 5-76 mo after initial treatment. The clinicopathologic features of these six patients were reviewed.

RESULTS: Six patients underwent hepatic resection (*n* = 5) or radio-frequency ablation (*n* = 1) due to primary sHCC. Five cases had an R1 resection margin, and one case had an ablative margin less than 5.0 mm. No vascular infiltration, microsatellites or bile duct/canaliculus affection was noted in the initial resected specimens. During the follow-up, imaging studies revealed a macroscopic BDTT extending to the common bile duct in all six patients. Four patients had a concomitant intrahepatic recurrent tumor. Surgical re-resection of intrahepatic recurrent tumors and removal of BDTTs (*n* = 4), BDTT removal through choledochotomy (*n* = 1), and conservative treatment (*n* = 1) was performed. Microscopic portal vein invasion was noted in three of the four resected specimens. All six patients died, with a mean survival of 11 mo after BDTT removal or conservative treatment.

CONCLUSION: BDTT occurrence is a rare, special recurrent pattern of primary sHCC. Patients with BDTTs extending to the common bile duct usually have an unfavorable prognosis even following aggressive surgery. Insufficient resection or ablative margins against primary sHCC may be a risk factor for BDTT development.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies, especially in Asian countries[1]. With advanced imaging techniques, small HCC (sHCC) (≤ 3.0 cm) can be detected with increasing ease during screening in patients with chronic hepatitis or cirrhosis. Surgical resection and local ablation therapy (including percutaneous ethanol injection, percutaneous microwave coagulation, and percutaneous radio-frequency ablation) are effective against sHCC[2-4]. Although major progress has been made in the detection and treatment of sHCC, the efficacy of sHCC treatments remains undesirable: the 3- and 5-year disease-free survival rates are only 49% and 30%, respectively[5]. A major cause of the unfavorable prognosis of sHCC is the high incidence of postoperative recurrence. Kumada *et al*[6] reported that the cumulative 3- and 5-year recurrence rates were up to 64.5% and 76.1%, respectively. HCC recurrence is a leading cause of death that affects patients' long-term survival.

Extrahepatic and intrahepatic recurrences are two different sHCC recurrent patterns. Extrahepatic recurrence may extend to lymph nodes, peritoneum and extra-abdominal organs, while intrahepatic recurrence includes local recurrence, intrahepatic metastasis and multicentric carcinogenesis in the remnant liver[6-10]. However, bile duct tumor thrombus (BDTT) occurrence is rarely reported as a recurrent pattern of primary sHCC. Herein we present the clinicopathologic features of six patients with macroscopic BDTT occurrence after primary sHCC resection or local ablation. To the best of our knowledge, there is no such report in the English-language literature.

MATERIALS AND METHODS

Between March 2002 and June 2010, 423 patients with primary sHCC admitted to our hospital underwent surgical resection or local ablation. Patients were followed up every 1 or 3 mo after initial treatment. During follow-up, only six patients were hospitalized due to obstructive jaundice, which occurred at 5-76 mo (median, 8.5 mo) after the initial treatment. We retrospectively analyzed the clinicopathologic features of the six sHCC patients who developed a BDTT after treatment. The surgical margin was classified by an experienced pathologist (HG Li) as follows. R0 resection indicated complete removal of all tumors without microscopic tumor cells in the surgical margin. R1 resection indicated that the edges of the resection specimen showed microscopic tumor cells. R2 resection indicated that portions of tumor visible to the naked eye were not removed.

RESULTS

The sex, age, chief complaint, hepatitis markers, presence of cirrhosis, α-fetoprotein (AFP) level, location and size of sHCC, treatment, and pathological diagnosis at the initial hospital visit are summarized in Table 1 for the six patients with primary sHCC. The patients were all male, with a median age of 44 years. Three patients had epigastric pain, while the others were asymptomatic. Five patients were hepatitis B surface antigen (HBsAg)-positive, and one was HBsAg-negative. The serum AFP level was elevated in each patient, ranging from 25.0 to 725.3 ng/mL (normal, ≤ 10.0 ng/mL). The primary sHCCs were 1.5-2.7 cm in diameter. Five patients underwent hepatic resection, and pathological examination showed poorly differentiated (n = 3) or moderately differentiated HCC (n = 2). One patient (case 3) underwent a biopsy before radiofrequency ablation (RFA), and the tumor was moderately differentiated HCC. Five cases had an R1 resection margin, and one case had an ablative margin less than 5.0 mm. No vascular infiltration, microsatellites or bile duct/canaliculus invasion was noted in the initial resected specimens.

The clinicopathologic features of macroscopic BDTT occurrence after therapy are summarized in Table 2. Imaging examination [computed tomography (CT) or magnetic resonance imaging (MRI)] revealed macroscopic BDTT and concomitant intrahepatic recurrence in all six patients. Total bilirubin (TBil) and direct bilirubin (DBil) increased in all six patients (normal ranges, ≤ 24.0 μmol/L and ≤ 11.0 μmol/L, respectively). Serum AFP was increased in four patients and was normal in two patients. Four patients showed concomitant intrahepatic recurrent HCC lesions and BDTTs, while the other two revealed no intrahepatic recurrence. Surgical re-resection of the intrahepatic recurrent tumor and removal of the BDTT was performed in four patients, and BDTT removal *via* choledochotomy was performed in one patient. The other patient (case 6) underwent conservative treatment including percutaneous transhepatic cholangial drainage (PTCD) and transarterial chemoembolization (TACE) because of poor liver function. Histologic examination showed the recurrent tumor or BDTT to be poorly (n = 4) or moderately differentiated HCC (n = 1). All patients died with a mean survival of 11 mo after BDTT removal or conservative treatment.

Clinical course of each case is briefly presented below

Case 1: A 35-year-old male underwent partial resection of segments V and Ⅷ (Couinaud's nomenclature) due to a moderately differentiated sHCC measuring 2.7 cm in diameter (Figure 1A). At follow-up 6 mo after the operation, the patient was hospitalized due to jaundice. Serum AFP was normal, and CA19-9 was 350.2 U/mL (normal range, ≤ 35 U/mL). Abdominal sonography and dynamic contrast-enhanced MRI examination showed a recurrent tumor of 2.0 cm in diameter at the edge of the residual cavity (segment Ⅷ) after resection of the primary sHCC, and a BDTT extending to the proximal segment of the common bile duct was depicted simultaneously (Figures 1B and C). The BDTT and intrahepatic recurrence were directly connected, and

[1]Interval between BDTT occurrence and initial treatment. AFP: Alpha-fetoprotein; TBil: Total bilirubin; DBil: Direct bilirubin; RIHBD: Right intrahepatic bile duct; CHD: Common hepatic duct; CBD: Common bile duct; RHD: Right hepatic duct; +: Positive; -: Negative; BDTT: Bile duct tumor thrombus.

both exhibited typical HCC enhancement characteristics, such as early enhancement in the hepatic arterial phase with rapid wash-out of contrast agent in the portal vein phase on dynamic contrast-enhanced MRI. The patient underwent partial resection of hepatic segments (Ⅳ, Ⅷ) and removal of the BDTT *via* choledochotomy. Pathological examination showed the intrahepatic recurrent tumor and the BDTT were moderately differentiated HCC (Figure 1D). The patient died 13 mo after surgery due to recurrence.

Case 2: A 57-year-old male underwent partial resection of segment Ⅴ due to a moderately differentiated sHCC measuring 2.0 cm in diameter (Figure 2A). Forty-three months after the initial operation, the patient underwent resection of segment Ⅴ again for a recurrent tumor of 1.8 cm in diameter that was detected on dynamic contrast-enhanced CT, and the recurrent tumor was a moderately differentiated HCC with a microscopic BDTT observed pathologically. Four months after the second operation, the patient developed jaundice with increased AFP, and serum CA125 was 122.0 U/mL (normal range, ≤ 35 U/mL). Dynamic contrast-enhanced CT showed no intrahepatic recurrence; however, a BDTT extending through the common hepatic duct to the common bile duct was noted. The BDTT depicted a typical HCC enhancement pattern (Figure 2B). The patient underwent PTCD to relieve jaundice prior to the third operation (Figure 2C). During the third operation, the BDTT was tightly adherent to the common bile duct, so the BDTT was removed through resection of the common bile duct and bilio-enteric reconstruction was performed. The BDTT specimen was positive for hepatocyte on immunohistochemical staining, and cancer nest invasion into the bile duct wall was noted (Figure 2D). The patient died 4 mo after surgery due to hepatic failure.

Case 3: A 45-year-old male underwent RFA therapy for

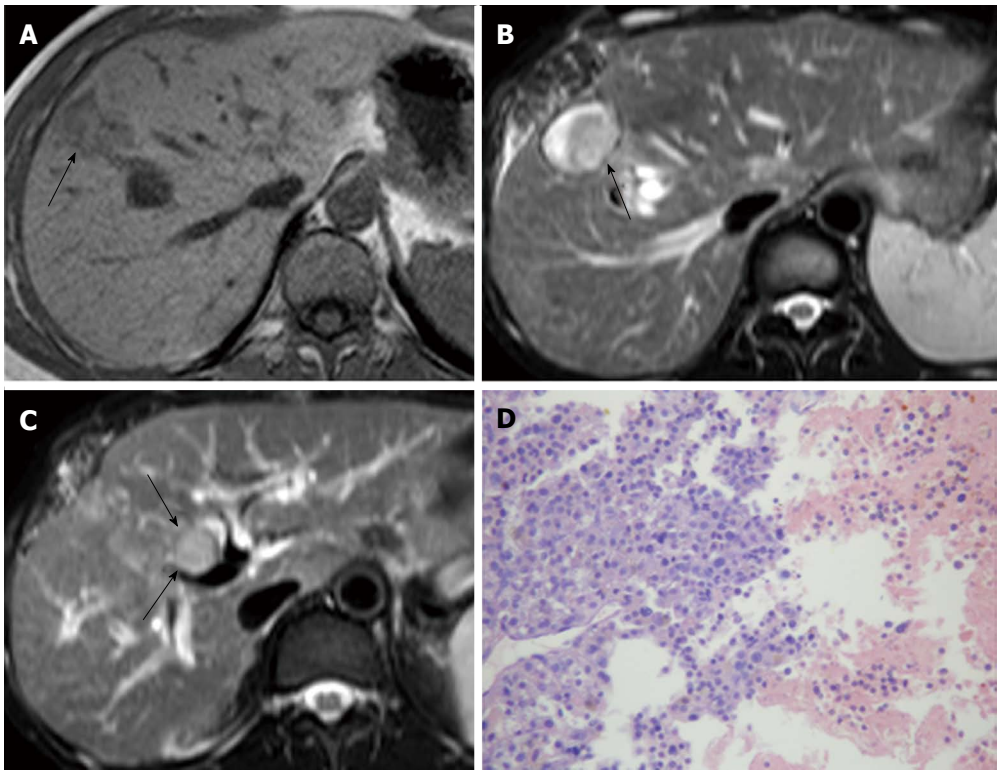

Figure 1 Small hepatocellular carcinoma in a 35-year-old male. Figure 2 Small hepatocellular carcinoma in a 57-year-old male. A: Computed tomography (CT) shows primary sHCC (arrow) in segment Ⅴ at the hepatic arterial phase; B: Forty-seven months after the initial operation, CT reveals a BDTT (arrows) with characteristics of early enhancement at the hepatic arterial phase; C: Tumor thrombus (arrows) extending through the common hepatic duct into the common bile duct is demonstrated during PTCD; D: Cancer nest invasion into the bile duct wall is observed histologically (HE, × 100). sHCC: Small hepatocellular carcinoma; BDTT: Bile duct tumor thrombus; HE: Hematoxylin and eosin; PTCD: Percutaneous transhepatic cholangial drainage.

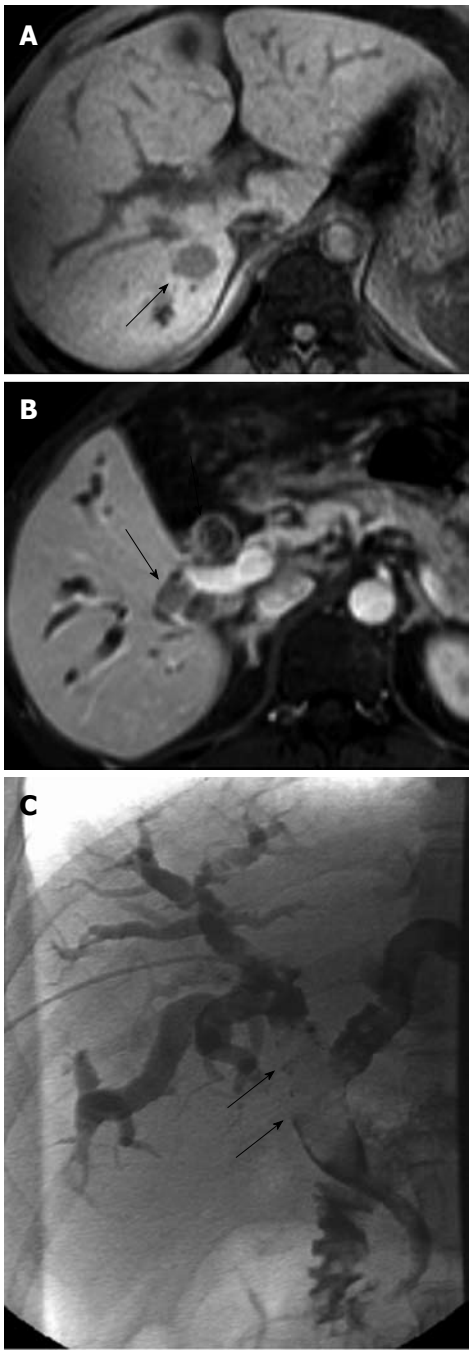

Figure 3 Small hepatocellular carcinoma in a 41-year-old male. A: T1-weighted MRI shows primary sHCC (arrow) in segment Ⅵ; B: A BDTT (arrows) in the right intrahepatic bile duct and the common bile duct is noted on contrast-enhanced T1-weighted MRI; C: Filling defect (arrows) in the biliary tree is depicted during percutaneous transhepatic cholangial drainage. MRI: Magnetic resonance imaging; sHCC: Small hepatocellular carcinoma; BDTT: Bile duct tumor thrombus.

a sHCC measuring 1.5 cm in diameter in segment Ⅵ. A recurrent tumor of 2.5 cm in diameter was found at the margin of the RFA site 17 mo after the initial RFA. He was again treated with RFA (ablative margin less than 5.0 mm). A recurrent tumor of 2.0 cm in diameter was again found at the margin of the RFA site 18 mo after second RFA therapy. Then TACE was performed. He developed jaundice 41 mo after TACE. Dynamic contrast-enhanced MR showed a BDTT extending through the right intrahepatic bile duct to the common bile duct, with typical HCC enhancement characteristics, and a recurrent tumor of 3.2 cm in diameter was found in segment Ⅵ. A plastic stent was placed for biliary decompression and drainage. He underwent resection of segment Ⅵ and removal of the BDTT *via* choledochotomy 2 mo after stent placement. Pathological examination showed that the intrahepatic recurrent tumor and the BDTT was poorly differentiated HCC. The patient died 19 mo after surgery due to intrahepatic recurrences and BDTT recurrence.

Case 4: A 50-year-old male underwent left lobectomy due to a poorly differentiated sHCC of 2.0 cm in diameter in segment Ⅳ. The patient had epigastric pain and jaundice 5 mo after the operation. Serum AFP was 251.6 ng/mL, and CA19-9 was 399.2 U/mL. MRI revealed a recurrent tumor of 5.2 cm in diameter near the resected hepatic stump (segments Ⅴ and Ⅷ) and a BDTT extending through the right hepatic duct to the common bile duct. He underwent resection of segments Ⅴ and Ⅷ and removal of the BDTT through resection of the common bile duct, followed by Roux-en-Y biliary-enteric anastomosis. The intrahepatic recurrence and the BDTT were diagnosed histologically as poorly differentiated HCC, and no bile duct wall invasion was noted. The patient died 14 mo after surgery due to HCC recurrence and distant metastasis.

Case 5: A 38-year-old male underwent partial resection of segment Ⅴ due to a poorly differentiated sHCC of 1.6 cm in diameter. The patient developed obstructive jaundice 8 mo after the operation. CT showed a recurrent tumor of 2.8 cm in diameter in segment Ⅵ and a BDTT extending through the right intrahepatic bile duct to the common bile duct. The patient received re-resection of segment Ⅵ and removal of the BDTT *via* choledochotomy. Histologically, the intrahepatic recurrence and the BDTT were diagnosed as poorly differentiated HCC. The patient died 10 mo after surgery due to distant metastasis.

Case 6: A 41-year-old male underwent resection of segment Ⅵ due to a poorly differentiated sHCC of 2.6 cm in diameter (Figure 3A). He developed jaundice 9 mo after the operation. MRI revealed a BDTT extending through the right intrahepatic bile duct to the common bile duct (Figure 3B); however, no intrahepatic recurrence was detected. A filling defect in the bile duct was noted during PTCD (Figure 3C). Because the patient had poor liver reserve and was classified in the Child-Pugh C subgroup, he underwent PTCD and TACE instead of surgery. The patient died 6 mo after PTCD and TACE due to multiple abscesses and hepatic failure.

DISCUSSION

HCC has a high frequency of portal vein or/and hepatic

vein invasion; however, bile duct invasion has been reported in only 0.79%-3% patients with primary HCC[11-13]. The size of primary HCC is not correlated with the occurrence of BDTT, and BDTTs may exist in patients with primary sHCC (≤ 3.0cm) and even in patients without detectable primary HCC[11,14,15]. However, BDTT occurrence after treatment of primary sHCC, which may be a new sHCC recurrence pattern, is very rare; only 1.4% (6/423) of patients with primary sHCC showed BDTTs recurrence in our study. Schmelzle *et al*[16] reported a case of extrahepatic growth of BDTT 3 mo after resection of multilocular HCC; however, the size of the primary multilocular HCC was not mentioned. The development of BDTT after primary sHCC treatment has not been reported in the English-language literature.

The mechanism for the emergence of HCC in the biliary system is still unknown, although the originally formed portal vein tumor thrombus may invade the bile duct *via* the peribiliary abundant vascular plexus or by direct invasion, or the primary HCC may rupture into the bile duct[13,17,18]. A wide ablative margin (more than 5 mm) or resection margin (2 cm) is the most important factor for local control of HCC[19,20]. In our cases, insufficient resection or ablative margins against sHCC seemed to be a risk factor for developing a BDTT after sHCC treatment because five cases had an R1 resection margin and one case had an ablative margin less than 5.0 mm. Residual microscopic tumor cells in resection margins may grow into the intrahepatic bile duct through injured bile duct walls due to hepatic resection or RFA and may extend distally to the left or right bile duct, or even the common bile duct. Interestingly, extrahepatic BDTT was reported by Schmelzle *et al*[16] in a patient with bile leakage after the resection of primary HCC, and BDTT development was supposed to be due to migration of cancer cells into the intrahepatic bile duct. Tumor thrombus in the portal vein was seen microscopically in the resected specimens in three cases (case 3, case 4 and case 5) in our group. A BDTT may develop *via* portal vein tumor thrombus invasion to the bile duct since the portal vein and bile duct are located in the same Galisson sheath[13,17,18].

Obstructive jaundice due to BDTT following sHCC treatment should be differentiated from jaundice that results from diffuse tumor recurrence infiltration, progressive hepatic failure, or hepatic hilum invasion due to intrahepatic recurrence, because the latter is often not curable, while the former may benefit from surgical resection[13]. Dynamic contrast-enhanced CT or MRI is valuable to detect BDTT and possible concomitant intrahepatic recurrence. As the BDTT directly connects to the intrahepatic tumor and is vascularized by the same blood supply with the intrahepatic tumor, they both show typical HCC enhancement characteristics in dynamic contrast-enhanced CT or MRI, including early enhancement in the hepatic arterial phase and rapid wash-out of contrast agent in the portal vein phase[14,21,22]. Magnetic resonance cholangiopancreatography is valuable for identifying the location and extent of a BDTT[23]. It is not necessary to diagnose a BDTT using invasive methods in most cases, such as endoscopic retrograde cholangio-pancreatography (ERCP) and PTCD because the obstruction site or extent depicted on ERCP or PTCD is not a specific finding for the diagnosis of BDTT, and cholangitis or pancreatitis may be easily induced by these invasive methods. Obstructive jaundice in a patient with a BDTT is marked by a predominant increase in DBil, making it distinct from jaundice that results from cirrhosis and active hepatitis[13]. The serum AFP level is of limited value in the diagnosis of BDTT occurrence because AFP reflects not only tumor cell proliferation but also the activity and severity of hepatitis[24].

Obstructive jaundice would not be regarded as a contraindication of surgery[13]. The goal of therapy is removal of the BDTT and intrahepatic recurrence. A BDTT is often easy to remove, as it is not tightly adhesive to the bile duct wall. Removal of BDTT *via* choledochotomy and re-resection of intrahepatic recurrence may be considered in patients with adequate hepatic function[13,25]. Removal of a BDTT through resection of the extrahepatic bile duct followed by biliary-enteric anastomosis should be adopted for cases with a tumor thrombus that is tightly adhesive to the extrahepatic bile duct wall, as it indicates that the tumor thrombus has invaded the bile duct[13]. Bile duct drainage, such as endoscopic nasobiliary drainage, plastic stent placement, PTCD, or PTCD plus stent placement, should be practiced to relieve jaundice in inoperable patients, such as patients with intrahepatic recurrence at unresectable sites, multiple recurrent lesions or inadequate hepatic function. After bile duct drainage is performed, TACE may be performed to inhibit the vascularization of the recurrent tumor and the BDTT and thereby control tumor growth or even prevent fatal bile duct bleeding caused by the BDTT[13,26]. However, TACE without prior bile duct drainage is highly risky, as it may induce progressive hepatic failure[13]. Some researchers have made efforts in using liver transplant therapy to treat primary HCC associated with BDTT, but in patients with BDTT occurrence after sHCC treatment this technique has not been reported[13,27].

Many recent studies have shown that there is no significant difference in survival between HCC patients with BDTT and those without BDTT following appropriate preoperative management and aggressive surgery. The 1-, 3-, and 5-year survival rates for such patients have reached 73.3%-93.2%, 40%-56.0% and 24%-28%, respectively[13,25,28,29]. As BDTT development could lead to further deterioration of liver function, early detection and early relief of biliary system obstruction caused by tumor thrombus is an important factor to improve survival[30]. During admission, BDTTs extended to the common bile duct in all six patients in our study, which may be a negative factor leading to poor prognosis (with a mean survival time of only 11 mo).

In conclusion, BDTT occurrence is a rare, special

recurrent pattern after treatment of primary sHCC. Insufficient resection or ablative margins against primary sHCC may be a risk factor for BDTT development. Patients with BDTTs extending to the common bile duct usually have unfavorable prognosis even following aggressive surgery. Early removal of BDTTs and possible concomitant intrahepatic recurrences is crucial to prolong the survival of patients.

COMMENTS

Background

Recurrence is an important unfavorable prognostic factor in small hepatocellular carcinoma (sHCC) after surgical resection or local ablation therapy. Two different sHCC recurrent patterns have been reported. Extrahepatic recurrence may extend to lymph nodes, peritoneum and extra-abdominal organs, while intrahepatic recurrence includes local recurrence, intrahepatic metastasis and multicentric carcinogenesis in the remnant liver. However, bile duct tumor thrombus (BDTT) occurrence is rarely reported as a recurrent pattern of primary sHCC.

Research frontiers

Bile duct invasion by primary HCC is rare, and its pathogenesis is still not completely understood. A BDTT may exist in patients with primary sHCC ($\leqslant$ 3.0cm) and even in patients without detectable primary HCC. The clinicopathologic features of primary HCC with BDTT have been clarified in the literature. However, BDTT occurrence after sHCC treatment has not been reported in the English-language literature, and its clinicopathologic features have not been specified.

Innovations and breakthroughs

Six patients with BDTT occurrence after primary sHCC treatment were reported in this study, and their clinicopathologic features were reviewed. This study showed that BDTT occurrence is a rare recurrent pattern of sHCC (1.4%), and insufficient resection or ablative margins against sHCC may be a risk factor for BDTT development. Patients with BDTTs extending to the common bile duct usually have unfavorable prognosis even following aggressive surgery.

Applications

With a better understanding of the clinicopathologic features of BDTT occurrence after sHCC treatment, sufficient wide resection or ablative margins against sHCC should be performed to avoid BDTT recurrence. Early detection and removal of BDTT may be crucial to prolong the survival of patients. Further studies are needed to clarify the mechanism of BDTT recurrence.

Terminology

BDTT formation can occur in HCC, combined hepatocellular and cholangiocellular carcinoma and liver metastasis. The mechanism for the emergence of a tumor thrombus in the biliary system is still uncertain. Patients with BDTT development are usually admitted due to obstructive jaundice, and the prognosis is generally dismal.

Peer review

In this report, Liu and colleagues provide a brief report on six patients who developed intrabiliary tumor thrombi after previous therapy for hepatocellular carcinoma. This is a useful series that demonstrates that the onset of intrabiliary recurrences portends a very poor prognostic outlook. In fact, based on the survival outcomes described following treatment interventions, it could be argued that aggressive surgical intervention should not be undertaken for patients presenting with this unique pattern of recurrent disease.

Abstract

AIM: To study the effects of synthetic nonmethylated CpG-containing oligodeoxynucleotides (CpG-ODNs), either alone or combined with recombinant Hepatitis B surface antigen (HBsAg) polypeptide, on the phenotype, function, and intracellular signaling pathways of monocyte-derived dendritic cells (DCs) in patients with chronic hepatitis B (CHB).

METHODS: Peripheral blood monocytes isolated from CHB patients and healthy volunteers were induced to be dendritic cells by recombinant human granulocyte-monocyte colony stimulating factor and interleukin-4. The DCs were then treated with CpG-ODNs, CpG-ODNs/HBsAg, or tumor necrosis factor (TNF)-α for 18 h. The expression of surface molecules including HLA-DR, CD86, and CD1a in DCs were detected by flow cytometry, and the expression of signal transducers and activators of transcription (STAT1, 3, 4, 5, 6) and suppressors of cell signaling (SOCS1, 3) were determined by Western blotting assay. In addition, the capacity of DCs to stimulate allogeneic T lymphocytes and the amount of IL-12p70 released from DCs were measured.

RESULTS: In the DCs derived from patients with CHB, treatment with TNF-α, CpG-ODNs, or CpG-ODNs/HBsAg, as compared to the vector control, significantly increased the expression of HLA-DR, stimulated the release of IL-12p70, and enhanced the capacity of DCs to stimulate allogenic T lymphocytes. The expressions of STAT1/4/6 and SOCS1/3, but not STAT3/5, were upregulated by TNF-α, CpG-ODNs, and CpG-ODNs/HBsAg. In addition, the expression of CD1a was upregulated only in the presence of both CpG-ODNs and HBsAg.

CONCLUSION: The treatment with CpG-ODNs, either alone or combined with HBsAg, has a remarkable stimulatory effect on the impaired phenotype and function of DCs in CHB, possibly by regulating the expression of STAT1, 4, 6 and SOCS1, 3.

INTRODUCTION

Peripheral blood monocyte-derived dendritic cells (MoDCs) from patients with chronic hepatitis B (CHB) are abnormal in morphology and function[1,2]. However, the molecular mechanism of the MoDCs' dysfunction in CHB remains unclear. This study aimed to evaluate the effect of synthetic nonmethylated CpG-containing oligodeoxynucleotides (CpG-ODNs), combined with recombinant hepatitis B surface antigen (HBsAg) polypeptide, on the phenotype and function of monocyte-derived dendritic cells (DCs) in patients with chronic hepatitis B. In addition, we attempted to shed light on the involvement of intracellular signaling molecules, including signal transducers and activators of transcription (STAT1, 3, 4, 5, 6) and suppressors of cell signaling (SOCS1, 3) in the MoDCs dysfunction under the condition of CHB[3,4,5].

MATERIALS AND METHODS

Patients

Twenty-four patients with CHB [23 males and 1 females, mean age (33.4 ± 11.8) years] were enrolled in this study. Diagnosis of CHB was made by clinical findings: elevated serum alanine aminotransferase (ALT) levels for more than six months and the presence of HBsAg, HBeAg, anti-HBc, and HBV DNA (> 1 × 106 copies/mL). Among all patients, other hepatitis-related virus infection such as hepatitis A virus, hepatitis C virus, hepatitis E virus, and transfusion transmitted virus were excluded. None of the enrolled patients had received treatment with interferon, thymosin, thymus extracts, or lamivudine. Thirteen healthy volunteers were selected as control subjects with the average age of (31.7 ± 8.7) years.

Reagents

The recombinant human granulocyte-macrophage colony-stimulating factor (hGM-CSF), recombinant human interleukin-4 (hIL-4), and recombinant human tumor necrosis factor-α (hTNF-α) were purchased from Peprotech EC Ltd. (London, United Kingdom). The recombinant HBsAg was purchased from ViroStat (Portland, United States). Fluorescent isothiocyanate (FITC) anti-human CD1a, Phycoerythrocin (PE)-Cy5 anti-human CD86, Phycoerythrocin (PE), and anti-human HLA-DR were purchased from Amersham Pharmacia Biotech Inc (United States). MACS CD14 MicroBeads and MS Separation Columns were purchased from Miltenyi Biotec (Bergisch Gladbach, Germany). Human T cell enrichment columns were purchased from R and D Systems, Inc. The human IL-12p70 ELISA kit was purchased from Jingmei Biotech (Shenzhen, China). The mouse monoclonal antibody against beta actin was purchased from Abcam Ltd (Cambridge, United Kingdom). The mouse monoclonal antibody against phosphorylated STAT1/3 and the rabbit polyclonal antibody against phosphorylated STAT4/5/6 were purchased from Cell Signaling Technology (Beverly, MA, United States). The rabbit polyclonal antibodies for SOCS1/3 were purchased from Assay Designs Ltd (Michigan, United States). NE-PER nuclear and cytoplasmic extraction reagents were purchased from Pierce Biotechnology (Rockford, United States). 3H-TdR (2 mci/mL) was purchased from Isotope Institute of Atomic Energy Academy of China. Mitomycin-C and HISTOPAQUE-1077 were purchased from SIGMA (ST. LOUIS, MO, United States). The CpG-containing phosphorothioated oligodeoxynucleotides (CpG-ODNs) was custom synthesized by Shanghai Sangon Biological Engineering Technology and Service Ltd, based on the report by Merad *et al*[4].

Cell preparation and culture

The DCs were prepared following a method described by Romani *et al*[6], with a few modifications. Briefly, peripheral blood mononuclear cells (PBMC) were separated from the peripheral blood of patients and volunteers by HISTOPAQUE-1.077 density gradient centrifugation, and the monocytes were further selected from PBMCs using CD14 MicroBeads. The monocytes were induced to differentiate into DCs by combined treatment with hGM-CSF (1000 U/mL), hIL-4 (500 U/mL), and hTNF-α (1000 U/mL) for five or seven days according to requirement. Dendritic cells were identified by inverted phase contrast microscopy, transmission electron microscopy and flow cytometry. The DCs were then collected for subsequent experiments.

Treatment of dendritic cells with different immune adjuvants

After 5-d culture, the immature DCs were collected and dispensed into a culture plate with 24 wells (1×10^6 cells/well). CpG-ODNs (10 μg/mL), CpG-ODNs (10 μg/mL) + HBsAg (10 μg/mL) or TNF-α (1000 U/mL) in phosphate buffer solution (PBS, 50 μL/mL) were added[6,7]. The DCs derived from volunteers were only treated with CpG-ODNs (10 μg/mL). All cells were cultured at 37 ℃ in a 5% CO_2 incubator for 18 h. The cells and culture supernatant were then separately collected for further assays.

Detection of surface molecules and cytokine release of dendritic cells

The expression rates of surface molecules, including HLA-DR-PE, CD86-(PE)-Cy5, and CD1a-FITC in DCs were analyzed by flow cytometry (FCM), and isotope control was performed as previously described[2]. The IL-12p70 content of the culture supernatant was detected by an ELISA kit according to the manufacture's

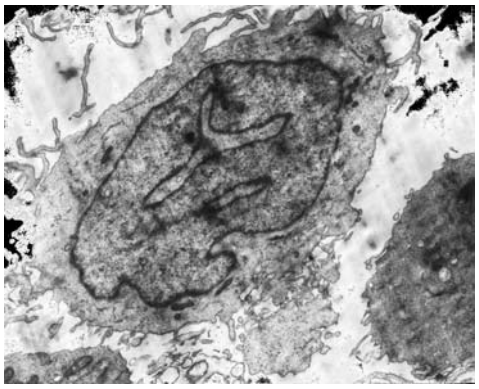

Figure 1 A representative image of monocyte-derive dendritic cells under transmission electron microscope after 7-d induction with recombinant granulocyte-macrophage colony-stimulating factor and interleukin-4 (magnification × 7500). Dendritic cells were irregular in form, and abundant in extended beard-like prick and mitochondria in cytoplasm.

instructions. The average optical density (OD) of three replicates was calculated.

Effect of dendritic cells treated with different immune adjuvants on proliferation of allogeneic T lymphocytes

The effect stimulation of DCs on T-cell proliferation was determined using a method described by Li *et al*[2]. T lymphocytes, separated by T cell separation columns, were used as response cells. The DCs exposed to different immune adjuvants for five days were further treated with mitomycin C (25 μg/mL) for 45 min and used as stimulating cells. The response cells and stimulating cells were co-cultured for 96 h at the ratio of 20:1, and 3H-TdR was added 18 h before the end of culture. The radioactivity (counts per minute, cpm), reflecting T-cell proliferation, was detected by a liquid scintillation counter and expressed as the mean value of five replicates.

Western blotting assay

Cytosolic proteins were extracted from DCs treated with different immune adjuvants, separated by 10% SDS-PAGE gel electrophoresis (30 μg protein per lane), and transferred onto a nitrocellulose membrane. The membrane was incubated in blocking buffer for 2 h at room temperature, a probed with a specific primary antibody (1:1000, 4 ℃, overnight), followed by the secondary antibody conjugated with horseradish peroxidase, and then developed by enhanced chemiluminescence (ECL) staining. All experiments were repeated three times and the protein signal was quantified by densitometry with a PrecisionScanLTX scanning apparatus, and normalized to β-actin as an internal reference.

Statistical analysis

The experimental data in this study were expressed as mean ± SD and analyzed by SAS6.12 statistical software. One-way ANOVA, followed by the Student-Newman-Keuls test, was used to compare the numerical data between multiple groups. A P value of < 0.05 was considered to be statistically significant.

Table 1 Effects of different immunologic adjuvants on expression levels of surface molecules (%) on DCs derived from blood monocytes of patients with chronic hepatitis B

Surface molecules	CpG	CpG + HBsAg	TNF-α	HBsAg	PBS
HLA-DR	93.8 ± 3.7[a]	95.1 ± 4.5[a]	94.8 ± 3.1	87.6 ± 4.3[a]	70.4 ± 3.9
CD86	83.7 ± 5.3	81.5 ± 3.2	82.3 ± 2.7	83.2 ± 3.6	80.2 ± 4.2
CD1a	12.0 ± 0.9	44.5 ± 1.2[a]	12.7 ± 1.9	15.0 ± 2.5	13.6 ± 0.8

DCs: Dendritic cells; CHB: Chronic hepatitis B; CpG-ODNs: Synthetic nonmethylated CpG-containing oligodeoxynucleotide; HBsAg: Hepatitis B surface antigen; PBS: Phosphate buffer solution; TNF: Tumor necrosis factor. HLA-DR, CD86 and CD1a are the specific surface molecules of DCs; CpG, CpG + HBsAg, TNF-α and HBsAg are the different adjuvants on DCs. [a]$P < 0.05$ using Student's t test, represents the stimulating effects of different immunologic adjuvants in comparison to control group (PBS).

RESULTS

In vitro development and identification of dendritic cells

DCs were developed from $CD14^+$ blood monocytes. Monocytes of high purity were separated from the peripheral blood using CD14 MicroBeads. After treatment with recombinant GM-CSF 1000 U/mL and IL-4500 U/mL, a large number of cell clusters appeared on day three, and most cells were suspended on day six to seven in irregular form. Abundant extended beard-like pricks and mitochondria were observed under inverted phase contrast microscope and transmission electron microscope (Figure 1). The purity of DCs was more than 85% according to the numbers of cells positive for HLA-DR, CD86 and CD1a detected by FCM. DCs treated with TNF-α (1000 U/mL) showed strong ability to stimulate the proliferation of allogeneic T lymphocytes (Figure 1).

Effect of CpG-ODN on the phenotype of dendritic cells

The number of DCs positive for HLA-DR, CD86, and CD1a after induction with GM-CSF and IL-4 were 70.4%, 81.3%, and 13.67% for CHB ($n = 6$), and were 83.2%, 80.6%, and 22.4% for healthy volunteers ($n = 3$), respectively. The number of cells positive for HLA-DR and CD1a were significantly lower in CHB than those in healthy volunteers ($P < 0.05$). Treatment with TNF-α, CpG-ODNs, or CpG-ODNs plus HBsAg, beginning at day 5 and continuing for 18 h, increased the numbers of cells positive for HLA-DR and CD86 by about 10%, and the rate of CD1a by about 20% in DCs from healthy volunteers ($n = 3$). By contrast, in DCs from the patients with CHB ($n = 6$), only the rates of HLA-DR were increased by those treatments (94.7%, 93.8%, and 95.14% for TNF-α, CpG-ODNs, and CpG-ODNs plus HBsAg, respectively), except that CpG-ODNs plus HBsAg significantly raised the positive rate of CD1a from 13.67% to 44.52% (Table 1).

Effects of CpG-ODNs on the amount of IL-12p70 secreted by dendritic cells

In DCs derived from CHB patients, treatment with CpG-ODNs and TNF-α, either alone or combined with HBsAg, resulted in significant increases of supernatant IL-12p70

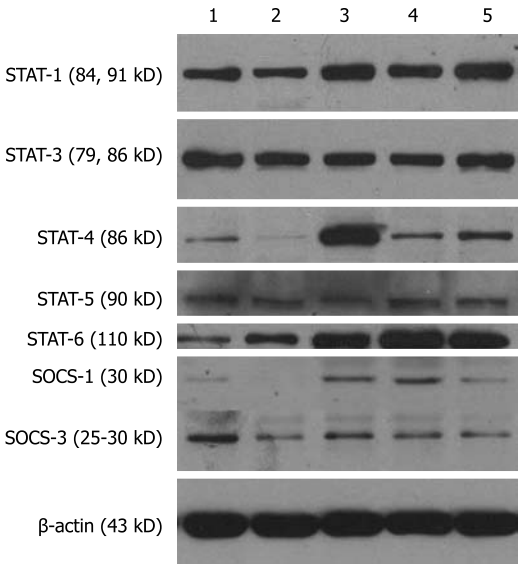

Figure 2 Expression levels of cytoplasmic signal transducers and activators of transcription and suppressors of cell signaling in dendritic cells stimulated with different immunologic adjuvants. 1: Dendritic cells (DCs) from healthy subjects stimulated with synthetic nonmethylated CpG-containing oligodeoxynucleotides (CpG-ODNs); 2-5: DCs from patients with chronic hepatitis B (CHB) stimulated respectively with PBS, CpG-ODNs, TNF-α and CpG-ODNs plus HBsAg. CpG, CpG + HBsAg, TNF-α, and HBsAg are the different adjuvants on DCs. STAT1, 3, 4, 5 and SOCS1, 3 respectively represents the expressing levels of the intracellular signaling molecules including signal transducers and activators of transcription-1, 3, 4, 5 and suppressors of cell signaling-1, 3 in CHB-derived DCs. HBsAg: Hepatitis B surface antigen; TNF: Tumor necrosis factor.

level, suggesting enhanced release of IL-12p70. However, the supernatant levels of IL-12p70 did not increase upon the treatment with HBsAg or PBS (Table 2).

Effects of CpG-ODN-induced dendritic cells on the proliferating response of allogeneic T lymphocyte

The radioactive counts (cpm) representing allogeneic T lymphocyte proliferation in a mixed lymphocyte reaction (MLR) for normal DCs was 2290 ± 1861.1. In contrast, the cpm for CHB-derived DCs was 487.4 ± 216.3, significantly lower than that for the normal DCs ($P < 0.05$). Treatment with CpG-ODNs, CpG-ODNs plus HBsAg, or TNF-α greatly increased the cpm for CHB-derived DCs to 5407 ± 2359, 5831 ± 2815.4, and 9947 ± 3395.2, respectively ($P < 0.05$). This suggested that CpG-ODNs, either alone or combined with HBsAg, enhanced the ability of CHB-derived DCs to present antigen, similar to the effect of TNF-α.

Effects of CpG-ODN on the expression of cytosolic STAT and SOCS proteins in DCs

As shown by the Western blotting experiments (Figure 2), the phosphorylation signal of STAT1, STAT3, and STAT6 in mature DC cytoplasm was relatively strong, while the expression intensities of STAT4, STAT5, SOCS1, and SOCS3 were relatively weak. Compared with mature DCs, the expression intensities of STAT1, STAT3, and STAT5 in immature DC cytoplasm (Lane 2, PBS group) were weak, the expression intensity of STAT6 was strong, the expressions of STAT4 and SOCS1 was almost absent, and the expression of SOCS3 was also weak. The immune adjuvants, CpG-ODNs, CpG-ODNs plus HBsAg and TNF-α, enhanced the expression of cytosolic STAT1, STAT4, STAT6, and SOCS1 in DCs derived from CHB. In particular, the protein band intensities of STAT4 and SOCS1 in CHB-derived DCs stimulated with CpG-ODNs were increased by 12 times and five times, respectively. However, the expression of STAT3, STAT5, and SOCS3 did not change between mature DCs and immature DCs (Lane 2, PBS group). In addition, the addition of HBsAg to CpG-ODNs did not alter the effects of CpG-ODNs on the expression of the above signal proteins (Figure 2).

Table 2 Supernatant IL-12p70 levels (ng/L) before and after the treatment with different immunologic adjuvants in dendritic cells derived from blood monocytes of patients with chronic hepatitis B

	CpG-ODN	TNF-α	CpG-ODN + HBsAg	TNF-α + HBsAg	HBsAg	PBS
Before treatment	43.1 ± 40.9[a]	58.5 ± 52.2[a]	31.8 ± 65.4	20.4 ± 8.3	21.5 ± 14.2	36.3 ± 27.6

DISCUSSION

Recent studies indicate that DCs derived from the peripheral blood of patients with CHB have abnormal phenotypes and functions, such as downregulated expression of surface molecules (HLA-DR, CD86, CD1a, CD11c and ICAM-1), reduced ability to stimulate the proliferation of allogeneic T lymphocytes, reduced secretion of IL-12p70 and IFNγ, and disorder in the proportion of DC1/DC2[1,2]. However, the molecular immunological mechanism of DC dysfunction in CHB is unclear, and immunotherapy aimed to improve the dysfunction of DC is in the initial stages. Bacterial lipopolysaccharide (LPS), TNF-α, and phytohemagglutinin (PHA) are able to stimulate maturation of DCs; however, as inflammatory compounds, their application is limited in *in vitro* research and animal experiments. As reported recently, bacterial genomic DNA containing a non-methylated CpG motif is able to activate antigen-presenting cells (APC), and preferentially induce a Th1-dominating immune response[7]. An artificially synthesized non-methylated CpG-containing oligodeoxynucleotides (CpG-ODNs), similar to LPS and TNF-α, is capable of inducing maturation of DCs derived from mouse bone marrow and human peripheral blood monocyte and en-

hances their antigen-presenting ability[6,8-11]. CpG-ODNs administered together with a hemopoietic growth factor or an immunomodulator was shown to improve the function of DCs in experimental tumor models and reinforce the immune ability of scavenging tumor[4,5]. As a highly effective Th1-type inducing adjuvant, a phase I clinical trial of CpG-ODNs has been carried out, but little research data exists to define the effects and mechanisms of CpG-ODNs on the proliferation and maturation of peripheral blood DCs in CHB.

It is reported that the flanking sequences of non-methylated CpG-containing CpG-ODNs with highest stimulating activity differ between mice and humans. The following CpG-ODNs sequence was adopted in this study, TCCATGTCGTTCCTGTCGTT, which has the highest immune stimulating activity in humans. Our data showed that CpG-ODNs, at a dose of 10 μg/mL, significantly induced the proliferation and maturation of peripheral blood DCs from CHB over a 5-d culture period. FCM detection showed that the HLA-DR expression on DCs treated with CpG-ODNs was significantly upregulated, the amount of IL-12p70 secreted by DC was also increased, and the ability of DCs to stimulate the proliferation of allogeneic T lymphocytes was enhanced. The effect of CpG-ODNs on the proliferation of DCs was similar to that of TNF-α. However, neither TNF-α nor CpG-ODNs increased the expression of CD1a, a specific marker of mature DCs. Interestingly, the combination of CpG-ODN and the specific antigen HBsAg of HBV significantly increased the number of cells positive for CD1a among DCs from CHB. The above data indicated that combined stimulation with a Th1-type immune adjuvant and a specific antigen such as HBsAg is essential for DCs to obtain ideal antigen-presenting ability against HBV.

The STAT and SOCS signaling pathway are an important pair of positive and negative feedback systems for the intracellular signal transduction of cytokines[12,13], and play crucial roles in the development of chronic hepatitis B[14-17]. The present study showed that, under the induction with GM-CSF and IL-4, the expression levels of STAT4, SOCS1, and SOCS3 in CHB-derived DCs were very low, the expression levels of STAT3 and STAT5 were similar to those of normal mature DCs, the expression of STAT1 was somewhat lower than that of normal control DCs, and the expression of STAT6 was more enhanced than that of control mature DCs. It is reported that a variety of cytokines such as IFNα/β/γ, IL-4, IL-12, IL-10, IL-6, and GM-CSF are dependent on the STAT and SOCS pathways to initiate a cascade of phosphorylation events that lead to changed expression of target genes[18,19]. These data suggest the complexity of cytokine signaling network in DCs from CHB, which might be an important molecular immunological mechanism for the differences between individuals in terms of the short-term and long-term therapeutic effects of antiviral drugs, such as interferon and lamivudine. Our data suggested that CpG-ODNs, TNF-α, and CpG-ODNs plus HBsAg increased, to some extent, the expression levels of STAT1, STAT4, STAT6, SOCS1, and SOCS3 in the cytoplasm of DCs from CHB. The enhancement effect of CpG-ODNs on the expression of STAT4 was particularly dramatic, but the expression of STAT3 and STAT5 showed no differences between immature and mature DCs, indicating that the actions of CpG-ODNs on the STAT and SOCS pathways in DCs might be a crucial mechanism of CpG-ODNs to promote proliferation and maturation and enhance the antigen-presenting function of DCs. It is CpG-ODNs, not other nucleoside analogs, that functions as a Th1-type immune adjuvant, which has been clarified many studies[3-5,7-8,20]. Thus, it is not unexpected that CpG-ODNs improved the partial function of DCs derived from peripheral blood monocytes of CHB in vitro. What is the exact mechanism of the above effects, besides those on the STAT and SOCS pathways, and whether there are expected effects on DCs from CHB *in vivo* in view of complicated immunological pathogenesis of CHB, remain important questions. In the subsequent research, our study group will further investigate the clinical/therapeutic consequences of this study and will uncover the exact mechanisms of DC dysfunction in CHB, with a view to developing novel immunological treatments for CHB[16,21,22].

ACKNOWLEDGMENTS

We are heartily thankful to Mr. Da-Kai Xiao, Mr. Dong Li and Mrs. Yi Zhang of Shanghai Institute of Hematology and Digestive Surgery for their selfless help with the experiments.

COMMENTS

Background

It has been demonstrated that the dendritic cells from patients with chronic hepatitis B (CHB) are abnormal in morphology and function, which is closely related to the immunologic pathogenesis of CHB. However, the molecular mechanism of dendritic cell (DC) dysfunction in CHB and how to regulate it remains unclear.

Research frontiers

As it is known, artificially synthesized non-methylated CpG containing oligodeoxynucleotides (CpG-ODNs), similar to lipopolysaccharide and tumor necrosis factor-α, is capable of inducing DCs derived from mouse bone marrow and human peripheral blood monocyte to mature and enhancing its antigen-presenting ability. However, few research data exist to define the effects and mechanisms of CpG-ODNs on the proliferation and maturation of peripheral blood DCs in CHB.

Innovations and breakthroughs

The treatment of CpG-ODNs either alone or combined with Hepatitis B surface antigen (HBsAg) has a remarkable stimulatory effect on the impaired phenotype and function of DCs in CHB possibly by regulating the expression of signal transducer and activator of transcription (STAT) 1,4,6 and suppressor of cytokine signaling (SOCS) 1,3, which might help to develop novel immunological treatments for CHB.

Applications

In the following research, the study group will try to deepen the clinical/therapeutic consequences of this study and further study is also needed to uncover the exact mechanisms of DC dysfunction in CHB, and to develop novel immunological treatments for CHB.

Terminology

Dendritic cell, Considered as a kind of professional antigen-presenting cell, is capable of initiating strong primary cellular immune response of host and determine its direction so as to play an important role in the immunologic response

of anti-infection. Artificially synthesized non-methylated CpG motif containing oligodeoxynucleotides (CpG-ODNs) might directly activate antigen-presenting cells, superiorly induce Th1 type immune reaction and have wide application prospect. However, there are few research data reported about the effects of CpG-ODNs on some important cell signal transducers in cytoplasm or nucleus of DC such as STAT, SOCS.

Peer review

The study is interesting, well done. The study improved the existing knowledge for DC dysfunction in chronic hepatitis B. It would be very well appreciated. Deepen the clinical/therapeutic consequences of this study possibly in the future research.

Abstract

A large cell neuroendocrine carcinoma (LCNEC) of the stomach is very rare. A 76-year-old Japanese man was admitted to our hospital because of epigastralgia and nausea. Endoscopy revealed 2 large tumors in the stomach. He did not have multiple endocrine neoplasia type I or Zollinger-Ellison syndrome. Imaging modalities, including computed tomography and magnetic resonance imaging, revealed no other tumors. Gastrectomy, cholecystectomy, and lymph node dissection were performed. The resected stomach had 2 tumors: one was an antral ulcerated type 3 tumor measuring 5 cm x 5 cm, and the other was a polypoid type 1 tumor measuring 6 cm x 6 cm x 3 cm in the fundus. Microscopically, the antral ulcerated tumor was a well differentiated adenocarcinoma with deep invasion. The fundus polypoid tumor was a LCNEC, being composed of malignant large cells arranged in trabecular and nested patterns. The tumor cells were large and the nuclei were vesicular. Nucleoli were frequently present, and there were many mitotic figures, apoptotic bodies, and necrotic areas. Much lymphovascular permeation was seen. Seven out of 29 dissected lymph nodes showed metastatic foci; 6 were from the LCNEC and 1 from the adenocarcinoma. Many intravascular tumor emboli of LCNEC were seen in the peritoneum around the lymph nodes. Mucins were present in the adenocarcinoma but not in the LCNEC. Immunohistochemically, the LCNEC tumor cells were positive for pancytokeratins, synaptophysin (50% positive), chromogranin A (10% positive), Ki-67 (90% labeled), and platelet-derived growth factor-α (80% positive). They were negative for KIT, p53, CD56, and neuron-specific enolase. The non-cancerous stomach showed a normal number of endocrine cells. The patient is now treated with adjuvant chemotherapy.

INTRODUCTION

Large cell neuroendocrine carcinoma (LCNEC) of the stomach is very rare, and has been reported mainly in Japan[1-4]. In the World Health Organization (WHO) Blue Book[5], gastric neuroendocrine tumors were classified into well differentiated endocrine neoplasms (carcinoid) and poorly differentiated endocrine neoplasms (small cell carcinoma). In the latter section of the Blue Book, LCNEC of the stomach was defined as follows: LCNEC is a malignant neoplasm composed of large cells having organoid, nesting, trabecular, rosette-like and palisading

patterns that suggest endocrine differentiation, and in which the last can be confirmed by immunohistochemistry and electron microscopy[5]. In contrast to small cell carcinoma, LCNEC has abundant cytoplasm, more vesicular nuclei, and prominent nucleoli[5]. Although single LCNEC[1-4] and composite LCNEC and adenocarcinoma[6] of the stomach have been reported, there has been no English literature of simultaneous and distinct LCNEC and adenocarcinoma of the stomach, to the best of the author's knowledge.

CASE REPORT

A 76-year-old Japanese man presented with epigastralgia and nausea, and attended our hospital. Upper gastric endoscopy revealed 2 large tumors in the stomach, and a biopsy from one tumor showed well differentiated tubular adenocarcinoma. He did not have multiple endocrine neoplasia type I or Zollinger-Ellison syndrome. Preoperative imaging techniques, including computed tomography and magnetic resonance imaging, revealed no other tumors. Gastrectomy, cholecystectomy, and lymph node dissection were performed. The resected stomach showed 2 large tumors (Figure 1). One was an antral ulcerated type 3 tumor measuring 5 cm × 5 cm, and the other was a polypoid type 1 tumor measuring 6 cm × 6 cm × 3 cm located in the fundus (Figure 1). Microscopically, the antral ulcerated tumor was a well differentiated adenocarcinoma invading the subserosa (Figure 2). The fundus polypoid tumor was composed of malignant large cells arranged in trabecular and nested patterns (Figure 3A). No tubular formations were recognized. The tumor cells were large and the nuclei were vesicular (Figure 3B). Nucleoli were frequently identified, and there were many mitotic figures, apoptotic bodies, and small necrotic areas (Figure 3B). The tumor was located in the mucosa and submucosa, and invasion into proper muscle and subserosa was not noted. Much lymphovascular invasion was seen. Seven out of 29 dissected lymph nodes showed metastatic foci; 6 were from the LCNEC and 1 was from the adenocarcinoma. Many intravascular tumor emboli of the LCNEC were seen in the peritoneum around the lymph nodes. The non-cancerous stomach showed chronic atrophic gastritis.

The adenocarcinoma was positive for mucins, while the LCNEC was negative for mucins, as revealed by mucin stains including d-periodic acid-Schiff, Alcian blue, and mucicarmine.

An immunohistochemical study was performed with the Dako Envision method (Dako Corp., Glostrup, Denmark) as previously described[7,8]. The tumor cells of the polypoid tumor were positive for pancytokeratins (AE1/3 and CAM 5.2) (Figure 4A), synaptophysin (50% positive) (Figure 4B), chromogranin A (10% positive), Ki-67 (90% labeled) (Figure 4C), and platelet-derived growth factor-α (PDGFRA) (80% positive) (Figure 4D). The cells were negative for KIT, p53, CD56, and neuron-specific enolase. The non-cancerous stomach showed a normal number of endocrine cells.

Figure 1 Gross features of the 2 tumors of the stomach. One is an ulcerated tumor in the antrum (arrow) and the other is a polypoid tumor in the gastric body (double arrows). The ulcerated tumor is an adenocarcinoma, and the polypoid tumor is a large cell neuroendocrine carcinoma. The organ on the right is the gallbladder.

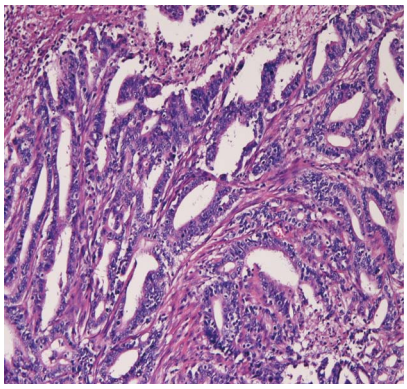

Figure 2 Microscopic features of adenocarcinoma. Well defined tubules are seen (× 200).

The gallbladder showed no significant changes. No peritoneal dissemination was recognized. The patient is now treated with adjuvant chemotherapy.

DISCUSSION

LCNEC of the stomach is not a well recognized entity. In the WHO Blue Book[5], neuroendocrine tumors of the stomach are classified into well differentiated tumors (carcinoids) and poorly differentiated neuroendocrine carcinoma (small cell carcinoma), and LCNEC is not included as a clinicopathological entity. However, as in the present case, a non-carcinoid and non-small neuroendocrine carcinoma may be present[1-6]. Therefore, LCNEC of the stomach should be listed as a neuroendocrine carcinoma in the WHO Blue Book.

The presentation of the current case is different from a carcinoid tumor because it showed significant atypia, mitosis, apoptotic cells, and necrosis, all of which are not seen in carcinoids. The present case is apparently different from small cell carcinoma because of the atypical features of the tumor cells.

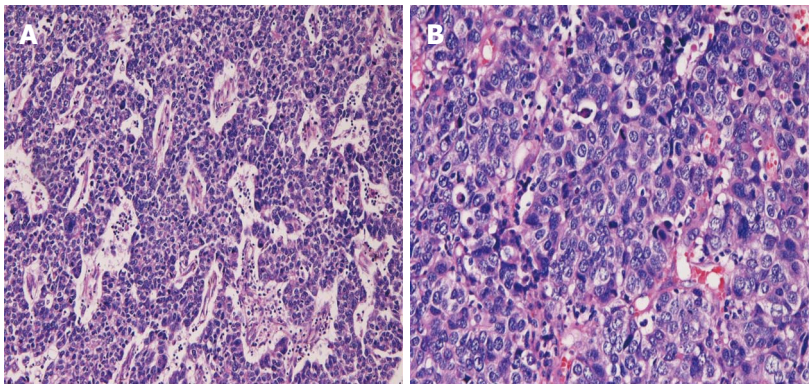

Figure 3 Polypoid tumor. A: The polypoid tumor consists of malignant cells with hyperchromatic nuclei arranged in a trabecular pattern (HE, × 100); B: Higher power view shows large cells, vesicular nuclei, nucleoli, mitotic figures and apoptotic bodies (HE, × 200). HE: Hematoxylin and eosin.

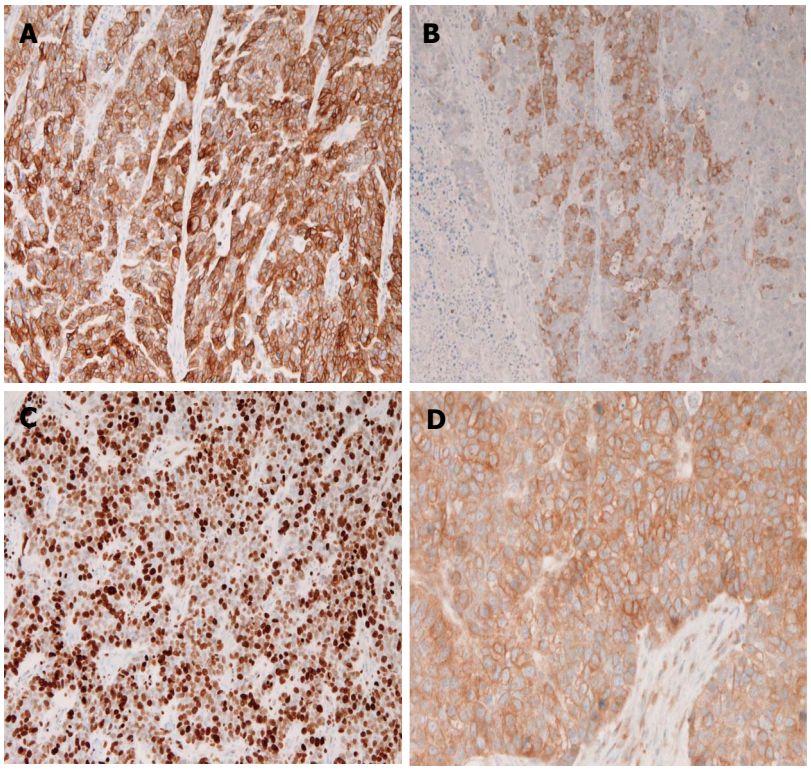

Figure 4 Immunohistochemical findings. Tumor cells are positive for pancytokeratin AE1/3 (A), synaptophysin (B), Ki67 (C), and PDGFRA (D) (× 100). PDGFRA: Platelet-derived growth factor-α.

The present case is not an adenocarcinoma with endocrine differentiation. Endocrine cells of the latter are a very minor component, accounting for less than 20%[2]. In the present case, the neuroendocrine component accounted for 50% of LCNEC cells, thus confirming that the current case is not an adenocarcinoma with neuroendocrine differentiation but a LCNEC.

The frequency of gastric LCNEC is unclear. Jiang *et al*[2] examined 2835 cases of gastric carcinoma and found 42 cases (1.5%) of LCNEC and 44 cases (1.6%) of adenocarcinoma with endocrine differentiation. The frequency is relatively high. In general, pathologists do not perform an immunohistochemical study of surgical specimens of gastric cancers. It is recommended that pathologists examine at least the immunohistochemistry of neuroendocrine markers in poorly differentiated carcinoma showing neuroendocrinoid histology.

The biological behavior of gastric LCNEC is significantly more aggressive than that of gastric adenocarcinoma[2]. Adenocarcinoma with an endocrine component is more aggressive than ordinary adenocarcinoma[2]. The authors think that the prognosis of the present case is poor because the adenocarcinoma is advanced and lymph node metastasis was found in 6 of 29 lymph nodes. In addition, there were many intravascular tumor emboli of LCNEC in the perilymphatic peritoneum.

The present tumor is not a composite or combined tumor, but a separate tumor. There is one report of com-

bined or collision LCNEC and adenocarcinoma[6]. In the present case, the LCNEC and adenocarcinoma were remote from each other, thus were simultaneous. Such a simultaneous LCNEC and adenocarcinoma of the stomach has not been reported in the English literature, to the best of the author's knowledge. It is very interesting that the present LCNEC expressed PDGFRA, but not KIT. Tumors expressing PDGFRA have been not examined. The PDGFRA may be related to neuroendocrine features of a LCNEC, as in gastrointestinal stromal tumors. Thus, a stomach LCNEC can be included in a group of tumors expressing PDGFRA.

Abstract

Lipomatous hemangiopericytomas (LHPCs) are rare soft-tissue tumors that are histologically characterized by hemangiopericytomatous vasculature and the presence of mature adipocytes. We present the clinicopathological features of a case of gastric LHPC in a 56-year-old female, along with a literature review. Endoscopy and endoscopic ultrasound showed a submucosal tumor 0.8 cm across in the greatest dimension in the lesser curvature side of the gastric antrum. Grossly, the well-defined mass had a solid and tan-white cut surface admixed with myxoid regions and yellowish areas. Histological examination revealed a submucosal well-circumscribed lesion composed of cellular nodules with the classic appearance of an hemangiopericytoma admixed with clusters and lobules of mature adipocytes. The ill-defined tumor cells had weakly eosinophilic cytoplasm and contained spindled nuclei with occasional small nucleoli. Nuclei atypia and mitoses were absent, and no cellular atypia, necrosis or vascular invasion was observed. Immunohistochemistry showed that the tumor cells were diffusely positive for CD34, CD99, and vimentin and were focally reactive for bcl-2. This is the first known report of an LHPC in the stomach. The patient was followed for 12 mo without any evidence of metastasis or recurrence.

INTRODUCTION

Lipomatous hemangiopericytoma (LHPC) is a recently recognized rare hemangiopericytoma (HPC) variant that is histologically composed of an admixture of benign hemangiopericytomatous and mature lipomatous components[1]. To date, 49 cases of LHPC have been documented in published English language reports (Table 1)[1-19], but tumors developing in visceral organs such as the stomach have not been reported. Herein, we report the clinicopathological and immunohistochemical features of what is, to our knowledge, the first case of an LHPC occurring in the stomach and present a review of the literature.

CASE REPORT

A 56-year-old female presented with slight left epigastric pain that had been present for two months. Her past medical history and family history were unremarkable.

M: Male; F: Female; NED: No evidence of disease; NA: Not available.

The laboratory data were within normal limits. Endoscopy showed a submucosal tumor of 0.8 cm in the greatest dimension in the lesser curvature side of the gastric antrum. The broad-base mass with a smooth external surface protruded into the lumen. The overlying mucosa was normal in texture and color. On endoscopic ultrasound, an oval, well-defined, hyperechoic mass was detected lying beneath the mucosa but protruding into the lumen. Given the clinical suspicion of a gastrointestinal stromal tumor (GIST), endoscopic resection was performed with a diathermy snare after ligation with a detachable snare. The neoplasm was completely excised. Her postoperative course was uneventful. She was well, without evidence of recurrence or metastasis, 12 mo after resection.

On gross pathology, the specimen consisted of a nodular mass measuring 0.8 cm × 0.6 cm × 0.5 cm with an attached portion of gastric mucosa. Sectioning revealed a well-demarcated, nonencapsulated mass with a solid and tan-white appearance admixed with myxoid regions and yellowish areas. The tumor was soft and rubbery in consistency without involving the overlying mucosa.

Histological examination revealed a submucosal well-circumscribed lesion composed of cellular nodules with the classic appearance of an HPC admixed with clusters and lobules of mature adipocytes. HPC-like areas showed a patternless architecture of oval to spindle cells surrounding the ectatic thin-walled branching vessels (staghorn configuration) (Figure 1A). The ill-defined tumor cells had weakly eosinophilic cytoplasm and contained spindled nuclei with occasional small nucleoli. Nuclei atypia and mitoses were absent, and no cellular atypia, necrosis, or vascular invasion was observed (Figure 1B). Mature, nonatypical adipocytes were identified throughout the lesion in varying proportions in various regions of the tumor, such as in lobules and foci of fat cells (Figure 1C). Focal myxoid changes were present.

Immunohistochemical staining demonstrated that the neoplastic oval and spindle (nonadipocytic) cells were strongly and diffusely positive for vimentin (Figure 2A), CD34 (Figure 2B), and CD99 and were focally reactive for bcl-2, whereas staining for smooth muscle actin (SMA), pankeratin, CD117, platelet-derived growth factor receptor α (PDGFRA), HMB45, melan-A, and S-100 protein was negative. MIB-1 stained only approximately 1% of the tumor cells (1000 cells counted).

DISCUSSION

An LHPC, which was first formally described as a new entity in the 2002 edition of the WHO classification of soft-tissue tumors, is a rare hemangiopericytoma variant composed of mature adipocytes and hemangiopericytoma-like areas[20]. LHPC was first described as a unique hemangiopericytoma variant by Nielsen *et al*[1] and was named "LHPC" in the English language literature in 1995. In 2000, Guillou *et al*[4] noted that LHPCs and solitary fibrous tumors (SFTs) share similar clinical, pathological, immunohistochemical, and ultrastructural features, except for the presence of mature adipocytes in LHPC, and suggested that LHPC does not correspond to a well-defined entity but, rather, represents a fat-containing variant of SFT.

To date, a total of 50 pathologically confirmed cases of LHPC have been reported, including our patient[1-19]. Most lesions presented clinically as long-standing, deep-seated, indolent tumors, discovered fortuitously in some patients, whereas others had symptoms of compression

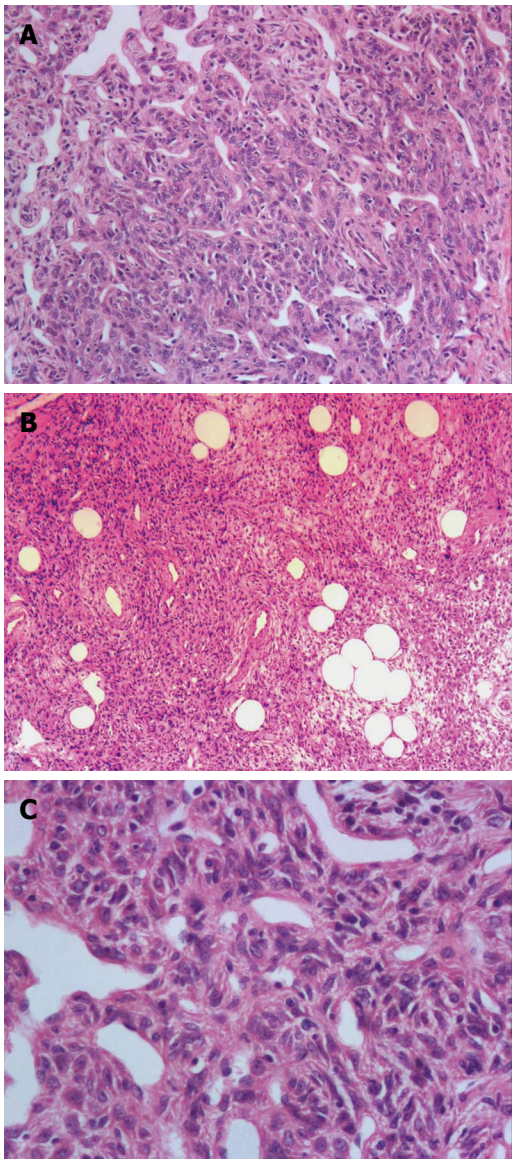

Figure 1 Histological findings of gastric lipomatous hemangiopericytoma by hematoxylin and eosin stains. A: Hemangiopericytoma-like areas in the lipomatous hemangiopericytoma (LHPC) showing a patternless architecture of oval to spindle cells surrounding the ectatic thin-walled branching vessels (HE, × 100); B: The clusters of mature adipocytes in the LHPC (HE, × 40); C: The nonatypical, ill-defined tumor cells had a weakly eosinophilic cytoplasm and contained spindled nuclei (HE, × 200). HE: Hematoxylin and eosin.

related to tumor enlargement[4]. As documented in Table 1, LHPC seems to occur in middle-aged adult patients (range, 21-79 years; mean, 51.7 years), similar to the mean age of 55 years reported by Folpe *et al*[3]. The sex distribution for the LHPC cases for which this information is known is 20 females and 29 males, demonstrating a slight male predilection of LHPC. The size of the lesions ranged from 0.8 cm to 21 cm (mean, 7.9 cm). LHPCs have a wide anatomical distribution, but the most commonly affected sites are the lower extremities (14/50), including the thigh, hip, calf, popliteal fossa, and inguina. Other sites (72%) included the retroperitoneum, orbit, mediastinum, and pelvic cavity. The thigh, retroperitoneum and the orbit were the most commonly affected sites. Most of the tumors were located in the deep soft tissue[4].

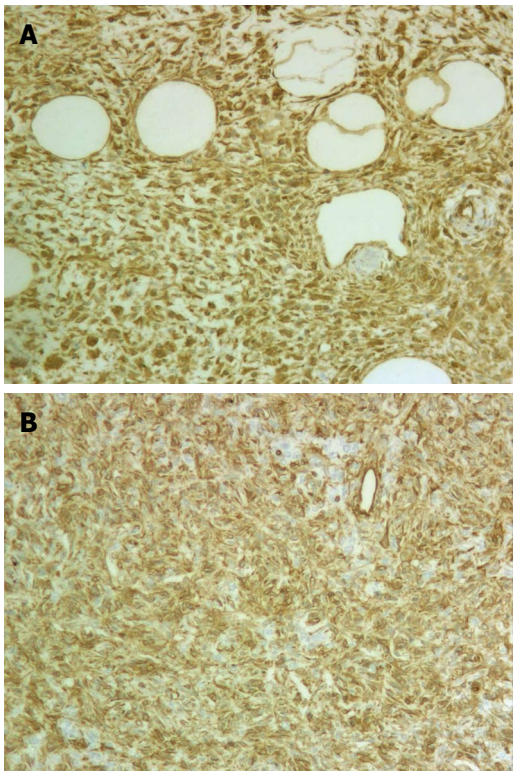

Figure 2 Immunohistochemical findings for vimentin and CD34. The tumor cells immunohistochemically expressed vimentin (A) and CD34 (B) (immunoperoxidase technique with hematoxylin counterstain, × 100).

Given that no LHPC patients developed recurrence during the follow-up interval and that all were without disease, some authors have concluded that LHPCs are likely to be benign tumors[3,4]. However, in our opinion, their biological behavior has yet to be determined because only 30 cases have been followed up in the English language literature to date, and the mean follow-up length was only 30.5 mo, not long enough to draw definitive conclusions about the prognosis of LHPCs. Davies *et al*[5] suggested that patients with LHPC should be followed up for more than 10 years.

Grossly, LHPC generally presents as a well-demarcated, variably encapsulated, medium-sized mesenchymal tumor. Cut sections show alternating areas of whitish and yellowish tumor tissue, in most cases with a lobular or fascicular appearance. Microscopically, the tissue characteristically shows a varying combination of cellular areas composed of round to spindle cells, collagenous or myxoid stroma with focal sclerotic areas, hemangiopericytoma-like vasculature made of small- to medium-sized thick-walled branched vessels, and lipomatous areas made up of mature adipocytes[4]. LHPCs may become large and occasionally show nuclear atypia within sclerotic zones, a phenomenon probably akin to that seen in degenerated schwannomas. LHPCs may also rarely show foci of high cellularity but do not approach the level seen in malignant LHPCs or in other malignancies that commonly show a hemangiopericytomatous pattern, such as synovial sarcoma or mesenchymal chondrosarcoma[3]. Immunohistochemistry showed that the nonadipocytic tumor cells are strongly and diffusely positive for

vimentin and CD34, and they can also be positive for CD99 and bcl-2[21]. Ultrastructurally, the nonadipocytic tumor cells show features consistent with fibroblastic, myofibroblastic or pericytic differentiation[21].

Considering the location and histological appearance of this type of tumor, the main differential diagnoses considered should include GIST, angiomyolipoma, liposarcoma, and spindle cell lipoma (SCL). The stomach is the most common location for GIST, with 60%-70% of tumors occurring in this location[22]. In fact, in our study, the initial clinical diagnosis was GIST. Briefly, GISTs contain bundles of spindle cells and do not contain the mature adipocytes characteristic of LHPC. LHPCs are positive for CD34 but are negative for CD117. In contrast, GISTs are positive for CD117, CD34, and PDGFRA[23]. There was consistent negative staining for CD117 and PDGFRA. Hence, the tumor was not a GIST but, judging by its histological and immunohistochemical features, an LHPC. Differentiating an angiomyolipoma, especially one with a prominent smooth muscle component, from an LHPC is based on the former's distinctive arrangement of the spindle cells around thick-walled vessels and their immunoreactivity for SMA and melanocytic markers (HMB45 and melan-A)[4,9]. Liposarcoma, especially the myxoid variant, can have a prominent vasculature. The vascular configuration should serve as a useful clue in distinguishing between liposarcoma and LHPC. The vessels in myxoid liposarcoma form a delicate plexiform capillary vascular network, unlike the staghorn pattern of LHPC. Furthermore, LHPCs are devoid of lipoblasts[1]. SCL usually develops in the subcutaneous tissue of the neck and upper back of male patients and contains short bundles of wiry collagen admixed with the spindle cells. SCLs do not contain the hemangiopericytoma-like vasculature of LHPCs[21].

In conclusion, the clinicopathological features of our case were entirely compatible with those of LHPC, and to our knowledge, this is the first reported case affecting the stomach. More cases of LHPC of the stomach must be studied to draw definitive conclusions about its distinct behavior and management.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions
Manuscripts should be submitted through the Online Submission

System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be

used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Juvenile polyposis syndrome is a rare autosomal dominant syndrome characterized by multiple distinct juvenile polyps in the gastrointestinal tract and an increased risk of colorectal cancer. The cumulative life-time risk of colorectal cancer is 39% and the relative risk is 34. Juvenile polyps have a distinctive histology characterized by an abundance of edematous lamina propria with inflammatory cells and cystically dilated glands lined by cuboidal to columnar epithelium with reactive changes. Clinically, juvenile polyposis syndrome is defined by the presence of 5 or more juvenile polyps in the colorectum, juvenile polyps throughout the gastrointestinal tract or any number of juvenile polyps and a positive family history of juvenile polyposis. In about 50%-60% of patients diagnosed with juvenile polyposis syndrome a germline mutation in the *SMAD4* or *BMPR1A* gene is found. Both genes play a role in the BMP/TGF-beta signalling pathway. It has been suggested that cancer in juvenile polyposis may develop through the so-called "landscaper mechanism" where an abnormal stromal environment leads to neoplastic transformation of the adjacent epithelium and in the end invasive carcinoma. Recognition of this rare disorder is important for patients and their families with regard to treatment, follow-up and screening of at risk individuals. Each clinician confronted with the diagnosis of a juvenile polyp should therefore consider the possibility of juvenile polyposis syndrome. In addition, juvenile polyposis syndrome provides a unique model to study colorectal cancer pathogenesis in general and gives insight in the molecular genetic basis of cancer. This review discusses clinical manifestations, genetics, pathogenesis and management of juvenile polyposis syndrome.

INTRODUCTION

Juvenile polyposis syndrome (JPS) is a rare autosomal dominant hereditary disorder characterized by multiple distinct juvenile polyps in the gastrointestinal tract and an increased risk of colorectal cancer. Sporadic solitary colorectal juvenile polyps occur in approximately 2% of the paediatric population but these polyps are not associated with an increased risk of gastrointestinal cancer[1,2]. Juvenile polyposis syndrome is defined by the presence of five or more juvenile polyps in the colorectum, juvenile polyps throughout the gastrointestinal tract or any

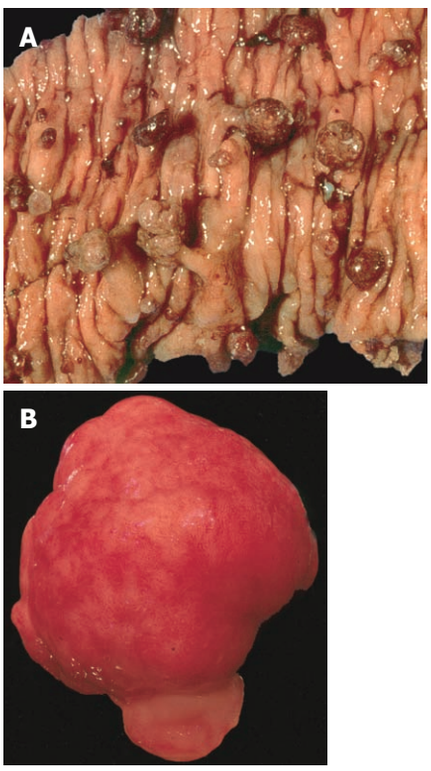

Figure 1 Macroscopic appearance of juvenile polyposis. A: Bowel resection of a patient with juvenile polyposis syndrome showing multiple spherical pedunculated polyps with a smooth surfaces; B: Gross appearance of a juvenile polyp from a patient with juvenile polyposis syndrome. Note the smooth surface, in contrast with a Peutz-Jeghers polyp.

number of juvenile polyps, and a positive family history of juvenile polyposis[1,3]. About 50%-60% of JPS patients have a germline mutation in the *SMAD4* or *BMPR1A* gene[4-6].

HISTOLOGY

The juvenile polyp is a histopathological entity first reported by Diamond[7] in 1939 and later described in more detail by Helwig[8]. Macroscopically, juvenile polyps vary in size from 5 mm to 50 mm, and typically have a spherical, lobulated and pedunculated appearance with surface erosion (Figure 1A and B). Microscopically, a juvenile polyp is characterized by an abundance of edematous lamina propria with inflammatory cells and cystically dilated glands lined by cuboidal to columnar epithelium with reactive changes (Figure 2A and B). The distinction between an inflammatory and a juvenile polyp is often difficult. In essence, juvenile polyps in juvenile polyposis syndrome appear similar to sporadic solitary juvenile polyps, although syndromic polyps often have a frond-like growth pattern with fewer stroma, fewer dilated glands and more proliferative smaller glands[9]. In addition, polyps in juvenile polyposis syndrome frequently show neoplastic changes to the epithelium not found in sporadic solitary juvenile polyps. Colorectal polyps from individuals with a *SMAD4* germline mutation often have a more proliferative epithelial phenotype and fewer stroma compared to those from patients with a *BMPR1A* germline mutation (Figure 2A and B)[10]. In addition, absence of the SMAD4 protein on immunohistochemistry of a juvenile polyp indicates that the patient carries a germline *SMAD4* mutation (Figure 2C)[11].

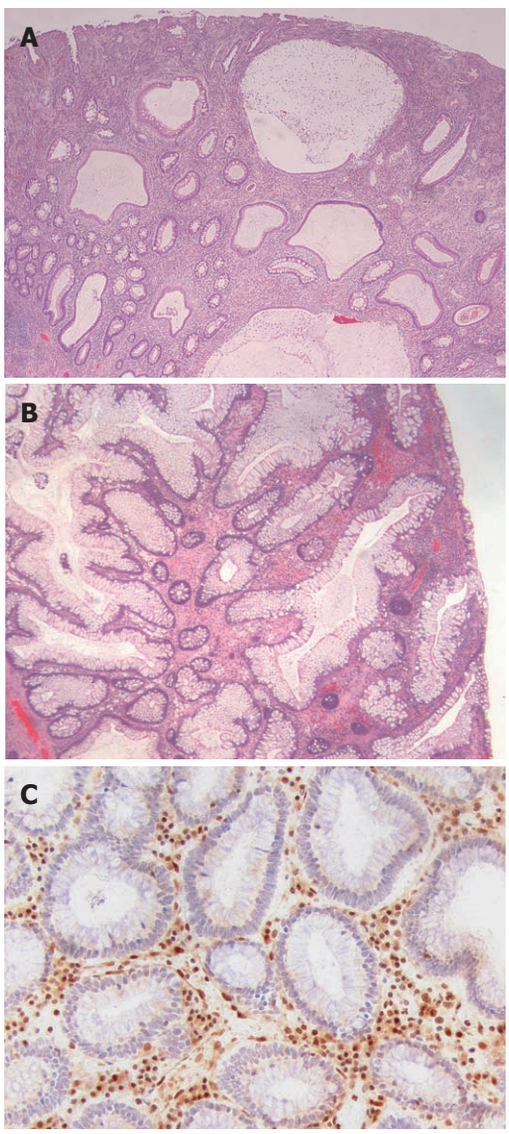

Figure 2 Histological appearance of juvenile polyposis. A: Histological section of a juvenile polyp from a juvenile polyposis patient with a germline mutation of *BMPR1A*. Typically, juvenile polyps are characterized by prominent lamina propria with edema and inflammatory cells, and cystically dilated glands lined by cuboidal to columnar epithelium with reactive changes; B: Histological section of a juvenile polyp from a juvenile polyposis patient with a germline mutation of *SMAD4*. This polyp shows relatively fewer stroma, fewer dilated glands and more proliferative smaller glands; C: SMAD4 immunohistochemistry on a juvenile polyp showing absent SMAD4 expression in the epithelium, indicating that this patient carries a germline *SMAD4* mutation.

Small intestinal polyps in JPS have been classified as juvenile[12,13], hyperplastic and/or inflammatory polyps[14-16], and as lymphoid hyperplasia[15,17]. The larger small intestinal polyps resemble juvenile polyps in the colon[17]. In addition, juvenile/hamartomatous polyps with dysplastic changes and adenomas have been found in the duodenum, jejunum, and ileum of patients with JPS[12,14,16]. Moreover,

we have seen a Brunner gland hamartoma in the duodenum of a juvenile polyposis patient with a *SMAD4* germline mutation. Most gastric polyps in JPS patients have been diagnosed as hyperplasic polyps[14] and are indistinguishable from gastric hyperplastic polyps[18].

GENETICS

A germline mutation in the *SMAD4* or *BMPR1A* gene is found in about 50%-60% of JPS patients[4-6]. Both genes are involved in the BMP/TGF-beta signalling pathway. Most germline defects are point mutations or small base pair deletions in the coding regions of *SMAD4* or *BMPR1A* that can be identified by conventional sequence analysis. About 15% of the germline genetic defects are deletions of one or more exons, or the entire *SMAD4* or *BMPR1A* coding sequence, which necessitates identification by techniques that analyze large genomic deletions, such as multiplex ligation-dependent probe amplification (MLPA)[4,6]. Recently, previously unknown mutations in the *BMPR1A* promoter region were found in about 10% of JPS patients[19].

About 30%-40% of JPS patients have no germline mutation; therefore, a number of candidate genes, mostly involved in the transforming growth factor β (TGF-β)/bone morphogenetic proteins (BMP) pathway, have been investigated for a role in JPS pathogenesis. Although not confirmed, and questioned by others, germline mutations of the TGB-β co-receptor Endoglin has been reported in two JPS patients[4,20]. In addition, *SMAD1*, *SMAD2*, *SMAD3*, *SMAD5*, *SMAD7*, *BMPR2*, *BMPR1B*, *ACVRL1, TGFBR II* and *CDX2* have been analyzed; however, no germline mutations have been found in these genes[20]. In addition, *PTEN*, the gene linked to Cowden (CS) and Bannayan-Riley-Ruvalcaba syndrome (BRRS), has been suggested as a *JPS* gene. However, *PTEN* mutations in patients with juvenile polyps likely represent CS or BRRS patients that have not (yet) developed extraintestinal clinical features specific to these conditions[21]. A recent study involving a large number of *PTEN* germline-mutation positive Cowden syndrome patients substantiated this notion by showing that both upper- and lower gastrointestinal polyps are a common manifestation of this syndrome[22]. Patients afflicted by Cowden syndrome may develop colorectal juvenile polyps indistinguishable from those in juvenile polyposis syndrome. Therefore, although the exact gastrointestinal manifestations of Cowden syndrome remain to be clarified, particularly with respect to the upper gastrointestinal tract, Cowden syndrome should be part of the differential diagnosis in a patient presenting with a juvenile polyp.

CLINICAL PRESENTATION

Clinically, juvenile polyposis can present in two forms. The first is called juvenile polyposis of infancy. This is a generalized form occurring in infants with polyps in the stomach, small bowel and colon. The polyps vary in size from 1 to 30 mm and may be sessile or pedunculated. These infants suffer from diarrhoea, haemorrhage, malnutrition and intussusception. Death usually occurs at an early age. In addition, many of these patients have congenital abnormalities, including macrocephaly and generalized hypotonia[23]. Some investigators suggest that this rare form of juvenile polyposis is caused by continuous deletion of *BMPR1A* and *PTEN* genes located on chromosome 10q23.2 and 10q23.3 respectively, although others disagree[24, 25].

In addition, generalized juvenile polyposis and juvenile polyposis coli (juvenile polyps restricted to the colorectum) have been defined[26]. However, these forms appear to be variable expressions of the same disease, because patients of both forms have been reported to segregate according to a dominant mode in the same family[24,27]. These forms may be sporadic, i.e., 'de novo', or inherited, and usually present later in childhood or in adult life. They are characterized by the presence of gastrointestinal juvenile polyposis and an increased risk of gastrointestinal cancer[28]. A variety of extra-intestinal manifestations have been reported in these patients[23]. In approximately 50% of juvenile polyposis coli or generalized JPS cases, a heterozygous germline mutation in the *SMAD4* or *BMPR1A* gene is identified[24]. Several differences in phenotypic expression between carriers of a *SMAD4* and *BMPR1A* mutations have been noted. *SMAD4* mutations are associated with a more aggressive gastrointestinal phenotype, involving higher incidence of colonic adenomas and carcinomas and more frequent upper gastrointestinal polyps and gastric cancer than patients with a *BMPR1A* mutation[6,29,30]. Also, the combined syndrome of JPS and hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome) is associated with germline mutations in *SMAD4*[31].

POLYP DISTRIBUTION

Polyps in JPS predominantly occur in the colorectum, varying in number from five to several hundred. In addition, polyps can be found in the stomach, duodenum, jejunum, and ileum, although the incidence of upper gastrointestinal tract polyps in JPS is less well studied. Rarely, profuse gastric juvenile polyposis is found in the absence colonic polyps[32]. As noted above, upper gastrointestinal polyposis and gastric cancer has been associated with *SMAD4* germline mutation[6,29,30].

Few studies systematically examined upper gastrointestinal tract involvement in juvenile polyposis[12,14,33]. One investigation found gastric polyps in 10 out of 12 (83%) patients, mostly located in the antrum, but throughout the stomach in six individuals. Rarely, profuse gastric juvenile polyposis is found in the absence of colonic polyps. Duodenal polyps were found in four out of 12 (33%) JPS patients, with two having multiple polyps ranging in size from 0.5 to 1.5 cm. and two others with minute polyps[14]. Using capsule endoscopy, small-bowel polyps beyond the range of standard gastroscopy were found

in 2 of 10 (20%) patients and duodenal polyps in 4 others (40%)[33]. Another study reported small bowel polyps in 8 of 56 JPS patients (14%)[12]. Moreover, a number of case reports of duodenal, jejunal, and ileal polyps in JPS patients exist[13,15-17,34], In addition, juvenile polyps are frequently found in the ileal pouch of juvenile polyposis patients who have undergone proctocolectomy[35,36].

CANCER RISK

Juvenile polyposis is associated with an increased risk of gastrointestinal cancer. A recent cancer risk analysis calculated a cumulative life-time risk for colorectal cancer in JPS of 39% and a relative risk of colorectal cancer of 34[37]. However, this may be a conservative estimate, because some patients in this study had already undergone prophylactic colectomy. Jass reported a 68% cumulative risk of colorectal cancer in patients from the St Mark's Registry, but details were not provided[38]. In addition, several cases of stomach, duodenal, and pancreatic cancer in JPS have been described in the literature, but no formal risk analysis for these malignancies exists[28]. One study found small bowel carcinoma in six out of 56 (11%) JPS patients, but four of these cancers occurred in one family[12]. Evaluation of literature reports suggests that gastric and small bowel carcinoma, together, occur at about one-fifth the frequency of colorectal cancers in this patient group[37].

CANCER PATHOGENESIS

Cancer pathogenesis in juvenile polyposis has not yet been unravelled and may develop through the so-called "landscaper mechanism". The landscaper model was proposed after the observation that the genetic alterations at chromosome 10q22 (*BMPR1A* locus) occurred predominantly in the stroma of juvenile polyps. This paradigm postulates that cancer develops as a result of an abnormal stromal environment, which leads to neoplastic transformation of the adjacent epithelium[39]. Support for a "landscaper" defect triggering juvenile polyposis came from a study in which disrupted BMP signalling, through expression of a natural pathway inhibitor, resulted in development a juvenile polyposis-like phenotype in mice[40]. BMP-4 expression is normally limited to the mesenchymal compartment of the murine intestine, suggesting that disruption of this mesenchymal signal is involved in mediating juvenile polyposis.

Notwithstanding the concept that faulty transmission or receipt of mesenchymal signals by the epithelium may trigger juvenile changes, others have found that homozygous *SMAD4* deletions are limited to the epithelium of juvenile polyps from JPS patients with germline *SMAD4* mutations and in *Smad4* knockout mice[11,41]. Although further studies are needed, this suggests that *SMAD4* may act as a "gatekeeper", instead of a "landscaper" in JPS pathogenesis, consistent with the role of *SMAD4* in other cancer types[42].

MANAGEMENT

Management of JPS is mainly based on expert opinion[23,43-45]. Patients at risk or with a high suspicion of JPS should have endoscopic screening of the colon and upper gastrointestinal tract at age 15 or at the time of first symptoms[44]. At diagnosis of JPS, the entire gastrointestinal tract should be examined for the presence of polyps[23]. Genetic testing can be useful for at-risk members from families, where germline mutations have been identified. If no germline mutation is found in at-risk persons, then they do not have JPS and can be followed according to the guidelines for screening programs for the general population[44].

Endoscopic examination of the colon and upper gastrointestinal tract is recommended every two to three years in patients with JPS. In patients with polyps, endoscopic screening should be performed yearly, until the patient is deemed polyp-free. Patients with mild polyposis can be managed by frequent endoscopic examinations and polypectomy[23,36,44]. Intraoperative enteroscopy to evaluate small intestinal polyps can be considered at the time of colorectal surgery[16]. Endoscopic treatment of gastric polyps can be difficult, and patients with symptomatic gastric polyposis (e.g., severe anaemia) may need subtotal or total gastrectomy.

Prophylactic surgery is considered in patients with colorectal polyposis unmanageable by endoscopy (> 50-100 polyps), those with severe gastrointestinal bleeding or diarrhoea, juvenile polyps with dysplasia, and patients with a strong family history of colorectal cancer[35-37]. Surgical options include subtotal colectomy with ileorectal anastomosis, or total proctocolectomy with pouch[35,36]. Analogous to familial adenomatous polyposis, surgical type may depend on the extent of rectal polyposis. Recurrence of rectal polyps in patients with subtotal colectomy is frequent, and about half of these individuals require subsequent proctectomy[35,36]. Therefore, total proctocolectomy has been advocated as the initial surgery for patients with massive juvenile polyposis, who are unable to be managed endoscopically[36]. Although the surgery of choice in JPS remains debatable, patients need frequent post-operative endoscopic surveillance because of the high recurrence rates of polyps in the remnant rectum and the pouch[35].

In JPS patients with a germline *SMAD4* mutation, screening should be considered for signs of hereditary hemorrhagic teleangiectasia, including chest radiography for arteriovenous malformations, magnetic resonance imaging of the brain, and liver sonography[31]. Digital clubbing and pulmonary osteoarthropathy are frequently described in combination with arteriovenous malformations[17].

COX-2 expression is higher in JPS polyps than in sporadic juvenile polyps and correlates with polyp size and dysplasia[46]. This observation suggests that chemoprevention using selective or non-selective *COX-2* inhibitors could be beneficial in JPS. Currently, nonsteroidal anti-in-

flammatory drugs (NSAID) chemoprevention in JPS has not been systematically studied; however, two JPS patients who had undergone proctocolectomy with pouch reconstruction and subsequent polypectomy from the pouch had no further polyp development in the pouch while on sulindac[35]. However, the value of NSAID chemoprevention in JPS requires further investigation.

CONCLUSION

JPS is a rare hamartomatous polyposis syndrome characterized by the presence of multiple distinct juvenile polyps in the gastrointestinal tract. The primary defect in JPS may be stromal rather than epithelial. This so-called 'landscaper' defect may ultimately lead to neoplastic transformation in the overlying epithelium, although the polyps are not neoplastic per se. On the contrary, juvenile polyps may be considered true hamartomas, i.e., anomalies in the developmental patterning of the gut. Juvenile polyposis syndrome is, therefore, a unique model for studying carcinogenesis in the gastrointestinal tract.

Although rare, recognition of this condition is important in view of the consequences for patients and their families. Each clinician confronted with the diagnosis of a juvenile polyp should consider the possibility of juvenile polyposis syndrome. The number of juvenile polyps should be documented, along with the family history of gastrointestinal polyps and cancer. If a patient fulfils the clinical criteria of JPS, further diagnostic evaluation is indicated.

Future studies on the molecular and clinical aspects of JPS will result in a better understanding of gastrointestinal carcinogenesis and improved management of patients afflicted by this disorder.

Abstract

Pancreatic cancer, as a highly malignant cancer and the fourth cause of cancer-related death in world, is characterized by dismal prognosis, due to rapid disease progression, highly invasive tumour phenotype, and resistance to chemotherapy. Despite significant advances in treatment of the disease during the past decade, the survival rate is little improved. A contributory factor to the poor outcome is the lack of appropriate sensitive and specific biomarkers for early diagnosis. Furthermore, biomarkers for targeting, directing and assessing therapeutic intervention, as well as for detection of residual or recurrent cancer are also needed. Thus, the identification of adequate biomarkers in pancreatic cancer is of extreme importance. Recently, accompanying the development of proteomic technology and devices, more and more potential biomarkers have appeared and are being reported. In this review, we provide an overview of the role of proteome-based biomarkers in pancreatic cancer, including tissue, serum, juice, urine and cell lines. We also discuss the possible mechanism and prospects in the future. That information hopefully might be helpful for further research in the field.

Key words: Biomarkers; Mass spectrometry; Pancreatic cancer; Proteome; Screening

INTRODUCTION

Pancreatic cancer is a highly lethal disease and despite continuous research efforts, results have only marginally improved patient outcome with minor overall changes in death rate over the last four decades. Pancreatic cancer is the fourth cause of cancer-related death and 36 800 pancreatic cancer-related deaths were reported in the United States in 2010, corresponding to 6.5% of all deaths from cancer[1]. Similar overall observations are reported from the other parts of the Western world[2-5].

Surgical resectable pancreatic cancer is associated with an improved outcome, especially if the diagnosis is obtained in an early phase. Regrettably, most symptoms, including e.g., profound weight loss, abdominal pain, new onset type 2 diabetes mellitus, jaundice and nausea, are usually vague and occur late during the course of disease. Only 20% of patients with pancreatic cancer are candidates for a potentially curative resection[6]. Efficient tumor markers for population screening are absent. Current markers used for pancreatic cancer, especially carcinoembryonic antigen and cancer antigen 19-9 (CA19-9), lack appropriate sensitivity and specificity. Biomarkers for therapeutic assessment, detection of residual or recurrent cancer and even for targeted therapy in pancreatic cancer in a more customized fashion are needed. The identification of biomarkers in pancreatic cancer is thus essential for improving outcome.

The development of proteomic techniques has increased the interest for clinical applications of biomarkers in pancreatic cancer. However, the identification of suitable biomarkers with good sensitivity and specificity for clinical use in pancreatic cancer has been sparse. In this review, we focus on potential proteome-based biomarkers to be used in pancreatic cancer (Table 1), hopefully indicative for further research within the field.

PROTEOMIC-BASED BIOMARKERS IN PANCREATIC CANCER TISSUE

Pancreatic cancer tissue is the most direct source of proteomic biomarkers for cancer detection, as it is likely to have the highest concentrations of cancer-specific markers. However, there are two major reasons that make it less available for cancer screening. Invasive biopsy material for screening is usually not readily available, and percutaneous biopsies might even result in seeding of cancer cells. Pathological evaluation renders the final diagnosis and is the best choice when pancreatic cancer tissue is available. Ongoing biomarker research obtained from pancreatic cancer tissue is not only done for diagnostic purposes, but also for the development of potential future targeted therapies.

When comparing pancreatic cancer tissue with normal pancreatic tissue by MALDI-TOF-MS, the levels of galectin-3 and calgizzarin (S100A11) protein were found to be 3-fold higher in cancer patients[7]. Galectin-3 is a member of a family of β-galactoside-binding animal lectins, and has been found helpful in diagnosing e.g., thyroid cancer[7], but is also up-regulated in liver, stomach, and tongue cancers. In the same family, galectin-1 has also been identified as a potential biomarker[8,9]. S100A11, a calcium-binding protein and a member of the S100 protein family is expressed in the nucleus and cytoplasm. S100 proteins regulate a number of cellular processes like cell growth, cell cycle, differentiation, transcription and secretion. S100 proteins have been reported overexpressed in different cancers, like breast and thyroid cancer[10]. Other studies have shown up-regulation of S100A6, S100A8, S100A9 and S100A10 in pancreatic cancer[11-13]. Using laser capture microdissection and 2-DE to analyze protein expression in stromal components of pancreatic cancer, it was demonstrated that high levels of S100A8 and S100A9 were present in the tumor-associated stroma but not in benign or malignant epithelium[12]. Immunohistochemistry confirmed high levels of both S100A8 and S100A9 in specific stromal cells, which were later identified as monocytes or immature macrophages ($CD14^+$/CD68). In a subset of these cells, S100A8 and S100A9 were co-expressed, and this relationship appeared to be influenced by the Smad4 status of the corresponding tumor cells. This study provides further evidence of the complex tumor-stroma interaction and demonstrates that stromal tissue can become a novel and highly promising source of biomarkers.

The differential diagnosis between pancreatic cancer and mass-forming chronic pancreatitis is clinically challenging. A large-scale immunoblotting analysis with more than 900 primary antibodies was performed on cancer tissue, chronic pancreatitis and normal pancreas[14]. A total of 30 proteins were found to be differentially expressed between chronic pancreatitis and normal pancreas, while 102 proteins were different between pancreatic cancer and normal pancreas. Several proteins, such as UHRF1, ATP7A and AOX1, differed in their expression between chronic pancreatitis and pancreatic cancer, suggesting their importance in pancreatic carcinogenesis. The combination of these proteins can become a useful diagnostic tool for endoscopic ultrasonography-guided fine needle aspiration specimens obtained before surgery or treatment.

Pancreatic cancer (PDAC) develops through several phases of pancreatic intraepithelial neoplasia (PanINs) lesions from benign to fully malignant. Pancreatic cancer pathology may be helpful for diagnosis and treatment by providing knowledge on which phases the patient is in. Despite research showing different genetic alternations during different phases, such as *K-ras* in the early PanIN-1A/B, *p16* in the intermediate PanIN-2 and *p53* in the late PanIN-3 phases[15], biological mechanisms still remain largely unclear. One reason is the difficulty in studying early molecular changes in pancreatic cancer, due to lack of suitable tissue specimens, as patients in the early phase often are without existing symptoms, and thus tissue samples are not available. Plectin-1 has been shown to be up-regulated in PanINs and in PDAC in genetic defect mouse models and early-stage pancreatic cancer cell lines[16]. Plectin-1 is a large 500 kDa protein associated with filamentous-actin, microtubules and intermediate filaments. Plectin-1 was found to be exclusively associated with mitochondria and may thus provide an important link of this organelle with the intermediate filament system[17]. Plectin-1 can also bind specific peptides, which may be helpful in detecting precursor lesions and PDAC, when conjugated to magnetofluorescent nanoparticles.

Proteome changes of pancreatic cancer tissue during different stages have been identified by 2-DE. Five candidate protein biomarkers were selected from a total of 31 identified nonredundant proteins, including 14-3-3 sigma, major vault protein (MVP), anterior gradient 2 (AGR2) and Annexin A4[13]. AGR2 is increased early on during tumor progression, and is also present in pancreatic juice[18]. MVP expression, associated with the PI3K pathway, and 14-3-3 sigma were found to be increased in PanIN-2 and -3[19,20]. On the other hand, annexin A4 was down-regulated. Annexin A4 is a Ca^{2+}- and phospholipid-binding protein like annexin A2, which previously has been reported in PDAC[21].

To decrease the complexity and large dynamic range of proteins found in pancreatic tissue samples, subcellular fractionation with mass spectrometric techniques has been used to identify potential biomarkers associated with pancreatic cancer. McKinney *et al*[22] and colleagues

Table 1 A selection of potential biomarkers for pancreatic cancer

Potential biomarkers for pancreatic cancer	Expression	Proteomic tools	Ref.
Tissue			
14-3-3 sigma	+	2-D SDS PAGE, MS	[13]
Annexin A4	+	2-D SDS PAGE, MS	[13]
Anterior gradient 2	+	2-D SDS PAGE, MS	[13]
AOX1	-	PowerBlot	[14]
ATP7A	+	PowerBlot	[14]
Biglycan	+	SDS-PAGE, LC-MS/MS	[22]
Galectin-1	+	2-D SDS PAGE, MS	[9]
Galectin-3	+	MALDI-TOF-MS	[7]
Gelsolin	-	Proteomic chip	[23]
Major vault protein	+	2-D SDS PAGE, MS	[13]
Pigment epithelium-derived factor	+	SDS-PAGE, LC-MS/MS	[22]
Plectin-1	+	Western blotting	[16]
S100A6	+	2-D SDS PAGE, MS	[11]
S100A8 (stroma)	+	2DE, LC-MS/MS	[12]
S100A9 (stroma)	+	2DE, MALDI-TOF-MS	[12]
S100A10	+	2-D SDS PAGE, MS	[13]
S100A11	+	MALDI-TOF-MS	[7]
Thrombospondin-2	+	SDS-PAGE, LC-MS/MS	[22]
βIGH3	+	SDS-PAGE, LC-MS/MS	[22]
UHRF1	+	PowerBlot	[14]
Serum/plasma			
α-1B-glycoprotein precursor	+	DIGE, MS/MS	[38]
Anterior gradient 2	+	iTRAQ, MS/MS	[18]
Apolipoprotein A-Ⅱ	-	SELDI-TOF, MS	[24]
Apolipoprotein C-Ⅰ	+	SELDI-TOF, MS	[24]
Caldecrin	-	ICAT, MS	[43]
CXCL 7	-	LC-MS	[29]
DJ-1	+	DIGE, MS/MS	[38]
Fibrinogen β chain	+	ICAT, MS	[43]
HSP27	+	Protein-chip technology	[33]
Pancreatic juice			
Lithostathine I α	-	2DE, MALDI-TOF-MS	[40]
Matrix metalloproteinase-9	+	DIGE, MS/MS	[38]
Neural cell adhesion molecule L1	+	ICAT, MS	[43]
p-Akt	+	Bio-Plex suspension array	[32]
p-ERK1/2	+	Bio-Plex suspension array	[32]
Phosphor-cAMP response element binding protein	+	Bio-Plex suspension array	[32]
Phosphor-p90 ribosomal S6 kinase	+	Bio-Plex suspension array	[32]
p-IκB-α	+	Bio-Plex suspension array	[32]
Plasminogen	+	ICAT, MS	[43]
Platelet factor 4	-	MALDI-TOF	[31]
p-MEK1	+	Bio-Plex suspension array	[32]
Transthyretin	+	2DE, MALDI-TOF-MS	[45]
Urine			
Annexin A2	-	2-D SDS PAGE	[46]
CD59	-	2-D SDS PAGE	[46]
Gelsolin	-	2-D SDS PAGE	[46]
Cell lines			
Apoprotein E	+	SILAC	[48]
Cadherin	Not in metastatic tumor cell	LC-MS/MS	[52]
Catenin	Not in metastatic tumor cell	LC-MS/MS	[52]
CD9	+	SILAC	[48]
Fibronectin receptor	+	SILAC	[48]
Galectin	Not in primary tumor cell	LC-MS/MS	[52]
Glucagon	+	Protein array	[53]
Integrin	Not in metastatic tumor cell	LC-MS/MS	[52]
Perlecan	+	LC-MS/MS	[48]
Prolactin	-	Protein array	[53]

SILAC: Stable isotope labelling with amino acids in cell culture; DIGE: Difference gel electrophoresis; MS: Mass spectrometry; iTRAQ: Isobaric tags for relative and absolute quantification; ICAT: Isotope-coded affinity tag; βIGH3: Ig-h3 precursor; A1BG: α-1B-glycoprotein precursor; +: Up-regulated; –: Down-regulated expression in pancreatic cancer as compared with controls.

identified 2393 unique proteins in normal and pancreatic tissue with cancer, and determined 104 proteins that were significantly changed in pancreatic cancer. Four secreted and up-regulated proteins have been validated as potential

biomarkers for diagnosing pancreatic cancer, biglycan, pigment epithelium-derived factor, thrombospondin-2 and transforming growth factor β induced protein Ig-h3 precursor, though data for sensitivity and specificity for these markers are not yet available.

Information on lymph node metastasis is very important for the surgical strategy-making and also for deciding other additional treatments (e.g., chemotherapy). Proteome comparison of pancreatic cancer tissue with corresponding non-cancerous normal tissue obtained from the same patients on antibody capture-based proteomic chips[23] identified gelsolin as a candidate biomarker for detection of lymph node metastasis in pancreatic cancer. Gelsolin is an important actin-binding protein that plays a major role in maintaining an organized actin cytoskeleton. The expression of gelsolin in pancreatic ductal adenocarcinomas with lymph node involvement (71.4%) was reported markedly increased as compared to lymph node negative pancreatic cancers (20%)[23].

BIOMARKERS IN BODY FLUIDS

Serum and plasma

Blood is the most frequently used source for biomarkers, being minimally invasive, easily accessible, generally inexpensive and reproducible to obtain and analyse. However, some highly abundant proteins, such as albumin or globulin, can affect the detection of less abundant, but for the diagnosis, valuable proteins.

One study aimed to identify biomarkers in a total of 319 serum samples from pancreatic cancer patients and controls. Using SELDI-TOF MS technology, 21 peaks were identified to be differentially expressed between pancreatic cancer and disease controls (DC), and 18 peaks between pancreatic cancer and healthy volunteers (HV)[24]. Apolipoprotein C-Ⅰ (ApoC-Ⅰ) and apolipoprotein A-Ⅱ (ApoA-Ⅱ) were significantly increased and decreased, respectively. ApoC-Ⅰ plays an important role in controlling plasma lipid metabolism, and is expressed in gastric, breast and pancreatic cancer[25]. ApoA-Ⅱ is present on the surface of lipid particles and may play a diagnostic role in prostate cancer[26]. The receiver operating characteristic area under the curve (AUC) of ApoA-Ⅱ, ApoC-Ⅰ and CA19-9 was greater than that of CA19-9 alone for pancreatic cancer *vs* DC (0.90 *vs* 0.84) and for pancreatic cancer *vs* HV (0.96 *vs* 0.90), results supported by others[27].

CXCL-7 is a chemokine member of the angiogenic ELRb CXC chemokine family, expressed within the megakaryocyte lineage[28]. Using a novel combination of hollow fiber membrane-based low-molecular-weight protein enrichment and LC-MS-based quantitative shotgun proteomics identified a peptide derived from CXCL-7 to be significantly reduced in pancreatic cancer patients[29]. These authors compared the plasma proteome in a small cohort (24 patients with pancreatic cancer and 21 healthy controls) to get 53 009 MS peaks. They then further validated their CXCL-7 finding in an independent blinded cohort (n = 237) using a high-density reverse-phase protein microarray. Combination with CXCL-7 significantly improved the AUC value of CA19-9 to 0.961. However, in this study, the precise molecular mechanisms explaining the CXCL-7 reduction in patients with pancreatic cancer remained unclear. Platelet factor 4 (PF4) is another member of the CXC chemokine family (CXCL-4), and is present in α-granules of all mammalian platelets, as well as in the granules of mast cells[30]. PF4 had been identified as a potential marker for pancreatic cancer by MALDI-TOF-MS-based clinical serum profiling in 80 samples[31]. Validation by ELISA techniques in 40 serum samples showed the AUCs of PF4 concentrations used for the discrimination between healthy controls and pancreatic cancer was 0.833. The discrimination between patients with pancreatic cancer and acute pancreatitis was 0.829.

Protein phosphorylation is one of the most common ways of modifying biological systems, including the carcinogenic progress. Several phosphoprotein levels were significantly increased in serum from pancreatic cancer patients as compared to controls. Six candidate phosphoproteins have been found in serum of pancreatic cancer patients by using a Bio-Plex suspension array; p-ERK1/2, p-MEK1, phospho-p90 ribosomal S6 kinase (p-p90RSK), phospho-cAMP response element binding protein (p-CREB), p-Akt and p-IκB-α[32]. These phosphoproteins are associated with the Ras/Raf/MEK/ERK signalling pathway, which is a dominating growth promoting pathway in pancreatic carcinomas. Further data from the same study showed a simultaneous increase in phospho- and total-ERK1/2 with a positive correlation to pancreatic cancer patients. In detecting pancreatic cancer, a combination of p-ERK1/2 and CA19-9 can potentially avoid false-negatives (87.2%) and improve the discriminatory power.

Heat shock protein 27 (HSP27) is a powerful molecular chaperone that can prevent the aggregation of nascent and stress-induced misfolded proteins[33]. HSP27 has been identified in serum of pancreatic cancer patients by ProteinChip technology and 2-DE. HSP27 was found to be up-regulated in pancreatic cancer as compared with normal tissue, with a sensitivity of 100% and a specificity of 84% in the detection of pancreatic cancer, and has further been suggested to play an important role in gemcitabine resistance[34,35].

Pancreatic juice

Pancreatic juice is rich in proteins directly secreted from pancreatic ductal cancer cells and should therefore constitute a perfect source for specific protein biomarkers for pancreatic cancer detection. However, pancreatic juice is not readily accessible and in addition, the endoscopic retrograde cholangiopancreatography procedure per se, in order to obtain pancreatic juice, may induce acute pancreatitis in 4%-7% of patients[36]. To date approximately 170 proteins have been identified in human pancreatic juice, one third of which are enzymes[37].

When comparing pancreatic juice from 9 PDAC patients and 9 healthy volunteers by using difference gel electrophoresis and tandem mass spectrometry (MS/MS), three potential biomarkers were identified: matrix metalloproteinase-9 (MMP-9), oncogene DJ1 (DJ-1) and α-1B-glycoprotein precursor (A1BG)[38]. DJ-1 is a mitogen-dependent protein involved in the Ras signalling pathway, reported to be increased in serum from pancreatic cancer patients[33,39]. A1BG, a secreted plasma protein from the immunoglobulin superfamily, was also increased in the cytoplasm of malignant epithelia in 86.3% of pancreatic cancer tissue specimens.

Obstruction of the main pancreatic ducts may alter the protein composition of pancreatic juice. Comparing the 2-DE profiles of pancreatic juice from a patient with pancreatic body cancer and a patient with benign pancreatic disease, it was found that blockade of juice secretion strongly affected protein composition[40]. A subsequent analysis of patients with comparable obstruction of the pancreatic ducts was performed. The isomeric form of lithostathine I α was identified as one of five protein spots that were consistently reduced in pancreatic cancer.

Quantitative proteomic analysis using stable isotope labelling (iTRAQ) and MS/MS were applied to identify proteins abnormalities, elevated in the pancreatic juice from PanIN-3 patients[18]. Anterior gradient-2 (AGR2) was significantly increased in PanIN-3 juice samples among 20 differently expressed proteins. AGR2 is a secreted protein and over-expressed in many cancers, including pancreatic cancer and influences pancreatic cancer cell proliferation and invasion. Further analyses showed that AGR2 had 67% sensitivity and 90% specificity in predicting PanIN-3 in pancreatic juice samples[41,42]. Proteomics can also be used to differentiate pancreatic cancer from pancreatitis. In a comparative study between pancreatic cancer and pancreatitis by Isotope-Coded Affinity Tag and MS, 72 variable proteins were identified in pancreatic juice[43]. Some of the identified proteins, including fibrinogen β-chain, plasminogen, neural cell adhesion molecule L1 and caldecrin, demonstrated at least a 2-fold change in abundance in pancreatic juice. In addition, 9 proteins (hemoglobin, fibrinogen, trypsin Ⅰ, trypsin Ⅱ, chymotrypsinogen b, Ig-α1 chain c region, Ig-μ chain c region, ribonuclease, and human serum albumin) were up-regulated both in the pancreatic juice of pancreatitis and pancreatic cancer patients.

Transthyretin (TTR) was identified as a potential protein biomarker in pancreatic juice for the detection of pancreatic cancer. Using 2-DE and MALDI-TOF-MS, it was shown that TTR in the pancreatic juice increased more than 2-fold in pancreatic cancer as compared with chronic pancreatitis and choledocholithiasis[44]. However, TTR was only present in islet cells and not expressed in pancreatic cancer cells, in line with what has been reported by others[45].

Urine

Urine is a potential source of biomarkers, as it is easily and noninvasively available. However, a limitation of urine is the dilution of the proteins of potential interest. Secondly, the urine is derived from the kidneys, only being "in contact" with the pancreas through blood, and most of the proteomic information exists in circulating blood.

Using proteomic techniques multiple deregulated proteins were detected in urine samples from patients with pancreatic cancer, implicating urine to potentially be a valuable source of biomarkers for pancreatic cancer[46]. Five potential protein biomarkers (including annexin A2, gelsolin, CD59 and S100A9) from a total of 127 statistically valid and differentially expressed protein spots were identified, most of which have been reported associated with pancreatic cancer in other studies.

BIOMARKERS IN CELL LINES

Cell lines are the most easily obtained proteomic source. This allows analysis of secreted proteins. The most relevant limitation when using data obtained from cell lines is that it may not be representative for primary tissue samples in the clinical setting. Thus, few studies have used cell lines for identifying biomarkers of relevance in pancreatic cancer[47].

By analysis of secreted proteins between Panc-1 pancreatic cancer cells and immortalized non-neoplastic HPDE cells, 145 differentially secreted proteins were identified. Several proteins were validated by immunohistochemistry, such as CD9, perlecan, apoprotein E (ApoE) and fibronectin receptor[48]. CD9 is a membrane protein expressed on the surface of human platelets. CD9 plays a role in many cellular functions, like adhesion, migration, signal transduction and differentiation[49]. Perlecan is involved in angiogenesis and growth, as a receptor for basic fibroblast growth factor[50]. ApoE is a protein component of lipoproteins that has anti-tumor activity in pancreatic cancer[51]. Fibronectin receptor is another member of the integrin family.

Development of metastases, as part of the progress of pancreatic cancer, evidently involves a number of important proteins. Proteomic research comparing primary and metastatic PDAC cell lines can reveal functional proteins, which are helpful for the prediction of metastasis and potential therapy against this process. One metastatic PDAC cell line, AsPC-1 and one primary PDAC cell line, BxPC-3, were studied for this purpose[52]. Using SDS-PAGE and LC-MS/MS, 221 and 208 proteins were identified from AsPC-1 and BxPC-3 cells, respectively, with 109 proteins present in both cell lines. Analysis of other proteins showed different levels in the two cell lines, including catenin, cadherins, integrins, galectins, annexins and collagens. Cadherins are a class of type-1 transmembrane proteins that depend on calcium ions and combined complexes with catenin to mediate cell adhesion. They were all found in primary tumor cells (BxPC-3), but not in metastatic tumor cells (AsPC-1), suggesting a defect in cellular adhesion in metastatic AsPC-1 cells. Integrins are glycoprotein members that form heterodimeric receptors.

Integrin α2 and α5, which represent major adhesion molecules, were only identified in BxPC-3 cells. Conversely, galectins, as carbohydrate-binding proteins on the cell surface and extracellular glycoproteins, were found only in AsPC-1. Most of these proteins play a role in tumor cell adhesion and motility.

Springbio Antibody Microarrays were used to detect different proteins between the pancreatic cancer cell lines SW1990 and SW1990HM, highly liver metastatic-related cell lines[53]. Increased glucagon and decreased prolactin were selected as potential biomarkers for cancer detection from 40 reproducible, altered proteins. Glucagon induces glucose production and regulates carbohydrate and protein metabolism. Prolactin is a hormone released by the pituitary gland with effects on female breast development and milk production. Both are localized at the plasma membrane, and can influence tumor cell adhesion.

FUTURE ASPECTS

Compared with other types of cancers, pancreatic cancer is probably one of the solid tumors with the highest levels of genetic alterations resulting in aberrant expression of a large number of proteins. A panel of proteomic biomarkers with the appropriate combination of high sensitivity and specificity will likely be better than a single biomarker. Many researchers have focused on proteomic profiling for pancreatic cancer detection using a combined biomarker approach and results so far have gained interest[54-56]. In addition, some studies have investigated differentially expressed proteins of pancreatic cancer stem cells, where increasing evidence indicates an important role in tumorigenesis, growth and formation of metastasis[57]. Targeting and eliminating pancreatic cancer stem cells may significantly improve the prognosis and avoid recurrence in pancreatic cancer patients after pancreatic resection[58].

CONCLUSION

Due to the characteristics of pancreatic cancer, with often vague symptoms, but associated tumor aggressiveness, resistance to standard therapy and a poor prognosis, identification of sensitive and specific biomarkers is essential. Such biomarkers would be of extreme value for disease detection during an earlier phase. Up to now, despite the development of novel techniques and potential markers reported, only a limited number may be of potential use in the clinical situation. Research on pancreatic cancer biomarkers is, however, intensive and the use of proteomic technology may provide a completely novel tool and possibility of potential improvement, achieving early diagnosis, targeted therapy, and discovery of recurrence in patients with pancreatic cancer.

Abstract

Epidemiological studies have provided overwhelming evidence for a causal role of chronic hepatitis B virus (HBV) infection in the development of hepatocellular carcinoma (HCC). However, the pathogenesis of HBV infection and carcinogenesis of HBV-associated HCC are still elusive. This review will summarize the current knowledge on the mechanisms involved in HBV-related liver carcinogenesis. The role of HBV in tumor formation appears to be complex, and may involve both direct and indirect mechanisms. Integration of HBV DNA into the host genome occurs at early steps of clonal tumor expansion, and it has been shown to enhance the host chromosomal instability, leading to large inverted duplications, deletions and chromosomal translocations. It has been shown that the rate of chromosomal alterations is increased significantly in HBV-related tumors. Prolonged expression of the viral regulatory HBV x protein may contribute to regulating cellular transcription, protein degradation, proliferation, and apoptotic signaling pathways, and it plays a critical role in the development of hepatocellular carcinoma.

Key words: Hepatocellular carcinoma; Hepatitis B virus infection; Hepatitis B virus genotypic variations; Hepatitis B virus x protein

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer worldwide, and the third most common cause of cancer mortality[1,2]. This tumor, which arises from hepatocytes, is often associated with liver cirrhosis resulting from chronic liver diseases. Among the environmental risk factors, the prevalence of chronic hepatitis B and C virus infections is linked directly to the incidence of HCC. There is now evidence for persistence within the tumor cells of a low level HBV multiplication potential. Hepatitis B virus (HBV) DNA replicative molecules and covalently closed circular DNA (cccDNA) are detectable by polymerase chain reaction (PCR). Moreover, the association between HCC and HBV recurrence after liver transplantation, and the detection of cccDNA in HCC cells point toward the possibility of HBV replication in tumor cells. The latter could act as potential reservoirs for HBV recurrence, especially in patients who present with a recurrence of HCC[3]. So far, chronic and persistent infection with hepatitis B virus is a major risk factor for the development of HCC.

Globally, it is estimated that 350 million people are chronically infected with the HBV[4]. Approximately 25% of

chronically HBV-infected individuals will develop HCC[5]. Chronic carriers of HBV have up to a 30-fold increased risk of HCC[6]. In areas of high HBV endemicity, persons with cirrhosis have an approximately 16-fold higher risk of HCC than the inactive carriers, and a 3-fold higher risk for HCC than those with chronic hepatitis but without cirrhosis[7]. Although the mechanisms of oncogenesis of HBV remain obscure, several factors have been identified to be associated with a high risk of developing HCC among chronic hepatitis B (CHB) patients. HBV exerts its oncogenic potential through a multi-factorial process, which includes both indirect and direct mechanisms that likely act synergistically[8].

HEPATITIS B VIRUS INFECTION AND LIVER CARCINOGENESIS

Hepatitis B virus DNA genome is able to integrate into the cellular chromosomal DNA, causing both viral and host genome rearrangements

HBV DNA is a small, circular DNA with a highly compact genetic organization and overlapping open reading frames. It shares with retroviruses the use of reverse transcription during its replication. It is well known that the HBV DNA genome is able to integrate into the cellular chromosomal DNA, causing both viral and host genome rearrangements. HBV DNA integration enhances the instability of the host chromosome, leading to large inverted duplications, deletions and chromosomal translocations. As a result of spontaneous errors in viral reverse transcription, variations in the HBV genome occur naturally. These mutations arise during the course of chronic infection with HBV. In fact, several HBV mutant strains, including those with mutations in the Pre-C/C, core promoter and deletion in the *Pre-S/S* genes, are involved in the pathogenesis of progressive liver disease and HCC development[9]. Several studies have shown that HBV DNA insertion into cellular genes was frequent, and could occur in genes encoding for proteins that were crucial for the control of cell signaling, proliferation and apoptosis[10,11].

HBV-related HCC can also arise in the absence of significant liver damage. Many of these chromosomal segments contain key players in liver carcinogenesis such as P53, PB Wnt/β-catenin, cyclins A and D1, transforming growth factor β (TGF-β) and Ras signaling[12]. In another study HBV DNA was integrated at random sites of human DNA; the *MLL4* gene was one of the targets for integration during hepatocarcinogenesis[13]. Furthermore, viral DNA integration into the cellular DNA is not necessary for viral replication, but allows for the persistence of the viral genome in the cell. Viral DNA insertion as well as cellular DNA replication occurs during liver cell proliferation, secondary to the necrosis/apoptosis of adjacent hepatocytes.

Viral genotype and the risk of hepatocellular carcinoma

The viral genotype is another factor that affects cancer risk. Genotype C has a higher risk of causing HCC than genotype B[14,15], and genotype D has a higher cancer risk than genotype A[16]. Compared to the Asian genotypes (B and C), the European genotypes (A and D) are less well established.

Hepatitis B virus genotypic variations and the risk of hepatocellular carcinoma

Specific genotypic variations in HBV have been associated with cirrhosis and HCC. These variations include, in particular, mutations in the pre-core region (Pre-C, A1896G inside the ε structure of the genome), in the basal Core promoter (A1762T/G1764A), and in ORFs encoding PreS1/PreS2/S and Pre-C/C. There is an overlap between Pre-C or basic core promoter (BCP) mutations and genotype, since these mutations appear to be more common in genotype C as compared to other genotypes[14]. The $1762^{T}/1764^{A}$ double mutations (1762 A-to-T and 1764 G-to-A) in the BCP region were commonly found to be borne by HCC patients in some high-risk populations, and were thus suggested as potential biomarkers for hepatocarcinogenesis[17,18]. Comparison of HBV isolates from different studies indicates that the mutation rate of A1762T/G1764A is 64% for genotype C, 40% for genotype B and 35% for other genotypes[19]. Kusakabe *et al*[20] investigated a population-based cohort consisting of 19 393 subjects (middle aged or older) with a follow-up of over 13 years in Japan. They found that HBV mono-infected subjects with the A1762T/G1764A double mutation could be at high risk for HCC development during the natural course of HBV infection[20]. In addition, the 1753^{V} mutations (1753-to-C/A/G) were also associated with the progression of liver disease[21]. Li *et al*[22] evaluated the roles of genetic variations of HBV in the development of HCC in Southern Guangxi China. Their study supported the hypothesis that both the 1762T/1764A double mutations and the 1753V/1752V mutations were associated with increased risk for HCC. Fan *et al*[23] found that patients with higher viral load and genotype C had a higher incidence of 1762/1764 double mutations, and that Enhancer Ⅱ and DR1 were significantly more in the HCC group than in the CHB group, which may play an important role in HCC development via nucleotide substitution. The BCP mutations could affect the core promoter that regulates the expression of both HBeAg and the core protein, and this may be related to the higher rate of replication of genotype C. Substitutions in the BCP may increase genotype virulence by deregulating the transcription of pcARN/pgARN, increasing the risk of HCC in patients infected with genotype C[24]. Thus, the BCP overlaps with the X region of the HBV genome, and mutations in the amino acid sequence at positions 130 and 131 in this region have been proposed as prognostic markers for the development of liver cancer[9].

Yang *et al*[14] found that the Pre-C mutation (A1896G) could prevent the production of HBeAg, by introducing a premature stop codon into the ORF Pre-C/C that abolished the production of HBeAg. However, HBV DNA synthesis persisted under these conditions; this may cause liver damage with progression to cirrhosis and cancer.

Mutations in Pre-S have been reported in HCC cases compared to chronic or asymptomatic cases. These mutations, including deletions in Pre-S in the integrated HBV DNA, may impair the secretion of HBsAg, leading to increased endoplasmic reticulum and oxidative stress in hepatocytes[25]. Truncated forms of Pre-S2 have also been shown to interact with cyclin A, a critical regulator of the cell division cycle, an observation that supports a role for Pre-S2 in hepatocyte hyperplasia and a likely role in the process of HBV-related tumorigenesis[26]. Thus, deletions of Pre-S may contribute to hepatocarcinogenesis by several mechanisms.

Altogether, this combination of genomic mutations, and/or deletions, together with transcriptional and post-transcriptional regulations, will therefore allow the establishment of viral persistence, and the ongoing synthesis of HBV antigens.

DNA METHYLATION AND THE RISK OF HEPATOCELLULAR CARCINOMA

DNA methylation occurs in the early stage of cancer development, including HCC. Genomic hypomethylation increases chromosome instability while localized hypermethylation decreases tumor suppressor gene expression, thus increasing the risk of HCC development[27]. Aberrant methylation of *RASSF1A* (Ras association domain family member 1) is thought to be an early event in the development of HCC[28]. The process is catalyzed by DNA methyltransferases (DNMT). DNMT inhibitors directly repress tumor angiogenesis, indicating that epigenetic modifications mediated by DNMT are involved in the regulation of gene expression during tumor angiogenesis[29]. Another significant link has been suggested between HCC development and the silencing by DNA hypermethylation of several tumor suppressor genes (*TSGs*). A number of TSGs, including $p16^{INK4A}$, *SOCS-1*, *APC*, *GSTP1* and *E-cadherin*, are silenced by DNA methylation in a large proportion of liver tumors, and this process often starts at the preneoplastic stage[30]. In some reports, a higher rate of promoter methylation for specific genes, such as $p16^{INK4A}$ and *E-cadherin*, has been observed in HBV-related tumors compared to nonviral tumors[31].

HEPATITIS B VIRUS X PROTEIN AND THE RISK OF HEPATOCELLULAR CARCINOMA

The hepatitis B virus x protein (HBx) protein is a 154 amino acid polypeptide with a molecular mass of about 17 kDa. HBx appears to play a critical role in the development of HCC. HBx is important for HBV replication and can regulate cellular transcription, protein degradation, proliferation, and apoptotic signaling pathways (reviewed by Bouchard and Schneider[32]). HBx protein does not bind directly to DNA, but rather acts on cellular promoters by protein-protein interactions and by modulating cytoplasmic signaling pathways. The cell cycle inhibition effect of HBx was validated through a liver regeneration experiment reported by Sidorkiewicz *et al*[33]. Kuo *et al*[34] reported that HBx can downregulate Wnt/β-catenin expression and suppress cell growth by not only repressing cell proliferation, but also triggering cell apoptosis. Furthermore, Hsien *et al*[35] have found that HBx protein interacts with the tumor suppressor adenomatous polyposis coli to activate Wnt/β-catenin signaling. Wnt/β-catenin has been shown to up-regulate the epithelial cell adhesion molecule in HCC cells to promote tumor initiation and stemness[36]. Thus HBx activation of Wnt/β-catenin may promote directly the transformation of liver cells into cancer initiating cells[37]. A number of ways in which HBx protein may induce antiapoptotic effects have been described. The most important of these is the ability of HBx to inhibit p53-mediated apoptosis. Recent experiments have suggested that HBx protein may increase the expression of telomerase reverse transcriptase and telomerase activity, prolonging the lifespan of hepatocytes and contributing to malignant transformation. The protein also interferes with nucleotide excision repair through both p53-dependent and p53-independent mechanisms. Carboxyl-terminal truncated HBx protein loses its inhibitory effects on cell proliferation and pro-apoptotic properties, and it may enhance the protein's ability to transform oncogenes. Dysregulation of IGF-Ⅱ enhances the proliferation and anti-apoptotic effects of oncogenes, resulting in uncontrolled cell growth. Another possible explanation for the anti-apoptotic effect of HBx protein involves the accumulation of the anti-apoptotic protein, survivin[37]. Guo *et al*[37] found that Hep3B cells expressing HBx protein increased the levels of hepatoma upregulated protein (HURP) RNA and protein, and showed resistance to cisplatin-induced apoptosis. Knockdown of HURP in these cells reversed this effect. The anti-apoptotic effect of HBx protein was shown to require activation of the p38/mitogen activated protein kinase (MAPK) pathway. In addition, the expression of survivin was upregulated by HBx protein in an HURP-dependent manner. High levels of HURP favored the expression of the anti-apoptotic survivin in HBx-expressing cells. These results indicate that HBx protein activates the expression of HURP *via* the p38/MAPK pathway, culminating in the accumulation of survivin. In recent years, evidence has accumulated that HBx protein modulates the transcription of methyl transferases, causing regional hypermethylation of DNA that results in silencing of tumor suppressor genes, or global hypomethylation. This, in turn results in chromosomal instability, thereby playing a role in hepatocarcinogenesis.

The $p16^{INK4A}$ gene is known as an abnormal tumor suppressor gene and critical cancer-related gene in human hepatocarcinogenesis. Several studies have shown that hypermethylation of the $p16^{INK4A}$ promoter is an important early event in carcinogenesis[38]. Zhu *et al*[39] found that HBx upregulates *DNMT1* and *DNMT3A* expression at both the mRNA and protein levels, and that HBx represses $p16^{INK4A}$ expression by inducing hypermethylation of

the $p16^{INK4A}$ promoter. Moreover, HBx induces the hypermethylation of the $p16^{INK4A}$ promoter through *DNMT1* and *DNMT3A*. Regulation of *DNMT1* and *DNMT3A* by HBx promotes the hypermethylation of the $p16^{INK4A}$ promoter region[39].

Among the activities of HBx, its trans-activation function may play a crucial role in hepatocarcinogenesis, because it is involved in the activation of a large number of signaling pathways and cellular genes that are involved in oncogenesis, proliferation and inflammation. For example, HBx transactivates a number of cellular promoters and enhancers containing binding sites for nuclear factor-kappa-B, activator protein 1 (AP-1), AP-2, cellular promoters of genes associated with cell proliferation such as IL-8, TNF, TGF-β, and epidermal growth factor receptor, and cytosolic signal transduction pathways including Src kinases, Cjun N-terminal kinase, JaK1/STAT and protein kinase, which have overlapping effects on cell proliferation and viability[40,41].

CONCLUSION

The studies we have reviewed here illustrate that HBV constitutes a major environmental etiological factor for primary liver cancer in humans. It will therefore be important to analyze gene expression and proteomic changes in a large series of samples from CHB at different stages, to identify suitable prognostic markers and therapeutic targets. Furthermore, detection of the viral genomes using sensitive, PCR-based, assays is mandatory to enable an accurate appraisal of their prevalence. Genomic alterations and epigenetic factors like methylation-associated gene silencing may play an important role in the deregulation of cellular functions, leading to malignant transformation. A better understanding of the complex role of HBV in liver tumorigenesis will undoubtedly contribute to the improvement of the management of liver diseases induced by CHB.

Abstract

AIM: To investigate the role of epidermal growth factor receptor (EGFR) in colitis-associated dysplasia using the EGFR tyrosine kinase inhibitor erlotinib.

METHODS: Sprague-Dawley rats received trinitrobenzene sulfonic acid (TNBS; 30 mg in 50% ethanol, ic), followed 6 wk later by reactivation with TNBS (5 mg/kg, iv) for 3 d. To induce colitis-associated dysplasia, rats then received TNBS (iv) twice a week for 10 wk. One group received erlotinib (10 mg/kg, ip) for 1 wk before the start of the reactivation of the colitis and 2 wk after (21 d); the rest received the vehicle. After rats were euthanized, the colons were removed and analyzed for damage and expression of the EGFR downstream effectors Erk1/2 and c-Myc.

RESULTS: Ninety percent of the vehicle-treated animals had dysplasia in any region of the colon. Erlotinib-treated animals had a significant decrease in the incidence of dysplasia compared to vehicle-treated animals in all regions of the colon (50.00% ± 11.47% *vs* 90.00% ± 10.00% in proximal, $P < 0.05$; 15.00% ± 8.19% *vs* 50.00% ± 16.67% in mid, $P < 0.05$; and 20.00% ± 9.17% *vs* 70.00% ± 15.28% in distal, $P < 0.01$). Erlotinib-treated animals also had reduced cell proliferation, reduced active Erk1/2, and reduced c-Myc in colon epithelium compared with the vehicle-treated animals. *In vitro*, erlotinib treatment was shown to markedly decrease c-Myc and pErk1/2 levels in rat epithelial cells. Proliferation of rat epithelial cells was stimulated by epidermal growth factor and inhibited by erlotinib ($P < 0.05$).

CONCLUSION: Erlotinib can decrease the development of colitis-associated dysplasia, suggesting a potential therapeutic use for erlotinib in patients with long-standing colitis.

Key words: Animal model; Epidermal growth factor receptor; Colitis; Dysplasia; Erlotinib

INTRODUCTION

Patients with inflammatory bowel diseases (IBD), including ulcerative colitis and Crohn's disease, are at increased risk of developing colorectal cancer (CRC)[1,2]. The known association of IBD with CRC presents an identifiable population for preventative intervention. This preventive effort, however, relies on understanding the molecular events critical for progression from IBD to dysplasia and CRC and on the identification of suitable molecular targets to block the disease development.

Epidermal growth factor receptor (EGFR) is a transmembrane receptor tyrosine kinase. Aberrant EGFR activity has been linked to different types of carcinoma, including CRC[3]. EGFR activates several signaling pathways that include Ras/Raf/Mek/Erk1/2 and phosphoinositide 3-kinase/PDK1/Akt to control epithelial cell proliferation and survival[4]. Aberrant EGFR activity, resulting in proliferative effects and anti-apoptosis, can be targeted with small molecule tyrosine kinase inhibitors or with specific antibodies. A number of EGFR tyrosine kinase inhibitors, such as erlotinib, gefitinib and lapatinib, have been developed to treat cancer patients or are in clinical development to treat various types of human cancer[3]. Moreover, two monoclonal antibodies to EGFR, cetuximab and panitumumab, have been approved by the US Food and Drug Administration to treat CRC patients[3,5].

During inflammatory processes like IBD, EGFR and its ligands play a repair role in colonic mucosa[6]. EGFR expression is increased in inflamed tissues of the bowel in animal models and in patients with IBD and colon cancer[7-9]. For example, in a study by Malecka-Panas, it was found that EGFR is increased in colonic mucosa by 35.2% in patients with adenomatous polyps, by 40.6% in patients with ulcerative colitis, and by 123% in patients with colon cancer[10]. One of the complications of long-standing IBD is the development of cancer[11]. The risk of cancer in patients with colitis increases with longer duration of the disease[1]. While it is not understood completely how IBD leads to neoplastic transformation and progression to CRC, higher levels of EGFR and its ligands could cause hyper-activation of growth promoting signaling pathways and may contribute to development of dysplasia. In the rat model of colon carcinogenesis induced by the carcinogen azoxymethane, EGFR is involved in the development of dysplastic lesions and colon cancer[12].

Erlotinib (Tarceva®) is the first EGFR tyrosine kinase inhibitor approved by the US Food and Drug Administration. It is currently used in clinics to treat lung and pancreatic cancer. In this study, we tested the effects of erlotinib on the occurrence of colitis-associated dysplasia in a rat model developed recently by us[13]. We hypothesized that, by inhibiting EGFR, the progression from chronic inflammation to dysplasia will be halted, as a result of the blockade of EGFR activity. Our data show that erlotinib significantly inhibits the colitis-induced dysplasia in this animal model.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley rats weighing 200-220 g at the start of the initial treatment were maintained in restricted-access rooms with controlled temperature (23 ℃) and 12-h light-dark cycle. Standard laboratory chow (8640 Teklad Rodent Diet, Harlan Laboratories; Tampa, FL) and drinking water were provided ad libitum. One week before beginning the protocol animals were acclimatized to avoid additional stress. Animal protocols were approved by the Institutional Animal Care and Use Committee at Ponce School of Medicine.

Induction and reactivation of the colitis and development of dysplasia

Chronic colitis was induced by intracolonic administration of trinitrobenzene sulfonic acid (TNBS; 0.5 mL of 60 mg/mL; Sigma Aldrich; St. Louis, MO) in 50% ethanol followed by reactivation with systemically administered TNBS 6 wk later[14]. The induction was performed by using a rubber catheter, and TNBS was introduced rectally into the colon, approximately 8 cm proximal to the anus. The reactivation was performed 6 wk after the induction. Briefly, the rats were lightly anesthetized with ether, and TNBS (5 mg/kg in 0.9% saline) was administered intravenously *via* a tail vein every 24 h for three consecutive days[14]. Dysplasia was developed by continuing to administer the TNBS (5 mg/kg) twice a week intravenously for 10 wk[13]. The rats were weighed weekly until they were sacrificed at 10 wk with an overdose of pentobarbital (about 1.5 mL of 65 mg/kg for rats of > 500 g). The experiments reported herein were performed in accordance with the principles described in the "Guide for the Care and Use of Laboratory Animals," publication No. DHHS (NIH) 86-23.

Drug treatment

One group of animals was treated with the EGFR inhibitor erlotinib (a kind gift of OSI Pharmaceuticals, Farmingdale, NY). Erlotinib was administered at a dose of 10 mg/kg per day (i.p. dissolved in 0.5% methyl cellulose) from 1 wk before the start of the reactivation of the colitis until 2 wk after (21 d, Figure 1)[15]. Methyl cellulose alone was administered to a control group for the same amount of time.

Measurement of macroscopic damage

After animals were euthanized, a macroscopic analysis of the colon was performed based on the criteria of Appleyard and Wallace[14]. Four variables were examined: the presence of diarrhea (0 or 1 for absence or presence), adhesions between the colon and other organs (0, 1 or 2 for none, minor or major, respectively), the thickness of each

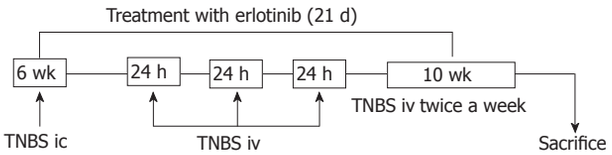

Figure 1 Experimental design for development of colitis-associated dysplasia in a rat model and timeline for administration of erlotinib (10 mg/kg, ip). TNBS: Trinitrobenzene sulfonic acid.

colon segment (in millimeters), and the degree of ulceration (0 for no damage; with increasing scores up to 10, depending on the extent of ulceration). These variables were added to give a total macroscopic damage score.

Sample collection

The colon length was measured in centimeters and cut in equal thirds representing the proximal, mid and distal parts of the colon. These segments were cut longitudinally; one half was weighed and stored at -80 ℃ for molecular analysis, and the other half was fixed in 10% buffered formalin for histological procedures. The Swiss-roll technique was used to evaluate each colon segment microscopically, allowing us to see the entire length of the intestine at once. Briefly, the tissue was rolled into a small piece with the help of forceps and then fixed and placed in a cassette for the remainder of the histological procedures[13].

Microscopic assessment

The tissues were scored microscopically for damage by a blinded observer, as previously described[13]. Criteria included loss of mucosal architecture (0-3: absent, mild, to severe), cellular infiltration (0, none; 1, in muscularis mucosae; 2, in lamina propria/villi; 3, in serosa), muscle thickening (0, muscle < 1/2 of mucosal thickness; 1, muscle = 1/2 to 3/4 of mucosal thickness; 2, muscle = mucosal thickness; 3 = all muscle), goblet cell depletion (0, absent; 1, present), and crypt abscess formation (0, absent; 1, present). The score of each variable was added to give a total microscopic damage score (maximum of 11).

Pathologic evaluation

Colonic sections (2-4 μm) stained with hematoxylin and eosin were analyzed by our pathologists in a blinded manner for dysplasia. Histologic analysis for dysplasia was scored based on previously published criteria[16,17]. Briefly, tissue sections were classified as either negative for dysplasia or positive for dysplasia or carcinoma. The tissues classified as negative for dysplasia adhered to one of the following: normal (small basally located nuclei and normal architecture), non-specific inflammation (cryptitis and glandular invasion by neutrophils), or active colitis (cryptitis, glandular invasion by neutrophils, crypt abscesses, microabscesses). A classification of positive dysplasia was characterized by low-grade dysplasia, which included hyperchromasia, loss of mucin, increased nuclear/cytoplasmic ratio, nuclear elongation and stratification, irregular nuclear outline, and increased number of normal mitoses. The criteria for high-grade dysplasia included the characteristics of low-grade dysplasia plus mucosal architectural distortion including fusion of glands (cribiform pattern) and presence of vesicular polygonal nuclei. For a diagnosis of carcinoma, the characteristics of high-grade dysplasia were included in addition to presence of atypical mitosis and/or of single tumor cells within the lamina propria[16].

Immunohistochemistry

Formalin-fixed 4 μm tissue sections were deparaffinized with xylene, 2 changes, 15 min each, and then hydrated through descending grades of ethanol to deionized water. Antigen retrieval was performed on a hot plate using a beaker with distilled water with the appropriate buffer (0.01 mol/L citrate-ethylene-diamine-tetra-acetic acid (EDTA) buffer, pH 6.0 - high to boiling or EDTA - high to boiling). Slides were cooled at room temperature for 20 min, rinsed with deionized water, and placed in phosphate-buffered saline (PBS) for 5 min. Endogenous peroxidase was blocked with 3% aqueous hydrogen peroxide. After slides were washed with PBS for 5 min, they were blocked with normal serum for 20 min, followed by incubation with the primary antibody. Antibodies were used as follows: phosphorylated epidermal growth factor receptor-pY1068 (Cell Signaling; Danvers, MA), 1:400, overnight; antigen retrieval-EDTA buffer; and 5-bromo-2' deoxyuridine (BrdU), mouse monoclonal antibody (Santa Cruz Biotechnology; Santa Cruz, CA), 1:100, overnight, antigen retrieval-citrate-EDTA buffer. The secondary antibody (Bio-Genex Kit; San Ramon, CA) was added to the sections for 20 min and washed again with PBS for 4 minutes. Using the Bio-Genex Kit, we incubated sections with streptavidin-LSab-Peroxidase for 20 min and washed them with PBS for 4 min. The development of the sections was performed using 3,3'-diaminobenzidine tetrahydrochloride (Bio Genex, San Ramon, CA). All samples were lightly counterstained with Mayer's hematoxylin for 15 s, dehydrated through graded alcohol, cleared with xylene, and mounted with resinous mounting medium.

Immunohistochemistry of c-Myc was performed using a Ventana Discovery XT automated slide staining instrument. The antigen retrieval method was Ventana Cell Conditioning-1. Immunohistochemical conditions for c-Myc (ab32072, Abcam) were as follows: 1:25 dilution (60 min), Ventana UltraMAP anti-rabbit (20 min).

The stains were semiquantitatively examined by two independent pathologists using the Allred 8-unit system with a combination of a proportion score from 0 to 5 and an intensity score on a scale from 0 to 3 (none, weak, moderate, strong). A total score of 2-3 was considered low, a score of 4-5 was considered intermediate, and a score of 6-8 was considered high[18].

Western and immunoblot analysis

Proteins were extracted using lysis buffer (50 mmol/L Tris-HCl, pH 7.5, 150 mmol/L NaCl, 1 mmol/L EDTA, 1 mmol/L EGTA, 25 mmol/L NaF, 5 mmol/L $Na_4P_2O_7$, 1% Triton X-100, 1 mmol/L Na_3VO_4, 20 mmol/L

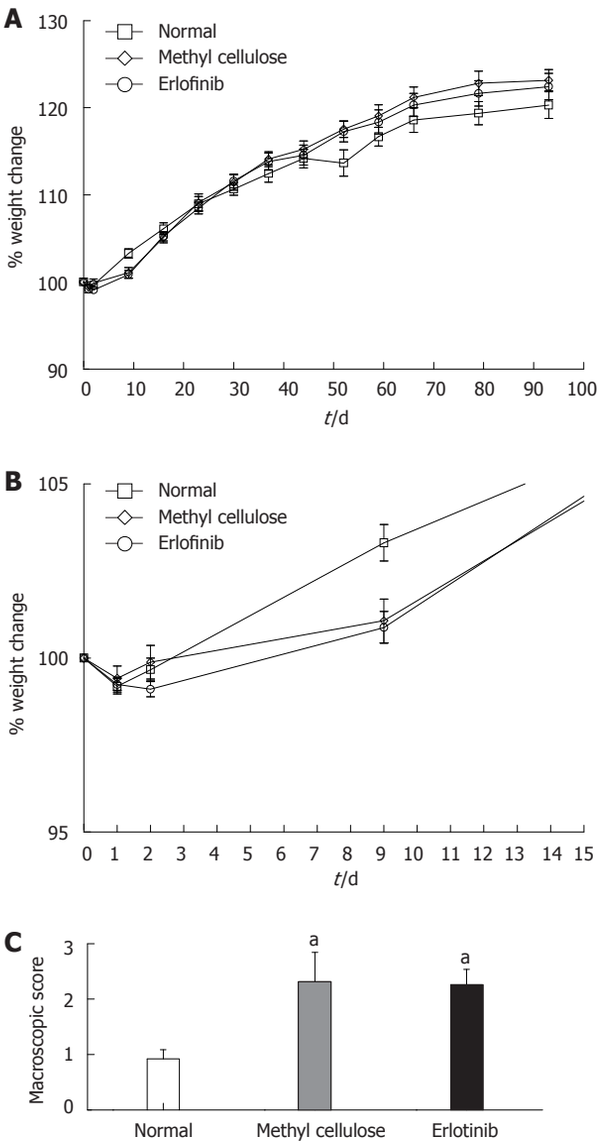

Figure 2 Erlotinib treatment did not worsen inflammation. A: Effect of erlotinib treatment on weight change in an animal model of colitis-associated dysplasia (n = 10-20 per group ± SE); B: Weight change following initial reactivation of colitis; C: Effect of erlotinib treatment on macroscopic damage score in an animal model of colitis-associated dysplasia. The average macroscopic score (including the presence of adhesions, thickness of the tissue, presence or absence of diarrhea, and grade of ulceration) was significantly higher in all trinitrobenzene sulfonic acid-treated animals whether treated with vehicle or drug ($^aP < 0.05$ *vs* normal animals, n = 12-20 ± SE).

p-nitrophenyl phosphate, 2 mg/mL leupeptin, 2 mg/mL aprotinin, and 1 mmol/L phenylmethyl-sulfonyl fluoride). Equal amounts (30 μg) of protein were separated on 12% sodium dodecyl sulfate gel and transferred to a polyvinylidene fluoride membrane (Bio Rad; Hercules, CA). Membranes were blocked with 5% non-fat dry milk in tris-buffered saline-tween (TBST) and incubated with one of the following primary antibodies: Erk1/2, pErk1/2, Akt, pAkt, Src, or Src-pY416 (Cell Signaling Technology; Danvers, MA). Membranes were washed with tris-buffered saline-tween and incubated with horseradish peroxidase-labeled secondary antibodies (Jackson ImmunoResearch Laboratories; West Grove, PA). The bands were detected using ECL-Plus reagent kit (GE Amersham; Piscataway, NJ). Western blotting bands were quantified by densitometry using ImageQuant 5.2 Software (Typhoon 9410; GE Amersham; Piscataway, NJ). pErk1/2, pAkt, and Src-pY416 bands were normalized for the corresponding total kinase.

Cell cultures

Rat intestinal epithelial-1 (RIE-1) cell line (American type culture collection CRL-1592) was cultured in RPMI 1640 containing 5% fetal bovine serum. For analysis of c-Myc, cells were treated with erlotinib (LC Laboratories) as indicated in the figure legends and epidermal growth factor (EGF, 10 ng/mL; Rocky Hill, NJ) for 24 h. For analysis of pErk1/2, erlotinib- or mock-treated RIE-1 cells were stimulated with EGF (10 ng/mL) for 5 min. Cell lysates (20 μg/each) were analyzed by immunoblotting.

Cell proliferation was assayed by plating cells in quadruplet in 96-well plates (1000 cells/well). Twenty-four hours after plating, EGF (10 ng/mL) or erlotinib (10 μmol/L) was added. Four days later, viable cells were measured using CellTiterGlo reagent (Promega) as reported previously[19].

Statistical analysis

Values are presented as means ± SEM where "*n*" represents one tissue from one animal used for a single replicate of an experiment. Statistical analyses were performed using GraphPad Instat V3.0 and Graph Pad Prism V4.0 (Graph Pad Software, San Diego, CA). Groups were analyzed using one-way analysis of variance with Turkey's post-test, and $P < 0.05$ was considered to represent a significant difference.

RESULTS

Erlotinib treatment did not worsen inflammation

During the study (10 wk), all of the rats increased their weight in comparison with their original starting weight, apart from the first 3 d of treatment, where all groups (normal, vehicle-treated, and erlotinib-treated) lost weight (Figure 2A and B). We have observed this phenomenon in prior studies and attribute it to a combination of the intravenous administration of TNBS and the stress initially associated with the procedure[13,16]. No differences in weight change were observed between the normal, vehicle-treated, and erlotinib-treated animals during the study, suggesting no major toxicity of the drug or vehicle.

After animals were euthanized, the colons were removed to score for ulceration, adhesions, diarrhea, and thickness and to measure colon length. As expected, animals treated with TNBS and receiving the vehicle methyl cellulose had significantly higher macroscopic damage scores than the normal animals (Figure 2C). Erlotinib treatment had no effect on the macroscopic score when compared with the vehicle-treated group, with damage scores still significantly higher than normal ($P < 0.05$; Figure 2C). The average length of the colon in TNBS/vehicle-treated animals was shorter that normal (10.55 ± 0.42 cm *vs* 12.17 ± 0.38 cm). This shortening was not at-

Vehicle is methyl cellulose. One-way analysis of variance between groups. [a]$P < 0.05$, [b]$P < 0.01$ *vs* normal animals within the same colonic region.

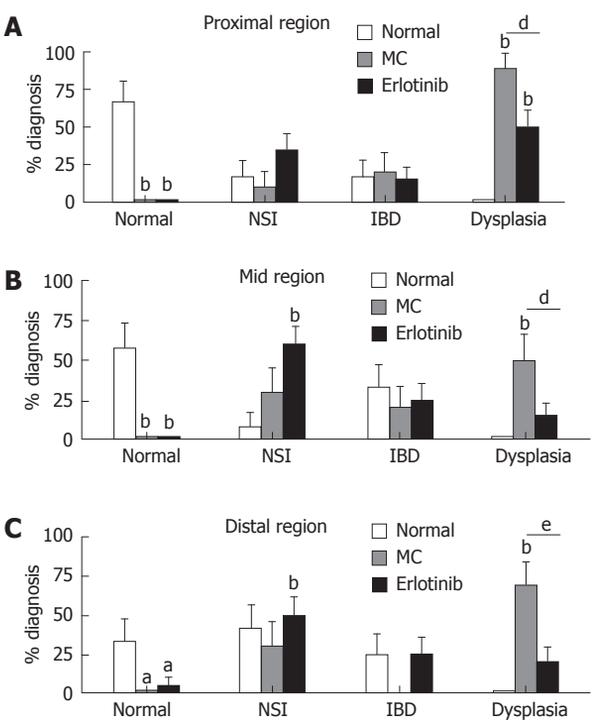

Figure 3 Effect of erlotinib treatment on pathological analysis in an animal model of colitis-associated dysplasia. The percentage of animals with the most severe diagnosis found in each region of the colon is shown ([a]$P < 0.05$, [b]$P < 0.01$ *vs* normal animals; [d]$P < 0.05$, [e]$P < 0.01$ *vs* vehicle-treated animals; *n* = 10-20 ± SE). MC: Methyl cellulose; NSI: Non-specific inflammation; IBD: Inflammatory bowel disease.

tenuated in erlotinib-treated animals (10.85 ± 0.45 cm).

Microscopic analysis of the colon revealed that total microscopic damage score was higher in all regions of the colon in animals receiving TNBS. The damage found was significantly higher in all regions of the colon from these animals than that shown in normal animals ($P < 0.01$, Table 1). Erlotinib had no effect on damage found.

Erlotinib treatment significantly decreased the occurrence of dysplasia

Pathological analysis identified areas of the colon as normal, showing inflammation (IBD and non-specific inflammation), and showing dysplasia. Ninety percent of the vehicle-treated animals had dysplasia in any region of the colon. This was decreased in the erlotinib-treated group such that only 55% of the animals had dysplasia in any area of the colon. When specific regions were analyzed, a decrease in dysplasia incidence was found in the proximal, mid, and distal regions with erlotinib treatment (50%, 15% and 20% in erlotinib *vs* 90%, 50% and 70% in vehicle). Moreover, in the erlotinib-treated group, a close to normal mucosal architecture was found, while in vehicle-treated animals a normal pathology was never observed (Figure 3). Erlotinib treatment increased non-specific inflammation in the mid-region when compared with both normal and vehicle-treated animals. No differences were observed in the identification of IBD in each region of the colon, suggesting that erlotinib may maintain animals in a milder stage of pathology, preventing progression to a more severe diagnosis (Figure 3). It was noted that some "normal" animals were found to have a finding of IBD in some areas; this may be explained by the fact that the normal animals were age-matched and, with increased age, inflammation in response to normal microflora begins to appear[20]. None of the normal animals developed dysplasia.

Erlotinib may decrease cell proliferation through Erk pathway

Proliferation of colon cells was examined by analyzing incorporation of BrdU. A significant increase in positively stained cells was found in animals treated with the vehicle compared with that shown in normal animals, suggesting that those animals have more cell proliferation (Figure 4). Erlotinib-treated animals had decreased cell proliferation compared to vehicle-treated animals, and this was not significantly different from that shown in the normal animals (Figure 4).

Attempts to examine EGFR Y1068 phosphorylation in rat tissue samples were not successful. The activation state of EGFR downstream signaling components Erk, Akt, and Src were then measured by Western blotting using phosphor-specific antibodies. Animals treated with erlotinib showed a tendency toward a decrease in the ratio of

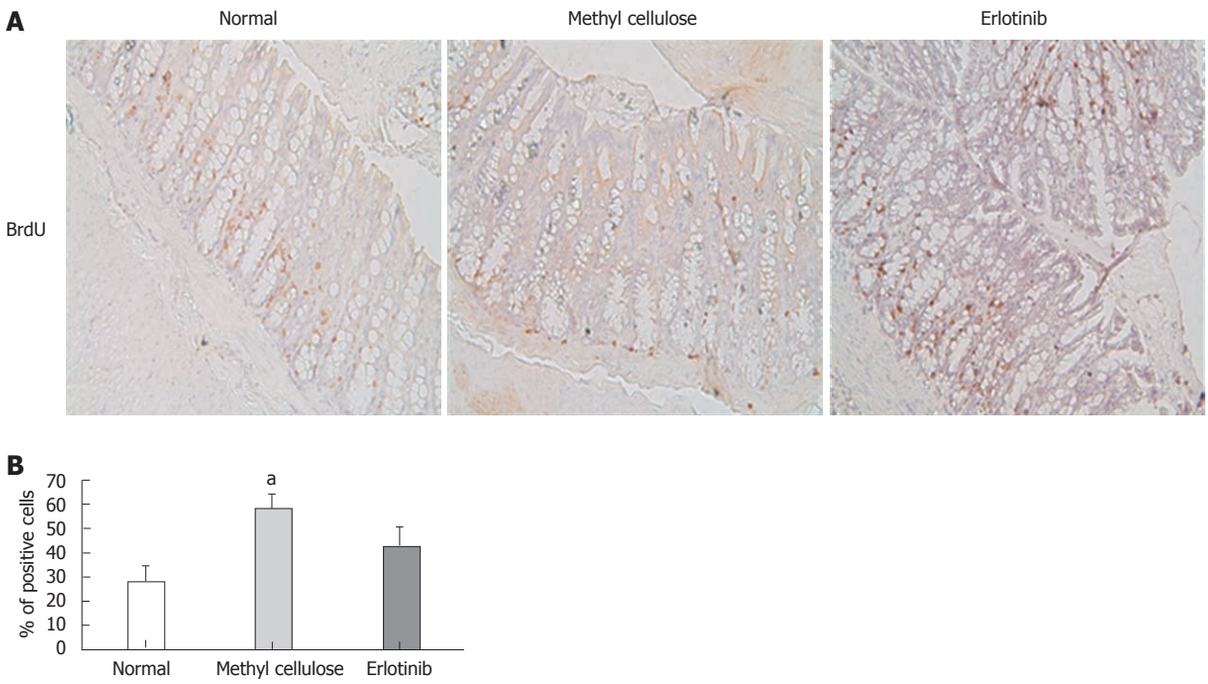

Figure 4 Erlotinib treatment inhibited cell proliferation. A: Representative immunohistochemistry for BrdU incorporation in normal, vehicle-treated and erlotinib-treated animals (200 x). B: Cell proliferation in erlotinib-treated animals was less than that shown in vehicle-treated animals and not significantly different from normal animals ($^aP < 0.05$; $n = 10 \pm SE$).

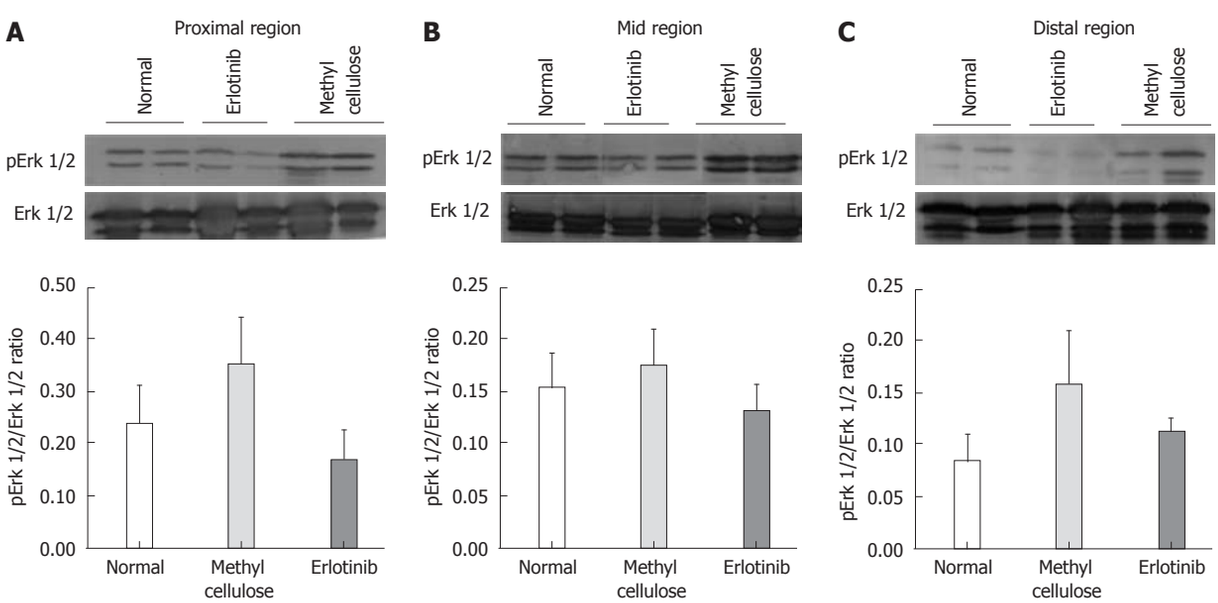

Figure 5 Effect of erlotinib in an animal model of colitis-associated dysplasia on mitogen-activated protein kinase components. Samples from (A) proximal, (B) mid, and (C) distal regions of normal rats and trinitrobenzene sulfonic acid (TNBS) + vehicle and TNBS + erlotinib treated animals were ground, and equal amounts of protein (30 μg) were separated by sodium dodecyl sulfate 12%-polyacrylamide gel electrophoresis before analysis by Western blotting. Antibodies against pErk1/2 and Erk1/2 were used. Lines are representative samples of 3 independent rats per group. Densitometry was performed by ImageQuant 5.2 Software (Typhoon 9410) (n = 10-20 ± SEM).

pErk1/2 when compared with the vehicle-treated group in the proximal, mid and distal regions, with an inhibition of the pErk1/2-to-Erk1/2 ratio of 63%, 24% and 31% in proximal, mid and distal regions, respectively, in animals treated with erlotinib compared to vehicle-treated animals (Figure 5). The ratios of pAkt/Akt and pSrc-pY416 /Src were unchanged in vehicle- and erlotinib-treated animals compared with normal animals (data not shown).

Erlotinib inhibits upregulation of c-Myc

c-Myc is frequently up-regulated in colon cancer and plays an important role in the tumorigenesis of colon cancer. We examined the presence of strong c-Myc staining in the nuclei of rat colon epithelial cells. Compared with the normal group, elevated c-Myc staining was observed in methyl cellulose-treated group, although the difference did not reach statistical significance. Importantly,

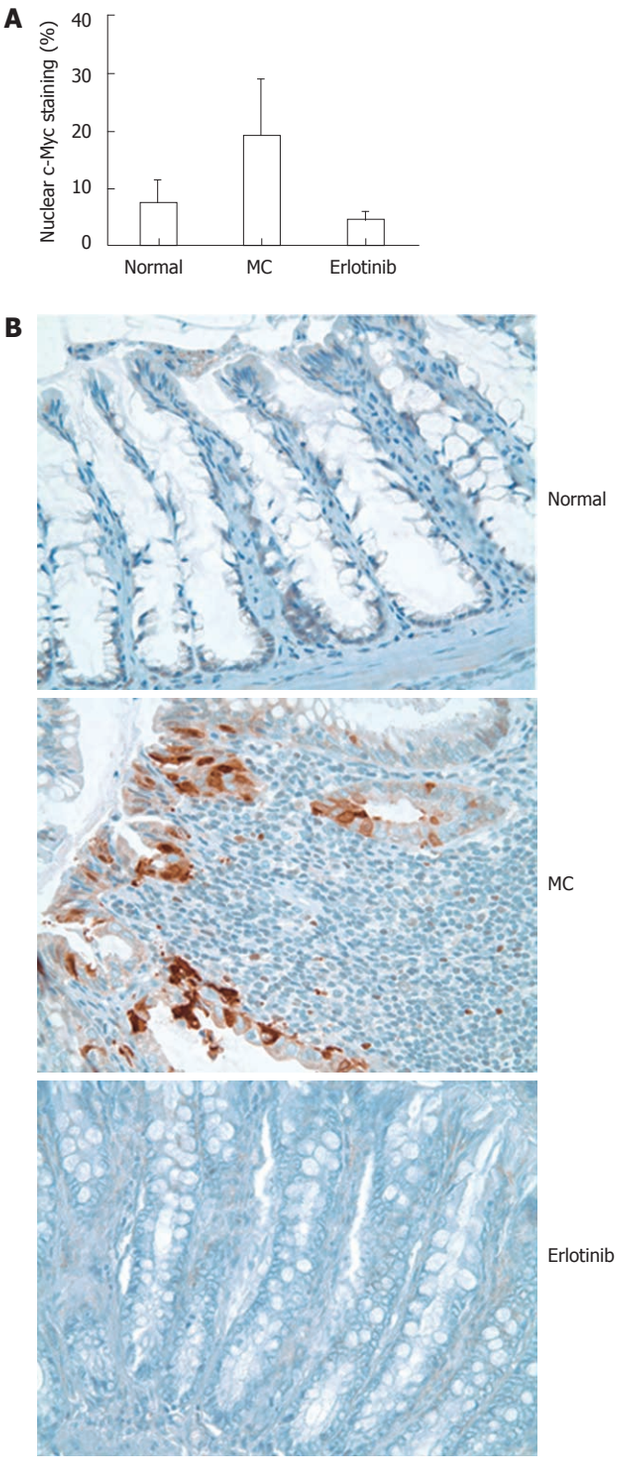

Figure 6 Immunohistochemistry analysis of c-Myc in rat colon tissue samples. A: Slides of formalin-fixed, paraffin-embedded tissues were stained with an anti-c-Myc antibody, and the percentage of strong nuclear c-Myc stain was enumerated. Samples (10, 8 and 11 samples, respectively) from normal, methyl cellulose-treated, and erlotinib-treated rat colon were analyzed; B: Representative immunohistochemistry staining of samples.

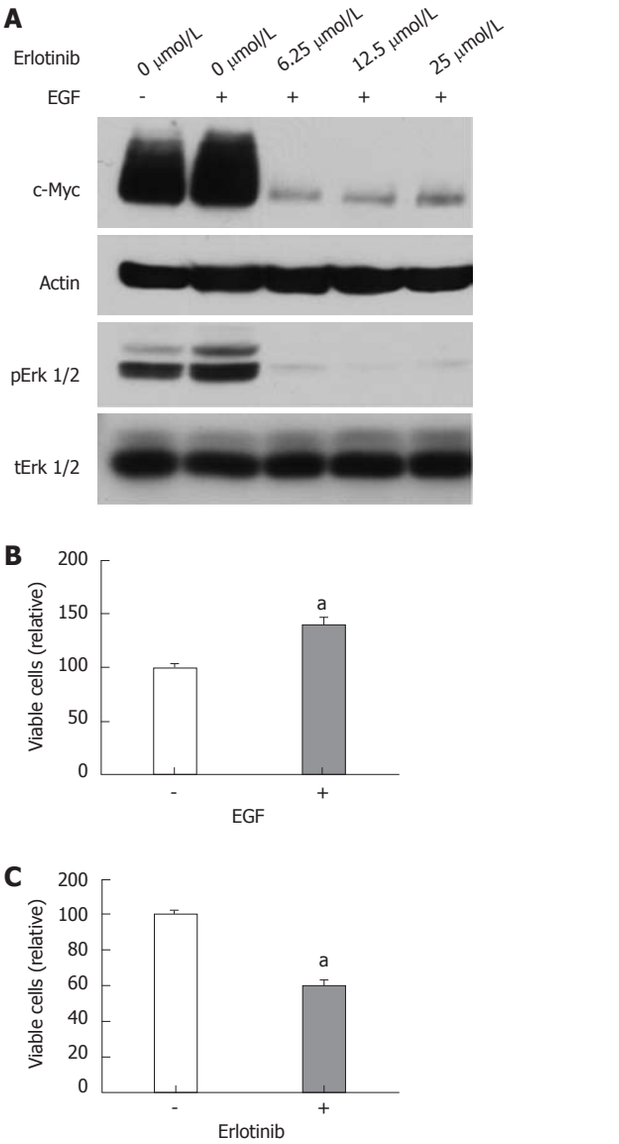

Figure 7 Effects of erlotinib on RIE-1 cells. A: Cells were incubated in RPMI 1640-5% FBS with or without EGF (10 ng/mL) and the indicated concentrations of erlotinib for 24 h. Cells were also pretreated with indicated concentration of erlotinib for 24 h and then stimulated with EGF (10 ng/mL) for 5 min. Cell lysates were analyzed by immunoblotting with indicated antibodies; B and C: Cell proliferation was assayed in the presence or absence of EGF (10 ng/mL) or erlotinib (10 μmol/L) as described in the Materials and Methods. EGF: Epidermal growth factor.

the c-Myc was reduced to a level similar to that found in the normal group in erlotinib-treated rats (Figure 6).

To further assess the effects of erlotinib on c-Myc expression and proliferation in rat epithelial cells, we examined the effects of erlotinib on c-Myc expression in RIE-1 cells. RIE-1 cells appeared very sensitive to serum starvation. In the presence of 5% fetal bovine serum, EGF slightly increased c-Myc and pErk1/2 levels in RIE-1 cells. Erlotinib treatment markedly reduced c-Myc and pErk1/2 levels (Figure 7A). RIE-1 cell proliferation was stimulated by EGF and inhibited by erlotinib (Figure 7B and C).

DISCUSSION

Although the underlying molecular mechanisms involved in colitis-associated cancer need to be further studied, EGFR has been implicated in the development of colonic dysplasia and CRC. The unraveling of molecules that play crucial roles in the transition from chronic inflammation to dysplasia and cancer is essential for iden-

tification of novel drug targets to develop for early intervention measures. Tumorigenesis and tumor promotion depend on cellular signaling pathways that control cell proliferation and survival, and many of these pathways are regulated by EGFR[4]. During chronic inflammation and tissue repair, EGFR activity is elevated. An overactive EGFR may promote the aberrant colonic epithelial cell proliferation and contribute to the development of dysplasia and CRC.

The investigation of the underlying events occurring in colitis-associated dysplasia is complicated by the fact that there are a limited number of animal models available to study the transition of inflammation to dysplasia. Our laboratory recently modified a well-established rat model of chronic colitis to develop an animal model that can be used to investigate ulcerative colitis-associated dysplasia[13,16]. The model uses a prolonged reactivation of inflammation with a proinflammatory drug (TNBS) to create an environment similar to that shown with long-standing colitis in humans, which progresses to cancer. This model shows a degree of dysplasia in 60%-70% of the rats[13,16], similar to what occurs in humans where not all patients develop cancer after a long period with colitis.

We show here that, in our TNBS-induced colitis-associated dysplasia model, animals that received an EGFR inhibitor (erlotinib) had significantly less dysplasia than vehicle-treated animals. This suggests that the EGFR inhibitor is effective in preventing the progression to dysplasia in this animal model. Importantly, we did not observe toxicity of erlotinib in the colon of animals treated with this EGFR inhibitor. It was reported previously that EGFR may have a protective role during acute and chronic inflammation in both the TNBS and dextran sulfate sodium animal models[6,21,22]. The signaling pathway proposed by those researchers involves substance P-NK-1R-EGFR, suggesting that the protective role of this pathway may be due to its effects on fibroblasts[6]. This cell type helps in the remodeling of damaged and/or dead cells or tissues; thus use of an EGFR inhibitor might have been expected to interfere with this process. However, our animals treated with erlotinib showed a milder expression of the disease than that shown in vehicle-treated animals (fewer animals treated with erlotinib progressed to IBD or dysplasia). Thus, erlotinib does not appear to worsen inflammation in our animal model of colitis-associated dysplasia. These data may also help to substantiate the idea of administering erlotinib in conjunction with an anti-inflammatory agent to treat the inflammation and prevent the risk of developing cancer.

The BrdU incorporation assay was used to measure proliferation activity of the colonocytes. Normal animals incorporated BrdU by 26%; this was more than doubled in our model of colitis-associated dysplasia, where vehicle-treated animals showed a 61% incorporation of BrdU, suggesting that these animals possess a higher proliferation rate. In contrast, erlotinib-treated animals showed less BrdU incorporation (37%). Consistently, higher levels of active Erk1/2 and c-Myc were observed in the colon mucosa of vehicle-treated animals but were reduced in erlotinib-treated animals. The Ras-Erk1/2 MAP kinase pathway is known to be activated by EGFR to control cell proliferation. c-Myc overexpression is commonly observed in colon cancer. In the adenomatous polyposis coli-mutant associated CRC, c-Myc is induced by β-catenin to promote colon tumorigenesis. Our data suggest that c-Myc is also up-regulated in colitis-induced dysplasia and erlotinib can inhibit such an increase. In support of this notion, we found that erlotinib is very effective in suppressing c-Myc expression in RIE-1 cells.

In summary, we found that erlotinib is effective in preventing colitis-associated dysplasia without causing unwanted side effects in our novel rat model. Several investigations are already underway to use erlotinib for the treatment of colorectal metastasis[23-25]. In contrast, there have been no investigations into its use as a possible treatment for colitis-associated cancer. Our results suggest that EGFR plays an important role in the progression from inflammation to dysplasia and that inhibition of EGFR, possibly in combination with an anti-inflammatory agent, is a potential approach for use in IBD patients to prevent the development of CRC.

COMMENTS

Background

Patients with ulcerative colitis are at increased risk of developing colorectal cancer. Epidermal growth factor receptor (EGFR) up-regulation is related to the development of some cancers including colorectal cancer. Erlotinib, a potent inhibitor of the EGFR tyrosine kinase, has been shown to inhibit the EGFR signaling pathway inside the cell and block tumor cell growth in pancreatic and non-small cell lung cancer; however, its role in the transition to dysplasia is unknown.

Research frontiers

The underlying mechanisms in ulcerative colitis-associated dysplasia are poorly understood. Understanding the mechanisms responsible for the transition from chronic inflammation to dysplasia and cancer might be helpful to diminish the risk that many patients have of developing colon cancer.

Innovations and breakthroughs

This is the first study to report that erlotinib is effective in preventing colitis-associated dysplasia without causing unwanted side effects in a rat model. Although erlotinib is currently under study for the treatment of colorectal metastasis, there have been no investigations into its use as a possible treatment for colitis-associated cancer. The results of this study demonstrated that erlotinib significantly inhibits the colitis-induced dysplasia in this animal model suggesting that EGFR plays an important role in the progression from inflammation to dysplasia.

Applications

Erlotinib may be an effective treatment for patients with long-standing colitis and with higher risk of developing cancer. In addition, it may be possible to combine an anti-inflammatory agent with erlotinib to reduce inflammation, and therefore the occurrence of dysplasia.

Terminology

EGFR: EGFR is a cell surface receptor involved in several downstream signaling pathways, and is also associated with many types of cancer including colorectal cancer. EGFR expression is increased in inflamed tissues of the

bowel in animal models and in patients with inflammatory bowel disease and colon cancer; Erlotinib: Erlotinib is a small molecule inhibitor which is already approved to treat non-small cell lung carcinoma and pancreatic cancer. Erlotinib exerts its biological action by reversible inhibition of tyrosine kinases on the intracellular domain.

Peer review

In the present paper, the authors used ertolinib, an EGFR tyrosine kinase inhibitor, and determined its effect on the occurrence of colitis-associated dysplasia in rat. They showed that this compound significantly inhibits colitis-induced dysplasia. This is an interesting and elegant study. The model of dysplasia, validated previously by the authors, is very original. These data have potential therapeutic implications in the domain of inflammatory bowel diseases.

Abstract

AIM: To characterize the implications of vascular endothelial growth factor (VEGF)-A in stromal cells and colorectal cancer and the expression of VEGF-A splice variants.

METHODS: VEGF-A expression in tumor and stromal cells from 165 consecutive patients with colorectal cancer was examined by immunohistochemistry. The association between VEGF-A expression status and clinicopathological factors was investigated. Twenty fresh-frozen samples were obtained for laser capture microdissection to analyze the splice variants of VEGF-A.

RESULTS: VEGF-A was expressed in 53.9% and 42.4% of tumor and stromal cells, respectively. VEGF-A expression in tumor cells (t-VEGF-A) was associated with advanced clinical stage (stage 0, 1/9; stage 1, 2/16; stage 2, 32/55; stage 3, 38/66; stage 4, 16/19, $P < 0.0001$). VEGF-A expression in stromal cells (s-VEGF-A) increased in the earlier clinical stage (stage 0, 7/9; stage 1, 6/16; stage 2, 33/55; stage 3, 22/66; stage 4, 5/19; $P = 0.004$). Multivariate analyses for risk factors of recurrence showed that only s-VEGF-A expression was an independent risk factor for recurrence (relative risk 0.309, 95% confidence interval 0.141-0.676, $P = 0.0033$). The five-year disease-free survival (DFS) rates of t-VEGF-A-positive and -negative cases were 51.4% and 62.9%, respectively. There was no significant difference in t-VEGF-A expression status. The five-year DFS rates of s-VEGF-A-positive and -negative cases were 73.8% and 39.9%, respectively. s-VEGF-A-positive cases had significantly better survival than s-VEGF-A-negative cases ($P = 0.0005$). Splice variant analysis revealed that t-VEGF-A was mainly composed of VEGF165 and that s-VEGF-A included both VEGF165 and VEGF165b. In cases with no venous invasion (v0), the level of VEGF165b mRNA was significantly higher (v0 204.5 ± 122.7, v1 32.5 ± 36.7, v2 2.1 ± 1.7, $P = 0.03$). The microvessel density tended to be lower in cases with higher VEGF165b mRNA levels.

CONCLUSION: s-VEGF-A appears be a good prognostic factor for colorectal cancer and includes VEGF165 and VEGF165b.

INTRODUCTION

The growth and metastasis of cancer depend on angiogenesis, and vascular endothelial growth factor (VEGF)-A. VEGF-A is known to be one of the most important angiogenic factors. VEGF-A protein was discovered by Ferrara in 1989 as a specific growth factor and a blood vascular permeability factor for endothelial cells[1-2]. As a result of alternative splicing, 6 VEGF isoforms of 121, 145, 165, 183, 189 and 206 amino acids are produced from a single gene[3-7]. Most studies suggest that VEGF165 is the most abundant and biologically active isoform[3,8]. The biological effects of VEGF165 are mediated by tyrosine kinase receptors, i.e., VEGF receptor (VEGFR) 1 (Flt-1), VEGFR2 (KDR/Flk-1), and VEGFR3 (Flt-4)[9-11]. In colorectal cancer, VEGF-A is highly expressed in the case of hematogenous metastasis; therefore, VEGF-A is assumed to have value as a prognostic factor. VEGF-A and its receptor system are deeply involved in tumor angiogenesis. Thus, they are important molecular targets in the therapeutic strategy against colorectal cancer. It has been reported that the combined chemotherapy and an anti-VEGF antibody improves the response ratio of the tumor and extends the length of survival[12-15]. Tumor cells are the predominant source of VEGF; however, stromal cells surrounding the tumor have also been shown to produce VEGF[16]. Researches on the invasive and metastatic mechanisms mainly focused on the characteristics of the cancer cell itself, and there are few reports concerning the stromal cells[17-19]. Over the past decade, the role of stromal cells has gradually become a matter of interest to many researchers. The median survival in stromal VEGF-A-positive patients was 9.7 years *vs* 4.3 years in stromal VEGF-A-negative patients with stage Ⅱ and Ⅲ colorectal cancers[20]. However, the reason why VEGF-A expression in stromal cells resulted in a better prognosis has not been clarified.

VEGF165b was recently isolated from kidney epithelial cells as an angiogenesis inhibitor[21]. This variant is identical to VEGF165 except for the last six amino acids encoded by alternative splicing. VEGF165b also binds to both the VEGF receptor 1 (VEGF-R1) and the VEGF receptor 2 (VEGF-R2) with a similar affinity to that of VEGF165. VEGF165b was shown to bind to VEGF-R2, but not to stimulate phosphorylation, and to inhibit VEGF165-mediated phosphorylation in human umbilical vein endothelial cells[22-25].

We examined the association between VEGF-A expression status and clinicopathological characteristics in order to determine how VEGF-A in stromal cells affects tumor progression. We also analyzed the expression of VEGF-165 and VEGF165b using fresh-frozen specimens.

MATERIALS AND METHODS

Patients

Tumor specimens were obtained from 165 consecutive patients with colorectal cancer who underwent resection at the First Department of Surgery, Sapporo Medical University from 1997 through 2001. Of these 165 patients, 146 at stages 0-Ⅲ received curative resection. None of the patients received radiation or chemotherapy before surgery. The pathological stages, depth, histology, venous invasion, and lymphatic invasion of the primary tumor are shown in Table 1. Venous invasion and lymphatic invasion were both classified into four grades according to the Japanese Classification of Colorectal Carcinoma. v0 and ly0 represent no invasion, v1 and ly1, slight invasion, v2 and ly2, moderate invasion, and v3 and ly3, high invasion. immunohistochemical (IHC) analysis was performed in these 165 cases. We also obtained 20 fresh-frozen samples from patients with colorectal cancer in 2006-2007 to analyze the expression of VEGF165 and VEGF165b mRNAs.

Immunohistochemistry

For IHC staining, paraffin-embedded tissues were cut at 4 μm. Slides were deparaffinized in xylene for 3 min three times, 3 min in absolute alcohol, 3 min in 90% ethanol,

3 min in 70% ethanol, and finally, 3 min in phosphate-buffered saline (PBS) for three times. After being deparaffinized, sections were incubated in 3% H_2O_2-methanol for 20 min to inactivate endogenous peroxidase. Deparaffinized and rehydrated sections were heated in DAKO Target Retrieval Solution (DAKO Japan, Tokyo, Japan) for 15 min in an autoclave at 105 ℃. Nonspecific binding was blocked with 10% goat serum for 15 min at room temperature followed by incubation with the primary antibody in a moist chamber at 4 ℃ overnight. After rinsing in PBS for 3 min three times, the sections were incubated with a biotinylated secondary antibody, ENVISION + Mouse/HRP (Dako Japan, Tokyo, Japan), for 30 min. Sections were stained using aminoethylcarbazole (Dako Japan, Tokyo, Japan). Slides were mounted prior to observation under conventional light microscope.

Monoclonal antibodies

The primary antibodies were mouse monoclonal antibodies against VEGF-A, anti-human VEGF (N5) (IBL, Takasaki, Japan), CD34, anti-human CD34 (QBEnd10) and mouse monoclonal antibody Dako N1632 (Dako, Japan, Tokyo, Japan).

Evaluation of immunohistochemistry

VEGF-A expression was examined under light microscope, and both the tumor and the stromal cells were separately classified into stained cells and unstained cells. Three sections of tumor cells and stromal cells were counted respectively at × 400 magnification for marginal cancer tissue to determine whether the cells were positive for VEGF-A, and the percentage of stained cells was averaged. Specimens were regarded as VEGF negative if less than 5% of the cells were stained and as VEGF positive if more than 5% were stained. These criteria were used in many previous reports[26-27]. Microvessel density (MVD) was assessed using light microscopy in invasive tumors containing the highest number of capillaries and small venules per unit area. Any single endothelial cell or cell cluster stained with CD34 was counted as a single vessel at × 400 magnification for marginal cancer tissues[28]. Three sections were counted in one case, and the number of vessels was averaged.

Laser capture microdissection

Laser capture microdissection (LCM) is a method for obtaining pure populations of cells from heterogeneous samples. Using this technique, colorectal tumor tissues were separated into tumor and stromal tissues. The frozen tissues were sectioned at a thickness of 8 μm using a cryostat and mounted on nonadhesive glass slides. Tissue sections were rehydrated using 70% ethanol for 3 min and rinsed twice in distilled water (Invitrogen Corp., Carlsbad, CA). They were then stained using hematoxylin for 30 s and rinsed in distilled water, followed by dehydration with 95% and 100% ethanol for 10 s in each case. Counterstaining was performed three times with eosin. Dehydration with xylene was conducted twice for 1 min each time, followed by air drying for 20 min. The PixCell LM200 system (Arcturus Engineering, Mountain View, CA) was used to microdissect the tumor cells and the stromal cells from the colorectal tissue sections. Ten sections were used to obtain sufficient RNA for reverse transcription polymerase chain reaction (RT-PCR), and each section needed at least 10 000 pulses. Processing of the total RNA began immediately following LCM. Extraction and isolation were performed using a QIAGEN RNeasy Mini Kit (QIAGEN, Valencia, CA).

Real-time polymerase chain reaction

We constructed the following primers to amplify fragments of human VEGF165 and VEGF165b specifically. The forward primer was located in exon 7a (TGTTTG TACAAGATCCGCAGACGTG). One reverse primer complementary to exon 8 (TCACCGCCTCGG CTTGT-CACATCTGCAAGTACGTT) detected VEGF165 but not VEGF165b, and the other reverse primer complementary to exon 9 (GTTCTGTATCAGTCTTTCCTG-GTGAGAGATCTGCA) detected VEGF165b but not VEGF165. Denaturing was conducted at 96 ℃ for 30 s, with annealing at 55 ℃ for 30 s and extension at 72 ℃ for 60 s in reactions cycled 30 times. PCR products were run on 3% agarose gels containing 0.5 μg/mL ethidium bromide and visualized under a UV transilluminator. This reaction consistently resulted in amplicons of 121 bp consistent with VEGF165b and 119 bp consistent with VEGF165. To confirm the amplification of VEGF165 and VEGF165b, we performed sequence analysis of these PCR products.

Real time PCR was performed on a LightCycler (Roche, Basel, Switzerland) for the semi-quantitation of VEGF165 and VEGF165b mRNA levels. The primer sequences were the same as those of the primers used for RT-PCR. The calculated amounts of VEGF165 and VEGF165b mRNAs were normalized to the endogenous reference control gene, human glyceraldehyde-3-phosphate dehydrogenase (h-GAPDH). All data were presented as the ratio of the target gene/GAPDH expression.

Statistical analysis

The χ^2 test and Mann-Whitney *U* test were used to examine the association between the expression status of VEGF and clinicopathological characteristics. To analyze the risk factors for recurrence, logistic regression analysis was conducted. Survival curves were computed according to the Kaplan-Meier method. The log-rank test was used to compare the survival curves. $P < 0.05$ was considered statistically significant.

RESULTS

Expression of VEGF-A in tumor and stromal cells

VEGF-A expression in tumor cells was positive in 53.9% (89/165) of the cases (Figure 1A). VEGF-A immunoreactivity was observed mainly in the cytoplasm of tumor cells. VEGF-A expression in stromal cells was observed in 42.4% (73/165) of the cases (Figure 1B).

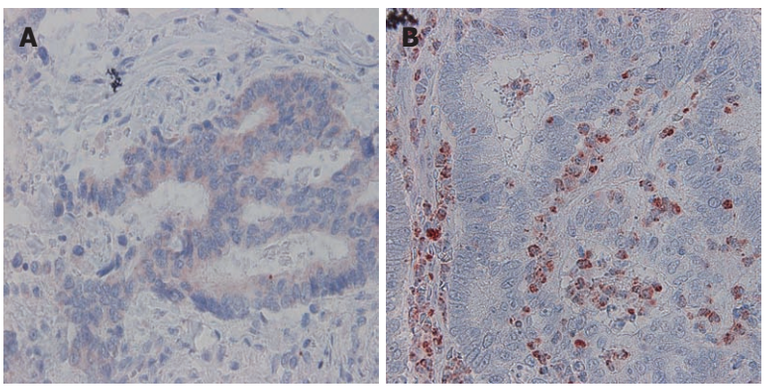

Figure 1 Immunohistochemical of colorectal cancer tissues used the anti-vascular endothelial growth factor-A antibody. A: Vascular endothelial growth factor (VEGF)-A was expressed in tumor cells but not in stromal cells; B: VEGF-A was expressed in stromal cells but not in tumor cells.

Association between VEGF-A expression status and clinicopathological characteristics

A summary of the correlation between VEGF-A expression and clinicopathological characteristics is shown in Table 2. Tumor VEGF-A (t-VEGF-A) expression rates in tumors were 11.1% (1/9) in stage 0, 12.5% (2/16) in stage Ⅰ, 58.2% (32/55) in stage Ⅱ, 57.6% (38/66) in stage Ⅲ, and 84.2% (16/19) in stage IV. t-VEGF-A expression was associated with the clinical stage ($P < 0.0001$). VEGF-A (s-VEGF-A) expression rates in stromal cells were 77.8% (7/9) in stage 0, 37.5% (6/16) in stage Ⅰ, 60.0% (33/55) in stage Ⅱ, 33.3% (22/66) in stage Ⅲ, and 26.3% (5/19) in stage Ⅳ. The s-VEGF-A expression rate increased in the earlier clinical stage ($P = 0.004$). The t-VEGF-A expression rate increased with the depth of invasion ($P = 0.0002$). Conversely, the s-VEGF-A expression rate decreased with the depth of invasion ($P = 0.01$). There was no significant association between VEGF-A expression and the histological type. t-VEGF-A expression became significantly higher with the grade of venous and lymphatic invasion, while s-VEGF-A expression became significantly lower with the grade of venous and lymphatic invasion.

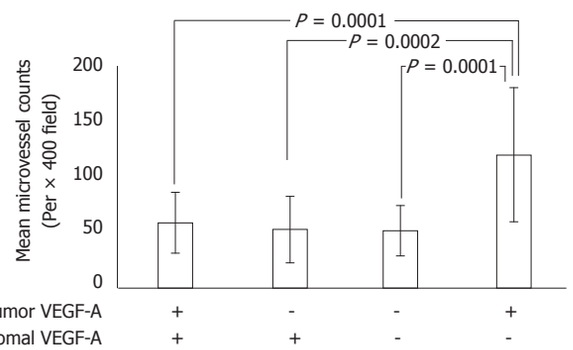

Figure 2 Microvessel density of vascular endothelial growth factor-A expression status. In s-vascular endothelial growth factor (VAEG)-A positive cases, microvessel density (MVD) was maintained at a low score regardless tumor VEGF-A (t-VEGF-A) expression. In s-VEGF-A negative cases, MVD was influenced by t-VEGF-A expression.

Microvessel density

MVD was calculated by counting CD34-positive vascular endothelial cells. The association between VEGF-A expression status and MVD is shown in Figure 2. The MVDs of t-VEGF-A and s-VEGF-A expression (+, +), (-, +), (-, -), and (+, -) were 58.5, 52.4, 51.2 and 119.0, respectively. In s-VEGF-A-positive cases, the low MVD score

was almost the same regardless of t-VEGF-A expression. t-VEGF-A-positive and s-VEGF-A-negative cases had significantly higher MVD scores.

Recurrence

Risk factors for recurrence in the 146 cases excluding stage Ⅳ cases were examined using logistic regression analysis. In univariate analysis, clinical stage, venous invasion, lymphatic invasion, t-VEGF-A positivity and s-VEGF-A negativity were risk factors for recurrence (Table 3). Multivariate analyses of these risk factors were performed, which showed that only s-VEGF-A expression was an independent risk factor for recurrence ($P = 0.0033$) (Table 3).

Survival analysis

Survival analysis was performed for stage Ⅱ and Ⅲ patients ($n = 121$). The five-year disease-free survival (DFS) rates of t-VEGF-A-positive ($n = 70$) and -negative cases ($n = 51$) were 51.4% and 62.9%, respectively. There was no significant difference in t-VEGF-A expression status (Figure 3A). The five-year DFS rates of s-VEGF-A-positive ($n = 55$) and -negative ($n = 66$) cases were 73.8% and 39.9%, respectively. s-VEGF-A-positive cases had significantly better survival than negative cases ($P = 0.0005$) (Figure 3B).

Expression analysis of VEGF165 and VEGF165b

Expression analysis of VEGF165 and VEGF165b was performed using specimens of 20 cases obtained by LCM. RT-PCR was performed using specific primer sets (exon7/exon8 and exon7/exon9) to investigate the expression of VEGF165 and VEGF165b. Sequence analysis revealed that the PCR products were VEGA165 and VEGF165b (data not shown)[26]. IHC analysis was performed in the same 20 cases. Expression of s-VEGF-A and t-VEGF-A was positive in 40% (8/20) and 70% (14/20), respectively. mRNA levels of VEGF165 and VEGF165b were semi-quantified by real time PCR for each VEGF-A expres-

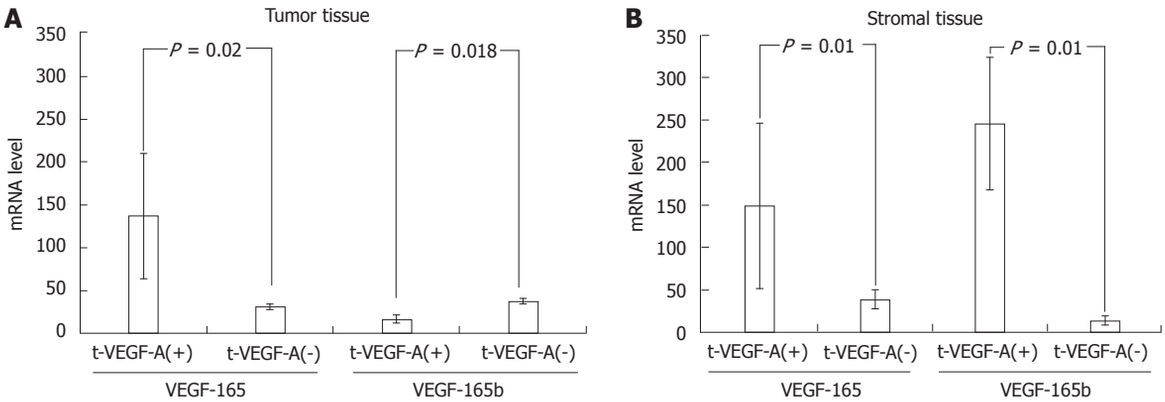

Figure 4 mRNA level of VEGF165 and VEGF165b semi-quantified by real-time polymerase chain reaction in tumor and stromal tissues. A: In tumor tissue, only vascular endothelial growth factor (VEGF) 165 expressed in t-VEGF-A positive cases; B: In stromal tissues, both VEGF165 and VEGF165b expressed in s-VEGF-A positive case.

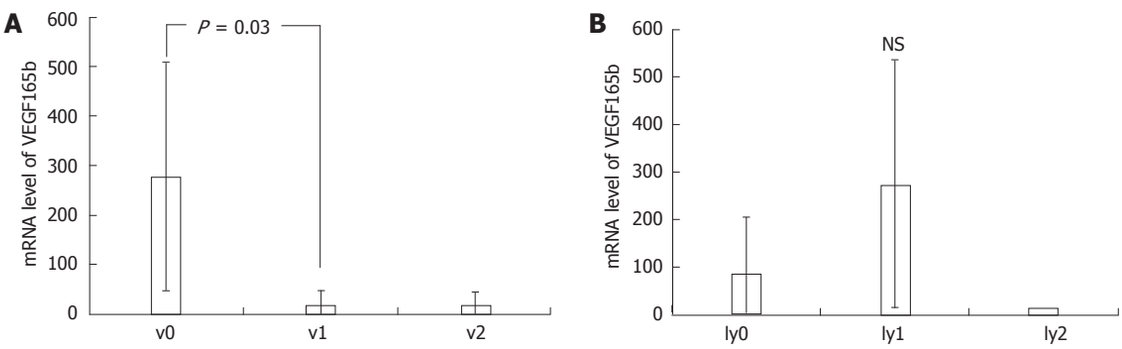

Figure 5 Correlations of vascular endothelial growth factor 165b expression in stromal tissue and tumors with venous and lymphatic invasion. A: Vascular endothelial growth factor (VEGF) 165b mRNA level in v0 cases was significantly higher than those in v1 cases; B: There were no significant differences of VEGF165bmRNA levels among degrees of the lymphatic invasion. NS: Not significant.

sion status determined by IHC. In tumor tissues, only VEGF165 was expressed in t-VEGF-A-positive cases (P = 0.02) (Figure 4A). In stromal tissues, both VEGF165 and VEGF165b were expressed in s-VEGF-A-positive cases (Figure 4B).

Correlation between VEGF165b expression in stromal tissues and venous invasion, VEGF165b expression in stromal tissues and lymphatic invasion

The VEGF165b mRNA level in v0 cases was significantly higher than in v1 cases (Figure 5A). There were no significant differences of VEGF165bmRNA levels among various degrees of lymphatic invasion (Figure 5B).

VEGF165 and VEGF165 mRNA levels and MVD in each case

In cases with lower VEGF165b mRNA levels (numbers 1-8), MVD depended on the VEGF165 mRNA level, while in cases with higher VEGF165b mRNA levels (numbers 14-20), MVD did not reach a high score regardless of the VEGF165 mRNA level (Figure 6).

DISCUSSION

Neoangiogenesis plays an important role in the progression and metastasis of colorectal cancer, and VEGF-A, among many molecules, is known to be of paramount importance because VEGF-A secreted from tumor cells chiefly binds to VEGFR-2 and induces angiogenesis. In colorectal cancer, it is well known that VEGF-A is highly expressed in cases with hematogenous metastasis[29,30]. Therefore, it is assumed that VEGF-A is one of the biomarkers for prognosis[31]. VEGF-A expression in tumor cells was examined to evaluate the degree of risk in many studies. However, there have been few reports focusing on stromal cells surrounding tumor cells. Concerning VEGF-A expression in stromal cells, stromal VEGF-A positivity generally results in a better prognosis than VEGF-A negativity[20].

In this report, IHC staining was performed in 165 consecutive patients with colorectal cancer to detect VEGF-A expression in tumor and stromal cells. Our results showed that s-VEGF-A expression might be a factor indicating a better prognosis. These results were consistent with a previous report[20] and implied that the functions of VEGF-A expressed in stromal cells might be different from those in tumor cells. Since VEGF has 6 splicing isoforms[2-6], we focused on one of them, VEGF165b, which was reported to inhibit neoangiogenesis. Our report demonstrated that s-VEGF-A, including VEGF165 and VEGF165b expressed in stromal cells, might inhibit

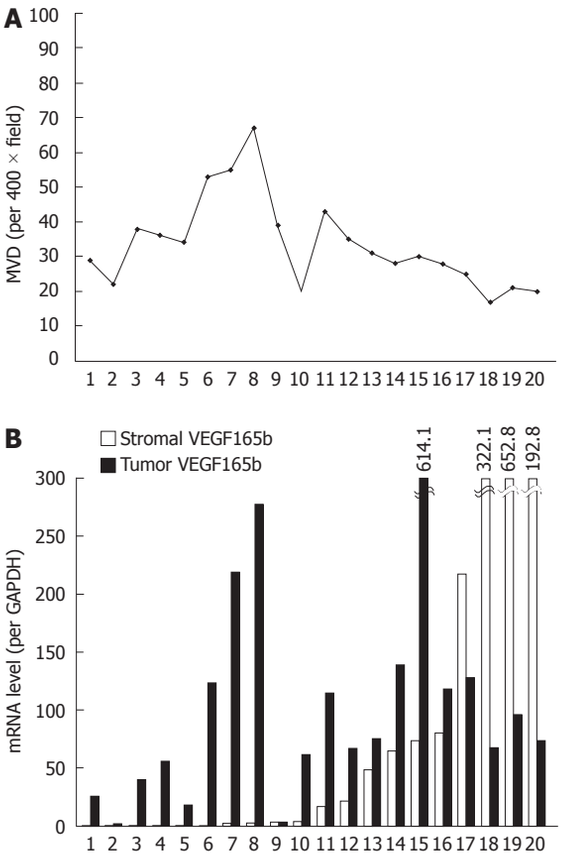

Figure 6 Relationship between the level of vascular endothelial growth factor 165 mRNA in tumor, vascular endothelial growth factor 165b mRNA in stromal tissues and microvessel density. Twenty cases are arrayed on the X axis in ascending order of the amount of vascular endothelial growth factor (VEGF)165b expression. A: The score of microvessel density (MVD); B: The mRNA level of VEGF165 and VEGF165b. MVD was maintained at a low level in the cases in which VEGF165b expressed in stromal tissues.

angiogenesis and reduce MVD. However, we could not conclude that VEGF165b expression improved the prognosis of colorectal cancer patients because the association between VEGF165b expression and the prognosis has not been investigated in a large series.

In this study, we clarified that s-VEGF-A, including VEGF165b, had a function to inhibit neoangiogenesis. However, it remains unexplained what kinds of cells secrete VEGF165b and what factors induce VEGF165b expression. A previous report showed that a subset of macrophages expressed VEGF-A resulting from CD68 (a macrophage-specific immunostain) macroIHC staining[32]. In our series, 76% of CD68-positive cases were s-VEGF-A positive and most of the s-VEGF-A(+) cells were identical to CD68(+) cells under light microscope (data not shown). CD68(+) stromal cells, and tumor-associated macrophages (TAMs) have been reported to have dual potential to improve and worsen the prognosis[33]. We speculate that CD68(+) stromal cells may secrete VEGF165b and inhibit the angiogenesis induced by VEGF165 from tumor cells to interfere with tumor progression. In the future, we will study TAMs in colorectal cancer, especially those expressing VEGF165b, which may be a key to developing a novel therapeutic strategy.

In summary, the s-VEGF-A appears be a good prognostic factor for colorectal cancer and includes VEGF165 and VEGF165b.

COMMENTS

Background

Neoangiogenesis plays an important role in the progression and metastasis of colorectal cancer and vascular endothelial growth factor (VEGF)-A, among many molecules, is known to be highly important because VEGF-A secreted from tumor cells chiefly binds to VEGFR-2 and induces angiogenesis. In colorectal cancer, it is well known that VEGF-A is highly expressed in cases with hematogenous metastasis. Therefore, VEGF-A is assumed to have value as a prognostic factor. VEGF-A and its receptor system are deeply involved in tumor angiogenesis. Thus, they are important molecular targets in the therapeutic strategy against colorectal cancer.

Research frontiers

It has been reported that combined chemotherapy and an anti-VEGF-A antibody improves the response ratio of the tumor and extends the length of survival. Tumor cells are the predominant source of VEGF-A; however, stromal cells surrounding the tumor have also been shown to produce VEGF-A. In many reports, VEGF-A expression in tumor cells was examined to evaluate the degree of risk. However, there have been few reports focusing on stromal cells surrounding tumor cells.

Innovations and breakthroughs

In this report, immunohistochemical staining was performed in 165 consecutive patients with colorectal cancer to detect VEGF-A expression in tumor and stromal cells. The results showed that s-VEGF-A expression might be a factor indicating a better prognosis. These results implied that the functions of VEGF-A expressed in stromal cells might be different from those in tumor cells. This report demonstrated that s-VEGF-A, including VEGF165 and VEGF165b, expressed in stromal cells, might inhibit angiogenesis and reduce microvessel density.

Applications

The authors clarified that s-VEGF-A, including VEGF165b, had a function to inhibit neoangiogenesis. However, it remains unexplained what kinds of cells secrete VEGF165b and what factors induce VEGF165b expression. Studies of TAMs in colorectal cancer, especially those expressing VEGF165b, may be a key to developing a novel therapeutic strategy.

Peer review

This is an excellent manuscript, with a well done methodological approach, and showing a correlation with stromal VGEF expression and colorectal cancer prognosis.

Abstract

AIM: To study the inhibition of tumor angiogenesis by 5,2,4′-trihydroxy-6,7,5′-trimethoxyflavone (TTF1) isolated from an extract of herbal medicine *Sorbaria sorbifolia*.

METHODS: Angiogenic activity was assayed using the chick embryo chorioallantoic membrane (CAM) method. Microvessel density (MVD) was determined by staining tissue sections immunohistochemically for CD34 using the Weidner capillary counting method. The mRNA and protein levels of vascular endothelial growth factor (VEGF), vascular endothelialgrowth factor receptor 2 (VEGFR2, Flk-1/KDR), basic fibroblast growth factor (bFGF), cyclo-oxygenase (COX)-2 and hypoxia-inducible factor (HIF)-1α were detected by quantitative real-time polymerase chain reaction and Western blotting analysis.

RESULTS: The TTF1 inhibition rates for CAM were 30.8%, 38.2% and 47.5% with treatment concentrations of 25, 50 and 100 μg/embryo × 5 d, respectively. The inhibitory rates for tumor size were 43.8%, 49.4% and 59.6% at TTF1 treatment concentrations of 5, 10, and 20 μmol/kg, respectively. The average MVD was 14.2, 11.2 and 8.5 at treatment concentrations of 5 μmol/kg, 10 μmol/kg and 20 μmol/kg TTF1, respectively. The mRNA and protein levels of VEGF, KDR, bFGF, COX-2 and HIF-1α in mice treated with TTF1 were significantly decreased.

CONCLUSION: TTF1 can inhibit tumor angiogenesis, and the mechanism may be associated with the down-regulation of VEGF, KDR, bFGF, HIF-1α and COX-2.

Key words: Chinese herbal medicine; *Sorbaria sorbifolia*; TTF1; Inhibition; Tumor angiogenesis

INTRODUCTION

Angiogenesis is the process by which a new blood-vascular system grows from the existing vascular bed through the interaction of cytokines, the cellular matrix and proteolylic enzymes. Tumor angiogenesis is closely associated with tumor growth, metastasis, recurrence and overall prognosis. For this reason, tumor angiogenesis is a desir-

able target for tumor treatment[1]. Anti-angiogenesis is an important strategy for tumor therapy[2]. Many studies have demonstrated that tumor angiogenesis can be inhibited by the flavones present in Chinese herbal medicines, including apigenin, silibinin, quercetin, wogonin, genistein and luteolin[3-9]. Previously, we have reported that acetic ether extracts of the medicinal plant *Sorbaria sorbifolia* (*S. sorbifolia*) inhibits the growth of HepG-2 cells[10] and mouse S180 sarcoma, down-regulates the levels of tumor necrosis factor (TNF)-α and interleukin (IL)-2, and reduced the cellular activity of natural killer cells[11]. In addition, extracts inhibit the placental glutathione S transferase formation of positive foci in hepatoma precancerous rats and down-regulated the expression of p53 and Bcl-2. They increase the activity of superoxide dismutase and glutathione peroxidase and decrease the nitrogen monoxide (NO) synthase activity and malondiadehyde and NO concentrations[12,13]. Six compounds have been identified in the *S. sorbifolia* acetic ether extracts, including 5,2′,4′-trihydroxy-6,7,5′-trimethoxyflavone (TTF1), 5,7- dihydroxy-8-methoxyflavone, rutin, quercetin, daucosterol, benzoate and p-hydroxybenzoic acid, and TTF1 was the first active flavonoid compound identified[11]. After testing the six compounds, we found that TTF1 inhibited vascular endothelial growth factor (VEGF) expression in HepG-2 cells and VEGF165-induced human umbilical vein endothelial cells proliferation and vascular endothelial growth factor receptor 2 (VEGFR2, Flk-1/KDR) protein expression[10]. This study focused on the effect of TTF1 specifically on the inhibition of tumor angiogenesis.

MATERIALS AND METHODS

Extraction of TTF1

TTF1 was separated using the water extraction and alcohol precipitation method from 10 kg *S. sorbifolia* (collected from Jilin Province) as previously described[11].

Cell culture

The HepG-2 cell line was purchased from KeyGEN Co., Ltd. (Nanjing, China). Cells were grown in RPMI1640 supplemented with 10% fetal bovine serum, 100 U/mL penicillin, and 100 mg/L streptomycin. Cells were cultured at 37 ℃ in a humidified incubator containing 5% CO_2. Cells in the logarithmic growth phase were used for tests.

Chick embryo chorioallantoic membrane assay

Angiogenic activity was assayed using a chick embryo chorioallantoic membrane (CAM) as described previously[14]. HepG-2 cell resuspensions (1×10^6) were inoculated into the chick embryo CAM. Using 4-d-old chick embryos in shells, 50 μL of different concentrations of TTF1, apigenin (KeyGEN), and normal saline were added to the chick chorioallantoic membrane once per day for 5 d. Each experimental group included five eggs, and experiments were repeated five times. Chorioallantoid membranes were collected for microscopy and photographic documentation. Five visual fields were randomly chosen for analyzing the angiogenesis inducing rate and inhibitory rate using the SmartScape microscope photography analysis system.

Inducing rate (%) = (vascular branchpoint number after inoculating tumor cells minus the vascular branchpoint number in non-inoculated tumor cells the vascular branchpoint number in non-inoculated tumor cells) × 100%

Inhibitory rate (%) = (vascular branchpoint number after inoculating tumor cells minus the vascular branchpoint number with drug treament/the vascular branchpoint number after inoculating tumor cells) × 100%

Nude mouse HepG-2 tumor model

BALB/c nude mice were obtained from the Laboratory Animal Center of the Academy of Military Medical Sciences (Jilin, China). All studies were in compliance with guidelines of the Institutional Animal Care and Use Committee. 0.1 mL HepG-2 cell resuspensions (1×10^6) were transplanted into the armpits of test mice subcutaneously as an experimental model. Ten days after HepG-2 cell transplantation, 40 mice bearing tumors were selected and divided into five groups, and orally administered 5, 10 or 20 μmol/kg of TTF1 or 10 μmol/kg of apigenin once a day for 10 d. The control group was treated with normal saline. Mice were sacrificed and the tumors were collected and weighed. The tumor inhibition rate was calculated as follows: inhibition rate (%) = (1- the tumor weight in treatment group/the tumor weight in control group) × 100%. Samples were fixed in a 10% formaldehyde solution to prepare the slides for hematoxylin and eosin staining and microscopy.

Immunohistochemistry

Tissues were fixed in 10% buffered formalin and embedded in paraffin. Immunodetection of blood vessels in mouse tumor sections was performed with an anti-CD34 Ab (Boshide Biotechnology Company, Wuhan, China). Sections were incubated with a biotinylated anti-rat Ab (CD34) and then with peroxidase-conjugated streptavidin (Boshide Biotechnology Company, Wuhan, China). To quantify angiogenesis, microvessel density (MVD) was determined by staining tissue sections immunohistochemically for CD34 using the Weidner capillary counting method[15]. Entire sections were scanned under low magnification, and vascularization was subjectively graded. Three highly vascularized areas per tumor were then evaluated at low magnification (× 200). Any brown-staining CD34 distinct from adjacent microvessels, tumor cells, or other stromal cells was considered a single countable microvessel. The total number of microvessels was determined from five vessels in each area, and the average number was recorded for each tumor. To test TTF1 treatment effect on VEGF and basic fibroblast growth factor (bFGF) expression in tumor, the slides were prepared by following the protocol of S-P Kit. Using the double-blind method, the pictures from at least five representative high-power fields were observed in each slice, and no less than 100 cells in each field were counted for analysis.

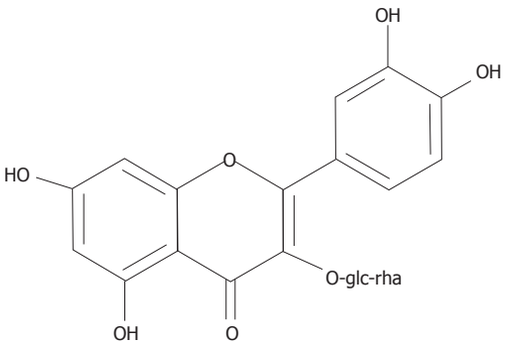

Figure 1 Chemical structure of TTF1.

Western blotting analysis

Tumors were lysed in lysis buffer (Pierce Roche, United States) and then centrifuged at 12 000 *g* for 15 min. Protein concentration was determined using the BCA kit (Pierce Rockford, United States) following the manufacturer's instructions. Seventy μg of protein was separated by 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis and then transferred to a polyvinylidene fluoride membrane (Pall Corporation, Port Washington, NY, United States). After blocking for 1 h with 5% milk in tris-buffuered saline and tween 20, the primary antibody (anti-VEGF, KDR, bFGF, COX-2 or HIF-1α; 1:400) (Boshide Biotechnology Company) was added and incubated at 4 ℃ overnight. After incubation with secondary antibodies (1:5000), membranes were visualized by chemiluminescence. The intensity of protein bands was quantitatively determined using a ultraviolet crosslinkers (Bio-Rad, United States) and normalized with the intensity of Actin band in each gel.

Quantitative real-time polymerase chain reaction

Total RNA was extracted from tumors using the RNeasy Plus Mini Kit (KeyGEN) following the manufacturer's instructions. cDNA was generated with the iScript Select cDNA Synthesis Kit (KeyGEN) and analyzed by quantitative real-time polymerase chain reaction (PCR) using SyberGreen qPCR primer assays (KeyGEN) and the iCycler iQ multicolor real time PCR detection system (KeyGEN). Relative expression levels were normalized against β-actin expression run concurrently as a reference control. The primers used were as follows: VEGF (forward, 5'-TACGTTGGTGCCCGCTGCTG-3'; reverse, 5'-GCCCTCCGGACCCAAAGTGC-3'; amplicon size of 400 bp), KDR (forward, 5'-AGCGTGTGGCACCCACGATC-3'; reverse, 5'-GGCAATCACCGCCGTGCCTA-3'; amplicon length of 338 bp); COX-2 (forward, 5'-TTGCCCGACTCCCTTGGGTGT-3'; reverse, 5'-CTCCTGCCCCACAGCAAACCG-3'; amplicon length of 397 bp); HIF1-α (forward, 5'-ACAGCAGCCAGACGATCATGCAG-3'; reverse, 5'-TGGCTACCACGTACTGCTGGCA-3'; amplicon length of 724 bp); β-actin (forward, 5'-GCTCGTCGTCGACAACGGCTC-3'; reverse, 5'-CAAACATGATCTGGGTCA TCTTCTC-3'; amplicon length of 353 bp).

Statistical analysis

Data in all experiments are shown as mean ± SD. Statistical difference was evaluated using a one-way ANOVA and independent *t* test of sample pairs with SPSS 13.0 software.

RESULTS

Effect of TTF1 on angiogenesis in chick embryo chorioallantoic membrane

The antiangiogenic activities of TTF1 (Figure 1) were tested using the CAM assay. HepG-2 cells induced CAM angiogenesis (Figure 2B). Capillary vessels were intensively spread in HepG-2 cell-inoculated regions, vessel branching significantly increased ($P < 0.05$) (Figure 2A, B and D), and the inhibitory rate was 53.9%. TTF1 inhibited angiogenesis: the number of capillary vessels significantly decreased ($P < 0.05$) in the TTF1 treatment group (Figure 2C and D), with inhibitory rates of 30.8%, 38.2% and 47.5% with TTF1 treatment concentrations of 25, 50 and 100 μg/embryo × 5 d, respectively (Figure 2D and E). The inhibitory effect on angiogenesis *in vivo* by TTF1 was dose-dependent. These results indicate that TTF1 inhibited angiogenesis induced by HepG-2 cells in CAM.

Changes in mouse tumor weight

To test whether TTF1 inhibited tumor growth, we measured tumor weight after TTF1 treatment. Compared to the control group, the tumor weights in the TTF1-treated group were significantly lower ($P < 0.01$), with inhibitory rates of 43.8%, 49.4% and 59.6% at treatment concentrations of 5, 10 and 20 μmoL/kg, respectively (Figure 3). These results suggest that TTF1 administration blocked the growth of HepG-2 cell-induced tumors in mice and that the inhibitory rate of TTF1 was dose-dependent.

Tumor pathology

Compared to the tumors in the control group, the tumors in the TTF1 and apigenin-treated groups were smaller in size with gray surfaces. Their texture was hard, and necrosis was present in the central area but few capillary hemorrhages were observed (data not shown). Microscopy of tumors from the TTF1 and apigenin-treated groups revealed that they had fewer tumor cells, increased cell gaps with clearly visible cell boundaries, and few capillaries in the central area (data not shown).

Changes in microvessel density in a mouse model

To quantify the HepG-2 cell-induced angiogenesis in mouse tumors, MVD was determined by staining tissue sections immunohistochemically for CD34. The positive staining of CD34 was brown and mainly located in the vascular endothelium of the cytomembrane and the cytoplast of capillary vessels, venules and arterioles (Figure 4A). The results showed that the number of capillary vessels greatly increased in tumor tissues in the control group, while they significantly decreased in the TTF1 treatment group (Figure 4B and C). The average MVD was 14.2, 11.2 and 8.5 at the treatment concentrations

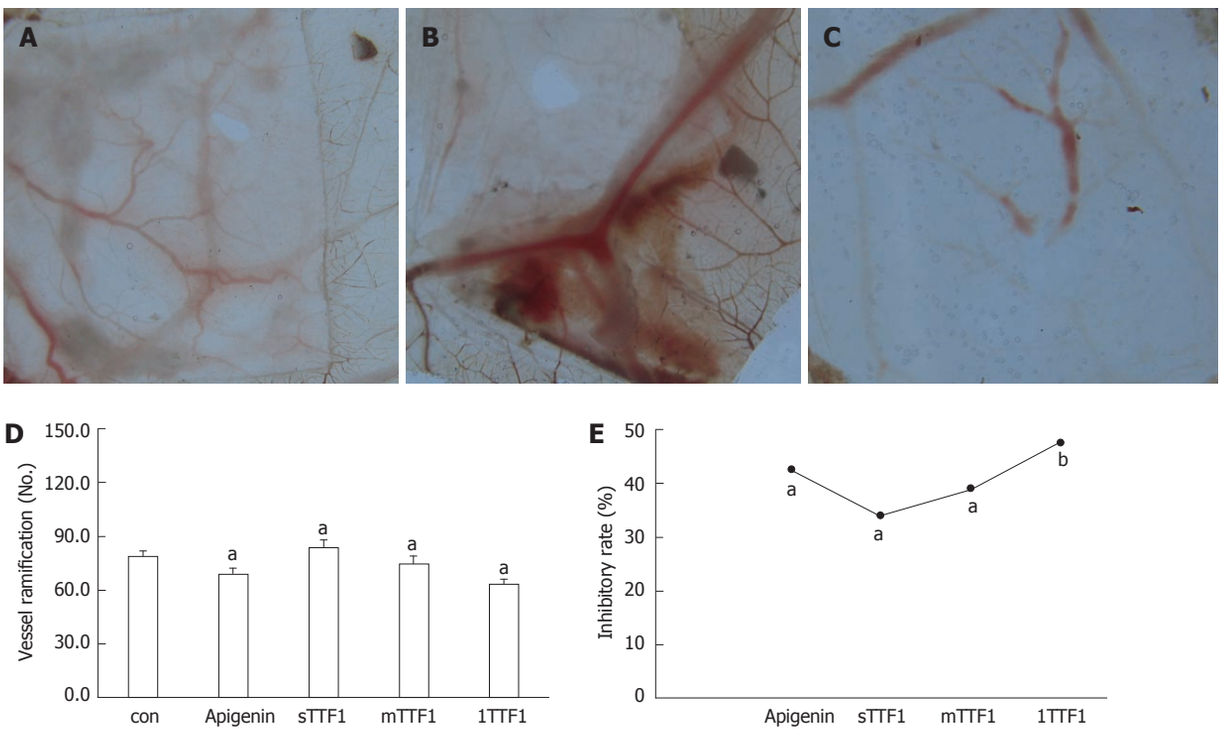

Figure 2 Inhibitory effect of TTF1 on HepG-2 cell-induced angiogenesis in chorioallantoic membrane. A: Control, inoculated with normal saline; B: Inoculated with HepG-2 cells; C: Inoculated with HepG-2 cells and treated with TTF1; D and E: Different doses of compound were used as treatments in the HepG-2 cell-induced angiogenesis in chorioallantoic membrane (CAM) as follows: sTTF1 (25 μg/embryo × 5 d); mTTF1 (50 μg/embryo × 5 d); lTTF1 (100 μg/embryo × 5 d); apigenin (100 μg/embryo × 5 d); and Con (control group treated with normal saline). $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control group.

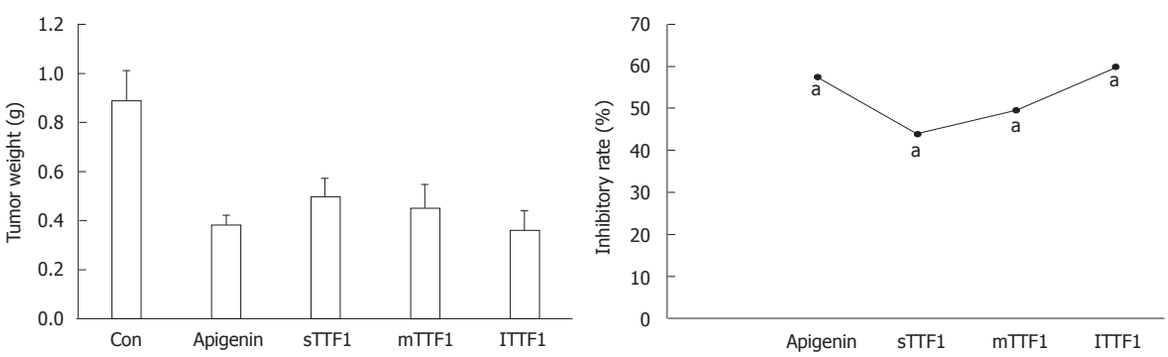

Figure 3 Effect of TTF1 on tumor weight in HepG-2-transplanted nude mice. Different doses of compound were used as treatments in the HepG-2-transplanted nude mice as follows: sTTF1 (5 μmol/kg); mTTF1 (10 μmol/kg); lTTF1 (20 μmol/kg); apigenin (40 μmol/kg); and Con (control group treated with normal saline). Compared to the control group. $^{a}P < 0.05$ *vs* control group.

of 5 μmol/kg, 10 μmol/kg and 20 μmol/kg TTF1, respectively, and it decreased in a dose-dependent manner (Figure 4C). These results indicated that TTF1 inhibited HepG-2 cell-induced angiogenesis in mouse tumors.

Effect of TTF1 on angiogenesis regulation factors

To test whether TTF1 affects the expression of the angiogenesis regulation factors including VEGF, KDR, bFGF, COX-2 and HIF-1α, we analyzed the protein levels of these factors in HepG-2 cell-induced tumors in mice. Immunohistochemistry results (as shown in Figures 5 and 6) showed the effect of TTF1 on the expression of VEGF and bFGF. In the control group, expression of VEGF and bFGF was demonstrated by brown staining of the cytoplasm and membrane of cancer cells, with a focal or diffuse distribution (Figures 5E and 6E). In the TTF1 treatment group, the brown-stained VEGF and bFGF cancer cells were significantly reduced, and most of the cells were stained blue (negative), as shown in Figures 5C and 6C. Combining these results showed that treatment with TTF1 resulted in significant down-regulation of VEGF and bFGF expression in tumors (Figure 7). Western blotting indicated that the protein levels of VEGF, KDR, bFGF, COX-2 and HIF-1α were lower in tumors that were treated with TTF1 than in control tumors (Figure 8A and B). We found that the decrease in protein levels occurred in a dose-dependent manner and showed significant differences at the 10 μmol/kg and 20 μmol/kg doses (as shown in Figure 8A and B) when compared to the controls. To explore whether TTF1

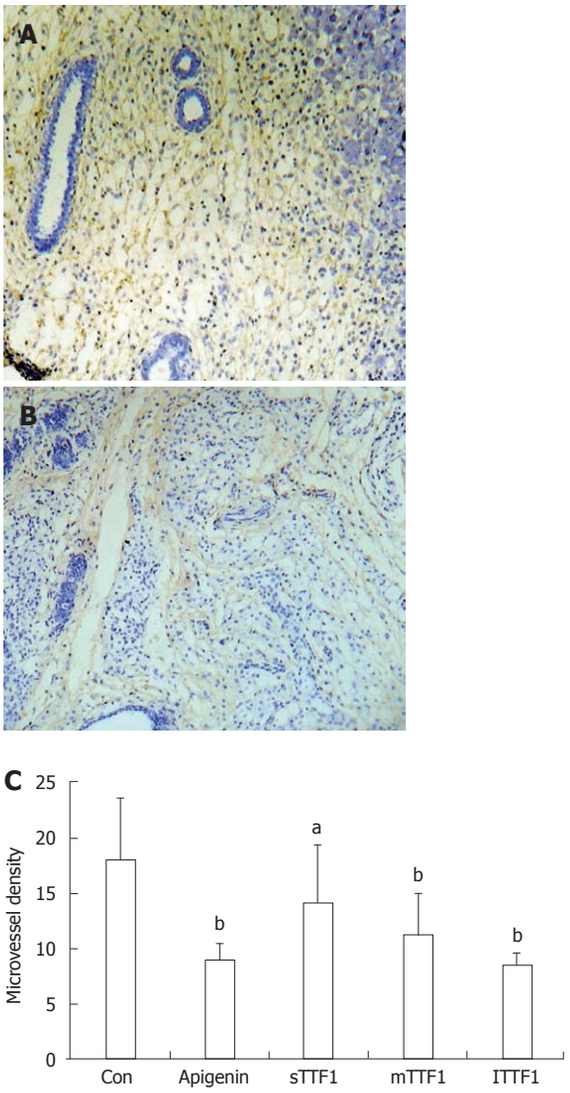

Figure 4 Microvessels in tumor tissue angiogenesis in HepG-2-transplanted nude mice. Brown staining indicates CD34 positive cells. A: Control, HepG-2-transplanted nude mouse treated with normal saline; B: TTF1, HepG-2-transplanted nude mouse treated with TTF1; C: Different doses of compound were used as treatments in the HepG-2-transplanted nude mice as follows: sTTF1 (5 μmol/kg); mTTF1 (10 μmol/kg); ITTF1 (20 μmol/kg); apigenin (40 μmol/kg); and Con (control group treated with normal saline). $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control group.

inhibits gene transcription to decrease the expression of these angiogenesis regulation factors, quantitative real-time PCR (qRT-PCR) was performed to determine the mRNA levels of VEGF, KDR, bFGF, COX-2 and HIF-1α in mice treated with TTF1. Representative qRT-PCR graphs for these genes is shown in Figure 8C-E. The effect of TTF1 on the mRNA levels of VEGF, KDR, bFGF, COX-2 and HIF-1α was consistent with the effect TTF1 on their protein levels. Our results indicate that TTF1 inhibits tumor angiogenesis by decreasing the RNA and protein levels of angiogenesis regulation factors (VEGF, KDR, bFGF, COX-2 and HIF-1α).

DISCUSSION

S. sorbifolia is a Chinese medicinal plant that grows on

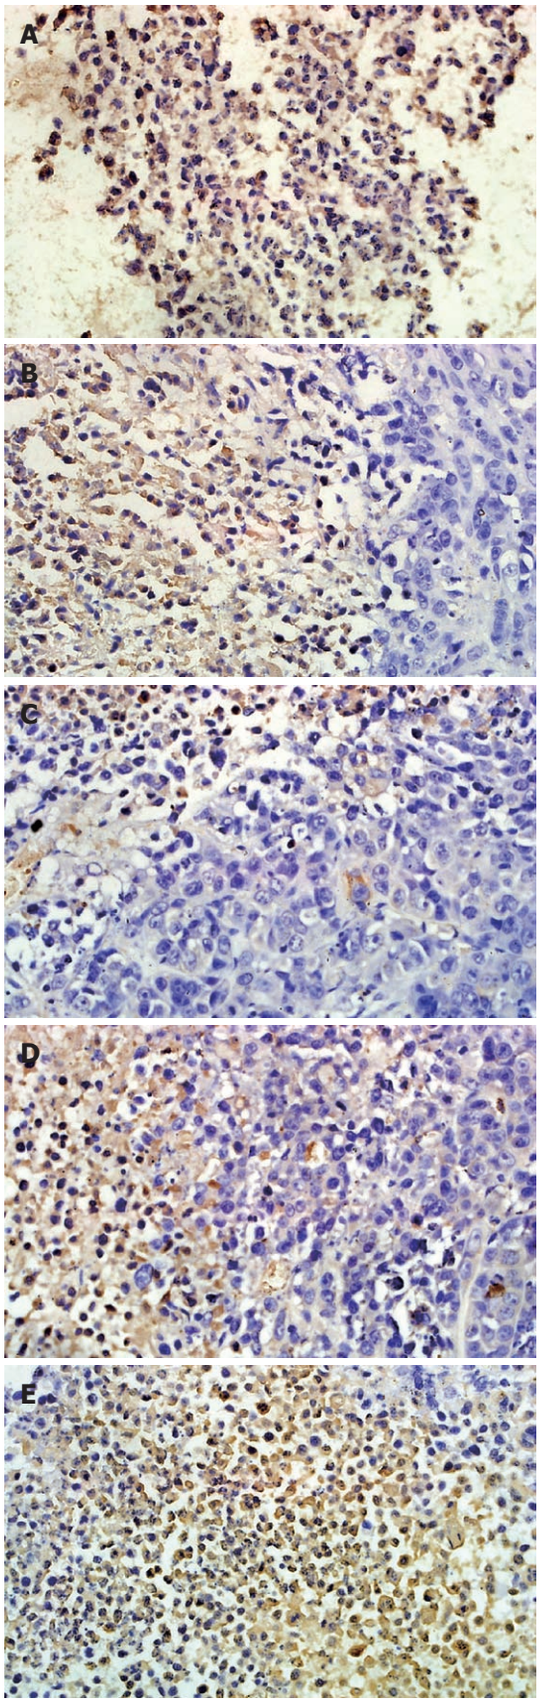

Figure 5 Down-regulation of expression of vascular endothelial growth factor by TTF1 (× 200). Brown staining indicates vascular endothelial growth factor positive. Different doses of compound were used as treatments in the HepG-2-transplanted nude mice as follows: A: sTTF1 (5 μmol/kg); B: TTF1 (10 μmol/kg); C: ITTF1 (20 μmol/kg); D: Apigenin (40 μmol/kg); E: Con (control group treated with normal saline).

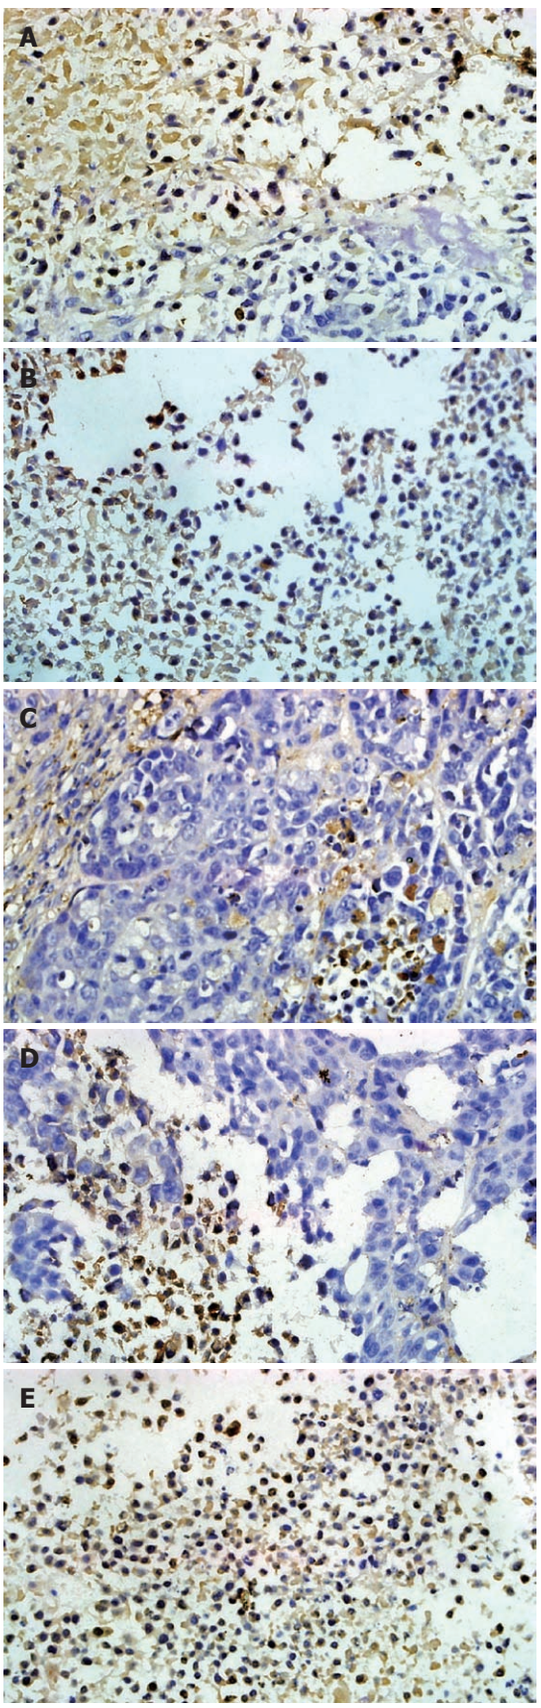

Figure 6 Down-regulation of expression of bFGF by TTF1 (× 200). Brown staining indicates bFGF-positive cells. Different doses of compound were used as treatments in the HepG-2-transplanted nude mice as follows: A: sTTF1 (5 μmol/kg); B: TTF1 (10 μmol/kg); C: lTTF1 (20 μmol/kg); D: Apigenin (40 μmol/kg); E: Con (control group treated with normal saline).

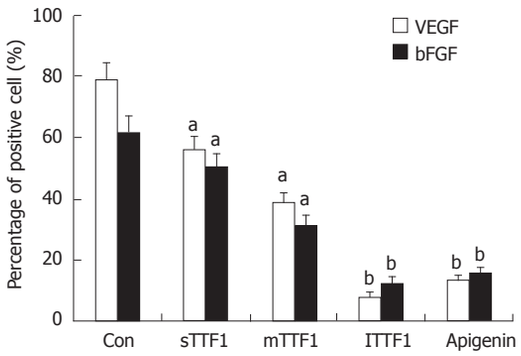

Figure 7 Quantify the effects of TTF1 on the expressions of vascular endothelial growth factor and basic fibroblast growth factor. Different doses of compound were used as treatments in the HepG-2-transplanted nude mice as follows: sTTF1 (5 μmol/kg), TTF1 (10 μmol/kg), lTTF1 (20 μmol/kg), apigenin (40 μmol/kg), and Con (control group treated with normal saline). $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control group. VEGF: Vascular endothelial growth factor; bFGF: Basic fibroblast growth factor.

Changbai Mountain. Our group began systematic research on its medicinal properties in 2002. An earlier study showed that an acetic ether extract of *S. sorbifolia* has anti-tumor, liver protective and anti-inflammatory effects. Six chemicals were identified in the acetic ether extract, and the novel monomeric compound TTF1 was separated for the first time.

Angiogenesis mainly occurs during embryo development as well as in some pathological conditions, such as damage repair, inflammation, and in particular, tumor growth and metastasis[16]. CAM is the ideal *in vivo* model to study angiogenesis and anti-vascular formation. Our research demonstrated that TTF1 inhibited HepG-2-induced CAM angiogenesis. We also found that TTF1 inhibited tumor growth in HepG-2-transplanted nude mice with an inhibition rate similar to that of apigenin, a flavone extracted from another Chinese medicinal plant that is currently in clinical use.

MVD is a marker to assess the level of tumor angiogenesis. An increase in MVD in tumor tissue suggests a fast-growing and potentially more metastatic tumor. After treatment with TTF1 on the transplanted tumors of nude mice, MVD decreased, suggesting that it inhibited tumor angiogenesis. VEGF is the most important inducing factor for angiogenesis, which specifically stimulates the proliferation of vascular endothelial cells and angiogenesis. VEGF proteins function in association with VEGF receptor (VEGFR) proteins. The five types of VEGFR include VEGFR-1 (Flt-1), VEGFR-2 (KDR), VEGFR-3 (Flt-4), NP-1 and NP-2. VEGF primarily functions through dimerization with KDR, and its intracellular tyrosine residues autophosphorylate after VEGF and KDR bind together. bFGF is another important inducing factor for angiogenesis. Tumor cells produce bFGF, and induce the vascular endothelial cells to produce bFGF, at the same time, increasing angiogenesis[17,18]. The expression levels of VEGF, VEGFR and bFGF were down-regulated after treatment with TTF1, suggesting that TTF1 may inhibit tumor growth through decreasing angiogenesis-inducing factors in HepG-2-transplanted nude mice.

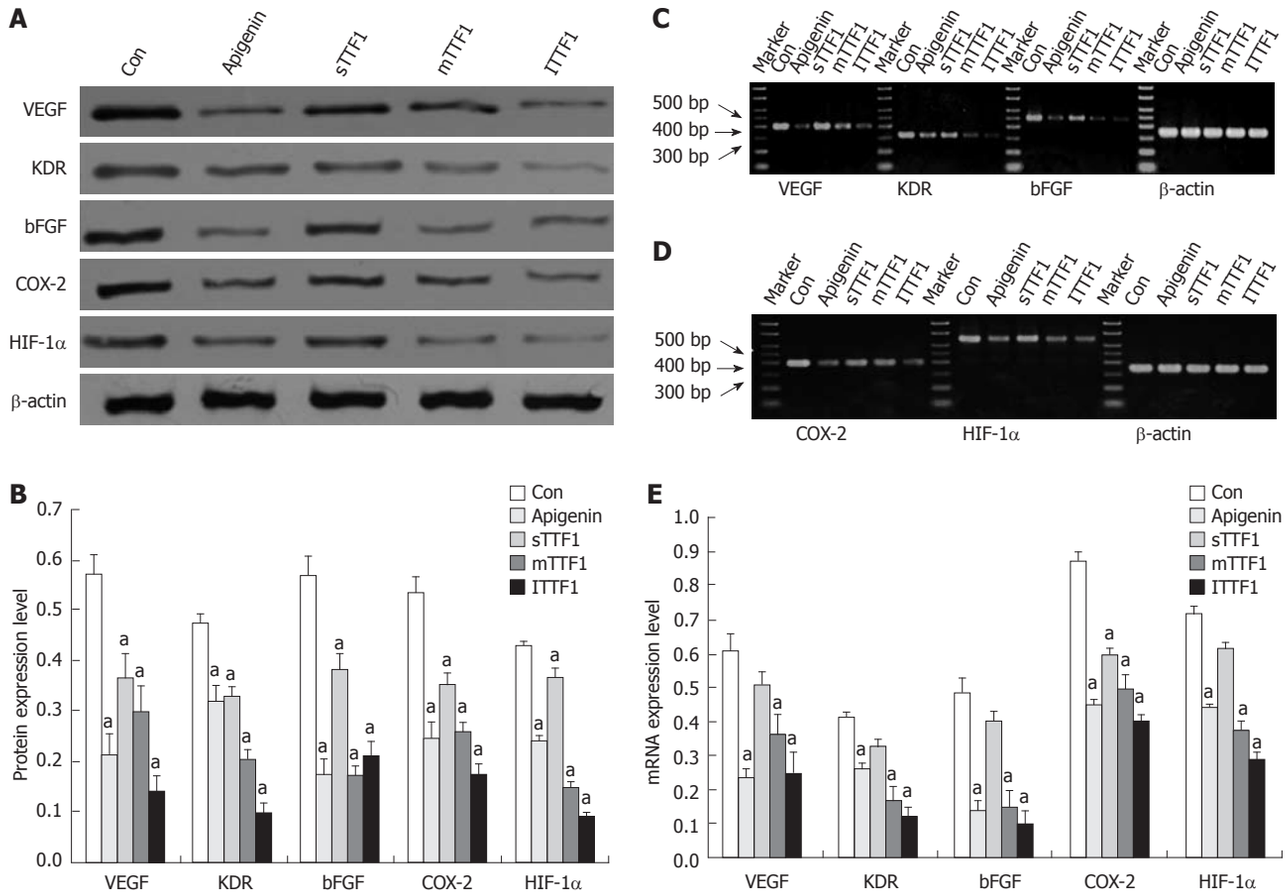

Figure 8 TTF1 decreases the gene and protein level of angiogenesis regulation factors. Western blotting analysis was used to determine the protein levels of VEGF, KDR, bFGF, COX-2 and HIF-1α. A: Tumor tissues were centrifuged at 12 000 *g* for 15 min and the supernatant (70 μg/lane) was subjected to sodium dodecyl sulfate polyacrylamide gel electrophoresis. Western blotting analysis was performed to detect the protein levels of VEGF, KDR, bFGF, COX-2 and HIF-1α. Different compounds and dosages were used as treatments in the HepG-2-transplanted nude mice as follows: sTTF1 (5 μmol/kg); mTTF1 (10 μmol/kg); ITTF1 (20 μmol/kg); apigenin (40 μmol/kg); and Con (control group treated with normal saline); B: The intensity of the VEGF, KDR, bFGF, COX-2 and HIF-1α protein bands were determined and normalized with β-actin's intensity by using the ultraviolet crosslinkers imager and plotted ($^aP < 0.05$ *vs* control group); C-E: Quantitative real-time PCR was performed to determine the mRNA expression levels of VEGF, KDR, bFGF, COX-2 and HIF-1α ($^aP < 0.05$ *vs* control group).

An insufficient blood supply in fast-growing tumor tissues may cause hypoxia. HIF-1α is the transcription factor that regulates gene transcription during tissue hypoxia. TTF1 may inhibit expression of HIF-1α by suppressing its association with the regulatory sequences of VEGF and bFGF, and therefore resulting in decreased transcription. The expression of VEGF and bFGF may further decrease the expression of KDR through negative feedback. Recent studies have shown that COX-2 is associated with tumor formation, development, and angiogenesis[19]. COX-2 was down-regulated after TTF1 treatment in tumor tissues, in accordance with the down-regulation of the other angiogenesis-inducing factors VEGF, bFGFand VEGFR.

Identification of the compounds responsible for the anti-tumor angiogenesis effects of Chinese herbal medicines is a research hotspot. Our study used the anti tumor drug apigenin as a positive control and comparison for TTF1 treament. Its mechanism of anti tumor activity includes inhibition of tumor angiogenesis, induction of tumor cell apoptosis, disturbing cellular signal pathways, and anti oxidation. Our experiments showed that the inhibitory effect of TTF1 on tumor angiogenesis surpassed that of apigenin.

S. sorbifolia is a rosaceous plant that grows extensively in Changbai Mountain, in Yunnan, Guizhou, Sichuan, Hubei, Gansu and Ningxia Provinces. It is traditionally used in activating blood, dissolving stasis, reducing swelling, easing pain, and healing fractures and injuries from falls[20]. It is a perennial herbaceous plant that has low toxicity and is liver-protective. Our study explored the inhibitory effect of TTF1 on tumor growth and angiogenesis. Further study needs to focus on the different regulatory factors and their interaction using molecular biological techniques after TTF1 inhibition of tumor angiogenesis. The relationship of the chemical structure of TTF1 to its activity should be studied, so that further structural modification may lead to new inhibitors of tumor angiogenesis with better curative effect and easier production. Moreover, further study is also needed to determine whether there are other pathways (such as inducing apoptosis, regulation of nuclear factor-κB or mitogen-activated protein kinase pathways) through which TTF1 inhibits tumor growth.

COMMENTS

Background

Anti-angiogenesis is an important strategy for tumor therapy. Many studies have demonstrated that tumor angiogenesis can be inhibited by the flavones present in Chinese herbal medicine. Previously, the authors reported that acetic ether extracts of the medicinal plant *Sorbaria sorbifolia* (*S. sorbifolia)* inhibites the growth of HepG-2 cells and mouse S180 sarcoma, down-regulates the levels of tumor necrosis factor-α and interleukin-2, and reduces the activity of natural killer cells. 5,2′,4′-trihydroxy-6,7,5′-trimethoxyflavone (TTF1) was the first active flavonoid compound identified in *S. sorbifolia*. This study focused on the effect of TTF1 specifically on the inhibition of tumor angiogenesis.

Research frontiers

Identification of the compounds responsible for the anti-tumor angiogenesis effects of Chinese herbal medicine is a research hotspot. The study used the anti-tumor drug apigenin, which is currently used clinically, as a positive control and comparison for TTF1 treatment. Its mechanism of anti-tumor activity includes inhibition of tumor angiogenesis, induction of tumor cell apoptosis, disturbing cellular signal pathways, and anti-oxidation. The experiments showed that TTF1 had an inhibitory effect on tumor angiogenesis, as did apigenin.

Innovations and breakthroughs

Six compounds were identified in acetic ether extracts of *S. sorbifolia*, including TTF1,5,7- dihydroxy-8-methoxyflavone, rutin, quercetin, daucosterol, benzoate, and p-hydroxybenzoic acid and TTF1 was the first active flavonoid compound identified in *S. sorbifolia*. After testing the six compounds, the authors found that TTF1 inhibited vascular endothelial growth factor (VEGF) expression in HepG-2 cells and VEGF165-induced human umbilical vein endothelial cell proliferation and vascular endothelial growth factor receptor 2 (VEGFR2, Flk-1/KDR) protein expression. The study explored the inhibitory effect of TTF1 on tumor growth and tumor angiogenesis.

Applications

The study results suggest that the TTF1 extracts of the medicinal plant *S. sorbifolia* is a potential therapeutic compound that could be used for tumor inhibition.

Terminology

Sorbaria sorbifolia (*S. sorbifolia)* is a Chinese medicinal plant that grows on Changbai Mountain. An earlier study has shown that an acetic ether extract of *S. sorbifolia* has anti-tumor, liver protective and anti-inflammatory effects. Chick embryo chorioallantoic membrane, is the ideal *in vivo* model for studying angiogenesis and anti-vascular formation. Microvessel density (MVD), is a marker to assess the level of tumor angiogenesis. An increase in MVD in tumor tissue suggests a fast-growing and potentially more metastatic tumor.

Peer review

The present paper examining the effects of extracts of the Chinese herb *S. sorbifolia* (TTF1) on tumor growth is work that extends and builds upon previously published work by this research group. The paper will gather a lot of interest amongst practicing gastroenterologists and oncologists.

Abstract

AIM: To investigate whether human acyl-CoA synthetase 5 (ACSL5) is sensitive to the ACSL inhibitor triacsin C.

METHODS: The ACSL isoforms ACSL1 and ACSL5 from rat as well as human ACSL5 were cloned and recombinantly expressed as 6xHis-tagged enzymes. Ni^{2+}-affinity purified recombinant enzymes were assayed at pH 7.5 or pH 9.5 in the presence or absence of triacsin C. In addition, ACSL5 transfected CaCo2 cells and intestinal human mucosa were monitored. ACSL5 expression in cellular systems was verified using Western blot and immunofluorescence. The ACSL assay mix included TrisHCl (pH 7.4), ATP, CoA, EDTA, DTT, $MgCl_2$, [9,10-^{3}H] palmitic acid, and triton X-100. The 200 μL reaction was initiated with the addition of solubilized, purified recombinant proteins or cellular lysates. Reactions were terminated after 10, 30 or 60 min of incubation with Doles medium.

RESULTS: Expression of soluble recombinant ACSL proteins was found after incubation with isopropyl beta-D-1-thiogalactopyranoside and after ultracentrifugation these were further purified to near homogeneity with Ni^{2+}-affinity chromatography. Triacsin C selectively and strongly inhibited recombinant human ACSL5 protein at pH 7.5 and pH 9.5, as well as recombinant rat ACSL1 (sensitive control), but not recombinant rat ACSL5 (insensitive control). The IC50 for human ACSL5 was about 10 μmol/L. The inhibitory triacsin C effect was similar for different incubation times (10, 30 and 60 min) and was not modified by the N- or C-terminal location of the 6xHis-tag. In order to evaluate ACSL5 sensitivity to triacsin C in a cellular environment, stable human ACSL5 CaCo2 transfectants and mechanically dissected normal human intestinal mucosa with high physiological expression of ACSL5 were analyzed. In both models, ACSL5 peak activity was found at pH 7.5 and pH 9.5, corresponding to the properties of recombinant human ACSL5 protein. In the presence of triacsin C (25 μmol/L), total ACSL activity was dramatically diminished in human ACSL5 transfectants as well as in ACSL5-rich human intestinal mucosa.

CONCLUSION: The data strongly indicate that human ACSL5 is sensitive to triacsin C and does not compensate for other triacsin C-sensitive ACSL isoforms.

INTRODUCTION

Acyl-CoA derivatives play a fundamental role in the lipid metabolism of eukaryotic cells including enterocytes. Several biological processes are influenced by acyl-CoA thioesters (acyl-CoAs), ranging from intermediary and mitochondrial metabolism to nuclear gene transcription[1]. The formation of long-chain acyl-CoA derivatives is catalyzed by acyl-CoA synthetases (ACSLs; E.C. 6.2.1.3.), which convert long-chain fatty acids (FAs) into acyl-CoAs[2]. In humans and rodents, five ACSL isoforms have been identified so far, differing in their substrate preferences, enzyme kinetics, cellular and organelle locations, as well as their expression[3]. Human ACSL5 is strongly expressed by enterocytes of the small and large intestine, and is suggested as a modifier of enterocytic maturation and cell death[4-6]. Impaired ACSL5 expression and synthesis has been found in colorectal carcinogenesis[7]. The diversity of ACSL proteins is of functional interest because recent studies suggest that ACSL proteins may play a role in channelling fatty acids toward diverse and complex lipid functions with high relevance for cellular behaviour[8,9].

Triacsin C [1-hydroxy-3-(E,E,E-2',4',7'-undecatrienylidine) triazene], an alkenyl-N-hydroxytriazene fungal metabolite, has been reported to be a potent competitive inhibitor of acyl-CoA synthetase activity[10]. The inhibitory capacity of triacsin C depends on the N-hydroxytriazene moiety of the molecule. In different cellular systems, consequences of ACSL inhibition by triacsin C were found, including a dramatic reduction in cholesterol as well as triglyceride synthesis with non-transition of macrophages to foam cells or enhanced eicosanoid release in leucocytes[11,12]. In endothelial cells, arachidonoyl-CoA synthesis was considerably inhibited by triacsin C[13]. Interference of triacsin C with cellular proliferation *via* inhibition of hu-ACSLs has been found[14,15]. It has been speculated that the plethora of triacsin C effects results from differences in the triacsin C susceptibility of ACSL isoforms. In accordance with this hypothesis, it has been demonstrated that triacsin C inhibits recombinant rat ACSL1 (r-ACSL1), rat ACSL3 (r-ACSL3), and rat ACSL4 (r-ACSL4), but not ACSL5 (r-ACSL5) enzyme activity and may therefore, be useful for discriminating amongst ACSL functions[16,17]. The activity of recently described rat ACSL6 subtypes (r-ACSL6_v1 and r-ACSL6_v2) was not affected by triacsin C at concentrations as high as 50 μmol/L[17]. However, ACSL6 is not essentially expressed in intestinal tissues and enterocytes are widely negative for ACSL6 species.

The aim of the present study was to characterize the effect of triacsin C on human ACSL5 protein *in vitro* and in the intestinal cellular environment. Our findings show that human ACSL5 is, unlike rat ACSL5, sensitive to triacsin C.

MATERIALS AND METHODS

Materials

The rat anti-human ACSL5 antibody KD7 was prepared as previously described[5]. Additional antibodies and substances were anti-beta-actin (Sigma, Deisenhofen, Germany), anti-histidine antibodies (Roche, Mannheim, Germany), HRP-conjugated secondary antibodies (Santa Cruz Biotechnology, Heidelberg, Germany; Dianova, Hamburg, Germany), enhanced chemiluminescence (PIERCE, Rockfort, United States), rainbow protein standard (Amersham Bioscience, United Kingdom), PVDF Immobilon-P membrane (Millipore, Bedford, United States), MitoTracker RedCMXRos (Molecular probes, Eugen, United States), and DAPI (Vysis Inc., Downer's Grove, United States). The alkenyl-N-hydroxytriazene fungal metabolite triacsin C (Biomol, Hamburg, Germany) and other materials were obtained from commercial sources. Standard cloning techniques were used for cloning hu-ACSL5 sequences (GeneBank accession no. AB033899) into the pENTRY vector of the GATEWAY cloning system (Invitrogen Life Technologies, Karlsruhe, Germany). Cytomegalovirus expression constructs were synthesized by recombination into the pcDNA_DEST40 vector. CaCo2 cell lines, stably transfected with hu-ACSL5 in pcDNA_DEST40 or empty pcDNA_DEST40, were cultured under appropriate culture conditions. In one approach, T5 promoter expression constructs with N-terminal fusion of hu-ACSL5 sequences to 6xHis-tag and factor Xa protease recognition sites were synthesized by recombination into the pQE-30Xa vector (Qiagen, Hilden, Germany). In a second approach, sequences of r-ACSL1 (EST clone IMAGp998O0814978Q in pExpress-1) and r-ACSL5 (I.M.A.G.E. full length cDNA clone IRBPp993B014D in pExpress-1), both delivered from RZPD Berlin, Germany, as well as the hu-ACSL5 sequence were cloned into pET22b(+) (Merck, Darmstadt, Germany) in *Escherichia coli (E. coli)* without a pelB leader sequence for cytosolic expression of C-terminal 6xHis-tagged proteins. Specimens of human normal intestinal mucosa (n = 10) were mechanically dissected from surgical resections and used fresh or immediately frozen in liquid nitrogen and stored at -80 ℃. The use of human tissues for study purposes was approved by each patient and by the local ethics committee at the University Hospital of the RWTH Aachen (EK019/06).

Cloning and recombinant expression of acyl-CoA synthetase species

For cloning of hu-ACSL5 into appropriate vectors, sequences were generated from human intestine by long distance RT-PCR using the following set of primers: 5'-GGGGACAAGTTTGTACAAAAAAGCAGGCTCTACCATGCTTTTTTATCTTTAACTTTTTTGTTTTCCCCACTTCC-3' (sense) and 5'-GGGGACCACTTTGTACAAGAAAGCTGGGTCATCCTGGATGTGCTCATACAGGCTGT-3' (antisense). Sequences of r-ACSL1 and r-ACSL5 were amplified for recombinant expression cloning. Correctness of all ACSL target sequences (accession nos.: AB033899, AM262166, NM_012820, NM_053607) were controlled by full length sequencing. Recombinant expression of different ACSL proteins in *E. coli* M15 or *E. coli* BL21 was induced with 1 mmol/L isopropyl beta-D-1-thiogalactopyranoside (IPTG) in LB medium when an OD_{600} of 0.6-0.9 was reached. In *E. coli* M15, formation of inclusion bodies was highly diminished by an incubation period of 45 min at 20 ℃. An incubation period of 24 h at 16 ℃ was used for r-ACSL1 and r-ACSL5 expression in *E. coli* BL21, whereas 6 h at 28 ℃ was optimal for expressing hu-ACSL5 in *E. coli* BL21. Expression of soluble ACSL proteins was verified by Western or Dot blotting of ultracentrifuged fractions and anti-ACSL5 or anti-His antibody probes. In control experiments, bacteria transformed with the empty vector were used.

Protein purification

Samples of IPTG-treated bacteria were sonicated in ice-cooled buffer (buffer A) containing 20 mmol/L Tris-HCl (pH 7.5), 1 mmol/L EDTA, 1% triton X-100, and 0.1% sodium cholate, and further processed by ultracentrifugation. The resulting supernatants were applied to a Ni^{2+}-affinity column (5 mL HisTrap HP; Amersham Pharmacia GE Healthcare, Freiburg, Germany). Elution was performed at a flow rate of 1 mL/min at 20 ℃; a linear gradient from buffer A to A/B (50:50, buffer B: buffer A + 500 mmol/L imidazole); 10 min with A/B (50:50); a linear gradient from A/B (50:50) to solvent B; finally with buffer B. Purification of ACSL proteins was controlled by SDS gel electrophoresis with subsequent silver staining, Western blotting, and ACSL activity assays of the purified proteins. ACSL proteins were purified to near homogeneity, migrating as single bands. The Lowry procedure was used for measurement of total protein, and bacteria transformed with the empty vector was used as a negative control.

Acyl-CoA synthetase activity assay

ACSL activity assays were performed as previously described[6]. The standard ACSL assay mix contained 150 mmol/L TrisHCl (pH 7.4), 40 mmol/L ATP, 1.2 mmol/L CoA, 2 mmol/L EDTA, 2 mmol/L DTT, 0.1 mol/L $MgCl_2$, 0.5 μmol/L [9,10-^{3}H] palmitic acid, and 0.2% triton X-100. The 200 μL reaction was initiated by adding solubilized purified recombinant hu- or r-ACSL proteins (ca. 0.1-2.0 μg) or cellular lysates in 0.1% sodium deoxycholate and 1% triton X-100 in 20 mmol/L Tris (pH 7.4). Reactions were terminated after 10, 30 or 60 min incubation with Doles medium. After phase separation, the watery phase was washed twice with palmitic acid-enriched n-heptane. Radioactivity was measured using Ultima Gold cocktail in a Tri-Carb liquid scintillation (2900TR) counter equipped with QuantaSmart software (PerkinElmer, Rodgau, Germany). The studies were repeated three times, and virtually identical results were obtained from each experiment. Enzyme activity was always demonstrated in percent of the related peak activity. Error bars are SEM.

Western blotting analysis

Cellular proteins were separated by one-dimensional SDS-PAGE and transferred to a PVDF Immobilon-P membrane. Immunodetection was performed with primary antibodies [mAB KD7, specific for ACSL5 (undiluted); anti-beta-actin (1:1000)], probed with HRP-conjugated secondary antibodies (1:10 000) and developed with enhanced chemiluminescence as suggested by the provider. Rainbow protein standard was used for molecular weight estimation.

Immunofluorescence

Cells were incubated with anti-histidine antibodies, specific for His-tagged proteins, followed by Cy2-labeled anti-mouse antibodies. For negative controls, the primary antibody was replaced by normal serum. MitoTracker RedCMXRos was used as a mitochondrial marker following the manufacturer's recommendations. Cells were incubated with 25 nmol/L MitoTracker for 15 min, washed, fixed (methanol at -20 ℃ for 5 min, followed by acetone at 4 ℃ for 2 min), and permeabilized with 0.2% Triton X-100. After incubation of primary and secondary antibodies, DAPI was applied for nuclear staining. Images were visualized using a confocal laser microscope (Nicon, Düsseldorf, Germany).

RESULTS

Expression and purification of recombinant hu-acyl-CoA synthetase 5 proteins

Expression of soluble recombinant hu-ACSL5 protein in *E. coli* M15 was found after incubation with IPTG for 45 min at 20 ℃. Soluble activity in supernatants after ultracentrifugation (about 10% of total ACSL activity) was further purified to near homogeneity using Ni^{2+}-affinity chromatography. The specific activity of recombinant hu-ACSL5 proteins from different preparations were in the range of 1.08-2.31 nmol/min per mg and independent of the epitope and its location at the N- or C-terminus (Figure 1).

Triacsin C strongly inhibits recombinant hu-acyl-CoA synthetase 5, but not r-acyl-CoA synthetase 5 activity

Since hu-ACSL5 displayed activity peaks at pH 7.5[6,16] and pH 9.5[6], conditions favouring maximal enzyme activity were chosen when the inhibitory effects of triacsin

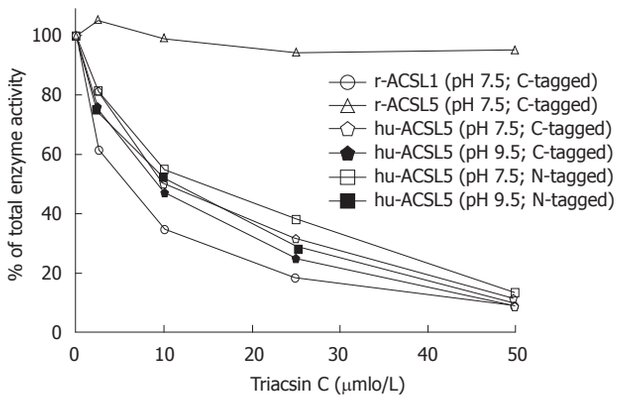

Figure 1 Sensitivity of recombinant acyl-CoA synthetase 5 proteins to triacsin C. Enzyme activity of Ni2+-affinity purified recombinant r-ACSL1, r-ACSL5, hu-ACSL5 C-terminal 6xHis-tagged enzyme, and hu-ACSL5 N-terminal 6xHis-tagged enzyme were assayed at pH 7.5 (white symbols) and pH 9.5 (black symbols) in the presence and absence of triacsin C as described in the methods section. ACSL5: Acyl-CoA synthetase 5.

C to ACSL proteins were tested. To test the effects of triacsin C on purified rat and human ACSL proteins in simultaneous reactions, the triacsin C substance dissolved in DMSO (2.5% of final assay reaction) was directly added to the reaction mixture (0-50 μmol/L) following the procedures by Kim *et al*[16]. Triacsin C selectively and strongly inhibited recombinant human ACSL5 protein (pH 7.5 and pH 9.5), as well as recombinant r-ACSL1 (sensitive control), but not recombinant r-ACSL5 (insensitive control) in a dose dependent manner (Figure 1). The IC50 for human ACSL5 proteins was about 10 μmol/L, and the inhibitory triacsin C effect was similar for different incubation times (10, 30 and 60 min) and was not modified by the N- or C-terminal location of the 6xHis-tag.

Triacsin C inhibits human acyl-CoA synthetase 5 activity in human intestine cellular systems

In order to further characterize the inhibitory potency of triacsin C on hu-ACSL5 protein in a cellular environment, stable hu-ACSL5 transfectants in CaCo2 cells (ATCC No. HTB-37) were used as previously published[6]. Transgenic and endogenous hu-ACSL5 protein expressions were controlled with Western blotting and indirect immunofluorescence (Figure 2). The shift between both ACSL5 proteins in Western blotting is due to the 6xHis-tag and a linker sequence, which result in a higher molecular weight of the transgenic ACSL5 protein (Figure 2A). N-terminal 6xHis-tagged hu-ACSL5 proteins are strongly co-localized with mitochondria. Some extramitochondrial signalling is found, including ER/ribosomes (Figure 2B). Monitoring of ACSL-activity in stable hu-ACSL5 N-terminal 6xHis-tagged transfectants and controls (wild type CaCo2 cells and CaCo2 transfectants with the empty vector) was performed between pH 5 and pH 10 (Figure 2C). In stable hu-ACSL5 CaCo2 transfectants, peak activity was found at pH 7.5 and pH 9.5, corresponding to the properties of recombinant hu-ACSL5 protein. This bimodal curve of ACSL activity was not observed in control cells, where the main ACSL activity was detectable at pH 7. The data further indicate that the bimodal distribution of ACSL activity was mainly due to hu-ACSL5 activity in the CaCo2 cellular environment.

In the presence of triacsin C (25 μmol/L), total ACSL activity was dramatically diminished in hu-ACSL5 transfectants as well as in controls. Importantly, the bimodal curve of ACSL activity with peak values at pH 7.5 and pH 9.5, due to hu-ACSL5 transgenic over-expression, was essentially smoothed in the presence of triacsin C (Figure 2C).

Next, mechanically dissected normal human intestinal mucosa with high ACSL5 expression (Figure 3A) was monitored for ACSL activity in the pH range of 5 to 10 (Figure 3B). Strong ACSL activity was found at pH 7, pH 8, and pH 9.5, partly reflecting the characteristic bimodal activity of human ACSL5 proteins. In the presence of triacsin C (25 μmol/L), ACSL activity was dramatically inhibited; the pH 9.5 peak was especially diminished (Figure 3B). The resulting smooth curve paralleled the findings with triacsin C treated purified hu-ACSL5 recombinant proteins and stable hu-ACSL5 transfected CaCo2 cells.

DISCUSSION

A considerable amount of data indicates that long chain fatty acids are essential in intestinal physiology and pathophysiology. In the modifier concept of intestinal carcinogenesis, the activity of intestinal long chain fatty acids is suggested as an important cell cycle modifier[18]. The function of ACSL mediated metabolic channelling of fatty acids in the regulation of intestinal cell behaviour includes the lipidation of proteins and translation of long chain fatty acid modifiers in several signalling cascades and receptor structures[19]. Specific inhibitors of enzyme activity are well established and powerful tools for determining enzymatic functions in cellular and non-cellular systems. Both sensitivity and specificity of inhibitors are essential prerequisites for a stringent functional analysis of target enzymes. Several molecular mechanisms in enzyme inhibition have been characterized so far, including covalent and non-covalent binding of substrate-like or non-substrate compounds. Competitive binding with the substitution of a characteristic substrate frequently underlies non-covalent enzyme inhibition. Competitive inhibition is the mechanism behind the triacsin C-mediated biochemical effects on ACSL isoforms[10,16,20].

The overwhelming number of studies concerning triacsin C mediated effects on ACSL molecules have been performed in rat models. There is convincing experimental data demonstrating the triacsin C sensitivity of rat ACSL isoforms 1, 3, 4 and 6, but insensitivity of the rat isoform 5[16,17]. However, many ACSL isoforms have splice variants, most of which have not been tested and characterized for triacsin C sensitivity. In addition, species-related differences of ACSL protein sensitivity to triacsin C have not been systematically examined up-

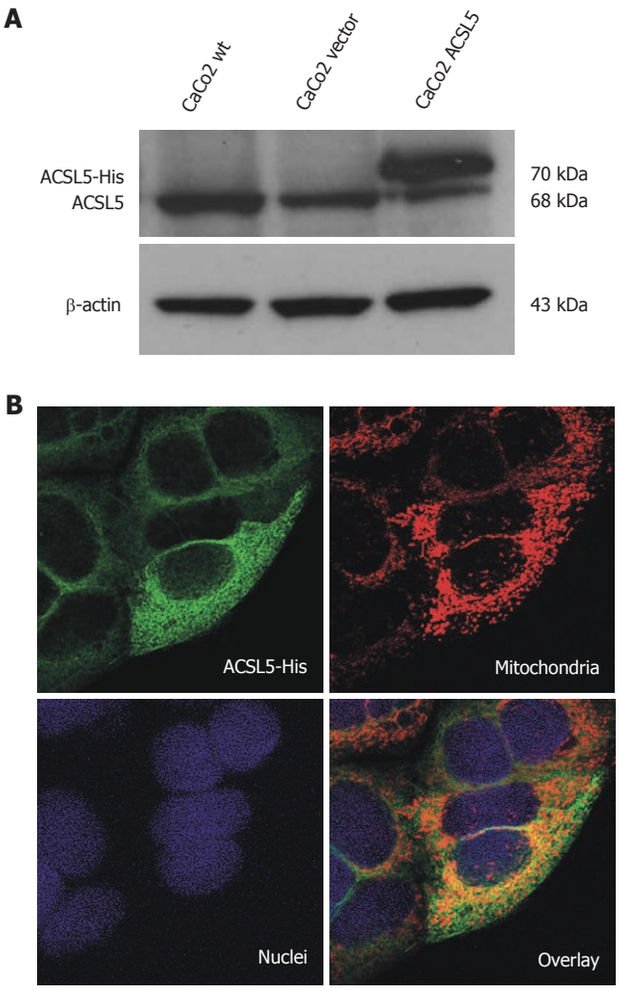

Figure 2 Human acyl-CoA synthetase 5 is triacsin C sensitive in CaCo2 cells. A: CaCo2 cells were stably transfected with the full-length ACSL5 expressing pcDNA_DEST40 plasmid or empty control vector. Expression of N-terminal 6xHis-tagged hu-ACSL5 protein in CaCo2 was analyzed by Western blot using anti-ACSL5 and anti-His antibodies; B: Indirect immunofluorescence of N-terminal 6xHis-tagged hu-ACSL5 proteins, mitochondria, and nuclei in CaCo2 cells shows the mitochondrial localization of recombinant ACSL5 proteins. Original magnification × 400; C: Analysis of ACSL activity (pH 5-10) in hu-ACSL5 CaCo2 transfectants and controls (pcDNA_DEST40 CaCo2 transfectants and CaCo2 wild type) in the presence (white symbols) or absence (black symbols) of 25 μmol/L triacsin C. A: Human small intestinal mucosa after indirect immunofluorescence with anti-ACSL5 antibodies; B: Analysis of ACSL activity in human intestinal mucosa in the presence or absence of 25 μmol/L triacsin C. Triacsin C strongly inhibits ACSL activity in human intestinal mucosa. ACSL5: Acyl-CoA synthetase 5.

to-now. The present study was, therefore, designed to systematically analyze triacsin C effects on human ACSL5 proteins, which are predominantly found in enterocytes of the human small intestinal mucosa.

In order to analyze the biochemical behaviour of hu-ACSL5, we cloned the respective sequences from an intestinal or plasmid cDNA resource, expressed the 6xHis-tagged recombinant proteins, and further purified the enzymes to near homogeneity using Ni^{2+}-affinity chromatography. As demonstrated by digestion experiments and the subsequent analysis of ACSL-activity, the N- or C-terminal 6xHis-tag did not alter the enzymatic activity of ACSL5 at 30 ℃ or 37 ℃ in a broad range of pH values (pH 5-10). Monitoring ACSL-activity of recombinant hu-ACSL5 protein revealed triacsin C-sensitivity with an IC50 about 10 μmol/L. In this experimental setting, insensitivity of recombinant r-ACSL5 and sensitivity of recombinant r-ACSL1 was found, identical to previously described data by Kim *et al*[16].

Additional experiments ruled out the possibility that triacsin C-sensitivity of purified recombinant hu-ACSL5 protein could be a result of the absence of a cellular environment. Stable hu-ACSL5 transfectants and stable controls were established from CaCo2 cells, and in another set of experiments, human intestinal mucosa was investigated. The ACSL activity of cellular systems and tissues

was monitored at different pH values in the presence or absence of triacsin C (25 μmol/L), and similar results to those with recombinant proteins were seen. Especially at pH 9.5, a pH value highly characteristic for hu-ACSL5 activity[6], ACSL activity was significantly decreased in cultured cells as well as intestinal mucosa. The background ACSL activity was probably due to enzymes other than ACSL5, including triacsin C insensitive ACSL splice forms, ACSL isoforms, and fatty acid binding proteins. In conclusion, we demonstrate experimental evidence that hu-ACSL5 is triacsin C sensitive as a purified recombinant protein, in hu-ACSL5 over-expressing epithelial cell lines, and in human small intestinal mucosa, a tissue with high ACSL5 expression levels. These findings imply that human ACSL5 is not able to compensate for triacsin C-inhibited ACSL isoforms, and triacsin C cannot be used to differentiate functions of different ACSL enzymes in human cells or tissues.

The insensitivity of human ACSL5 to triacsin C has been postulated by the observation that recombinant rat ACSL5 was not inhibited by this fungal metabolite[16]. This has been addressed in several studies[15,21-24]. In all of these studies, triacsin C was preferentially used to incubate cultured cells in a concentration clearly below the $IC50^{hu\text{-}ACSL5}$ of approximately 10 μmol/L, and the substance was not directly added to the acyl-CoA activity assay mixture. In our study triacsin C was always used as a competitive inhibitor. Identical to the experimental approach of Kim *et al*[16], triacsin C was directly added to the acyl-CoA activity assay mixture.

We hypothesize that the divergent triacsin C effects on ACSL activity are species-related and determined by human and rat ACSL5 protein sequences. A sequence analysis of the proteins revealed that these were only 81% identical, and that discrepancies existed in exon 20 splicing as well as in the organization and length of functional domains, like the ATP-binding domain or the FA activation domain (NCBI data base: http//www.nlm.nih.gov/nlmhome.html). Species-related differences in ACSL5 activity are further suggested by expression experiments. Over-expression of r-ACSL5 in a rat cellular environment increases fatty acid incorporation into diacylglycerol and triacylglycerol but does not affect fatty acids used for beta-oxidation[25], whereas r-ACSL5 in a human cellular environment increases palmitate oxidation[26].

In the present study, sensitivity of human ACSL5 protein to triacsin C was demonstrated using purified recombinant protein, CaCo2 cells, and human intestinal mucosa. The divergent inhibitory effect of triacsin C with sensitivity of hu-ACSL5 and insensitivity of rat-ACSL5 is most likely species-related. Our findings indicate that human ACSL5 does not compensate for other triacsin C sensitive ACSL isoforms.

COMMENTS

Background

Strong expression of acyl-CoA synthetase 5 (ACSL5) is found in surface lining epithelia of the large and small intestine. ACSL5 enzyme activity is probably related to enterocytic maturation and intestinal carcinogenesis. Triacsin C is an inhibitor of several ACSL isoforms and is used to differentiate amongst ACSL functions. In rat, ACSL5 is insensitive to triacsin C.

Research frontiers

Analysis of human ACSL5 *in vitro* as well as in a cellular environment revealed sensitivity to the inhibitor triacsin C, which is in contrast to rat ACSL5. The data indicate that a species-related difference in triacsin C inhibition of ACSL5 exists, and human ACSL5 does not compensate for other triacsin C-sensitive human ACSL isoforms.

Innovations and breakthroughs

In previous triacsin C related studies of ACSL activity, cultured cells were preferentially incubated with triacsin C in a concentration clearly below the $IC50^{hu\text{-}ACSL5}$ of approximately 10 μmol/L. Moreover, triacsin C was not used as a competitive inhibitor. In particular, species-related differences of ACSL protein sensitivity to triacsin C have not been systematically addressed up to now.

Applications

The recent finding that human ACSL5 is sensitive to the inhibitor triacsin C should be considered in related experiments. In human tissues, the differentiation of ACSL activities and the characterization of ACSL5 function with triacsin C are limited. The current finding suggests that human ACSL5 does not compensate for other triacsin C-sensitive ACSL isoforms.

Terminology

Acyl-CoA synthetase 5 is an enzyme that catalyzes formation of long-chain acyl-CoA derivatives and belongs to the family of acyl-CoA synthetases (ACSLs; E.C. 6.2.1.3.). Five ACSL isoforms differing in their enzyme kinetics, substrate preferences, and cellular expression have been identified so far in humans and rodents. Triacsin C [1-hydroxy-3-(E,E,E-2',4',7'-undecatrienylidine) triazene], an alkenyl-N-hydroxytriazene fungal metabolite, has been reported to be a potent competitive inhibitor of acyl-CoA synthetase activity.

Peer review

Kaemmerer *et al* showed that human intestinal ACSL5 is sensitive to triacsin C using purified recombinant protein, CaCo2 cells, and human intestinal mucosa. The experimental design is good and interpretation of results was conducted appropriately.

Abstract

AIM: To evaluate the clinical significance of oxidative stress markers in patients with hepatitis C virus (HCV)-related hepatocellular carcinoma (HCC).

METHODS: Sixty-four consecutive patients who were admitted to Kagoshima University Medical and Dental Hospital were enrolled in this retrospective study. All patients had chronic liver disease (CLD) due to infection with HCV. Thirty patients with HCV-related HCC, 34 with HCV-related CLD without HCC (non-HCC), and 20 healthy volunteers (HVs) were enrolled. Possible associations between serum manganese superoxide dismutase (MnSOD) and thioredoxin (TRX) levels and clinical parameters or patient prognosis were analyzed over a mean follow-up period of 31.7 mo.

RESULTS: The serum MnSOD levels were significantly higher in patients with HCV-related HCC than in patients without HCC ($P = 0.03$) or HVs ($P < 0.001$). Similarly, serum TRX levels were also significantly higher in patients with HCV-related HCC than in patients without HCC ($P = 0.04$) or HVs ($P < 0.01$). However, serum levels of MnSOD and TRX were not correlated in patients with HCC. Among patients with HCC, the overall survival rate (OSR) was lower in patients with MnSOD levels $\geqslant$ 110 ng/mL than in patients with levels < 110 ng/mL ($P = 0.01$), and the OSR tended to be lower in patients with TRX levels < 80 ng/mL ($P = 0.05$). In addition, patient prognosis with HCC was poorest with serum MnSOD levels $\geqslant$ 110 ng/mL and serum TRX levels < 80 ng/mL. Furthermore, a multivariate analysis using a Cox proportional hazard model and serum levels of five factors (MnSOD, prothrombin time, serum albumin, serum α-fetoprotein (AFP), and serum des-γ-carboxy prothrombin) revealed that MnSOD levels $\geqslant$ 110 ng/mL (risk ratio: 4.12, 95% confidential interval: 1.22-13.88, $P = 0.02$) and AFP levels $\geqslant$ 40 ng/mL (risk ratio: 6.75; 95% confidential interval: 1.70-26.85, $P < 0.01$) were independent risk factors associated with a poor patient prognosis.

CONCLUSION: Serum MnSOD and TRX levels are potential clinical biomarkers that predict patient prognosis in HCV-related HCC.

INTRODUCTION

As a significant cause of global cancer morbidity and mortality, hepatocellular carcinoma (HCC) is the fifth- and seventh-most frequently diagnosed cancer worldwide in men and women, respectively, and is the second- and sixth-most frequent cause of cancer deaths in men and women, respectively[1]. HCC is most frequently caused by persistent infection with hepatitis C or B virus. Early HCC diagnosis and better treatments have helped to improve the prognosis for patients with HCC. Also, interferon (IFN)-based treatments not only eliminate hepatitis C virus (HCV) infection, but also prevent HCC in patients with chronic hepatitis C (CHC)[2]. However, IFN-based therapies do not always effectively eliminate HCV infection or prevent HCC. Thus, biomarkers that are indicative of HCC pathological condition would have many clinical benefits, including aiding in the selection of the most appropriate treatment for a patient's disease.

Oxidative stress results from an imbalance in the production of reactive oxygen species (ROS) and the antioxidative defenses that maintain a cellular redox state. ROS include superoxide anions, hydrogen peroxide, hydroxyl radicals and nitric oxide, all of which are indispensable elements in many biochemical processes[3]. ROS are mainly derived from Kupffer and inflammatory cells in the liver[4], and upon exposure to other cells are thought to induce apoptosis, necrosis, inflammation, immune responses, fibrosis and tissue regeneration[5]. In liver disease, there is an overproduction of ROS from endogenous sources such as the mitochondria, peroxisomes, and activated inflammatory cells. In particular, ROS of mitochondrial origin were recently reported to be elevated in patients with alcoholic liver disease, non-alcoholic steatohepatitis (NASH)[6,7] and HCV-related chronic liver disease (CLD)[8]. Conversely, cells are protected from oxidative stress by intracellular antioxidants such as glutathione (GSH) and thioredoxin (TRX) and by various antioxidant enzymes such as superoxide dismutase (SOD), GSH peroxidase, catalase, and heme oxygenase-1[9-11]. Collectively, the relative expression levels of these molecules may serve as biomarkers for various liver diseases, including HCV-related HCC.

Manganese SOD (MnSOD) is an antioxidant enzyme that catalyzes the dismutation of the highly reactive superoxide anion to O_2 and to the less reactive species H_2O_2. We have previously demonstrated that MnSOD expression was induced in primary cultured hepatocytes that were loaded with hydrogen peroxide *in vitro* and that serum MnSOD levels can be used to distinguish between NASH and simple steatosis in patients with nonalcoholic fatty liver disease[7]. However, the clinical significance of serum MnSOD levels in HCV-related CLD has not been fully investigated.

TRX was originally discovered in *Escherichia coli* as a proton donor for ribonucleotide reductase[12]. Subsequently, the human *TRX* gene was cloned as an adult T-cell leukemia-derived factor and was originally described as an interleukin-2 receptor inducer present in the cell culture supernatant of human T-lymphotropic virus type-1 -transformed cells[13]. TRX expression is induced by various oxidative stressors in patients with acquired immunodeficiency syndrome[14], Sjögren's syndrome[15], rheumatoid arthritis[16], and malignant neoplasms[17,18]. Previous studies have reported that serum TRX is an oxidative stress marker and that serum TRX levels increase in patients with HCV-related CLD during liver fibrosis progression[19]. In addition, serum TRX levels are reported to be elevated in patients with NASH compared to patients with simple steatosis[20]. However, the clinical significance of elevated TRX levels among patients infected with HCV in relation to HCC diagnosis and prognosis has not been elucidated.

In this study, we aimed to clarify the clinical significance of serum levels of MnSOD and TRX in patients with HCV-related CLD, and in particular among patients with HCC.

MATERIALS AND METHODS

Patients

Sixty-four consecutive patients who were admitted to Kagoshima University Medical and Dental Hospital between December 2006 and November 2008 were enrolled in this retrospective study. All patients had CLD due to an HCV infection and were diagnosed with HCC (30 patients; HCC group) or without HCC (34 patients; non-HCC group). Twenty healthy volunteers (HVs) were also enrolled in this study.

In this study, HCC was diagnosed based on findings from abdominal ultrasound, abdominal computed tomography, and serum levels of α-fetoprotein (AFP) and des-γ-carboxy prothrombin (DCP, also known as PIVKA-Ⅱ). Patients were excluded from this study if they were positive for hepatitis B surface antigen; other types of hepatitis, including autoimmune hepatitis and alcoholic liver disease; or other malignancies.

The study endpoint was patient death, the available follow-up date, or December 31, 2010. Patient follow-up

periods ranged from 5.1 to 44.6 mo, with a mean observation time of 31.7 mo. Informed consent was obtained from all study patients and healthy controls. This study was approved by the ethical committees of Kagoshima University Graduate School of Medical and Dental Sciences and Kagoshima University Medical and Dental Hospital.

Laboratory markers

The clinical laboratory parameters assessed included platelet count (Plt), prothrombin time (PT), albumin (Alb), total bilirubin (T-Bil), alanine aminotransferase (ALT), γ-glutamyl transpeptidase (γ-GTP), AFP and DCP. The serologically defined HCV genotype (HCV serotype) was determined using a serological genotyping assay kit (Immunocheck F-HCV Grouping; International Reagents Co., Tokyo, Japan). If the HCV serotype could not be determined, the HCV genotype was evaluated using the HCV Core Genotype assay (SRL, Tokyo, Japan). HCV genotype 1b was included with serotype Ⅰ, while genotypes 2a and 2b were included with serotype Ⅱ. No other HCV genotype was detected in this study population. HCV RNA titers were quantified using either quantitative RT-PCR (Amplicor monitor version 2, Roche, Tokyo, Japan) or the Cobas TaqMan PCR assay (Roche, Tokyo, Japan). Patients were categorized as having a high viral load if their values were 100 KIU/mL or greater based on quantitative RT-PCR analysis, or 5 log IU/mL or more based on the Cobas TaqMan PCR assay.

Evaluation of clinical stage

Hepatic function was assessed in the HCC group using Child-Pugh staging based on both clinical (ascites and encephalopathy) and laboratory (Alb, T-Bil, and PT) parameters. HCC clinical stage was assessed based on a patient's Cancer of the Liver Italian Program (CLIP) score, which was calculated by adding points for the following four variables: Child-Pugh stage, tumor morphology, AFP value, and portal venous invasion[21,22]. The Japan Integrated Staging (JIS) system[23,24], developed by the Liver Cancer Study Group of Japan and based on a combination of Child-Pugh stage and HCC TNM classification, was used to clinically stage HCC.

Serum MnSOD and TRX levels

Serum was obtained from peripheral blood samples by centrifugation at 4000 *g* for 5 min at room temperature. Serum samples were frozen at -80 ℃ until further use. Serum MnSOD or TRX levels were measured using the Human Superoxide Dismutase 2 (AbFRONTIER, Seoul, Korea) and human thioredoxin (Redox Bio Science, Kyoto, Japan) ELISAs, respectively.

Statistical analysis

Results are expressed as the mean and standard deviation. *P* values less than 0.05 were regarded as statistically significant. Statistical analyses were performed using the Fischer's exact test or the Mann-Whitney *U* test, as appropriate. The area under the curve (AUC) was calculated for the receiver operating characteristic (ROC) curve in order to measure the overall accuracy of the test. The sensitivity, specificity, positive predictive value, negative predictive value and accuracy of diagnostic test were additionally determined according to the protocol described previously[25]. Differences among the three groups were evaluated using the Kruskal-Wallis test followed by Dunn's multiple comparison tests. Correlation coefficients were calculated using Spearman's rank correlation analysis. The Kaplan-Meier method was used to estimate death for each parameter that had been identified at enrollment, and the death distribution curves were compared using the log-rank test. Univariate and multivariate analyses of patient outcome risk ratios were performed using Cox's proportional hazards regression analyses. All statistical analyses were conducted using PASW Statistics v. 18 (SPSS Inc., Chicago, IL).

Table 1 Patient clinical characteristics

Characteristics	Non-HCC group (*n* = 34)	HCC group (*n* = 30)	*P* value[1]
Age (yr)	62.3 ± 11.0	72.2 ± 7.5	< 0.001
Sex (male/female)	10/24	21/9	< 0.01
Plt (× 10^4/μL)	17.0 ± 5.5	10.3 ± 5.2	< 0.001
PT (%)	99.7 ± 13.3	77.6 ± 11.8	< 0.001
Alb (g/dL)	4.3 ± 0.4	3.6 ± 0.6	< 0.001
T-Bil (mg/dL)	0.8 ± 0.3	1.5 ± 0.8	< 0.001
ALT (IU/L)	44.8 ± 30.2	52.0 ± 28.2	0.12
γ-GTP (IU/L)	31.3 ± 16.1	56.2 ± 44.3	< 0.01
AFP (ng/mL)	7.2 ± 22.8	85.9 ± 197.6	< 0.001
DCP (mAU/mL)	22.8 ± 14.7	485.5 ± 1982.6	0.001
HCV serotype group (1/2)	18/10 (*n* = 28)	21/3 (*n* = 24)	0.06
HCV RNA level (high/low)	28/5 (*n* = 33)	21/4 (*n* = 25)	0.99

Data are shown as the mean ± SD. *n*: Number of patients or the number of samples analyzed. [1]Differences between mean values were evaluated using either the Fischer's exact test or the Mann-Whitney *U* test, as appropriate. Plt: Platelet count; PT: Prothrombin time; Alb: Albumin; T-Bil: Total bilirubin; ALT: Alanine aminotransferase; γ-GTP: γ-glutamyl transpeptidase; AFP: alpha-fetoprotein; DCP: des-γ-carboxy prothrombin; HCV: Hepatitis C virus; RNA: Ribonucleic acid.

RESULTS

Patient characteristics and classification according to the presence of hepatocellular carcinoma

Table 1 summarizes the baseline clinical characteristics of the 64 patients who were classified based on the presence or absence of HCC. Age, sex, and clinical laboratory parameters, including Plt, PT, Alb, T-Bil, γ-GTP, AFP and DCP, were significantly different between these two groups.

Serum MnSOD and TRX levels in hepatocellular carcinoma patients

Serum MnSOD levels were significantly higher in patients with HCC compared to patients without HCC ($P = 0.03$) and HVs ($P < 0.001$) (Figure 1A). The serum TRX levels were also significantly higher in the HCC group compared to the non-HCC group ($P = 0.04$) and HV group ($P < 0.01$) (Figure 1B). However, there was no correlation between these two markers in the HCC group ($P = 0.28$, $r = 0.20$) (Figure 1C).

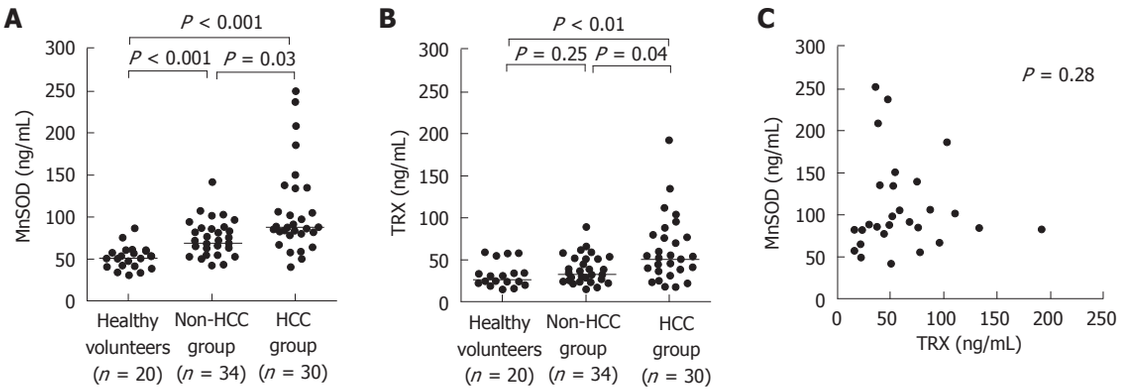

Figure 1 Serum levels of manganese superoxide dismutase and thioredoxin in the hepatocellular carcinoma, non-hepatocellular carcinoma and healthy volunteer groups. A: Serum manganese superoxide dismutase (MnSOD) levels were significantly higher in the hepatocellular carcinoma (HCC) group than in either the non-HCC group ($P = 0.03$) or the healthy volunteers (HV) group ($P < 0.001$); B: Serum thioredoxin (TRX) levels were also significantly higher in the HCC group than in either the non-HCC group ($P = 0.04$) or the HV group ($P < 0.01$); C: No significant correlation was detected between serum MnSOD and TRX levels in the HCC group.

Table 2 Sensitivity, specificity, positive predictive value, negative predictive value and accuracy of manganese superoxide dismutase and α-fetoprotein serum levels for diagnosis of hepatocellular carcinoma in all patients (%)

Factors	Sensitivity	Specificity	PPV	NPV	Accuracy
MnSOD (≥ 110 ng/mL)	26.7	97.1	88.9	60.0	64.1
AFP (≥ 40 ng/mL)	33.3	97.1	90.9	62.3	67.2
Combination[1]	46.7	94.1	87.5	66.7	71.9

[1]MnSOD ≥ 110 ng/mL and/or AFP ≥ 40 ng/mL. PPV: Positive predictive value; NPV: Negative predictive value; MnSOD: Manganese superoxide dismutase; AFP: α-fetoprotein.

Table 3 Correlation between serum manganese superoxide dismutase or thioredoxin levels and laboratory data in the hepatocellular carcinoma group

Factors	HCC group ($n = 30$)			
	Serum MnSOD levels		Serum TRX levels	
	Correlation coefficient	*P* value	Correlation coefficient	*P* value
Age (yr)	-0.97	0.61	0.11	0.55
Plt (× 10^4/μL)	0.03	0.89	0.66	< 0.001
PT (%)	-0.36	0.05	0.12	0.53
Alb (g/dL)	-0.63	< 0.001	0.19	0.33
T-Bil (mg/dL)	0.25	0.18	0.05	0.79
ALT (IU/L)	0.12	0.52	0.15	0.42
γ-GTP (IU/L)	0.30	0.11	0.28	0.13
AFP (ng/mL)	0.38	0.04	0.11	0.57
DCP (mAU/mL)	0.57	0.001	0.12	0.52

P values were assessed by Spearman's rank correlation analysis. MnSOD: Manganese superoxide dismutase; TRX: Thioredoxin; HCC: Hepatocellular carcinoma; Plt: Platelet count; PT: Prothrombin time; Alb: Albumin; T-Bil: Total bilirubin; ALT: Alanine aminotransferase; γ-GTP: γ-glutamyl transpeptidase; AFP: α-fetoprotein; DCP: des-γ-carboxy prothrombin.

Diagnostic value of serum MnSOD and TRX levels for patients with hepatocellular carcinoma and hepatitis C virus infection

Serum AFP and DCP concentrations are established diagnostic markers for HCC. To evaluate the utility of MnSOD and TRX for the diagnosis of HCC, we measured AFP and DCP expression in addition to MnSOD and TRX expression. In an AUC-ROC analysis, AFP was the strongest diagnostic marker for HCC (AUC-ROC, 0.90). AUC-ROCs for MnSOD, TRX and DCP were 0.73, 0.77 and 0.77, respectively. Additional analyses showed that the accuracy of AFP (≥ 40 ng/mL) for diagnosis of HCC was higher than that of MnSOD (≥ 110 ng/mL) (Table 2), while the combination of AFP and MnSOD was a more accurate marker of HCC than either marker alone.

Association of serum MnSOD or TRX levels with laboratory data in the HCC group

Serum MnSOD levels for the 30 patients in the HCC group were positively correlated with serum AFP and DCP levels and were negatively correlated with serum Alb levels (Table 3). Serum MnSOD levels were also significantly higher in patients with two or more HCC tumors than in patients with a single HCC tumor [average ± SD (ng/mL), 125.4 ± 50.9 *vs* 87.4 ± 48.8, $P = 0.008$], although HCC tumor size was not associated with serum MnSOD levels. In addition, HCC patient serum MnSOD levels increased in parallel with the Child-Pugh stage, CLIP score and JIS score (Figure 2A-C). In contrast, serum TRX levels were only associated with platelet counts (Table 3). Serum TRX levels were not associated with HCC tumor number or size. Furthermore, there were no significant correlations between serum TRX levels for various scores (Figure 2D-F).

Overall survival rate based on serum MnSOD or TRX levels in the HCC group

In the HCC group, the overall patient survival rate was significantly lower ($P = 0.01$) in patients with MnSOD levels ≥ 110 ng/mL compared to patients with levels < 110 ng/mL (Figure 3A). In addition, the overall survival rate tended to be lower ($P = 0.05$) in patients with TRX levels < 80 ng/mL compared to those with levels ≥ 80 ng/mL (Figure 3B). Furthermore, among all HCC groups, patients who had both serum MnSOD levels ≥ 110

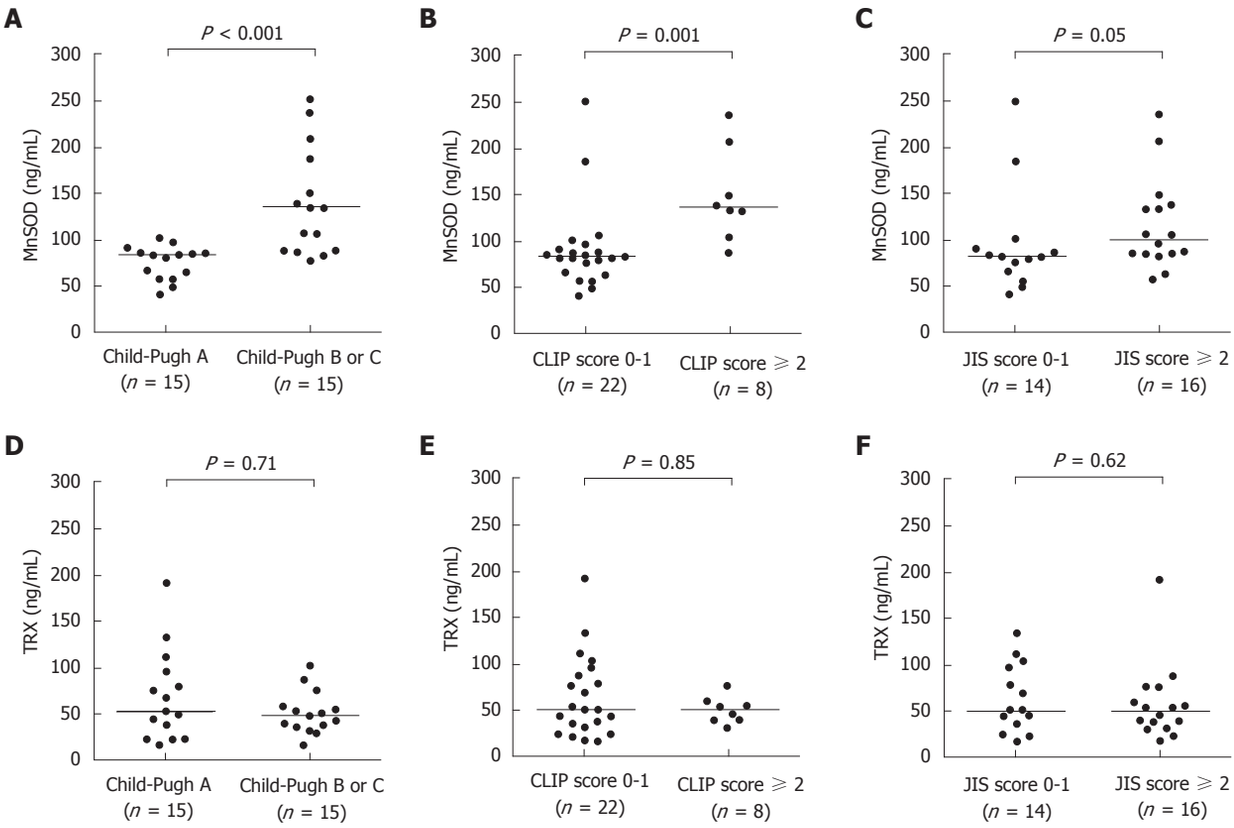

Figure 2 Clinical significance of serum manganese superoxide dismutase and thioredoxin levels in hepatocellular carcinoma. In the hepatocellular carcinoma (HCC) group, differences in serum manganese superoxide dismutase (MnSOD) and thioredoxin (TRX) levels were evaluated based on Child-Pugh stage, cancer of the liver italian program (CLIP) score and Japan integrated staging (JIS) score. A: Serum MnSOD levels were significantly higher in patients with Child-Pugh B or C compared to those with Child-Pugh A ($P < 0.001$); B: Serum MnSOD levels in patients with a CLIP score of 2 or greater were significantly higher compared to levels in patients with a CLIP score of 0 or 1 ($P = 0.001$); C: In addition, serum MnSOD levels tended to be higher in patients with a JIS score of 2 or greater compared to patients with a JIS score of 0 or 1 ($P = 0.05$); D-F: In contrast, serum TRX levels were not significantly different based on Child-Pugh stage, CLIP score or JIS score.

ng/mL and TRX levels < 80 ng/mL had a significantly poorer prognosis. Conversely, patients with a serum TRX level ⩾ 80 ng/mL had a favorable prognosis, regardless of their serum MnSOD level (Figure 3C).

In addition to serum MnSOD and TRX levels, other possible prognostic factors were also investigated in the HCC group. A univariate analysis (log-rank test) revealed that the survival rate was significantly different between patients with high and low levels of MnSOD, PT, Alb, AFP and DCP, but not other factors such as TRX (Table 4). A multivariate analysis using a Cox proportional hazard model and five markers (MnSOD, PT, Alb, AFP and DCP) selected based on the results of the univariate analysis revealed that MnSOD levels ⩾ 110 ng/mL and AFP levels ⩾ 40 ng/mL were independent risk factors that were associated with a poor patient prognosis (Table 5). In addition, similar results were obtained from a similar multivariate analysis using the same five factors and TRX, supporting the finding that TRX is not an independent risk factor associated with HCC prognosis. Furthermore, patient Child-Pugh stage, CLIP score and JIS score, which were calculated based on several factors including clinical symptoms and laboratory data, were also prognostic factors for patients with HCC (Table 4). A multivariate analysis using the three markers of MnSOD, Child-Pugh stage and CLIP score indicated that Child-Pugh stage was also a significant prognostic factor (risk ratio: 6.19, 95% confidential interval: 1.33-28.95, $P = 0.02$).

DISCUSSION

HCV infection is the most important known contributor to the etiology of HCC. An increasing incidence of HCC has been largely attributed to a rise in HCV infections in the general population during the last 50 to 60 years[26]. During HCV infection, ROS production increases and persists throughout the infection. In addition, ROS are thought to play a major role in the pathogenesis of chronic inflammatory changes in the liver, leading to increased hepatic fibrosis and decreased hepatic function. In this study, we have shown that both serum MnSOD and TRX levels are elevated in patients with HCV-related HCC, with no correlation between these two markers. In addition, serum MnSOD and TRX levels were a useful predictor of overall patient survival. Serum MnSOD and TRX levels are reported to be biomarkers of oxidative stress in several diseases, including liver disease[7,14,17,19,27-29]. There were a small number of enrolled patients in this study and other contributors to liver diseases such as chronic hepatitis B infection should be further evaluated. However, our

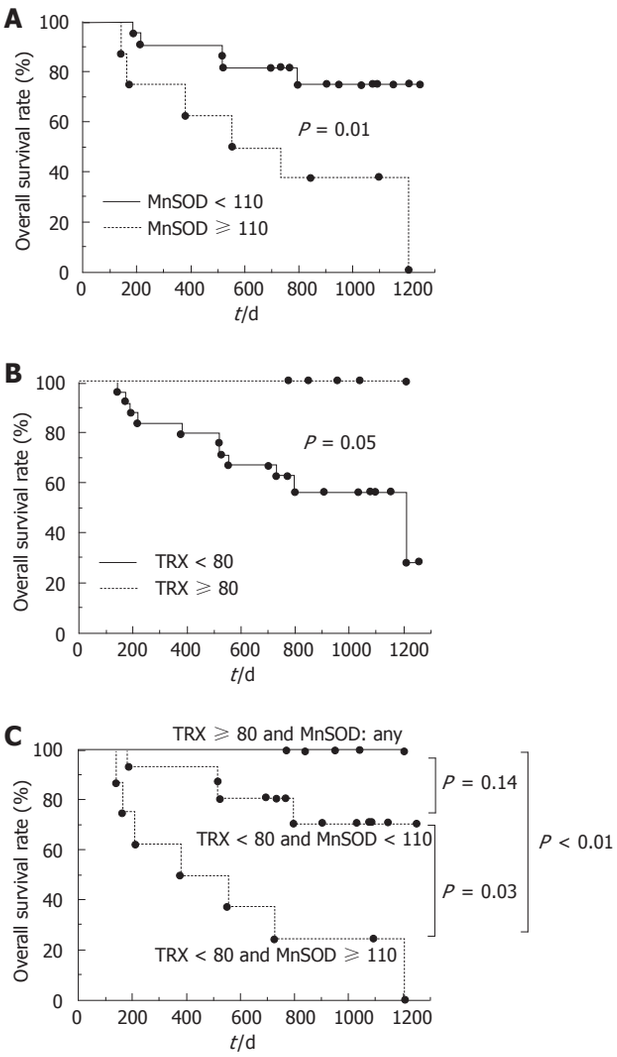

Figure 3 Overall hepatocellular carcinoma patient survival based on serum levels of manganese superoxide dismutase or thioredoxin. Overall survival was plotted using the Kaplan-Meier method after separation into two or three groups defined as follows: A: Manganese superoxide dismutase (MnSOD) < 110 ng/mL or ⩾ 110 ng/mL; B: Thioredoxin (TRX) < 80 ng/mL or ⩾ 80 ng/mL; TRX ⩾ 80 ng/mL, TRX < 80 ng/mL; C: MnSOD < 110 ng/mL, or TRX < 80 ng/mL and MnSOD ⩾ 110 ng/mL. The overall survival rate was lower in patients with MnSOD levels ⩾ 110 ng/mL (P = 0.01) (A). Also, cumulative patient survival rate tended to be lower in patients with TRX levels < 80 ng/mL (P = 0.05) (B). Among these groups, patients with serum TRX levels < 80 ng/mL and serum MnSOD levels ⩾ 110 ng/mL had the poorest prognosis (C).

Table 5 Multivariate analysis of prognostic factors in the hepatocellular carcinoma group

Factors	Risk ratio	95% CI	*P* value
MnSOD (⩾ 110 ng/mL)	4.12	1.22-13.88	0.02
AFP(⩾ 40 ng/mL)	6.75	1.70-26.85	< 0.01

95% CI: 95% confidence interval; MnSOD: Manganese superoxide dismutase; AFP: α-fetoprotein.

study has clearly demonstrated the clinical significance of these markers in patients with HCV-related HCC.

Serum MnSOD and TRX levels should both reflect hepatic oxidative stress. The results of the current study showed that both of these markers were increased in the HCC group relative to levels in the non-HCC group and the HV group (Figure 1A and B). However, there was no correlation between these two markers in the HCC group (Figure 1C). MnSOD is primarily localized to the mitochondrial matrix[3] and abnormal mitochondrial morphologies are frequently observed in CHC[8]. Therefore, MnSOD may be an indicator of mitochondrial disorders that are induced by oxidative stress. On the other hand, there are two TRX proteins, cytoplasmic TRX1 and mitochondrial TRX2[30]. TRX1 negatively regulates the apoptosis signal-regulating kinase 1 (ASK1)-c-Jun N-terminal kinase/P38 apoptotic pathway by binding to and inhibiting the kinase activity of ASK1, which plays an important role in ROS-induced cellular responses[31]. TRX2 is an essential regulator of mitochondrial ROS levels that has been associated with mitochondrial outer membrane permeability[32]. In the present study, we examined the serum levels of TRX1, but not TRX2, using a sandwich ELISA. Thus, the MnSOD and TRX proteins that were examined in this study have different origins in the mitochondria and cytoplasm, respectively, which could contribute to the lack of correlation between these two markers.

Several studies have shown that the HCV core protein directly inhibits the electron transport system and modulates apoptosis, transcription, and cell signaling[33]. Abdalla *et al*[34] reported that expression of not only the HCV core protein but also the HCV NS proteins increases ROS and further showed that the presence of these proteins can increase endogenous expression levels of antioxidant enzymes and prooxidants such as MnSOD. Several reports have shown that serum MnSOD levels in patients with HCV-related CLD[35-37] are associated with

various clinical findings, such as fibrosis and hepatic oxidative stress. However, the significance of serum MnSOD levels has not been fully examined in patients with HCC. We previously reported that serum MnSOD levels may be correlated with fibrosis in patients with NAFLD[7]. In addition, serum MnSOD levels decreased in patients with CHC after administration of an interferon-based treatment (data not shown). These results indicate that serum MnSOD levels are likely associated with hepatic fibrosis or oxidative stress in patients with CHC. In the present study, however, MnSOD levels were not associated with platelet counts, which is a simple predictor of hepatic fibrosis in this patient population[38]. Thus, advanced hepatic fibrosis or oxidative stress may be one reason why serum MnSOD levels have diagnostic and prognostic utility with HCC, but other mechanisms should also be considered.

The present study revealed that serum MnSOD levels were significantly higher in the HCC group than in the non-HCC group (Figure 1A). In the HCC group, serum MnSOD levels were negatively correlated with serum Alb and tended to negatively correlate with PT (Table 3); these results showed an association between MnSOD and Child-Pugh stage (Figure 2A). It is known that in humans, MnSOD activity is comparatively higher in the liver compared to other tissues[39]. In addition, although a previous immunohistochemical study showed that MnSOD expression was higher in both cancerous and non-cancerous liver tissues from patients with HCC, this positive immunoreactivity was strongly observed in non-cancerous liver tissues, especially in normal hepatocytes surrounding HCC, regenerative small hepatocytes in the tumor boundary, and mononuclear inflammatory cells in necroinflammatory lesions[40]. Furthermore, ROS are overproduced by Kupffer cells and inflammatory cells in liver disease[5,41]. In the present study, serum MnSOD levels were also positively correlated with the serum tumor markers AFP and DCP (Table 3) and with Child-Pugh stage and CLIP score (Figure 2). These results indicate that increased MnSOD expression reflects hepatocyte oxidative stress and correlates with decreased hepatic function, increased hepatic fibrosis and ROS production by inflammatory cells in liver cirrhosis. These features comprise the main background characteristics leading to HCC and may be associated with the indirect effects of liver cancer progression. These associations may also explain why serum MnSOD levels predicted the overall survival of patients with HCC.

It was previously reported that serum levels of TRX, which is a stress-induced protein, increase relative to the degree of hepatic fibrosis, and that high serum concentrations of TRX may indicate advanced hepatic fibrosis[19,20]. In contrast, it has also been reported that a higher degree of hepatic fibrosis is associated with lower platelet counts[38]. Therefore, the present study may present a conflict, since results indicated that serum TRX level was positively correlated with platelet count. A previous report showed that the survival rate following LPS plus GalN-induced hepatitis was much higher in transgenic mice overexpressing TRX than in wild-type mice, and that thioacetamide-induced hepatic fibrosis was suppressed in TRX transgenic mice compared to wild-type mice[42]. Although it is still unclear why TRX and platelet counts are positively correlated, we speculate that elevated serum TRX in patients with HCC and advanced hepatic fibrosis potentially improves overall survival by suppressing oxidative stress[43]. In addition, patients with HCC, low levels of TRX, and high levels of MnSOD, which may be indicative of excessive oxidative stress without TRX attenuation, have the poorest prognosis. This result supports the hypotheses presented above. In order to better assess these findings, future studies are needed that incorporate sequential observations of serum TRX and MnSOD levels over time in patients with chronic hepatitis, cirrhosis and HCC.

Serum MnSOD and TRX may be useful biomarkers for HCC diagnosis (Figure 1). AFP is also a diagnostic marker for HCC, and the present results indicate that AFP can be used to distinguish between patients with and without HCC (Table 2). However, AFP is not a sufficiently sensitive marker for identification of the majority of patients with small HCCs[44,45], and AFP testing is not currently included in the recommendations for HCC surveillance in the updated HCC guidelines published by the American Association for the Study of Liver Disease[46]. Therefore, clinicians and clinical researchers should consider using MnSOD and TRX as diagnostic biomarkers for early HCC or as additional markers in a HCC surveillance program using ultrasonography or AFP. In addition, it is highly important to know whether these markers decrease in response to HCC therapy and reductions in tumor burden. These markers also may have utility in patients on a transplant waiting list who are treated with neo-adjuvant therapy for tumor downstaging.

Our study demonstrated that elevated serum AFP level is indicative of a poor prognosis for patients with HCC (Table 4), as was previously reported[47]. The CLIP score, which is calculated based on four factors such as the AFP value, was also useful to predict the prognosis of HCC patients in this study as well as in a previous report[48]. Other markers such as the protein survivin have been reported as poor prognostic factors for HCC[49]. Similarly, MnSOD was an independent predictive factor for overall survival in the HCC group (Figure 3A, Table 5). Although TRX was not an independent predictor of overall survival in patients with HCC (Table 4), we speculate that a combination assay using both MnSOD and TRX could be used to predict overall patient survival. It will be important to conduct further prospective evaluations of each individual marker as well as a combination of these markers using a large number of patients.

In conclusion, serum MnSOD and TRX levels increased as HCV-related chronic liver disease progressed, especially among patients with HCC. Although there was no correlation between serum levels of MnSOD and TRX, higher serum MnSOD levels and lower TRX levels in patients with HCC trended towards an indication of poor

patient prognosis. These results suggest that serum Mn-SOD and TRX levels are not only a potential biomarker for HCV-related progressed liver disease, but may also serve as prognostic markers in HCC.

We thank Ms. Yuko Nakamura for technical assistance.

COMMENTS

Background

During hepatitis C virus (HCV) infection, production of reactive oxygen species (ROS) is persistently increased throughout HCV infection. ROS are thought to play an important role in the pathogenesis of chronic inflammatory changes in the liver, which may lead to the development of hepatic fibrosis, decreased hepatic function or hepatocellular carcinoma (HCC). However, there is little information currently available regarding serum oxidative stress markers in patients with HCV-related HCC.

Research frontiers

Cells are protected from oxidative stress by antioxidant enzymes such as superoxide dismutase (SOD) and by intracellular antioxidants such as thioredoxin (TRX). Serum manganese SOD (MnSOD) and TRX are thought to be biomarkers for various liver diseases, including HCV-related liver disease, but these possibilities have not been fully investigated. In this study, the authors demonstrated the clinical significance of serum levels of MnSOD and TRX in patients with HCV-related HCC.

Innovations and breakthroughs

Although there was no correlation between serum levels of MnSOD and TRX, serum levels of both markers increased as HCV-related chronic liver disease progressed, and in particular among patients with HCC. In addition, higher serum MnSOD levels and lower TRX levels tended to indicate a poor prognosis among patients with HCC.

Applications

Serum MnSOD and TRX levels are not only potential biomarkers for progression of HCV-related liver disease, but they may also serve as prognostic markers for patients with HCC. Therefore, clinicians should consider using serum levels of MnSOD and TRX as diagnostic biomarkers for early HCC or as additional markers in HCC surveillance programs. In addition, it will be important to know whether these markers change after therapy for liver disease, including HCC.

Peer review

Oxidative stress is closely associated with carcinogenesis. If oxidative stress markers could be useful in predicting clinical outcome in chronic hepatitis C and HCV-related HCC, they would provide us with a practical and informative tool. However, there are some limitations of this investigation, including a relatively small number of patients studied. Thus, the overall assessment is "good".

Abstract

AIM: To identify the characteristic clinical, laboratory and radiological findings and response to treatment in patients with fascioliasis.

METHODS: Patients who were diagnosed with Fasciola hepatica infection were included in this prospective study. Initial clinical, laboratory and radiological findings were recorded. All patients were followed until a complete response was achieved or for 6 mo after treatment discontinuation.

RESULTS: Fasciola hepatica infection was diagnosed in 30 patients (24 females; mean age: 42.6 years) between January 2008 and February 2011. Twenty-two (73%) patients had hepatic phase fascioliasis, 5 patients had biliary phase, and 3 patients had biliary phase associated with acute pancreatitis. Of the 8 patients with biliary phase fascioliasis, 2 patients displayed features that overlapped with both hepatic and biliary phase. Abdominal pain and right upper abdominal tenderness were the most prominent signs and symptoms in all patients. Eosinophilia was the most prominent laboratory abnormality in both patients with hepatic and biliary phase (100% and 50%, respectively). Multiple nodular lesions like micro-abscesses on abdominal computerized tomography were the main radiological findings in patients with hepatic phase. Small linear filling defects in the distal choledochus were the main endoscopic retrograde cholangiopancreatography (ERCP) findings in patients with biliary phase. Patients with hepatic phase were treated with triclabendazole alone, and patients with biliary phase were treated with triclabendazole and had live Fasciola hepatica extracted from the bile ducts during ERCP.

CONCLUSION: Fasciola hepatica infection should be considered in the differential diagnosis of patients with hepatic or biliary disease and/or acute pancreatitis associated with eosinophilia.

Key words: Fasciola hepatica; Liver abscesses; Cholangitis; Pancreatitis; Triclabendazole

INTRODUCTION

Fascioliasis is an infection caused by a trematode of the liver, Fasciola hepatica, that particularly affects sheep, goats and cattle. The flukes are leak-like, flat worms, measuring 2-4 cm[1]. The number of reports of humans infected with Fasciola hepatica has increased significantly since 1980, and several geographical areas have been described as endemic for the disease in humans, with preva-

lence and incidence ranging from low to very high[2,3]. In humans, the infection begins with the ingestion of watercress or contaminated water containing encysted larva. The larva excyst in the stomach, penetrate the duodenal wall, escape into the peritoneal cavity, and then pass through the liver capsule to enter the biliary tree[1]. Human fascioliasis has two phases. The hepatic phase of the disease begins one to three months after ingestion of metacercariae, with penetration and migration through the liver parenchyma toward the biliary ducts[1,4,5]. Common signs and symptoms of the hepatic phase are abdominal pain, fever, eosinophilia, and abnormal liver function tests[1,4,6-8]. The biliary phase of the disease usually presents with intermittent right upper quadrant pain with or without cholangitis or cholestasis[9-11].

In non-endemic areas, diagnosis of fascioliasis can be difficult and usually is delayed because the disease is not often encountered and the symptoms may be confused with other hepatic or biliary disorders. Diagnosis of Fasciola hepatica infection has traditionally relied on detecting the presence of eggs in fecal samples, but this method is unreliable and complex[1,4]. Among human cases in non-endemic areas, low egg outputs, e.g., 1-2 eggs per g of feces (epg) and 1-4 epg were being considered rare. These egg outputs are much lower than those found among humans in endemic areas[3]. Computerized tomographic (CT) findings in patients with hepatic phase and ultrasonographic findings in patients with biliary phase are used for the diagnosis of fascioliasis[5,6]. Confirmation of the diagnosis is necessary and should be based on serological findings and parasitic tests[12]. Triclabendazole and bithionol are effective agents for the treatment of fascioliasis[8].

The aim of this prospective study was to identify the characteristic clinical, laboratory and tomographic findings and response to treatment during follow-up in patients with fascioliasis.

MATERIALS AND METHODS

Patients who were admitted to our clinic and were diagnosed with Fasciola hepatica infection between January 2008 and February 2011 were prospectively enrolled in this study. All patients received an initial complete clinical exam, laboratory tests (including complete blood counts and routine biochemical analyses), and abdominal CT. All of the CT scans were obtained using a 4-channel multislice CT scanner (Sensation 4; Siemens Medical Solutions, Erlargen, Germany). A specific indirect hemagglutination assay (IHA) using purified adult Fasciola hepatica F1 antigen (Laboratoires Fumouze Diagnostic, Levallois Perret, France; cut-off 1/320) was used for serological diagnosis of fascioliasis. The diagnosis of Fasciola hepatica infection with hepatic phase was based on: (1) the presence of characteristic findings on the abdominal CT examination, as previously described[5-8]; (2) exclusion of all other known diseases that cause hepatic lesions on tomographic examination; and (3) a positive specific IHA for Fasciola hepatica; and/or (d) the presence of Fasciola hepatica eggs in the fecal examination. The diagnosis of Fasciola hepatica infection with biliary phase was based on the extraction of live Fasciola hepatica during endoscopic retrograde cholangiopancreatography (ERCP). In all patients, clinical and laboratory response to treatment was assessed monthly. In patients with hepatic phase fascioliasis, radiological improvement was assessed at a 3-mo interval. All patients were followed until complete clinical and laboratory response or until 6 mo after treatment discontinuation.

This work has been carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association. This prospective study was approved by Institutional Review Board, and all patients provided informed written consent for participation.

RESULTS

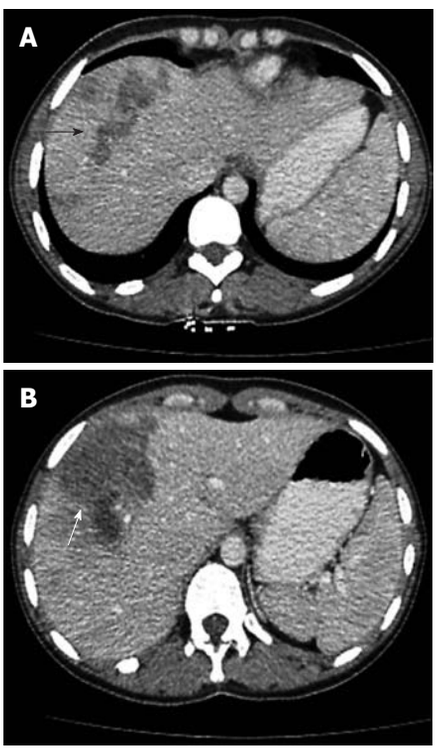
Fasciola hepatica infection was detected in 30 patients (24 females, mean age: 42.6 years, range: 19-79 years). In 22 (73%) patients, the diagnosis of fascioliasis was based on radiological findings on abdominal CT examination and positive IHA test (≥ 1/620). We did not perform ERCP in these patients because they did not have clinical or laboratory findings compatible with extrahepatic biliary obstruction; therefore, these patients were accepted as hepatic phase fascioliasis. In the remaining 8 (27%) patients, the diagnosis of fascioliasis was confirmed by extraction of live, mobile Fasciola hepatica from extrahepatic biliary ducts during ERCP; therefore, these patients were accepted as biliary phase fascioliasis. Microscopic examination of fecal specimens for Fasciola hepatica eggs revealed a positive result for only 2 (7%) of the 30 patients, one with biliary and one with hepatic phase.

Patients with hepatic phase fascioliasis

The mean antibody titer in the IHA was 1/2720 ± 1/549 (range: 1/640-1/5120) in the 22 patients with hepatic phase fascioliasis. Three patients were sisters and were admitted to the hospital on the same day. All patients were admitted at least five (mean: 7 ± 2) d before diagnosis. The mean duration of symptoms was 25 ± 36.6 (range: 3-144) wk. Abdominal pain was reported by all patients (100%), fever in 13 (59%), nausea in 3 (14%), chills in 4 (18%), weight loss in 4 (18%), pruritus and urticaria in 1 (5%), and recurrent oral aft and asthenia in 1 (5%) patient. On physical examination, there was mild right upper quadrant tenderness in 15 (68%) patients and hepatomegaly in 6 (27%) patients. Although 13 patients had a history of intermittent fever, only 3 (14%) patients had fever > 38 ℃ (2 of them were sisters), during clinical follow-up.

Table 1 shows the laboratory results for patients before treatment. Anemia was present in 6 (27%) patients, leukocytosis in 11 (50%), eosinophilia in 22 (100%) and elevations in the erythrocyte sedimentation rate (ESR) in 18 (82%) patients, alanine aminotransferase (ALT) in 6 (27%), aspartate aminotransferase (AST) in 2 (9%), alkaline phosphatase (ALP) in 13 (59%) , γ glutamyl transferase (GGT)

Figure 1 A 19-year-old female patient presented with right upper abdominal pain and fever lasting 3 wk. Abdominal computerized tomographic examination showed enlargement of the liver and extensive micro-abscesses (arrows).



Figures 2 A 30-year-old female patient presented with right upper abdominal pain lasting 8 wk. A: Tubular branching lesions in the right lobe (arrow); B: Abdominal computerized tomographic examination showed a sub-capsular low density area surrounded by a rim of parenchyma (arrow).

in 13 (59%), and total bilirubin in 1 (5%) patient. Platelet counts were normal in all patients.

On abdominal CT examination, the main abnormalities were multiple nodular lesions like micro-abscesses (Figure 1) in 21 (95%) patients, tubular branching lesions (Figure 2A) in 11 (50%), subcapsular low density areas surrounded by a rim of parenchyma (Figure 2B) in 7 (32%), solitary nodular lesions with hazy margins (Figure 3) in 5 (23%), lymph node enlargement in the portal area in 4 (18%), and localized perihepatic fluid accumulation in 2 (9%) patients.

After diagnosis of fascioliasis, triclabendazole was administered at a dose of 10-12 mg/kg for 1 d to all patients. We did not observe any side-effects related to triclabendazole administration. None of the patients with hepatic phase was administered antibiotics. Three months after treatment, we observed complete clinical and laboratory recovery in 18 (82%) patients and complete improvement on abdominal CT examination in 12 (55%) patients. Six months after treatment, there was complete clinical and laboratory recovery in all patients, but abdominal CT examination showed complete improvement in only 16 (73%) patients and residual hypo-dense lesions (Figure 4) in 6 (27%) patients.

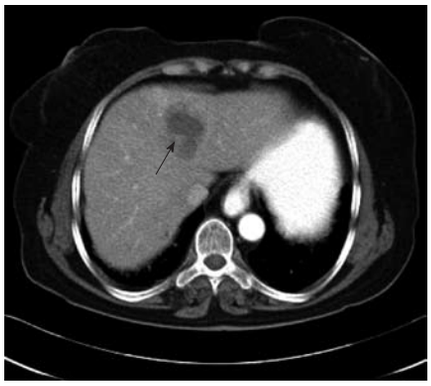


Figure 3 A 70-year-old female patient presented with right upper abdominal pain lasting 16 wk. Abdominal computerized tomographic examination showed low density masses with hazy margins located to medial segment of the left lobe (arrow).

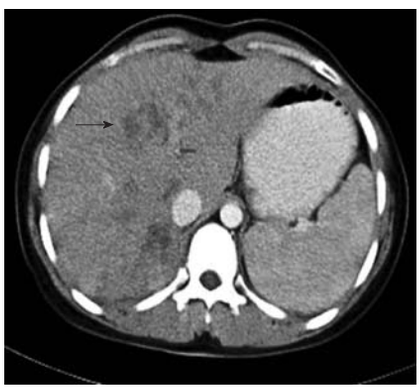

Figure 4 In the patient whose pre-treatment computerized tomographic image is shown in Figure 1, abdominal computerized tomographic examination showed residual lesions (arrow) and minimally enlarged spleen 6 mo after treatment with triclabendazole.

Patients with biliary phase fascioliasis

The mean duration of symptoms was 63.5 ± 80.6 (range: 1-208) wk in the 8 patients with biliary phase fascioliasis. One female patient underwent a cholecystectomy 6 mo ago after developing acute cholecystitis of unknown etiology. Abdominal pain was reported by all patients, fever in 2 (25%), nausea in 3 (38%), and weight loss in 1 (13%) patient. On physical examination, there was right upper quadrant tenderness in 5 (63%) and scleral icterus in 1 (13%) patient.

Table 1 Demographic features and laboratory results for patients with hepatic phase and biliary phase fascioliasis

Variables	Hepatic phase (mean ± SD)	Biliary phase (mean ± SD)
Age (yr)	40 (19-79)[1]	41 (29-49)[1]
Gender (M/F)	(5/17)	(1/7)
Hb (g/dL)	12.5 ± 1.4	12.7 ± 1.57
WBC (n/mm^3)	11862 ± 2829	8765 ± 1307
Eosinophil (% of total WBC count)	34.2 ± 16.2	14 ± 13.5
Plt (n/mm^3)	290 ± 62	273 ± 70
ESR (mm/h)	48 ± 26	17 ± 12
ALT (U/dL)	44 ± 49	220 ± 217
AST (U/dL)	26 ± 9	260 ± 357
ALP (U/dL)	157 ± 65	166 ± 85
GGT (U/dL)	64 ± 40	226 ± 128
Total bilirubin (U/dL)	0.57 ± 0.32	1.65 ± 2.02

[1]Age is represented using the median and range. Hb: Hemoglobin; WBC: White blood cell; Plt: Platelet; ESR: Erythrocyte sedimentation rate; ALT: Alanine aminotransferase (range, 10-40 U/L); AST: Aspartate aminotransferase (range, 10-35 U/L); GGT: γ glutamyl transferase (range, 9-64 U/L); ALP: Alkaline phosphatase (range, 40-150 U/L); Total bilirubin: range, 0.2-1.2 mg/dL; M: Male; F: Female.

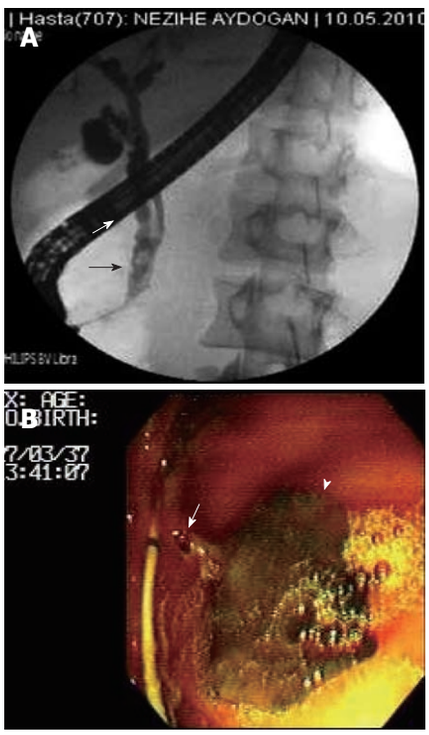

Figure 5 Live and mobil Fasciola hepatica removed from the choledochus by balloon catheter during endoscopic retrograde cholangiopancreatography. A: A 35-year-old female patient presented with acute pancreatitis associated with elevated liver enzymes. Endoscopic retrograde cholangiopancreatography image showed a radiolucent, roughly crescent-shaped shadow in the common bile duct (arrows); B: A 49-year-old female patient presented with acute cholangitis associated with eosinophilia. Arrow: Head of Fasciola hepatica; Arrowhead: Body of Fasciola hepatica.

The laboratory findings before treatment (Table 1) showed that mild anemia was present in 2 (25%) patients, eosinophilia in 4 (50%), and elevations in the ESR in 4 (50%), ALT in 7 (87%), AST in 6 (75%), ALP in 4 (50%), GGT in 7 (87%), and total bilirubin in 3 (38%) patients. Total white blood cell (WBC) and platelet counts were normal in all patients. One patient had a normal initial eosinophil count but elevated eosinophil count after the ERCP procedure (2.7% of total WBC before ERCP *vs* 23% after ERCP).

Abdominal CT examination showed no abnormalities in 6 (75%) and subcapsular low density areas surrounded by a rim of parenchyma in 2 (25%) patients. Although these 2 patients had clinical findings consistent with biliary phase fasciolisis, they had radiological findings consistent with hepatic phase fascioliasis. One of the patients was a 46-year-old woman who had cholangitis with a normal eosinophil count and live Fasciola hepatica extracted from the extrahepatic bile ducts. The other patient was a 29-year-old man who had acute pancreatitis, cholangitis, and eosinophilia (25% of total WBC); this patient also was one of the 3 patients who had biliary phase fascioliasis associated with acute pancreatitis.

Three (38%) patients (two females) with biliary phase fascioliasis also had acute pancreatitis. Two of these patients had elevated eosinophil counts, and all 3 patients had elevated liver enzymes and amylase (> 1275 U/dL). They also had acute edematous pancreatitis and were treated by extraction of live Fasciola hepatica by balloon during ERCP and conservative management.

ERCP was performed in all patients because there were clinical and laboratory findings of extrahepatic biliary obstruction. Before ERCP, we considered the diagnosis of fascioliasis in 4 (50%) patients with eosinophilia. Cholangiography showed slight extrahepatic and intrahepatic biliary dilatation in 1 (13%) patient with acute pancreatitis. In the remaining 7 (87%) patients, the intrahepatic and extrahepatic biliary systems were within normal diameter. ERCP demonstrated a radiolucent, roughly crescent-shaped shadow in the common bile duct in all patients (Figure 5A). After standard sphincterotomy, live Fasciola hepatica (3-5 Fasciola hepatica per patient) were removed using a balloon catheter from the extrahepatic bile ducts (Figure 5B).

We routinely administered 1 *g* ceftriaxone at least one hour before ERCP to prevent post-ERCP cholangitis. We did not administer antibiotics to any patient after ERCP. Triclabendazole was administered at a dose of 10-12 mg/kg for 1 d to all patients. Complete clinical and laboratory recovery was observed in all patients 3 mo after treatment. There was complete resolution on abdominal CT examination in the 2 patients who had initial lesions.

DISCUSSION

Fascioliasis is an emerging disease in humans. The epidemiological and transmission characteristics of fascioliasis suggest that the disease has a patchy distribution, with foci related to the local distribution of the intermediate snail host population in freshwater bodies as well as climatic conditions[2,3]. Epidemiological studies on the incidence of fascioliasis in our region have not been reported previously, but the results from this prospective single-center study suggest that Fasciola hepatica infection is not very rare in our region. Our hospital is a tertiary care cen-

ter in the southeast of Turkey that serves approximately 3 million people. All of the patients in this study resided in rural areas and had a history of consuming watercress grown in areas where sheep were raised. Twenty-four (80%) patients were female, and all of them were homeworking, suggesting that the females had more contact with watercress than the men.

Fascioliasis has a hepatic phase and a biliary phase, each displaying different clinical signs and symptoms. The acute stage of fascioliasis (hepatic phase) begins with the slow migration of Fasciola hepatica through the liver parenchyma; the mature flukes digest and consume hepatocytes, dig tunnels and caves, and reside in the liver for months[1,7,13]. The hepatic phase is characterized by fever with chills, upper abdominal pain, hepatomegaly, mild hepatitis, weight loss and prominent eosinophilia[6-8,14]. Reports suggest that the clinical presentation of hepatic phase fascioliasis is similar to that of liver abscesses of other etiology[1,8]. In our patients with hepatic phase fascioliasis, the common clinical signs and symptoms were right upper abdominal pain, intermittent fever, right upper quadrant tenderness and hepatomegaly. Based on our clinical experience with pyogenic liver abscesses[15], patients with Fasciola hepatica infection had a longer duration of symptoms (25 ± 36.6 wk *vs* 5.7 ± 1.6 wk), a healthier condition, and less upper abdominal tenderness than patients with pyogenic liver abscesses. Although 13 (59%) of 22 patients with hepatic phase fascioliasis had a history of intermittent fever, we recorded fever in only 3 patients. These findings suggest that fever in hepatic phase fascioliasis is not a prominent finding.

In the biliary phase of the disease, patients often present with biliary colic, epigastric pain, jaundice and abdominal tenderness due to the obstruction of the bile ducts by adult worms and the resultant inflammatory response. In this stage, the main laboratory findings are cholestasis including predominantly elevated serum ALP, GGT and total bilirubin[9-11]. Adult flukes in the extrahepatic bile ducts are visualized as a filling defect on cholangiogram[1,6,9,10]. Because of the chronic inflammation, the thickened walls of the extrahepatic ducts and gallbladder are visible on abdominal CT examination[1,5,6]. Although our patients with biliary phase fascioliasis had clinical signs and symptoms of biliary obstruction, we did not find the typical cholestatic biochemical abnormalities in these patients. We also found no specific abnormalities on abdominal CT examination in our patients with biliary phase except for slight dilatation of intrahepatic and extrahepatic bile ducts in 1 patient and subcapsular low density areas surrounded by a rim of parenchyma in 2 patients. The absence of bile duct wall thickness on CT examination and the absence of biochemical findings indicative of cholestasis in our patients may reflect intermittent rather than chronic biliary obstruction or our patients may have had early stage biliary duct involvement. The 2 patients with parenchymal lesions probably had overlapping hepatic and biliary phase fascioliasis. The most specific cholangiographic finding in our patients with biliary phase fascioliasis was a radiolucent, roughly crescent-shaped shadow in the extrahepatic bile ducts without dilatation.

Major causes of acute pancreatitis include alcohol ingestion and gallstones[16-18]. A small number of patients who have Fasciola hepatica infection complicated with acute pancreatitis have been reported. The pathogenesis of acute pancreatitis secondary to fascioliasis is unknown. Intermittent biliary obstruction and cholangitis caused by adult Fasciola hepatica may be the principle mechanism involved in the development of acute pancreatitis[19-21]. In our case series, 3 (38%) of 8 patients (2 with eosinophilia) with biliary phase fascioliasis also had acute edematous pancreatitis. One of the 3 patients, had both hepatic and biliary phase fascioliasis. Although our number of cases is small, we suggest that Fasciola hepatica infection should be considered during differential diagnosis in patients with acute pancreatitis associated with cholangitis and eosinophilia.

Diagnosis of fascioliasis may be delayed because of the wide spectrum of the differential diagnosis and the low incidence of Fasciola hepatica infection[3]. The abnormal laboratory and radiological findings in Fasciola hepatic infection may represent viral hepatitis, liver abscess, malignancy, cholecystitis, sclerosant cholangitis, AIDS-related cholangitis, ruptured hydatic cyst, and infection with parasites such as ascariasis and clonorchiasis[1,5,8]. The specificity of the indirect hemagglutination test (*IHA*) using purified adult Fasciola hepatica antigen F1 is 96.9% for serological diagnosis of Fasciola hepatica infection[12]. Diagnosis is confirmed only by demonstrating live parasites or eggs in the bile or feces[1,5,8]. The disease cannot be ruled out by a negative stool examination[3,5,8]. A high index of suspicion and specific radiological findings are very helpful in the diagnosis. We suspected of the possibility of fascioliasis in all patients with hepatic phase because of the presence of eosinophilia, characteristic abdominal CT findings, and typical clinical sign and symptoms. We found eggs in stool samples in 1 of 22 patients with hepatic phase fascioliasis and 1 of 8 patients with biliary phase fascioliasis. Diagnosis in patients with hepatic phase was confirmed by the clinical, laboratory and radiological responses to triclabendazole treatment and the high titer in the IHA. Diagnosis in patients with biliary phase fascioliasis was confirmed by extraction of live Fasciola hepatica form bile ducts. We suggest that stool examination for eggs is not a reliable method and that both serological testing and extraction of live parasites form bile ducts are very reliable methods for the diagnosis of fascioliasis.

Treatment of human fascioliasis has been difficult for a long time. Today, triclabendazole is the drug of choice for its effectiveness against both adult and immature worms[7,13,21]. Its anti-parasitic effect is derived from the inhibition by an active sulfoxide metabolite of the synthesis of the tegumental ultra-structure of Fasciola hepatica[22]. Triclabendazole at a dose of 10 mg/kg body weight (single or split postprandial dose) reportedly is effective in about 80%-90% of patients and is well tolerated. The most common drug-related side-effects are nausea, vomiting and abdominal pain[23]. All of our patients with hepatic phase were treated with triclabendazole alone, and those patients with biliary phase were treated with endoscopic

sphincterotomy, extraction of live parasite from bile ducts, and administration of triclabendazole. We observed that triclabendazole improved both clinical and laboratory findings in a few weeks; radiological improvement, however, required a longer period.

In conclusion, in addition to classically defined hepatic phase and biliary phase fascioliasis, some cases may have overlap of these two phases with or without acute pancreatitis. In cases of right abdominal pain, elevated eosinophil count, and multiple micro-abscesses and/or tunnel-like hypo-dense lesions on abdominal CT examination, hepatic phase fascioliasis should be considered, and a serological test for Fasciola hepatica should be used for diagnosis. In cases of biliary colic and/or acute pancreatitis associated with eosinophilia, we suggest that biliary phase fascioliasis should be considered, and ERCP should be used for both diagnosis and treatment.

COMMENTS

Background

In non-endemic areas, diagnosis of fascioliasis is difficult and usually is delayed because the disease is relatively rare and the symptoms may be confused with other hepatic or biliary disorders. Confirmation of the diagnosis is necessary and patients should be followed for response to treatment.

Research frontiers

Fascioliasis has a hepatic phase and a biliary phase, each displaying different clinical signs and symptoms. In addition to classically defined hepatic phase and biliary phase fascioliasis, some cases may have overlap of these two phases with or without acute pancreatitis.

Innovations and breakthroughs

Fascioliasis may have different clinical presentations. In cases of abdominal pain and elevated eosinophil count, fascioliasis should be considered in differential diagnosis. Serological tests and abdominal computerized tomographic (CT) examination are the methods of choice for diagnosis. But, fecal examination for Fasciola hepatica eggs is not a reliable diagnostic method. It may take a long time for complete clinical and radiological improvement after triclabendazole administration.

Applications

Fasciola hepatica infection should be considered in the differential diagnosis of patients with hepatic or biliary disease and/or acute pancreatitis associated with eosinophilia.

Terminology

Fascioliasis is an infection caused by a trematode of the liver. Fasciola hepatica, particularly affects sheep, goats and cattle. The flukes are leak-like, flat worms, measuring 2-4 cm. In humans, the infection begins with the ingestion of watercress or contaminated water containing encysted larva.

Peer review

The authors investigated the characteristic clinical, laboratory, and tomographic findings and response to treatment during follow-up in patients with fascioliasis. They revealed that fascioliasis has different clinical presentations and in cases of right abdominal pain, elevated eosinophil count, and multiple micro-abscesses and/or tunnel-like hypo-dense lesions on abdominal CT examination, the diagnosis of hepatic phase fascioliasis should be considered, and a serological test for Fasciola hepatica should be used for diagnosis.

Abstract

AIM: To investigate the association between prognosis of rectal cancer treated with chemoradiotherapy (CRT) and expression of sensitive-to-apoptosis (SAG), B-cell lymphoma-extra large (Bcl-X_L) and Bcl-2 homologous antagonist/killer (Bak).

METHODS: Real-time quantitative polymerase chain reaction was used to determine the expression of proteins of interest, namely SAG, Bcl-X_L, Bak and β-actin, in rectal carcinoma patients who had a follow-up period of 3 years after CRT. Biopsy specimens were excised from the rectal tumor preceding CRT.

RESULTS: SAG, Bcl-X_L and Bak proteins showed significant correlations with each other. In multivariate analysis, patients with high *vs* low SAG expression showed a statistically significant difference in 2-year survival rates: 56% *vs* 73%, respectively (P = 0.056). On the other hand, there were no significant correlations between the expression levels of all three genes and metastatic rates or tumor responses to CRT. Mean overall survival in the patients with elevated SAG expression was 27.1 mo ± 3.9 mo [95% confidence interval (CI): 19.3-34.9], and in patients with reduced expression, it was 32.1 mo ± 2.5 mo (95% CI: 27.3-36.9). The corresponding values for Bcl-X_L were 28.0 mo ± 4.1 mo (95% CI: 19.9-36.1) and 31.7 mo ± 2.9 mo (95% CI: 26.0-37.5), and those for Bak were 29.8 mo ± 3.7 mo (95% CI: 22.5-37.2) and 30.6 mo ± 2.4 mo (95% CI: 25.5-35.0), respectively.

CONCLUSION: Two-year survival rates significantly correlated with low SAG expression, and SAG may be a candidate gene for good prognosis, independent of therapeutic response of different individuals.

INTRODUCTION

Colorectal cancer is one of the most common cancers worldwide, and 30% of patients experience local recurrence, thus posing a serious problem in treatment[1,2]. Currently, preoperative radiotherapy alone or in combination with chemotherapy is widely accepted to improve local control and overall survival.

The most frequently chosen treatment methods are either short-course irradiation (25 Gy in five fractions) followed by surgery after 1 wk, or conventional fractionated chemoradiotherapy (CRT) with delayed surgery[3]. Multidrug- and/or radiation resistance is one of the main causes of treatment failure in rectal carcinoma, as in other types of cancer. Predictors of treatment response are highly valuable, and they help to reduce the occurrence of undesirable treatment side effects, improve efficacy, and reduce costs, especially in long treatment schedules. Therefore, it is very important to identify those patients who will not show a good response to CRT. The success of CRT is strongly dependent on the molecular and cellular characteristics of the cells, therefore, identification of candidate molecular markers with significant prognostic power to estimate the response to CRT is crucial. Despite accumulation of data on prognostic markers, reliable markers for satisfactory clinical outcomes remain limited in number.

Sensitive-to-apoptosis gene (SAG)/regulator of cullins (ROC) 2/RING box protein (Rbx) 2/Hrt2 is a recently identified component of Skp/Cullin/F-box containing complex (SCF) E3 ubiquitin ligase, which controls cell-cycle progression by promoting ubiquitination and degradation of cell-cycle inhibitors. It has also been reported that SAG protects cells from apoptosis induced by redox agents such as hydroxyl radicals and radiation. The prognostic value of apoptotic activity in different cancer types has been previously described[4-7]. SAG overexpression has been shown in 60% of primary colon carcinomas; furthermore, significant correlation between SAG overexpression and poor survival has been demonstrated in non-small cell lung carcinoma[8,9]. Thus, it is proposed that SAG may regulate carcinogenesis *via* modulating both cell proliferation and apoptosis.

Ionizing radiation causes DNA damage that can lead cell to apoptosis and thus eradication of cancer cells. Antiapoptotic proteins such as SAG may have a major impact on the progress of cancer cell formation and proliferation. The present study investigated SAG expression as a potential molecular marker of ionizing radiation effect in rectal cancer. Two members of the Bcl-2 family, B-cell lymphoma-extra large (Bcl-Xl) and Bcl-2 homologous antagonist/killer (Bak), which are suggested as the most probable candidate biomarkers, were also analyzed. Our results indicate that SAG expression is a useful marker for early prognosis, regardless of local response to CRT, and that targeting SAG may have a potential role in the treatment of rectal cancer.

MATERIALS AND METHODS

Patients and tissue collection

This prospective study included 31 patients referred to the Kartal Education and Research Hospital with a diagnosis of stage Ⅱ and Ⅲ rectal cancer, according to the conventional tumor, node and metastases (TNM) classification[10]. The appropriate ethics committees related to the institution approved the study and all patients provided written informed consent before undergoing diagnostic colon biopsy. Prior to the start of treatment, all patients underwent examinations, including complete blood counts, liver and renal function tests, and tumor markers. Additionally, lung X-rays were evaluated before the start of treatment. Abdominal-pelvic magnetic resonance imaging or computed tomography was used for clinical staging and supplemented with transrectal ultrasound when needed. Biopsy specimens from the tumor and adjacent normal rectal tissues were obtained during colonoscopy. Freshly removed specimens were immediately immersed in RNAlater solution (Qiagen, Germany) and stored at -20 ℃ for RNA extraction.

Therapy

All patients received preoperative CRT. Patients were irradiated using the four-box-field technique and high-energy photon radiotherapy beams (15 mV), with a daily exposure of 1.8-2 Gy for five consecutive days. A cumulative dose of 45-50 Gy was administered during 5 wk and an additional 5.4-Gy boost was administered in three fractions. A short infusion of fluorouracil (320-400 mg/m^2) and of calcium folinate (20 mg/m^2) was administered on the first and last weeks, concomitantly[11,12].

Patients who were histopathologically diagnosed with rectal cancer underwent CRT prior to surgery. After a 4-6-wk interval, the patients underwent surgery. Patients were staged according to the TNM classification system[10], based on routine histopathological reports following surgery.

Real-time polymerase chain reaction

SAG, Bcl-Xl and Bak mRNA expression levels in tumor tissues and adjacent normal tissues were quantified by real-time polymerase chain reaction (PCR) analysis. Total RNA was extracted from RNAlater-conserved tissues using the RNeasy Plus Mini Kit (Qiagen) according to the manufacturer's guidelines. RNA samples were treated with DNase I (MBI Fermentas, Burlington, Canada) to

Clinical features of the 31 patients who received preoperative chemoradiotherapy and a summary of the relationship between protein expression level and patient survival after 1, 2 and 3 years of follow-up. SAG: Sensitive-to-apoptosis; CRT: Chemoradiotherapy.

remove possible genomic DNA contamination. RNA was quantified by measuring A_{260} using a conventional spectrophotometer. cDNA was synthesized from RNA using the 1st Strand cDNA Synthesis Kit for RT-PCR according to the manufacturer's instructions (Roche Applied Science, Mannheim, Germany). Following synthesis, 5 μg of cDNA was amplified using the appropriate primers. SAG expression was analyzed using following primers: forward (5'-CGGGATCCATGGCCGACGTGGAAG-3') and reverse (5'-CGAAGCTTTCATTTGCCGATTCTTTG-GAC-3'). Expression of two other apoptotic pathway genes (Bcl-X_L and Bak) was analyzed using the following primers: Bcl-X_L forward (5'-CCAGAAGGGACT-GAATCG-3') and Bcl-X_L reverse (5'-CCTTGTCTAC-GCTTTCCAC-3'); Bak forward (5'-GACCCAGAGA-TGGTCACCTT-3') and Bak reverse (5'-TCATAGC-GTCGGTTGATGT-3'). β-actin gene expression was used in parallel reactions as an internal PCR control. The β-actin primers were as follows: β-actin forward (5'-CT-GTGCTGTCCCTGTATGCC-3') and β-actin reverse (5' -GTGGTGGTGAAGCTGTAGCC-3'). Amplification products were 341, 361, 103 and 203 bp, respectively. Real-time PCR was performed using a Light-Cycler 480 system (Roche) and amplification conditions were set according to the instructions supplied with the Light Cycler FastStart DNA Master SYBR Green kit (Roche). The annealing temperature for amplifications was 56 ℃ for β-actin, 50 ℃ for Bcl-X_L and 60 ℃ for SAG and Bak proteins.

Statistical analysis

Multivariate analysis was performed using the logistic regression test. $P < 0.05$ was considered statistically significant. The relationship between protein regulations and disease-free survival up to 3 years was assessed by a log-rank comparison of Kaplan-Meier survival curves. All statistical analyses were conducted using SPSS 13 statistical software (SPSS, Chicago, IL, United States).

RESULTS

The study included 31 patients (17 males and 14 females) diagnosed with locally advanced rectal cancer. RNA was extracted from both normal and tumor tissues. Mean age of the patients was 59.9 years (range: 35-85 years). Survival, according to patient sex and age, was not significantly different (Table 1). Median follow-up was 3 years. In all, 8 of the 31 patients (34.8%) developed distant metastases. Table 1 summarizes the patients' 1-, 2- and 3-year survival rates, the corresponding data for some known prognostic factors, and the levels of SAG, Bcl-X_L and Bak protein expression.

There was an association between protein expression and survival following CRT. The 1- and 2-year survival rates were 93% and 73%, respectively, in patients with low SAG expression (fold change > 0.99), *vs* 62% and 56%, respectively, in patients with high SAG expression (fold change < 0.99); the correlation between SAG expression and survival was moderate ($P = 0.056$). A similar trend was observed in the expression of antiapoptotic protein Bcl-X_L; the corresponding survival values were 84% and 68%, respectively, in patients with low Bcl-X_L expression, *vs* 66% and 58%, respectively in patients with high Bcl-$X_L$expression. The levels of Bak were also in agreement with its apoptotic function. In accordance with our expectations, patients with high Bak expression had a higher 2-year survival rate (62%) than those with low Bak expression (56%). The expression patterns of SAG, Bcl-X_L and Bak proteins exhibited good correlations with the 1- and 2-year survival rates, in accordance with their anti- and pro-apoptotic roles, even though statistical

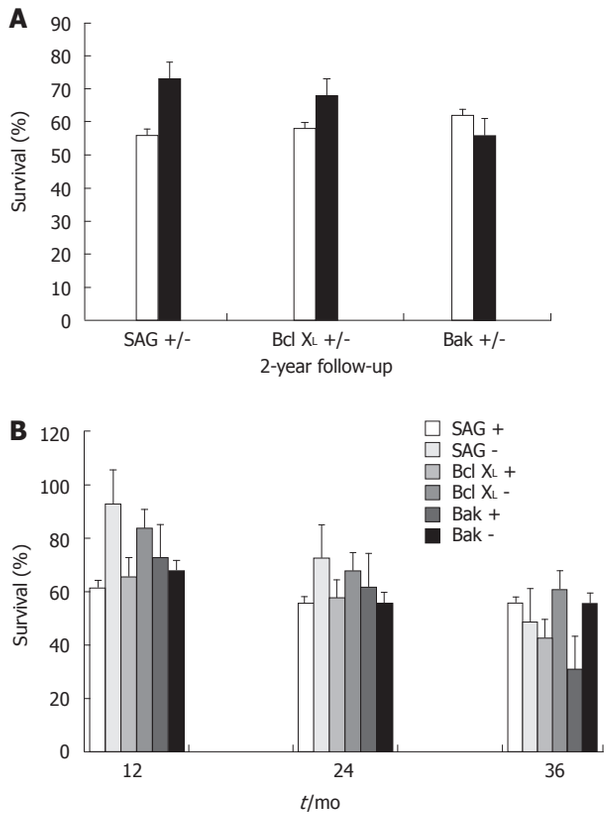

Figure 1 Dependence between gene expression and outcome of patients. A: Comparison for 2-year survival; B: Comparison after 1, 2 and 3 years of follow-up. All values were normalized with respect to β-actin expression. Calculations were based on the Pfaff method. +/- signs correspond to the subjects with increased or decreased expression with respect to their non-tumor tissues, respectively. SAG: Sensitive-to-apoptosis; Bcl-XL: B-cell lymphoma-extra large; Bak: Bcl-2 homologous antagonist/killer.

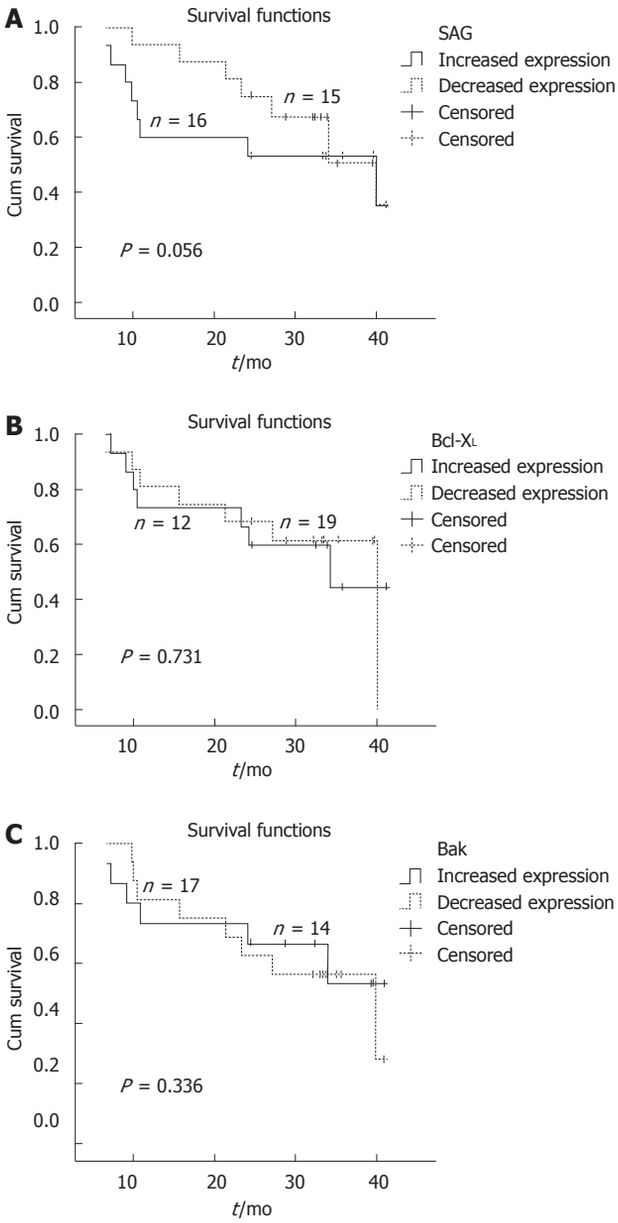

Figure 2 Kaplan-Meier survival curves with univariate log-rank comparisons at the end of 3 years for the three genes of interest. A: Sensitive-to-apoptosis; B: B-cell lymphoma-extra large; C: Bcl-2 homologous antagonist/killer. Metastasis was the major cause of death (seven cases). Information was not available for four of the patients. Other reasons of death were variable, but included advanced age, Alzheimer's disease and stroke. The median values for high- and low-level SAG expression in the study population were 24.5 and 30.4 mo, respectively. SAG: Sensitive-to-apoptosis gene, Bcl-XL: B-cell lymphoma-extra large, Bak: Bcl-2 homologous antagonist/killer.

significance was low, possibly due to the small number of patients included in the study (Figure 1A). There was no significant association in the expression of any gene with better survival at the end of the 3-year follow-up (Figure 1B).

Kaplan-Meier survival curves for SAG, Bcl-XL and Bak proteins are shown in Figure 2A-C, respectively. Mean overall survival in the patients with elevated SAG expression was 27.1 mo ± 3.9 mo [95% confidence interval (CI): 19.3-34.9]; and in patients with reduced expression, it was 32.1 mo ± 2.5 mo (95% CI: 27.3-36.9). The corresponding values for Bcl-XL were 28.0 mo ± 4.1 mo (95% CI: 19.9-36.1) and 31.7 mo ± 2.9 mo (95% CI: 26.0-37.5), and those for Bak were 29.8 mo ± 3.7 mo (95% CI: 22.5-37.2) and 30.6 mo ± 2.4 mo (95% CI: 25.5-35.0), respectively.

Tumor progression caused by distant metastases occurred only in eight patients (25.8%), of whom, seven had liver metastasis and one, who was alive at the time of evaluation, had bone metastasis. Mean overall survival was 41 mo. When the levels of SAG in tumor tissue were compared to the corresponding normal tissue, half of the patients expressed higher levels of SAG, whereas the other half had lower expression. Interestingly, patients with high SAG expression had a higher mean survival (28 mo) than did patients with low expression (18 mo). These results contradict those obtained in the non-metastatic patients. Among the non-metastatic patients, those with low SAG expression showed a higher survival (36 mo) and those with high SAG expression had lower survival (26 mo) (Table 1).

Pathological complete response was observed in five patients (5/31); three of whom (60%) had lower SAG expression and two (40%) had higher SAG expression.

DISCUSSION

Almost 50% of patients with rectal carcinoma who undergo potentially curative resection die from the disease, due to high recurrence rates. There is mounting evidence indicating that local control of disease and survival rates can be significantly improved with neoadjuvant CRT; however, responses to therapy vary widely among individuals and, as such, the ability to predict the response to CRT in patients with rectal cancer significantly improves therapeutic efficacy.

One of the immediate damaging effects of ionizing irradiation is the induction of cell-cycle arrest to provide time for DNA repair or apoptosis. Spontaneous apoptosis has been reported to be an important predictor of tumor regression in rectal cancer[13]. Reactive oxygen species, such as hydroxyl radical radicals, produced by ionizing radiation are highly reactive and easily trigger apoptosis, possibly by an indirect action on redox-sensitive molecules such as *p53* and *p27*[14,15]. Recently, SAG was identified as a redox-sensitive protein that protects cells from apoptosis, either by scavenging oxygen radicals or by acting on apoptosis-related proteins as part of the ubiquitin ligase complex SCF, thereby affecting the apoptotic sensitivity of cells. Moreover, SAG was identified as a potential regulator of *p27*, through inhibition of *p27* accumulation[16]. SAG overexpression has also been detected in a subset of human colon cancers and non-small lung carcinomas and has been shown to be associated with poor prognosis[8,9,17].

The present results, which are in agreement with above-mentioned studies, showed that low SAG expression in tumor tissue, as compared to normal tissue, had a positive effect on survival. The patients with low SAG expression had a median disease-free survival of 31.7 mo, as compared to 28 mo in those with high SAG expression. The clinical outcomes of the 31 patients revealed a strong discrepancy at the 2-year follow-up period between the groups with high *vs* low SAG expression, but this profile seemed to vanish at 3 years of observation.

Previously, Bak and Bcl-Xl, which are members of the Bcl-2 family, were also identified as candidate proteins for regulating chemotherapy-induced apoptosis[18]. Bcl-2 was shown to block γ-radiation-induced cell death[19,20]. Bak can form heterogenous dimers with Bcl-2 or Bcl-Xl to inhibit their antiapoptotic functions. Strong interaction between endogenous Bak and Bcl-Xl has been reported in hepatocytes as well as in other cells[21]. Furthermore, quantitative expression levels of Bcl-Xl and Bak have also been determined to correlate with apoptotic sensitivity of tissues in different carcinomas. Both genes have previously been shown to play a major role in colorectal carcinogenesis and tumor progression. Bcl-Xl, on the other hand, is suggested to be more crucial than Bcl-2 for regulation of apoptotic cell death in colon cancer[22]. Significant overexpression of Bcl-Xl mRNA has been observed in the majority of colorectal carcinomas as compared to the corresponding normal tissues. Krajewska *et al*[23] have also reported elevated Bcl-Xl and reduced Bak expression in colorectal adenocarcinoma. These studies reinforce the major roles of Bcl-Xl and Bak in colorectal carcinogenesis and tumor progression; furthermore, they also imply that expression levels of Bak and Bcl-Xl can be used as prognostic factors in rectal carcinoma, as pointed out by some other studies[24,25].

Thus, in addition to SAG, we also evaluated the expression of two other Bcl-2 family proteins, Bcl-Xl and Bak. The expression levels of antiapoptotic Bcl-Xl and proapoptotic Bak were well correlated with those of SAG, which lends further support to the role of apoptotic factors in the malignant potential of tumors. Higher survival rates for 2 years were recorded for increased expression of proapoptotic Bak, as opposed to SAG and Bcl-Xl levels.

We did not observe any correlation between development of metastases and expression of apoptotic factors; however, in patients who did not develop metastases, gene regulation, especially that of SAG, was closely associated with survival. In non-metastatic tumors, tissues with low-level SAG expression (n = 12) were associated with longer mean survival (36 mo), as opposed to those with high expression levels (27.9 mo, n = 11).

In conclusion, the present study shows that the level of expression of apoptosis-related genes may be associated with the degree of resistance to radiation exposure and may significantly affect therapeutic outcome. We observed an inverse correlation between SAG expression and survival. Furthermore, the data obtained in this study imply that SAG and Bak expression may serve as predictive parameters of disease progression. On the other hand, SAG and Bak expression levels did not significantly affect overall survival. This pilot study included a rather small number of patients, therefore, prospective studies with larger cohorts that include other proteins in the molecular apoptotic pathway are required to assess the roles of individual regulators in anticancer therapy.

COMMENTS

Background

Apoptotic proteins have been reported to be important prognostic factors in various cancers. Sensitive-to-apoptosis gene (SAG) is a recently identified apoptotic protein, which may be a new candidate to estimate the outcome of treatment in rectal cancers.

Research frontiers

SAG was identified as a redox-sensitive protein that protects cells from apoptosis, either by scavenging oxygen radicals or by acting on apoptosis-related proteins as part of the ubiquitin ligase Skp/Cullin/F-box containing complex (SCF), thereby affecting the radiation sensitivity of cells. This study investigated the correlation between expression levels of SAG and survival rates of patients, who have advanced rectal carcinoma. In addition to SAG, this study also examined two other proteins, B-cell lymphoma-extra large (Bcl-XL) and Bcl-2 homologous antagonist/killer (Bak) proteins, which are important members of the mitochondrial apoptotic pathway.

Innovations and breakthroughs

The present study showed that the level of expression of some apoptosis-related genes may be associated with the degree of resistance to radiation ex-

posure and may significantly affect therapeutic outcome. The present research observed an inverse correlation between SAG expression and 2-year survival, although the overall survival rate was not affected significantly. There were no significant correlations between the expression levels of all three genes and metastatic rates or tumor responses to chemoradiotherapy (CRT).

Applications

The data obtained in this study imply that SAG and Bak expression may serve as predictive parameters of disease progression. This pilot study included a rather small number of patients, therefore, prospective studies with larger cohorts that include other proteins in the molecular apoptotic pathway are required to assess the roles of individual regulators in anticancer therapy.

Terminology

SAG/regulator of cullins 2/Rbx/Hrt2 is a recently identified component of SCF E3 ubiquitin ligase, which controls cell-cycle progression by promoting ubiquitination and degradation of cell-cycle inhibitors. It has also been reported that SAG protects cells from apoptosis induced by redox agents such as hydroxyl radicals and radiation. The Bcl-2 family proteins are members of the intrinsic apoptotic pathway. Bak is a proapoptotic member, while Bcl-X_L blocks apoptosis in many systems.

Peer review

This was an interesting and well conducted study which should be published because it confirms the usefulness of SAG in the prognostication of rectal cancer patients.

Abstract

AIM: To evaluate the therapeutic effects of abdominal decompression plus continuous regional arterial infusion (CRAI) *via* a drug delivery system (DDS) in severe acute pancreatitis (SAP) patients with abdominal compartment syndrome (ACS).

METHODS: We presented our recent experience in 8 patients with SAP. The patients developed clinical ACS, which required abdominal decompression. During the operation, a DDS was inserted into the peripancreatic artery (the catheter was inserted from the right gastroepiploic artery until it reached the junction between the pancreaticoduodenal and gastroduodenal artery). Through this DDS, a protease inhibitor, antibiotics and octreotide were infused continuously. The duration of the regional artery infusion ranged from 8 to 41 d. The outcomes and the changes in the APACHE Ⅱ score, computed tomography (CT) severity index and intra-abdominal pressure (IAP) of the patients were retrospectively evaluated.

RESULTS: Eight patients with an initial APACHE Ⅱ score of 18.9 (range, 13-27) and a Balthazar CT severity index of 9.1 (range, 7-10) developed severe local and systemic complications. These patients underwent subsequent surgical decompression and CRAI therapy because of intra-abdominal hypertension (IAH). After a mean interval of 131.9 ± 72.3 d hospitalization, 7 patients recovered with decreased APACHE Ⅱ scores, CT severity indexes and IAP. The mean APACHE Ⅱ score was 5.4 (range, 4-8), the CT severity index was 2.3 (range, 1-3), and IAP decreased to 7.7 mmHg (range, 6-11 mmHg) 60 d after operation. One patient died of multiple organ failure 1 wk after surgery.

CONCLUSION: CRAI and laparotomic decompression might be a therapeutic option for SAP patients with ACS.

Key words: Severe acute pancreatitis; Arterial infusion; Laparotomy; Abdominal compartment syndrome

INTRODUCTION

Acute pancreatitis is an inflammatory disease that is self-

limited in the majority of patients and resolves within 48-72 h. However, approximately 20% of the patients develop a more severe form of the disease with evidence of organ dysfunction and complications such as pancreatic necrosis, abscess or pseudocyst. This acute form is classified as severe acute pancreatitis (SAP) according to the Atlanta classification and has a mortality approaching 30%[1]. Previous studies have shown that 60% of the patients developed organ failure on admission, and those with persistent organ failure had the worst outcomes[2].

The current treatment paradigm calls for non-operative management of SAP as long as there is no evidence of infection. However, there is a subset of patients with acute pancreatitis who may need an urgent laparotomy in the absence of an infection to decompress the clinically significant abdominal compartment syndrome (ACS)[3].

SAP with ACS, which is defined as a sustained intra-abdominal pressure (IAP) greater than 20 mmHg that is associated with the development of organ dysfunction or failure[4], is the most severe form of acute pancreatitis and has a high morbidity and mortality. SAP with ACS injures not only the pancreas itself but also the surrounding organs. Despite various treatment protocols, including intensive care therapy and blood filtration, the mortality rate of SAP with ACS is still reported to be 30%-60%[2].

In a number of recent studies, continuous regional arterial infusion therapy (CRAI) for SAP using protease inhibitors and antibiotics has been shown to control the inflammation of the pancreas and to prevent the extension of the inflammatory process, which would decrease the rate of infection and mortality[5-11].

Accordingly, in this study, we used a new system during our decompressing surgical procedure in 8 patients suffering from SAP with ACS, and the therapeutic effects of continuous regional intra-arterial infusion were retrospectively evaluated.

MATERIALS AND METHODS

Eight patients, 6 men and 2 women, with a mean age of 51.5 year (35-66 year) were diagnosed with SAP at Xiamen University Zhongshan Hospital from April 2009 to July 2010. SAP was diagnosed based on clinical manifestation, biological findings and contrast-enhanced abdominal computed tomography (CT) within 3 d after admission. These patients presented with multiple organ dysfunction (MOD) or multiple organ failure (MOF) within 3 d of admission, and they continued to deteriorate under intensive medical support (Table 1).

Laparotomy was performed 3-9 d after the onset of SAP in these patients because of clinical deterioration despite intensive medical care and persistent abdominal hypertension. The abdominal pressure was measured by the bladder technique[4]. In contrast to the traditional surgical procedure for SAP, necronectomy (debridement) was not performed. For abdominal decompression and placement of wide-bore drains for continuous postoperative irrigation, the catheter of a drug delivery system (DDS) was inserted into the peripancreatic artery. Because the pancreas has a multiple-sourced blood supply, an appropriate drug distribution in the pancreas can not be achieved unless the catheter is properly placed. The proper position of the catheter tip was decided based on the methylthionine chloride injection. By injecting methylthionine chloride from the head of DDS, we could find the dyeing area, and adjust the position of catheter tip. In cases which it was difficult to find the right gastroepiploic artery, an intraoperative ultrasound was used for guiding. The injection head of the DDS was subcutaneously placed for postoperative drug delivery (Figure 1), and the patients subsequently received an arterial infusion with protease inhibitor, antibiotics and octreotide. In addition, patients with biliary stones had emergency surgery such as endoscopic sphincterotomy, endoscopic nasobiliary drainage, cholecystectomy or common bile duct lithotomy. If we had difficulties with the closure after laparotomy, we left the abdomen open and applied a temporary closure device until suturing again.

Table 1 Multiple organ dysfunction or multiple organ failure within 3 d after admission

Dysfunction (failure)	*n* (%)
Pulmonary insufficiency	8 (100.0)
Requiring mechanical ventilation	8 (100.0)
Renal insufficiency	7 (87.5)
Requiring dialysis	6 (75.0)
Shock	7 (87.5)
Requiring catecholamines	8 (100.0)
Sepsis (or SIRS)	8 (100.0)
Coagulopathy	7 (87.5)
Hepatic dysfunction (failure)	7 (87.5)
Cardiovascular disable	7 (87.5)
Gastrointestinal bleeding	7 (87.5)
Center nerve system problem	5 (62.5)

Ulinastatin (100 000 U), antibiotics (imipenem/cilastatin 0.5 g) and octreotide (0.3 mg) were dissolved into the saline (48 mL) and continually infused through the DDS twice a day. To ensure the therapeutic effects, the infusion was continued even after the patients' conditions had improved and until the Balthazar CT severity index had decreased to 3 or less.

All patients were treated in the intensive care unit (ICU). Fluid, electrolytes, albumin, and insulin were replaced dependent on central venous pressure (6-10 mm H_2O), hematocrit (30%-35%), urinary excretion, and blood glucose measurement. Assisted ventilation was begun if the partial pressure of oxygen could not be maintained at a level of > 60 mmHg with an oxygen mask. In patients with progressive renal failure (serum creatinine > 3.0 mg/dL), hemodialysis or continuous venovenous hemodialysis (CVVHD) was performed.

The clinical data of patients, transvesical measurement of IAP, CT severity index[12], APACHE Ⅱ score[13], presence of MOD, local-regional complications and outcome were examined and reported.

RESULTS

The severity of the pancreatitis was judged according to

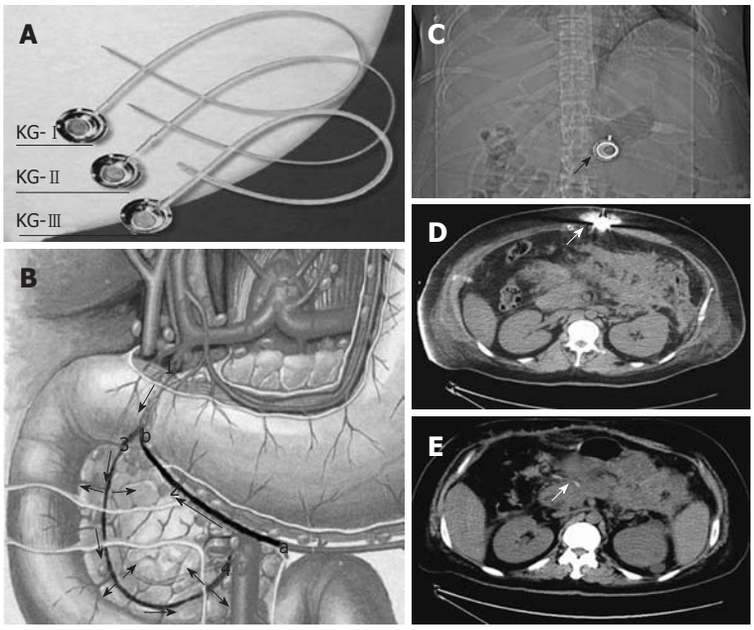

Figure 1 Procedure of placing drug delivery system and imaging after drug delivery system was inserted. A: Drug delivery system; B: Anatomy and how it is inserted; 1: Gastroduodenal artery; 2: Right gastroepiploic artery; 3: Superior pancreatico-duodenal artery; and 4: Inferior pancreatico-duodenal artery (arrows indicate the direction of drug delivery and blood flow); a: The inserting point; and b: The end in which the catheter should be inserted; C: Abdominal X-ray film showed the subcutaneous drug delivery system (DDS) head (arrow); D: Computed tomography (CT) scan showed the subcutaneous DDS and the drug delivery needle inside the DDS (arrow); E: DDS catheter around the pancreas (arrow) in the CT scan.

Table 2 Clinical data of 8 patients with severe acute pancreatitis treated by postoperative peripancreatic artery infusion

Patients	Sex/age (yr)	Area of pancreatitis	Operation	AI (d)	IAP		Apache Ⅱ		CT-SI (d)		ICU (d)	Hosp. (d)	Outcome

No more fluid could be seen around the pancreas (CT scan before discharge).

the APACHE Ⅱ score[1,14,15] , with a score of > 8 points considered indicative of severe disease[16]. In our patients, the APACHE Ⅱ score ranged from 13 to 27 points, with a mean of 18.9 points. The Balthazar CT severity index was evaluated at each CT study[12]. The CT severity index of the 8 patients ranged from 7 to 10 (average 9.1) before arterial infusion. The abdominal pressure of the patients was measured before operation, and the results suggested that every patient had high abdominal pressure and was diagnosed as having ACS. The average abdominal pressure was 29.1 mmHg (range, 23-38 mmHg). The cause of the pancreatitis was cholelithiasis in 4 cases, alcoholism in 1, hyperlipidemia in 2, and unknown in 1. The arterial infusion was started 3-9 d after the onset of SAP in these patients, and lasted 8-41 d (mean, 26.3 d).

The clinical conditions of the patients improved within 3 d after decompression and the initiation of the arterial infusion. The APACHE Ⅱ score was decreased from 13-27 (mean, 18.1) to 4-8 (mean, 5.4), and the CT severity index from 7-10 (mean, 9.0) to 1-3 (mean, 2.3), respectively, 60 d after the operation. IAP decreased to 7.7 mmHg (range, 6-11 mmHg). One patient died of MOF, and all other patients were discharged from the hospital within 68-259 d (mean, 131.9 d). The patients are all in good health now. The catheter was removed percutaneously 1 year after discharge, and there were no complications related to the procedure or drug delivery after long-term catheter placement. The clinical data are shown in Table 2 and Figure 2.

DISCUSSION

SAP injures not only the pancreas itself but also the surrounding organs, culminating in ACS and MOF in many cases. Despite the various treatment protocols, including intensive care therapy and blood filtration, SAP is still has a high mortality. The basic principles of the initial management of acute pancreatitis are adequate monitoring of vital signs, fluid replacement, correction of any electrolyte imbalance, nutritional support, and prevention of local and systemic complications.

Infected necrosis is generally accepted as an indication for surgery, but there is a subset of acute pancreatitis which may need an urgent laparotomy in the absence of infection to decompress abdominal pressure, which is unique as a compartment syndrome and virtually affects all organ systems within the body. Pathophysiologically, it deranges cardiovascular hemodynamics, respiratory and renal functions and may eventually lead to multi-organ failure. In addition, the gold standard for the treatment of established ACS is surgical decompression of the abdomen[17].

Our main purpose was to decompress the intra-abdominal hypertension (IAH). A double drainage tube was placed in peritoneal cavity around the region of pancreas, through which the patient's cavity was persistently douched using a large amount of saline solution. This can help drain the intra-abdominal hemorrhagic ascites, alleviate IAH, dilute the inflammatory mediators and activated amylase, and reduce toxin absorption through the peritoneum. In addition, we placed a DDS for postoperative treatment based on the positive results of regional infusion reported by other authors[5-11]. In contrast to their methods of vascular intervention using an angiocatheter, we inserted the DDS catheter into the pancreaticoduodenal artery from the right gastroepiploic artery to the gastroduodenal artery during the procedure. The DDS was subcutaneously fixed and did not result in any discomfort after drug delivery. In the ICU, the DDS could be easily used for the continuous injection of protease inhibitors, antibiotics and octreotide. This device was simple, safe and did not hinder the patient's movement. No complications related to the procedure or the device setting were observed, even after long-term placement.

Regarding the drug infusion, because acute pancreatitis is an autodigestive disease, protease inhibition has been the focus of experimental and clinical research. However, in clinical settings, the effect of protease inhibitors in the treatment of acute pancreatitis is still controversial. Some randomized, controlled trials failed to demonstrate any significant benefits[18,19]. For this reason, in Europe and the United States, protease inhibitors are not usually applied in the treatment of acute pancreatitis. In Japan, however, protease inhibitors are often applied, and in particular, it has been demonstrated that the CRAI of protease inhibitors and antibiotics are beneficial for severe acute necrotizing pancreatitis[5-11]. They believed that there were many reasons why the protease inhibitors were not as effective as expected in the experimental studies, such as the timing of administration, the concentration of the protease inhibitor in the pancreatic tissue, the diminution of the vasculature of the pancreas and so on. With intravenous administration, the concentration of the agent reaching the pancreas eventually becomes insufficient for controlling the inflammation. As a result of drug dilution as well as serum and hepatic metabolism, most of the aprotinin administered intravenously tended to go into the liver and thereafter accumulate in the kidneys, with only a small amount of aprotinin distributed in the pancreas. In contrast, with intra-arterial administration in experimental studies, the local concentration in the pancreas was high enough to improve the biochemical indices of inflammation and survival[20,21].

Because pancreatic and extrapancreatic infections are determining factors leading to death in patients with SAP, much attention has been paid to the potential role for antibacterial prophylaxis, especially in those patients with pancreatic necrosis. Many studies on the prophylactic effect of antibiotics have demonstrated that broad-spectrum antibiotics with good pancreatic tissue penetration decreased the incidence of infectious complications and mortality[22,23]. The antibacterial agent of first choice is likely to be imipenem because it reaches a higher distribution in the pancreatic tissue and provides higher bactericidal activity against most of the bacteria present in pancreatic infection compared with other types of antibiotics. An alternative antibiotic regimen is either ciprofloxacin

or ofloxacin in combination with metronidazole[24]. It also has been suggested that the effect was induced markedly by intra-arterial administration.

Octreotide reduces exocrine pancreatic secretion in acute pancreatitis, which would decrease pancreatic autodigestion, and it may also significantly prevent the bacterial translocation by preventing mucosal damage[25]. As a treatment guideline for acute pancreatitis, octreotide has been widely used in clinical practice, although the results of clinical investigations using somatostatin or its analogue are controversial. In a multicenter randomized controlled study with a large number of patients (n = 302) with an adequate level of disease severity, no benefit of octreotide on progression or outcome was found[26], but other research suggests that octreotide may have a beneficial effect in the treatment of SAP[27]. One study suggested that octreotide seemed to have a dose- and time-dependent effect on histopathology and lipid peroxidation: an early bolus application of octreotide reduced the severity of histopathological changes in acute pancreatitis and decreased lipid peroxidation in the pancreatic tissue samples. However, a late bolus application and continuous intravenous infusion did not influence pancreatitis or lipid peroxidation[28].

According to the above-mentioned clinical and experimental results, in this study, we used a combination of these three kinds of drugs *via* DDS as regional therapy in the 8 patients. Their clinical conditions improved after the treatment and the overall mortality was 12.5%, which is much lower than that reported in the literature. These results suggest that CRAI plus laparotomic decompression might be a therapeutic choice for SAP with ACS.

COMMENTS

Background

Severe acute pancreatitis (SAP), characterized by intricate mechanism, variant symptoms, poor prognosis and multiple complications, seriously threatens the life of patients. About 11% of SAP patients suffer from abdominal compartment syndrome (ACS). SAP complicated by ACS has a mortality rate of that is 30%-60%.

Research frontiers

ACS has been recognized as a contributing factor for the multiple organ failure commonly seen in SAP. Surgical decompression is the preferred method of treatment for ACS. Although decompression has a significant effect in lowering IAP, the mortality still remains high in SAP patients with ACS. Some recent studies showed that continuous regional arterial infusion of protease inhibitors and antibiotics may reduce the mortality rate and incidence of infectious complications in SAP.

Innovations and breakthroughs

SAP with ACS is the most severe form of acute pancreatitis and has a high morbidity and mortality which need an urgent laparotomy. In this study, a new system was applied during the decompressing surgical procedure in 8 patients. In addition to abdominal decompression and the placement of wide-bore drains for continuous postoperative irrigation, the catheter of a drug delivery system (DDS) was inserted into the peripancreatic artery for postoperative continuous regional arterial infusion, which increased the tissue concentration of the drugs in the inflamed pancreas and improved the biochemical indices of inflammation and survival.

Applications

The DDS applied for continuous regional arterial infusion (CRAI) in this study is simple, safe and easy to implement. These positive results suggest that CRAI plus laparotomic decompression might be a therapeutic choice for SAP with ACS.

Peer review

Even if it is not accepted by all, the presence of an ACS in severe pancreatitis is a very difficult complication to deal with. The paper reports a small group of patients with such a complication treated with a multidisciplinary approach (surgery, antibiotics, anti protease, *etc.*). It is difficult to understand the real value of each therapy, but the utility of the paper lies in reporting the complexity of such a disease.
