es about the primary tumor in stomach. At the sixth week, the primary tumor began to grow fast, resulting in incrustation of the gastric wall and stenosis of the gastric cavity, and metastases into the liver and lymph nodes were detected. The tumor, which compressed the adjacent organs, gradually became bigger and bigger followed by stenosis or vanishment of the gastric cavity from 8 to 12 wk. There were massive metastases, and the rate of metastasis was 58% in lymph nodes, 78% in liver, 39% in kidney, and 81% in peritoneum or septum.

CONCLUSION: A gastric cancer model is established, which can simulate the clinical tumor behavior and provide experimental carrier for clinical trials of gastric cancer treatment.

Serial observations on an orthotopic gastric cancer model constructed using improved implantation technique. *World J Gastroenterol* 2011; 17(11): 1442-1447 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i11/1442.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i11.1442>

INTRODUCTION

Metastasis is not only still the barrier to tumor therapy, but also linked with the prognosis of patients. Patients with gastric cancer hardly have symptoms in their early stage

so that they are always found with metastases after clinical examinations. Therefore, novel tumor models are needed to study the metastasis mechanism as well as therapeutic approaches. It is well known that orthotopic transplantation technique has gain popularity in the field of the animal model^[1-12]. Orthotopic tumor models not only mimic clinical cancer course, but also promote metastasis^[13]. In recent years, the procedure of orthotopic implantation has been improved from the “sewing” method to the “adhering” one^[2-4,14]. The progress greatly shortens the course of surgical operation and decreases the mortality of animals. To our knowledge, gastric cancer models of orthotopic implantation with intact tumor tissue have been well established^[1-3,5-8]. However, serial examination of tumor development and metastasis needs to be made in order to tailor the treatment strategies. Based on the previous researches, we intend to establish an orthotopic model of gastric cancer using tissue glue and observe tumor progress and metastasis consecutively to detect an appropriate therapeutic target for clinical trials.

MATERIALS AND METHODS

Cell line

Human gastric cancer cell lines SGC-7901 (poorly differentiated) was used for this study. The cell was obtained from the Centre of Cell Cultures of Chinese Academy of Medical Sciences, Shanghai, China, and cultured at 37°C in a humidified air with 5% CO₂, in RPMI-1640 medium (Gibco, Grand Island, NY) supplemented with 10% fetal calf serum (FCS; Gibco, Grand Island, NY), 100 U/mL penicillin, 100 µg/mL streptomycin, 2 mmol/L glutamine, and 1 mmol/L sodium pyruvate.

Animals

Five to six-week-old male Balb/c nu-nu mice weighing 18-20 g were obtained from the Shanghai Experimental Animal Center of the Chinese Academy of Medical Sciences, China. All mice were maintained in a pathogen-free environment (temperature 25-27°C, humidity 45%-50%) and supplied with food and water *ad libitum*. All experimental procedures were conducted in conformity with institutional guidelines for the care and use of laboratory animals in Chongqing Medical University, China, and the National Institutes of Health Guide for Care and Use of Laboratory Animals.

Orthotopic implantation in stomach

SGC-7901 cells were collected at the log phase and injected subcutaneously into the mice at 10⁷/0.2 mL. Two weeks later, tumors (about 2.0 cm × 2.0 cm × 1.0 cm) were harvested from the mice under anesthesia and minced into small pieces (1mm³) in RPMI-1640 basal medium. All procedures were then performed under anesthesia with Sumianxin II (0.02 mL per animal; China Academy of Military Medical Sciences). For implantation, the mouse stomach was gently exteriorized *via* a left-side upper abdominal incision, and one small tissue pocket was formed in the

middle wall of the greater curvature using a microscissor. One tumor fragment was placed into the pocket and fixed with a drop of medical tissue glue (gifts from Shunkang Corporation of Biological Adhesive, Beijing, China). The quantity of the tissue adhesive should be strictly controlled to avoid adhering to adjacent normal tissues. The stomach was then relocated into the abdominal cavity followed by the abdominal closure with 4-0 absorbable sutures.

Evaluation of tumor growth and metastasis

All mice were divided into 6 groups of 6 animals each after orthotopic implantation. One group was sacrificed every two weeks. At autopsy, the primary tumor, lymph nodes, and other organs were examined in detail. The samples were fixed in 10% formalin for paraffin sections, and stained with hematoxylin and eosin for microscopic examination.

Immunohistochemistry

Paraffin sections were examined histologically with the Cytokeratin 20 (CK20) mAb KS20.8 and Epithelial Membrane Antigen (EMA) mAb GP1.4 (MAB-0057, MAB-0061; Maixin Inc., Fuzhou, China), which are usually combined to diagnose the gastrointestinal adenocarcinoma. Ultrasensitive streptavidin-peroxidase (SP) kit (KIT-9710; Maixin Inc., Fuzhou, China) and DAB kit (DAB-0031; Maixin Inc., Fuzhou, China) were used in the immunohistochemical stain according to the manufacture's instructions. CK20 and EMA expression was defined as positive if the stained region of tumor cells was in the cytoplasm.

Assessment of primary tumor growth

The primary tumor volume was calculated by the following formula: $V = 0.4 \times ab^2$ (a: maximum diameter; b: minimum diameter)^[15]. Then the tumor growth curve was depicted reflecting the tumor growth trend.

RESULTS

Macroscopic examination

From 2 to 4 wk, the primary tumor developed without obvious volume change, and showed insufficient blood supply. The gastric cavity of tumor-bearing mice appeared almost normal in size. At the 2nd wk after orthotopic implantation, metastatic infiltration was not found in all detected organs. However, tumor invasion into the liver was found at the 4th wk. Six weeks after transplantation, the tumor *in situ* grew increasingly in size, with sparse blood vessels. The stomach wall of mice was thickened and gastric cavity decreased, accompanied with enlargement of lymph nodes from gastric area and hilus pulmonis. The tumor invaded into the liver, resulting in metastatic nodules formation. At the 8th wk, the stomach tumor was characterized by large-size, irregular volume and rich blood supply. The resulting tumor squeezed the adjacent organs and deformed the stomach contributing to distal stenosis. The lymph nodes of the gastric area, hilus pulmonis and mesenterium presented enlargement caused by tumor metastasis. Metastatic lesions were

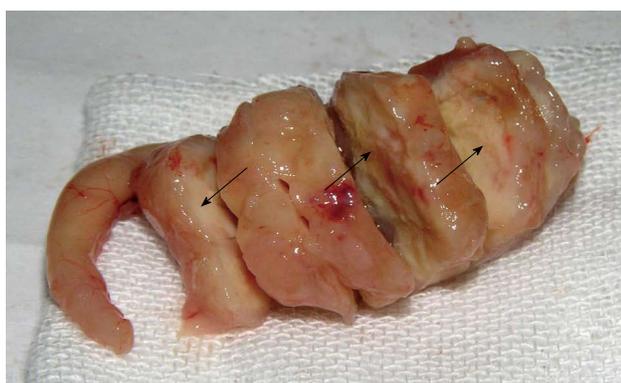

Figure 1 Macroscopic examination of the primary tumor in SGC-7901 model. The gastric cavity occupied by primary tumor was found vanished, and pylorus was obstructed totally (arrows).

found in the organs such as liver, kidney, peritoneum and diaphragm. From 10 to 12 wk, the tumor grew fast and huge, occupying almost the upper abdomen and squeezing severely the surrounding organs. The necrosis from central tumor areas was macroscopically visible, indicating that the tumor outgrew the sufficient blood supply. In most mice, the gastric cavity became narrow, even vanished, and pylorus was obstructed partly or totally (Figure 1). The stomach of some mice was so severely disfigured that the greater and lesser curvature failed to be distinguished. Enlargement of many lymph nodes was visible in the gastric area, hilus pulmonis and mesenterium. The metastatic infiltration into the liver and kidney was always detected, with characteristics of grey-white neoplastic nodules. At autopsy, a little clear and yellowish ascites was found (Table 1).

Histology

Tumor cells spread with schistose, nest-like, or cable-like structure, with characteristics of nuclear polymorphism,

nuclear hyperchromatism, much red nucleolus, and rich pathological karyokinesis. Mucus secreted in the cytoplasm, which resulted in mucus lake, was visible in part of tumor cells (Figure 2A). Glandular differentiation and rich vascularity were present in tumor areas. The stomach tumor invaded the gastric wall following the disruption of the integrity of the mucous layer or muscularis mucosae (Figure 2B). The lymph nodes were infiltrated and destroyed by metastatic tumor, characterized by the narrowness or diminishment of the lymph sinus (Figure 2C). Metastases were also detected in the liver (Figure 2D) and the kidney (Figure 2E), occasionally in the paranephros or pancreas (not shown). Metastatic lesions were always separated from adjacent normal tissues by fibrous integument, and lymphoid infiltration was found in the peripheral tumor areas. Tumor metastasized to the lung and surrounded bronchia or bronchiole (Figure 2F). Smear of cast-off cells from ascites confirmed the malignant cells from the primary adenocarcinoma (Figure 2G).

Immunohistochemistry

All primary tumors and metastases from other organs by immunohistochemical staining showed the positive expression of CK-20 (Figure 3A and B) and EMA (Figure 4A-C) protein.

Varying volume of primary tumor

The tumor volume gradually increased from the 6th wk after implantation, and reached a peak when nude mice died at the 12th wk (Figure 5). From 10 to 12 wk, the model mice declined in their general conditions, accompanied by cachexia and ascites.

Incidence of metastasis

After all mice were sacrificed, the metastasis incidence of involved organs was analyzed and the following results were obtained: lymph nodes 58% (21/36), liver

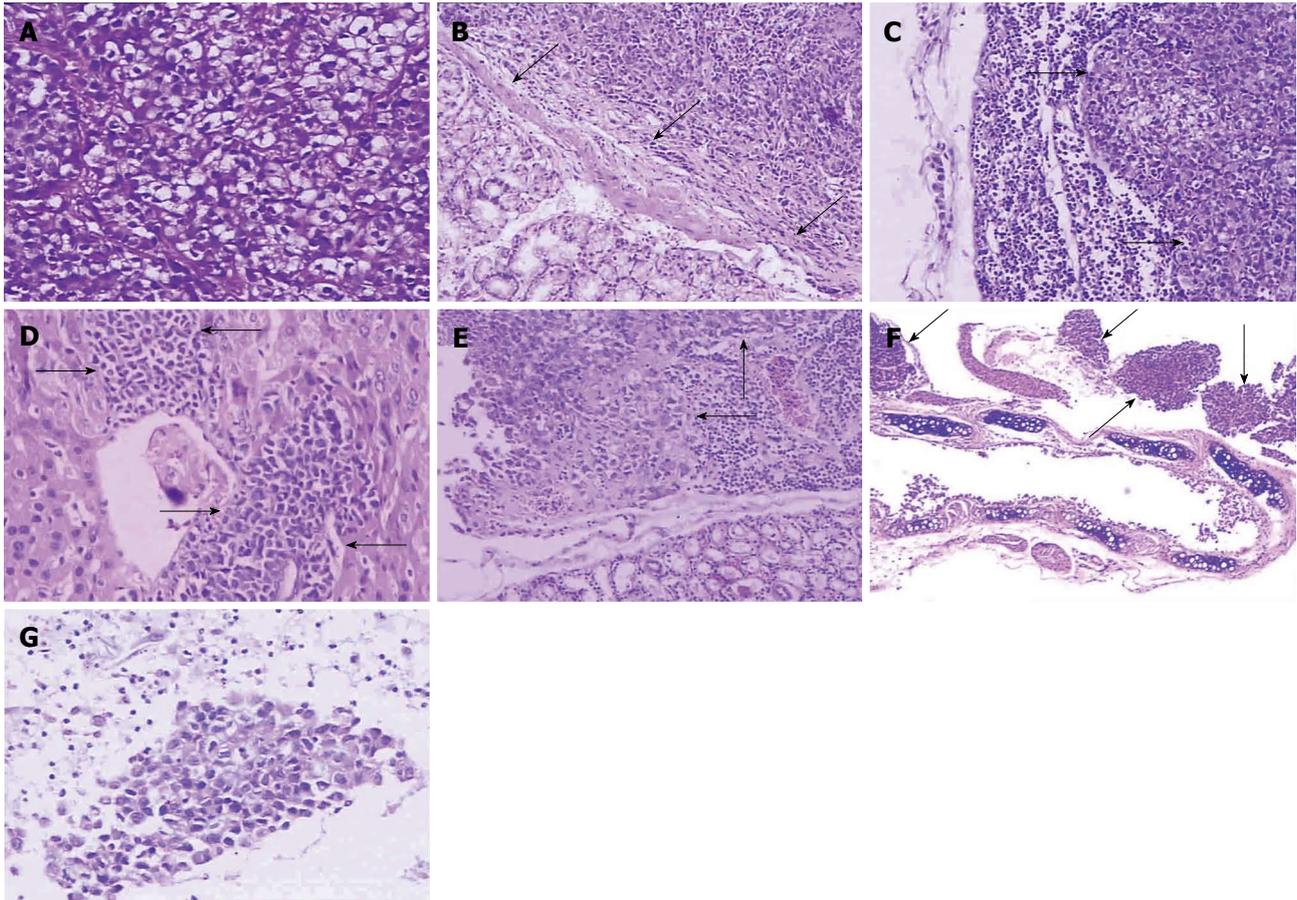

Figure 2 Histopathologic structure of SGC-7901 tumors by HE staining. A: Tumor cells showed nuclear polymorphism, nuclear hyperchromatism, and much mucus in the cytoplasm ($\times 200$); B: The primary tumor destroyed muscularis mucosae (arrows) ($\times 100$); C: The lymph nodes were infiltrated by metastatic tumor (arrows) ($\times 100$); D: Metastases (arrows) infiltrated into the liver ($\times 200$); E: Metastatic tumor (arrows) invaded the kidney ($\times 100$); F: Tumor (arrows) metastasized to the lung and surrounded bronchia or bronchiole ($\times 40$); G: Cast-off tumor cells were detected in ascites ($\times 200$).

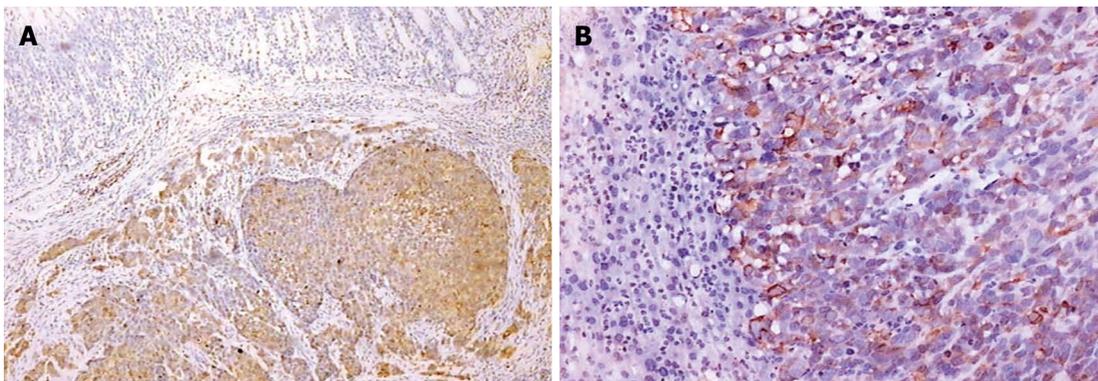

Figure 3 Immunohistochemistry of SGC-7901 tumor by streptavidin-peroxidase method. Expression of Cytokeratin 20 (CK20) protein was positive, which was stained brown in the cytoplasm in the tumor of stomach (A $\times 40$) and liver (B $\times 100$).

78% (28/36), kidney 39% (14/36), and peritoneum and diaphragm 81% (29/36).

DISCUSSION

There are little proofs supporting serial observations on gastric cancer models although many researchers have constructed orthotopic models using intact tumor tissues. This makes it difficult to learn the whole process of

tumor growth and metastasis occurrence. In this study, we presented in detail such evidences as the process of primary tumor growth, the time point of metastasis, and the sites and incidence of metastasis.

The patients with gastric cancer hardly have symptoms in their early stage, whereas they are always tortured by gastrointestinal symptom and metastasis in their terminal stage. In the present study, an animal model of stomach cancer was established to replicate the tumor

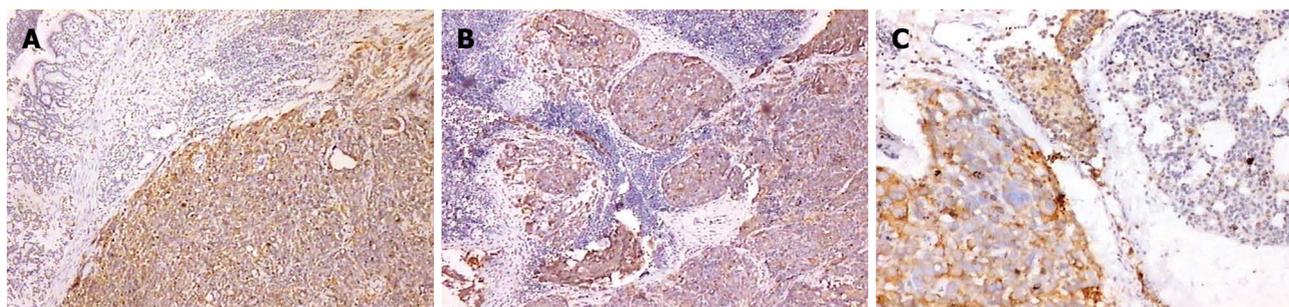

Figure 4 Immunostaining of SGC-7901 tumor using streptavidin-peroxidase method. Epithelial membrane antigen signal stained brown in the cytoplasm was positive in the tumor of stomach (A \times 40), lymph node (B \times 40) and lung (C \times 100).

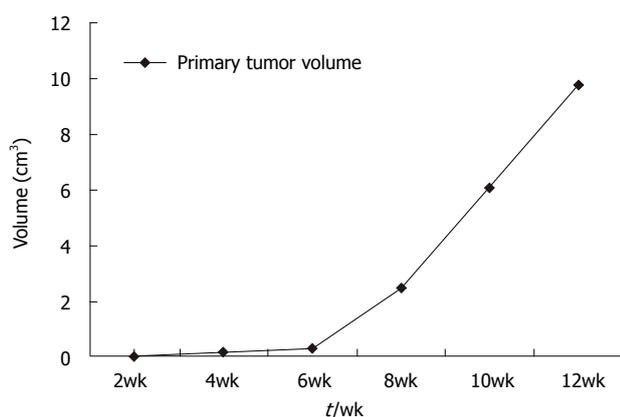

Figure 5 The curve of tumor growth at different time points. The tumor volume gradually increased from the 6th wk after implantation, and reached a peak at the 12th wk.

behavior of clinical patients. It showed that the primary tumor grew into the log phrase from the 6th wk after implantation and thereafter the tumor volume gradually increased. From the 6th wk, lymph node metastases and distant metastases were detected, accompanied by the increase of involved organs with the tumor progress. The tested mice revealed obvious cachexia from the 10th wk, and systemic failure at the 12th wk or so.

There are several pathways such as direct infiltration, lymphatic metastasis, vascular spread, and implantation dissemination which play important roles in metastasis of gastric cancer. Previous studies recapitulated the metastatic incidence of systematic organs, but did not mention the metastatic pathways of gastric cancer models. Moreover, there are uneven metastasis rates among different laboratories resulting from different experimental conditions, animal species and cell lines^[1,2,3,10,11,14]. The SGC-7901 cell line used in our study was derived from metastatic lymph node of poorly differentiated human gastric carcinoma. We could detect the metastatic lesions in the lymph nodes from gastroepiploic plexus, hilus pulmonis and mesentrium, which accorded with the feature of this cell line. It is well known that liver is the most sensitive organ to vascular metastasis. In the present study, we found that the liver was not only invaded by the neoplastic cells from blood pathway but also directly infiltrated by the primary tumor. In addition, the fringe of kidney also showed metastatic

spread, yet only under renal capsule rather than in parenchyma. Hereby, we consider that metastatic tumor may float in the ascites by breaking through the stomach serous coat and then invade straightly the kidney, or metastasize to the lymphatic system of renal capsule *via* lymphatic route, instead of invading kidney through blood vessel.

The model constructed in our study could simulate the clinical tumor behavior and provide basic theory on gastric cancer models. However, orthotopic implantation models still have some limitations such as failure in clinical staging. It is well known that gastric cancer stage (early, median, late) is judged by tumor growth and infiltration and metastasis rather than disease course, i.e. TNM staging published by Union for International Cancer Control (UICC). The morphological changes of gastric carcinogenesis are as follows: diffuse hyperplasia \rightarrow focal proliferation and metaplasia \rightarrow benign tumor \rightarrow grade I, II or III dysplasia \rightarrow carcinoma in situ \rightarrow invasive carcinoma, which reveals that the pathological changes of gastric cancer originate from mucous layer and progress layer-by-layer towards serous coat^[16]. However, orthotopic implantation was performed with tumor fragments under the stomach serous coat, which is unable to mimic the histopathological mechanism of gastric cancer. In fact, the procedure of orthotopic implantation mimics the artificial advanced stage which is characterized by tumor growth from serous coat to mucous layer or outside membrane serosa. The histological origin of primary tumor was not consistent with the principle of TMN stage although lymph node metastasis or distant dissemination was also detected. So the orthotopic model of gastric cancer is not suitable for clinical staging.

Some researchers had established the models of stomach cancer with chemical carcinogens which could simulate the histological origin of gastric carcinoma^[16-20]. But there are some disadvantages such as long period and accidental animal death. Some authors employed transgenic techniques in attempt to replicate the mechanism of gastric cancer^[18,21,22]. However, transgenic method is limited due to expensive cost, long period and advanced technical requirements for molecular biology. Compared with other methods for constructing gastric cancer model, the surgical orthotopic implantation is still a desired technique characteristic of short period, low cost and simple practice.

Some experimental skills for this animal model should

be noticed. For example, necrotic area should be removed from tumor tissues used for orthotopic implantation; the quantity of medical glue should be strictly controlled to avoid adhering to adjacent organs; and the middle part of the greater gastric curvature is the first choice for orthotopic implantation because of the operational convenience and rich blood supply.

In conclusion, we can succeed in establishing a gastric cancer model if only we master the experimental skills above and avoid the adverse factors.

COMMENTS

Background

Metastasis is still the barrier to the treatment of patients with gastric cancer. Gastric cancer models of orthotopic implantation with intact tumor tissues have been well established. Moreover, the procedure of orthotopic implantation has been improved from the "sewing" method to the "adhering" one. However, there are little evidences regarding serial observations on gastric cancer models to tailor treatment strategies.

Research frontiers

It is well known that orthotopic transplantation technique plays an important role in establishing animal models of various tumors. Gastric cancer model of orthotopic implantation could mimic clinical cancer process and contribute to metastasis occurrence. The procedure greatly facilitates surgical operation course and decreases the mortality of animals.

Innovations and breakthroughs

Orthotopic implantation with "glue paste technique" is a popular and new method in recent years which is characterized by easy performance, low cost and short operation course. This study makes it possible to help researchers learn the whole process of tumor development and metastasis, thus choosing the appropriate therapy target for clinical trials.

Applications

Serial observations on the models can provide evidences for researchers to treat stomach cancer and test the therapeutic effects.

Peer review

The study is interesting and well done. The model used by the Authors well mimics the dynamics of local growth and spread of gastric cancer cells at both lymph-nodes and distant organs.

Abstract

AIM: To demonstrate the value of Diosmin (flavonoidic fraction) in the management of post-haemorrhoidectomy symptoms.

METHODS: Eighty-six consecutive patients with grades III and IV acute mixed hemorrhoids admitted to the

Anorectal Surgical Department of First Affiliated Hospital, Xinjiang Medical University from April 2009 to April 2010, were enrolled in this study. An observer-blinded, randomized trial was conducted to compare post-haemorrhoidectomy symptoms with use of Diosmin flavonoidic fraction vs placebo. Eighty-six patients were randomly allocated to receive Diosmin flavonoidic fraction 500 mg for 1 wk ($n = 43$) or placebo ($n = 43$). The Milligan-Morgan open haemorrhoidectomy was performed by a standardized diathermy excision method. Pain, bleeding, heaviness, pruritus, wound edema and mucosal discharge were observed after surgery. The postoperative symptoms and hospitalization time were recorded.

RESULTS: The mean age of the Diosmin group and controls was 53.2 and 51.3 years, respectively. In Diosmin group, haemorrhoid piles were of the third degree in 33 patients and the fourth degree in 10; and in the control group, 29 were of the third degree and 14 were of the fourth degree. There was no statistically significance in age, gender distribution, degree and number of excised haemorrhoid piles, and the mean duration of haemorrhoidal disease between the two groups. There was a statistically significant improvement in pain, heaviness, bleeding, pruritus from baseline to the 8th week after operation ($P < 0.05$). Patients taking Diosmin had a shorter hospitalization stay after surgery ($P < 0.05$). There was also a significant improvement on the proctoscopic appearance ($P < 0.001$). However, there was no statistical difference between the two groups in terms of wound mucosal discharge. Two patients experienced minor bleeding at the 8th week in Diosmin group, and underwent surgery.

CONCLUSION: Diosmin is effective in alleviating post-operational symptoms of haemorrhoids. Therefore, it should be considered for the initial treatment after haemorrhoid surgery. However, further prospective randomized trials are needed to confirm the findings of this study.

INTRODUCTION

Hemorrhoid is one of the most common anorectal disorders. Although haemorrhoidectomy is considered as a minor inpatient procedure, it is usually associated with significant postoperative complications, including pain, bleeding, heaviness, pruritus, mucosal discharge and anal stenosis, resulting in a protracted period of recovery. The Milligan-Morgan open haemorrhoidectomy is the most widely practiced surgical approach for the management of hemorrhoids and is considered the "gold standard". Hemorrhoids are divided into 4 stages depending on symptoms and degree of prolapse. The 3rd and 4th stages are indicated for Milligan-Morgan open haemorrhoidectomy. Hemorrhoidectomy is usually associated with considerable pain, bleeding, and mucosal discharge after operation^[1], which seem to be multifactorial, such as individual tolerance, mode of anesthesia, postoperative analgesics, and surgical technique^[2].

Pain is a major postoperative complication after haemorrhoidectomy. Although Longo's procedure (the procedure for prolapse and hemorrhoids, PPH) has been widely used in recent years, it can also be confronted with the postoperative management dilemma after the procedure. A Meta-analysis comparing the PPH procedures and open haemorrhoidectomy did not show any significant differences in terms of post-operative pain. Although the post-operative bleeding and blood loss were significantly lower in the PPH group, there was no statistical difference in the aspect of other complications such as pain, pruritus, and mucosal discharge. In identifying approaches to reduce the symptoms after haemorrhoidectomy, published studies have mainly focused on the choice of surgical technique or the prevention of secondary infection in the wound^[3-8]. The superiority of stapled haemorrhoidectomy in terms of less post-operative pain and quicker recovery was confirmed by a more recent systematic review of 25 randomized trials that compared stapled haemorrhoidectomy and conventional haemorrhoidectomy^[9]. However, the control

of hemorrhoid symptoms is not striking. Both open and closed haemorrhoidectomy have been evaluated in terms of postoperative pain. Two predominant factors responsible for post-operative pain include discomfort from the surgical wound in the sensitive anoderm as well as perianal skin and edema from tissue inflammation around the wound^[10]. Alleviation of pain from the surgical incision should be achieved by minimizing tissue dissection and using different electrosurgical devices, such as diathermy, Harmonic scalpel[®], and ligature[™], which diminishes thermal injury to the subjacent tissues^[11]. For reduction of pain from the open wound of haemorrhoidectomy, various kinds of medication, including metronidazole, glyceryl trinitrate (0.2%), steroids, local anesthetics (bupivacaine), anti-inflammatory drugs, hemorrhoid creams, are being used with variable outcome^[11-13]. These studies indicated some limitations with these medications such as short duration of action and occurrence of serious side effects.

Postoperative bleeding is another important complication in hemorrhoids due to its frequency, which varies between 0.6% and 10%^[14,15]. Post-haemorrhoidectomy bleeding is commonly associated with the passage of a hard stool. Sometimes bleeding may be alarming, because it may cause anemia very rapidly in patients. The causes of post-operative bleeding are not easily explained: in some cases it should be attributed to falling off of a scar due to electrocoagulation, whereas in other cases it is due to the lack of a thrombus, its expulsion or its dissolution, concomitant with the falling or reabsorption of the transfixed stitch.

Diosmin, flavonoidic fraction, which is derived from some plants or the *flavonoid Hesperidin*, is promoted as a high-quality active ingredient in vein improvement supplements. Diosmin reduces inflammation and increases vein tonicity, two important factors that contribute to hemorrhoids. Researches indicate that Diosmin also appears to significantly shorten the duration of haemorrhoid bleeding as well as reduce the postoperative pain^[16]. A 2000 Italian study of 66 haemorrhoid patients reported that Diosmin decreased pain by 79% and bleeding by 67% during the first week of treatment, followed by an astonishing 98% and 86% reduction in these symptoms by the second week^[17]. After haemorrhoid surgery, flavonoids were found to relieve pain, bleeding and other symptoms more rapidly than standard antibiotic/anti-inflammatory treatment alone, with especially significant symptom relief during the first 3 d after surgery^[18].

This study was designed to evaluate the influence of Diosmin on reducing postoperative pain, bleeding, heaviness, pruritus, and mucosal discharge after the Milligan-Morgan open haemorrhoidectomy in a randomized, observer-blinded, placebo-controlled clinical trial.

MATERIALS AND METHODS

Study design

Protocol synopsis for this trial and supporting CONSORT checklist were used as supporting information

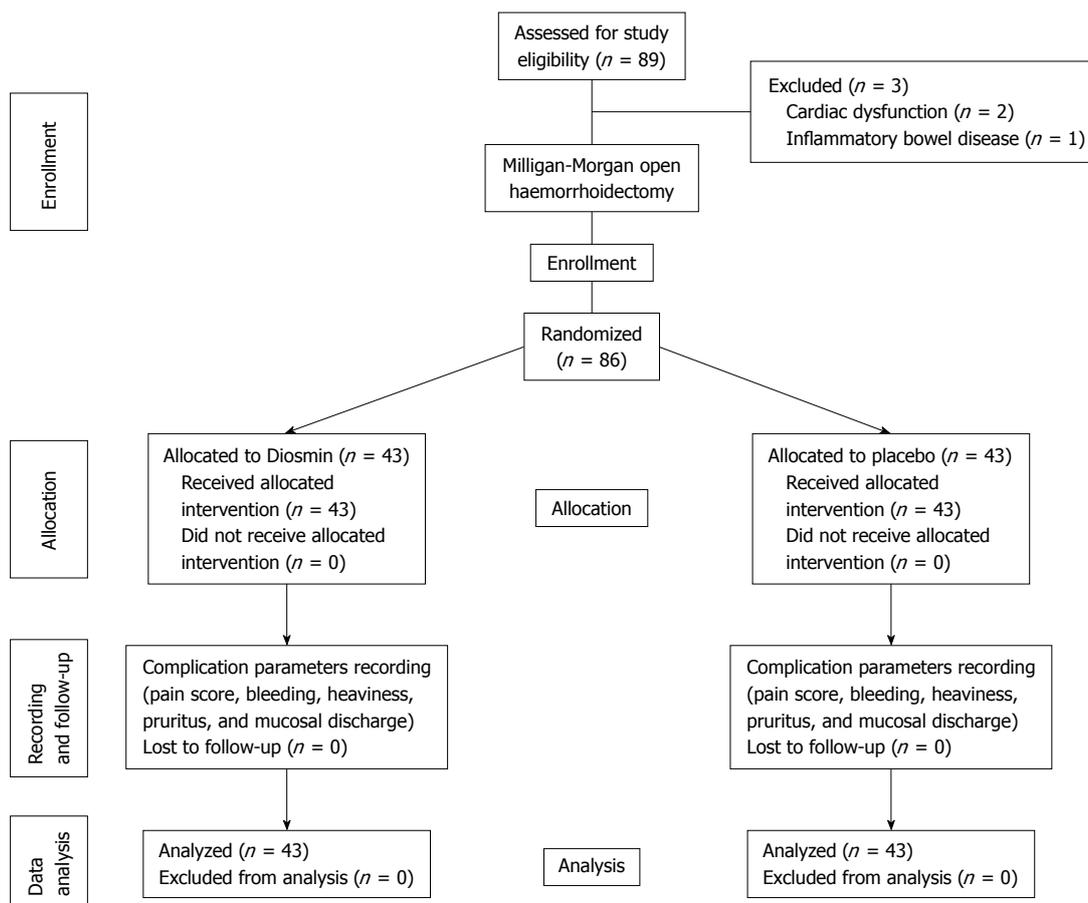

Table 1 Demographic data in Diosmin and control groups

| | Diosmin group ¹ (n = 43) | Control group ² (n = 43) | P value |
|--|--|--|---------|
| Mean age(yr) | 53.2 (11.2) | 51.3 (10.4) | 0.6332 |
| Male/female ratio | 26/17 | 24/19 | 0.6620 |
| No. of resected hemorrhoids | 3.4 ± 0.4 | 3.8 ± 0.5 | 0.1522 |
| Grades III/IV hemorrhoids | 33/10 | 29/14 | 0.9247 |
| Mean duration of hemorrhoidal disease (mo) | 21.6 (12.6) | 22.8 (14.5) | 0.6821 |
| Operating time (min) | 15.8 (1.9) | 16.9 (1.5) | 0.1295 |

(Figure 1). Diosmin clinical trial was a phase II randomized, prospective, observer-blinded, placebo-controlled clinical trial.

Inclusion/exclusion criteria

Patients aged 12-75 years with an indication for haemorrhoidectomy were eligible for the study, provided that they met the following inclusion criteria: symptomatic and prolapsing hemorrhoids Grade III or IV and informed consent. Patients complicated with fistula or anal fissure, inflammatory bowel disease, dermatitis, proctitis, pregnancy or severe cardiovascular state or pulmonary complication were excluded from the study.

Patients

The study was conducted using a computer-randomized design. A total of 86 consecutive patients with the grades III and IV acute mixed hemorrhoids admitted to Anorectal Surgical Department of First Affiliated Hospital, Xinjiang Medical University from April 2009 to April 2010, were enrolled in this study. Demographic data (age and gender), disease grades, preoperative constipation status, mean duration of disease, operating time and number of resected piles were recorded for each patient. There were no statistical differences between the two groups in these aspects (Table 1).

Medical and research ethics

The trial was conducted in accordance with the principles of the Declaration of Helsinki^[19], the Guidelines for Good Clinical Practice (GCP) for Trials on Pharmaceutical Products^[20]. The study protocol was approved by China governmental law and local regulations of Xinjiang Uygur Autonomous Region. This study was also conducted according to a protocol approved by the Medical Ethics Committee of First Affiliated Hospital of Xinjiang Medical University. Informed consent was obtained from all the patients or their relatives before the trial. The whole study consisted of two periods of observation (4 wk for each period). The last visit should be terminated in 90 d after operation.

Formal written informed consent was obtained from each patient after the preliminary assessment of patient's detailed history of the disease and general and systemic examination. The patients were subjected to a few baseline investigations (haemoglobin, bleeding time, clotting time, urine complete examination). They were randomly subjected to Diosmin or placebo depending on their choice, after discussing the advantages and disadvantages of both drugs with them. The study was "blind" and the observers evaluating the complication symptom parameters were unaware of the individual treatment schedules. Blinding and coding of the drugs were done by an independent monitor who was not an investigator after repacking the look-alike capsules by a pharmaceutical company in Xinjiang. The codes were broken only after completion of the study.

Surgery

Two fixed anorectal surgeons performed all the procedures with the patient in the supine lithotomy position or jackknife position. All patients underwent proctoscopy in order to exclude other diseases in the rectum before surgery. The operations were carried out under spinal anesthesia with 15 mL bupivacaine with 1:200 000 adrenalin. Further 5 mL of the same solution was used to dissect the haemorrhoidal nodules from the internal sphincter. Except 3 patients, who had a considerable rectal mucosal prolapse and were treated with stapled haemorrhoidopexy, all the patients underwent the standard Milligan-Morgan haemorrhoidectomy.

We removed the haemorrhoidal nodule using an upside-down V-shaped incision on the anal dermis, without widening the surgical wound while approaching the sphincters. This was done in order to maintain ample mucous membrane bridges. Possible secondary nodules were removed through submucosa. Ligature of the vascular pedicle was performed clear of the internal sphincter. The extent of surgical incision was tailored according to the number of haemorrhoidal complexes. Hemorrhoids were excised to the anorectal junction or dentate line. The intervening skin and anoderm bridges were preserved adequately. Coagulation with electrotome on the anal sphincters was avoided for all patients. The edges of the residual surgical wound have to be as sharp as possible. No packs were left in the anus postoperatively. After operation, patients in both groups were prescribed fiber supplements and naproxen sodium 550 mg tablets or intramuscular pethidine (1 mg/kg body weight) as required. All patients were also advised to gently shower their perianal wounds with lukewarm water twice daily, and after bowel movements. The data concerning the complications were compared between the two groups of patients. No antibiotic prophylaxis or any kind of analgesics has ever been administered.

Randomization

Computer-based sequential method was used for the randomization at the completion of surgery into one of the

two groups. This computer generated random codes used for envelopes containing the information "Diosmin" or "Placebo". These envelopes were prepared by a statistician who was not involved the patient's treatment or other work specific to the study. The computer randomization was completed in the Medical Statistical Center of Xinjiang Medical University.

Diosmin treatment

All patients were routinely discharged on the first postoperative day unless otherwise clinically indicated. Eighty-six patients each were either given Diosmin 500 mg or received placebo medication according to the computer-randomized result. Diosmin 500 mg was given at a dose of 3 tablets twice daily, after meals, for 3 d followed by 2 tablets twice daily from day 4 to day 7. Each complication symptom was recorded at hours 6 and 12 and on days 1, 2, 7 and 14 after operation. On the 7th day, the symptoms and any relief were recorded and the dose was further reduced to one tablet twice daily for the next 15 d. Consequent follow-ups were made on days 15, 30 and 90.

Assessment of postoperative symptoms

The Milligan-Morgan open haemorrhoidectomy was performed by a standardized diathermy excision method. Diosmin was started on the 6th day after surgery. A standardized questionnaire was completed which included postoperative information about pain, bleeding, heaviness, pruritus, wound edema and mucosal discharge. The evolution of these symptoms during the postoperative period was assessed by means of patient's self-questionnaires. Two predominant observatory parameters were postoperative pain and bleeding. Pain was assessed using verbal response and visual analog scale at hours 6 and 12 and on days 1, 2, 7 and 14, respectively after operation. The verbal response scales had four options: no pain, mild pain, moderate pain, and severe pain. The visual analogue scale consisted of a 10-cm line with the words "no pain" on the left hand side and "worst pain imaginable" on the right. Two types of pain were assessed, pain on defecation and pain during the preceding 24 h. The scales for pain on defecation were completed immediately after defecation and the scales for 24 h pain completed each evening. In order that pain could be assessed for seven postoperative days, patients were asked to complete the forms at hospital. Patients were discharged from hospital at the discretion of their consultants.

The use of narcotic drugs, antibiotics and laxatives, complication symptoms and hospital stay in all the patients were recorded after surgery. At the conclusion of the study, the codes were broken and the results were analyzed. The visual analogue scores were measured in cm, and the score for each 24 h was a single value. The score for pain on defecation was the mean value of scores during that day.

Statistical analysis

Before initiating the trial, sample size was calculated us-

Table 2 Postoperative course of Diosmin and control groups

| | Diosmin group ¹ (n = 43) | Control group ² (n = 43) | P value |
|---|--|--|---------|
| Median hospital stay (d) | 6.1 (1.3) | 7.3 (3.4) | 0.0306 |
| Median time to first bowel action (h) | 48 (4.2) | 56 (4.6) | 0 |
| Median No. of bowel actions in the first week | 9 (2.3) | 14 (3.1) | 0 |

¹Patients treated with Diosmin; ²Patients treated with placebo drug. P value was the result of Mann-Whitney U test.

Table 3 Postoperative symptoms of Diosmin and control groups n (%)

| | Diosmin group ¹ (n = 43) | Control group ² (n = 43) | P value |
|-------------------|--|--|---------|
| Minor bleeding | | | |
| At 2 wk | 3 (6.97) | 11 (25.58) | 0.0409 |
| At 8 wk | 2 (4.65) | 3 (4.64) | 0.6449 |
| Heaviness | | | |
| At 2 wk | 4 (9.30) | 14 (32.56) | 0.0171 |

¹Patients treated with Diosmin; ²Patients treated with placebo drug.

ing SPSS software 15.0 version. A power calculation estimated that 40 patients would be needed in each group to demonstrate a reduction of 20% pain with a power of 80% and at a 5% significance level. Discrete variables were analyzed using χ^2 test with Yates correction when appropriate. Continuous variables were analyzed by Wilcoxon signed tests for paired observations. Pain scores at each time interval were compared between groups with Wilcoxon's rank-sum test (nonparametric analysis of ranked data). A two-tailed Spearman's correlation coefficient was calculated where indicated. Statistical significance was assumed when $P < 0.05$. Statistical evaluation was done as intend-to-treat analysis. When not otherwise specified, data were presented as median and range.

RESULTS

After standard hemorrhoid surgery, 86 patients were allocated to receive Diosmin (experimental group, $n = 43$) and placebo capsules (control group, $n = 43$). None of the patients in either study group complained of any severe symptoms during the 90-d follow-up after treatment. The two groups were well matched for age, sex, disease grades, and number of piles. There were no statistical differences between the two groups in these aspects (Table 1).

The Diosmin group defecated earlier ($P = 0.00$), had more frequent bowel actions in the first postoperative week ($P = 0.00$), and had a shorter hospital stay ($P = 0.03$)

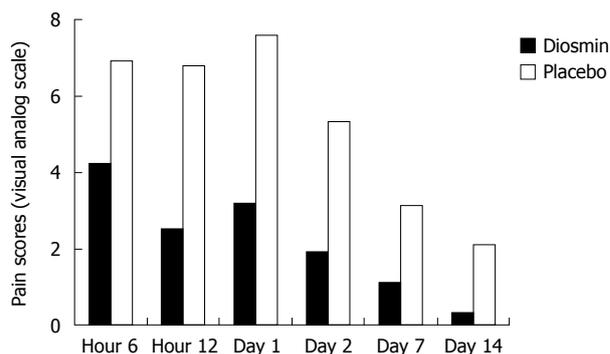

Figure 2 Postoperative pain scores in Diosmin and placebo groups. Pain scores ranged from 0 (no pain) to 10 (very severe pain).

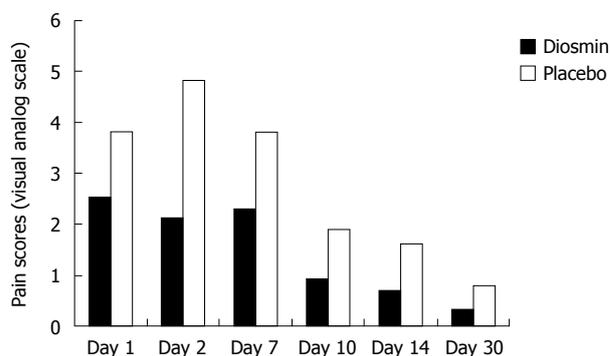

Figure 3 Pain on defecation in Diosmin and placebo groups. Pain scores ranged from 0 (no pain) to 10 (very severe pain).

compared with the placebo group (Table 2). No patient withdrew from the study because of any complaints. Significantly more placebo patients were troubled by minor rectal bleeding at 2 wk, although these rates were similar at 8 wk. The follow-up after 8 wk found that two patients experienced minor bleeding in Diosmin group, and therefore, underwent surgery. There was a statistically significant ($P < 0.05$) improvement in pruritus and heaviness at both 2 and 8 wk (Table 3). In addition, there was no statistical difference between the two groups in terms of wound mucosal discharge.

Patients in Diosmin group experienced significantly less pain at 6 and 12 h after surgery ($P = 0.03$, $P < 0.01$), and on days 1, 2, 7, 10, and 14 ($P = 0.02$, $P < 0.01$, $P = 0.02$, $P = 0.03$, $P < 0.01$) (Figure 2). There was also significant ($P < 0.001$) improvement on the proctoscopic appearance. Patients in the experimental group had significantly less defecation pain compared with the placebo group on days 1, 2, 7, 10, 14, and 30 ($P = 0.03$, $P < 0.01$, $P < 0.01$, $P = 0.02$, $P = 0.04$, $P = 0.04$) (Figure 3). No significant Diosmin-related complications or allergic reactions were reported by any patient. A similar number of patients reported burning with both treatments at the 2nd week after surgery (3 in Diosmin and 2 in placebo).

DISCUSSION

Haemorrhoid is a common disease affecting people of

all ages and both sexes. It is estimated that 50% of the people older than 50 years have hemorrhoid symptoms at least for a period of time. The causes of haemorrhoidal disease are multiple, but most are attributable to difficult passage of stool or constipation. Over the last few years, there has been increasing attention on surgical procedures to treat haemorrhoids. Several comparative studies have been performed to evaluate the available procedures to treat grades II, III, and IV hemorrhoids, and new surgical techniques, such as haemorrhoidectomy with Harmonic scalpel[®][21-23] and LigasureTM[24], Doppler-guided haemorrhoidal plexus ligation^[25,26] and the stapled haemorrhoidopexy^[27-31]. The most recent medium- and long-term studies on ample case series provide data on the efficacy, the results and complications of these techniques^[24-31]. None of them proved to reduce complications such as pain and bleeding^[21]. The ideal method should combine the high safety and efficacy of the treatment, yielding low postoperative pain and bringing comfort to the patients. Such considerations are related to the severity of the disease and can be addressed by evidence-based medicine by randomized, controlled trial. According to a recent meta-analysis of the Cochrane library^[32,33], conventional haemorrhoidectomy as first described by Milligan and Morgan, is still the most widely used, effective, and definite surgical treatment for patients with symptomatic grades III and IV haemorrhoids. However, it is associated with significant postoperative complications such as pain, bleeding and mucous discharge. Although there is a consensus on the treatment of grades III and IV haemorrhoids, there is still confusion regarding the ideal treatment for these complications after surgery.

In 1971, Daflon, consisting of 90% Diosmin and 10% Hesperidin (Daflon 500; Serdia Pharmaceuticals, India and Vinosmin; Elder Pharmaceuticals, India), was firstly introduced in France by Bensaude *et al*^[34] for the treatment of haemorrhoids and other capillovenous diseases. Diosmin mainly works on the inflammatory pathology of haemorrhoids by increasing the contraction of veins and local lymphatic drainage and decreasing the synthesis of prostaglandins such as PGE2 and thromboxane B2^[35-37]. The anti-inflammatory effects of Diosmin are reflected in the reduction of capillary hyperpermeability and fragility in controlled clinical studies. Damom *et al*^[38] found the same effects of Diosmin in increasing the duration of vascular contraction and prostaglandin components which are responsible for the inflammatory process. Diosmin also increases the local lymphatic drainage. Side-effects of the drugs are limited according to Meyer^[39] who was first used Diosmin to treat hemorrhoid symptoms. He reported mild gastrointestinal and autonomic disturbances in 10% cases. A fixed micronized combination of the citrus bioflavonoids Diosmin (90%) and hesperidin (10%) has been widely used in Europe to treat diseases of the blood vessels and lymphatic system since 2000. The combination also appears to be beneficial for chronic venous insufficiency and venous stasis ulcers. Extensive safety evaluations have found that Diosmin/hesperidin was free

from toxicological risk. From 2005, Diosmin was used to treat vascular diseases^[40-45]. The obtained evidence strongly supports its use in haemorrhoids in recent years although only several randomized controlled trials were available.

In this randomized trial, we concluded that Diosmin leads to the rapid cessation of haemorrhoidal bleeding, alleviation of the associated symptoms and gives objective relief from complications of post-haemorrhoidectomy. This result is similar to Mlakar's study^[46]. In their study, Flavonoids was found very effective in the first 30 d of treatment and led to the rapid relief of various associated symptoms of haemorrhoid surgery. Because, up to now, there have only a few randomized controlled studies to investigate the effectiveness and safety of Diosmin to treat symptoms after haemorrhoidectomy in the world, we could not perform meta-analysis for these studies. In our study, Diosmin was more effective to control postoperative pain than placebo capsules during the early phase of the surgery. This is a highlight in our study. The Diosmin group defecated earlier ($P < 0.05$), had more frequent bowel actions in the first postoperative week ($P < 0.05$), and had a shorter hospital stay ($P < 0.05$) compared with the placebo group. This is and a striking result compared with Mlakar's study^[46]. In spite of some minor bleeding, no patient withdrew from the study because of any kind of adverse events. This may be associated with proper drug usage after surgery, especially in the early phases. Significantly more placebo patients were troubled by minor rectal bleeding at 2 wk, although these rates were similar at 8 wk. However, during the follow-up after 8 wk, we found that two patients had minor bleeding in experimental group, therefore, they underwent surgery. Postoperative bleeding is a particularly important complication in hemorrhoids treatment due to its frequency varying between 0.6% and 10%^[15,47]. Sometimes bleeding may be alarming, because it may cause anemia very rapidly in the patients. Several randomized controlled studies evaluated the use of oral micronized, purified flavonoid fraction in the treatment of haemorrhoidal bleeding. In these studies, bleeding was relieved rapidly, and no complication was reported. This is somewhat conflict with our bleeding cases. However, we used 500 mg Diosmin capsules compared with 450 mg micronized purified flavonoid fraction in Yo YH's study^[16]. The most important reason of our poor result related with bleeding is that we included grades III and IV piles, but Yo YH's study included only grades I, II, and III piles. A similar study of 100 patients reported that acute bleeding had subsided by the third day of treatment in 80% of patients receiving micronized flavonoids, 2 d sooner than in patients receiving a placebo. But, the different points compared with our trial, which were also disadvantages of their studies, were associated with the difference of their study designs. They compared micronized flavonoids medication with hemorrhoid surgery itself. Although we think Milligan-Morgan open haemorrhoidectomy is the most widely practiced "gold standard" surgical approach and the stages III and IV are the clear indication for this procedure, it is not necessary to alter the

indication for hemorrhoid surgery to medication. Another point is the cost of medication. A limitation of the drug is the lack of patient compliance due to the long duration of treatment and the high cost of the drug. The safety of the drug has already been proved but more studies need to be done to see if the total dose of Diosmin can be increased so as to increase the response rate and decrease the duration of postoperative treatment. A decrease in the cost of the drug should also be considered.

Purified flavonoid fraction is a botanical extract from citrus. It exerts its effects on both diseased and intact vasculature, increasing vascular tone, lymphatic drainage, and capillary resistance; it is also assumed to have anti-inflammatory effects and promote wound healing. In another recent randomized controlled trial, postoperative use of micronized, purified flavonoid fraction, in combination with short-term routine antibiotic and anti-inflammatory therapy, reduced both the duration and extent of postoperative symptoms and wound bleeding after haemorrhoidectomy, compared with antibiotic and anti-inflammatory treatment alone^[18].

Postoperative pain is the most important unacceptability which was also our predominant observatory parameter. Post haemorrhoid pain is difficult to assess, though verbal response scales and visual analogue scales are recognized methods. Maxwell concluded that the *t* test is "very robust" when comparing differences between visual analogue scale scores^[48], and we therefore used this method of analysis. On two occasions, the verbal response scale in pain was a day less than the visual analogue scale. This may be because the discrete verbal response scale is less sensitive than the continuous visual analogue scale. Another highlight in our study was that patients in Diosmin group experienced significantly less pain at hours 6 and 12 ($P < 0.05$), and on days 1, 2, 7, 10, and 14 after surgery ($P < 0.05$). At the same time, patients in the experimental group had significantly less defecation pain compared with placebo groups on days 1, 2, 7, 10, 14 and 30 after surgery ($P < 0.05$). The exact cause of pain after haemorrhoidectomy has not yet to be defined. Various factors believed to be responsible for the pain including incarceration of smooth muscle fibers and mucosa in the transfixed vascular pedicle, epithelial denudation of the anal canal, and spasm of the internal sphincter^[3]. Another reason for pain could be the development of linear wounds extending up to the anorectal ring, which appear similar to those of a chronic anal fissure^[18]. Postoperative pain was also associated with bacterial fibrinolysis and defecation stress^[49]. In our study, postoperative pain in the placebo group can be explained by the traction of the nonsensitive sliding haemorrhoidal tissue at the highly sensitive anal skin. The diminished postoperative pain in the Diosmin group might be related to its capillary resistance and diminished tissue edema and anti-inflammatory process. There was significant difference in different postsurgical days and weeks. Based on these results, we suggested that Diosmin has a clear action against anorectal postoperative pain. Therefore, it should be considered

initially for patients presenting with haemorrhoidal symptoms after surgery. In addition, there was also a significant improvement on the proctoscopic appearance ($P < 0.001$).

Although there was a statistically significant improvement in heaviness and pruritus from baseline to the 8th week postoperatively, however, there were no statistical differences between the two groups in terms of wound mucosal discharge ($P < 0.05$). Our hypothesis was that our nonabsorbable suture used for internal mucosa ligation is responsible for this poor result.

In a 12-wk study of 50 pregnant women suffering from acute hemorrhoids, micronized Diosmin/hesperidin therapy was reported to be a "safe, acceptable and effective" treatment, and 66% obtained relief from symptoms within 4 d^[50]. However, we suggest not using Diosmin for pregnant women, considering Diosmin is a new alternative for hemorrhoids.

This study has shown that Diosmin can reduce the complications from haemorrhoidectomy, especially in the early phase. We therefore suggest that this regimen should be a part of the routine postoperative management of patients for haemorrhoidectomy.

In conclusion, Diosmin (flavonoid fraction) has shown to be effective in alleviating symptoms after haemorrhoidal surgery and improving the proctoscopic appearance. Therefore, it should be considered initially for patients presenting with haemorrhoidal symptoms after surgery. However, further prospective randomized trials and longer follow-up are needed to confirm the findings of this study and observe the side effects of this drug.

COMMENTS

Background

Over the past few years, there has been increasing attention on surgical procedures to treat haemorrhoids. The Milligan-Morgan haemorrhoidectomy is still a major surgical approach for haemorrhoids. This study was designed to evaluate the influence of Diosmin on reducing postoperative pain, bleeding, heaviness, pruritus, and mucosal discharge after the Milligan-Morgan open haemorrhoidectomy in a randomized, observer-blinded, placebo-controlled clinical trial.

Research frontiers

Phlebotropic activity, protective effect on the capillaries and the anti-inflammatory effect of Diosmin have been reported in several studies in recent years. More recent clinical studies showed that flavonoid fraction such as Dalfon (phlebotropic agent) can reduce postoperative pain, bleeding and heaviness after haemorrhoidectomy.

Innovations and breakthroughs

This clinical trial has confirmed that Diosmin (flavonoid fraction) can reduce postoperative pain, bleeding and heaviness after Milligan-Morgan open haemorrhoidectomy.

Applications

Diosmin (flavonoid fraction) has shown to be effective in alleviating symptoms after haemorrhoidal surgery and improving the proctoscopic appearance. Therefore, it should be considered initially for patients presenting with haemorrhoidal symptoms after surgery. However, further prospective randomized trials and longer follow-up are needed to confirm the findings of this study and observe the side effects of this drug.

Terminology

Diosmin is derived from some plants or used as a high-quality active ingredient in vein improvement supplements. Diosmin reduces inflammation and increases duration of vascular contraction that contributes to hemorrhoids.

Peer review

The authors engagingly described a pathomechanism of anal pain after haemorrhoidectomy and Diosmin's action. The article is worth publishing.

Abstract

AIM: To investigate glucose homeostasis and in particular gluconeogenesis in a large animal model of acute liver failure (ALF).

METHODS: Six pigs with paracetamol induced ALF under general anaesthesia were studied over 25 h. Plasma samples were withdrawn every five hours from a central vein. Three animals were used as controls and were maintained under anaesthesia only. Using ^1H NMR spectroscopy we identified most gluconeogenic amino acids along with lactate and pyruvate in the animal plasma samples.

RESULTS: No significant changes were observed in the concentrations of the amino acids studied in the animals maintained under anaesthesia only. If we look at the ALF animals, we observed a statistically significant rise of lactate ($P < 0.003$) and pyruvate ($P < 0.018$) at the end of the experiments. We also observed statistically significant rises in the concentrations of alanine ($P < 0.002$), glycine ($P < 0.005$), threonine ($P < 0.048$), tyrosine ($P < 0.000$), phenylalanine ($P < 0.000$) and isoleucine ($P < 0.01$). Valine levels decreased significantly ($P < 0.05$).

CONCLUSION: Our pig model of ALF is characterized by an altered gluconeogenetic capacity, an impaired tricarboxylic acid (TCA) cycle and a glycolytic state.

INTRODUCTION

Acute liver failure (ALF) is a clinical syndrome defined by massive cell death in the absence of chronic liver disease, resulting in hepatic encephalopathy^[1]. Although brain oedema and brain herniation are common causes

of death in ALF multi organ failure is also common^[2,3]. Previous studies have shown that metabolic pathways are affected in ALF and systemic changes in metabolite levels could be the pathophysiological reason behind multi organ failure in ALF^[4-6].

Orthotopic liver transplantation remains the most widely accepted treatment for ALF^[1,2,7]. Chronic donor shortages however, motivate the search for alternative non-surgical therapies. In that quest animal models of ALF play an important role. Most studies have explored mouse models of ALF which although useful do not adequately address the issue^[4-6]. We have recently developed in our laboratory a porcine model of paracetamol induced ALF^[7]. It is characterized histologically by severe centrilobular necrosis with coagulative necrosis. The animals invariably develop acidosis, hypoglycaemia, coagulopathy and acute renal failure.

Acidosis could be explained by lactate production and energy depletion in the liver of our animal model^[5]. Coagulopathy is due to loss of production of factors of the coagulation cascade namely Factors V and VIII^[8]. Acute renal failure is a characteristic of paracetamol overdose. Often patients develop acute renal failure through toxic injury and require dialysis in that setting without serious liver injury^[9].

The hypoglycaemia observed in our model is a hallmark of disrupted hepatic glucose metabolism. Studies on other animal models of ALF and cirrhosis have shown that, despite a relative glucose homeostasis, there is a decrease in gluconeogenesis and tricarboxylic acid (TCA) cycle coupled with an increase in lactate production^[6,10-12].

We hypothesized that there was a loss of gluconeogenic capacity in our large animal model with an increase in lactate production, an inhibited TCA cycle and a switch to glycolysis during injury to compensate for energy demands.

MATERIALS AND METHODS

Animals

Large white pigs (median body mass 35 kg) were used for this study. Animal experiments were performed in accordance with the Home Office regulations under the Animal (Scientific Procedures) Act 1986 as per Project Licence 60/2389. All animals received humane care and study protocols complied with our institution's guidelines.

Our experimental model was described in detail elsewhere^[7]. Briefly animals were anaesthetized with ketamine and midazolam as induction agents and maintained with isoflurane and nitrous oxide. Animals were hydrated with normal saline and glucose. All animals received similar amounts of glucose. Haemodynamic variables and intracranial pressure were continuously monitored.

Animals were pretreated with phenobarbital 20 mg orally for 5 d to induce cytochrome P450 activity. In six animals intravenous paracetamol was administered while the three animals used as controls were monitored but did not receive any paracetamol. A loading dose of paracetamol was administered by intravenous infusion (0.1875 g/kg) followed by an infusion for 12 h (1.8 mg/kg per min). Ex-

periments lasted 28 h and at that time point any surviving animals were euthanized.

Sample preparation for NMR spectroscopy

Samples were prepared by adding a D₂O solution of (150 μ L) to plasma (600 μ L) thus providing an internal field frequency lock for the spectrometer. As a reference substance 20 μ L of sodium 3-(trimethylsilyl) 2, 2, 3, 3-2H₄-1 propionate (TSP) were added to the plasma. Chemical shifts were referenced internally to the singlet methyl resonance of TSP at zero ppm.

The following potentially gluconeogenic amino acids were quantified by NMR: leucine, isoleucine, valine, tyrosine, phenylalanine, histidine, methionine, alanine, threonine, glutamate and glutamine. Lactate, pyruvate and the gluconeogenic amino acids were measured to provide information on glycolysis and gluconeogenesis.

Proton NMR spectroscopy

¹H-NMR spectra were measured from plasma samples taken from a large central vein at 5 hourly intervals until the experiments were terminated at $t = 28$ h. Data were acquired on a Varian INOVA 600 NMR Spectrometer operating at 600 MHz for protons. All spectra were acquired at ambient probe temperature (298 ± 0.2 °K). For each sample 128 transients (FID's) were acquired into 32 K complex data points over a spectral width of 6 KHz. 300 pulses were applied with an acquisition time of 2.5 s to achieve better resolution followed by an additional pulse recycle time of 4 s to allow for complete T₁ relaxation. Water signal suppression was achieved by applying a gated secondary irradiation field at the water resonance frequency. Spectral assignments were made by reference to literature values of chemical shifts in various media and biological fluids and coupling constants^[13]. The coefficient of variation between samples was < 6% and reproducibility for the same sample was good with a difference of < 2% on the same sample. The CPMG (Carr-Purcell-Meiboom-Gunn) sequence was applied for data acquisition, as this sequence enabled observation of a flat baseline in our spectra from plasma samples by minimising the signals acquired from macromolecules present in the plasma such as proteins and lipoproteins^[14]. NMR spectra analysis was performed using the MNova platform for NMR analysis (Mestrelab, Santiago de Compostela, Spain).

Statistical analysis

To compare between groups in the initial sample the Student's *t*-test for parameters with non-missing values and the Mann Whitney *U* test for parameters with missing values were used. Values were expressed as mean (range and standard error). A *P* value of < 0.05 was taken as statistically significant (two-tail test of significance). Numeric results are expressed as μ mol/L. All analysis was done using the SPSS statistical package (Version 9.0).

RESULTS

On all samples studied we were able to identify the fol-

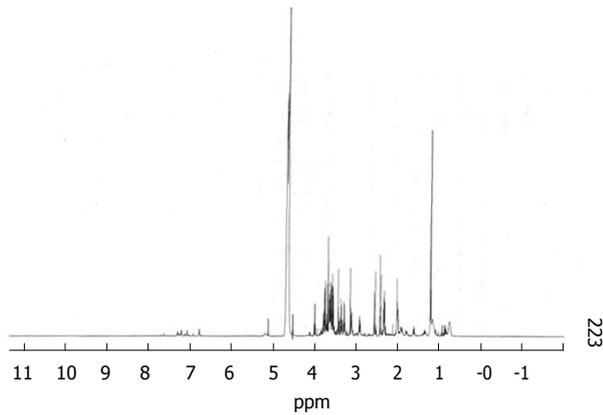

Figure 1 A representative ¹H-NMR spectrum of plasma taken at *t* = 15 h from one of the acute liver failure animals. Relevant peaks identified and used for analysis are as follows: Lactate CH₃ @1.33 ppm doublet Pyruvate CH₃ @ 2.38 ppm singlet; Alanine CH @1.48 ppm doublet Threonine CH₃ @ 1.34 ppm doublet; Glycine CH₂ @ 3.57 ppm singlet Leucine CH₃ @ 0.96 ppm triplet; Isoleucine CH₃ @ 1.01 ppm doublet Valine CH₃ @1.04 ppm doublet; Tyrosine H₃/H₅ @ 6.91 ppm PhenylalanineH₄ @ 7.38 ppm multiplet doublet.

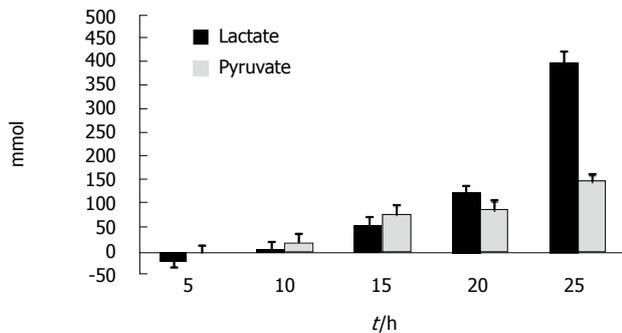

Figure 2 There was a net increase of lactate and pyruvate concentrations during the experiments.

lowing metabolites: lactate, pyruvate, leucine, isoleucine, valine, tyrosine, phenylalanine, histidine, arginine, glycine, alanine, threonine, glutamate and glutamine. Resonances from proline, methionine and ornithine were not suitably characterised and results from those amino acids are not available. Figure 1 shows a sample spectrum.

In control pigs there were no significant differences in the concentrations of the substrates studied at any time point sampled. Animals who received paracetamol showed statistically significant differences in the concentrations of lactate, pyruvate and the amino acids.

Lactate and pyruvate

Figure 2 shows the results for lactate and pyruvate. Increases in the concentration of lactate became significant at *t* = 15 h and at *t* = 25 h; compared to *t* = 0 an average increase of 405% was seen (*P* < 0.003). Increases in the concentration of pyruvate became significant at *t* = 20 h and at *t* = 25 h; compared to *t* = 0 an average increase of 150% was seen (*P* < 0.018).

Amino acids

Figure 3 shows the results for threonine, alanine and gly-

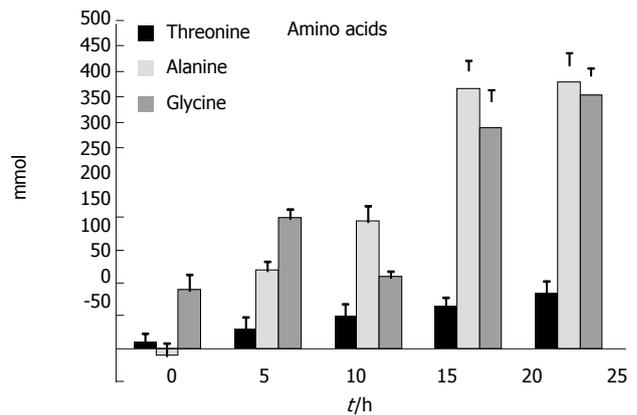

Figure 3 There was a net increase in the concentrations of alanine, threonine and glycine during the experiments.

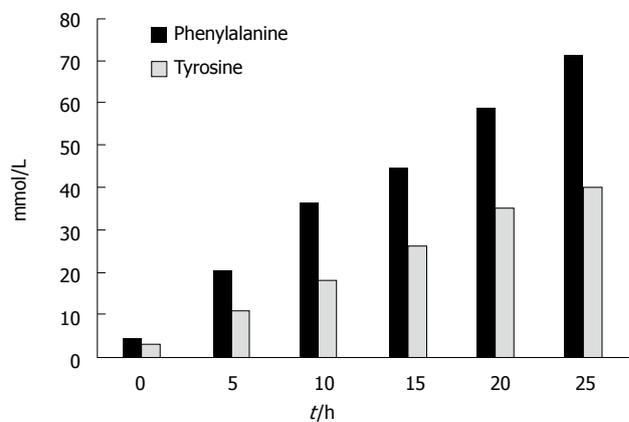

Figure 4 There was a net increase in the concentrations of tyrosine and phenylalanine during the experiments.

氨酸. Increases in the concentration of threonine became significant at *t* = 20 h and at *t* = 25 h; compared to *t* = 0 an average increase of 82% was seen (*P* < 0.048). Increases in the concentration of alanine became significant at *t* = 10 h and at *t* = 25 h; compared to *t* = 0 an average increase of 410% was seen (*P* < 0.002). Finally, increases in the concentration of glycine became significant at *t* = 5 h and at *t* = 25 h; compared to *t* = 0 an average increase of 390% was seen (*P* < 0.005).

Figure 4 shows the results for the aromatic amino acids. Tyrosine levels significantly increased at *t* = 5 h and at *t* = 25 h; There was an average increase of 1330% (*P* < 0.000). Phenylalanine levels also increased significantly at *t* = 5 h and at *t* = 25 h; There was an average increase of 1420% (*P* < 0.000).

Figure 5 shows the results for the branch chain amino acids. There were no statistically significant changes in the concentration of leucine between the beginning and the end of the experiments (0.17 ± 0.02 vs 0.175 ± 0.02). Isoleucine levels increased significantly at *t* = 10 h and at *t* = 25 h; an average increase of 250% was seen (*P* < 0.01). Valine levels, on the contrary, significantly decreased at *t* = 20 h and at *t* = 25 h; an average decrease of 150% was seen (*P* < 0.05)

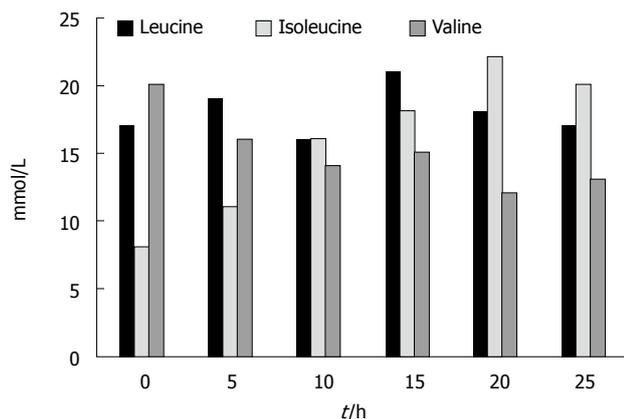

Figure 5 Isoleucine concentrations significantly increased during the experiments. Valine concentrations significantly decreased during the experiments. No changes were seen in the concentration of leucine.

No statistically significant differences were observed in the concentrations of glutamate, glutamine, arginine and histidine up to the end of the experiments.

DISCUSSION

In this study in a large animal model of paracetamol induced acute liver failure we have shown that glucose homeostasis is impaired with hypoglycaemia, increased concentrations of lactate and pyruvate and increased concentrations of most gluconeogenic amino acids.

It is common knowledge that patients with severe acute liver injury due to paracetamol overdose quickly develop hypoglycaemia. In contrast, most animal models of ALF do not develop hypoglycaemia. In ALF the hepatic production of glucose is inhibited but there is compensation by kidney gluconeogenesis^[4,5,14,15].

In our model the concentration of lactate, despite a temporary decline at the beginning of the experiments, increased quickly and was significantly increased at $t = 15$ h. Likewise, pyruvate concentration increased and that increase became significant at $t = 20$ h. This suggests that early on glycolysis is switched on in the liver. As paracetamol also affects the kidney and an early kidney toxic injury is usually seen in cases of paracetamol induced ALF^[16], attempted compensatory gluconeogenesis maybe occurring in the kidney but it is not sufficient to maintain normal glucose levels in this model of ALF.

We have also observed that major gluconeogenic amino acids were not taken up by the liver. Concentrations of alanine increased significantly throughout the study along with concentrations of threonine and glycine. Likewise the concentrations of the aromatic amino acids tyrosine and phenylalanine increased very early on and rose dramatically at the end of the experiments. This is in accordance with previous studies in mice that showed similar results^[4-6,17]. This is a good indication that gluconeogenesis in the liver is impaired and the TCA cycle is not functioning properly.

If we look at the branch chain amino acids the re-

sults are somehow different. No change was seen in the concentration of leucine and a decrease was observed in the concentration of valine. Significant increases at the end of the experiments were only seen in the concentrations of isoleucine.

ALF is characterized by the development of encephalopathy. In that respect Fischer's ratio (the ratio of branch chain to aromatic amino acids) is believed to be a good index^[18]. A decrease of the ratio is a good marker of severe hepatic encephalopathy. As we have shown previously in our model a significant decrease in the Fischer's ratio was observed by $t = 15$ h of the experiments^[7]. In a previous study we have shown that although in patients with non-paracetamol induced ALF all branch chain amino acids are increased, in patients with paracetamol induced ALF valine is an exception and decreases over time^[19]. We believe our results to be in accordance with this observation. We should point out though that the attempts to correct hepatic encephalopathy with correction of the Fischer's ratio by exogenous substitution of branch chain amino acids were not a success and the reason might lie in the fact that it is the aromatic and not the branch chain amino acids that are disturbed^[20].

An interesting finding was that we observed no significant changes in the concentrations of glutamate, glutamine, histidine and arginine, key metabolic components of the urea cycle. We unfortunately were unable to quantify aspartate but there is strong evidence that the urea cycle in this model remains largely unaffected by paracetamol poisoning. This is in accordance with other studies that have shown that ALF induced hyperammonemia is caused by gut production of ammonia, a by-product of the production of alanine from glutamate^[21]. Novel attempts to correct the metabolic abnormalities of hepatic encephalopathy by providing ornithine as a substrate for urea synthesis might be a good path^[22-25].

The major drawback of this study is that we performed a study that describes changes in amino acids that pertain to gluconeogenesis and that we assumed that the changes were provoked by the inhibition of gluconeogenesis by the acute liver injury. We had no means to exclude the possibility that some other metabolic function could be responsible for the observed amino acid disturbances.

In conclusion, in this large animal model of paracetamol induced ALF we have observed an inhibition of gluconeogenesis in the liver with subsequent dysfunction of the TCA cycle. This has led to ATP and energy depletion and the liver switching to glycolysis to compensate. Further studies in animals and also in humans are needed to fully characterize the metabolic abnormalities of liver failure and to provide a pathophysiological basis for the new emerging metabolically centred therapies for hepatic encephalopathy^[26].

COMMENTS

Background

Acute liver failure in humans is a deadly condition which could lead to multi-organ failure and death of the patient. Abnormalities in many metabolic

pathways are known to exist but there are very few large animal models where the authors are able to reproduce the acute liver injury. Recently the authors have developed such a porcine model in our laboratory.

Research frontiers

Paracetamol induced acute liver injury in humans and animal models is characterised by profound hypoglycaemia in a very short time from the liver injury. The exact mechanism of hypoglycaemia remains debatable.

Innovations and breakthroughs

In this article the authors were able to provide some evidence that gluconeogenesis is impaired in a porcine model of acute liver injury as manifested by a relative increase in the plasma concentrations of the gluconeogenic amino acids. Gluconeogenic amino acids are the main substrate for glucose production after the exhaustion of glycogen stock very early in the acute liver injury.

Applications

This paper provides some insight into the metabolism in acute liver failure. It shows that gluconeogenesis a key metabolic pathway in paracetamol induced acute liver failure fails, early on in the disease. This needs to be confirmed in human studies and it could have implications in the way these patients are managed.

Peer review

The article by Dabos *et al.* describes increased lactate, pyruvate and distinct amino acids in a pig model of paracetamol induced acute liver injury.

Abstract

AIM: To explore the feasibility of dual camera capsule (DCC) small-bowel (SB) imaging and to examine if two cameras complement each other to detect more SB lesions.

METHODS: Forty-one eligible, consecutive patients underwent DCC SB imaging. Two experienced investigators examined the videos and compared the total number of detected lesions to the number of lesions detected by each camera separately. Examination tolerability was assessed using a questionnaire.

RESULTS: One patient was excluded. DCC cameras detected 68 positive findings (POS) in 20 (50%) cases. Fifty of them were detected by the "yellow" camera, 48 by the "green" and 28 by both cameras; 44% ($n =$

22) of the "yellow" camera's POS were not detected by the "green" camera and 42% ($n = 20$) of the "green" camera's POS were not detected by the "yellow" camera. In two cases, only one camera detected significant findings. All participants had 216 findings of unknown significance (FUS). The "yellow", "green" and both cameras detected 171, 161, and 116 FUS, respectively; 32% ($n = 55$) of the "yellow" camera's FUS were not detected by the "green" camera and 28% ($n = 45$) of the "green" camera's FUS were not detected by the "yellow" camera. There were no complications related to the examination, and 97.6% of the patients would repeat the examination, if necessary.

CONCLUSION: DCC SB examination is feasible and well tolerated. The two cameras complement each other to detect more SB lesions.

INTRODUCTION

Small bowel video capsule endoscopy is an established

method for examining the small-bowel (SB). However, a recent systematic review of 227 studies showed that the examination's detection rate of positive findings (POS) (that explain the symptoms for which the test was performed and assist the further management of the patient) varies from 55.3% to 60.5% (overall 59.4%)^[1]. To increase the examination's diagnostic yield, several methods have been proposed, including the use of cathartics and prokinetics, changing body posture, repeating a negative exam, with varying results^[2].

Recently, a dual camera capsule (DCC) endoscope (PillCam Colon, Given Imaging, Yoqneam, Israel) designed for colon examination has been introduced to the market. This DCC is 6 mm longer than the conventional SB capsule (PillCam Small Bowel 2, Given Imaging, Yoqneam, Israel). Its specific technological properties include: two cameras - the "yellow" and the "green", enabling the device to acquire video images from both ends, optics with more than twice the coverage area of the small bowel capsule, automatic light control, a frame acquisition rate of four frames per second (double the rate of the SB capsule), and a total operating duration of approximately 10 h. After initial capsule activation and several minutes of image transmission, the capsule enters a delay mode of approximately 2 h, after which it spontaneously restarts the transmission of images. Similarly to the SB capsule, the system includes a sensor array and data recorder connected to the patient during the procedure. The recorded data are downloaded into the Rapid Viewer (Given Imaging, Yoqneam, Israel) workstation for review of the video. The reviewer can review images captured from each individual camera and from both cameras simultaneously^[3].

Given these properties, this capsule has the theoretical potential to detect more lesions than the conventional SB capsule during SB capsule examination. Whether this advantage is relevant clinically remains to be proven. The aim of our study was to explore the feasibility and tolerability of DCC SB imaging and to examine if the capsule's two cameras can complement each other to detect more SB lesions.

MATERIALS AND METHODS

Ethics

The study was approved by the Ethics Committees of both Hospitals and each participant gave informed consent.

Patients

This prospective, non-randomized, feasibility study on consecutive outpatients was conducted in two Academic Departments in Athens, Greece, over a 5-mo period from September 2008 to January 2009. We included 41 patients with indications for SB capsule endoscopy. Exclusion criteria were: known or suspected gastrointestinal obstruction, stricture or fistula, conditions associated with delayed capsule endoscopy gastric/small bowel transit time (i.e. diabetes mellitus), gastrectomy, pregnancy, paralysis

or impaired mobility, medication use that could affect gastrointestinal motility (i.e. prokinetics, antidepressants, anticholinergics, and narcotics) or mucosa visibility (iron, sucralfate), and renal impairment in which sodium phosphate is contraindicated.

Bowel preparation and DCC procedure

All patients received detailed written instructions on their bowel preparation. They ingested only clear liquids the day before the procedure and they fasted for 8 h overnight, prior to testing.

Capsule examinations started at between 8 and 10 o'clock the next morning. After its initial activation, the DCC remained beside the patients during the delay mode period. Patients ingested the DCC, after its definite re-activation, approximately 2 h later. Thereafter, patients were checked every 10 min with the Real Time Viewer (Given Imaging, Yoqneam, Israel) until the entrance of the capsule into the duodenum. At this time, they drank 45 mL of sodium phosphate (Phospholaxat, Pharma Line, Athens, Greece) and were advised to drink two liters of water during the following 2 h^[4]. This type of SB preparation has been shown to improve mucosa visibility during SB capsule endoscopy in a prospective, randomized, double blind study^[4] and it is the preferred preparation strategy in our Departments. Patients ate a light snack 4 h after DCC ingestion and they dined when recording ceased. Before discharge, patients were asked to fill a questionnaire, answering the following questions: (1) "Will you repeat the examination, if needed?" (yes - no); (2) "How comfortable were you during the examination" (very comfortable - comfortable - neither comfortable nor uncomfortable - uncomfortable - very uncomfortable); and (3) "Did you experience any unwanted symptoms during the examination?" (yes - no, if yes, please describe). In cases where the DCC had not been expelled before discharge, we advised patients to search for the capsule in their feces during the following days. In cases of capsule retention, patients were followed clinically and radiologically until capsule excretion.

Video review

Downloaded videos were first read locally for patients' clinical management and thereafter, they were coded and submitted to two investigators for video review and data analysis.

Both investigators had experience of at least 200 capsule endoscopy studies (SB and colon), they were aware of the study indication, but they were blinded to the results of the local review. They examined the videos independently, in random order, using the Rapid Reader, version 5.1 (Given Imaging Ltd, Yoqneam, Israel) software, as outlined below: (1) they rated the overall quality of SB mucosa visibility using a four steps scale: bad - fair - good - excellent^[5]; (2) they counted the POS and the findings of unknown significance (FUS)^[6] detected by either the "yellow" or the "green" camera only, or by both cameras. POS are those that explain the symptoms for which the test was performed, assist the further man-

agement of the patient, or are subsequently confirmed by other diagnostic modalities. Findings of uncertain significance (red spots, small erosions, lymphangiectasias, *etc.*) are those that fail to completely explain the symptoms, thus necessitating further investigation^[6]; and (3) they provided a diagnosis for each examination according to the “yellow” and “green” camera’s findings. In cases of disagreement, a decision was made by a third independent experienced investigator.

The tolerability of the examinations was assessed by the completed questionnaires. Any serious adverse events were also recorded.

Statistical analysis

The main results of the study are reported in descriptive manner. Qualitative data are presented as absolute and value percent and quantitative data are presented as median value (IQR).

Agreement between investigators for the quality of SB mucosa visibility and between the two cameras regarding diagnosis was assessed by κ statistics. Correlations were assessed by regression analysis. For these comparisons, a *P* value of < 0.05 indicated statistical significance.

RESULTS

We prospectively enrolled 41 consecutive patients who met the study’s criteria. In one patient, the capsule remained in the stomach for 9 h, for no apparent reason. The capsule was excreted 2 d later but the patient did not consent to undergo another examination. One capsule failed to re-activate after entering the delay mode, but the patient received another capsule that worked properly. Therefore, we report the results of 40 DCC SB examinations. The patients’ baseline characteristics are shown in Table 1.

DCC reached the cecum in 36/40 (85%) patients. DCC’s gastric and SB transit times were 45.5 (IQR: 17.7-78.5) min and 200 (IQR: 117-277) min, respectively. There was moderate - good agreement between the two investigators regarding SB mucosa visibility ($\kappa = 0.66$, $P < 0.001$). Thirty two (80%) and 27 (67.5%) cases were rated with good-excellent mucosa visibility by investigators 1 and 2, respectively.

DCC cameras’ findings

There was excellent correlation ($r > 0.9$, $P < 0.001$) between the two investigators regarding the number of findings detected by DCC. Therefore, we analyzed the mean value of their measurements. Overall, DCC cameras detected 68 POS in 50% of the cases. The “yellow” and the “green” camera detected 50 and 48 POS, respectively, while both cameras detected 28 POS findings simultaneously. Figure 1 shows that the two DCC cameras detected different POS: 44% ($n = 22$) of the “yellow” camera’s POS were not detected by the “green” camera and 42% ($n = 20$) of the “green” camera’s POS were not detected by the “yellow” camera. More precisely, Figure 2 shows that the POS detected by the two capsule’s cam-

eras were identical only in 6 of the 20 cases. Moreover, there were two (0.05%) cases (case 18 and 20 in Figure 2) where only one camera -the “green” one- detected significant findings (three and one angiodysplasias, respectively).

All participants had FUS and the capsule’s cameras detected 216 FUS overall; 171 detected by the “yellow” camera, 161 detected by the “green” one, and 116 by both of them simultaneously (Figure 1). Moreover, 32% ($n = 55$) of the “yellow” camera’s FUS were not detected by the “green” camera and 28% ($n = 45$) of the “green” camera’s FUS were not detected by the “yellow” camera.

Diagnostic yield of the two cameras

There was agreement between the investigators in 39/40 cases regarding the diagnosis. Disagreement occurred for one chronic diarrhea case with erosions detected by DCC and the case was finally assigned to a diagnosis of Crohn’s disease by the third investigator. Overall, the diagnostic yield of DCC SB examination was 50%. The diagnostic yield of each DCC camera is shown in Table 2: 45% and 50% for the “yellow” and the “green” camera, respectively ($P = 0.987$). The agreement between the DCC cameras diagnosis was high ($\kappa = 0.92$, $P < 0.001$). However, there was numerical difference because of the two cases with angiodysplasia(s) missed by the “yellow” camera.

Examination’s tolerability

There were no serious adverse events related to the ex-

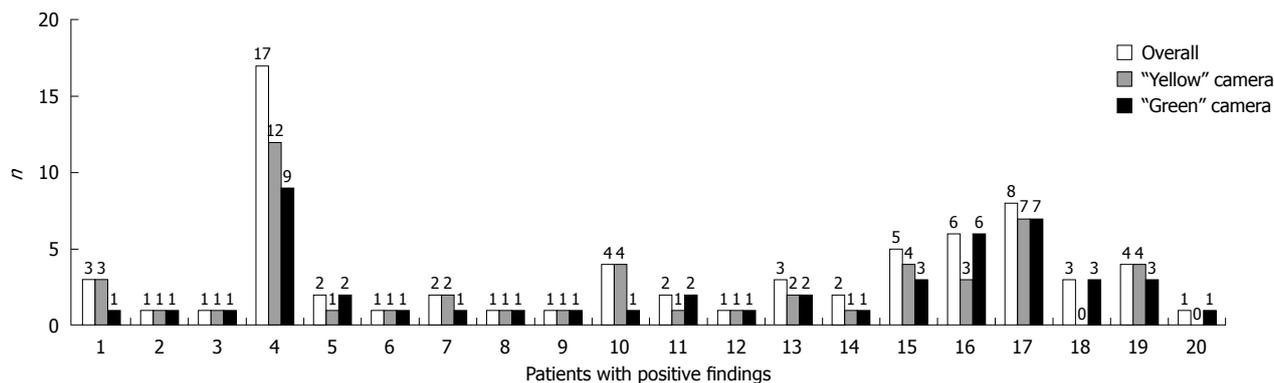

Figure 2 Positive findings detected in each of the 20 positive dual camera small-bowel capsule endoscopy examinations; overall, by the “yellow” and by the “green” camera, respectively.

amination. There was no capsule retention. Forty (97.6%) of the 41 initially included participants stated that they would repeat DCC SB examination -if necessary. 90% of patients were not uncomfortable during the examination, while 20% of them reported mild adverse reactions related to bowel preparation (Table 3).

DISCUSSION

The diagnostic yield of SB capsule endoscopy varies across the indications of the examination^[1]. Capsule

endoscopy is expensive and time consuming; therefore efforts have been made to improve its performance^[2]. Meta analysis has shown that only purgative small bowel preparation increases the diagnostic yield of the examination^[7], while other modalities have shown conflicting results^[2]. The properties of the new DCC designed for colon examination (mainly the two cameras and the rate of capturing images) provide an opportunity to test its utility in SB imaging. Our study showed, for the first time, that SB capsule endoscopy with DCC is feasible, well tolerated, and that the two cameras have the potential to detect more SB lesions by complementing each other. While our study was underway, a study was published in abstract form examining the same hypothesis. Investigators from Portugal using DCC SB endoscopy detected 44 SB findings overall - 24 exclusively from the “yellow” camera, 13 from the “green”, and only one from both - in 10 patients, concluding that using a device with two cameras would increase the diagnostic acuity of capsule endoscopy SB examination^[8]. Our study revealed that each DCC camera misses 40% of the significant and 30% of the FUS detected by the other one. It is not clear why this happens. Although the SB lumen is small enough in diameter to allow lesion detection by one camera, our study indicates that because the capsule endoscope is trembling and rotating in SB lumen, there might be blind spots along its passage that can be detected on a second camera recording. More importantly, there were two cases with significant SB examination findings detected by only one camera, raising the possibility that the correct diagnosis might have been missed if the small bowel had been explored with a single camera video capsule. This finding might extrapolate to one additional positive DCC SB examination for every 20 false negative conventional SB capsule explorations, in which case a formal comparison between the two capsules would confirm our study results. However, this assumption has to be proven in a controlled trial.

Two previous studies highlighted the results of sequential SB capsule endoscopy in patients with obscure gastrointestinal bleeding. In each study, 51^[9] and 40^[10] patients, respectively, underwent sequential SB capsule endoscopy with two different capsule endoscopy systems

(PillCam SB and Olympus EndoCapsule). Patients ingested the capsules in a randomized order and data showed that the DY of the two systems was similar. However in the German study^[10], the second capsule detected angiodysplasias in two (5%) more patients. The results of these studies differ from the results of studies that investigated the value of a second capsule endoscopy, using the same endoscopy system, in patients with obscure gastrointestinal bleeding or iron deficiency anemia with one previous non-diagnostic capsule investigation. Bar-Meir *et al*^[11] showed significant lesions in seven of the 20 included severe iron deficiency patients, Jones *et al*^[12] revealed positive finding in 18 of 24 obscure gastrointestinal bleeders, while Viazis *et al*^[13] established a diagnosis in 37 of 76 obscure gastrointestinal bleeders who underwent second look capsule endoscopy. Whether dual camera SB capsule endoscopy can reduce repeat SB examination (including capsule endoscopy) until a confirmed diagnosis remains to be investigated.

Apart from establishing a diagnosis, SB capsule endoscopy also estimates the extent of the disease in cases of multiple angiodysplasias and Crohn's disease, in which the involvement of different parts of the small bowel might dictate different therapeutic approaches. Therefore, missing lesions may underestimate disease extent. For example in case 3 with multiple small bowel ulcers/erosions shown in Figure 2, the "yellow" camera detected erosions throughout the recording, while all "green" camera's POS were detected by the end of the recording (terminal ileum).

In our study, mucosa visibility was good-excellent in 68% and 80% of the cases, as rated by each investigator, respectively, with a half dose colonoscopy preparation regimen given after the insertion of the capsule at the duodenum. While this purge is given as a boost in colon capsule endoscopy studies, in our departments we use it as the standard preparation scheme for SB capsule endoscopy to both avoid prolonging the capsule's gastric transit time and to improve mucosa visibility, specifically in the ileum^[4]. This preparation was both effective and well tolerated, causing mild adverse reactions in only 20% of the participants, which is similar to the complication rate published in the literature^[2,7].

Finally, we addressed patient's acceptance, which is one of the major issues for a successful diagnostic modality^[4]. The acceptance rate of DCC SB examination in our study was high: all participants (apart from one who was excluded initially) agreed to repeat the study if necessary. More importantly, there was no capsule retention and 90% of the patients did not feel uncomfortable during the examination.

Our study was a prospective feasibility trial aiming to find grounds for further formal investigation of DCC SB imaging. Therefore, the results should be interpreted with caution in clinical practice and some reservations should be noted. Firstly, the study design is not optimal for detecting firm conclusions and the sample size is small. The ideal trial to explore whether DCC endoscopy of the SB results in higher DY compared to the conventional

capsule, should include patients with one specific indication (e.g. obscure gastrointestinal bleeding) who would ingest a single camera capsule operating on a different frequency than the DCC initially and the DCC later, or vice versa. Secondly, the capsule is 6 mm longer and this might result in swallowing difficulties, in a higher retention rate of the capsule in the stomach, and in a higher rate of incomplete SB examinations^[3]. All our patients swallowed the capsule easily. However, in one case, the capsule remained in the stomach during the life span of the capsule's battery, without any predisposing factor. We did not detect increased DCC gastric and small bowel transit time, compared to those published with the conventional SB capsule^[7], and the rate of complete SB examinations with cecal visualization was 85%, similar to that reported in the literature with the conventional SB capsule^[7]. Furthermore, complete colon examination was observed in 42.5% of the cases without any further purgative boost; however, bad-moderate bowel cleansing in 79%-85% of the cases prevented any thorough colon examination (data not shown in the results). Thirdly, the longer time required to review the videos from each individual camera and from both cameras simultaneously might be an issue. However, we have not addressed this parameter. Lastly, it might be not acceptable by many patients to wait 2 h until the definite DCC activation. However for the purpose of our study, we have not tried the capsule's initial activation in advance.

In conclusion, we showed that DCC SB endoscopy is feasible and well tolerated. Moreover, the two capsule's cameras complement each other to detect more SB lesions. It remains to be determined whether DCC SB endoscopy can increase the diagnostic yield of capsule endoscopy SB examination and if it can improve the clinical outcome of patients undergoing the examination.

ACKNOWLEDGMENTS

Part of our study has been presented in the 2009 Digestive Diseases Week, Chicago, IL, USA (in poster form) and in the GASTRO 2009, London, UK (oral presentation).

COMMENTS

Background

Wireless video-capsule endoscopy is a non-invasive and patient friendly examination, which has revolutionized small-bowel (SB) exploration. It has been proved to be superior to any other radiographic or endoscopic modality for SB mucosa examination. However, it is expensive and its diagnostic yield varies across the indications. Until recently several methods have been introduced to improve the method's diagnostic yield, with conflicting results.

Research frontiers

Wireless capsule endoscopy is an evolving technology. Recently, a new capsule endoscope designed for colon examination has been introduced to the market. It is a dual camera capsule (DCC) that compared to the single camera conventional SB capsule has a theoretical advantage to detect more SB lesions.

Innovations and breakthroughs

This theoretical advantage has been tested in 41 consecutive patients with an indication for SB mucosa examination and DCC endoscopy was performed to examine whether the two cameras complement each other to detect more le-

sions than each of them alone. The results showed that each camera missed 40% of the findings that explain patient's symptoms detected by the other one. More importantly, there were two cases with significant SB examination findings detected by only one camera, raising the possibility that the correct diagnosis might have been missed if the small bowel had been explored with a single camera video-capsule. In conclusion, this study revealed that DCC SB endoscopy is feasible, well tolerated, and that the two capsule's cameras complement each other to detect more SB lesions.

Applications

Given that a feasibility trial can not reach firm conclusions, the hypothesis that DCC may increase the diagnostic yield of wireless capsule SB endoscopy must be tested in a formal way. If proven, DCC SB endoscopy will be the standard for SB mucosa exploration.

Terminology

Wireless video-capsule endoscopy is an endoscopy system equipped with a capsule endoscope that acquires images from the gut lumen and transmits them to a data recorder using wireless emission technology. Images are processed and reviewed in a video format using a commercially available computer.

Peer review

The trial of a colon capsule to view the small intestine is an innovative idea and the results indicate that it has considerable clinical importance. This is a well designed and clinically relevant study.

Abstract

AIM: To determine whether distinct symptom groupings exist in a constipated population and whether such grouping might correlate with quantifiable pathophysiological measures of colonic dysfunction.

METHODS: One hundred and ninety-one patients presenting to a Gastroenterology clinic with constipation and 32 constipated patients responding to a newspaper advertisement completed a 53-item, wide-ranging self-report questionnaire. One hundred of these patients had colonic transit measured scintigraphically. Factor analysis determined whether constipation-related symptoms grouped into distinct aspects of symptomatology. Cluster analysis was used to determine whether indi-

vidual patients naturally group into distinct subtypes.

RESULTS: Cluster analysis yielded a 4 cluster solution with the presence or absence of pain and laxative unresponsiveness providing the main descriptors. Amongst all clusters there was a considerable proportion of patients with demonstrable delayed colon transit, irritable bowel syndrome positive criteria and regular stool frequency. The majority of patients with these characteristics also reported regular laxative use.

CONCLUSION: Factor analysis identified four constipation subgroups, based on severity and laxative unresponsiveness, in a constipated population. However, clear stratification into clinically identifiable groups remains imprecise.

Factor analysis identifies subgroups of constipation. *World J Gastroenterol* 2011; 17(11): 1468-1474 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i11/1468.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i11.1468>

INTRODUCTION

Constipation is a heterogeneous disorder, the most consistent generic descriptor for which is difficult or infrequent passage of stool^[1,2]. A fundamental aim in researching and treating any heterogeneous disorder is to subclassify

the condition into categories that are predictive of either pathophysiology or treatment outcome. Constipation is currently conceptualized in three broad categories: normal transit constipation (NTC), slow transit constipation (STC) and disorders of defecation or rectal evacuation^[3-5]. This distinction among subgroups, in some cases, has proven beneficial in planning treatment and in predicting therapeutic outcome^[4,6-12].

It remains unknown whether subtypes of constipation can be identified reliably on the basis of symptoms. The mathematical techniques of factor and/or cluster analysis, to determine whether certain symptoms and/or subjects do group together more than expected by chance, can provide empiric evidence of the existence of true syndromes. Studies applying these techniques have found conflicting results, with Mertz *et al.*^[13] identifying 3 subtypes while Eltringham *et al.*^[14] did not. These findings suggest that the *a priori* assumption that these subtypes are distinct or distinguishable from each other on the basis of symptoms may be incorrect, or that investigators have yet to combine the correct symptoms to identify pathophysiologically distinct abnormalities.

Utilizing a 53-item specific constipation questionnaire and colonic scintigraphy our aim was to identify symptoms or groups of symptoms that identify underlying severe constipation subgroups. Specifically, we hypothesized that within this constipation population at least three distinct subgroups, STC, evacuation disorder and irritable bowel syndrome (IBS), can be identified by groups of symptoms and that these symptom groups will be predictive of specific underlying objective physiological measures such as colonic transit time.

MATERIALS AND METHODS

Design of the questionnaire and assessment of symptoms

The Sydney Constipation Questionnaire (SCQ) was derived from the previously validated Bowel Disease Questionnaire^[15] and the Bowel Symptom Questionnaire^[16]. The SCQ comprises 53 items, including 42 symptom items and the validated Bristol stool scale^[17]. Additional constipation items were then added and the face validity was assessed by responses from 29 internationally recognised constipation experts who were asked to rate each question according to clinical relevance. The test-retest reliability of the final questionnaire was evaluated in 47 patients who repeated the questionnaire within 3 wk of initial testing^[18]. The design of the questionnaire took place long before the release of Rome III criteria for bowel^[19] and anorectal^[20] dysfunction, nevertheless the questionnaire does contain all of the symptomatic questions that define constipation, IBS and outlet obstruction by the Rome III criteria.

Population sample

Subjects were obtained through two sources: (1) *via* referrals from specialists in the Sydney area; and (2) by direct

advertisement that specified criteria approximating tertiary-referred subjects. The impact of subject source was considered in the statistical analysis. Overall, the sample was designed to reflect community members suffering serious constipation symptoms. Subjects were deliberately not selected based on Rome III constipation criteria, but rather on the basis of serious symptoms to avoid making assumptions and because we wanted also to examine the proportion of the study cohort and its clusters that would be positive for Rome III criteria for constipation or IBS.

Referrals to colorectal surgeons or gastroenterologists in Sydney metropolitan region, seeking treatment for constipation, were recruited over a 4-year period and were given a questionnaire if they fulfilled the following criteria: (1) had not undergone any form of colectomy, rectocele or rectal prolapse repair; and (2) their constipation was not deemed secondary to a metabolic or neurological disease or pregnancy. Additionally, the questionnaire was given to potential patients who responded to advertisements in Sydney newspapers recruiting subjects for a randomized control trial of sacral nerve stimulation for the treatment of constipation (in progress; to be reported in future). These potential patients were screened during an initial phone conversation and if they fulfilled the criteria listed above the questionnaires were mailed out to them. As these were chronically constipated patients, who for the most part had been taking laxatives for many years, they were not asked to report on what their symptoms are, were or might be, in the absence of laxatives. Studies have shown that the correlation between a patient's reported stool frequency and actual measures is poor^[21] and in our experience a patient's ability to recall symptoms from the years prior to laxative use is also poor.

Allowing 3 wk for the questionnaire to be completed and returned, each non-responder was then phoned and asked if they intended to return the questionnaire. A proportion of community responders had decided that their symptoms were not severe enough to warrant sacral nerve stimulation and these patients did not return the questionnaire. Allowing an additional 4 wk, all other non-responders were excluded from the study. All participants in this study gave written, informed consent and the study was approved by the Human Ethics Committees of the South Eastern Area Health Service, Sydney and the University of New South Wales.

A priori symptom groups

Three symptom groups were defined *a priori*: (1) STC was considered to comprise infrequent bowel movements (less than 2 defecations/wk), lack of defecation urge, excessive straining and hard stools^[22-24]; (2) Obstructed defecation was classified when all of the following symptoms were present: (a) an inability to initiate defecation following the urge to do so, or difficulty with stool evacuation; (b) excessive straining at stool more than 25% of the time or self-digitation to facilitate defecation more than 25% of the time; and (c) a feeling of incomplete evacuation after

defecation^[1,22,25-29]; and (3) IBS classified those patients with symptoms of abdominal pain and bloating that improve with defecation or in whom the onset of such symptoms is associated with a change in frequency or form of the stool^[19,22,24,30].

Transit studies

Colonic transit was measured using a standard nuclear medicine technique^[31,32]. Briefly, the subjects attended a Nuclear Medicine Department on a Monday morning and were given 4 MBq ¹¹¹In-DTPA orally at approximately 9:00 am. They returned to the department the same day at approximately 3:00 pm and on subsequent days at approximately 24, 48, 72 and 96 h following the oral administration. On each occasion, anterior and posterior abdominal images were obtained each for 10 min using a large field-of-view gamma camera and medium energy collimator. Background images were obtained for background correction. All laxative medications were stopped 3 d before and during the scan. No effort was made to control the patient's diet during the scan period. Method of the scintigraphic analysis is reported elsewhere^[33]. Briefly, at each time point, profiles of the activity along the colon were derived from a geometric mean image obtained from the anterior and posterior images. Total percent retention (T%R) and mean activity position (MAP) at each time were calculated for each subject. T%R indicates the retained activity in the colon using the value at 6 h as 100%. MAP indicates the geometric center of the activity, where position 0 is at the cecum, position 98 at the anus, and position 99 being excreted activity. The scintigraphic definition of delayed transit constipation was met if the study showed isotope retention of greater than 9% in the right (cecum to mid-transverse) or left colon (mid-transverse to distal descending colon) at 72 h^[31,32].

Data analysis

Since this has been a vexed question to date, a naturalistic approach was adopted in which multivariate statistical techniques were used to identify distinct clusters of individuals with respect to bowel symptom patterns and these clusters were then examined with respect to their symptom profiles to determine what, if any, clinically meaningful differences existed between them. Analysis proceeded in two steps; the first reduced the data dimensionality from 42 observed symptom variables to 15 latent variables which were then used in the second step in a cluster analysis to form internally homogeneous clusters of individuals: details follow. The first step identified independent dimensions of symptom profile through principle components analysis followed by orthogonal rotation of the factor space. Identifying independent dimensions of bowel symptoms has several advantages. Bowel symptom questionnaires typically ask several questions around a given bowel symptom to fully characterize patients' symptomatology. Despite the clinical value of these questions, they are typically strongly correlated, leading to statistical

redundancy amongst them. In addition, cluster analysis is prone to dominance by scales that are numerically large and factor scores calculated for individuals follow a unit of normal distribution (mean zero, standard deviation 1.0) and are therefore standardized. Factors were interpreted and used in the subsequent cluster analysis if the corresponding eigenvalue was > 1.0, which corresponds to approximately 2% explained variance in the original data. The variance in the original data explained by each factor is reported in Table 1, as well as the total explained variance across all 15 factors used. A score was calculated for each factor for each subject, which is in effect a weighted sum across all original data items deemed to load on a given factor. These are reported in Table 1, along with the rotated factor loading for each item, using a criterion of rotated factor loadings > 0.4 (in absolute value). Factor loadings can be interpreted as the correlation between a given original data item and its corresponding latent variable. In the second analytic step, these scores were used in a non-hierarchical (K-Means) cluster analysis. It is important to note that only symptom latent variables were utilized in cluster formation, not transit times. Based on an *a priori* expectation of a moderate number of distinct clusters, solutions between 1 and 6 clusters were considered. A single cluster solution would imply the subjects were not differentiated in any systematic fashion, while six clusters would represent a quite complex system of constipation subgroups. The choice of cluster solution adopted was a trade-off of within-cluster homogeneity and minimizing unnecessary complexity. In a K-Means analysis the algorithm assigns individuals to clusters such that the overall within-cluster variance is minimized and the between-cluster variance is maximized, given the pre-specified number of clusters. Euclidean distance was used to measure the distance between individual points and their cluster centroid.

Determination of the clinical value of the clusters identified was through a comparison of profiles of individual symptom items and by comparing rates of *a priori* criteria, Rome III-defined constipation, IBS and outlet dysfunction, and rates of slow transit measured as described earlier.

RESULTS

The questionnaire was given to a total of 326 individuals suffering from constipation. Of these, 246 were referrals to colorectal surgeons or gastroenterologists and 80 were recruited from the community by advertisements. Of these, a total of 223 responded, representing an overall response rate of 68% [191 (78%) response rate for clinic cases; 32 (40%) response rate for community cases]. Of the 223 returned questionnaires, 4 were not able to be utilized (2 incomplete; 2 were multivariate outliers) leaving $n = 217$ for final analysis. There was no significant age or gender difference between the clinic group (45 ± 17 years; range 18-81 years; 13 M:178 F) and community groups (56 ± 20 years; range 24-82 years; 5 M:27 F). The

Table 1 Factor loadings derived from the rotated factor matrix

| | Factor loading | Percent variance |
|---|----------------|------------------|
| Factor 1: Straining | | 17.3 |
| Strain hard: How often | 0.82 | |
| Straining: How bad usually | 0.80 | |
| Straining: How long | 0.76 | |
| Straining: How often | 0.71 | |
| How long to bowel motions take | 0.59 | |
| How often incomplete evacuation | 0.55 | |
| How often unsuccessful attempts | 0.52 | |
| Frequency of any bowel problems | 0.47 | |
| How troubling is constipation | 0.41 | |
| Change positions: How often | 0.35 | |
| Factor 2: Pain frequency and severity | | 8.4 |
| Abdominal pain: How often | 0.80 | |

| Urge for bowel motion: How often | 0.72 | |
| Perceive an urge before attempt to open bowels | 0.68 | |
| Visits to toilet: How often | 0.56 | |
| Urgency for bowel motion: How often | 0.42 | |
| Factor 6: Diarrhea frequency | | 3.8 |
| Loose/watery stool: How often | 0.75 | |
| Pebble-like stool: How often | -0.42 | |
| Rectal disimpaction: How often required | -0.45 | |
| Hard/lumpy stool: How often | -0.63 | |
| Factor 7: Alternating between diarrhea and constipation | | 3.4 |
| Usually alternating | 0.87 | |
| Usually constipated | -0.86 | |
| Factor 8: Bloating frequency | | 3.2 |
| Stomach swelling in the last 12 mo: How often | 0.71 | |
| Felt bloated in the last 12 mo: How often | 0.68 | |
| Felt blocked: How often | 0.47 | |
| Factor 9: Laxative efficacy | | 2.9 |
| Laxative use: Longest gap between taking and bowel motion | 0.70 | |
| Bowel motions: Fewer than usual past 12 mo | 0.56 | |
| Laxative use: How often | 0.44 | |
| Factor 10: Rectal urgency | | 2.7 |
| Urge from rectum | 0.89 | |
| Urge from abdomen and rectum | -0.80 | |
| Factor 11: Bowel motion frequency | | 2.6 |
| Longest gap between bowel motions | 0.81 | |
| Usual bowel frequency | -0.56 | |
| Factor 12: Change in bowel frequency | | 2.4 |
| Bowel motions: More than usual past 12 mo | 0.74 | |
| Bowel motions: Looser than usual past 12 mo | 0.62 | |
| Factor 13: Abdominal urge | | 2.3 |
| Experience an urge from abdomen | 0.89 | |
| Factor 14: Diarrhea predominance | | 2.2 |
| Usually experience diarrhea | 0.79 | |
| Factor 15: Antecedent to constipation | | 2.0 |
| An antecedent for the constipation | 0.71 | |
| Experience upper abdominal pain | 0.51 | |
| Total (1-15) | | 69.3 |

mean age of the entire group was 47 ± 17 years (range 18-82 years).

Colonic transit was performed in all patients who had access to a nuclear medicine facility; in total 100 patients (52%) underwent the procedure study.

Factor analysis

The factor analysis produced a rotated factor matrix comprising 15 factors. Table 1 lists these 15 factors and the labels that we have attached to each factor, along with the loadings of the associated questions. For brevity, we have only shown questions within each factor for which the absolute value of the loading was ≥ 0.35 . While this process is simply an intermediary step towards cluster analysis, there are a number of potentially relevant observations to be made from this matrix. An IBS-like factor emerged, indicating that IBS-like symptoms stand out as a distinct entity in this population. Despite the population being selected for its constipation, a diarrhea factor emerged, probably accounted for by laxative usage (see below).

Cluster analysis

Cluster 1: Patients in this cluster are less likely than average to report preservation of their defecatory urge (compared to cluster 4) despite 80% using laxatives regularly. This cluster is relatively laxative-responsive with 83% describing laxatives as somewhat or very effective. Although clusters 1 and 4 share some similarities, they differ dramatically in their responsiveness to laxatives. Cluster 1 patients experience less upper abdominal pain than patients in clusters 2 and 4. Patients in cluster 1 have more IBS-like features than those in other clusters and they gain pain relief following a bowel action.

Cluster 2: This group has features similar to those of cluster 1 but when compared with cluster 1, their pain is somewhat less severe and less prevalent and they describe a shift in the site of their pain from lower to the upper abdomen. They describe similar laxative usage and responsiveness to patients in clusters 1 and 3. These patients are least likely to visit the toilet daily (63%) despite the fact that they report the highest rate of "urge prior to attempting to defecate" (72%). They are relatively laxative-responsive with 76% reporting them "somewhat or very effective".

Cluster 3: Patients in this cluster have the lowest pain scores of all 4 clusters, have a short history of constipation and are more likely to report a weekly stool frequency within the Rome III defined range for constipation. They report the lowest laxative usage, but they are the most laxative-responsive of all patients. They rarely report a feeling of rectal blockage and are less likely to adopt self digitation to facilitate evacuation. These patients never report diarrhea and rarely report hard stool.

Cluster 4: These patients report the highest pain scores and are strikingly unresponsive to laxatives, despite re-

Table 2 Summary of the proportion of patients within each cluster who were positive for constipation¹ or irritable bowel syndrome on the basis of Rome III criteria, as well as proportions in each group with slow transit constipation

| | Clusters (4-fold solution) | | | |
|-----------------------|----------------------------|---------------|---------------|---------------|
| | 1 (n = 71) | 2 (n = 44) | 3 (n = 34) | 4 (n = 43) |
| Rome III constipation | | | | |
| Yes | 84.50% | 77.30% | 58.80% | 72.10% |
| Rome III IBS | | | | |
| Yes | 52.10% | 27.30% | 20.60% | 53.50% |
| Outlet dysfunction | | | | |
| Yes | 52.10% | 56.80% | 52.90% | 48.80% |
| Colonic transit | n = 43 | n = 28 | n = 16 | n = 29 |
| Delayed transit | 74.40% | 71.40% | 62.50% | 79.30% |
| Normal transit | 25.60% | 28.60% | 37.50% | 20.70% |

¹With the exception that symptoms were assessed irrespective of laxative usage. IBS: Irritable bowel syndrome.

porting the highest laxative usage of all (98% use them > 50% of the time). Abdominal pain is described as more severe, more frequent and lasting longer than in the other clusters. Importantly, patients in this cluster report that a bowel motion does not relieve their pain. They are less likely to have an antecedent (e.g. hysterectomy, pregnancy) than those in the other clusters. In comparison with other clusters, these patients report increased frequency of defecatory urge with 30% reporting an urge to defecate more than 3 times/d, more frequent toilet visits (60% > once/d), frequent unsuccessful attempts at defecation (73%) and frequent sense of blockage (66%) during passage of stool.

Correlation with Rome III criteria for constipation or IBS

In this population with severe constipation, the positivity rate for Rome III constipation was 59%-85% across the 4 clusters (Table 2). In this severely constipated population, with the exception of cluster 3, 78%-98% were habitual laxative users. Clusters 1 and 4 are characterized by high rates of Rome III IBS (over 50%, Table 2) compared with 20%-27% in clusters 2 and 3 (Table 2). The majority (92%) of patients that met Rome III IBS criteria were also associated with heavy laxative use.

Correlation with symptomatically-defined obstructed defecation

A remarkably constant 49%-57% of patients reported symptoms that have traditionally been attributed to obstructed defecation. The prevalence of this pattern did not differ among the four clusters.

Correlation with scintigraphically confirmed slow transit

Between 63% and 79% of patients had slow transit (Table 2). The prevalence of slow transit was least in cluster 3 (63%), the cluster with the mildest symptoms, but this still represents a sizable majority of this group. Of the 25% of severely constipated patients that report > 3 bowel motions a day, 75% have demonstrable STC. The vast majority of

these patients are also heavy laxative users, report mainly liquid stool, and a feeling of incomplete evacuation.

DISCUSSION

The ability to subtype severely constipated patients based upon symptoms has merit because it focuses and systematizes epidemiological enquiry, and has the potential to dictate logical and cost effective investigation algorithms for clinicians, to influence management and to predict therapeutic outcome. However, this study highlights the difficulties in using symptoms as discriminators of severe constipation subtypes. Although four groupings were identified by cluster analysis, it is difficult to attach clearly recognizable pathophysiological labels to these clusters. The major finding of this study is the identification of a group (cluster 4) with long history of constipation, a profound lack of response to laxatives despite extremely high laxative usage, and the highest pain scores. In contrast, cluster 3 was characterized by low pain scores, low rates of co-morbidity and the lowest rate of delayed colonic transit. Overall, our data appear to suggest subtypes based on severity and chronicity of disease which is reflected in rates of, and responsiveness to, laxative therapy.

The positivity rate for Rome III-defined constipation was 59%-85% across the four clusters. Interestingly, of the patients that did not meet the Rome criteria, 63%-80% across the 4 clusters have demonstrable delayed colonic transit. In other words, Rome III criteria will not pick up a substantial proportion of people who are severely troubled by constipation and who clearly have markedly disturbed physiology as confirmed by delayed colonic transit. In addition, a large proportion of patients, particularly in clusters 1 (52%) and 4 (54%), met the Rome III criteria for IBS. In our experience this overall high prevalence of criteria satisfying the definition of IBS is in keeping with the situation commonly encountered by clinicians and has been reported previously^{13,41}.

One of the potential problems with subtyping constipated patients into categories based on questionnaire data is the prevalence of laxative use. Given that the approach to constipation subtyping used in this study relied upon symptom patterns, laxative use is a potential confounder because these agents can induce symptoms of bloating and pain and alter stool frequency/consistency. While laxative use is mentioned in previous studies^{13,14,34-36}, little or no attempt is made to discern their impact upon symptoms. For example, of those patients that met IBS criteria in this study, 92% were heavy laxative users. Asking patients to detail their symptoms in the absence of laxatives has been attempted¹⁴. However, in our experience such questions are difficult to answer for a chronically constipated population who, for the most part, have been taking laxatives for many years. Indeed, previous studies have shown a poor concordance between a patient's recollection of events and actual measures²¹.

Furthermore, high rates of laxative use may also con-

found attempts to identify symptom-based distinct subtypes of constipation that correspond to pathophysiological subtypes. This becomes evident when examining the correlation between delayed transit and infrequent stool frequency. There is literature to support infrequent bowel movements in predicting delayed transit^[36-38]. Those studies found that < 3 bm/wk predicted delayed transit in 85%-100% of patients. Indeed, it is the practice of some groups to only evaluate transit formally in patients with infrequent stools^[39]. However, this study indicates that a high percentage (75%) of patients who use their bowel > 3/d have demonstrable slow colonic transit. Importantly, these patients also report high laxative use. Therefore, these data suggest that normal stool frequency, in the context of concurrent laxative use, certainly does not preclude STC.

Delayed colonic transit was found in the majority of patients in whom scintigraphy was performed, which is comparable with the reports of others^[38,40,41]. While it was lowest in cluster 3, a sizable 63% in this relatively mildly affected group had delayed transit; hence, our findings suggest that delayed transit cannot be predicted accurately on the basis of a combination of symptoms.

Using existing criteria for obstructed defecation based purely on symptoms^[1,22,25-28], this syndrome was both common and equipvalent across all four clusters (49%-57%). This lack of discriminatory ability of clusters to co-localize with these symptoms supports the consistent findings of a number of investigators that symptoms are not predictive of pelvic dyssynergia demonstrated by anorectal manometry and balloon expulsion testing^[34-36,42] or demonstrated by defecography^[43]. Grotz *et al*^[34] found that only a sense of anal blockage correlated with proven pelvic floor dysfunction. However, as Grotz *et al*^[34] point out, the usefulness of this finding must be questioned because this symptom was present in 67% of pelvic floor dysfunction but was found in 50% of patients with STC and in 53% with NTC. Indeed, in their multivariate analysis, they could not identify any colonic symptoms as discriminators of constipation subtypes.

Clinical history remains a "blunt instrument" and while combinations of symptoms do point towards 4 subsets of constipation, we are some distance yet from defining those subsets in unequivocal and specific terms. In light of the overlap with IBS symptoms in this study, it behooves the clinician to consider severe delayed transit in patients presenting with constipation-predominant IBS as this may influence management and avoid mislabeling the patient. Currently, combinations of symptoms cannot predict accurately whether the patient that is categorized into one of these 4 clusters has normal or delayed transit. However, laxative use in severely constipated patients may influence the reported symptoms and this potential confounder needs to be taken into consideration when interpreting these results.

a number of studies confirm that constipation has a significant adverse effect on a patient's quality of life. Constipation is a heterogeneous disorder and a fundamental aim in researching and treating any heterogeneous disorder is to subclassify the condition into categories that will help guide treatment options. As a patient's symptoms are the first point of discussion with their doctor, the ability to subclassify on the basis of symptoms is a primary goal.

Research frontiers

The mathematical techniques of factor and/or cluster analysis have been used in an attempt to determine whether certain symptoms can predict constipation subtypes. However, studies applying these techniques have found conflicting results suggesting that the *a priori* assumption that these subtypes are distinct or distinguishable from each other on the basis of symptoms may be incorrect, or that investigators have yet to combine the correct symptoms to identify pathophysiologically distinct abnormalities. Utilizing a 53-item specific constipation questionnaire our aim was to identify groups of symptoms that identify underlying severe constipation subgroups, such as slow transit constipation, evacuation disorder and irritable bowel syndrome.

Innovations and breakthroughs

Factor analysis of 221 questionnaires yielded a 4 cluster solution with the presence or absence of pain and laxative unresponsiveness providing the main descriptors. Amongst all clusters there was a considerable proportion of patients with demonstrable delayed colon transit, irritable bowel syndrome positive criteria and regular stool frequency. Therefore, as with previous studies, we have demonstrated that significant overlap exists between mathematically defined clusters of symptoms and globally accepted sub-types of constipation.

Applications

Laxative use in severely constipated patients may influence the reported symptoms and this potential confounder needs to be taken into consideration when interpreting these results.

Peer review

This is an important study in which authors attempted to evaluate whether cluster of symptoms can help to understand pathophysiology of constipation.

Abstract

AIM: To determine the incidence and factors responsible for anastomotic leaks and stricture following anterior resection (AR) and its subsequent management.

METHODS: Retrospective analysis of data from 108 patients with rectal carcinoma who underwent AR or low anterior resection (LAR) to identify the various pre-operative, operative, and post operative factors that might have influence on anastomotic leaks and strictures.

RESULTS: There were 68 males and 40 females with an average of 47 years (range 21-75 years). The median distance of the tumor from the anal verge was 8 cm (range 3-15 cm). Sixty (55.6%) patients underwent handsewn anastomosis and 48 (44.4%) were stapled. The median operating time was 3.5 h (range

2.0-7.5 h). Sixteen (14.6%) patients had an anastomotic leak. Among these, 11 patients required re-exploration and five were managed expectantly. The anastomotic leak rate was similar in patients with and without diverting stoma (8/60, 13.4% with stoma and 8/48; 16.7% without stoma). In 15 (13.9%) patients, resection margins were positive for malignancy. Nineteen (17.6%) patients developed anastomotic strictures at a median duration of 8 mo (range 3-20 mo). Among these, 15 patients were successfully managed with per-anal dilatation. On multivariate analysis, advance age (> 60 years) was the only risk factor for anastomotic leak ($P = 0.004$). On the other hand, anastomotic leak ($P = 0.00$), mucin positive tumor ($P = 0.021$), and lower rectal growth ($P = 0.011$) were found as risk factors for the development of an anastomotic stricture.

CONCLUSION: Advance age is a risk factor for an anastomotic leak. An anastomotic leak, a mucin-secreting tumor, and lower rectal growth predispose patients to develop anastomotic strictures.

INTRODUCTION

Anterior resection (AR), especially low anterior resection (LAR), for rectal carcinoma and colorectal anastomosis is a technical challenge to surgeons. The introduction of circular stapling devices has made more and more LARs technically feasible. The two most serious complications following AR/LAR, anastomotic leaks and stenosis, are causes of concern because these affect the long-term outcome and quality of life. The incidence of these complications has been variably reported in the literature because of the different definitions used. The objective of this study is to determine the incidence of anastomotic leaks and anastomotic strictures following AR/LAR, the factors responsible for these complications, and to define their management.

MATERIALS AND METHODS

Between January 1989 and December 2008, 280 patients were operated on for rectal carcinoma in the department of Surgical Gastroenterology, a tertiary level referral hospital in Northern India. One hundred and eight of these patients underwent AR/LAR. For the purpose of the study, information was collected both from medical records and a computerized database. Colonoscopy or sigmoidoscopy was performed on all patients to localize the lesion and for tissue sampling for histopathology. A barium enema was administered to some patients to assess the proximal colon for synchronous lesions in cases where a colonoscopy was either incomplete or could not be performed for technical reasons. Chest X-rays were performed on all patients to rule out lung secondaries. Contrast enhanced computed tomography (CECT) was performed to determine the extent of the tumor, to assess lymph nodes, and to detect liver secondaries. Neoadjuvant chemoradiotherapy was given to patients with unresectable T4 lesions (infiltration to adjacent organs) for downstaging. Routine hemogram, liver function, and renal function tests were ordered as part of the pre-operative work up. All patients received mechanical bowel preparation with Polyethylene Glycol (PEG) solution the day before the planned procedure. Prophylactic antibiotics were administered at the time of induction. Antibiotics were continued for 5 d postoperatively. The procedures were performed either by consultants or registrars. The decision to perform hand-sewn *vs* stapled anastomosis (CDH, Ethicon, Johnson and Johnson, Illinois, USA), and the decision to add a proximal diverting stoma (either a loop ileostomy or a loop colostomy) were taken by the operating surgeon on a case-to-case basis. Suction drains were routinely left in the pelvis, near the anastomosis, in all patients and were removed when the drainage was serous in nature and the amount less than 50 mL/d. A contrast study was performed in patients with clinical suspicion of a leak.

An anastomotic leak is defined as either evidence of feculent drainage or a leak demonstrated on contrast imaging. An anastomotic stricture is defined as anastomotic

Table 1 Factors analyzed for their significance in anastomotic leaks

| Factor | Leak (n = 16) | No leak (n = 92) | P value (univariate analysis) |

| Mucin secreting tumour | 10 | 23 | 0.029 ¹ |

¹Factors found to be significant.

narrowing that does not allowing the passage of the distal inter-phalangeal joint of the index finger, or narrowing causing difficulty in the evacuation of stool. Patients with T3, T4 disease and/or lymph node positive disease, and/or positive histological margins received chemoradiation as an adjuvant treatment. The diverting stoma was closed after 8-12 wk when a contrast study revealed no anastomotic leak or stricture.

Various clinical, tumor related, and intra-operative factors, which might influence the development of leaks (Table 1) and strictures (Table 2), were analyzed. Univariate analysis was done using Pearson's χ^2 test, Fishers exact test, or Student's *t* test. Multivariate analysis was done

using the binary logistic regression method. SPSS 15 software was used for the analysis. Significance was calculated at the 95% CI and P value < 0.05 .

RESULTS

Among 108 patients who underwent AR/LAR, there were 60 males and 48 females with a median age of 47 years (range 21 to 75 years). The median distance of the tumor from the anal verge was 8 cm (range 3-15 cm). The tumor was situated within 5 cm from the anal verge in 30 patients, between 5 and 10 cm in 46 patients, and above 10 cm in 32 patients. Endoscopic biopsy revealed adenocarcinoma in 100 and adenoma with dysplasia in four. The biopsy was inconclusive in remaining four patients. No patient had lung metastasis on X-ray chest. Based on pre-operative staging, five patients received neo-adjuvant treatment.

LAR (anastomosis below the level of the peritoneal reflection) was performed in 93 patients (86%). Fifteen patients (14%) underwent anterior resection (anastomosis above the level of the peritoneal reflection). Sixty patients (55.6%) underwent hand-sewn anastomosis and 48 (44.4%) had stapled anastomosis. The median distance of the tumor from the anal verge in the hand sewn anastomosis group was 10.2 cm (range 4-15 cm) and it was 6 cm (range 3-15 cm) in the stapled group. Twenty-nine anastomoses were performed using CDH29, ten with CDH31, and three with CDH33. In the remaining six patients, no information regarding the size of the stapler was available. Information regarding anastomotic doughnuts was available in 39 patients. Doughnuts were complete in 34 patients and incomplete in five. Diverting stomas were created in 60 patients (55.6%); 33 (69%) with stapled anastomosis and 27 (45%) with hand-sewn anastomosis. The median duration of operation was 3.5 h (range 2.0-7.5 h). Final histopathology revealed adenocarcinoma in all patients. Resection margins were positive for malignancy in 15 (13.9%) patients. Seven patients with stapled anastomosis and eight with hand-sewn anastomosis had positive resection margins. The resections were R0 (no microscopic or gross residual disease) in 77 patients (71.3%) and R1/R2 (microscopic/macroscopic residual disease left) in 31 (28.7%) patients. Nineteen patients (17.6%) had evidence of distant metastases at operation (liver in 13, peritoneal in three, and both liver and peritoneal in three).

Fifty Six patients (51.8%) had post operative complications. Major complications included wound infection ($n = 27$, 25%), intra-abdominal bleed ($n = 4$, 3.7%), anastomotic leak ($n = 16$, 14.6%), anastomotic stricture ($n = 19$, 17.6%), and intestinal obstruction ($n = 16$, 14.6%). Of the 16 patients who had anastomotic leaks, eight had diverting stoma. Overall, 18 patients (16.7%) required re-exploration for the management of post-operative complications. Eleven patients with anastomotic leaks required re-exploration, and in seven of these, diverting stomas were created at second surgery. The remaining

Table 3 Significant factors determined by multivariate analysis

| Factors | P value | Odds ratio |
|---|---------|------------|
| Factors affecting anastomotic leak | | |
| Advance age (> 60 yr) | 0.004 | 7.23 |
| Factors affecting anastomotic stricture | | |
| Anastomotic leak | 0.000 | 13.6 |
| Distance of growth from anal verge | 0.011 | 6.5 |
| Mucin secreting tumor | 0.021 | 5.3 |

five patients with leaks were managed expectantly. There were two (1.85 %) postoperative deaths (one due to an intra-abdominal bleed and the other due to pneumonitis). Local pelvic recurrence developed in eight patients during the follow up (follow up duration: 1-15 years). Nineteen (17.6%) patients presented with anastomotic strictures at a median duration of 8 mo (range 3-20 mo) after surgery. Biopsy from these strictures revealed no evidence of malignancy in any of them. Seven of these strictures were managed with dilatation using Hegar's dilators under general anesthesia. In others, the dilatations were carried out on an outpatient basis. The median number of dilatation required was 1 (1-4). Diverting stomas were closed in all patients, except for four who had severe fibrotic strictures and did not respond to dilatations even after multiple sessions.

Advanced age (greater than 60 years) and incomplete doughnuts were found to be significant risks for anastomotic leaks on univariate analysis (Table 1). However, age was the only significant risk factor for anastomotic leaks on multivariate analysis (Table 3). On the other hand, increased distance of the tumor from the anal verge, a mucin secreting tumor, and an anastomotic leak were the factors found significant for the development of stricture, both on uni- and multivariate analysis (Tables 2 and 3).

DISCUSSION

Incidence of anastomotic leaks following AR/LAR has been reported to be 3%-21%^[1-7]. Various patient-related, tumor-related, and technique-related factors have been enumerated as predisposing factors for anastomotic leaks. Male sex has been reported to be one such factor because of their unfavorable pelvic anatomy^[1,2]. No significant difference in the number of leaks between males and females was observed in our study.

Distance of the tumor from the anal verge and the position of the anastomosis were found to be associated with the development of anastomotic leaks^[2-4]. The reported higher incidence of leaks as the anastomosis becomes lower may be because of the increasing technical difficulty and ischemia of the distal end. In our series, distance of the tumor from the anal verge was not associated with leaks on univariate analysis. A leak rate of 3%-18% following stapled anastomosis in AR has been reported by various authors^[1,2,3,6]. Law *et al*^[1] and Rullier *et al*^[2] demonstrated a higher leak rate following stapled anastomosis compared to hand-sewn. They attributed

this to the difficulty of the cases undergoing stapled anastomosis. A systematic review of nine randomized controlled trials could not find any significant difference in leak rates between the two groups^[8]. The leak rates of 16.7% for stapled anastomosis and 12.5% for hand-sewn anastomosis in our study were comparable to the published series^[8]. The high leak rates in our study may reflect the experience of operating surgeons (both trainee and consultants). We assume that, as the number of patients and experience increase, the leak rate will decrease.

Although the use of a protective stoma has not been shown to decrease the overall anastomotic leak rate, it reduces the rate of re-operation and postoperative mortality in the event of a leak^[9,10]. In the present series, creation of a protective stoma did not reduce the anastomotic leak rate. The majority of authors recommend a selective policy in providing covering stoma after AR/LAR, reserving it for patients with high risk for of leaks (anastomosis within 5 cm from the anal verge, male gender, and incomplete doughnut)^[4,7,11].

Although anastomotic leak and positive resection margin were implicated as factors promoting recurrence after AR^[12,13], the relation between the leak and a positive resection margin is not well studied. A positive resection margin was not a significant risk factor for anastomotic leak in our patients.

Over all, the anastomotic stricture rate after hand-sewn anastomosis varies from 5%-9%^[14]. The incidence of strictures after hand-sewn anastomosis that necessitated treatment, was 0.6% in Goligher's experience^[15]. The low stricture rate in Goligher's series compared to recent experience could be due to the lower number tumors close to the anal verge. Today, as more and more low rectal tumors are being submitted for LAR and ultra low AR, the stricture rate may also show a similar increase. Stricture rates of up to 20% have been reported^[16]. Some animal studies have suggested that healing by scarring of the of the exposed seromuscular layer with poor epithelial bridging might explain the significant incidence of strictures following stapled anastomosis^[17]. A meta-analysis of 13 randomized controlled trials showed increased stricture rates following stapled anastomosis compared to hand-sewn^[18]. In our series, 22.9% developed strictures after stapled anastomosis, which is higher than the 13.3% developed after hand-sewn anastomosis; however, it was not statistically significant. Waxmann *et al*^[19], in a review of 10 series, reported 6% incidence of strictures with stapled anastomosis. They also noticed a reduced stricture rate with Russian staples, which deliver a single row of staples, compared to the new generation staples, which deliver two rows of staples. The size of the stapler has also some bearing on the stricture rate, according to some published series. Miller *et al*^[20], in their report of 103 patients with stapled anastomosis, had a 4 % stricture rate, and the strictures were more common when a 28 mm diameter stapler was used as compared to one of 31 mm.

The high incidence of anastomotic leaks (14.6%) was another reason for the high stricture rate (17.6%), because a leak predisposes the patient to intense inflamma-

tion and scarring. The stricture rate will therefore invariably increase.

The need for permanent stoma because of anastomotic stricture has been variably reported (1%-9%)^[21-23]. Although the incidence of anastomotic stricture was high in our series (17.6%), it is noteworthy that 15/19 (78.9%) strictures were successfully managed by per-anal dilations. The incidence of anastomotic leaks and strictures are bound to be high in a teaching hospital where there will always be an influx of new trainees.

In conclusion, in our study, advance age was the only factor significantly associated with anastomotic leaks. On the other hand, anastomotic leaks, an aggressive tumor (mucin secreting), and growth in the lower rectum were predisposing factors for development of anastomotic strictures.

COMMENTS

Background

Two major complications of anterior resection (AR) and Low AR, anastomotic leaks and anastomotic strictures, were analyzed retrospectively. The effects of various factors that can lead to anastomotic leaks and anastomotic strictures were analyzed.

Research frontiers

Neoadjuvant Chemotherapy is under evaluation for locally advance tumors. Intersphincteric resections are under evaluation for patients with lower rectal tumors.

Innovations and breakthroughs

Introduction of total mesorectal excision was a major achievement in the development of surgery for lower rectal growth, leading to significant decreases in the complications rate and a significant decrease in local recurrence. Development of end-to-end staplers was also a significant breakthrough, which made anastomosis possible in the lower rectum, thus facilitating sphincter preservation.

Applications

As advance age is a significant risk factor for anastomotic leaks, so attention to detail is important while performing surgery on elderly patients. Similarly, special precautions are needed while performing anastomosis on low-lying growths, and mucin positive tumors; these patients should be operated on only by an experienced surgeon.

Peer review

This is a good paper, but the study is over a period of 20 years, and changes may have happened regarding management.

Abstract

AIM: To investigate the predictors of success in step-down of proton pump inhibitor and to assess the quality of life (QOL).

METHODS: Patients who had heartburn twice a week or more were treated with 20 mg omeprazole (OPZ) once daily for 8 wk as an initial therapy (study 1). Patients whose heartburn decreased to once a week or less at the end of the initial therapy were enrolled in study 2 and treated with 10 mg OPZ as maintenance therapy for an additional 6 mo (study 2). QOL was in-

vestigated using the gastrointestinal symptom rating scale (GSRS) before initial therapy, after both 4 and 8 wk of initial therapy, and at 1, 2, 3, and 6 mo after starting maintenance therapy.

RESULTS: In study 1, 108 patients were analyzed. Their characteristics were as follows; median age: 63 (range: 20-88) years, sex: 46 women and 62 men. The success rate of the initial therapy was 76%. In the patients with successful initial therapy, abdominal pain, indigestion and reflux GSRS scores were improved. In study 2, 83 patients were analyzed. Seventy of 83 patients completed the study 2 protocol. In the per-protocol analysis, 80% of 70 patients were successful for step-down. On multivariate analysis of baseline demographic data and clinical information, no previous treatment for gastroesophageal reflux disease (GERD) [odds ratio (OR) 0.255, 95% CI: 0.06-0.98] and a lower indigestion score in GSRS at the beginning of step-down therapy (OR 0.214, 95% CI: 0.06-0.73) were found to be the predictors of successful step-down therapy. The improved GSRS scores by initial therapy were maintained through the step-down therapy.

CONCLUSION: OPZ was effective for most GERD patients. However, those who have had previous treatment for GERD and experience dyspepsia before step-down require particular monitoring for relapse.

INTRODUCTION

Gastroesophageal reflux disease (GERD) is defined as the reflux of gastric contents into the esophagus; it may lead to esophagitis, reflux symptoms sufficient to impair quality of life (QOL), and/or long-term complications^[1]. In Japan, GERD was, in the past, considered to be a rare disease, but is now one of the most common chronic disorders. One systematic review of Japan^[2] reported that 15.4% (725) of 4723 patients had heartburn twice or more per week; 42.2% had symptoms of heartburn, including those who had heartburn once or less per week; and 16.7% (602) of 3608 patients had reflux esophagitis. Some papers have suggested that the increasing prevalence of GERD is a result of rising acid secretion in the general Japanese population, caused by the westernization of lifestyle and diet (to include dairy products) and decline in *Helicobacter pylori* (*H. pylori*) infection^[3].

Proton pump inhibitors (PPIs) provide the highest levels of symptom relief, healing of esophagitis, and prevention of relapse and complications^[4]. They are the first choice for therapy in most GERD patients with or without esophageal mucosal injury^[5,6]. However, PPIs cost more than do other acid-inhibiting agents. Some papers suggest that long-term PPI therapy, particularly at high doses, is associated with increased risks of community-acquired pneumonia^[7] and hip fracture^[8]. Therefore, if possible, PPIs should be administered at the lower dose. Full-dose PPI first "step-down" therapy is superior, both to administering histamine-2-receptor antagonist (H₂RA) first and low-dose PPI first "step-up" strategy, with regard to both efficacy and cost-effectiveness^[9,10]. However, some patients experience a recurrence after step-down^[11,12].

On the other hand, there is increasing interest in evaluating the QOL of patients with GERD. It is widely accepted that patients with GERD have a decreased QOL compared with the general population^[13-15], similar to that seen in patients with other chronic diseases^[16]. Consequently, patient-reported symptoms and QOL are important in assessing treatment outcome.

In this article, we describe 2 series of studies devised to investigate the predictors of success in step-down PPI therapy and to assess symptom-related QOL as determined by a questionnaire administered during GERD therapy.

MATERIALS AND METHODS

Study 1 (PPI initial therapy for GERD)

Subjects: This multicenter trial was conducted at Okayama

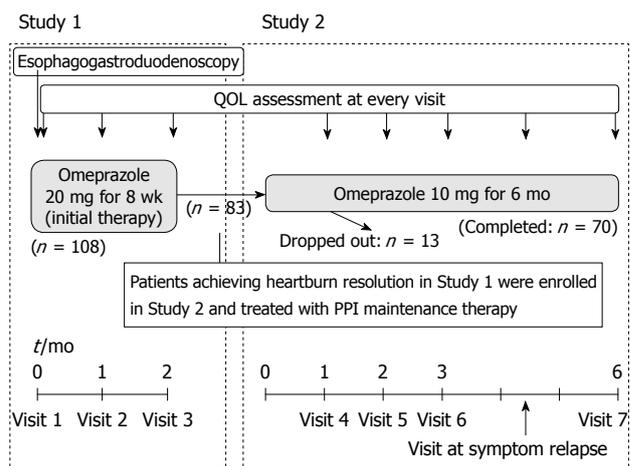

Figure 1 Overview of the study design. QOL: Quality of life; PPI: Proton pump inhibitor.

ma University Hospital and 20 affiliated hospitals in Japan. The study protocol was approved by the local institutional review boards of Okayama University Hospital and of each of the affiliated hospitals. Written informed consent was obtained from each patient before their enrollment in this study.

The major eligibility criteria were the following: heartburn that occurs twice a week or more; age 20 years or older; and either erosive esophagitis (EE) or non-erosive reflux disease. The exclusion criteria were as follows: use of PPIs within 1 mo of the start of the study; open gastric or duodenal ulcer; malignant neoplasm; serious systemic disease; and pregnancy, signs of pregnancy, or occurrence during a lactation period.

Study design: Patients who met the above-mentioned inclusion criteria were asked to complete the Gastrointestinal Symptom Rating Scale (GSRS) to assess gastrointestinal symptom-related QOL. Additional information, including demographic data, height and weight measurements used to assess body mass index (BMI), comorbid conditions, concurrent medication use, history of GERD symptoms, and previous GERD medication, was collected at the initial visit. Upper gastrointestinal endoscopy was performed to assess hiatus hernia, esophagitis, and upper gastrointestinal disorders before treatment.

PPI therapy was performed according to the following strategy (Figure 1): Patients were treated with 20 mg of omeprazole (OPZ) once daily for 8 wk as an initial therapy. GSRS results were evaluated before the initial therapy and after both 4 and 8 wk of treatment.

The primary analysis was to investigate the rate of success of initial PPI therapy. Success was defined as having heartburn once a week or less at the end of the initial therapy. Secondary analyses examined changes in QOL during the initial treatment of PPI.

Study 2 (PPI step-down therapy as maintenance therapy of GERD)

Subjects: Patients whose incidence of heartburn de-

creased to once a week or less at the end of study 1 (the initial therapy) were enrolled in this study. Study 2 subjects included patients who achieved complete remission and those who achieved partial remission of GERD symptoms.

Study design: Patients received PPI step-down therapy: namely, 10 mg of OPZ once daily for 6 mo (Figure 1). QOL related to gastrointestinal symptoms was evaluated at 1, 2, 3, and 6 mo after the beginning of maintenance therapy. If heartburn recurred twice a week or more during maintenance therapy, the treatment was stopped and the QOL at that time was evaluated.

The primary analysis was designed to identify predictors of subjects who were successful in PPI step-down therapy—defined as having no recurrence of heartburn 6 mo after PPI step-down. Secondary analyses examined changes in QOL during the maintenance treatment of PPI.

Endoscopic assessment

The severity of esophagitis was established by endoscopic examination using the modified Los Angeles (LA) classification of Grade A to D, with Grade M and N^[17]. This adds an additional grade N (defined as no apparent mucosal change) and grade M (defined as minimal changes in the mucosa, such as erythema and/or whitish turbidity). The modified LA system has recently become widely used in Japan^[18]. A diagnosis of hiatus hernia was made when the retroflexed endoscope, under the condition of gastric inflation, showed gaping esophageal lumen allowing the squamous epithelium to be viewed below^[19]. Atrophic gastritis was diagnosed by endoscopy using the Kimura-Takemoto endoscopic classification^[20], in which atrophic gastritis was divided largely into closed type (C-type) and open type (O-type) by the location of an atrophic border detected by endoscopy. C-type means that the atrophic border remains on the lesser curvature of the stomach, while O-type means that the atrophic border no longer exists on the lesser curvature but extends along the anterior and posterior walls of the stomach. In this study, atrophic gastritis was defined as only the O-type of the Kimura-Takemoto classification: the endoscopic diagnosis of C-type atrophic gastritis may be unreliable because of interobserver variation.

QOL assessment

Symptom-related QOL was assessed using the GSRS. The GSRS is a disease-specific 15-item questionnaire developed, based on reviews of gastrointestinal symptoms and clinical experience, to evaluate common symptoms of gastrointestinal disorders^[21,22]. Patients are asked to numerically score their subjective symptoms on a Likert-type scale of 1-7. The sum of the scores for all 15 items is regarded as the total GSRS score. Because each of the 15 questions can be scored from 1 to 7, the minimum total score obtainable is 15, and the maximum total score is 105. This total is then divided by 15 to obtain the overall

GSRS score, from a minimum of 1 to a maximum overall score of 7. Furthermore, the scores for the 5 symptom categories (reflux, abdominal pain, dyspepsia, diarrhea, and constipation) are obtained by calculating the means of the scores on the items for each symptom category. The higher the overall score, the more severe the symptoms^[23].

Statistical analysis

All categorical variables were analyzed using chi-square or Fisher's exact test.

Analyses of efficacy parameters were performed on 2 populations: the intention-to-treat (ITT) and the per-protocol (PP) populations.

The time to first symptom relapse after PPI step-down was assessed by Kaplan-Meier analysis. To determine the predictors of successful step-down, univariate and multivariable logistic regression analyses were planned. Variables found in the univariate analysis to be significantly associated with successful step-down were included in a multivariable logistic regression analysis. Changes in QOL were analyzed with paired *t* tests. An overall significance level of 5% was used in all tests. Statistical analysis was performed with SPSS version 11.0 using Windows.

RESULTS

Study 1

Between April 2004 and March 2007, 108 eligible patients were entered into study 1. For reasons that were apparently not causally related to the medication, 21 out of 108 patients dropped out of the study. The demographic characteristics of the patients are shown in Table 1. In the ITT analysis, 83 (76%) of 108 patients completed the 8 wk of initial therapy successfully. In the PP analysis, 83 (95.4%) of 87 patients were successful. The reasons for failure of the 4 patients in initial therapy were insufficiency of GERD symptoms in 2 patients and side effects of PPI in the other 2. The adverse reactions were diarrhea (one patient) and tinnitus (one patient). The reasons for dropout of 21 patients in study 1 were as follows: one patient withdrew her consent before the initial therapy, 12 patients never came to the hospital after the initial visit without excuse, 8 patients never came to the hospital after the second visit without excuse (3 of them still had symptoms of reflux at that time), the others got relief of reflux symptoms.

Symptom-related QOL analysis was performed for subjects who successfully completed the initial therapy. The changes in QOL during therapy are shown in Figure 2. The GSRS total score significantly improved from the baseline after 4-wk treatment ($P < 0.0001$). Of the 83 patients who had heartburn once a week or less at the end of the initial therapy, 55 patients (66%) had a reflux score of one, indicating no symptoms, 23 patients (28%) had a score of two, and the others had a score of three. In other words, 78 (94%) of 83 patients having heartburn

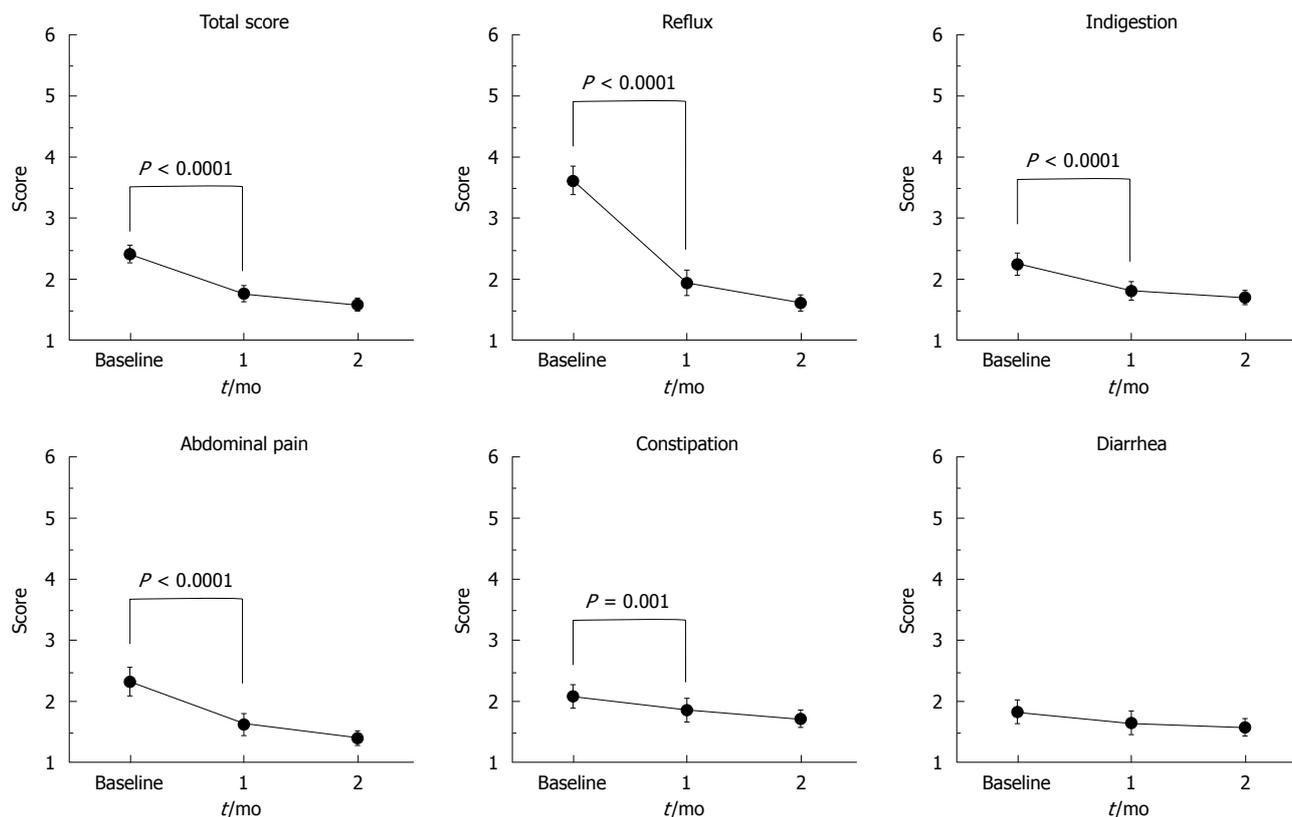

Figure 2 Gastrointestinal Symptom Rating Scale scores during the initial treatment (study 1).

| Characteristic | ITT population (n = 108) |

| Bronchial asthma | 4 (3.7) |

¹Atrophic gastritis was defined as only the O-type of the Kimura-Takemoto classification^[20]. BMI: Body mass index; GERD: Gastroesophageal reflux disease; ITT: Intention-to-treat.

once a week or less complained of little or no symptoms of reflux at the end of the initial therapy. Not only the GSR reflux scores but also the abdominal pain, indigestion, and constipation scores showed significant improvements ($P < 0.0001$).

Study 2

Eighty three eligible patients who had heartburn resolution after the initial 8 wk of therapy were recruited for study 2-step-down treatment as maintenance therapy. Thirteen patients dropped out during the maintenance therapy without recurrence or adverse reactions; 70 patients completed the study 2 protocol. Of 13 dropout patients, one patient experienced exaggerated symptoms of reflux before dropout, nine experienced complete resolution of reflux symptoms before dropout, and the others never came to the hospital after starting the step-down therapy.

Demographic and baseline characteristics of the study 2 population are summarized in Table 2. In the ITT analysis, 56 (67.5%) of 83 patients did not suffer a recurrence during maintenance therapy. In the PP analysis, 56 (80%) of 70 patients were successful in step-down therapy (Figure 3). Of 14 failures, 10 occurred within the first 3 mo of maintenance therapy. The mean time to failure was 56 d (range, 16-180 d).

In the univariate analysis of the ITT population, there were no significant predictors for successful step-down. In the univariate analysis of the PP population ($n = 70$), the significant predictors for successful step-down were:

ning of step-down ($P = 0.014$) were predictive factors for successful step-down (Table 4).

Symptom-related QOL analysis was performed on subjects for whom maintenance therapy was successful. The changes in QOL during therapy are shown in Figure 3. The improved GSRS scores of initial therapy were maintained throughout step-down therapy (Figure 4).

DISCUSSION

In study 1, we investigated the effectiveness of OPZ (20 mg) for the initial treatment of GERD and changes in symptom-related QOL during the initial therapy. Previous studies of patients with GERD using PPIs showed that 64%-88% of patients with typical reflux symptoms respond to PPI therapy^[24-26]. The heartburn resolution rate of the present study (95.4%) was higher than that of previous studies. It is reasonable to assume that a less rigorous end-point of the present study, namely having heartburn once a week or less, would have resulted in a higher rate of symptom response.

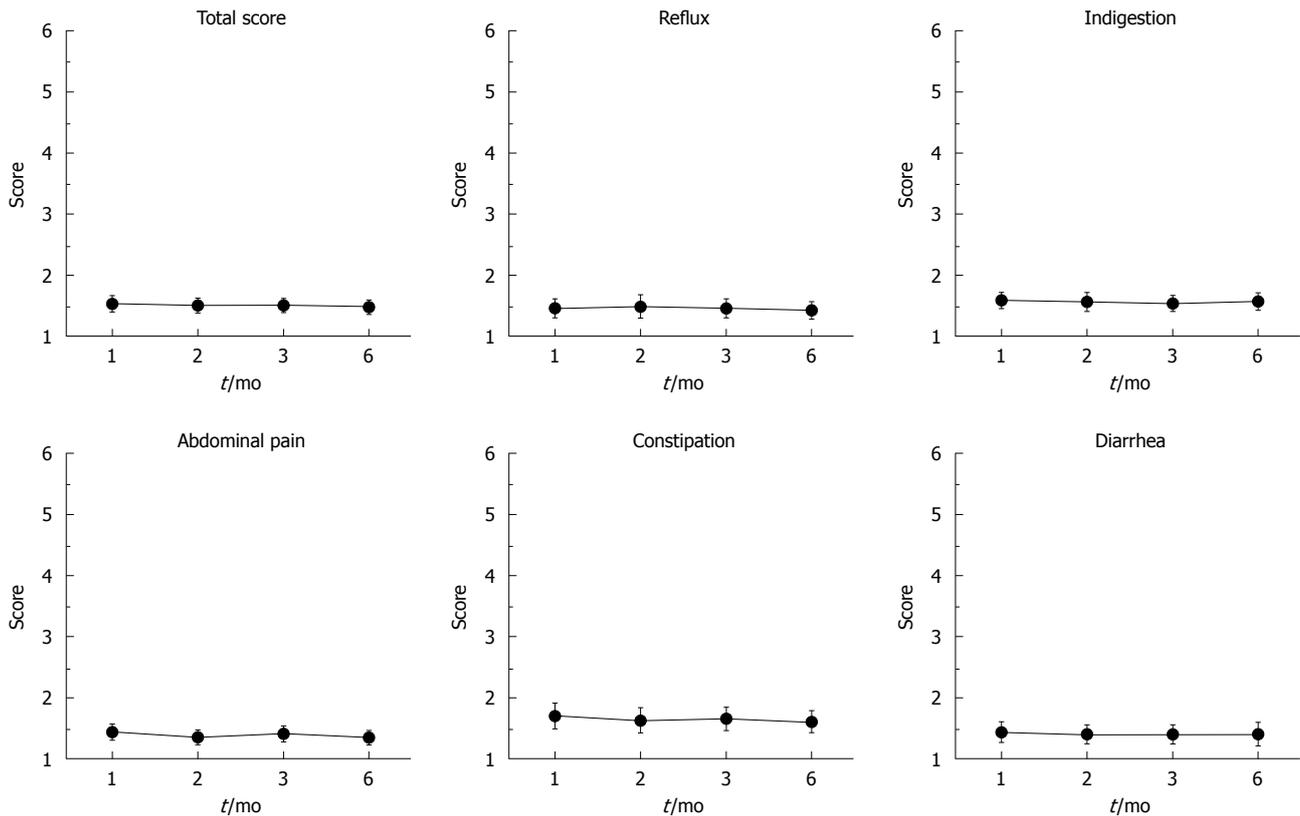

Figure 4 Gastrointestinal Symptom Rating Scale scores during maintenance treatment (study 2).

The assessment of symptom-related QOL in study 1 demonstrated that PPI therapy for GERD produced an improvement not only in reflux symptoms but also in other symptoms, such as abdominal pain and symptoms of indigestion. We could not exclude other factors possibly related to improvement of those symptoms in addition to the drug effect, for instance, regression toward mean, the nature of symptom fluctuation, Hawthorn effect, *etc.* This result confirms that most GERD patients have other gastrointestinal symptoms (dyspepsia and abdominal pain), which, if they are related to acid reflux, are improved by acid suppressants^[27-29].

In study 2, we determined the characteristics of GERD patients whose heartburn relief achieved by the initial therapy could be sustained through maintenance therapy with a half-dose of PPI therapy. The results showed that 80% of subjects whose symptoms were controlled with full-dose PPI could be successfully managed with a lower dose of PPI for 6 mo. The success of step-down was predicted only by no previous treatment for GERD and a better GSRS indigestion score at the beginning of step-down. Inadomi *et al.* showed that the success of step-down was predicted only by the duration of PPI use before the study^[30]. This result is similar to that of the present study in that both studies suggest that the other baseline patient factors likely to influence the efficacy of step-down therapy, such as BMI, *H. pylori* infection, LA classification and erosive esophagitis in endoscopic findings, and hiatus hernia were not predictors of successful step-down. There was no significant difference in

the therapeutic outcome according to LA classification, probably because there were a few patients with severe esophagitis; i.e. grade C or D, in the present study.

It is interesting that the indigestion score after initial therapy is associated with the success of step-down. This result means that patients who are in remission from GERD symptoms, but have dyspeptic symptoms after initial therapy, need stronger acid-suppression than do those who have no symptoms after a standard dose of PPI therapy. The patients with PPI non-responsive dyspepsia may have delayed gastric emptying, which could increase the frequency of transient lower esophageal sphincter relaxation and stimulate gastric acid secretion^[31,32]. This is probably the reason why stronger acid-suppression is necessary for heartburn control. These results demonstrate that physicians who treat GERD should ask patients about several conditions in addition to reflux.

There are several limitations to the present study. First, there were a relatively large number of dropouts during maintenance therapy. So, when analysis regarded dropouts as failures on the basis of the ITT principle, there were no predictors for successful step-down. When the pursuit period of study 2 was shortened from 6 mo to 3 mo, ITT analysis showed several statistically significant differences. In a univariate analysis, significant predictors for successful step-down were no H₂RA use at baseline ($P = 0.05$) and a better GSRS indigestion score at the beginning of step-down ($P = 0.009$). In a multivariate analysis, only the better GSRS indigestion scores at the beginning

of step-down ($P = 0.016$) were predictive factors for successful step-down. In the present study, most patients had mild esophagitis, which would probably benefit from the mild treatment or even by non-drug therapy, for instance, light and early dinner, inclined bed, and straight posture^[33]. This may explain why many patients dropped out. Indeed, most patients discontinued therapy because they had no further symptoms. Furthermore, it cannot be denied that some patients with successful step-down may have had good control of their GERD symptoms by non-drug therapy because we did not take into account the recommended life-style and dietary changes in our study protocol.

Second, in this study, many patients (75% of patients who received 8 wk of initial therapy) did not have the post-treatment endoscopic assessment. Some patients in clinical remission after the initial therapy did not have endoscopic remission. If all subjects underwent post-treatment endoscopy, the endoscopic findings could be the candidate predictor of successful step-down.

Third, cytochrome P450 2C19 genotypic differences, which are related to the cure rates for GERD with PPIs (OPZ and lansoprazole)^[11,34,35], are not considered in this study. This factor could also be the candidate predictor^[11,36]. The analysis of these factors may provide more information for GERD treatment.

In conclusion, our study revealed that the majority of patients whose heartburn decreased to once a week or less on full-dose OPZ therapy can be successfully stepped-down to a half-dose of PPI. The predictors of successful step-down are no previous treatment for GERD and a better indigestion score in the GSRS at the beginning of step-down. Improvement of symptom-related QOL was maintained throughout the step-down therapy.

COMMENTS

Background

Gastroesophageal reflux disease (GERD) is one of the most common disorders not only in the Western world but also in Japan, with increasing prevalence and incidence in the last decades. Typical GERD symptoms include heartburn, acid regurgitation into the pharynx, and dysphagia. The GERD patients sometimes suffer from chest pain, dyspepsia, and other atypical symptoms including coughing, wheezing, hoarseness, etc.

Research frontiers

Proton pump inhibitors (PPIs) are the first choice of therapy for most GERD patients with or without esophageal mucosal injury. Full dose PPI-first "step-down" therapy is superior to histamin-2-receptor antagonist (H₂RA) or low dose PPI-first "step-up" strategy with regard to both efficacy and cost-effectiveness. However, there is no clear consensus regarding the predictors for successful step-down. Treatment of GERD aims not only at healing esophagitis but also at managing the symptoms of GERD associated with decreased quality of life (QOL). In this study, we investigated the predictors of success in step-down PPI therapy and assessed the symptom-related QOL.

Innovations and breakthroughs

Many studies evaluating the efficacy of PPI in terms of the symptoms of GERD patients in the Western world did not evaluate the grade of esophagitis with endoscopy. Recently, many studies in Japan have focused mainly on non-erosive reflux disease (NERD) patients. The data of this study originated from GERD patients (both erosive gastritis and NERD) who were diagnosed with endoscopy. Therefore, the results may reflect those of the GERD patients in the Japanese general population and can be considered useful for GERD treatment in the clinical practice.

Applications

By considering the clinical features of GERD patients with recurrence during the step-down therapy, this study's findings may suggest new strategies for additional PPI dose reduction including every-other-day administration, on-demand therapy, step-down to H₂RA, and drug-free management.

Peer review

The authors investigated the effect of omeprazole and subsequent step-down maintenance therapy in patients with GERD. This study must be a very interesting topic for readers in view of the rarity of PPI outcome studies in the Asia pacific region.

Abstract

AIM: To examine the frequency and prevention of musculoskeletal pain in Japanese gastrointestinal endoscopists and non-endoscopist physicians.

METHODS: Questionnaires were sent to 275 endoscopists and 173 non-endoscopists working in Hiroshima University Hospital and its affiliated hospitals.

RESULTS: The completed questionnaires were returned by 190 (69%) endoscopists and 120 (69%) non-endoscopists. The frequency of pain in the hand and wrist, and especially the left thumb, was significantly higher in endoscopists than in non-endoscopists (17% vs 6%, $P = 0.004$). Using multivariate analysis, the only significant factor associated with this pain was the age of the endoscopist (odds ratio 2.77, 95% confidence interval,

1.23-6.71, $P = 0.018$). Interestingly, endoscopists had made significantly fewer modifications to their endoscopic practices than non-endoscopists (12% vs 33%, $P < 0.0001$) to prevent pain.

CONCLUSION: Pain in the hand and wrist may be endoscopy-related. However, endoscopists made little modifications in practice to prevent such pain. More attention to prevention appears necessary.

INTRODUCTION

Muscle and joint pain is a common complaint in individuals whose jobs require repetitive isometric maneuvers or awkward body positions^[1]. Such pain has been reported in individuals with various occupations such as bus drivers^[2], unskilled laborers^[3], musicians^[4], physical therapists^[5], and computer keyboard operators^[6]. Recently, ergonomic mechanisms related to the development of work-related musculoskeletal disorders have drawn substantial interest.

Endoscopy in clinical gastroenterology is becoming more important not only in Western countries but also in

Eastern countries including Japan^[7,8], and the number of endoscopic examinations and treatments has increased rapidly. In addition, procedures requiring long performance time such as endoscopic submucosal dissection^[7,9], endoscopic sphincterotomy, and endoscopic papillary balloon dilatation are commonly performed. The work burden of endoscopists has significantly increased.

Evidence suggests that endoscopists frequently report a variety of musculoskeletal problems including neck pain, low back pain, and thumb and hand pain^[10,11]. On the basis of previous reports, it has been suggested that the performance of endoscopy predisposes the operator to the development of musculoskeletal pain. However, there is little published evidence of this, and most of this evidence comes from Western countries; little evidence has come from Eastern countries including Japan. More attention needs to be paid to the impact of musculoskeletal pain and its prevention in Eastern countries. Therefore, we examined the frequency of musculoskeletal pain in Japanese gastrointestinal endoscopists and non-endoscopist physicians. The use of pain prevention strategies and physician requests to improve endoscopic design were also examined.

MATERIALS AND METHODS

General overview

Questionnaires were sent to endoscopists and non-endoscopist physicians working in Hiroshima University Hospital and its affiliated hospitals. The questionnaires were sent with an introductory letter explaining the study. The survey was conducted between March and May, 2010.

Subjects

Subjects consisted of endoscopists and non-endoscopist physicians in Hiroshima University Hospital and its affiliated hospitals. A control group was also included and consisted of a random sample of non-endoscopist physicians.

Questionnaire

The questionnaire for endoscopists consisted of questions on the endoscope model primarily used, mean number of endoscopic examinations and treatments per week, mean amount of time spent performing endoscopic procedures per week, location and description of pain present at the time of the survey, impact of pain on the endoscopist, type of treatment needed for the pain, and injury prevention strategies currently in place, if any. Non-identifying demographic information including age, sex, body mass index (BMI), hand dominance, physical activity level, and practice years was obtained. A modified survey was sent to the non-endoscopists.

Statistical analysis

Student *t*-tests were performed to evaluate differences in weight, height, and BMI between the groups. χ^2 tests were used to assess variables including age, sex, hand dominance, physical activity level, and practice years. To identify the factors associated with musculoskeletal pain,

Table 1 Non-endoscopist physicians who participated in this survey

| Endoscopic ultrasonography (<i>n</i> = 48) | 2.2 \pm 1.9 |

especially pain in the hand and wrist among endoscopists, univariate and multivariate logistic regression analyses were performed with JMP IN (Cary, NC, USA) software. All significance levels were set at $P < 0.05$.

RESULTS

Subject characteristics

questionnaires were sent to 275 endoscopists and 173 non-endoscopist physicians. One hundred ninety (69%) endoscopists and 120 (69%) non-endoscopists returned

Table 4 Environmental factors affecting endoscopic procedures

| Factor | No. per week (<i>n</i> = 190) |
|---|--------------------------------|
| Use of height-adjustable examination table (yes/no) | 186 (98)/4 (2) |
| Position of monitor (directly in front of endoscopist, at eye level/other position) | 133 (70)/57 (30) |
| Manufacturer of endoscope primarily used (Olympus/Fujifilm/NI) | 138 (73)/47 (25)/5 (3) |

NI: Not informed.

completed questionnaires. The details of non-endoscopist physicians who participated in this survey are shown in Table 1. The two groups were similar in terms of age, years in practice, sex, hand dominance, and BMI (Table 2). Physical activity level was significantly lower in endoscopists than in non-endoscopists ($P = 0.046$).

Endoscopy information

The number of esophagogastroduodenoscopies completed per week was 15.0 ± 8.7 (mean \pm SD) (Table 3). Of the 190 endoscopists, 161 (85%) performed colonoscopies, and the mean number of colonoscopies performed per week was 6.7 ± 3.7 (mean \pm SD). Sixty-three (33%) endoscopists performed endoscopic retrograde cholangiopancreatography (ERCP). Forty-eight (25%) endoscopists performed endoscopic ultrasonography (EUS). On average, the amount of time spent per week performing endoscopy was 11.9 ± 8.7 h (mean \pm SD).

Environmental factors affecting endoscopic procedures

Most (98%) endoscopists indicated that they used height-adjustable examination tables (Table 4). As for monitor position, 133 of 190 (70%) endoscopists replied that the monitor was directly in front of the endoscopist and at eye level. With regard to the manufacturer of the endoscope used, 138 (73%) endoscopists used Olympus, 47 (25%) used Fujifilm, and 5 (3%) gave no response.

Musculoskeletal pain in endoscopists

None of the endoscopists reported a history of preexisting musculoskeletal conditions. Eighty-one (43%) endoscopists had musculoskeletal pain at the time of the survey, and 21 (26%) of those reporting pain sought medical care as a consequence.

The most frequent sites of pain identified by the endoscopists were the lower back ($n = 50$, 26%), the neck ($n = 18$, 9%), the right shoulder ($n = 18$, 9%), and the left thumb ($n = 16$, 8%) (Table 5). Pain in the hand and wrist was reported by 32 (17%) endoscopists.

Musculoskeletal pain in non-endoscopists

None of the non-endoscopists reported a history of preexisting musculoskeletal conditions. Forty-nine (41%) non-endoscopists reported musculoskeletal pain at the time of the survey, and 7 (14%) of these physicians sought medical care as a consequence.

The most frequent sites of pain identified in the non-endoscopists were the lower back ($n = 24$, 20%), the right shoulder ($n = 14$, 12%), the neck ($n = 13$, 11%), and the left shoulder ($n = 12$, 10%) (Table 5). Pain in the hand and wrist was reported by 7 (6%) non-endoscopists.

Comparison of musculoskeletal pain between endoscopists and non-endoscopists

The frequency of overall musculoskeletal pain did not differ significantly between the endoscopists and non-endoscopists (81 of 190 (43%) *vs* 49 of 120 (41%), $P = 0.755$). However, the frequency of pain in the left thumb was significantly higher in the endoscopists than in the non-endoscopists (16 of 190 (8%) *vs* 0 of 120 (0%), $P = 0.001$). Pain in the hand and wrist was significantly higher in the endoscopists than in the non-endoscopists (32 of 190 (17%) *vs* 7 of 120 (6%), $P = 0.004$). There were no significant differences between the groups in the frequency of pain at other locations, such as the shoulder and lower back.

Univariate and multivariate logistic regression analyses for factors associated with thumb, finger, hand, and wrist pain in endoscopists

Results of univariate analysis for factors related to thumb, finger, hand, and wrist pain in endoscopists are shown in Table 6. The only significant factor was age of the endoscopist (> 40 years *vs* ≤ 40 years, $P = 0.011$). The mean number of colonoscopies per week and dominant hand tended to be significant (> 6.7 *vs* ≤ 6.7 , $P = 0.091$, left *vs* right, $P = 0.098$, respectively). Thus, endoscopists who performed more than 6.7 colonoscopies per week or who were left-handed tended to have more frequent pain in the hand and wrist.

Results of multivariate analysis for factors related to pain in the hand and wrist in endoscopists are shown in Table 7. Only age was found to be a significant factor associated with pain in endoscopists (> 40 years *vs* ≤ 40 years, odds ratio (OR) 2.77, 95% confidence interval, 1.23-6.71, $P = 0.018$) by multivariate analysis.

Pain prevention

Only 23 (12%) endoscopists had made modifications to their endoscopic practice in response to pain arising due to performing endoscopic procedures. The most common practice modifications endorsed are shown in Table 7. These modifications were stretching exercises ($n = 11$, 6%), taking breaks ($n = 11$, 6%), wearing athletic shoes ($n = 8$, 4%), and less work ($n = 5$, 3%). Interestingly, endoscopists had made significantly fewer modifications to their practice than non-endoscopists to address pain prevention.

Requests to improve endoscopic design from endoscopists

The requests made by Japanese endoscopists to improve endoscope design are shown in Table 8. The most frequent request was to make the operating part lighter ($n = 85$, 45%), followed by making the operating part

Table 5 Frequency of major types of musculoskeletal pain in Japanese endoscopists and non-endoscopists *n* (%)

| Site of pain | Endoscopists (<i>n</i> = 190) | Non-endoscopists (<i>n</i> = 120) | <i>P</i> value |

smaller (*n* = 41, 22%), and reducing the resistance of the angulation controller (*n* = 36, 19%). There were no significant differences between the frequency of requests and the manufacturers of the endoscope primarily used (data not shown).

DISCUSSION

Our data indicate that the frequency of pain in the hand and wrist, and especially in the left thumb, was significantly higher in endoscopists than non-endoscopists (17% *vs* 6%, *P* = 0.004). By multivariate analysis, the only significant factor associated with pain was the age of the endoscopist (OR 2.77, *P* = 0.018).

Previous studies have reported that the incidence of symptoms or injuries attributable to the performance of endoscopy ranges from 39% to 78%^[11]. These results suggest that musculoskeletal pain is prevalent in

Table 7 Modifications to prevent musculoskeletal pain

| Make the resistance of the angulation controller heavier/lighter | 0 (0)/36 (19) |

endoscopists. In the present study, 43% of endoscopists had musculoskeletal pain, which is similar to that in previous reports. In addition, a U.S. study showed that the frequency of reported musculoskeletal pain was higher in endoscopists than non-endoscopists (74% *vs* 35%, *P* < 0.001)^[10]. In the present study, pain in the hand and wrist was significantly more frequent in endoscopists than in non-endoscopists, indicating that endoscopists may be at higher risk for musculoskeletal pain, especially in the hand and wrist, than non-endoscopists.

The most frequent sites of pain reported in our study were the lower back, neck, right shoulder, and left thumb. Previous studies have reported similar anatomic sites of pain associated with performing endoscopy, including a case report of de Quervain’s syndrome or “endoscopists’ thumb”^[11-14]. Buschbacher^[15] found that 27% of responders reported low back pain, 19% thumb pain, and 19% shoulder pain. Preliminary results from an American Society for Gastrointestinal Endoscopy web-based survey found that 43% reported hand or carpal tunnel injuries, 29% reported back pain, and 28%

reported neck pain^[16]. Specific aspects of performing endoscopy which may contribute to musculoskeletal pain are as follows: adjusting the tip of angulation controls, torquing with the right hand, and standing for prolonged periods of time. Manipulation of the tip angulation controls and torquing of the endoscope may lead to hand and wrist pain, whereas standing for prolonged periods of time may lead to back and neck pain.

In the present study, only age of the endoscopist was significantly associated with pain. Several researchers reported that age did not have an impact on the musculoskeletal pain identified. However, the location of pain has been reported to be different between a beginner group (duration of practicing endoscopy, < 39 mo) and an experienced group^[11]. The left thumb and fingers were the most common painful areas in beginners (43%), whereas the left shoulder was most painful in experienced endoscopists (33%). Furthermore, older age and sex were associated with many musculoskeletal disorders^[17]. Age may be an important factor associated with the musculoskeletal pain reported by endoscopists.

ERCP and EUS are both procedures requiring long endoscopy times with special devices. Some may think that these procedures are more likely to lead to musculoskeletal pain than other procedures. However, in the present study, performance of these procedures was not a significant factor associated with pain, whereas the mean number of colonoscopies performed per week and dominant hand tended to be significant by univariate analysis. In other words, the performance of colonoscopy may be a risk factor for the development of pain in the hand and wrist rather than the performance of ERCP or EUS. The torquing technique is very important in the performance of colonoscopy, and it is done frequently and for long periods of time. Furthermore, colonoscopy may require stronger torquing power than any other procedures, including ERCP and EUS. Therefore, torquing of the colonoscope appears to be another risk factor associated with pain. The colonoscope is torqued with the right hand, which is the weaker hand for left-handed endoscopists, and it is plausible that left-handed endoscopists tend to have more pain in the hand and wrist than right-handed endoscopists. A larger study is needed to investigate this issue.

Methods to prevent back pain include the use of a height-adjustable examination table, rubberized floor mats, and a short foot stool to alternate weight distribution^[18]. Monitor placement is an especially important determinant of torso and head posture. Monitors should be placed directly in front of the endoscopist while in the working position to avoid rotation and flexion of the cervical spine and should be adjusted to eye level^[18]. Most (98%) responders in the present study reported use of an adjustable examination table. However, 30% of responders reported that the position of monitors was inadequate. None of the endoscopists used rubberized floor mats or a short foot stool. There is much room for improvement in relation to these factors.

Improving posture, increasing physical activity, and stretching exercises before endoscopy have been suggested to prevent disability^[18]. Interestingly, in the present study, endoscopists made significantly fewer modifications to their endoscopic practices to prevent musculoskeletal pain, especially in regard to performing stretching exercises, than non-endoscopists. The reason for this is unknown. One possibility is that Japanese endoscopists may be busier than other non-endoscopist physicians and may not have enough time or willingness to exercise or stretch. Of course, selection bias may be undeniable. Education on methods to reduce endoscopic-related injuries must be carried out in a positive manner.

Endoscopic techniques that can help to prevent pain include minimizing torque and having an assistant apply torque when necessary. Ultimately, reevaluating the design of the endoscope with regard to ergonomics may be the best long-term strategy to reduce overuse injuries in an era of high-volume endoscopy. Endoscopists in the present study requested a lighter and smaller operating part and reduced resistance of the angulation controller. These requests may be useful for improving the design of the endoscope.

In conclusion, our data suggest that pain in the hand and wrist may be endoscopy-related. However, endoscopists made few modifications to their practices to prevent pain. More attention to pain prevention appears to be needed. Given the importance of endoscopy in the clinical setting, our results support a further controlled study on this subject in a much larger and more diverse population of endoscopists.

COMMENTS

Background

It has been suggested that the performance of endoscopy predisposes the operator to the development of musculoskeletal pain.

Research frontiers

There is little published evidence of this, especially from Eastern countries including Japan.

Innovations and breakthroughs

Frequency of occurrence of pain in the hand and wrist, and especially the left thumb, was significantly higher in endoscopists than in non-endoscopists (17% vs 6%, $P = 0.004$). By multivariate analysis, the only significant factor associated with the pain was the age of the endoscopist (odds ratio 2.77, 95% confidence interval, 1.23-6.71, $P = 0.018$).

Applications

The authors' data suggest that pain in the hand and wrist may be endoscopy-related. More attention toward pain prevention appears necessary.

Peer review

This is a study on an important issue, musculoskeletal pain in endoscopists. As authors described, more attention toward pain prevention in endoscopists should be paid.

Abstract

AIM: To evaluate the long-term efficacy and safety of endoscopic obliteration with Histoacryl[®] for treatment of gastric variceal bleeding and prophylaxis.

METHODS: Between January 1994 and March 2010 at SoonChunHyang University Hospital, a total of 127 patients with gastric varices received Histoacryl[®] injections endoscopically. One hundred patients underwent endoscopic Histoacryl[®] injections because of variceal bleeding, the other 27 patients received such injections as a prophylactic procedure.

RESULTS: According to Sarin classification, 56 patients were GOV1, 61 patients were GOV2 and 10 patients were IGV. Most of the varices were large (F2 or F3, 111 patients). The average volume of Histoacryl[®] per each session was 1.7 ± 1.3 cc and mean number of sessions was 1.3 ± 0.6 . (1 session-98 patients, 2 sessions-25 patients,

≥ 3 sessions-4 patients). Twenty-seven patients with high risk of bleeding (large or fundal or RCS+ or Child C) received Histoacryl[®] injection as a primary prophylactic procedure. In these patients, hepatitis B virus was the major etiology of cirrhosis, 25 patients showed GOV1 or 2 (92.6%) and F2 or F3 accounted for 88.9% ($n = 24$). The rate of initial hemostasis was 98.4% and recurrent bleeding within one year occurred in 18.1% of patients. Successful hemostasis during episodes of rebleeding was achieved in 73.9% of cases. Median survival was 50 mo (95% CI 30.5-69.5). Major complications occurred in 4 patients (3.1%). The rebleeding rate in patients with hepatocellular carcinoma or GOV2 was higher than in those with other conditions. None of the 27 subjects who were treated prophylactically experienced treatment-related complications. Cumulative survival rates of the 127 patients at 6 mo, 1, 3, and 5 years were 92.1%, 84.2%, 64.2%, and 45.3%, respectively. The 6 mo cumulative survival rate of the 27 patients treated prophylactically was 75%.

CONCLUSION: Histoacryl[®] injection therapy is an effective treatment for gastric varices and also an effective prophylactic treatment of gastric varices which carry high risk of bleeding.

Long-term result of endoscopic Histoacryl[®] (N-butyl-2-cyanoacrylate) injection for treatment of gastric varices. *World J Gastroenterol* 2011; 17(11): 1494-1500 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i11/1494.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i11.1494>

INTRODUCTION

Gastric varices occur in 18%-70% of patients with portal hypertension^[1,2] and are classified as gastro-esophageal varices (GOV) 1 (esophageal varix extending down to the cardia or lesser curve) or GOV2 (esophageal and fundal varices). Isolated gastric varices (IGV) may be located either in the fundus (IGV1) or elsewhere in the stomach (IGV2)^[1]. Although the incidence of bleeding from gastric varices is relatively low (10%-36%), when it occurs it tends to be more severe, to require more transfusion, and to have a higher mortality rate than esophageal variceal bleeding^[1,3-5] while acute bleeding is controlled. Gastric varices have a high rate of rebleeding (38%-89%)^[6-8]. Precisely what triggers a bleed from a gastric varix is not known. However a number of risk factors for gastric variceal bleeding have been identified: location in the fundus, advanced Child's stage, presence of red spots, and increasing size of the varices are the important factors in determining the risk of a first bleed from gastric varices^[9,10].

A number of treatment modalities for acute gastric variceal bleeding and prevention of bleeding are available. These include endoscopic treatment (sclerotherapy, band ligation, *etc*), TIPS (transjugular intrahepatic portosystemic shunt), and B-RTO (balloon-occluded retrograde transvenous obliteration). Of these, the first-line treatment for gastric variceal bleeding is endoscopic obliteration with Histoacryl® (N-butyl-2-cyanoacrylate)^[11,12].

Though it has been used worldwide for the treatment for gastric varices, data regarding the long-term efficacy and safety of this procedure are still lacking. Indeed, although rare, fatal complications do occur^[13,14].

We evaluated the long-term efficacy and safety of endoscopic obliteration with Histoacryl® for treatment of gastric variceal bleeding in terms of the prevalence of complications, ability to predict rebleeding and survival rates. Furthermore, the efficacy, prevalence of complications and survival rates of prophylactic endoscopic injection sclerotherapy with Histoacryl for high risk gastric varices found incidentally also assessed.

MATERIALS AND METHODS

Patients

This study was a retrospective analysis of patients with cirrhosis who underwent endoscopic Histoacryl® injection. From January 1994 to March 2010, patients (127) who presented to our hospital with acute gastric varices as evidenced by hematemesis or melena, or who had gastric varices without bleeding evidence, were considered for enrollment. This included 100 patients with active gastric variceal bleeding and 27 with high-risk varices (large, located in the fundus, red color sign (RCS), Child C)^[10] who underwent primary prophylaxis.

Of the 127 patients, 97 (76.4%) were male and 30 (23.6%) female, and the mean age was 55.69 years. The most common etiology of gastric varices was hepatitis B-related cirrhosis in 50 patients (39.3%), followed by alcoholic liver cirrhosis in 48 (37.8%), unknown in 19 (15%) and hepatitis C virus in 10 (7.9%). Twenty-one patients (16.5%) had been

diagnosed with hepatocellular carcinoma. The lesions of 42 patients (33.1%) were classified as Child-Pugh class A, 59 (46.4%) as Child-Pugh B, and 26 (20.5%) as Child-Pugh C. Endoscopic Histoacryl® injection was conducted within 24 h of gastric variceal bleeding in 48 patients (37.8%). Of the 127 patients, GOV1 was present in 56 (44.1%), GOV2 in 61 (48%), IGV1 in 8 (6.3%), and IGV2 in 2 (1.6%). Most varices ($n = 111$) were large (F2 or F3) (Table 1)^[9].

Twenty-seven patients with high risk gastric varices underwent endoscopic Histoacryl® injection as a primary prophylaxis. Of these, 21 (71.4%) were male and six (28.6%) female, and the mean age was 55.29 years. The most common etiology of gastric varices was hepatitis B-related cirrhosis (14 patients, 51.9%), followed by alcoholic liver cirrhosis in 6 (22.2%). Five of the 27 (18.5%) patients were diagnosed with hepatocellular carcinoma. Twelve (44.4%) were classified as Child-Pugh A and 11 (40.7%) as Child-Pugh B to Child-Pugh C. Of the 27, GOV1 was seen in 15 patients (55.6%) and GOV2 in 10 (37%). Most varices ($n = 24$) were categorized as size F2 or F3 (Table 2).

Treatment methods

Histoacryl® injection was performed using a GIFQ 230 or GIFQ 240 endoscope (Olympus C, Tokyo, Japan) and 23-gauge disposable injection needle catheter (1650 mm in length). Each shot contained 1.0-2.0 cc Histoacryl® and an equal volume of Lipiodol (Guerbet, Aulnay-Sous-Bois, France). The endoscopic suction channel was flushed with lubricant (olive oil) before insertion of the catheter. The preload sclerotherapy catheter was advanced through the endoscope into the stomach, and the needle was inserted directly in the gastric varix (Figure 1A and B). Immediately

GOV: Gastro-esophageal varices; IGV: Isolated gastric varices.

following injection of cyanoacrylate mixture into the gastric varix, the location of lipiodol in the gastric varix was assessed using fluoroscopic visualization (Figure 2). Lipiodol was given through the catheter to deliver the glue mixture into the varix, and the needle was then withdrawn while glue was still flowing to decrease the risk of needle embedment. The catheter was then flushed with sterile water. Typically 2 cc of a 1:1 mixture of lipiodol and Histoacryl® was administered per injection. Injections were repeated until gastric varices appeared to occlude, as judged by probing with a blunt probe.

Outcome measures

Successful hemostasis was defined as vital sign stability, no drop in hemoglobin and no rebleeding within 24 h of after sclerotherapy. Rebleeding was defined as hematemesis and/or melena, hypotension (a drop in systolic blood pressure of > 20 mm Hg from baseline), 2 mg/dL fall in hemoglobin and/or transfusion requirement of ≥ 2 units of packed red blood cells after 24 h.

Statistical analysis

Statistical interpretation of data was performed using the Statistical Program for Social Sciences (SPSS) version 14. Results were expressed as mean ± SD for continuous variables and as numbers (percentage) for categorical data. Analysis was performed using the independent *t*-test, χ^2 test and Fisher’s exact test, as appropriate. A *P*-value < 0.05 was considered statistically significant. Kaplan-Meier method and then log rank test were used to examine predictive factors of rebleeding rate within 1 year and survival rates.

RESULTS

Hemostatic outcomes

A total of 162 endoscopies were performed and the mean

number of sessions was 1.3 ± 0.6. Obliteration of gastric varices was achieved with one session in 98 patients and two sessions in 25. Four patients required three or more sessions. The mean volume of Histoacryl® administered was 1.7 ± 1.3 cc. Initial hemostasis was achieved in 125 patients (98.4%). Total number of rebleeding episodes in 127 patients was 29 (22.8%). The mean follow-up period of rebleeding was 322.71 ± 551.14 d. Episodes of rebleeding from 1 d to 1 year post-therapy occurred in 23 (18.1%) subjects with recurrent bleeding. One patient of these was considered to have treatment failure, whereas the others (22, 73.9%) experienced successful hemostasis after rebleeding (Table 3).

Only one Histoacryl® treatment was needed in 21 of 27 subjects (77.8%) who underwent primary prophylaxis. The other 6 patients received several sessions of Histo-

acryl® injection therapy because of incomplete obliteration of varices. The mean volume of Histoacryl® administered to these individuals was 2.1 cc. Three patients died due to hepatic failure and one due to hepatocellular carcinoma (HCC). No prophylactic treatment-related complications were noted (Table 4).

Complications

Complications were observed in 73/127 patients. The most common was fever ($n = 44$), followed by mild abdominal pain ($n = 22$) which subsided within 24 h. Two patients developed post-treatment infections; *Klebsiella pneumoniae* and *Escherichia coli* were identified through blood cultures. One developed pulmonary embolism (Figure 3A) and one patient suffered splenic infarction (Figure 3B); two patients developed adrenal abscesses (Figure 4A). Adrenal abscesses were drained through the catheter percutaneously, and both individuals recovered fully (Figure 4B). A conservative treatment strategy for both pulmonary embolism and splenic infarction was conducted (Table 5).

Predictive factors of rebleeding

Rebleeding occurred in 9 of 21 patients with HCC ($P = 0.000$). Also it occurred in 15 patients with GOV2 and 8 patients with GOV 1 ($P = 0.009$). The presence of HCC or GOV2 by Sarin classification was significantly associated with rebleeding within 1 year of the initial Histoacryl® injection (Figure 5A and B).

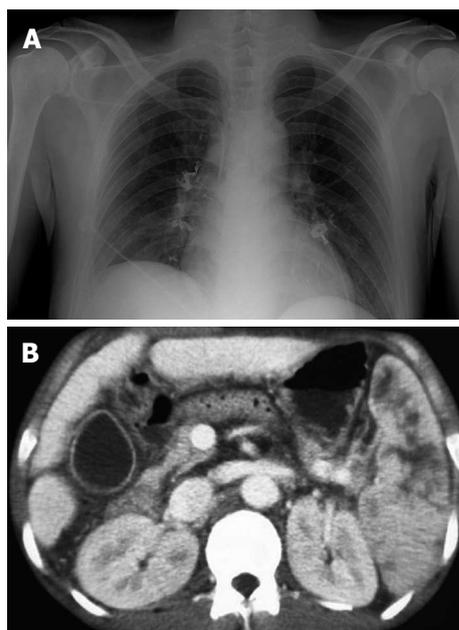

Figure 3 Embolic complications of Histoacryl® injection. A: Chest radiography showing pulmonary embolism after Histoacryl® injection; B: Computed tomography showing the presence of lipiodol in the splenic vein after Histoacryl® injection.

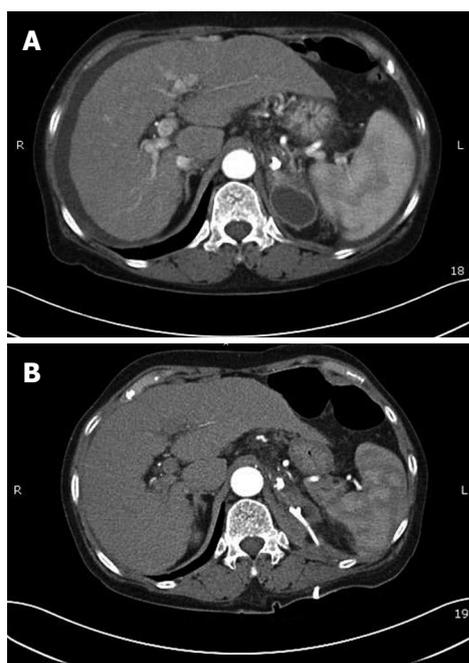

Figure 4 Adrenal abscess after Histoacryl® injection. A: Computed tomography scan showing adrenal abscess after Histoacryl® injection; B: Adrenal abscess was resolved after PCD insertion.

One year rebleeding rates were not associated with sex ($P = 0.597$), the cause of cirrhosis ($P = 0.707$), forms of varices ($P = 0.269$), time from bleeding to hemostasis ($P = 0.815$) or CTP grade ($P = 0.230$) (Table 6).

Survival

The median survival duration was 50 mo (95% CI 30.5-69.5). The cumulative survival rates of the 127 patients at 6 mo

and at 1, 3, and 5 years were 92.1%, 84.2%, 64.2%, and 45.3%, respectively (Figure 6A). Four of the 27 patients who underwent primary prophylaxis died of hepatic failure or HCC (Table 4). The 6-mo cumulative survival rate of these patients was 75% (Figure 6B).

DISCUSSION

Gastric varices and their association with portal hypertension were first described in 1931^[15]. The overall incidence of gastric varices in patients with portal hypertension is 18%-70%^[1,2]. The incidence of bleeding from gastric varices is relatively lower, ranging from 10%-36%, compared with bleeding from esophageal varices^[1]. Mortality associated with a first variceal bleed appears to have improved in recent years but remains as high as 20% within 6 wk of the index bleed^[3,4].

Endoscopic injection of Histoacryl® is the currently recommended in recent consensus and guidelines as the initial treatment for acute gastric variceal bleeding^[11,12]. Endoscopic injection of tissue glue for gastric variceal

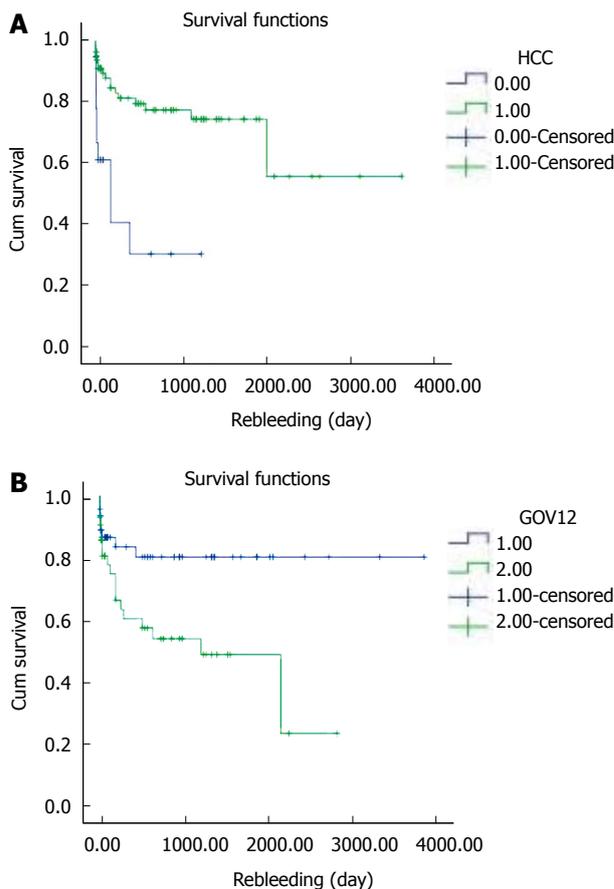

Figure 5 The 1-year rebleeding rate using the Kaplan-Meier method and then log rank test. A: Comparing the groups with hepatocellular carcinoma (HCC) or without HCC; B: Comparing GOV1 and GOV2. GOV: Gastro-esophageal varices.

bleeding was first reported in 1986 by Soehendra *et al*^[16]. However, the rebleeding rate remains high, at 22%-34% and episodic complications such as systemic embolism have been the main issues^[13]. Cerebral stroke, portal vein embolization, splenic infarction, coronary embolism, and nonfatal pulmonary emboli in 4.6% of cases were reported as complications of tissue adhesive use^[14,17-19]. But the complication rate was relatively low and most of the complications were not severe. The common adverse effects of Histoacryl® injection therapy include fever and abdominal discomfort. In this study, unusual adverse effects, such as pulmonary embolism, splenic infarction, and adrenal abscess were noted. We already reported two cases of adrenal abscess after NBC injection (Gut and Liver, article in press). The routes for gastric variceal drainage are gastrorenal shunt or gastro-caval shunt. In our cases, the adrenal abscesses developed 4-6 mo after the Histoacryl® injection. The reason why adrenal abscesses after Histoacryl® injection were so delayed is that insufficient drainage and stasis of adrenal vein blood by the Histoacryl® material made a significant contribution to abscess formation. In theory, using undiluted Histoacryl® may prevent distal embolization because the polymer solidifies rapidly upon contact with blood^[20]. D'Imperio *et al*^[21] studied undiluted Histoacryl® in 80 patients with bleeding gastric, esophageal, and duodenal varices. Distal embolization to distant abdominal

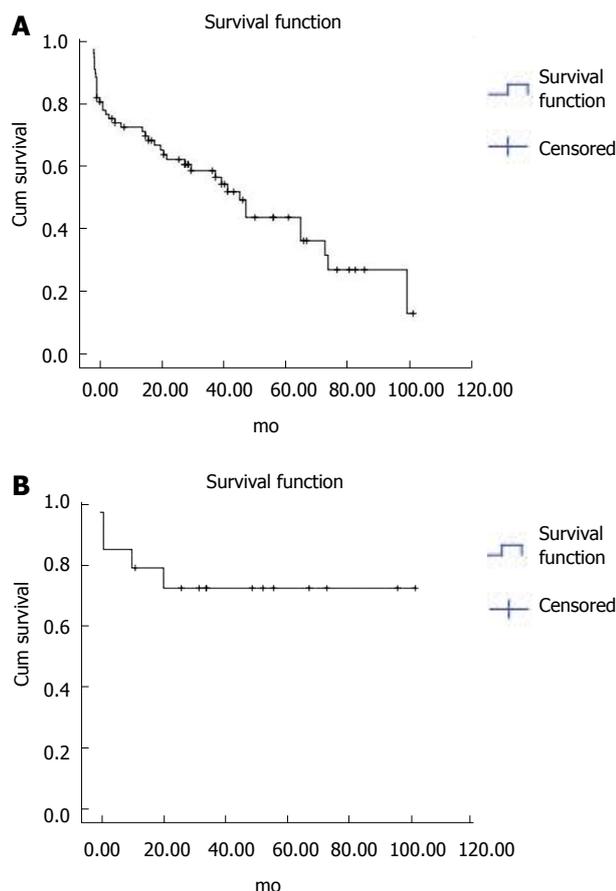

Figure 6 Survival of Histoacryl® injected patients. A: Survival of 127 Histoacryl®-injected patients using the Kaplan-Meier method. The 6 mo cumulative survival rate of these patients was 75%.

sites occurred in two patients. Therefore, using undiluted Histoacryl® does not preclude the risk of embolisation. In our cases, all subjects recovered fully; no symptoms such as cough and chest pain caused by migration of Histoacryl® from the variceal location to the pulmonary vein were noted. PCD was inserted into the adrenal abscess and follow-up CT indicated completed resolution.

Accurate classification of gastric varices is essential in determining optimal management. The most widely used classification is that proposed originally by Sarin *et al*^[1]. Unlike esophageal varices, a high porto-systemic pressure (> 12 mmHg) does not cause gastric variceal bleeding, likely due to the high frequency of spontaneous gastro-renal shunts^[22]. In one study, fundal varices had a significantly higher bleeding incidence (78% and 55% for IGV1 and GOV2, respectively) than either GOV1 or IGV2 (10%)^[23]. In the present study, of 127 patients, GOV1 was seen in 56 (44.1%), GOV2 in 61 (48%), IGV1 in 8 (6.3%), and IGV2 in 2 (1.6%). No significant difference in 1-year rebleeding rate rates between GOV1 and GOV2 were detected ($P = 0.173$).

Billi *et al*^[24] conducted a 24 mo follow-up of 50 patients who underwent Histoacryl® injections for gastric varices and reported that acute hemostasis was achieved in 92% of patients. Also Fuster *et al*^[25] reported good results

from Histoacryl® use in pediatric patients. In this study, the success rate of acute hemostasis was 98.4%, comparable to or better than that reported elsewhere^[26,27].

The reported rebleeding rate after Histoacryl® injection for acute gastric variceal bleeding ranged from 22%-59%^[26,28]. This was reduced by improvement of treatment technique, use of prophylactic antibiotics and effective vasoactive agents, and so on. Also the higher the MELD score was the more rebleeding occurred^[29]. In our study the rebleeding rate was 22.8% ($n = 29$). This is consistent with other reports^[26,28]. Episodes of rebleeding from 1 d to 1 year occurred in 23 patients (18.1%). Twenty-two patients experienced successful hemostasis after rebleeding (73.9%).

In our study, rebleeding within 1 year was associated with the presence of HCC ($P = 0.000$) and Sarin classification (GOV2) ($P = 0.009$). However, no statistically significant difference in rebleeding rates among Child-Pugh scores A, B, and C ($P = 0.230$) or form of gastric varices ($P = 0.269$), sex ($P = 0.597$) and etiology ($P = 0.707$) was found. We assume that complete obliteration in GOV2 is not easy because GOV2 is wider than GOV1, and that was the reason for more frequent rebleeding in GOV2 than GOV1.

Use of β -blockers for the primary prevention of gastric variceal bleeding is not supported by significant data^[5]. Because the mortality rate of gastric variceal bleeding is high, it has been suggested that patients at high risk for bleeding should undergo primary prophylaxis of the gastric varix^[10,30]. Hashizume *et al*^[9] reported a number of risk factors for gastric variceal bleeding: red colored spots, larger nodular varix, and location in the fundus. According to Kim *et al*^[10] advanced Child-Pugh class, varices > 5 mm in size, and the presence of a red spot were associated with an increased risk for a first bleed. On the basis of these facts, 27 patients with high-risk gastric varices (large, fundus, RCS, Child C) underwent primary prophylaxis with endoscopic Histoacryl® injection. Four of these patients died of hepatic failure or HCC. The others had survived to the time of writing this report. Thus the 6 mo cumulative survival rate of these patients was 75%. No treatment-related complications were noted.

In conclusion, Histoacryl® injection therapy is effective for the treatment of gastric varices with high initial hemostasis and rare complications. On the basis of our analysis, rebleeding rates were linked to the presence of HCC or GOV2. Furthermore, Histoacryl® injection therapy is effective for prophylaxis of gastric varices which carry high risk of bleeding.

COMMENTS

Background

Gastric variceal bleeding tends to be more severe than esophageal variceal bleeding. Furthermore, acute bleeding was controlled, gastric varices have a high rate of rebleeding. Precisely what triggers a bleed from a gastric varix is not known. Also the effect of primary prophylaxis of gastric varices is not studied well.

Research frontiers

In this study, the authors demonstrate the long-term efficacy and safety of endoscopic obliteration with Histoacryl® for treatment of gastric variceal bleeding and prophylaxis.

Innovations and breakthroughs

The rate of initial hemostasis was 98.4% and recurrent bleeding within one year

occurred in 18.1% of patients. The rebleeding rate in patients with hepatocellular carcinoma (HCC) or GOV2 was higher than in those with other conditions. Median survival was 50 months (95% CI 30.5–69.5). Cumulative survival rates of the 127 patients at 6 months, 1, 3, and 5 years were 92.1%, 84.2%, 64.2%, and 45.3%, respectively. The 6-month cumulative survival rate of the 27 patients treated prophylactically was 75%.

Applications

Histoacryl® injection therapy is effective for the treatment of gastric varices with high initial hemostasis and rare complications. On the basis of our analysis, rebleeding rates were linked to the presence of HCC or GOV2. Furthermore, Histoacryl® injection therapy is effective for prophylaxis of gastric varices which carry high risk of bleeding.

Terminology

Histoacryl® (N-butyl-2-cyanoacrylate) is a watery solution, which polymerizes and hardens within 20 seconds in a physiological milieu and instantaneously upon contact with blood. This makes it ideal for obliterating vessels and controlling bleeding. It is necessary to dilute it with the oily contrast agent Lipiodol® is not only compatible with the tissue glue for dilution but also allows fluoroscopic monitoring of delivery of the substance.

Peer review

The authors reported their results of a retrospective study on patients who underwent endoscopic NBC injection for gastric varices. Important data including the success rate of initial haemostasis, rebleeding rate, long-term complications and prognostic predictors were reported. Though being limited by the retrospective nature of the study, the strength of the study was the relatively large number of patients with active bleeding.

Abstract

AIM: To study the HER-2/neu protein expression and gene amplification in gastric carcinoma and their relation.

METHODS: One hundred and forty-five formalin-fixed and paraffin-embedded tumor tissue samples from Chinese gastric carcinoma patients were studied with immunohistochemistry (IHC) and fluorescence *in situ* hybridization (FISH) methods. Clinicopathologic data about all patients were collected.

RESULTS: The levels of HER-2 3+, HER-2 2+ and HER2

1+ were measurable in 6.9%, 8.3% and 17.2% of the samples, respectively. No HER-2 was stained in 67.6% of the samples. FISH showed that *HER-2* gene was amplified in 18 samples, 10 HER-2 3+ samples, 5 HER-2 2+ samples, and 3 HER-2 1+ samples with IHC staining. HER-2 status was not correlated with the sex and age of patients, and tumor size, location or differentiation, but with the depth of invasion, TNM stage, lymph node and distant metastasis as well as histopathological classification of gastric cancer ($P < 0.05$).

CONCLUSION: All samples with IHC as HER-2 expression should be analyzed with FISH. Detection of *HER-2* gene amplification can assess the malignant biological behaviors and prognosis of gastric cancer.

Clinicopathologic significance of HER-2/neu protein expression and gene amplification in gastric carcinoma. *World J Gastroenterol* 2011; 17(11): 1501-1506 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i11/1501.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i11.1501>

INTRODUCTION

Gastric cancer is the second most common cause of cancer-related death worldwide. Surgery is the only curative procedure for localized gastric cancer, which is at the advanced stage when diagnosed in most cases. Currently

available agents are not very effective, resulting in a high recurrence rate, a low survival rate, and a poor prognosis of advanced gastric cancer patients. Thus, treatment of gastric cancer remains a challenge for physicians. New targeted therapies for advanced gastric carcinoma are needed, which may open up a new avenue for cancer treatment. Current targeted therapy for advanced gastric carcinoma depends on the evaluation of target gene status^[1-3].

HER-2/neu or CerbB-2 is a member of growing factors (EGFR, erbB-2, erbB-3 and erbB-4) in the HER family with intrinsic protein tyrosine kinase activity, and its increased activity is the assumed mechanism underlying cell transformation^[4]. It is an oncogene that regulates the biological functions such as cell proliferation, differentiation, motility, and apoptosis. It was reported that HER-2 is over-expressed in cancer of breast, lungs, salivary gland, ovary, colon, prostate and pancreas^[5,6]. HER-2 plays an important role in activation of HER-2 protein, and is over-expressed in 10%-38% of gastric cancer patients^[7]. However, the correlation between the expression of HER-2 protein and the prognosis of gastric cancer is still controversial. Different studies showed different HER-2 expression levels in gastric carcinoma^[8-10].

Detecting the HER-2 status in gastric carcinoma is a prerequisite of monoclonal antibody therapy for gastric cancer. In this study, immunohistochemistry (IHC) was used in detecting HER-2 oncoprotein and fluorescent *in situ* hybridization (FISH) was used as a follow-up test for ambiguous results.

MATERIALS AND METHODS

Materials

Paraffin-embedded tumor tissue blocks were provided by Cancer Hospital of Fudan University and Institute of Traditional Chinese Medicine of Jiangsu Province. One hundred and forty-five (95 males and 50 females) out of the 476 Chinese patients with gastric adenocarcinoma, admitted to Department of Surgery, Cancer Hospital of Fudan University, and Institute of Traditional Chinese Medicine of Jiangsu Province in 2006-2009 for surgery, were enrolled in this study. Tumor tissue blocks from patients with full clinical data (including diagnosis, age, sex, address, disease history, *etc.*) were cut into 20 slides. The average age of the patients was 60 years. Cancer was classified as stage I in 32 cases, stage II in 35 cases, stage III in 37 cases, and stage IV in 41 cases, respectively, according to the TNM Cancer Staging System of the American Joint Committee of Cancer. The study was approved by The Review Board of Fudan University Cancer Hospital and Institute of Traditional Chinese Medicine of Jiangsu Province. Informed consent was obtained from all patients.

Tumor tissue was cut into 4- μ m thick sections which were stained with hematoxylin and eosin for histopathological types, differentiation stage, IHC and FISH evaluation.

Immunohistochemical staining

Slides were deparaffinized, rehydrated, and heated in a microwave oven containing 0.01 mol/L citrate buffer (pH 6.0) for 5 min at 100°C for antigen retrieval, cooled for 20 min and washed with water and a buffer solution. Peroxidase was applied for 5 min and washed with a buffer solution for 2 \times 5 min. Primary antibody diluted at 1:200 was applied for 30 min, link and streptavidin were applied for 10 min, respectively, and then washed with a buffer solution for 2 \times 5 min. The bound antibody was visualized using a DAB-chromogen substrate. The sections were then counterstained with hematoxylin, covered with a cover-slip. Negative control was stained by omission of the primary antibody. Over-expression of HER-2 protein in paraffin-embedded invasive breast carcinoma tissue slides was used as a positive control.

A strong brown staining was located in cell membrane of malignant cells using this staining method. The DAKO Hercep Test™ Protocol System^[11] was used to grade the membrane staining. The staining was scored as negative (0) when no membrane was stained or when membrane was stained in less than 10% of tumor cells, weakly positive (1+) if focal membrane was stained in more than 10% of tumor cells, intermediately positive (2+) if complete membrane was weakly- moderately stained in more than 10% of tumor cells, and strongly positive (3+) if complete membrane was intensely stained in more than 10% of tumor cells. Scores 0 and 1 were considered negative, while scores 2 and 3 were considered positive.

FISH analysis

HER-2 gene was amplified with dual-color FISH using a Passvision HER-2 DNA probe kit (Vysis Inc. Downers Grove, IL, USA) according to its manufacturer's instructions. Briefly, hybridization buffer, DNA probe, and purified water were centrifuged, and heated to 73°C for 5 min in a water bath. Slides were immersed in a denaturing bath (70% formamide 2 \times SSC) for 5 min at 73°C, followed by dehydration in increasing ethanol concentrations, and then dried. The probe mixture was applied to each slide. The slides were placed in a 42°C incubator for 30 min, washed with 0.4 \times SSC/0.3% NP-40 for 2 min, air-dried in darkness, counterstained with 4',6-diamidino-2-phenylindole (DAPI), and covered with a cover-slip. HER-2/neu-spectrum orange probe contains a DNA sequence specific for the HER-2 human gene locus and hybridized to the region 17q11.2-q12 of human chromosomes. CEP17 (chromosome enumeration probe 17)/spectrum green probe containing alpha-satellite DNA that hybridizes to the D17Z1 locus (centromere region of chromosome 17) was used as a control. Nuclei were counterstained with DAPI. The slides were observed under a B \times 60 fluorescence microscope equipped with a digital camera (DP50; Olympus, Tokyo, Japan) and the images were captured on a Windows PC with the Viewfinder Lite software. A cell was considered to be amplified when a definite cluster or more than 10 signals for

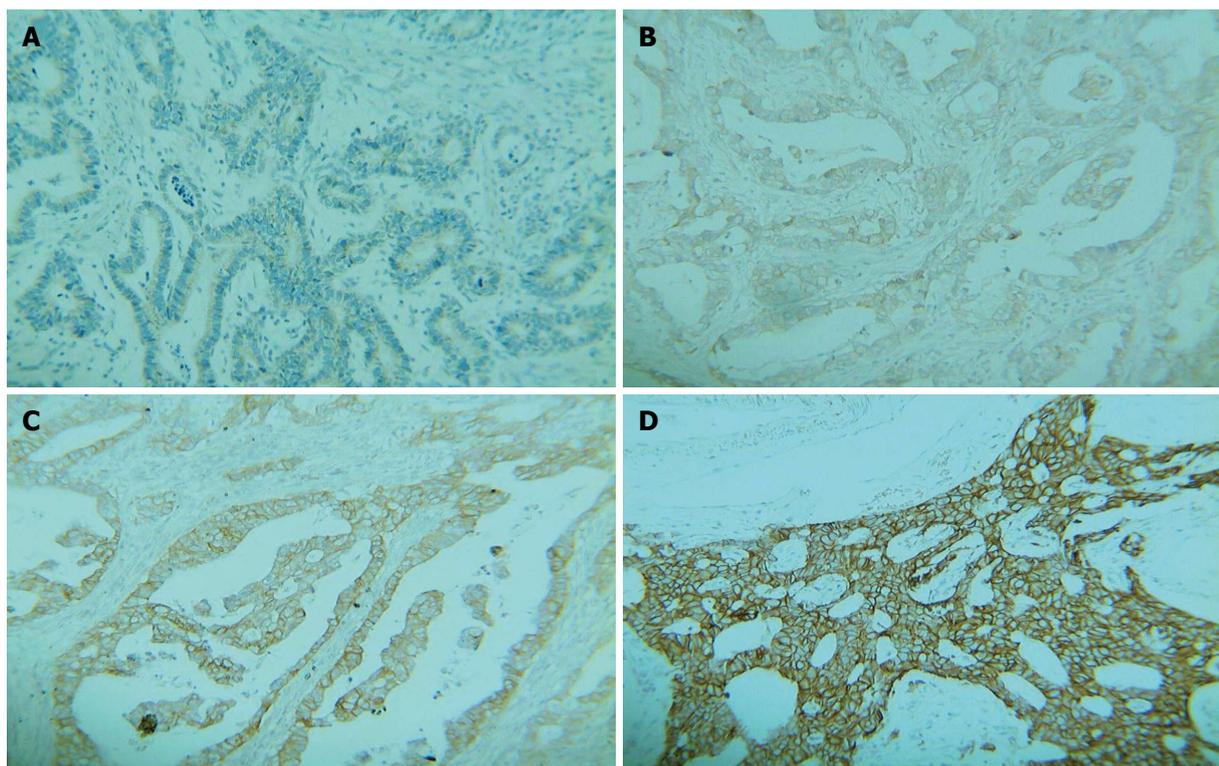

Figure 1 Immunohistochemistry staining of gastric carcinoma tissue samples showing negative HER-2 protein expression (A, B), positive HER-2 protein expression (C, D) (original magnification $\times 200$).

Table 1 Correlation between HER-2 protein expression and *HER-2* gene amplification

HER-2 were found. Known positive and negative cells were used as controls for each FISH. Gene amplification was scored when a minimum of 20 cancer cell nuclei exhibited a HER-2/CEP17 ratio ≥ 2 , or when a HER-2 signal cluster was observed.

Statistical analysis

Statistical analysis of data was performed by Student's *t* test. $P < 0.05$ was considered statistically significant.

RESULTS

Expression of HER-2 protein in gastric carcinoma

HER-2 protein status in 145 gastric carcinoma tissue samples was determined with immunohistochemical staining (Figure 1). Of the 145 gastric carcinoma tissue samples, 98 (67.6%) were scored as 0, 25 (17.2%) as 1, 12 (8.3%) as 2, and 10 (6.9%) as 3. The positive rate was approximately 15.2% (22/145).

HER-2 gene amplification in gastric carcinomas

The HER-2/CEP17 ratio was determined using the rate of HER-2/neu signals and CEP17 signals in 20 nuclei. The total number of HER-2/neu signals was divided by the total number of CEP17 signals, with a ratio was ≥ 2 according to the indications given by the Abbott-Vysis Company. IHC showed complete membrane immunostaining (2+ and 3+). In addition, 123 samples negative for *HER-2* over-expression with IHC staining were also analyzed by FISH. *HER-2* gene was amplified in 18 out of the 145 gastric carcinoma tissue samples, including HER-2 3+ in 10 samples, HER2 2+ in 5 samples, and HER2 1+ in 3 samples with IHC staining (Table 1). The 10 tumors with strong complete membrane immunostaining (3+) exhibited *HER-2* gene amplification, accounting for 55.6% (10/18) of all HER-2 amplifications. The positive amplification rate of *HER-2* gene was about 12.4% (18/145) in all gastric carcinoma tissue samples (Figure 2).

Correlation between clinicopathologic findings and HER-2 status

The clinicopathological differences were observed in gastric carcinoma tissue samples with or without HER-2 protein expression or *HER-2* gene amplification. The HER-2 protein expression and *HER-2* gene amplification rates were 86.4 % (19/22) and 94.4 % (17/18) in intestinal type gastric carcinomas, respectively ($P < 0.05$). The HER-2 status was correlated with the depth of invasion, TNM stage, lymph node and distant metastasis ($P < 0.05$). However, no significant relation was found between clini-

DISCUSSION

Gastric cancer is the second most frequent cause of cancer-related death worldwide and the most common

cancer in Asian countries^[12]. Although various therapies for gastric carcinoma are available, such as gastrectomy with extensive lymphadenectomy and surgery combined with chemotherapy, the control of advanced stage gastric cancer is still a challenge for physicians. In recent years, molecular target therapy is a new treatment modality for gastric cancer and HER-2 has been identified as a poten-

tial therapeutic target. However, molecular target therapy for gastric cancer depends on the evaluation of the target gene status.

HER-2 amplification and over-expression play a key role in initiation, progression, and metastasis of some common cancers, including breast and gastric cancer. HER-2 status has been recognized as an important prognostic factor for cancer. The survival time of patients with breast cancer and positive HER-2 disease is significantly shorter than that of those with HER-2 negative tumors^[13-15]. Thus, detecting HER-2 status is of important significance in diagnosis of gastric cancer.

It was reported that the HER-2 over-expression rate in gastric carcinoma is 8.2%-34.0%^[2,16-18], whereas the concordance of FISH and IHC is 93.5% in diagnosis of gastric cancer^[9]. In the present study, the HER-2 gene amplification was evaluated using the FISH method and the HER-2 protein expression levels were compared. The positive rate of HER-2 gene amplification was 12.4% (18/145). Recent studies showed that the HER-2 gene amplification rate in gastric carcinoma is 8.2%-5%^[19,20], which is consistent with our findings (12.4%). HER-2 gene amplification is a golden criterion for target therapy with trastuzumab. In this study, the HER-2 gene was amplified in all samples with oncoprotein over-expression at 3+ level, but HER-2 gene was not amplified at 0 level in all samples, which is consistent with the reported data^[21], suggesting that target therapy is not necessary for gastric cancer patients with HER-2 protein expression but necessary for those with HER-2 protein over-expression at 3+ level. Although FISH shows a high sensitivity and specificity and remains a criterion for determining gene amplification status, IHC for HER-2 protein expression may be a good alternative when FISH cannot be performed.

In this study, the HER-2 protein expression and the HER-2 gene amplification rates were 86.4% (19/22) and 94.4% (17/18), respectively, in most intestinal types of gastric carcinoma ($P < 0.05$), and the HER-2 status was correlated with the depth of invasion, TNM stage, lymph node and distant metastasis of gastric cancer ($P < 0.05$), with no significant relation found between clinicopathologic variables (sex and age of patients, and tumor diameter, differentiation, and location), which is consistent with the reported findings^[22]. Furthermore, it has been shown that HER-2 status is only correlated with the histopathological classification of gastric cancer^[23]. It was also reported that HER-2 over-expression is correlated with well or moderately differentiated gastric cancer but not with pathologic stage of gastric cancer or the age and sex of gastric cancer patients^[24].

In conclusion, HER-2 status is correlated with the depth of invasion, TNM stage, lymph node and distant metastasis of gastric cancer. Detecting HER-2 status may contribute to the target therapy for gastric carcinoma using trastuzumab.

ACKNOWLEDGMENTS

The authors thank the patients who took part in this

study and Department of Pathology of Cancer Hospital, Fudan University and Institute of Traditional Chinese Medicine of Jiangsu Province for sending tumor specimens. The authors also appreciated the help from Professor Shi DR for selecting the study cases and controlling the quality of HER-2 IHC.

COMMENTS

Background

HER-2 protein over-expression and gene amplification in gastric carcinoma are the prerequisite for monoclonal antibody therapy. Detecting HER-2 status in gastric carcinoma is very important in clinical practice. HER-2 protein expression and gene amplification were detected using immunohistochemistry (IHC) and fluorescence *in situ* hybridization (FISH) in this study.

Research frontiers

HER-2 is over-expressed in 10%-38% of gastric cancer patients. However, few studies are available on HER-2 status in gastric carcinoma in China.

Innovations and breakthroughs

In this study, HER-2 over-expression was detected with IHC and HER-2 gene amplification was found with FISH. FISH testing is unnecessary for patients with HER-2 protein expression at 0 or 3+ level and necessary for patients with HER-2 protein expression at 1+ or 2+ levels. HER-2 status was correlated with the depth of invasion, TNM stage, lymph node and distant metastasis of gastric cancer.

Applications

IHC may be used to screen the HER-2 status in gastric carcinoma patients. FISH testing may be necessary for patients with HER-2 protein expression at 1+ or 2+ levels. The screening method may determine whether target therapy is necessary for gastric carcinoma using trastuzumab.

Terminology

IHC and FISH are the abbreviation forms of IHC and FISH, respectively. HER-2 status contains negative or positive HER-2 protein expression, HER-2 gene amplification or no HER-2 gene amplification.

Peer review

The authors showed the expression of HER-2 in approximately one third of patients. Interestingly, they found that HER-2 was amplified not only in IHC +3 cases but also in some of IHC +2 and even +1 cases, suggesting that FISH should be performed in all cases with positive IHC and HER-2 expression is correlated with the key indicators for cancer progression, such as TNM stage and metastasis.

Abstract

AIM: To analyze the antiviral mechanism of Epigallocatechin gallate (EGCG) against hepatitis B virus (HBV) replication.

METHODS: In this research, the HBV-replicating cell line HepG2.117 was used to investigate the antiviral mechanism of EGCG. Cytotoxicity of EGCG was analyzed by 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay. Hepatitis B virus e antigen (HBeAg) and hepatitis B virus surface antigen (HBsAg) in the supernatant were detected by enzyme-linked immunosorbent assay. Precore mRNA and pregenomic RNA (pgRNA) levels were determined by semi-quantitative reverse transcription polymerase chain reaction (PCR) assay. The effect of EGCG on HBV core promoter activity was measured by dual luciferase reporter assay. HBV covalently closed circular DNA and replicative intermediates of DNA were quantified by real-time PCR assay.

RESULTS: When HepG2.117 cells were grown in the presence of EGCG, the expression of HBeAg was suppressed, however, the expression of HBsAg was not affected. HBV precore mRNA level was also down-regulated by EGCG, while the transcription of precore mRNA was not impaired. The synthesis of both HBV covalently closed circular DNA and replicative intermediates of DNA were reduced by EGCG treatment to a similar extent, however, HBV pgRNA transcribed from chromosome-integrated HBV genome was not affected by EGCG treatment, indicating that EGCG targets only replicative intermediates of DNA synthesis.

CONCLUSION: In HepG2.117 cells, EGCG inhibits HBV replication by impairing HBV replicative intermediates of DNA synthesis and such inhibition results in reduced production of HBV covalently closed circular DNA.

INTRODUCTION

Hepatitis B virus (HBV) infection remains a major world

health problem despite the availability of an effective vaccine. Approximately 350 million people are chronically infected with HBV worldwide^[1,2]. HBV possesses a 3.2 kb relaxed circular partially double-stranded DNA (RC-DNA) genome^[3]. After infection, this viral genome is released into cytoplasm and converted into covalently closed circular DNA (cccDNA) in the host cell nucleus. The cccDNA is the template for production of all viral RNAs. Among HBV RNAs, the pregenomic RNA (pgRNA) is packaged into new capsid and serves as the template for HBV DNA synthesis. The nucleocapsid acquires an envelope and then buds as a mature virion. Progeny nucleocapsids may redeliver their RC-DNA genomes to the nucleus for accumulation of a cccDNA pool^[4].

Currently, there is no reliable treatment that completely eliminates HBV infection in all chronic carriers. Several nucleos(t)ide analogues (lamivudine, adefovir, entecavir, and telbivudine) and interferon- α (IFN- α) have been approved as antiviral drugs against HBV infection, however, they have their own limitations, e.g. drug resistance and side effects^[5]. Several non-nucleoside natural products have also been reported to inhibit HBV replication using various mechanisms. For example, oxymatrine was shown to block HBV DNA synthesis and cccDNA formation^[6]. A helioxanthin derivative, 8-1, was demonstrated to diminish HBV promoter activities and thus suppress HBV gene expression and DNA synthesis^[7,8].

Epigallocatechin gallate (EGCG) is one of the most abundant polyphenols present in green tea^[9]. EGCG is well known for its anti-tumor activity while other pharmaceutical effects were discovered subsequently^[10-14]. Recently, it has also been reported that EGCG could inhibit HBV replication in a HBV stably replicating cell line - HepG2-N10^[15]. However, the mechanism by which EGCG inhibits HBV replication is unclear. In fact, it is difficult to dissect the detailed anti-HBV mechanism of EGCG using HepG2-N10 cells, because the processes from cccDNA to antigen expression are severely affected by transcription from integrated HBV DNA^[16].

In order to investigate the antiviral mechanism of EGCG against HBV in detail, we adopted a newly reported HepG2.117 cell line^[17]. HBV replication is controllable using doxycycline in this cell line. More importantly, due to the delicate design, HBV precore mRNA can only be transcribed from replicated HBV DNA but not the integrated HBV DNA. As a result, hepatitis B virus e antigen (HBeAg) can only be translated from precore mRNA that is solely produced from replicated HBV DNA. Therefore, the precore mRNA and HBeAg level represents HBV DNA synthesis. On the other hand, PreS1/S2 mRNAs, which are templates for the translation of hepatitis B virus surface antigen (HBsAg), are mainly transcribed from integrated HBV DNA rather than replicated HBV DNA in this cell line, thus, HBsAg has little correlation to HBV DNA synthesis level.

In this study, we investigated the inhibition of HBV replication by EGCG in HepG2.117 cells. Our results showed that HBV replicative intermediates of DNA (RI-

DNA) synthesis was significantly inhibited by EGCG, which resulted in less cccDNA production. In contrast, the production of HBV pgRNA, precore mRNA and the translation of HBeAg were not affected by EGCG.

MATERIALS AND METHODS

Cell line and cell culture

HepG2.117 (a gift from Dr. Dian-Xing Sun, University Hospital Freiburg, Germany) is an inducible HBV-replicating cell line^[17]. It contains a slight over-length HBV genome under the control of a tetracycline responsive CMV promoter. Transcription of HBV pgRNA is induced upon doxycycline removal from the culture medium, leading to capsid assembly and DNA synthesis. A small portion of the *de novo* synthesized RC-DNA is transported into the nucleus and converted to cccDNA which serves as a transcriptional template for the production of viral RNAs.

The HBeAg start codon and precore mRNA transcription initiation point are inexistent in chromosome integrated HBV genome in HepG2.117 cells^[17]. Therefore, HBeAg and precore mRNA can not be generated from the integrated genome. However, once HBV starts to replicate, a functional precore mRNA would be produced from cccDNA in this cell line, since the promoter and transcription initiation point would be restored in the process of cccDNA formation^[17]. Subsequently, HBeAg would be produced from this precore mRNA where HBeAg start codon is also restored.

HepG2.117 cells were cultured in DMEM medium (Invitrogen) supplemented with 10% fetal bovine serum (Gibco), 100 U/mL penicillin and 100 μ g/mL streptomycin (Sigma). When needed, doxycycline (Sigma) was routinely added at 1.5 μ g/mL to suppress HBV pgRNA transcription.

Plasmid construction

To generate pHBVCP-Luc reporter plasmid, a 442 bp fragment corresponding to the HBV core promoter region containing enhancer II was amplified from pCH9-3091 (an ayw subtype HBV over-length genomic plasmid, kindly provided by Professor Michael Nassal, University Hospital, Freiburg)^[18] by polymerase chain reaction (PCR) (forward primer: GGGGTACCCGC-GGGACGTCCTTTG; reverse primer: CCAAGCITTA-CAAGAGATGATTAGGCAG). This fragment was then inserted into the pGL3-basic vector (Promega, Madison, WI, USA), producing pHBVCP-Luc reporter construct.

Drug treatment and cytotoxicity assay

Three days after the removal of doxycycline, HepG2.117 cells were seeded into 24-well plates. Twenty-four hours later, cells were treated with fresh DMEM medium containing various concentrations of EGCG (Hubei Institute of Chemistry, Wuhan), or lamivudine (NIH AIDS Research and Reference Reagent Program, Rockville, MD, USA), respectively. The drug-containing media were

replaced each day for 3 d. The medium was then collected for antigen detection and attached cells were used for DNA and RNA analysis (see below) or EGCG toxicity analysis using the 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Cells cultured with DMEM medium without EGCG were used as a negative control.

Enzyme-linked immunosorbent assay detection of HBsAg and HBeAg

Collected media were subjected to $10\,000 \times g$ centrifugation to remove cellular debris. Secreted HBsAg and HBeAg were quantified by enzyme-linked immunosorbent assay (ELISA) kits (Kehua, Shanghai) following the manufacturer's instructions. All the data on HBsAg or HBeAg are presented as percentage of antigen level detected in the negative control samples.

Semi-quantitative reverse transcription polymerase chain reaction detection of HBV mRNA

Total cellular RNA was extracted with Trizol reagents (Invitrogen) and treated with RQ1 RNase-free DNase I (Promega) to digest residual DNA molecules. For the semi-quantification of precore mRNA and pgRNA, 1 μ g total cellular RNA was subjected to cDNA synthesis using MMLV reverse transcriptase (Promega) and random hexamer as a primer based on the manufacturer's instructions. The cDNAs were then measured by semi-quantitative PCR using Ex *Taq* (Takara, Dalian) and subsequently analyzed by agarose gel electrophoresis. The specific primers for semi-quantitative detection of precore mRNA were as follows: forward, 5'-TCTGCGCACCAG-CACCATG; reverse, 5'-TGCCTCGTCTCTAACAA. The forward primer for pgRNA amplification was 5'-TC-GGGAAGCCTTAGAGTC, while the reverse primer was 5'-TGCCTCGTCTCTAACAA. Primers used for Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) mRNA amplification were as previously reported^[19].

Dual luciferase reporter assay detection of HBV core promoter activity

Three days after the removal of doxycycline, HepG2.117 cells were seeded into 24-well plates. Twenty-four hours later, the cells were transiently co-transfected with pH-BVCP-Luc reporter plasmid and normalizing plasmid pRL-TK with FuGENE-HD reagent according to the manufacturer's instructions (Roche Applied Science, Mannheim, Germany). Twelve hours after transfection, cells were subjected to a 3-d period of treatment with EGCG. HBV core promoter activity was determined by measuring luciferase activity using the Dual Luciferase Reporter Assay System (Promega).

Real-time PCR detection of HBV DNA

Extraction of cccDNA was carried out using a modified Hirt extraction procedure^[16,20]. Briefly, cells from one well in the 24-well plate were lysed in 300 μ L of 10 mmol/L Tris-HCl, 10 mmol/L EDTA and 0.7% SDS.

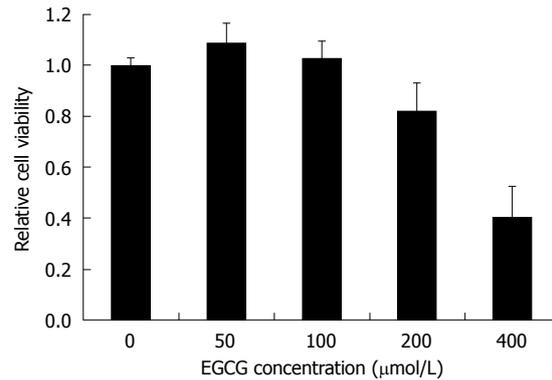

Figure 1 The cytotoxic effect of Epigallocatechin gallate on HepG2.117 cells. Twenty four hours after seeding, cells were incubated with medium containing different concentrations of Epigallocatechin gallate (EGCG) for 3 d, and cell viability was determined by the 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay. Cell viability of the control well not treated with EGCG was determined and arbitrarily designated as 1. Error bars indicate standard deviation of 3 independent experiments.

After 30 min incubation at room temperature, the lysate was mixed with 80 μ L 5 mol/L NaCl and incubated at 4°C overnight. The lysate was clarified by centrifugation at $12\,000 \times g$ for 30 min at 4°C, and then extracted twice with phenol and once with phenol:chloroform. DNAs were precipitated with ethanol overnight at -20°C and dissolved in TE buffer, followed by further treatment of plasmid-safe DNase (Epicenter) to digest residual linear and open circular DNA molecules. When the reaction was finished, the plasmid-safe DNase was removed by phenol:chloroform extraction and the DNA was precipitated with ethanol at -20°C overnight and dissolved in TE buffer. Total cellular HBV DNA was extracted from the cell monolayer with the total DNA extraction kit (Takara, Dalian) according to the manufacturer's instructions.

A pair of primers (corresponding to HBV S ORF) introduced by Liu *et al.*^[21] was applied to quantify HBV DNA copies. In order to quantify cccDNA, extracted cccDNA samples were subjected to real-time PCR and the quantification was normalized by cell numbers. The total HBV DNA samples, which contained several types of HBV DNA forms (99% of them were HBV DNA replicative intermediates), were analyzed by real-time PCR and the quantification was normalized to the GAPDH DNA copies.

RESULTS

HBsAg expression level in HepG2.117 cells was down-regulated by EGCG

In order to choose an appropriate initial concentration of EGCG in the HBV inhibition assay, the MTT assay was used to determine the cytotoxicity of EGCG to HepG2.117 cells. As shown in Figure 1, the cytotoxic effects of EGCG were undetectable when the EGCG concentration was below 100 μ mol/L, while slight cytotoxicity (18% inhibition of cell viability) and significant cytotoxicity (60% inhibition of cell viability) were ob-

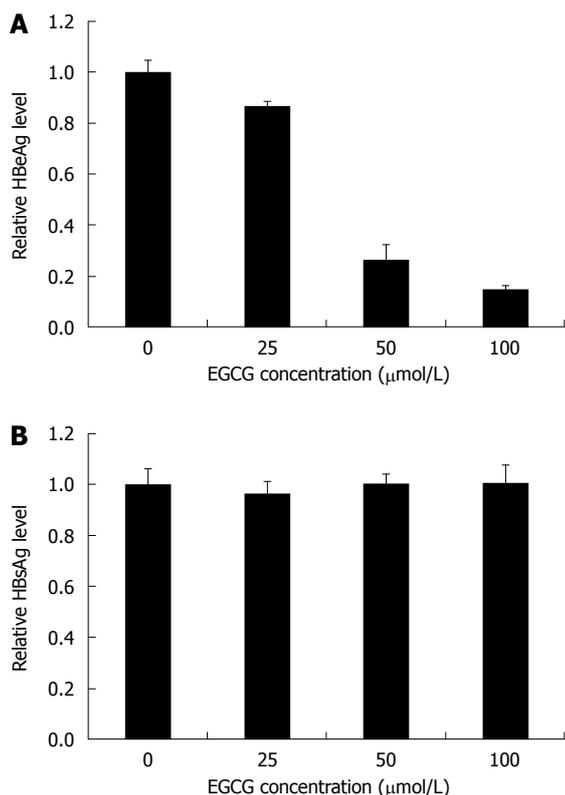

Figure 2 Epigallocatechin gallate inhibited hepatitis B virus e antigen expression level but not hepatitis B virus surface antigen expression level in the HepG2.117 cell line. Twenty four hours after seeding, cells were incubated with medium containing different concentrations of Epigallocatechin gallate (EGCG) for 3 d. The hepatitis B virus e antigen (HBeAg) and hepatitis B virus surface antigen (HBsAg) expression levels in the supernatants were measured using enzyme-linked immunosorbent assay kits for measuring HBeAg and HBsAg, respectively. The level of HBeAg (A) and HBsAg (B) from cells not treated with EGCG (the control) were arbitrarily designated as 1. The levels of HBeAg (A) and HBsAg (B) in EGCG-treated cells were normalized with the control and expressed as relative levels. Error bars indicate standard deviation of 3 independent experiments.

served when 200 and 400 μmol/L of EGCG were used, respectively. Therefore, the maximum non-toxic concentration was 100 μmol/L, and this was used as the highest concentration of EGCG in the HBV inhibition assay.

EGCG was reported to inhibit the expression of both HBeAg and HBsAg in HepG2-N10 cells^[15]. To investigate the antiviral mechanisms of EGCG against HBV in HepG2.117 cells, a cell-based assay was used. The levels of HBeAg and HBsAg in the supernatant of EGCG-treated HepG2.117 cells were measured by ELISA. As shown in Figure 2A, HBeAg expression was dose-dependently inhibited by EGCG with an IC₅₀ of 39.4 μmol/L. However, the expression level of HBsAg was largely unaffected (Figure 2B). These results indicated that EGCG could down-regulate HBeAg level but not HBsAg level in HepG2.117 cells.

HBV precore mRNA level was down-regulated in the presence of EGCG

Unlike several HBV DNA stably transfected cell lines (e.g. HepG2.2.15) whose HBeAg is mainly translated from the

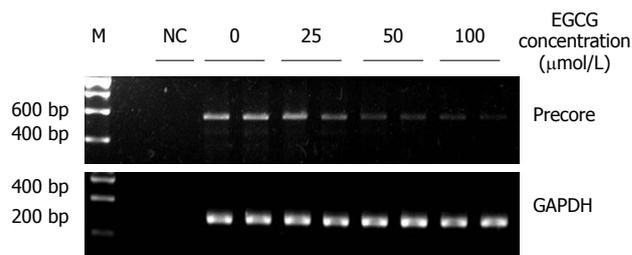

Figure 3 Epigallocatechin gallate inhibited the production of hepatitis B virus precore mRNA. Twenty four hours after seeding, HepG2.117 cells were treated with medium containing different concentration of Epigallocatechin gallate (EGCG) for 3 d. Total RNAs were prepared and were quantitated by semi-quantitative reverse transcription polymerase chain reaction (RT-PCR) with a pair of precore mRNA selective primers. Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) mRNA was semi-quantitatively RT-PCR amplified and used for normalization. NC: Total RNA sample was subjected to PCR without reverse transcriptase and used as the negative control.

long early RNA that is transcribed from the inserted exogenous promoter (e.g. CMV promoter), in the HepG2.117 cell line, HBeAg is exclusively translated from precore mRNA that is transcribed from cccDNA, akin to the actual HBV life cycle in HBV-infected hepatocytes. Since EGCG down-regulates HBeAg level but not HBsAg level in HepG2.117 cells, we determined whether the down-regulation of HBeAg by EGCG was due to inhibition of the transcription of precore mRNA.

Precore mRNA and pgRNA share the same sequence, except that precore mRNA is 35 nt longer at the 5' terminal^[16]. In order to distinguish precore mRNA from pgRNA, a specific forward primer complementary to the 5' terminal of precore mRNA was designed for the precore mRNA specific reverse transcription PCR (RT-PCR) assay. Briefly, the 19 nt forward primer was designed to anneal to the 5' terminal of precore RNA (nt 1800-1818) which is absent in pgRNA. The reverse primer was complementary to a sequence (nt 2345-2362) present in both precore mRNA and in pgRNA. Thus, a 563 bp fragment could be amplified from precore mRNA but not pgRNA.

After HepG2.117 cells were treated with EGCG for 3 d, total RNAs were extracted and subjected to semi-quantitative RT-PCR analysis using the precore mRNA specific primers. As shown in Figure 3, the amount of 563 bp specific RT-PCR products amplified from precore mRNA decreased in a dose-dependent manner with increasing concentrations of EGCG. The total RNA sample for RT-PCR was free of DNA contamination as this specific product did not appear in reactions without reverse transcription (Figure 3, NC lane). These results indicated that after EGCG treatment, precore mRNA level was down-regulated in HepG2.117 cells, and the lowered precore mRNA level accounted for the decreased production of HBeAg.

Transcriptional efficiency of HBV precore mRNA was not affected by EGCG

Precore mRNA is transcribed from cccDNA and this process is controlled by HBV core promoter^[22]. To investigate

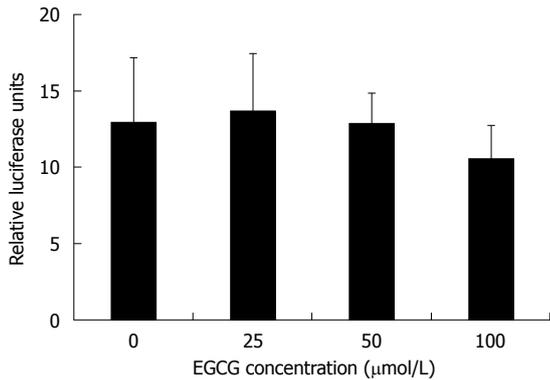

Figure 4 Epigallocatechin gallate does not affect hepatitis B virus core promoter activity. Twelve hours after cotransfection with pHBVCP-Luc and pRL-TK, HepG2.117 cells were treated with media containing different concentrations of Epigallocatechin gallate (EGCG) for 3 d, and were lysed for the dual luciferase reporter analysis. Core promoter activity was normalized with control TK promoter activity and presented as relative luciferase units. Error bars indicate standard deviation of 3 independent experiments.

whether EGCG can inhibit HBV core promoter activity, a reporter plasmid, pHBVCP-Luc, was constructed by inserting HBV core promoter before the firefly luciferase gene in the pGL3-basic vector and thus the measured firefly luciferase activity represented core promoter activity. Twelve hours after HepG2.117 cells were transfected with pHBVCP-Luc, different concentrations of EGCG were added and maintained for 3 d, and the cells were then subjected to luciferase reporter assay. As shown in Figure 4, HBV core promoter activity was not inhibited even in the presence of 100 μmol/L of EGCG, in which the expression of HBeAg was down-regulated by 85.5%. Thus, the down-regulation of precore mRNA level was not attributed to the inhibition of core promoter activity by EGCG.

The production of HBV cccDNA and RI-DNA was dose-dependently inhibited by EGCG

Since the precore mRNA in the HepG2.117 cell line was exclusively transcribed from HBV cccDNA, and EGCG did not suppress HBV precore mRNA transcription efficiency, we speculated that the down-regulation of precore mRNA by EGCG may be due to decreased HBV cccDNA formation.

To quantitatively analyze the amount of HBV cccDNA, EGCG-treated HepG2.117 cells were collected to obtain cccDNA, and real-time PCR analysis was used to detect cccDNA production. The results showed that EGCG could decrease cccDNA formation in a dose-dependent manner (Figure 5A). The inhibitory rates of cccDNA formation were 36.3%, 63% and 72.4%, following treatment with 25, 50 and 100 μmol/L of EGCG, respectively. As a control, the HBV polymerase inhibitor, lamivudine, also showed dose-dependent inhibition of HBV cccDNA production (Figure 5B).

HBV cccDNA is repaired from RC-DNA. RC-DNA and other forms of HBV DNA (double-stranded linear DNA and single-stranded DNA), which are collectively known as HBV replicative intermediates of DNA (RI-

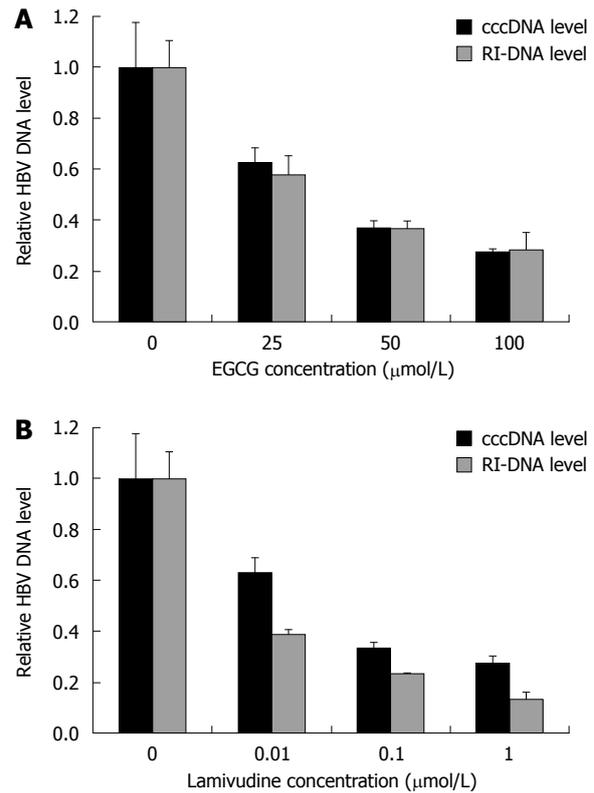

Figure 5 Epigallocatechin gallate down-regulates hepatitis B virus covalently closed circular DNA and replicative intermediates of DNA level.

A: Epigallocatechin gallate (EGCG) treatment was the same as described in Figure 1. Hepatitis B virus (HBV) covalently closed circular DNA (cccDNA) and total cellular HBV DNA were extracted and subjected to real-time polymerase chain reaction analysis; B: Lamivudine, the potent HBV DNA synthesis inhibitor, was used as a control inhibitor in this analysis. DNA level in the no treatment control was arbitrarily designated as 1. Error bars indicate standard deviation of 3 independent experiments. RI-DNA: Replicative intermediates of DNA.

DNA), represent HBV DNA synthesis efficiency. In HepG2.117 cells, RI-DNA molecules constitute 99% of HBV DNA molecules^[17]. Therefore, total HBV DNA level can reflect HBV RI-DNA level as well as HBV DNA synthesis level.

We suspected that impairment of cccDNA production was a result of less RI-DNA molecules produced when the cells were treated with EGCG. To verify this, total HBV DNA was extracted from EGCG-treated HepG2.117 cells and then subjected to real-time quantitative PCR analysis. As shown in Figure 5A, EGCG inhibited the level of RI-DNA dose-dependently, and the inhibitory rates were 42.2%, 63.4% and 71.8% following treatment with 25, 50 and 100 μmol/L of EGCG, respectively. The inhibitory rates were almost the same as that for cccDNA production, suggesting that the inhibition of cccDNA formation was mainly due to the decrease in HBV RI-DNA template.

Interestingly, it was observed that when treated with the same concentration of lamivudine, the decline in RI-DNA level was slightly stronger than the decline in cccDNA level (Figure 5B), e.g. 1 μmol/L lamivudine decreased RI-DNA production by 86.8% and only decreased cccDNA production by 72.4%. The reason for this could

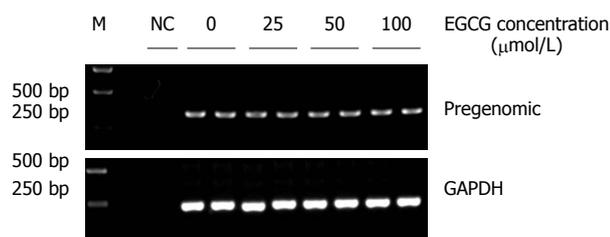

Figure 6 Epigallocatechin gallate did not inhibit hepatitis B virus pregenomic RNA transcription. When doxycycline was removed from the cell culture medium, different concentrations of Epigallocatechin gallate (EGCG) were added to the HepG2.117 cells. After 3 d of culture, total RNA were extracted from the treated cells and the pregenomic RNAs (pgRNAs) were analyzed by semi-quantitative reverse transcription polymerase chain reaction. Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) mRNAs were used for normalization. NC: Total RNA sample was subjected to polymerase chain reaction without reverse transcription.

be that part of the cccDNA can be repaired from a certain amount of pre-existing RC-DNA^[23,24]. The observed minimal difference in the inhibition of cccDNA and RI-DNA production implies that EGCG may partly inhibit cccDNA formation.

Transcription of pgRNA from integrated HBV genome was not affected by EGCG

HBV RI-DNA is synthesized from pgRNA and catalyzed by HBV polymerase. In the HepG2.117 cell line, pgRNA is transcribed from chromosome-integrated HBV DNA genome. Since RI-DNA level was down-regulated by EGCG in this cell line, we determined whether this down-regulation was actually caused by inhibition of RI-DNA synthesis rather than suppression of pgRNA transcription.

To analyze whether EGCG inhibited pgRNA transcription, doxycycline was removed from the culture medium, and EGCG was added at the same time. Three days later, total RNAs were extracted from HepG2.117 cells and pgRNAs were analyzed semi-quantitatively. As shown in Figure 6, EGCG treatment did not interfere with pgRNA production even when 100 $\mu\text{mol/L}$ of EGCG was applied. Therefore, the transcription of pgRNA from integrated HBV DNA genome was not affected by EGCG. Taken together, we conclude that the decrease in RI-DNA resulted from the inhibition of RI-DNA synthesis, rather than the down-regulation of pgRNA production.

DISCUSSION

In this study, we investigated the anti-HBV mechanism of EGCG in HepG2.117 cells, an inducible HBV-replicating cell line. Our results showed that EGCG down-regulated HBeAg level, precore mRNA level, cccDNA level and RI-DNA level to a similar extent, however, the production of HBV pgRNA was not affected. Therefore, the inhibition of HBV replication mainly occurred in HBV RI-DNA synthesis. When comparing the down-regulation of HBV cccDNA and RI-DNA production

mediated by EGCG and lamivudine, we speculated that EGCG may inhibit HBV cccDNA formation to a minor extent. Taken together, suppression of HBV DNA synthesis is the major anti-HBV mechanism of EGCG, while cccDNA formation might be slightly impaired in the presence of EGCG. Lowered RI-DNA level leads to decreased cccDNA formation, which in turn leads to a decline in precore mRNA level and HBeAg level. HBV precore mRNA transcription and HBeAg translation were unaffected by EGCG.

In a previous study, the anti-HBV activity of EGCG was reported to down-regulate extracellular HBsAg and HBeAg level, intracellular cccDNA level and RI-DNA level. That research was conducted in the HepG2-N10 cell line which was constructed by stable transfection of a 1.3-fold adw subtype HBV genome into HepG2 cells. We reasoned that EGCG could inhibit HBsAg production in HepG2-N10 but not in HepG2.117 cells, which may be due to the different HBV subtype (adw *vs* ayw) and DNA length (1.3-fold *vs* slightly more than 1.0-fold). The results obtained in HepG2-N10 cells were not adequate to elucidate the antiviral mechanism of EGCG against HBV replication, because all HBV mRNAs are mainly transcribed from integrated HBV genomic DNA in HepG2-N10, and thus the antigens (representing mRNA levels) can not truly reflect the levels of HBV RI-DNA synthesis, cccDNA formation and mRNA transcription in the cells.

On the other hand, in the HepG2.117 cell line, HBsAg could be produced from both integral HBV genome and cccDNA, however, cccDNA copy numbers constitute only 1% of the integrated HBV genome copy number. Thus, nearly all of the HBsAg produced from mRNA is transcribed from integrated HBV genome rather than from HBV cccDNA. Therefore, we speculate that the inability of EGCG to inhibit HBsAg production in the HepG2.117 cell line was attributed to the unchanged transcription level of HBsAg mRNA from integrated HBV DNA, even in the presence of EGCG. However, in actual infected hepatocytes, HBsAg can only be produced from cccDNA^[25,26], like HBeAg in the HepG2.117 cell line. Thus, we speculate that EGCG is able to inhibit HBsAg in HBV infection because cccDNA can be suppressed by EGCG treatment.

HBV DNA stably transfected cell lines are frequently used in cell-based assays for the discovery of antiviral drugs against HBV^[27,28]. In such cell lines, all HBV replicative intermediate DNA forms, cccDNA, nucleocapsid and infectious virion (Dane particle) can be detected, hence, it is generally accepted that the HBV life cycle is complete. However, all HBV RNAs and antigens can be produced from both chromosome-integrated HBV genomic DNA and replicated HBV genomic DNA. More importantly, the strong HBV DNA synthesis inhibitor, lamivudine, does not affect HBV RNA levels and antigen levels in such cell models^[29], indicating that HBV RNA transcription from integrated HBV DNA is much stronger than that from cccDNA. The amount of HBV RNAs and antigens in these cell lines do not reflect the

actual HBV DNA replication level. In contrast, in the HepG2.117 cell line, HBeAg and precore mRNA exclusively come from HBV cccDNA, consequently, the pathway from HBV cccDNA to precore mRNA and then HBeAg can be quantitatively analyzed. Although the authenticity of the HBeAg signal in antigen detection is controversial^[30], the precore mRNA is a solid and positive parameter in this cell system. In summary, the HepG2.117 cell line is a better cell model to analyze the anti-HBV mechanism of potential drugs against HBV replication.

Currently, researchers have focused mainly on the potential application of EGCG in treating cancers. EGCG is known to block each stage of carcinogenesis by modulating signal transduction pathways involved in cell proliferation, transformation, inflammation, apoptosis, metastasis and invasion^[31,32]. In this study, we investigated the anti-HBV mechanism of EGCG in detail and found that the suppression of HBV RI-DNA synthesis is the major anti-HBV mechanism of EGCG, while cccDNA formation might be slightly impaired in the presence of EGCG. Although the detailed replication mechanism of HBV remains unclear, it is estimated that multiple cellular factors are involved in HBV genome replication. We assume that EGCG may interact with certain cellular proteins and interfere with the function of the DNA replication machinery. As a result, HBV RI-DNA synthesis is impaired and HBV replication is inhibited. To fully understand the antiviral mechanism of EGCG against HBV and explore the potential use of EGCG as anti-HBV drug, further study needs to be done to determine how EGCG impairs HBV RI-DNA synthesis and which cellular factors are affected.

COMMENTS

Background

Hepatitis B virus (HBV) infection remains a major world health problem despite the availability of an effective vaccine. Currently, there is no reliable treatment that completely eliminates HBV infection in all chronic carriers. Epigallocatechin gallate (EGCG) is one of the most abundant polyphenols present in green tea. Recently, it has been reported that EGCG could inhibit HBV replication in a HBV stably replicating cell line. However, the mechanism by which EGCG inhibits HBV replication is unclear.

Research frontiers

Currently, there are very few cell lines which can be used to investigate HBV replication. HepG2.117 is a newly reported cell line in which HBV replication is controllable using doxycycline. Hepatitis B virus e antigen (HBeAg) can only be translated from precore mRNA solely produced from replicated HBV DNA. HBeAg level correlates well with HBV DNA synthesis, whereas hepatitis B virus surface antigen level does not. Hence, this cell line is more convenient when investigating the antiviral mechanisms of leading compounds against HBV.

Innovations and breakthroughs

Results from this report showed that HBV replicative intermediates of DNA synthesis was significantly inhibited by EGCG, which resulted in reduced covalently closed circular DNA (cccDNA) production. In contrast, the production of HBV pregenomic RNA and the translation of HBeAg were not affected by EGCG.

Applications

The finding that EGCG can inhibit HBV relaxed circular partially double-stranded DNA synthesis is important both when exploring the potential of new drugs against HBV and in understanding which targets might be valid in eliminating viral replication.

Peer review

The authors investigated the anti-viral mechanism of epigallocatechin gallate against HBV replication. It was observed that epigallocatechin gallate impairs replicative intermediate DNA synthesis, resulting in reduced production of cccDNA of the virus. The study is well conducted and the methodology was sound.

Abstract

Lymphangioma of the colon is a relatively rare non-epithelial tumor and usually presents as a submucosal polypoid lesion. Many cases incidentally discovered are usually asymptomatic. However, they may present as abdominal pain or bleeding, and their resection is normally required. Lymphangioma itself is generally recognized as a benign tumor and no cases of malignant transformation have yet been reported, although its natural history is currently unknown. To the best of our knowledge, this study is the first to describe a case of spontaneous resolution in multiple colonic lymphangiomas without any specific treatment.

INTRODUCTION

Lymphangioma is a benign tumor commonly found in children. The majority of lymphangiomas are considered to be lymph vessel anomalies. The condition involves several expanded lymphatics surrounded by benign endothelial cells and usually occurs in the head, neck and axillary regions, and rarely in the gastrointestinal tract^[1-3]. Recently, the number of case reports has been increasing with the increased use of endoscopic colon examination. Many lymphangiomas are asymptomatic and require no treatment, because the condition is considered absolutely benign. No cases, in which lymphangioma underwent malignant transformation, have been reported. However, some cases of lymphangioma accompany colon cancer^[2]. When symptoms such as bleeding, intussusceptions or protein losing enteropathy are present, resection of lymphangioma is necessary^[4-7]. Thus far, the natural history of colonic lymphangioma has remained unknown. Herein, we report the first case of spontaneous resolution of multiple colonic lymphangiomas during the follow-up.

CASE REPORT

A 54-year-old male patient suffered intermittently from

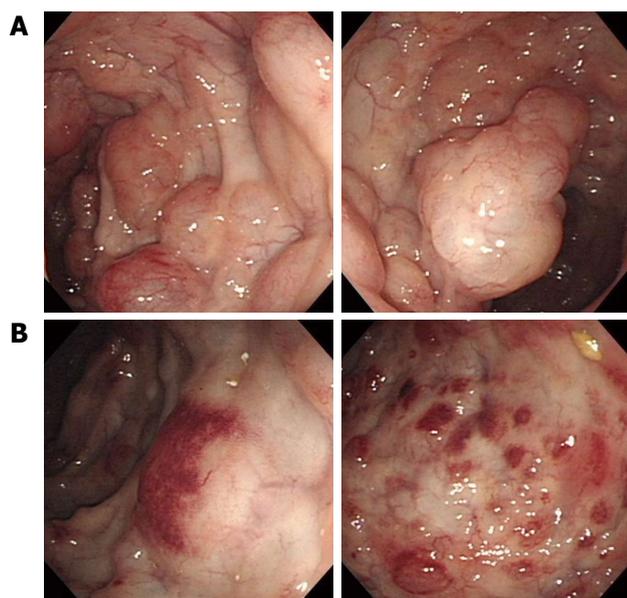

Figure 1 Initial colonoscopy showing multiple elevated or protruding lesions with semi-transparent and smooth surfaces (A), and petechiae on the surfaces of lesions in the sigmoid colon (B).

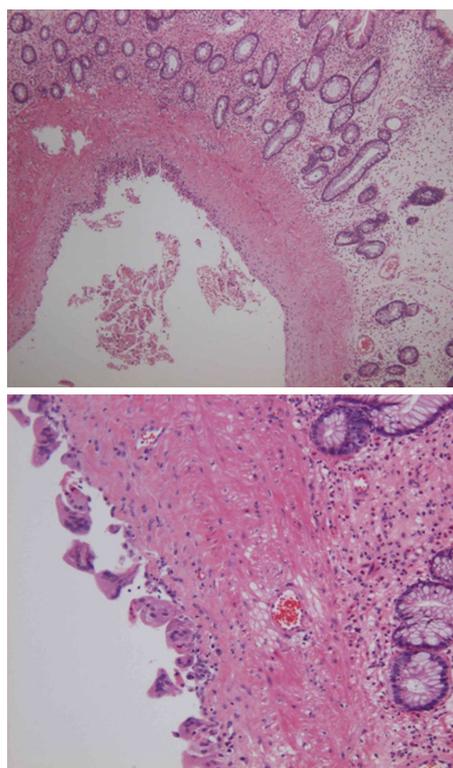

Figure 3 Histopathological examination 12 mo after initial examination showing cystically dilated lesion lined with endothelium (upper, HE stain, $\times 40$) and focal multinucleated giant cells (bottom, HE stain, $\times 100$).

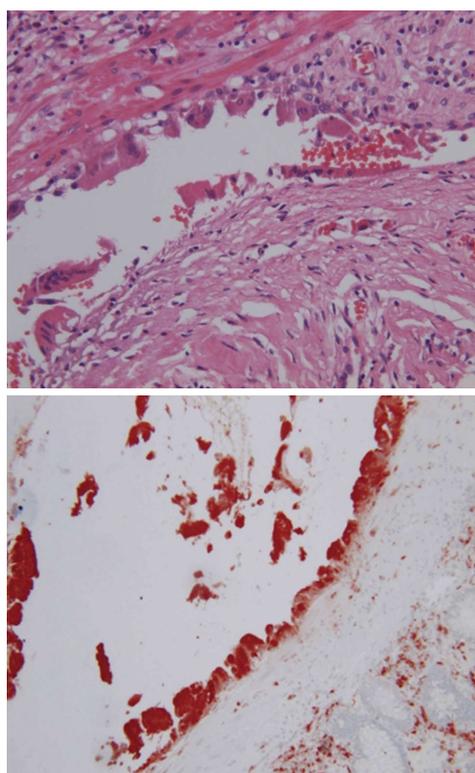

Figure 2 Initial histopathological examination showing a submucosal cystic structure lined with cuboidal endothelial cells for the CD68 histiocytic marker (bottom) and a few giant cells (upper, HE stain, $\times 200$).

blood-tinged stool with no personal or familial history of any specific disease. Physical examination showed no remarkable abdominal abnormality. Laboratory test or chest and abdominal radiography displayed no specific findings. Initial colonoscopy revealed numerous elevated

lesions with smooth surfaces throughout the entire colon, which evidenced morphological changes as shown by endoscopy. In particular, the lesions on the left side of the colon evidenced surface petechiae (Figure 1). A diagnostic procedure and endoscopic mucosal resection were performed for the appropriate diagnosis and treatment of the lesions. Histopathological examination showed that the cystic lesion was lined with cuboid-shaped cells that were positive for CD68 histiocytic markers (Figure 2) but negative for CD34 and CK on immunohistochemical examination, the patient was thus diagnosed with colonic lymphangioma. Abdominal computed tomography showed no definite abnormalities, and the possibility of secondary events was excluded. The complaint of mild symptoms led to medical observation and use of stool softener.

After 12 mo, the patient visited our department for colonoscopy, which showed no more remarkable changes than the previous findings. Biopsy procedure was repeated, which demonstrated that the cystic lesion had no lining endothelium but was lined with focal multinucleated giant cells in the submucosa (Figure 3). After 24 mo, colonoscopy revealed complete resolution of colonic lymphangiomas without any specific treatment (Figure 4).

DISCUSSION

In most reported cases of colonic lymphangioma, the condition is solitary. Only a few cases of multiple lymph-

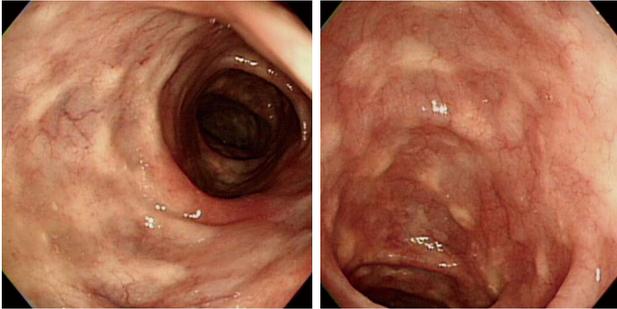

Figure 4 Follow-up colonoscopy 24 mo after initial examination showing multiple whitish scars throughout the entire colonic mucosa and resolved lymphangioma without specific therapy.

angiomas of the colon, the so-called “colonic lymphangiomatosis”, have been reported so far^[8,9]. Endoscopic findings of colonic lymphangioma are characterized by the presence of submucosal tumor properties covered with normal mucosa, round and soft surfaces, a wide base area, pink color and semi-transparency. Histological observations of lymph vascular dilation and outgrowth in the submucosal layer are important for its correct diagnosis in these cases. The condition is classified into capillary, cavernous, and cystic types^[10]. The cystic type, as in our case, is also the most frequently reported and characterized by dilated lymphatic vessels surrounded by flat endothelial cells between fat, fibrotic and lymphatic structures. To the best of our knowledge, the formation of lymphangioma impedes lymph flow for a prolonged period, resulting in lymph vessel expansion or further progression and is generally perceived as a developmental malformation or agenesis of lymphatic tissue. Other causes such as abdominal trauma, lymphatic obstruction, inflammatory processes, cancer, surgery, or radiation may result in secondary lymphangioma formation^[11-16]. In the case of lymphangioma appearing late in adulthood, the lesion may have developed secondarily from a local disturbance of the lymphatic circulation^[2]. Therefore, the clinicians should look out for the causative condition, particularly in adults. Abdomen computed tomography showed no co-morbid disease in our case.

Although a definitive diagnosis of colonic lymphangioma requires complete excision including the submucosal layer, unnecessary surgery should be avoided. Moreover, as in our case, it is quite difficult to perform a total colectomy to remove lesions involving the entire colon. The spontaneous resolution of cystic hygromas originating in the neck or mediastinum has been reported^[14,15]. Several investigators have suggested that increased pressure in the lymphatic system may overcome incomplete obstructions, which may explain why the lesions are spontaneously resolved. In contrast, spontaneous resolution presumably results from the establishment of alternative routes of lymphatic drainage in cases of septated lesions^[16-18]. Although this hypothesis has been applied to cystic hygroma of the neck or the spleen, it may match well in our case. The mild leakage induced by in-

creased pressure of the cyst may stimulate dendritic cells or macrophages in the stroma. In a prolonged state of lymphatic stagnation, CD68-positive cells, which can be dendritic cells or macrophages, might correspond to the cells equipped with phagosomes and lysosomes^[19]. These stimulated cells would evidence phagocytic activity on the lining cells, which continues until the lymphangioma is resolved.

In conclusion, conservative management coupled with close surveillance may be an effective treatment strategy for lymphangioma, and resection of lymphangioma should be reserved in mild symptomatic or asymptomatic patients, because of its benign nature and possible spontaneous resolution.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclu-

sion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Baishideng Publishing Group Co., Limited

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declara-

tion of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUC-

TIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself.

Instructions to authors

File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of P values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the

cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 $24.5 \mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP,

EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

Instructions to authors

Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the

revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

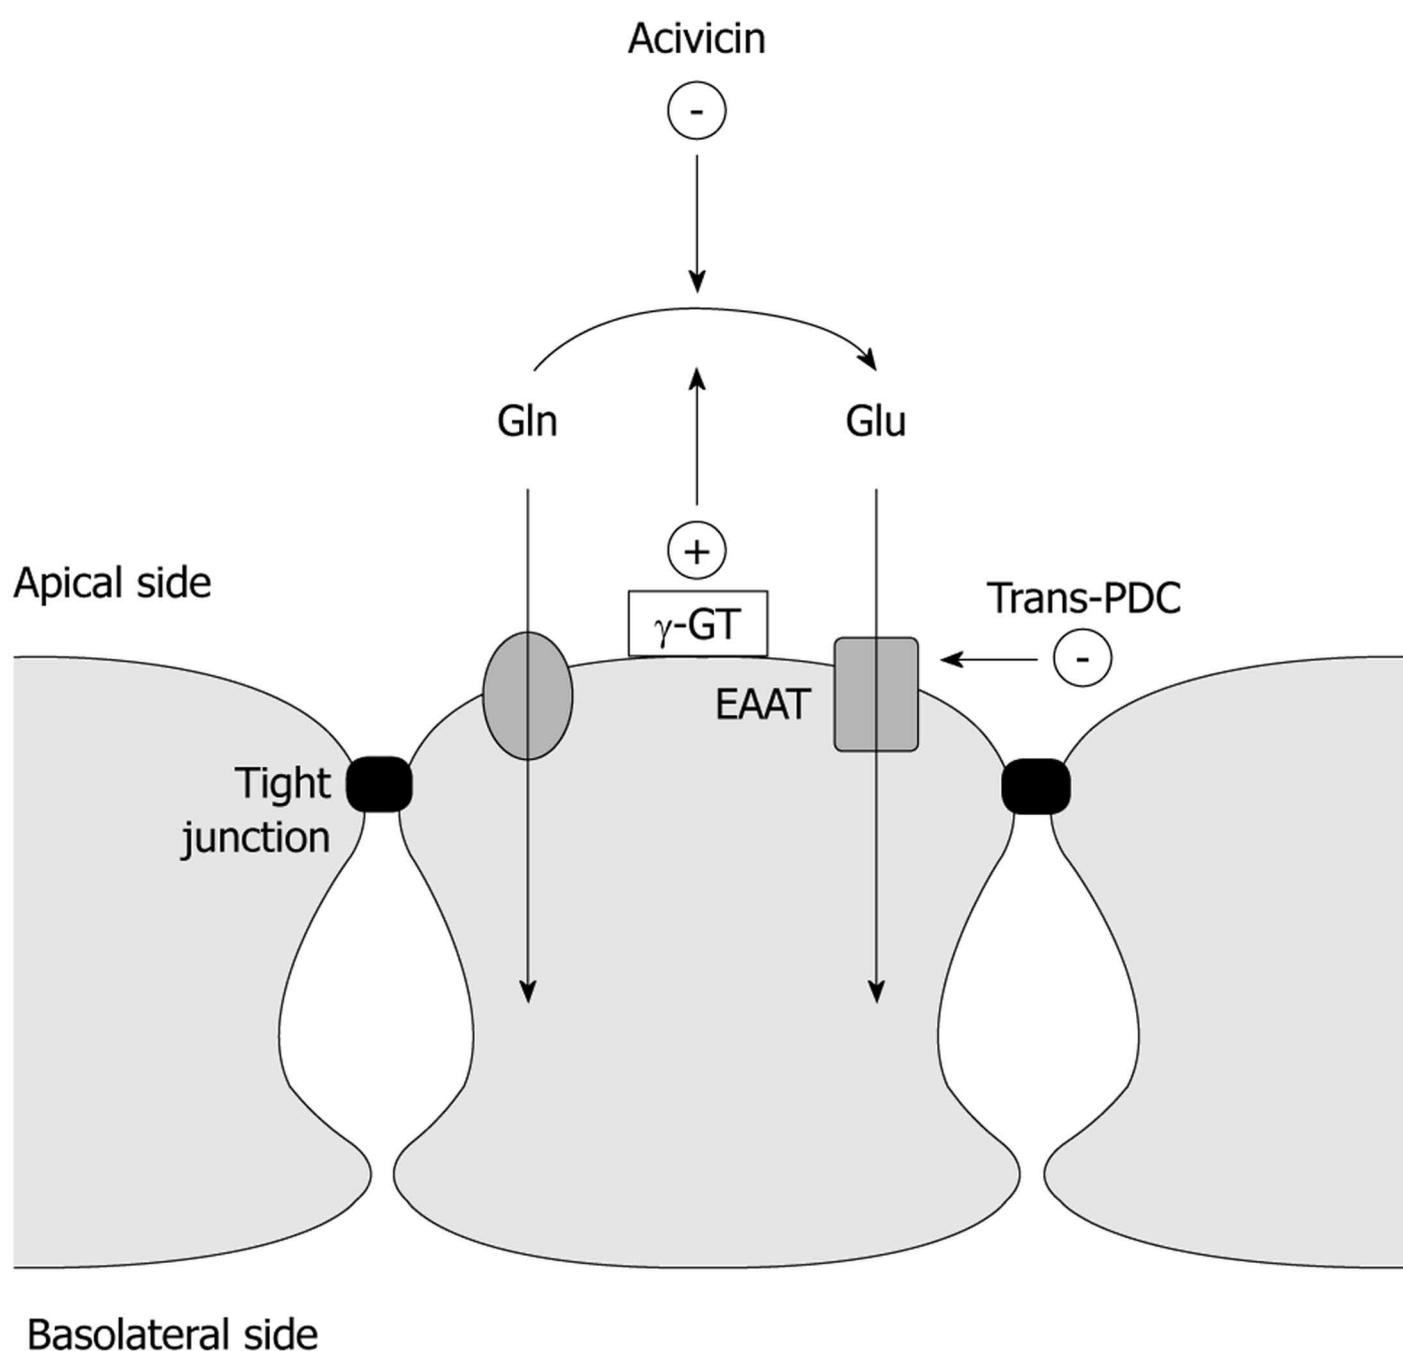

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

World Journal of *Gastroenterology*

World J Gastroenterol 2011 March 28; 17(12): 1519-1654

Editorial Board

2010-2013

The *World Journal of Gastroenterology* Editorial Board consists of 1144 members, representing a team of worldwide experts in gastroenterology and hepatology. They are from 60 countries, including Albania (1), Argentina (8), Australia (29), Austria (14), Belgium (12), Brazil (10), Brunei Darussalam (1), Bulgaria (2), Canada (20), Chile (3), China (69), Colombia (1), Croatia (2), Cuba (1), Czech (4), Denmark (8), Ecuador (1), Egypt (2), Estonia (2), Finland (8), France (24), Germany (75), Greece (14), Hungary (10), India (26), Iran (6), Ireland (7), Israel (12), Italy (101), Japan (112), Jordan (1), Kuwait (1), Lebanon (3), Lithuania (2), Malaysia (1), Mexico (10), Moldova (1), Netherlands (29), New Zealand (2), Norway (11), Pakistan (2), Poland (11), Portugal (4), Romania (3), Russia (1), Saudi Arabia (3), Serbia (3), Singapore (10), South Africa (2), South Korea (32), Spain (38), Sweden (18), Switzerland (11), Thailand (1), Trinidad and Tobago (1), Turkey (24), United Arab Emirates (2), United Kingdom (82), United States (249), and Uruguay (1).

<http://www.wjgnet.com/1007-9327/full/v17/i12/1569.htm>

AIM AND SCOPE *World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.
The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

The multiple beneficial effects on human health of the short-chain fatty acid butyrate, synthesized from non-absorbed carbohydrate by colonic microbiota, are well documented. At the intestinal level, butyrate plays a regulatory role on the transepithelial fluid transport, ameliorates mucosal inflammation and oxidative status, reinforces the epithelial defense barrier, and modulates visceral sensitivity and intestinal motility. In addition, a growing number of studies have stressed the role of butyrate in the prevention and inhibition of colorectal cancer. At the extraintestinal level, butyrate exerts potentially useful effects on many conditions, including hemoglobinopathies, genetic metabolic diseases, hypercholesterolemia, insulin resistance, and ischemic stroke. The mechanisms of action of butyrate are different; many of these are related to its potent regulatory effects on gene expression. These data suggest a wide spectrum of positive effects exerted by butyrate, with a high potential for a therapeutic use in human medicine.

INTRODUCTION

The development of the intestinal ecosystem is crucial for many gastrointestinal functions and body health. The intestinal ecosystem essentially comprises the epithelium, immune cells, enteric neurons, intestinal microflora, and nutrients. The coordinate interplay between all these components is the object of intensive research efforts to design new strategies for many intestinal and extraintestinal diseases. In this context, short-chain fatty acids (SCFAs), produced by intestinal microflora, represent a clear example of the importance of the intestinal ecosystem. SCFAs are organic acids produced by intestinal microbial fermentation of mainly undigested dietary carbohydrates, specifically resistant starches and dietary fiber, but also in a minor part by dietary and endogenous proteins. SCFAs are 2-carbon to 5-carbon weak acids, including acetate (C2), propionate (C3), butyrate (C4), and valerate (C5). SCFAs are essentially produced in the colon. The ratio of SCFA concentrations in the colonic lumen is about 60% acetate, 25% propionate, and 15% butyrate. As a result of increasing concentrations of acidic fermentation products,

the luminal pH in the proximal colon is lower. This pH seems to boost the formation of butyrate, as mildly acidic pH values allow butyrate-producing bacteria to compete against Gram-negative carbohydrate-utilizing bacteria, such as *Bacteroides spp.*^[1]. The ability to produce butyrate is widely distributed among the Gram-positive anaerobic bacteria that inhabit the human colon. Butyrate-producing bacteria represent a functional group, rather than a coherent phylogenetic group. Numerically, two of the most important groups of butyrate producers appear to be *Faecalibacterium prausnitzii*, which belongs to the *Clostridium leptum* (or clostridial cluster IV) cluster, and *Eubacterium rectale/Roseburia spp.*, which belong to the *Clostridium coccoides* (or clostridial cluster XIVa) cluster of firmicute bacteria^[2]. Butyrate is the major energy source for colonocytes and is involved in the maintenance of colonic mucosal health^[3]. Recently several intestinal and extraintestinal effects of butyrate have been demonstrated (Figure 1 and Table 1). This review is focused on new evidence for possible applications of butyrate in human medicine.

EFFECTS OF BUTYRATE AT THE INTESTINAL LEVEL

Effects on transepithelial ion transport

Potentially, SCFAs are absorbed by each intestinal segment, as demonstrated in animal models and human volunteers. The colonocytes absorb butyrate and other SCFAs through different mechanisms of apical membrane SCFA uptake, including non-ionic diffusion, SCFA/HCO₃⁻ exchange, and active transport by SCFA transporters. The transport proteins involved are monocarboxylate transporter isoform 1 (MCT1), which is coupled to a transmembrane H⁺-gradient, and SLC5A8, which is Na⁺-coupled co-transporter^[3,4]. The absorption of these fatty acids has a significant impact on the absorption of NaCl and on the electrolyte balance generally^[5]. In particular, butyrate is able to exert a powerful pro-absorptive stimulus on intestinal NaCl transport and an anti-secretory effect towards Cl⁻ secretion. The powerful regulatory pro-absorptive/anti-secretory effects induced by butyrate on the transepithelial ion transport occurs through several mechanisms: (1) Stimulation of NaCl absorption by the action of two coupled transport systems on the intestinal brush border: Cl⁻/HCO₃⁻ and Na⁺/H⁺ and Cl⁻/butyrate and Na⁺/H⁺; and (2) inhibition of Cl⁻ secretion by blocking the activity of the cotransporter Na-K-2Cl (NKCC1) on the enterocyte basolateral membrane. *In vitro* studies have shown that butyrate has an inhibitory effect on Cl⁻ secretion induced by prostaglandin E₂, cholera toxin, and phosphocholine. This effect is due to reduced production of intracellular cAMP secondary to the expression and regulation of adenylate cyclase^[4]. Comparison studies showed that the pro-absorptive and anti-secretory effects of butyrate are significantly higher than those of all other SCFAs^[6]. Clinical studies in chil-

dren with acute diarrhea caused by *V. cholerae* showed a reduction in stool volume and a more rapid recovery in patients who received oral rehydration therapy in addition to resistant starch, a precursor of butyrate, in the diet^[7,8]. These results were confirmed in other forms of infectious diarrhea in children and in animal models studies^[9,10]. Moreover, butyrate therapy is beneficial in patients affected by Congenital Chloride Diarrhea (CLD)^[11,12]. This rare genetic disease is caused by mutations in the gene encoding the solute-linked carrier family 26-member A3 (SLC26A3) protein, which acts as a plasma membrane anion exchanger for Cl⁻ and HCO₃⁻^[13]. The mechanism underlying this therapeutic effect could be related, at least in part, to stimulation of the Cl⁻/butyrate exchanger activity^[11]. It is also possible that butyrate could reduce mistrafficking or misfolding of the SLC26A3 protein, as demonstrated for other molecules involved in transepithelial ion transport^[14]. Alternatively, butyrate may enhance gene expression: the *SLC26A3* gene contains a 290-bp region between residues -398 and -688 that is crucial for high-level transcriptional activation induced by butyrate. This may explain the variable response of patients affected by CLD to butyrate^[12]. In fact, depending on the patient's genotype, mutations in the above-mentioned regulatory regions of the *SLC26A3* gene could affect the gene transcription rate. It is also conceivable that other channels could be involved in the therapeutic effect of butyrate in CLD. SLC26A3, like other components of the SLC26 family, interacts with cystic fibrosis transmembrane conductance regulator (CFTR)^[15,16]. The interaction between CFTR and these components is mediated by binding of the regulatory domain of CFTR to the sulfate transporter and anti sigma factor antagonist (STAS) domain of SLC26. The interaction is enhanced by phosphorylation of the regulatory domain by protein kinase A^[17] and is modulated by PDZ-binding scaffold proteins. An important consequence of this interaction is that SLC26 anion exchange activity is enhanced when CFTR is activated by phosphorylation. Moreover, the two genes regulate each other: the overexpression of SLC26A3 or -A6 causes upregulation of CFTR and *vice versa*^[18]. In patch-clamp experiments, protein kinase A-stimulated CFTR channel activity was six-fold higher in HEK293 cells co-expressing both SCL26 exchanger and CFTR than in HEK293 cells expressing CFTR alone^[12,15,16,18]. Mutations may impair the interactions between channels and thus reduce the effect of butyrate therapy. Interestingly, it has been demonstrated that butyrate can act by different mechanisms in *in vitro* models of cystic fibrosis: it can increase the expression of the apical epithelial membrane of the CFTR, and it can act as a "chaperone-like" molecule, as shown in the ΔF508del CFTR cell line model^[19]. Similar mechanisms could occur in CLD. Lastly, Clausen *et al.*^[20] demonstrated that antibiotic-associated diarrhea was related to reduced fecal concentrations and production rates of butyrate. Their results suggest that

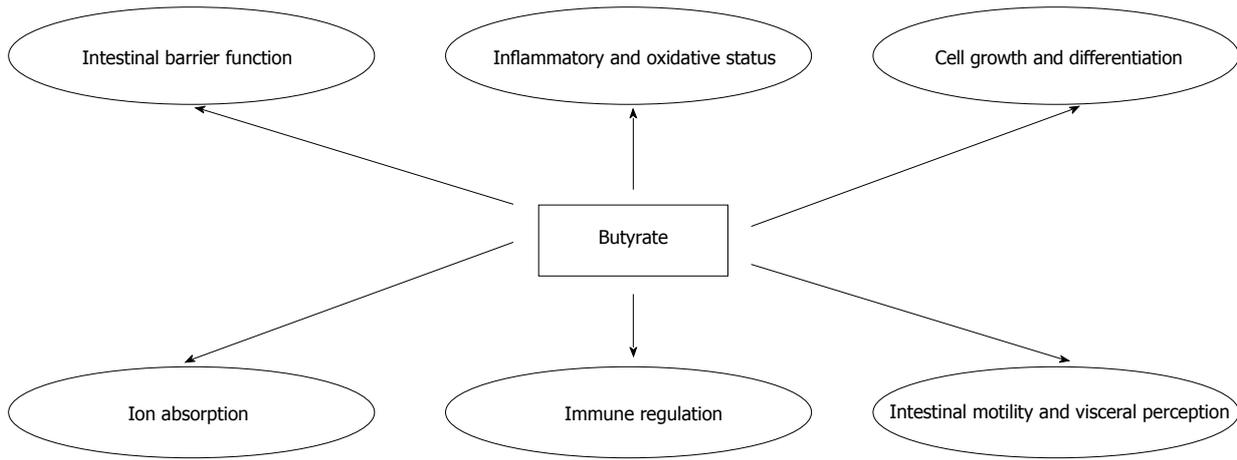

Figure 1 The multiple effects of butyrate at intestinal level.

| Table 1 Main butyrate effects potentially useful in human medicine | |
|--|---|
| Intestinal level | Extraintestinal level |
| Ion absorption | Insulin sensitivity |
| Cell proliferation | Cholesterol synthesis |
| Cell differentiation | Energy expenditure |
| Intestinal barrier function | Ammonia scavenger |
| Immune-regulation | Stimulation of β -oxidation of very long chain fatty acids and peroxisome proliferation |
| Oxidative stress | CFTR function |
| Intestinal motility | Neurogenesis |
| Visceral perception and rectal compliance | HbF production |

CFTR: Cystic fibrosis transmembrane conductance regulator; HbF: Butyrate to increase fetal hemoglobin.

the antibiotic-associated diarrhea might be secondary to impaired colonic fermentation in otherwise disposed subjects, resulting in decreased butyrate and fluid absorption. In this case, the administration of butyrate could also alleviate the symptoms associated with antibiotic use.

Effects on cell growth and differentiation

Several epidemiological studies support the role of dietary fiber in the protection against colorectal cancer^[21-26]. Different mechanisms have been proposed for fiber’s cancer preventive properties: reduction in transit time of the feces in the gut, which reduces exposure of the mucosa to luminal carcinogens; absorption of bile acids, biogenic amines, bacterial toxins, and production of butyrate. Most of the anticarcinogenic effects of butyrate are observed in *in vitro* carcinoma cell lines. In these models, addition of butyrate leads to inhibition of proliferation, induction of apoptosis, or differentiation of tumor cells^[27-30]. Butyrate’s anticarcinogenic effects are in contrast with the effects of this compound in normal enterocytes. In fact, it has been shown that butyrate stimulates the physiological pattern of proliferation in the basal crypt in the colon,

whereas it reduces the number and the size of aberrant crypt focus, which are the earliest detectable neoplastic lesions in the colon^[31]. These contradictory patterns of butyrate represents the so called “butyrate paradox”^[27]. An important mechanism by which butyrate causes biological effects in colon carcinoma cells is the hyperacetylation of histones by inhibiting histone deacetylase (HDAC). This compensates for an imbalance of histone acetylation, which can lead to transcriptional dysregulation and silencing of genes that are involved in the control of cell cycle progression, differentiation, apoptosis and cancer development^[32,35]. In particular, in human colon cancer cell lines butyrate, acting as HDAC inhibitor, increases the p21 (*WAF1*) gene expression by selectively regulating the degree of acetylation of the gene-associated histones, and induces G1 cell cycle arrest^[36]. A novel contributory mechanism to the chemopreventive effect of butyrate is the downregulation of the key apoptotic and angiogenesis regulator Neuropilin-1 (NRP-1), which has been shown to promote tumor cell migration and survival in colon cancer in response to vascular endothelial growth factor (VEGF) binding^[37]. Several reports have shown that the apoptosis triggered by butyrate *in vitro* is associated with dysregulation of Bcl2 family proteins, especially upregulation of BAK and downregulation of BclxL^[38,39], rather than cellular damage. A study by Thangaraju *et al* suggests a novel mode of action of butyrate in the colon involving GPR109A, a G-protein–coupled receptor for nicotinate^[40,41], which recognizes butyrate with low affinity. This receptor is expressed in the normal colon on the lumen-facing apical membrane of colonic epithelial cells, but is silenced in colon cancer *via* DNA methylation. Thangaraju *et al*^[42] showed that inhibition of DNA methylation in colon cancer cells induces GPR109A expression and that activation of the receptor causes tumor cell–specific apoptosis. Butyrate is an inhibitor of HDAC, but apoptosis induced by activation of GPR109A with its ligands in colon cancer cells does not involve inhibition of histone deacetylation. The primary changes in this apoptotic pro-

cess include downregulation of Bcl-2, Bcl-xL, and cyclin D1 and upregulation of death receptor pathway. Moreover, a recent study suggested that the protective role of dietary fiber, and its breakdown product butyrate, against colorectal cancer could be determined by a modulation of canonical Wnt signaling, a pathway constitutively activated in the majority of colorectal cancers^[43]. Butyrate is recognized for its potential to act on secondary chemoprevention, by slowing growth and activating apoptosis in colon cancer cells^[44], but it can also act on primary chemoprevention. The mechanism proposed is the transcriptional upregulation of detoxifying enzymes, such as glutathione-S-transferases (GSTs). This modulation of genes may protect cells from genotoxic carcinogens, such as H₂O₂ and 4-hydroxynonenal (HNE)^[45,46].

Effects on inflammatory and oxidative status

Butyrate has a role as an anti-inflammatory agent, primarily *via* inhibition of nuclear factor κ B (NF- κ B) activation in human colonic epithelial cells^[47], which may result from the inhibition of HDAC. NF- κ B regulates many cellular genes involved in early immune inflammatory responses, including IL-1b, TNF- α , IL-2, IL-6, IL-8, IL-12, inducible nitric oxide synthase (iNOS), cyclooxygenase-2 (COX-2), intercellular adhesion molecule-1 (ICAM-1), vascular cellular adhesion molecule-1 (VCAM-1), T cell receptor- α (TCR- α), and MHC class II molecules^[48-50]. The activity of NF- κ B is frequently dysregulated in colon cancer^[51,52] and in inflammatory bowel diseases (IBDs), such as ulcerative colitis (UC) and Crohn's disease (CD)^[53-55]. In CD patients, butyrate decreases pro-inflammatory cytokine expression *via* inhibition of NF- κ B activation and I κ B α degradation^[53]. The upregulation of peroxisome proliferator-activated receptor γ (PPAR γ) a nuclear receptor highly expressed in colonic epithelial cells, and the inhibition of IFN γ signaling, are another two of butyrate's anti-inflammatory effects^[56,57]. Butyrate can act on immune cells through specific G-protein-coupled receptors (GPRs) for SCFAs, GPR41 (or FFA3) and GPR43 (or FFA2), which are both expressed on immune cells, including polymorphonuclear cells, suggesting that butyrate might be involved in the activation of leucocytes^[58]. The possible immune-modulatory functions of SCFAs are highlighted by a recent study on GPR43 -/- mice. These mice exhibit aggravated inflammation, related to increased production of inflammatory mediators and increased immune cell recruitment^[59].

Most clinical studies analyzing the effects of butyrate on inflammatory status focused on UC patients. Hallert *et al.*^[60] instructed 22 patients with quiescent UC to add 60 g oat bran (corresponding to 20 g dietary fiber) to their daily diet. Four weeks of this treatment resulted in a significant increase of fecal butyrate concentration and in a significant improvement of abdominal symptoms. In a double blind, placebo-controlled multicenter trial, Vernia *et al.*^[61] treated 51 patients with active distal UC with rectal enemas containing either 5-aminosalicylic acid (5-ASA) or

5-ASA plus sodium butyrate (80 mmol/L, twice a day). The combined treatment with topical 5-ASA plus sodium butyrate significantly improved the disease activity score more than 5-ASA alone. These and other intervention studies^[62-64] suggested that the luminal administration of butyrate or stimulation of luminal butyrate production by the ingestion of dietary fiber results in an amelioration of the inflammation and symptoms in UC patients.

Numerous studies have reported that butyrate metabolism is impaired in intestinal inflamed mucosa of patients with IBD. Recent data show that butyrate deficiency results from the reduction of butyrate uptake by the inflamed mucosa through downregulation of MCT1. The concomitant induction of the glucose transporter GLUT1 suggests that inflammation could induce a metabolic switch from butyrate to glucose oxidation. Butyrate transport deficiency is expected to have clinical consequences. Particularly, the reduction of the intracellular availability of butyrate in colonocytes may decrease its protective effects toward cancer in IBD patients^[65].

Limited evidence from pre-clinical studies shows that oxidative stress in the colonic mucosa can be modulated by butyrate. Oxidative stress is involved in both inflammation^[66] and the process of initiation and progression of carcinogenesis^[67]. During oxidative stress there is an imbalance between the generation of reactive oxygen species (ROS) and the antioxidant defense mechanisms, leading to a cascade of reactions in which lipids, proteins, and/or DNA may get damaged. In healthy humans, it has been demonstrated that locally administered butyrate in physiological concentrations increased the antioxidant GSH and possibly decreased ROS production, as indicated by a decreased uric acid production^[68]. As the human colon is continuously exposed to a variety of toxic stimuli, enhanced butyrate production in the colon could result in an enhanced resistance against toxic stimuli, thus improving the barrier function. This might be relevant for the treatment of gastrointestinal disorders, such as post-infectious irritable bowel syndrome (IBS), microscopic colitis, IBD, and diversion colitis.

Effects on non-specific intestinal defense mechanisms

The main components of nonspecific intestinal barrier defense mechanisms are the mucous layer covering the epithelium, the production of antimicrobial peptides, and tight junctions, which protect the gastrointestinal mucosa against pathogens. Evidence suggests a role for butyrate in reinforcing the colonic defense barrier. Butyrate stimulates MUC2 mucin production in a human colonocytes cell line (LS174T). The increased expression of MUC2 gene, and the induction of mucin synthesis, can affect the mucous layer leading to enhanced protection against luminal agents^[69,70].

Combined with other components of the innate immune system, antimicrobial peptides (AMPs) form the first line of defense against infections. The two major

classes of AMPs found in humans are defensins and cathelicidins. While the intestine expresses numerous defensins, LL-37 is the only cathelicidin-derived peptide expressed in humans. Several studies demonstrated an effect of butyrate on LL-37 gene expression and proposed that the molecular mechanism may be linked to an increase in histone acetylation and mitogen-activated protein (MAP) kinase signaling^[71-75]. The use of HDAC inhibitors, such as butyrate, to enhance the expression of the LL-37 gene may become a novel approach for strengthening innate immunity to treat or prevent intestinal infections.

Butyrate also regulates the colonic defense barrier through its effects on intestinal permeability, which depends on its concentration. At low concentrations, butyrate induces a concentration-dependent reversible decrease in permeability in intestinal cell line models^[76,77]. The effect of butyrate on the intestinal epithelial permeability involves the assembly of tight junctions *via* AMP-activated protein kinase (AMPK)^[78].

Effects on visceral perception and intestinal motility

Little is known about the environmental and nutritional regulation of the enteric nervous system (ENS), which controls gastrointestinal motility. Butyrate regulates colonic mucosa homeostasis and can modulate neuronal excitability. Soret *et al.*^[79] investigated the effects of butyrate on the ENS and colonic motility, and showed, *in vivo* and *in vitro*, that butyrate significantly increased the proportion of choline acetyltransferase (ChAT), but not nitric oxide synthase (nNOS) immunoreactive myenteric neurons. Butyrate increases the cholinergic-mediated colonic circular muscle contractile response *ex vivo*. The authors suggest that butyrate might be used, along with nutritional approaches, to treat various gastrointestinal motility disorders associated with inhibition of colonic transit.

A recent study by Van Houten *et al.*^[80] shows that intraluminal administration of a physiologically relevant dose (50 to 100 mmol/L) of butyrate into the distal colon increases compliance and decreases pain, urge, and discomfort measured with a rectal barostat procedure in healthy subjects. This study suggests a potential beneficial effect of butyrate in disorders that are associated with visceral hypersensitivity, such as IBS and infantile colics, and provides a basis for future trials with dietary modulation resulting in intracolonic butyrate production in both healthy and IBS subjects. The decrease in visceral perception induced by butyrate treatment could be due to an increased 5-HT release, as previously suggested by others^[81]. Another possible mechanism by which butyrate could affect visceral perception is the previous reported inhibition of histone deacetylase. In fact, Chen *et al.*^[82] showed that these inhibitors induce microglial apoptosis and attenuate inflammation-induced neurotoxicity in rats, which may affect visceral perception. Butyrate has been reported to induce enhancement of colonic motility *via* the release of 5-HT^[83]. In functional studies, butyrate and propionate induced phasic and tonic contractions in rat

colonic circular muscle. The dose-dependent contractile effect occurred only when SCFAs were applied on the mucosal side and disappeared in mucosal free preparations, suggesting the presence of sensory mechanisms near the epithelium^[84,85].

EFFECTS AT THE EXTRAINTESTINAL LEVEL

Hemoglobinopathies

Clinical trials in patients with sickle cell disease and β -thalassemia confirmed the ability of butyrate to increase fetal hemoglobin (HbF) production^[86-89]. Butyrate is an inducer of HbF through an epigenetic regulation of fetal globin gene expression *via* HDAC inhibition, resulting in global histone hyperacetylation, including nucleosomes at the γ -globin promoters^[90]. Other experiments have shown that butyrate can cause a rapid increase in the association of γ -globin mRNA with ribosomes^[91]. Other authors have demonstrated activation of p38 mitogen-activated protein kinases (MAPK) and cyclic nucleotide signaling pathways in association with butyrate induction of HbF^[92]. Taken together, these studies suggest that global histone hyperacetylation induced by HDAC inhibition is not the unique mechanism underlying butyrate stimulation of HbF.

Genetic metabolic diseases

Sodium phenylbutyrate 4 (4-PBA) was approved by the Food and Drug Administration (FDA) for use in patients with urea cycle enzyme deficiency, in which it acts as a scavenger of ammonia. Indeed, 4-PBA is oxidized to phenylacetate, which binds to glutamine and determines the urinary excretion. In patients with ornithine transcarbamylase deficiency, the use of 4-PBA allows for better metabolic control and increased intake of natural protein in the diet^[93].

The possible use of butyrate in the treatment of X-linked Adrenoleukodystrophy (X-ALD), a disorder of peroxisomes characterized by altered metabolism and accumulation of very long chain fatty acids, has also been studied. Sodium phenylbutyrate 4 induces, *in vitro* on fibroblasts from patients with X-ALD and *in vivo* in X-ALD knockout mice, an increase in β -oxidation of very long chain fatty acids and peroxisome proliferation^[94].

Hypercholesterolemia

Under normal lipidemic conditions, the liver is the most important site of cholesterol biosynthesis, followed by the intestine. Biosynthesis in the liver and intestine account for about 15% and 10%, respectively, of the total amount of cholesterol biosynthesis each day^[95,96]. In hypercholesterolemia, when cholesterol biosynthesis is suppressed in most organs by fasting, the intestine becomes the major site of cholesterol biosynthesis, and its contribution can increase up to 50%. Importantly, recent evidence shows that the global effect of butyrate is to downregulate the

Table 2 Possible therapeutic indications of butyrate in gastroenterology

| Functions | Therapeutic indications | Potential applications |
|---|--|--|
| Regulation of fluid and electrolyte uptake | Acute gastroenteritis ^[9,10] Cholera ^[7,8] Congenital chloride diarrhea ^[11,12] | Irritable bowel syndrome ^[80] Aspecific chronic diarrhea ^[4] Traveler's diarrhea ^[4] Antibiotic associated diarrhea ^[4,20] Chronic secretory diarrhea ^[4] Cystic fibrosis ^[14,19] Mucosal atrophy in malnutrition ^[101] |

IBD: Inflammatory bowel disease.

expression of nine key genes involved in intestinal cholesterol biosynthesis, potentially inhibiting this pathway^[97].

Obesity and insulin resistance

Dietary supplementation with butyrate can prevent and treat diet-induced obesity and insulin resistance in mouse models. After a 5-wk treatment with butyrate, obese mice lost 10.2% of their original body weight. Consistent with the change in body weight, fat content was reduced by 10%. Furthermore, fasting glucose was reduced by 30%, insulin resistance was reduced by 50%, and intraperitoneal insulin tolerance was improved significantly by butyrate. The mechanism of butyrate action is related to promotion of energy expenditure and induction of mitochondrial function. Stimulation of peroxisome proliferator-activated receptor (PPAR) coactivator (PGC-1 α) activity has been suggested as the molecular mechanism of butyrate. Activation of AMPK and inhibition of histone deacetylases may contribute to the PGC-1 α regulation. These data suggest that butyrate may have potential application in the prevention and treatment of metabolic syndrome in humans^[98].

Ischemic stroke

Cerebral ischemia enhances neurogenesis in neurogenic and non-neurogenic regions of the ischemic brain of adult animal models. A recent study demonstrated that post-insult treatment with sodium butyrate stimulated the incorporation of bromo-2'-deoxyuridine (BrdU) in the ischemic brain of rats subjected to permanent cerebral ischemia. Butyrate treatment also increased the number of cells expressing polysialic acid-neural cell adhesion molecule, nestin, glial fibrillary acidic protein, phospho-cAMP response element-binding protein (CREB), and brain-derived neurotrophic factor (BDNF) in various brain regions after cerebral ischemia^[99]. Furthermore, extensive co-localization of BrdU and polysialic acid-neural cell adhesion molecule was observed in multiple regions after ischemia, and butyrate treatment upregulated protein levels of BDNF, phospho-CREB, and glial fibrillary acidic protein. Intraventricular injection of K252a, a tyrosine kinase B receptor antago-

nist, markedly reduced the long-lasting behavioral benefits of butyrate, inhibiting cell proliferation, nestin expression, and CREB activation^[99]. Together, these results suggest that butyrate-induced cell proliferation, migration, and differentiation require BDNF-tyrosine kinase B signaling and may contribute to long-term beneficial effects of butyrate after ischemic injury.

ISSUES RELATED TO THE CLINICAL USE OF BUTYRATE

Data from literature and clinical experience of several research groups show a wide spectrum of possibilities for potential therapeutic use of butyrate by oral administration without having serious adverse events (Table 2). Some butyrate-based products are marketed, but their spread is still very limited and greatly understaffed in view of the wide spectrum of possible indications, especially in chronic diseases, where it is possible to predict a lasting use of the compound. The main problem is of the availability of formulations of butyrate that can be easily administered orally, in particular for pediatric patients, and to the extremely poor palatability of the products available on the market. The unpleasant taste and odor make oral administration of butyrate extremely difficult, especially in children. Thus, new formulations of butyrate with a better palatability, which can be easily administered orally, are needed. Another possible solution could be the modulation of intestinal microflora by probiotics. Probiotics are live and viable microorganisms, which, if given in adequate amounts, confer a beneficial effect to the host. Probiotic microorganisms generate small molecular metabolic byproducts, referred to as "postbiotics", which exert beneficial regulatory influence on host biological functions, including butyrate^[100].

CONCLUSION

The SCFA butyrate, a main end product of microbial fermentation of dietary fibers in the human intestine,

plays an important role in the maintenance of intestinal homeostasis and overall health status. The effects exerted by butyrate are multiple and involve several distinct mechanisms of action. Its well-known epigenetic mechanism, through the inhibition of HDACs, results in the regulation of gene expression and in the control of cell fate. At the intestinal level, butyrate exerts multiple effects such as the prevention and inhibition of colonic carcinogenesis, the improvement of inflammation, oxidative status, epithelial defense barrier, and the modulation of visceral sensitivity and intestinal motility. At the extraintestinal level, potential fields of application for butyrate seem to be the treatment of sickle cell disease, β -thalassemia, cystic fibrosis, urea cycle enzyme deficiency, X-linked adrenoleukodystrophy, hypercholesterolemia, obesity, insulin resistance, and ischemic stroke.

In conclusion, a growing number of studies have revealed new mechanisms and effects of butyrate with a wide range of potential clinical applications from the intestinal tract to peripheral tissues. However, more clinical studies to elucidate the role of butyrate in health and diseases and new solutions for easier administration are needed.

Abstract

Occult hepatitis B virus (HBV) infection is a world-wide entity, following the geographical distribution of detectable hepatitis B. This entity is defined as the persistence of viral genomes in the liver tissue and in some instances also in the serum, associated to negative HBV surface antigen serology. The molecular basis of the occult infection is related to the life cycle of HBV, which produces a covalently closed circular DNA that persists in the cell nuclei as an episome, and serves as a template for gene transcription. The mechanism responsible for the HBsAg negative status in occult HBV carriers is a strong suppression of viral replication, probably due to the host's immune response, co-infection with other infectious agents and epigenetic factors. There is emerging evidence of the potential clinical relevance of occult HBV infection, since this could be involved in occult HBV transmission through orthotopic liver transplant and blood transfusion, reactivation of HBV infection during immunosuppression, impairing chronic liver disease outcome and acting as a risk factor for hepatocellular carcinoma. Therefore it is important to bear in mind this

entity in cryptogenetic liver diseases, hepatitis C virus/HIV infected patients and immunosuppressed individuals. It is also necessary to increase our knowledge in this fascinating field to define better strategies to diagnose and treat this infection.

EDITORIAL

The persistence of hepatitis B virus (HBV) in hepatitis B surface antigen (HBsAg) negative individuals is termed occult HBV infection (OBI)^[1]. Since the early 80's it was suspected that hepatitis B virus could persist in the host despite not being detectable. In the last decade after the appearance of highly sensitive molecular biology techniques the presence of HBV in the liver and serum of HBsAg negative individuals has been shown^[2]. OBI-infected subjects maintained HBV infection due to the peculiar HBV life cycle which is characterised by the production of covalently closed circular DNA that serves as a template for gene transcription^[3]. In occult HBV carriers the viral replication from this episome is strongly suppressed and several factors could contribute to this situation^[4]. A high HBV-specific immunological pressure could contribute to the development of occult HBV infection and this could

explain why in immunosuppressive condition an HBV infection reactivation is observed. Another hypothetical factor associated with OBI is the co-infection with other pathogens. HCV infection is strongly associated with HBV occult infection and moreover it has been shown that HCV core protein is able to inhibit *in vitro* HBV replication. Finally, there is some evidence that epigenetic factors could contribute to reduce HBV replication efficiency through the regulation of the HBV transcriptional program. The prevalence of this entity is difficult to assess due to the difference in the technical procedures and the tissues studied. The distribution is similar to the HBVAg positive HBV infection being more prevalent in certain groups such as HCV and HIV populations^[5,6]. Anyway epidemiological data are still scarce and more studies in the general population and cryptogenic hepatitis are necessary^[7]. From the clinical point of view this entity is extremely relevant because it could be the cause of liver disease in different scenarios not well described currently. Carriers of occult HBV infection may be a source of HBV transmission in the case of blood transfusion^[8]. Moreover, HBV occult infection can be also transmitted during orthotopic liver transplantation from anti hepatitis B core positive individuals as well as from HBV seronegative cases^[9]. Another important clinical manifestation of HBV occult infection is its reactivation of the infection during immunosuppression. After the restoration of the immune system after finishing immunosuppressive treatment it is possible that acute hepatitis may occur. This is important in haematological malignancies, hematopoietic stem cell transplantation and organ transplantation^[10]. Clinicians should be aware of these clinical events to prevent this situation with the appropriate prophylaxis. Moreover, hepatologists should not think that this infection in immunocompetent individuals is an inoffensive condition. The long-lasting persistence of the virus in the liver may provoke a mild but continuous inflammation which could have clinical implications in cases of previous liver damage. Different reports suggest that HBV occult infection could be responsible for the acceleration of chronic HCV progression and interfere with treatment response^[5]. More studies are needed to clarify this important issue. Finally HBV occult infection could be related to the development of hepatocellular carcinoma among HBsAg negative chronic hepatitis patients^[11]. This could be through the induction of chronic inflammation and by means of HBV DNA integration into the host's genome. In summary, it is clear that a large amount of information has been produced in recent years about this topic but the data are still too incomplete to describe properly the clinical impact of this infection and more bio-medical research is still needed in this fascinating field. In this issue of *World Journal of Gastroenterology* the current knowledge on the HBV occult infection field is updated, addressing all the topics^[12-18] with a practical point of view to make this "Topic Highlight" interesting and useful to most clinicians.

Abstract

Reactivation of hepatitis B is defined as the recurrence or an abrupt rise in hepatitis B virus (HBV) replication, often accompanied by an increase in serum transaminase levels, and both events occurring in a patient with a previous inactive hepatitis B infection. This reactivation can occur in situations in which the ratio of HBV replication and immune response is altered. It can happen during the treatment of hemato-oncological malignancies with chemotherapy and in immunosuppression of autoimmune diseases. Clinical manifestations of hepatitis B reactivation are variable and can range from asymptomatic to acute hepatitis, which are sometimes serious and result in acute liver failure with risk of death, and usually occur in the periods between cycles or at the end of chemotherapy. Immunosuppressive drugs such as corticosteroids or azathioprine can induce HBV reactivation in patients carrying hepatitis B virus surface antigen (HBsAg) or anti-HBc, but much less frequently than chemotherapy treatments. The tumor necrosis factor α inhibitors infliximab, etanercept and adalimumab may cause reactivation of hepatitis B, and the overall frequency with infliximab may be similar (50%-66%) to

that caused by chemotherapy. Baseline HBV serology is recommended for all patients receiving chemotherapy and immunosuppressive drugs, and HBsAg positive patients should receive anti-HBV prophylaxis to decrease virus reactivation and death rates.

SITUATIONS ASSOCIATED WITH REACTIVATION OF HEPATITIS B

Hepatitis B is a major health problem worldwide with a prevalence that varies according to geographic area. This prevalence is changing due to the growing phenomenon of immigration. There are four distinct dynamic phases of chronic infection with hepatitis B virus (HBV) and this process is unidirectional, depending on the interaction between the virus itself, hepatocytes and the host immune system^[1]. Because of this interaction, situations that lead to immunosuppression in patients with chronic HBV infection may alter the natural history of this infection and give rise to the phenomenon of reactivation.

Reactivation of hepatitis B (HBV reactivation) is defined as the recurrence or abrupt rise in HBV replication by at least an increase in serum HBV DNA levels of 1 log₁₀, often accompanied by an increase in transaminase levels (at least three times the baseline). Both events occur in a patient with a previous inactive HBV infection, i.e. either an inactive carrier state or a patient with resolved hepatitis^[2]. HBV reactivation can occur in situations in which HBV replication increases or the immune response decreases. This can happen spontaneously, generally when the virus mutates and the immune system needs time to rebuild the immune response. It also appears when the virus replicates again abruptly and becomes resistant to a drug or when antiviral medications have been withdrawn. In patients with coinfection by the human immunodeficiency virus (HIV) this happens when progressive immunodeficiency lowers specific T cells response against HBV. A major cause of HBV reactivation is solid organ transplantation. Finally, the most common causes and the focus of this report, are chemotherapy (CMT), used in the treatment of onco-hematological diseases, and immunosuppressive drugs used in the treatment of autoimmune diseases (Table 1)^[2]. The risk of HBV reactivation depends on factors such as the state of HBV: the higher the level of viral replication, the higher the risk of reactivation. This risk is much lower in patients with resolved infection. Another factor that influences HBV reactivation is the type of disease: the risk is higher in patients with lymphoma than in those with solid tumors. This can be attributed to the fact that hematological disease itself induces a greater degree of immunosuppression or that CMT is stronger in cases of hematological malignancies^[3]. All types of drugs used in CMT have been involved in HBV reactivation, from the classic cytostatics to monoclonal antibodies and steroids, as they all have immunosuppressive activity (Table 2). HBV reactivation associated with CMT occurs frequently. In one of the first series, published in 1991, reactivation in 48% of hepatitis B virus surface antigen (HBsAg) carriers and in 4% of resolved hepatitis B patients were observed^[4]. In patients with reactivation, 53% showed icteric hepatitis and 20% died. In a meta-analysis carried out in 2008, which included 14 studies of HBsAg carriers, an average reactivation rate of 33% (with a wide range of 24%-88%) was observed, in addition to hepatitis in 33% and death in 7% of cases^[5]. Therefore, HBV reactivation does not occur in all HBsAg carriers undergoing CMT. Multivariate analysis identified various risk factors: male gender, young age, high HBV replication at baseline (HBV-DNA > 20000 IU/mL or hepatitis B virus e antigen positive), CMT regimens including corticosteroids or rituximab, and bone marrow transplantation (BMT). In patients with the same hematologic disease and undergoing the same CMT treatment, the addition of corticosteroids significantly increased the HBV reactivation risk from 38% to 72%, and the number of cases of hepatitis and severe hepatitis^[6]; in contrast, patients treated with steroids had an improvement in treatment outcome in terms of remission and survival, endpoints which need

to be clarified in larger series. Rituximab is a HBV reactivation risk factor even greater than corticosteroids: in a series of patients with lymphoma treated with CMT, the only significant difference between the reactivation group with resolved hepatitis and the group without reactivation was treatment with rituximab alone or associated with steroids^[7]. Rituximab is a monoclonal anti-B lymphocyte that causes apoptosis, and the B cell plays a key role in the multiple immune response against HBV: besides neutralizing antibodies, it is an antigen presenting cell and enhances the cytotoxic response of CD8 T lymphocytes. Therefore, its destruction decreases dramatically favoring the immune response of HBV replication. This also explains why rituximab can cause fulminant hepatitis and death in 50% of patients with resolved hepatitis B in the case of seroreversion^[8].

BMT is a major risk factor. Reactivation was reported almost universally among patients with positive HBsAg, and reverse seroconversion from resolved hepatitis B is twice as common in these patients as in patients without BMT. High doses of CMT with or without radiation are necessary to destroy the recipient's bone marrow before infusion of donor bone marrow, followed by an initial intense and prolonged immunosuppression followed by maintenance immunosuppression^[2].

CLINICAL MANIFESTATIONS OF HEPATITIS B REACTIVATION

HBV reactivation is associated with a wide range of clinical manifestations, from asymptomatic to acute hepatitis that can be serious and cause liver failure which can be life-threatening. In some patients, HBV reactivation has a subclinical onset and resolves spontaneously. In other patients it progresses to a persistent infection that can not be detected. At the time of diagnosis there is already advanced liver disease^[2]. HBV reactivation often manifests in periods between cycles of CMT/immunosuppressive treatment or at the end of therapy. Following immunosuppression caused by CMT/immunosuppressive treatment, a period of time is necessary for immune reconstitution and subsequent attack on the liver^[9]. Therefore, in HBsAg carriers the time between CMT treatment and HBV reactivation detection is very variable: from 1-36 mo, but usually ranges between 1 and 4 mo. Although not all patients go through the following stages, HBV reactivation usually has three phases: (1) replication, in which serum HBV-DNA levels increase; and (2) hepatitis, which appears 2-3 wk after HBV-DNA levels increase and is characterized by an elevation of transaminases and, sometimes, symptoms such as fatigue, malaise and jaundice. In some cases, hepatitis can be fulminant (hepatic encephalopathy, coagulopathy, *etc.*) and if the patient does not die of fulminant hepatitis, the infection moves to the third phase or recovery. In this phase, HBV-DNA and transaminase levels return to their previous state, usually by suspending CMT. In patients

| Monoclonal antibodies | Rituximab (anti-CD20), alemtuzumab (anti-CD52) |
| Corticosteroids | Dexamethasone, methylprednisolone, prednisone |
| Others | Folinic acid, colaspase, docetaxel, etoposide, fludarabine, interferon, procarbazine |

with resolved hepatitis, HBV reactivation usually begins later than 4 mo, but has the same clinical features. Sometimes reactivation only occurs with HBV-DNA elevation, without increased transaminases. Other times the patient does not move into the full recovery phase, but has elevated HBV DNA levels, although there is no significant immune reconstitution or liver damage. This is common in patients undergoing organ transplantation and treatment with immunosuppressive drugs. Finally in some cases, the hepatitis phase persists and a chronic hepatitis is established^[10].

TREATMENT AND PREVENTION OF HEPATITIS B REACTIVATION

The first step following HBV reactivation is to suspend CMT. However, this can affect the efficacy of this treatment.

Interferon- α is the classic treatment of chronic hepatitis B, but should not be used in cases of HBV reactivation, because its immunomodulatory action can cause a serious hepatitis outbreak that added to HBV reactivation can have serious consequences.

Lamivudine is the most frequently used nucleoside analog in the treatment of HBV reactivation and has been available since 1999. This drug is capable of inhibiting HBV replication and can reverse HBV reactivation.

However, treatment with lamivudine can cause mortality in patients with HBV reactivation, which ranges between 13% and 80% with an average of about 36%^[2]. Therefore, at least one third of patients die from HBV reactivation despite treatment with lamivudine. This could be due to its lower antiviral potency (less than that of other nucleoside/nucleotide analogs such as telbivudine, entecavir and tenofovir), its high rate of resistance (up to 67% at 4 years in immunocompetent individuals), and possibly because HBV reactivation is less effective when it is already in progress. These facts led to the conclusion that in such patients it would probably be best to administer preventive treatment for HBV reactivation with the aim of inhibiting the replication of HBV, as this would hinder the development of hepatitis and thus mortality.

Prophylaxis in patients treated with chemotherapy

In eight retrospective case studies of patients with positive HBsAg treated with CMT, HBV reactivation occurred in 2.4% of those receiving prophylaxis with lamivudine compared with 56% who did not receive prophylaxis. Similarly, in four prospective case studies with historical controls, HBV reactivation occurred in 4% of those receiving prophylaxis with lamivudine compared with 28% who did not receive prophylaxis^[8]. In a prospective controlled clinical trial, prophylaxis with lamivudine for 2 wk before starting CMT and for six wk thereafter was compared to treatment with lamivudine when there was already HBV reactivation. HBV reactivation occurred in 53% of patients who received no prophylaxis, however, none of those who received prophylaxis showed evidence of HBV reactivation; hepatitis occurred in 47% of those without prophylaxis and 7% died. None of the patients who received prophylaxis developed hepatitis or died^[11]. A similar trial also compared lamivudine prophylaxis 2 wk prior to CMT until 2 mo after CMT with lamivudine treatment for HBV reactivation. Again there were significant differences in favor of prophylaxis, although this did not prevent reactivation in 12% of cases and hepatitis in 8%, attributable to the average antiviral potency of lamivudine and the possibility of the development of resistance. Importantly, following discontinuation of prophylaxis an increase in the number of patients with hepatitis reactivation, including death, occurred indicating that prophylaxis should be maintained beyond 2 mo after completion of CMT^[12]. In another study, prophylaxis was continued for 3 mo after CMT. After 26 mo of follow-up, hepatitis B was reactivated in 24% of patients, and reached 40% at 40 mo, being more common in those patients with high HBV replication at baseline^[13]. A meta-analysis of 14 studies also found significant differences in favor of prophylaxis with lamivudine compared with untreated controls, although again prophylaxis with lamivudine did not eliminate all risk of HBV reactivation^[5]. Finally, in another systematic review with a meta-analysis that included 21 studies, significantly lower numbers of reactivation, hepatitis and death were found in the group receiving prophylaxis with lamivudine^[14]. In summary, the

findings from these 8 retrospective case series, 4 prospective case series with historical controls, two controlled trials published to date and 2 meta-analyses showed that prophylactic lamivudine significantly reduces HBV reactivation. In addition, prophylaxis should last approximately 3 mo after completion of CMT, especially in patients with high HBV replication at baseline. There are no studies on the time prophylaxis should be extended and recommendations by experts range from 6-12 mo post-CMT treatment. These recommendations have even been extended to patients with risk factors such as high basal HBV-DNA, use of rituximab or BMT. All consensus and clinical practice guidelines^[15-17] recommend baseline screening for HBV (HBsAg, anti-HBc and anti-HBs) in all patients who are scheduled to receive CMT. In seronegative patients, the possibility of anti-HBV vaccination should be assessed. HBsAg positive patients should receive anti-HBV prophylaxis: patients who undergo CMT for less than 1 year may be treated with lamivudine (100 mg/d) from 1-2 wk before and 6-12 mo after. If CMT continues over 1 year and, especially, if there is high HBV replication, more potent drugs with less resistance such as telbivudine, tenofovir or entecavir should be evaluated. Patients with resolved hepatitis may be carriers of hidden HBV. Thus, HBV reactivation prophylaxis in patients assessed for BMT or subjected to aggressive and prolonged immunosuppressive therapy, such as patients undergoing solid organ transplantation should be considered^[4]. The appearance of HBsAg and HBV DNA in up to 50% of patients with anti-HBc undergoing BMT have been reported. The serial determination of anti-HBs in the serum of these bone marrow recipients has shown a steady decline to undetectable levels by 1-3 years after transplantation. With the loss of anti-HBs (anti-HBc), HBV DNA increases and HBsAg reappears. Some of these patients with HBs seroreversion do not develop clinical hepatitis, but among those who have HBs seroreversion, severe infection is rare. HBsAg seroreversion occurs late in patients with BMT, and therefore, in these cases long-term antiviral prophylaxis is recommended^[18,19]. Resolved hepatitis B patients with hematologic malignancies who receive CMT may also develop HBV reactivation, especially those with only positive anti-HBc (HBV reactivation in 25%). Risk factors are: negative anti-HBs or serum HBV DNA levels often < 100 IU/mL, treatment with more than one chemotherapeutic agent or with rituximab and BMT. In 20%-40% of cases, HBV reactivation may be fatal and prophylaxis with lamivudine again does not prevent reactivation in all cases^[20,21].

Prophylaxis in patients receiving biological treatments

Classical immunosuppressive drugs (corticosteroids, azathioprine, methotrexate) have been used for many years in multiple autoimmune diseases and organ transplantation. These drugs can induce HBV reactivation in patients carrying HBsAg or anti-HBc, but much less frequently than CMT. Therefore, reported cases of HBV reactivation are isolated^[2].

The new immunosuppressants are called biological therapies, because these drugs block the action of biological products involved in the immune-inflammatory pathogenesis of many diseases. There are four main types: anti-inflammatory cytokines, anti-lymphocyte, anti-leukocyte adhesion and migration and anti-immunoglobulin^[22]. Within the first group of anti-cytokines there are tumor necrosis factor (TNF) α inhibitors, such as infliximab, etanercept and adalimumab. All three are used in the treatment of various rheumatic diseases and inflammatory bowel disease^[23], since the cytokine TNF α is dominant in these diseases and its inhibition improves the disease. However, the inhibition of TNF α can reactivate hepatitis B^[24], as TNF α is also important in the immune pathogenesis of hepatitis B, it takes part in cytolytic immunodepletion by CD8 cytotoxic lymphocytes, and is involved in noncytolytic immunodepletion with other cytokines produced by CD4 lymphocytes suppressing HBV replication and, ultimately, increases all immunocompetent cells. Therefore, administration of anti-TNF α inhibits the anti-HBV immune response, thus favoring HBV replication and the expression of a large amount of hepatitis B virus core antigen (HBcAg) in infected hepatocytes. When the administration of anti-TNF α is suspended, inhibition of the immune response is stopped and thus, there is immune reconstitution which attacks the large number of hepatocytes expressing HBcAg in their membranes. This results in an outbreak of hepatitis^[25].

Seventeen publications in the past 6 years have reported 21 patients who experienced reactivation of hepatitis B when treated with infliximab (Table 3). Infliximab was used to treat Crohn's disease in 8 cases, rheumatoid arthritis in 6 patients, ankylosing spondylitis in 5 cases, Still's disease in 1 case and psoriasis in 1 case. HBV infection at baseline was the inactive carrier state in 15 cases, chronic active hepatitis in 4 cases, occult HBV in 1 case and delta virus co-infection in 1 case. None of the six

patients who received lamivudine prophylaxis had HBV reactivation. This was not the case in the remaining 15 patients who did not receive prophylaxis and were distributed as follows: in 8 cases (53%), reactivation was treated with lamivudine and the outcome was good, 3 cases (20%) had fatal fulminant hepatitis, in another 3 cases (20%) withdrawal of infliximab was followed by regression of the alterations, and in one case (7%) evolution was spontaneously favorable. It should be noted that the usual pattern of treatment with infliximab in these publications was three doses at week 0, 2 and 6 followed by maintenance treatment every 8 wk. It is, therefore, a long-term treatment and resistance to lamivudine can appear, particularly in patients with high HBV replication. In such cases, it is preferable to use drugs with lower rates of resistance such as tenofovir or entecavir.

In the last 3 years, 7 patients who had HBV reactivation with etanercept have been reported. All had rheumatic disease and 5 patients at baseline were in the inactive carrier state of HBV, one patient had chronic active hepatitis and the other case had hidden hepatitis B infection. None of the three patients receiving prophylaxis with lamivudine showed reactivation of hepatitis B. Of the four patients without prophylaxis, 3 responded favorably to treatment with lamivudine and 1 responded without treatment. These results suggest that etanercept could lead to a revival milder than that with infliximab, but it is difficult to determine because it was described as a case of reactivation of resolved hepatitis, which generally is interpreted as a result of increased immunosuppression^[43].

To our knowledge, there are only two case reports of HBsAg-positive patients treated with adalimumab, which accounted for three patients with rheumatoid arthritis and an inactive carrier state of HBV^[44,45]. In one case, lamivudine prophylaxis was administered and there was no HBV reactivation. Of the other two cases, one had an increase in HBV DNA, which remained stable for 2 years without associated hepatitis, despite continuing with adalimumab; the other case did not show any evidence of reactivation. It is difficult to draw conclusions from so few data, except to say that prophylaxis prevents HBV reactivation.

Both etanercept and adalimumab probably cause less HBV reactivation than infliximab. In a series of 103 patients with rheumatic diseases treated with anti-TNF α , 8 cases were inactive HBsAg carriers and 2 cases were treated with infliximab, 4 cases with etanercept and 2 cases with adalimumab HBV reactivation occurred in one of these 8 patients and this patient was one of the two treated with infliximab^[46]. Thus, the frequency of reactivation with infliximab may be 50%, similar to that observed with cancer treatments. However, there is evidence that this frequency may be even higher. In another series of 80 cases of Crohn's disease treated with infliximab, 3 patients were HBsAg positive: one of them received prophylaxis with lamivudine and demonstrated no evidence of HBV reactivation, but the other two cases

who received no prophylaxis demonstrated evidence of HBV reactivation, i.e. the frequency of HBV reactivation was 66%^[47].

CONCLUSION

In HBsAg carriers who undergo CMT, the risk of HBV reactivation is high: 30%-50%. The risk is greater in patients with high HBV replication at baseline, and in patients receiving CMT regimens which include corticosteroids or rituximab, or individuals who undergo a BMT. These patients should be screened for HBV at baseline: HBsAg, anti-HBc and anti-HBs. Anti-HBV vaccination should be assessed for seronegative patients.

Anti-HBV prophylaxis is indicated in patients with positive HBsAg, to decrease reactivation rates, hepatitis and death. Although there is a lack of information, prophylaxis should begin 1-2 wk prior to CMT and should be maintained until 6-12 mo after treatment. A longer treatment period may be necessary in patients with factors that promote reactivation.

Most studies on prophylaxis have been conducted with lamivudine. This drug should be used in patients with low HBV DNA levels at baseline who will receive treatment for less than 1 year. In other cases, more potent drugs with less risk of resistance such as tenofovir or entecavir should be used.

Positive anti-HBc patients may have an occult HBV infection that can be reactivated by CMT. There is insufficient evidence to recommend routine prophylaxis, but treatment is recommended for patients with risk factors and, in other cases, follow-up and early treatment should be recommended in case of reactivation.

The TNF α inhibitors infliximab, etanercept and adalimumab may cause reactivation of HBV. The overall frequency seems less than that caused by CMT, but the frequency with infliximab may be similar (50%-66%). Prophylaxis prevents HBV reactivation in patients treated with infliximab. There are insufficient data to advise routine prophylaxis with etanercept and adalimumab, but until such data are available it seems prudent to administer prophylaxis.

Abstract

Occult hepatitis B virus (HBV) infection (OBI) is characterized by the persistence of HBV DNA in the liver tissue in individuals negative for the HBV surface antigen. The prevalence of OBI is quite variable depending on the level of endemic disease in different parts of the world, the different assays utilized in the studies, and the different populations studied. Many studies have been carried out on OBI prevalence in different areas of the world and categories of individuals. The studies show that OBI prevalence seems to be higher among subjects at high risk for HBV infection and with liver disease than among individuals at low risk of infection and without liver disease.

INTRODUCTION

Chronic hepatitis B virus (HBV) infection is characterised by persistence of HBV surface antigen (HBsAg) and presence of HBV DNA in serum.

Occult HBV infection (OBI) is the persistence of viral genome in the liver tissue in individuals negative for HBsAg. OBI is defined by the presence of HBV DNA in the liver (with detectable or undetectable HBV DNA in the serum) in patients with serological markers of previous infection (anti-HBc and/or anti-HBs positive) or in patients without serological markers (anti-HBc and/or anti-HBs negative). The prevalence of OBI is quite variable depending on the level of endemic disease in different parts of the world, the different assays utilized in the studies, and the different populations studied^[1]. The populations in which prevalence of OBI has been investigated are: patients with liver disease (HCV infected patients and patients with cryptogenetic liver diseases), patients at high risk of parenteral-transmitted infection (intravenous drug addicts, hemophiliacs), patients on hemodialysis, human immunodeficiency virus (HIV) infected patients and apparently healthy individuals (blood donors, general population)^[1]. The purpose of this review is to provide comprehensive information on overall OBI prevalence as well as in patients with different chronic liver diseases.

HCV INFECTED PATIENTS

As HBV and HCV share many of the same transmission

routes, and infection with both viruses is common, the high prevalence of OBI in patients with hepatitis C is not unexpected. HCV infected patients have the highest prevalence of OBI^[2,3]. Cacciola *et al*^[2] published the first study of prevalence of OBI in patients with chronic hepatitis C; in this study HBV sequences were found in liver tissue from 66 of the 200 (33%) HCV infected patients and in 7 of the 50 (14%) HCV negative patients, 46 of the 66 patients were anti-HBc positive and 20 of the 66 were anti-HBc negative. They also found very low levels of viremia and the prevalence of OBI was particularly high among patients with anti-HBV antibodies although OBI was also detected in patients who were negative for all HBV serum markers^[2]. The study of Cacciola *et al*^[2] also demonstrated that OBI was significantly correlated with cirrhosis among HCV infected patients; 22 of the 66 patients (33%) with HCV infection and OBI had cirrhosis as compared with 26 of the 134 (19%) with HCV infection and no OBI, suggesting that OBI can accelerate the evolution to cirrhosis in HCV infected patients. Bréchet *et al*^[4] reviewed all the studies published in anti-VHC patients using PCR on serum and liver and the conclusion was that about 20%-30% and 40%-50% of serum and livers respectively showed HBV DNA positivity.

CRYPTOGENETIC LIVER DISEASE

In patients with cryptogenetic liver disease there is less available information than in HCV patients but the prevalence is thought to range from 19% to 31%^[5,6]. Chemin *et al*^[6] studied 50 patients with chronic hepatitis non-A non-E and reported a high prevalence of low-grade HBV infection. HBV DNA was detected by PCR in serum in a high proportion of cases (15/50; 30%); in all cases HBV DNA detection in serum was further confirmed on liver biopsies. 11 of the 15 (73%) patients who were HBV DNA positive were found to be anti-HBc positive, and all the patients had 10⁴ or less HBV DNA copies per mL. Among the positive HBV DNA patients 8/15 (53%) had severe fibrosis and cirrhosis and none of the patients had steatosis, so low-grade HBV infection was associated with more severe liver disease. The histopathological follow-up showed that some patients progressed to cirrhosis^[5]. Berasain *et al*^[5] investigated 1075 patients with chronic liver disease and in 109 (10%) the aetiology could not be defined by clinical, biochemical and serological data. In these cases liver biopsy was reviewed, then the histopathological findings and implication of hepatitis viruses B and C was investigated in cryptogenetic liver disease. HBV DNA and HCV RNA were determined in serum by PCR. HBV DNA and HCV RNA were detected in the serum of 18% and 8% patients with cryptogenetic and noncryptogenetic liver diseases respectively. Liver biopsies showed non specific changes or non-alcoholic steatohepatitis (NASH) in 48% and chronic hepatitis or cirrhosis in 52%. The proportion of cases with detectable HBV DNA or HCV RNA was 14% in the first group, 30% in the group with

chronic hepatitis and 61% in the group with cirrhosis, so occult viral infection was found in a high proportion of patients with chronic hepatitis or cirrhosis and in a low percentage of patients with NASH or non-specific changes. Two patients with cryptogenetic cirrhosis underwent liver transplantation, and in these 2 cases HBV DNA was detected in the explanted liver^[6].

DIALYSIS

Hemodialysis patients are at high risk of acquiring parenterally transmitted infections, not only because of the large number of received blood transfusions, and the invasive procedures that they undergo, but also because of their immunosuppressed state. Several reports have been published about prevalence in haemodialysis patients ranging from 0% to 36%. Most of these studies show that OBI is usually associated with low levels of HBV and have investigated the presence of of OBI in the context of chronic HCV infection^[7-13]. These studies demonstrated HBV DNA by PCR in serum samples; there were no studies demonstrating HBV DNA in liver extracts because of the lack of available liver tissue in the setting of haemodialysis. The studies of Fabrizi *et al*^[9] and Minuk *et al*^[10] show that conventional serological features of HBV DNA positive subjects do not distinguish these individuals from the remainder of the dialysis patient population; therefore, routine serological testing is not able to identify the occult infection in this population. Several studies have demonstrated that the prevalence of OBI is not associated with the presence of anti-VHC antibodies in hemodialysis patients^[14-16]. Recently, one study has shown an OBI prevalence of 9.8% in continuous ambulatory peritoneal dialysis (CAPD)^[17].

HIV INFECTED PATIENTS

OBI in HIV infected patients may be viewed as the result of opportunistic reactivation of HBV due to cellular immune deficiency, as reflected by the decreased CD4 counts in HIV infection. The prevalence of OBI in HIV infected patients remains controversial and the available data are widely divergent. Published studies report a prevalence between 0% to 89%^[18-26]. The cause of these variations is the same as in HIV-negative patients: level of endemic disease in differences parts of the world, the different assays utilized in the studies, and the different populations studied. HIV patients with OBI have significantly lower CD4 counts and high plasma HIV RNA loads^[20,27]. The risk factors, the clinical significance and the effect of highly active antiretroviral therapy (HAART) are unknown. Recently, Cohen Stuart *et al*^[28] analyzed the prevalence of OBI in 191 HIV and anti-HBc positive before HAART and also during the immune reconstitution phase that follows initiation of HAART. Anti-HBs was positive in 128/191 (67%), and negative in 45/191 (24%). Plasma HBV DNA was detected in 9/191 corresponding to a prevalence of 4.7%. In the isolated anti-HBc group

the prevalence was 11.1%, whereas in those anti-HBs positive the prevalence was 3.1%; this difference was not significant. The study demonstrated the absence of hepatic flares after start of HAART and showed that HBV DNA remained undetectable in all patients after starting HAART. Therefore OBI has no clinical impact when immune reconstitution is achieved with HAART containing at least one HBV inhibiting compound.

BLOOD DONORS

Despite continuous technical improvement in blood donation screening, hepatitis B infection remains a major risk of transfusion-transmitted viral infection. Reduction of HBV residual risk is achieved by developing more sensitive HBsAg tests, by adopting anti-HBc screening if appropriate and implementing HBV nucleic acid test (NAT).

The prevalence of OBI among HBsAg negative blood donors is quite variable depending on the level of endemic disease and on the assays employed in routine serological or NAT screening. Screening of anti-HBc is feasible in non-endemic areas, but would cost an unnecessary loss of blood donations in endemic areas (where nearly 90% of adults are positive for both anti-HBc and anti-HBs due to past exposure to HBV).

Hollinger^[29] provide an excellent summary of the prevalence of serological markers in HBsAg negative blood donors in different regions of the world. The studies of prevalence in North America reveal that HBV DNA was detected in 0.1%-1.05% of those who were HBsAg negative and anti-HBc-positive (with or without anti-HBs) and that HBV DNA was detected in 2.03%-2.8% in the anti-HBc only category (no anti-HBs)^[30-34]. The studies of prevalence in Europe reveals that HBV DNA was detected in 0%-1.59% of those who were HBsAg negative and anti-HBc-positive (with or without anti-HBs) and HBV DNA was not detected in patients who were anti-HBc only^[35-38]. In the study of Allain *et al.*^[35] no occult hepatitis B was detected in any of the samples because the level of sensitivity was only approximately 1300 copies/mL. The studies of prevalence in the Middle East and Asia revealed that HBV DNA was detected in 1.09%-3% of those who were HBsAg negative and anti-HBc-positive (with or without anti-HBs) and that HBV DNA was detected in 8.1% in the anti-HBc only category (no anti-HBs)^[39-41].

GENERAL POPULATION

There are few studies about OBI prevalence in the general population. Minuk *et al.*^[42] detected a prevalence of OBI in 18% of those with serological evidence of previous HBV infection and in 8% of HBV seronegative individuals. Kim *et al.*^[43] found HBV DNA in 16% of Korean healthy subjects with normal transaminase values and who were HBV/HCV negative. Hui *et al.*^[44] detected occult HBV genomes in 15% of healthy hematopoietic stem cell donors from Hong-Kong. Raimondo *et al.*^[45] investigated the prevalence of OBI in subjects free from liver disease

through the analysis of liver DNA extracts by performing four different in-house nested-PCR amplification assays. HBV DNA sequences were detected in liver tissues from 16 of the 98 cases examined (16.3%). DNA was detected in 10 of the 16 (62.5%) anti-HBc positive cases vs 6 of the 82 (7.3%) HBV marker negative cases, so OBI status was strongly related with the anti-HBV antibody positive status.

CONCLUSION

Although studies on OBI prevalence have been extensive, the precise prevalence of this clinical entity remains very difficult to define for several reasons. These studies show that OBI prevalence seems to be higher among subjects at high risk of HBV infection and with liver disease than among individuals at low risk of infection and without liver disease. In general about 20% of OBI individuals are negative for all serological markers, and 80% are positive for serological markers of previous infection. Most studies show that OBI is usually associated with low levels of HBV DNA. The importance of this entity is that OBI may have significant impact in several clinical contexts. It might favour the progression of liver fibrosis and the development of hepatocellular carcinoma in patients with additional causes of liver damage; OBI may become reactivated when an immunosuppressive status occurs; and it may be transmitted through blood transfusion and organ transplantation. While awaiting for more sensitive methods for blood HBV DNA measurement, anti-HBc should be recommended in patients undergoing chemotherapy or immunosuppressive treatments as well as all organ donors.

the viral DNA, is due in most cases to the strong suppression of viral replication and gene expression that characterizes this "occult" HBV infection; although the mechanisms responsible for suppression of HBV are not well understood. The majority of OBI cases are secondary to overt HBV infection and represent a residual low viremia level suppressed by a strong immune response together with histological derangements which occurred during acute or chronic HBV infection. Much evidence suggests that it can favour the progression of liver fibrosis and the development of hepatocellular carcinoma.

Abstract

Occult hepatitis B infection (OBI) is characterized by hepatitis B virus (HBV) DNA in serum in the absence of hepatitis B surface antigen (HBsAg) presenting HBsAg-negative and anti-HBc positive serological patterns. Occult HBV status is associated in some cases with mutant viruses undetectable by HBsAg assays; but more frequently it is due to a strong suppression of viral replication and gene expression. OBI is an entity with world-wide diffusion. The failure to detect HBsAg, despite the persistence of

INTRODUCTION

Hepatitis B virus (HBV) infection is a major global health problem. It is estimated that about 350 000 000 individuals are infected by HBV; infection can induce a wide spectrum of clinical forms, ranging from a healthy carrier state to cirrhosis and hepatocellular carcinoma^[1]. HBV infection is usually diagnosed when circulating hepatitis B sur-

face antigen (HBsAg) is detected. However, the availability of highly sensitive molecular biology techniques has also allowed the identification of HBV infection in HBsAg-negative individuals, with or without circulating antibodies to HBsAg (anti-HBs) and/or hepatitis B core antigen (anti-HBc)^[2-5]. Furthermore, it is estimated that as much as one third of the world population have been exposed to HBV^[6]. Many of these individuals may unknowingly carry the virus. The natural history of chronic HBV infection is highly heterogeneous as many host, virus and environmental factors play an integrated role in affecting rates of disease progression and long term clinical outcomes.

CHRONIC HBV INFECTION AND ITS VIROLOGICAL PHASES

The natural course of chronic infection includes four phases based on the virus-host interaction: immune tolerance, immune clearance, low or non-replication, reactivation and HBsAg negative (occult) HBV^[6-8].

Immune tolerance phase

This phase is characterized by presence of hepatitis B e antigen (HBeAg), high serum levels of HBV DNA, normal or minimally elevated serum alanine aminotransferase (ALT) and normal liver or only minimal histological activity. The immunotolerant phase may persist for 10-30 years in perinatally infected subjects, whereas it is generally short-lived or absent in childhood or adult-acquired HBV infection.

Immune clearance phase

This initiates when immune tolerance to the virus is lost and the immune response starts to kill infected hepatocytes. This phase is characterized by fluctuating, but progressively decreasing, HBV DNA levels, high levels of ALT and hepatic necroinflammation. Serum HBV DNA levels are > 20000 IU/mL (10^5 copies/mL) in the phase of HBeAg positive chronic hepatitis and may remain elevated or drop rapidly at the time of anti-HBe seroconversion.

Inactive carrier state

An important outcome of the active immune response is seroconversion from HBeAg to anti-HBe, with transition to the third phase of inactive HBsAg carrier state, characterized by HBeAg negativity and anti-HBe positivity, low levels of HBV DNA < 2000 IU/mL (10^4 copies/mL), normal ALT and inactive liver histology.

Reactivation phase

Some inactive HBsAg carriers may develop HBV reactivation while remaining anti-HBe positive. This phase is characterized by HBeAg negativity with anti-HBe positivity, HBV DNA levels > 2000-20000 IU/mL (10^4 - 10^5 copies/mL), high ALT and moderate or severe necroinflammation with variable amounts of fibrosis on liver biopsy (HBeAg negative chronic hepatitis).

HBs negative (occult) HBV

A final phase of chronic HBV infection may eventually follow in some long term carriers, with loss of HBsAg but persistence of HBV DNA in liver. These cases usually do not have active liver disease but show the histological consequences of previous damage with variable amounts of residual fibrosis. Immunosuppression, however, may cause HBV reactivation and sometime severe exacerbation of liver disease with HBsAg, HBV DNA, and even HBeAg rebound.

DEFINITION OF HBsAg LOSS

In "inactive carriers" the HBsAg may become undetectable which is defined as HBsAg loss. A loss of HBsAg is a sign for deep and usually durable suppression of HBV DNA replication and usually announces a stable status of recovery, even though other complications caused by pre-existing liver cirrhosis or fibrosis or an elevated risk for development of hepatocellular carcinoma can still lead to severe complications^[9,10]. However, HBsAg may reappear and replication may reincrease, especially if the HBsAg loss was observed during a period of antiviral therapy. The spontaneous HBsAg loss in anti-HBe-positive asymptomatic HBsAg carriers has long been recognized as a very rare event with increasing probability during long term follow up. Accordingly, a cumulative rate of HBsAg seroclearance of 8.1% was described after the first 10 years of infection. Chu *et al*^[11] observed that the cumulative probability of HBsAg seroclearance increased to 24.9% after 20 years and to 44.7% after 25 years of HBV infection. The authors also pointed out that age at infection, sustained remission of liver disease and male sex were factors independently associated with HBsAg seroclearance.

ETIOPATHOGENESIS OF OCCULT HEPATITIS B INFECTION

Occult HBV is found more frequently in patients with serologic evidence of HBV infection (anti-hepatitis B core antibody positive) than in core antibody-negative individuals^[12,13]. Occult HBV is found in a significant proportion of patients with chronic hepatitis due to hepatitis C virus, with HBV DNA detectable in up to 30% of serum samples and 50% of liver biopsies^[12]. Occult HBV infection is defined as the existence of HBV DNA in the serum, cells of the lymphatic (immune) system, and/or hepatic tissue in the absence of serum HBsAg. Most frequently, occult HBV infection follows resolution of acute hepatitis and continues indefinitely after clearance of HBsAg and biochemical improvement in liver function^[13-17]. Recent estimates suggest that up to 20% of individuals with occult HBV carriage evidenced by HBV DNA detection could be nonreactive for anti-HBc or any other serological indicator of exposure to HBV^[15]. Although viruses with replication deficits could theoretically explain occult HBV, the finding of cccDNA, RNA transcripts, and pregenomic replicative RNA intermediates in a large proportion of pa-

tients suggests that most occult infections are due to low-level replication of wild-type virus^[19,20]. In addition, the transmissibility of acute HBV *via* liver transplant or blood product transfusion from donors with occult infection^[21-23] provides evidence against the presence of defective viruses. Occult HBV may also result from mutations in HBsAg coding or transcription control regions that alter antigenicity or expression levels^[24-26]. Such mutant viruses have been reported as the sole circulating strain in up to 40% of patients with occult HBV^[27-30]. Occult hepatitis B infection (OBI) has been detected in the following clinical situations: (1) chronic hepatitis unrelated to HVC, atypical alcoholic hepatitis and hepatocellular carcinoma (HCC); (2) viral reactivation following immunosuppression; and (3) transmission through transplantation, transfusion or experimental transmission to chimpanzees^[31]. Low level HBV DNA has been detected in liver tissue of patients with HCC^[32] and in serum of blood donors and their recipients. Occult silent or serologically negative HBV infection was reported for the first time more than 20 years ago in the context of blood transfusion *via* the transmission of HBV by a donor positive for anti-HBc as the only marker of HBV infection^[33]. Schematically, the available data suggest that (a) the host's immune response; (b) coinfection with others infectious agents; and (c) epigenic factors may play important roles in inducing the occult status.

VIROLOGICAL ASPECTS

The molecular basis of occult infection is strictly related to the peculiar life cycle of the HBV. A fundamental step is the conversion of the ~3 kb relaxed circular genome into a covalently closed-circular DNA (cccDNA), a long lived HBV replicative intermediate that persists in the cell nuclei as a stable chromatinized episome and that serves as a template for gene transcription^[34,35]. The stability and long-term persistence of viral cccDNA molecules, together with the long half-life of hepatocytes, imply that HBV infection, once it has occurred, may possibly continue for life^[36]. Reduced HBV viraemia may result from extrahepatic HBV replication, such as in peripheral blood mononuclear cells or from coinfection with others viruses, especially with VHC, which down regulate HBV replication^[31].

Latent hepatitis B virus infection in healthy individuals with antibodies to hepatitis B core antigen

Several recent reports have shown that HBV could be frequently transmitted to recipients from donors who have antibodies to hepatitis B core antigen (anti-HBc) through liver transplantation. Marusawa *et al*^[19] provide the molecular evidence of latent HBV infection accompanied with ongoing viral replication in the liver tissue of anti-HBc-positive healthy individuals. They have demonstrated that HBV DNA was detectable in 13 of 14 healthy donors who were positive for both anti-HBc and antibodies to hepatitis B surface antigen (anti-

HBs), but in none of 3 who were positive for anti-HBs alone. The detected HBV genomes from these subjects included cccDNA and pregenomic RNA, the replication intermediate of HBV. Notably, 5 of 7 cases tested were predominantly infected with wild type HBV strains without any mutations in the precore and core promoter regions under the presence of circulating antibody to hepatitis B e antigen, but we can not draw conclusions because of the small number of patients.

Therefore the majority of healthy individuals positive for anti-HBc, which had been assumed to denote a past history of transient HBV infection, were latently infected with the episomal form of HBV accompanied by ongoing viral replication and few nucleotide mutations in the precore and core regions.

Why are the occult HBV carriers HBsAg negative despite the presence in their liver of episomal, free HBV genomes?

This is an unresolved question. Some of these individuals are infected by viral variants either producing an antigenically modified HBV S protein undetectable by the available HBsAg assays^[37], or carrying mutations capable of inhibiting S gene expression and/or viral replication^[38,39]. The occult infection appears to be mostly due to a strong suppression of viral replication and gene expression affecting viruses whose genetic variability is comparable to that of HBV strains from individuals with "overt" chronic HBV infection^[40].

EXPERIMENTAL OCCULT HBV INFECTION

Recent studies^[41] on this silent form of hepadnavirus carriage in an experimental woodchuck hepatitis virus (WHV) infection, which is considered to be the closest natural model of HBV disease, revealed that the life-long occult persistence of traces of pathogenic virus is an invariable consequence of recovery after hepadnaviral invasion and that this state always co-exists with a steady low-rate virus replication in both the liver and the lymphatic system. This experimental model has been validated during the last 2 decades as one of the most valuable tools in reach on hepatitis B^[42,43]. Importantly, this serologically concealed infection can be accompanied by development of hepatocellular carcinoma in convalescent animals and is transmittable from mothers to offspring as an asymptomatic, indefinitely long infection which involves the lymphatic system but not always the liver^[44]. Furthermore, it became apparent that the detection of anti-WHc in the absence of other serological indicators of infection is a reliable indicator of occult WHV persistence^[45]. This state, which is similar in strength to HBV-specific cytotoxic T cell (CTL) and T helper lymphocyte responses detectable years after resolution of acute hepatitis B^[46,47], is likely a consequence of sustained stimulation of the immune system with a viral protein produced during low-level virion assembly^[15]. The high degree of compatibility between WHV and HBV infections and the data from studies on otherwise healthy anti-HBc-positive individuals suggest

that the occurrence of isolated anti-HBc could also be of value in identifying occult HBV persistence. The virus recovered from woodchucks with OBI remains infectious. It was observed that WHV harvested from PBMC isolated during OBI and *ex vivo* stimulated with lipopolysaccharide (LPS) induced classical acute WHV hepatitis in virus-naïve animals^[45]. In the case of hepadnaviruses, studies on occult WHV infection point to a direct link between virus persistence and its lymphotropism. They also reveal that infection of the lymphatic system could be a natural and unavoidable consequence of hepadnavirus invasion and that, under certain circumstances, such as a low virus dose, lymphoid cells can be the only temporary or permanent site of virus propagation. Another important fact established through analysis of the WHV model is that a state of occult virus persistence is a normal and ultimate aftermath of WHV infection, which is symptomatic, followed by recovery, or serologically silent from the start. A generalized concept is proposed for the possible progression pathways and outcomes of hepadnaviral infection in relation to variable virus and/or variation of virus in the host. Because of significant virological and pathobiological similarities between HBV and WHV, and close analogies in the patterns of progression and outcomes of the induced liver disease, this concept might also be applicable to human HBV infection^[14].

RELATIONSHIP OF OCCULT HEPADNAVIRAL INFECTION AND THE HOST'S IMMUNE SYSTEM

The host's immune-surveillance probably has a critical role in the development of occult HBV infection, as suggested by at least two arguments: (1) there is evidence showing that a vigorous memory T-cell response against HBV antigens is still present many years after clinical recovery from acute B hepatitis, probably because the long-lasting persistence of the occult infection produces a minute amount of antigens able to maintain an efficient antiviral T-cell response^[46,47]; and (2) all the conditions inducing immunosuppression may provoke the reactivation of the occult HBV infection with the reappearance of the typical serological profile of the productive infection^[48,49]. During occult infection a balance between the virus and the host's immune system is established, and as well as the cytotoxic T lymphocytes, the cytokines synthesized in the liver might also exert a control on HBV replication^[16]. On the other hand, it also is conceivable that this extrahepatic pattern of virus expression is a consequence of another property of the virus that, at low doses, displays its natural predisposition for invading lymphoid cells. In this regard, of note are our findings documenting the existence of the cell-binding site in the preS1 domain of the WHV envelope which mediates a strictly host and cell-type-specific recognition. Synthetic analogues of the site have considerably greater ability to interact with woodchuck lymphoid cells than with hepatocytes^[50]. Different molecular forms of HBV

DNA, including replicative intermediates and cccDNA, and viral RNA have been detected in lymphoid cells of patients with clinically evident hepatitis B^[51,52], although discrimination between synthesized *de novo* viral nucleic acids and those potentially adhered to the cell surface has not always been made. Also, traces of HBV antigens have been found on peripheral blood mononuclear cells isolated from actively infected individuals^[53]. The observation that cultured peripheral blood mononuclear cells from WHsAg-positive animals produced infectious virus strongly argued that lymphoid cells can support the complete replication cycle of WHV^[54].

TRANSMISSIBILITY OF MATERNAL OCCULT HEPADNAVIRAL INFECTION TO NEWBORNS

Vertical transmission of viral hepatitis is considered to be a cause of many perinatal viral infections, and it is postulated that a specific variant can influence virus tropism and outcome of infection in the newborn.

Since mother-to-child transmission is one of the main routes for HBV dissemination, it was important to determine whether hepadnavirus persistently carried as an occult infection can be passed from mothers to their newborns. To investigate this possibility, Michalak *et al*^[44] have examined woodchuck offspring born in captivity and they found not only that such mothers transmit WHV to newborns but also that the induced infection is asymptomatic and progresses for years after birth in the absence of serum WHsAg, anti-WHs and, in contrast to convalescent adults, anti-WHc-antibodies. Results of these experiments revealed that under certain natural conditions long-term persistence of hepadnavirus can be maintained exclusively at an extrahepatic location. Thus, there were newborns that did not have any detectable WHV DNA in sequential liver biopsies, yet the viral genomes were expressed in livers of other offspring from the same litter. There also were offspring that initially had lymphoid-restricted patterns of WHV infection, yet at 19 mo after birth became liver WHV DNA reactive^[55].

Albeit maternal transmission of hepadnavirus from mother to offspring might differ in some aspects in humans and woodchucks, the essential pathobiological similarity between HBV and WHV suggests that HBV could also be passed from apparently healthy mothers convalescent from hepatitis B to their babies. Children born to these mothers may persistently carry traces of infectious virus and, possibly, have an increased long-term risk for the development of disorders of the lymphatic system and, in some cases, the liver.

CONCLUSION

Occult HBV infection is defined as HBV DNA detection in serum or in the liver of HBsAg-negative patients with or without serologic markers of previous viral

exposure. With the introduction of highly sensitive diagnostic tests for viral proteins the paradigms of HBV infection were challenged. Accumulated evidence indicates that occult HBV can be both a source of virus contamination in blood and organ donations, as well as the reservoir from which full blown hepatitis can arise. The oncogenic potency of occult HBV persistence becomes progressively evident. Certain co-morbidities support occult HBV infection as co-infection with hepatitis C virus or human immunodeficiency virus. Persistence of OBI could involve different mechanisms: mutation or integration of the viral sequence which may alter HBsAg expression, decrease of HBV replication, or hindrance of HBsAg through circulating immune complex. OBI has important clinical implications: any case reports indicate that immunosuppression caused by chemotherapy^[56], immunomodulatory agents^[57], or immune deficiencies, such as HIV infection^[58] or hematological malignancies^[59], can reactivate occult infection. However most patients with hepatitis B who recover from the infection do not experience any problems during their lives.

In the case of hepadnavirus, studies on occult WHV infection point to a direct link between virus persistence and its lymphotropism. Infection of the lymphatic system could be a natural and unavoidable consequence of hepadnavirus invasion and that, under certain circumstances, such as low virus dose, lymphoid cells can be the only temporary or permanent site of virus propagation. Occult HBV may also result from mutations in HBsAg coding or transcription control regions that alter antigenicity or expression levels^[19,25,26]. In addition, the transmissibility of acute HBV *via* liver transplant or blood product transfusion from donors with occult infection^[5,22,23] provides evidence against the presence of defective viruses.

Abstract

Occult hepatitis B virus (HBV) infection (OBI) is defined as the presence of HBV DNA in the liver (with or without detectable HBV DNA in serum) for individuals testing HBV surface antigen negative. Until recently, the clinical effect of OBI was unclear on the progression of liver disease; on the development of hepatocellular carcinoma; and on the risk for reactivation or transmission of HBV infection. Several studies suggest a high prevalence of OBI among patients with cryptogenic chronic liver disease, but its role in the progression to cirrhosis remains unclear. Although OBI has been well documented in human immunodeficiency virus (HIV)-positive patients, especially among those coinfecting with hepatitis C virus, further studies are needed to determine its current clinical impact in HIV setting.

CLINICAL SIGNIFICANCE OF OCCULT HEPATITIS B VIRUS INFECTION

Occult hepatitis B virus (HBV) infection (OBI) was redefined by international experts, meeting in Italy in 2008, as the presence of HBV DNA in the liver (with or without detectable HBV DNA in serum) for individuals testing HBV surface antigen (HBsAg) negative^[1]. These experts also introduced a cut-off value for HBV DNA of < 200 IU/mL. A serum concentration greater than 200 IU/mL should be interpreted as an infection caused by escape mutants, not an OBI. Nevertheless, other experts prefer the traditional definition of OBI: the presence of HBV DNA in blood or liver tissues in patients negative for HBsAg, with or without any HBV antibodies.

Patients with OBI were further classified as either seronegative, when both antiHBs and antiHBc are negative, or seropositive when antiHBc is present^[2]. These patients are also found to be positive for antiHBcs plus antiHBs or only positive for antiHBc but without antiHBs. For both of these latter patients, the HBV viral load is greater^[3]. Moreover, viral replication seems to be controlled by different mechanisms: for antiHBc positive patients by a T-cell response of protective memory; whereas antiHBc negative individuals have no HBV-specific T-cell expan-

sion, suggesting that low level infection is insufficient for protective memory to mature.

There are scant data for the molecular mechanisms that explain the lack of detection of HBsAg in the presence of HBV DNA. One possible explanation is defective transcription control of both the HBV-polymerase and HBsAg coding regions that can lead to a significant decrease of the viral replication levels and the circulating HBsAg titres. The presence of HBsAg/anti-HBs immune-complex, especially in those patients with low titres of surface antigen may interfere in the detection of circulating HBsAg.

Until recently, the clinical effect of OBI was unclear in the following contexts: for its influence on the progression of liver disease; on the development of hepatocellular carcinoma; and on the risk for reactivation or transmission of HBV infection^[4].

OBI IN OTHERWISE HEALTHY INDIVIDUALS

For patients with OBI but who are otherwise healthy, the key issues are HBV prognosis and transmission. From the 5 blood donors with OBI and the 55 recipients of their blood studied by Gerlich *et al*^[5], 22 probable cases of HBV transmission were identified, but these patients remained healthy. Nevertheless, fulminant hepatitis B was found in 3 of these blood recipients that were immunosuppressed. Although transmission is possible, this risk appears to be negligible when concurrent antiHBs are present (> 100 mIU/mL)^[6]. In addition, HBV transmission was not found by Satake *et al*^[7] for OBI blood donors that were antiHBs positive, whereas 27% of antiHBs negative donors transmitted HBV infection. These results were confirmed by other studies^[8,9]. While HBV transmission by OBI donors is possible transmission risk is negligible when antiHBs titres are present (even at low levels).

After transplantation, organs, particularly livers from antiHBe positive donors, may transmit HBV infection. Cholongitas *et al*^[10] reviewed 39 studies that included 903 recipients of antiHBe positive donors. *De novo* HBV infection developed in 19% of HBsAg-negative recipients, but was less frequent for antiHBe and antiHBs positive recipients than for HBV naïve recipients. Adequate prophylaxis with lamivudine or specific gammaglobulin, or both in combination, reduced *de novo* infections in these two groups.

A second issue is patients with OBI developing complications. Mild necrosis and inflammation can be present in liver biopsies of humans after acute hepatitis and in woodchucks infected by woodchuck hepatitis virus (WHV). This mild inflammation probably has no repercussion if the patient has no other cause of liver disease^[11]. For 18 patients with OBI who underwent liver transient elastometry^[11], the median liver stiffness was 4.2 kPa (healthy people 4.6 kPa), showing absence of fibrosis for them. Additionally, no significant mortality was found caused by hepatocellular carcinoma in patients developing

unapparent hepatitis B^[6]. Therefore, immune individuals with only OBI but no other concomitant liver disease usually show no clinical evidence of hepatic damage.

OBI AND CRYPTOGENIC CHRONIC LIVER DISEASE

For a cohort of 159 patients with cryptogenic chronic liver disease, the prevalence of OBI investigated by Fang *et al*^[12] was 28% for serum HBV DNA positivity, but for antiHBe positive individuals the prevalence reached 100%. Similar results for patients with cryptogenic cirrhosis were reported by Chan *et al*^[13]: 32% had OBI, most of them with antiHBe and/or antiHBs. By contrast, Kaviani *et al*^[14] only found OBI in 1.9% of patients with cryptogenic hepatitis. These results, however, may be explained by both the variation in methods for the measurement of HBV DNA and differences in endemicity for the geographic areas studied. In the paper by Kaviani *et al*^[14], OBI was found in patients with cryptogenic hepatitis by qualitative polymerase chain reaction (PCR) with a sensitivity of 150×10^3 copies/L. Therefore, it is very important to use the most sensitive tools to measure HBV viral load, such as “real-time” PCR methods (lower detection limit 10-15 IU/mL) in order to define OBI. Yet, it is nevertheless unclear if OBI was the main cause of this liver disease and its role in the progression to cirrhosis.

OBI AND DIALYSIS PATIENTS

In a study including 366 patients from six dialysis units in Central Greece, an OBI prevalence of 0.9% was recently reported by Mina *et al*^[15]: 15 patients were HBV DNA positive, 12 had overt HBV infection (one HBeAg positive, 10 antiHBe positive and 1 antiHBe plus antiHBs positive) and OBI was diagnosed in 3 patients (two had no serological markers of HBV infection and one was antiHBe and antiHBs positive). For both groups the HBV DNA levels were low. Additionally, there was no association with HCV infection. In the setting of continuous ambulatory peritoneal dialysis and hemodialysis (71 patients in each group), another study^[16] reported a higher prevalence of OBI than the Greek study (17% in peritoneal dialysis and 10% in hemodialysis). Similarly, HBV viral loads were low and HCV positivity was not a contributing factor to OBI. These low HBV DNA titres may be explained by both the transfer of HBV DNA from serum to the dialysate compartment and also the destruction of the HBV genome during the haemodialysis session^[15].

OBI AND HUMAN IMMUNODEFICIENCY VIRUS-INFECTED PATIENTS

Human immunodeficiency virus (HIV) infection modifies the natural history of hepatitis B disease. Coinfected patients have higher HBV DNA levels and are more likely to have accelerated loss of protective anti-HBs and an increased risk for liver morbidity and mortality. The in-

creasing survival of patients with HIV-HBV treated with HAART allows a longer time for liver cirrhosis to develop, with some patients experiencing accelerated progression to clinically significant liver disease.

The prevalence of OBI for patients with HIV has been estimated by several studies with controversial results^[17-20]: from a Brazilian group's^[19] estimate of 5% to one in India^[18] of nearly 25%. The Indian group described the presence of detectable HBV DNA in 21% of antiHBc positive patients. Additionally, HIV patients are at a higher risk for HCV coinfection^[18]. Morsica *et al*^[17] reported that OBI is more frequent in HCV-coinfected patients. However, other studies^[18,19] did not confirm these results.

Because most HIV-infected patients currently on HAART receive drugs with anti-HBV activity, recognition of OBI in these patients may be difficult. Although reactivation of HBV infection in HIV-positive/HBsAg-negative is rare, it would be possible after withdrawal of antivirals against HBV, such as lamivudine or tenofovir^[21]. Recently, Bloquel *et al*^[20] described reactivation for two HIV patients with anti-HBc after withdrawal of HAART with anti-HBV activity. Consequently, it would be very important to know the HBV virological status of these patients before starting antiretroviral therapies in order to avoid reactivations if treatment is stopped. Further studies are needed to determine the current clinical impact of OBI for HIV setting.

OBI AND HCV INFECTED PATIENTS: REACTIVATION AFTER IMMUNOSUPPRESSION THERAPY

These issues will be reviewed in other chapters. Although the presence of OBI in HCV infected patients has been well established, its significance is currently under investigation. Some studies have shown higher fibrosis stages in patients with OBI compared with individuals without it. Nevertheless, others have failed to show this finding. Central questions include the implication of OBIs on hepatic carcinogenesis and their effect on response to HCV treatment.

Patients positive for HBsAg have a high risk of reactivation of hepatitis B after cytotoxic or immunosuppressive therapy. In this regard, OBI patients under immunosuppressant conditions may show a reactivation of viral replication when immunological reconstitution is achieved with a consequently CTL-mediated hepatocyte injury^[1]. Therefore, reactivation more often appears after end of treatment. Hui *et al*^[22] studied 244 patients who received rituximab plus steroids. All were HBsAg-negative and 8 patients developed HBV reactivation. Thus, for these patients starting antivirals early, close monitoring of HBV DNA is mandatory before the occurrence of *de novo* hepatitis.

CONCLUSION

Although the clinical significance of OBI remains unclear,

the more recent data suggest an important role in reactivation of hepatitis B in immunosuppressed patient (especially after treatment with cytotoxic drugs and biologic therapies) and in HBV transmission in liver transplantation, particularly livers from antiHBc positive donors. Other issues such as cryptogenic liver disease, or the relevance in "healthy" patients should be clarified with more studies.

Abstract

In 2008, the European Association for the study of the liver (EASL) defined occult hepatitis B virus infection (OBI) as the "presence of hepatitis B virus (HBV) DNA in the liver (with detectable or undetectable HBV DNA in the serum) of individuals testing hepatitis B surface antigen (HBsAg) negative by currently available assays". Several aspects of occult HBV infection are still poorly understood, including the definition itself and a standardized approach for laboratory-based detection, which is the purpose of this review. The clinical significance of OBI has not yet been established; however, in terms of public health, the clinical importance arises from the risk of HBV transmission. Consequently, it is important to detect high-risk groups for occult HBV infection to prevent transmission. The main issue is,

perhaps, to identify the target population for screening OBI. Viremia is very low or undetectable in occult HBV infection, even when the most sensitive methods are used, and the detection of the viral DNA reservoir in hepatocytes would provide the best evaluation of occult HBV prevalence in a defined set of patients. However, this diagnostic approach is obviously unsuitable: blood detection of occult hepatitis B requires assays of the highest sensitivity and specificity with a lower limit of detection < 10 IU/mL for HBV DNA and < 0.1 ng/mL for HBsAg.

INTRODUCTION

According to European Association for the study of the liver (EASL), about one third of the world's population have serological evidence of past or present hepatitis B virus (HBV) infection, and more than 350 million people may be affected by chronic HBV infection^[1]. In addition, chronic HBV infection is the worldwide primary cause of cirrhosis and hepatic cellular carcinoma, and it is among

the top ten causes of death^[2]. The clinical evolution of HBV is variable, ranging from mild liver disease to fulminate hepatitis, cirrhosis, or hepatic cellular carcinoma (HCC). In some individuals, in whom the HBV infection persists, serological markers can identify different clinical states of viral persistence^[2,3].

Chronic hepatitis B

Patients with hepatitis B surface antigen (HBsAg) detectable for six months or more are defined as having chronic hepatitis B. Usually these patients have elevated serum liver enzymes, high levels of HBV DNA, and high risk of transmission, both related to the positivity of the hepatitis B e antigen (HBeAg). They also have the highest risk of cirrhosis and HCC^[2]. In some patients, HBeAg is undetectable, in spite of persistent replication of the virus.

In these patients, the virus has mutations that prevent expression of the “e” protein. The mutations are located in the basal core promoter (BCP) region (A1762T and G1764A) and in the precore (PC) region (G1896A) of HBV genome^[4]. These variants are more common in Mediterranean countries and Asia. The appearance of hepatitis B e antibody (anti-HBe) does not necessarily indicate clinical improvement. The HBV DNA levels in these subjects tend to be lower^[5].

“Healthy” carrier

These patients are characterised by a positive HBsAg that persists more than six months, but with normal liver enzymes values. They are negative for HBeAg, and are associated with low or undetectable serum HBV DNA and low risk for progression to cirrhosis or HCC^[2].

Occult hepatitis B infection

Owing to modern molecular analysis we know the viral genome of HBV can persist indefinitely in previously infected HBsAg-negative subjects^[5]. This persistence occurs by conversion to a covalently closed circular HBV DNA (ccc) DNA in the hepatocyte, which then binds to proteins, forming a mini chromosome. This cccDNA is the molecular basis of occult hepatitis B infection because of its stability and long-lasting persistence in the nuclei of hepatocytes^[6].

SEROLOGICAL PATTERN OF OCCULT HEPATITIS B INFECTION

The antibodies produced by the host and proteins released from the virus provide us with valuable information. Within the group of occult hepatitis B infection (OBI) patients, it is possible to observe differences based on the results from serological markers.

Seropositive subjects

These are OBI subjects with anti-HBc and/or positive anti-HBs in which serum HBsAg is not detected because of the resolution of acute hepatitis B (after a few months of HBsAg carriage) or after years of chronic

HBsAg positive infection^[1]. Thirty-five percent of patients with OBI have positive anti-HBs and forty-two percent of have positive anti-HBc^[2]. The HBV DNA detection rate is higher in individuals who are positive anti-HBc but negative for anti-HBs. When patients give a positive result for both antibodies, they have intermediate HBV DNA levels^[3]. One explanation for this serological pattern is that positive anti-HBc patients with chronic HBV infection clear HBsAg to an undetectable level, with or without anti-HBs: this pattern is associated with older age and anti-HBe^[5].

Seronegative OBI

Patients who are not positive for anti-HBc and anti-HBs represent twenty-two percent of OBI patients^[2]. They have very low levels of HBV DNA^[7]. This pattern of antibodies may appear from the beginning of the infection when patients have not yet developed positive hepatitis B specific antibody (“primary OBI”) or because of clearance of the hepatitis B specific antibodies^[1]. Therefore, this pattern should always be kept in mind, because almost anybody can be a potential carrier of occult B hepatitis.

Moreover, there are cases termed as “False” OBI. They are carriers of mutations in HBsAg (in the S gene) that are not recognized by some routine detection assays. In these cases, the DNA result resembles other cases of HBV, because they are usually positive for HBsAg^[1].

MARKERS FOR SCREEN OBI PATIENTS

HBsAg

OBI diagnosis is based upon detection of HBV DNA when HBsAg is absent. It is very important to define the optimal methodology to test this marker to prevent false positive results, depending on HBsAg assay sensitivity.

The quantification of HBsAg presents several problems associated with the virus, the host, or the test kits. To correctly test HBsAg, International Standard samples with known quantities of HBsAg are required. Thus, using World Health Organization (WHO) International Standard for HBsAg (00/588) with a potency of 33 IU/vial, it is possible to know that 1 international unit (IU) is equivalent to 5.6 Abbott ng, 1.9 French ng, and 0.43 PEI units or ng (confirming that ng values applied to other standards are not equivalent and some of the values have changed over time)^[7].

The correlation between the HBsAg and the number of HBV particles is a key point, because this marker is used with a wide range of HBV particles in blood, depending on the infection state. One ng of HBsAg protein is equivalent to approximately 2×10^8 22 nm subviral particles and to approximately 5×10^7 HBV particles (assuming the virus particles have a four times larger surface). Different assays for testing HBsAg have variable detection limits, from 0.04 to 0.62 ng/mL. At a detection limit of 0.04 ng/mL, there must be around 2 million particles in the blood for a positive result. The presence of excess

Table 1 Serological markers and hepatitis B virus DNA in different states of persistence of hepatitis B virus^[2,4]

| | HBV DNA | HBsAg | Total anti-HBc | anti-HBs | HBeAg | anti-Hbe |
|--|-------------------------|-------|----------------|----------|-------|----------|
| Chronic hepatitis B | +++ | + | + | - | + | - |
| Chronic hepatitis B with variants pre-core | ++ | + | + | - | - | +/- |
| Healthy carrier | < 10 ⁶ IU/mL | + | + | - | - | + |

| OBI seronegative | < 1000 IU/mL | - | - | - | - | - |

HBV DNA data are copies/mL. -: Negative, the marker is not present in the serum of the patient; +/-: The marker can be present in the serum of the patient; +: Positive, the marker is present in the serum of the patient; HBV: Hepatitis B virus; HBsAg: Hepatitis B surface antigen; anti-HBs: Hepatitis B surface antibody; HBeAg: Hepatitis B e antigen; anti-Hbe: Hepatitis B e antibody; OBI: Occult hepatitis B virus infection; IU: International unit.

subviral particles can improve detection.

A level of 2 million HBV genomes/mL (quantity estimated at the time of HBsAg seroconversion) is considered to exist in a ratio of 1:1000 for the amount of HBsAg in the virus to that in subviral particles^[8]. However, this is not always true. Minegishi *et al*^[9] found six HBsAg seroconverters among 76 prism-negative blood donations with > 10⁴ genomes/mL, generating a ratio of 1: < 200. Gerlich *et al*^[8] found a blood donor in the incubation phase with a ratio of 1:100, which became 1:500 during the chronic phase.

Accordingly, the ratio is variable, from 1:100 in patients with OBI (HBsAg negative with high levels of HBV DNA) to 1:100000 or more when HBsAg is detected in association with low concentrations of HBV DNA. Most HBsAg commercial assays are able to detect all genotypes and subtypes of the wild-type virus, but some of them may miss mutations in the S region^[9,10]. Usually, wild-type virus is the dominant species detected at the beginning of the infection; however, mutations can increasingly appear because of the lack of viral proofreading exonuclease activity.

Mutations in the S gene cause changes in the amino acids of the “a” region, which is very important for inducing immunity, being a target of anti-HBs^[7,10]. Immunological pressure may cause a decrease of HBsAg, but might favour the selection of HBsAg mutants. Thus, the presence of anti-HBs and the clearance of AgHBs do not necessarily reflect viral clearance.

In this apparent “resolved” infection, cytotoxic T cells are responsible for controlling the replication (but absolutely eliminating it). The role of Anti-HBs would be in controlling traces of circulating virus, although there is a risk of selecting mutants. This process may underlie seropositive OBI, and it is very important in patients under immunosuppressive therapy, in patients with liver disease, or in cases of blood donors, because of the risk for transmitting the virus^[8]. Mutants have also been detected in vaccinated patients, in patients who have been treated with hepatitis B immunoglobulin, and in patients with chronic infection^[11]. As a consequence, all patients with a serological pattern consistent with possible OBI should be investigated to rule out HBsAg mutants. HBsAg should be tested with an alternative method that can detect the most common mutants. Quantitative HBV DNA testing should also be considered^[11].

HBV DNA

The gold standard for OBI diagnosis is the study of extracted DNA (from liver or blood). For this purpose, a very sensitive and specific assay is required. The experts meeting in Taormina^[1] recommended assays with detection limits of less than 10 copies of HBV DNA per reaction. Current technologies used for DNA detection are: nested-PCR, real-time PCR, and transcription based mediated amplification (TMA). Using these assays, it is possible to decrease the lower detection limit (< 5 IU/mL of HBV DNA). This is particularly important in OBI, because the HBV DNA levels vary from < 10 to 425 copies/mL. However, the false negative and positive rates are around the cut-off level due to the Poisson distribution of the virions and blank specimens^[7].

According to Taormina Group recommendations, primers must be specific for different HBV genomic regions and be complementary to highly conserved (genotype shared) nucleotide sequences^[1]. Usually, the genes amplified by PCR are S and X; the former has been found to be the most sensitive in serum, and the second has been described as the most sensitive in the liver^[2]. The use of very sensitive methods, such as PCR, increases the risk of false positive results, due to contamination or to different amplicons within the target. To resolve these problems, inclusions of appropriate controls in each assay run, as well as sequencing the amplicons, are recommended. In the case of serum samples, it is recommended DNA from is extracted from at least 1 mL of serum^[1,2].

Differences can be observed because of the different amounts of material used in the assay. To reduce this problem, it is possible to quantify the DNA in comparison with, or normalized to, a host cell gene (such as beta-globin)^[1]. DNA detection from a liver biopsy would be the best option because of the persistence of viral genomes in hepatocytes. For this procedure, frozen samples are preferred to formalin fixed tissues^[1,7].

Usually, when a blood sample is positive for HBV DNA, the liver sample is too; however, HBV DNA from the liver can be detected even when HBV cannot be detected in serum. Patients with undetectable HBV DNA in the liver have also undetectable levels of HBV DNA in peripheral blood^[2]. However, there are no standardized assays and liver specimens are not routinely obtained^[7]. Commercial assays use serum or plasma to de-

termine the presence and the amount of HBV DNA. In some studies using the woodchuck model, occult WHV was shown to persist in peripheral blood mononuclear cells (PBMC)^[13,14]. Samples for studying HBV DNA should be collected and stored in appropriate conditions, and the risk of cross-contamination should be avoided^[1]. However, which is the best DNA extraction method to apply in the OBI diagnosis remains unclear^[2].

To reduce variability and risk of contamination, reagents that are ready to use or that use automatic systems to extract DNA have been proposed. Nine years ago twenty-two laboratories participated in an international collaborative study to establish a WHO international standard (97/746) for HBV DNA nucleic acid amplification techniques (NAT)^[15]. A subtype adw2 genotype A isolate was used. Based on this study, one IU of the standard is equivalent to 6.31-6.42 genomic equivalents (geg) if a PCR assay is used. Therefore, the results of the DNA for HBV must be expressed as IU/mL, but accurate conversion factors depend on the chemistry used for HBV DNA quantification, and range from 5.26 to 7.3 copies/IU. Despite these attempts, there is still variability in the results; therefore, using one assay should be used to monitor any particular patients or group of patients^[7]. In case of blood banks the NAT is used to screen for Hepatitis C virus (HCV), Human Immunodeficiency Virus 1 (HIV-1), and HBV. Plasma pooling is often used because of high cost issues, which introduces a dilution factor and decreases the sensitivity of the assay. This is critical in the case of OBI, because the levels of HBV DNA are very low. Moreover, the use of plasma pooling can be aggravated by using triplex assays to detect the three viral genomes at the same time. González *et al.*^[16], using blood donors in Madrid, found that donors in the window period and donors with OBI were not uncommon. Furthermore, they were detected at a higher frequency using individual nucleic acid testing (NAT) than with minipool NAT blood.

Other assays to detect a genome use a probe labelled with a different dye to permit the identification of the different viruses. However, a positive result from this type of screen needs to be confirmed by other tests^[17].

Anti-core antibody

This is the first antibody to appear, even preceding HBsAg, and targets the nucleocapsid of HBV. The anti-core antibody can induce anti-HBc responses without T-cell activation. This antibody can be found in almost every patient with a previous contact with HBV, even in HBV carriers without other responses. This serological pattern is called "anti-HBc alone", and might reflect an occult HBV infection. Anti-HBc is present in the different phases of hepatitis, including recovery, and may persist longer than anti-HBs or anti-HBe; however, it is not protective. Anti-HBc IgM may help in the diagnosis of the acute phase. Moreover, this IgM can be positive during flares^[3].

In some patients, anti-HBc cannot be detected at any phase of HBV infection because of a defective host immunological response (such as in HIV coinfection or organ transplantation) or virus infection by variants of

HBV^[3,8]. Although anti-HBc is not an ideal marker, the Taormina group recommended its use as a surrogate marker whenever an HBV DNA test is not available to identify potential seropositive OBI individuals such as in cases of blood, tissue or organ donation, or in cases of patients undergoing immunosuppressive therapy^[1].

In addition, anti-HBc determination is useful in OBI diagnosis, even when HBV DNA is available, because of the possibility of intermittent viremia^[3]. In such cases, not all anti-HBc positive individuals are positive for HBV DNA, and anti-HBc tests might provide false-positive results^[1]. Furthermore, the absence of this antibody does not exclude OBI (seronegative OBI). If this marker is used in combination with HBV DNA, the prevalence of HBV infection in the area should be considered, because when prevalence of anti-HBc is higher than a 50% of the donor population, a positive result is unhelpful^[17].

Anti-surface antibody

This is the last antibody to appear (about three months after acute phase), and it is able to neutralize the virus. In vaccinated subjects it is the only positive marker.

This antibody can be used with anti-HBc to study the serological status of patients with a probable OBI.

TARGET POPULATIONS FOR INVESTIGATING THE PRESENCE OF OBI

Investigation of possible OBI should be done in case of blood and solid organ donors, because of the risk of transmission to others^[7]. The study and monitoring of reactivation in case of serologic markers of past HBV infection must also be done in patients undergoing immunosuppressant therapy, because of the risk of reactivation after the therapy.

Reactivation risk can be explained if immunosuppression permits viral replication, represses the function of immune cells, and after the treatment, the response of the immune system is exaggerated, leading to cellular injury. The main factors for reactivation are positive HBsAg, grade of immunosuppressant, liver disease, primary malignancy, and toxicity of these drugs. Among the group of patients treated with immune suppressors, there are patients with autoimmune liver diseases. In this group Georgiadou *et al.*^[18] studied the prevalence of OBI in patients treated with immunosuppressants, and they concluded that there was a significantly higher proportion of OBI cases among these patients compared to blood donors. Interestingly, under immunosuppression, these patients did not seem to deteriorate during the follow-up^[18,19].

Patients undergoing haemodialysis must also be studied for OBI because of the risk of reactivation due to immunosuppression and the risk of infection^[7].

On the other hand, patients with chronic hepatitis C, patients affected by a Hepatic cellular Carcinoma, and patients with cryptogenetic liver disease, must be investigated for OBI because of its possible influence on the development of these diseases^[7].

In case of pregnant women, Kwon *et al*^[20] studied the prevalence of HBV DNA in 202 healthy pregnant women. They concluded that the vertical transmission of OBI through the cord blood does not represent a clinical problem because of the low HBV DNA level in the mother's blood, although they acknowledged that more studies are needed.

CONCLUSION

The study of occult HBV infection involves serological and molecular assays. The serology should include, firstly, AgHBs. This test must be done using the most sensitive method, because, depending on this result, the hepatitis B infection can be further classified. With a negative HBsAg result, HBV DNA should be studied only in cases previously exposed, to rule out OBI. Moreover, serological tests should include anti-HBc and anti-HBs.

Abstract

Persistence of hepatitis B virus-DNA in the sera, peripheral blood mononuclear cells or in the liver of hepatitis B surface antigen (HBsAg)-negative patients with or without serological markers of previous exposure (antibodies to HBsAg and/or to HB-core antigen) defines the entity called occult hepatitis B infection (OBI). Co-infection with hepatitis B and hepatitis C viruses is frequent in highly endemic areas. While this co-infection increases the risk of liver disease progression, development of cirrhosis and hepatocellular carcinoma and also increases the rate of therapeutic failure to interferon-based treatments than either virus alone, a potentially negative effect of OBI on clinical outcomes and of therapeutic response to current antiviral regimes of patients with chronic hepatitis C remains inconclusive.

INTRODUCTION

Hepatitis B virus (HBV) and hepatitis C virus (HCV) share common routes of transmission, which explains the high prevalence of occult HBV infection reported in patients with chronic hepatitis C^[1-5]. While there is persuasive evidence suggesting that HBV-HCV co-infection accelerates the liver disease progression and increases the risk of developing hepatocellular carcinoma (HCC)^[6] the effect of occult hepatitis B infection (OBI) on the natural history of chronic hepatitis C infection remains elusive. Despite its potential clinical importance, knowledge on the effect of OBI on chronically HCV infected subjects is limited as HBV-DNA detection may require liver tissue and liver biopsies are not routinely performed in the majority of patients. In addition, most studies addressing this issue are cross-sectional or have included small size cohorts or heterogeneous populations. Furthermore, the use of different methods with variable sensitivity for HBV-DNA determination in serum, PBMCs and liver may explain the discrepant results on the effect of OBI on chronic hepatitis C^[1-3,7-12]. The purpose of this review is to critically examine the current evidence for a potential effect of OBI on HCV chronic infection. Specifically, we will review possible mechanisms of viral interaction, the

potential effect on liver histology, on clinical outcomes such as the risk of developing HCC or disease decompensation in these patients.

LITERATURE SEARCH

Electronic searches of the National Library of Medicine's (PubMed and OVID Technologies), EMBASE (OVID Technologies), Current Contents (Institute for Scientific Information) and manual of selected specialty journals were made to select all relevant literature. The key words "Occult hepatitis B virus AND hepatitis C virus", "Impact of occult hepatitis B virus on chronic hepatitis C", were used. All articles were identified by a search from June 1999 to May 2010. Eligibility and exclusion criteria were previously specified. Case reports and human immunodeficiency virus co-infection articles were excluded while case-series, cross sectional, retrospective and prospective studies of occult hepatitis B and chronic hepatitis C were included.

DO HEPATITIS B AND HEPATITIS C VIRUSES INTERACT IN THE HOST?

Some *in vitro* studies have shown that the HCV "core" protein suppresses HBV replication^[13-15]. However, these results have not been confirmed by more recent studies which have demonstrated little or null interaction between HCV and HBV in a Huh7 cells culture^[16,17]. Nonetheless, *in vitro* experiments cannot be extrapolated to the host viral infection scenario as a host active immunological and cytokine response to the human infection is lacking in *ex vivo* experiments. This immunological response may determine both the liver damage and the clinical outcome. In the clinical setting, Jardi *et al.*^[18] found that HCV displayed strong inhibitory action in the reciprocal viral inhibition seen in HBV/HCV coinfecting individuals. An inhibition of HCV replication by HBV-DNA was also observed in hepatitis B surface antigen (HBsAg)-negative Austrian patients^[19]. However, Alberti *et al.*^[20] studied 30 patients with symptomatic acute hepatitis and markers of active HBV and HCV coinfection; all patients underwent long-term follow-up and their chronic infection rates were similar to those patients with single HBV and HCV infection. Nevertheless, the risk of fulminant/subfulminant hepatitis is increased in cases of acute HCV superinfection in chronic hepatitis B^[21-23] and causes a higher cumulative risk of cirrhosis and HCC than HDV superinfection does^[24].

OBI AND CHRONIC HEPATITIS C: EFFECT ON HISTOLOGY AND CLINICAL OUTCOMES

Cacciola *et al.*^[2] found that patients with chronic hepatitis C and OBI more frequently had cirrhosis than patients with chronic hepatitis C alone. Likewise, Mrani *et al.*^[10] found

that 47 of a cohort of 203 HCV positive French patients (23%) had occult HBV infection with a low HBV load (10^2 - 10^4 copies/mL). The serum HCV-RNA titer, the liver inflammatory activity and the stage of fibrosis were significantly higher in HBV-DNA positive than in HBV-DNA negative patients. However, these findings have not been confirmed by other studies. Sagnelli *et al.*^[7] found occult HBV infection by using PCR as defined by two different positive results of HBV-DNA in plasma, peripheral blood mononuclear cells (PBMCs) and liver compartments in 37 of 89 patients with biopsy proven chronic hepatitis C (41.6%) and found no association between occult HBV infection and the degree of liver necro-inflammation and fibrosis. Fabris *et al.*^[12] studied a cohort of 51 HBsAg-negative patients with chronic hepatitis C, and studied liver fibrosis progression by using paired liver biopsies. HBV-DNA was found by nested PCR in 1.9% of sera and 29.4% of liver tissue samples. The authors found no significant differences in mean serum aminotransferase values, baseline HCV viral load, HCV genotypes, or grading and staging in patients with or without HBV-DNA. Hui *et al.*^[25] retrospectively compared fibrosis progression and progression to severe fibrosis (fibrosis stage 3 or 4) in 74 HCV patients with at least two consecutive biopsies, and found occult HBV infection in 31 (41.9%). Patients with occult HBV co-infection did not progress more than patients without occult HBV infection. Kannangai *et al.*^[26] reported liver flares that were associated with serum HBV-DNA detection in a small group of patients with OBI and hepatitis C; the authors proposed that flares might be the pathogenetic mechanism underlying liver disease progression in patients with OBI and chronic hepatitis C^[19]. By contrast, no effect on liver biochemistry was observed in other studies^[27,28]. In summary, results of the combined effect of OBI and chronic hepatitis C on liver disease progression have yielded controversial results and no firm conclusion can be reached on this issue.

EFFECT OF OBI ON THE RISK FOR DEVELOPMENT OF HCC IN CHRONIC HEPATITIS C

Pollicino *et al.*^[29] found a significant association between OBI and HCC, and provided persuasive evidence that OBI maintains several of the oncogenic mechanisms of HBV such as the capacity to be integrated in the host's genome and production of transforming proteins. Therefore, it is conceivable that OBI might increase the risk for developing HCC in patients with chronic hepatitis C in the same way as HBV infection does. Adachi *et al.*^[11] found that positive HBcAb, which indicates a previous HBV infection, but not positive HBV-DNA patients, was associated with an increased risk for developing HCC. Independent risk factors for development of HCC were male gender, α -fetoprotein ≥ 20 ng/mL, serum ALT ≥ 80 IU/L and the presence of anti-HBc. Likewise, Ikeda *et al.*^[30] prospec-

Table 1 Studies assessing the effect of occult hepatitis B infection on liver histology, clinical outcomes and effect on the sustained virological response rate in patients with chronic hepatitis C

OBI: Occult hepatitis B infection; HBV: Hepatitis B virus; HCV: Hepatitis C virus; PCR: Polymerase chain reaction; SVR: Sustained virological response; CHC: Chronic hepatitis C; HCC: Hepatocellular carcinoma; F-U: Follow up.

tively studied a large multicenter cohort of patients with chronic HCV infection and occult HBV infection (negative results for HBsAg and HBV-DNA but positive for anti-HBc on serologic testing). Patients with HCV-related cirrhosis and positive anti-HBc were at higher risk for HCC. Anti-HBc positivity was associated with increased risk for HCC, even in patients with a prior virological response to interferon therapy. Shetty *et al*^[31] prospectively examined the rate of HCC in 44 explanted livers from patients with HCV-associated cirrhosis and found that those patients with occult HBV infection had a significantly higher rate of explant-proven HCC (59%) compared to patients without OBI (36%); OR: 3.1 (2.1-5.4). In another large prospective study, Matsuoka *et al*^[28] investigated the influence of occult HBV infection on the histopathological features and clinical outcomes of 468 HBsAg-negative patients with chronic hepatitis C. These authors determined the HBV-DNA in serum and the hepatitis B core (HbC) parti-

cles in hepatocytes by immunohistochemistry and electron microscopy. The authors found a significant increase in the degree of inflammatory cell infiltration, higher irregular regeneration of hepatocytes and a higher probability of developing HCC in patients with OBI. Tamori *et al*^[32] found that patients with chronic hepatitis C who achieved sustained virological response and developed HCC had a higher rate of OBI than a control group of 50 patients with chronic hepatitis C without OBI. Miura *et al*^[33] found that occult HBV infection, high ALT levels (≥ 80 IU/L) and the staging of liver fibrosis after interferon (IFN) therapy were important independent factors affecting the appearance of HCC. By contrast, Toyoda *et al*^[34] found that Circulating low-level HBV does not appear to play an important role in hepatocarcinogenesis in HBsAg-negative HCC. Overall, these results suggest that OBI may increase the likelihood of developing HCC in patients with chronic hepatitis C.

DOES OCCULT HBV INFECTION IMPAIR SUSTAINED ANTIVIRAL RESPONSE RATE IN CHRONIC HEPATITIS C INFECTED PATIENTS?

Cacciola *et al*^[2] found that the sustained virological response (SVR) rate to alfa IFN monotherapy was lower in patients with chronic hepatitis C and OBI. By contrast, Fabris *et al*^[12] studied twenty-five patients who were treated with alfa IFN and ribavirin and followed for at least 18 mo; there was no significant difference in the SVR among patients with and without OBI. Mrani *et al*^[10] reported that sustained response to IFN and Ribavirin was achieved in 11 (28%) of 40 HBV-DNA positive cases with chronic hepatitis C, compared with 65 (45%) of the 144 HBV-DNA negative cases ($P < 0.05$). Hasegawa *et al*^[35] analyzed 140 HCV patients without HBsAg and found that 7.9% of the cohort patients were positive for serum HBV-DNA; 4 of these 11 patients achieved SVR with IFN compared with 39 of 129 without HBV-DNA (NS). However this small group of patients precluded drawing firm conclusions regarding the SVR. Levast *et al*^[36] retrospectively studied a cohort of 140 HCV patients in France and found no effect on the SVR. Overall, these results do not support the concept that OBI impairs SVR in patients with chronic hepatitis C. Table 1 summarizes the main results analyzing the effect of OBI on liver damage, on clinical outcomes, risk of developing HCC and on response to antiviral treatment in patients with chronic hepatitis C.

CONCLUSION

Prospective studies using standardized laboratory techniques and well-designed large prospective studies with homogeneous cohorts and uniform selection criteria of patients are needed to elucidate the effect of OBI on individuals with chronic hepatitis C. Currently available data do not support a conclusive role of OBI in accelerating liver disease progression in patients with chronic hepatitis C or a potential negative effect of OBI on the SVR in patients with chronic hepatitis C. However, populations studied were small and heterogeneous and most of them included patients prior to the current standard of treatment, i.e. peginterferon-alfa plus ribavirin. By contrast, most studies including those with a longitudinal design that incorporated large cohorts strongly suggest that the risk of HCC is increased in OBI/HCV co-infection.

Abstract

Occult hepatitis B virus (HBV) infection (OBI) is defined by the presence of HBV DNA in the liver tissue of individuals who test negative for hepatitis B surface antigen (HBsAg). Patients who have recovered from acute hepatitis B can carry HBV genomes for a long time and show histological patterns of mild necro-inflammation, even fibrosis, years after the resolution of acute hepatitis, without showing any clinical or biochemical evidence of liver disease. At least in conditions of immunocompetence, OBI is inoffensive itself, but when other relevant causes of liver damage are present it might make the course of the liver disease worse. The risk of HBV transmission through transfusion is related to blood donations negative for HBsAg that have been collected during the pre-seroconversion period or during chronic OBI. Use of HBV nucleic acid amplification testing and multivalent anti-HBs antibodies in the HBsAg assays is recommended for detection of true and false OBI, respectively. It is not known if prior hepatitis B immunization with an optimal anti-HBs response in cases of HBV transmission through organ transplantation can effectively modulate or abort the infection. Use of anti-

viral agents as prophylaxis in patients with serological evidence of past HBV infection prevents reactivation of OBI after transplantation in most cases. Reactivation of OBI has been observed in other conditions that cause immunosuppression, in which antiviral therapy could be delayed until the HBV DNA or HBsAg becomes detectable. OBI might contribute to the progression of liver fibrosis and hepatocellular carcinoma development in patients with chronic liver disease.

INTRODUCTION

Occult hepatitis B virus (HBV) infection (OBI) is defined by the presence of HBV DNA in the liver tissue of individuals who test negative for hepatitis B surface antigen (HBsAg), by currently available assays, regardless of the detection of HBV DNA in the serum. When detectable, the level of HBV DNA in the serum is usually very low (< 200 IU/mL). Depending on the HBV antibodies detected, OBI may be seropositive [anti-hepatitis B core (HBc)

and/or anti-HBs positive] or seronegative (anti-HBc and anti-HBs negative) (> 20%)^[1].

The molecular basis of OBI is linked to the intrahepatic persistence of covalently closed circular DNA and to strong suppression of viral replication activity and gene expression. Host immune response, co-infection with other infectious agents, and epigenetic factors probably play a relevant role in HBV inhibition. This suppression of HBV activity is responsible for the very low or undetectable levels of serum HBV DNA in OBI cases^[2,3]. If serum HBV-DNA levels are similar to those detected in serologically evident HBV infection, it should be considered as false OBI, usually due to infection by HBV variants with mutations in the S gene. These variants produce a modified HbsAg that is not recognized by commercially available detection assays^[1]. OBI is more prevalent among subjects at high risk for HBV infection and with liver disease^[1].

The gold standard for diagnosis of OBI is the analysis of HBV-DNA extracts from the liver and blood samples. As liver samples are only available in a minority of cases, the most common diagnosis of OBI is based on the analysis of serum samples^[1]. In all cases, it is recommended to use a highly sensitive and specific test, like HBV nucleic acid amplification testing (NAT), a PCR technique with detection limits of < 10 copies HBV DNA per reaction. Only if this highly sensitive HBV-DNA testing is not possible, should anti-HBc be used to identify potential seropositive OBI cases^[1].

OBI is a complex entity that comprises many conditions and different situations. The evidence of its potential relevance is the reason for the growing interest in this topic. The purpose of this review is to synthesize the current evidence regarding OBI management, with special emphasis on strategies for prevention of OBI transmission in different scenarios (Table 1).

OBI AFTER ACUTE HEPATITIS

Patients who have recovered from acute hepatitis B might carry HBV genomes for several years without showing any clinical or biochemical evidence of liver disease^[4-6]. The question is if patients with this disorder are at risk for transmitting infection to others or for progression of their disease.

In a woodchuck model of OBI, maternal-fetal transmission has been observed from mothers with occult infection. Low levels of virus were detected in peripheral blood mononuclear cells and liver of newborns that had recovered from hepatitis, and this was associated with liver injury that occasionally led to hepatocellular carcinoma (HCC) development^[4,7-9].

In immunocompetent humans who have developed anti-HBc and anti-HBs following acute hepatitis B, no transmission of HBV has ever been demonstrated in blood donations^[10]. The persistence of virus-specific cytotoxic T lymphocytes as a consequence of stimulation by viral replication and gene expression in this population is necessary to control HBV infection and maintain the long-term persistence of anti-HBc and anti-HBs in these pa-

Table 1 Scenarios in which occult hepatitis B virus infection is of clinical importance

tients^[9]. Mild necro-inflammation, even fibrosis, has been observed in patients who have recovered from acute hepatitis B for several years after resolution of hepatitis^[11,12].

With regard to the management of these patients, we know that, at least in conditions of immunocompetence, OBI is innocuous in itself, but when other relevant causes of liver disease are present, mild liver damage produced by the occult virus might contribute to making the course of the liver disease worse^[2,13].

OBI AND BLOOD DONATIONS

HBsAg-negative blood donations that contain HBV DNA are considered infectious and might transmit HBV that usually induces typical type B hepatitis in recipients^[14]. Nowadays, OBI is the major cause of post-transfusion hepatitis B in western countries^[15] and in countries like India and Taiwan where the incidence of this problem is considerable^[16,17]. Although post-transfusion hepatitis B is rare in western countries^[15], the risk of transmission of HBV by transfusion is probably higher than for hepatitis C virus or human immunodeficiency virus (HIV)^[18].

The risk of HBV transmission through transfusion is related to blood donations that have been collected during the so-called pre-seroconversion period or during chronic OBI^[10]. The risk of transmission is high with blood that lacks anti-HBs, but it might not reach 100%. There are several possible explanations as to why not all recipients of HBV-DNA-positive, HBsAg-negative blood develop hepatitis^[9]: (1) vaccination or prior disease in recipients can induce immunity to HBV; (2) concurrent infusion of anti-HBs in another blood component; (3) presence of immune complexes; (4) inocula below the minimum infectious dose of HBV; (5) presence of defective or replication-incompetent virions; and (6) viral interference from another pathogen. The risk of transmission is insignificant when anti-HBs is present in the blood, regardless of anti-HBc status^[19,20]. The concentration of anti-HBs which makes transfusion safer is a matter of debate. However, caution is recommended when immunodeficient patients receive anti-HBc-positive, anti-HBs-positive donations. This is important if we consider that almost 50% of transfused blood in Western Europe is given to immunodeficient patients^[20].

With regard to the management of these patients, the use of multivalent anti-HBs antibodies in the HBsAg assays is strongly recommended for detection of false OBI^[1]. In cases of pre-seroconversion period donation, HBsAg or anti-HBc screening cannot detect OBI, and we

must use HBV-DNA NAT^[10]. NAT detects potentially infectious blood units before donation and consequently reduces the risk of transmitting HBV through blood transfusion. In HBV-endemic regions of the world, where a universal hepatitis B vaccination program is not available, NAT has higher potential benefit for reducing this risk. However, in low-prevalence countries, the availability of highly sensitive and specific HBsAg and anti-HBc assays limits the benefit of NAT^[9,10,21].

OBI AND ORGAN TRANSPLANTATION

Grafts from donors who are HBsAg-negative and anti-HBc-positive might transmit HBV to recipients after organ transplantation; particularly in the case of orthotopic liver transplantation (OLT), and especially if the recipient is negative for all HBV serum markers, because of the presence of viral strains in the hepatocytes, which can be reactivated during immunosuppression^[22-24]. In OLT, this occurs in 17%-90% of cases^[24]. Transmission of occult infection from HBV-seronegative (anti-HBs negative/anti-HBc-negative) individuals is uncertain. There is no evidence of this theoretical possibility, which is probably underestimated by a regular allocation to *de novo* HBV infection after transplantation^[1].

The risk of occult HBV transmission is very low after kidney, heart or bone marrow transplantation^[25,26]. Reactivation of OBI is possible in liver transplant recipients with a serological profile of past exposure to hepatitis B (anti-HBc positive), as a consequence of immunosuppression after transplantation^[27]. Hepatitis B infection usually has a benign course and is often less severe following solid organ transplantation obtained from anti-HBc positive donors when compared to hepatitis B that develops as a result of recurrent disease^[22,28].

With regard to the management of these patients, it is not known if prior hepatitis B immunization with an optimal anti-HBs response can modulate or abort the infection^[9]. Prophylaxis with antiviral agents prevents reactivation of OBI in most of these cases^[24].

REACTIVATION OF OBI

The risk of HBV reactivation is well documented in HBsAg-positive patients who receive chemotherapy and/or with hemato-oncologic diseases, and there is consensus that these patients require prophylaxis with an antiviral agent^[29,30]. However, the risk of HBV reactivation in OBI is less defined^[31-33]. The state of strong suppression of viral replication and gene expression activity by the host immune system in OBI patients might be discontinued, which leads to the development of a classical hepatitis B that often has a severe clinical course^[2]. This situation has been observed in several conditions including HIV infection^[34,35], hematological malignancies^[29], patients undergoing chemotherapy^[36,37], transplantation (bone marrow, liver, or kidney)^[38-40], and treatment with potent immunosuppressive drugs like rituximab (anti-CD20), alemtuzumab (anti-CD52) or infliximab (anti-tumor necrosis factor)^[41-43].

Various mechanisms are involved in HBV reactivation^[9]: (1) immunosuppression with cytotoxic agents can enhance HBV replication and lead to direct hepatic damage; (2) cytotoxic/immunosuppressive agents can suppress T-cell function and/or deplete B cells; and (3) suppressed immunological response leads to widespread HBV infection of hepatocytes. Once recovery is achieved following withdrawal of cytotoxic agents and immune surveillance is reconstituted, a rebound in cytotoxic-T-cell response is induced that leads to the development of cellular injury and hepatitis.

The clinical significance of HBV reactivation in HIV-positive patients is uncertain^[44-46]. Severe HBV reactivation has been reported after withdrawal of antiretrovirals that are active against HBV^[35].

Graft reinfection and reactivation of OBI is possible in liver transplant recipients with a serological profile of past exposure to hepatitis B (anti-HBc positive)^[27,47]. OBI patients with cirrhosis need close monitoring because the mortality rate following reactivation approaches 5%-40%^[9].

All patients who receive chemotherapy and immunotherapy should be tested for HBV serology and/or viremia before starting therapy, especially if they are positive for antibody to viral antigens, and monitored for several months or years after stopping treatment^[2,29]. Early identification of virological reactivation is essential to start antiviral therapy and prevent the occurrence of hepatitis B, which can be very dangerous in these patients^[2,32,48].

Use of antiviral agents as prophylaxis against HBV in HBsAg-positive patients who are undergoing cytotoxic chemotherapy is a standard strategy^[9,30,49]. However, for patients with OBI and those who are serologically HBV-DNA-negative but anti-HBc-positive, current data are insufficient to recommend routine prophylaxis and antiviral therapy could be delayed until the HBV DNA becomes detectable^[9,49-51].

For those with OBI, especially in the absence of anti-HBs, a prudent therapeutic approach is to initiate HBV antiviral therapy (lamivudine, telbivudine, adefovir, entecavir or tenofovir) prior to chemotherapy. This should be continued for ≥ 6 mo after stopping immunosuppressive treatment. If long-term treatment (> 12 mo) is predicted, then adefovir, entecavir or tenofovir should be chosen, and if a more rapid response is needed, then entecavir or tenofovir could be considered. Antiviral therapy is usually unsuccessful if started after alanine aminotransferase becomes elevated^[9].

For those patients who are HBV-DNA-negative and anti-HBc-positive, the following approach could be considered based on the kinetics of reactivation^[9,32]: (1) monitor at 4-wk intervals with HBV-DNA NAT (low limit of detection < 10 IU/mL) and begin antiviral therapy when the result is > 30 IU/mL; or (2) monitor at 4-wk intervals with a highly sensitive HBsAg assay (low limit of detection < 0.1 ng/mL) and begin antiviral therapy when the test becomes positive. Further studies are needed to clarify the clinical usefulness, safety and cost-effectiveness of these strategies in OBI. In HIV-positive patients, the risk

of HBV sero-reversion is low; therefore, it does not justify any prophylaxis.

OBI AND CHRONIC LIVER DISEASE

OBI has been detected in patients with cryptogenic chronic liver disease^[52-54] and could be associated with progression of liver fibrosis and cirrhosis development in these patients^[52,55,56]. HBV-infected patients might present with progressive reduction of viral replication and serum HBsAg levels. HBsAg might disappear over time, despite the presence of severe liver injury that has been provoked by overt hepatitis B, and then maintained once the occult HBV status has been established^[2,57].

It has been reported that close monitoring of serum HBV-DNA levels and liver-enzyme levels could be useful in the management of patients with OBI and cryptogenic liver disease in two respects^[58]: (1) to predict the risk of cirrhosis or HCC; and (2) to decide on the possibility of antiviral treatment to prevent HBV reactivation or transmission in the case of transplantation. However, the role of OBI in accelerating the development of cirrhosis is still unresolved. Prospective studies using well-defined selection criteria of patients and standardized laboratory techniques are needed^[1,56,59].

OBI AND HCC DEVELOPMENT

Many epidemiological and molecular studies have indicated that OBI is a potential risk factor for HCC development. OBI seems to maintain HBV oncogenic mechanisms such as the capacity to be integrated in the host genome, and production of transforming proteins^[1,52,59-68]. This pro-oncogenic role is not only the consequence of the integration of viral DNA into the host genome. Other factors might contribute^[2]: (1) persistence of replicating virus might induce mild liver necro-inflammation that continues for life; (2) occult strains usually persist as free genomes, and maintain the capacity to transcribe and replicate^[68-70]; and (3) OBI might contribute to progression towards cirrhosis, which is the most important risk factor for HCC development. However, further molecular pathogenesis studies and prospective molecular epidemiological studies are needed to reach the conclusion that OBI plays a major role in hepatocellular transformation. Until then, it is premature to recommend testing all HBsAg-negative patients with HCC for OBI^[62].

CONCLUSION

OBI is a complex entity that comprises many conditions and different situations. Patients who have recovered from acute hepatitis B can carry HBV genomes for a long time, and the virus might aggravate the course of their liver disease, when other causes of liver damage are present. Use of HBV-DNA NAT and multivalent anti-HBs antibodies in the HBsAg assays is recommended for detection of true and false OBI, respectively, and to minimize the risk of HBV transmission through transfusion. It is not known if

prior hepatitis B immunization with an optimal anti-HBs response can effectively modulate or abort the infection in the case of HBV transmission through organ transplantation. In patients with serological evidence of past infection with hepatitis B, prophylaxis with antiviral agents prevents reactivation of hepatitis B after transplantation in most cases. Reactivation of OBI has been observed in several other conditions that cause immunosuppression in which antiviral therapy could be delayed until HBV DNA or HBsAg becomes detectable. OBI might contribute to the progression of liver fibrosis and HCC development in patients with chronic liver disease. However, further studies are needed to clarify the clinical usefulness, safety and cost-effectiveness of strategies for management of OBI.

Abstract

AIM: To assess whether glutamate plays a similar role to glutamine in preserving gut wall integrity.

METHODS: The effects of glutamine and glutamate on induced hyperpermeability in intestinal cell lines were studied. Paracellular hyperpermeability was induced in Caco2.BBE and HT-29CL.19A cell lines by adding phorbol-12,13-dibutyrate (PDB) apically, after which the effects of glutamine and glutamate on horseradish peroxidase (HRP) diffusion were studied. An inhibitor of glutamate transport (L-trans-pyrrolidine-2,4-dicarboxylic acid: trans-PDC) and an irreversible blocker (acivicin) of the extracellular glutamine to glutamate converting enzyme, γ -glutamyltransferase, were used.

RESULTS: Apical to basolateral HRP flux increased significantly compared to controls not exposed to PDB ($n = 30$, $P < 0.001$). Glutamine application reduced hyperpermeability by 19% and 39% in the respective cell lines. Glutamate application reduced hyperpermeability by 30% and 20%, respectively. Incubation of HT29CL.19A cells with acivicin and subsequent PDB and glutamine addition increased permeability levels. Incubation of Caco2.BBE cells with trans-PDC followed by PDB and glutamate addition also resulted in high permeability levels.

CONCLUSION: Apical glutamate -similar to glutamine- can decrease induced paracellular hyperpermeability. Extracellular conversion of glutamine to glutamate and subsequent uptake of glutamate could be a pivotal step in the mechanism underlying the protective effect of glutamine.

Glutamate reduces experimental intestinal hyperpermeability and facilitates glutamine support of gut integrity. *World J Gastroenterol* 2011; 17(12): 1569-1573 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i12/1569.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i12.1569>

INTRODUCTION

Intestinal hyperpermeability, whether cause or effect, seems

to be related to the occurrence of sepsis, bacteraemia, and multiple organ failure^[1,2].

Managing this change in gut physiology might contribute to substantial health improvement. The semi-essential amino acid, glutamine, is thought to improve clinical outcome in these situations. It has been ascribed several properties that are supportive of intestinal cell function and relevant to cell survival^[3]. Additionally, plasma and muscle glutamine concentrations drop dramatically in critically ill patients^[4-6]. *In vivo* experiments, however, have not yet provided definitive evidence to support the claim that glutamine supplementation has a beneficial effect on gut permeability^[7]. In contrast, *in vitro* experiments do show a positive influence of glutamine. Kouznetsova *et al.*^[8] induced hyperpermeability in the intestinal HT-29CL19A cell line and found that glutamine significantly reduced this increased permeability. Furthermore, Le Bacquer *et al.*^[9] demonstrated that glutamine helps to preserve adequate paracellular permeability levels in nutritionally deprived intestinal Caco-2 cells. The precise mechanisms underlying these findings remain to be clarified. Glutamate might play a pivotal role in the effects of glutamine therapy considering the metabolic fate of glutamine: it is mostly converted to glutamate, either intra- or extracellularly^[10]. Welbourne *et al.*^[11] provide support for this theory by demonstrating that blocking the extracellular glutamine to glutamate converting enzyme γ -glutamyltransferase (γ -GT) and blocking glutamate uptake, both increase paracellular permeability in the proximal tubule-like LLC-PK₁-F⁺ cells.

The aim of this study was to assess whether glutamate might play a similar role in the intestine (Figure 1). To do so, an experimental model that allows differentiation between the effects of glutamine and glutamate on induced hyperpermeability in intestinal cell lines was used.

MATERIALS AND METHODS

Study design

We created an experimental set-up using two intestinal cell lines: Caco2.BBE and HT-29CL19A (both human colon adenocarcinoma derived cell lines). In culture, both cell lines exhibit polarity and apical brush-border membranes, similar to *in vivo* structure^[12,13]. Cells were therefore placed in a bicameral system to simulate a physiological situation in which they are exposed to distinct apical and basolateral compartments, and thereby allowing permeability experiments.

Paracellular hyperpermeability was induced by adding phorbol-12,13-dibutyrate (PDB) to the apical compartment after which the effects of glutamine and glutamate on horseradish peroxidase (HRP) diffusion were studied. To differentiate between the effect of glutamine and glutamate on permeability, an inhibitor of glutamate transport (L-trans-pyrrolidine-2,4-dicarboxylic acid: trans-PDC) and an irreversible blocker (acivicin) of the extracellular glutamine to glutamate converting enzyme, γ -GT, were used.

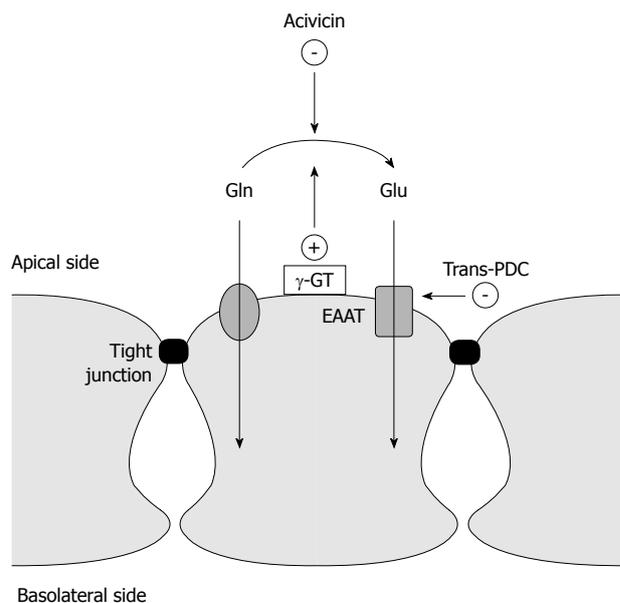

Figure 1 Model illustrating intestinal cell lineage with tight junctions and EAAT transporter. The extracellular enzymatic conversion of glutamine to glutamate by γ -glutamyltransferase (γ -GT) is shown on the apical side. The experimental design of the study using the γ -GT blocking enzyme, acivicin, and the blocker of the glutamate transporter, EAAT L-trans-pyrrolidine-2,4-dicarboxylic, is included in the figure.

Cell culture

The HT29CL19A cell line, passage number 14-35 and the Caco2.BBE cell line, passage number 34-62, were grown in Dulbecco's modified Eagle's medium supplemented with 10% fetal calf serum. The medium contained penicillin 40 mg/L, ampicillin 8 mg/L and streptomycin 9 mg/L. The cells were seeded in 12 cm² culture flasks which were placed in an incubator with a humidified atmosphere of 5% CO₂ and 95% O₂. The cells were subcultured on transparent filters (12 mm diameter; Falcon, Micronic, Lelystad, The Netherlands) for 14 (HT29CL19A) and 21 (Caco2.BBE) days to form confluent monolayers. The medium contained glutamine (2 mmol/L) and was replaced every other day. During the last 2 d before the experiments, the cells were cultured in glutamine-free medium.

Flux experiments

The culture medium was discarded after cell cultivation and filters were rinsed with Ringer's solution (containing 117.5 mmol/L NaCl, 5.7 mmol/L KCl, 25 mmol/L NaHCO₃, 1.2 mmol/L NaH₂PO₄, 2.5 mmol/L CaCl₂, 1.2 mmol/L MgSO₄ and 27.8 mmol/L mannitol, kept at pH 7.4). Filters were placed in a bicameral system with 300 μ L of Ringer's solution added to the apical chamber and 700 μ L to the basolateral chamber. The bicameral setup with filters was then placed in an incubator with humidified gas (5% CO₂, 95% O₂) where a temperature of 37°C was maintained. After an equilibration period of 30 min, HRP (type IV; Sigma Chemical Co., St Louis, MO, USA) dissolved in Ringer's solution was added apically to reach a final concentration of 10⁻⁵ mol/L. For the next 4 h, basolateral samples of 5 μ L were taken, in

triplicate, each hour and replaced by oxygenated Ringer's solution. The appearance of HRP in these samples was measured enzymatically. To this end, samples were mixed with 180 μL citrate buffer (0.1 mol/L citrate + 0.1 mol/L citric acid at pH 5.5) containing 3.6 μL bovine serum albumin (BSA 20 $\mu\text{L}/\text{mL}$). Three samples of 25 μL were taken from the resulting mixture and were added to 200 μL substrate. Substrate was prepared by adding 340 μL TMB stock (3.3-5.5 tetramethylbenzidine) (6 mg/mL in H_2O) and 200 μL 0.3% H_2O_2 to 20 mL citrate buffer.

Samples were then incubated for 30 min at normal room temperature, after which the positive samples were blue in colour. The reaction was stopped by adding 50 μL HCl (2 mol/L). The samples were read at 450 nm by a spectrophotometer. Data were recorded using Microplate Manager 5 Software, Bio-Rad Laboratories Ltd., UK.

Experiments with PKC-mediated hyperpermeability were conducted by simultaneously adding 1 $\mu\text{mol}/\text{L}$ of PDB and HRP to the apical chamber. The effects of L-glutamine (0.6 mmol/L) and L-glutamate (0.6 mmol/L) were (separately) studied by apical application with simultaneous PDB and HRP application. Acivicin experiments were conducted by incubating the cells with 10 μL of the following solution: 1.7 mg acivicin, dissolved in 50 μL HCl (2.0 mol/L) and 50 μL DES (buffering the medium). Inhibition of glutamate transporters EAAT 1-5 was achieved by pre-incubating the cells with 1 mmol/L trans-PDC.

Chemicals

Falcon filters were obtained from Micronic (Lelystad, The Netherlands), penicillin/streptomycin from Boehringer Mannheim (Almere, The Netherlands) and ampicillin from Sigma-Aldrich Chemie BV (Zwijndrecht, the Netherlands). All other cell culture materials were obtained from Gibco (Breda, the Netherlands). Chemicals used for the Ringer's solution were obtained from Merck (Merck Nederland BV, Amsterdam). PDB, L-glutamate, L-glutamine and trans-PDC were obtained from Sigma-Aldrich Chemie BV (Zwijndrecht, The Netherlands).

Statistical analysis

Statistical analyses of differences between groups were performed by one way ANOVA and the Tukey-Kramer test. A P -value < 0.05 was considered significant. HRP flux results are presented graphically as percentages of total flux. Total flux is defined by the HRP + PDB groups, which therefore represent the 100% mark. Graphpad Prism 3.03 for Windows[®] (GraphPad Software Inc., California, USA) was used for analyses and graphical output.

RESULTS

Hyperpermeability was successfully induced by PDB stimulation: apical to basolateral HRP flux increased significantly in the HT29Cl.19A and the Caco2.BBE cell line (with a maximum after 4 h) compared to controls not exposed to PDB ($n = 30$, $P < 0.001$). Cells in the PDB group defined the 100% mark, and all values were

composed of triplicate measurements per group per experiment and were repeated 3-11 times.

In HT29Cl.19A cells, glutamine application reduced hyperpermeability by 45% ($n = 11$, $P < 0.001$) (Figure 2A). In the Caco2.BBE cell line, glutamine application reduced hyperpermeability by 30% ($n = 3$, $P < 0.05$) (Figure 2B).

Glutamate application reduced hyperpermeability by 25% in the HT29Cl.19A cell line ($n = 3$, $P < 0.01$) (Figure 2C) and by 25% in the Caco2.BBE cell line ($n = 4$, $P < 0.001$) (Figure 2D).

Incubation of HT29CL.19A cells with acivicin and subsequent PDB and glutamine addition resulted in high permeability levels which were not significantly different from the PDB group ($n = 11$, Figure 2A).

Incubation of Caco2.BBE cells with trans-PDC and subsequent PDB and glutamate addition also resulted in high permeability levels, once again not significantly different from the PDB group ($n = 4$, Figure 2D).

Control experiments revealed that acivicin and trans-PDC did not alter HRP permeability (results not shown).

DISCUSSION

We found that both glutamine and glutamate can reduce an induced form of hyperpermeability in human colon derived cell lines. The effect of glutamine could be nullified by blocking the extracellular converting enzyme, γ -GT, whereas the effect of glutamate could be nullified by blocking the glutamate transporters EAAT 1-5.

These results lead to two suggestions: firstly, the conversion of glutamine to glutamate is essential for its beneficial effect on permeability. Secondly, transport of glutamate into the cell is essential for the beneficial effect of glutamate on permeability.

Because the effect of trans-PDC on the protective action of glutamine was not studied, and similarly, the effect of acivicin on the protective action of glutamine was not studied, further research will be necessary to confirm these suggestions. Not all of the experiments were performed with both cell lines due to inherent differences between the two cell lineages. The HT29Cl.19A cell line proved unstable during later experiments compared to the Caco2.BBE cell line. Additionally, the Caco2.BBE cell line has been shown to possess EAATs^[14], making it the favourable cell line for trans-PDC related experiments. Moreover, these inconsistencies might account for the observed differences in the reduction of induced hyperpermeability between the cell lines^[15]. However, our study design was not focussed or powered on cell line comparison.

Glutamine and glutamate seem to reduce this hyperpermeability by acting on the paracellular permeability (tight junction) as opposed to transcellular permeability (endocytosis). PDB, induces a Protein Kinase C (PKC)-mediated hyperpermeability. This signal transduction pathway is also activated by clinically relevant mediators, including lipopolysaccharides^[16]. PKC is thought to regulate tight junction (TJ) permeability *via* tightening and loosening of the cell's perijunctional actomyosin ring

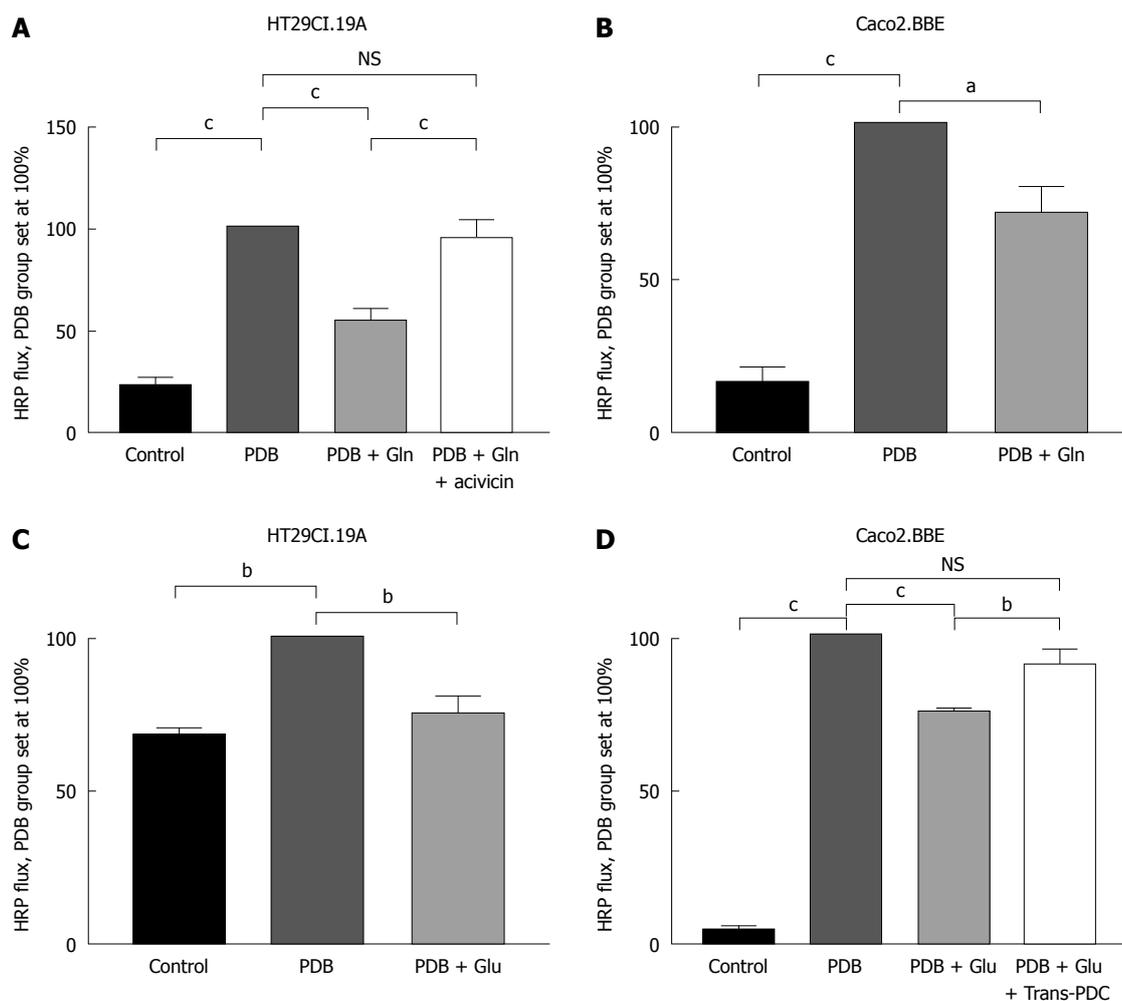

Figure 2 Effects of glutamine and glutamate on phorbol-12,13-dibutyrate-induced permeability in the two intestinal cell lines. A: In the HT29Cl.19A cell line, glutamine addition resulted in a 45% decrease in permeability. Acivicin nullified this effect, $n = 6$; B: In the Caco2.BBE cell line, glutamine addition resulted in a 30% decrease in permeability, $n = 3$; C: In the HT29Cl.19A cell line, glutamate addition resulted in a 25% decrease in permeability, $n = 3$; D: In the Caco2.BBE cell line, glutamate addition resulted in a 25% decrease in permeability. Trans-PDC nullified this effect, $n = 4$. ^a $P < 0.05$, ^b $P < 0.01$, ^c $P < 0.01$.

(PAMR)^[17-19]. Furthermore, rinsing the PDB from the cells restored permeability levels to control values, indicating that the effect of PDB is not due to cell destruction (results not shown). In such, PDB addition creates a paracellular hyperpermeability which can be monitored by HRP diffusion from apical to basolateral compartments.

HRP needs to remain enzymatically active to be measured. Approximately 97% of the HRP that reaches the basolateral compartment *via* the transcellular pathway is degraded^[20,21] and loses its enzyme activity. The detection of enzymatically active HRP in this study therefore verified that we measured paracellular permeability.

Our results suggest that glutamine needs transamination to glutamate to exert its effect. In a broader scope, it would be interesting to quantify the transamination by glutaminase intracellularly. However, since blocking γ -GT extracellularly immediately showed a decrease in the effect of glutamine, the extracellular conversion seems important independent of intracellular mechanisms.

The protective effect of glutamine on gut mucosa is often thought to result from cell proliferation and at-

tenuation of apoptosis^[22]. Our study indicates that this is probably not the sole reason. HRP flux was inhibited within the four hour window of this study. Enterocyte proliferation, however, takes more than 4 h, thus cell proliferation can not (completely) explain the observed favourable effect. To exclude indirect effects of glutamine and glutamate metabolism, the measurement of metabolites by HPLC could pinpoint such effects.

Proliferation and maintaining the integrity of enterocytes requires an adequate supply of glutamine. Hence, plasma levels are normally maintained around 0.6 mmol/L^[23,24]. This physiological concentration was therefore used in the present study. For easier comparison the glutamate concentration was also set at 0.6 mmol/L, even though its physiological concentration approaches 24-80 μ mol/L^[23,24].

The 0.6 mmol/L of glutamine and glutamate were applied to the apical chamber. *In vivo*, however, luminal concentrations of glutamine and glutamate commonly exceed 0.6 mmol/L after protein-rich meals^[25]. It is, therefore, interesting to see that this concentration can already elicit advantageous effects. Future studies comparing differ-

ent concentrations of glutamine and glutamate should be performed to optimally quantify dosage effects. To allow a comparison with catabolic patients, it would also be interesting to detect a minimum dose of glutamine and glutamate which still elicits a protective effect on hyperpermeability.

In summary, we have shown that apical glutamate-similar to glutamine can decrease an induced paracellular hyperpermeability in two human colon derived cell lines. Because of the nature of the permeability inducing agent, PDB, glutamine and glutamate probably exert their effect through interaction with tight junctions. Furthermore, the extracellular conversion of glutamine to glutamate and the subsequent uptake of glutamate could be a pivotal step in the mechanism underlying the protective effect of glutamine. Yet, to certify this mechanism, the focus should be on different concentrations of apically applied glutamine and glutamate in different cell lines or in co-cultured cell lines, in parallel with research on intracellular conversion.

COMMENTS

Background

Intestinal hyperpermeability seems to be related to the occurrence of sepsis, bacteraemia, and multiple organ failure. The semi-essential amino acid, glutamine, is thought to improve clinical outcome in these situations. Glutamate might play a pivotal role in the effects of glutamine therapy considering the metabolic fate of glutamine: it is mostly converted to glutamate.

Research frontiers

The authors found that both glutamine and glutamate can reduce an induced form of hyperpermeability in colon cell lines.

Innovations and breakthroughs

Glutamine and glutamate seem to reduce this hyperpermeability by acting on paracellular permeability as opposed to transcellular permeability.

Applications

These results suggest further research on glutamate in feeding.

Peer review

The paper by Vermeulen *et al* describes experiments demonstrating that glutamate has a similar protective effect on intestinal hyperpermeability as glutamine. The used two different cell lines and appropriate inhibitors to show that extracellular conversion of glutamine to glutamate and subsequent uptake of glutamate could be a pivotal step in the mechanism underlying the protective action of glutamine. This is the first report showing the protective effect of glutamate itself.

Abstract

AIM: To elucidate the effect and underlying mechanisms of omeprazole action on Mg^{2+} transport across the intestinal epithelium.

METHODS: Caco-2 monolayers were cultured in various dose omeprazole-containing media for 14 or 21 d before being inserted into a modified Ussing chamber apparatus to investigate the bi-directional Mg^{2+} transport and electrical parameters. Paracellular permeability of the monolayer was also observed by the dilution potential technique and a cation permeability study. An Arrhenius plot was performed to elucidate the activation energy of passive Mg^{2+} transport across the Caco-2 monolayers.

RESULTS: Both apical to basolateral and basolateral to apical passive Mg^{2+} fluxes of omeprazole-treated epithelium were decreased in a dose- and time-dependent manner. Omeprazole also decreased the paracellular cation selectivity and changed the paracellular selective permeability profile of Caco-2 epithelium to Li^+ , Na^+ , K^+ ,

Rb^+ , and Cs^+ from series VII to series VI of the Eisenman sequence. The Arrhenius plot revealed the higher activation energy for passive Mg^{2+} transport in omeprazole-treated epithelium than that of control epithelium, indicating that omeprazole affected the paracellular channel of Caco-2 epithelium in such a way that Mg^{2+} movement was impeded.

CONCLUSION: Omeprazole decreased paracellular cation permeability and increased the activation energy for passive Mg^{2+} transport of Caco-2 monolayers that led to the suppression of passive Mg^{2+} absorption.

INTRODUCTION

Magnesium plays an important role in numerous biological functions. Mg^{2+} deficiency is associated with several diseases, e.g. Alzheimer's disease^[1], osteoporosis^[2], and hypertension^[3]. Therefore, its plasma level is tightly regulated within a narrow range (0.7-1.1 mmol/L) by intestinal absorption and renal excretion^[4]. In human intestine, fractional Mg^{2+} absorption varies from 11% to 65% depending on the amount of Mg^{2+} intake^[5]. Intestinal epithelium absorbs Mg^{2+} via both saturable transcellular and non-saturable paracellular pathways. Transcellular Mg^{2+} transport is an

active process that requires the activity of transient receptor potential melastatin 6 (TRPM6) and the basolateral Na⁺/Mg²⁺ exchanger^[6,7]. On the other hand, paracellular Mg²⁺ transport is a passive mechanism and is implicated in about 90% of intestinal Mg²⁺ absorption^[7]. The paracellular Mg²⁺ transport process is modulated by the tight junction proteins, i.e. Claudin-16 and Claudin-19^[8].

Omeprazole is a common therapeutic tool for acid-peptic disorders. Its active sulphenamide form selectively and covalently interacts with the H⁺/K⁺-ATPase, particularly the extracellular cysteine 813, leading to potent inhibition of H⁺/K⁺-ATPase activity^[9]. Previous reports demonstrated that prolonged omeprazole administration led to hypomagnesemia and hypomagnesuria in humans^[10,11]. Withdrawal of omeprazole and intravenous Mg²⁺ replacement, but not high dose oral Mg²⁺ supplement, could normalize the plasma and urinary Mg²⁺ levels^[10,12]. Renal Mg²⁺ handling was normal in patients with severe hypomagnesemia associated with long-term use of omeprazole^[12-14]. This body of evidence suggested an inhibitory effect of omeprazole on intestinal Mg²⁺ absorption. However, the direct action of omeprazole on intestinal Mg²⁺ transport is still elusive. The present study, therefore, aimed to elucidate the effect of omeprazole as well as obtain information regarding possible mechanisms of omeprazole action on Mg²⁺ transport across the intestinal epithelium. This study employed a monolayer of Caco-2 cells which is a suitable *in vitro* model for studying intestinal transport of divalent cations, e.g. Ca²⁺^[15] and Mg²⁺^[16].

MATERIALS AND METHODS

Cell culture

Caco-2 cells (ATCC No. HTB-37) were grown in Dulbecco's modified Eagle medium (DMEM) (Sigma, St. Louis, MO, USA) supplemented with 15% fetal bovine serum (FBS-Gold) (PAA Laboratories GmbH, Pasching, Austria), 1% L-glutamine (Gibco, Grand Island, NY, USA), 1% non-essential amino acid (Sigma, St. Louis, MO, USA), and 1% antibiotic-antimycotic solution (Gibco, Grand Island, NY, USA) and maintained at a humidified atmosphere containing 5% CO₂ at 37°C. The Caco-2 monolayers were developed by seeding cells (5.0 × 10⁵ cells/cm²) onto permeable Snapwell[™] inserts (12-mm diameter and 0.4-μm pore size polyester filter) (Corning, Corning, NY, USA). In the omeprazole-treated group, Caco-2 monolayers were grown in 200, 400, 600, 800, or 1000 ng/mL omeprazole (Calbiochem, San Diego, CA, USA) containing culture media. The culture medium was changed three times a week. On day 14 or 21 after seeding, the Snapwell was inserted into a modified Ussing chamber (1.13 cm² exposed area).

Measurement of Mg²⁺ flux

In the Ussing chamber, the monolayer was equilibrated for 20 min in bathing solution at 37°C, pH 7.4, and osmolarity of 290-293 mmol/kg H₂O^[17]. To avoid the unstirred water layer and to maintain pH at 7.4, the bathing solution in each hemi-chamber was continuously gassed with humidified 5% CO₂ in 95% O₂. After equilibration, the api-

cal or basolateral bathing solution was replaced with 2.5, 5, 10, 20, 40, or 80 mmol/L MgCl₂-containing bathing solution, while the contralateral side was replaced with MgCl₂-free bathing solution. At 1 and 2 h, 500 μL solution was collected from the side that contained MgCl₂-free bathing solution and Mg²⁺ concentration was measured. Mg²⁺ flux (nmol/h per cm²) was calculated using Equation (Eq. 1):

$$\text{Mg}^{2+} \text{ flux} = C_{\text{Mg}} / (t \times S) \quad (1)$$

Where C_{Mg} is Mg²⁺ concentration (nmol/L); t is time (h); and S is transport surface area (cm²).

To elucidate the involvement of solvent drag-induced mechanism on Mg²⁺ transport, 100 μmol/L phlorizin (Fluka Chemie AG, Buchs, Switzerland) and 100 μmol/L phloretin (Calbiochem, San Diego, CA, USA) were added to the apical and basolateral solution, respectively. Mg²⁺ transport was also observed at different temperatures (15, 25, or 35°C) and the results were presented as an Arrhenius plot^[18] (Eq. 2):

$$\ln(P_{\text{Mg}}) = (-E_a) / (RT) + \ln(E) \quad (2)$$

Where $\ln(P_{\text{Mg}})$ is the natural logarithm of Mg²⁺ permeability (cm/s); E_a is activation energy (kJ/mol); R is gas constant; T is absolute temperature (273+°C), E is pre-exponential factor. The temperature coefficient Q_{10} was determined as previously described^[19].

Measurement of Mg²⁺ concentration

The concentration of Mg²⁺ was determined by Xylidyl Blue (Sigma, St. Louis, MO, USA) colorimetric assay, modified from the method of Tang and Goodenough^[20]. In brief, the sample solutions were spun at 1000 × g for 10 min and a 200 μL sample of the upper solution was collected. An aliquot was added to 100 μL water, gently mixed, and then 200 μL of 1.25 mmol/L EGTA was added to the assay tube. After mixing well, 500 μL of Xylidyl Blue solution (pH 10.5) was added to the assay tube. After 5 min of incubation at room temperature, the assay solution was subjected to colorimetric analysis using a spectrophotometer at 520 nm (model UV-2550; Shimadzu, Kyoto, Japan).

Measurement of epithelial electrical parameters

Trans-epithelium resistance (TER), potential difference (PD), and short-circuit current (I_{sc}) were determined as previously described^[21]. These electrical parameters were recorded after 20 min equilibration at 30 min intervals throughout the 2 h of Mg²⁺ flux study.

Ion permeability measurement

Absolute permeabilities of Na⁺ (P_{Na}) and Cl⁻ (P_{Cl}), as well as the relative permeability of Na⁺ to Cl⁻ ($P_{\text{Na}}/P_{\text{Cl}}$), of Caco-2 monolayers were obtained by the dilution potential technique as previously described^[21]. The absolute permeability of group I alkaline metals (Li⁺, K⁺, Rb⁺, and Cs⁺), i.e. P_{Li} , P_{K} , P_{Rb} , and P_{Cs} was determined as previously described^[21] using the same calculation as that used to obtain P_{Na} .

The Mg²⁺ permeability (P_{Mg}) of Caco-2 monolayers was calculated using Eq. 3:

$$P_{\text{Mg}} = \text{Mg}^{2+} \text{ flux} / \Delta C_{\text{Mg}} \quad (3)$$

Mg²⁺ transport kinetic analysis

To estimate the kinetic values of the saturable active and non-saturable passive Mg²⁺ transport, the rate of apical to basolateral Mg²⁺ transport (Mg_{A→B} transport) was fitted to a modified Michaelis-Menten kinetic plus linear component as shown in Eq. 4:

$$\text{Mg}_{A \rightarrow B} \text{ transport} = (V_m \times C_{Mg}) / (K_m + C_{Mg}) + mC_{Mg} \quad (4)$$

Where V_m is the maximal rate of saturable Mg_{A→B} transport; K_m is the rate constant of saturable Mg_{A→B} transport; m is the rate constant for non-saturable Mg_{A→B} transport; and C_{Mg} as mentioned above. This study was performed using a nonlinear regression program of GraphPad Prism version 5.0 for Window (GraphPad Software Inc., San Diego, CA, USA).

Statistical analysis

Results were expressed as means ± SE. Two sets of data were compared using the unpaired Student's *t*-test. One-way analysis of variance (ANOVA) with Dunnett's posttest was employed for multiple sets of data. The level of significance was P < 0.05. Linear regression and slope analysis were performed to obtain the basolateral to apical Mg²⁺ transport (Mg_{B→A} transport)-Mg concentration relationship. The curve of P_{Mg}-Δmagnesium relationship was obtained using one phase exponential decay equation. All data were analyzed by GraphPad Prism (GraphPad Software Inc.).

RESULTS

Omeprazole decreased Mg_{A→B} transport and P_{Mg} in both a dose- and time-dependent manner

As demonstrated in Figure 1, the Mg_{A→B} transport vs Mg²⁺ concentration plots of Caco-2 monolayers were curvi-

linear similar to that reported in humans^[5]. After 14 d in the omeprazole-treated groups, Mg_{A→B} transport was inhibited when compared with its corresponding untreated group (Figures 1A-F). The level of inhibition progressively increased with higher concentrations of omeprazole. Omeprazole selectively decreased non-saturable Mg_{A→B} transport, but not the saturated component, as clearly demonstrated by the lower rate constant for non-saturable Mg_{A→B} transport (Table 1). For 21 d omeprazole-treated groups, the results were similar to those of the 14 d omeprazole-treatment (Figure 1G-L, Table 1). When the same omeprazole concentration was considered, 21 d-treated groups showed a significantly lower Mg_{A→B} transport than the 14 d-treated groups (Figure 1, Table 1). Therefore, omeprazole decreased Mg_{A→B} transport in a dose- and time-dependent manner. According to the Mg_{A→B} transport, omeprazole also decreased the apical to basolateral P_{Mg} in a dose- and time-dependent mechanism (Figure 2). Moreover, omeprazole significantly increased TER, but not PD or I_{sc}, of Caco-2 monolayers (Table 2), indicating the lower paracellular permeability to ion transport.

Omeprazole decreased Mg_{B→A} transport

Since the Mg_{B→A} transport occurred solely through the paracellular pathway, the Mg_{B→A} transport vs Mg²⁺ concentration plot was linear (Figure 3A). Omeprazole significantly decreased the slope of the Mg_{B→A} transport-Mg²⁺ concentration plot. The slope progressively decreased with increased concentration of omeprazole (Figure 3A). In addition, omeprazole significantly suppressed the basolateral to apical P_{Mg} in a dose-dependent manner (Figure 3B). The collective results clearly showed that omeprazole suppressed paracellular passive Mg²⁺ transport across Caco-2 monolayers.

Omeprazole decreased paracellular cation selectivity

Similar to previous reports^[21,22], Caco-2 monolayers

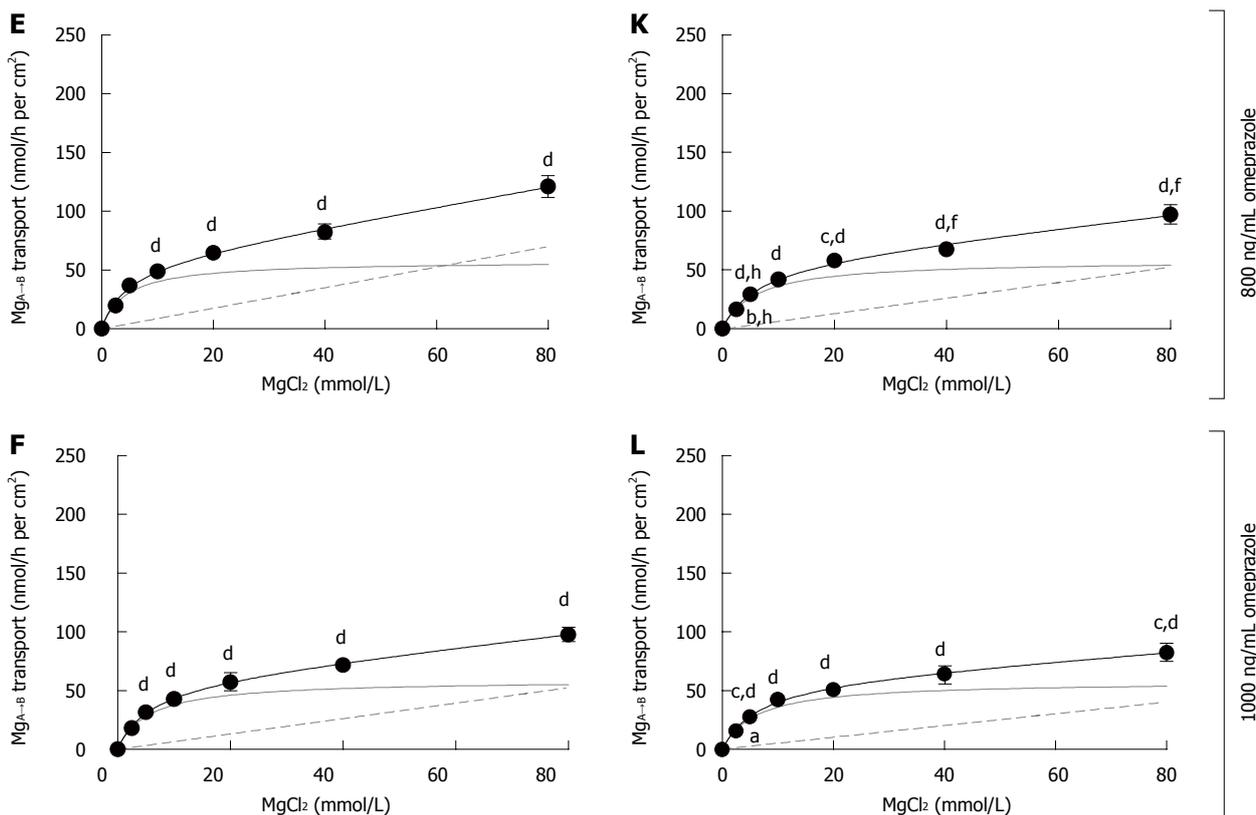

Figure 1 Mg_{A-B} transport across Caco-2 monolayers. For Mg_{A-B} transport of 14 d monolayers, A: Control; B: 200 ng/mL omeprazole-treated; C: 400 ng/mL omeprazole-treated; D: 600 ng/mL omeprazole-treated; E: 800 ng/mL omeprazole-treated; and F: 1000 ng/mL omeprazole-treated monolayers. For Mg_{A-B} transport of 21 d monolayers, G: control; H: 200 ng/mL omeprazole-treated; I: 400 ng/mL omeprazole-treated; J: 600 ng/mL omeprazole-treated and L: 1000 ng/mL omeprazole-treated monolayers. Light solid lines represent the saturable component. Dashed lines represent the non-saturable component. ^a*P* < 0.05, ^b*P* < 0.01, ^d*P* < 0.001 vs the age-matched control group, ^c*P* < 0.05, ^f*P* < 0.01, ^h*P* < 0.001 vs the concentration-matched 14 d omeprazole-treated groups. For each data point, *n* = 9.

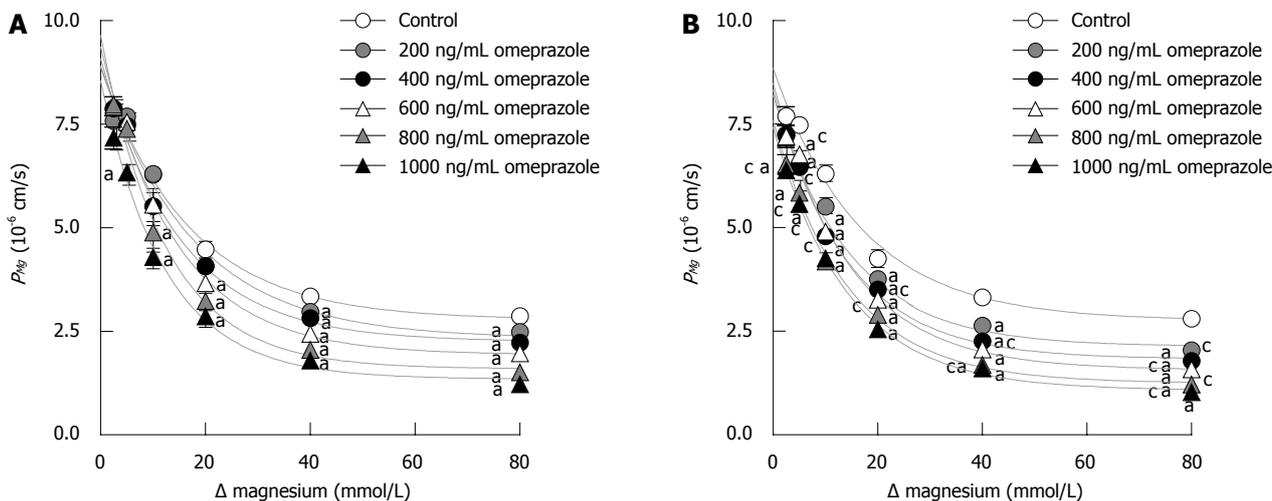

Figure 2 Apical to basolateral *P_{Mg}*. A: *P_{Mg}* of 14 d control and various dose omeprazole-treated monolayers; B: 21 d control and various dose omeprazole-treated monolayers. ^a*P* < 0.05 vs the age-matched control group, ^c*P* < 0.05 vs the concentration-matched 14 d omeprazole-treated group. For each data point, *n* = 9.

showed high *P_{Na}/P_{Cl}* (3.79 ± 0.15 in 14 d monolayers; 3.96 ± 0.22 in 21 d monolayers) from the higher *P_{Na}* (8.28 ± 0.20 in 14 d monolayers; 8.11 ± 0.25 in 21 d monolayers) than *P_{Cl}* (2.08 ± 0.09 in 14 d monolayers; 2.07 ± 0.11 in 21 d monolayers) (Figure 4A-C). Therefore, the Caco-2 monolayer was a cation selective epithelium. In 14 d- as well as

21 d-omeprazole-treated groups, omeprazole significantly suppressed *P_{Na}/P_{Cl}* and *P_{Na}* but enhanced *P_{Cl}* in a dose-dependent manner (Figure 4A-C), indicating that omeprazole decreased cation selectivity of Caco-2 monolayers.

Moreover, the present study also examined the paracellular permeability to monovalent cations, i.e. Li⁺, Na⁺,

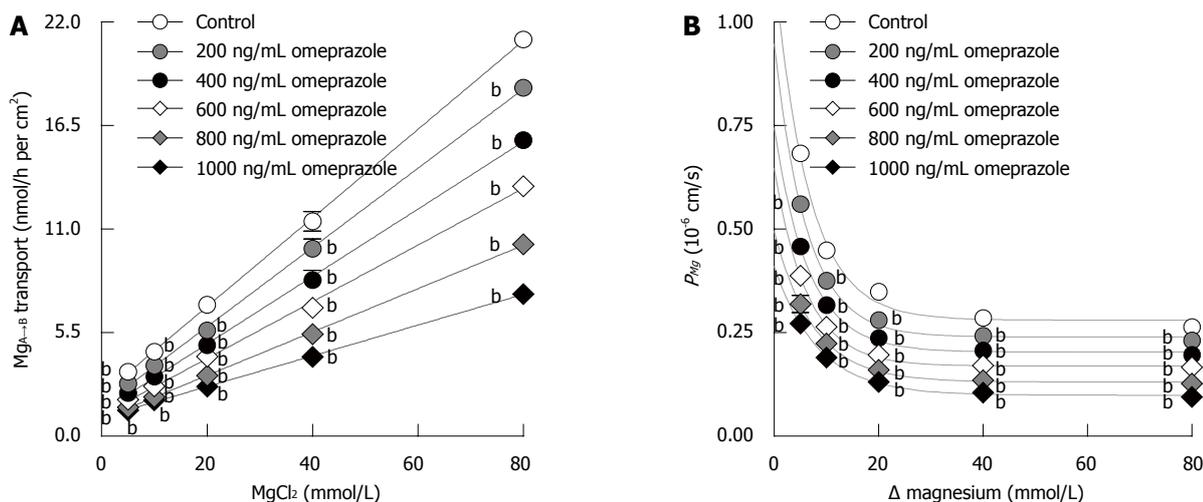

Figure 3 Mg_{B-A} transport and basolateral to apical P_{Mg} . A: Mg_{B-A} transport; B: Basolateral to apical P_{Mg} of 14 d control and various dose omeprazole-treated monolayers. ^b $P < 0.01$ vs the control group. For each data point, $n = 6$.

K⁺, Rb⁺, and Cs⁺. In control conditions, Caco-2 monolayers showed the following selective sequence: P_{Na} (8.62 ± 0.18) > P_K (7.99 ± 0.19) > P_{Rb} (5.84 ± 0.08) > P_{Cs} (4.82 ± 0.07) > P_{Li} (3.98 ± 0.12) (Figure 4D). Interestingly, 14 d-omeprazole (600 ng/mL)-exposed monolayers showed a different permeability sequence as follows: $P_K > P_{Na} > P_{Rb} > P_{Cs} > P_{Li}$ (Figure 4D). In addition, omeprazole also inhibited Caco-2 permeability to all of these monovalent cations in a dose-dependent manner.

In a parallel study, TER was simultaneously recorded when the monolayers were exposed to group I alkaline metals containing solution. In control conditions, Caco-2 monolayers showed the highest conductance (lowest TER) to Na⁺ (Figure 4E). The TER-Pauling radii relationship showed a V-shaped profile. Omeprazole-treated Caco-2 monolayers showed the lowest TER when the primary ion was K⁺ (Figure 4E). Omeprazole also changed the TER-Pauling radii graph to a U-shape relationship and increased TER in all groups.

Omeprazole inhibited paracellular Mg²⁺ transport

Theoretically, ions can move transversely across Caco-2 monolayer *via* four transport mechanisms, i.e. solvent drag-induced active, voltage dependent active, transcellular active, and paracellular passive transport. Therefore, the present experiment aimed to identify the relative involvement of each mechanism in Mg²⁺ transport across Caco-2 monolayers. Inhibitors of solvent drag-induced ion transport (phlorizin and phloretin) had no effect on Mg_{A→B} transport (40 mmol/L Mg²⁺ concentration gradient) in both control and omeprazole-treated monolayers (Figure 5D). In another set of experiments, Caco-2 monolayers received continuous application of I_{SC} , simultaneously with the Mg²⁺ flux study, to nullify trans-epithelial PD and to abolish voltage dependent Mg²⁺ transport. The Mg_{A→B} transport in both control and omeprazole-treated monolayers were unaffected by I_{SC} , (Figure 5A). The results indicated that solvent drag-induced and voltage dependent Mg_{A→B} transport were negligible.

Since transcellular Mg²⁺ transport required apical Mg²⁺ influx, inhibition of Mg²⁺ influx should abolish Mg²⁺ transport. When 20 μmol/L ruthenium red (RR), a TRPM6 inhibitor^[23], was added to the apical solution, a linear relationship between Mg_{A→B} transport and Mg²⁺ concentration was observed (Figure 5B). The rate constant for non-saturable Mg_{A→B} transport of control monolayers (2.18 ± 0.13) was not different from the slope of Mg_{A→B} transport (2.09 ± 0.06) of RR-treated control monolayers. In parallel experiments, 14 d-600 ng/mL omeprazole-treated monolayers were bathed in bathing solution with or without 20 μmol/L RR (Figure 5C). Similar to control conditions, RR inhibited the saturable component, but not the non-saturable component, of Mg_{A→B} transport in omeprazole-treated monolayers. In RR-treated monolayers, the 14 d-omeprazole-treated group showed a less steep slope when compared with that of the control group (1.29 ± 0.04 vs 2.09 ± 0.06 , $P < 0.001$, Figure 5B and C). Therefore, omeprazole suppressed the non-saturable passive Mg²⁺ transport across Caco-2 monolayers.

Temperature dependent Mg²⁺ permeability

To elucidate the temperature dependent Mg²⁺ transport, Caco-2 monolayers were bathed in 40 mmol/L MgCl₂ containing apical solution, while the basolateral solution had no MgCl₂. As shown by the Arrhenius plot (Figure 5E), the $\ln(P_{Mg})$ decreased in lower temperatures. The control monolayers showed E_a of 14.28 ± 1.19 kJ/mol and Q_{10} of 1.22 ± 0.04 . Fourteen days of 600 ng/mL omeprazole exposure significantly suppressed Mg²⁺ transport and increased E_a (19.24 ± 1.98 kJ/mol, $P < 0.05$), but not Q_{10} (1.31 ± 0.05), of Caco-2 monolayers.

DISCUSSION

The present study demonstrated the effect of omeprazole on Mg²⁺ transport across Caco-2 intestinal epithelium. Omeprazole-treated monolayers showed a dose- and time-dependent decrease in Mg²⁺ transport and P_{Mg} (Figures 1-3).

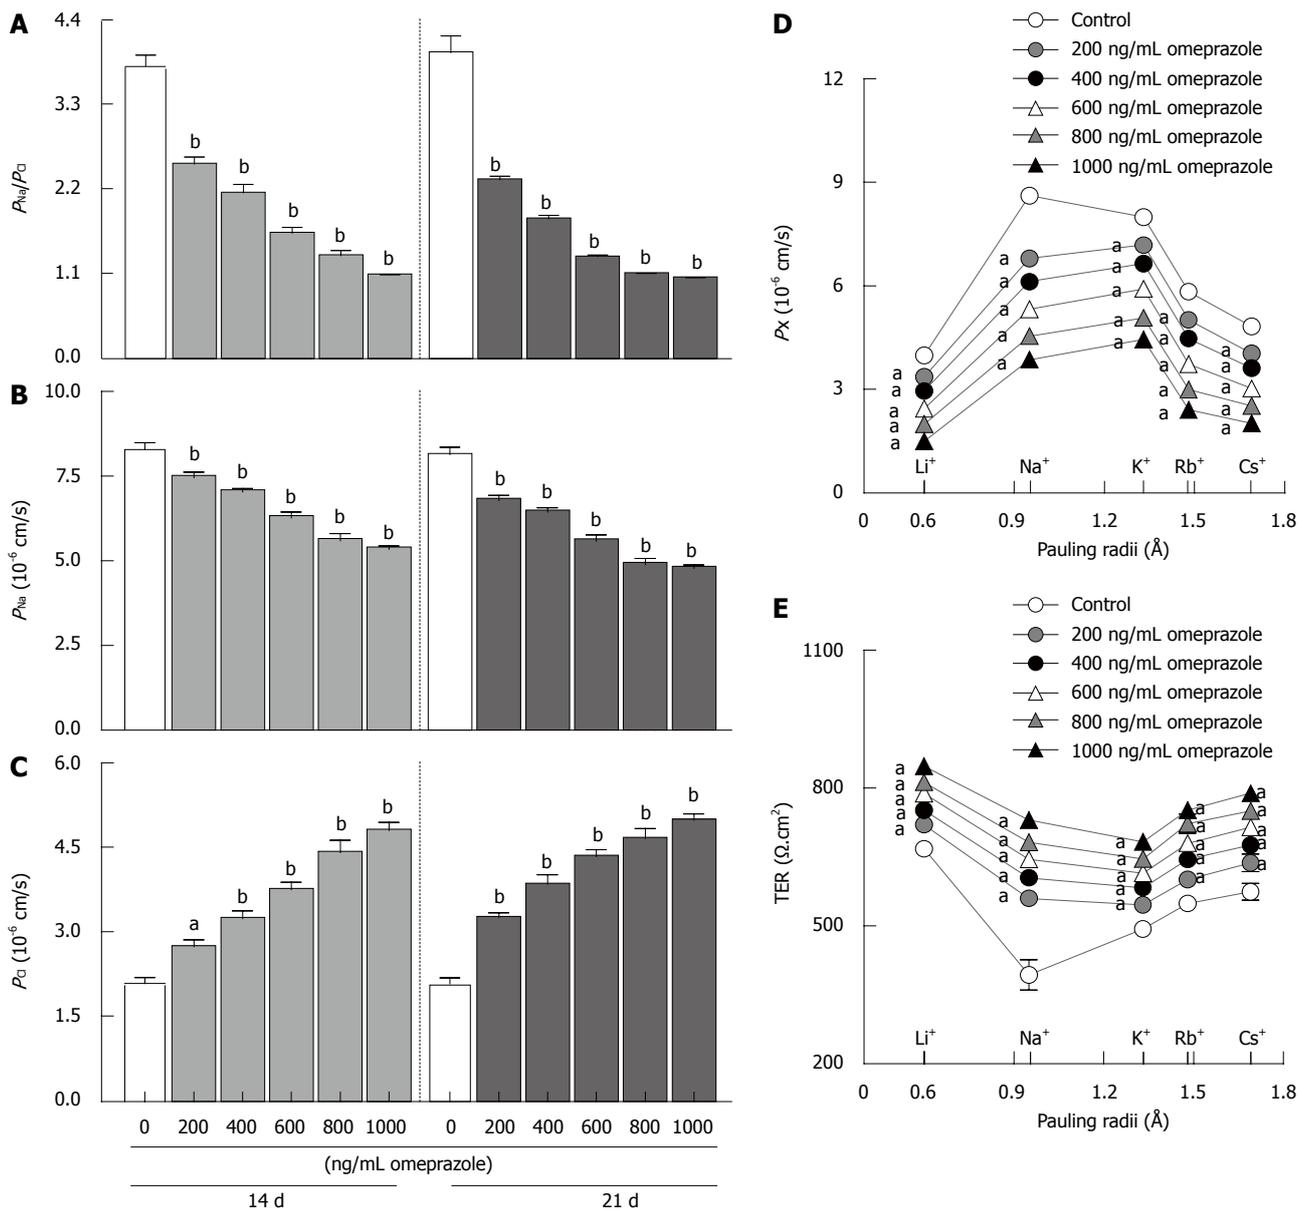

Figure 4 Paracellular charge selectivity and selective permeability profile. For each data point, $n = 6$.

Omeprazole selectively inhibited the non-saturable passive component, but not the saturable active component, of transepithelial Mg²⁺ transport (Table 1 and Figure 5). The paracellular cation selectivity of the monolayers was also reduced after prolonged exposure to omeprazole (Figure 4). Results of the Arrhenius plot (Figure 5) showed the higher E_a in the omeprazole-treated group, indicating impediment of the paracellular channel to Mg²⁺ movement.

In humans, intestinal Mg²⁺ absorption *vs* Mg²⁺ intake exhibited a curvilinear relationship^[5] from the combination of saturable active and non-saturable passive absorption. Moreover, lower intestinal passive Mg²⁺ absorption as compared with passive Ca²⁺ absorption was also demonstrated^[5,24]. Similarly, in Caco-2 monolayers, a plot of Mg_{A→B} transport (representing Mg²⁺ absorption) against Mg²⁺ concentration (in apical solution) was also curvilinear

(Figure 1) and Mg_{A→B} transport was lower than the apical to basolateral Ca²⁺ transport^[21]. Therefore, the Caco-2 monolayer was a suitable *in vitro* model of intestinal Mg²⁺ absorption^[16].

Several case reports demonstrated severe hypomagnesemia associated with prolonged omeprazole usage^[10-14], suggesting that intestinal Mg²⁺ absorption, but not renal Mg²⁺ handling, was defective. On the other hand, short-term omeprazole administration had no effect on intestinal Mg²⁺ absorption^[25] because its bioavailability was low and its half-life was short^[9,26]. Therefore, the later development of hypomagnesemia was probably associated with the depletion of Mg²⁺ store in the human body^[13]. The present study demonstrated an inhibitory effect of omeprazole on Mg²⁺ fluxes across 14 and 21 d-omeprazole-treated Caco-2 monolayers, suggesting that the intes-

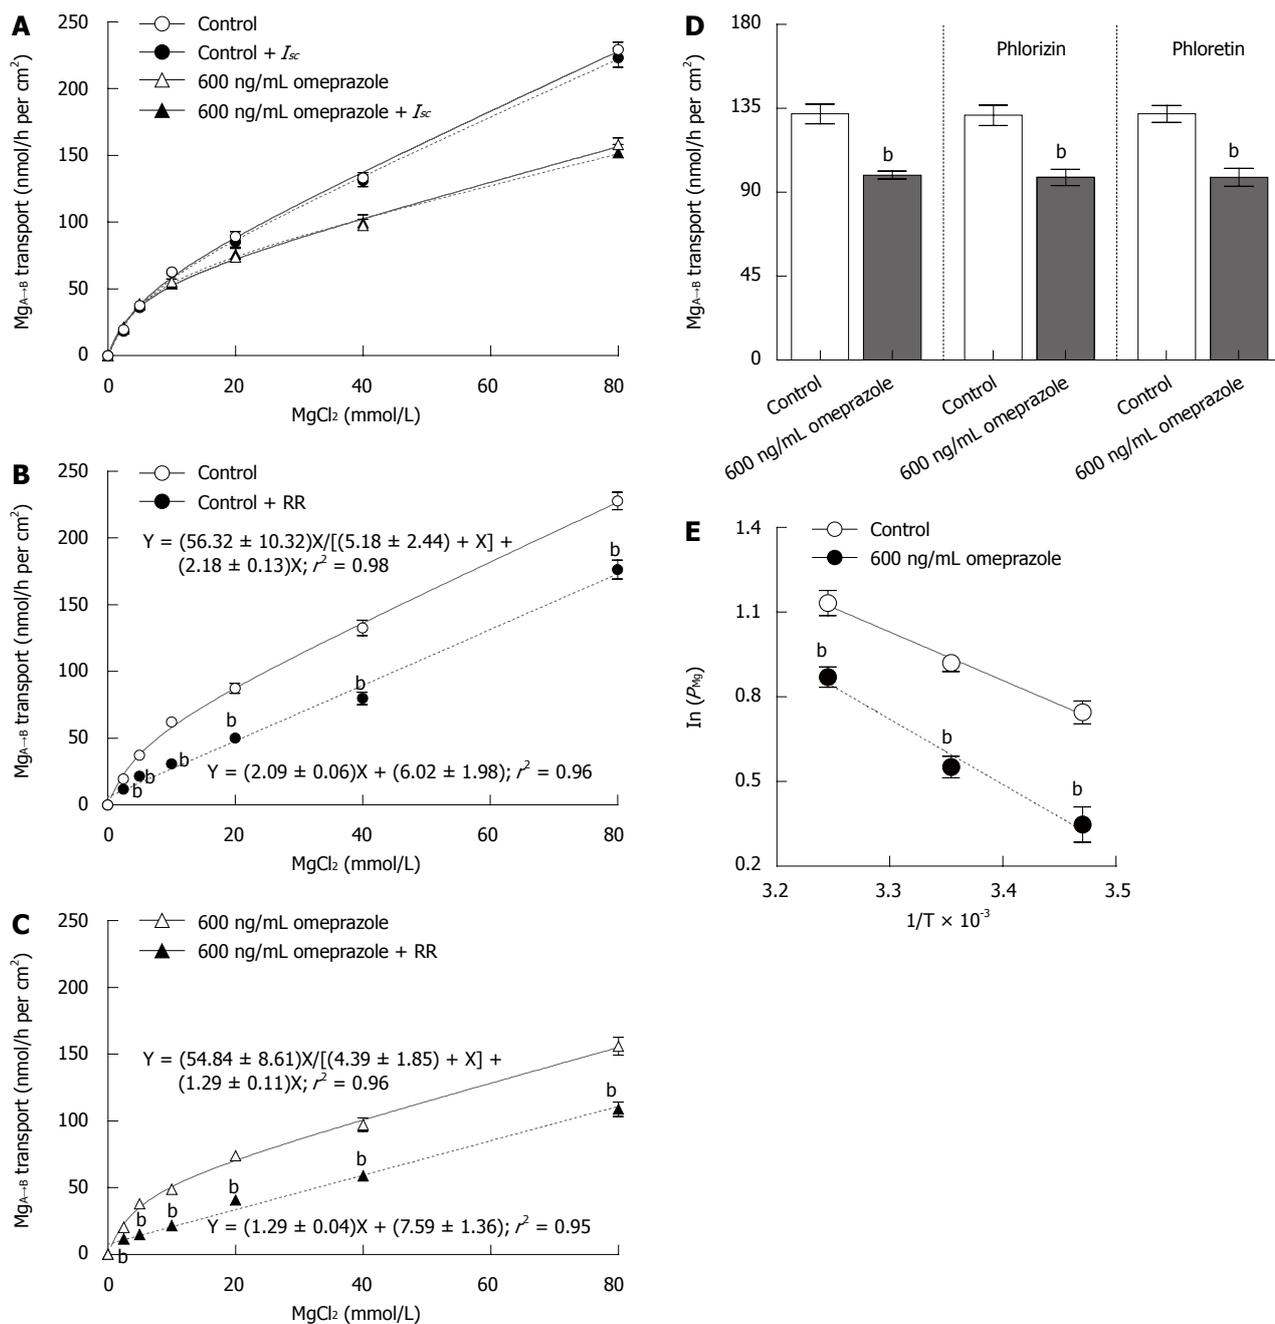

Figure 5 Mechanism of Mg_{A-B} transport. tinal Mg²⁺ flux defect could not be responsible for later development of hypomagnesemia in omeprazole use.

There are two transport mechanisms for Mg²⁺ absorption, i.e. transcellular active and paracellular passive transport, across the intestinal epithelium^[7]. Previous reports suggested that omeprazole inhibited active intestinal Mg²⁺ absorption and TRPM6 activity because high dose oral Mg²⁺ supplement partially^[13] and totally^[14] resolved hypomagnesemia in prolonged omeprazole use. On the other hand, other reports showed different results i.e. high dose oral Mg²⁺ supplement, but not intravenous Mg²⁺ replacement and withdrawal of omeprazole, failed to normalize plasma and urinary Mg²⁺ levels^[10,12]. The later evidence

indicated that omeprazole inhibited passive Mg²⁺ absorption, which agreed with the present findings. In the present study, omeprazole inhibited the non-saturable passive, but not saturable active, Mg²⁺ transport across Caco-2 monolayers (Table 1). In addition, the role of transcellular active Mg²⁺ transport was examined using the TRPM6 inhibitor RR. Inhibition of TRPM6 in Caco-2 cells^[27] abolished the saturable active Mg²⁺ transport and revealed the inhibition of non-saturable passive Mg²⁺ transport in omeprazole-treated monolayers (Figure 5B and C). Therefore, the paracellular passive Mg²⁺ absorption defect should be recognized in omeprazole usage.

Consistent with previous findings that the paracellular

passive transport of cations, such as Na⁺, Cs⁺, H⁺, Ca²⁺, and Mg²⁺, was a temperature variance mechanism^[18,20], the present Arrhenius plot (Figure 5E) showed the temperature-dependent Mg²⁺ transport. Since the temperature coefficient Q_{10} of passive ion diffusion through the open ion channel ranged from 1.2 to 1.4^[28] and the paracellular pore of the tight junction behaved as the channel^[20], therefore, the Q_{10} of control (1.22) and omeprazole treated (1.31) monolayers indicated that Mg²⁺ mainly moved through the paracellular channels of Caco-2 epithelium. The paracellular passive H⁺ transport occurred *via* the claudin-8 channel of MDCK II epithelium^[18]. The paracellular claudin-8 channel was found to impede H⁺ transport by increasing the E_a ^[18]. Therefore, the higher E_a of omeprazole-treated Caco-2 epithelium suggested that the paracellular channel of Caco-2 epithelium impeded Mg²⁺ transport. In addition, the higher TER (Table 2) also indicated lower paracellular permeability. The present study supported a previous report by Hou *et al.*^[29], who demonstrated that the epithelium with higher TER showed lower passive Mg²⁺ transport.

The paracellular transport of Mg²⁺ was regulated by the paracellular charge selectivity, i.e. cation selectivity, of the tight junction^[29,30]. Caco-2 epithelium was a cation selective epithelium (Figure 4A-C)^[21,22] that favored the transport of cations through the paracellular pathway. Similar to a previous report^[21], the paracellular selective permeability profile of Caco-2 monolayers to monovalent cations was Na⁺ > K⁺ > Rb⁺ > Cs⁺ > Li⁺ (Figure 4D) which was classified as series VII of the Eisenman sequence^[31]. Series VII indicated the presence of moderate negative electrical field strength in the paracellular channel of Caco-2 epithelium. However, omeprazole changed the selective permeability profile to series VI of the Eisenman sequence (K⁺ > Na⁺ > Rb⁺ > Cs⁺ > Li⁺)^[31]. Since series VI was characterized by lower negative electrical field strength than that of series VII^[31], the paracellular cation selectivity was decreased when the monolayers were exposed to omeprazole (Figure 4A-C). Hou *et al.*^[29] also demonstrated lower paracellular Mg²⁺ transport due to lower paracellular cation selectivity of the epithelium. Thereby, omeprazole-induced suppression of paracellular cation selectivity led to the inhibition of paracellular Mg²⁺ transport across Caco-2 epithelium.

The present study demonstrated the inhibitory effect of omeprazole on passive Mg²⁺ transport which was consistent with previous reports^[29,30,32-34]. The paracellular passive Mg²⁺ transport was mainly mediated by claudins at the tight junction^[29,30], the distribution of which could be affected by the change in extracellular fluid pH. Inhibition of H⁺/K⁺-ATPase activity in Caco-2 cells^[35] by omeprazole might decrease the extracellular H⁺ concentration, which in turn increased the sensitivity of the extracellular calcium sensing receptor (CaSR)^[32,33], which was expressed in Caco-2 cells^[36,37]. Ikari *et al.*^[34] clearly demonstrated that the activation of CaSR led to the translocation of claudin-16 from the tight junction into the cell, thus inhibiting paracellular Mg²⁺ transport. Therefore, omeprazole-inhibited passive Mg²⁺ transport appeared to involve the CaSR-tight junction-dependent mechanism.

In conclusion, omeprazole inhibited paracellular passive Mg²⁺ transport across Caco-2 epithelium in a dose- and time-dependent fashion. The inhibition of passive Mg²⁺ transport was due to the decrease in paracellular cation selectivity. The results from the present study provided evidence for the regulation of intestinal Mg²⁺ absorption. However, the underlying mechanism of omeprazole inhibiting passive Mg²⁺ transport requires further study.

ACKNOWLEDGMENTS

We express our gratitude to Assistant Professor Narattaphol Charoenphandhu of the Department of Physiology and Consortium for Calcium and Bone Research (COCAB), Faculty of Science, Mahidol University, Bangkok, Thailand, for critical suggestions. We also thank Ms Jirawan Thongbunchoo of COCAB, for technical assistance.

COMMENTS

Background

Previously, it was widely believed that intestinal Mg²⁺ transport in humans depended on the amount of Mg²⁺ intake and was not tightly regulated by any hormones. Omeprazole, a common therapeutic drug for acid-peptic disorders, has been found to have effects on Mg²⁺ metabolism.

Research frontiers

Several previous reports have demonstrated an association between severe hypomagnesemia and prolonged omeprazole usage in humans. Those patients had normal renal Mg²⁺ handling, suggesting that a defect in intestinal Mg²⁺ absorption may be responsible for hypomagnesemia. However, the direct action of omeprazole on intestinal Mg²⁺ absorption is unknown. In this manuscript, an inhibitory effect of omeprazole on intestinal passive Mg²⁺ absorption is demonstrated.

Innovations and breakthroughs

In this manuscript, the authors reported a direct inhibitory action of prolonged omeprazole treatment on paracellular passive Mg²⁺ absorption across the intestinal epithelium. This finding provides an explanation on how prolonged usage of omeprazole could lead to hypomagnesemia.

Applications

Acid-peptic disorders, e.g. gastro-oesophageal reflux disease, erosive oesophagitis, heartburn, and Barrett's disease, are chronic diseases that require prolonged omeprazole administration. Therefore, plasma Mg²⁺ assessment should help prevent hypomagnesemia in these patients.

Terminology

The paracellular charge selectivity is a property of epithelium that is selectively permeable to specific charged molecules, e.g. ions. This property is regulated by proteins of the tight junction, i.e. claudins. Alterations in claudin expression in the tight junction directly affect the charge selectivity and the paracellular ion transport across the epithelium.

Peer review

This is an interesting paper investigating the inhibitory action of omeprazole on magnesium transepithelial transport at intestinal level. The study is well-done, the rationale is clear, the experimental design correct, and the results shown convincingly support the conclusions drawn.

Abstract

AIM: To study whether over-starvation aggravates intestinal mucosal injury and promotes bacterial and endotoxin translocation in a high-altitude hypoxic environment.

METHODS: Sprague-Dawley rats were exposed to hy-

pobaric hypoxia at a simulated altitude of 7000 m for 72 h. Lanthanum nitrate was used as a tracer to detect intestinal injury. Epithelial apoptosis was observed with terminal deoxynucleotidyl transferase dUTP nick end labeling staining. Serum levels of diamino oxidase (DAO), malondialdehyde (MDA), glutamine (Gln), superoxide dismutase (SOD) and endotoxin were measured in intestinal mucosa. Bacterial translocation was detected in blood culture and intestinal homogenates. In addition, rats were given Gln intragastrically to observe its protective effect on intestinal injury.

RESULTS: Apoptotic epithelial cells, exfoliated villi and inflammatory cells in intestine were increased with edema in the lamina propria accompanying effusion of red blood cells. Lanthanum particles were found in the intercellular space and intracellular compartment. Bacterial translocation to mesenteric lymph nodes (MLN) and spleen was evident. The serum endotoxin, DAO and MDA levels were significantly higher while the serum SOD, DAO and Gln levels were lower in intestine ($P < 0.05$). The bacterial translocation number was lower in the high altitude hypoxic group than in the high altitude starvation group (0.47 ± 0.83 vs 2.38 ± 1.45 , $P < 0.05$). The bacterial translocation was found in each organ, especially in MLN and spleen but not in peripheral blood. The bacterial and endotoxin translocations were both markedly improved in rats after treatment with Gln.

CONCLUSION: High-altitude hypoxia and starvation cause severe intestinal mucosal injury and increase bacterial and endotoxin translocation, which can be treated with Gln.

INTRODUCTION

Multiple organs can be damaged by rapid ascent to an altitude above 3000 m. High altitude cerebral edema (HACE) and high altitude pulmonary edema (HAPE) are the clinical manifestations of acute mountain sickness (AMS)^[1-3]. AMS is a threat to those who live at or ascend to a high altitude. Our previous study showed that multiple organ dysfunction syndrome (MODS) can occur if HAPE and HACE are not treated timely and properly, and the condition of such patients can deteriorate, thus complicating their treatment^[4]. However, the mechanism underlying acute severe mountain sickness (ASMS) accompanying MODS is still poorly understood.

The gastrointestinal tract is an important organ, and its primary function is to digest and absorb nutrients. However, in addition to nutrient absorption, the gastrointestinal tract functions as a barrier to prevent the translocation of intraluminal bacteria and endotoxin to systemic organs and tissues. It has been confirmed that intestinal mucosal injury caused by a variety of factors may decrease the intestinal barrier function, thus leading to the translocation of intraluminal bacteria and endotoxin to systemic organs and tissues, which is a principal cause of systemic inflammatory response syndrome (SIRS), MODS and multiple organ failure^[5-7]. However, little is known about the relation between intestinal barrier dysfunction and ASMS accompanying MODS, and whether the intestinal barrier dysfunction caused by hypobaric hypoxia promotes bacterial translocation and spread of endotoxin. In addition, the degree of dysfunction caused by hypobaric hypoxia and the role of acute intestinal barrier dysfunction in the occurrence and development of ASMS are still unclear.

To explore the detrimental effect of hypobaric hypoxia on intestinal barrier function and the role of acute intestinal barrier dysfunction in the occurrence and development of ASMS, we examined the microstructure and ultra-structure of intestinal mucosa from rats exposed to hypobaric hypoxia, under light and electron microscopes. The activity of serum and intestinal diamine oxidase (DAO), malondialdehyde (MDA), superoxide dismutase (SOD) and NO, as well as glutamine (Gln) was assayed. In addition, rats were given Gln intragastrically to explore its protective effect on intestinal mucosa. The results of

this study may provide the functional and morphological information about the effect of ASMS on the spread of endotoxin and bacterial translocation, as well as important information about the pathogenesis, prevention and treatment of MODS caused by hypobaric hypoxia.

MATERIALS AND METHODS

Instruments

Instruments used in the present study were animal decompression chamber (Guizhou Aviation Industry, China), electronic balance (Shanghai Balance, China), ultralow freezer (Heraneus, Germany), microplate reader (Biotek, USA), spectrophotometer (Changsha Persee, China), endotoxin detection system (Tianjin Wireless Electronics, China), scanning electron microscope (Hitachi, Japan) and transmission electron microscope (Philips, Netherlands).

Reagents

Reagents used in this study include compound glutamine granules (Heilongjiang Aolida, China), horseradish peroxidase (Shanghai Guoyuan Biotech, China), 3,3'-dimethoxybenzidine (Sigma, USA), cadaverine dihydrochloride (Sigma, USA), lysine (Sigma, USA), protein kinase (Amresco, USA), levamisole (Sigma, USA), sodium dimethyl arsenite (Shanghai Genebase, China), limulus test kit (Zhanjiang Bokang, China), control standard endotoxin (Zhanjiang Bokang, China), terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) kit (Roche, Switzerland), MDA kit (Nanjing Jiancheng, China), NO kit (Nanjing Jiancheng, China), SOD kit (Nanjing Jiancheng, China), glutamine kit (Nanjing Jiancheng, China) and lanthanum nitrate (Chongqi Boyi, China).

Animals and grouping

A total of 40 male Sprague-Dawley rats weighing 200 ± 20 g were purchased from Animal Center of Third Military Medical University (Chongqing, China) and housed in dedicated cages. The rats were randomly divided into normal control group (C), hypobaric hypoxia group (H), hypobaric hypoxia plus starvation group (HH), and hypobaric hypoxia plus Gln group (HG), 10 rats in each group. All procedures were performed in accordance with the Animal Care Guidelines of Third Military Medical University, conforming to the Health Guide for the Care and Use of Laboratory Animals of Third Military Medical University. This study was approved by the Ethics Committee of Third Military Medical University.

Experimental regimen

Rats in the control group were housed under a normal atmospheric pressure and weighed daily, with free access to food. Rats in groups H, HH and HG were exposed to a simulated altitude of 7000 m for 72 h in an animal decompression chamber, to established rat model of hypoxia exposure. Rats in group H had free access to food and water and weighed daily, rats in group HH were fasted with free access to water, and rats in group HG had free access to food and water in addition to intragastric Gln (0.5 g/d per

100 g body weight) at 09:00, am, daily. Gln was prepared in warm water at a dilution of 1:4. The animals were taken out of the chamber for feeding, medication, weighing and cleaning for 30 min, and returned to the chamber for continuous hypoxia exposure.

Three days after exposed to hypobaric hypoxia, the rats were sacrificed by decapitation with 5 mL blood collected into a pyrogen-free tube. The blood was centrifuged at 2500 r/min at -4°C, and serum was stored at -20°C before use. Additionally, the heart, liver, spleen, lungs and mesenteric lymph nodes (MLN) were removed from rats, weighed, and subjected to bacterial culture. About 5 cm of ileum, approximately 5 cm from the ileocecal junction, was obtained for light and electron microscopy. About 3 cm of intestine was put into a 3-fold volume of PBS (0.1 mol/L, pH 7.2), homogenized and centrifuged at 1000 r/min for 30 min. Then, the supernatant was collected.

General observations

The spontaneous activity, mental state, eating status and weight of rats were observed.

Light microscopy

About 2 cm of intestine at 5 cm from the ileocecal valve was obtained and cut open longitudinally. The intestine was washed with normal saline, fixed in 10% formaldehyde at 4°C for 24 h, rinsed with PBS, embedded in paraffin and consecutively cut into 4- μ m thick sections which were stained with hematoxylin and eosin (HE). The structure of intestinal mucosal epithelium was observed and the thickness of mucosa was measured^[8]. The height and area of 15 randomly selected intestinal villi were measured and averaged^[9] according to the following equation: $\text{Area} = 2\pi rh$, where r represents the radius of villus and h is the height of villus. The number of villi was counted in each field of vision.

Assay of apoptotic intestinal mucosal epithelial cells

About 2 cm of intestine at 5 cm from the ileocecal valve was obtained and cut open longitudinally. The intestine was washed with normal saline, fixed in 10% formaldehyde at 4°C for 24 h, rinsed with PBS, embedded in paraffin, and consecutively cut into 4- μ m thick sections which were mounted onto 0.05% lysine-treated slides. The slides were dried at room temperature for 20 min, dry-heated at 60°C for 30 min and stored at room temperature before use. The sections were stained with TUNEL as previously described^[10]. The cells with blue nuclei were considered positive cells. Two slides of each sample were selected, and 4 randomly selected fields were used to calculate the apoptotic intestinal mucosal epithelial cells at a magnification $\times 400$. The counts were averaged. The apoptotic index (AI) was calculated as follows: number of TUNEL positive cells/number of total cells^[11].

Observation of intestinal mucosa ultra-structure by scanning electron microscopy

Part of the ileum was obtained, rinsed with cold normal

saline, and cut into 2 mm \times 2 mm sections which were fixed in 2.5% glutaraldehyde and 10% osmium, dehydrated in sucrose solution containing PBS. Subsequently, the cells were labeled with gold and observed under a scanning electron microscope^[12]. The arrangement of microvilli in intestinal mucosa and organelles in columnar epithelial cells were observed. Special attention was paid to the deformed and exfoliated villi and the intercellular space between epithelia.

Observation of intestinal mucosa ultra-structure by transmission electron microscopy

Jejunal tissue was cut into 0.7 cm \times 0.7 cm sections and adherent feces were removed from the colon mucosa with saline. The sections were immediately placed into a 4°C fixative (4 g paraformaldehyde, 20 mL glutaraldehyde, 100 mL 0.2 mol/L phosphate buffer solution, and 80 mL distilled water, pH 7.4) for 2 h, and then cut into 1 mm \times 1 mm \times 1 mm pieces. The specimens were washed three times (10 min each) with 10% sucrose phosphate buffer, fixed in 1% osmium tetroxide at 4°C for 1 h, dehydrated, embedded in resin, then cut into ultra-thin sections which were stained with uranyl acetate and lead citrate, and examined by transmission electron microscopy and photographed. The tight junctions between intestinal mucosal epithelia, arrangement of microvilli, integrity of columnar epithelial cells, organelles and nuclei, and structure of glands in lamina propria were observed.

Detection of intestinal mucosal injury

Two rats in each group were anesthetized through intraperitoneal administration of 1% sodium pentobarbital (1.0 mL/100 g body weight). Transcardial perfusion was performed with a mixture containing 3% glutaraldehyde, 4% paraformaldehyde and 2% lanthanum nitrate. The mixture was prepared with 0.1 mol/L sodium dimethyl arsenite in PBS. Part of the intestine was obtained and fixed in the same mixture followed by 1% osmium. The tissues were rinsed with 0.1 mol/L sodium dimethyl arsenite solution, and slides were prepared as indicated for transmission electron microscopy^[13].

Detection of bacterial translocation

The blood, heart, liver, spleen, lungs and MLN were independently placed into a 9-fold volume of normal saline, and the mixture was homogenized. Then, 0.5 mL homogenates was loaded onto the MacConkey solid medium to culture bacteria for 24 h, and the bacteria were analyzed biochemically.

Measurement of serum endotoxin level

The serum endotoxin level was measured by limulus test as previously described^[14]. The serum was prepared with warm water, and 0.1 mL serum was mixed with 0.9 mL processing solution and incubated at 70°C for 15 min. Subsequently, 0.2 mL serum was added into the enzyme reaction solution and reacted in the endotoxin detection

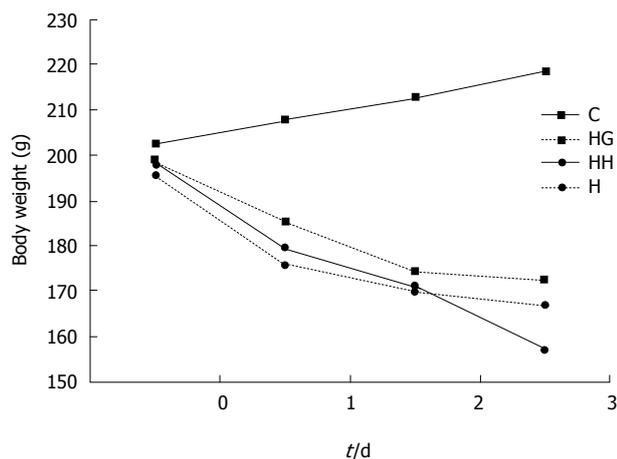

Figure 1 Body weight changes in rats of different groups. The body weight of rats in group C increased stably, and reduced body weight was observed in all rats exposed to hypobaric hypoxia. Decreased body weight was most evident in group HH, followed by groups H and HG. C: Control group; H: Hypobaric hypoxia group; HH: Hypobaric hypoxia plus starvation group; HG: Hypobaric hypoxia plus Gln group.

system EDS-99 for 1 h. The serum endotoxin level was automatically outputted from the system.

Measurement of serum DAO, SOD, MDA, NO, Gln, DAO and Gln levels in intestine

About 0.5 mL serum was mixed with a solution containing 0.1 mol/L PBS (3 mL, pH 7.2), horseradish peroxidase (4 g, 0.1 mL), 3,3'-dimethoxybenzidine (500 g, 0.1 mL) and cadaverine dihydrochloride (175 g, 0.1 mL) and incubated at 37°C for 30 min. The solution was replaced by PBS as a blank control. The optical density (OD) was detected at 436 nm, and the DAO content was measured. The standard curve was delineated with DAO^[15]. About 0.5 mL intestinal homogenates was used to measure the DAO content with the same method. Approximately 0.1 mL serum was used to detect the SOD activity and measure the NO and MDA content as previously described^[16]. The SOD and NO contents were measured using the nitrate reductase activity, the MDA content was measured using the thiobarbituric acid method, and the OD values of Gln were calculated using the Gln synthetic enzymatic method. In addition, the content of proteins in homogenates was measured with Coomassie brilliant blue, and the OD value of Gln was obtained and the Gln content was measured.

Statistical analysis

Statistical analysis was performed using the SPSS version 13.0, and quantitative data were presented as mean ± SD. One-way ANOVA was used for comparison between groups. Qualitative data were expressed as percentages, and *t* test was used for comparison of means between groups. *P* < 0.05 was considered statistically significant.

RESULTS

General information

No rats died during the experiment. The activity of rats

Table 1 Morphological manifestations of intestinal mucosa in different groups (mean ± SD)

| Group | Rats (n) | Height of villi | Thickness of mucosa | Villous area (m ²) |
|-------|----------|-----------------------|----------------------|--------------------------------|
| C | 10 | 242 ± 19 | 380 ± 4 | 15324 ± 1027 |
| H | 10 | 228 ± 23 ^a | 296 ± 7 ^b | 13450 ± 999 ^b |
| HH | 10 | 200 ± 24 ^b | 314 ± 7 ^b | 11341 ± 997 ^b |
| HG | 10 | 215 ± 23 ^c | 370 ± 9 ^d | 12901 ± 989 ^d |

^a*P* < 0.05, ^b*P* < 0.01 vs group C; ^c*P* < 0.05, ^d*P* < 0.01 vs group H. C: Control group; H: Hypobaric hypoxia group; HH: Hypobaric hypoxia plus starvation group; HG: Hypobaric hypoxia plus Gln group.

was markedly lower in groups H, HH and HG with a poor mental state than in control group. The food-intake was significantly higher in group C than in group H (50 g/d vs 23 g/d, *P* < 0.05). The food intake was slight decreased in group HG (38 g/d). The body weight in group C increased stably, and decreased most evidently in group HH, followed by groups H and HG (Figure 1).

Light microscopy

The intestinal mucosa was smooth with intact epithelia and ordered arrangement of villi in group C with no defects detected in villi (Figure 2A). The intestinal mucosa was exfoliated and the villi became thinner in group H. In addition, the number of mucosal villi was reduced, and the villi were irregular and disorganized (Figure 2B). In group HH, atrophic and thinned of villi accompanying a loose and disordered arrangement were observed with edema and infiltration of inflammatory cells in the mastoid lamina of villi, lodged and exfoliated villi with loss of goblet cells and effusion of red blood cells around the capillaries (Figure 2C). In group HG, the intestinal mucosal villi were relatively intact with ordered arrangement with alleviated edema in the mastoid lamina of villi accompanying a few infiltrated inflammatory cells (Figure 2D). The height of intestinal villi and the thickness of mucosa accompanying a decreased villous area were lower in groups H and HH than group C (*P* < 0.05). The height and area of intestinal villi and the thickness of mucosa were significantly higher in group HG than in group H (*P* < 0.05, Table 1).

Scanning electron microscopy

Orderly intestinal villi with a smooth surface and fullness were observed in group C (Figure 3A). The epithelia were atrophic with disordered arrangement of the villi and widened villous spaces in group H (Figure 3B). Villous atrophy and disordered villi with widened villous spaces and exfoliated microvilli were observed in group HH (Figure 3C). The intestinal mucosa was almost intact with orderly villi with few lodged villi, less effusion of red blood cells and no disc-shaped cells and cellulose in group HG (Figure 3D).

Observation by transmission electron microscopy with nitric acid lanthanum tagging

Orderly mucosal villi and integrated tight junctions as

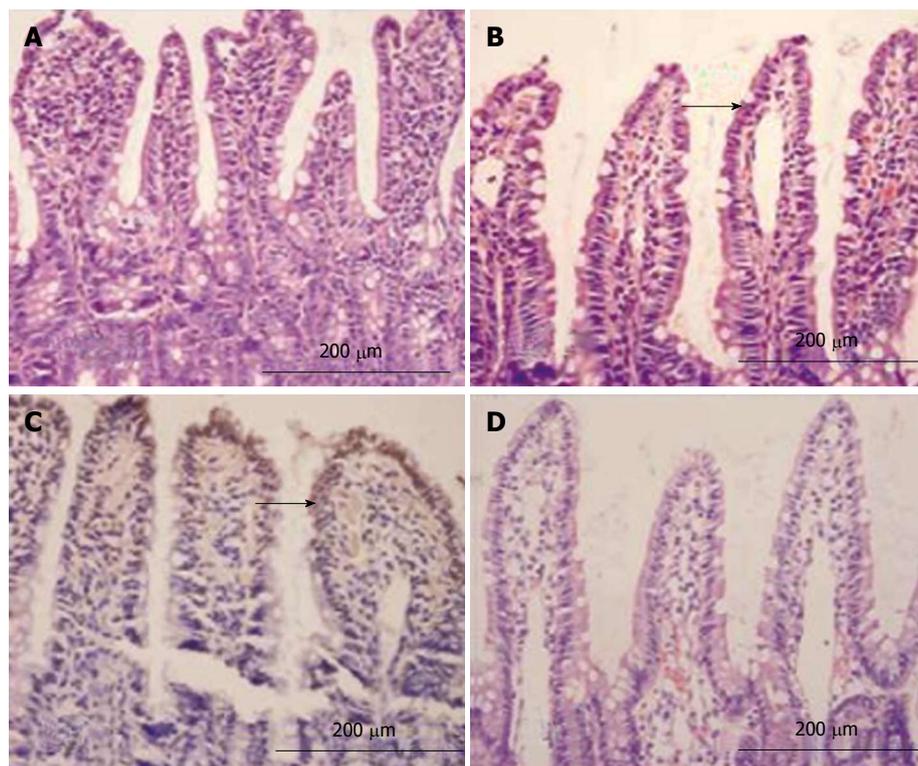

Figure 2 Light microscopy. Smooth intestinal mucosa with intact epithelia and ordered villi in group C (A), exfoliated and incomplete intestinal mucosa with thickened mucosa and reduced villi accompanying irregular morphology and disorganized villous epithelia in group H (B), atrophic and thinned villi accompanying a loose and disordered arrangement as well as edema and infiltration of inflammatory cells in mastoid lamina of villi and lodged and exfoliated villi with loss of goblet cells and red blood cell effusion around the capillaries in group HH (C), relatively intact intestinal mucosal villi with ordered arrangement and alleviated edema in mastoid lamina of villi accompanying a few infiltrated inflammatory cells in group HG (D) (HE, $\times 200$).

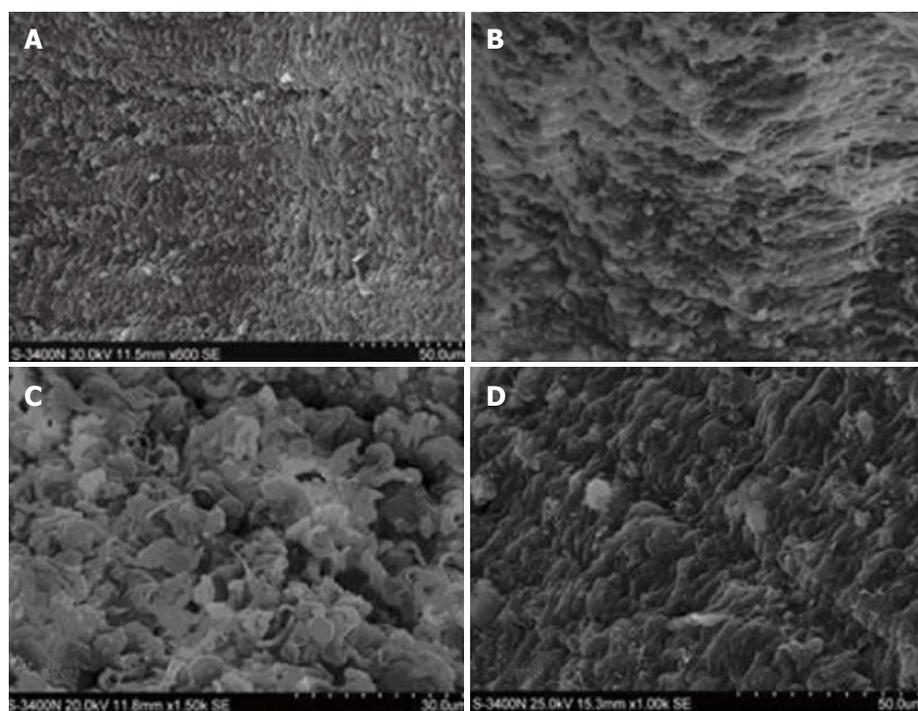

Figure 3 Scanning electron microscopy. A smooth surface of intestinal mucosa with a clear structure as well as complete and orderly villi in group C (A) ($\times 6900$), atrophic epithelial structure of intestinal mucosa and lodging villi accompanying a rough surface with disordered villi and widened villous spaces in group H (B) ($\times 6900$), severely injured intestinal mucosa as well as disc-shaped cells and cellulose in mucosal defects along with evident atrophy and disordered villi with widened villous spaces and exfoliated microvilli in group HH (C) ($\times 11\,500$), almost intact intestinal mucosa with orderly villi and less effusion but no disc-shaped cells and cellulose in group HG (D) ($\times 11\,500$).

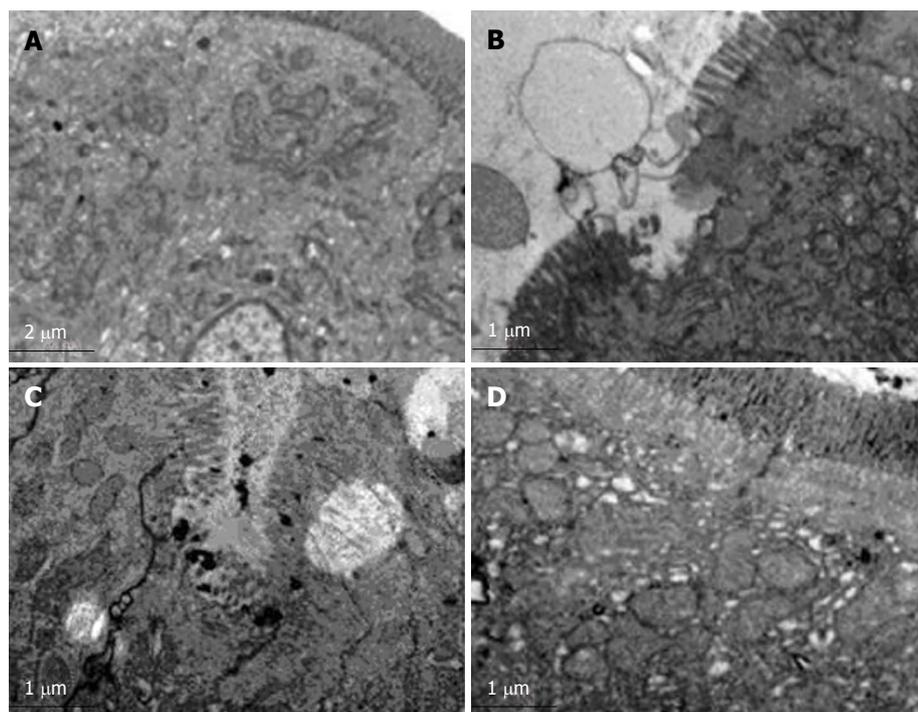

Figure 4 Transmission electron microscopy with nitric acid lanthanum tagging. Orderly mucosal villi and integrated tight junctions as well as intact organelles with regular nuclei in group C (A), exfoliated and incomplete microvilli accompanying widened intercellular spaces as well as swollen endoplasmic reticulum and mitochondria and a small number of lanthanum granules in tissue spaces in group H (B), dilated Golgi complex with irregular nuclei and edge aggregation in chromatin as well as lanthanum granules in the tight junction gap and cells in group HH (C), mildly deformed microvilli and swollen mitochondria in lamina propria accompanying a small number of lanthanum granules confined to vessels and epithelial surface in group HG (D) ($\times 8900$).

well as intact organelles with regular nuclei were observed with no edge aggregation in chromatin and no lanthanum granules in tissue space and cells in group C (Figure 4A). The microvilli were exfoliated and incomplete with widened cellular spaces, swollen endoplasmic reticulum and mitochondria as well as a small number of lanthanum granules in group H (Figure 4B). The Golgi complex was dilated with irregular nuclei with edge aggregation in chromatin and a large number of lanthanum granules in the tight junction gap and cells in group HH (Figure 4C). Mildly deformed microvilli and gland proliferation in the lamina propria and a small number of lanthanum granules were confined to vessels and epithelial surface in group HG (Figure 4D). The number of blue particles was 3.5 ± 1.5 unit/cell/gap in group C, 17.5 ± 2.5 unit/cell/gap in group H, 36 ± 2.7 unit/cell/gap in group HH, and 12 ± 2.1 unit/cell/gap in group HG, respectively.

Detection of bacterial translocation

Negative bacterial cultures were obtained in group C. Bacterial translocation occurred in MLN and spleen of group H and group HH but not in peripheral blood ($P < 0.05$). The translocation organ number of bacteria was the greatest in group HH. The incidence of bacterial translocation was markedly lower in group HG than in group H ($P < 0.05$, Table 2).

Serum DAO, Gln and intestinal homogenate levels in different groups

The serum DAO level was higher in groups H and HH than in group C ($P < 0.05$), and lower in group HG than in groups H and HH ($P < 0.05$). The serum Gln level was lower in groups H and HH than in group C ($P < 0.05$), and higher in group HG than in groups H and HH ($P < 0.05$, Table 3). The intestinal DAO and Gln levels were lower in

groups H and HH than in group C (*P* < 0.05) and higher in group HG than in groups H and HH (*P* < 0.05, Table 4).

Serum endotoxin, SOD, MDA, NO and AI levels in different groups

The serum MDA and endotoxin levels were higher in groups H and HH than in group C (*P* < 0.05) and lower in group HG than in groups H and HH (*P* < 0.05, Table 5). The serum SOD and NO levels were lower in groups H and HH than in group C (*P* < 0.05) and higher in group HG than in groups H and HH (*P* < 0.05, Table 5).

DISCUSSION

The normal intestinal barrier function depends on the intact intestinal mechanical, biological, immunological and chemical barriers. The mechanical barrier is the most important. Complete intestinal mucosal epithelium is the dominant component of the mechanical barrier, and the integrity of mucosal epithelium plays a critical role in protection against the spread of endotoxin and bacterial translocation^[17]. The tight junction between adjacent cells, composed of proteins with various functions, can be found between villous and duct epithelia, and plays a crucial role in preventing molecules and ions from passing between cells^[18,19].

Gastrointestinal motility is another component of the intestinal mechanical barrier. The swing of intestinal villi reduces the adhesion of pathogens to mucosal epithelia. Furthermore, intestinal peristalsis pushes the food residue to the distal end and reduces the stay time of bacteria in intestinal mucosa and the chance of bacteria reaching epithelia through the mucous layer, which re-

sults in intestinal self-cleaning. The normal flora in intestine forms a biological layer with multiple levels, which comprises the immunological barrier of intestine with no specific immune functions^[20].

The balance between bacterial location, amount and type is critical for the maintenance of intestinal homeostasis. Numerous environmental changes may lead to an imbalance between humans and bacteria, and between different types of bacteria, thus resulting in injury to the intestinal biological barrier^[21]. The immunological barrier is composed of secretory IgA, which is secreted by plasma cells in the lamina propria and lymphoid tissues in intestine. A few Paneth cells consume necrotic cells and secrete several immune substances, which function as an immunological barrier^[22]. Additionally, gastric acid, bile, lysozymes, mucopolysaccharide and proteolytic enzymes form a gastrointestinal chemical barrier that exerts bactericidal effects. Normally, a viscoelastic layer on intestinal mucosa constitutes the chemical barrier, with no specific immunological function. The mucus secreted by goblet cells mainly consists of mucin and its main function is to lubricate the intestinal mucosa, thus protecting the mucosa against mechanical and chemical injury. In addition, the non-specific and specific adhesions between oligosaccharides in mucin and cells interfere with the colonization of opportunistic pathogens.

It has been shown that a variety of factors cause intestinal barrier functional injury, and that hypobaric hypoxia may directly damage mucosal epithelia^[23]. As a result of energy deficiency, the swing of mucosal villi is also compromised, accompanying suppressed intestinal peristalsis, which enhances intestinal absorption. Furthermore, hypoxia may damage aerobic metabolism and increase glycolysis, resulting in intracellular acidosis. Subsequently, the mucosal permeability increases, leading to intestinal barrier functional injury. Intestinal mucosal injury, cytolysis of goblet cells, and reduced amount of mucus caused by hypobaric hypoxia may attenuate the ability of intestinal mucosa to combat gastric acid and pepsin. At the same time, the gastrointestinal vagus nerve is in an excitatory state, which increases the secretion of gastrin, and the gastric acid and pepsin deteriorate the intestinal injury. Hypobaric hypoxia may also reduce secretion of secretory IgG, which compromises the specific immune function of intestine. Moreover, the expressed adhesion molecules of white blood cells and endothelia enhance

the phagocytosis of neutrophils, which release several proteolytic enzymes, thus resulting in intestinal mucosal injury^[24,25]. There is evidence that hypobaric hypoxia can reduce bile secretion and cause disorderliness of enterohepatic circulation, leading to gastrointestinal dysfunction and overpopulation of intestinal bacteria, and further intestinal biological barrier damage. The damaged biological barrier, together with the injured mechanical barrier and increased mucosal permeability, increases the possibility of overproduced bacteria and endotoxin entering parenteral organs through injured mucosa, thus resulting in the spread of endotoxin and bacterial translocation^[26], which is also the basic cause of SIRS.

In the present study, after the rats were exposed to a simulated altitude of 7000 m for 72 h, their food intake was significantly reduced, accompanying weight loss. Light microscopy showed that the intestinal mucosa was exfoliated, and the height of mucosa decreased. The number of villi was reduced, along with their height, accompanying an irregular morphology. The epithelia had different sizes and disordered arrangement. The number of goblet cells was decreased, and a few of them showed signs of degeneration. Electron microscopy revealed atrophic and thinned intestinal villi and disordered epithelia. The villi were incomplete and exfoliated, accompanying widened intercellular spaces. Swollen endoplasmic reticulum and mitochondria and dilated Golgi complex were observed with irregular nuclei and edge aggregation of chromatin. In addition, lanthanum granules were found in intercellular spaces, basement membrane, tissue spaces, and intracellular compartment. At the same time, TUNEL staining showed that the number of apoptotic epithelial cells was significantly elevated after the rats were exposed to hypobaric hypoxia. Under a hypobaric hypoxia environment, starvation might markedly enhance the mucosal injury that leads to exfoliation, atrophy and decreased height of mucosal villi. Vacuolar degeneration was noted in a few epithelia with effusion of red blood cells around capillaries, accompanying infiltration of inflammatory cells. The intestinal mucosal injury was dramatically improved after treatment with Gln. These findings demonstrate that acute hypobaric hypoxia can severely damage intestinal mucosa, thus resulting in intestinal barrier functional injury. In this study, Gln exerted its protective effects on the injured intestinal mucosa to a certain extent.

Damage to the intestinal barrier function may increase mucosal permeability, which leads to bacterial translocation and SIRS. Therefore, detection of bacterial translocation and spread of endotoxin, as well as measurement of some parameters (DAO, MDA, SOD, NO and Gln) related to intestinal function and systemic inflammatory reaction, may directly reflect the intestinal barrier function. The spread of endotoxin and bacterial translocation represent an increased mucosal permeability, which occurs after intestinal mucosal injury. The activity of DAO in mucosal villi may reflect the structure and function of intestine^[27,28]. When mucosal cells are injured and necrotized, DAO is released into the blood or enters the intestinal tract together with necrotic mucosal cells, thus increasing the serum and intes-

tinal tract DAO level and decreasing the DAO levels in intestinal mucosa. The activity of SOD represents its ability to scavenge free radicals. MDA is the end product of lipid oxidation and indirectly represents lipid peroxidation. NO is an antioxidant. When the intestinal mucosa is damaged, the activity of SOD decreases, accompanying decreased NO and increased MDA contents. It was reported that the serum Gln level is decreased in intestinal mucosa of patients with some critical illnesses. In the present study, the activity of serum DAO and MDA and endotoxin levels were markedly higher in rats exposed to hypobaric hypoxia than in those not exposed to hypobaric hypoxia. However, the activity of DAO and the content of Gln, and the serum NO and Gln levels in intestinal mucosa were significantly lower in rats exposed to hypobaric hypoxia than in those not exposed to hypobaric hypoxia. These changes were more evident in rats after exposed to hypobaric hypoxia and starvation. The serum activity of DAO, MDA and endotoxin was dramatically decreased after treatment with Gln. Moreover, the activity of DAO in intestinal mucosa and the serum NO and Gln levels in intestine were markedly increased. These results suggest that Gln, as an intestinal nutrient, can confer protective effects against intestinal mucosal injury caused by hypobaric hypoxia.

The results of this study show that hypobaric hypoxia can severely injure the intestinal barrier function and increase the intestinal mucosal permeability. In addition, the release of factors involved in SIRS was enhanced accompanying reduced production of protective factors after exposed to hypobaric hypoxia. At the same time, the ability of hypobaric hypoxia to combat lipid peroxidation was reduced. These changes finally resulted in the spread of endotoxin and bacterial translocation. The spread of endotoxin and bacterial translocation, on one hand, activates Kupffer cells in the liver, resulting in the release of numerous cytokines, and on the other hand, leads to endotoxemia, which activates monocytes, macrophages, T and B lymphocytes, and promotes the release of a large number of cytokines, thus resulting in a cytokine cascade^[24]. Additionally, the release of numerous inflammatory mediators, including metabolites of arachidonic acid (prostaglandin E₂, prostacyclin, NO, platelet activating factor, leukotriene and bradykinin), may induce SIRS^[29]. SIRS further promotes the release of inflammatory mediators, which result in inflammatory-mediator-related cascade effects, exacerbation of intestinal mucosal injury^[30], and suppression of intestinal immune function, thus leading to aggravation of bacterial translocation and spread of endotoxin, which are the basis of the later stage of SIRS^[31]. Therefore, the intestinal tract is not only the target organ of SIRS but also the initiator of SIRS^[32], which forms a vicious cycle that results in an endogenous and uncontrollable systemic inflammatory reaction, deterioration of tissue, organ injury, and finally, MODS. Therefore, the damaged intestinal barrier function resulting from hypobaric hypoxia may be one of the important causes of high-altitude MODS.

Both high-altitude hypoxia and starvation may cause severe intestinal barrier function injury, and increased bacterial and endotoxin translocation, but high-altitude

starvation causes more severe intestinal mucosal injury, and bacterial and endotoxin translocation than simple hypoxic exposure. High-altitude over-starvation can aggravate intestinal mucosal injury and promote bacterial and endotoxin translocation, which can be markedly alleviated after intragastric administration of Gln.

COMMENTS

Background

Rapid access to 3000 m above sea level can lead to body function change, and even acute severe mountain sickness (ASMS), which can be life-threatening. High altitude pulmonary edema and high altitude cerebral edema are normal in ASMS. If they are not treated effectively, many people can develop multiple organ dysfunction syndrome (MODS). However, the mechanism for complication of ASMS by MODS is still unclear. It has been demonstrated that gastrointestinal mucosal barrier dysfunction plays an important role in translocation of intestinal bacteria and endotoxin, systemic inflammatory response syndrome (SIRS), and MODS. However, whether high altitude hypoxia can cause gastrointestinal mucosal barrier dysfunction promoting bacterial and endotoxin translocation is currently unknown.

Research frontiers

Studies have shown that high altitude hypoxia can directly cause pathological damage to the intestinal mucosa, and increase intestinal permeability. High altitude hypoxia can reduce secretion of IgG from the gastrointestinal mucosa, decrease the mucosal immune barrier, reduce bile secretion, cause enterohepatic circulation disorders, and destroy the intestinal biological barrier. Intestinal barrier damage can increase intestinal permeability, which results in bacterial translocation and occurrence of SIRS and MODS. Therefore, observation of intestinal translocation of bacteria and endotoxins can indirectly reflect intestinal mucosal barrier function.

Innovations and breakthroughs

In this study, the authors found that high altitude hypoxia altered intestinal barrier function, and increased permeability and bacterial translocation. High altitude hypoxia complicated by excessive hunger can increase damage to the intestinal barrier function and translocation of intestinal bacteria and endotoxins, and induce high altitude MODS. Glutamine has a protective effect on gastrointestinal mucosal injury in the hypoxic environment, reduces intestinal bacterial and endotoxin translocation, and promotes repair of intestinal injury.

Applications

This study has high clinical significance and practical value. First, it reminds people to improve monitoring of gastrointestinal mucosal injury in ASMS. Second, when gastrointestinal mucosal injury is found, glutamine should be administered early.

Terminology

Intestinal mucosal barrier function: It included mechanical barriers, biological barrier, immune barriers and chemical barriers. Mechanical barrier is complete gastrointestinal mucosa to prevent bacterial translocation; biological barrier is the normal intestinal bacteria group in the intestine to form a multi-level special biological layer, a non-specific immune intestinal biological barrier; immune barrier is the intestinal immune barrier lamina propria plasma cells by the secretion of secretory immunoglobulin A (SIgA) and together constitute the gut-associated lymphoid tissue; chemical barrier is the gastrointestinal tract such as gastric acid, bile, lysozyme, mucopolysaccharide and proteolytic enzymes have a certain material form the bactericidal effect of the chemical barrier. Bacterial and endotoxin translocation: Intestinal bacteria and endotoxin from the intestine into other organs or blood when the intestinal mucosal barrier is broken, the body can be an "intestinal" sepsis-like. Systemic inflammatory response syndrome (SIRS): When subject was suffered a variety of damage, and show a high metabolic response. As the body in a high metabolic state, it can increase oxygen consumption; on the other hand, metabolic hyperactivity can enhance the body break down protein, negative nitrogen balance; sugar enhanced anaerobic glycolysis, lactate accumulation, acidosis, eventually leading to tissue failure. Multiple organ dysfunction syndrome: MODS is defined as severe trauma, infection and shock, the original organ dysfunction in patients with no more than two successive system and organ dysfunction.

Peer review

This is a study of the effects of hypobaric hypoxia on intestinal integrity in rats

($n = 40$). Animals exposed to hypobaric hypoxia for 72 h demonstrated histological damage to the small intestine, translocation of lanthanum particles, and increased serum levels of DAO, MDA and endotoxin. This was accompanied by increased translocation of bacteria into lymph nodes and the spleen. Concomitant treatment of rats with glucosamine reduced the severity of intestinal injury.

Abstract

AIM: To investigate the effect of Simotang (Decoction of Four Powered Drugs) on gastrointestinal motility, motilin and cholecystokinin expression in chronically stressed mice.

METHODS: Forty mice were randomly divided into control group, stress group (model group), mosapride group and Simotang group, 10 in each group. A variety of unpredictable stimulations were used to induce chronic stress in mice. Then, the mice were treated with distilled water, mosapride or Simotang for 7 d. Gastric emptying and intestinal propulsion function were detected. Serum level of motilin was measured by enzyme-linked immunosorbent assay. Expression of cholecystokinin (CCK) in intestine, spinal cord and brain of mice was detected by immunohistochemistry and semi-quantitative reverse transcription polymerase chain reaction, respectively.

RESULTS: Simotang improved the gastric emptying

and intestinal propulsion in chronically stressed mice. Furthermore, the serum motilin level was significantly higher and the expression levels of CCK-positive cells and genes were significantly lower in intestine, spinal cord and brain of Simotang group than in those of model group ($P < 0.05$). No significant difference was found in serum motilin level and expression levels of CCK-positive cells and genes between the mosapride and Simotang groups.

CONCLUSION: Simotang enhances the gastrointestinal motility in chronically stressed mice by regulating the serum motilin level and the expression of cholecystokinin.

Cai GX, Liu BY, Yi J, Chen XM, Liu FL. Simotang enhances gastrointestinal motility, motilin and cholecystokinin expression in chronically stressed mice. *World J Gastroenterol* 2011; 17(12): 1594-1599 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i12/1594.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i12.1594>

INTRODUCTION

Functional dyspepsia (FD), a common functional gastrointestinal disorder, is steadily becoming a public health problem. Its prevalence in the United States is 15%^[1], 11% in the general Italian population^[2], and 12%-25% in China^[3].

The pathogenesis of FD remains unknown, but is likely to involve many factors. In recent years, gastrointestinal motor dysfunction has been considered as the

main pathogenesis of FD^[4]. Gastrointestinal motility is modulated by many hormones and brain-gut peptides. Motilin, a polypeptide hormone containing 22 amino acids, is secreted by endocrine M cells and regulates gastrointestinal motility by increasing the migrating myoelectric complex^[5,6]. cholecystokinin (CCK), a brain-gut peptide, is widely distributed in the gastrointestinal tract and central/peripheral nervous system, and regulates the gastrointestinal motility and food intake^[7,8].

Simotang (Decoction of Four Powered Drugs) is a classical formula that has been used in treatment of gastrointestinal disorders for hundreds of years^[9] and approved as an oral liquid drug by the Chinese National Food and Drug Administration in the 1980s. It has been shown that Simotang can affect the gastrointestinal motility in cold-restraint stressed mice^[10]. Some monomer constituents, such as arecoline^[11] and hesperidin^[12] detected in Simotang, can affect gastrointestinal function. However, the mechanism of Simotang underlying gastrointestinal motility is still unknown. In the present study, we investigated the effect of Simotang on gastrointestinal motility in chronically stressed mice and measured the serum motilin levels, expression of CCK-positive cells and genes in intestine, spinal cord and brain of chronically stressed mice.

MATERIALS AND METHODS

Drugs

Simotang, composed of *Fructus aurantii*, *Radix linderae*, *Radix Aucklandiae*, and *Semen arecae* (specification: 10 mL/division), was purchased from Hunan Hansen Pharmaceutical Company, Ltd (Yiyang, Hunan Province, China). Mosapride citrate was purchased from Chengdu Kanghong Pharmaceutical Company, Ltd (Chengdu, Sichuan Province, China), and dissolved in distilled water to a final concentration of 0.5 mg/mL.

Animals and drug administration

Forty male adult ICR mice weighing 15-22 g were provided by Hunan Slac Jingda Laboratory Animal Company, Ltd (Changsha, China) and randomly divided into control group, stress group (model group), mosapride group and Simotang group. Mice in mosapride and Simotang groups were fed with mosapride citrate (30 mg/kg) or Simotang (1.2 g/kg) consecutively for 7 d from day 21 after stress. Mice in control and model groups received the same volume of distilled water. All animals were housed in a 12 h light and dark cycle (7 Am), in accordance with the National Institutes of Health Guide for Care and Use of Laboratory Animals.

Mouse model of chronic stress

Mice in model, mosapride and Simotang groups were exposed to chronic stress. A mouse model of chronic stress was induced as previously reported^[13]. In brief, mice were randomly exposed to different stressors daily from day 1 to day 21 as follows: high-speed agitation for 1 min, food deprivation for 48 h, water deprivation for 24 h, tail pinching (2 cm apart from the end of the tail) for 1 min, hung

upside-down for 5 min, heat stimulation at 45°C for 5 min, day and night reversal, and cold stimulation at 4°C for 5 min. Each stressor was repeated twice during the 21 d stress procedure.

Detection of gastric emptying and intestinal propulsion

Gastrointestinal motility was evaluated by testing gastric emptying and intestinal propulsion. Six days after drug or water administration, mice were fasted for 24 h and then administered the last drug or water. One hour later, each mouse administered 0.4 mL semi-solid paste. Twenty minutes later, the mice were sacrificed with 10% chloral hydrate (10.0 mL/kg), and the rate of semi-solid paste in the stomach and the rate of semisolid paste propulsion in the small intestine were measured. The gastric emptying and intestinal propulsion rates in 20 min were calculated according to the following equations^[14]: gastric emptying rate (%) = (semi-solid paste quality-gastric residue quality)/semi-solid paste quality, and intestinal propulsion rate (%) = advanced length of black semi-solid paste/total length of the small intestine × 100%.

Tissue preparation

Intestine, spinal cord and brain were rapidly removed from the mice and immediately fixed with 4% paraformaldehyde for immunohistochemistry. Specimens were cut into 15-μm thick sections with a cryostat and mounted onto silane-coated slides, and dried at 37°C for 60 min. The sections were stored at -70°C. Samples were quickly removed from an environment with a low temperature and immediately stored in liquid nitrogen for RT-PCR.

Measurement of serum motilin level

Serum was collected from the heart of mice after anesthesia, and serum motilin level was measured by ELISA according to its manufacturer's protocol (R&D, USA).

Immunohistochemistry

The sections were incubated with 10 μL normal goat serum at room temperature for 10 min, and treated with rat anti-CCK diluted at 1/100 (Boster Biological Technology, Wuhan, China) at room temperature for 60 min to detect CCK-positive cells in intestine, spinal cord and brain of the mice. The sections were then incubated with biotinylated secondary broad IgG antibody (Zymed Laboratories, CA, USA) for 30 min, reacted with streptavidin peroxidase and aminoethyl carbazole (Zymed Laboratories CA, USA), counterstained with aminoethyl carbazole and observed under an Olympus BX51 microscope (Olympus, Tokyo, Japan). CCK-positive cells were counted under a light microscope (200 × magnification) using the Olympus MicroImage 4.0 software (BX51, Olympus). Ten 200 × microscopic fields per sample were randomly selected from each group, and the cell counts per mm² from 10 fields were averaged.

RT-PCR

Total RNA was extracted using Trizol reagent (Invitrogen,

Table 1 Effect of Simotang on gastric emptying and intestinal propulsion rates in chronically stressed mice (mean \pm SD)

| Groups | n | Gastric emptying rate (%) | Small intestine advancing rate (%) |
|-----------------|----|-----------------------------|------------------------------------|
| Control group | 10 | 48.4 \pm 6.3 | 54.3 \pm 4.5 |
| Model group | 10 | 62.7 \pm 8.5 ^b | 38.2 \pm 3.8 ^b |
| Simotang group | 10 | 51.6 \pm 7.4 ^d | 50.2 \pm 4.7 ^d |

CA, USA) according to its manufacturer's instructions. RNA concentration was measured by 1.5% agarose gel electrophoresis. RT-PCR was performed using a TaKaRa RNA PCR kit (TaKaRa Biotechnology Co., Ltd., Dalian, China) and the sequences of primers used are 5'-TCC-GTGCTTCTGCTAATA-3' for CCK forward primer and 5'-CAGCCATCACTGTCTTCC-3' (242 bp) for reverse primer, 5'-AGGGAAATCGTCGTGGAC-3' for β -actin forward primer and 5'-TGGAAAGGTGGACAGT-GAGG-3' (443 bp) for reverse primer. The PCR products were electrophoresed on 1.5% agarose gels and analyzed using the GIS-1000 digital gel image analysis system (Tanon Science & Technology Co., Ltd., Shanghai, China). Expression levels of CCK mRNA were normalized to those of β -actin mRNA. The experiments were performed at least in triplicate.

Statistical analysis

Data are expressed as mean \pm SD. Statistical analysis was performed by one-way analysis of variance (ANOVA). $P < 0.05$ was considered statistically significant.

RESULTS

Gastric emptying and intestinal propulsion rates for chronically stressed mice after treatment with Simotang

Whether Simotang affects gastrointestinal motility in chronically stressed mice was observed by evaluating their gastric emptying and intestinal propulsion rates. The gastric emptying and intestinal propulsion rates were significantly lower in model group than in control group ($P < 0.01$, Table 1), suggesting that chronic stress leads to gastrointestinal motility disorder in chronically stressed mice. The gastric emptying and intestinal propulsion rates were significantly higher in Simotang or mosapride group than in model group ($P < 0.01$, Table 1).

Serum motilin level in chronically stressed mice after treatment with Simotang

To determine the potential mechanism of Simotang underlying gastrointestinal motility, the serum motilin levels were measured in chronically stressed mice, showing that the serum motilin levels were significantly lower in model group than in control group and significantly higher after treatment with Simotang or mosapride ($P < 0.01$, Figure 1).

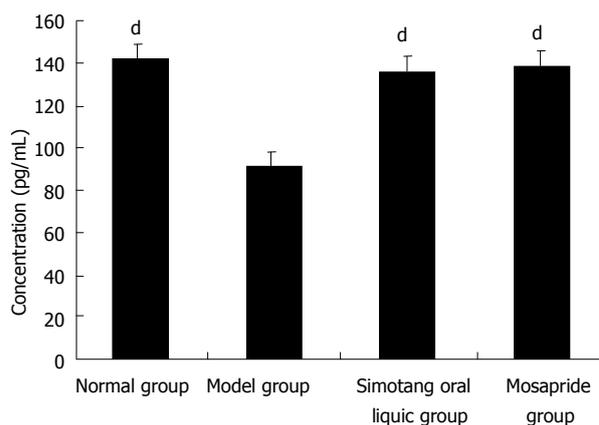

Figure 1 Effect of Simotang on serum motilin level in chronically stressed mice. Values are expressed as mean \pm SD, $n = 10$ /group. ^d $P < 0.01$ vs model group.

Expression level of CCK-positive cells in small intestine, spinal cord and brain of chronically stressed mice after treatment with Simotang

The expression level of CCK-positive cells in control group is shown in Figure 2A-C. The expression level of CCK-positive cell protein was significantly higher in model group than in control group ($P < 0.01$, Figure 2D-F) and remarkably lower in Simotang group (Figure 2G-I) and mosapride group (Figure 2J-L) than in model group ($P < 0.01$, Figure 3).

Expression level of CCK mRNA in spinal cord and brain of chronically stressed mice after treatment with Simotang

The expression level of CCK mRNA was significantly higher in model group than in control group and significantly lower in Simotang and mosapride groups than in model group after treatment with Simotang ($P < 0.01$, Figure 4).

DISCUSSION

FD, a meal-related and pain-predominant symptom in the absence of organic disease according to the Rome III criteria^[15], is considered hazardous to health because of its high prevalence and recurrence rates. Although its etiology and pathogenesis have not been clearly identified, a wide variety of pathogenetic mechanisms are involved. For example, gastrointestinal motor abnormality is thought to be an important mechanism underlying FD^[16]. It has been reported that 20%-40% of FD patients have delayed gastric emptying and altered duodenojejunal motility^[17,18]. With the development of neural gastroenterology in recent years, it has been shown that gastrointestinal motility is modulated by the central nervous system, autonomic nervous system and enteric nervous system (brain-gut axis) through hormones or brain-gut peptides, and that external stimuli can affect the motility or sensation of the gastrointestinal tract through the brain-gut axis^[19]. Psychological factors are considered another important etiology of FD,

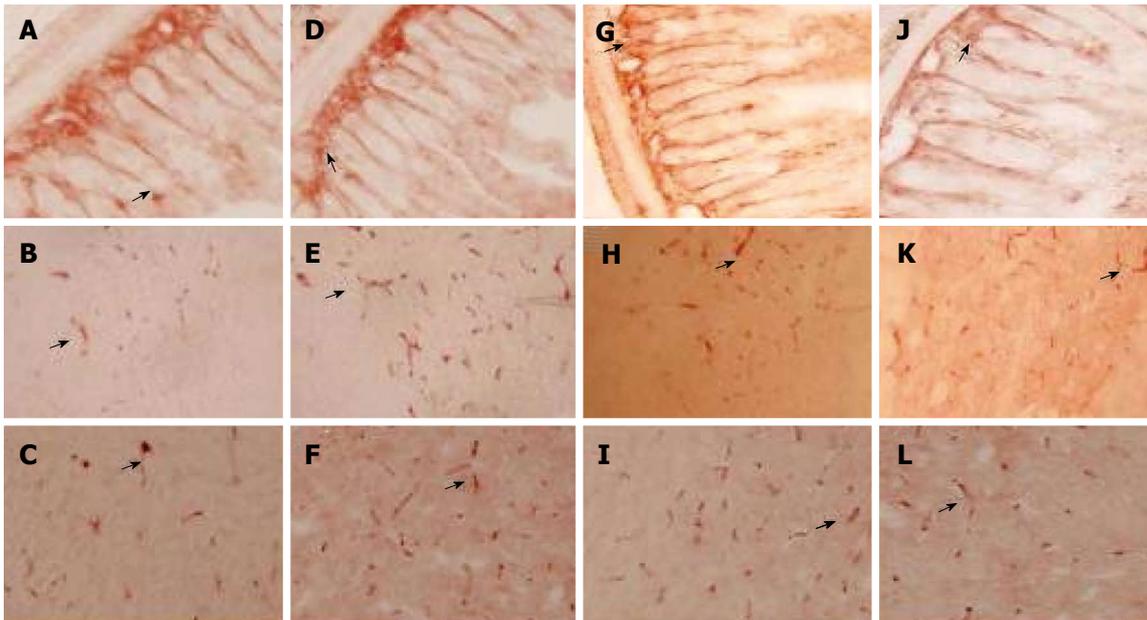

Figure 2 Effect of Simotang on expression of cholecystokinin-positive cells in the small intestine, spinal cord and brain of chronically stressed mice with immunostaining with cholecystokinin in small intestine (A, D, G and J), spinal cord (B, E, H and K) and brain cortex (C, F, I and L) in control group (A-C), model group (E, F), Simotang group (G-I) and mosapride group (J-L). Magnification $\times 200$.

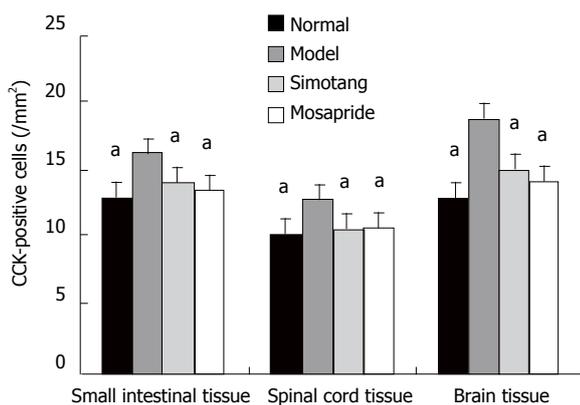

Figure 3 Effect of Simotang on the number of cholecystokinin-positive cells in the small intestine, spinal cord and brain of chronically stressed mice (mean \pm SD, $n = 5$ /group). ^a $P < 0.05$ vs model group.

and FD is currently considered to be a biopsychosocial disorder^[20]. The proportion of psychosocial factors, such as depression and anxiety, is higher in FD patients than in healthy people, and psychosocial factors also affect gastric motility^[21]. Stressed animals are often used as a model of FD. In the present study, the gastrointestinal motility was lower in chronically stressed mice than in unstressed control mice, which is consistent with the reported findings^[22].

Motilin, a hormone secreted by endocrine cells in the duodenal mucosa, interacts directly with its receptor, induces smooth muscle contraction and improves peristalsis in the small intestine^[23,24]. Its concentration is closely related with gastric emptying^[25]. Although the role of motilin in the pathogenesis of FD has not yet been determined, the plasma motilin concentration is lower in FD patients than in healthy people^[6]. FD patients have a similar proximal gastric motor response to motilin as healthy volunteers^[24]. In

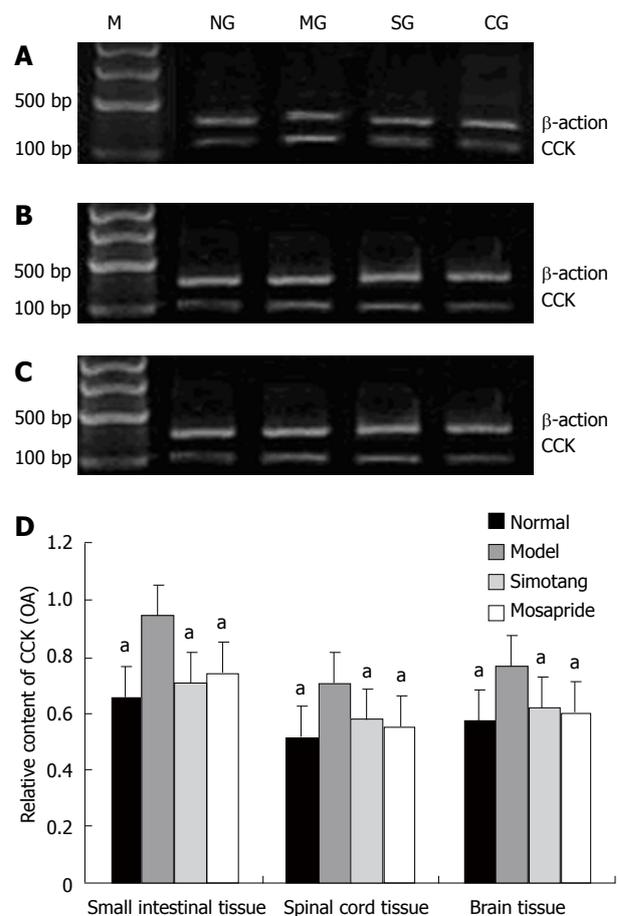

Figure 4 Effect of simotang on cholecystokinin gene expression in the small intestine (A), spinal cord (B), brain (C) of chronically stressed mice, and relative optical density of cholecystokinin RNA in small intestine, spinal cord and brain of chronically stressed mice (D). the present study, the serum motilin level was significantly lower in stressed mice than in unstressed control mice and significantly higher after treatment with Simotang.

CCK is not only a gastrointestinal hormone, but also a neurotransmitter which is widely distributed in both the enteric and central nervous systems^[7,8]. As an established brain-gut peptide, CCK transfers signals between the gut and central nervous system, plays an important role in regulation of gastrointestinal function, and is linked to the etiology of stress-related anxiety disorders. CCK not only inhibits gastric motility and emptying^[26], but also is related to food intake and satiety^[27]. It has been shown that the CCK levels are higher in FD patients than in controls^[28]. Exogenous CCK can suppress the appetite and gastric emptying in healthy volunteers^[29,30]. In the present study, the CCK protein and mRNA levels were increased not only in the small intestine but also in the spinal cord and brain of chronically stressed mice, and the CCK expression level was higher in the brain than in the small intestine and spinal cord of chronically stressed mice. Furthermore, the CCK expression level was higher in the small intestine, spinal cord and brain of chronically stressed mice after treatment with Simotang.

In conclusion, Simotang affects the gastrointestinal motility in chronically stressed mice by regulating the serum motilin level and expression of CCK, which provides a pharmacological basis for its clinical application in treatment of functional gastrointestinal disorders.

COMMENTS

Background

Simotang has been used in treatment of gastrointestinal disorders for hundreds of years but its mechanism is unknown. Dysfunction of the brain-gut axis is thought to be involved in the pathogenesis of functional dyspepsia.

Research frontiers

As one of the brain-gut peptides, cholecystokinin (CCK) not only affects gastric motility and emptying, but also plays an important role in the pathogenesis of Functional dyspepsia (FD). However, how CCK is regulated by Simotang still remains unknown. In the current study, the authors demonstrated that chronic stress could inhibit gastric emptying and intestinal propulsion by investigating the mechanism of Simotang underlying gastrointestinal motility.

Innovations and breakthroughs

The results of this study show that Simotang can improve gastric emptying and intestinal propulsion in chronically stressed mice by regulating the serum motilin level and expression of cholecystokinin in the small intestine, spinal cord and brain of chronically stressed mice.

Applications

By understanding the mechanism of Simotang underlying FD and providing a pharmacological basis for Simotang, it can be used in treatment of functional gastrointestinal disorders.

Peer review

The authors investigated the effect of Simotang on the expression of motilin and cholecystokinin, showing that Simotang can improve gastric emptying and intestinal propulsion in chronically stressed mice by regulating the expression of motilin and cholecystokinin, thus providing a pharmacological basis for the clinical application of Simotang in treatment of functional gastrointestinal disorders.

Abstract

AIM: To characterize the increasing incidence and geographic variation of acute diverticulitis.

METHODS: Using the nationwide inpatient sample (NIS) we identified a cohort who had been admitted with diverticulitis between 1998 and 2005. We calculated age-, sex-, and region-specific rates of hospitalizations for diverticulitis over time.

RESULTS: The age-adjusted hospitalization rate for diverticulitis increased from 61.8 per 100 000 to 75.5 per 100 000 between 1998 and 2005, and increased similarly in both sexes. Diverticulitis-associated admissions were male-predominant in those younger than age 45 years but were female-predominant thereafter. Admission rates increased the most among those < 45 years, while remaining unchanged for those \geq 65 years. By 2005, the majority of hospitalized patients were < 65 years. Age-adjusted rates of diverticulitis-associated

hospitalizations were lower in the West (50.4/100 000) compared to the Northeast (77.7/100 000), South (73.9/100 000), and Midwest (71.0/100 000).

CONCLUSION: Diverticulitis-associated hospitalizations have steeply risen, especially in young adults. These epidemiological trends vary by geographic region and warrant further investigation into potential dietary and environmental etiologies.

INTRODUCTION

Diverticular disease of the colon is among the most prevalent conditions in Western society and is among the leading conditions for outpatient visits and hospitalizations^[1,2]. The prevalence of diverticular disease increases with age, occurring in less than 10% of those who are younger than 40 years and being as high as 66% in those older than 80 years^[3]. Between 10%-25% of individuals with colonic diverticula will develop diverticulitis^[4], of which a quarter can develop life threatening complications such as obstruction, perforation and intraperitoneal abscess formation^[5].

There is significant geographic variation in the preva-

lence of diverticular disease, occurring much less commonly among Asians compared to western populations^[4]. This observation has led to the theory that low-fibre diets may contribute to the development of colonic diverticula^[6]. Additionally, there is emerging evidence that obesity and body mass index may also be predisposing factors^[7,8].

Though diverticular disease is generally thought to be a disease of older adults, there are increasingly common reports of diverticulitis in individuals younger than 50 years^[9]. Based on single-centre reports, these cases were often male-predominant^[10] accompanied by a more aggressive disease course^[8,11]. Using the nationwide inpatient sample (NIS), we sought to ascertain nationwide trends in hospitalizations for diverticulitis particularly among cases of younger onset and to evaluate for geographic variations in hospitalization rates within the US.

MATERIALS AND METHODS

Data source

All data were extracted from the NIS between 1998 and 2005. The NIS is maintained as part of the Healthcare cost and utilization project (HCUP) sponsored by the Agency for healthcare research and quality (AHRQ). These databases reflect a 20% stratified sample of non-federal, acute-care hospitals in the United States. The sampling frame includes community and general hospitals and academic medical centers comprising approximately 90% of all hospital discharges in the United States. Hospitals were grouped into 60 strata based on five hospital characteristics: US census region, location (urban versus rural), teaching versus non-teaching status, ownership (non-federal private or public), and bed-size (tertiles). Each data entry included a unique identifier, demographic variables (defined as age, gender, and race/ethnicity, median income for ZIP code), discharge disposition, primary and secondary diagnoses (up to 15), primary and secondary procedures (up to 15), primary insurance payers, total hospital charges, and length of stay. NIS data concurs with the National hospital discharge Survey, supporting data reliability^[12].

Eligibility criteria

Our analysis included all hospital discharges between the years of 1998 and 2005 that were admitted with a primary or secondary diagnosis of diverticulitis as identified by Clinical Modification of the international classification of diseases, 9th revision (ICD-9-CM) codes (562.11, 562.13) and with a length of stay greater than 1 d.

Statistical analysis

Data were analyzed using the Stata 10.0 SE software package (Stata Corp LP, College Station, Texas). Analyses took into account the stratified two-stage cluster design using stata's SVY (survey data) commands and incorporating individual discharge-level weights. Weighting functions using these hospital and discharge weights were applied to the 20% NIS sample to estimate the total number hospitalizations for diverticulitis throughout the US stratified.

¹Based on admissions with race data which was missing in 25%.

The primary outcome was rate of hospitalization for diverticulitis in the US population. We used the US resident population census from 1998 to 2005 published by the US Census Bureau as the denominator for rate calculations. We calculated age-adjusted rates with the direct standardization method using the US standard population from 2000. We also calculated age-specific and sex-specific rates of hospitalization for diverticulitis and then calculated the percent increase for each year of the study relative to the baseline rate in 1998 within each age group. These analyses were repeated stratified by the US geographic regions: the Northeast, West, South, and Midwest.

Ethical considerations

The analysis of the Nationwide inpatient sample uses completely unidentified data with no risk of loss of confidentiality and an initial expedited review by the Institutional Review Board of the Johns Hopkins Medical Institutions deemed it exempt from further ethical review.

RESULTS

Demographics of diverticulitis admissions

There were 323 097 hospital admissions for acute diverticulitis in the NIS database between 1998 and 2005. The demographic characteristics of the study population are shown in Table 1 stratified by geographic region. There was a greater proportion of diverticulitis admissions in patients who were 65 and older in the Midwest (50%) and the South (49%) compared to the Northeast (44%) and the West (46%). There was a greater percentage of minority Blacks and Hispanics in the South and the West (Table 1).

Epidemiological trends

The rate of hospitalization increased with age in both males and females as shown in Figure 1. Diverticulitis admissions were male-predominant in those younger than 44 years with male-to-female ratio that is as high as 2.8 among those between those 25 and 34 years. For those

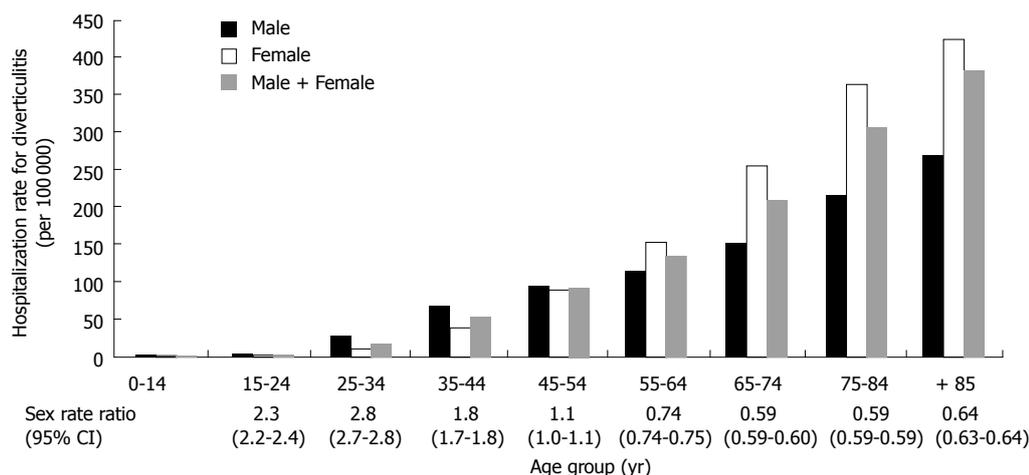

Figure 1 Age-specific hospitalization rates for diverticulitis stratified by sex in the US. Males are shown in black, females in white, and both sexes in gray. Male-to-female ratios with 95% confidence intervals (95% CI) are shown below each age subgroup.

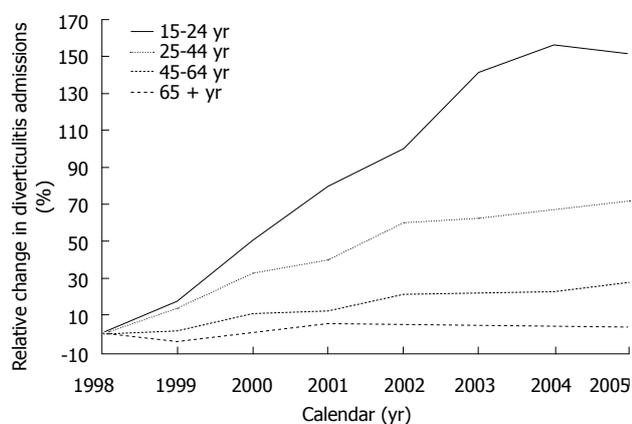

Figure 2 Relative increase in hospitalization rates for diverticulitis in the US between 1998 and 2005, compared to the reference year (1998) stratified by age group.

between 45 and 54 years of age, hospitalizations for diverticulitis were similar between sexes, while after age 54 years, it became increasingly female-predominant.

Table 2 shows the age- and sex-specific rates of hospitalization for acute diverticulitis during the 8 year study period. Age-adjusted diverticulitis-associated hospitalizations increased in both males (52.8 to 59.2 per 100 000) and females (67.3 to 79.6 per 100 000) and across all age groups. The overall age-adjusted hospitalization rate for diverticulitis increased from 61.8 per 100 000 to 75.5 per 100 000 during the study period. Figure 2 depicts the relative percentage increase in hospitalization rate for each age group relative to the baseline rate in 1998. This relative increase was inversely proportional with age, being sharpest in those between 15-24 years (150% overall increase), and gradually less with a 70% increase in those aged 25-44 years, 30% increase in those 45-64 years, and approaching 8% in those

aged 65 years and older. In 1998, the proportion of admissions for diverticulitis in patients who were older than 65 years was 55%. Over the 8 year study period, that percentage decreased to 44%, with the majority of patients being under the age of 65 years by 2005. Those who were under the age of 45 years comprised 12.7% of all admissions for diverticulitis in 1998 and increased to 16.3% in 2005.

Geographic variation in diverticulitis admissions

Table 3 shows age-specific and region-specific rates of admissions for diverticulitis. There was significant geographic variation in overall and age-specific growth rate of hospitalizations for acute diverticulitis. The overall age-adjusted rates of diverticulitis-related hospitalizations were 77.7 per 100000 for the Northeast, 71.0 per 100000

for the Midwest, 73.9 per 100000 for the South, and 50.4 per 100000 for the West. The age-adjusted incidence rate ratio for diverticulitis-associated admission in the West compared to the Northeast was 0.60 (95% CI, 0.59-0.60). There was significant variation in the region-specific proportional change in hospitalization rates relative to the baseline rate in 1998, as shown in Figure 3. The sharpest increases were observed in the Northeast (64.8 to 90.2 per 100000; overall 39%) and the Midwest (60.5 to 74.8 per 100000; overall 33%). The trends were more moderate in the South (69.9 to 76.5 per 100000, overall 11%) and in the West (46.7 to 53.3 per 100000, overall 14%).

There was also regional variation in rising incidence of hospitalizations for diverticulitis among those younger than age 45 years. Rates increased the most in the Northeast (from 24.2 to 44.7 per 100000, overall 85%) and Midwest (from 17.2 to 32.6 per 100000, overall 90%). The rise in hospitalizations in patients younger than 45 years was more moderate in the South (from 17.5 to 29.9 per 100000, overall 71%) and was lowest in the West (from 12.1 to 18.4 per 100000, overall 53%).

DISCUSSION

Our nationwide analysis has demonstrated geographic variations in the burden of diverticulitis and underscores rapidly increasing rates of diverticulitis-associated hospitalizations among individuals younger than age 45 years. These findings have implications for understanding the underlying etiology of diverticulitis as well as for the timely diagnosis of this condition in younger individuals. The rising epidemiological trends and geographic variations in diverticulitis-associated admissions, particularly

among younger individuals, may correlate with observed temporal changes and regional differences in diet and obesity in America.

Diverticular disease is an age-related disorder of the large bowel affecting greater than half of the population over the age of 65 years^[13]. Current evidence suggests that dietary deficiency (of fibre), colonic pressure, motility changes and colonic structural alterations may collectively contribute to diverticula formation^[4]. Parallel epidemiological trends of decreasing dietary fibre and increasing diverticular disease have led to a hypothesized role of fibre deficiency in the pathogenesis of diverticular disease^[6,14]. A large prospective study of 43888 US male health care professionals^[15] found that a decreased intake of insoluble dietary fibre, specifically fruits and vegetables, was associated with increased symptomatic diverticular disease. Similarly, obesity has also been linked to higher incidence of diverticulitis and diverticular bleeding^[7,8]. It is hypothesized that adipose tissue secretes numerous cytokines that are known to participate in local and generalized inflammation and may play a role in the development of diverticulitis^[16].

Our study showed that the overall rates of acute diverticulitis hospitalizations increased in the US in the last decade, which has been previously reported in the US^[9] as well as in the UK^[17] and Finland^[18]. An epidemiological study of adults aged 40-74 years has also shown a rise in obesity, decreased physical activity, and decreased fibre intake which may all contribute to the increasing incidence of diverticular disease^[19]. Similarly, a decline in fibre intake among children and 3-fold rise in childhood obesity in the US over the last 3 decades may also partially explain the sharp rise in admissions for diverticulitis among younger age groups^[20,21].

The higher prevalence of obesity in the South and Midwest may correlate with our findings of higher rates of diverticulitis admissions in those regions compared to the West. Data from the Center for Disease Control showed that in 1991, the Midwest and the South had higher obesity rates compared to the Northeast and West, and this difference had persisted in the ensuing decade 2000^[22]. Data from NHANES-III also showed that BMI was greater in the South and Midwest compared to the other regions^[23]. Childhood obesity has been similarly shown to be most prevalent in the South ($\geq 18\%$) while being least prevalent in the West (11.4%)^[20].

Regional variation in diet may also contribute to geographic differences in diverticulitis admissions. Based on self-reported data, residents from the South consumed more fatty acids and the least amount of fibre, while those from the West consumed higher amounts of fibre than other regions^[23]. One could hypothesize that there may be a protective association between higher fibre intake in the West and corresponding relatively lower age-adjusted rates of diverticulitis admissions. However, the roles of dietary fibre and obesity in geographic variations in diverticulitis remain speculative, and do not explain high rates of diverticulitis admissions in the Northeast. Thus, other environmental and health systems-based factors may be involved. Racial and ethnic differences in risk of diverticulitis may

also contribute to geographic variations in hospital admissions for diverticulitis, particularly in the West, where there is a higher composition of Hispanics and Asians. There is evidence that these ethnic groups may be at lower risk for diverticulitis^[24,25]. Unfortunately, because nearly 25% of racial and ethnic data is missing in the NIS database, we were not able to readily determine race- and ethnic-specific rates in diverticulitis admissions.

Our current study has several limitations inherent to administrative data analyses. The NIS data set does not contain personal identifiers, which does not allow linkage to medical records in order to validate ICD-9 codes for diverticulitis. However, we would not expect the degree of errors in administrative coding to be different with respect to time or age. Thus, this type of non-differential misclassification usually leads to conservative estimates of temporal trends. Additionally, this study evaluated only rates of hospitalization, and would not have included milder cases of diverticulitis managed in an outpatient setting. Furthermore, this is a cross-sectional study and we are unable to longitudinally follow patients after discharge to assess long-term mortality and morbidity such as recurrent diverticulitis or surgery.

Despite these limitations, this nationally representative analysis has demonstrated geographic variations in epidemiological trends in the burden of diverticulitis that will hopefully stimulate hypotheses into the aetiology of diverticular disease. Prospective studies are needed to determine if there is an association between diverticulitis and obesity, dietary intake, and other environmental factors, particularly among younger adults. From a clinical perspective, these findings drive the need for increased vigilance for diverticular disease among younger adults presenting with abdominal pain.

COMMENTS

Background

The incidence of diverticular disease increases with age. Between 10%-25% of individuals with colonic diverticula develop diverticulitis. Recent epidemiologic studies have shown a male predominant increase in diverticulitis in those under 45 years.

Research frontiers

The nationally representative analysis indicates that the burden of diverticulitis and the time trends in admissions vary by geographic region and may be associated with a decreased intake of insoluble dietary fibre and increasing obesity.

Innovations and breakthroughs

The steep rise in diverticulitis admissions among young adults is striking. From a clinical perspective, these findings drive the need for increased vigilance for diverticular disease among younger adults presenting with abdominal pain.

Applications

Prospective studies are needed to determine if there is an association between diverticulitis and obesity, dietary intake, and other environmental factors, particularly among younger adults.

Peer review

While this study is not entirely unique, it is well-written and would make a useful addition to the current literature on diverticular disease.

Abstract

AIM: To investigate the spleen vascular involvement and the presence of liver fibrosis in a population of subjects with established systemic sclerosis (SSc).

METHODS: In a cross-sectional fashion, 17 patients with SSc were compared with 18 patients suffering from hepatitis C virus (HCV)-related liver cirrhosis, grade A and B Child-Pugh classification. Eighteen non elderly subjects, apparently healthy, were used as the control group. Splenic artery resistivity index (SARI) at

doppler ultraSound, transient elastography of liver and nailfold capillaroscopy were the main outcomes.

RESULTS: Transient elastography values of SSc patients were similar to those of controls; 5.2 ± 1.1 vs 4.5 ± 1 , ($P = 0.07$). Median Alanine amino transferase (ALT) concentrations of cirrhotic patients were greater than those of controls and SSc patients, i.e. 66.5 (36-89) U/L vs 29 (22-34) U/L and 31 (22-41) U/L, respectively, ($P = 0.005$). SARI determinations in cirrhotic patients, although significantly higher than those found in controls and SSc patients, showed some degree of overlap with SSc patients, i.e. 0.59 vs 0.52 and 0.57, respectively, ($P = 0.04$). Mean systolic blood pressure was significantly higher in SSc patients than in cirrhotics and controls, i.e. 142 mmHg vs 128.2 mmHg and 127 mmHg, respectively, ($P = 0.005$). Mean diastolic blood pressure behaved in a similar fashion, i.e. 84 mmHg vs 72.2 mmHg and 76.9 mmHg ($P = 0.005$). Nailfold Capillaroscopy grades and diastolic blood pressure values correlated well with SARI results.

CONCLUSION: An enhanced resistivity of the splenic artery was found in patients suffering from SSc; they did not have evidence of splenomegaly as well as no liver fibrosis or any other form of liver damage.

INTRODUCTION

Systemic sclerosis (SSc) is a disease characterized by a complex interplay of inflammation, fibrosis and vascular damage. In fact, the arterial microvessels of SSc display rarefaction and mural thickening, including medial smooth muscle and intimal cell hyperplasia^[1]. Vasculopathy, showing surprising similarities in various areas, i.e. pulmonary, renal, cerebral and peripheral, induces pulmonary arterial hypertension (PAH), scleroderma renal crisis, severe cerebral vasculopathy and digital tip ulcers. Endothelin-1 is a potent mediator of vascular features in SSc^[2], but immunological mechanisms also participate in SSc pathogenesis. They include a Th1/Th2 imbalance in CD4+ T cells^[3], an increase of type 2 cytokine-producing T cells in target organs^[4] and the presence of autoantibodies with fibroblast-activating capacities^[5]. Finally, caveolin-1 has been thought to regulate the signaling of transforming growth factor- β ^[6], a key determinant in SSc. In fact, the core lesion of SSc is the uncontrolled fibrosis involving internal organs and derma.

There are some *a priori* reasons, mainly indirect causations, for predicting a reasonable incidence of hepatic fibrosis in patients with SSc. The hepatic mesenchymal tissue would be expected to share enhanced synthesis and/or deposition of collagen. The liver having a double blood supply, playing a central role in the induction of immune tolerance and also being a target for immune-mediated damage, it could actively participate in systemic diseases. Surprisingly, the extensive literature on SSc provides no definitive indications of the incidence and nature of associated hepatic fibrosis in the direct, the indirect (hepatotoxicity) or the fortuitous (occult viral infection and associated autoimmune or metabolic co-morbidities) types. As the “companion” organ of the liver, the spleen plays an important role in splanchnic hemodynamics, beyond its established immunologic functions^[7]. This occurs through changes in intrasplenic microvascular tone and through reflex activation of the splenic afferent sympathetic nerves^[8]. Actually, it is recommended to perform a biopsy examination to assess the liver participation in SSc^[9,10]. However, what about unravelling hepatic fibrosis when ethical and legal issues do not permit invasive tests? Systematic reviews have demonstrated that evaluation of liver stiffness by transient elastography (TE) is clinically useful for the diagnosis of various grades of fibrosis in the course of chronic liver diseases^[11], even though it is better at excluding than at predicting cirrhosis^[12]. Parameters of doppler ultrasound (DUS) are reckoned to be the new biomarkers of the liver-spleen circulatory axis^[13,14], by way of substituting the estimation of hepatic venous pressure gradient (HVPG) that is an expensive technique^[15] based on catheterism. Among these hemodynamic indices SARI has one of the closest

correlations to HVPG < 12 (non-severe portal hypertension)^[16]. On the other hand, enlargement of spleen may be associated with portal hypertension-related events in most patients with advanced chronic liver disease^[17]. Thus, hypothesizing a diffuse vascular injury^[18], and considering that mechanisms similar to those of SSc play a role in cirrhotic portal hypertension^[19,20], it is conceivable that a hemodynamic alteration of the spleno-portal axis could be present in SSc patients. Therefore, in a population of subjects with established SSc, the presence of liver fibrosis was investigated by TE and assessment of the spleen vascular involvement was carried out by DUS; the results of DUS were compared with those found in subjects with an advanced chronic liver disease characterized by a hyperdynamic circulation and increased resistance in the hepatic and spleen vascular bed. Furthermore, we tried to track the possible association between DUS findings and other vascular parameters such as blood pressure and nailfold capillaroscopy (NFC).

MATERIALS AND METHODS

Patients

Seventy-two subjects formed the initial study population. Twenty-six consecutive patients who fulfilled the American College of Rheumatology (formerly, the American Rheumatism Association) criteria for SSc^[21], having been classified as having limited cutaneous (lc) SSc or diffuse cutaneous (dc) SSc according to the criteria described by LeRoy *et al.*^[22], were selected. Three SSc patients were disallowed as they were on penicillamine therapy. Six other patients were excluded, two of whom due to contextual HCV infection, one to alcohol abuse and three to non-alcoholic fatty liver disease (NAFLD) presence in diabetics. The remainder (17 patients), who were on low doses of prednisone \leq 10 mg and vasodilators, acted as the SSc group. Mean duration of disease was 3.5 years.

Twenty-six patients suffering from HCV-related liver cirrhosis, genotype 1b, grade A and B Child-Pugh classification, were selected to be compared with the SSc patients. They were diagnosed on the basis of liver biopsy (8 cases), the remainder on the grounds of appropriate tests. Briefly, the presence of cirrhosis was established by appropriate clinical (spider nevi, hepato-splenomegaly), laboratory (low serum total cholesterol, prothrombin activity and pseudocholinesterase levels, reduced white blood cell and platelet count, globulin/albumin ratio > 1) as well as imaging data of the liver (coarse echo-texture, nodularity presence, increased caudate/right lobe ratio, hypertrophy of the left lobe, characterized by a rounded inferior marginal edge, and portal vein enlargement with decreased flow velocity, absence of a normal doppler waveform, hepatofugal flow). Eight patients were excluded as they were cryoglobulinemic and likely suffering from vasculitis. Eighteen patients were finally considered as forming the cirrhotic group. A cohort of non elderly subjects (18 cases), apparently healthy, was used as a control group. Laboratory data and instrumental measurements were strictly

carried out within one month of each other. The protocol was consistent with the principles of the Declaration of Helsinki, and participants gave their informed consent. The study had no external funding source.

Transient elastography

Liver stiffness was assessed by means of a Fibroscan (Echosens, France). At least 10 measurements per patient were obtained, using the standard probe. These were averaged and reported as kPa. A success rate of at least 60% was considered necessary. In our population, special care was taken in order to make sure there was no A-shaped wave on the elastogram, which indicates an incorrectly accepted (non-automatically rejected) measurement, leading to an overestimation of the stiffness produced by influence of the surrounding rib bone and soft tissue.

Doppler ultrasonography

Spleen longitudinal diameter (SLD) was performed by postero-lateral scanning at US, using a Tecnos (EsaOte, Italy). The Maximum Length (ML, the optically greatest overall longitudinal dimension obtained from one of the two poles) and the Cranio-Caudal Length (CCL, the optically maximal transversal dimension intercepting one of the two poles) were measured; the resulting values were then averaged, since the two measurements do not always coincide. SLD (ML+CCL/2) was also measured in controls to set reference intervals as mean values of TE.

SARI values at DUS were automatically calculated with the following formula: RI = peak systolic velocity-end systolic velocity/peak systolic velocity. The probe was positioned below the left costal arch or in the left costal spaces. Color Doppler allowed identification of the main branches of the splenic artery. Antihypertensive drugs were withdrawn at least three days before the test.

Nailfold capillaroscopy

All nailfold capillaroscopy (NFC) procedures were performed in a stereomicroscope (Olympus-SZ40) under 10-20x magnification according to the protocol proposed by Andrade *et al.*^{23]}. All the ten digits of the hands were examined, except when prevented by extremely poor visibility. The following parameters were analyzed: (1) number of capillary loops/mm; (2) vascular deletion score; (3) number of enlarged loops (about four times the normal afferent, transition, and efferent limb widths); and (4) number of giant capillary loops (10 or more times the normal width of capillary limbs). Enlarged and giant loops were counted together. The vascular deletion score was assessed according to a well-known method^{24]}, in which a deletion area is defined as the absence of two or more consecutive loops. Each finger was rated from 0 to 3: grade 0, no deletion area; 1, one or two discrete deletion areas; 2, more than two discrete deletion areas; and 3, extensive and confluent deletion areas. For each patient the NFC parameters were calculated as the average obtained in all analyzed digits.

Transthoracic echocardiography

Because transthoracic echocardiography (TTE) is a reproducible method, it was used as a non-invasive diagnostic tool to determine pulmonary arterial pressure and helped us exclude any secondary causes of PAH in SSc patients with unexplained dyspnea. According to a peak velocity of tricuspid regurgitation (VTR) ≥ 3.0 m/s at TTE, which is consistent with international guidelines^{25]}, PAH was diagnosed. Once the diagnosis of PAH was established, together with several parameters (ventricular function, exercise parameters, peak oxygen uptake or peak systolic blood pressure), NYHA functional classes were selected to predict prognosis in these patients.

Blood pressure measurements

The systolic/diastolic blood pressure (SBP, DBP) was the average of three consecutive readings taken by the physician during the day, during usual practice hours, after subjects had rested for five minutes in the sitting position.

Laboratory data

ALT activity was determined by in-house standard procedures. Sera samples were tested for anti-nuclear antibodies (ANA) using indirect immunofluorescence and HEp-2 cells as antigen substrate (Antibodies Inc., Davis, CA). Anti-centromere antibodies (ACA) were determined by their distinctive IIF pattern on HEp-2 cells. Autoantibodies to topoisomerase I (ATA) were determined by passive immunodiffusion against calf thymus extract (Inova Diagnostics, San Diego, CA).

Statistical analysis

Liver stiffness, age, SARI, SLD, systolic blood pressure and diastolic blood pressure data derived from a normally distributed population (Shapiro-Wilk test (S-W), $P = 0.94$; S-W, $P = 0.98$; S-W, $P = 0.23$; S-W, $P = 0.064$; S-W, $P = 0.26$; S-W, $P = 0.11$, respectively) were expressed as mean plus SD. A variable not normally distributed, such as ALT (S-W, $P = 0.001$) was expressed as median (range). NFC grades were considered ordinals and managed in the same way. The difference of means was evaluated by Two-Sample t test, two-tailed probability. Frequencies were evaluated by χ^2 , or in case of more than two groups by χ^2 for trends. Tracking the degree of association between single parameters, i.e. NFC scores and SARI determinations, Spearman's rho for non uniform intervals was used. The Pearson's coefficient (r) was employed to analyze the correlation between blood pressure values and SARI determinations. One-way analysis of variance (ANOVA) with the Student-Newman-Keuls test for all pairwise comparisons was performed to examine differences among groups; when dealing with a variable not normally distributed the Kruskal-Wallis test with post-hoc analysis was adopted. To predict the presence of PAH, logistic regression (enter method), with relative odds ratio (OR) and 95% confidence intervals (CI), was employed, utilizing as independent variables ATA positivity. Following the clinical and laboratory standards

Table 1 Demographic, clinical and instrumental data of the population (mean \pm SD)

| Variables | SSc | Liver cirrhosis | Controls | P-value |
|---------------------------|-----------------|-----------------|-----------------|--------------------|
| The number of patients | 17 | 18 | 18 | |

PAH: Pulmonary arterial hypertension; ATA: Anti-topoisomerase 1 antibodies; ACA: Anti-centromere antibodies; ANA: Anti-nuclear antibodies; GI: Gastro-intestinal motility disorders; DUS: Doppler ultrasonography; US: Ultrasonography; SLD: Spleen longitudinal diameter at US; ALT: Alanine amino-transferase; TE: Transient elastography; NFC: Nailfold capillaroscopy; SD: Standard deviation; C-P: Child-Pugh classification; ND: Not determined; ¹: χ^2 for trend.

institute 2008 guidelines (C28-A3) for smaller samples, the 90% CIs were estimated to set our normal range of TE and SLD at US. The concordance correlation coefficient (ρ_c), which measures precision and accuracy, was adopted to evaluate the degree of pair observations at US. Statistical analysis was performed operating on medcalc version 10.4.8[®] (Frank Schoonjans) software package.

RESULTS

In order to allow readers to gauge the internal validity of this study, we emphasize that the minimal required sample size, with a type I error of 0.05 and power of 68%, when breaking the population into two groups (i.e. controls and SSc patients) by SARI values (means = 0.56 and 0.52 with a pooled SD of 0.06), was calculated in 18 subjects. Additionally, to weigh how well the study findings apply to the patients (external validity) we stress that the fifty-three subjects, divided into three cohorts well balanced for gender and age, were studied in a cross-sectional fashion.

Demographic, clinical and instrumental characteristics of the full population are represented in Table 1. TE values of SSc patients were similar to those of controls, 5.2 \pm 1.1 *vs* 4.5 \pm 1, $P = 0.07$, two-sample *t* test, two-tailed probability.

Median ALT concentrations of cirrhotic patients were greater than those of controls and SSc patients, i.e. 66.5 (36-89) U/L *vs* 29 (22-34) U/L and 31 (22-41) U/L, respectively, $P = 0.005$, Kruskal-Wallis with post-hoc analysis (Figure 1).

In cirrhotic individuals, SLD showed values superior to those of control subjects and SSc patients, i.e. 130.4 mm *vs* 100.9 mm and 102.3 mm, respectively, $P = 0.0001$, ANOVA with Student-Newman-Keuls test (Figure 2). In contrast, SARI determinations in cirrhotics, although significantly higher than those found in controls and SSc patients, showed some degree of overlap with SSc patients, i.e. 0.59

vs 0.52 and 0.57, respectively, $P = 0.04$, ANOVA with Student-Newman-Keuls test (Figure 3). Successively, we failed to find much higher values of SARI in the SSc subjects suffering from PAH, this being present in only three out of 17 individuals (18%), at least at the time of observation.

Mean systolic blood pressure was significantly higher in SSc patients than in cirrhotics and controls, i.e. 142 mmHg *vs* 128.2 mmHg and 127 mmHg, respectively, $P = 0.005$, ANOVA with Student-Newman-Keuls test (Figure 4). Mean diastolic blood pressure behaved similarly, i.e. 84 mmHg *vs* 72.2 mmHg and 76.9 mmHg, respectively, $P = 0.005$, ANOVA with Student-Newman-Keuls test (Figure 5).

Associations and prediction

There was a substantially good association between SARI measurements and NFC grades, i.e. Spearman's rho = 0.51, $P = 0.04$ (Figure 6).

Diastolic blood pressure values correlated well with SARI results (i.e. Pearson's $r = 0.57$, $P = 0.01$); meanwhile, systolic blood pressure did not (i.e. Pearson's $r = 0.25$, $P = 0.05$).

SARI data were not correlated with SLD measurements, both in cirrhotics and SSc patients (i.e. Pearson's $r = -0.20$, $P = 0.43$ and Pearson's $r = 0.19$, $P = 0.45$, respectively). At univariate analysis, ATA positivity did not predict PAH presence, OR 1.5, 95% CI: 0.1 to 20.7, $P = 0.7$.

Agreement

The intra-observer and inter-observer errors at US and DUS, measured as concordance correlation coefficients, were found more than acceptable, i.e. $\rho_c = 0.89$ and 0.88, respectively.

Reference Intervals

The non-parametric percentile methods of TE and SLD yielded the following normal ranges, i.e. 2.4-6.1 kPa and 83-110 mm, respectively.

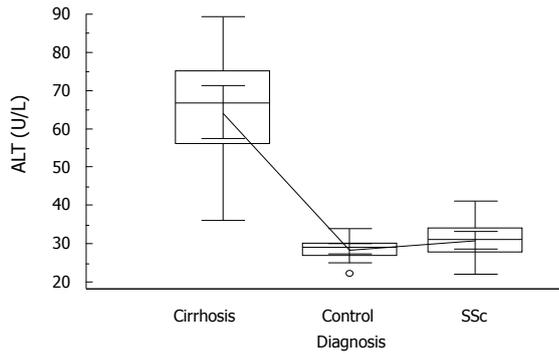

Figure 1 Behavior of alanine amino transferase activity in the various groups. Cirrhotic patients clearly showed a median value higher than that of scleroderma (SSc) patients and control subjects, both of whom were characterized by values within normal range.

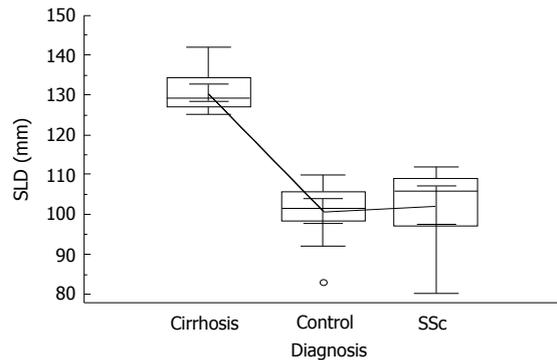

Figure 2 Behavior of spleen longitudinal diameter in the various groups. As is evident, cirrhotic patients showed a mean value significantly higher than that of scleroderma (SSc) and control subjects, both of whom were characterized by normal values.

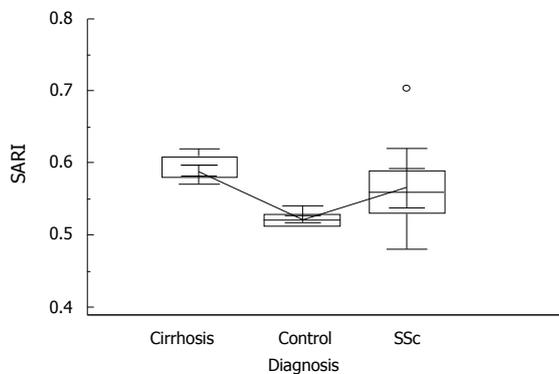

Figure 3 Behavior of splenic artery resistivity index in the various groups. Scleroderma (SSc) patients clearly showed a mean value significantly higher than that of control subjects, whose values were within the normal range, but significantly lower than that of cirrhotic patients and somewhat overlapping with them.

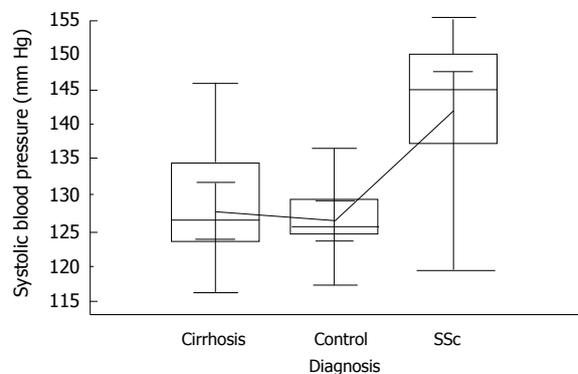

Figure 4 Behavior of systolic blood pressure, expressed in mmHg, in the various groups. Scleroderma (SSc) patients clearly showed a mean value significantly higher than that of control subjects and cirrhotic patients, both groups showing values within the normal range.

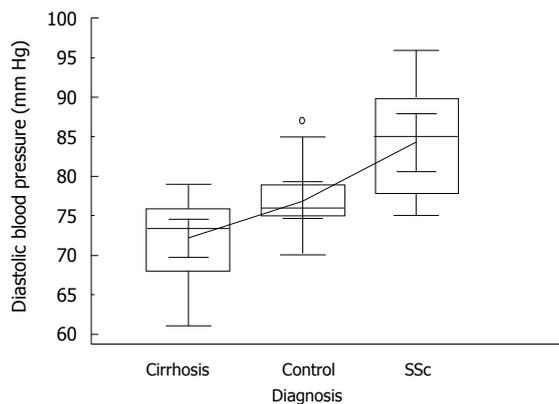

Figure 5 Behavior of diastolic blood pressure, expressed in mmHg, in the various groups. Scleroderma (SSc) patients clearly showed a mean value significantly higher than that of control subjects, but a little overlapping, as were cirrhotic patients; both groups showing values within the normal range.

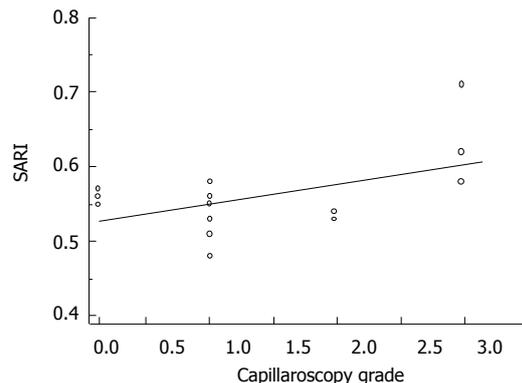

Figure 6 Good correlation between nailfold capillaroscopy grades (0-1-2-3) and splenic artery resistivity index in scleroderma patients.

DISCUSSION

To provide a brief synopsis of key findings, we stress the following: (1) an enhanced resistivity of the splenic artery was found in patients suffering from SSc; and (2) they did not demonstrate splenomegaly as well as liver

fibrosis or any other form of liver damage.

Our data agree with the body of present knowledge that provides evidence for the idea that, in addition to inflammatory infiltrates and an accumulation of extracellular matrix proteins, vascular changes are a hallmark in the pathogenesis of SSc. Consistent with the systemic vascular damage (the vasoactive endothelin-1 system?) we find important evidence, i.e. the strict association between SARI

values and the severity of features at NFC and between the same DUS parameter and diastolic blood pressure values. Surprisingly, SARI values were somewhat overlapping with those found in patients suffering from liver cirrhosis.

Considering possible discrepancies of our findings, such as why SARI does not keep up with increased spleen volume in SSc, we hypothesize that high values of this parameter are due to an intrinsic spleen vascular damage and not to portal hypertension as canonically present in cases of marked liver fibrosis following chronic liver injury. This divergence requires a distinct involvement of the two organs, i.e. spleen and liver in SSc; the former characterized by a vascular change and the latter apparently not damaged. However, what is the significance of the splenic artery in determining the increased spleen volume in the cirrhotic patients group? It is believed that passive venous congestion is the major cause of splenomegaly in advanced chronic liver disease, even though blood hyper-afflux plays an important part. Our data do support the concept of venous congestion. In fact, there was no correlation between spleen size and SARI measurements in cirrhotics, shedding further light on the mechanisms of portal hypertension in these patients with a quite compensated form.

Returning to the possible deposition of connective tissue in liver, beyond the reliance on a preliminary impression that has basis in the fragmentary published data, hepatic involvement in SSc is generally considered rare. As previously emphasized, treatment with potentially hepatotoxic drugs, coincident viral chronic hepatitis or NAFLD have usually been implicated as the main causes of liver disease in patients with connective tissue diseases. However, even after careful exclusion of these etiologies, the question remains whether to classify the patient as having a primary liver disease with associated autoimmune disorder or as having liver disease as a manifestation of generalized connective tissue disease. Now, when addressing the hepatic entanglement in our cohort of SSc patients, the absence of liver damage had been sufficiently documented, at least until the study period, even if it could not be rejected with certainty, due to the lack of histology. Obviously, if we take into consideration that nearly all the hepatic co-morbidities were excluded, we would end up in reinforcing the hypothesis that the vascular changes of the spleen are not linked to a concomitant chronic liver disease. It is therefore natural to ask whether the normal volume of spleen could play a role in explaining the absence of a liver disease. First of all, it is necessary to stress that a light-moderate chronic injury could not always be linked to an increased spleen volume. On the other hand, normal spleen size excludes an idiopathic portal hypertension complicating SSc^[26].

Commenting on drawbacks of the present study and the methods used to compensate for the main ones, we pinpoint that, although liver biopsy remains the 'best standard' to assess liver fibrosis presence, limitations are considerable, including patient discomfort and rare, but serious, complications such as bleeding or pneumothorax and a mortality rate of 1/10000 to 1/12000. Moreover, only 1/50000 of the liver volume is investigated, resulting in

sampling error^[27]. Furthermore, this tool, representing an 'instant snapshot' of a dynamic process, does not reflect a long-lasting assessment. For this reason, other authorities employ substitute 'gold standards' as relate to the natural history of the disease. Alternative attempts to diagnose and follow-up the collagen deposition in liver range from routine biochemistry (AST/platelets calculated ratio, APRI) to surrogate fibrosis markers in serum^[28], hepatic clearance tests, various imaging techniques and, more recently, the use of non-invasive TE. The reported values of this tool give a good correlation with various markers of fibrosis and increase proportionally with the progression of the hepatic fibrosis stage^[29]. There are no evidence-based data justifying biopsy as a first line estimate of liver fibrosis. Health authorities in some countries have already approved validated biomarkers as the first line procedure for the staging of liver fibrosis^[30]. However, HVPG should have been employed in our SSc cohort to exclude increased portal hypertension, but this is based on an invasive technique and X-ray exposure; thus, heavy ethical restrictions did not permit its use in our patients without evidence of serious liver chronic diseases. In this respect, DUS examination is gaining widespread consensus in order to provide patients, suspected of having portal hypertension, with important diagnostic/prognostic information. Moreover, it is important to pinpoint the lack of data from TE in cirrhotic patients; but this tool, as previously emphasized, is very good at excluding advanced chronic disease, not at confirming its presence. Final flaws could be the small sample size due to the fact that this study was carried out using "strict" inclusion criteria and the fact that SSc is a heterogeneous disease; clinical presentations are highly variable among the patients. This may result in a wide range of SARI in patients with SSc. We should have analyzed which disease subset (diffuse *vs* limited cutaneous SSc, short *vs* long disease duration, or the presence *vs* absence of individual organ involvement) was associated with high SARI in SSc, although the number of patients enrolled was too small to perform sub-analysis.

In conclusion, as we have revealed spleen vascular changes, the crucial future research direction should zero in on other vascular areas, such as retinal artery^[31] or renal artery^[32], by means of the simple and reliable tool that is DUS, to evaluate to what extent vasculopathy is represented in SSc. If these data are confirmed and expanded in a larger population, physicians will be advised to investigate the spleen circulation at the "earliest possible time" in the progression of disease to provide another window on systemic vasculopathy of these patients. How significant a role can this clinical study play? The clinical implications of this work summarized in a straightforward and circumspect manner are that our data support the possibility of a new tool (SARI) to evaluate this ongoing process in SSc, mainly before and after disease-modifying treatment.

COMMENTS

Background

Systemic sclerosis is a disease characterized by a complex interplay of inflam-

mation, fibrosis and vascular damage. In fact, the arterial microvessels of systemic sclerosis display rarefaction and mural thickening, including medial smooth muscle and intimal cell hyperplasia.

Research frontiers

There are some a priori reasons, mainly indirect causations, for predicting a reasonable incidence of hepatic fibrosis in patients with systemic sclerosis. The hepatic mesenchymal tissue would be expected to share enhanced synthesis and/or deposition of collagen.

Innovations and breakthroughs

The key findings in this study were the following: (1) an enhanced resistivity of the splenic artery was found in patients suffering from systemic sclerosis; and (2) they did not demonstrate splenomegaly as well as liver fibrosis or any other form of liver damage.

Applications

Having revealed spleen vascular changes, the crucial future research directions should zero in on other vascular areas, such as retinal artery or renal artery, by means of the simple and reliable tool that is doppler ultraSound, to evaluate to what extent vasculopathy is represented in systemic sclerosis. If these data are confirmed and expanded in a larger population, physicians will be advised to investigate the spleen circulation at the "earliest possible time" in the progression of disease to provide another window on systemic vasculopathy of these patients.

Peer review

The authors investigated the spleen vascular involvement and the presence of liver fibrosis in patients with established SSc. In order to proceed as described above, they have included in the present study seventeen patients with SSc compared with eighteen patients suffering from hepatitis C virus-related liver cirrhosis and eighteen non elderly subjects as a control group. As findings, the authors relate an enhanced resistivity of the splenic artery in patients suffering from SSc, who did not demonstrate splenomegaly as well as liver fibrosis or any other form of liver damage.

RESULTS: Wild type survivin mRNA isoform was expressed in 48% of the 52 tumor samples, survivin-2b in 38% and survivin- Δ Ex3 in 29%, while no expression was found in normal tissues. The mRNA expression of wild type survivin presented a significant correlation with the expression of the ratio of survivin-2b, survivin- Δ Ex3, survivin-2b/wild type survivin and survivin- Δ Ex3/wild type survivin ($P < 0.001$). The mRNA expression of wild-survivin and survivin- Δ Ex3 was related with tumor size and invasion ($P = 0.006$ and $P < 0.005$, respectively). A significant difference was found between survivin-2b and morphologic cancer type. Also, the ratio of survivin- Δ Ex3/wild-survivin was significantly associated with prognosis. No association was observed between the three isoforms and grade, metastasis, Dukes stage and gender. The three isoforms were not correlated with CEA and CA19-9.

CONCLUSION: Survivin isoforms may play a role in cell apoptosis and their quantification could provide information about clinical management of patients suffering from colorectal cancer.

Abstract

AIM: To investigate three isoforms of survivin in colorectal adenocarcinomas.

METHODS: We used the LightCycler Technology (Roche), along with a common forward primer and reverse primers specific for the splice variants and two common hybridization probes labeled with fluorescein and LightCycler-Red fluorophore (LC-Red 640). Real time quantitative polymerase chain reaction (PCR) was performed on cDNAs from 52 tumor specimens from colorectal cancer patients and 10 unrelated normal colorectal tissues. In the patients group, carcinoembryonic antigen (CEA) and CA19-9 tumor markers were also measured immunohistochemically.

Key words: Survivin; mRNA isoforms; Apoptosis gene; Colorectal adenocarcinomas; Real time quantitative polymerase chain reaction; Lightcycler

Survivin isoforms and clinicopathological characteristics in colorectal adenocarcinomas using real-time qPCR. *World J Gastroenterol* 2011; 17(12): 1614-1621 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i12/1614.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i12.1614>

INTRODUCTION

Apoptosis is a tightly controlled procedure of cellular death, which is crucial for tissue homeostasis^[1]. Inhibition of apoptosis results in tumorigenesis by cell survival allowing the accumulation of genetic mutations that promote transformation of normal tissues^[2]. Among key regulators of apoptosis are proteins of the bcl-2 family and the inhibitors of apoptosis (IAP) family of proteins^[3-5].

Survivin was originally identified by structural homology to IAPs in human B-cell lymphomas. It is a multifunctional protein implicated in the control of cell proliferation, inhibition of apoptosis and the promotion of angiogenesis^[6,7]. Survivin, as an inhibitor of apoptosis directly inhibits caspase-3 and -7 activity and regulates the cell cycle in the G2/M phase^[8].

Survivin is expressed during embryonic and fetal development, is down regulated in normal adult tissues and is overexpressed in a variety of human cancers^[9,10]. A strong association between expression of survivin mRNA and aggressive tumor behavior has been found in many types of cancer such as colorectal, breast, non-small lung cancer, gliomas and B-cell lymphomas^[11-15].

In addition to the wild type survivin full length transcript, five other splice variants have been identified: survivin-ΔEx3 that arises from the removal of exon 3, survivin-2b^[16] that originates from the inclusion of intron 2, survivin-3b that stems from the inclusion of intron 3^[17] survivin-2a made from the insertions of exon 1 and 2 at the 5' end of intron 2^[18], and the recently described survivin-2b + 32 which combines intronic sequence 2b and an insertion of 32 additional nucleotides from intron 2^[19] (Table 1).

Wild type survivin and survivin-ΔEx3 have been shown to act as inhibitors of apoptosis while survivin-2b presents pro-apoptotic functions by dimerizing with wild type survivin and reducing the anti-apoptotic effects of wild type survivin^[16,20,21]. The ratio survivin-2b/wild-survivin is higher in tumor samples compared to normal tissues. Survivin-2a is also expressed at high levels in malignant cells and attenuates the antiapoptotic effect of wild-survivin^[22]. Inhibition of apoptosis by survivin predicts a poor prognosis and a shorter survival in patients suffering from carcinomas^[23-28].

Till now, there has only been one other study in the literature investigating the expression of survivin's isoforms in colorectal cancer using quantitative real time-PCR^[24]. In this study, we obtained quantitative data for the distribution of the most described transcripts, which are wild type survivin, survivin-ΔEx3 and survivin-2b in colorectal adenocarcinomas by using the accurate and sensitive real time-qPCR in the Lightcycler platform. Then, we investigated their correlation with clinicopathological characteristics of colorectal cancer, and evaluated their prognostic significance.

MATERIALS AND METHODS

Patients

Fifty-two tissues from patients with colorectal cancer and another 10 unrelated normal samples were obtained from

the 4th Department of Surgery, Attikon University General Hospital. Part of the resected specimens at surgery was immediately stored in RNA Later (Ambion, USA) for at least 2 d at 4°C and then stored at -80°C until total RNA extraction. Our sample population included 21 males and 31 females [mean age: 63 years, standard deviation (SD) ± S13, range: 36-93 years]. The histological type and grade were reviewed and classified according to the World Health Organization classification criteria, and the disease stage was determined according to the Dukes staging system. The clinical characteristics of 52 patients with colorectal cancer are shown in Table 2. No patients underwent chemotherapy or radiation therapy before surgery.

Total RNA isolation

Total RNA was extracted by the Illustra RNAspin Mini RNA isolation kit (GE Healthcare, USA) according to the manufacturer's instructions. DNA contamination was eliminated by the use of RNase-free DNase I (GE Healthcare). The extracted total RNA was dissolved in free diethylpyrocarbonate (DEPC) treated water and stored at -80°C until further manipulations. RNA concentration was determined by the Quant-iT RNA Assay kit in Qubit fluorometer (Invitrogen, USA).

Reverse transcription- quantitative real-time PCR analysis

For complementary DNA (cDNA) synthesis, the Transcriptor First strand cDNA synthesis kit (Roche Applied Science, USA) was used according to the manufacturer's instructions. In each reaction, 3 μ g of quantitated total RNA was included. The cDNAs were stored at -20°C until real time quantitative PCR was performed in the Light-Cycler 1.5 platform (Roche Applied Science). One μ L of cDNA mixture was subjected to amplification in 10 μ L total volume reaction mixtures in glass capillaries. Real time PCR was performed with the FastStart DNA Master Hybprobe kit (Roche Applied Science) and cycling conditions were: initial denaturation at 95°C for 10 min, followed by 45 cycles of denaturation at 95°C for 10 s, annealing for 10 s at 62°C, extension at 72°C for 10 s, respectively. Standard curves for each of the three transcripts were generated from purified and quantified amplicons in serial dilutions from total RNA extracted from MCF-7 cells, according to previous experience^[29]. Primer pairs and hybridization probes for the three transcripts of survivin, survivin-2B, survivin- Δ Ex3 were described previously^[24] and are shown in Table 3.

Real time PCR products were additionally checked for their proper size and purity by electrophoresis on 2% agarose gels containing ethidium bromide and visualized under UV transillumination. Briefly 10 μ L of real-time PCR products were run along with 10 μ L of a 100 bp ladder MW marker (New England Biolabs, USA).

Normalization

Real time PCR is widely used to quantify biologically relevant changes in mRNA levels but a number of problems exist and are associated with its use due to the inherent variability of RNA, variability of extraction protocols, different reverse transcription and PCR efficiencies. It is important that an accurate method of normalization is chosen to control for these errors. Unfortunately, normalization remains one of real time PCR's most difficult problems^[30]. In our protocol, we ensured that our tissues had similar size (approximately 50 mg) and performed normalization against the same amount of total RNA (3 μ g), since when dealing

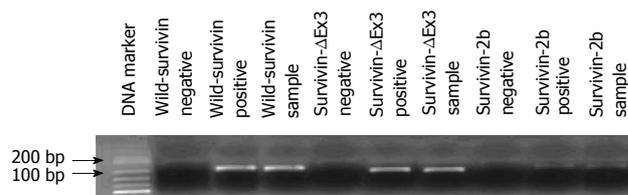

Figure 1 Electrophoresis of the survivin transcripts cDNA (wild survivin 185 bp, survivin- Δ Ex3 184 bp, and survivin-2b 214 bp).

with *in vivo* samples it is not possible to predict which of the housekeeping genes is stable and appropriate^[31,32].

Determination of immunochemical parameters

The cancer antigens carcinoembryonic antigen (CEA) and carbohydrate antigen 19-9 (CA 19-9) were measured using Elecsys 210 (Roche, USA) with electro-chemiluminescent immunoassays. The reproducibility of controls 1 and 2 (Roche) were for CEA, CV₁ = 3.6% and CV₂ = 3.0% and for CA19-9, CV₁ = 4.8% and CV₂ = 3.8%. The analytical sensitivity for CEA was 0.25 ng/mL and for CA19-9 < 0.85 U/mL. The cut-off values for CEA and CA19-9 were 5.0 ng/mL and 37 U/mL, respectively.

Statistical analysis

Statistical analysis of the data was performed using SPSS[®] version 17 for Windows statistical software package. Initially data were assessed through simple cross-tabulations and by using χ^2 test for categorical variables, *t*-test for normally distributed variables and Mann-Whitney *U* test for not normally distributed variables. Normality hypothesis was tested by Kolmogorov-Smirnov test, measures of asymmetry and Shapiro-Wilk test. In order to compare means of cases amongst different subgroups, one-way ANOVA test for normally distributed variables or Kruskal-Wallis test for not normally distributed variables were conducted. Post hoc pairwise comparisons were performed using the Bonferroni method. The Pearson or Spearman correlation coefficients (*r*) were used as measurements of correlation for continuous normally or not normally distributed variables respectively. In order to estimate survival functions, Kaplan-Meier curves were generated and subsequently compared using the log-rank test, the Breslow test or the Tarone-Ware test. For all tests performed, a two-sided *P* value of less than 0.05 was considered as significant.

RESULTS

Expression of mRNA survivin transcripts variants in cancer and normal tissues

The specificity of amplification products obtained by real time qPCR was confirmed by agarose gel electrophoresis, which revealed distinct bands for all PCR products. PCR for full length survivin mRNA produced a band of 185 bp, while those of survivin-2b and survivin- Δ Ex3 were 214 and 184 bp, respectively (Figure 1). Among the 52

tumor samples, wild type survivin expression was detected in 25 samples (48%), survivin-2b expression was detected in 20 samples (38%) and survivin-ΔEx3 was expressed in 15 samples (29%). Eighteen samples were positive for both the expression of wild type survivin and survivin-2b (34.6%), 14 samples were positive for both the expression of wild-survivin and survivin-ΔEx3 (26.9%) and 14 samples were positive for both the expression of survivin-2b and survivin-ΔEx3 (26.9%). All 3 survivin isoforms were found in 13 samples (25%). None of the 3 variants of survivin mRNA were expressed in the 10 unrelated normal samples, indicating a significant difference in survivin expression between cancerous and healthy tissues (P < 0.001).

Relationship between the levels of expressed survivin transcripts and clinicopathological parameters

Wild type survivin was significantly more expressed than the other two splice variants in the 52 samples, as shown in Figure 2. Quantitative data from tissue mRNA and serum tumor markers from the 52 patients are shown in Table 4. The 3 survivin isoforms were not correlated with CEA and CA19-9 (Table 5). In general, no association was found between the 3 isoforms and tumor size, survival, Dukes stage, grade and gender, although wild survivin was almost present in tumors more than 5 cm in diameter (P = 0.088), and the ratio survivin-ΔEx3/wild-survivin was almost significantly higher in tumors less than 5 cm (P = 0.097) and in advanced Dukes stage (P = 0.097) (Table 6). The mRNA expression of wild type

survivin presented a significant correlation with the expression of survivin-2b and survivin-ΔEx3 (P < 0.001) and the ratio of survivin-2b/wild-survivin was strongly related to the ratio of survivin-ΔEx3/wild-survivin (P < 0.001). Wild type survivin and survivin-ΔEx3 expression levels presented an association with T (P = 0.006 and P = 0.041 respectively, Table 5). Mean survivin-2b expression levels were significantly higher in ulcerous carcinomas than in polypoid (ecblastetic) ones (P = 0.030, Table 6).

Association of survivin isoforms with prognosis

We examined the association of survivin isoforms with prognosis in 52 patients using the Kaplan-Meier survival curve. The ratio of survivin-ΔEx3/wild-survivin presented a significant association with patient prognosis (P = 0.015, Figure 3). Specifically, when the ratio of survivinΔEx3/wild-survivin was ≥ 0.24, patients survived a shorter time (mean survival 41 mo) compared to patients with a ratio of survivin-ΔEx3/wild-survivin < 0.24 (mean survival 62.2 mo). No other association was found between survivin isoforms and the ratio of survivin-2b/wild-survivin with overall patient survival.

DISCUSSION

Although survivin is cytoprotective, it is also an essential protein for cell division. In vitro survivin interacts directly with the chromosomal passenger proteins, aurora-B kinase, borealin and INCENP. These proteins are mutually dependent upon each other, and together they form

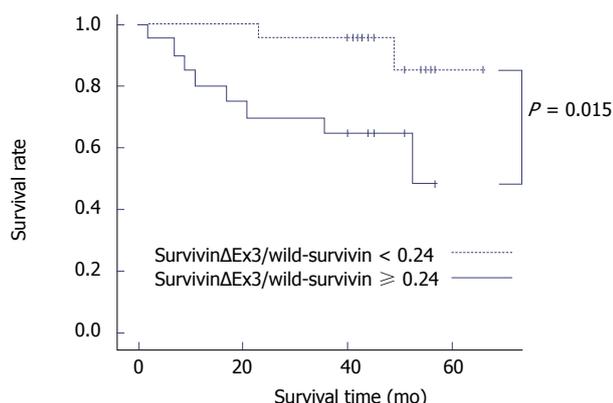

Figure 3 Kaplan-Meier survival curve for the ratio of survivin Δ Ex3/wild-survivin in 52 patients suffering colorectal adenocarcinomas.

a complex during mitosis, the chromosomal passenger complex, which is required for chromosome movements, proper spindle checkpoint control, and cell division^[33]. The overexpression of survivin in cancer may obliterate this apoptotic checkpoint and allow aberrant progression of transformed cells through mitosis. Survivin expression has been associated with increased aggressiveness and decreased patient survival in a number of different malignancies^[34]. Despite their ability to interact with wild type survivin, survivin-2b and survivin- Δ Ex3 don't act as competitors during mitosis or have an essential function^[33]. They could be responsible for the fine tuning of wild type survivin's function. Survivin- Δ Ex3 exhibits pronounced antiapoptotic properties, whereas survivin-2b has largely lost its antiapoptotic activity^[24].

Real-time technology has significantly extended the use and scope of Real time-PCR assays, with the potential

for quantification of mRNA targets being a particular advantage^[35]. Our study is the first to examine the expression of survivin and its splice variants by using quantitative Real time-PCR exclusively in colorectal adenocarcinomas. As far as the expression of the mRNA of survivin and its splice variants is concerned, previous researchers have performed mainly qualitative RT-PCR analysis or Northern blot analysis^[10,36-38]. In some studies, TaqMan quantitative real Time-PCR was used with only wild type survivin mRNA determination^[39-41]. Only recently, Mahotka *et al*^[2] made the first successful quantitative analysis of survivin splice variants in renal cell carcinoma specimens. We investigated the expression of survivin's transcript variants mRNA in patients with colorectal adenocarcinomas, while until now there have been other studies concerning colorectal cancer that used western immunoblotting, Real time PCR with SYBR Green^[42,43], microarray expression analysis and immunofluorescence^[44].

In our experiments, the prevalence of wild-survivin mRNA expression compared to the other splice variants is similar to the previous study that used specific hybridization probes^[24] raising the question if those two isoforms might act as antagonists of wild-survivin or play a role in tumor progression. The mean copy numbers of quantitative RT-PCR amplification of wild survivin, survivin-2b and survivin- Δ Ex3 in tumor samples were respectively 842.5 ± 2380.3, 58.1 ± 192.3 and 393.9 ± 1988.8, while Suga *et al*^[24] found 3554.1 ± 3513.7, 1233.4 ± 1280.9 and 482.0 ± 568.1. Suga *et al*^[24] didn't find any significant association between the expression of survivin and its splice variants with gender, location, size, age, macroscopic type, histologic type, lymphatic vessel invasion, blood vessel invasion, lymph node metastasis and serosa invasion.

On the contrary, they observed a significant correlation of survivin and its splice variants with histologic disease stages, a correlation not found in our study. The differences in the results of our study with the results of Suga *et al.*^[24] might be due to race difference, genetic alterations or method performance.

The presence of transcripts of survivin isoforms has been associated with cancer. The expression of survivin in normal and cancerous samples is controversial since in previous studies data have indicated that survivin is expressed during fetal development, but not in most normal adult tissues. Using reverse transcription PCR, Mahotka *et al.*^[21] found that wild type survivin and survivin- Δ Ex3 were expressed in cell lines derived from renal carcinomas but not normal renal cells. The previous isoforms are elevated in a wide variety of tumors but are not expressed to a significant extent in normal tissues^[44]. Studies using sensitive quantitative Real time-PCR revealed that survivin mRNA was expressed in normal fetal tissue panels and at a very low level in the normal adult brain template. In contrast, data from a recent study have demonstrated survivin expression in normal adult tissues, such as those of skin, endometrium, endothelial cells, normal blood lymphocytes, pancreas, spleen, colon, stomach, small intestine, large intestine, lung, kidney, prostate, pancreas, heart, and thymus^[45]. By using sensitive quantitative Real time-PCR analysis, low levels of total survivin mRNA were detectable in normal tissue adjacent to soft tissue sarcoma tumor cells (e.g. muscle) or in lymphocytes of blood donors. Further studies are needed in order to find out whether expression of survivin in normal tissue is due to mitotically active cells^[7]. The expression of survivin mRNA by semi-quantitative Real time PCR was detected in a significantly greater proportion of colorectal carcinoma samples than in adjacent normal colorectal tissues (67.3% *vs* 25%, $P < 0.01$)^[25]. With the use of tissue microarrays, survivin was detected in 147 of 230 cases of colorectal adenocarcinoma (63.9%) and no expression of survivin was observed in normal tissues^[34]. Our study showed that the expression of survivin's transcript variants mRNA was detected only in colorectal cancer tissues while it was absent in normal samples. On the contrary, Suga *et al.*^[24] found out that 60% of the normal tissues expressed survivin.

In our study, there was no significant correlation between the expression of the three isoforms and grade, Dukes stage, lymph metastasis, sex, N (TNM staging system) as well as CEA and CA19-9, two serum tumor markers not examined in any other study. Suga *et al.*^[24] found no correlation between survivin immunoreactivity and age, sex, tumor size and site, morphologic subtype, tumor grade and clinical stage ($P > 0.05$). On the other hand, our study was the only one showing that the ratio of survivin- Δ Ex3/wild-survivin was strongly related with age ($P < 0.05$), while wild-survivin and survivin- Δ Ex3 were associated with T (TNM staging system) and their mRNA expression was highly elevated in patients who belonged to the group T4 ($P = 0.006$ and $P = 0.041$ respectively). Another important finding of our study is that survivin-2b

was associated, for the first time in colorectal adenocarcinomas, with morphologic type, particularly overexpressed in ulcerous colorectal adenocarcinomas ($P < 0.05$). A differential expression of survivin-2b was also reported in gastric carcinomas with a negative correlation with disease progression. Other reports have linked the expression of survivin isoforms with poor patient prognosis^[33]. In our study, we examined the association of survivin transcript variants with overall patient survival showing for the first time a significant correlation of the ratio of survivin- Δ Ex3/wild-survivin with prognosis. Therefore, the ratio survivin- Δ Ex3/wild-survivin might be a novel prognostic marker for colorectal carcinomas.

Despite the relative rarity of colon cancer in the Greek population and the application of expensive molecular biology methodology, we implemented a sufficiently powered study, which albeit its modest size, was adequate to generate statistically significant associations with the above variables. We also examined tissues from patients with no cancerous diseases in order to investigate the expression of survivin's isoforms in healthy samples.

Further larger studies are required in order to examine the three other isoforms of survivin, for an overall view of survivin's function. Moreover, other methodology could be used, such as Northern blot analysis, microarray expression analysis, nested PCR, *etc* to further validate the results of our study.

Recent studies showed that the phenomena of chemoradioresistance were prevalent in survivin positive tumors and indicated that survivin may play an important role in chemoresistance of cancer cells. The survivin expression might guide chemotherapy and radiation therapy decisions. The clinical importance of survivin expression remains unclear in patients with colorectal cancer, since there are few studies on the subject. Survivin might provide important predictive and prognostic perspectives, and could offer new therapeutic alternatives for cancer^[25]. Our results suggest that survivin splice variants might be related with the action of survivin in colorectal carcinogenesis but further studies are required to identify the potential role and mechanism of survivin's isoforms in the development of colorectal cancer.

COMMENTS

Background

Survivin may provide prognostic information, because of its relation with increased tumor aggressiveness. The authors investigated three isoforms of survivin in colorectal adenocarcinomas (wild type survivin, survivin-2b and survivin- Δ Ex3).

Research frontiers

Survivin expression has been associated with increased aggressiveness and decreased patient survival in a number of different malignancies but little has been done so far in colorectal cancer. In this study, the authors used for the first time quantitative real time-polymerase chain reaction (PCR) in order to detect three isoforms of survivin in colorectal adenocarcinomas. The authors found a significant correlation of the ratio survivin- Δ Ex3/wild-survivin with prognosis. Therefore, the expression level of survivin- Δ Ex3/wild-survivin might be a novel prognostic marker. Another important finding was that wild-survivin and survivin- Δ Ex3 were associated with TNM staging system, underscoring their association with increased tumour aggressiveness.

Innovations and breakthroughs

Till now, there is only one other study dealing with survivin's isoforms in colorectal carcinomas using the technology of real time-qPCR. Using the same technology in colorectal adenocarcinomas the authors obtained different results.

Applications

The clinical importance of survivin expression remains unclear in patients with colorectal cancer, since there are few studies on the subject. Survivin might provide important predictive and prognostic perspectives and could offer new therapeutic alternatives for cancer. Further studies are required to identify and clarify the potential role and mechanism of survivin in the development of colorectal cancer.

Peer review

The authors have performed a nice study on the different forms of survivin and a lot of work has gone into producing the manuscript.

Abstract

AIM: To describe our own experience with pyogenic liver abscesses over the past 10 years and investigate the risk factors associated with failure of initial percutaneous therapy.

METHODS: A retrospective study of records of 63 PLA patients presenting between 1998 and 2008 to Australian tertiary referral centre, were reviewed. Amoebic and hydatid abscesses were excluded. Demographic, clinical, radiological, and microbiological characteristics, as well as surgical/radiological interventions, were recorded.

RESULTS: Sixty-three patients (42 males, 21 females) aged 65 (± 14) years [mean \pm (SD)] had prodromal symptoms for a median (interquartile range; IQR) of 7 (5-14) d. Only 59% of patients were febrile at presentation; however, the serum C-reactive protein was elevated in all 47 in whom it was measured. Liver function tests were non-specifically abnormal. 67% of patients had a solitary abscess, while 32% had > 3 abscesses with a median (IQR) diameter of 6.3 (4-9) cm. Causative organisms were: *Streptococcus milleri* 25%,

Klebsiella pneumoniae 21%, and *Escherichia coli* 16%. A presumptive cryptogenic cause was most common (34%). Four patients died in this series: one from sepsis, two from advanced cancer, and one from acute myocardial infarction. The initial procedure was radiological aspiration \pm drainage in 54 and surgery in two patients. 17% underwent surgical management during their hospitalization. Serum hypoalbuminaemia [mean (95% CI): 32 (29-35) g/L vs 28 (25-31) g/L, $P = 0.045$] on presentation was found to be the only factor related to failure of initial percutaneous therapy on univariate analysis.

CONCLUSION: PLA is a diagnostic challenge, because the presentation of this condition is non-specific. Intravenous antibiotics and radiological drainage in the first instance allows resolution of most PLAs; However, a small proportion of patients still require surgical drainage.

INTRODUCTION

The management of pyogenic liver abscesses is changing. Depending on the cause and local expertise, a varying proportion of patients are treated with antibiotics

alone, surgical therapy or radiological intervention, or a combination of the above. However, there appears to be an overall trend for antibiotics and radiological intervention (either drainage or aspiration) to be the initial treatment of choice^[1]. Surgical management is increasingly limited to cases of failed radiological management or to the management of complications^[2-5].

Furthermore, there is an increasing recognition that pyogenic liver abscesses seen in Western and Asian countries differ in demographic characteristics, aetiological factors, and clinical behaviour. Many of the recent large case series are from South East Asian institutions, where a large proportion of pyogenic liver abscesses are caused by *Klebsiella pneumoniae*. These abscesses are typically associated with diabetes or a cryptogenic aetiology^[5-7]. This contrasts with the predominance of *Escherichia coli* pyogenic liver abscesses of biliary aetiology found in Western institutions.

Continued changes to the management and aetiology of this disease entity prompted us to review it and describe our own experience with pyogenic liver abscesses over the past 10 years. In addition, we aim to investigate the risk factors associated with failure of initial percutaneous therapy.

MATERIALS AND METHODS

A retrospective study of all patients treated at Royal North Shore and affiliated hospitals for pyogenic liver abscesses was conducted. A list of patients was generated by accessing the ICD-10 codes of the hospital admissions database, which dated back to 1996. This data was augmented with data from individual (upper gastrointestinal) surgeons' databases to ensure that all possible treated patients during the study period were captured. A total of 63 patients were identified during the study period of August 1998 to November 2008. The diagnosis of pyogenic liver abscess was based upon clinical features, evidence from imaging studies (ultrasound or computed tomography), as well as microbiology (blood or aspirate culture results). Liver abscesses with demonstrated positive amoebic or hydatid serology were excluded.

Basic demographic characteristics (history, examination and investigation findings at presentation), radiological/microbiological results, antibiotic use, and surgical/radiological intervention were reviewed and recorded on a standardised data sheet.

For the purposes of data recording, the examination findings of the patients were defined by the findings from the first examination by senior surgical or medical staff (registrar or above). The degree of peritonism and the location of tenderness were recorded. The presence of fever was defined as a temperature taken within the first 24 h of presentation of greater than 37.5°C. All other vital signs were defined by the first available set of observations after presentation. Tachycardia was defined as a heart rate greater than or equal to 100 beats per minute, and hypotension as a systolic blood pressure of less than 100 mmHg. For blood test results, the first available test

within the first 48 h of presentation was used for analysis. Reference ranges of laboratory tests were defined by the reference ranges supplied by the local laboratory, Pacific Laboratory Medicine Services—these are included in results of Table 1. Acute renal failure was defined as an increase in the serum creatinine level of 50% over the baseline. With regards to imaging findings, the size of the abscess was defined by its greatest diameter, and in cases with multiple abscesses, as the greatest dimension of the largest abscess. Radiological intervention was subdivided into drainage and aspiration, depending on whether a drain was left in situ. The presumptive aetiology of the liver abscess was a subjective judgement made by either the treating team at the time or retrospectively by the investigators. A standard protocol for investigation of the underlying cause of the liver abscess was not used.

At our unit, patients with suspected or proven pyogenic liver abscesses are managed initially by empirical broad spectrum intravenous antibiotics, usually a combination of a third generation cephalosporin, such as ceftriaxone, along with metronidazole. The penicillin-based combination with ampicillin, an aminoglycoside (such as gentamicin), and metronidazole is also commonly used. The antibiotic regimen is modified according to response to initial therapy and available microbiology results, in consultation with the local microbiology team. Antibiotics are generally continued for 4–6 wk, with the initial 2 wk administered intravenously. First line intervention is radiological drainage of the liver abscess. This is performed with sedation and local anaesthesia under computed tomography or ultrasound control. Typically, a “pigtail” drain (8–12 French) is placed into the abscess, which is then left on free drainage with or without periodic normal saline flushes. Repeated procedures may be indicated. In some cases, rather than placing an indwelling drain, radiological guided aspiration was used as the first line treatment. The choice of indwelling drain or aspiration depends on clinician preference, but aspiration is generally only used when the abscess is small or multiple. Indications for surgical intervention or drainage include - signs of peritonitis, ruptured abscesses, abscesses not responding to antibiotics and drainage, and multiloculation.

All statistical analysis and plotting were performed with Intercooled Stata version 9.1 (Statacorp, Texas, USA). Note that, because of missing data for certain characteristics, some denominators of proportion statistics are not consistently equal to 63 (the full cohort of subjects).

RESULTS

Demographic characteristics and presentation

Sixty-three patients (42 males and 21 females) were identified for this study, with a mean (SD, range) age of 64 (14, 31–97) years. The peak incidence was in the 8th decade of life (70–79 years). Almost a quarter of patients (15/62, 24%) had a history of gallstones or cholecystectomy. Nearly a quarter of patients ($n = 14$) had a history (past or current) of malignancy at presentation. Of these, 10 (16%)

Table 1 Summary of laboratory results at initial presentation

| | Reference range | No. of patients measured | mean \pm SD | % of patients outside reference range |
|--------------------------------------|-----------------|--------------------------|----------------|--|
| White cell count ($\times 10^9/L$) | 4.0-11.0 | 62 | 15.0 \pm 6.3 | 74% |
| Neutrophil count ($\times 10^9/L$) | 2.0-8.0 | 62 | 12.9 \pm 5.9 | 82% |
| Haemoglobin (g/L) | 135-180 | 62 | 118 \pm 21 | 24% Hb < 100 g/L |
| Platelets ($\times 10^9/L$) | 150-400 | 62 | 320 \pm 202 | 42% |
| C-reactive protein (mg/L) | < 5 | 47 | 272 \pm 119 | 100% (47/47) |
| Urea (mmol/L) | 3.1-8.1 | 62 | 8.2 \pm 5.96 | 29% Urea > 8.1 mmol/L |
| Creatinine (μ mol/L) | 60-100 | 62 | 105 \pm 60 | 42% Cr > 100 μ mol/L 16% Cr > 150 μ mol/L |
| Albumin (g/L) | 35-46 | 62 | 30 \pm 7.0 | 73% |
| AST (U/L) | 12-36 | 61 | 127 \pm 301 | 67% |
| ALT (U/L) | 5-40 | 62 | 118 \pm 222 | 73% |
| ALP (U/L) | 41-119 | 61 | 209 \pm 140 | 71% |
| GGT (U/L) | 5-65 | 62 | 191 \pm 201 | 75% |
| Bilirubin (μ mol/L) | 3-18 | 61 | 30 \pm 39 | 54% Bil > 18 μ mol/L 13% Bil > 50 μ mol/L |
| Glucose (mmol/L) | 3.5-5.5 | 47 | 7.8 \pm 2.6 | 15% (7/47) Glucose > 10 mmol/L |
| INR | \leq 1.5 | 53 | 1.3 \pm 0.56 | 13% (7/53) |

AST: Aspartate transaminase; ALT: Alanine transaminase; ALP: Alkaline phosphatase; Bil: Serum bilirubin; GGT: γ glutamyl transpeptidase; INR: International normalized ratio; RR: Reference range. Reference ranges supplied by local pathology laboratory.

Table 2 Summary of physical examination findings on presentation

| Clinical finding | n (%) |
|-----------------------------|---------|
| Fever (T > 37.5) | 33 (59) |
| Hypotension (SBP < 100) | 7 (13) |
| Tachycardia (HR \geq 100) | 29 (52) |
| Peritonism | |
| None | 49 (86) |
| Localized guarding | 8 (14) |
| Generalized peritonism | 0 (0) |
| Location of tenderness | |
| Non tender abdomen | 20 (35) |
| Right upper quadrant | 22 (39) |
| Other abdominal tenderness | 15 (26) |

HR: Heart rate in beats per minute; SBP: Systolic blood pressure in mmHg; T: Body temperature in degrees Celsius.

had a current diagnosis of malignancy: three with cholangiocarcinoma, three with pancreatic cancer, and one each with colon cancer, gastric cancer, prostate cancer, and follicular dendritic cell tumour of the liver. Only 13% (8/62) had a history of diabetes mellitus.

The median (IQR) duration of symptoms prior to presentation was 7 (5-14) d. Table 2 summarises the presentation of these patients. Note that the presence of fever and tachycardia was found in only slightly more than half of the patients. It was uncommon for patients to be hypotensive on presentation. Abdominal signs were non-specific in most cases.

The initial laboratory results were available for all but one patient. They are summarised in Table 2. Markers of inflammation [white cell count, neutrophil count, and the serum C-reactive protein (CRP)] were generally raised. In particular, CRP was elevated in all of the 47 tested patients.

Forty-two percent of patients had elevated serum creatinine levels, but only 16% had a serum creatinine of greater

than 150 μ mol/L at presentation. Liver enzymes were each elevated in about 70% of the patients. Serum bilirubin was elevated in slightly more than half of the patients, but only 13% had a clinically significant hyperbilirubinaemia of greater than 50 μ mol/L. Only 15% of the subjects had a blood glucose level of greater than 10 mmol/L.

Imaging

Computer tomography was used in all patients, but the initial diagnosis was made with abdominal ultrasonography in 14 cases. Detailed imaging reports or films were available for 60 patients. Sixty-seven percent had solitary liver abscesses: one patient had two abscesses and 32% had three or more abscesses. The median (IQR) maximum dimension of liver abscesses was 6.3 (4.0-9.0) cm. Note that in five cases multiple "microabscesses" (< 1 cm diameter) were identified. Sixty-six percent had involvement of the right liver only, 19% had left liver involvement only, and 15% (9/58) had bilateral involvement. Twelve percent demonstrated evidence of gas formation within the abscess and 15% had imaging evidence of biliary dilatation.

Microbiology and aetiology

Although all 63 patients had either culture of blood or of the abscess, the causative organism was identified in only 50 (79%). The yield from liver abscess aspirate, 67%, was higher than from blood cultures (48%). The most common causative pathogens were *Streptococcus milleri* 25%, *Klebsiella pneumoniae* 21%, and *Escherichia coli* 16% (Table 3). Note that many patients had more than one set of cultures taken during the study period. In one patient the abscess culture grew *Corynebacterium urealyticum* but blood cultures grew *Staphylococcus aureus*; however, that was likely to be a skin contaminant.

The aetiology of the abscess was only evident in 59 patients (Table 4). *Streptococcus milleri* was associated with

Table 3 Summary of microbiology results for blood culture results, liver abscess aspirate culture results, and presumed causative pathogen

| Organism | n (% of patients with culture results) | | |

| Haematogenous (other bacteremic source) | 7 (11) |
| Direct (e.g. pericholecystic abscess, RFA) | 6 (9.4) |

RFA: Radiofrequency ablation.

portal sepsis in 4/12, *Escherichia coli* was associated with biliary sepsis in 5/14, and *Klebsiella species* was associated with cryptogenic sepsis in 7/20.

There were two cases on *Clostridium perfringens*-both were isolated as mixed growths on cultures. Organisms isolated with *Clostridium perfringens* in these cases were *Escherichia coli* and *Enterococcus faecalis* in one case, and *Enterococcus faecalis* and *Citrobacter freundii* in the other. One of the patients had rapidly progressing sepsis and underwent a laparoscopy; however, the patient rapidly deteriorated. The second patient developed sudden onset of severe sepsis following radiofrequency ablation (RFA) of a liver metastasis. She underwent radiological guided drainage of the liver abscess and eventually thoracotomy for decortication and drainage. She returned to good health but died of progression of her pancreatic cancer six months later.

Intervention

Five patients were treated by intravenous antibiotics followed by oral antibiotics, without any need for other intervention (Table 5). Radiological drainage was the most frequent initial intervention, which was used in 43 (68%) cases. Of these, almost a third required a second drain-

AB: Antibiotics only; RA: Image guided aspiration of abscess; RD: Image guided insertion of indwelling drain; SG: Surgical intervention. Note that all patients received intravenous antibiotics before any interventional treatment.

age/aspiration procedure and of these, three required further drainage procedures. In this group, surgery was eventually required in six (14%) cases. Eleven patients were initially treated with image-guided aspiration of the liver abscess. Of these, two required drain placement, and a further two required surgical drainage. Surgical drainage was performed as the initial procedure in two (3.2%) of patients. In total, 11 patients (17%) underwent surgical drainage or resection.

Two patients had other types of initial intervention. One had endoscopic retrograde cholangiopancreatography (ERCP), sphincterotomy, and removal of choledocholithiasis for biliary sepsis. Another patient had a laparoscopic appendectomy. In both cases, the pyogenic liver abscesses were small and thought to be secondary to biliary/portal pyaemia. The patient with biliary sepsis eventually required a laparoscopic cholecystectomy and

Table 6 Complications occurring in 21 patients

| Complication | n |

| Subcapsular hematoma from percutaneous drainage | 1 |
| Myocardial infarction | 1 |
| Necrosis of terminal phalanges | 1 |

bile duct exploration due to failed endoscopic retrieval of choledocholithiasis.

Other forms of surgical interventions were performed because of pleural sepsis requiring drainage of pleural empyema and decortications of lung ($n = 4$).

Indications for surgery as the initial management in two cases were as follows: peritonitis on clinical examination requiring laparoscopy (which was converted to laparotomy), and sepsis in a patient on cyclosporin, methotrexate, and prednisolone for rheumatoid arthritis.

Indications for surgical intervention as a subsequent procedure included: leakage of abscess from a percutaneous drainage, haemorrhage from percutaneous drainage ($n = 2$), failure of resolution or recurrence of the abscess ($n = 4$), and laparoscopic cholecystectomy for an intrahepatic extension of a pericholecystic abscess ($n = 1$).

Complications and outcomes

Twenty-one patients (33%) developed complications (Table 6) that were directly related to the sepsis or abscess and which required specific intervention.

In two patients, the abscess ruptured through the upper surface of the liver into the pleural cavity: one was related to the placement of a drain and the other was related to a subphrenic abscess. A further patient developed a large thoracic empyema related to her subphrenic abscess and one developed a large fibrinous pleural effusion with no pus.

Two patients had severe haemorrhage associated with the radiological intervention (ultrasound guided drain placement and computed tomography (CT) guided aspiration/biopsy) and required resection of the liver segment that contained the abscess.

The systemic effects of the sepsis were severe enough to cause acute renal failure in seven patients and multi-organ failure in two. A patient who presented with severe shock was treated in Intensive Care with antibiotics and inotropes and he gradually recovered; however, he developed necrosis of the terminal phalanges of his hands and feet. He was well enough to be discharged to the ward, but because of recurrence of sepsis, surgical opinion was sought. He required drainage of the abscess and associated cholecystectomy, which was successfully treated by laparo-

scopic approach, following which he rapidly recovered and was discharged.

Two patients developed biliary fistulae post radiological drainage. One patient underwent biliary decompression with ERCP and nasobiliary drainage, which resolved the fistulae. The second patient had a history of a cholangiocarcinoma resected with roux-en-Y and hepaticojejunostomy eight months prior to the development of her multiple liver abscesses. Three CT guided percutaneous drains were inserted following which she developed a controlled biliary fistula through one of the drains. Following choledochoscopy, which showed no tumour recurrence, the drain was removed but recurrent abscesses occurred. A percutaneous drain guided surgical debridement was undertaken and sepsis settled; however, a chronically low-volume draining fistula remained. She was discharged home to independent living, but after five months became unwell again and decided to accept palliative care.

Four patients died during the hospital admission. One patient who had a severe sepsis due to *Clostridium perfringens* underwent a desperate surgical procedure but, not unexpectedly, the resuscitation failed. Two died from progression of pancreatic cancer managed in a palliative fashion. A further patient, a 97 year old lady, died from a cardiac arrest secondary to acute myocardial infarction six days after the insertion of a percutaneous drain.

Risk factors predicting failure of initial percutaneous therapy

Table 7 summarises the results of univariate analysis of factors that predict the failure of initial percutaneous therapy. A low serum albumin level was the only statistically significant factor found to be associated with failure of initial percutaneous therapy ($P = 0.045$). Importantly, the initial type of percutaneous therapy (drain *vs* aspiration) was not associated with initial success.

Multivariate analysis was not performed as the small number of treatment failures would mean that the event per variable rate would be unacceptably high.

DISCUSSION

Consistent with other recent studies, most patients with liver abscesses are elderly, with a mean age of 64 years^[2,8-10]. This is about 10 years older than subjects in previous reports^[4,5,11]. Again, a preponderance of males was noted.

The presentation of pyogenic liver abscesses is often non-specific and its diagnosis requires a high degree of clinical suspicion. This is reflected in the finding that the median duration of symptoms of a week, with a further quarter of patients having symptoms between 1-2 wk, prior to presentation. Clinical abdominal findings were largely unhelpful, with localised peritonism found in only 14% and localised right upper quadrant tenderness in less than 40%. The literature indicates that these signs are found in 15%-55% of cases^[2,4,9,11].

Laboratory tests were equally non-specific, apart from

demonstrating signs of inflammation. Notably, not only did all tested patients have a raised serum C-reactive protein, but the levels were also significantly raised, with a mean of 272 mg/L. By comparison, only 82% of patients demonstrated neutrophilia. In addition, consistent with a

systemic inflammatory response, the serum albumin was depressed in 73% of patients. CRP is not a commonly measured laboratory parameter documented in older studies: Rintoul *et al*^[3] reported that all nine of their patients with PLA had a raised CRP level. However, a recent paper

by Foo *et al*^[12] demonstrated that the CRP was elevated in all 133 tested patients. Whilst each of the “liver enzymes” was abnormal in about 70% of cases, neither a “cholestatic” or “hepatic” pattern of LFT derangement predominated. In addition, mild hyperbilirubinaemia occurred in more than half of the patients, but clinically significant hyperbilirubinaemia was uncommon. These results are largely consistent with recent large case series (from both Asian and “Western” countries)^[2,8,12,13].

It is interesting to note that four large Asian case series^[2,5,8,12], with a total of more than 600 cases over the last ten years, demonstrated a large proportion of patients with Klebsiella species: accounting for 43% to 66% of cases. In each of these studies, the biliary tree was the most commonly identified aetiology. However, the most common aetiology overall was “cryptogenic” in the three studies, where Klebsiella species accounted for more than half of all cases. Indeed, it has been suggested that Klebsiella is associated with “cryptogenic” liver abscesses^[9]. It is noted that Klebsiella liver abscess may represent a new syndrome in diabetic patients in Taiwan^[5] or perhaps in Asia. Recent “Western” series, however, suggested that *Escherichia coli* is still the most common causative organism^[10,13-15]. A new finding that has come to light in two papers published in 2010 from Western institutions with about 60 patients each, is the high prevalence (48% and 55%) of polymicrobial infections^[14,16]. The latter study was characterised by a very large proportion of patients with malignancy (88%).

The microbiological results of the current study fall somewhere in between Asian and Western series. We found that *Streptococcus milleri* was the most common organism, followed by Klebsiella species, and then *Escherichia coli*. This perhaps reflects the most common presumptive aetiology of liver abscesses in this series: cryptogenic, biliary, and portal. It is interesting to compare our results with another Australian study published a decade ago, which found that *Escherichia coli*, *Streptococcus milleri*, and *Enterococcus faecalis*, in this order of frequency, were the most commonly isolated organisms. Thirty-eight percent of the cases in that study had a cryptogenic origin, and 48% had a biliary aetiology^[4]. Interestingly, our series also had a large proportion of cryptogenic abscesses. Only 8% of all cases in our study had a polymicrobial culture result.

The first line treatment for all pyogenic liver abscesses is broad spectrum antibiotics. Our empirical antibiotic choice and duration of treatment are similar to those reported elsewhere in the literature^[1,2]. Shorter durations of treatment have also been described^[17].

There has been a trend for increasing use of radiological management of pyogenic liver abscesses, although the proportion of patients treated with radiological intervention varies greatly between centres^[3,11,13]. Successful use of radiological intervention as the first line intervention is reflected in three large series: Wong *et al*^[2] described 80 patients who were all treated either with antibiotics alone or antibiotics and percutaneous aspiration/drainage with no patients requiring surgical drainage. Two other series from Taiwan described 111/128 (87%) and 79/86 (92%)

patients, respectively, who underwent radiological drainage/aspiration^[5,9]. This continued trend away from surgical therapy is confirmed by three studies published this year (2010), with only 11/377 (2.9%), 1/61 (1.6%), and 5/51 (9%) requiring surgical therapy^[12,14,16].

However, Tan *et al*^[8] suggested that radiological aspiration may not be appropriate in all patients, and that the use of surgical drainage is advantageous in patients with abscesses larger than 5 cm, due to likely multiloculation. They found no difference in mortality or morbidity between the surgical and percutaneous drainage groups. This finding was confirmed by Alvarez Pérez *et al*^[13] who described 133 consecutive patients in which they found no difference in mortality or morbidity between treatment groups (open *vs* percutaneous). Interestingly, the latter study also found that abscess size did not predict morbidity or mortality, which would appear to contradict the conclusion of Tan *et al*^[8]. Consistent with this, we have found that abscess diameter did not predict failure of percutaneous therapy.

Image guided catheter drainage was favoured over radiological needle aspiration at our institution. There is no consistently favoured option in the literature, with some groups preferring needle aspiration over catheter drainage, and some *vice versa*. An early randomised study suggested that catheter drainage in patients with liver abscesses (pyogenic and amoebic) had a higher success rate compared with needle drainage alone^[18]. However, a more recent randomised study did not find any statistically significant difference between the two groups^[19]. Therefore, it is likely that both radiological interventions appear to be equally effective.

The need for a secondary intervention is similar between the drainage (19/43, 44%) and the aspiration groups (4/11, 36%) in this study. Indeed, no statistically significant difference in failure rate was found between the two groups. It may be noted that this “failure” rate is high compared to what is described in the literature. This may relate to the fact that approximately 90% of patients received radiological drainage as the initial procedure. It may also be related to the definition of a secondary procedure—we included repositioning and increasing the size of drains, as well as re-aspiration, as secondary procedures, whereas, in other case series, this may be considered an extension of the primary procedure. The overall rate of surgical drainage of 17% (11/63) in our series is consistent with the abovementioned studies.

Over the past few decades, the mortality associated with liver abscesses has decreased gradually. Prior to 1980, the mortality in published case series was consistently greater than 50%^[1]. Improvements in mortality in the 1980s were attributed to the use of effective antibiotics. Case series with study periods in the 1980s demonstrated a mortality rate of between 13%-18%^[11,20]. Further improvements in mortality then occurred due to the advent of cross sectional imaging with computed tomography and ultrasonography. The mortality rate for studies with study periods during and after 1990s was between 4%-10%^[2,4,5,8,9,19]. The mortality rate in the current study was 6.3%, continuing this trend for improving mortality.

This can be compared with the mortality of 8% in another Australian case series by Barakate *et al*^[4], which had a study period of a decade earlier than our current study. The deaths that occurred in both these studies principally occurred in already infirm patients, such as those with advanced cancer. The association of mortality with malignancy is reflected in the high mortality rate of 29% in a recent study by Mezhir *et al*^[16] where 88% of patients had a history of malignancy.

Many studies have investigated the risk factors for morbidity and mortality of the disease. However, as the mortality (and to a lesser extent, morbidity) has decreased, the focus has shifted to identifying patients who would successfully be treated with percutaneous therapy. Mezhir *et al*^[16] have found that the presence of yeast and communication with an untreated biliary obstruction were associated with failure of percutaneous therapy. Our current study has focused on the failure of initial percutaneous therapy and has found hypoalbuminaemia to be associated with failure. Hypoalbuminaemia may be associated with failure of initial therapy owing to its association with the severity of the underlying septic process.

Unlike mortality, morbidity is more difficult to compare between studies, because of differences in completeness of data collection in retrospective studies and therefore tends to be under-reported. Complications such as biliary fistula, leakage, and haemorrhage following percutaneous drainage or aspiration are known, but uncommon, complications. Tan *et al*^[8] described in the percutaneous drainage group ($n = 36$), one patient (2.8%) with fistula formation and four patients (11%) with peritonitis post drainage. This is similar to our reported rates of bile fistula and abdominal sepsis. Hemoperitoneum after needle aspiration has also been described—Yu *et al*^[19] had one such patient in a series with 64 patients. Furthermore, there are large case series, such as Wong *et al*^[2] with 80 patients who underwent percutaneous aspiration, that report no “major” complications. Operative management of liver abscesses may be associated with significant morbidity. In a study of 32 patients who underwent operative management (either for failed drainage or presenting as a surgical emergency), Christein *et al*^[21] reported a morbidity rate of 41%. This included two patients with persistent bile leaks. A similarly high morbidity rate of 27% was described by Tan *et al*^[8] in their surgical drainage group.

This is a retrospective review and was not undertaken with a standardized protocol variance in management, which could distort the conclusions; however, the surgeons involved in this study kept prospective records of their experience. The results, however, do reflect a changing trend towards a more conservative treatment protocol with an improving outcome. It provides the basis for a standardized protocol to be prospectively applied to our institution.

In conclusion, pyogenic liver abscess can be a diagnostically and therapeutically challenging problem. Often, the presentation and investigations are non-specific, although the serum CRP appears to be the simplest and most sensitive test. However, it is not specific. CT or magnetic reso-

nance scans allows imaging of the abscess for diagnosis and assessment of progress, and also allows percutaneous image guided drainage. A combination of broad spectrum intravenous antibiotics and radiological drainage usually allows resolution of pyogenic liver abscesses. A proportion of patients will require repeat procedures—this appears to be predicted by low serum albumin at presentation. A further smaller proportion of patients will ultimately require surgical drainage.

COMMENTS

Background

Pyogenic liver abscesses are most frequently caused by *Escherichia coli*, *Streptococcus milleri*, or *Klebsiella* species often through, biliary, portal sepsis, or cryptogenic sepsis, respectively. It is a diagnostic and therapeutic challenge because patients usually present with a non-specific septic illness. Although the mortality rate has greatly improved, the occurrence of a liver abscess threatens a patient's survival if not adequately treated.

Research frontiers

Improving the frequency of early diagnosis will depend on education of clinicians about the need for clinical suspicion aided by the finding of an elevated C-reactive protein and confirmed by radiological imaging. Early cases may be treated by antibiotics, but larger abscesses also frequently require image guided percutaneous aspiration or drainage. Surgery is only required in complex cases. Cryptogenic infections with *Klebsiella* are the most common cause in Asian series, while biliary sepsis and a portal source of sepsis are most common in Western society. This series was a mixture of the two patient groups.

Innovations and breakthroughs

This article describes a moderate sized case series from an Australian tertiary referral centre, where patient presentation and outcome appear to be similar to other Western case series. There was a large proportion of *Klebsiella* organisms, indicating that the aetiology appears lie between the Asian and Western case series. This study also confirms the value of percutaneous therapy.

Applications

This article confirms that elevated C-reactive protein level is an important guide to the diagnosis, which is frequently delayed. Intravenous antibiotics in combination with percutaneous image guided aspiration or drainage is usually a successful treatment.

Peer review

This is a retrospective case series of 63 Australian patients with pyogenic liver abscesses. The text is generally well written, with a structured abstract and organized sections. The manuscript has scientific value since it includes relevant information about an important condition with multiple therapeutic options. I believe it can be considered for publication, provided that the authors adequately address some key issues and suggestions.

METHODS: *TFF* mRNA levels, gene copy number and protein expression were determined respectively by quantitative reverse transcription polymerase chain reaction (PCR), quantitative PCR and immunohistochemistry in bile duct epithelium biopsies collected from individuals with CCA, precancerous bile duct dysplasia and from disease-free controls. The functional impact of recombinant human (rh)TFF2 peptide treatment on proliferation and epidermal growth factor receptor (EGFR)/mitogen-activated protein kinase (MAPK) signaling was assessed in the CCA cell line, KMBC, by viable cell counting and immunoblotting, respectively.

RESULTS: *TFF1*, *TFF2* and *TFF3* mRNA expression was significantly increased in CCA tissue compared to disease-free controls, and was unrelated to gene copy number. TFF1 immunoreactivity was strongly increased in both dysplasia and CCA, whereas TFF2 immunoreactivity was increased only in CCA compared to disease-free controls. By contrast, TFF3 immunoreactivity was moderately decreased in dysplasia and further decreased in CCA. Kaplan-Meier analysis found no association of *TFF* mRNA, protein and copy number with age, gender, histological subtype, and patient survival time. Treatment of KMBC cells with rhTFF2 stimulated proliferation, triggered phosphorylation of EGFR and downstream extracellular signal related kinase (ERK), whereas co-incubation with the EGFR tyrosine kinase inhibitor, PD153035, blocked rhTFF2-dependent proliferation and EGFR/ERK responses.

CONCLUSION: *TFF* mRNA/protein expression is indicative of CCA tumor progression, but not predictive for histological sub-type or survival time. TFF2 is mitogenic in CCA via EGFR/MAPK activation.

Abstract

AIM: To investigate trefoil factor (*TFF*) gene copy number, mRNA and protein expression as potential biomarkers in cholangiocarcinoma (CCA).

Key words: Cholangiocarcinoma; Trefoil factors; Liver fluke; Epidermal growth factor receptor; Mitogen-activated protein kinase

Peer reviewer: Masahiro Iizuka, MD, PhD, Director, Akita Health Care Center, Akita Red Cross Hospital, 3-4-23, Nakadori, Akita, 010-0001, Japan

INTRODUCTION

Cholangiocarcinoma (CCA) is a malignant tumor arising from the biliary tract and classified according to the site of formation as either intrahepatic or extrahepatic type^[1,2]. CCA accounts for 3% of all gastrointestinal cancers and is the second most common primary hepatic tumor^[3]. The Southeast Asian liver fluke, *Opisthorchis viverrini* (*O. viverrini*) is a trematode parasite that infects the bile duct^[4]. Previous studies have shown a strong positive correlation between CCA incidence and the prevalence of *O. viverrini* infection, as measured by anti-*O. viverrini* antibody titers in the general population residing in the northeast Thailand^[5-7], where the Khon Kaen Province has shown the highest incidence of CCA in the world^[8]. The truncated age-standardized incidence of CCA in Khon Kaen in age ranges older than 35 years varied between 93.8 and 317.6 per 100 000 population, depending on geographical location^[5].

Several lines of evidence implicate an interaction between chemical carcinogens, especially nitrosamines, and *O. viverrini* infestation in the development of CCA in Thailand^[9,10]. Mechanical injury to bile duct epithelial cells from feeding activity and migration of the liver fluke may also contribute to biliary damage in the human host. In addition, secretion or excretion of metabolic products from the liver fluke results in chronic irritation, hyperplasia and adenomatous changes of the bile duct epithelium^[9]. Subsequent DNA damage in the biliary epithelium may drive malignant transformation^[7,11].

To date, knowledge of the molecular basis of carcinogenesis and pathogenesis of CCA is limited. Previous studies in CCA patients exploring the fine mapping of chromosome region 21q22-qter showed an amplification with a frequency of more than 30% in the markers D21S1890-D21S1893, and *TFF3*, a member of the trefoil factor (*TFF*) gene family^[12]. Kaplan-Meier survival curves demonstrated that patients who have amplifications at D21S1893, D21S1890 and the *TFF* locus had a poor prognosis, whereas patients who had deletions showed a favorable prognosis, indicating that this region may harbor candidate genes involved in the tumorigenesis and pathogenesis of CCA.

TFF genes are involved in restitution and repair of the gastric and intestinal epithelium and are rapidly up-regulated in response to mucosal injury^[13,14]. In particular, *TFF1* has been shown to function as a gastric tumor sup-

pressor gene^[15]. However, *TFF* peptides are overexpressed in other solid tumors such as esophagus, breast, and pancreas and in some circumstances may function as tumor progression factors^[16-18]. Prolonged inflammation caused by parasitic infection frequently occurs in liver fluke-related CCA. *TFFs* may exert beneficial effects during the early steps of bile duct epithelial injury and inflammation, but have undesirable effects during subsequent chronic inflammation and neoplastic progression.

The molecular basis of *TFF* activity remains enigmatic and a specific *TFF* receptor has not been identified. The epidermal growth factor receptor (EGFR) is a type- I transmembrane glycoprotein receptor with tyrosine kinase activity in its cytoplasmic domain. EGFR is activated following the binding of multiple cognate ligands and plays a significant role in initiating the signaling that directs growth, proliferation, survival, and differentiation in mammalian cells^[19]. Several ligands of EGFR have been identified^[20], and there is some evidence for the transactivation of EGFR by *TFFs*. EGFR is a key signaling pathway for *TFF1*- and *TFF2*-mediated cellular invasion in kidney and colonic cancer cells^[21], suggesting the capability of *TFFs* to directly, or indirectly, transactivate the EGFR. While EGFR signaling has been shown to be important in CCA, there has been no report of *TFF*-mediated EGFR pathway activation in CCA.

With the available evidence in mind, we hypothesized that *TFFs* play important roles in the molecular pathogenesis of CCA, and mediate their actions, at least in part, through the transactivation of EGFR. We also hypothesized that an increase in *TFF* gene copy number resulting in the inappropriate overexpression of mRNA and the corresponding protein, contributes to the progression of CCA. Accordingly, we have measured *TFF* copy number, mRNA and protein in CCA patients, and have analyzed their association with clinicopathological parameters. In addition, *TFF*-mediated proliferation, EGFR transactivation and downstream signaling *via* the mitogen-activated protein kinase (MAPK) cascade was also investigated in a human CCA cell line.

MATERIALS AND METHODS

Patients and sample processing

Frozen liver tissues were obtained from 110 CCA patients undergoing surgical resection at Srinagarind Hospital, Faculty of Medicine, Khon Kaen University, Thailand. CCA cases were diagnosed by physicians using clinical findings, laboratory investigations and histological examinations. Clinicopathological data, such as age, gender, histological type, and tumor invasion, were obtained from medical records. The protocols were approved by the Ethical Committee of Khon Kaen University (HE480229). Informed consent was obtained from all patients who participated in the project.

Serum anti *O. viverrini* antibody was tested for association between liver fluke infection and CCA by enzyme-linked immunosorbent assay (ELISA) as described previously^[22]. The cut-off value was 0.200 optical density for

O. viverrini-positive subjects^[23]. There were 20/29 (69%) *O. viverrini*-positive cases (Table 1), which agreed well with general screening for anti *O. viverrini* antibody in other sample set (68%) (unpublished data) and a previous study^[5].

DNA preparation

DNA of CCA patients was prepared from frozen liver tissues using the Puregene™ DNA purification system (Gentra System, Minneapolis, MN, USA). Because establishing standard curves for analysis of *TFF* gene copy number by quantitative polymerase chain reaction (qPCR) required a large amount of DNA, DNA prepared from placental tissue which was collected from a patient after normal labor (postpartum) was used in this study.

Gene expression and copy number analysis

Total RNA was prepared from frozen liver tissues using RNeasy mini kits (QIAGEN, Valencia, CA, USA) according to the manufacturer's protocols. For quantitative reverse transcription PCR (QRT-PCR), oligo-dT primed first strand cDNA was synthesized from 1 µg template RNA using Omniscript Reverse Transcriptase reagents (QIAGEN) according to the manufacturer's protocols. RNA was also prepared from stomach and colon tissues collected from cancer patients who underwent surgical resection at Srinagarind Hospital, and was used to establish standard curves for analysis of *TFF* mRNA expression.

Oligonucleotide primer sequences for DNA copy number and QRT-PCR expression analysis, together with corresponding amplicon sizes are shown in Table 2. Primers sequences were designed using pDRAW32 (<http://www.acaclone.com/>).

Quantitative PCR amplification was performed on a Rotor Gene 3000 Real-time Amplification (Corbett Research, Australia) using a standard curve and SYBR Green I dye method (Amresco, Solon, OH, USA). The standard curve of each primer was generated using serial dilutions of placental DNA (for genomic *TFF1*, *TFF2*, and *TFF3*), stomach cDNA (for *TFF1* and *TFF2* mRNA), and colon cDNA (for *TFF3* mRNA). The standard curve was constructed in each PCR run and the copy number or cDNA expression of genes in each sample was interpolated using these standard curves. A coefficient of variation (CV) of each sample was determined based on triplicate test. The sample with a CV higher than 15% was re-tested. The melting curves of the PCR products were performed for each reaction to demonstrate that there were no nonspecific products or primer dimers.

TFF copy number was determined from a standard curve. The relative copy number of *TFF* was determined in comparison to the reference gene, β -actin, which is not amplified in CCA. The normal reference range was derived as we described previously^[12]. The relative copy number was interpreted as loss when the ratio was less than the mean - 2SD of the normal reference range, and as gain when the ratio was greater than mean + 2SD.

Immunohistochemistry

Tissue samples were processed for histology examination using standard procedures^[24]. A 4-µm thick section was cut from each paraffin block. TFF1, TFF2 and TFF3 proteins were detected by immunohistochemical staining using rabbit polyclonal anti-TFF1 and -TFF3 antibodies (Gifts from Professor Andrew Giraud, Murdoch Children's Research Institute, Royal Children's Hospital, Parkville, VIC 3052, Australia) at a dilution of 1:1000, and mouse monoclonal anti-NCL-HSP (anti-TFF2) (clone GE16C, Novocastra Lab, Newcastle, UK) at a dilution of 1:200. In brief, deparaffinized sections were boiled in 0.01 mol/L citrate buffer (pH 6.0) for 3 min for antigen retrieval. Sections were then incubated with 5 mL/L hydrogen peroxide in absolute methanol for 30 min to block endogenous peroxidase activity, then incubated with 50 mL/L horse serum (Seromed Biochrom, Berlin, Germany) for 30 min and incubated overnight at 4°C with anti-TFF antibodies. The sections were incubated with the DAKO EnVision™+ solution (rabbit or mouse/horseradish peroxidase; DAKO Corporation, Carpinteria, CA, USA) for 30 min. Histochemical reaction for peroxidase visualization was carried out with 0.5 mL/L 3,3'-diaminobenzidine tetrahydrochloride and 1 mL/L hydrogen peroxide, and was then counterstained with hematoxylin. The amount of TFF was classified into 4 groups based on the percentage of positive staining tumor cells: score 0, for percent positive staining cells < 1%;

score 1, 1% to 25%; score 2, 26% to 50%; and score 3, > 51%. Slides were examined independently by two pathologists. Results in agreement were considered to be valid. All studies were accompanied by a negative (no primary antibody) and a positive control (gastric tissues for TFF1 and TFF2, and colonic tissues for TFF3). In addition, we also observed TFF immunostaining in normal bile ducts and dysplasia of 110 CCA patients to evaluate protein expression and stepwise carcinogenesis in CCA.

Cell viability and proliferation

The KMBC cell line, derived from extrahepatic CCA, was maintained in RPMI-1640 medium supplemented with 5 mL/L fetal bovine serum (FBS); 50 IU/mL penicillin; 50 µg/mL streptomycin, at 37°C in 50 mL/L CO₂/air. To determine cell viability and proliferation rates, cells were serum starved overnight, then seeded (5×10^4 cells/well) in 24-well plates containing RPMI-1640 medium supplemented with 5 mL/L FBS; 50 IU/mL penicillin; 50 µg/mL streptomycin, and incubated with recombinant human (rh)TFF2 (Gift from Professor Andrew Giraud, Murdoch Children's Research Institute, Royal Children's Hospital, Parkville, VIC 3052, Australia) (5, 50, 500 µg/mL) or EGF (Promega, Indianapolis, IN, USA) (5, 25, 50 ng/mL). Viable cell numbers were counted with 0.4% trypan-blue dye exclusion on a slide hemocytometer. For EGFR blockade the EGFR tyrosine kinase inhibitor, PD153035 (10 µmol/L), was added to abrogate EGFR 1 h before adding rhTFF2 or EGF. All cell viability assays were performed in triplicate for each concentration and each experiment was repeated twice ($n = 6$ /group).

Immunoblotting

For immunoblotting, cell lysates were size fractionated by 10%-15% SDS-PAGE, transferred to nitrocellulose membranes (GE Healthcare Bio-Sciences, Piscataway, NJ, USA) and blocked in 5% non-fat milk powder/Tris-buffered saline pH 7.4, 0.1% Tween-20 as described. Membranes were incubated with primary antibodies overnight at 4°C. Detection was performed with anti-rabbit/anti-mouse IgG-HRP conjugates (DAKO Corporation, Carpinteria, CA, USA) and enhanced chemiluminescence re-

agents (GE Healthcare Bio-Sciences). Sources of primary antibodies: rabbit polyclonal anti-human EGFR (#2232) diluted 1:250; anti-human phospho-tyrosine 1173 EGFR (#4407) diluted 1:500; rabbit polyclonal anti-human extracellular signal-related kinase (ERK)1/2 (#9102) diluted 1:1000; anti-human phospho-threonine 202, phospho-tyrosine 204 ERK (#9101) diluted 1:1000; mouse monoclonal anti-human cyclin E (#4129) diluted 1:1000 (all Cell Signalling Technology, Danvers, MA, USA); rabbit polyclonal anti-human glyceraldehyde-3-phosphate dehydrogenase (GAPDH; #ab9485) diluted 1:3000 (Abcam, Cambridge, MA, USA).

Statistical analysis

Correlations between *TFF* DNA copy number and mRNA expression were analyzed using linear regression. Associations between *TFF* copy number, mRNA expression and protein expression, and clinicopathological parameters of CCA patients were evaluated using χ^2 tests. The difference in protein expression in normal bile ducts, dysplasia and CCA was assessed by Wilcoxon's rank sum test. Survival curves of patients (with *vs* without abnormal DNA copy number, normal *vs* high mRNA expression, and negative *vs* positive protein expression of *TFF* genes) were calculated using the Kaplan-Meier method. Differences in survival between two groups were assessed by the log-rank test. $P < 0.05$ was considered statistically significant.

RESULTS

Expression of TFF mRNA in CCA

To evaluate the role of TFFs in CCA, we measured *TFF* mRNA levels in tumor tissues of CCA patients using quantitative reverse transcription PCR (QRT-PCR). For comparison, tissues were also collected from tumor-free margin areas of 16 individuals. *TFF* mRNA level was normalized to that of *RPLP0* mRNA. The relative mRNA expression level of *TFF1*, *TFF2* and *TFF3* in normal samples ranged from 0.000-0.052 (mean, 0.004), 0.000-0.056 (mean, 0.008), and 0.000-0.329 (mean, 0.048), respectively. Relative mRNA expression level of *TFF1*, *TFF2* and *TFF3* in 46 tumor samples ranged from 0.000-9.773 (mean, 1.178),

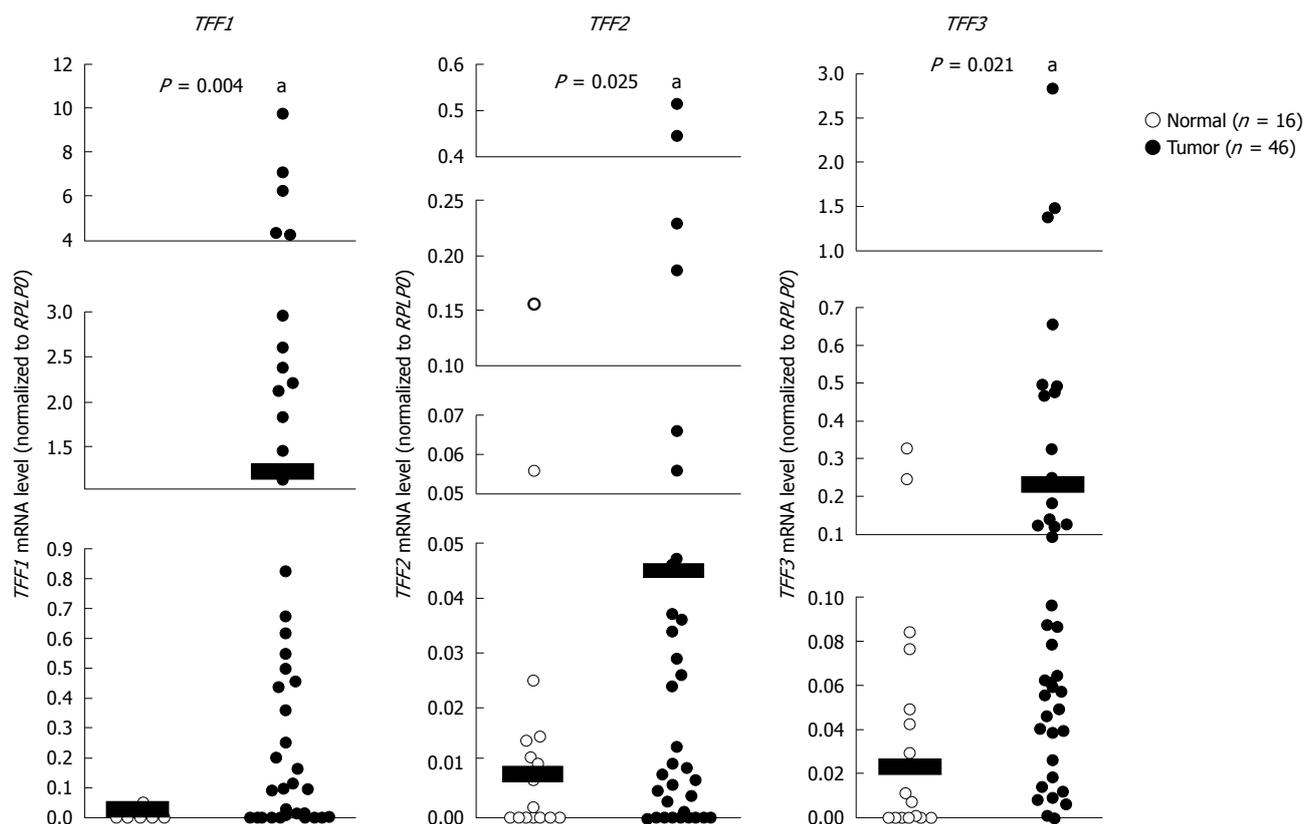

Figure 1 The mRNA expression levels of Trefoil factor genes in normal and cholangiocarcinoma tissues. Quantitative reverse transcription polymerase chain reaction analysis of trefoil factor (*TFF1*, *TFF2* and *TFF3*) mRNA levels in cholangiocarcinoma tumors ($n = 46$) compared with normal controls ($n = 16$). Scatter plots show mRNA abundance for each data point normalized to the internal reference gene *RPLP0*. Horizontal black bars show mean mRNA levels. $^aP < 0.05$. A statistical outlier in the *TFF2* normal control data set is +3.58 standard deviations from the mean and failed a Z-test, which requires that values must fall within 3 standard deviations of the mean for statistical validity. This sample (shown in bold font) was excluded from all statistical calculations for this data set.

0.000-0.516 (mean, 0.045), and 0.000-2.827 (mean, 0.229), respectively. The expression of *TFF1*, *TFF2* and *TFF3* mRNA in tumor tissues was significantly higher than in normal tissues ($P < 0.05$) (Figure 1). These results demonstrate that increased *TFF* gene expression correlates with tumor progression in CCA.

TFF protein expression in CCA

Immunohistochemistry was performed to determine TFF protein levels and cellular distribution in tissues collected from CCA patients. Examination of subcellular distribution revealed that all TFFs were present in fine cytoplasmic vesicles and at the apical/luminal surface of the epithelial cells. Faint and scattered *TFF1* immunoreactivity was observed in normal bile ducts with low frequency (24.6%). However, *TFF1* immunoreactivity was intense (Figure 2A) and markedly frequent in dysplasia. *TFF2* immunoreactivity was present mainly in peribiliary glands and rarely expressed in normal bile ducts and dysplasia (Figure 2B). *TFF3* immunoreactivity was distributed widely and expressed faintly in normal bile ducts but more intensely in dysplasia (Figure 2C) with high frequency in each case.

In tumor samples, *TFF1* was present mostly in the cytoplasm (Figure 3A), but in three cases, *TFF1* staining was also found in secreted mucus. *TFF1* immunoreactiv-

ity was detected in 56/110 (50.9%). Its frequency was markedly increased compared with normal ($P < 0.001$) (Figure 4A). *TFF2* was detected mostly in the cytoplasm with less frequency in 28/110 (25.5%). Interestingly, some positive staining was found at the invasion front (Figure 3B). *TFF3* immunoreactivity was observed in 54/110 (49.1%) of patients analyzed. Two patterns of *TFF3* staining were found in tumor cells: in cytoplasm as fine granules and in the apical/luminal surfaces, and as a goblet cell pattern in which *TFF3* was diffusely distributed as coarse granules (Figure 3C). In addition, *TFF3* immunoreactivity was highly frequent in disease-free control tissue (68.2%) but less frequent in dysplasia (55.5%) and CCA (49.1%) (Figure 4C). Although *TFF2* expression in CCA was less frequent compared to those of *TFF1* and *TFF3*, its frequency was markedly increased in comparison with those of normal bile ducts and dysplasia ($P < 0.01$) (Figure 4B) suggesting a role in tumor progression. Moreover, we found a significant correlation between *TFF1* and *TFF3* expression ($P = 0.014$), whereas *TFF2* expression was not correlated with either *TFF1* or *TFF3* expression (Table 3).

TFF copy number in CCA

The normal range of gene copy number derived from our previous study is 0.54-1.34 under a 95% CI^[12]. The

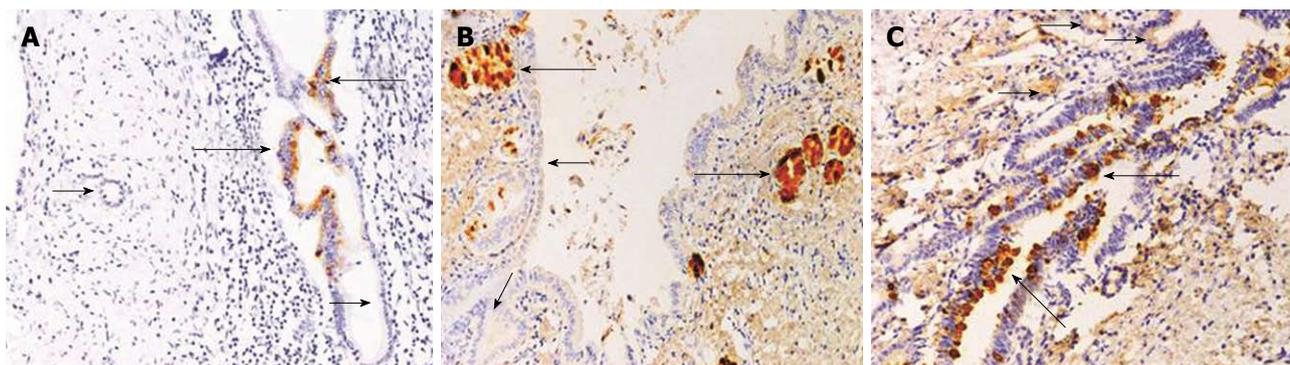

Figure 2 Immunohistochemical detection of trefoil factor proteins in normal and dysplasia bile ducts (Original magnification $\times 400$). A: Small and large normal bile ducts (short arrows) showing no trefoil factor (TFF)1 expression, whereas dysplasia showed moderately increased expression (long arrows); B: TFF2 expression was strongly positive in peribiliary glands (long arrows) but rarely present in dysplasia (short arrows); C: TFF3 was distributed widely at low level in small and large normal bile ducts (short arrows) and markedly increased in dysplasia (long arrows).

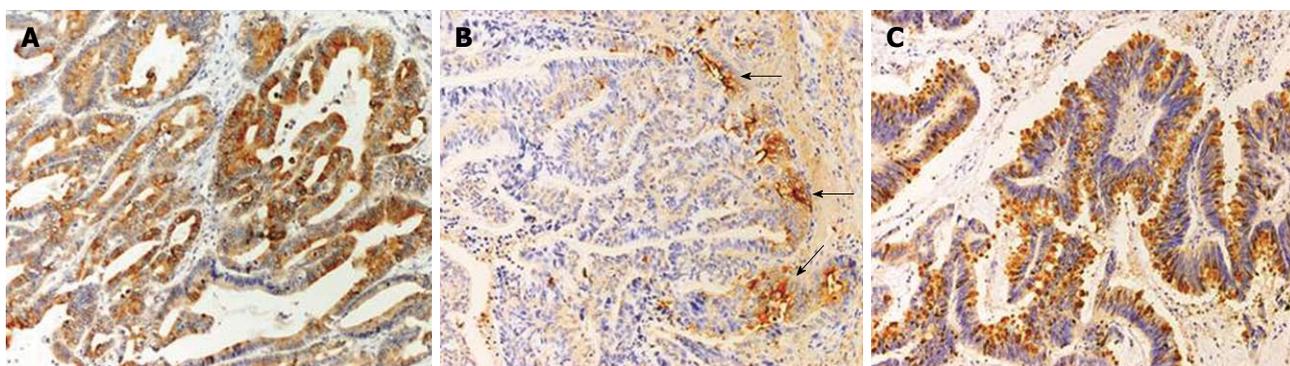

Figure 3 Immunohistochemical examinations of trefoil factor proteins in cholangiocarcinoma (Original magnification $\times 400$). A: Trefoil factor (TFF)1 staining was markedly positive and was mostly seen in the cytoplasm; B: TFF2 staining was mostly in the cytoplasm and at the invasion front (arrows); C: TFF3 staining showing a goblet cell pattern manifested as diffusely distributed coarse granules.

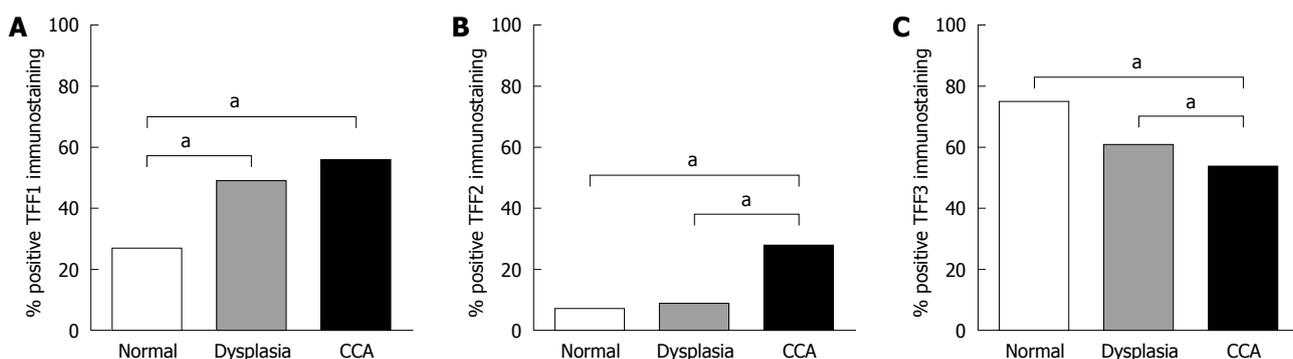

Figure 4 Frequencies of trefoil factor immunostaining in normal bile ducts, dysplasia and cholangiocarcinoma. A: Trefoil factor (TFF)1 positive immunostaining was markedly frequent in dysplasia and cholangiocarcinoma (CCA) compared to normal; B: Frequency of TFF2 positive immunostaining was significantly higher in CCA than in dysplasia and normal controls; C: TFF3 positive immunostaining was less frequent in CCA than in dysplasia and controls. $^aP < 0.05$.

percentage of CCA patients who had relative amplification at *TFF1*, *TFF2*, and *TFF3* was 25%, 12%, and 30%, respectively while that of CCA patients who had relative deletion at *TFF2* was 5%, and deletion of *TFF3* was 4% (Table 4). Relative amplification of these genes ranged from 1.35-3.67 and deletion from 0.37-0.51. Statistical analysis showed no associations of *TFF* mRNA, protein and copy number with age, gender, histological type, and survival time of the patients (Figure 5).

TFF2 stimulates CCA cell proliferation via EGFR-mediated MAPK

Our data showed increased *TFF2* expression in CCA tumor tissue compared to normal bile ducts and dysplasia, suggesting an important role in tumor progression. To address this question in greater detail, we next utilized an *in vitro* culture model to manipulate *TFF2* levels in CCA. The KMBC cell line is derived from extrahepatic CCA and is atypical in that it does not express significant lev-

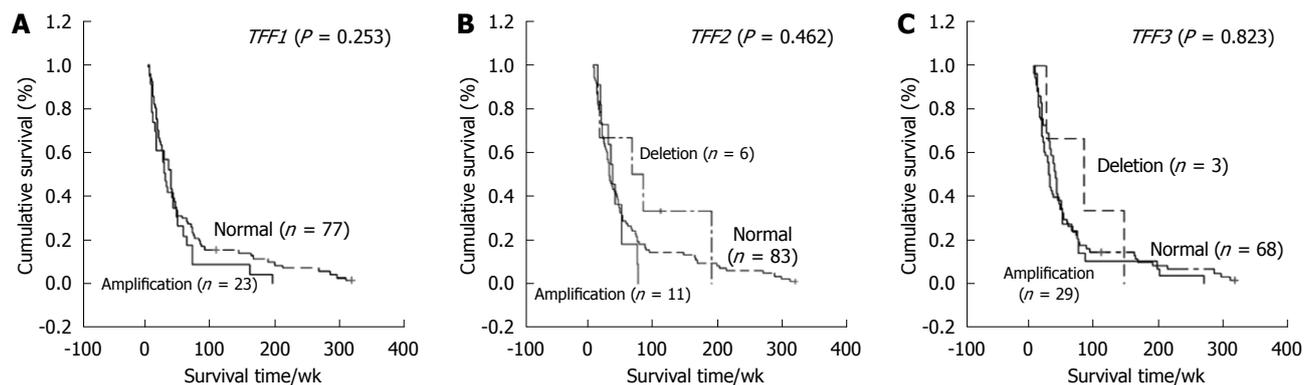

Figure 5 Kaplan-Meier survival curves with regard to trefoil factor copy number in cholangiocarcinoma. No association between trefoil factor (TFF) copy number and survival time (week) was found for A: TFF1; B: TFF2; C: TFF3.

Table 3 Associations of trefoil factor protein expression in cholangiocarcinoma

| TFF protein expression | n | TFF2 | | | TFF3 | | |

TFF: Trefoil factor.

els of TFF2. With this in mind, we designed a series of experiments to compare the proliferation rate of KMBC cells treated with or without recombinant human (rh)TFF2 peptide. EGF is a well-known mitogen and was used to validate KMBC proliferation as a positive control. Treatment with rhTFF2 (and EGF) increased the proliferation rate of KMBC cells (Figure 6A). While signaling receptors for TFFs have not been identified, studies in other cancer cells have shown that TFF signals can be transduced by transactivation of the EGFR^[21]. To determine whether rhTFF2 mediates proliferation responses *via* the EGFR, a specific EGFR antagonist, PD153035 (10 μ mol/L), was used to abrogate EGFR activity at least 1 h before treatment with 5 μ g/mL rhTFF2 or 50 ng/mL EGF. PD153035 treatment abolished both rhTFF2 and EGF dependent proliferative responses (Figure 6B). We next determined cyclin-E protein levels as a molecular endpoint of proliferation, finding that cyclin-E abundance was directly correlated with the viable cell count data (Figure 6C). Collectively, these results indicate that TFF2 stimulates CCA cell proliferation *via* transactivation of EGFR. To confirm this finding, we next determined the levels of EGFR activity by immunoblotting for EGFR (tyrosine-1173) phosphorylation. Consistent with expectation, rhTFF2 treatment triggered a significant increase in EGFR phosphorylation (tyrosine 1173). A similar effect was obtained by treatment with EGF. On the other hand tyrosine EGFR phosphorylation was significantly attenuated after treatment with PD153035 (Figure 6D).

The MAP-kinase cascade is the predominant signal

transduction pathway utilized by the EGFR. To confirm the identity of the intracellular mediator(s) of EGFR-dependent TFF2 activity we next investigated the response of the terminal MAP-kinases, p44/p42 or ERK 1/2 to rhTFF2 treatment in KMBC cells. Consistent with the effect on EGFR activity, exogenous rhTFF2 treatment significantly increased ERK phosphorylation compared to untreated controls ($P = 0.016$). A similar effect was obtained with EGF treatment, while both rhTFF2 and EGF-dependent activation of ERK was abolished by co-incubation with the EGFR antagonist, PD153035 (Figure 6E). These results suggest that increased TFF2 expression drives CCA tumor progression by increasing cell proliferation *via* activation of EGFR and MAPK signaling.

DISCUSSION

Previous studies have revealed differences in TFF gene expression in biliary pathologies depending upon the size of bile duct; small, medium or large^[25-27]. In addition, there are variations of TFF expression observed among these studies. They showed that TFF1 and TFF3 are moderately expressed in normal bile ducts, particularly large bile ducts and markedly increased in biliary epithelial diseases^[25-27], suggesting their significant roles in cytoprotection and biliary epithelial repair. Sasaki *et al*^[28] studied TFF1 expression in normal, biliary epithelial dysplasia, and CCA associated-hepatolithiasis. It was found that TFF1 was only modestly expressed in disease-free control tissue, yet was dramatically upregulated in dyspla-

Figures indicate relative copy number of trefoil factor (*TFF*) genes (*TFF1*, *TFF2*, *TFF3*) compared to the reference gene, β -*actin*. ¹Amplification; ²Deletion. Other figures are normal.

sia and noninvasive CCA. Paradoxically, *TFF1* expression was significantly decreased in invasive CCA with a positive rate of 60% due to promoter hypermethylation^[28]. In this context, it seems that *TFF1* expression positively regulates CCA tumor growth, but negatively regulates tumor invasion, potentially by acting as a tumor suppressor in the latter. In contrast, we found that *TFF1* mRNA expression was significantly increased in tumor tissue compared to adjacent disease-free tissues. Progressive increases in *TFF1* expression in dysplasia and CCA in our study strongly argues for a role in the stepwise carcinogenesis of liver fluke-associated CCA. Moreover, Vestergaard *et al.*^[29] showed that *TFF1* and *TFF3* promoter hypomethylation correlates with increased mRNA expression in prostate cancer compared to benign prostatic hyperplasia. It is therefore conceivable that increased *TFF1* expression in our CCA cohort was due to promoter hypomethylation.

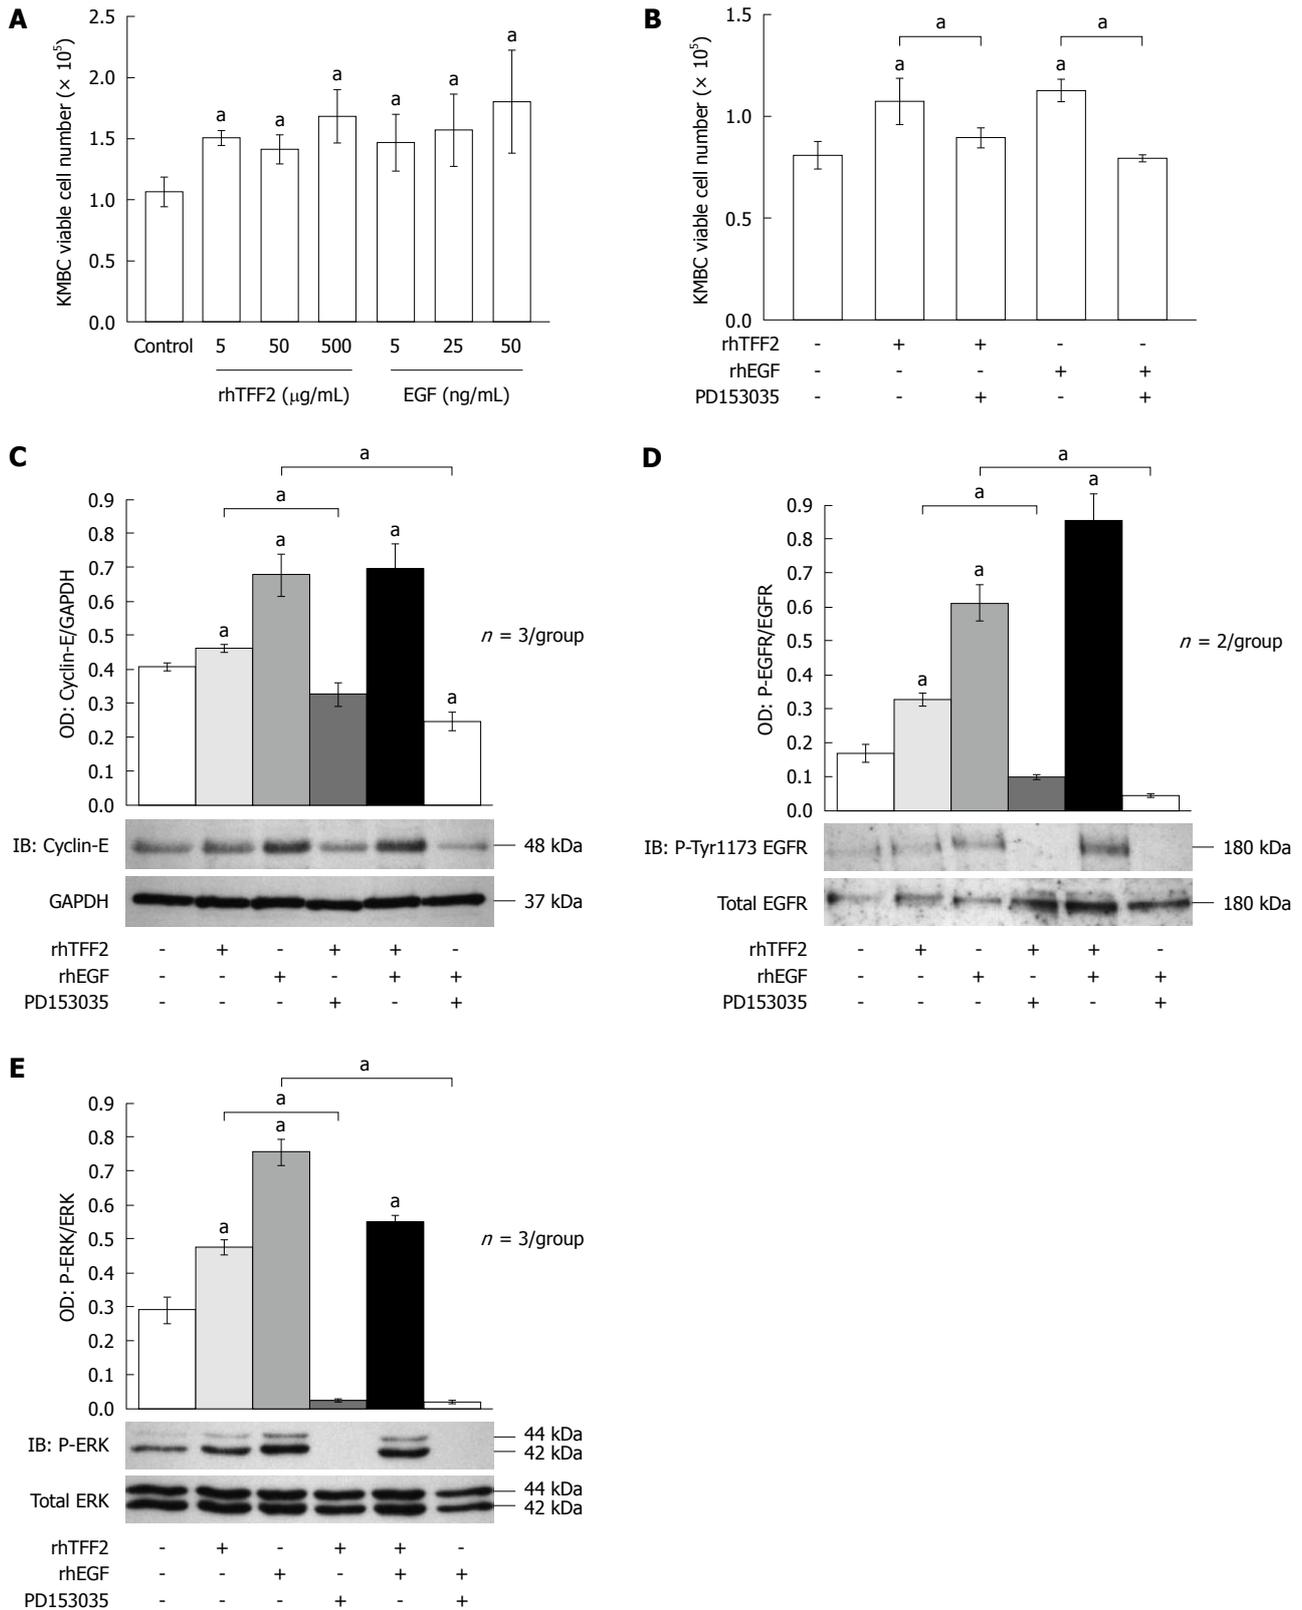

Figure 6 Trefoil factor 2 drives proliferation of KMBC cholangiocarcinoma cells via epidermal growth factor receptor tyrosine kinase and mitogen-activated protein kinase pathway activation. A: Proliferation of KMBC human cholangiocarcinoma cells determined by viable cell number counting with recombinant human trefoil factor (rhTFF)2 dose response (5, 50, 500 μg/mL) and epidermal growth factor (EGF) (5, 25, 50 ng/mL). Histograms show mean cell number per well. Error bars show standard error of the mean (SE). ^aP < 0.05; B: Proliferation of KMBC cells determined by viable cell number counting following treatment with combinations of 5 μg/mL rhTFF2, 50 ng/mL EGF, and 10 μmol/L PD153035 [EGF receptor (EGFR) antagonist]; C-E: Immunoblot analysis of intracellular signaling events and cell cycle regulators in KMBC cells treated with combinations of 5 μg/mL rhTFF2, 50 ng/mL EGF, and 10 μmol/L PD153035; C: Cyclin-E (48 kDa) protein abundance relative to GAPDH abundance; D: EGFR (180 kDa) phosphorylation level at tyrosine 1173 relative to total EGFR protein; E: extracellular signal related kinase (ERK; 42-44 kDa)1/2 phosphorylation at threonine 202/tyrosine 204 relative to total ERK1/2 protein. Histograms show mean normalized optical density (OD) of protein bands relative to untreated control (n = 3/group). Representative protein bands are shown. Error bars show standard error of the mean (SE). ^aP < 0.05.

The pathological features common to liver fluke infestation and other CCA are chronic inflammation of the biliary tract, bile stasis, and increased biliary epithelial cell turnover^[7]. However, the molecular mechanisms of carcinogenesis and pathogenesis of liver fluke- and non-liver fluke-associated CCA have not been well characterized and may differ according to the background of hepatobiliary lesions, and also to the stage or progression of CCA. This contradiction has been recently clarified by differential gene expression profiling of liver fluke- and non-liver fluke-associated CCA^[30]. We revealed that TFF1 protein expression in liver fluke-associated CCA was 50.7% compared with 20% in non-liver fluke-associated group suggesting that different underlying etiologies may lead to different mechanism of tumorigenesis and progression.

In contrast to previous studies^[25-27], we found down-regulation of TFF3 during stepwise carcinogenesis in liver fluke infestation. *TFF3* mRNA expression in tumors was significantly higher than in normal ($P = 0.021$) (Figure 1), whereas the positive rate of TFF3 expression in tumors was significantly lower than normal ($P = 0.003$) (Figure 4C). This suggests that TFF3 expression levels may be modified by posttranscriptional processing events. The substantially decreased TFF3 expression in CCA may reduce tumor suppressor activity, which leads to increased cell proliferation and tumor development. We found a significant association between TFF1 and TFF3 expression in our CCA cases ($P = 0.014$), suggesting that TFF1 and TFF3 were co-expressed in response to tumor progression and may adversely affect CCA patients. Although median survival time of CCA patients with the co-expression of TFF1 and TFF3 (29.43 wk) was shorter than that of CCA patients without co-expression (45.28 wk), no statistically significant difference was found between these two groups analyzed by Kaplan-Meier. Poulson *et al.*^[31] reported the co-expression of *TFF1* and *TFF3* mRNA in normal, hyperplasia, and neoplasia human breast epithelium, implicating them in the growth and progression of mammary carcinoma.

TFF2 was rarely expressed in normal and pre-malignant bile ducts but expressed mainly in peribiliary glands and markedly increased in CCA. Srivatsa *et al.*^[26] reported that TFF1 and TFF3 are induced in biliary diseases but not TFF2. However, Sasaki *et al.*^[25] showed that TFF2 expression was correlated with the degree of small bile duct damage, not with the disease etiology. Taken together, TFF2 expression in our cases was not responsible for stepwise carcinogenesis but rather was involved in the pathogenesis of CCA.

The proliferative effects of TFF2 have been investigated in other organ systems. Most significantly *TFF2*-deficient mice showed reduced gastric proliferation compared to wild-type littermate controls^[32]. Furthermore, it has been shown that TFF2 acting *via* the EGF signaling pathway promotes cell invasion and can be blocked by an EGFR inhibitor (ZD1839) in kidney and colon cell lines^[21]. Recently, Dubeykovskaya *et al.*^[33] have identified ectopically expressed CXCR4 chemokine receptor as a signaling receptor for TFF2 in lymphocytic and gastric cell lines. This study also demonstrated a distinct proliferative effect of TFF2 protein in gastric cancer cells

expressing CXCR4. Our study showed that rhTFF2 mediated CCA cell proliferation *via* the EGFR and MAPK activation, suggesting that TFF2 could act as a proliferative factor *via* the EGFR and intracellular MAPK pathway. An important conclusion of our study is the usefulness of these signaling molecules, acting downstream of TFF2, as potential therapeutic targets in invasive CCA.

This is the first study to directly analyze copy numbers of the three *TFF* genes and their relationship with mRNA and protein levels. Although a correlation among these parameters was not found, our study suggests that several mechanisms such as transcriptional and post-transcriptional processes are involved in the modulation of *TFF* gene expression in CCA, which plays an important role in the pathogenesis of this cancer.

Although *TFF* genes are involved in epithelium restitution and repair processes, the expression of *TFF* family members is tissue-specific. For example, TFF1 and TFF2 are expressed predominantly in the stomach, whereas TFF3 is predominantly expressed in the intestinal epithelium^[34]. The differential expression of *TFF* genes is consistent with distinct functional roles in different cell types. However, a “switch” in *TFF* gene expression patterns has been observed in other cancers, as exemplified by the upregulation of TFF3 in the intestinal metaplasia lineage and its association with poor prognosis in gastric cancer^[35]. Our data, showing aberrant expression and mitogenic effects of TFFs, suggests not only a mechanism for tumor progression in CCA, but also highlights the potential usefulness of TFFs as clinical biomarkers or even therapeutic targets using small molecule inhibitors.

COMMENTS

Background

Cholangiocarcinoma (CCA) in northeast Thailand is related to liver fluke infection. Previous study showed that > 30% of CCA patients have amplification of D21S1893, D21S1890 and the trefoil factor (*TFF*) gene family, which is associated with poor prognosis suggesting a role of TFFs in tumor progression. The authors hypothesized that an increase in *TFF* gene copy number resulting in the inappropriate overexpression of mRNA and corresponding protein, contributes to the progression of CCA in which TFFs mediate their actions, at least in part, through the transactivation of epidermal growth factor receptor (EGFR).

Innovations and breakthroughs

This is the first study to directly analyze copy numbers of the three *TFF* genes and their relationship with mRNA and protein levels. This is also the first report showing that TFF2 is mitogenic in CCA *via* activation of EGFR and the mitogen-activated protein kinase pathway.

Applications

Aberrant expression and mitogenic effects of TFFs suggests not only a mechanism for tumor progression in CCA, but also highlights the potential usefulness of TFFs as clinical biomarkers or even therapeutic targets using small molecule inhibitors.

Peer review

The authors clearly demonstrate that TFF2 peptide increased cell proliferation in a CCA cell line, and they first show that TFF2 activated EGFR and the ERK1/2 MAP kinase in CCA cell line, showing both the function and its mechanism of TFF2 in CCA.

Abstract

AIM: To compare the outcome of surgical treatment of colorectal adenocarcinoma in elderly and younger patients.

METHODS: The outcomes of 122 patients with colorectal adenocarcinoma who underwent surgical treatment between January 2004 and June 2009 were analyzed. The clinicopathological and blood biochemistry data of the younger group (< 75 years) and the elderly group (\geq 75 years) were compared.

RESULTS: There were no significant differences between the two groups in operation time, intraoperative blood loss, hospital stay, time to resumption of oral intake, or morbidity. The elderly group had a significantly higher rate of hypertension and cardiovascular disease.

The perioperative serum total protein and albumin levels were significantly lower in the elderly than in the younger group. The serum carcinoembryonic antigen level was lower in the elderly than in the younger group, and there was a significant decreasing trend after the operation in the elderly group.

CONCLUSION: The short-term outcomes of surgical treatment in elderly patients with colorectal adenocarcinoma were acceptable. Surgical treatment in elderly patients was considered a selectively effective approach.

INTRODUCTION

Colorectal adenocarcinoma is one of the most common malignant diseases worldwide, and colorectal adenocarcinoma is also the leading cause of cancer-related deaths in developed countries. Moreover, the incidence of colorectal adenocarcinoma has been reported to increase with age in the some countries^[1-3]. According to the published statistical data, the incidence of colorectal adenocarcinoma in elderly patients has been increasing slightly over

the past several decades, and especially in people aged > 75 years old in Japan^[4]. Surgery has always been the main curative treatment for colorectal adenocarcinoma, which can be resected curatively for primary tumor lesions and lymph node dissection. As a result of preexisting comorbidity in elderly patients with colorectal adenocarcinoma, there is controversy as to whether surgical treatment is beneficial. The average life expectancy in many developed countries is reported to be > 80 years^[5], and the number of colorectal adenocarcinoma patients is expected to increase in the future, therefore, the issue of the treatment of elderly patients with colorectal adenocarcinoma needs to be addressed. Some studies on surgery for colorectal adenocarcinoma in the elderly have been published^[6-12], but not a sufficient number.

The survival rate and quality of life after surgical treatment of colorectal adenocarcinoma are affected by postoperative complications. To clarify the impact of surgery on elderly patients with colorectal adenocarcinoma, we investigated and evaluated the short-term results of surgical treatment for colorectal adenocarcinoma in elderly patients aged ≥ 75 years, in comparison with those < 75 years.

MATERIALS AND METHODS

We studied 122 patients with pathologically diagnosed colorectal adenocarcinoma who were treated surgically at the Northern Fukushima Medical Center in Japan between January 2004 and June 2009. The patients were divided into two groups according to age: an elderly group of 54 patients aged ≥ 75 years, and a younger group of 68 patients aged < 75 years. All operations were performed by experienced surgeons in our hospital, and none of the patients received chemoradiotherapy before surgery. Operation time, intraoperative blood loss, length of postoperative hospital stay, morbidity, and mortality were analyzed to compare the risks and benefits of surgery in the two groups, and the two groups were compared with regard to blood examination data before and after surgery.

All of the patients were investigated routinely by physical examination, colonoscopy, colorectal contrast radiography, and thoracoabdominal computed tomography. Preoperative risk and preexisting comorbidity was evaluated using the American Society of Anesthesiology (ASA) scoring system. The results of surgical treatment and tumor staging were evaluated according to the International Union against Cancer tumor-node-metastasis classification, followed by pathological examination of the surgical specimen.

Information concerning the clinical characteristics of the patients upon admission was collected from the medical records. The general nutritional status of the patients was assessed on the basis of their body mass index (BMI), and their serum total protein and albumin levels. The tumor index, which was calculated by multiplying the longest diameter of the lesion by its shortest diameter, was used to evaluate the tumor. Serum carcinoembry-

onic antigen (CEA) level and carbohydrate antigen 19-9 (CA19-9) level were measured by enzyme immunoassay (EIA) before and after the operation. Systematic inflammatory response was assessed on the basis of the white blood cell (WBC) count and serum C-reactive protein (CRP) level at different times before and after surgery.

Laparoscopic-assisted colectomy for patients with colorectal adenocarcinoma was still assessed. The anastomoses were made with a circular stapler when the single-stapler technique was used, and with gastrointestinal anastomotic devices when functional end-to-end anastomosis was performed after both laparoscopic-assisted and open colectomy.

Postoperatively, oral intake of clear liquids was started after flatus was detected, provided the patient did not have severe nausea, vomiting, or abdominal distention, and a liquid diet was given, provided the patient had no trouble with the clear liquid regimen. Patients were discharged when a solid diet was well accepted and no postoperative complications were detected. Their length of postoperative hospital stay was measured from the day of surgery to the day they were discharged.

All data are reported as mean \pm SD. Statistical analyses for the categorical variables were performed by means of the χ^2 or Fisher's exact test, and the Mann-Whitney *U* test was used for measured variables. $P < 0.05$ was regarded as statistically significant.

RESULTS

One hundred and twenty-two patients with colorectal adenocarcinoma were treated by surgery, and 115 (94.3%) patients were evaluated by postoperative pathologically. The clinicopathological characteristics of the patients in the two groups are shown in Table 1. Of the 68 patients in the younger group, 40 (58.8%) were male, and 28 (51.9%) patients in the elderly group were male. The age range was 40-74 years in the younger group and 75-94 years in the elderly group. BMI was 22.23 ± 3.25 kg/m² in the younger group and 21.08 ± 3.58 kg/m² in the elderly group, and it was significantly lower in the elderly group than in the younger group ($P < 0.05$). There were no significant differences between the two groups for site of colon tumor, lesion type, tumor index, operation time, intraoperative blood loss, or pathological stage. Laparoscopic-assisted colectomy was performed in 35 (64.8%) patients in the elderly group as opposed to 19 (27.9%) in the younger group, and the percentage of patients treated by laparoscopic-assisted colectomy was significantly higher in the elderly group. Only one patient in the elderly group had 30-d surgical mortality. The numbers of lymph nodes harvested, proximal and distal to the tumor site are shown in Table 2, and there were no significant differences between the two groups.

Surgical procedure

The surgical procedures used and pathological characteristics of the resected tumors are also shown in Table 2. There were no significant differences between the two

NS: Not significant.

blood loss, surgical site infection, or anastomotic leakage. Although the difference between the intraoperative blood loss in the two groups was not significant, a significantly higher percentage of patients in the elderly group required a postoperative blood transfusion ($P < 0.01$).

Resumption of oral feeding

After surgical treatment, the percentage of patients who could drink water before postoperative day 3 was 78% (53/68) in the younger group, compared to 72.2% (39/54) in the elderly group. The number of patients who received the liquid diet before postoperative day 4 was 46 (67.7%) in the younger group and 34 (63.0%) in the elderly group. There were no significant differences between the two groups for the time after surgery when a clear liquid or a liquid diet was started.

Assessment of comorbidity and surgical outcome

There was a preexisting comorbidity, such as cardiovas-

cular disease, hypertension, diabetes mellitus, or cerebrovascular disease, in 36 (66.7%) patients in the elderly group. Eleven (20.4%) patients in the elderly group were assessed as worse than ASA II at the time of operation, compared to seven (10.3%) patients in the younger group (Table 1), and the difference between the groups was statistically significant. The mean length of postoperative hospital stay was 23.24 \pm 14.27 d in the younger group and 24.59 \pm 14.48 d in the elderly group. Although the comorbidity rate was higher in the elderly group, the length of postoperative hospital stay was not significantly longer than in the younger group.

Right hemicolectomy and sigmoid colon resection were performed in one patient in the elderly group, because the lesions were located in the ascending and sigmoid colon. Furthermore, six patients in the younger group underwent a synchronous operation, including cholecystectomy, inguinal hernia operation, ovariectomy, and partial liver resection for liver metastasis, and two patients in the elderly group underwent synchronous cholecystectomy. Postoperative complications in the younger group consisted of surgical site infection in five patients, anastomotic leakage in four, and other morbidity, such as anastomotic bleeding, abscess in the peritoneal cavity, and wound rupture, whereas in the elderly group they consisted of anastomotic leakage in three patients, surgical site infection in seven, and anastomotic bleeding, abscess in the abdominal cavity, pancreatitis, necrosis of the stoma, and ileus in one each. There was no significant difference in the operation-related morbidity between the two groups. We compared the proximal and distal distances from the tumor lesion, lesion circulation rate, total number of lymph nodes dissected, and times after surgery when the clear liquid and liquid diets were begun, but there were no significant differences between the two groups in surgical outcomes evaluated on this basis.

Perioperative systematic inflammatory response level

The severity of the systematic inflammatory response before and after surgery was assessed on the basis of WBC count and serum C-reactive protein level in the younger and elderly groups (Figure 1). On postoperative day (POD) 1, the mean WBC count and C-reactive protein level were 10092.39 \pm 3258.60/mL and 6.88 \pm 3.02 mg/dL, respectively, in the younger group and 10866.67 \pm 3480.92/mL and 5.98 \pm 2.84 mg/dL, respectively, in the elderly group. Although the WBC count on POD 1 was higher in the elderly group, the difference between the two groups was not significant. After POD 1, the WBC count and CRP level gradually decreased in both groups, and there were no significant differences between the two groups in either parameter on POD 4 or POD 7.

Perioperative nutritional status

The perioperative nutritional status of the patients was assessed on the basis of their serum total protein level, serum albumin level and BMI. The total serum protein and serum albumin levels before and after surgery are shown in Figure 1, and the BMI values before the opera-

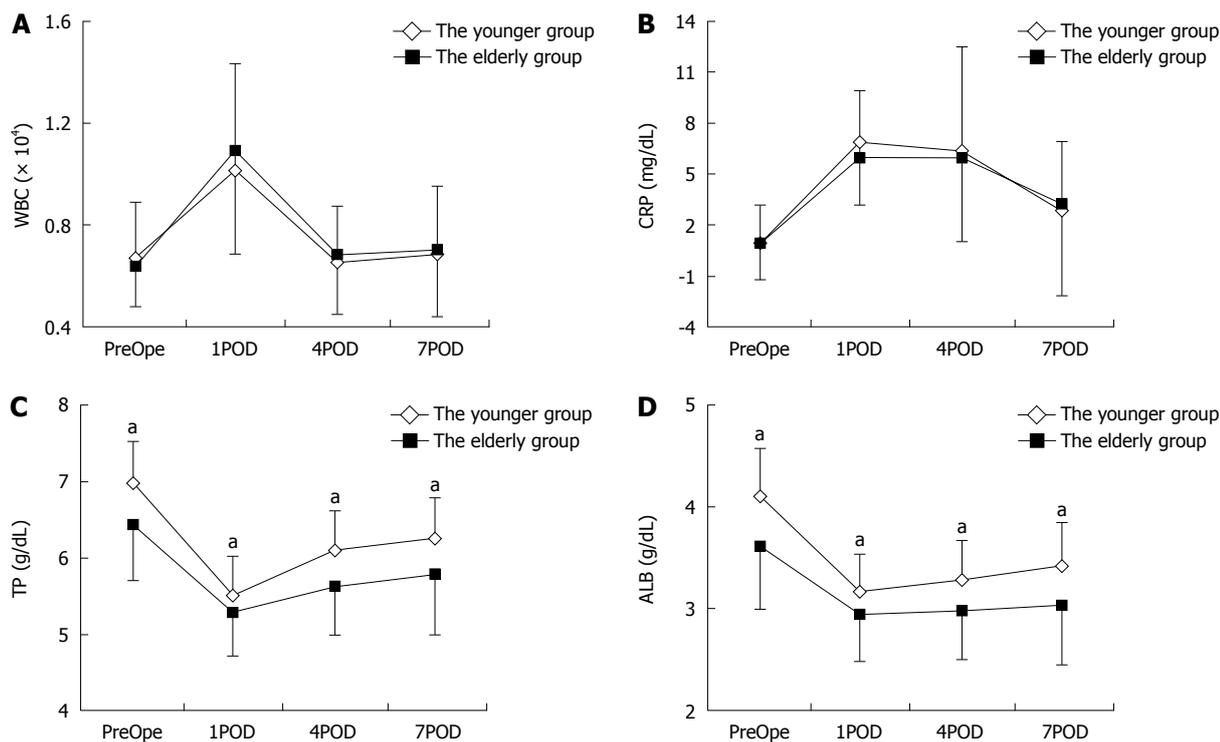

Figure 1 Changes in laboratory data of elderly and younger patients with colorectal adenocarcinoma at different times perioperatively: white blood cell count (A), serum C-reactive protein level (B), serum total protein level (C), and serum albumin level (D). Serum total protein (TP) and albumin (ALB) levels in the elderly group were significantly lower than in the younger group at different times perioperatively. The white blood cell (WBC), C-reactive protein (CRP), TP and ALB data are expressed as mean ± SD. Preop: Before surgery (^a*P* < 0.05). POD: Postoperative day.

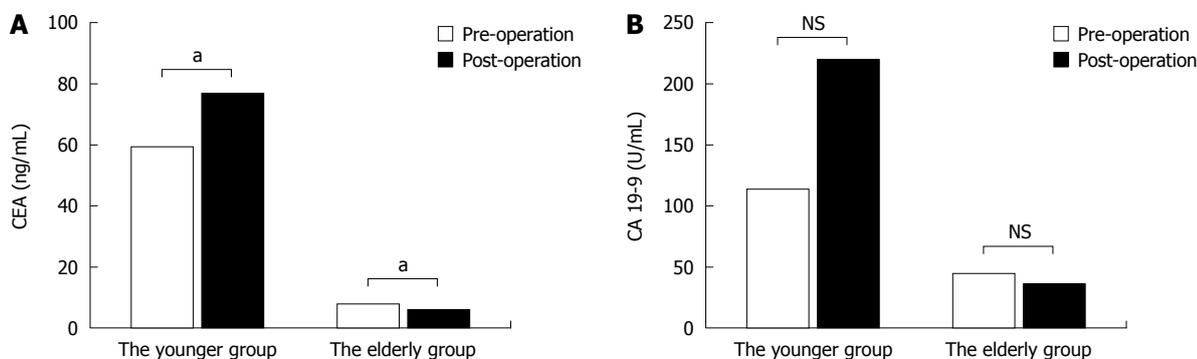

Figure 2 Serum carcinoembryonic antigen (A) and carbohydrate antigen 19-9 (B) levels measured by enzyme immunoassay in patients with colorectal adenocarcinoma were compared pre- and postoperatively between the younger and elderly groups. Postoperative carcinoembryonic antigen (CEA) level in the younger group was significantly higher than the preoperative level, and the postoperative level in the elderly group was significantly lower than the preoperative level. However, there were no significant differences for the change in carbohydrate antigen 19-9 (CA19-9) levels pre- and postoperatively in the two groups. CEA and CA19-9 data are expressed as mean. ^a*P* < 0.05. NS: Not significant.

tion are shown in Table 1. The serum total protein and albumin levels preoperatively were 6.97 ± 0.55 and 4.08 ± 0.49 g/dL, respectively, in the younger group and 6.42 ± 0.73 and 3.61 ± 0.61 g/dL, respectively, in the elderly group, and the nadirs of both of these parameters in both groups were recorded on POD 1. The nutritional status of the patients based on their BMI, serum total protein level, and serum albumin level was poorer in the elderly group than in the younger group, and the differences in all three parameters between the younger group and the elderly group were statistically significant.

Perioperative changes in tumor marker values

The serum CEA and CA19-9 levels were measured before and after surgery (Figure 2). The mean serum CEA and CA19-9 levels in the younger group were 59.52 ± 374.69 ng/mL and 113.24 ± 381.16 U/mL, respectively, before surgery and 77.05 ± 494.09 ng/mL and 221.85 ± 1186.01 U/mL after surgery. In the younger group, the serum CEA and CA19-9 levels were higher after the operation than before. By contrast, the mean serum CEA and CA19-9 levels in the elderly group were 8.22 ± 15.37 ng/mL and 45.24 ± 194.35 U/mL, respectively,

before surgery and 6.65 ± 18.83 ng/mL and 36.78 ± 137.65 U/mL, respectively, after surgery, and both were lower after surgery than before. There were significant differences in the level of CEA in the younger and elderly groups perioperatively.

DISCUSSION

We compared the short-term outcomes of surgical treatment of colorectal adenocarcinoma in younger and elderly groups. Of the 122 patients included in this study, 54 (44.3%) were aged ≥ 75 years old, and the oldest patient was 94 years old. The patients in the elderly group had a high incidence of preexisting comorbidity, therefore, the effect of surgery for colorectal adenocarcinoma was unclear, except in those who had colon obstruction or bleeding caused by the tumor. The patients in the elderly group had other diseases, including hypertension, cardiovascular disease, diabetes mellitus, and cerebrovascular disease. Although preoperative status evaluated by the ASA scoring system was worse in the elderly group than in the younger group, almost all of the patients with colorectal adenocarcinoma could be treated with surgery.

There were no significant differences between the younger and the elderly groups with regard to operative factors, including bowel-margin-positive rate, tumor index, number of lymph nodes harvested, extent of lymph node dissection, intraoperative blood loss, or operation time. This could partly explain why the elderly patients with colorectal adenocarcinoma could be treated curatively by surgery if they were managed appropriately before and after the operation. Curative colectomy could not be performed in four patients in the elderly group because of distant metastasis and local deep invasion. Thus, the rate of diagnosis of colorectal adenocarcinoma in the early stage needs to be improved, especially in high-risk populations.

It has been reported that preoperative nutritional status can greatly affect the postoperative complications of the colorectal carcinoma patients after surgery^[13]. The serum albumin and total protein levels, and BMI were assessed to evaluate the nutritional status of the patients with colorectal adenocarcinoma, and there was a significantly higher prevalence of hypoproteinemia and hypoalbuminemia in the elderly group than in the younger group, before and after surgery. Although the nutritional status of the patients in the elderly group was poorer than in the younger group, the percentages of patients with anastomotic leakage and wound infection in the elderly group were not significantly higher. Our results suggest that hypoproteinemia and hypoalbuminemia do not affect the recovery of elderly patients with colorectal adenocarcinoma after surgical treatment, if they are appropriately managed during the perioperative period. Dixon *et al.*^[14] have found that patients with a low albumin level have a significantly shorter survival time after surgery for colorectal adenocarcinoma, and that the long-term outcomes of surgery need to be examined to establish

the essential benefits of surgery in elderly patients with colorectal adenocarcinoma.

A relationship between the systematic inflammatory response and survival has been reported in colorectal cancer patients who have undergone curative surgery^[15]. In the present study, the systematic inflammatory response was evaluated on the basis of the perioperative WBC count and serum CRP level between the two groups, and there was no significant difference between the severity of the systematic inflammatory response in the elderly and younger groups. These results suggested that the postoperative survival rate of the elderly patients was no worse than that of the younger patients, and that surgical treatment was acceptable for patients who could endure the operation, regardless of their age.

CEA and CA19-9 are the tumor-associated antigens that are most commonly used in the management of colorectal adenocarcinoma. It has been reported that CEA is a high-molecular-weight glycoprotein member of the immunoglobulin superfamily that plays a pivotal role in such biological phenomena as adhesion, immunity, and apoptosis of tumor cells, and in the assessment of sensitivity to antitumor agents^[16,17]. Moreover, some previous studies have shown an association between high preoperative serum CEA level and poor outcome^[18,19] of colorectal adenocarcinoma patients who underwent surgical treatment. In the present study, the serum CEA levels were significantly lower in the elderly group preoperatively and postoperatively. Moreover, the serum CEA levels exhibited a significantly decreasing trend after surgical treatment in the elderly group ($P < 0.05$), whereas the serum CEA levels in the younger patients were significantly higher after surgery than before ($P < 0.05$). These results suggest that surgical treatment might be beneficial and be one of the selectively effective strategies for elderly patients with colorectal adenocarcinoma. Some studies have found that CA19-9 level is a prognostic factor for colorectal cancer patients^[20,21]. In the present study, the serum CA19-9 levels in the elderly group were lower than in the younger group, and the levels in the elderly group showed a decreasing trend after surgical treatment, but not in the younger group. These findings also suggested that the elderly patients benefited more from surgical treatment.

The elderly population was considered to be a high-risk group for malignant diseases, and the prognosis of elderly patients with colorectal adenocarcinoma treated by surgery was estimated to be worse than for younger patients, especially for emergency surgery. The relation between emergency and elective surgery in patients with colorectal adenocarcinoma was not compared in this study. Furthermore, the number of the patients enrolled in this study was small, therefore, the results were limited. A larger sample study is needed to establish the effect of surgical treatment in elderly and younger patients.

In conclusion, the short-term outcomes of surgical treatment of elderly patients with colorectal adenocarcinoma in this study were acceptable. Surgical treatment of elderly patients with colorectal adenocarcinoma was considered a selectively effective approach.

COMMENTS

Background

Colorectal adenocarcinoma is one of the most common malignant diseases worldwide, and colorectal adenocarcinoma is also the leading cause of cancer-related deaths in developed countries. Moreover, the incidence of colorectal adenocarcinoma has been reported to increase with age in some countries. Some articles on surgery for colorectal adenocarcinoma in the elderly have been published, but their number has not been sufficient.

Research frontiers

To clarify the impact of surgery on elderly patients with colorectal adenocarcinoma, the authors investigated and evaluated the short-term results of surgical treatment for colorectal adenocarcinoma in elderly patients ≥ 75 years old in comparison with patients < 75 years old.

Innovations and breakthroughs

There were no significant differences between the two groups with regard to surgery-related factors. However, serum carcinoembryonic antigen level was lower in the elderly than in the younger group, and there was a significant decreasing trend after surgery in the elderly group.

Peer review

The present study is helpful in initiating further clinical studies to validate the results. Furthermore, the use of a comprehensive geriatric assessment instrument to determine operative risk could assist with selection of elderly patients who are most likely to benefit from surgery, and make the results of future studies more generalizable.

Abstract

AIM: To assess the application of multiple planar volume reconstruction (MPVR) and three-dimensional (3D) transparency lung volume rendering (TL-VR) with 64-row multidetector-row computed tomography (MDCT) in neonates with congenital esophageal atresia (EA) and distal tracheoesophageal fistula (TEF).

METHODS: Twenty neonates (17 boys, 3 girls) with EA and distal TEF at a mean age of 4.6 d (range 1-16 d) were enrolled in this study. A helical scan of 64-row MDCT was performed at the 64 mm × 0.625 mm collimation. EA and TEF were reconstructed with MPVR and TL-VR, respectively. Initial diagnosis of EA was made by chest radiography showing the inserted catheter in the proximal blind-ended esophageal pouch. Manifestations of MDCT images were compared with the findings at surgery.

RESULTS: MDCT showed the proximal and distal esophageal pouches in 20 cases. No significant difference was observed in gaps between the proximal and distal esophageal pouches detected by MPVR and TL-VR. The lengths of gaps between the proximal and distal esophageal pouches detected by MPVR and TL-VR correlated well with the findings at surgery ($R = 0.87$, $P < 0.001$). The images of MPVR revealed the orifice of TEF in 13 cases, while TL-VR images showed the orifice of TEF in 4 cases.

CONCLUSION: EA and distal TEF can be reconstructed using MPVR and TL-VR of 64-row MDCT, which is a non-invasive technique to demonstrate the distal esophageal pouches and inter-pouch distance in neonates with EA and distal TEF.

INTRODUCTION

Esophageal atresia (EA), with or without tracheoesophageal fistula (TEF), is the most important and common congenital malformation of the esophagus^[1,2]. The reported incidence of EA and TEF is approximately one in 3000-4500 live births^[1]. The majority of patients

have an associated fistula between the trachea and distal esophageal pouch. In neonates with EA and distal TEF, the anatomy of esophageal pouch, inter-pouch gap and up-growth of tracheobronchial tree, especially inter-pouch gap, not only influences the surgical approach and postoperative strategy but also predicts prognosis of such patients^[1,3,4]. If a short inter-pouch gap (e.g. shorter than 2 cm) with two longer pouches is detected, esophageal reunion with a primary anastomosis is relatively easy and postoperative complications are few. On the contrary, surgical procedure may be difficult for a longer inter-pouch gap with hypogenetic pouches, postoperative complications such as anastomotic leak may occur and ventilatory support is possibly required.

The application of multidetector-row computed tomography (MDCT) in reconstruction of 3D volume rendering (VR) has increased due to its ability to demonstrate the anatomy of hollow viscera. MDCT can generate VR images of the trachea and esophagus quickly and non-invasively, show the anatomy and 3D relation between the two structures more clearly and accurately, and provide valuable guidance for any surgical approach^[5]. Multiple planar volume reconstruction (MPVR) by MDCT is a reliable and straightforward technique to show hollow viscera in a multidirectional view and their adjacent tissues and organs clearly.

In this study, the ability of 3D TL-VR and MPVR to reconstruct EA and distal TEF in neonates was assessed by 64-row MDCT.

MATERIALS AND METHODS

The study was approved by the local ethics committee. Written informed consent was obtained from the parents of patients. Twenty neonates (17 boys and 3 girls) with EA and distal TEF were included in this study. Their birth weight was 1900-4000 g (mean 2888 g). Of the 20 neonates, 18 were full-term and 2 were pre-matured at a gestational age of 35 and 36 wk, respectively. Their age at the time of CT scan was 1-16 d with a mean age of 4.6 d. All patients had different degrees of respiratory distress and were not able to swallow food and saliva. Initial diagnosis of EA was made according their clinical symptoms and chest radiography showing the inserted catheter in the proximal blind-ended esophageal pouch and intestinal gas in the upper abdomen. Nineteen cases had different degrees of aspiration pneumonia, and only one had no inflammation of the lungs. Before CT scan, the proximal pouch was suctioned with an aspirating catheter, and then air (5 mL) was hand-injected into the proximal pouch. To avoid respiratory distress, the patients were not given sedatives. Body straps were used to immobilize the patients and decrease the motion artifacts. After CT scan, all patients underwent operation, and CT manifestations were compared with the findings at surgery.

CT data were collected with a 64-row MDCT scanner (GE Lightspeed VCT64, GE Healthcare, Wis, USA). All scans were performed from the level of larynx to the dia-

phragm. CT scan protocol was as follows: 120 kVp, z-axis automatic tube current modulation (ATCM) (AutomA; GE Healthcare) for all children with the noise index (NI) of 10 with a mean calculated CTDI dose of 1.57 mGy, a 64 mm × 0.625 collimation, 1.375:1 pitch, 0.8 s rotation time, and 512 × 512 matrix. The scanning time was 2-3.5 s. Images were reconstructed in the axial plane at a 0.625 mm interval with a standard reconstruction algorithm. CT images were transferred to an independent workstation (Advantage Workstation 4.3; GE Medical Systems) for further image reconstruction. Chest MPVR images were collected at the axial and sagittal and coronal view with a minimum intensity projection (MinIP), and 3D transparency lung VR models of the tracheobronchial system and the esophagi with a lower threshold of -704 HU and an upper threshold of -280 HU. Gaps between the proximal and distal esophageal pouches were measured at the workstation by two consultant radiologists with experiences in pediatric radiology and pediatric computed tomography. The average findings were recorded. The total image processing time was 20-30 min in each patient. Because the proximal and distal esophageal pouches were not frequently observed in the same plane of sagittal or in coronal view of multiple plane reconstruction (MPR), pulmonary air leaks were not discovered in all cases, chest MPVR with minimum intensity projection (MinIP) was used instead of MPR. However, it should be emphasized that MPR could provide more information about esophageal walls and the surrounding tissues of esophageal pouches than MPVR or TL-VR. View of the original axial and MPR images was indispensable before the measurement of MPVR and TL-VR.

The 20 patients underwent operation within 30 h (average 19 h) after CT scan. The inter-pouch distance and caliber of fistulae were measured with a silk thread between two artery forceps during operation. Then different lengths (centimeters) of silk thread were measured with a ruler.

RESULTS

The trachea and bronchial systems including the major lobe bronchi, proximal and distal esophageal pouches, and inter-pouch gaps in 20 patients could be clearly observed on the 3D TL-VR and MPVR images. The MPVR images showed the distal fistulae including their orifice in 13 cases, while the TL-VR images revealed the distal fistulae including their orifice in only 4 cases. Zigzag artifacts were trifling in most patients because of their motion and respiration. Different lengths of the gaps and different degrees of the fistulae are shown in Figures 1-4, and Figure 2 revealed that the lower fistula opened into the trachea within 1 cm of the carina.

The CT data and findings at surgery in the patients are summarized in Table 1. The inter-pouch gap was measured at surgery after the fistulae were divided in 17 cases and before the fistulae were cut in 3 cases. The diameter of fistulae was measured at surgery before the fistulae were ligated and divided in the 20 cases.

The inter-pouch distance was measured in 17 cases

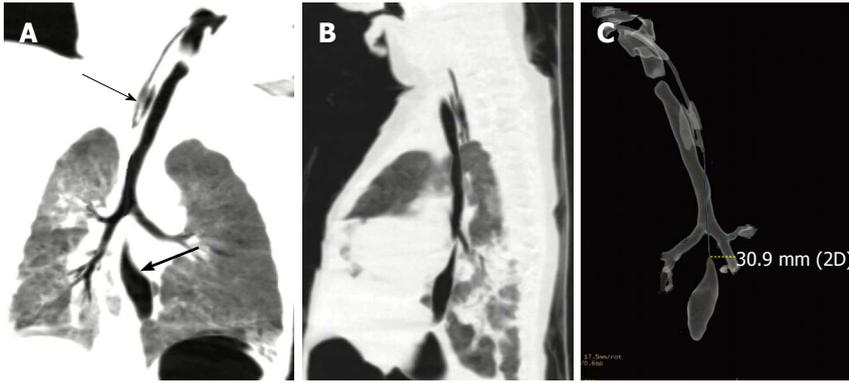

Figure 1 The reconstruction techniques of multidetector-row computed tomography show a case of esophageal atresia and tracheoesophageal fistula with a long inter-pouch gap. A: Coronal view of multiple planar volume reconstruction showing a long gap between the proximal pouch (thin arrow) and distal pouch (thick arrow) as well as the tracheobronchial tree with an aspirating catheter in the proximal esophageal pouch; B: Oblique sagittal view of multiple planar volume reconstruction showing a long inter-pouch distance with a tenuous fistula; C: Posteroanterior projection of transparency lung volume rendering demonstrating the distance between esophageal segments and three-dimensional anatomy of esophageal pouches and tracheobronchial tree after removal of lungs in case 3 (a 3-d old male neonate).

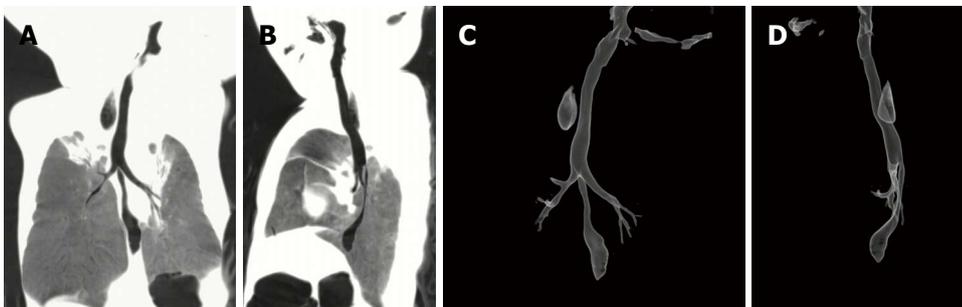

Figure 2 The reconstruction techniques of multidetector-row computed tomography clearly demonstrate not only inter-pouch distance but also the distal fistula. A: Coronal view of multiple planar volume reconstruction showing esophageal pouches and tracheobronchial tree; B: Oblique sagittal view of multiple planar volume reconstruction demonstrating inter-pouch distance and tracheal connection with the distal esophageal pouch; C, D: Transparency lung volume rendering showing anteroposterior (C) and sagittal projection (D) in three-dimensional anatomy of esophageal pouches and fistula in case 8 (a 5-d old male infant).

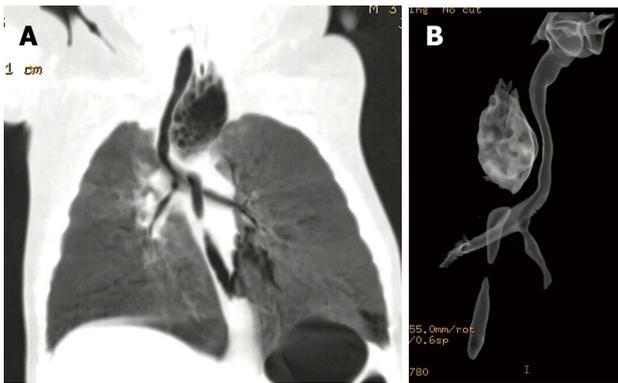

Figure 3 The proximal esophageal pouch full of air was distended and pressed the trachea rightwards. A: Coronal view of multiple planar volume reconstruction showing a short inter-pouch gap, a distended proximal esophageal pouch, and rightward- shifted trachea; B: Oblique posteroanterior view of transparency lung volume rendering demonstrating the three-dimensional anatomy of esophageal pouches and shifted trachea case 6 (a 3-d-old female neonate).

after the fistulae were cut. The inter-pouch gaps measured by MPVR and TL-VR correlated well with the findings at surgery ($R = 0.87, P < 0.001$). Scattered plots of the gaps in 17 patients after MPVR and surgery, and after TL-VR and surgery are shown in Figure 5A and B. Nevertheless,

the inter-pouch gaps measured by MPVR and TL-VR were shorter than those measured at surgery except for cases 3 and 11. Paired *t*-test demonstrated that the preoperative CT data detected by MPVR and TL-VR were significantly different from those observed at surgery ($P < 0.001$) in 17 patients. On the other hand, the inter-pouch distance in 3 cases 9, 13 and 16 was measured after initial dissection of the fistulae to define the esophageal pouches, but not measured before ligation and division of the fistulae. In cases 9 and 13, the inter-pouch distance on CT images was very coincident with that observed at surgery. The findings of CT in case 16 were slightly less than those at surgery.

The inter-pouch gaps in 20 patients measured by MPVR correlated well with those measured by TL-VR ($R = 0.98, P < 0.001$). Statistical analysis demonstrated no significant difference in inter-pouch gaps measured by MPVR and TL-VR. A scattered plot of the gaps was determined by MPVR and TL-VR in the patients (Figure 5C).

The 13 fistulae detected by MPVR were thinner than those observed at surgery. The 13 fistulae on CT images did not correlate with those observed at surgery.

DISCUSSION

EA with or without TEF is one of the most challenging

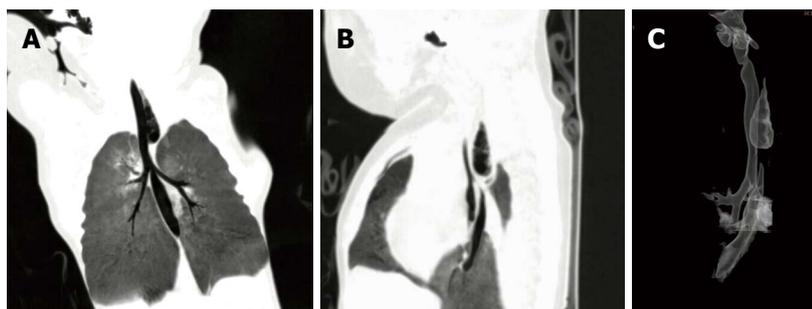

Figure 4 Multiple planar volume reconstruction revealed the inter-pouch distance and the thin fistula which was not visualized by transparency lung volume rendering. A: Coronal view of multiple planar volume reconstruction showing esophageal segments and tracheobronchial tree; B: Oblique sagittal view of multiple planar volume reconstruction showing inter-pouch distance and tracheal connection with the distal esophageal pouch; C: Oblique sagittal view of transparency lung volume rendering demonstrating the three-dimensional anatomy of esophageal pouches but no fistula in case 20 (a 4-d old male infant).

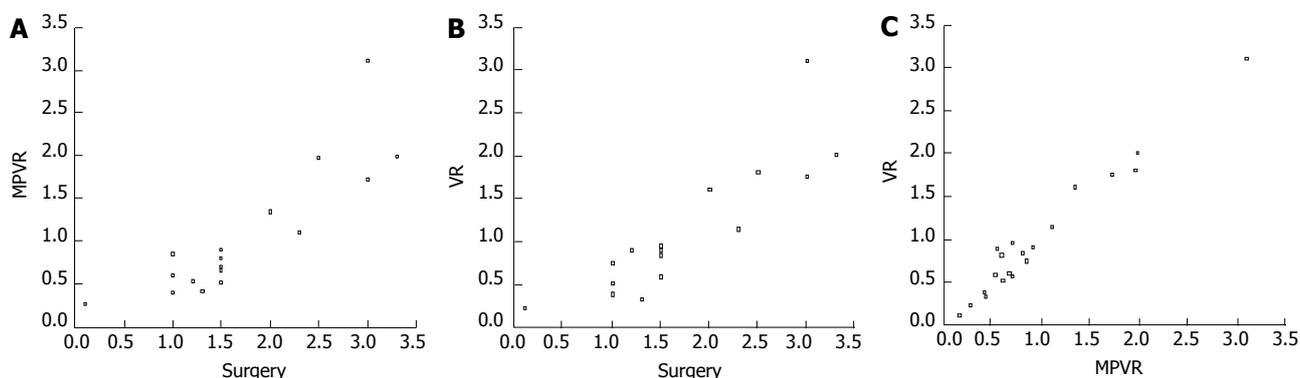

Figure 5 Scattered plots about the findings of the reconstruction techniques of multidetector-row computed tomography and surgery. Scattered plot showing gaps determined by multiple planar volume reconstruction (MPVR) (y-axis) and observed at surgery (x-axis) (A), by transparency lung volume rendering (TL-VR) (y-axis) and observed at surgery (x-axis) (B) in 17 patients, and by MPVR and TL-VR (C) in 20 patients.

The age stated is the age when computed tomography was performed. ¹The inter-pouch distance was measured before division of the fistula. EI: Esophageal inter-pouch; TF: Tracheoesophageal fistula; IN: Invisible (fistulae not shown); MPVR: Multiple planar volume reconstruction; TL-VR: Transparency lung volume rendering.

congenital anomalies in pediatric surgery because of its high morbidity and mortality^[1,4]. The distance between

esophageal segments and anatomy of the esophageal pouch as well as the tracheobronchial tree is highly valuable before operation. Frontal and lateral chest radiography can make unambiguous diagnosis of EA by inserting a catheter into the upper blind-ended esophageal pouch, and may give an estimate of the proximal pouch length. Nevertheless, they cannot show distal esophagus and fistulae in most patients. Although combined endoscopy and radiography can show distal esophagus and esophagus pouches^[6], it is highly invasive with a low resolution^[1]. Although the small size of airway in neonates naturally renders images poor in resolution, and cardiac and respiratory motion artifacts are relatively bigger in neonates than in adults, application of CT in reconstruction of EA with or without TEF has achieved encouraging results^[1,2,5,7].

Our study concentrated on the application of MPVR and TL-VR with 64-row MDCT in neonates with congenital EA and distal TEF. TL-VR is a novel technique using insufflated air as a negative contrast medium and can produce high quality, more intuitive and reproducible 3D VR images^[5]. MPVR technique is simple and efficient and has been widely used in demonstration of the anatomy of multi-organs. In this study, MPVR and TL-VR with MDCT clearly demonstrated the gaps between the proximal and distal esophageal pouches, tracheobronchial tree, as well as shape, size and position of the pouches. Furthermore, the fistulae and their orifice were observed on the images of some cases.

The inter-pouch gaps measured by MPVR and TL-VR were shorter than those observed at surgery in most cases (Table 1), which is not consistent with the reported findings^[1,2,7]. Ratan *et al*^[3] found that the shortest inter-pouch distance is increased to 5 mm after the fistula is divided. In our study, the inter-pouch distance was measured only once at surgery after and, before the fistula was cut. The CT data and findings at surgery were normally distributed in the 17 cases. The mean difference in MPVR and findings at surgery, and in TL-VR and findings at surgery was 0.67 ± 0.43 cm and 0.64 ± 0.42 cm, respectively, which is closely coincided with the reported findings^[3]. Moreover, the lengths of gaps measured by MPVR and TL-VR correlated well with the findings at surgery ($R = 0.87$, $P < 0.001$) in 17 cases (Figure 5A and B). In addition, the inter-pouch distance in 3 cases was measured at surgery before the fistula was cut. The CT data about cases 6 and 13 were almost identical with the findings at surgery, only the CT manifestations of case 16 were slightly less than the findings at surgery.

Besides division of the fistula, there were some possible causes for the less CT data than the findings at surgery. First, about 5 mL air was injected into the proximal esophageal pouch through the catheter in order to demonstrate the pouch, which may extend the proximal pouch and shorten the inter-pouch distance. For example, the proximal pouch was distended due to filling of air and pressed the trachea rightwards in case 6 (Figure 3). It was reported that CT data correspond well with the findings at surgery although no gas is injected into the proximal esophageal pouch^[1,3,7], indicating that less or

no air should be injected into the proximal pouch. As an apparent exception, distention of the proximal esophageal pouch was not seen in case 3 (Figure 1) because it was short, thin and immovable as confirmed at surgery. Second, selection of opacity threshold level for TL-VR techniques can affect the measurement of diameters and lengths of lumens, and visualization of thin tracts, so does selection of window width and location of MPVR. We selected the parameters and settings according to our experience. However, the selection was not doubtlessly optimal. Considering this drawback, we correlated the inter-pouch distance, diameters and lengths of proximal and distal esophageal pouches might measured by TL-VR and MPVR with those observed on MPR images at multidirectional view to avoid erroneous results.

On the other hand, the inter-pouch gaps measured by MPVR correlated well with those measured by TL-VR ($R = 0.98$, $P < 0.001$) in the 20 cases. Statistical analysis demonstrated no significant difference in them, indicating that the two different reconstruction techniques with MDCT do not differ in evaluation of the inter-pouch distance in neonates with EA and distal TEF.

Certainly, demonstration of the fistulae is also very significant. MPVR showed the distal fistulae and their orifice in 13 cases, whereas TL-VR revealed the fistulae and their orifice in only 4 cases. The 13 fistulae shown by MPVR were thinner than those observed at surgery. The findings in 13 fistulae on CT images did not correlate with those at surgery. MDCT demonstrated the invisible and thinner fistulae because of no interior gas, as well as peristalsis and shrinkage of esophagi, mucous plugs or secretions of respiratory tracts in the fistulae, and narrower lumen of fistulae than their diameters and walls seen at surgery. In addition, selection of threshold level for TL-VR and display of MPVR in lung window may interfere with visualization of the fistula orifice. Fitoz *et al*^[11] reported that shaded surface display (SSD) and virtual bronchoscopy reconstruction techniques can satisfactorily show the distal fistulae, which is consistent with the report of Lam *et al*^[2]. We used TL-VR instead of SSD, and virtual bronchoscopy was not performed in our study because it is inconvenient to measure inter-pouch gaps.

The results of this study demonstrate that 3D TL-VR and MPVR with MDCT can provide valuable preoperative information about neonates with EA and distal TEF. Nevertheless, due to expenses and concept of parents, gastrostomy and multiply-staged esophageal elongation are rarely performed in our institution. Therefore, the information acquired before operation in our study mainly helped the Department of Surgery to decide whether anastomosis should be performed by an experienced surgeon or an ordinary surgeon with/without supervision, anticipate the need for ventilatory assistance after operation, decrease the anesthesia and surgery time and its attendant morbidity, and predict outcome of a case. Because we focused on visualization of distal esophageal pouches and fistulae, possible consistency of measurements between MDCT reconstruction techniques and surgery, further operative procedures and follow-up were not discussed.

TL-VR and MPVR techniques are useful for neonates with EA and distal TEF. However, in those types of esophageal atresia without distal TEF in which the distal lumen is lack of air, it seemed difficult to visualize distal pouch with MPVR and TL-VR. The distal pouch might be observed to some extent on the original axial scan images or the MPR images.

The primary pitfalls of this study are lack of measurements of inter-pouch gaps at surgery before and after ligation and division of the fistulae, the number of neonatal cases was insufficient, and selection of technical parameters and preparations before scan might not be optimal.

With increased detector rows of MDCT and development in scan and reconstruction techniques, MDCT has been increasingly applied in demonstration of the anatomy of hollow viscera. However, its application in neonates is not common. Although the number of patients was limited, our findings suggest that MDCT plays a complementary role in diagnosis of congenital EA and distal TEF. MPVR and 3D TL-VR reconstruction of MDCT are useful and noninvasive for demonstrating the distal esophageal pouches, can evaluate the distance between two esophageal pouches in rough and show distal fistulae. 3D TL-VR images can show the complex anatomic features of EA, thus enabling a better orientation before operation.

COMMENTS

Background

Esophageal atresia (EA) with distal tracheoesophageal fistula (TEF) is the most important and common congenital malformation of the esophagus. The anatomy of esophageal blind pouches and inter-pouch gaps not only influence the surgical approach and postoperative strategy, but also predict prognosis of EA patients. Conventional radiography cannot show distal pouches and inter-pouch gaps, for which reconstruction techniques of multidetector-row computed tomography (MDCT) are highly valuable.

Research frontiers

The reconstruction techniques of MDCT can visualize esophageal pouch, inter-pouch gap and tracheoesophageal fistula in neonates with EA and distal TEF. Whether inter-pouch gaps determined with CT correlate well with operating measurements remains unclear.

Innovations and breakthroughs

Air was used as a negative contrast medium for visualizing esophageal pouches and fistulae by multiple planar volume reconstruction (MPVR) and 3D TL-VR reconstruction techniques of MDCT. To our knowledge, the number of cases in this study is the largest.

Applications

The reliability and accuracy of reconstruction techniques of MDCT for evaluation of EA and distal TEF still need to be confirmed by further researches. However, they are really useful and play a complementary role in diagnosis of EA and distal TEF.

Terminology

EA and distal TEF: The most common congenital malformation of esophagus, in which esophagus only has the proximal and distal blind-ended pouch and distal pouch communicates with trachea through a fistula; VR: Volume rendering, a 3D reconstruction technique of MDCT; TL-VR: Transparency lung VR model, a type of VR, which utilizes air as a negative contrast medium for visualizing hollow viscera; MPVR: Multiple planar volume reconstruction, a reconstruction technique of MDCT; MinIP: Minimum intensity projection, a reconstruction pattern of MDCT.

Peer review

The authors of this paper assessed the application of multiple planar volume reconstruction (MPVR) and three-dimensional (3D) transparency lung volume rendering (TL-VR) with 64-row multidetector-row MDCT in congenital EA and distal TEF in neonates, showing that MDCT plays a complementary role in diagnosis of congenital EA and distal TEF. MPVR and 3D TL-VR reconstruction of MDCT are useful and noninvasive for demonstrating the distal esophageal pouches, can evaluate the distance between two esophageal pouches in rough and show distal fistulae, thus enabling a better orientation before operation.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclu-

sion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit on-

line. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review.

Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use

Instructions to authors

uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of P values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date,

volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

Instructions to authors

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the

revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Since the first description of the concept of natural orifice transluminal endoscopic surgery (NOTES), a substantial number of clinical NOTES reports have appeared in the literature. This editorial reviews the available human data addressing research questions originally proposed by the white paper, including determining the optimal method of access for NOTES, developing safe methods of luminal closure, suturing and anastomotic devices, advanced multitasking platforms, addressing the risk of infection, managing complications, addressing challenges with visualization, and training for NOTES procedures. An analysis of the literature reveals that so far transvaginal access and closure appear to be the most feasible techniques for NOTES, with a limited, but growing transgastric, transrectal, and transesophageal NOTES experience in humans. The theoretically increased risk of infection as a result of NOTES procedures has not been substantiated in transvaginal and transgastric procedures so far. Development of suturing and anastomotic devices and advanced platforms for NOTES has progressed slowly, with limited clinical data on their use so far. Data on

the optimal management and incidence of intraoperative complications remain sparse, although possible factors contributing to complications are discussed. Finally, this editorial discusses the likely direction of future NOTES development and its possible role in clinical practice.

INTRODUCTION

The concept of natural orifice transluminal endoscopic surgery (NOTES[®]) has generated intense interest in the surgical and gastroenterology communities. Accessing the peritoneal or thoracic spaces through internal, transvisceral incisions instead of transabdominal incisions has the potential benefits of decreasing postoperative pain, wound complications, improving cosmesis, decreasing the physiologic and immune response to surgery, decreasing

anesthesia requirements, accelerating patient recovery and return to normal function, and improving access to organs that are currently difficult to reach with conventional open or laparoscopic approaches (e.g. esophagus, rectum). Given the intense interest in NOTES and its potential to revolutionize current surgical therapy, several working groups throughout the world have been formed to help guide NOTES research and clinical development. These groups include EURO-NOTES, EATS (European Association for Transluminal Surgery™), D-NOTES, ASIA-NOTES, NOSLA (Natural Orifice Surgery Latin America), Japan-NOTES, India NOTES, NOTES Research Group Brazil, and NOSCAR, which published a white paper in 2006 outlining the perceived barriers to the clinical adoption of NOTES^[1]. These barriers included determining the optimal orifice to access the peritoneal cavity, developing a reliable means to close a viscotomy, minimizing the risk of infection as a result of access through a non-sterile orifice, developing an endoscopic suturing device, addressing difficulties with spatial orientation inherent to a NOTES technique, developing multi-tasking platforms to perform NOTES procedures, managing intraoperative complications, and developing NOTES training to allow safe, widespread adoption of the techniques. Although there have been numerous studies addressing some of these questions in animal and cadaver models, reports of clinical NOTES procedures in humans, and human data addressing these questions have only started to appear since 2007. This editorial will discuss the progress made on these questions by reviewing the currently available human outcomes data and clinical NOTES publications in the literature.

ACCESS TO THE PERITONEAL CAVITY

A comprehensive review of the human NOTES literature was conducted using PubMed to search the MEDLINE database with the search terms of “human natural orifice surgery, human transvaginal, human transrectal, human transgastric, or human NOTES surgery,” for articles published between January 1, 2004 and September 1, 2010. Manuscripts describing clinical human NOTES procedures include the use of transgastric, transvaginal, transrectal, and transesophageal approaches. Currently, the most frequently used orifice for NOTES is the vagina, with cholecystectomy accounting for the highest number of cases in the published literature^[2]. Transvaginal access has the longest history of use for intraperitoneal procedures, prior to the recent description of NOTES. In 1949, Bueno described a series of transvaginal appendectomies performed with open instruments (without an endoscope) at the time of hysterectomy^[3]. Since then, transvaginal access for intraperitoneal procedures in the form of culdoscopy has developed as an accepted, safe procedure in the gynecology community^[4-7]. Transvaginal access can be established using a posterior colpotomy created under direct vision with open instruments, or with the use of

direct trocar insertion under laparoscopic guidance. Establishment of transvaginal access does not require the use of a flexible endoscope or transanal endoscopic microsurgery (TEM) platform, unlike transgastric, transrectal, and transesophageal approaches that have been described to date. Likewise, closure of transvaginal access sites is performed with direct suturing using open instruments.

While transvaginal access is the most frequently used NOTES approach to date and can be safely performed, the potential for complications should not be overlooked. The close proximity of the rectum posteriorly, the ureters laterally, and the tendency for the small intestine to occupy the pelvis should be kept in mind while performing transvaginal NOTES. Reported complications of NOTES transvaginal access include rectal and colonic injuries, small bowel injuries, ureterovaginal fistula formation, vulvar lacerations, and bladder injuries^[8-14]. Given the possibility of these complications, assistance from a gynecologist experienced in transvaginal access should be considered, at least initially, in the performance of transvaginal NOTES. In addition, simultaneous visualization of colpotomy creation with a transumbilical laparoscope, along with the use of a uterine manipulator to anteriorly retract the uterus may minimize the likelihood of rectal, bladder, or bowel injuries during the creation of transvaginal access. Most cases reported so far have utilized a “hybrid” NOTES approach, with at least one laparoscopic port used for initial visualization, retraction, and assistance with the dissection. Until instruments for NOTES improve, a “hybrid” NOTES approach may be preferable to a “pure” NOTES approach (without any percutaneous or laparoscopic assistance) in order to increase the safety of the procedures.

Transgastric access is the second-most frequently reported access route after transvaginal access in the literature. Experience with transgastric NOTES includes at least 70 transgastric peritoneoscopy procedures reported by Nau *et al.*^[15,16] and Nikfarjam *et al.*^[17], as well as several series which have reported at least 42 cholecystectomies, 15 appendectomies, PEG rescue, and 6 cases of transgastric, stapled cystogastrostomy^[11,15,16,18-24]. Transgastric access in all of these cases was obtained in the anterior stomach (antrum or body) using needle knife cautery and balloon dilation through a flexible endoscope, except in cases of PEG-rescue and cystogastrostomy. Most cases were performed with placement of a laparoscopic port prior to gastrotomy creation to allow laparoscopic guidance and insufflation, while some were performed without any previous laparoscopic ports or insufflation. It is interesting to note that although no bowel injuries were recorded in transgastric peritoneoscopy cases performed without prior laparoscopic port placement, the authors noted there were instances of cautery burns to the anterior peritoneum or the under surface of the liver that were discovered after subsequent abdominal inspection with a laparoscope^[15]. As such, it is not surprising that the majority of transgastric cases have been performed in a hybrid fashion, with laparoscopic visualization of

the access point in order to prevent injuries to surrounding organs or the gastropiploic vessels, which may be difficult or impossible to see from inside the stomach^[2].

Transesophageal access has been used to perform esophageal myotomies in a series of 17 patients with achalasia, reported by Inoue *et al.*^[25]. This procedure, termed Per-Oral Esophageal Myotomy (POEM), incises the inner circular muscle layer of the distal esophagus and lower esophageal sphincter, while completely avoiding the hiatal dissection and disruption of the phrenoesophageal ligament that occurs during laparoscopic Heller myotomy. Transesophageal access begins at the anterior, mid-esophagus with the creation of a submucosal bleb using a sclerotherapy needle. The submucosal bleb is then incised using electrocautery and the endoscope is advanced through the incision to create a submucosal tunnel distally past the gastro-esophageal (GE) junction onto the cardia of the stomach. The inner circular muscle distal to the mucosal incision is then incised. Currently transesophageal access has been used to perform only procedures on the esophageal wall. In one case, full separation of the outer longitudinal esophageal muscle layer occurred, exposing the mediastinum. Per the authors, however, this patient did not have any adverse consequences as a result; this suggests that as long as closure of the proximal mucosal incision is ensured, transesophageal mediastinal or thoracic access through a submucosal tunnel may be clinically feasible in the future. However, no clinical studies have been performed to date investigating the safety of transesophageal mediastinal or thoracic access.

In contrast to other forms of NOTES access, transrectal access has been the least reported in the literature. The only two published cases are of a proctosigmoidectomy for cancer^[26], and a transanal pull-through for Hirschsprung's disease^[27]. The proctosigmoidectomy was performed using a TEM platform, with a circumferential rectal dissection proceeding cephalad from the distal rectum, assisted by laparoscopy. The transanal pull-through was performed in an infant, without the use of the TEM; instead the authors reported using trocars inserted directly through the rectal wall to allow passage of a rigid laparoscope and rigid instruments. Although no complications were reported to have occurred in either case, further data is needed in order to accurately determine the risks of this approach.

Although so far various access points for a variety of NOTES procedures have been attempted, the specific indications that are best suited for each orifice will need to be defined. For example, the ideal indications for transoral access may end up being limited to therapeutic esophageal or gastric procedures, or diagnostic procedures in the intraperitoneal cavity. Transoral access may be poorly suited to advanced therapeutic intraperitoneal procedures given the requirement for complex, flexible instrumentation, as well as the small native diameter of the esophagus which makes extraction of large, bulky specimens potentially hazardous. Similarly, transrectal access may be best suited

to colorectal applications, and transvaginal access may end up being ideally suited for gynecologic indications. However, if these two approaches prove to be the most forgiving in terms of ease of access, ability to reach the upper abdomen, complications, and the ability to introduce both flexible and rigid instruments through the orifice, it is possible that these approaches may become "workhorse" approaches for intraperitoneal NOTES procedures or specimen removal in female and male patients, respectively.

VISCERAL CLOSURE

Transvaginal closure is currently the most feasible closure method for NOTES, as the incision is closed by direct suturing. Aside from potential injuries to surrounding structures as previously mentioned, there have been no reports of vaginal dehiscence or herniation through the vaginal incision. Also, the consequences of a vaginal wound dehiscence would likely not be as potentially dangerous as a gastric leak or a rectal leak, which would introduce highly caustic or infectious luminal contents into the abdomen.

In contrast to transvaginal closure, transgastric closure currently requires the use of flexible endoscopic clips or tissue anchors, with or without laparoscopic sutures to buttress the closure. Although several groups have reported successful performance of transgastric closures without leaks, data on the true safety of current transgastric closure techniques are sparse at best. In 2010, Zorron *et al.*^[14] reported results from a prospective, multi-center NOTES registry, including data from 43 transgastric operations (29 cholecystectomies and 14 appendectomies), in which the stomach was closed using laparoscopic suturing. No gastric leaks were reported in this study. Similarly, reports of transgastric closure by other groups using endoscopic clips or anchors, with or without laparoscopic sutures, accounting for a total of approximately 30 patients, did not include any postoperative gastric leaks^[18-21,23,24]. However, there has been at least one reported complication of gastric closure: a pneumothorax which occurred due to the aberrant placement of a tissue anchor through the diaphragm^[24]. Innovative solutions for transgastric closure that have been reported in humans include the creation of a gastric valve mechanism made with tissue anchors, through which a gastrotomy is created^[21]. The gastrotomy is then closed with additional tissue anchors once the procedure is finished. Although this technique has been successfully used in 5 patients so far, the majority of transgastric cases reported in the literature continue to rely on laparoscopic suturing alone or in combination with endoscopic instruments. Completely endoscopic means for closing gastrotomies will need to be developed and evaluated in human studies for transgastric NOTES to become feasible without laparoscopic assistance. Numerous prototype closure devices and techniques have been developed and tested in pre-clinical models. However, a detailed discussion of these devices and their results in animals are beyond the scope of this editorial.

Transesophageal NOTES closure has so far been reported using endoscopic clips to close the longitudinal mucosal incision at the entrance to the submucosal tunnel during POEM. No esophageal leaks or mediastinitis were reported in a series of 17 patients^[25]. These clips slough off into the GI tract, with healing of the mucosal incision demonstrated on follow-up endoscopy.

Closure of transrectal NOTES access has so far been accomplished by incorporating the rectotomy into a hand-sewn coloanal anastomosis. This technique increases the safety of transrectal NOTES since it uses currently accepted anastomotic techniques, but it is limited to resections of the left colon and rectum. The safety of transrectal closures left in situ (not incorporated into the anastomosis) remains to be determined, although there is evidence from the TEM literature suggesting that intraperitoneal rectal closures can be performed as safely as those without peritoneal entry during full-thickness rectal tumor excision^[28]. Research to test closure techniques for transrectal surgery will ultimately need to be performed on human tissue rather than porcine models for it to be useful. However, initial closure tests should be attempted on tissues that are already targeted for removal, such as in portions of the colon that will be removed following colectomy, to ensure patient safety.

RISK OF INFECTION

Concerns about potentially higher rates of infection have repeatedly been raised in regards to NOTES. The notion of introducing surgical instruments through non-sterile orifices into the normally sterile peritoneal cavity runs counter to years of established surgical dogma. Many groups performing clinical NOTES have adopted the routine use of preoperative intravenous (IV) antibiotics combined with local application of antibiotic or antiseptic solutions such as povidone-iodine at the site of visceral entry as a precaution. Although the data are currently limited, concerns about increased infectious risk with a transvaginal approach compared to conventional laparoscopy have not been substantiated. The best data so far are from a large, prospective NOTES registry including 488 patients that underwent transvaginal cholecystectomy^[13]. Complications reported in this registry included urinary tract infection, abscess in the pouch of Douglas, wound infection, vaginal mycosis, and bacterial vaginitis, with a combined incidence of 1%, which is comparable to the rate of infectious complications seen with conventional laparoscopic cholecystectomy^[29].

Bacterial contamination has been quantified during performance of laparoscopic roux-en-y gastric bypass (LRYGB) as a surrogate for NOTES, and during actual transgastric NOTES peritoneoscopy by investigators at Ohio State University^[30,31]. These authors measured contamination in 50 patients undergoing LRYGB given preoperative IV Cefazolin alone without additional luminal decontamination, and showed that native levels of bacte-

ria in the stomach were higher (mean 22 303 CFU/mL) compared to that of the peritoneum after the operation (1102 CFU/mL), with significant correlation between these levels. These results indicate that some cross-contamination occurs during transgastric peritoneoscopy, but that the degree of contamination is not dependent on the pre-existing level of bacteria in the stomach. In addition, despite the documented levels of contamination, no clinically obvious infections were found with a minimum of 30 d of follow-up for all patients. A follow-up study in patients undergoing transgastric NOTES peritoneoscopy prior to a planned pancreaticoduodenectomy also showed minimal cross-contamination with insignificant levels of intra-operative peritoneal contamination (160 CFU/mL), and no infectious complications in a group of 10 patients with 30 d follow-up. An observation requiring further investigation, though, was that patients on proton-pump inhibitors (PPIs) had significantly higher levels of bacteria in the stomach (median 33 000 CFU/mL) compared to those not on PPIs (median 0 CFU/mL). Differences in post-operative peritoneal contamination between patients with or without PPI use preoperatively approached, but did not reach, statistical significance due to a limited number of patients in the study. Thus, while the risk of clinically significant infection as a result of transgastric NOTES appears to be low, the optimal perioperative management of patients on PPIs undergoing NOTES requires further study.

In contrast to transvaginal and transgastric NOTES access, transesophageal and transrectal access have a theoretically higher risk of infectious complications due to their proximity to the oropharyngeal and colonic flora, respectively. Unfortunately, to date no human studies have directly quantified the levels of bacterial contamination from either of these NOTES approaches, or the true incidence of clinically significant infections. Nevertheless, in the reported series of 17 POEM patients who received preoperative IV antibiotics and irrigation of the submucosal tunnel with dilute antibiotic solution prior to closure, no infectious complications were noted with a mean follow-up period of 5 mo (minimum 1 mo)^[25]. In addition, the two transrectal NOTES procedures reported in the literature to date did not report any infectious complications. The rectosigmoid resection patient underwent preoperative mechanical bowel preparation with oral sodium phospho soda, received preoperative IV Cefoxitin, and had a dilute Betadine irrigation of the rectum^[26]. The 5-d-old patient who underwent a NOTES transanal pull-through received perioperative systemic antibiotics for 24 h following the case with no reported complications. In short, more data are needed to accurately estimate the risk of infectious complications with transrectal and transesophageal NOTES approaches.

The fear of increased infectious risk from NOTES procedures has so far not been substantiated by examining available clinical outcomes and bacteriologic studies. It is likely that IV antibiotics alone for transgastric proce-

dures, along with some form of luminal disinfection for transvaginal, transrectal or transesophageal procedures will be the ultimate strategy adopted clinically.

DEVELOPMENT OF ENDOSCOPIC SUTURING OR ANASTOMOTIC DEVICES

The development of endoscopic suturing and anastomotic devices was deemed by the white paper to be necessary in order for NOTES to ultimately be applied to the wide spectrum of current surgical therapy^[1]. However, the development of these devices and their use in clinical trials has proceeded slowly since 2005. Currently, two types of endoscopic suturing devices have been approved: OverStitch™ (Apollo Endosurgery, Inc., Austin, TX, USA) and the Tissue Apposition System (TAS, Ethicon Endosurgery, Cincinnati, OH, USA). However, only use of the TAS has so far been reported clinically to approximate partial colonic wall defects at the time of laparoscopic-assisted polypectomy^[32]. The TAS system works by sequentially deploying a threaded T-tag through the bowel wall on each side of a defect using an endoscopic hollow bore needle; once two threaded T-tags have been placed on either side of a defect, the two threads are cinched together and trimmed by a one-way locking mechanism in order to approximate both sides of the luminal defect. A similar endoscopic T-tag closure technique using instruments from Cook Medical (Bloomington, IN, USA) was employed by Park *et al.* to close gastrotomy defects during transgastric NOTES^[24]. One of the difficulties with existing endoscopic T-tag systems, however, is the inability to directly visualize deployment of the T-tag from the extraluminal side of the defect without a laparoscope. This impaired visualization may contribute to the risk of inadvertent injury to surrounding organs, or deployment through a vessel. As mentioned previously, inadvertent deployment of a T-tag through the diaphragm during a gastric closure was reported to have resulted in a pneumothorax discovered post-operatively^[24]. The OverStitch™, in contrast to T-tag based systems, employs a lateral needle-passing mechanism more similar to conventional suturing techniques. However, the OverStitch™ still requires assistance from an endoscopic grasper, and may be limited by the visual and mechanical constraints of conventional flexible endoscopes. Human use data will be needed to adequately evaluate the potential of the OverStitch™ for use in luminal closures.

The development of endoscopic anastomotic devices for NOTES has proceeded even more slowly than the development of suturing devices. The only reports of NOTES procedures with anastomoses have utilized hand-sewn coloanal anastomoses during colorectal resections, or a flexible, powered surgical stapler (SurgAssist™ SLC 55, Power Medical Interventions, Langhorne, PA, USA) during cystogastrostomy^[33]. In the cystogastrostomy cases, the stapler was passed down the esophagus through an

overtube, alongside a flexible gastroscope. Although this stapler was used successfully to create a cystogastrostomy, the authors reported significant difficulty in passing the rigid part of the stapler through the esophagus, even through a previously placed overtube. In addition, the authors reported significant difficulty directing the stapler into the appropriate angle once inside the stomach. Unfortunately, since the publication of the study, the stapler has been removed from the market due to the acquisition of Power Medical, Inc. by Covidien (Mansfield, MA) and is not currently available for use. Development of flexible, articulating, low-profile staplers is needed to make creation of anastomoses or luminal closures during NOTES more feasible. Additional features which may make application of stapling technology to NOTES more feasible include the addition of visualization and steering capabilities. These features might allow staplers to be more precisely directed into difficult to reach areas and fired with more confidence.

SPATIAL ORIENTATION

The difficulty with correct spatial orientation during NOTES and its consequences in hindering the performance of advanced procedures was foreseen in the white paper. These difficulties are inherent to the use of current flexible endoscopes to perform NOTES, and have the potential to create not only a difficult operation, but may also increase the risk of complications during NOTES. Perretta *et al.*^[34] reported a case of misinterpretation of biliary anatomy during transgastric NOTES which was fortunately recognized, preventing the occurrence of a common bile duct injury. The authors in this case converted to a laparoscopic view temporarily to clarify the unclear biliary anatomy. As emphasized by the authors, current NOTES techniques may alter the usual surgical anatomy that is seen due to the difficulty in achieving adequate retraction without laparoscopic instruments, and the spatial confusion created by retroflexion when using a flexible endoscope. A solution to the problem of difficult spatial orientation during NOTES may be the use of rigid endoscopes whenever possible. However, the use of rigid endoscopes is potentially feasible only through transvaginal or transrectal approaches, or through the umbilicus in the case of transgastric surgery. Short of using a rigid endoscope routinely, surgeons performing NOTES with flexible endoscopes should have a low threshold to convert to a laparoscopic view, even temporarily, to resolve any confusion in regards to the surgical anatomy. Although image-guided systems have been described as having potential applications for NOTES, none of these systems have been applied in a clinical setting so far^[35]. Future solutions to the problem of spatial orientation may also involve the use of small, wireless cameras that are able to provide a wider, overhead view of the surgical field, and can be moved to the appropriate location as needed. Use of this type of camera has been described for human single-incision laparoscopy (SIL) cases^[36]. However,

Figure 1 The Transanal Endoscopic Operations device from Karl-Storz allows the insertion of rigid or flexible instruments through the anus and is currently used for performing transanal endoscopic microsurgery excisions of rectal tumors. It also has the potential to serve as a stable transrectal natural orifice transluminal endoscopic surgery (NOTES[®]) platform. Image used with permission (©Karl Storz).

Figure 2 The TransPort™ multi-channel access device from USGI has been used as a transgastric natural orifice transluminal endoscopic surgery platform. It has a steering mechanism similar to a flexible endoscope, along with multiple, large-diameter channels to accommodate a small-diameter flexible endoscope and other large caliber flexible endoscopic instruments (g-Prox[®] tissue anchor device is shown). Image used with permission (©USGI Medical).

it should be noted that these cameras are not currently FDA-approved.

DEVELOPMENT OF A MULTITASKING PLATFORM

The creation of a multitasking platform to allow the performance of multiple NOTES procedures with the same platform continues to be an issue of the highest priority in the development of NOTES as a viable technique. Although several types of advanced operations (nephrectomy^[12,37], partial gastrectomy^[38,39], sigmoidectomy^[40,41], and splenectomy^[42]) have been reported using a NOTES technique, many of these procedures have relied heavily on laparoscopic instruments for visualization and dissection. In order for “pure” NOTES (without laparoscopic or percutaneous assistance) to become feasible, a multi-tasking platform that balances flexibility and maneuverability with

Figure 3 The Anubis[®] platform from Karl-Storz is an advanced flexible natural orifice transluminal endoscopic surgery platform (in development), with a tip that opens to expose working instruments capable of multiple degrees of freedom controlled by the surgeon. Image used with permission (©Karl Storz).

the ability to provide powerful retraction and instrument mobility, as well as an intuitive interface for the surgeon will need to be developed. Examples of the novel application of multi-lumen operating platforms for NOTES include use of a TEM platform (Figure 1) to perform proctosigmoidectomy, and the use of the TransPort™ (USGI Medical, San Clemente, CA, USA) multi-channel access port for transgastric NOTES (Figure 2). Use of a TEM platform for transrectal surgery allows the simultaneous use of rigid instruments with a flexible or rigid endoscope to perform intra-abdominal surgery. This combination of operating instruments permits strong retraction, while allowing flexible visualization and dissection capabilities through the flexible endoscope. Current limitations of such a system, however, include the difficulty of reaching beyond the sacral promontory with rigid instruments, and the limitations of dissection performed with current flexible endoscopes. The TransPort™ device is a flexible, multi-channel device which allows passage of a flexible endoscope through one channel as well as additional flexible instruments through the other channels. This device is flexible enough to be passed transgastrically and has the ability to retroflex and assume a rigid configuration independent of the endoscope. While it has been used for transgastric cholecystectomy and appendectomy^[19,21,23], use of the flexible instruments through its channels is similar to the use of accessories through a conventional flexible endoscope in that the instruments have limited degrees of freedom and lack the ability to make lateral or vertical movements independent of the endoscope in an intuitive fashion. The limitations of both of these platforms make them less than ideal multi-tasking platforms for NOTES. However, the development of a system combining aspects of both platforms, along with robotic control may greatly facilitate the performance of NOTES procedures and may be the crucial enabling technology that would allow NOTES development to proceed exponentially, similar to the way the development of the charge-coupled device (CCD) camera revolutionized laparoscopy. Examples of experimental platforms with some of these

Figure 4 EndoSamurai is a prototype, advanced platform in development by Olympus. To operate the system, a surgeon uses an intuitive, bi-manual interface to control instruments with multiple degrees of freedom (inset shows close-up of endoscope tip with working instruments). Image used with permission (©Olympus Medical Systems Corp.).

capabilities that may be seen in future clinical reports include Anubis (Karl-Storz, Tuttlingen, Germany, Figure 3), EndoSamurai (Olympus, Tokyo, Japan, Figure 4), and the Direct-Drive Endoscopic System (Boston Scientific, Natick, MA, USA, Figure 5). Economic concerns continue to be an issue with regard to the development of these platforms, however. The emergence of single-incision laparoscopy (SIL) has caused a tremendous amount of resources to be redirected away from NOTES, towards the development of SIL technology. Although some of this technology may end up being adapted for NOTES, the development of SIL will likely delay the development of NOTES-specific technology such as advanced multitasking platforms. Both industry and innovators in minimally-invasive surgery need to not lose sight of the potential promise of NOTES, while SIL occupies the spotlight.

TRAINING

There are currently not enough data from human studies to make quantitative recommendations in regards to the ideal amount of previous endoscopic or laparoscopic clinical or laboratory NOTES training prior to the performance of clinical NOTES procedures. Nevertheless, a conservative approach described in the white paper recommends that NOTES procedures be performed by multi-disciplinary teams after a period of laboratory training in a properly equipped facility in order to maximize patient safety and ensure continuing regulatory acceptance of early NOTES development.

Future NOTES practitioners will likely need some form of fundamental surgical training, along with platform-specific and procedure-specific training once the field has undergone significant development. The current paradigm of performing NOTES primarily with flexible endoscopes is reaching the limits of practicality and safety, and will arguably become quickly obsolete with the availability of advanced multitasking platforms. Thus, rec-

Figure 5 Direct-Drive Endoscopic System from Boston Scientific is a prototype, advanced multi-channel platform currently in development, featuring instruments with multiple degrees of freedom controlled through a bi-manual user interface. Inset figure shows close-up of device tip with a small diameter flexible endoscope in place. Image used with permission (©Boston Scientific).

ommendations made in regards to training surgeons for NOTES using currently available instruments and techniques may quickly become obsolete.

COMPLICATIONS OF NOTES

Complications are an inevitable part of surgical practice, especially during the application of new techniques such as NOTES. Intraoperative complications inherent to all procedures, such as bleeding, will need to be managed appropriately to ensure patient safety. Along with the development of better endoscopic instruments to manage hemorrhage, surgical decision-making will need to evolve based on laboratory and clinical data. Although the method of hemorrhage control will always depend on the situation and surgeon judgment, it will be useful to determine what is realistically manageable using a pure versus hybrid NOTES technique, and when it would be most beneficial to convert to a full laparoscopic procedure. Unfortunately, data from human studies to answer this question are currently limited. The reported incidence of bleeding in a prospective NOTES registry of 488 transvaginal cholecystectomy patients was 0% for intraoperative bleeding, and 0.6% for postoperative bleeding, comparable with the incidence of bleeding during laparoscopic cholecystectomy¹³. However, it should be kept in mind that the dominant technique in these cases did not include the use of any flexible endoscopes or accessories, and relied heavily on dissection through a transumbilical laparoscopic port. These results may thus only apply to NOTES performed exclusively with rigid instruments, as opposed to NOTES performed using a combination of flexible and rigid instruments. A more accurate picture of NOTES outcomes from operations performed primarily with flexible endoscopes (with or without laparoscopic assistance) may be derived from the registry by Zorron *et al.*¹⁴, which reported the incidence of intraoperative bleeding to be approximately 2% for transvaginal cholecystectomy (all from

the cystic artery), 8% for transvaginal appendectomy (all from the appendiceal artery), and a combined incidence of 4.7% for all transgastric procedures (7% for the appendiceal artery and 3.4% from the gastroepiploic artery)^[14]. Although these rates of bleeding may seem high, it should be kept in mind that all of these bleeding complications occurred intraoperatively and were managed laparoscopically or endoscopically with the exception of 1 instance of gastroepiploic bleeding during transgastric access which required conversion to an open procedure. In addition, no cases of delayed postoperative bleeding were reported. Future research on the optimal method to control hemorrhage during NOTES will likely need to be performed in animal models (for ethical reasons), and should involve both the development of new instruments and algorithms to help guide intraoperative decision-making.

In addition to bleeding, the authors of the white paper foresaw the possibility that physiologic complications and compression syndromes might be more frequently seen during NOTES procedures, compared to existing laparoscopic procedures. So far the incidence of these complications in the literature has been low (0.8% of 362 NOTES procedures), however, as reported by Zorron *et al*^[14] in a large, multi-institutional registry. These complications consisted of two episodes of intraoperative abdominal hypertension which resolved with desufflation of gas and fluid therapy, as well as one episode of facial and cervical subcutaneous emphysema following transvaginal, retroperitoneal cyst excision from the kidney^[14,43]. This complication was reported to have been managed with oxygen therapy and observation in the intensive care unit, without requiring re-intubation. Although it was reported that most groups in the registry used laparoscopic insufflators through a transabdominal port or Veress needle, the case with subcutaneous emphysema used a laparoscopic carbon dioxide (CO₂) insufflator connected to one of the flexible endoscopic channels with pressure maintained between 12 to 16 mmHg. Although the overall incidence of physiologic and compression syndrome complications was low in this registry report, surgeons performing NOTES should be aware that these complications may still occur and the risk of their occurrence may depend on the insufflation gas or insufflators used, and the anatomic compartment where dissection is performed.

Although the use of pressure-controlled CO₂ insufflation is likely to continue being a key component of NOTES procedures, lower insufflation pressures compared to conventional laparoscopy may be feasible, further reducing the risk of compression syndromes and subcutaneous emphysema.

More serious complications during NOTES cases have been reported that would otherwise be rare in the corresponding laparoscopic operations. These are worth noting to caution those who might be tempted to prematurely or over-enthusiastically adopt this still nascent approach to intra-abdominal surgery, and also to prioritize areas for potential improvement through better patient selection or

technical modifications to NOTES procedures. Reported complications of this kind during transvaginal cholecystectomy include 4 bladder injuries (0.8%), 2 rectal injuries (0.4%), and 1 small bowel injury (0.2%). All bladder injuries were reported to have occurred in older, obese women. However, it was not clear from the report whether these injuries occurred during the establishment of transvaginal access using a transvaginal trocar inserted under laparoscopic guidance or whether they occurred during the latter parts of the procedures. The occurrence of these complications emphasizes the extreme care that should be taken when establishing transvaginal access, closing the defect, and with the use of rigid transvaginal laparoscopic instruments. Similarly, the registry report by Zorron *et al* noted 2 esophageal hematomas, 1 esophageal laceration, and 1 esophageal perforation during 29 transgastric cholecystectomies, accounting for a combined rate of 13.7% esophageal complications. This is an unacceptably high rate of complications compared to conventional laparoscopic cholecystectomy, which is normally performed with minimal morbidity and mortality. Investigators from the International Multicenter Trial on Clinical Natural Orifice Surgery (IMTN) investigators addressed this high rate of esophageal complications and recommended the use of esophageal overtubes to protect the esophagus during the procedures, especially during specimen extraction. In agreement with this recommendation, a study conducted by our group found that preoperative ultrasound measurements of gallbladder stones can be used to help predict which gallbladders are able to be extracted through an esophageal overtube^[44]. Gallbladders found to be full of multiple small stones, in which the size of the largest stone cannot be determined, as well as those in which the largest gallstone is greater than or equal to 10 mm, are unlikely to pass through an overtube. Patients with these ultrasound findings may be better managed with conventional laparoscopic cholecystectomy. Criteria such as these may help improve patient selection for transgastric cholecystectomy, for example.

Ultimately, once more human data on the risks and benefits of NOTES procedures become available surgeons will have to decide whether the benefits of NOTES are worth the risks. It should be kept in mind that just because a procedure has an inherently higher rate of a specific complication doesn't mean it is not worthwhile. Laparoscopic cholecystectomy, for example, has been shown have increased rates of common bile duct injury compared to open cholecystectomy^[45,46]. However, this risk is acceptable given that the other benefits of laparoscopic cholecystectomy (decreased postoperative pain, decreased wound complications, improved cosmesis, and a faster rate of recovery for patients) outweigh its potential for harm. The same type of analysis weighing the risks and benefits of NOTES will need to be applied to determine its ultimate role in surgical practice.

NOTES MOVING FORWARD

In the five years since the publication of the NOTES

white paper, there has been a substantial proliferation of clinical NOTES publications. Progress has been made addressing the questions originally foreseen as the likely barriers to the introduction of NOTES into clinical practice. However, NOTES development in the next 10-15 years is likely to change surgical practice through a series of small incremental gains, rather than through an overnight revolution as in the case of laparoscopic surgery. This evolution may involve first a change in the practice of specimen extraction, with the use of natural orifices instead of the abdominal wall. Finally, once advanced platforms reach the clinical arena surgeons may shift to using the natural orifice not only for specimen extraction, but also for dissection. The evolution may also occur more quickly for some indications than others. For example, esophageal and colorectal NOTES applications may evolve more quickly compared to hernia, solid-organ, biliary, and general intra-abdominal applications given the already excellent outcomes and ease of laparoscopic techniques in performing these later procedures. NOTES may be able to more easily establish a niche in the thoracic esophagus, distal colon and rectum, or other anatomic locations where laparoscopic approaches are currently challenging or where there is still significant morbidity with traditional approaches. For example, limited resections performed through a natural orifice may replace the current practice of removing a large segment of colon or rectum for endoscopically unresectable polyps, assuming that oncologic outcomes can be maintained or equaled using alternative methods to assess or treat the possibility of disease in regional lymph nodes.

Given this likely evolutionary pattern for NOTES, the original goals of NOTES should be re-thought and re-prioritized. Transgastric NOTES in the near-term is unlikely to be useful to perform advanced therapeutic procedures or operations requiring removal of bulky specimens, even with the appearance of suturing devices for conventional flexible endoscopes. Rather transgastric NOTES may be better suited for diagnostic peritoneoscopy, using lower profile endoscopes that are able to traverse the gastric wall without the need for complicated closures of large, potentially dangerous gastrostomies. In addition to a decreased primary emphasis on transgastric NOTES as the access route of choice, the NOTES community should re-think its primary emphasis on flexible endoscopy as the preferred platform for NOTES, and instead be open to the use of rigid, pre-bent, or articulating instrumentation either in concert or instead of flexible instruments, until more advanced platforms become available.

CONCLUSION

In summary, since the first description of the concept of NOTES, many clinical NOTES cases have been reported in the literature, adding to the body of human data with which to begin to answering questions raised by the white paper. So far, transvaginal access has been the most feasible access route for NOTES procedures, although there

is growing experience with transgastric, transesophageal, and transrectal approaches. Luminal closure appears to be most feasible with a transvaginal approach, with smaller but nevertheless good outcomes also reported for transgastric and transesophageal closures. Data on the feasibility of true, intraperitoneal transrectal closures remain limited by the fact that the only closures performed to date have been hand-sewn coloanal anastomoses. Infection appears to be a non-issue with regard to transvaginal and transgastric surgery with the use of preoperative IV antibiotics (and local disinfection in the case of transvaginal procedures), with additional data required to more accurately estimate the risk with transesophageal and transrectal procedures. Development of suturing and anastomotic devices for NOTES has progressed slowly, with limited clinical data on their use so far. Likewise, the development of true multitasking platforms for NOTES has been slow and has not yet reached the clinical arena. The optimal management of intraoperative complications has still not been determined, but the data suggest that intraoperative hemorrhage may not automatically require conversion to laparoscopy. The incidence of compression syndromes appears low, as long as procedures are performed primarily with controlled, laparoscopic insufflation using CO₂. Additional major complications specific to NOTES procedures that would normally not occur during the corresponding laparoscopic operations have been noted in the literature. These types of complications absolutely need to be reported in order to constructively analyze the current status of NOTES and optimize patient selection and techniques to minimize their occurrence. As far as recommendations for NOTES training, there are no data to provide more specific recommendations outside of previous recommendations in the white paper and those from large NOTES registries. Finally, it may be useful to re-prioritize the development of NOTES to focus on high-yield colorectal and esophageal applications that are more likely to succeed in the near-term, instead of seeking the holy-grail of being able to perform entire, complicated procedures through transgastric access alone.

Abstract

Gut-associated lymphoid tissue is supposed to play a central role in both the organization of colonic repair mechanisms and colorectal carcinogenesis. In inflammatory conditions, the number, diameter and density of isolated lymphoid follicles (ILFs) increases. They are not only involved in immune surveillance, but their presence is also indispensable in normal mucosal regeneration of the colon. In carcinogenesis, ILFs may play a dual role. On the one hand they may support tumor growth and the metastatic process by vascular endothelial growth factor receptor signaling and producing a specific cytokine and cellular milieu, but on the other hand their presence is sometimes associated with a better prognosis. The relation of ILFs to bone marrow derived stem cells, follicular dendritic cells, subepithelial myofibroblasts or crypt formation, which are all involved in mucosal repair and carcinogenesis, has not been directly studied. Data about the putative organizer role of ILFs is scattered in scientific literature.

INTRODUCTION

The imbalance of colonic epithelial proliferation and apoptosis may lead to both ulcer- and carcinoma development of the mucosa. The final direction of this imbalance depends on complex pathogenetic pathways in which isolated lymphoid follicles (ILFs) seem to have a specific role.

Some steps of colonic epithelial regeneration are known, but the connection among them is not fully understood. The continuous reformation of the epithelial layer is important in avoiding the aggregation of pernicious mutations induced by intraluminal factors. In inflammation, the lack of regenerative factors and the disturbance of the regulation of regenerative mechanisms favour ulcer development. It has also been observed that in colonic inflammation there is a tight connection between the degree of epithelial damage and the number, diameter and cellular compounds of subepithelial lymphoid follicles^[1,2]. The more severe the epithelial destruction that develops, the higher the number of ILFs that can be found in adjacent mucosa.

It has recently been reported that lymphoid follicles are also present in carcinomas of the lung^[3], endometrium^[4], liver^[5], and colon^[1]. They are supposed to have immune-mediated anti-tumoral effects, as their elevated number is in positive correlation with a better prognosis and a longer survival^[6]. However, the density of lymphoid

follicle-associated flat dysplastic aberrant crypt foci was significantly higher compared to the rest of the mucosa in azoxymethane-treated rats^[6]. Several reports have investigated the association between lymphoid aggregates and colonic tumors in rodents^[7,8]. The results indicate that colonic crypts overlying ILFs show a significantly higher proliferative activity, which may also influence genetically defected epithelial cells. Hence, the risk of carcinoma is increased in the colonic mucosa of ILFs compared to mucosa without ILFs. It has also been shown that the incidence of ILFs in early human colorectal cancers significantly differs by gender, location, macroscopic type and histology, but moreover, their localization significantly differs by their macroscopic type^[9].

However, the exact role of ILFs in colonic epithelial repair and colorectal carcinogenesis is not yet known. Some data show^[10] that the lack of lymphoid follicles results in abnormal crypt formation in the case of epithelial destruction. On the other hand, Apc gene mutation causes impairment of developmental and apparent differentiation blockade in proliferative tissues, including those of the lymphoid follicles^[11]. Whether ILFs act as a regenerative pool containing putative stem cells in case of mucosal damage, or they are responsible only for the optimal cytokine milieu for the differentiation of immigrating stem cells or invasive carcinoma cells^[12] need to be further examined.

THE ORGANIZATION OF THE GUT-ASSOCIATED LYMPHOID TISSUE

The gut-associated lymphoid tissue (GALT) is a component of the mucosa-associated lymphoid tissue, in which approximately 70 percent of the body's immune cells are found^[13,14]. GALT differentiates between pathogens and commensal bacteria.

The majority of GALT is composed of isolated and aggregated lymphoid follicles dispersed throughout the small and large intestines^[15]. These lymphoid follicles, including Peyer's patches (PPs) of the small intestine and ILFs of the large intestine, are composed of a specialised follicle associated epithelium (FAE), which overlies a sub-epithelial dome containing numerous macrophages, dendritic cells, T, B lymphocytes, and special antigen sampling microfold/M/cells^[15-17]. The FAE has a crucial role in the initiation of the mucosal and systemic immune response^[18]. ILFs have, in general, an average diameter of 0.1-0.7 mm and number of around 30000 in humans^[19].

ILFs are innervated sites of GALT. Functionally, antigen-triggered mast cell and eosinophil activation affects both the secretory and motor functions of the intestines^[20], and these defensive reactions can be modulated by the enteric nervous system^[21]. It has been recently recognised that there is a dense neuronal network at the level of the supra-follicular dome region, but not within the germinal centers in lymphoid follicles^[22]. Neuronal alterations of PPs and ILFs, such as nerve-eosinophil associations or increasing neuronal cell adhesion molecule expression, may have consequences on the uptake of particular pathogens^[16,23].

VASCULARIZATION OF ILFS

ILFs have rich blood and lymphatic vascularization^[14,19]. Vasculogenesis may play a dual role in mucosal organization, in that it is not only necessary for nutritional and metabolic processes, but the homing of the repopulating bone marrow derived stem cells to the site of tissue damage may happen *via* blood vessels. In the case of cancer development, the vascular system is essentially involved in tumor growth, invasion and metastasis formation.

Revascularization is a key point of colonic mucosal repair. During inflammatory stages, due to cytokine action and intercellular adhesion, molecules signalling some of the vessels differentiate into high endothelial venules (HEVs)^[24,25]. In the case of lymphocytes and neutrophils, it is supposed that they firstly reach the inflammatory sites *via* a transcellular pathway through the HEVs^[26], but an intercellular pathway is also known^[27]. Upon epithelial injury the circulating bone marrow derived cells (BMDCs) migrate to the stromal layer of the damaged colonic wall, presumably *via* HEVs at an increased number regulated by overexpressed inflammatory chemokines^[28].

Based on the result of Witmer *et al.*^[29], it has been suggested that in lymphoid tissues, including GALT, the signaling system of the vascular endothelial growth factor (VEGF) and its receptor play a permanent role in the vasculogenesis of ILFs. Whereas the inhibition of VEGF has shown promising results in sporadic colon cancer, it has been recently published that VEGF receptor signaling acts as a direct growth factor for tumor cells in colitis-associated cancer, providing a molecular link between inflammation and the development of colon cancer^[30].

BONE MARROW DERIVED STEM CELLS OF ILFS

Based on the former results^[31-33], emerging evidence suggests that bone marrow derived stem cells contribute to tissue regeneration partly by promoting neovascularization or arteriogenesis. After human hematopoietic cell transplantation epithelial tissue chimerism appears^[34-36].

The bone marrow origin of epithelial cells may be supposed by observations in which epithelial cell markers and leukocyte markers showed that double positive cells were found in inflamed mucosa adjacent to lymphoid aggregates^[2,37-39]. The presence of cytokeratin, epithelial growth factor receptor, hepatocyte-derived growth factor receptor or CDX2 co-expression in CD45+ cells of ILFs may support the mesenchymal origin of epithelial stem cells. Based on these results, it seems that ILFs are involved in the homing and differentiation of BMDCs in the case of colonic mucosal damage (Figure 1).

The cause of metastasis remains elusive despite a vast amount of information on cancer cells. According to recent research, cancer cell fusion with macrophages or immigrating BMDCs provides an explanation^[40,41]. BMDCs fused with tumor cells were present not just in animal tumor xenografts where they were associated with metastases, but in

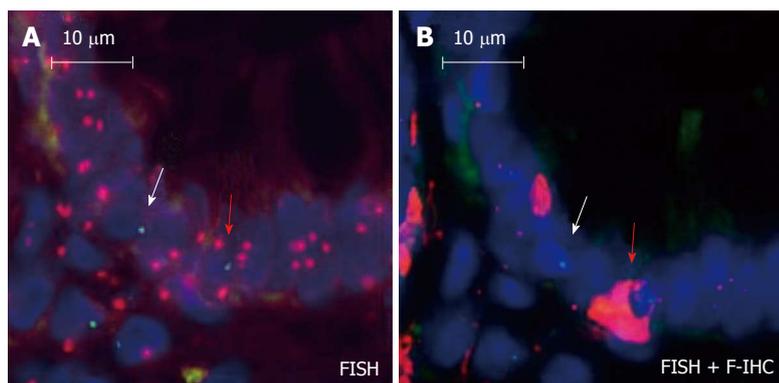

Figure 1 Intraepithelial male donor bone marrow origin CD45+/Y-FISH+ cell (white arrow) and CD45+/Y-FISH+ intraepithelial lymphocyte (red arrow) in the colonic biopsy specimen of a female acceptor. A: Chromosomal detection (green: Y-chromosome, red: X-chromosome; fluorescence *in situ* hybridization); B: CD45 and cyokeratin (green: cyokeratin, red: CD45; fluorescence immunohistochemistry; 130 × magnification).

human carcinomas, including colon cancer. BMDC-tumor cell fusion explains the epidermal-mesenchymal transition in cancer since BMDCs express mesodermal traits and epithelial-mesenchymal transition regulators (i.e.: Twist, SPARC). If BMDC-tumor cell fusion underlies invasion and metastasis in human cancer, new therapeutic strategies would be mandated.

DENDRITIC CELLS IN ILFS

Follicular dendritic cells (FDCs) in lymphoid follicles retain native antigens in the form of immune complexes on their membrane for months, and present these antigens to B cells during the secondary response^[42,43]. The origin and cell lineage of FDCs are controversial. Whereas their immune functions and expression of hemopoietic cell-associated antigens suggest that they belong to the hemopoietic lineage^[44], their spindle-shaped morphology “*in vitro*”, lack of CD45, and presence of antigens expressed by fibroblasts^[45] indicate that FDCs may be mesenchymal cells. Based on studies with mouse radiation chimeras, Humphrey *et al.*^[46] concluded that FDCs were not derived from the bone marrow, but came from a local mesenchymal precursor. However, Kapasi *et al.*^[44], using mice homozygous for the SCID mutation, which lack T, B lymphocytes, and FDCs, demonstrated that after reconstitution with bone marrow from donor mice, the FDCs of the reconstituted mice expressed the donor phenotype. These authors concluded that FDC precursors came from bone marrow.

According to the results of Muñoz-Fernández *et al.*^[47], FDCs seem to be a specialized form of myofibroblasts and derive from bone marrow stromal cell progenitors. The authors were able to isolate and culture 18 follicular dendritic cell lines from human tonsils. These cells were CD45-negative and expressed antigens associated with FDCs (CD21, CD23, CD35, CD40, CD73, BAFF, ICAM-1, and VCAM-1) and antigens specific for FDC (DRC-1, CNA.42, and HJ2). These cell lines were also able to bind B cells and secrete CXCL13, and they had functional activities characteristic of FDCs. Nevertheless, the additional expression of STRO-1, together with CD10, CD13, CD29, CD34, CD63, CD73, CD90, ICAM-1, VCAM-1, HLA-DR, al-

kaline phosphatase, and α -smooth muscle actin (α -SMA) indicated that FDCs are closely related to bone marrow stromal cell progenitors. The expression of α -SMA also relates FDCs with myofibroblasts. Like myofibroblasts, FDC lines expressed stress fibers containing α -SMA and were able to contract collagen gels under the effect of TGF β 1 and platelet-derived growth factor.

In various inflammation models, tissue-derived dendritic cells have been shown to migrate from the inflammatory site *via* lymphatics to secondary lymphoid organs where they interact with lymphocytes^[48]. Based on their dual phenotype, follicular dendritic cells may represent a transformation switch point among immigrating bone marrow derived stem cells in ILFs and the surrounding subepithelial myofibroblasts.

The origin of dendritic cells (DCs) in tumors remains obscure. Recent studies indicate that conventional DCs in lymphoid tissues arise from a distinct population of committed conventional DC precursors (pre-cDCs) that originate in bone marrow and migrate *via* blood. Diao *et al.*^[49] showed that pre-cDCs are precursors for conventional DCs in tumors, and they migrate from blood into the tumor where they generate conventional DCs. The chemokine CCL3, which is markedly upregulated in tumors (including colon cancer) and in tumor-infiltrating stromal and immune cells, promotes pre-cDC recruitment. Both pre-cDCs and their conventional DC progeny actively proliferate within the tumor, and have the ability to mature and stimulate Ag-specific lymphocytes. This finding suggests that in several cases the migration of pre-cDCs to tumors may represent a normal response to inflammation. Further studies are needed to delineate the role of pre-cDCs in other inflammatory processes and to compare them with monocytes, which are currently considered the main source of inflammatory DCs in peripheral tissues^[50,51].

MYOFIBROBLASTS SURROUNDING ILF ADJACENT EPITHELIUM

Subepithelial myofibroblasts (SEMFs) exist as a syncytium that extends throughout the colonic lamina propria, merg-

ing with the pericytes surrounding the blood vessels^[52,53]. SEMFs are involved in two epithelial repair processes^[54,55]. One process is called restitution^[56]. This is an important response to minor to moderate injury. The other process is observed when the wound is deep, and the subepithelial tissues and the basement membrane need to be reconstituted^[55].

According to recent studies^[54,57,58], myofibroblasts are thought to derive from two major sources, bone marrow or locally activated fibroblasts, in response to transforming growth factor- β 1. In the case of serious tissue injury (i.e. active ulcerative colitis) the regeneration capacity of local stem cells is not enough to complete tissue repair. In this case, bone marrow derived mesenchymal stem cells migrate into the gastrointestinal wall where they may contribute to the repair progress^[59,60] as differentiated mesenchymal cells (e.g. myofibroblasts)^[61].

Despite the increasing number of publications illustrating the role of tumor-associated stromal cells in cancer progression, there still exists a significant ambiguity with respect to the identification of cancer-associated fibroblasts, myofibroblasts and peritumoral fibroblasts in the cancer tissue. SEMFs appear early in the cancer's development. The mutual interaction (through direct cell-cell contacts and paracrine signals) between cancer cells and SEMFs is essential for invasive growth and is translated into a poor clinical prognosis^[62].

TOLL-LIKE RECEPTOR EXPRESSION IN ILFS

Beside immune functions, PPs and ILFs are supposed to be involved in mucosal repair *via* Toll-like receptors (TLRs). In ILFs, TLRs are expressed on the cells of the monocyte/macrophage system, on some kinds of T cells, as well as on intestinal epithelial, endothelial and stromal cells^[63]. Using the dextran sodium sulfate (DSS) model of colitis, mice lacking TLR2, TLR4 or MyD88 all developed more severe colitis than wild type mice when exposed to orally administered DSS^[64]. These findings suggest that signaling from commensal bacteria throughout TLRs resulted in protection from DSS colitis through enhanced epithelial cell proliferation, and worked as a compensatory factor against epithelial damage^[64].

TLRs can also bind endogenous ligands including necrotic cells, heat shock proteins, and extracellular matrix components^[65-67]. Necrotic cells may activate NF- κ B through TLR2, leading to the expression of tissue repair-associated genes^[65]. It is supposed that necrosis induced inflammation in tissue damage may provide danger signals functioning as inducers of tissue repair responses through TLRs. The TLR ligands released from necrotic cells have not been identified, although heat shock proteins produced by damaged cells are known to be TLR ligands^[66]. Components of the extracellular matrix, such as hyaluronan, can be an endogenous ligand for TLR4^[67]. Increased hyaluronan production has been demonstrated in both DSS colitis in mice and in human Crohn's disease^[68]. It

is possible that TLR activation may occur in the absence of microbial products^[68]. In the case of inflammatory mucosal damage, ILFs may induce repair mechanisms *via* endogenous TLR activation.

TLR4 was also shown to be expressed on human colon carcinoma cells and functionally active. It may play important roles in promoting immune escape of human colon carcinoma cells by inducing immunosuppressive factors and apoptosis resistance, and it may also promote the proliferation and migration of cancer cells^[69,70].

The analysis of isolated tumor cells from primary colon cancers showed co-expression of TLR7 and TLR8 with CD133 and gave evidence for a subpopulation of colon cancer-initiating cells^[71]. Persistent TLR-specific activation of NF- κ B in colorectal cancer, particularly in tumor-initiating cells, may sustain further tumor growth and progression through perpetuated signaling known from inflammatory and tissue repair mechanisms with consecutive self-renewal in pluripotent tumor cells. Activation through self-ligands or viral RNA fragments from tumor-associated lymphoid aggregates may putatively maintain this inflammatory process, suggesting a key role in cancer progression.

THE EFFECT OF THE PRESENCE OF ILFS ON MUCOSAL REPAIR

The epithelia of intestinal crypts associated with ILFs and PPs have an increased proliferation rate^[10,14]. Saxena *et al*^[10] showed that PPs in rats have a facilitative effect on the healing of intestinal wounds by promoting both epithelial cell migration on the defect and epithelial cell proliferation in the crypts adjacent to the wound and by decreasing the rate of wound contraction.

In rats, a difference in epithelial apoptosis between the FAE of PPs and intestinal villi was described^[72]. Onishi *et al*^[72] showed that the progression of the apoptotic process in the epithelial cells of FAE occurs later than in the intestinal villi, so the possibility of epithelial differentiation might remain in FAE, unlike in intestinal villi. PPs are supposed to have a regulatory effect on the epithelial proliferation as well^[73].

The Wnt signaling pathway is critical for regulating a number of basic cell functions, such as cell proliferation, cell fate, polarity, differentiation, and migration, leading to morphogenesis and organogenesis^[74,75]. There is strong genetic evidence that Wnt signaling play critical roles in the regulation of epithelial stem cells in the intestinal tract^[76]. The Wnt target gene *Lgr5* has been recently identified as a novel stem cell marker of the intestinal epithelium and the hair follicle^[77]. In the intestine, *Lgr5* is exclusively expressed in cycling crypt base columnar cells^[77]. Many Wnt family proteins are expressed in hematopoietic tissues, and can also be secreted by lymphoid cells^[78,79]. The Wnt-*Lgr5* pathway may be a potential switch between the ILFs and colonic epithelial renewal. Lymphoid cells of ILFs may produce Wnts which are essential components of a milieu in which bone marrow derived stem cells immigrated to ILFs to engage in epithelial differentiation (Figure 2).

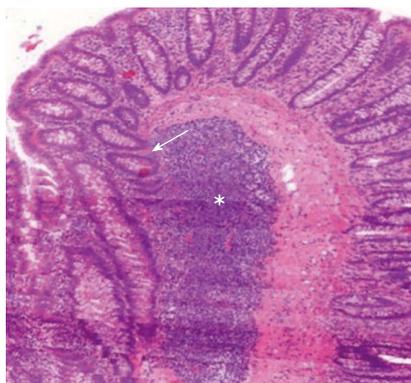

Figure 2 3D reconstruction of a human colonic surgical sample (MIRAX Viewer, 3D, 3DHISTECH Ltd., Budapest). A large subepithelial isolated lymphoid follicle (white star) can be seen. Colonic crypts (white arrow) with no connection to the luminal surface “outgrow” from the isolated lymphoid follicle.

THE EFFECT OF THE PRESENCE OF ILFS ON COLORECTAL CARCINOGENESIS

Results from experimental colon cancer studies indicated that ILFs might promote the development of adenocarcinomas^[7,8]. However, studies in experimental animals have also shown that the intestinal lymphoid system plays an important role in immunologic defense mechanisms; that is, antigenic stimuli result in germinal center formation, antibody production, and finally enlargement of the follicles^[80]. In humans, the presence of tumor-infiltrating lymphocytes is associated with an improved prognosis in colorectal cancers, as does the presence of high level DNA microsatellite instability^[81]. These results suggest that ILFs in early colorectal neoplasms play an important role in defense rather than in promotion.

In a recent study, Fu *et al*^[9] found that the incidence of ILFs in early human colorectal neoplasms significantly differs by gender, location, macroscopic type, and histology, but moreover, their localization significantly differs by macroscopic type.

In squamous cell carcinomas of the esophagus, cyclin A expression in the germinal center cells of ILFs beneath the superficial tumorous lesions was shown to be an immunological signal toward the proliferation and progression of the tumors^[82]. Gutfeld *et al*^[83] found that the cells of colonic ILFs, inflammatory cells, ganglion cells, and endothelial cells express serum amyloid A, an acute phase reactant, whose level in the blood is elevated in response to trauma, infection, inflammation, and neoplasia, on both mRNA and protein levels. The serum amyloid A mRNA expression in epithelial cells was found to gradually increase as it progressed through different stages of dysplasia to overt carcinoma. While expression of the serum amyloid A1 and -4 genes in colon carcinomas was confirmed by RT-PCR analysis, this expression was barely detectable in normal colon tissues. Their findings indicate local and differential expression of serum amyloid A in human colon cancer and tumor-associated ILFs, and suggest its role in colorectal carcinogenesis.

MESENCHYMAL-EPITHELIAL AND EPI-THELIAL-MESENCHYMAL TRANSITION IN ILFS

Epithelial-mesenchymal transition (EMT) is a physiological mechanism present during development, and is also encountered in several pathological situations such as renal interstitial fibrosis, endometrial adhesion, and cancer metastasis^[84]. A reverse phenomenon, mesenchymal-epithelial transition (MET) also takes place during normal development in processes such as somitogenesis, kidney development and coelomic cavity formation^[85]. In adult organisms, it has been proposed that restrictive mechanisms repress EMT and MET^[86]. During tumor development, these mechanisms appear to fail, allowing EMT described in metastasis generation^[87].

In inflammation, MET can also be altered because mesenchymal stem cells are mobilized to these sites of injury and consequently subjected to the inflammatory response^[88]. BMDCs could differentiate into mature-appearing epithelial cells in response to tissue damage^[89]. It was recently published that versican, a large chondroitin sulfate proteoglycan, mediates MET^[90]. The results of Hirose *et al*^[91] indicate that versican can bind specific chemokines through its chondroitin sulfate chains and that the binding tends to down-regulate the chemokine function. This raises the possibility that versican may act as a regenerative factor in colonic mucosa, and may be an important switch point between ILFs and MET. The presence of CDX2 and cytokeratin positive subepithelial cells in the marginal zone of ILFs also suggests that MET may take place in these immune formations^[2].

Stroma-tissue, including lymphoid aggregates and ILFs surrounding the cancer cells, plays an important role in the tumor behavior. Mesker *et al*^[92] analyzed the expression of markers involved in pathways related to stroma production and EMT (β -catenin, TGF- β -R2, SMAD4) in high-risk colorectal cancer patients, and found that patients with stroma-high and SMAD4 loss are of high risk. The anti-EMT effect of SMAD4 was also proven in colon carcinoma cells^[93].

CONCLUSION

Based on the summarized results of literature, it seems that ILFs act like a switch between colonic mucosal regeneration and colorectal carcinogenesis.

Subepithelial revascularization after mucosal damage takes place partly under the direction of ILFs with the prominent help of vascular endothelial growth factor and its receptors. Immigrating stem cells from bone marrow may leave circulation *via* high endothelial venules in ILFs and their surroundings. Their differentiation throughout mesenchymal-to-epithelial transition may also happen in ILFs, and follicular dendritic cells, as well as the subepithelial myofibroblasts, seem to be crucial parts of colonic crypt formation and epithelial renewal.

Vasculogenesis in ILFs supports not just tumor growth

and the metastatic process, but the VEGF receptor signaling acts like a direct growth factor for tumor cells. The fusion of BMDCs immigrating to ILFs with tumor cells may explain EMT in colorectal cancers. The presence of ILFs, dendritic cells and subepithelial myofibroblasts may also result in a specific milieu for tumor formation, growth and invasion.

Better understanding of the role of ILFs in mucosal repair may lead to the development of new therapeutic agents for inflammatory colon diseases that not only decrease the activity of inflammation, but also accelerate epithelial barrier recovery, hence dramatically decreasing clinical symptoms. Moreover, by revealing the exact connections between ILFs and colorectal carcinogenesis, the basis of individualized anti-cancer immunotherapies may be established.

Abstract

Improvements in surgery and the application of combined approaches to fight rectal cancer have succeeded in reducing the local recurrence (LR) rate and when there is LR it tends to appear later and less often in isolation. Moreover, a subtle change in the distribution of LRs with respect to the pelvis has been observed. In general terms, prior to total mesorectal excision the most common LRs were central types (perianastomotic and anterior) while lateral and posterior forms (presacral) have become more common since the growth in the use of combined treatments. No differences have been reported in the current pattern of LRs as a function of the type of approach used, that is, neo-adjuvant therapies (short-term or long-course radiotherapy, or

chemoradiotherapy versus extended lymphadenectomy, though there is a trend towards posterior or presacral LR in patients in the Western world and lateral LR in Asia. Nevertheless, both may arise from the same mechanism. Moreover, as well as the mode of treatment, the type of LR is related to the height of the initial tumor. Nowadays most LRs are related to the advanced nature of the disease. Involvement of the circumferential radial margin and spillage of residual tumor cells from lymphatic leakage in the pelvic side wall are two plausible mechanisms for the genesis of LR. The patterns of pelvic recurrence itself (pelvic subsites) also have important implications for prognosis and are related to the potential success of salvage curative approach. The re-operability for cure and prognosis are generally better for anastomotic and anterior types than for presacral and lateral recurrences. Overall survival after LR diagnosis is lower with radio or chemoradiotherapy plus optimal surgery approaches, compared to optimal surgery alone.

INTRODUCTION

Over the past two decades, there have been improvements in the management of rectal cancer in terms of postoperative death (falling from 10% to 2%), locoregional failure (dropping from 30%-40% to less than 15%), conservative surgery rates (increasing from 20% to 60%) and survival, with advances made in the understanding of the biology of this type of tumor as well as staging and the use of combined therapies^[1]. The anatomical and technical basis of tumor recurrence within the pelvis has been extensively investigated by surgeons and pathologists, and this has led to major improvements in surgical therapy. Nonetheless, although surgery remains the mainstay of treatment aimed at achieving locoregional control, nowadays the therapeutic approach to rectal cancer is eminently multidisciplinary.

The key to successful surgery is complete excision of the tumor proximally, distally and around its circumference with sufficient margin of normal tissue (R0 resection). In total mesorectal excision (TME) surgery the rectum and its perirectal lymphatic and fatty tissue (mesorectum) is completely mobilized by sharp dissection, as an intact package surrounded by an undamaged peri-mesorectal layer of proper rectal (visceral) fascia, avoiding spillage and growth of residual tumor cells into the pelvis and subsequent development of a local recurrence (LR). Educational programs aimed at training surgeons in this pelvic dissection technique have demonstrated reproducible results in achieving a reduction of the LR of rectal cancer rate by 40%^[2] and even greater when associated with radiotherapy (RT)^[3] or neoadjuvant chemoradiotherapy (CRT)^[4].

Nevertheless, LR of rectal cancer remains a significant clinical problem, associated with severe morbidity, low rates of success of salvage procedures, and eventual death in the majority of patients^[5].

It is important to review the patterns of treatment failure resulting after rectal cancer management. Improvements in surgical and adjuvant therapies may affect not only the likelihood of tumor recurrence in the pelvis but also the pattern of pelvic recurrence itself (i.e. pelvic subsites). Knowledge of the pattern and natural history of LR, the associated risk factors for their development and the mechanism by which they occur may serve as the foundation for efforts to improve the results of multidisciplinary care (i.e. RT field design, suitability of lymphadenectomies, strategy in the follow-up monitoring, *etc.*).

The aim of this review is to characterize and analyze the pattern of LR today following different curative approaches for rectal cancer, with special emphasis on the correlation between subsites of pelvic recurrences and treatment modalities.

LIMITATIONS OF THIS REVIEW

Many of the studies that report patterns of pelvic recurrence have multiple limitations. Some are outdated or do not give exact anatomical information of the location of recurrent tumors in the pelvis. In particular, the diagnostic procedures, methods of documentation, acknowledge-

ment or confirmation of diagnosis, presence or absence of histology, the use of interval pain, anatomic definitions of the rectum, first site of recurrence and cumulative recurrence data, as well as the definition of the LR itself and other details all affect the analysis of incidence rates, timing, and patterns^[6].

Old literature concerning the pattern of local failure in rectal cancer was based on planned or symptomatic reoperations data or autopsy series. Planned "second look" procedures and symptomatic surgery were performed in the pre-TME surgery era and LR data obtained may be outdated. Furthermore, autopsies reveal only the end pattern of failure.

On the other hand, most recent reports are based on clinical or imaging data which can be also misleading as the methods of diagnosing and confirming LR and length of follow-up are not described consistently. The actual rate of pelvic recurrence may be somewhat higher than estimated by these reports, as some studies report only first sites of failure, and pelvic relapse later in the course of disease is not always assessed in patients under palliative chemotherapy for distant metastasis.

Trials of preoperative RT or CRT in resectable rectal cancer are characterized by multiple methodological problems because treatments are combined (RT and surgery) to address a heterogeneous condition (various populations and stages of rectal carcinoma) and to achieve a variety of goals (downstaging and improving resectability, as well as decreasing local and possibly distant recurrences and improving survival).

DEFINITION AND CLASSIFICATION OF LOCAL RECURRENCE

Although by definition the term LR is only applicable when the initial or primary surgery is expected to be curative (no remaining macroscopic evidence of disease locally, that is R0 and R1 according to the UICC (International Union Against Cancer), it must be seen as the further development of tumor cell remnants: there is a close biological similarity between a primary tumor and an LR, in contrast to the situation with corresponding organ metastases^[7].

Recurrent rectal cancer may be isolated (local or metastatic) or combined (local and metastasis). Indeed LR can be defined as any tumor located within the pelvis, either alone or in conjunction with metastases^[6]. Several authors have classified locoregional pelvic recurrence in order to facilitate treatment and compare outcomes. Specifically, the distinction between localized and diffuse pelvic recurrence is pivotal in defining subsequent management and prognosis.

The Mayo Clinic^[8] described recurrence in terms of degree of fixation both in term of site (anterior, sacral, right or left) and number of points of fixation (F0-F3). Wanebo *et al*^[9] proposed a classification based on the UICC TNM system: TR1 and TR2 corresponding to intraluminal LR, either following local excision or at the anastomosis; TR3 corresponding to LR at or around the level of the anastomosis with limited extramural spread

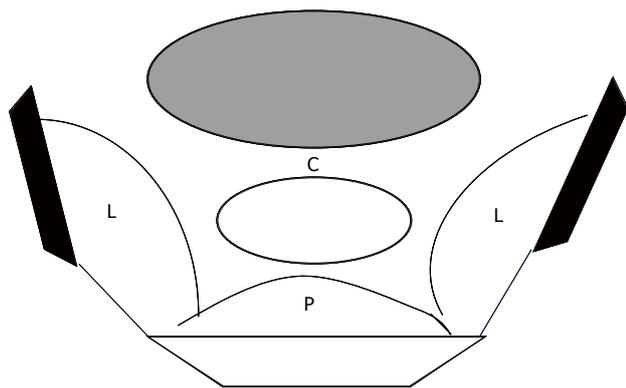

Figure 1 Types of pelvic recurrence. C: Central; L: Lateral; P: Posterior.

and without pelvic fixation; TR4 corresponding to invasion into either adjacent urogenital organs or presacral tissues with tethering but no fixation; and TR5 corresponding to invasion into the sacrum or pelvic side walls. On the other hand, others divided pelvic local failures into just three basic types of recurrence: localized (central), sacral and pelvic sidewall.

The Memorial Sloan Kettering^[10] group describe a nomenclature based on the anatomical region of the pelvis that is involved (Figure 1). Accordingly, LR is defined as either: axial, subdivided into anastomotic, mesorectal (residual mesorectum) or perirectal soft tissue within the center of the pelvis or perineum following an abdominoperineal resection (APR); anterior, involving the genitourinary tract; posterior, involving the sacrum and presacral fascia and sacral root sheaths; or lateral, involving the muscles (piriformis, elevator), soft tissue of the pelvic sidewall, lymph nodes, major iliac vessels, sacral nerve plexus and lateral bony pelvis. Lastly, the Dutch TME trial^[11] classifies LR based on the same pelvic subsites, although the perineum and anastomotic recurrences are grouped separately. We have found the latter to be the most useful classification, although it does not distinguish between two different origins of the pelvic sidewall involvement itself: true lateral involvement by growth of tumor deposit in lymph nodes along the iliac vessels and continuous extension of tumors of central origin.

DIAGNOSIS OF RECURRENT RECTAL CANCER

Patients with recurrent cancer are a heterogeneous group. To establish LR or pelvic disease after definitive resection of rectal cancer^[12], most authors accept at least one of the following major criteria: (1) Histological confirmation; (2) Palpable or evident disease with subsequent clinical progress; (3) Clear evidence of bone destruction; and (4) Positive positron emission tomography examination, and at least one of the minor criteria: (1) Progressive enlargement of soft tissue mass on repeated computed tomography (CT) or magnetic resonance (MRI) examination; (2) invasion of adjacent organs; (3) subsequent rise in tumor

markers; and (4) typical appearance in endoscopic ultrasound, CT or MRI imaging.

Note that according to these major criteria no patient should be accepted as having pelvic recurrence by diffuse pelvic pain.

RISK FACTORS FOR LR

Many factors affect the risk of local recurrence.

Pathological factors

The pelvic recurrence rate is tumor stage dependent: the more advanced the stage the more likely it is that rectal cancer will recur^[13]. Many authors have confirmed the association between advanced UICC or Dukes' stage and the likelihood of recurrence. Not surprisingly, the extent of invasion beyond the rectum affects recurrence, with an incidence of less than 1% in patients in whom no local extension is noted, compared to between 5% and 10% in patients with moderate spread and 15%-25% in those with more extensive spread^[14,15]. The number of positive lymph nodes^[16] as well as a positive circumferential resection margin (CRM) also influence both LR and survival^[11]. Even with combined treatments, the incidence of LR in patients with one of these risk factors (that is, TMN stage IV, T4 tumor, N2 disease or positive CRM in T3 disease) reaches 20%, compared to less than 5% in patients who do not have these characteristics^[11]. It is also clear that the combination of risk factors is also important: in patients at T1-T2 the incidence of LR is 1% with a negative CRM but this rises to 12% for a positive CRM, while for those at T3-T4 it is 15% for a negative CRM but 25% for a positive CRM^[11]. In patients undergoing surgery with or without preoperative RT, the combination of CRM and lymph node status has been shown to be a more effective discriminator of prognosis than TNM staging^[11].

Height of the tumor is also a critical factor as LR is also more likely with tumors in the lower third of the rectum (10%-15%) than in patients with tumors in either the middle third (5%-10%) or upper third (2%-5%)^[3,5,11,15]. The risk of LR is also related to the position of the tumor within the circumference of the rectum. In the series of Chan *et al*^[17] the rate of LR was 15% (95% CI, 11-22) for tumors affecting the anterior side of the rectum but was 5.8% (95% CI, 3-11) for other locations. Anterior tumors tend to be more advanced, at least in male patients, and the anterior aspect of the TME dissection more difficult to perform in the narrow male pelvis, presenting a higher risk of LR and death than tumors in other sites^[18].

The shape (exophytic versus non-exophytic) of the tumor, the presence or absence of budding, lymphatic, venous or perineural invasion, the presence of obstruction or perforation of the tumor together with the degree of tumor differentiation, and fixity of the tumor, all influence the risk of local recurrence adversely^[13,19].

Therapeutic factors

Inadequate removal of the primary tumor is the most

Table 1 Patterns and rates of recurrences after different approaches

TME: Total mesorectal excision; sRT: Short-term preoperative radiotherapy; LRT: Preoperative long-term radiotherapy; CRT+TME: Pre-operative chemoradiotherapy; TME+CRT: Post-operative chemoradiotherapy; EL: Extended lymphadenectomy; NA: Not available; LR: Local recurrence.

important factor determining whether the tumor recurs^[20]. In addition to the involvement of the CRM, the plane of surgery achieved, as a measure of the quality of mesorectal excision, has been shown to be an important prognostic factor for LR^[21]. Surgeon variability is also a widely studied phenomenon. In multivariate analysis “the surgeon factor” has emerged as a critical treatment-independent variable, and is not only related to the volume of operations performed^[22].

The incidence of lateral lymph node involvement has been extensively investigated by Japanese authors. The term “extended lymphadenectomy” (EL) refers to the removal of the lymph nodes in the extra-mesenteric area. Generally rates of node involvement have been reported to be 5%-10%, but are markedly higher in stage III tumors in the lower third of the rectum, with rates of up to 15%-25%^[23]. However, it is doubtful that remaining lateral lymph nodes after an R0 resection is the major or only source of tumor regrowth^[24].

There is abundant clinical data supporting the importance of the pathologic response and downstaging to preoperative CRT. All patients who developed cancer recurrence in the German trial had positive lymph node involvement post-treatment^[25]. A pathological complete response (pCR) or greater than 95% CR in the post-CRT is a predictive factor of low LR rate and good prognosis, and several studies have shown that this is the most important independent prognostic factor in multivariate analysis for disease-free survival^[4,26].

While attention was traditionally focused solely on the optimal distal mucosal margins required to achieve an oncologically safe resection, not only have these margins been reduced significantly, but also greater importance has come to be placed on the lateral margins for achieving an R0 resection. Short (but negative) distal margins have

repeatedly been found not to be associated with pelvic recurrence^[27,28]. The risk is not so much of intramural spread as of intramesorectal spread, and probably the risk for mesorectal tumor deposit is higher in node-positive than in node-negative patients^[27].

Other factors that may increase a patient's risk of LR are related to increasing body mass index^[29]. It has been shown that obese men are more likely than normal weight males to develop an LR, and that adiposity is a strong predictor of requiring an APR^[30].

SITES OF LOCAL RECURRENCE AFTER SURGERY ALONE

In the late 1970s, areas of failure found on planned reoperation (“second look” procedures) of patients at risk of recurrence, in spite of an initial curative resection, were investigated. The seminal article by Gunderson and Sosin^[31] showed that as distant metastases alone were uncommon (7%), LR as the only type of failure occurred in nearly 50% of cases of recurrence and as some component in 92%. They also depicted the pattern of pelvic subsites LR (Table 1), showed that disease relapse rates were indeed related to the degree of bowel wall penetration and the extent of nodal disease, and paved the way for the exploration of radiation therapy.

In the era before the adoption of TME, surgery alone was associated with local failures of up to 30%-50%. The classic article of Pilipshen *et al*^[32] describes the pattern of LR at a prestigious institution (Sloan-Kettering) in the pre-TME era, with LR rates of 31% in cases at T3-T4 and 49% in cases at N2. Hruby *et al*^[33] provide a detailed analysis of the sites of LR after undergoing surgery for rectal cancer in a series of 269 patients mainly during the 1980s. As can be seen in Table 1, at that time most LR was axial

or central, in the block of fatty tissue surrounding the rectal wall, within or contiguous to the operative site, and appeared 6-16 mo before the appearance of metastasis.

In the 1980s details emerged of the first series of patients treated with TME surgery. Heald *et al*^[34] published an accumulated local recurrence rate of 3.7% in a personal series of 115 cases of “curative” low anterior resections^[5]. Ten years later, the same author reported actuarial 5- and 10-year recurrence rates of 6% (95% CI, 2%-10%) and 8% (95% CI, 2%-14%) respectively with TME surgery alone. Another TME pioneer, Enker, published a rate of 4.1% for Dukes’ B and 8.2% for Dukes’ C patients^[35].

In the 1990s large reductions in local and distant recurrences were reported with TME and so, even without a proper randomized control trial, the TME resection became the new gold standard of surgery for rectal cancer.

Although regarded as equivalent in the pre-TME surgical era, the superiority in terms of LR of the TME low anterior resection (LAR) over the “traditionally” executed APR soon became clear. “Standard” or “traditional” APR for low rectal cancer is associated with a higher rate of positive CRM (30%-60%) and operative perforation (20%-33%), leading to higher LR and poorer survival rates than with LAR^[36]. Recently a more radical excision of the levators and puborectalis muscles, carried out in the prone jack-knife position, has been proposed (“extralevator APR”)^[37].

As the surgical techniques worldwide evolved to TME resections, European researchers focused on the delivery of a short course of high-dose preoperative RT, without chemotherapy, after ascertaining that adjuvant RT, both before and after surgery, substantially reduced the risk of LR when biologically effective doses of 30 Gy or more were used^[38].

LOCAL FAILURES AFTER SHORT-TERM PREOPERATIVE RT

The Swedish Rectal Cancer Trial^[39] randomized 1168 patients to surgery alone or to surgery following a 1-wk of pelvic RT (25 Gy in 5 daily fractions), and showed that not only was the 5-year LR rate significantly improved with preoperative RT (23% *vs* 9%, among the curatively treated patients) but also the 5-year survival rate significantly improved (58% *vs* 48%). However, this trial was conducted in the surgical era prior to the adoption of TME.

Syk *et al*^[40] reviewed the incidence and location of LR in a group of 880 patients from Stockholm after the introduction of TME surgery, and half of the group also received short-term preoperative RT. In this study, 42% of LR originated from tumors in the upper rectum, and a majority of these patients had not received RT. In all these cases, the recurrence was at the anastomosis and virtually all had visible signs of residual mesorectal fat. Eighteen percent of the patients had LR involving the lateral wall of the pelvis, but only 6% of the tumors involved sites consistent with recurrence in iliac lymph nodes. The authors concluded that lateral pelvic lymph node metastases are not a major cause of local recurrence after TME, and

that partial mesorectal excision may be associated with an increased risk of local recurrence due to presacral and/or pelvic sidewall involvement in the upper rectum.

As surgery improved, Dutch researchers then asked whether preoperative short-term RT would still be beneficial in the setting of TME resection properly executed. In the Dutch TME trial a significant benefit was seen with preoperative RT in patients with TNM stage II and III disease, with the two-year local relapse rates decreasing from 5.6% to 1% and from 15% to 4.3%, respectively^[41]. The update of the trial reported in 2007 noted a drop in local relapse from 22% to 11% for stage III patients but no significant reduction for stage II patients, and no difference in distant metastasis rate or 5-year overall survival^[42].

Subgroup analysis showed a significant fall in patients with cancer in the lower rectum, with nodal involvement but uninvolved CRM. Although those CRM positive patients who received preoperative RT had a lower LR rate than the group with TME alone, this difference was not statistically significant (9.3% *vs* 16.4%, *P* = 0.08). The authors arguably concluded that short-term preoperative RT “hardly compensate” for involved CRM^[43].

The Dutch group has also recently published a complete and updated analysis of the pattern of LR and the most likely mechanism of recurrence in the trial^[11]. They showed that preoperative RT reduces LR in all subsites. However the appearance of LR was slower in the group who underwent RT (2.6 years *vs* 1.5 years), and if distant metastases diagnosed within 1 mo of LR diagnosis were also considered to have occurred simultaneously, the rate of combined recurrences was higher in the RT + TME group (74% *vs* 40% in the TME group). In the TME group the recurrences were predominantly anastomotic and posterior, while in the RT + TME group most were posterior and lateral. The anastomotic recurrences were significantly more common in the TME only group, suggesting that RT is especially effective in preventing anastomotic recurrence. Lateral recurrences represented more than 25% of the total in the RT + TME group and most appeared together with metastasis. After LAR, the recurrences were mostly perianastomotic while after APR they were mostly presacral. Perineal LR were found after APR in the TME only group, but not in the RT + TME group. TME alone in node positive disease resulted in considerable local recurrence when the distal margin was 2 cm or less, while RT resulted in a small number of LRs, except when distal margins were less than 5 mm. In total 17% of the patients had a positive CRM, and of those 17% developed LRs (12% in those with T1-T2 tumors, and 24% in T3-T4 tumors with positive CRM).

Given the higher LR rates with narrow CRM, the question of whether selective postoperative RT could improve outcomes in this setting was addressed by researchers in the United Kingdom. The MRC CR07 trial^[44] randomized 1350 patients to TME preceded by short-term RT (25 Gy in 1 wk) *vs* TME followed by CRT (45 Gy plus 5-fluorouracil) if the CRM was < 1 mm. The results showed that the 5-year local recurrence rate was significantly better in

the preoperative RT group (4.7%) than the postoperative CRT group (11.5%). However, in those patients with a positive CRM, the LR rates were not statistically different (16% preoperative *vs* 23% postoperative).

PATTERN OF PELVIC FAILURE AFTER LONG COURSE RT PLUS CHEMOTHERAPY

Postoperative adjuvant strategies to improve outcomes following rectal resection have mainly been explored in the United States. Indeed, in 1990, after positive trials conducted by the Gastrointestinal Tumor Study Group^[45] and the Mayo Clinic/North Central Cancer Treatment Group^[46], the NCI issued a statement declaring combined postoperative therapy the new standard of care in this setting^[47].

Researchers, however, were questioning whether preoperative combined therapy would be even more beneficial. In the 1990s, data from the Memorial Sloan-Kettering Cancer Center and the MD Anderson Cancer Center accumulated^[48] in support of that benefit. Moreover, results from three randomized trials (the Uppsala trial^[49], NSABP R03^[50] and above all the German CAO/ARO/AIO trial^[25]), demonstrated the clear superiority of preoperative RT regimens over postoperative therapy in terms of local control with better compliance to treatment and lower toxicity.

The next step was to test the hypothesis that chemotherapy plus preoperative RT significantly improved local control, tumor downsizing and downstaging compared with RT alone. Two randomized trials compared preoperative RT *vs* preoperative CRT, the study by the Fédération Francophone de Cancérologie Digestive (FFCD 9203)^[51] and the EORTC 22921 trial^[52], and similar results were reported. In the latter, the five-year results showed that chemotherapy increased the rate of pCR (14% *vs* 5.3%), translated into a 3% benefit in terms of sphincter preservation and significantly reduced LR rate from 17% without chemotherapy down to 8% with CRT. Thus chemotherapy, regardless of whether it is administered before or after surgery, confers a significant benefit with respect to local control. The main criticism that can be made of those trials is that TME resections were not uniformly implemented.

On the other hand, the favorable effect of delaying surgery after CRT on downstaging (and possibly also sphincter preservation) was shown in the Lyon R90-01 trial^[53].

There is, however, limited data on patterns of relapse in rectal cancer patients treated with TME surgery and CRT. Such information might help determine whether modifications in RT dose or field design are warranted (i.e. a local recurrence after RT may be inside or outside the RT field; recurrence outside the field requires an increase in the size of the field, and recurrence inside the field implies the need for an increase in the total dose). We have identified reports on only four series of patients that contain detailed analysis of the pattern of pelvic recurrence after CRT and TME surgery.

From the MD Anderson Cancer center, Yu *et al.*^[54] presented a thorough study attempting to identify subsites of pelvic LR in an effort to correlate sites of relapse on

CT images with RT simulation films in 46 rectal cancer patients. Of all the LR, approximately two-thirds were in-field (within the radiation field) recurrences and only one-third were marginal (inside but within 1 cm of the border of the field) or out-of-field (more than 1 cm from the border) recurrences. Of the in-field recurrences, nearly 80% occurred in the low pelvic and presacral regions. Multivariate analysis showed that the risk of in-field LR was significantly associated with pathological N stage, while it was notably not with positive CRM or downstaging. The authors suggested various strategies to improve locoregional control in low pelvic and presacral regions.

Hötch *et al.*^[12] published a large-scale multicenter study based in Germany to evaluate pelvic sites of recurrence with special attention to radiation ports. Nearly 80% of LR occurred within the treated volume, in the central pelvis, and the pelvic sidewall structures were involved in fewer than 5% of tumor relapses. They found no significant differences in the incidence of pelvic sidewall involvement between APR and LAR cases, however there was a significant difference in the spread of recurrent tumors in the inferior part of the pelvis.

However, a quite different picture has been reported from Korea, where Kim *et al.*^[56] examined the patterns of locoregional recurrences in 366 patients with locally advanced rectal cancer who underwent preoperative CRT and curative TME surgery, and assessed the effect of clinical parameters on lateral pelvic recurrence. Eight percent of the patients had LR, of which around 20% and 80% occurred in central and lateral pelvic areas respectively. Multivariable analysis showed that lateral pelvic recurrence was significantly associated with ypN classification (lymph node status after preoperative CRT) and lateral lymph node size. The authors suggested that lateral lymph node metastasis is a risk factor for LR and could be a potentially curable regional disease rather than a sign of systemic disease. Accordingly, they suggested that patients with lateral lymph node size of > 10 mm and ypN0 or lateral lymph node size of 5 mm and ypN+ are a potential subgroup of patients who might benefit from lateral lymph node dissection.

In tumors of the middle and lower rectum, lateral lymph nodes remain a potential cause of locoregional recurrence after conventional TME because they are not removed. EL has been championed mainly by Asian surgeons, who are internationally renowned for their skills in radical surgery.

PATTERN OF RECURRENCES AFTER EXTENDED LYMPHADENECTOMY AND TME, WITH OR WITHOUT ADJUVANT TREATMENT

Around 40% of patients treated for rectal cancer present with lymph node metastases, which occur along the mesorectal nodal chain, along the inferior mesenteric artery lymph nodes or in the lateral pelvic lymph nodes (along the obturator, internal iliac or medial aspect of the external

iliac artery). Whether pelvic sidewall lymph nodes should be considered metastatic disease as suggested by the TNM classification (M1) or part of the regional lymphatics (N3) as outlined in Japanese guidelines that are amenable to curative resection, is a contentious issue. Japanese surgeons have adopted the technique of EL to supplement TME, with the aim of minimizing LR and improving survival. Western surgeons do not use EL regularly, and this might pose a risk of local recurrence in the pelvic sidewall in patients operated on without preoperative RT.

In a recent detailed topological analysis of the pattern of lymphatic spread in 605 cases of rectal cancer, 285 cases (47%) were identified as having lymph node metastases. Of this total, 71.5% were mesenteric, 21.5% were lateral and mesenteric, and only 4.7% were exclusively lateral (so-called skip metastases), while among the cases of lateral metastases slightly more than a third were bilateral. The authors^[23] concluded that lateral lymph node status is reflective of overall mesenteric lymph node status and that evidence of lateral lymph node involvement may be an ominous sign of advanced disease with an inherent dismal prognosis.

EL is associated with high degrees of urinary and sexual dysfunction and while it is possible to undertake lateral node dissection with autonomic nerve-sparing surgery (NSEL), there are problems with this surgical technique in terms of worldwide uniformity. Moriya *et al.*^[57] have studied the pattern of recurrence after NSEL surgery in 306 patients, of which 14% were in Dukes' stage C, and found an overall LR rate of 6.2%. Dukes' A and B patients with relapse had suture-line recurrence. In contrast, in the Dukes' C group, 70% of the recurrences were in patients who had had involvement of more than 5 lymph nodes and 40% in those in whom there had been lateral spread, the number of mesenteric lymph node metastases being the factor which had the strongest impact on the LR. The authors judged that the LR rate with NSEL is similar to that obtained with conventional EL.

Kusters and Van de Velde^[58] reviewed 351 patients operated for rectal carcinoma at or below the peritoneal reflection at the National Cancer Center in Tokyo. Standard TME surgery was performed for T1 and T2 ($n = 145$), and NSEL was added to TME for T3 and T4 (unilateral = 73; bilateral, when the tumor was located centrally, $n = 133$). They noted that overall there was lymph node involvement in 42% of cases, and lateral involvement in 10%, with "skip" metastases in 3% (mesorectal nodes negative and lateral nodes positive). Overall the 5-year LR rate was 6.6%, while for node-positive (N+) patients the difference between the uni- and bilateral NSEL (32% *vs* 14%, respectively) was significant.

On the other hand, studies of EL are observational and the reported outcomes are far from uniform even within series reported from Japan. Moreira *et al.*^[24] indicated that EL has no advantages for patients in Dukes' stages A and B and that for cases in stage C it does not significantly reduce LR rates compared to TME. Other series, from both Western and Asian countries, suggested that despite undergoing EL few patients survive for 5 years or more if carcinoma has spread to the pelvic lymph nodes.

Yano *et al.*^[59] proposed selective use of extra-mesenteric nerve-sparing lymphadenectomy for those cases in which lateral node metastasis is detected in the CT scan. These authors reported a high level of sensitivity and accuracy (88%) of CT scans for detecting lateral node metastasis, in marked contrast to their diagnostic accuracy for mesorectal lymph node involvement. This same group has published a recent review of lateral lymph node spread in a Japanese journal, emphasizing in particular the rates (20%) of lateral node involvement in T3-T4 cases of low rectal cancer with positive mesorectal nodes. Similarly, Min *et al.*^[60] reserved EL for cases in which high-resolution MRI detected extra-mesenteric lymph node metastasis. These authors found a positive predictive value of MRI of 86.4% and 40% for the lateral and paraaortic nodes respectively, and that the location of the lymph node metastasis was the only prognostic factor for cancer-specific survival, with disease in the paraaortic area indicating a worse prognosis than lateral or mesenteric involvement. This suggestion accords with the recommendation in the Guidelines 2000 for Colon and Rectal Cancer Surgery that dissection should be attempted to remove clinically suspected lateral lymph node disease, as far as is technically feasible^[61].

A different approach would be to consider EL in various combinations with RT. In the only randomized control trial of EL ($n = 23$) versus non-EL ($n = 22$) after preoperative RT (50 Gy) in both groups, Nagawa and colleagues^[62] reported no difference in disease-free survival or local recurrence. However, given the small sample size and the fact that the study did not include patients with lateral pelvic lymph node involvement, no safe conclusion can be drawn on the role of either RT or EL in this particular group of patients. Wanatabe *et al.*^[63] in a retrospective non-randomized study of four patient groups comparing EL with non-EL using either 50 Gy pre-operative RT or no RT found a 5-year survival advantage in the RT group. In addition, the authors reported no significant survival difference between the patients who had preoperative RT with conventional TME surgery compared with those who had EL without preoperative RT, and concluded that preoperative RT could be an alternative to EL.

A comparative non-randomized study by Kim *et al.*^[64] recently reported a higher local recurrence rate in patients with TME plus EL than in those with TME plus postoperative CRT. Among those with stage III lower rectal cancer, they successfully demonstrated that the EL group showed a 2.2-fold increase in local recurrence rate compared to the CRT group. However, the 5-year LR rate in stage III in the EL group was much higher than the rate previously reported by the same Japanese group (16.7% *vs* 7.4%), therefore either a patient selection bias or a different definition of LR cannot be ruled out in this study.

A recent meta-analysis^[65] comparing EL and non-EL TME surgery showed no overall difference in cancer-specific outcomes (5-year survival, 5-year disease-free survival and local or distant recurrence). However, as the authors state, the question of whether EL provides benefits in terms of survival or just local control in a subset of

Table 2 Relative incidence of sub-site locations of pelvic recurrences

| Authors (yr) | Treatment | Axial or central (%) | | | | Lateral (%) | Other (%) |
|--|-----------------|-------------------------------|--------------------------|-----------------------|-----------------|-----------------|-----------|
| | | Anastomotic (perianastomotic) | Anterior (genitourinary) | Posterior (presacral) | Perineal | | |
| Gunderson <i>et al</i> ^[31] | Pre-TME surgery | - ¹ | 40 | 19 | 31 | 10 | |

APR: Abdominoperineal resection; Anast: Anastomotic; perin: Perineal; Ant: Anterior. ¹0% were APR; ²Post + perineum; ³Anast + ant; ⁴Perin + ant + anast; ⁵Axial o central; ⁶20% ipsilateral and 20% contralateral. TME: Total mesorectal excision; sRT: Short-term preoperative radiotherapy; EL: Extended lymphadenectomy; CRT: Chemoradiotherapy.

patients with advanced rectal cancer could not be safely answered by this meta-analysis.

PATTERNS OF RECURRENCE AFTER INTRA-OPERATIVE RADIOTHERAPY PLUS EXTENDED SURGERY

Several authors reported the impact of intra-operative radiotherapy (IORT) with or without preoperative external beam irradiation and surgical resection in patients with locally advanced or recurrent cancer. The overall available data on IORT showed a favorable impact on local control and in overall survival for patients resected for cure (R0, R1); However, there is a need for randomized studies of the effect of IORT. From a Dutch national referral center, the pattern of LR in 247 patients with locally advanced rectal carcinoma after IORT including multimodal treatment (preoperative CRT and extended surgery) has been analyzed in detail^[55]. The 5-year LR rate was 13.2% (7.5% after R0 resections). The most prominent sites of LR were the presacral (44%) followed by the anterior (21%) subsites and lateral spread accounted for less than 10% of recurrences. Around 50% of the LRs appeared in the IORT field, particularly high rates of infield recurrences being observed after dorsal IORT (75%). The authors hypothesize that migration of remaining tumor cells to the presacral space would explain the occurrence of this LR.

PATTERNS OF RECURRENCE FOLLOWING COMPLETE CLINICAL RESPONSE AFTER CRT

The definitive role of an initially non-surgical approach to treatment following complete clinical response (cCR) after CRT has not yet been determined and no definitive conclusions can be drawn before long-term results concerning LR and distant failure are available.

However, Habr-Gama *et al*^[66] have reported the pattern of recurrence and survival of 99 patients with distal rectal cancer (0-7 cm) and cCR following adjuvant CRT, sustained for at least 12 mo, managed by initial non-operative treatment. They observed 13 recurrences: five endorectal (limited to the rectal wall), seven systemic, one combined (endorectal and distant), and no pelvic recurrence outside the rectal wall was detected. There were no significant clinical differences either between patients with and without recurrence, or these same patients according to the location of the recurrence. Surprisingly, systemic recurrence occurred sooner than LR. The authors suggest that a change in the approach to follow-up monitoring may be necessary.

CLOSING REMARKS

The reported patterns and rates of local recurrence, after the aforementioned range of treatment approaches to rectal cancer, used in isolation and as combined therapies are summarized in Table 1. Overall, combining therapies reduces LR rates, delays the appearance of LR and means that when there is recurrence it is less often isolated than after surgery alone.

Table 2 lists the relative frequency of LRs in various pelvic subsites. In recent years, a subtle change has been observed in the distribution of LRs in terms of location within the pelvis, implying the involvement of a different mechanism in their development. In general terms, in the pre-TME years most recurrences were central, perianastomotic and anterior and since the adoption of combined therapies lateral and posterior (presacral) forms dominate. However, the LR distribution is not only related to therapy modality but also to the height of the tumor. LRs in the upper rectum are relatively rare, but when they do occur are usually perianastomotic, originating in the residual mesorectal fatty tissue (as they are treated with partial mesorectal excision, transecting the rectum at about 5 cm below the tumor), and are comparatively more common when only surgical treatment is used. This suggests that while

preoperative RT helps to prevent LR at all sites, it is especially effective in preventing anastomotic recurrences^[67]. Isolated anastomotic recurrences are also seen in select cases of very low rectal cancer treated using intersphincteric resection (ISR)^[68]. Surgical technique and attention to distal margin can also play a role in preventing this type of LR. The LR rate after ISR is higher in poorly selected cases of pT3 with no previous RT, due to accidental tumor spillage into the intersphincteric space or positive CRM^[69]. A lower LR rate has been reported with stapled coloanal anastomosis than for ISR even in T1-T2 patients^[70]. As expected, after transanal endoscopic microsurgery, intramural recurrence is the most common type of LR^[71].

Most local recurrences of mid-rectal cancers treated with RT or CRT + TME are related to the advanced nature of the disease. Tumor height of 5 cm or more is associated with a higher incidence of presacral and lateral LR^[72]. If the CRM is found to be positive after CRT, the hazard ratio for LR after surgery is significantly higher than if the CRM is involved when no preoperative CRT has been administered (6.3 *vs* 2.0), possibly because of selection of a population of tumor cells that are resistant to therapy^[73]. LR may also sometimes occur even in the absence of an involved CRM possibly owing to lymphatic spread from the distal rectum to lymph nodes in the pelvic side wall^[57]. Unilateral EL (lateral lymph nodes on one side of the pelvis are left intact) result in more LR than bilateral ELs, and it has been suggested that the mechanism for the formation of posterior-lateral recurrences may be the migration of tumor cells through the lateral lymphatic vessels to the presacral space under gravity^[55]. This would explain why presacral local recurrence is more common in advanced disease than in limited disease.

The highest rates of positive CRM are found with low-rectum tumors. Indeed, TME surgery is not a universal solution for all rectal carcinomas: in low rectal cancer TME may be insufficient to obtain the desired circumferential clearance because of this lack of mesorectum at the level of the pelvic floor. On the other hand, APR surgery mainly results in perineal and presacral LR, which may be prevented by a wider resection^[57].

The pelvic pattern of recurrence itself (i.e. pelvic subsites) also has important prognostic value and is related to the potential success of repeat curative intent surgery^[74,75]. The operability for cure and prognosis for anastomotic and anterior recurrence are generally better than for presacral and lateral recurrences^[75]. Moreover, the upper sacral/lateral invasive type of LR is often associated with synchronous metastatic disease^[74]. The type of pelvic invasion is also closely associated with survival after re-resection^[74-76]. Finally, it is worth noting that overall survival after LR diagnosis is lower with RT and CRT+TME approaches, than after TME surgery alone^[74].

Abstract

Hepatocellular carcinoma (HCC) is one of the most common malignancies, ranking the sixth in the world, with 55% of cases occurring in China. Usually, patients with HCC did not present until the late stage of the disease, thus limiting their therapeutic options. Although surgical resection is a potentially curative modality for HCC, most patients with intermediate-advanced HCC are not suitable candidates. The current therapeutic modalities for intermediate-advanced HCC include: (1) surgical procedures, such as radical resection, palliative resection, intraoperative radiofrequency ablation or cryosurgical ablation, intraoperative hepatic artery and portal vein chemotherapeutic pump placement, two-stage hepatectomy and liver transplantation; (2) interventional treatment, such as transcatheter arterial chemoembolization, portal vein embolization and image-guided locoregional therapies; and (3) molecularly targeted therapies. So far, how to choose the therapeutic modalities remains controversial. Surgeons are faced with the challenge of providing the most appropriate treatment for patients with intermediate-advanced HCC. This review focuses

on the optional therapeutic modalities for intermediate-advanced HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the sixth most common cancer in the world and the third most common cause of cancer-related death^[1]. Patients at the early stage are those who present with an asymptomatic single HCC with the nodule < 5 cm in diameter or ≤ 3 in number. Patients exceeding these limits, but free of cancer-related symptoms and vascular invasion or extrahepatic spread, are considered at the intermediate stage. The patients with the cancer-related symptoms and vascular invasion or extrahepatic spread are deemed at the advanced stage. HCC is frequently diagnosed at the late stage and has a high mortality rate. Surgical resection is a potentially curative therapy for HCC, however, only 10%-30% of patients with HCC are eligible for curative hepatectomy. Comprehensive therapy for HCC has become the focus of interest in recent years^[2-6]. The current therapeutic modalities

for intermediate-advanced HCC are collected and evaluated as follows.

SURGICAL PROCEDURES

Radical resection is still the first choice for treatment of HCC^[7,8], even at the intermediate or advanced stage^[9,10]. If radical resection is impractical, palliative resection combined with comprehensive therapy can significantly prolong patients' survival time^[11,12]. Intraoperative comprehensive therapy includes radiofrequency ablation, cryosurgical ablation, and hepatic artery and portal vein chemotherapeutic pump placement. Two-stage hepatectomy can improve the survival rate in selected patients with advanced HCC^[13,14]. Liver transplantation has been shown to achieve excellent survival rate in appropriate HCC patients^[15,16].

Radical resection

Radical resection for intermediate-advanced HCC is indicated as follows: (1) single HCC with large or huge tumor nodule, swelling outward, clear border or pseudocapsule, and less than 30% hepatic tissue destroyed measured by computed tomography (CT) or magnetic resonance imaging (MRI) scan, or more than 50% compensatory hepatic hypertrophy; (2) multiple HCC with 3 or fewer nodules localized in one lobe or segment of the liver^[17,18]. It should be pointed out that tumor nodules limited to the liver are not the absolute operative indication. The outcome of radical resection could be affected by multicentric occurrence of HCC, tumor nodule adjacent to major blood vessel or bile duct, and the hepatic insufficiency induced by coexisting cirrhosis^[19].

With the deeper recognition of the pathology of HCC, the rational criteria of negative surgical margin are initially determined as follows: (1) > 2 cm margin free from tumors < 5 cm in diameter; (2) > 1 cm margin free from tumors 5-10 cm; and (3) > 0.5 cm margin free from tumors > 10 cm. More than 90% hepatectomies fulfilling the above-mentioned criteria can achieve negative surgical margin^[20]. Thereby, healthy hepatic tissue should be reserved as much as possible during radical resection so as to enhance the operative security, to facilitate the postoperative recovery and to help with further treatment.

Palliative resection

The indications of palliative resection for intermediate-advanced HCC are: (1) multiple HCC with 3-5 tumor nodules, exceeding half of the liver; (2) multiple HCC with nodules localized in 2-3 adjacent segments or half of the liver, more than 50% compensatory hypertrophy in the tumor-free liver demonstrated by image examinations; (3) central HCC with more than 50% compensatory hypertrophy in the tumor-free liver; (4) hilar lymph node metastasis should be cleared up during hepatectomy; and (5) invaded organs around the liver, such as colon, stomach, diaphragm, right adrenal gland, *etc.*, and single metastatic neoplasm far from the liver (e.g. lung metastasis) should be resected^[17].

Intraoperative radiofrequency ablation

Radiofrequency ablation (RFA) is a technique in which an electromagnetic energy deposition is used to thermally ablate the hepatic tumor tissue^[21]. During RFA treatment, heat energy generated by high-frequency alternating currents targeted at the living tissues causes protein denaturation at a temperature of 60-110°C through ionic vibration, resulting in coagulative necrosis of the target lesion. In addition, RFA treatment stimulates the immune system and provides an easy way to achieve *in vivo* vaccination against tumoral antigens^[22].

RFA is generally indicated for HCC patients who are not candidates for either liver resection or transplantation^[23]. HCC patients are required to have ≤ 5 nodules, each < 3 cm in diameter, no evidence of vascular invasion or extrahepatic spread, 0 score performance status of the Eastern Cooperative Oncology Group (ECOG), and liver cirrhosis in Child-Pugh class A or B. The more versatile radiofrequency probes allow ablation of nodule > 5 cm. When complete resection by major hepatectomy is dangerous because of difficult nodule location, selective use of intraoperative RFA will be helpful^[24]. The integration of intraoperative RFA into resection surgery contributes to complete removal of nodules with adequate margin, diminishes the extent of parenchymal resection, and improves the resectability rate for patients with advanced HCC^[24].

Pretreatment imaging must carefully define the location of tumor nodule with respect to the surrounding structures for RFA in HCC: nodules located on the surface of the liver can be considered; nodules adjacent to the hepatic vessels may be considered because flowing blood usually protects the vascular wall from thermal injury; nodules adjacent to the hepatic hilum represents a relative contraindication due to the risk of thermal injury of the biliary tract; and nodules adjacent to any part of the gastrointestinal tract must be avoided^[25].

Intraoperative cryosurgical ablation

Although RFA has been the most widely utilized ablation modality for HCC, cryosurgical ablation has several advantages (most significantly, the ability to produce larger and more precise zones of ablation) over RFA^[26].

Cryosurgical ablation for HCC patient relies on nonspecific tissue necrosis due to freezing as well as microvascular thrombosis. Argon-helium cryosurgical ablation is able to induce the necrosis of tumor cells through the formation of extracellular and intracellular ice crystals and then cell dehydration due to rapidly freezing (< -140°C) as well as rapidly thawing (20-40°C) the tumor tissues with argon/helium gas. Therefore, argon-helium cryosurgical ablation has become one of the major therapeutic approaches for unresectable intermediate-advanced HCC.

The indications of cryosurgical ablation for HCC patient are: (1) nodules < 5 cm in diameter, ≤ 3 in number; (2) nodule > 5 cm with irregular margin, may be given intraoperative cryosurgical ablation with or without excision of nodule. Intraoperative cryosurgical ablation offers

an effective and safe option for management of advanced HCC^[27]. HCC patients with diffuse infiltrative disease or large bilobar nodules (> 50% of liver volume) are not candidates for cryosurgical ablation because complete ablation of the nodules might induce hepatic failure.

Intraoperative hepatic artery and portal vein chemotherapeutic pump placement

The liver has a dual blood supply from the hepatic artery and the portal venous system. For HCC patients who are not suitable for hepatectomy confirmed by intraoperative exploration, two chemotherapeutic pumps could be implanted subcutaneously into the upper abdominal wall near the incision, with the tip of pump catheter separately inserted into the hepatic artery and portal vein during the operation, followed by postoperative chemotherapy. The advantage of intraoperatively implanted chemotherapeutic pump is the ability to accurately and selectively place into the main trunk or branch of hepatic artery and portal vein. For resectable intermediate-advanced HCC, the postoperative hepatic artery and portal vein dual perfusion chemotherapy *via* chemotherapeutic pumps could prevent tumor recurrence^[28].

Two-stage hepatectomy

Two-stage hepatectomy has been developed as a surgical strategy for extremely difficult patients with intermediate-advanced HCC^[7]. This strategy is applied when it is impossible to resect the tumor in a single procedure. The main principles of this strategy are: huge HCC with the remnant liver volume cannot maintain hepatic function after hepatectomy; central or hilar HCC adjacent to or invaded major blood vessel; and serious cirrhosis with possible hepatic decompensation after hepatectomy.

For unresectable HCC, preoperative intervention with transcatheter arterial chemoembolization (TACE)^[29], portal vein embolization (PVE)^[30,31], or percutaneous RFA could control tumor progression and invasion, downstage tumor status, increase remnant liver volume, and decrease tumor recurrence rate, thus making the two-stage hepatectomy possible. The indication of two-stage hepatectomy is that tumor diameter reduced to 50% of the initial size, and nontumorous liver tissue had significant compensatory hyperplasia. Sequential TACE and PVE could broaden the surgical indication and the safety of major hepatic resection for advanced HCC patient with damaged liver^[32,33].

Non-anatomic local excision of liver cancer or hepatic segmentectomy should be used in the two-stage hepatectomy so as to maximally preserve the normal liver tissue. For the patients with HCC invading the hepatic hilum and inferior vena cava, total hepatic vascular exclusion (HVE) should be prepared to avoid massive hemorrhage during hepatectomy.

Liver transplantation

Liver transplantation is an ideal treatment option, as it simultaneously cures HCC. However, up to date, there are no uniform criteria of liver transplantation for HCC

patients in China. The United Network for Organ Sharing (UNOS) criteria for liver transplantation are usually adopted in the world: single tumor ≤ 5 cm; 2-3 tumors, each ≤ 3 cm; no macrovascular invasion; and no extrahepatic spread to surrounding lymph nodes, lungs, abdominal organs, or bones^[34]. However, if the UNOS criteria are strictly adopted in China, it means that most HCC patients will lose the opportunity of liver transplantation, because more than 100 000 patients die of advanced HCC each year. For this reason, the indication of liver transplantation for advanced HCC should be relatively loose in China. For the patients with unresectable huge or multiple HCC, if no vascular invasion and no extrahepatic spread, liver transplantation is the treatment of choice. Considering the limited organ supply, high cost, and considerable risk, we suggest that only those HCC patients with a high probability of survival benefit should be selected to receive liver transplantation. The shortage of donor livers is the major constraint of liver transplantation.

INTERVENTIONAL TREATMENT

Although surgical resection has been the first choice for treatment of HCC, a simple surgical exploration could accelerate the process of disease and even cause death due to the postoperative complication of patients with unresectable HCC. With advances of medical imaging and improvement of interventional technology, interventional treatment has become an effective approach to inoperable HCC^[35-37]. The common approaches of interventional treatments for inoperable HCC include transcatheter arterial chemoembolization, portal vein embolization, and image-guided locoregional therapies.

Transcatheter arterial chemoembolization

For the treatment of inoperable HCC demonstrated by preoperative image examination, the priority is transcatheter arterial chemoembolization (TACE). The theoretical basis of TACE is the special vascular supply of liver and HCC. Liver derives dual blood supply from portal vein and hepatic artery, the former accounts for 2/3 to 3/4 while the latter for only 1/4 to 1/3. HCC derives 90% blood supply from hepatic artery and only 10% from portal vein. Thus, TACE provides a higher local concentration of chemotherapeutic drugs into tumor compared with intravenous perfusion chemotherapy, and meanwhile, it blocks blood supply of HCC, but only exerts little influence on blood supply of the liver. The consequence is that the major portion of cancer nodule becomes necrotic, while hepatic function remains unchanged or little impaired.

Better patient selection and selective segmental chemoembolization may improve the benefit-risk ratio of TACE^[38]. TACE is indicated in intermediate-advanced HCC even in the setting of portal vein involvement (excluding main portal vein)^[39]. The presence of main portal vein thrombosis, extrahepatic metastasis, Child-Pugh class C liver function, and severe hepatic arterio-portal shunts is considered as contraindications for TACE.

Portal vein embolization

Percutaneous transhepatic portal vein embolization (PVE) is a useful procedure for the preoperative intervention of advanced HCC patients selected for hepatectomy. PVE could increase the volume and function of the future remnant liver through the acceleration of hepatocyte proliferation, and embolize possible hepatic arterio-portal shunts, so as to prevent postoperative liver insufficiency.

For the treatment of intermediate-advanced HCC, the combination of TACE and PVE not only blocks most blood supply of main tumor and satellite lesions, but also increases the local concentration of chemotherapeutic drugs into tumor, so as to more effectively control the tumor growth and decrease tumor recurrence. Contraindications to PVE include distant metastases, uncontrolled coagulopathy, active cholangitis, portal hypertension, and renal failure^[40].

Image-guided locoregional therapies

Ultrasound or CT guided locoregional therapies have a therapeutic effect in advanced HCC patients by means of thermoablative therapy (radiofrequency ablation, microwave coagulation, laser ablation), cryotherapy (argon-helium knife, liquid nitrogen), or chemical therapy (ethanol injection, acetic acid injection) to destroy tumor tissues. To date, the commonly used therapies include percutaneous RFA, microwave coagulation, cryoablation therapy, and ethanol injection, especially with percutaneous RFA as the first choice to inoperable HCC. The roles of different locoregional therapies may change with further development of technology and availability of data from future prospective randomized trials^[38,41-43].

MOLECULARLY TARGETED THERAPIES

Recently, molecularly targeted therapies, including sorafenib, sunitinib, brivanib, cetuximab, erlotinib plus bevacizumab, and lapatinib, have emerged as promising therapeutic approaches for advanced HCC^[44,45]. Sorafenib, as an orally-active multikinase inhibitor targeting both tumor cells and the tumor vasculature, and the first agent to improve the overall survival status for patients with advanced HCC, has been approved for systemic therapy in patients with advanced HCC in Eastern and Western countries^[3,46-48]. Many other molecularly targeted agents of blocking epidermal growth factor receptor (EGFR), vascular endothelial growth factor receptor (VEGFR), platelet-derived growth factor receptor (PDGFR), and mammalian target of rapamycin (mTOR) are at different stages of clinical development for the treatment of advanced HCC^[49-51].

CONCLUSION

For the treatment of intermediate-advanced HCC, various surgical procedures may produce the definite therapeutic effects. The interventional treatment can also improve the prognosis to a great extent, but so far there is still lack of a special effective approach. In recent years, the model of comprehensive therapies mainly based on surgical

resection has been adopted to further enhance the curative effect, prolong the survival time, and improve the life quality of the patients. According to the indications and advantages of each therapeutic method, combined with the patient's clinical stage, the selection of therapeutic approaches to maximize the efficacy and minimize the adverse effect is very important for designing a more rational therapeutic plan for intermediate-advanced HCC.

Abstract

Atrophic gastritis, is the main consequence of long-standing *Helicobacter pylori* infection, and is linked to the development of gastric cancer. The severity of atrophic gastritis is related to the lifetime risk of gastric cancer development, especially in terms of its degree and extent of mucosal damage. Therefore, it is important for clinicians to assess the severity of atrophic gastritis, interfere with the disease progress, and reverse gastric mucosal atrophy. In the article, we demonstrated some methods (conventional endoscopy, modern endoscopic technology and noninvasive methods) that may help assess the severity of atrophic gastritis and select the reasonable treatment protocols.

INTRODUCTION

Atrophic gastritis (AG) is a histopathological entity that is characterized by chronic inflammation of the gastric mucosa with loss of gastric glandular cells and replacement by intestinal-type epithelium, pyloric-type glands, and fibrous tissue. Atrophy of the gastric mucosa is the endpoint of chronic processes, such as chronic gastritis associated with *Helicobacter pylori* (*H. pylori*) infection, other unidentified environmental factors, and autoimmunity directed against gastric glandular cells^[1]. It has been established that people with AG have a high risk for gastric cancer^[2,3], and it has been reported that about 10% of the patients with moderate-severe AG will develop gastric malignancies during a mean follow-up of 7.8 years^[4]. Thus, the assessment of the severity of AG may be an important challenge for the management of these patients because its features (i.e. extension of atrophy and intestinal metaplasia, and hypochlorhydria) may be considered as potential surrogate markers for the increased risk for gastric cancer. Here, we demonstrate some methods used to assess the severity of AG.

DEFINITION AND CLASSIFICATION OF AG

Gastric mucosal atrophy is defined as the loss of appropriate glands, which occurs when glands damaged by inflammation are replaced either by connective tissue (scarring) or by glandular structures inappropriate for location (metaplasia). Most often, as in the antral mucosa, the metaplastic transformation assumes the phenotype of the glands lined by intestinal-type epithelium (IM), but in the oxyntic mucosa, it may also take the form of mucin-secreting antral glands (pseudopyloric metaplasia)^[5]. Traditionally, AG can be divided into gastric body atrophy

and sinuses ventriculi atrophy: the former is mostly associated with autoimmune diseases, and the latter is often associated with *H. pylori* infection^[6,7]. However, in general practice, the diagnosis of atrophy and IM is troublesome due to an unsatisfactory interobserver agreement among pathologists, therefore in 2000, an international group of pathologists from Atrophy Club reviewed once again the spectrum of gastric atrophy and IM, and proposed a simplified definition of atrophy, which includes a metaplastic and a non-metaplastic category, thus making metaplasia an absolute concept to demonstrate the severity of the disease^[5].

CONVENTIONAL ENDOSCOPY AND AG

In 2003, the Chinese Society of Digestive Endoscopy established endoscopic criteria for chronic gastritis in Dalian meeting. The scar lesions were characterized by the following attributes: mucosal atrophy, granular mucosa, flattened folds, gray intestinal-type epithelium and blood vessel permeability. AG was classified into three patterns of ridges: (1) fine granular mucosa, permeability of some blood vessels and a single nodule of gray intestinal-type epithelium; (2) medium granular mucosa, permeability of blood vessels, multiple nodules of gray intestinal-type epithelium; and (3) coarse granular mucosa, blood vessels can be seen up to the surface, diffuse nodules of gray intestinal-type epithelium^[8].

MAGNIFYING ENDOSCOPY AND AG

Magnifying endoscopy has been developed to visualize the microstructure of gastrointestinal surface mucosa and mucosal vascularity, which provides a magnified image of up to 200 times^[9]. The pit patterns observed on the mucosal surface are considered to reflect the arrangement and structure of surface epithelia, morphology, number, distribution and function of glands, mucosal edema and inflammation, and vascular morphology, arrangement, number and distribution. The basic units of the microstructures on the surface of gastric mucosa are countless gastric pits that form gastric areas separated by minor gastric grooves (also called interval grooves). As the openings of glands, gastric pits are the first to undergo structural change due to gastric mucosal lesions. Yagi *et al*^[10] thought that the presentation of gastric mucosal atrophy was that gastric pit became white, expanded in size, and was surrounded by areas of erythema. In the study of Sakaki *et al*, magnifying endoscopy patterns of gastric erosion pits were classified into six types: A (round spot pits), B (short rod pits), C (sparsely and thickly linear), D (patchy), E (villous) and F (unclear or disappearance of pits or abnormal hyperplasia blood capillary)^[11]. Yuan *et al*^[12] used magnifying endoscopy in combination with methylene blue staining to examine the microstructures of gastric mucosa in 180 patients with gastric erosion. Their results showed that types A and B were found in normal gastric mucosa, while types C-F were found in gastric mucosa with active inflammation, atrophic

inflammation, intestinal metaplasia and dysplasia of varying degrees. Type E mucosa (81.8%) suggested intestinal metaplasia, type F indicated existence of dysplasia (86.3%), and type F with abnormal hyperplasia blood capillary suggested dysplasia (89.9%).

MAGNIFYING NARROW-BAND IMAGING AND AG

Narrow-band imaging (NBI) is an endoscopic imaging technique for the enhanced visualization of mucosal microscopic structure and capillaries of the superficial mucosal layer. Images are obtained using narrower bands of red, blue and green filters, which are different from conventional red-green-blue filters^[13]. Combining the NBI system and magnifying endoscopy allows for simple and clear visualization of microscopic structures of the superficial mucosa and its capillary patterns^[14]. In the study of Tahara *et al*^[15], gastric mucosal patterns seen with magnifying NBI in uninvolved gastric corpus were divided into the following categories: normal small, round pits with regular subepithelial capillary networks; type 1, slightly enlarged, round pits with unclear or irregular subepithelial capillary networks; type 2, obviously enlarged, oval or prolonged pits with increased density of irregular vessels; and type 3, well-demarcated oval or tubulovillous pits with clearly visible coiled or wavy vessels. They found that the mucosal patterns were associated with the degree of endoscopic gastric atrophy. As mucosal patterns advanced from normal to types 1, 2 and 3, the degree of endoscopic gastric mucosal atrophy increased simultaneously. The sensitivity and specificity for types 1, 2 and 3 for detection of *H. pylori* infection and type 3 for detection of intestinal metaplasia were 95.2%, 82.2%, 73.3%, and 95.6%, respectively. Uedo *et al*^[16] found in their study that the appearance of a light blue crest on the epithelial surface was correlated with histological evidence of intestinal metaplasia with a sensitivity of 89% (95% CI: 83-96), specificity of 93% (95% CI: 88-97), positive predictive value of 91% (95% CI: 85-96), negative predictive value of 92% (95% CI: 87-97), and accuracy of 91% (95% CI: 88-95).

AUTO-FLUORESCENCE IMAGING VIDEOENDOSCOPY AND AG

Auto-fluorescence imaging (AFI) produces real-time pseudocolor images based on natural tissue auto-fluorescence emitted by light excitation from endogenous fluorophores such as collagen, nicotinamide, adenine dinucleotide, flavin and porphyrins. AFI enables the detection of mucosal features not visible with conventional endoscopy, therefore, it might improve the identification and characterization of the premalignant status in gastric mucosa^[17,18].

The fluorescence is almost purple, weaker in the normal gastric gland mucosa than that in the pyloric gland mucosa.

When gastric mucosa is atrophic, the color is green, which is the same as that in the pyloric gland mucosa. Gastric biopsy is taken separately from purple and green region for pathological studies, and the green region is significantly increased in AG and intestinal metaplasia^[19]. The extent of chronic atrophic fundal gastritis (CAFG) was considered to be the green areas in the gastric body and was classified into six categories by Inoue *et al.*^[20]: AF-C-I, the entire gastric body appears purple to dark green; AF-C-II, a color border on the lesser curvature was observed at a lower part of the gastric body; AF-C-III, a color border on the lesser curvature at an upper part of the gastric body; AF-O-I, a color border between the lesser curvature and the anterior wall; AF-O-II, a color border between the anterior wall and the greater curvature; and AF-O-III, a color border on the greater curvature proximal to the lower gastric body. They found that the diagnostic accuracy of green areas in the gastric body of the patients in the activity, inflammation, atrophy and intestinal metaplasia was 64%, 93%, 88% and 81%, respectively. However, the diagnostic accuracy of AFI was not compared with that of white-light images in relation to the histology. Therefore, whether the accuracy of AFI is superior to that of white-light images is not known.

SERUM BIOMARKERS AND AG

Pepsinogen I and II

Pepsinogens (PGs) are aspartic proteinases that are mainly secreted by gastric cells. They can be immunologically classified into two major types: pepsinogen I (PG I) and pepsinogen II (PG II). PGI is secreted only from the gastric fundic mucosa, whereas PG II is secreted from the cardiac, fundic and antral mucosa of the stomach, and also from the duodenal mucosa^[21]. Patients with gastric fundic atrophy have a lower mean serum PG I concentration than those without atrophy. Both mucosal types secrete PG II, however, serum PG II levels remain stable or are increased during progression from a normal stomach to one with severe atrophy^[22]. The net effects of severe atrophy on serum PG concentrations are lower PGI and a stable or increased PG II, and this leads to a lower PG I / II ratio^[22]. Ren *et al.*^[23] have confirmed a strong association between gastric fundic atrophy and PGs, as estimated by a low serum PGI and PG I / II ratio in a prospective study. They have found that compared to the subjects with a PG I / II ratio of > 4, those with a ratio \leq 4 had hazard ratios (HRs) of 2.72 (95% CI: 1.77-4.20) and 2.12 (95% CI: 1.42-3.16) for non-cardiac and cardiac gastric adenocarcinoma, respectively. Storskrubb *et al.*^[24] found that the phenotype of gastritis is characterized by normal levels of serum PGs (PG I \geq 25 ng/mL and PG I / PG II ratio \geq 3 indicate that the corpus mucosa is normal). For the diagnosis of atrophic corpus gastritis, three different criteria have been used as follows^[25-27]: Mild: PG I \leq 70 ng/mL and PG I / II ratio \leq 3.0; Moderate: PG I \leq 50 ng/mL and PG I / II \leq 3.0; Strict: PG I \leq 30 ng/mL and PG I / II \leq 2.0. Both cut-offs for PG I and PG I / II should be fulfilled at the same time for each criterion.

Gastrin-17

Gastrin-17 (G-17) is secreted exclusively by the G-cells of

the gastric antrum. The levels of G-17 are depressed in cases of atrophy in this area^[28]. Leja *et al.*^[29] found that G-17 < 5 pmol/L is related to atrophy in the antral region ($P = 0.007$) with a 36.8% sensitivity and a 86.5% specificity. They indicated that G-17 used for the detection of atrophy in the antral part of the stomach requires further evaluations due to its low sensitivity.

H. pylori testing

H. pylori is now recognized as a major cause of gastric cancer and is classified as a group I carcinogen by the WHO^[30,31]. *H. pylori* infection causes persistent chronic gastritis, which in susceptible individuals can progress to atrophy, intestinal metaplasia and dysplasia, and finally, intestinal-type gastric cancer^[31,32]. Nearly all infected individuals (> 90%) exhibit *H. pylori*-specific IgG antibodies. Most (70%) of these individuals also exhibit IgA antibodies and *H. Pylori* proteins, including cytotoxin-associated gene A (CagA) protein and vacuolating cytotoxin A (VacA) protein. These proteins are used for *H. pylori* testing. A combined use of the serological biomarkers (PGI, PGII, G-17 and *H. pylori* antibodies) shows a high accuracy as a noninvasive method to diagnose gastric atrophy, which is common in the general population^[23,24,33].

CONCLUSION

In the cases of AG, its severity is mainly related to the lifetime risk to develop gastric cancer, especially in terms of the degree and extension of mucosal damage. The application of conventional endoscopy, modern endoscopic technology and noninvasive methods is useful for the identification of those patients with atrophic gastritis at higher risk for gastric malignancies. Using these technologies to assess the severity of atrophic gastritis, interfering with the disease progress, and reversing gastric mucosal atrophy are the important issues for clinicians.

Abstract

AIM: To determine the effect of Legalon-SIL (LS) on hepatitis C virus (HCV) core and NS5A expression and on heme oxygenase-1 (HMOX-1) and its transcriptional regulators in human hepatoma cells expressing full length HCV genotype 1b.

METHODS: CON1 cells were treated with 50 $\mu\text{mol/L}$ or 200 $\mu\text{mol/L}$ LS. Cells were harvested after 2, 6 and 24 h. HCV RNA and protein levels were determined by quantitative real-time polymerase chain reaction and Western blotting, respectively.

RESULTS: HCV RNA (core and NS5A regions) was

decreased after 6 h with LS 200 $\mu\text{mol/L}$ ($P < 0.05$). Both 50 and 200 $\mu\text{mol/L}$ LS decreased HCV RNA levels [core region (by 55% and 88%, respectively) and NS5A region (by 62% and 87%, respectively) after 24 h compared with vehicle (dimethyl sulphoxide) control ($P < 0.01$). Similarly HCV core and NS5A protein were decreased (by 85%, $P < 0.01$ and by 65%, $P < 0.05$, respectively) by LS 200 $\mu\text{mol/L}$. Bach1 and HMOX-1 RNA were also downregulated by LS treatment ($P < 0.01$), while Nrf2 protein was increased ($P < 0.05$).

CONCLUSION: Our results demonstrate that treatment with LS downregulates HCV core and NS5A expression in CON1 cells which express full length HCV genotype 1b, and suggests that LS may prove to be a valuable alternative or adjunctive therapy for the treatment of HCV infection.

INTRODUCTION

Over 170 million people are infected by hepatitis C virus (HCV) worldwide, and of these, approximately 85% will develop chronic hepatitis C (CHC). This could potentially

lead to fibrosis, cirrhosis, end-stage liver disease and hepatocellular carcinoma^[1]. The ultimate goal of antiviral treatment for hepatitis C is the sustained elimination of HCV. Currently, the standard of care for individuals with CHC is pegylated interferon (IFN) α -2a or IFN α -2b plus ribavirin. However, this protocol is far from ideal. Even under the best conditions of sponsored clinical trials, sustained virologic responses have been achieved in only 40%-50% of those with HCV genotype 1 infection^[2,3]. Furthermore, serious side effects are associated with this therapy. The paucity of effective and affordable treatments for HCV-infected patients has led scientists to seek alternative therapies. At present, novel therapeutic agents with various mechanisms of action are under development or in clinical trials.

Although the precise mechanisms underlying hepatocellular injury associated with HCV has yet to be determined, there is compelling evidence that HCV produces increased oxidative stress in human liver cells that is linked to the production of reactive oxygen species (ROS), and consequent increases in cellular lipid peroxidation and other oxidative damage. Oxidative stress appears to be an important aspect of HCV-induced hepatocellular injury^[4]. Microsomal heme oxygenase-1 (HMOX-1) is an inducible cytoprotective enzyme that catalyzes the initial and rate-limiting reaction in heme catabolism to release free iron and equimolar amounts of carbon monoxide and biliverdin^[5,6]. A variety of DNA-binding proteins interact with regions that contain multiple antioxidant response elements (ARE). Among these are nuclear factor erythroid 2-related factor 2 (Nrf2) and Bach1, a leucine zipper transcription protein, which form heterodimers with the small Maf proteins^[7,8]. Nrf2 is known to be associated with activation of HMOX-1 and numerous other antioxidant genes in response to multiple agents^[9], while Bach1 is a negative regulator of HMOX-1^[10].

Milk thistle (*Silybum marianum*) has been used since ancient times as a liver tonic. Silymarin (SI), a purified extract of polyphenolic flavonoids isolated from milk thistle, is composed mainly of silychristin, silydianin, silybin A, silybin B, isosilybin A and isosilybin B. After oral administration, the SI flavonolignans are rapidly metabolized^[11]. Silybin (SBN) constitutes approximately 50% of SI and is the most biologically active component^[12]. A number of studies have shown that SI has potent antioxidant and immunomodulatory effects in addition to numerous metabolic actions that may contribute to its purported hepatoprotective actions^[13-15].

We recently showed that SI downregulates HCV RNA (core region) and protein in CNS3 cells that stably express HCV RNA core to the amino terminal of NS3 proteins^[16]. Another recent study *in vitro* showed that SI exerts antiviral and antiinflammatory effects in hepatoma cell lines expressing the HCV full length genome of genotype 2a^[17]. On the other hand, a randomized, double-blind, placebo-controlled study administering oral SI to CHC patients failed to show a significant effect on either serum aminotransferase levels or quality-of-life measures^[18].

Legalon-SIL (LS) is a form of SBN which is a water-soluble formulation of the dihydro-succinate sodium salt of SBN A and SBN B in equal proportion. Recent results

from a pilot study in patients with chronic HCV using LS indicate that some SI flavonolignans may have antiviral activity^[19]. In this study we assessed the effects of LS on HCV RNA and protein levels in cell lines expressing the full length genome of HCV genotype 1b. We also determined the effects of LS on HMOX-1, Bach1, and Nrf2 expression in these cells.

MATERIALS AND METHODS

Chemicals and antibodies

LS was obtained from Rottapharm-Madaus (Italy). Dimethyl sulphoxide (DMSO) was purchased from Thermo Fisher Scientific Inc (Rockford, IL, USA). A 100 mmol/L LS stock solution (molecular weight = 726) was prepared in DMSO and filtered through a 0.2 μ mol/L nylon filter. LS was prepared fresh just prior to use in each experiment. Mouse monoclonal antibody against HCV core protein was purchased from Abcam (Cambridge, MA, USA). Mouse monoclonal antibody against HCV NS5A was purchased from Virogen Corporation (Watertown, MA, USA). Rabbit polyclonal antibody against HMOX-1 was purchased from Stress Gene (Ann Arbor, MI, USA). Goat monoclonal antibody against Bach1, rabbit polyclonal antibody against Nrf2, and mouse anti-glyceraldehyde-3-phosphate dehydrogenase (GAPDH) monoclonal antibody were purchased from Santa Cruz Biotechnology Inc. (Santa Cruz, CA, USA). Enhanced chemiluminescence (ECL)-Plus Western blotting detection reagent was obtained from Amersham Biosciences (Piscataway, NJ, USA).

Cell cultures and treatments

Huh-7.5 and CON1 subgenomic genotype 1b HCV cell lines were from Apath LLC (St. Louis, MO, USA). Huh-7.5 is a highly permissive, IFN-cured Huh-7 human hepatocellular carcinoma cell line derivative. The CON1 cell line is a Huh-7.5 cell population containing the full-length HCV genotype 1b replicon.

Huh-7.5 and CON1 cells were maintained in Dulbecco's Modified Eagle's Medium (DMEM) supplemented with 10% fetal bovine serum, 100 U/mL penicillin, 100 μ g/mL streptomycin, and selection antibiotic for CON1 cells (750 μ g/mL G418).

Colorimetric MTT assay

Cellular proliferation of treated CON1 cells was assessed by measuring the conversion of MTT [3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyl tetrazolium bromide] to MTT formazan (Sigma-Aldrich). The absorbance was measured on a Synergy HT microtiter plate reader (Biotek Instruments, Winooski, VT, USA), at a wavelength of 570 nm with background subtraction at 690 nm. Decreases in absorption were taken as an index of decreased cellular proliferation.

Propidium iodide assay

The viability of CON1 cells treated with LS was also confirmed by the standard propidium iodide [(PI); Invitrogen,

USA)] assay. The experiment was performed according to the manufacturer's recommended protocol. CON1 cells were plated in 12-well plates 24 h before treatment and incubated at 37°C. LS was dissolved in DMSO and added to the cell culture medium. The effects of LS on cell viability were studied at various concentrations (0, 50, 100, 200, 300, 400 and 500) $\mu\text{mol/L}$ and at different time points (4, 8, and 24 h). Percent cell viability was determined by counting cell density in drug-treated cells and in DMSO-treated cells as control in the same incubation period [percentage of cellular viability = (total cell count-PI positive cell count)/total cell count*100]. All experiments were repeated 3 times.

RNA isolation and quantitative reverse transcriptase polymerase chain reaction

RNA from treated cells was isolated by TRIZOL reagent (Invitrogen). The RNA concentration and purity were determined by measuring absorbance at 260/280 nm. Reverse transcription was performed on 1 μg of total RNA to generate cDNA using the iScript cDNA Synthesis Kit (Bio-Rad Laboratories, Hercules, CA, USA). Quantitative real time reverse transcriptase (RT)-polymerase chain reaction (PCR) was performed using a CFX-96 Real-Time PCR Detection System (Bio-Rad Laboratories) and iQTM SYBR Green Supermix (Bio-Rad Laboratories). Sequence specific primers for HMOX-1, Bach1, and GAPDH were designed as described^[20]. Nucleotide sequences of other primers are as follows: NS5A: Forward primer, 5'-CG-GACGTAGCAGTGCTCACTTC-3' and reverse primer, 5'-TGATGAGCTGGCCAAGGAGG-3'; Nrf2: Forward primer, 5'-CCTTTCTCGCCTAGGCATCA-3', reverse primer, 5'-CCCTTCAGCTCTCCCTACCG-3'. Fold change values were calculated by comparative cycle threshold (Ct) value analysis after normalizing for the quantity of GAPDH mRNA in samples.

Protein preparation and Western blotting

Cells were grown to near confluence and washed with phosphate-buffered saline (PBS), lysed in a buffer containing 1% Triton X-100 with PBS and Halt Protease Inhibitor Cocktail (Pierce Chemicals, Rockford, IL, USA). Protein concentrations were measured using the bicinchoninic acid method. Total proteins (10 μg) were separated on 4%-12% gradient sodium dodecyl sulphate-polyacrylamide gel (Invitrogen Laboratories) and electrophoretically transferred onto an Immun-Blot PVDF (Invitrogen Laboratories). The membranes were blocked for 1 h in PBS containing 5% nonfat dry milk, and then incubated for 1 h with the primary antibody at room temperature. The dilutions of the primary antibodies were as follows: 1:1000 for anti-HCV core antibody; 1:1000 for anti-HCV NS5A antibody; 1:500 for anti-HMOX-1, and 1:1000 for anti-Bach1, anti-Nrf2, and anti-GAPDH antibody. After 4 washes with 0.1% Tween 20 in PBS (PBS-T), the membranes were incubated for 1 h with a secondary antibody (anti-rabbit, anti-goat or anti-mouse immunoglobulin G; dilution 1:10000). Finally, the membranes were washed 4 times with PBS-T, and the

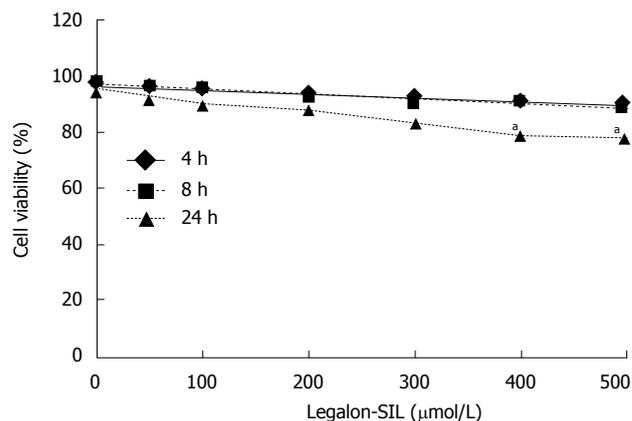

Figure 1 Effects of legalon-SIL on CON1 cell viability. Cellular viability of CON1 cells was measured using the propidium iodide assay after 4, 8, and 24 h of exposure to legalon-SIL (LS) at varying concentrations ranging from 0-500 $\mu\text{mol/L}$. The mean \pm SE from 3 independent experiments. ^a $P < 0.05$ vs DMSO control.

bound antibodies were visualized with the ECL-Plus chemiluminescence system. A computer based imaging system, LAS 3000 (Fuji Film, USA) was used to measure the relative optical density of each specific band obtained after Western blotting.

Statistical analysis

Data are expressed as mean \pm SE of the mean. Statistical differences between groups were analyzed by analysis of variance followed by Dunnett's test. $P < 0.05$ was considered significant.

RESULTS

Cytotoxicity of Legalon-SIL in CON1

Appropriate doses of LS in the cell lines were determined. Effects of different doses of LS on cell viability in CON1 cells were assessed by PI staining (Figure 1). LS concentrations of 50-300 $\mu\text{mol/L}$ had no significant effect on cell viability, whereas concentrations equal to or more than 400 $\mu\text{mol/L}$ caused significant cytotoxicity in the cells ($P < 0.05$). Similar results were demonstrated with the MTT proliferation assay (data not shown).

Legalon-SIL downregulates HCV RNA as well as HCV core and NS5A proteins in CON1 cells

LS downregulated HCV RNA (core region) in a dose-dependent and also a time-dependent manner in CON1 cells. The HCV RNA (core region) level was decreased 21% following 6 h treatment with LS 200 $\mu\text{mol/L}$ compared with the DMSO control ($P < 0.05$, Figure 2A). HCV RNA (core region) levels were further decreased after 24 h treatment by both LS 50 $\mu\text{mol/L}$ (55% decrease, $P < 0.05$) and 200 $\mu\text{mol/L}$ (88% decrease, $P < 0.01$) when compared with vehicle (DMSO) control (Figure 2A). The HCV RNA (NS5A region) level was also decreased 43% following 6 h treatment with LS 200 $\mu\text{mol/L}$ compared with DMSO control ($P < 0.01$ Figure 2B), and was also further decreased after

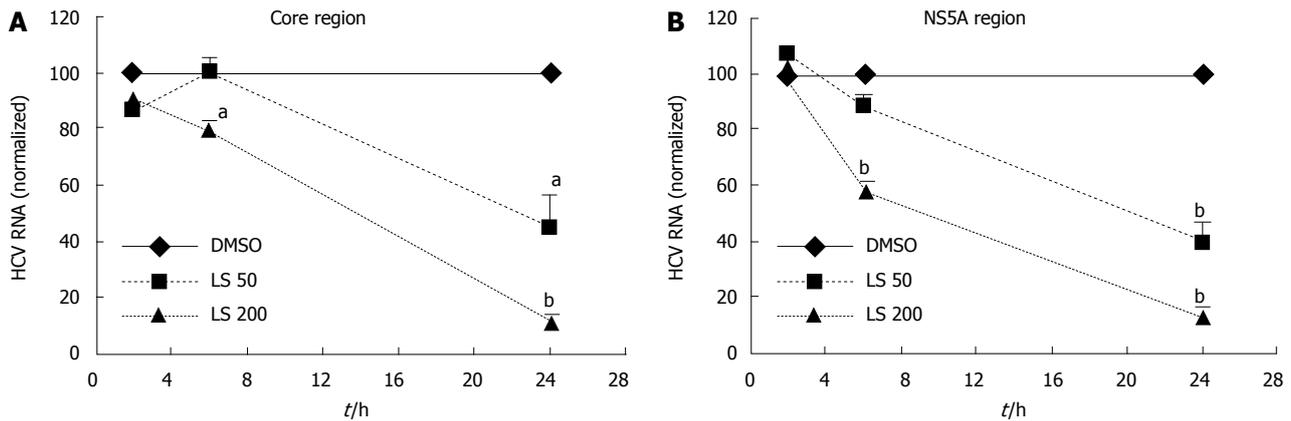

Figure 2 Time course of effects of legalon-SIL on hepatitis C virus RNA in CON1 cells. CON1 cells were grown to near confluence and the medium was changed to 5% fetal bovine serum (FBS) plus Dulbecco's modified Eagle's medium, then treated with vehicle only (DMSO) or 50 or 200 $\mu\text{mol/L}$ legalon-SIL (LS). The cells were harvested after 2, 6, and 24 h after treatment. The levels of hepatitis C virus (HCV) RNA [core region (A) and NS5A region (B)] were quantified using qRT-PCR as described in "Materials and Methods". The amounts of HCV RNA were normalized to glyceraldehyde-3-phosphate dehydrogenase. A: LS 50 $\mu\text{mol/L}$ downregulated HCV RNA (core region) after 24 h. LS 200 $\mu\text{mol/L}$ downregulated HCV RNA (core region) after 6 and 24 h; B: LS 50 $\mu\text{mol/L}$ downregulated HCV RNA (NS5A region) after 24 h. LS 200 μM downregulated HCV RNA (core region) after 6 and 24 h. Data for RNA levels are mean \pm SE ($n = 3$ independent experiments). ^a $P < 0.05$, ^b $P < 0.01$ vs DMSO control.

24 h treatment by both LS 50 $\mu\text{mol/L}$ (62% decrease, $P < 0.01$) and 200 $\mu\text{mol/L}$ (87% decrease, $P < 0.01$) (Figure 2B). LS 200 $\mu\text{mol/L}$ also downregulated HCV core (by 57%) and NS5A protein (by 49%) after 24 h of treatment although this was statistically significant only for HCV core protein, $P < 0.05$). This effect was more pronounced following 48 h of treatment: LS 200 $\mu\text{mol/L}$ decreased HCV NS5A protein expression by 65% ($P < 0.05$), while LS significantly decreased HCV core protein expression in a dose-dependent manner (52% reduction at 50 $\mu\text{mol/L}$ and 85% reduction at 200 $\mu\text{mol/L}$ $P < 0.01$) (Figure 3).

Legalon-SIL downregulates HMOX-1 and Bach1 mRNA levels in CON1 cells while it upregulates Nrf2 protein expression

HMOX-1 and Bach1 mRNA levels were significantly decreased following 24 h treatment by both LS 50 $\mu\text{mol/L}$ and 200 $\mu\text{mol/L}$ when compared with the DMSO control (HMOX-1 decreased by 40%, $P < 0.01$; Bach1 decreased by 35%, $P < 0.01$; Figure 4). LS treatment decreased Bach1 protein level, although not significantly, while it significantly increased Nrf2 protein expression ($P < 0.05$) (Figure 5).

HMOX-1 expression is increased in CON1 cells in comparison with its expression in the parental Huh7.5 cell line

For investigation of possible effects of stable transfection of the HCV genome in CON1 replicon system, we compared HMOX-1, Bach1, and Nrf2 mRNA levels between CON1 cells and Huh7.5 cells, the 'parental' cell line. In untreated CON1 cells, the HMOX-1 mRNA level was 3-fold higher than in untreated Huh7.5 cells ($P < 0.01$), while there was no significant difference in the level of Bach1 or Nrf2 mRNA between CON1 and Huh7.5 cells (Figure 6).

DISCUSSION

The current treatment for CHC is a combination of pe-

gylated IFN- α and ribavirin which is effective only in 40%-50% of treated patients infected with genotype-1, by far the most frequent HCV genotype worldwide. This therapeutic regimen is expensive, prolonged (usually at least 48 wk) and causes serious side effects. Therefore investigations continue to search for alternative treatments for hepatitis C. SI is an herbal remedy that has been used to treat acute and chronic liver diseases for millennia^[12-22]. Despite this broad use, the exact molecular mechanism by which SI confers hepatoprotection is yet to be elucidated. Ferenci *et al.*^[19] recently showed that LS, as used in our studies, significantly reduced serum HCV RNA level in patients who had not responded to combination therapy with full dose pegylated IFN and ribavirin. They showed that SBN was effective only when administered intravenously, as LS, and that the antiviral effect was dose-dependent. They reported that HCV RNA was undetectable in 7 (out of 14) patients receiving 15 and 20 mg/kg SBN as LS. In a recent study *in vitro*^[23], SBN A, SBN B, a mixture of SBN A and SBN B, and LS were shown to inhibit HCV RNA-dependent RNA polymerase (RdRP) function and inhibited HCV genotype 1b sub-genomic replicon replication and HCV genotype 2a strain JFH1 replication in cell culture. Our results extend these findings showing that LS inhibits HCV replication in human hepatoma cells expressing full-length HCV genotype 1b. In this study, we also showed that LS doses equal to 400 $\mu\text{mol/L}$ and higher are cytotoxic for human hepatoma cells similar to other recent results^[23]. The exact pharmacokinetics of SI and LS remain to be determined. However, it is suggested that oral doses of SI up to 2.1 g/d are safe and well-tolerated^[24]. In the present study, we showed that LS started to downregulate HCV RNA in a dose-dependent manner after 2 h, but the significant effect was observed after 6 h of treatment. Although LS 200 $\mu\text{mol/L}$ was found to downregulate HCV RNA and proteins significantly in CON1 cells, LS 50 $\mu\text{mol/L}$ was also found to be effective in downregulation of HCV RNA.

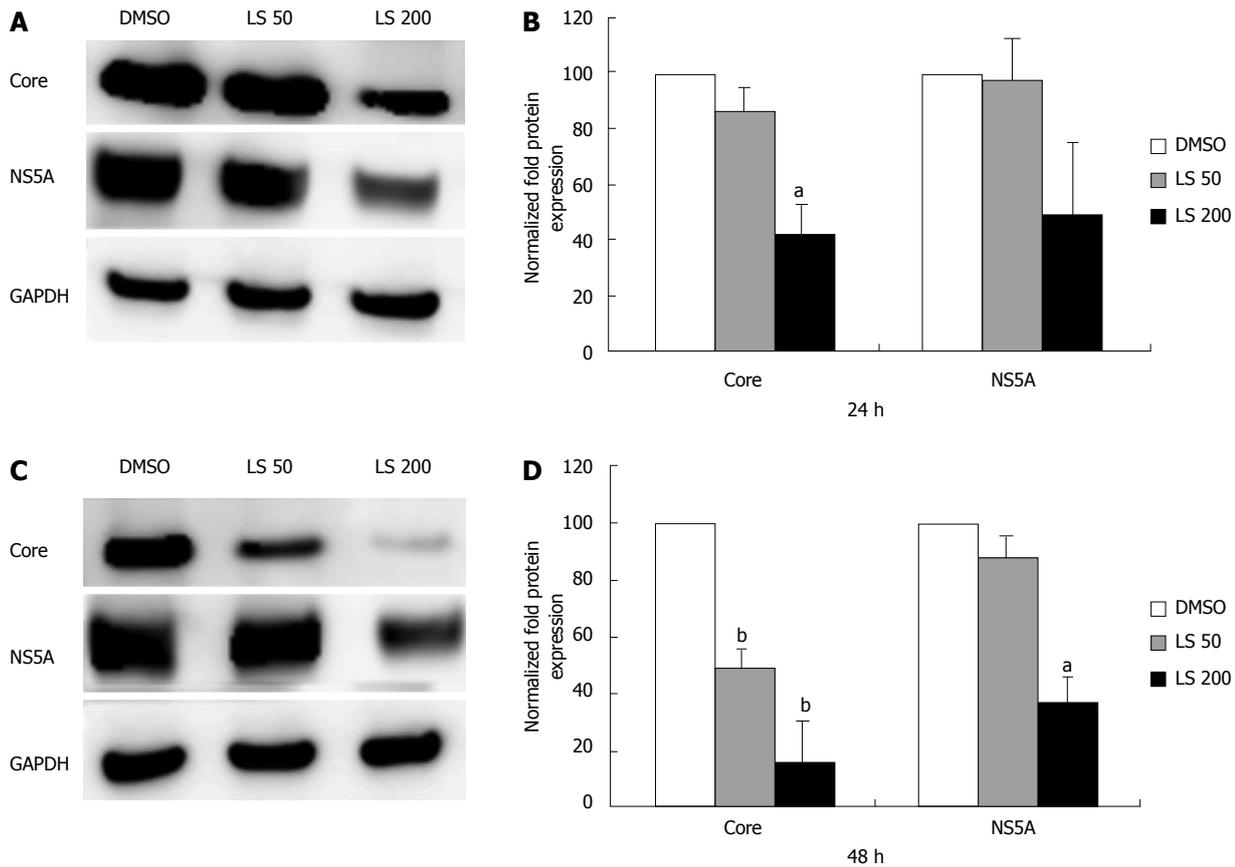

Figure 3 Effects of legalon-SIL on hepatitis C virus core and NS5A protein levels in CON1 cells after 24 and 48 h. CON1 cells were grown to near confluence and the medium was changed to 5% FBS plus Dulbecco's modified Eagle's medium, then treated with vehicle only (DMSO) or 50 or 200 $\mu\text{mol/L}$ legalon-SIL (LS). The cells were harvested 24-48 h after treatment. Total protein (10 μg) was separated on 4%-12% gradient sodium dodecyl sulphate-polyacrylamide gel electrophoresis and electrophoretically transferred onto an Immun-Blot PVDF. Hepatitis C virus core and NS5A protein levels were assessed through Western blotting. Representative Western blots, and glyceraldehyde-3-phosphate dehydrogenase (GAPDH)-normalized quantifications are shown after 24 h (A, B), and 48 h (C, D). Data for protein levels are mean \pm SE ($n = 3$ independent experiments). ^a $P < 0.05$, ^b $P < 0.01$ vs DMSO control.

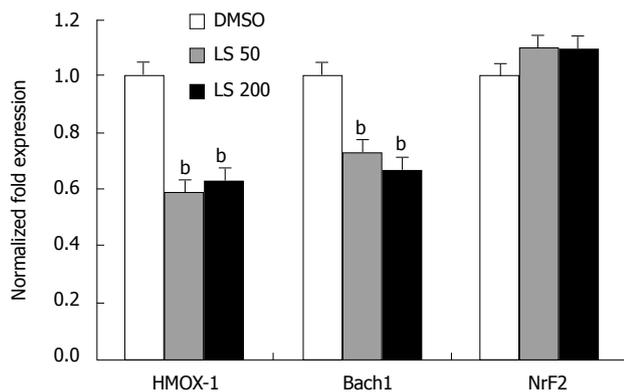

Figure 4 Effects of legalon-SIL on heme oxygenase-1, Bach1, and nuclear factor erythroid 2-related factor 2 mRNA levels after 24 h. CON1 cells were grown to near confluence and medium was changed to 5% FBS plus Dulbecco's modified Eagle's medium, then treated with vehicle only (DMSO) or 50 or 200 $\mu\text{mol/L}$ legalon-SIL (LS). The cells were harvested 24 h after treatment. The levels of HMOX-1, Bach1, and nuclear factor erythroid 2-related factor 2 (Nrf2) mRNA were quantified using quantitative reverse transcriptase polymerase chain reaction as described in "Materials and Methods". The amounts of HMOX-1, Bach1, and Nrf2 mRNA were normalized to glyceraldehyde-3-phosphate dehydrogenase. Data are presented as the mean \pm SE experiments were performed 3 times. ^b $P < 0.01$ vs DMSO control.

for instance inhibition of RdRP, LS might downregulate HCV through interaction with signaling molecules or other as yet unknown host factors. For example, Polyak *et al*^[25] reported that SI suppresses TNF- α activation of nuclear factor- κ B-dependent transcription, without affecting binding of p50 and p65 to DNA. They also reported that all SI-related compounds which they studied blocked JFH-1 virus-induced oxidative stress, including compounds that lacked antiviral activity.

In the present study, we found that LS decreased HMOX-1 mRNA in CON1 cells as well as the mRNA level of Bach1, which is its transcriptional repressor. However, no effect was observed on HMOX-1 and Bach1 protein levels, despite modest upregulation of Nrf2 protein. Bach1 and Nrf2 compete for binding to the ARE and exert their Bach1-induced repressive, or Nrf2-induced activating effects on HMOX-1 transcription. It is noteworthy to mention that for Nrf2 to bind to ARE, Bach1 needs to be dislocated from the binding sites^[26]. Therefore, a lower level of Bach1 is necessary for the maximal effect of Nrf2 on HMOX-1 transcription. As our study did not show downregulation of Bach1 protein, it is possible to hypothesize that Bach1 does not dissociate from ARE to allow Nrf2 to bind. Therefore HMOX-1 is not upregulated despite mod-

In addition to a direct effect of LS on HCV replication,

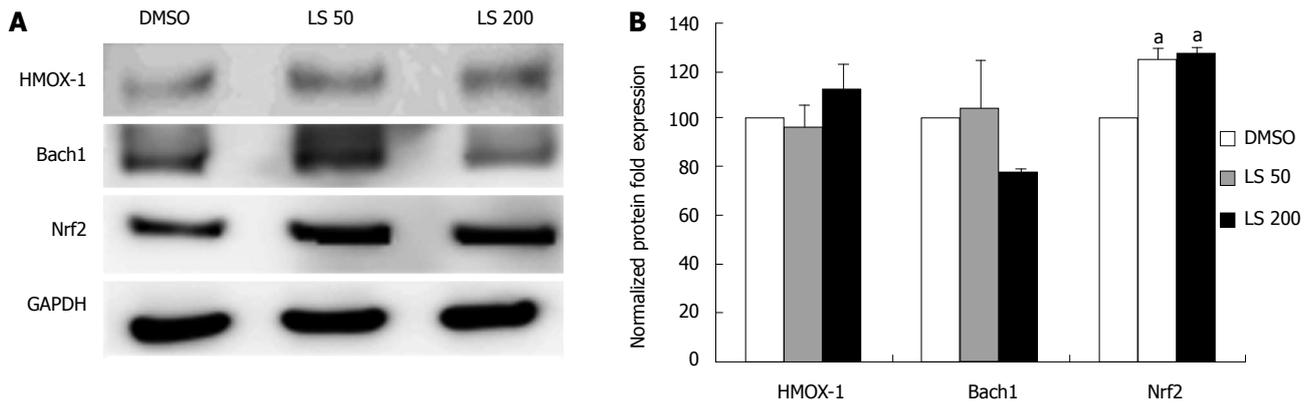

Figure 5 Effects of legalon-SIL on HMOX-1, Bach1, and Nrf2 protein levels in CON1 cells after 48 h. CON1 cells were grown to near confluence and the medium was changed to 5% FBS plus Dulbecco's modified Eagle's medium, and then treated with vehicle only (DMSO) or 50 or 200 $\mu\text{mol/L}$ legalon-SIL (LS). The cells were harvested 48 h after treatment. Total protein (10 μg) was separated on 4%-12% gradient sodium dodecyl sulphate-polyacrylamide gel electrophoresis and electrophoretically transferred onto an Immun-Blot PVDF. HMOX-1, Bach1, and Nrf2 protein levels were assessed through Western blotting, and normalized to glyceraldehyde-3-phosphate dehydrogenase (GAPDH). A: Representative Western blottings. B: Results of these independent experiments quantified and normalized to GAPDH. Data for protein levels are mean \pm SE ($n = 3$ independent experiments). ^a $P < 0.05$ vs DMSO control.

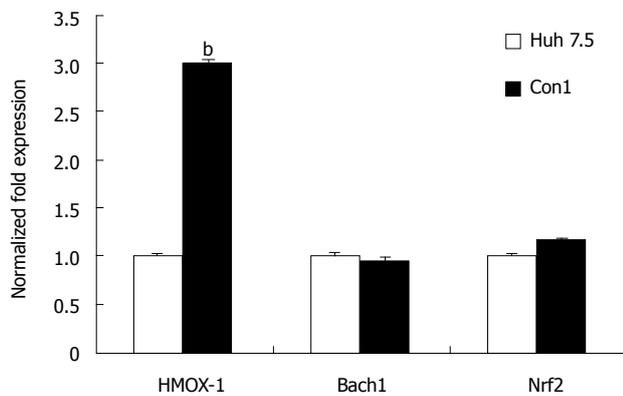

Figure 6 HMOX-1, Bach1, and Nrf2 mRNA levels in CON1 vs Huh 7.5 cells. The levels of HMOX-1, Bach1, and Nrf2 mRNA in untreated Huh 7.5 and CON1 cells were quantified using quantitative reverse transcriptase polymerase chain reaction as described in "Materials and Methods". The amounts of HMOX-1, Bach1 and Nrf2 mRNA were normalized to GAPDH. Data for mRNA levels are mean \pm SE. ^b $P < 0.01$ vs Huh7.5.

est elevation of Nrf2 protein. Additionally, other HMOX-1 transcriptional factors may be affected by LS (e.g. changes in Keap1 or Kelch, glutathione, other thiol-containing compounds, levels of heme, other metalloporphyrins, *etc.*) which were not all examined in this study^[27].

Oxidative stress plays an important role in various diseases, including viral infection and chronic inflammation. HCV gene expression, in particular HCV RNA (core region) expression, can increase the levels of ROS^[28], and therefore upregulate HMOX-1^[20,29]. We also compared HMOX-1 mRNA levels between CON1 cells and its parental cell line (Huh7.5), and we identified a 3-fold upregulation of HMOX-1 in the HCV replicon system compared with the parental cell line. Although SBN is a well-known antioxidant and cytoprotective enzyme, and upregulation of Nrf2 protein could be attributed to this antioxidant effect of LS, lack of HMOX-1 upregulation could be explained by anti-HCV activity of LS. Since HMOX-1 is already

increased by HCV infection in CON1 cells, its level is decreased toward normal levels as LS attenuates HCV infection. This downregulatory effect of LS on HMOX-1 seems to be more pronounced at the RNA level, and is compensated by an Nrf2 increase at the protein level.

In conclusion, LS downregulates HCV in hepatoma cell lines expressing full length HCV genotype 1b. LS treatment is also associated with downregulation of HMOX-1 mRNA and upregulation of Nrf2 protein. Further research is needed to further delineate mechanisms of the LS effect on HCV replication and on CHC.

COMMENTS

Background

Chronic hepatitis C virus (HCV) infection is a global health problem, and one causal factor for development of liver cirrhosis and hepatocellular carcinoma. The current therapy for HCV is interferon (IFN) α -2a or IFN α -2b plus ribavirin which is effective in only 40%-50% of those with HCV genotype 1 infection. Furthermore, serious side effects are associated with this therapy. The paucity of effective and affordable treatments for HCV-infected patients has led scientists to seek alternative therapies.

Research frontiers

Silymarin, also known as milk thistle extract, inhibits HCV infection and also displays antioxidant, antiinflammatory, and immunomodulatory actions that contribute to its hepatoprotective effects. In this study the authors demonstrated that Legalon-SIL (LS), a water-soluble formulation of silybin A and silybin B downregulates expression of HCV mRNA and protein in replicon CON1 cells which are human hepatoma cell lines stably transfected with full-length HCV genotype 1b.

Innovations and breakthroughs

This report highlighted that LS decreases HCV core and NS5A expression. Additionally, the authors demonstrated that LS modulates expression of heme oxygenase-1 and its transcriptional regulators, Bach1 and Nrf2. This is the first study examining the effects of LS using a human hepatoma cell line expressing full-length HCV genotype 1b.

Applications

Our results suggest that LS may prove to be a valuable alternative or adjunctive therapy for the treatment of HCV infection.

Terminology

LS is a form of SBN which is a water-soluble formulation of the dihydro-succinate sodium salt of silybin A and silybin B in equal proportions.

Peer review

The paper will appeal to clinicians as well as researchers involved in the field of elucidating the mechanisms of silymarin in HCV positive patients.

Abstract

AIM: To investigate the indication, feasibility, safety, and clinical utility of endoscopic submucosal dissection (ESD) in the management of various gastrointestinal pathologies.

METHODS: The medical records of 60 consecutive patients (34 female, 26 male) who underwent ESD at the gastroenterology department of Kocaeli University from 2006-2010 were examined. Patients selected for ESD

had premalignant lesions or non-invasive early cancers of the gastrointestinal tract and had endoscopic and histological diagnoses. Early cancers were considered to be confined to the submucosa, with no lymph node involvement by means of computed tomography and endosonography.

RESULTS: Sixty ESD procedures were performed. The indications were epithelial lesions ($n = 39$) (33/39 adenoma with high grade dysplasia, 6/39 adenoma with low grade dysplasia), neuroendocrine tumor ($n = 7$), cancer ($n = 7$) (5/7 early colorectal cancer, 2/7 early gastric cancer), granular cell tumor ($n = 3$), gastrointestinal stromal tumor ($n = 2$), and leiomyoma ($n = 2$). En bloc and piecemeal resection rates were 91.6% (55/60) and 8.3% (5/60), respectively. Complete and incomplete resection rates were 96.6% (58/60) and 3.3% (2/60), respectively. Complications were major bleeding [$n = 3$ (5%)] and perforations [$n = 5$ (8.3%)] (4 colon, 1 stomach). Two patients with colonic perforations and two patients with submucosal lymphatic and microvasculature invasion (1 gastric carcinoid tumor, 1 colonic adenocarcinoma) were referred to surgery. During a mean follow-up of 12 mo, 1 patient with adenoma with high grade dysplasia underwent a second ESD procedure to resect a local recurrence.

CONCLUSION: ESD is a feasible and safe method for treatment of premalignant lesions and early malignant gastrointestinal epithelial and subepithelial lesions. Successful en bloc and complete resection of lesions yield high cure rates with low recurrence.

INTRODUCTION

New developments in the optical technology of endoscopes allow early detection of mucosal abnormalities that are amenable to endoscopic therapies. Endoscopic therapies are used for premalignant lesions and noninvasive early cancers with low risk of lymph node metastasis. Endoscopic therapies include ablation and resection-based modalities. Resection-based modalities consist of endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD). The major advantage of resection-based modalities is the recovery of the specimen for histopathological analysis. A recent study has shown the long-term prognosis of complete en bloc EMR to be comparable to surgery for differentiated early gastric cancer with 10-year survival rates of 99%^[1]. Although lesions with a diameter of less than 20 mm can be resected in an en bloc fashion with EMR, larger lesions can only be removed in a piecemeal fashion. It is difficult to have an accurate histopathological evaluation of a lesion that is removed in a piecemeal fashion. Furthermore, the risk of local recurrence after piecemeal resection is higher than that of en bloc resection^[1-3].

ESD is a newly developed technique that allows en bloc resection of larger (usually more than 20 mm) mucosal as well as subepithelial gastrointestinal lesions above the muscularis propria with the use of cutting devices. En bloc resection rate of ESD ranges between 83%-98%, which is significantly higher than EMR. Local recurrence rates range between 0%-3%^[4]. However, compared to EMR, ESD is technically more challenging, requires higher endoscopic skills, is time consuming and has a prolonged learning curve^[5-7]. Although ESD has been accepted in the armamentarium of endoscopic management of premalignant and noninvasive early gastrointestinal cancers in Japan and Asia, the Western experience with this new modality has been quite limited. This may be related to differences in the epidemiology of certain gastrointestinal diseases (e.g. gastric cancer), differences in technical expertise, due to its prolonged procedure time, due to its long learning curve, or possibly due to legal concerns, as well as procedural reimbursement. Our study is the first series of ESD cases from Turkey and among the few studies performed in Europe. The aim of this study is to describe indications, feasibility, safety, complications, and recurrence rate of the

mucosal and subepithelial ESD cases in the upper and lower gastrointestinal tract.

MATERIALS AND METHODS

Patients

From September 2006 to June 2010, a consecutive series of patients who underwent an ESD at a tertiary referral center (Kocaeli University Hospital) were reviewed. Premalignant lesions larger than 15 mm in size and noninvasive early cancers with low risk for lymph node metastasis larger than 10 mm were included in the study. The inclusion criteria for carcinoma were histological well differentiation, diameter of ulceration \leq 30 mm, lack of submucosal invasion and lymph node involvement detected with computed tomography (CT) or endoscopic ultrasound (EUS). Prior to an ESD attempt, each case was reviewed by a team consisting of an oncologist, a general surgeon, and an anesthesiologist. ESD indications, procedural information (instruments, sedation, procedure duration, findings, interventions, outcome, and complications) were retrospectively collected and analyzed. The research protocol was approved by the local ethics committee. Both oral and written informed consents were obtained from the patients. This study was conducted in accordance with the ethical principles of the Declaration of Helsinki and in compliance with good clinical practice.

Equipment and procedure

All ESD procedures were performed by a single operator (S.H.) who had studied ESD in 2006 for three months (under the supervision of Hironori Yamamoto, MD; Jichi Medical School, Tochigi, Japan). During his study as a visiting professor he studied the indication, techniques and other basic knowledge regarding ESD for the esophagus, stomach and colon in the endoscopy unit of Jichi Medical University. The author also joined ESD courses in porcine stomach models organized by the gastrointestinal endoscopy society during national gastroenterology weeks. In these courses he achieved more experience, but also contributed to the education of physicians interested in this area.

Prior to an ESD attempt, all lesions were examined with an optical magnifying endoscope (EG-450 ZW5; Fujinon) and colonoscope (-EC-590 Z/WL; Fujinon), with 1% Indigo Carmine used as an adjunct to magnification. The lesion size was determined upon the comparison of standard open biopsy forceps with the lesion. The invasion depth of the lesions was examined either with high frequency ultrasound mini probes (P1912-MB, P1915-MB, P2012-M, 12-20 MHz; Fujinon) or echoendoscopes (GF-UE 160-AL5; Olympus) depending on the size and location of the lesion. Superficial lesions were classified according to the Paris classification system as type I (protruding), type II (flat) a, b, c and type III (excavated)^[8]. Kudo classification was used for characterization of colonic pit patterns^[9].

ESD procedures were performed in a standardized way. The margins of the lesion were marked with an

electrocautery (30 W soft coagulation) to determine the resection border (except in the colon). Then submucosal injection was performed to lift the lesion. For the injection, a special mixture (1 unit of 2% sodium hyaluronic acid, 3 units of saline, 0.5 mL of epinephrine (1/10000) and 0.5% of indigo carmine) was used. After sufficient lifting, a flush knife (DK2618JN 20; Fujinon), insulated-tip knife (KD-610L; Olympus) or needle knife (KD-11Q-1) was used to create a circumferential incision around the lesion extending into the submucosa. After circumferential incision, a submucosal dissection was performed to remove the lesion in an en bloc fashion.

A high frequency generator with an automatically controlled system (Endo-cut mode; ERBE ICC 200, Elektromedizin GmbH, Germany) was used for dissection and coagulation. A specialized cap (EMR ST Hood DH 15CR, Fujinon) was placed on the tip of the endoscope to make the dissection easier by increasing stability. Initially marked lesions were dissected with a diathermic knife (Olympus or Fujinon) circumferentially using endo-cut mode (2-3/80 W). An insulated-tip (IT) knife (KD-610L; Olympus) was used to dissect the borders of the lesions with a high perforation risk (wide based lesions and colonic lesions between haustral folds) using endo-cut mode (3/120 W). Submucosal dissection was performed with spray coagulation (45 W). Small vessels were coagulated with spray coagulation. Larger vessels or arteries with high bleeding risk were coagulated with hemostatic forceps (Fujinon).

Circumferential incision was completed in all cases. In colonic lesions, semi-circumferential incision was performed initially. After submucosal dissection, circumferential incision was completed. A few cases were finished with snare resection, but only after 80% of ESDs were completed. Standard or therapeutic gastroscopes (Fujinon EG-530 D) were used for lesions located in the rectum and sigmoid colon. Lesions close to the anus were treated in the retroflexion position. Colonoscopes were used for lesions proximal to the splenic flexure.

The first gastric lesions treated by ESD were located at the antrum in our series, as most gastric lesions were. Later on, cardiac lesions were treated by ESD in the retroflexion position.

All of the ESD procedures were performed under deep sedation. A combination of propofol and fentanyl was provided by an anesthesiologist. Patients were continuously monitored with an electrocardiogram, and blood pressure and oxygen saturation were monitored. The position of the patient could be easily changed whenever required with the help of medical attendants under the control of the anesthesiologist.

Definitions and follow-up strategy

All the specimens were examined by a single pathologist who is specialized in gastrointestinal pathology. En bloc resection was defined as the removal of a lesion in a single piece. Piecemeal resection was defined as the removal of a lesion in more than one piece.

A recurrent disease was defined as the reappearance of neoplastic tissue at the site of initial ESD at the 6th mo

follow-up endoscopy. In the case of a perforation, hemoclips were used. Bleeding that could be managed with endoscopic intervention was considered as minor bleeding. Bleeding with hemodynamic instability and blood transfusion requirement with or without the need for surgical intervention was considered as major bleeding.

A lesion was considered to be completely removed (R0 resection), when the vertical and lateral surgical margins were 2 mm away from the lesion. When neoplastic cells were present at surgical margins, this was considered as an incomplete resection (R1). Patients found to have undifferentiated or signet cell adenocarcinoma and submucosal/lymphovascular invasion on histopathological evaluation were referred to surgery. Patients were hospitalized for observation after the procedure and underwent a control endoscopy within 2 d of the ESD procedure. Patients underwent follow-up endoscopies at 3 and 6 mo. After a normal endoscopy at the 6th mo, annual follow-up was offered.

Statistical analysis

A median of continuous variables was used to present data. The Kruskal-Wallis test was used to compare median procedure time of ESD groups. When Kruskal-Wallis test results were statistically significant ($P < 0.05$), a Mann-Whitney test using Bonferroni correction was used to compare median procedure time between ESD groups. $P < 0.01$ was accepted as statistically significant. Statistical Packages for Social Sciences version 16.0 for Windows (SPSS, Chicago, IL, USA) was used for statistical analysis.

RESULTS

Over the 46-mo period, 60 ESD procedures were performed by a single operator (S.H.). There were 34 female (56.6%) and 26 male (43.3%) patients. The mean age (*via* standard deviation) of patients was 54.6 (\pm 14.1) years.

The majority of ESD procedures (65%) were performed for intraepithelial lesions ($n = 39$) (33/39 adenoma with high grade dysplasia, 6/39 adenoma with low grade dysplasia). The indication of the remaining ESD procedures were as following: neuroendocrine tumor (NET) ($n = 7$), cancer ($n = 7$) [5/7 early colorectal cancer (ECC), 2/7 early gastric cancer (EGC)], granular cell tumor ($n = 3$), gastrointestinal stromal tumor (GIST) ($n = 2$), and leiomyoma ($n = 2$). Microscopic types of the lesions in the different locations according to Paris classification is given in Table 1. En bloc and piecemeal resection rates were 91.6% (55/60) and 8.3% (5/60), complete and incomplete resection rates were 96.6% (58/60) and 3.3% (2/60), respectively.

An adenoma (piecemeal resection is done on purpose, Figure 1), early gastric cancer located in the antrum, and three flat adenomas with lateral invasion in the colon were resected in piecemeal fashion. A patient with a NET that was incompletely resected was referred to surgery due to vascular invasion noted on histopathologic evaluation. A patient with an incompletely resected early colon cancer (ECC) due to lateral spreading was referred to surgery. Invasion into the muscularis propria was seen

in the surgical specimen of the patient with gastric NET referred for surgery. But there was no invasion in the surgical specimen of the patient with ECC (this patient was referred for surgery because histology revealed neoplastic cells at the surgical margins of the specimen resected in en bloc fashion). En bloc, piecemeal, complete, and incomplete resection rates are shown in Table 2.

The duration of ESD procedures per cm² were as follows; 27.8, 21.8, and 18.3 min for stomach, esophagus, and

colon, respectively. However, the mean procedure durations were as follows; 158, 90.4 and 50.5 min for colon, stomach, and esophagus, respectively. The mean procedure time of colonic and gastric lesions was significantly longer than esophageal lesions [Kruskal-Wallis test ($P < 0.01$)]. This is due to the differences in size of the lesions removed in different anatomic locations; colon (8.61 cm²) > stomach (3.25 cm²) > esophagus (2.34 cm²). Technical challenges related to the anatomic location of lesions as well as nature of lesions contribute to the procedure time (endoscopic resection should be done in the retroflexed position for lesions located in the cardia and proximal corpus, neuroendocrine tumors (NET) with rich vascularization have more bleeding).

Esophageal lesions

Seven esophageal lesions consisting of 3 granular cell tumors, 2 adenomas with high grade dysplasia, 1 gastrointestinal stromal tumor (submucosal), and 1 leiomyoma (submucosal) were treated with ESD (Table 3). No complications occurred in patients with esophageal lesions that were removed with ESD. No recurrences were not-

ed in the 7 patients that had follow-up data. The mean follow-up period for these 7 patients was 15 mo.

Gastric lesions

Twenty four gastric lesions, consisting of 16 adenomas (12 adenomas with HGD, 4 adenomas with LGD), 4 carci-

noid tumors, 2 early gastric cancers, 1 GIST (submucosal), and 1 leiomyoma (submucosal) were treated with ESD (Table 4) (Figures 1 and 2). One lesion was located in the cardia (adenoma with HGD), 3 lesions were located in the gastric corpus (3 carcinoid tumors), and 20 lesions were located in the antrum (11 adenomas with HGD, 4 adenomas with LGD, 2 EGC, 1 GIST, 1 carcinoid tumor, 1 leiomyoma). A patient with a gastric adenoma with HGD had recurrence at the site of prior resection. This patient had a second ESD, 12 mo after the first ESD.

Colonic and small intestinal lesions

Twenty-nine lesions including 21 adenomas (2 tubulovillous adenoma with HGD in duodenal bulb, 1 tubulovillous adenoma with HGD in cecum, 2 tubulovillous adenoma with HGD in transverse colon, 3 tubulovillous adenoma with HGD in sigmoid colon, 1 tubular adenoma in sigmoid colon, 9 tubulovillous adenoma with HGD in rectum, and 3 tubular adenoma in rectum), 3 carcinoid

tumors (1 in duodenal bulb, 1 in terminal ileum and 1 in rectum), and 5 early colon cancers (4 in rectum and 1 transverse colon) were treated with ESD (Table 5) (Figures 3 and 4). All early colon cancers were classified as II a + II c according to the Paris classification.

Safety

Among 5 perforations (8.3%), four were located in the colon (1 early colon cancer, 2 laterally spreading lesions and 1 large tubulovillous adenoma located on a colonic haustra) and one (carcinoid tumor) was located in the stomach.

| Location | Number | Histology (n) |
|-------------------------|--------|---|
| Duodenal bulb | 3 | HGD (TVA) (2) NET (1) |
| Terminal ileum | 1 | NET (1) |
| Cecum | 1 | HGD (TVA) (1) |
| Transverse colon | 3 | HGD (TVA) (2) ECC (1) |
| Sigmoid colon | 4 | HGD (TVA) (3) LGD-TA (1) |
| Rectum | 17 | ECC (4) HGD (9 TVA, 2 TA) LGD-TA (1) NET (1) |
| Specimen size (median) | | 8.61 cm ² (1.5-25 cm ²) |
| Procedure time (median) | | 158 min (18.3 min/cm ²) |

HGD: High grade dysplasia; NET: Neuroendocrine tumor; TA: Tubular adenoma; ECC: Early colonic cancer; LGD: Low grade dysplasia; TVA: Tubulovillous adenoma.

Two colonic perforations were managed with surgical intervention and the other three were managed with hemoclip application. Those managed with hemoclip application were smaller than 5 mm in size; hence it was easy to treat them. The patients with perforation were hospitalized for an average of ten days. There was no association of perforation with scarring and fibrosis from previous procedures. No post-ESD stenosis was noted. Major bleeding occurred

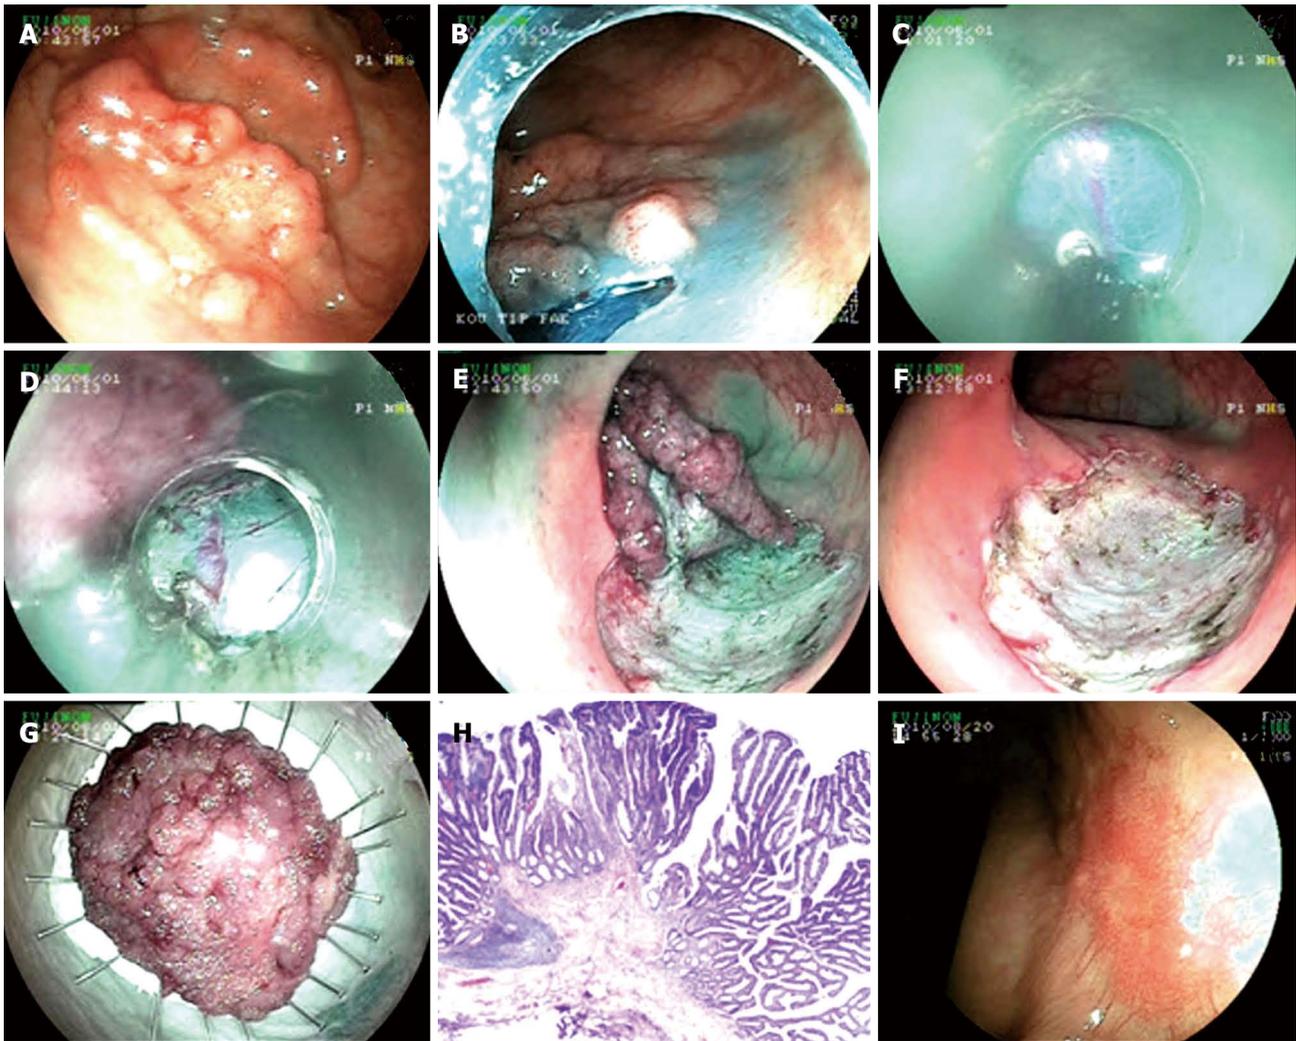

Figure 4 Endoscopic submucosal dissection procedure for pseudo-depressed type lateral spreading tumor with high grade dysplasia at rectum. A: Pseudo-depressed type lateral spreading tumor at rectum; B: Cutting the lesion circumferentially with endo-cut; C, D: Submucosal dissection with semipermeable cap; E: Endoscopic view just before completing submucosal dissection; F: Appearance of the mucosa after the lesion being extracted; G: Microscopic view of the lesion; H: Histology; tubulovillous adenoma including fields of focal pattern loss and dysplasia (HE $\times 20$); I: Endoscopic view ten weeks after the procedure.

in three patients (5%). One of these patients had a lesion located in the colon and two of them had lesions located in the stomach. Contributing factors to major bleeding may possibly be the nature as well as the location of the lesion, possibly due to the rich vascularization of the lesion. Both of the bleeding lesions in the stomach were NETs and located in the lesser curvature. Bleeding from gastric lesions was delayed and required blood transfusion. The colonic case that had a major bleed was an early colonic cancer. Minor bleeding occurred in 13 cases (7 lesions located in the colon and 6 lesions located in the stomach) (21.7%). Table 6 shows complications in detail.

DISCUSSION

Although endoscopic resection-based therapeutic modalities (EMR and ESD) are considered to be the treatment of choice for premalignant and early gastrointestinal neoplasias in Japan, they are not widely practiced by Western endoscopists^[10]. This is the first study from Turkey and among the few studies from outside of Japan and Asia on

the application of ESD in the management of premalignant and noninvasive early gastrointestinal cancers from various anatomic locations in the gastrointestinal tract.

It is difficult or impossible to remove large lesions with EMR technique in one fragment. Removal of a lesion in one piece is very important to accurately diagnose the tumor depth as well as decreasing the risk of local recurrence. A recent study has illustrated that this problem can be solved with the use of ESD for larger lesions^[11]. In early esophageal cancers with a diameter of less than 20 mm, en bloc and curative resection rate of ESD (97%) was found to be significantly higher than that of EMR using a transparent cap (71%) and 2-channel EMR (46%)^[11]. However, no significant difference was found between ESD and EMR using a transparent cap in en bloc and curative resection rate of lesions less than 15 mm in diameter. Therefore, ESD would be a better therapeutic modality than EMR for esophageal lesions with a diameter of greater than 15 mm. Given the size (median size of esophageal/gastric/colonic lesions 2.34 cm²/3.25 cm²/8.61 cm² respectively), various anatomic location of

Table 6 Complications with regard to location and diagnosis

GIST: Gastrointestinal stromal tumor; NET: Neuroendocrine tumor; EGC: Early gastric cancer; ECC: Early colorectal cancer.

lesions and subepithelial nature of some lesions, ESD would be the treatment of choice for our cases.

There are few studies from Europe that were published in full manuscript format. Dinis-Ribeiro *et al*^[12] evaluated feasibility and effectiveness of ESD in 19 gastric superficial lesions with HGD, LGD and noninvasive epithelial neoplasias. Probst *et al*^[13] evaluated ESD in 71 flat adenomas, early cancers and submucosal tumors located in various locations of the gastrointestinal tract (51 gastric, 17 rectal, 2 esophageal and 1 duodenal). In the study of Dinis-Ribeiro *et al*, complete and en bloc resection rates were 89% and 79%, respectively. Major bleeding occurred in 1 case (5%). There were no perforations. Recurrence of a lesion (5%) was noted within a mean follow-up of 10 mo. In order to evaluate ESD learning curve, Probst *et al*^[13] compared various aspects of ESD procedures performed in the first and second halves of the study.

A statistically significant increase in specimen size and decrease in procedural duration were noted between the two groups. En bloc resection rates and R0 en bloc resection rates in the first half of the study (77.1% and 65.7%, respectively) increased when compared with the second half of the study (86.1% and 72.2%, respectively), however this difference did not reach statistical significance. No recurrence occurred after R0 en bloc resection; however 38% recurrence occurred after piecemeal resection. Complications in the study of Probst included 2 perforations (gastric submucosal tumors) that required surgery (2.7%), 2 other perforations (large flat rectal lesions) (2.7%), 8 minor bleedings (10.9%) and 3 pyloric stenosis (4.1%) that were endoscopically managed.

ESD complication rates among the published studies have been variable depending on the size of the study as well as the experience of the operator. In our study, a patient (1.7%) was found to have a recurrence of an adenoma with HGD at the site of prior ESD on 12-mo follow-up endoscopy. The recurrent lesion was treated with a repeat ESD. The patient was free of disease at the 6-mo follow-up. No recurrences were noted with esophageal and colonic lesions. Compared to other studies, lower

recurrence rate in our study may be related to the relatively shorter follow up (median = 12.5 mo) of the patients after ESD. Our bleeding rate is consistent with other studies. Our perforation rate is higher than the study of Probst *et al*^[13]. However, all of our perforations occurred at the first half of the study, which is a reflection of the impact of the operator's experience with the success of ESD procedures. Eighty percent of perforations occurred with colonic cases, which may be related to the relatively thinner colonic wall thickness and larger size of colonic lesions. Most perforations took place in initial cases. In those cases needle knives were used. We believe that the use of these knives also contributed to this relatively high number of perforations. After providing IT-knives we did not encounter any perforations. As stated above we could not refuse the patients and it is true that we had to perform colorectal cases with insufficient experience in gastric ESD, resulting in relatively high perforation rates.

In a review article from Japan, the en bloc resection rate of early gastric cancers was reported to be 79%-100%, with local recurrence, bleeding and perforation rates of 0%-1%, 1.7%-38%, 0%-5%, respectively^[14]. Another study from Japan evaluating ESD in colorectal epithelial neoplasms revealed the rate of en bloc resection and en bloc resection with tumor free margins to be 91.5% and 70.5%^[15]. In this study, perforation and local recurrence rates were found to be 5% and 1.7%, respectively. The sample size of studies coming from outside of Japan and Asia is quite modest; therefore it is premature to compare Western experience with the Asian one.

Ideally one should begin with gastric cases located in the antrum. After getting sufficient experience in gastric cases they can proceed with esophageal and colorectal cases, which are more risky. Our practice seems incompatible with this idea. But ESD is only performed in our institute in Turkey and patients are referred to our hospital from the entire country. So we did not have the chance to refuse the patients and performed esophageal and colorectal cases before having sufficient experience in gastric cases.

We believe that, besides EMR and endoscopic piecemeal mucosal resection, ESD will be a good alternative in the treatment of non-epithelial esophageal lesions. We observed that neuroendocrine tumors which have rich vascularization are more likely to bleed, so more attention should be paid when operating on them. During the ESD procedures in the colon and esophagus, a needle knife should be avoided in endo-cutting because of the perforation risk. Perforation risk is even higher in laterally spreading colonic lesions so IT-knife is a better choice for those lesions.

In summary, ESD, which originates in Japan, has been gaining popularity in other parts of the world as well. Comparable outcomes of ESD to surgery play an important role in the rapid propagation of this therapeutic endoscopic modality. Although no procedure related mortality has been reported, there is considerable morbidity with this technique. There is a significant learning curve to achieve proficiency in order to acquire skills to perform ESD safely and effectively. Therefore, importance of training can not be overemphasized. Further studies from outside of Japan and Asia are needed to better determine the global role of

ESD in the management of premalignant and early malignant epithelial, as well as subepithelial lesions.

COMMENTS

Background

Advances in endoscopic diagnosis techniques allowed premalignant lesions and non-invasive cancers of the gastrointestinal system to be detected early and be treated effectively and safely by endoscopic methods. Among these methods, endoscopic submucosal dissection (ESD) is being used more and more commonly and has pleasing results.

Research frontiers

ESD is a safe and effective modality for the treatment of premalignant lesions and early non-invasive cancers of the gastrointestinal system and when compared to surgery it has the advantage of preserving the gastrointestinal system and its functions. This is the first study on ESD reported from Turkey.

Innovations and breakthroughs

Complications related to ESD are similar to other studies in the literature except for the complication rate. Recurrence rates are lower compared to other studies. In this study we observed that neuroendocrine tumors had higher bleeding rates due to hypervascularization and the use of a needle knife in colonic and esophageal lesions increased the risk of perforation.

Applications

When performed by experienced endoscopists ESD has pleasing results and can be safely performed for the treatment of premalignant lesions and early cancers of gastrointestinal system.

Terminology

ESD is being used for the treatment of premalignant and lesions (with no lymph node involvement) of the gastrointestinal tractus confined to mucosa and submucosa. After lifting the lesion by injecting the specially prepared solution (Na - Hyaluronate + Adrenalin + Saline + Indigo carmine), the basement of the lesion, along with the surrounding area, are cut with special knives and the lesion is extracted.

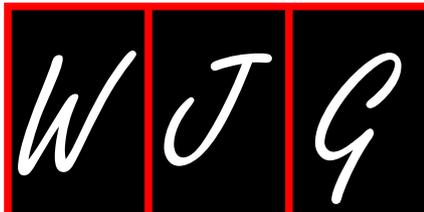

Peer review

This retrospective study sets out to evaluate the feasibility, safety and clinical outcomes of ESD for premalignant lesions and early gastrointestinal cancers. It establishes that the rates of en bloc and complete resection of these lesions were good, and comparable those of previous studies.

Abstract

AIM: To develop a prognostic gene set that can predict patient overall survival status based on the whole genome expression analysis.

METHODS: Using Illumina HumanWG-6 BeadChip followed by semi-supervised analysis, we analyzed the expression of 47 296 transcripts in two batches of gastric cancer patients who underwent surgical resection. Thirty-nine samples in the first batch were used as the training set to discover candidate markers correlated to overall survival, and thirty-three samples in the second batch were used for validation.

RESULTS: A panel of ten genes were identified as prognostic marker in the first batch samples and classified patients into a low- and a high-risk group with significantly different survival times ($P = 0.000047$). This prognostic marker was then verified in an independent validation sample batch ($P = 0.0009$). By comparing with the traditional Tumor-node-metastasis (TNM) staging system, this ten-gene prognostic marker showed consistent prognosis results. It was the only independent prognostic value by multivariate Cox regression analysis ($P = 0.007$). Interestingly, six of these ten genes are ribosomal proteins, suggesting a possible association between the deregulation of ribosome related gene expression and the poor prognosis.

CONCLUSION: A ten-gene marker correlated with overall prognosis, including 6 ribosomal proteins, was identified and verified, which may complement the predictive value of TNM staging system.

INTRODUCTION

Gastric cancer is the second leading cause of cancer related death worldwide^[1]. As a complex and heterogeneous disease, it comprises multiple tumor entities associated with distinctive histological patterns and biological features, as well as clinical behaviours^[2]. The 5-year survival rate of patients with advanced disease is only 20%-30%^[3]. The current treatment plan and prognosis prediction for gastric cancer mainly depend on the clinicopathologic staging of the disease, and TNM staging system is still the golden standard for survival prediction among gastric cancer patients. However, prognosis varies among patients with a similar tumor stage, therefore disease staging alone can not accurately predict the outcome for individual patients.

Although great efforts have been made in the identification of prognostic markers from gene expression profiling to improve prognosis prediction for many cancers especially breast cancer^[4], limited research has been conducted in the field of gastric cancer. To date, most studies on the selection of prognosis markers were conducted by cDNA array or quantitative RT-PCR, in which only a few thousand genes were analyzed^[5-9]. In an attempt to predict peritoneal relapse after gastrectomy for gastric cancer, the whole genome microarray consisting of 30K transcripts was employed in a very recent gene expression analysis^[10]. Such a robust approach may provide not only more signals in marker selection, but also more comprehensive information in understanding molecular mechanisms of tumor-related processes. In this study, we explored the gene expression by microarray containing over 47K probes in two batches of surgical samples from 79 Chinese gastric cancer patients. A ten-gene marker for overall survival was identified and verified in an independent batch of samples.

MATERIALS AND METHODS

Patients and samples

Seventy-nine tissue samples from patients who were surgically treated for primary gastric carcinoma were procured at the Beijing Cancer Hospital (Peking University, School of Oncology) from 1999 to 2003. No patient received chemotherapy or radiotherapy before surgery. All patients were treated with curative surgical resection, which was, in some cases, followed by second-line treatment at the time

of recurrence. Macroscopic and microscopic evaluations were conducted by pathologist according to the general rules for gastric cancer. Follow-up was performed every three month for the first two years, and every three to six months thereafter. Stage of gastric cancer was classified according to 2002 tumor-node-metastasis (TNM) classification system recommended by the American Joint Committee on Cancer.

Overall survival was calculated from the date of primary surgery to the date of last follow-up or to the date of death due to cancer relapse or metastasis. All tumor samples were obtained at the surgery, followed by fresh freezing in liquid nitrogen and stored at -80°C. Informed consent was obtained from each patient for the collection and storage of tissue samples in a tissue bank for future research. This investigation was performed after approval by Ethics Committee of Peking University.

RNA preparation and microarray analysis

Total RNA was purified from clinical samples using TRIzol reagent (GibcoBRL, Grand Island, New York, USA). And mRNA was linearly amplified by in vitro transcription using T7 RNA polymerase (MEGAscript T7 kit, Ambion, Inc, USA). The quality and integrity of total and amplified mRNA (cRNA) was monitored by both spectrophotometry (OD UV 260/280 ratio > 1.8) and agarose gel electrophoresis.

Gene-expression profiling was performed using Illumina HumanWG-6 BeadChip, which contains 47 296 transcripts. BeadChips were scanned with a BeadStation 500 GX and data are available at Gene Expression Omnibus (GSE21983). <http://www.ncbi.nlm.nih.gov/geo>.

Statistical analysis

Average normalization in BeadStudio software was conducted for probe level average normalization and background correction. A detection *P* value was used in BeadChip to calculate probability to see a certain signal level without specific probe-target hybridization. All genes and probes with *P* value > 0.01 were filtered and removed from the analysis. Among 47 296 transcripts, 18 819 were expressed with *P* values < 0.01.

The supervised principal components method was used for survival profiling^[11]. In the training set, we calculated the modified univariate Cox proportional-hazard scores for all genes (*n* = 18 819), which were measured to identify genes with their expression correlated to the duration of survival. We selected a set of genes whose absolute Cox score exceeded a threshold using cross-validation. For each iteration of the complete cross-validation, 10% of the cases were omitted, and principal components derived from the remaining 90% of the cases were included in a Cox model to predict the survival in 10% of the cases. By repeating the iteration process for 10 times, we found that a threshold of 2.6 yielded the highest average partial log-likelihood ratio. Principal component analysis (PCA) was then performed using 10 transcripts whose absolute Cox score equalled or exceeded the threshold for all cases in the training data set.

Table 1 Clinicopathological characteristics of all patients

| Variables | Cases | Training dataset (<i>n</i> = 39) | Validation dataset (<i>n</i> = 33) | <i>P</i> |

¹The multiple comparisons of different subclasses; ²Data was incomplete.

Kaplan-Meier survival curves were then plotted to predict overall survival. All analysis and plotting were conducted using R package superpc (<http://www-stat.stanford.edu/~tibs/superpc>).

Based on the transcript level in the 10 transcripts and the weight assigned to each transcript from the training set, a discrete risk score (the supervised principal components risk score) was then calculated for each patient in the validation dataset.

Multivariate analysis was conducted to evaluate the prediction accuracy of our survival profile in comparison with the standard clinicopathological covariates by Cox proportional hazards regression using SPSS software.

Functional gene set enrichment analysis was performed to find the pathways associated with prolonged and poor survivals. A total of 249 sets of canonical pathways (Gene Set Enrichment Analysis-Molecular Signatures Database) were analysed to indicate their correlations with overall survival to a greater degree than expected by chance^[12].

RESULTS

Patient characteristics

Totally, 79 gastric cancer patients treated with surgical resection were recruited in this study. Samples were randomly separated into two batches with no significant differences between the two sets with respect to age, sex and other clinicopathological features. Microarray was conducted in all samples, and the data of batch one served as the training dataset for marker discovery and data of batch two as the validation dataset. In batch one, microarray Quality Control

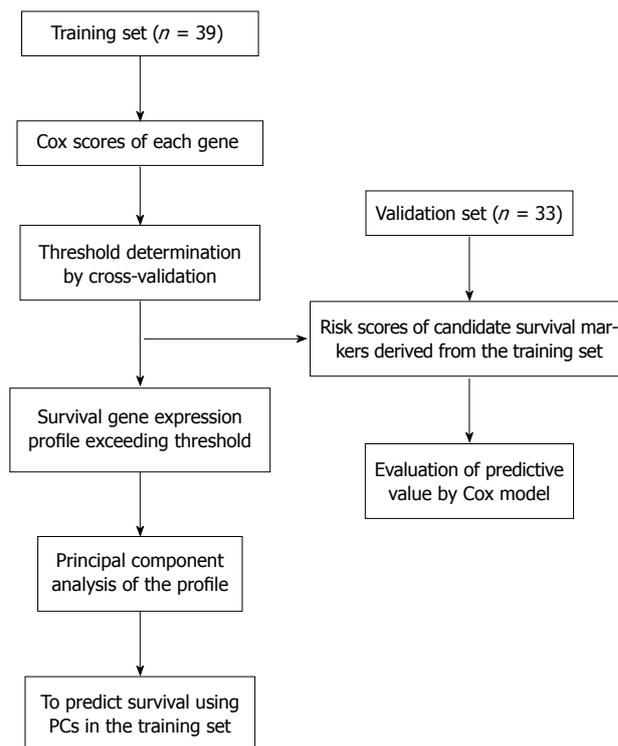

Figure 1 Overview of the strategy used for the development and validation of prognostic markers.

(QC) removed 7 samples due to failure in hybridization or failure to meet the analysis criteria, resulting in a total of 39 samples included in the training set. All of 33 samples in the second batch passed QC and were used in validation phase. The characteristics of the 72 patients are summarized in Table 1. The median overall survival time of all samples was 31 mo, ranging from 4.2 to 73.6 mo, and the 5-year overall survival was 33%.

Gene expression profile associated with the overall survival

The “semi-supervised” learning approach was used to identify the gene expression profile related to the overall survival in the training dataset^[12] (Figure 1). A total of 18 819 expression signals passed QC. First, we calculated the Cox scores of all 18 819 genes based on the survival times versus the expression levels obtained in 39 training observations. To choose the genes with the best prediction power, the threshold of Cox scores was calculated by 10-fold cross-validation. The expression profile of 10 transcripts whose Cox score equalled or exceeded the threshold was obtained (Table 2). Next, we performed PCA on the entire training set. For each case, a risk score that represents the sum of the weighted expression levels of the 10 prognostic transcripts was computed by supervised component analysis in a regression model. As shown in the Kaplan-Meier survival curves in Figure 2A and B, the patients were categorized into two groups based on their scores above or below the median risk of death. The low-risk group (*n* = 20) had a median survival of 42.1 mo, whereas the high-risk group (*n* = 19) had a median survival of only 26.5 mo.

Nine genes were associated with the prolonged survival and one gene with poor survival. Red, high expression; green, low expression; B: Kaplan-Meier survival curves based on the expression profile of the ten-gene prognostic marker; C: Overall survival curves according to the tumor-node-metastasis stages.

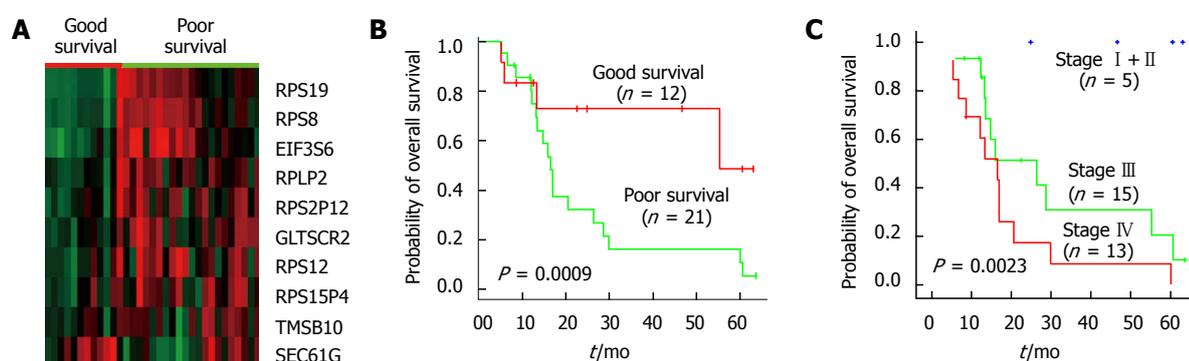

Figure 3 Overall survival curves and the expression profile of the ten-gene prognostic marker in the validation dataset. A: The gene expression pattern of the ten-gene prognostic marker. Red, high expression; green, low expression; B: Kaplan-Meier survival curves based on the expression profile of the ten-gene prognostic marker; C: Overall survival curves according to the tumor-node-metastasis stages.

Table 2 The ten-gene prognostic marker correlated to patients' survival

| Symbol | Cox score | Description |
|---------|-----------|--|
| RPS19 | 2.93 | Ribosomal protein S19 |
| RPS8 | 2.90 | Ribosomal protein S8 |
| RPS2P12 | 2.62 | Predicted ribosomal protein S2 |
| RPS12 | 2.59 | Ribosomal protein S12 |
| RPS15P4 | 2.57 | Predicted 40S ribosomal protein S15 |
| RPLP2 | 2.51 | Ribosomal protein, large, P2 |
| EIF3S6 | 2.61 | Eukaryotic translation initiation factor 3 |
| GLTSCR2 | 2.67 | Tumor suppressor candidate region gene 2 |
| TMSB10 | 2.47 | Thymosin, beta 10 |
| SEC61G | -2.98 | Sec61 gamma subunit |

The correlation of the risk score and the survival status ($P = 0.000047$, log-rank) indicates that this transcriptional pattern was associated with the patient outcomes. A similar classification was also seen by TNM staging ($P = 0.00016$, log-rank; Figure 3A).

Among the ten-gene prognostic markers, high expression levels of 9 genes were associated with poor survival (Figure 2B). SEC61G, a subunit of the heteromeric SEC61 complex, was the only gene with its high expression associated with prolonged survival. Interestingly, six out of the

10 genes in this profile are either identified or predicted ribosomal proteins, including RPLP2, RPS12, RPS8, RPS19, RPS2P12, and RPS15P4. The involvement of numerous ribosomal genes with survival times suggested either their regulation by tumor suppressor or oncogenes, or their direct participation in certain pathways other than protein synthesis. Furthermore, RPS8 and RPS12 were previously reported as cancer related markers in colorectal tumor and cervical squamous cell carcinoma^[13,14]. EIF3S6, a member of eukaryotic translation initiation factor 3, was identified as a prognostic factor in Stage I non-small cell lung cancers^[15]. To test if the survival categories relate to known pathways, we applied gene set enrichment analysis (GSEA) to microarray data of 18 819 transcripts using 249 canonical gene sets collected by MsigDB. Glucocorticoid receptor (GCR) pathway gene set, referring to glucocorticoid receptor-related inhibition of inflammatory response, was significantly associated with the overall survival (FDR = 0.15, $P = 0.004$).

Independent validation of prognostic markers

Next we evaluated the ten-gene prognostic marker in an independent dataset containing 33 cancer samples. As shown in Figure 3A and B, based on the expression of these 10 genes, the patients were classified into either a

Table 3 Association between different prognosis groups identified by the ten-gene marker and the clinicopathological characteristics

| Variables | Cases | Prolonged survival (n = 12) | Poor survival (n = 21) | P |
|-------------------------------|-------|--------------------------------|---------------------------|-------|
| Sex | | | | |
| Male | 14 | 9 | 5 | 0.070 |
| Female | 18 | 3 | 15 | |
| Age (yr) | | | | |

| III | 15 | 5 | 10 | |
| IV | 13 | 2 | 11 | |

¹Data was incomplete. *P* values for stage, grade and location of tumors were derived from the Pearson χ^2 test. *P* value for age was derived from the *t* test.

“low-risk group” or “high-risk group” with significantly different survival times ($P = 0.0009$, log-rank). The low-risk group patients had a median survival of 31.7 mo whereas the high-risk group one had a median survival of 21.4 mo. The expression patterns of these 10 genes in validation set were also similar to the observation in the data training set (Figure 3B). The results in validation dataset showed the consistency of our ten-gene prognostic marker in survival prediction. For pathway analysis, no significant association was observed by GSEA.

Analysis of candidate survival markers with clinicopathological parameters

As certain clinicopathological parameters, especially TNM staging, have been used as prognosis indicators, we also compared our ten-gene prognostic marker with the clinicopathological characteristics in the validation dataset in order to assess the impact of clinicopathological factors on overall survival. First we examined the distribution of prognostic factors as a function of risk assignment based on our ten-gene prognostic marker (Table 3). Certain variation such as age was seen between high- and low-risk groups, while gender, tumor location and differentiation grade, the depth of wall invasion, and metastasis showed no significant difference between the two groups except for the TNM staging ($P = 0.0023$).

Since the TNM staging is used most widely in clinical

Table 4 Multivariate Cox regression for overall survival in validation dataset

| Variables | P | HR | CI (95%) |
|----------------------------|-------|------|-----------|
| Depth of wall invasion | 0.370 | 1.66 | 0.55-4.90 |
| Differentiation | 0.240 | 4.93 | 0.15-1.58 |
| Lymph node metastasis | 0.780 | 0.77 | 0.13-4.53 |
| Distance metastasis | 0.120 | 0.32 | 0.08-1.35 |
| Ten-gene prognostic marker | 0.007 | 0.13 | 0.29-0.56 |

CI: Confidence interval; HR: Hazard ratio.

prognosis prediction, we compared the predictive power of our survival markers with the TNM staging. All the TNM stage II patients were categorized into the low-risk group and the entire high-risk group patients were in stage III or IV. A consistency between TNM staging and the staging was found by the ten-gene marker. However, two IIIb patients of the low-risk group had a survival of 63.7 and 22.5 mo at last follow-up, respectively. By Kaplan-Meier survival plots and log-rank tests, we assessed the patient survival status predicted by our prognosis candidates and TNM staging. Relatively more accurate predictions were shown by the ten-gene prognostic marker in both sample groups (TNM, $P = 0.00016$ and $P = 0.0023$; survival markers $P = 0.000047$ and $P = 0.0009$, Figure 2B and C, Figure 3B and C). As a result, in multivariate analysis, our ten-gene marker was the only independent indicator in prognosis prediction with statistical significance ($P = 0.007$; Hazard ratio 0.13; 95% CI: 0.29-0.56, Table 4).

DISCUSSION

It has been known that the environment and genetic background among ethnic groups correlate to the genesis and development of gastric cancer^[6]. Up until now, very limited studies have been conducted in finding prognosis markers for gastric cancer, especially in the Chinese population. Moreover, only one set of prognosis markers was reported recently using the whole genome microarray (> 30K), which, however, could predict peritoneal relapse but not overall survival^[10]. In addition, in previous reports, by the classical supervised method to select survival markers, “low-risk” and “high-risk” subgroups are contrived based on survival times before analysis. Such a subjective step may result in bias for next process or lead to the classification which is not biologically meaningful. Therefore, in this study, we adopted a supervised PCA strategy to build prognosis profiles with the consideration of survival time as continuous parameters^[11]. And based on the whole genome expression profiling, we found and verified a set of ten genes as candidate survival markers from the discovery panel of 39 samples and the validation panel of 33 samples.

In these 10 survival genes markers, 3 genes (RPS12, EIF3S6, RPS19) were previously reported as candidate

markers of diagnosis or prognosis in various types of cancers^[13,17,18]. TMSB10, a migration-inducing gene, was shown to relate to cancer metastasis^[19]. Additionally, a few genes (RPS19, RPLP2, GLTSCR2) are known factors involved in cell cycle control and apoptosis^[20-22]. None of our 10 markers was reported in other sets of candidate genes for gastric cancer prognosis^[5-8]. This is not a surprise since these 10 genes were selected based on the whole genome expression profiling followed by supervised PCA, whereas much less genes were included in earlier studies with the analysis strategy of supervised classification. Patients' genetic background may also contribute to such diversity.

Unexpectedly but also interestingly, 6 out of 10 candidate markers identified are ribosomal proteins (RPs). There may be a few explanations for this phenomenon. First, RPs have been shown to be the targets of several tumor suppressors and proto-oncogenes which affect the formation of the mature ribosomes or regulate the activity of proteins^[23]. Moreover, the deregulated expression of RPs was reported to associate with the carcinogenesis and metastasis of various cancers^[14]. Therefore, besides their unknown mechanisms possibly related to p53 and MYC^[24,25], RPs appear to have various cellular roles independent of protein biosynthesis, including their functions in DNA replication and DNA repair, transcription, RNA splicing and modification, cell proliferation, apoptosis, and cellular transformation.^[26] Among 6 RPs of our candidate prognosis markers, RPLP2, RPL19, RPS8 and RPS12 were all found to be involved in the carcinogenesis and progression of various cancers^[13,17,27]. RPS12 was also seen to have significant higher expression in gastric tumors in comparison with normal tissues in Chinese^[28].

In a number of diagnosis and prognosis sets identified in expression profiling from various cancer researches, the gene profile in most panels came from various pathways with different cellular functions. The result of our ten-gene prognostic marker containing 6 RPs raised another interesting issue on the molecular composition of biomarkers, i.e. which type is more powerful and more accurate in prediction, a set consisting of single gene tags from multiple individual pathways, or a group of genes from a few and related pathways. This issue needs more tests and evaluations for convincing answers. At this point, however, a few facts shall be brought into attention. First, our prognostic marker resulted from systematic analysis of whole genome expression profiling, and our strategy of supervised PCA largely reduced subjective attribution in analysis. Thus, a group of pinpointed signals will be more representative in biological meaning, thus providing more accurate prediction. Second, obviously in comparison with individual single signatures from multi-pathways, a group of signals would significantly overcome the individual bias, in which the pathway components in tumors vary widely^[29]. Finally, it has been shown that even for genetic alterations of a large number of genes in cancer, these variations may function through a relatively small number of pathways and processes^[29]. In our prognostic marker, although the details of the interrelationship

among those 6 RPs are still unknown, they have the same elevation in high-risk group, indicating the concordance of their functions in gastric cancer.

To reduce the heterogeneity among patients and samples which may bring bias to the analysis in this study, samples were randomly separated into training and validation batches. And no significant difference with respect to age, sex and other clinicopathological factors was found between the two batches (Table 1). And, by comparing clinicopathological factors between the high-risk group and low-risk group predicted by ten-gene markers, there was no significant difference between the two groups except for TNM staging (Table 3). Then we compared this ten-gene prognostic marker with TNM staging system. Both ten-gene prognostic marker and TNM classification can predict survival with statistical significances in discovery and validation sample batches (Figure 2C and 3C), indicating that our prognosis set can effectively complement traditional clinicopathological staging (Figure 2B and C, Figure 3B and C). The applicability of a marker with only 10 genes also suggests its potential to be developed as the prognosis marker panel for pre-operative molecular staging from endoscopic biopsy. Further validation with large scale samples are warranted for clinical application.

In conclusion, based on the whole genome expression profiling, we found and validated a ten-gene prognostic marker for overall survival prognosis of gastric cancer patients, which may be used with the TNM staging system as a parallel and complementary approach. However, the predominance of ribosome protein genes in our molecular prognostic marker warrants further research on their roles in cancer progression.

We would like to thank Dr. Yong Tao and Dr. Wei-Wei Zhai for their excellent suggestions and assistance in improving our manuscript.

COMMENTS

Background

Gastric cancer is the second leading cause of cancer related death in China and worldwide. The 5-year survival rate of patients with advanced disease is very poor. Currently, treatment plan and prognosis prediction for gastric cancer mainly depend on the clinicopathological staging. However, prognosis varies among patients with the same clinicalpathological stage. An individualized expression test for selected markers in biopsy and surgical samples will complement the current staging system, especially for prognosis prediction.

Research frontiers

The gene expression profiling has enabled researchers to quantify the biological states and consequently to uncover the subtle phenotypes in cancer. Such analyses have provided unique opportunities to develop various profiles that can distinguish, identify, and classify discrete subsets of disease, predict the disease outcome, and even predict the response to therapy.

Innovations and breakthroughs

In this study, based on the whole genome expression profiling, the authors identified and validated a ten-gene set that can be further developed as clinical prognosis markers to predict overall survival of gastric cancer patients. This marker set showed consistent prognosis results with the traditional Tumor-

node-metastasis (TNM) staging system. The findings in this study also provided new clues about the possible association between the deregulation of ribosome related gene expression and survival status of the patients after surgery.

Applications

Based on the whole genome expression profiling, a ten-gene prognostic marker set for overall survival prognosis of gastric cancer patients may be applied in combination with the TNM staging system as a parallel and complementary approach. However, the predominance of ribosome protein genes in these molecular prognostic markers awaits for further research on their roles in cancer progression.

Terminology

TNM: The TNM system is one of the most widely used staging systems in tumor classification. The system is based on the extent of the tumor (T), the extent of spread to the lymph nodes (N), and the presence of distant metastasis (M). A number is added to each letter to indicate the size or extent of the primary tumor and the extent of cancer spread. **Principal component analysis (PCA):** A mathematical tool used to reduce the number of variables while retaining the original variability of the data. The first principal component accounts for as much of the variability in the data as possible, and each succeeding component accounts for as much of the remaining variability as possible. **Gene set enrichment analysis (GSEA):** A computational method that determines whether a prior identified set of genes shows statistically significant, concordant differences between two biological states. It is a method which focuses on the analysis at the level of functional related gene sets instead of a single gene. It helps biologists to interpret the DNA microarray data by their previous biological knowledge of the genes in a gene set. GSEA has been shown to efficiently identify gene sets containing known disease-related genes in the real experiments.

Peer review

A ten-gene prognostic marker, including 6 ribosomal proteins, for overall survival prognosis of gastric cancer were identified and validated based on whole genome expression profiling. By comparing with the traditional TNM staging system, this ten-gene prognostic marker showed consistent prognosis results, which may complement the predictive value of current TNM staging system.

Abstract

AIM: To investigate expression of Bcl-2 and Bax in gastric ischemia-reperfusion (GI-R) and involvement of extracellular signal-regulated kinase (ERK) 1/2 activation.

METHODS: The GI-R model was established by ligation of the celiac artery for 30 min and reperfusion in Sprague-Dawley rats. Rats were assigned to groups in accordance with their evaluation period: control, 0, 0.5, 1, 3, 6, 24, 48, and 72 h. Expression and distribution of Bcl-2 and Bax proteins were analyzed by immunohistochemistry and western blotting in gastric tissue samples after sacrifice.

RESULTS: Compared with controls, the percentage of positive cells and protein levels of Bcl-2 decreased in

the early phases of reperfusion, reached its minimum at 1 h ($P < 0.05$); it then increased, reaching its peak at 24 h of reperfusion ($P < 0.05$). The pattern of Bax expression was opposite to that of Bcl-2. Bax expression increased after reperfusion, with its peak at 1 h of reperfusion ($P < 0.05$), and then it decreased gradually to a minimum at 24 h after reperfusion ($P < 0.05$). On the other hand, inhibition of activation of ERK1/2 induced by PD98059, a specific upstream MEK inhibitor, had significant effects on Bcl-2 and Bax in GI-R. Compared with GI-R treatment only at 3 h of reperfusion, PD98059 reduced the number of Bcl-2 positive cells (0.58% of R3h group, $P < 0.05$) and Bcl-2 protein level (74% of R3h group, $P < 0.05$) but increased the number of Bax-positive cells (1.33-fold vs R3h group, $P < 0.05$) and Bax protein level (1.35-fold of R3h group, $P < 0.05$).

CONCLUSION: These results indicated that the Bcl-2 and Bax played a pivotal role in the gastric mucosal I-R injury and repair by activation of ERK1/2.

INTRODUCTION

Current research into gastric ischemia-reperfusion (GI-R)

has focused on its pathogenic and underlying molecular mechanism^[1-8]. GI-R injury and repair is related to the changes in gastric mucosal cellular apoptosis and proliferation induced by GI-R in rats. In our previous experiments, we have explored the time course of gastric mucosal apoptosis and proliferation induced by GI-R, and the role of the extracellular signal-regulated kinase 1 and 2 (ERK1/2) signaling pathway in GI-R-induced gastric mucosal injury and repair^[7]. We have found that serious gastric mucosal damage occurs rapidly at the early stage of reperfusion and is closely related to the suppression of ERK1/2 activation. The activity of ERK1/2 increases as the time of reperfusion is extended, and the activated ERK1/2 might inhibit apoptosis and promote proliferation in gastric mucosal cells. However, the precise mechanisms by which activated ERK1/2 accomplishes gastric mucosal apoptosis and proliferation are unknown.

The balance between apoptosis and cellular proliferation is a key in gastric injury and repair, and is regulated by several genes, including p53 and members of the Bcl-2 family such as Bax and Bcl-2^[9-11]. The Bax gene is a proliferative suppressor gene that encodes Bax protein that promotes apoptosis. On the other hand, bcl gene encodes Bcl-2 protein that blocks wild type p53-mediated apoptosis, and heterodimers with Bax, antagonizing the function of Bax^[12].

Therefore, it is conceivable that increased cellular apoptosis and proliferation, because of altered expression of the regulating proteins such as Bax and Bcl-2, may be associated with gastric injury and repair induced by GI-R. Although Bcl-2 and Bax are expressed in gastric mucosa, their presence in normal gastric mucosa is controversial. Liu *et al.*^[13] have reported that Bcl-1 mRNA and protein are expressed in the gastric gland zone at a middle level and Bax protein is expressed in the epithelial cells of normal gastric mucosa. Xia *et al.*^[14] have found that, in intact gastric tissue, Bcl-2 and Bax are localized predominantly in the glandular base region in chief cells in normal rat gastric mucosa. However, a conflicting study has found that no expression of Bcl-2 protein is detected in the glandular epithelium of normal gastric mucosa^[15]. On the other hand, Bcl-2 and Bax show significant changes in many conditions including gastric cancer, gastritis, and GI-R^[15-18]. El Eter *et al.*^[15] have reported that cytoplasmic expression of Bcl-2 protein is observed in the superficial portion of gastric mucosa sections obtained from rats subjected to GI-R injury.

The available data on expression of Bcl-2 and Bax proteins in the stomach, and their relation to apoptosis of gastric mucosal cells, seem equivocal, thus, a further study of Bcl-2 and Bax expression in the stomach is clearly important. In the present study, we used an immunohistochemical assay and western blotting to determine the changed courses of Bcl-2 and Bax at different reperfusion durations after GI-R, and whether ERK1/2 activation was involved in this process.

MATERIALS AND METHODS

Animals

Groups of six adult Sprague-Dawley rats, regardless of

sex, weighing 220-270 g, were provided by the Experimental Animal Centre of Xuzhou Medical College. All experiments were performed in accordance with the National Institutes of Health Guidelines for the Care and Use of Laboratory Animals. Rats were housed under controlled temperature (22-24°C) and photoperiod (12 h light/12 h dark), and allowed food and water *ad libitum*. Rats were fasted for 24 h before the experiment, but were allowed free access to tap water. Animals were randomly assigned to groups: GI-R (different reperfusion time points after 30 min of ischemia); PD98059 + R3h (PD98059 + reperfusion for 3 h after 30 min of ischemia); and vehicle control (PD98059 replaced with vehicle but otherwise the same as PD98059 + R3h). PD98059 was given 20 min before operation [150 µg/kg, administered intraperitoneally (i.p.), dissolved in dimethyl sulfoxide]. A sham group in which only the same surgical procedure without clamping the celiac artery was performed served as a control.

Reagents

PowerVision™ two-step immunohistochemistry detection kit were purchased from Zhongshan Biotech Co. (Beijing, China), anti-Bcl-2 and anti-Bax polyclonal antibodies were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA), alkaline-phosphorylase-tagged goat anti-rat IgG antibody, PD98059 was from Promega (Madison, WI, USA), and sodium pentobarbital was purchased from Sigma (St. Louis, MO, USA).

Preparation of GI-R model

GI-R models were induced according to the method of Qiao *et al.*^[7]. The randomly grouped rats were all anesthetized with sodium pentobarbital (40 mg/kg, i.p.). Their abdomens were incised along the midline, and the celiac artery and its adjacent tissues were carefully isolated. The celiac artery was clamped with a small non-traumatic vascular clamp for 30 min to induce gastric ischemia and then released for 0, 0.5, 1, 3, 6, 24, 48 and 72 h to allow reperfusion. Following reperfusion, the rats were sacrificed and the stomachs were removed immediately. The stomachs were incised along the greater curvature and flushed with ice-cold PBS (0.1 mol/L). One half of the gastric mucosa was frozen at -80°C for western blotting, and the other was fixed in Bouin's fixative for immunohistochemical staining.

Immunohistochemical staining

The fixed stomach was embedded in paraffin, sliced into 4-µm-thick sections, and mounted on glass slides. The immunohistochemistry was performed with a PowerVision two-step immunohistochemistry detection kit. The sections were stained with 3,3'-diaminobenzidine (DAB), then counterstained using hematoxylin. The sections were examined with a microscope (Model IX71; Olympus, Tokyo, Japan). Gastric mucosal cells with brown granules visible in the cytoplasm or nucleus were considered positive. The number of positive cells per section was counted in 10 random lower-power (× 10) fields, and the percentage

of positive cells (positive cells/total cells \times 100%) was calculated. Three non-consecutive sections were selected from each specimen and those indexes were averaged.

Western blotting

The frozen gastric mucosa was homogenized with a Teflon glass homogenizer in 1:10 (w/v) ice-cold homogenization buffer consisting of 50 mmol/L 3-(N-morpholino) propanesulfonic acid (MOPS, pH 7.4), 50 mmol/L NaF, 20 mmol/L sodium pyrophosphate (NaPPi), 20 mmol/L b-glycerophosphate, 1 mmol/L EDTA, 1 mmol/L EGTA, 1 mmol/L phenylmethylsulphonyl fluoride, 10 mg/mL leupeptin, 10 mg/mL aprotinin and 10 mg/mL pepstatin A. The homogenate was centrifuged at 800 *g* for 15 min at 4°C, and the supernatant was retained as cytoplasmic parts. Protein concentrations were determined by Coomassie brilliant blue protein assay. The proteins were heated at 100°C for 5 min with loading buffer containing 0.125 mol/L Tris-HCl (pH 6.8), 20% glycerol, 4% SDS, 10% mercaptoethanol and 0.002% bromophenol blue, then separated by 10% SDS-PAGE. The proteins were isolated by 12.5% SDS-PAGE and transferred to a nitrocellulose membrane. The blots were incubated with 4% bovine serum albumin in TBST (10 mmol/L Tris, pH 7.5; 150 mmol/L NaCl, 0.05% Tween-20) at 4°C for 6 h and probed with primary antibodies (anti-Bcl-2 polyclonal antibody 1:500, anti-Bax polyclonal antibody 1:400) at 4°C overnight. Membranes were rinsed and incubated with secondary antibody for 2 h and were detected with an NBT/BCIP assay kit. After immunoblotting, the bands were scanned and analyzed by Image J software. The optical density (OD) of the band in each lane was expressed as the fold change versus the OD of the sham control.

Statistical analysis

All results are presented as mean \pm SD. Comparisons between two groups were made with Student's *t* test; multiple-group analyses were made by one-way ANOVA. Statistical analyses were performed with SPSS for Windows version 11.5. *P* < 0.05 was considered statistically significant.

RESULTS

Quantitative changes in Bcl-2 and Bax positive cells of the gastric mucosa for different reperfusion durations after ischemia

Immunohistochemical staining clearly showed that Bcl-2 and Bax were expressed and limited to the cytosol of the cells in the gastric mucosa (Figure 1). Bcl-2 expressing cells were found predominantly in the lower part of the gastric gland, and were present only in gland cells of the stomach fundus (Figure 1A-D). Bax positive cellular distribution was similar to that of Bcl-2, with prominent expression in the base, but staining for Bax was also noticeable in the cells of the pit. Bax appeared to be absent from the middle part of the gastric gland, and weak expression of Bax was detected in most cells of the gastric mucosa (Figure 1E-H). The control sample (sham-operated) obtained prior to the ischemic period showed a

normal appearance of Bcl-2 (Figure 1A and B) and Bax (Figure 1E and F), and there were significant differences between the GI-R (Figure 1C, D, G and H) and control groups (Figure 1A and E) in the quantities of Bcl-2 and Bax immunoreactive cells.

The percentage of Bcl-2 and Bax positive cells in various groups is shown in Figure 2. Bcl-2 and Bax positive cells decreased in the early phase of reperfusion, with a nadir (10.02% \pm 1.21%) at 1 h of reperfusion, then increased significantly after reperfusion for 3 h, with a peak (29.76% \pm 3.32%) at 24 h of reperfusion, and returned to near the base level (20.47% \pm 2.97%) at 72 h of reperfusion. The opposite pattern was observed for Bax positive cells. The percentage of Bax positive cells increased in the initial stages of reperfusion, reached the highest Bax positive cell count (49.34% \pm 3.83%) at 1 h of reperfusion, then decreased gradually, with its nadir (13.36% \pm 3.05%) at 24 h of reperfusion, and recovered to base level (24.94% \pm 2.83%) at 72 h of reperfusion.

Protein expression of Bcl-2 and Bax in gastric mucosa at different reperfusion durations after ischemia

Figure 3 shows the Bcl-2 and Bax protein levels in the gastric mucosa in different groups of the study. After reperfusion, expression of Bcl-2 protein was significantly lower than that of the controls, and the lowest level was observed at 1 h of reperfusion (0.59% of sham group, *P* < 0.05). A peak of Bcl-2 protein expression was displayed in the 24 h reperfusion group (1.36 fold *vs* sham group, *P* < 0.05). The Bax protein level increased in the early stage of reperfusion, reached its peak (1.62-fold *vs* sham group, *P* < 0.05) at 1 h of reperfusion, and then decreased gradually to its lowest levels (0.57% of sham group, *P* < 0.05) at 24 h of reperfusion. At 72 h of reperfusion, Bcl-2 and Bax protein levels were the same as that of the control group.

Effects of PD98059 on expression of Bcl-2 and Bax

PD98059 is a specific upstream inhibitor of ERK1/2. By immunohistochemical assay, we found PD98059 had significant effects on Bcl-2 and Bax expression in GI-R. Compared with the control group (R3h group), the PD98059 + R3h group showed a fall in the number of Bcl-2 positive cells (0.58% of R3h group, *P* < 0.05) but an increase in Bax positive cells (1.31-fold *vs* R3h group, *P* < 0.05) (Figure 4). To ascertain the effect of PD98059 on expression levels of Bcl-2 and Bax protein, western blotting was performed. In the PD98059 + R3h group, gastric mucosal Bcl-2 protein level was 74% of that in the R3h group (*P* < 0.05), whereas Bax protein level was 1.35-fold more than that in the R3h group (*P* < 0.05) (Figure 5).

DISCUSSION

Previous studies have shown that many stress conditions, such as hemorrhagic shock, burns, sepsis, major surgery, ischemia and trauma can lead to GI-R injury. In recent years, studies on GI-R injury have revealed that reactive

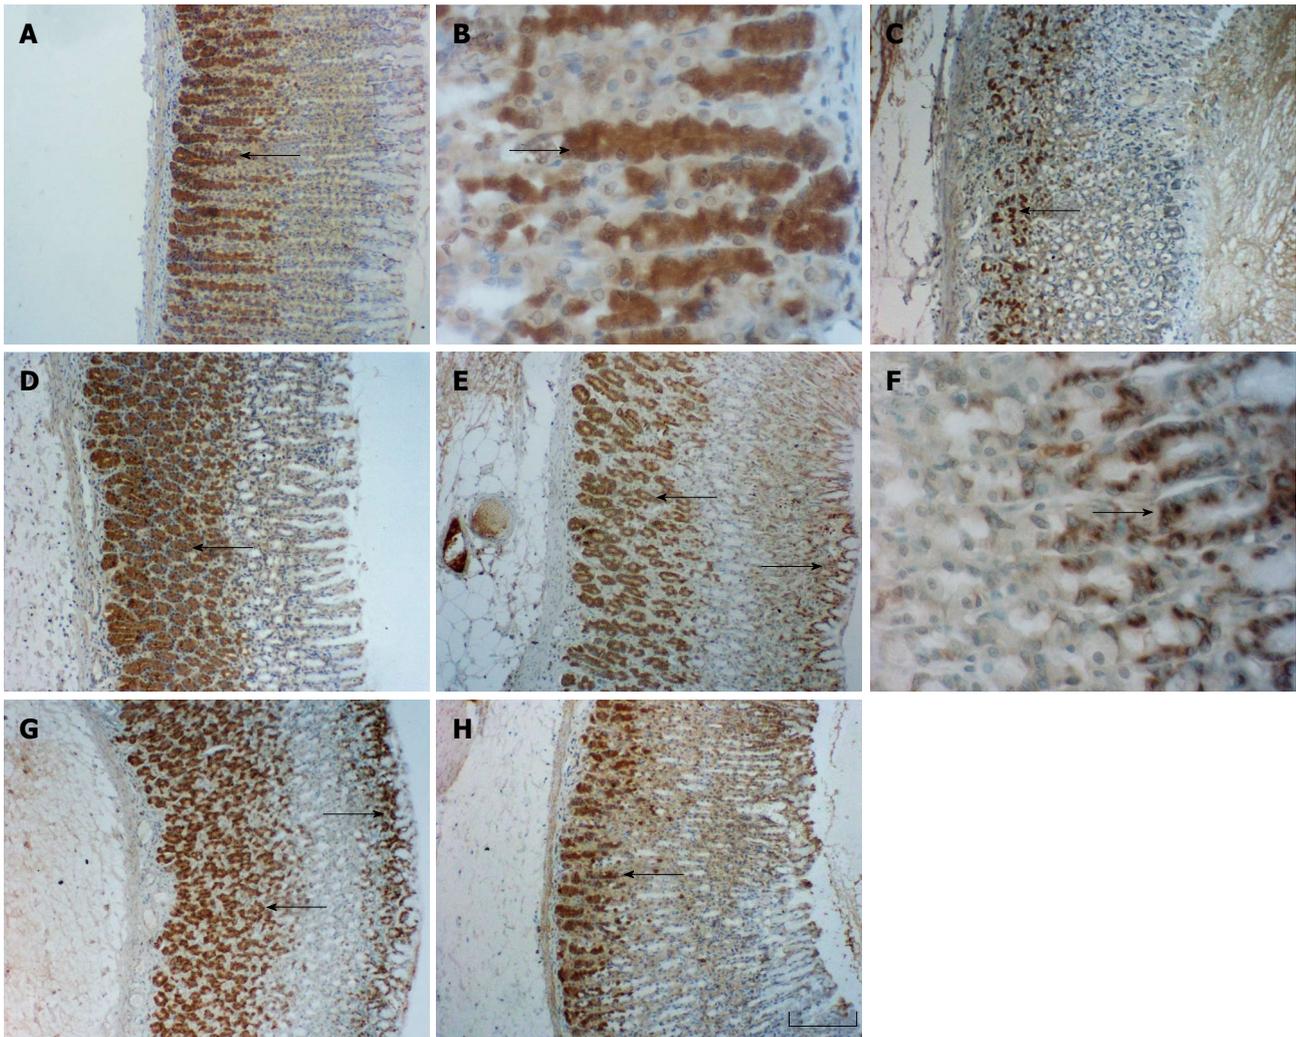

Figure 1 Histological exhibition of Bcl-2 and Bax positive cells in the gastric mucosa at different reperfusion times after ischemia, by immunohistochemical staining in rats. The Bcl-2 and Bax positive cells were respectively probed with anti-Bcl-2 and anti-Bax polyclonal antibodies in rat gastric mucosa. Nuclear counterstaining was performed with hematoxylin. The examples of immunoreactive cells are those with dark brown staining in their cytosol (arrows). A and B: Bcl-2, control; C: Bcl-2, GI-R at 1 h after reperfusion; D: Bcl-2, GI-R at 24 h after reperfusion; E and F: Bax, control; G: Bax, GI-R at 1 h after reperfusion; H: Bax, GI-R at 24 h after reperfusion. Images were obtained at $\times 100$ (A, C, D, E, G and H, Bar 100 μm) and $\times 400$ (B and F, Bar 400 μm).

oxygen species, endothelin, microvascular dysfunction, polymorphonuclear leukocyte infiltration, nitric oxide release, gastric acid secretion and decreased prostaglandin concentrations may play a role in the pathogenesis of gastric mucosal injury induced by GI-R^[1,5,19-25]. Although the gastric mucosa is vulnerable to damage by various factors, it can quickly repair the damage^[26]. Mucosal integrity is maintained by a balance between proliferation and apoptosis of the gastric mucosal cells. To understand better the causes of gastric lesions, it is important to study the imbalance between proliferation and apoptosis^[27,28].

In previous experiments^[7], we have shown the changed courses of gastric mucosal injury and repair induced by GI-R, and the role of ERK1/2 in this process. Our results indicated clearly that the gastric mucosal injury induced by GI-R was mainly the result of reperfusion. The serious gastric mucosal lesions occurred in the initial stages of reperfusion and the aggravating processes of mucosal lesions were at 1 h after reperfusion, which were main-

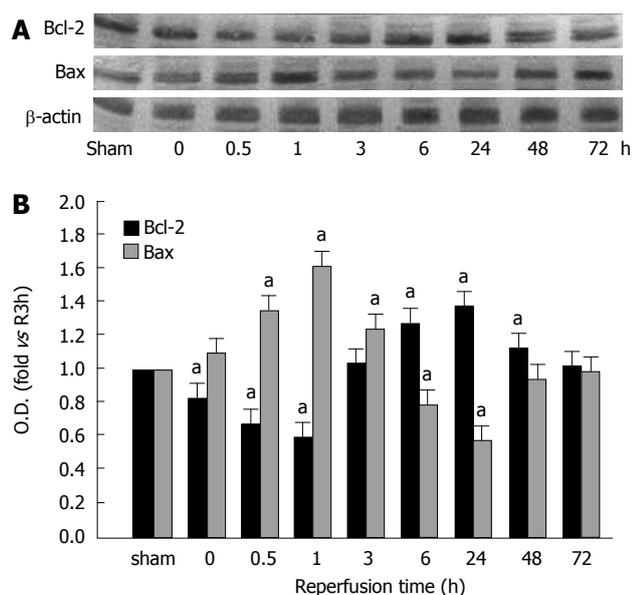

Figure 3 Expression of Bcl-2 and Bax proteins in cytoplasm extracts from rat gastric mucosa for different reperfusion durations after gastric ischemia-reperfusion. Extracts were obtained from sham-operated rats or from gastric ischemia-reperfusion rats with different reperfusion durations (0, 0.5, 1, 3, 6, 24, 48, or 72 h) after 30 min of ischemia, and were analyzed respectively by western blotting with anti-Bcl-2 and anti-Bax antibodies. A: Representative blots corresponding to expression levels of Bcl-2 and Bax proteins; B: Semi-quantitative analysis of the levels of Bcl-2 and Bax. Sham: Sham-operated. tained about 3 h after reperfusion. The gastric mucosal repairs started after 3 h of reperfusion, and the complete recovery took almost 3 d. Based on these facts, it indicated that gastric mucosa has an amazing self-repairing ability. ERK1/2 are important members of the mitogen-activated protein kinase family. The activation of ERK1/2 participates in the regulation of cellular injury and repair in many tissues. Our researches have also shown that the p-ERK1/2 protein level decreased at 0.5 h after reperfusion began, and then gradually increased, reaching its peak after 3 h of reperfusion. Inhibition of the activation of ERK1/2 aggravated the gastric mucosal injury, with apoptosis increased and proliferation reduced in the gastric mucosal cells at the same duration of reperfusion. Therefore, activated ERK1/2 inhibited apoptosis and promoted proliferation in gastric mucosal cells.

Apoptosis and proliferation are fundamental mechanisms for cell death and survival and differentiation in the gastric mucosa. The status of the Bcl-2 family proteins determines whether a cell will live or die through the regulation of cytochrome c release from the mitochondria^[29,30]. Bcl-2 protein mainly inhibits apoptosis and facilitates cellular survival and differentiation, whereas overexpression of Bax protein induces apoptosis and inhibits the effect of Bcl-2^[31-33]. Our data showed that Bcl-2 expression decreased significantly after the start of the reperfusion, reaching its nadir at 1 h, before increasing gradually to a peak after 24 h of reperfusion. The pattern of change in Bax expression was opposite to that of Bcl-2 expression. Bax expression increased at first, reaching its maximum

after 1 h of reperfusion, and then decreased. Bcl-2 and Bax recovered gradually to base level at 72 h of reperfusion. PD98059, a specific upstream inhibitor of ERK1/2, downregulated expression of Bcl-2 and upregulated expression of Bax in GI-R. These results suggest that the course of expression of Bcl-2 and Bax were closely correlated with p-ERK1/2. Activation of ERK1/2 causes upregulation of Bcl-2 and downregulation of Bax.

In conclusion, Bcl-2 and Bax played a pivotal role in GI-R injury and repair by activation of ERK1/2. Bcl-2 was involved in recovery of GI-R-mediated gastric mucosa injury by promoting cellular proliferation, and Bax

was involved in gastric mucosal injury induced by GI-R by promoting apoptosis.

COMMENTS

Background

It is well known that many hemorrhagic and stress conditions lead to gastric ischemia-reperfusion (GI-R) injury. Gastric ulceration is very prevalent in humans and is usually preceded by burns, sepsis, major surgery, ischemia, trauma and other heterogeneous forms of stress. Erosions in the gastric mucosa can be demonstrated in as many as 75%-100% of patients within 24 h of admission to the intensive care unit (ICU). Clinically apparent gastrointestinal bleeding can occur in as many as 25% of ICU patients.

Research frontiers

In recent years, studies on GI-R injury have focused on its pathogenic and underlying molecular mechanism. In recent years, studies on GI-R injury have revealed that reactive oxygen species, endothelin, microvascular dysfunction, polymorphonuclear leukocyte infiltration, nitric oxide release, gastric acid secretion and decreased prostaglandin concentrations during reperfusion may play a role in the pathogenesis of gastric mucosal injury induced by GI-R. Mucosal integrity is maintained by the equilibrium between proliferation and apoptosis of the gastric mucosal cells. To understand better the pathogenesis of gastric lesions, it is of great importance to study the imbalance between proliferation and apoptosis.

Innovations and breakthroughs

This is believed to be the first study to investigate changes in expression of Bcl-2 and Bax at different times of reperfusion after gastric ischemia, and whether extracellular signal-regulated kinase 1/2 activation was involved in this process.

Applications

Not only does our study provide insights into the mechanism of gastric mucosal tissue injury and repair; it also provides information that could potentially guide development of a new therapeutic strategy.

Peer review

The quality of the paper is excellent and deserves a fast publication, considering the contribution importance.

Abstract

AIM: To determine if natural killer T cell (NKT) populations are affected in nonalcoholic fatty liver disease (NAFLD).

METHODS: Patients undergoing bariatric surgery underwent liver biopsy and blood sampling during surgery. The biopsy was assessed for steatosis and immunocyte infiltration. Intrahepatic lymphocytes (IHLs) were isolated from the remainder of the liver biopsy, and peripheral blood mononuclear cells (PBMCs) were isolated from the blood. Expression of surface proteins on both IHLs and PBMCs were quantified using flow cytometry.

RESULTS: Twenty-seven subjects participated in this

study. Subjects with moderate or severe steatosis had a higher percentage of intrahepatic CD3+/CD56+ NKT cells (38.6%) than did patients with mild steatosis (24.1%, $P = 0.05$) or those without steatosis (21.5%, $P = 0.03$). Patients with moderate to severe steatosis also had a higher percentage of NKT cells in the blood (12.3%) as compared to patients with mild steatosis (2.5% $P = 0.02$) and those without steatosis (5.1%, $P = 0.05$).

CONCLUSION: NKT cells are significantly increased in the liver and blood of patients with moderate to severe steatosis and support the role of NKT cells in NAFLD.

INTRODUCTION

With the epidemic of obesity burgeoning across much of the world, nonalcoholic fatty liver disease (NAFLD) has become an increasingly pressing problem. The prevalence of NAFLD in western countries is as high as 17%-33%^[1], and the more severe form of NAFLD, non-alcoholic steatohepatitis (NASH), will progress to cirrhosis in 20% of patients^[1]. Due to its increasing prevalence, NAFLD has become the third leading indication for liver transplantation^[2].

The etiopathogenesis of NAFLD/NASH involves a number of environmental, genetic, and inflammatory influences. However, many of the factors that play a role in the development of NAFLD and NASH remain unknown. What is clear is that NASH is associated with hepatic infiltration of inflammatory cells, resulting in hepatocyte injury and hepatocyte death. The prevailing two-hit theory, posited by Day *et al*^[3], proposes an initial hit whereby obesity is associated with hepatic accumulation of free fatty acids and triglycerides, followed by a second hit, whereby oxidative stress, mitochondrial dysfunction, elaboration of pro-inflammatory cytokines and inflammatory cell infiltration leads to development of NASH.

Natural killer T (NKT) cells are a highly conserved subset of lymphocytes with properties of both T cells (CD3+ expression) and NK cells (CD56+ and CD161+ expression)^[4] and have been implicated in NAFLD. NKT cells are concentrated in the liver where they serve an important role in innate immunity. In the murine liver, NKT cells comprise 30%-50% of all hepatic lymphocytes^[5]. These cells can be directly cytotoxic *via* FasL-dependent and perforin-mediated mechanisms, but also produce an array of cytokines that direct cytokine secretion by other cells within their microenvironment^[5]. These functions may be responsible for cell death seen in NAFLD. NKT cells are believed to be primarily stimulated by various glycolipids, which are presented by CD1d, an MHC-like molecule on antigen presenting cells, such as Kupffer cells, to the NKT cells' invariant T cell receptor^[6]. The role of NKT cells in immunity has yet to be fully elucidated and there have been many proposed functions for this unique cell, ranging from antitumor activity to autoimmune diseases^[7]. In addition, murine models of obesity and fatty liver disease, using leptin-deficient, *ob/ob* mice, have suggested that NAFLD is associated with depletion of NKT cells^[8]. The loss of CD4-expressing NKT cells is particularly intriguing as this cell subset is believed to primarily secrete Th2-type cytokines, including IL-4 and IL-13^[9]. This loss of Th2 cytokines might tip the inflammatory milieu of the liver into a pro-inflammatory Th1 state, leading to excessive production of TNF- α and IFN- γ . The increase in pro-inflammatory cytokines likely plays a role in hepatic oxidative stress and recruitment of additional inflammatory cells into the liver, resulting in NASH^[10]. The transfer of NKT lymphocytes back into leptin deficient mice has been shown to reduce hepatic steatosis and improves glucose intolerance^[11]. In addition, inducing expansion of the NKT cell population, by norepinephrine injection or by stimulation with glucocerebroside, has also been shown to reduce hepatotoxicity and improve hepatic fat content in murine models^[12,13].

While murine models of NAFLD clearly support a pivotal role of NKT cells in pathogenesis, data on the role of NKT cells in human NAFLD is limited. Xu and colleagues found that peripheral blood NKT cells are depleted in patients with clinically diagnosed NAFLD^[14]. Three other studies evaluated intrahepatic NKT cells and had differing results. The study by Kremer *et al*^[15] found that NKT cells

are depleted with increased steatosis, whereas the one by Tajiri and colleagues found an increase in NKT cells with steatosis^[16]. Finally a study by Syn *et al*^[17] also found an increase in NKT cells with steatosis. In this study, we sought to further investigate the changes in lymphocyte populations that occur in NAFLD.

MATERIALS AND METHODS

Patients and lymphocyte isolation

From January to November 2007, peripheral blood and hepatic tissue were collected from obese subjects undergoing laparoscopic gastric banding surgery. Patients were excluded if they were under the age of 18, infected with hepatitis B virus, hepatitis C virus, HIV, were known to have pre-existing hepatic disease, or found to have any non-NAFLD pathological processes found on histological examination of the liver biopsy material. Patients were also excluded if they had a known history of excessive alcohol ingestion. All enrolled subjects signed an informed consent form that was approved by the institutional review board of NYU Langone Medical Center.

Immediately prior to surgery, 10 mL of blood was obtained from each subject by venipuncture. During the surgery a 2 cm³ liver scissor biopsy was obtained. The liver biopsy sample was placed in 15cc of sterile RPMI 1640 (Mediatech Inc, Herndon, VA) and was transported to the laboratory with the blood sample for lymphocyte isolation. An additional portion of the biopsy was evaluated by a single hepatopathologist who made the diagnosis of NAFLD and NASH using the staging system proposed by Brunt *et al*^[18]. Mild steatosis was defined as steatosis involving up to 33% of hepatocytes, moderate steatosis involved 33%-66% of hepatocytes, and severe steatosis involved greater than 66% of hepatocytes. Steatohepatitis was defined by a number of features including steatosis, ballooning, and acinar and portal inflammation.

Once transported to the laboratory, the liver biopsy sample was washed in sterile phosphate-buffered saline (PBS) and was minced to 1 mm³ pieces in a petri dish with 30 mL of RPMI 1640 containing 0.5 mg/mL collagenase type II (Clostridiopeptidase A), 0.02 mg/mL DNase I, 100 U/mL penicillin, 100 mg/mL streptomycin and 2 mmol/l L- glutamine (all from Sigma-Aldrich, St. Louis, MO) and 10% fetal calf serum (FCS) (Invitrogen, Carlsbad CA). The minced liver was incubated in this digestion solution at 37°C for 30 min after which it was strained through a 70 mm disposable plastic strainer. Immediately after isolation, cells were washed and re-suspended in PBS. The cell solution was then pipetted onto a 30%-70% percoll (Sigma-Aldrich, St. Louis MO) gradient and was centrifuged at 2000 r/min for 30 min. The isolated lymphocytes were removed from the gradient, washed with PBS, resuspended in 1 mL PBS/10% FCS containing 2% formaldehyde (Sigma-Aldrich, St. Louis MO) and placed at 4°C. Peripheral blood mononuclear cells (PBMCs) were prepared by centrifugation on a Ficoll-Hypaque density gradient (Mediatech, Herndon, VA).

Table 1 Patient characteristics

| | No. steatosis (n = 10) | Mild steatosis (n = 11) | Moderate-severe steatosis (n = 6) | Reference values |
|--------------------------------------|------------------------|-------------------------|-----------------------------------|------------------|
| Age | 36.3 ± 13.1 | 44.5 ± 14.4 | 48.3 ± 11.3 | N/A |
| Gender (% female) | 90% | 73% | 66% | N/A |
| Body mass index (kg/m ²) | 42.4 ± 3.2 | 44.2 ± 6.2 | 41.9 ± 4.3 | 18.5-24.9 |
| Aspartate transaminase (U/L) | 28.8 ± 13.2 | 42.8 ± 34.2 | 47.0 ± 26.9 | 0-40 |
| Alanine transaminase (U/L) | 36.1 ± 18.7 | 50.1 ± 48.2 | 75.8 ± 40.1 | 0-45 |
| Alkaline phosphatase (IU/L) | 79.2 ± 18.0 | 89.5 ± 16.6 | 82.5 ± 12.7 | 20-140 |

All results except gender presented as mean ± standard deviation.

Flow cytometric analysis of lymphocyte populations

Cell surface expression of lymphocyte antigens was identified by monoclonal antibody staining of freshly isolated IHLs and PBMCs, followed by flow cytometry using a BD LSR II (Becton Dickinson Immunocytometry Systems (BDIS), Mountain View CA) flow cytometer with analysis using CellQuest[®] software (BDIS, Mountain View CA). Monoclonal antibodies used in this study included anti-human CD3 (clone UCHT1) (BDIS, Mountain View, CA), anti-human CD4 (clone RPA T4) (PharMingen, San Diego, CA), anti-human CD8 (clone RPA T8) (PharMingen, San Diego, CA), anti-human CD56 (clone NCAM16.2) (PharMingen, San Diego, CA), anti-human CD161 (clone DX12) (PharMingen, San Diego, CA), anti-human $\nu\alpha 24$ (clone C15) (Immunotech, Fullerton, CA), and the appropriate isotype controls. During flow cytometry, lymphocytes, initially identified by their forward and side scatter characteristics, were subject to phenotypic analysis. Dead cells were excluded from analysis using 7-aminoactinomycin D (Calbiochem, La Jolla, CA).

ELISA for quantification of IFN- γ and IL-4 secretion

IFN- γ and IL-4 secretion by intrahepatic and peripheral blood lymphocytes was determined by ELISA (BD PharMingen) after culture for 12 h. For these assays, 1×10^5 lymphocytes derived from the liver or blood were co-cultured with monocyte-derived macrophages in the presence of alpha-galactosyl ceramide at 10 $\mu\text{g}/\text{mL}$ in a 96-well flat-bottom plate.

Statistical analysis

Values are expressed as mean ± SD. Statistical comparisons were made between PBMCs and IHLs from individuals using a paired *t*-test. Statistical comparisons were made between subjects without hepatic steatosis, those with mild steatosis and those with moderate-to-severe steatosis using a two-sample, unequal variance *t*-test. All reported *P* values were two-sided at the 0.05 significance level using SPSS[™] 11.0 for Windows software (SPSS, Chicago, IL).

RESULTS

Subject cohort characteristics

Table 1 describes the clinical characteristics of the 27 patients enrolled in this study. Ten of the twenty-seven subjects (37%) had normal liver biopsies, without steatosis, while 11 of 27 (41%) had mild hepatic steatosis and 6 of 27 (22%) had moderate-severe hepatic steatosis. Of the patients with mild steatosis, 10 had increased hepatic lymphocyte infiltration, but were not felt to be severe enough to merit a diagnosis of NASH. One of the six subjects with moderate-severe steatosis had grade 3 steatohepatitis with grade 1 fibrosis. Seventy-eight percent of the subjects were female, their mean age was 42 years, and their mean body mass index (BMI) was 42.9. There were no significant differences between patient cohorts with regard to age, gender, BMI, or serum levels of liver-associated enzymes.

Moderate-to-severe hepatic steatosis is associated with increased percentages of intrahepatic and blood NKT cells

Using the most common phenotypic definition of NKT cells, we sought to compare the percentage of CD3+/CD56+ in the liver and the periphery of subjects without hepatic steatosis with those with moderate-to-severe steatosis. As shown in Table 2, the liver and blood of subjects with steatosis had significant increases in the percentage of NKT cells. CD3+/CD56+ NKT cells comprised $38.6\% \pm 10.5\%$ of all intrahepatic T cells of subjects with moderate-to-severe steatosis, compared to $21.5\% \pm 14.3\%$ T cells in the liver of subjects without any steatosis ($P = 0.03$). The percentage of CD3+/CD56+ T cells in the liver of subjects with mild steatosis ($24.1\% \pm 12.4\%$) was intermediate between that of normal and moderate-to-severe steatosis, and was significantly lower than that of the subjects with moderate-to-severe steatosis ($P = 0.05$) with a correlation of 0.93. While in all three subject cohorts, the percentage of CD3+/CD56+ cells was significantly lower in the blood compared to the liver, the percentage PBMC CD3+/CD56+ NKT cells of subjects with moderate-to-severe steatosis ($12.3\% \pm 5.6\%$) was significantly greater than both subjects with no steatosis ($5.1\% \pm 5.5\%$, $P = 0.05$) and those with mild steatosis ($2.5\% \pm 1.5\%$, $P = 0.02$).

Percentage of invariant $\nu\alpha 24$ NKT cells in patients with steatosis and IFN- γ and IL-4 expression

We also analyzed invariant NKT cells; the CD-1d-reactive, glycolipid-activating NKT cells which express $\nu\alpha 24$ ^[7]. We found that a minority of CD3+/CD56+ NKT cells express $\nu\alpha 24$. In addition, we did not find significant differences in expression of $\nu\alpha 24$ between subjects without steatosis, those with mild or those with moderate-to-severe steatosis in the liver or blood (Table 2). When stimulated by alpha-galactosylceramide, the prototypical stimulant of $\nu\alpha 24$, invariant NKT cells, hepatic-derived lymphocytes produced greater amounts of IFN- γ , as measured

Table 2 Percentage of CD3+ lymphocyte populations in patients with normal livers, mild hepatic steatosis, and moderate to severe steatosis *n* (%)

| Lymphocyte population | N steatosis | M steatosis | MS steatosis | P value (N vs M) | P value (N vs MS) | P value (M vs MS) | Correlation coefficient |
|------------------------|-------------|-------------|--------------|------------------|---------------------|--------------------|-------------------------|
| CD3+/CD4-/CD8- PBMC | 8.13 | 3.62 | 22.88 | 0.22 | 0.1 | 0.04 ^a | 0.73 |
| CD3+/CD4-/CD8- IHL | 12.61 | 9.12 | 26.58 | 0.4 | 0.1 | 0.05 ^a | 0.76 |
| CD3+/CD56+ PBMC | 5.09 | 2.45 | 12.32 | 0.22 | 0.049 ^a | 0.016 ^a | 0.71 |
| CD3+/CD56+ IHL | 21.49 | 24.13 | 38.62 | 0.7 | 0.03 ^a | 0.048 ^a | 0.93 |
| CD3+/CD56+/CD161+ PBMC | 2.45 | 1.15 | 9.64 | 0.3 | 0.027 ^a | 0.017 ^a | 0.79 |
| CD3+/CD56+/CD161+ IHL | 15.50 | 18.90 | 35.81 | 0.6 | 0.006 ^a | 0.017 ^a | 0.93 |
| CD3+/Vα24+ PBMC | 0.60 | 0.53 | 0.57 | 0.48 | 0.23 | 0.14 | -0.43 |
| CD3+/Vα24+ IHL | 0.43 | 0.42 | 0.76 | 0.9 | 0.37 | 0.36 | 0.85 |
| CD3+/CD8+ IHL | 55.59 | 49.30 | 26.58 | 0.51 | 0.0003 ^a | 0.006 ^a | -0.95 |

Each percentage is the proportion of a specific CD3+ lymphocyte population out of all CD3+ lymphocytes. ^a*P* < 0.05. PBMC: Peripheral blood mononuclear cell; IHL: Intrahepatic lymphocyte. N: Normal; M: Mild; MS: Mod/sev.

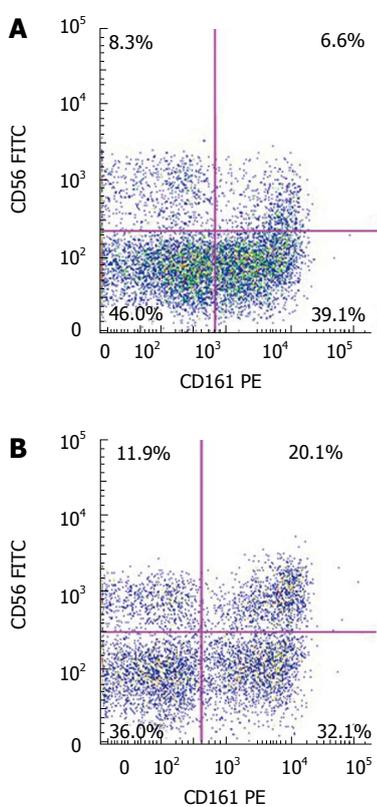

Figure 1 Flow cytometry of CD3+/CD56+/CD161+ intrahepatic lymphocytes in a patient with a normal liver versus a patient with moderate steatosis. Cells were initially selected *via* CD3+ gating prior to analysis for expression of CD56 and CD161. There are a greater percentage of natural killer T cells (CD56+/CD161+) in patients with moderate steatosis (20.1%) as compared to patients with normal livers (6.6%). A: Normal liver; B: Moderate steatosis.

by ELISA, compared to peripheral lymphocytes, though no differences were noted between patient cohorts (data not shown). In the majority of samples, IL-4 secretion remained undetectable.

Expression of CD161+ on NKT cells is increased in patients with moderate to severe steatosis

CD161 (NKR-P1A) is a receptor that is primarily associ-

ated with NK cells, but is also expressed on NKT cells, and may indicate an effector and memory subset of such cells^[19]. We therefore assessed the expression of CD161 on the CD3+/CD56+ populations in the liver and blood (Figure 1). Again, in each cohort, there were a higher percentage of CD3+/CD56+ cells that expressed CD161 in the liver, compared to the blood (Table 2). Further, the percentage of CD161-expressing CD3+/CD56+ cells in the liver (35.8% ± 9.1%) and blood (9.6% ± 4.9%) of subjects with moderate-to-severe hepatic steatosis were significantly increased compared to those without steatosis (liver: 15.5% ± 12.6%, *P* = 0.01, blood: 2.5% ± 3.8%, *P* = 0.03) and those with mild hepatic steatosis (liver: 18.9% ± 12.5%, *P* = 0.02, blood: 1.2% ± 1.1%, *P* = 0.02).

Moderate-to-severe steatosis alters the percentages of non NKT cell lymphocyte population

In addition to increases in the percentages of NKT cells, other minor lymphocyte subsets were significantly affected in patients with moderate-to-severe hepatic steatosis. Intrahepatic percentages of double negative T cells (CD3+, CD4-, CD8-) were increased in the liver of subjects with moderate-severe steatosis (26.6% ± 17.0%), compared to those without steatosis [12.6% ± 10.4%, *P* = 0.05 (Table 2)].

The CD3+/CD8+ lymphocytes were the only lymphocyte population found to significantly decrease in patients with moderate-to-severe steatosis. In these patients, the percentage of CD3+/CD8+ lymphocytes (27.3% ± 9.6%) decreased significantly as compared to patients with mild steatosis (49.9% ± 10.7%, *P* < 0.001) or without steatosis (55.6% ± 14.3%, *P* < 0.001). CD3+/CD8+ lymphocytes also decreased in the peripheral blood in patients with moderate-to-severe steatosis as compared to normal livers and approached significance (17.4% ± 8.5% *vs* 26.2% ± 7.0%, *P* = 0.06).

DISCUSSION

NAFLD and NASH are increasing in importance throughout the world. While our immune system plays an important role in the pathogenesis of this disease, our under-

standing of the specifics of the immunopathogenesis of NAFLD is limited. Much of our information regarding NAFLD has come from murine models, and NKT cells have been shown to be a key mediator of murine fatty liver disease^[12]. However, there are very few studies of intrahepatic NKT cells in humans. In this study, we sought to investigate the changes in lymphocyte populations, with a focus on NKT cells, in obese patients with histologically confirmed steatosis or steatohepatitis. We found that NKT cells, defined as CD3+/CD56+ lymphocytes, are significantly increased in patients with moderate to severe steatosis as compared to patients with no steatosis or mild steatosis. These findings differ from the numerous studies performed in mice and suggest a different role of NKT cells in fatty liver disease in humans.

There have been 4 previous studies investigating NKT cells and fatty liver disease in humans, each using different techniques and yielding different results. In a study by Xu and colleagues, the investigators found a decrease in peripheral $\nu\alpha 24+$ NKT cells as compared to healthy matched non-obese controls^[14]. In that study, the diagnosis of NAFLD was made on a clinical basis, as opposed to our utilization of histology, which is a more specific means of diagnosis, and IHLs were not examined. In a study by Kremer and colleagues, the investigators also found a decrease in NKT cells in patients with moderate to severe steatosis^[15]. However, they defined NKT cells by expression of CD3+/CD57+, and used immunohistochemistry staining instead of flow cytometry for quantification, both of which can account for the differences in their results and ours. Finally, Tajiri and colleagues evaluated liver biopsy specimens of patients with NAFLD and performed flow cytometry on 20 of the specimens. In these 20 specimens, they found that in patients with more severe steatosis there was an increase in CD3+/CD56+ NKT cells^[16], and is in agreement with the results reported here. Finally Syn *et al*^[17] studied 6 liver biopsies, 2 of which had confirmed NASH cirrhosis, and found an increase percentage of NKT cells in the livers with NASH cirrhosis compared to healthy controls and patients with other forms of hepatitis. With 27 patients enrolled in this study, this is the largest sample size to date to evaluate lymphocyte populations in patients with NAFLD. Further, we also quantified the presence of invariant NKT cells, expression of CD161 and other minor T cell populations in our biologic samples, as well as examining cytokine production.

NKT cells may play a number of immunoregulatory roles in the liver and are considered by some to be a bridge between the innate and adaptive immune systems^[20]. NKT cells participate in pro-inflammatory, Th1, and anti-inflammatory Th2 mediated pathways *via* the secretion of IFN- γ and IL-4, respectively. In murine models, it has been proposed that depletion of NKT cells shifts the hepatic immune environment toward a Th1 milieu, leading to immunocyte infiltration and development of steatohepatitis^[9]. Leptin deficient mice develop steatosis and NASH, but they do not develop cirrhosis^[20]. Alternatively, NKT cells, when shifting the immune environment toward a Th2

milieu may be responsible for collagen deposition in the liver. Stimulation and proliferation of NKT cells in leptin deficient mice, through adrenergic stimulation, results in hepatic collagen deposition and fibrosis secondary to IL-4 and IL-13 secretion and activation of Th2 mediated pathways^[12,20]. In our study, we found an increased percentage of intrahepatic CD3+/CD56+ NKT cells in patients with moderate to severe steatosis and a low incidence of steatohepatitis, which could support a protective role of NKT cells against steatohepatitis. In addition we found a decrease in CD3+/CD8+ intrahepatic lymphocytes which may implicate NKT cells in shifting the hepatic immunoregulatory environment towards more Th2 mediated mechanisms. We were unable to identify a difference in the secretion of IFN- γ or IL-4 by NKT cells in patients with various degrees of steatosis, although interferon, but not IL-4 production was elaborated when NKT cells were stimulated in the liver samples studied. Future studies should focus on investigating the functional role of NKT cells in human fatty liver disease.

The multiple definitions of NKT cells can lead to much confusion when discussing their role in the liver. We classified NKT cells in two different ways, both by expression of CD3+/CD56+, as well as by expression of $\nu\alpha 24+$. Human NKT cells were initially described in liver donor patients by Doherty *et al*^[21] as CD3+/CD56+ cells and were shown to be capable of lysing NK sensitive cells. CD3+/CD56+ lymphocytes have been analyzed for mRNA expression of $\nu\alpha 24$ and approximately 5% of human hepatic CD3+/CD56+ lymphocytes expressed $\nu\alpha 24$ mRNA, which encodes the TCR that recognizes CD1d ligands^[21]. Thus, NKT cells are also defined functionally as $\nu\alpha 24+$ lymphocytes or *via* isolation of CD3+ lymphocytes using CD1d ligands, and are classified as invariant NKT cells. The CD3+/CD56+ lymphocytes, which are also called NKT-like cells, are populations that incorporate many different type of lymphocytes such as invariant T-cells and CD161+ lymphocytes which can potentially create confusion^[22,23]. Thus, although we find that this broader more diverse population (CD3+/CD56+ NKT cells) is significantly increased with greater degrees of steatosis, the more specific subgroup of invariant $\nu\alpha 24$ NKT cells were unchanged. It is possible that other functional subgroups of CD3+/CD56+ lymphocytes such as CD161+ lymphocytes play a larger role in human NAFLD and NASH. This is in contrast to the murine model where there are higher percentages of invariant NKT cells normally found in the liver^[24]. These findings highlight the importance of investigating the role of invariant NKT and NKT-like lymphocytes in human disease, rather than just using murine models.

The results of the study are limited by the small sample size, and impaired our ability to further characterize the role of NKT cells in NAFLD. Nevertheless the increase in NKT cells in moderate to severe steatosis was significant and correlates with other studies. Absolute lymphocyte numbers were not reported here because the values were affected by the varied size of the liver biopsy samples

taken in each patient. Thus, NKT cell percentages of total lymphocyte were reported for more precise comparison between subjects. Immunohistochemistry has not yet been performed on the liver biopsies, however we hope to conduct future studies to further elucidate the role of NKT cells in NAFLD.

In this study, we examined the change in lymphocyte populations in obese patients with NAFLD, with a focus on intrahepatic NKT cells. We found an increase in NKT cells, defined as CD3+/CD56+ and as well as CD161+ lymphocytes, in obese patients with moderate and severe steatosis. These results differ from previous murine models and some human studies. In addition we reported other changes in lymphocyte populations, such as depletion in CD3+/CD8+ lymphocytes and an increase in CD3+/CD4-/CD8- cells, which have not yet been reported in NAFLD. The results of this study highlight the importance of investigating NKT cells and other lymphocyte populations in humans with NAFLD since the pathophysiology of human NAFLD likely differs from that in murine models. Future studies to investigate the role of NKT cells in NAFLD in humans are warranted in order to elucidate the mechanisms behind the pervasive disease of NAFLD.

COMMENTS

Background

Non alcoholic fatty liver disease (NAFLD) is a common disease where fat infiltrates the liver, which can lead to inflammation and cirrhosis. natural killer T (NKT) cells have been implicated in the pathogenesis of NAFLD. In obese mice, NKT cells are depleted in the liver and are associated with a greater degree of steatosis. When the NKT cells are upregulated in mice, the degree of fatty infiltration diminishes. There is limited data about NKT cells in human NAFLD, and this study adds to our understanding of NKT cells in human NAFLD.

Research frontiers

The data on intrahepatic NKT cells and its role in human steatosis has been mixed. There have been 3 studies investigating NKT cells and NAFLD. One found that NKT cells are depleted with increased steatosis whereas the others found an increase in NKT cells with steatosis. This study contains the largest sample to date which investigates NKT cells in human NAFLD.

Innovations and breakthroughs

The authors found that NKT cells, defined as CD3+/CD56+ lymphocytes are increased in human livers with moderate and severe steatosis. In addition, they reported other changes in lymphocyte populations with steatosis, such as depletion in CD3+/CD8+ lymphocytes and an increase in CD3+/CD4-/CD8- cells, which have not yet been reported in NAFLD.

Applications

These findings further support the role of NKT cells in NAFLD and highlight an important difference between NKT cells in the murine model of fatty liver disease and human NAFLD.

Terminology

NKT cells are a highly conserved subset of lymphocytes with properties of both T cells (CD3+ expression) and NK cells (CD56+ and CD161+ expression). The liver contains a high percentage of these unique lymphocytes, which have been implicated in the pathogenesis of non alcoholic fatty liver disease.

Peer review

The authors showed that patients with moderate or severe steatosis had a higher percentage of intrahepatic CD3+/CD56+ NKT cells than that with mild steatosis or without steatosis. Further, the percentage of CD3+/CD56+CD161+ cells in the liver of subjects with moderate-to-severe hepatic steatosis were significantly increased compared to those with mild hepatic steatosis or without steatosis. This is an interesting finding and may provide more information about the NKT

cells in human NAFLD because the data on NKT cells in human NAFLD is limited at present. However, there are several areas of the manuscript that the authors should expand upon that would enhance the presentation.

Abstract

AIM: To evaluate the feasibility, reproducibility and efficacy of a new tissue anchoring device in a porcine survival model.

METHODS: Gastrotomies were performed using a needle-knife and balloon dilator in 10 female Yorkshire pigs weighing 30-35 kg. Gastric closure was attempted using a new tissue anchoring device. The tightness of the closure was confirmed by means of air insufflation and the ability to maintain gastric distension with stability in peritoneal pressure measured with a Veress needle. All animals were monitored daily for signs of peritonitis and sepsis over 14 d. During necropsy, the peritoneal cavity and the gastric access site were examined.

RESULTS: Transgastric access, closure and 14 d survival was achieved in all pigs. The mean closure time was 18.1 ± 19.2 min and a mean of 2.1 ± 1 devices were used. Supplementary clips were necessary in 2 cases. The closure time was progressively reduced (24.8 ± 13.9 min in the first 5 pigs vs 11.4 ± 5.9 min in the last 5, $P = NS$). At necropsy, the gastric access site was correctly closed in all cases with all brace-bars present. One device was misplaced in the mesocolon. Minimal adhesions were observed in 3 pigs and signs of mild peritonitis and adhesions in one.

CONCLUSIONS: The use of this new tissue anchoring device in porcine stomachs is feasible, reproducible and effective and requires a short learning curve.

INTRODUCTION

Natural orifice transluminal endoscopic surgery (NOTES) has changed the approach to the peritoneum in the last

few years^[1-5]. This novel technique permits access to the peritoneal organs through the mouth, rectosigmoid or vagina with diagnostic and therapeutic purposes. Numerous hybrid NOTES procedures (combining NOTES with laparoscopy) have been described in the last five years^[6-9], but it was not until 2007 that the first pure NOTES procedures in humans were reported^[10-13]. Although the transluminal approach holds great potential, secure access site closure remains a critical issue^[14]. In recent cases and series, endoscopic closure is substituted by use of rigid instruments, using the transvaginal access in almost all cases. However, this approach excludes the male population.

Considering the safety of laparoscopy, studies are mandatory to evaluate secure and reproducible closure methods in NOTES procedures^[15]. Several closure techniques have been tested^[16], including clips^[11,17-19], septal occluders^[20], T-tags^[21-23], more complex suturing devices^[24-26], and linear endoscopic staplers^[27]. T-tags have been tested recently to treat gastrogastic fistulas in humans^[28]. However, most of these devices are time consuming and often difficult to implement endoscopically and the current data do not allow definitive conclusions regarding the different options^[16,29].

The aim of this study was to assess the feasibility, reproducibility and efficacy of a new tissue anchoring device as a gastric suture system in a porcine survival model.

MATERIALS AND METHODS

Animals

A total of ten female Yorkshire pigs weighing 30-35 kg were included in the study. Animals underwent a 3-d quarantine and acclimation period. During this period of time, veterinary personnel evaluated each animal to ensure baseline health. Animals were fed the same diet and had unlimited access to water. The study was conducted at the University of Barcelona Medical School's animal facilities. The protocol was approved by the University of Barcelona's Animal Ethics Committee.

Preoperative care and anesthesia

Animals fasted from solids 24 h prior to the procedure. All procedures were performed with pigs under general anesthesia with endotracheal intubation and mechanical ventilation.

Procedure

A non sterile endoscope (GIF 160, Olympus Medical Systems, Europe, Hamburg, Germany) was first inserted through the pig's mouth and the esophagus and stomach were inspected. Afterwards, gastric lavage was performed with water until the stomach was free of solid particles. An iodated solution followed by an antibiotic suspension (ceftriaxone 1 g/300 mL saline solution) was instilled and the antibiotic solution was left in the stomach for 10 min. From this point on, all the instruments used were sterile or high level disinfected. With a regular endoscope, an overtube was inserted and a double channel gastroscope (GIF 2T160, Olympus Medical Systems, Europe, Hamburg, Germany)

Figure 1 The incision is enlarged with a balloon dilator. Through the balloon we can see peritoneal structures.

was used until the end of the peritoneoscopy. By external palpation, the anterior gastric wall was selected to perform the gastric access. A 5 mm incision was made with a needle-knife (KD-V451M, Olympus Europe, Hamburg, Germany) and it was subsequently dilated with an 18 mm balloon (CRE wire-guided balloon, Boston Scientific Microvasive, Natick, MA) (Figure 1). Then, the scope was passed through the gastric wall for a 30 min peritoneoscopy.

A Veress needle was placed at the lower left quadrant of the abdomen to control intraperitoneal pressure. To avoid respiratory compromise and impaired venous return, intraperitoneal pressures were monitored and maintained below 15 mm H₂O. Pneumoperitoneum was maintained with CO₂ insufflation through the scope.

Tissue-anchoring device

The tissue-anchoring device prototype is called brace-bar (Olympus Medical Systems, Europe, Hamburg, Germany) and is an evolution of a former prototype^[21]. It consists of a single 18-gauge flexible needle catheter (Figure 2A), and a bifurcated nylon thread ("Y" shaped) with 3 small tags (2 regular tags fixed at both bifurcated distal ends and the other tag stopper at the single proximal end, which will be used for tightening) (Figure 2B). The tag stopper is movable and can be slid forward for cinching of the other tissue-anchoring tags. The proximal end of the thread is fixed to the needle with a small metallic guide (Figure 2C). Before deployment, the device has to be extracorporally loaded inside the needle catheter. The two distal tags are consecutively inserted into the needle (Figure 2D) and, finally, the needle is pulled back into the sheath inserting also the stopper tag (Figure 2E). Once inside the gastric cavity, the needle is pushed forward and the device is ready for use. The pusher button (Figure 2F) allows release of one tag at each side of the incision and the suture is tightened by pressing the tag Stopper with the needle sheath. Finally, the suture is released by extracting the metallic guide that fixed it to the needle.

The tightness of the closure was confirmed by means of air insufflation and the ability to maintain gastric distension with stability in peritoneal pressure measured with the Veress needle.

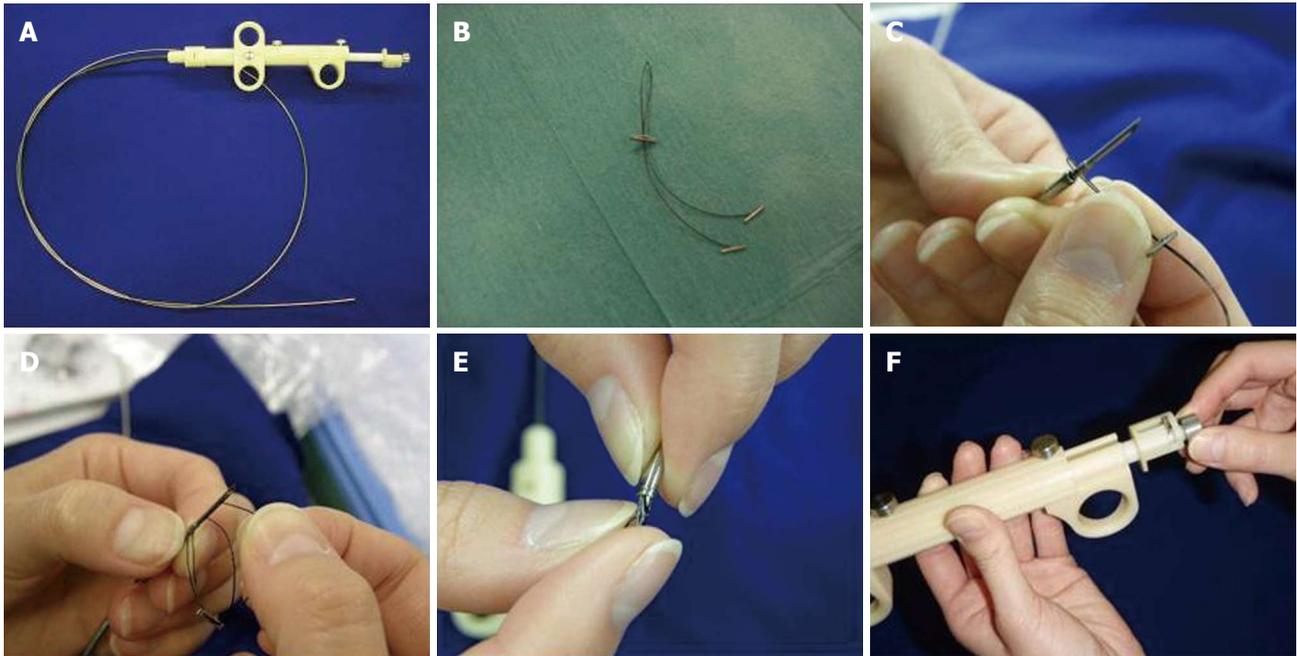

Figure 2 Description of the tissue anchoring device. A: Single 18-gauge flexible needle catheter; B: Bifurcated nylon thread (“Y” shaped) with 3 small tags (2 regular tags fixed at both bifurcated distal ends and the other tag stopper at the single proximal end, which is used for tightening); C: The proximal end of the thread is fixed to the needle with a small metallic guide; D: The two distal tags are consecutively inserted into the needle; E: The needle is pulled back into the sheath inserting also the stopper tag; F: The pusher button allows releasing one tag at each side of the incision.

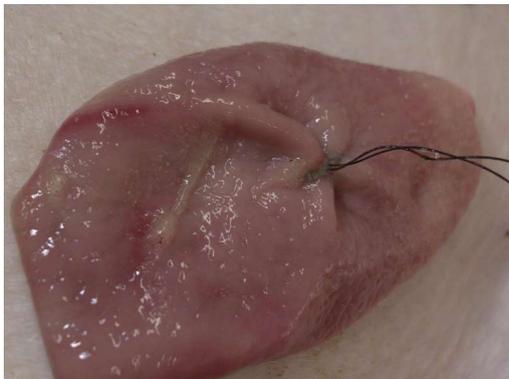

Figure 3 The incision looks completely sealed after the insertion of one brace-bar and the stomach is able to maintain air distension.

A single channel scope (Olympus GIG 160) was only used for the suture. Endoclips were added when the sutures were not placed at the middle of the incision and one of the sides seemed not completely sealed.

Postoperative care and necropsy

Water was immediately allowed and food was allowed after 24 h. All animals received intravenous ceftriaxone 1 g daily for 3 d and they were monitored daily for signs of peritonitis and sepsis during the next 14 d. Weight was controlled prior to surgery and necropsy. During necropsy, the peritoneal cavity and the gastric access site were examined for signs of peritonitis (exudates, abscesses) or other complications.

Statistical analysis

Data were expressed as mean \pm SD or range. Results were analyzed using the χ^2 test with Yates correction and Fisher exact test for qualitative variables and Mann-Whitney test for quantitative parameters. A P value < 0.05 was considered statistically significant. Statistical analysis was performed with SPSS Statistical Package (version 17.0, SPSS Inc., Chicago, IL).

RESULTS

All transgastric accesses were achieved with no difficulties and a mean time of 5.7 ± 3.6 min (range 2-14). No major complications occurred. Minor complications included an accidental injury to the anterior abdominal wall and 4 minor bleedings during the use of the needle-knife. A 30 min peritoneoscopy was possible in all animals.

The brace-bar was used in all cases and closure was easily achieved in 18.1 ± 19.2 min. This time was reduced to 11.4 ± 5.9 min when considering only the last 5 cases and was less than 9 min in the last 3 cases, whereas it was 24.8 ± 13.9 min in the first 5 ($P = 0.1$). Details of all procedures are described in Table 1. A total of 21 sets of sutures (mean 2.1 ± 1 , range 1-4) were used to achieve closure but only 15 (mean 1.5 ± 0.5 , range 1-2) could be completely tightened. Therefore, in 5 cases, the incision was closed with only 1 suture (Figure 3), but in two of them 1 and 3 clips respectively, were added.

In total, 6 sutures (29%) were ineffectively positioned. In 5 attempts one of the tags did not stay attached to the

Table 1 Summary of procedure details

| Case | Number of brace-bars used | Number of brace-bars correctly placed | Cause of Misplaced brace-bar | Adjunctive method | Closure time (min) | Endoscopic view |
|------|---------------------------|---------------------------------------|---|-------------------|--------------------|-----------------|
| 1 | 2 | 2 | | Omental patch | 8 | Correct |

Table 2 Summary of necropsy findings

| Case | Weight gain (kg) | Abdominal cavity | Incision | Location of tags |
|------|------------------|--------------------------------------|----------------|--|
| 1 | 6.85 | Minimal adhesions | Totally closed | 1 tag at mesocolon 3 tags at gastric serosa |
| 2 | 6.90 | Normal | Totally closed | 2 tag stoppers at gastric mucosa 2 tags at gastric serosa. |
| 3 | 5.00 | Minimal adhesions | Totally closed | 1 tag stopper at gastric mucosa 4 tags at gastric serosa |
| 4 | 3.70 | Normal | Totally closed | 2 tag stoppers at gastric mucosa 4 tags inside gastric wall |
| 5 | 1.90 | Normal | Totally closed | 1 tag at gastric serosa 1 tag inside gastric wall |
| 6 | 3.74 | Small clot | Totally closed | 1 tag stopper at gastric mucosa 3 tags at gastric serosa 1 tag inside gastric wall |
| 7 | 0.90 | Normal | Totally closed | 1 tag stopper at gastric mucosa 1 tag at gastric wall |
| 8 | 0.00 | Normal | Totally closed | 1 tag stopper at gastric mucosa 1 tag at gastric serosa 3 tags at gastric wall |
| 9 | -2.78 | Fibrin exudates Minimal adhesions | Totally closed | 2 tag stoppers at gastric mucosa 2 tags at gastric wall |
| 10 | 6.42 | Minimal adhesions | Totally closed | 1 tag stopper at gastric mucosa 2 tags at gastric wall 1 tag stopper at gastric mucosa |

mucosa either immediately after the tag release or when tightening the suture. The remaining failure was caused by a thread rupture after steady tightening.

Immediately after gastrotomy closure, all brace-bars seemed well positioned and gastric distension with air was possible in all cases without changes in intraperitoneal pressure, suggesting the closure was correct (mean peritoneal pressure before and after the closure: 14.3 ± 3.3 mmHg, range 3-15).

The mean procedure time, including gastric access creation, peritoneoscopy and gastrotomy suture, was 63.7 ± 18.2 min.

All the pigs completed the 14 d follow-up period. They had a weight gain of 3.3 ± 3.2 kg. At necropsy, the gastric access site was completely closed in all cases and all brace-bars were present (Table 2). The tags were usually attached

at the gastric serosa ($n = 15$) or inside the gastric wall ($n = 14$). In the first case, 1 tag was misplaced inside the mesocolon. In this case, an omental patch had been added to the suture pulling the omentum inside the stomach through the incision. Minimal adhesions were observed in 3 pigs and signs of mild peritonitis and adhesions in one.

DISCUSSION

NOTES holds great appeal as a less invasive alternative to laparoscopic surgery. As NOTES heads toward human trials, it is essential that the creation and closure of transluminal incisions be performed in a safe, rapid, and reproducible manner^[14-16,28].

In this study, we assessed the feasibility of a new generation tissue anchoring device with relatively good results.

Moreover, it turned out to be easy and intuitive to use and the time for placement was short and progressively reduced. It was not necessary to use complementary clips when we gained experience with the system. One of the advantages of this device (and the main difference with the former prototype used by Sumiyama *et al.*^[22]) is that it can be used with a single channel endoscope. The same needle catheter is used for releasing the tags and tightening them later without need for a different forceps grasper, and this makes the procedure shorter. Furthermore, the depth of the needle insertion is limited to 20 mm and this might decrease the risk of complications.

However, we still found some problems with the device: the needle had to be loaded extracorporally after each set of tissue anchors was applied and this prevented sequential stitching. Moreover, we observed a dysfunction of the needle after several attempts which could explain the high rate of sutures being ineffectively positioned because the tags could not be released deeply enough. We think that pre-charged and non-reusable devices might improve the procedure time and security. On the other hand, we did not drop any tags in the peritoneal cavity and, since each pair of tags is attached to a thread, we think that the possibility of dropping one in the peritoneum is extremely low.

The possibility of an inadvertent injury of organs and structures outside of the gut wall has been described as a possible limitation of T-tag based systems^[30,31]. Sumiyama *et al.*^[22] produced 12 gastric perforations in 6 pigs that were closed with 48 tissue anchor sets and three of the 24 used in the anterior gastric wall (12.5%) penetrated surrounding organs (2 penetrated the liver and 1 the anterior abdominal wall). However, as mentioned above, with the new brace-bar prototype the depth of the needle insertion is limited to 20 mm and this fact was crucial in the low incidence of surrounding structure injuries in our series (1 tag out of 21 sets, 4.8%). This was the first case and we tried to perform an omental patch pulling the omentum through the incision. During this maneuver, the mesocolon was probably unsafely moved towards the gastric wall causing this complication. In the remaining cases in which the omental patch was not attempted no lesions occurred at the adjacent structures. The importance of the depth of the needle to avoid complications has been demonstrated very recently by Park *et al.*^[32] These authors performed needle punctures of 1-1.5 mm using a different anchor-based endoscopic system (the TAS o tissue apposition system) and they did not have any adjacent organ penetration with a 100% of closure effectiveness.

Although the ex-vivo study of Voermans *et al.*^[33] suggested that t-tag based methods do not permit the serosa to serosa approach and leaking pressure is lower than with other devices, the surviving pigs showed a good post-operative course. This fact could be explained because physiological intraluminal pressures are much lower than pressures obtained in acute bursting tests and, therefore, might not be a necessary objective test for viscerotomy closure^[34]. From a clinical standpoint, the critical test for a

gastric closure is animal survival without clinical signs of leakage or complications.

Previous studies have demonstrated that peritoneal contamination occurs when using transgastric access. A conservative interpretation of these findings is that the current “aseptic” technique may require further refinement, as suggested by Rolanda *et al.*^[18] and Ryou *et al.*^[35]. In fact, we had some difficulties in completely cleaning some of the stomachs and it was very common to notice residual liquid near the incision. Only one pig did not have a satisfactory recovery and the necropsy showed the presence of fibrin exudates in the upper abdomen. Although the incision site was seen completely sealed at necropsy, we cannot totally exclude the possibility that an initial suture failure occurred but it could be also related with a potential contamination of the abdominal cavity by the stomach content. Because in this case we used only one brace-bar, we now consider it prudent to use two devices to ensure a safer closure.

The present study has some limitations: first, the number of cases is low and we did not include a control group. Second, the 14 d survival period might be short to evaluate late complications. Finally, the use of complementary clips in two cases might modify the results of the study.

In conclusion, the use of a brace-bar in a gastric porcine model is easy, fast, and reproducible after a short learning curve and permits the use of a single channel endoscope. We believe this tissue anchoring system holds tremendous potential as a suturing method for both iatrogenic and intentional perforations of the gastric wall. Unfortunately, it is still far from a safe application in humans. Further studies and more technological improvements are still mandatory before expanding its use to humans.

ACKNOWLEDGMENTS

Dr. Fernández-Esparrach thanks the Generalitat de Catalunya (AGAUR, BE-100022) and the Societat Catalana de Digestologia for supporting her training and research in NOTES. The authors would like to thank Olympus Europe (Hamburg, Germany) for providing with endoscopic closure devices for free for this study.

COMMENTS

Background

Natural orifice transluminal endoscopic surgery (NOTES) has changed the approach to the peritoneum in the last few years. Secure closure of the gastrotomy access is one of the most important issues for the development of NOTES. However, most new suturing devices are time consuming and often difficult to implement endoscopically.

Research frontiers

T-tag based systems have already been used with variable results. The possibility of an inadvertent injury of organs and structures outside of the gut wall has been described as a possible limitation of these devices. In this study, the authors demonstrate the usefulness and safety of a new tissue-anchoring-device prototype.

Innovations and breakthroughs

One of the advantages of this device (and the main difference with the former prototype) is that it can be used with a single channel endoscope. On the other hand, the same needle catheter is used for releasing the tags and tightening

them later without need for a different forceps grasper, and this makes the procedure shorter. Furthermore, the depth of the needle insertion is limited to 20 mm and this might decrease the risk of complications.

Applications

Because the use of the brace-bar is easy, fast, and reproducible after a short learning curve, we believe this tissue anchoring system holds tremendous potential as a suturing method for both iatrogenic and intentional perforations of the gastric wall.

Terminology

Natural orifice transluminal endoscopic surgery permits access to the peritoneal organs without the need of skin incisions. Tissue-anchoring devices are endoscopic suturing devices based on a nylon thread and a small tag at the distal end that are deployed within the gastric wall. When two or more of them are tight together, the margins of the incision approach and the incision is sealed.

Peer review

This is well written and succinct with appropriate interpretation and caution in the discussion.

Abstract

AIM: To evaluate the benefit and effectiveness of MR-arteriportography (MR-AP) to achieve the highest sensitivity for detection and evaluation of hepatocellular carcinoma (HCC).

METHODS: Twenty liver cirrhosis patients with suspected HCC were included before transarterial chemoembolization. In all patients double-enhanced Magnetic resonance imaging (MRI) was performed. A bolus of 10 mL Magnevist® was injected through a selectively placed catheter in the superior mesenteric artery and MRI of the liver was performed in arteriportographic phase. Two independent readers evaluated number, size and localization of detected lesions. Diagnostic quality was determined using a 4-point scale. Differences were analyzed for significance using a *t*-test. Interobserver variability was calculated.

RESULTS: In all 20 patients (100%), MR-AP was feasible. Diagnostic quality was, in all cases, between 1 and

2 for both modalities and readers. MR-AP detected significantly more lesions than double-enhanced MRI (102.5 vs 61, respectively, $P < 0.0024$). The inter-observer variability was 0.881 for MRI and 0.903 for MR-AP.

CONCLUSION: Our study confirmed that the MR-AP as an additional modality for detection of HCC is beneficial, as significantly more lesions were detected compared to MRI with liver-specific contrast.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common primary malignant tumor of the liver and often develops in patients with underlying liver cirrhosis due to excessive alcohol intake, chronic hepatitis or primary biliary cirrhosis.

In the treatment of hepatocellular carcinoma, surgical resection is considered the only potentially curative therapy. However, technical improvements in hepatic surgery have extended the indications for surgery remarkably, and also regional therapeutic procedures such as transcatheter

arterial chemoembolization (TACE)^[1-3] and radiofrequency ablation (RFA)^[1,4,5] have proved to be very successful. A prolonged time of survival following diagnosis is noted. Therefore, the pre-operative or pre-interventional workup of patients with suspected liver malignancy is even more important, especially concerning the evaluation and characterization of focal or diffuse lesions in the cirrhotic liver. Magnetic resonance imaging (MRI) has been used to improve identification of focal hepatic masses in a cirrhotic liver.

Dynamic MRI after a bolus injection of gadopentetate dimeglumine has been accepted as a valuable method for the detection and characterization of liver tumors^[6-9]. Studies have shown that superparamagnetic iron oxide-enhanced magnetic resonance imaging (SPIO-MRI) increases sensitivity^[4,10].

In order to determine the treatment of choice for HCC, studies have shown that examinations by both computed tomography angiography (CTA) and computed tomography arteriportography (CT-AP) are indispensable because of the high sensitivity of CT-AP in detecting hepatic lesions and the capability of CTA to characterize them^[11,12]. However, in contrast to its high sensitivity in detecting lesions, the specificity of CT-AP for characterizing intrahepatic lesions is low. Tumor-mimicking benign perfusion abnormalities and benign lesions (e.g. hemangiomas, arterio-venous shunts) have led to a reported incidence of false-positive lesions between 9% and 63% in primary and secondary liver lesions^[13,14].

Despite advances in CT or MRI, ultrasound (US) with or without application of contrast agents also plays a key role in the diagnostic algorithm of HCC due to its low cost, availability and non-invasiveness.

Until now, there have hardly been any studies comparing the effectiveness of MR-arteriportography (MR-AP) and contrast-enhanced MRI for diagnosis of malignant liver lesions. Thus, the purpose of this study was to combine the advantages of modern contrast-enhanced MRI with the technique of arteriportography to achieve the highest sensitivity for diagnosis of malignant liver lesions in patients suffering from HCC.

MATERIALS AND METHODS

Patients

Approval for this study was obtained from the institutional review board in conformity with the Declaration of Helsinki. Before the procedures were conducted, written informed consent was obtained from each patient for MRI, MR-AP and angiography after the nature of the procedure was fully explained.

During the period from February 2005 to September 2007, 20 patients [18 men, 2 women, age range from 47 to 76 years (mean age, 62 years)] with symptoms suggestive of primary malignant hepatic tumors were referred to our department. As HCC is commonly associated with liver cirrhosis, all patients had deteriorated liver but a tolerable renal function, and the cardiovascular status was stable. Twelve of our 20 patients suffered from alcohol toxic

liver cirrhosis. In 4 out of 20 patients the underlying disease was chronic hepatitis (2 patients with chronic hepatitis B, 2 patients with chronic hepatitis C). In 4 out of 20 patients, the fundamental disease could not be elicited. Concerning the severity of cirrhosis, 8 out of 20 patients were classified as Child Pugh score A, 7 out of 20 patients as Child Pugh score B and 5 out of 20 patients as Child Pugh score C.

The existence of malignant hepatic tumors was confirmed using multislice MRI and CT. MR-AP was performed to evaluate the tumor extent in order to suggest interventional therapy, surgery or chemotherapy.

Diagnosis of HCC was histologically confirmed in 15 out of 19 patients. In one patient (patient No. 16), existence of a malignant hepatic lesion was excluded histologically following liver transplantation.

In 13 out of 20 patients the α -fetoprotein (AFP) level was elevated, ranging from 16.4-2513 ng/mL (mean 488.1 ng/mL). In 7 patients (including patient No. 16) AFP levels were within a normal range.

Imaging procedures

Angiography: Before TACE and for MR-arteriportography, the femoral common artery was punctured under local anesthesia using the Seldinger technique and a 5-French angiographic catheter (Cobra, Cook Medical, USA) was positioned in the proximal superior mesenteric artery. A diagnostic angiography was performed to visualize the portal vein and to exclude shunts which could involve contrasting *via* the portal vein.

MRI: MRI was performed on a 1.5-T whole-body scanner (Magnetom Sonata, Siemens Medical Solutions, Germany) equipped with a high-performance gradient (Quantum) system (maximum gradient strength, 30 mT/m; slew rate, 125 T/ms). A combination of the standard body phased-array coil with spine array coils was used for signal reception.

MR-AP standard protocol (Table 1): For MR-AP, 10 mL gadopentetate dimeglumine was injected through the catheter placed in the superior mesenteric artery at a rate of 2 mL/s with a power injector (Medrad Spectris MR Injector, USA).

MRI standard protocol (Table 2): For MRI, 0.2 mmol/kg body weight gadopentetate dimeglumine was injected intravenously at a rate of 2 mL/s with a power injector (Medrad Spectris MR Injector). T1-weighted VIBE transversal Dynamic scans were acquired 20, 40, and 120 s after application of gadopentetate dimeglumine. T2-star-weighted Flash 2D scans and T2-weighted TSE FS scans were obtained after application of 1.4 mL Ferucarbotran (Resovist[®], Bayer Schering Pharma AG, Germany).

Image analysis

In the retrospective reviewing procedure, all images of each technique were interpreted and evaluated independently by two observers with great experience in abdominal MRI.

¹Dynamic scans were started immediately following application of Gd-DTPA (0.2 mmol/kg); ²Following application of 1.4 mL Resovist.

No clinical information or patient diagnosis was given to the observers. The images from each technique were interpreted in separate sessions in a randomized sequence. In the first session, the two observers reviewed a set of images that included both unenhanced and gadopentetate dimeglumine-enhanced, as well as Resovist-enhanced, images.

In the second session, each observer reviewed a set of images (MR-AP set) that included gadopentetate dimeglumine-enhanced images after injection *via* the superior mesenteric artery.

For characterization of liver lesions, all images of each examination were reviewed together using all the sequences available. Each observer recorded the number of suspected lesions noted, their size, and the segmental location. Furthermore, the image quality of MR and MR-arteriportography was documented on a four point scale: 1-excellent, 2-minor diagnostic limitations, 3-major diagnostic limitations, 4-non-diagnostic.

Statistical analysis

Statistical software (SPSS, version 14, Chicago, USA) was used for statistical analysis. We evaluated the differences with regard to number of lesions found using MR-arteriportography and MRI. Furthermore, the inter-observer differences in evaluation of MR-arteriportography and double-enhanced MRI were analyzed. Paired-samples

Table 3 Number of lesions detected in MR-arteriportography and magnetic resonance imaging

¹Patient No. 8 was excluded from the evaluation for diffuse infiltration of virtually all liver segments. *P* = 0.0024 (relation of the number of lesions detected in MR-AP and MRI). MR-AP: MR-arteriportography; MRI: Magnetic resonance imaging.

t tests and χ^2 test were used to compare. In paired-samples *t* tests, *P* < 0.05 indicated a statistically significant difference.

RESULTS

Twenty patients with liver cirrhosis underwent combined MR-arteriportography and SPIO-MRI examinations. No adverse reactions were experienced by any of the patients who received Gd-DTPA and SPIO.

In all 20 patients (100%), MR-arteriportography was feasible. The image quality in both modalities (MR-AP and MRI) was excellent (1-2 in MR-arteriportography, SD: 0.4865; 1-2 in MR, SD: 0.4292). In patient No. 8, a MR-AP evaluation was not suitable due to a diffuse infiltration of virtually all liver segments, thus the patient was excluded. Altogether, 102.5 hepatic lesions were detected using MR-AP, whereas only 61 lesions could be detected using MRI (Table 3). This difference is considered to be statistically significant (*P* < 0.0024).

The kappa analyses of two observers regarding the number of lesions detected by both modalities showed substantial to excellent agreement (κ = 0.903, 95% CI: 0.844 to 0.962 for MR-AP; and κ = 0.881, 95% CI: 0.795 to 0.966 for MRI). In particular, κ values with MR-AP imaging indicated excellent agreement.

The lesions found in all patients ranged in size from 7-120 mm (mean 28.24 mm) for MRI and from 4-120 mm (mean 24.62 mm) for MR-AP. This difference is not con-

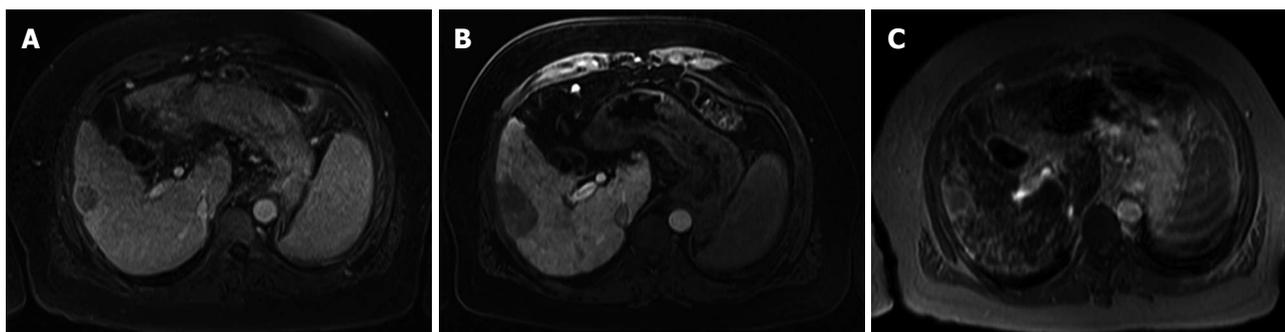

Figure 1 A 49-year-old man with hepatic cirrhosis due to chronic hepatitis B and C infection. Histology obtained following liver transplantation confirmed the diagnosis of a multifocal hepatocellular carcinoma. A: Magnetic resonance imaging (T1-weighted VIBE) during early venous phase shows a low signal intensity nodule with a diameter of approximately 3 cm in segment VIII/V; B: SPIO-enhanced T2-weighted fast image shows an area of increased signal intensity (segment VIII/V) within the otherwise lower but very inhomogenous signal of the liver parenchyma with profound cirrhosis; C: MR-AP (T1-weighted VIBE) during early venous phase displays an area of decreased enhancement (approx. 4.5 cm diameter) in segment VIII/V. Note the multiple smaller hypointense lesions in segments VII/VI. SPIO: Superparamagnetic iron oxide-enhanced.

sidered to be statistically significant. In MRI, 16 lesions (26.2%) were 10 mm or less in diameter. In MR-AP, 30 lesions (29.3%) were 10 mm or less in diameter.

In a total of 15 out of 19 patients, more lesions were detected by MR-AP compared to MRI with liver-specific contrast. According to the characteristic features displayed in MR-AP, all lesions were classified as malignant. Thus, as a consequence of the finding of these additional lesions, further treatment (TACE, RFA or surgery) was performed upon the patients.

In all but one patient (patient No. 16), the lesions found displayed a characteristic MRI signal, including arterial enhancement to a greater or lesser extent, with late wash out and an absent accumulation of Ferucarbotran (Resovist®). Thus, these lesions were classified as malignant. In addition, these lesions also showed characteristic features in MR-AP, such as absent enhancement of gadopentetate dimeglumine with profound demarcation compared to healthy liver tissue. Hence, the lesions were also classified as malignant.

Diagnosis of HCCs was histologically confirmed in 15 out of 19 patients. In patient No. 16, one lesion was found in segment 8 of the liver which showed a portal venous enhancement with accumulation of Ferucarbotran and no traceability in MR-AP. The lesion therefore was classified as benign, i.e. regenerated nodule that was confirmed histologically following liver transplantation (Figures 1 and 2).

DISCUSSION

Before decisions are made as to hepatic resection of hepatocellular carcinoma or interventional treatment such as TACE, percutaneous ethanol injection therapy and radiofrequency ablation (RFA), accurate information regarding the number and localization of lesions is essential.

Because of its high sensitivity for detecting lesions, CT-AP is one of the most reliable tools for detection of liver lesions. The rationale of CT-AP is for contrast material to be delivered directly to the liver through the portal vein before it can return to the hepatic artery from the

systemic circulation, to optimize the detection of tumor lesions that do not have portal vein flow and appear as hypodense nodules. The aim of our study was to combine the advantages of arteriportal contrast and MRI to detect liver lesions in patients with HCC. MRI with liver-specific contrast agents is currently the imaging modality of choice. Most studies that have directly compared MRI with CT-AP in patients with HCC or metastases reported no significant differences in sensitivity^[15-17], but in some studies a higher specificity for MRI is reported^[13].

Preoperative or pre-interventional workup of patients with suspected liver malignancy is even more important, especially concerning the evaluation and characterization of a focal lesion or diffuse infiltration of the cirrhotic liver.

Previous studies have shown the usefulness of ferumoxide-enhanced MR imaging for the detection of hepatic tumors of different histological types^[18,19]. After intravenous injection, the SPIO-particles are cleared by macrophages and can be identified histologically in Kupffer's cells of the liver. Poorly differentiated hepatic tumors lack Kupffer's cells; therefore, the T2 relaxation does not change after the administration of SPIO causing an increased lesion-to-liver contrast.

Studies of patients with hepatic metastases have shown that ferumoxide-enhanced MR imaging is more sensitive than unenhanced MR imaging^[20,21] or contrast-enhanced CT^[22,23], and at least as accurate as CT during arteriportography^[10].

Regarding the detection of HCCs, it has been reported that the sensitivity of combined CT during arteriportography and CT hepatic arteriography is 89%-95%^[24,25] in comparison to 80.4% on contrast-enhanced CT alone^[26]. Furthermore, the sensitivity of MR sequences with ferumoxide enhancement was reported to be 78%-92%^[18,19,24], and that of MR-AP 94%-97%^[27,28].

Diffusion-weighted imaging (DWI) is a MRI technique that provides imaging of diffusion in biological tissues. Recent technical developments have reduced the image deformation associated with this technique and have increased the signal to-noise ratio, thus making DWI of the

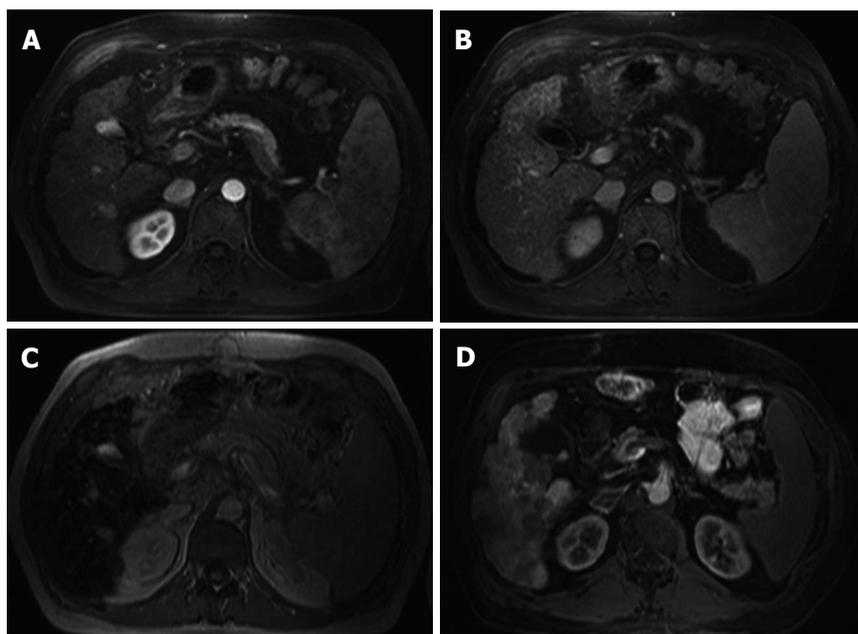

Figure 2 A 63-year-old man with hepatic cirrhosis due to a chronic hepatitis C infection. Histology obtained following liver transplantation confirmed the diagnosis of a well differentiated hepatocellular carcinoma. A: Magnetic resonance imaging (T1-weighted VIBE) during arterial phase shows a singular hyper-vascularized nodule with a diameter of approximately 2 cm in segment VII; B: T1-weighted VIBE during early venous phase shows an inhomogenous signal of the liver parenchyma with masking of the lesion in segment VII; C: SPIO-enhanced T2-weighted fast image shows an area of increased signal intensity (segment VII) within a low signal of the liver parenchyma; D: MR-AP (T1-weighted VIBE) during early venous phase displays an area of decreased enhancement (approx. 3 cm diameter) in segment VII and various low signal lesions in segments I, IVa, VIII and VII. SPIO: Superparamagnetic iron oxide-enhanced.

body feasible^[29], especially for detection of liver malignancies^[30]. Studies have reported a higher sensitivity of DWI for detection of small hepatic metastases compared to SPIO-enhanced T2-weighted images and breath-hold T2-weighted images^[31,32], particularly due to a profound signal intensity of the HCC in the cirrhotic liver. In comparison, cysts and hemangiomas, the most frequently found benign lesions of the liver, typically show low or absent signal intensities^[33].

Our study demonstrated that MR-arteriportography as an alternative method for detection of HCC is not only feasible but showed a significantly larger number of lesions than ferumoxide-enhanced MR imaging, especially in patients with hepatic cirrhosis.

Also, the lesion's size seems to play a crucial role. Out of the 41 lesions that were exclusively found using MR-AP, 21 were 10 mm or less in diameter. This confirms the high sensitivity of MR-AP, especially regarding smaller lesions. However, a definite differentiation among HCC nodules, regenerative dysplastic nodules or, for example, small arterio-venous shunts that are very common in patients with hepatocellular carcinoma is not possible.

One limitation of the study is that a histological confirmation of HCC or benign lesions could only be obtained in 16 out of 20 patients. In the other 4 patients, further treatment was based upon the combination of typical image morphology and elevated alpha fetoprotein. Another limitation is the relatively small number of patients that were examined in this study. Prospective studies are necessary in order to ascertain the diagnostic reliability of MR-AP compared to established methods.

In summary, our study confirmed that the use of MR-arteriportography as an additional modality for detection of hepatocellular carcinoma is useful. Using this technique, significantly more lesions could be detected in comparison to MRI with liver-specific contrast agent.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is the most common primary malignant tumor of the liver and often develops in patients with underlying liver cirrhosis. In the treatment of HCC, surgical resection is considered the only potentially curative therapy; however, other regional therapeutic procedures such as transcatheter arterial embolization or radiofrequency ablations have proved to be very successful. Thus, the pre-interventional evaluation of patients with suspected liver malignancy is even more important, especially concerning the evaluation and characterization of focal or diffuse lesions in the cirrhotic liver.

Research frontiers

MR imaging with liver-specific contrast agents has been used to improve identification of focal hepatic masses in a cirrhotic liver. Also, studies have shown that examinations by computed tomography arteriportography (CT-AP) have a very high sensitivity for detection of hepatic lesions compared to a relatively low specificity. In this study, the benefit and effectiveness of MR-arteriportography (MR-AP) in achieving the highest sensitivity for detection and evaluation of HCC was evaluated.

Innovations and breakthroughs

Until now, there have hardly been any studies comparing the effectiveness of MR-AP and contrast-enhanced MRI for diagnosis of malignant liver lesions. This study confirmed that MR-arteriportography as an additional modality for detection of HCC is truly beneficial and may lead to change in treatment in many patients.

Applications

The results showed that using the MR-AP approach, significantly more lesions could be detected in comparison to MRI with liver-specific contrast agent. Thus, it might play an important role for future strategy of therapeutic interventions.

Terminology

MR-AP is an MRI procedure where the contrast agent is injected through a catheter placed in the superior mesenteric artery.

Peer review

It is well-written and is novel work.

Abstract

AIM: To investigate the effect of carbachol on gastrointestinal function in a dog model of oral resuscitation for burn shock.

METHODS: Twenty Beagle dogs with intubation of the carotid artery, jugular vein and jejunum for 24 h were subjected to 35% total body surface area full-thickness burns, and were divided into three groups: no fluid resuscitation (NR, $n = 10$), in which animals did not receive fluid by any means in the first 24 h post-burn; oral fluid resuscitation (OR, $n = 8$), in which dogs were gavaged with glucose-electrolyte solution (GES) with volume and rate consistent with the Parkland formula; and oral fluid with carbachol group (OR/CAR, $n = 8$), in which dogs were gavaged with GES containing carbachol (20 $\mu\text{g}/\text{kg}$), with the same volume and rate as the OR group. Twenty-four hours after burns, all animals were given intravenous fluid replacement, and 72 h after injury, they received nutritional support. Hemodynamic

and gastrointestinal parameters were measured serially with animals in conscious and cooperative state.

RESULTS: The mean arterial pressure, cardiac output and plasma volume dropped markedly, and gastrointestinal tissue perfusion was reduced obviously after the burn injury in all the three groups. Hemodynamic parameters and gastrointestinal tissue perfusion in the OR and OR/CAR groups were promoted to pre-injury level at 48 and 72 h, respectively, while hemodynamic parameters in the NR group did not return to pre-injury level till 72 h, and gastrointestinal tissue perfusion remained lower than pre-injury level until 120 h post-burn. CO_2 of the gastric mucosa and intestinal mucosa blood flow of OR/CAR groups were 56.4 ± 4.7 mmHg and 157.7 ± 17.7 blood perfusion units (BPU) at 24 h post-burn, respectively, which were significantly superior to those in the OR group (65.8 ± 5.8 mmHg and 127.7 ± 11.9 BPU, respectively, all $P < 0.05$). Gastric emptying and intestinal absorption rates of GES were significantly reduced to the lowest level (52.8% and 23.7% of pre-injury levels) in the OR group at about 2 and 4 h post-burn, and did not return to 80% of pre-injury level until 24 h. In the first 24 h post-burn, the rate of gastric emptying and intestinal water absorption were elevated by a mean 15.7% and 11.5%, respectively, in the OR/CAR group compared with the OR group. At 5 days, the mortality in the NR group was 30% (3/10), 12.5% in the OR group (1/8), and none in the OR/CAR group.

CONCLUSION: Carbachol had a beneficial effect on oral resuscitation of burn shock by promoting gastric emptying and intestinal absorption in our canine model.

Hu S, Che JW, Tian YJ, Sheng ZY. Carbachol promotes gastrointestinal function during oral resuscitation of burn shock. *World J Gastroenterol* 2011; 17(13): 1746-1752 Available from: URL: <http://www.wjnet.com/1007-9327/full/v17/i13/1746.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i13.1746>

INTRODUCTION

Rapid intravenous infusion of large quantity of fluids containing electrolytes and colloidal solutions remain the key measure to resuscitate hypovolemic shock as a result of a massive burn injury. This life-saving measure has unanimously been accepted worldwide. It has also been recognized that a delay in such replenishment could sometimes be fatal due to complications subsequent to delayed resuscitation of hypovolemic shock. Unfortunately, in certain cases, such as mass casualties in an incendiary bomb attack in battlefields, or a forest or prairie fire in regions with an austere environment with poor medical support and transportation facilities due to geographical barriers, not only there would be a shortage of medics to introduce an intravenous needle, but also the weight and bulk of the necessary intravenous fluids would make the treatment unrealistic. In such cases, it is our supposition that oral administration of fluids might be more practical, and it might be able to maintain the life of the victims till intravenous fluid replacement was available.

Oral fluid resuscitation has been reported with success in early clinical studies of burn care^[1]. Thomas *et al*^[2] have described oral fluid replacement in burn patients, and have concluded that oral resuscitation may have a slower initial onset of hemodynamic effectiveness, but after 3-4 h, it can be similarly effective. It is unanimously recognized that the main limiting factors for effective oral resuscitation of burn shock are diminution of gastric emptying capacity and intestinal absorption of fluid and electrolytes due to undermined gastrointestinal perfusion. It seems to be necessary to overcome these two hurdles before oral hydration can be successful for treatment of burn shock.

As enough data of oral resuscitation of burn shock could not be accumulated in clinical practice in ordinary situations, most investigations have been done with animals^[3,4]. We found that the previous animal experiments have been limited by their short experimental duration of < 24 h post-burn, and performed under general anesthesia, which might interfere with the observation of gastric emptying and intestinal absorption of fluid and electrolytes. With these in mind, a canine model of burn shock was devised in which oral resuscitation was given in the first 24 h post-burn, followed by delayed intravenous fluid replacement, and the whole course of the experiment lasted for 120 h. Also, in this experiment, the effect of general anesthesia was eliminated, and carbachol, which is a cholinergic receptor agonist, was used in

an attempt to shorten gastric emptying time and restore intestinal peristalsis.

MATERIALS AND METHODS

All the experimental protocols were reviewed and approved by the Committee of Scientific Research of First Affiliated Hospital of General Hospital of PLA (Beijing, China).

Surgical preparation

Pure bred Beagle dogs (purchased from Experimental Animal Center of Academy of Military Medical Sciences of PLA, Beijing, China, License of qualification SCX 2005-0005), aged 16-20 mo, body weight 11-13 kg, were used. They were acclimatized in the animal house of our Research Laboratory for 2 wk before use. They were fasted for 24 h, and water was withheld for 4 h before the surgical preparation. Under anesthesia with 8 mg/kg ketamine (Gu-Tian Pharmacy, Fu Jian Province, China), the right carotid artery and jugular vein were individually cannulated for hemodynamic monitoring, collecting blood samples, and administration of drugs. Both cannula were led out through a subcutaneous passageway and fixed to the skin. A midline incision was made to open the peritoneal cavity to expose the proximal part of the jejunum, and small incisions were made on the jejunum 10, 20, and 50 cm distal to the Treitz ligament. A Silastic tube, 3 mm in diameter and 25 cm in length, was introduced into the jejunal lumen through each of the above openings. They were fixed with purse-string sutures, led out through a subcutaneous tunnel and fixed to the skin. A cystostomy was done for collecting urine.

Burn protocol

Twenty-four hours after the above surgical procedures, an intravenous injection of 0.5 mL/kg propofol was given to all the animals to produce brief anesthesia for 10-15 min, which was long enough to eliminate pain during burn injury. Napalm (3%) was applied to the shaved neck and back of the dogs, and it was ignited for 30 s to produce a full-thickness burn that involved about 35% of the total body surface area (TBSA). The depth of the burn injury was verified by pathological examination.

Experimental groups

The injured dogs were grouped into no fluid replacement (NR, $n = 10$), oral fluid replacement (OR, $n = 8$), and oral replacement of fluid with addition of carbachol (OR/CAR, $n = 8$). For NR, the animals received no fluid replacement or any other treatment. Dogs in the OR group received intragastric, pre-warmed glucose saline solution (each 1 L containing 59.83 mmol/L NaCl, 29.76 mmol/L NaHCO₃, 20.18 mmol/L KCl, and 114.94 mmol/L glucose in distilled water), and the rate of gastric infusion was consistent with that of the Parkland formula^[5] (4 mL/kg for each % TBSA burn, half of the total amount given in the first 8 h). In the OR/CAR group, 20 µg/kg carbachol (Sigma, St Louis, MO, USA) was added to the glucose-saline solution. Twenty-four hours after the burn injury, all the animals in the three groups were given intravenous fluid

replenishment. Seventy-two hours after the burn injury, all the surviving animals were given 10% glucose with a mixture of 17 amino acids (Beijing Pharmaceutical, Beijing, China) and 30% fat emulsion (Hua Rui Pharmaceutical, Wu Xi, China). Also, intravenous Ringer's solution was given to make up 100-150 mL of fluid per kg body weight and maintain blood potassium level > 3.5 mmol/L.

Measurement of hemodynamics

Picco-Plus (Pulsion, Germany) was used to determine mean arterial pressure (MAP) and cardiac output (CO). Plasma volume was determined with the indigo green dilution method^[6]. At each time point for determination, 12.5 mg indocyanine green (ICG) (Dan Don Pharmaceutical, Liaoning, China) was intravenously given, and 3-mL blood samples were obtained at 1, 2 and 3 min after injection. The specimens were centrifuged at 1800 *g* at 4°C, and 1 mL plasma was obtained to determine the OD value of ICG with a 723N spectrophotometer (wave length, 820 nm), and the concentration of ICG was obtained from a plotted standard curve.

Measurement of gastrointestinal mucosal perfusion

To determine CO₂ partial pressure of the gastric mucosa (PgCO₂), a gastric mucosa tonometer (Tonoca, Finland) was used. Intestinal mucosal blood flow (IMBF) was determined by passing a fiberoptic detector of a laser Doppler flow monitor (Peri Flus 5000 Master; Perimed, Jaarnfalla, Sweden) through the intestinal catheters, ensuring that the tips of the detectors were in contact with intestinal mucosa. The signals were transformed into blood perfusion units (BPU), which were input into a computer, and the PEIMED software package PSW 2.0 was used to plot the curves. Thirty seconds were spent for each measurement, and a stable curve that covered 10 s was taken for the calculation of the average.

Gastric emptying rate

The gastric emptying rate was determined by using phenol red (Sigma) as a signal, according to the Scarpignato principle^[7]. Before the experiment, a standard curve was plotted with ODs of different dilutions of phenol red at 500 nm. To determine gastric emptying time, 2 mL phenol red at 100 mg/L was introduced into the stomach through an indwelling gastric tube. Two milliliters of gastric juice was obtained when the dye was well mixed with the gastric juice. The amount of the dye in the gastric content was determined by spectrophotometry. Thirty minutes later, another sample of gastric content was withdrawn and phenol red was again determined. With this process, the gastric emptying time was calculated.

Intestinal absorption rate

Intestinal absorption rate was determined using a modified Cooper method^[8]. Since phenol red is a large molecular dye, it is not absorbed by the intestinal mucosa. With the absorption of fluid, the concentration of the dye increases. Thus, intestinal absorption rate of fluid could be assessed. The method used in our experiment

was as follows. Since three enteral tubes were implanted into the jejunum in equal distance, a known amount of fluid was introduced into the most proximal catheter (A) with a known velocity V_a (mL/h) using an intelligent infusion pump (ZNB-XB; Xu-li Scientific Technology Co. Beijing, China), and then specimens of intestinal fluid (1 mL) were collected from two distal catheters, where fluid velocities were V_b and V_c . By measuring the concentrations of phenol red in various specimens, the intestinal absorption rate was calculated: $V_b = V_a \times C_a / C_b$, $V_c = V_b \times C_v / C_c$, $\Delta V = V_b - V_c$.

ΔV was the absorption rate in the segment of intestine between catheters B and C. By dividing the value by the length of the intestinal segment between B and C, the intestinal absorption rate of the oral feeding fluid could be calculated, and it was expressed as mL/h.m², i.e. the amount of orally fed liquid absorbed by unit length of the intestine during unit time.

Statistical analysis

All data are presented as the mean \pm SD. Statistical analysis was done using SPSS 11.0 statistical software for the *F* test. *P* < 0.05 was considered statistically significant.

RESULTS

Deaths within 5 d

In the NR group, three animals died at 12, 18 and 23 h after burn injury, with a 5 d mortality of 30.0% (3/10). In the OR group, one dog died 18 h after burn injury, with a 5 d mortality of 12.5% (1/8). In the OR/CAR group, no deaths occurred within 5 d of injury, with zero 5 d mortality.

Hemodynamic parameters

As depicted in Table 1, MAP was lowered 2 h after burn injury in all three groups (all *P* < 0.05). It gradually rose after this period, and MAP in the OR and OR/CAR groups was higher than that in the NR group (*P* < 0.05) 4 h post-burn, and returned to pre-injury level 8 h after injury, but it was still lower than the pre-injury level at 72 and 120 h after injury in the NR group. CO and plasma volume (PV) were lowest at 24 h post-burn in the NR group, and increased later, but never to the level before burn injury. However, CO and PV in the OR and OR/CAR groups were higher than in the NR group at 4 and 8 h post-burn (all *P* < 0.05). CO and PV in the OR/CAR group were higher than in the OR group at 8 and 24 h post-burn (all *P* < 0.05). However, MAP showed no significant change between the OR/CAR and OR groups.

Gastro-intestinal perfusion

As shown in Table 2, PgCO₂ was rapidly elevated, and IMBF sharply decreased in all three groups. They were seen to elevate gradually afterwards. In the NR group, these two values were still worsen than that before injury at 120 h post-burn (all *P* < 0.05). However, in the OR and OR/CAR groups, they recovered to pre-burn levels at 72 h post-burn. From 2 h post-burn, PgCO₂ in the OR group was lower than that in the NR group (*P* < 0.05), al-

Compared with that at 0 h, ^a*P* < 0.05; compared with no fluid resuscitation (NR), ^b*P* < 0.05; compared with oral fluid resuscitation (OR), ^c*P* < 0.05. IMBF: Intestinal mucosal blood flow; CAR: Carbachol.

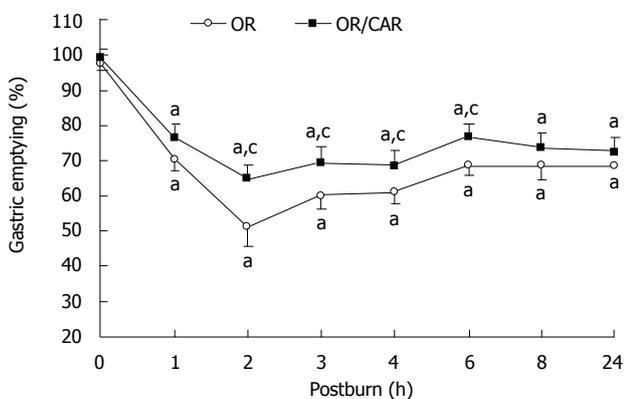

Figure 1 Carbachol promoted gastric emptying rate in oral fluid resuscitation/Carbachol group compared with those of oral fluid resuscitation group at 2, 3, 4 and 6 h after burn injury. ^a*P* < 0.05 vs 0 h, ^b*P* < 0.05 vs oral fluid resuscitation (OR) group (one-way ANOVA). Error bars represent mean ± SD. CAR: Carbachol.

though it was higher than that in the OR/CAR group, but there was no significant difference (*P* > 0.05). IMBF was always higher in the OR and OR/CAR groups compared with the NR group (all *P* < 0.05), but the value was lower in the OR group compared with the OR/CAR group at 4, 8 and 24 h post-burn (all *P* < 0.05).

Gastric emptying rate

Figure 1 shows that, in the OR and OR/CAR groups, gastric emptying rate was lowered, especially in the for-

mer group, with 52.8% of the normal emptying rate at 2 h, and 70.5% at 24 h post-burn. In the OR/CAR group, it was also lowered, but reached 65.2% at 2 h, and 73.0% at 24 h post-burn, and the values were all significantly higher than those in the OR group at 2, 3, 4 and 6 h post-burn (all *P* < 0.05). Thus, it was estimated that approximately 15.7% more gastric content was expelled from the stomach in 24 h in the OR/CAR group as compared with the OR group.

Intestinal absorption rate

As shown in Figures 2 and 3, the rate of absorption of orally administered water and Na⁺ was lowest at 3 h post-burn in the OR group, and the values were 23.7% and 50.3% of pre-injury levels. These absorption rates were gradually increased to 44.4% and 65.1%, respectively, at 24 h post-burn. In the OR/CAR group, all these values were higher than those in the OR group at 3, 4 and 6 h post-burn (all *P* < 0.05). In the first 24 h post-burn, the rate of intestinal water absorption was elevated by 11.5% in the OR/CAR group. It was estimated that within 24 h after injury, the water absorption rate at 24 h in the OR and OR/CAR groups was 110.9 ± 17.1 mL/h.m and 127.8 ± 17.3 mL/h.m, respectively, and they were actually higher than the pre-requisite of the Parkland formula 82.1 ± 11.2 mL/h.m (*P* < 0.05).

DISCUSSION

Mass casualties from burn injury may occur in a region

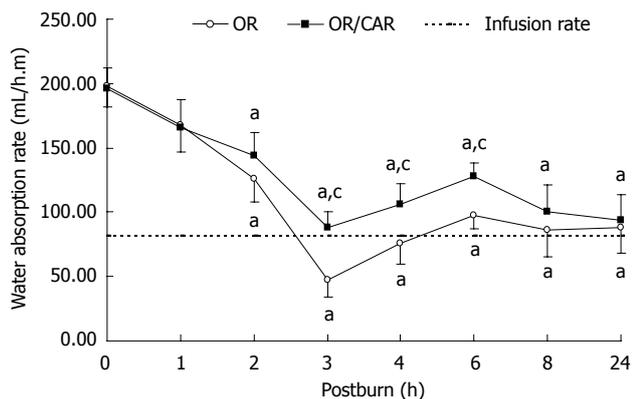

Figure 2 Carbachol significantly improved rate of water absorption of intestine in oral fluid resuscitation/Carbachol group compared with those of oral fluid resuscitation group at 3, 4 and 6 h after burn injury. ^a*P* < 0.05 vs 0 h, ^c*P* < 0.05 vs oral fluid resuscitation (OR) group (one-way ANOVA). Error bars represent mean ± SD. CAR: Carbachol.

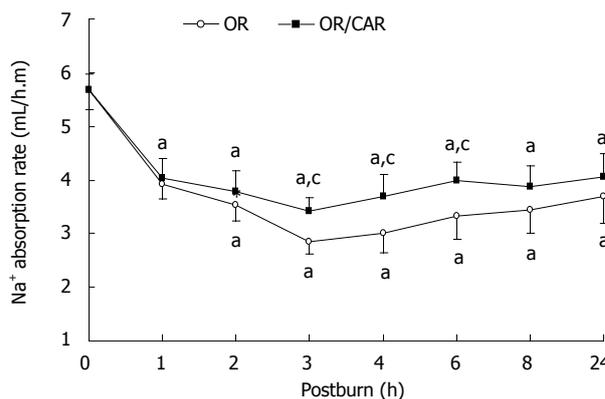

Figure 3 Carbachol significantly improved rate of Na⁺ absorption of intestine in oral fluid resuscitation/Carbachol group compared with those of oral fluid resuscitation group at 3, 4 and 6 h after burn injury. ^a*P* < 0.05 vs 0 h, ^c*P* < 0.05 vs oral fluid resuscitation (OR) group (one-way ANOVA). where the major problems facing medical personnel are the availability and probability of fluid replacement with sterile intravenous fluids. If we resuscitate a single burn victim weighing > 60 kg with a burn of 30% TBSA it would require > 5-7 kg of fluid for a medic to carry. In a very harsh environment with lack of decent medical support, resuscitation of burn shock is severely handicapped, and the life of those with extensive burn injury is jeopardized. One strategy for reducing such a hazard is to try to supplement liquid with sufficient electrolytes by mouth until intravenous infusion fluids are available^[9]. Early in 1970, Monafó^[10] reported a clinical trial of oral administration of hypertonic lactated saline solution to patients with burn injury of various extents, and he found that at least partial oral resuscitation of severe burns could be successful. However, oral resuscitation of burn shock has not been popular, because, ordinarily, intravenous resuscitation is almost always available, especially in cities, and even in many rural areas where medical facilities have been established. Nevertheless, in certain scenarios, such as fire disasters in cities after a strong earthquake, forest fires in mountainous terrain, or in combat zones after incendiary devices have exploded, when transportation is seriously lacking or hampered due to geographical barriers, and medical support is lacking, so that sterile intravenous fluids and trained personnel are not available, oral intake of fluids should be considered, in the hope that the victims can be tided over burn shock.

Sufficient data about oral resuscitation of burn shock can not be accumulated in clinical practice under normal circumstances, therefore, most investigations have been done with animals. In these experiments, animals were always under general anesthesia to prevent restlessness of the animals^[1,3,4]. Thus, the results of oral hydration might not reflect the true states of fluid absorption because the anesthesia inevitably inhibits gastrointestinal motility and other functions. The present study was planned to measure all the physiological parameters in a conscious state. All the catheters for measuring physiological indexes were implanted 1 d before burn injury. Burn injury was

produced under brief anesthesia to eliminate mental strain and pain. Thereafter, all the measurements were made with the animals in a fully conscious state. Pure bred Beagle dogs were used because they were tame, docile and cooperative. No restriction of the body was necessary during the whole course of the experiment, which rendered all the measurements complete without any restriction of the animals or general anesthesia. Thus, all the disturbances to gastrointestinal mobility or absorption were greatly alleviated. Therefore, there was no external interference to influence the measurements during the whole course of the experiment, which lasted for 120 h, which increased the reliability of the measurements.

The degree of perfusion of the gastrointestinal tract is at present considered as an important index of circulatory shock and tissue oxygen delivery. The determination of PCO₂ of the gastric mucosa has been used to estimate the pH of the mucosa, and the change in pH of the mucosa reflects the condition of blood perfusion and oxygen delivery to the gastric tissue^[11]. The procedure is untraumatic, and the catheter can also be used to give necessary fluids as well as a convenient tool for measuring gastric emptying rate. To determine blood perfusion of the intestinal mucosa by way of preformed fistulae has already been a standard method in monitoring the circulatory state of transplanted intestine^[12]. In our experiment, a flexible fiberoptic detector of a laser Doppler flow monitor was passed through the preformed fistulae. Each reading took about 1 min only, so that it did not give any discomfort to the animal, and sequential measurements were assured. The experimental results showed that, in injured dogs without the benefit of fluid gavage, blood perfusion was rapidly diminished in the intestinal mucosa. It was also shown that this change was consistent with a decrease gastrointestinal mucosal perfusion, and its recovery lagged behind the improvement in hemodynamic parameters. Up to 120 h after injury, it was still lower than that before injury. These phenomena corroborated that which was found in human patients with hypodynamic shock.

When a solution with electrolytes and glucose is intro-

duced into the stomach, the emptying rate of the liquid from the stomach depends on the pressure gradient between the stomach and duodenum. It also is influenced by the state of blood supply to the stomach and regulatory activity of the vagus nerve (cholinergic nerve) and humoral agents (motilin)^[13]. Absorption of water through the intestinal mucosa depends on translocation of Na^+ ions, while the latter process could only be realized with the presence and activity of Na^+/K^+ -ATPase, which is localized in the basal layer of the intestinal mucosal epithelium. Therefore, it is obvious that the rate of absorption of water by the intestinal mucosa is under the influence of the intestinal blood flow, activity of Na^+/K^+ -ATPase, and aquaporin (AQP)-1 expression, along with consumption of ATP. Thus, it is evident that with ischemia and hypoxia of the intestinal mucosa during hypovolemic shock, water absorption by the intestinal mucosa is hampered.

Heavy leakage of fluid from the circulation results in a sharp decrease in ATP. This shortage in ATP is further amplified by an increased demand created by feeding and absorption of water and electrolytes. Under such conditions, the presence of glucose, which can be metabolized into lactic acid, alanine and CO_2 to produce ATP under anaerobic conditions, is essential. This additional ATP is helpful for the absorption potential of the intestinal mucosa. During the process of absorption, the transport of glucose is coupled with the transport of water molecules and Na^+ ions, and two Na^+ ions and 223 water molecules are absorbed. Therefore, addition of glucose to an electrolyte solution is an ideal liquid for oral replacement during hypovolemic shock^[14,15].

Thomas *et al.*^[2] have described an experiment to study gastric emptying with oral replacement of fluid in hypovolemic shock. They gavaged glucose-electrolyte solution (GES) into the stomach of pigs with 40% TBSA burn injury, according to the Parkland formula. They showed that the gastric emptying volume increased with an increase in the volume of gavaged fluid. However, the volume of fluid passed into the duodenum was one half of the volume required by the Parkland formula, and hemodynamic parameters did not recover to the pre-injury level. Michell *et al.*^[4] have performed a study of duodenal infusion of glucose-electrolyte solution in pigs with 40% TBSA burns, and demonstrated that a total of 93% of infused solution was absorbed during the course of the 4 h experiment. However, these experiments were performed in animals under general anesthesia, and there was unavoidable impairment of gastrointestinal peristalsis and absorption ability. Therefore, the results could not be considered as reflecting the true condition of the gastrointestinal tract.

In our present study, we determined the gastric emptying and intestinal absorption rate of GES without the interfering effects of general anesthesia. We found that gastric emptying and intestinal absorption were significantly reduced to the lowest level (52.8% and 23.7% of pre-injury levels) in the OR group at about 2 and 4 h post-burn, respectively, and did not return to 80% of pre-injury level until 24 h. It was estimated that within 24 h

after injury, the water absorption rate in the OR group was 110.9 ± 17.1 mL/h.m, and it was actually higher than the pre-requisite of the Parkland formula (82.1 ± 11.2 mL/h.m). This intestinal absorptive rate was similar to that of Michael *et al.*^[4]. The above results suggest that, in large animals (e.g. pigs or dogs), with < 40% TBSA burns, almost all GES infused according to the Parkland formula could be fully absorbed, although intestinal absorption was inhibited due to gut hypoperfusion. Therefore, we considered that gastric emptying is the main limitation to effective gastrointestinal resuscitation.

The results of using carbachol in our experiment clearly demonstrated that this drug could improve tissue blood perfusion of the gastrointestinal tract. Thus, it was helpful in expediting gastric emptying of its contents and improving intestinal absorption of water and electrolytes. Carbachol is a cholinergic receptor agonist. It stimulates peristalsis of the gastrointestinal tract by activating M cholinergic receptors, and also activates $\alpha 7$ subunits of cholinergic nicotinic receptors on macrophage and endothelial cells which leads to cellular deactivation and inhibition of cytokine release, thus attenuating the systemic or regional inflammatory response^[16-18]. In addition, it is an antioxidant and inhibitor of apoptosis^[19,20]. In our study, the addition of carbachol to the resuscitation fluid did improve blood perfusion of the gastrointestinal tissues, expedite gastric emptying, and improve intestinal absorption rate of water and electrolytes. These beneficial effects of carbachol may be attributable to the following mechanisms: (1) inhibition of release of proinflammatory cytokines alleviates the inflammatory reaction of the gastrointestinal tissue, thus resulting in reduced loss of AQP1^[21,22]; (2) improvement in intestinal peristalsis and blood perfusion due to stimulation of M receptors facilitates intestinal absorption; and (3) promotion of activity of Na^+/K^+ -ATPase, which is essential for absorption of water and especially Na^+ by intestinal mucosa^[23]. Our experiment showed that the gastric emptying time was promoted by 15.7%, and the intestinal absorption rate was increased by 11.5%.

In conclusion, our experiment has successfully reproduced a canine model of serious burn injury. In this model, we are able to study the effects of oral replenishment of GES for resuscitation of burn shock. The hemodynamic parameters, gastric emptying rate, and intestinal absorption of GES can be relatively accurately determined. The results of the experiment also show that burn shock can be ameliorated to a certain extent by administration of GES, with the addition of carbachol to enhance gastric emptying and intestinal absorption of fluids. Oral resuscitation for burn shock might be a surrogate measure where mass casualties from burn injury occur in an area where medical support is minimal and transportation is difficult. Carbachol may be beneficial because it is a cholinergic receptor agonist, and it possesses the function of enhancing gastric emptying and intestinal absorption of fluid when given by mouth. Therefore, in circumstances when intravenous replacement of fluids for resuscitation of burn shock is not fea-

sible, oral feeding of GES, with addition of carbachol, may be possible.

COMMENTS

Background

Rapid intravenous infusion remains unanimously the key measure to resuscitate hypovolemic shock as a result of massive burn injury. Unfortunately, in armed conflicts or massive disasters (such as forest fire, earthquake, or terrorist attack) mass casualties occur in an austere environment with poor medical support and transportation facilities. In such cases, it is our supposition that oral or gastrointestinal administration of fluids might be more practical, and could have a positive effect in maintaining the life of the victims until intravenous replacement of fluids is available.

Research frontiers

Gastrointestinal tract ischemia and hypoxia due to massive surgical stresses such as severe trauma, extensive burns and major surgery resulting in hypovolemic shock can lead to dysfunction of gastric emptying and intestinal absorption, followed by poor transportation and absorption of oral electrolytes and nutrients in the gastrointestinal tract. Improvement of mucosal blood perfusion, and enhancement of gastrointestinal tolerance to oral rehydration fluid and enteral nutrition are not only the foci of research in the surgical and critical care fields, but they are key factors for facilitation of oral resuscitation of hypovolemic shock.

Innovations and breakthroughs

A large animal model of severe burn injury was reproduced to investigate the feasibility of oral resuscitation of burn shock, without the disturbing effects of general anesthesia. The effects of carbachol, which is a cholinergic receptor agonist, on blood circulation, gastrointestinal perfusion, gastric emptying and intestinal absorption of fluid and electrolytes were investigated. The results indicated that oral resuscitation with the help of such a drug might be an ideal way in lieu of intravenous resuscitation for burn shock, especially in battlefields or other sites of mass casualties.

Applications

Orally administered fluid can be considered to be a simple and effective means of replacement of body fluid that is feasible for resuscitation of hypovolemic shock, especially when there is an extreme shortage of means of medical support in an austere environment such as battlefields and disasters.

Peer review

The manuscript is very well written and the conclusions applicable.

Abstract

AIM: To evaluate the esophageal motility and abnormal acid and bile reflux incidence in cirrhotic patients without esophageal varices (EV).

METHODS: Seventy-eight patients with liver cirrhosis without EV confirmed by upper gastroesophageal endoscopy and 30 healthy control volunteers were prospectively enrolled in this study. All the patients were evaluated using a modified protocol including Child-Pugh score, upper gastrointestinal endoscopy, esophageal manometry, simultaneous ambulatory 24-h esophageal pH and bilirubin monitoring. All the patients and volunteers accepted the manometric study.

RESULTS: In the liver cirrhosis group, lower esophageal sphincter pressure (LESP, 15.32 ± 2.91 mmHg), peristaltic amplitude (PA, 61.41 ± 10.52 mmHg), peristaltic duration (PD, 5.32 ± 1.22 s), and peristaltic velocity (PV, 5.22 ± 1.11 cm/s) were all significantly abnormal in comparison with those in the control group ($P < 0.05$), and LESP was negatively correlated with Child-Pugh score. The incidence of reflux esophagitis (RE) and pathologic reflux was 37.18% and 55.13%, respectively

(vs control, $P < 0.05$). And the incidence of isolated abnormal acid reflux, bile reflux and mixed reflux was 12.82%, 14.10% and 28.21% in patients with liver cirrhosis without EV.

CONCLUSION: Cirrhotic patients without EV presented esophageal motor disorders and mixed acid and bile reflux was the main pattern; the cirrhosis itself was an important causative factor.

INTRODUCTION

Gastroesophageal reflux disease (GERD) is one of the most common diseases in modern civilization, which greatly affects people's health and quality of life^[1]. GERD is defined as reflux of gastroduodenal content to the esophagus, and includes reflux esophagitis (RE), nonerosive reflux disease (NERD) and Barrett's esophagus (BE). GERD originates from a disturbance in the structure and function of the lower esophageal sphincter (LES) barrier, and dysfunctional esophageal motility coupled with a weak LES can cause uncoordinated propulsion, regurgitation of gastric and/or duodenal contents into the esophagus^[2].

Gastroesophageal reflux consists of a broad mixture

of oral-esophageal, gastric, and duodenal secretions. It is accepted that acid reflux plays an important role in the pathogenesis of GERD^[3]. But the role of non-acid reflux is still a controversy^[4,5], and some recent studies have shown that duodenogastroesophageal reflux (DGER) is another important causative factor in esophageal mucosal damage^[6,7]. So the combination of esophageal pH and bilirubin monitoring is indispensable for a precise diagnostic test in acid and non-acid reflux of GERD.

GERD can be induced or aggravated under many conditions including liver diseases. It has been reported that in patients with liver cirrhosis and portal hypertension, gastroesophageal reflux occurs at a high frequency (64%)^[8]. Moreover, hepatic cirrhosis has a high morbidity and mortality due to the portal hypertension with the development of esophageal varices, and the possibility of a digestive hemorrhage and worsening of hepatic insufficiency^[9-11]. It is important to identify predictive or aggravating factors and if possible, to prevent these factors. Esophageal motor disorders have been found to be associated with acid gastroesophageal reflux in cirrhotic patients with esophageal varices, and functional studies have shown decreased functions of the lower esophageal sphincter with low amplitude of primary peristalsis and acid clearance, which might attribute to a mechanical effect of the presence of varices^[12]. It is still unclear whether the presence of cirrhosis itself presents as a causative factor for the onset of gastroesophageal reflux, and there are few studies on the incidence of acid reflux and DGER in the cirrhotic patients without esophageal varices. Therefore, this study was designed to evaluate the esophageal motility and abnormal acid and bile reflux incidence in cirrhotic patients without esophageal varices.

MATERIALS AND METHODS

Patients

Seventy-eight patients with liver cirrhosis without EV confirmed by upper gastroesophageal endoscopy from March 2008 to November 2010 were prospectively enrolled to this study. All the patients were the inpatients of Beijing Tiantan Hospital, Capital Medical University. Patients with systemic diseases related to esophageal motor disorders and/or gastroesophageal reflux diseases (progressive systemic sclerosis, diabetes mellitus, neuromuscular disorders), alcohol abusers within 6 mo and chronic drug users that influence esophageal motility (such as theophylline, nitrates and calcium channel blockers) were excluded.

All the patients were evaluated by the same physician according to a modified protocol including Child-Pugh score^[13], ascites, and other complications and a reflux disease questionnaire (RDQ; AstraZeneca R and D, Wuxi, China). RDQ is a detailed questionnaire regarding the severity and frequency of four symptoms: heartburn, acid regurgitation, food regurgitation, and retrosternal pain, and each symptom is graded in severity and frequency. The diagnosis of liver cirrhosis was verified by the clinical, laboratory, radiologic and histopathological results according to the criteria of the Chinese Medical

Society for Liver Diseases^[14].

Thirty healthy volunteers (15 women) with a mean age of 33 years served as controls in this study. None of them had a history of reflux disease or of surgery in the upper gastrointestinal tract or thorax. All the volunteers accepted the manometric study without medication.

The written informed consent for the study was approved by the hospital ethics committee, and obtained from all the subjects and the procedure followed the principles of the Declaration of Helsinki.

Methods

Upper gastrointestinal endoscopy. To exclude the EV cases, all patients received the upper gastrointestinal endoscopic examination (OlympusXQ260; Olympus, Japan). Gastric varices and/or related congestive gastropathy were also recorded. Reflux esophagitis if present was classified according to the Los Angeles classification standards. Barrett's esophagus was defined as a columnar-lined esophageal mucosa with intestinal metaplasia.

Esophageal manometry. Manometry was performed using a water-perfused manometric assembly (Medtronic, Deutschland). The manometric probe consisted of a 4.5-mm polyvinyl catheter (Medtronic) with eight measuring sites (0, 1, 2, 3, 5, 10, 15, and 20 cm). The position, length and pressure of the lower esophageal sphincter (LES) were identified by the method of stepwise retraction of the probe through gastroesophageal junction (GEJ). After correct positioning of the catheter in the esophageal lumen, patients were asked to swallow ten 5-mL boluses of water. Manometric signals were recorded on a computer for subsequent display and analysis, and the information included: the length of the LES, antegrade and retrograde peristalses, synchronous and isolated contractile waves, peristaltic amplitude (PA), peristaltic duration (PD), and peristaltic velocity (PV) of primary peristaltic wave in distal esophagus. LES disorder and esophageal body dysmotility were diagnosed according to the criteria in a previous study^[15].

Simultaneous ambulatory 24-h esophageal pH and bilirubin monitoring. After esophageal manometry, an antimony esophageal pH electrode and fiber optic probe for detecting acid and bilirubin were positioned pernasally 5 cm above the upper border of the LES and connected with an ambulatory pH recorder (Digitrapper Mk III 2000, Syntec Medical, Sweden) and an ambulatory duodenogastroesophageal reflux (DGER) monitoring system (Bilitic 2000, Syntec Medical, Sweden), respectively. The method was reported previously^[16]. The recorded data were analyzed using the Syntec PM Software.

In brief, the 24-h pH ambulatory recording was carried out with a portable digital system composed of a catheter with an antimony electrode and external reference electrode. Patients were instructed to keep a diary recording the time of meals, position changes, and the time and type of their symptoms, and encouraged to pursue their normal daily activities and maintain their usual diet, avoiding citric fruit and soft drinks. Proton pump inhibitor if in use, were discontinued at least 7-10 d prior to the

Table 1 Results of esophageal manometry in liver cirrhosis patients and controls (mean \pm SD)

| Group | LESP (mmHg) | PA (mmHg) | PD (s) | PV (cm/s) |
|----------------------------------|-------------------------------|--------------------------------|------------------------------|------------------------------|
| Liver cirrhosis (<i>n</i> = 78) | 15.32 \pm 2.91 ^a | 61.41 \pm 10.52 ^a | 5.32 \pm 1.22 ^a | 5.22 \pm 1.11 ^a |
| Child A (<i>n</i> = 28) | 16.18 \pm 2.81 | 70.52 \pm 8.93 ^a | 3.91 \pm 1.03 ^a | 4.56 \pm 1.22 ^a |
| Child B (<i>n</i> = 27) | 15.41 \pm 3.13 ^c | 67.4 \pm 9.3 ^c | 5.11 \pm 1.21 ^c | 5.10 \pm 1.02 ^c |
| Child C (<i>n</i> = 23) | 14.52 \pm 2.91 ^e | 56.13 \pm 10.06 ^e | 6.02 \pm 1.23 ^e | 5.91 \pm 1.01 ^e |
| Control (<i>n</i> = 30) | 16.21 \pm 5.33 | 74.41 \pm 17.53 | 2.70 \pm 0.81 | 3.71 \pm 1.82 |

^aCompared with control, $P < 0.05$; ^cCompared with Child A, $P < 0.05$; ^eCompared with Child B, $P < 0.05$. LESP: Lower esophageal sphincter pressure; PA: Peristaltic amplitude; PD: Peristaltic duration; PV: Peristaltic velocity.

examination, H₂ blockers at least 48-72 h and prokinetics agents 24 h. An esophageal pH of less than 4 for at least 15 s was considered to be a reflux episode. Pathological acid reflux was considered if the percentage of the time with the intraesophageal pH less than 4 was greater than 4%, the number of reflux episodes was larger than 50 or the DeMeester value was higher than 14.72^[17].

The fiber optic spectrophotometer Bilitec 2000 was used to quantify DGER. The system consisted of a miniaturized probe measuring 1.5 mm in diameter that carried light signals into the esophagus and backed *via* a plastic fiberoptic bundle. Before each study, the probe was calibrated in water, and the probe tip was checked for obstruction after completion of the study.

Patients were also encouraged to maintain normal activities, sleep schedule, and to follow a particular low-fat diet containing light food elements, and not to take coffee, tea and fruit juice, in order to prevent any interference with the spectrophotometric recording. Skimmed milk and non-sparkling water were allowed. An episode of DGER was defined as an increase in esophageal bilirubin absorbance 0.14 for more than 10 s^[18,19].

Blood sample detection

Blood samples were drawn for a complete analysis of blood cell count and levels of prothrombin, albumin, alanine transaminase (ALT), aspartate transaminase (AST), alkaline phosphatase, gamma glutamyl transferase, bilirubin, cholesterol, creatinine.

Statistical analysis

Statistical analysis was performed using the statistical program SPSS 13.0 for Windows (SPSS Inc., Chicago, USA). All data were presented as mean \pm SD, and P values lower than 0.05 were considered statistically significant.

RESULTS

Patient characteristics

Seventy-eight patients met the inclusion criteria, 40 males (51.28%) and 38 females (48.72%), with a mean age of 56.41 \pm 9.72 years (range, 18-75 years). Twenty-eight patients were classified as Child A, 27 as Child B and 23 as Child C patients. Typical symptoms of gastroesophageal reflux disease were present in 25 (32.05%) patients. The RDQ scores were significantly higher in liver cirrhosis group (11.32 \pm 3.14) than in control group (6.25 \pm 3.31)

($P < 0.01$). There were no statistical differences of RDQ scores among the liver cirrhosis subgroups, and no relationship between Child-Pugh score and abnormal reflux ($P > 0.05$).

Esophageal manometry

In the liver cirrhosis group, LESP (15.32 \pm 2.91 mm Hg), PA (61.41 \pm 10.52 mmHg), PD (5.32 \pm 1.22 s), and PV (5.22 \pm 1.11 cm/s) were all significantly abnormal in comparison with those in the control group ($P < 0.05$) (Table 1). The results showed a gradual decrease of LESP and PA, also an extension of PD and PV in the liver cirrhosis group from Child A to Child C. LESP was negatively correlated with Child-Pugh score ($P < 0.01$, $r = -0.625$).

24-h esophageal pH monitoring

The results demonstrated a stepwise increase of pathologic esophageal pH-metry in liver cirrhosis patients, and an increase of acid reflux episodes and percentage of a pH $<$ 4 in the upright, supine and total phases of measurement ($P < 0.05$) (Table 2).

24-h esophageal bilirubin monitoring

The results showed a significant stepwise increase of pathologic esophageal bilirubin-metry in liver cirrhosis patients, along with significant increases of bile reflux episodes and percentage of absorbance $>$ 0.14 in the upright, supine, and total phases of measurement ($P < 0.05$) (Table 3).

Incidence of RE and abnormal reflux

The incidence of RE and pathologic reflux was 37.18% and 55.13% in patients with liver cirrhosis, respectively, which were all higher than those in the control group ($P < 0.05$) (Table 4 and Figure 1). The incidence of isolated abnormal acid reflux, bile reflux and mixed reflux was 12.82%, 14.10% and 28.21% in patients with liver cirrhosis, respectively (Table 5). And the incidence of BE was 5.13% (4/78) in patients with liver cirrhosis, and none was found in the control group.

DISCUSSION

As a complication of chronic liver disease, GERD in cirrhotic patients with EV accounted for about 20%, which mainly belongs to a dyskinetic type^[20]. Previous studies found that esophageal varices played an important role

in the development of esophageal motor disorders and abnormal gastroesophageal reflux in these patients, who presented obvious esophageal motor and motility disorders^[21,22]. The most prevalent disorder was the inefficient esophageal motility, along with abnormal PA, PD and PV^[12,21-23]. Some studies found that motor disorders existed in the esophageal body in these cirrhotic patients with EV, as compared with the cirrhotic patients without varices and control group^[24]. Thus, it seemed that EV itself, inde-

pendent of the cirrhosis, delayed esophageal clearance and increased the contact time between acid and mucosa.

In this study, LESP, PA, PD and PV in cirrhotic patients without esophageal varices were significantly abnormal as compared with those in the control group. LESP was markedly lower in patients with severe liver function damage, and negatively correlated with Child-Pugh score ($P < 0.01$, $r = -0.625$). The results showed that cirrhosis itself was another important factor for the esophageal motor disorder.

The incidence of esophageal acid reflux among cirrhotic patients with EV has also been studied in the last decades using pH-metry recording. It has been postulated that acid reflux may contribute to esophagitis and variceal bleeding in cirrhotic patients, and it occurs at a high frequency (64%) in patients with liver cirrhosis and portal hypertension, irrespective of the etiology of cirrhosis and the grade of esophageal varices^[8]. The results indicated that there was a correlation between typical gastroesophageal reflux disease and abnormal reflux, but no relationship between ascites, variceal size, congestive gastropathy and Child-pugh score and abnormal reflux.

The high incidence of RE in patients with severe chronic liver disease was also demonstrated, and asymptomatic RE was more common in cirrhotic and liver failure patients^[25,26]. In the present study, abnormal reflux and RE were demonstrated in 55.13% and 37.18% of the cirrhotic patients without esophageal varices, and the more severe liver function damage, the more abnormal parameters of acid and bilirubin reflux. In the mean time, typical symptoms of gastroesophageal reflux disease were presented in only 32.05% of the cirrhotic patients in this study, and abnormal reflux was found in 62% of the patients in the night possibly due to the lowered esophageal defenses during this period, with reduction of saliva production, swallowing and esophageal clearance.

GERD may occur in acid, bile or a mixed form, and DGER is considered as an independent risk factor for complicated GERD. However, few studies have reported the incidence of DGER among cirrhotic patients. Patients with Barrett's esophagus had significantly higher levels of DGER than patients with uncomplicated GERD, and bile reflux either alone or mixed with acid reflux contributed obviously to the severity of erosive and non-erosive reflux disease^[6]. Moreover, DGER in acid medium was more injurious to the esophagus than DGER in alkaline pH^[7]. We studied for the first time the incidence of BE and DGER in cirrhotic patients without esophageal varices. We found that the mixed acid and bile reflux was the predominant pattern of reflux in GERD patients, and the reflux incidence was also higher in Child B or C group than in Child

A group. A stepwise increase of mixed reflux was demonstrated along with the severity of liver function damage. Four BE patients (2 with mixed abnormal reflux, 2 with DGER) were found in Child C group.

The causes and the mechanism of liver cirrhosis in patients with abnormal GERD have not been fully elucidated. In this study, we demonstrated an obvious esophageal motility disorder and abnormal gastroesophageal reflux in cirrhotic patients without esophageal varices, and abnormalities of esophageal motility and reflux parameter were correlated with the severity of liver function damage. It seemed that not only mechanical effect (EV), but also neural and humoral factor are related to the high incidence of GERD in patients with liver cirrhosis. The progress of liver dysfunction decreased the incidence of LESP, worsened the esophageal motility and the reflux in the cirrhotic patients. In some studies, the levels of plasma vasoactive peptides and neurotensin were markedly higher in patients with liver cirrhosis than in the normal population, which were also known to lower the pressure of the LES, facilitating the reflux of the stomach content^[21,27].

The importance of nitrous oxide (NO) in the exacerbation of portal hypertension in liver cirrhosis was also reported^[28,29]. This substance can be found in large amounts in the systemic circulation of cirrhotic patients, and NO concentration increased significantly in patients with liver disease, which was closely related to the transient LES relaxation, suggesting that NO played an important role in the process of GERD. Whether the excessive NO in cirrhotic patients could exacerbate these manifestations, needs to be further confirmed.

We found that gastric half-emptying of liquid food was delayed in patients with liver cirrhosis, and the function of gastric emptying was also influenced by the damaged liver function^[30]. Ascites induced an increase in intra-abdominal pressure, compressing the stomach and the stomach content reflux^[31].

In summary, the majority of cirrhotic patients without EV presented esophageal motor disorders; mixed acid and bile reflux was the main pattern of reflux in GERD patients; and the presence of cirrhosis itself was an important causative factor for the onset of gastroesophageal reflux. Further researches on the functional and humoral factors and mechanism of GERD in liver diseases will gain a broad attention and interest in this field.

COMMENTS

Background

Gastroesophageal reflux disease (GERD) is one of the most common diseases

in modern civilization, and it has been reported that gastroesophageal reflux disease occurs at a high frequency in patients with liver cirrhosis.

Research frontiers

The relationship between esophageal motor disorders and acid gastroesophageal reflux in cirrhotic patients with esophageal varices has been reported. This study was designed to evaluate the esophageal motility and abnormal acid and bile reflux incidence in cirrhotic patients without esophageal varices.

Innovations and breakthroughs

This study showed that the presence of cirrhosis itself was an important causative factor for the onset of gastroesophageal reflux in patients with liver cirrhosis without varices. It is the first research on the incidence of Barrett's esophagus and DGER in cirrhotic patients without esophageal varices.

Applications

This study helped better understand the mechanism of GERD in patients with liver cirrhosis, and contributed to the diagnosis and treatment of liver cirrhosis and its complications in clinical practice.

Peer review

This is an interesting study on GERD in patients with liver cirrhosis, but without esophageal varices. Since it has before been thought that esophageal varices somehow have something to do with the increased frequency of GERD in patients with liver disease, the authors have made an interesting contribution to the literature by showing that reflux symptoms and pathologic esophageal motility changes are more common in patients with cirrhosis but without varices.

Abstract

AIM: To explore the association between single nucleotide polymorphisms (SNPs) at 8q24 and gastric cancer risk.

METHODS: A case-control investigation including 212 gastric cancer patients and 377 healthy controls was conducted. The genotypes of SNPs (rs6983267, rs7008482 and rs10808555) were examined and established through polymerase chain reaction-restriction

fragment length polymorphism (PCR-RFLP). Multivariate logistic regression models were used to evaluate the association between SNPs and gastric cancer.

RESULTS: The genotype frequencies of rs6983267 in gastric cancer patients were obviously different from those in the control ($P = 0.005$). GT genotype of rs6983267 was associated with an increased risk of gastric cancer compared with GG genotype (adjusted odds ratio = 2.01, 95% confidence interval: 1.28-3.14). Further stratified analysis indicated that rs6983267 GT genotype facilitated the risk of gastric cancer of non-cardiac and intestinal type (OR: 2.638, 95% CI: 1.464-4.753; OR: 1.916, 95% CI: 1.166-3.150, respectively).

CONCLUSION: This study demonstrates for the first time that rs6983267 is involved in susceptibility to gastric cancer, although further large-sample investigations are still needed.

INTRODUCTION

Gastric cancer is the second most common cause of death

from cancer in the world^[1] and the incidence rate was 16.2 per 100 000^[2]. Despite of a marked decrease in gastric cancer mortality rate in many countries, there is a higher prevalence of gastric cancer in the Chinese population than in other races. No doubt, either a high absolute number or a high mortality of gastric cancer has become a key public health issue in China.

Although numerous biological and epidemiological studies have shown risk factors for gastric cancer, the available knowledge is still insufficient to reveal the exact mechanism of gastric cancer. Current researches have shown that both genetic and environmental factors play an important role in gastric carcinogenesis^[3,4] and genetic susceptibility accounts for 35% of disease etiology^[5]. Recently, the association between variants at 8q24 and breast, prostate and colorectal cancers has been discovered and confirmed by several research groups^[6-15], which suggested a complex contribution of polymorphisms at 8q24 to the formation of multiple adenomas. However, whether these common variants in 8q24 are also associated with the risk of gastric cancer has so far not been published.

In the present study, we conducted a case-control association study to evaluate the effect of rs6983267, rs7008482 and rs10808555 in 8q24 in the risk of gastric cancer in the Chinese population.

MATERIALS AND METHODS

Subjects

A total number of 216 cases and 400 controls were enrolled from January 2009 to January 2010 in Tongji Hospital, Shanghai. Among the 1360 subjects who were invited to take part in this study, only 45% individuals agreed to participate and donated 3 mL venous blood sample. All the gastric cancer cases had been checked by the gastroscopy and diagnosed by the specialized physician. The exclusion criteria of cases included: (1) Having a history of any other cancers or any metastasized cancer (carcinomas were not originally from stomach); and (2) Having undergone radiotherapy or chemotherapy. Controls were randomly selected among the first-visit outpatients who were confirmed to have no cancer or a prior history of neoplasm. Available baseline characteristics, including age, gender, race, tumor location, histological type, were recorded. All the subjects were genetically unrelated ethnic Han Chinese. This study was approved by the institutional review board of Tongji University School of Medicine. Written informed consent was obtained from all participants.

Genotyping

According to the manufacturer's protocol, we used Flexi Gene DNA Kit (Qiagen, Hilden, Germany) to extract genomic DNA from peripheral blood leukocytes of the subjects and stored extracted DNA at -20°C. Unique primer sequences were designed in the website of primer3 (<http://frodo.wi.mit.edu/primer3/input.htm>) and primer sequences for rs6983267, rs7008482 and rs10808555 were as follows: 5'-ATGAAGGCGTTCGTCCTCAAATGA-3'

(forward) and 5'-TTGGCTGGCACTGTCTGTATA-3' (reverse); 5'-CCAAGCAGAGAGGAACCAACT-3' (forward) and 5'-GCCACCCCTTATTCTCCAACC-3' (reverse); 5'-ATATGGTCCCTGCCCTCAAG-3' (forward) and 5'-CACTGTGCTAAAGGAATCAGCAA-3' (reverse), respectively. Polymorphisms genotyping was performed by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). Amplification reactions were carried out in a total volume of 15 µL containing 0.3 mmol/L of each deoxynucleoside triphosphate, 10 mmol/L Tris-HCl, 50 mmol/L KCl, 2 mmol/L MgCl₂, 20% Q solution (Qiagen, Hilden, Germany), 0.16 µmol/L of each primer, 10 ng genomic DNA, and 1 U Taq (TaKaRa, Otsu, Shiga, Japan). Cycling conditions were: 94°C for 3 min, followed by 10 cycles of 94°C for 30 s, 64°C for 30 s with a 0.5°C decrement of the annealing temperature per cycle and 72°C for 30-45 s, followed by 30 cycles of 94°C for 30 s, 59°C for 30 s and 72°C for 30 s, followed by 72°C for 8 min. PCR products were digested overnight at 37°C with a predicted restriction enzyme, Ts-p45I (Fermentas, Vilnius, Lithuania) for rs6983267, CviQI (Fermentas, Vilnius, Lithuania) for rs7008482, Eco130I (Fermentas, Vilnius, Lithuania) for rs10808555 and were analyzed on 3% agarose with ethidium bromide staining. Three sorts of PCR products were digested into 3 different types of fragments. For rs6983267, the G allele resulted in two fragments of 198-bp and 344-bp, and the C allele produced one fragment of 498-bp. For rs7008482, the G allele resulted in two fragments of 270-bp and 131-bp, while the T allele produced one fragment of 401-bp. For rs10808555, the G allele digested into two fragments of 193-bp and 110-bp, and the A allele generated one fragment of 303-bp.

All the samples were assayed blindly without knowing the case or control status. After genotyping was performed, two research assistants read the gel pictures independently. When they failed to reach a consensus on the tested genotypes (< 1%), they would repeat the genotyping again so as to achieve a final consensus. To ensure the genotyping accuracy, randomly selected PCR products were reevaluated by DNA sequencing^[16]. In addition, 5% of all samples were randomly selected and genotyped in duplicate, and the results were 100% concordant.

Statistical analysis

Hardy-Weinberg equilibrium was tested using the two-sided χ^2 test. χ^2 test was used to compare genotype frequency and demographic distributions between cases and controls. Multivariate unconditional logistic regression was used to calculate odds ratios (OR) and 95% confidence intervals (CIs) for the association between genotypes and gastric cancer, adjusting for age and gender. The co-dominant and the dominant models were used for the analysis. In the co-dominant model, each SNP was separated into three categories, 1 for each genotype, with one genotype chosen as the reference group. For the dominant model, each SNP was modeled as a dichotomous variable with

Table 1 Characteristics of cases and control

| Variables | Gastric cancer <i>n</i> (%) | Control <i>n</i> (%) | <i>P</i> value ² |
|-----------------------------|-----------------------------|----------------------|-----------------------------|
| Overall | 212 | 377 | |
| Sex | | | 0.063 |
| Male | 152 (71.7) | 242 (64.2) | |
| Female | 60 (28.3) | 135 (35.8) | |
| Age | | | 0.670 |
| Mean ± SD (yr) | 62.47 ± 11.6 | 62.89 ± 11.3 | |

| Cardia | 74 (38.5) | | |
| Noncardia | 118 (61.5) | | |

¹The number of subjects in cases for tumor location (*n* = 192) was less than the total number (*n* = 212) because some information was not obtained; ²Two-sided χ^2 test for the frequency distribution of variants between gastric cancer cases and controls.

1 genotype chosen as the reference group, and the other two genotypes combined into one category. All tests were two-sided and *P* values < 0.05 were considered statistically significant. All statistical analyses were performed using SPSS 16.0 software package (SPSS, Chicago, IL)

RESULTS

Demography

Among 216 gastric cancer cases and 400 controls, 4 cases and 23 controls were dropped out due to poor-quality genomic DNA. Of the 212 cases of gastric cancer, 155 were intestinal type, 44 diffuse type and 13 mixed-type. The mean age of cases was 62 years and the mean age of controls was 63 years. The characteristics of the cases and controls are summarized in Table 1. There was no significant difference between the groups with respect to the age and gender distributions.

SNPs and gastric cancer risk

Among the controls, the genotype distributions of rs6983267 and rs7008482 were in Hardy-Weinberg equilibrium (*P* > 0.1 and *P* > 0.9, respectively), but rs10808555 did not fit Hardy-Weinberg equilibrium (*P* < 0.05). The genotype frequencies of rs6983267 were obviously different between gastric cancer patients and control ($\chi^2 = 10.8$, *P* = 0.005). Analysis under both co-dominant model and dominant model showed that only rs6983267 was significantly associated with gastric cancer risk, after adjustment for age and gender (Table 2). In the co-dominant model, rs6983267 GT genotype was associated with approximately 2 times higher odds of gastric cancer risk (OR: 2.01, 95% CI: 1.28-3.15) compared with the GG genotype. In the dominant model, combined genotypes (GT + TT) of rs6983267 were significantly associated with increased risk of gastric cancer in comparison with GG genotype (OR: 1.82, 95% CI: 1.18-2.81). However, the genotype frequencies of rs7008482 were similar between gastric cancer

Table 2 Association between variation in single nucleotide polymorphisms rs6983267 and rs7008482 and risk of gastric cancer

| Genotype | Control <i>n</i> (%) | Cases <i>n</i> (%) | <i>P</i> value |
|-----------|----------------------|--------------------|----------------|

patients and controls (*P* > 0.05).

Furthermore, we evaluated the contributions of SNPs to subgroups according to age, gender, different histological types and tumor locations (Table 3). In the subgroup aged ≤ 60 years, rs6983267 GT genotype markedly increased the risk of gastric cancer referring to GG genotype (OR: 3.21, 95% CI: 1.52-6.68), but in the subgroup aged > 60 years, no significant difference was found (*P* = 0.137). In addition, rs6983267 GT genotype was significantly associated with augmentation of gastric cancer risk in both male and female. As to the histological types and tumor sites, rs6983267 GT heterozygote had a significantly increased risk for non-cardiac gastric cancer (OR: 2.64, 95% CI: 1.46-4.75) and intestinal-type gastric cancer (OR: 1.92, 95% CI: 1.17-3.15) in contrast with GG genotype. Further analysis in Table 4 demonstrated that rs6983267 GT genotype increased the risk of an intestinal-type gastric adenocarcinoma from non-cardiac region. For rs7008482, only GG genotype was associated with significantly increasing risk of gastric cancer compared with TT genotype in male subgroup (OR: 1.88, 95% CI: 1.01-3.47) (Table 3).

DISCUSSION

This is the first study to discover the association between rs6983267 at 8q24 and the susceptibility of gastric cancer, although other previous studies had reported that rs6983267 was associated with the risk of colorectal cancer and prostate cancer^[13,17]. Our observation and analysis indicated that compared with GG genotype of rs6983267, GT genotype and combined genotypes (GT + TT) were both markedly associated with the increasing risk for gastric cancer. And further stratified investigation confirmed that rs6983267 GT genotype facilitated the risk of non-cardiac and intestinal-type gastric cancer. Therefore, rs6983267 is a novel gastric cancer associated polymorphism in 8q24 in Chinese Han population.

Rs6983267 resides at 8q24, proximal to a processed pseudogene, *POU5F1P1*, which is a retrotransposed copy of the POU-domain transcription factor Oct4^[18]. At least one mouse *Oct4* pseudogene has been shown to mediate stem cell regulatory function^[19], suggesting that *Oct4*

pseudogene may exert influence in regulating stem cell proliferation^[7]. *Oci4* also plays a critical role in maintaining stem cell pluripotency^[20], self-renewal, and lineage commitment^[21]. *Oci4* has been found to promote tumor growth in a dose-dependent manner^[22] and epithelial dysplasia by interfering with progenitor cell differentiation^[23]. Although the expression of many *Oci4* pseudogenes in poorly differentiated tumors^[24] has been observed, the related molecular mechanism in cancer is unknown.

On the other hand, rs6983267 is located in the region which is 335 kb away from the nearest gene, *MYC*. *MYC* is able to increase the growth and proliferation of normal gastric cells^[25], and may enhance the canceration of gastric epithelial cells by regulating a variety of genes related to proliferation, differentiation^[26], and apoptosis^[27].

MYC overexpression has been described in over 40% of gastric cancer (in both intestinal- and diffuse-type gastric adenocarcinoma)^[28]. Overexpression of *MYC* gene can influence some biological characteristics of normal gastric cells, directly regulate the genes involved in cell cycle regulation^[29], such as *cyclin A*, *cyclin B* and *cdk4*^[30], and accelerate cancerous growth ultimately. The promotion of the growth and proliferation of these cells helps tumor cells maintain malignant phenotype. Moreover, the therapeutic medicine inhibits gastric cancer cell growth by suppressing *MYC* gene expressions, which consistently confirms the crucial function of *MYC* in gastric cancer cell growth^[31]. The region harboring rs6983267 is a transcriptional enhancer and differentially binds transcription factor 7-like 2 (TCF7L2) due to rs6983267, leading to a different physi-

cal interaction with *MYC*^[32]. Given that the cancer risk-associated SNP enhances the expression of *MYC* through increased distal enhancer activity^[32,33], it is reasonable to speculate that rs6983267 may alter expression of *MYC* through modifying regulatory sequences in this region. Despite the research progress, further studies are needed about the concrete molecular mechanisms of the joint effect between *MYC* and rs6983267 polymorphism.

Previous studies have demonstrated that rs6983267 is possibly related to some kinds of malignant tumor. In the present study we found that rs6983267 is a novel gastric cancer related polymorphism. Stratified analysis indicated that the associations between rs6983267 GT genotype and gastric cancer tended to vary with tumor sites and histological types. Rs6983267 GT genotype was associated with both intestinal and non-cardiac type of gastric cancer but not associated with the diffuse and cardiac type, and increased the risk of intestinal type among the non-cardiac gastric cancer, which suggested that rs6983267 GT genotype is more important in modulating the intestinal and non-cardiac type of gastric cancer. However, TT genotype in rs6983267 tended to be a protective factor in intestinal type among the non-cardiac gastric cancer although this was not significant in the association analysis. This phenomenon could be explained, because distinct clinical, epidemiological and molecular features have been noted among tumors arising from cardia or non-cardia, and among intestinal or diffuse histological subtypes^[34]. For instance, the loss of p16 and smad4 protein expression and the positive *EPstein-Barr virus (EBV)* status are more frequent in cardiac carcinomas than that in non-cardiac carcinomas reported by Kim *et al.*^[35]. Lu *et al.*^[36] reported that intestinal-type gastric cancer predominates in high-risk geographic areas, especially in Japan, Korea and China, whereas the diffuse-type gastric cancer has a uniform geographic distribution. The observed differences between gastric cancers in tumor location and histological types suggest that they are distinct diseases with different etiologies^[37]. Thus, various genetic factors, including rs6983267, may be involved in different subtypes of gastric cancer (cardiac or non-cardiac; intestinal or diffuse). Another plausible explanation for this situation may be the genetic heterogeneity which may limit the ability to detect an association between TT genotype and gastric cancer. Other variants, which have a strong association with risk of gastric cancer, including as yet undiscovered susceptibility genes, may affect the outcome of this research. Moreover, the limited sample size may be not sufficient to generate this association. Overall, the genetic susceptibility and environmental factors have been proposed to play an important role in the etiology of gastric cancer, and different subtypes of gastric cancer may have diverse biological mechanisms.

Apart from the discovery in rs6983267, this study failed to demonstrate the association between rs7008482 and the risk of gastric cancer, although rs7008482 was reported to be associated with prostate and colorectal cancer^[10,11]. Nevertheless, positive association between rs7008482 GG genotype and risk of gastric cancer in male subgroup has been

shown. Rs7008482 lies within an intronic region of the *NSMCE2* (also called *MMS21*) gene, and MMS21 protein is a SUMO ligase which is required for DNA replication, recombination and repair^[11]. Considering the function of *NSMCE2* gene and MMS21 protein, we wonder whether the limited sample size hampered the detection of association between rs7008482 and gastric cancer risk. Therefore, further studies are still needed to confirm it.

In conclusion, our data demonstrated for the first time that rs6983267 may predispose to the susceptibility of gastric cancer, especially the intestinal and non-cardiac type. However, as the sample size of the present study is relatively small, additional tests of variant at 8q24 for its association with gastric cancer in a larger population, and functional studies of *MYC* and other nearby genes will be required to fully understand the mechanisms of the cancer-specific risk at 8q24.

COMMENTS

Background

Gastric cancer (GC) is one of the most common cancers, and the second most frequent cause of cancer-related deaths in the world. Epidemiological studies have shown that genetic factors play a crucial role in gastric carcinogenesis. Recently, common polymorphisms located at chromosome 8q24 have been identified to increase the tumor risk. The authors investigated the associations between rs6983267 polymorphisms and GC risk.

Research frontiers

Chromosome 8q24 is an established risk locus for many common epithelial cancers. Polymorphism rs6983267 is a susceptibility marker for prostate and colon cancers, and perhaps also ovarian and other cancers. The relationship between rs6983267 polymorphism and GC needs to be addressed.

Innovations and breakthroughs

To our knowledge, this is the first study of GC risk variant at 8q24 in a Chinese population. Polymorphism rs6983267 was found to be associated with an increased risk of GC, which had been not reported before. The result of stratified analysis according to histological types confirms the contribution of rs6983267 in non-cardiac and intestinal type of gastric carcinogenesis.

Applications

These findings might be of value in the explanation of gastric carcinogenesis. They could be used for further investigations about the association between genetic predisposition and the risk of GC at 8q24.

Terminology

MYC is an oncogene, the protein encoded by this gene is a multifunctional, nuclear phosphoprotein that plays a role in cell cycle progression, apoptosis and proliferations. Single nucleotide polymorphism is a DNA sequence variation occurring when a single nucleotide-A, T, C, or G-in the genome (or other shared sequence) differs between members of a species or paired chromosomes in an individual.

Peer review

The authors investigated the association of the 3 single nucleotide polymorphisms (SNPs) (rs6983267, rs7008482 and rs10808555) with the risk of gastric cancer by a case-control study, and found that GT genotype of rs6983267 was associated with an increased risk of gastric cancer compared with GG genotype (AOR = 2.01, 95% CI: 1.28-3.14). After stratification, rs6983267 GT genotype was associated the risk of non-cardiac and intestinal type of gastric cancer. This study provides some new SNP for the evaluation of gastric cancer risk.

Abstract

AIM: To evaluate the value of endoscopic ultrasonography (EUS) in the choice of endoscopic therapy strategies for mesenchymal tumors of the upper gastrointestinal tract.

METHODS: From July 2004 to September 2010, 1050 patients with upper gastrointestinal mesenchymal tumors (GIMTs) were diagnosed using EUS. Among them, 201 patients underwent different endoscopic therapies based on the deriving layers, growth patterns and lesion sizes.

RESULTS: Using EUS, we found 543 leiomyomas and 507 stromal tumors. One hundred and thirty-three leiomyomas and 24 stromal tumors were treated by snare electrosection, 6 leiomyomas and 20 stromal tumors

were treated by endoloop, 10 stromal tumors were treated by endoscopic mucosal resection and 8 stromal tumors were treated by endoscopic submucosal dissection. Complete resection of the lesion was achieved in all cases. Of the mesenchymal tumors, 90.38% diagnosed by EUS were also identified by pathohistology. All wounds were closed up nicely and no recurrence was found in the follow-up after 2 mo.

CONCLUSION: EUS is an effective means of diagnosis for upper GIMTs and is an important tool in choosing the endoscopic therapy for GIMTs, by which the lesions can be treated safely and effectively.

EUS for choosing best endoscopic treatment of mesenchymal tumors of upper gastrointestinal tract. *World J Gastroenterol* 2011; 17(13): 1766-1771 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i13/1766.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i13.1766>

INTRODUCTION

Gastrointestinal mesenchymal tumors (GIMTs) originate from mesenchymal cells other than epithelial cells or lymphocytes. They are further classified as stromal tumors, leiomyomas, leiomyosarcomas, neural tumors, fibroblast tumors or liparomphalus. Clinically, mesenchymal tumors are usually incidentally discovered as subepithelial bulges during routine endoscopic examinations for unrelated conditions. The classification and management of these

lesions can be challenging. In recent years, with the wide use of endoscopic ultrasound (EUS) to clarify the nature and origin of the subepithelial tumor, great progress has been made in diagnosis and treatment of GIMTs^[1,2]. Importantly, under the guidance of the EUS, GIMTs can be removed by appropriate endoscopic treatment without severe complications^[2-4].

From July 2004 to September 2010, we analyzed 1050 patients with GIMTs diagnosed by EUS in our hospital. Of these patients, 201 underwent different endoscopic therapies based on the EUS results. Our aim in this retrospective study was to evaluate the value of EUS in the choice of endoscopic therapy strategies for mesenchymal tumors of the upper gastrointestinal tract.

MATERIALS AND METHODS

Patients

The medical records of 1050 patients with upper GIMTs diagnosed by EUS examination in the First Affiliated Hospital of Zhejiang University were retrospectively reviewed. All these patients with submucosal protruding lesions in the upper gastrointestinal tract by routine endoscopy were examined by EUS. There were 499 men and 551 women, with a mean age of 52.6 years (range, 19-86 years). Of these patients, 201 patients underwent endoscopic therapy in the First Affiliated Hospital of Zhejiang University, Beilun Zongrui Hospital, the Traditional Chinese Medical Hospital of Ninghai and Jinhua Wenrong Hospital, respectively.

Methods

A two-channel endoscope (GIF-2T240, Olympus, Tokyo, Japan) and a 12 MHz probe (GF-UM 2R, Olympus, Tokyo, Japan) were used for the ultrasonographic study. Scanning of the tumor was performed after filling the upper gastrointestinal tract with 100-500 mL of deaerated water. Diagnosis was made according to the layer of origin, size, nature, internal echo pattern, outer margin and grow pattern of the lesion. Following the EUS procedure, if the lesion was identified as an intramural lesion ≤ 2.5 cm, endoscopic treatment was performed. A lesion > 2.5 cm in size and suspected to be malignant was suggested for surgery. A large proportion of patients were followed up with EUS, because their poor conditions were unsuited for the therapy or the lesion was too small.

An Olympus GIF-XQ240/260 gastroscope (Tokyo, Japan) was used for the resection when it was indicated. Informed consent was given by each patient before the endoscopic therapy. Four different resection techniques were used: snare electrosection, endoloop, endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD).

EMR procedure: Epinephrine (0.001%) was injected into the submucosal layer to lift the lesion, and then a conventional electrosectional snare (FD-IU, Olympus, Tokyo, Japan) and an electrosectional unit (VIO 200D,

ERBE, Tübingen, Germany) were used for removal of the overlying mucosa and resection of the tumor.

ESD procedure: the surrounding area of the lesion was marked with argon plasma coagulation (APC 300A, ERBE, Tübingen, Germany). Normal saline solution with 0.002% indigo carmine and 0.001% epinephrine was injected into the submucosal layer to lift the lesion. An initial incision was made outside the marking dots with a hook-knife (KD-620LR, Olympus, Tokyo, Japan). The submucosal resection under the lesion was done with insulation-tipped (IT) electrosectional knife (KD-610L, Olympus, Tokyo, Japan). Finally, a snare was used to remove the surrounding tissues. Bleeding and visible vessels in the resection area were closed using hemoclips (HX-201YR-135, Olympus, Tokyo, Japan).

Postoperative EUS examination was made to check whether the lesions were completely removed except those with endoloop ligation. The specimens were sent for pathologic study, some of which were assayed by immunohistochemistry. All 201 patients were examined two months later with EUS.

RESULTS

Using EUS, we identified 1050 patients with GIMTs, 543 of them had leiomyomas. Five hundred and twenty lesions were in the esophagus, 22 in the stomach, and 1 in the duodenum. The mean maximal tumor diameter was 3.3 cm. Five hundred and seven cases were stromal tumors. Forty-nine lesions were in the esophagus, 428 were in the stomach, and 30 were in the duodenum. The mean maximal tumor diameter was 6.6 cm. EUS features of leiomyomas and stromal tumors were characteristic with regular borders, a hypoechoic mass with homogeneous or heterogeneous echo patterns (Figures 1-4). The echogenicity of leiomyomas was slightly lower than the normal proper muscle layer, while that of stromal tumors was slightly higher. Malignant stromal tumors often appeared as a heterogeneous mass with irregular borders.

One hundred and thirty-nine leiomyomas and 62 stromal tumors underwent endoscopic therapy after EUS examination. No obvious malignant signs were seen in these lesions. The location, origin level and removal methods of the lesions are shown in Table 1. The mean maximal tumor diameter was 2.5 cm. For a tumor protruding into the cavity, if it originated from the muscularis mucosa or from submucosa ≤ 1 cm, snare electrosection was directly used. If the lesion originating from submucosa was flat and > 1 cm, electrosection would be expected to fail, and other treatments, such as endoloop, EMR or ESD, were used. For a lesion originating from muscularis propria but not growing outward, endoloop or ESD was used. Among these patients, 133 leiomyomas and 24 stromal tumors were treated by snare electrosection, 6 leiomyomas and 20 stromal tumors were treated by endoloop, 10 stromal tumors were treated by EMR and 8 stromal tumors were treated by ESD (Figures 1-4). Complete resection of

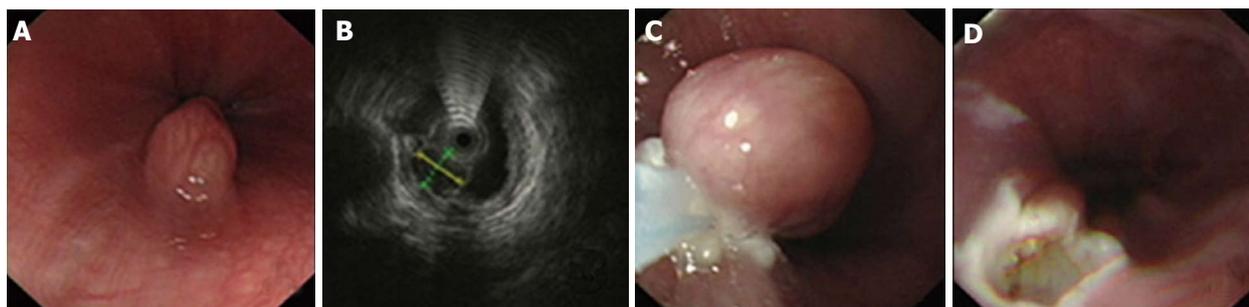

Figure 1 An esophageal leiomyoma treated by snare electrosection. A: An elevated lesion in the lower esophagus; B: A homogeneous, hypoechoic mass ($1.0 \times 0.7 \text{ cm}^2$) with a regular border originated from muscularis mucosa, which was diagnosed as a leiomyoma by endoscopic ultrasonography; C: The tumor was snared at the base, and then it was resected by snare electrosection; D: Postoperative wounds.

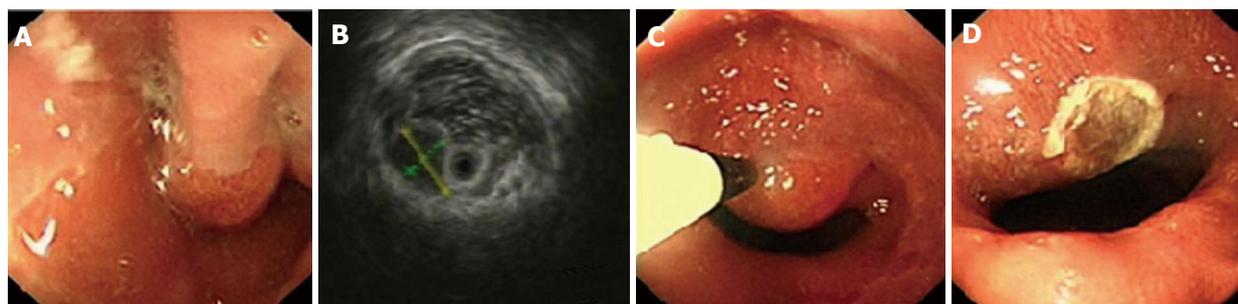

Figure 2 A gastric stromal tumor treated by endoscopic mucosal resection. A: An elevated lesion in the cardia; B: A homogeneous, hypoechoic mass ($1.4 \times 0.8 \text{ cm}^2$) with a regular border originating from submucosa, which was diagnosed as a stromal tumor by endoscopic ultrasonography; C: Epinephrine (0.001%) was injected into the submucosa to lift the lesion; D: Postoperative wounds.

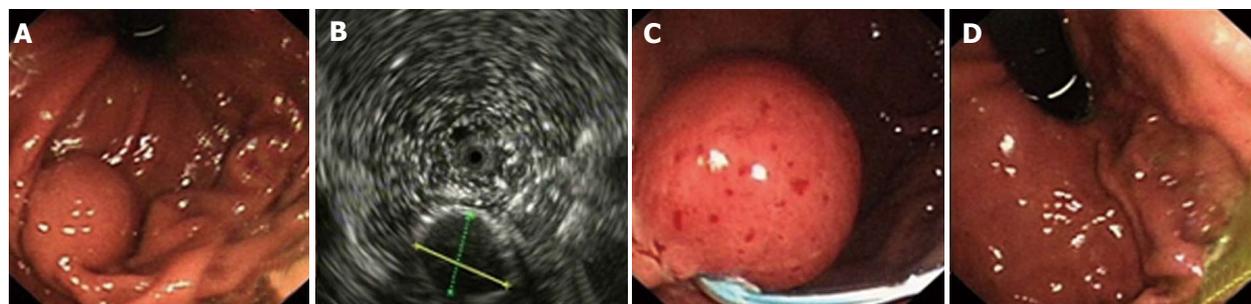

Figure 3 A gastric stromal tumor treated by endoloop. A: An elevated lesion in gastric fundus; B: A homogeneous, hypoechoic mass ($2.0 \times 1.5 \text{ cm}^2$) with a regular border originating from muscularis propria, which was diagnosed as a stromal tumor by endoscopic ultrasonography; C: Endoscopic ligation with an endoloop; D: Endoscopic view of an ulcer scar without tumor recurrence at the ligation site 2 mo later.

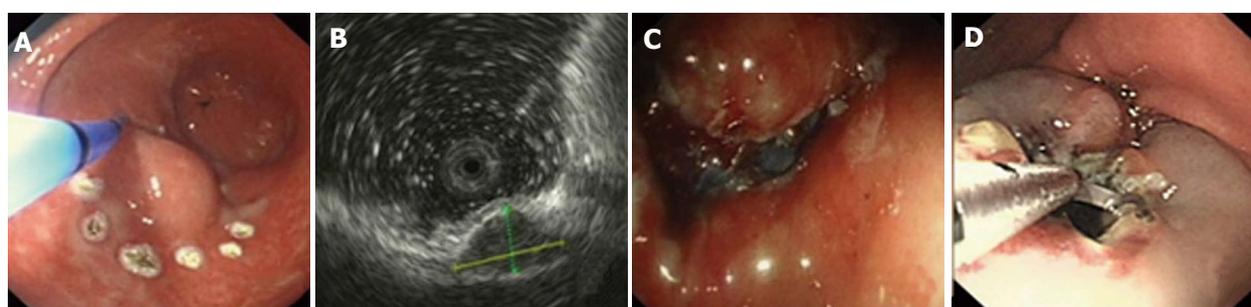

Figure 4 A gastric stromal tumor treated by endoscopic submucosal dissection. A: An elevated lesion in the gastric antrum; B: A homogeneous, hypoechoic mass ($2.0 \times 1.2 \text{ cm}^2$) with a regular border originating from muscularis propria, which was diagnosed as a stromal tumor by endoscopic ultrasonography; C: The surrounding area of the lesion was marked with argon plasma coagulation. After normal saline solution with 0.002% indigo carmine and 0.001% epinephrine was injected into the submucosal layer to lift the lesion, an initial incision was made outside the marking dots with hook-knife. Submucosal dissection under the lesion was performed with an IT knife; D: The tumor was dissected and the postoperative wounds were closed using hemoclip.

Table 1 Location, origin and treatment of 201 gastrointestinal mesenchymal tumors

| Diagnosis by EUS | Location | | Layer of origin | | | Treatment | | | |
|------------------|-----------|---------|-------------------|-----------|--------------------|----------------------|----------|-----|-----|
| | Esophagus | Stomach | Muscularis mucosa | Submucosa | Muscularis propria | Snare electrosection | Endoloop | EMR | ESD |
| Leiomyoma | 134 | 5 | 121 | 15 | 3 | 133 | 6 | 0 | 0 |
| Stromal tumor | 22 | 40 | 18 | 19 | 25 | 24 | 20 | 10 | 8 |
| Total | 156 | 45 | 139 | 34 | 28 | 157 | 26 | 10 | 8 |

EUS: Endoscopic ultrasonography; EMR: Endoscopic mucosal resection; ESD: Endoscopic submucosal dissection.

the lesion was achieved in all cases. No residual lesion was detected by postoperative EUS examination except for those by endoloop ligation. None of the patients suffered from severe hemorrhage or resection-related perforation. Postoperative histological results showed that 141 of 156 patients were in agreement with the preoperative diagnosis of EUS. All the specimens tested had complete envelope and negative resection margin in pathology. Wounds were closed up nicely in all patients when rechecked after two months. No residual lesion was detected by EUS examination and pathology demonstrated negative results at the same time.

DISCUSSION

Leiomyomas and stromal tumors are the most common GIMTs of the upper gastrointestinal tract. Many lesions are subepithelial, and they are often difficult to diagnose by general endoscopy. Some also need to be identified with extrinsic compression. EUS can reliably characterize the nature, size, and layer of origin of lesions, and accurately differentiate intramural from extramural, leading to a diagnosis^[5]. Features of leiomyomas and stromal tumors seen with EUS often include: a round shape, and a homogeneous, hypoechoic mass with regular borders^[6]. A marginal halo, hyperechogenic spots and higher echogenicity as compared with the normal muscle layer is seen more frequently in stromal tumors than in the leiomyomas^[7]. Malignant stromal tumors are characterized by large size (> 5 cm), irregular borders, and echogenic foci^[8,9].

In this study, we identified 1050 patients with GIMTs using EUS. There were 543 leiomyomas and 507 stromal tumors. The majority of leiomyomas were located in the esophagus while most stromal tumors were located in the stomach, which is in accordance with other studies^[6-10]. For these mesenchymal tumors, 90.38% diagnosed by EUS were also identified by pathohistology. Among these, 5 retention cysts, 4 stromal tumors with leiomyoma differentiation, and 1 hyperplastic polyp were diagnosed as leiomyoma, and 3 leiomyoma and 2 hyperplastic polyps were diagnosed as stromal tumors by EUS. Submucosal retention cysts are small and often filled with thick fluid, and thus the ultrasonographic image is of a hypoechoic mass that may be confused with mesenchymal tumors. Stromal tumors with leiomyoma differentiation are also difficult to discriminate by routine pathology and should be identified by immuno-

histochemistry. Samples from EUS-guided fine-needle aspiration biopsies can be sent for cytological, pathological and immunohistochemical assays which may enable clinicians to make more accurate diagnoses than using EUS examination alone^[6-11].

In the past, conventional endoscopy could not accurately determine the location and categorization of subepithelial lesions. Therefore, GIMTs were usually treated by surgery. The introduction of EUS has solved these problems and it has played an important role in the choice of endoscopic therapy for mesenchymal tumors. Based on EUS images, we treated 201 GIMTs with different endoscopic therapies, including snare electrosection, endoloop, EMR and ESD. Complete resection of the lesions was achieved in all cases. None of the patients suffered from severe hemorrhage or resection-related perforation. All wounds were closed up nicely and no recurrence was found in the follow-up after 2 mo.

Electrosection is the most common endoscopic treatment, and its value for the treatment of gastrointestinal submucosal tumors has been recognized^[12,13]. It is mainly used for protuberant lesions (especially the pedunculated ones). In this study, 157 GIMTs arising from non-muscularis propria, with a diameter of ≤ 1 cm, were treated by snare electrosection after EUS examination. It is reported that serious complications rarely occurred when electrosection is used to cut non-muscularis propria tumors with a diameter ≤ 3 cm^[3]. Tumors originating from muscularis propria are associated with an increased risk of perforation and hemorrhage complications during endoscopic treatment, and snare electrosection was not used in these cases.

Compared with ordinary snare removal, EMR is more suitable for the treatment of flat lesions generally confined to < 2 cm^[14]. In this study, 10 flat lesions were treated by EMR. We injected 0.001% epinephrine into the submucosal layer to lift the lesion and made it easy to snare. Furthermore, this may provide a buffer to protect the inherent muscle function, which could reduce the bleeding and perforation risk during the process of muscle removal. Examination by EUS before surgery to determine the size and depth of lesions could help determine the injection site and the resection scope.

Endoloop ligation of tumors at the base, blocking blood supply and causing tumor necrosis, could significantly reduce the risk of hemorrhage and perforation^[15,16]. But, the procedure is not suitable for large lesions. Incomplete ligation might leave residual tumors,

while ligation could increase the risk of hemorrhage and perforation. Therefore, the range and depth of ligation should be strictly controlled according to the results of EUS during surgery. In the past, the majority of tumors studied have been only the muscularis mucosa and submucosa^[3]. Recently, it was reported that endoloop could remove tumors arising from muscularis propria safely and effectively^[15,17]. In this study, we also used endoloop removal of lesions arising from muscularis propria, without hemorrhage or perforation. The tumor from the muscularis propria can grow inside or outside the cavity, therefore, preoperative EUS for defining the tumor growth pattern is very important to determine whether the lesion can be safely and completely removed.

ESD should be performed using a high-frequency electric knife to dissect the subepithelial tumor, which is more suitable for treatment of large and flat lesions. Tumors derived from the muscularis mucosa and submucosa can be completely dissected^[18,19]. It is difficult to dissect lesions from the muscularis propria because of the increased risk of hemorrhage and perforation. In Lee *et al.*'s^[20] study, among 12 cases of gastrointestinal submucosal muscle tumors arising from muscularis propria treated by ESD, 9 tumors were completely dissected. The size of these tumors ranged from 0.6 to 4 cm (average, 2 cm). In this study, 8 stromal tumors arising from submucosa or muscularis propria were treated safely by ESD. All of them were dissected once and clipping was used to close deep wounds to reduce hemorrhage and perforation risk.

Our clinical practice demonstrates that endoscopic treatment can be applied to GIMTs arising from muscularis mucosa, submucosa and muscularis propria. Based on the results of the EUS procedure, lesions > 2.5 cm in size and suspected to be malignant should be considered for surgery. Moreover, if the tumor grew outside the cavity, endoscopic treatment should be aborted as well. We also suggested a follow-up with EUS for the few patients who are not indicated for the endoscopic therapy or whose tumor is too small.

In conclusion, EUS can help determine the origin, size, shape, nature and growth pattern of lesions, with a high diagnostic accuracy for upper GIMTs. Preoperative EUS examination is important for choosing the type of endoscopic therapy for mesenchymal tumors, by which the lesions can be treated safely and effectively.

COMMENTS

Background

Clinically, gastrointestinal mesenchymal tumors (GIMTs) are usually incidentally discovered as subepithelial bulges during routine endoscopy for unrelated conditions. The classification and management of these lesions can be challenging.

Research frontiers

With the wide use of endoscopic ultrasonography (EUS) to clarify the nature and origin of the subepithelial tumor, great progress has been made in diagnosis and treatment of GIMTs. However, the value of EUS in the choice of endoscopic treatment strategies for GIMTs has not been well established.

Innovations and breakthroughs

This study indicated that EUS could help determine the origin, size, shape,

nature and growth pattern of lesions, with a high diagnostic accuracy for upper GIMTs. Under the guidance of the EUS, GIMTs could be removed by appropriate endoscopic treatment, such as snare electrosection, endoloop, endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) without severe complications.

Applications

The results of this study demonstrate that EUS is an effective means of diagnosis for upper GIMTs. Preoperative EUS examination is important for choosing the type of endoscopic therapy for mesenchymal tumors. The study will guide the clinical application of EUS in the endoscopic therapy for upper GIMTs.

Terminology

GIMTs are tumors which originate from mesenchymal cells other than epithelial cells or lymphocytes. They are further classified as stromal tumors, leiomyomas, leiomyosarcomas, neural tumors, fibroblast tumors or liparomphalus. EMR is a minimally invasive technique for resection of a lesion that requires the separation of the submucosa by injecting a fluid agent. ESD is a new endoscopic method using special knife for complete en bloc resection of early gastrointestinal neoplasms.

Peer review

This is a well written paper which describes the experience of the authors in the EUS diagnosis and subsequent endoscopic treatment of gastrointestinal mesenchymal tumors. The pictures well support the authors' findings and conclusions.

Abstract

AIM: To identify the differentially over-expressed genes associated with β -catenin accumulation in nuclei of hepatocellular carcinoma (HCC) cells.

METHODS: Differentially expressed genes were identified in radiation-induced B6C3 F1 mouse HCC cells by mRNA differential display, Northern blot and RT-PCR, respectively. Total glutathione-s-transferase (GST) activity was measured by GST activity assay and β -catenin localization was detected with immunostaining in radiation-induced mouse HCC cells and in HepG2 cell lines.

RESULTS: Two up-regulated genes, glutamine synthetase and glutathione-s-transferase M3 (GSTM3), were identified in radiation-induced mouse HCC cells. Influence of β -catenin accumulation in nuclei of HCC cells on up-regulation of GSTM3 mRNA was investigated. The nearby upstream domain of GSTM3 contained the β -catenin/Tcf-Lef consensus binding site sequences [5'-(A/T)(A/T)CAAAG-3'], and the total GST activity ratio was considerably higher in B6C3F1 mouse HCC cells with β -catenin accumulation in nuclei of HCC cells than in those without β -catenin accumulation (0.353 ± 0.117 vs 0.071 ± 0.064 , $P < 0.001$). The TWS119 (a distinct GSK-3 β inhibitor)-induced total GST activity was significantly higher in HepG2 cells with β -catenin accumulation than in those without β -catenin accumulation in nuclei of HCC cells. Additionally, the GSTM3 mRNA level was significantly higher at 24 h than at 12 h in TWS119-treated HepG2 cells.

CONCLUSION: β -catenin accumulation increases GST activity in nuclei of HCC cells, and GSTM3 may be a novel target gene of the β -catenin/Tcf-Lef complex.

INTRODUCTION

Hepatocellular carcinoma (HCC) is a primary cancer of the liver chronically injured by infection, metabolic disease or various drugs^[1]. As generally observed in other carcinomas, HCC is attributed to accumulated genetic alterations, including (1) Activation of oncogenes N-ras, H-ras, and K-ras, c-erbA, c-met, RB and c-myc^[2-5]; (2) Transcriptional activation of c-jun and nuclear factor kB by hepatitis B virus factors^[6]; (3) Repression or mutation of the p53 anti-oncogene^[7]; and (4) Accumulation of β -catenin^[8]. Although the genetic events responsible for either HCC initiation or progression are not clear, they involve at least three carcinogenesis pathways: the p53, RB and Wnt/ β -catenin signaling pathways^[1-10].

β -catenin is an essential downstream effector of the canonical Wnt signaling pathway^[11,12]. Approximately 20% of HCC cells display β -catenin aberrant activation^[9,13]. In the normal steady state, β -catenin is continuously phosphorylated at serine and threonine residues by glycogen synthase kinase 3 β (GSK-3 β) in a complex with adenomatous polyposis coli (APC)-axin/conductin and is quickly degraded through the ubiquitin/proteasome pathway. In mice, liver-specific deletion of APC induces β -catenin stabilization and increases the number of HCC cells. Although the activation of β -catenin is likely an initiating or contributory factor for HCC, more fundamental information is required for a better understanding of the detailed genetic mechanism underlying HCC associated with β -catenin.

To uncover the detailed genetic mechanisms underlying HCC in the present study, several genes in mouse cancerous liver tissue samples were identified to disclose more of the genes that play a very important role in the regulation of cell proliferation and the development of HCC. We identified several cDNA fragments that were differentially expressed in radiation-induced mouse HCC and compared with those in matched nontumorous liver tissue. Samples using a differential display technique^[14]. We determined whether the nearby upstream domain of those genes contain the β -catenin/Tcf-Lef consensus binding site sequences. The influence of β -catenin accumulation in nuclei of HCC cells on activation of protein encoded by the gene containing β -catenin/Tcf-Lef consensus binding site sequences was further investigated.

MATERIALS AND METHODS

Sample preparation

Surgically resected HCC and adjacent nontumorous tissue samples were taken from the livers of 18-mo-old mice irradiated by 3.5 Gy 60Co γ -ray for 1 wk immediately after they were born. B6C3F1 mouse HCC and matched nontumorous liver tissue samples were obtained immediately under the same conditions for measurement of total GST activity^[15], isolation of total RNA^[16], and immunohistochemical expression of β -catenin and hematoxylin-eosin (HE) staining. Histological analysis of HCC tissue samples from mice was carried out according to the general rules for clinical and pathological study of primary liver cancer.

Table 1 Primer sets used in mRNA differential display analysis

| Anchor primers | Arbitrary primers |
|-------------------------------------|---|
| T ₁₂ MG (10 μ mol/L) | AP-10 (2 μ mol/L), 5'-TAGCAAGTGC-3' |
| T ₁₂ MA (10 μ mol/L) | AP-11 (2 μ mol/L), 5'-CAGACCGTTC-3' |
| T ₁₂ MT (10 μ mol/L) | AP-12 (2 μ mol/L), 5'-TGCTGACCTG-3' |
| T ₁₂ MC (10 μ mol/L) | AP-14 (2 μ mol/L), 5'-AATGGGCTGA-3' |

M represents a degenerated mixture of dA, dG and dC. The 16 different primer sets used for PCR amplification were randomly combined from the four arbitrary primers and the four anchor primers.

On the other hand, HepG2 cells obtained from China Center for Type Culture Collection were maintained in DMEM supplemented with 10% fetal calf serum (Sigma, Louis, MO), 200 mmol/L L-glutamine and 1% penicillin/streptomycin (Invitrogen, Carlsbad, CA) at 37°C in a water-saturated atmosphere containing 5% CO₂. Cell cultures were allowed to reach 90% confluence. The cells were then treated with or without 1 μ mol/L of 4, 6-disubstituted pyrrolopyrimidine (TWS119, Cayman Chemical, Ann Arbor, MI) and incubated at 37°C for 24 h. Finally, total RNA or cytoplasmic proteins, including total GST proteins, were extracted from surgically resected frozen tissue samples or HepG2 cells by homogenization with a Vibra cell sonicator (Sonics and Materials, Inc., Danbury, CT) under a regularity condition.

mRNA differential display analysis and DNA sequencing

mRNA differential display analysis was performed as previously described^[14] with a RNAmapping kit A (GenHunter, Nashville, TN) (Table 1). Total RNA (0.4 μ g) extracted from radiation-induced mouse HCC and matched nontumorous liver tissue samples was reverse-transcribed with different combinations of arbitrary and anchor primers (Table 1) for initial cDNA synthesis. The thermal cycler parameters were as follows: 1 cycle at 94°C for 4 min, followed by 40 cycles at 94°C for 30 s, at 40°C for 2 min and at 72°C for 30 s. Amplified subpopulations were distributed on a 6% DNA sequencing gel. The bands of interest were cut out from the polyacrylamide gel, and cDNA fragments were re-amplified using the same pair of primers and the same cycle parameters as described above. The re-amplified cDNA fragments were purified from 2% agarose gels and subcloned into pCRII-TOPO vectors using a TOPO TA cloning kit (Invitrogen, Carlsbad, CA). Clones were selected by the same size of bands cut from the polyacrylamide gel as described above, followed by inverse hybridization and DNA sequencing. DNA sequences were compared with those in GenBank by the Blast Service provided by NIH (Bethesda, MD).

Northern blot analysis

Total RNA extraction (10 μ g) was denatured and electrophoresed in a 1.2% agarose gel containing 0.66 mol/L formaldehyde and then transferred onto a Hybond-nylon membrane (Amersham Biosciences, Buckingham, England). The membranes were UV cross-linked, pre-hybrid-

ized and hybridized. The respective cDNA fragments obtained from the differential display reaction were used as a probe for Northern blot analysis. Probes were [α -³²P] dCTP (110 TBq/mmol) labeled using the Megaprime™ DNA labeling kit (Amersham, UK), pre-hybridized to filters at 42°C for 30 min, and then hybridized to the filters overnight at 42°C. The filters were washed twice at 55°C in 1 × SSC, 0.1% SDS for 15 min, and then exposed to X-ray film for 24–72 h at -80°C.

Immune staining

Immunofluorescence and immunocytochemistry analyses of β -catenin localization were performed, respectively, with mouse monoclonal anti- β -catenin antibody diluted at 1:500 for immunofluorescence, and diluted at 1:100 for immunocytochemistry (Sigma, Louis, MO) on 5- μ m paraffin-embedded sections and paraformaldehyde-fixed HepG2 cell sections that were differentially resected from 24 radiation-induced B6C3F1 mouse HCC and adjacent nontumorous liver tissue samples^[17,18]. The tissue sections were then incubated for 1 h at room temperature with Alexa Fluor 546 goat anti-mouse IgG diluted at 1:1000 (Molecular Probes, Eugene, OR, USA), washed three times with PBS and visualized under a Nikon Eclipse Ti fluorescent microscope (Japan). The HepG2 cell sections were further treated with a Histofine simple stain rat MAX-PO (MULTI) kit (Nichirei, Tokyo, Japan), stained brown with a DAB substrate kit (Nichirei, Tokyo, Japan) and blue with hematoxylin. Negative controls were stained with the omitted primary antibody. Omission of the primary antibody resulted in no staining of the cells.

GST activity assay

Total GST activity was assayed as previously described^[15]. Total GST activity with aromatic substrates was determined by monitoring changes in absorbance with a microplate reader (Infinite M200, Tecan, Switzerland). A complete assay mixture without total GST was used as a control. HepG2 cells, HCC cells and matched nontumorous liver tissue cells were broken for 20 s at 4°C, respectively, in 1 mL 0.1 mol/L potassium phosphate buffer (pH 6.5) using a sonicator. Samples were collected into different tubes containing EDTA, centrifuged at 10000 r/min for 1 h at 4°C, and the supernatant was stored at -20°C. GST activity was assayed with 5 μ g protein in duplicate with 1 mmol/L 1-chloro-2, 4-dinitrobenzene and glutathione (Sigma, Louis, MO) and used without further purification in a total volume of 1 mL. Optical density of GST was measured within at least 3 min after incubation at 25°C for 15 min at a wavelength of 340 nm (ϵ = 9.6 mmol/L per cm). The activity of GST was expressed as a unity of nmol mg per min.

Real-time PCR for detection of glutathione-s-transferase M3 mRNA expression

Total RNA harvested from HepG2 cells was subjected to reverse transcription into cDNA using a Superscript kit (Life Technologies, Gaithersburg, MD) according to

its manufacturer's protocol. Thereafter, 2 μ g of cDNA samples was used immediately in measurement of GSTM3 mRNA level by real-time PCR with iQ SYBR Green Supermix (Bio-Rad, Tokyo, Japan), forward primer (5'-GCTCCTGGAGTTCACGGATA-3'), and reverse primer (5'-GCTCCTGGAGTTCACGGATA-3') on a DNA engine Opticon 2 real-time PCR detection system (Bio-Rad, Tokyo, Japan). The thermal cycler parameters were as follows: 1 cycle at 95°C for 3 min, followed by 40 cycles at 95°C for 15 s, at 60°C for 30 s and at 72°C for 30 s^[19]. A β -actin control was run simultaneously with the same reaction recipe listed in the instruction manual for the iQ SYBR Green Supermix (Bio-Rad, Tokyo, Japan). All data were normalized to β -actin mRNA levels to account for any variation in RNA concentrations between the samples obtained from three separate experiments.

Statistical analysis

The data are presented as mean \pm SE. Statistical analyses were performed among the three groups by a one-way analysis of variance followed by Bonferroni's test, and between two groups by the unpaired Student's *t*-test. *P* < 0.05 was considered statistically significant.

RESULTS

Identification of differentially expressed genes in mouse HCC and matched nontumorous liver tissue samples

Differential display analysis is a powerful tool for the comparison of differential gene expressions between two or more mRNA populations^[14]. Using this method, we compared the mRNA expression patterns of B6C3F1 mouse HCC and matched nontumorous liver tissue samples. Representative differentially displayed autoradiographs of "I and II" cDNAs are shown in Figure 1A. The interesting "I and II" cDNA fragments were successfully recovered from the dried DNA sequencing gel, re-amplified (Figure 1B), purified, and subcloned into the TA cloning site of pCRII-TOPO vector. Its nucleotide sequences were compared with those in GenBank (Figure 1C). Concurrently, the purified products of "I and II" fragments from 2% agarose gels were used as probes for reverse Northern blotting. The Northern blotting patterns of "I and II" fragments differentially expressed in mouse HCC cells are shown in Figure 2A. In comparison with a nucleotide sequence in GenBank, "I and II" nucleotide sequences were identified as the up-regulated gene coding products, such as glutathione-s-transferase M3 (GSTM3) and glutamine synthetase (GLNS) in radiation-induced B6C3 F1 mouse HCC cells.

Dependence of mouse GSTM3 activity on β -catenin in B6C3F1 mouse HCC

It has been reported that nuclear translocation of β -catenin may represent an early event in liver carcinogenesis^[20]. Therefore, we are interested in the relation between β -catenin and the discovered gene described above. Analysis of mRNA expression showed that the expression level

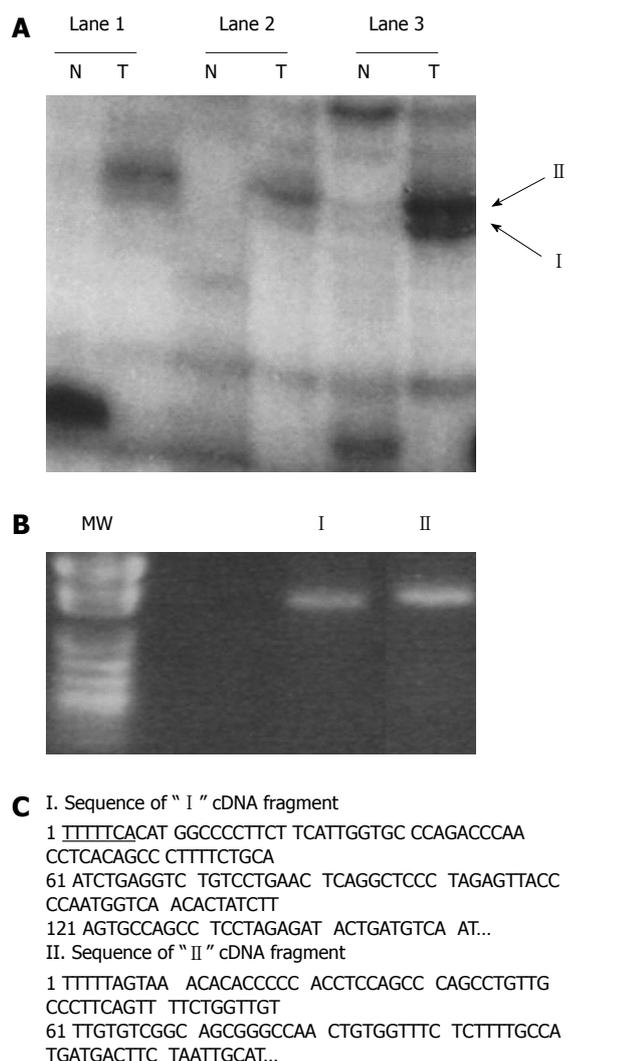

Figure 1 Identification of differentially displayed cDNA fragments from paired hepatocellular carcinoma cells (T) and nontumorous liver tissues (N). A: Differentially displayed PCR products (" I " and " II ") amplified with AP-10 primer and T₁₂MA. Lanes 1-3 denote the three B6C3 F1 mouse samples, respectively; B: Recovered " I " and " II " from the dried DNA sequencing gel reamplified by PCR. MW lane shows the pUC118 DNA fragments cut by HapII (a restriction enzyme) as molecular weight markers; C: Nucleotide sequences of the bands shown in A. Flanking sequences of T₁₂MA primers are underlined. The two insert-containing fragments were sequenced and identified as gene fragments of GLNS and GSTM3 in comparison with those of nucleotide in GenBank.

of GSTM3 mRNA was significantly higher in cell nuclei of B6C3F1 mouse HCC cells with β -catenin accumulation than in those without β -catenin accumulation (Figure 2B), suggesting that β -catenin can increase the GSTM3 activity. To confirm whether β -catenin increases the GSTM3 activity, the gene near the upstream domain of individual mouse GSTM3 containing the β -catenin/Tcf-Lef consensus binding site sequence [5'-(A/T)(A/T) CAAAG-3'^[21]] was detected by searching it in GenBank. On the other hand, whether the increased GSTM3 activity in mouse HCC cells is correlated with β -catenin accumulation in nuclei of HCC cells was also assayed (Figure 3), showing that the nearby upstream domain of mouse GSTM3 contains β -catenin/Tcf-Lef consensus binding site sequences [5'-(A/T)(A/T) CAAAG-3']. Because the GSTM3 activity

Bars: 50 μ m. GLNS: Glutamine synthetase; GSTM3: Glutathione-s-transferase M3.

level was rather variable in normal mouse tissue samples, it was difficult to estimate the β -catenin dependence on GSTM3 activity using the absolute GST activity level. Therefore, we analyzed the increased total GST activity in HCC tissue samples relative to that of normal tissue samples by the ratio of (T-N)/N, where T and N denote the total GST activity in HCC and normal tissue samples, respectively. On the other hand, to see the directly significant relation between total GST activity and β -catenin accumulation in nuclei of HCC cells, the average total GST activity level was also measured in B6C3F1 mouse HCC and matched nontumorous liver tissue samples with or without β -catenin accumulation (Table 2). It can be clearly seen from Table 2 that the total GST activity ratio was considerably higher in B6C3F1 mouse HCC tissue samples with β -catenin accumulation than in those without β -catenin accumulation in nuclei of HCC cells. The

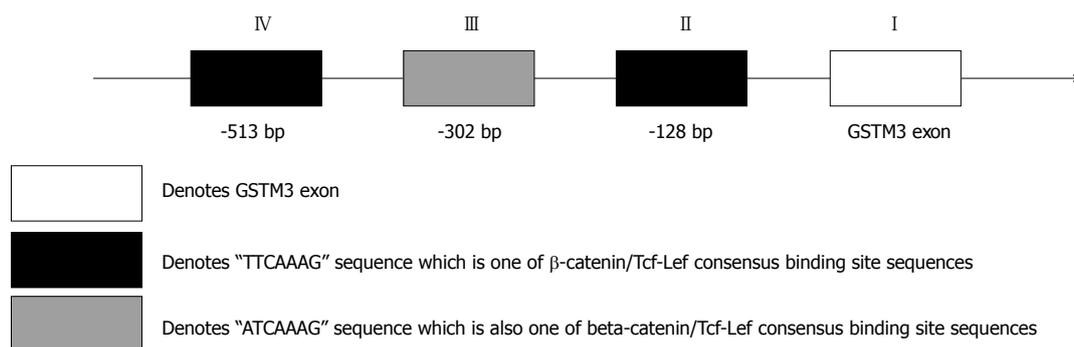

Figure 3 Identification of β -catenin/Tcf-Lef consensus binding sites with three β -catenin/Tcf-Lef consensus binding site sequences [5'-(A/T)(A/T) CAAAG-3'] located at the nearby upstream domain of mouse GSTM3 by searching GenBank.

Table 2 Total glutathione-s-transferase activity in B6C3F1 mice hepatocellular carcinoma cells (T) and matched nontumorous (N) liver tissue samples

| Samples | Total GST activity (nmol/mg per min) | | Values of GST activity ratio (T-N)/N |
|---------|--------------------------------------|------------------------|--------------------------------------|
| | T | N | |
| (+) | 3122 ± 189 (n = 13) | 2447 ± 180 (n = 13) | 0.353 ± 0.117 ^a |
| (-) | 2644 ± 199 (n = 11) | 2523 ± 205 (n = 11) | 0.071 ± 0.064 |

[(T-N)/N] indicates the glutathione-s-transferase (GST) activity values for the samples with and without β -catenin accumulation in hepatocellular carcinoma (HCC) cell nuclei. "(+)" or "(-)" denotes the samples from B6C3F1 mice with or without β -catenin accumulation in nuclei of HCC cells. ^a*P* < 0.001 *vs* negative β -catenin staining group.

averaged GST activity ratio was also significantly higher in HCC tissue samples with β -catenin accumulation than in those without β -catenin accumulation (0.353 ± 0.117 *vs* 0.071 ± 0.064, *P* < 0.001), suggesting that the GST activity ratio is significantly different (Table 2).

Similarly increased GST activity and β -catenin accumulation in nuclei of HepG2 cells

To further elucidate the above findings, we mimicked the canonical Wnt pathway in cultured HepG2 cells using TWS119 (an inhibitor of GSK-3), which led to phosphorylation, nuclear translocation, and abnormal accumulation of β -catenin in nuclei of HepG2 cells. We treated the cultured HepG2 cells with or without 1 μ mol/L TWS119 at 37°C for 24 h, measured the total GST activity in these cells, and then analyzed the relation^[15] between GST-GSH protein complex concentration and time (at least 15 min) in "control" and "TWS119" groups using a microplate reader at a wavelength of 340 nm. Concurrently, the β -catenin accumulation in HepG2 cells was detected with immunocytochemical staining with a rabbit polyclonal antibody against β -catenin as previously described^[17]. Thereafter, we comprised the linear function of total GST-GSH protein complex concentration between the two groups. It can be clearly seen from Figure 4A that the total GST activity ratio was considerably higher in the "TWS119" group with abnormal nuclear accumulation of β -catenin in

HepG2 cells than in the "control" group with low β -catenin nuclear accumulation. Additionally, both the GSTM3 mRNA expression level and the GST activity were significantly higher in HepG2 cells and controls after treatment with 1 μ mol/L TWS119 for 24 h (100% ± 5% *vs* 137% ± 7%, *P* < 0.05, Figure 4B), supporting that β -catenin nuclear accumulation in nuclei of HCC cells up-regulates the GSTM3 mRNA expression and the GSTM3 activity.

DISCUSSION

The experimental results of this study demonstrate that mRNAs originally identified from gene expression profiles are differentially expressed in mouse HCC cells. The expression levels of GSTM3 and GLNS mRNAs were higher in mouse HCC tissue samples than in matched nontumorous liver tissue samples. However, the detailed genetic mechanism underlying HCC remains unknown.

GSTM3 is a GST Mu-class subunit. Little is known about the role of GSTM3 in metabolism of harmful agents, except for its overlapping substrate specificity to GSTM1^[22]. As one of the primary phase II detoxification enzymes, GST can be divided into four classes, namely Alpha, Mu, Pi and Theta^[23], which protect against the oxidative stress of their products^[24]. GST is a potentially important enzyme that regulates the susceptibility to cancer because of its ability to metabolize reactive electrophilic intermediates to usually less reactive and more water soluble glutathione conjugates^[25]. It was reported that the GST activity, as an indicator of resistance to chemotherapy, is high in human cancer, because GST increases the formation of drug glutathione (GSH) conjugates^[26]. In this study, the total GST activity was assayed to understand why the GSTM3 mRNA expressions are up-regulated in HCC cells. Based upon these observations, the results of this study showing the up-regulated expression of GSTM3 mRNA in B6C3F1 mouse HCC cells suggest that the increased GSTM3 mRNA expression is a significant phenomenon in cellular detoxification, namely enhancing the metastatic potential in HCC cells.

It was reported that β -catenin plays an important role in cell-cell adhesion^[27] and in Wnt signaling pathway^[28,29]. β -catenin can enter the nuclei of HCC cells by binding the

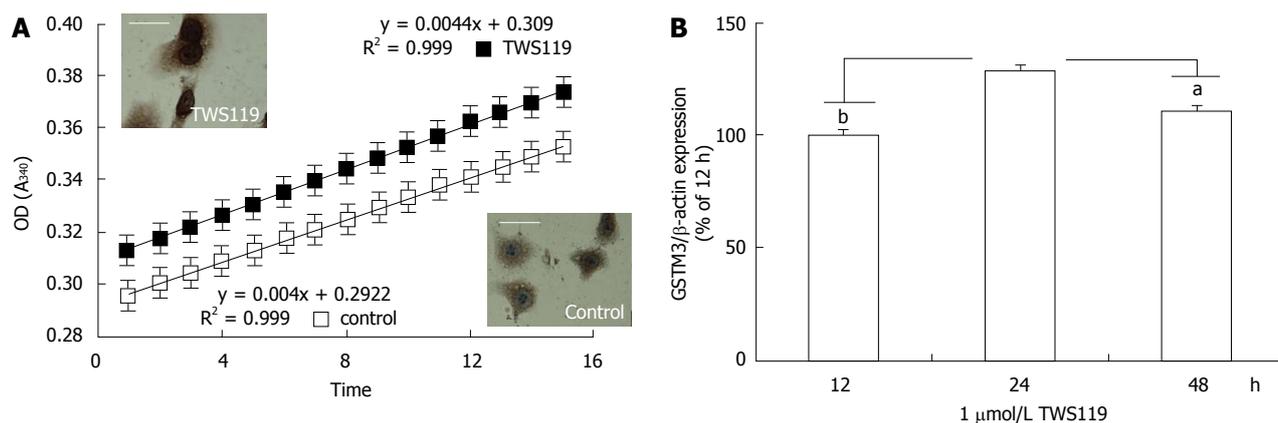

Figure 4 Total glutathione-s-transferase activity (A) and glutathione-s-transferase M3 mRNA expression (B) in HepG2 cells. ^a $P < 0.05$, ^b $P < 0.01$ vs TWS119 at 24 h by one-way analysis of variance followed by Bonferroni's test.

Tcf-Lef family of DNA binding proteins, and regulate the transcription of target genes (for example, c-myc, gastrin, cyclin D1 and PPAR are identified as target genes of the β -catenin/Tcf-Lef complex)^[30-33]. In the present study, the GSTM3 mRNA level was higher in B6C3F1 mouse HCC cells with β -catenin accumulation than in those without β -catenin accumulation. To our knowledge, no similar observation has been reported. The total GST activity was much higher in B6C3F1 mouse HCC cells with β -catenin accumulation than in normal tissue samples without β -catenin accumulation (Table 2). The averaged GST activity ratio was significantly higher in HCC cells with β -catenin accumulation than in those without β -catenin accumulation (0.747 ± 0.360 vs 0.071 ± 0.213 , $P < 0.001$), suggesting that the GST activity ratio is significantly different (Table 2). Furthermore, by searching the GenBank, we found that the upstream region of the GSTM3 gene contained three β -catenin/Tcf-Lef consensus binding site sequences in mouse GST polymorphisms. The canonical Wnt pathway in cultured HepG2 cells was further mimicked using TWS119, a GSK-3 β inhibitor, which caused abnormal β -catenin accumulation. As a result, TWS119-induced β -catenin accumulation enhanced the GST activity and the GSTM3 mRNA expression in HepG2 cells, suggesting that β -catenin accumulation in nuclei of HCC cells can increase the activity of mouse GSTM3, one of the enzymes responsible for the metabolism of a variety of xenobiotics and carcinogens, and that mouse GSTM3 may be a novel downstream target gene of the β -catenin/Tcf-Lef complex in mouse HCC.

It was reported that GLNS can catalyze the synthesis of glutamine^[34], a major energy source of cells (an important ATP source), and is a precursor for the synthesis of nucleotides and numerous amino acids, and up-regulated in a subset of human HCC^[35]. In this study, at 3 wk after tumor implantation, the glutamine synthetase activity in rats increased by 34%, which is consistent with the reported findings^[36]. However, further study is needed to observe the possible pharmacological action (s) of β -catenin in the up-regulated expression of GLNS mRNA.

In conclusion, GSTM3 and GLNS genes are differen-

tially expressed in mouse HCC cells. The expression level of GSTM3 mRNA and total GST activity are higher in B6C3F1 mouse HCC cells with β -catenin accumulation than in those without β -catenin accumulation, indicating that GSTM3 may be a novel target gene for the β -catenin/Tcf-Lef complex in mouse HCC.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is a primary cancer of the liver. However, the genetic events responsible for HCC initiation and progression are not clear. Since approximately 20% of HCC display β -catenin aberrant activation, Wnt/ β -catenin signaling pathways may be involved in HCC occurrence.

Research frontiers

Recent data show that β -catenin may be an initiating or contributory factor for HCC. In this study, the authors demonstrated that glutathione-s-transferase M3 (GSTM3) might be a novel target gene of the β -catenin/Tcf-Lef complex in mouse HCC.

Innovations and breakthroughs

The authors identified two up-regulated genes, glutamine synthetase (GLNS) and GSTM3, in nuclei of radiation-induced mouse HCC cells with β -catenin accumulation. Three β -catenin/Tcf-Lef consensus binding site sequences were observed in mouse glutathione-s-transferase (GST) polymorphisms. GST activity and GSTM3 mRNA levels were induced in cultured HepG2 cells by TWS119 (an inhibitor of GSK-3 β). To our knowledge, no similar observation has been reported.

Applications

By demonstrating that GSTM3 may be a novel target gene of the β -catenin/Tcf-Lef complex in mouse HCC, this study may represent a future strategy for therapeutic intervention in patients with HCC.

Terminology

β -catenin plays an important role in cell-cell adhesion and in Wnt signaling pathway, can enter nuclei by binding to the Tcf-Lef family of DNA binding proteins and regulate the transcription of target genes.

Peer review

This paper reports the results of investigations on some differentially over-expressed genes associated with β -catenin accumulation in nuclei of HCC cells, showing that GSTM3 may be a novel target gene of the β -catenin/Tcf-Lef complex in mouse HCC using mRNA differential display, Northern blot analysis, immunostaining and RT-PCR techniques, respectively. It is worthy of publication.

Abstract

AIM: To review the application of nutrition support in patients after surgery for colorectal cancer, and to propose appropriate nutrition strategies.

METHODS: A total of 202 consecutive surgical patients admitted to our hospital with a diagnosis of colon cancer or rectal cancer from January 2010 to July 2010, meeting the requirements of Nutrition Risk Screening 2002, were enrolled in our study. Laboratory tests were performed to analyze the nutrition status of each patient, and the clinical outcome variables, including postoperative complications, hospital stay, cost of hospitalization and postoperative outcome, were analyzed.

RESULTS: The "non-risk" patients who did not receive postoperative nutrition support had a higher rate of postoperative complications than patients who received postoperative nutrition support (2.40 ± 1.51 vs 1.23 ± 0.60 , $P = 0.000$), and had a longer postoperative hospital stay (23.00 ± 15.84 d vs 15.27 ± 5.89 d, $P = 0.009$). There was higher cost of hospitalization for patients who received preoperative total parenteral nutrition (TPN)

than for patients who did not receive preoperative TPN ($62\,713.50 \pm 5070.66$ RMB Yuan vs $43\,178.00 \pm 3596.68$ RMB Yuan, $P = 0.014$). Applying postoperative enteral nutrition significantly shortened postoperative fasting time (5.16 ± 1.21 d vs 6.40 ± 1.84 d, $P = 0.001$) and postoperative hospital stay (11.92 ± 4.34 d vs 15.77 ± 6.03 d, $P = 0.002$). The patients who received postoperative TPN for no less than 7 d had increased serum glucose levels (7.59 ± 3.57 mmol/L vs 6.48 ± 1.32 mmol/L, $P = 0.006$) and cost of hospitalization ($47\,724.14 \pm 16\,945.17$ Yuan vs $38\,598.73 \pm 8349.79$ Yuan, $P = 0.000$). The patients who received postoperative omega-3 fatty acids had a higher rate of postoperative complications than the patients who did not (1.33 ± 0.64 vs 1.13 ± 0.49 , $P = 0.041$). High level of serum glucose was associated with a high risk of postoperative complications of infection.

CONCLUSION: Appropriate and moderate nutritional intervention can improve the postoperative outcome of colorectal cancer patients.

INTRODUCTION

Colorectal cancer is the fourth most common cancer in men and the third most common cancer in women

worldwide^[1]. It is also a significant cause of morbidity and mortality throughout the world^[2]. Malnutrition is common in patients presenting for surgical management of colorectal cancer, and multiple factors, such as tumor location, tumor type, tumor stage, and preoperative radiation or chemotherapy, may predispose the patients to malnutrition^[3]. Postoperative outcomes, including incidence of complications, morbidity and survival, are usually better in the patients who are in a good nutritional condition^[4]. Comprehensive clinical application of nutrition support in colorectal cancer patients appears to be necessary.

Unfortunately, malnutrition has remained a troublesome problem because of lack of nutrition support routines and a discrepancy between clinical practice and guidelines regarding nutrition support^[5].

Currently, international guidelines on nutrition support have been established, such as the European Society for Clinical Nutrition and Metabolism (ESPEN) guidelines and the American Society for Parenteral and Enteral Nutrition (ASPEN) guidelines. Both are the authoritative guidelines at present, and should be followed and used in clinical practice as appropriate to the specific medical condition. However, since fewer than one sixth of the recommendations in the current guidelines are Grade A, and more than 50% are Grade C^[6], more and better controlled trials are needed in the specific fields.

We carried out a retrospective study to evaluate the nutritional risk of colorectal cancer patients who underwent elective surgery, and assessed the nutrition support process by analyzing the postoperative clinical outcomes and comparing with the international recommendations or guidelines. In particular, we investigated the current status of nutrition support for patients undergoing surgery for colorectal cancer, and determined the requirements of feasible and appropriate nutrition support strategies for such patients.

MATERIALS AND METHODS

Case selection

We reviewed a total of 220 consecutive patients admitted to our hospital with a diagnosis of colon cancer or rectal cancer from January 2010 to July 2010, and excluded 18 patients, including one with hydroperitoneum according to the exclusion criteria of the Nutrition Risk Screening (NRS) 2002^[7], and 17 who had received non-surgical treatment. The remaining 202 patients were enrolled in this study.

Methods

In order to evaluate the clinical effect of different nutritional strategies in colorectal cancer patients with different nutritional status, we stratified the patients into five groups.

In Group A, to evaluate the effect of NRS score, we excluded the patients who received preoperative nutritional support, and divided the remaining 199 patients into a "non-risk" group ($n = 148$) whose NRS score was 0-2, and an "at-risk" group ($n = 51$) whose NRS score was ≥ 3 . We further divided the two groups into two subgroups, a

nutrition support group (NS) who received postoperative nutrition support and a non-nutrition support group (NNS) who did not receive postoperative nutrition support (Table 1). Diagnosis and tumor stage were used to illustrate preoperative health status. The tumor stage was determined according to the 7th edition of the AJCC cancer staging manual (American Joint Committee on Cancer)^[8]. Complications, postoperative hospital stay, cost of hospitalization and postoperative outcomes were used to assess the clinical effect of postoperative nutritional intervention. In addition, we graded complications as none = 1, infection = 2, fistula = 3, others = 4, and postoperative outcome as recovery = 1, no recovery = 2, death = 3, for statistical evaluation of the results.

Group B consisted of five patients whose NRS score was > 4 , the clinical effect of preoperative TPN in patients with severe malnutrition was evaluated. They were divided into two groups: group 1 ($n = 2$) who received preoperative TPN and group 2 ($n = 3$) who did not (Table 2). Diagnosis, tumor stage, and preoperative albumin, potassium, and sodium levels reflected the preoperative nutrition status. Postoperative enteral nutrition (EN), postoperative TPN and postoperative TPN duration were indicative of the postoperative nutritional intervention. Postoperative serum glucose level was fluctuated according to the proportion of insulin in TPN. Postoperative day 1 (POD1) albumin, potassium and sodium, and POD5 albumin, potassium and sodium levels reflected the postoperative nutritional status. Complications, postoperative hospital stay, cost of hospitalization, and postoperative outcomes were used to assess clinical outcome.

In Group C, the application of postoperative EN in colorectal cancer patients was assessed. Patients who received preoperative nutrition support were excluded, and the remaining 199 patients were divided into two groups: group 1 ($n = 25$) who received postoperative EN and group 2 ($n = 174$) who did not (Table 3). Diagnosis, tumor stage and NRS 2002 score reflected the preoperative nutrition status. As an interferential factor in this group, postoperative TPN was used in the statistical analysis to identify the effect of postoperative EN. Postoperative fasting time, occurrence of complications, postoperative hospital stay, cost of hospitalization, and postoperative outcome indicated clinical outcome.

In Group D, to determine the effect of postoperative TPN duration, we excluded the patients who received preoperative nutrition support and postoperative EN, and included the remaining 174 patients who received postoperative TPN only, dividing them into two groups: group 1 ($n = 66$) with postoperative TPN duration of no less than 7 d, and group 2 ($n = 108$) with a duration of less than 7 d (Table 4). Diagnosis, tumor stage, NRS 2002 score, preoperative albumin, potassium and sodium levels gave an indication of preoperative nutrition status. POD1 albumin, potassium and sodium, and POD5 albumin, potassium and sodium reflected postoperative nutritional status. Complications, postoperative hospital stay, cost of hospitalization and postoperative outcome

Group 1: The duration of postoperative total parenteral nutrition (TPN) was not less than 7 d; Group 2: The duration of postoperative TPN was less than 7 d. NRS: Nutrition Risk Screening.

(SPSS for Windows Ver. 11.5). Results of different groups were compared using descriptive statistics (mean ± SD). $P \leq 0.05$ was considered statistically significant.

RESULTS

Nutrition risk screening is a necessary and effective tool to identify the nutritional status of colorectal cancer patients, and to aid in providing the appropriate nutrition intervention. As Table 1 shows, the “non-risk” patients who did not receive postoperative nutrition support had a higher rate of postoperative complications than those who received postoperative nutrition support (2.40 ± 1.51 vs 1.23 ± 0.60 , $P = 0.000$), and also had a longer postoperative hospital stay (23.00 ± 15.84 vs 15.27 ± 5.89 , $P = 0.009$), which indicated that postoperative nutrition support may be necessary for “non-risk” patients. Postoperative nutrition support or not did not show a significant difference in the outcome of “at-risk” patients, though postoperative nutrition support tended to improve the postoperative outcome (1.10 ± 0.30 vs 1.50 ± 0.70 , $P = 0.090$), thus moderate nutrition support is allowable for “at-risk” patients.

Table 2 shows that the cost of hospitalization for malnourished patients who received preoperative TPN was significantly higher than in patients who did not ($62\,713.50 \pm 5070.66$ RMB Yuan vs $43\,178.00 \pm 3596.68$ RMB Yuan, $P = 0.014$) with no significant difference in the outcome.

Postoperative EN markedly improved postoperative recovery course, including a reduction in postoperative fasting time (5.16 ± 1.21 d vs 6.40 ± 1.84 d, $P = 0.001$) and postoperative hospital stay (11.92 ± 4.34 d vs 15.77

± 6.03 d, $P = 0.002$), as shown in Table 3.

Longer postoperative TPN was not associated with better clinical outcome (Table 4). The patients who received postoperative TPN for no less than 7 d had increased POD5 serum glucose (7.59 ± 3.57 mmol/L vs 6.48 ± 1.32 mmol/L, $P = 0.006$) and cost of hospitalization ($47\,724.14 \pm 16\,945.17$ Yuan vs $38\,598.73 \pm 8\,349.79$ Yuan, $P = 0.000$), compared to those with less than 7 d postoperative TPN, suggesting that less than 7 d nutrition support for postoperative colorectal cancer patients is adequate.

More postoperative complications occurred in the patients with postoperative administration of omega-3 fatty acid (1.33 ± 0.64 vs 1.13 ± 0.49 , $P = 0.041$) than in patients who did not receive the fatty acid (Table 5).

Postoperative complications were positively correlated with the postoperative serum glucose level, a high postoperative serum glucose level being associated with a higher risk of complications of infection (Figure 1).

DISCUSSION

Malnutrition is common in patients with colorectal cancer, and in our study, 52 (25.7%) of the 202 cases had a NRS score of more than 3, and had a high nutrition risk^[7]. Poor nutrition status impacts on the recovery of physical performance status in cancer patients after treatment^[9]. It was reported that about 20% of cancer patients died of malnutrition or related complications rather than the malignant disease itself^[10]. Malnutrition is often neglected in our daily clinical practice, and can also induce many clinical problems, including impaired wound-healing, immunocompromization, diminished cardiac and respiratory function, and a host of other complications that can lead to longer hospitalization and a higher mortality rate^[11]. Although provision of nutrition support to cancer patients may cause tumors to grow more quickly, nutrition support is recommended when the nutrition status is so compromised that patients are at a high risk of complications, or cannot comply with the oncologic therapy as reported in the clinical practice ESPEN guidelines^[12]. Thus perioperative nutrition support is beneficial for moderately or severely malnourished gastrointestinal cancer patients^[13]. The implementation of nutrition support guidelines has facilitated many appropriate nutritional support procedures for colorectal cancer patients^[4,6,14-16].

Preoperative nutrition risk screening can identify nutritional risks

Patients with cancer are at a risk of malnutrition, and nutrition screening should be performed to identify those who require nutrition support^[17]. When a patient is admitted to our ward, knowledge of the nutritional status, which is a clinical predictor of postoperative mortality and morbidity in surgery for colorectal cancer^[18-20], is essential, not only for screening malnourished or non-malnourished patients, but also for multimodal oncological treatment^[21]. There are various kinds of screening methods, including NRS 2002, which is a rapid screening tool recommended by ESPEN^[7], and has been proven to be an appropriate scoring system for predicting unfavorable clinical outcomes^[22]. ASPEN suggested using a subjective global assessment (SGA) as a screening tool^[23], and was shown to be a reliable assessment tool which could predict hospital stay and medical expenditure of surgical gastrointestinal cancer patients^[24,25]. We believe that the assessment of nutritional status requires a multidimensional approach, which includes different clinical indices and various nutritional parameters, so it is better to use both SGA and NRS 2002 to predict the clinical outcome^[26]. Our study indicated that, for “non-risk” colorectal patients, postoperative nutrition support is necessary to avoid postoperative complications and shorten postoperative hospital stay. Although postoperative nutrition support to “at-risk” colorectal patients showed no significant advantage, in our opinion, moderate nutrition support is allowable, as no harm or economic burden was incurred. Further prospective studies are necessary to confirm this.

Preoperative TPN is not always necessary

The goal of preoperative nutrition support is to minimize negative protein balance by avoiding starvation, to maintain muscle, immune and cognitive functions, and to enhance postoperative recovery, as the ESPEN guidelines indicated^[27]. Preoperative parenteral nutrition is indicated in severely undernourished patients in whom enteral nutrition cannot be adequately administered either orally or enterally. Conversely, its use in well-nourished patients has no benefit but increased morbidity. In our study, preoperative nutrition support in severely malnourished colorectal cancer patients only increased the economic burden, with little beneficial effect. This is in agreement with the ASPEN guidelines, which recently recommended that nutrition support should not be used routinely in patients undergoing major cancer surgeries^[17]. Because of the limited sample size, further prospective studies with a larger sample size should be carried out.

Gunerhan’s study^[28] recently showed that preoperative immunonutrition resulted in a significant increase in serum prealbumin levels, but it did not significantly alter the T lymphocyte subpopulation count, the rate of postoperative complications and the hospitalization duration, thus preoperative immunonutrition should not be provided routinely. None of our patients received preoperative immunonutrition.

Postoperative EN can shorten the fasting time and hospital stay

Previously, many colorectal doctors believed that nutrients in the gut disrupted anastomoses, so they preferred delaying the EN postoperatively, and administered TPN instead to avoid anastomotic leak, which requires substantial use of hospital resources^[29]. However, Seidner^[11] emphasized that there were no significant differences in morbidity and mortality between patients who received EN or TPN, and recommended the guideline: if the gut works, use it. The available evidence lends support to the use of enteral over parenteral feeding in inpatients with functioning gastrointestinal tracts^[30]. The application of EN can reverse the loss of gut mucosal integrity resulting from surgical trauma^[31], and early nutrition support (EEN) is associated with a decreased infection risk, a decreased mortality, a reduced hospital stay, an increase in collagen deposition at anastomosis and wound strength, and a clear trend of a reduction in anastomotic breakdown^[32,33]. In addition, EEN can reduce the use of nasogastric tubes, which may delay the return of bowel function and increase pulmonary complications^[34,35]. Osland^[3] even suggested adopting EEN as a standard of care in cancer patients undergoing gastrointestinal resections. As Table 3 shows, postoperative EN in colorectal cancer patients can significantly shorten the postoperative fasting time and postoperative hospital stay, and there is a tendency to reduce postoperative complications ($P = 0.060$). Although it remains to be determined how much should be provided initially, underfeeding with a small amount of nutrients, which “bathe” the gut mucosa, makes EEN necessary or desirable.

The risk of overfeeding should not be neglected, as it can overwhelm the digestive and absorptive capacity of the gastrointestinal tract, and lead to occurrence of some clinical complications, such as gastric distention, nausea, and diarrhea^[32].

Postoperative TPN can offer a smooth postoperative recovery

Parenteral nutrition (PN) has been widely used in clinical practice, and a safe PN system must be developed which minimizes procedural incidents and maximizes the ability to meet individual patient requirements^[36]. Thus, it is desirable to provide, devise, or make available customized PN formulations for individuals who have complex requirements secondary to disease or underlying illness, or when otherwise warranted by routine monitoring of electrolytes, organ function, growth, and development. Not only fat and carbohydrates, but also a full range of vitamins and trace elements should be important components of the TPN bag, and optimal nitrogen-sparing can be achieved when all components of the PN mix are administered simultaneously over 24 h. However, when early oral food intake or EN is combined with PN, intravenous supplementation with vitamins appears to be unnecessary^[27].

Should colorectal cancer patients be administered postoperative TPN? Planas^[4] recommended that such patients having elective surgery should not be given postoperative PN routinely. Seidner^[11] implied that administering PN in disregard of the patient's nutritional status could do more harm than good, and suggested that postoperative TPN should be reserved for patients who have a prolonged postoperative ileus, generally more than 7-10 d, and for those who are severely malnourished and whose feeding cannot be started within 3-5 d. According to the ESPEN guidelines^[27], postoperative PN is recommended in patients who cannot meet their caloric requirements within 7-10 d both orally or enterally, and in patients who require postoperative artificial nutrition, enteral feeding or a combination of enteral and supplementary parenteral feeding.

In our study, most colorectal cancer patients could resume feeding 5-8 d postoperatively (Table 3), so postoperative TPN may be beneficial during the period of postoperative fasting. Should we give the patients TPN for 7 d or more, or is less than 7 d adequate? The results in Table 4 indicate that a longer duration of TPN incurs high hospitalization costs and induces hyperglycemia, which is associated with a higher rate of postoperative complications (Figure 1), thus less than 7 d postoperative TPN appears to be appropriate.

PN can be delivered through short-term, non-tunneled central venous catheters, and the appropriate choice, insertion, and monitoring of the venous access are of paramount importance to avoid a catheter-related bloodstream infection, an important and still very common complication of PN^[37]. Such infections can be reduced by adopting cost-effective, evidence-based interventions, including specific training of staff, an adequate handwashing, the correct type

of device and site of insertion, the use of maximal barrier protection during insertion, and removal of central lines as soon as they are no longer necessary.

Postoperative application of omega-3 fatty acids

There is controversy as to whether visceral proteins should be used to assess nutrient status in hospitalized patients. Seidner^[11] suggested that visceral proteins can be used in the hospital setting, because they can identify patients at risk of a poor outcome who may benefit from nutrition support. In addition, the total lymphocyte count can be used to assess a patient's immune function, which has been shown to correlate with the degree of visceral protein depletion and clinical outcome. Therefore, total lymphocyte counts were used in our study to assess the effect of the omega-3 fatty acids.

Postoperative supplementation of omega-3 fatty acids by TPN has been reported to have a favorable effect in the outcomes of colorectal cancer patients undergoing radical resection, by lowering the magnitude of the inflammatory response and modulating the immune response^[38,39]. In contrast, the application of omega-3 fatty acids showed no significant benefit in our study, and indeed there was a trend of an increased risk of postoperative complications, an increased economic burden, and a poorer postoperative outcome. Further prospective research is necessary with a larger sample to assess the functional benefit or otherwise of omega-3 fatty acids in the postoperative setting.

Currently, many barriers, including low priority of nutritional support, no routine or established procedures in many medical centers, insufficient knowledge of nutritional support, lack of qualified and optional nutritional menus for the patients, and lack of leadership support from the medical team, make the nutritional therapy difficult to carry out in many hospitals^[40]. A greater effort should be made in the nutritional assessment of patients.

In conclusion, nutrition support is an important therapy for colorectal cancer patients, and appropriate and moderate nutritional intervention can significantly improve the postoperative recovery course, relieve the patient's suffering, and reduce the medical cost of the patients. Clinicians must be aware of nutrition support principles and methods in order to administer appropriate nutrition support and avoid blind nutrition administration.

COMMENTS

Backgrounds

Nutrition support has been widely used in the area of surgery, where the benefit on patients' prognosis is evident. Colorectal cancer is the fourth most common cancer in men and the third most common cancer in women worldwide, and is also a significant cause of morbidity and mortality throughout the world, thus an appropriate and feasible nutrition support strategy is necessary and beneficial for patients' prognosis.

Research frontiers

Nutritional support is widely used in postoperative colorectal cancer patients, but the role of nutrients has not been clearly defined. This study investigated the effect of nutrition support on the outcomes of patients with different nutritional status.

Innovations and breakthroughs

The authors found that appropriate and moderate nutritional intervention can significantly improve the postoperative outcome of the patients with colorectal cancer.

Applications

The study provides a reference for daily clinical practice and future research. A prospective, multicenter, randomized, controlled trial with a larger sample is necessary to validate the statistical results and diminish bias.

Peer review

Although this is a retrospective review, I believe it will be of interest to the readers. And, it does add something to the literature.

Abstract

Therapeutic endoscopic retrograde cholangiopancreatography (ERCP) is the mainstay treatment for bile duct disease. The procedure is difficult per se, especially when a side-viewing duodenoscope is used, and when the patient has altered anatomical features, such as colonic interposition. Currently, there is no consensus on the standard approach for therapeutic ERCP in patients with total esophagectomy and colonic interposition. We describe a novel treatment design that involves the use of a side-viewing duodenoscope to perform therapeutic ERCP in patients with total esophagectomy and colonic interposition. A gastroscope was initially introduced into the interposed colon and a radio-opaque standard guidewire was advanced to a distance beyond the papilla of Vater, before the gastroscope was withdrawn. A side-viewing duodenoscope was then introduced along the guidewire under fluoroscopic guidance. After cannulation into the papilla of Vater, endoscopic retrograde chol-

angiography (ERC) revealed a filling defect (maximum diameter: 15 cm) at the distal portion of the common bile duct (CBD). This defect was determined to be a stone, which was successfully retrieved by a Dormia basket after complete sphincterotomy. With this treatment design, it is possible to perform therapeutic ERCP in patients with colonic interposition, thereby precluding the need for percutaneous drainage or surgery.

INTRODUCTION

The application of a side-viewing duodenoscope in total esophagectomy with colonic interposition is technically difficult, because of the altered structure of the colon and the redundancy of the endoscopic route. We report a wire-guided treatment designed to overcome this pitfall by introducing a side-viewing duodenoscope along a radio-opaque standard guidewire to facilitate therapeutic ERCP in patients undergoing esophagectomy with colonic interposition. The use of this treatment method ensured the safety of wire-guided therapeutic ERCP in patients undergoing total esophagectomy with colonic interposition.

CASE REPORT

An 87-year-old man was referred to our hospital, a tertiary referral medical center, for the management of episodic fever, chills, and right upper quadrant abdominal pain, which had been occurring intermittently for two months. He had undergone total esophagectomy with colonic interposition 17 years ago for the treatment of intractable esophageal ulcers with massive bleeding (Figure 1). He denied having passed tea-colored urine or clay-colored stool. Abdominal ultrasonography revealed dilatation of the common hepatic duct (CHD) and common bile duct (CBD; diameter: 1.45 cm). Magnetic resonance cholangiopancreatography (MRCP) showed the presence of a stone impacted at the distal portion of the CBD (Figure 2). The patient was intravenously administered midazolam (3 mg), pethidine (50 mg), and butylscopolamine (20 mg), and ERCP was performed with the patient in the left lateral position. A forward-viewing gastroscope (GIF-Q260, Olympus) was initially introduced; it was advanced through the interposed colonic segment, gastric remnant, and duodenum to reach the papilla of Vater. A radio-opaque standard guidewire (THSF-35-480, Wilson-Cook) was inserted deep into the small intestine, up to a distance beyond the papilla of Vater, via the accessory channel (Figure 3). The gastroscope was then withdrawn over-the-wire. Under fluoroscopic guidance, and with the patient in the left-lateral position, a side-viewing duodenoscope (IJF-240, Olympus) was introduced carefully along the guidewire until it reached the papilla of Vater. After cannulation with an ERCP catheter (StarTip cannula, PR-106Q-1, Olympus) as usual, cholangiography showed a filling defect (diameter, 1.5 cm) in the distal portion of the CBD; the lesion was determined to be a CBD stone (Figure 4). Complete sphincterotomy with a traction sphincterotome was performed (Figure 5). The pigmented stone was successfully retrieved using a Dormia basket (Figure 6). Subsequent balloon-occlusion cholangiography showed complete clearance of the CBD. The patient was followed up in the outpatient department and remains well.

DISCUSSION

The colon has been used as an esophageal substitute since 1911. It has been proven to be superior to other substitutes, such as the stomach and small intestine, because of its length, acid resistance, and richness of vascular supply. It affords good overall satisfaction and allows maintenance of a wider surgical resection margin in patients with cancers of the gastroesophageal junction. The disadvantages of its application include prolonged operation time, extensive preoperative preparation, and the late redundancy of colonic grafts^[1,2].

Therapeutic ERCP with the application of a side-viewing duodenoscope is widely used in the management of pancreatic or hepatobiliary diseases, such as biliary stones^[3]. Technically, it is difficult to advance a side-viewing duodenoscope through the colon because the duodenoscope affords visualization of only areas to the sides of the scope, and because of the presence of colonic interhaustral folds,

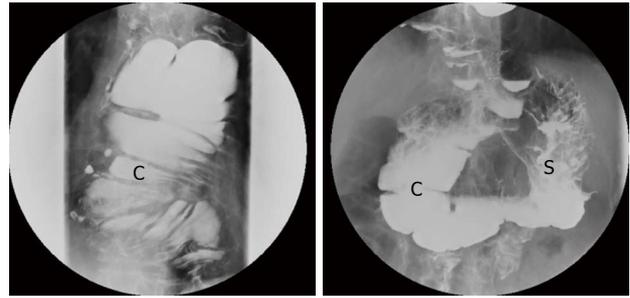

Figure 1 Esophagography showing the interposition of the colon (C) and the gastric remnant (S).

Figure 3 The radio-opaque standard guidewire (arrowhead) was inserted through the working channel of the gastroscope.

the angulation of the colon, and the redundancy of the colonic graft^[4]. To date, several techniques have been described for using the side-viewing duodenoscope to visualize the colon. Dafnis reported the successful application of a unique technique for approaching an inaccessible colonic polyp at the splenic flexure using an overtube to advance the side-viewing duodenoscope^[5]. Another report of a case series on the management of inaccessible colonic polyps, advocated the technique of slightly bending the tip of the side-viewing duodenoscope, thereby providing a sloped-forward view for performing polypectomy^[6]. We believe that the use of a wire-guided side-viewing duodenoscope

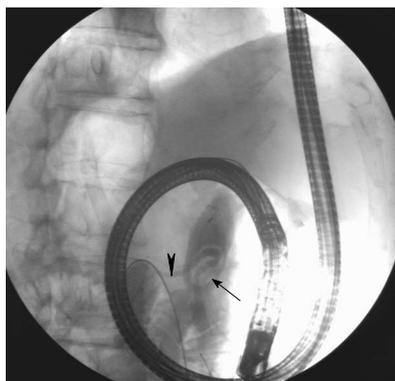

Figure 4 With the patient in the left-lateral position, endoscopic retrograde cholangiopancreatography showed a filling defect in the distal part of the common bile duct (arrow). The arrowhead shows the pancreatic duct.

Figure 5 Complete sphincterotomy.

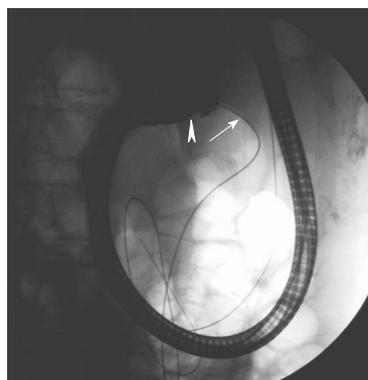

Figure 7 The duodenoscope (arrowhead) was pushed along the guidewire (arrow) at the same axis under fluoroscopic guidance .

might represent a safe technique for approaching inaccessible colonic polyps.

In the present case, our most important concern was the smooth advancement of the duodenoscope through the colonic graft. To address this concern, we inserted a radio-opaque guidewire to serve as a roadmap. Fry *et al*^[7] reported an over-the-wire method by using a Super-Stiff Amplatz guidewire, which was actually designed for cardiac catheterization, to intubate the duodenum with a side-viewing duodenoscope in a patient with large paraesophageal hernia. The reason we chose the standard guidewire, instead of a Super-Stiff Amplatz guidewire, was because it is entirely radio-opaque. It facilitated the localization and visualization of the tip of the duodenoscope under close fluoroscopic guidance. Despite this, the duodenoscope did, at one point, move away from the appropriate path in the gastrointestinal tract, during the procedure. When the graft lumen could not be visualized on the endoscopic screen, we pushed the duodenoscope forward once its axis was the same as that of the wire, as determined by fluoroscopy; the scope was advanced in this manner until the graft lumen could be seen (Figure 7). The duodenoscope was advanced through the graft, and the CBD stone was eventually retrieved.

Manipulation of the guidewire is an art. One of its principles is to avoid looping, especially in a spacious cavity, such as the stomach. In our experience, we have observed

that the looping of the guidewire may cause the failure of esophageal or duodenal metallic stent implantation in patients with malignant obstruction. The looping of the guidewire could render it difficult to introduce the scope further. To avoid this looping, we advanced the tip of the guidewire to a distance beyond the papilla of Vater, instead of stopping within the stomach.

Some experienced endoscopists prefer to backload the guidewire through the working channel of the duodenoscope. However, we think that this is not feasible because the side-viewing characteristic, with its acute angle of elevation. Backloading would render it difficult to insert the duodenoscope and would increase the number of loops formed. Furthermore, the double-balloon enteroscope could not be applied in our case because it is a forward-viewing scope and lacks the angle of elevation required to support the use of ERCP accessories.

Another technique that could have been considered in the present case would be the direct introduction of the side-viewing duodenoscope without the initial use of the forward-viewing gastroscope; however, this would have made it difficult to clearly visualize the lumen, especially as this patient had undergone colonic interposition. Such an approach would be accompanied by a high risk of perforation. The successful application of our technique for performing therapeutic ERCP is proof of the feasibility of this technique. To the best of our knowledge, this is the

first report on the use of this novel technique for treating a CBD stone in a patient with esophagectomy and colonic interposition.

In conclusion, in cases with rare clinical presentations, it is necessary to carefully and accurately estimate possible hindrances and develop appropriate solutions to successfully overcome them.

Acknowledgments to reviewers of World Journal of Gastroenterology

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

Shiu-Ming Kuo, MD, University at Buffalo, 15 Farber Hall, 3435 Main Street, Buffalo, NY 14214, United States

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclu-

sion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit on-

line. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review.

Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use

Instructions to authors

uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:....; B:....; C:....; D:....; E:....; F:....; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of P values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^{1,2b}". If references are cited directly in the text, they should be put together within the text, for example, "From references^{19,22-24}, we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date,

volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

Instructions to authors

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the

revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.
