Abstract

Chronic Groin Pain (Inguinodynia) following inguinal hernia repair is a significant, though under-reported problem. Mild pain lasting for a few days is common following mesh inguinal hernia repair. However, moderate to severe pain persisting more than 3 mo after inguinal herniorrhaphy should be considered as pathological. The major reasons for chronic groin pain have been identified as neuropathic cause due to inguinal nerve(s) damage or non-neuropathic cause due to mesh or other related factors. The symptom complex of chronic groin pain varies from a dull ache to sharp shooting pain along the distribution of inguinal nerves. Thorough history and meticulous clinical examination should be performed to identify the exact cause of chronic groin pain, as there is no single test to confirm the aetiology behind the pain or to point out the exact nerve involved. Various studies have been performed to look at the difference in chronic groin pain rates with the use of mesh *vs* non-mesh repair, use of heavyweight *vs* lightweight mesh and mesh fixation with sutures *vs* glue. Though there is no convincing evidence favouring

one over the other, lightweight meshes are generally preferred because of their lesser foreign body reaction and better tolerance by the patients. Identification of all three nerves has been shown to be an important factor in reducing chronic groin pain, though there are no well conducted randomised studies to recommend the benefits of nerve excision *vs* preservation. Both non-surgical and surgical options have been tried for chronic groin pain, with their consequent risks of analgesic side-effects, recurrent pain, recurrent hernia and significant sensory loss. By far the best treatment for chronic groin pain is to avoid bestowing this on the patient by careful intra-operative handling of inguinal structures and better patient counselling pre- and post-herniorrhaphy.

Hakeem A, Shanmugam V. Inguinodynia following Lichtenstein tension-free hernia repair: A review. *World J Gastroenterol* 2011; 17(14): 1791-1796 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i14/1791.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i14.1791>

INTRODUCTION

Chronic Groin Pain (Inguinodynia) is a potential complication following inguinal hernia mesh repair and has significant impact on the quality of life^[1]. The incidence varies among studies, ranging between 0% and 62.9%, with 10% of patients fitting in the moderate to severe pain group^[2-6]. However, only 2%-4% of the patients are adversely affected by chronic groin pain in their everyday

life. This is significant, considering the volume of the operations performed worldwide^[7]. Management of chronic groin pain constitutes challenging issues for the clinician. Additionally, it has an impact on the health system and economy. In this review, we highlight various aspects of chronic groin pain (inguinodynia) following Lichtenstein's open inguinal herniorrhaphy.

LICHTENSTEIN TENSION-FREE HERNIA REPAIR

Lichtenstein *et al*^[8] described the tension-free hernioplasty in 1989. By using prosthetic mesh, Lichtenstein showed that inguinal hernias could be repaired without distortion of the anatomy and, most importantly, without any tension along the suture line. In spite of various modifications over the last two decades, Lichtenstein hernia repair (LHR) is still considered the gold standard in the management of inguinal hernia by open technique^[9]. With significant reduction in recurrence with LHR, the most common morbidity has been chronic groin pain.

CHRONIC GROIN PAIN (INGUINODYNIA)

It is vital to differentiate early post-operative pain from chronic groin pain. The post-operative pain is usually relieved with analgesics, whereas chronic groin pain would need further assessment and medical or surgical intervention^[10,11]. Different studies have quoted various time scales for chronic groin pain. These range from first postoperative day to any empirical time period after surgery. However, the International Association for the Study of Pain (IASP) described chronic groin pain as "groin pain reported by the patient at or beyond 3-mo following inguinal hernia repair"^[12]. Major consensus currently has been to take 3 mo as a cut-off point to differentiate between patients with post-operative pain and chronic groin pain due to various causes^[13].

REASONS FOR INGUINODYNIA

The main reasons hypothesised for chronic groin pain are peri-operative nerve damage, post-operative fibrosis, or mesh-related fibrosis. They have been classified as either neuropathic or non-neuropathic pain. The three nerves potentially involved are the Ilioinguinal Nerve (IIN), Iliohypogastric Nerve (IHN) and genital branch of the Genitofemoral Nerve (GFN). These nerves can be damaged either by trauma during dissection or retraction of tissues, or nerve entrapment from post-operative fibrosis, mesh-related fibrosis or sutures used to fix the mesh. Smeds *et al*^[14] suggested that the injury is mainly due to inadequate dissection, failure to visualise and protect the nerves, and failure to recognise the aberrant location and anatomic variations of the nerves. Any partial or complete transection of the nerve leads to neuroma formation and consequent pain along the distribution of that nerve.

The explanations for non-neuropathic causes are ex-

cessive scar formation resulting from prosthetic mesh reaction, periosteal reaction from sutures or staples inserted into the pubic tubercle or due to rolled-up bulky mesh leading to mechanical pressure. Another group of patients may have diffuse pain situated in the proximity of the spermatic cord without nerve entrapment, which may be due to venous congestion or mesh-related inflammation of the spermatic cord^[15].

Fränneby *et al*^[16] predicted the possible factors contributing to inguinodynia. It has been shown that age below median, absence of a visible bulge before the operation, recurrent hernia repair and history of moderate to severe pre-operative groin pain are some of the common factors that influence the post-operative inguinodynia.

Sexual dysfunction secondary to chronic groin pain

Ducic *et al*^[17] and Aasvang *et al*^[18] have shown that chronic groin pain contributes to sexual dysfunction with symptoms of chronic genital pain, erectile dysfunction and dysejaculation. A nationwide survey in Denmark by Aasvang *et al*^[19] showed pain during sexual activity in 22.1% of patients, of whom 6.7% had moderate or severe pain occurring every third time or more. Ejaculatory pain was noted in 12.3% of post-herniorrhaphy patients, with a quarter of them describing that the pain impaired their sexual activity significantly resulting in the avoidance of sexual activity. The ejaculatory pain was usually secondary to compression and dilatation of the vas deferens resulting from post-operative fibrosis or direct contact between the mesh and the vas deferens causing inflammation and fibrosis. The study also pointed out that only 1.8% of the patients who reported pain during sexual activity reported this to the physician, thereby showing under-reporting of this problem.

A prospective follow-up study was conducted by Zieren *et al*^[20] to assess post-herniorrhaphy sexual function by preserving IIN in the control group and elective division in the intervention group. This study showed that prophylactic IIN excision led to reduced sexual symptoms post-operatively in comparison with those who had preserved nerve.

ASSESSMENT TOOLS USED FOR DIAGNOSING INGUINODYNIA

The symptom complex of chronic groin pain varies from a dull ache to sharp shooting pain along the distribution of inguinal nerves. Walking, twisting or hyperextension of the hip often triggers the symptoms. They can be relieved by bed rest, sedentary life style or flexion of the thigh. The complex nature of chronic groin pain has led researchers to use diverse measurement tools, thereby leading to difficulty in comparison of the studies. The most frequently used self-rating pain tools that assess multidimensional nature of the pain are the Visual Analogue Scale (VAS) and McGill Pain Questionnaire, both of which have been shown to be reliable, valid and consistent^[21]. The McGill Pain Questionnaire assesses the

multidimensional nature of the pain using 78 different pain descriptors^[22]. The most commonly used simple assessment tool has been VAS and this uses a scale 10 cm in length, with no pain at 0 to severe pain at 10.

Neuropathic pain can be reproduced by tapping the skin medial to the antero-superior iliac spine or over an area of tenderness. It is extremely difficult to identify the exact nerve involved in causing the pain because of the overlapping nature of their sensory innervations and peripheral communication between the nerves. All three nerves arise from T12-L1 nerve roots. One, two or all three of them can be involved in the aetiology of chronic groin pain, thus making it difficult to pinpoint the entrapped nerve. Clinicians have tried peripheral nerve block or paravertebral block to differentiate the neuropathic pain. Beldi *et al*^[23] showed that the objective assessment of pain and hypoesthesia by von Frey monofilament prior to and after surgery is a good clinical tool. Ultrasound and computed tomography scans have helped in the diagnosis of non-neuropathic chronic groin pain by identifying excess fibrosis or mesh-related factors.

MESH VS NO-MESH

In an attempt to reduce chronic groin pain, researchers have tried tension-free repairs without mesh. A Cochrane review showed that the recurrence rate is reduced by 50%-75% when mesh is used for inguinal hernia repair compared to repairs without mesh^[24]. There is also some evidence of earlier return to work and of lower rates of persisting pain following mesh repair. A meta-analysis of RCTs comparing hernia repair with or without synthetic mesh showed a significant reduction in chronic groin pain when a mesh was applied, by the simple principle of reducing tension between suture lines^[25]. As a general consensus, mesh repair is considered to be more effective in reducing recurrence and chronic groin pain, in comparison with no-mesh repair.

TYPE OF MESH AND PAIN

The majority of patients who present with chronic groin pain also suffer from foreign body sensation and stiffness in the groin area. Post *et al*^[26] and O'Dwyer *et al*^[27] suggested that the pain might be caused by the weight and composition of implanted prosthetic material itself. Heavy-weight (HW) polypropylene meshes such as Prolene® (Ethicon) and polymer meshes with both polypropylene and polyglactin fibres such as Vypro I® and Vypro II® increase the surface area of the mesh, thereby causing extensive fibrosis and greater risk of infection and pain. An implant knitted from monofilament fibres, such as Ultrapro® (Ethicon) which is composed of polypropylene and poliglecaprone absorbable fibres, causes less tissue reaction^[28,29]. Alternatively, light-weight (LW) meshes have shown promise in reducing the groin pain rate. However, because of their lesser tensile strength, there have been recent reports of increases in early and mid-term recurrence rates^[30,31].

A randomised controlled trial comparing HW with LW mesh showed higher incidence of groin pain for HW mesh at 6 mo follow-up (6.3% *vs* 0%, respectively). This was statistically significant^[32]. Randomised controlled trials have shown that the feeling of foreign body sensation is higher in HW mesh groups compared to LW mesh: 43.8% *vs* 17.2% by Post *et al*^[26] and 32.8% *vs* 20.9% by Nikkolo *et al*^[32]. However, the follow-up in both these RCTs was only for 6 mo, thereby they did not account for higher recurrence rates associated with LW meshes. O'Dwyer *et al*^[27] randomised 162 patients in a LW group and 159 in a HW group and showed that the recurrence rate was higher in the former group (5.6% *vs* 0.4%) at 12 mo follow-up, which was statistically significant.

There are very few reports of well controlled RCTs on LW meshes with long-term follow-up. In a RCT of 590 patients with 3 year follow-up, Bringman *et al*^[33] showed no differences in neuralgic pain, hypoesthesia or hyperaesthesia between the HW and LW mesh groups. There were no major differences in response to the pain questionnaire, except that fewer men with LW mesh had pain when rising from lying down to a sitting position. Significantly more men in the standard mesh group could feel the mesh in the groin: 22.6% *vs* 14.7%. More importantly, this study with longer follow-up showed no difference in recurrence rates with either HW or LW meshes^[33]. Similar views were shared by a single centre RCT on three different composite meshes with a 2 year follow-up^[34].

European hernia guidelines for open hernia repair emphasise a Grade A recommendation for the use of synthetic non-absorbable flat mesh or composite mesh with a non-absorbable component. Though the use of lightweight/material-reduced/large pore (1000 µm) meshes in open inguinal hernia repair can be considered to decrease long-term discomfort, this is possibly at the cost of increased recurrence rate (possibly due to inadequate fixation and/or overlap). Large randomised studies with longer follow-up are needed to justify the routine use of LW meshes.

MESH FIXATION VS PAIN

Complications associated with sutured fixation of the mesh have prompted surgeons to use atraumatic fixation using substances such as human fibrin glue^[35]. These adhesives have shown reduced incidence of chronic groin pain, foreign body sensation and groin numbness in both randomised trials and observational studies^[36-39].

Randomised controlled trials regarding skin staples to fix the mesh have shown reduced intra-operative times and early return to normal activity. However, there was no difference in complications or post-operative pain rates^[40]. A randomised trial in which bilateral hernias received sutured fixation of the mesh on one side and glue fixation on the opposite side showed less inflammatory reaction and therefore post-operative pain on the glue fixed side, with no increased recurrence rates^[37]. Similar results were shown in a RCT with 3 mo of follow-up^[36].

A randomised study comparing sutures, fibrin glue and

N-butyl-2-cyanoacrylate for mesh fixation showed higher post-operative pain, numbness and haematoma formation both in the short term and 12 mo following hernia repair, with an increased rates of foreign body sensation and chronic groin pain, in the sutured fixation group^[39]. There was no recurrence in any group, confirming the fact that tissue adhesives form enough fibrotic reaction to give the much needed tensile strength and at the same time negate the nerve or tissue damaging effects of suture repair. However, the lack of long-term follow-up reports on recurrence rates with glue fixation and increased cost of these glues have made their routine use uncommon.

IMPORTANCE OF NERVE IDENTIFICATION

Lange *et al*^[41] and Alfieri *et al*^[42] showed there was less incidence of chronic groin pain with identification of all 3 nerves during open inguinal hernia repair compared to no nerve identification. A large prospective multicentre study conducted at 11 Italian institutions involving 955 patients showed that the overall pain rate was 5.5% and moderate to severe pain rate was 1.3% when all three nerves were identified. If no nerves were identified the rates of overall pain and moderate to severe pain were 21.6% and 4.7%, respectively. This was statistically significant. Alfieri *et al*^[42] showed that relative risk of chronic groin pain increases from 2.2 to 19.2 if one or three nerves have not been recognised during the inguinal hernia repair.

Smeds *et al*^[43] showed that non-identification of nerves leads to worse pain rates and that non-identification of IIN is worse than actual identification of both IHN and GFN. Amid and Wijsmuller suggested that identification of inguinal nerves helps avoid damage to them by mesh or sutures and also that it is beneficial to cut clean if already damaged during dissection in order to avoid neuroma formation^[44,45]. This is from the understanding that neurectomy causes only numbness, whereas nerve injury causes pain.

The practice of identification of all 3 nerves is quite poor. Ravindran *et al*^[46] conducted a survey in the United Kingdom regarding the handling of inguinal nerves during open hernia repair and showed that IIN was routinely identified by 88% of surgeons, IHN by 58% and GFN by 54%. The individual nerves were routinely divided by 7%, 5% and 6% of surgeons, respectively. There was no definite consensus available on routine identification of inguinal nerves and preservation or division. The survey also pointed out that those surgeons who performed more than 50 hernias per year were more likely to preserve the nerve and others were more likely to ignore it^[46].

The difficulty in nerve identification has been shown to be due to variation in the anatomy and absence of one or more nerves, which is not uncommon in the inguinal area. An anatomical study by Wijsmuller *et al*^[47] defined identification zones which make all three nerve identifications feasible. Lange *et al*^[41], in a prospective anatomical study, showed that identifying all three ingui-

nal nerves should only add 3-4 min of operating time. Overall, the general consensus has been to identify all 3 nerves during open inguinal hernia repairs to avoid iatrogenic injury and consequent chronic groin pain.

NERVE EXCISION VS NERVE PRESERVATION

Traditional teaching has always been to preserve the nerve, but recent studies have looked into the intentional severance based on the concept of “no nerve, no pain”^[48]. RCTs comparing deliberate IIN neurectomy *vs* preservation have shown conflicting results. Two RCTs have shown significant reduction in chronic groin pain post-neurectomy^[49,50], whereas two other studies concluded there was no influence of neurectomy on pain rates^[46,51]. The diverse results may be due to different assessment tools used and poorly conducted and underpowered studies. All of these studies have taken only IIN into consideration, leaving the other two nerves unaccounted for.

A recent RCT by Karakayali *et al*^[52] has shown significant reduction in chronic groin pain with IIN and IHN neurectomy in comparison with all 3 nerves preserved. Nevertheless, this study does not address the fact that all 3 nerves traverse the inguinal area, and that any of the 3 nerves can be involved in causing chronic groin pain. Though studies have shown high incidence of groin numbness and sensory loss following deliberate neurectomy of the inguinal nerves, no significant differences have been shown in the quality of life with such neurosensory changes^[52].

A previous systematic review by Wijsmuller *et al*^[47] in 2007 showed no significant difference in pooled mean percentage of patients with chronic groin pain following either IIN preservation or division. A Cochrane systematic review is currently being undertaken to address this issue.

SOLUTION FOR CHRONIC GROIN PAIN

Avoiding chronic groin pain should be a prime goal for any hernia surgeon, considering that 5-7% of patients with post-herniorrhaphy groin pain will sue their surgeons^[53] amidst proposed measures to avoid chronic groin pain. These important steps are: leaving the cremasteric layer to safeguard IIN; not to recreate too small an external ring to prevent constriction of the IIN during external oblique closure; not to lift the IIN from its bed; careful adequate dissection to prevent injury to the prematurely surfaced branches of the IIN or IHN; and also, avoid suturing the lower edge of the internal oblique muscle to the inguinal ligament because passing sutures can lead to injury to the intramuscular portion of the IIN. One way to avoid nerve scarring in the operative field is to transect the nerve under tension so that it retracts behind the peritoneum or else to implant the transected nerve within the fibres of internal oblique muscle, to prevent it adhering to the inguinal ligament or external oblique aponeurosis.

Even if conventional thinking dictates that every effort should be made for preservation of the nerves from trauma, this is often impossible. Detailed discussion about various treatment options is beyond the remit of this article.

CONCLUSION

There has been increasing evidence in the literature over the last decade regarding the growing incidence of chronic groin pain. The exact cause for the pain is still unclear and various aetiologies have been suggested, including the type of mesh, suture materials and tissue handling techniques. It is important to understand the definition of chronic groin pain occurring after 3 post-operative months following herniorrhaphy and this should not be confused with immediate post-operative pain. This will give the opportunity for better reporting of this complex problem and proper understanding of its aetiology. By far the best treatment for chronic groin pain is to avoid bestowing this on the patient by careful intra-operative handling of inguinal structures and better patient counselling pre- and post-herniorrhaphy.

Abstract

Outstanding progress regarding the pathophysiology of Crohn's disease (CD) has led to the development of innovative therapeutic concepts. Numerous controlled trials have been performed in CD. This review concentrates on the results of randomized, placebo-controlled trials, and meta-analyses when available, that provide the highest degree of evidence. Current guidelines on the management of CD recommend a step-up approach to treatment involving the addition of more powerful therapies as the severity of disease and refractoriness to therapy increase. The advent of biological drugs has opened new therapeutic horizons for treating CD, modifying the treatment goals. However, the large majority of patients with CD will be managed through conventional therapy, even if they are a prelude to biological therapy.

INTRODUCTION

Medical treatment of the acute exacerbation of Crohn's disease (CD) is successful in most patients, but some of the most difficult tasks in medicine are to modify the pattern of chronic inflammatory disease, preventing complications such as strictures, abscesses, fistulae and chronic disease activity, and maintaining remission^[1]. The location of CD changes infrequently over time, in contrast to disease behavior, which changes in most patients with increasing disease duration. Whereas the great majority of patients have inflammatory, non-penetrating and non-stricturing disease behavior at diagnosis, the risk of intestinal complications ultimately affects the majority over time^[2]. Although medical treatment of CD is the focus of this review, non-pharmacological factors, including changes in lifestyle, should not be neglected. Probably the most important recommendation is smoking cessation. Smoking has been shown to be a risk factor for CD relapse after medically- or surgically-induced remission^[3] and is associated with the need for higher doses of corticosteroids and immunosuppressants^[4]. Furthermore, a prospective trial has shown that only one

year of smoking cessation leads to a more benign course of disease with a lower rate of relapse^[5]. This trial also showed that the ability to quit smoking clearly depended on the physician's role. Consequently, conventional treatment of CD should start, if you will, with convincing the patient to stop smoking when appropriate.

ACTIVE DISEASE

The general principles for treating active disease are to consider activity, site and behavior (inflammatory, stricture, fistulating) of disease^[1]. The choice of treatment is also influenced by the previous response to treatment, side effect profile of medication, presence of extraintestinal complications and the course of disease.

The activity of CD can be assessed clinically and endoscopically, or more formally by different indices^[6]. The most established way for clinical trials is through the Crohn's disease activity index (CDAI), which includes symptoms and objective criteria such as anemia and body weight^[7]. Index values of 150 and below are associated with quiescent disease; values above that indicate active disease, and values above 450 indicate extremely severe disease. Other markers of activity such as erythrocyte sedimentation rate, C-reactive protein (CRP), or platelet count should also be taken into account. Fecal lactoferrin and calprotectin are highly sensitive and specific markers for detecting intestinal inflammation. These markers are similarly useful for both CD and ulcerative colitis to monitor the therapeutic response to treatments^[8-10].

Endoscopic evaluation is unnecessary in every exacerbation, but helps when there is a disparity between symptoms and objective markers of inflammation, or when it is necessary to re-evaluate disease localization. The American College of Gastroenterology has characterized the different disease activities in clinical practice as follows^[11]: mild to moderately active disease as "ambulatory patients able to tolerate oral alimentation without manifestations of dehydration, toxicity (high fevers, rigors, and prostration), abdominal tenderness, painful mass, obstruction or > 10% weight loss". In contrast, moderate to severe disease can be recognized in "patients who have failed to respond to treatment for mild to moderate disease, or those with more prominent symptoms such as fever, significant weight loss, abdominal pain or tenderness, intermittent nausea or vomiting (without obstructive findings), or significant anemia". Severe disease refers to "patients with persisting symptoms despite the introduction of steroids as outpatients, or individuals presenting with high fever, persistent vomiting, evidence of intestinal obstruction, rebound tenderness, cachexia, or evidence of an abscess".

Aminosalicylates

No debate regarding the therapy for CD has been as longstanding and controversial as whether 5-aminosalicylic acid (5-ASA)-containing drugs in CD are justified or not. Numerous studies have been performed over the last 25 years, but the data from those currently available do not unequivocally support either point of view. This is partly because

differences in study design and dosage render comparison of the outcomes rather difficult. Sulfasalazine is the parent compound, consisting of 5-ASA linked by an azo-bond to sulfapyridine which is split off by bacterial azo-reductase in the colon. The efficacy of sulfasalazine can therefore be expected to be limited to colonic disease. Furthermore, up to 50% of patients are unable to tolerate sulfasalazine at a dose of 4 g/d, due to nausea, headache, vomiting, or epigastric pain. These side effects are usually caused by the sulfapyridine moiety. Therefore, other 5-ASA formulations (mesalazine formulations and the pro-drugs olsalazine and balsalazide) without sulfapyridine have been introduced with different pharmacodynamic and pharmacokinetic profiles. These different preparations are best considered to be different and not interchangeable.

Sulfasalazine is significantly better than placebo in randomized clinical trials for inducing remission in active CD^[12-14]. As anticipated, subgroup analyses suggest that patients with isolated colonic disease benefit most from sulfasalazine therapy^[11,12], whereas patients treated previously with prednisone fail to respond^[11]. Treatment with prednisolone is likely to be a marker of disease severity, rather than a generic modification of the response to sulfasalazine. Sulfasalazine has not been shown to have steroid-sparing properties^[13-15]. The European Crohn's and Colitis Organisation (ECCO) consensus on the management of CD states that active colonic CD can be treated with sulfasalazine if only mildly active, but that it cannot be recommended as first-line therapy because of the high incidence of side effects^[1]. It may, however, be appropriate in selected patients, such as those with arthropathy. Once 5-ASA was identified as the active moiety in sulfasalazine, it is not surprising that other 5-ASA-containing formulations (such as mesalazine) were tested in CD.

Different pharmacological preparations allow release of the active drug in different parts of the intestine. Therefore, mesalazine, in contrast to sulfasalazine, might conceivably be used in CD affecting the small bowel. The studies on induction of remission in active CD with mesalazine, however, have yielded conflicting data. Six placebo-controlled trials with different dosages of mesalazine for treating active CD have so far been published. Two studies did not detect a benefit of mesalazine over placebo for inducing remission^[16,17]. Tremaine observed a significantly greater number of patients with a response (defined as a decrease in CDAI ≥ 70 and/or CDAI < 150), but this benefit was minute (9 patients with mesalazine treatment *vs* 4 patients in the placebo group). However, there was no significant difference for clinical remission alone^[18]. Singleton *et al*^[15] conducted three separate trials with mesalazine (Pentasa) that have been combined in a meta-analysis, even though two of the three trials were never published in full^[19]. This analysis observed a statistically significant benefit of mesalazine over placebo, but the benefit was technical (a greater reduction in CDAI of 18 points compared to placebo in the intention-to-treat-analysis), and of debatable clinical significance. Consequently, if mesalazine is used to treat active CD, the physician must be aware that it is little more effective than

placebo. On the other hand, treatment with placebo is not the same as no treatment at all!

Budesonide

The introduction of the topically acting steroid budesonide has become an attractive option for treating patients with CD located in the terminal ileum or right colon. Due to rapid metabolism by cytochrome P-450 enzymes in the liver, budesonide has less systemic bioavailability than conventional corticosteroids. Budesonide has been shown to be effective in inducing remission of active CD in several controlled studies^[20-26], with remission rates ranging from 51% to 69% of patients over a period of 8 to 12 wk. A Cochrane Systematic Review combined data from 12 published studies investigating budesonide in comparison to placebo, 5-ASA and systemic corticosteroids^[27], and showed that budesonide is more effective at inducing short-term remission, within 8 wk of treatment, in moderately active CD than placebo [relative risk (RR): 1.96, 95% confidence interval (CI): 1.19 to 3.23] or mesalamine (RR: 1.63; 95% CI: 1.23 to 2.16). Budesonide was significantly less effective than conventional steroids for induction of remission (RR: 0.86, 95% CI: 0.76 to 0.98), particularly among patients with severe disease (CDAI > 300) (RR: 0.52, 95% CI: 0.28 to 0.95). Fewer adverse events occurred in those treated with budesonide compared to conventional steroids (RR: 0.64, 95% CI: 0.54 to 0.76) and budesonide was better able to preserve adrenal function (RR for abnormal ACTH test 0.65, 95% CI: 0.55 to 0.78). The recommended dose of budesonide is 9 mg/d, usually for 6 wk, and then tapered 3 mg every 2-4 wk unless continued therapy with budesonide is considered (see below). The ECCO Consensus recommends budesonide 9 mg daily as the preferred treatment for mildly active localized ileocecal CD^[1].

Systemic corticosteroids

The effect of systemic steroids for remission induction in CD has been studied in several uncontrolled^[2-4] and controlled trials^[5,6]. Overall, the clinical response rate achieved varies from 60% to 97% over a period of 1 to 5 mo. In active CD, corticosteroids have been shown to be superior to sulfasalazine, azathioprine and placebo^[11,12]. Remarkably, no dose-finding studies have been performed. Reported doses range from 30 mg/d up to 1 mg/kg per day, but most clinicians start with prednisolone 40-60 mg/d, although some vary this according to body weight (1 mg/kg), especially in children. A Cochrane Systematic Review by Benchimol *et al*^[7] included data from two placebo-controlled and six 5-ASA-controlled studies. Systemic steroids were significantly more effective (RR: 1.99, 95% CI 1.51-2.64, $P < 0.00001$) than placebo and significantly more effective than 5-ASA (RR: 1.65, 95% CI: 1.33-2.03, $P < 0.00001$). Across the different studies, systemic steroids have been shown to be effective in mild to severely active CD of any localization.

However, the short-term (i.e. 7 to 18 wk) high remission rate induced by systemic corticosteroids does not last, as 16% to 36% of patients become steroid-dependent, and less than half of the initially responding patients will still

be in remission 1 year after the initial treatment with steroids^[2,12]. In a multi-center, randomized, open-label study comparing a conventional treatment algorithm (steroids followed by immunomodulators in case of relapse after tapering off steroids) *vs* early combined immunosuppression [three infusions of infliximab (IFX) and concomitant immunomodulators], 74% of patients in the conventional arm were receiving immunomodulators at week 104^[13], again underlining the poor long-term outcome of remission induced with systemic steroids. Comparing the two arms with respect to the primary end-point, steroid-free remission, 40/65 (61.5%) in the early combined immunosuppression arm *vs* 27/64 (42.2%) in the conventional arm were in remission at week 54 (absolute difference 19.3%, 95% CI: 2.4-36.3, $P = 0.0278$). However, beyond 1 year of follow-up, there was no difference in the steroid-free remission rate between the two groups. It is thus currently unclear whether replacing steroids by anti-tumour necrosis factor (TNF) agents in first-line therapy for active CD will lead to better long-term outcomes. There are no data available offering a direct comparison of treatments other than IFX (e.g. immunomodulators) with corticosteroids as first-line therapy for remission induction.

The short-term outcome of a first course of steroids shows that approximately 50%-60% of patients have a complete response, 30% a partial response, and about 10%-20% have no response. However, at 1 year, only a third of patients will have a durable response, while another third become corticosteroid-dependent and cannot be withdrawn from treatment without a relapse of symptoms, and another third develop steroid resistance^[27,28]. Corticosteroid-dependence is a particular concern due to well-established systemic and metabolic toxicities associated with long-term corticosteroid use. Recent data from a referral centre in France identified the need for corticosteroids during the first flare as a predictor of a disabling disease course over the subsequent 5 years^[29].

Tapering should be performed according to improvement of clinical symptoms and is usually done in steps of 5-10 mg/wk. At lower dosages, tapering might be reduced to 2.5-5 mg/wk. Intravenous steroids are frequently used when oral treatment has not been effective, but whether this has an advantage over oral therapy in acute severe flares is unclear. The ECCO Consensus on CD management recommends that systemic corticosteroids should be used initially in patients with moderate to severe disease^[1].

Corticosteroids are undoubtedly effective in relieving symptoms in CD^[12,13]; however, high-dose corticosteroids induce complete mucosal healing in only 13% of patients and a proportion of patients who achieve clinical remission on corticosteroids may in fact have worsened disease at the mucosal level^[30].

Azathioprine/mercaptopurine

The most commonly used immunomodulators are the thiopurines, mercaptopurine (MP) and its prodrug azathioprine (AZA). A number of clinical trials have studied the efficacy of these immunomodulators in active CD. The most convincing data were obtained in the early trial

by Present where 67% patients in the MP group achieved remission compared to 8% given placebo^[31]. Other trials have not observed a significant difference of AZA compared to placebo^[11,32], but this partly reflects trial design, dose and duration of therapy for this drug, which takes up to three months to be effective.

Despite these conflicting data, a recent Cochrane analysis evaluated 8 randomized placebo-controlled trials of AZA and 6-MP therapy in adult patients: five dealt with active disease and three had multiple therapeutic arms. The odds ratio (OR) of a response to AZA or 6-MP therapy compared with placebo in active CD was 2.43 (95% CI: 1.62 to 3.64). This corresponded to a number needed to treat (NNT) of about 5 to observe an effect of therapy in one patient. When the two trials using 6-MP in active disease were excluded from the analysis, the OR was 2.06 (95% CI: 1.25 to 3.39). Treatment > 17 wk increased the OR to 2.61 (95% CI: 1.69 to 4.03). A steroid-sparing effect was seen with an OR of 3.69 (95% CI: 2.12 to 6.42), corresponding to a NNT of about 3 to observe steroid-sparing in one patient. Adverse events requiring withdrawal from a trial, principally allergy, leukopenia, pancreatitis and nausea, were increased with active therapy with an OR of 3.44 (95% CI: 1.52 to 7.77). The NNT to observe one adverse event in one patient treated with azathioprine or 6-mercaptopurine was 14^[33].

Because thiopurines are slow-acting drugs they are used less frequently to induce remission and more commonly to maintain remission. A combination of prednisolone and AZA was superior to prednisolone monotherapy in one study^[34]. Consequently, the main role for thiopurines is as a steroid-sparing therapy and they should be started for corticosteroid-dependent or corticosteroid-refractory patients.

Most evidence is available to support the dose-escalating method: AZA may be started at 50 mg daily and the dose increased by 25 mg every 1-2 wk to a target dose of 2.0-3.0 mg/kg along with monitoring for leukopenia and other potential adverse events. Similarly, 6-MP may be started at 50 mg daily and the dose increased by 25 mg every 1-2 wk to a target dose of 1.0-1.5 mg/kg along with similar monitoring for leukopenia and other potential adverse events. In a recent survey study, most gastroenterologists escalated the dose of AZA or 6-MP relatively rapidly, generally within 4 wk, reporting weight-based target dosing^[35].

However, benefits of this therapy are offset by higher treatment-related risk of lymphoproliferative disorders. In particular, it has been shown recently^[36] that a multivariate-adjusted hazard ratio of lymphoproliferative disorder between patients receiving thiopurines and those who had never received the drugs was 5.28 (95% CI: 2.01 to 13.9, $P = 0.0007$).

The ECCO Consensus recommends that AZA/MP be added to corticosteroids for severe CD in the event of relapse^[1]. Thiopurines are capable of achieving mucosal healing. AZA heals the mucosa in up to 58% of patients at 1 year and 70% at 2 years, and is superior to budesonide (mucosal healing rate 15%)^[37,38]. For those who had been on AZA for longer than 3.5 years and who were in clinical remission, complete mucosal healing was seen in 36% and absence of ulcers in 53%^[12].

In the same study, endoscopic scores correlated well with clinical activity indicators. In the postoperative setting, AZA can achieve complete mucosal healing of recurrent ileitis in 40% of patients and improvement in 93% after at least 6 mo of therapy^[12]; however, endoscopy at 6 mo may be too early to assess the effect of AZA in *de novo* disease, as seen in the Study of Biologic and Immunomodulator-Naive Patients in CD (SONIC)^[39].

AZA/6-MP treatment should be maintained for several years due to the high relapse rate of patients when these drugs are discontinued. Many studies have investigated the duration of maintenance of remission after AZA/6MP withdrawal in CD patients who were in long-term remission while on this therapy. Withdrawal of AZA/6-MP after up to a median of 6 years under treatment and long-standing remission was associated with a high risk of relapse, whatever the duration of remission under this treatment. Thus, AZA/6-MP withdrawal is not equivalent to continued therapy for maintenance of remission in patients with CD who have been in remission on this therapy. These data suggest that if AZA/6-MP is well tolerated, it should not be interrupted^[40,41]. Younger age and a higher daily dose of 6-MP were associated with a higher rate of relapse^[40].

Methotrexate

In a pivotal trial conducted by Feagan, methotrexate (MTX) given intramuscularly 25 mg once a week was more likely to induce remission than placebo. Steroid-sparing properties were noted^[41]. However, side effects were more common with MTX therapy than with placebo. Other studies using low-dose MTX have not shown a significant benefit^[42,43] and no benefit was observed when high-dose intravenous MTX was compared to oral AZA^[43]. Like AZA/MP, MTX is only rarely used to treat acute exacerbations of CD, but much more frequently for persistently active CD^[44]. Side effects of MTX (notably liver dysfunction and myelotoxicity) need to be monitored and it is contradicted during pregnancy. Consequently, it should be used very cautiously in women of child-bearing potential. MTX has the same indications for treating CD as the thiopurines (although neither are licensed for treating CD in most countries), but because of greater familiarity with thiopurines, most gastroenterologists reserve MTX for active or relapsing CD in patients refractory to, or intolerant of, AZA/MP.

Antibiotics

Although antibiotics are frequently used to treat CD, there is little substantive evidence from randomized trials. Nevertheless, increasing awareness of the importance of mucosal bacteria in the pathogenesis of CD provides a rationale for exploring antibiotic therapy^[45]. Metronidazole (20 mg/kg per day) was superior to placebo at reducing the CDAI, but not at inducing remission, in one of the few randomized trials^[46]. Furthermore, this benefit was only seen in patients with colonic or ileocolonic disease and no benefits were found with disease limited to the ileum. Similar findings were reported in another trial where a few patients with Crohn's colitis showed an improve-

ment^[47]. On the other hand, another study reported no benefit of metronidazole compared to placebo^[48], nor to sulfasalazine, in a 4 mo cross-over study. However, in the cross-over study, patients switched to metronidazole showed CDAI response, although there was no change in CDAI in those switched from metronidazole to sulfasalazine^[49,50].

Ciprofloxacin is the other antibiotic used in clinical practice, commonly in combination with metronidazole. Ciprofloxacin was significantly better than placebo at inducing remission in a small trial^[51] and similarly effective to mesalazine^[52]. In contrast, corticosteroids resulted in higher rates of clinical remission compared to ciprofloxacin and metronidazole^[53]. In patients with persistent disease activity given budesonide, the addition of metronidazole and ciprofloxacin was not superior over budesonide monotherapy, despite a trend towards benefit in patients with colonic CD^[54]. Further studies are warranted to establish the role of antibiotics in the treatment of CD, but for the time being they cannot be recommended as standard therapy.

As stated by the ECCO, at present, antibiotics are only considered appropriate for septic complications, symptoms attributable to bacterial overgrowth, or perineal disease. Anti-mycobacterial therapy cannot be recommended on the evidence from controlled trials^[1].

MAINTENANCE OF REMISSION

Maintaining medically- or surgically-induced remission of disease is one of the most important, but most difficult, therapeutic goals in the treatment of CD. Maintenance therapy in CD is hampered by few available drugs, moderate rates of efficacy and frequent side effects. In total, 40%-70% of CD patients will experience a symptomatic relapse within a year of medically- or surgically-induced remission^[11,12]. Silverstein reported that a surgically-induced remission lasted a mean 766 d, whereas a non-surgical induced remission lasted only 120 d, suggesting that a surgically-induced remission might be more stable^[55]. However, surgery is generally used for obstructive symptoms and not for inflammatory disease, so like was not being compared with like, although physicians should not forget the relatively extended period of medication- or symptom-free remission that surgery can offer. It is generally recommended to base decisions regarding a relapse-preventing therapy on the likelihood of relapse in an individual patient. Estimates of risk remain controversial, but well-established risk factors such as continuing to smoke, frequent relapses in the past, perianal or penetrating disease are widely accepted^[56]. To stop smoking is an important therapeutic goal^[2,57]. Systemic corticosteroids should not be used for maintaining remission due to lack of efficacy and severe long-term side effects.

MEDICALLY-INDUCED REMISSION

5-ASA

Numerous randomized, placebo-controlled studies, including four meta-analyses, have tried to establish a role for

5-ASA in the maintenance of remission. Different study regimens, dosages and durations of therapy have been performed, while a substantial number of trials included small numbers of patients. The two most recent meta-analyses failed to show a benefit for mesalazine over placebo in the maintenance of medically-induced remission^[57,58].

Azathioprine/mercaptopurine

Azathioprine or mercaptopurine is the treatment of choice for patients with a high risk of relapse. The effectiveness of AZA has been confirmed in the most recent meta-analysis which included 7 trials of AZA therapy and one of 6-MP. Azathioprine and 6-mercaptopurine both had a positive effect on maintaining remission. The Peto OR for maintenance of remission with AZA was 2.32 (95% CI: 1.55 to 3.49) with a NNT of 6. The Peto OR for maintenance of remission with 6-MP was 3.32 (95% CI: 1.40 to 7.87) with an NNT of 4. Higher doses of AZA improved response. A steroid-sparing effect with AZA was noted, with a Peto OR of 5.22 (95% CI: 1.06 to 25.68) and NNT of 3 for quiescent disease. Withdrawals due to adverse events were more common in patients treated with AZA (Peto OR 3.74; 95% CI: 1.48 to 9.45, NNT = 20) than with placebo^[59].

A steroid-sparing effect has also been confirmed^[60]. The following indications for starting thiopurine maintenance therapy are generally accepted: frequent flares (two or more per year), persistent disease activity, and steroid dependence. The thiopurines are slow-acting drugs and an effect is usually observed after 2-3 mo, with approximately 90% of patients who are going to respond doing so within the first 4 mo.

An early AZA maintenance study suggested that the drug might no longer be effective after 3.5 years^[61]. However, a subsequent randomized, placebo-controlled withdrawal study showed that AZA remained effective at 3.5 years and beyond^[62]. Treton *et al*^[63] showed that even after a long duration of clinical remission under AZA, withdrawal of this drug is associated with a high risk of relapse. Interruption of AZA can be reasonably considered, at least temporarily, in a selected group of patients having no predictive factor of relapse. Debate continues about the potential for a small increase in the risk of lymphoma and this cannot be excluded in long-term treatment with AZA/MP^[64,65]. This must be weighed against the improved quality of life from thiopurine therapy for patients with CD and discussed with individual patients.

Methotrexate

In a follow-up to the induction study, patients who had achieved remission after 25 mg intramuscular MTX/week were randomized to 15 mg/wk MTX or placebo. Methotrexate was found to be significantly better than placebo at maintaining remission^[66]. However, side effects were significantly higher than with placebo. Methotrexate has not been studied after remission has been induced surgically or by other drugs (such as corticosteroids). In general, MTX is considered an alternative to AZA/MP for the maintenance of remission. It also has steroid-sparing properties and the mean time to respond is about 2 mo.

With regard to the ECCO consensus on CD management, patients receiving azathioprine or mercaptopurine who relapse should be evaluated for adherence to therapy and have their dose optimized. Change of their maintenance therapy to methotrexate or anti-TNF therapy should be considered^[1].

Budesonide

Low doses of budesonide (3 or 6 mg) have been studied for their potential to maintain remission. The maintenance of remission with budesonide has been studied in several controlled trials. These have been reviewed by Benchimol *et al*^[38] in a Cochrane Systematic Review, based on 10 controlled trials. Eight studies used a controlled ileal release form of budesonide, while three used a pH-modified release formulation. Budesonide is not more effective than placebo or weaning prednisolone for maintenance of remission in CD. Some modest benefits are noted in patients receiving budesonide compared with placebo in terms of lower CDAI scores and longer time to relapse of disease. However, these benefits are offset by higher treatment-related adverse event rates and more frequent adrenocorticoid suppression in patients receiving budesonide.

The ECCO Consensus on CD management states that corticosteroids are not effective for maintenance of medically-induced remission in CD. Budesonide may delay relapse after medically-induced remission, but is not effective at maintaining remission for 12 mo. Budesonide can replace prednisolone in steroid-dependent patients to improve tolerability^[1].

POSTOPERATIVE CD (SURGICALLY-INDUCED REMISSION)

About 75% of CD patients with ileal or ileocolonic disease will require surgery within the first 20 years of diagnosis^[66,67]. Recurrence rates after surgical resection are high, but are influenced by the definition of recurrence^[68]. After the first resection, up to 80% of patients show an endoscopic recurrence within the first year, although most patients are not symptomatic^[66,67,69]. Up to 20% have clinical symptoms and 5% require further surgical intervention within the first year. After 5 years, about half have had a clinical relapse. Neither systemic corticosteroids nor budesonide are effective at preventing postoperative relapse^[69,73]. Risk factors for postoperative recurrence have rarely been studied in a prospective manner. Continued smoking is the most consistently described risk factor for postoperative relapse^[57,74]. Rutgeerts has shown that preoperative disease activity and endoscopic lesions in the neoterminal ileum within the first year after surgery are also associated with a higher risk of postoperative recurrence^[69]. A more recent study has suggested that CD patients with CARD15 mutations have a higher risk of postoperative relapse compared to patients without mutated CARD15^[74].

5-ASA

Despite the controversies about 5-ASA in the medical treatment of active or quiescent CD, data on the preven-

tion of postoperative recurrence are relatively solid. A meta-analysis by Cammà described a risk reduction of 13.1% in clinical relapse during mesalazine treatment compared to placebo^[58]. A subsequent placebo-controlled trial reported no effect of mesalazine after surgical resection for CD, except in patients with isolated small bowel resection^[75]. 5-ASA is well tolerated and generally recommended after resection^[74]. The ECCO Consensus on CD management suggested that high dose mesalazine is an option for patients with an isolated ileal resection^[1].

Azathioprine/Mercaptopurine

A recent meta-analysis evaluated 4 controlled trials comparing azathioprine ($n = 3$) or 6-MP ($n = 1$) with control arms (placebo with or without antibiotic induction therapy or mesalamine). In the overall analysis, purine analogs were more effective than control arms in preventing clinical recurrence at 1 year (mean difference, 95% CI: 8, 1%-15%, $P = 0.021$, NNT = 13) and at 2 years (mean difference, 95% CI: 13, 2%-24%, $P = 0.018$, NNT = 8). In sensitivity analyses, the efficacy of purine analogs was superior to that of placebo for the prevention of clinical and endoscopic recurrence at 1 year (mean differences, 95% CI: 13, 1.8%-25%, $P = 0.025$, NNT = 7, and 23, 9%-37%, $P = 0.0016$, NNT = 4, respectively). At 1 year, in the overall analysis, purine analogs were more effective than control arms were in preventing severe (Rutgeerts score ≥ 2 -4) endoscopic recurrence (mean difference, CI 95%: 15, 1.8%-29%, $P = 0.026$, NNT = 7), but they were not effective in the prevention of very severe (≥ 3 -4) recurrence. The rate of adverse events leading to drug withdrawal was higher in thiopurine-treated patients than in control arms (17.2% *vs* 9.8%, respectively, $P = 0.021$)^[76].

Although there are no robust data to support the use of AZA/MP for preventing postoperative relapse, many clinicians use these drugs for this indication^[77].

The ECCO Consensus on CD management recommends prophylactic treatment after small intestinal resection. Thiopurines are more effective than mesalazine or imidazole antibiotics alone for preventing both clinical and endoscopic recurrences. Azathioprine/6-mercaptopurine are the drug of choice in patients with a risk factor for early postoperative recurrence^[1].

Antibiotics

In a randomized, placebo-controlled trial of metronidazole, a significant decrease in the incidence of severe endoscopic recurrence was observed after ileal resection^[78]. Metronidazole therapy significantly reduced clinical recurrence rates at 1 year, but it is rarely used for this indication because of poor tolerability. Another nitroimidazole antibiotic, ornidazole, has been studied by the same group. Ornidazole significantly reduced the clinical and endoscopic recurrence rate at 1 year compared to placebo, but still more patients in the ornidazole group dropped out because of side effects^[79].

Imidazole antibiotics, as suggested by the ECCO Consensus on CD management, may be a therapeutic option after ileocolic resection but are poorly tolerated^[1].

CONCLUSION

Based on currently available data from randomized, placebo-controlled trials and meta-analyses we have described the conventional therapy of CD. Biological therapy has opened new therapeutic horizons and novel treatment goals; however, current guidelines advocate a step-up approach to treatment, with the addition of more powerful therapies as the severity of disease or refractoriness to therapy increases. In contrast to the cautious, conventional step-up approach, a proactive top-down approach to treatment has been proposed. This regimen advocates biological and immunomodulator therapy at an early stage, shortly after diagnosis of CD.

However, it is important to keep in mind that the CD course in the majority of patients is relatively mild. About three-quarters of patients suffering from CD present at diagnosis with inflammatory disease and one-quarter with either stricturing and/or penetrating disease^[80,81]. After the first year of diagnosis, 55% of patients are in remission and 15% have only mild disease, leaving around 30% suffering from frequently active disease. Generally, 20% display active disease during each of the first 7 years^[82]. In a Markov model, a representative patient with CD spends 65% of lifetime disease course in medical or surgical remission, 27% with mild disease, 7% with severe disease, and 1% in surgery^[55]. Disease behavior tends to alter over time towards a more aggressive phenotype characterized by the development of disabling complications such as abscesses, internal fistulae and strictures^[2]. Most of these complications need surgical interventions that lead to more disabling disease. In a Norwegian cohort, the probability of surgery was 14%, 27% and 38% at 1, 5 and 10 years, respectively^[83].

Specific clinical, serological and/or genetic predictors are needed to help identify patients with the highest risk of developing a disabling disease. At present, no predictors which have been fully validated and replicated in adequately powered studies are available. Active smoking, age less than 40 years, extensive length of affected digestive tract, perianal lesions and steroid therapy during the first flare have been proposed as predictors of a worse prognosis in medically-treated CD patients^[29]. Furthermore, in an Olmsted County cohort, patients with ileal or ileocolonic extent at baseline were five to seven times more likely to experience an evolution in disease behavior from non-penetrating, non-fistulizing to fistula, abscesses or strictures than those with isolated colonic extent^[84]. The only biological index that has been identified as a predictor of more severe clinical course of adult CD is C-reactive protein (CRP)^[85]. Obviously, we don't need predictors at diagnosis when the disease is already considered as severe (stricturing or perforating lesions, multifocal or extensive lesions, severe systemic damage not reversible with treatment). Initiation of immunosuppressives or biologicals early in the disease course in patients at risk of, or already with, complicated disease seems reasonable since this may induce long-term deep remission. The goal should be the induction of mucosal healing and the achievement of symptom-free everyday life, both with

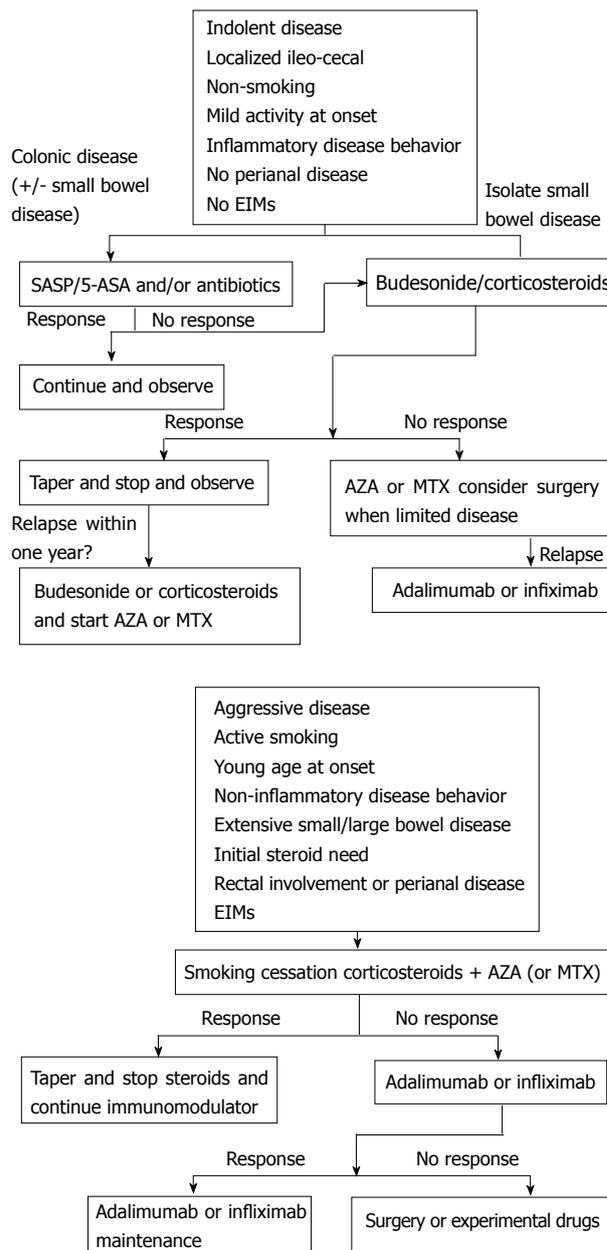

Figure 1 Treatment Algorithms. EIMs: Extraintestinal manifestations; SASP: Sulfasalazine; 5-ASA: Five-aminosalicylic acid; AZA: Azathioprine; MTX: Methotrexate.

minimal use of steroids. Clearly, the potential of early immunosuppressive or biological initiation must be weighed against the possibility of increased risk of treatment side effects, such as more frequent infections or a higher rate of malignancies. Overtreating patients who would have a benign course of the disease is the wrong choice, because of the risk of drug-induced complications. To obtain a sustained remission in CD it is important to optimize conventional therapy, to strictly monitor patients, to identify patients for biological therapy with full consideration of the individual risk/benefit profile, and to introduce biologicals in a timely manner, identifying patients who would most benefit from early use (Figure 1).

In conclusion, conventional treatments still remain an important option for management of patients with CD.

Abstract

AIM: To examine trends in and correlates of liver disease and viral hepatitis in an human immunodeficiency virus (HIV)-infected cohort.

METHODS: The multi-site adult/adolescent spectrum of HIV-related diseases (ASD) followed 29490 HIV-infected individuals receiving medical care in 11 U.S. metropolitan areas for an average of 2.4 years, and a total of 69487 person-years, between 1998 and 2004. ASD collected data on the presentation, treatment, and outcomes of HIV, including liver disease, hepatitis screening, and hepatitis diagnoses.

RESULTS: Incident liver disease, chronic hepatitis B virus (HBV), and hepatitis C virus (HCV) were diagnosed in 0.9, 1.8, and 4.7 per 100 person-years. HBV and HCV screening increased from fewer than 20% to over 60% during this period of observation ($P < 0.001$). Deaths

occurred in 57% of those diagnosed with liver disease relative to 15% overall ($P < 0.001$). Overall 10% of deaths occurred among individuals with a diagnosis of liver disease. Despite care guidelines promoting screening and vaccination for HBV and screening for HCV, screening and vaccination were not universally conducted or, if conducted, not documented.

CONCLUSION: Due to high rates of incident liver disease, viral hepatitis screening, vaccination, and treatment among HIV-infected individuals should be a priority.

INTRODUCTION

As highly active antiretroviral therapy (HAART) has improved the health of people living with human immunodeficiency virus (HIV), acquired immune deficiency syndrome (AIDS)-related morbidity and mortality have decreased and mortality from other illnesses, including hepatitis and liver disease, has grown^[1-4]. Among HIV-infected individuals, chronic co-infection with hepatitis B virus (HBV) and/or hepatitis C virus (HCV) are associated with excess morbidity and mortality^[1,4,5]. Liver dis-

ease, from HBV/HCV or other etiologies, is now one of the most frequent causes of death among HIV-infected people^[6,7].

Current care treatment guidelines for people living with HIV include HBV screening, plus vaccination as indicated, and HCV screening^[8]. However, it is not known how widely these guidelines are followed, nor are there clear recommendations regarding the frequency of repeat screening following a negative test for HBV and HCV when risk of infection remains present. Screening for HBV is particularly important before initiating antiviral therapy for HIV, because several therapeutic agents are active against both viruses and use of these agents may cause HBV resistance and subsequent hepatitis flares, if the provider is unaware of HBV infection. Similarly, initiation of HBV treatment without the protection of HAART can lead to HIV antiretroviral resistance.

It is also important to follow trends in HBV, HCV, and hepatic disease diagnoses among people living with HIV for care planning purposes, prevention, education, and treatment of preventable and modifiable factors contributing to liver disease. Although most serious liver morbidity among people living with HIV is attributed to HBV and HCV^[9,10], other factors contributing to liver morbidity may include the HIV virus itself, HIV-induced immunosuppression and/or inflammation, cirrhosis, hepatic carcinoma, alcohol use, aging, injection drug use, and hepatotoxic therapies-including some antiretroviral therapies.

To examine trends in, and factors associated with, both incident and prevalent liver disease and hepatitis diagnoses and screening in a modern HAART-era cohort, we analyzed data from a longitudinal medical record review cohort study, the national adult/adolescent spectrum of HIV-related diseases project 1998-2004.

MATERIALS AND METHODS

The adult/adolescent spectrum of HIV related diseases (ASD) project was a multicenter medical record review surveillance project funded by the centers for disease control and prevention (CDC) and conducted in Atlanta, Detroit, Seattle, Denver, Houston, Dallas, San Antonio, Puerto Rico, New Orleans, Los Angeles, and New York City^[11]. HIV-infected persons of at least 13 years of age who attended participating clinics were eligible for inclusion. ASD began data collection in 1990 and continued until 2004. Data for this manuscript were left truncated to start in 1998 due to protocol revisions at that time-including the addition of hepatitis screening-which remained in place through the project end in 2004. Medical records of ASD enrollees were retrospectively reviewed for the 12-mo period prior to their enrollment date, and at subsequent six month intervals until death, relocation, or loss to follow-up (no contact for 18 mon). Information collected included basic demographic data, mode of exposure to HIV, prescription of antiretrovirals and other medications, CD4+ T-lymphocyte (CD4+) counts, HIV RNA viral

load, complete history of AIDS-defining opportunistic illnesses (OIs)^[12], other infections, selected medical and psychosocial conditions, and behaviors of medical importance. Over 100 medical facilities participated in ASD, including HIV specialty clinics, private practitioners' offices, and community clinics, both hospital-based and freestanding. Men of color and women were oversampled at selected sites. All data were collected by trained abstractors; sites conducted a variety of quality assurance activities, including duplicate record abstraction audits and double data entry.

To describe the mode of HIV infection, we used four categories: men who have sex with men (MSM), injection drug users (IDU), individuals with both exposures (MSM-IDU), and other, including heterosexual exposure to an individual with HIV infection or with a known HIV risk and blood/blood product exposure (transfusion, blood products to treat hemophilia, organ transplant recipient, health care workers with needle stick exposure). For these analyses, substance use included those with a history of IDU as an HIV risk factor, and those with ongoing IDU, non-injection use of illicit drugs (including cocaine and marijuana), and problem alcohol use (defined as a diagnosis of alcoholism or treatment for past or current alcoholism). Cigarette smoking and other tobacco use was not collected in the national ASD project.

HBV and HCV screening for each year was defined as screening conducted up to and including each year individuals contributed follow-time to the project. A prior diagnosis of HCV or HBV was also considered indicative of screening for each infection. To examine trends in prevalence over time and overall death rates, individuals with a prior diagnosis of chronic HBV or any diagnosis of HCV or liver disease were considered to have these conditions in their diagnosis year and all subsequent years of follow time. Acute and chronic HBV and HCV infection were defined by provider diagnosis or laboratory evidence. IgM anti-HBc was considered diagnostic of acute HBV and IgG anti-HBc, or other characteristic antigen and antibody combinations, distinguished chronic HBV. Age at entry was coded as 14-29, 30-39, 40-49, 50-59, and 60 years and greater. Nadir CD4+ was aggregated to < 200, 200-499, and 500+ CD4+ cells/ μ L. Indicator (dummy) variables were used for mode, race/ethnicity, and nadir CD4+ cell count with MSM, Blacks, and CD4+ \geq 500 cells/ μ L as reference groups. Intensity of health services utilization was measured with a grouped continuous variable of the total number of outpatient visits (in 10 visit increments).

An aggregate variable, "liver disease", was created and included cirrhosis (both alcoholic and non-alcoholic), necrosis, abscess, primary liver cancers and liver failure. Liver disease included International Classification of Diseases 9th Revision (ICD-9) codes 570 (acute and subacute necrosis of liver), 571 (chronic liver disease and cirrhosis), 572 (liver abscess and sequelae of chronic liver disease), 573 (other disorders of liver), 572.3 (portal hypertension), 277.1 (α 1 antitrypsin deficiency), 456.0-456.2 (esopha-

geal varices), 789.5 (ascites), and 275.1 (Wilson's disease). Esophageal varices and ascites may not be specific for liver disease; therefore, we compared characteristics of individuals with liver disease including and excluding these additional diagnoses, and found the populations were nearly identical before making the decision to include these with liver disease. HBV and/or HCV alone, when we were able to distinguish these, were not sufficient to define liver disease. A dichotomous variable used only through 1999 indicating liver failure was also included with liver disease. Liver failure was defined by medical practitioner diagnoses recorded in the medical record and supported by abnormal liver function tests, jaundice, and/or special hepatic dietary management. Liver neoplasms and morphology codes of malignant and not-otherwise-specified (NOS) neoplasms were collected.

Death rates

Follow time from 1/1/98 or start of observation until death or censor was calculated overall and for individuals diagnosed with chronic HBV, HCV, or liver disease—starting from the follow-up interval of diagnosis if after 12/31/1997. Death rates were calculated due to any cause and separately for deaths that may have been due to liver disease. Deaths that may have been due to liver disease were defined as those listing liver disease as a contributing factor on a death certificate or individuals with a diagnosis of liver disease during follow-up interval during in which death occurred (thus including individuals with a new or ongoing diagnosis of liver disease at the time of death or within six months of death).

Statistical analyses

Demographic characteristics of individuals with chronic HBV, any diagnosis of HCV, and liver disease were compared to individuals without these diagnoses by χ^2 testing (SAS version 9.1, Cary NC). Multivariate Cox proportional hazards analyses were performed to calculate estimates of the relative risks (proportional hazards ratio) of HCV, chronic HBV, and liver disease (excluding those with prevalent diagnoses at baseline) and simultaneously adjusting for HIV risk mode (specifically, IDU, MSM, and hemophilia), race/ethnicity, nadir CD4+ group (nadirs of < 200 cells/ μ L and 200-499 cells/ μ L), age, gender, alcohol use, IDU, antiretroviral use, intensity of health services utilization, and year entered cohort. Ninety-five percent confidence intervals are given for the proportional hazard ratios; intervals that do not include the value “one” are considered statistically significant. Individuals included in the multivariate analyses were required to have two or more outpatient visits documented in follow-up intervals ending in 1998 or later to minimize the contributions of persons unlikely to be assessed for any of the potential risk factors for liver disease (hepatitis, alcohol use, *etc.*). In the multivariate analyses examining liver disease as an outcome, all exposures were limited to those occurring prior to the diagnosis of liver disease. For chronic HBV and HCV, co-variables could be simultaneous with infection.

RESULTS

From January 1, 1998 to June 30, 2004, 29 490 individuals were followed for an average of 2.4 years per person, and for a total of 69 487 person-years. The proportion of the 29 490 observed each year from 1998 to 2004 was 56% in 1998, gradually declining to 42% in 2003; in 2004 (due to project end) 5% were followed. Liver disease was diagnosed in 3% of the cohort, HCV in 19%, and chronic HBV in 8% (Table 1). Individuals diagnosed with HBV, HCV, and liver disease were more likely to be male ($P < 0.001$), have a history of IDU ($P < 0.001$), use other illicit drugs ($P < 0.001$), be diagnosed with problem alcohol use ($P < 0.001$), and have more advanced HIV disease as measured by diagnoses of AIDS, including low nadir CD4 counts ($P < 0.001$). Sixty-five percent of individuals diagnosed with HCV had a history of IDU, relative to 25% overall. Twenty-five percent of HCV infected individuals were current IDU (medical records documented ongoing IDU over the course of observation) relative to 8% overall. Over half (57%) of individuals diagnosed with liver disease died over the period of observation, compared to a 15% overall mortality rate ($P < 0.001$).

Trends in hepatitis screening, HBV vaccination, and diagnoses of HBV and HCV

Cumulatively, 38% of the cohort was documented to have been screened for HBV and 37% had been screened for HCV. Screening increased significantly over the seven years ($P < 0.0001$ χ^2 for trend test for HBV and HCV, Figure 1). Repeat screenings were uncommon, even in the presence of ongoing risk. For example, for individuals without any documented HBV vaccination and with ongoing injection drug use noted in their medical record, only 12% of those followed for two or more years had two or more HBV screenings documented.

The proportion of the cohort diagnosed with chronic HBV (at any time up to and including the observation year) increased from 7% in 1998 to 8.5% in 2004 ($P < 0.0001$). Similarly 9% were diagnosed with HCV in 1998, increasing to 24% in 2004 ($P < 0.0001$). Over the course of follow-up, chronic HBV was diagnosed at a rate of 1.8 per 100 person-years, and HCV was diagnosed in 4.7 per 100 person-years (Table 2). Between 1998 and 2003, vaccination for HBV among those without a prior diagnosis of HBV increased from 10% to 28%.

Liver disease

Among the 832 individuals diagnosed with liver disease, 262 (31%) were diagnosed with non-alcoholic (or alcohol not specified) cirrhosis, 165 (20%) with alcoholic cirrhosis, 3% with a primary liver cancer, 3% with liver failure not otherwise specified, (these numbers and percents include 7% with two or more of these conditions diagnosed), and 244 (29%) with other liver diseases (Table 3). Of the 832 with liver disease, 212 individuals (25% of those with liver disease, 1% of the cohort) had a liver disease diagnosis

¹All comparisons of clinical and demographic characteristics presented in this table between individuals with and without chronic Hepatitis B virus and with and without liver disease are highly statistically significant (P values \leq 0.001); ²All except two comparisons between individuals with and without chronic hepatitis C virus (HCV) are highly statistically significant (P values \leq 0.001). These exceptions are gender and HCV (P = 0.004) and highly active antiretroviral (HAART) and HCV (P = 0.05). MSM: Male-male sex; IDU: Injection drug use.

present at baseline (prevalent disease) and 621 individuals (75% with liver disease, 2% of the cohort) had new or incident diagnoses over follow-up (Table 2). Between 1998 and 2004, the proportion of individuals followed each year with a diagnosis of liver disease increased from 1.8% to 2.2% (χ^2 for trend P value = 0.03, Figure 1). Overall, 496 of the 5005 people who died (9.9%) had a diagnosis of liver disease. This ranged from 8.6% to 11.0% over the seven years of the study, with no significant trend (data not shown).

Death rates

Table 4 presents the death rates per 1000 person-years observed among the entire ASD cohort from 1998-2004, and separately for people with diagnoses of liver disease, chronic HBV, HCV, and none of these diagnoses. Death rates ranged from 61/1000 for individuals without liver disease, HCV, and chronic HBV diagnoses to 74/1000 for people diagnosed with HCV. About 1% of overall deaths may have been due to liver disease among the entire co-

Table 4 Overall death rates and deaths potentially due to liver disease among individuals with chronic hepatitis B, hepatitis C, and liver disease diagnoses among human immunodeficiency virus-infected individuals followed by the Adult/adolescent spectrum of human immunodeficiency virus-related diseases project, 11 U.S. metropolitan areas; 1998-2004

| Diagnoses | Number of deaths | Overall death rate [Per 1000 person-years (py)] | Potential liver disease death rate [(Per 1000 person-years py)] ¹ |
|------------------------|------------------|---|--|
| Entire cohort | 4461 | 64.2 | 2.9 |
| Liver disease | 475 | 73.0 | 31.0 |
| HCV | 1073 | 74.4 | 7.0 |
| Chronic hepatitis B | 455 | 68.9 | 6.4 |
| No HCV, no chronic HBV | 3099 | 61.4 | 1.5 |

¹A potential liver disease death was a death where liver disease was included as a contributing factor on a death certificate or a death occurring within approximately six months of a new or ongoing diagnosis of liver disease. HCV: Hepatitis C virus; HBV: Hepatitis B virus.

hort. Among those with HCV or chronic HBV, about 2% of deaths may have been due to liver disease (defined as liver disease as a contributing illness on a death certificate or as a new or ongoing diagnosis within six months of death). Death rates potentially attributable to liver disease ranged from 3/1000 for the entire cohort to 31/1000 among those with a prior diagnosis of liver disease.

Overlapping diagnoses and death rates

Figure 2 presents the cumulative number and proportions of individuals with HCV, HBV, liver disease, overlapping diagnoses, and none of these three conditions. Cumulative death rate per 100 persons and 95% confidence intervals for HCV, HBV, liver disease, and overlapping diagnoses are presented in Figure 3. Death rates were similar for individuals with only HBV and only HCV, but increased with dual HBV & HCV infection. The highest death rates occurred among individuals with liver disease regardless of HBV, HCV, and dual HBV/HCV infection status.

Multivariate analyses

Correlates of incident liver disease were examined by proportional hazards regression among 29 279 individuals (excluding the 212 with prevalent disease; Table 2). All demographic and clinical characteristics from Table 1 were included as covariates with the exception of AIDS as it was redundant with AIDS-defining CD4+ cell count categories. We also adjusted for intensity of health services utilization and year of enrollment. IDU and hemophiliacs had more than double the risk of liver disease relative to those without these risk factors (Table 5). Relative to Blacks, all other racial/ethnic groups had a two to three-fold higher risks of a liver disease diagnosis. Risk of liver disease also increased

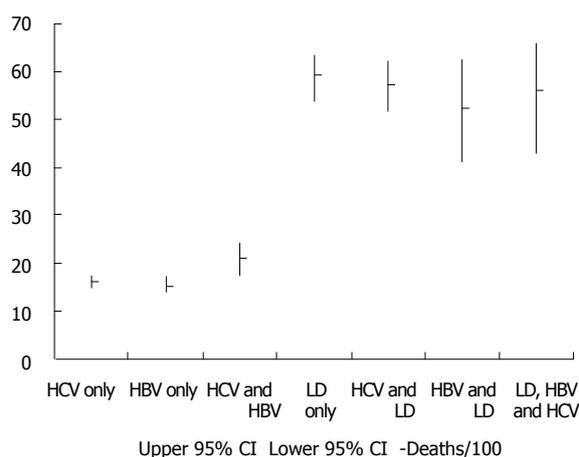

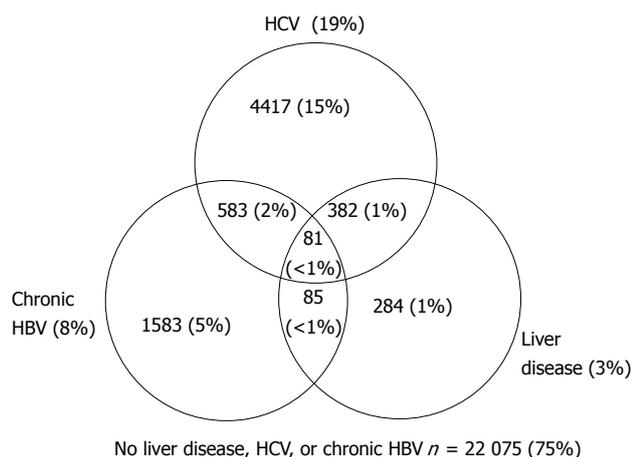

Figure 2 Cumulative prevalence of hepatitis C virus, chronic hepatitis B virus, liver disease, and overlapping diagnoses among 29 490 individuals; Adult/adolescent Spectrum of human immunodeficiency virus-related Diseases Project, 11 U.S. metropolitan areas; 1998-2004. HCV: Hepatitis C virus; HBV: Hepatitis B virus.

| Chronic HBV | 1.4 (1.1-1.7) | N/A | 1.3 (1.1-1.4) |
| HCV | 1.6 (1.3-1.9) | 1.6 (1.4-1.8) | N/A |

¹Adjusted for each factor in the model plus intensity of health services utilization (number outpatient visits in a grouped linear variable) and study entry year. HAART: Highly active antiretroviral; CD4: CD4+ lymphocyte; N/A indicates not applicable; HBV: Hepatitis B virus; HCV: Hepatitis C virus; MSM: Male-male sex; IDU: Injection drug use.

with increasing age, with AIDS-defining nadir CD4+ cell counts (< 200 cells/ μ L), alcohol use, and a prior diagnosis of HBV or HCV. Once these other factors were adjusted for, neither HAART in aggregate nor any specific antiretrovirals were associated with excess risk of liver disease.

Correlates of chronic HBV and HCV diagnoses were also examined by multivariate proportional hazards regression analyses, excluding those with prevalent chronic HBV ($n = 1120$) and HCV ($n = 2334$), respectively. IDU and hemophiliacs were 4.7-fold and seven-fold more likely to be diagnosed with HCV relative to those with other HIV risk factors. Men, Whites, Latinos, and those co-infected with HBV were all more likely to be diagnosed with HCV.

HCV risk also increased with age among individuals 30 years of age and older relative to those less than 30 years of age. Factors associated with chronic HBV diagnosis include male gender, MSM, IDU, lower CD4+ cell count nadir, alcohol use, and co-infection with HCV.

Liver cancers

There were 25 diagnoses of liver cancer in the cohort. All of these patients were documented to have died, excluding three individuals lost to follow-up. Fifteen of the 25 had hepatocellular carcinoma, four had other specified morphologies (one diagnosis each of sarcoma, hepatoblastoma, lymphoma, and giant cell type), and six were

unspecified. Of the 25, 13 were diagnosed with HCV and 10 with chronic HBV (this includes two diagnosed with both). Of the four diagnosed with neither virus, none had evidence of HBV or HCV screening documented in their medical chart.

DISCUSSION

We found that chronic HBV, HCV, and liver disease were frequent diagnoses among HIV-infected people followed in the ASD project from 1998 to 2004. Roughly one person out of a hundred people followed for a year was diagnosed with liver disease, two per 100 followed for a year were diagnosed with chronic HBV, and five out of a hundred were diagnosed with HCV. We observed relatively low rates of HBV and HCV screening, especially in earlier years of observation, despite consistent recommendations that all HIV-infected patients be screened for both infections in the guidelines for the treatment of HIV and prevention of opportunistic illness (including screening of HBV prior to administration of vaccine) covering 1998-2004^[13]. Fortunately, over the observation period, increasing proportions of individuals were screened for HBV and HCV. Diagnoses of HBV and HCV also increased over the seven years of the study. Among individuals who died, liver disease was present at any point in nearly 10%, and liver disease was listed as a contributing factor or as a new or ongoing diagnosis within six months of death in 1% of deaths. The overall prevalence of liver disease was about 1% each year-this increased only slightly over the seven years. As expected, IDU was associated with all three outcomes examined by multivariate analyses (chronic HBV, HCV, and liver disease). Hemophilia, and thus an exposure to unscreened blood products, was most strongly associated with HCV, and alcohol use was associated with liver disease.

Other researchers have found high rates of liver diseases and viral hepatitis among HIV-infected persons, especially HIV-infected hemophiliacs and injection drug users. The prevalence of HBV and HCV infection varies within HIV-infected cohorts largely due to the underlying prevalence of these infections in the general populations from which the cohorts are drawn and the proportion of IDU included. Relative to the 8% with chronic HBV and the 19% with HCV in our cohort, a New York City HIV clinic following 5639 people living with HIV from 1999 until 2007, found that 4% were HBV-infected and 25% were HCV infected^[14]. The HIV Outpatient Survey (HOPS) conducted at 10 facilities in eight U.S. cities followed 7618 HIV-infected individuals 1996-2007 and found a 24% prevalence of HCV^[15]. In a serological study of incarcerated individuals in three U.S. cities, of those who were HIV-infected, 38% were co-infected with HCV and 8% were HBsAg positive^[16].

The D:A:D Study followed 23441 individuals on three continents between 1999 and 2004, finding a 23% prevalence of HCV and a 7% prevalence of active HBV^[17]. In this study, HCV was associated with a seven-fold excess

risk of liver-related deaths (e.g. hepatocellular carcinoma, end stage liver disease, or hepatic failure) and active HBV was associated with a four-fold excess risk of liver-related deaths. This compares to our similar finding of liver related deaths occurring over four times more frequently among individuals infected with HCV or chronic HBV relative to uninfected individuals. In the Swiss HIV Cohort Study, 37% of 3111 people living with HIV were HCV-infected; this included 92% of IDU and 7% of those with other HIV risks^[18]. In this study, 9% of HCV-co-infected individuals died relative to 4% of those without HCV. Of the deaths among HCV-infected individuals, 16% were possibly to definitely associated with end-stage liver disease relative to 5% of deaths among HIV-infected individuals without HCV^[18]. In the Multicenter Cohort Study of MSM, about 8% of HIV-infected men followed between 1984 and 2000 were HBsAg positive, and liver-related mortality was about seven times higher (14 deaths per 1000 person-years) among HBsAg positive men relative to HBsAg negative men (two deaths per 1000 person-years)^[19].

Of 755 people living with HIV evaluated following initiation of antiretrovirals at one Italian HIV clinic, 3% developed severe hepatotoxicity (4/100 person-years). Nearly all (96%) of these patients had evidence of HCV infection (relative to 67% without hepatotoxicity), 19% had evidence of HBV, and 19% had a history of alcohol abuse (relative to 7% and 13% prevalence of these diagnoses among those without hepatotoxicity, respectively)^[20]. This is consistent with our finding of no excess risk of liver disease for individuals prescribed antiretrovirals once these other factors (HCV, HBV, alcohol use, *etc.*) were controlled for by multivariate analyses. In a Veteran's Affairs cohort with comprehensive evaluations of 299 HIV-infected individuals over 6 mo, 27% had abnormal liver functions and for 51% of these, no underlying cause was established. Among the remainder, 30% had non-alcoholic fatty liver disease as a diagnosis, alcohol was attributed to 13%, chronic HBV to 9% and chronic active HCV to 5%^[21].

Studies of HIV-infected hemophiliacs include a cohort study of 158 HIV-infected hemophiliacs followed in the pre- and post-HAART eras^[22]. The predominant cause of non-AIDS mortality in both periods was end-stage liver disease (ESLD). Of 223 HIV-infected hemophiliacs without clinical AIDS, 9% of those co-infected with HCV developed liver failure after 10-20 years^[23]. In Germany, 144 HIV and HCV co-infected hemophiliacs were examined, and the authors concluded that declining immune function may be associated with progression of liver failure^[24].

Relative to the increase in HCV screening that we observed (from 11% to 69%), the HOPS study documented a very similar trend-HCV screening increasing from 11% to 77% from 1996 to 2007^[15]. However, even if patients are screened, few receive ongoing screening despite ongoing risk, fewer than half are evaluated, and a minority are treated, reflecting the many hurdles that HIV and HCV and HIV and HBV co-infected patients must surmount to

be appropriately managed and treated for HBV and HCV when indicated^[25,26].

Although the number of liver cancers we observed was small ($n = 25$), all 21 with hepatitis screening documented were HBV or HCV-infected. Our study was not designed to compare the occurrence of liver cancer among people living with HIV relative to the general population, but other researchers have found three to six fold excess risk of liver cancer associated with HIV infection^[27,28].

Limitations of our analyses included that the data were collected solely by medical record review. Collecting data by chart review rather than targeted medical examinations, may have introduced errors. Exposures and diagnoses may have been missed, especially if an individual sought medical care at facilities other than those included in ASD. Other diseases recorded may have been in error, such as mistaking a “rule out” diagnosis with a true diagnosis. Further, the use of ICD-9 codes to define liver disease likely resulted in some losses of sensitivity and specificity (for example, including a code such as 571.4-chronic hepatitis-which might have included viral hepatitis infections without any known liver damage). Similarly ICD-9 code 571 includes both fatty liver and nonalcoholic steatohepatitis (NASH), which could not be distinguished from each other without additional information. Information on performance of liver biopsy was not collected, and biopsies were not likely to have been frequently performed, leaving us to rely upon broad clinical diagnoses rather than histological diagnoses. HBV and HCV were particularly difficult diagnoses to ascertain through chart review because of under-diagnosis-especially of asymptomatic infections, false negative screening tests due to low or transient antibody production^[29-31], and abstractor (and practitioner) confusion regarding distinguishing markers of acute, chronic, and chronic active or chronically persistent infection. Observed trends in HBV and HCV diagnoses could have been caused by increases in screening, not increases in incidence and prevalence. Some known predisposing conditions of certain liver disease (such as obesity) were not routinely collected. Deaths and causes of death may have been under-ascertained as well, as some ASD sites linked to core surveillance and national death index data and others did not. Finally, although ASD data collection ended in 2004, we believe there have been no major changes in hepatitis screening, HBV vaccination, or liver disease trends among HIV-infected individuals and that our findings remain highly relevant today.

Despite its limitations, ASD provided a large single cohort in a contemporary HAART era, collected with a consistent protocol and including a wealth of data on the screening and diagnosis HBV and HCV and liver disease and mortality as outcomes. Although HIV case reporting was not required throughout the U.S. during the period of our study, the socio-demographic characteristics (age, gender, race-ethnicity, and HIV risk category) of 38 398 newly diagnosed HIV cases in 2004 for the 34 states and five dependent areas, with name-based reporting at that

time, were highly similar to the characteristics of ASD, suggesting ASD was largely representative of national HIV cases at this time^[32].

In conclusion, patients with HIV and liver disease had a much higher mortality compared to those with HIV without a liver disease diagnosis. Although HBV vaccination rates have improved and screening rates for HBV and HCV have climbed steadily, they are still inadequate, and efforts are needed to improve vaccination and screening rates. The high rates of incident HCV (5/100 person-years) indicate that individuals at risk should be screened and while remaining at risk, re-screened on a regular basis. Similarly, a sizable HBV incidence (2/100 person-years) supports improved screening and vaccination^[33]. Further studies are needed to determine the optimal frequency of repeated HCV screening among those with ongoing risk, as well as a frequency to re-visit HBV vaccination among unvaccinated individuals. Until better data are available, annual screenings for HCV and HBV vaccination discussions are suggested. Treatment of HBV and HCV should be considered for all HIV co-infected individuals.

COMMENTS

Background

Despite widespread availability of antiretroviral treatment in the U.S., over 17 000 people living with human immunodeficiency virus (HIV) are estimated to die each year. Although increasing, the median age at death among HIV-infected people was 46 years in 2006, indicating most HIV deaths occur among relatively young individuals. Hepatitis and liver disease are major causes of premature death among people living with HIV. The authors conducted this review of liver disease and hepatitis screening and diagnoses to describe preventive care and the impact of these conditions among HIV-infected individuals receiving medical care in the U.S.

Research frontiers

In this report, the authors examined hepatitis and other hepatic diseases in a dynamic medical record review cohort of over 29 000 HIV-infected people. The authors found, over the study period of 1998 to 2004, improvements in hepatitis screening and hepatitis B vaccination, but the authors also saw there was much room for improvement in screening and vaccination coverage. On average, among 100 HIV-infected people followed for a year one person had a diagnosis of acute hepatitis B infection, two were diagnosed with chronic hepatitis B, five were diagnosed with hepatitis C, and one person with liver disease. Fewer than one-third (28% in 2003) of those without a documented diagnosis of hepatitis B had evidence of any hepatitis B vaccination.

Innovations and breakthroughs

The authors examined hematological diagnoses and risk factors in nearly 30 000 HIV infected individuals from a broad range of HIV risk groups and geographic locations within the U.S. Among other findings, the authors saw elevated death rates among people with chronic hepatitis B, hepatitis C, and liver disease, but mortality rates were elevated the most among individuals with liver disease, with or without chronic hepatitis B and hepatitis C. When the authors conducted a multivariate analysis, the authors saw that Blacks were at lower risk of liver disease than individuals with other racial/ethnic identities, older individuals, injection drug users, alcoholics/problem drinkers, and individuals with AIDS all had increased risks of liver disease. Antiretroviral use was not associated with liver disease.

Applications

The authors' results highlight a need for improved hepatitis screening and vaccination. All HIV-infected individuals should be screened for hepatitis and, if at risk, vaccinated for hepatitis B. Uninfected individuals should be counseled in hepatitis risk reduction strategies, and individuals with chronic hepatitis infections should be assessed for treatment. It is likely that the authors' estimates

for hepatitis screening and vaccination are low, and that documentation of prior screening and vaccinations may have been missed, for example if they occurred at medical facilities not participating in ASD.

Peer review

A series of experiments are well-planned and well-performed and this manuscript is well written.

Abstract

AIM: To analyze the radiological features of multiple primary carcinoma (MPC) in the upper gastrointestinal (GI) tract, study its biological characteristics and evaluate X-ray examination in its diagnosis.

METHODS: Hypotonic double-contrast GI radiography was performed in 59 multiple primary carcinoma cases, pathologically proved by surgery or endoscopy biopsy. Radiological findings were analyzed.

RESULTS: Of the 59 cases, esophageal MPC (EMPC) was seen in 24, esophageal and gastric MPC (EGMPC) in 27 and gastric MPC (GMPC) in 8. Of the 49 lesions found in 24 EMPC, hyperplastic type was seen in 23, medullary type in 9. The lesions were located at the upper ($n = 17$), middle ($n = 19$) or lower ($n = 13$) segment of the esophagus. In 27 EGMPC, the esophageal lesions were located at the middle ($n = 16$) or lower ($n = 11$) segment of the esophagus, while the gastric le-

sions were located at the gastric cardia ($n = 16$), fundus ($n = 1$), body ($n = 3$) and antrum ($n = 7$). The esophageal lesions were mainly of the hyperplastic type ($n = 12$) or medullary type ($n = 7$), while the gastric lesions were mainly of the hyperplastic type ($n = 18$). A total of 119 lesions in the 59 patients with synchronous multiple carcinoma were proved by surgery or endoscopy biopsy, and preoperative upper radiographic examination detected 100 of them (84.03% sensitivity). Eighteen (52.94%) of the T₁ lesions were found during preoperative diagnosis by radiographic examination. Moreover, only 3 (3.53%) of the T₂₋₄ lesions were misdiagnosed.

CONCLUSION: Hypotonic double-contrast upper gastrointestinal examination, providing accurate information about lesion morphology, location and size, can serve as a sensitive technique for the preoperative diagnosis of MPC.

INTRODUCTION

Although malignant tumors are currently detected more often than in the past due to continued and vast improvements in medical modalities, the incidence of synchronous multiple primary carcinoma (MPC), defined as two

or more primary carcinomas occurring in an individual simultaneously, is low^[1]. Most of these synchronous cancers are in the head and neck region. Other frequently reported sites of synchronous cancer associated with esophageal cancer are the stomach, lung, and urinary bladder^[2,3]. The mucous epithelium of the head and neck, lung, and esophagus is exposed to common carcinogenic agents, leading to multiple carcinomas in these regions. The etiology of synchronous multiple primary carcinomas is still unclear, strong epidemiologic evidence implicates tobacco as the main carcinogen and alcohol as a promoter of carcinogenesis^[4]. Other potential risk factors include hot beverages^[5], nutritional deficiencies^[6], pickled vegetables, nitrosamine-rich food^[7], and some genetic factors^[8,9]. Radiation therapy is also associated with esophageal cancer^[8,10]. Their coexistence can be problematic for surgeons, oncologists and pathologists, as regards diagnosis, treatment and follow-up.

Multiple primary malignant neoplasms in a single patient have been well documented with regard to the frequency of occurrence of primary multiple carcinomas, identification of high-risk groups, early diagnosis, treatment methods, and prognostic factors over the past hundred years^[11]. For some reason, synchronous multiple primary carcinomas of the upper gastrointestinal (GI) tract can often be overlooked at the time of diagnosis, and so far, there has not been a consensus on how best to diagnose mucosal lesions of multiple primary carcinomas in the upper GI tract: by endoscopy or barium radiography? The double-contrast upper GI examination is a safe, noninvasive, inexpensive and cost-effective test for the work-up of a host of GI diseases. However, reports exclusively on evaluating X-ray examination in the diagnosis of synchronous MPC of the upper gastrointestinal tract have been few. In this study, we retrospectively analyzed 59 synchronous MPC cases proved by surgery or endoscopy biopsy: each of the patients underwent radiographic examination. The aim was to analyze the radiological features of synchronous MPC in the upper GI tract, study its biological characteristics, evaluate X-ray examination in its diagnosis, and seek ways to improve its preoperative diagnosis.

MATERIALS AND METHODS

Patients

Patients with MPC were selected from January 1988 to December 2008 at the First Affiliated Hospital of Zhengzhou University. Of the 59 patients aged 42-85 years (mean: 61.20 years), 44 were men and 15 were women. Main clinical manifestations were choking or swallowing difficulties, some cases were associated with anemia, weight loss, abdominal pain and other upper GI signs or symptoms. Specimens for pathologic confirmation of the 59 cases were obtained by endoscopy biopsy alone in 13 patients, by endoscopy biopsy and surgery in 27, and by surgery alone in 19. Thirteen patients did not have surgery, either because they were not considered surgical candidates or because they chose to be treated elsewhere.

X-ray examinations

After 6-8 h of fasting, patients first received 20 mg hypotonic drugs as well as anisodamine (654-2) intravenous injection. Ten minutes later, the patient swallowed 3 g aerogenic agents, and then, as fast as possible, 150 mL of resuspended barium sulfate at 200% weight for volume (w/v). Three to four spot radiographs were obtained in sequence at different levels of the esophagus, and double-contrast esophagograms were obtained with the patient in the upright LPO position. Multi-position dynamic observation of the stomach and duodenum was performed for all cases, and all patients were pathologically confirmed by endoscopic biopsy or surgery.

Imaging criteria

According to the principle of Warren and Gates, multiple primary carcinomas are defined as follows^[12]: (1) Each lesion is histopathologically malignant; (2) Each lesion is separated by the normal mucosa; and (3) Each lesion is not the result of local extension or metastasis of another lesion. Multiple primary cancers may be synchronous or metachronous depending on the interval between their diagnosis. Synchronous carcinomas were diagnosed simultaneously or within an interval of about 6 mo, and metachronous carcinomas were secondary cancers that developed more than 6 mo after the diagnosis of primary cancers usually after treatment of primary lesions. In our series of 59 cases, all were synchronous multiple primary carcinoma.

The radiographs were reviewed retrospectively by two authors to determine the location, size, morphology and interval distance of these tumors. Lesions were classified morphologically as hyperplastic, medullary, infiltrative, ulcerative or mixed type. Pathologic records were also reviewed to determine the postoperative histological classification, depth of invasion and number of lesions being misdiagnosed in this group.

Statistical analysis

We evaluated the clinicopathological differences of esophageal lesions between esophageal MPC (EMPC) and esophageal-gastric MPC (EGMPC), and of gastric lesions between gastric MPC (GMPC) and EGMPC. Statistical analyses were performed using software from SPSS for Windows 17.0. The statistical methods used included χ^2 test for categorical variables and *t* test for continuous variables. *P* < 0.05 was taken to indicate statistical significance.

RESULTS

Characteristics of MPC

In our series of 59 cases, all were synchronous multiple primary carcinoma, and mostly occurred in males: male/female ratio = 2.93/1, 71.19% of the patients were older than 55 years, and average age was 61.2 years old. Table 1 shows the age and sex distribution of these 59 patients.

Multiple esophageal carcinoma was seen in 24, and 49 lesions were found. One case was a triple lesion (Figure 1), and the remaining 23 cases were double lesions (Figures

GMPC: Gastric multiple primary carcinoma; EGMPC: Esophageal-gastric multiple primary carcinoma; EMPC: Esophageal multiple primary carcinoma.

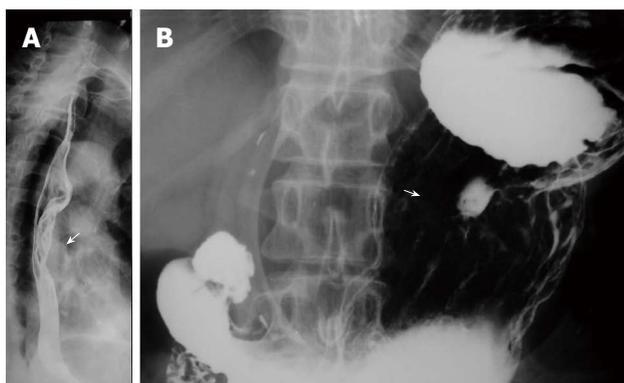

Figure 7 Forty six-year-old female with esophageal-gastric multiple primary carcinoma. The esophageal lesion was proliferative located at the middle (↑); the gastric lesion was ulcerative located at the body (↑).

tric cardia (*n* = 16) (Figure 5B), followed by antrum (*n* = 7) (Figure 6B), body (*n* = 3) (Figure 7B) and fundus (*n* = 1). Seventeen proliferative lesions were mainly located at the gastric cardia and the fundus, numbers of ulcerative type and infiltrating type were 6 and 4 respectively, found mainly at the antrum. In this series, one case of esophageal lesion was pathologically confirmed as sarcoma with a size of 9.1 cm × 5.3 cm × 5.2 cm, the others were squamous cell carcinoma. Twenty-three cases of gastric lesions were adenocarcinoma, and the other four cases were squamous cell carcinoma located at the cardia. From Table 3, we see that the largest dimension of esophageal lesions in EGMPC (5.56 ± 2.34 cm) was significantly larger than that of EMPC (4.33 ± 2.35 cm), and T₁ esophageal lesions were more frequent in EGMPC, especially in the middle region.

Eight patients (13.56%) were found to have synchronous multiple gastric carcinoma, all were double lesions and divided into 2 categories: main lesions (larger or

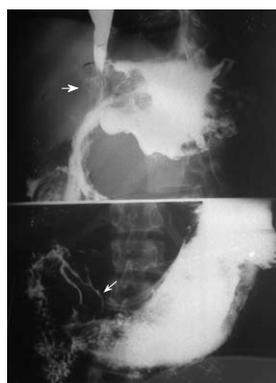

Figure 8 Fifty nine-year-old male with two gastric lesions. The main lesion was proliferative (↑) located at the cardia, with fundus infiltration; the additional one was also a proliferative lesion located at the antrum, with disruptive mucosa (↑). All were adenocarcinoma, pathologically proved.

advanced lesion) and additional lesions. The additional lesions were mostly located in the cardia; of them, two cases had evidence of invasion of the gastric fundus (Figure 8). Four main lesions were located in the antrum, and three at the gastric body. Thirteen (81.25%) cases were proliferative lesions, of which five cases were early gastric protruded lesions. All lesions were adenocarcinoma, pathologically proved. Table 4 shows that the main lesions were significantly larger than the accessory lesions (*P* = 0.001). Regarding the depth of invasion, T₁ lesions were more frequent in accessory lesions, especially in the cardia. Moreover, the largest dimensions of gastric lesions in EGMPC were significantly larger than those of GMPC (*P* = 0.007), and also showed significant differences in the depth of invasion.

Accuracy of pre-operative diagnosis

A total of 119 lesions in the 59 patients with synchronous multiple carcinoma were proved by surgery or endoscopy biopsy, and preoperative upper radiographic examination detected 100 of them (84.03% sensitivity). Thus, 19

(15.97%) lesions were missed out of a total of 119 lesions. Regarding the depth of invasion, 18 (52.94%) of the T₁ lesions were accurately found out of a total of 119 lesions during preoperative diagnosis by radiographic examination. Moreover, only 3 (3.53%) of the T₂₋₄ lesions were misdetected. Table 5 summarizes the clinicopathological characteristics of 19 misdetected lesions in the 19 patients with MPC. By retrospectively reviewing the missed radiographs, we found four lesions mistaken for bubbles, uneven coating of barium appearance, and two lesions in the gastric cardia and lower esophagus were misdiagnosed as invasion. Of the 19 missed lesions, 16 lesions were microscopic early stage and T₁ lesions. Moreover, missed gastric lesions showed a tendency to be of the flat type. The mean size of the missed lesions was 2.40 ± 1.01 cm.

DISCUSSION

X-ray features and clinicopathological characteristics of MPC

Interest in multiple primary malignancies is long-standing, since Warren and Gates description in 1932, and several reports have indicated that the incidence of MPCs has been increasing in recent years. The incidence of synchronous cancers in patients with esophageal cancer varies from 3.6% to 27.1%^[2,13]. In this series, we found that synchronous MPCs in the upper gastrointestinal tract mostly occurred in males: ratio of males/females = 3.21/1, 86.21% of the patients were older than 55 years, and average age was 62.7 years old. As shown in Table 1, 87.5% of patients with multiple gastric carcinomas were men older than 55 years. These findings are comparable to previous studies, and we conclude that elderly individuals aged 65 years or more are at significantly greater risk for multiple gastric carcinomas^[14-16].

In our findings, X-ray characteristics of MPC in general were as follows: (1) Each lesion had a familiar X-ray appearance; (2) Normal X-ray appearance, namely continuous mucous membrane and soft margins, was seen between two lesions; (3) The main morphological feature of multiple primary carcinoma lesions, regardless of whether in the esophagus or stomach, was proliferative in 34 and 30, respectively, total 64 (53.78%); (4) The size of proliferative esophageal MPC lesions was limited, with an average of 2.7 cm; while the size of medullary lesions was relatively extensive, with an average of 7.6 cm; and (5) The distance between every two esophageal lesions ranged from 5 to 13, 8.21 cm on average.

Lesions of esophageal MPC were more commonly located at the upper (17/49) segment close to their predilection sites, which suggests we should pay more attention to observing lesions of the upper segment rather than the middle and lower segments. As to synchronous esophageal-gastric carcinoma, we found that the esophageal lesions were concentrated in the lower segment, while the gastric lesions were concentrated in the cardia, and this finding indicates that the occurrence of the tumor had a concentric trend. Concerning the depth of invasion,

there were significant differences between the first lesion and the second lesion in esophageal MPC; T₁ lesions were more frequent in first lesions (75%), especially in the upper segment. Furthermore, from Table 3 we see that esophageal lesions of synchronous esophageal-gastric carcinoma tend to be less invasive than esophageal MPC ($P = 0.036$). These findings are in accordance with Nagasawa *et al.*^[3], and support the concept that the second malignancy occurred late after carcinogenesis of the main carcinoma lesion or was less aggressive to invade^[17]. In addition, we found that in EMPC the sizes of the first lesions were significantly smaller than second ones; the mean size of esophageal lesions in EMPC was 4.33 ± 2.35 cm, significantly smaller than that of EGMPC (5.56 ± 2.34 cm).

Only 8 patients (13.56%) were found to have synchronous multiple gastric carcinoma, the additional lesions mostly located in the cardia. Of them, 2 cases had evidence of invasion of the gastric fundus. Four main lesions were located in the antrum, and 3 at the gastric body. Lee *et al.*^[18], however, believed that the distribution of location was not significantly different between the main and accessory lesions, and the fact that our sample size was very small should be taken into account. Nevertheless, all assessments indicated the main lesions were significantly larger than the accessory lesions. Regarding the depth of invasion, T₁ lesions were more frequent in accessory lesions, especially in the cardia. Thus, more attention should be paid to this multi-positional location, and detailed and thorough examination is particularly critical. In addition, the largest dimensions of gastric lesions in EGMPC were significantly larger than those of GMPC ($P = 0.007$), and also showed significant differences in the depth of invasion. These findings are in accordance with Lee *et al.*^[18], and support the “collision theory”; that is, that early multiple gastric lesions “fuse” together to form single, advanced gastric cancer lesions^[15].

Diagnostic value of X-ray in MPC compared with endoscopy

So far, there has not been a consensus on how best to diagnose mucosal lesions of the upper GI tract. Despite the diagnostic advantages of upper endoscopy, it is more expensive and requires more staff and technological expertise than upper GI X-ray. In financial terms, the test is not as effective if the cost is high. The cost of upper endoscopy is 3 to 4-fold more expensive than that of upper GI X-ray in Japanese gastric cancer screening programs^[19,20]. Furthermore, it is unlikely that upper endoscopy would be feasible as a mass screening program, even in highly developed countries such as Japan, because of a lack of experienced endoscopists^[19,21]. It is also a more invasive procedure than the barium examination, and associated with a small but measurable risk of complications related to sedation on perforation of the upper gastrointestinal tract^[22,23]. In addition, it is difficult to find lesions located in the upper and middle thirds of the stomach because of technical difficulties of forward-viewing endoscopy.

In a review of a large series of gastric cancers, ma-

lignant tumor was diagnosed or suspected by the use of double-contrast technique with a sensitivity of 96%^[24]. This is comparable with the reported sensitivity of endoscopy and biopsy of 94% and 99%, respectively^[25]. In the same study, only 4% of all patients had been recommended for endoscopy because of the unequivocal findings in double-contrast studies^[24]. In our investigation, preoperative upper radiographic examination detected 100 out of 119 lesions (84.03% sensitivity). Regarding the depth of invasion, 18 (52.94%) of the T₁ lesions were accurately detected during preoperative diagnosis by radiographic examination; moreover, only 3 (3.53%) of the T₂₋₄ lesions were misdetected. As a result, double-contrast studies have a high sensitivity in the diagnosis of upper gastrointestinal carcinoma. As the double-contrast study is safer and less expensive than endoscopy, and also has high diagnostic sensitivity (84.03%), we believe that it is an excellent technique for the detection of synchronous multiple primary carcinomas of the upper GI tract. On the other hand, application of hypotonic measures to restrict the motility of the esophageal or stomach wall, which can better display the fine structure of the stomach, greatly improve the detection rate of smaller lesions and reduce the rate of misdiagnosis.

It is also important to recognize that barium studies are also operator dependent, and our experiences are as follows: (1) Radiologists should recognize the characteristics of multiple primary carcinomas of the upper GI tract, and special attention should be given to elderly male patients to avoid missing synchronous lesions; (2) In order to avoid misdiagnosis, when one lesion is found on barium images, the entire upper GI tract should be carefully evaluated for other synchronous lesions; (3) When esophagus or gastric cardia are seriously obstructed, measures such as hypotonic drugs, diluted barium, multi-position and delayed check should be taken; and (4) It should also be noted that adjacent multiple foci should be carefully observed to judge whether normal tissue exists between two lesions, in order not to automatically make a diagnosis of local extension or metastasis of another lesion.

As to early gastric cancer, the following points should be noted during double-contrast barium examination: (1) Good filling is essential for displaying abnormal gastric margins, 300-350 mL is an appropriate amount to extend the gastric body; (2) Middle or small volumes would be suitable for depressed lesions; (3) Mobile technology and thin-layer technology is necessary. After the lesion is found, local fine structure around the stained lesions should be repeatedly observed under flowing conditions; (4) For depression lesions of the greater curvature, the check bed can first be level and then gradually become erect. In the process, observe the barium slowly down from the upper stomach along the greater curvature, so the positive outlook of depressed lesions can be fully displayed; and (5) For lesions of the anterior, compression methods can best show the lesions.

The incidence of multiple synchronous upper gastrointestinal cancers is increasing gradually; early diagnosis, and thus screening of patients at risk, is key. We believe

that hypotonic double-contrast upper gastrointestinal examination is a sensitive, safe, noninvasive and relatively inexpensive global examination, which can serve as the first choice for the screening and diagnosis of synchronous upper gastrointestinal MPC, especially in China. Furthermore, careful radiographic follow-up is also required to detect metachronous lesions at the earliest possible stage, which will substantially increase patient survival.

COMMENTS

Background

The incidence of multiple synchronous upper gastrointestinal (GI) cancers is increasing gradually, but for some reason, some synchronous primary lesions can often be overlooked at the time of diagnosis. Accurate diagnosis of these synchronous primary lesions before operation is crucial because it can significantly alter clinical management. However, so far, there has not been a consensus on how best to diagnose mucosal lesions of multiple primary carcinomas in the upper GI tract: endoscopy or barium radiography?

Research frontiers

Compared with endoscopy, double-contrast upper GI examination is a safe, non-invasive, inexpensive and cost-effective test for providing accurate information about lesion morphology, location, size, and interval distance of these tumors. In addition, because of improved imaging modalities and application of hypotonic measures to restrict the motility of esophageal or stomach wall which can better display the fine structure of the GI tract, the detection rate of smaller lesions is greatly improved with a reduced rate of misdiagnosis.

Innovations and breakthroughs

Synchronous multiple primary carcinomas (MPC) in the upper GI tract mostly occurred in males, 86.21% of the patients were older than 55 years, and average age was 62.7 years old; the fact that elderly individuals aged 65 years or more are at greater risk for multiple gastric carcinomas is clinically significant. Esophageal MPC (EMPC) and esophageal-gastric MPC (EGMPC) are the main types of MPC in the upper GI tract. In esophageal lesions of EMPC/EGMPC, hyperplastic and medullary types are commonly seen; the lesions are mainly located at the middle and lower segment of the esophagus. Gastric lesions are usually located at the gastric cardia, and hyperplastic type is mostly seen. This series supports the concept that double-contrast upper GI examination is safer and less expensive than endoscopy, and also has high diagnostic sensitivity (84.03%); it can serve as an excellent technique for the detection of synchronous MPC of the upper GI tract.

Applications

Hypotonic double-contrast upper GI examination is a sensitive, safe, noninvasive and relatively inexpensive global examination, which can serve as the first choice for the screening and diagnosis of synchronous upper gastrointestinal MPC, especially in China.

Terminology

Synchronous MPC is defined as two or more primary carcinomas occurring in an individual simultaneously. Most of these synchronous cancers are in the head and neck region; other frequently reported sites of synchronous cancer associated with esophageal cancer are the stomach, lung, and urinary bladder. Their coexistence can be problematic for surgeons, oncologists and pathologists with regard to diagnosis, treatment, and follow-up.

Peer review

It is very interesting for the readers. It is well written, the data is very valuable and the conclusions applicable. It should be accepted for publication in the journal.

Abstract

AIM: To study the effect of breviscapine (Bre) on activity of protein kinase C α (PKC α) and nuclear factor (NF)- κ B in pancreas, and the mechanism of Bre attenuating acute pancreatitis (AP).

METHODS: One hundred and eight rats were randomly divided into acute necrotizing pancreatitis (ANP) group, Bre group (ANP + Bre group) and sham operation (SO) group, 36 rats in each group. ANP model was induced by a retrograde injection of 4% sodium deoxycholate into the bilio-pancreatic duct. Fifteen minutes after the ANP model was induced, the rats in Bre group were intraperitoneally injected with Bre (0.4 mg/100 g body weight or 0.1 mL/100 g body weight). Survival time and mortality of rats were calculated. Serum amylase and malondialdehyde levels were measured, volume of ascites was recorded and morphology of pancreas

and lung was evaluated at 1, 5 and 10 h, after the ANP model was induced, respectively. Expressions of PKC α and subunit p65 of NF- κ B in pancreas were detected by immunohistochemistry and Western blotting.

RESULTS: The life span of rats was longer and the mortality was lower in Bre group than in ANP group 13.51 ± 5.46 vs 25.36 ± 8.11 ($P < 0.05$). The amylase and MDA levels as well as the volume of ascites were lower and the pathological changes in pancreas and lung were less in Bre group than ANP group ($P < 0.05$), indicating that the pancreatitis is less severe in Bre group than ANP group. The activation of PKC α and NF- κ B p65 in pancreas was induced rapidly and reached their peak at 1 h or 5 h after ANP, but their activity in Bre group was significantly inhibited.

CONCLUSION: Bre exerts its therapeutic effect on AP by inhibiting the activation of PKC α and NF- κ B p65 in pancreas.

INTRODUCTION

The complete mechanism of acute pancreatitis (AP) has not been established so far. The initial events in this disorder occur in pancreatic acinar cells, including activation of zymogens in acinar cells and release of inflammatory cytokines. It has been shown that nuclear factor (NF)- κ B is a key regulator of the expression of many inflammatory molecules^[1,2]. In experimental pancreatitis, NF- κ B activation in acinar cells is one of the early events^[3], and the inhibition of NF- κ B activation attenuates inflammatory response and the severity of AP^[4,5]. However, the signaling mechanisms mediating NF- κ B activation are unclear.

One candidate for mediating NF- κ B activation in pancreatic acinar cells is protein kinase C^[6,7]. Protein kinase C (PKC) is a member of serine/threonine kinases comprising 10 isoforms that differ in their structures and regulations^[8]. These isoforms can be subdivided into conventional PKC, novel PKC, and atypical PKC isoforms based on their molecular structure and mode of activation. PKC α belongs to conventional PKC isoforms which can mediate pathological secretory processes in experimental pancreatitis and regulate expression of inflammatory mediators^[9]. PKC inhibitors significantly reduce pancreatic and pulmonary levels of myeloperoxidase (MPO) and pancreatic protease activity, and further ameliorate inflammatory injury of organs^[10].

Breviscapine (Bre), a commercially available plant extract from the herb *erigeron breviscapus*, can inhibit PKC activation^[11,12]. Bre possesses comprehensive pharmacological effects and has been widely used in treatment of disorders in blood supply to the heart and brain, as well as ischemic diseases^[12,13]. Bre can elevate the activity of ATPase and superoxide dismutase SOD and reduce the malondialdehyde (MDA) level in brain mitochondria of rats after trauma^[14]. MDA as a product of thiobarbituric acid reactant, is considered a good indicator of lipid peroxidation and one of the useful makers for AP^[15]. It was reported Bre is effective against AP^[16]. However, its therapeutic mechanism is still unclear^[17]. In an attempt to further explore its mechanism in treatment of AP, a rat model of acute necrotizing pancreatitis (ANP) was induced to observe whether Bre exerts its protective effect against ANP by inhibiting the activation of PKC α and NF- κ B.

MATERIALS AND METHODS

Animals and materials

One hundred and eight Sprague-Dawley rats weighing 200-250 g, obtained from Experimental Animal Center of Fourth Military Medical University (Grade SPF Certificate No.2005-005), were fasted for 12 h with free access to water. Antibodies against PKC α and NF- κ B P65 were purchased from Santa Cruz Biotechnology Company (CA, USA). Secondary antibody and kits for immunohistochemistry were provided by Zhongshan Company (Beijing, China). Bre injection was purchased from Feixia Pharmacology Company (Harbin, China). Kits for amylase and

MDA were obtained from Nanjing Jiancheng Biotechnology Company (Nanjing, China). All other chemicals were those of the highest purity.

Induction of rat AP model

The rats were randomly divided into acute necrotizing pancreatitis (ANP) group, Bre group (ANP + Bre group) and sham operation (SO) group, 36 rats in each group. A rat model of ANP was induced by retrograde injection of 4% sodium deoxycholate (0.1 μ L/100 g body weight) into the bilio-pancreatic duct (BPD) as previously described^[18]. Briefly, a small median laparotomy was performed to exposed the pancreas, the BPD was temporarily closed at the hilum of liver with a small soft bulldog clamp to prevent reflux of the infused material into the liver, and then 4% sodium deoxycholate (100 μ L/100 g body weight) was injected into the distal BPD at a pressure of 50 cmH₂O. The clamp was removed 5 min after the injection of sodium deoxycholate. The rats in SO group only underwent laparotomy. Finally, the abdomen was closed with a silk suture. Fifteen minutes after the model was induced, the rats in Bre group were intraperitoneally injected with Bre (0.4 mg/100 g body weight or 0.1 mL/100 g body weight) and those in the other two groups were given the same volume of normal saline.

Preparation of serum and tissue samples

Twelve rats in each group were observed during 72 h, their survival time and mortality in 24 h were recorded. The rats were sacrificed at 1, 5 and 10 h, respectively, after the rat AP model was induced. Whole blood samples were centrifuged at 4°C, and serum was stored at -80°C for amylase and MDA analysis. Ascites volume was recorded, and pancreas and lung morphology was evaluated. Expressions of PKC α and subunit p65 of NF- κ B in pancreas were detected by immunohistochemistry or Western blotting.

Histopathologic score

Pancreas and lung were removed at 1, 5 or 10 h for morphological analyses after the model was induced, immediately immersed in 4% neutral phosphate-buffered paraformaldehyde for 12 h, embedded in paraffin, and cut into 5- μ m thick sections which were stained with H&E to observe the morphological changes under a light microscope. The severity of AP was blindly graded by a semi-quantitative assessment of vacuolization, edema, inflammatory cell infiltration and acinar cell necrosis as previously described^[19]. Ten microscopic fields were randomly chosen to observe them in each rat. Histological scoring of pancreatic tissue was performed to grade the extent of acinar cell vacuolization (0: none, 1: < 20% acini with vacuoles, 2: < 50% acini, 3: > 50% acini), edema (0: no edema, 1: interlobular edema, 2: intralobular edema 3: interacinar edema), inflammation (0: no inflammation, 1: inflammatory cells present at intralobular, 2: inflammatory cells present at intralobular 3: inflammatory cells present at interacini) and acinar cell necrosis (0: no necrosis, 1: < 10% necrosis, 2: < 40% necrosis, 3: > 40% necrosis).

Immunohistochemistry

Immunohistochemical analysis was performed. In brief, frozen pancreas was cut into 8- μ m sections which were air-dried and treated sequentially with acetone at 4°C for 10 min, three times of phosphate-buffered saline (PBS) at pH 7.4, 5% bovine serum album (BSA) in PBS at pH 7.4 for 30 min, PKC α (Santa Cruz Biotechnology Inc. sc-8393) diluted at 1:100 or NF- κ B P65 (Santa Cruz Biotechnology Inc. sc-8008) diluted at 1:80 in a humid chamber overnight, three times of 0.02% Tween 20 in PBS for 10 min each time, biotinylated secondary antibody diluted at 1/500 for 40 min. The bound peroxidase was visualized by reaction for 2-5 min in a solution containing 50 mg of 3, 3-diaminobenzidine (DAB), counterstained with hematoxylin, dehydrated and embedded. For PKC α in common status, the cytoplasm of positive cells was stained, and translocation of positive cells to membrane from cytoplasm meant activation of PKC α . For NF- κ B P65 in common status, the cytoplasm of positive cells was stained, and translocation of positive cells to nuclei from cytoplasm meant activation of NF- κ B P65. The slides were observed under a light microscope.

Western blotting

For Western blotting analysis, cellular proteins were prepared from pancreas with standard methods. Protein concentration was measured (Bio-Rad protein assay) and adjusted to 4 μ g/ μ L with loading buffer. The samples were boiled at 95°C for 5 min before they were loaded 10 μ L, subjected to SDS-polyacrylamide gel electrophoresis, and blotted to PVDF membranes. The membranes were probed with anti-PKC α diluted at 1/1000 (Santa Cruz Biotechnology Inc. sc-8393) and anti-NF- κ B P65 diluted at 1/1000 (Santa Cruz Biotechnology Inc. sc-8008). A low molecular weight protein marker was used to determine the size of bands detected by Western blotting.

Statistical analysis

Data were expressed as mean \pm SD, compared by non paired Student *t* test and one-way analysis of variance (ANOVA). $P < 0.05$ was considered statistically significant.

RESULTS

Bre reduced the mortality and prolonged the survival time of rats with AP

No rat in SO group died in 72 h. The mortality of rats in ANP group was 100% in 24 h with a life span of 13.51 ± 5.46 h, while the mortality of rats in Bre group was 50% with a life span of 25.36 ± 8.11 h ($P < 0.01$, Figure 1A).

Bre decreased the production of ascites and the serum amylase level in rats with AP

Ascites was not produced in SO group at any time points. The volume of ascites was 4.46 ± 1.62 mL at 1 h and 8.57 ± 2.38 mL at 5 h after the model was induced in ANP group. The volume of ascites was smaller in Bre group than in ANP group ($P < 0.01$, Figure 1B).

The serum amylase level was significantly higher at 1, 5, and 10 h after the model was induced in ANP group than in SO group ($P < 0.01$). The amylase activity was lower in Bre group at each time point than in ANP group ($P < 0.05$, Figure 1C).

Bre improved the pancreas and lung morphology in rats with AP

The pancreas and lung morphology was significantly different in rats with AP. Sodium deoxycholate caused mild interlobular edema at 1 h, and inflammatory cell infiltration, hemorrhage and acinar cell necrosis at 5 and 10 h after the model was induced. The morphological change of pancreatic tissue was milder (Figure 1D) and the morphological score was lower in Bre group than in ANP group ($P < 0.01$, Figure 1E). In contrast to the rats in SO group, those in ANP group exhibited severe inflammation of the lungs as indicated by alveolar fluid accumulation and progressive thickening of the interalveolar tissue, while those in Bre group showed milder morphological changes in lungs.

Bre inhibited the production of MDA in rats with AP

The MDA increased significantly with the development of AP in ANP group. The MDA level was significantly lower in Bre group than in ANP group at 1, 5, and 10 h after the model was induced ($P < 0.05$, Figure 1F).

Bre suppressed the expression of PKC α and NF- κ B P65 in pancreas of rats with AP

Immunohistochemical analysis showed no PKC α and NF- κ B P65 expression in acinar cells of rats in SO group at any time points. PKC α was detected at 1 h after the model was induced and localized in cytoplasm of acini (Figure 2A). However, the PKC α expression increased in cytoplasm at 5 h after the model was induced and could be detected on the membrane of acini. Only little staining of acini was observed at 10 h after the model was induced. The expression of NF- κ B P65 was detected at 1 h after the model was induced and localized in cytoplasm or nuclei of acini and inflammatory cells (Figure 2B). The NF- κ B P65 expression level in pancreas was lower at 5 and 10 h than at 1 h after the model was induced AP ($P < 0.05$). Western blotting showed that the expression level of PKC α and NF- κ B P65 in pancreatic tissue was significantly lower in Bre group than in ANP group ($P < 0.05$, Figure 2C).

DISCUSSION

PKC can mediate NF- κ B activation in pancreatic acinar cells^[6,7] and pathological secretory processes in experimental pancreatitis, and regulate the expression of inflammatory mediators^[9]. In our study, ANP was induced with sodium deoxycholate and the expression of PKC α and NF- κ B P65 in frozen sections of pancreas tissue was observed by immunohistochemical analysis. PKC α was detected only in acini, while NF- κ B P65 was localized in acini and inflammatory cells. The expression of PKC α and NF- κ B P65 increased

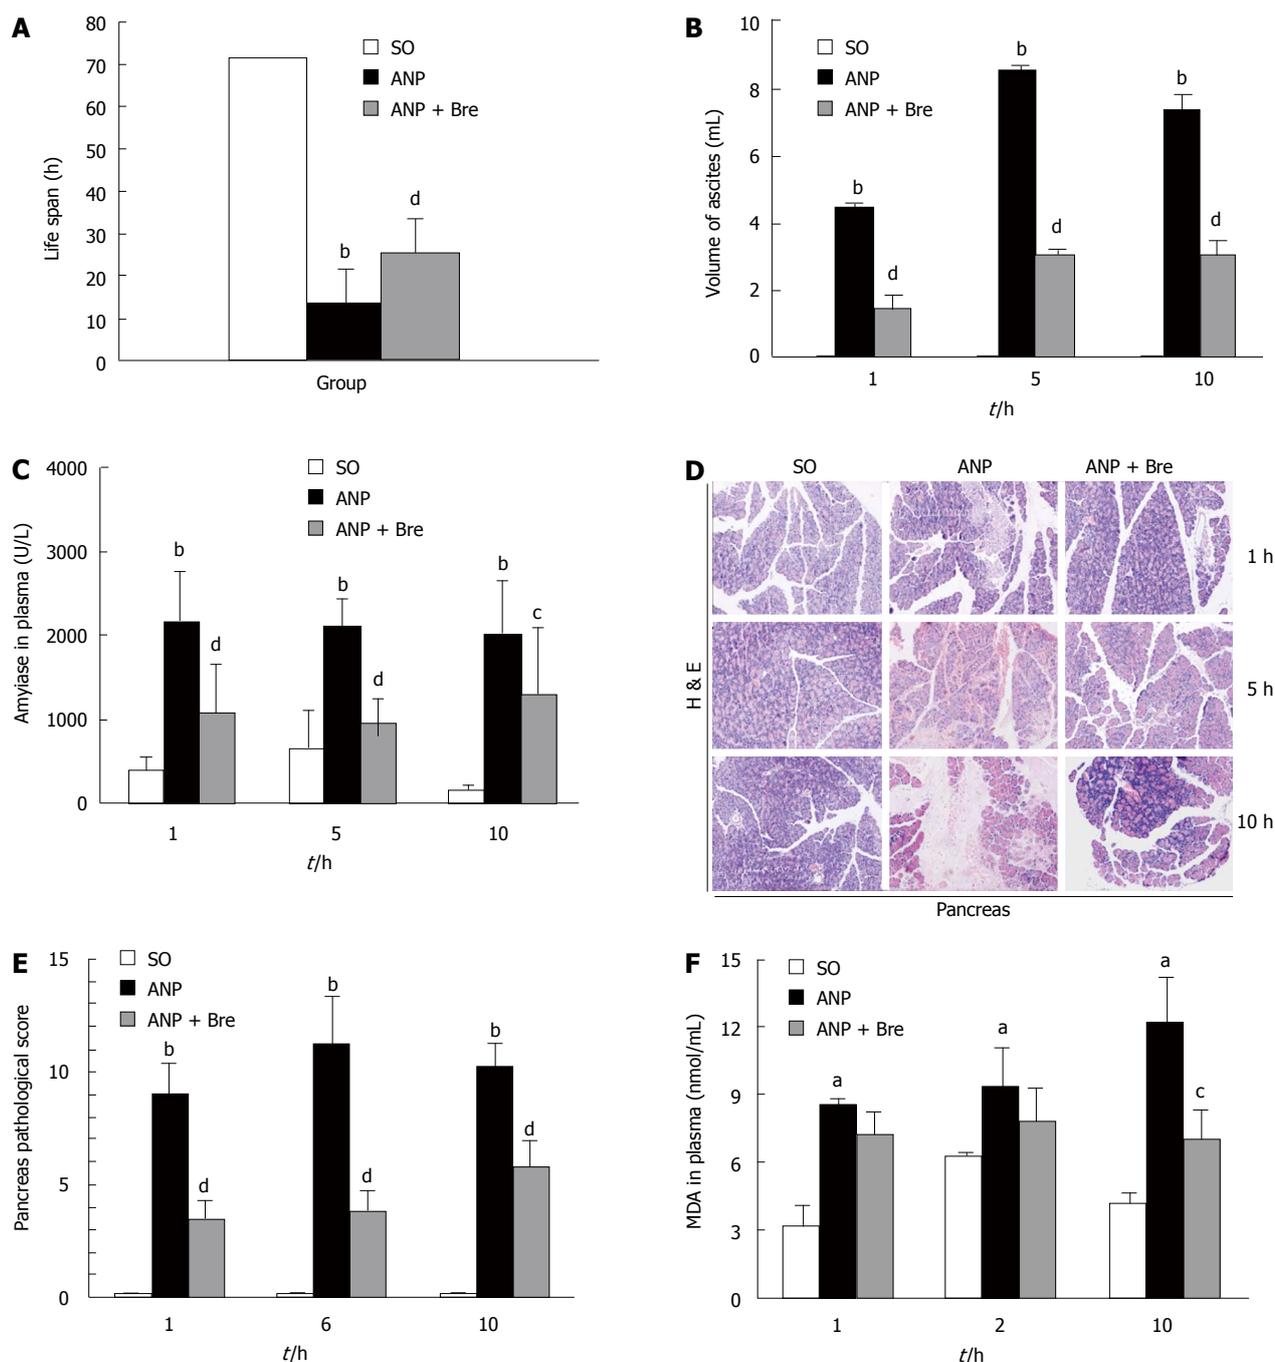

Figure 1 Effect of breviscapine on mortality (A), ascites volume (B) and amylase activity (C), morphological change (D), morphological score (E), and malondialdehyde level (F) in rats with acute pancreatitis. ^a*P* < 0.05, ^b*P* < 0.01 vs SO group; ^c*P* < 0.05, ^d*P* < 0.01 vs ANP group. Bre: Breviscapine; SO: Sham operation; ANP: Acute necrotizing pancreatitis; MDA: Malondialdehyde.

in the early stage of ANP, and both PKC α and NF- κ B P65 played an important role in the development of ANP.

It was reported that NF- κ B can be activated by protein kinase C and intracellular Ca²⁺[6,7], suggesting that PKC is an upstream regulator of NF- κ B activation in pancreatic acinar cells. In the present study, the effect of Bre, a PKC inhibitor, on ANP and activation of PKC α and NF- κ B was observed, showing that Bre could decrease the mortality, the severity of AP, the ascites production, the serum amylase level in rats with ANP, and prolonged their survival time. The morphological changes in pancreas and lungs of rats with ANP after treated with Bre were milder, sug-

gesting that PKC is related to AP and can alleviate the pathological injury by inhibiting PKC. Furthermore, the serum MDA level was lower in Bre group than in ANP group, suggesting that Bre can eliminate the production of oxygen-free radicals and further attenuate the harmful influence of peroxidation on pancreas and lungs^[20,21]. The expression of PKC α and NF- κ B P65 was significantly lower in Bre group than in ANP group, indicating that Bre can inhibit the activation of PKC α and NF- κ B which are important for the release of many inflammatory molecules and inflammatory response^[3,22,23].

In conclusion, PKC activation may contribute to in-

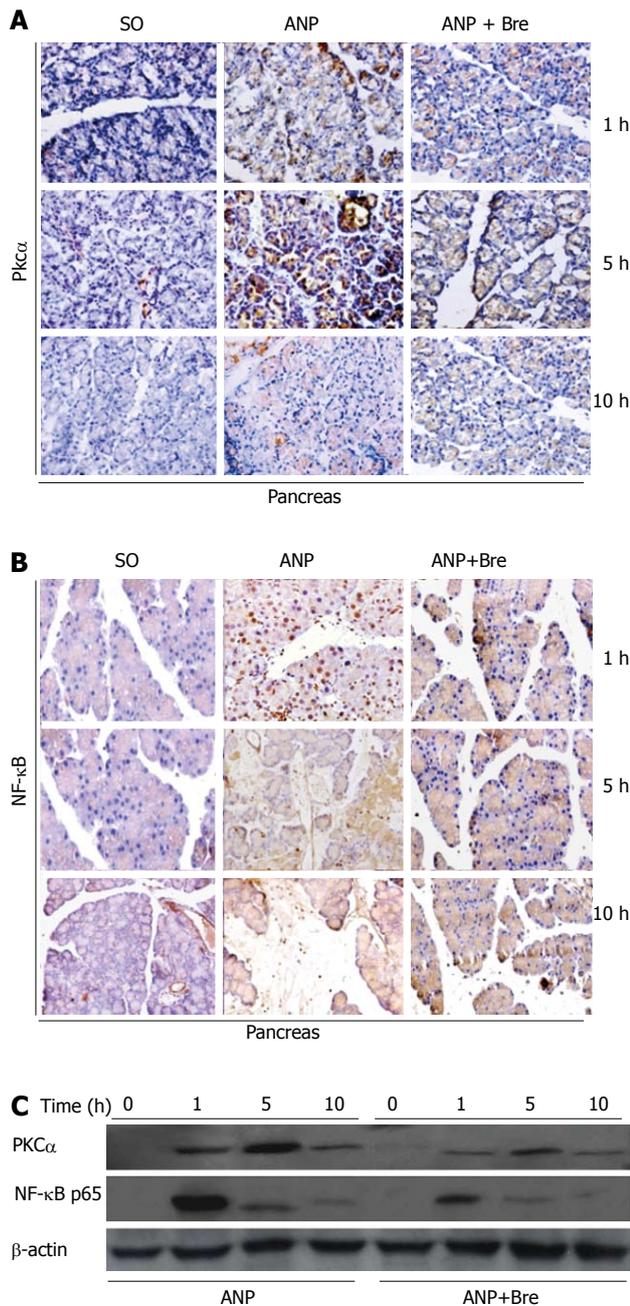

Figure 2 Immunohistochemical analysis showing expression of protein kinase C alpha (PKC α) (A) and nuclear factor (NF)- κ B P65 (B) in cytoplasm, membrane or nuclei of acini and inflammatory cells in pancreas, and western blotting showing the expression level of PKC α and NF- κ B P65 in breviscapine and acute necrotizing pancreatitis groups at different time points (C). Bre: Breviscapine; SO: Sham operation; ANP: Acute necrotizing pancreatitis.

flammatory response and cell injury in pancreas and lungs. Bre exerts its protective effect against ANP by inhibiting PKC and NF- κ B activation, which can explain the therapeutic mechanism of Bre for AP at molecular level.

COMMENTS

Background

Inflammatory response is important in the development of acute necrotizing pancreatitis (ANP). Nuclear factor (NF)- κ B can regulate the expression of many

inflammatory molecules. One candidate for mediating NF- κ B activation in pancreatic acinar cells is protein kinase C (PKC). Breviscapine (Bre) extracted from erigeron can inhibit the activation of PKC.

Research frontiers

Some studies demonstrated that PKC activation plays an important role in the development of acute pancreatitis (AP). PKC inhibitor can significantly reduce pancreatic protease activity and myeloperoxidase (MPO) level in pancreas or lungs, and further alleviate the inflammatory injury of organs.

Innovations and breakthroughs

As an inhibitor of PKC activation, Bre is effective against AP. However, its therapeutic mechanism is still unclear. In the authors' present study, a rat model of ANP was induced to observe the effect and mechanism of Bre on ANP, showing that Bre exerts its protective effect against ANP by inhibiting PKC and NF- κ B activation.

Applications

The results of this study suggest that PKC activation may contribute to inflammatory response and cause cell injury in pancreas and lungs, which may explain the therapeutic mechanism of Bre for AP at biological level and accelerate its applications in treatment of AP.

Terminology

PKCs are a family of serine/threonine kinases comprising 10 isoforms that differ in their structures and regulations. These isoforms can be subdivided into three classes based on their molecular structure and mode of activation, namely conventional PKC isoforms, novel PKC isoforms, and atypical PKC isoforms. PKC α belongs to conventional PKC isoforms which can mediate pathological secretory processes in experimental pancreatitis and regulate the expression of inflammatory mediators.

Peer review

In this study, the authors showed that Bre exerts its protective effect against ANP by inhibiting PKC and NF- κ B activation. As a PKC inhibitor, Bre can significantly reduce pancreatic protease activity and MPO level in pancreas or lungs, and further alleviate the inflammatory injury of organs, and can thus be applied in treatment of AP.

Abstract

AIM: To identify factors predicting the clinical response of ulcerative colitis patients to granulocyte-monocyte apheresis (GMA).

METHODS: Sixty-nine ulcerative colitis patients (39 F, 30 M) dependent upon/refractory to steroids were treated with GMA. Steroid dependency, clinical activity index (CAI), C reactive protein (CRP) level, erythrocyte sedimentation rate (ESR), values at baseline, use of immunosuppressant, duration of disease, and age and extent of disease were considered for statistical analysis as predictive factors of clinical response. Univariate and multivariate logistic regression models were used.

RESULTS: In the univariate analysis, CAI ($P = 0.039$) and ESR ($P = 0.017$) levels at baseline were singled out as predictive of clinical remission. In the multivariate analysis steroid dependency [Odds ratio (OR) = 0.390, 95% Confidence interval (CI): 0.176-0.865, Wald 5.361, $P = 0.0160$] and low CAI levels at baseline ($4 < CAI <$

7) (OR = 0.770, 95% CI: 0.425-1.394, Wald 3.747, $P = 0.028$) proved to be effective as factors predicting clinical response.

CONCLUSION: GMA may be a valid therapeutic option for steroid-dependent ulcerative colitis patients with mild-moderate disease and its clinical efficacy seems to persist for 12 mo.

INTRODUCTION

Ulcerative colitis (UC) is a chronic inflammatory bowel disease characterized by periods of remission and clinical relapses most likely related to a multifactorial dysfunction of the mucosal immune system^[1].

The available pharmacological therapies are aimed at inducing remission and preventing relapses. In active UC, depending on the site of disease and on disease activity, the principle therapy is represented by oral and topical steroids with maintained remission in half of the examined patients (49%) at a 1 year follow-up. Steroids, which

offer a good initial response rate, are however ineffective as maintenance therapy and well-known side-effects are observed in 22% of the patients who develop steroid dependence/resistance^[2].

In those patients with chronic active disease, unresponsive to steroids, immunomodulators are largely used even though these treatments are limited by side-effects occurring in 6%-30% of cases as well as concerns over long-term toxicity^[3]. In severe disease, as azathioprine has a delayed onset of efficacy, cyclosporine or tacrolimus may offer an alternative. The encouraging development of biologicals, such as infliximab (an anti-TNF α antibody showing effect in moderate to severe UC), is counterbalanced by the need for long-term efficacy and safety profile evaluations^[4,5].

Granulocyte-monocyte apheresis (GMA), a selective apheresis technique, represents a recent alternative therapeutic option. Several open trials have been performed so far, showing efficacy rates up to 65%-75% associated with an excellent safety profile^[6-13].

While its safety has been largely proven in the treatment of steroid refractory/dependent UC patients, few and conflicting results are available concerning the long-term follow-up and factors predicting clinical response, therefore current data do not help in identifying UC patients eligible for GMA treatment. The aim of the present study has thus been to single out factors predicting the clinical response to GMA.

MATERIALS AND METHODS

Patients

Between April 2005 and January 2008, a total of 69 patients with mild/moderate UC either steroid-dependent or resistant were selected for GMA treatment, from patients admitted to the GI Units of the Department of Clinical Sciences, Policlinico Umberto I and of Pisa Hospital.

The characteristics of the patient population (39 females, 30 males, mean age 42.36 years; range 27-75 years) are shown in Table 1. Mean disease duration was 41.34 mo (range 12-252 mo). Disease activity was mild/moderate in all the patients as established by a clinical activity index (CAI) value > 4; The mean clinical activity index (CAI) value was 9.10 (range 6-12; lower quartile = 8, median value = 9, upper quartile = 10, interquartile range = 2). Forty-seven patients presented left colitis and 22 pancolitis. Arthralgia was present in 15 patients.

All patients considered for GMA had failed to respond to mesalazine or sulphasalazine, and were under steroid treatment. Forty-nine patients had been found to be dependent on, and 20 resistant to, steroid treatment. The steroid-dependence/resistance have been respectively defined: relapse within 30 d after a complete tapering or at dose reduction impeding discontinuation of prednisolone treatment for more than one year; No response within 30 d at standard maximum daily dosage of prednisone^[14].

The 20 patients resistant to steroids had started azathioprine (at a dose of 1.5-2.5 mg/kg per day) from 6 mo before enrolment.

Major exclusion criteria were severe cardiovascular

disease (acute myocardial infarction, brain hemorrhage, severe arrhythmia or heart failure) within the past 6 mo, severe renal failure, hypotension (< 80 mmHg systolic pressure), body weight < 35 kg, age < 12 years, pregnancy.

GMA treatment

After giving informed consent, all selected patients were submitted to GMA with Adacolumn (Otzuka Production, Milan, Italy). GMA was performed with the help of the Transfusional Unit of the two Institutions.

Each patient was submitted to 5-10 GMA sessions (1 session/wk), as a basic treatment course, according to the standard protocols^[15]. Each GMA session lasted 60 min.

In particular, enrolled patients were divided into two groups: Presenting mild and moderate disease, respectively, according to their baseline CAI levels (4 < CAI < 7, 7 < CAI < 12 respectively). Out of 69, 29 patients with mild disease were submitted to a 5 session treatment, whereas 40 patients with moderate disease were treated with a further cycle of GMA.

During the GMA sessions, the treatment with oral and topical mesalazine and/or azathioprine was continued, at a stable dosage. Steroid tapering was started after the first session, according to the response to therapy. At the end of the treatment period, all concomitant therapies were carried on (oral and topical mesalazine, azathioprine).

Assessment of clinical response

Clinical efficacy was assessed at enrolment, within the first week after the last GMA session (short-term follow-up) and at 12 mo (long-term follow-up).

All patients were evaluated by clinical and laboratory assessment, including full blood count, erythrocyte sedimentation rate (ESR), C reactive protein (CRP).

Disease activity was evaluated by measuring the CAI according to the Rachmilewitz's criteria^[16]. Clinical remission was defined as a final CAI value equal or < 4. A partial response was defined as a reduction of CAI score from baseline. The increasing of CAI value was classified as no response.

To complete the clinical assessment, QoL was also evaluated by a questionnaire adapted to the Italian population^[17], with 29 questions grouped into 4 domains: Intestinal symptoms, systemic symptoms, emotional and social

functions. Mucosal lesions were measured using the endoscopic score of Rachmilewitz, which evaluates the granular pattern (no = 0, yes = 2), the characteristics of the vascular pattern (normal = 0, impaired = 1, absent = 2), fragility of the mucosa (no = 0, upon touch = 2, spontaneously = 4) and mucosal lesions (no = 0, minor = 2, severe = 4). Endoscopic remission was defined by a score < 2^[16].

All responder patients underwent a clinical evaluation at 12 mo of follow-up. All the parameters collected were inserted in a standard database.

Predictive factors of clinical response

Demographic and clinical characteristics of enrolled patients were considered for statistical analysis as predictive factors of clinical response in the short-term follow-up. Steroid dependency, CAI, CRP and ESR values at baseline, use of immunosuppressant, duration of disease (mo), age (year) and extent of disease (left side, pancolitis), were analyzed. No complete laboratory and clinical data were available in the long-term follow-up, so that no data were analyzed to identify factors predicting a sustained response.

Statistical analysis

Univariate analysis of parameters considered at baseline was performed by using the *t* test and the McNemar test for paired data, whereas comparing the same parameters between responders and non-responders, univariate analysis was performed using the *t* test for unpaired data. The parameters proving significance ($P < 0.05$) on univariate analysis were entered into a multivariate logistic regression model with the calculation of relative risk as odds ratios (OR) with 95% confidence intervals (CI), in order to determine the independent contributors to remission.

RESULTS

Assessment of clinical response to GMA treatment

Twenty-nine mild UC patients (CAI < 7) were treated with 5 GMA sessions, and 40 moderate UC patients (CAI < 12) were treated with 10 GMA sessions, following standard protocols. All patients completed the GMA sessions. During the overall 545 sessions of apheresis no major side-effects were registered. Two patients experienced dizziness and headache and one patient experienced a transient episode of arrhythmia.

At 11 wk of follow-up, 40 patients showed a complete clinical remission associated with endoscopic response. The end of treatment corresponded to the complete tapering of steroids in all cases. A partial response was evidenced in 10, and no variation in 19 patients.

As far as the CAI was concerned, the mean value dropped from 9.1 (range 6-13) at enrolment to 4.2 (range 0-10) at the end of GMA treatment ($P < 0.01$). Indeed, a final CAI value < 4 was observed in 40 patients.

In consideration of the individual parameters contributing to the CAI evaluation, complete disappearance of urgency and tenesmus was observed in 38 out of 40 responder patients. In 5 out of 15 patients, peripheral arthralgia

Table 2 Univariate analysis of predictive factors of clinical response to granulocyte-monocyte apheresis: Age, White blood cells, erythrocyte sedimentation rate and clinical activity index score, C reactive protein, location duration of disease at baseline and use of immunosuppressant (mean \pm SD)

| | Responders (n = 40) | Non responders (n = 29) | P-value |
|---|------------------------|----------------------------|---------|
| Age (yr) | 42.7 \pm 13.8 | 41.9 \pm 6.6 | 0.774 |
| WBC 10 ³ | 10.2 \pm 2.7 | 11.2 \pm 2.2 | 0.106 |
| ESR (mm/h) | 30.6 \pm 13.5 | 38.4 \pm 12.5 | 0.017 |
| CAI | 8.6 \pm 2.1 | 9.7 \pm 2.2 | 0.039 |
| CRP (mg/dL) | 1.2 \pm 1.2 | 1.4 \pm 1.4 | 0.526 |
| Location of disease (left side/pancolitis) | 28/12 | 19/10 | 0.795 |
| Duration of disease (yr) | 11 | 6 | 0.581 |
| Use of immunosuppressant | 5 | 15 | 0.601 |

CAI: Clinical activity index; ESR: Erythrocyte sedimentation rate; CRP: C reactive protein; WBC: White blood cells.

disappeared. The mean QoL score significantly decreased from 37.9 (range 18-67) to 24.4 (range 7-42) ($P < 0.01$).

ESR, CRP and WBC decreased at the end of the GMA sessions as follows: mean ESR decreased from 33.9 mm/h (range 7-60 mm/h) to 20.1 mm/h (range 2-20 mm/h) ($P < 0.01$); Mean CRP decreased from 2.04 mg/dL (range 0.3-7.3 mg/dL) to 0.29 mg/dL (range 0.15-1.5 mg/dL) ($P = \text{NS}$); Mean WBC count decreased from 10.59 k/ μ L to 7.7 k/ μ L (range 5.7-14 k/ μ L) ($P < 0.01$).

The endoscopic evaluation improved greatly in 40/69 patients with a score ranging from a mean value of 8.08 (range 4-10) to 3.9 (range 1-8). Thirteen patients presented an improvement with the reduction of at least 1 grade of inflammation before the end of treatment. In 16 patients, the endoscopic aspect showed no change.

At 12 mo of follow-up, 46 out of 50 responder patients were evaluated; Thirty-two of them were still in clinical remission (CAI < 4). Twelve patients presented an early moderate relapse (CAI < 12) and started azathioprine (at a dose of 1.5-2.5 mg/kg per day). The remaining 2 patients showed a severe relapse (CAI > 13) and underwent surgery and biological therapy with infliximab, respectively.

Assessment of predictive factors of clinical response

At univariate analysis the differences between responders and non-responders was analyzed. Out of the considered parameters, only CAI ($P = 0.039$) and ESR ($P = 0.017$) levels at baseline were singled out as independent contributors to predict remission in the short-term follow-up, with low rates in the responders group (Table 2).

The logistic regression identified steroid dependency as an independent predictor of clinical response (OR = 3.71, 95% CI: 1.239-11.129, $P = 0.016$) (Figure 1).

Multivariate analysis revealed that steroid dependency (OR = 0.390, 95% CI: 0.176-0.865, Wald 5.361, $P = 0.016$) and low CAI levels at baseline ($4 < \text{CAI} < 8$) (OR = 0.770; 95% CI: 0.425-1.394, Wald 3.747, $P = 0.028$) were independent predictors of favorable clinical response in the short-term follow-up (Table 3).

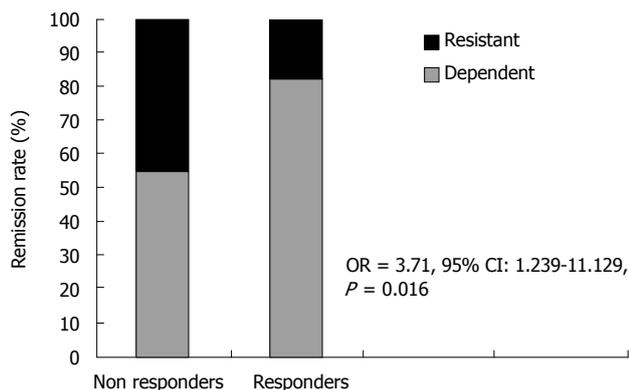

Figure 1 Correlation between clinical remission rate and steroid course. OR: Odds ratio; CI: Confidence interval.

DISCUSSION

GMA induced a complete response in 40 out of 69 patients with mild-moderate UC, with a significant reduction of CAI score levels, ESR, CRP, numbers of circulating neutrophils, as well as a significant improvement in QoL in accordance to the literature data^[18-25]. Sustained remission was also observed in the follow-up in half of the treated patients.

A few heterogeneous studies have been carried out for identifying predictive factors of clinical response to GMA, but to our knowledge predictive factors of sustained remission have not been so far reported.

Moreover, small studies using Adacolumn (GMA) have reported that high CAI level at baseline represented a significant risk factor for GMA failure and that cumulative doses of steroids, previously used for UC treatment, were inversely related to clinical efficacy^[21,24]. Conversely, a relatively large study, performed using Cellsorba device (leucocytapheresis), demonstrated that a steroid-dependent course and a high CRP concentration were independent predictors of favorable response^[26].

The present data confirm that a steroid-dependent course is a predictor of clinical efficacy in GMA-treated patients. Thus, the present study is not in accordance with the previously reported negative association between remission and high cumulative dose of prednisone. Furthermore, these data support the use of standard treatment protocols in steroid-resistant patients, such as cyclosporine/tacrolimus, biological agents, immunosuppressant therapy, or surgery, rather than GMA, with regard to cost-effectiveness and time-saving.

Low baseline CAI scores were predictive of GMA treatment efficacy, thus confirming previously reported data and indicating GMA treatment only for mild-moderate disease.

Albeit a large multicenter, sham-controlled trial has been performed using GMA which did not support its effectiveness (response rate: 44% *vs* 39%, *P* = NS)^[27], in that protocol duration of the disease was not indicated as well as the duration of concomitant medication. As suggested by the authors, unlike other studies, the study group did not include mainly steroid dependent/refractory patients,

Table 3 Multivariate analysis of predictive factors of clinical response to granulocyte-monocyte apheresis: Steroid course and clinical activity index score at baseline

| Independent variables | OR | 95% CI | Wald | P-value |
|--|-------|-------------|-------|---------|
| Steroid course | 0.390 | 0.176-0.865 | 5.361 | 0.016 |
| 4 < CAI < 8 | 0.770 | 0.425-1.394 | 3.747 | 0.028 |
| CRP (mg/dL) | 0.908 | 0.381-2.166 | 0.047 | 0.828 |
| ESR (mm/h) | 0.965 | 0.491-1.896 | 0.011 | 0.917 |
| Location of disease (Left side/pancolitis) | 0.822 | 0.462-1.462 | 0.446 | 0.504 |
| Duration of disease > 120 mo | 1.089 | 0.485-2.466 | 0.043 | 0.836 |

CAI: Clinical activity index; ESR: Erythrocyte sedimentation rate; CRP: C reactive protein; OR: Odds ratio; CI: Confidence interval.

thus the need for further studies for better defining the issue is strongly suggested.

A recent meta-analysis, drawn from 7 randomized controlled trials, has shown homogeneous evidence that confirm GMA is much more effective in UC as compared to conventional therapy^[28].

Despite limitations deriving from the retrospective nature of data analysis and the lack of long-term follow-up, the present study suggests that steroid dependency and mild disease represent good predictors of favorable clinical response to GMA treatment. The improvement in QoL related to the steroid-sparing effects was also relevant in the present series, suggesting an indication for GMA in pediatric UC patients, in whom steroid dependence is expected to interfere with a normal growth and development.

In conclusion, GMA may represent a useful therapeutic tool in steroid-dependent UC patients with mild to moderate disease, although further well designed sham-controlled studies are needed.

COMMENTS

Background

In a proportion of ulcerative colitis patients, the current pharmacological therapy is responsible for side-effects. A non-pharmacological approach, such as granulocyte-monocyte apheresis (GMA), proves effective in these patients and displays an excellent safety profile. Data are also available from studies involving pediatric patients showing good results, without side-effects. The efficacy of GMA has been documented by several studies, but few data are available on long-term follow-up and on factors predicting clinical response.

Research frontiers

This study showed that steroid dependency [Odds ratio (OR) = 4.097, *P* = 0.01] and low clinical activity index levels at baseline (OR = 0.745, *P* = 0.02) proved to be effective as factors predicting clinical response. GMA may be a valid therapeutic option for steroid-dependent ulcerative colitis patients with mild-moderate disease and its clinical efficacy appears to persist for 12 mo.

Innovations and breakthroughs

These findings support other published evidence on the association of clinical efficacy with an extremely favorable safety profile. The study also indicates that steroid dependency and low activity of the disease help identify those ulcerative colitis (UC) patients who are most likely to respond to treatment. Thus, GMA

represents a promising non-pharmacological approach to UC, to be used when stable remission cannot be obtained by conventional therapy. Its use in pediatric UC patients, in whom steroid dependence is expected to interfere with a normal growth and development, could be an important challenge.

Peer review

The paper is generally well written and results analysed with appropriate statistical methods. The size of the cohort is fair and is enough to make some meaningful recommendations. The results are clearly tabulated and noted in the results section. The discussion is clearly written and the conclusions are appropriate to the findings.

Abstract

AIM: To report our experience of gastrointestinal stromal tumors (GISTs) during the last 29 years.

METHODS: Thirty two cases of GIST referred to our Institution from the 1st January 1981 to the 10th June 2010 were reviewed. Metastases, recurrence and survival data were collected in relation to age, history, clinical presentation, location, size, resection margins and cellular features.

RESULTS: Mean age was 63.7 years (range, 40-90) and incidence was slightly higher in males (56%). R0 resection was performed in 90.7% of cases, R1 in 6.2% (2 cases) and R2 in 3.1% (one case). Using Fletcher's classification 8/32 (25%) had high risk, 9/32 (28%) intermediate and 15/32 (47%) low risk tumors. Follow-up varied from 1 mo to 29 years, with a median of 8 years; overall survival was 75% (24/32), disease-free survival was 72% and tumor-related mortality was 9.3%. Three patients with high risk GIST were treated with imatinib mesylate: one developed a recurrence after 36 mo, and 2 are free from disease at 41 mo.

CONCLUSION: Surgical treatment remains the gold standard therapy for resectable GISTs. Pathological and

biological features of the neoplasm represent the most important factors predicting the prognosis.

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are mesenchymal tumors that arise from the gastrointestinal tract and account for < 1% of all gastrointestinal neoplasms^[1,2]. The term "stromal tumor" was first used by Mazur and Clark^[3] in 1983; later the acronym GIST was introduced^[4,5] to define a well established pathological entity, whose constitutive elements derive from the interstitial cell of Cajal, an intestinal pacemaker cell, and express a highly specific marker called KIT (CD117).

The estimated incidence of GISTs is approximately 10-20 per million people annually worldwide^[6]. This tumor affects men slightly more often than women and the mean age at the time of diagnosis is 60 years^[7,8]. The majority of GISTs arise in the stomach (60%) and small bowel (30%); the remaining 10% in the esophagus and rectum^[9].

Clinical presentation is heterogeneous, even if GISTs are usually asymptomatic and are diagnosed incidentally during endoscopy, radiological imaging or abdominal exploration^[10,11]. Preoperative biopsy is not recommended for resectable masses^[12], because of the fragility and predisposi-

tion to hemorrhage of these masses, and the possibility that the biopsy needle touches a necrotic portion of the tumor. Biopsy is justified only for masses preoperatively judged unresectable, in that a definitive pathological diagnosis would allow medical treatment using imatinib to commence.

Surgery represents the gold standard treatment for resectable GISTs. Principles of a correct procedure include negative margins on the specimen and integrity of the pseudocapsule^[13]. GISTs do not metastasize through lymphatic spread, so systematic lymphadenectomy is not indicated.

Survival after 5 years is extremely variable in the reported series, ranging from 48% to 80%. This variability could be explained by the amount of knowledge of the disease and, most of all, by the introduction of the inhibitors of tyrosine kinases. Imatinib mesylate was first used as medical therapy for GIST in 2000^[14]. Several clinical trials later confirmed that imatinib was safe and effective in the treatment of advanced and metastatic GISTs^[15-17]. In 2009 the American College of Surgeons Oncology Group presented the results of a randomised Phase III Multicentre Trial that showed the effectiveness of imatinib as adjuvant therapy for primary GISTs in term of recurrence free and overall survival^[18].

The purpose of this study is to analyze pathological features and treatment modality of 32 cases of GIST operated on at San Luigi Teaching Hospital (Turin) during the last 29 years.

MATERIALS AND METHODS

The study is a retrospective analysis of 32 cases of GIST referred to our Institution between 1st January 1981 and 10th June 2010. In every case, the diagnosis of GIST was confirmed by a positive immunohistochemical assay for CD117. Before GISTs were recognized as well defined pathological entities and the CD 117 assay was available, GISTs were diagnosed as leiomyoma, fibroleiomyoma or leiomyosarcoma. All specimens labeled with these diagnoses were tested for CD 117 and the positive ones classified as GISTs and included in the study. In this group, metastases, recurrence and survival data were collected in relation to age, history, clinical presentation, location, size, resection margins and cellular features such as mitotic index and immunohistochemistry (Table 1).

RESULTS

During the last 29 years, 32 patients underwent surgical intervention for GIST at San Luigi Teaching Hospital. Mean age was 63.7 years (range, 40-90) and prevalence was slightly higher in males (56%). Among males the mean age was 62, while among females it was 66. Gastrointestinal bleeding with acute or chronic anemia represented the most common clinical presentation (16 cases, 50%), followed by non-specific abdominal pain (12 cases, 37.5%), dysphagia (one case, 3.1%) and lumbar pain (one case, 3.1%); in 2 cases (6.3%) GISTs were found incidentally on the resected specimen. The medical histories did not show any association between GISTs and associated pathologies, which were extremely heterogeneous.

The majority of tumors were located in the stomach (18 cases, 56.3%); 2 in the antrum, 3 in the fundus, 13 in the corpus (5 in the anterior wall, 3 in the posterior wall, 2 along the great curve and 3 along the small curve). The others were found in the small bowel (10 cases, 31.3%; 7 in the ileum, 2 in the jejunum and one in the duodenum), mesentery (2 cases, 6.2%), esophagus (one case, 3.1%) and rectum (one case, 3.1%). Tumor size varied between 1 and 30 cm, with a mean diameter of 7 cm. Even though wedge or segmental resection was the most frequent surgical procedure, one anterior rectal resection, 4 total gastrectomies, one subtotal and one extended to the pancreatic tail, were performed. Only 4 operations (12.5%) were executed laparoscopically for tumors with a mean diameter of 4.5 cm: one segmental resection of the ileum and 3 gastric resections, one of which was converted. R0 resection was performed in 90.7% of the cases, R1 in 6.2% (2 cases) and R2 in 3.1% (one case). Using Fletcher's classification^[19], 8 out of 32 cases (25%) were high risk, 9 (28%) intermediate and 15 (47%) low risk tumors.

Follow-up varies from 1 mo to 29 years, with a median of 8 years. To date, 24 patients (75%) are alive; 8 patients (25%) died: 3 patients (9.3%) died due to recurrence at 13, 14, and 36 mo after the first operation, one died from lung cancer, 2 from gastric cancer, one from gallbladder cancer and one died of AIDS. Among the 24 surviving patients, only one, who had a high risk GIST, developed a recurrence and underwent a second surgical intervention, so that to date 23 patients (72%) are actually free from disease. If we consider a 3-year follow-up, we can include 25 patients from our series. In this group overall survival is 68% (17 out of 25) and disease-free survival is 64% (16 out of 25).

The rate of metastatic disease did not exceed 9.3% (3 cases); in 2 cases the primary tumor was a high risk GIST (a rectal GIST with liver metastasis and a mesenteric GIST with ileal metastasis), but, interestingly, in one case the patient was affected by a low risk jejunal tumor with lung metastasis.

Two patients underwent an R1 resection and one an R2 resection; they were treated with imatinib mesylate: one patient (R2) developed a recurrence after 36 mo that required a second surgical intervention followed by continued therapy with imatinib (no other tyrosine kinase inhibitors were available); 2 patients (R1) are free from disease at 41 mo. Tumors were located in the rectum, ileum and stomach, respectively.

DISCUSSION

During the last 10 years, since the GIST has been recognized as a well-defined pathological entity with its own characteristics, the surgical management of GISTs has changed. The lack of lymphatic spread of this kind of tumor makes lymphadenectomy unnecessary, so the only oncological criteria is to maintain the integrity of the capsule and to perform an R0 resection. Wedge resection is a correct procedure from an oncological point of view, but if technically unfeasible, as for esophageal or rectal GISTs, a segmental resection becomes necessary. Our experience was over a period of 29 years. Patients operated before 2000 underwent more extensive resections than patients operated after 2000, without any difference in overall survival or disease-

Table 1 Distribution of gastrointestinal stromal tumors by site and their features

| Organs | Number of cases | Low risk | Moderate risk | High risk | Mitotic index > 5 × 50 HPF | Mean size (cm) | CD117+ | CD34+ | Ki67 > 10% |

HPF: High power field.

free survival. The types of intervention were extremely heterogeneous, demonstrating that there is no standardized procedure to approach this kind of neoplasm. Epidemiological features found in our series are comparable with the literature: DeMatteo *et al.*^[20] reported a median age of 58, with predominant localization of the tumors in the stomach (39%) followed by small bowel (32%); Ahmed *et al.*^[21] reported a mean age of 64.4, with tumors mainly localized in the stomach (52%) and colon (13%). Clinical presentation is extremely heterogeneous in the literature as in our series: a recent Swedish study demonstrated that 70% of GISTs had associated symptoms, 20% had none and 10% were detected at autopsy^[22]. Symptoms were generally non specific: nausea, vomiting, abdominal pain or discomfort; sometimes GISTs caused gastrointestinal bleeding, because of the erosion of gastric or small bowel mucosa; dysphagia occurred rarely, and was associated with a tumor located in the esophagus; biliary obstruction could occur if the tumor was located in the duodenum; and intussusception, could occur if the tumor was located in the small bowel.

The R0 resection rate was higher in our series (90.7%) than in others: DeMatteo *et al.*^[20] reported 47%; Ahmed *et al.*^[21] 51%. The difference can be explained by the larger number of patients in those series and the larger number of locally advanced or metastatic GISTs treated. In our series, 9.3% of the patients died of disease. Ahmed reported 11% with a mean follow-up of 6.8 years and De Matteo 50% with a mean follow-up of 24 mo. The difference is due to the large number of patients with GISTs at low and moderate risk of relapse in our series compared with that of De Matteo.

Four laparoscopic operations (12.5%) were performed in our series for tumors with a mean diameter of 4.5 cm located in the anterior wall of the stomach and in the jejunum; none of these patients developed local or distant recurrence. DeMatteo and Ahmed did not deal with a laparoscopic approach to GISTs. Even if our laparoscopic series is limited to 4 operations we report results of other series, avoiding every comparison with our own. Novitsky *et al.*^[23] reported a series of 50 laparoscopic gastric resections for GISTs. Mean diameter of the neoplasm was 4.4 cm; the conversion rate was 0% and disease-free survival 92% at 36 mo. Huguet *et al.*^[24] reported a series of 33 patients affected by gastric GISTs of mean diameter of 3.9 cm and treated with a laparoscopic approach. The conversion rate was 6% and disease-free survival 100% with a median

follow-up of 13 mo. Similar results were obtained by Basu *et al.*^[25], Nishimura *et al.*^[26] and Pitsinis *et al.*^[27]. Tabrizian *et al.*^[28] reported a series of 76 laparoscopic resections for GISTs. Of these, 72% were located in the stomach and 28% in the small bowel, with mean diameter of 4.2 and 3.9 cm, respectively. The conversion rate was 14% and disease-free survival 78% at 41 mo (77% gastric *vs* 82% small bowel). Laparoscopic treatment of GIST is a safe and effective procedure, but should only be performed at centers with excellent laparoscopic experience, taking strict oncological precautions to avoid rupture of the pseudocapsule and spreading of neoplastic cells. If these precautions cannot be assured, the surgeon must not hesitate to convert, because this kind of mistake can change a curable disease into a poor prognostic one and this must be avoided. International guidelines recommend the employment of laparoscopic surgery only for tumors smaller than 5 cm^[13].

In conclusion, surgical treatment remains the gold standard therapy for resectable GISTs. Surgical strategies are different and heterogeneous, as the only oncologic criteria imposes the preservation of the integrity of the capsule and the avoidance of infiltration of the resection margins. The laparoscopic approach is considered safe and effective for masses not exceeding 5 cm, in centers experienced in advanced laparoscopic surgery. In the presence of resectable and non metastatic masses, correctly removed by the surgeon, pathological and biological features of the tumor, expressed by Fletcher's classification, remain the most important factors for predicting the prognosis. For high risk or metastatic tumors as for non resectable masses, molecular therapy with the tyrosine kinase inhibitor imatinib mesylate has improved survival. The use of the laparoscopic technique in combination with molecular therapy will permit the development of a minimally invasive treatment for this type of neoplasm, improving patients' survival and quality of life.

COMMENTS

Background

Gastrointestinal stromal tumors (GISTs) are tumors arising from the wall of the gastrointestinal tract, from the esophagus to the rectum. As in the heart, where pacemaker cells regulate the beat, so in the intestinal tract there are similar pacemaker cells regulating intestinal motility (peristalsis) called interstitial cells of Cajal. GISTs are a neoplastic proliferation of this kind of cell and account for < 1% of all gastroin-

testinal tumors.

Research frontiers

A correct definition of GIST is quiet recent. During the last 15 years knowledge about the biological behavior and natural history of these tumors has improved, but treatment is not yet perfectly standardized.

Innovations and breakthroughs

The purpose of this article is to report the cases of GIST treated during the last 29 years at San Luigi University Hospital. Many changes occurred in diagnosis and treatment, but it is possible to extract from these data relevant information about epidemiology, natural history and therapy of GISTs. Data are comparable with other important series from the USA, UK, and Japan. The authors can conclude that surgical treatment remains the gold standard therapy for resectable tumors. For advanced or metastatic GISTs medical therapy with imatinib mesylate, an inhibitor of tyrosine kinase, is safe and effective.

Applications

The study is a further confirmation of the epidemiological features and correct treatment modality for GISTs.

Terminology

Stromal refers to the connective tissue, that is the structural tissue of the organs. Tyrosine kinases are molecules implicated in cell proliferation and tyrosine kinase inhibitors block this cellular pattern, controlling tumor proliferation.

Peer review

The article presented by the authors is interesting.

Abstract

AIM: To assess feasibility of a finger prick-based kit as method for self-testing of first and second-degree relatives of coeliac disease (CD) patients.

METHODS: A total number of 379 subjects were invited to participate in this study, consisting of 197 first-degree and 182 second-degree relatives of CD patients. The self-testing kit (Biocard™) was sent out with included instructions for use. Completed tests were sent back to the study coordinator for assessment.

RESULTS: One hundred and ninety-six invited relatives carried out the Biocard™ test at home. Amongst these, 70% were children. In 97% of the cases the test was performed correctly. Three tests revealed a positive result, all of which were later confirmed by serology and histology as coeliac disease.

INTRODUCTION

Coeliac disease (CD) is an autoimmune disorder induced by gliadin in genetically predisposed individuals. The "classical" gastrointestinal malabsorption syndrome is characterised by the acute onset of diarrhoea, steatorrhoea, weight loss and anaemia, which typically occurs in children under the age of one year following their first gluten exposure during the weaning process. However, the vast majority of CD patients frequently present later with mild and less specific symptoms such as abdominal discomfort, bloating, altered stool habit and reduced energy levels. An increasing number of children are completely asymptomatic but are detected as part of screening programs^[1,2]. Disease prevalence has been rapidly increasing and several serological screening studies from Europe, South America, Australasia and the USA

have shown a prevalence of up to 0.5%-1% with disease affecting both children and adults equally^[5]. Given the fact that CD is a lifelong condition that can be treated by strict gluten exclusion, early diagnosis is desirable as it helps avoid unnecessary symptoms and reduces long-term complications^[4,5].

While a screening of all healthy individuals is difficult to perform, routine testing of asymptomatic individuals in high-risk groups is being increasingly recommended. Amongst the groups at greater risk are first- and second-degree relatives of patients with CD^[6]. Currently, the most frequently used screening tools are based on the detection of specific IgA against endomysial antibody (EMA) and tissue transglutaminase (tTG) and are routinely performed on patients in primary and secondary care^[7]. Whilst testing symptomatic individuals can often be done by venepuncture at their primary visit, screening asymptomatic patients would be made much easier if this were possible outside a healthcare environment and without the need for a trained phlebotomist. Testing first- and second-degree relatives with such a test should improve acceptability and hence uptake of the test. The Biocard™ Coeliac Test (ANI Biotech) measures serum levels of anti-tTG IgA antibodies and total IgA levels in 15 min using a finger prick blood sample. This test has been specifically designed for use by non-professionals and has already demonstrated high efficacy in clinical settings^[8]. The result is stable over time and hence can be returned by mail for confirmation.

The aim of this study was to assess the feasibility of using the Biocard™ Coeliac Test as a method for home self-testing of first- and second-degree relatives of CD patients.

MATERIALS AND METHODS

Patient recruitment and testing procedure

All first- and second-degree relatives of children with known CD who attended an outpatient clinic for follow-up at the Centre for Paediatric Gastroenterology, Royal Free Hospital (London, UK) were invited to participate in the study. CD of all paediatric index cases had been diagnosed according to the European Society of Paediatric Gastroenterology, Hepatology and Nutrition (ESPGHAN) criteria^[9]. One or both parents of eligible families were contacted by telephone or asked during their child's clinic appointment to participate in the study. All invited participants had not been tested for CD previously. Detailed information on the study was provided and written consent obtained from parents and relatives, as well as from older children as appropriate. Following recruitment, all families received Biocard kits with included written instructions and contact details of the study coordinator by post. Adult participants were asked to perform the test at home using manufacturer's instructions only. Parents were asked to perform the test on their children. Completed tests were returned in a pre-paid envelope. All patients with a positive test result for the Biocard™ Coeliac Test were followed up in hospital and underwent serum testing

Table 1 Participant characteristics

| | |
|-------------------------|-----------------|
| Invited family members | 379 |
| Male | 174 (46%) |
| Female | 205 (54%) |
| Age (yr), mean (range) | 37.5 (1.3-85.1) |
| 0-18 | 70 (18.5%) |
| > 18 | 309 (81.5%) |
| First-degree relatives | 197 |
| Second-degree relatives | 182 |

for anti-tTG IgA, EMA IgA and total IgA. In the case of a confirmed positive test result, an upper endoscopy was offered to affected individuals.

In the period from March 2008 to March 2009, 67 families were contacted and a total of 423 family members were invited to take part in the study. Amongst these, 379 subjects agreed to try out the test (197 first-degree and 182 second-degree relatives of CD patients) (Table 1). The mean age of subjects was 37.5 years (range, 1.3-85.1 years); including 70 children (0-18 years) and 309 adults (> 18 years).

Description of Biocard test

The test requires 1 drop (10 µL) of blood, obtained by performing a finger prick with a sterile lancet. The drop of blood is collected in a capillary tube which is inserted into the testing tube with the reagent solution. Following the insertion of the sample strip into the test reagents, results are available after 15 min. There are two separate indicator fields on the test strip. A test is considered positive if a line appears both in the control field as well as in the test field. The line in the test field indicates that there are anti-tTG IgA antibodies present in the blood sample, while the control line indicates normal levels of total IgA. Hence, a test is considered positive if both lines are visible, and negative if a line is present only in the control field but not in the test field. If there is no line or only a faint line in the control field, the result is indeterminate, indicating insufficient IgA antibody levels (or IgA deficiency) requiring further serological tests (tTG IgG and/or EMA IgG and total IgA).

Ethical approval

Ethical approval was obtained prior to the start of the study (Royal Free Hospital and Medical School Research Ethic Committee, 08/H0720/29).

RESULTS

Patient compliance

Of 379 subjects who agreed to participate in the study, 196 (51%) carried out the Biocard test at home. Amongst these, 70% were children (Table 2). In 100% of the cases the test was performed correctly, confirmed by clear lines in the appropriate test/control field on return of the test strip. One hundred and eighty-eight (49%) of the enrolled participants did not perform the test (adult 82%, children 18%). Families who failed to return the test strip received

Table 2 Feasibility and results of Biocard test

| | |
|---------------------------------|------------|
| Tests performed | 196 |
| Correctly performed at home | 196 (100%) |
| Test not performed | 188 (49%) |
| Change of mind | 185 |
| Afraid | 2 |
| Felt too unwell to perform test | 1 |

a phone call to record reasons for not completing the test; 98.5% of enrolled subjects admitted to changing their mind after initially agreeing to take part. Only 2 subjects (1%) stated they were afraid of performing the test, while 1 subject had felt too unwell.

Test results and follow-up

Of the 196 subjects who performed the Biocard test correctly, 3 tested positive with clear lines in control and test field. CD was then confirmed by serological testing as well as on histology following duodenal biopsy. One of these 3 individuals had a positive line in the test field and no line in the control field, indicating an IgA deficiency, which was also confirmed on more formal testing.

DISCUSSION

First- and second-degree relatives of patients with CD have been identified as one of the main groups at higher risk of silent CD and hence are recommended to be screened. Additionally, doctors involved in the care of CD patients are often confronted with great anxiety that other family members could be affected. Hence, in such situations, reliable, minimally invasive and easy to perform tests should be offered. However, current screening tests are cost- and labour-intensive as well as requiring venepuncture performed by trained health professionals. In this study, we aimed to assess the feasibility of using a finger prick-based kit as a method for home self-testing of first- and second-degree relatives of CD patients. A recent study validating this test has demonstrated sensitivity and specificity comparable to those of conventional serological coeliac screening^[8]. Moreover, the test can easily be performed by non-professionals following only written instructions. Results are available within 15 min and include a reference test line to confirm adequate levels of total IgA antibodies. Of all relatives enrolled in our study, 51% ($n = 196$) performed the test at home. Despite the fact that 49% of potential family members chose not to perform the test, the majority (98.5%) did so for reasons unrelated to the test itself, a phenomenon frequently encountered amongst populations undergoing voluntary screening programs. Importantly, all returned tests revealed valid results as assessed by the study coordinator, indicating that it was performed correctly. Also, the fact that our study included a significant proportion of children further highlights the potential of this test to be used in this population. However, it is important to state that a positive test result currently still requires further investigation and follow-up by appropriate paediatric medi-

cal and dietetic health professionals.

In summary, results of our study indicate that the Biocard™ Coeliac Test is suitable for use in home self-testing of first- and second-degree relatives of children with CD. Moreover, given that the test can reliably be performed by non-professionals combined with its high validity, the application of this test could be further extended and offered to high risk groups in a non-specialist outpatient setting such as general practitioners surgeries or health practitioner clinics.

COMMENTS

Background

Frequently, coeliac disease (CD) presents with mild, non-specific abdominal symptoms or is even diagnosed in asymptomatic individuals. Being at an increased risk, first- and second-degree relatives of CD patients are often screened routinely or request to be screened. Highly reliable, cost effective and easy to use tests are required to meet this growing demand. The aim of this study was to assess the feasibility of using a finger prick-based kit as a method for home self-testing of first- and second-degree relatives of CD patients.

Research frontiers

The Biocard™ Coeliac Test (ANI Biotech) measures serum levels of anti-tissue transglutaminase IgA antibodies and total IgA levels in 15 min using a finger-prick blood sample. This test has been specifically designed for use by non-professionals and has already demonstrated high efficacy in clinical settings.

Innovations and breakthroughs

First- and second-degree relatives of patients with CD have been identified as one of the main groups at higher risk of silent CD and hence are recommended to be screened for the disease. Doctors involved in the care of CD patients are often confronted with great anxiety that other family members could be affected. Hence, in such situations, reliable, minimally invasive and easy to perform tests should be offered. However, current screening tests are cost and labour intensive, as well as requiring venepuncture performed by trained health professionals.

Applications

The authors' study indicates that the Biocard™ Coeliac Test is suitable for use in home self-testing of first- and second-degree relatives of children with CD. Moreover, given the test can reliably be performed by non-professionals combined with its high validity, the application of this test could be further extended and offered to high risk groups in a non-specialist outpatient setting such as general practitioners surgeries or health practitioner clinics.

Peer review

The manuscript presents original data on feasibility of self-testing for CD among patients' relatives. This strategy could improve the compliance to a screening test among asymptomatic subject, while maintaining good sensitivity and reliability.

Issa H, Al-Salem AH. Role of ERCP in the era of laparoscopic cholecystectomy for the evaluation of choledocholithiasis in sickle cell anemia. *World J Gastroenterol* 2011; 17(14): 1844-1847 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i14/1844.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i14.1844>

Abstract

AIM: To evaluate the role of endoscopic retrograde cholangiopancreatography (ERCP) for choledocholithiasis in patients with sickle cell anemia (SCA) in the era of laparoscopic cholecystectomy (LC).

METHODS: Two hundred and twenty four patients (144 male, 80 female; mean age, 22.4 years; range, 5-70 years) with SCA underwent ERCP as part of their evaluation for cholestatic jaundice (CJ). The indications for ERCP were: CJ only in 97, CJ and dilated bile ducts on ultrasound in 103, and CJ and common bile duct (CBD) stones on ultrasound in 42.

RESULTS: In total, CBD stones were found in 88 (39.3%) patients and there was evidence of recent stone passage in 16. Fifteen were post-LC patients. These had endoscopic sphincterotomy and stone extraction. The remaining 73 had endoscopic sphincterotomy and stone extraction followed by LC without an intraoperative cholangiogram.

CONCLUSION: In patients with SCA and cholelithiasis, ERCP is valuable whether preoperative or postoperative, and in none was there a need to perform intraoperative

INTRODUCTION

Sickle cell anemia (SCA) is one of the commonest hemoglobinopathies in the Eastern Province of Saudi Arabia with a sickle cell trait frequency of about 25% and a sickle cell disease frequency of about 2% in some areas^[1,2]. One of the common complications of SCA is cholelithiasis and choledocholithiasis. The prevalence of cholelithiasis in patients with SCA is variable, ranging from 17% to 55%, but the frequency increases with age^[3-5]. In the Eastern Province of Saudi Arabia, an overall frequency of cholelithiasis of 19.7% was reported in children with SCA. This frequency however, increased to 36% in those 15-18 years of age^[6]. The incidence of choledocholithiasis in patients with SCA undergoing cholecystectomy was reported to be around 30%^[7,8]. In the past, and based on this high incidence of common bile duct (CBD) stones, routine intraoperative cholangiography (IC) was recommended during cholecystectomy as this may necessitate

CBD exploration^[7]. This however is not the case in the era of LC. Laparoscopic IC and CBD exploration, although feasible, is not easy to perform, requires expertise, and may be time-consuming. Add to this the possibility of converting a LC into an open one once CBD stones are diagnosed and found to be difficult to retrieve laparoscopically. The question now is whether routine laparoscopic IC is necessary for patients with SCA undergoing LC.

MATERIALS AND METHODS

Two hundred and twenty four patients with SCA underwent endoscopic retrograde cholangiopancreatography (ERCP) as part of their evaluation for cholestatic jaundice (CJ). Their medical records were reviewed for: age at diagnosis, sex, indication for ERCP, hemoglobin (Hb) electrophoresis, liver function tests, including total and direct bilirubin, alanine aminotransferase (ALT), aspartate aminotransferase (AST) and alkaline phosphatase, and abdominal ultrasound. The indications for ERCP were divided into 3 categories based on ultrasound findings: (1) patients with CJ and normal ultrasound; (2) patients with CJ and dilated bile ducts on ultrasound; and (3) patients with CJ and CBD stones on ultrasound. All ERCPs were performed in the radiology department using Olympus TJF 240 or JF 260 side-viewing duodenoscopes under general anesthesia, with nasotracheal intubation for children less than 10 years old, and under deep sedation using meperidine (1 mg/kg) and diazepam (midazolam) (0.1-0.2 mg/kg) for those above 10 years of age. The ampulla of Vater was cannulated with tapered or regular catheters and the biliary ducts were visualized under fluoroscopy using Hexabrix (320 mg diluted to 50%). Appropriate radiographs were obtained and, where indicated, sphincterotomy was performed using a 5F sphincterotomy (Olympus); bile duct stones, if found, were extracted with a basket, balloon extractor or mechanical lithotripter.

RESULTS

There were 144 male and 80 female patients, mean age 22.4 years (range, 5-70 years). Mean HbS was 76.8% (range, 64.7%-92.3%); their mean HbF was 20.4% (range, 5.1%-34.0%); mean total bilirubin was 224 mg/L (range, 55-395 mg/L); mean direct bilirubin was 134 mg/L (range, 40-263 mg/L); mean alkaline phosphatase was 486 IU/mL (range, 81-1189 IU/mL; normal: 50-136 IU/mL); mean ALT was 234.3 IU/mL (range, 50-761 IU/mL; normal: 30-50 IU/mL) and mean AST was 206.3 IU/mL (range, 63-317 IU/mL; normal: 15-37 IU/mL). The indications for ERCP were: CJ only in 97 patients, CJ and dilated bile ducts on ultrasound in 103, and CJ and CBD stones on ultrasound in 42. In those with CJ only, ERCP revealed CBD stones in 18 (18.6%), and the ampulla of Vater was edematous and inflamed in 4, suggestive of recent stone passage. In those with CJ and dilated bile ducts, ERCP revealed CBD stones in 48 (46.6%), and inflamed edematous ampulla in 8. In those with CJ and CBD stones, ERCP revealed stones in 22 (52.4%), and the ampulla was inflamed

and edematous in 4. In total, CBD stones were found in 88 (39.3%) patients, and there was evidence of recent stone passage in 16. Fifteen of these were post-cholecystectomy patients, who had endoscopic sphincterotomy and stone extraction. The remaining 73 had endoscopic sphincterotomy and stone extraction followed by LC without an IC. Two (2.3%) patients developed minor bleeding from the sphincterotomy site. This was controlled with local diluted adrenaline injection. Two (2.3%) developed transient mild pancreatitis.

DISCUSSION

In the general population with cholelithiasis the incidence of CBD stones has been reported as 5%-15% whereas in those with SCA it ranges from 18% to 30%^[7-10]. Because of the high incidence of choledocholithiasis in patients with SCA, routine IC was advocated^[7]. With the recent advances in LC, exclusion of CBD stones is of great importance. This is specially so in patients with SCA who frequently present with CJ and are known to have a high incidence of cholelithiasis and choledocholithiasis. There are those who advocate routine laparoscopic IC to delineate the anatomy and to detect CBD stones^[11-16]. Lillemoe *et al*^[17] on the other hand advocate the selective use of laparoscopic cholangiography. Although laparoscopic IC is feasible, it has several disadvantages. It requires operators who are experienced in laparoscopic surgery, it is not technically easy, and it is known to increase the operative time. It also makes it difficult to decide, when CBD stones are diagnosed and difficult to retrieve, whether to convert the operation to open or wait and do a post-LC ERCP. Add to this a 20%-25% false positive rate of IC that may lead to unnecessary CBD exploration or conversion to open cholecystectomy^[16]. In a prospective study of CBD calculi in patients undergoing cholecystectomy, Nathanson *et al*^[18] found choledocholithiasis in 3.4%, and concluded that laparoscopic IC would result in unnecessary interventions in 50% of patients who had either false positive results or subsequently passed the stones. Another study in 343 patients who underwent LC concluded that routine IC should be discouraged in view of the low yield and significant rate of false positive results^[19]. However, Targarona *et al*^[20] stated that the choice of diagnostic and therapeutic strategies for CBD stones should depend on local circumstances and available expertise. We found ERCP to be valuable both for the diagnosis and management of CBD stones in patients with SCA who were scheduled to have LC, or in those who presented with retained CBD stones following LC. Our policy is that all SCA patients with cholelithiasis who have a dilated CBD on ultrasound, biochemical evidence of obstructive jaundice (elevated alkaline phosphatase, elevated total bilirubin of more than 50 mg/L), or a history of pancreatitis either alone or in combination, and those who have choledocholithiasis detected on ultrasound, should undergo ERCP to confirm and extract the stones, followed by LC. We, like others, support a policy of preoperative ERCP for those with risk factors for CBD stones followed by LC^[21,22]. However, magnetic resonance

cholangiopancreatography and or endoscopic ultrasound, if available, should replace ERCP as a diagnostic method to detect CBD stones as this will reduce the number of negative ERCPs and avoid the risks and complications of ERCP particularly for those with dilated CBD without stones.

In conclusion, considering the high incidence of CBD stones in patients with SCA, it is important to exclude them as a cause of CJ whether pre- or post-cholecystectomy. This is specially so in the era of LC. Laparoscopic IC, although feasible, is not easy to perform, is time-consuming, requires expertise, and may necessitate conversion to open surgery if CDB stones are identified. We found ERCP valuable in this regard whether pre- or post-LC, and in none of our patients was there a need to perform laparoscopic IC. Sequential endoscopic sphincterotomy and stone extraction followed by LC is beneficial in these patients^[23,24]. Since we started using ERCP, none of our patients required CBD exploration and all CBD stones, whether diagnosed preoperatively or postoperatively, were managed by endoscopic sphincterotomy and stone extraction. Endoscopic sphincterotomy may also prove to be useful in these patients as it may prevent the future development of biliary sludge and bile duct stones.

COMMENTS

Background

Cholelithiasis and choledocholithiasis are common in patients with sickle cell anemia, and it is important to exclude choledocholithiasis in those undergoing cholecystectomy. In the past and at the time of open cholecystectomy, routine intraoperative cholangiography (IC) was part of the operative procedure as they have a high incidence of choledocholithiasis. The question now is whether routine laparoscopic IC is necessary for patients with Sickle cell anemia (SCA) undergoing laparoscopic cholecystectomy.

Research frontiers

Common bile duct (CBD) stones were found in 88 (39.3%) of 224 patients and there was evidence of recent stone passage in 16. Fifteen of these were post-laparoscopic cholecystectomy patients and had endoscopic sphincterotomy and stone extraction. The remaining 73 had endoscopic sphincterotomy and stone extraction followed by laparoscopic cholecystectomy without IC.

Innovations and breakthroughs

Laparoscopic IC, although feasible, is not easy to perform, is time-consuming, requires expertise, and may necessitate conversion to open surgery if bile duct stones are identified. We found endoscopic retrograde cholangiopancreatography (ERCP) valuable whether pre- or post-laparoscopic cholecystectomy and in none of our patients was there a need to perform laparoscopic IC. Sequential endoscopic sphincterotomy and stone extraction followed by laparoscopic cholecystectomy are beneficial in these patients. Since we started using ERCP, none of our patients required CBD exploration and all CBD stones whether diagnosed preoperatively or postoperatively were managed by endoscopic sphincterotomy and stone extraction. Endoscopic sphincterotomy may also prove to be useful in these patients as it may prevent the future development of biliary sludge and bile duct stones.

Applications

All patients with SCA and cholelithiasis who have a dilated CBD on ultrasound, elevated alkaline phosphatase, elevated total bilirubin of more than 50 mg/L, or a history of pancreatitis either alone or in combination, and those who have choledocholithiasis detected on ultrasound should undergo ERCP to confirm and extract stones followed by laparoscopic cholecystectomy. However, magnetic resonance cholangiopancreatography and or endoscopic ultrasound should replace ERCP as a diagnostic method to detect CBD stones as this will reduce the number of negative ERCPs and avoid the risks and complications of ERCP particularly for those with dilated CBD without stones.

Terminology

ERCP: Endoscopic retrograde cholangio pancreatography. SCA: Sickle cell anemia, a hereditary hemoglobinopathy resulting from a single change of one amino acid, valine instead of glutamic acid of the hemoglobin B-chain. This will lead to a change in the shape of red blood cells causing their adherence together, blocking the small blood vessels and their hemolysis.

Peer review

The authors discussion of routine cholangiography in patients with SCA with high suspicion of choledocholithiasis is highly appreciated.

in liver transplantation, because TMA is an infrequent but life-threatening complication in the transplantation field.

METHODS: A total of 206 patients who underwent living-donor liver transplantation (LDLT) were evaluated, and the TMA-like disorder (TMALD) occurred in seven recipients.

RESULTS: These TMALD recipients showed poor outcomes in comparison with other 199 recipients. Although two TMALD recipients successfully recovered, the other five recipients finally died despite intensive treatments including repeated plasma exchange (PE) and re-transplantation. Histopathological analysis of liver biopsies after LDLT revealed obvious differences according to the outcomes. Qualitative analysis of antibodies against a disintegrin-like domain and metalloproteinase with thrombospondin type 1 motifs (ADAMTS-13) were negative in all patients. The fragmentation of red cells, the microhemorrhagic macules and the platelet counts were early markers for the suspicion of TMALD after LDLT. Although the absolute values of von Willebrand factor (vWF) and ADAMTS-13 did not necessarily reflect TMALD, the vWF/ADAMTS-13 ratio had a clear diagnostic value in all cases. The establishment of adequate treatments for TMALD, such as PE for ADAMTS-13 replenishment or treatments against inhibitory antibodies, must be decided according to each case.

CONCLUSION: The optimal induction of adequate therapies based on early recognition of TMALD by the reliable markers may confer a large advantage for TMALD after LDLT.

INTRODUCTION

Thrombotic microangiopathy (TMA) is a microvascular occlusive disorder induced by facilitation of endothelial damage and primary platelet (PLT) aggregation^[1]. Currently, the concept of TMA encompasses two previous entries, i.e., thrombotic thrombocytopenic purpura and hemolytic uremic syndrome^[2]. Although the specific pathophysiological mechanism is still not understood, many investigators have focused on a disintegrin-like domain and metalloproteinase with thrombospondin type 1 motifs (ADAMTS)-13 as a metalloproteinase that specially cleaves the multimeric von Willebrand factor (vWF)^[3-5]. The vWF is an essential factor for the adhesion/aggregation of circulating PLTs associated with high shear stresses^[6,7]. Following the identification of ADAMTS-13 in 2001^[3-5], some investigators suggested that a deficiency of ADAMTS-13 activity^[3,8] and/or inhibitory autoantibodies against ADAMTS-13^[2,9] may cause TMA *via* a pathway in which unusually large vWF multimers elevate the shear stress and lead to excessive PLT clumping^[6,7,10]. As a consequence, PLTs would be consumed in TMA patients, and finally result in organ failure because of microvascular occlusion.

Clinically, TMA patients develop thrombocytopenia accompanied by hemolytic anemia and show a hemorrhagic tendency^[1,2,11]. The TMA is clinically defined as thrombocytopenia and microangiopathic hemolytic anemia with no apparent alternative explanations^[1,12,13]. The diagnostic criteria for TMA are defined as follows^[1,2,14,15]: (1) the presence of thrombocytopenia (PLT count < $5.0 \times 10^4/\text{mm}^3$) or the progressive decline in PLT counts (decrease of $> 3.0 \times 10^4/\text{mm}^3$ within 24 h); (2) microangiopathic hemolytic anemia [hemoglobin (HB) < 8.0 g/dL]; (3) sharply elevated levels of serum lactate dehydrogenase (LDH) (typically > 500 IU/L); (4) the presence of fractionated erythrocytes in a blood smear; and (5) severe deficiency in ADAMTS-13 activity (< 5% in normal plasma)

or prevalence of ADAMTS-13-specific antibodies (Abs) categorized as immunoglobulin G (IgG) isotypes.

TMA is well known as a fatal complication after transplantation, and its frequencies are documented to be 6% after bone marrow transplantation^[16] and 3%-5% after solid-organ transplantation^[17,18]. The first case of TMA in the liver transplantation (LT) field was reported in 1984^[19], and thereafter some researchers have reported that the frequency of TMA after LT is 3.8%-5.0%^[2,14]. Repeated plasma exchange (PE)/exchange transfusion (ET) is considered to be the standard therapy for TMA from the viewpoint of the replenishment of ADAMTS-13 and the depletion of inhibitory Abs^[13,15,20-22]. To date, a total of 739 pediatric and 669 adult LTs have been performed in our institution. Although we have no experience of cases that completely fulfilled the TMA criteria described above, seven cases were retrospectively considered to be TMA-like disorder (TMALD) after living-donor liver transplantation (LDLT). Here, we focused on post-LDLT TMA cases and present our results for TMALD patients. The pathophysiological basis, the early marker for the recognition of TMALD, the reliable factors for diagnosis and further clinical strategies are discussed in the LDLT field.

MATERIALS AND METHODS

Patients

A total of 155 adult and 51 pediatric recipients who underwent LDLT at Kyoto University Hospital from April 2006 to March 2009 were evaluated in this study. Seven patients (five adults and two pediatric recipients) showed thrombocytopenia and microangiopathic hemolytic anemia with no apparent alternative causes. They were given the intensive TMALD treatments.

These seven patients comprised one male and six females, and their age range was 0.8-65.2 years. The primary diseases for LDLT included two cases each of primary biliary cirrhosis and liver cirrhosis caused by hepatitis C virus (HCV), and one case each of liver cirrhosis caused by autoimmune hepatitis, biliary atresia (post-Kasai's portoenterostomy) and fulminant hepatic failure (etiology unknown). The United Network for Organ Sharing statuses were estimated to be four cases of II A, two of II B and one of I. The mean Child-Pugh score was 12.0 ± 1.7 points (range, 10-14 points). The mean score of the model for end-stage liver disease (MELD) or pediatric end-stage liver disease (PELD) was 23.7 ± 8.8 points (range, 17-41 points). The ABO blood groups were characterized as three cases each of identical and incompatible and one case of compatible. The donor relationships were four spouses, one grandmother, one father and one son.

The protocol of the study was approved by the Ethics Review Committee for Clinical Studies of Kyoto University Graduate School of Medicine.

Operation

There were three left-lobe grafts, two extended lateral-segment grafts and one right-lobe graft without the middle

hepatic vein. The range of the graft/recipient weight ratios was 0.74-4.58. Normal findings for histopathological analyses of biopsy specimens during the donor operation were confirmed in all cases. The mean operative time was 690.7 ± 150.0 min (range, 480-873 min) and the mean blood loss was 4180.0 ± 2843.3 mL (range, 370-7700 mL). The mean cold ischemic time, warm ischemic time and anhepatic phase were 49.4 ± 18.9 min (range, 27-77 min), 63.0 ± 32.9 min (range, 40-133 min) and 150 ± 76.6 min (range, 51-267 min), respectively. All the recipients received blood transfusions of a red cell concentrate and fresh-frozen plasma (FFP) during LDLT, and two recipients received a PLT transfusion. The patient profiles are shown in Table 1.

Immunosuppression

Immunosuppression after LDLT was started with tacrolimus and methylprednisolone. The trough level of tacrolimus was maintained at 8-15 ng/mL during the early postoperative period, based on the clinical findings in each case. Calcineurin inhibitors (CNIs) were converted to cyclosporin A from tacrolimus at postoperative day (POD) 15 in one case. Methylprednisolone was given intravenously (1 mg/kg) once daily from POD 1 to POD 3 followed by 0.5 mg/kg once daily for the next three days. On POD 7, 0.3 mg/kg of methylprednisolone was given intravenously. Steroid administration was switched to oral prednisolone 0.3 mg/kg once daily on POD 8. This dose was reduced to 0.1 mg/kg at one month after LDLT. We had already overcome ABO-incompatibility in LDLT, and our regimens for these recipients, including heparin usage, were described previously^[23,24].

The exclusion of other diseases

To exclude other diseases, such as humoral rejection (HR), hematological diseases, heparin-induced thrombocytopenia and autoimmune diseases, detailed examinations, such as bone-marrow puncture, liver needle biopsy, immunological assays and measurements of anti-platelet factor 4/heparin Abs and anti-PLT autoantibodies were performed.

Measurements of individual variables

In our institution, laboratory examinations were routinely performed at least every 8-12 h in all recipients during the early postoperative period after LDLT and in critical LDLT recipients. The appearances of fragmentation of

red cells (FRC) and microhemorrhagic macules (MHMs) were checked, and temporal changes in the counts or levels of PLTs, HB, LDH, prothrombin time-international normalized ratio (PT-INR) and total bilirubin (T-BIL) were estimated.

The values for vWF and ADAMTS-13 were measured by enzyme-linked immunosorbent assays, and subsequently used to calculate the vWF/ADAMTS-13 ratio. Quantitative determination of inhibitory IgG (anti-ADAMTS-13 Abs) was performed by the Bethesda method (the detection limit was 0.5 Bethesda units/mL).

Normal ranges of vWF, ADAMTS-13 and the vWF/ADAMTS-13 ratio were calculated in a control group, with 10% rejection region. A control group was composed of 54 healthy volunteers (26 males and 29 females). Normal values of vWF, ADAMTS-13 and the vWF/ADAMTS-13 ratio were 60%-170%, 70%-120%, and 0.51-2.43, respectively. The anti-ADAMTS-13 Abs were non-existent in healthy individuals (under the detection limit).

The definition of TMALD

We still do not have any experience of patients who strictly fulfilled all of the TMA criteria. In this study, TMALD was defined as the LDLT recipients who fulfilled the diagnostic criteria of TMA without the absolute value of ADAMTS-13 activity or the presence of ADAMTS-13-specific Abs.

The risk factors for LT outcomes

Previous investigators have documented the important factors for LT outcomes, such as recipient age, disease, donor age, MELD/PELD score, ABO incompatibility, lymphocyte cross-match, cold ischemic time, operative time, blood loss, graft-recipient weight ratio, the type/number of anastomosis and conventional liver function test at early postoperative period^[23,25-33]. There were no statistical differences between the 2 groups in each risk factor for LDLT outcomes, respectively.

Histopathological analysis

A protocol liver needle biopsy (LNB) is not employed in our institution. However, all cases underwent an LNB before and after the treatments for TMALD, except for one case in which an LNB could not be performed because of a severe hemorrhagic tendency. The graft damage

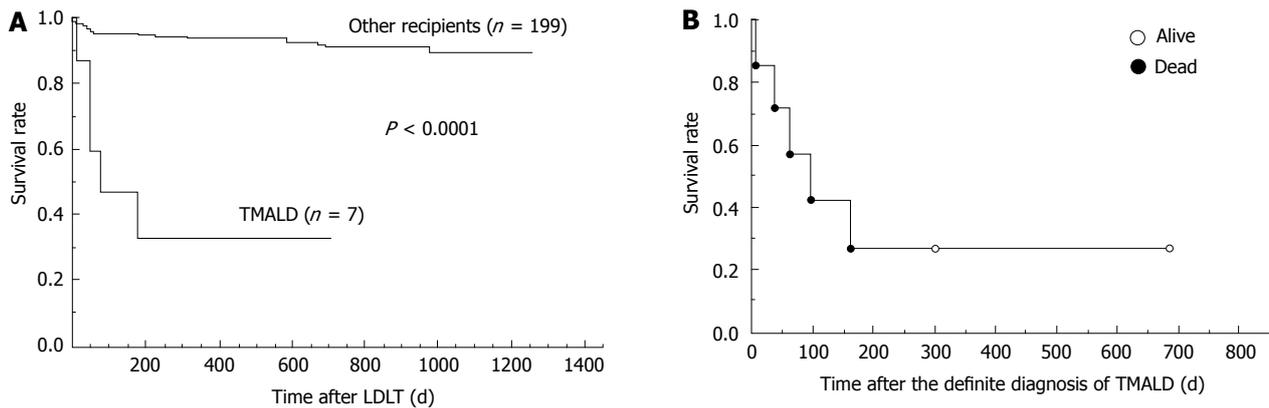

Figure 1 Outcomes of thrombotic microangiopathy like disorder after living-donor liver transplantation. A: The seven thrombotic microangiopathy like disorder (TMALD) patients clearly showed a poor prognosis compared with the other 199 patients ($P < 0.0001$). TMALD after living-donor liver transplantation (LDLT) therefore had a negative impact upon the LDLT outcomes. A total of 206 LDLT recipients at Kyoto University Hospital (from April 2006 to March 2009) were evaluated; B: The thrombotic microangiopathy patients showed a poor prognosis despite intensive treatments after the diagnosis of TMALD. The open circles represent two recipients who were successfully treated, and the closed circles represent five recipients who finally died.

score was estimated according to established guidelines^[34], and was calculated as the total of points of the following parenchymal features: hepatocyte ballooning (0 point = no, 1 = yes), hepatocyte necrosis (0 = none, 1 = small foci, 2 = confluent areas, 3 = bridging necrosis), congestion (0 = no, 1 = yes), microvesicular fat (0 = none, 1 = 1/3 hepatocytes, 2 = between 1/3 and 2/3 hepatocytes, 3 = 2/3 hepatocytes), neutrophil aggregate (0 = none, 1 = minimal, 2 = moderate, 3 = extensive), and cholestasis (0 = none, 1 = mild, 2 = moderate, 3 = severe).

Statistical analysis

The results are expressed as the mean \pm SD. The differences between unpaired continuous or discontinuous data between two groups were analyzed by Student's *t*-test. Survival rates were calculated by the Kaplan-Meier method, and the log-rank test was used for between-group comparisons. All calculations were performed using SPSS Software Version 16.0 (SPSS Inc., Chicago, IL 60606, USA). Differences with *P* values of < 0.05 were considered to be statistically significant.

Ethical approval

The protocol of this study was approved by the Ethics Review Committee for Clinical Studies of Kyoto University Graduate School of Medicine.

RESULTS

TMALD onset after LDLT

TMALD was confirmed in seven cases, and the frequency in our institution was 3.4%. The definite diagnoses were reached at a mean time point of POD 11.1 ± 5.7 (range, 4-21 d).

Clinical courses after TMALD and outcomes in TMALD patients

Five adult recipients clearly showed prolonged jaundice after TMALD [T-BIL peak, 38.9 ± 11.2 mg/dL (range,

21.0-51.0 mg/dL)]. Four of these five cases suffered massive bleeding because of a hemorrhagic tendency in TMALD, and surgical hemostasis was emergently required in three cases. Thrombosis in the hepatic blood flow occurred after TMALD in one of the five cases. Consequently, these five cases fell into graft loss after TMALD, and two of the five recipients suffered hepatic encephalopathy. The details of the clinical courses are shown in Table 1.

On the other hand, two pediatric recipients (ABO-incompatible combinations) showed good responses to the treatments for TMALD, and recovered from their severe graft damage (Table 1).

In comparisons of the survival rates, the TMALD patients clearly showed poor outcomes compared with the other patients who underwent LDLT during the same period in our institution (Figure 1A).

Critical events occurred after TMALD in five recipients and their clinical conditions tended to become worse despite the intensive treatments (Table 1). All of these five recipients with TMALD finally died despite intensive treatments (Figure 1B), and their mean survival time after the TMALD diagnosis was only 70 ± 63 d (range, 5-161 d). Although one of the five patients underwent a re-transplantation because of graft loss, she also finally died (Table 1).

The values of diagnostic early markers and important signs

The fragmentation of red cells was obviously detected in all cases. The haptoglobin level was also decreased to < 5.0 mg/dL in all cases. MHMs were observed in five patients. The mean lowest value of the PLT counts was $1.2 \pm 5.5 \times 10^4/\text{mm}^3$ (range, $0.6\text{-}2.1 \times 10^4/\text{mm}^3$) while that of HB was 6.61 ± 0.68 g/dL (range, 5.9-7.6 g/dL). The mean peak value of the LDH level was 1202.3 ± 603.9 IU/L (range, 518-2089 IU/L). The PT-INR value was prolonged to > 1.5 in only one case at the time of a definite diagnosis, although the mean value for the most prolonged PT-INR after TMALD was 2.66 ± 1.85 (range, 1.22-5.64).

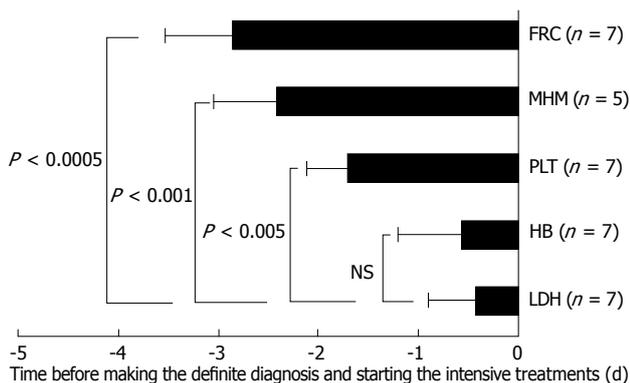

Figure 2 Temporal changes in important markers and signs for thrombotic microangiopathy. The statistical significances of the differences in each factor in comparison with the time points for lactate dehydrogenase (LDH) are shown. Note that although microhemorrhagic macules (MHMs) were only observed in five of the seven cases (71.4%), the MHMs unexpectedly appeared at the early phase of thrombotic microangiopathy like disorder (TMALD) onset after living-donor liver transplantation, as well as fragmentation of red cells (FRC). In each case, the LDH levels proved decisive for making a diagnosis of TMALD, while the appearance of sufficient elevations of the LDH level were mostly late, similar to the case for hemoglobin (HB). PLT: Primary platelet.

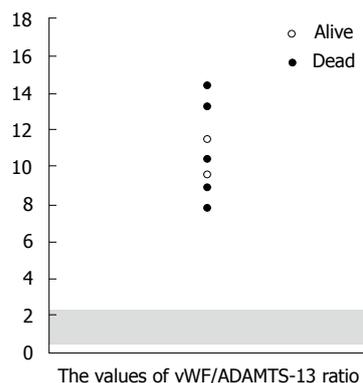

Figure 4 Balance between von willebrand factor and a disintegrin-like domain and metalloproteinase with thrombospondin type 1 motifs-13. From the viewpoint of an imbalance between von Willebrand factor (vWF) and a disintegrin-like domain and metalloproteinase with thrombospondin type 1 motifs (ADAMTS)-13, the ratio of vWF/ADAMTS-13 strictly revealed the abnormalities in all thrombotic microangiopathy like disorder (TMALD) recipients after living-donor liver transplantation (LDLT). The shaded area represents the normal range. The mean value of the vWF/ADAMTS-13 ratio was 11.0 ± 2.4 (range, 7.8-14.6). The open circles represent two recipients who were successfully treated, and the closed circles represent five recipients who finally died.

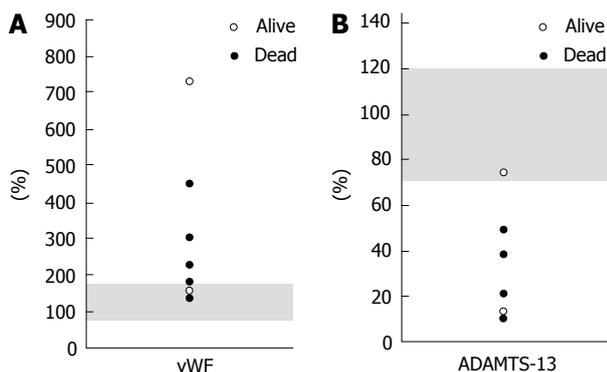

Figure 3 Absolute values of von willebrand factor and a disintegrin-like domain and metalloproteinase with thrombospondin type 1 motifs-13. A The mean absolute value of von Willebrand factor (WF) was $306.6\% \pm 212.0\%$ (range, 135%-723%), and the vWF levels were within the normal range in two cases. The shaded area represents the normal range of vWF. The open circles represent two recipients who were successfully treated, and the closed circles represent five recipients who finally died; B The mean absolute value of a disintegrin-like domain and metalloproteinase with thrombospondin type 1 motifs (ADAMTS)-13 was $31.1\% \pm 24.3\%$ (range, 10%-75%), and the level of ADAMTS-13 was within the normal range in one case. The shaded area represents the normal range of ADAMTS-13. The open circles represent two recipients who were successfully treated, and the closed circles represent five recipients who finally died. Consequently, the degrees of abnormalities in the absolute values of both vWF and ADAMTS-13 did not seem to precisely reflect the thrombotic microangiopathy like disorder outcomes after living-donor liver transplantation.

Changes over time in important indicators for TMA

In two cases, the PLT counts before TMA onset were continuously $< 5.0 \times 10^4/\text{mm}^3$. Progressive decreases of $> 3.0 \times 10^4/\text{mm}^3$ within 24 h were considered to be the time points of fulfilling the TMALD criteria in these cases. Although MHMs were not necessarily observed in all cases, MHMs surprisingly appeared at the early phase of TMALD onset after LDLT, as well as FCR (Figure 2). In each case, elevated LDH levels proved decisive for making

a diagnosis of TMALD, although their appearances were mostly late, similar to the case for HB (Figure 2).

Absolute values of vWF and ADAMTS-13 and the vWF/ADAMTS-13 ratio

In two cases, the vWF levels were within the normal range. The mean absolute value of vWF was $306.6\% \pm 212.0\%$ (range, 135%-723%) (Figure 3A). The ADAMTS-13 level also revealed no abnormalities in one case. The mean absolute value of ADAMTS-13 was $31.1\% \pm 24.3\%$ (range, 10%-75%) (Figure 3B). Therefore, the degrees of alterations in these absolute values did not seem to precisely reflect the TMALD outcomes after LDLT (Figure 3).

On the contrary, from the viewpoint of an imbalance between vWF and ADAMTS-13, the ratio of vWF/ADAMTS-13 strictly revealed the abnormalities in all of the TMALD recipients after LDLT (Figure 4). The mean value for the vWF/ADAMTS-13 ratio was 11.0 ± 2.4 (range, 7.8-14.6).

Inhibitors of ADAMTS-13

Qualitative analysis of anti-ADAMTS-13 Abs produced negative results in all cases. Even in the quantitative determinations, only two cases showed subtle elevations at approximately the cut-off level, although some TMA patients in the hematological field in our hospital showed obvious elevation of anti-ADAMTS-13 Abs.

Repeated PE/ET

Intensive care procedures for secondary complications, such as continuous hemodiafiltration for renal failure, respiratory control for pulmonary dysfunction and intravenous administration of antibiotics for sepsis, were performed in each case based on real-time estimations of their physical conditions, if necessary.

PE/ET (FFP 80-100 mL/kg per day) were repeated

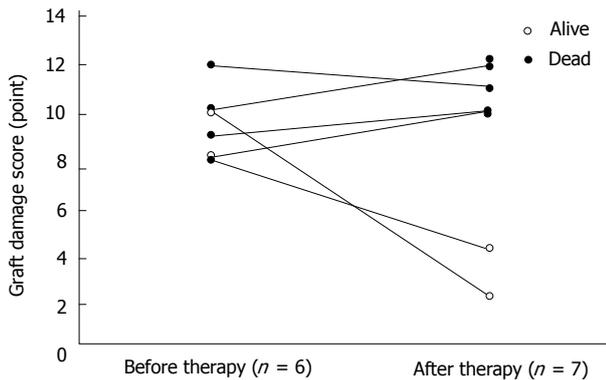

Figure 5 Graft parenchymal damage before and after thrombotic microangiopathy like disorder treatments. The mean graft damage scores before and after thrombotic microangiopathy like disorder (TMALD) treatments in all patients were 8.9 ± 2.2 points (range, 5-12 points) and 8.7 ± 4.0 points (range, 2-12 points), respectively. In comparisons of the histopathological findings before and after TMALD treatments, the graft damage scores clearly demonstrated that five recipients who had poor outcomes (closed circles) showed no improvements despite repeated plasma exchange (PE). The mean graft damage score after TMALD treatments in these five recipients was 8.8 ± 2.6 points (range, 5-12 points). On the other hand, the two surviving recipients (open circles) recovered from their graft parenchymal damage. The graft damage scores after TMALD treatments in these two recipients were two and four points.

as the standard therapy for TMALD in six cases immediately after making a definite diagnosis of TMALD. The mean number of times of repeated PE/ET was 6.5 ± 2.9 (range, 3-10). Repeated PE therapy was not introduced in only one patient who successfully recovered from TMALD. It has been suggested since that repeated PE for the liver failure before LDLT can cause a recurrence of herpes simplex infection after LDLT because of the depletion of antigen-specific Abs by PE and the non-specific immunosuppression after LDLT.

Graft parenchymal damage

Histopathological analysis of LNB specimens clearly revealed that the five recipients who had poor outcomes suffered graft loss after TMALD.

The mean graft damage scores before and after TMALD treatments in all patients were 8.9 ± 2.2 points (range, 5-12 points) and 8.7 ± 4.0 points (range, 2-12 points), respectively (Figure 5).

In comparisons of the histopathological findings before and after TMALD treatments, the results clearly demonstrated that the five recipients who had poor outcomes still showed severe graft parenchymal damage despite of repeated PE [mean graft damage score after TMALD treatments, 8.8 ± 2.6 points (range, 5-12 points)], although the two surviving recipients recovered from their graft parenchymal damage after repeated ET (four times) or no PE/ET treatment. The graft damage scores after TMALD treatments in the successfully treated recipients decreased to two or four points.

DISCUSSION

Although the specific mechanism remains unknown, previ-

ous reports have documented that CNIs and infections, including cytomegalovirus (CMV) and HCV infections, may be possible causes of TMA after LT^[2,17,35-39]. Despite the fact that our institution is a major transplant center in Japan, the frequency of TMA in our institution may be slightly lower than those in previous reports^[16,18]. A possible explanation for this is the well-controlled conditions aimed at preventing CMV and HCV infections after LDLT in our institution^[40,41]. In particular, our clinical strategy brings about excellent long-term outcomes after LDLT for recipients with HCV^[40], and the frequency of TMALD in such recipients is 3.2% (2 TMALD cases among 62 HCV patients after LDLT) in our institution. Paradoxically, uncontrolled HCV infection may be a trigger of TMA onset as previously described^[2,42]. TMA occurs as a long-term complication after LT by association with viral infections^[2], whereas our patients presented with TMALD during the early postoperative period. One of the possible explanations is the good control of viral infections as described above, although we are sometimes troubled by Epstein-Barr virus infections, including long-term complications of post-transplantation lymphoproliferative disorders^[43]. Regarding CNIs, our results that CNIs were used in all cases (tacrolimus was switched to cyclosporin A in 1 case) reveal an undeniable possibility of CNI effects, as previously documented^[17,35,36,39]. We also cannot negate the possibility that CNI introduction caused TMALD during the early postoperative period in our cases. However, we consider that complete CNI-free LDLT for preventing TMA is a distant ideal, since CNIs are key immunosuppressants for LDLT during this period^[15,44].

The mortality of TMA patients without effective treatments can be as high as 90%^[1,16], and 10%-20% of TMA patients still die even after PE/ET^[13,45]. The outcomes of TMALD patients are truly poor in our institution. Serious problems, such as massive bleeding, vascular thrombosis and organ failures, actually appeared in these recipients because of PLT consumption and microvascular occlusion mediated by TMALD. Five TMALD patients died without long survival times despite receiving continuous intensive treatments including re-transplantation for graft loss. Our own results indicate that further improvements in clinical strategies, including diagnostic methods and effective treatments based on the TMA mechanism after LDLT, are still needed.

Currently, the criteria for TMA are established as described above. We still do not have any experience of patients who strictly fulfilled all of the TMA criteria. Therefore, we consider that our patients were TMALD rather than TMA. However, we think that our recipients are homogeneously the same as other TMA patients in their clinical events. Based on our results in assays for TMA diagnosis, TMA recipients after LT may not be considered in the same manner as congenital or autoimmune TMA patients purely in the hematological field, when making a definite diagnosis. Inherently, TMA involves microvascular occlusion and unusually large vWF multimers are present at its inception^[1,7]. Although we

initially focused on vWF and ADAMTS-13, similar to previous studies^[2-5,8,9,14], we found that these absolute values were not necessarily reliable for the confirmation of TMA in LDLT recipients. Our results revealed only tendencies toward high vWF and low ADAMTS-13, while a few cases showed normal absolute values. However, the balance between vWF and ADAMTS-13 was clearly broken down. We suggest that this imbalance is a true entity in TMA after LDLT, and that evaluation of the vWF/ADAMTS-13 ratio is more suitable after LDLT to establish the patient's condition and achieve a precise diagnosis of TMA. Since a precise diagnosis is always required in order to administer appropriate treatments^[2,14,15], we suggest that this variable is one of the keys for improving the TMALD outcomes after LDLT.

Immunologically and pharmaceutically, numerous unpreventable influences exist in LDLT recipients. The phenomena of microvascular occlusive disorders accompanied by endothelial damage, PLT aggregation and hemolysis will be observed for other reasons, such as HR. On making a diagnosis of TMA after LDLT, many examinations including hematological, immunological and histopathological assays are therefore required to rule out other possible reasons, such as HR, sepsis and autoantibodies as well as HIT and drug-induced disorders^[2,14]. Therefore, reaching a definite diagnosis of TMA usually requires many considerations and much time. Actually, in our results, we retrospectively considered that TMALD onsets were earlier rather than at the point of diagnosis and/or treatment induction. We suggest that although the LDH level has a specific sensitivity for TMA/TMALD this variable will not work as an early marker for TMA/TMALD. Decreases in PLT counts can cause serious problems which sometimes require additional surgery. FRC and PLT decreases were observed at earlier points, and unexpectedly, MHMs were also reliable as an early sign of TMALD after LDLT if they appeared. A possible explanation is the time-lag between an initial high shear stress and the resultant microvascular occlusion^[6,7]. Ironically, transplant surgeons cannot decide actual treatments based on FRC, MHMs and PLT decreases even with earlier appearances, while TMA basically contraindicates a PLT transfusion. Although the changes over time in vWF and ADAMTS-13 could not be estimated in these patients because of cost-saving reasons, we hypothesize that the ratio of vWF/ADAMTS-13 is the earliest marker after LDLT for ruling out TMA and deciding appropriate treatments from the viewpoint of an essential cause of TMA.

Basically, the treatments must be chosen based on each cause of TMA, i.e. the lack of ADAMTS-13 and/or the inhibition of ADAMTS-13 via specific Abs^[2,3,8,9]. We suggest that adequate therapies, i.e. PE/ET for ADAMTS-13 replenishment or additional treatments against inhibitory Abs, must be decided according to each cause of TMA/TMALD. The PE/ET has effects on both replenishment of ADAMTS-13 and depletion of inhibitory Abs against ADAMTS-13. Therefore, PE/ET (80-100 mL/kg per day) is widely considered

as the standard therapy for TMA^[13,15,20-22]. As described above, the essence of TMA after LDLT is an imbalance between vWF and ADAMTS-13, and we expect that PE/ET will have a sufficient effect from the viewpoint of the replenishment of ADAMTS-13. However, the five TMALD patients who finally died revealed that the graft loss caused by TMALD resulted in poor outcomes, even in a re-transplanted case, and that graft parenchymal damage became worse one-sidedly despite the intensive treatments. On the contrary, the other two TMALD patients were successfully treated, even though the treatment in one case excluded PE/ET. The graft damage caused by TMALD exhibited sufficient responses to the administered treatments in these successfully treated patients. Our results indicate that further improvements for TMALD after LDLT are truly required. We suggest that PE/ET itself has an anticipated efficacy in TMALD patients who lack ADAMTS-13^[3,8]. Furthermore, optimal timing of the PE/ET induction according to the TMALD onset can improve the outcomes in these patients, even though the same treatment is performed^[2,13-15,45]. The morbidity and mortality may increase if we hesitate to introduce the therapy until the criteria for TMA are completely fulfilled. We therefore suggest that earlier induction will improve the outcomes in ADAMTS-13-deficient patients when TMALD is suspected after LDLT based on early markers or an imbalance of the vWF/ADAMTS-13 ratio. Since our results showed that successful treatments are difficult once the TMA criteria are completely fulfilled, we consider that some data and/or signs accompanied by a PLT decrease are sufficient for PE/ET induction after LDLT, e.g. FCR, MHMs and a discrepancy of LDH elevation (even under the criteria) compared with other transaminases. On the other hand, PE/ET also has a benefit in TMALD patients accompanied by inhibitors from the viewpoint of Ab depletion^[2,9,15]. However, our results for the TMALD patients who died might sustain the previous opinion that PE/ET has a limited usage for the depletion of specific Abs^[15,46], and the actual results of poor outcomes oblige us to challenge some other therapies for TMALD patients after LDLT. Although we have no experience of Ab-positive TMA after LDLT, we now take anti-CD20 monoclonal Ab or intravenous high-dose IgG administration under consideration, if repeated PE/ET has insufficient effects on TMA progress.

Previous investigators suggested the diagnostic and therapeutic advices for TMA, and previous reports which focused TMA after LT were summarized in Table 2^[2,14,15,37-39,47,48]. In our institution, the outcomes of TMALD recipients were poor despite the intensive treatments, especially in adult LDLT recipients. Previous researchers investigated the risk factors for TMA after LT^[15,39], and Nishi *et al.*^[15] suggested that the onset POD, the value of urea nitrogen and the level of albumin were important for TMA outcomes after LDLT. In our institution, the levels of urea nitrogen were not measured routinely. A possible explanation for the poor outcomes of TMALD after LDLT in our institution was the early

PE: Plasma exchange; TMA:Thrombotic microangiopathy; CNI: Calcineurin inhibitor; LDLT: Living-donor liver transplantation; HCV: Hepatitis C virus; vWF: von Willebrand factor; CMV: Cytomegalovirus.

postoperative onset of TMALD within 30 d after LDLT (Table 1), though the albumin levels showed no statistical differences between groups. Current therapeutic strategies were still not enough, and we therefore speculated that an earlier induction of adequate treatments based on the early markers may improve the prognosis of TMALD after LDLT. We considered that the earlier recognition of TMALD and the earlier induction of treatments even under a suspicion of TMALD are crucial for LDLT recipients with TMALD.

TMA/TMALD stands as an infrequent but life-threatening complication in the LT field. Although retransplantation may seem to be a therapeutic option, this is strictly limited from the viewpoints of donor shortage and donor safety. We suggest that adequate therapies, i.e. PE/ET for ADAMTS-13 replenishment or additional treatments against inhibitory Abs, must be decided according to each cause of TMA/TMALD. We conclude that the optimal induction of these therapies based on earlier or reliable markers and the establishment of more advanced therapeutic strategies confers a large advantage for TMA/TMALD patients after LDLT and consequently improves LT outcomes.

COMMENTS

Background

The thrombotic microangiopathy (TMA) is an infrequent but life-threatening complication in the transplantation field. Here, the authors focused on post-living-donor liver transplantation (LDLT) TMA cases.

Research frontiers

Some researchers have reported that the frequency of TMA after LT is 3.8%-5.0%. To date, a total of 1408 LTs have been performed in the authors' institution. However, although the authors have no experience of cases that completely fulfilled the TMA criteria, seven cases were retrospectively considered to be thrombotic microangiopathy like disorder (TMALD) after LDLT. The pathophysiological basis, the early marker for the recognition of TMALD, the reliable factors for diagnosis and further clinical strategies are discussed in the LDLT field.

Innovations and breakthroughs

Only tendencies toward high von Willebrand factor (vWF) and low a disintegrin-like domain and metalloproteinase with thrombospondin type 1 motifs (ADAMTS)-13 were seen, while a few cases showed normal absolute values.

However, the balance between vWF and ADAMTS-13 was clearly broken down. This balance reflected the condition of TMA after LDLT. Moreover, this variable is reliable along with earlier markers for TMALD recognition.

Applications

On making a diagnosis of TMA after LDLT, many examinations are required to rule out other possible reasons. Therefore, reaching a definite diagnosis of TMA usually requires many considerations and much time. The authors suggest that although the LDH level has a specific sensitivity for TMA/TMALD, this variable will not work as an early marker for TMA/TMALD. Fragmentation of red cell (FRC) and primary platelet (PLT) decreases were observed at earlier points and unexpectedly, microhemorrhagic macules were also reliable as an early sign of TMALD after LDLT if they appeared. Ironically, transplant surgeons cannot decide actual treatments based on FRC, MHMs and PLT decreases even with earlier appearances, while TMA basically contraindicates a PLT transfusion. They suggested that the ratio of vWF/ADAMTS-13 is the earliest marker after LDLT for ruling out TMA and deciding appropriate treatments from the viewpoint of an essential cause of TMA.

Terminology

The establishment of adequate treatments for TMALD, such as plasma exchange for ADAMTS-13 replenishment or treatments against inhibitory antibodies, must be decided according to each case. The optimal induction of these therapies based on early recognition of TMALD by the early and/or reliable markers may confer a large advantage for TMALD recipients after LDLT. Consequently, their outcomes will be improved.

Peer review

A very interesting manuscript for a rare disorder. It should be accepted with minor revisions.

Abstract

AIM: To investigate whether potent acid inhibition is effective in non-erosive reflux disease (NERD) refractory to standard rabeprazole (RPZ) treatment.

METHODS: We treated 10 Japanese patients with NERD resistant to standard dosages of RPZ: 10 mg or 20 mg od, 20 mg bid, or 10 mg qid for 14 d. All patients completed a frequency scale for symptoms of gastroesophageal reflux disease questionnaire frequency scale for the symptoms of GERD (FSSG); and underwent 24 h pH monitoring on day 14.

RESULTS: With increased dosages and frequency of

administration of RPZ, median intragastric pH significantly increased, and FSSG scores significantly decreased. With RPZ 10 mg qid, potent acid inhibition was attained throughout 24 h. However, five subjects were refractory to RPZ 10 mg qid, although the median intragastric pH in these subjects (6.6, range: 6.2-7.1) was similar to that in the remaining five responsive subjects (6.5, range: 5.3-7.3). With baseline RPZ 10 mg od, FSSG scores in responsive patients improved by > 30%, whereas there was no significant decrease in the resistant group.

CONCLUSION: NERD patients whose FSSG score fails to decrease by > 30% after treatment with RPZ 10 mg od for 14 d are refractory to higher dosage.

INTRODUCTION

Gastroesophageal reflux disease (GERD) is defined as the presence of acid-reflux-related symptoms, or esophageal mucosal damage, caused by the abnormal reflux of gastric contents into the esophagus^[1]. The diagnosis of GERD is therefore relatively easy when patients complain of typical acid-reflux-related symptoms (i.e. heartburn

Table 1 Frequency scale for the symptoms of gastroesophageal reflux disease

| Question | Never | Occasionally | Sometimes | Often | Always |
|---|-------|--------------|-----------|-------|--------|
| 1 Do you get heartburn? | 0 | 1 | 2 | 3 | 4 |
| 2 Does your stomach get bloated? | 0 | 1 | 2 | 3 | 4 |
| 3 Does your stomach ever feel heavy after meals? | 0 | 1 | 2 | 3 | 4 |
| 4 Do you sometimes subconsciously rub your chest with your hand? | 0 | 1 | 2 | 3 | 4 |
| 5 Do you ever feel sick after meals? | 0 | 1 | 2 | 3 | 4 |
| 6 Do you get heartburn after meals? | 0 | 1 | 2 | 3 | 4 |
| 7 Do you have an unusual (e.g. burning) sensation in your throat? | 0 | 1 | 2 | 3 | 4 |
| 8 Do you feel full while eating meals? | 0 | 1 | 2 | 3 | 4 |
| 9 Do some things get stuck when you swallow? | 0 | 1 | 2 | 3 | 4 |
| 10 Do you get bitter liquid (acid) coming up into your throat? | 0 | 1 | 2 | 3 | 4 |
| 11 Do you burp a lot? | 0 | 1 | 2 | 3 | 4 |
| 12 Do you get heartburn if you bend over? | 0 | 1 | 2 | 3 | 4 |

Patients were asked to score each question as never = 0; occasionally = 1; sometimes = 2; often = 3; or always = 4. In the frequency scale for the symptoms of gastroesophageal reflux disease (FSSG), there are seven acid-reflux-related symptoms (questions 1, 4, 6, 7, 9, 10 and 12), and five dysmotility-like symptoms (questions 2, 3, 5, 8 and 11). The acid reflux, dysmotility and total scores (acid reflux and dysmotility scores) were calculated, and a total score of ≥ 8 was considered to indicate probable GERD/NERD.

and regurgitation), and/or esophageal mucosal breaks are seen by gastroduodenal endoscopy. Recently, non-erosive gastroesophageal reflux disease (NERD) has been defined as the presence of acid-reflux-related symptoms without esophageal mucosal breaks^[2]. NERD is classified into two types: grade M and grade N. Grade M is characterized by minimal mucosal changes, such as erythema, without sharp demarcation, whitish turbidity, and/or translucency in the lower esophageal mucosa; and grade N reveals no endoscopic abnormality^[3]. The clinical characteristics of patients with NERD—that they are less likely to smoke or have an esophageal hiatal hernia, and more likely to be female, underweight, and have *Helicobacter pylori* (*H. pylori*) infection—differ from those of erosive GERD patients^[2,4,5]. Furthermore, the fact that esophageal mucosal sensitivity in NERD patients tends to be higher than those with erosive GERD is another important clinical characteristic of patients with NERD^[6]. These findings suggest that NERD is not simply a milder type of erosive GERD, and that the pathophysiology of erosive GERD differ from that of NERD^[7].

Proton pump inhibitors (PPIs), which potently inhibit gastric acid secretion, improve acid-reflux heartburn symptoms and esophageal mucosal breaks^[8-12]. Meta-analyses of treatment for erosive GERD patients have shown that PPIs are much more effective in curing esophageal erosions and acid-reflux-related symptoms than are H₂ receptor antagonists (H₂RAs) or prokinetics^[13,14]. However, improvement of heartburn associated with NERD using standard PPI dosages are lower (around 30%-60%) than for erosive GERD^[2,15,16]. This raises the question whether PPI-resistant NERD is an acid-related disease. Although PPIs potently inhibit acid secretion, standard PPI dosages do not sufficiently control intragastric pH throughout 24 h^[17-19]. For patients with NERD refractory to a standard PPI dosage, therefore, treatment with potent acid inhibition will be required to determine whether PPI-resistant NERD is caused by insufficient acid inhibition.

To the best of our knowledge, no earlier studies have investigated whether acid-related symptoms in patients with NERD refractory to standard PPI dosages improve

when sufficient acid inhibition is attained using PPI qid therapy. In this study, we investigated the effects of frequent PPI dosing on subjects with PPI-resistant NERD, with the aim of determining the clinical characteristics of subjects with PPI-refractory NERD that was resistant to potent acid inhibition.

MATERIALS AND METHODS

Subjects

After obtaining written informed consent, we invited 15 Japanese NERD patients with acid-reflux symptoms more than once a week to participate in our study. They underwent testing for CYP2C19 genotyping and gastroduodenal endoscopy. Endoscopy was performed in all subjects after fasting overnight, and the presence of esophageal mucosal breaks was assessed according to the Los Angeles classification (grade A-D)^[20]. In addition, grade M NERD was defined as mucosal findings of redness, edema or white granules in the esophagocardial junction (EC) junction, and grade N as normal mucosa, in subjects with acid-reflux-related symptoms. Subjects were administered a standard PPI dosage (rabeprazole 10 mg od) for 4 wk. Of the 15 enrolled subjects, 10 *H. pylori*-negative subjects with a score higher than 8 on the Frequency Scale for the Symptoms of GERD (FSSG) questionnaire (Table 1) were diagnosed with PPI-resistant NERD, and were enrolled in the study proper^[21,22]. However, because a score on the FSSG questionnaire in the remaining five NERD patients decreased to < 7 after PPI treatment (PPI-responded NERD), we did not enroll them in the study.

Study protocol

All subjects were administered the four different regimens in the following order: Rabeprazole (Pariet[®]; Eisai Co. Ltd., Tokyo, Japan) 10 mg od [RPZ(10)] at 08:00 h, rabeprazole 20 mg od [RPZ(20)], rabeprazole 20 mg bid [RPZ(20*2)] at 08:00 and 19:00 h, and rabeprazole 10 mg qid [RPZ(10*4)] at 07:00, 13:00, 19:00 and 0:00 h for 14 d each. On day 14 of each regimen, subjects filled in the FSSG question-

Table 2 Demographic characteristics of subjects with non-erosive gastroesophageal reflux disease

| | | Grade N | Grade M | Total | P value |
|---------|---------------|---------------|---------------|---------------|---------|
| Number | | 3 | 7 | 10 | |
| Age | | 22.3 ± 5.8 | 22.1 ± 0.7 | 22.2 ± 0.6 | 0.73 |
| Height | | 159.7 ± 3.2 | 156.7 ± 8.3 | 157.6 ± 7.0 | 0.31 |
| Weight | | 52.2 ± 2.5 | 52.7 ± 6.0 | 52.6 ± 5.0 | 0.91 |
| CYP2C19 | RM/IM/PM | 1/2/0 | 3/2/2002 | 5/2/2003 | 0.41 |
| 24 h pH | Gastric pH | 2.6 (2.6-2.6) | 2.4 (1.5-2.8) | 2.5 (1.5-2.8) | 0.31 |
| | Esophageal pH | 6.6 (6.4-7.6) | 6.6 (6.4-7.5) | 6.6 (6.4-7.6) | 0.75 |
| FSSG | | 19 (15-24) | 22 (19-31) | 21 (15-31) | 0.3 |

Age, height, body weight and height are given as mean ± SD. Twenty-four hour pH and frequency scale for the symptoms of gastroesophageal (FSSG) score are given as median (range). RM: Rapid metabolizer; IM: Intermediate metabolizer; PM: Poor metabolizer.

naire and underwent 24 h intraesophageal and intragastric pH monitoring. All subjects were provided three meals a day (breakfast at 07:00 h, lunch at 13:00 h, and dinner at 19:00 h). Mineral water was allowed *ad libitum*, but no other beverages (e.g. grapefruit juice) were permitted. There was a washout period of at least 2 wk between the study periods. There were no rescue drugs during and between the study periods. No subjects drank alcohol or smoked. No subjects had taken any medications for at least 1 mo prior to the study, nor were they allowed during the study. All protocols for each subject were completed within 6-10 mo.

The protocol was approved in advance by the Human Institutional Review Board of the Hamamatsu University School of Medicine. Written informed consent was again obtained from each subject before participation in each of the four trial phases.

Twenty-four hour intraesophageal and intragastric pH monitoring

Intraesophageal and intragastric pH readings were recorded using a DigiTrapper pH 400 (Medtronic Functional Diagnostic A/S, Skovlunde, Denmark). On day 14 of each trial phase, after fasting overnight, an antimony pH catheter (Medtronic Inc., Minneapolis, MN, USA) was inserted transnasally under local anesthesia and placed 5 cm distal to the gastric cardia, and pH readings were recorded for 24 h.

Evaluation of reflux symptoms

GERD-related symptoms were evaluated using the FSSG, which includes seven acid-reflux-related questions and five dysmotility related questions^[21,22]. Subjects answered questions about the frequency of their symptoms, scoring them as follows: never, 0; occasionally, 1; sometimes, 2; often, 3; and always, 4. We calculated the acid reflux, dysmotility and total scores, with a total score of ≥ 8 considered to indicate probable GERD/NERD.

CYP2C19 genotyping PPIs are mainly metabolized by hepatic CYP2C19, and there are genetic differences in the activity of this enzyme^[17-19]. In poor metabolizers (PMs) of CYP2C19, the plasma PPI concentrations are markedly increased and the pharmacodynamic effects of PPIs are enhanced in comparison with those in rapid metabolizers (RMs) or intermediate metabolizers (IMs). Therefore, we tested CYP2C19.

DNA was extracted from each subject's leukocytes

using a commercially available kit (IsoQuick; ORCA Research Inc., Bothell, WA, USA). Genotyping procedures for identifying the CYP2C19 wild-type (*1) gene and the two mutated alleles, CYP2C19*2 (*2) and CYP2C19*3 (*3), were performed using an allele-specific primers-polymerase chain reaction method with allele-specific primers^[23]. CYP2C19 genotypes were classified into three groups, RMs (*1/*1), IM (*1/*2 or *1/*3), and PM (*2/*2, *3/*3 or *2/*3).

Data analysis

Differences between different regimens and groups were determined using Wilcoxon's signed rank test, when significant differences were obtained using Friedman's test. All *P* values were two-sided, and *P* < 0.05 was taken to indicate statistical significance.

RESULTS

Japanese subjects with NERD resistant to standard PPI dosages enrolled in this study exhibited no demographic differences in age, body weight, CYP2C19 genotype status, median intragastric and intraesophageal pH, or baseline FSSG score between subjects with NERD grade N and grade M (Table 2). No severe adverse events occurred with any of the study regimens, and all regimens were well tolerated by all subjects.

Twenty-four hour pH profiles according to dosage regimen

The median 24 h intragastric pH at baseline and on day 14 for the RPZ(10), RPZ(20), RPZ(20*2) and RPZ(10*4) regimens was 2.5 (range: 1.5-2.8), 5.0 (3.3-7.5), 6.1 (3.8-6.8), 6.2 (4.9-7.4) and 6.5 (5.3-7.3), respectively (Figure 1A). Median intragastric pH significantly increased in a dosage and dosing frequency-dependent manner, and was significantly higher with RPZ(10*4) than with RPZ(20*2), although the total daily dosage (40 mg) was the same (Figure 1A). The median percentage of intragastric pH < 4.0 in a day with the RPZ(20), RPZ(20*2) and RPZ(10*4) regimens was 17.2% (range: 0.8%-66.6%), 13.0% (0.0%-43.6%) and 5.2% (0.0%-36.8%), respectively, which was significantly lower than those at baseline [85.6% (78.3%-97.0%), *P* < 0.01] and with the RPZ(10) regimen [34.8% (3.5%-73.7%), *P* < 0.01] (Figure 1B).

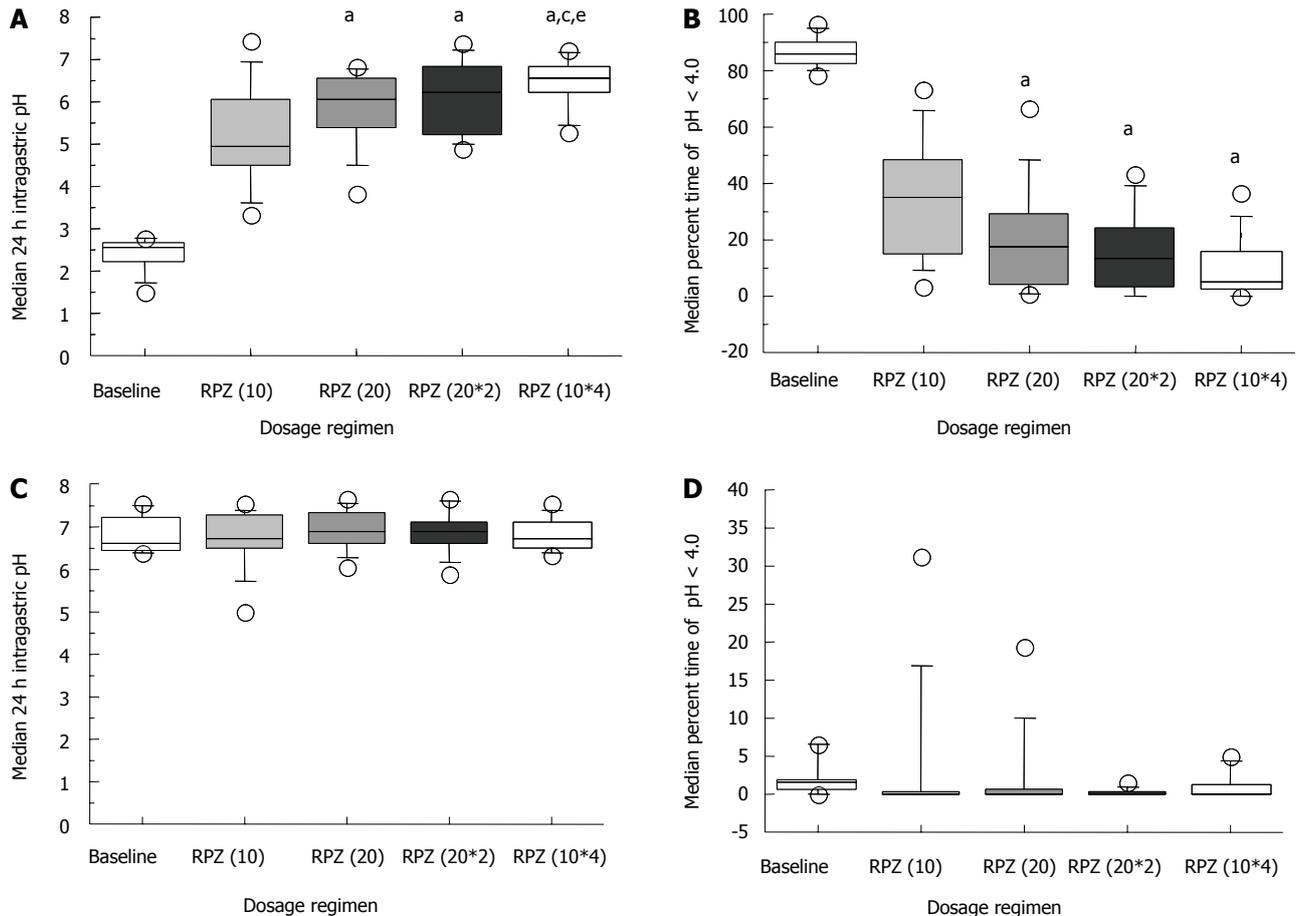

Figure 1 Median 24 h intragastric and intraesophageal pH (A and C) and median percentage time with intragastric and intraesophageal pH < 4.0 (B and D) with five different treatment regimens on day 14. ^a $P < 0.05$ [vs RPZ (10)]; ^c $P < 0.05$ [vs RPZ (20)]; ^e $P < 0.05$ [vs RPZ (20*2)]. RPZ: Rabeprazole.

Median 24 h intraesophageal pH and the percentage of intraesophageal pH < 4.0 in a day were similar for the four different RPZ dosage regimens (Figure 1C and 1D). Most baseline measurements showed no abnormal acid reflux; defined as > 5% of patients with intraesophageal pH < 4.0 (Figure 1D). The median reflux frequency of gastric acid to the esophagus at baseline, RPZ(10), RPZ(20), RPZ(20*2) and RPZ(10*4) was 58.5 (range: 7-137), 5 (3-244), 4.5 (0-180), 13.5 (0-251) and 4.5 (0-506), respectively (Figure 2). Differences were not statistically significant in comparison with baseline.

Median 24 h intraesophageal and intragastric pH, the percentage of intraesophageal and intragastric pH < 4.0 in a day, and the frequency of reflux of gastric acid to the esophagus were similar between patients with different CYP2C19 genotype status (data not shown).

FSSG score and acid inhibition

FSSG scores improved significantly in a dose-dependent manner (Figure 3A). The median FSSG score at baseline was 20.5 (range: 15-31), which significantly decreased with each RPZ dosage regimen [RPZ(10), 13.5 (10-31); RPZ(20), 10.5 (1-28); RPZ(20*2), 10.0 (0-24); and RPZ(10*4), 6.5 (0-20), $P < 0.05$] (Figure 3A). When patients with NERD were administered RPZ 10 mg od, their FSSG scores were all > 8. FSSG scores with the RPZ(20),

RPZ(20*2) and RPZ(10*4) regimens were significantly lower than that with the RPZ(10) regimen (Figure 3A).

When FSSG scores were subdivided into acid reflux and dysmotility scores (Table 1), these were seen to decrease significantly with changes in RPZ dosage schemes in acid reflux scores (Figure 3B and C). The FSSG acid reflux scores with the RPZ(20*2) [3.5 (0-17)], RPZ(20*2) [3 (0-12)] and RPZ(10*4) [2.5 (0-11)] regimens were significantly lower than that with RPZ(10) [6.5 (3-18)] ($P < 0.05$).

Also in dysmotility scores, these were seen to decrease significantly with changes in RPZ dosage schemes (Figure 3C). The FSSG acid reflux scores with the RPZ(20*2) [6.5 (1-13)], RPZ(20*2) [6 (0-12)] and RPZ(10*4) [4 (0-9)] regimens were significantly lower than that with RPZ(10) [7.5 (6-13)] ($P < 0.05$) (Figure 3C). The FSSG dysmotility score with the RPZ(10*4) regimen was significantly lower than that with RPZ(20*2), although the total daily dosage was the same (40 mg) (Figure 3C).

When patients were classified into a responsive (FSSG score: < 8, $n = 5$) and resistant (FSSG score: > 8, $n = 5$) group for the RPZ(10*4) regimen, the median intragastric pH was similar for the two groups [responsive group: 6.5 (5.3-7.3) and resistant group: 6.6 (6.2-7.1)] (Figure 4), which indicated that sufficient acid inhibition was attained in both subjects with PPI-resistant as well responsive NERD. Median total, acid reflux and dysmotility FSSG scores signifi-

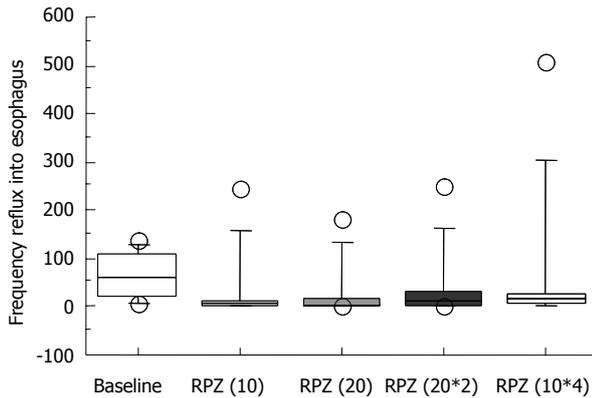

Figure 2 Number of reflux episodes of gastric contents to the esophagus with five different treatment regimens on day 14. RPZ: Rabeprazole.

cantly decreased in a dose-dependent manner in subjects who responded to, or were refractory to, the RPZ(10*4) regimen (Figure 5A-D). Acid reflux and dysmotility FSSG scores both differed significantly between the two groups (Figure 5A-D). FSSG scores in subjects with NERD responsive to the RPZ(10*4) regimen improved by > 30% in comparison with baseline scores with RPZ 10 mg od. On the other hand, in subjects with NERD refractory to the RPZ(10*4) regimen, FSSG scores decreased by < 30% compared with the baseline with RPZ 10 mg od.

DISCUSSION

Recently, the rising prevalence of NERD worldwide^[24], and its adverse impact on quality of life^[25], have led to the acceptance of NERD as a gastrointestinal disease that requires treatment. Intraesophageal and intragastric pH directly correlate with the degree of esophageal mucosal damage and the degree of sensitivity^[26], therefore, treatment strategies for NERD recommend that pH levels in both the esophagus and stomach should be maintained above 4.0 by optimal use of acid inhibitory agents^[27]. We previously have reported that it is difficult to maintain the intragastric pH above 4 throughout 24 h with standard PPI dosages (omeprazole 20 mg, lansoprazole 30 mg and rabeprazole 10 mg)^[17-19], but that PPI qid therapy^[18] and H2RA + PPI combination therapy^[28] provide profound inhibition of gastric acid secretion. These therapies may be the main strategies for treating PPI-resistant, acid-related GERD with/without nocturnal acid breakthrough, as well as peptic ulcers and *H. pylori* infection. Complete remission of endoscopic esophageal mucosal injury and reflux-related symptoms are achieved in around 30%-60% of patients with NERD using standard PPI dosages^[2,15,16], which suggests that PPI-resistant NERD may be due to insufficient acid inhibition by standard PPI dosages. In this study, we demonstrated that the qid RPZ regimen maintained intraesophageal and intragastric pH above 4.0 throughout 24 h, and that our subjects with PPI-resistant NERD responded to varying degrees. Accordingly, we assume that cases of PPI-resistant NERD are caused by insufficient acid inhibition, and that the pathogenesis of NERD may be related

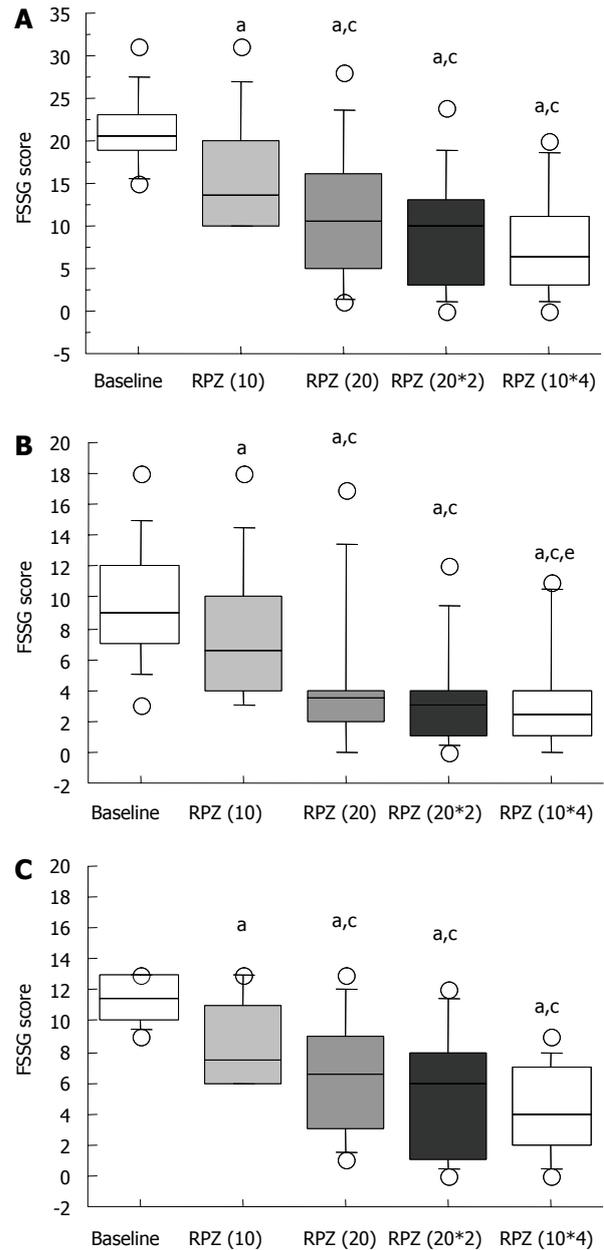

Figure 3 Median total (A), acid reflux (B) and dysmotility (C) Frequency scale for the symptoms of gastroesophageal reflux disease scores. Frequency scale for the symptoms of gastroesophageal reflux disease scores in RPZ(20), RPZ(20*2), and RPZ(10*4) regimens significantly improved compared with that at baseline and RPZ(10). ^a*P* < 0.05 [vs baseline (10)]; ^c*P* < 0.05 [vs RP (10)]; ^{a,c}*P* < 0.05 [vs RP (20)]. RPZ: Rabeprazole; FSSG: Frequency scale for the symptoms of gastroesophageal reflux disease.

to weak acid reflux into the esophagus, and not observed as abnormal reflux and not inhibited by standard PPI dosages. In subjects with NERD responsive to potent acid inhibition by RPZ 10 mg qid, FSSG scores decreased by > 30% compared with baseline after RPZ 10 mg od for 14 d. Therefore, NERD patients whose FSSG reduces by > 30% by a standard dosage of PPI will respond to a higher dose of PPI, although the clinical effects of standard PPI dosages on their symptoms are limited.

Cases of NERD that are resistant to high PPI dosages appear to be acid-independent, and are considered to have

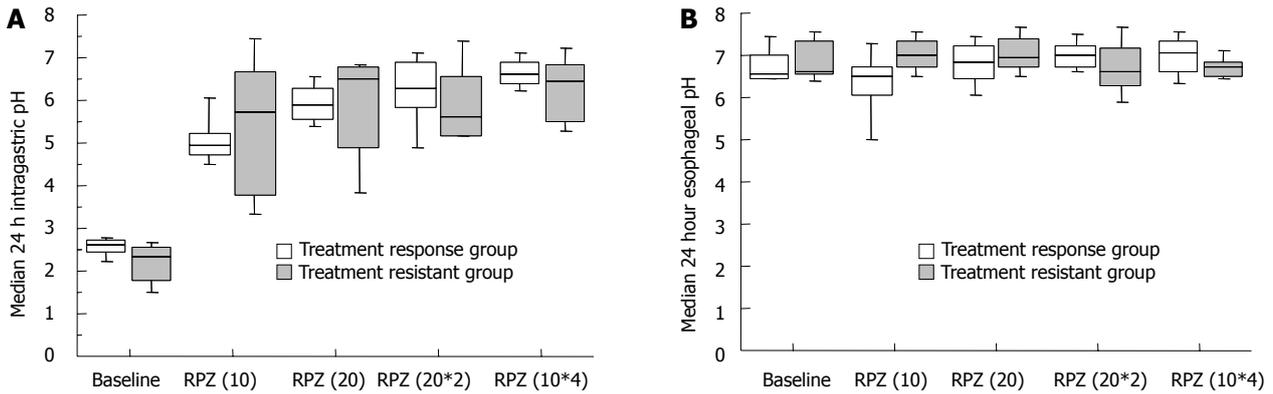

Figure 4 Median intragastric and intraesophageal pH in subjects responsive ($n = 5$) and refractory ($n = 5$) to rabeprazole 10 mg qid. Median intragastric pH was the same in patients responsive and refractory to RPZ 10 mg qid. RPZ: Rabeprazole.

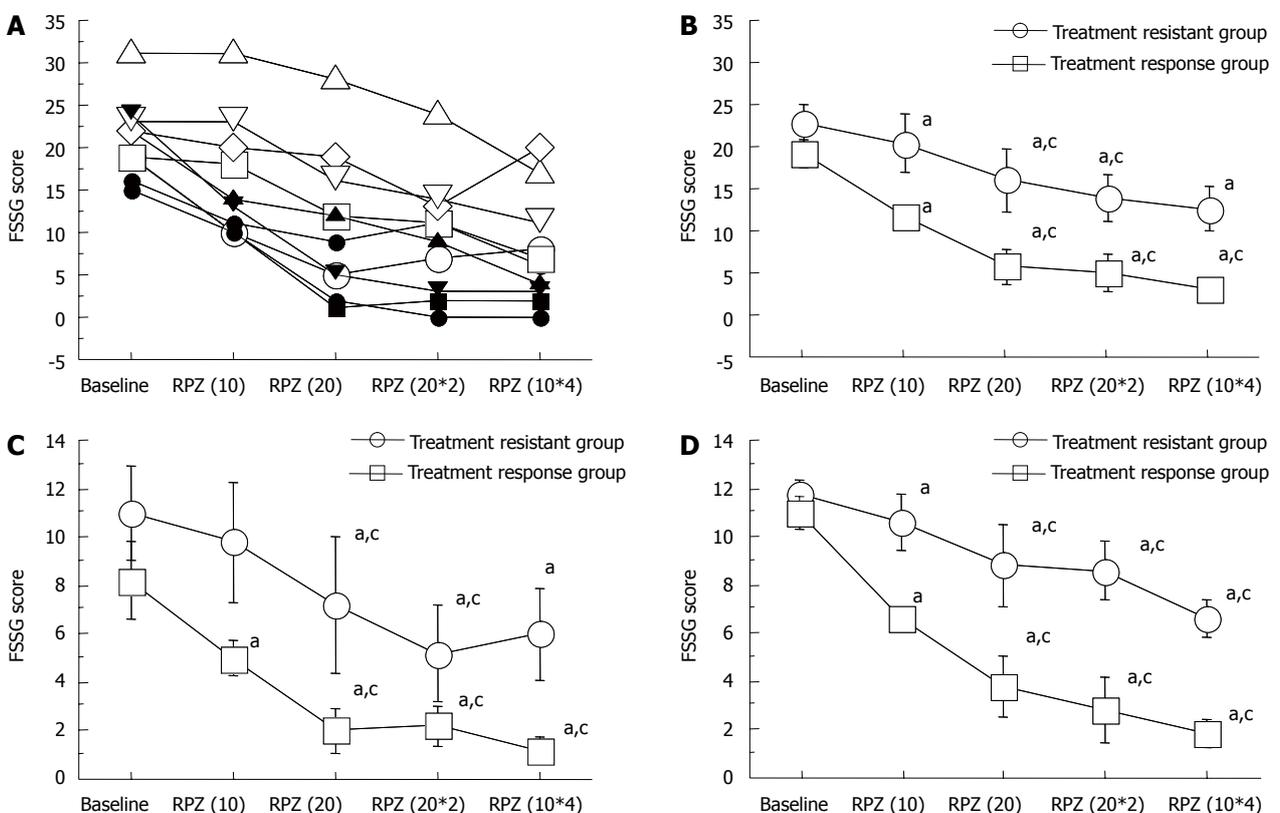

Figure 5 Each patient's (A), total (B), acid reflux (C) and dysmotility (D) FSSG scores in subjects with non-erosive gastroesophageal reflux disease responsive and refractory to the rabeprazole(10*4) regimen. Frequency scale for the symptoms of gastroesophageal reflux disease (FSSG) scores in subjects with non-erosive gastroesophageal reflux disease (NERD) who responded to the RPZ(10*4) regimen improved > 30% compared with baseline with rabeprazole 10 mg od. RPZ: Rabeprazole. ^a $P < 0.05$ [vs baseline]; ^c $P < 0.05$ [vs RP (10)].

been caused by other factors, such as esophageal hypersensitivity and/or functional heartburn. In fact, the prevalence of NERD grade N patients with abnormal acid reflux into the esophagus (> 5% with intraesophageal pH < 4.0) is reported to be only 11.8% in Japanese^[29] and 33%-50% in Caucasians^[30,31]. In this study, also, no abnormal acid reflux was detected in most of the baseline trials in subjects with NERD. Moreover, in some patients, NERD resembles postprandial distress syndrome type functional dyspepsia, which is characterized by dysmotility symptoms, and there is considerable overlap between NERD and functional

dyspepsia^[32,33]. It is not easy to distinguish NERD patients from functional heartburn using either the Montreal definition or the Rome III criteria^[34].

Although double-dosage PPI therapy is recommended for patients with PPI-resistant NERD, this study shows that additional PPI therapy is not indicated for all NERD patients refractory to standard-dosage PPI. In patients with NERD resistant to potent acid inhibition by PPIs, FSSG scores improve < 30% with a standard PPI dosage compared with baseline. We can therefore easily select PPI-resistant patients using the FSSG questionnaire; the simplest

and time-saving method of diagnosing GERD/NERD refractory to higher PPI dosages^[21,22]. Recently, Futagami *et al.*^[35] have reported that combination therapy with a PPI and mosapride citrate significantly improves acid reflux symptoms in patients with PPI-resistant NERD. It may therefore be better to treat PPI-resistant patients with other drugs, such as prokinetics, rather than with increased PPI dosages.

Patients with grade M NERD are more likely to have pathological acid reflux than those with grade N disease, and acid reflux symptoms in patients with grade M disease are more likely to be attributable to acid reflux^[29]. However, there have been a number of reports of similar rates of complete resolution of heartburn, clinical features and quality of life scores with PPI therapy in patients with grade M and N NERD^[16,29,36,37]. Also in this study, there were no significant differences in FSSG scores and intraesophageal pH values between patients with grade M and grade N NERD (data not shown). The pathophysiological differences between the two types of NERD are unclear, and further studies are required to clarify the pathogenesis of NERD.

In this study, we demonstrated the effectiveness of RPZ on both dyspeptic and acid-reflux-related symptoms, which improved in a dose-dependent manner in subjects with PPI-resistant NERD. Miner *et al.*^[8] and Kusano *et al.*^[22] previously have reported that RPZ significantly improves dyspeptic symptoms in patients with NERD. It is reasonable to conclude that dyspeptic symptoms in patients with NERD can be expected respond to PPI treatment.

The limitations of this study included low sample power and a lack of placebo effect. However, in this study the most important point was to prove that NERD patients who were refractory to a standard PPI dosage, caused by insufficient acid inhibition, were improved by a greater dosage of PPI. Moreover, we analyzed intragastric and intraesophageal pH with each regimen in each subject, and were able to demonstrate the characteristics of subjects with PPI-resistant NERD using the FSSG. We believe that the FSSG score after RPZ 10 mg od for 14 d can be used to predict whether a patient with NERD refractory to a standard dosage of a PPI will respond to a higher dosage of that PPI (e.g. RPZ 10 mg qid).

In conclusion, we demonstrated that patients with NERD with a > 30% decrease in their FSSG score with RPZ 10 mg od responded to a higher PPI dosage, although they appeared to be refractory to the standard PPI dosage. On the other hand, symptoms in patients completely resistant to a standard dosage of a PPI (FSSG reduction < 30% after RPZ 10 mg od) do not resolve even if the PPI dosage is increased (e.g. RPZ 10 mg qid). We recommend that such patients should be treated with other agents such as prokinetics rather than increasing the PPI dosage^[35]. The FSSG score after rabeprazole 10 mg od for 14 d shows promise in determining the optimal treatment for patients with NERD refractory to a standard PPI dosage. The clinical usefulness of the FSSG in the PPI treatment of NERD requires verification in further studies with larger subject numbers.

COMMENTS

Background

Half of patients with non-erosive reflux disease (NERD) are resistant to treatment with standard proton pump inhibitor (PPI) dosages, due to insufficient control of acid secretion throughout 24 h. However, no earlier studies have investigated whether acid-related symptoms in patients with NERD refractory to standard PPI dosages improve when sufficient acid inhibition is attained using PPI qid therapy.

Research frontiers

PPIs are rapidly eliminated from the systemic circulation (*t*_{1/2}: 2-3 h). H⁺,K⁺-ATPase newly generated or activated in gastric parietal cells after the rapid elimination of PPI can secrete gastric acid. Frequent PPI dosing sustains plasma PPI levels for a longer time to achieve sufficient acid inhibition over 24 h. Sugimoto *et al.* have investigated the effects of frequent PPI dosing on subjects with PPI-resistant NERD, with the aim of determining the clinical characteristics of subjects with PPI-refractory NERD resistant to potent acid inhibition.

Innovations and breakthroughs

Sugimoto *et al.* have highlighted the clinical characteristics of PPI-refractory NERD patients. In subjects with NERD that is responsive to potent acid inhibition, the Frequency Scale for the Symptoms of GERD (FSSG) scores decreased by > 30% compared with baseline after a standard dose of PPI. Therefore, NERD patients whose FSSG reduces by > 30% after a standard dosage of PPI will respond to a higher dose of PPI, although the clinical effects of standard PPI dosages on their symptoms are limited.

Applications

The FSSG score after PPI treatment may show promise in determining the optimal treatment for patients with NERD that is refractory to a standard PPI dosage; increasing the PPI dosage or other agents such as prokinetics. The clinical usefulness of the FSSG in the PPI treatment of NERD requires verification in further studies with larger subject numbers.

Peer review

The study analyzed the problem of patients with symptoms of GERD but refractory to PPIs. This is a very important problem in the treatment of these patients. The study was well designed and the results are clearly described.

Abstract

AIM: To investigate the role of glucose transporter 1 (GLUT1) expression in colorectal carcinogenesis and evaluate the correlation with clinicopathological parameters and apoptosis-activating factor-1 (Apaf-1) expression in colorectal adenocarcinomas.

METHODS: We used tissue microarrays consisting of 26 normal mucosa, 50 adenomas, 515 adenocarcinomas, and 127 metastatic lesions. Medical records were reviewed and clinicopathological analysis was performed.

RESULTS: GLUT1 expression was absent in normal mucosa and low or moderately apparent in 19 cases (38.0%) of 50 adenomas. However, GLUT1 expression was detected in 423 (82.1%) of 515 adenocarcinomas and in 96 (75.6%) of 127 metastatic lesions. GLUT1 expression was significantly correlated with female

gender ($P = 0.009$), non-mucinous tumor type ($P = 0.045$), poorer differentiation ($P = 0.001$), lymph node metastasis ($P < 0.001$), higher AJCC and Dukes stage ($P < 0.001$ and $P < 0.001$, respectively). There was a significant inverse correlation between GLUT1 expression and Apaf-1 expression ($P = 0.001$). In univariate survival analysis, patients with GLUT1 expression demonstrated poor overall survival and disease-free survival ($P = 0.047$ and $P = 0.021$, respectively, log-rank test).

CONCLUSION: GLUT1 expression was frequently increased in adenocarcinomas and metastatic lesions. GLUT1 expression was significantly correlated with poorer clinicopathologic phenotypes and survival of patients with colorectal adenocarcinomas.

INTRODUCTION

Colorectal cancer is the second leading cause of cancer-related death in men and women in the industrialized nations^[1,2]. There have been marked advances in the understanding of the carcinogenesis in colorectal cancer and cancer biology; however, the specific therapeutic problem continues to persist^[3]. Most patients with colorectal ma-

lignancy, except for the advanced stage, undergo curative resection. Stage II patients with obstruction, perforation or certain tumor markers, and stage III patients, receive adjuvant chemotherapy after surgical resection^[4]. However, there is no appropriate targeted therapy to further improve the clinical outcome. The molecular prognostic factors associated with a distinct prognostic outcome would be of great help for patients who are likely to benefit from adjuvant therapies, leading to an improvement in prognosis^[5].

The transition from normality to malignancy through the adenoma-carcinoma carcinogenesis sequence is accompanied by various alterations in the expression of a number of genes associated with the maintenance of cellular homeostasis^[6]. Previous studies have revealed an enhancement of glycolytic metabolism in malignant tumors. Increased glucose uptake and use is one of the major characteristics found in many malignant tumors. This process is mediated by the glucose transporters (GLUTs) which are membrane proteins responsible for the transport of glucose across cellular membranes^[7].

Among seven cloned glucose transporters, GLUT1 is an isoform that is expressed in erythrocytes, the blood-tissue barriers such as the blood-brain and blood-nerve barriers, and the placenta^[8]. GLUT1 protein expression can be altered by a number of different conditions, including cellular differentiation and transformation, and also can be altered under the influence of growth factors, insulin, glucose, and even stress^[9]. The increased expression of GLUT1 mRNA and protein has been demonstrated in various cancer tissues which indicates that GLUT1 may play an important role in glucose uptake by various cancers and that GLUT1 expression could be useful as a marker for malignant transformation^[10-15].

In this study, we immunohistochemically determined the GLUT1 expression in a large series of 26 normal mucosa, 50 tubular adenomas, 515 adenocarcinomas, and 127 metastatic lesions. This was to investigate the membranous GLUT1 expression in colorectal carcinogenesis and to evaluate the correlation between GLUT1 expression and the clinicopathological parameters and between GLUT1 expression and cytoplasmic apoptosis-activating factor-1 (Apaf-1) expression, as well as its effect on survival of patients with colorectal adenocarcinomas.

MATERIALS AND METHODS

Patients and tissue samples

Our study enrolled a consecutive series of 515 patients with colorectal adenocarcinoma. All patients were diagnosed and treated at the Hanyang University Hospital (Seoul, Korea) between January 1991 and August 2001. There were 293 male and 222 female patients. The mean age of patients was 58 years. The tumor growth pattern was fungating in 239 cases and infiltrative in 276 cases. The tumors consisted of 489 non-mucinous adenocarcinomas and 26 mucinous adenocarcinomas. The tumors were located in the cecum ($n = 18$), ascending colon ($n = 75$), hepatic flexure ($n = 12$), transverse colon ($n = 25$), splenic

flexure ($n = 4$), descending colon ($n = 25$), sigmoid colon ($n = 107$), and rectum ($n = 249$). The mean tumor size was 5.7 cm. The mean follow-up interval was 6.0 years. One hundred and eighty (35%) patients died and 335 (65%) patients survived. Twenty-six cases of normal mucosa, 50 cases of tubular adenomas, 127 metastatic lesions (lymph nodes and distant organs) were randomly selected to evaluate the role of GLUT1 in the multistep carcinogenesis.

Tissue microarray construction

Tissue microarrays were constructed from archival formalin-fixed, paraffin-embedded tissue blocks using a manual tissue arrayer (Quick-Ray Manual Tissue Microarrayer, Unitma Co, Ltd, Seoul, Korea). As described previously^[16], for each sample, areas rich in tumor cells were identified by light microscopic examination of hematoxylin-eosin-stained sections and then selected for use in tissue microarrays. Tissue cylinders with a diameter of 2 mm were punched from the previously marked tumor area of each block (donor block) and then transferred to a recipient paraffin block. This resulted in a 6×10 array for 60 cases.

Immunohistochemical staining

For immunohistochemical staining, multiple 4 μm sections were cut with a Leica microtome. Sections were transferred to adhesive-coated slides. Tissue microarray (TMA) slides were dewaxed by heating at 55°C for 30 min and by three washes, 5 min each, with xylene. Tissues were rehydrated by a series of 5 min washes in 100%, 90% and 70% ethanol and phosphate buffered saline (PBS). Antigen retrieval was performed by microwaving the samples for 4 min 20 s at full power in 250 mL of 10 mmol/L sodium citrate (pH 6.0). Endogenous peroxidase activity was blocked with 0.3% hydrogen peroxidase for 20 min. The primary mouse monoclonal GLUT1 antibody (ab40084, Abcam, Cambridge, UK) was diluted 1:100 using goat serum and the primary polyclonal rabbit Apaf-1 antibody (Novocastra Laboratories, Newcastle upon Tyne, UK) was diluted 1:200 using goat serum and incubated at room temperature for 1 h. After three washes, 2 min each with PBS, the sections were incubated with a biotinylated goat anti-mouse secondary antibody for 30 min (DAKO, Carpinteria, CA, USA). After three washes, 2 min each with PBS, horseradish peroxidase-streptavidin (DAKO, Carpinteria, CA, USA) was added to the sections for 30 min, followed by another three washes, 2 min each with PBS. The samples were developed with 3,3'-diaminobenzidine substrate (Vector Laboratories, Burlington, Ontario, Canada) for 1 min and counterstained with Mayer's hematoxylin. Then, the slides were dehydrated following a standard procedure and sealed with coverslips. Negative controls were performed by omitting the GLUT1 and Apaf-1 antibodies during the primary antibody incubation.

Interpretation of GLUT1 and Apaf-1 immunostaining

The GLUT1 and Apaf-1 expression was evaluated semi-quantitatively by two independent pathologists (Jang SM and Paik SS) without prior knowledge of the clinical follow-up data for each case. The GLUT1 immunostaining

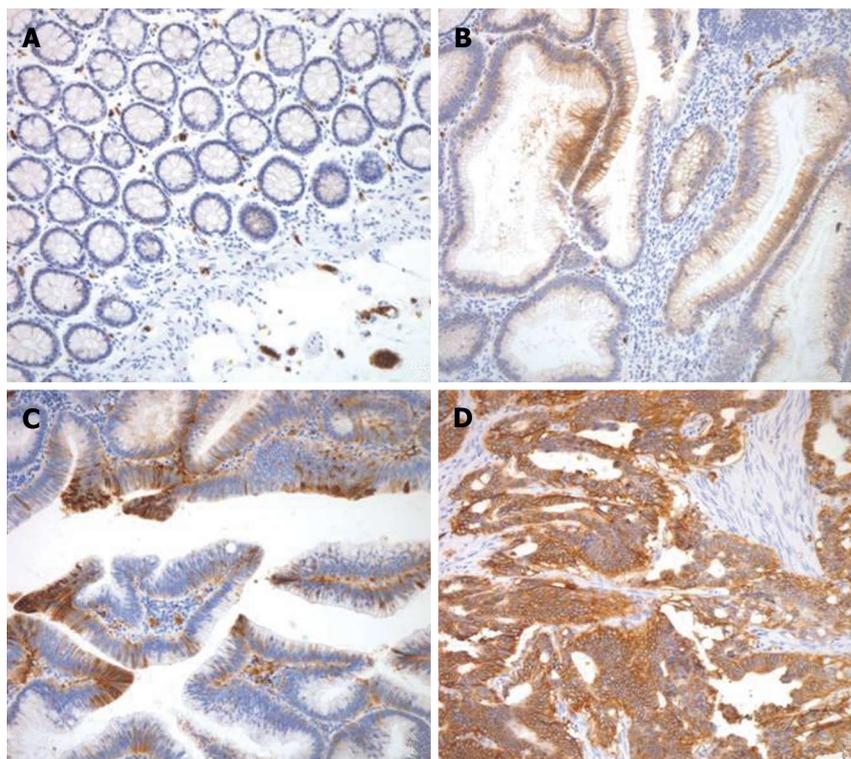

Figure 1 Representative photomicrograph of glucose transporter 1 immunostaining in normal mucosa (A), tubular adenoma with low grade dysplasia (B), tubular adenoma with high grade dysplasia (C), and adenocarcinoma (D). The glucose transporter 1 was stained in the cytoplasmic membrane of the cells.

was semi-quantitated by grading the proportion of cells that were GLUT1-positive, as described previously^[7,11]; grade 0: negative (positive cells are 0%), grade 1: low positive (positive cells are less than 10%), grade 2: moderate positive (positive cells are 10%-50%) and grade 3: high positive (positive cells are more than 50%). For purposes of statistical analysis, a cut-off value of 50% was adopted. Each tissue section was classified as either < 50% or > 50% GLUT1-positive. Apaf-1 expression was evaluated based on the staining intensity and staining extent, as described previously^[17]. Staining intensity for Apaf-1 was scored as 0 (negative), 1 (weak), 2 (moderate) and 3 (strong). Staining extent was scored as 0 (0%), 1 (1%-25%), 2 (26%-50%), 3 (51%-75%) and 4 (76%-100%) according to the percentage of positive-stained cells. The sum of intensity and extent scores was used as the final staining score. All cases were divided into four expression groups according to their sum scores which were as follows: 0 = negative; 1-3 = weak; 4-5 = moderate; and 6-7 = strong. If the sum scores were moderate or strong, cases were classified as Apaf-1-positive. If the sum scores were negative or weak, cases were classified as Apaf-1-negative. In cases of discrepant assessments, slides were reinvestigated by both pathologists under a multi-head microscope and an agreement was obtained.

Statistical analysis

Statistical analysis was performed using SPSS software (version 12.0, SPSS, Chicago, IL, USA). The chi-square test for linear trend, Fisher exact test, and one-way

ANOVA test were used to examine the association between the GLUT1 expression and clinicopathological parameters including age, gender, tumor location, tumor size, tumor gross, tumor type, differentiation, TNM category, AJCC stage, Dukes stage, and Apaf-1 expression. The Kaplan-Meier method was used to calculate overall survival and disease-free survival curves. Univariate survival analysis with the log-rank test was used to compare the difference between the survival rates of the patient subgroups. Multivariate survival analysis with the Cox proportional hazards regression model was used to evaluate the independent prognostic factors. A difference of $P < 0.05$ between groups was considered significant.

RESULTS

Pattern of GLUT1 expression

The GLUT1 expression was evaluated in 26 normal mucosa, 50 tubular adenomas, 515 adenocarcinomas, and 127 metastatic lesions. As expected, erythrocyte membranes were strongly GLUT1-positive. Various grades of membranous GLUT1 expression were observed in the included tissue samples. The representative photomicrographs of GLUT1 immunostaining are shown in Figure 1. All 26 normal mucosa specimens (100%) were negative for GLUT1 expression with no exception. Twenty-one (80.8%) of 26 tubular adenomas with low grade dysplasia were negative for GLUT1 expression and only 5 cases (19.2%) revealed a low grade of GLUT1 expression. Ten (41.7%) of 24 tubular adenomas with high grade dyspla-

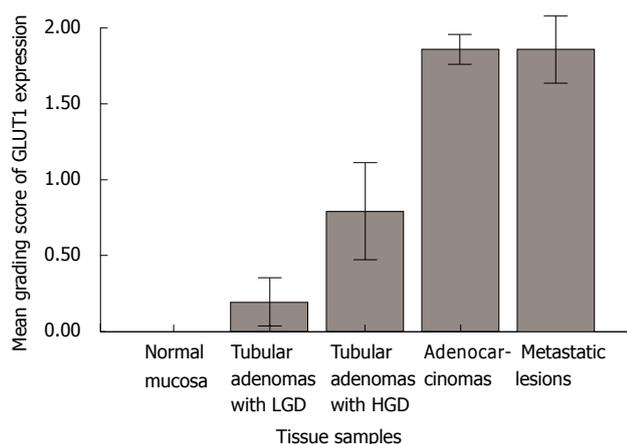

Figure 2 Representation showing the difference of mean grading score of glucose transporter 1 expression in normal mucosa, tubular adenomas with low grade dysplasia, tubular adenomas with high grade dysplasia, adenocarcinomas, and metastatic lesions (lymph nodes and distant organs). One-way ANOVA test was used. GLUT1: Glucose transporter 1; LGD: Low grade dysplasia; HGD: High grade dysplasia.

Normal mucosa were negative for GLUT1 expression, 9 cases (37.5%) revealed a low grade of GLUT1 expression, and 5 cases (20.8%) showed a moderate grade of GLUT1 expression. However, in colorectal adenocarcinomas, 187 (36.3%) of 515 cases revealed a high grade of GLUT1 expression and 161 cases (31.2%) and 75 cases (14.6%) showed moderate grade and low grade of GLUT1 expression, respectively. Only 92 (17.9%) of 515 cases were negative for GLUT1 expression. In metastatic lesions, 59 (46.5%) of 127 cases showed high grade of GLUT1 expression and 22 cases (17.3%) and 15 cases (11.8%) showed moderate grade and low grade of GLUT1 expression, respectively. Thirty-one cases (24.4%) were negative for GLUT1 expression. A significant difference in the GLUT1 expression among normal mucosa, tubular adenomas, adenocarcinomas, and metastatic lesions was observed (Table 1 and Figure 2).

Correlation between GLUT1 expression and clinicopathologic parameters and Apaf-1 in colorectal adenocarcinomas

To assess the clinicopathologic significance of GLUT1 expression, we evaluated the correlation between GLUT1 expression and the clinicopathologic parameters in 515 colorectal adenocarcinomas. We found that a higher ex-

pression of GLUT1 correlated with more aggressive phenotypes of colorectal adenocarcinomas. GLUT1 expression was significantly correlated with female gender (*P* = 0.009), non-mucinous tumor type (*P* = 0.045), poorer differentiation (*P* = 0.001), frequent lymph node metastasis (*P* < 0.001), higher AJCC and Dukes stage (*P* < 0.001 and *P* < 0.001, respectively). There was a significant inverse correlation between GLUT1 expression and Apaf-1 expression (*P* = 0.001) (Table 2).

Correlation between GLUT1 expression and overall survival and disease-free survival

We examined the impact of GLUT1 expression on patient survival. As we expected, a significant prognostic influence of patient age, tumor differentiation, AJCC stage, and vascular invasion on overall and disease-free survival was found in univariate and multivariate analyses (Table 3). Notably, GLUT1 expression was significantly correlated with poor overall survival (*P* = 0.047, log-rank test) and disease-free survival (*P* = 0.021, log-rank test) in univariate analysis. However, in multivariate survival analysis with the Cox proportional hazards model, GLUT1 expression was not an independent prognostic factor for overall survival and disease-free survival (*P* = 0.534 and *P* = 0.416, respectively). Kaplan-Meier survival curves showed a significant difference in patient survival according to GLUT1 expression (Figure 3).

DISCUSSION

In the present study, we investigated the expression of GLUT1 in normal mucosa, tubular adenomas, adenocarcinomas and metastatic lesions and evaluated the correlation with the clinicopathologic parameters and patient survival in patients with adenocarcinomas. GLUT1 expression was absent in 26 normal mucosa specimens with no exception. Only 5 of 26 tubular adenomas with low grade dysplasia showed low GLUT1 expression and 14 of 24 tubular adenomas with high grade dysplasia revealed low or moderate GLUT1 expression. On the other hand, 423 of 515 adenocarcinomas and 96 of 127 metastatic lesions showed GLUT1 expression with variable grades. Furthermore, the GLUT1 expression was closely correlated with poor prognostic parameters.

The activation of GLUT1 gene expression is a molecular feature of malignant phenotype in a variety of

cancers and has been shown to be associated with malignant transformation. Various malignant tumors, including colorectal cancers, show increased glucose metabolism and utilization^[12-14]. Increased GLUT1 expression in neoplastic tissue reflects an increased glycolytic metabolism and is observed under conditions that induce greater dependence on glycolysis as an energy source, such as ischemia or hypoxia^[7,18-20]. Previous studies suggest that GLUT1 expression may play an important role in the

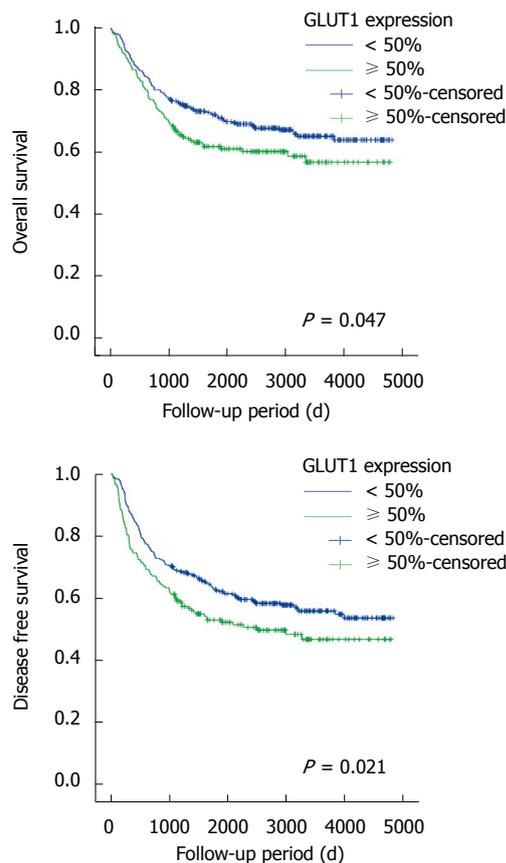

Figure 3 Cumulative overall survival curves (A) and disease-free survival curves (B) according to glucose transporter 1 expression in 515 colorectal cancer patients (Kaplan-Meier method with log-rank test). GLUT1: Glucose transporter 1.

survival of tumor cells by promoting an adequate energy supply^[21,22]. Two possible mechanisms were suggested to explain the activation of GLUT1 gene expression in cancers. Firstly, increased glycolysis and concomitant GLUT1 expression may be a constitutive feature of the malignant phenotype in many cancers. Secondly, local hypoxia in the tumor microenvironment may result in an adaptive increase in glycolytic metabolism and GLUT1 expression^[11].

Sakashita *et al*^[7] demonstrated that GLUT1 expression was positive in 18% of low-grade adenomas and in 63% of high-grade adenomas. In our results, GLUT1 expression was demonstrated in 19.2% (5/26) of tubular adenomas with low grade dysplasia and in 58.3% (14/24) of tubular adenomas with high grade dysplasia. Haber *et al*^[11] demonstrated GLUT1 expression in 101 (90%) of 112 colorectal adenocarcinomas. GLUT1 expression was undetected in 11 cases (9.8%) and detected in < 10% of the tumor cells in 39 cases (34.8%), in 10%-50% of the tumor cells in 42 cases (37.5%), and in > 50% of the tumor cells in 20 cases (17.9%). In our study, GLUT1 expression was demonstrated in 423 (82.1%) of 515 colorectal adenocarcinomas and undetectable in 92 cases (17.9%). Furthermore, we evaluated GLUT1 expression in 127 metastatic lesions, including lymph nodes and distant organs. The GLUT1 expression was significantly different between normal mucosa, tubular adenomas with low grade dyspla-

¹Log-rank test, ²Cox proportional hazards model. GLUT1: Glucose transporter 1; CI: Confidence interval.

sia, tubular adenomas with high grade dysplasia, adenocarcinomas and metastatic lesions (Table 1, $P < 0.001$). Our findings indicate that GLUT1 expression may play an important role at the late stage in the adenoma-carcinoma carcinogenesis sequence.

Some studies have reported the correlation between GLUT1 expression and the clinicopathologic parameters in colorectal adenocarcinomas. Sakashita *et al.*⁷¹ reported that GLUT1 expression was significantly different between well differentiated and less differentiated groups (positivity of 67% vs 93%, $P < 0.05$). The rate of GLUT1 expression, both moderate and strong, was also significantly different between these two groups (49% vs 74%, $P < 0.05$). Ito *et al.*¹⁵¹ demonstrated that GLUT1 immunostaining was stronger in tumors with less differentiation in lung adenocarcinomas. However, Younes *et al.*¹⁰¹ and Haber *et al.*¹¹¹ reported that there was no correlation between GLUT1 expression and histologic differentiation. In our results, GLUT1 expression was < 50% of tumor cells in 19 cases (90.5%) and > 50% of the tumor cells in 2 cases (9.5%) of well differentiated adenocarcinomas. In moderately differentiated adenocarcinomas, GLUT1 expression was < 50% of tumor cells in 252 cases (65.3%) and > 50% of the tumor cells in 134 cases (34.7%). In poorly differentiated adenocarcinomas, GLUT1 expression was < 50% of tumor cells in 57 cases (52.8%) and > 50% of the tumor cells in 51 cases (47.2%). There was a significant correlation between GLUT1 expression and the histologic differentiation ($P = 0.001$).

The relationship between GLUT1 expression and the depth of invasion has been reported in colorectal adenocarcinomas. Sakashita *et al.*⁷¹ reported that GLUT1 expression was significantly different between T1 and T2 groups (positivity of 61% vs 97%, $P < 0.01$). The rate of moderate and strong GLUT1 expression was also significantly different between these two groups (45% vs 74%, $P < 0.01$). However, Younes *et al.*¹⁰¹ demonstrated that there was no significant difference between GLUT1 expression and the depth of invasion. Our results revealed that there was no significant correlation between GLUT1 expression and the depth of invasion. Younes *et al.*¹⁰¹ documented that there was a close correlation

between strong GLUT1 expression and the frequency of lymph node metastasis in colorectal adenocarcinomas. Sakashita *et al.*⁷¹ reported that the rate of GLUT1 expression in colorectal carcinomas with nodal metastasis was higher than that in those without, but the difference was not significant due to the small size of lymph node metastases-positive carcinomas. In our study, there was a close correlation between GLUT1 expression and the presence of lymph node metastasis ($P < 0.001$). This result indicates that GLUT1 may be important for maintaining the high-energy requirements of aggressive cancers. The immunohistochemical detection of GLUT1 in biopsies of colorectal cancers may be useful as a marker of aggressive biologic behavior, especially in lymph node metastasis¹¹⁰.

There has been no documented report as to the relationship between GLUT1 expression and tumor stages in colorectal adenocarcinomas. Haber *et al.*¹¹¹ reported the association of GLUT1 staining status with Dukes stage; however, no statistical significance was revealed. Our results documented that there was a close correlation between GLUT1 expression and tumor stages, AJCC and Dukes stages ($P < 0.001$ and $P < 0.001$, respectively). The correlation between GLUT1 expression and survival in colorectal adenocarcinomas has been reported¹¹¹. There was a significant increase in mortality in those patients whose tumors had more than 50% of GLUT1-positive cells (relative risk, 2.4; $P = 0.02$ by the log rank test). Our study showed that GLUT1 expression was significantly correlated with poor overall survival ($P = 0.047$) and disease-free survival ($P = 0.021$) in univariate analysis. However, in multivariate analysis with the Cox proportional hazards model, GLUT1 expression was not an independent prognostic factor of overall survival and disease-free survival ($P = 0.534$ and $P = 0.416$, respectively).

There are multiple interactions between the cellular machinery involved in glucose uptake and metabolism, and the cellular mechanism of programmed cell death or apoptosis. Glucose deprivation can promote apoptosis in a variety of cells. The induction of glucose uptake and metabolism can prevent or reduce apoptosis^{23,24}. Enhanced GLUT1 expression has been shown to inhibit cytochrome c release and downstream caspase activa-

tion during hypoxia^[25,26]. Vesely *et al.*^[27] documented that GLUT1 prevents hypoxia-induced apoptosis in vascular smooth muscle cells and cardiac myocytes largely *via* a mitochondrial, caspase 9-dependent pathway. In this study, we evaluated the correlation between GLUT1 expression and the expression of Apaf-1, one of the key regulators in the mitochondrial apoptotic pathway^[4,28]. Our results revealed that there is a significant inverse correlation between GLUT1 expression and Apaf-1 expression ($P = 0.001$). The GLUT1 expression may prevent apoptosis through the suppression of Apaf-1 expression *via* a mitochondrial apoptotic pathway.

In conclusion, we tried to clarify the clinicopathologic significance of GLUT1 expression in a large cohort consisting of 26 normal mucosa, 50 tubular adenomas, 515 adenocarcinomas, and 127 metastatic lesions. The GLUT1 expression pattern suggested an important role in colorectal cancer development, especially at the late stage of the adenoma-carcinoma sequence, and GLUT1 expression was closely correlated with poor clinicopathologic factors in colorectal adenocarcinomas.

COMMENTS

Background

Colorectal cancer is the second leading cause of cancer-related death in men and women in the industrialized nations. There have been marked advances in the understanding of the carcinogenesis in colorectal cancer and cancer biology; however, the relevant therapeutic problem continues to persist. Previous studies revealed an enhancement of glycolytic metabolism in malignant tumors. The increased expression of glucose transporter 1 (GLUT1) mRNA and protein has been demonstrated in various cancer tissues which indicates that GLUT1 may play an important role in glucose uptake by various cancers and that GLUT1 expression could be useful as a marker for malignant transformation.

Research frontiers

This study was to investigate the membranous GLUT1 expression in colorectal carcinogenesis and to evaluate the correlation between GLUT1 expression and the clinicopathological parameters, and between GLUT1 expression and cytoplasmic Apaf-1 expression, as well as its effect on survival of patients with colorectal adenocarcinomas.

Innovations and breakthroughs

GLUT1 expression was significantly correlated with female gender, non-mucinous tumor type, poorer differentiation, lymph node metastasis, higher AJCC and Dukes stage. There was a significant inverse correlation between GLUT1 expression and Apaf-1 expression. Patients with GLUT1 expression demonstrated poor overall survival and disease-free survival in univariate survival analysis.

Applications

The authors evaluated the correlation between GLUT1 expression and expression of Apaf-1, one of the key regulators in the mitochondrial apoptotic pathway. The results revealed that there is a significant inverse correlation between GLUT1 expression and Apaf-1 expression. These results warrant further careful and well-designed studies of GLUT1 and Apaf-1 expression in colorectal cancers for clinical therapeutic application.

Terminology

GLUTs are membrane proteins responsible for the transport of glucose across cellular membranes. GLUT1 is an isoform that is restricted to erythrocytes and blood-tissue barriers such as the blood-brain and blood-nerve barriers. Apaf-1 is one of the key regulators in the mitochondrial apoptotic pathway. Apaf-1 binds to a protein called cytochrome-c, which is released from mitochondria under the control of p53, and this complex activates caspase-9, which then triggers executioner caspases, leading to apoptosis.

Peer review

The paper investigated the role of GLUT1 expression in colorectal carcinogenesis and evaluated the correlation with the clinicopathological parameters and Apaf-1 expression in colorectal adenocarcinomas. It is very interesting.

Abstract

AIM: To evaluate the potential usefulness of acoustic radiation force impulse (ARFI) images for evaluation of hepatocellular carcinomas (HCC)-associated radiofrequency ablation.

METHODS: From January 2010 to June 2010, a total of 38 patients with HCC including recurred HCCs after RFA underwent ARFI elastography. The brightness of tumor was checked and the shear wave velocity was measured for the quantification of stiffness. According to the brightness, the tumors were classified as brighter, same color and darker compared with adjacent parenchyma. Using the same methods, 8 patients with recurred HCCs after RFA state were evaluated about the brightness compared with adjacent RFA ablation area.

RESULTS: In the 38 patients with HCCs, 20 (52.6%)

were brighter than surrounding cirrhotic parenchyma. Another 13 (34.2%) were darker. The others (5 cases, 13.2%) were seen as the same color as the adjacent liver parenchyma. Post-RFA lesions were darker than previous tumor and surrounding parenchyma in all 38 cases. However, recurred HCCs were brighter than the treated site in all 8 cases.

CONCLUSION: Using ARFI technique is helpful for differential diagnosis in order to detect recurred HCCs more easily in patients with confusing status.

INTRODUCTION

In recent decades, there has been an increasing interest in assessing the viscoelastic properties of tissues with ultrasound. Ultrasonography (US) tissue-strain analysis can be performed under compression using Hitachi Real-time Tissue elastography (HI-RTE, Hitachi Medical Systems Europe, Zurich, Switzerland), eSie Touch (Siemens, Erlangen, Germany) or Elasticity Imaging (Simems)^[1-8].

Acoustic radiation force impulse (ARFI) imaging is a new ultrasound imaging modality to evaluation of tissue

stiffness by radiation forced-based imaging method that is provided with conventional B-mode US.

In ARFI imaging, an initial ultrasonic pulse is transmitted at diagnostic intensity levels to obtain a baseline signal for later comparison. A short-duration (approximately 0.3 s), high intensity acoustic “pushing pulse” is then transmitted by the same transducer, and followed by a series of diagnostic intensity pulses, which are used to track the displacement of the tissue caused by the pushing pulse^[9-11]. The response of the tissue to the radiation force is observed using conventional B-mode imaging pulses and it is possible to display the quantitative shear wave velocity (SWV, m/s) of ARFI displacement^[12,13]. Because the velocity of the shear wave depends on the tissue stiffness, it is possible to apply ARFI technology to elastography^[14-19].

Until now, there are no studies that have evaluated ARFI elastography’s usefulness in differentiating HCC, post RFA HCC and recurred HCC after RFA and no studies have been reported on the quantification of tumor stiffness using shear wave velocity, which may help in the diagnosis.

The present study was performed to investigate the potential usefulness of ARFI elastography for evaluation of HCC associated RFA, assuming that different features can be shown on ARFI elastography images according to the HCC, post RFA HCC and recurred HCC after RFA.

MATERIALS AND METHODS

Patients

Between January 2010 and June 2010, a total of 38 patients with viable HCC were evaluated by ARFI elastography. Eight patients had recurred HCC after RFA. Because every patient each had one HCC, a total of 38 HCCs were included in this study.

In cases of technical failure such as patient motion, the presence of a deep-seated lesion or the patient’s inability to hold their breath properly, recurred HCC after TACE or operation, and multiple HCCs were excluded from this study.

Mean tumor diameter was 2.4 cm (0.8-3.5 cm).

The diagnosis of all HCCs was based on the typical findings determined using either computed tomography (CT) or magnetic resonance (MR) imaging and/or biopsy. The following imaging findings were considered for the diagnosis of HCC: (1) tumors showing typical enhancement pattern (early enhancement on the arterial phase and wash-out on the portal and delayed phases); and/or (2) mass showing high signal intensity on the T2 weighted image.

A detailed medical history was obtained from all 38 patients. All patients had underlying liver disease which was established according to serum markers and liver biopsy as follows: chronic viral hepatitis was diagnosed as serum positive HBV-DNA and/or HCV-RNA with an elevated serum alanine amino transferase (ALT). Chronic alcoholic hepatitis was diagnosed as a history of long term alcohol consumption with an elevated serum ALT. Liver cirrhosis was diagnosed based on cross-sectional imaging findings and/or biopsy.

Table 1 Stiffness of hepatocellular carcinomas on acoustic radiation force impulse imaging

| Acoustic radiation force impulse imaging | Darker (stiffer) | Same color (equally stiff) | Bright (softer) |
|--|------------------|----------------------------|-----------------|
| Pre-RFA HCCs (38) | 13 | 5 | 20 |
| Recurred HCCs (8) | 0 | 0 | 8 |
| Post-RFA HCCs (38) | 38 | 0 | 0 |

HCCs: Hepatocellular carcinomas; RFA: Radiofrequency ablation.

Image protocol and analysis

B-mode standard US scanning and ARFI elastography were performed using a SIEMENS Acuson S2000 using a 4-1 MHz curved array probe. Two experienced radiologists participated in the US scanning. Prior to RFA, the radiologists scanned the liver to locate the HCC detected on the other cross-sectional imaging technique, such as CT, MRI, and/or prior US. After fitting the ARFI image box to cover the lesion, an ARFI image was obtained with a corresponding B-mode image. The SWV was obtained from the HCC and hepatic parenchyma, three times. After RFA, ARFI images and SWV were obtained, as before RFA.

Two radiologists, who performed US, reviewed all of the B-mode and ARFI images. The stiffness of the pre- and post-RFA HCCs were analyzed on the ARFI images. The HCCs were categorized according to the brightness, darker (stiffer), same color (equally stiff), or brighter (softer), based on the HCCs brightness relative to the hepatic parenchyma on the ARFI images. The SWV of HCCs and hepatic parenchyma were averaged. These SWVs were used for quantification of stiffness.

Discrepancies between the two reviewers were resolved through consensus.

RESULTS

Table 1 summarized the stiffness of HCCs on the ARFI image. Before RFA, 20 HCCs (52.6%) appeared as a bright color, which meant the HCC were softer than hepatic background (Figure 1). When compared with the hepatic parenchyma, 13 HCCs (34.2%) had a darker appearance, which indicated HCCs were stiffer than surrounding hepatic parenchyma (Figure 2). The remaining HCCs (5 cases, 13.2%) were seen as the same color as the adjacent hepatic parenchyma, which indicated the HCC had the same stiffness as the hepatic background. After RFA, all HCCs (38 cases, 100%) revealed a darker color (Figure 3). All recurred HCC after RFA (8 cases), showed a bright appearance compared to the RFA site (Figure 4). This means that RFA ablation site was harder than before RFA, so the recurred HCC were softer than the surrounding area of the prior RFA site. 5 cases of recurred HCC after RFA were treated by re-RFA. The others were treated by TACE (2 cases), or operation (1 case).

The tumor diagnosis of recurrence after RFA was based on the typical findings determined using either CT or MRI and serum tumor marker elevation (AFP and/or PIVKA).

Two cases showed typical imaging findings of tumor re-

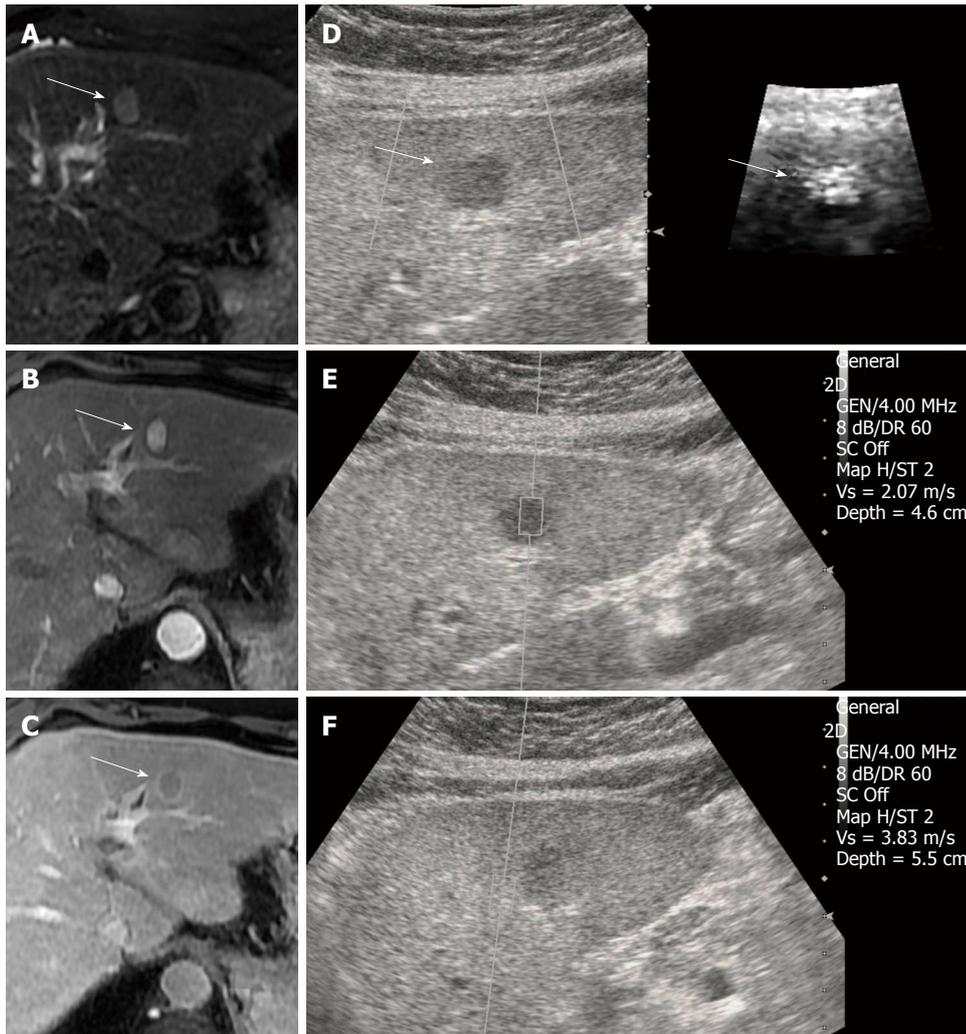

Figure 1 Hepatocellular carcinoma in a 59-year-old man with underlying liver cirrhosis. A: T2-weighted magnetic resonance (MR) image shows a high signal intensity mass in segment 2 of the liver (arrow); B: On dynamic study, the mass revealed an arterial enhancement; C: Delayed wash-out, which is a typical finding of hepatocellular carcinoma (HCC) (arrow); D: On B-mode image, the HCC appears as a well defined, hypoechoic mass and the HCC have a bright (softer) color on the acoustic radiation force impulse (ARFI) image (arrows); E: The shear wave velocity (SWV) of HCC is 2.07 m/s; F: SWV of surrounding cirrhotic hepatic parenchyma measures 3.83 m/s. GEN: General; SC: Spatial compounding; Vs: Velocity.

Figure 2 Hepatocellular carcinoma in a 45-year-old woman with underlying liver cirrhosis. A: T2-weighted magnetic resonance image shows a high signal intensity hepatocellular carcinoma (HCC) in segment 4 of the liver (arrow); B: On a B-mode image, the HCC is seen as an ovoid, hypoechoic mass (arrow), that appears darker (stiffer) than hepatic background on the acoustic radiation force impulse image (arrow). The shear wave velocity of HCC and surrounding hepatic parenchyma were measured as 2.20 m/s and 1.57 m/s, respectively (not shown).

currence at CT, but serum tumor marker level was normal. But one showed typical imaging findings of tumor recurrence on MRI, another imaging study. The other recurrent HCC was confirmed after surgery.

Table 2 summarized the SWV of HCCs and hepatic

parenchyma. Cirrhotic liver parenchyma and non-cirrhotic liver parenchyma had a mean SWV of 2.62 m/s and 1.04 m/s, respectively. The mean SWVs of pre-RFA HCCs and recurrent HCCs after RFA were 2.04 m/s and 2.02 m/s. All post-RFA HCCs were uncheckable, and their numerical value was shown 'X.XX'. This nonnumerical value is due to abrupt tissue degeneration in the RFA site preventing a reliable reading.

DISCUSSION

Recently, ARFI sonoelastography has been used to noninvasively generate internal mechanical excitation and has attracted great attention for its use in the measurement of tumor stiffness^[20-21]. To our knowledge, no other investigators have evaluated the use of ARFI sonoelastography for the evaluation of post-RFA recurrent HCC. In our study, pre-RFA HCCs showed variable hardness as compared with the liver parenchyma on ARFI images. These results seem to be inconsistent

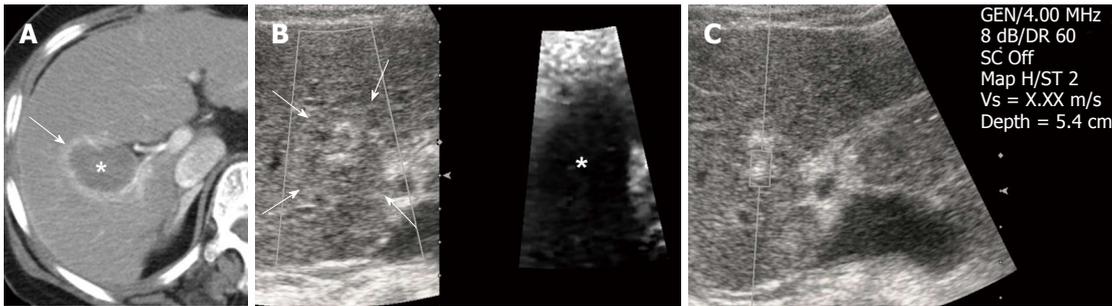

Figure 3 Post-radiofrequency ablation hepatocellular carcinoma in a 71-year-old woman with underlying liver cirrhosis. A: Contrast-enhanced arterial phase computed tomography scan obtained immediately after radiofrequency ablation (RFA) shows the ablation zone of low attenuation (asterisk) with a surrounding ring of benign enhancement (arrows) in segment 5 of the liver; B: Next day, follow up B-mode image of post-RFA hepatocellular carcinoma (HCC) is seen as an ill-defined heterogeneous echogenic lesion (arrow) and the HCC appears darker on the acoustic radiation force impulse image (asterisk); C: The shear wave velocity of post-RFA HCC is uncheckable, shown as X.XX m/s. GEN: General; SC: Spatial compounding; Vs: Velocity.

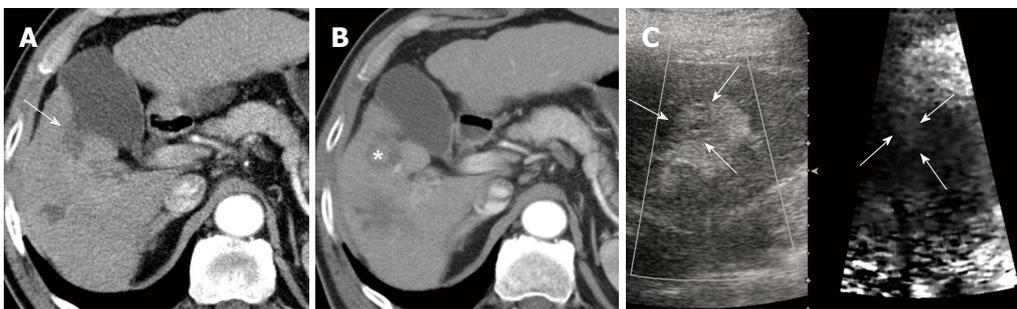

Figure 4 Recurred hepatocellular carcinoma after radiofrequency ablation in a 65-year-old man with underlying liver cirrhosis. A: Follow-up post-radiofrequency ablation (RFA) computed tomography (CT) scan shows the ablation zone of low attenuation without residual or recurrent tumor in segment 5 of the liver (arrow); B: Contrast-enhanced CT scan obtained after 6 mo shows enhancing nodule in the ablated lesion (asterisk). The serum alpha-fetoprotein increased from 2.6 ng/mL to 16.8 ng/mL; C: On a B-mode image, prior RFA site and recurrent hepatocellular carcinoma (HCC) are seen as homogeneous hyperechoic lesions and subtle heterogeneous echogenic nodules with a thin hypoechoic rim (arrows). The recurrent HCC appears as a brighter color (softer) with a distinct border on the acoustic radiation force impulse image.

Table 2 Stiffness of hepatic parenchyma and hepatocellular carcinomas on shear wave velocity

| Mean shear wave velocity (m/s) | | | | |
|--------------------------------|---------------|--------------|---------------|---------------|
| Cirrhosis | Non-cirrhosis | Pre-RFA HCCs | Recurred HCCs | Post-RFA HCCs |
| 2.62 | 1.04 | 2.04 | 2.02 | uncheckable |

HCCs: Hepatocellular carcinomas; RFA: Radiofrequency ablation.

with the results of Fahey’s study^[22,23], in which all HCCs were softer than the surrounding liver. This discordancy was thought to be the difference in parenchymal hardness between chronic hepatitis and liver cirrhosis. Additionally, differences in severity of liver cirrhosis also might be contributing to the discrepancy.

Actually according to the other report^[24], there was no statistically significant difference at the HCCs in terms of tumor stiffness suggested by ARFI elastography ($P > 0.05$).

In all post-RFA HCCs, thermal ablated necrotic lesions were seen as a darker color on the ARFI images and had uncheckable SWV. In the RFA site, the system constantly provided a nonnumerical value. It was considered an unknown mechanical error that was associated with immediate post-RFA state^[25].

Although remarkable advances in surgical and imaging

techniques have improved the prognosis of HCC patients, the high incidence of intrahepatic recurrence remains a major challenge in HCC therapy^[26,27]. However, sometimes B-mode imaging for assessment of HCC recurrence is not satisfactory.

On ARFI imaging, most of the recurrent HCCs appeared brighter than the pre-RFA ablation sites. Moreover, most of the cases revealed distinct borders, unlike the B-mode images. The RFA ablation site comprised hard lesions that showed coagulative necrosis and fibrotic scarring. As a result, recurrent HCCs were found to be softer with improved contrast compared to the surrounding pre-RFA ablation area. Thus, we thought that the ARFI images were superior to the B-mode images for evaluating HCC recurrence after RFA and also useful to guide the second round of RFA for recurrent HCC.

COMMENTS

Background

Recently, acoustic radiation force impulse (ARFI) sonoelastography has been used to noninvasively generate internal mechanical excitation and has attracted great attention for its use in the measurement of tumor stiffness.

Research frontiers

To our knowledge, no other investigators have evaluated the use of ARFI sonoelastography for the evaluation of post-radiofrequency ablation (RFA) recurrent hepatocellular carcinoma (HCC).

Innovations and breakthroughs

The RFA ablation site was comprised of hard lesions that showed coagulative necrosis and fibrotic scarring. As a result, recurrent HCCs were found to be softer with improved contrast compared to the surrounding pre-RFA ablation area.

Applications

ARFI images are superior to B-mode images for evaluating HCC recurrence after RFA and also useful to guide the second round of RFA for recurrent HCC.

Terminology

ARFI imaging is a new ultrasonography (US) imaging modality used to evaluate tissue stiffness by a radiation force-based imaging method that is provided with conventional B-mode US.

Peer review

This is an interesting report of the effect of RFA on HCC by use of ARFI techniques.

Abstract

AIM: To evaluate the efficacy and safety of cetuximab plus irinotecan in irinotecan-refractory metastatic colorectal cancer (mCRC) patients from South-East Asia and Australia.

METHODS: In this open-label, phase II study, the main eligibility criteria were epidermal growth factor receptor-positive mCRC with progressive disease within 3 mo of an irinotecan-based regimen as the most recent chemotherapy. Patients received cetuximab 400 mg/m² initially, then 250 mg/m² every week, with the same regimen of irinotecan on which the patients had progressed (4 pre-defined regimens allowed). The primary objective was evaluation of progression-free survival (PFS) at 12 wk. Secondary objectives included a further investigation of PFS, and an assessment of the overall response rate (ORR), duration of response, time to treatment failure (TTF), overall survival and the safety profile.

RESULTS: One hundred and twenty nine patients were enrolled from 25 centers in the Asia-Pacific region and of these 123 received cetuximab plus irinotecan. The most common recent irinotecan regimen used was 180 mg/m² every 2 wk which had been used in 93 patients (75.6%). The PFS rate at 12 wk was 50% (95% confidence interval (CI, 41-59) and median PFS time was 12.1 wk (95% CI: 9.7-17.7). The ORR was 13.8% (95% CI: 8.3-21.2) and disease control rate was 49.6% (95% CI: 40.5-58.8). Median duration of response was 31.1 wk (95% CI: 18.0-42.6) and median overall survival was 9.5 mo (95% CI, 7.5-11.7). The median TTF was 11.7 wk (95% CI: 9.1-17.4). Treatment was generally well tolerated. The most common grade 3/4 adverse events were diarrhea (13.8%), neutropenia (8.9%), rash (5.7%) and vomiting (5.7%).

CONCLUSION: In patients from Asia and Australia, this study confirms the activity and safety of cetuximab plus irinotecan observed in previous studies in Europe and South America.

Cetuximab plus irinotecan in pretreated metastatic colorectal cancer patients: The ELSIE study. *World J Gastroenterol* 2011; 17(14): 1879-1888 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i14/1879.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i14.1879>

INTRODUCTION

Based on 2002 estimates, there are approximately 1 million new cases of colorectal cancer (CRC) annually worldwide, with 529 000 deaths from the disease^[1]. Approximately 25% of patients with CRC present with metastatic CRC (mCRC), and 25%-30% of newly diagnosed patients with CRC will eventually develop metastatic disease^[2]. Five-year survival rates for patients with newly diagnosed mCRC have improved from 9.1% during 1990-1997 to 19.2% for 2001-2003 to a predicted value of 32% for 2004-2006^[3]. The observed increase in survival is associated with the adoption of hepatic resection and improved chemotherapy regimens^[3]. In 2002, the annual incidence and mortality associated with CRC in Eastern and South-East Asia were approximately 307 600 and 160 000 cases, respectively, and in Australia, they were around 12 300 and 4900 cases, respectively^[1]. While the incidence and mortality rates for CRC are generally stabilizing in Western and developed countries, those in economically developing countries and in Eastern and South East Asia are increasing^[1,4,5].

The epidermal growth factor receptor (EGFR) is frequently expressed in CRC^[6-9], where high levels of expression have been reported to be associated with reduced survival time in patients with mCRC^[10]. Cetuximab (Erbix[®] developed by Merck KGaA (Darmstadt, Germany) under license from ImClone Systems, a wholly-owned subsidiary of Eli Lilly, Branchburg, NJ, USA) is a monoclonal immunoglobulin G1 antibody that specifically targets the EGFR with high affinity, and exerts an inhibitory effect on tumor cell proliferation, survival, motility, invasion and angiogenesis^[11]. Cetuximab has been shown to be efficacious and well tolerated in patients failing irinotecan therapy either in combination with irinotecan or as monotherapy^[7], and in combination with irinotecan in patients failing first-line oxaliplatin-based therapy^[12]. In the pivotal registration study (BOND) for cetuximab conducted in European mCRC patients failing irinotecan-based therapy, cetuximab

plus irinotecan was well tolerated and was associated with a disease control rate of 56%, a median time to progression of 4.1 mo and median overall survival of 8.6 mo^[7]. The NCIC-CO.17 trial demonstrated that cetuximab monotherapy significantly improved response rate, progression-free survival (PFS) and overall survival time in heavily pretreated patients with mCRC with *KRAS* wild-type tumors compared with patients receiving best supportive care alone^[13]. Findings from the BOND study have been confirmed in a community practice setting in the large Monoclonal Antibody Erbitux in a European Pre-License Study (MABEL)^[14]. This study investigated the combination of different irinotecan regimens with cetuximab in 1147 patients with mCRC progressing on irinotecan. To date the MABEL study is the largest published cetuximab study in this setting, reporting a PFS rate at 12 wk of 61% and an estimated median survival time of 9.2 mo^[14]. Data from the Latin American Erbitux Pre-License Study (LABEL) in Latin American patients with EGFR-expressing mCRC progressing on irinotecan suggest cetuximab to be active and tolerable, with a safety profile similar to that described in European patients^[15].

At the time of the design of this study there were no standard treatment options available for patients in this setting. Approval following the BOND trial, for cetuximab in combination with irinotecan for mCRC patients in this setting therefore provided the rationale for this study. Thus the phase II Erbitux[®] pre-License Study In the East (ELSIE) was designed to investigate the combination of irinotecan-containing regimens with cetuximab in irinotecan-refractory patients with mCRC from Asia and Australia.

MATERIALS AND METHODS

Patients

All patients provided written informed consent. Main inclusion criteria were age \geq 18 years, Karnofsky performance status (KPS) \geq 80, histologically confirmed diagnosis of adenocarcinoma of the colon or rectum, metastatic disease not suitable for curative treatment, immunohistochemical evidence of EGFR expression in the primary tumor or metastasis, previous treatment with 1 of 4 pre-defined irinotecan regimens for \geq 6 wk as the most recent chemotherapy, disease progression on or within 3 mo of the most recent irinotecan regimen, able to tolerate irinotecan continuation, no more than 3 previous lines of chemotherapy, and adequate hepatic, renal and bone marrow function. Main exclusion criteria were known or suspected brain metastases, radiotherapy or major surgery within the 4 wk prior to study entry, previous EGFR-targeted therapy, coronary heart disease or history of myocardial infarction or uncontrolled arrhythmia, other malignancy within 5 years (except basal cell carcinoma of the skin or pre-invasive carcinoma of the cervix), and pregnancy.

Study design

This was an open-label, uncontrolled, multicenter, phase II study carried out in 25 centers in 8 countries in the Asia-Pacific region. Patients initially received an infusion of ce-

tuximab 400 mg/m² over 2 h followed by weekly infusions of 250 mg/m² over 1 h in addition to irinotecan treatment at the same dosage regimen (including previous dose reductions) on which the subject had become refractory to irinotecan. Irinotecan was administered intravenously over 30-90 min with at least 1 h between the end of cetuximab and the start of infusion of irinotecan. The irinotecan regimens allowed as pre-study treatment and continued during the study were 100 or 125 mg/m² weekly for 4 wk then 2 wk rest (1 cycle); 100 or 125 mg/m² weekly for 2 consecutive wk out of 3 (1 cycle); 180 or 210 mg/m² every 2 wk (1 cycle); and 300 or 350 mg/m² every 3 wk (1 cycle). The first 3 pre-study irinotecan regimes could have been administered either as single-agent irinotecan or in combination; however, only single-agent irinotecan was accepted for the fourth regimen. Study treatment was continued until disease progression or unacceptable toxicity. In case of an irinotecan-related toxicity, irinotecan could be stopped and treatment could be continued with cetuximab monotherapy. Two irinotecan dose reductions were allowed for toxicity prior to study entry and during the study for all regimens except for patients receiving 100 mg/m² weekly where only 1 dose reduction was allowed.

The primary objective was the assessment of PFS rate after 12 wk of treatment. Secondary objectives included further evaluation of PFS, and the assessment of best overall confirmed response rate, duration of response, time to treatment failure (TTF), overall survival time, safety and toxicity.

The study was conducted in accordance with the ethical principles of the Declaration of Helsinki as well as the International Conference on Harmonization-Good Clinical Practice (ICH-GCP, 1996).

Assessments

Pre-screening of patients was performed within 3 mo after confirmation of disease progression on irinotecan-based chemotherapy and included informed consent, collection of demographic data, tumor diagnosis and the determination of tumor EGFR expression which was performed by designated pathology laboratories in Hong Kong, India and China by immunohistochemical staining of tumor tissue slides using a standardized protocol with the DAKO EGFR pharmDX kit (DAKO Corporation, Carpinteria, CA, USA). Baseline evaluations were performed within 21 d prior to the start of study treatment; pre-study staging by computed tomography (CT) or magnetic resonance imaging (MRI) was performed within 28 d. After the start of treatment, imaging (CT or MRI) was performed every 6 wk. Based on these images, the tumor response was assessed according to modified World Health Organisation (WHO) criteria every 6 wk during study treatment. Follow-up for survival occurred every 12 wk from the end of the study visit and included recording of subsequent treatments.

Adverse events (AEs) were reported weekly at each infusion visit, at the time of disease progression or study discontinuation, and up to 6 wk after the last infusion of study treatment. AEs were reported by severity according to National Cancer Institute Common Toxicity Criteria (NCI-

CTC) version 2 using Medical Dictionary for Regulatory Activities (MedDRA) version 10 preferred terms as event category and MedDRA body system/primary system organ class (SOC) as SOC category.

Statistical analysis

Safety and efficacy analyses were carried out considering the intention-to-treat (ITT)/safety population, which comprised all patients who had received any dose of study treatment. As patients were not randomized to treatment and the number of patients per individual treatment regimen was expected to be small, all data were analyzed independently of the on-study irinotecan regimen. The primary objective of this study was to determine the PFS rate at 12 wk after initiation of cetuximab treatment. Time-to-event analyses were based on Kaplan-Meier estimates. Confidence intervals (CIs) for the median were calculated according to Brookmeyer and Crowley^[16]. CIs for the event-free rate estimates, including the primary variable, were derived from the Kaplan-Meier curve at defined time points. The estimate of the standard error was computed using Greenwood's formula^[17]. PFS was defined as the time from the first study medication to the first observation of radiologically confirmed disease progression, symptomatic deterioration leading to discontinuation of study treatment (unless imaging confirmed absence of progressive disease), or death due to any cause within 60 d of the last on-study tumor assessment. The best overall confirmed response was defined as the best confirmed response from start of treatment until disease progression. Duration of response in patients with a complete response (CR) or partial response (PR) was defined as the time from first assessment of CR/PR to the first time disease progression was documented or death within the trial or until death within 60 d after last tumor assessment, whichever occurred first. The time to TTF was defined as the time from the start of the first cetuximab treatment until the date of the first occurrence of an event defining treatment failure, i.e. withdrawal of any study treatment due to AEs or progressive disease or withdrawal of consent or death, whichever occurred first. The overall survival time was defined as the time from the day of first infusion of study medication to death. For subjects who were still alive at the last survival follow-up, or who were lost to follow-up, survival was censored at the last recorded date that the subject was known to be alive.

A subgroup analysis that used a landmark method for the analysis of time-dependent covariates was carried out to examine whether the development and severity of acne-like rash that occurred during the first 21 d of treatment was associated with prolonged survival time. To avoid selection bias as a consequence of the early exclusion of patients, this analysis was limited to all patients in the ITT/safety population who were still under on-study treatment at day 21. Consequently, overall survival time was analyzed for this subgroup by using the landmark of study day 22 (and not day 1) as the start day. Survival was further analyzed in other subgroups based on known prognostic variables.

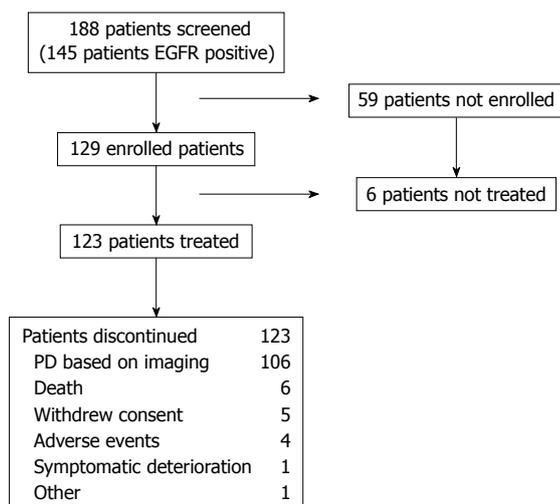

Figure 1 Disposition of patients at each stage of the study. EGFR: Epidermal growth factor receptor; PD: Progressive disease.

To ensure adequate precision of estimates, the sample size determination was based on a confidence limit approach. The expected rate of progression-free patients 12 wk after start of study treatment was 50%. It was calculated that with the enrollment of 150 patients, the observed 95% CI for this point estimate would have a range of approximately $\pm 8\%$.

RESULTS

Patient demographics

Patient characteristics are summarized in Figure 1. Between November 2005 and September 2006, 188 patients were screened at 25 centers in Australia (3 centers), China (6), Hong Kong (2), India (3), Korea (5), Singapore (1), Taiwan (3), and Thailand (2). Of these patients, 145 (77%) had EGFR detected in their tumor sample (data were missing for 4 patients), 129 patients were enrolled and of these, 123 patients were treated and formed the ITT/safety population. The main reason for study discontinuation was disease progression (86.2%). There were 6 patients who were treated until death (5 of these deaths due to disease progression, 1 due to chemotherapy-related AEs, 4 patients stopped treatment due to AEs and 5 patients withdrew consent).

Patient and disease characteristics at baseline are summarized in Table 1. The majority of patients were male (59.3%), the median age was 56 years (range, 24-78 years) and 74.8% of patients were aged < 65 years. The most common primary tumor site was the colon (57.7%), and 74.8% of patients had liver metastases, 56.1% had lung metastases and more than 30% of patients had other organs involved. The median duration of mCRC at baseline was 8.8 mo (range, 1-56).

The most common recent irinotecan regimen used was 180 mg/m² every 2 wk, which had been used in 93 patients. Approximately half of the patients (49.6%) had a time interval of 1-3 mo between the last pre-study dose of irinotecan and the first dose of cetuximab and the interval was < 1 mo in 35% of patients. All other patients had an interval

¹Relative dose intensity calculated for patients receiving at least 1 maintenance dose only, the initial dose was excluded for the calculation of relative dose intensity; ²Duration, cumulative dose by cycle and relative dose intensity overall and by cycle were not calculated for 4 patients who received "other" irinotecan regimens (n = 119 for these calculations).

Treatment exposure

Treatment exposure is summarized in Table 2. At least 50% of patients received cetuximab treatment for ≥ 12 wk and were administered ≥ 12 infusions. The longest treatment duration was 98 wk and almost 5% of patients received more than 50 infusions of cetuximab. Relative dose intensity (RDI) of cetuximab of ≥ 90% was achieved in 89.2% of patients. Furthermore, 118 patients (95.9%) were treated at the planned standard dose of cetuximab. Four patients (3.3%) had at least 1 dose reduction of cetuximab and information was missing for 1 patient. Dose reductions were required at the occurrence of second or third incidences of grade 3 skin toxicity according to the protocol.

The median duration of irinotecan exposure was 12 wk, with patients receiving a median of 6 cycles. RDI of ≥ 90% of irinotecan was achieved in 65% of patients. Approximately three-quarters of patients (74%, n = 91) received ≥ 80% of the planned dose of irinotecan. In total, 74 patients (60.2%) required at least 1 dose reduction of irinotecan, which included pre-study dose reductions.

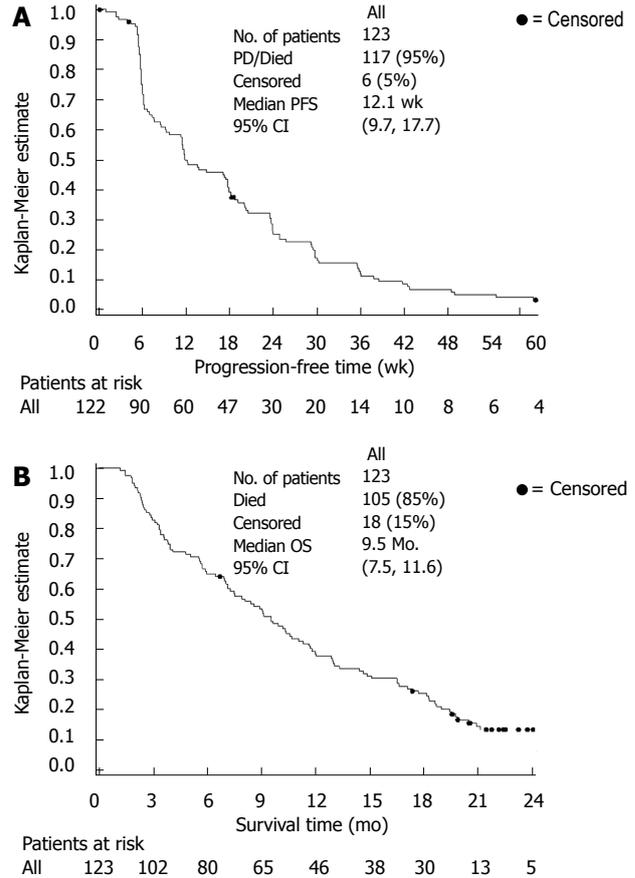

Figure 2 Kaplan-Meier curve. A: Progression-free survival (PFS); B: Overall survival (OS) in the intention-to-treat/safety population. CI: Confidence interval.

Treatment outcome

Study results are summarized in Table 3. The 12-wk PFS rate was found to be 50% (95% CI: 41-59). The median PFS time was 12.1 wk (95% CI: 9.7-17.7) (Figure 2A). In general, there were no marked or unexpected differences in PFS time for any of the prognostic variables or characteristics of previous treatment which were considered in the pre-specified subgroup analyses (data not shown).

The median overall survival time was 9.5 mo (95% CI: 7.5-11.6) (Figure 2B), with a 1-year survival rate of 38% (95% CI: 29-46) (Table 3). The median follow-up time for survival was 22.4 mo (95% CI: 21.4-24.4). There were generally no marked or unexpected differences for any of the prognostic variables or characteristics of previous treatment which were considered in pre-specified subgroup analyses of overall survival time (Table 4). A landmark analysis investigated the impact of early occurrence of acne-like rash (during the first 21 d of treatment) on overall survival time. Median overall survival was longer in patients with acne-like rash compared with those patients who experienced no acne-like rash (9.5 mo *vs* 6.2 mo). Median overall survival time was shorter in patients with grade 3/4 early acne-like rash (4 patients only) compared with grade 1/2 acne-like rash. As the sample size in the subgroup with grade 3/4 acne-like rash was very small, this observation is likely to be an artifact due to differences between patients with and

PFS: Progression-free survival; CI: confidence interval.

without early acne-like rash with regard to other prognostic factors, such as gender, age and KPS.

The objective response rate was 13.8% (95% CI: 8.3-21.2) (Table 3). The median duration of response was 31.1 wk (95% CI: 18.0-42.6). In addition, 44 patients (35.8%) had stable disease and the disease control rate was 49.6% (95% CI: 40.5-58.8). A higher response rate of 25.0% (5/20 patients) was observed for patients with CR and PR as best response to the most recent irinotecan schedule as compared with subjects with progressive disease and stable disease who had a response rate of 11.8% (12/102 patients). In addition, patients with KPS ≤ 80 at baseline had lower response rates [7.7% (95% CI: 1.6-20.9)] than the KPS > 80 subgroup [16.7% (95% CI: 9.4-26.4)]. There were generally no marked or unexpected differences in response rates between other pre-specified subgroups (data not shown). Disease control rates in the subgroups were consistent with those observed for response rate. The median TTF was 11.7 wk (95% CI, 9.1-17.4).

Ninety patients (73.2%) received post-study anti-cancer treatments, consisting of best supportive care (66 patients; 53.7%), chemotherapy (59 patients, 48.0%), surgery (6 patients, 4.9%), radiotherapy (15 patients, 12.2%) and other treatments (15 patients, 12.2%).

Adverse events

Treatment was generally well tolerated. The most common AEs of any grade according to MedDRA SOC were skin and subcutaneous tissue disorders (85.4%), gastrointestinal disorders (85.4%) and general disorders and administration

Grade 3/4 AEs (Adverse events) in > 2% and any grade AEs in > 20% of patients in the intention-to-treat/safety population and composite AE categories of special interest. ¹Composite categories where several Medical Dictionary for Regulatory Activities preferred terms have been pooled; ²Terms included acute myocardial infarction, acute respiratory failure, anaphylactic reaction, anaphylactic shock, anaphylactoid reaction, anaphylactoid shock, angina pectoris, apnea, asthma, blood pressure decreased, bronchial obstruction, bronchospasm, cardiac failure, cardiopulmonary failure, chills, clonus, convulsion, cyanosis, drug hypersensitivity, dyspnea, dyspnea at rest, dyspnea exacerbated, dyspnea exertional, epilepsy, hyperpyrexia, hypersensitivity, hypotension, hypoxia, infusion-related reaction, loss of consciousness, myocardial infarction, myocardial ischemia, orthopnea, pyrexia, respiratory distress, respiratory failure, shock, sudden death, and syncope; ³Terms included acne, acne pustular, dermatitis acneiform, dry skin, erythema, folliculitis, pruritus, rash, rash erythematous, rash follicular, rash generalized, rash macular, rash maculo-papular, rash papular, rash pruritic, rash pustular, skin exfoliation, skin hyperpigmentation, telangiectasia, and xerosis; Preferred terms included in the infusion-related reactions category regardless of when they occurred; all other preferred terms in this category were included only if the onset date of the AE was on the day of the first cetuximab administration.

mely infusion-related reactions and acne-like rash (Table 5). Grade 3/4 infusion-related reactions occurred in 3 patients (2.4%; 2 patients with Grade 3, 1 patient with Grade 4). Ten patients (8.1%) had grade 3 acne-like rash (Table 4), with no occurrences of grade 4 rash reported. Overall, 7 patients (5.7%) had AEs that led to the discontinuation of cetuximab and 13 patients (10.6%) had AEs leading to the discontinuation of chemotherapy. Three patients (2.4%) had AEs leading to the discontinuation of both.

At the time of database closure (February 27th, 2009), 105 patients in the ITT/safety population had died, of which 8 died within 30 d after the last dose of study medication. Seven deaths (5.7%) occurred due to disease progression and 1 patient (0.8%) died due to events related to irinotecan-based therapy. There were no deaths related to cetuximab treatment.

DISCUSSION

The ELSIE study was designed to further investigate, in patients from the Asia-Pacific region, the observations initially made in the BOND study^[7] relating to efficacy and safety of the combination of cetuximab with irinotecan in mCRC patients progressing on irinotecan-based chemotherapy. The PFS rate at 12 wk of 50% (95% CI: 41-59) met the expectation for the primary endpoint of the study made at the time of study planning. A sample size of 150 patients was considered sufficient to meet the primary study objective in the current study; however, only 129 patients were actually enrolled. The low recruitment rate in some of the participating countries is thought to be due to the fact that irinotecan was not a preferred treatment option in many of the study centers. Consequently, few patients fulfilled the protocol requirement of having received irinotecan-based treatment as the most recent therapy.

Cross comparisons of the results of this study and similar studies in relation to the interpretations of the efficacy data should be undertaken with some degree of caution, particularly where differences exist in study design^[18]. The ELSIE study was comparable in design to the combination arm of the BOND study and the LABEL study^[7,15], although all 3 differed slightly in study design from the MABEL study, particularly in the interval for imaging assessment of the tumor^[14]. Except for the notable differences in geographical location, there were only minor variations in the patient populations of these studies. Furthermore, the disposition of these populations with respect to the disease under investigation, namely, the number of previous treatment lines, the number of metastatic sites, and best response to most recent irinotecan treatment were considered comparable^[7,14,15,19].

A comparison of the treatment outcomes of patients receiving cetuximab in combination with irinotecan-based chemotherapy in the ELSIE, BOND, MABEL and LABEL studies is shown (Table 6). The PFS rate at 12 wk in the present study was slightly lower than that reported in the MABEL and LABEL studies and in the combination therapy arm of the BOND study (PFS rate at 3 mo). The variations across the studies may also reflect differences in the CT scanning schedules for tumor assessment. Tumors were assessed according to modified WHO criteria in these studies every 6 wk by the investigators in the ELSIE and LABEL studies^[15], every 12 wk in the MABEL study^[14], and every 6 wk by an independent review committee in the BOND study^[7]. In addition, differences may reflect other factors relating to patient characteristics, such as different KPS.

Consistent with the primary endpoint, tumor response rate and median PFS (12.1 wk) were also slightly lower in the current study than reported in the MABEL and LABEL studies and the combination arm of the BOND study. However, the treatment with cetuximab in combination with irinotecan results translated into very similar overall survival across all four studies in this irinotecan refractory setting (Table 6). Importantly, the median survival

time obtained with cetuximab in combination with irinotecan in this and the other studies is in the upper range of results reported for irinotecan or oxaliplatin/5-fluorouracil (5-FU)/folinic acid in less heavily pre-treated patients^[20-24].

The current study demonstrates that cetuximab plus irinotecan is generally well tolerated in patients from the Asia-Pacific region. The most frequently reported grades 3 to 4 AEs were typical for irinotecan (e.g. diarrhea and neutropenia), or cetuximab (e.g. composite AE of acne-like rash). Cetuximab did not appear to increase the incidence or severity of irinotecan-associated AEs and *vice versa*. Diarrhea was the most common grade 3/4 AE reported in the current study (13.8%), in BOND (21%), MABEL (19%) and LABEL (20%) with neutropenia and rash also frequently observed in each of the studies^[7,14,15]. Severe infusion-related reactions occurred in 2.4% of patients in the present study, which is the same proportion as observed in the MABEL study^[14]. Interestingly, results from the MABEL study suggest that the incidence of severe infusion-related reactions may be minimized by prophylactic premedication with an antihistamine/corticosteroid combination^[25].

In the ELSIE study all-grade and grade 3/4 acne-like rash (composite AE category) were reported in 80.5% and 8.1% of patients respectively, which is comparable with that reported in other studies^[14,26]. An association between any early acne-like rash with prolonged overall survival was found. Saltz and colleagues described a correlation between the presence and severity of acne-like rash and survival; median survival in heavily pretreated mCRC patients experiencing no rash was 1.9 mo compared with 9.5 mo in patients experiencing any rash ($P = 0.02$)^[26]. A trend was also observed between the increasing severity of rash and prolonged survival^[26]. Comparable results between the presence and severity of acne-like rash with clinical outcome (PFS) have also been reported in the MABEL study^[14].

Randomized studies in the first-line treatment of mCRC patients^[27,28] and in heavily pretreated mCRC patients^[13], have recently demonstrated that the benefit conferred from cetuximab in combination with chemotherapy occurs mainly in patients whose tumors are wild-type for the *KRAS* gene. In a study of cetuximab plus irinotecan, 5-FU, and leucovorin as first-line treatment for mCRC, pa-

tients with *KRAS* wild-type tumors had a response rate of 59.3% compared with 36.2% in those with mutated *KRAS* tumors^[27]. These data led to revised guidance from regulatory and advisory authorities concerning the administration of cetuximab only to patients with *KRAS* wild-type mCRC. Thus *KRAS* mutation testing of tumors should be routine clinical practice when cetuximab is to be administered in this setting. At the time of the ELSIE study design this knowledge was not available and therefore material was not collected for tumor *KRAS* testing. This might suggest that the benefit observed from combining cetuximab with irinotecan in unselected patients with mCRC in the current study would be smaller than the effect in patients with *KRAS* wild-type tumors. The future tailoring of this cetuximab-containing regimen to selected patients is therefore likely to enhance the efficacy and cost-effectiveness of treatment in this patient population.

To conclude, the ELSIE study has demonstrated that the combination of cetuximab with irinotecan is well tolerated and active in mCRC patients from Asia and Australia. The efficacy and safety profiles of the combination are similar to those described in previous studies in European and Latin American patient populations. The use of cetuximab and irinotecan may be particularly beneficial in patients with wild-type *KRAS*, and further studies in this patient population are warranted.

ACKNOWLEDGMENTS

We thank Dr. Anja Loos for statistical support. This study was sponsored by Merck KGaA Darmstadt Germany, who also supplied the study drug cetuximab. Editorial assistance in the preparation of this manuscript was provided by Dr Paul Hoban, Cancer Communications and Consultancy Ltd., funded by Merck KGaA, Darmstadt, Germany.

COMMENTS

Background

The incidence and mortality rates for colorectal cancer (CRC) in Eastern and South-East Asia are increasing. Patients with metastatic CRC (mCRC) who progress following first-line therapy have few treatment options. This open-label, phase II study evaluated the efficacy and safety of cetuximab plus irinote-

can in irinotecan-refractory mCRC patients from South-East Asia and Australia.

Research frontiers

Research in the field of mCRC has recently focused on the development of targeted therapies in disease treatment. Epidermal growth factor receptor (EGFR) is frequently expressed in mCRC and is associated with tumor growth and metastasis. Cetuximab is an EGFR-targeted monoclonal antibody which binds EGFR inhibiting its activity. Registration of cetuximab was based on the pivotal BOND trial in which patients with mCRC progressing on an irinotecan-containing regimen achieved a higher overall survival rate when cetuximab was added to irinotecan compared with irinotecan alone. The subsequent Monoclonal Antibody Erbitux in a European Pre-License Study (MABEL) and Latin American Erbitux Pre-License Study (LABEL) studies confirmed the efficacy of this treatment combination in a community-based setting.

Innovations and breakthroughs

The safety and efficacy of cetuximab in combination with irinotecan in mCRC patients failing on irinotecan-containing regimens has been demonstrated in phase II studies. The ELSIE study supports these findings in patients from the Asia-Pacific region. Median overall survival was comparable with that reported in the LABEL and MABEL studies and the combination arm of the BOND study. There were slightly lower tumor response rates, median PFS and PFS rate at 12 wk in the ELSIE study. Patients were unselected in the ELSIE and the observed treatment benefit may be greater in patients selected for KRAS wild-type tumors.

Applications

The results of this study confirm the activity of cetuximab in combination with irinotecan in patients with mCRC from Asia and Australia. In the future cetuximab-containing regimens are likely to be tailored to selected patients in this setting with KRAS wild-type tumors.

Peer review

The paper on the whole is well written and the abstract reflects the basic design and findings.

Abstract

AIM: To identify the clinicopathological risk factors correlated with residual tumor in hepatocellular carcinoma (HCC) patients after resection.

METHODS: From January 2001 to April 2007, 766 HCC patients who had undergone resection were included in this research. Lipiodol angiography was performed within 2 mo after surgery and followed by post-Lipiodol computed tomography (CT) 4 wk later for all 766 patients to monitor tumor in the remnant liver. Tumor detected within the first 3-mo postoperative period was defined as residual tumor. Patients were divided into 2 groups: disease or disease-free within the first 3 mo after surgery. Risk factors for residual tumor were investigated among various clinicopathological variables.

RESULTS: A total of 63 (8.22%) patients were found to

have residual tumor after surgery. Three independent factors associated with residual tumor were identified by multivariate analysis: preoperative serum α -fetoprotein (AFP) level [odds ratio (OR) = 1.68 (95% confidence interval (CI): 1.20-2.36)], tumor size [OR = 1.73 (95% CI: 1.29-2.31)] and microvascular invasion [OR = 1.91 (95% CI: 1.12-3.24)].

CONCLUSION: Residual tumor is related to AFP level, tumor size and microvascular invasion. Patients at high risk should undergo closer follow-up and could be candidates for multimodality therapy.

Risk factors for residual tumor after resection of hepatocellular carcinoma. *World J Gastroenterol* 2011; 17(14): 1889-1894 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i14/1889.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i14.1889>

INTRODUCTION

Hepatocellular carcinoma (HCC) accounts for 80%-90% of primary liver cancer and is a global health problem^[1,2]. About 55% of all HCC incidences are identified in China^[1]. Surgical resection has a major role in the treatment for HCC and offers a chance of cure for patients^[3,4]. Although resection is complete, there is still a possibility of early recurrence which occurs mainly because of pre-existing microscopic tumor foci that are undetected by

imaging modalities before or during operation^[5]. Tumor detected soon after resection is thought to be related to the presence of residual tumor, and it is associated with a poor prognosis.

Determination of factors predicting residual tumor may allow for identification of patients who are more likely to have this problem after so-called radical resection. In view of Lipiodol angiography with its post-Lipiodol computed tomography (CT) being regarded as the most sensitive means to confirm the presence of tumor, we identify in this study the risk factors correlated with residual tumor in HCC patients who received Lipiodol angiography within 2 mo after resection followed up by CT scan 4 wk later. Knowledge of these risk factors could be useful for clinicians to assess patient prognosis and determine treatment strategies, for the purpose of improving the long-term outcome.

MATERIALS AND METHODS

Patients

From January 2001 to April 2007, pathologically confirmed HCC patients who underwent their first radical hepatic resection at the Liver Cancer Institute & Zhongshan Hospital of Fudan University were recruited for this study if they met the following entry criteria: (1) received no preoperative anticancer treatment; (2) age between 18-80 years; (3) liver function classified as Child Pugh Grade A or B; (4) recovered within 6 wk of the operation; and (5) general health satisfactory for toleration of the Lipiodol angiography within 2 mo after resection.

We defined radical resection in this study as: (1) complete removal of all tumor nodules and the cut surface being free of cancer by histological examination; (2) no cancerous thrombus found in the portal vein (main trunk or two major branches), hepatic veins, or bile duct by imaging and histological examination; (3) no demonstrable evidence of residual disease in the remnant on intraoperative ultrasonographic examination; (4) the number of tumor nodules not exceeding three^[6]; and (5) no extrahepatic metastasis found.

There were 766 patients who satisfied the selection criteria. This study was approved by the Research Ethics Committee of Zhongshan Hospital.

Lipiodol angiography

Lipiodol angiography was performed within 2 mo after resection in all these 766 patients. The hepatic artery supplying the liver remnant was selectively catheterized *via* the femoral artery under fluoroscopic guidance. An approximately 3 mL suspension of iodized oil was injected into the hepatic artery. A contrast CT scan of the liver was performed an average of 4 wk later. If there was early local lesion, it would be shown as dense foci of Lipiodol uptake, or as enhancing nodule not present in the preoperative CT.

Residual tumor and patient grouping

The injection of Lipiodol into the hepatic artery is effective for aiding in the diagnosis of tumor by post-Lipiodol

CT and it can detect the lesion in its earliest period. In this study, patients received Lipiodol angiography within 2 mo after resection, followed up by CT scan 4 wk later to monitor tumor in the remnant liver; so, if there was no demonstrable evidence of lesion within the first 3 mo after resection, the surgery could be regarded as a truly curative resection. Therefore, residual tumor was defined as tumor detected within the first 3-mo postoperative period. We divided the 766 patients into two groups: Group 1 = disease detected within 3 mo after surgery; Group 2 = no disease detected within 3 mo after surgery.

Follow-up and statistics

Follow-up cutoff date was April 2008. All surviving patients had a minimum follow-up of 12 mo, 16 patients were lost during follow-up. The median follow-up period of all 766 patients was 26 mo (range: 3-87 mo). Statistically significant differences between categorical variables were examined using the Chi-square or Fisher's exact test where appropriate. The logistic regression model was applied to evaluate the risk factors related to residual tumor. Diagnostic accuracy of predictive risk factors was evaluated using receiver operating characteristic (ROC) analysis. Survival analysis was studied by the Kaplan-Meier method with a log-rank test to detect the statistical difference. The statistical analysis was performed using Stata 7.0. *P* values < 0.05 were considered statistically significant.

RESULTS

Survival of patients with or without residual tumor

Tumor was detected in 314 (314/766, 40.99%) patients during the follow-up period. Of the 766 patients, 63 patients were found to have residual tumor (Group 1), whereas the other 703 patients showed no lesion detected within 3 mo after resection (Group 2). Respective cumulative survival rates at 1-, 2-, 3-, 4-, 5-years in Group 1 were 44.44%, 35.90%, 23.08%, 17.31% and 0.00% compared with 92.18%, 80.99%, 71.08%, 62.48% and 56.95% in Group 2 (*P* < 0.0001) (Figure 1).

Clinicopathologic characteristics of patients with or without residual tumor

The distribution of selected clinical and pathological characteristics between Group 1 and Group 2 is shown in Table 1. No significant differences were observed regarding sex, age, HBsAg-positive rate, cirrhotic nodules, liver function status, serum alanine aminotransferase (ALT) level, tumor number, cell differentiation grade and the percentage of incomplete/absent capsule. However, serum gamma-glutamyl transferase (GGT) level ($\chi^2 = 4.6062$, *P* = 0.032) and α -fetoprotein (AFP) level ($\chi^2 = 16.0745$, *P* < 0.0001) were statistically different between the two groups. The ratio of large tumor size in Group 1 was significantly higher than that in Group 2 ($\chi^2 = 23.3257$, *P* < 0.0001), and there was a significantly higher incidence of microvascular invasion ($\chi^2 = 9.7556$, *P* = 0.002) noted in Group 1 compared with that in Group 2. As for tumor staging, there was a significantly poorer degree of pTNM staging ($\chi^2 = 15.1735$, *P* = 0.001) in Group 1; BCLC clas-

¹ALT value (normal value, ≤ 75 IU/L), using 80 IU/L as cutoff, and GGT level > 60 IU/L (normal range, 11-50 IU/L) was used as the elevated level [7].

²Tumor size: Diameter of the largest nodule was used as tumor size when multiple.

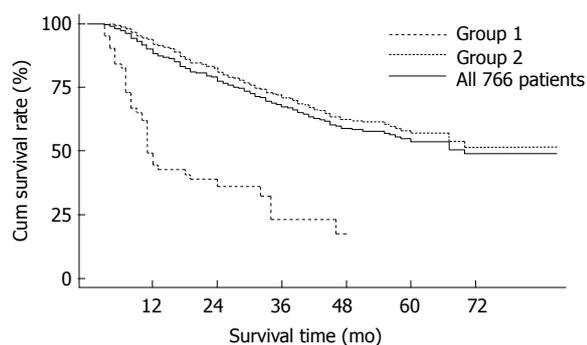

Figure 1 Survival curves for all 766 patients and for patients with (Group 1) or without (Group 2) residual tumor.

sification also showed a trend towards significance ($\chi^2 = 3.4501$, $P = 0.063$) between the two groups.

Predictive factors for residual tumor

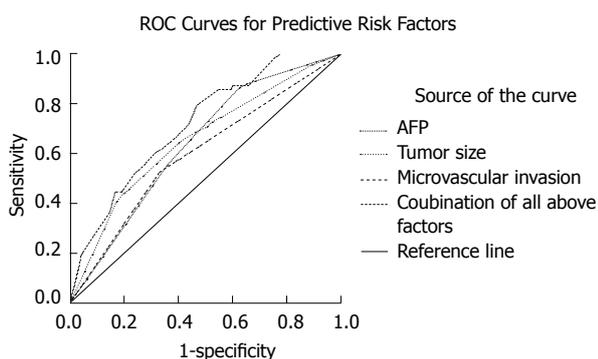

A multivariate stepwise logistic regression model was constructed to predict risk factors for residual tumor including

sex, age, HBsAg, cirrhosis nodules, Child-Pugh class, ALT, GGT and AFP levels, tumor size (diameter of the largest nodule was used as tumor size when multiple), tumor number, capsule, microvascular invasion, and cell differentiation grade. Only serum AFP level [odds ratio (OR) = 1.68 (95% confidence interval (CI): 1.20-2.36)], tumor size [OR = 1.73 (95% CI: 1.29-2.31)] and microvascular invasion [OR = 1.91 (95% CI: 1.12-3.24)] were revealed as independently predictive factors for residual tumor (Table 2).

Analysis of the prevalence of these three parameters among the entire population of 766 patients showed that the incidence of residual tumor was very low (nil, 0/24) when none of these three factors was present, and the simultaneous presence of the risk factors increased the probability of residual tumor: this rate increased to 28.15% (9/32) when AFP > 400 ng/mL, tumor size > 8 cm and the presence of microvascular invasion were present at the same time. ROC curves for the combination of these three risk factors showed an area under the curve (AUC) of 0.717 (95% CI: 0.657-0.778) to predict residual tumor. ROC curves for serum AFP level had an AUC of 0.640

Table 2 Multivariate stepwise logistic regression analysis of independent risk factors related to residual tumor

| Risk factor | Coefficient | OR (95% CI) | P-value |
|------------------------|--|--------------------------|---------|
| AFP level (ng/mL) | ≤ 20 = 0 20-400 = 1 > 400 = 2 | 0.52 1.68 (1.20-2.36) | < 0.01 |
| Tumor size (cm) | ≤ 2 = 0 2-5 = 1 5-8 = 2 > 8 = 3 | 0.55 1.73 (1.29-2.31) | < 0.01 |
| Microvascular invasion | No = 0 Yes = 1 | 0.65 1.91 (1.12-3.24) | 0.02 |

**Figure 2** Receiver operating characteristic curves for predictive factors (α -fetoprotein, Tumor size, Microvascular invasion and the combination of all above three factors) related to residual tumor. ROC: Receiver operating characteristic; AFP: α -fetoprotein.

(95% CI: 0.575-0.704), for tumor size had an AUC of 0.655 (95% CI: 0.582-0.728), and for microvascular invasion had an AUC of 0.598 (95% CI: 0.523-0.672). Significant difference was observed among these four curves ($P < 0.0001$) (Figure 2).

DISCUSSION

The distinction between recurrence after a radical resection and residual tumor after a palliative resection is crucial^[8]. Tumor detected soon after resection is thought to be related to the presence of residual tumor. Residual tumor cells in the remnant liver can acquire more malignant characteristics, and may accelerate tumor progression and induce intrahepatic metastasis due to the enhanced growth and increased neovascularization after surgery^[9]. The shorter is the disease-free interval time; the poorer is the prognosis^[10]. In this study, we showed that postoperative patients with residual tumor carried a significantly poorer prognosis than those who did not (Figure 1).

Complete surgical excision is an important factor for long-term outcome. However, it is difficult to remove all tumor cells in most patients^[11]. Even with so-called radical resection, there is still a possibility of residual tumor with a rate of up to 37.6%^[12]. The curative operation for HCC is difficult to define and the presence of residual tumor influences the evaluation of radical resection for

HCC. Determination of predictive factors for residual tumor can help the selection of patients suitable for more aggressive therapy to supplement surgery.

With regard to the definition of residual tumor, there is no consensus on this definition in the literature. Some authors have suggested the demonstration of intrahepatic disease found by imaging studies (ultrasonography, angiography, and post-Lipiodol CT) within one or two months after resection as residual tumor^[10]. In this study, positive finding by angiography followed by Lipiodol-CT within the first 3-mo postoperative period was defined as residual tumor. We then investigated the risk factors for residual tumor among various pathologic and clinical factors.

Results suggested that only high preoperative level of serum AFP, large tumor size and the presence of microvascular invasion were significantly associated with residual tumor at the univariate and multivariate analysis. When none of these three factors was present, the incidence of residual tumor was nil and increased up to 28.15% when AFP > 400 ng/mL, tumor size > 8 cm and the presence of microvascular invasion were present in the same patient. ROC analysis suggested that combination of these three factors was more sensitive to predict residual tumor than any single factor.

HCC is characterized by its propensity for vascular invasion. Numerous previous studies have demonstrated that the presence of microvascular invasion is the risk factor for early tumor occurrence after resection of HCC^[13-16]. In addition, tumor size, especially > 5 cm, also predicts a high risk of tumor recurrence after resection^[15,17,18]. Large tumor size is always correlated with increased invasiveness, as demonstrated by a higher incidence of intrahepatic metastasis and portal venous invasion^[13,15,17,19,20]. The larger the tumor is, the earlier the lesion occurs^[21].

As for preoperative serum AFP level, Hanazaki *et al*^[22] reported that AFP ≥ 1000 ng/mL was an independently significant factor for poor disease-free survival; Imamura *et al*^[23] identified serum AFP level > 32 ng/mL as a factor for early (< 2 years) recurrence; and Furihata *et al*^[24] also suggested that patients with AFP/volume > 20.0 were likely to experience recurrence within 6 mo after radical hepatectomy. Serum AFP level may represent a marker for either tumor bulk or aggressive tumor biology, such as tumor cell proliferation and spread^[25]. An HCC patient with a high serum AFP concentration (≥ 400 ng/mL) tends to have greater tumor size, bilobar involvement, massive or diffuse type of recurrence, portal vein thrombosis^[26,27]. All of these may be due to be the ability of AFP to elicit the escape of carcinoma cells from the host's lymphocyte immune surveillance^[28,29]. However, there are several studies which have shown no relation between serum AFP level and recurrence^[30,31]. In this present study, we support the concept of elevated serum AFP level as a candidate for early tumor occurrence^[7].

Here, our study showed tumor number was not a predictive factor for residual tumor. This might be because, in this study, we defined radical resection as the number of tumor nodules not exceeding three (since multiple tumors

may be the sign of intrahepatic metastasis^[16]). Accordingly, radical resection could be achieved as long as tumor number was no more than three.

High preoperative level of serum AFP, large tumor size or the presence of microvascular invasion may indicate an increased biological aggressiveness of tumor and a greater possibility of systemic diffusion. The simultaneous presence of these factors increases the risk of residual tumor, and patients presenting these three risk factors in association are prone to have residual tumor. This information is beneficial for better clinical decision-making and future trial design. Some aggressive therapies can be tested in selected patients, such as utilizing neoadjuvant or adjuvant therapy (including hepatic artery chemotherapy or chemoembolization, immunotherapy, targeted therapy and differentiation therapy, *etc.*) to supplement surgery for a better chance of a cure or at least a longer survival. Patients with high risk factors for residual tumor should be monitored very carefully for early detection, and the surveillance interval also needs to be shortened to have a chance to eradicate the residual tumor at its earlier period, because long-term survival after recurrence is still possible if appropriated therapy is adopted^[32].

One limitation in the present study is the low discriminative power of the identified predictive factors (with the specificity < 75%). In other words, even if patients have all these three risk factors, many are unlikely to have residual tumor after surgery. To resolve these issues, a more discriminatory method is required, such as molecular analysis. In addition, in our hospital, Lipiodol angiography is usually recommended to each postoperative patient for the purpose of early detection of residual tumor. A patient can receive this examination as long as his general condition allows. It may be that there is a bias in patient selection, but considering the large sample size in this study and the eligible patients presenting various clinicopathologic characteristics, this bias should be reduced. Certainly, further studies to confirm the present results are still needed.

In conclusion, this study showed that factors reflecting tumor behavior were correlated with residual tumor. High preoperative serum AFP level, large tumor size and the presence of microvascular invasion were independent predictors associated with an increased risk of residual tumor detected by angiography followed by Lipiodol-CT. This finding may have clinical implications in determining rational strategies in surveillance, prevention and management of postoperative residual tumor.

COMMENTS

Background

Even with so-called radical resection for hepatocellular carcinoma (HCC), there

is still a possibility of residual tumor. Determination of factors predicting residual tumor can help the selection of patients suitable for more aggressive therapy to supplement surgery. However, the definition of residual tumor and its prognostic factors have not been fully determined.

Research frontiers

Complete surgical excision offers a chance of cure to HCC patients, while recurrence is common and is the main cause of death. A large number of studies have investigated the prognostic risk factors for recurrence appearing at different times.

Innovations and breakthroughs

Lipiodol angiography followed by post-lipiodol computed tomography (CT) is the most sensitive means to confirm the presence of tumor. In this study, high preoperative serum α -fetoprotein (AFP) level, large tumor size and the presence of microvascular invasion were independent predictors associated with an increased risk of residual tumor detected by angiography followed by Lipiodol-CT. The simultaneous presence of these factors increases the risk of residual tumor.

Applications

Patients with high risk factors for residual tumor should be monitored very carefully for early detection, and the surveillance interval also needs to be shortened to have a chance to eradicate the residual tumor at its earlier period.

Terminology

Lipiodol angiography is an imaging technique for HCC using the injection of Lipiodol into the hepatic artery. Lipiodol-CT, which involves computed tomography after intrahepatic arterial injection of Lipiodol, is regarded as the most sensitive imaging modality for HCC.

Peer review

This is a large experience with HCC treated with resection, with careful follow-up using sensitive imaging studies. Recurrence within the first 3 mo was appropriately considered as residual tumor. The three independent factors associated with residual tumor were AFP level, tumor size, and microscopic invasion.

Abstract

AIM: To evaluate the biological and clinical characteristics of miR-622 in gastric cancer.

METHODS: We analyzed the expression of miR-622 in 57 pair matched gastric neoplastic and adjacent non-neoplastic tissues by quantitative real-time polymerase chain reaction. Functional analysis of miR-622 expression was assessed *in vitro* in gastric cancer cell lines with miR-622 precursor and inhibitor. The roles of miR-622 in tumorigenesis and tumor metastasis were analyzed using a stable miR-622 expression plasmid in nude mice. A luciferase reporter assay was used to assess the effect of miR-622 on inhibitor of growth family, member 1 (ING1) expression.

RESULTS: Expression of miR-622 was down-regulated in gastric cancer. MiR-622 was found involved in differentia-

tion and lymphatic metastasis in human gastric cancer. Ectopic expression of miR-622 promoted invasion, tumorigenesis and metastasis of gastric cancer cells both *in vitro* and *in vivo*. ING1 is a direct target of miR-622.

CONCLUSION: These findings help clarify the molecular mechanisms involved in gastric cancer metastasis and indicate that miR-622 modulation may be a bona fide treatment of gastric cancer.

Down-regulation of miR-622 in gastric cancer promotes cellular invasion and tumor metastasis by targeting *ING1* gene. *World J Gastroenterol* 2011; 17(14): 1895-1902 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i14/1895.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i14.1895>

INTRODUCTION

Gastric cancer is the fourth most common cancer and is the second most common cause of death from cancer in the world^[1-3]. For most solid malignancies, metastasis is the predominant cause of cancer death^[4-6]. Elucidation of the molecular mechanisms that regulate the sequential steps of metastasis formation is critical for the reduction of cancer mortality. The regulatory mechanism involved in the development of gastric cancer is not well understood; the discovery of critical carcinogenic pathways and the identification of new therapeutic targets for gastric cancer are crucial for local and global public health.

Recently, researchers discovered a novel class of short,

endogenous non-coding RNAs, called microRNAs (miRNAs) described in not only animals and plants, but also in humans as well^[7-9]. It is clear that miRNAs play pivotal roles in a wide array of biological processes, including cell proliferation, differentiation and apoptosis^[10,11]. MiRNAs regulate the expression of protein-coding genes by degrading target mRNAs or by inhibiting gene translation^[12]. Emerging evidence strongly suggests that abnormal miRNA expression is a common and important feature of human malignancies^[13,14], and some studies show that some miRNAs are associated with metastasis from gastric cancer^[15-18].

In this study, we investigated the biological effects and potential mechanisms of miR-622 in gastric carcinoma. We examined the expression of miR-622 in gastric cancer and found that miR-622 was associated with differentiation and lymphatic metastasis of human gastric cancer. Exogenous expression of miR-622 promotes invasion, tumorigenesis and metastasis formation both *in vitro* and *in vivo*. Using bioinformatics analysis, we identified inhibitor of growth family, member 1 (*ING1*) as a putative miR-622 target. Subsequent experiments confirmed that up-regulation of miR-622 repressed the expression of *ING1* at translational level.

MATERIALS AND METHODS

Cell lines and tissue samples

MKN-45, AGS, MKN-28, SGC-7901 and human embryonic kidney cell lines 293T (HEK 293T) were maintained in our central laboratory. Gastric cancer cell lines SNU-1 and NCI-N87 were obtained from American Type Culture Collection (Manassas, VA, USA). Cells were grown in RPMI-1640 or Dulbecco's modified Eagle's medium (DMEM; Sigma, St Louis, MO, USA) supplemented with 10% fetal bovine serum. Cultures were maintained at 37°C in a humidified atmosphere with 5% CO₂. Primary gastric tumor tissues and adjacent non-tumor gastric tissues were collected from either routine therapeutic surgery or gastrointestinal endoscopy at our department. All samples were obtained with informed consent from the patients and approval by the hospital institutional review board.

Analysis of miRNA expression using TaqMan real-time polymerase chain reaction

Total RNA from tissue samples and cell lines was isolated using the mirVana miRNA Isolation Kit (Ambion, USA). Expression of mature miRNAs was detected using the Taqman MicroRNA Assay (Applied Biosystems, Carlsbad, CA, USA) specific for hsa-miR-622. Briefly, 5 ng small RNA or total RNA was reversely transcribed using specific stem-loop RT primers. The reverse transcription products were then amplified and detected using PCR with specific primers and TaqMan probes. The PCR was run in a 7900 HT Fast Real-Time polymerase chain reaction (RT-PCR) System (Applied Biosystems) and SDS2.2.2 software (Applied Biosystems) was used for comparative ΔCt analysis. U6 snRNA (RNU6B, Applied Biosystems) was used as an endogenous control.

MiRNA target prediction

The miR-622 sequence was obtained from miRBase (<http://www.microrna.sanger.ac.uk>). Predicted miRNA targets were determined using the TargetScan^[19], PicTar^[20], and Miranda^[7] algorithms.

Construction of miR-622 expression plasmids

For miR-622 expression, human miR-622 precursor (622 bp) was cloned into pSilencer 4.1 (Ambion, Austin, TX, USA) using the following primers: Forward: 5'-ATCCCAGGGAGACAGAGATCGAGG-3', Reverse: 5'-AAGCTTGGTGGTGGACTTTTGGTTGT-3'. The plasmid was named pS-miR-622, and the control plasmid, consisting of a scrambled sequence (Ambion), was named pS-control. Transfected cells were selected with puromycin 48 h after transfection and then diluted for clonal selection. Mature miRNA expression in selected clones was assessed by RT-PCR as described above. All constructs were verified by sequencing. Stability-enhanced miR-622 precursor and negative control 1 ribo-oligonucleotides were obtained from Ambion. To inhibit miR-622 function, an Ambion miRNA inhibitor for miR-622 (AS-miR-622) was used, along with the negative control (AS-control).

Transfection

For transfection, a complex of Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA) and 200 nmol/L RNAs described above was prepared according to the manufacturer's instructions and directly mixed with cells in 24-well cell culture plates at a density of 4×10^4 cells per well. The level of miR-622 expression in transfected cell lines was assayed by real-time RT-PCR 72 h after transfection.

Invasion and scratch healing assays

Cell invasion assays were performed using insert membranes coated with diluted Matrigel (BD Biosciences, San Jose, CA, USA). Cells (1×10^5) were added to the upper chamber and cultured for 48 h. Finally, the insert membranes were cut and stained with Crystal violet (0.04% in water, 100 mL) and permeable cells were counted under an inverted microscope and photographed. For the scratch assay, cells were treated with 10 mg/mL mitomycin C (Sigma) for 3 h and then wounded with a pipette tip. Fresh, full medium was added, and wound healing was observed for 48 h. Photographs were taken every 6 h.

Tumorigenesis and metastasis assay in nude mice

Cells (1×10^6), transfected with pS-miR-622 or pS-control, were collected and inoculated subcutaneously into right flank regions of 4-wk-old male BALB/c nude mice (Institute of Zoology, Chinese Academy of Sciences, Shanghai). In another group, male nude mice were injected through the tail vein. Tumor nodules were measured every 4 d with a caliper. Mice were sacrificed at the end of one month and the number of metastatic tumors in the liver; tumor growth rate and rate of inhibition were calculated. Two independent experiments were performed for each experimental group.

Immunohistochemistry

Mouse tissues were fixed in 10% neutralized formalin and embedded in paraffin blocks. Sections were then prepared for immunohistochemical examination. After deparaffinization and rehydration, antigen retrieval was performed by boiling samples in 10 mmol/L citrate buffer (pH 6.0) for 10 min. After inhibition of endogenous peroxidase activity for 30 min with methanol containing 0.3% H₂O₂, sections were blocked with 2% bovine serum albumin in phosphate-buffered saline (PBS) for 30 min and then incubated with human anti-rabbit ING1 monoclonal antibody (Abcam, dilution 1:500). The immune complex was visualized using the Dako REAT[™] Envision[™] Detection System and Peroxidase/DAB (Dako) according to the manufacturer's instructions. Nuclei were counterstained with hematoxylin.

Western blotting

ING1 protein levels were quantified by standard Western blotting procedures, using the anti-rabbit ING1 monoclonal antibody (Abcam, dilution 1:500). Protein levels were normalized to the total glyceraldehyde-3-phosphate dehydrogenase (GAPDH) using a rabbit monoclonal anti-GAPDH antibody (Sigma).

Luciferase miRNA target reporter assay

Total cDNA from SGC-7901 cells was used to amplify the 3'-UTR of *ING1* by PCR, using the forward primer: 5'-TAGTCGAGTGGTTCCACTTCTCGTGC-3' and the reverse primer: 5'-TTACAGCTCACATACAGCAG-GAAG-3'. After digestion of the PCR product by *Spe* I and *Hind* III, the *ING1* 3'UTR was cloned into the *Spe* I and *Hind* III sites of pMir-Report (Ambion), yielding pMir-Report-ING1. Mutations were introduced at potential miR-622 binding sites using the QuikChange site-directed mutagenesis kit (Stratagene). HEK 293T cells were transfected with the pMir-Report vectors containing the 3'UTR variants, and 5 h after transfection, the cells were transfected again with 100 nmol/L of miR-622 precursor, miR-622-inhibitor or control plasmids. Five ng of the pRL-TK vector (Promega) harboring the Renilla luciferase gene was co-transfected as an internal control to determine the transfection efficiency. Cells were harvested 48 h after transfection and analyzed for luciferase activity using the Dual-Luciferase Reporter Assay System (Promega) and the GloMax[™] 20/20 detection system (E5331, Promega).

Statistical analysis

Statistical analysis was performed using SPSS 15.0 software (SPSS, USA). Data were expressed as the mean \pm SD from at least three separate experiments. Differences between groups were analyzed using Student's *t* test and the χ^2 test. *P* < 0.05 was considered statistically significant.

RESULTS

Relationship between miR-622 expression levels and clinicopathological factors in patients with gastric cancer

To determine whether miR-622 expression is associated

Table 1 Clinicopathological features and miR-622 expression in gastric cancer patients

| Factors | No. of patients | Mean expression of miR-622 | <i>P</i> value |
|--------------------------|-----------------|----------------------------|--------------------|
| Age (yr) | | | |
| < 65 | 42 | 4.84 \pm 3.78 | 0.973 ¹ |
| \geq 65 | 15 | 4.89 \pm 4.65 | |

with gastric cancer, we examined and compared miR-622 expression in primary gastric cancer tissues and in pair-matched adjacent non-tumor tissues using quantitative RT-PCR. A decrease of miR-622 expression was found in 70.18% of the 57 patients with gastric cancer with a median change by about 1.83-fold (*P* < 0.05, Figure 1). We then investigated the relationship between miR-622 expression levels and clinicopathological factors in the 57 patients. We found that the expression level of miR-622 was associated with the differentiation and lymphatic metastasis (*P* < 0.05, Table 1). As shown in Table 1, miR-622 expression levels were not associated with tumor size and distal metastasis, TNM stage or invasion.

Expression of miR-622 and ING1 in gastric cancer cell lines

We detected miR-622 and ING1 expression using qRT-PCR in six different gastric cancer cell lines (AGS, SNU-1, NCI-N87, SGC-7901, MKN-45 and MKN-28). Based on the miR-622 expression levels in these cell lines, we chose to further analyze SGC-7901 and NCI-N87 cells for miR-622 gain-of-function and loss-of-function studies, respectively

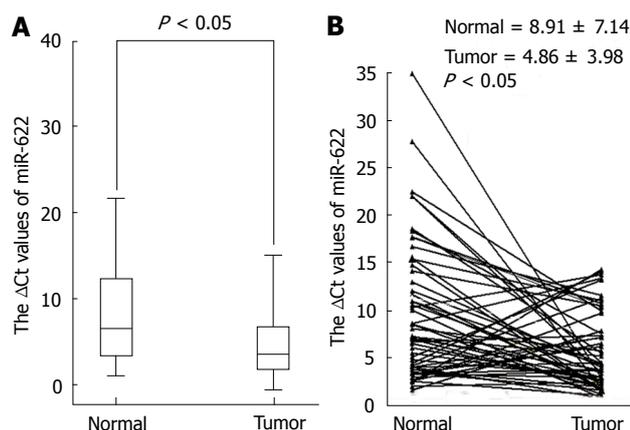

Figure 1 Expression of miR-622 was down-regulated in gastric cancer. A: Level of miR-622 expression in gastric cancer tissues ($n = 57$) was lower than that in non-tumor tissues ($n = 57$). B: The values (Δ Ct) are relative to those of U6 small RNA.

(Figure 2A). After transfection, we examined the expression of miR-622 in cancer cells by real-time PCR. The expression level of miR-622 was significantly up-regulated in SGC-7901 cells transfected with miR-622 precursor ($P < 0.01$, Figure 2B) and the expression level of miR-622 was significantly down-regulated in NCI-N87 cells transfected with miR-622 inhibitor, compared with the negative controls ($P < 0.01$, Figure 2B). We also analyzed the expression of *ING1* in the same gastric cancer cells. The expression of miR-622 was inversely correlated with the expression of *ING1* (Figure 2A).

Ectopic expression of miR-622 promotes invasion and migration of gastric cancer cells *in vitro*

We examined cell invasion and migration ability using the transwell invasion (Figure 2C) and scratch healing assays (Figure 2D). The number of invasive cells in the miR-622 precursor-transfected sample was significantly increased compared with the control (731.51 ± 3.16 vs 362.24 ± 5.18 , $P < 0.01$). MiR-622 precursor-transfected cells healed the wound 48 h after scratching, whereas control-transfected cells were unable to heal the wound. The mean wound distances of the experimental sample and the control 48 h after scratching were significantly different (11.23 ± 7.19 μ m vs 176.31 ± 7.24 μ m, $P < 0.01$). Conversely, miR-622 inhibitor-transfected cells showed inhibited invasion (127.31 ± 11.62 vs 329.18 ± 5.18 , $P < 0.05$) and migration ability (384.06 ± 9.35 μ m vs 176.31 ± 7.24 μ m, $P < 0.01$) compared with the control group (Figure 2C and D).

Ectopic expression of miR-622 promotes tumorigenesis and metastasis *in vivo*

We then tested whether ectopic expression of miR-622 could promote tumor growth *in vivo*. We constructed a miR-622 expression vector (pS-miR-622) and selected SGC-7901 cells stably transfected with pS-miR-622. Subsequently, pS-miR-622-transfected SGC-7901 cells and pS-control-transfected SGC-7901 cells were injected subcutaneously into nude mice, and tumor formation was monitored. After 30 d, the animals were euthanized,

and the tumor volume was measured. Tumor growth was significantly promoted in the mice injected with pS-miR-622-transfected SGC-7901 cells compared with pS-control-transfected SGC-7901 cells (Figure 3A and B). The average tumor volume of mice inoculated with pS-miR-622-transfected SGC-7901 cells at day 30 was 29.91 ± 2.13 cm^3 , which was significantly larger than that of mice inoculated with pS-control-transfected SGC-7901 cells (23.81 ± 1.95 cm^3 , $P < 0.05$, Figure 3A and B). Thus, miR-622 can promote tumorigenesis *in vivo*. We found that ectopic expression of miR-622 promoted migration and invasion of gastric cancer cells *in vitro*; therefore, we further tested whether ectopic expression of miR-622 could affect tumor metastasis *in vivo*. SGC-7901 cells stably transfected with pS-miR-622 or pS-control vector were injected into 4-wk-old male nude mice through the tail vein. One month after the injection, the mice were euthanized. The average number of hepatic metastatic nodes per mouse was much larger in mice injected with SGC-7901 cells stably transfected with pS-miR-622 vector than that in the control group (3 ± 0.68 vs 12.32 ± 0.21 , $P < 0.01$) (Figure 3C). In addition, immunohistochemical analysis confirmed that the *ING1* protein was down-regulated in pS-miR-622-transfected SGC-7901 cells compared with pS-control-transfected SGC-7901 cells (Figure 3D). Thus, these results indicate that miR-622 has the ability to promote metastasis of gastric cancer cells *in vivo*, which is consistent with the data obtained from the *in vitro* migration and invasion assays.

MiR-622 directly inhibits the expression of *ING1* through *ING1* 3'UTR

Bioinformatics analysis identified several candidate miR-622 target genes. As shown in Figure 4A, a target sequence for miR-622 was found in the 3'UTR of *ING1* at position 253-260 nt. To test whether the 3'UTR of *ING1* is a functional target of miR-622, we engineered a reporter plasmid containing the wild-type 3'UTR of *ING1* in the 3' position of the firefly luciferase reporter gene. In parallel, we engineered another reporter plasmid in which the conserved target sequence within nt253-260 was specifically mutated, a modification that was predicted to inhibit miR-622-nt253-260 interactions (Figure 4A). To investigate the influence of miR-622 on *ING1* expression, we searched for changes in *ING1* protein and mRNA levels in HEK 293T cells transfected with the miR-622 precursor or the miR-622 inhibitor or in control-transfected cells. As shown in Figure 4B, miR-622 precursor transfection led to a significant decrease in *ING1* protein levels ($P < 0.05$, Figure 4B). In contrast, miR-622 inhibitor transfection did not significantly alter *ING1* protein levels compared with control-transfected cells.

These findings suggest an interaction between miR-622 and *ING1* that we further investigated by luciferase assay analysis. To show a direct interaction between miR-622 and the 3'UTR of *ING1*, we cloned the 3'UTR region that is predicted to interact with miR-622 into a luciferase reporter vector. We then assessed luciferase activity by co-transfection the luciferase reporter vector bearing

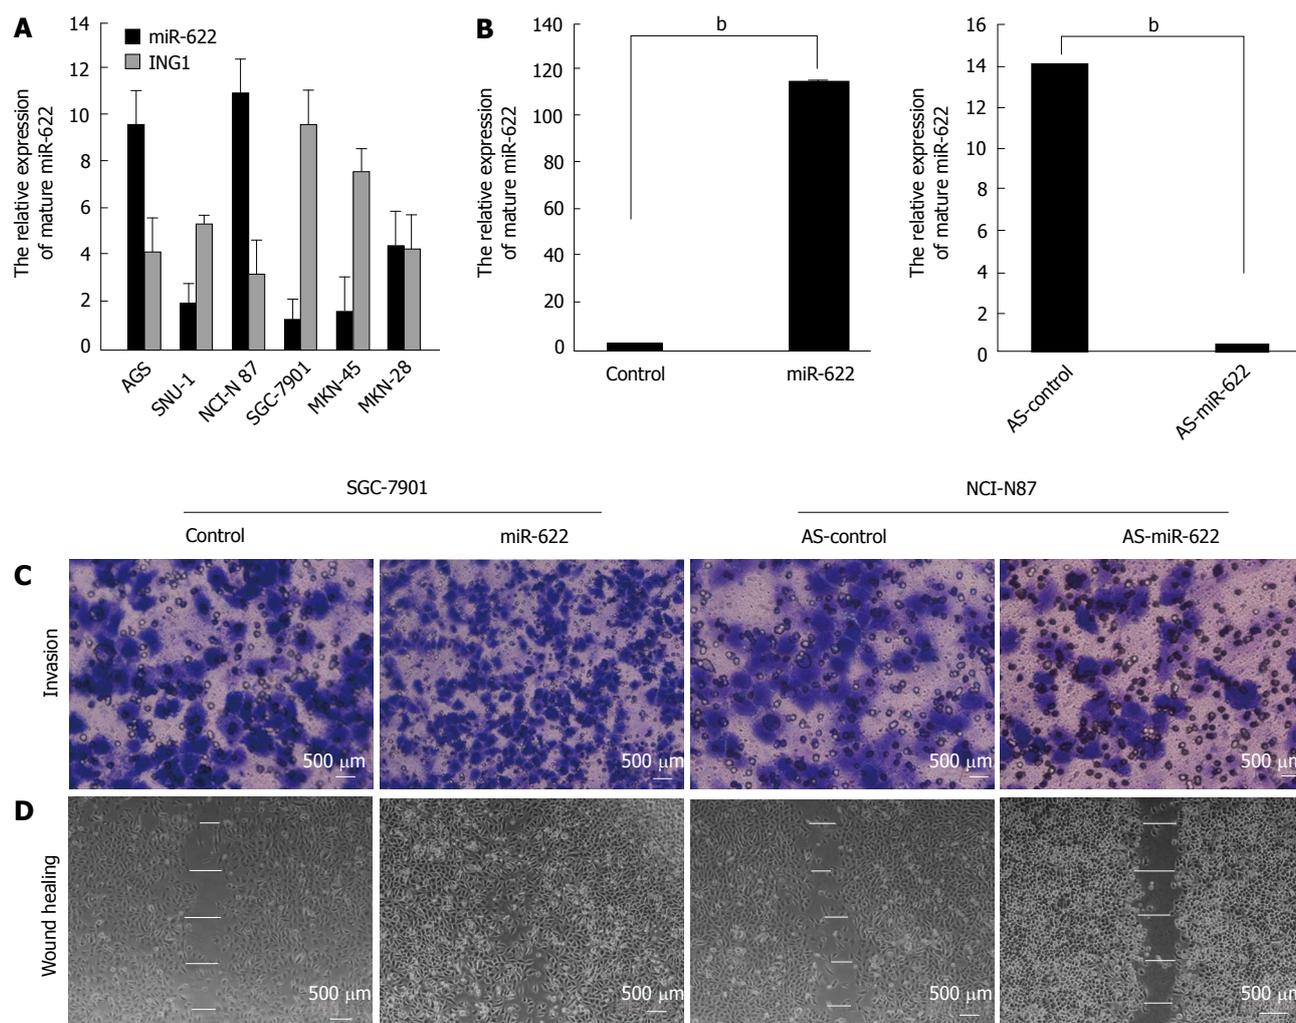

Figure 2 Restoration of miR-622 promotes gastric cancer cell invasion and migration. A: q-real time polymerase chain reaction for the expression of miR-622 and ING1 was performed using six gastric cancer cell lines. The lowest and highest levels of miR-622 expression among the six gastric cancer cell lines were found in SGC-7901 and NCI-N87 cells, respectively, and the expression of miR-622 was inversely correlated with the expression of ING1; B: Expression of miR-622 was restored or suppressed in gastric cancer cells after miR-622 precursor or miR-622 inhibitor transfection, compared with the controls ($P < 0.01$); C and D: Over-expression of miR-622 promotes increased cell invasion and migration compared with the miR-control transfectants. However, down-regulation of miR-622 inhibited cell invasion and migration compared with AS-control transfectants. ^b $P < 0.01$, compared with miR-control transfectants. Scale bars: 500 μm . AS-miR-622: An ambion miRNA inhibitor for miR-622.

the 3'UTR of *ING1* with the miR-622 precursor or the miR-622 inhibitor or with control plasmids. Luciferase activity was markedly diminished in the cells transfected with the miR-622 precursor and wild-type 3'UTR reporter plasmid, compared with the cells transfected with the miR-622 precursor and mutant 3'UTR reporter plasmids (Figure 4C, $P < 0.05$). Conversely, a significant increase in luciferase activity was observed after transfection with miR-622 inhibitor (Figure 4C). Taken together, these data imply that miR-622 may attenuate the expression of *ING1* by directly targeting the *ING1* 3'UTR.

DISCUSSION

Invasion and metastasis, two of the most important hallmarks of cancer, are the leading factors of malignant cancer that lead to lethality, especially for gastric cancer. The long-term survival of patients with gastric cancer after curative resection is confounded by a high recur-

rence rate, which is mainly due to the spread of lymphatic metastasis^[4,21]. Therefore, the identification of metastatic factors and an understanding of the underlying molecular pathways involved in the progression of metastasis are critical issues. Recent studies have shown that miRNAs play a fundamental role in the invasion and metastasis of gastric cancer^[15,16,18], thereby opening a novel avenue to investigate the molecular mechanism of gastric cancer progression and to develop potential therapeutics against gastric cancer.

Prior to this study, very little was known about miR-622 expression in gastric carcinoma and its correlation with the clinicopathologic features of these patients. To address these issues, miR-622 expression levels and the clinicopathologic characteristics of 57 patients with gastric cancer were examined. There was a significant association between miR-622 expression and differentiation as well as lymphatic metastasis. However, no relationship was found between miR-622 expression and gender, tumor size, differentiation grade, distant metastasis or TNM stage. Given

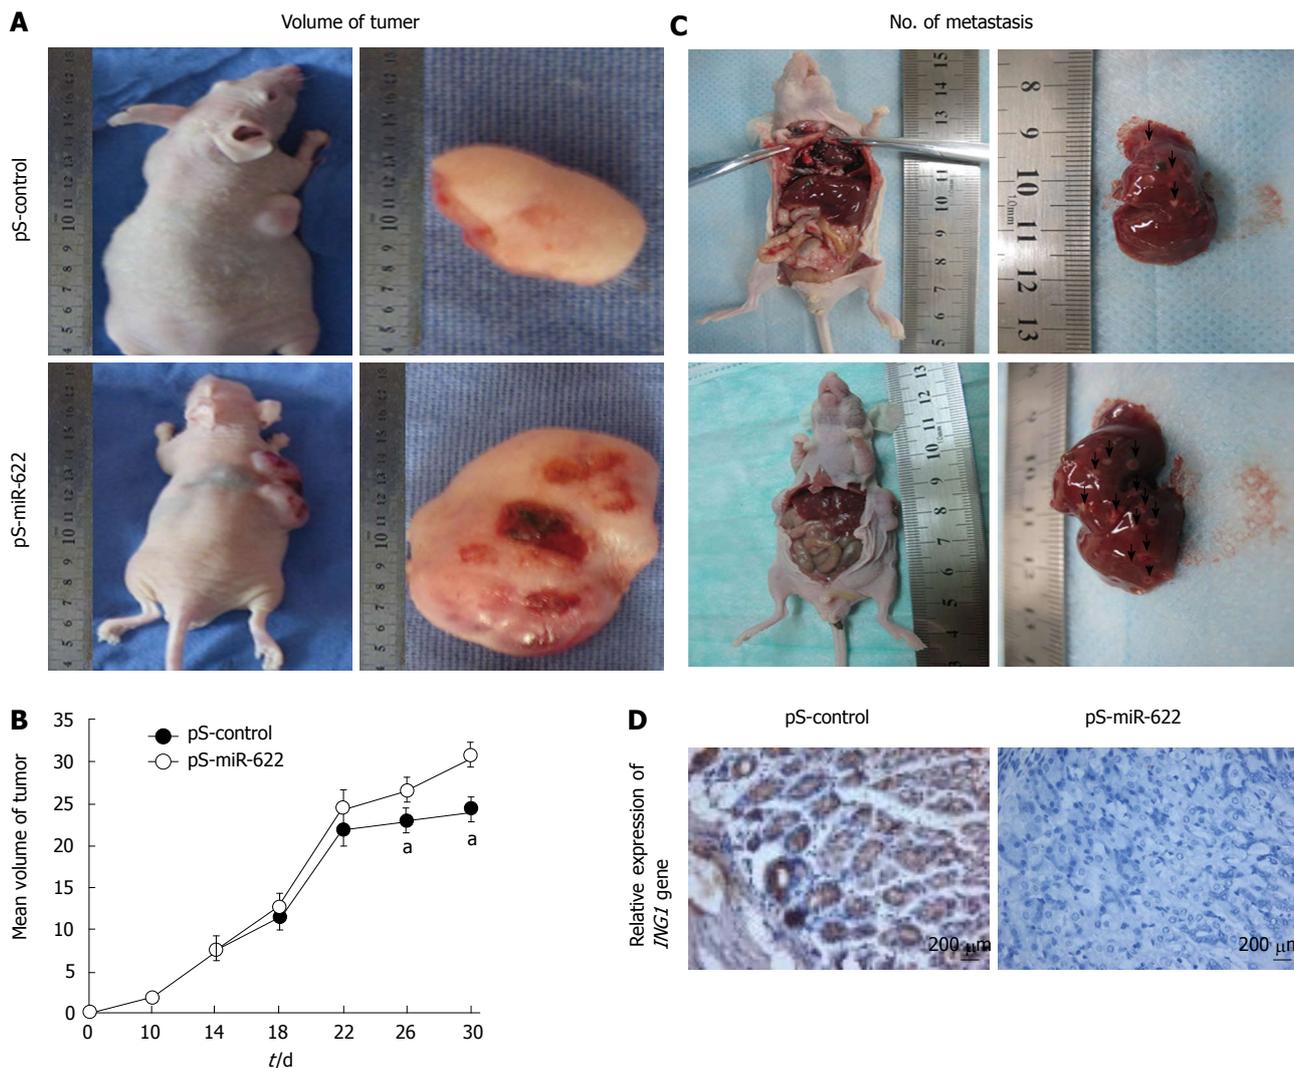

Figure 3 MiR-622 promotes tumorigenesis and metastasis *in vivo*. **A**: Photographs of tumors in nude mice resulting from injection of miR-622 expression vector (pS-miR-622) or control plasmid (pS-control) stably transfected SGC-7901 cells; **B**: Tumorigenesis curves. Rapid tumor growth was observed in the pS-miR-622 group (data expressed as mean ± SD; $P < 0.05$); **C**: Photographs of the number of liver metastatic nodes in nude mice injected with pS-miR-622 or pS-control vector stably transfected SGC-7901 cells. that the expression levels of miR-622 were significantly associated with lymphatic metastasis and differentiation, we speculated that up-regulation of miR-622 might promote the malignant phenotypes of gastric cancer cells. Therefore, we used miR-622 precursor and inhibitor constructs to perform miR-622 gain-of-function or loss of-function studies in human gastric cells. Invasion and migration ability assays revealed that miR-622 over-expression induced invasion and migration of gastric cancer cells *in vitro*. Conversely, miR-622 inhibitor can inhibit invasion and migration. These findings suggest that miR-622 functions as a key mediator of cell invasion and migration in gastric cancers. Cell migration plays an important role in many diverse biological processes^[22]. Aberrant activation of cell migration in neoplastic cells results in tumor metastasis, which is the principal event leading to death in the majority of cancer patients^[5].

We observed that miR-622 promotes cell invasion and migration ability in gastric cancers; however it was unclear

whether up-regulation of miR-622 also affects gastric cancer cell tumorigenesis and metastasis. Therefore, we constructed specific miR-622 plasmids and established permanent transfected cell lines to investigate the potential role of miR-622 in tumorigenesis and metastasis of gastric cancer. We showed, for the first time, that miR-622 over-expression significantly induced tumorigenesis and metastasis of gastric cancer cell lines in nude mice. Cellular tumorigenesis assays and metastasis assays both *in vitro* and *in vivo*, revealed that miR-622 over-expression resulted in the promotion of tumorigenesis and metastasis of SGC7901 cells. These findings lend evidence that miR-622 may indeed function as a key mediator of cell tumorigenesis and metastasis and that it will be a promising target for gastric cancer treatment.

The fundamental function of miRNAs is to regulate target genes by direct cleavage of the mRNA and/or by inhibition of protein synthesis, according to the degree of

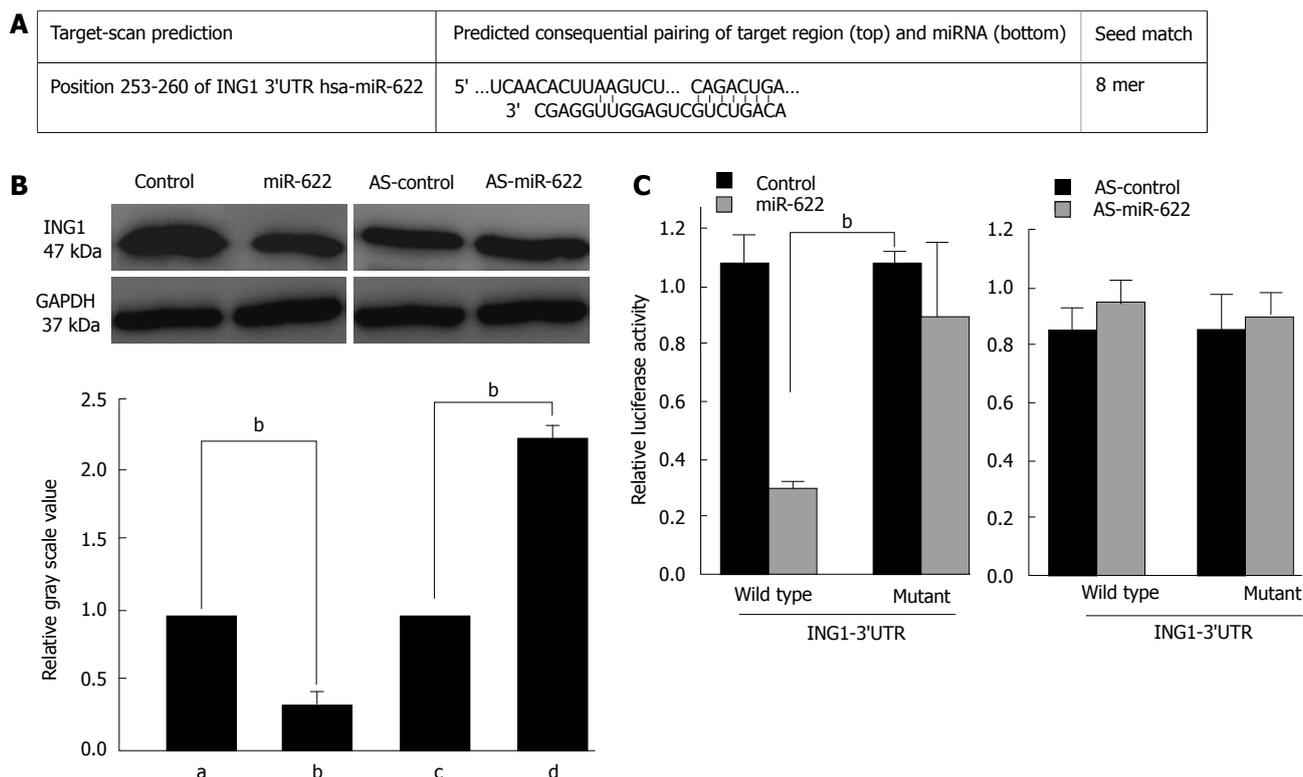

Figure 4 MiR-622 binds to the 3'UTR of Inhibitor of growth family, member 1 to post-transcriptionally repress the protein levels. A: Representative nucleotide sequence matches between possible target genes and miRNAs. Putative binding site of miR-622 in the *ING1* 3'UTR region (detected by TargetScan). Only matched nucleotides with miRNA seed sequences are indicated with vertical lines; B: Effects of miR-622 on *ING1* protein levels. HEK 293T cells were transfected with 100 nmol/L of miR-622 precursor or miR-622 inhibitor. Whole-cell lysates were prepared 72 h after transfection and subjected to immunoblot analysis using antibodies against *ING1* and glyceraldehyde-3-phosphate dehydrogenase (GAPDH). Relative gray scale values were compared with GAPDH; C: Luciferase reporter assay. A total of 1×10^5 HEK 293T cells were transfected with 100 ng wild-type-UTR-reporter or mutant-UTR-reporter constructs together with 100 nmol/L of miR-622 precursor or miR-622 inhibitor as indicated. $^*P < 0.01$. Each bar represents mean values \pm SE from three independent experiments. *ING1*: Inhibitor of growth family, member 1; AS-miR-622: An ambion miRNA inhibitor for miR-622.

complementarity with the target mRNA 3'UTR^[23]. Computational algorithms have been the major driving force in predicting miRNA targets, which are based mainly on base pairing of miRNAs and target gene 3'UTRs^[24]. To explore the molecular mechanism underlying miR-622 function, we searched for its direct target genes using bioinformatics analysis of miRNA-mRNA 3'UTR matching. Among the putative targets for miR-622, *ING1* was detected by the TargetScan program. This gene encodes a tumor suppressor protein that can induce cell growth arrest and apoptosis; the encoded protein is a nuclear protein that physically interacts with the tumor suppressor protein TP53 and is a component of the p53 signaling pathway^[25-28]. The bioinformatics analysis revealed that the conserved binding sites on *ING1* that can be recognized by miR-622 are located in the 3'UTR. To test this assumption, we investigated whether miR-622 affects *ING1* protein levels. We found that miR-622 leads to a significant decrease in *ING1* protein levels, suggesting that *ING1* is a functional target of miR-622. Lastly, results from our dual-luciferase reporter assays suggest that *ING1* is a functional downstream target of miR-622.

In summary, we have shown that expression levels of miR-622 in gastric cancer tissues correlates with the differentiation and lymphatic metastasis. Using gain-of-function

and loss-of-function studies, we demonstrated that up-regulation of miR-622 expression promotes gastric cancer cell invasion, tumorigenesis and metastasis both *in vitro* and *in vivo*. Therefore, miR-622 is likely to play an important role in tumorigenesis and metastasis of human gastric cancer and is a promising molecular target for gastric cancer therapy.

COMMENTS

Background

Gastric cancer is a worldwide cancer with poor prognosis. Identification of diagnostic biomarkers and effective therapeutic targets is important in the treatment and diagnosis of gastric cancer. Recently, researchers discovered a novel class of short, endogenous non-coding RNAs, called microRNAs (miRNAs), in plants, animals, and humans. It is clear that miRNAs play pivotal roles in a wide array of biological processes, including cell proliferation, differentiation and apoptosis.

Research frontiers

MiRNAs are 18-22 nucleotides, non-coding RNAs that regulate gene expression in a post-transcriptional manner. The fact that miRNAs are widely expressed in various species and tissues indicates that miRNAs may play an essential role in cell growth, differentiation, apoptosis as well as carcinogenesis. MiRNAs regu-

late the expression of protein-coding genes by degrading target mRNAs or by inhibiting gene translation. Emerging evidence strongly suggests that abnormal miRNA expression is a common and important feature of human gastric cancer.

Innovations and breakthroughs

The present study demonstrated that miR-622 is associated with differentiation and lymphatic metastasis in human gastric cancer. Exogenous expression of miR-622 promotes invasion, tumorigenesis and metastasis, both *in vitro* and *in vivo*. Using bioinformatics analysis, the authors identified the inhibitor of growth family, member 1 (*ING1*) as a putative miR-622 target. Subsequent experiments confirmed that up-regulation of miR-622 represses the expression of *ING1* at the translational level.

Applications

In this study, the expression of miR-622 was found down-regulated in gastric cancer. miR-622 was involved in differentiation and lymphatic metastasis in human gastric cancer. The ectopic expression of miR-622 promoted invasion, tumorigenesis and metastasis of gastric cancer cells both *in vitro* and *in vivo*. *ING1* was a direct target of miR-622. These findings help clarify the molecular mechanisms involved in gastric cancer metastasis and indicate that miR-622 modulation may be a *bona fide* treatment of gastric cancer.

Terminology

MiRNAs are 18-22 nucleotides, non-coding RNAs that regulate gene expression in a post-transcriptional manner. *ING1* is an inhibitor of growth family, member 1. This gene encodes a tumor suppressor protein that can induce cell growth arrest and apoptosis. The encoded protein is a nuclear protein that physically interacts with the tumor suppressor protein TP53 and is a component of the p53 signaling pathway.

Peer review

The authors evaluated the possible pathogenetic role of miR-622 in metastasis formation and invasiveness of gastric cancer using not only human samples and miRNA expression arrays, but also functional assays on cell lines and mouse animal model. The topic is of significant clinical importance and their results may be used in clinical research of gastric cancer, and it may give some evidences for new therapeutic strategies.

group, medium-dose salvianolate (24 mg/kg) treatment group, and high-dose salvianolate (48 mg/kg) treatment group, and treated for 2 wk. Another 10 healthy rats served as a normal control group. Mortality of cirrhotic rats in each group was evaluated after treatment with salvianolate. Serum samples were taken from portal vein for the detection of endotoxin. Morphological changes in tissue samples from the ileocecum were observed under a light microscope. Expression of TNF- α and IL-6 mRNA in the small intestine of rats was analyzed by real-time reverse-transcriptase polymerase chain reaction.

RESULTS: The mortality of cirrhotic rats in the non-treatment group was 37.5%. No cirrhotic rat died in the high-dose salvianolate treatment group. The serum endotoxin level was significantly higher in the non-treatment group than in the salvianolate treatment and normal control groups. The intestinal mucosal and villous atrophy, necrosis and shedding of the intestinal mucosal epithelium, observed in the non-treatment group, were reversed in different salvianolate treatment groups. The TNF- α and IL-6 mRNA expression levels in small intestine were significantly lower in different salvianolate treatment groups than in the non-treatment group.

CONCLUSION: Salvianolate can reduce the endotoxin level, ameliorate the injury of intestinal mucosa, and inhibit the expression of TNF- α and IL-6 mRNA in small intestine of cirrhotic rats.

Abstract

AIM: To study the effect of salvianolate on expression of tumor necrosis factor (TNF)- α and interleukin (IL)-6 mRNA in small intestine of cirrhotic rats.

METHODS: Cirrhosis in rats was induced using CCl₄ (0.3 mL/kg). Rats were randomly divided into non-treatment group, low-dose salvianolate (12 mg/kg) treatment

Yang DH, Ye ZY, Jin B, He XJ, Zhang Q, Zhou WM, Xu WJ, Lu HX. Salvianolate inhibits cytokine gene expression in small intestine of cirrhotic rats. *World J Gastroenterol* 2011; 17(14): 1903-1909 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i14/1903.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i14.1903>

INTRODUCTION

In liver cirrhosis patients, disruption of intestinal barrier function (IBF) and increased intestinal permeability lead to bacterial translocation (BT) and endotoxemia^[1-6], which increase susceptibility to infection, with spontaneous bacterial peritonitis (SBP) being the most frequent and severe^[1,4]. Endotoxemia, resulting from BT^[4], may provoke sustained activation of the immune system with release of proinflammatory cytokines, such as tumor necrosis factor (TNF)- α and interleukins (IL)-1, 6 and 8, and nitric oxide (NO), which in turn decrease IBF and increase severe complications^[7,8]. Intestinal cytokines play an important role in the pathogenesis of intestinal injury and inflammation^[9,10], especially TNF- α and IL-6, which may contribute to the systemic hemodynamic derangement of liver cirrhosis^[11] and lead to liver failure^[12]. Therefore, restoration of the intestinal barrier integrity and inhibition of the cytokine expression are the important goals in preventing intestinal endotoxemia. However, no effective remedy is available at present for the prevention and treatment of intestinal endotoxemia.

Radix Salviae Miltiorrhizae, a traditional Chinese medical herb known as “danshen”, has been widely used in treatment of various cardiovascular diseases^[13,14]. Its extracts contain lipid-soluble diterpene quinones (tanshinones) and water-soluble phenolic acid derivatives, such as salvianolic acids A and B as well as lithospermic acid B^[15]. Recent pharmacological studies showed that *Salviae Miltiorrhizae* (*S. miltiorrhiza*) can eliminate oxygen free radicals, enhance antioxidant activity, decrease serum levels of cytokines, and inhibit endotoxemia^[16]. It has been demonstrated that *S. miltiorrhiza* can block the lethal toxicity of lipopolysaccharide (LPS) in mice by suppressing TNF- α release^[17]. Salvianolate is a new water-soluble phenolic compound that is one of the most bioactive compounds in *S. miltiorrhiza* Bge. As far as we are know, no reports are available at present on the pharmacological activities of salvianolate in liver cirrhosis patients. TNF- α and IL-6 are the most frequent cytokines associated with liver dysfunction in cirrhosis patients^[18], and show an increased local production in mesenteric lymph nodes in response to BT induced by intestinal injury^[19].

The present study was designed to investigate the effect of salvianolate on endotoxin level in the portal vein and expression of TNF- α and IL-6 mRNA in small intestine of rats with CCl₄-induced liver cirrhosis. Whether different doses of salvianolate can enhance the intestinal mucosal barrier function and prevent intestinal endotoxemia is also

studied. The results of the present study provide a new strategy for the treatment of liver cirrhosis.

MATERIALS AND METHODS

Animals

Ninety male Sprague-Dawley rats weighing 180-220 g were provided by Department of Animal Care, Zhejiang Traditional University (Hangzhou, China). Experimental animals were housed in individual cages at 22-25°C in a 12-h light/dark cycle with free access to standard laboratory diet and tap water.

Experimental protocol

The rats were randomly divided into normal control group ($n = 10$) and model group. Rats in the model group received subcutaneous injection of 40% CCl₄ in a 2:3 mixture with olive oil (0.3 mL/kg), once a week for 12 wk. Liver cirrhosis was induced in 55 rats at the end of 12 wk, as shown by liver histological evaluation (Figure 1). The 55 rats in model group were further divided into non-treatment group (group B, $n = 14$), low-dose salvianolate (12 mg/kg) treatment group (group C, $n = 14$), medium-dose salvianolate (24 mg/kg) treatment group (group D, $n = 14$), and high-dose salvianolate (48 mg/kg) treatment group (group E, $n = 13$). Rats in group A were intraperitoneally (ip) injected with 5% glucose solution, once a week for 2 wk. Rats in groups C-E were ip injected with different doses of salvianolate dissolved in a 5% glucose solution, once a week for 2 wk. At the same time, 40% CCl₄ was continued for an experimental period of 14 wk. At the end of the 14-wk experimental period, all rats were anesthetized with 3% chloral hydrate and dissected. Blood samples were taken from the portal vein and intestinal tissue for further analysis.

Measurement of serum endotoxin level

Five milliliters of blood was taken from the portal vein and immediately put into a tube containing heparin. Plasma was taken after the blood was centrifuged at 3000 r/min for 1 min at 0°C. Endotoxin level in blood was measured by photometry, using a MB-80 microbiology kinetic rapid reader (Beijing, Gold Mountainriver Tech Development Co., Ltd, China).

Assessment of morphological changes in intestinal mucous membrane

At the end of the 14-wk experimental period, a horizontal incision was made along the mid-section to expose the abdominal cavities of all rats with their intestines excised. Ileal tissue samples were taken immediately and washed 3 times with cold physiological saline, fixed in a 10% formalin solution, dehydrated and embedded in paraffin. Each sample was cut into 4 μ m-thick sections which were stained with hematoxylin and eosin (H and E), and examined under a light microscope (Olympus BX50; Tokyo, Japan).

Isolation and analysis of mRNA expression by real-time reverse transcriptase polymerase chain reaction

Total RNA was isolated from snap-frozen ileal tissue samples using the Trizol method (Invitrogen, Carlsbad, CA, USA) and treated with RNase-free water. Single-stranded cDNA was synthesized from the total RNA as follows. In brief, 1 μg RNA was pre-incubated with 1 μL oligo (dT)₁₅ primer, and diethylpyrocarbonate (DEPC)-treated water was added to a total volume of 9.5 μL at 70°C for 10 min, and then rapidly chilled on ice. To the annealed primer/template, 4 μL 5 × RT (reverse transcriptase) buffer, 0.5 μL dNTP (10 mmol/L each), 25 U ribonuclease inhibitor (Takara, Dalian, China), 200 U Moloney murine leukaemia virus reverse transcriptase (Takara) and DEPC-treated water were added to a final volume of 20 μL. The reaction was incubated at 42°C for 1 h and terminated by placing it on ice after deactivation at 70°C for 10 min. The resultant cDNA was used as a template for subsequent polymerase chain reaction (PCR).

The PCR mixture contained 5 μL 10 × Taq buffer (Takara), 4 μL dNTP (10 mmol/L each), 2 μL gene-specific primers, 2.5 U Taq DNA polymerase (Takara) and 2 μL cDNA in a total volume of 50 μL. Thirty cycles of PCR amplification were performed with an initial incubation

Table 2 Mortality of rats in different groups

| Group | n | Mortality values |
|-------|----|-----------------------|
| A | 10 | 0 (0/10) ^a |
| B | 14 | 37.5% (6/14) |
| C | 14 | 21.42% (3/14) |
| D | 14 | 21.42% (3/14) |
| E | 13 | 0 (0/13) ^a |

^a*P* < 0.05 vs non treatment group. A: Normal control group; B: Non treatment group; C: Low-dose salvianolate treatment group; D: Medium-dose salvianolate treatment group; E: High-dose salvianolate treatment group.

at 94°C for 3 min and a final extension at 72°C for 7 min. Each cycle consisted of denaturation at 94°C for 30 s, annealing at 53°C for 30 s, and extension at 72°C for 30 s. The primer sequences used for PCR are shown in Table 1.

The quantities of cDNA that produced an equal amount of β-actin PCR product were used in PCR with the primers for IL-6 and TNF-α. Following reverse transcription polymerase chain reaction (RT-PCR), 5 μL samples of the amplified products was resolved by electrophoresis on 1% agarose gel and stained with ethidium bromide. The level of each PCR product was semi-quantitatively evaluated using a digital camera and an image analysis system (Vilber Lourmat, Marne La Vallée, France), and normalized to GAPDH.

DNA was amplified and detected by BioRad iCycler iQ PCR (BioRad Laboratories, California, USA) in a final volume of 20 μL, using SYBR green master mix reagent at a final concentration of 1 × (Applied Biosystems, Foster City, CA, USA). The PCR amplification conditions for DNA were 95°C for 3 min and 40 cycles at 95°C for 30 s at 55°C for 30 s, and at 72°C for 30 s. A melting curve analysis was carried out after amplification. The threshold cycle (Ct) values and baseline settings were determined by automatic analysis settings. Data were analyzed using the Opticon Monitor 3 software, which was supplied by The BioRad iCycler iQ PCR. Data about relative mRNA copies were expressed as relative quantification (RQ), which was calculated using the 2^{-ΔΔCt} method, where ΔΔCt = ΔCt (cirrhosis group) - ΔCt (normal group), ΔCt = (Ct_{sample} - Ct_{β-actin}).

Statistical analysis

Statistical analysis was performed with the SPSS version 13.0 (Chicago, IL, USA). Mortality of rats was compared using Fisher's exact test. Endotoxin level was analyzed using Kruskal-Wallis *H* test. Results of quantitative RT-PCR were assessed by ANOVA. Data were expressed as mean ± SD. *P* < 0.05 was considered statistically significant.

RESULTS

Mortality

At the end of 14-wk experimental period, 6 rats in group B, 3 rats in groups B and C, and no rats in groups A and E died. The mortality rate of rats was significantly higher in group B than in groups A and E (*P* < 0.05, Table 2).

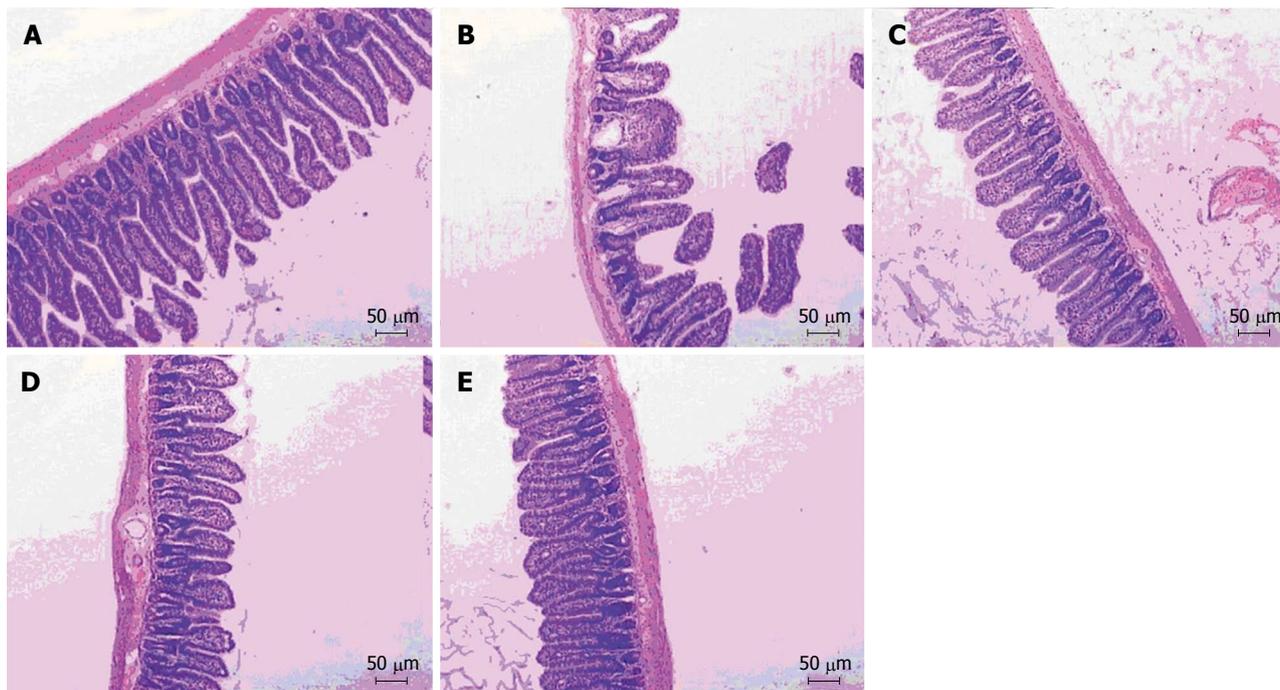

Figure 2 Mucosal morphology of ileal tissue in normal control group (A), non-treatment group (B), low-dose salvianolate treatment group (C), medium-dose salvianolate treatment group (D), and high-dose salvianolate treatment group (E) (HE staining, × 100).

Table 3 Distribution of endotoxin levels in serum of different groups

| Group | n | Dose (mg/kg) | Levels of endotoxin (pg/L) | | | | Mean rank |

^a*P* < 0.05, ^b*P* < 0.01 *vs* non treatment group. A: normal control group; B: non treatment group; C: low-dose salvianolate treatment group; D: medium-dose salvianolate treatment group; E: high-dose salvianolate treatment group.

Plasma endotoxin level

The plasma endotoxin level was < 20 pg/L in groups A and E, > 20 pg/L in 7 rats of group B, and significantly higher in the non-treatment group than in different salvianolate treatment groups and normal control group (*P* < 0.01). No marked difference was found in the plasma endotoxin level between the normal control and high-dose salvianolate treatment groups (Table 3).

Histological changes in ileal tissue

As shown in Figure 2, the intestinal mucosa in normal control group was intact and the villi were presented in an orderly fashion. No inflammatory cell infiltration occurred in the chorioepithelioma. In contrast, the intestinal mucosal villi in rats of the non-treatment group were atrophic, shorter and fractured. Some epithelial cells were necrotic. The mucous membrane showed signs of thinning. The intestinal

mucosa was infiltrated with inflammatory cells (Figure 2B) and repaired gradually in different salvianolate treatment groups. The intestinal mucosal villi in rats of different salvianolate treatment groups were in good order and the mucous membrane became thicker. Inflammatory cell infiltration was decreased, especially in the high-dose salvianolate treatment group (Figure 2A-E).

Expression of TNF-α and IL-6 mRNA in small intestine

The bands (300-500 bp) of RT-PCR amplification products were visualized by 1% agarose gel electrophoresis (Figure 3). Real-time RT-PCR showed that the IL-6 and TNF-α mRNA expression levels were significantly higher in the non-treatment group than in the highest salvianolate dose (3.82 ± 1.30 *vs* 1.71 ± 0.27, 6.13 ± 4.13 *vs* 1.57 ± 0.31) treatment group (*P* < 0.01, *P* < 0.05, Figure 4).

DISCUSSION

To the best of our knowledge, this is the first study to show that salvianolate can decrease the plasma level of endotoxin in the portal vein and restores intestinal mucosal injury in rats with CCl4-induced liver cirrhosis. During the development of cirrhosis, impaired intestinal mucosal barrier^[10,20] and decreased function of hepatocytes and Kupffer cells can lead to invasion of enteric organisms/endotoxin in blood and formation of bacteremia and intestinal endotoxemia^[21,22]. Endotoxin itself can destroy mitochondria and lysosomes in enteric epithelial cells, leading to cell autolysis. Bacteria and their products (e.g. LPS) can activate innate immune responses by triggering a complex gene program in intestinal epithelium^[23], which can increase secretion

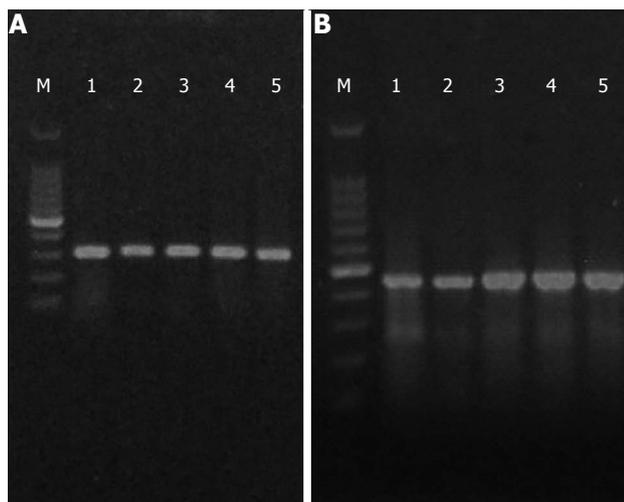

Figure 3 Electrophoretograms of tumor necrosis factor- α (A) and IL-6 (B). M: Marker; lane 1: Normal control group; lane 2: Untreated group; lane 3: Low-dose salvianolate-treated group; lane 4: Medium-dose salvianolate-treated group; lane 5: High-dose salvianolate-treated group.

of cytokines in the intestine and intestinal inflammatory disorders^[24,25]. Ultimately, a vicious cycle can arise between intestinal endotoxemia and increased permeability of enteric mucosa, and lead to liver injury and sepsis, resulting in a high mortality^[12,20]. In the present study, the plasma endotoxin level and mortality of cirrhotic rats were significantly higher in non-treatment group than in different salvianolate treatment groups.

In this study, the intestinal histopathological changes in cirrhotic rats were improved after treatment with salvianolate, indicating that salvianolate can protect intestine against villous atrophy, epithelial cell necrosis, and inflammatory cell infiltration. In parallel with these findings, endotoxemia was significantly reduced in rats after treatment with salvianolate, suggesting that salvianolate exerts its effect on the intestine by protecting the mucosal barrier integrity.

In this study, the altered IBF in rats with liver cirrhosis was found to be associated with the up-regulation of TNF- α and IL-6 mRNA expression levels in intestinal wall. It has shown that serum TNF- α and IL-6 expression levels are significantly increased in cirrhosis patients^[21]. TNF- α is a cytokine that is mainly released by mononuclear cells in response to inflammatory stimuli. The gut and its associated lymphoid tissue, including mesenteric lymph nodes (MLN), have been shown to produce TNF- α in response to BT induced by intestinal injury^[25,27]. More recently, increased TNF- α production by MLN with BT has been detected in cirrhotic rats^[19]. It was reported that local production of TNF- α in MLN is increased in patients with advanced liver cirrhosis, especially ascites^[19], which in common with experimental cirrhosis may also be induced by BT. It seems that enhanced TNF- α expression in gut of cirrhotic rats can result from increased intestinal leakiness, which allows penetration of bacteria and endotoxin into the gut wall. In return, TNF- α can affect the structure of intestinal mucosa, decrease the expression of

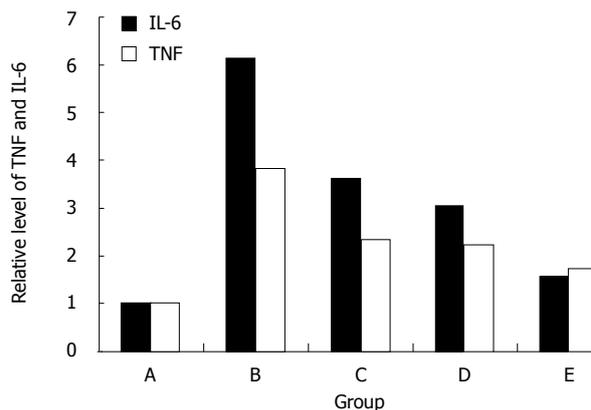

Figure 4 Real-time reverse transcription polymerase chain reaction for the expression of relative mRNA level of TNF and IL-6 in normal control group (A), non-treatment group (B), low-dose salvianolate treatment group (C), medium-dose salvianolate treatment group (D), and high-dose salvianolate treatment group (E). TNF: Tumor necrosis factor; IL: Interleukins.

tight junction (zona occludens 1), and change the morphology of colon in a mouse model of acute liver failure (ALF)^[28]. It may also participate in the pathophysiology of SBP complicating ALF. In this context, the reduced intestinal TNF- α levels observed in rats with cirrhosis after treatment with salvianolate might reflect the improvement of IBF. The increased production of TNF- α in intestine is a crucial event that leads to loss of IBF and BT, and anti-TNF- α therapy may prevent BT and SBP.

IL-6 is a pleiotropic cytokine which can regulate the biological responses of several target cells, including hepatocytes. Similarly, a link between IL-6 and liver fibrosis/cirrhosis has also been reported^[29,30]. Toda *et al*^[21] reported that IL-6 has a direct mitogenic effect on hepatic stellate cells. The activation status of intestinal immune system cells is much higher than that of analogous peripheral cells. Porowski *et al*^[31] reported that the intestine is an important source of IL-6 in patients with liver cirrhosis. Increased production of IL-6 is induced by LPS in intestinal injury^[32,33]. In the present study, the intestinal IL-6 levels were higher in the non-treatment group and lower in different salvianolate treatment groups, suggesting that salvianolate has a direct anti-inflammatory effect on the intestine, and can thus prevent IBF by inhibiting the expression of TNF- α and IL-6 mRNA.

In conclusion, salvianolate can reduce endotoxin level, restore intestinal mucosal injury, and inhibit expression of TNF- α and IL-6 in small intestine of cirrhotic rats. Clinical trials are needed to determine whether the aqueous extract from *Radix Salviae Miltiorrhizae* can favorably influence the natural history of liver cirrhosis, and reduce the risk of SBP and other septic complications in cirrhotic patients.

COMMENTS

Background

In liver cirrhosis, disruption of intestinal barrier function (IBF) leads to bacterial translocation and endotoxemia, which increase susceptibility to spontaneous

bacterial peritonitis. Intestinal cytokines play an important role in the pathogenesis of IBF disruption and intestinal endotoxemia. Inhibition of cytokine gene expression in small intestine is an important goal in enhancing IBF in cirrhotic patients.

Research frontiers

Currently, no effective remedy is available for the prevention and treatment of IBF disruption in liver cirrhosis patients. Recent studies have shown that soluble phenolic acid derivatives can eliminate oxygen free radicals, enhance antioxidant activity, decrease serum levels of cytokines, and inhibit endotoxemia. In the present study, the authors demonstrated that salvianolate, a new water-soluble phenolic compound, could enhance IBF in cirrhotic rats.

Innovations and breakthroughs

Recent studies have highlighted the anti-inflammatory effects of soluble phenolic acid derivatives in *Salvia miltiorrhiza* Bge. The present study is the first to investigate the pharmacological activities of salvianolate in liver cirrhosis, showing that salvianolate decreases the plasma endotoxin level in the portal vein and restores intestinal mucosal injury in cirrhotic rats. The authors demonstrated that salvianolate could protect small intestine of cirrhotic rats by inhibiting tumor necrosis factor (TNF)- α and interleukin (IL)-6 gene expression and enhancing the intestinal mucosal barrier function, thus preventing intestinal endotoxemia.

Applications

By demonstrating the effects of salvianolate on expression of TNF- α and IL-6 mRNA in small intestine of cirrhotic rats, this study provides a new strategy for the treatment of liver cirrhosis. Salvianolate can be applied in clinical practice due to its potential pharmacological activities.

Terminology

Radix Salviae Miltiorrhizae is a traditional Chinese medical herb known as "dan-shen". Salvianolate is a new water-soluble phenolic compound that is isolated from *Radix Salviae Miltiorrhizae* and one of the most bioactive compounds in *S. miltiorrhiza* Bge.

Peer review

The authors have illustrated the pharmacological activity of salvianolate using molecular biology techniques in an animal model of cirrhosis. The results of the study provide a new strategy for the treatment of liver cirrhosis. Further studies are needed to establish the mechanism of action of antifibrotic activity of salvianolate in cirrhotic rats.

Abstract

AIM: To identify and assess the novel makers for detection of Shiga toxin producing *Escherichia coli* (STEC) O157:H7 with an integrated computational and experimental approach.

METHODS: High-throughput NCBI blast (E-value cutoff e-5) was used to search homologous genes among all sequenced prokaryotic genomes of each gene encoded

in each of the three strains of STEC O157:H7 with complete genomes, aiming to find unique genes in O157:H7 as its potential markers. To ensure that the identified markers from the three strains of STEC O157:H7 can serve as general markers for all the STEC O157:H7 strains, a genomic barcode approach was used to select the markers to minimize the possibility of choosing a marker gene as part of a transposable element. Effectiveness of the markers predicted was then validated by running polymerase chain reaction (PCR) on 18 strains of O157:H7 with 5 additional genomes used as negative controls.

RESULTS: The blast search identified 20, 16 and 20 genes, respectively, in the three sequenced strains of STEC O157:H7, which had no homologs in any of the other prokaryotic genomes. Three genes, *wzy*, Z0372 and Z0344, common to the three gene lists, were selected based on the genomic barcode approach. PCR showed an identification accuracy of 100% on the 18 tested strains and the 5 controls.

CONCLUSION: The three identified novel markers, *wzy*, Z0372 and Z0344, are highly promising for the detection of STEC O157:H7, in complementary to the known markers.

INTRODUCTION

Shiga toxin producing *Escherichia coli* (STEC) O157:H7 is a food-borne pathogen that can cause both epidemic outbreaks and sporadic cases of diarrhea, hemorrhagic colitis, hemolytic-uremic syndrome and thrombotic thrombocytopenic purpura^[1]. In recent years, epidemic outbreaks of STEC O157:H7 occurred in the United States, Japan and other industrial countries as well as in developing nations, thus posing a serious threat to human health and economic developments^[2]. The effectiveness of current treatment remains frustratingly limited with major side effects, antibiotics-based treatment of patients with STEC O157:H7 infection increases the risk of hemolytic uremic syndrome, especially in children and seniors^[3]. The potential for large-scale outbreaks of STEC O157:H7 infection and the lack of effective treatment have inspired intensive researches on the early detection of O157:H7.

A number of methods have been developed for the detection of STEC O157:H7. Morphological analysis and serotype identification are time-consuming, laborious and not always reliable^[4]. A fast, highly sensitive and reliable technique, polymerase chain reaction (PCR) assay, has been employed to detect the specific target genes associated with STEC O157:H7^[5]. A number of virulence genes can be used in detecting STEC O157:H7, such as representative virulence gene (*eaeA*) and *stx*^[6]. However, these marker genes have unacceptably high false positive and negative rates^[7]. It is, therefore, urgently necessary to identify novel and more effective diagnostic markers for the detection of STEC O157:H7 with a high sensitivity and reliability.

One of the key reasons for the sub par performance of existing markers is that studies that identified the current markers have not fully taken the advantages of available genomic sequence data of STEC O157:H7 and hundreds of other prokaryotes with complete genomes. In this paper, we present an integrated study that combined large-scale genome sequence comparisons, sequence feature analysis and PCR-based experimental validation of marker identification, and report three marker genes based on our sequence feature analysis and experimental validation. These genes represent the promising complements to the known marker genes.

MATERIALS AND METHODS

Genome sequence data

Seven hundred and fifty completely sequenced prokaryote genomes, including 3 strains of STEC O157:H7, were downloaded from the NCBI Prokaryotic Genome Database (<ftp://ftp.ncbi.nih.gov/genomes/Bacteria/>) in January 2009.

Computational identification of candidate marker genes

NCBI blast was used to identify the candidate marker genes across any of the 750 prokaryotic genomes analyzed for each gene encoded by each of the 3 strains of STEC O157:H7 with complete genomes as previously

Table 1 Characteristics and genotypes of Shiga toxin producing *Escherichia coli* O157:H7 isolates

described^[8]. A gene of STEC O157:H7 was considered a potential marker gene if it did not have a blast hit with *E-value* < 10⁻⁵ and identity > 95%, which was identical in the 3 strains of STEC O157:H7.

Stability analysis of candidate marker genes

The following strategy was employed to predict the instability of a gene. A gene was considered stable in STEC O157:H7 if the flanking region (1500 bps on each side of the gene) had a higher sequence identity than 50% with the corresponding flanking region of its orthologous genes in the other two strains of STEC O157:H7. A stable gene should also have no transposons^[9,10] or phages^[11,12] in the flanking region. *rRNA* was closely associated with the pathogenicity islands^[13], thus genes within 3000 bps of *rRNA* genes on the safe side were excluded.

A genomic barcode scheme was developed for visualizing a genome, which demonstrated that genomic barcodes can effectively identify “abnormal” genes^[14]. A key step of the approach was to calculate the 4-mer frequencies of each 4-mer together with its reverse complement, representing these 4-mer frequencies as a vector of the number of combined 4-mer frequencies and their corresponding reverse complements, with 136 arranged in the alphabetical order. A key interesting observation was that the majority of fragments in a genome had highly similar 4-mer frequencies calculated throughout a genome. Sequence fragments with distinct 4-mer frequencies often indicate horizontal gene transfers. The distance between two vectors of 4-mer frequencies was expressed as the Euclidean distance between the two vectors.

Validation of predicted marker genes by PCR

Ten STEC O157:H7 isolates were obtained from the University of Maryland and 8 STEC O157:H7 isolates were obtained from the Center for Disease Control of China (Table 1). The isolates were cultured on

sorbitol-substituted MacConkey agar and serologically typed for O and H antigens. Shiga toxin genes (*stx1* and *stx2*) of all the isolates were detected by PCR as previously described^[15]. Five non-STEC O157 isolates were used as negative controls in PCR, namely *Escherichia coli* (*E. coli*) w3110, *E. coli* ATCC25922, *S. aureus* ATCC25923, *P. aeruginosa* ATCC27853, and *K. pneumonia* ATCC700603, which were obtained from Clinical Test Center of Ministry of Public Health, China.

PCR was carried out in a 50 µL reaction mixture containing 5 × Flexi buffer, 25 mmol/L MgCl₂, 10 mmol/L dNTP, Taq DNA polymerase (Promega, USA), 10 pmol of each primer (IDT, USA) and 3 µL bacterial lysates. PCR amplification conditions were optimized to obtain the optimal reaction parameters. The PCR amplification products were visualized by separation on a 2% agarose gel stained with ethidium bromide and by UV transillumination. The primer, annealing temperature and expected product size for each gene are listed in Table 2.

RESULTS

Candidate marker genes for Shiga toxin producing *E. coli* O157:H7

The three sequenced genomes of STEC O157:H7 were scanned with 20, 16 and 20 genes identified in STEC O157:H7 Sakai, STEC O157:H7 EDL933 and STEC O157:H7 EC4115, respectively (Table 3), and no whole-genome homology was observed in any of the 750 prokaryotic genomes as detected by blast with E-value < 5 and sequence identity > 95% presented in the 3 STEC O157:H7 genomes. Functional analyses, based on Pfam_Scan^[16] and Blast2GO^[17], indicated that most of these genes encoded the hypothetical proteins except for *wzy* (O antigen polymerase). These genes could potentially serve as markers for STEC O157:H7. Virulence marker genes, such as *eaeA*, *stx* and *nidA*, were not included in these genes, because most of them are part of (horizontally transferred) phages, plasmids and pathogenicity islands, with homologs in other prokaryotic genomes.

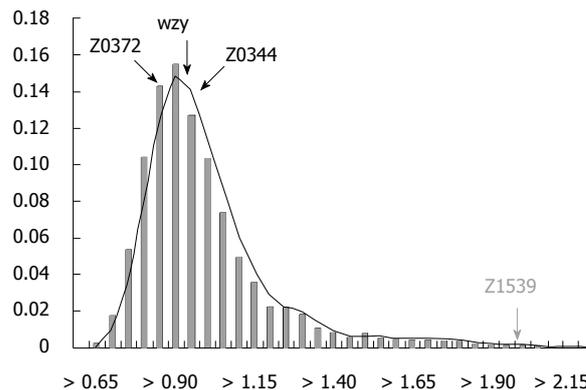

Figure 1 Distance distribution histogram for the barcode k-mer compositions of each gene compared with the average k-mer compositions of the whole genome. The x-axis is the k-mer genomic barcode distance, and the y-axis is the frequency. The bar indicates the frequency of different ranges of k-mer distance throughout the whole genome. The curve is the fitting curve to the histogram.

Assessment of instability of candidate marker genes

The instability of candidate marker genes was assessed if each predicted marker overlapped a known mobile genetic element. In addition, whether the flanking region (1500 bps on each side) of each gene is well conserved across the flanking regions of its orthologous genes in the other two strains of STEC O157:H7 was evaluated using sequence identity 50% as the cutoff, which showed that four genes, *wzy*, Z0372, Z0344 and Z1539 (Table 3), are probably not part of any mobile genetic elements.

Genomic barcode analysis

A conserved approach was taken by removing candidate marker genes with substantially different nucleotide compositions from the rest of the genome, measured with the genomic barcode. The distance distribution between the k-mer compositions of each gene in the genome and the average k-mer compositions of the whole genome is shown in Figure 1, which reveals that among the four candidate genes, Z1539 had a large k-mer composition-based distance to the average k-mer compositions of the genome, while the other three candidate genes had highly similar k-mer compositions to those of the whole genome, thus Z1539 was removed from our list of the candidate markers.

In preparation of our manuscript, the genome of a new strain of STEC (TW14359) was available with the 3 marker genes as we predicted here.

PCR validation

PCR was performed using the three predicted markers, *wzy*, Z0372, Z0344, and one STEC O157:H7 representative virulence gene (*eaeA*), on 18 STEC O157:H7 strains and 5 control organisms, including two non-O157 *E. coli* strains. The 18 STEC O157:H7 strains were detected using the three genes, with an accuracy of 100% compared to 77.8% using the existing marker *eaeA* (Figure 2). The virulence genes *stx1* and *stx2* were present in the 18 STEC

"Ident %" is the identity percentage of 3000-bp flanking regions among the three genomes. "+" and "-" in column "tRNA", "Tpase" and "phage" represent if the 3000-bp flanking regions contain any tRNA, transposase or phage. The gene names and their functions were retrieved from the NCBI Prokaryotic Genome Database, as described in materials and methods.

DISCUSSION

The accelerated production of microbial genome sequences provides a unique opportunity for the early diagnosis of pathogenic microbes based on comparative genomic studies. Due to the extremely complex and varied STEC genotype, the current diagnostic targets cannot meet the demand for rapid, accurate diagnosis of this pathogen. Furthermore, a number of multi-drug resistant bacteria

strains survive in the natural environment and pose a great threat to the human health, and the multi-drug resistance results from the horizontally transferable genes. So it is essential to identify these genes specific to a group of closely related pathogenic microbes, and the microbes should be early diagnosed by detecting these marker genes.

In the present study, such gene islands in STEC O157:H7 were identified with three completely sequenced strains of STEC O157:H7. Through a large-scale existence scanning of the genes in the three genomes, 20, 16 and 20 genes in the three strains were identified, respectively. Our previous study^[14] suggested that genes with barcodes significantly different to the host genomes are usually acquired,

and may easily excise the host genomes. These genes were removed from the further analysis in our study. Our computational pipeline reached 3 genes for each of the three strains. The wet laboratory PCR experiments confirmed their existence in 18 clinically retrieved STEC O157:H7 strains but not in 5 control pathogenic microbial samples. We believe that these three marker genes can complement the current detection technique of STEC O157:H7.

We are also working on the identification of marker genes for other human pathogenic microbes, especially for multi-drug resistant strains.

COMMENTS

Background

Shiga toxin producing *Escherichia coli* (STEC) O157:H7 is an important food-borne pathogen of human gastrointestinal diseases. The potential for large-scale outbreaks of STEC O157:H7 and the lack of effective treatments have inspired intensive researches on the early detection of this pathogen.

Research frontiers

Traditional morphological analysis and serotype identification for detecting STEC O157:H7 are time-consuming, laborious and not always reliable. Polymerase chain reaction (PCR) is a highly desirable method to detect specific target genes associated with O157:H7. However, existing marker genes have unacceptably high false-positive and negative rates. The advantages of available genomic sequence data of O157:H7 and hundreds of other prokaryotes with complete genomes will provide us a great opportunity to select diagnostic markers for rapid and reliable detection of STEC O157:H7.

Innovations and breakthroughs

To the best of the authors' knowledge, this is the first study to use bioinformatics approach for high-throughput screen of diagnostic markers for detection of pathogens. Furthermore, the authors combined computational biology and molecular biology to solve biological problems, which will provide us a new vision for the prevention of infectious diseases.

Applications

The authors identified and validated three novel and highly promising markers, *wzy*, Z0372 and Z0344, which may outperform the existing markers for rapid and reliable detection of STEC O157:H7 in food and patients.

Terminology

Genomic barcode is a computational technique, representing the *k-mer* nucleotide sequence frequency distributions across a whole genome as a 2-D image. In this paper, the authors used this technique to visualize the genome, showing that parts of the genome may have foreign origins.

Peer review

This manuscript is a well-planned, executed study. Although the work was not carried out in gastrointestinal tissue or cells, it is a good example of using bioinformatics approach for the prevention and management of intestinal diseases.

Abstract

AIM: To investigate the relation of reactive oxygen species (ROS) to hypoxia induced factor 1 α (HIF-1 α) in gastric ischemia.

METHODS: The animal model of gastric ischemia reperfusion was established by placing an elastic rubber band on the proximal part of the bilateral lower limb for ligation for 3 h and reperfusion for 0, 1, 3, 6, 12 or 24 h. Ischemic post-conditioning, three cycles of 30-s reperfusion and 30-s femoral aortic reocclusion were conducted before reperfusion. Histological and immunohistochemical methods were used to assess the gastric oxidative damage and the expression of HIF1- α in gastric ischemia. The malondialdehyde (MDA) content and superoxide dismutase (SOD), xanthine oxidase (XOD) and myeloperoxidase (MPO) activities were determined by colorimetric assays.

RESULTS: Ischemic post-conditioning can reduce

post-ischemic oxidative stress and the expression of HIF-1 α of gastric tissue resulting from limb ischemia reperfusion injury. MDA, SOD, XOD and MPO were regarded as indexes for mucosal injuries from ROS, and ROS was found to affect the expression of HIF-1 α under gastric ischemic conditions.

CONCLUSION: ROS affects HIF-1 α expression under gastric ischemic conditions induced by limb ischemia reperfusion injury. Therefore, ROS can regulate HIF-1 α expression in gastric ischemia.

INTRODUCTION

Recent studies have suggested that limb ischemia can induce ischemia reperfusion (IR) of remote organs (lung, liver, kidney and gastrointestinal tract), and limb ischemia reperfusion-induced gastric mucosal injury can cause the occurrence of stress ulcer. Although the incidence of acute postoperative gastric ulcers decreased after the introduction of H₂ receptor-blockers and HK-pump inhibitors, there are still some problems to be solved. Oxidative stress plays a very important role through the free radicals and or reactive oxygen species (ROS)^[1] in gastric ischemia reperfusion injury, and ROS production during reperfusion may

play a role in the pathogenesis of gastric mucosal injury induced by IR. Many studies demonstrated that besides the lesions induced by ischemia, the reperfusion causes additional cellular damage not only in the primary sites but also in remote structures^[2,3], such as gastric tissues.

The main factor involved in tissue lesions in the course of ischemia is hypoxia. It initiates intracellular signaling pathways, hence leading to the activation of the hypoxia-induced factor 1 (HIF-1)^[4]. HIF-1 is a critical regulator of the transcriptional response to low-oxygen (O₂) conditions (hypoxia/anoxia) in mammalian cells under both physiological and pathophysiological circumstances^[5]. Heterodimeric protein is composed of a constitutively expressed HIF-1 β subunit, and an O₂-regulated HIF-1 α subunit. Since the clinical data first indicated that HIF-1 α may play an important role in human cancer progression in the 1999^[6], significant knowledge has been accumulated and it has played a major role in gastric tumor and ischemia through activation of various genes that are linked to regulation of angiogenesis, cell survival, energy metabolism, and apoptotic and proliferative responses^[7-9].

The mechanism of ROS in HIF-1 α expression in ischemia could be solely related to H₂O₂ initial concentrations and production. Some studies have shown increased ROS expression in hypoxia, and increased HIF-1 α expression has been found to contribute to mitochondrial activity, and especially ROS formation during hypoxia^[10,11]. However, little is known about oxidative stress and the role of HIF-1 α in rat gastric injury after limb ischemia reperfusion injury (LI-RI). We aimed to investigate the oxidative stress and HIF-1 α protein expression in gastric ischemia induced by limb ischemia reperfusion, and to test if HIF-1 α is regulated by reactive oxygen species. We used rat hind limbs ischemia as the primary lesion and the gastric mucosa as the remote site in order to find out a potential etiologic factor of acute gastric ulcers.

MATERIALS AND METHODS

Animal and reagent

Male Wistar rats weighing 220-250 g were purchased from the Animal Experimental Center, Gansu College of Traditional Chinese Medicine (Lanzhou, China). All procedures were performed in accordance with the Declaration of Helsinki of the World Medical Association. The kits used to determine superoxide dismutase (SOD), malondialdehyde (MDA), xanthine oxidase (XOD) and myeloperoxidase (MPO) were obtained from Nanjing Jiancheng Bioengineering Institute (Nanjing, China), and rat HIF-1 α assay kits were purchased from Wuhan Boster Bioengineering Institute (Wuhan, China).

Model and grouping

Animals were divided into three groups randomly, and each group contained 36 rats. Group 1, (sham-operated, control), a rubber band was used without any constriction; group 2, (ischemia/reperfusion, I/R), gastric ischemia/reperfusion injury (GI-RI) was induced with bilateral lower

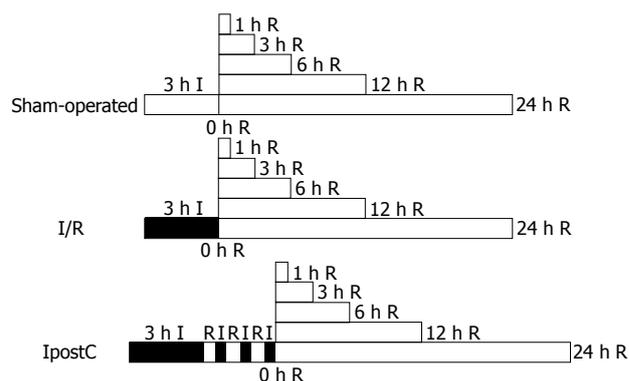

Figure 1 Experimental protocol. In the sham-operated group ($n = 36$) there was no intervention; ischemic/reperfusion (I/R, $n = 36$) was elicited by 3 h I followed by 0, 1, 3, 6, 12 or 24 h R; ischemic post-conditioning (IpostC) ($n = 36$) was performed by 3 circles of 30 s of R followed by 30 s of I before 0, 1, 3, 6, 12 or 24 h of R, respectively. R: reperfusion; I: ischemia.

limb ligated for 3 h by placing an elastic rubber band under a pressure of 290-310 mmHg on the proximal part of the lower limb^[12,13] and then released to allow reperfusion; and group 3, (ischemic post-conditioning, IpostC), at the start of reperfusion, three cycles of 30-s reperfusion and 30-s femoral aortic reocclusion^[14] were conducted before reperfusion as shown in Figure 1. Global ischemia in hind limb was verified by the absence of blood flow in femoral aorta and vein. Each group was housed in wire mesh cages at room temperature and in a 12/12 h day/night cycle. Prior to the experiment, all rats were fasted for 24 h and allowed access to tap water ad libitum. The animals were anesthetized by inhalation 2%-3% isoflurane^[15] and the anesthesia was only maintained in the course of the experimental operation. The three groups underwent 0, 1, 3, 6, 12 or 24 h reperfusion. Following reperfusion, blood samples from the inferior vena cava were collected, and six rats were humanely killed by venous bloodletting and the stomachs were immediately removed to collect tissue samples at each time point, respectively.

Measurement of malondialdehyde content and activity of superoxide dismutase, xanthine oxidase and myeloperoxidase

The stomach was homogenized in 0.9% saline solution using a homogenizer. The homogenate was then centrifuged at 2000-3000 rpm for 10 min at 4°C. The supernatant obtained was used to determine the MDA content and SOD, XOD and MPO activities according to the manufacturer's instructions. MDA content was determined spectrophotometrically at 532 nm by the thiobarbituric acid method, and was expressed in nmol/mg of protein. The protein concentrations were determined by Coomassie brilliant blue protein assay. SOD activity was evaluated spectrophotometrically at 550 nm by the xanthine oxidase method, and SOD activity was expressed in U/mg of protein. XOD was determined spectrophotometrically at 530 nm using a commercial XOD kit, and XOD activity was expressed in U/g of protein.

MPO activity was determined spectrophotometrically at 460 nm by the O-dianisidine method, and MPO activity was expressed as U/g of wet tissue. Each measurement was performed in triplicate.

Measurement of gastric mucosal injury

The murine stomach was incised along the lesser gastric curvature and fixed in 10% phosphate-buffered formalin, paraffin-embedded and sectioned at 4 μ m in thickness. After deparaffinization and gradual hydration, they were examined using hematoxylineosin staining. Based on a cumulative-length scale where an individual lesion was limited to the mucosal epithelium (including pinpoint erosions, ulcers, and hemorrhagic spots), the index was scored according to its length: 1, \leq 1 mm; 2, $>$ 1 mm and \leq 2 mm; and 3, $>$ 2mm and \leq 3 mm. For lesions $>$ 1 mm in width, the score was doubled. The sum total of the scores of all lesions represented the gastric mucosal injury index as outlined by Zhang *et al.*^[6]. To avoid bias, the index was determined by a researcher who was blind to the treatment.

Histological examination

The stomach fixed in 10% phosphate-buffered formalin was paraffin-embedded and sectioned 4 μ m thick. After deparaffinization and gradual hydration, it was examined using hematoxylin-eosin staining. Morphologic assessment was performed by an experienced pathologist who was unaware of the treatment under a light microscope.

Immunohistochemical staining of HIF-1 α

The best tissue section for immunohistochemistry was selected and the corresponding formalin-fixed, paraffin-embedded resection specimens were obtained. Immunohistochemical detection of HIF-1 α was performed using the image pro-plus 6.0 analysis system (Media Cybernetics Co., America) based on a StreptAvidin-Biotin Complex formation. Sections 4 mm in thickness were deparaffinized and the antigen was retrieved by microwaving in 10 mmol/L citrate buffer (pH 6.0) for 20 min followed by blocking steps according to the manufacturer's protocol. Mouse monoclonal antibody (Wuhan Boster Co., China), diluted at 150-200, was applied and the slides were incubated overnight at 41 °C. The biotinylated goat anti-rat secondary antibody (Wuhan Boster Co., China), was applied using additional blocking precautions to minimize the amplification of nonspecific background. The antibody was visualized using diaminobenzidine and the sections were counterstained with haematoxylin, dehydrated and mounted. Substitution of the primary immunoadsorption with immunizing peptide served as negative control. Batch-to-batch variation was assessed by choosing two sections showing high and low HIF-1 α expressions and running additional sections from these biopsies in each batch.

Assessment of HIF-1 α staining in tissue sections

The extent of hypoxia gastric tissue staining was quantified on 24-h specimens. Digital images of the gastric tissue

overlying 3 regions of the lesser gastric curvature (mucosae, muscularis mucosae and glands) were obtained using a microscope at \times 20 magnification. The total thickness of the gastric tissue and positive staining cells were measured using Image Pro Software. In each field, 5 measurements were obtained and averaged. The HIF-1 α protein level was expressed as the sum of the integrated optical density (SUMIOD) value in different groups. HIF-1 α was also assessed by an experienced pathologist who was unaware of the treatment.

Statistical analysis

Data were entered into a database and analyzed using SPSS software (SPSS, Chicago, IL, USA) and were expressed as mean \pm SD. Data were analyzed by Repeated Measures Analysis, and the means of all groups were compared using the least significant difference (LSD) test for multiple comparisons. $P < 0.05$ was considered as significant difference.

RESULTS

Gastric oxidative stress and lipid peroxidation after gastric I/R injury

Significant elevation in MDA content and decrease in SOD activity were observed in the gastric tissue of I/R group when compared with the sham-operated group. Treatment with IpostC prevented marked elevation in MDA content and decrease in SOD activities (Figure 2A and B). XOD and MPO activities were also much higher than in the sham-operated group, whereas administration of IpostC reversed this change (Figure 2C and D).

Effects of ischemic postconditioning on pathological changes of gastric mucosa

Gastric IR resulted in significant injury as evidenced by gastric mucosal edema, gastric epithelial hemorrhage, hyperemia and erosion, and was infiltrated with inflammatory cells between the muscularis mucosa and the glands. In contrast, IpostC treatment ameliorated severe gastric damages (Figure 3A-C). According to the Yong-Mei Zhang scores, 3 h gastric ischemia followed by 6 h reperfusion resulted in severe acute gastric lesions. Quantitative analysis showed dramatically increased scores in the I/R group compared with the sham-operated group and decreased scores in the IpostC group compared with the I/R group (Figure 3D).

Expression of HIF-1 α in gastric tissue

Photomicrographs of HIF-1 α staining in the gastric tissues of all groups are shown in Figure 4A-C. The thickness of gastric specimens containing HIF-1 α -positive gastric cells was determined at a 6-h time point. HIF-1 α was seen in the glandular epithelial cytoplasm and the vascular endothelial cytoplasm or nucleus of normal gastric tissues, but expression increased in density and intensity with progression to GI-RI (Figure 4D). Compared with group I/R, HIF-1 α expression level was decreased signifi-

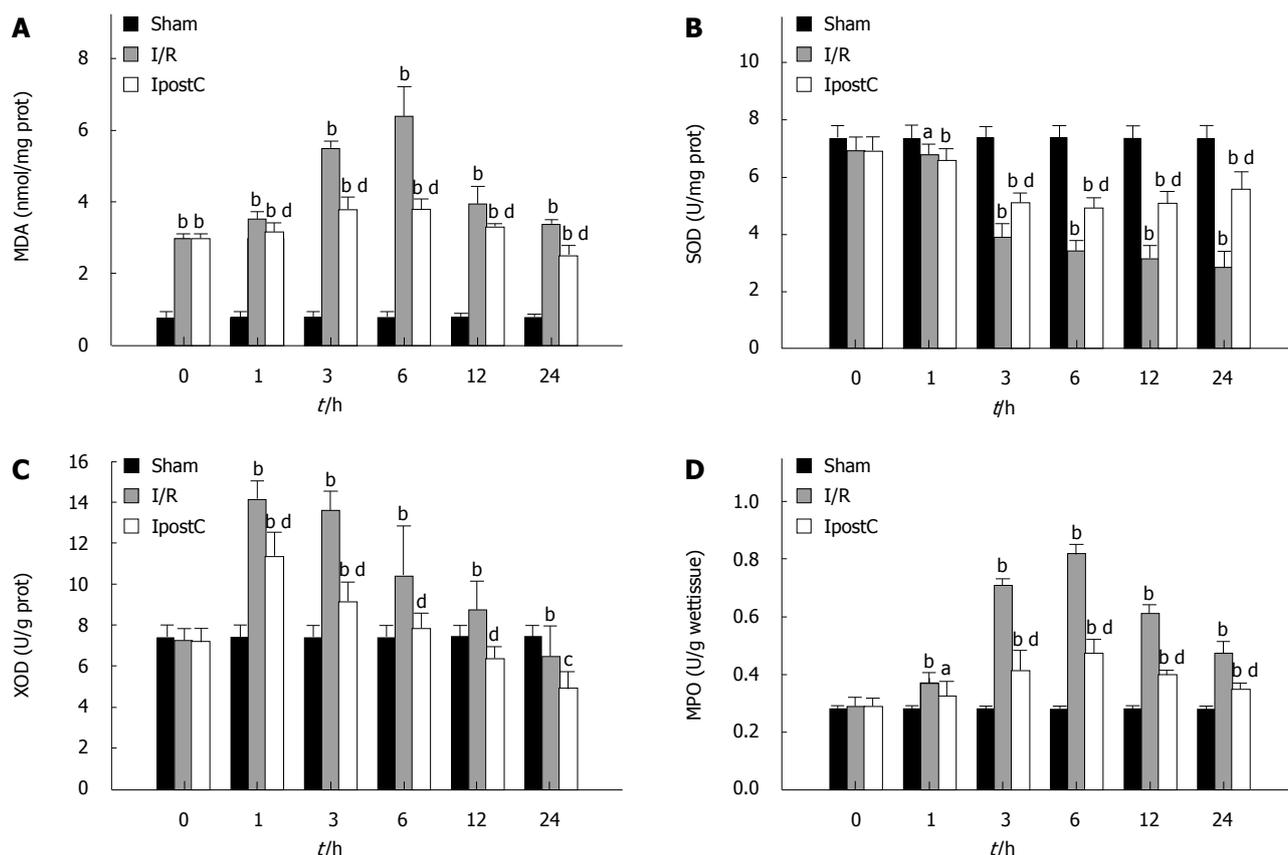

Figure 2 Gastric oxidative stress and lipid peroxidation after gastric ischemia/reperfusion injury of 3 h of ischemia and 24 h of reperfusion (mean \pm SE, $n = 36$). A: The level of malondialdehyde (MDA); B: The activity of superoxide dismutase (SOD); C: The activity of xanthine oxidase (XOD); D: The activity of myeloperoxidase (MPO). The activity of SOD decreased with the activities of XOD, MPO and the level of MDA increased in the ischemia/reperfusion (I/R) group compared with those of the sham-operated group at 1, 3, 6, 12, and 24 h. However, ischemic post-conditioning (IpostC) treatment significantly increased the activity of SOD, and decreased the activities of XOD, MPO and the level of MDA at each time. ^a $P < 0.05$, ^b $P < 0.01$ vs sham group; ^c $P < 0.05$, ^d $P < 0.01$ vs I/R group.

cantly in the glandular epithelial cytoplasm, and the vascular endothelial cytoplasm and nucleus of gastric tissues of the IpostC group (Figure 4D).

Changes of malondialdehyde content, superoxide dismutase, xanthine oxidase and myeloperoxidase activities and expression of HIF-1 α in gastric tissue

Changes of MDA content, SOD, XOD and MPO activities and expression of HIF-1 α are shown in Figures 2 and 4. MDA content, XOD and MPO activities increased, and SOD activity decreased. Consequently, the expression of HIF-1 α significantly increased in the I/R group; and when MDA content, XOD and MPO activities decreased and SOD activity increased, the expression of HIF-1 α was also decreased in the IpostC group.

DISCUSSION

The ischemia of lower extremities is one of the most common clinical problem. The ischemia reperfusion injury (IRI) of extensive muscle tissue mass and the sensitive vascular tissues and endothelium often leads to systemic complications with distant organ damage (e.g. lung, liver, gastrointestinal mucosa and kidney), and even systemic inflammatory response syndrome (SIRS) and multiple or-

gan dysfunction syndrome (MODS)^[17,18]. Therefore, limb ischemia can result in IRI of the gastric mucosa, which is an important clinical condition with undesirable outcomes concerning patients' morbidity and mortality. In recent years, studies on GI-RI have revealed that reactive oxygen species (ROS), microvascular dysfunction, polymorphonuclear leukocyte (PMN) infiltration and gastric acid secretion during reperfusion may play a role in the pathogenesis of gastric mucosal injury induced by IR. Additionally, oxidative stress, due to free radicals and/or ROS, is known to cause organ injury and plays an important role during ischemia reperfusion injury in the gastrointestinal tract^[1]. HIF-1 α is a nuclear transcription factor and is critical for initiating cellular response to hypoxia. Many studies demonstrated that there was a very close relationship between the expression of HIF-1 α and the formation of ROS in cancer and ischemia^[19]. This is the first study to investigate the relationship between the formation of ROS and the expression of HIF-1 α of gastric tissue following GI-RI. In this study, we investigated the oxidative stress and HIF-1 α expression of gastric tissue resulting from LI-RI, and found that IpostC can reduce post-ischemic oxidative stress and HIF-1 α expression of gastric tissue, and that ROS can modulate HIF-1 α expression under gastric ischemic condition.

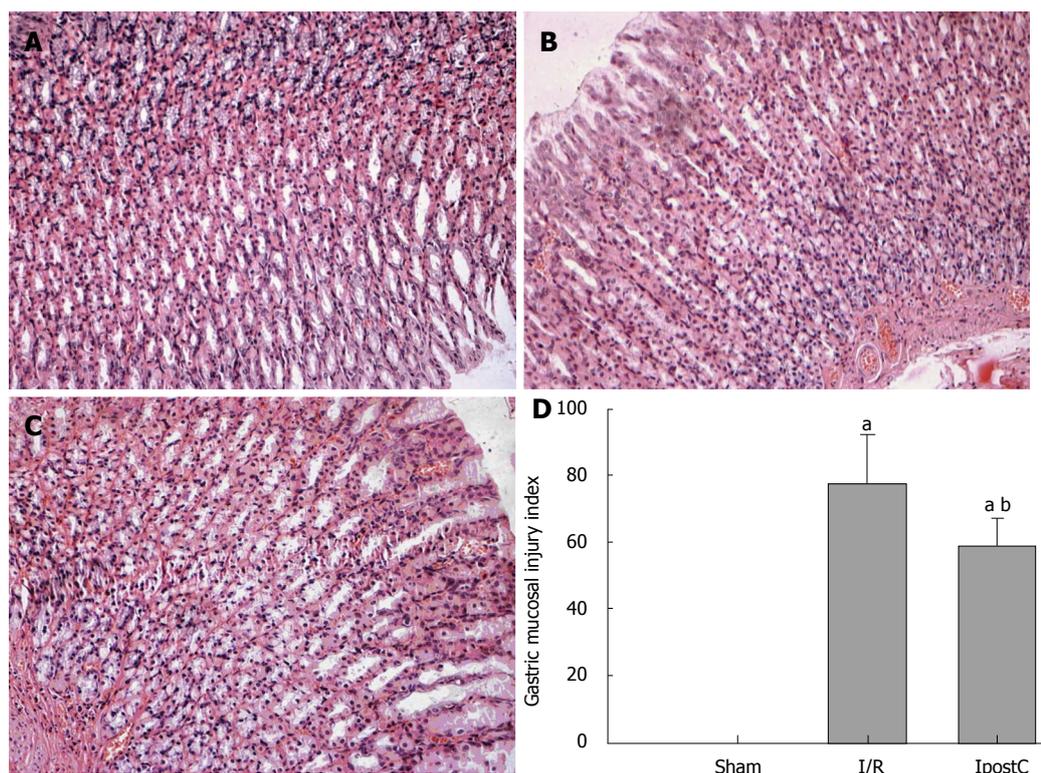

Figure 3 Histological evaluations of gastric tissue. Representative gastric sections were obtained 6 h after sham-operated surgery or ischemia/reperfusion (I/R). A: Section from sham-operated group; B: Section from I/R group; C: Section from IpostC group. All of the sections stained with hema-toxylin and eosin $\times 200$; D: Yong-Mei Zhang scores for acute gastric lesions from sham, I/R and ischemic post-conditioning (IpostC) groups (mean \pm SD; $n = 6$); ^a $P < 0.01$ vs sham-operated group; ^b $P < 0.01$ vs I/R group.

In the present study, ischemia-reperfusion (3 + 24 h) insult was sufficient to attain a considerable degree of gastric injury. IpostC prevented this deleterious effect. Some studies suggested that IpostC may reduce the post-ischemic oxidative damage through its antioxidant action^[20]. MDA and XOD are regarded as indexes for mucosal injuries from ROS. Scarcity of MDA and low activity of XOD were detected in normal mucosa. MDA is an important product of lipid peroxidation that causes cell injury and death^[21]. XOD exists in nonischemic tissue predominantly as xanthine dehydrogenase (XDH) and converts to oxygen radical-producing XOD with ischemia^[22], which is derived from XDH and is capable of generating ROS. Oxygen radicals derived from XOD are important mediators of the cellular injury associated with reperfusion of ischemic intestine, stomach, liver, kidney, and pancreas. Our study showed that gastric MDA content and XOD activity were also significantly increased, whereas administration of IpostC reversed this change. These data indicated that IpostC against GI-RI may be related to the decreased lipid peroxidation caused by oxidative stress.

The primary ROS produced in aerobic organisms is superoxide, which is a highly reactive cytotoxic agent. Superoxide is converted to H_2O_2 by SOD. H_2O_2 , in turn, is converted to water and molecular oxygen by either catalase (CAT) or glutathione peroxidase (GSH-Px). Accordingly, their deficiencies can cause oxidative stress. The overproduction of oxygen-derived free radicals (OFRs) during IRI brings about a consumption and depletion of these en-

dogenous scavenging antioxidants. Concurrently, a member of endogenous antioxidant system SOD was found to be attenuated in I/R group, reflecting the over-production of OFRs. SOD is an enzyme that exists in cells removing oxyradicals, whose activity variation may represent the degree of tissue injury. In this study, compared with the I/R group, IpostC showed significantly increased antioxidant activities as well as the activities of SOD. MPO is an enzyme located mainly in the primary granules of neutrophils, thus tissue MPO levels may suggest neutrophil accumulation in the site of inflammation and generate reactive oxygen and nitrogen species and proteases^[23,24]. Polymorphonuclear neutrophil infiltration is characteristic of acute inflammation and has the collective action of chemotactic mediators. Once neutrophils migrate into the ischemic area, they release ROS, proteases, elastase, MPO, cytokines, and various other mediators, all of which are involved in tissue injury. According to our findings, MPO activity, an index of tissue neutrophil infiltration, was increased by GI-RI, whereas IpostC inhibited neutrophil infiltration and protected the tissue against further injuries. These results indicated that the protective effects of IpostC against GI-RI may be related to the improvement in the endogenous antioxidant system and anti-inflammatory action.

It is apparent that gastric tissue is vulnerable to remote organs or tissue IRI. Some studies found that generation of ROS through xanthine oxidase, lipid peroxidation and Ca^{++} -dyshomeostasis trigger secondary release of leukotriene (LTB4) and platelet activating factor (PAF) and pro-

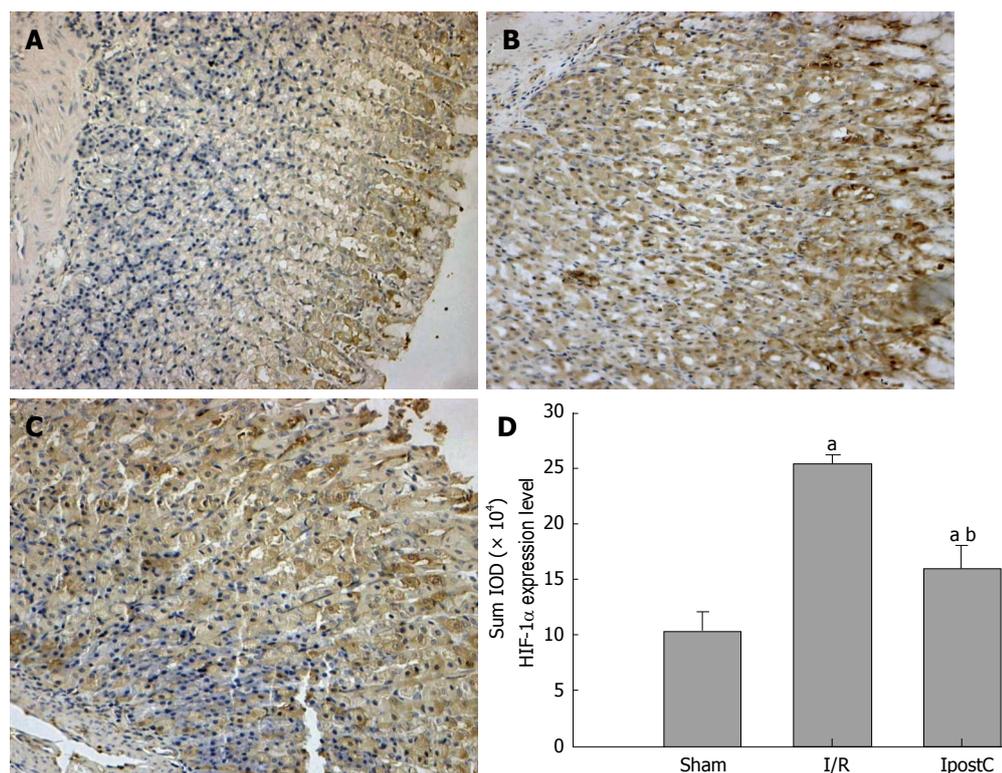

Figure 4 Photomicrographs of hypoxia-induced factor 1 α (HIF-1 α) immunohistochemistry in the gastric tissue (magnification 20 \times). The thickness of gastric containing HIF-1 α -positive gastric cells was determined at a 6-h time point. A: Weak the glandular epithelial cytoplasm and the vascular endothelial cytoplasm staining in Sham-operated group gastric; B: Strong the glandular epithelial cytoplasm, and the vascular endothelial cytoplasm and nuclear staining in ischemia/reperfusion (I/R) group gastric; C: Moderate the glandular epithelial cytoplasm, and the vascular endothelial cytoplasm and nuclear staining in ischemic post-conditioning (IpostC) group gastric; D: SUM IOD of HIF-1 α expression level in sham-operated, I/R and IpostC groups of gastric tissue (mean \pm SD; $n < 8$); ^a $P < 0.01$ vs sham-operated group; ^b $P < 0.01$ vs I/R group.

mote PMN sequestration within stomach that initiates an amplification loop via further liberation of ROS (oxidative burst) and proteolytic enzymes^[23,25]. In our study, MDA, SOD, XOD and MPO were used as indexes to mucosal injuries from ROS, and ROS was found to cause direct damage to cellular membranes as well as proteins and induce lipid peroxidation, leading to GI-RI that may be complicated by mucosal edema, microcirculation disturbance, epithelia hemorrhagic erosions and impaired function.

We also found that the expression of HIF-1 α protein significantly increased in I/R group, and when ROS decreased, the expression of HIF-1 α also decreased in IpostC group. Besides, hypoxia obviously induced the expression of HIF-1 α in the gastric epithelial cells (GECs) and the vascular endothelial cells (VECs) of gastric tissue. Thus, we suggested that ROS might contribute to the initiation and progression of gastric ischemic injury, and oxidative stress resulting from gastric oxidative damage can induce the expression of HIF-1 α in gastric ischemia induced by LI-RI.

HIF-1 α is a nuclear transcription factor that mediates adaptive responses to hypoxia in mammalian cells. It is now recognized that HIF-1 α is central to the regulation of genes involved in angiogenesis, vasomotor regulation and regulations of cell proliferation. HIF-1 α plays a critical role in limb ischemia^[26]. Some studies demonstrated that HIF-1 α can stimulate neovascularization of vessels of

ischemia tissue that respond to vascular endothelial growth factor (VEGF) and placental growth factor (PLGF)^[27], and stimulate the recovery of blood flow in operative models of hindlimb ischemia^[28]. ROS is generated from a number of sources including the mitochondrial electron transport system, xanthine oxidase, the cytochrome p450, the NADPH oxidase, uncoupled NOS and MPO, including superoxide radical (O₂⁻), hydrogen peroxide (H₂O₂), and hydroxyl radical. They are closely related to the oxygen content in cells and extensive biologic activities. Exogenous ROS stimulate induction of VEGF by various cell types, and promote cell proliferation and migration, cytoskeletal reorganization and tubular morphogenesis in endothelial cells (ECs). Some studies demonstrated that ROS was also involved in physiological repair processes such as ischemia-induced angiogenesis and wound healing *in vivo*^[29,30]. Therefore, ROS also play an important role in neovascularization during limb ischemia.

According to some studies, ROS can regulate the expression of HIF-1 α via some pathways. Firstly, HIF-1 α expression is regulated in terms of not only its stability but also its transcriptional and translational activities. The extracellular signal regulated kinase (ERK) and phosphatidylinositol 3-kinase (PI3K)/Akt (protein kinase B, PKB) signaling pathways are involved in the transcription and translation of HIF-1 α and can be activated by ROS. The PI3K/PKB signaling pathway phosphorylates the components that

regulate translation, and provokes the accumulation of HIF-1 α in response to growth factors, hormones, and cytokines^[31]. Secondly, HIF-1 α is a highly phosphorylated protein *in vivo* and this phosphorylation of HIF-1 α induces strong changes in the HIF-1 α 's migration pattern. Activation of the p42 and p44 mitogen-activated protein kinase (MAPK) pathway in quiescent cells induced the phosphorylation and shift of HIF-1 α , which was abrogated in presence of the MEK inhibitor. This interaction between HIF-1 α and p42/p44 MAPK suggests a cooperation between hypoxic and growth factor signals that ultimately leads to the increase in HIF-1-mediated gene expression^[32]. Some studies suggested that ROS induced HIF-1 α expression by decreasing the activity of prolyl hydroxylases (PHDs) in cancer and ischemia^[19] at high concentrations, and ROS would upregulate HIF-1 α independently and then PHD2 would be upregulated by ROS, leading to HIF-1 α down-regulation^[33]. So, ROS as a signaling molecule, can stimulate HIF-1 α protein synthesis via activation of the PI3K/AKT and p42/p44MAPK pathways, and ROS may also have the potential to interfere with prolyl hydroxylase activity to regulate HIF-1 α expression.

Some reports^[34,35] found that a variety of non-hypoxic stimuli including growth factors, hormones, vasoactive peptides and metal ions can induce HIF-1 α in normoxia, and many of these factors can stimulate ROS production as part of their signaling cascades. These indicate that ROS regulates HIF stability and transcriptional activity in well oxygenated cells, as well as under hypoxic conditions.

Our study showed that the expression of HIF-1 α protein significantly increased in gastric ischemia, and when ROS was reduced, the expression of HIF-1 α also decreased. It is shown that, at least in GECs and VECs, ROS may control the levels of HIF-1 α expression and the proliferation of GECs and VECs through regulating HIF-1 α expression. The effects of ROS on HIF-1 α can be attributed to three factors: the degree of hypoxia, the form and intracellular location of ROS produced, and the molecular microenvironment of the cell.

In conclusion, our findings suggest that LI-RI can markedly induce oxidative stress and the expression of gastric tissue HIF-1 α , and ROS controls the expression of HIF-1 α probably as a signaling molecule and has the potential to interfere with prolyl hydroxylase activity under gastric ischemic condition. Thus, ROS plays an important role in the regulation of HIF-1 α expression in gastric ischemia. The possible mechanisms of how ROS interacts with the HIF-1 pathway and alters HIF-1 α expression might be related to the activation of the PI3K/AKT, p42/p44MAPK pathways. Further understanding of these mechanisms will be undoubtedly a major contribution to the studies in the pathogenesis of GI-RI.

COMMENTS

Background

The transcription factor hypoxia-induced factor (HIF) plays a critical role in the mammalian response to oxygen (O₂) levels. HIF-1 transcriptionally activates hundreds of genes associated with angiogenesis in cancer, ischemia, as well as energy metabolism, nutrient transport, cell cycle, and cell migration. HIF-1 α

and HIF-1 β make up the HIF-1 heterodimer. The intracellular HIF-1 α rapidly accumulates in the cell nucleus and triggers gene expression under hypoxia conditions. Concomitantly, the study of reactive oxygen species (ROS) and the interest in antioxidants as potential dietary supplements for prevention of cancer, cardiac dysfunction, and neurodegeneration has grown rapidly. Oxidant stress, due to free radicals and/or reactive oxygen species, is known to cause organ injury. Although, some studies have shown that increased HIF-1 α expression contributed to mitochondrial activity, and especially the ROS formation in hypoxia. However, other studies have demonstrated a decrease of HIF-1 α with increasing ROS, and related observations seem to be conflicting.

Research frontiers

HIF-1 α is a key determinant of oxygen-dependent gene regulation in angiogenesis. HIF-1 α overexpression may be beneficial in cell therapy of hypoxia-induced pathophysiological processes, such as ischemic heart disease. Oxidative stress plays an important role in the pathogenesis of many clinical conditions involving cardiovascular diseases, liver diseases, lung disease, gastrointestinal disorders, neurological disorders, muscle damage, diabetes, aging and ischemia reperfusion (I/R). These clinical evidence focuses on the role of oxidant stress in the mechanism of I/R injury and the use of antioxidant agents for its treatment.

Innovations and breakthroughs

The authors used a rat model of hindlimb ischemic reperfusion to observe oxidative stress and the expression of HIF-1 α in the gastric injury induced by limb ischemic reperfusion. This study demonstrated that limb ischemia reperfusion injury markedly induced oxidative damage resulting from ROS and the expression of HIF-1 α of gastric tissue, and suggested that ROS controls the expression of HIF-1 α under ischemic conditions.

Applications

HIF-1 α overexpression may be beneficial in cell therapy of hypoxia-induced pathophysiological processes of many clinical conditions. The use of antioxidant agents for oxidant stress treatment in pathophysiological processes of many clinical diseases.

Peer review

The authors examined oxidative stress and HIF-1 α protein expression, and the relationship between ROS and HIF-1 α in gastric ischemia induced by limb ischemia reperfusion. It revealed that limb ischemia reperfusion injury markedly induced oxidative damage and the expression of HIF-1 α of gastric tissue, and ROS controls the expression of HIF-1 α under ischemic conditions. The paper describes a very careful biochemical and histological documentation.

Abstract

A case of intraductal papillary neoplasm of the bile duct (IPNB) arising in a patient with hepatitis B-related liver cirrhosis with hepatocellular carcinoma (HCC) is reported. A 76-year-old man was admitted to our hospital with recurrent HCC. Laboratory data showed that levels of carcinoembryonic antigen and carbohydrate antigen 19-9 were elevated. He died of progressive hepatic failure. At autopsy, in addition to HCCs, an intraductal papillary proliferation of malignant cholangiocytes with fibrovascular cores was found in the dilated large bile ducts in the left lobe, and this papillary carcinoma was associated with an invasive mucinous carcinoma (invasive IPNB). Interestingly, extensive intraductal spread of the cholangiocarcinoma was found

from the reactive bile ductular level to the interlobular bile ducts and septal bile ducts and to the large bile ducts in the left lobe. Neural cell adhesion molecule, a hepatic progenitor cell marker, was detected in IPNB cells. It seems possible in this case that hepatic progenitor cells located in reactive bile ductules in liver cirrhosis may have been responsible for the development of the cholangiocarcinoma and HCC, and that the former could have spread in the intrahepatic bile ducts and eventually formed grossly visible IPNB.

INTRODUCTION

Intraductal papillary neoplasms of the bile duct (IPNB) are characterized by a grossly visible, exophytic proliferation of neoplastic cholangiocytes with delicate fibrovascular cores in large bile ducts^[1-3]. IPNB not infrequently presents with mucin hypersecretion and prominent cysts in the affected bile ducts^[4,5], and is regarded as a precursor of invasive cholangiocarcinoma^[1-3]. IPNB has been reported in association with chronic biliary diseases, including hepatolithiasis,

primary sclerosing cholangitis, and parasitic biliary diseases, as well as apparently normal bile ducts, though the exact histogenesis of IPNB remains unclear.

Here, we report a case of IPNB arising in a patient with hepatitis B virus (HBV)-related liver cirrhosis associated with hepatocellular carcinoma (HCC). In this case, the malignant transformation of hepatic progenitor cells (HPCs) may be responsible for the development of IPNB and also HCC.

CASE REPORT

A 76-year-old man was admitted to hospital with recurrent HCC in the right liver lobe for transcatheter arterial chemoembolization (TACE). He had been found to have hepatitis B surface antigen 17 years ago and had suffered from HBV-related cirrhosis for nearly 10 years. HCC was found in the right lobe, and a partial hepatectomy was performed, 4 years ago. On admission, the laboratory values of tumor markers were as follows: the serum α -fetoprotein (AFP) level was within the normal range, the carcinoembryonic antigen level was 114.6 ng/mL (normal range: < 22 ng/mL) and the carbohydrate antigen 19-9 level was 52000 U/mL (normal range: < 37 U/mL). Contrast-enhanced computerized tomography revealed mild dilatation of the left intrahepatic bile duct and HCC after TACE in segment 6 of the liver. The patient died of progressive hepatic failure after hospitalization for 4 mo.

At autopsy, the liver weighed 615 g, and the majority of the liver showed cirrhotic nodules measuring less than 5 mm in diameter. Two distinct tumorous nodules (1.7 cm \times 1.4 cm and 1.2 cm \times 1.3 cm) were identified in the right lobe (Figure 1A), and these tumors showed largely coagulative necrosis compatible with HCC after TACE, while the remaining parts showed a trabecular growth pattern of HCC (Figure 1B). The rest of the liver was associated with mild to moderate necroinflammatory changes and ductular reactions.

The intrahepatic large bile ducts in the left lobe showed cystic or fusiform dilatation, and were filled with yellowish-tan papillary masses and hypersecreted mucin (Figures 1 and 2A). The affected bile duct lumen was obstructed, and the left liver was atrophic due to the obstruction. Within the left dilated intrahepatic bile ducts, the neoplastic cholangiocytes showed exophytic and papillary proliferation with delicate fibrovascular stalks (Figure 2B). The neoplastic cholangiocytes showed multilayered nuclei, an increased nucleo-cytoplasmic ratio and nuclear hyperchromasia, and these papillary tumors were diagnosed as cholangiocarcinomas. Such cholangiocarcinoma cells spread along the luminal surface of the bile ducts, with a flat and micropapillary configuration. In the subepithelial stroma, no ovarian-like mesenchymal stroma was observed. Near the large-sized bile duct with IPNB, stromal invasion of cholangiocarcinoma accompanied by mucinous carcinoma in the left lobe was observed. Mucin was positive by Alcian blue (pH 2.5) and diastase-periodic acid Schiff stains. Taken together, these carcinomas were regarded as invasive IPNB. Immunohistochemical staining revealed that cytokeratin-7 (CK7)

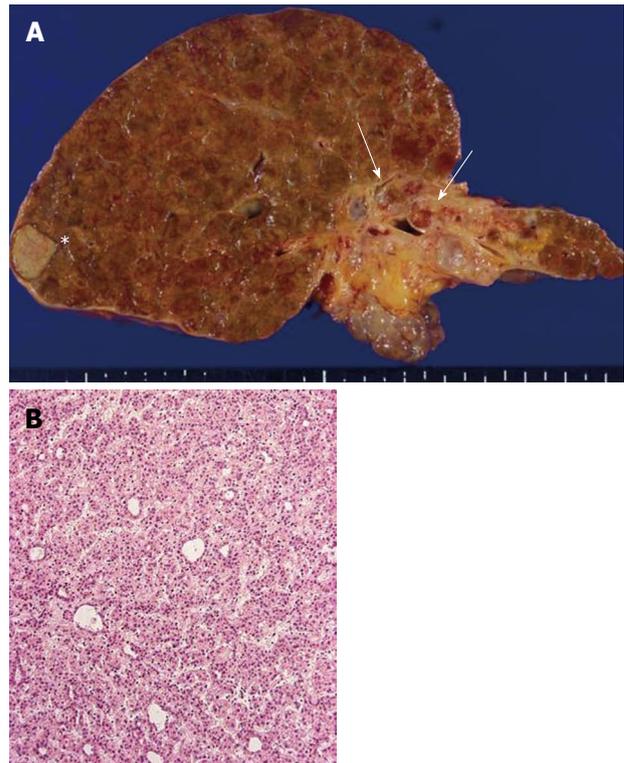

Figure 1 Liver pathology. A: The autopsied liver tissue shows cirrhosis with a solid whitish lesion (*) in segment 6 of the right lobe (hepatocellular carcinoma after transcatheter arterial chemoembolization) and cystic dilatation in the left intrahepatic bile ducts filling with yellowish-tan papillary masses and mucin production (arrows). The left liver appears atrophied; B: Well-differentiated hepatocellular carcinoma. Hematoxylin and eosin staining (H and E).

and CK19 were diffusely expressed, mucin (MUC) 5AC was moderately expressed, and CK20, CDX2, NCAM and MUC1 were focally expressed in IPNB. However, MUC2, MUC6, HepPar-1 and AFP were not observed.

Interestingly, in the left lobe including the areas near or adjacent to the left hepatic bile duct, carcinomatous cholangiocytes partially replaced the normal biliary epithelia of some septal intrahepatic bile ducts and totally replaced the epithelia of the interlobular bile ducts (Figure 3A). They showed similar mucinous and immunohistochemical profiles as seen in IPNB, and NCAM was frequently expressed in spreading neoplastic cells (Figure 3B). Interestingly, some foci of the proliferated bile ductules located in the fibrous stroma surrounding regenerative nodules showed cellular and nuclear atypia (Figure 4A) and were positive for MUC1 and focal NCAM (Figure 4B). They were considered to represent an extensive intra-bile duct spread of cholangiocarcinoma cells from reactive bile ductules, interlobular bile ducts and septal bile ducts to the large bile ducts. In contrast, the hilar bile ducts and bile ducts in the right lobe were not affected.

DISCUSSION

HCC grows occasionally in the bile duct as a tumor cast and presents clinical symptoms related to biliary obstruction^[6]. Here, we report a case of papillary cholangiocar-

cinoma secreting much mucin in the dilated intrahepatic large bile duct of the left lobe and showing invasion as a mucinous carcinoma. Immunohistochemically, the papillary carcinoma was strongly and diffusely positive for CK7 and CK19, and also expressed MUC5AC. CDX2, CK20, and MUC1 were also focally positive. This phenotypic profile suggests that the neoplastic cells retain a biliary phenotype (CK7 and CK19) and a gastric phenotype (MUC5AC), and intestinal metaplasia (CK20, CDX2) was also focally expressed. Carcinoma cells in the invasive area showed an apical membranous pattern for MUC1, while MUC2 (intestinal-type mucin) and MUC6 (pyloric gland-type mucin) were negative in the present case. These features are compatible with invasive IPNB. Compared with previous reports of IPNB^[1-3], the present case is unique in 2 points: (1) atypical biliary cells regarded as cholangiocarcinoma cells spread not only in the large bile ducts but also in the small bile ducts and the reactive bile ductules; and (2) IPNB was found in HBV-related liver cirrhosis associated with HCC, which was separate from the cholangiocarcinomatous components.

Papillary cholangiocarcinoma arising from extrahepatic and/or intrahepatic bile ducts occasionally shows

extensive intraductal luminal spread^[7-12]. However, the extensive intraluminal spread of atypical biliary epithelial cells extending to the reactive bile ductules found in our case, has not been reported in the literature. Recently, Ashima *et al*^[13] demonstrated 2 cases of biliary intraepithelial neoplasia (BilIN), a flat biliary epithelial neoplastic lesion, with extensive intraductal spread associated with liver cirrhosis. Rougemont *et al*^[14] also reported a case of extensive BilIN and multifocal intrahepatic cholangiocarcinoma associated with non-biliary cirrhosis. A review of the literature revealed 3 cases of biliary papillomatosis, corresponding to IPNB, associated with liver cirrhosis^[3,15-18]. However, in these cases, the involvement of interlobular bile ducts and reactive bile ductules was not shown.

It has long been controversial whether hepatic malignancies arise from stem cells or HPCs undergoing a malignant transformation^[19,20]. According to recent studies, some primary hepatic malignancies, including combined hepatocellular cholangiocarcinoma (HC-CC), originate from the transformation of HPCs^[7]. These *et al*^[17] demonstrated one case of biliary papillomatosis (in the left liver lobe) associated with HC-CC (in the right liver lobe)

on a background of liver cirrhosis secondary to hepatitis B, and speculated that the HC-CC was derived from neoplastic transformation of HPCs. However, they did not refer to the relationship of HC-CC with biliary papillomatosis.

It is possible that activated HPCs located in reactive bile ductules underwent neoplastic transformation leading to hepatocellular and biliary differentiation. The former may have been followed by the development of HCC at the first step, while the latter may have been followed by superficial spread from the neoplastic foci in reactive bile ductules to the interlobular bile duct, the septal intrahepatic bile ducts, and, eventually, the left hepatic bile ducts, where the cholangiocarcinoma developed as multiple papillary growths and then an invasive mucinous adenocarcinoma. Interestingly, NCAM, a HPC marker, was also focally expressed in invasive IPNB and in the small bile ducts replaced by neoplastic cholangiocytes (Figure 3), suggesting that the cholangiocarcinoma spreading into the intrahepatic bile ducts retained a HPC phenotype.

In conclusion, a rare case of IPNB arising in a patient with liver cirrhosis associated with HCC was reported. Neoplastic transformation of bile ductules containing HPCs may have been responsible for the HCC as well as the IPNB showing extensive bile duct spread.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclu-

sion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declara-

tion of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUC-

TIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself.

Instructions to authors

File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of P values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the

cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 $24.5 \mu\text{g/L}$; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP,

EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D, Ocean International Center, No. 62 Dongsihuan Zhonglu, Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-5908-0039

Instructions to authors

Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the

revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

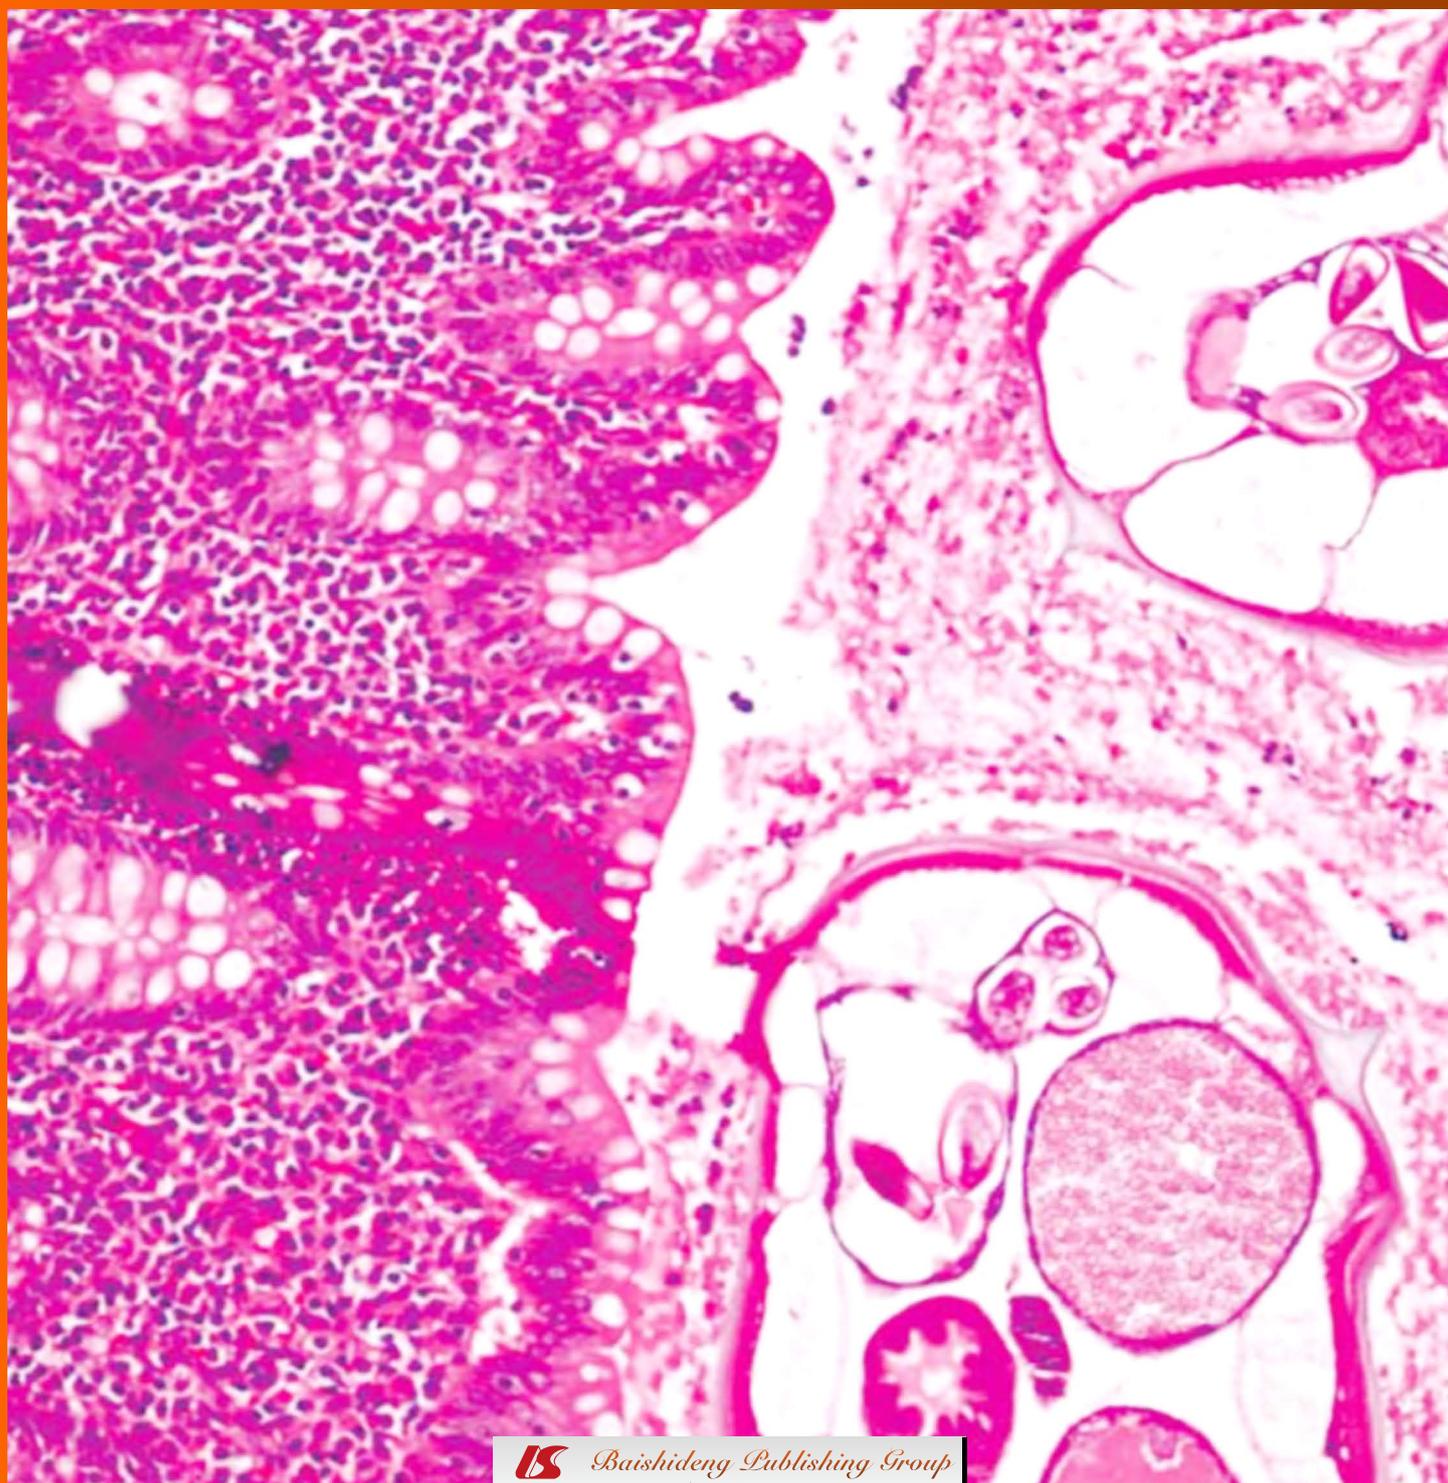

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Occult hepatitis B virus (HBV) infection (OBI), alternatively defined as occult hepatitis B (OHB), is a challenging clinical entity. It is recognized by two main characteristics: absence of HBsAg, and low viral replication. The previous two decades have witnessed a remarkable progress in our understanding of OBI and its clinical implications. Appropriate diagnostic techniques must be adopted. Sensitive HBV DNA amplification assay is the gold standard assay for detection of OBI. Viral as well as host factors are implicated in the pathogenesis of OBI. However, published data reporting the infectivity of OBI by transfusion are limited. Several aspects including OBI transmission, infectivity and its relation to the development of chronic liver diseases and hepatocellular carcinoma have to be resolved. The aim of the present review is to highlight recent data on OBI with a focus on its virological diagnosis and clinical outcome.

Said ZNA. An overview of occult hepatitis B virus infection. *World J Gastroenterol* 2011; 17(15): 1927-1938 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i15/1927.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i15.1927>

INTRODUCTION

Hepatitis B virus (HBV) remains a major public health problem worldwide^[1]. Among many transmission routes, transfusion is the one that should be prevented. Implementation of hepatitis B surface antigen (HBsAg) in routine screening of blood donors in the early 1970s has greatly enhanced transfusion safety. The incidence of transfusion-transmitted hepatitis B has been steadily reduced over the last four decades^[2]. However, it was demonstrated that HBV transmission by blood components negative for HBsAg can still occur^[3] and HBV transmission remains the most frequent transfusion-transmitted viral infection^[4-6]; thus, the term occult hepatitis B virus infection (OBI) was introduced. OBI is simply defined as serologically undetectable hepatitis B surface antigen (HBsAg-ve), despite the presence of circulating HBV DNA^[7,8]. OBI was reported for the first time almost 30 years ago in a case report of HBV infection through blood transfusion by an antibody to hepatitis B core antigen (anti-HBc) only positive donor^[9]. The residual risk of HBV transfusion transmission is mainly related to blood donations negative for HBsAg that have been collected either during the pre-seroconversion "window period" (WP), defined as the time between infection and detection of a viral antigen or antibody marker, or during the late stages of infection^[1]. Additionally, OBI has high significance in management of bone marrow and organ transplantations^[10-13]. Implementation of HBV DNA screening has the potential to significantly reduce the WP and to reveal OBI or HBV carriage^[14].

Allain^[15] reported OBI in several clinical contexts including: (1) recovery from past infection indicated by the presence of hepatitis B surface antibody (anti-HBs); (2) chronic hepatitis with surface gene escape mutants that are not recognized by current assays; (3) chronic carriage without any marker of HBV infection other than HBV DNA (referred to as “seronegative”); and (4) most commonly in endemic areas, chronic carriage stage with HBsAg too low to be detected and recognized by the presence of anti-HBc as the only serological marker (referred to as “anti-HBc alone” or “isolated anti-HBc”)^[15].

DEFINITION OF OCCULT HEPATITIS B INFECTION

Several definitions for OBI have been proposed by many authors. Bremer *et al*^[16] emphasized that the term “occult hepatitis B virus infection” has been introduced to describe a pattern with the presence of replication-competent HBV DNA in the liver but without detectable HBsAg in the serum. This often occurs after progressive disappearance of HBsAg in the years after infection^[17] and persists in low-level carriers^[14]. Early phase of HBV infection before appearance of HBsAg is not considered OBI, as the infection becomes eventually non-occult^[18].

A more specific definition was provided by Allain^[15] in 2004, who defined OBI as the presence of HBV DNA without HBsAg, with or without the presence of HBV antibodies outside the acute phase window period. This is in accordance with findings by Gerlich *et al*^[19], who identified two blood donors whose donations tested HBsAg- and HBV DNA-negative, but transmitted HBV. Both subsequently developed HBsAg and acute hepatitis. It was confirmed that such cases are transient OBI and should not be considered as true OBI. A true OBI remains HBsAg-negative during the entire course^[19]. Nevertheless, a 2008 international workshop on occult hepatitis B virus (HBV) infection (OBI), endorsed by the European Association for the Study of the Liver (EASL)^[20], as well as The Taormina Consensus Conference in 2008, defined “OBI” as the “presence of HBV DNA in the liver of individuals testing HBsAg-negative with currently available assays”^[10] and introduced a cutoff value for serum HBV DNA (< 200 IU/mL). Therefore, cases whose serum HBV DNA levels are comparable to those with different serologically evident (overt) HBV infection are generally due to infection with HBV escape mutants and should be labeled as “false” OBI^[10]. As confirmed by Hollinger *et al*^[21], this definition implies that infectious viral clones may be present. However, the detection of HBV DNA does not always correspond to infectivity or to the number of HBV progeny viruses released from hepatocytes; therefore, the authors suggested a more comprehensive term “occult hepatitis B (OHB)”^[21] rather than OBI. Moreover, nosocomial sources should be carefully excluded before speculating that blood donors with OBI were involved in HBV viral disease transmission^[22].

POSSIBLE MECHANISMS OF OBI

Several possible mechanisms have been hypothesized for the pathogenesis of OBI and the condition is probably multifactorial. Both host and viral factors are important in suppressing viral replication and keeping the infection under control^[21,23,24]. The majority of OBI cases are secondary to overt HBV infection and represent a residual low viremia level suppressed by strong immune response together with histological derangements occurring during acute or chronic HBV infection^[25]. It was previously suggested that long-term maintenance of an active anti-viral T cell response several years after clinical recovery from acute hepatitis B could be important, not only for protection against reinfection, but also for keeping the persisting virus under tight control where detection of minute amounts of virus in some recovered subjects was confirmed^[26]. Also, in a study to characterize the features of the HBV-specific T-cell response in patients with OBI, 2 different profiles were defined. Anti-HBc-positive patients showed a T-cell response typical of protective memory, suggesting that this condition represents a resolved infection with immune-mediated virus control. In contrast, HBV-specific T cells in anti-HBc-negative patients did not readily expand, suggesting the possibility of a low-dose infection insufficient to allow maturation of protective memory^[27]. Additional mechanisms not related to the host response were also extensively studied by many authors, where it was shown that the low level of viral replication was a result of the presence of defective interfering particles or of mutations in transcription control regions or the polymerase domain leading to decrease in HBV DNA replication and HBsAg expression^[21,24,28-30].

Humoral and cellular immune pressure on the HBV envelope proteins are major mechanisms generating OBI. Amino acid substitutions are significantly concentrated in the immunologically active parts of the Pre-S/S proteins affecting both cellular CD8 T-cell epitopes and B-cell neutralizing major hydrophilic region epitopes^[31]. Escape mutation is one mechanism which also leads to decreased reactivity in HBsAg detection assays^[32]. This is confirmed by Gerlich *et al*^[19]. van Hemert *et al*^[33] in 2008 proposed an evolutionary scenario for occult HBV infection. They identified a novel RNA splicing event (deleting nucleotides 2986-202) that abolishes surface protein gene expression without affecting polymerase, core or X-protein related functions. This 2986-202 splicing generates intracellular virus particles devoid of surface protein, which subsequently accumulate mutations due to relaxation of coding constraints. Such viruses are deficient in autonomous propagation and cannot leave the host cell until it is lysed^[33].

Masking of HbsAg by HbsAg-anti-HBs immune complexes is another postulated mechanism for the development of OBI^[34,35]. Also, coinfection with hepatitis delta virus or hepatitis C virus (HCV) which results in down-regulation of HBV replication and a reduction in HBsAg synthesis has been reported^[21]. Sagnelli *et al*^[36] showed an inhibitory effect of HCV on HBV replication. This inhibitory activity of HCV on HBV replication has also

been reported by other investigators in a follow-up study of 6 years duration, where it was shown that the rate of HBsAg clearance is 2.5 times higher in HBsAg/anti-HCV-positive cases than in those with HBV infection alone; it was suggested that HCV is the most important hepatotropic virus that enhances HBsAg clearance in chronic hepatitis B^[37]. The underlining molecular mechanism responsible for this suppressive effect has been extensively studied both *in vitro*^[38] and *in vivo* studies^[39]. Indirect mechanisms mediated by innate and/or adaptive host immune responses have also been postulated as being involved^[40]. In this regard, we have recently studied the prevalence of occult HBV among children and adolescents with hematological diseases with or without HCV in an area of high endemicity of HCV infection. It was shown that HCV RNA was a significant predictor for OBI ($P < 0.05$), with an increased frequency of HBV DNA in those who were HBsAg-negative and HCV RNA positive (63.2%) compared with patients negative for HCV RNA (25%) ($P = 0.009$)^[41].

Additional mechanisms for OBI have been thoroughly investigated, emphasizing that integration of viral sequence may alter HBsAg expression and decrease HBV replication^[42]. Meanwhile, reduced HBV viremia may result from extra-hepatic HBV replication such as that takes place in peripheral blood mononuclear cells (PBMCs)^[42]. Patients with long-standing abnormal results of liver function tests with unknown etiology may have HCV RNA or HBV DNA in their PBMCs in the absence of anti-HCV antibodies, HBV markers, serum HBV DNA and serum HCV RNA^[43].

EVALUATION OF DIFFERENT OBI DIAGNOSTIC TECHNIQUES

Most OBIs are asymptomatic and would only be detected by systematic screening of large populations^[7]. No published guidelines are provided up till now, categorizing those who should be screened for OBI. However, such investigations should be considered in the following situations: (1) HCV-infected patients with flares in viral replication and liver damage^[44]; (2) infected patients becoming immune deficient mainly by receiving immunosuppressive regimens for various clinical conditions^[7]; (3) screening of blood donations for immunocompromised recipients^[41]; and (4) subjects with unexplained liver diseases. Candotti *et al*^[1] further clarified that OBIs are mainly found in older donors, nearly 100% carry anti-HBc, and approximately 50% also carry anti-HBs, suggesting that OBIs occur largely in individuals having recovered from the infection but unable to develop a totally effective immune control^[31].

Liver biopsy

Detection of HBV DNA in liver biopsy is the best way for diagnosis of OBI. However, liver biopsy tissue is not always available, and standardized and valid assays for detection of HBV DNA in liver tissue are not FDA ap-

proved^[21]. A recent Italian study investigated the prevalence of occult HBV in the general population by examining 98 liver specimens from liver disease-free individuals who were HBsAg-negative, and detected HBV DNA in sixteen of them (16.3%); 10/16 (62.5%) were anti-HBc positive^[20].

HBsAg testing

The main target for antibodies used in diagnostic tests is the major hydrophilic loop (MHL, amino acids 100-160) that contains the "a" determinant (amino acids 124-147) and is coded by the envelope (S) gene. The existence of mutations in this region could cause diagnostic failure^[45]. Current HBsAg screening assays are enzyme immunoassays (EIAs), including enzyme-linked immunosorbent assays (ELISAs), and chemiluminescence immunoassays (CLIAs)^[1]. These different assays have sensitivity ranging between < 0.1 and 0.62 ng of HBsAg per mL (1 ng/mL corresponds to approximately 2 IU/mL)^[1,46,47]. Performance of commercial assays would be improved by the incorporation of OBI mutants in reagent development^[32].

The course of HBV markers during the early phase of true OBI is not well known, where, in spite of transient strong HBV replication, much less HBsAg in the serum than the normal courses is shown^[16]. This has been previously confirmed in a Japanese study by Yoshikawa *et al*^[48], where 17 million donations were tested for occult infection, and 328 HBV DNA-positive donations were found. From 26 of these donors, sequential samples were examined for the dynamics of viral markers in acute HBV infection. Six of the 26 donors were infected with mutant viruses, and 3 of these 6 donors did not develop detectable HBsAg during the entire observation period, despite a moderately high viral load of 10^4 to 10^5 HBV DNA copies per mL. The authors concluded that HBV nucleic acid amplification test (NAT), even in minipool (MP) configuration, is more effective than HBsAg testing and capable of excluding infected donors in the pre- and post-HBsAg window periods^[48].

A novel immunoassay that detects simultaneously HBV PreS1 and/or core-related antigens was developed and evaluated for its potential value for detecting HBsAg variants. The detection limits of the assay were $10 (2.9 \pm 0.5)$ copies/mL (mean \pm SD) for HBsAg-positive sera with different genotypes, and $10 (3.5 \pm 1.2)$ copies/mL for HBsAg variants containing sera. The specificity of the assay was 99.9% (95% CI: 99.7-99.9, 4551 healthy individuals). The sensitivities were 93.9% (95% CI: 92.8-94.9), 59.3% (95% CI: 38.7-77.6) and 80% (95% CI: 44.4-97.5) in three independent groups which included: 2065 hepatitis patients, 27 patients with OBI and 10 HBsAg variants, respectively. In addition, a novel premature stop code mutation at position 112 of HBsAg was observed in two patients with chronic hepatitis B with different genotypes^[49].

Anti-HBc testing

Serological profiling of HBV infection showed that OBI may be antibody (anti-HBc alone or together with anti-HBs) positive (seropositive OBI) or antibody negative

(seronegative OBI)^[13]. The HBV DNA detection rate is highest in subjects who are anti-HBc-positive but anti-HBs-negative, and these individuals are more likely to be infectious^[21].

Recently, Urbani *et al*^[50] illustrated that the serological assay for the long-lasting antibody response to the highly immunogenic HBV core antigen (anti-HBc) represents a qualified candidate as a surrogate for DNA amplification, or for increasing overall sensitivity when assessing the risk of occult hepatitis in peripheral blood. The risk of occult hepatitis associated with anti-HBc seropositivity has been demonstrated extensively, and the presence of antibody response to HBc can be considered a sentinel marker of occult HBV infection^[50].

In a recent review conducted by Candotti *et al*^[1] in 2009^[1], it was emphasized that approximately 90% of blood donors carrying anti-HBc also carry anti-HBs, indicating recovered HBV infection^[51]. The remaining 10% are either false-positive anti-HBc due to poor assay specificity and the lack of confirmatory assays, or true anti-HBc (anti-core antigen alone)^[1,52,53]. Anti-HBc only samples may originate either from recovered infections having lost detectable anti-HBs or from late stage chronic infections having lost detectable HBsAg^[1]. Recent studies have confirmed the existence of occult HBV infection in samples with anti-HBc alone^[54,55]. Nevertheless, low levels of HBV DNA were reported not only in anti-HBc alone positive blood donations but also in some blood units carrying low-level anti-HBs^[1]. A serologic testing algorithm with anti-HBc followed by anti-HBs (anti-HBs \geq 100 IU/L probably non-infectious) or implementation of highly sensitive HBV DNA screening are adopted in different countries; however, this is still an area of debate by many authors. In our recent study, OBI was detected in blood units from healthy volunteer blood donors showing adequate level of anti-HBs (under publication).

OBI is observed in anti-HBc-positive patients with chronic HBV infection following the decline of HBsAg to an undetectable level that is sometimes associated with the appearance of anti-HBs. This serological pattern occurs at a rate of 0.7%-1.3% per year and is associated with older age and hepatitis B e antibody (anti-HBe) reactivity^[21,56-58]. In an experimental study to determine the relationship between anticore detection and the molecular status of virus replication in a primary woodchuck hepatitis virus (WHV) surface antigen (WHsAg)-negative infection or long after resolution of WHV hepatitis, it was shown that the long-term presence of anticore antibodies alone is a consequence of sustained restimulation of the immune system by virus nucleocapsid produced during low-level hepadnaviral assembly^[59]. On the other hand, it was shown that about 20% of OHB sera are negative for all serological markers of HBV infection except HBV DNA^[21].

HBV nucleic acid (DNA) testing

The gold standard test for detection of OBI is the amplification of HBV DNA^[50]. At present, the optimal standard

for diagnosis is the analysis of HBV DNA extracts from plasma performed by real-time, nested polymerase chain reaction (PCR) techniques^[21]. False results of these assays could be avoided by choosing PCR primers that span at least three genomic regions of the HBV genome such as the S, X and core genes, and validation should require detection from at least two regions of the genome^[20]. Unfortunately, this suggestion is not usually fulfilled, and only one segment of a region is amplified. The preferred lower limit of detection (LLOD) for HBV DNA is 5 IU/mL^[21]. Some investigators prefer to repeat extraction and testing under the assumption that according to Poisson distribution, repeated testing increases the chances of detecting a low number of template sequences^[7]. Nucleic acid testing (NAT) for HBV DNA detection that combines simultaneous detection of human immunodeficiency virus (HIV) RNA, HCV RNA, and HBV DNA (“multiplex” NAT assays) and use of an automated testing platforms have made HBV NAT blood screening feasible^[1]. In order to standardize these newly developed assays, the World Health Organization International Standard for hepatitis B virus DNA (NAT)-based assays was created (code 97/750) with a potency of 10⁶ IU/mL (500000 IU/vial)^[60].

Biswas *et al*^[46] showed that pooled-sample NAT would reduce the WP by 9 to 11 days; and single-sample NAT would reduce the WP by 25 to 36 d, compared to currently licensed HBsAg tests^[46]. This leaves WPs of 40-50 d and 15-34 d with minipool (MP) and individual donor (ID) HBV NAT, respectively^[1]. As emphasized by Candotti *et al*^[1], the ability of NAT to reduce the WP depends not only on the sensitivity of both the molecular and serological tests, but also on the sample volume (200 or 500 μ L) as well as the dilution factor introduced by pooling samples, the prevalent HBV genotype at the location and the level of HBV endemicity^[7,46,61-63]. Beyond shortening the WP, NAT screening, particularly in individual units, has uncovered a relatively large number of HBsAg-negative “occult” HBV infection or carriage^[11,14].

OBI is usually characterized by very low HBV DNA load in plasma (< 200 IU/mL)^[1]. Detection of OBI requires assays of the highest sensitivity and specificity with a lower limit of HBV DNA detection of less than 10 IU/mL and < 0.1 ng/mL for hepatitis B surface antigen (HBsAg)^[21].

Regarding estimation of HBV residual transfusion transmission risk, Candotti *et al*^[1] in their recent review clarified that HBV DNA yield appears directly related not only to the analytical sensitivity and serum pool size used for the HBV NAT assay, but also to the analytical sensitivity of the HBsAg test used for screening and to the general HBV prevalence in the donor population. They further added that HBV NAT yields reported from countries with low, moderate, and high HBsAg prevalence range between 1:4000 and 1:730000^[52,64-69], 1:4000 and 1:20300^[70-74], and 1:192 and 1:5200^[51,75-80], respectively^[1].

Role of Anti S

It is believed that occult HBV carriers without detectable

antibodies to the surface antigen could be infectious^[45]. Indeed, Candotti *et al*^[11] emphasized that the presence of anti-HBs following natural infection, vaccination, or passive immunoprophylaxis prevents *de novo* HBV infection in transplanted patients receiving anti-HBc positive livers^[81-84]. Experiments in chimpanzees showed no HBV infection in animals transfused with blood from three anti-HBs positive human plasma samples, despite exposure to an HBV DNA dose known to be infectious in the absence of anti-HBs^[85]. However, it has been reported by many authors that among individuals positive for anti-HBs, 0.5%-15% still tested positive for serum HBV DNA, though at a very low titer^[3,86]. Countries such as Germany, Austria and Japan allow transfusion of units with anti-HBs titers higher than 100 IU/L^[87].

CLINICAL SIGNIFICANCE

Continuous progress in molecular biology techniques has led to greater recognition and diagnosis of OBI. It has been reported in healthy blood donors, patients with chronic liver disease and patients with hepatocellular carcinoma (HCC)^[21], in viral reactivation following immunosuppression, accidental transmission through transplantation, transfusion or experimental transmission to chimpanzees^[42]. Therapy should be considered during reactivation and in cirrhotic settings^[25].

As illustrated by Shi *et al*^[88], a dynamic balance between viral replication and host immune response is pivotal to the pathogenesis of liver disease. Most HBV infections are spontaneously resolved in immunocompetent adults, whereas they become chronic in most neonates and infants who are at great risk of developing complications such as cirrhosis, chronic liver disease (CLD) and HCC. Those with chronic HBV infection may present in one of the four phases of infection: immune tolerance, immune clearance (HBeAg-positive chronic hepatitis B), inactive carrier state, and reactivation (HBeAg-negative chronic hepatitis B)^[88].

OBI is a complex biological entity with possible relevant clinical implications, mainly related to the intrahepatic persistence of viral covalently closed circular DNA (cccDNA) and to a strong suppression of viral replication and gene expression^[13]. Detection of virus-specific nucleic acid does not always translate into infectivity, and the occurrence of primer-generated HBV DNA that is of partial genomic length in immunocompetent individuals who have significant levels of anti-HBs may not be biologically relevant^[21]. Several authors concluded that as a general rule, immune individuals who have recovered from acute hepatitis B have no clinical evidence of liver disease despite the detection of traces of HBV DNA in their blood, PBMC and/or liver decades later^[20,21,23,26].

Cross-sectional studies across the spectrum of HBV infection have revealed a marked increase in OBI prevalence towards patients with cirrhosis or HCC^[25,42,89]. However, data collected in Poland indicated that approximately 50% of OBIs occur in asymptomatic, apparently healthy

blood donors carrying anti-HBs^[70]. Levels of DNA and anti-HBs are variable^[90].

OBI infectivity by transfusion

It is well known, and recently confirmed by Candotti *et al*^[11], that the estimated residual risk of HBV transfusion transmission remains significantly higher than the risk of either HIV-1 or HCV. Whether residual risk estimates translate into true rate of infection is largely unknown since estimates are generally based on the simplification that all HBV DNA-containing donations are infectious^[11].

All forms have been shown to be infectious in immunocompromised individuals, such as organ- or bone marrow-transplant recipients. In immunocompetent recipients, there is no evidence that anti-HBs-containing components (even at low titer) are infectious. Anti-HBc only, with HBV DNA, can be associated with infectivity, as can rare cases of HBV DNA without any serological HBV marker^[14].

HBV transmission was previously reported from OBI donors who had circulating HBV DNA at a low level^[74,91,92]. However, as reported by Candotti *et al*^[11], in some cases units from WP and OBI donors were not infectious even though viral load ranging between < 20 and > 500 IU/mL (< 100 and > 2500 geq/mL) was transfused^[86,91,93]. These authors emphasized that the lack of a clear relationship between infectivity and viral load in blood components may be related to immune factors affecting the susceptibility to infection in recipients. In addition, HBV infectivity is related to the amount of plasma transfused and the viral load in the product^[11].

Few data regarding the infectivity of blood components or donated organs containing both anti-HBc and anti-HBs are available. Theoretically, if HBV particles are present in the peripheral blood of subjects with high-titer anti-HBs, the anti-HBs may neutralize the infectivity of the viral particles^[3]. Nevertheless, an OBI carrier with anti-HBs was found to have transmitted HBV to two immunocompetent transfusion recipients^[90]. Gerlich *et al*^[94] reported five donors (4 genotype D, one genotype A2) with OBI, also carrying only anti-HBc, transmitting HBV to recipients. Candotti *et al*^[11] examined the infectivity of HBV-containing blood products according to the immune status of recipients and concluded that: (1) WP and anti-HBs-positive and negative OBI units can transmit HBV; (2) the confirmed HBV transmission rate of WP-derived donations is higher than by occult carriers (81% *versus* 19%) but may be biased by the large number of Japanese cases identified, with a peculiar set of anti-HBc and DNA screening protocols^[91]; (3) viral transmission can be associated with extremely low levels of HBV DNA in anti-HBc-positive only units (< 20 IU/mL) or blood collected during the very early phase of acute infection (eclipse phase) in which neither HBsAg nor HBV DNA is detectable^[86,95]; (4) HBV DNA load is similar in infectious and non-infectious anti-HBc-positive donations, suggesting that viral load is not the only factor for infectivity; and (5) the presence of anti-HBs seems to largely protect from transmission^[91,94], except in rare cases^[1,90].

No transmission of HBV has ever been demonstrated in blood donors who developed anti-HBc and anti-HBs following acute hepatitis B^[24]. Satake *et al*^[91] in Japan found that no HBV infections occurred in 22 recipients of HBsAg-negative, HBV DNA-positive blood that contained anti-HBs compared to 10 HBV infections that occurred among 37 recipients (27%) of OHB units that were devoid of anti-HBs^[21].

OBI in blood donors

It is generally admitted that pre-seroconversion WP infections are most likely to transmit HBV but transmission from occult HBV infection remains a debated subject^[11]. Occult HBV is transmissible through blood transfusion in HBV-naïve recipients^[96]. Post-transfusion hepatitis B virus (HBV) infection still occurs, although its incidence has been found to be substantially reduced since the introduction of screening for HBsAg in blood donors^[97]. A similar study was recently conducted in India and showed that a considerable number of HBV-infected donors remain undetected, if only HBsAg is used for screening^[98].

Occult HBV in blood donors has a wide range of potential origin within the natural history of the infection. It may originate from previous infections with development of anti-HBs, but be accompanied by persistent, low-level, viral replication and/or escape mutants undetected by the HBsAg assays or healthy chronic carriage. The latter situation is mostly found with anti-HBc only. Over time, antibody markers may become undetectable leaving HBV DNA as the only marker of the infection^[15].

A European study conducted by Candotti *et al*^[31] confirmed that 91% of 77 donor samples of European origin were HBV DNA-positive/HBsAg-negative. Viral load ranged between unquantifiable and 5640 IU/mL (median 25 IU/mL).

A recent study conducted in Taiwan showed that in HBV hyperendemic areas, occult hepatitis B transfusion might not lead to HBsAg carriage or post-transfusion hepatitis. The risk of transfusion-transmitted HBV infection was probably lower than that in non-endemic areas because most recipients had already experienced HBV infection^[96]. Infection of vaccinated individuals favors development of OBI, as was observed in 6 blood donors. HB vaccination may solve the problem of overt HBV infection but may favor OBI^[19].

Addition of anti-HBc testing for donor screening, although leading to rejection of a large number of donor units, will definitely eliminate HBV-infected donations and help in reducing HBV transmission with its potential consequences, especially among the immunocompromised population^[98].

OBI blood donors have very low HBV replication, and normal liver biochemistry and histology, conferring a favorable prognosis^[99].

Donations carrying anti-HBc only and HBV DNA can be infectious and this is a threat where anti-HBc is not screened. Anti-HBc screening identifies most OBI but not all. HBV NAT needs either extreme sensitivity or to be performed on individual donations to eliminate HBV

DNA-containing units^[15]. Reduction of HBV residual risk depends upon developing more sensitive HBsAg tests, adopting anti-HBc screening when appropriate, and implementing HBV NAT, either in minipools or more efficiently in individual samples^[1].

Liu *et al*^[3] emphasized that anti-HBc screening has the potential to exclude the vast majority of OHBs, leaving only the probably rare cases with HBV DNA alone undetected. This approach, however, has two main drawbacks: it does not detect the seronegative WP infections; and most importantly, it would not be practical in most parts of the world where the prevalence of anti-HBc is > 10%, as too many otherwise healthy donors will be ineligible^[3].

The transmission risk of OBIs is not well defined, although some cases of OBIs with anti-HBc only which were infectious by transfusion have been described^[91,94]. HBV transmission by blood components from a single anti-HBs-positive OBI donation to two recipients was recognized and it was clearly illustrated that the neutralizing capacity of low-level anti-HBs is limited, reinforcing the validity of considering anti-HBs below 100 IU/L to be poorly protective from infectivity when HBV DNA is present^[90]. Authors further emphasized that even in the presence of higher levels of anti-HBs in a severely immunodeficient recipient, HBV DNA-containing blood might be infectious and the clinical expression severe.

However, as emphasized by Candotti *et al*^[1], iatrogenic sources of infection should be systematically investigated before concluding that HBV-infected blood donors are involved in viral transmission^[22,100,101]. They further added that adequate donor follow-up and laboratory testing have to be performed, and more importantly, pre- and post-transfusion testing of recipients has to be completed^[1]. Definitive evidence of transfusion transmission can be obtained by genomic analysis of the viral strains present in both donor and recipient^[1]. In addition, sequencing, which might be informative, becomes very difficult to perform at levels of viremia below 200 IU/mL^[7]. Limited but convincing evidence that OBIs can be infectious and can be detected by HBV DNA screening should be carefully considered by the health authorities of countries where neither anti-HBc nor HBV NAT are implemented^[90].

Occult infection may have impact in several different clinical situations. Extensive studies have evaluated the risk of acquiring OBI in several clinical entities including the following.

OBI and chronic liver diseases

The long-lasting persistence of the virus in the liver may provoke a very mild but continuing necro-inflammation that (if other causes of liver damage coexist) may contribute over time to the progression of the chronic liver damage towards cirrhosis^[13].

In studying the situation of OBI and HCV coinfection, Hollinger *et al*^[21] reviewed several cross-sectional studies where it was suggested that HBV replication accounts for many of the ALT flares that occur in patients with HCV^[40]. OHB is also known to decrease the

response to interferon therapy when employed in patients with chronic hepatitis C^[102] and to accelerate the progression of cirrhosis, hepatic decompensation and HCC^[40,103]. A strong association was noted between the presence of OHB in 204 patients with chronic hepatitis C and the development of HCC when compared to HCV mono-infected patients^[21,104].

Chemin *et al*^[42] previously put forward the theory that estimating the percentage of OBI among non-A-E hepatitis cases depends on several parameters including: (1) the method of detection, including PCR primer selection; (2) patient recruitment; (3) patients from countries highly endemic for HBV are more likely to develop occult HBV infections; and (4) prevalence may also vary depending on the nature of biological material tested, with a higher proportion for liver compared to serum specimen^[42].

Occult hepatitis B and fulminant hepatic failure

The state of suppression of viral replication and gene expression may be discontinued when an immunosuppressive status occurs, leading to typical hepatitis B with severe - and sometimes fulminant-course^[13,105]. Gerlich *et al*^[19] studied 5 blood donors with OBI and 55 of their recipients. In 22 recipients, transmission was probable, but they remained healthy. However, in 3 recipients, who were immunosuppressed at the time of transfusion, fatal fulminant hepatitis B developed. The majority of anti-HBc-positive healthy individuals have HBV DNA in the liver which may start replication under severe immunosuppression.

Occult hepatitis B and hepatocellular carcinoma

OBI is supposed to be an important risk factor for HCC development since it maintains the pro-oncogenic properties typical of the overt infection^[13]. It has been suggested that the occult viral strains, maintaining the transcriptional activity and the pro-oncogenic assets of the clear HBV infection (HBsAg+), may harbor a potential risk for liver cancer development^[8]. A recent study conducted in Japan confirmed the existence of serum HBV DNA in OBI as a predictor of a high hepatocellular carcinogenesis rate in a cohort of patients with non-B, non-C cirrhosis. Eighty-two consecutive Japanese patients with cirrhosis, who showed negative HBsAg and negative anti-hepatitis C virus, were observed for a median of 5.8 years. The carcinogenesis rates in the patients of the positive HBV DNA group and negative DNA group were 27.0% and 11.8% at the end of the 5th year, and 100% and 17.6% at the 10th year, respectively ($P = 0.0078$)^[106]. The mechanisms leading to HCC in OBI seem similar to those in overt HBV-infected patients with low-grade but diagnosable HBV replication that retains its pro-oncogenic properties^[13,42].

Occult hepatitis B infection and immune suppression

Patients with an OBI undergoing immunosuppression are at risk of HBV reactivation. As emphasized by Allain^[7], the severity of the immunosuppression and its duration play a considerable role in triggering reactivation of HBV infection. Reactivation during relatively mild and

short immunosuppression for homologous bone marrow transplantation or solid tumor chemotherapy elicits lower frequency of reactivation than more severe regimens such as employed in allogeneic bone marrow or organ transplantation^[7]. The reactivation of OBI in hematological malignancies (< 5%), although at a lower rate than that of HBsAg-positive cases, carries a significant risk of mortality and morbidity^[107], which is much higher in the setting of stem cell transplantation^[108].

Occult HBV infection harbors potential risk of HBV transmission through hemodialysis. A recent study conducted in Italy showed that occult HBV infection is frequent among hemodialysis patients, particularly correlated to the presence of isolated anti-HBcAg and anti-HCV antibodies. The authors recommended that the presence of isolated anti-HBcAg should prompt the clinician to evaluate a possible occult HBV infection, especially if anti-HCV antibodies are also detectable^[109].

Furthermore, another recent Iranian study assessed OBI in 289 hemodialysis patients with isolated hepatitis B core antibody (18 subjects). HBV DNA was detected quantitatively in 9 of 18 patients (50%) where plasma HBV DNA load was less than 50 IU/mL^[110]. Meanwhile, a recent study conducted in Brazil found that OBI was not observed in hemodialysis patients and immunosuppression in HIV-positive patients was not a determining factor for occult HBV infection^[111].

On the other hand, Demir *et al*^[112] showed that the prevalence of occult HBV infection is higher in diabetics compared with healthy controls, which may contribute to the increased prevalence of primary HCC in diabetics^[112].

OBI and organ transplantation

OBI often leads to HBV transmission and subsequent infection during organ transplantation^[21]. In studying occult HBV infection in HBsAg-negative patients undergoing liver transplantation, Ghisetti *et al*^[113] found that OBI is not associated with increased episodes of acute rejection, coinfection with hepatotropic viruses, different responses to HBV vaccination, or the development of *de novo* hepatitis B. In OBI, a particular virus-host interaction can explain the low intrahepatic HBV content and the lack of extrahepatic HBV replication, thus justifying the low risk of hepatitis B reactivation, in absence of specific prophylaxis, once the recipient liver is removed^[113]. On the other hand, Hollinger *et al*^[21] emphasized that liver transplant recipients with serological evidence of past infection with hepatitis B (anti-HBc-positive) may have reactivation of OHB under immunosuppression in the post-transplant period^[21]. A recent systematic review by Cholongitas *et al*^[114] covering the last 15 years, identified 39 studies including 903 recipients of anti-HBc-positive liver grafts. They found that liver grafts from anti-HBc-positive donors can be safely used, preferentially in HBsAg-positive or anti-HBc/anti-HBs-positive recipients. HBsAg-negative recipients should receive prophylaxis with lamivudine, while both anti-HBc- and anti-HBs-positive recipients may need no prophylaxis at all^[114].

Transmission of HBV after kidney and heart transpla-

ntation from an anti-HBc-reactive donor occurs at a much lower rate^[21]. A study in the USA which included 1067 cadaveric kidneys, 38 of them from HBsAg(-)/HBcAb(+) donors, showed that recipients of kidneys from HBsAg(-)/HBcAb(+) donors are at a small risk of hepatitis B seroconversion and are at no excess risk of graft failure or short-term morbidity or mortality^[115]. This low viral transmission risk was also confirmed in transplantation of hearts from donors with hepatitis-B core antibodies^[116].

Currently, the critical issue in transfusion safety is to identify blood or tissue donors with OHB, and then to block this transmission route. Liu *et al*^[3] concluded that the strategy to prevent transmission of HBV by OHB carriers will be different in endemic and nonendemic areas; in low-endemic areas it is still a subject of debate whether anti-HBc screening should be implemented^[117]. Whether ID-NAT would eventually be able to replace HBsAg or anti-HBc testing also remains to be studied^[3]. On the other hand, in HBV endemic areas, the priority is to examine the prevalence of OHB in blood donors on a large scale, and so establish the cost-effectiveness of implementing sensitive ID-HBV NAT blood screening technology in order to reduce the risk of HBV transmission^[3].

PREVALENCE OF OCCULT HEPATITIS B

The prevalence of occult HBV is unclear and depends in part on the sensitivity of the HBsAg and DNA assays used as well as the prevalence of HBV infection in the study population^[117]. OHB varies significantly between different geographical regions^[11]. Studies have shown that the prevalence of occult HBV infection is closely related to the endemicity of HBV infection^[118,119]. Patients from countries highly endemic for HBV are more likely to develop occult HBV infections^[42]. As in highly endemic countries, the majority of infections are contracted perinatally or in early childhood; a higher proportion of the infected adults have late chronic HBV with undetectable HBsAg. This may account for the higher rate of OHB in anti-HBc-positive populations in these areas^[3]. Prevalence may also vary depending on the nature of biological material tested, with a higher proportion for liver compared to serum specimens^[42].

Occult HBV infection has been reported in 0.1%-2.4% of HBsAg-negative, anti-HBc-positive (\pm anti-HBs) blood donors in Western countries such as the United States, where only 5% of the population has prior exposure to HBV, and in up to 6% of a similar cohort of donors who reside in endemic areas where 70%-90% of the population has been exposed to HBV^[11,21]. When anti-HBc only data is evaluated, the rates range from 0% to 15% (median of 1.1%)^[11]. In this regard, our recent unpublished data show that OBI is present among 15% of HBsAg-negative, anti-HBc-positive (\pm anti-HBs) healthy blood donors in an area of intermediate prevalence for HBV.

CONCLUSION

OBI is defined as the presence of HBV DNA in liver/

serum with undetectable HBsAg. Advanced progress in molecular biology techniques helps in early detection of OBI and paves the way for implementing a detecting strategy to eliminate post-transfusion occult HBV infection, with consideration for the immune status of blood recipients. Evidence is accumulating supporting the prevalence of OBI among blood donors and in CLD patients. However, current data emphasize the low prevalence of OBI, implying a low impact on transfusion services. Detection of HBV DNA does not always indicate infectivity. Available data encourage testing for OBI in HCV-infected patients, in patients under immunosuppression, in people with unexplained liver diseases and in blood units for immunocompromised recipients where proper recruitment and selection of donors are highly recommended. Further work is needed to clarify the clinical significance of OBI, infectivity, possible transmission and its pathogenic consequences, reactivation and progression to chronic liver disease or hepatocellular carcinoma.

Abstract

Perianal lesions are common in patients with Crohn's disease, and display aggressive behavior in some cases. An accurate diagnosis is necessary for the optimal management of perianal lesions. Treatment of perianal Crohn's disease includes medical and/or surgical options. Recent discoveries in the pathogenesis of this disease have led to advances in medical and surgical therapy with good results. Perianal lesions in Crohn's disease remain a challenging aspect for both gastroenterologists and surgeons and lead to a greatly impaired quality of life for all patients affected by this disease. A multidisciplinary approach is mandatory to obtain the best results.

INTRODUCTION

Perianal lesions are common in patients with Crohn's disease (CD); these may consist of anal skin tags, hemorrhoids, anal fissures and ulcers, anorectal strictures, perianal fistulas and abscesses, rectovaginal fistulas or ultimately carcinoma^[1].

In the literature, the incidence of perianal inflammation in patients with CD ranges from 25% to 80%^[2]. Risk factors for the development of disabling disease in CD patients are an initial need for steroids, an age below 40 years, and the presence of perianal disease^[3]. Perianal lesions show a more aggressive CD phenotype, especially if perianal disease is present at the initial diagnosis^[3-5].

In approximately 10% of patients perianal fistulization is the initial manifestation, usually preceding the diagnosis by several years^[6]; less than 5% of patients have perianal disease as a unique manifestation of disease^[7]. In a population-based study of fistulizing CD the incidence of perianal fistulas was 26%^[8]. Perianal fistulizing CD should be considered as a distinct disease phenotype from luminal fistulizing disease, and it has a greater association with colonic and upper gastrointestinal rather than small bowel disease^[9].

The pathogenesis of perianal fistulas, despite the prevalence of fistulas in CD, is poorly understood. There are 2 theories: the first suggests that fistulas begin as deep penetrating ulcers, and the second that fistulas result from an anal gland abscess^[10]; but it is believed that the etiology of perianal CD involves microbiological, genetic (susceptibil-

ity locus on chromosome 5) and immunological factors^[11]. This could explain the aggressive and chronic behavior of perianal lesions.

CYTOKINES

The success of antibodies towards tumor necrosis factor (TNF)- α has led to recent studies investigating other cytokines in perianal CD. In one study^[12], the serum levels of TNF- α , interleukin (IL)-12, IL-1 β , and IL-6 were analyzed in 12 patients with chronic perianal CD and a CD activity index (CDAI) score < 150 to exclude active intestinal disease, in 7 patients with indeterminate colitis (IC) after restorative proctocolectomy with perianal complications, in 7 patients with active intestinal CD without perianal manifestations, and in 19 healthy controls. Serum TNF- α levels were significantly higher in patients with IC than perianal CD patients and healthy controls. Serum TNF- α levels significantly correlated with perianal CDAI score and with the presence of anal fistulas. Serum IL-12 levels correlated with the presence of anal strictures and were similar in all groups. Serum IL-6 levels were significantly higher in the presence of perianal fistulas and lower in the presence of anal strictures. This study found that the efficacy of anti-IL-12 antibodies appeared doubtful in chronic perianal CD or IC without anal strictures while the role of IL-6 as a systemic mediator for active chronic inflammation was confirmed.

In a subsequent study^[13], the cytokine profile was assessed in the rectal mucosa of patients affected by perianal CD in order to understand its relations with the systemic cytokine profile and inflammatory parameters and the need for surgery. Seventeen patients affected by perianal CD, 7 affected by CD without perianal involvement, and 17 healthy controls were enrolled and underwent blood sampling and endoscopy. During endoscopy rectal mucosal samples were taken and the expression of TNF- α , IL-6, IL-1 β , IL-12, and transforming growth factor (TGF)-1 was quantified by enzyme-linked immunosorbent assay. Local cytokine levels were compared and correlated with diagnosis, therapy, phenotype (fistulizing and stenosing), and disease activity parameters. In the group with perianal CD, rectal mucosal IL-1 β , IL-6, and serum IL-6 and TNF- α were higher than in patients with small bowel CD and healthy controls. IL-12 and TGF-1 mucosal levels did not show any differences among the 3 groups. Mucosal IL-6 significantly correlated with the perianal disease activity index (PDAI) and mucosal TNF- α and IL-1. Mucosal TNF- α and IL-1 β showed a direct correlation with the histological grade of disease activity. Furthermore, mucosal levels of IL-6 and IL-12 seemed to be predictors of recurrence and of need for surgery in perianal CD patients.

Further prospective and randomized studies are necessary to evaluate the use of these cytokines in this complex disease.

CLASSIFICATION

In 1998, the Vienna classification categorized CD phe-

notypes, considering age at onset, location and behavior^[14], but only in the Montreal modification (2005) of this classification was perianal disease added as a subclassification of behavior; perianal fistulizing disease is not necessarily associated with intestinal fistulizing disease, and it was felt that perianal disease alone required separate subclassification^[15].

At the present time, there are different classification systems for perianal CD, but no one has achieved a widespread agreement. In 1976 Parks *et al*^[16] proposed a classification of perianal fistulas that uses the external sphincter as a landmark, describing 5 types: inter-sphincteric, trans-sphincteric, supra-sphincteric, extra-sphincteric, and superficial. However, the value of this classification is limited because it does not consider the connection with other organs such as the bladder or the vagina. In 1978, Hughes proposed the Cardiff classification, an anatomic and pathologic classification in which each major manifestation of perianal CD (ulceration, fistula and stricture) is graded on a 2-point scale. This classification has never been globally accepted because it is considered of limited clinical relevance and difficult to use in daily practice^[17,18]. In 2003, the American Gastroenterological Association (AGA) technical review^[1] proposed an empiric approach that included: physical examination of the perianal area, endoscopic evaluation and a classification of fistulas as simple or complex: simple fistulas are low (superficial, low inter-sphincteric or low intra-sphincteric origin) with a single external opening and are not associated with perianal abscess, rectal stenosis or macroscopic proctitis and have no connection to the vagina or bladder; complex fistulas are high (high inter-sphincteric, high trans-sphincteric, supra-sphincteric or extra-sphincteric origin) and may have several external openings associated with perianal abscess, rectovaginal fistula, anorectal stenosis or macroscopic proctitis.

In 1995, Irvine described an index to evaluate perianal disease morbidity in CD patients, the PDAI, comprised of 5 categories: presence of fistula discharge, pain, restriction of daily activity, restriction of sexual activity, type of perianal disease, and degree of induration. Each category is graded on a 5-point scale, ranging from no symptoms to severe symptoms. It is widely used but it has never been compared with a reference standard^[19,20]. Another method proposed to measure perianal disease activity is the Fistula Drainage Assessment: the presence of purulent drainage from the cutaneous opening after compression is considered an index of activity, but it does not consider the morbidity of the patient and the association with an abscess^[20].

DIAGNOSIS

An accurate diagnosis is necessary for the optimal management of perianal lesions. Recently, the goal of treatment has changed from symptomatic improvement to cessation of drainage or even fistula healing. Therefore, the priority of diagnostic tools is to define the anatomy and the number of the fistulas, their complexity, and complicating features such as abscess and anal stenosis^[6].

Besides physical examination (findings of skin tags, ulcers, fissures, abscesses, fistulas or anorectal stenoses), there are several other diagnostic modalities. Endoscopic examination is important to identify macroscopic inflammation or stenosis in the rectum; furthermore AGA and the European Crohn's and Colitis Organization (ECCO) agreed on the need to complete the study of perianal disease with other diagnostic methods such as examination under anesthesia (EUA), magnetic resonance imaging (MRI) and endoscopic ultrasound (EUS)^[21].

EUA is considered the gold standard for assessing fistulas; it has an accuracy of up to 90 for diagnosis and classification of fistulas and abscesses^[22]. At the same time, it is possible to perform several surgical procedures to treat fistulas. However, as suggested by one author, anesthesia can produce a loss of tone and could compromise precise identification of underlying muscles^[23]. MRI, an expensive modality, has an accuracy of between 76% and 100% and, combined with EUA, can obtain additional information in 15%-21% of patients; in contrast, EUS, known to be operator-dependent, has a diagnostic accuracy of between 56% and 100% and its findings can alter the surgical approach in 10%-15% of cases^[21]. When any 2 modalities are combined, the accuracy is 100%, suggesting that EUA in combination with either EUS or pelvic MRI is the best approach for evaluating and classifying perianal fistulas^[22]. The diagnostic accuracy of conventional fistulography and computed tomography (CT) does not exceed 50%-60%, which is considered too low to be clinically useful^[1]. Even though fistulography was the first technique used to assess perianal fistula, nowadays it is rarely performed because of several weak points: extensions from the primary track may fail, the sphincter muscles are not directly imaged, the levator plane cannot be visualized, and there is dissemination of septic fistula contents and discomfort for patients^[6,21]. Since CT exposes patients to not inconsiderable amounts of ionizing radiation, it may only be used for the diagnosis of fistulas associated with pelvic abscesses if other techniques are unavailable or cannot be tolerated^[23,24].

THERAPY

Treatment of perianal CD includes medical and/or surgical options. The primary aim is to heal perianal lesions, but in many cases, because of the aggressiveness of the disease, the physician's role is to relieve symptoms and treat complications of the disease to improve the patients' quality of life. The percentage of spontaneous healing for perianal fistulas is very low, ranging from 6% to 13% in the placebo arm of 2 controlled studies^[25,26].

MEDICAL THERAPY

Drugs with definite or potential efficacy for treating perianal CD include antibiotics (metronidazole and ciprofloxacin), immunosuppressors (azathioprine and 6-mercaptopurine), calcineurin inhibitors (cyclosporine and tacrolimus) and biologic agents (infliximab, adalimumab and certolizumab)^[1,6].

Antibiotics

Antibiotics are used as first-line treatment for fistula healing, and also for abscesses and infection associated with fistulas. Despite the widespread use of antibiotics for the treatment of perianal CD, there is a lack of controlled studies in the literature and usually data consist of small sample size trials^[27,28]. In these studies, the clinical response generally occurs after 6 to 8 wk, as a decreased drainage, while fistula closure is uncommon and symptoms may recur after the end of treatment. Recently, Thia *et al.*^[29] performed a randomized, double-blind, placebo-controlled trial to evaluate ciprofloxacin and metronidazole for the treatment of perianal CD, concluding that remission and response occurred more frequently in patients treated with ciprofloxacin, but the difference between the treatment arms was not significant. The limit of this study was probably the small sample size. Antibiotics are also used as a bridge to immunosuppressive therapy with azathioprine. In a prospective open-label trial, the use of metronidazole and/or ciprofloxacin at week 8 induced fistula closure in 25% of cases^[30]. At week 20, patients treated with additional azathioprine had a better mid-term response (48% *vs* 15%). Antibiotics can be also used as an adjuvant to other drugs. In a recent placebo-controlled study, all patients received infliximab and were randomized to receive either 500 mg ciprofloxacin twice daily or a placebo for 12 wk. The response at week 18 showed a better result of ciprofloxacin in combination with infliximab compared to infliximab alone^[31]. Recently, in a randomized controlled study^[32], 74 patients with perianal CD received 0.7 g 10% metronidazole ointment or placebo ointment applied perianally 3 times daily. Metronidazole ointment was not effective in reducing the perianal DCAI score, but some secondary outcomes showed improvement, suggestive of a treatment effect and it was well tolerated, with minimal adverse effects.

Immunosuppressants

Azathioprine and 6-mercaptopurine are immunosuppressive agents that, as demonstrated in the literature, successfully treat intestinal CD inflammation^[33]. A meta-analysis of 5 randomized controlled studies, in which the closure of various fistulas was considered, showed a complete closure or decreased drainage in 54% of the patients treated with azathioprine or 6-mercaptopurine compared with 21% in the placebo group^[34]. However, in this meta-analysis the fistula response was a secondary endpoint in all of the studies considered and at the moment there are no controlled trials in which fistula closure is the primary endpoint. Azathioprine or 6-mercaptopurine could be used as a second-line treatment in patients in whom immediate surgery is not mandatory, and when other pharmacological treatments have already been initiated^[6].

Cyclosporine selectively blocks T-helper and cytotoxic lymphocytes through the inhibition of the transcription of IL-2. Several uncontrolled case series reported the use of intravenous cyclosporine in perianal CD patients resistant to traditional therapy, but the initial response was rapidly lost on drug withdrawal^[35]. The effects of tacrolimus,

which has a similar mechanism, on fistulizing CD have been evaluated in a randomized, double-blind, placebo-controlled, multicenter study: 43% of the tacrolimus-treated patients had fistula improvement compared with only 8% of the placebo group; however fistula remission was comparable in the 2 groups^[36]. More studies are warranted and at the moment the use of cyclosporine and tacrolimus for treatment of fistulizing CD is not recommended^[6].

Methotrexate is used as a third-line therapeutic agent for CD patients intolerant to azathioprine and 6-mercaptopurine. No prospective studies have investigated its use for the treatment of fistulizing CD; however, in a retrospective study, 44% of patients treated with methotrexate had partial or complete fistula closure after 6 mo^[37].

Studies evaluating therapies such as sargramostim (a granulocyte-macrophage colony-stimulating factor), mycophenolate mofetil (an antimetabolite agent) and thalidomide concluded that these could be considered as potential treatments for perianal CD^[38-40].

Biologic therapy

The use of anti-TNF- α agents has changed the approach to CD, especially in patients with severe and refractory disease; in fact TNF- α is believed to play a key role in the pathogenesis of this disease^[41].

Infliximab is a murine/human chimeric monoclonal antibody directed toward soluble and membrane-bound TNF- α ^[42]. There are 2 randomized, double-blind, placebo-controlled trials that demonstrated the efficacy of infliximab in fistulizing CD^[25,43]. Present *et al*^[30] assessed infliximab induction therapy and reported that 3 infusions of infliximab, 5 or 10 mg/kg, at weeks 0, 2, and 6 resulted in complete perianal fistula closure in 46% of patients. The median length of time the fistula remained closed was 12 wk, and the response rate was higher with the 5 mg/kg dose. The ACCENT II (Adjuvant Colon Cancer End Points) study evaluated infliximab as maintenance therapy with 5 mg/kg infliximab at weeks 0, 2 and 6^[43]. Of those patients, 64% had a response to therapy at weeks 10 and 14. At week 14, responders were randomized to receive placebo or infliximab 5 mg/kg every 8 wk for 54 wk. The time to loss of response was 40 wk in the infliximab maintenance group *versus* 14 wk in the placebo group. Cessation of drainage at week 54 was maintained in 36% of the patients in the infliximab group compared with 19% of the placebo group. The regime proven to be efficacious in clinical studies comprises induction therapy with 5 mg/kg infliximab at weeks 0, 2 and 6; maintenance therapy can then be continued at 5 mg/kg every 8 wk and the dose may be increased to 10 mg/kg if loss of response is seen at the lower dose. Adverse events of infliximab include infusion reactions, an increased rate of infections, delayed hypersensitivity reactions, formation of antibodies to infliximab, formation of anti-double-stranded DNA antibodies and drug-induced lupus^[1].

Adalimumab is a fully humanized monoclonal antibody directed toward TNF- α and has proven effectiveness and efficacy in CD^[44]. Its effects have been evaluated in 2

randomized, double-blind, placebo controlled, short-term (4 wk) induction trials. In the CLASSIC-1 trial (Clinical Assessment of Adalimumab Safety and Efficacy Studied as an Induction Therapy in Crohn's Disease), adalimumab was administered at 2 different doses during weeks 0 and 2; instead in the GAIN study (Gauging Adalimumab Efficacy in Infliximab Nonresponders), adalimumab was administered at a high dose and all participants were intolerant to infliximab or had experienced loss of response during week 4 of treatment^[45]. In both studies, fistula closure was not significantly higher in patients treated with adalimumab compared with placebo. In the CHARM (Crohn's Trial of the Fully Human Antibody Adalimumab for Remission Maintenance) study, adalimumab was associated with an increased fistula closure compared with placebo. Closure of all fistulas that were draining at baseline was achieved in 30%-33% of adalimumab-treated patients compared with 13% of placebo-treated patients^[46]. CD patients, including those with a fistula, should receive an induction dose of adalimumab (160 mg in the USA and 80 mg in Europe), with a second dose (80 mg in the USA and 40 mg in Europe) during week 2; the recommended maintenance dose in both the USA and Europe is 40 mg every other week, beginning at week 4 and the dose frequency can be increased to once weekly if there is no response^[6].

Two randomized, double-blind, placebo-controlled trials that investigated the efficacy of certolizumab on fistula closure, for comparison with infliximab and adalimumab^[47], were not sufficiently powered^[48,49], and its effects require further study. Ng *et al*^[50] evaluated CD perianal fistula closure after anti-TNF- α using MRI: even though fistulas appeared clinically healed, MRI demonstrated the persistence of the fistulous tracks as already demonstrated by previous studies^[51]; so MRI fistula resolution could be useful to determine the duration of anti-TNF- α therapy.

A recent Japanese study investigated the effects of adsorptive carbon in fistulizing CD patients^[52]. Thirty-seven percent of patients treated with an oral adsorptive carbon agent (AST-120) showed an improvement compared to 10% of the placebo group; the former group also had a significantly lower rate of remission (29.6% *vs* 6.7%). Probably adsorptive carbon reverses abnormalities in the luminal environment and gut microflora. In the ECCO consensus statement antibiotics and azathioprine or 6-mercaptopurine are considered the first-line therapy in complex perianal disease, and infliximab or adalimumab are reserved as a second-line treatment in case of failure^[53]. In the AGA technical review infliximab is recommended for the treatment of complex perianal disease along with azathioprine or 6-mercaptopurine and antibiotics for the induction phase^[1]. Maintenance is recommended with azathioprine or 6-mercaptopurine, and just in some cases in association with infliximab.

Surgical therapy

In the literature the incidence of perianal CD fistulas that require surgery ranges from 25% to 30%^[54,55]. The primary goal of surgery is fistula healing and avoidance of sphinc-

ter damage. Patients with superficial or low perianal fistulas without proctitis can be treated by fistulotomy, which has reported healing rates of up to 85%^[56,57]. Surgical treatment of complex perianal fistulizing disease requires abscess drainage and usually placement of non-cutting setons^[58] before biologic therapy. Setons can be removed after 3 mo in the presence of fistula healing or can remain if the healing process has not been established. However, patients who were assessed 10 years after placement of a seton showed that complete healing was obtained in only 20% of patients^[59]. Fistulectomy or fistulotomy are rarely indicated in complex fistulas because of the high rate of subsequent proctectomy due to closure failure or incontinence caused by the transection of both anal sphincters^[53,58]. Endorectal flaps are useful when there are severe cases of high fistulas^[58,60]. An advancement flap consists of incising a flap of tissue (mucosa, submucosa, circular muscle) around the internal opening of a fistula, excising the internal opening of the fistula tract, and pulling the flap down to cover the opening^[61].

Makowiec *et al.*^[62] reported an initial healing rate of 89% in patients treated with an advancement-flap procedure, but fistulas recurred in 34% of cases during follow-up. If a second flap fails, the failure rate of subsequent flaps increases up to 75% and a temporary stoma might be necessary^[63]. In patients with severe refractory disease, fecal diversion (loop ileostomy or end colostomy) is necessary and has an early response rate of 70%-80%^[64,65]. Quality of life in symptomatic patients is rapidly improved by fecal diversion^[53]. A recent study showed that patients with complicated perianal CD, colonic involvement, and a high rate of abdominal procedures carried a significant risk for a permanent stoma; the incidence of patients requiring a permanent stoma was 31%^[66]. In another series of 86 patients with perianal CD disease, 49% of patients finally required permanent fecal diversion^[67]. In the literature, proctocolectomy is necessary in only 18% of patients^[66].

Primary closure after extended resection can be limited by scar tissue and healing can be impaired by contamination and immunosuppressive medication. Thus, myocutaneous flaps such as the gracilis and the distally based rectus abdominis muscle are used to repair perineal and vaginal defects that are too big to be closed directly.

The use of myocutaneous flaps are well described after proctectomy for cancer and there are only a few reports focusing on CD patients undergoing proctocolectomy and primary closure with myocutaneous flaps^[68-70]. Schaden *et al.*^[69] concluded that a combined proctocolectomy and a perineal single-stage myocutaneous flap closure technique can reduce recovery time, obtain complete healing and improve patients' quality of life.

The treatment of rectovaginal fistulas in CD patients remains challenging. Rectovaginal fistulas seem to be a negative prognostic indicator for successful anti-TNF- α therapy^[71]. In a study evaluating a series of 52 CD patients undergoing surgery for a rectovaginal fistula the outcome of surgery and the effect of anti-TNF therapy on healing were assessed^[72]. Fistula closure was achieved in 81% of patients. Primary and secondary surgical suc-

cess rates were 56% and 57% respectively. The primary healing rate was similar in patients who received anti-TNF treatment before the first operation (12 of 18 patients) and those who did not (19 of 34). In univariate analysis, duration of CD and previous extended colonic resection were significantly related to failure of primary surgery, but only the latter remained significant in multivariate analysis. The authors concluded that fistula closure was achieved in most patients, but more than one operation was often required.

A recent systematic review was performed including 11 observational studies with a total of 219 flap procedures for rectovaginal fistulas in CD^[73]. The pooled primary fistula closure rate was 54.2% after rectal advancement flaps and 69.4% after vaginal advancement flaps. Four studies were eligible for direct comparison between the 2 procedures. Although limited by the small number of studies at a low clinical evidence level, no significant difference in terms of outcome between rectal and vaginal advancement flaps was observed. The risk of recurrence after rectal advancement flaps compared with vaginal advancement flaps also seemed similar.

New therapies

New therapies include laser and adhesive treatment. In an uncontrolled study in perianal CD patients carbon dioxide laser ablation is considered an alternative treatment^[74]. The injection of fibrin glue into fistulas is a simple and safe procedure^[75]. The first series studies regarding this treatment reported good healing rates (52%-60%), while recent trials have not achieved the same success^[76].

Fibrin glue variants include human granulocyte colony-stimulating factor^[77] and autologous mesenchymal adult stem cells. Adult stem cells are obtained from adipose tissue with liposuction and initial studies have shown a complete response in 75% of perianal CD patients with complex fistulas^[78,79].

More recently bioprosthetic plugs, incorporating porcine intestinal submucosa, have been used in the treatment of patients with anal fistulas^[80], but in a retrospective review the use of anal fistula plugs was associated with a lower success rate (15%) than previously reported^[81]. Finally, there are other local therapies which are under development. Tacrolimus is a macrolide compound isolated from *Streptomyces tsukubaensis*. Hart *et al.*^[82], in a randomized, double-blind, placebo-controlled trial showed that, although complete healing was not observed, improvement occurred rapidly, but there was no clear clinical indication that tacrolimus was helpful for fistulizing disease. Topical tacrolimus may have a role in patients who do not respond to infliximab. Similarly, infliximab^[83,84], and more recently adalimumab^[85], injected directly into the fistula seem to result in healing in some patients resistant to systemic therapy; the rationale of this approach is to avoid systemic toxicity.

CONCLUSION

Perianal lesions in CD remain a challenge for both gas-

troenterologists and surgeons and they lead to a greatly impaired quality of life for all affected patients. A multidisciplinary approach is mandatory to obtain the best results.

RESULTS: Use of the chicken (β -actin) promoter proved superior for both the production and maintenance of doxycycline-inducible cell lines. The system proved versatile, enabling transient inducible expression of a variety of genes, including GST-P, CYP2E1, S100A6, and the actin capping protein, CapG. To determine the physiological utility of this system in pancreatic cancer cells, stable inducible CapG expressors were established. Overexpressed CapG was localised to the cytoplasm and the nuclear membrane, but was not observed in the nucleus. High CapG levels were associated with enhanced motility, but not with changes to the cell cycle, or cellular proliferation. In CapG-overexpressing cells, the levels and phosphorylation status of other actin-modulating proteins (Cofilin and Ezrin/Radixin) were not altered. However, preliminary analyses suggest that the levels of other cellular proteins, such as ornithine aminotransferase and enolase, are altered upon CapG induction.

CONCLUSION: We have generated pancreatic-cancer derived cell lines in which gene expression is fully controllable.

Abstract

AIM: To establish stable tetracycline-inducible pancreatic cancer cell lines.

METHODS: Suit-2, MiaPaca-2, and Panc-1 cells were transfected with a second generation reverse tetracycline-controlled transactivator protein (rtTA2S-M2), under the control of either a *cytomegalovirus* (CMV) or a chicken β -actin promoter, and the resulting clones were characterised.

INTRODUCTION

The ability to precisely control the levels of specific proteins in cells, either positively through overexpression, or negatively through siRNA-mediated depletion, provides an invaluable opportunity to examine their function. The most widely used technique for stringently controlling gene expression levels is the tetracycline-regulated system, originally proposed by Gossen and Bujard^[1]. Using this approach, cells are transfected with a plasmid encoding a tetracycline-controlled transactivator protein (tTA), and subsequently transfected with a plasmid carrying a gene of interest that has a tetracycline response element (TRE) in its 5' regulatory region. The addition of a tetracycline derivative, doxycycline (dox) to the cell culture medium prevents the tTA from binding to the TRE, thus inactivating the system (tet-off).

The tet system has undergone several improvements since it was first introduced. One improvement is the creation of a reverse tTA (rtTA), which can bind to the TRE in the presence of dox (Tet-on), obviating the need for the continuous presence of dox in the cell culture medium^[2-4]. Further improvements came with the introduction of the second generation rtTA, termed rtTA2s-M2^[5], which enhanced the transactivation potential and reduced the affinity for the TRE in the absence of dox. This overcame the problem of leakiness; low level gene expression in the absence of dox, sometimes observed with the earlier generation tTA^[5]. The system continues to be modified for new applications in cell lines^[6,7] and in animals^[8].

For certain cell types, such as pancreatic cancer cells, there are remarkably few reports of dox-inducible cells^[9,10]. This reflects the difficulty in obtaining such cell lines, and efficient methods for generating them are required. In this study, we attempted to derive dox-inducible pancreatic cancer cell lines, using vectors expressing rtTA2S-M2 under the control of either a viral (CMV) promoter^[5] or a chicken (β -actin) promoter^[11]. Using the resulting tet-inducible system, we went on to generate pancreatic cancer cells stably overexpressing CapG, an actin capping protein, which was previously shown to be upregulated in pancreatic ductal adenocarcinoma^[12]. CapG is activated by calcium and caps actin filaments, a function that is inhibited by membrane polyphosphoinositides^[13]. Depletion of CapG from a variety of pancreatic cancer cell lines has been associated with decreased cell motility and wound healing capacity^[12]. The dox-inducible overexpression of CapG enabled further characterisation of its role in pancreatic cancer cells, and exemplified the utility of this model system in studying the role of specific genes in pancreatic cancer cells.

MATERIALS AND METHODS

Construction of vectors

Two Tet-on plasmids were used in this study. The rtTA2S-M2^[5], which contains a viral CMV promoter driving the tet-transactivator rtTA2S-M2 (denoted here as CMV-

rtTA2S-M2), was a kind gift from Professor W Hillen, University of Heidelberg. The pN1 β actin-rtTA2S-M2-IRES-EGFP^[11], in which the CMV promoter has been replaced with a strong chicken β -actin promoter, was a kind gift from Dr. A Welman, Paterson Institute for Cancer Research, Manchester. The full-length CapG coding sequence was amplified using a forward primer 5'-AGAACGCGT-CAGCATGTACACAGCCAATTC-3', which includes an Mlu I restriction site, highlighted in bold, and a reverse 5'-AGAGCGGCCCGCCACCCTCATTTCAGTCCT-3' containing a Not I restriction site, in bold. The full size CapG amplicon was inserted directionally into the pTRE-2hyg vector (Clontech, Saint-Germain-en-Laye, France) using the Mlu I and Not I restriction sites. The full-length S100A6 sequence was amplified using the following forward 5'-TCAGCCCTTGAGGGCTTCAT-3' and reverse 5'-ATGGCATGCCCCCTGGATCA-3' primers. The amplicon was ligated into the EcoRV restricted pTRE2hyg vector. Vector inserts were verified by sequencing (Eurofins MWG Operon, London, UK) and aligned using the Basic Local Alignment Search Tool (Blast). pTRE2hygGST-P, containing the full length coding sequence of human glutathione S-transferase P (GST-P), and pTRE2hygCYP2E1, containing the full-length coding sequence of cytochrome P-450 2E1, were described previously^[14].

Cell culture

Pancreatic cancer cells, Suit-2, Panc-1, and MiaPaca-2 cells were maintained in RPMI-1640 medium supplemented with 10% foetal bovine serum, 10 mmol/L L-glutamine, 100 units/mL penicillin, and 100 μ g/mL streptomycin (Sigma-Aldrich, Gillingham, UK). Growth media for cell lines stably expressing the rtTA protein was supplemented with 50 μ g/mL G418 sulphate (Invitrogen, Paisley, UK). The media for the transgenic cell lines stably transfected with the inducible CapG was supplemented with 100 μ g/mL hygromycin B (Sigma-Aldrich, Gillingham, UK). Cells were maintained at 37°C and 5% CO₂. For the induction of CapG protein expression in clones harbouring stable inducible CapG, cells were cultured for 24 h with antibiotic-free medium, and for an additional 24 h with or without 500 ng/mL dox (Sigma-Aldrich, Gillingham, UK) in RPMI-1640 media, supplemented with 10 % FBS and L-Glutamine.

Cell transfection

Cells were transfected using Lipofectamine 2000 (Invitrogen, Paisley, UK) at a 1:3 DNA: lipofectamine ratio, following the manufacturer's protocol. Briefly, cells were plated at a density of 3×10^6 per 10 cm² dish and grown for 24 h, placed in serum- and antibiotic-free medium and transfected with 5 μ g of CMV-rtTA2S-M2 or 20 μ g pN1 β actin-rtTA2S-M2-IRES-EGFP or with pTRE2hygCapG (5 μ g or 20 μ g). Cells were selected for integration of rtTA2S-M2 coding sequences by treating with G418 (300 μ g/mL; Invitrogen, Paisley, UK) for two weeks. Single colonies were separated into 96-well

plates, and positive clones identified using a luciferase assay (described below), expanded, and cryopreserved. Stable CapG-inducible cell populations were selected by incubation with hygromycin B (200 µg/mL). After two weeks, single colonies were separated into 96-well plates, cultured until confluence, and subsequently transferred to 24- and 6-well plates, respectively. Tet-on CapG-overexpressing clones were identified by Western Blotting for CapG, using dox as an inducer (see below). The transient transfection of the tetracycline responsive vectors pTRE-2hygGST-P, pTRE2hygCYP2E1, and pTRE2hygS100A6 was undertaken as described above, and 24 h later expression was induced using 500 ng/mL dox in PBS. PBS alone was used as a vehicle control. Twenty-four hours following doxycycline induction, cells were lysed, and evidence of induction of protein expression was assessed using Western blotting, as described below.

Luciferase assay

To test CMV-rtTA2S-M2 or pN1βactin-rtTA2S-M2-IRES-EGFP-transfected clones for dox inducibility, cells were seeded into 96-well plates and transfected with 50 ng pTRE2hygluc vector (Clontech, Saint-Germain-en-Laye, France) using a 1:3 DNA: Lipofectamine ratio. Twenty-four hours later, clones were treated with 500 ng/mL dox in PBS or with PBS only as a control and incubated for 24 h. Cells were harvested in 50 µL 1 × Glo Lysis buffer (Promega, Southampton, UK) and assayed for luciferase activity according to the manufacturer's instructions, using a plate reader (PerkinElmer, Bucks, UK). Each clone was assayed in triplicate and experiments were repeated at least three times. Data were analysed statistically using Student's two-tailed paired *t*-test.

Western blotting

Cells were lysed in SDS lysis buffer (0.1 mol/L Tris/HCl pH 6.8, 2% SDS) containing protease inhibitor (Roche Diagnostics Ltd., Burgess Hill, UK). For separation into cytoplasmic and nuclear fractionations, the NE-PER Nuclear and Cytoplasmic Extraction Reagents (Thermo Fisher Scientific, Rockford, IL, USA) were used. For analysis of phospho-proteins, cells were lysed in RIPA buffer, supplemented with protease and phosphatase inhibitor (Roche Diagnostics Ltd., Burgess Hill, UK). Protein concentrations were determined using a Bradford assay (Bio-Rad, Hemel Hempstead, UK). For Western blotting, membranes were blocked with 5% milk (Bio-Rad, Hemel Hempstead, UK) in PBS containing 0.1% Tween 20 (PBST) for 1 h at RT. As primary antibodies, polyclonal chicken anti-CapG (1:7000, GenWay Biotech, San Diego, USA), monoclonal mouse anti-β-actin (1:200000, Sigma-Aldrich, Gillingham, UK), rabbit anti-GAPDH (1:400, Santa Cruz Biotechnology, Heidelberg, Germany), monoclonal mouse anti-α-tubulin (1:3000; Sigma Aldrich, Gillingham, UK), monoclonal mouse anti-GST-P (1:2500; Sigma Aldrich, Gillingham, UK), rabbit anti-CYP2E1 (1:2500; Sigma Aldrich, Gillingham, UK) and rabbit anti-S100A6 polyclonal

antibody (1:3000; DAKO UK Ltd., Ely, UK) were used. The primary antibodies were incubated overnight at 4°C with gentle shaking. As secondary antibodies, goat anti rabbit HRP (1:3000, Dako UK Ltd., Ely, UK), goat anti mouse HRP (1:3000, Dako UK Ltd., Ely, UK), or goat anti chicken HRP (1:14000, GenWay Biotech, San Diego, USA) were used. For Cofilin and Ezrin the Actin-Reorganization Kit (Cell Signalling Technology Inc., Danvers, Maryland, USA) was used according to the manufacturer's protocol. Bound horse radish peroxidase was detected using enhanced chemiluminescence western lightning reagent (Perkin-Elmer Life Sciences, Waltham, USA). For quantification purposes, X-ray films were scanned using a GS-800- densitometry scanner (Bio-Rad, Hemel Hempstead, UK) and evaluated using the Quantity One software (Bio-Rad, Hemel Hempstead, UK), or directly developed using a Kodak Gel Logic 1500 imaging station and analysed using Kodak Molecular Imaging software (Carestream Health UK, Hemel Hempstead, UK).

Two-dimensional electrophoresis

The dox-inducible CapG-expressing clones, Sβtet29Cap35, Sβtet29Cap43, and negative control Sβtet29 were incubated for 18 h with or without 500 ng/mL dox and solubilised in lysis buffer (7 mol/L urea, 2 mol/L thiourea, 4% 3-[(3-cholamidopropyl) dimethylammonio]-1-propane sulphonate, 40 mmol/L Tris base and 1% dithiothreitol) by sonication. Extracted proteins (200 µg) were focused on pH 3-10 non-linear strips, 18 cm in length, as described^[15], and then separated on 12% sodium dodecyl sulphate-polyacrylamide gel electrophoresis gels. Gels were stained with colloidal Coomassie Blue. Gel images were scanned using a GS-800 scanner, acquired using PDQuest software (Bio-Rad, Hemel Hempstead, Herts, UK) and analysed using Progenesis Workstation software V2002.1 (NonLinear Dynamics, Newcastle, UK).

MTS proliferation assay

The proliferation of Sβtet29Cap35, Sβtet29Cap43 and control Sβtet29 clones was determined by MTS assay (EZ4U nonradioactive cell proliferation and cytotoxicity assay, Fa. Biomedica, Vienna, Austria) following the manufacturer's protocol. This assay is based on the reduction of the nontoxic yellow tetrazolium salt (450 nm) to an intensively coloured red formazan deriviate (620 nm). Reduction requires functional mitochondria, an indicator of cell viability and cell proliferation. Cells (*n* = 3000) were plated in 100 µL antibiotic free RPMI medium onto 96-well plates. Dox was added at a final concentration of 0 or 500 ng/mL. After 48 h, 100 µL substrate was added to each well, and cells incubated before absorbance readings were measured at 0, 1, 2, 3, and 4 h at 450 and 620 nm in an Multiskan EX plate reader (Thermo Scientific, Basingstoke, UK). Within each experiment, each condition was plated in twelve replicates and experiments were repeated on three independent occasions. Data were analysed statistically using Student's two-tailed paired *t*-test.

Cell cycle analysis

For cell cycle analysis, cells were plated in triplicate 12 h prior to treatment with or without 500 ng/mL doxycycline for an additional 24 h or 72 h. Cells were harvested, washed twice with ice-cold PBS, and fixed with ice-cold 70% ethanol for 1 h. Cells were centrifuged at 1000 r/min for 4 min, and cell pellets washed twice with PBST. Cell pellets were resuspended in PBS containing 100 μ L RNase A (10 mg/mL) and incubated for 5 min at 4°C. Cells were then stained with 900 μ L of a PBS solution containing propidium iodide (55 μ g/mL) and 10 000 cells analysed by flow cytometry.

In vitro wound healing assay

S β tet29Cap35, S β tet29Cap43, and, as the control, S β tet29 cells were plated into 12-well plates at 5×10^6 cells per well and incubated for 24 h with or without 500 ng/mL doxycycline. Wounds were made using a P200 plastic pipette tip and photographed ($t = 0$ h) before being returned to 37°C. Wounds were photographed again eight hours later. The distance migrated by the cell monolayer was measured and the results expressed as a migration index (i.e. the distance migrated by the experimental condition, e.g. dox stimulated CapG inducible cells, divided by the distance migrated by the control treated cells, e.g. dox stimulated control cells). Experiments were performed in triplicate and repeated on three independent occasions. Statistical significance between the different conditions was determined using Student's paired *t*-test, with significance set at $P \leq 0.05$.

In vitro motility assay

Motility assays were performed using 24-well cell culture inserts (modified Boyden chambers, BD Biosciences, Oxford, UK) with 8 μ m pore size. CapG-inducible S β tet29Cap35, S β tet29Cap43, and, as the control, S β tet29 cells were plated in T25 flasks in RPMI media supplemented with 10% FBS and incubated with or without 500 ng/mL dox for 24 h. Cells were counted and 5×10^4 cells were plated into 24-well Boyden chamber inserts in 500 μ L serum-free RPMI medium. The medium in the lower chamber was supplemented with 1% FBS. For cells undergoing dox induction, treatment was continued by supplementing both upper and lower chambers with 500 ng/mL dox. The Boyden chambers were incubated at 37°C, 5% CO₂ for 18 h. Cells that had migrated to the lower side of the transwell insert were fixed and stained using Diff-Quik (Siemens Healthcare Diagnostics, Deerfield, USA) and counted on a Leica CME microscope (Leica, Microsystems UK, Milton Keynes, UK) at $\times 40$ total magnification. All experimental conditions were performed in triplicate with three independent repeats. Experiments were statistically analyzed using paired Student's *t*-test (Stat-View, version 5.0.1, Adept Scientific Plc., Letchworth, UK).

Immunohistochemistry

For immunohistochemistry (IHC), cells were grown on glass chamber slides (LabTek II, Nunc GmbH, Langensfeld, Germany) overnight at 37°C and cultured for

an additional 24 h with or without 500 ng/mL dox. Cells were fixed using acetone which had been equilibrated at -20°C for 10 min and washed with PBST. Cells were permeabilized by incubation with 0.1% Triton X-100 in PBS for 10 min at RT. Peroxidase was blocked by a 3% H₂O₂/methanol treatment for 30 min in the dark. Slides were washed with PBST and unspecific binding blocked by incubation in 1:10 diluted goat serum in PBST for 30 min at RT. The primary antibody, chicken anti CapG antibody (1:1000; GenWay Biotech, San Diego, USA), was incubated in 1% BSA/PBST overnight at 4°C in a humidified chamber. Slides were washed with PBST and incubated with the secondary anti-chicken HRP conjugated (1:1000; GenWay Biotech, San Diego, USA) for 1 h at room temperature in 3% BSA/PBS. The staining was developed with DAB and counterstained with hematoxylin.

RESULTS

Development of dox-inducible pancreatic cells

Pancreatic cancer cells, Suit-2, Panc-1 and MiaPaca-2 were transfected with plasmids CMV-rtTA2S-M2 and pN1 β actin-rtTA2S-M2-IRES-EGFP, in which rtTA2S-M2 expression is under the control of the CMV and β -actin promoters respectively. Cells were selected for resistance to G418. Emergent clones were tested for dox inducibility by transient transfection with a luciferase expression plasmid under the control of a TRE (pTRE2hygluc). Elevated luciferase activity in the presence of dox when compared to the untreated (-dox) control was taken as evidence of expression of the rtTA protein. Of the Suit-2 cells transfected with CMV-rtTA2S-M2, 167 G418-resistant clones were screened, although only three of these clones (29, 85 and 109) showed evidence of statistically significant dox-inducible luciferase activity (Figure 1A, $P < 0.05$, Student's paired *t* test). Of the Suit-2 cells transfected with pN1 β actin-rtTA2S-M2-IRES-EGFP, 49 G418-resistant Suit-2 clones were screened. Nineteen of these clones showed a greater than five-fold dox-inducibility of luciferase activity compared to the untreated (-dox) control. The luciferase measurement for twelve representative clones is shown in Figure 1B. The induction of luciferase was significantly increased in all clones shown ($P < 0.05$, Student's paired *t* test) except for clone 18 ($P < 0.09$).

Stably-transfected Panc-1 (Figure 2A) and MiaPaca-2 (Figure 2B) cell clones harbouring the pN1 β actin-rtTA2S-M2-IRES-EGFP Tet-on plasmid were also identified. Thirteen G418-resistant CMV-rtTA2S-M2 Panc-1 clones emerged; however, none showed evidence of dox-inducible luciferase activity. No G418-resistant CMV-rtTA2S-M2 MiaPaca 2 clones were obtained despite four transfection and selection attempts.

Doxycycline-inducible pancreatic cells are suitable for the induction of a variety of genes

We next wished to determine the versatility of stable dox-inducible pancreatic cells for the expression of a variety of

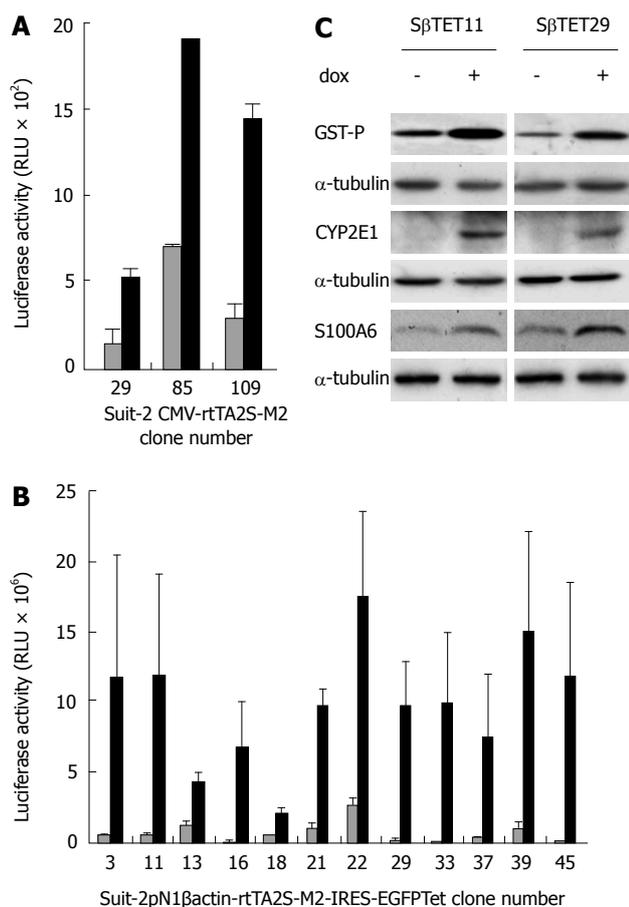

Figure 1 Identification of clones transfected with CMV-rtTA2S-M2 or pN1βactin-rtTA2S-M2-IRES-EGFP-SUIT-2 cell clones. Suit-2 cells were transfected with CMV-rtTA2S-M2 (A) or pN1βactin-rtTA2S-M2-IRES-EGFP (B) and stable clones selected using 300 μg/mL G418. Clones were isolated and transfected with pTRE2hygLuc, used as an indirect measure of rtTA activity. Cells were treated for 24 h with 500 ng/mL doxycycline (black bars) or an equivalent volume of PBS (white bars), and luciferase activity measured in 50 μg protein (1 mg/mL protein; 50 μL was assayed per sample). Error bars represent standard errors for three experiments. C: Cells were transiently transfected with pTRE2hygGST-P, pTRE2hygCYP2E1, and pTRE2hygS100A6 and treated with 500 ng/mL doxycycline or PBS as control for 24 h. Protein lysates were prepared and subjected to Western Blotting using anti-GST-P, CYP2E1 and S100A6 antibodies. α-tubulin was used as a loading control.

heterologous genes. To do this, two pN1βactin-rtTA2S-M2-IRES-EGFP-derived Suit-2 clones (Sβtet11 and Sβtet29), which showed good inducibility, were transiently transfected with plasmids containing the genes for glutathione S transferase P (GST-P), cytochrome P450 2E1 (CYP2E1), and S100A6, each under the control of a TRE. These genes were chosen because of our previous experience of their inducible expression in hepatoma cells (GST-P, CYP2E1)^[14] or because of our interest in them as genes that are overexpressed in pancreatic cancer (S100A6 and CapG)^[12,16,17]. Their inducibility was measured using dox. Western blotting (Figure 1C) revealed that dox treatment of the transiently transfected Sβtet11 and Sβtet29 clones resulted in induction of GST-P, CYP2E1, and S100A6. Two inducible pN1βactin-rtTA2S-M2-IRES-EGFP-derived Panc-1 clones and two pN1βactin-rtTA2S-M2-

IRES-EGFP-derived MiaPaca-2 clones were also evaluated by transient transfection of a plasmid carrying a pTRE-dependent *CapG* gene, and induction of expression with dox. Both Panc-1 and MiaPaca-2 clones showed increases in the CapG protein following dox treatment (Figure 2C).

Development of stable Suit-2 derived pTRE2hygCapG clones

Having observed good transient inducible gene expression, we wished to determine whether stable inducible CapG overexpressing cells could be derived. Transgenic cells stably expressing the inducible form of CapG (pTRE-2hygCapG) were constructed using Suit-2 pN1βactin-rtTA2S-M2-IRES-EGFP derived Tet-on cell clones (Sβtet11 and Sβtet29). Hygromycin B-resistant clones ($n = 49$) were screened for plasmid integration by treating with 500 ng/mL dox for 24 h and measuring CapG protein overexpression by Western blotting. The fold increase in CapG relative to expression of actin is shown in Figure 3A. Six CapG clones (clones 30-35) are shown on a representative Western blot presenting the dox-dependent CapG inducible expression (Figure 3B). From the 49 clones analysed, 20 (40%) showed no change in CapG expression, whereas 22 (44%) showed a 1.5 to 3 fold increase in CapG expression following dox treatment. For eight clones (16%), a greater than three-fold increase in CapG protein level was observed. For a proportion of clones (38%), actin levels appeared to be reproducibly induced following dox treatment/CapG induction. Since CapG is an actin-capping protein, it was decided that subsequent experiments would use alternative internal control proteins, such as tubulin or GAPDH.

Stable pTRE2CapG expressing cells show time- and dose-dependent increases in CapG expression

The time and dose-dependent inducibility of CapG protein expression was investigated. Concentration dependency was examined by inducing CapG overexpression with different concentrations of dox (0-1000 ng/mL) for 36 h (Figure 3C). CapG expression was not induced at low concentrations of dox (1-10 ng/mL), but was induced at concentrations of dox above 50 ng/mL. There was no concentration-dependent increase in the amount of CapG protein induced. For the time course study (Figure 3D) and further experiments, a concentration of 500 ng/mL dox was chosen. An increase in CapG protein level was observed after 12 h of dox treatment and was stable for at least a further 60 h (from 12 to 72 h) (Figure 3D).

Alteration in cellular protein expression associated with CapG overexpression

We next sought to determine whether artificially increasing the levels of CapG would alter the levels or activation status of other actin-modulating proteins, such as Cofilin and Ezrin/Radixin. We found that neither protein was changed in level or in phosphorylation status when CapG levels were increased (Figure 4A and B). This led us to ask

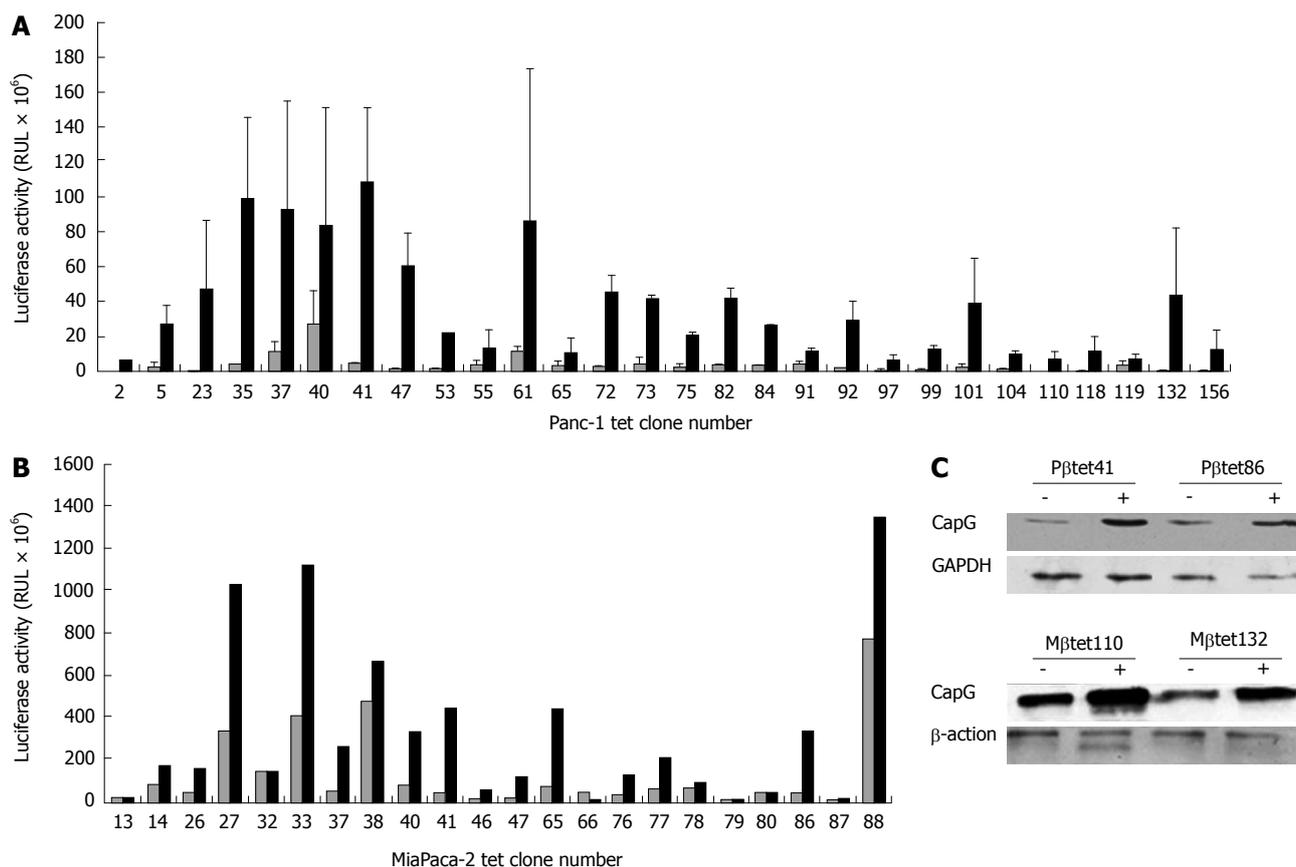

Figure 2 Identification of stable pN1βactin-rTA2S-M2-IRES-EGFP- expressing Panc-1 (A) and MiaPaca (B) cell clones and their functionality (C). Panc-1 and MiaPaca cells were transfected with pN1βactin-rTA2S-M2-IRES-EGFP and stable expressors selected using 300 μg/mL G418. Clones were isolated and transfected with pTRE2hygLuc, used as an indirect measure of rTA activity. Cells were treated for 24 h with 500 ng/mL doxycycline (black bars) or an equivalent volume of PBS (white bars) and luciferase activity measured in 50 μg protein (1 mg/mL protein; 50 μL was assayed per sample). A: 90 G418 resistant clones were isolated from Panc-1 cells, of which 25% showed > 5-fold increase in luciferase activity in the stimulated (black bars in Figure 1) compared to the unstimulated (white bars in Figure 1) condition; B: Of 170 G418-resistant cells identified in MiaPaCa-2 cells, 60% showed > 5-fold increase in luciferase expression; C: Two stable pN1βactin-rTA2S-M2-IRES-EGFP Panc-1 (Pβtet41 and Pβtet86) and MiaPaCa-2 (Mβtet110 and Mβtet132) cell lines were transiently transfected with the pTRE2hygCapG vector and treated for 24 h with or without 500 ng/mL doxycycline. Cell lysates were subjected to Western Blotting for the detection of CapG. β-actin and GAPDH were used as loading controls, respectively. Tet: Tetracycline.

a broader question of whether elevated CapG affected the expression of any cellular proteins. CapG overexpression was analysed by 2D-gel electrophoresis in two stable CapG inducible clones (Sβtet29Cap35 and Sβtet29Cap43), and, as the control, the rTA protein expressing clone from which those two clones were derived (TetSβtet29). An increase in the intensity of a 38 kD protein (Figure 5A) was observed on 2-D gels following dox treatment of Sβtet29Cap35 and Sβtet29Cap43, but in not the control TetSβtet29, indicating that treatment with doxycycline alone is not sufficient to induce the expression of CapG, i.e. the cells must harbour a doxycycline-inducible CapG construct. Matrix-assisted laser desorption/ionization-mass spectrometry (MALDI-MS) confirmed the identity of this protein as CapG (Figure 5B). This finding is consistent with our previously obtained Western blot data (Figure 3). A number of other proteins also differentially expressed in cells induced to express high levels of CapG were also identified by MALDI-MS (Figure 6). HNRPH1, T-complex protein 1 subunit alpha, Adenosylhomocysteinase, and Ornithine aminotransferase were upregulated in CapG overexpressing cells. Conversely, Eno-

lase, P27BBP protein, eukaryotic translation elongation factor 1 beta 2, and human pre-mRNA splicing factor SF2p32 were downregulated in CapG overexpressing cells. As none of these proteins are associated with the cytoskeleton, they were not validated further.

Subcellular localization of capG

The localisation of CapG in the inducible clones Sβtet29Cap35, Sβtet29Cap43 and the control clone Sβtet29 was examined by immunohistochemistry. In untreated (-dox) cells, CapG was expressed homogeneously in the cytoplasm (Figure 7A), and nuclei were devoid of staining. After treatment of cells with doxycycline for 24 h, the intensity of CapG staining (brown colour) increased in the cytoplasm and around the nuclear membrane of Sβtet29Cap35 and Sβtet29Cap43 cells, suggesting CapG overexpression in the cytoplasmic compartment of these cells. As expected, the control clone Sβtet29 did not show any change in staining intensity upon treatment with dox, and no staining was observed in the nucleus. The relative levels of CapG in the cytoplasm and nucleus were quantitatively

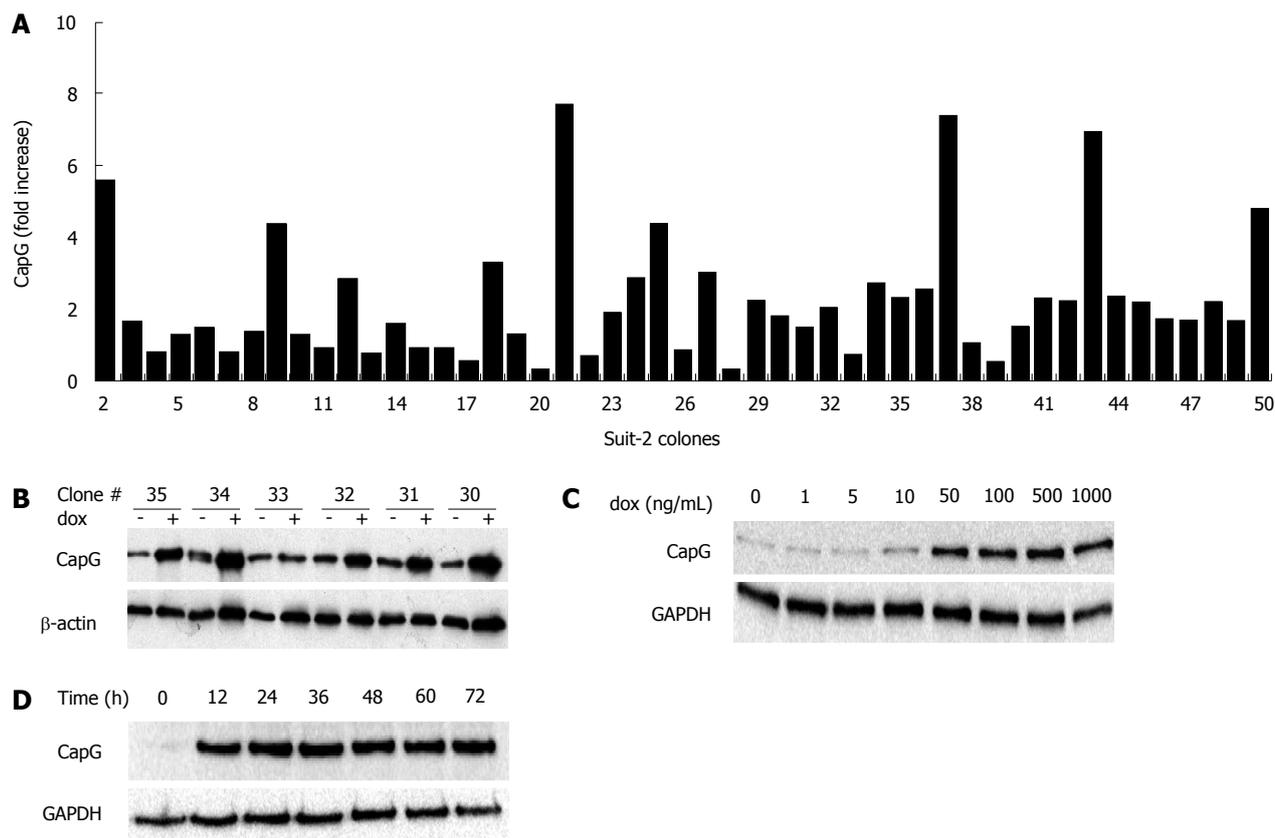

Figure 3 Selection (A, B) and inducibility (C, D) of stably-transfected Sβtet29Cap clones. The stable Sβtet29 clone was transfected with the pTRE2hygCapG full size vector and clones selected with hygromycin B (200 μg/mL). A: Individual clones (*n* = 49) were induced with 500 ng/mL doxycycline for 24 h and the protein lysate subjected to Western blotting. The CapG level was calculated for each individual clone in the non-induced and the induced state. The fold increase (normalised to actin) in CapG for each of the 49 clones is shown in the bar chart; B: A representative Western blotting for CapG is shown for pTRE2hygCapG clones 30 to 35. The indicates the basal CapG expression, + doxycycline (dox) induced; C: The inducibility of CapG protein expression was investigated by treating the Sβtet29Cap35 cells with 0, 1, 5, 10, 50, 100, 500, 1000 ng/mL dox for 24 h. The resulting Western blotting for CapG and GAPDH as a loading control is shown; D: The Western blotting represents the CapG protein level of Sβtet29Cap35 cells, induced with 500 ng/mL doxycycline for 0, 12, 24, 36 and 48 h. GAPDH was used as a loading control.

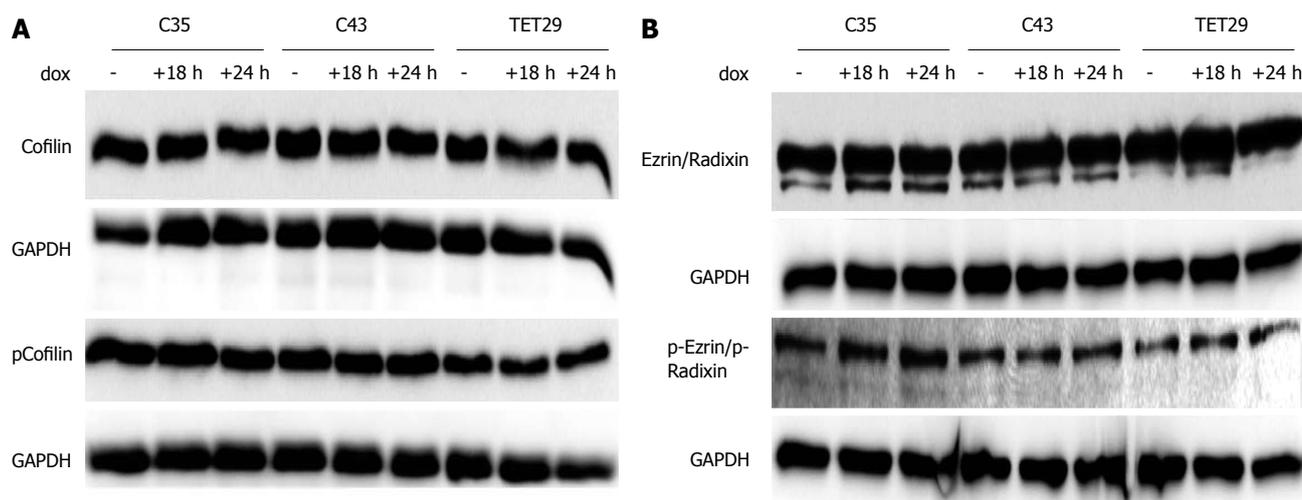

Figure 4 The effects of CapG overexpression on Cofilin and Ezrin/Radixin levels and phosphorylation status. Sβtet29Cap35 (C35), Sβtet29Cap43 (C43) and control Sβtet29 (TET29) cells were incubated with dox (500 ng/mL) for the indicated times and lysates assayed by Western blotting for changes in the levels of Cofilin (A) and Ezrin/Radixin (B) and phospho-Cofilin (A) and phosphor-Ezrin/Radixin (B).

evaluated. The nuclear and cytoplasmic fractions of Sβtet29Cap35 cells were enriched and Western blotting for CapG performed. The levels of CapG in non-

fractionated extracts in the non-induced and induced state are shown Figure 7B, lanes 1 and 2 respectively. Lanes 3, 4 and 5, 6 show nuclear and cytoplasmic CapG levels in

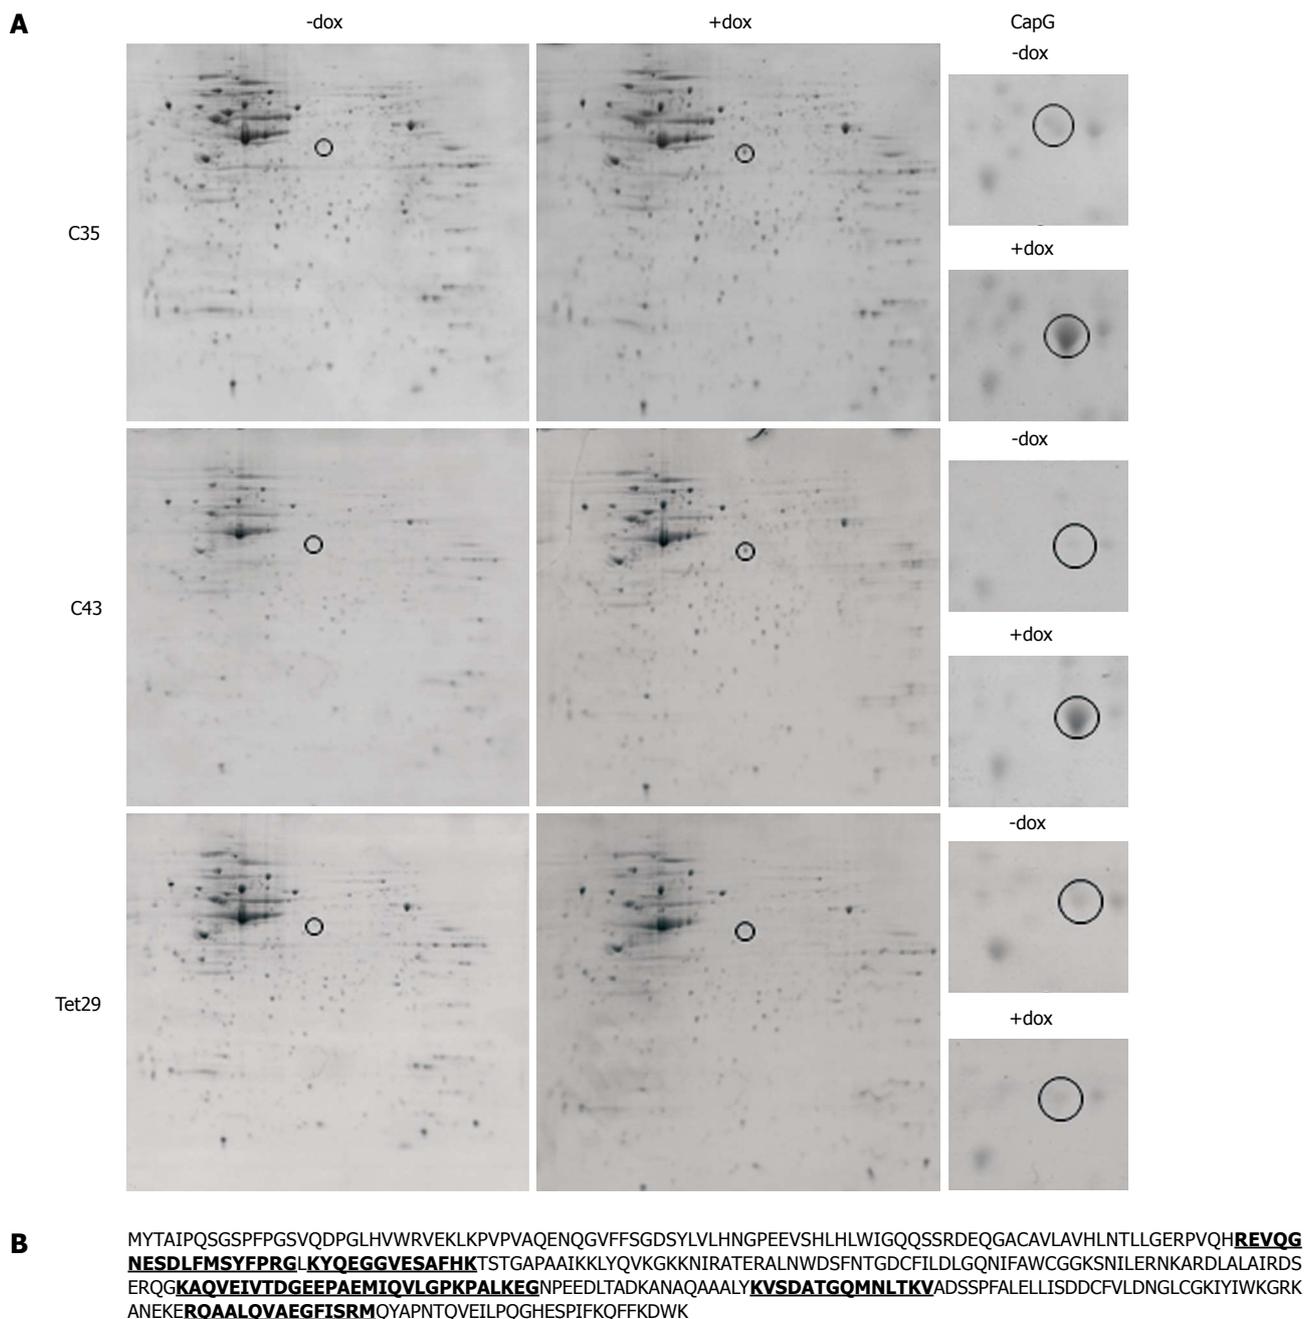

Figure 5 Two-dimensional gel analysis of stable inducible CapG overexpressing cells. A: Colloidal Coomassie Blue stained gels displaying the proteome of Sβtet29Cap35 (C35), Sβtet29Cap43 (C43) and control Sβtet29 (TET29) cells. Cells were lysed in their uninduced state (- dox) and 18 h after treatment with 500 ng/mL doxycycline (+ dox). The area around the spot representing CapG (black circle) was magnified in the right hand column (CapG); B: The spot representing CapG was excised from the gels, trypsin digested, and analysed by MALDI-ToF. The sequence is shown and peptides identified by MALDI are bold and underlined.

the uninduced and induced states respectively. The enrichment of Lamin A is used as a marker of the nuclear fraction and GAPDH as a marker of the cytoplasmic fraction. A low level contamination of the nuclear fraction by the cytoplasmic fraction was observed. CapG protein was found exclusively in the cytoplasmic fraction in the non-induced state (lane 3). Following 24 h treatment with dox, the level of CapG was greatly increased in the cytoplasmic fraction (lane 5), with a very small proportion observed in the nuclear fraction (lane 6). The low level of CapG observed in the nuclear fraction may be due to contamination from the cytoplasmic fraction.

Stable pTRE2CapG cells show no difference in viability, proliferation or cell cycle

The viability of Sβtet29Cap35, Sβtet29Cap43, and Sβtet29 cells was measured 48 h after plating with or without 500 ng/mL dox. The MTS solution was added (*t* = 48 h) and the absorbance measured at 0, 1, 2, 3, and 4 h later. The kinetics for the turnover of the MTS solution was similar in all cell lines, as can be seen by the slope of the lines (0.3577 ± 0.031 , Figure 8A). This indicates that 500 ng/mL dox was not toxic in any of the cell clones, including those in which dox caused induction of CapG (Sβtet29Cap35, Sβtet29Cap43).

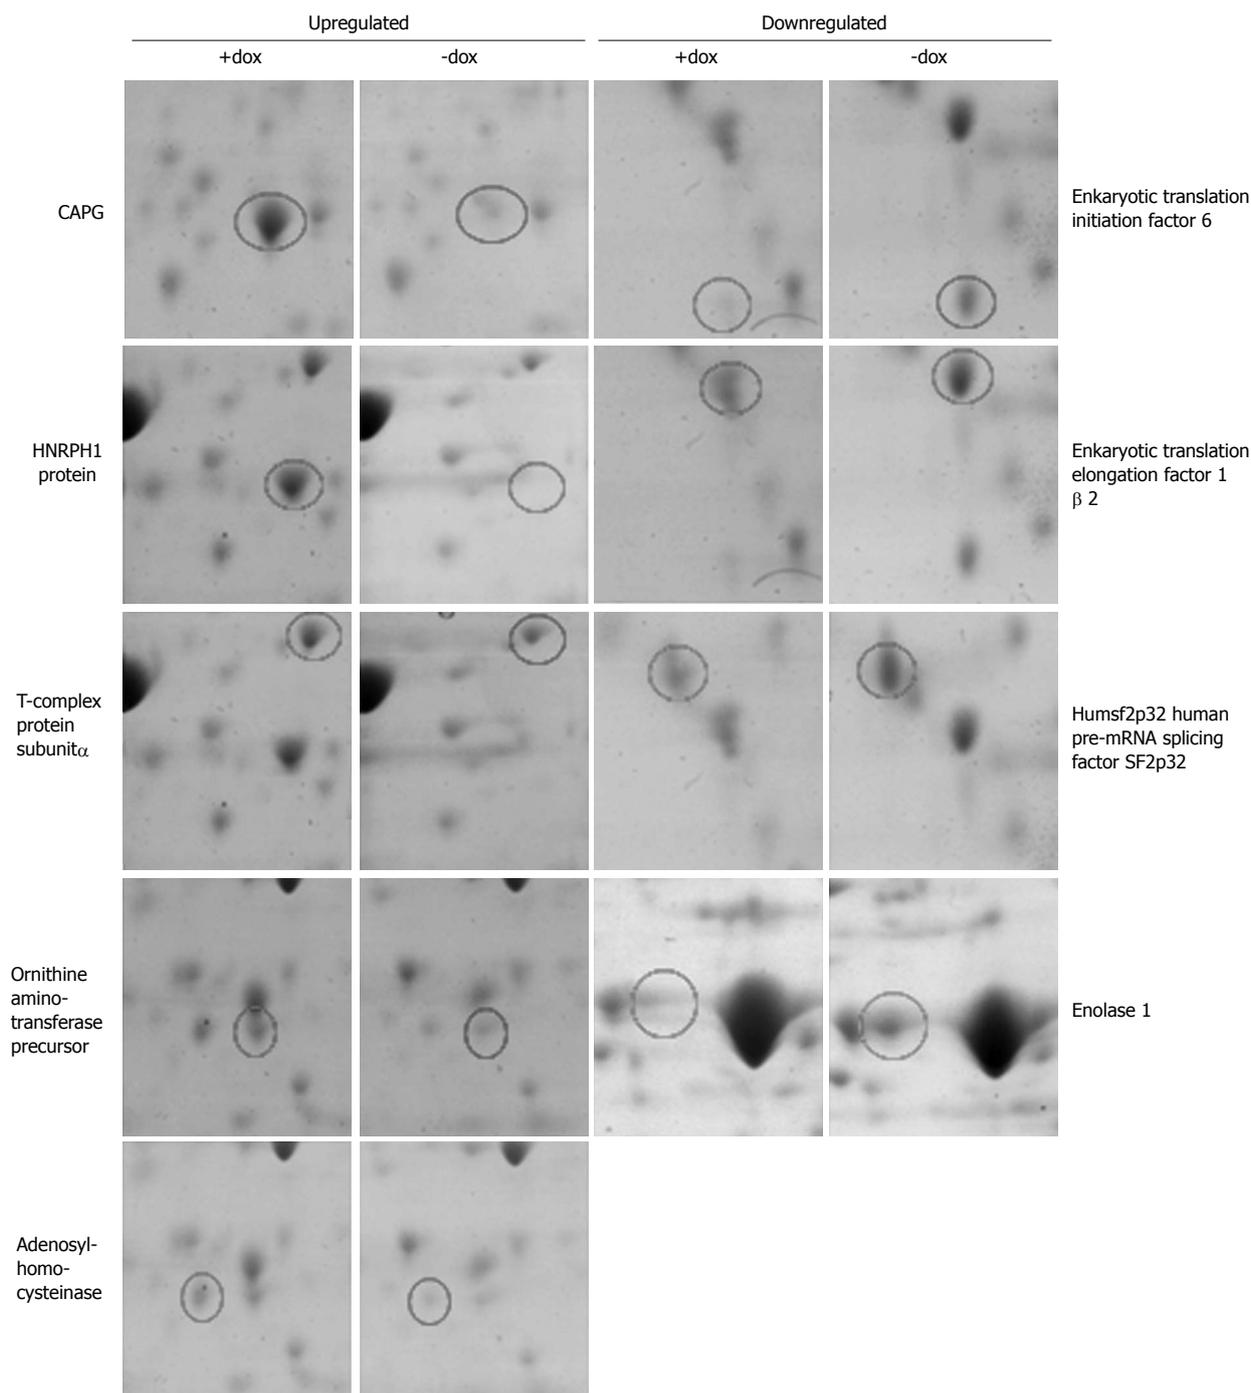

Figure 6 Two-dimensional gel analysis shows up- or downregulation of proteins associated with CapG overexpression. Colloidal Coomassie Blue stained gel insets displaying proteins found to be up- or downregulated in Sβtet29Cap35 (C35), Sβtet29Cap43 (C43) but not in control Sβtet29 (TET29) cells, following treatment for 18 h with 500 ng/mL doxycycline (+dox). Spots were excised from the gels, trypsin digested, and analysed by MALDI-ToF, leading to the identification of proteins.

Cell cycle analysis at 24 and 72 h after dox treatment did not result in any significant change in cell cycle profile. A representative figure showing the cell cycle profile of Sβtet29Cap35 (C35) and the parental cell line Sβtet29 (TET29) cultured for 24 or 72 h with or without 500 ng/mL dox is presented (Figure 8B). The percentage of cells in G1, G2 and S-Phase for all three experiments is summarized in Figure 8C and Table 1. There was a considerable change in cell cycle phases between the two time points

(24 and 72 h), as cells are cultured for 48 h (24 h ± dox) or 96 h (72 h ± dox). There was no difference in the cell cycle phases between the groups cultured with or without dox. This shows that neither dox nor CapG overexpression affected the cell cycle of Suit-2 cells.

CapG overexpression increases Suit-2 wound healing capacity and motility

To investigate the effect of CapG overexpression on cell

| Table 1 Cell cycle analysis (%) | | | | | | |

10000 cells were measured, and the percentage of cells in G1, G2, and S-phase are presented with their error values. The experiment was repeated thrice.

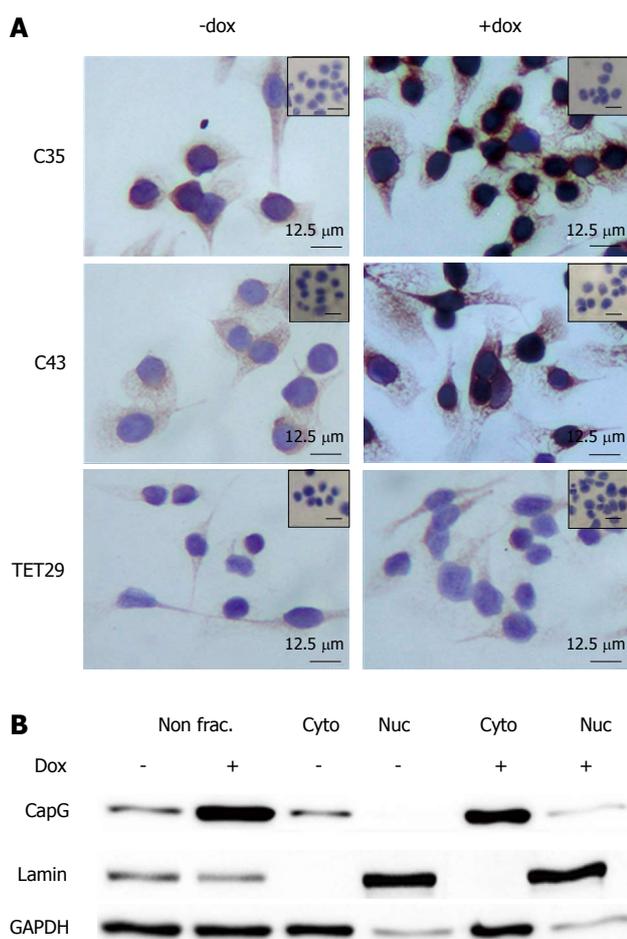

Figure 7 Subcellular localization of CapG in stable CapG inducible clones by immunohistochemistry (A) and subcellular fractionation (B). A: CapG protein expression and localization in Sβtet29Cap35 (C35), Sβtet29Cap43 (C43) and the control Sβtet29 (TET29) cells was analyzed 24 h after treatment with 500 ng/ml doxycycline (+ dox) or PBS as control (- dox). Specific antibody reaction (anti-CapG) was visualized by a peroxidase labelled secondary antibody (DAB detection, brown colour). Nuclei were counterstained with hematoxylin (blue colour). Bars = 12.5 μm. B: Whole protein lysate (non frac.) or enriched nuclear (Nuc) and cytoplasmic (Cyto) fractions of Sβtet29Cap35, Sβtet29Cap43 and the control Sβtet29 clones 24 h after treatment with 500 ng/mL doxycycline (+) or PBS as control (-) were analysed using Western blotting for the detection of CapG, Lamin (marker for nuclear fraction) and GAPDH (marker for cytoplasmic fraction). The experiment was performed three times. A representative Western blot of Sβtet29Cap35 is shown.

motility, wound healing and translocation assays were performed. When CapG was induced following dox treatment, we observed a significant increase in the distance travelled by the Sβtet29Cap35 and Sβtet29Cap43 cell clones. The distance travelled by Sβtet29Cap35 increased by 23% ± 5% and for Sβtet29Cap43 by 35% ± 7%. When treated with dox, the control clone Sβtet29 did not show any change in wound healing capacity (Figure 9A).

In Boyden chamber translocation assays, we observed a significant increase in cell migration by the Sβtet29Cap35 and Sβtet29Cap43 cell clones when CapG was induced following dox treatment (Figure 9B). The capability of Sβtet29Cap35 to cross through the membrane pores increased by 62% ± 10% and for Sβtet29Cap43 cells by 84% ± 16%. The control clone Sβtet29 did not show any change in cell migration capacity when treated with dox (Figure 9B).

DISCUSSION

In this study, we have described the generation and use of a tetracycline-inducible expression system in pancreatic cancer cell lines. Our use of both a CMV and a β-actin promoter-driven second generation reverse tetracycline transactivator protein (the rtTA2S-M2) led us to conclude that the latter was superior in terms of both production and maintenance of dox-inducible cell lines. Although we did not formally investigate mechanisms that might explain this, it is possible that the viral CMV promoter is silenced through methylation, whilst the chicken β-actin promoter remains active^[6].

Recently, Zhang *et al.*^[10], successfully used a commercially available Tet-on system with a CMV-driven tetracycline transactivator protein, in Panc-1 cells. The authors reported dox-induced overexpression of the zinc finger transcription factor INSM1, although the fold increase in INSM1 protein level, as shown by Western blotting, was modest compared to the fold increases observed in the current study. This may reflect differences in the proteins under investigation in the respective studies, although it could be due to enhanced inducibility when using the β actin-rtTA2S-M2-IRES-EGFP vector.

The pancreatic cancer cell lines Suit-2, MiaPaca-2 and

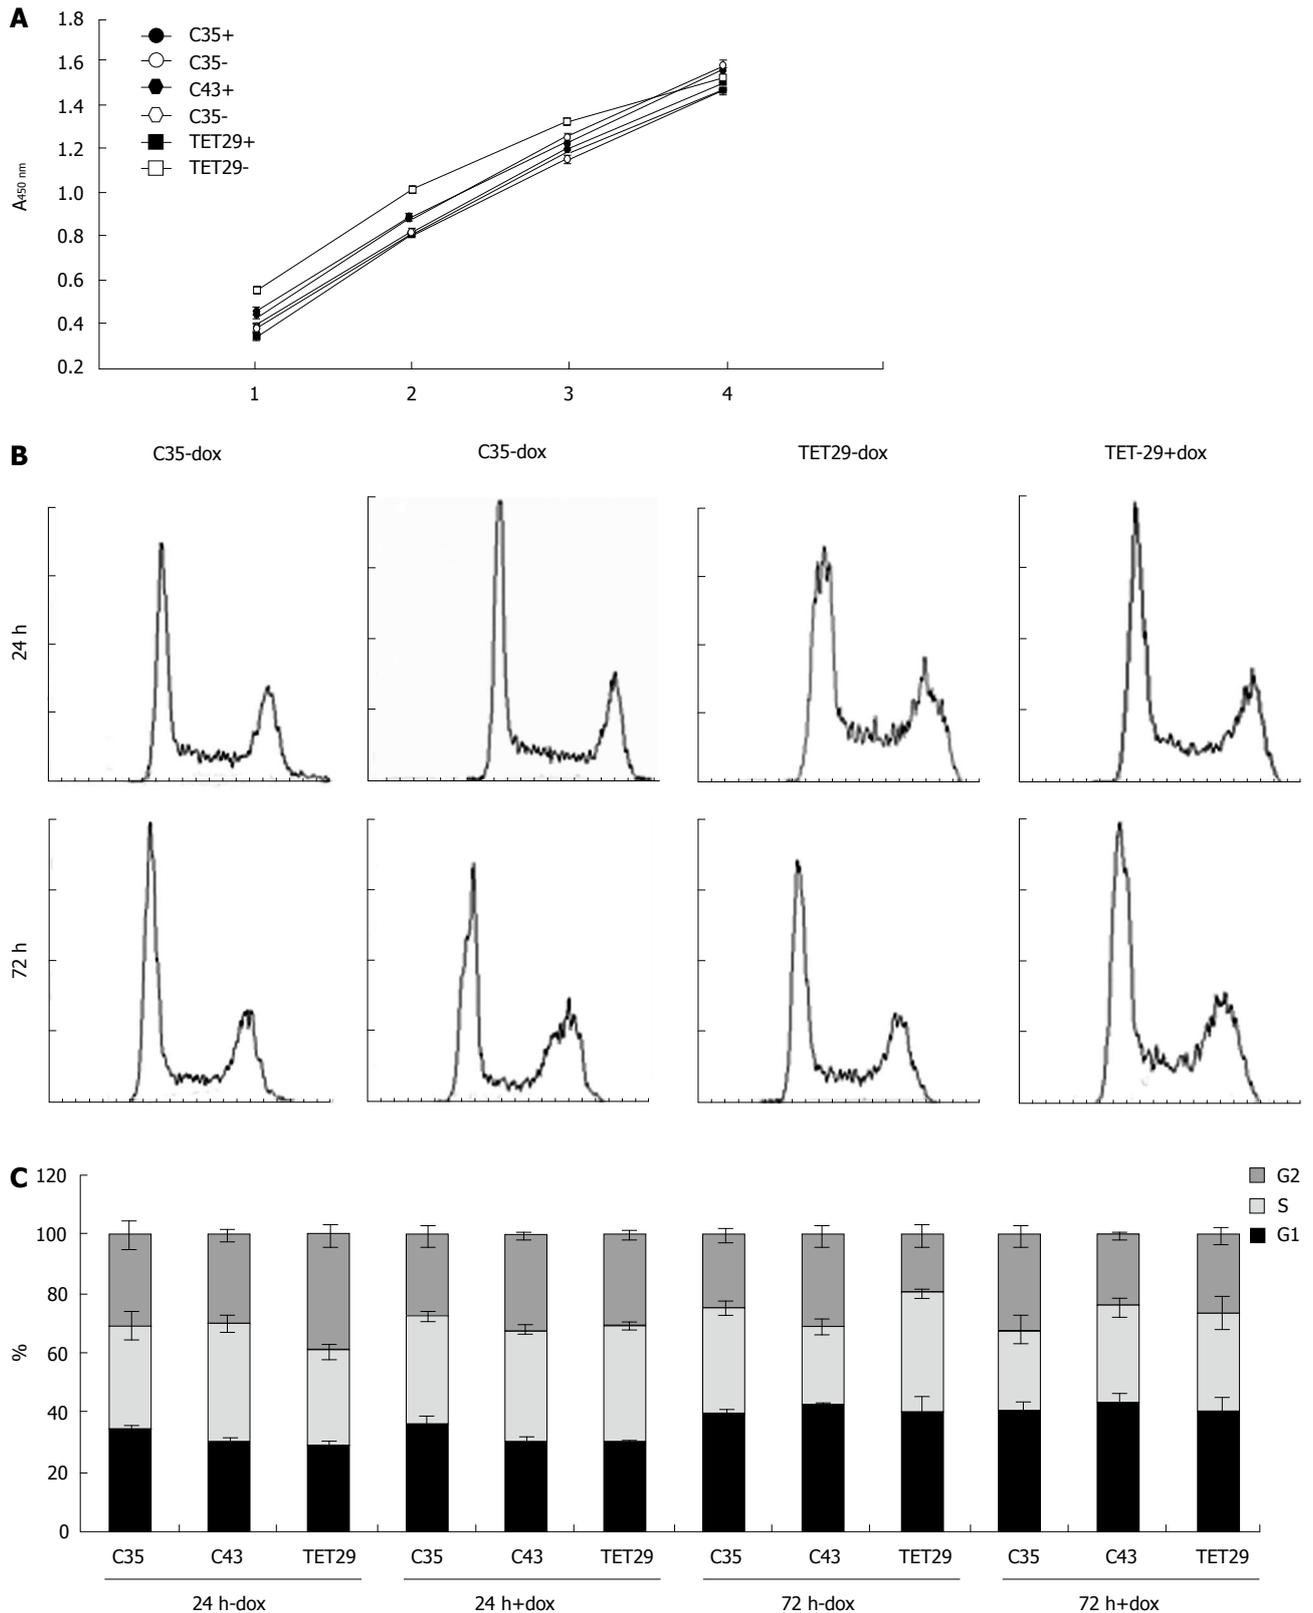

Figure 8 Cell proliferation (MTS-assay) (A) and cell cycle analysis (B) of doxycycline induced CapG overexpressing cells. A: S β tet29Cap35 (C35), S β tet29Cap43 (C43) and the control S β tet29 (TET29) cells were treated with 500 ng/mL doxycycline (+) or PBS as control (-) for 48 h. Mitochondrial activity was measured with the EZ4U assay and absorbance measured 1 h, 2 h, 3 h, and 4 h after substrate incubation. The experiment was performed three times with at least ten replicates; B: S β tet29Cap35 (C35), S β tet29Cap43 (C43) and the control S β tet29 (TET29) cells were treated with 500 ng/ml doxycycline (+) or PBS as control (-) for 24 h and 72 h. The cells were propidium iodide stained and FACS analyzed. 10 000 cells were measured and the experiment was performed in triplicate with three replicates each. A representative chart for the cell cycle of C35 and TET29 cells is presented; C: The graphics represent the average percentage (\pm SE) of cells in G1, G2, and S phase in the different experimental conditions.

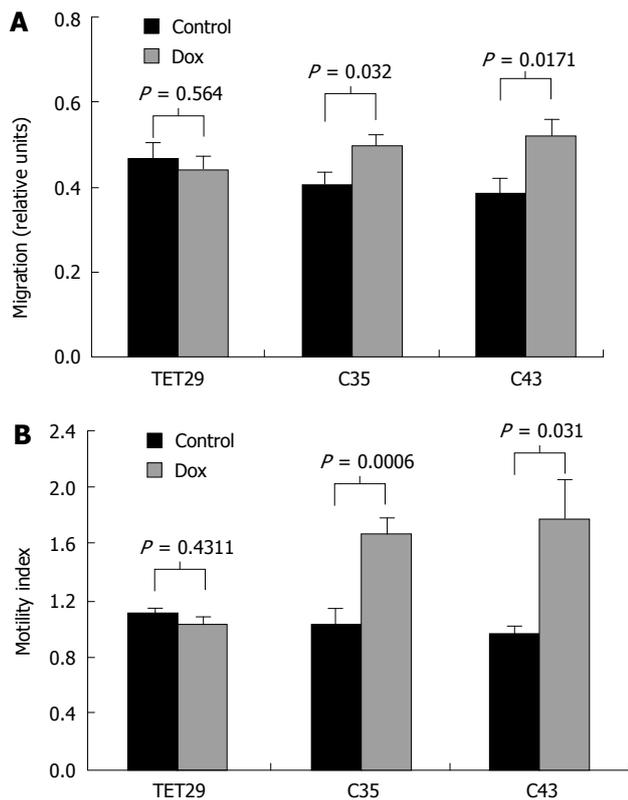

Figure 9 Wound healing capacity (A) and motility (B) of CapG-overexpressing cells. A: Bars represent the migration in relative units for Sβtet29Cap35 (C35), Sβtet29Cap43 (C43) and the control Sβtet29 (TET29) cells treated with doxycycline (dox, grey bar) or PBS (Control, black bar). Error bars present the SE for three experiments carried out in triplicate; B: The motility investigated by a Boyden Chamber assay of Sβtet29Cap35 (C35), Sβtet29Cap43 (C43) and the control Sβtet29 (TET29) cells treated with doxycycline (dox, grey bar) or PBS (Control, black bar) is shown. Each experiment was performed in triplicate with three replicates.

Panc-1 were all capable of stably harbouring the pN1βactin-rtTA2S-M2-IRES-EGFP vector. Moreover, inducible gene overexpression was observed for GST-P, CYP2E1, and S100A6 in Suit-2 and for CapG in all three investigated cell lines. This indicates that the system functions for a variety of different proteins. Equally, the method was efficient with 80% of pN1βactin-rtTA2S-M2-IRES-EGFP transfected Suit-2 clones and 60% of MiaPaca-2 clones showing greater than five-fold luciferase induction. Only Panc-1 cells showed relatively low efficiency, with only 14.4% of the selected cell clones showing a greater than five-fold luciferase increase. A clear advantage of the Tet-on system is the time and dose-dependent activation of expression of the gene of interest. Investigation of stable CapG overexpressing Suit-2 cell clones showed that CapG protein expression was dox-inducible in a time dependent manner. The level of CapG increased from 12 h after induction, and was maintained up to 72 h after induction. A similar time-dependent induction of gene expression in the liver carcinoma cells, HepG2 has been described previously^[14]. However, we did not observe a linear correlation between dox concentration and protein expression, as was reported in the HepG2 cells^[14]. Instead, we detected little increase in CapG protein concentration between 0-10 ng/mL dox, and overexpression of CapG

with concentrations of 50 ng/mL and greater (up to 1000 ng/mL). Possible reasons for these different results could be related to the particular protein overexpressed or the different promoter used to drive the rtTA2S-M2 in both studies. The HepG2 Tet-on clones harboured CMV driven rtTA2S-M2, unlike the pancreas clones in this study.

Concerns have been raised about the toxicity of dox, the agent used to activate gene expression in the Tet-on vector system^[18]. The cell growth of PC-12 cells was reduced after 96h incubation with concentrations ranging from as low as 0.2 to 100 μg/mL. Growth perturbations were observed with WI-38 VA-13 cells, but only with concentrations of dox greater than 2 μg/mL^[18]. It appears that the concentration of dox which mediates a toxic effect is cell-line-dependent. At the concentrations of dox used in this study, no loss of proliferation was observed 48 h after dox treatment. These data were supported by cell cycle analyses profiles, which showed no change in cell cycle following dox treatment for 24 h and 72 h.

The function of CapG in the cytoplasm is well described. CapG caps and therefore blocks rapidly growing actin filaments, promoting the elongation of shorter actin filaments. It thus contributes to cell motility^[19] and membrane ruffling^[20]. Increased levels of CapG protein have been described in several tumors, including pancreatic ductal adenocarcinoma^[12,21] and glioblastomas^[22]. Transient CapG knockdown experiments in pancreatic cancer cell lines Suit-2, MiaPaca-2, and Panc-1 cell lines led to a significant decrease in wound healing capacity and cell motility^[12]. Furthermore, Van den Abbeele *et al*^[23] showed that downregulation of CapG in the breast cancer cells MDA-MB 231 and the prostate cancer cells PC-3 also decreased invasion and motility. Here, we show for the first time that overexpression of CapG in a pancreatic cancer cell line caused a significant increase in motility and a modest, but significant, increase in wound healing capacity. This is consistent with a previous report of an increase in invasion after CapG overexpression in Madin-Darby Canine Kidney Epithelial Cells MDCK cells^[24]. Interestingly, it has been reported that active nuclear import of CapG is necessary for CapG to promote invasion^[24]. Prevention of nuclear accumulation of CapG in MDCK cells abolished collagen invasion, whereas restoring the nuclear import also restored collagen invasion of these cells. We found no evidence for elevated nuclear levels of CapG following overexpression in Suit-2 derived cells. Immunohistochemical staining localized CapG to the cytoplasm in Suit-2 cells. Dox treatment of stable inducible CapG expressors led to an increase in cytoplasmic staining, with increased CapG around the nuclear membrane, but CapG did not accumulate in the nucleus. Subcellular fractionation further validated this finding, showing increased CapG protein levels in the cytoplasmic fraction after dox treatment. We observed increased motility, suggesting that elevated cytoplasmic CapG may be sufficient for increased cancer cell motility.

CapG has been shown to interact with microtubule-dependent organelles during the cell cycle^[25], possibly mediating cross-talk between the actin cytoskeleton and

microtubule-based organelles involved in mitosis. CapG is imported into the nucleus by NTF2, Ran GTPase and nucleoporin Nuc62^[20], a phenomenon that was observed in HEK293T, HeLa, and MDCK-AZ cells. We found no changes in the cell cycle following induction of CapG overexpression. This suggests that an excess of CapG is not sufficient to alter cell cycle dynamics, but it does not exclude a role for CapG in cell cycle processes.

In summary, we have shown that the pN1 β actin-rtTA2S-M2-IRES-EGFP Tet-on vector system can be stably transfected in a variety of pancreatic cancer cell lines, permitting the investigation of dox inducible gene overexpression in a time and dose-dependent manner. Our use of this system to overexpress CapG in Suit-2 cells resulted in accumulation of CapG protein in the cytoplasmic cellular compartment with associated increases in wound healing and cell motility, but no alterations to the cell cycle or to cellular proliferation.

ACKNOWLEDGMENTS

We thank W Hillen for the kind gift of the rtTA2S-M2 plasmid and Dr. A Welman for the pN1 β actin-rtTA2S-M2-IRES-EGFP plasmid.

COMMENTS

Background

Pancreatic cancer cells have traditionally been recalcitrant to the tetracycline gene regulatory system, a method that allows precise control of the level of expression of specific proteins, enabling functional analysis of those proteins. In this study, the authors compare the performance, in pancreatic cancer cells, of a stable Tet-on system employing a *cytomegalovirus* (CMV) promoter with a system employing a chicken β -actin promoter. In doing so, the authors generated cells exhibiting stable inducible expression of the actin capping protein CapG, which plays a role in cell migration. This protein was recently shown to be overexpressed in pancreatic cancer tissue, and its downregulation is associated with loss of motility.

Research frontiers

Use of the chicken (β -actin) promoter proved superior to the CMV promoter for both the production and maintenance of tetracycline-inducible pancreatic cancer cell lines. The authors observed that the system was versatile, enabling transient inducible expression of a variety of genes. Moreover, with the newly developed Tet-on system, the authors showed that CapG overexpression in pancreatic cancer cells led to increased cell motility, but did not alter the cell cycle, or cellular proliferation.

Innovations and breakthroughs

The Tet-on system using a chicken (β -actin) promoter allowed the generation of stable inducible pancreatic cancer cell lines, providing an important tool for investigating doxycycline induced overexpression of proteins associated with pancreatic cancer. Furthermore, the study illustrated that cytoplasmic CapG overexpression in pancreatic cancer cells increases motility of these cells.

Applications

The stable Tet-on pancreatic cancer cell lines developed are an excellent system that will provide quantitative and temporal information on the role of given proteins in these cells.

Terminology

Panc-1, Suit-2 and MiaPaca-2 are pancreatic cancer cell lines. CapG belongs to the family of actin regulatory proteins. CapG caps the ends of barbed actin filaments and therefore contributes of the actin associated motility of cells. Nuclear CapG is involved in the cell cycle regulation.

Peer review

There are precious few published papers describing the use of stable tetracycline-inducible pancreatic cancer cells for the overexpression of proteins. This reflects the difficulty that scientists in this field have faced with the available

systems. The authors describe the successful generation of stable tetracycline-inducible pancreatic cancer cells, using a chicken β -actin promoter to express the reverse tetracycline-controlled transactivator protein. This is an important advance, illustrating an improvement to the system which other pancreatic cancer researchers could also benefit from.

Abstract

AIM: To document unusual findings in appendectomy specimens.

METHODS: The clinicopathological data of 5262 patients who underwent appendectomies for presumed acute appendicitis from January 2006 to October 2010 were reviewed retrospectively. Appendectomies performed as incidental procedures during some other operation were excluded. We focused on 54 patients who had unusual findings in their appendectomy specimens. We conducted a literature review *via* the PubMed and Google Scholar databases of English language studies published between 2000 and 2010 on unusual findings in appendectomy specimens.

RESULTS: Unusual findings were determined in 54 (1%) cases by histopathology. Thirty were male and

24 were female with ages ranging from 15 to 84 years (median, 32.2 ± 15.1 years). Final pathology revealed 37 cases of enterobiasis, five cases of carcinoids, four mucinous cystadenomas, two eosinophilic infiltrations, two mucoceles, two tuberculosis, one goblet-cell carcinoid, and one neurogenic hyperplasia. While 52 patients underwent a standard appendectomy, two patients who were diagnosed with tuberculous appendicitis underwent a right hemicolectomy. All tumors were located at the distal part of the appendix with a mean diameter of 6.8 mm (range, 4-10 mm). All patients with tumors were alive and disease-free during a mean follow-up of 17.8 mo. A review of 1366 cases reported in the English literature is also discussed.

CONCLUSION: Although unusual pathological findings are seldom seen during an appendectomy, all appendectomy specimens should be sent for routine histopathological examination.

INTRODUCTION

Appendicitis is one of most common acute surgical condi-

tions of the abdomen, and an appendectomy is one of the most frequently performed operations worldwide. The incidence of acute appendicitis roughly parallels that of lymphoid development, with peak incidence in the late teens and twenties. Obstruction of the lumen is the dominant factor in acute appendicitis, and although fecoliths and lymphoid hyperplasia are the usual cause of obstructions, some unusual factors could also be involved^[1-128]. Obstruction may be due to enterobiasis^[1,4,7,29], ascariasis^[57,92-94], balantidiasis^[2,92], taeniasis^[14,18], actinomycosis^[52-58], schistosomiasis^[2,8,42-51,57], amebiasis^[7,84-86,90], trichuriasis^[52,57], *Blastocystis hominis*^[20], tuberculosis (TB)^[8,23,53-55,57], carcinoid tumor^[1-3,5,9,12,26,28,31,95], goblet-cell carcinoid (GCC)^[5,12,21,25], primary or secondary adenocarcinoma^[16,31], cystadenocarcinoma^[31], lymphoma^[2], dysplastic changes^[2], endometriosis^[1,16,58-69], granulomatous diseases^[31,32], gastrointestinal stromal tumor (GIST)^[71,72,103], mucocele^[1-3,52], villous adenoma^[24,39,56], tubulovillous adenoma^[24], tubular adenoma^[24,31], leiomyoma^[2], eosinophilic granuloma^[32,52], or neurogenic appendicopathy^[30].

MATERIALS AND METHODS

Between January 2006 and October 2010, 5262 patients with presumed acute appendicitis underwent surgical treatment at Diyarbakir Education and Research Hospital, Turkey. Appendectomies performed as an incidental procedure during some other operation were excluded. The data of 54 (1%) patients who were pathologically reported to have unusual appendix findings were retrospectively collected. The original pathology specimens with unusual findings were evaluated again by an experienced pathologist. The records analysis was composed of the patient's age, gender, clinical presentation, operative reports, radiological tools, pathological report, and follow-up. The length of follow-up was calculated by months from the date of diagnosis until the last clinical information available on the patient up to November 2010.

English medical language PubMed and Google Scholar database searches were conducted for case reports, retrospective and prospective studies, and literature reviews relating to "unusual causes of appendicitis". Keywords used were parasites, enterobiasis, schistosomiasis, amebiasis, yersiniosis, strongyloidiasis, actinomycosis, TB, idiopathic granulomatous appendicitis, Crohn's disease, endometriosis, appendicular adenocarcinoma, carcinoid, GCC, mucocele, mucinous cystadenoma, lymphoma, polypoid lesion, appendectomy, and appendicitis. The search included all articles from 2000 until November 2010. Patients who had undergone an operation for presumed acute appendicitis and had "unusual findings" pathology were included in the study, whereas articles that provided inconclusive information about patients and those in which the patients could not be reached were excluded. Additionally, appendicitis cases that developed due to foreign bodies were also excluded^[1-128].

RESULTS

In total, 5262 appendectomies were performed with a

diagnosis of acute appendicitis at Diyarbakir Education and Research Hospital from January 2006 through October 2010. All patients were diagnosed clinically with acute appendicitis on the basis of physical and laboratory examinations. Of all appendectomies performed, 54 (1%) specimens revealed incidental abnormal histopathological diagnoses. The general characteristics of these 54 patients are summarized in Table 1. Thirty of the patients were male and 24 were female with ages ranging from 15 to 84 years (median, 32.2 ± 15.1 years). Thirty-seven of the 54 patients revealed *Enterobius vermicularis*, five a carcinoid tumor, six a mucinous cystadenoma (two were mucoceles), two TB, and two eosinophilic infiltration, and two each were diagnosed with GCCs and neurogenic hyperplasia (Figure 1). While 52 patients underwent a standard appendectomy, two patients, who were preoperatively diagnosed with tuberculous appendicitis, had a right hemicolectomy. All patients with malignant tumors were diagnosed clinically with acute appendicitis, and none of them had symptoms of carcinoid syndrome or were preoperatively diagnosed with an appendicular tumor. After pathological confirmation of the diagnosis, the patients were referred to our clinic for staging. Staging included abdominal ultrasonography (US), computed tomography (CT), and 24-h urinary 5-hydroxyindoleacetic acid levels. After staging, all patients were followed up at the outpatient clinic every 3 mo for the first year. All patients with tumors were alive and disease-free during a mean follow-up of 17.8 mo. The clinicopathological characteristics of six patients with tumors are summarized in Table 2.

A histopathological examination of patients with *E. vermicularis* revealed 12 with acute inflammation and 25 with no evidence of any pathological change. After obtaining the pathology reports, the patients with oxyuris were prescribed a single oral dose of 100 mg mebendazole, which was repeated 7-10 d later. All patients with oxyuris were asymptomatic on follow-up (mean, 7.2 mo;

performed in patients with an acute abdomen in the follow-up, considering the intraoperative findings. We have presented the details of these two cases in a previous article^[53].

Results of the literature review

Using the PubMed and Google Scholar databases, 128 studies published between January 2000 and November 2010 were compatible with our criteria. Fifty-one of these were written as original articles (50 retrospective and 1 prospective), 67 as case reports, eight as letters to the editor, and two as case series. When we looked at the countries in which the articles were prepared, 59 were from Europe, 40 from Asia, 19 from the Americas, six from Africa, and four were from Australia. In total, 80 698 cases

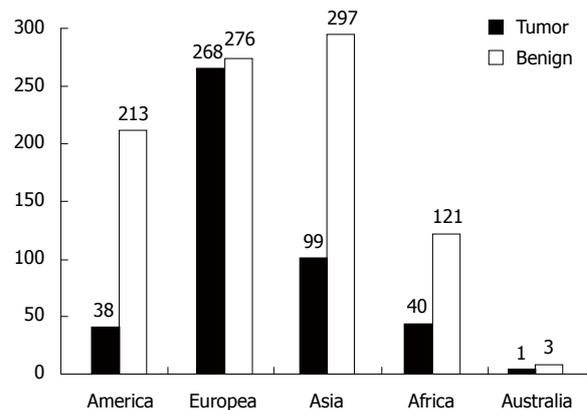

Figure 2 Worldwide distribution of the 1366 cases defined as “unusual findings”. Tumor: Carcinoid, goblet cell carcinoid, mucocele, appendix adenocarcinoma, lymphoma, mucinous cystadenoma and adenocarcinoma, polypoid lesions, leukemia, gastrointestinal stromal tumor, dysplastic change; Benign: Non-tumoral causes.

were discussed in these articles, and all patients who were operated on had presumed acute appendicitis. Unusual findings were detected in 1366 (1.7%) of the cases with or without histopathologically acute appendicitis in their appendectomy specimens. We have summarized the causes that we qualified as “unusual findings in appendectomy specimens” in Table 3. As shown in the table, causes such as enterobiasis, schistosomiasis, amebiasis, and carcinoid tumor comprised 75.7% of all cases. The etiological (tumoral and non-tumoral causes) distribution of the 1366 patients by continent is summarized in Figure 2 to demonstrate the effects of geographic and sociocultural differences.

DISCUSSION

Acute appendicitis is the most common general surgical emergency, and obstruction of the appendiceal lumen seems to be essential for developing an appendiceal infection. Although fecaliths and lymphoid hyperplasia are the usual causes of the obstruction, some unusual factors could also be involved^[2,8,16,57].

Appendiceal tumors, occurring in less than 3% of all appendectomies, are rarely associated with clinical manifestations; they are frequently recognized either during an operation or the pathological examination. Malignant tumors of the appendix include carcinoids, GCCs, lymphomas, mucoceles, primary adenocarcinomas, and mucinous cystadenocarcinomas. Benign tumors of the ap-

pendix consist of tubular adenomas, villous adenomas, leiomyomas, neuromas, and lipomas^[2,5,31].

An appendiceal carcinoid tumor is considered the most common type of appendiceal primary malignant lesion and accounts for almost 60% of all appendiceal tumors^[28]. An appendiceal carcinoid tumor is found in 0.3%-2.27% of patients undergoing an appendectomy. Characteristics of all appendiceal carcinoids predicting aggressive behavior include tumor size, histological subtype, and mesoappendiceal involvement. The tumors are smaller than 1 cm in 70%-95% of cases^[26-28]. The calculated risk of metastasis from tumors 1 cm or smaller is nearly zero and therefore may be managed with a simple appendectomy. An increase in metastasis risk of up to 85% occurs with a tumor of 2 cm or larger. An appendiceal carcinoid tumor larger than 2 cm should be managed with a formal right hemicolectomy^[1,3,5,6,9-13,16,26,28].

GCCs, also known as adenocarcinomas and first described by Gagne in 1969, are uncommon primary tumors of the vermiform appendix characterized by dual endocrine and glandular differentiation^[129]. Whether GCCs represent a morphological variant of appendiceal classical carcinoid or a mucin-producing adenocarcinoma is a matter of conjecture^[12]. GCCs account for 2% of primary appendiceal malignancies. Most tumors are less than 2 cm in diameter and 20% metastasize to the ovaries. Recent studies suggest that GCCs have biological and immunohistochemical profiles more similar to adenocarcinomas than to classical carcinoids, which may explain their aggressive behavior and therefore requirement for more extensive treatment^[12]. A right hemicolectomy is generally advised if any of the following features are present: tumors greater than 2 cm, involvement of resected margins greater than 2 mitoses/10 high-power fields, extension of the tumor beyond the serosa, lymphovascular invasion, or lymph node metastases^[5,12,21,25]. In our series, one patient had a GCC tumor located distally in the appendix that measured 1 cm in diameter. The patient was advised to undergo a right hemicolectomy, but he refused the procedure.

Mucinous cystadenoma is a rare tumor of the appendix associated with cystic dilatation, to which the more general term of mucocele has been applied. A mucocele of the appendix denotes an obstructive dilatation of the appendiceal lumen due to abnormal accumulation of mucus, which may be caused by a retention cyst, endometriosis, mucosal hyperplasia, cystadenoma, or a cystadenocarcinoma. The incidence of mucocele ranges from 0.2% to 0.3% of all appendectomy specimens. Mucoceles are often asymptomatic and discovered as incidental findings at appendectomy, or during laparotomy for another indication or at histological examination of an operative specimen. However, mucoceles may be diagnosed clinically from features of acute appendicitis. Appendectomy is the standard of care for mucinous cystadenoma, whereas a cystadenocarcinoma requires a right hemicolectomy. Because of the high association of mucinous cystadenoma with colon and ovarian malignancy, follow-up CT, US, and colonoscopy examinations must be performed during the postoperative period^[1-3,5,16,25,27,31,52,106,107].

Mucinous cystadenocarcinoma of the appendix, also known as a mucinous adenocarcinoma or malignant mucocele, constitutes a rare malignancy of the appendix and is often associated with a second malignancy of the gastrointestinal (GI) tract. The most common type of presentation is that of acute appendicitis. The diagnosis of mucinous adenocarcinoma of the appendix is usually given after an appendectomy, or other explorative surgical procedure, and consequent pathological evaluation of the appendiceal specimen^[5,25,31,108].

Primary adenocarcinoma of the appendix is an extraordinarily rare tumor, and its incidence was 0.01% (11 of 80 698 cases) in our literature review. Adenocarcinomas behave aggressively and in a fashion similar to that of colonic adenocarcinomas, so in the case of an appendicular adenocarcinoma, oncologic resection with right hemicolectomy is the treatment of choice^[2,16,23,31,105].

The GI tract is the most common site for extranodal lymphomas and accounts for 30%-45% of all extranodal cases. The stomach is the most commonly involved organ followed by the small intestine, colon, and esophagus. The incidence of primary appendiceal lymphoma has been estimated at 0.015%-0.022% of all appendiceal specimens. An appendiceal lymphoma usually presents in the second and third decades of life, usually manifests as acute appendicitis, and is often diagnosed postoperatively by histopathology. Therapy guidelines for primary appendiceal lymphomas are unclear because of their rarity. Our literature review revealed 14 lymphoma cases with clinical evidence of acute appendicitis; 12 of these were of B-cell origin, whereas two were of T-cell origin^[2,8,97-101,109-112].

Leukemia can involve the GI tract but rarely involves the appendix. Although appendicitis is a known complication in patients with leukemia, leukemic cell involvement in the appendix is extremely rare. When the leukemia involves soft tissue including the appendix, it is called granulocytic sarcoma. The incidence of leukemic appendicitis was 0.005% (4 of 80 698 cases) in our literature review. Surgical management of patients with leukemia and acute abdomen has not been advocated because of the high rate of operative mortality. However, some support exists for surgically managing appendicitis as the most effective method of therapy in acute leukemia cases. Systemic chemotherapy is necessary prior to additional surgery in patients with leukemia^[113-115].

GISTs, which occur most commonly in the stomach (60%) and the small bowel (30%), are the most common primary mesenchymal neoplasms of the GI tract. GISTs, known as leiomyoma or leiomyosarcoma before 1983, primary to the vermiform appendix are exceptionally rare, with only eight cases reported so far^[2,71,72,103]. Five out of eight patients were operated due to acute appendicitis symptoms. The size of the mass and degree of mitotic activity play a crucial role in tumor behavior and recurrence development. Therefore, when approaching the appendix for GIST tumors, tumor location should be evaluated along with tumor size and mitotic activity.

Enterobius vermicularis, also known as pinworm or oxyuris, is a widespread parasitic infection estimated to

affect up to 200 million people worldwide. The association of oxyuris and appendicitis was first made in the late 19 century, when Still initially documented this organism in the appendix lumen. While the reported incidence of pinworm in appendectomy specimens of patients with presumed appendicitis ranged from 0.2% to 41.8%, the reported rates of inflammation in specimens from appendices infested with pinworm ranged from 13% to 37%^[4,7,14,29]. Patients must receive antihelminthic treatment because the appendectomy treats only the consequence and not the cause of the disease. An *E. vermicularis* infestation is treated with an oral dose of mebendazole, which is repeated in 1-2 wk^[1,2,4,7,11,14,16-20,22,29,52,57,92,93].

TB may affect all tissues and organs in the body, but it most frequently involves the lungs. The GI system is ranked sixth among all extrapulmonary involvements. TB may affect all of the segments of the GI system, from the mouth to anus. However, the ileum and ileocecal region are the sites most commonly involved, followed by the colon and vermiform appendix. The appendix may be affected secondarily to ileocecal TB, but appendicular TB may occur in an even rarer primary form without any evidence of the disease elsewhere. The reported incidence of appendicular TB varies from 0.1% to 3.0% among all appendectomies performed. An accurate diagnosis is usually established after histopathological examination of a specimen. Classic histopathological analysis of an appendectomy specimen usually reveals the presence of caseating granulomas and Langhans giant cells, suggesting TB of the appendix. Although some studies have reported that treatment is not necessary for the primary disease and that appendectomy alone is sufficient, no consensus has been reached. When we reviewed the literature, 34 cases of patients undergoing an appendectomy with presumed appendicitis have been published in the last decade, including our own two cases^[23,32,53-55,57].

Actinomycosis is an uncommon chronic infectious disease. Common sites of involvement include the cervicofacial, thoracic, and abdominopelvic regions. In abdominal actinomycosis, the ileocecal region including the appendix is the most commonly involved site. A correct diagnosis can be made by culture or histopathological examination, although a definitive diagnosis of actinomycosis requires microscopic proof of either the pathogen itself or the presence of specific sulfur granules. After the diagnosis has been confirmed, the general therapeutic recommendation is to initiate treatment with intravenous antibiotic therapy for 2-12 mo. Eight cases of patients undergoing an appendectomy with presumed appendicitis have been published in the last decade^[32-38].

Taeniasis, a well-known worm infection, is characterized by the presence of the helminth in the intestine. Infection is generally recognized when a segment of the parasite appears in the stool. The occurrence of *Taenia spp.* in the appendix is so rare that the situation invites a case report. In our literature review, *Taenia* was found in only five of the cases operated on for presumed acute appendicitis. In cases of taeniasis, specific species identification is not required for treatment, as patients are treated with a

single dose of praziquantel^[14,18,93,127,128].

Amebiasis is an infection of the large intestine caused by *Entamoeba histolytica*, which affects 10% of the world population and has a worldwide distribution. This parasite is occasionally found in the appendix, usually in the lumen without accompanying inflammation, but is rarely associated with acute appendicitis. A preoperative diagnosis of amebic appendicitis is almost impossible because no clinical features or diagnostic laboratory tests distinguish amebic from bacterial appendicitis, other than a stool examination. The clinical picture presented in this report represents a typical case of amebic appendicitis with a good outcome after surgical resection and treatment with metronidazole^[84,85,87-93].

Schistosomiasis, also known as bilharziasis and most commonly caused by *Schistosoma haematobium*, only rarely leads to appendicitis, even in nations in which schistosomiasis is endemic. The pathogenesis is most probably due to a periappendicular granulomatous reaction of the host against the schistosome. Inflammation and repair causes scarring and strictural deformation of the appendiceal wall, leading to luminal obstruction and acute appendicitis. Histologically, appendices may show transmural inflammation rich in eosinophils, with a granulomatous reaction to ova. Treatment for schistosomal appendicitis consists of an appendectomy and administration of praziquantel^[2,8,13,16,32,40-52,57,93,125,126].

Ascaris lumbricoides, also known as roundworm, is one of the most common human helminthic diseases worldwide. The highest prevalence of ascariasis occurs in tropical and semitropical countries. The domain of the worm extends from the stomach to the ileocecal valve; 99% of worms inhabit the jejunum and proximal ileum, and it is rarely seen in the appendix. Appendicitis due to migration of roundworm into the appendix is still debatable because the symptoms of this migration may simulate appendicitis but rarely cause it^[57,92,94].

Because parasites such as *Balantidium coli*^[2,92], *Blastocystis hominis*^[20], *Trichuris trichiura*^[52,57,92], and *Strongyloides stercoralis*^[121] have few causative roles, interpreting their pathogenesis is difficult. A final diagnosis should be established with a histopathological evaluation of all three parasites, and antihelminthic treatment should be administered after the appendectomy.

Endometriosis is defined as the presence of ectopic endometrial tissue outside the lining of the uterine cavity. Many women of reproductive age suffer from this disease, but its occurrence in the GI tract is rare. Intestinal endometriosis is classified as external endometriosis and occurs in only about 10% of women with endometriosis. Most intestinal endometriosis occurs in the rectum and sigmoid colon but rarely in the appendix. Appendiceal endometriosis is usually asymptomatic, but it occasionally causes appendicitis, perforation, and intussusception. The diagnosis of appendiceal endometriosis is based on the histological presence of endometrial tissue in the specimen. The treatment strategy consists mainly of surgery and hormone therapy^[1,16,27,57-69,102].

The incidence of granulomatous appendicitis (GA),

a rare condition that may be discovered incidentally in a patient with a clinical presentation of acute appendicitis, ranges from 0.31% to 0.95%. Various infectious and non-infectious factors cause GA. Systemic conditions, such as Crohn's disease and sarcoidosis, may also be associated with granulomatous inflammation of the appendix. The initial belief that it represented a manifestation of Crohn's disease is incorrect in the great majority of cases, as only 5%-10% of patients with GA develop Crohn's disease elsewhere in their GI tract. Distinguishing idiopathic granulomatous appendicitis from early Crohn's disease, which affects only the appendix, is difficult. A definitive diagnosis can only be made after long-term follow-up, and sometimes further investigations are required^[31,52,116-120,122,123].

Crohn's disease is a chronic transmural inflammation characterized by epithelioid granulation formation in the intestinal wall. The clinical presentation is always variable, and patients often present with findings consistent with acute appendicitis such as right-lower quadrant pain, fever, nausea, and anorexia. The diagnosis of appendiceal Crohn's disease requires exclusion of multiple entities. Infectious causes of granulomatous appendicitis include *Yersinia*, *Mycobacterium tuberculosis*, blastomycosis, *Schistosoma*, *Actinomyces*, *Campylobacter*, *Histoplasma capsulatum*, and some parasites. An appendectomy is a routine surgical procedure when the Crohn's disease is limited to the appendix with no postoperative or intraoperative mortality and a low rate of fistula formation^[16,32,123].

In summary, although fecaliths and lymphoid hyperplasia are the usual causes of acute appendicitis, some unusual factors may also cause appendicitis. The most common unusual findings in appendectomy specimens are parasites and benign or malignant tumors. A simple appendectomy or right hemicolectomy can be performed depending on the localization, size, and histopathological structure of the tumor in the primary malignant appendiceal tumor, whereas an appendectomy alone is sufficient for benign tumors. Administering the appropriate antibacterial or antiparasitic treatment after the appendectomy is the proper approach for parasitic and bacterial infections that cause chronic inflammation. We emphasize and strongly recommend that all appendectomy specimens be examined histopathologically regardless of whether the specimens are macroscopically normal.

COMMENTS

Background

Appendicitis is one of most common acute surgical conditions of the abdomen, and an appendectomy is one of the most frequently performed operations worldwide. Obstruction of the lumen is the dominant factor in acute appendicitis, and although fecoliths and lymphoid hyperplasia are the usual causes of obstructions, some unusual factors could also be involved.

Research frontiers

The authors conducted a literature review via the PubMed and Google Scholar databases of English language studies published between 2000 and 2010 on unusual findings in appendectomy specimens. Also, we presented 54 patients who had unusual findings in their appendectomy specimens.

Innovations and breakthroughs

The authors emphasize and strongly recommend that all appendectomy

specimens be examined histopathologically regardless of whether the specimens are macroscopically normal.

Peer review

This is a very interesting paper. It will be cited many times in the future and this is good for our journal.

Abstract

AIM: To test if total ghrelin is present in infant formulas.

METHODS: Using a radioimmunoassay, we measured total ghrelin concentrations in 19 samples of commercial infant formulas and in 20 samples of human milk. We also determined ghrelin concentration in the serum of infants and lactating mothers.

RESULTS: Ghrelin concentrations were significantly higher in artificial milk (2007.1 ± 1725.36 pg/mL) than in human milk (828.17 ± 323.32 pg/mL) ($P = 0.005$). The mean ghrelin concentration in infant serum ($n = 56$) was 1115.86 ± 42.89 pg/mL, and was significantly higher ($P = 0.023$) in formula-fed infants (1247.93 ± 328.07 pg/mL) than in breast-fed infants (1045.7 ± 263.38 pg/mL). The mean serum ghrelin concentration (mean \pm SD) in lactating mothers ($n = 20$) was 1319.18 ± 140.18 pg/mL.

CONCLUSION: This study provides evidence that total ghrelin is present in infant formulas. This finding

INTRODUCTION

It is now well established that early life nutrition plays an important role in long-term appetite control^[1]. Indeed, neonatal nutrition is involved in the programming of feeding regulatory mechanisms in the central nervous system, and in those mediated by factors secreted from peripheral tissues. Besides peripheral circulating factors that regulate energy balance and adiposity, gastrointestinal peptides have been demonstrated to act as hunger signals. Among the known orexigenic peptides, ghrelin has been found to be the most powerful^[2].

Ghrelin is involved in the short-term regulation of food intake, by stimulating appetite, and in the long-term regulation of weight and energy metabolism, by inducing adiposity^[3]. It is released in a pulsatile manner, with a nocturnal peak. Ghrelin responds to meals, increasing 1-2 h before eating and returning to trough levels 1-2 h after a meal^[4,5]. Ghrelin secretion increases under negative energy-balance

conditions, and decreases under positive energy-balance conditions, such as food intake and obesity^[6,7]. It is one of the most powerful orexigenic and lipogenic hormones and represents an interface between energy balance regulation, glucose homeostasis and hypothalamic neuropeptides^[8]. The amino acid sequence of ghrelin is highly conserved throughout mammalian species^[9]. Ghrelin has been found in human milk, but the source of the hormone is unclear. Aydin *et al*^[10] reported that its levels in colostrum, transitional and mature milk were lower than those found in plasma and they assumed that ghrelin present in milk probably comes from the plasma of lactating mothers. In contrast, Kierson *et al*^[11] showed that ghrelin levels in breast milk are higher than plasma levels and identified ghrelin mRNA from human mammary epithelial cells and mammary gland. Based on these findings these authors suggested that ghrelin in breast milk is probably synthesized and secreted from the breast. The identification of ghrelin in breast milk suggests that breast milk is a source of compounds critical for the metabolic development of infants^[12,13].

Early feeding mode affects growth and body composition^[14]. Breast-fed (BF) and formula-fed (FF) infants have similar weight gains in the first three months of life, however, BF infants gain weight less rapidly during the following months of the first year^[15]. BF and FF infants have different feeding behaviors: FF infants eat less frequently and consume higher amounts of food than BF infants^[16,17]. We previously reported that serum ghrelin concentrations were higher in infants exclusively FF than in infants exclusively BF^[18]. Recently, serum ghrelin values were positively correlated with fasting times only in FF infants^[19].

The aim of this study was to investigate whether infant formulas contain ghrelin.

MATERIALS AND METHODS

In this study, we enrolled 56 infants aged from 11 d to 5 mo (mean \pm SD: 81 \pm 46 d) born from a normal spontaneous vaginal delivery, consecutively referred to the Department of Paediatrics of the University of Turin, Regina Margherita Children's Hospital. The inclusion criteria for infants were gestational age between 37 and 42 wk, birth weight appropriate for gestational age (between 2500 and 4000 g), Apgar score higher than 7 at 5 min, no fetal anomaly, absence of acute or chronic gastroenteric diseases or other growth-affecting pathologies.

We collected milk samples from 20 lactating mothers of the infants enrolled. Eligibility criteria for mothers were: no maternal medical complications, non-smoking mothers, normal response to a glucose tolerance test, no mastitis, no prescribed medication, no digestive disorders.

Appropriate Ethics Committee permission was obtained and each parent signed a written informed consent. Milk samples (2 mL) were collected from the lactating women ($n = 20$) before breakfast at around 09:00 h. Samples of 19 infant formulas were collected: 9 starting formulas, 6 follow-on formulas and 4 special formulas (anti-regurgitation and hydrolyzed casein protein formulas). We

also obtained unpasteurized milk samples (2 mL) from 5 dairy cows. Breast, cow and artificial milk were separated by centrifuging the samples twice at 2000 r/min and 4°C for 20 min. After the first centrifugation, the thick fat layer at the top of the tube, which could interfere with detection of the hormone, was removed with a sterile toothpick. We collected a venous blood sample from 56 infants (37 BF infants and 19 FF infants) after a fast of 3 h. We also collected venous blood samples from 20 lactating mothers. Blood samples were immediately centrifuged at 4000 r/min and 4°C for 10 min and each sample of the resulting serum was divided in 3 tubes and these were stored at -30°C until analysed.

Hormone assays

Serum and milk total ghrelin were assayed by radioimmunoassay using a commercial kit (Ghrelin (total) RIA 3967, DRG Diagnostic, New Jersey, USA) according to the manufacturer's instructions (using a polyclonal antibody that recognizes octanoylated and non-octanoylated ghrelin with I¹²⁵ ghrelin as a tracer molecule). Measurements of total ghrelin in mature milk and serum samples have been validated as reported elsewhere^[10]. The intra-assay and inter-assay coefficients of variation of ghrelin were 5% and 7.6%, respectively. The lowest level of ghrelin that can be detected by this assay is 93 pg/mL with a 100- μ L sample size. The specificity for human ghrelin is 100%. The limit of linearity for the ghrelin assay is 6000 pg/mL (any result greater than 6000 pg/mL was repeated on dilution using Assay Buffer as a diluent). Spike and Recovery of ghrelin in human plasma are shown in Table 1. As the kit is designed for human samples, a validation process was undertaken for use with bovine milk. We obtained 3 measurements of the hormone for each blood sample and milk sample. The manufacturer's protocol was followed and standard validations, including parallelism and recovery, conducted.

Statistical analysis

Statistical analysis was performed with SPSS 16.0 for Windows (SPSS Inc., Chicago, IL, USA).

A normal distribution was verified with the Shapiro-Wilk test ($P > 0.05$). The data are expressed as arithmetic means \pm SD; $P < 0.05$ was considered statistically significant. Differences in ghrelin concentrations between human milk and formula milk were determined by the Student's *t* test.

RESULTS

As shown in Table 2, the mean \pm SD of ghrelin concentration in human milk was 828 \pm 323 pg/mL. Ghrelin levels varied widely in infant formulas (from 300 to 6110 pg/mL; mean: 2007 \pm 1725 pg/mL). The mean ghrelin concentration in starting formulas and in follow-on formulas was 2699 \pm 233.5 pg/mL and 2561 \pm 215.2 pg/mL, respectively, whereas the mean ghrelin concentration was 1160 \pm 340 pg/mL in special formulas (Table 3). Ghrelin

Table 1 Spike and recovery of ghrelin in human plasma (mean of the observed levels from 3 duplicate determinations in 3 separate assays)

| Sample No. | Ghrelin added ¹ (pg/mL) | Recovery (%) |
|------------|------------------------------------|--------------|
| 1 | 500 | 96 |
| 2 | 1000 | 90 |
| 3 | 2000 | 91 |

¹Different concentrations of human ghrelin were added to 3 different human plasma samples and the ghrelin content was determined by RIA. Percent recovery was calculated on the observed *vs* expected.

Table 2 Ghrelin concentrations in infant formulas, in mother's milk, in cow's milk and in serum of lactating mothers, breast-fed infants and formula-fed infants

| | Ghrelin concentration (pg/mL ± SD) |
|---|------------------------------------|
| Milk | |
| Different kinds of artificial infant formula (n = 19) | 2007.1 ± 1725.36 ^a |
| Breast milk (n = 20) | 828.17 ± 323.32 ^a |
| Non pasteurized cow milk (n = 5) | 2816.00 ± 219.00 |
| Serum | |
| Lactating mothers (n = 20) | 1319.18 ± 140.18 |
| Breast-fed infants (n = 37) | 1045.7 ± 263.38 ^b |
| Formula-fed infants (n = 19) | 1247.93 ± 328.07 ^b |

^a*P* = 0.005, infant formulas *vs* human milk, student's *t* test; ^b*P* = 0.023, breast-fed infants *vs* formula-fed infants, student's *t* test.

levels were significantly higher in infant formulas than in human milk (*P* = 0.005). The mean ghrelin concentration in unpasteurized cow milk was 2816 ± 219 pg/mL. The mean ghrelin concentration in infant serum was 1115.86 ± 42.89 pg/mL, and was significantly higher (*P* = 0.023) in FF infants (1247.93 ± 328.07 pg/mL) than in BF infants (1045.7 ± 263.38 pg/mL). The mean serum ghrelin concentration (mean ± SD) in lactating mothers was 1319.18 ± 140.18 pg/mL.

DISCUSSION

In this study, we showed that artificial milk contains the orexigenic hormone, ghrelin, and that its concentration was higher in infant formulas than in human milk. This finding might explain the higher serum levels we previously observed in FF infants *vs* BF infants, which was also confirmed in the present research^[18,19].

If FF infants receive a higher amount of ghrelin, it is conceivable that they have a greater feeding stimulus than BF infants, and a consequent increase in weight and growth rate. Our observations could explain the more appropriate growth curves of BF infants, who physiologically receive less ghrelin^[20]. Therefore, breast-feeding may protect against the development of obesity in childhood and adulthood, not only because of its nutrient composition, but also because of the presence of bioactive factors such as ghrelin, leptin and adiponectin^[12,21].

Table 3 Ghrelin concentrations in three different types of artificial infant formula

| Type of infant formula | Ghrelin concentration (pg/mL ± SD) |
|---|------------------------------------|
| Starting infant formulas (n = 9) | 2699 ± 233.5 |
| Follow-on infant formulas (n = 6) | 2561 ± 215.2 |
| Special infant formulas (anti-regurgitation and hydrolyzed casein protein formulas) (n = 4) | 1160 ± 340 |

Several assays are available to measure human serum ghrelin, whereas there is no commercial milk ghrelin assay kit. Consequently, we carried out a validation process using a basic clinical chemistry method (linearity)^[10]. Similarly, there is no assay kit specific for bovine ghrelin; however, given the high structural homology between human ghrelin and mammalian ghrelin, the kit used in our study to detect ghrelin in infant formulas can be considered reliable^[22].

The ghrelin concentrations reported in our study refer to the final volume after centrifugation, because the RIA kit instructions indicate that samples with high lipidemia be avoided. After centrifugation, we removed the supernatant and the fat layer that could interfere with detection of the hormone. This method has been used in previous studies^[10]. Kierson *et al.*^[11] reported higher ghrelin levels in whole milk than skimmed milk, with a direct relationship between estimated milk fat content and ghrelin levels. Therefore, it is possible that ghrelin levels detected in milk after centrifugation are lower than those present in whole milk and consumed by the infants.

The mechanism by which ghrelin influences growth in early infancy is not yet completely known. Ghrelin levels are higher in small-for-gestational-age (SGA) newborns than in adequate-for-gestational age (AGA) newborns^[23]. Reduced ghrelin suppression and higher postprandial ghrelin concentrations in SGA infants could cause a sustained orexigenic drive and may contribute to catch-up growth in these infants. Kitamura *et al.*^[24] reported high ghrelin levels during the early neonatal period. Onal *et al.*^[25] observed that plasma ghrelin concentration was inversely associated with birth weight and body length in term newborns. We previously observed a negative correlation between ghrelin concentration and weight gain in BF infants in the first months of life, which suggests that ghrelin may play a role in body weight regulation in healthy infants^[26,27]. More recently, we found a positive correlation between circulating ghrelin concentration and fasting time in FF infants; these infants have a higher serum ghrelin concentration, longer fasting time and fewer meals than BF infants^[19]. Clearly, we need to learn more about early feeding and the mechanisms regulating satiety and feeding behavior.

Finally, it should be noted that, similar to previous studies^[11,28], we measured total milk ghrelin level. Deacyl ghrelin influences food intake, gut motility, insulin secretion and resistance and adipogenesis, whereas the acylated form of ghrelin, known as active ghrelin, is essential for binding to the growth hormone secretagogue receptor 1a^[29]. Additional studies are needed to evaluate active ghre-

lin in infant formulas.

There have been some studies conducted on the effects of ghrelin administration (i.e. in anorexia, cachexia), however, the hormone was administered intravenously and not orally^[30]. More recently, animal studies have investigated the effects of oral administration of ghrelin receptor agonist, and found that it survives the acid environment of the stomach and could exert some of its biological functions^[31,32].

In conclusion, specific research is needed to understand the origin of ghrelin found in infant formulas. Furthermore, it would be interesting to determine whether ghrelin present in infant formulas survives the acid environment of the stomach in humans, exerts biological activity through receptors present in the gastrointestinal tract of newborns and whether the higher ghrelin concentration in infant formulas result in a higher serum concentration in FF infants. Lastly, investigations are required to determine whether these higher levels of ghrelin affect feeding habits and thus obesity in later life.

COMMENTS

Background

Current research highlights the importance of early life nutrition in long-term appetite control, with consequent programming of regulatory mechanisms. Ghrelin is a recently discovered hormone involved both in the short-term regulation of food intake, by stimulating appetite, and in the long-term regulation of weight and energy metabolism, by inducing adiposity.

Research frontiers

Ghrelin has recently been detected in breast milk, but data on ghrelin in infant formula are lacking. Using a radioimmunoassay, the authors measured ghrelin concentrations in commercial infant formulas versus concentrations in human milk. Surprisingly, ghrelin was significantly higher in artificial formulas. This finding raises diverse questions.

Innovations and breakthroughs

Little is known about ghrelin regulation, especially in early infancy. Breast milk contains ghrelin, but it was not known whether infant formulas contain ghrelin. The finding that infant formulas do indeed contain ghrelin, and at levels higher than those found in breast milk, raises questions about the uptake, absorption and metabolic effects of this feeding stimulus and growth rate of artificially fed infants. Further research is needed to determine whether the higher levels of ghrelin in formulas could affect infant feeding habits and thus obesity in later life.

Applications

The higher ghrelin levels found in artificial milk in the present study might explain the higher serum values the authors recently observed in formula-fed infants compared with breast-fed infants. Thus, if artificially fed infants receive a higher amount of ghrelin together with a higher intake of protein, it is conceivable that formula-fed infants have a greater feeding stimulus with a consequent increase in weight and growth rate.

Terminology

Ghrelin is involved in the short-term regulation of food intake, with an orexigenic action, and in the long-term regulation of weight and energy metabolism, by inducing adiposity.

Peer review

The manuscript by Savino *et al* provides original data on the presence of the

orexigenic hormone ghrelin cow's milk formulas. The authors suggest that the high levels of hormone present in formulas can influence the feeding habits of formula feed subjects in infancy and also later and can be responsible for the high risk of obesity observed in formula fed infants as compared to breast fed ones. The article could be of some general interest, both for pediatricians and for nutritionists.

METHODS: This was a cross-sectional study. A questionnaire based on the Bowel Disease Questionnaire that records gastrointestinal symptoms was given to 294 patients in 4 dialysis centers. A total of 196 (67%) subjects returned the survey. A multivariable logistic regression model was used to identify factors significantly associated with IBS symptoms.

RESULTS: Symptoms compatible with IBS were present in 27 (13.8%) subjects and independently associated with low post-dialysis serum potassium [OR = 0.258, 95% CI (0.075-0.891), $P = 0.032$], paracetamol use [OR = 3.159, 95% CI (1.214-8.220), $P = 0.018$], and Kidney Disease Quality of Life (KDQOL) cognitive function score [OR = 0.977, 95% CI (0.956-0.999), $P = 0.042$]. Univariate regressions were also performed and the reported significance is for multivariate analysis. No association was detected for age, gender, depressed mood, smoking (present or past), body mass index, albumin level, Kt/V, sodium pre- or post-dialysis level, change in potassium level during HD, proton pump inhibitor or H2 blocker use, aspirin use, residual diuresis, hepatitis B or C infection, diabetes mellitus, marital status and education level.

CONCLUSION: This study examined potential risk factors for symptoms compatible with IBS in HD patients and identified an association with paracetamol use, post-dialysis potassium level and KDQOL-cognitive function score.

Abstract

AIM: To investigate clinical characteristics associated with the presence of irritable bowel syndrome (IBS) symptoms in hemodialysis (HD) patients.

Fiderkiewicz B, Rydzewska-Rosołowska A, Myśliwiec M, Bi-recka M, Kaczanowska B, Rydzewska G, Rydzewski A. Factors associated with irritable bowel syndrome symptoms in hemodialysis patients. *World J Gastroenterol* 2011; 17(15): 1976-1981 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i15/1976.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i15.1976>

INTRODUCTION

Chronic gastrointestinal symptoms are common in patients with chronic kidney disease (CKD). The prevalence rate is reportedly as high as 70%^[1-4], and there is an association with impaired psychological well-being^[5]. Among these gastrointestinal symptoms, irritable bowel syndrome (IBS) is also more frequent than in the general population, and is present in 11%-44% of hemodialysis (HD) patients^[2-4]. Although the pathophysiology of IBS is uncertain, altered gut reactivity (motility, secretion), visceral hypersensitivity and dysregulation of the brain-gut axis are believed to play an important role^[6]. The risk factors associated with IBS in HD patients are not known. The aim of this study was to determine the possible relationship between IBS symptoms in HD patients and their clinical characteristics.

MATERIALS AND METHODS

Patients

This was a cross-sectional study. All patients in 4 HD centers (2 state financed and 2 privately owned) were asked to complete a questionnaire. The questionnaires were given to patients during a planned hemodialysis procedure. The study was approved by the local Ethics Committee.

All of the subjects were Caucasian. They were dialyzed 3 times a week for 180 to 300 min using either polysulfone or cellulose acetate dialyzers and bicarbonate dialysis fluid containing 2 mEq/L of potassium in 3 centers and 2 or 3 mEq/L (adjusted on the basis of the knowledge of prevailing pre-dialysis serum potassium levels in a given individual) in 1 center.

Causes of ESRD were as follows: glomerulonephritis, $n = 60$ (30.6%); diabetic nephropathy, $n = 32$ (16.3%); amyloidosis, $n = 11$ (5.6%); polycystic kidneys, $n = 22$ (11.2%); hypertension/atherosclerosis, $n = 16$ (8.2%); tubulointerstitial disease, $n = 39$ (19.9%); unknown/uncertain, $n = 15$ (7.7%); nephrectomy, $n = 1$ (0.5%).

Questionnaire

A questionnaire based on the Bowel Disease Questionnaire was used^[7]. It was translated to the Polish language by 2 of the authors (BF, AR). Translations were compared and discrepancies reconciled. The resulting translation was then tested in 20 randomly selected dialysis patients, and as a result some of the expressions in the translation were altered to make them easier to understand. The question-

naire was then checked by a person who was not involved in translation (ARR), and finally evaluated by a certified gastroenterologist (GR).

IBS was defined using Manning criteria^[8] as described by Talley *et al.*^[9], as an ache or pain that occurred more than 6 times per year which was either often made better by a bowel movement or often associated with more frequent or looser bowel movements when the pain began. In addition, 2 or more of the following symptoms had to be present: fewer than 3 bowel movements per week or more than 3 bowel movements per day; loose, watery stools or hard stools; straining to have bowel movements; feelings of incomplete rectal evacuation; urgency; mucus; or bloating with distention.

Additionally, we included questions taken from the validated Polish translation of Kidney Disease Quality of Life (KDQOL) questionnaire, related to depressed mood and cognitive function^[10]. Depressed mood was measured by the following KDQOL items: How much of the time during the last 30 d have you felt so down in the dumps that nothing could cheer you up? and How much of the time during the last 30 d have you felt downhearted and blue? The six possible responses to these questions were (1) none of the time; (2) a little of the time; (3) some of the time; (4) a good bit of the time; (5) most of the time; and (6) all of the time. Patients were classified as reporting depressed mood when they indicated that they had felt down in the dumps or felt downhearted and blue a good bit of the time or more often^[11].

Cognitive function was measured by the KDQOL-CF score. Patients had to answer the following questions: During the past 4 wk, did you react slowly to things that were said or done? Did you have difficulty concentrating or thinking? Did you become confused? Responses on a six-point scale were weighted and transformed to a score ranging from 0 to 100, with higher scores indicating better self-assessed cognitive function^[12].

Relevant laboratory and clinical data were extracted from medical records. Data corresponding closest to the date of the HD session during which the questionnaire was distributed, were used. We allowed for a time span of 14 d before and after HD.

Statistical analysis

Results are expressed as means \pm SD or frequency. Variables were tested for normality of distribution using the Wilk-Shapiro test. The Fisher's exact test and χ^2 test were used for comparing categorical variables, as appropriate.

Univariate and multivariable logistic regression was used to identify patient characteristics associated with IBS compatible symptoms. Risk factors considered in this analysis included age, sex, education level, marital status, presence of diabetes mellitus, procedure, hemoglobin level, pre- and post-HD potassium level, change in potassium level during HD, use of paracetamol in the last year, KDQOL-CF score, depressed mood, smoking

Table 1 Patients' demographic and clinical data expressed as (mean \pm SD) *n* (%)

| Group | IBS symptoms | | All | P value |
|---|-----------------|-----------------|-----------------|--------------------|
| | (+) | (-) | | |
| <i>n</i> | 27 | 169 | 196 | |
| Gender (M/F) | 13/14 | 105/64 | 118 / 78 | 0.168 |

IBS: Irritable bowel syndrome; BMI: Body mass index. ^a*P* < 0.05.

(present or past), body mass index (BMI), albumin level, Kt/V, sodium pre- and post-dialysis level, proton pump inhibitor (PPI) or H2 blocker use, aspirin and paracetamol use, residual diuresis, hepatitis B or C infection. Variables were included in the multivariable logistic model if *P* < 0.10 in the univariate analysis. A *P* value less than 0.05 was considered statistically significant. The software, used for statistical computations was Stata 9.2 (StataCorp, College Station, TX, USA).

RESULTS

Patients

A total of 294 HD patients were asked to complete the questionnaire, of which 196 were returned giving a 67% response rate. All the responders completed the questionnaires by themselves. Their clinical characteristics are given in Table 1.

IBS symptoms

Symptoms compatible with IBS were present in 27 (13.8%) subjects. They were more common in women (18.0%) than in men (11.0%), but the difference was not statistically significant (*P* = 0.168). Symptoms of IBS were more frequent in patients with a post-hemodialysis potassium level \leq 3.5 mEq/L than in subjects with potassium > 3.5 mEq/L. Also pre-dialysis potassium level was related to the frequency of IBS symptoms (Figure 1).

In univariate logistic regression, pre-dialysis serum potassium [OR = 0.462, 95% CI (0.222-0.965), *P* = 0.040], post-dialysis serum potassium [OR = 0.237, 95% CI (0.084-0.666), *P* = 0.006], hemoglobin level [OR = 1.403, 95% CI (1.038-1.897), *P* = 0.028], use of paracetamol in the last year [OR = 3.541, 95% CI (1.499-8.364), *P* = 0.004], and KDQOL-CF score [OR = 0.972, 95% CI (0.954-0.991), *P* = 0.004] were associated with IBS symptoms. Age (*P* = 0.076), gender (*P* = 0.172), depressed mood (*P* = 0.118), smoking (present or past) (*P* = 0.105), BMI (*P* = 0.896),

Table 2 Multiple logistic regression analysis to identify independent predictors of irritable bowel syndrome symptoms in hemodialysis patients

| Variable | <i>b</i> coefficient (SE) | <i>P</i> value | OR (95% CI) |
|-------------------------|---------------------------|--------------------|---------------------|
| Potassium level pre-HD | -0.325 \pm 0.437 | 0.457 | 0.723 (0.307-1.703) |
| Potassium level post-HD | -1.356 \pm 0.633 | 0.032 ^a | 0.258 (0.075-0.891) |
| Paracetamol use | 1.150 \pm 0.488 | 0.018 ^a | 3.159 (1.214-8.220) |
| Cognitive function | -0.023 \pm 0.011 | 0.042 ^a | 0.977 (0.956-0.999) |
| Hemoglobin | 0.327 \pm 0.168 | 0.052 | 1.387 (0.998-1.928) |
| Age | 0.026 \pm 0.021 | 0.213 | 1.027 (0.985-1.070) |

HD: Hemodialysis; OR : Odds ratio. ^a*P* < 0.05.

albumin level (*P* = 0.856), Kt/V (*P* = 0.353), sodium pre- (*P* = 0.961) or post-dialysis level (*P* = 0.176), change in potassium level during HD (*P* = 0.556), PPI or H2 blocker use (*P* = 0.857), aspirin use (*P* = 0.172), residual diuresis (*P* = 0.411), hepatitis B or C infection (*P* = 0.358), diabetes mellitus (*P* = 0.822), marital status (*P* = 0.941) and education level (*P* = 0.377) were not associated with IBS symptoms.

When the risk factors for symptoms of IBS were assessed by multiple logistic regression analysis, independent predictors of IBS symptoms included: paracetamol use, post-dialysis serum potassium and KDQOL-CF score (Table 2).

DISCUSSION

The frequency of symptoms compatible with IBS in our study is somewhat higher than that reported (11%) among 105 Austrian HD patients^[3] using similar criteria, and lower than that among 148 English HD patients (21%) using Rome II criteria^[2]. In the latter study, IBS was significantly more common in HD subjects than in both hospital outpatients and community controls^[2]. In a study from Turkey, the prevalence of IBS, using Rome II criteria, was 44% among 93 HD patients, significantly more common than in healthy volunteers (21%)^[4].

The overall IBS prevalence in Europe is 11.5%^[13]. It varies, however, widely among countries, being highest in the UK and Italy^[13], depending to a large extent on the diagnostic criteria used^[14]. There is even more variability between continents^[13]. Unfortunately, there is no data on IBS prevalence in the general population in Poland.

As there is no biologic marker of the disease, the diagnosis of IBS relies heavily on symptom-based criteria. The most widely used is a consensus definition called the Rome criteria^[16,17], where IBS is defined chiefly by abdominal pain associated with defecation or a change in bowel habit and with features of disordered defecation. Some researchers have suggested that these criteria over-emphasize abdominal pain and fail to emphasize post-prandial urgency, abdominal pain, and/or diarrhea^[18,19]. We thought that for the HD population, with frequent comorbidities, the use of supportive symptoms that are not part of the Rome criteria would be more appropriate. The Kruis scoring system^[20], which in addition to self-reported symptoms includes: erythrocyte sedimentation

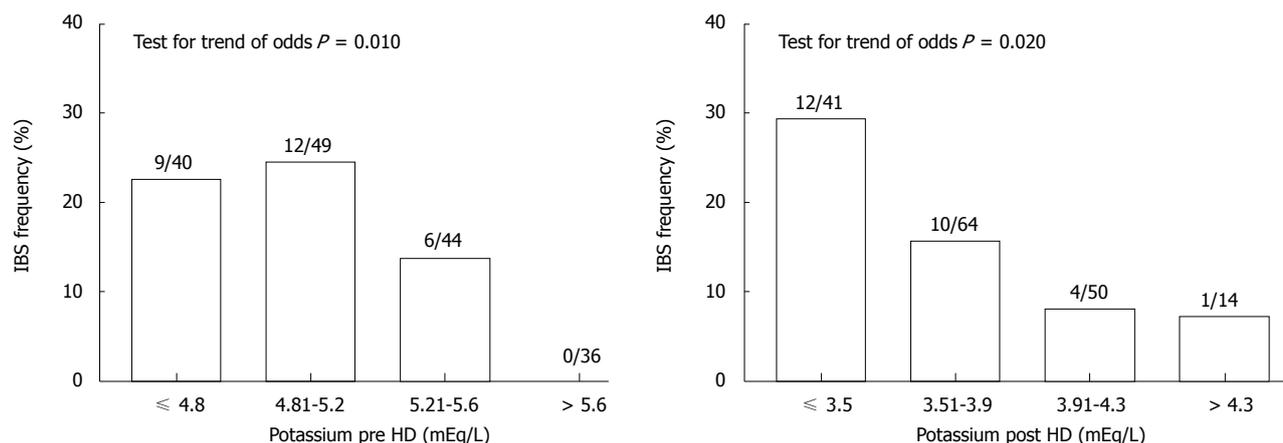

Figure 1 Frequency of irritable bowel syndrome symptoms in hemodialysis subjects stratified by pre- or post-hemodialysis potassium level. Numerator corresponds to number of irritable bowel syndrome (IBS) cases and denominator to number of all patients with given potassium level. HD: Hemodialysis.

rate, leukocytosis and anemia could not be used in HD patients for obvious reasons.

Fulfillment of IBS criteria is not unequivocally diagnostic of IBS, however, to make a positive diagnosis of IBS the use of diagnostic criteria is the recommended method, rather than exhaustive investigations to exclude an underlying organic cause^[21]. Surprisingly, however, very few studies have examined the utility of the various diagnostic criteria in differentiating IBS from organic disease. The authors of a recent systematic review were able to find only 4 studies that reported on the accuracy of the Manning criteria, 1 study that reported on the Rome I criteria, and no studies on the Rome II or Rome III criteria^[21].

In clinic-based studies, IBS has been associated with female gender, psychological distress, physical and sexual abuse, food allergies, enteric infections, and previous abdominal surgeries^[22]. In a community-based study Locke *et al*^[23] found associations with somatic symptoms, analgesic use, and food allergies and sensitivities^[23].

The association between acetaminophen use and IBS has been previously reported, and is difficult to explain^[23]. A possibility exists that most people take paracetamol for their IBS. It is interesting that there was no association between aspirin use and IBS symptoms, similar to Locke *et al*^[23] when the use of these drugs was reported independently. Additionally, in this country aspirin is most frequently used for cardiovascular prophylaxis.

Cognitive deficits often accompany chronic illnesses, although the underlying mechanisms are not fully understood and may differ between diseases. Cognitive impairment is common in HD patients^[24]. Risk factors include: age, race, stroke, diabetes, low education status, anemia, measures of malnutrition and an equilibrated Kt/V ≥ 1.2 ^[25,26]. Also, IBS in the general population is associated with cognitive impairment^[27,28]. An observed association between IBS symptoms and KDQOL-CF score might suggest that IBS worsens cognitive deficits in HD patients. We used the KDQOL-CF self reported score for the assessment of cognitive function. Although

the KDQOL-CF provides estimates rather than a definitive assessment of cognitive function, it was shown that the KDQOL-CF scale scores correlate with the Modified Mini-Mental State Examination, and are acceptable for estimating cognitive function in dialysis subjects^[12,29].

In the general population, IBS is associated with stress^[6]. In our study, the presence of IBS compatible symptoms was not related to the presence or absence of anxiety or depression. This is similar to the findings by Cano and colleagues^[2]. They, therefore, concluded that IBS in HD patients might be related to either the “uremic” state or the treatment method. This is in contrast to Kahvecioglu *et al*^[4] who found that IBS in dialyzed patients was associated with depression and anxiety. In the general population, IBS seems to be more common in younger people. Our population was mostly over 50 years, and that might explain the lack of an age effect on the frequency of IBS symptoms.

Patients suffering from diabetes mellitus report a greater prevalence of gastrointestinal symptoms than controls, which is not related to glycemic control^[30]. We did not observe, however, any difference in the frequency of IBS symptoms between diabetic and non-diabetic HD patients. This is in agreement with Cano *et al*^[2].

It is difficult to offer an explanation for the unexpected univariate association between IBS symptoms and hemoglobin level. Patients dialyzed in central and eastern European dialysis centers have lower mean hemoglobin levels and are less likely to attain target levels than those treated in western European counterparts^[31]. HD patients with higher hemoglobin levels report higher quality of life, and IBS patients in the general population have lower health-related quality of life^[32]. Additionally, gastrointestinal symptoms in patients with chronic kidney disease are associated with impaired general psychological well-being^[5]. However, IBS patients have a propensity to report pain and label negatively expected adverse sensations, so it is conceivable that IBS specific symptoms are “unmasked” in patients who have an overall higher quality of life.

To our knowledge, the association between serum potassium level and the frequency of symptoms compatible with IBS has not been reported before. This finding, however, has to be treated with caution. Although gastrointestinal motility is impaired in chronic pre-dialysis kidney disease^[33], it is alleviated by hemodialysis^[34]. Thus, another mechanism may be responsible. Hypokalemia may cause decreased motility and propulsive activity of the intestine, and even lead to ileus. We recorded potassium levels before and after a single HD session, whereas a level prevailing over a specific time period might be more appropriate. It may be, however, that episodes of hypokalemia, which are likely just after hemodialysis, are responsible for the appearance of IBS symptoms. A consistent trend of a higher prevalence of IBS compatible symptoms with lower potassium concentration, also suggests a causative role for hypokalemia. During conventional HD, large amounts of potassium are removed, approximately 40% of which originates from the extra- and the remainder from the intracellular space^[35]. A change in the plasma potassium concentration during hemodialysis, however, is difficult to predict, due to the concomitant movement of the ion into cells due to correction of metabolic acidosis. After HD, plasma potassium concentration increases rapidly during the first hour and steadily thereafter. The post-dialysis rise in potassium concentration is not correlated with pre- or post-dialysis plasma K^[35].

In CAPD patients, it has been reported that episodes of hypokalemia are a risk factor for developing peritonitis and bacterial overgrowth, possibly due to altered intestinal motility^[36,37].

In our study, neither the dialysis session time nor the change in potassium level influenced the prevalence of IBS symptoms, what suggests that the between dialyses level rather than the intradialytic change is important. In line with this electrophysiological mechanism reasoning, is the observation that pre-dialysis potassium < 4.0 or > 5.6 mEq/L is associated with increased mortality in HD patients, most probably due to cardiac arrhythmias^[38]. Despite the plausible electrophysiological mechanism, the association between potassium level and IBS symptoms might be confounded by other factors. It has been suggested for both HD and PD patients, that hypokalemia could be a surrogate marker for poor nutrition and associated comorbidities^[38,39].

This study has a number of shortcomings: firstly the Bowel Disease Questionnaire was not formally validated. To that end we ensured that the Polish translation was faithful and easy to understand. Additionally, the number of subjects was rather low, the study was observational and could not prove causality in relationships. Finally, the study potentially lacked generalizability due to cross-cultural differences in the symptomatology of functional gastrointestinal disorders^[15].

In summary, this study examined potential risk factors for symptoms compatible with IBS in HD patients and identified an association with acetaminophen use, serum potassium level, and KDQOL-cognitive function score.

The role of hypokalemia requires further well designed and controlled clinical studies.

COMMENTS

Background

Chronic gastrointestinal symptoms are very common in patients with chronic kidney disease (CKD) treated by hemodialysis (HD) including irritable bowel syndrome (IBS). Risk factors associated with IBS in HD patients are not known.

Research frontiers

Risk factors that are associated with IBS in the general population include: somatic symptoms, female gender, psychological distress, physical and sexual abuse, food allergies, enteric infections, previous abdominal surgeries, analgesic use, and food allergies and sensitivities. Of the 196 HD patients included in this study, symptoms compatible with IBS were present in 27 (13.8%) subjects and were independently associated with low post-dialysis serum potassium, paracetamol use, and KDQOL cognitive function score.

Innovations and breakthroughs

This study showed that low post-dialysis serum potassium, paracetamol use, and KDQOL cognitive function score are independently associated with increased risk of IBS compatible symptoms.

Applications

This analysis of the risk factors for IBS may be helpful in reducing the risk of abdominal symptoms in HD patients.

Peer review

The authors report an observational study looking at various factors associated with IBS as defined by Manning criteria in haemodialysis patients.

Abstract

AIM: To study the effect of viscosity on axial force in the esophagus during primary peristalsis using a newly validated impedance-based axial force recording technique.

METHODS: A probe able to simultaneously measure both axial force and manometry was positioned above the lower esophageal sphincter. Potable tap water and three thickened fluids were used to create boluses of different viscosities. Water has a viscosity of 1 mPa·s. The three thickened fluids were made with different concentrations of Clinutren Instant thickener. The viscous fluids were in appearance comparable to pudding (2 kPa·s), yogurt (6 kPa·s) and slush ice (10 kPa·s). Six healthy volunteers swallowed 5 and 10 mL of boluses multiple times.

RESULTS: The pressure amplitude did not increase with the bolus viscosity nor with the bolus volume whereas the axial force increased marginally with bolus volume ($0.1 > P > 0.05$). Both techniques showed that contraction duration increased with bolus viscosity ($P < 0.01$). Association was found between axial force and pressure but the association became weaker with

increasing viscosity. The pressure amplitude did not increase with the viscosity or bolus volume whereas the axial force increased marginally with the bolus size.

CONCLUSION: This indicates a discrepancy between the physiological functions that can be recorded with axial force measurements and pressure measurements.

INTRODUCTION

The primary function of the esophagus is to transport swallowed material from the pharynx to the stomach. A voluntary swallow initiates coordinated neuro-motor activity resulting in an aborally propagating contraction termed primary peristalsis. The primary effect of peristalsis is to develop force in the axial direction to pass the food into the stomach. Esophageal peristalsis depends on several factors such as body position, gravity, bolus size, and bolus viscosity^[1,2].

The most common method to study esophageal peristalsis is manometry using low-compliance perfused catheters or more recently high-resolution manometry using multiple solid state transducers mounted on the catheter.

It has been shown that bolus volume affects the peristaltic contraction velocity and duration^[3,4]. The interval between swallows^[5,6], body position^[2,4] and temperature of the bolus^[7] also affect peristalsis. However, the pressure amplitude is not affected by increasing bolus viscosity whereas the duration and velocity is reduced^[7,8].

Since the swallowed material is transported in the axial (longitudinal) direction of the esophagus, axial force measurements from a theoretical and practical standpoint better reflect esophageal function than pressure recordings do. Manometry measures the radial pressure which merely is an indirect measurement of the radial force (perpendicular to the axial force direction). Video-fluoroscopy is used to visually assess esophageal motor flow but it does not provide quantitative information on force in either radial or axial directions^[9,10]. Several attempts have been made to develop techniques to measure the axial force in the esophagus^[11-14]. Despite promising initial results based on strain gauge technology, this method has never been thoroughly tested or never made a breakthrough in clinical studies. Thus, only scarce data exist on the axial force in the esophagus. To the best of our knowledge, no studies have been published on the effect of bolus viscosity with axial force recordings.

The aim of this paper was to study the effect of bolus viscosity on axial force in the esophagus during primary peristalsis using a newly validated impedance-based force recording technique^[15,16] and to compare these results with manometric recordings.

MATERIALS AND METHODS

Probe design and hardware setup

The probe was custom-made to measure axial force and pressure simultaneously at different positions on the probe (Ditens A/S, Aalborg, Denmark). The probe was 60 cm long and constructed from three different catheters. The proximal catheter of the probe was used for manometry, the middle catheter contained the transducer for axial force measurement, and the distal catheter was 2.5 cm long and contained a small bag (Figure 1).

The proximal catheter of the probe was made from an 8-lumen polyurethane catheter with an outer diameter of 4.6 mm. The 8 channels had different diameters. Three channels (diameters of 0.5 mm) were used for manometric measurements using a low compliance perfusion system. The side holes for manometric measurements were placed 6, 8 and 10 cm proximal to the tip of the catheter. Steel threads were placed in a 1.0 mm lumen to avoid elongation of the proximal catheter. One 0.5 mm lumen contained two wires connected to the force transducer electrodes in the middle catheter. Two channels with diameters of 2.0 mm were used to re-circulate saline (0.09%) in the middle catheter and to inflate the bag. The last lumen with a diameter of 1.3 mm contained a temperature sensor (TC Ltd., Uxbridge, England) for measurement 0.5 cm proximal to the force transducer. It was used to temperature compensate the impedance signal.

The middle catheter was 2 cm long and consisted

of three single-lumen catheters/cylinders inside each other^[15,17]. The innermost catheter was 3 mm in diameter and made of elastic Natvar catheter (Colorite Polymers, Belfast, Ireland). Two electrodes for electrical impedance measurement were placed inside this catheter. One electrode was mounted on the distal catheter and the other on the proximal catheter. Two overlapping rigid cylinders (outer diameters of 4 and 5 mm) surrounded the inner catheter. They protected the elastic catheter from radial forces and from bending, factors that would introduce errors.

The distal catheter was a non-stretchable catheter with an outer diameter of 1.5 mm through which inflation of the bag was done. The cylindrical shaped bag was made of 25 μ m thick polyurethane (Ditens A/S, Aalborg, Denmark) and contained up to 13 mL. It was mounted on the outer rigid cylinder and the distal catheter. Tensile axial force applied to the bag made the rigid cylinders and electrodes move apart, resulting in increased electrical impedance. The electrical impedance, measured as the electrical potential difference (voltage), was calibrated to axial force [g] by applying precision weights in the range of 0-200 g.

Subjects

Six healthy men were included in the study (mean 38.3 years, range 25-61). Oral and written informed consent was obtained from all subjects. Ethics approval for the study was obtained from the Local Ethics Committee (Protocol No. VN 2003/120 mch).

Protocol

The catheter was first inserted through the mouth and esophagus into the stomach. The lower esophageal sphincter (LES) was located by the proximal pressure recordings. The probe was further retracted, placing the middle of the bag 5 cm proximal to the LES. Pressure was recorded 8, 10 and 12 cm proximal to the LES. Axial force was recorded 6.5 cm proximal to the LES.

Potable tap water and three thickened fluids were used to create boluses of different viscosities. Water has a viscosity of 1 mPa·s. The three thickened fluids (TF1-TF3) were made by mixing 100 mL tap water with 13.8, 16.5 and 19.3 g Clinutren Instant thickener (Nestlé, Vevey, Switzerland), respectively. An analysis of the instant thickener product was generated prior to the study by Vysera Biomedical Ltd., showing the viscosity as a function of the concentration in water (Figure 2). The selected viscosities of the thickened fluids were 2 kPa·s, 6 kPa·s and 10 kPa·s. The viscous fluids were in appearance comparable to pudding (2 kPa·s), yogurt (6 kPa·s) and slush ice (10 kPa·s). The bag was inflated with 2 mL of fluid throughout the experiments to enable peristalsis to grip the bag. The protocol included four series of five dry swallows, five 5 mL swallows and five 10 mL swallows. Each series tested a different fluid. At the end of each series the fluid used for the next series was mixed. All boluses were given at room temperature (23-26°C). The interval between swallows was at least 45 s. All subjects were studied in upright position with the upper body tilted

30 degrees posterior and instructed to swallow as normally as possible. The volunteers drank 65 mL water between each series (after the five consecutive swallows) to clear the esophagus from any excess fluids of high viscosity.

Analysis

Contraction amplitude and duration were analyzed for both force and pressure measurements. The start of a contraction was defined as the interception with the x-axis for the linear fit of the steep incline of a contraction wave. The end of a contraction was defined as the interception with the x-axis for the linear fit to the steep decline of a contraction. This definition was used because the bolus itself affected the measures before the arrival of a peristaltic contraction. This definition has previously been verified by video fluoroscopy^[18] and used in different manometric studies^[8,19]. The linear fit was calculated using a semi-automatic program custom made for the purpose using MatLab® version 7 (Mathworks, Natick, MA, USA).

Complete absence of motor activity (manometry < 15 mmHg^[20,21], force < 10 g) at a given site was termed “failure of contraction”. Double-peaked, triple-peaked and repetitive waves were quantified manually during the semi-automatic analysis.

Statistics analysis

The results are given as grand mean ± SD. The correlation coefficient ρ between the force and pressure measurements was computed with Pearson’s correlation test for duration and amplitude at individual bolus size. Two-way analysis of variance (ANOVA) was used for the analysis of axial force and pressure. ANOVA was also used to analyze differences between bolus size. The axial force and pressure amplitude cannot be compared directly. Therefore, normalization was done by division with the overall mean of the axial force amplitude and pressure amplitude, respectively. The overall mean was computed from all the contraction amplitudes. $P < 0.05$ was considered significant.

RESULTS

The study was conducted without adverse events for the subjects. The age of the subjects was 27.7 ± 4.2 years. Representative recordings obtained in a subject swallowing 5 mL of water and 10 mL of thickened fluid (10 kPa·s) are shown in Figure 3. The arrival of the bolus in front of the peristaltic wave can be seen in the recording from the 10 mL swallow (marked with an arrow). The number of peristaltic contractions was higher during 5 and 10 mL swallows when compared to dry swallows; that is fewer wet swallows failed to induce contraction. The number of contractions was lower for multi-peaked contractions for both manometry and axial force during 5 mL swallows compared to dry swallows. Manometry and axial force showed an equal number of contractions. Only contractions, but not the events that did not fulfill the contraction criteria, were included in the subsequent analysis. No qualitative changes in the shape of the peristaltic contraction were found in association with the quantitative changes described. No increase or decrease in contractile amplitude or duration was found during the five subsequent swallows in a series. Thus, in the following analysis the averages were used.

Contraction amplitude

The most distal pressure recording site had the biggest amplitude for both 5 mL swallows ($F = 22.5, P < 0.001$) and 10 mL swallows ($F = 26.3, P < 0.001$). Thus, the manometric amplitude increased distally when comparing

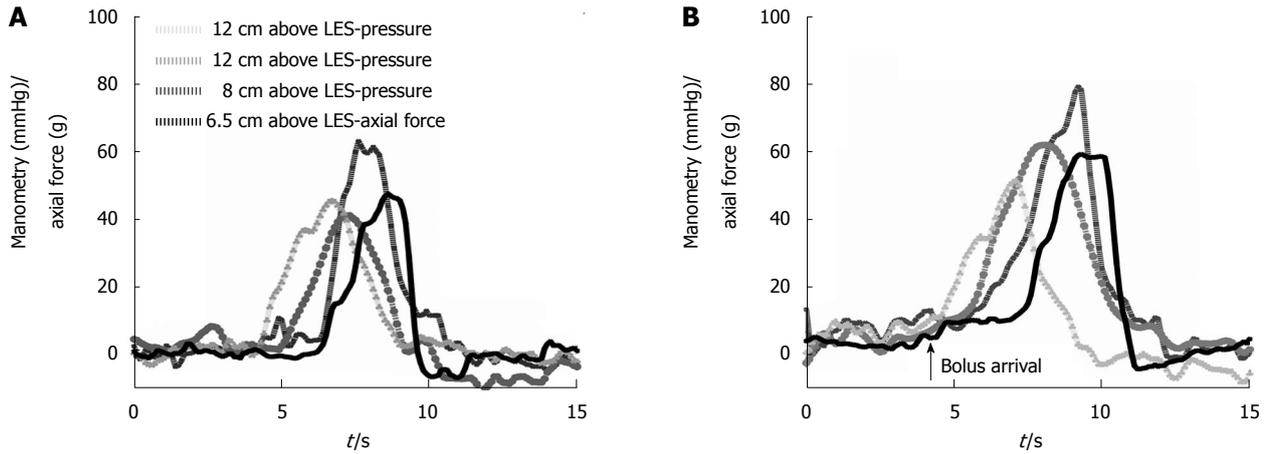

Figure 3 Two swallows (initiated at time = 0) from one subject. One swallow of 5 mL water (A) and one swallow of 10 mL thickened fluid (B). The arrival of the fluid before the actual peristaltic wave was clear during swallowing of 10 mL thickened fluid. LES: Lower esophageal sphincter.

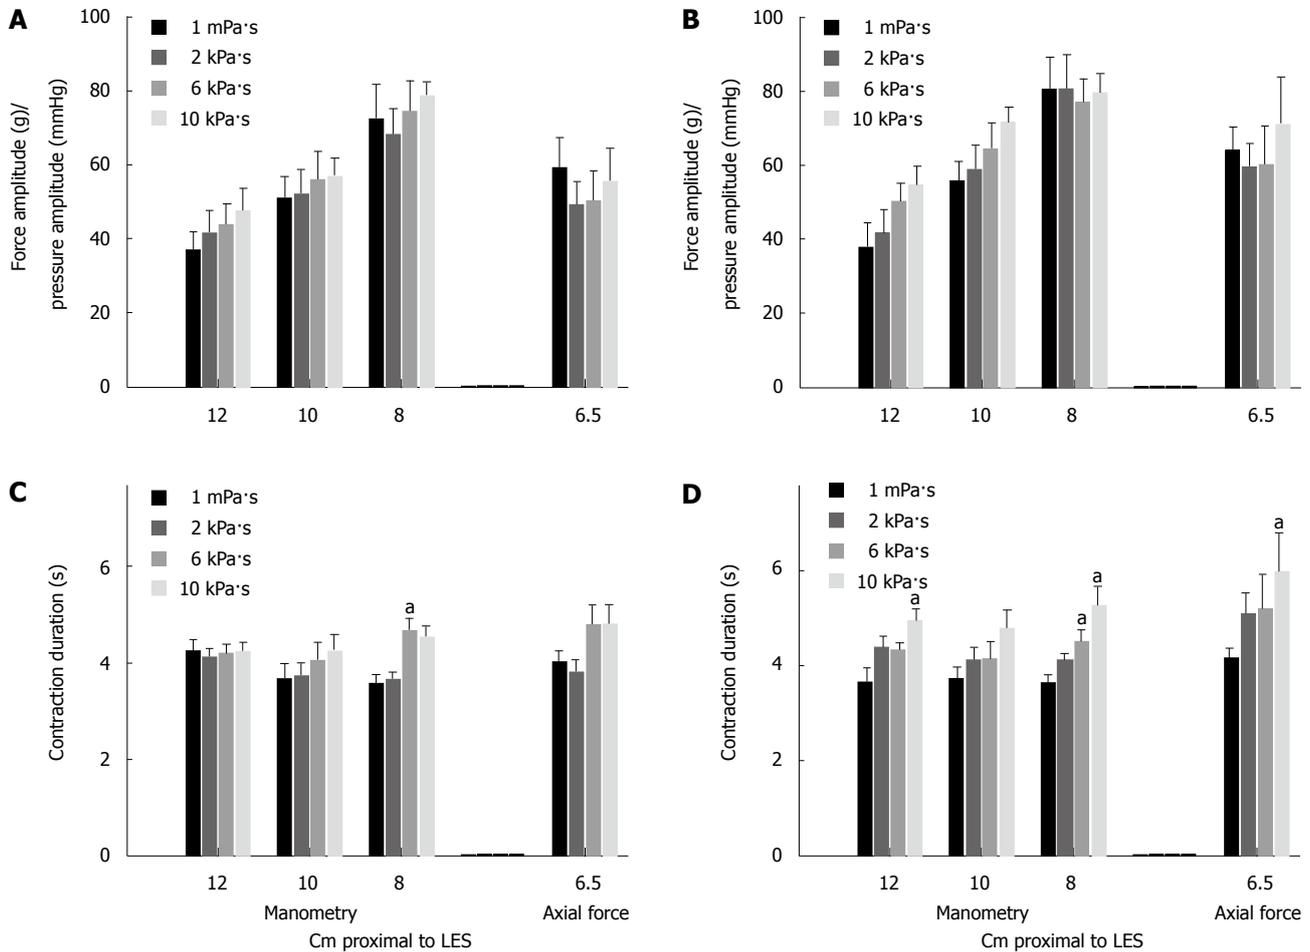

Figure 4 The mean \pm SE amplitude (A, B) and duration (C, D) for manometry and axial force recordings during 5 mL swallows (A, C) and 10 mL swallows (B, D). The color of the columns represents the viscosity from 1 to 10 kPa·s. The axial force amplitude was marginally affected by bolus size ($F = 3.5$, $P = 0.069$) while pressure recordings were unaffected. The duration of the contraction increased as the viscosity increased. ^a $P < 0.05$ vs water. LES: Lower esophageal sphincter.

recordings at different levels.

The pressure amplitude did not depend on viscosity or bolus size at any recordings site (Figure 4). The axial force amplitude was 38.7 ± 17.2 g during dry swallows (not shown). The axial force amplitude was marginally

influenced by bolus size ($F = 3.5$, $P = 0.069$) but did not increase with the bolus viscosity (Figure 4). Using 2-way ANOVA no difference was found when normalized amplitudes for pressure recorded 8 cm proximal to LES was compared to normalized axial force amplitudes.

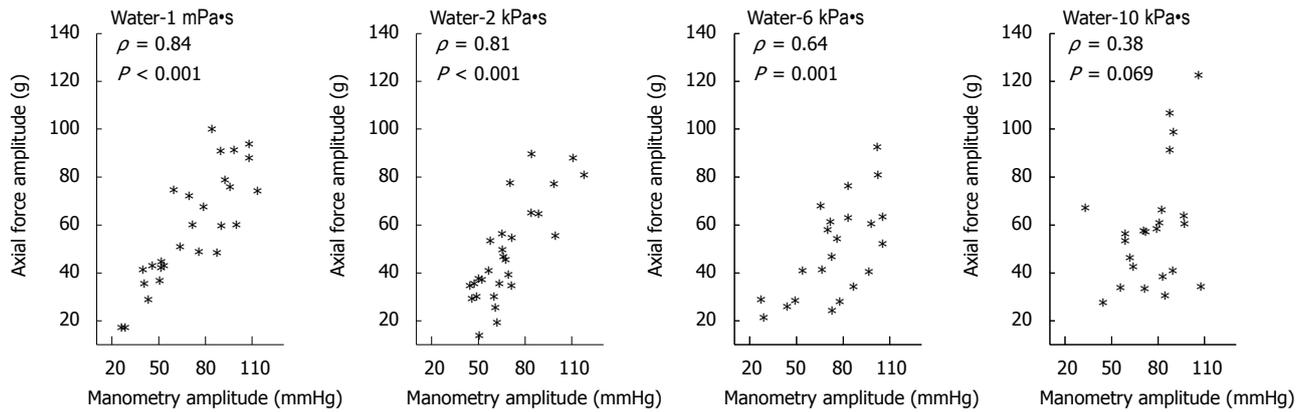

Figure 5 The correlation between manometry amplitude recorded 8 cm proximal to LES and axial force recorded 6.5 cm proximal to LES. The graphs from left to right are swallows of fluids with viscosities of 1 mPa*s, 2 kPa*s, 6 kPa*s and 10 kPa*s, respectively. LES : Lower esophageal sphincter.

The association between axial force [6.5 cm proximal to the lower esophageal sphincter (LES)] and manometry recorded 8, 10 and 12 cm proximal to the LES for both duration and amplitude. ^aIndicate a significant association ($P < 0.05$).

Contraction duration

The contraction duration recorded with manometry was not influenced by the recording site (Figure 4). The duration increased with viscosity for pressure recorded 8 cm above LES ($F = 12.3, P < 0.01$) (Figure 4).

The contraction duration measured with axial force increased with increasing viscosity ($F = 4.3, P = 0.01$) and bolus size (5 mL versus 10 mL) ($F = 4.9, P = 0.03$). The pressure duration recorded 8 cm proximal to the LES was lower than that for axial force for 10 mL swallows ($F = 4.9, P = 0.033$). Pressure recorded 8 cm proximal to the LES showed a change with viscosity ($F = 12.3, P < 0.001$) and the post hoc analysis showed difference between water and 10 kPa*s fluid ($P < 0.001$) and between water and 6 kPa*s fluid ($P = 0.001$). Contrary to the amplitude the duration did not change when comparing the different manometric recording sites.

Association between pressure and axial force

The association between the pressure amplitude measured 8 cm proximal to the LES and force amplitude recorded

during 5 mL swallows decreased with increasing bolus viscosity (Figure 5 and Table 1). The correlation coefficients for amplitudes during 10 mL swallows were lower compared to 5 mL swallows. Association was not found at any viscosity or bolus volume when comparing axial force amplitudes to pressure amplitudes recorded 12 cm proximal to the LES (all $P > 0.05$). With regard to contraction duration no association was found for 5 mL swallows except in one case (Table 1). A weak association between axial force and manometry 8 cm proximal to LES was found for 10 mL swallows ($P < 0.58$).

DISCUSSION

The major results were that the pressure and force amplitude did not increase with the viscosity. The axial force amplitude depended on the bolus size. This was not the case for the pressure amplitude. The association between pressure and force amplitudes was weak at large bolus size (10 mL), indicating that pressure will be a less exact measure of the esophageal function.

Methodological considerations

The swallow sequence was not randomized or blinded since pilot experiments showed that the subjects could easily tell the difference between dry swallows, 5 mL and 10 mL volumes in the mouth. The same accounted for the fluids of different viscosity. However, the lack of blinding is of minor importance as a previous study did not show a learning effect regarding the swallowed bolus size^[22].

The viscous fluids did not influence subsequent recordings by accumulating around the probe or bag between swallows since the parameters for dry swallows did not change and the number of contractions remained constant. Individual successive contractions showed no increase in amplitude or duration in five succeeding swallows.

In the current study the viscosity ranged from 1 mPa·s to 10 kPa·s. A previous study used somewhat lower viscosities between 1 mPa·s to 860 mPa·s^[8]. Since the viscosity curve is highly non-linear this may not affect the appearance of the fluid to the same degree. However, it is important to emphasize that the exact viscosity should be given in scientific publications.

The association between manometric data recorded 8 cm proximal to the LES and axial force recorded 6.5 cm proximal to the LES was calculated. However, the distance between recording sites is of minor importance because the amplitude and duration were calculated for each curve individually. One may argue that it is important to evaluate intrabolus pressure since it will be influenced by viscosity^[18]. However, we believe that the contraction pressure is more important.

Amplitudes as function of viscosity

This study confirms the results of Dooley and coworkers^[7] that the contraction pressure amplitude is not affected by changes in bolus viscosity. We further show that the axial force amplitude does not depend on the viscosity.

Previous studies found a poor correlation between the axial force and manometry^[23-25]. Pope and Horton found that swallowing 10 mL of salad oil reduced the axial force amplitude by 50% in the subsequent swallows^[13]. This shows the frictional force is an important factor and the esophagus ability to “grip” the bolus is of great importance to a powerful forward-moving peristaltic wave. In the present study the pressure amplitude was not affected in the same way as axial force amplitude when the frictional force is changed. We believe that one of the reasons that the association between pressure amplitudes and axial force amplitudes became weaker as viscosity increased was due to a change in the frictional resistance (the frictional force resisting fluid movements). It is suspected that the range in frictional resistance between water and the viscous fluids was too low to reveal any difference when comparing axial force amplitudes and manometry amplitudes. Frictional resistance is a complex mechanism and will change depending on e.g. the bolus content, amount of mixed saliva, bolus velocity^[26]. Thus the axial force amplitude (or function) generated by the esophagus may be affected.

Duration in relation to viscosity

The duration of the peristaltic wave was affected by bolus viscosity, especially for 10 mL swallows. This confirms previous manometric studies^[7,8] showing a difference in the whole range of viscosities compared to water. It has been suggested that the increased duration is due to that the bolus reside longer time at the recording site^[7]. However, this is not likely to happen even with very viscous fluids. As seen in the raw tracings the bolus reached the axial force transducer before the actual wave arrived. This implies that the bolus has passed the pressure recordings sites.

In conclusion, the study provided information about the pressure and axial force during peristaltic contractions when exposed to change in bolus viscosity and volume. Though the contractile patterns appeared the same for pressure and force measurements, clear differences were found between the recordings, especially at high volumes and high viscosities. It is expected that profound differences between manometry and axial force will be found between patient groups with esophageal diseases. For example it is well known that some achalasia patients show a “common cavity phenomenon” with aperistalsis. This will create a radial pressure without changes in axial force. The same may account for other esophageal diseases. Thus, it is expected that axial force measurements will have clinical relevance. This will be a subject for subsequent studies.

COMMENTS

Background

Development of diagnostic tools within esophageal motility diseases have for a long time been based on manometry. The development has mainly focused on use of multiple pressure sensors (high resolution manometry). Several authors have previously shown that relying on manometry alone can lead to erroneous conclusions.

Research frontiers

Axial force measurements, also known as traction force, provide additional information not currently available through manometry examinations alone. Axial force provides a more physiological measurement. However few studies have compared simultaneous manometry and axial force.

Innovations and breakthroughs

This is the first study of its kind to examine axial force in relation to viscosity. The data suggests that axial force can provide additional information in relation to motility.

Applications

These data are in accordance with other studies relying on axial force measurements though the areas of interest have been bolus size, temperature etc. The data, together with other papers, suggests that using axial force to assist manometry in motility examinations will provide additional information important to provide a valid diagnosis.

Peer review

This is a very interesting experimental study with important clinical implications in the diagnosis of esophageal disease.

Abstract

AIM: To investigate the technical success and clinical complication rate of a cannulated pancreatic duct with guidewire for biliary access.

METHODS: During a five-year study period, a total of 2843 patients were included in this retrospective analysis. Initial biliary cannulation method consisted of single-guidewire technique (SGT) for up to 5 attempts, followed by double-guidewire technique (DGT) when repeated unintentional pancreatic duct cannulation had taken place. Pre-cut papillotomy technique was reserved for when DGT had failed or no pancreatic duct cannulation had been previously achieved. Main outcome measurements were defined as biliary cannu-

lation success and post-endoscopic retrograde cholangiopancreatography (ERCP) complication rate.

RESULTS: SGT (92.3% success rate) was characterized by statistically significant enhanced patient outcome compared to either the DGT (43.8%, $P < 0.001$), pre-cut failed DGT (73%, $P < 0.001$) or pre-cut as first step method (80.6%, $P = 0.002$). Pre-cut as first step method offered a statistically significantly more favorable outcome compared to the DGT ($P < 0.001$). The incidence of post-ERCP pancreatitis did not differ in a statistically significant manner between either method (SGT: 5.3%, DGT: 6.1%, Pre-cut failed DGT: 7.9%, Pre-cut as first step: 7.5%) or with patients' gender.

CONCLUSION: Although DGT success rate proved not to be superior to SGT or pre-cut papillotomy, it is considered highly satisfactory in terms of safety in order to avoid the risk of a pre-cut when biliary therapy is necessary in difficult-to-cannulate cases.

Pancreatic duct guidewire placement for biliary cannulation in a single-session therapeutic ERCP. *World J Gastroenterol* 2011; 17(15): 1989-1995 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i15/1989.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i15.1989>

INTRODUCTION

Endoscopic retrograde cholangiopancreatography (ERCP) is widely considered as the most demanding endoscopic interventional procedure offering the least invasive way for biliary manipulations. In terms of procedure-related safety, atraumatic biliary cannulation is the fundamental prerequisite to secure a successful therapeutic-intended ERCP^[1]. Nowadays, non-invasive imaging modalities [such as magnetic resonance cholangiopancreatography (MRCP) and endoscopic ultrasound (EUS)] have superseded diagnostic ERCP, reducing the potential complication rate and giving better selection criteria for patients who would benefit from therapeutic biliary manipulations^[2].

Long discussions and reports from ERCP experts have proposed a plethora of different ways to provide an uncomplicated biliary cannulation^[1]. Several factors during ERCP may lead an endoscopist to use the appropriate technique according to his experience and training. Many reports have shown that selective cannulation of the common bile duct (CBD) by insertion of a hydrophilic guidewire through a papillotome may minimize procedure-related complications (particularly post-ERCP pancreatitis-PEP), as opposed to standard CBD access method with direct injection of contrast media^[3-7].

In difficult-to-cannulate cases, pre-cut papillotomy has been established as the alternative method to gain CBD access when biliary therapy is strongly indicated^[8,9]. However, pre-cut technique predisposes to a higher rate of post-ERCP complications including hemorrhage, pancreatitis and perforation, even in the most experienced hands^[10-14].

Furthermore, several studies have documented that a pancreatic duct (PD) previously cannulated with a guidewire may facilitate selective CBD cannulation with a second wire preloaded into a papillotome (double guidewire technique - DGT)^[15-19]. Placement of such a guidewire into the pancreatic duct may act as an endoscopic road map for the CBD, open a stenotic papillary orifice, stabilize the papilla or straighten the common channel when dealing with a tortuous intraduodenal segment^[1].

In view of the above, we retrospectively analyzed our data concerning the use of this method (DGT) in terms of procedure-related efficacy, safety and complication rate.

MATERIALS AND METHODS

Patients

During a 5-year period (from June 2003 through July 2008), 2843 therapeutic ERCPs were performed in our hospital. A retrospective database review was conducted in order to identify all cases involving the use of DGT. Inclusion criteria were the existence of an intact papilla (no prior ERCP attempts) in patients with clinical, laboratory and radiological (transabdominal US, abdominal CT scans, MRCP) findings of pancreatobiliary pathology. Patients with previous gastrointestinal surgical operation, use of needle-knife fistulotomy for papilla impacted stones and suspected sphincter of oddi dysfunction (SOD) were excluded from our study. Endoscopic sphincterotomy (EST) was performed in all patients.

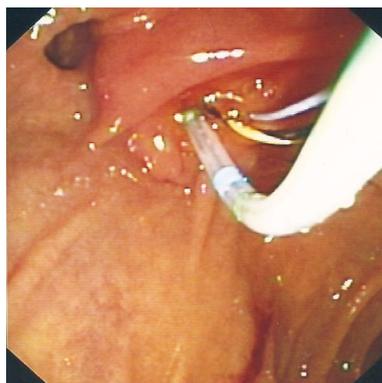

Figure 1 Endoscopic view of the papilla with a hydrophilic wire advanced into the pancreatic duct. A sphincterotome is advanced alongside the pancreatic wire with its tip oriented in the anticipated bile duct position.

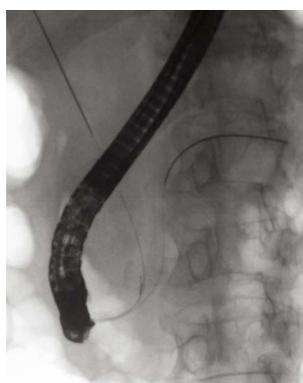

Figure 2 Biliary cannulation with the use of double-guidewire technique. One guidewire has been inserted into the distal part of the pancreatic duct and another is being moved in the direction of common bile duct through the sphincterotome inserted into the ampulla.

Methods and definitions

Our department protocol for biliary cannulation consists of a 3-step procedure undertaken in a single session. In the first step, attempts to cannulate the CBD consist of the use of a sphincterotome preloaded with a hydrophilic guidewire (single guidewire technique-SGT). Initial cannulation using SGT is both time- and cost-efficient when sphincterotomy is anticipated. The use of a guidewire seems to reduce the possibility of chemical-and pressure-related pancreatic injury by avoiding unintentional injection of contrast medium into the main PD or the papilla itself (submucosal injection). Up to 5 attempts within a 15-min period are considered adequate to provide safe cannulation without significant injury of the papillary area (i.e. trauma, edema, bleeding). If these attempts fail and repeated deep PD insertion has resulted, then the guidewire is left distally in the main PD and DGT technique is performed up to 3 times. The tip of the papillotome is positioned against the first wire placed in the PD (Figure 1) and its curve is altered in the anticipated CBD axis. The guidewire into the PD acts as a radiological marker for the PD and facilitates endoscopic location of the biliary orifice (Figure 2). Pre-cut technique with needle-knife is reserved as the 3rd step in cases when DGT has failed or no PD cannulation has

| Primary sclerosing cholangitis | 11 (0.5) |

been achieved in the first place.

Procedural success was defined as the insertion of the guidewire into the CBD. To determine safety and complication rate, all patients underwent measurement of serum amylase before and 24 h after ERCP. Asymptomatic hyperamylasemia was defined as a threefold rise in serum amylase without epigastric pain at 24 h after ERCP. Definition of PEP was the incidence of epigastric pain associated with serum amylase elevation to greater than 3 times normal values at 24 h after the procedure. Bleeding, perforation and other post-ERCP-related adverse events were recorded in detail.

Statistical analysis

Due to the fact that the distribution of the variables under study was not Gaussian, analysis of differences between these parameters, in each patient group, was performed with the non-parametric Mann-Whitney, χ^2 , or Fischer's exact statistical tests, where applicable. The correlation between the employment of different cannulation methods and either final patient outcome, or presence of asymptomatic hyperamylasemia or clinical pancreatitis, was studied using univariate logistic regression analysis.

RESULTS

Of the 2843 ERCPs performed in the study period, 511 were excluded as patients had previously undergone endoscopic manipulations (EST, endoscopic papillary balloon dilation), or altered anatomy was observed due to gastrectomy, or SOD was suspected on the basis of clinical and ERCP findings. A total of 2332 patients met selection criteria. Indications for therapeutic ERCP varied, with suspected common bile duct stones and suspected malignant biliary strictures being the most common (Table 1).

Using SGT as the first step method, CBD cannulation was achieved in 2153 patients (92.3%). Unintentional PD guidewire insertion after 5 attempts was documented in 112 patients. In these cases, DGT was performed after the last effort and selective CBD access was successful in 49 out of 112 patients (43.8%). In the 63 failed DGT cases pre-cut papillotomy gained CBD access in 46 patients (73%). In 67 patients no CBD or PD cannulation was possible with the initial 5 attempts. Fifty-four of them underwent successful pre-cut papillotomy at the same session (80.6%).

SGT was characterized by statistically significant enhanced patient outcome compared to either the DGT ($P < 0.001$), pre-cut failed DGT ($P < 0.001$) or pre-cut as first

step method ($P = 0.002$) (Tables 2 and 3). In addition, pre-cut as first step method offered a statistically significantly ($P < 0.001$) more favorable outcome compared to the DGT method. These observations were further confirmed using univariate logistic regression analysis (Table 4).

Thirty patients in whom therapeutic ERCP failed were referred to surgical or interventional radiological treatment. The total success rate of CBD cannulation in the study population was 98.7% (2302/2332).

The development of asymptomatic hyperamylasemia was significantly more frequent in the DGT and pre-cut failed DGT group of patients, compared to the SGT patients (Table 2). Employing regression analysis, patients who underwent DGT were 2.15 times [HR] more likely (95% CI 1.39-4.60, $P = 0.002$) to develop asymptomatic hyperamylasemia than the SGT patients.

The rates of PEP did not differ in a statistically significant manner between groups of patients who underwent different types of cannulation (Tables 2 and 3). The presence of PEP in the DGT group of patients was statistically significantly ($P = 0.010$) more evident in younger individuals (Median = 42.00 years) than in older ones (63.00 years), without statistical correlation with the initial pathology (Table 4).

In the group of patients who underwent SGT, a statistically significant difference ($P = 0.005$) between age and outcome was observed, as younger patients (Median = 64.00 years) were more likely to be attributed with a successful outcome than older ones (Median = 67.00 years). However, PEP was more frequently present ($P < 0.001$) in younger (Median = 62.00 years) patients than older ones (Median = 67.00 years). Patients who suffered from choledocholithiasis were more likely to present PEP than patients who suffered from malignancy, without reaching statistically significant difference (Table 5).

In the pre-cut failed DGT group of patients, PEP was more frequently present ($P = 0.021$) in younger (Median = 45.00 years) patients than older ones (Median = 63.50 years). As far as the pre-cut as first step method is concerned, the presence of PEP was found more frequently ($P = 0.017$) in younger patients (Median = 52.00 years) than older patients (Median = 68.00 years). The presence of PEP was statistically more evident in patients with choledocholithiasis compared to patients with malignancy in both groups of patients in which pre-cut technique was performed (Table 5).

Patients' gender did not seem to relate in any statistically significant way with the presence of asymptomatic hyperamylasemia and PEP within patients who underwent pre-cut first step, DGT or pre-cut failed DGT method. On the contrary, female patients who underwent SGT showed a statistically significant elevated presence of asymptomatic hyperamylasemia (14.0%) compared to male patients (Table 6).

One case of retroperitoneal perforation was recorded using SGT, and 2 patients developed massive bleeding using pre-cut as first step and sphincterotomy after successful SGT, respectively. These patients underwent immediate surgical treatment without further complications.

DISCUSSION

In the era of modern non-invasive imaging modalities, the role of ERCP has been focused in the therapeutic management of pancreatobiliary diseases. Several techniques and accessories have been used in order to achieve selective CBD cannulation and to decrease the rate of post-ERCP complications.

In the present study, SGT proved to be an effective and safe CBD cannulation approach. The ability to manually control the angle of orientation of the sphincterotome has been shown to be advantageous when dealing with unusually oriented or distorted papillas caused by either diverticula or surgically altered anatomy^[20]. Moreover, the use of hydrophilic coated-tip guidewires seems to

offer a direct way of CBD cannulation under fluoroscopy with less papillary trauma compared to the rather blind method of contrast media injection^[4].

Three large prospective randomized studies comparing post-ERCP complications between the use of a papillotomy with a guidewire (SGT) and papillotomy with contrast media injection as cannulation methods, demonstrated significantly lower incidence of PEP in the SGT group (0%-8.6% *vs* 4.1%-16.6%)^[4-6]. In addition, PEP rate was

lower if unintentional guidewire cannulation of the PD occurred compared to that of unintentional PD opacification by contrast injection (0%-5.1% *vs* 4.4%-19%). In a SGT group, Lee *et al*⁶¹ reported a total of 3 cases of PEP, two in patients with SOD diagnosis, a well-known risk factor for PEP. In these studies, the authors concluded that the reduction in PEP in SGT groups of patients was mainly the result of avoiding elevation of hydrostatic pressure into the PD, partly attributed to the contrast media injection.

Dumonceau *et al*²¹¹ first described the successful use of PD guidewire placement as an adjunct to cannulate CBD in a case of Billroth I gastrectomy with a distorted prepapillary segment of CBD. Later on, Gyökeres *et al*¹⁵¹ reported successful use of DGT in 24 difficult CBD cannulation cases with no significant difference in PEP rate when compared to conventional cannulation. Maeda *et al*¹⁶¹, in a prospective study, documented a superior CBD cannulation rate (93%) with a modified technique, using a PD wire placement and a cannula instead of a papillotome, as opposed to the conventional method with cannula and contrast media (58% success rate). No episodes of pancreatitis with either method were noted, but a significantly higher incidence of hyperamylasemia occurred in the PD wire group. It should be mentioned, however, that patients of the latter group were submitted to pancreatography prior to PD wire insertion, thus increasing the risk of overinjection into the PD with possible acinarization.

In our study, using DGT, selective CBD cannulation was achieved in 43.8% of patients (49/112) with previously failed SGT. Three patients of this group developed pancreatitis (6.1%) and 11 patients asymptomatic amylasemia (22.4%), showing an acceptable safety profile comparable to SGT (5.3% and 12%, respectively). Recently published data from a prospective randomized study assessing clinical efficacy and safety of DGT *versus* conventional cannulation method reported almost equivalent CBD cannulation

success in difficult cases (47.3% *vs* 54%). The DGT group showed an increased incidence of clinical pancreatitis compared to the SGT group, without, however, reaching a statistically significant difference (17% *vs* 8%)¹²².

According to our results, PD reaction (i.e. PEP) seems to be affected by both iatrogenic and patient-related characteristics. Young patients suffering from choledocholithiasis proved to be statistically more prone to develop pancreatitis when pre-cut access papillotomy as first step was used, or after a failed DGT technique was performed. On the other hand, elderly patients, despite repeated PD wire insertion and use of pre-cut, demonstrated hyperamylasemia as part of a benign post-ERCP clinical course. In addition, 12.5% and 13.8% of female patients who underwent a successful DGT and pre-cut failed DGT developed PEP, respectively. Although these observations were not found to be statistically significant, patients' gender seems to carry an independent risk factor concerning pancreatic injury following PD manipulations.

Age, sex, prior PEP or recurrent history of acute pancreatitis and SOD are well known risk factors for PEP^{23,24} and many experts have already proposed the use of a temporary prophylactic pancreatic stent in these situations^{11,25}. Several uncertainties remain regarding patients' selection criteria for pancreatic stent use and the appropriate diameter. These may be attributed to the lack of long-term data on changes in PD anatomy and stent-induced complications in failed stent placement cases¹²⁶. Goldberg *et al*¹²⁷ documented the aid of a 5F pancreatic stent placement for CBD cannulation in 39 patients with 97.4% success rate. To achieve biliary cannulation, 59% of patients underwent pre-cut sphincterotomy over the pancreatic stent with only 5% PEP rate. The authors, however, do not mention the existence of SOD indication, nor do they report in how many cases pancreatic sphincterotomy was performed to facilitate stent insertion.

No pancreatic stent insertion was performed in our series, as our initial aim was to investigate the contribution of a simple and non-time-consuming technique involving the use rather than abuse of PD. In addition, patients with suspected SOD were excluded due to the lack of manometry which would imply a clear therapeutic indication and the need for a pancreatic stent use. What seems technically more important in DGT technique, regarding success and complication rate, is the gentle straight deep passage of the wire into the PD. Insertion of the wire in angulated mode into a normal PD may potentially increase side-branch acinarization associated with the occurrence of PEP.

It should always be kept in mind that basic CBD cannulation techniques cannot be substituted by any available trick and only proper expertise in ERCP secures periprocedural efficacy. Based on this knowledge, the wire into the PD seems to be helpful for cases of difficult cannulation, particularly when the papilla is mobile with small orifice or disoriented due to a diverticulum or malignancy. In these cases, the anatomical axis of the common channel is stabilized by the inserted wire into the PD, offering the possibility of a new, less traumatic, wire cannulation attempt than pre-cut access papillotomy may cause.

The special incisional technique of pre-cut has been estimated to enable biliary access in about 5% to 10% of hard-to-cannulate cases, according to several reports^[28]. However, pre-cut has been described to be an independent risk factor for post-ERCP complications (variation between 8% and 35.3%) and only recommended as an expert's alternative method^[14]. In full agreement with these reports, 5.6% of patients in the period of our study underwent pre-cut papillotomy (77% overall success rate) and 10 patients experienced PEP (7.7%). Data analysis showed no statistically increased possibility of PEP in patients with previously failed DGT followed by pre-cut (7.9% of cases), compared to patients who underwent pre-cut as initial cannulation technique (7.5% of cases).

The decision as to the appropriate CBD cannulation method in specialized situations should be dependent on a patient's individual clinical and anatomical basis as well as on an endoscopist's experience in the available techniques. In the present study, while proposing the SGT as the standard technique for achieving CBD cannulation, DGT offered a remarkable alternative in difficult cases before proceeding to pre-cut papillotomy. DGT success and low complication rate is considered highly satisfactory in order to avoid the risk of a pre-cut when biliary therapy is necessary. Further randomized prospective trials comparing various pre-cut techniques and pancreatic duct cannulation approaches, as rescue methods to facilitate biliary access, will eventually offer an evidence-based approach.

ACKNOWLEDGMENTS

We particularly wish to thank El Papakonstantinou for her valuable aid with fluoroscopic procedures. There are no potential conflicts of interest for any of the authors.

COMMENTS

Background

Biliary cannulation is the fundamental prerequisite to secure a successful therapeutic-intended magnetic resonance cholangiopancreatography (MRCP). Selective biliary cannulation by insertion of a hydrophilic guidewire tends to be the standard method of choice in terms of efficacy and safety [single guidewire technique (SGT)]. In difficult-to-cannulate cases, pre-cut papillotomy has been established as the alternative method to gain biliary access. However, pre-cut technique predisposes to a higher rate of post-ERCP complications, even in the most experienced hands.

Research frontiers

Several studies have documented that a pancreatic duct previously cannulated with a guidewire may facilitate selective biliary cannulation with a second wire (double guidewire technique-DGT).

Innovations and breakthroughs

In a single-center, retrospective study using DGT, selective biliary cannulation was achieved in 43.8% of patients with previously failed SGT. Pre-cut papillotomy gained biliary access in 73% of failed DGT cases and 80.6% of cases as first step method, respectively. Univariate analyses revealed no statistically significant difference in terms of complication rate between patients with different types of cannulation.

Applications

Although the DGT success rate proved not to be superior to that of SGT or pre-cut papillotomy, it is considered a highly satisfactory technique in terms of safety in order to avoid the risk of a pre-cut when biliary therapy is necessary.

Peer review

In this study, the authors conclude that the DGT may be safely performed before proceeding to pre-cut if repeated pancreatic duct cannulation occurs.

Abstract

AIM: To determine the prevalence of increased intraepithelial lymphocytes, using immunohistochemistry in patients with normal colonoscopy and near normal biopsy.

METHODS: We retrospectively reviewed all non-malignant colon mucosal biopsies between 2005 and 2007, reported as normal, chronic inflammation or melanosis coli in patients who were undergoing routine colonoscopy. Immunohistochemistry using CD3 was performed on all mucosal biopsies and an intraepithelial lymphocyte count (IEL) was determined. Cases with an IEL count of ≥ 20 IELs per 100 surface epithelial cells were correlated with demographic, clinical and follow-up data. A further subgroup was evaluated for lymphocytic colitis.

RESULTS: Twenty (8.3%) of 241 cases revealed an IEL count ≥ 20 . Six (2.5%) patients were identified as having lymphocytic colitis ($P < 0.001$), of whom, five were missed on initial evaluation ($P = 0.01$). Four of these five patients were labeled with diarrhea-predominant irritable bowel syndrome (IBS). On follow-up, three of the remaining 20 cases were diagnosed with malignancy (renal cell carcinoma and myelodysplastic syndrome) and one had an unknown primary tumor with multiple liver metastases. Two cases of collagenous colitis with an IEL count < 10 were included in this study. Increased IELs were not confined to patients with diarrhea as a primary presenting symptom, but were also present in patients with abdominal pain ($n = 7$), constipation ($n = 3$) and loss of weight ($n = 1$).

CONCLUSION: Immunohistochemistry using CD3 is of value in identifying and quantifying IELs for the presence of microscopic colitis in patients with diarrhea-predominant IBS.

INTRODUCTION

Microscopic colitis is regarded as a common cause of chronic watery diarrhea, accounting for approximately

4%-13% of patients presenting with this symptom^[1]. By definition the colon appears normal or nearly normal on colonoscopy, with set histopathological criteria required for the diagnosis on mucosal biopsy. Lymphocytic colitis and collagenous colitis constitute the two major subtypes of microscopic colitis that share many similarities, including almost identical clinical symptoms, together with a macroscopically normal colonic mucosa. Both entities demonstrate colonic intraepithelial lymphocytosis, increased inflammatory cells within the lamina propria, and preserved crypt architecture, but are distinguished by the presence of a thickened basement membrane in collagenous colitis.

In the past, microscopic colitis was thought to be a rare disorder and very little was known about its etiology or epidemiology. It has become apparent that microscopic colitis is now regarded as common cause of diarrhea in middle-aged and elderly patients. Many recent publications have shown that the incidence of microscopic colitis is on the increase. Epidemiological data have now been reported from seven major regions^[2], with most of the reported data coming from North American and European studies. The incidence rates for collagenous colitis is 0.8-6.2/100 000 and lymphocytic colitis is 0.5-12.9/100 000^[2]. According to various studies, the prevalence of collagenous colitis and lymphocytic colitis is 10-15.7/100 000 and 14.4/100 000, respectively^[1,3-5]. There are very few data available from developing countries, with a few case series reported from India^[6], Turkey^[7] and Sri Lanka^[8].

Currently there are no data regarding this disease in South Africa, where infectious diseases are more prevalent. Isolated cases have been reported from Nigeria^[9,10]. In this region, microscopic colitis is underdiagnosed because of a lack of colonoscopic facilities and the assumption that most cases of chronic diarrhea are likely to be infective, therefore, most patients self medicate and do not present to a hospital^[10,11].

At Tygerberg Hospital, a tertiary referral center, approximately 1700 colonoscopies are performed each year, which include colonoscopies for non-infective diarrhea-related causes. Colonic biopsies at our institution are often reported as chronic inflammation, indeterminate colitis, chronic colitis or normal in the investigation of diarrheal disease. It is possible that the diagnosis of LC may have been missed in a proportion of these cases, because under-reporting of cases is common and has been documented in other studies^[12]. According to a Swedish study, in a third of cases the diagnosis was missed in the primary histological examination^[13,14]. The important role of the pathologist was clearly illustrated in this study that showed the difficulties in diagnosing microscopic colitis, especially the lymphocytic subtype^[14]. According to Nielson, terms such as "unspecific chronic inflammation" or "signs of chronic inflammatory bowel disease but not diagnostic" should be avoided^[14].

Immunostaining does not seem to play a major role in the diagnosis of LC. According to Tysk *et al*^[2] and

Chang *et al*^[15], in some uncertain cases, immunostaining may facilitate the assessment of intraepithelial counts. There have been no studies to validate the benefit of performing immunohistochemistry in uncertain cases. Currently, the histological diagnosis is based on hematoxylin and eosin (H and E) assessment of criteria: (1) increase in intraepithelial lymphocytes (IELs > 20/100 surface epithelial cells); (2) surface epithelial damage; and (3) infiltration of lymphocytes and plasma cells into the lamina propria, with no subepithelial collagen deposition, as identified in collagenous colitis^[16,17]. The diagnosis of lymphocytic colitis remains a challenge because it is often difficult to identify and quantify lymphocytes due to orientation of the biopsy, or nuclei having similar cytological features to those of columnar cell nuclei. Immunohistochemistry staining with CD3 has been shown to play a role in the counting and identification of IELs in celiac disease; incidentally, there is also an association between microscopic colitis and celiac disease^[18].

Only one recent study has examined the reproducibility of histological diagnosis in microscopic colitis. That study found excellent correlation in distinguishing microscopic colitis and non-microscopic colitis amongst pathologists using H and E- stained slides. That study claimed κ values of 0.90 and 0.83 for inter-observer agreement and 0.89 for intra-observer agreement^[19]. However, the authors have stated that their high rate of concordance was due to their particular expertise within the field of gastroenterology. In their study, immunohistochemistry was not performed to assess whether it allows easier identification of IELs.

In the present study, we aimed to determine the prevalence of increased IELs with the use of immunohistochemistry and described the spectrum of disease in all non-malignant biopsies reported as normal or chronic inflammation over a 3-year period. By facilitating counting of IELs, we hoped to identify cases that may have the lymphocytic colitis subtype.

MATERIALS AND METHODS

Study design and population

The study design was a retrospective analysis of all non-malignant colonoscopic biopsies diagnosed as normal or chronic inflammation in patients who underwent colonoscopy at the Tygerberg Hospital Gastroenterology Unit, for the period 2005-2007. Cases were retrieved from the Department of Pathology, Division of Anatomical Pathology, DisaLAB database for the 3-year period. Of the 1212 cases identified, only 247 met the criteria necessary for our analysis: (1) normal or chronic colitis on histology; (2) melanosis coli; or (3) microscopic colitis including collagenous and lymphocytic colitis. The melanosis coli category was incorporated as it is possible that reported cases of diarrhea might not be due to laxative abuse. Cases that were excluded were: (1) known cases of inflammatory bowel disease, malignancy, radiotherapy, infective diarrhea, rectal bleeding, and an abnormal colonoscopy.

Table 1 Microscopic colitis cases identified by IHC using CD3

| | No. of cases | ¹ P value |
|--|--------------|----------------------|
| Cases marked as normal, chronic inflammation or melanosis coli | 241 | |
| IELs > 20 | 20 | < 0.001 |
| Known case of LC | 1 | 0.158 |
| Missed LC | 5 | < 0.001 |
| Collagenous colitis | 2 | 0.078 |
| Microscopic colitis (Total No. of cases) | 8 | < 0.001 |

¹P value for comparing whether the proportion was different from 0. LC: Lymphocytic colitis.

Immunohistochemistry

Immunohistochemistry using antibodies against CD3 was performed on all cases as the primary evaluation method for IELs. The staining was performed on 4- μ m thick, formalin-fixed, paraffin-embedded tissue sections, using the Bond max autoimmune stainer with the Bond Polymer Refine Detection system (DS9800). Antibodies against CD3 (Leica Biosystems, Newcastle, UK; NCL-L-CD2-565, dilution 1:300) were applied to each case. For epitope retrieval ER2 (Leica Biosystems) was used for 20 min.

All immunohistochemical slides were randomly assigned a study number and an IEL count was performed. For a lymphocyte to be counted, the nucleus had to be visible with cytoplasmic and membrane staining. Intercryptal areas were counted and areas overlying lymphoid follicles were avoided. Only cases with ≥ 20 per 100 IELs were further investigated. In addition, all H and E-stained sections were re-evaluated for basement membrane thickening. In suspected cases, a Masson Trichrome stain was performed and the basement membrane measured with an Olympus ocular micrometer. Poorly orientated biopsies were excluded from evaluation.

Data regarding presenting history, microscopic diagnosis, patient age, sex and follow-up of patients with ≥ 20 IELs were recorded. A subcategory of patients presenting with chronic diarrhea was identified and further evaluated for microscopic colitis. The results were correlated with clinical findings.

Histological criteria

Histological diagnosis of lymphocytic colitis was confirmed with ≥ 20 IELs per 100 surface epithelial cells, with normal being < 5 ^[16,19,20]. In addition, a mixed inflammatory infiltrate in the lamina propria that consisted of lymphocytes and plasma cells with surface epithelial damage was noted^[3,16]. Diagnosis of collagenous colitis was established with a subepithelial collagen layer reaching or exceeding 10 μ m^[16,21,22].

Ethics

The study protocol was approved by the University of Stellenbosch Ethics committee.

Statistical analysis

Microsoft Excel was used to capture the data and STA-

TISTICA version 9 was used to analyze the data. Summary statistics were used to describe the demographic variables and certain laboratory parameters. Medians and means were used as the measures of central location and SDs and quartiles as indicators of spread. For demographic variables such as laboratory parameters, 95% CIs were calculated. Incidence rates in the population studied were determined as proportions and these were compared to determine whether they were significantly different from zero. $P < 0.05$ represented statistical significance in hypothesis testing.

RESULTS

Clinical and immunohistochemical findings

Immunohistochemical evaluation of 241 cases revealed a mean lymphocyte count of 7.7 (95% CI = 6.4-8.9). Twenty cases (8.3%) were identified as having an IEL count of ≥ 20 per 100 surface epithelial cells ($P < 0.001$) (Table 1).

These 20 patients were further categorized and the clinicopathological features summarized in Table 2. Six (2.5%) of the 241 patients were identified as having lymphocytic colitis ($P < 0.001$). Five (2%) of these patients were only diagnosed in this review and were therefore missed on initial evaluation ($P = 0.01$). Four of the five patients were labeled with irritable bowel syndrome (IBS). On follow-up, 3/5 patients had persistent diarrhea, despite ongoing investigations. On review, their diagnosis was changed to microscopic colitis. The remaining 2/5 patients were lost to follow-up. Clinical symptoms that were not in keeping with irritable bowel syndrome in this group included increase stool frequency of up to three times per day and abdominal pain that woke the patient at night. These patients were not evaluated for response to treatment.

We included two patients who were later diagnosed with malignant disease (myelodysplastic syndrome and renal cell carcinoma) after a 2-year follow-up. A third patient developed multiple liver lesions with an unknown primary tumor. In addition, three patients initially reported as having normal colonoscopy were diagnosed with diverticular disease ($n = 2$) and ulcerative colitis ($n = 1$). Subsequent review of the surgical notes indicated an error in documentation.

Among the remaining eight patients, the primary presenting symptom resolved in four. Two patients with abdominal pain were later diagnosed with pancreatitis and Behcet's disease. It is not clear if the latter patient's abdominal pain was related to her condition. Two patients were lost to follow-up.

The two (0.8%) cases of collagenous colitis that were included in the total study population of 241 ($P = 0.07$) had an IEL count of 7 and 8, respectively. No additional cases of collagenous colitis were identified by selective staining with the Masson Trichrome technique.

The most common presenting complaint was chronic diarrhea in 9/20 cases, abdominal pain in 7/20, and constipation in 3/20, followed by loss of weight in 1/20. Seventeen cases were originally reported as normal on histology; one of lymphocytic colitis and two of melanosis coli (Table 2).

Table 2 Clinicopathological features and follow-up data in patients with > 20 intra-epithelial lymphocytes

| Age | Sex | IEL count | Presenting symptom | Original biopsy diagnosis | Follow-up period for 2 yr |
|-----|-----|-----------|--------------------|---------------------------|------------------------------------|
| 32 | F | 22 | Chronic diarrhea | Normal | Lymphocytic colitis ^{1,2} |

| 64 | F | 18 | Normal | Diabetic, asthmatic, previous sigmoidectomy for benign stricture | Hypothyroid | Persistent |

IEL: Intra-epithelial lymphocyte; FU: Follow-up.

In addition, patients with an IEL > 10 and < 19 who presented with chronic diarrhea were documented to identify possible cases of paucicellular lymphocytic colitis (Table 3). Although no patients could be confidently diagnosed in this subgroup, comorbid disease such as diabetes accounted for several cases of diarrhea within this subgroup.

Histological findings

The histological findings among the different groups were very similar with IELs apparent in all 20 cases by H and E staining. However, the lymphocytes were more easily identified with the aid of CD3 (Figure 1). Poor staining quality and tangential biopsies accounted for misidentification of lymphocytes by H and E staining (Figure 2). Chronic inflammation was mild to moderate within the lamina propria.

In the lymphocytic colitis group, chronic inflammation was regarded as moderate in the lamina propria and 3/6 cases showed surface epithelial damage. Crypt branching was absent. Again, lymphocytes were more easily counted and identified with the immunohistochemical stain compared to H and E.

The two cases of collagenous colitis had a thick collagen band that measured 10 and 11 μm with visible entrapment of capillaries and mild to moderate chronic inflammation in the lamina propria.

Pigment was confirmed in two cases of melanosis coli but was subtle. The site of most biopsies could not be verified because it was not documented. None of the patients with microscopic colitis was evaluated for response to medical treatment.

DISCUSSION

An increase in the awareness of the entity of microscopic colitis has resulted in it being recognized as a known cause of chronic watery diarrhea^[2,13,23]. Although the incidence of this disease seems to be rising, there has been very little documentation of this entity from our hospital. The importance of recognizing this condition is crucial, firstly, because chronic diarrhea is a debilitating illness, and secondly, treatment of this condition is no longer empirically based, as several recent randomized, double-blind, placebo-controlled trials have shown budesonide to be ef-

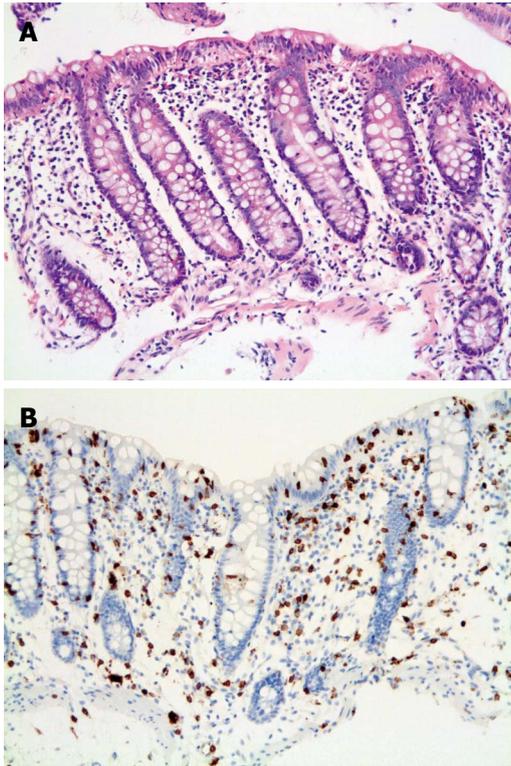

Figure 1 Lymphocytic colitis. A: Classic form. Colonic biopsy showing typical findings of diffuse increase in intraepithelial lymphocytes, mild inflammation with surface epithelial damage (H and E stain $\times 200$); B: CD3 immunohistochemistry highlighting lymphocytes ($\times 200$).

fective in the treatment of this disorder^[24-27].

Our study is novel in the sense that we reviewed all our non-malignant colon biopsies reported as normal or chronic inflammation, to identify patients with chronic diarrhea that might have had microscopic colitis. Using this bottom up approach, we focused on lymphocytic colitis. Neither the incidence nor the prevalence of this disease could be estimated using this approach, because our sample population did not consist of patients presenting exclusively with chronic diarrhea. Instead, we identified secondary causes of intraepithelial lymphocytosis that included diverticular disease, ulcerative colitis, and malignancy. These secondary causes need to be excluded before making a diagnosis of microscopic colitis^[14]. Other secondary causes of intraepithelial lymphocytosis, not identified in this study but described by Nielson, include Crohn's disease, colonic infections and amyloidosis^[14]. According to Fenoglio-Preiser^[28], there have also been reports of lymphocytic-colitis-like histology in patients with constipation, which is similar to our findings. We have also identified patients with abdominal pain as another group presenting with lymphocytosis. Although the clinical symptoms of constipation and abdominal pain resolved in a few cases, others were later identified as having significant pathology. Our results suggest that any normal colonoscopy with a finding of intraepithelial lymphocytosis should be carefully monitored for future disease.

In the present study, the diagnosis of lymphocytic

colitis was missed in five patients at the initial histological evaluation. It is particularly interesting to note that four of these patients were labeled as having IBS, in view of the biopsy being reported as normal. In a population-based cohort from Olmsted County, approximately one half of patients with microscopic colitis met the symptom-based criteria for IBS^[29]. It is therefore not surprising that there is symptomatic overlap between these two entities. The recommendations from the Olmsted County study are that patients with diarrhea-predominant IBS should undergo colonoscopy to exclude microscopic colitis^[29]. Similarly, Madisch *et al*^[30] have shown that 30% of patients with microscopic colitis had clinical symptoms that overlap with IBS. We can therefore conclude that patients with microscopic colitis can be misdiagnosed with IBS.

Even though there is very little inter- and intra-observer variability in the histological diagnosis^[19], the diagnosis of microscopic colitis can be challenging at times, especially due to the morphological heterogeneity described in microscopic colitis. Since the initial description of lymphocytic colitis in 1989, there have been several atypical forms of microscopic colitis described^[15], including a paucicellular variant^[31]. In this variant, patients still have the same clinical symptoms, but the IEL count is less, with only 10-12 IELs/100 enterocytes cited^[32]. We feel that, in these cases, immunostaining might be of more diagnostic value in determining a low IEL that is not so apparent by H and E staining. A recent study has challenged the notion of regarding paucicellular lymphocytic colitis as a variant of classical lymphocytic colitis, based on the dem-

onstration of a distinct immunological difference^[33]. This group also has indirectly claimed that immunostaining displays a clear contrast between immunoreactive lymphocytes and negative epithelial cells. However, the comparison between H and E staining and immunohistochemistry was not directly evaluated in their study^[33]. Our study was not designed to identify cases of paucicellular lymphocytic colitis, but it is an area that requires further study.

As stated earlier, the prevalence of microscopic colitis is difficult to estimate from our study due to our selection criteria and referral bias. However, this study does indicate that microscopic colitis, especially the lymphocytic colitis subtype, is underdiagnosed at our institution ($P < 0.05$). For a true estimate of the prevalence of this disorder, further studies are needed, combining data from all referral centers in the region. Other factors not taken into account in this study are the site of the biopsy and drug history. It is well known that lymphocytic colitis and collagenous colitis can be patchy in distribution, and the topographic gradient of IELs decreases from the right colon to the rectum^[34]. Therefore, representative biopsies should be taken from each part of the colon and submitted in a separate container. Concomitant drug use can cause or worsen drug-induced microscopic colitis. It is important to recognize these drugs because drug withdrawal may improve symptoms. Among the more common drugs implicated are non-steroidal anti-inflammatory drugs, lansoprazole, clozapine, ranitidine, ticlopidine, carbose and flutamide^[32]. Future studies at our institution need to take these factors into account.

We identified that intraepithelial lymphocytosis may be an early manifestation of a disease other than microscopic colitis within our defined population. IEL count alone is not specific for microscopic colitis and the biopsy findings need to be correlated with clinical information for a more specific diagnosis. In cases in which there is a history of chronic watery diarrhea, the use of CD3 immunohistochemistry may be of additional value in making the diagnosis of lymphocytic colitis. We suggest that patients with diarrhea-predominant IBS should have a routine colonoscopy and be evaluated for microscopic colitis.

COMMENTS

Background

Microscopic colitis was previously considered a rare disorder, but it now accounts for approximately 10% of cases of chronic watery diarrhea. Cases are often under-recognized despite there being well-established histopathological criteria. It is suspected that colon mucosal biopsies are often under-reported as chronic inflammation, normal or colitis, not otherwise specified.

Research frontiers

Intra-epithelial lymphocytes (IELs) are crucial to the histological diagnosis of the lymphocytic colitis subtype. Immunohistochemistry has been shown to be of value in the quantification of IELs in celiac disease, but not in the identification and quantification of IELs in lymphocytic colitis.

Innovations and breakthroughs

A recent randomized, double-blind, placebo-controlled study has confirmed that budesonide is effective in the treatment of lymphocytic colitis. It has therefore become increasingly important to recognize this condition. This is believed to be the first time that normal colon biopsies were retrospectively reviewed and evaluated for IELs. The authors demonstrated that a subset of patients with chronic diarrhea was identified as having lymphocytic colitis using this approach.

Application

The value of this study demonstrates that immunohistochemistry is a useful adjunct to hematoxylin and eosin staining in the evaluation of IELs required for the diagnosis of lymphocytic colitis.

Terminology

Microscopic colitis is an umbrella term that comprises lymphocytic and collagenous subtypes. Although the latter is distinguished histologically by a thickened membrane, the clinical symptoms and colonoscopy findings are identical.

Peer review

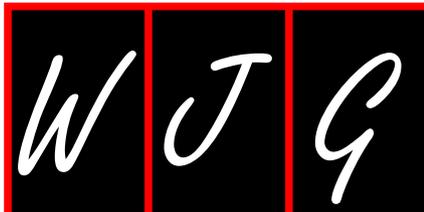

This study illustrates well that patients with diarrhea-predominant irritable bowel syndrome should have a colon biopsy with close scrutiny of mucosal lymphocytes to exclude microscopic colitis.

Abstract

AIM: To evaluate the presence of extracapsular invasion (ECI) in positive nodes as a predictor of disease recurrence disease in colorectal cancer.

METHODS: Two hundred and twenty-eight consecutive patients who underwent colorectal resection were identified for inclusion in this study, of which 46 had positive lymph nodes. Among 46 cases with stage III colorectal cancer, 16 had ECI at positive nodes and 8 had disease recurrence. The clinical and pathological features of these cases were reviewed.

RESULTS: In the univariate analysis, the number of positive lymph nodes and depth of tumor invasion were significantly associated with the presence of ECI at positive nodes. Multivariate analysis demonstrated that only ECI was a predictor of recurrence. The recurrence-free interval differed significantly among patients with ECI at positive nodes.

INTRODUCTION

The role of systemic adjuvant chemotherapy in colorectal cancer patients with lymph node involvement has been established in a large number of clinical trials^[1-3]. Lymph node status is one of the most important prognostic factors for colorectal carcinoma. However, patients with TNM stage III colorectal cancer are a heterogeneous group. Some patients with stage III colorectal cancer have good prognoses, similar to that of patients with stage II disease, whereas others develop disease recurrence. It is of utmost importance to develop markers that can predict which patients are at high risk for disease recurrence.

Previous studies have demonstrated and confirmed that the presence of extracapsular invasion (ECI) at metastatic lymph nodes is significantly related to prognosis in various types of carcinoma including colorectal cancer^[4-11]. We have also recently demonstrated that ECI at metastatic nodes in breast and colorectal cancer was strongly associated with

further regional nodes metastasis^[12]. The purpose of this study was to investigate the correlation between the presence of ECI in positive lymph nodes and disease recurrence in cases of colorectal cancer undergoing curative operation. It will be advantageous to be able to tailor therapy individually, using ECI as an indicator of the risk of recurrence.

MATERIALS AND METHODS

Two hundred and twenty-eight consecutive patients who underwent colorectal resection in the Department of General Surgical Science, Graduate School of Medicine, Gunma University, from January 2007 to December 2009 were identified for inclusion in this study. Patients with recurrence or metastasis at operation, neo-adjuvant chemotherapy, radiation, or incomplete clinical information were excluded. Of the eligible cases, 46 (20.2%) with positive lymph nodes, identified as TNM stage III colorectal, were analyzed in this study. The clinical features of these cases were reviewed according to the presence or not of ECI at positive lymph nodes, and statistical analysis was performed. ECI was defined as extracapsular growth of tumor cells, invasion into perinodal fat or extranodal location of tumor cells^[12]. Informed consent was obtained from all patients.

Age, sex, primary tumor size, location, depth of tumor invasion, histological type, lymphovascular invasion at the primary tumor site, number of metastatic lymph nodes, ECI at positive lymph nodes, administration of adjuvant therapy and serum tumor markers (carcinoembryonic antigen) were tested as possible predictors of disease recurrence. Recurrence-free interval was defined as the interval from surgery to the time disease recurrence was diagnosed. The overall median follow-up period was 1.7 years and none of the patients died of surgical complications. Fisher's exact test, the Chi-squared test, and the Student t-test were used to compare the 2 groups. Multivariate analysis was performed with logistic regression analysis to select covariates (primary tumor size and ECI at positive lymph nodes). The recurrence-free interval was calculated by the Kaplan-Meier method. The log-rank test was used to evaluate differences between recurrence-free intervals. Differences were considered to be significant at $P < 0.05$.

RESULTS

Table 1 summarizes the characteristics of the patients who underwent colorectal resection with TNM stage III colorectal cancer. The series consisted of 16 cases with ECI at positive nodes and 30 with no ECI at positive nodes. Table 1 also summarizes the results of the univariate analysis conducted to determine the relationship between the clinicopathologic variables and the presence of ECI at positive nodes. The number of positive lymph nodes and the depth of tumor invasion were significantly associated with the presence of ECI at positive nodes.

The 46 cases with metastatic lymph nodes were divided into 2 groups based on the presence of disease recurrence. Among 46 cases with stage III colorectal cancer, 8 (17.4%) had disease recurrence. Table 2 summarizes the results of

Table 1 Patients characteristics and clinicopathological features associated with the presence of extracapsular invasion at lymph node metastases

| | ECI | Positive <i>n</i> = 16 | Negative <i>n</i> = 30 | <i>P</i> value |

the univariate analysis conducted to determine the relationship between the clinicopathologic variables and disease recurrence. In the univariate analysis ECI at positive nodes and the depth of tumor invasion were the factors significantly associated with disease recurrence. Among those, multivariate analysis demonstrated that only ECI was a predictor of the recurrence ($P = 0.016$). Time to tumor recurrence by Kaplan-Meier curves was significantly shorter among patients with ECI at positive nodes (Figure 1).

DISCUSSION

The key observations made in this study can be summarized as follows: (1) the presence of ECI at positive nodes

Table 2 Patient characteristics and clinicopathological features associated with recurrent disease

| Recurrent disease | Positive 8 | Negative 38 | P value |
|-------------------------|---------------|----------------|---------|
| Age (yr) | 68.0 ± 17.2 | 65.7 ± 14.0 | 0.780 |
| Sex | | | |
| Male | 3 | 25 | 0.278 |
| Female | 5 | 13 | |

| T 3, 4 | 8 | 27 | |
| Tumor size (mm) | 44.9 ± 11.6 | 42.5 ± 20.8 | 0.679 |
| Number of positive LNs | 2.38 ± 1.41 | 2.37 ± 2.02 | 0.906 |
| ECI | 6 | 10 | 0.009 |
| Lymphovascular invasion | 8 | 37 | 0.643 |
| CEA ≥ 3.0 | 3 | 3 | 0.093 |
| Adjuvant treatment | 5 | 31 | 0.473 |

ECI: Extracapsular invasion; CEA: Carcinoembryonic antigen.

was significantly associated with the number of positive lymph nodes and depth of tumor invasion; (2) multivariate analysis demonstrated that only ECI was a predictor of recurrence; and (3) the recurrence-free interval by Kaplan-Meier curves was significantly shorter among patients with ECI at positive nodes. These findings suggest that the presence of ECI at positive lymph nodes is a strong predictor for short-term recurrence in cases with colorectal cancer undergoing curative surgery.

The surgical stage remains the most accurate predictor of survival for colorectal cancer^[13]. Pathologic prognostic factors of primary tumor invasion and regional node involvement predict the risk of relapse of cases with colorectal cancer undergoing curative operation. In the current study, both the number of positive lymph nodes and the depth of tumor invasion were significantly associated with the presence of ECI at positive nodes. Lymph node metastasis is one of the most important prognostic factors in patients with colorectal cancer, and many studies have indicated that the location and number of metastatic nodes affect prognosis^[5,14-16]. Regarding ECI, previous studies have demonstrated and confirmed that the presence of ECI at metastatic lymph nodes is significantly associated with prognoses in various types of carcinoma including colorectal carcinoma^[4-11]. The ability of metastatic nodes to recruit degradation factors that permit cancer cells to break through the lymph node capsule is indicative of a very aggressive cancer. We previously demonstrated that the presence of ECI in positive lymph nodes is significantly related to the nodal spread of tumor cells in colorectal and breast cancer patients^[12]. These studies imply that ECI is a biologic marker of aggressive cancer and essentially support our findings. Tumor cells are thought to invade the lymphovascular vessels, which enables tumor cells to spread metastatic or recurrent disease.

Adjuvant therapy is systemic treatment administered

with the intent of reducing the risk of recurrence. The benefit of adjuvant therapy in patients with lymph node involvement (stage III) has been well established in large prospective randomized trials^[1-3]. In Japan, the oxaliplatin plus 5-fluorouracil/leucovorin (LV) (FOLFOX) regimen has not been approved for adjuvant therapy for patients with stage III colorectal cancer at this time. In this Japanese population study, oral chemotherapeutic agents, including capecitabine or UFT (tegafur plus uracil) with oral LV, were used for adjuvant therapy for stage III colorectal cancer. Oral chemotherapeutic agents are advantageous because of their ease of administration. However, in the current series, 13 (81.3%) of the 16 cases with ECI in positive nodes had oral adjuvant therapy but 6 of 16 cases (37.5%) had disease recurrence. These results imply that high-risk patients with ECI at positive nodes should receive stronger adjuvant chemotherapy, including FOLFOX with or without monoclonal antibody.

This study has several potential limitations. The major limitation of our study is that it used retrospective methods of data collection. In addition, the number of cases in our study was relatively small and the follow-up periods were relatively short. However, the clinical implications of this data are very important, and these findings serve to emphasize that ECI at metastatic lymph nodes is an important prognostic factor for stage III colorectal carcinoma and will be advantageous in tailoring therapy to the individual case. In patients treated in phase III adjuvant clinical trials, disease-free survival and overall survival have been highly correlated, both within studies and across trials^[17]; however, in a number of patients, improving the quality of life and the length of recurrence-free intervals may be more important statistical parameters than median overall survival. Additional research is needed to explore this putative association between the presence of ECI and the risk of recurrence.

In conclusion, we have demonstrated that ECI at met-

astatic lymph nodes may predict which cases are at high risk of short-term disease recurrence in colorectal cancer. Thus, it will be possible to tailor therapy individually, using ECI as an indicator of the risk of recurrence. Analyses from large randomized trials or experimental data are warranted to evaluate this relationship between the presence of ECI and disease recurrence.

COMMENTS

Background

The authors have demonstrated that extracapsular invasion (ECI) at metastatic nodes in breast and colorectal cancer was strongly associated with further regional nodes metastasis. The purpose of this study was to evaluate the presence of ECI in positive nodes as a predictor of disease recurrence disease in colorectal cancer.

Research frontiers

Lymph node status is one of the most important prognostic factors for colorectal carcinoma. However, patients with TNM stage III colorectal cancer are a heterogeneous group. It is of utmost importance to develop markers that can predict which patients are at high risk for disease recurrence.

Innovations and breakthroughs

This study suggests that the presence of ECI at positive lymph nodes is a strong predictor for short-term recurrent-free interval in cases with colorectal cancer undergoing curative operation.

Applications

It will be possible to tailor therapy individually, using ECI as an indicator of the risk of recurrence.

Terminology

ECI was defined as extracapsular growth of tumor cells, invasion into perinodal fat or extranodal location of tumor cells.

Peer review

The key observations made in this study suggest that the presence of ECI at positive lymph nodes is a strong predictor of short-term recurrent-free interval in cases with colorectal cancer undergoing curative operation.

Abstract

AIM: To investigate whether illness severity has an impact on gastric residual volume (GRV) in medical critically ill patients.

METHODS: Medical intensive care unit (ICU) patients requiring nasogastric feeding were enrolled. Sequential Organ Failure Assessment (SOFA) score was assessed immediately preceding the start of the study. Acute Physiology and Chronic Health Evaluation (APACHE) II scores were recorded on the first, fourth, seventh, and fourteenth day of the study period. GRV was measured every 4 h during enteral feeding. The relationship be-

tween mean daily GRV and SOFA scores and the correlation between mean daily GRV and mean APACHE II score of all patients were evaluated and compared.

RESULTS: Of the 61 patients, 43 patients were survivors and 18 patients were non-survivors. The mean daily GRV increased as SOFA scores increased ($P < 0.001$, analysis of variance). Mean APACHE II scores of all patients correlated with mean daily GRV ($P = 0.011$, Pearson correlation) during the study period. Patients with decreasing GRV in the first 2 d had better survival than patients without decreasing GRV ($P = 0.017$, log rank test).

CONCLUSION: GRV is higher in more severely ill medical ICU patients. Patients with decreasing GRV had lower ICU mortality than patients without decreasing GRV.

INTRODUCTION

Malnutrition is prevalent in intensive care unit (ICU) patients and is associated with increased morbidity and mortality^[1]. Early administration of enteral nutrition to

critically ill patients has been associated with a significantly lower incidence of infections and a reduced length of hospital stay^[2,3]. However, intragastric enteral nutrition often is complicated by intolerance, as indicated by elevated volumes of aspirated gastric residuals^[4]. Disordered upper gastrointestinal (GI) tract motility occurs frequently in ICU patients. Intolerance to nasogastric delivery of feeding is the most important consequence of the abnormal upper GI motility that occurs in critically ill patients^[5]. Several factors related to critical illness have been reported to be associated with gastric dysmotility and feeding intolerance including age, admission diagnosis, hyperglycemia, the nature of the acute illness, mechanical ventilation, sedatives, cytokine release and splanchnic hypoperfusion due to shock and sepsis^[6]. Two studies have shown that “upper digestive intolerance” and “enteral feeding intolerance” are linked to adverse outcomes, suggesting that decreased gastric emptying (GE) is related to clinical deterioration and worsening of patient outcomes^[7,8]. Direct measurement of GE is usually inconvenient and impractical in routine clinical practice. Clinically, gastric residual volumes (GRVs) are easier to measure than GE, and GRV measurements are by far the most frequently recommended assessment for GE^[9]. They are used as a surrogate marker to determine the success or failure of nutrition delivered *via* a nasogastric route. However, the relationship between GRV and disease severity is not clear. The aim of this study is to investigate whether disease severity has an impact on GRV and whether GRV is a predictor of ICU mortality.

MATERIALS AND METHODS

This prospective, observational study was conducted during a 2-year period from January 2005 to December 2006 in a medical ICU of a tertiary medical center. Patients who required enteral feeding were enrolled. Criteria for exclusion included abdominal surgery, acute pancreatitis, GI bleeding, intestinal obstruction, and patients with subtotal or total gastrectomy. The protocol was approved by the Human Investigation and Research Committee of the hospital.

After informed consent was obtained, the following demographic data were collected: primary ICU admission diagnosis, age, gender, body mass index (BMI), use of mechanical ventilation, Sequential Organ Failure Assessment (SOFA) score^[10], Acute Physiology and Chronic Health Evaluation (APACHE) II score^[11], blood glucose level, number of ICU days, ventilator days, hospital days, and Glasgow Coma Scale score. A standard 12 French enteral feeding tube (Abbott, Chicago, IL, USA) for general patients was placed into the stomach. The correct position of the nasogastric tube was confirmed by injecting 50 mL of air with a syringe into the tube and auscultating the epigastric area, or by radiograph if necessary. We checked the tube position by measuring the exposed portion of the tube and compared the length with previous measurements. The patients were fed in a semi-recumbent position, and the patient's position and tube length were kept the same in each measurement. As soon

as the feeding tube was inserted, continuous tube feeding using enteral feeding pumps (Abbott) was started. Enteral feeding was initiated at 20 mL/h. The rate was increased by 20 mL/h every 4 h until the volume required to meet the patient's optimum caloric support was achieved. The rate of continuous enteral feeding was controlled by the pumps. GRV was measured by aspirating with a 50-mL syringe every 4 h until the end of enteral feeding. Feeding was stopped for 30 min before GRV was measured. After measurement, the nurses stopped enteral tube feedings if residual volume was higher than 500 mL or residual volume was between 200 to 500 mL and patients had abdominal distension, absence of bowel sounds, or presence of nausea or vomiting^[12]. Feeding re-started immediately at original rate if GRV < 200 mL and there was low risk of aspiration. Daily GRV was calculated by summation of each GRV measurement. Serum glucose was controlled by an intensive insulin control protocol in order to reach the target glucose level of 140 mg/dL.

APACHE II scores^[11] were recorded on the first, fourth, seventh, and fourteenth day of the study period. Study observations continued from start of enteral feeding until one of the following events occurred: the enteral tube was removed, the patient was discharged from the ICU, or he/she expired. SOFA scores^[10] were assessed within a 24-h period preceding the start of study as the presence or absence of prospectively defined cardiovascular, respiratory, renal, hepatic and hematologic dysfunction, as well as level of consciousness. Dysfunction of cardiovascular, respiratory, renal, hepatic, hematologic and central nervous systems was determined based on laboratory data, vasopressor dosage, Glasgow Coma Scale score, and PaO₂/FiO₂.

Patients were classified as diabetic on the basis of their medical history. Survivors were defined as patients who were alive when discharged from the ICU or transferred to a general medical ward; this was determined at time of ICU discharge.

Statistical analysis

All the statistical analyses were done with the SPSS (Inc., Chicago, IL, USA) version 12.0. mean \pm SE were recorded for all continuous variables. For discrete variables, the frequencies were reported. One way analysis of variance (ANOVA) was used to compare differences among more than 2 groups. Pearson correlation was used to compare correlation between daily GRV and APACHE II score. Kaplan-Meier curves were used to estimate the probability of survival. Log-rank test was used to compare the difference between the patients with decreasing daily GRV and patients without decreasing daily GRV in the first 2 d. Cox model was used to construct the relative risk among the percentage change of daily GRV in the first 2 d. All *P* values were two-tailed. A *P* value < 0.05 was considered as significant.

RESULTS

Demographics

Sixty-one patients were enrolled in this study. Patient char-

Table 1 Demographic data of the 61 study subjects (mean \pm SE) *n* (%)

| | |
|--------------------------------------|-----------------|
| Average age (yr) | 67.9 \pm 2.0 |
| Gender (male) | 43/61 (70.1) |
| Body mass index (kg/m ²) | 23.1 \pm 0.5 |
| Diabetic patients | 22/61 (36.1) |
| Mechanically ventilated patients | 61/61 (100) |
| Study days | 11.7 \pm 0.8 |
| ICU days | 19.1 \pm 1.6 |
| Ventilator days | 23.8 \pm 2.3 |
| Hospital days | 31.7 \pm 2.7 |
| SOFA score | 7.5 \pm 0.6 |
| APACHE II score | 20.2 \pm 0.9 |
| Blood glucose level (mg/dL) | 184.7 \pm 8.6 |

| Toxic overdose | 1/61 (1.6) |

ICU: Intensive care unit; SOFA: Sequential organ failure assessment; APACHE: Acute physiology and chronic health evaluation; CHF: Congestive heart failure; ARDS: Acute respiratory distress syndrome; COPD: Chronic obstructive pulmonary disease.

acteristics are summarized in Table 1. The mean patient age was 67.9 \pm 2.0 years, and 70.1% of the patients were male. The mean BMI was 23.1 \pm 0.5 kg/m². Thirty-six percent of patients had diabetes and all patients were mechanically ventilated. The mean number of study days was 11.7 \pm 0.8 d, mean number of ICU days was 19.1 \pm 1.6 d, mean number of ventilator days was 23.8 \pm 2.3 d, mean number of hospital days was 31.7 \pm 2.7 d, mean SOFA score was 7.5 \pm 0.6, mean APACHE II score was 20.2 \pm 0.9, and mean blood glucose was 184.7 \pm 8.6 mg/dL. The ICU mortality rate was 29.5%. The 4 most common admission diagnoses were pneumonia (*n* = 19), sepsis (*n* = 18), congestive heart failure (*n* = 6) and acute respiratory distress syndrome (*n* = 6).

Relationship between mean daily GRV and SOFA score

We stratified study patients into 4 groups by SOFA score. There were 27 patients with SOFA scores below 6; 18 patients with scores in the range of 6-10; 10 patients with scores in the range of 11-15; and 6 patients with scores above 15. Figure 1 demonstrates that the mean daily GRV was 7.8 \pm 1.3 mL in the patients with a SOFA score below 6, 26.6 \pm 4.8 mL in the patients with SOFA scores in the range of 6-10, 59.8 \pm 4.5 mL in the patients with SOFA scores in the range of 11-15, and 133.2 \pm 40.0 mL in the patients with a SOFA score above 15. Patient with higher SOFA scores had significantly higher daily GRV (*P* < 0.001, ANOVA).

Relationship between daily GRV and APACHE II score during study period

During the study period, the mean APACHE II scores

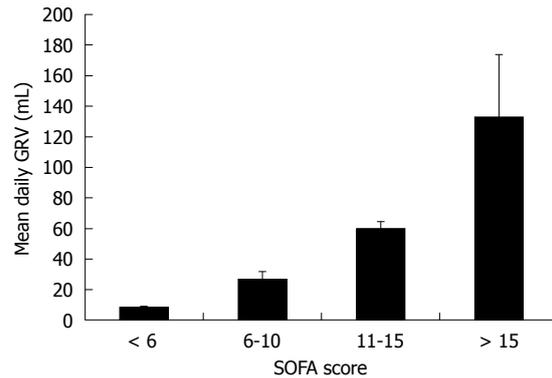

Figure 1 Mean daily gastric residual volume of patients with different Sequential Organ Failure Assessment scores (*P* < 0.001). SOFA: Sequential Organ Failure Assessment.

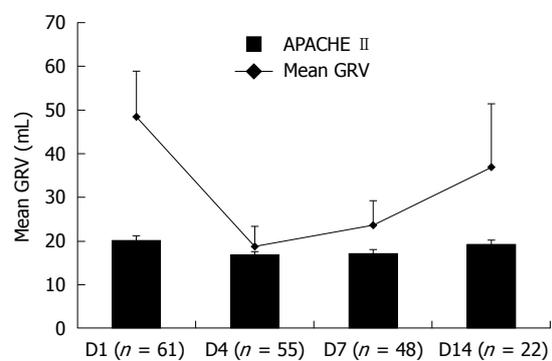

Figure 2 The relationship of mean daily Acute Physiology and Chronic Health Evaluation II score to mean daily gastric residual volume on different study dates (*P* = 0.011).

and mean daily GRV of all patients on the first, fourth, seventh, and fourteenth day are shown in Figure 2. The mean APACHE II scores of all patients on the first, fourth, seventh, and fourteenth day were 20.2 \pm 0.9, 16.8 \pm 0.7, 17.0 \pm 0.9 and 19.1 \pm 1.1, respectively. The mean daily GRVs of all patients on the first, fourth, seventh, and fourteenth day were 48.4 \pm 10.4, 18.6 \pm 4.6, 23.6 \pm 5.5 and 36.9 \pm 14.4 mL, respectively. The mean daily GRV fluctuated simultaneously with the mean APACHE II scores during the study period. There was a significant correlation between daily GRV and APACHE II score (*P* = 0.011, Pearson correlation = 0.338).

Difference of mean daily GRV between survivors and non-survivors

We divided study patients into survivors and non-survivors. There were 43 patients in the survivor group and 18 patients in the non-survivor group. Figure 3 shows the mean daily GRV of survivors and non-survivors during the study period. The mean daily GRV of non-survivors was higher than that of survivors in the early and late stages of the study period. Non-survivors had a trend of increasing mean daily GRV in the first 2 d, while survivors had a decreasing trend of GRV.

Table 2 demonstrates that the mean GRV1 (daily GRV on the first day) was 74.4 \pm 31.0 mL in non-survivors

Table 2 Difference of GRV1 and PDay12 between survivors and non-survivors (mean ± SE)

| | Non-survivors (n = 18) | Survivors (n = 43) |
|-----------|------------------------|--------------------|
| GRV1 (mL) | 74.4 ± 31.0 | 38.0 ± 6.9 |
| PDay12 | -1.1 ± 0.6 | 0.3 ± 0.1 |

GRV1: Gastric residual volume on the first day; GRV2: Gastric residual volume on the second day. PDay12 = (GRV1 - GRV2)/GRV1.

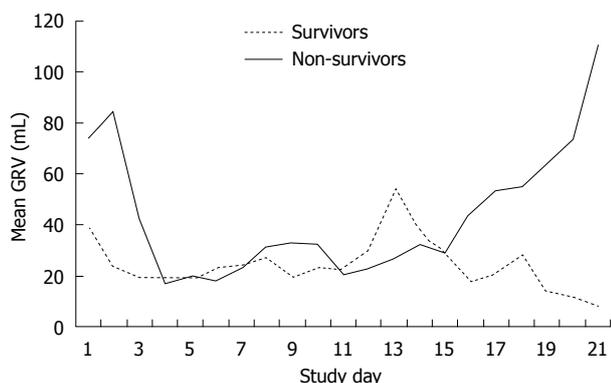

Figure 3 Mean daily gastric residual volume change of survivors and non-survivors during the study period.

and 38.0 ± 6.9 mL in survivors. Additionally, the mean [GRV1-GRV2 (daily GRV on the second day)]/GRV1 was -1.1 ± 0.6 mL in non-survivors and 0.3 ± 0.1 mL in survivors. If we define the percentage of daily GRV change from day 1 to day 2 (PDay12) as (GRV1-GRV2)/GRV1, non-survivors had a negative PDay12 while survivors had a positive PDay12.

Change of daily GRV in first 2 d and ICU mortality

We categorized patients into 2 groups; one group was patients without a decreasing daily GRV (PDay12 ≤ 0) in the first 2 d, and the other group was patients with a decreasing daily GRV in the first 2 d (PDay12 > 0). Thirty patients did not have a decreasing daily GRV (PDay12 ≤ 0) and 31 patients had a decreasing daily GRV (PDay12 > 0). Patients with PDay12 > 0 had a significantly higher ICU survival rate than patients with PDay12 ≤ 0 (P = 0.017) (Figure 4). Relative risk among the percentage change of daily GRV in the first 2 d was constructed by Cox model. The relative risk is equal to exp {-1.211x} where x represents the percentage change of daily GRV in the first 2 d. If the daily GRV decreased by 10% in the second day, the relative risk is equal to 0.886 (= exp {-0.1211}). If the daily GRV increased by 10% in the second day, the relative risk is equal to 1.129 (= exp {0.1211}). There was no evidence indicating that the proportional hazards assumption was not fixed in the data set.

DISCUSSION

In this prospective study, we found disease severity was associated with GRV in these medical ICU patients. This

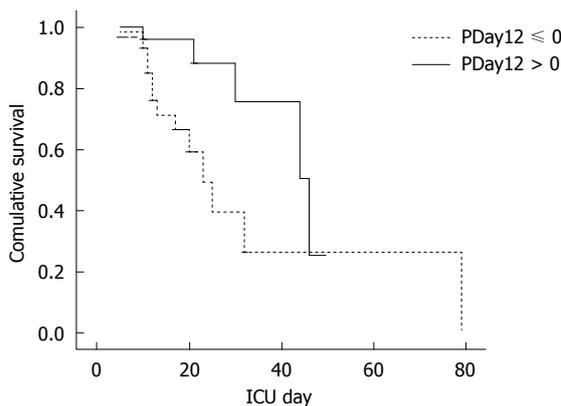

Figure 4 Kaplan-Meier estimates of the probability of survival between patients with decreasing change of daily gastric residual volume (PDay12 > 0) and patients without decreasing change of daily gastric residual volume (PDay12 ≤ 0) (P = 0.017).

study showed patients with higher SOFA scores had higher GRV, i.e. GRV tended to be higher in more severely ill patients. These results are similar to those of the study by Mentec *et al*^[8], in which patients with high gastric aspirate volume had a higher ICU mortality rate. Slow GE may partly explain why patients with more severe illness had higher GRV. GRV is determined by the balance between the amount of infused formula plus endogenous secretions (saliva and gastric secretions), and the amount of fluid emptied from the stomach^[9]. GE is influenced by many factors, including admission diagnosis, nature of illness, age, medications and mechanical ventilation^[5,6,8,9]. Nguyen *et al*^[6] reported that slow GE was more common in patients who were older, had higher admission APACHE II scores, admission blood glucose and bilirubin concentrations, and were ventilated with synchronized intermittent mandatory ventilation. Of these, APACHE II scores correlated best with GE, suggesting that illness severity is an important determinant of GE in critically ill patients. Patients with severe illnesses have high levels of circulating catecholamines which are likely to have an impact on GI motor function. Adrenaline reduces GE *via* a β-adrenergic effect^[13].

During the study period, we also found a significant correlation between mean APACHE II scores and mean GRV. There was a trend that patients with higher APACHE II scores had higher daily GRV. Our results also demonstrated that illness severity was related to GRV, and illness severity varied during the ICU course. Concurrent day-to-day variation in illness severity and daily GRV were seen in this study. GRV was the greatest in the first few days of tube feedings. Some of the severely ill patients with high APACHE II scores expired in the first few days, thus the overall illness severity of patients declined from the first day to the fourth day, so mean APACHE II score also decreased from the first day to the fourth day. Mean daily GRV decreased as mean APACHE II score decreased. As the study went on, some patients improved, they were extubated, and their enteral feeding stopped; therefore the number of

study patients decreased gradually. The rest of the study patients were more complicated or severely ill and they had higher APACHE II scores, thus the mean APACHE II score increased gradually after the seventh day of the study. From that time on, mean daily GRV also increased gradually. Mean daily GRV exhibited a good correlation with APACHE II scores ($P < 0.05$).

In the interim analysis, we also found that patients with the same SOFA score had widely different daily GRV. This suggests that there was wide variability of daily GRV among patients with the same disease severity, since GRV is not only influenced by disease severity but also by other factors such as GE, medications, size of the feeding tube and timing of measurement.

GE itself is influenced by many factors. Admission diagnosis had modest impact on GE in critically ill patients^[6]. Most patients with increased intracranial pressure after a head injury have been found to have slow GE, and elevated intracranial pressure is thought to be the main mediator of impaired gastric motility and emptying^[14]. Other diseases associated with delayed GE include burns, multiple trauma, sepsis, chronic liver disease, and renal disease^[6,15]. Patients with myocardial injury and non-intestinal post-operative respiratory failure have the lowest incidence of delayed GE^[6]. Hyperglycemia has also been shown to result in delayed GE^[16].

Medications used routinely in ICU patients are also likely to have clinically important effects on GI motor function. Opioids and benzodiazepines can impair gastric motility and reduce GE^[17,18]. High gastric aspirate volume was more frequently seen in patients who received at least 1 d of sedation^[8]. Both endogenous and administered opiates, acting *via* μ receptors, may contribute to abnormal upper GI motor function^[19,20]. Dopamine slows GE by reducing antral contractions^[21]. Its negative effect on GI motility can be seen at doses as low as 5 $\mu\text{g}/\text{kg}$ per minute, and the effect increases with increasing rates of infusion^[22]. Proton pump inhibitors^[23] and cimetidine^[24] can delay GE. Other medications such as phenothiazines, diltiazem, verapamil and anticholinergic drugs also cause GI hypomotility^[5]. Use of promotility agents is associated with reduced GRV^[25], e.g. erythromycin is a powerful stimulator of gastric contractions^[26].

The size of enteral feeding tube has also been shown to influence the measurement of GRV. Higher GRVs are found in patients with larger enteral feeding tubes^[27]. Timing of measurement of GRV also affects the value of GRV. GRV typically increases and then plateaus in the first 3 to 6 h after feeding. The highest GRV tends to occur in the 2 to 4 h after initiation of feedings. Additionally, GRV may vary with different infusion rate. To avoid this confounding factor, we stopped feeding for 30 min prior to measurement of GRV. This is the reason why the measured GRV values in this study are lower than in previous studies^[28,29].

As discussed above, there are many factors that influence GRV. This results in wide variability of daily GRV in patients with the same illness severity. For this reason,

we used daily GRV change rather than a single daily GRV to predict a patient's ICU outcome. This may avoid some of the confounding factors such as admission diagnosis, nature of illness, medications and age, as it reflects the change of illness severity more accurately. In addition, we also found that there was a different trend of GRV change between survivors and non-survivors in the first 2 d. Daily GRV tended to increase in non-survivors and decrease in survivors. We found that patients with a decreasing change of daily GRV had better ICU survival than those without a decreasing change of daily GRV in the first 2 study days. Because daily GRV correlated with illness severity, decreasing changes of daily GRV in the earlier ICU days represented decreasing illness severity; thus could indicate a positive sign for the medical ICU patients.

There are limitations in this study. Firstly, this was not a double-blind study. However, nurses who measured GRV were not aware of the study purpose. Secondly, all patients in this study were mechanically ventilated and enrolled from a medical ICU; thus, the results may not be applicable to all critically ill patients. Further larger studies including all critically ill patients are needed. Thirdly, we did not know how many patients had diabetes with gastroparesis which is characterized by severely slow GE; such patients may have increased GRVs secondary to gastroparesis^[30].

In conclusion, illness severity has an impact on daily GRV. There was a trend that more severely ill medical ICU patients had higher daily GRV. Patients with decreasing change of daily GRV in the earlier ICU days had better ICU survival than patients without decreasing change of daily GRV.

ACKNOWLEDGMENTS

The authors would like to thank Shiu-Ping Kang and the medical staff (physicians, nurses and dietitians) in the intensive care units of Kaohsiung Veterans General Hospital for their assistance in this study.

COMMENTS

Background

Disordered upper gastrointestinal tract motility occurs frequently in critical patients, resulting in intolerance to nasogastric delivery of feeding. Upper digestive intolerance and enteral feeding intolerance are linked to adverse outcomes, suggesting that decreased gastric emptying (GE) is related to clinical deterioration. It is easier to measure gastric residual volume (GRV) than GE, but it is not clear whether illness severity has an impact on GRV.

Research frontiers

GE was influenced by age, Acute Physiology and Chronic Health Evaluation (APACHE) II score, nature of illness, medication and mechanical ventilation. Of these, APACHE II score correlated best with GE. This study found disease severity had an impact on GRV. Concurrent day-to-day variation in illness severity and daily GRV were seen during hospitalization course. There is a trend that GRV increases when disease severity increases, and *vice versa*.

Innovations and breakthroughs

Patients with decreasing change of GRV in the earlier intensive care unit (ICU) had better ICU outcome than patients without decreasing change. We emphasized that change of daily GRV, not a single daily GRV, can predict ICU

outcome. Since GRV was influenced by many factors, change of daily GRV can avoid some confounding factors other than illness severity.

Applications

Increasing change of daily GRV is a negative sign for critical patients. In the clinical situation, we should be careful if a patient has increasing change of daily GRV day by day as it may indicate the patient getting gradually worse.

Terminology

GRV is determined by the balance between the amount of infused formula plus endogenous secretion and the amount of fluid emptied from the stomach. APACHE II score, a system for classifying disease severity, is widely used to predict hospital mortality based on a number of laboratory values and patient characteristics. Sequential Organ Failure Assessment scores were assessed as presence or absence of cardiovascular, respiratory, renal, hepatic, hematologic and central nervous systems dysfunction. A higher score means more severe illness.

Abstract

AIM: To evaluate the effect of multidisciplinary team (MDT) treatment modality on outcomes of patients with gastrointestinal malignancy in China.

METHODS: Data about patients with gastric and colorectal cancer treated in our center during the past 10 years were collected and divided into two parts. Part 1 consisted of the data collected from 516 consecutive complicated cases discussed at MDT meetings in Peking University School of Oncology (PKUSO) from December 2005 to July 2009. Part 2 consisted of the data collected from 263 consecutive cases of resect-

able locally advanced rectal cancer from January 2001 to January 2005. These 263 patients were divided into neoadjuvant therapy (NT) group and control group. Patients in NT group received MDT treatment, namely neoadjuvant therapy + surgery + postoperative adjuvant therapy. Patients in control group underwent direct surgery + postoperative adjuvant therapy. The outcomes in two groups were compared.

RESULTS: The treatment strategy was altered after discussed at MDT meeting in 76.81% of gastric cancer patients and in 58.33% of colorectal cancer patients before operation. The sphincter-preservation and local control of tumor were better in NT group than in control group. The 5-year overall survival rate was also higher in NT group than in control group (77.23% vs 69.75%, $P = 0.049$).

CONCLUSION: MDT treatment modality can significantly improve the outcomes of patients with gastrointestinal malignancy in China.

Effect of multidisciplinary team treatment on outcomes of patients with gastrointestinal malignancy. *World J Gastroenterol* 2011; 17(15): 2013-2018 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i15/2013.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i15.2013>

INTRODUCTION

Treatment of cancer has evolved toward a multidisciplinary

team (MDT) approach^[1-3]. The effect of MDT treatment modality on cancer is significantly better than that of conventional treatment modalities^[4-6]. Although the MDT treatment modality has been successfully implemented in Western countries for decades, no report is available on its application in China. We conducted a study on the MDT treatment modality in a representative cancer center of China to evaluate its effect on outcomes of patients with gastrointestinal malignancy in China.

MATERIALS AND METHODS

Clinical data

Data about patients with gastric and colorectal cancer were collected and divided into two parts. Part 1 consisted of the data collected from 516 consecutive complicated cases discussed at MDT meetings in Peking University School of Oncology (PKUSO) from December 2005 to July 2009. Complicated cases were defined as those with synchronous distant metastasis, marginally resectable or unresectable lesions, postoperative progression, and other conditions leading to difficulty in making treatment strategy. Records and treatment plans or recommendations for MDT treatment were used to investigate the effect of MDT treatment modality on clinical decision making and outcomes of patients with gastrointestinal malignancy (Table 1).

Part 2 consisted of the data collected from 263 consecutive cases of resectable locally advanced rectal cancer from January 2001 to January 2005. Patients included in this study were those with resectable rectal cancer located 12 cm or less from the anal verge, histologically identified primary carcinoma of the rectum, no clinical evidence of preoperative distant metastasis, transabdominal radical resection based on the principle of total mesorectal excision (TME)^[7], and R0 resection. Finally, 263 eligible patients included in this study (Table 2) were divided into neoadjuvant therapy (NT) group and control group according to whether they underwent neoadjuvant radiotherapy.

Treatment strategy

Patients in NT group received neoadjuvant therapy + surgery + postoperative adjuvant therapy. The total preoperative radiation dose was 30 Gy (30 Gy/10 fractions, bioequivalent dose 36 Gy) recommended by the Chinese Anti-Cancer Association (CACA)^[8], and 5-FU or capecitabine was used in postoperative chemotherapy.

Contrast to MDT treatment, the conventional treatment strategy for locally advanced rectal cancer in China is surgery followed by postoperative chemoradiotherapy which was commonly used in China 5 years ago. Patients in NT group were evaluated before operation by special MDT members while those in control group were not evaluated.

Follow-up

Patients were followed-up every three months for the first 2 years after surgery followed by every six months for 5 years. Serum carcinoembryonic antigen (CEA) level was

measured and abdominal ultrasound, pelvic MRI, chest radiograph were performed every six months, and colonoscopy was performed annually during the follow-up. The follow-up time ranged from six to ninety-six months, with a median time of seventy-two months. The outcomes of

patients with gastrointestinal malignancy were evaluated at the end of 5-year follow-up with a follow-up rate of 87.8% (231/263).

Statistical analysis

Demographic and clinicopathologic data were analyzed by χ^2 test. Kaplan-Meier life table and log-rank test were used to compare the disease-free survival (DFS) and overall survival (OS) rates. Cox proportional hazards regression was used in multivariate analysis. Statistical analysis was performed using the SPSS version 16.0 software. $P < 0.05$ was considered statistically significant.

RESULTS

MDT treatment modality

The working model of MDT in our center includes two major components: weekly MDT meetings to discuss complicated clinical cases and interdisciplinary consultations for preoperative and postoperative evaluation and therapy. Most patients receive MDT therapy according to interdisciplinary consultations while only complicated cases are discussed at MDT meetings. Although the MDT team modalities are different, the treatment strategies for patients are made by the same team in our center. The key members of MDT team include a surgeon, a medical oncologist, a radiation oncologist, a radiologist, a pathologist, and specialized nurses. Attendance of the key members at MDT meetings is not compulsory but enhanced by a special coordinator who is responsible for organizing and recording the MDT meetings. The discussion processes and conclusions for each patient are recorded in special tables.

Effect of MDT meetings on clinical decision making and outcomes of cancer patients

Complicated cases of gastric cancer ($n = 181$), colon cancer ($n = 130$), and rectal cancer ($n = 205$) were discussed at MDT meetings during the last 5 years (Table 1). Among the discussed cases, outpatients accounted for 84.69% ($n = 437$) and inpatients accounted for 15.31% ($n = 79$), respectively. For each disease classification, patients with postoperative recurrence or metastasis accounted for 48%-59%, suggesting that such patients are needed to be discussed at MDT meetings.

The MDT team modality directly influenced the clinical decision making. Of the 69 preoperative patients with gastric cancer discussed at MDT meetings, 53 (76.81%) underwent neoadjuvant chemotherapy instead of direct surgery. Of the 63 preoperative patients with extensive lesions or synchronous distant metastasis of colorectal cancer who underwent MDT treatment, including chemotherapy, chemoradiotherapy, or target therapy, 7 with initially inoperable liver metastasis underwent radical resection after MDT treatment.

Effect of MDT treatment on clinical outcomes of rectal cancer patients

To verify the comparability of outcomes in NT and con-

Table 3 Clinical outcome of patients in two groups n (%)

| Clinical outcome | NT group ($n = 101$) | Control group ($n = 162$) | Odds ratio (95% CI) | P value |
|-------------------------------------|---------------------------|--------------------------------|------------------------|-----------|
| Sphincter preservation ¹ | 13 (37.14) | 5 (13.51) | 3.78 (1.18-12.13) | 0.041 |
| Local recurrence | 4 (3.96) | 18 (11.11) | 0.33 (0.11-1.00) | 0.042 |
| Distant metastasis | 22 (21.78) | 36 (22.22) | 0.87 (0.48-1.57) | 0.933 |
| 5-yr disease-free survival rate | 77 (76.24) | 109 (67.28) | - | 0.039 |
| 5-yr overall survival rate | 78 (77.23) | 113 (69.75) | - | 0.049 |

¹Within the patients whose distance of tumor from anal verge were less than 5 cm, $n = 72$ (Table 1). NT: Neoadjuvant therapy.

trol groups, the major demographic and tumor variables were analyzed (Table 2). No difference was found in gender and age of the patients, tumor location, preoperative serum carcinoembryonic antigen (CEA) level, pretreatment clinical stage and lymphovascular invasion (LVI) of tumor between the two groups. The histological differentiation of tumor appeared poorer in control group than in NT group, implying that the prognosis of patients with gastrointestinal malignancy is potentially better in control group than in NT group. However, multivariate analysis demonstrated that it was not a major factor for the clinical outcome of such patients, indicating that the outcomes of patients in the two groups are comparable.

Different pretreatment evaluation strategies for the outcomes of patients in two groups

The staging tools used for pretreatment evaluation of the two groups differed significantly. Magnetic resonance imaging (MRI) was more frequently used in NT group than in control group (60.4% *vs* 40.7%, $P < 0.05$), while computed tomography (CT) was more commonly used in control group than in NT group.

Effect of MDT treatment on the clinical outcomes of patients in two groups

Although no significant difference was found in pretreatment stage between the two groups, the proportion of pathologic stage I was higher in NT group than in control group (34.7% *vs* 7.4%), while that of stage III was higher in control group than in NT group (Table 2).

Among the patients with low rectal cancer less than 5 cm from the anal verge ($n = 72$), the sphincter preservation rate was 37.14% (13/35) and 13.51% (5/37), respectively, for the NT group and control group ($P < 0.05$, Table 3).

The local recurrence rate was 3.96% (4/101) and 11.11% (18/162), the 5-year DFS rate was 76.24% and 67.28% ($P < 0.05$, Figure 1), and the 5-year OS rate was 77.23% and 69.75% (Figure 1, Table 3), for the NT group and control group, respectively.

Multivariate analysis demonstrated that the pretreat-

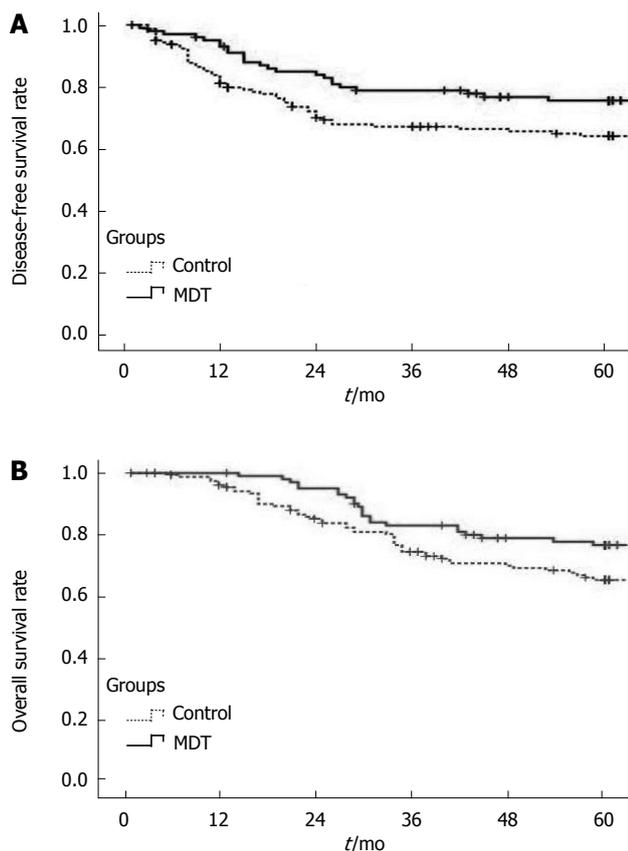

Figure 1 Disease-free survival rate (A) and overall survival rate (B) for patients in two groups. MDT: Multidisciplinary team.

ment serum CEA level, pathologic TNM stage, and LVI were the major factors for the long-term survival rate of patients with gastrointestinal malignancy (Table 4). Other variables, including neoadjuvant radiotherapy, were not the independent factors for the OS rate.

DISCUSSION

Treatment of cancer increasingly requires the cooperation of specialists from various disciplines^[9], although surgery still plays a critical role in cancer treatment. Currently, most doctors around the world have recognized the effect of MDT approach^[10,11] and endorse it as a principal treatment modality for cancer^[1,2]. Although the composition of MDT in China is similar to that in Western countries, there are many distinct differences in working models of China. First, no special rules or guidelines are available on MDT in China, thus it is not compulsory for all cancer patients to receive MDT treatment. Second, not all but some big cancer centers adopt MDT treatment modality without consistent indications for discussion at MDT meetings in different hospitals. In general, MDT is still under development in China^[12,13].

Our cancer center is one of the earliest hospitals adopting MDT approach in China. It is difficult to quantify improvement in outcomes of cancer patients, especially those with complicated clinical conditions, after MDT treatment. In this study, data on cases of locally advanced

Table 4 Multivariate analysis of overall survival rate by COX model (enter method)

| Variables | Hazard ratio | 95% CI | P value |

CEA: Carcinoembryonic antigen; LAR: Low anterior resection; APR: Abdominal-perineal resection; NT: Neoadjuvant therapy.

rectal cancer, which is considered the most successful and mature model of MDT approach^[14-16], were collected to evaluate the effect of MDT treatment on the clinical outcomes of patients with gastrointestinal malignancy. Cases discussed at MDT meeting were reviewed to assess the influence of MDT treatment modality on the treatment strategy for patients with gastrointestinal malignancy. The data included in the two parts were completely independent without any overlap.

Several studies demonstrated that MDT approach can optimize the decision making, enhance the quality of cancer care, and improve the clinical outcomes of cancer patients^[1,11,17,18]. Our data indicate that MDT meetings change a considerable proportion of treatment strategies, including neoadjuvant therapy for preoperative patients and MDT treatment modality for patients with tumor recurrence and metastasis. In this study, 7 patients with inoperable liver metastasis of colorectal cancer underwent R0 resection after MDT treatment. However, the limited time of MDT meetings and the large number of patients who need to be discussed at MDT meetings made it impossible to discuss and evaluate all patients, thus the vast majority of patients were evaluated before operation and neoadjuvant therapy was evaluated according to the interdisciplinary consultations.

It is widely believed that accurate and integrative evaluation before operation, as well as active strategies for adjuvant therapy used by MDT members, are the primary factors for improving the clinical outcomes of cancer patients^[2,3,16,19,20]. The meticulous and reliable assessment of patients with locally advanced rectal cancer before operation by MDT members is closely associated with the treatment strategy. It was reported that MRI is more accurate in clinical staging of tumor and in predicting of circumferential resection margin (CRM) when it is used in evaluation of rectal cancer^[21-23]. In this study, the strategy for preoperative evaluation of the two groups differed significantly. MRI was used more frequently in NT group than in control group (60.4% *vs* 40.7%, *P* < 0.01), suggesting that MRI can improve the accuracy of clinical tumor staging in NT group.

It has been shown that neoadjuvant radiotherapy for

rectal cancer can improve the local control of cancer before operation^[24-27], which constituted the major difference between MDT and traditional treatment modalities in this study. Neoadjuvant radiotherapy can decrease the size or stage of low rectal cancer, thus preserving the anus^[28-30]. In this study, the sphincter preservation, the local control of cancer, and the 5-year OS rate were better in NT group than in control group, suggesting that patients may benefit from MDT treatment.

Finally, although our study showed the advantages of MDT treatment modality for gastrointestinal cancer, its widespread use in China is still problematic. First, administrative support is insufficient in some places, leading to organizational problems and even its discontinuation. Second, MDT meetings are time-consuming and incomplete attendance is a barrier to success. However, these problems will not hinder the popularity and application of MDT treatment modality in China.

In conclusion, MDT treatment modality can significantly improve the clinical strategies for the treatment of gastrointestinal malignancy, and Chinese patients can benefit from it.

ACKNOWLEDGMENTS

The authors thank all the doctors and nurses who attended our MDT meetings and those who gave us constructive advices for the MDT treatment modality.

COMMENTS

Background

Treatment of cancer has evolved toward a multidisciplinary team (MDT) approach. Although the MDT treatment modality has been successfully implemented in Western countries for decades, it is not widely applied in China. The authors conducted a study on the MDT treatment modality in a representative cancer center in China to evaluate its effect on clinical decision making and outcomes in patients with gastrointestinal malignancy.

Research frontiers

MDT treatment modality is the major concern in cancer treatment, and this study addressed it for cancer in China.

Innovations and breakthroughs

MDT treatment modality, systematically introduced in this study, can significantly improve the clinical strategies for the treatment of gastrointestinal malignancy, and Chinese patients can benefit from it.

Applications

MDT treatment modality is of high values for patients with gastrointestinal malignancy and can be commonly used in hospitals of China in treatment of cancer patients.

Peer review

This paper is very good and shows that neoadjuvant therapy can improve the outcomes of patients with gastrointestinal malignancy, thus providing a novel therapy for gastrointestinal cancer.

Abstract

AIM: To elucidate the molecular and cellular features responsible for the increase of regulatory T cells (Tregs) in gastric cancer.

METHODS: The frequencies of CD4⁺Foxp3⁺ Tregs and the level of transforming growth factor-β1 (TGF-β1) were analyzed from 56 patients with gastric cancer by

flow cytometry and enzyme-linked immunosorbent assay respectively. *Foxp3* gene expression was analyzed by real-time polymerase chain reaction. The gastric cancer microenvironment was modeled by establishing the co-culture of gastric cancer cell line, MGC-803, with sorting CD4⁺ T cells. The normal gastric mucosa cell line, GES-1, was used as the control. The production of TGF-β1 was detected in supernatant of MGC and GES-1. The carboxyfluorescein diacetatesuccinimidyl ester (CFSE) dilution assay was performed to evaluate the proliferation characteristics of induced Tregs. Neutralizing anti-TGF-β1 antibody was added to the co-culture system for neutralization experiments.

RESULTS: The level of serum TGF-β1 in gastric cancer patients (15.1 ± 5.5 ng/mL) was significantly higher than that of the gender- and age-matched healthy controls (10.3 ± 3.4 ng/mL) ($P < 0.05$). Furthermore, the higher TGF-β1 level correlated with the increased population of CD4⁺Foxp3⁺ Tregs in advanced gastric cancer ($r = 0.576$, $P < 0.05$). A significant higher frequency of CD4⁺Foxp3⁺ Tregs was observed in PBMCs cultured with the supernatant of MGC than GES-1 (10.6% ± 0.6% vs 8.7% ± 0.7%, $P < 0.05$). Moreover, using the purified CD4⁺CD25⁻ T cells, we confirmed that the increased Tregs were mainly induced from the conversation of CD4⁺CD25⁻ naive T cells, and induced Tregs were functional and able to suppress the proliferation of effector T cells. Finally, we demonstrated that gastric cancer cells induced the increased CD4⁺Foxp3⁺ Tregs *via* producing TGF-β1. Gastric cancer cells upregulated the production of TGF-β1 and blockade of TGF-β1 partly abrogated Tregs phenotype.

CONCLUSION: Gastric cancer cell can induce Tregs development *via* producing TGF-β1, by which the existence of cross-talk between the tumor and immune cells might regulate anti-tumor immune responses.

Gastric cancer cells induce human CD4⁺Foxp3⁺ regulatory T cells through the production of TGF- β 1. *World J Gastroenterol* 2011; 17(15): 2019-2027 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i15/2019.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i15.2019>

INTRODUCTION

Gastric cancer (GC) is a common fatal malignancy from cancer worldwide^[1,2]. Although the incidence of GC is declining in most developed countries, it remains one of the most common causes of cancer-related death in many Asian countries, such as China, Japan, and Korea^[3,4]. Certain tumors, including GC, have developed the capacity to escape immune surveillance or to inhibit immune functions. Recently, emerging evidence suggests that CD4⁺ regulatory T cells (Tregs) play an important role in tumor escape from immunological control by suppressing the activation and proliferation of T cells, B cells, and natural killer (NK) cells^[5,6].

Our recent results have showed that the existence of Tregs maintained immune tolerance in gastric tumor micro-environments^[7]. In addition, we found increased expression of Foxp3 protein per cell in tumor-infiltrating Tregs and Tregs can mediate immune suppression *via* COX-2 production^[8]. Interestingly, our and others data showed that after patients received curative resection for GC, the increased proportion of Tregs was significantly restored to normal levels^[7,9,10]. These results strongly suggest that gastric cancer-related factors induce and/or expand the accumulation of Tregs. However, the detailed mechanism underlying the induction of Tregs during GC progress remains undefined.

Transforming growth factor- β 1 (TGF- β 1), as well as other mediators such as prostaglandin E2 and H-ferritin, has been reported to induce Treg cells^[11]. In vitro, studies have shown that TGF- β 1 can impose a regulatory phenotype on CD4⁺CD25⁻ T cells through the induction of Foxp3 expression^[12,13]. In contrast, other studies have shown that the development and functional capacity of CD4⁺CD25⁺ Tregs is normal in TGF- β 1 deficient mice^[14], questioning a role for TGF- β 1 in mediating Treg development and function. Over the past few years, significant progress has been made in defining the cellular and molecular basis for these protumorigenic effects of TGF- β 1 within tumor microenvironment^[15]. The mechanism of TGF- β 1 function in gastric cancer is believed to be mediated primarily by increasing the deposition of extracellular

matrix and immunosuppression. However, the underlying mechanism of TGF- β 1 responsible for regulating gastric cancer immunosuppression has not been fully elucidated yet.

In this study, we examined the serum level of TGF- β 1 in gastric cancer patients and analyzed the correlation of TGF- β 1 with the prevalence of Tregs. We confirmed that serum level of TGF- β 1 was elevated in GC and correlated with increased CD4⁺Foxp3⁺ Treg cells. By the co-culture system in vitro, we evaluated the contribution of GC cell supernatant to CD4⁺ T cell dysfunction. Our results indicated that MGC supernatant can induce the increase of Tregs, which especially from the conversation of CD4⁺CD25⁻ naive T cell and blockade of TGF- β 1 production partly impaired the development of Tregs. These results suggested that the gastric cancer cells played a pivotal role in impairing the antitumor T cell response by induction of Tregs.

MATERIALS AND METHODS

Patients

Fifty six patients with gastric cancer, who underwent surgery at Xinhua Hospital affiliated to Shanghai Jiaotong University School of Medicine, China, were included in this study. Prior to the sample collection, appropriate permission was granted from the research ethical committee of Xinhua hospital, Shanghai Jiao Tong University School of Medicine. Peripheral bloods were collected from each patient and from 20 healthy volunteers as previously described^[7]. Sera were frozen at -80°C immediately after centrifugation for later determination of concentrations of TGF- β 1. Peripheral blood mononuclear cells (PBMCs) were isolated by Ficoll density gradient. All patients were diagnosed by pathological analyses based on the UICC (International Union Against Cancer) criteria. At the time of sample collection, none of the patients had suffered other cancer, acute and chronic infections, autoimmune diseases, inflammatory diseases and none were receiving concomitant medications. The laboratory characteristics of patients were as follow: WBC $4.2-10.6 \times 10^9/L$; RBC $3.9-5.7 \times 10^{12}/L$; platelets $181-350 \times 10^9/L$; neutrophils 47.8%-73.9%; lymphocytes 15.2%-44.9%; monocytes 2.9%-10.2%. The clinicopathologic characteristics of the tumors are summarized in Table 1.

Cell culture and supernatant collection

Human GC cell lines (MGC-803, SGC-7901) were obtained from Shanghai Institute of Cell Biology, Chinese Academy of Sciences (Shanghai, China), and normal gastric mucosa cell line (GES-1), derived from a human fetal gastric mucosa epithelium, was obtained from Beijing Institute for Cancer Research. The cells were routinely cultured in DMEM media (GIBCO, Invitrogen, USA) supplemented with 10% fetal calf serum (FCS), 100 U/mL penicillin and 100 μ g/mL streptomycin (Gibco) in 5% CO₂ at 37°C. MGC, SGC and GES cells were washed twice with PBS when they grew to 60%-80% confluence and then

TGF: Transforming growth factor; Tregs: Regulatory T cells.

kept in serum-free culture medium for an additional 48 h. Supernatant was collected and debris was removed by centrifugation at 1500 *g* for 10 min, and then passed through a 0.45 mm filter (BD, USA). 100 μ L supernatants were stored at -80°C for later determination of concentrations of TGF- β 1. For co-culture assay, all the remaining supernatants were further concentrated 20-fold with a Microcon Ultracel YM-10 filter (Millipore, USA) according to the manufacturer's instructions. In the induction experiments, different volumes of supernatant protein concentrate from MGC or GES were added to sorted naive T cell culture system.

TGF- β 1 measurement

The cell supernatants of MGC, GES-1 and GC patients' sera previously stored at -80°C were thawed, and measured for TGF- β 1 concentration by enzyme-linked immunosorbent assay using human TGF- β 1 immunoassay kit (R&D, USA) in triplicate following the manufacturer's protocol. The minimum detectable dose of this assay is 30.0 pg/mL. The intra-assay coefficient of variation (CV) was 5.7% and the interassay CV was 10.6%.

Treg cells analysis and sorting by FCM

Phenotype analysis of regulatory T cells (Tregs) and cell sorting were performed by BD FACS Aria flow cytometer (BD, USA) as previously described^[8]. Briefly, the cells were labeled with CD3-PC7, CD127-PE, CD4-APC, and CD25 PerCP. Intracellular staining for Foxp3 was performed using Alexa Fluor[®] 488 anti-human Foxp3 Antibody and Foxp3 Fix/Perm Buffer Set (BioLegend, USA) following the manufacturer's protocol. In the preliminary experiments, we found that CD25 expression was nonspecific and was higher in CD4⁺ T cells after coculturing with GC cells. Therefore, for consistency, the gating strategy for Tregs was based on the expression of CD4 and Foxp3. To analyze the prevalence of Treg cells, CD4⁺Foxp3⁺ Treg

cells were evaluated after gating on CD3⁺CD4⁺ T cells and expressed as a percentage of the total CD4⁺ T cells. The FACS Aria was adjusted with Accudrop Fluorescent Beads (BD bioscience, USA) for optimum sorting conditions which allowed CD4⁺CD25⁺CD127^{low/-} T cells and CD4⁺CD25⁻CD127⁺ T cells to be sorted. The purity of the isolated T cells was greater than 95%.

Induction and neutralization experiments

The purified CD4⁺CD25⁻CD127⁺ T cells (1×10^5) were cultured with conditioned medium described above in 96-well plates at 37°C and 5% CO₂ in the presence or absence of soluble anti-human CD3 (10 μ g/mL; eBioscience) plus anti-CD28 (10 μ g/mL; eBioscience) and IL-2 (100 U/mL; Sigma, USA). After 72 h of cultivation, the proportion of CD4⁺Foxp3⁺ T cells was detected by FCM, and Foxp3 gene expression was analyzed by real-time PCR. For anti-TGF- β 1 antibody neutralization experiments, neutralizing mouse anti-TGF- β 1 antibody (500 μ g/mL; Clone: 27235; R&D Systems, USA) and normal mouse IgG1 (500 μ g/mL; Clone: 11711; R&D Systems, USA) were added to the culture medium with a final concentration of 0.1 μ g/mL at the beginning of the culture.

Real-time quantitative RT-PCR

Foxp3 mRNA expression was performed using the SYBR Premix Ex Taq[™] (Takara) according to the manufacturer's instructions. Amplification reactions were performed by primers specific for Foxp3 (forward, 5'-CAGCACATTCCCAGAGTTCCTC-3'; reverse, 5'-GCGTGTGAACCAGTGGTAGATC-3'). The relative quantity of the Foxp3 mRNA was normalized to the level of the internal control GAPDH mRNA level.

CFSE-based suppression assay in vitro

For the proliferation inhibition assay, the carboxyfluorescein diacetate succinimidyl ester (CFSE) dilution assay was performed per standard technique. Briefly, the sorted CD4⁺CD25⁻CD127⁺ T cells were co-cultured with MGC-803, GES-1 or medium only for 2 d. As suppressor cells, equal numbers of cells were removed and placed in co-culture with CFSE-labeled CD4⁺CD25⁻ T cells at a ratio of 1:1 in the presence of soluble 10 μ g/mL mouse anti-human CD3 and 10 μ g/mL mouse anti-human CD28 antibodies (eBioscience, USA). After 4 d, the cells were harvested and proliferation was measured by loss of CFSE dye with flow cytometry. Cell proliferation indices were calculated with Modfit software (Topsham, USA) based on the reduction of CFSE positive cells.

Statistical analysis

Data were expressed as mean \pm SD. The statistical significance of the difference between the two means was assessed using Student's *t*-test, and the one-way ANOVA with Tukey's post test was performed for multiple comparisons. Correlation between variables was evaluated by Pearson's rank correlation coefficients. All the statistical analyses were performed using GraphPad Prism version 5.0

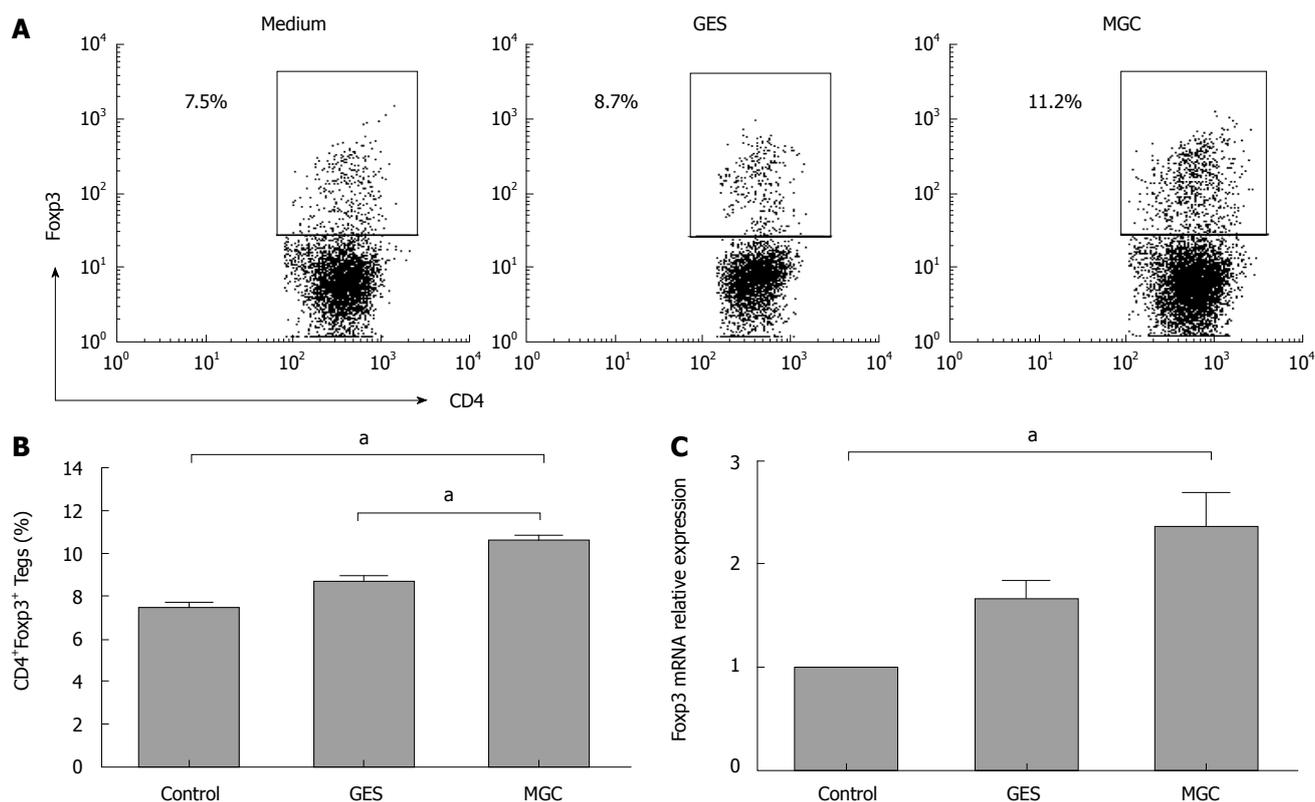

Figure 1 Gastric cancer cell supernatant induces the increased Tregs in coculture with peripheral blood mononuclear cells. A: Representative flow cytometry analysis of CD4⁺Foxp3⁺ Tregs frequency in CD4⁺ T cells population following peripheral blood mononuclear cells co-culture with medium, GES, or MGC supernatants. Rectangles show double positive gating and numbers reflect percentage of cells in that gate; B: Summarized data from all subjects showed that CD4⁺Foxp3⁺ Tregs increased in coculture with MGC supernatants (^a*P* < 0.05); C: Relative quantity of Fxp3 mRNA was measured by real-time polymerase chain reaction before and after culture with medium, GES, or MGC supernatants.

for Windows (GraphPad Software, USA) and a significant difference was considered as *P* < 0.05.

RESULTS

Elevated serum level of TGF-β1 in gastric cancer correlated with increased CD4⁺Foxp3⁺ Treg cells

To determine whether serum TGF-β1 correlated with the clinicopathological findings, we summarized the mean values of TGF-β1 in patients with GC according to clinical variables as shown in Table 1. The mean level of serum TGF-β1 in GC patients (15.1 ± 5.5 ng/mL) was significantly higher than that of the gender- and age-matched healthy controls (10.3 ± 3.4 ng/mL) (*P* < 0.05), which was consistent with previous reports^[16,17]. Furthermore, the serum TGF-β1 levels increased as GC stage progressed. Compared to those with early stage disease, patients with advanced stage disease had significantly elevated serum TGF-β1 (*P* < 0.05). As shown in Table 1, no significant differences in serum TGF-β1 levels were found in GC patients with different age, genders, and histological types (*P* > 0.05). However, the serum concentration of TGF-β1 was positively correlated with lymph node metastasis (*P* < 0.05). The results also showed that the population of CD4⁺Foxp3⁺ Tregs in the peripheral blood of advanced stage GC patients

was significantly higher than that in healthy controls or early stage GC patients (*P* < 0.05) (Table 1).

The consistency of Tregs and serum TGF-β1 level in patients with GC encouraged us to perform a correlation study, and the results showed that the increased TGF-β1 was correlated with the Treg cells (*r* = 0.576, *P* < 0.05) in advanced stage patients, but not in early stage patients (*r* = 0.248, *P* < 0.05). The present results indirectly suggested the relationship of TGF-β1 and Tregs in gastric cancer.

GC cell supernatant induces the increase in CD4⁺Foxp3⁺ Treg cells

Based on the above results, we hypothesized that gastric cancer-derived stimulators may contribute to increased Tregs. To address this hypothesis, we established a co-culture system with human GC cells and PBMCs from healthy donors to model the gastric cancer microenvironment *in vitro*. After 3 d of culture, our data showed that a higher frequency of Tregs was observed in PBMCs cultured with the supernatant of MGC. However, the frequency of Tregs had almost no significant difference in PBMCs cultured with GES-1 cell supernatants and medium control (Figure 1A and B). When cocultured with MGC cell culture supernatant, Fxp3 mRNA expression level was higher than that with GES-1 and medium (Figure 1C).

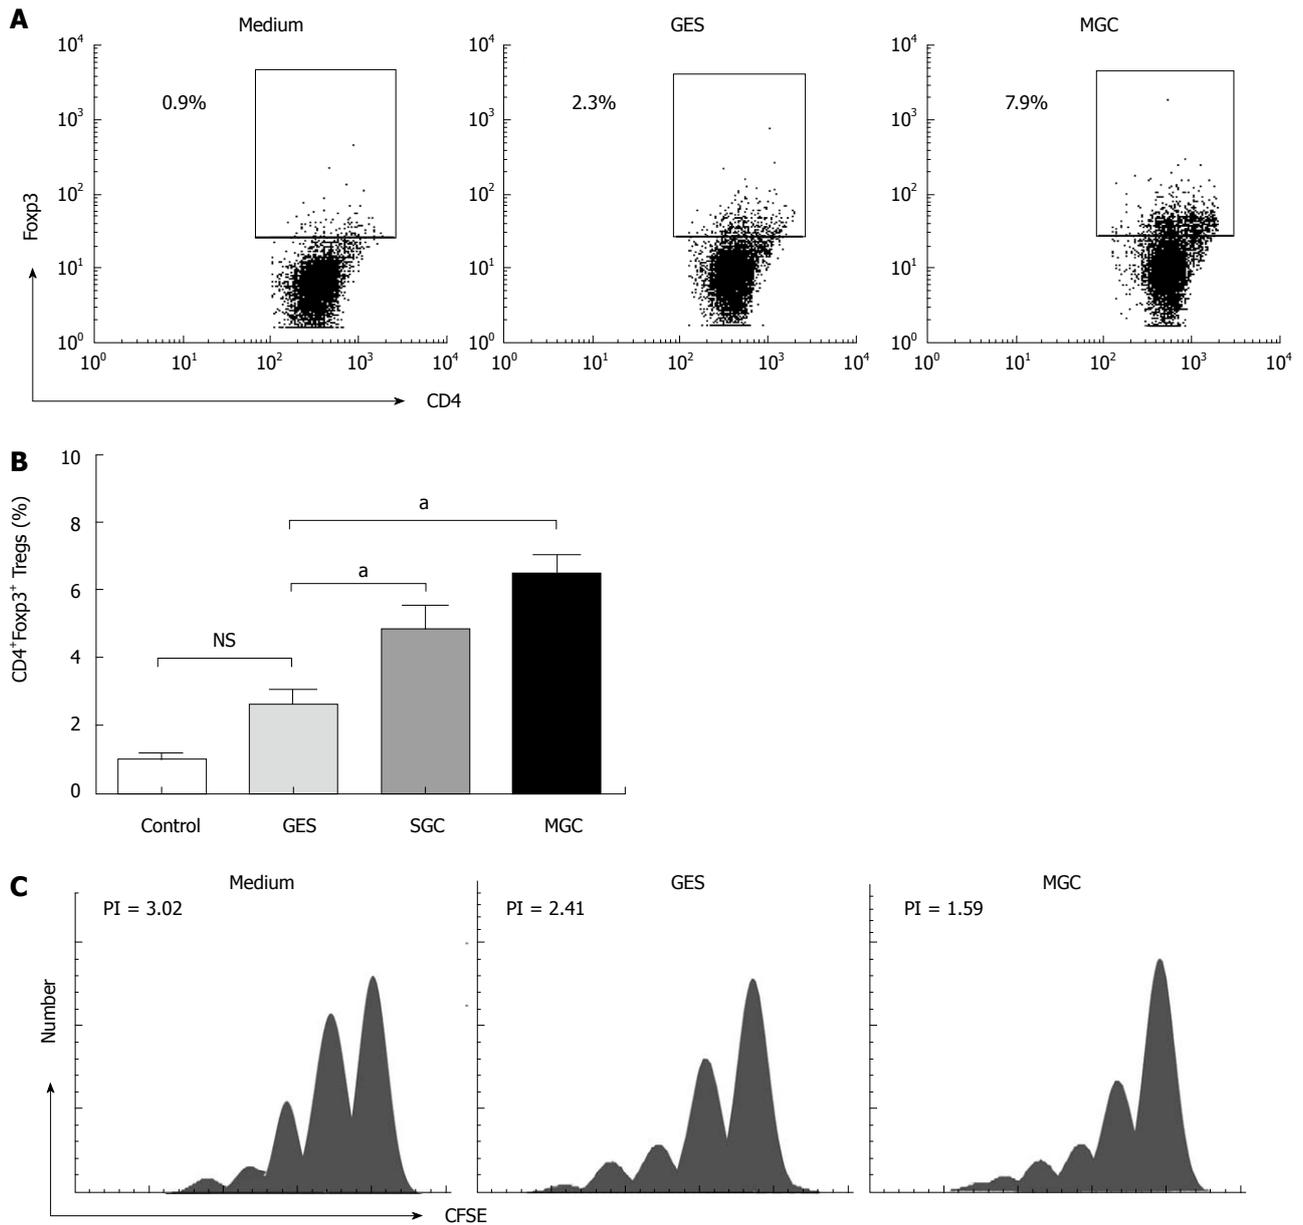

Figure 2 Gastric cancer cell supernatant mediates the conversion of CD4⁺CD25⁻ T cell to CD4⁺Foxp3⁺ Tregs. A: Representative flow cytometry analysis of CD4⁺Foxp3⁺ Tregs frequency in CD4⁺ T cells population following sorted CD4⁺CD25⁻CD127⁻ T cells co-culture with medium, GES, or MGC supernatants; B: Summarized data showed that both MGC and SGC supernatants induced higher CD4⁺Foxp3⁺ Tregs ($P < 0.05$); C: After co-culture with MGC, GES or medium, CD4⁺CD25⁻ T cells were placed in coculture with CFSE-labeled CD4⁺CD25⁻CD127⁻ T cells at a ratio of 1:1 in the presence of soluble anti-CD3/CD28 as well as IL-2. The representative data from three independent experiments are shown.

GC cell supernatants induce the conversion of CD4⁺CD25⁻ naive T cells to CD4⁺ Foxp3⁺ Tregs

To investigate whether the supernatant of GC cell culture induced the increased Tregs from the conversion of natural CD4⁺CD25⁻ T cells, we performed co-culture experiments with the sorted natural CD4⁺CD25⁻ T cells using our previous method^[7]. Because naive CD4⁺ T cells were more susceptible to the induction of Foxp3 by TGF-β1^[18] and to minimize any potential contaminating CD25⁺Foxp3⁺ nTregs, we used the CD4⁺CD25⁻CD127^{low/-} population for all of our coculture experiments. To ensure consistency, the same cell culture supernatants were used for conversion experiments. Our results showed that

MGC cell supernatant can induce a higher population of CD4⁺Foxp3⁺ Tregs than GES-1 and medium ($P < 0.05$) (Figure 2A and B) and, the CD4⁺CD25⁻ cells decreased respectively in coculture system. More interesting is that the induced Tregs correlated with the TGF-β1 level in different repeated experiments ($r = 0.635$, $P < 0.05$).

To further confirm that the supernatant of GC cell culture could increase Tregs population and Foxp3 expression, the cell culture supernatant from another GC cell strain, SGC-7901, was collected. As observed in the culture with supernatant of MGC cell culture, the supernatant of SGC cell cultures also increased Foxp3 expression in naive T cells (Figure 2B). Collectively, our results suggested

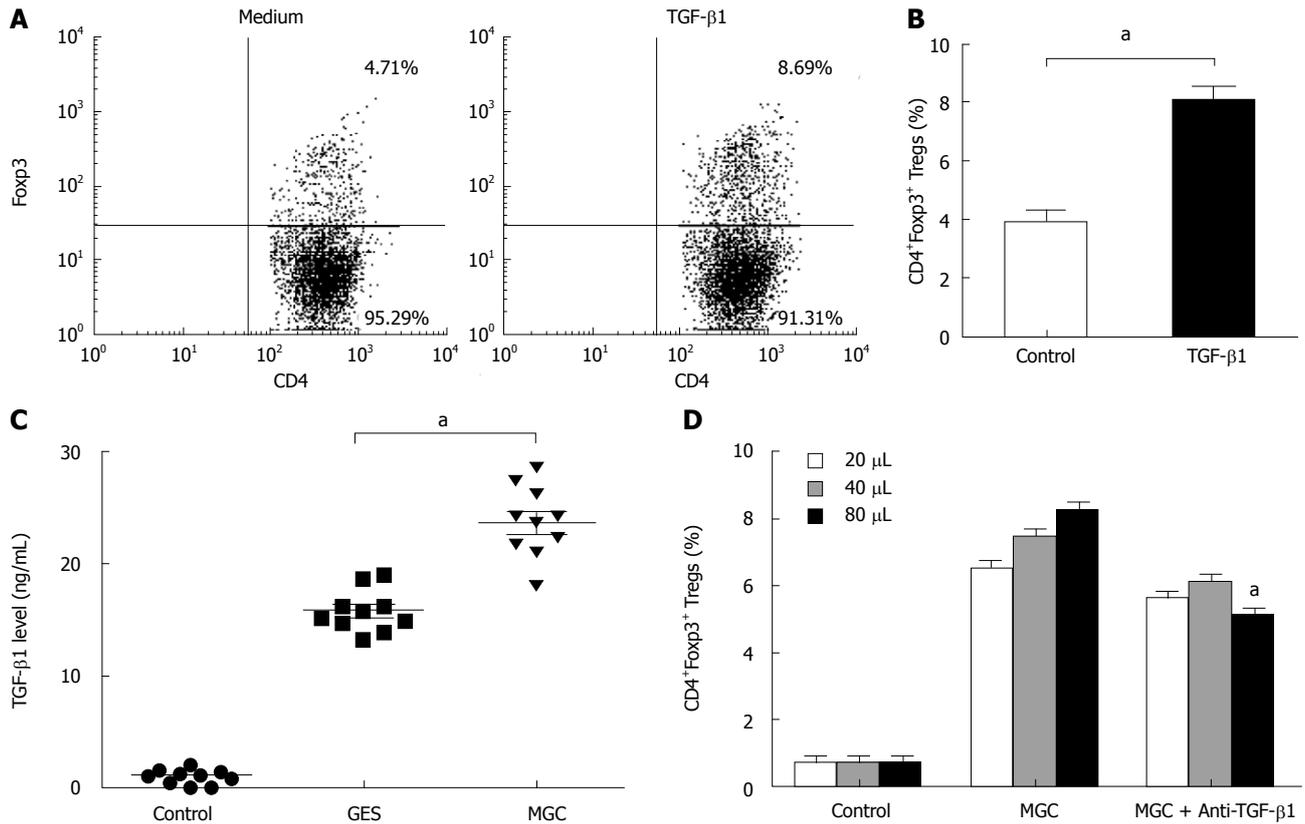

Figure 3 Gastric cancer cells producing transforming growth factor- β 1 can partially mediate the conversion of $CD4^+CD25^-$ T cells to $CD4^+Foxp3^+$ Treg cells. A: Representative flow cytometry analysis of $CD4^+Foxp3^+$ Tregs frequency in the presence or absence of transforming growth factor- β 1 (TGF- β 1); B: Summarized data showed that $CD4^+Foxp3^+$ Tregs frequency increased in presence of TGF- β 1 in comparison with that in absence of TGF- β 1 ($^*P < 0.05$); C: Gastric cancer cell TGF- β 1 production was assessed by enzyme-linked immunosorbent assay in supernatants. ($^*P < 0.05$); D: TGF- β 1 blocking antibody or control IgG1 antibody was added to the co-culture in order to monitor impairment of Tregs development within the coculture system. Different volumes of supernatant protein concentrate (20, 40, and 80 μ L) from MGC were added to the co-culture system. ($^*P < 0.05$).

that the GC supernatant can induce the increased Tregs, which was mainly because of the conversion of natural $CD4^+CD25^-$ T cells.

Gastric cancer cell induced $CD4^+Foxp3^+$ Treg cells that can suppress T cell activation

In order to understand whether GC cell supernatant induced $CD4^+Foxp3^+$ Tregs can inhibit effector T cells, we analyzed the suppressive function of GC cell induced Tregs. To eliminate the influence of cell culture related factors, the induced co-cultured supernatants were removed after coculture with MGC, GES-1, or medium. Then the CFSE dilution assay was used to evaluate the proliferation characteristics of T cells. Compared with medium, a significant decrease in the proliferative response of responder $CD4^+CD25^-$ T cells could be found with MGC after being cocultured (Figure 2C). These results demonstrated that GC cell induced Treg cells displayed the suppressive activity *in vitro*.

Gastric cancer cells induce conversion of naive T cells into Treg through TGF- β 1

To further elucidate the possible mechanism of the conversion, we presumed that TGF- β 1 from gastric cancer cells can serve as a key factor in the induction of Foxp3

expression of natural $CD4^+CD25^-$ T cells. To address this possibility, we firstly performed the inducing experiments for TGF- β 1. Consistent with other studies, compared with control Ab, TGF- β 1 can induce an increase in Tregs (Figure 3A and B). MGC cells secreted significant higher TGF- β 1 into supernatant than that GES-1 and medium (Figure 3C).

To test the role of TGF- β 1 in GC cell mediated increasing Tregs, we compared the effects of neutralizing monoclonal antibody with activity against TGF- β 1 and isotypic control antibody. To some extent, blocking TGF- β 1 activity in MGC supernatant with anti-TGF- β 1 mAb, instead of the isotypic control antibody, reduced the frequency of induced $CD4^+FOXP3^+$ T cells. But our results also showed that this blocking effect was not complete because the converted numbers of $CD4^+Foxp3^+$ T cells in MGC were still higher than that of the control (Figure 3D). Our data indicated that gastric cancer-derived TGF- β 1 played a certain role in the conversion of natural $CD4^+CD25^-$ T cells to $CD4^+Foxp3^+$ Treg cells.

DISCUSSION

In the current study, we showed that higher levels of TGF- β 1 in gastric cancer patients have been correlated with the frequency of $CD4^+Foxp3^+$ regulatory T cell. Nu-

merous studies have respectively reported an increased frequency of circulating Tregs and higher level of TGF- β 1 during GC progression^[7,9,16,19]. However, to date, there has been no report to directly demonstrate the relationship of higher TGF- β 1 levels and increased frequency of Tregs in GC. Given that TGF- β 1 is a key factor for Foxp3 expression maintenance, regulatory function, and homeostasis in peripheral CD4⁺CD25⁺ Treg cells^[20], tumor-derived TGF- β 1 may contribute to the development of Tregs during GC progression. Indeed, our work supports this possibility by demonstrating a mechanism of CD4⁺Foxp3⁺ Tregs development mediated through TGF- β 1 production by GC cells.

TGF- β 1 is a tumor suppressor growth factor, anti-inflammatory cytokine, and immunosuppressant. Therefore, the levels of TGF- β 1 were different according to the carcinogenic process, the stage of carcinogenesis, and organ. It has been reported that high levels of TGF- β 1 are produced by many types of tumors, including melanomas and cancers of the colon, stomach, liver, and prostate, as well as other malignancies^[16,21,22]. Generally defective TGF- β 1 signaling seems to be essential in the carcinogenic process, but the level of TGF- β 1 is increased in advanced cases or some types of cancer. TGF- β 1 levels were significantly increased in gastric cancer tissue compared with adjacent normal tissues^[17]. In this study, our data confirmed the higher level of serum TGF- β 1 in patients with gastric cancer. Furthermore, compared to early stage patients, elevated serum TGF- β 1 was observed in patients with advanced stages. However, the role of TGF- β 1 varied in different tumor stages, in which TGF- β 1 seems to act as a tumor suppressor in early stages of tumorigenesis and during later stages of tumorigenesis, TGF- β can foster tumor progression, and metastasis^[23,24]. Our results showed that the serum concentration of TGF- β 1 was positively correlated with lymph node metastasis in GC. This study reinforced the role of TGF- β 1 in promoting GC progression. An increase in the Treg population has been observed in both the periphery and tumor microenvironment in patients with cancer^[25]. We find a positive correlation between TGF- β 1 and Tregs in advanced stage GC patients. To our knowledge, this is the first report to show the correlation of TGF- β 1 level with increased Treg cells in GC.

In this report, an *in vitro* co-culture system was used to understand the underlying mechanisms responsible for the upregulation of Tregs observed in our clinical cohorts. After co-culture with GC cell supernatants, an increased population of CD4⁺Foxp3⁺ T cells was found in PBMCs. Of note, upregulation of Foxp3 mRNA expression supported that Tregs increased in the culture system. This increase was observed using a different GC cell line, suggesting that the induction of Tregs is a feature common to GC cells. Multiple mechanisms have been involved in production of increased Treg cells in the tumor microenvironment including expansion, conversion and recruitment. Mizukami *et al.*^[26] found that CCL17 and CCL22 are related to the increased population of Foxp3⁺ Tregs in early GC^[26]. Using the optimized conditions for sorting effector and Treg cells, we

provided evidence that the conditioned medium obtained from GC supernatant was capable of inducing the conversion of CD4⁺CD25⁻ T cells to CD4⁺Foxp3⁺ Tregs, which is different from the effects of chemokines on Treg infiltration in GC microenvironment. Moreover, the induced Tregs were functional and inhibited the proliferative response of CD4⁺CD25⁻ effector T cells. Although a prior study showed that increased Treg frequency was derived from natural Treg self expansion by factors secreted by hepatocellular carcinoma cell^[27], our data clearly demonstrated that the conversion of natural CD4⁺CD25⁻ T cells may be an important pathway of Treg cell maintenance in GC. Of course, we cannot discount the important role of chemokines in inducing Tregs migration to the microenvironment of GC.

Tumor cell supernatants include a complex protein component. Based on the fact that GC cells could produce a higher level of TGF- β 1 and TGF- β 1 correlated with Tregs from our data, we questioned if gastric cancer derived TGF- β 1 induced Treg increases in the coculture system. Although TGF- β 1 can promote the generation of Tregs *in vitro*, it has been controversial whether TGF- β 1 is involved in the generation or maintenance of Tregs under pathologic conditions, especially in tumor environments^[28]. Some studies showed that tumor-derived factors such as TGF- β 1 may contribute to CD4⁺CD25⁺ Treg cell expansion^[29], but also enhance their suppressor ability^[27]. In contrast to them, Zhao *et al.*^[30] recently found that neutralization of TGF- β 1 did not affect Foxp3 expression in ovarian carcinoma cells. The role of TGF- β 1 needs to be elucidated in GC. Our results demonstrated that a higher TGF- β 1 level was found in GC cell supernatant and TGF- β 1 can induce increased Treg cells. Surprisingly, although blocking TGF- β 1 could decrease the conversion activity in our study, it was not completely abrogated. Accordingly, we could not rule out that a fraction of converting Treg cells may be generated in the presence of other unknown tumor-derived soluble factors besides TGF- β 1. It is likely that multiple cytokines are involved in the induction of Foxp3 expression^[30]. TGF- β 1, together with other factors, seemed to account for the induction of Treg cells in the GC microenvironment. Further research is needed to elucidate the potential mechanism of GC derived other factors for induction of Tregs. Additionally, what should be noted is that TGF- β 1 derived from GC can also account for immunosuppression of other cell types, and besides GC cells, macrophages and stromal cell also can secrete TGF- β 1 in tumor environments^[31]. It is documented that TGF- β 1 is important for the inhibition of CD8⁺ CTL and NK cells, which play a critical role in the prevention and clearance of tumors^[32]. A better understanding of the mechanisms of the Treg increase in GC may allow for future immunotherapeutic and diagnostic opportunities in this population. Recent reports have shown that functional polarization of Th subsets of lymphocytes has been implicated in tumor promotion. Tumor derived TGF- β 1 in the tumor microenvironment could promote tumor eradication by influencing the polarization of Th1/Th2 and controlling Treg/Th17 cell polarization^[33]. This study

only focuses on the specific role of TGF- β 1 in the induction of Tregs. However, the polarization of other Th cells in the tumor environment by TGF- β 1 needs to be further elucidated. A complete understanding the role of TGF- β 1 in controlling T cell polarization in tumors is crucial for dissecting the beneficial use of TGF- β 1 in future immunotherapies against gastric cancer.

In conclusion, we provide evidence that a higher TGF- β 1 level is related to the increased population of CD4⁺Foxp3⁺ Tregs. GC cell supernatants can stimulate induction of human CD4⁺Foxp3⁺ Treg cells. This study suggests that gastric cancer cell supernatants can induce the conversion of Tregs from CD4⁺CD25⁻ naive T cells partly *via* mechanisms involving TGF- β 1. Our data support the existence of intercellular cross-talk between the tumor cell and Tregs that might regulate anti-tumor immune responses.

COMMENTS

Background

Regulatory T cells (Tregs) accumulate in the tumor environment and suppress tumor-specific T-cell responses. Previous studies have suggested that Tregs were elevated in gastric cancer and increased populations of Tregs impaired anti-tumor immunity. However, the molecular and cellular features responsible for the increase and maintenance of Treg cell levels in gastric cancer remain elusive.

Research frontiers

Recently, emerging evidence suggests that Tregs play an important role in tumor escape from immunological control. Although the precise mechanism causing the increased numbers of Treg cells is unknown, transforming growth factor- β 1 (TGF- β 1), as well as other mediators, has been reported in inducing Treg cells. However, there are contradictory reports regarding the role of TGF- β 1 in the induction of Tregs in cancer. The research aimed to explore whether or not gastric cancer cells producing this cytokine would account for the increased Treg and promote tumor progression.

Innovations and breakthroughs

In this study, the data confirmed the higher level of serum TGF- β 1 in patients with gastric cancer. Moreover, the higher TGF- β 1 level correlated with the increased population of CD4⁺Foxp3⁺ Tregs in advanced gastric cancer. Gastric cancer cell induced the increase of functional CD4⁺Foxp3⁺ Tregs, mainly from the conversion of CD4⁺CD25⁻ naive T cells. Furthermore, gastric cancer cells can induce Tregs development *via* production of TGF- β 1.

Applications

The results indicated that the gastric cancer cell played a pivotal role in impairing the antitumor T cell response by induction of Tregs. This study supports the existence of intercellular cross-talk between the tumor cell and Tregs that might regulate anti-tumor immune responses. A complete understanding of the role of TGF- β 1 in tumors is crucial for dissecting the beneficial use of TGF- β 1 in future immunotherapies against gastric cancer.

Terminology

Regulatory T cell (Treg cell) is functionally defined as a T cell that inhibits an immune response by influencing the activity of another cell type. Tregs are characterized by specific expression of the forkhead transcription factor Foxp3, and make up 5%-10% of the normal peripheral CD4⁺ T cell population. Treg cells within the tumor microenvironment are a crucial component of the tumor immunosuppressive network.

Peer review

The authors examined the level of serum TGF- β 1, and found that it was higher in

patients with gastric cancer than in healthy controls. In addition, they also found that gastric cancer cells induced the increased CD4⁺Foxp3⁺ Tregs *via* production of TGF- β 1. Gastric cancer cells upregulated the production of TGF- β 1 and blockage of TGF- β 1 partly abrogated Tregs phenotype. These experiments are well-designed and results are clear.

Abstract

AIM: To investigate the expression of markers that are correlated with the prognosis of colorectal cancer (CRC) patients.

METHODS: One hundred and fifty-six CRC patients

were followed up for more than 3 years after radical surgery. Immunohistochemical (IHC) analysis was performed to detect the expression of 14 pathway-related markers (p53, APC, p21ras, E-cadherin, endothelin-B receptor, Shp2, ADCY-2, SPARCL1, neuroligin1, hsp27, mmp-9, MAPK, MSH2 and rho) in specimens from these patients. Bioinformatics analysis involving a Support Vector Machine (SVM) was used to determine the best prognostic model from combinations of these markers.

RESULTS: Seven markers (SPARCL1, Shp2, MSH2, E-cadherin, p53, ADCY-2 and MAPK) were significantly related to the prognosis and clinical pathological features of the CRC patients ($P < 0.05$). Prognostic models were established through SVM from combinations of these 7 markers and proved able to differentiate patients with dissimilar survival, especially in stage II/III patients. According to the best prognostic model, the p53/SPARCL1 model, patients having high p53 and low SPARCL1 expression had about 50% lower 3-year survival than others ($P < 0.001$).

CONCLUSION: SPARCL1, Shp2, MSH2, E-cadherin, p53, ADCY-2 and MAPK are potential prognostic markers in CRC. A p53/SPARCL1 bioinformatics model may be used as a supplement to tumor-nodes-metastasis staging.

INTRODUCTION

The incidence and mortality of colorectal cancer (CRC) are in the forefront of all cancers in western developed countries^[1]. In China, the incidence of CRC has also increased in recent years, with 177 000 new cases and 99 000 deaths every year and a 5-year survival rate of 63.4%^[2]. Tumor-nodes-metastasis (TNM) staging is helpful in predicting the survival of most patients. However, the heterogeneity of patients in their clinical outcome and their response to adjuvant chemotherapy calls for more useful prognostic pooled/panel molecular markers that will provide evidence for the choice of adjuvant therapy, especially for stage II and III patients.

Recently, Parsons *et al*^[3] analyzed DNA mutations in CRC patients, and found that genetic changes of tumors are based on signaling pathways. Additionally, Wood *et al*^[4] listed the number of mutations of all 140 genes included in 38 groups or pathways, which provided an impetus for the ongoing research on markers in CRC. After ranking these genes and pathways by the number of mutations listed by Wood *et al*^[4], we selected three genes (p53, APC, ras) and 11 pathways which included genes with several mutations, and 14 genes were ultimately chosen from the pathways as candidate markers for our study. The genes are p53, APC, p21ras, E-cadherin, endothelin-B receptor, Shp2, ADCY-2, SPARCL1, neuroligin1, hsp27, mmp-9, MAPK, MSH2 and rho.

To identify prognosis-related markers of CRC, 156 patients who were followed up for more than 3 years after radical surgery were included in our survey. Immunohistochemical (IHC) analysis was performed to individually detect the expression of the 14 candidate markers in the specimens. The survival status of these patients was also analyzed. We found that seven tumor markers were found to be significantly related to the prognosis and clinical pathological features of these patients.

With the rapid development of the life sciences, bioinformatics has been developed and applied to collect, deposit and analyze large datasets and screen for useful information. In order to select molecular biomarkers more intelligently, we used a bioinformatics tool, the Support Vector Machine (SVM) classifier, to discriminate patients with different prognoses. SVM is based on the principles of Structure Risk Minimization and Vapnik-Chervonenkis Dimension as statistical learning theory, and thus provides a good generalization control^[5]. SVM applications are actively used in various areas, from face recognition to genomics^[6], and SVM is also a powerful tool for analyzing multiple markers. In this study, the seven prognostic markers were randomly combined, and SVM was used to evaluate which combination model was the best for predicting the prognosis of CRC patients.

MATERIALS AND METHODS

Ethics

This work has been carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association and approved by the Ethics Committee of the Second Affiliated Hospital of Zhejiang University, College of Medicine, along with the patients' informed consent.

Patients and specimens

Tumor specimens included in this study were from 156 CRC patients who underwent a radical resection operation in the Second Affiliated Hospital of Zhejiang University, College of Medicine, between 1999 and 2004, with a median age of 60 years (range 20-92 years) at diagnosis. The clinical data of all patients are presented in Table 1. Tumor specimens for IHC were from filed blocks in the histopathological department.

Living patients were all followed up for > 36 mo after the radical operation, with a median follow-up of 62 mo (range 36-108 mo). The follow-ups were performed by history and physical surveillance every 3-6 mo for 2 years, then every 6 mo up to 5 years and every year after 5 years (conforming to NCCN V.2.2010). No patient was lost during the follow-up.

IHC

All 156 specimens in paraffin blocks were made into tissue arrays using a ZM-1 tissue array machine^[7]. Sections (4- μ m thick) were cut, and immunostaining for each antigen was conducted using the avidin-biotin peroxidase complex technique (MaxVision™ HRP-Polymer IHC Kit, MAIXIN-Bio), following the manufacturer's instructions. The antibodies used were p53 (monoclonal mouse, ZhongShan), APC (polyclonal rabbit, ZhongShan), p21ras (monoclonal mouse, MAIXIN), E-cadherin (monoclonal mouse, ZhongShan), endothelin-B receptor (polyclonal rabbit, CHEMICON), Shp2 (monoclonal rabbit, Abcam), ADCY-2 (monoclonal rabbit, Abcam), SPARCL1 (polyclonal goat, R & D), neuroligin (polyclonal rabbit, CHEMICON), HSP27 (monoclonal mouse, ZhongShan), mmp9 (polyclonal rabbit, ZhongShan), ERK1 + ERK2 (monoclonal mouse, ZhongShan), MSH2 (monoclonal mouse, ZhongShan) and Rho(-A,-B,-C) (monoclonal rabbit, MILLIPORE).

The IHC results were assessed using a semi-quantitative system, as previously described^[8]. According to the percentages of positive cells (0: none, 1: < 25%, 2: 25%-50%, 3: 50%-75% and 4: > 75%) and staining intensity (0: negative, 1: weak, 2: moderate and 3: strong), the expression levels of the proteins were divided into four groups by the sum of the two scores above: 0 (0, negative expression), 1 (2-3, low expression), 2 (4-5, medium expression) and 3 (6-7, high expression).

Bioinformatics analysis

Experimental data were then analyzed by the Zhejiang University ProteinChip Data Analysis System (ZUCIPDAS, www.zlzx.net). We constructed a non-linear SVM classifier (with a radial based function kernel, a parameter Gamma of

0.6, and a cost of the constraint violation of 19) to distinguish groups with different prognoses, and validated results by a 10-fold cross validation method.

One hundred and thirty-one patients with complete data were then filtered for the ongoing bioinformatics analysis. The seven prognostic biomarkers (SPARCL1, Shp2, MSH2, E-cadherin, p53, ADCY-2 and MAPK) were combined randomly to build 127 SVM models. For each model, the expression of these markers was the input, and the 3-year survival status of each patient was the evaluation criteria. The model with the highest accuracy for predicting the 3-year survival of the patients was selected as the best prognostic model, and the accuracy of the models was then validated by 10-fold cross validation between training sets and test sets.

Of the 131 patients, 44 died within 3 years after surgery, but the other 87 were still alive after 3 years. Because the number of patients dead at 3 years was about half of the number of living ones, the model showed low sensitivity due to the unbalanced data. Obviously, sensitivity is important for a prognostic model, so we next defined an

The immunohistochemical (IHC) results were assessed using a semi-quantitative system, as previously described^[9]. According to the percentages of positive cells and staining intensity, the expression levels of the proteins were divided into four groups as negative, low, medium and high expression. ¹Data were missing because some specimens were lost during sectioning and staining of tissue arrays.

adjusted accuracy [accuracy = (sensitivity+specificity)/2 + sensitivity]/2; sensitivity = true positive/(true positive + false negative), specificity = true negative/(true negative + false positive). This increased the weight of sensitivity and allowed SVM to select models with higher sensitivity.

Statistical analyses

Kaplan-Meier survival analysis (log-rank test) was used to evaluate the relationship between marker expression and the survival of patients. Kruskal-Wallis test was used to evaluate the relationship between the expression of candidate markers and some pathologic features in IHC analyses. SPSS Version 13.0 software (SPSS Inc., Chicago, IL) was used for all statistical analyses. *P* < 0.05 was considered to be statistically significant, and all *P* values were two-sided.

RESULTS

Association between the expression of candidate markers and the survival of CRC patients

The expression of candidate markers in CRC was investigated by IHC (listed in Table 2). It should be noted that some specimens were lost during sectioning and staining of tissue arrays, resulting in an average of 3.6 specimens per marker (2.3%). Representative examples of immunohistochemical slides for each marker are shown in Figure 1.

Kaplan-Meier survival analysis revealed that markers significantly related with survival were SPARCL1, Shp2, MSH2, E-cadherin, p53, ADCY-2 and MAPK. The higher protein expression of SPARCL1, Shp2, MSH2, E-cadherin, and MAPK in CRC patients was related to better survival, while the higher expression of p53 and ADCY-2 was related to worse survival. The Kaplan-Meier survival curves of these markers are shown in Figure 2.

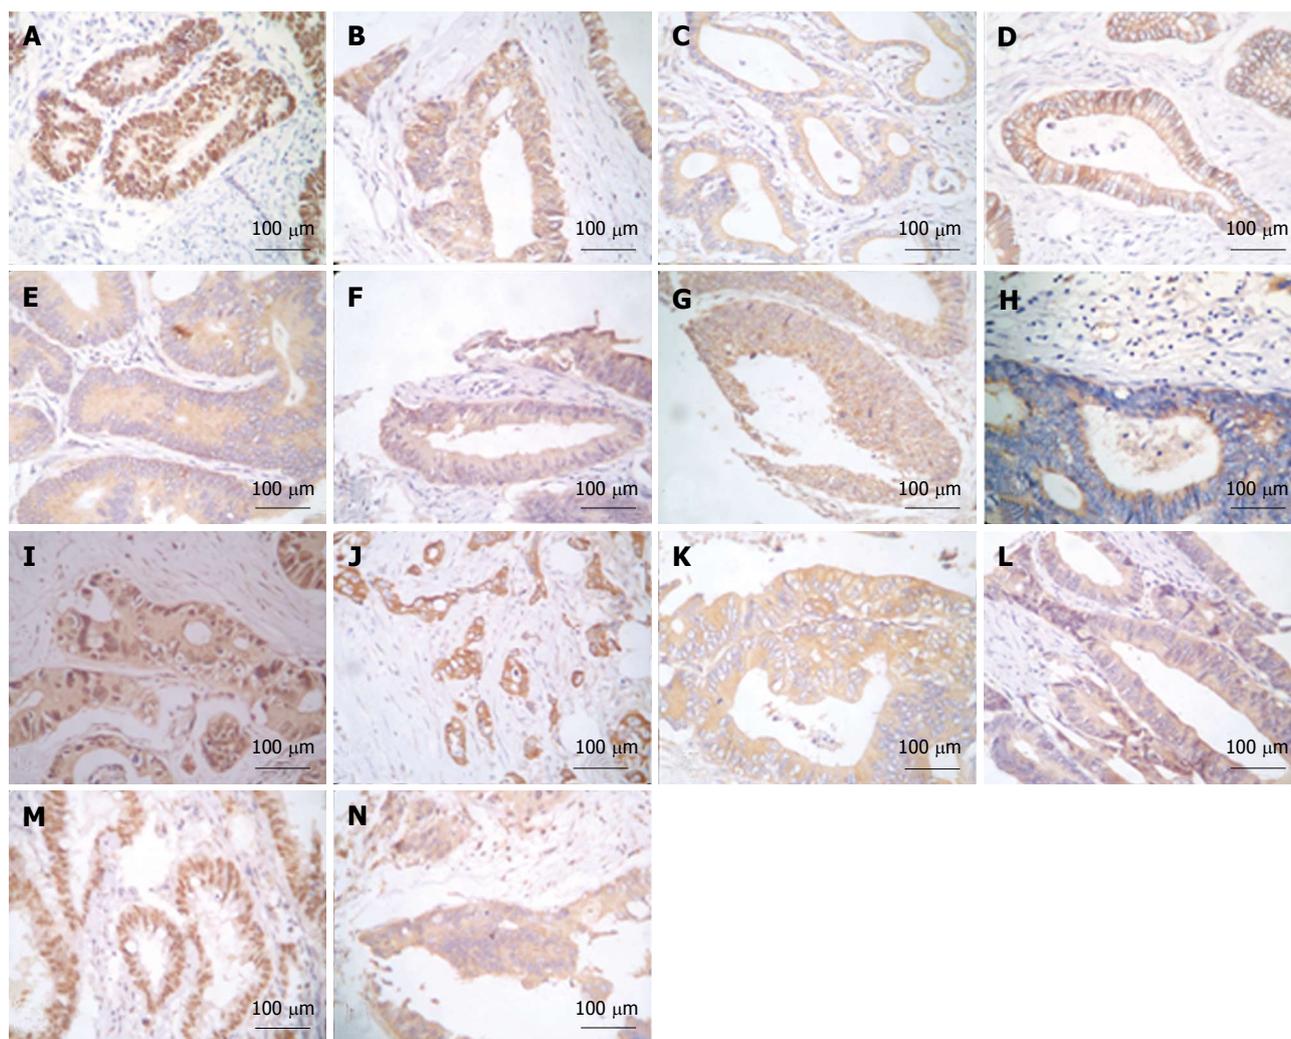

Figure 1 Immunohistochemical expression of 14 markers. The markers and the cellular location of positive staining are listed below: A: P53: nuclear; B: APC: cytoplasm; C: P21ras: cytoplasm; D: E-cadherin: membrane or cytoplasm; E: Endothelin B receptor: cytoplasm; F: Shp2: cytoplasm; G: ADCY-2: cytoplasm; H: SPARCL1: cytoplasm; I: neuroligin1: nuclear or cytoplasm; J: hsp27: nuclear or cytoplasm; K: MMP9: cytoplasm; L: MAPK: cytoplasm; M: MSH2: nuclear; N: Rho: cytoplasm. (Scale bar = 100 μ m).

Kruskal-Wallis tests revealed that among these markers, SPARCL1, Shp2 and MSH2 were noticeably associated with the most clinical pathological features of CRC patients, including differentiation, bowel wall invasion (pT), lymph node metastasis (pN), distant metastasis (pM), TNM stage, post-surgery recurrence or metastasis. P53 was mainly related to TNM staging; E-cadherin and MAPK were mainly related to post-surgery recurrence and metastasis (Table 3). However, other markers, such as endothelin B receptor, APC and rho, were just related to differentiation or stages (data not shown).

Prognostic bioinformatics model established by combining the seven markers and evaluated by survival analysis

By SVM, the seven markers can randomly form 127 combinations. After being validated by 10-fold cross validation, the model with the highest accuracy (65.3) was the p53/SPARCL1 combination among all these combinations.

According to the prediction result (PR) given by the

p53/SPARCL1 model, patients can be divided into two groups: “high risk” (PR > 0) and “low risk” (PR < 0). Three-year survival of the low risk group (88.30%) was more than twice as high as that of the high risk group (37.84%). Kaplan-Meier analysis revealed that the difference of survival was significant between these two groups ($P < 0.001$) (Figure 3A).

Prognostic value of the p53/SPARCL1 model for stage II and III CRC patients

Among these 131 patients, 99 patients were classified as stage II or III. We found that the difference in 3-year survival was not great between stage II ($n = 43$) and III ($n = 56$) patients, i.e. 88.40% vs 62.50% ($P = 0.039$) (Figure 3B). However, when these 99 patients were grouped by the PR of the p53/SPARCL1 model, the 3-year survival rate was very different between the low risk ($n = 70$) and high risk ($n = 29$) groups, i.e. 87.14% vs 37.93% ($P < 0.001$) (Figure 3C). Thus, the survival difference was much greater between low and high risk groups than between stage II and

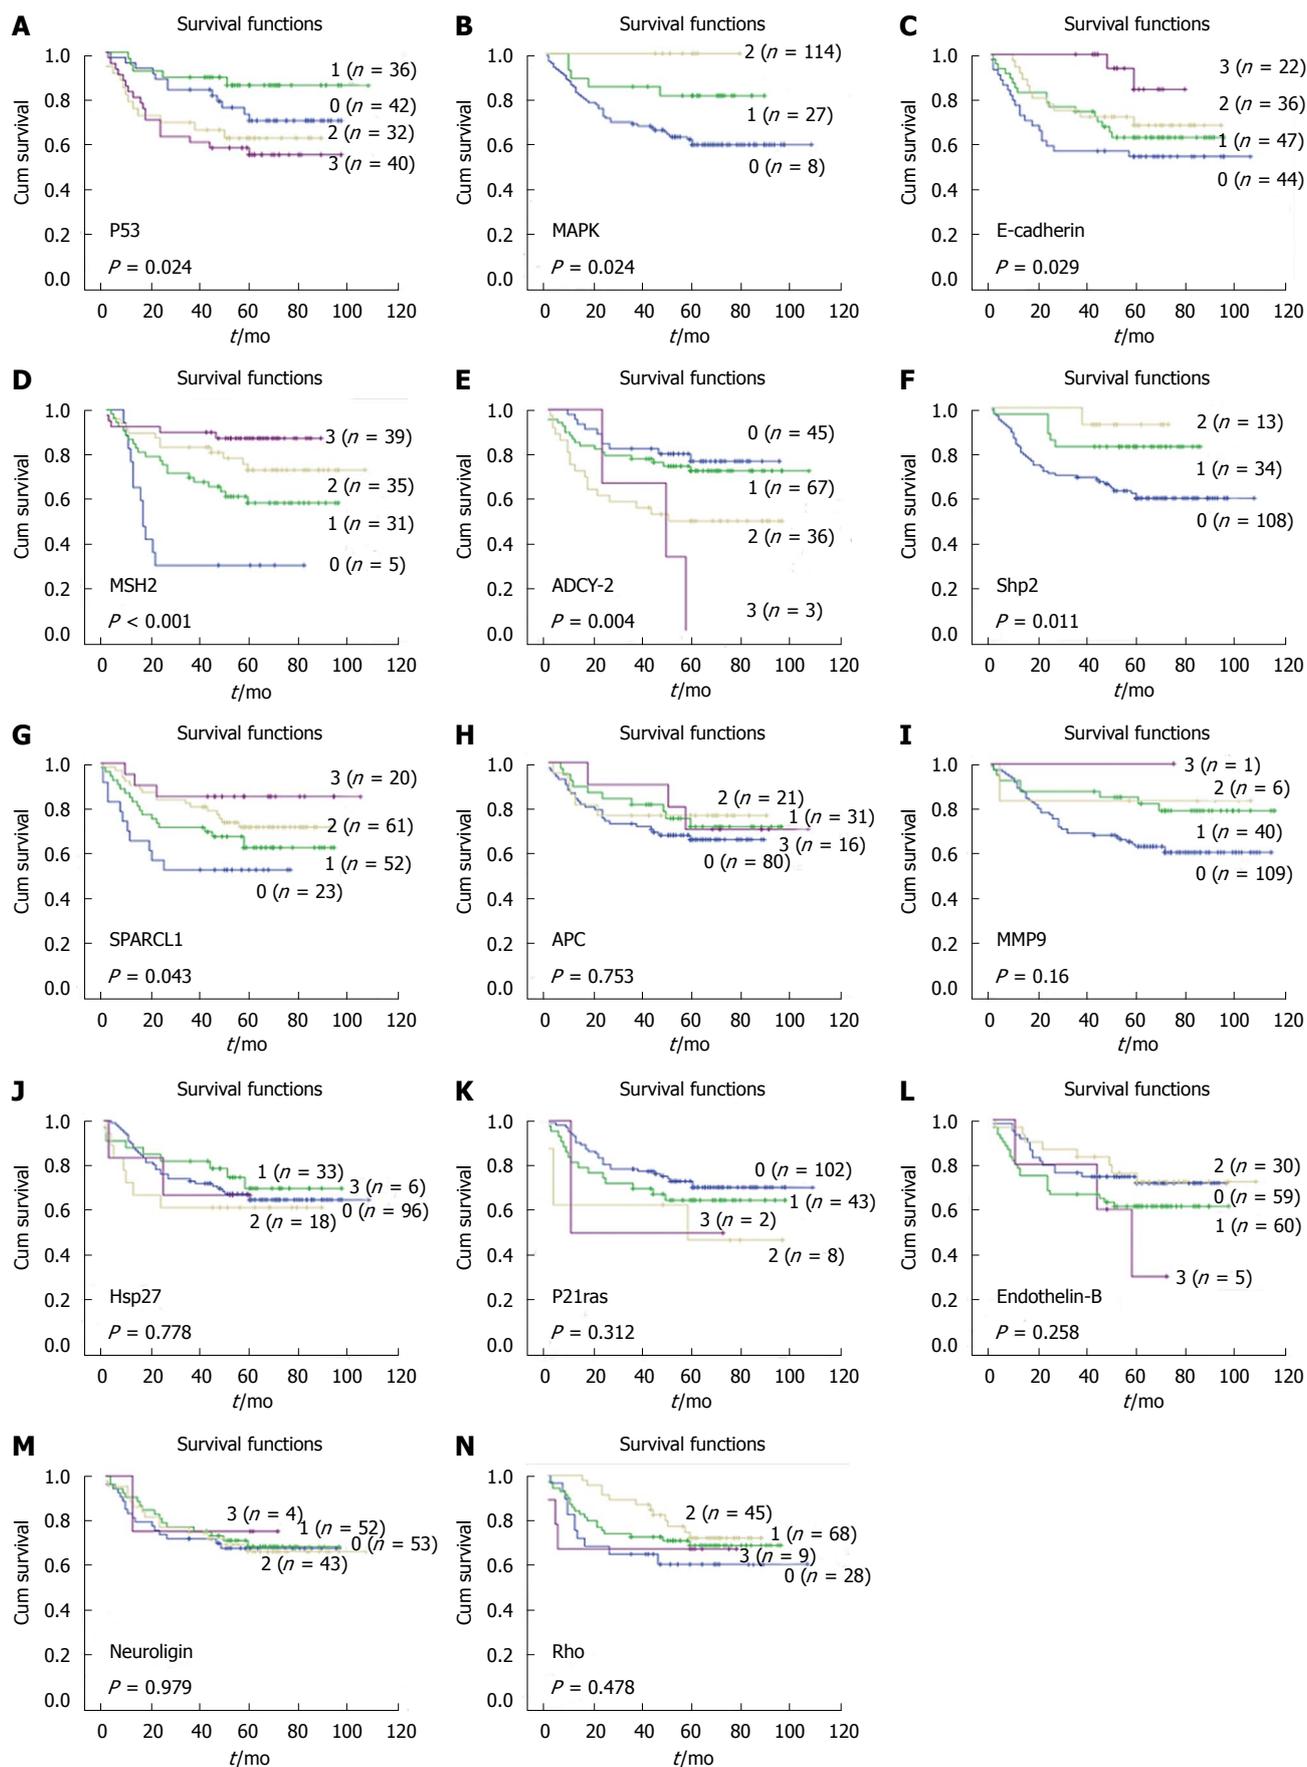

Figure 2 Kaplan-Meier curves of 14 markers. A: P53; B: MAPK; C: E-cadherin; D: MSH2; E: ADCY-2; F: Shp2; G: SPARCL1; H: APC; I: MMP9; J: Hsp27; K: P21ras; L: endothelin-B receptor; M: Neuroligin1; N: Rho.

Table 3 Relationship between marker expression and clinical features (*P* values)

| Markers | <i>P</i> values | | | | | |
|------------|--------------------|--------------------|--------------------|--------------------|--------------------|--------------------|
| | Differentiation | pT | pN | pM | TNM | Post-surgery |
| P53 | 0.671 | 0.654 | 0.003 ^b | 0.119 | 0.024 ^a | 0.207 |
| MAPK | 0.186 | 0.597 | 0.230 | 0.188 | 0.182 | 0.001 ^b |
| E-cadherin | 0.028 ^a | 0.342 | 0.080 | 0.041 ^a | 0.223 | 0.004 ^b |
| MSH2 | 0.964 | 0.006 ^b | 0.012 ^a | 0.061 | 0.001 ^b | 0.001 ^b |
| ADCY-2 | 0.458 | 0.430 | 0.779 | 0.470 | 0.878 | 0.082 |
| Shp2 | 0.020 ^a | 0.004 ^b | 0.035 ^a | 0.849 | 0.006 ^b | 0.006 ^b |
| SPARCL1 | 0.002 ^b | 0.171 | 0.037 ^a | 0.021 ^a | 0.044 ^a | 0.014 ^a |

The relationship between the expression of candidate markers and some pathologic features was evaluated by Kruskal-Wallis test (SPSS Version 13.0 software) in immunohistochemistry analyses. All *P* values are two-sided (^a*P* < 0.05, ^b*P* < 0.01). The pathologic features in the table were differentiation, bowel wall invasion (pT), lymph node metastasis (pN), distant metastasis (pM), TNM stage (TNM), post-surgery recurrence or metastasis (Post-surgery).

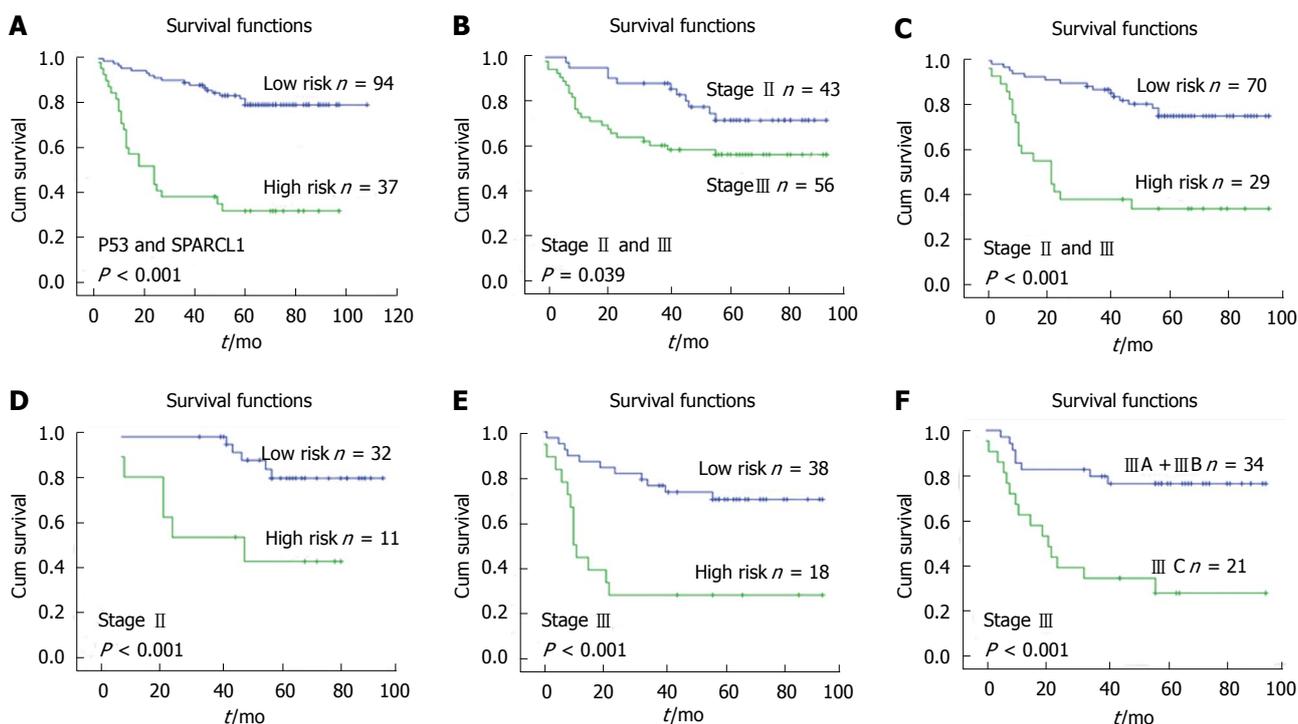

Figure 3 Prognostic value of p53/SPARCL1 model in colorectal cancer patients. According to the prediction result (PR) given by the p53/SPARCL1 model, patients could be divided into two groups: "high risk" (PR > 0) and "low risk" (PR < 0). A: 3-year survival of the "low risk" group was 88.30%, significantly higher at twice that of the "high risk" group, which was only 37.84% (*P* < 0.001). B: The 3-year survival of stage II (*n* = 43) and III (*n* = 56) patients was 88.40% vs 62.50% (*P* = 0.039), with an only 15.90% survival difference (*P* = 0.039); C: The same 99 stage II/III patients, when divided by the PR of the p53/SPARCL1 model: the 3-year survival of "low risk" (*n* = 70) and "high risk" (*n* = 29) group was 87.14% vs 37.93%, with a survival difference of 49.21% (*P* < 0.001), much more than the difference between stage II and III patients; D: According to the PR of the p53/SPARCL1 model, the 3-year survival of "low risk" and "high risk" patients at stage II was 100% and 54.55%, respectively, with a significant difference of 45.45% (*P* < 0.001); E: At stage III (*n* = 56), the 3-year survival was 78.95% of "low risk" patients and 27.78% of "high risk" patients, with a 51.17% higher survival rate (*P* < 0.001); F: At stage III (*n* = 56), the 3-year survival was different between stage IIIA/IIIB (*n* = 34) and IIIC (*n* = 22) patients: 82.36% vs 31.82% (*P* < 0.001).

III patients.

Among the 99 stage II/III patients, 43 patients were of stage II, all of whom were classified as stage II A. According to the PR of the p53/SPARCL1 model, the 3-year survival rates of low risk and high risk stage II patients were 100% and 54.55%, respectively. This 45.45% difference between the survival rates of low risk and high risk stage II patients was significant (*P* < 0.001) (Figure 3D).

Among the 56 stage III patients, the 3-year survival was 78.95% for low risk patients and 27.78% for high risk ones, and this 51.17% difference was statistically

significant (*P* < 0.001) (Figure 3E). Similar survival difference was found between stage IIIA/IIIB (*n* = 34) and IIIC (*n* = 22) patients, i.e. 82.36% vs 31.82% in 3-year survival rates (*P* < 0.001) (Figure 3F).

DISCUSSION

Which CRC patients should receive adjuvant chemotherapy after radical resection? Currently, it is a standard recommendation for stage III but not stage II patients. However, the 5-year survival rate of stage II B (T4N0M0)

patients is even lower than stage IIIA (T1-2N1M0)^[9]. One explanation for this may be due to not dissecting enough lymph nodes during surgery. Another potential cause is that stage II B tumors penetrate to the surface of the visceral peritoneum or directly invade the adjacent organs, which indicates that the biological behavior of the tumor is poor. Further, we do not know which of the stage II patients are at high risk and should receive adjuvant chemotherapy to improve their survival. Therefore, better molecular tumor markers are urgently needed to predict which patients may potentially benefit from adjuvant chemotherapy.

In the network of cancer-related genes, pathways are the frame by which we can understand the network logically. In the present study, 14 candidate markers were selected based on the most frequently mutated genes and pathways listed in the study of Wood *et al*^[4], and their expression levels in CRC specimens were detected by IHC, which is generally used for regular pathological detection. Among these 14 markers, seven markers (SPARCL1, Shp2, MSH2, E-cadherin, p53, ADCY-2 and MAPK) were significantly prognosis-related.

Shp2 is an essential component in several oncogene signaling pathways^[10]. Here, we surprisingly found that Shp2 is a predictive marker for good prognosis, which is in stark contrast to previous studies indicating a role for Shp2 in promoting carcinogenesis in other cancers^[11-13]. MSH2 is a vital mismatch repair gene. Patients with high MSH2 expression had better survival in CRC^[14,15], and higher gene expression of MSH2 in responders to 5-fluorouracil-based chemotherapy indicates a predictive value of MSH2 in chemotherapy^[16,17]. The MAPK signal pathway is associated with proliferation, survival and apoptosis of tumor cells and therefore plays a very important role in carcinogenesis^[18,19]. E-cadherin, a member of the cadherins, is related to invasion and metastasis in many cancers^[20]. Loss or low expression of E-cadherin is more frequent in CRC patients with liver metastasis^[21], demonstrating that loss of E-cadherin is related to poor prognosis. ADCY is involved in the G-protein system-related GnRH signal pathway. The proliferation of rat pancreatic tumoral AR4-2J cells can be stimulated by pituitary ADCY-activating peptide through the ADCY pathway^[22,23], which suggests that ADCY promotes the growth of tumor cells. Among these markers in the present study, Shp2, MSH2, MAPK and E-cadherin were significant markers for predicting good prognosis, but ADCY-2 was not.

P53 is an indispensable tumor suppressor that plays an important role in several carcinogenic processes. Previous studies suggest that p53 has an influence on the prognosis of patients in many cancers^[24] including CRC, and is associated with tumor staging, multi-drug resistance, response to chemotherapy or radiotherapy, post-surgery recurrence and metastasis^[25-30]. Recently, research has shown that mutant p53 proteins not only lose their tumor suppressive functions but may also gain new abilities that enhance tumorigenesis^[31]. Indeed, the p53 mutation is linked with chemo-resistance and trans-

formation to a more aggressive disease in many tumor types^[32]. The p53 codon 72 polymorphism causes an increased risk for liver metastases in CRC patients positive for p53 overexpression^[33]. In the present study, we found that a high expression of mutant p53 protein was associated with more frequent lymph node metastasis, advanced TNM stage and poor survival (Table 2), which is consistent with other reports.

SPARCL1, also known as hevin^[34], belongs to the matricellular protein family. SPARCL1 is down-regulated in transformed prostate epithelial cell line P69SV40T^[35,36], and tissues of metastatic prostate adenocarcinoma, non-small cell lung cancer, bladder and pancreatic ductal carcinoma, but up-regulated in liver cancer tissues^[35-39]. Additional work by our group has revealed that SPARCL1 expression is significantly different between CRC specimens with and without liver metastasis (to be published). In the present study, the expression of SPARCL1 was not only significantly associated with histological differentiation and survival but also with distant and lymph node metastasis, suggesting that SPARCL1 is likely to be an important negative regulator in the progression or metastasis of CRC.

In the present study, SVM was utilized to analyze and establish prognostic models of CRC from the combinations of the 7 prognostic biomarkers mentioned above. For SVM, the right balance is struck between the accuracy attained on a particular training set and the "capacity" of the machine, i.e. the ability of the machine to learn any training set without error to achieve the best generalization ability. The remarkably robust performance of SVM with respect to sparse and noisy data has made it the system of choice in a number of applications. When used for classification, SVM separates a given set of binary labeled training data and can work in combination with the kernels technique for cases in which no linear separation is possible. The accuracy of our models was evaluated by 10-fold cross validation.

Ultimately, the combination of p53 and SPARCL1 was found to be the best prognostic model of those tested. Survival analysis proved that the prediction result of the p53/SPARCL1 model was a statistically significant prognostic factor for CRC patients in all stages or only stage II / III (Figure 3).

Other researchers have attempted to identify biomarkers to further stratify stage II or stage III patients. Prognostic advantages were found in patients with MSI-high tumors and stage II and III CRC patients treated with 5-fluorouracil-based adjuvant therapy^[40,41]. In the PETACC-3 study, the prognostic value of MSI status was found to be more significant in patients with stage II disease than in stage III cases^[42]. However, value of MSI status as a prognostic or predictive marker may be affected by mutations in other genes involved in cancer etiology, such as the BRAF gene^[43]. Additionally, chromosome 18q loss of heterozygosity (LOH) has been associated with poor prognosis in stage II and stage III CRC patients in some studies^[40,44] but not others^[45,46]. Differences in the methodologies used possibly explained the contradictory

findings reported. In a large prospective study of patients with non-MSI-high CRC, 18q LOH was also not associated with patient survival, indicating that 18q LOH is not an independent survival predictive marker^[47].

In our study, according to the p53/SPARCL1 model, the survival rate of low risk stage II A patients was 45.45% higher than that of high risk ones. Moreover, low risk stage III patients had a 51.17% higher 3-year survival rate than high risk ones ($P < 0.001$), the same as the survival difference between stage IIIA/IIIB and IIIC. Therefore, the p53/SPARCL1 model established in this study can likely be used to supplement TNM staging, especially in stage II and III patients.

In conclusion, we discovered that SPARCL1, Shp2, MSH2, E-cadherin, p53, ADCY-2 and MAPK are significant prognostic markers in CRC. The p53/SPARCL1 model is of predictive use in discriminating patients with high or low risk, especially at stage II and III. Patients may benefit from accurate valuation and realistic treatment strategies for their disease with the help of potential prognostic markers. Larger scale studies and those involving multiple centers are planned to confirm clinic applicability of this prognosis model.

COMMENTS

Background

The incidence and mortality of colorectal cancer (CRC) are in the forefront of all cancers in China and western developed countries. More useful prognostic markers are urgently needed to provide evidence for the strategy of adjuvant therapy, especially for stage II and III patients.

Research frontiers

There are many ways to find useful markers in cancers. Cancer genomic research from the Vogelstein group has provided an enormous amount of information on genetic alterations in colorectal cancers. In this study, the authors set out to utilize this information to help in choosing their candidate markers. Moreover, the bioinformatics tool, which is used more and more to screen useful information from a large data set, was used here to further build prognostic models in CRC patients.

Innovations and breakthroughs

Some biomarkers have been identified as being related to the prognosis of CRC patients, including MSH2, E-cadherin and p53. However, this is the first study to report that SPARCL1, Shp2, ADCY-2 and MAPK are also potential prognostic markers in CRC. Furthermore, survival analysis proved that the p53/SPARCL1 model, established by the bioinformatics tool, could differentiate CRC patients with different prognoses in all stages or only stage II/III.

Applications

By finding significant prognostic markers in CRC, patients could be discriminated with high or low risk, especially in stage II and III. Patients may benefit from accurate valuation and realistic treatment strategies for their disease with the help of potential prognostic markers and models.

Terminology

The Support Vector Machine (SVM) classifier is a kind of bioinformatics tool, which is considered to be powerful for identifying the best discriminator from a large data set. Therefore, SVM applications are actively used in various areas from face recognition to genomics and SVM is also a powerful tool for analyzing multiple markers.

Peer review

This paper reports some novel findings on patient outcome with colorectal cancer. The array of genetic markers is extensive and worthy of publication.

differentiated embryo chondrocyte 1 (DEC1) in hepatocellular carcinoma (HCC) and corresponding adjacent non-tumor and the normal liver tissues, the association between DEC1 expression and histopathological variables and the role of DEC1 in hepatocarcinogenesis.

METHODS: The expression of DEC1 was detected immunohistochemically in 176 paraffin-embedded sections from 63 patients with HCC and 50 subjects with normal liver tissues.

RESULTS: DEC1 protein was persistently expressed in the cytoplasm of hepatocytes in normal liver and HCC tissues. Compared with adjacent non-tumor liver tissues, HCC tissues showed high nuclear expression of DEC1 protein. However, high DEC1 nuclear expression was more frequently detected in well-differentiated (83.3%) than in moderately (27.3%) and poorly differentiated HCC (16.7%). Low DEC1 expression was associated with poor histological differentiation and malignancy progression. A correlation was found between the nuclear expression of DEC1 protein and histological differentiation ($r = 0.376$, $P = 0.024$).

CONCLUSION: DEC1 is expressed in the cytoplasm of hepatocytes and because nuclear DEC1 expression is decreased with decreasing differentiation status of HCC, nuclear DEC1 might be a marker of HCC differentiation.

Abstract

AIM: To investigate the expression patterns of human

INTRODUCTION

Hepatocellular carcinoma (HCC) is a major global health problem, with an estimated incidence of 500 000-1 000 000 cases and 600 000 deaths annually. It is the fifth most common cancer in the world and the third most common cause of cancer-related death^[1]. The high morbidity and mortality of HCC is due to pre-existing primary chronic liver diseases, such as chronic viral hepatitis, aflatoxin B1, alcoholic liver disease and dysmetabolism, including hereditary haemochromatosis, obesity, diabetes and steatosis^[2]. Each of these scenarios has its own genetic and epigenetic alterations, chromosomal aberrations, gene mutation and altered molecular pathways in the process of hepatocarcinogenesis^[2,3]. Because of these varied background and heterogeneity, HCC is complex. Although dysregulation of signaling pathways such as Wnt/b-catenin, Ras, p14ARF/p53, p16INK4A/Rb, transforming growth factor-beta (TGF-beta) and PTEN/Akt has been reported in some HCC cases^[4], the specific gene mutation(s) and exact molecular mechanism involved in hepatocarcinogenesis is not well known.

Human differentiated embryo chondrocyte 1 (DEC1), a basic helix-loop-helix (bHLH) transcription factor, has rat and mouse orthologs, named enhancer of split and hairy-related protein-2 (SHARP-2) and stimulation of retinoic acid 13 (Stra13), respectively^[5-7]. The factors play important roles in regulation of gene expression in cell differentiation, proliferation, immune regulation and metabolism homeostatic control^[8]. DEC1 is expressed ubiquitously in both embryonic and adult tissues with human and various extracellular stimuli such as growth factors, serum starvation, hypoxia, hormones, nutrients, cytokines, UV radiation, and infection, which regulate its expression^[8,9]. The regulation of DEC1 is cell-type specific^[5,9-11].

Several studies have described various DEC1 expression patterns in different tumor tissues, which suggest that it might contribute to oncogenesis. In human breast cancer, the overexpression of DEC1 contributes to a more aggressive phenotype^[12]. The association between upregulation of DEC1 expression and differentiation of gastric cancer suggests its important role in the differentiation and progression of gastric cancer^[13]. Linked to oncogenesis, DEC1 is highly expressed in colon carcinomas but not in the adjacent normal tissues^[14]. It is involved in the UV signal transduction pathway and takes part in the process leading to skin cancer^[15]. In combination with carbonic anhydrase-IX (CAIX) and carbonic anhydrase-X II (CAX II), DEC1 may help with a more accurate classification of all renal carcinomas^[9]. However, in lung cancer, upregulated or downregulated DEC1 expression has been found^[16,17]. The expression patterns

and level of DEC1 protein in HCC have not been systematically investigated, and its potential role in hepatocarcinogenesis is unknown.

We aimed to investigate the expression of DEC1 in HCC. We evaluated the distribution and level of expression of DEC1 protein in 176 paraffin-embedded tissue sections from 63 patients with HCC and 50 subjects with normal liver tissues by immunohistochemistry. We also investigated the correlation of DEC1 expression with clinicopathological features and differentiation status of HCC to evaluate the functional characteristics of DEC1 in the development of HCC.

MATERIALS AND METHODS

Patients and samples

Three kinds of human liver sections ($n = 176$) were evaluated, including 126 HCC and adjacent non-tumor tissues from 63 patients with primary HCC, and 50 normal liver tissues from patients with hepatic hemangioma who underwent hepatectomy in Qianfoshan Hospital and Jinan Central Hospital, Shandong University, China. The 63 HCC patients included 52 males; the median age was 56 years (range, 35-77 years), and the 50 normal liver patients included 17 males. The formalin-fixed, paraffin-embedded tissue samples were retrospectively collected and randomly selected from the files of the Department of Pathology after the protocol was approved by the local research ethics committee. All HCC patients underwent surgery without prior radiotherapy or chemotherapy and other diseases such as viral hepatitis had been excluded in the hemangioma patients. All sections were reviewed independently by pathologists blinded to the clinicopathological characteristics, 63 HCC and 50 normal livers with the same pathological results were selected in our study. Among the 63 HCC samples, 18 were well differentiated, and 45 were moderately and poorly differentiated. We also collected data on sex, age, tumor size, hepatitis B virus infection, presence of cirrhosis, and α -fetoprotein (AFP) level in HCC.

Immunohistochemical staining

The tissues were fixed in 10% neutral buffered formalin for 12 h and routinely processed. Paraffin wax-embedded tissue blocks were cut into 4- μ m-thick sections. Briefly, formalin-fixed, paraffin-embedded sections were heated at 60°C for 60 min and placed into xylene to be deparaffinized and graded ethanol to be rehydrated, and then washed in phosphate-buffered saline (PBS). Antigen retrieval was performed in a prewarmed pressure cooker with a solution of antigen retrieval citrate buffer (pH 6.8) for 3 min. Following de-pressurization, cold water was poured into the cooker for 10 min, and then sections were rinsed well in warm water. Endogenous peroxide and oxidative compounds were quenched by incubation in 3% H₂O₂ in methanol for 10 min. Sections were washed 3 times with PBS, and incubated with rabbit polyclonal DEC1 antibody diluted in TBS-Tween20 (1:300 dilution)

(Bethyl Laboratories Inc, Montgomery, TX) overnight in a moist chamber at 4°C . After a final wash, secondary antibody (KIT-5010, Max Vision, Maixin.Bio, China) was applied, and TBS-Tween20 was used in all the dilutions and intervening rinses involved. Diaminobenzidine (DAB) was the chromogenic substrate. Sections were allowed to develop in DAB for 5 min, and then counterstained with hematoxylin. Slides were reviewed under microscope. Sections incubated without primary antibody were used as negative controls, and breast cancer sections were used as positive controls. Positive and negative controls were included in each run.

In hepatocytes, DEC1 protein was persistently expressed in all cytoplasm. We used a scoring standard for nuclear DEC1 expression according to our former paper^[13]: negative expression, no nuclear staining; low expression, nuclear staining $< 10\%$ of cancer cells; and high expression, nuclear staining $> 10\%$ of cancer cells. The staining was evaluated by two independent observers.

Statistical analysis

Categorical variables were compared by χ^2 test or Fisher's exact test as appropriate. Spearman analysis was used to assess the correlation between DEC1 expression and tumor differentiation status. All statistical analyses were performed using SPSS v11 for Windows (SPSS, Inc., Chicago, IL). $P < 0.05$ was considered statistically significant.

RESULTS

DEC1 expression in normal liver tissues

In normal liver tissues, DEC1 expression was diffuse in the cytoplasm of hepatocytes accompanied by a varying degree of nuclear immunoreactivity (Figure 1A). A strong granular pattern of DEC1 staining was seen within the cytoplasm of the hepatocytes around the central vein in the intact hepatic lobule, and this special staining strength became gradually weakened away from the central vein (Figure 1B). However, no granular cytoplasmic staining was seen around the portal area (Figure 1C). The two different cytoplasmic staining patterns may result from the special anatomic structure and the particular blood supply of the hepatic lobule. The specific conditions around the central vein, such as hypoxia, low nutrition and acidity, could affect DEC1 expression status and lead to the granular pattern, and the diffusive expression pattern may be hypoxia independent. In addition, endothelial and bile duct epithelial cells showed nuclear and/or cytoplasmic DEC1 immunoreactivity (Figure 1A, B, D).

DEC1 expression in HCC and adjacent non-tumor tissues

Diffuse cytoplasm expression of DEC1 protein was observed in all 126 HCC and adjacent non-tumor liver tissues, except in 2 poorly differentiated HCC samples with weak cytoplasmic staining. Nuclear DEC1 expression was

Table 1 Differentiated embryo chondrocyte 1 nuclear expression in hepatocellular carcinoma and adjacent non-tumor tissues *n* (%)

| | Negative | Positive |
|---------------------------------|-----------|------------------------|
| HCC (63) | 27 (42.9) | 36 (57.1) ^a |
| Adjacent non-tumor tissues (63) | 46 (73.0) | 17 (27.0) |

^a*P* < 0.05 vs adjacent non-tumor tissues. HCC: Hepatocellular carcinoma.

detected in 36 (57.1%) of 63 samples of primary HCC, with 26 (41.3%) samples showing high nuclear expression (Table 1). Nuclear DEC1 expression was observed in only 17 (27.0%) of the 63 matched adjacent non-tumor tissues. Compared with HCC tissue, adjacent non-tumor tissues showed reduced nuclear DEC1 expression (*P* = 0.001). The proportion of positive DEC1 nuclear staining was higher in normal (66.7%) than in HCC tissues, but was not significantly different (*P* = 0.650). In LO-2 cells (normal hepatocytes), nuclear DEC1 expression was higher than in HepG-2 cells (data not shown). Compared with the normal control, adjacent non-tumor tissues showed a significantly low positive staining rate (*P* = 0.002), which may result from extrusion around the tumor or the response of hepatocytes to extracellular stimulation from the tumor. In addition, in HCC tissues with negative nuclear staining, only two cases showed positive nuclear staining in the corresponding adjacent non-tumor tissues. Therefore, the specific microenvironment around the HCC tumor and the present chronic liver disease such as viral hepatitis may affect DEC1 expression in adjacent non-tumor tissues.

Clinical significance of DEC1 nuclear expression in HCC

For the 36 cases with positive DEC1 nuclear staining, the proportion of DEC1 staining in well, moderately and poorly differentiated HCC tissues was 94.4% (17/18), 42.4% (14/33) and 41.7% (5/12), respectively. Negative DEC1 nuclear protein staining was associated with high histological HCC grade (Table 2). Well-differentiated tissue was significantly different from moderate and poorly differentiated tissues (*P* < 0.001). Factors such as sex (*P* = 0.886), age (*P* = 0.383), tumor size (*P* = 0.571), hepatitis B virus infection (*P* = 0.842) and cirrhosis (*P* = 0.616) had no significant association with DEC1 nuclear expression.

Nuclear DEC1 expression in HCC tissues is correlated with tumor differentiation

As a transcription factor, DEC1 plays its role in the nucleus. We found strong nuclear-positive staining and high nuclear DEC1 expression in well-differentiated HCC samples. In poorly differentiated tumors with large and pleomorphic cells, DEC1 nuclear expression was weak, even negative. We investigated the nuclear immunoreactivity of DEC1 related to differentiation status (Figure 2A-C). The proportion of high DEC1 nuclear expression in well, moderately and poorly differentiated HCC tissues was 83.3%, 27.3% and 16.7%, respectively (Figure 2D).

¹Corrected χ^2 analysis; ²Fisher's exact test.

We found a correlation between nuclear DEC1 protein expression and histological differentiation in HCC (*r* = 0.376, *P* = 0.024) (Table 3).

DISCUSSION

HCC is a complex and heterogeneous cancer, and the key drivers are not well known^[3,4]. Human DEC1 and the homologs rat SHARP-2 and mouse Stra13 belong to the bHLH family^[8]. In many tumor-derived cell lines and tumor tissues, DEC1 mRNA levels are upregulated^[9,18]. Its protein is also widely expressed with restricted patterns in many tissues^[9,10]. Nevertheless, the distribution and role of DEC1 in carcinogenesis and in the differentiation of human HCC are unknown. A previous study showed 5 of 6 cases of HCC with positive cytoplasmic and nuclear staining^[9]. However, the number of samples in this study was too small. In the current research, we studied the expression of DEC1 in 176 samples of HCC and normal liver tissues by immunohistochemistry.

We found that DEC1 protein was persistently expressed in the cytoplasm of both normal and malignant hepatocytes, with varying degrees of nucleic immunoreactivity and two staining patterns, granular and diffusive, in the cytoplasm of hepatocytes. Compared with the adjacent non-tumor tissues, HCC tissue showed predominant

¹Number of cases. DEC1: Differentiated embryo chondrocyte 1.

DEC1 nuclear protein expression, but the nuclear expression of DEC1 was decreased from well to moderately and poorly differentiated HCC. It seems that low DEC1 expression is associated with poor histological differentiation and malignancy progression in HCC. However, the mechanism of this distribution of DEC1 expression in HCC needs further investigations.

The intracellular distribution of DEC1 protein shows cell specificity: in Hela cells, DEC1 is equally present in both the nucleus and cytoplasm; in HepG2 cells, DEC1 is located mostly in the cytoplasm; and in the 786-0 cell line, the nuclear expression of DEC1 is predominant^[9]. In the present study, DEC1 protein was persistently expressed in almost all cytoplasm of hepatocytes, with a varying degree of nuclear immunoreactivity. This expression pattern implies that DEC1 may take part in the normal vital

functions of the liver such as metabolism and detoxification. DEC1-positive granular staining gradually weakened outward from the central vein in the cytoplasm of hepatocytes. The mechanism underlying this phenomenon might be the hypoxic environment around the central vein. Hypoxia-induced factor-1α (HIF-1α), the most important hypoxia effector, can upregulate the expression of DEC1 by binding hypoxia response element (HRE) on *DEC1* gene promoter^[19]. We also found that the DEC1 expression level in HCC was higher than in normal liver tissues. The oxygen tension in HCC was similar to that in normal liver tissues, so the overexpressed HIF-1α in HCC was independent of hypoxia^[20]. Thus, the diffuse staining pattern of DEC1 in normal liver tissues and HCC was independent of hypoxia, and the granular staining pattern of DEC1 may represent a low oxygen concentration. Whether the different patterns of staining imply a different function of DEC1 in the cytoplasm of hepatocytes awaits further investigations. Additional studies are required to unravel the mechanism by which DEC1 performs its function in cytoplasm. Furthermore, the subcellular localization of DEC1 may be helpful in identifying the primary origin of certain tissues and cells.

DEC1 usually acts as a transcription repressor, but it also can function as a transcriptional activator under particular circumstances. It has been shown that signal transducers and activators of transcription 3 (STAT3), which

are essential for the carcinogenesis of HCC, are a protein partner of DEC1^[21,22]. DEC1 can bind with phosphorylated STAT3 β and/or STAT3 α isoforms, thus activating the downstream transcription from STAT-dependent cis-elements^[22]. For example, co-expression of STAT3 α or STAT3 β with DEC1 can modify the transcription status of Fas, which can regulate cell survival and apoptosis^[22]. DEC1, together with STAT3, is involved in complex regulation of STAT downstream transcriptional targets. Thus, inappropriate co-activation of DEC1 and STAT3 may lead to oncogenic transformation in hepatocytes. Through this network, DEC1 may contribute to the regulation of critical processes of cell survival and growth in hepatocellular carcinogenesis.

Unlike other bHLH proteins, such as c-Myc and ID, which exhibit intrinsically growth-promoting activity, DEC1 can cause proliferation inhibition and differentiation promotion. In NIH 3T3 cells, induced Stra13 strongly represses the expression of the cell proliferation-associated gene c-Myc by interacting with the basal transcription factor TFIIB^[18]. The proximal promoter region of ID1 gene contains several potential DEC1 responsive elements by which DEC1 can inhibit ID1 expression, thus promoting cell differentiation^[23]. DEC1 has been involved in various differentiation processes, such as neurogenesis^[6,7], chondrogenesis^[5] and myogenesis^[24]. The differentiation inducer hydroxyurea can markedly induce the expression of DEC1^[13]. The promotion or inhibition function of DEC1 in cell differentiation is cell-type specific and differs in different original tissues. Overexpression of Stra13 inhibits mesodermal but promotes neuronal differentiation in P19 cells^[6]. In rats, the expression of sharp-2 mRNA was slightly higher in the well-differentiated than in the poorly differentiated malignant hepatoma cell lines^[25]. Similarly, in our study, high DEC1 nuclear expression was more frequently detected in well-differentiated HCC than in poorly differentiated HCC. Thereby, DEC1 may serve as a marker for the degree of HCC differentiation. As a transcription repressor, DEC1 can regulate expression of many other transcription factors and maintain the homeostasis of the tissues and cells^[8]. The reduced expression of DEC1 in poorly differentiated HCC might lead to exacerbation through impairing the homeostasis of the liver.

Epidemiological studies indicated that metabolic disturbance, especially abnormal lipid and glucose metabolism, is a major characteristic of the cause of HCC^[4]. Liver X receptor (LXR), together with sterol-regulatory-element-binding protein 1c (SREBP1c) and fatty acid synthase (FAS), enhances the development of HCC caused by chronic viral infection^[26]. And insulin resistance increases the risk of HCC^[27]. Recent reports have proved that DEC1 was closely associated with LXR, SREBP1c, FAS and insulin^[28-31]. However, further researches are needed about the relationship between the function of DEC1 interacted with these genes in liver metabolism and the differentiation grade of HCC.

In summary, we demonstrated DEC1 protein expression patterns in the liver and characterized the relationship

between nuclear DEC1 protein expression and histological differentiation of HCC. DEC1 might be a marker of HCC differentiation. However, DEC1 expression can be regulated through several pathways to contribute to its specific functions in different tissues. In the liver, DEC1 may be situated at the crossroads of a complex transcriptional network that is able to modulate metabolism, energy, physiological function and tumor genesis. Dysregulation of *DEC1* gene causes alteration of homeostasis in tissues and cells, leading to abnormal cell proliferation, differentiation and death as well as subsequent development of cancer in a cell type-dependent manner.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is one of the common fatal cancers worldwide. The aggressive phenotype and resistance to therapy makes HCC particularly dangerous. Recent reports indicate that the transcription factor differentiated embryo chondrocyte 1 (DEC1) contributes to tumorigenesis. The expression of DEC1 and its role in human HCC are unknown. DEC1 may take part in the vital metabolism function of liver and in the procession of hepatocarcinogenesis.

Research frontiers

DEC1 is a new transcriptional factor with helix-loop-helix (HLH) domains. It plays an important role in the maintenance of the homeostasis of metabolism and energy, oncogenesis, cell growth and apoptosis, immune balance and circadian rhythm.

Innovations and breakthroughs

This is the first study to describe the expression of DEC1 in HCC and normal liver tissues. In this study, an inverse relationship was found between the nuclear DEC1 protein expression and the histological grade of HCC. DEC1 might be a marker for HCC differentiation. Based on all these results, DEC1 may be situated at the crossroads of a complex transcriptional network that is able to modulate metabolism, energy, physiological function and tumor genesis in the liver.

Applications

By understanding the distribution of DEC1 protein expression and the function of this bHLH molecule, this study may represent a future strategy for therapeutic intervention in patients with HCC.

Terminology

Dec1 and Hif are transcriptional factors with HLH domains. They are important in oncogenesis. Sterol-regulatory-element-binding protein 1c (SREBP1c), fatty acid synthase (FAS) and liver X receptor (LXR) play vital functions in metabolism and tumor genesis in the liver. All these proteins take part in the maintenance of the homeostasis of metabolism and energy, cell growth and apoptosis, oncogenesis.

Peer review

The morbidity and mortality of HCC are high in China. In the procession of hepatocarcinogenesis, there are already pre-existing chronic liver diseases. In this paper, the authors demonstrated for the first time that DEC1 protein expression patterns in normal liver tissue and HCC systematically. It is important for further studying the development of HCC and the function of DEC1.

CD34+ cells was $15.00\% \pm 15.81\%$ and $5.73\% \pm 1.57\%$ ($t = 2.367$, $P < 0.05$) in cirrhosis and control groups, respectively. The percentage of apoptotic marrow CD34+ cells was $6.25\% \pm 3.30\%$ and $20.92 \pm 18.5\%$ ($t = 2.409$, $P < 0.05$) in Child-Pugh A and Child-Pugh B + C cirrhotic patients, respectively. The percentage of late apoptotic marrow CD34+ cells was positively correlated with the total bilirubin and aspartate aminotransferase serum levels in patients with cirrhosis.

CONCLUSION: The status of CD34+ marrow cells in cirrhotic patients may suggest that the ability of hematopoietic progenitor cells to transform into mature blood cells is impaired.

Abstract

AIM: To access the frequency and level of apoptotic CD34+ cells isolated from the marrow fluid of patients with post-hepatitis cirrhosis.

METHODS: The frequency of bone marrow CD34+ cells and apoptotic bone marrow CD34+ cells in 31 in-patients with post-hepatitis cirrhosis (cirrhosis group), and 15 out-patients without liver or blood disorders (control group) was calculated by flow cytometry. Parameters were collected to evaluate liver functions of patients in cirrhosis group.

RESULTS: The percentage of normal bone marrow CD34+ cells was $6.30\% \pm 2.48\%$ and $1.87\% \pm 0.53\%$ ($t = 3.906$, $P < 0.01$) while that of apoptotic marrow

INTRODUCTION

Cirrhosis represents the final stage for a wide variety of chronic liver diseases. One of its main clinical manifestations in its decompensatory stage is cytopenia. The causes have been generally recognized as hypersplenism and abnormal bone marrow^[1]. However, the more detailed mechanism underlying cytopenia in cirrhotic patients is not clear. An understanding of its mechanism underlying loss of peripheral blood cells would shade further insight

Table 1 Characteristics of patients in cirrhosis and control groups

into the progress of cirrhosis and its treatment.

Peripheral blood cells are derived from hematopoietic stem cells (HSC). HSC are derived from mesenchymal cells located in wall of yolk sac during the embryonic stage. After establishment of embryonic blood circulation, HSC spread to the liver and hematopoiesis is initiated in the 6th week of embryonic stage and reoccurs in the spleen when hematopoiesis in the liver is decelerated. After birth, the production of blood cells in the liver and spleen dwindles, and almost halts altogether^[2]. HSC settle mainly in the bone marrow and produce blood cells for life. As yet, very few studies are available on the phenotypic change of HSC located in bone marrow of cirrhotic patients and its impact on the production of peripheral blood.

CD34, a well known marker for HSC, is a type of phosphoglycoprotein belonging to type 1 trans-membrane protein, helps HSC/hematopoietic progenitor cells (HPC) to adhere to marrow stroma, inhibits differentiation of hematopoietic cells, stimulates formation of HPC, and is involved in intracellular signal transduction, *etc.* The number of CD34+ cells including hematopoietic cells at several stages is heterogeneous and can differentiate to all blood cell lineages. The CD34 molecule gradually disappears when HSC/HPC differentiate into mature blood cells^[3].

In this study, the percentage of apoptotic CD34+ bone marrow cells in patients with post-hepatitis cirrhosis at different stages was calculated by flow cytometry.

MATERIALS AND METHODS

Study subjects

Thirty-one patients with post-hepatitis cirrhosis, admitted to Department of Infectious Diseases, Second Affiliated Hospital of Xi'an Jiaotong University from November 2008 to April 2009, were divided into three groups according to the Child-Pugh classification. The patients did not receive treatment with interferon and only 6 patients were treated with lamivudine or adefovir intermittently before they were enrolled in this study. The control group consisted of 15 patients attending the Outpatient Department of Hematology in our hospital. Bone marrow smears showed that they had no liver and hematological

disorders. Laboratory tests were performed to evaluate their liver functions. The clinical details of cirrhosis and control groups are shown in Table 1. Bone marrow was aspirated from each patient. Mononuclear cells (MNC) were isolated from 4 mL freshly-heparinized marrow fluid by Isopaque-Ficoll (Bioer, Hangzhou, China) gradient centrifugation. The study was approved by the local ethical committee, and informed consent was obtained from the patients.

Flow cytometry evaluation

After Ficoll gradient separation, the MNC were washed with 100 mL of phosphate-buffered saline (PBS), and 10^6 cells were stained with anti-CD34-FITC MAb (Biosynthesis, Beijing, China) for 30 min at 4°C. Percentage of CD34+ cells was assayed with a Keygen annexin V apoptosis detection kit containing annexin V-PE, propidium iodide (PI; Sigma, US) solution and annexin V binding buffer. CD34+ cells were analyzed to determine the early annexin V+/PI- or late annexin V+/PI+ apoptotic phase.

The MNC were stained again with anti-CD34-FITC MAb, annexin V-PE (Keygen, Nanjing, China) and PI, washed again with PBS and re-suspended in 100 mL of annexin V-PE for 15 min at room temperature. Another 200 mL of binding buffer and 5 mL of PI solution were added and 800 000 cells were obtained by flow cytometry (BD, USA)^[4].

Statistical analysis

Statistical analysis was conducted using the SPSS 13.0 statistical package. Difference in independent variables of apoptotic CD34+ cells was detected by *t*-test and one way ANOVA. *P* < 0.05 was considered statistically significant.

RESULTS

Percentage of bone marrow CD34+ cells in cirrhotic patients

Marrow CD34+ cells were gated from the side scatter height (SSC-H)/CD34 FITC dot plot according to the Milan protocol (Figure 1).

^aP < 0.05, ^bP < 0.01 vs early apoptotic cells.

The percentage of normal bone marrow CD34+ cells (out of mononuclear cells -CD34+/MNC) was 6.30% ± 2.48% and 1.87% ± 0.53% (*t* = 3.906, *P* < 0.01), respectively, in cirrhosis and control groups, while that of CD34+/MNC was 7.01% ± 2.1%, 4.58% ± 2.56%, and 7.72% ± 1.49% (*F* = 3.586), respectively, in Child-Pugh A-C cirrhosis patients (Figure 2).

Percentage of apoptotic bone marrow CD34+ cells in cirrhotic patients

The percentage of bone marrow CD34+ cells was determined by FACS analysis with annexin V/PI staining (Figure 3). The percentage of early apoptotic bone marrow CD34+ cells (out of total marrow CD34+ cells) was 6.60% ± 5.83% and 3.88% ± 1.22% (*t* = 0.912), respectively, while that of late apoptotic bone marrow CD34+ cells was 9.24% ± 13.67% and 1.86% ± 0.86% (*t* = 2.207, *P* < 0.05), respectively, in cirrhosis and control groups. The total percentage of apoptotic bone marrow CD34+ (out of total marrow CD34+ cells) cells was 15.00% ± 15.81% and 5.73% ± 1.57% (*t* = 2.367, *P* < 0.05), respectively, in cirrhosis and control groups.

The total percentage of apoptotic bone marrow CD34+ cells (out of total marrow CD34+ cells) was 6.25% ± 3.30% and 20.92% ± 18.5% (*t* = -2.409, *P* < 0.05), re-

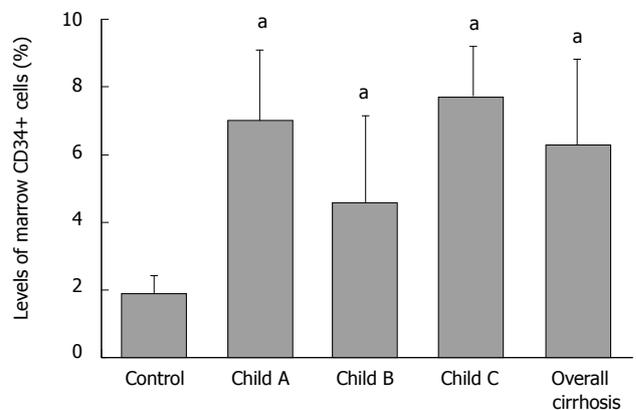

Figure 2 Percentage of bone marrow CD34+ cells in two groups. ^aP < 0.01 vs control control.

spectively, in early (Child-Pugh A) and late stage (Child-Pugh B+C) cirrhotic patients (Figure 4).

Correlation between apoptotic CD34+ bone marrow cells and reduced bilitubin and aminotransferase serum levels

The correlation between apoptotic CD34+ bone marrow cells and reduced bilitubin and aminotransferase serum levels was assessed (Table 2), which showed that the early apoptotic CD34+ bone marrow cells were positively correlated with the serum levels of γ-GT and albumin, while the late apoptotic CD34+ bone marrow cells were negatively correlated with the serum levels of total bilirubin and aspartate aminotransferase (AST) in cirrhotic patients.

DISCUSSION

HSC, the ancestors of different blood cells, are multipotent and self-renewable with a great ability to proliferate, and can differentiate into HPC which then differentiate into red blood cells, white blood cells and platelets. HPC, derived from HSC, are not able to renew. The number of HPC is retained by proliferation which expands different mature blood cells^[5].

In this study, the expression of CD34 antigen in bone

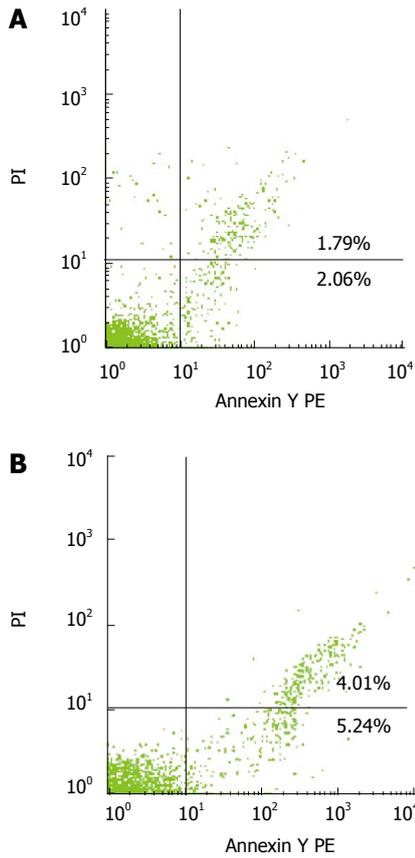

Figure 3 Scatter plot showing percentages of early and late apoptotic bone marrow CD34+ cells in control group (A) and cirrhosis group (B).

marrows of 31 patients with post-hepatitis cirrhosis was detected by flow cytometry. The percentage of bone marrow CD34+ cells was significantly higher in cirrhosis group than in control group, indicating that bone marrow CD34+ cells are activated in patients with post-hepatitis cirrhosis. HSC/HPC have a compensatory proliferation capacity for cytopenia in cirrhotic patients and enhance their ability to differentiate into mature blood cells, in order to make up the loss of mature blood cells because of hypersplenism, which is significantly different from that for aplastic anemia, in which cytopenia is caused by abnormal HSC/HPC^[6].

In this study, the percentage of apoptotic bone marrow CD34+ cells was significantly different in cirrhosis and control groups, and between early and late stage cirrhosis. The percentage of apoptotic CD34+ cells was significantly higher in cirrhosis group than in control group. The percentage of apoptotic bone marrow CD34+ cells (20.92% ± 18.5%) was very high in late stage cirrhotic patients, and almost comparable between early stage cirrhotic patients and controls (6.25% ± 3.30% *vs* 5.73% ± 1.57%), suggesting that the compensatory ability of HSC/HPC to proliferate is impaired, thus limiting their ability to differentiate into mature blood cells, which may be the cause of cytopenia in late stage cirrhotic patients. This could also explain why the peripheral blood cell count in early stage cirrhotic patients remains normal and the peripheral blood cell count is decreased in late stage cirrhotic patients, although the number of bone marrow CD34+ HPC is still

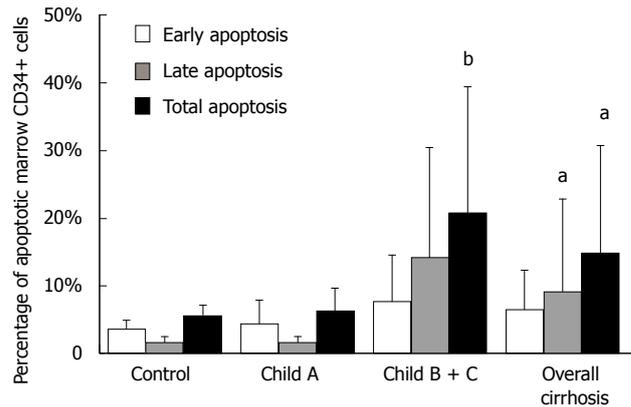

Figure 4 Percentage of apoptotic bone marrow CD34+ cells in controls and Child A, Child B + C cirrhotic patients. ^a*P* < 0.05 vs controls, ^b*P* < 0.05 vs Child A patients.

high^[7]. Our previous study showed that the Fas expression level is significantly higher in rats with carbon tetrachloride-induced cirrhosis than in normal rats^[8]. It is also known that the serum TNF- α and IFN- γ levels are higher in cirrhotic patients, thus up-regulating the expression of Fas, leading to cell apoptosis. We therefore speculate that the TNF- α and IFN- γ /Fas pathways may contribute to the apoptosis of bone marrow HSC/HPC^[9-13].

Finally, the correlation between parameters used to evaluate liver functions and apoptotic HSC/HPC was analyzed. The late apoptotic CD34+ bone marrow cells were positively correlated with the serum levels of total bilirubin and AST, indicating that the impaired function of bone marrow CD34+ cells is correlated with late stage cirrhosis. The establishment of such a correlation can be used in evaluating hematopoiesis in bone marrow of cirrhotic patients.

It has been shown that hypersplenism is the main cause of cytopenia in cirrhotic patients. Decreased production of thrombopoietin in liver may also contribute to thrombocytopenia^[14,15]. In this study, the number of HSC/HPC was increased and become more active in cirrhotic patients leading to compensatory effects of peripheral cytopenia. However, as cirrhosis progresses and apoptosis of HSC/HPC increases, hematopoiesis in bone marrow is impaired, eventually leading to disordered homeostasis and poor prognosis, in addition to liver failure and hypersplenism, in end-stage cirrhotic patients. The subjects involved in this study had hepatitis B or hepatitis C-associated cirrhosis. The virological impact on activation of bone marrow CD34 cells and functional impairment therefore merits further investigation.

In conclusion, the percentage of CD34+ bone marrow cells is high in cirrhotic patients, and increased apoptotic CD34+ HSC/HPC are correlated with late stage cirrhosis and total bilirubin and AST serum level.

COMMENTS

Background

Peripheral cytopenia is quite common in cirrhotic patients and the percentage of apoptotic CD34+ cells in bone marrow of cirrhotic patients was calculated.

Research frontiers

The relation between bone marrow CD34+ cells and liver cells has been reported. Bone marrow CD34+ cells can transform into hepatocytes *in vitro* and *in vivo*. Meanwhile, autologous or umbilical stem cell transplantation seems to be a promising new therapy for cirrhosis.

Innovations and breakthroughs

Bone marrow CD34+ cells were studied in cirrhotic patients. In this study, the percentage of bone marrow CD34+ cells was high in cirrhotic patients and that the increased apoptotic CD34+ HSC/HPC are correlated with late stage cirrhosis and the total bilirubin and AST serum level.

Applications

The findings in the study can partly explain why peripheral cytopenia occurs in patients with post-hepatitis cirrhosis.

Terminology

HSC: Multipotent stem cells that increase different blood cells including myeloid and lymphoid lineages and are defined by their ability to replenish different blood cells and their ability to self-renew.

Peer review

This is an interesting manuscript describing the role of CD 34+ cells, a well known marker for hematopoietic stem cells, in cirrhotic patients. The flow cytometry evaluation is adequate. The statistical analysis has well been conducted.

Abstract

AIM: To investigate the relationship between salt intake and salty taste and risk of gastric cancer.

METHODS: A 1:2 matched hospital based case-control study including 300 patients with gastric cancer and 600 cancer-free subjects as controls. Subjects were interviewed with a structured questionnaire containing 80 items, which elicited information on dietary, lifestyle habits, smoking and drinking histories. Subjects were tested for salt taste sensitivity threshold (STST) using

concentrated saline solutions (0.22-58.4 g/L). Conditional logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (95% CI).

RESULTS: Alcohol and tobacco consumption increased the risk of gastric cancer [OR (95% CI) was 2.27 (1.27-4.04) for alcohol and 2.41 (1.51-3.87) for tobacco]. A protective effect was observed in frequent consumption of fresh vegetable and fruit [OR (95% CI) was 0.92 (0.58-0.98) for fresh vegetable and 0.87 (0.67-0.93) for fruit]. Strong association was found between STST ≥ 5 and gastric cancer [OR = 5.71 (3.18-6.72)]. Increased STST score was significantly associated with salted food intake and salty taste preference ($P < 0.05$).

CONCLUSION: A high STST score is strongly associated with gastric cancer risk. STST can be used to evaluate an inherited characteristic of salt preference, and it is a simple index to verify the salt intake in clinic.

Yang WG, Chen CB, Wang ZX, Liu YP, Wen XY, Zhang SF, Sun TW. A case-control study on the relationship between salt intake and salty taste and risk of gastric cancer. *World J Gastroenterol* 2011; 17(15): 2049-2053 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i15/2049.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i15.2049>

INTRODUCTION

Gastric cancer is the fourth most common cancer in the world, and is the second most common cause of death

from cancer^[1]. Its incidence shows wide geographical variation, but almost two-thirds of the cases are from developing countries, including 42% from China. Although gastric cancer is decreasing in most populations, the absolute number of cases is predicted to increase up to the year 2050 due to the aging of the population^[2]. In China, gastric cancer is the third most common cancer, with an age-standardized incidence of 37.1 and 17.4 cases per 100000 person-years in men and women, respectively^[3]. Therefore, prevention of gastric cancer is one of the most important cancer control strategies both in China and around the world.

High intake of salt is hypothesized to be a cause of cancer and an important cause of gastric cancer^[4,5]. Evidence has proved that a high salt intake damages the gastric mucosa producing atrophy and intestinal metaplasia^[6,7]. In addition, a high salt diet has been shown to have a synergistic interaction with gastric carcinogens^[8,9]. In animal experiments, the co-administration of a high dietary salt intake enhances both the initiation and promotion of gastric cancer induced by carcinogenic N-nitroso compounds^[10]. It has been shown that a high intake of salted food is associated with increased risk for gastric cancer. But a recent meta-analysis showed a weak association between salt and gastric cancer^[4], and the relationship between quantity of salt intake and gastric cancer is hard to estimate. Most studies evaluated the salt preference only by the subjective feeling of subjects, and salty taste sensitivity test has the capacity to identify the flavor of salt, and its threshold can influence salt appetite or salt food preference^[11]. This method can be used to assess the association between salt preference and gastric cancer. The purpose of this study was to analyze the relationship between salt intake, salty taste and risk of gastric cancer.

MATERIALS AND METHODS

A hospital-based case-control study was carried out in the Shanyin People's Hospital in Shanyin of Shanxi. The study included 300 patients aged 40-75 years who had histologically confirmed diagnosis of gastric cancer from January 2006 to July 2010. Hospital-based controls were individually matched to cases by gender and age (\pm 5 years). Controls were patients selected from the Surgical Department, Plastic Surgery Department, ENT Department and Department of Gynecology. Ratio of cases to controls was 1:2. Totally, there were 600 controls who were non-cancer or cancer-free subjects.

A self-administered structured questionnaire consisting of 80 items was used in the study. It included questions about demographic information, dietary and lifestyle habits, smoking and drinking history and so on. Face to face interview was made for all subjects by trained interviewers. A completed questionnaire was obtained from 900 subjects. Cancer patients were asked of habits a year before the disease diagnosed. After interviewing for questionnaires, the salt taste sensitivity test was performed in all the subjects. The salt taste sensitivity threshold (STST) was measured using NaCl solutions on the tip of the tongue with

Table 1 Concentration of sodium chloride *n* (%)

| STST score | NaCl concentration | | Cases (<i>n</i> = 300) | Controls (<i>n</i> = 600) |

STST: Salt taste sensitivity threshold.

a dropper. Five drops of the test solution were dripped on the tongue. Ten seconds after closing the mouth, the cases and controls who tasted the usual food were perceived. The solutions were offered in increasing concentrations. Between the tests, the subjects were asked to wash their mouths with distilled water at a 30-s interval during the successive tests. The concentrations of each test NaCl solution were classified into ten grades from 0.22 g/L to 58.4 g/L, and the STST value for salt recognition in normal individuals was 0.015 mol/L of NaCl (0.9 g/L) (Table 1).

Questions included the frequency of intake of various food. For diet preference, the subjects chose one of the following frequencies: < 3 times/wk and \geq 3 times/wk. Salty food preference was classified into not salty, medium, and salty. Cigarette smoking was measured in pack-years (number of cigarette smoking per day/20 \times smoking time in years) and divided into two categories: smokers who consumed < 40 packs/year and \geq 40 packs/year or more; alcohol consumption was calculated according to the amount of alcohol consumed per day in grams. The subjects were classified into two categories: drinkers who consumed less than 22.8 g alcohol per day and \geq 22.8 alcohol per day.

The ethics committee of each collaborating institution reviewed and approved the study, and informed consent was obtained from all the participants.

Statistical analysis

The conditional logistic regression was used to calculate odds ratios (ORs), and corresponding 95% confidence intervals (CI) for gastric cancer in relation to exposure of interest. Two models were examined: (1) none-adjusted; (2) age, sex, smoking, drinking, fresh fruit and fresh vegetables adjusted. Tests for trend were computed by fitting conditional logistic regression model to ordinal values representing levels of exposure. All reported trend test significance levels (*P* values) were two-sided^[12]. The relationship between STST score and lifestyle and dietary factors was evaluated by Chi-square test. The coherence of STST score with salty taste preference was detected by Anova test. All the calculations were performed by statistical package version 9, STATA 9, College Station, TX.

STST: Salt taste sensitivity threshold.

RESULTS

The characteristics of the subjects are listed in Table 2. Among the 300 cases and 600 controls, 71% were males, and their mean age was 52.1 and 52.4 years, respectively. There was a significant difference in educational level between cases and controls. Smokers and drinkers showed an increased risk of developing gastric cancer with OR (95% CI) = 2.27 (1.27-4.04) and 2.41 (1.51-3.87), respectively. In contrast, consumed protective effect was found in those who took 3 times/wk of fresh vegetable and fruit, OR (95% CI) = 0.92 (0.58-0.98) and 0.87 (0.67-0.93), respectively. The mean STST score of cases was significantly higher than that of controls.

We analyzed the association between STST score and other risk factors. The results showed that STST score was increased with age and duration of smoking and drinking, but no significant association was found (Table 3). STST score was significantly increased with a higher salted food intake.

The mean STST score of all subjects was 4.8 ± 1.1 , and the median NaCl concentration was 3.6 g/L (3.6-7.3) or 0.06 (0.06-0.12) mol/L corresponding to a score of 5 (Table 2). There were more patients with STST ≥ 5 than the controls (Table 4). We defined the STST cut-point as 5 (3.6 g/L or 0.06 mol/L). Subjects with STST ≥ 5 had 5.71 times greater risk of gastric cancer than those with STST < 5 (Table 4).

The relationship between the salty taste preference and STST score indicated that the salty taste preference was significantly associated with STST score ($P < 0.001$) (Table 5), which means that the subjects with a higher STST score was more likely to prefer a salty taste.

DISCUSSION

The present hospital based case-control study indicated that high consumption of smoking, drinking and salty taste preference elevated the risk of gastric cancer, and that the gastric cancer was associated with a higher STST score. The STST score of 3.6 g/L (0.03 mol/L) was independently associated with a high risk of gastric cancer with the OR (95% CI) of 5.71 (3.18-6.72).

STST is a personal characteristic of an individual and is a useful index to evaluate the salty preference^[13]. STST test was used for predicting hypertension in previous studies^[14,15], and it indicated that hypertensive individuals were more salt sensitive than the normal individuals^[16]. Our study proved that subjects with a higher STST score were more likely to have salty taste preference and a high intake of salty food (Table 4), and it further indicated that STST is a helpful test to evaluate the salty taste preference and

Table 4 Odds ratio and 95% CIs for salt-related factors and gastric cancer *n* (%)

STST: Salt taste sensitivity threshold.

salt intake. The 24 h urinary excretion of salt was used previously as an objective method for salt intake measurement^[17,18], and epidemiologic studies indicated that gastric cancer mortality is weakly or non-significantly correlated with dietary salt measured by the 24 h urinary salt excretion. This method is impracticable for a large-scale population study and case-control study because it can only reflect the situation of 24 h salt intake. However, STST test is simpler, cheaper and more acceptable than the 24 h urinary salt excretion, and patients can identify the taste before diagnosis.

In our study, significantly increased risk for gastric cancer was observed among those with a high STST score. Age, histories of smoking and drinking, and consumption of fruit and vegetables did not show any significant interactions with STST for gastric cancer. STST ≥ 5 showed a higher risk for gastric cancer in our study, and the possible explanation may be that the high STST is associated with a high intake of salty food such as salted meat or fish (Table 3). Previous studies indicated that ingestion of salt could induce gastritis and co-administration with N-methyl-N-nitro-N-nitrosoguanidine could enhance the effect of gastric carcinogens^[9,19], and high intragastric salt concentration could destroy the mucosal barrier, leading to inflammation and damage such as diffuse erosion and degeneration. The induced proliferous change might enhance the effect of food-derived carcinogens.

There are various methods for measuring salt intake and salt preference. Most studies only use the frequency of salt consumption and self-reported salty taste preference, but these methods could not objectively reflect the real situation of the subjects. The mean salt intake varies among different populations, and salt consumption levels which were considered high in one study might be considered low in another one^[19]. Salt can be derived from different food species, so it is difficult to calculate the total salt consumption from all food. Self-reported salty taste preference is a method often biased

by subject's feelings. Therefore, the methods of measuring salt intake from food consumption and self-reported salty taste preference could induce measurement bias and confounding bias. In contrast, STST test is a simple method which is related to salt intake and consumption, and it could indirectly reflect the objective salty preference and avoid the measurement bias.

Several limitations of this study should be considered. Firstly, the STST test was not conducted before the cancer occurred, and the patients may change their salt preference after clinical symptom appearance, so there is recall bias in our study. But as the recall bias could not be avoided in every case-control study, we used the method of STST and the habits were defined to a year before the disease was diagnosed. Secondly, the cases and controls were selected from a hospital, which may have selection bias. We selected controls from the Surgical Department, Plastic Surgery Department, ENT Department and Department of Gynecology. Thirdly, we did not detect the *Helicobacter pylori* (*H. pylori*) infection in both the cases and controls, and *H. pylori* could bias the effect of STST score in gastric cancer, but the *H. pylori* could not reverse the result of STST score in gastric cancer due to the high OR. We will detect the *H. pylori* infection in the future studies. Fourthly, the objective method of measuring salt intake is the 24 h urinary salt excretion, but we did not use it to verify STST in our study. Because 24 h urinary salt excretion could not reflect the previous salt habit, we could only used salt preference questionnaire to verify it. Further cohort studies on the relationship between STST and 24 h urinary salt excretion are needed. Finally, there may be variability in the taste of each subject, and it may induce measurement bias. In order to avoid the bias, we offered the same concentration of NaCl solution to subjects after they chose the usual taste concentration.

To summarize, this study suggests that a high STST score is strongly associated with gastric cancer risk. STST

may be used as a test to evaluate an inherited characteristic of salt preference, and a useful index to verify the salt intake in clinic. However, the role of STST has to be further studied to answer the questions raised from the present study.

COMMENTS

Background

A high intake of salt is hypothesized to be a cause of cancer and an important cause of gastric cancer. But the salt intake and salt preference are hard to measure. salt taste sensitivity threshold (STST) test was once used to predict hypertension, and this study used it to measure the salt intake in an attempt to explore its association with gastric cancer.

Research frontiers

Salt taste sensitivity is independently associated with gastric cancer, and it is proved to be a better index to reflect the salt preference in this study. This method could help identify the risk population of gastric cancer.

Innovations and breakthroughs

This study for the first time explored the relationship between salt taste sensitivity and risk of gastric cancer. A high STST score was found to be strongly associated with gastric cancer risk, and STST score could also reflect the salt preference and salt intake of the subjects, and it may be used for predicting the risk population of gastric cancer.

Applications

STST test is a cheap and fast examination to evaluate an inherited characteristic of salt preference, and it is a simple method to verify the salt intake in clinic.

Peer review

This is an interesting study, and the data suggest that STST may be a potentially useful tool to screen patients at risk of developing gastric cancer.

Laparoscopic repair of hiatal hernia with mesenterioaxial volvulus of the stomach. *World J Gastroenterol* 2011; 17(15): 2054-2057 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i15/2054.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i15.2054>

Abstract

Although mesenterioaxial gastric volvulus is an uncommon entity characterized by rotation at the transverse axis of the stomach, laparoscopic repair procedures have still been controversial. We reported a case of mesenterioaxial intrathoracic gastric volvulus, which was successfully treated with laparoscopic repair of the diaphragmatic hiatal defect using a polytetrafluoroethylene mesh associated with Toupet fundoplication. A 70-year-old Japanese woman was admitted to our hospital because of sudden onset of upper abdominal pain. An upper gastrointestinal series revealed an incarcerated intrathoracic mesenterioaxial volvulus of the distal portion of the stomach and the duodenum. The complete laparoscopic approach was used to repair the volvulus. The laparoscopic procedures involved the repair of the hiatal hernia using polytetrafluoroethylene mesh and Toupet fundoplication. This case highlights the feasibility and effectiveness of the laparoscopic procedure, and laparoscopic repair of the hiatal defect using a polytetrafluoroethylene mesh associated with Toupet fundoplication may be useful for preventing postoperative recurrence of hiatal her-

INTRODUCTION

Intrathoracic gastric volvulus is an uncommon disease entity characterized by an enlarged esophageal hiatus and weakened gastrosplenic and gastrocolic ligaments^[1]. Although gastric volvulus possibly occurs in all ages, it often occurs over the fourth decade of life. If undiagnosed, it can lead to ulceration, perforation, hemorrhage or ischemia of the incarcerated gastrointestinal tract^[2]. Two types of gastric volvulus have been recognized: an organoaxial form and a mesenterioaxial form^[3,4]. The mesenterioaxial form is characterized by rotation at the transverse axis, extending from the middle of the greater curvature to the porta hepatis.

We recently experienced a case of intrathoracic mesenterioaxial volvulus of the distal portion of the stomach and duodenum, which was successfully treated with laparoscopic repair of the hiatal defect using a polytetrafluoroethylene mesh associated with Toupet fundoplication. The laparoscopic technique employed is described and its therapeutic implications, mesh-related complications, and long-term clinical outcome are discussed.

CASE REPORT

A 70-year-old Japanese woman had been diagnosed with hiatal hernia for several years by her home doctor. Because the patient had complained of no specific symptoms related to the hiatal hernia, no treatment had been undertaken during that period. She had no other past history of any diseases except for a significant kyphosis. She was admitted to our hospital because of the sudden onset of epigastralgia and nausea. Physical examination at admission revealed no abdominal tenderness suggesting diffuse peritonitis. A chest X-ray film showed a large-sized air pocket associated with air-fluid level in the chest, which was likely to be a dilated stomach incarcerated into the intrathoracic cavity (Figure 1). She was dehydrated and vomited during the placement of a nasogastric tube which resulted in aspiration pneumonia. She then presented with acute prerenal failure as a complication, and further treatment was required. Total parenteral nutrition was performed for the management of the intermittent abdominal pain and nausea. The patient responded to intravenous fluid management and the administration of antibiotics. The patient soon recovered from the critically-ill condition and further examinations were performed for precise diagnosis. An upper gastrointestinal series revealed an incarceration of the distal portion of the stomach and the duodenum into the thoracic cavity (Figure 2). An abdominal computed tomography scan also showed an incarcerated upper gastrointestinal tract (Figure 3). These findings were compatible with a mesenterioaxial volvulus of the stomach and duodenum incarcerated into the thoracic cavity through an esophageal hiatus. A laparoscopic approach for the repair of hiatal hernia was selected for complete repair.

During surgery, pneumoperitoneum was established at an intraabdominal pressure of 12 mmHg. A total of 4 ports were placed, 3 ports of 5 mm diameter in the right and left upper abdomen and left upper abdomen and 1 port of 12 mm diameter in the right middle abdomen. The endoscopic port was placed in the umbilicus. The laparoscopic view during the operation showed a hiatal hernia of the sliding type and also showed that the distal portion of the stomach and the proximal portion of the duodenum were rotated at its transverse axis of the upper gastrointestinal tract, and were incarcerated through the porta of the left crus of the diaphragm. The incarcerated distal stomach and proximal duodenum through the esophageal hiatus was covered with the hernia sac. Because there was no adhesion of the herniated content with the surrounding tissues, the incarcerated stomach and duodenum were deliberately pulled out from the thoracic cavity through a relatively large-sized paraesophageal hiatal defect (Figure 4A). The hernia sac and crus of the diaphragm were then dissected. The lower esophagus was also mobilized. The hiatal defect was closed and was reinforced by using a polytetrafluoroethylene (PTFE) mesh (Figure 4B). Toupet fundoplication was then added to prevent gastroesophageal reflux. The fundic wrap was sutured with the right crus and left-sided diaphragm with interrupted sutures. No intra- and/or postoperative complications were observed. Postoperative upper gastrointestinal

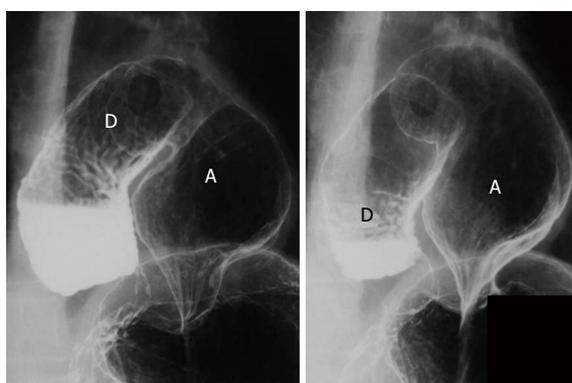

Figure 2 An upper gastrointestinal series performed preoperatively, revealing dislocated distal portion of the stomach (A) and duodenum (D) into the thoracic cavity rotated in the mesenteric axis, which corresponded to a mesenterioaxial volvulus of the upper gastrointestinal tract.

series performed 5 d after surgery revealed appropriate arrangement of the upper gastrointestinal tract and no sign of recurrence of the hiatal hernia (Figure 5).

The postoperative course was uneventful and the patient was discharged from the hospital 15 d after surgery. The patient was in good condition, and complained of no symptoms suggesting the recurrence of hiatal hernia and/or intrathoracic gastric volvulus for 4 years after surgery. The patient has undergone annual check-ups using upper gastrointestinal endoscopic examinations for 4 years after surgery and no recurrence has been found to date.

DISCUSSION

Although hiatal hernia is commonly encountered, hiatal hernia with mesenterioaxial intrathoracic gastric volvulus is extremely uncommon. Two types of gastric volvulus have been recognized: an organoaxial form and a mesenterioaxial form^[3,4]. The organoaxial type is a common type of gastric volvulus, in which the stomach rotates on a vertical axis. This type of gastric volvulus is usually caused by eventuation, diaphragmatic hernia, pyloric obstruction, adhesions, or enlarged esophageal hiatus. This is also described as an intrathoracic stomach or upside down stomach. Another type is the mesenterioaxial form. In this form, the stomach

rotates on a horizontal axis, which extends from the middle of the greater curvature to the porta hepatis. The rotated stomach is located in the chest from the hiatal defect. Mesenterioaxial volvulus is even more uncommon and represents about 29% of all torsions occur in the stomach. Of mesenterioaxial volvulus, the idiopathic pattern was 37%^[3].

In the present case, the patient had gastrointestinal obstruction, dehydration and acute prerenal failure caused by the volvulus of the stomach. Elective surgery was performed after recovering from these complications. In fact, emergency surgery is occasionally required for cases with

acute gastric obstruction associated with strangulation due to gastric volvulus^[5]. If there is no gastrointestinal ischemia and/or necrosis requiring emergency surgery, placement of a nasogastric tube may be useful for the effective decompression of the stomach, which may allow a reduction of the volvulus and thereby enabling elective surgery.

Treatment of gastric volvulus has classically involved reduction of the stomach, gastropexies in its normal intra-abdominal position, and correction of the associated diaphragmatic defect^[4]. The laparoscopic repair of intrathoracic gastric volvulus and large paraesophageal hernias has been proved to be feasible and safe^[4,6-9]. Previously published reports have confirmed the significant benefits of the minimally-invasive approach in these often elderly and/or debilitated patients^[7]. Therefore, laparoscopic repair of gastric volvulus is best suited as a minimally-invasive approach as long as the precise repair of hiatal aperture and reinforcement are added.

In the present case, Toupet fundoplication was added to prevent gastroesophageal reflux because a simple reduction of the volvulus associated with gastropexy has been shown to be unsatisfactory^[10]. A concomitant antireflux procedure has been recommended^[8]. The fundoplication is mandatory as it prevents reflux because of the extensive dissection at the hiatus, and provides a good anchor for the repair. This approach is considered to be safe and effective, and it also provides for rapid recovery from the operation.

In the present case, neither mesh-related complications

nor recurrence of hiatal hernia was found for 4 years after surgery. It has been reported that primary laparoscopic hiatal hernia for paraesophageal hernia is associated with up to a 42% recurrence rate^[11,12]. The most important reason is the absence of strong fascia at the hiatal aperture leading to suture pullout^[13]. We decided to use synthetic mesh reinforcement for the crural repair, because direct suturing of the aperture of paraesophageal defect was difficult due to the size and the absence of strong fascia. Although mesh repair improved the recurrence rate^[14], the use of mesh for the repair of hiatal hernia has still been controversial because mesh-related complications have frequently reported. Several clinical studies with significant patient numbers have demonstrated the safety and effectiveness of synthetic mesh reinforcement for the repair of hiatal hernia^[14,15,16]. An improved recurrence rate has been reported in cases with the use of mesh for the tension free crural repair^[17]. However, some surgeons have pointed out the risk of erosion into the esophageal or gastric lumen caused by placing the mesh^[15,11,18]. Because several types of non-absorbable mesh have recently been used for the repair of hiatal hernia^[9,19], further evaluation of clinical outcome may be required. Stadlhuber *et al*^[17] analyzed 28 cases of mesh-related complications in patients undergoing laparoscopic or open hiatal closure. They demonstrated that 23 cases required reoperation, and surprisingly 7 patients required esophagectomy. Among the patients who required reoperation, PTFE was used in 12 cases for the hiatal repair. A total of 10 patients had mesh intraluminal erosion, 2 patients had dense hiatal fibrosis. Although there is no apparent relationship between mesh type and configuration with the complications, they suggested that it may be due both to the technical aspects of mesh placement and to the type of mesh material used^[17]. Nonetheless, they concluded that complications related to synthetic mesh placement at the esophageal hiatus are more common than previously reported and that further studies are needed to determine the best method and type of mesh for implantation.

In summary, we experienced a case with mesenterioaxial volvulus of the stomach and duodenum associated with hiatal hernia, which was successfully treated with complete laparoscopic repair of the large-sized hiatal defect using a PTPE mesh associated with Toupet fundoplication. These laparoscopic procedures are safe and useful to obtain short-term as well as long-term clinical outcomes of patients with a large-sized hiatal hernia. Further accumulation of cases is required to precisely determine the best method and type of mesh for reinforcement and long-term clinical outcome.

Abstract

Renal transplantation is a standard procedure for end-stage renal disease today. Due to immunosuppressive drugs and increasing survival time after renal transplantation, patients with transplanted kidneys carry an increased risk of developing malignant tumors. In this case report, 3 patients with advanced rectal cancer after renal transplantation for renal failure were treated with anterior resection or abdominoperineal resection plus total mesorectal excision, followed by adjuvant chemotherapy. One patient eventually died of metastasized cancer 31 mo after therapy, although his organ grafts functioned well until his death. The other 2 patients were well during the 8 and 21 mo follow-up periods after rectal resection. We therefore strongly argue that patients with advanced rectal cancer should receive standard oncology treatment, including operation and adjuvant treatment after renal transplantation. Colorectal cancer screening in such patients appears justified.

INTRODUCTION

Renal transplantation, commonly performed for end-stage renal disease (ESRD), is an alternative to dialysis. An increased incidence of malignancy in transplant recipients is well recognized, which may be related to impaired immunosurveillance, direct neoplastic action of immunosuppressive agents, oncogenic viruses such as Epstein-Bar virus or cytomegalovirus, and chronic antigenic stimulation, uremia, or genetic predisposition^[1].

There is evidence that renal transplant recipients are approximately three times more likely to develop cancer than the general population^[2,3]. Their risks vary in different tumors. The risk of Kaposi's sarcoma is the highest (200 times increased risk) followed by that of non-melanocytic and melanocytic skin cancer (9-20 times increased risk)^[2,3]. The risk other solid-organ cancers, such as colorectal cancer, is increased by approximately 2-3 times higher in renal transplant recipients than in general population^[3,4]. Cancers occurring in transplanted patients are generally de novo and mainly diagnosed after the third year with an increase after 10 years^[5]. The mean onset time of colorectal malignancies is 10.4 years^[1].

The prognosis of renal transplant recipients with advanced-stage cancer is extremely poor. Currently, posttransplant malignancies are an important cause of mortality and the leading reason of death within the next 20 years^[6]. Immunosuppression and late diagnosis have been implicated^[7]. We report 3 cases of advanced rectal cancer after renal transplantation for renal failure.

CASE REPORT

In the past 5 years, 3 male patients at a mean age of 55.3 years who developed rectal cancer (RC) after renal transplantation were diagnosed and treated in Shanxi Cancer Hospital (Taiyuan, China). The mean elapsed time from renal transplantation to development of RC was 6.5 years. The 3 patients who underwent anterior resection (AR) or abdominoperineal resection (APR) plus total mesorectal excision (TME) had an uneventful postoperative course. The clinical data about each patient are listed in Table 1.

Case 1

A 68-year-old man who underwent renal transplantation for ESRD due to hydropigenous nephritis in 1993 at the age of 54 years. He received a second left renal transplantation in 2002 for graft failure followed by immunosuppressive therapy. In 2007, he underwent colonoscopy for rectal bleeding and dyschezia, which revealed a 5.0 cm mass at the upper rectum with 80% luminal occlusion. Biopsy showed a well-differentiated adenocarcinoma. Laboratory tests showed that his preoperative CEA level was 26.20 µg/L and his cellular immune function was low. The patient underwent AR with TME. Pathologic examination revealed a 5.0 cm moderately-differentiated adenocarcinoma with invasion through the serous membrane. Of the removed 7 lymph nodes, 1 was positive (pT₄N₁M₀). The postoperative course was uneventful. Following the operation, the patient did not receive any chemotherapy and radiotherapy due to his refusal. In November 2009, he received 3 cycles of Xeloda after liver and lung metastasis was discovered. The patient died in March, 2010.

Case 2

A 44-year-old man who received immunosuppressive therapy for ESRD in 2004 after renal transplantation. In 2009, he underwent colonoscopy for heme-positive stools, which revealed a 4 cm mass at the rectum with 60% luminal occlusion. Biopsy showed an adenocarcinoma of the rectum. Laboratory tests showed that his preoperative CEA level was 0.04 µg/L and his cellular immune function was low. The patient underwent APR with TME. Pathologic examination revealed a 4.0 cm poorly-differentiated adenocarcinoma with invasion of the adjacent perirectal fatty tissues. Eight lymph nodes were found with no malignant lymph node involved (pT₃N₀M₀). The patient was recovered uneventfully. He received a course of Xeloda and was well during the 21-mo follow-up period.

Case 3

A 54-year-old man with chronic pyelonephritis who underwent renal transplantation for ESRD in 2009. After the operation, he received immunosuppressive therapy. In 2010, 6 mo after renal transplantation, the patient presented with diarrhea and rectal bleeding. Colonoscopy showed a rectal mass with 70% luminal occlusion and a pedunculated polyp in sigmoid colon which was excised by electrocautery. Histology of the rectal mass showed a well-differentiated adenocarcinoma of the rectum while histology

of the polyp suggested a tubular adenoma. Laboratory tests showed that his preoperative CEA level was 1.05 µg/L and his cellular immune function was low. The patient underwent APR with TME. Pathologic examination revealed a 5 cm moderately-differentiated adenocarcinoma and partial mucinous adenocarcinoma with invasion of the pericolic adipose tissue. Thirteen lymph nodes were found with no lymph node metastasis (pT₃N₀M₀). Cancer emboli were identified in vessels of the mass. He received a course of Xeloda and recovered uneventfully during the 8-mo follow-up period.

DISCUSSION

It has been shown that the incidence of cancer is significantly higher in patients who underwent renal transplantation than in those who did not undergo renal transplantation^[2,3]. For example, the risk of colorectal cancer is increased by approximately 2-3 times higher in patients than in general population^[3,4]. However, some of the tumors may arise in renal recipients without any relation with renal transplantation, because they might have already presented at the time of renal transplantation but not detected. As a general rule, tumors detected within the first 12 mo after renal transplantation are considered pre-existed. Such patients should be excluded from the “*de novo*” group.

In our study, the 3 RC patients who underwent renal transplantation were males, and the onset interval from renal transplantation was 14 years, 5 years and 0.5 year, respectively. One patient was diagnosed with RC within the first 12 mo after renal transplantation, and pathological stage was pT₃N₀M₀ (advanced cancer). The other 2 patients were diagnosed with post-transplantation RC with a mean onset interval of 9.5 years. The 3 patients had radical AR and APR with TME.

It is well known that immunosuppressive treatment increases the incidence of cancers, which is supported by the fact that the incidence of tumors is higher in patients treated with immunosuppressants following renal transplantation due to chronic renal failure than in normal population. The causes for this difference might be explained by the immunological abnormalities induced by immunosuppressants^[8-10]. Therefore, screening and early diagnosis of tumors are essential both before and after renal transplantation, which means that tumors, if existed, should be detected, thus unnecessary renal transplantation can be avoided. Furthermore, annual tumor screening after renal transplantation should be conducted so that treatment can be commenced at an early stage of malignancy. In our study, the patient who was diagnosed with advanced RC within 6 mo after renal transplantation had no tumor screening before renal transplantation. It is likely that he developed RC while he was on dialysis and waiting for renal transplantation.

In general, the prognosis of transplant recipients who develop malignancy following immunotherapy are poor due to delayed diagnosis^[6,8,11-14]. Most cancers are at advanced stages when they are diagnosed, and usually progress rapidly with more than 50% of such patients died within the first year of diagnosis^[15]. The average survival time is proximally 25.8 mo^[15]. Evidence from National Cancer Institute Surveillance Epidemiology and End Results Database suggests

Table 1 Parameters of patients with rectal cancer after renal transplantation

| Age (yr) | Elapsed time (yr) | Location | Grade | pTNM | Operation | Screening | Outcome |
|----------|-------------------|----------|------------------|---|-----------|-----------|-------------------|
| 68 | 14 | Rectum | Moderate | pT ₄ N ₁ M ₀ | AR + TME | No | Died after 31 mo |
| 44 | 5 | Rectum | Poor | pT ₃ N ₀ M ₀ | APR+TME | No | Alive after 21 mo |
| 54 | 0.5 | Rectum | Moderate to poor | pT ₃ N ₀ M ₀ | APR + TME | No | Alive after 8 mo |

that transplant patients develop colorectal cancer at a younger age (58 *vs* 70 years, $P < 0.001$) and have a worse 5-year survival rate than the general population (overall, 44% *vs* 62%, $P < 0.001$; Dukes A and B, 74% *vs* 90%, $P < 0.001$; Dukes C, 20% *vs* 66%, $P < 0.001$; and Dukes D, 0% *vs* 9%, $P = 0.08$) mainly due to chronic immunosuppression which results in a more aggressive tumor biology^[16]. RC patients who underwent renal transplantation usually develop more advanced (AJCC stage > II) colon cancer with a worse disease-specific survival rate (all stages) than those who did not undergo renal transplantation. Multivariate analyses showed that renal transplantation is a negative risk factor for survival, and cancer stage at diagnosis is the most profound negative survival predictor^[17], indicating that colorectal cancers in transplant recipients are biologically more aggressive, thus resulting to a worse prognosis in such patients than in general population. Moreover, Ho *et al*^[7] also highlighted that immunosuppression and late diagnosis should be blamed for the poor prognosis of colorectal cancer patients after renal transplantation. In the present study, of the 3 patients with advanced rectal cancer, 1 died of multiple liver and lung metastases 31 mo after operation, indicating that frequent colorectal cancer screening should be warranted after renal transplantation.

Zittel *et al*^[18] reported a case of a 48-year-old patient who developed advanced RC 6.5 years after pancreas-kidney-transplantation for type I diabetes. The patient received neo-adjuvant radio and chemotherapy followed by low anterior rectal resection with total mesorectal excision. Within the next thirteen months, he underwent consecutive resections for a solitary hepatic metastasis, a solitary pulmonary metastasis and a chest wall metastasis. The patient eventually died of metastasis 32 mo after the initial therapy although the organ grafts functioned well until his death, suggesting that although a higher degree of morbidity might be encountered, transplantation patients should receive standard oncology treatment, including neo-adjuvant therapy, if their general condition is good and the organ graft functions well.

In conclusion, early prevention, detection and treatment of malignancies after renal transplantation are the important management strategies for improving the survival time and quality of life of cancer patients because malignancies develop more frequently in cancer patients after renal transplantation than in general population. Surgical resection is still the first choice of treatment which is a safe procedure when indicated. However, if the patients have an advanced disease (local or metastatic), the standard oncology treatment, including neo-adjuvant treatment can be used.

Abstract

There is an ongoing discussion on how to diagnose a hyperechogenic pancreas and what is the clinical significance of diffusely hyperechogenic pancreas. Computerized tomography and magnetic resonance imaging are the more appropriate methods to diagnose pancreatic hyperechogenicity when compared with transcutaneous or endoscopic ultrasound examination. More importantly, pancreatic hyperechogenicity may not be a certain indicator of pancreatic fat infiltration. Even if it is true, we do not know the clinical significances of pancreatic fat accumulation. Some suggested that excess fat in the pancreas is associated with chronic pancreatitis. However, several histological studies on human alcoholic chronic pancreatitis did not prove the presence of fatty pancreas in such cases. Thus, except for aging, it is very rare to have truly steatotic pancreas in the absence of certain human diseases.

TO THE EDITOR

We read with interest the article by Choi *et al*^[1] entitled "Associated factors for a hyperechogenic pancreas (HP) on endoscopic ultrasound examination". The authors investigated the risk factors for hyperechogenic pancreas on endoscopic ultrasound (EUS). Their study group included 53 cases of HP and the control group consisted of 79 cases having various indications for endosonographic examination with normal pancreas echogenicity on EUS. They noted that HP was significantly associated with fatty liver, male gender, age older than 60 years, hypertension and visceral adipose tissue area (cm²).

Pancreatic fat, readily observed on EUS, is only suspected when an overt HP is noted. However, as the authors in their study noted, mild hyperechogenic pancreas with respect to liver is a normal finding on ultrasound examination. Since the quantitative analysis of pancreatic parenchymal echogenicity was not conducted in their study, how could the authors be sure that pancreatic echogenicity they saw can be "hyper"? The authors also indicated the limitations of their study as the absence of direct determination of the pancreatic fat and visceral fat in pancreatic tissue. It would be unethical to get pancreatic biopsy samples. However, they could estimate the pres-

ence of pancreatic steatosis with the help of computerized tomography (CT) imaging which was already done to estimate the visceral adipose tissue area in all cases in their study. CT can be very helpful for the diagnosis and quantification of the existence of pancreatic steatosis^[2].

We also do not know the clinical consequences of pancreatic steatosis as yet. Some epidemiologic data suggest that obesity is a risk factor for pancreatic cancer development^[3] and that obese patients develop more severe pancreatitis than lean individuals^[4]. Furthermore, postoperative fistula develops more commonly in obese subjects than in lean individuals^[5]. However, in the absence of regular alcohol consumption, the obese patients with increased visceral adiposity are not accepted as having increased risk for chronic pancreatitis. We know that diffusely increased parenchymal echogenicity has not been suggested to be a EUS finding associated either with early or with late stage chronic pancreatic inflammation. Unlike the current evidence for the association between fatty liver and steatohepatitis, there is no similar evidence as yet to suggest that steatotic pancreas progresses to pancreatohepatitis and then to chronic pancreatitis. Indeed, pancreatic hyperechogenicity may not be a certain indicator of pancreatic fat infiltration. The belief that hyperechogenicity of the pancreas indicates the presence of fat in this organ has now been largely abandoned^[6]. Moreover, several histological studies on human alcoholic chronic pancreatitis did not support the presence of fatty pancreas^[7-9].

Thus, it would not be appropriate to diagnose diffuse HP solely on EUS, but CT or Magnetic resonance imaging would be more reliable for such a diagnosis. More importantly, we need to clarify what is the clinical importance of HP on EUS. We are even not sure that HP

represents pancreatic steatosis. Even if it does, we do not know the clinical consequences of pancreatic steatosis.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copy-right" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under

study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission

System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +,

country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be

Instructions to authors

used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of P values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated

first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantumms can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published

by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office**World Journal of Gastroenterology**

Editorial Department: Room 903, Building D,
Ocean International Center,

Instructions to authors

Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interac-

tions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

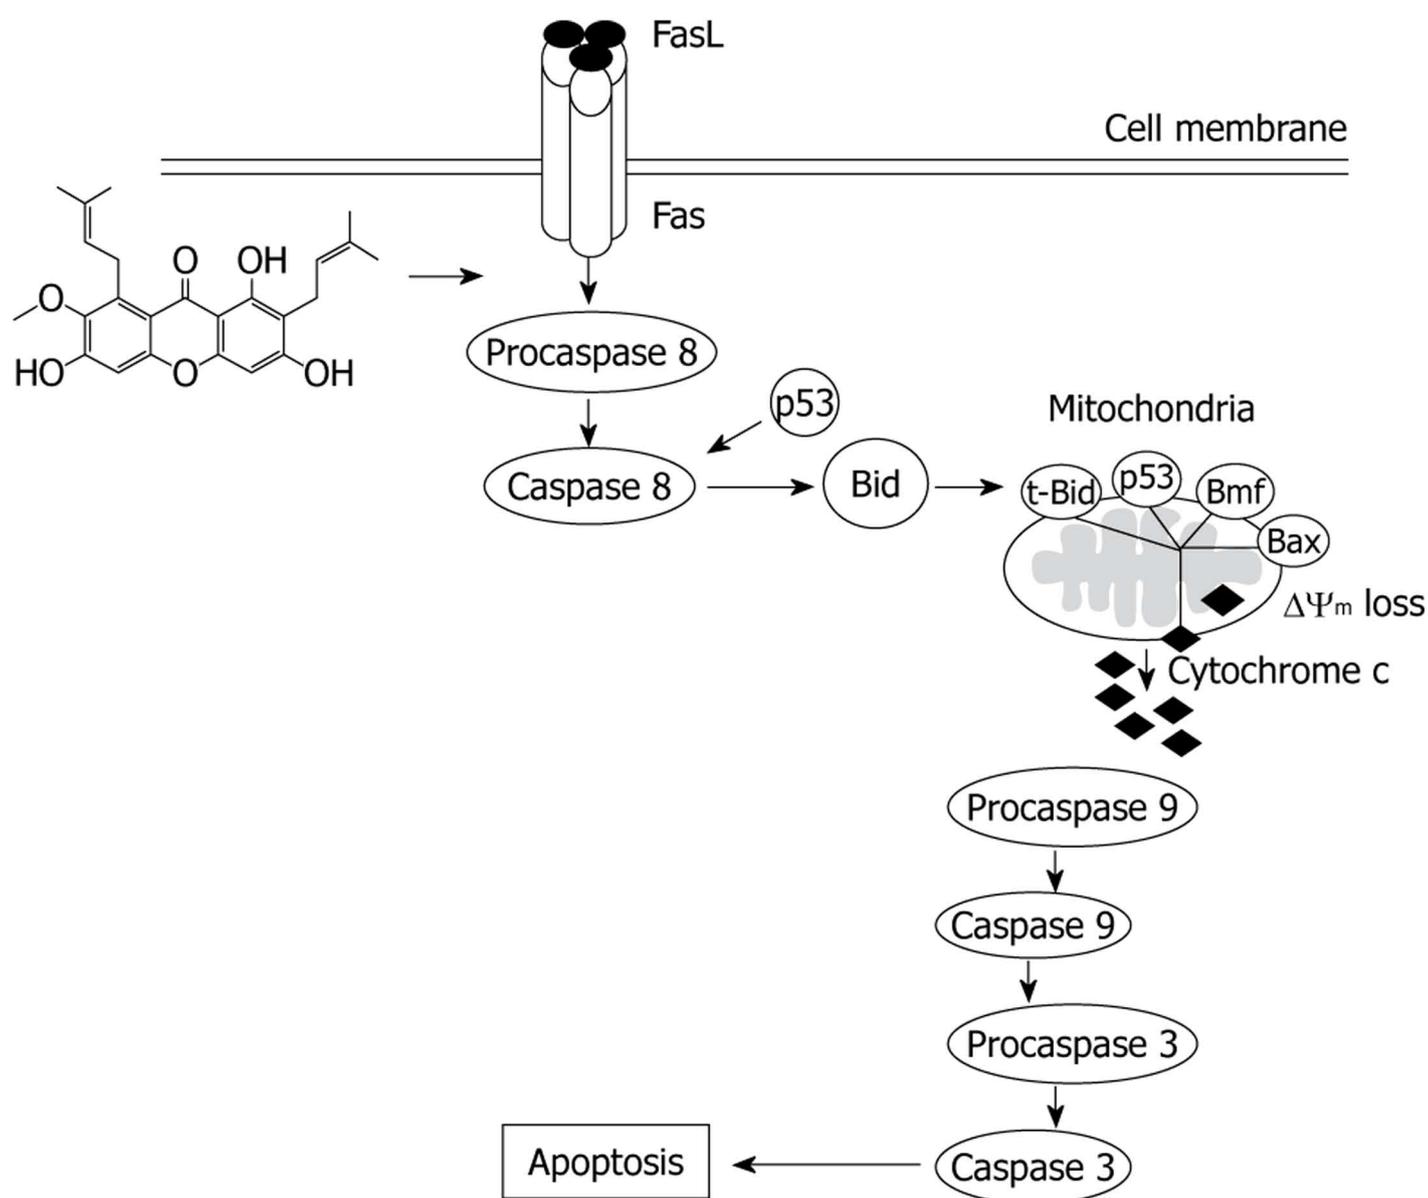

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Esophageal adenocarcinoma is a major cause of cancer death in men in the developed world. Continuing poor outcomes with conventional therapies that predominantly target apoptosis pathways have led to increasing interest in treatments that target the cell cycle. A large international effort has led to the development of a large number of inhibitors, which target cell cycle kinases, including cyclin-dependent kinases, Aurora kinases and polo-like kinase. Initial phase I/II trials in solid tumors have often demonstrated only modest clinical benefits of monotherapy. This may relate in part to a failure to identify the patient populations that will gain the most clinical benefit. Newer compounds lacking the side effect profile of first-generation compounds may show utility as adjunctive treatments targeted to an individual's predicted response to treatment.

Key words: Esophageal adenocarcinoma; Cell cycle; Cyclin-dependent kinase; Aurora kinases; Polo-like kinase

Peer reviewer: Luis Grande, Professor, Department of Surgery, Hospital del Mar, Passeig Maritim 25-29, Barcelona 08003, Spain

Dibb M, Ang YS. Targeting the cell cycle in esophageal adenocarcinoma: An adjunct to anticancer treatment. *World J Gastroenterol* 2011; 17(16): 2063-2069 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i16/2063.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i16.2063>

INTRODUCTION

Esophageal cancer is a major cause of cancer death worldwide^[1]. It was the fourth most common cause of death from cancer in men in the United Kingdom between 2004 and 2006^[2]. Although in the developed world the incidence and mortality of cancer in general has decreased with advances in diagnosis and treatment, the incidence and mortality of esophageal carcinoma have increased^[1].

Esophageal cancer carries a poor prognosis with a 5-year survival rate of < 10%^[3]. This probably reflects the fact that the majority of esophageal cancers present late with symptoms after invasion of the muscularis propria and lymph node metastasis have occurred^[4]. Extensive disease means that few patients are suitable for definitive surgical therapy^[4,5]. Poor outcomes from conventional therapies including surgery and radiochemotherapy have led to increasing interest in understanding the molecular mechanisms that underpin the development of esophageal cancer. This may assist in developing new diagnostic techniques and identifying potential therapeutic targets.

The mechanism by which cells reproduce has fascinated biologists since Virchow's 1855 observation that cells could only arise from pre-existing cells. By the

early 20th century, pathologists had recorded extensive descriptions of the cytological events of cell division, including division of the nucleus and partitioning of the cytoplasm to the formation of two daughter cells^[6]. It has become increasingly clear since those early descriptions of the normal cell cycle that disorders in this process can lead to disease. It was not however until the 1970s, that molecular biology allowed a deeper understanding of the cell cycle and its role in health, disease and cancer development. The past three decades, in particular, have seen major advances in our understanding of the genetic and molecular mechanisms by which cells reproduce and how this process is regulated and controlled. It has also been aptly described that cell cycle deregulation, in the form of growth self-sufficiency and insensitivity to growth inhibitory signals, have become fundamental hallmarks of cancer development^[7-9]. Targeting these pathways in cancer development for diagnostic and therapeutic use has become increasingly important. We assess in this review the potential for targeting the cell cycle to treat esophageal adenocarcinoma.

HALLMARKS OF CANCER

It is clear that cellular reproduction is carefully controlled and regulated to prevent uncontrolled proliferation of cells^[10]. A number of alterations in cell physiology are required to lead to carcinogenesis^[7]. First, a cell must become able to move from its dormant inactive state (known as quiescence) to enter the cell cycle without stimulation from external growth factors. Second, the cell must lose response to growth-inhibitory signals. Cells must evade senescence and programmed cell death to gain limitless replicative potential. Finally, it must be able to develop and maintain an adequate blood supply (angiogenesis), which allows the cancer cell to invade and metastasize throughout the organism^[11].

Many genes responsible for the carcinogenesis have been identified. Broadly, they fall into two categories: oncogenes and tumor suppressor genes. Oncogenes are created by mutations in genes that cause them to become constitutively active, whereas in tumor suppressor genes, mutations reduce or inactive the gene product^[12]. Oncogenes and tumor suppressor genes increase tumor cell number by stimulation of cell division or prevention of cell death.

CELL CYCLE

Embryonic cells can undergo DNA replication and nuclear division at rapid rates. A full cycle of embryonic cell division can last just 30 min^[13]. Division of adult stem cells requires more complex control (Figure 1). Gaps or pauses are inserted between the phases of nuclear division (M phase) and DNA synthesis (S phase). These gaps are known as G1 (between M and S phases) and G2 (between S and M phases).

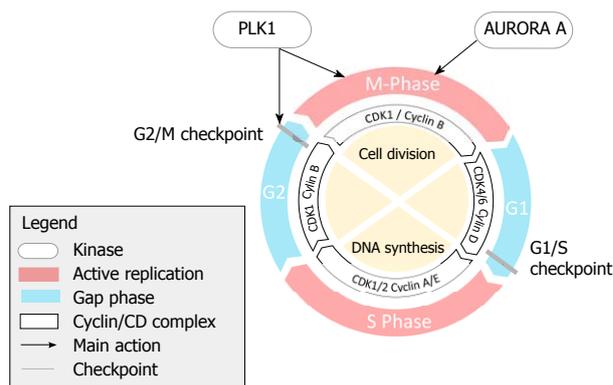

Figure 1 Cell cycle.

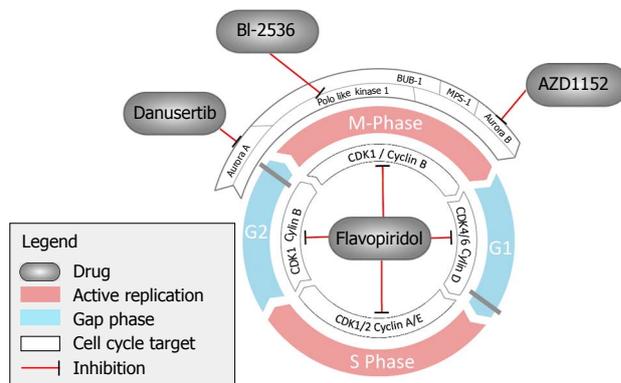

Figure 2 Compounds targeting the cell cycle.

Events in the cell cycle happen in a temporally organized sequence, with later events depending on successful completion of earlier events^[14].

Control of the cell cycle is driven by the cyclin-dependent kinases (CDKs), a family of serine/threonine kinases. Cells cannot enter S phase, without CDK activation. In order to become catalytically active, CDKs need to bind to a cyclin subunit that acts as an activator. CDKs can also be modulated by inhibitors such as CDK inhibitor 1A (p21^{CIP1}), CDK inhibitor 1B (p27^{KIP1}) or CDK inhibitor 2B (p15^{INK4B})^[10]. It has previously been thought that mammalian cells require the sequential activation of a number of the CDKs to complete the cell cycle successfully^[15]. Recent evidence from mouse models has suggested that CDK1 alone is sufficient to complete the cell cycle, although other CDKs are required for normal development and cell type specialization^[16]. Cell cycle defects can contribute to esophageal cancer development in a number of different ways (Figure 2).

Mitosis itself contains a series of phases that lead to chromosome separation and cell division. Mitosis is a vital step in the cell cycle, which involves carefully regulated interactions between multiple proteins. Abnormalities throughout the cell cycle can lead to genomic instability through unrestrained proliferation or defects in the transmission of genetic information to daughter cells. A number of established chemotherapy agents, including

the vinca alkaloids and the taxanes work by targeting the mitotic phase of the cell cycle.

CELL CYCLE CHECKPOINTS

Cells need mechanisms that prevent progression of the cell cycle if there is significant genomic damage, until the damage is repaired or the cell undergoes apoptosis. These have become known as cell cycle checkpoints. There are two major checkpoints: the G1/S checkpoint and the G2/M checkpoint. Checkpoint kinases ATM and ATR mediate these checkpoints, through effector kinases such as CHK1 and CHK2, by preventing activation of CDKs and progression through the cell cycle^[17]. Double-stranded DNA breaks activate preferentially ATM, whereas UV light activates ATR kinase. Defects in this DNA damage response can contribute to cancer formation by allowing tumor cell survival despite genome instability and enhanced mutation rates^[18,19]. The DNA damage response is commonly activated in early neoplastic lesions^[20,21].

G1/S checkpoint

The G1/S checkpoint occurs towards the end of the G1 phase, prior to entry into G2. During G1, the cell remains responsive to external mitogenic and anti-mitogenic stimuli. These can either cause the cell to become quiescent (entering the G0 phase) or allow re-entry to the cell cycle. This decision is controlled by the pocket protein RB. Immediately after mitosis, RB is dephosphorylated by protein phosphatase type 1. Whilst in this dephosphorylated state, RB binds to a group of transcription factors called E2Fs and inhibits their activity. During G1, RB is hypophosphorylated by the complex of CDK4 and cyclin D. CDK2 and cyclin E complexes then act to hyperphosphorylate RB, which causes dissociation from E2Fs. Free E2Fs trigger increased transcription of CDK2 and cyclin E, which creates a positive feedback loop that drives the cell into DNA synthesis (S phase). CDC25 phosphatases act to regulate CDK and cyclin complexes by removing inhibitory phosphate groups thereby promoting cell cycle progression^[13]. In genomic damage, CHK2 activates the p53 pathway, which stimulates production of p21^{CIP1} as well as phosphorylation of CDC25A. This prevents activation of the CDK/cyclin complexes^[13].

G2/M Checkpoint

The G2/M checkpoint acts as a final check to prevent mitosis occurring if the genome is damaged. A complex of cyclin B and CDK1 regulates this transition. Throughout G2, the inhibitory kinases CHK1, WEE1 and MYT1 phosphorylate CDK1, which prevents its activation and progression to mitosis. Polo-like kinase 1 (PLK1) protein levels begin to accumulate during S phase and G2/M phases, having been relatively low during G1^[22,23]. *PLK1* transcription is most abundant in cells that are in G2/M phase^[24]. In the absence of DNA damage, PLK1 is phosphorylated by Aurora A at its phosphorylation site

at T210^[25]. Phosphorylated PLK1 then activates CDC25 phosphatases that remove inhibitory phosphates from the ATP-binding site located at Thr14 and Tyr15 in human CDK1. This causes the activation of the CDK1/cyclin B complex and drives the cell into mitosis^[26]. PLK1 also increases phosphorylation-dependent cyclin B import to the nucleus^[27]. PLK1 phosphorylates WEE1 and MYT1, which leads to ubiquitination and degradation of WEE1 and inhibition of MYT1^[28,29]. PLK1 is then inactivated and degraded during anaphase by ubiquitin-dependent degradation mediated by the anaphase promoting complex^[30]. Cell cultures show severely impaired growth when PLK1 is either overexpressed or functionally depleted^[31,32].

CELL CYCLE AS A TARGET FOR CANCER THERAPEUTICS

Many oncogenes and tumor suppressors have downstream effects on cellular functions involving cell cycle entry and exit. Healthy or normal cells have the ability to stop at predetermined checkpoints in the cell cycle in the presence of damage or unfavorable conditions. Cancer cells develop mechanisms that eliminate these checkpoints, which leads to uncontrolled proliferation. One example of this is the INK4 family member *p16*. This occurs as a result of epigenetic silencing by DNA hypermethylation at the *p16* promoter, which leads to reduced transcription and loss of gene expression. *p16* is a CDK inhibitor and loss of *p16* function leads to unrestrained cellular proliferation. This has been demonstrated to occur with a number of different tumors^[33]. Abnormalities of *p16* function have been described in Barrett's esophagus and esophageal adenocarcinoma^[34]. DNA hypermethylation of the *p16* promoter has also been shown to be a strong predictor of the progression to high-grade dysplasia and esophageal adenocarcinoma^[35].

CDK inhibitors

Abnormal expression of CDKs and their partner cyclins has been noted in esophageal cancer^[36-39]. Polymorphisms of *CCND1*, which encodes cyclin D1 has been shown to be associated with an increased risk of esophageal adenocarcinoma^[40]. *CCND1* amplification and nuclear staining of cyclin D1 have been shown to correlate negatively with survival^[41,42]. Abnormal activity of the CDK/cyclin complexes in esophageal adenocarcinoma has been shown to be a marker of acquired chemoradioresistance^[42,43]. The observation that inhibition of CDKs leads to cell cycle arrest and apoptosis has led to the development of CDK inhibitors as antitumor drugs. There are a number of drugs that target these pathways. The pioneer compound for this group is flavopiridol, a semi-synthetic inhibitory flavonoid of CDKs. Flavopiridol prevents the phosphorylation and activation of CDK1, CDK2, CDK4 and CDK6, which leads to reduced expression of cyclin D1, cell cycle arrest, and induction of apoptosis^[44].

In vitro, it has been demonstrated that even at nanomolar doses, flavopiridol can enhance the antitumor activity

of cytotoxic drugs by increasing apoptosis^[45]. Phase I and II studies have been undertaken with various combinations of chemotherapeutic agents with variable results. Most promising is the combination with irinotecan and cisplatin. A phase I trial of relapsed gastric and esophageal cancer patients showed that eight out of 14 patients achieved a partial response^[46]. Further clinical studies are awaited.

Aurora kinases inhibitors

The Aurora kinase family is an important family of serine/threonine kinases that are evolutionarily conserved and act as mitotic regulators throughout the cell cycle. There are three mammalian aurora kinases, Aurora A, Aurora B, and Aurora C, which have differing roles throughout mitosis^[47]. Aurora A is required for centrosome maturation and spindle formation, in addition to its role at the G2/M checkpoint described above. Aurora B is required for chromosome segregation and cytokinesis. Small molecule inhibitors of Aurora B lead to premature mitotic exit without successful chromosome separation. Continued inhibition of Aurora B results in large multiploid cells that eventually undergo apoptosis^[48]. This potentially has the advantage that Aurora B inhibitors could be combined with other agents that act during other phases of the cell cycle. Aurora C is abundant in the testes. Its global functions are unclear, however, it has recently been shown to have some overlap with the functions of Aurora B during mitosis^[49]. Aurora kinases have been shown to be overexpressed in a number of different tumors. Aurora A has been shown to be overexpressed in Barrett's esophagus and esophageal adenocarcinoma^[50,51]. Cell line models suggest that Aurora A overexpression protects developing esophageal adenocarcinoma cells against drug-induced apoptosis^[51]. In other forms of cancer, Aurora A expression has been shown to correlate with chromosomal instability^[52]. A number of Aurora kinase inhibitors are undergoing phase I and II evaluation. Danusertib, a pan-Aurora kinase inhibitor has undergone phase I testing in patients with advanced solid tumors. Forty-six percent of patients treated with danuserib had stable disease following treatment and a number of prolonged objective responses were noted^[53,54]. The major dose limiting effect of these drugs is neutropenia.

PLK1 inhibitors

PLKs form a group of prominent mitotic kinases. They were first described in mutants that failed to undergo a normal mitosis in *Drosophila melanogaster* (polo)^[55,56]. They are highly conserved from yeast to humans. There are four members of the polo family in mammals (PLK1-4)^[57,58]. They are involved in multiple functions throughout the cell cycle in mitosis and meiosis. PLK1 is the best characterized of the four known PLKs^[58].

PLK1 is a candidate for development as a therapeutic target because it contains two functionally relevant sites: a C-terminal regulatory region containing two polo box domains (PBDs) and an N-terminal catalytic kinase domain^[59]. The highly conserved PBD has been identi-

fied as a phosphopeptide-binding motif^[60]. The polo box motif is only observed in the PLK family and contains a characteristic sequence. Drugs that target the PBD are specific to the human family of PLKs.

PLK1 is overexpressed in a broad range of primary gastrointestinal tumors, including gastric, colorectal and pancreatic carcinoma^[61-63]. In contrast, one study has noted downregulation of PLK1 within tumor cells^[64]. There is now increasing evidence that PLK1 expression levels have prognostic significance within different cancers, including esophageal cancer^[65]. Two separate reports of PLK1 overexpression in esophageal carcinoma primarily relate to squamous cell carcinoma (SCC) in the far east^[63,65]. Given the high impact of environmental factors (e.g. aflatoxin) on SCC development in these populations, it is unclear whether the findings can be directly applied to western populations. There are no data on PLK1 expression in adenocarcinoma patients. Some reports of other cancers have suggested that PLK1 expression is a reliable marker of metastasis^[66]. PLK1 has also been used in the context of larger arrays of genes as a prognostic marker to predict metastasis in breast cancers^[67]. Current cancer staging systems and histological assessments often fail to predict individual outcomes reliably but correlation of PLK1 protein and mRNA expression levels with clinical stage has the potential to improve clinical decision making in a number of different tumors^[68].

The unique PLD of PLK1 also makes it a good candidate for the development of alternative cancer therapies. Initial efforts have focused on specific phosphorothioate antisense oligonucleotides that are able to block protein translation^[69]. Use of siRNAs, which cause depletion of PLK1, has also been considered. Whilst there are drawbacks of siRNAs, including off-target effects and nuclease sensitivity, these hold promise in cancers such as bladder cancer in which they can act locally^[70]. There are now a number of small molecule inhibitors of PLK1, which act either in an ATP-competitive or non-ATP-competitive manner^[68]. The multiple actions of PLK1 throughout the cell cycle mean that these new agents need to be carefully assessed for specificity and side effects. In particular, it is possible that anti-PLK1 agents have similar toxicity to other microtubule inhibitors. PLK1 inhibitors are now in early clinical testing (phase I and II). Early clinical experience suggests that neutropenia and thrombocytopenia are dose-related effects, although neuropathy has not been seen^[71].

MPS1 inhibitors

Cell cycle translational research has focused on the development of inhibitors of the major kinases discussed above. There are additional mitotic kinases that may have relevance for inhibiting tumor growth. Inhibitors of MPS1, a kinetochore-associated kinase that is involved in the spindle assembly checkpoint, have been shown to arrest tumor cell proliferation *in vitro*^[72,73]. This appears to be mediated at least in part by impaired Aurora B func-

Table 1 Compounds targeting the cell cycle under active development

| Inhibitor | Main target | Sponsor | Clinical trials |
|-------------------------------------|-------------------------------------|---------------------------|---|
| BI2536 | PLK1 (partial inhibition of PLK2/3) | Boehringer Ingelheim | Phase II pancreatic cancer |
| Danusertib (Formerly PHA-739358) | Pan-aurora kinase inhibitor | Pfizer Italia | Phase II advanced solid tumors |
| MLN8237 | Aurora a inhibitor | Millennium | Phase I / II advanced solid tumours |
| BI6267 | PLK1 inhibitor | Boehringer Ingelheim | Phase II ovarian cancer/phase I advanced solid tumors |
| P276-00 | Small molecule cyclin inhibitor | Piramal Life Sciences | Phase I advanced malignancy/phase II head and neck malignancy |
| NMS-1286937 | PLK1 selective inhibitor | Nerviano Medical Sciences | Phase I advanced solid tumours |
| P1446A-05 | CDK selective inhibitor | Piramal Life Sciences | Phase I advanced malignancy |
| SCH727965 | CDK inhibitor | Schering-Plough | Phase I advanced malignancy |
| Seliciclib (Roscovitine) | CDK inhibitor | Cyclacel Pharmaceuticals | Phase I advanced malignancy |

CDK: Cyclin-dependent kinase; PLK1: Polo-like kinase 1.

tion at centromeres, which leads to impaired alignment of chromosomes^[74]. Detailed information on MPS1 in esophageal cancer is lacking, however, MPS1 inhibition has been demonstrated as a chemotherapy sensitization strategy *in vitro*^[75].

CONCLUSION

Established esophageal carcinoma chemotherapy regimes are relatively blunt tools that predominantly target apoptosis pathways and are often associated with significant side effects. This has led to a large international effort to develop targeted therapy.

Current therapies that target the cell cycle have largely disappointed with relatively modest effects seen in phase I / II trials (Table 1). This may be in part related to failure to identify the patient populations that will gain the most clinical benefit. Few treatments are targeted towards specific pathways or personalized to the individual tumor proteome or genomic signature.

Efforts are now being made to assess gene expression profiles from histological specimens from solid tumors such as breast cancer in an attempt to predict response to chemotherapy^[76]. Initial steps in this direction have been taken by the UK Oesophageal Cancer Clinical and Molecular Stratification (OCCAMS) Study Group, which has demonstrated a four-gene signature associated with poor prognosis in esophageal adenocarcinoma, as well as a larger group of genes associated with lymph node metastasis^[77]. Efforts have also been made to identify Barrett's esophagus patients who are likely to progress to adenocarcinoma, however, little work has been undertaken on response to chemotherapy in the esophagus^[78]. Careful studies are needed in esophageal adenocarcinoma to define patient populations that are likely to respond well to treatment with both established and novel chemotherapy regimes. Optimizing individual chemotherapy regimens for patients will assume greater significance as health economics demand most clinical benefit from limited resources. In this setting of personalized targeted therapy, new cell cycle treatments may hold promise as carefully selected adjuncts to existing chemotherapy regimes.

Patients with esophageal adenocarcinoma unfortunately often still present late with a large burden of dis-

ease. Given the large number of cells involved it is likely that some tumor cells will abrogate the inhibited pathways and escape from chemotherapy-induced apoptosis. Targeted cell cycle therapy in esophageal cancer presents an alternate strategy as cell cycle inhibitors affect multiple essential pathways involved in replication and DNA damage repair. They may provide a useful adjunct in patients with late presenting esophageal tumors who have failed standard chemotherapy regimens.

Potts JR, Verma S. Optimizing management in autoimmune hepatitis with liver failure at initial presentation. *World J Gastroenterol* 2011; 17(16): 2070-2075 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i16/2070.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i16.2070>

Abstract

Autoimmune hepatitis (AIH) is a disease of unknown etiology, its hallmark being ongoing hepatic inflammation. By its very nature, it is a chronic condition, although increasingly, we are becoming aware of patients with acute presentations, some of whom may have liver failure. There are very limited published data on patients with AIH with liver failure at initial diagnosis, which consist mostly of small retrospective studies. As a consequence, the clinical features and optimal management of this cohort remain poorly defined. A subset of patients with AIH who present with liver failure do respond to corticosteroids, but for the vast majority, an urgent liver transplantation may offer the only hope of long-term survival. At present, there is uncertainty on how best to stratify such a cohort into responders and non-responders to corticosteroids as soon as possible after hospitalization, thus optimizing their management. This editorial attempts to answer some of the unresolved issues relating to management of patients with AIH with liver failure at initial presentation. However, it must be emphasized that, at present, this editorial is based mostly on small retrospective studies, and it is an

INTRODUCTION

Autoimmune hepatitis (AIH) is a disease that is characterized by chronic hepatic inflammation, presence of autoantibodies [antinuclear antibody (ANA), anti-smooth muscle antibody (SMA), and liver kidney microsomal (LKM) antibody], female preponderance and elevated serum gamma-globulins, especially IgG^[1]. Earlier studies have established the beneficial effects of corticosteroids in AIH and up to 80% of patients can now achieve remission with immunosuppressants^[2,3]. At accession, 10%-20% of patients with AIH can be negative for the conventional autoantibodies^[4], although their outcomes, especially response to immunosuppression, are no different from those that are autoantibody-positive^[5].

AIH can have protean manifestations, with the majority of patients presenting with subclinical or chronic disease. However, in > 25%, the disease may present acutely with jaundice, a subset of whom may have fulminant or subacute liver failure (LF)^[6-8]. Fulminant hepatic failure (FHF) is a devastating clinical condition that occurs in patients

with no prior history of liver disease, and is characterized by development of hepatic encephalopathy and coagulopathy within 8 wk after onset of jaundice^[9]. In contrast, those with subacute LF present with encephalopathy at 8-26 wk after onset of symptoms^[10]. In a survey in the United States carried out between 1998 and 2008, the major etiologies of FHF in 1147 patients were acetaminophen overdose (46%), followed by indeterminate causes (14%), drug-induced (11%), hepatitis B virus (7%), other causes (7%), AIH (5%), ischemic hepatitis (4%), hepatitis A virus (3%) and Wilson's disease (2%)^[11]. Similar data were reported from Europe where 2%-5% of patients with FHF have AIH as the underlying etiology^[12,13]. Unfortunately, neither the International Autoimmune Hepatitis Group (IAIHG) criteria^[14] nor the simplified diagnostic criteria for diagnosis of AIH^[15] have been extensively validated in patients with LF; largely because of the small number of cases encountered. Thus, diagnosis of AIH and LF remains clinical and is supported by positive autoantibodies, negative viral serology, absence of alcohol excess and culprit drugs, and compatible liver biopsy. This has been corroborated by an earlier study in which 28 patients with FHF were clinically diagnosed with AIH, but after application of the IAIHG criteria and simplified scoring systems only 50% and 46%, respectively, fulfilled the criteria, with the concordance of the two scoring systems being only 46%^[16].

Immunoparesis is commonly seen in critically ill patients with LF in whom both autoantibodies and/or elevated IgG concentrations may be absent^[17]. In addition, because of the severity of the hepatic insult (massive/submassive necrosis), histological evaluation may be difficult or impossible^[16]. Although challenging, AIH can still be diagnosed in such a scenario by excluding other liver diseases, and by testing for other autoantibodies [perinuclear antineutrophil cytoplasmic antibodies (pANCA), and antibodies to soluble liver antigen (SLA)]^[18,19]. Furthermore, if the patient is HLA B8, DR3 or DR4 positive, has a concurrent immunological disorder, and responds to corticosteroid therapy, this further lends credence to the diagnosis of AIH^[4]. Nonetheless, the decision to initiate corticosteroids in patients who do not fulfill conventional diagnostic criteria for AIH must be made on an individual basis, and remains the prerogative of the treating hepatologist.

AIH AND LF

There is a paucity of published data on patients with AIH with LF at initial diagnosis; consisting mostly of anecdotal case reports or small case series^[20,21]. Thus the clinical characteristics, response to immunosuppression, and outcomes with/without liver transplantation (LT) of this cohort remain poorly described. Much of the controversy hinges on a critical management issue, namely should such patients be given a trial of corticosteroids, be priority listed for LT, or both. If corticosteroids are indeed initiated, how and at what time point do we define failure of medical treatment? This editorial attempts to address some of these controversies with the aim to develop strategies that could optimize

management of patients with AIH that present with LF.

We therefore searched the medical literature (PubMed) to collect published data on AIH with initial presentation with LF. Only studies providing data on type and duration of immunosuppressive therapy and outcomes were included. Case reports/small case series, and studies in which authors reported acute AIH in the absence of LF were excluded. We identified five studies that met our inclusion criteria and these included a total of 85 patients with AIH and LF^[7,22-25] (Table 1). In three of the five studies^[7,23,24], patients were diagnosed with AIH according to IAIHG criteria, although information regarding probable or definite AIH was only available in two^[7,24]. In the remaining two studies^[22,25], the diagnosis of AIH was based on the presence of autoantibodies, elevated IgG levels, exclusion of Wilson's disease, negative viral serology, absence of culprit drugs, and compatible liver histology (1). The patients were very heterogeneous as regards ethnicity, presence/absence of cirrhosis, and inclusion of acute and subacute LF. It is well known that these factors have a prognostic value in patients with AIH and in those with LF^[7,26-28]. In addition, all the studies were retrospective, and one has only been published in an abstract form^[22]. Nonetheless, these five studies do provide valuable information about the natural history of AIH with LF at initial presentation.

In these five studies, the prevalence of LF at initial presentation in patients with AIH varied from 8.7% to 19.8%^[7,23]. In all but one patient this was the first presentation of their disease. The majority (> 75%) were women in the third to the sixth decade with type 1 AIH. Almost all patients had either encephalopathy at admission and/or had significant coagulopathy (Table 1). IgG levels were available in two studies^[24,25], and 74% had levels in excess of 1800 mg/dL.

OUTCOMES IN PATIENTS WITH AIH AND LF

Table 2 shows treatment data and outcomes in these five above studies. Of the total of 85 patients, 69 (89.2%) received immunosuppression, mostly corticosteroids (Table 2). For the majority of the patients, there was no rationale provided for initiation or withholding corticosteroids, and the decision appeared to have been made on an *ad hoc* basis. The remission rates with immunosuppression varied from 8.3% to 50% (average: 33.3%, 23/69) (Table 2). Overall, 43.5% (37/85) either underwent or were listed for LT and 32.9% (28/85) died. These outcomes are certainly poorer than those reported in patients with chronic AIH (remission with corticosteroids ~80%^[2,3], need for LT 1.4%-8.4% and mortality 1.8%-4.9%^[27,29]), and makes for dismal reading.

The variability in remission rates with corticosteroid therapy in these five studies is most certainly a reflection of the heterogeneous patient population. Unsurprisingly, the lowest remission rates were seen in the study of Ichai *et al.*^[25], which had the sickest patients, as reflected by their high admission MELD scores. However, those patients with AIH and LF that did respond to corticosteroid

therapy survived, obviating the need for a subsequent LT. Unfortunately, among the non-responders to corticosteroids in these five studies ($n = 46$), death was the inevitable outcome in the absence of LT (Table 2). The duration of steroid therapy prior to death was highly variable (3-95 d). Clearly, in some, the illness was so fulminant that death occurred rapidly after hospitalization, thereby precluding LT, and in others, there were active contraindications to transplantation, such as sepsis (Table 2). Nevertheless, in these five studies, there were a subset of patients with AIH and LF in whom death may have been preventable had LT been more aggressively pursued. It is conceivable that initiation of steroids provided a false sense of security, thereby delaying transplant evaluation.

One could argue that the low remission rates to corticosteroids in this cohort were partly related to delay in initiating therapy. However, where available, the data do not support this conclusion, as corticosteroids were initiated promptly, especially in the sicker patients. In our study, subsequent non-responders to corticosteroids were commenced on therapy within 2.6 ± 1.8 d of admission, compared to 6.4 ± 5.5 d in those who eventually responded to

corticosteroids^[7]. It is more likely that non-responders to corticosteroids had aggressive disease at the time of diagnosis with a critical degree of liver cell death already having occurred prior to the introduction of medical treatment^[24]. This hypothesis is supported by the study of Ichai *et al.*^[25], in which all patients had massive/sub-massive liver necrosis (median MELD score at admission: 37), with only 8.3% responding to corticosteroids and > 80% needing LT.

OPTIMIZING MANAGEMENT IN PATIENTS WITH AIH AND LF

Assessing patients with LF for LT is a complex process. The most widely used criteria for prioritizing patients for LT are the King's College criteria^[30]. However, neither the King's College criteria^[29] nor the more recently developed MELD score^[31] have been validated in patients with AIH and LF. This is most likely due to the fact that the prevalence of AIH in patients with LF being evaluated for LT is low (0%-5%)^[12,13,32]. As is evident from the published data^[7,22-25], there certainly are a subset of patients with AIH and LF who will respond to corticosteroids. Inappropri-

ate transplantation in such patients would mean subjecting them to unnecessary surgery (and its attendant complications) and lifelong immunosuppression. In addition, it would deprive another more suitable recipient from receiving the graft^[33]. On the other hand, denying LT to a patient with AIH and LF who is unlikely to respond to corticosteroids means condemning them to a certain death, which is unacceptable, especially since post-transplant survival for AIH is excellent [estimated 5-year survival probability after first LT is 0.73 (95% CI: 0.67-0.77)]^[34].

The contentious issue thus is how best to stratify patients with AIH and LF into likely responders and non-responders to corticosteroids as soon as possible after hospitalization; hence optimizing their management. In our study^[7], all responders to corticosteroid therapy had a MELD score ≤ 28 at admission. This is also supported by Ichai *et al.*^[25], who showed that the only patient to respond to corticosteroids had a MELD score of 24, and none with an initial MELD score > 28 responded to corticosteroids. Furthermore, in our study, responders to corticosteroids were more likely to have either an improvement or stabilization in bilirubin and INR within 3.7 ± 0.6 d of initiation of corticosteroid therapy, whereas non-responders tended to have a trend for higher bilirubin and INR^[7]. Villamil *et al.*^[22] also observed that a 20% increase in prothrombin time (PT) at day 3 of corticosteroid therapy to be a predictor of poor outcome, along with PT $< 20\%$, grade 4 encephalopathy, and LKM antibody/liver cytosol (LC) antibody positivity at diagnosis. Histological evidence of sub-massive/massive necrosis is also invariably associated with need for LT and/or death (Table 1). Surprisingly, in our study, the presence of cirrhosis was more likely associated with response to corticosteroids^[7]. Although the impact of cirrhosis on the natural history of AIH remains controversial^[27,28,35,36], it is likely that this group has long-standing indolent disease that progresses to cirrhosis, with LF representing an acute relapse of AIH^[37]. This is in contrast with the study of Ichai *et al.*^[25], in which absence of significant hepatic fibrosis in all the patients indicated a *de novo* fulminant disease process.

CORTICOSTEROIDS AND INFECTIONS

Whether steroids increase the risk of septic complications in patients with severe liver disease is subject to an ongoing debate. The issue becomes even more contentious in the presence of LF because in itself that has been associated with an increased risk of bacterial and fungal infections^[25,38,39]. In fact, earlier studies have shown that up to 35% of patients with LF can develop bacteremia in the pre-transplant period^[39]. This increased propensity for sepsis is further aggravated in the post-transplant setting due to use of immunosuppression. Therefore, not surprisingly, sepsis with or without multiorgan failure, accounts for almost one-third of all deaths in patients undergoing LT for LF and is the most common cause of mortality in this cohort^[40]. In the study of Ichai *et al.*^[25] (which had the sickest cohort of patients with a median MELD score of 37 at admission), 42.3% developed a septic event, and this prevalence is not higher than that reported previously^[39]. It is however noteworthy that in Ichai *et al.*'s study septic events were more likely to occur in those initiated (6/12) versus those not initiated (1/4) on corticosteroids^[25]. It is unclear whether patients received prophylactic antibiotics in this study. Reich *et al.*^[41] also have reported an increased trend for wound infection in corticosteroid-treated patients with AIH undergoing LT (30.7% *vs* 5.2%). In a recent publication that analyzed data from the European Transplant Registry, in comparison with transplantation for primary biliary cirrhosis and alcoholic cirrhosis, the probability of infectious complications limiting patient survival was significantly increased after transplantation for AIH. This was especially relevant to patients aged > 50 years and within the first 3 mo of transplantation^[34]. Unfortunately, data on disease severity and use of pre-transplant immunosuppression and prophylactic antibiotics were not available in that study. On the other hand, others have reported corticosteroids not to be associated with increased risk of infections in patients with severe AIH^[42]. These discordant results most likely reflect the heterogeneous patient groups (in-

cluding the whole spectrum from chronic disease to FHF), use of varying immunosuppressive regimens, and inconsistent use of prophylactic antibiotics. Nonetheless, Ichai *et al.*^[25] caution against injudicious use of corticosteroids in patients with AIH and LF, and on the contrary, emphasize the need for expedited LT evaluation in such a cohort. Furthermore, it lends credence to the argument for the use of prophylactic antibiotics and antifungal agents, because such a strategy has been shown to reduce the risk of infections in the pre-transplant setting^[43].

THE FUTURE

Prospective multicenter studies are clearly needed to address this complex and important clinical issue. In future, testing for additional autoantibodies and HLA typing might also help risk-stratify patients. For example, presence of antibodies to SLA have been associated with DRB1*0301, and such patients have aggressive disease and are more likely to require LT and/or die^[44,45].

CONCLUSION

The diagnosis and management of patients with AIH with AF at initial diagnosis can be challenging. Although there are only limited published data available, mostly in the form of small retrospective studies, up to 8.7%-19.8% of patients with AIH may have this form of presentation. On the whole, about one-third can respond to corticosteroids and have a good outcome, although for the vast majority, LT may offer the only hope of long-term survival. A MELD score at admission of ≤ 28 , more severe hepatic fibrosis, absence of sub-massive/massive necrosis, and early (within 4 d) improvement or stabilization in bilirubin and INR, identify those who are likely to respond to corticosteroid therapy, and thus survive without the need for LT. If clinical and biochemical improvement does not occur within the first few days, then continuation of corticosteroids may be a futile exercise, as it would be unlikely to change the clinical outcome, and on the contrary, may result in adverse events, especially sepsis. Nonetheless, if a decision is made to continue therapy with corticosteroids it is imperative that LT be actively pursued concomitantly. Furthermore, it may not be unreasonable to consider prophylactic antimicrobial and antifungal agents in such high-risk patients. It must however be emphasized that, at present, these recommendations are based on small retrospective studies. This underlines the urgent need for prospective multicenter studies to address this important clinical issue.

Abstract

Autoimmune pancreatitis is a disease characterized by specific pathological features, different from those of other forms of pancreatitis, that responds dramatically to steroid therapy. The pancreatic parenchyma may be diffusely or focally involved with the possibility of a low-density mass being present at imaging, mimicking pancreatic cancer. Clinically, the most relevant problems lie in the diagnosis of autoimmune pancreatitis and in distinguishing autoimmune pancreatitis from pancreatic cancer. Since in the presence of a pancreatic mass the probability of tumour is much higher than that of pancreatitis, the physician should be aware that in focal autoimmune pancreatitis the first step before using steroids is to exclude pancreatic adenocarcinoma. In this review, we briefly analyse the strategies to be followed for a correct diagnosis of autoimmune pancreatitis.

INTRODUCTION

Autoimmune pancreatitis (AIP) is now a well defined entity among the inflammatory diseases of the pancreas^[1-3]. The number of studies in literature has constantly increased since the first one published in 1995 by Yoshida *et al*^[4] (Figure 1). Despite the fact that in the first paper from Japan the disease was described as diffusely involving the pancreatic gland^[5-8], later publications pointed out that the pancreas may also be focally involved by the autoimmune process^[3,9-12]. Therefore, some authors have classified AIP as focal or diffuse^[3]. Focal AIP is characterized by a segmental involvement of the parenchyma with the possibility of a low-density mass being present at imaging.

Clinically, the focal form, particularly in the presence of a low-density pancreatic mass, requires a more careful patient evaluation, since it may be easily confused with pancreatic cancer. Several series indicate that in 5%-21% of resected pancreatic masses suspected of being cancer, the final diagnosis excluded malignancy (Table 1)^[13-20]. Since AIP responds dramatically to steroid treatment^[1], a correct diagnosis of the disease is important to avoid surgery. On the other hand, in the presence of a resectable pancreatic mass, the probability of cancer is very high (> 90%). A

misdiagnosis of AIP implies 2-3 week's steroid treatment and a one month delay in surgery, with the consequent risk of not operating because of the progression of the malignancy with the onset of metastasis or of vascular involvement. A correct and quick diagnosis of AIP is therefore an important goal in clinical practice, particularly in focal AIP.

AIP diagnosis may be attained through well established diagnostic criteria. There is agreement on the use of four main criteria based on histological findings, radiological features, other organ involvement and clinical and instrumental response to steroid therapy. HISORT criteria introduced by Chari *et al*^[21] in 2006 and based on surgical specimens of operated AIP patients can be considered standard criteria for the diagnosis of AIP. Serum IgG4^[22-24] and positive IgG4+ plasma cells in pancreatic surgical specimens or pancreatic biopsies may also support the diagnosis of AIP^[25-29].

There is agreement on the use of these diagnostic criteria (pathology, imaging, presence of other organ involvement, response to steroids), but not on the strategy to be followed in making the diagnosis.

THE STRATEGIES IN THE DIAGNOSIS OF AIP

Three main strategies, from Japan, the USA and Italy, have been suggested. The clinical approach to the disease by these strategies is different.

In the USA distinguishing the different pathological subtypes of AIP^[21,30,31] is considered prominent for the diagnosis. In the USA and in Europe, AIP may be classified as type 1 (or Lympho-Plasmacytic Sclerosing Pancreatitis-LPSP) and type 2 (or Idiopathic Duct-centric Chronic Pancreatitis- IDCP)^[31-34]. Since the clinical evolution of these forms seems to be different, some authors have suggested obtaining the diagnosis of AIP subtypes from EUS-guided biopsy^[31,35].

The main pathological and serological features in type 1 AIP are^[31,36]: (1) Prevalence of storiform fibrosis, with obstructive phlebitis; (2) high levels of serum IgG4; (3) presence of IgG4+ plasma cells in the involved pancreatic tissue; and (4) absence of granulocytic epithelial lesions (GEL), that are the expression of an aggression against epithelial ductal cells, with rupture and destruction of ductal structures. The pathological characteristics in type 2 AIP are on the contrary^[31,36]: (1) prevalence of inflammation; (2) presence of GEL; and (3) absence of serum IgG4 and of IgG4+ plasmavcells in the inflamed pancreatic tissue.

The clinical aspects and the evolution are different in type 1 and 2 AIP^[31,36,37]. In type 1 AIP (LPSP), there is a prevalence of males, patients are older, other organs may be involved (more commonly salivary glands, biliary tract, kidney, lung, retroperitoneum) and the relapse of the disease is more frequent after steroid treatment. In type 2 (IDCP), male/female ratio is about 1, patients are younger, the colon only may be involved (ulcerative colitis) and relapse after steroids is infrequent. Both forms respond quickly to steroid treatment^[31,36-38].

The diagnostic approach is therefore aimed at diagnosing

AIP subtypes, mainly through pancreatic core biopsy, and this appears to have a good sensitivity and specificity^[28,29,39].

In Japan, only type 1 AIP (LPSP) is considered an autoimmune disorder and an IgG4-mediated systemic disorder associated with pancreatic lesions^[40]. Only in a few cases has type 2 AIP (IDCP) been described in Japan and it is not considered an autoimmune disease, despite its quick response to steroids just as type 1 AIP. Instrumentally, in the majority of cases the disease diffusely involves the pancreas. Several diagnostic algorithms have been suggested in Japan and Korea^[8,41-44]. A comprehensive diagnosis should be based on pancreatic imaging (including ERCP), serological tests (IgG4, total IgG, non organ specific autoantibodies, antibodies to carbonic anhydrase type I and II, antibodies to lactoferrin) and pathological findings. The presence of extrapancreatic lesions may suggest the possibility of AIP.

THE ITALIAN STRATEGY: A CLINICAL APPROACH TO THE DISEASE

The Italian proposal for the diagnosis of AIP, which is different from that suggested in Japan and the USA, is based on the instrumental distinction between focal and diffuse forms of the disease^[2,3].

A wide range of symptoms are reported by patients at the clinical onset of the disease. Jaundice, abdominal pain, usually mild, symptoms secondary to pancreatic exocrine and endocrine insufficiency (weight loss, diabetes), and persistent elevation of serum levels of pancreatic enzymes may be observed in AIP patients. In a few cases AIP is discovered incidentally by US or other imaging techniques performed without an indication for a pancreatic disorder.

On the basis of imaging, these patients can be divided in those with focal involvement of the pancreas and those with diffuse enlargement of the pancreatic gland^[12]. In the case of focal AIP, particularly in the presence of a low-density pancreatic mass, the clinical challenge is to exclude pancreatic cancer and correctly diagnose AIP. Therefore, focal and diffuse types AIP should be strictly separated, since the problem of differential diagnosis with pancreatic cancer involves only focal AIP.

Diffuse AIP may be confused with acute pancreatitis. The clinical picture of diffuse AIP, however, differs from those observed in acute pancreatitis. In AIP, pain, if present, is mild, no risk factors for pancreatitis (biliary lithiasis, alcohol) are present, a persistent increase in serum pancreatic enzymes may be observed, jaundice is caused by enlargement of the pancreas without the presence of a mass, with a stricture on the intrapancreatic tract of the common bile duct. Since pancreatic necrosis has never been described in AIP, the differential diagnosis should be with oedematous pancreatitis. This can be achieved through imaging, since the radiologic features of AIP are different from those observed in acute oedematous pancreatitis. Hypodensity of the pancreas in arterial phase and the absence of a peripancreatic strand appear to differentiate AIP from acute oedematous pancreatitis, where the pancreatic gland shows normal perfusion and the peripancreatic strand is a common radiological picture (personal unpublished data). We do not suggest pancreatic biopsy in diffuse AIP. The diagnosis may be definitely made after treatment with steroids, which produces complete disappearance of the pancreatic changes.

In the diffuse form associated with jaundice secondary to a common bile duct stricture, a diagnosis of cholangiocarcinoma should be considered and, if necessary, ruled out before steroid therapy through ERCP with biliary biopsies and/or intraductal biliary ultrasonography.

In the focal form, particularly in the presence of a low-density pancreatic mass at imaging, the first diagnostic goal is to exclude pancreatic cancer, even if the presence of clinical (young age, other organ involvement), radiological (perfusion of the pancreatic mass suggestive of inflammation, no or mild dilation of the main pancreatic duct) and serological (high level of IgG4, presence of autoantibodies, low serum levels of Ca 19-9) findings are suggestive of AIP. Therefore, pancreatic biopsy is mandatory, preferably EUS-guided, first of all to exclude neoplasia and possibly to confirm the diagnosis of AIP.

If pancreatic biopsy confirms the diagnosis of AIP, a 3 wk steroid treatment is indicated. The diagnosis of AIP is final in the presence of a significant clinical and radiological response. Since significant improvement/resolution

of jaundice is an indication of response to steroid therapy, biliary stenting is not recommended, unless serum bilirubin levels are very high.

If pancreatic biopsy is only suggestive of AIP or non diagnostic, a careful evaluation of HISORt criteria is necessary to decide whether the patient should be treated with steroids or undergo resective surgery. The decision is actually a challenge and should be made in experienced centres only, because it requires expert clinicians, radiologists, pathologists and surgeons. After a complete or significant response to steroid therapy, a definitive diagnosis of AIP may be made.

CONCLUSION

The diagnosis of AIP still remains difficult. The diagnostic algorithm is different in the diffuse and focal forms of the disease, particularly in the presence of a low-density pancreatic mass at imaging. Biopsy or fine needle aspiration cytology is mandatory in the presence of a low-density pancreatic mass. In some cases, only a full or significant response to steroids allows a final diagnosis of AIP to be made. Agreement among experienced clinicians, radiologists, pathologists and surgeons is needed to adopt the response to steroid therapy as a diagnostic criterion in patients where the diagnosis cannot be made through pancreatic biopsy.

Abstract

Endoscopic ultrasonography is an established diagnostic tool for pancreatic masses and chronic pancreatitis. In recent years there has been a growing interest in the worldwide medical community in autoimmune pancreatitis (AIP), a form of chronic pancreatitis caused by an autoimmune process. This paper reviews the current available literature about the endoscopic ultrasonographic findings of AIP and the role of this imaging technique in the management of this protean disease.

INTRODUCTION

Endoscopic ultrasonography (EUS) is superior to standard imaging techniques in detecting pancreatic cancer or masses and in the assessment of early parenchymal changes in chronic pancreatitis^[1,2]; however, its role in the diagnosis of autoimmune pancreatitis (AIP) has yet to be standardized, even though its high accuracy together with its safety make it a promising tool in the management of this disease.

To date, no consensus about the diagnosis of AIP has been reached^[3]. Several criteria have recently been proposed, reflecting the different clinical entities that AIP can adopt worldwide^[4-9]. The diffuse form of AIP has typically been included in the first set of criteria^[4], and in 2008 only, a focal pancreatic enlargement evident upon imaging was classified as a form of AIP.

Obstructive jaundice is the most common presentation of AIP and, together with biochemical and imaging features, can mimic neoplastic conditions^[10,11]. Because

Table 1 Endoscopic ultrasonography features of autoimmune pancreatitis

| | Pancreas | | Extrahepatic bile duct | Gallbladder | Lymph nodes ¹ | Peripancreatic vessels |
|------|--|---|---|---|---|--|
| | Diffuse AIP | Focal AIP | | | | |
| EUS | Gland volume: increased | Gland volume: focal enlargement/s | Caliber: dilated | Wall: diffuse and uniform thickening, "sandwich-pattern" ¹ | Volume: enlarged (also substantially) | Loss of interface between pancreas and portal or mesenteric veins ¹ |
| | Echotexture: echopoor, with echogenic interlobular septa Gland border: thickened Wirsung: narrowed | Echotexture: echopoor, with echogenic interlobular septa Wirsung: narrowed within the lesion, dilated upstream to the lesion | Wall: diffuse and uniform thickening, "sandwich-pattern" ¹ | | Echotexture: echopoor Sites: liver hylum, peripancreatic, celiac | |
| IDUS | Wirsung wall: thickened ¹ | Wirsung wall: thickened ¹ | Wall: diffuse and uniform thickening, "sandwich-pattern"; differential diagnosis with cholangiocarcinoma ¹ | | | |

¹Indicates the features which are detected only or substantially better by endoscopic ultrasonography (EUS) and not seen in conventional cross-sectional imaging. AIP: Autoimmune pancreatitis; IDUS: Intraductal ultrasonography.

AIP is a benign disease, a definitive diagnosis without the need for surgery is desirable.

AIP can present with extrapancreatic lesions, the most frequent being IgG4-related sclerosing cholangitis (IgG4-SC), followed by hilar lymphadenopathy^[12].

EUS can display both of these conditions in addition to parenchymal, ductal and vascular lesions. Moreover, this technique offers the advantage over other diagnostic tools of allowing clinicians to perform biopsies to achieve a definitive diagnosis^[13-16].

In this article, we describe the EUS findings of AIP (Table 1) by reviewing the currently available literature in this field.

PANCREATIC FINDINGS

The predominant finding in the diffuse form of AIP is a diffuse pancreatic enlargement with altered echotexture (Figure 1)^[14,15]. A recent retrospective study proposed to differentiate early from advanced stage AIP according to EUS findings^[15]. In 19 patients with AIP, the presence of parenchymal lobularity and a hyperechoic pancreatic duct margin were significantly correlated with early stage AIP^[17]. Other EUS findings that are indicative of AIP, such as reduced echogenicity, hyperechoic foci and hyperechoic strands (Figure 1), are found in both AIP stages^[17]. Should these results be confirmed in prospective studies, EUS would acquire an essential role in the identification of early stage AIP, which is characterized by a prompt response to steroid therapy. Stones and cysts similar to those described in chronic alcoholic pancreatitis can occur in the late stage of AIP^[18].

The Sahai criteria for chronic pancreatitis were found

to be inadequate to evaluate parenchymal and ductal changes in AIP^[19]. According to the scoring system, a series of 25 patients with AIP were classified as normal or displaying mild disease^[16].

In the focal form of AIP a solitary (Figure 2), irregular hypoechoic mass, generally located in the head of the pancreas, is observed^[13-15]. In addition, upstream dilatation of the main pancreatic duct could be observed^[13,17]. In this setting, the overlap with EUS findings of pancreatic cancer is remarkable, and EUS-elastography (Figure 1) can provide further information about pancreatic lesions. In a case-control study of five patients with AIP, EUS-elastography showed a typical and homogeneous stiffness pattern of the focal lesions and of the surrounding parenchyma that is different from that observed in ductal adenocarcinoma^[20].

COMMON BILE DUCT FINDINGS

The common bile duct is the most frequent extrapancreatic organ involved in AIP and was found to affect 58% of patients in a Japanese survey^[12]. Biliary strictures can mimic both sclerosing cholangitis and biliary cancer. EUS allows visualization of the entire common bile duct and enables identification of the cause of a biliary stricture. In patients with either diffuse or focal AIP, EUS can show dilatation of the common bile duct and thickening of its wall better than other diagnostic techniques^[3,13-16,21]. The typical EUS feature of the common bile duct is a homogeneous, regular thickening of the bile duct wall, called "sandwich-pattern", which is characterized by an echopoor intermediate layer and hyperechoic outer and inner layers, has been described as a EUS feature of the

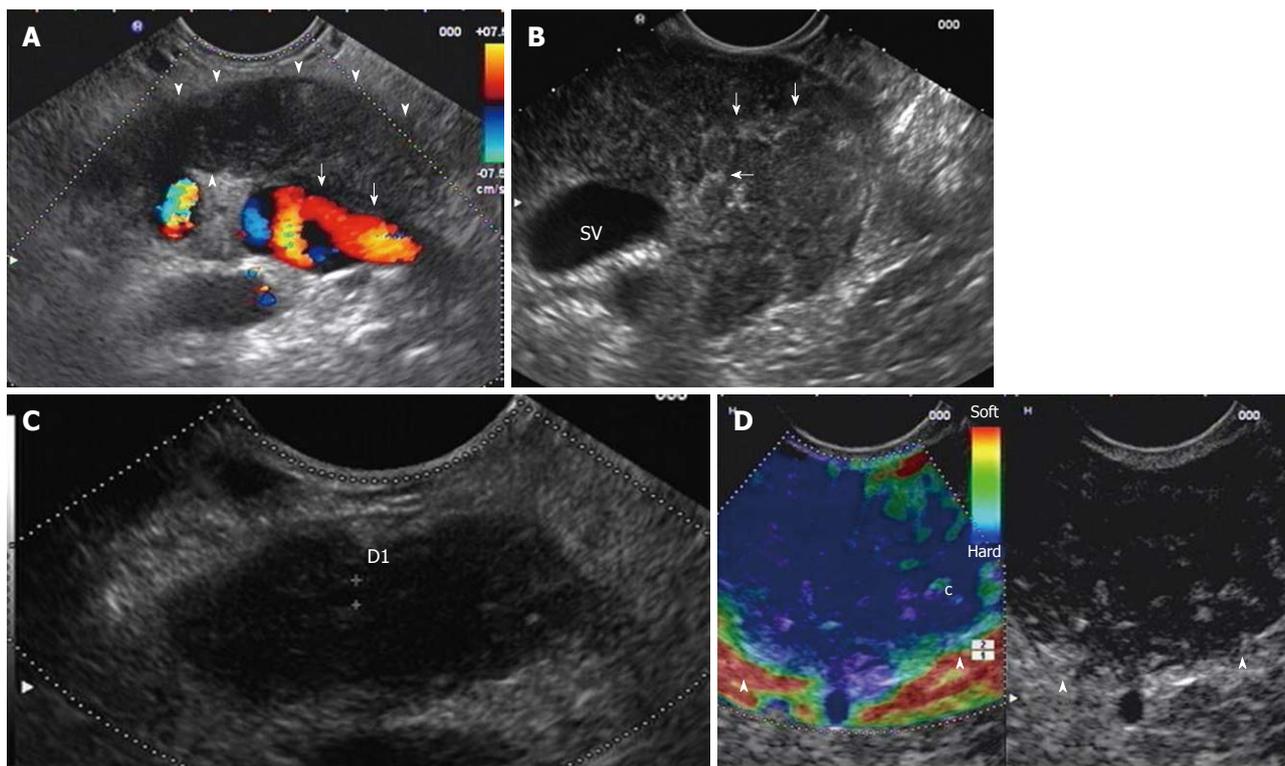

Figure 1 Diffuse form of autoimmune pancreatitis. A: Endoscopic ultrasonography (EUS) linear scanning shows a diffuse pancreatic enlargement (arrowheads) with echopoor echotexture, and with loss of interface with splenic vein (arrows); B: Parenchymal lobularity and hyperechoic strands (arrows) are visible in the enlarged gland; C: Pancreatic duct calliper is 1.8 mm; D: EUS-elastography demonstrates the diffuse pancreatic stiffness (arrowheads).

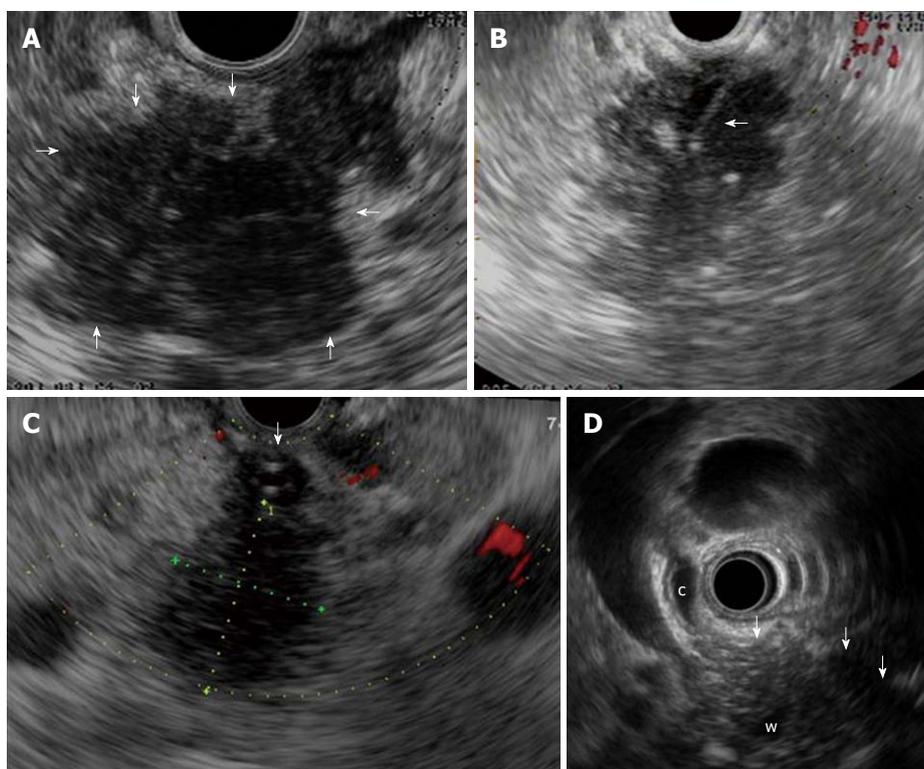

Figure 2 Focal form of autoimmune pancreatitis. A: Endoscopic ultrasonography (EUS) shows a focal lesion (arrows) of pancreatic head which is echopoor with hyperechoic strands; B: A EUS-guided fine needle aspiration is performed (arrow) for tissue characterization; C: Another case of focal autoimmune pancreatitis (AIP) with echopoor lesion of pancreatic head (between callipers) and marked echopoor thickening of the choledochal wall (arrow); D: In this case of focal AIP EUS shows an echopoor lesion (arrows) of pancreatic head, with upstream dilatation of both common bile duct (c) and pancreatic duct (w); notice the thickened choledochal wall.

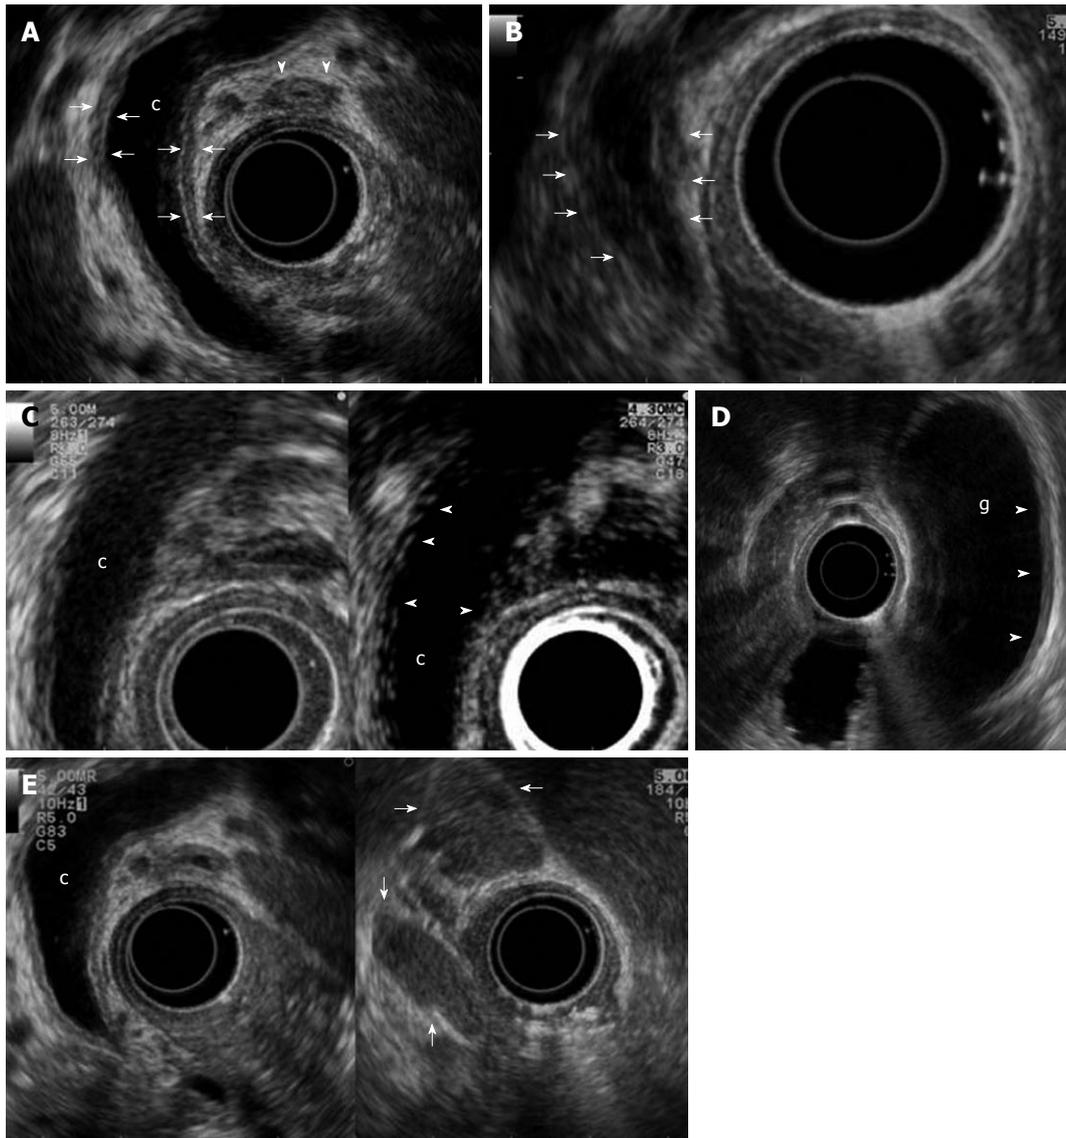

Figure 3 Biliary and peripancreatic findings in autoimmune pancreatitis. Autoimmune pancreatitis presenting with jaundice: A: Endoscopic ultrasonography (EUS) shows a dilated common bile duct (c) upstream to a distal funnel-shaped stenosis; EUS demonstrates the diffuse thickening of the biliary wall (between arrows) with "sandwich-pattern", either of common bile duct or of cystic duct (arrowheads). This thickening is equally visible both in the dilated region of the common bile duct; B: In the distal strictured tract (arrows); C: After contrast administration (Sonovue, Bracco) the biliary wall shows an early and persistent enhancement (arrowheads); D: EUS shows the same thickening of the gallbladder (g) wall (arrowheads); E: Enlarged lymph nodes to the hepatic hilum (arrows).

common bile duct; the cause of the biliary stricture is the thickened wall itself rather than extrinsic pancreatic compression (Figure 3)^[3,13].

A further application of EUS is intraductal ultrasonography (IDUS), which can be performed during endoscopic retrograde cholangiography for the characterization of biliary stenosis. Naitoh *et al*^[22] recently evaluated IDUS findings in 23 patients with IgG4-SC. They found that a circular, symmetric wall thickness, smooth inner and outer margins and a homogeneous intermediate layer in the stricture were significantly more common in AIP than in cholangiocarcinoma. The wall thickness in IgG4-SC in regions of non-stricture on the cholangiogram was significantly greater than that in cholangiocarcinoma and therefore a bile duct wall thickness exceeding 0.8 mm in regions of non-stricture on the cholangiogram was

highly suggestive of IgG4-SC. Contrast enhancement of conventional EUS and IDUS showed an inflammatory pattern of the bile duct wall, with a long-lasting enhancement starting in the early phase instead of the poor enhancement found in bile duct cancer (Figure 3)^[21].

PERIPANCREATIC FINDINGS

Hilar lymphadenopathy is one of the most frequently described extrapancreatic lesions^[12]. Other sites of enlarged lymph nodes are the peripancreatic and celiac regions. EUS nodal features that accurately predict nodal metastasis have been previously identified in patients with esophageal cancer^[23]; they include size (> 1 cm in diameter on the short axis), hypoechoic appearance, round shape, and smooth border. However, these conventional EUS cri-

teria have proven inaccurate for staging non-esophageal cancers, including those that are biliopancreatic^[24,25]. EUS can detect single or multiple enlarged lymph nodes in patients with AIP (Figure 3), reflecting the underlying inflammatory process, which can involve extra-pancreatic organs^[14,15].

Hoki *et al.*^[16] reported a significant difference in detection of lymphadenopathy by EUS imaging over CT (72% *vs* 8%) in patients with AIP. Moreover, in the same series, a trend toward a higher prevalence of lymphadenopathy in AIP compared to pancreatic cancer was reported.

In the absence of specific nodal features indicating malignancy, the differential diagnosis with biliopancreatic neoplasms is arduous but can be achieved by evaluating the broad spectrum of clinical and imaging data of AIP patients.

EUS criteria for vascular invasion of pancreatic cancer have been established^[26,27].

In a series of 14 patients with AIP, EUS suspected invasion of the portal or mesenteric veins in 21% of patients compared to 14% on CT. No pancreatic cancer developed during the follow-up of these patients. Such EUS features, easily mistaken for malignancy, are due to the inflammatory process of AIP, which can involve medium and large-sized vessels (Figure 1)^[15].

Peripancreatic fluid collections are less common and not specific for AIP.

INTERVENTIONAL EUS IN AIP

In recent years, the possibility of guiding tissue sampling with either fine needle aspiration (EUS-FNA) (Figure 2) or Tru-cut biopsy (EUS-TCB) has increased the diagnostic potential of EUS by the acquisition of cytological and histological specimens from gastrointestinal lesions^[28-30].

In the setting of AIP, EUS-FNA can be employed to yield specimens of pancreatic lesions, the common bile duct wall or lymph nodes^[13,15]. Although a cytologic pattern specific for AIP has not been identified, high cellularity of stromal fragments with lymphoplasmacytic infiltrate has emerged as a discriminating feature in a retrospective series of 16 patients with an AIP diagnosis confirmed by histology of the respective specimens. Indeed, 56% of AIP patients presented such a feature *vs* 19% of patients with pancreatic carcinoma, and none of the chronic pancreatitis controls exhibited this feature^[31]. Immunohistochemical staining can show IgG4-positive plasma cells which are a useful marker for the tissue diagnosis of AIP.

EUS-FNA can fail in diagnosis because of the small size of the specimens that do not have preserved tissue architecture. Moreover, sampling error due to the patchy distribution of AIP can occur. EUS-TCB can overcome these limitations by acquiring large samples fit for histological examination^[30-32].

A recent study compared EUS-FNA and EUS-TCB performed in 14 patients for the diagnosis of AIP. EUS-TCB showed higher sensitivity (100%) and specificity (100%) compared to EUS-FNA (36% and 33%, respec-

tively). Both procedures were found to be safe, with no complications^[33].

However, the diagnostic accuracy of EUS-FNA for pancreatic cancer has been reported to range between 60% and 90%^[34-36], and the shortcomings of EUS-TCB due to technical difficulties of the sampling of lesions in the pancreatic head should also be considered.

Hence, when AIP is suspected, a sequential sampling strategy has been proposed based on using EUS-FNA first, which is followed by EUS-TCB when cytologic examination is inconclusive^[33].

In cases of inconclusive cytology, an additional aid for AIP diagnosis could come from molecular analysis of EUS-FNA samples, which has shown high accuracy in the differential diagnosis between AIP and pancreatic cancer^[37].

CONCLUSION

AIP represents 20%-25% of benign diagnoses undergoing resection for presumed malignancy^[38,39]. Thus, a definitive diagnosis based on safe and reliable methods should be obtained. In this setting, EUS could play an important role in diagnosis, identifying typical features of AIP and distinguishing it from biliopancreatic neoplasms. The higher sensitivity over standard imaging for pancreatic, biliary and nodal lesions should make it a cornerstone in the process of diagnosing AIP. If validated in large prospective series, newly available techniques such as EUS-elastography and CE-EUS could add useful information about focal lesions without resorting to invasive procedures. Finally, EUS-FNA or EUS-TCB can provide pathological specimens, as required by some diagnostic criteria.

Abstract

AIM: To investigate the effect of α -mangostin on the growth and apoptosis induction of human colon cancer cells.

METHODS: The three colorectal adenocarcinoma cell lines tested (COLO 205, MIP-101 and SW 620) were treated with α -mangostin to determine the effect on cell proliferation by MTT assay, cell morphology, chromatin condensation, cell cycle analysis, DNA fragmentation, phosphatidylserine exposure and changing of

mitochondrial membrane potential. The molecular mechanisms of α -mangostin mediated apoptosis were further investigated by Western blotting analysis including activation of caspase cascade, cytochrome c release, Bax, Bid, p53 and Bcl-2 modifying factor.

RESULTS: The highest inhibitory effect of α -mangostin on cell proliferation of COLO 205, MIP-101 and SW 620 were $9.74 \pm 0.85 \mu\text{g/mL}$, $11.35 \pm 1.12 \mu\text{g/mL}$ and $19.6 \pm 1.53 \mu\text{g/mL}$, respectively. Further study showed that α -mangostin induced apoptotic cell death in COLO 205 cells as indicated by membrane blebbing, chromatin condensation, DNA fragmentation, cell cycle analysis, sub-G1 peak ($P < 0.05$) and phosphatidylserine exposure. The executioner caspase, caspase-3, the initiator caspase, caspase-8, and caspase-9 were expressed upon treatment with α -mangostin. Further studies of apoptotic proteins were determined by Western blotting analysis showing increased mitochondrial cytochrome c release, Bax, p53 and Bmf as well as reduced mitochondrial membrane potential ($P < 0.05$). In addition, up-regulation of tBid and Fas were evident upon treatment with α -mangostin ($P < 0.01$).

CONCLUSION: α -Mangostin may be effective as an anti-cancer agent that induced apoptotic cell death in COLO 205 *via* a link between extrinsic and intrinsic pathways.

INTRODUCTION

Searching for new biologically active compounds, novel chemotherapeutic agents derived from active phytochemicals, could be used to improve the anti-carcinogenicity of standard drug treatment. A variety of tropical plants have useful biological activities and some offer potential therapeutic applications. Mangosteen (*Garcinia mangostana* L.) in the Clusiaceae family has been used in Southeast Asia as traditional medicine for treatment of wounds, skin infection, diarrhea and chronic ulcer^[1]. Phytochemical studies showed that the fruit hull of mangosteen is rich in a variety of oxygenated and prenylated xanthenes^[2,3] which possess different biological properties, such as anti-mycobacterial^[4], anti-fungal^[5], anti-oxidant^[6-8], cytotoxicity^[9-12] and anti-inflammatory activities^[13]. However, the underlying molecular mechanisms of α -mangostin in COLO 205 cells are not yet reported.

Apoptosis plays a vital role in controlling cell number in many physiological and developmental stages, tissue homeostasis, and regulation of immune system^[14], while insufficient apoptosis is an integral part of cancer development^[15]. Mammalian cells have two major apoptotic pathways. One pathway (extrinsic pathway) is triggered when ligands [Fas/CD95, tumor necrosis factor (TNF)- α] bind to receptors on cell surface leading to the activation of caspase-8 and -3^[16], respectively. The other involves mitochondrial (intrinsic) pathway induced by anti-cancer drugs, prostaglandin, *etc.* resulting in disruption of mitochondrial membrane and release of various pro-apoptotic factors^[17-19]. The pro-apoptotic and anti-apoptotic members of B-cell CLL/lymphoma 2 (Bcl-2) family regulate the release of cytochrome c, a mitochondrial protein that can activate caspases.

Fas/CD95 belongs to the TNF superfamily and is the prototype of death receptor that initiates an apoptotic cascade^[20]. FasL, the tumor necrosis factor-related cytokine, is a ligand of Fas and synthesized as a type II membrane protein^[21]. Upon FasL binding, activated death receptors engage the Fas associated death domain (FADD)^[22], which in turn recruits caspase-8 and forming the death inducing signaling complex (DISC). The DISC then activates caspase-8 through a proximity-inducing dimerization mechanism. In type I cells, caspase-8 directly activates caspase-3, -6 and -7, leading to cell death. In contrast, in type II cells the small amount of active caspase-8 generated at the DISC is not sufficient to induce cell death, therefore the mitochondria-dependent apoptosis pathway is needed^[23]. As such, the pro-apoptotic signal has to be amplified *via* cleavage of the BH3-only protein Bid, Bax/Bak-assisted release of cytochrome c from the mitochondria, an activation of caspase-9 and subsequently caspase-3^[24].

The objective of the present study was to purify the α -mangostin from the fruit hull of *Garcinia mangostana* L. and explore its effect on apoptosis induction and mechanisms involved in COLO 205 cells.

MATERIALS AND METHODS

α -mangostin preparation

Mangosteen fruit (*G. mangostana*) was collected from Kambang District, Chantaburi Province, Thailand in April, 2007. A voucher specimen (Ms Porntip Wongnapa No. 002) was deposited at the Faculty of Science, Ramkhamhaeng University. The dried and pulverized fruit hull of *G. mangostana* (0.5 kg) was thoroughly extracted with ethyl acetate (EtOAc) at 50°C. The combined extract after filtration was concentrated under reduced pressure to yield the extract as a yellowish solid (285 g). A portion of the extract was subjected to repeated column chromatography over silica gel using a gradient of hexane/acetone which yielded the pure major compound, α -mangostin, including other minor xanthenes. Purity of α -mangostin exceeded 98% as determined by LC analysis and its spectroscopic data (NMR and MS) was consistent with the reported values^[12].

Cell lines and culture conditions

Three human colorectal cancer cell lines were used: COLO 205 (colorectal adenocarcinoma), MIP-101 (colorectal carcinoma) and SW620 (colorectal adenocarcinoma). COLO 205 and SW620 were obtained from the American Type Culture Collection (Manassas, VA). MIP-101 was a generous gift from Peter Thomas, Boston University School of Medicine, Boston, MA. COLO 205 and MIP-101 were maintained in the RPMI 1640 medium (Invitrogen), supplemented with 10% fetal calf serum (Invitrogen). SW620 were cultured in Dulbecco's modified Eagle's medium (Invitrogen), supplemented with 10% fetal calf serum. All cell lines were maintained in culture at 37°C in an atmosphere of 5% CO₂.

Cell proliferation and cell viability assays

The cytotoxic activity of α -mangostin was determined by cell proliferation analysis using MTT assays as previously described^[25]. Briefly, cells were cultured in 96-well plates at a density of 1×10^4 /well in complete medium. Then the cells were treated with varying concentrations of α -mangostin and incubated at 37°C for 24 h. The final DMSO concentration in each well was 0.05%, at which concentration no appreciable effect on cell proliferation was seen. Then, 100 μ L of 5.0 mg/mL MTT in culture media was added to each well and incubated at 37°C for 2 h. The metabolic product of MTT, formazan, in each well was dissolved in DMSO, and the absorbance was determined at 595 nm. Effect of α -mangostin on the viability of COLO 205 cells was analyzed by using a trypan blue exclusion method. Briefly, cells were cultured in 96-well plates at cell density of 1×10^4 /well at 37°C for 24 h. α -mangostin was then added to culture wells at 0, 10, 20,

30 and 40 $\mu\text{g}/\text{mL}$ or vehicle (in DMSO), incubated at 37°C then collected periodically (0, 3, 6, 9 and 12 h). The number of viable cells was determined with hemocytometers under a light microscope. Cell viability was expressed as a percentage of the number of viable cells to that of the control, to which no α -mangostin was applied.

Apoptosis assay

Characterization of the anticancer activity of α -mangostin in COLO 205 cells was further conducted. Based on the preliminary experiments, 20 $\mu\text{g}/\text{mL}$ of α -mangostin was used to study cell and nuclear morphology, cytochrome c release, mitochondrial transmembrane potential, expression of pro-apoptotic proteins, Fas and truncated-Bid (*t*-Bid). However, a selective range of test concentrations, ranging from 10 to 30 $\mu\text{g}/\text{mL}$ was used to study DNA fragmentation and for cell cycle analysis and annexin V-FITC assays.

Microscopic analysis of cell and nuclear morphology

COLO 205 cells were cultured in 24-well culture plates at the initial number of 2×10^4 /well in the presence of 20 $\mu\text{g}/\text{mL}$ α -mangostin for 3, 6, 9 and 12 h. As controls, cells were cultured in the same fashion in the absence of α -mangostin. The cells were examined under a phase-contrast inverted microscope (model CKX31/CKX41, Olympus) for cell morphology.

The nuclear morphology was analyzed by treatment of COLO 205 cells with 20 $\mu\text{g}/\text{mL}$ α -mangostin for 3, 6, 9 and 12 h. Control cells were grown in the same manner in the absence of α -mangostin. Cells were trypsinized and fixed with methanol. Then, cell nuclei were stained by treatment with 1 $\mu\text{g}/\text{mL}$ Hoechst 33342 (Sigma) at 37°C for 15 min in the dark. Stained cells were examined under a fluorescence inverted microscope (model BX50, Olympus).

Analysis of DNA fragmentation

COLO 205 cells were treated with varying concentrations, 10, 20 and 30 $\mu\text{g}/\text{mL}$, of α -mangostin for 12 h and then lysed in 500 μL of lysis solution, consisting of 5 mmol/L Tris-Cl (pH 8.0), 0.5% Triton X-100, and 20 mmol/L ethylenediaminetetraacetic acid (EDTA). The cells were then treated with RNase A (0.5 mg/mL) for 1 h at 37°C. DNA fractions were prepared using phenol-chloroform-isoamyl alcohol (25:24:1) and electrophoresed on 1.8% agarose gels. Approximately 20 μg of DNA was loaded in each well and the agarose gels were run at 50 V for 2 h in Tris-borate/EDTA electrophoresis buffer. DNA was stained with ethidium bromide and visualized under a UV light trans-illuminator and photographed.

Flow cytometer analysis

The cell cycle analysis, annexin V binding and mitochondrial transmembrane potential were investigated by flow cytometric analysis (FACScan, Becton Dickinson). The proper filters and optimal setting of the instrument were chosen, the histograms generated by FACS were analyzed by Cell Quest™ software (Becton Dickinson).

Cell cycle analysis using flow cytometer

COLO 205 cells were cultured in 6-well culture plates at 4×10^6 cells/well and treated with 0, 10, 20 and 30 $\mu\text{g}/\text{mL}$ of α -mangostin for 3 h. The cells were then harvested, washed with PBS and resuspended in 200 μL PBS and fixed in 800 μL of ice-cold 70% ethanol at -20°C, overnight. The cells were stained with 1 mL of 50 $\mu\text{g}/\text{mL}$ propidium iodide solution (containing 0.1% Triton X-100, and 0.1% sodium citrate) for 30 min at 37°C. The samples were then analyzed by a flow cytometer (FACScan, Becton Dickinson). Excitation was done at 488 nm, and emission filter at 600 nm. Histograms generated by FACS were analyzed by Cell Quest™ software (Becton Dickinson) to determine the percentage of cells in each phase.

Annexin V-FITC assay

Percentage of α -mangostin-treated cells undergoing apoptosis was determined using an annexin V-fluorescein isothiocyanate (FITC) apoptosis detection kit (BD Bioscience, San Jose, CA). COLO 205 cells at 1×10^5 cells/mL were treated with 0, 10, 20 and 30 $\mu\text{g}/\text{mL}$ of α -mangostin for 3 h and resuspended in 100 μL of annexin V binding buffer (10 mmol/L HEPES, 150 mmol/L NaCl, 5 mmol/L KCl, 1 mmol/L MgCl₂, 1.8 mmol/L CaCl₂), then incubated with 5 μL of 1 $\mu\text{g}/\text{mL}$ FITC-conjugated annexin V and 1 $\mu\text{g}/\text{mL}$ propidium iodide for 15 min at room temperature prior to analysis on a FACScan, Becton Dickinson.

Analysis of mitochondrial transmembrane potential

COLO 205 cells at 1×10^6 cells/mL were treated with 20 $\mu\text{g}/\text{mL}$ of α -mangostin for 3 h, and then incubated with 10 $\mu\text{g}/\text{mL}$ JC-1 (5,5',6,6'-tetrachloro-1,1',3,3'-tetraethylbenzimidazolcarbocyanine iodide) at 37°C for 10 min in darkness. Stained cells were washed with PBS, followed by FACS analysis. The mitochondrial function was assessed as JC-1 green (uncoupled mitochondria) or red (contact mitochondria).

Western blotting analysis of cytochrome c

COLO 205 cells were cultured in 6-well culture plates at 4×10^6 cells/well and then incubated in the absence or presence of 20 $\mu\text{g}/\text{mL}$ α -mangostin for 3, 6, and 9 h. Cell lysates was prepared as previously described^[25]. Briefly, cell suspensions were sonicated for 10 s and the cell lysates was centrifuged at 4°C at $10000 \times g$ for 30 min. The supernatants (cytosol fractions) were subjected to SDS-PAGE using 12% polyacrylamide gels, and transferred onto Immobilon P membrane and subjected to immuno-detection of cytochrome c using a mouse monoclonal antibody against human cytochrome c (7H8, mouse monoclonal Ig G 2b, Santa Cruz, Biotechnology) with goat anti-mouse IgG conjugates to horse radish peroxidase (Cell Signaling Technology) and detected using an ECL Plus Western Blotting Detection System (Amersham Biosciences).

Western blotting analysis of caspases, Bid, p53, Bax, Bmf and Fas

COLO 205 cells were treated with 20 $\mu\text{g}/\text{mL}$ α -mangostin

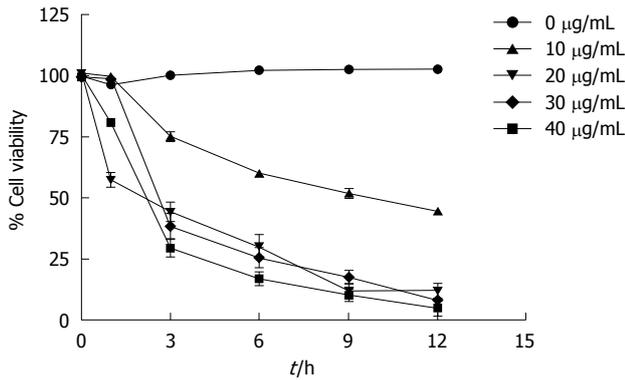

Figure 1 Effect of α -mangostin on the viability of COLO 205 cells. Different concentrations of α -mangostin (0–40 $\mu\text{g}/\text{mL}$) at different incubation times were studied. Cell viability is expressed as a percentage of the number of viable cells to that of the control, to which no α -mangostin was applied. Each data point shown is the mean \pm SD from three independent experiments.

for 3 h, lysed in lysis buffer. Cell lysates were subjected to SDS-PAGE using 12% Tris/HCl ready gels (BioRad). The transferred proteins were incubated with appropriate antibodies at 4°C overnight: rabbit polyclonal anti-caspase-3 (8G10); mouse polyclonal anti-caspase-8 (1C12); mouse monoclonal anti-caspase-9 (C9); rabbit polyclonal anti-Bid; mouse monoclonal anti-p53; rabbit polyclonal anti-Bax, anti-Bmf (Cell Signaling Technology) and mouse monoclonal anti-Fas (CD 95) (CH 11, MBL international). After the removal of unbound primary antibodies, the blots were incubated with a secondary antibody (goat anti-rabbit IgG and goat anti-mouse IgG, each of which was conjugated with horse radish peroxidase; (Cell Signaling Technology) as described for Western blotting analysis of cytochrome c above.

Statistical analysis

Data were expressed as mean \pm SD. Statistical comparisons were performed by using one-way analysis of variance. A *P* value less than 0.05 was considered statistically significance.

RESULTS

Cell growth inhibition by α -mangostin

The IC_{50} value of the three human colonic cancer cell lines, after 24 h incubation with serial dilutions of α -mangostin, COLO 205, MIP-101 and SW 620 were $9.74 \pm 0.85 \mu\text{g}/\text{mL}$, $11.35 \pm 1.12 \mu\text{g}/\text{mL}$ and $19.6 \pm 1.53 \mu\text{g}/\text{mL}$, respectively. Among the three cell lines tested, the highest inhibitory effect of α -mangostin on cell proliferation was detected with COLO 205. Thus, COLO 205 cells were used as the primary target in subsequent experiments.

The viability of COLO 205 cells decreased by the treatment with α -mangostin in both concentration- and time-dependent fashions (Figure 1). Treatment of COLO 205 cells with α -mangostin at 20 $\mu\text{g}/\text{mL}$ or higher for 12 h reduced the number of viable cells to approximately 5%–10% of the control cells, to which no α -mangostin was applied.

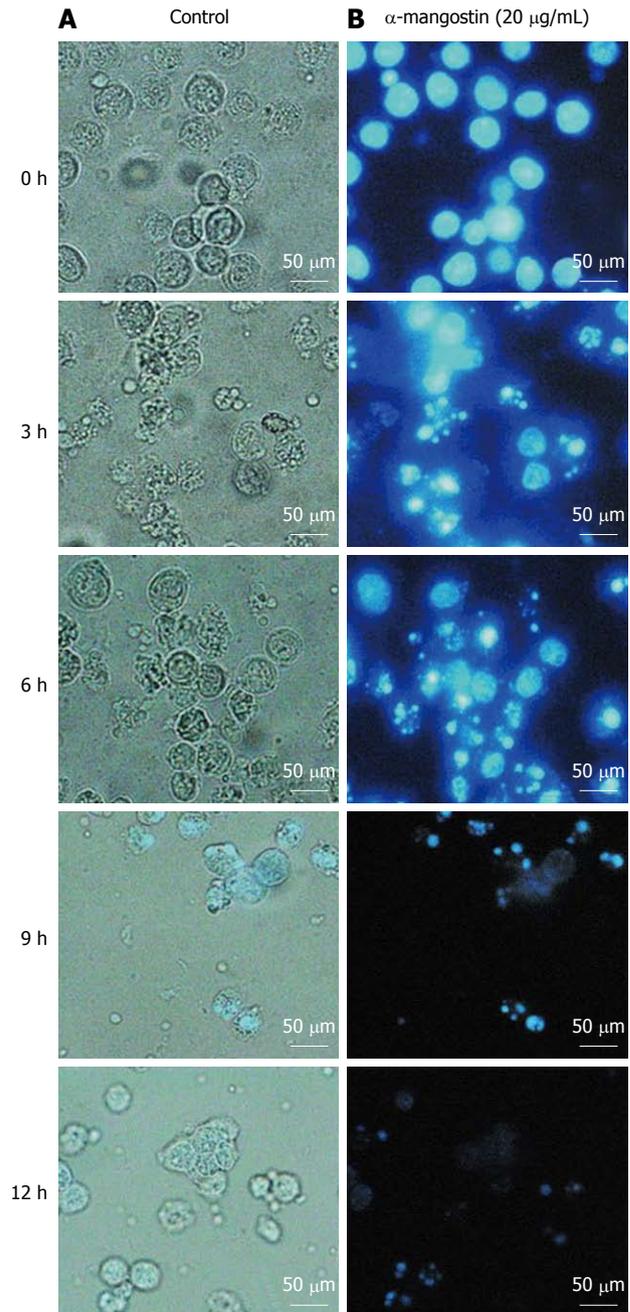

Figure 2 Effect of α -mangostin on the cell morphology and nuclear condensation of COLO 205 cells. A: Untreated control cells were examined for cell morphology and Hoechst 33342 stained cells were examined for nuclei morphology; B: Cells were cultured for 0, 3, 6, 9 and 12 h in the presence of 20 $\mu\text{g}/\text{mL}$ α -mangostin.

Morphological and nuclei changes

Cells treated with 20 $\mu\text{g}/\text{mL}$ α -mangostin for 3, 6, 9 and 12 h showed evident morphological changes including rounding and blebbing as well as the presence of apoptotic bodies (Figure 2A, 3, 6, 9 and 12 h). Such morphological changes were not seen with control cells (without the α -mangostin treatment) (Figure 2A, 0 h). For nuclei staining with Hoechst 33342, chromatin condensation and destructive fragmentation of the nucleus with intact cell membrane was seen with COLO 205 cells which had been

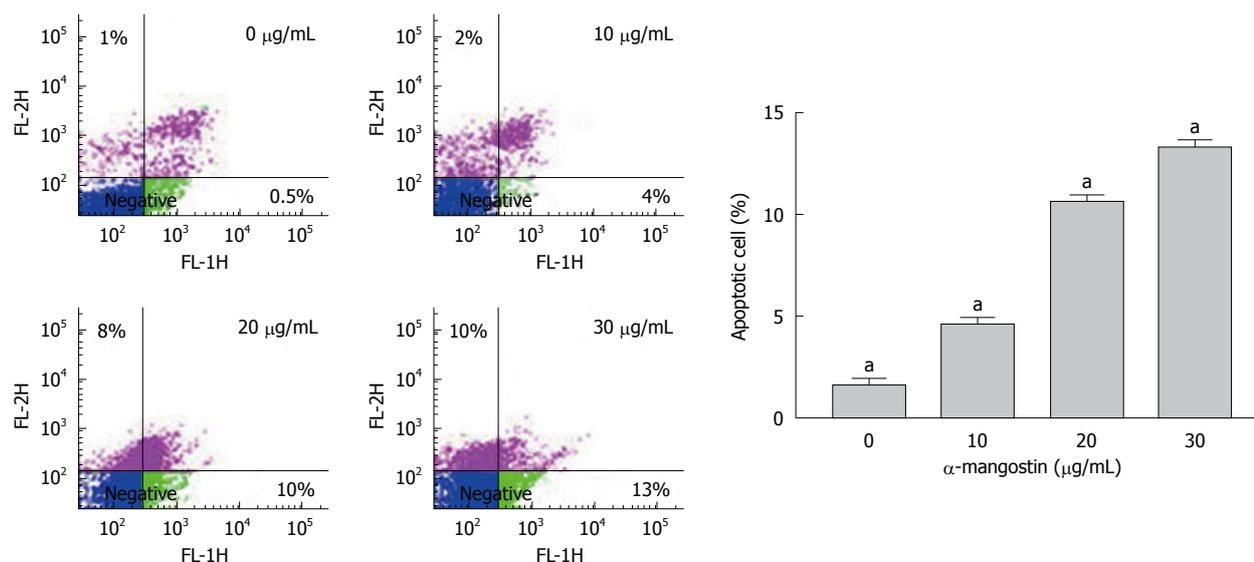

Figure 3 Fluorescent-activated cell sorter analysis of COLO 205 cells stained with Annexin V-FITC. Cells were treated with 10, 20 and 30 µg/mL α-mangostin for 3 h. α-mangostin induced early apoptosis in a concentration dependent manner. The values are expressed as mean ± SD; ^a $P < 0.05$.

treated with 20 µg/mL of α-mangostin for 3, 6, 9 and 12 h (Figure 2B, 3, 6, 9 and 12 h), indicated early apoptosis while the nuclei of control cells without α-mangostin treatment showed normal morphology (Figure 2B, 0 h).

α-mangostin mediated apoptotic cell death

The early apoptosis was detected upon treatment of COLO 205 cells with 0, 10, 20 and 30 µg/mL of α-mangostin for 3 h using Annexin V-FITC assay. The results indicated significant increases in apoptotic populations in COLO 205 cells approximately 0.50% ± 0.02%, 4.00% ± 0.25%, 10.00% ± 0.50% and 13.00% ± 0.30%, ($P < 0.05$) respectively (Figure 3). Exposure of COLO 205 cells to increasing concentrations (0, 10, 20 and 30 µg/mL) of α-mangostin for 3 h resulted in increased percentage of cells arrested in sub G-1 phase (apoptotic cell death) of 1.03% ± 0.15%, 7.00% ± 0.20%, 51.00% ± 1.53% and 80.00% ± 2.08% ($P < 0.05$), respectively (Figure 4). It is evident that the formation of apoptotic cells at sub-G1 phase was directly proportional to the increased concentration of α-mangostin.

Fragmentation of chromosomal DNA

Fragmentation of genomic DNA was apparent by the presence of DNA ladders when COLO 205 cells were treated with 10, 20 and 30 µg/mL α-mangostin for 12 h (Figure 5). The characteristic ladder pattern of discontinuous DNA fragments was observed only in the treated cells, whereas the untreated control showed no DNA fragmentation.

Activation of caspases upon α-mangostin treatment

The activation of caspases-3, -8 and -9 was detected (Figure 6). The amount of the pro-enzyme form of caspase-3 (pro-caspase-3, 35 kDa), pro-caspase-8 (57 kDa) and pro-caspase-9 (47 kDa) decreased with increasing concentration of α-mangostin (10, 20, 30 and 40 µg/mL).

Accordingly, cleaved activated forms of caspase-3 (19 and 20 kDa), caspase-8 (41 and 43 kDa) and caspase-9 (35 and 37 kDa) ($P < 0.01$) became apparent upon treatment of α-mangostin at 20 µg/mL or higher. Activated caspase-3 was apparent upon treatment with 20 µg/mL α-mangostin but not at higher concentrations (30 and 40 µg/mL α-mangostin) due to cell death at higher concentrations, as the effector caspase-3 is the late event of the pathways. On the other hand, caspase-8 and -9 were also detected implying the consecutive activation of caspases of the intrinsic pathway. In addition, induction of apoptosis by α-mangostin was accompanied by increased phospho-p53, pro-apoptotic Bax and Bmf ($P < 0.01$) (Figure 7). The release of cytochrome c from mitochondria to cytosol was evident upon treatment of COLO 205 cells with 20 µg/mL α-mangostin for 3 h and 6 h (Figure 8). The non-cytosolic fraction (pellet) of the treated cells showed no cytochrome c expression (data not shown). At 9 h of α-mangostin treatment, cytochrome c was reduced due to increasing cell death. No appreciable amount of cytochrome c was detected in the cytosol fraction of control COLO 205 cells, to which no α-mangostin was applied (Figure 8). This implied that α-mangostin mediated apoptosis is accompanied by mitochondrial dysfunction, which could be further strengthened by mitochondrial membrane depolarization detected by a carbocyanine fluorescence dye, JC-1, upon treatment with α-mangostin. The results indicated the increased percentage of cells with depolarized mitochondrial membrane potential (red to green) approximately 82% after α-mangostin treatment for 3 h (Figure 9). These results further confirmed that α-mangostin is an efficient inducer of apoptosis that both extrinsic and intrinsic pathway may be involved. Thus, we further conducted the Western blotting analysis of Bid, t-Bid, the linker between extrinsic and intrinsic pathway, and Fas receptor and found that they were up-regulated upon α-mangostin treatment ($P < 0.01$) (Figure 7).

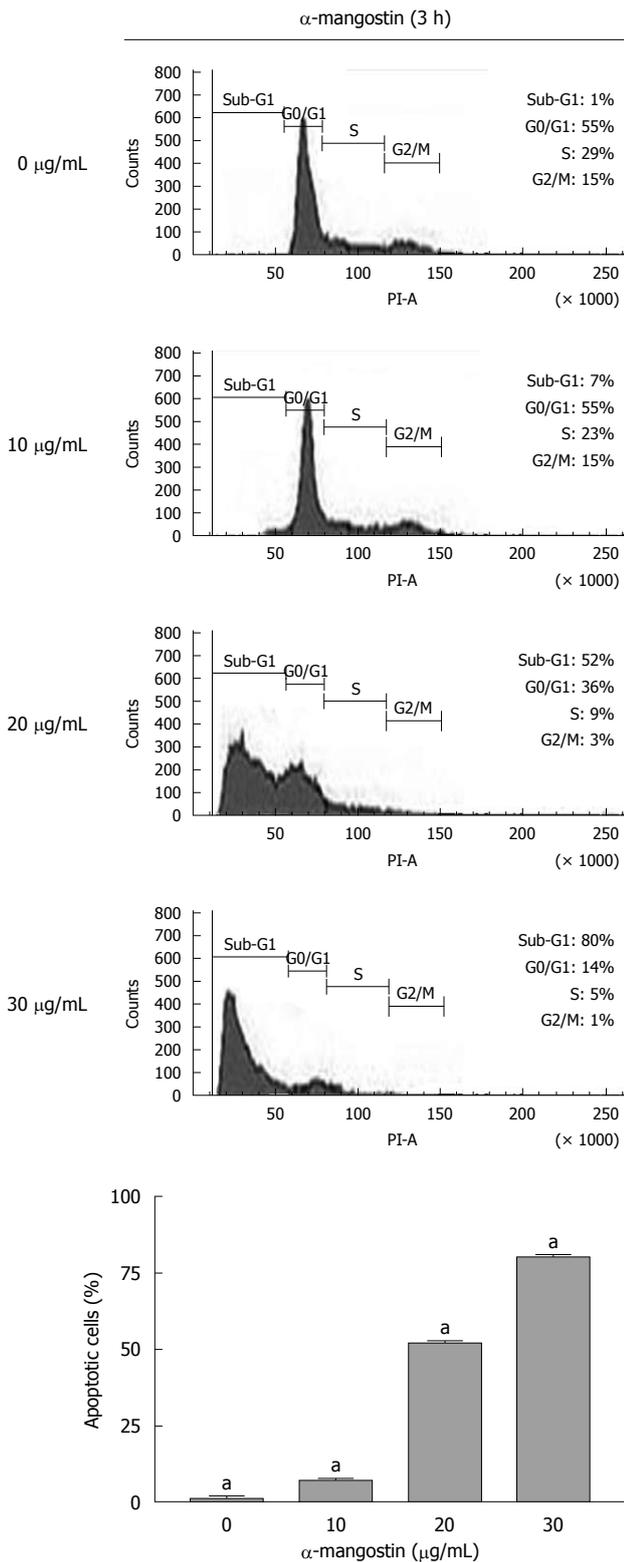

Figure 4 Flow analysis of cell cycle. Representative plots of PI staining of COLO 205 cells that were treated with 0 (control), 10, 20 and 30 µg/mL α-mangostin for 3 h. The values are expressed as mean ± SD; **P* < 0.05.

DISCUSSION

The evident goal of medical research is to be able to manipulate the machinery of cell death. Regulation of apoptosis might also lead to new possibilities for cancer ther-

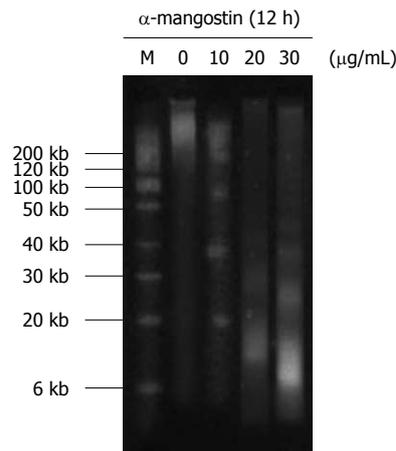

Figure 5 Analysis of DNA integrity in COLO 205 cells upon treatment with α-mangostin. COLO 205 cells were treated with varying concentrations of α-mangostin (10, 20 and 30 µg/mL) for 12 h. Cells were lysed, followed by phenol-chloroform extraction. DNA fractions were then electrophoresed on 1.8% agarose gels. DNA was stained with ethidium bromide and visualized under a UV light trans-illuminator.

apy^[26]. In the present study, we showed that α-mangostin treatment of human colon COLO 205 induced cytotoxic effects in a dose and time dependent fashion. We then investigated the apoptotic effects of α-mangostin in COLO 205 cells to advance our knowledge of its biological functions and also health advantages. The membrane shrinkage, chromatin condensation and fragmentation were detected. As cancer growth is associated with the loss of cell cycle checkpoints, which regulate the DNA integrity and ensure that the genes are co-ordinately expressed^[27]. The sub-G1 fraction and phosphatidylserine translocation is an indication of apoptosis cell death that naturally occurs in cells and is beneficial for cancer therapy^[28]. Therefore, to characterize apoptotic cells upon treatment of COLO 205 cells with α-mangostin, a bi-parametric cytofluorimetric analysis was performed using PI and annexin V-FITC, which stained DNA and phosphatidylserine residues, respectively. In the early apoptotic process, a phosphatidylserine residue became exposed on the cell surface by flipping from the inner to outer leaflet of the cytoplasmic membrane^[29,30]. Our results demonstrated the increased sub-G1 population and numbers of early apoptotic cells upon treatment of COLO 205 cells with 20 µg/mL α-mangostin for 3 h as compared to untreated control. The Bcl-2 family of proteins regulates apoptosis and it has been shown that the gene products of Bcl-2 and Bax play important roles in apoptotic cell death^[14]. The Bcl-2 family comprises of both pro-apoptotic and anti-apoptotic proteins that elicit opposite effects on mitochondria. Anti-apoptotic members include Bcl-2, Bcl-xL, Bcl-W, Mcl-1, whereas pro-apoptotic members are Bid, Bax, Bakm, Bmf and others. Several pathways involve p53-mediated apoptosis, and one of these is the Bcl-2 and Bax proteins. The Bax protein is a p53 target and known to promote cytochrome c release from mitochondria which in turn activates caspase-3. Regulation of Bax/Bcl-2 and caspases activity becomes impor-

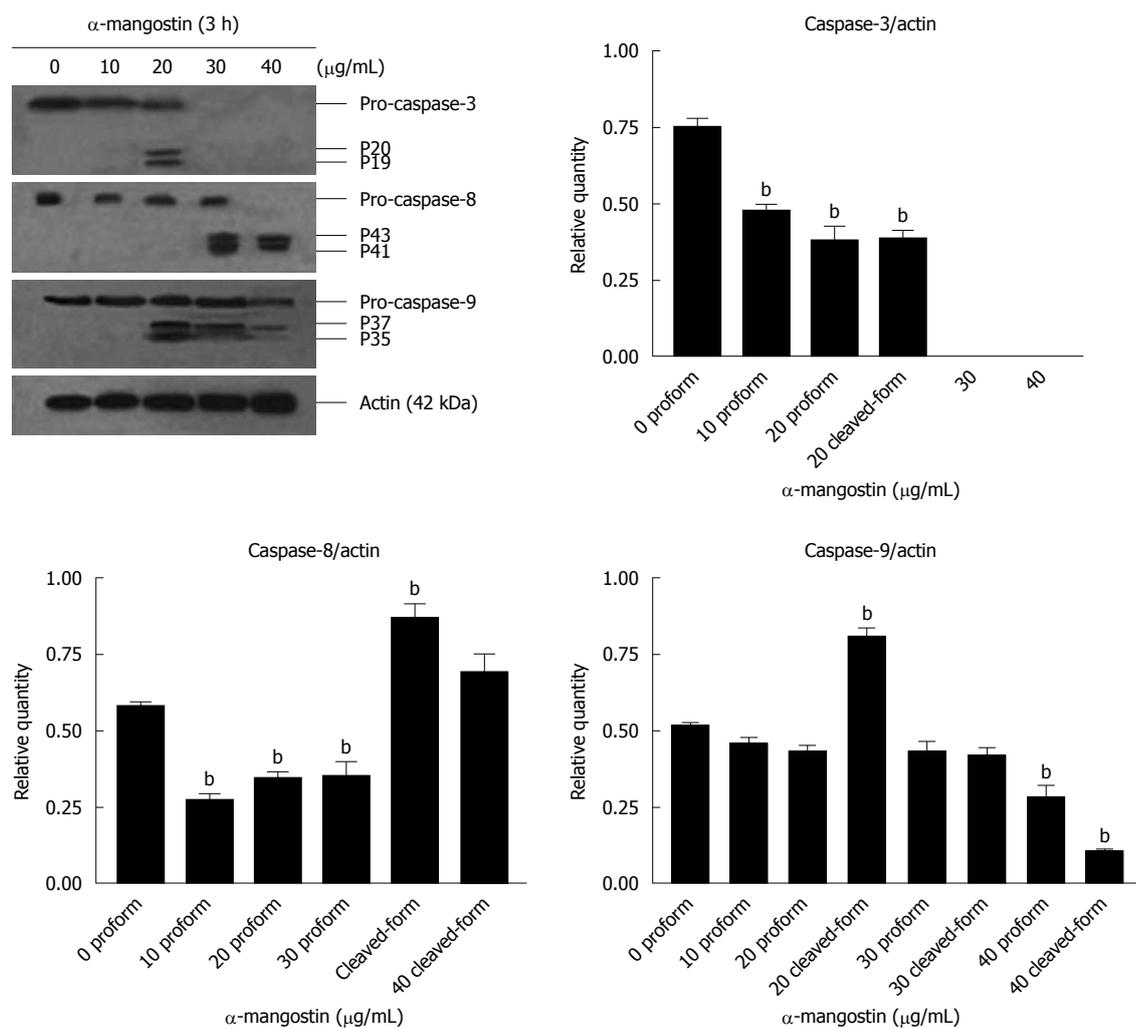

Figure 6 Effects of α -mangostin on the activation of caspase-3, -8 and -9 in COLO 205 cells. Cells were treated with 10, 20, 30 and 40 $\mu\text{g/mL}$ α -mangostin for 3 h. Cell lysates were separated by SDS-PAGE using 12% polyacrylamide gels. Proteins were subjected to immuno-detection of caspases-3, -8, and -9 using appropriate anti-caspase antibodies at 4°C. The expression of cleaved-caspase-3, -8 and -9 were detected. The density of each band was determined, equal protein loading was verified by β -actin staining. The values are expressed as mean \pm SD; ^b $P < 0.01$.

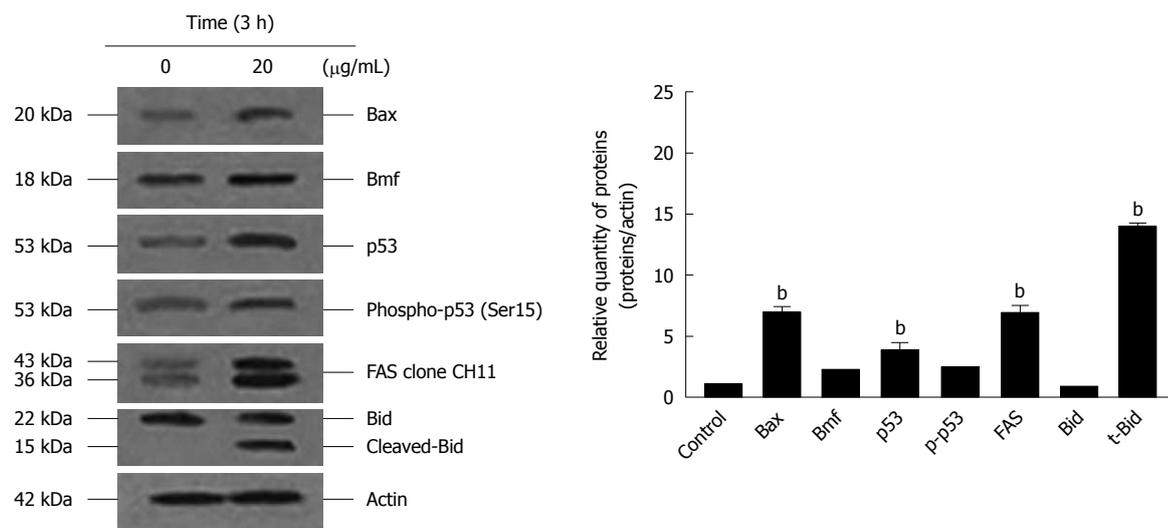

Figure 7 Effects of α -mangostin on the activation of Bax, Bmf, p53, Fas and Bid. Cells were treated with 20 $\mu\text{g/mL}$ α -mangostin for 3 h. Cell lysates were separated by SDS-PAGE using 12% polyacrylamide gels. Proteins were subjected to immuno-detection of Bax, Bmf, p53, p-p53, Fas, Bid and t-Bid using appropriate antibodies. The density of each band was determined, equal protein loading was verified by β -actin staining. The values are expressed as mean \pm SD; ^b $P < 0.01$.

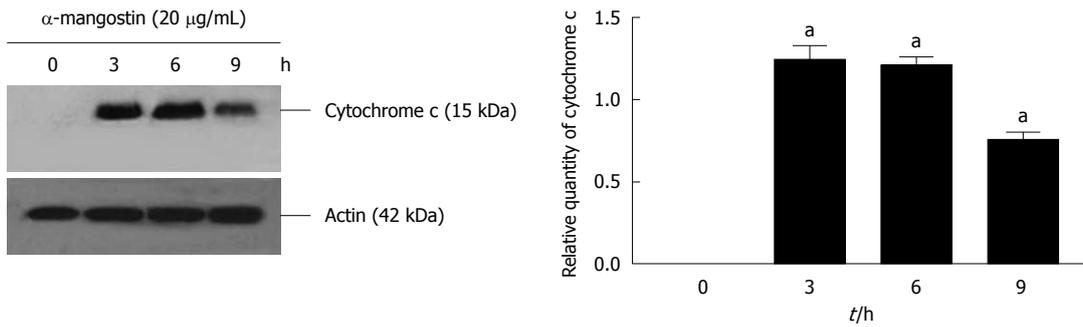

Figure 8 Release of cytochrome c from the mitochondria in COLO 205 cells. Upon treatment with 20 µg/mL α-mangostin for 3, 6 and 9 h, cytosol fractions were prepared from these cells and separated by SDS-PAGE using 12% polyacrylamide gels. Proteins were subjected to immuno-detection of cytochrome c using a mouse monoclonal antibody against human cytochrome c. The density of each band was determined, equal protein loading was verified by β-actin staining. The values are expressed as mean ± SD; ^a*P* < 0.05.

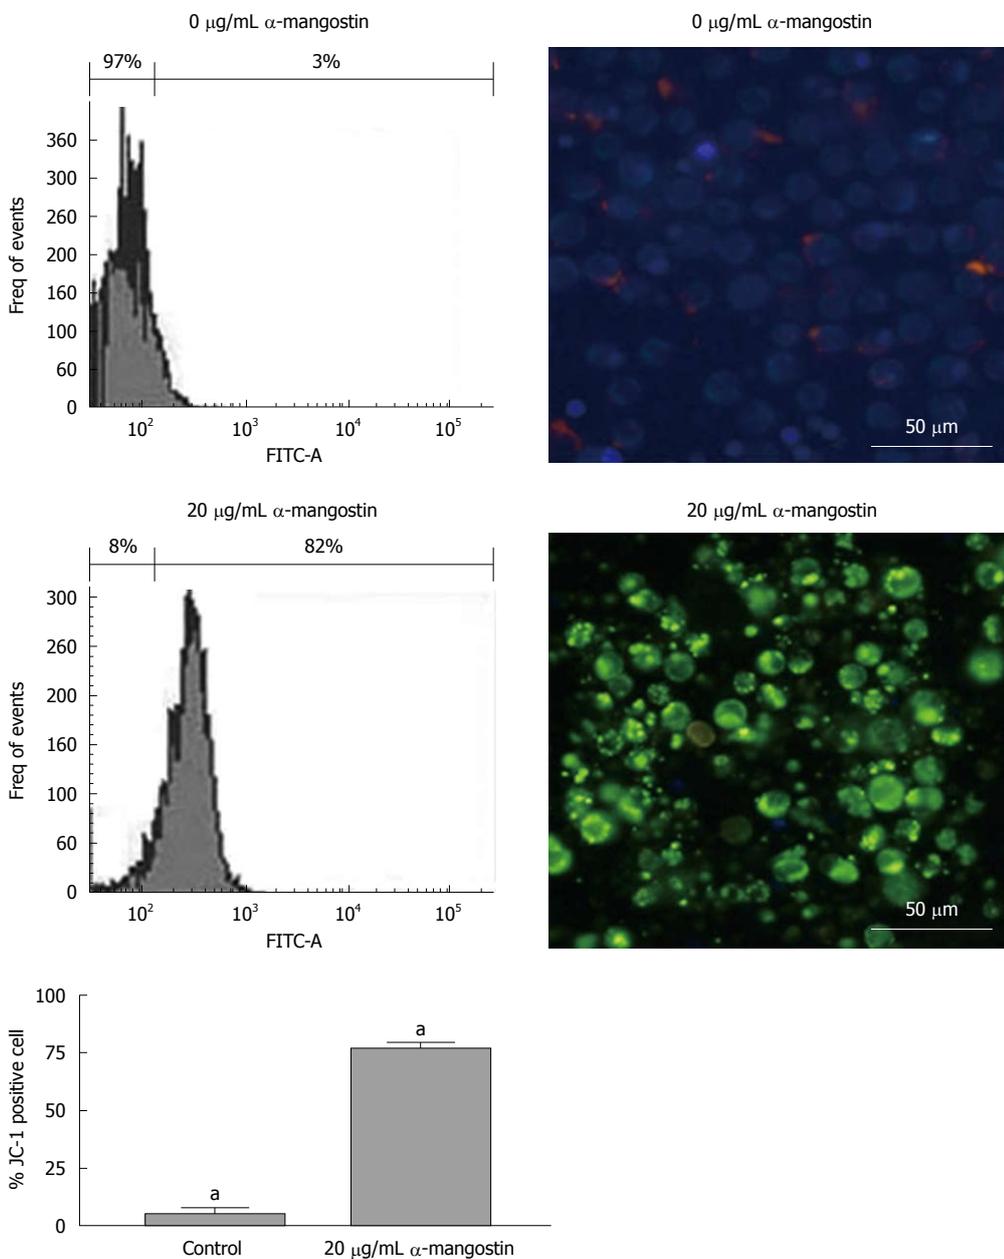

Figure 9 Measurements of mitochondrial membrane depolarization in COLO 205 cells. Cells were treated with 0 (control) and 20 µg/mL α-mangostin for 3h and then incubated with JC-1 (10 µg/mL in PBS) at 37°C for 10 min. Stained cells were subjected to FACS analysis. The mitochondrial function was assessed as JC-1 green. The values are expressed as mean ± SD; ^a*P* < 0.05.

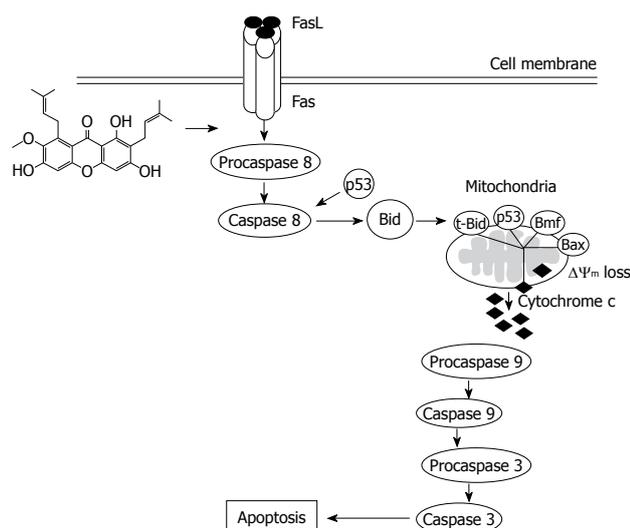

Figure 10 A proposed diagram for α -mangostin-induced apoptosis in COLO 205 cells. Upon α -mangostin treatment, extrinsic pathway was activated, procaspase-8 was cleaved to caspase-8 which then further activated the cleavage of Bid to t-Bid. The t-Bid then translocates to mitochondria resulting in the activation of mitochondrial apoptotic pathway.

tant targets for cancer intervention. Caspase-3 being the major executioner caspase^[31], thus we examined whether activated caspase-3, -8 and -9 is involved in apoptotic induction and found evident expression of activated caspase-3, -8 and -9.

Under the influence of α -mangostin treatment in COLO 205 cells, a cell death pathway both *via* death receptor pathway and mitochondrial pathway may be involved, as caspase-8 and -9 were expressed. We further demonstrated the loss of mitochondrial membrane potential, release of cytochrome c into the cytosol and DNA fragmentation. Our results are in agreement with a study showing that apoptosis was associated with a loss of mitochondrial membrane potential, which may correspond to the opening of an outer membrane pore, leading to cytochrome c release from mitochondria into the cytosol. The released cytochrome c later triggered the cleavage and activation of caspases and onset of apoptosis^[32]. The expression of Fas and caspase-8 implies the death receptor pathway, while regulation of mitochondrial membrane permeability by upregulation of Bax and p-Bad triggering the release of cytochrome c from mitochondria to cytosol. Our further investigation showed the expression of Fas, Bid, t-Bid, p-53, phospho-p53 and the proteins in Bcl-2 family (Bax and Bmf). Expression of t-Bid is the important linkage between death receptor and mitochondrial pathway. When Bid is cleaved into t-Bid by the activated caspase-8 and translocated towards the mitochondria to activate Bax and Bak, then changing the mitochondrial membrane permeability and the release of cytochrome c^[33] which form a complex with apoptotic enzyme activators and caspase-9. It activates and starts a caspase cascade reaction, which further activates the downstream caspase-3 and other caspase family members for apoptosis induction. We also noticed that α -mangostin

up-regulated the expression of Bax in COLO 205 cells at protein level, suggesting that Bcl-2 family protein regulate α -mangostin mediated apoptotic cell death.

Taken together our results evaluating the molecular mechanism that α -mangostin induced apoptosis cell death in COLO 205 cells may occur *via* caspase-8 dependent cleavage of Bid to tBid providing a link between extrinsic and intrinsic pathways (Figure 10). This could be a promising chemotherapeutic agent and may also serve as a model to develop and design new derivatives which may be more potent.

COMMENTS

Background

Cancer causes significant morbidity and mortality and is a major public health problem worldwide. Globally, colorectal cancer is one of the most common types of cancer in both men and women. Phytochemical studies showed that a variety of tropical plants have useful biological activities and some offer potential therapeutic applications. However, the molecular mechanisms underlying α -mangostin induced apoptosis in human colorectal adenocarcinoma have not yet been fully understood.

Research frontiers

Apoptosis plays a vital role in controlling cell number in many physiological and developmental stages, tissue homeostasis, and regulation of the immune system, while insufficient apoptosis is an integral part of cancer development. The main function of apoptosis is to dispose of a cell without causing damage or stress to neighbouring cells. Thus, the anti-cancer drug that induces apoptotic cell death would be more suitable for use in patients and should be further developed. Therefore, the effect of α -mangostin on the growth and apoptosis induction of human colon cancer cells was investigated in this study.

Innovations and breakthroughs

The results showed that α -mangostin induced apoptotic cell death in COLO 205 cells indicating by membrane blebbing, chromatin condensation, DNA fragmentation, cell cycle analysis, sub-G1 peak, and phosphatidylserine exposure. The expression of caspase-3, caspase-8 and caspase-9, cytochrome c release, Bax, p53 and Bcl-2 modifying factor (Bmf) as well as reduced mitochondrial membrane potential were demonstrated. In addition, upon treatment with α -mangostin, up-regulation of tBid and Fas were evident. Therefore, α -mangostin may be effective as an anti-cancer agent that induces apoptotic cell death in COLO 205 *via* a link between extrinsic and intrinsic pathways.

Applications

α -mangostin could be used as a future promising anti-cancer agent for the treatment of colorectal adenocarcinoma cells.

Terminology

The fruit hull of mangosteen (*Garcinia mangostana* L.) in the Clusiaceae family is rich in a variety of oxygenated and prenylated xanthenes which possess different biological properties, such as anti-mycobacterial, anti-fungal, anti-oxidant, cytotoxicity and anti-inflammatory activities.

Peer review

In this study the authors examined the effect of α -mangostin on the growth and apoptosis induction of human colon cancer cells. They showed that α -mangostin induced apoptotic cell death in COLO 205 cells, activated caspase-3, -8, and -9, increased the mitochondrial cytochrome c release, Bax, p53 and Bmf, reduced mitochondrial membrane potential, and up-regulated tBid and Fas. From these results, the authors suggested that α -mangostin may be effective as an anti-cancer agent *via* a link between extrinsic and intrinsic pathways. It is interesting that the authors clearly showed the mechanism through which α -mangostin induced apoptosis in colon cancer cells.

Abstract

AIM: To evaluate the usefulness of differentially expressed proteins from colorectal cancer (CRC) tissues for differentiating cancer and normal tissues.

METHODS: A Proteomic approach was used to identify the differentially expressed proteins between CRC and normal tissues. The proteins were extracted using Tris buffer and thiourea lysis buffer (TLB) for extraction of aqueous soluble and membrane-associated proteins, respectively. Chemometrics, namely principal component analysis (PCA) and linear discriminant analysis (LDA), were used to assess the usefulness of these proteins for identifying the cancerous state of tissues.

RESULTS: Differentially expressed proteins identified were 37 aqueous soluble proteins in Tris extracts and 24 membrane-associated proteins in TLB extracts. Based on the protein spots intensity on 2D-gel images, PCA

by applying an eigenvalue > 1 was successfully used to reduce the number of principal components (PCs) into 12 and seven PCs for Tris and TLB extracts, respectively, and subsequently six PCs, respectively from both the extracts were used for LDA. The LDA classification for Tris extract showed 82.7% of original samples were correctly classified, whereas 82.7% were correctly classified for the cross-validated samples. The LDA for TLB extract showed that 78.8% of original samples and 71.2% of the cross-validated samples were correctly classified.

CONCLUSION: The classification of CRC tissues by PCA and LDA provided a promising distinction between normal and cancer types. These methods can possibly be used for identification of potential biomarkers among the differentially expressed proteins identified.

INTRODUCTION

Proteomic research has made great achievements in biomarker discovery, especially when incorporated with high-

throughput analytical tools and technology, for example 2D-PAGE and LC-MS/MS^[1]. Two-dimensional gel electrophoresis is a fundamental tool for protein analysis to detect alterations in protein expression between control and disease states of cells, which can lead to the discovery of various biomarkers that contribute to pathogenesis or carcinogenesis^[2]. Biomarkers can be used to discriminate variables for subsequent classification of normal and diseased groups^[3]. The complexity of variables generated by mass spectra, microarray and immunohistochemistry often requires advanced statistical techniques or chemometrics to evaluate their clinical value.

Multivariate analyses including the dimension reduction method known as principal component analysis (PCA), and classification methods such as linear discriminant analysis (LDA) are often employed in proteomic studies. PCA reduces the number of variables for further data analysis and interpretation while identifying the variables that retain most of the data variance^[4]. A principal component (PC) is defined as a new variable to explain the maximum amount of variance in the original data and corresponds to a linear combination of the original variables. PCs are presented orthogonally to each other, which provides a more effective representation of the data than the original variables^[2]. LDA is a multivariate technique to classify observations into groups or categories. LDA forms new variables from the original data and identifies the variables that provide the best discrimination between the groups^[5].

Djidja *et al.*^[6] have used a novel approach that combines matrix-assisted laser desorption ionization-ion mobility separation-mass spectrometry (MALDI-IMS-MS) and PCA-discriminant analysis (PCA-DA) to generate tumor classification models based on pancreatic cancer protein patterns. Furthermore, Kamath *et al.*^[7] have used PCA-based k-nearest neighbor analysis to classify normal and cancerous autofluorescence spectra of colonic mucosal tissues. Zwielly *et al.*^[8] have investigated the use of Fourier transform infrared microscopy for colon cancer diagnosis. Their model uses PCA to define spectral changes among normal and cancerous human biopsied colon tissues. Ragazzi *et al.*^[9] have reported the use of multivariate techniques on plasma proteins to diagnose colorectal cancer (CRC). The plasma protein profile generated by MALDI-MS is analyzed by PCA and LDA to discriminate ionic species from normal subjects and CRC patients.

In this study, we carried out the comparison of 2-D images of cancerous and normal colorectal tissues. The differentially expressed proteins from Tris and thiourea lysis buffer (TLB) extractions were respectively tested on a PCA-LDA model to find out the possibility of using protein expression to classify the disease and non-disease tissues of CRC.

MATERIALS AND METHODS

Tissue specimen collection

Matching pairs of normal colonic mucosa and cancerous colonic tissue (located 10 cm from each other) from 26

CRC patients were collected after surgery at the Penang General Hospital, Penang, Malaysia. The study was approved by the Human Ethical Committee of Universiti Sains Malaysia. Informed written consent was received from all patients before the study was conducted. Prior to surgery, the patients did not receive preoperative neoadjuvant chemotherapy and radiotherapy. The tissues were confirmed as cancerous and normal, respectively, by the hospital's pathologist. The cancerous tissues were classified using the TNM system. Surgically removed samples were stored at -80°C until use.

Protein analysis

The method of protein analysis was as described in Yeoh *et al.*^[10]. Frozen tissue (250 mg) was rinsed in distilled water to remove cell debris and excess blood. The tissues were homogenized in ice-cold Tris buffer (0.5 g tissue/mL buffer) [40 mmol/L Tris and 1 × Protease Inhibitor Cocktail (Sigma, St Louis, MO, USA)] and centrifuged at 12000 rpm for 15 min at 18°C. The supernatant was recovered and labeled as Tris extract. The pellet was subjected to further extraction using TLB (1 g tissue/1 mL buffer) [8 mol/L urea, 2 mol/L thiourea, 4% (w/v) CHAPS, 0.4% (w/v) carrier ampholytes and 50 mmol/L dithiothreitol] and centrifuged at 12000 rpm for 15 min at 18°C. The supernatant was recovered and labeled as TLB extract. The extracts were subjected to 2D gel separation on 11 cm ReadyStrip™ IPG strip (linear pH 4-7, Bio-Rad, USA) followed by separation on 10% (w/v) PAGE at a constant voltage of 200 V. The gels were stained with Coomassie Blue. The images obtained were analyzed by PDQuest version 7.3 (Bio-Rad). Comparison of the protein expression levels was carried out between cancerous and normal tissues. Differentially expressed proteins were defined as proteins with a spot intensity that was 1.5-fold higher or lower in cancerous tissues when compared to that in the corresponding normal tissues. A differentially expressed protein was defined as upregulated when it was found at greater intensity in cancerous tissue than in the corresponding normal tissue. The downregulated proteins were detected at greater intensity in normal tissues than in the corresponding CRC cancerous tissues.

Protein identification

The differentially expressed proteins were excised from the gel and subjected to in-gel digestion using trypsin and the tryptic peptides were analyzed by LC/MS/MS using an electrospray ionization ion trap mass analyzer (Agilent Technologies, Santa Clara, CA, USA). The MS/MS data were subjected to the MASCOT protein database search engine for protein identification. The identities of a few proteins (dependent on the availability of antibodies) were further confirmed using western blotting.

Statistical analysis

The differential expression of the proteins was tested by the paired Student's *t* test that is included in PDQuest, to determine their statistical significance ($P < 0.05$). For

MD: Moderately differentiated adenocarcinoma.

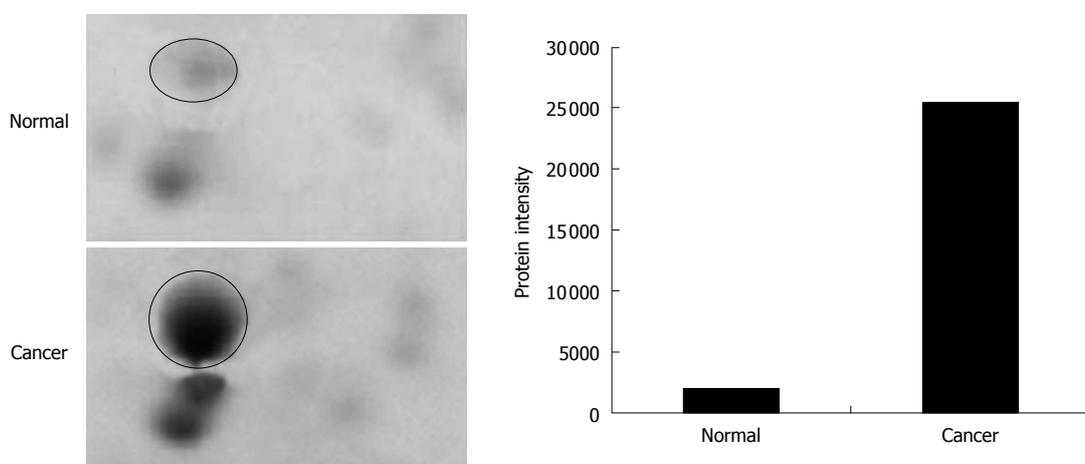

Figure 1 Comparison of protein spot intensity between normal and colorectal cancer tissues for glutathione S-transferase P.

PCA and LDA, the protein spot intensities were exported out from PDQuest and imported into SPSS version 15.0 (Chicago, IL, USA) to perform multivariate analyses. Protein spot intensities were used as variables.

RESULTS

The tissues specimens from each patient were collected in pairs of cancerous and normal tissues. Table 1 shows the details of the tissues used in the analysis. The tissues were subjected to a sequential extraction method to extract aqueous soluble proteins and membrane-associated proteins in two different fractions using Tris and TLB, respectively. Tables 2 and 3 show the 37 and 24 differentially expressed proteins identified in Tris and TLB extracts, respectively. The average fold change indicates the degree of differentiation in expression levels of the protein in cancerous tissues compared to normal tissues in all the patients tested, where a positive sign indicates a greater expression level in cancerous tissues, whereas a negative sign indicates a greater expression level in normal tissues. The MOWSE score refers to the score values given by the MASCOT search. Tables 4 and 5 show the mean intensity of spots and SD, and percentage coefficient of variation (%CV) of spot intensity of differentially ex-

pressed proteins in all patients for Tris and TLB extracts, respectively. An example of the differentially expressed protein, as represented by different intensities of protein spots between normal and cancerous tissues for glutathione S-transferase P (GST-P), is shown in Figure 1; the bar chart was plotted according to the intensity of the respective protein spots. GST-P was detected as upregulated in cancerous tissues.

Data analysis

The significance of the expression levels of the differentially expressed proteins in both Tris and TLB extracts was analyzed by Student's *t* test. After univariate analysis was performed, the normalized intensities of 37 differentially expressed protein spots in Tris extracts were subjected to PCA. The PCA reduced the original data to 12 PCs based on an eigenvalue of > 1, and these 12 PCs contributed 76.43% of the total data variance of the Tris extract data. Figure 2 shows the 3D PC plot with the x-, y- and z-axes representing the first, second and third PC number. The variables that had the highest loadings were those that contributed most to the differentiation of the disease state. Figure 3 shows the scree plot of Tris extracts. Six PCs were chosen and these components contributed 53.97% of the total variance of the Tris extract

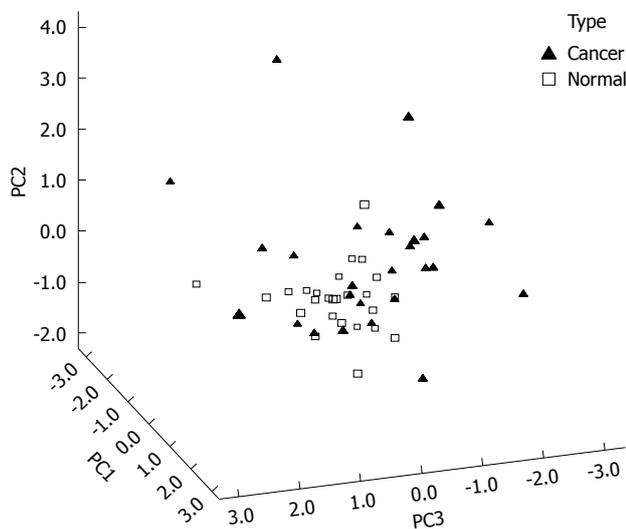

Figure 4 Principal component plot of thiourea lysis buffer proteins.

Both original and cross-validation samples had an average 82.7% correct classification.

Figure 4 shows the 3D view of the PCs plot for the TLB extract. PCA reduced the original data of the TLB extract to seven PCs based on an eigenvalue one of > 1, and the seven PCs accounted for 72.46% of the total data variance. The 3D view indicates that tissues can be grouped according to CRC disease state. Figure 5 shows the scree plot of the TLB extracts. Six PCs were chosen based on the slope of scree plot, which contributed

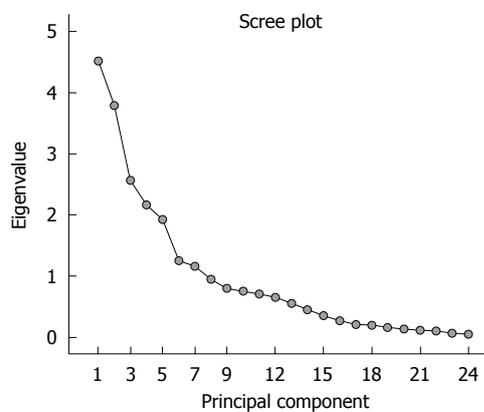

Figure 5 Scree plot showing principal components and their eigenvalues in thiourea lysis buffer extracts.

67.61% of the total data variance of TLB extracts. Table 7 shows the LDA results of TLB extracts, where 22 out of 26 original normal tissues, and 19 out of 26 original cancerous tissues were correctly classified. In cross-validated samples, 21 out of 26 normal tissues and 16 out of 26 cancerous tissues were correctly classified. The average percentages of correct classification for original and cross-validation samples were 78.8% and 71.2%, respectively.

DISCUSSION

The expression levels of the differentially expressed protein between colorectal cancerous and normal tissues were

CV: Coefficient of variation.

analyzed using PCA based on a multivariate analysis approach, to assess their usefulness in classifying colorectal tissues as cancerous or normal. The differentially expressed proteins identified showed good consistency in their expression levels in cancerous and normal tissues. The proteins were extracted in two fractions according to their polarities. In the PCA-LDA model, the selected proteins from the first few PCs were able to discriminate colorectal tissues with and without CRC.

A scree plot was derived by plotting the eigenvalues against the PC number. The shape of the plot was used to evaluate the number of PCs to be retained. In general, the point at which the scree plot straightens out indicates the number of PCs to be extracted^[11]. Cross-validation is a method to estimate the accuracy of a predicted classification model if performed using new future data sets (samples); this is because a classification model is considered incomplete until the prediction error is estimated^[12]. One method of cross validation is leave-one-out cross-validation, where one sample from the data set of N

| Normal (26) | 5 | 21 | |

samples is removed, the discriminant rule is recalibrated, and a classification model is built based on the remaining $N - 1$ data. The one sample that is left out is classified in this model and the process repeated N times^[12].

PCA and LDA results from Tris extract indicated that six out of 37 proteins were reliable to determine the tissues with CRC. The proteins comprised five upregulated proteins, namely GST-P, tropomyosin α -3C-like protein, F-actin capping protein subunit β , selenium binding protein 1 and DJ-1 protein, and one downregulated protein, namely, proteasome subunit β type 6. DJ-1 protein and GST-P contributed the most to the first PC based on the weight of their loadings. This was followed by the tropomyosin α -3C-like protein and proteasome subunit β type 6 that contributed to the second PC, while F-actin capping protein subunit β and selenium binding protein 1 contributed to the third PC. The initial PCA reduced the original data and therefore enabled LDA to be carried out because LDA is sensitive to the number of variables. In LDA, the six PCs chosen were shown to be capable of predicting whether the tissues were with or without CRC. Two-way validation by using original and cross-validation analyses was applied to validate the state of the tissues, where the cancerous and normal tissues were classified correctly at 82.7% for both original and cross-validation samples.

Two proteins that contributed most to PC1 in Tris extract were DJ-1 and GST. DJ-1 is a putative oncoprotein that is able to transform cells with H-Ras^[13]. Overexpression of DJ-1 activates protein kinase B, which subsequently increases cell survival. Furthermore, increased DJ-1 expression also activates Nrf2 (nuclear factor erythroid 2-related factor), which in turn increases expression of antioxidant enzymes that confer a survival advantage to tumor cells^[14]. Upregulation of DJ-1 protein in esophageal squamous cell carcinoma is correlated with lymph node metastasis^[15]. Although there is no reported role of DJ-1 in CRC, its upregulation in CRC is undeniable, and we have shown that its expression can be used to discriminate between CRC cancerous and normal tissues.

GST catalyzes the conjugation of reduced glutathione to electrophiles^[16]. GST functions to remove peroxides from endogenous compounds such as lipids and DNA^[17]. Overexpression of GST-P1 in CRC may be involved in cell proliferation, differentiation and apoptosis^[18]. GST-P1 is overexpressed in liver cancer cells^[19].

In TLB extract, six of the 24 differentially expressed proteins identified were found to be useful in discriminating CRC cancerous from normal tissues. These proteins were protein disulfide isomerase (PDI), complement component 1 Q subcomponent-binding protein (GC1q-R), chloride intracellular channel protein 1, triosephosphate isomerase, annexin A5 and actin cytoplasmic 2. All the proteins were downregulated in TLB extracts, except chloride intracellular channel protein 1 and triosephosphate isomerase. PDI and GC1q-R contributed the most to the first PC based on the weight of their loadings. This was followed by the chloride intracellular channel protein 1 and triosephosphate isomerase that contributed the most to the second PC, while annexin A5 and actin cytoplasmic 2 contributed most to the third PC. In LDA, the six PCs that explained 67.61% of the total variance were able to distinguish CRC cancerous from

normal tissues. The leave-one-out cross-validation obtained 71.2% correct classification of normal and cancerous tissues. The value for original grouped samples was higher with 78.8% correct classification.

Two proteins that contributed most to PC1 in TLB extracts were PDI and GC1q-R. PDI catalyzes the formation and breakage of disulfide bonds between two cysteine residues^[20]. PDI regulates cell transformation and intracellular and extracellular redox activities *via* its reductase activity^[21]. PDI regulates STAT3 signaling and proliferation, which is thought to induce malignancy^[22]. PDI is upregulated in CRC cell lines and its upregulation is correlated with cancer cell differentiation^[23,24].

GC1q-R is a cell surface glycoprotein, which binds to the globular heads of C1q molecules^[25]. C1q molecules bind to a variety of cells such as B cells, monocytes, macrophages, endothelial and smooth muscle cells^[26]. C1q elicits responses such as phagocytosis in monocytes and activation of tumor cytotoxicity of macrophages^[27,28]. GC1q-R is overexpressed in colon cancer cells and may be involved in tumor metastasis. However, PDI and GC1q-R were downregulated when using average fold change to determine their expression levels.

Proteins are the expression components that regulate cell activity. Differential expression of proteins is expected upon transformation of normal cells to cancerous cells. These differentially expressed proteins are useful in diagnosis and prognosis of the disease. In the present study, the specimens used in the analysis comprised tissues from female and male patients who were diagnosed with various stages, grades and locations of CRC. Regardless of the sex of the patients and pathological specification of the tissues, we showed that the differentially expressed protein identified from 2D protein profiles of cancerous and normal tissues could be used to separate and classify normal and cancerous tissues by combining PCA and LDA. The data reduction technique of PCA was sufficient to provide a classification of tissues according to CRC disease state. These statistical models simplify the data management through the reduced dimensionality of protein spots from the 2D gel images. Therefore, multivariate analysis of differentially expressed proteins identified from cancerous and normal tissues may be used as a tool for diagnosis and prognosis of CRC disease state.

ACKNOWLEDGMENTS

We want to express our appreciation to Universiti Sains Malaysia for provided the grant under RU funding to conduct this project. We would also like to thank National Institute of Pharmaceutical and Nutraceutical for their generosity in allowing us to conduct the LC/MS/MS experiments.

COMMENTS

Background

Colorectal cancer (CRC) is one of the leading causes of death worldwide. Dif-

ferentially expressed proteins between cancerous and normal colonic tissues were identified using 2D gel separation followed by LC/MS/MS analysis. The protein spot intensities of the 2D gel images were analyzed using principal component analysis (PCA) and linear discriminant analysis (LDA) for their possible use in classification of disease state.

Research frontiers

Multivariate analyses, including the dimension reduction method known as PCA and classification methods such as LDA, are used in cancer proteomic studies to identify the protein variables that provide the best discrimination between the cancerous and normal tissues.

Innovations and breakthroughs

The authors used sequential protein extraction to extract aqueous soluble and membrane-associated proteins from colorectal tissues. Differentially expressed proteins were analyzed using a combination of PCA and LDA to determine their usability in differentiating normal and cancerous colonic tissues. Using this method, the authors successfully classified the tissues according to their respective types. DJ-1 protein and glutathione S transferase P1 of the aqueous soluble proteins, protein disulfide isomerase and complement component 1 Q subcomponent-binding protein of the membrane-associated proteins gave the best classification of the tissues.

Applications

The identified biomarkers may be used for the diagnosis and prognosis of CRC.

Terminology

Chemometrics is defined as the information aspects of complex biological and chemical systems. Chemometrics utilize mathematical, statistical or formal logic-based methods to extract chemical information, which in this case, is for biomarker discovery.

Peer review

This study investigated the use of PCA and LDA of differential protein expression between normal and cancerous tissues for classification of disease state. The method gave good classification of cancerous and normal colonic tissues.

Abstract

AIM: To evaluate the impact of feeding colicky infants with an adapted formula on the hydrogen breath test and clinical symptoms.

METHODS: Hydrogen expiration was measured by SC MicroLyzer gas chromatography at inclusion and 15 d after treatment with an adapted low-lactose formula in 20 colicky infants.

RESULTS: All babies were symptomatic: 85% with excess gas, 75% with abnormal feeding pattern, and 85% with excessive crying. The hydrogen breath test at inclusion was abnormal: 35 ± 3.1 ppm. After 15 d feeding with an adapted low-lactose formula, crying and flatulence decreased in 85% of patients ($P < 0.001$). For infants in whom no decrease of gas was reported, crying was still reduced ($P < 0.01$). Moreover, the feeding pattern was improved in 50% of infants when it was initially considered as abnormal. Finally, the hydrogen

breath test decreased significantly (10 ± 2.5 ppm, $P < 0.01$).

CONCLUSION: This study showed an association between clinical improvement and evidence of decreased levels of hydrogen when the infants were fed with a specially designed, low-lactose formula.

INTRODUCTION

Infant colic continues to be one of the most disconcerting issues in pediatric medicine. Wessel in 1954 established the famous "rule of three" criteria: "a symptomatic disorder characterized by paroxysms of fussing, agitation or crying, lasting more than 3 h a day and occurring more than 3 d a week for at least 3 wk"^[1]. These criteria are now outdated and as there is no clear definition for the condition, studies on its causes, prevalence and treatment inevitably include a heterogeneous group of infants with different problems^[2-4]. The definition of "excessive infant crying syndrome"^[5] is preferred, although the word

“colic” is still used and can be defined as an acronym standing for “Cause Obscure Lengthy Infant Crying”. It is characterized by paroxysms of excessive and inconsolable crying. The infant might present with a tense abdomen, flex the leg to the abdomen, and appear flushed. Symptoms typically start around the second week of life, peak around 3-6 wk and resolve by 3 mo^[4,6]. This term now includes digestive disorders such as constipation, gastroesophageal reflux, allergy to cow milk proteins, and excess intestinal gas due to malabsorption of lactose, and its prevalence has been established^[6,7].

These disorders, although not serious from a medical point of view, can be very distressing for the baby and his/her family, and can be associated with symptoms of depression in the mother in the first months after birth^[8]. For most of these disorders, some dietary solutions have been developed in compliance with the international expert group coordinated by ESPGHAN (European Society for Paediatric Gastroenterology, Hepatology and Nutrition)^[9].

The objective of this study was to provide clinical and biochemical evidence of the efficacy of an adapted formula in colic caused by excessive gas, due to physiological hypolactasia, which led to excessive infant crying syndrome.

MATERIALS AND METHODS

We included formula-fed infants who were referred to their pediatrician and/or the Unit of Gastroenterology, Hepatology and Nutrition, Children's Hospital, Vall d'Hebron, Barcelona, Spain because of excessive crying reported by their parents. Infants with vomiting/regurgitation, constipation or cutaneous rash were excluded. When the parents reported “rumbling tummies” excessive flatus, and frothy stools, we considered it as suggestive of carbohydrate malabsorption. Other symptoms were taken into account such as feeding difficulties (e.g. crying during meals) and excessive crying time per 24 h. The hydrogen breath test was performed in case of suspected excess intestinal gas, or infant crying for > 3 h/d to diagnose possible reduced lactose absorption.

Twenty consecutive infants with positive hydrogen breath test were included in this study. All infants were fed with an adapted formula, from various brands having a lactose content of 7 g/100 mL equivalent to 10.4 g of lactose/100 kcal (caloric density of formulas 67 kcal/100 mL).

All of them were eutrophic, Caucasian, healthy full term infants whose growth and development had been normal since birth. Infants were 3.7 wk old on average (range: 1.7-6 wk). They were switched to an adapted formula, Novalac AC (United Pharmaceuticals SA, Paris, France) during the intervention period (Table 1).

Duration of crying, intestinal bloating and behavior during feeding (such as interruption of the meal due to crying) were evaluated through a questionnaire at baseline and during a second consultation 15 d later. A second hydrogen breath test was also performed during the second visit in these 20 infants.

Table 1 Composition of Novalac AC®

| Average composition for 100 mL | |
|--------------------------------|-------|
| Energy (kcal) | 65.7 |
| Proteins (g) | 1.4 |
| Carbohydrates (g) | 7.5 |
| Lactose (g) | 2.3 |
| Maltodextrin (g) | 5.2 |
| Fat (g) | 3.3 |
| C18:2 (mg) | 610.0 |
| C18:3 (mg) | 59.8 |
| Calcium (mg) | 50.7 |
| Phosphorus (mg) | 31.2 |

The persons legally responsible for the children were invited to give their informed consent for participation in the study. The study was approved by the local ethics committee.

Method of hydrogen breath test

Breath samples were collected before the start of feeding, as well as at 90, 120 and 180 min after the beginning of the meal. The feeding schedule was not modified. Samples were taken using face masks with a two-way valve and a pot system. Breath samples were collected in duplicate. The samples were injected in an SC MicroLyzer gas chromatograph (Quinton Instrument Company, USA) for simultaneous detection of hydrogen, CO₂ and methane^[10]. This model had an internal gas chromatographic column through which the sample was flushed. Material in the column retarded components which might have interfered with the measurement, and hydrogen thus appeared by itself at the detector and was accurately measured. The gas was inserted in a SvRite-10 cartridge before being analyzed. Prior calibration was performed with a standard gas that contained 102 ppm hydrogen, 23 ppm methane, and 5% CO₂. The results were expressed as parts per million (ppm). The result was considered to be positive when there was an increase > 20 ppm; the normal level for methane being < 10 ppm applying a correction factor for CO₂. The hydrogen breath data were analyzed as a nested factorial design by analysis of variance. For each infant, the maximum hydrogen value was defined as being the highest mean of the hydrogen breath test, because the actual time from the beginning of the feeding did not have a consistent impact on the value.

Statistical analysis

Hydrogen values were expressed as mean ± SE. The values of expired hydrogen were compared using Student's *t* test. A χ^2 test was used for categorical variables when both groups were compared. *P* < 0.05 was considered significant. The statistical analysis was performed using SPSS version 18.0 (SPSS Inc., Chicago, IL, USA).

RESULTS

Table 2 shows the clinical evolution (data reported by

Table 2 Clinical evaluation of associated symptoms in infants with crying secondary to excess gas *n* (%)

| | Inclusion | After 15 d | χ^2 | <i>P</i> |
|--------------------|-----------|------------|----------|----------|
| Excess gas | 17 (85) | 5 (25) | 14.56 | < 0.001 |
| Abnormal feeding | 15 (75) | 6 (30) | 8.22 | < 0.01 |
| Duration of crying | | | | |
| < 1 h/d | | 85% | | |
| 1-3 h/d | 13 (65) | 3 (15) | 10.41 | < 0.001 |
| > 3 h/d | 7 (35) | 0 (0) | 8.48 | < 0.01 |

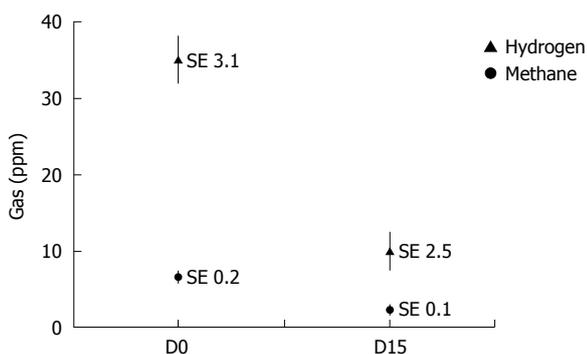

Figure 1 Evolution of breath hydrogen and methane before (D0) and after 15 d (D15) of consumption of low-lactose formula. Values are expressed as mean \pm SE. Only the change in expired hydrogen was significant (*P* < 0.01).

relatives) of infants who were included because of crying secondary to excess gas. The duration of crying was reduced in all infants regardless of the initial duration, and 85% cried for < 1 h/d. Moreover, of the 85% of infants reported with excessive gas at inclusion, only 25% still had excessive gas at the end of the study period (*P* < 0.001). Four out of the five infants who were described by their parents as having excessive gas were crying for < 1 h/d. The proportion of infants for whom feeding was described as abnormal decreased from 75% at inclusion to 30% after 2 wk feeding with Novalac AC (*P* < 0.01). The level of hydrogen expired (biochemical evidence) decreased from 35 \pm 3.1 ppm at inclusion to 10 \pm 2.5 ppm (*P* < 0.01) after 2 wk feeding with Novalac AC. The methane excretion was unchanged (Figure 1).

DISCUSSION

Many authors tend to include digestive disorders in the etiology of “excessive infant crying syndrome” (COLIC), and recommend dietary treatment of this functional disorder^[6,7]. Therefore, this study focused on transient lactose intolerance in infants with colic^[11,12] and we do not discuss other etiologies such as food hypersensitivity, which has been reviewed by Hill *et al*^[13].

As a result of the failure to break down all the lactose ingested, part of it enters the large bowel where it becomes a substrate for lactobacilli and bifidobacteria. This reaction (fermentation) produces hydrogen and other substances. Therefore, subsequent increases in breath hydrogen are accepted as an indirect sign of hypolactasia^[6,11,12,14].

Miller *et al*^[12] have shown that the expired hydrogen in 65 infants with colic was significantly higher than in control subjects (29 ppm *vs* 11 ppm, *P* < 0.001). Sixty-two percent of children with colic had expired hydrogen > 20 ppm, but 38% of control subjects also had abnormal levels of expired hydrogen. Similar results have been shown by Moore *et al*^[14], with 80% of colicky infants having positive expired hydrogen *vs* 36% in normal infants. The assignment of infants to the colicky or control groups according to the mothers’ perception of the duration of crying might not distinguish clearly colicky or non-colicky infants. This might explain the dissociation between clinical and hydrogen values reported by some studies^[12-14]. Moreover, among infants with positive expired hydrogen, individual response to abdominal distension might vary, and this is why some infants cry more than others. Therefore, the issue of personal susceptibility to stimuli and a lengthy crying response varies considerably between infants.

Our baseline data are close to those reported by Miller *et al*^[12]. In this pilot study, we assessed the efficacy of the studied formula only in children younger than 6 wk who had a positive expired hydrogen test and clearly defined symptoms.

Mature breast milk contains 7 g lactose per 100 mL (10.2 g/100 kcal), as do several standard infants formulas. In the first few weeks, infants present a physiological or functional lactase deficiency that limits the amount of lactose that they can digest^[15]. Twenty-seven point five percent of neonates present a positive hydrogen breath test (i.e. > 20 ppm) after lactose ingestion, regardless of sex or gestational age, with only weight playing a significant role: hydrogen expired is more important in infants with a birth weight < 2.5 kg than in those > 2.5 kg^[16]. One study^[17] has found that infants who weigh < 1.8 kg, fed with a low-lactose formula (< 5% lactose) ingested more calories, finished their bottles sooner, presented less milk residue in the stomach, and required feeding more often and with less interruptions than those fed with a formula with normal lactose content (7 g/100 mL). The study of Douwes *et al*^[18] has indicated that abnormal expired hydrogen is more frequent in breast-fed infants or those fed with a 7.5% lactose formula, than in infants fed with a 1% lactose formula.

Furthermore, the concentration of hydrogen in the breath of healthy infants increases from birth to reach its highest level in the second month of life, and declines to low concentrations by 3-4 mo of age. This pattern is parallel to the evolution of crying in infants with COLIC^[4]. Children selected in our study were almost as old as those in the clinical studies of Barr *et al*^[4] or Moore *et al*^[14] (3.7 wk *vs* 28.4 d and 2.6 wk, respectively) and younger than those studied by Miller *et al*^[12] (median age: 8 wk).

Fermentation of the disaccharide generates osmotic active substances such as lactic acid, short chain fatty acids, and hydrogen and/or methane. Methane production in lactose malabsorbers is normal, and without significance^[10].

Colic can result directly from the hyper-peristaltic

stimulus of the fluid load imposed by the osmotic action of unabsorbed lactose in the small intestine, and gas or pharmacologically active metabolites might be responsible for the symptomatic signs. In many susceptible infants, this excess of gas is responsible for triggering colic.

Several studies have investigated lengthy crying and have related it to excess intestinal gas^[14,19,20]. The rapid production of hydrogen in the lower bowel distends the colon, which causes different symptoms. This model of colic implies that symptoms could be relieved by reducing the lactose content of the infant feed. Four clinical trials that have used artificial lactase have been published^[19,21-23]. When lactase is added to a formula 30 min before it is fed, 30% of the lactose is not hydrolyzed. In a double-blind, placebo-controlled crossover study, 10 colicky infants were fed breast milk and cows' milk formulas, untreated and treated with lactase^[19]. This study showed no evidence that low-lactose milk reduced the severity and amount of crying^[19]. In another double-blind, placebo-controlled crossover trial in 12 infants, no effects on duration of crying and fussing were demonstrated^[21]. In a third study with the same methodology, the lactase-treated formula reduced crying time by 1.14 h/d^[22]. Yet another double-blind placebo-controlled crossover study was performed on 53 infants with colic who were treated with placebo or lactase added to their formula 4 h before they were fed. Data on 46 infants were available for crying time analysis and hydrogen breath tests were available in 34. Only 32 infants complied with treatment. In these infants, crying time and median expired hydrogen were significantly lower in the active group than in the placebo group^[23]. The results of our study were in agreement with Kanabar's study that also included an expired hydrogen measurement.

Differences in hydrogen breath excretion between colicky and control infants might also be associated with factors other than the amount or rate of delivery of lactose to the colon. The microbiota, the colonic bacterial metabolic pathways, the partial pressure of hydrogen in the colon, the buffering capacity of the colon, gut perfusion, and incomplete monosaccharide absorption might all play a part. Therefore, the volume of gas released by a fecal sample reflects the end result of a complex interaction of several factors.

This pathophysiological mechanism explains the clinical and biochemical response of these infants to an adapted, low-lactose diet^[22,23]. However, when calcium absorption is enhanced by the presence of lactose^[24], the formula has a lactose content (3 g/100 mL) that provides a daily amount close to absorption capacity in young infants of 4.5 g/kg per day^[23].

Even in the absence of a placebo control group, we believe that the clinical improvement observed in our study was related to dietary management. This clinical improvement appeared earlier (after 15 d feeding with the test formula only) than the usual resolution of colic. Moreover this improvement was endorsed by a decrease in expired hydrogen.

In conclusion this non-randomized, non-placebo-con-

trolled pilot study demonstrates that the use of an adapted infant formula with a low lactose concentration leads to clinical improvement and a decrease in expired hydrogen in colicky infants. Thus, infants with colic might benefit from a switch from standard formula to this specific adapted formula. Larger randomized clinical trials on the efficacy of this formula are needed.

COMMENTS

Background

Infant colic is still one of the most disconcerting issues in pediatric medicine. This term now includes digestive disorders such as constipation, gastroesophageal reflux, allergy to cow milk proteins, and excess intestinal gas due to lactose malabsorption.

Research frontiers

In infants with colic, the possibility of functional lactase deficiency has led to clinical trials with lactase supplementation of infant formulas. These studies have given conflicting results.

Innovations and breakthroughs

This article reports the clinical and biological efficiency of an adapted low lactose formula in infants with colic and positive hydrogen expiration.

Applications

In colicky infants with excess abdominal gas, a diet with an adapted low lactose formula can be tried for several days. If the results are positive, the diet can be continued for several months.

Peer review

The experiments were well designed and the paper is well written. However, there is one major concern about the data analysis.

Abstract

AIM: To evaluate the levels of preoperative serum matrix metalloproteinase-1 (MMP-1) and tissue inhibitor of metalloproteinase-1 (TIMP-1) in gastric cancer.

METHODS: One hundred gastric cancer patients who underwent gastrectomy were enrolled in this study. The serum concentrations of MMP-1 and TIMP-1 in these patients and in fifty healthy controls were determined

using an enzyme-linked immunosorbent assay.

RESULTS: Higher serum MMP-1 and TIMP-1 levels were observed in patients than in controls ($P < 0.001$). Serum MMP-1 and TIMP-1 levels were positively associated with morphological appearance, tumor size, depth of wall invasion, lymph node metastasis, liver metastasis, perineural invasion, and pathological stage. They were not significantly associated with age, gender, tumor location, or histological type.

CONCLUSION: Increased MMP-1 and TIMP-1 were associated with gastric cancer. Although these markers are not good markers for diagnosis, these markers show in advanced gastric cancer.

INTRODUCTION

Matrix metalloproteinases (MMPs) are a family of zinc-dependent neutral endopeptidases that play a significant role in the degradation of all matrix partitions, which

are crucial for malignant tumor growth, invasion, and metastasis^[1,2]. MMPs are inhibited by tissue inhibitors of metalloproteinase (TIMPs), which are secreted proteins. TIMPs bind to enzymatically active MMPs at a 1:1 molar stoichiometry, thus inhibiting proteolysis^[3]. The role of TIMPs in the imbalance of the extracellular matrix is significant and may inhibit or stimulate tumorigenesis^[4].

MMP-1 is also known as collagenase (EC 3.4.23.7)^[5]. Saffarian *et al*^[6] showed that activated MMP-1 acts by processing on the collagen fibril. The biological implications of MMP-1 acting as a molecular retainer, tied to the cell surface, prompted recent mechanisms for its status in tissue remodeling and cell-matrix interaction to be proposed. MMP-1 in the stromal tumor microenvironment can change the behavior of cancer cells to promote cell migration and invasion^[7].

TIMP-1 is a 28.5 kDa glycoprotein that has been studied in many human malignancies, including gastric cancer^[8]. TIMP-1 mRNA expression is increased in gastric, esophageal, and pancreatic cancer^[9-11]. TIMP-1 is present in human peripheral blood and body fluids^[12]. MMP-1 and TIMP-1 levels have been studied in plasma or serum of patients with cumulative malignancies^[13,14].

Our study was carried out to analyze serum MMP-1 and TIMP-1 levels in gastric cancer patients and to investigate their clinicopathological correlations.

MATERIALS AND METHODS

A total of 100 patients who underwent gastrectomy with gastric cancer between December 2007 and April 2010 were enrolled. Their median age was 58.5 years (range, 34-78 years), and the ratio of men/women was 47/53. There were 50 healthy volunteer controls without family history of cancer, whose average age was 56 years (range, 48-65 years) (22 men, 28 women). Peripheral venous blood of patients and controls was taken before gastrectomy and stored at 4°C. Blood from controls was taken on the day of a physical examination. The blood samples were centrifuged 1000 rpm, in 15 min, at 20°C to separate the serum, which was stored at -70°C until analysis. The mean storage time of all samples was 2 mo (45-80 d).

Resected tumor specimens were studied pathologically according to the criteria of the UICC's pTNM classification^[15]. Information recorded included age, gender, tumor location, tumor size, wall invasion, resection margin, histological type, lymph node metastasis, vascular invasion, lymphatic invasion, and perineural invasion. The histological features were classified into two types: (1) intestinal or differentiated type, consisting of papillary and/or tubular adenocarcinomas; and (2) diffuse or undifferentiated type, consisting of poorly differentiated, signet-ring cells, and/or mucinous adenocarcinomas.

Enzyme-linked immunosorbent assay (ELISA) for serum MMP-1 and TIMP-1 was performed using an ELISA kit (R&D System, USA) following the manufacturer's instructions.

As appropriate, the Mann-Whitney *U* test or Fisher's exact test was used for group comparisons. Correlations

Table 1 Serum matrix metalloproteinase-1 and tissue inhibitor of metalloproteinase-1 levels in patients and controls

| Variables | Controls (<i>n</i> = 50) | Patients (<i>n</i> = 100) | <i>P</i> |
|-------------------|---------------------------|----------------------------|----------|
| Age (yr) | 56 (48-65) | 58 (47-64) | |
| Gender female (%) | 37 | 40 | |
| MMP-1 (ng/mL) | 256 (109-342) | 785 (457-900) | < 0.0001 |
| TIMP-1 (ng/mL) | 220 (198-267) | 725 (417-1134) | < 0.0001 |

MMP-1: Matrix metalloproteinase-1; TIMP-1: Tissue inhibitor of metalloproteinase-1.

between parameters were tested by Spearman's correlation coefficient. A *P* < 0.05 was considered statistically significant.

RESULTS

Serum MMP-1 and TIMP-1 levels in gastric cancer patients and controls are shown in Table 1 and Figure 1A and B. The serum levels of MMP-1 and TIMP-1 in gastric cancer patients were significantly higher than in the control group (*P* < 0.0001). Clinicopathological variables are shown in Table 2. Serum MMP-1 and TIMP-1 levels were positively associated with the depth of wall invasion (*P* < 0.01), lymph node metastasis (*P* < 0.001), and lymphatic invasion (*P* < 0.001). The serum levels of MMP-1 and TIMP-1 were closely associated with distant metastasis (*P* < 0.001). In particular, higher MMP-1 and TIMP-1 levels were significantly associated with positive lymphovascular invasion (*P* < 0.001), tumor size \geq 4 cm (*P* < 0.001), positive lymph node metastasis (*P* < 0.001), T stage

Table 2 Clinicopathological variables of serum matrix metalloproteinase-1 and tissue inhibitor of metalloproteinase-1 in patients

| Variables | MMP-1 | TIMP-1 | P |
|-------------------------|---------------|----------------|---------|
| Lymphovascular invasion | | | |
| Negative | 543 (500-678) | 489 (450-573) | |
| Positive | 801 (768-845) | 642 (567-703) | < 0.001 |
| Tumor size (cm) | | | |
| < 4 | 478 (460-501) | 429 (425-479) | |
| ≥ 4 | 675 (509-725) | 671 (532-690) | < 0.001 |
| Lymph node metastasis | | | |
| Negative | 563 (503-650) | 642 (598-709) | |
| Positive | 742 (657-799) | 756 (570-876) | < 0.001 |
| T stage | | | |
| T0-2 | 521 (498-599) | 598 (564-783) | |
| T3-4 | 674 (578-783) | 749 (570-794) | < 0.001 |

| II | 534 (467-563) | 521 (478-589) | |
| III | 714 (546-857) | 753 (512-699) | < 0.001 |
| IV | 765 (699-900) | 975 (812-1134) | < 0.001 |

MMP-1: Matrix metalloproteinase-1; TIMP-1: Tissue inhibitor of metalloproteinase-1.

(T3-T4) ($P < 0.001$), or TNM stage (III and IV) ($P < 0.001$). MMP-1 and TIMP-1 levels were not significantly associated with negative lymphovascular invasion, tumor size < 4 cm, negative lymph node metastasis, T stage (T0-T2), and TNM stage (I and II). Overall, they were associated with pathological stage ($P < 0.001$). Serum MMP-1 and TIMP-1 levels were not associated with age ($P = 0.237$), gender ($P = 0.281$), tumor location ($P < 0.142$), histological type ($P = 0.103$), vascular invasion ($P = 0.247$), or peritoneal seeding ($P = 0.271$).

Higher serum MMP-1 and TIMP-1 levels were correlated with gastric cancer ($P < 0.001$, $r = 0.77$). Figure 1A shows that MMP-1 levels in patients with gastric cancer were significantly higher than in control groups. Figure 1B shows that TIMP-1 levels in patients with gastric cancer were significantly higher than in control groups.

DISCUSSION

In our study, we investigated MMP-1 and TIMP-1 levels in gastric cancer patients and compared them with a control group. We also investigated their associations with clinicopathological features.

Matrix metalloproteinases are involved in many normal biological processes (e.g. embryonic development, blastocyst implantation, organ morphogenesis, nerve growth, ovulation, cervical dilatation, postpartum uterine involution, endometrial cycling, hair follicle cycling, bone remodeling, wound healing, angiogenesis, and apoptosis) and pathological processes (e.g. arthritis, cancer, cardiovascular disease, nephritis, neurological disease, breakdown of the blood brain barrier, periodontal disease, skin ulceration, corneal ulceration, liver fibrosis, emphysema, and fibrotic lung disease). Although the main function of matrix metalloproteinases is elevation of ECM during tissue resorption and progression of many diseases, it is

obvious that matrix metalloproteinases also alter the biological functions of ECM molecules by definite proteolysis. MMP-1 and TIMP-1 are thought out to be involved in dissemination of cancer cells by dissolving the ECM, but they are also important in creating an environment that supports the initiation and growth of primary and metastatic tumors. These effects may be associated with proteolytic release of growth factors and/or modification of cellular environments^[16].

The most important finding in our study was the association between high MMP-1 and TIMP-1 levels in gastric cancer patients. In addition, high MMP-1 and TIMP-1 levels were significantly associated with certain clinicopathological variables. High MMP-1 expression has been associated with hematogenous metastasis^[17,18], rising depth of invasion, and metastasis in colorectal cancer^[18,19]. Our study also suggested that MMP-1 levels are associated with depth of invasion and metastasis.

Patients with colorectal cancer, ovary, lung, and liver diseases have increased TIMP-1 levels compared to control groups^[14,20-22]. Wang *et al.*^[23] suggested that serum TIMP-1 levels were higher in gastric cancer patients than control groups and were associated with clinicopathological variables. However, they suggested that serum TIMP-1 levels were associated with depth of wall invasion, distant metastasis, peritoneal seeding, lymphatic invasion, lymph node metastasis, and perineural invasion. However, we did not find that serum TIMP-1 levels were associated with peritoneal seeding and perineural invasion.

MMP-1 is associated with the primal pace of invasion and angiogenesis in gastric cancer, which may make it a useful marker for prognosis. TIMP-1 is more simply released into the blood^[24]; therefore, the sensitivity of the assay is higher than that for MMP-1.

High blood levels of MMP-1 and TIMP-1 are associated with poor prognosis of malignancies. Thus, they might useful as markers for malignant potential (i.e. tumor growth and/or differentiation) for cancer. Notably, serum TIMP-1 levels have been established as an independent factor in gastric cancer^[23].

Some metalloproteinases have been shown to degrade over time when measured in stored blood samples. However, we do not think that such protein decay is a significant factor when proteins are stored for 2 mo. This assumption is supported by the work of Papazoglou *et al.*^[25], Kardeşler *et al.*^[26] and Karapanagiotidis *et al.*^[27].

MMP-1 and TIMP-1 can be considered as 'traditional' and conventional serum biomarkers; many studies have measured both of these proteins as serum biomarkers^[28].

This study demonstrated that high serum MMP-1 and TIMP-1 levels in gastric cancer patients are significantly associated with disease progression. Their levels are important markers of tumor progression or advanced tumor stages.

COMMENTS

Background

The incidence of gastric cancer is rising worldwide. Collagenases may play a role

in degradation of the cell matrix, possibly leading to growth of malignant tumors, lymph node metastasis, increased depth of invasion and other metastases.

Research frontiers

Matrix metalloproteinase-1 (MMP-1) and tissue inhibitor of matrix metalloproteinase-1 (TIMP-1) change the environment of cancer cells to promote cell migration and invasion. Changes caused by these endopeptidases have a role in the progression of the gastric cancer.

Innovations and breakthroughs

High blood levels of MMP-1 and TIMP-1 are associated with poor prognosis of malignancies, making them potentially useful biomarkers for the malignant potential (i.e. tumor growth and/or differentiation) of cancer. These effects may be associated with proteolytic release of growth factors and/or modification of tumor cells.

Applications

The data generated in this paper might be used to explain the development of gastric cancer, to prevent metastasis, and to aid early diagnosis.

Terminology

MMP-1 and TIMP-1 zinc-dependent neutral endopeptidases. The role of MMP-1 and TIMP-1 in the imbalance of the extracellular matrix is significant and may inhibit or stimulate tumorigenesis. These effects have been demonstrated, and these molecules may represent useful markers of tumorigenesis.

Peer review

It is a nice study, with interesting results.

(PR), and 9 stationary disease (SD); 15/23]. In 12 patients harboring mutations of the kit gene at exon 11, the clinical benefit rate (CR, PR, and SD) was 75.0% and 6 patients with tumors containing kit exon 9 mutations had a clinical benefit of 50.0% (not significant, $P = 0.344$). The progression free survival (PFS) and overall survival (OS) did not differ between patients whose GISTs had wild type, KIT exon 9, or KIT exon 11 mutations. Hand-foot syndrome was the most common cause of grade III adverse effect (26.1%), followed by anemia (17.4%), and neutropenia (13.0%). During the median 7.5-mo follow-up after sunitinib use, the median PFS and OS of these 23 GIST patients after sunitinib treatment were 8.4 and 14.1 mo, respectively.

CONCLUSION: Sunitinib appears to be an effective treatment for Taiwanese with IM-resistant/intolerant GISTs and induced a sustained clinical benefit in more than 50% of Taiwanese advanced GIST patients.

Sunitinib for Taiwanese patients with gastrointestinal stromal tumor after imatinib treatment failure or intolerance. *World J Gastroenterol* 2011; 17(16): 2113-2119 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i16/2113.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i16.2113>

Abstract

AIM: To report preliminary results of the efficacy and safety of sunitinib in the management of Taiwanese gastrointestinal stromal tumors (GIST) patients facing imatinib mesylate (IM) intolerance or failure.

METHODS: Between 2001 and May 2010, 199 Taiwanese patients with metastatic GIST were treated at Chang Gung Memorial Hospital. Among them, 23 (11.6%) patients receiving sunitinib were investigated.

RESULTS: Sixteen male and 7 female patients with a median age of 59 years (range: 24-83 years) received sunitinib. Twenty-two GIST patients changed to sunitinib because of IM failure and 1 because of intolerance. The median duration of sunitinib administration was 6.0 mo (range: 2-29 mo). The clinical benefit was 65.2% [2 complete response (CR), 4 partial response

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) primarily arise from mesenchymal tissue in the gastrointestinal (GI) tract

and abdomen. Although GISTs are rare, representing only an estimated 0.1% to 3% of all GI tract tumors^[1] GISTs account for the most common mesenchymal malignancy of the GI tract with unknown incidence^[2]. GISTs appear to be related to the interstitial cells of Cajal^[3] and express the cell surface transmembrane receptor KIT, which has tyrosine kinase activity. Gain-of-function mutations of KIT are frequent in GISTs and result in constitutive activation of KIT signaling and lead to uncontrolled cell proliferation and resistance to apoptosis^[4,5]. The KIT tyrosine kinase inhibitor imatinib mesylate (IM) has shown a promising clinical result for an advanced GIST patient^[6], and several trials have shown a promising effect of this target therapy^[6,7]. Our previous study showed that IM significantly affected survival in GIST patients^[8,9].

Surgical resection remains the mainstay therapy for GIST, but recurrence is common. The 5-year survival rates for GIST after complete resection range from 40% to 65%^[6,10-13]. Unresectable or metastatic GIST is a fatal disease that resists conventional chemotherapy. IM selectively inhibits certain protein tyrosine kinases: intracellular ABL kinase, chimeric BCR-ABL fusion oncoprotein of chronic myeloid leukemia, the transmembrane receptor KIT, and platelet-derived growth factor receptors (PDGFR)^[14-17]. IM induced a sustained objective response in more than 50% of patients with advanced GISTs in the West and in Taiwan^[8,9]. However, progression of GIST eventually develops and emerges as a challenge.

Sunitinib is an oral multi-targeted tyrosine kinase inhibitor with activity against KIT and PDGFRs, as well as vascular endothelial growth factor receptors (VEGFRs), glial cell line-derived neurotrophic factor receptor (rearranged during transfection; RET), colony-stimulating factor 1 receptor (CSF-1R), and FMS-like tyrosine kinase-3 receptor (FLT3)^[18-23]. Sunitinib received multi-national approval for the treatment of GIST after failure of IM because of resistance or intolerance based on the results of an international, randomized, double-blind, placebo-controlled phase III trial^[24]. The clinical safety and efficacy of both IM and sunitinib in GIST have primarily been established in Western patients living in the USA or Europe and have not been thoroughly studied in Asian patients. Fifty-six centers in 11 countries participated in the phase III trial of sunitinib in GIST, but only 15 of the 312 patients were of Asian descent (10 and 5 in the sunitinib and placebo groups, respectively)^[25]. Therefore, we report our preliminary results to clarify the efficacy and safety of sunitinib in management of Taiwanese GIST patients facing IM intolerance or failure.

MATERIALS AND METHODS

Between 2001 and May 2010, 199 patients who had histologically confirmed, recurrent, unresectable, or metastatic GIST that expressed CD117 or CD34 and were treated at the Department of Medical Oncology, and Surgery, Chang Gung Memorial Hospital were retro-

spectively reviewed. Failure of prior IM therapy, as demonstrated by disease progression [based on Response Evaluation Criteria in Solid Tumors (RECIST)]^[26] or discontinuation of IM due to toxicity was the inclusion criteria in this study. Additional eligibility criteria included an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1 and adequate cardiac, hepatic, renal, coagulation, and hematologic function. Key exclusion criteria included lack of recovery from the acute toxic effects of previous anticancer therapy or imatinib treatment, discontinuation of imatinib therapy within 2 wk or of any other approved or investigational drug for GIST within 4 wk before starting sunitinib treatment, clinically significant cardiovascular events or disease in the previous 12 mo, diabetes mellitus with clinical evidence of peripheral vascular disease or diabetic ulcers, or a diagnosis of any second malignancy within the previous 5 years. Patients could have previously received chemotherapeutic regimens (the last chemotherapy treatment must have been at least 4 wk before study entry) and undergone radiotherapy, or surgery, or both. The study was approved by the local institutional review board of Chang Gung Memorial Hospital, and written informed consent for drug administration and the analysis of tumor-associated genetic alteration was obtained independently from each patient.

Study design and follow-up study

A retrospective study was conducted to evaluate the effect of sunitinib in inducing objective response in Taiwanese GIST patients. Patients were administered 50 mg (4 wk on and 2 wk off; for clinical trial) or 37.5 mg continuously of sunitinib in 12.5 mg capsules taken orally daily with food. Patients had regular physical examinations and evaluations of performance status, body weight, complete blood count, and serum chemistry. The administration of each dose and any adverse events were recorded for each patient. Standard computed tomography (CT) was performed on each patient every 3 mo for the first 3 years and every 6 mo for the following 2 years to assess patient response. Measurement of efficacy was based on objective tumor assessments made using RECIST with a minor modification to allow use of standard radiographic protocols for spiral CT. Time to response (TTR) was defined as the interval for better drug response during sunitinib treatment. Time to progression (TTP) was defined as the interval for worse drug response during sunitinib treatment. Progression free survival (PFS) was defined as no progression after sunitinib use. Overall survival (OS) was defined as survival after administration of sunitinib and death was the endpoint of the study. Response rate, PFS, OS, TTR, duration of response, and TTP were recorded. Safety and tolerability were assessed by analysis of adverse events, physical examinations, vital signs, ECOG performance status, and laboratory abnormality assessments (for example, complete blood count with differential count, serum electrolyte measurements, and electrocardiogram). Cardiac function was assessed at screening, at day 28 of

all treatment cycles, and treatment end with 12-lead electrocardiogram and multigated acquisition scans. Toxic effects were recorded in accordance with the National Cancer Institute Common Toxicity Criteria^[27].

Analysis of KIT and PDGFRA mutations

Sections were prepared from formalin-fixed, paraffin-embedded pretreatment specimens trimmed to enrich tumor cells. Polymerase chain reaction amplification of genomic DNA for KIT and PDGFRA was performed and amplification was analyzed for mutations as previously described^[28].

Statistical analysis

All data are presented as percentages of patients or means with standard deviation. Pearson χ^2 test and Fisher exact test were used for nominal variables. Survival rate was calculated and plots constructed by the Kaplan-Meier method and compared between groups with a log-rank test. All statistical analyses were performed using the SPSS computer software package (Version 10.0, Chicago, IL, USA). A *P*-value < 0.05 was considered statistically significant.

RESULTS

Clinical features

Table 1 summarizes the demographic features of 23 GIST patients receiving sunitinib. There were 16 male and 7 female patients with a median age of 59 years (range from 24 to 83 years). The stomach was the most common site for GISTs treated with sunitinib (8/23; 35%), followed by the jejunum (5/23; 22%), the ileum (5/23; 22%), and the rectum (3/23; 13%) (Table 1).

Treatment and outcomes before and after use of sunitinib

In Taiwan, sunitinib has been approved for treatment of metastatic GIST patients facing IM intolerance or failure since February 2009. Before 2009, sunitinib was administered to selected patients with unresectable or metastatic (advanced) GISTs facing IM failure or intolerance because they were enrolled in clinical trials. Sunitinib (12.5-50 mg/d) was given to 23 patients and all 23 patients were followed after administration of sunitinib at regular intervals until death or until the time of this manuscript writing. The median follow-up time after sunitinib was 7.5 mo, range: 1.2-58.0 mo. Overall, 2 patients (8.7%) had a complete response (CR), 4 (17.4%) had a partial response (PR), 9 had stationary disease (SD) (39.1%), and 8 had progressive disease (PD) (34.8%). A clinical benefit was observed in 65.2% of GIST patients. Among the 23 patients, the median TTR for 2 patients with CR was 3.73 mo and was 3.67 mo for 4 PR patients. The median TTP was 2.37 mo and the median survival is still unknown in the 8 PD patients (Table 2). During the median 7.5 mo follow-up after sunitinib use, the median PFS and OS of these 23 GIST patients after sunitinib treatment was 8.4 and 14.1 mo, respectively (Figures 1 and 2).

Spectrum of mutations in 23 advanced GIST patients

Tumor specimens suitable for genetic analysis were available from 21 (84.4%) of the 23 GIST patients with IM failure or intolerance. Overall, 18 (85.7%) of the 21 examined GISTs had activated mutations of KIT exon 9 and 11. Six of 21 (28.6%) GISTs had exon 9 mutation, 12 (57.1%) had exon 11 mutation, and 1 (4.8%) had no mutation of KIT. One PDGFRA exon 18 mutation was found. One patient had a concurrent deletion mutation in exon 11 and a missense mutation in exon 13; however, the exon 13 mutation was followed by the deletion mutation in exon 11. This patient developed acquired resistance and expired from disease progression. All 6 GISTs had KIT exon 9 mutation and displayed in-frame duplication of nucleotides, resulting in insertion of alanine (A) and tyrosine (Y) at codons 502 and 503. The KIT exon 11 mutations in the 12 GIST patients included insertion and deletion mutations, deletion mutations, and missense mutations.

Treatment and outcomes after use of sunitinib in terms of mutation status

In 12 patients with GISTs harboring KIT exon 11 mutations, the clinical benefit rate was 75% (2 CR, 2PR, and 5 PR) and 3 of 6 patients with tumors containing a KIT exon 9 mutation had a clinical benefit of 50% (1 PR and 2 SD) (not significant, $P = 0.344$) (Table 3). The median PFS and OS for the 12 GIST patients who had KIT exon 11 mutations after sunitinib use was 8.8 mo and still not reached, respectively. The median PFS and OS for the 6

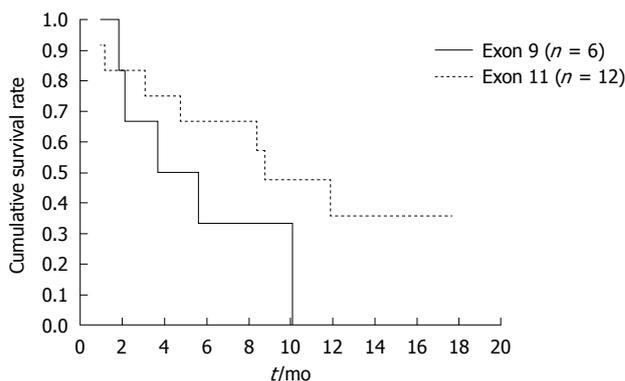

Figure 3 Progression free survival of 18 Taiwanese with metastatic gastrointestinal stromal tumor treated with sunitinib after imatinib failure or intolerance (exon 9 vs exon 11). Median/mean (mo): 3.7/5.6 (exon 9), 8.8/10.2 (exon 11); 95% CI: 0.9-7.9/2.5-8.6 (exon 9), 2.24-14.4/6.5-14 (exon 11). Log-rank test, $P = 0.221$.

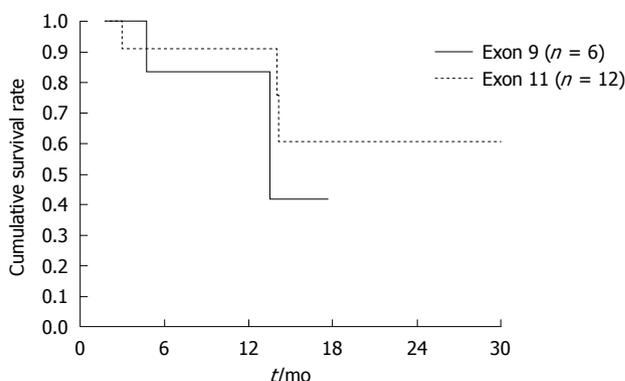

Figure 4 Overall survival of 18 Taiwanese with metastatic gastrointestinal stromal tumor treated with sunitinib after imatinib failure or intolerance (exon 9 vs exon 11). Median/mean (mo): 13.5/13.7 (exon 9), Not achieved/22.6 (exon 11); 95% CI: 0.9-26.1/9.8-17.7 (exon 9), NA/16.1-29.1 (exon 11). Log-rank test, $P = 0.473$.

patients with tumors containing a KIT exon 9 mutation were 3.7 and 13.5 mo, respectively. The twelve GIST patients who had KIT exon 11 mutations had similar PFS and OS to that of 6 patients with tumors containing a KIT exon 9 mutation (Figures 3 and 4).

Adverse events in 23 advanced GIST patients receiving sunitinib

Hand-foot syndrome was the most common cause of grade III adverse effects (26.1%), followed by anemia (17.4%), and neutropenia (13.0%). None of 11 patients had hypothyroidism after use of sunitinib (Table 4).

DISCUSSION

We had shown that IM significantly prolongs the post-recurrence and OS of Taiwanese patients with advanced GISTs^[8,9]. However, approximately 50% of GIST patients eventually develop progression in 24 mo after IM treatment and emerge as a challenge^[7]. This study confirmed the positive effect of sunitinib on improving PFS

Table 4 Adverse events and selected laboratory abnormalities

| Variable | Sunitinib (n = 23) | | | |
|--------------------------|--------------------|---------|---------|---------|
| | Grade 1 | Grade 2 | Grade 3 | Grade 4 |

and OS of advanced GIST patients facing IM failure or intolerance. This study reported a median PFS and OS for 23 advanced GIST patients of 8.4 and 14.1 mo, respectively, after sunitinib administration for a median period of 6.0 mo.

Sunitinib induced a sustained clinical benefit in more than 50% of Taiwanese patients with advanced GISTs (15/23; 65.2%)^[29] in our study, which was better than Heinrich's report. A CR induced by tyrosine kinase inhibitors on GIST patients has been sporadically reported. The US S0033 phase III study revealed that the CR rate was 3% for 751 metastatic or unresectable GIST patients receiving 400 or 800 mg IM daily^[30]. In the EORTC 62005 phase III study, the CR rate was 4.76% for 923 metastatic or unresectable patients receiving 400 or 800 mg imatinib daily^[31]. In contrast to the 2 previous studies, the CR rate in this study was 8.7% (2/23) and the median TTR for 2 patients that had a CR was 3.73 mo. The high incidence of CR in this study, even for patients using the second line tyrosine kinase, is because 1 of these 2 patients underwent surgery to achieve complete tumor removal. The limited experience on CR after sunitinib treatment for advanced or metastatic GIST patients facing IM failure or intolerance may still not justify the use of surgery as an adjunct method for target therapy in selected patients.

Regarding the relationship between response rate and kinase mutation, KIT exon 11 and exon 9 mutations predict a favorable response to IM^[32]. Heinrich reported that the clinical activity of sunitinib after IM failure is

significantly impacted by both primary and secondary mutations in the predominant pathogenic kinases, which has implications on optimal treatment of patients with GIST. Heinrich reported that both the clinical benefit and the objective response rates with sunitinib were higher in patients with primary KIT exon 9 mutations than with exon 11 mutations. Similarly, PFS and OS were significantly longer in patients with primary KIT exon 9 mutations or a wild-type genotype than in those with KIT exon 11 mutations^[29]. A possible explanation is that the potency of sunitinib against wild-type and exon 9 mutant KIT was superior to that of imatinib *in vitro*, whereas both drugs exhibited similar potency against KIT exon 11 mutant kinases. These results suggest that the greater clinical benefit seen in sunitinib-treated patients with exon 9 mutant or wild-type imatinib-resistant GISTs may be related to the greater potency of sunitinib against these kinases^[29]. In contrast to Heinrich's study, the clinical benefit, PFS, and OS did not differ between the groups of patients whose GISTs had KIT exon 9 or exon 11 mutation. Although the KIT oncoproteins encoded by exon 9 and exon 11 mutants were unequally sensitive to sunitinib *in vitro*^[29], the limited case number and racial difference might partly explain the similar clinical response rate of sunitinib in terms of KIT exon mutations in Taiwanese GIST patients.

Sunitinib was reasonably well tolerated in our study and the most common treatment-related adverse events were fatigue, diarrhea, skin discoloration, and nausea. Treatment-related adverse events of any severity grade were reported in 83% of sunitinib-treated patients, and serious treatment-related adverse events were reported in 20% of patients^[24]. In contrast to western GIST patients, hand-foot syndrome was the most common cause of grade III adverse events in our study. The reason for this discrepant incidence of hand-foot syndrome is still unknown and needs to be fully clarified. Racial differences in drug metabolism or pharmacokinetics are possible reasons for this observation^[33]. However, Lee *et al.*^[34] reported a higher frequency of hand-foot syndrome in Asian patients at Asian sites compared to Asian patients at non-Asian sites and in non-Asian patients in more than 4000 renal cell carcinoma patients receiving sunitinib. A lower frequency of some GI-related adverse events (AEs) in Asian patients at non-Asian sites compared to frequencies in Asian patients at Asian sites and in non-Asian patients has been observed. Recent evidence suggest that heterogeneity in toxicity and efficacy among patients receiving anti-VEGF therapy can be partially explained by genomic variability, including single-nucleotide polymorphisms, providing a possible explanation for the differences in AE frequencies between Asians and non-Asians in this analysis^[34].

Sunitinib-induced hypothyroidism was reported as a side effect in 12% of GIST patients. No hypothyroidism was noted in our series and primary hypothyroidism is not a common complication of therapeutic drugs. Drugs known to affect thyroid function are lithium, thioamides,

amiodarone, and cytokines such as interferon and interleukin-2. The molecular mechanisms of sunitinib-induced hypothyroidism are currently unknown but one possible mechanism by which sunitinib directly affects the thyroid is through the inhibition of VEGFR and/or PDGFR. Recent studies in a mouse model have shown that VEGFR inhibition can induce capillary regression in various organs, including the thyroid. Moreover, the vasculature of the thyroid showed the greatest regression of all organs^[35,36].

In conclusion, sunitinib appears to be a safe and effective treatment for Taiwanese patients with imatinib-resistant/intolerant GIST. Sunitinib induced a sustained clinical benefit in more than 50% of Taiwanese advanced GIST patients, even those facing imatinib failure or intolerance, with a median 8.4 mo PFS. ORR, PFS, and OS did not differ between patients whose GISTs had wild type KIT, KIT exon 9 mutation, or KIT exon 11 mutation. However, hand-foot syndrome accounted for the most common cause of grade III adverse event.

ACKNOWLEDGMENTS

We would like to thank Novartis (Taiwan) Co., Ltd. for financial support of genetic analysis.

COMMENTS

Background

The clinical safety and efficacy of both imatinib mesylate (IM) and sunitinib in gastrointestinal stromal tumors (GIST) have primarily been established in Western patients living in the USA or Europe and have not been thoroughly studied in Asian patients. Fifty-six centers in 11 countries participated in the phase III trial of sunitinib in GIST, but only 15 of the 312 patients were of Asian descent (10 and 5 in the sunitinib and placebo groups, respectively).

Research frontiers

To clarify the efficacy and safety of sunitinib in management of Taiwanese GIST patients facing IM intolerance or failure. The response of this second line target therapy also correlates with genetic status of the tumor.

Innovations and breakthroughs

Sunitinib appears to be a safe and effective treatment for Taiwanese patients with imatinib-resistant/intolerant GIST. Sunitinib induced a sustained clinical benefit in more than 50% of Taiwanese advanced GIST patients, even those facing imatinib failure or intolerance, with a median 8.4 mo progression free survival (PFS). ORR, PFS, and overall survival did not differ between patients whose GISTs had wild type KIT, KIT exon 9 mutation, or KIT exon 11 mutation. However, hand-foot syndrome accounted for the most common cause of grade III adverse event.

Applications

The preliminary report helps to clarify the efficacy and safety of sunitinib in management of Taiwanese GIST patients facing IM intolerance or failure.

Peer review

This is a review of therapeutic effects of sunitinib on 22 Taiwanese patients with metastatic GISTs after IM failure. Their data showed that sunitinib was helpful in 15 of the 23 patients, and the clinical benefits of sunitinib did not differ in patients with either primary KIT exon 9 or exon 11 mutation. Although the finding of this study is not new for sunitinib has been shown effective for IM failure, it is an interesting report showing authors' experience in using sunitinib in Taiwanese patients.

Abstract

AIM: To investigate the outcomes, as well as risk factors for 6-wk mortality, in patients with early rebleeding after endoscopic variceal band ligation (EVL) for esophageal variceal hemorrhage (EVH).

METHODS: Among 817 EVL procedures performed for EVH between January 2007 and December 2008, 128 patients with early rebleeding, defined as rebleeding within 6 wk after EVL, were enrolled for analysis.

RESULT: The rate of early rebleeding after EVL for acute EVH was 15.6% (128/817). The 5-d, 6-wk, 3-mo, and 6-mo mortality rates were 7.8%, 38.3%, 55.5%, and 58.6%, respectively, in these early rebleeding patients. The use of beta-blockers, occurrence of hypovolemic

shock, and higher model for end-stage liver disease (MELD) score at the time of rebleeding were independent predictors for 6-wk mortality. A cut-off value of 21.5 for the MELD score was found with an area under ROC curve of 0.862 ($P < 0.001$). The sensitivity, specificity, positive predictive value, and negative predictive value were 77.6%, 81%, 71.7%, and 85.3%, respectively. As for the 6-mo survival rate, patients with a MELD score ≥ 21.5 had a significantly lower survival rate than patients with a MELD score < 21.5 ($P < 0.001$).

CONCLUSION: This study demonstrated that the MELD score is an easy and powerful predictor for 6-wk mortality and outcomes of patients with early rebleeding after EVL for EVH.

MELD score can predict early mortality in patients with rebleeding after band ligation for variceal bleeding. *World J Gastroenterol* 2011; 17(16): 2120-2125 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v17/i16/2120.htm> DOI: <http://dx.doi.org/10.3748/wjg.v17.i16.2120>

INTRODUCTION

Esophageal variceal hemorrhage (EVH) is a serious com-

plication of liver cirrhosis and causes 70% of all upper gastrointestinal bleeding episodes in patients with portal hypertension^[1]. According to the Baveno Consensus Workshop in portal hypertension, endoscopic variceal band ligation (EVL) therapy is recommended for acute EVH, although endoscopic sclerotherapy may be used if ligation is technically difficult^[2]. According to the natural course of EVH, the risk of a recurrent episode of EVH increases after the first EVH but becomes similar to non-bleeding esophageal varices (EV) after 6 wk^[3]. Therefore, rebleeding within 6 wk after the first EVH is coined as early rebleeding. Secondary prophylaxis could reduce the early rebleeding rate to 20%^[11]. Several factors have been identified as predictors of mortality after EVH, including early rebleeding, bacterial infection^[4], hepatic venous pressure gradient (HVPG) > 20 mmHg measured shortly after admission^[5], active bleeding at initial endoscopy, severity of initial bleeding, hematocrit level, AST levels, presence of portal vein thrombosis or of hepatocellular carcinoma (HCC), alcoholic liver disease, serum bilirubin and albumin levels, Child-Turcotte-Pugh (CTP) score^[11], and Model for End-stage Liver Disease (MELD) score^[6-8]. Among these predictors, early rebleeding is the most important one^[3,9]. However, little information is known about the risk factors for mortality in the group of patients with early rebleeding. Thus, the goal of this retrospective study was to investigate the predictive factors for mortality in patients with early rebleeding.

MATERIALS AND METHODS

A total of 817 consecutive EVL procedures for esophageal variceal bleeding were recorded and evaluated in a 3500-bed tertiary referral medical center between January 2007 and December 2008. All of the patients with early rebleeding, defined as rebleeding between one day and 6 wk after ligation, were enrolled. The patients without endoscopic confirmation of rebleeding focus were excluded. The appropriately convened Institutional Review Board approved this study. Finally, 128 cirrhotic patients (15.6%) with early rebleeding were enrolled in our study. Among these patients, 49 patients who died within 6-wk after rebleeding were classified as the mortality group. The remaining 79 patients who survived more than 6 wk were classified as the survival group. The clinical characteristics and laboratory data of the patients in these 2 groups were collected for comparison. Vasoactive drug therapy (terlipressin, somatostatin, or octreotide) was routinely administered before diagnostic endoscopic examination and was continued for at least 3 d according to national insurance guidelines of Taiwan for variceal hemorrhage. Prophylactic antibiotic treatment with intravenous ceftriaxone and non-selective beta-blockers were prescribed for some, depending on the patients' clinical condition, contraindication, adverse effect with tolerability, and physician's preference. Diagnosis of liver cirrhosis was based on a previous liver biopsy or compatible clinical, laboratory, and imaging findings. Hepatocellular carcinoma (HCC) was diagnosed by liver biopsy, fine needle aspiration cytology, or com-

bined typical dynamic imaging appearance and elevated α -fetoprotein (AFP). According to the tumor size, patients with HCC were divided into early (one nodule \leq 5 cm or maximum three nodules, each < 3 cm) or advanced (one nodule > 5 cm or > 3 nodules). The diagnosis of infection was made by positive results of blood, sputum, urine, and ascites bacterial culture or elevated ascites fluid and absolute neutrophil count (ANC) \geq 250 cells/ μ L. In addition, 6-wk mortality was defined as death occurring within 6 wk after rebleeding. The first EVL procedure applied to esophageal variceal bleeding during our study period was considered as the index EVL and index bleeding. The following definitions were used on the basis of the recommendations of the Baveno Consensus Workshop: (1) esophageal variceal bleeding: (a) visible oozing or spurting of blood from a esophageal varix, (b) white nipple sign or blood clot adherent to a varix, (c) presence of medium or large esophageal varices with no other potential bleeding lesion; (2) EVL ulcer bleeding: bleeding from esophageal ulcers after endoscopic EVL with one of the following: (a) active bleeding from the ulcer site, (b) adherent clot at the ulcer site, or (c) absence of other potential bleeding lesions; (3) bleeding duration: the acute bleeding episode was considered finished at the beginning of the first 24-h interval with no hematemesis, stable hemoglobin concentration without blood transfusions, and stable hemodynamic condition; (4) early rebleeding: recurrence of clinically significant hemorrhage (hematemesis/melena, aspiration of greater than 100 mL of fresh blood from nasogastric tube or > 3 g/dL decrease of Hb if no transfusion is given) within 6 wk after index bleeding episode was considered finished; (5) rebleeding 5-d failure: uncontrolled bleeding, death, or recurrent hemorrhage within 5 d since rebleeding; and (6) portal hypertensive gastropathy (PHG) bleeding: a macroscopic finding of a characteristic mosaic-like pattern of gastric mucosa with red-point lesions, cherry red spots, and/or black-brown spots (severe PHG) and the absence of other potential bleeding lesions.

Statistical analysis

Statistical analysis was performed after proper tabulation of data. Continuous variables were expressed as mean with range, and categorical variables were expressed as count with percentage. Groups were compared using Student's software *t*-test for continuous variables and χ^2 test for categorical variables. Multivariate analysis was performed using logistic regression, and a receiver operating characteristic (ROC) curve was generated to assess the predictive accuracy of the variables. All of these values were considered statistically significant if the *P*-value was < 0.05. Cumulative survival estimates were calculated by using the Kaplan-Meier method. All statistical analyses were performed with SPSS statistical for Windows (Version 16; SPSS, Inc., Chicago, IL, USA).

tients are reported in Table 1. The mean age of the patients was 54 years old (range 14-82); 83.6% were male and 16.4% were female. The etiologies of liver cirrhosis were virus (47.7%), alcohol (24.2%), or combined virus and alcohol (21.9%). The endoscopic findings at index bleeding were active EV bleeding (30.5%), blood in the esophageal or gastric lumen (38.3%), and clean esophago-gastro-duodenal lumen (31.2%). The average interval between index EVL and rebleeding was 14 \pm 10.8 d. The average CTP scores at the time of index bleeding and rebleeding were 9.8 \pm 2.3 and 10.1 \pm 2.6, and the average MELD scores were 19.8 \pm 8.9 and 21.4 \pm 9.8, respectively.

The surveillance of rebleeding sites was carried out by upper GI endoscopy within 1 day for all enrolled patients; the rebleeding site, therapeutic methods, and outcomes are shown in Table 2. The surveillance revealed 75 patients with residual EV bleeding (58.6%), 24 patients with EVL-related esophageal ulcer bleeding (18.8%), 7 patients with gastric variceal bleeding (5.5%), 11 patients with peptic ulcer bleeding (8.6%), and 11 patients with PHG-related bleeding (8.6%). The management methods for rebleeding included combined endoscopic and pharmacologic therapy (71.9%) and pharmacologic therapy only for EVL ulcers or PHG with mild oozing (27.3%). Only one patient was treated with surgical intervention (0.8%). In total, 24 pa-

EV: Esophageal varices; EVL: Endoscopic variceal band ligation; GV: Gastric varices; PHG: Portal hypertensive gastropathy; GI: Gastrointestinal.

tients (18.8%) were associated with 5-d failure at rebleeding of which 8 patients had uncontrolled bleeding and died within 5 d, 2 patients died of other causes within 5 d, and 14 patients had recurrent bleeding within 5 d. The rebleeding mortality rates at 5 d, 6 wk, 3 mo, and 6 mo were 7.8%, 38.3%, 55.5%, and 58.6%, respectively. The causes of death within 6 wk after rebleeding were sepsis-induced multiple organ failure (53.1%), upper gastrointestinal tract hemorrhage (36.7%), and liver failure (10.2%).

We then further divided the patients into two groups according to their mortality or survival during the 6-wk period after rebleeding. The clinical characteristics of patients in the 6-wk mortality group and the survival group are displayed and compared in Table 3. There were no significant differences between these two groups with regard to gender, age, etiology of cirrhosis, HCC, PVT, duration between rebleeding and index EVL, rebleeding focus and treatment methods, antibiotic use, serum platelet count, and sodium and potassium level at rebleeding. However, higher CTP score (11.9 *vs* 8.9), higher MELD score (28.9 *vs* 16.8), and hypovolemic shock during rebleeding ($P < 0.001$); higher serum total bilirubin, creatinine, and white cell count levels; lower serum albumin and hemoglobin levels; longer prothrombin time (INR) and active bleeding on endoscopy; and higher hepatic encephalopathy grade were markedly seen in the 6-wk mortality group. Beta-blocker use after rebleeding was also significantly associated with 6-wk mortality.

Furthermore, by multivariate logistic regression analysis, hypovolemic shock (OR = 9.25, 95% CI: 1.68-50.93, $P = 0.011$), beta-blocker use after rebleeding (OR = 0.18, 95%

UV: Univariate analysis; MV: Multivariate analysis; CTP: Child-turcotte-pugh; MELD: Model for end-stage liver disease; HE: Hepatic encephalopathy; INR (PT): International normalised ratio of a patient's prothrombin time to a normal control sample; EGD: Esophagogastroduodenoscopy.

cut-off value of the MELD score is 21.5. As shown in Table 5, the MELD score had a good sensitivity of 78%, specificity of 81%, positive predictive value (PPV) of 72%, and negative predictive value (NPV) of 85% for predicting 6-wk mortality. By the above analyses, a MELD score of ≥ 21.5 was subsequently chosen as the value for identifying patients with a high risk of death at 6 wk after rebleeding.

The Kaplan-Meier survival curves in patients classified according to a MELD score of < 21.5 and ≥ 21.5 revealed a significant difference as shown in Figure 1. The mortality rate was 14.7% in patients with MELD < 21.5 and 71.7% in patients with MELD ≥ 21.5 at 6 wk ($P < 0.001$); 36% in patients with MELD < 21.5 and 83% in patients MELD ≥ 21.5 at 3 mo ($P < 0.001$); and 40% in patients with MELD < 21.5 and 84.9% in patients MELD ≥ 21.5 at 6 mo ($P < 0.001$), respectively.

DISCUSSION

Our study has revealed that potential rebleeding sources in cirrhosis cases after index EVL for EVH were esophageal varices (58.6%), esophageal ulcer (18.8%), peptic ulcer (8.6%), PHG (8.6%), and gastric varices (5.5%). The results were consistent with a previous study^[1] reporting that residual esophageal varices were a major source of rebleeding. In addition, beta-blocker usage after rebleeding, hypovolemic shock, and higher MELD score at the time of rebleeding were independent predictors of 6-wk mortality. In addition, we found that the 6-wk mortality rate was 14.7% for patients with MELD scores less than 21.5 and

Table 5 Sensitivity, specificity, positive predictive value, and negative predictive value for predicting 6-wk mortality in patients with rebleeding after endoscopic variceal band ligation for esophageal varices bleeding *n* (%)

| 6-wk mortality | Sensitivity | Specificity | PPV | NPV |
|-----------------------------------|-------------|-------------|------|-------|
| MELD score ≥ 21.5 | 77.55 | 81.01 | 71.7 | 85.33 |
| Hypovolemic shock (+) | 42.86 | 96.20 | 87.5 | 26.92 |
| Beta-blocker use after rebleeding | 83.67 | 46.84 | 49.4 | 82.22 |

PPV: Positive predictive value; NPV: Negative predictive value; MELD: Model for end-stage liver disease.

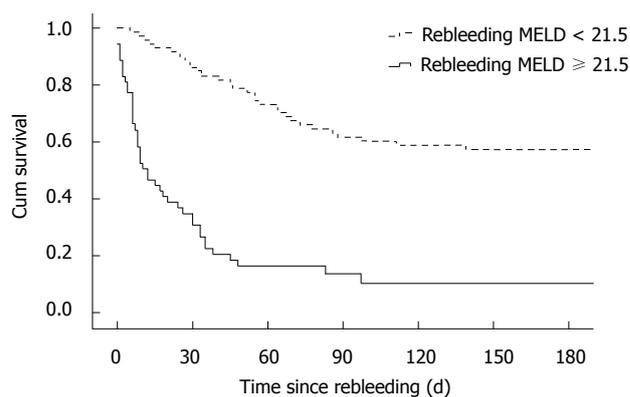

Figure 1 Kaplan-Meier survival curves in patients classified according to model for end-stage liver disease score < 21.5 or ≥ 21.5 ($P < 0.001$). MELD: Model for end-stage liver disease.

71.7% for patients with MELD scores more than 21.5.

The mortality rate within 6 wk in our study was 38.3%, which is higher than the mortality rate of patients after acute variceal bleeding^[1,6]. This is probably because the patients with rebleeding after EVH were more advanced in disease severity than patients with initial acute EVH. This difference in severity could be reflected in the mean MELD score; the mean score was 21.4 in the rebleeding patients of our study group, higher than the group of acute variceal bleeding with a MELD score of 12 as previously reported^[6].

The presence of HCC could influence both early rebleeding and mortality in patients with EVH, as reported previously^[11,10]. However, in the present study, advanced HCC and portal vein thrombosis were not predictors of 6-wk mortality, which is consistent with previous reports that advanced HCC is not an independent risk factor but MELD score is a good predictor for early mortality after EVH^[11].

Another independent factor associated with 6-wk mortality in our study was rebleeding related to hypovolemic shock. This observation was similar to previous studies that found that the severity of the hemorrhage was predictive of 6-wk mortality in acute EVH of all cirrhotic patients^[1,6]. The third independent factor associated with 6-wk mortality was the use of beta-blockers, which reflected the general consensus that the use of beta-blockers for the secondary prevention of EVH could reduce mortality^[12]. Overall, 49 patients (38.3%) died within 6 wk after early rebleeding;

among of them, 10 died within 5 d, and 39 died from day 6 to day 42. In our study, the causes of death were sepsis-related multiple organ failure (53.1%), GI bleeding-related complications (36.7%), and liver failure-related complications (10.2%); our results were similar to a recent study reporting that early mortality after cessation of initial EV bleeding is significantly associated with bacterial infection and rebleeding^[13]. This finding provides evidence to support the AASLD guidelines for the treatment of acute variceal bleeding regarding the early use of pharmacological agents and emergent endoscopic procedure within 12 h^[14]. Additionally, for reducing sepsis-related multi-organ failure, prophylactic use of antibiotics for all patients with cirrhosis and GI hemorrhage should be encouraged^[2,15]. Patients with a CTP classification of A respond well to current therapies with minimal risk of death and represented only 2% of the patients in the 6-wk mortality group in our study. Whether current treatment recommendations should be applied to all patients should be further investigated^[16].

In conclusion, this study examined the focuses of rebleeding and treatment outcomes in cirrhotic patients with early rebleeding after EVL for acute EVH. Specifically, the study revealed that hypovolemic shock and MELD scores ≥ 21.5 at the time of rebleeding are predictors for 6-wk mortality in patients with early rebleeding after EVL for acute EVH. Also, beta-blocker use after rebleeding was associated with lower 6-wk mortality.

COMMENTS

Background

The management of variceal bleeding remains a clinical challenge with high mortality. At the present time, available treatments have reduced the 6-wk rebleeding rate to 20%. Early rebleeding is a strong predictor of death from variceal bleeding. Endoscopic therapy increases control of bleeding and decreases the risk of rebleeding and mortality. Despite the fact that endoscopic variceal ligation (EVL) is recommended for acute esophageal variceal bleeding in recent practice guidelines, there has been relatively little research investigating the situation of early rebleeding after EVL for esophageal variceal bleeding.

Research frontiers

Currently, treatment recommendations are applied to all patients with variceal bleeding. At present, only 40% of deaths are directly related to bleeding, while the majority are caused by infection-related multiple organ failure that is paralleled with the severity of liver cirrhosis. Patients with Child-Pugh classification A have good response to current therapy, with a minimal risk of mortality. However, treatment strategies might be different with different Child-Pugh classification.

Innovations and breakthroughs

This study provides evidence that there are independent predictors for 6-wk mortality and rebleeding origin in cirrhotic patients with early rebleeding after therapeutic endoscopic band ligation of initial esophageal varices bleeding.

Applications

This article shows significantly less beta blocker use in the mortality group and recognizes this as an independent poor predictor. To prevent rebleeding with associated mortality, secondary prophylaxis with beta blockers should start as soon as possible from the day after stopping usage of vasoactive drugs. Furthermore, the authors demonstrate that Model for End-Stage Liver Disease (MELD) score is an easy and accurate predictor of 6-wk mortality of patients with early rebleeding after EVL for esophageal variceal bleeding. Accurate predictive rules are provided for early recognition of high risk patients.

Terminology

The Model for End-Stage Liver Disease, or MELD, is a scoring system for assessing the severity of chronic liver disease. It was initially developed

to predict death within three months of surgery in patients who had undergone a transjugular intrahepatic portosystemic shunt procedure, and was subsequently found to be useful in determining prognosis and prioritizing for receipt of liver transplant instead of the older Child-Pugh score. MELD Score = $[0.957 \times \ln(\text{Serum Cr}) + 0.378 \times \ln(\text{Serum Bilirubin}) + 1.120 \times \ln(\text{INR}) + 0.643] \times 10$.

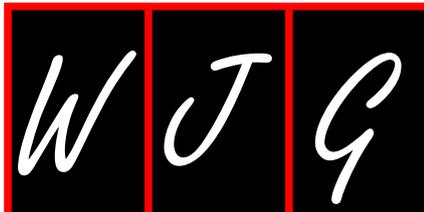

Peer review

The manuscript is a well designed retrospective study with the aim to investigate the predictive factors for mortality in patients with early rebleeding.

The parameters were as follows: spectral width, 15 KHz; time domain, 64 K; number of scans, 512; and acquisition time, 2.128 s.

RESULTS: The main component of pancreatic juice included leucine, iso-leucine, valine, lactate, alanine, acetate, aspartate, lysine, glycine, threonine, tyrosine, histidine, tryptophan, and phenylalanine. On performing 1D ^1H and 2D total correlation spectroscopy, we found a triplet peak at the chemical shift of 1.19 ppm, which only appeared in the spectra of pancreatic juice obtained from patients with alcoholic chronic pancreatitis. This triplet peak was considered the resonance of the methyl of ethoxy group, which may be associated with the metabolism of alcohol in the pancreas.

CONCLUSION: The triplet peak, at the chemical shift of 1.19 ppm is likely to be the characteristic metabolite of alcoholic chronic pancreatitis.

Abstract

AIM: To investigate the markers of pancreatic diseases and provide basic data and experimental methods for the diagnosis of pancreatic diseases.

METHODS: There were 15 patients in the present study, among whom 10 had pancreatic cancer and 5, chronic pancreatitis. In all patients, pancreatic cancer or chronic pancreatitis was located on the head of the pancreas. Pathology data of all patients was confirmed by biopsy and surgery. Among the 10 patients with pancreatic cancer, 3 people had a medical history of long-term alcohol consumption. Of 5 patients with chronic pancreatitis, 4 men suffered from alcoholic chronic pancreatitis. Pancreatic juice samples were obtained from patients by endoscopic retrograde cholangiopancreatography. Magnetic resonance spectroscopy was performed on an 11.7-T scanner (Bruker DRX-500) using Call-Purcell-Meiboom-Gill pulse sequences.

Key words: Pancreatic juice; Pancreatic cancer; Chronic pancreatitis; Magnetic resonance spectroscopy; Magnetic resonance imaging

INTRODUCTION

Pancreatic cancer accounts for about 2% of all cancer cases, but it has the worst prognosis of all cancers with a 5-year

survival rate of less than 3%^[1,2]. Because of the deep-seated location of the pancreas and no apparent symptoms at the initial stages of pancreatic cancer, it is difficult to diagnose this disease in the early stages. Chronic pancreatitis is a kind of localized or diffuse inflammation, and is caused by many factors. One of the medical dilemmas is to distinguish pancreatic cancer from chronic pancreatitis with a mass in the head of the pancreas; both these diseases have similar clinical behavior and imaging features^[3]. A puncture biopsy is usually preferred over an operation when diagnosing the disease, but this is an injurious procedure and may lead to some complications^[4].

Magnetic resonance imaging (MRI) is the most common procedure used in the diagnosis of pancreatic cancer. An MRI helps obtain images of the pancreas and its surrounding structures^[5]. The deep-seated location of the pancreas and similar clinical manifestations of chronic pancreatitis and pancreatic cancer are the main barriers in differentiating between these two diseases even with advanced MRI techniques. Magnetic resonance spectroscopy (MRS) has high sensitivity and resolution, allows in vitro testing of metabolites, and has been widely used in the field of metabolomics^[6-12]. MRS will be the most potent tool to help differentiate between pancreatic cancer and chronic pancreatitis, and it will be the most effective tool for the early diagnosis of a pancreatic tumor.

Usually, in the process of cancerization, gene and metabolite abnormalities appear before tissue structure transformation. Detection of abnormalities in metabolites facilitates early diagnoses of tumors. Clinically, the serum marker CA19-9^[13] and gene tumor markers such as the K-ras gene^[14,15], p53 anti-oncogene, and p53 protein^[16-19] are widely used as markers of pancreatic cancer; however, these markers are not sensitive, show low specificity, and are used as auxiliary tools^[20]. Beger *et al.*^[10] had successfully used MRS and mass spectrum (MS) to analyze blood constituents of patients with pancreatic cancer and of healthy volunteers; they were able to make a good distinction between pancreatic cancer and the control group by performing lipid profiling of the blood. Pancreatic juice is the exocrine of the pancreas, and is closely related with pancreatic tissues. We wanted to investigate whether it is possible to obtain some information to help differentiate between chronic pancreatitis and pancreatic cancer by analyzing pancreatic juice samples. In the present study, we used MRS technology to analyze the pancreatic juice of patients with pancreatic cancer or chronic pancreatitis with a mass in the head of the pancreas and tried to explore the markers of these diseases. We provided basic data and experimental methods for the study of pancreatopathy.

MATERIALS AND METHODS

The initial subject population comprised 35 patients with pancreatic cancer (24 men and 11 women; mean age, 67.2 years; age range, 47-85 years) recruited between January 2006 and June 2009. We selected 10 subjects (7 men and 3 women; mean age, 67.7 years; age range, 57-74 years) with surgically confirmed pancreatic cancer. The mean maxi-

mum lesion diameter was 26.1 mm (range, 11-51 mm), and all lesions were located in the head of the pancreas. We chose 5 patients (4 men and 1 woman; mean age, 58.3 years) with chronic pancreatitis, confirmed by in vivo biopsy, and lesions located at the head of the pancreas. The medical history of every patient was recorded in detail. All study protocols were approved by our Institutional Review Board, and informed consent was obtained from all patients before they were enrolled in this study.

Pancreatic juice samples were obtained from patients by endoscopic retrograde cholangio-pancreatography (ERCP) in frozen tubes and immediately placed in liquid nitrogen before storing the tubes in a -80°C refrigerator for MRS experiments. All patients were diagnosed by biopsy analyses of pathology data. Both the tumor marker CA19-9 and the cancer gene maker p53 were detected in patients with pancreatic cancer, whereas these markers were not detected in patients with chronic pancreatitis.

MRS experiments

MRS experiments were performed on a Bruker DRX-500 spectrometer (¹H frequency, 500.13 MHz; Bruker Biospin, Rheinstetten, Germany). Pancreatic juice samples were diluted with phosphate buffer in D₂O and placed in sample tubes (diameter, 5 mm), which are used in MRS experiments. Spectra were acquired at 300.0 K using Call-Purcell-Meiboom-Gill (CPMG) pulse sequence^[21,22] along with water presaturation during the relaxation delay of 2 s. The CPMG pulse sequence was applied as a T₂ filter to suppress signals from molecules with short T₂ values (such as macromolecules and lipids), using a total echo time (TE) time of 320 ms. The main parameters for the 1D ¹H-MRS spectra were as follows: spectral width (SW), 15 KHz; time domain (TD), 64 K; number of scans (NS), 512; and acquisition time (AQ), 2.128 s. Spectral assignments were confirmed by 2D ¹H-¹H TOCSY^[23] and J-resolved (JRES) along with the values obtained from the literature^[24]. The main parameters used for TOCSY were as follows: TD (F1-dimensional), 512; TD, (F2-dimensional), 1 K; SW (F1 and F2-dimensional), 5 KHz; and NS, 32. The main parameters used for JRES were as follows: TD (F1-dimensional), 256; TD (F2-dimensional), 8 K; SW (F1-dimensional), 78 Hz; SW (F2-dimensional), 8 KHz; and NS, 32. In both the 2D MRS experiments, the delay time was 2 s. The stability of the pancreatic juice samples was evaluated by repeating a 1D MRS experiment after overall acquisition. No biochemical degradation of any of the pancreatic juice samples was observed.

RESULTS

On combining 2D MRS experimental results (Figure 1) obtained in the present study with results from related literature^[25-27] we identified the main resonances in ¹H MRS spectra of pancreatic juice. TOCSY is a useful 2D MRS technology, it can be used to distinguish the frequencies in the total spin system and improve the sensitivity of detecting small J couplings^[28]. On the basis of TOCSY data, the resonances in 1D ¹H MRS spectra (Figure 2) of some

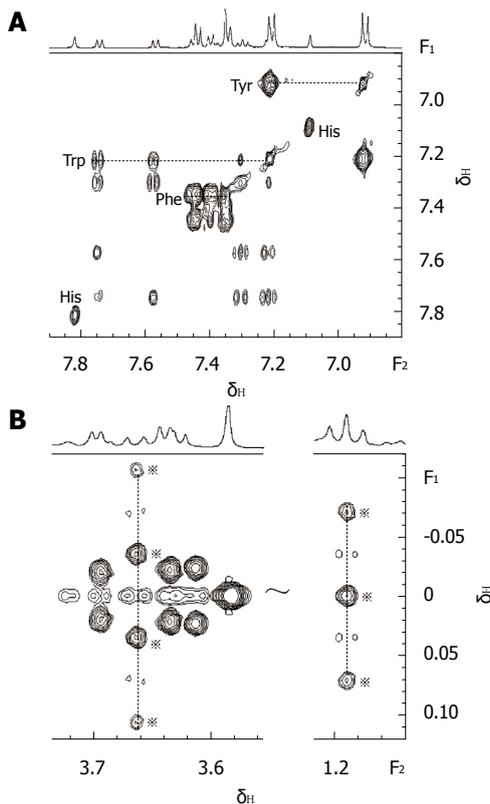

Figure 1 Assignments of partial resonances in ^1H spectra of pancreatic juice. A: 2D Total correlation spectroscopy (TOCSY) of human pancreatic juice; B: JRES spectra of human pancreatic juice. Tyr: Tyrosine; His: Histidine; Trp: Tryptophan; Phe: Phenylalanine.

amino acids were identified. The components, including leucine (Leu), iso-leucine (Ileu), valine (Val), lactate (Lac), alanine (Ala), acetate (Ace), aspartate (Asp), lysine (Lys), glycine (Gly), threonine (Thr), tyrosine (Tyr), histidine (His), tryptophan (Trp) and phenylalanine (Phe), and the locations were also identified.

From the analysis of 1D ^1H MRS spectra of all pancreatic juice samples, it was easy to find a triplet peak at the chemical shift of 1.19 ppm (Figure 3), which only appeared in some spectra. Four of the pancreatic juice samples of patients with chronic pancreatitis showed a triplet peak at the chemical shift of 1.19 ppm on ^1H MRS, whereas the spectra of the pancreatic juice of patients with pancreatic cancer did not show a peak at the chemical shift of 1.19 ppm. When subjected to 2D TOCSY, the spectra of pancreatic juice samples of patients with chronic pancreatitis only showed one correlation peak at the chemical shift of 1.19 ppm and 3.36 ppm (Figure 4). By chemical shift and J coupling constant, we found that the peak at the chemical shift of 1.19 ppm was the ^1H peak of the methyl of ethoxy group ($\text{CH}_3\text{CH}_2\text{O}-$). The 1D ^1H spectra of the 4 pancreatic juice samples of patients with chronic pancreatitis showed a triplet peak at the chemical shift of 1.19 ppm; further, these patients had a history of drinking, which was found from the analysis of pathology data. The 1D ^1H spectra of pancreatic juice obtained from the female patient with chronic pancreatitis did not show a triplet peak at the chemical shift of 1.19 ppm.

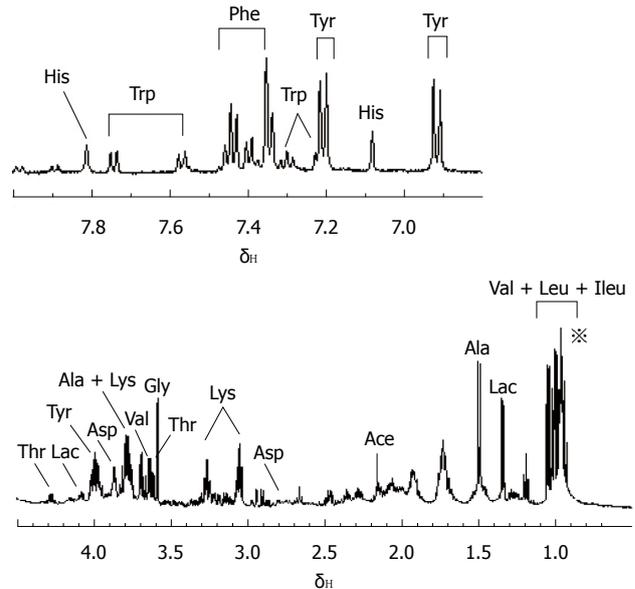

Figure 2 The assignment of proton magnetic resonance spectroscopy spectra of pancreatic juice with chronic pancreatitis. Ace: Acetate; Ala: Alanine; Asp: Aspartate; Gly: Glycine; His: Histidine; Ileu: Iso-leucine; Lac: Lactate; Leu: Leucine; Lys: Lysine; Phe: Phenylalanine; Thr: Threonine; Tyr: Tyrosine; Trp: Tryptophan; Val: Valine.

Among the 10 patients with pancreatic cancer, diagnosed by postoperative analyses of pathology data, 3 people had a medical history of long-term alcohol consumption. Of 5 patients with chronic pancreatitis, 4 men had a medical history of long-term alcohol consumption, and they were typical patients with alcoholic chronic pancreatitis. The female patient suffered from auto-immune chronic pancreatitis by analyses of the pathology data.

DISCUSSION

In recent years, there has been much debate on the relation between chronic pancreatitis and pancreatic cancer. While some scholars^[29] believe that both diseases have a close connection, others^[30] disagree. The results of our study show that there is no apparent difference between the components of pancreatic juice obtained from patients with chronic pancreatitis and pancreatic cancer, except that 1D ^1H spectra of pancreatic juice obtained from the former group of patients who suffered from alcoholic chronic pancreatitis shows a triplet peak of the methyl of ethoxy group ($\text{CH}_3\text{CH}_2\text{O}-$) at the chemical shift of 1.19 ppm. This finding may be used to differentiate pancreatic cancer from alcoholic chronic pancreatitis with a mass in the head of the pancreas.

In the present study of the 10 patients with pancreatic cancer, 3 had a medical history of long-term alcohol consumption, but the 1D ^1H spectra of their pancreatic juice did not show the triplet peak of the ethoxy group ($\text{CH}_3\text{CH}_2\text{O}-$); further, the pathology data of these patients did not show symptoms related to chronic pancreatitis. Hence, we can conclude that alcohol is not the main factor that causes pancreatic cancer. It is controversial whether

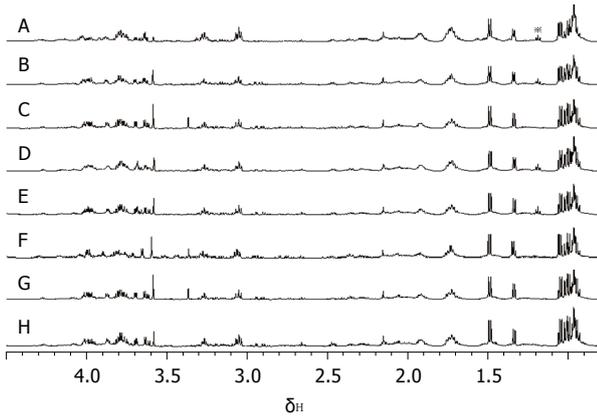

Figure 3 ^1H magnetic resonance spectroscopy spectra of human pancreatic juice with chronic pancreatitis and pancreatic cancer. A-E: 1D ^1H MRS spectra of pancreatic juice of patients with chronic pancreatitis; F-H: 1D ^1H magnetic resonance spectroscopy spectra of pancreatic juice of patients with pancreatic cancer, other 7 similar spectra of pancreatic juice of patients with pancreatic cancer are not shown.

long-term alcohol consumption can cause pancreatic cancer. Riediger *et al.*^[31] found that the association between alcohol and pancreatic cancer was not apparent during epidemiological investigation, which is in accord with our results.

We applied MRS to study pancreatic juice obtained from patients with chronic pancreatitis and pancreatic cancer, and separated the various components of different amino acids in human pancreatic juice by 1D and 2D ^1H spectra. Recently, many analyses on the components of pancreatic juice have focused on the aspect of proteomics. Our study in the field of metabolomics is auxiliary to proteomics, and goes a step further in the study of pancreatopathy.

It is difficult to differentiate between pancreatic cancer and chronic pancreatitis with a mass in the head of the pancreas solely by MRI, because both these diseases have similar clinical behaviors and imaging features. There is no noninvasive method that can be successfully used to diagnose these diseases. Biopsy is frequently used to diagnose pancreatic cancer or chronic pancreatitis with a mass in the head of the pancreas but has some disadvantages, e.g. false negative results, many complications (bleeding, seepage of bile and pancreatic juice), and risk of tumor metastasis. ERCP causes some injury, but it is better than biopsy, because it causes fewer complications. ERCP, when combined with MRS technology, helps obtain more information on metabolites, which cannot be obtained from biopsy or MRI, and is likely to be used to distinguish pancreatic cancer from alcoholic chronic pancreatitis with a mass in the head of pancreas on the basis of ^1H MRS spectra of pancreatic juice.

There are some limitations to this study. Lack of control groups and the content of metabolites in the pancreatic juice being small meant we could not perform a quantitative analysis, and only obtained some qualitative results. The excreta of patients with pancreatic cancer or chronic pancreatitis may not only have different components but also differ in quantity.

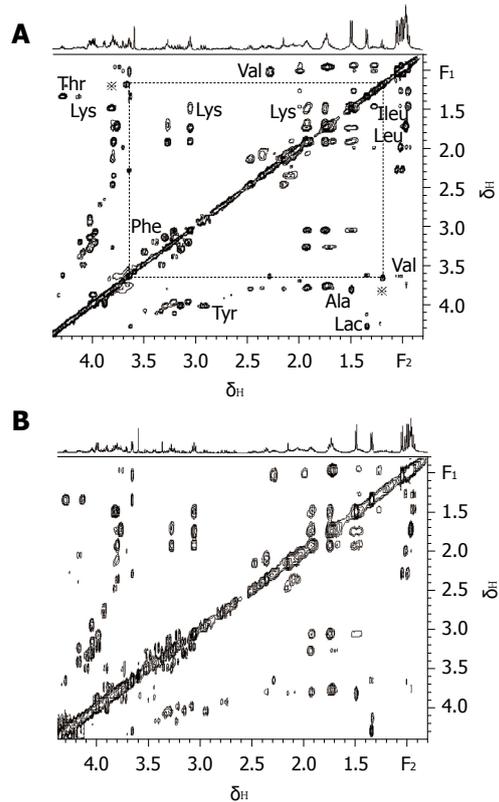

Figure 4 2D total correlation spectroscopy spectra of pancreatic juice with chronic pancreatitis and pancreatic cancer. A: Total correlation spectroscopy (TOCSY) spectra of pancreatic juice from patients with alcoholic chronic pancreatitis; B: TOCSY spectra of pancreatic juice from patients with pancreatic cancer. Ala: Alanine; Ileu: Iso-leucine; Lac: Lactate; Leu: Leucine; Lys: Lysine; Phe: Phenylalanine; Thr: Threonine; Tyr: Tyrosine; Val: Valine.

In conclusions, MRS is a powerful tool that can be applied to the study of pancreatic juice obtained from patients by ERCP, and does not cause injury. The triplet peak, which is at the chemical shift of 1.19 ppm in 1D ^1H -MRS data of pancreatic juice obtained from the patients with alcoholic chronic pancreatitis, was identified as resonance of the methyl of ethoxy group ($\text{CH}_3\text{CH}_2\text{O}-$). The ethoxy group may be associated with alcohol metabolism in the pancreas, and is likely to be used to distinguish pancreatic cancer from alcoholic chronic pancreatitis with a mass in the head of the pancreas. In view of small numbers, further confirmation of the results in a larger number of patients is required.

COMMENTS

Background

Pancreatic cancer is a malignant neoplasm of the pancreas, and it has a high death rate. One of the medical dilemmas is to distinguish pancreatic cancer from chronic pancreatitis with a mass in the head of the pancreas; both diseases have similar clinical behavior and imaging features. Exploring the markers to distinguish the diseases is very important to the therapies of patients in clinic.

Research frontiers

CA19-9, *K-ras* gene, p53 anti-oncogene, and p53 protein are widely used as markers of pancreatic cancer, but they are not sensitive and show low specificity. Searching characteristic markers of the diseases is still the goal of tireless pursuit. Magnetic resonance spectroscopy (MRS) has high sensitivity and

resolution, allows in vitro testing of metabolites, and has been widely used in the field of metabolomics. MRS will be the most potent tool to help differentiate between pancreatic cancer and chronic pancreatitis.

Innovations and breakthroughs

It is difficult to differentiate between pancreatic cancer and chronic pancreatitis with a mass in the head of the pancreas solely by Magnetic Resonance Imaging (MRI). Biopsy is frequently used to diagnose the diseases but has many complications and risk of tumor metastasis. Endoscopic retrograde cholangio-pancreatography (ERCP) combined with MRS helps obtain more information on metabolites, which cannot be obtained from biopsy or MRI. We separated the various components of different amino acids in human pancreatic juice. The triplet peak which is at the chemical shift of 1.19 ppm in 1D ¹H MRS spectra was identified as resonance of the methyl of ethoxy group (CH₃CH₂O-), and it may be the characteristic metabolites of the patients with alcoholic chronic pancreatitis.

Applications

This study provides basic data and experimental methods for the diagnosis of pancreatic diseases. The ethoxy group is likely to be used to distinguish pancreatic cancer from alcoholic chronic pancreatitis with a mass in the head of the pancreas.

Terminology

Chemical shift is a basic concept in MRS, the peak appearing in the ¹H MRS spectra with different chemical shift means the nuclear of proton spins with different frequency. The same rotation frequency of nuclear of protons only shows one peak in the ¹H MRS spectra. The triplet peak at the chemical shift of 1.19 ppm is caused by the interaction of nearby nuclear of protons. In fact, it is split by one peak.

Peer review

In my opinion, the article is acceptable for publication.

Abstract

AIM: To evaluate the possible relationship between the *Ku80* gene polymorphism and the risk of gastric cancer in China.

METHODS: In this hospital-based case-control study of gastric cancer in Jiangsu Province, China, we investigated the association of the *Ku80* G-1401T (rs828907) polymorphism with gastric cancer risk. A total of 241 patients with gastric cancer and 273 age- and sex-matched control subjects were genotyped and analyzed by polymerase chain reaction-restriction fragment length polymorphism.

RESULTS: The frequencies of genotypes GG, GT and

TT were 65.6%, 22.8% and 11.6% in gastric cancer cases, respectively, and 75.8%, 17.6% and 6.6% in controls, respectively. There were significant differences between gastric cancer and control groups in the distribution of their genotypes ($P = 0.03$) and allelic frequencies ($P = 0.002$) in the *Ku80* promoter G-1401T polymorphism.

CONCLUSION: The T allele of *Ku80* G-1401T may be associated with the development of gastric cancer.

INTRODUCTION

Gastric cancer is one of the most frequent malignancies in many countries, accounting for 8.7% of all cancers and 10.4% of all cancer deaths in the year of 2000^[1]. In China, gastric cancer remains the leading cause of cancer-related mortality among men and women^[1,2]. It is estimated that about 39% of gastric cancer cases occur in Chinese population^[1,2]. The environmental factors, diet, tobacco, alcohol and *Helicobacter pylori* infection are well-known causes of gastric cancer in China^[3-5]. However, only a fraction of individuals exposed to these factors

develop gastric cancer, suggesting that individual susceptibility to gastric cancer should be different. Currently, the genomic etiology of gastric cancer is of great interest but largely unknown.

DNA damage drives the formation and development of malignant tumors that ameliorate this damage, and its sequelae can be categorized as either gatekeeper or caretaker tumor suppressors, depending on their mode of action^[6]. Nonhomologous end joining (NHEJ) repairs DNA double-strand breaks (DSBs) by joining ends without using a homologous template strand and has been described as a caretaker^[7,8]. Many studies have shown that NHEJ is the predominant repair system in humans, which included the DNA ligase IV and its associated protein XRCC4, and the three components of the DNA-dependent protein kinase (DNA-PK) complex, Ku70, Ku80, and the catalytic subunit PKcs^[9]. The *Ku80* gene, also known as XRCC5, is an important and specific member of NHEJ. Ku70 and Ku80 form a heterodimer called Ku that is well known for its role in NHEJ pathway^[10].

Ku acts as a regulator of transcription by interacting with the recombination signal binding protein J κ and the nuclear factor (NF)- κ B p50 homodimer to up-regulate p50 expression, which may regulate the proliferation of gastric cancer cells^[11]. Gastric cancer cells with a low level of constitutive NF- κ B had a lower expression level of Ku70 and Ku80, which was reflected in the lower nuclear levels of Ku proteins, than the wild-type cells and the cells transfected with control vector^[12,13]. In addition, several studies reported that gastric cancer patients with a lower Ku80 expression level had a slightly prolonged survival after neoadjuvant chemotherapy^[14-16].

Genetic polymorphisms in *Ku80* genes influence DNA repair capacity and change predisposition of several cancers, including colorectal^[17], bladder^[18] and oral cancers^[19]. In addition, in these hospital-based case-control studies of other cancers, it was reported that the frequency of GT/TT type of the *Ku80* gene at promoter G-1401T (rs828907) was significantly higher in cases than in controls^[17-19]. Thus, we assumed that the specific polymorphism of *Ku80* gene may also contribute to gastric cancer. To test the hypothesis that the promoter G-1401T polymorphism is associated with the risk of gastric cancer, we used polymerase chain reaction-restriction fragment length polymorphism (PCR-RELP) to genotype this polymorphism in a hospital-based case-control study of 241 patients with gastric cancer and 273 age- and sex-matched cancer-free controls. The results of this research will lead to a better understanding of the role of SNPs in the *Ku80* genes in gastric cancer carcinogenesis. Such knowledge may eventually lead to the development of better preventive measures for gastric cancer.

MATERIALS AND METHODS

Study population

The case-control study consisted of 241 patients with gastric cancer and 273 cancer-free control subjects. The

gastric cancer patients were confirmed histologically. Genetically unrelated cancer-free individuals were recruited as controls who were selected by matching for age and gender during the same period. All subjects were Han Chinese from the eastern region of China and randomly selected from the Department of General Surgery of the First Affiliated Hospital of Nanjing Medical University between 2005 and 2009. All patients and control subjects voluntarily participated in the study, completed a self-administered questionnaire and donated 5 mL of blood samples. The questionnaire included questions on sex, age, residence, diabetes, hypertension and smoking status. Smoking was defined as ≥ 10 cigarettes per day. This research protocol was approved by the Institutional Review Board of Nanjing Medical University.

Genotyping analysis

Genomic DNA was isolated from peripheral blood lymphocytes using standard phenol-chloroform extraction, as previously described^[20,21]. PCR-RELP assay was used to type the *Ku80* G-1401T (rs828907) polymorphisms. In brief, the primers of the *Ku80* G-1401T polymorphism were 5'-TAGCTGACAACCTCACAGAT-3' (forward) and 5'-ATTCAGAGGGTGCTCATAGAG-3' (reverse)^[19], which generated a 252-bp fragment. The PCR reaction was performed in a total volume of 20 μ L containing 2 μ L 10 \times PCR buffer, 1.25 mmol/L MgCl₂, 0.1 mmol/L dNTPs, 0.25 μ mol/L each primer, 200 ng of genomic DNA and 1 U of *Taq* DNA polymerase (MBI Fermentas). The PCR was performed at 94°C for 5 min and followed by 35 cycles of 30 s at 94°C, 30 s at 55°C and 30 s at 72°C, with a final elongation at 72°C for 10 min. The restriction enzyme *Bfa*I (New England BioLabs) was used to distinguish the PCR product, and the genotypes were discriminated on 3% agarose gel and visualized by staining with 0.5 μ g/mL ethidium bromide. The wild-type G-allele produced a single 252-bp fragment, and the polymorphic T-allele produced 2 fragments of 81-bp and 171-bp. Approximately, 10%-15% of the samples were randomly selected for repeated assays, and the results were 100% concordant.

Statistical analysis

Continuous variables are presented as mean \pm SD and compared by unpaired Student's *t* test. Continuous variables departing from the normal distribution were presented as median and interquartile range and analyzed by Mann-Whitney *U*-test. Discrete variables were represented as frequencies and percentages and evaluated by the Pearson's χ^2 test. Pearson's χ^2 test was also used to compare the distribution of the *Ku80* genotypes between cases and controls. The association between the *Ku80* G-1401T polymorphism and the risk of gastric cancer was estimated by odds ratio (OR) and 95% CI using multivariate logistic regression. *P* < 0.05 was considered statistically significant. All statistical analyses were performed using SPSS version 13.0 for Windows (SPSS Inc., Chicago, IL, USA).

Table 1 Baseline characteristics of cases and controls *n* (%)

| Characteristics | Cases (<i>n</i> = 241) | Controls (<i>n</i> = 273) | <i>P</i> |
|-------------------|-------------------------|----------------------------|----------|
| Sex (male) | 181 (75.1) | 193 (70.7) | 0.43 |
| Age (yr) | 57.9 ± 12.9 | 56.9 ± 14.1 | 0.52 |

$\chi^2 = 7.26$, *df* = 2, *P* = 0.03.

RESULTS

Baseline characteristics

The frequency distributions of selected characteristics of the cases and controls are presented in Table 1. There was no significant difference between the cases and controls in sex (male: 75.1% *vs* 70.7%, *P* = 0.43) and age (57.9 ± 12.9 years *vs* 56.9 ± 14.1 years, *P* = 0.52), indicating that the matching for the subjects was successful. More smokers were found among gastric cancer cases compared with controls (25.3% *vs* 14.3%, *P* = 0.014). No significant differences were noted in residing in the rural area (46.1% *vs* 52.0%, *P* = 0.32), hypertension (8.7% *vs* 10.3%, *P* = 0.58) and diabetes (6.2% *vs* 8.1%, *P* = 0.51).

Genotype distributions and allele frequencies

Table 2 shows the distribution of the genotypic for the *Ku80* G-1401T (rs828907) between gastric cancer patients and controls. The genotypic frequencies in both gastric cancer and control groups were in agreement with those predicted by Hardy-Weinberg equilibrium (*P* = NS). The distribution of the *Ku80* G-1401T genotypes (GG, GT and TT) was markedly different between cases (65.6%, 22.8%, and 11.6%) and controls (75.8%, 17.6%, and 6.6%, *P* = 0.03). A significantly different distribution of the *Ku80* G-1401T genotype was demonstrated among the cases and controls. As shown in Table 3, the frequency of T allele was significantly higher in gastric cancer patients than in control subjects (23.0% *vs* 15.4%, *P* = 0.002).

Stratified analyses for the variant *Ku80* genotype in cases and controls

The multivariate logistic regression analysis was further used to evaluate the association between the G-1401T polymorphism and gastric cancer stratified by risk factors including age, sex, smoking and residence under control (Table 4). Adjusted OR (for age, sex, smoking status,

Table 3 Allele distribution of *Ku80* G-1401T polymorphism in cases and controls *n* (%)

| Allele | Cases | Controls |
|--------|------------|------------|
| G | 371 (77.0) | 462 (84.6) |
| T | 111 (23.0) | 84 (15.4) |

$\chi^2 = 9.73$, *df* = 1, *P* = 0.002.

residence, diabetes and hypertension) with 95% CI for mutant genotypes was all described. In statistical analyses stratified by the median age of controls (58 years), the increased risk associated with the GT/TT genotypes tended to be more evident in the younger subjects aged < 58 years (adjusted OR = 1.97, 95% CI: 1.05-2.90). However, we did not note a statistically significant inverse association with gastric cancer risk in older subjects aged ≥ 58 years (adjusted OR = 1.31, 95% CI: 0.88-1.96). The adjusted OR for the GT/GT genotypes was 1.81 (95% CI: 1.28-2.52) in male subjects and 1.33 (95% CI: 0.81-2.24) in female subjects. We did not note a statistically significant inverse association with gastric cancer risk in both non-smokers (adjusted OR = 1.48; 95% CI: 1.08-2.02) and smokers (adjusted OR = 2.52; 95% CI: 1.25-5.18). In urban subjects, there was significant evidence of an increased risk of gastric cancer in the variant genotypes (adjusted OR = 1.88; 95% CI: 1.26-2.76), while the association was not statistically significant in rural subjects (adjusted OR = 1.48; 95% CI: 0.99-2.15).

DISCUSSION

In this hospital-based, case-control study, we assessed the potential association between the *Ku80* G-1401T polymorphism and the presence of gastric cancer in Chinese population. To our best knowledge, this is the first study linking the *Ku80* G-1401T polymorphism with gastric cancer risk. Our data showed that the *Ku80* -1401 G to T variant was associated with the increased risk of gastric cancer.

Gastric cancer is a genetic disease developing from a multifactorial, multigenetic and multistage process^[22,23]. It was widely accepted that both genetic and environmental factors may be involved in the etiology of gastric cancer^[24]. During the multistage carcinogenesis, *Ku80* may be involved in multiple important cellular processes. To date, several studies have reported abnormal expression of *Ku80* protein in various cancers^[13,25-28]. Over-expression of *Ku80* increased the capability of cancer acquired resistance to radiation and chemical drugs^[29-31], while suppression of *Ku80* expression decreased cellular proliferation, colony formation and inhibited tumorigenicity in a xenograft model^[32]. As an important component of NHEJ, *Ku80* and *Ku70* form a heterodimer, which acts as a regulatory subunit of the DNA-dependent protein kinase complex DNA-PK by increasing the affinity of the catalytic subunit PRKDC to DNA^[17]. The *Ku80* gene plays an important and specific role in removing DSBs. Chang *et al*^[18]

| Rural | 73 (65.8) | 38 (34.2) | 105 (73.9) | 37 (26.1) | 1.48 (0.99-2.15) | 0.16 |

¹Adjusted for age, sex, smoking status, hypertension, diabetes and residence.

found evidence that the *Ku80* G-1401T variant was associated with increased risk of bladder cancer in a central Taiwanese population. A recent study, involving 362 patients with colorectal cancer and 362 age- and gender-matched healthy controls, showed that the T allele *Ku80* G-1401T conferred a significantly ($P = 0.0069$) increased risk of colorectal cancer^[17]. These observations were consistent with the findings previously described by other investigators from Asian populations^[19].

To further investigate the association between the *Ku80* promoter G-1401T polymorphism and the risk of gastric cancer, we conducted this hospital-based case-control study in a Chinese population which incorporated the information on exposure to smoking, residence and other potential confounding factors (age and sex) that were frequency matched between cases and controls and further adjusted in the analysis. In our study, a significant difference of the *Ku80* G-1401T genotype distribution was found between gastric cancer cases and controls. The frequency of T allele was significantly higher in gastric cancer patients than in control subjects.

The precise mechanisms underlying the relationship between *Ku80* polymorphism and stomach carcinogenesis remain unclear. Although the *Ku80* promoter G-1401T genetic variation does not directly lead to amino acid coding change, presumably, it is plausible that this SNP influences the expression level or stability of the *Ku80* protein by the alternative splicing, intervention, modification, determination or involvement. It is similar to another important member of NHEJ, XRCC4. A few reports provided evidence that its SNPs located on the promoter region are significant in various cancers^[33,34].

Our data also showed that the association between increased gastric cancer risk and the mutant genotypes (GT + TT) was more evident in younger subjects aged < 58 years than in older subjects. We also found an interaction between genotype and sex. The adjusted OR was 1.81 (95% CI: 1.28-2.52) for GT/TT genotype compared with GG genotype among male subjects. But the OR (adjusted OR = 1.33; 95% CI: 0.81-2.24) was not statistically significant among female subjects. Our findings

were inconsistent with previous observations by Yang *et al.*^[17] and Chang *et al.*^[18]. The reason for the different observations remains unclear.

In addition, we did not note a statistically significant inverse association with gastric cancer risk in both non-smokers (adjusted OR = 1.48; 95% CI: 1.08-2.02) and smokers (adjusted OR = 2.52; 95% CI: 1.25-5.18). But Yang *et al.*^[17] reported that the GT and TT genotypes, in association with smoking, conferred an increased risk (adjusted OR = 2.537; 95% CI: 1.398-4.601) for colorectal cancer. Similarly, Chang *et al.*^[18] and Hsu *et al.*^[19] found a significantly decreased risk of bladder cancer (adjusted OR = 2.053; 95% CI: 1.232-3.419) and oral cancer in smokers with GT or TT genotypes^[18,19]. The results are inconsistent with our findings. The reason for the different observations remains unclear. Several studies have reported that smoking is associated with free radical-induced DNA damage and strand breaks^[26], and tobacco smoke contains some potential carcinogens including polycyclic aromatic hydrocarbons, tobacco nitro-amines, aromatic amines and BPDE, which form DNA bulky adducts and DNA strand breaks^[27,35].

The stratified analyses by residence revealed that the association was significant in variant genotypes in urban subjects (OR = 1.88; 95% CI: 1.26-2.76) but not in rural subjects (adjusted OR = 1.48; 95% CI: 0.99-2.15). The different results may be explained, at least in part, between rural and urban subjects. Environmental factors, including air, soil, diet, occupation and lifestyle, may be responsible for the different observations between rural and urban subjects. It was plausible, considering the better environment in rural areas^[36].

The potential limitations of the present study should be stressed. Firstly, in this hospital-based case-control study, we selected controls from individuals with a variety of nonmalignant diseases. These may cause the possibility of selection bias and confound the results. Nevertheless, the frequencies of *Ku80* G-1401T polymorphism variant alleles were similar to those reported in the NCBI Website in the Asian population studies. T allele frequencies of *Ku80* promoter G-1401T are 15.4% in our

control group and 17.4% for Asian population in NCBI. The genotype distribution of controls in our study met Hardy-Weinberg equilibrium conditions. Secondly, the sample size of the present study was relatively small, which may limit the statistical power. Finally, our study was conducted in Chinese population. Caution should be exercised when extrapolating the data to other ethnic groups.

In conclusion, we found a significant difference in the *Ku80* G-1401T polymorphism distribution between the patients with gastric cancer and the control group. The T allele of the *Ku80* G-1401T was found more frequently in patients with gastric cancer and it may be associated with an increased risk of gastric cancer, suggesting that the polymorphism of *Ku80* G-1401T, involved in the gastric tract carcinogenesis, may be a useful marker for primary prevention and anticancer intervention. Further studies are needed to determine the exact nature of this relationship.

COMMENTS

Background

The *Ku80* gene is an important and specific member of NHEJ. Genetic polymorphisms in *Ku80* genes (G-1401T) influence DNA repair capacity and change the predisposition of several cancers, including colorectal, bladder and oral cancer. Whether genetic variants are involved in the risk of gastric cancer in a Chinese population is unknown.

Research frontiers

In this study, the frequency of the *Ku80* G-1401T GT/TT genotypes was significantly higher in the gastric cancer patients than in control subjects. This is the first analysis of the association between genetic predisposition and gastric cancer risk in Chinese population.

Innovations and breakthroughs

The *Ku80* G-1401T polymorphisms may modulate the development of gastric cancer in a Chinese population.

Applications

The *Ku80* G-1401T GT/TT genotypes can be used as biomarkers for selecting patients from the individuals at high risk for gastric cancer in China. Identifying such susceptibility polymorphisms may lead to the development of tests that allow more focused follow-ups of high-risk groups.

Terminology

The *Ku80* gene, also known as XRCC5, is an important and specific member of NHEJ. As an important component of NHEJ, Ku80 and Ku70 form a heterodimer, which acts as a regulatory subunit of the DNA-dependent protein kinase complex DNA-PK by increasing the affinity of the catalytic subunit PRKDC to DNA.

Peer review

The quality of the work and the methodology are sound. The conclusions are appropriate, although it seems unlikely that these findings represent a major breakthrough.

Abstract

AIM: To test the ability of penehyclidine hydrochloride (PHC) to attenuate intestinal injury in a rat cardiopulmonary bypass (CPB) model.

METHODS: Male Sprague-Dawley rats were randomly divided into six groups (eight each): sham-operated control; sham-operated low-dose PHC control (0.6 mg/kg); sham-operated high-dose PHC control (2.0 mg/kg); CPB vehicle control; CPB low-dose PHC (0.6 mg/kg); and CPB high-dose PHC (2.0 mg/kg). Blood samples were collected from the femoral artery 2 h after CPB for determination of plasma diamine oxidase (DAO), D-lactate and endotoxin levels. Spleen, liver, mesenteric lymph nodes and lung were removed for biochemical analyses. Intestinal tissue ultrastructure was examined by electron microscopy.

RESULTS: In the sham-operated groups, high- and low-dose-PHC had no significant impact on the levels of DAO, D-lactate and endotoxin, or the incidence of

intestinal bacterial translocation (BT). Serum levels of DAO, D-lactate, endotoxin and the incidence of intestinal BT were significantly increased in the surgical groups, compared with the sham-operated groups (0.543 ± 0.061 , 5.697 ± 0.272 , 14.75 ± 2.46 , and $0/40$ vs 1.038 ± 0.252 , 9.377 ± 0.769 , 60.37 ± 5.63 , and $30/40$, respectively, all $P < 0.05$). PHC alleviated the biochemical and histopathological changes in a dose-dependent manner. Serum levels of DAO, D-lactate, and endotoxin and the incidence of intestinal BT in the high-dose PHC group were significantly lower than in the low-dose PHC group (0.637 ± 0.064 , 6.972 ± 0.349 , 29.64 ± 5.49 , and $14/40$ vs 0.998 ± 0.062 , 7.835 ± 0.330 , 38.56 ± 4.28 , and $6/40$, respectively, all $P < 0.05$).

CONCLUSION: PHC protects the structure and function of the intestinal mucosa from injury after CPB in rats.

INTRODUCTION

Cardiopulmonary bypass (CPB) is essential during some cardiovascular surgical procedures; however, it can cause

peripheral hypoperfusion as a result of non-pulsatile flow, low blood pressure, hemodilution, and other non-physiological conditions. Furthermore, an increase in intestinal permeability and bacterial translocation (BT) has been demonstrated, not only in animal models, but also in patients during CPB^[1-3]. Perioperative gastrointestinal integrity is therefore now recognized as an important factor determining the outcome of cardiac surgical procedures^[4]. In general, changes in mucosal permeability and morphology during CPB reflect the degree of damage to intestinal mucosal barrier function.

Previous *in vitro* studies have demonstrated that tropane alkaloids can stabilize the cell membrane and prevent oxidative stress. The new anticholinergic drug, penheyclidine hydrochloride (PHC), has been evaluated for its protective effects on the cardiovascular system^[5-7]. Its selective blocking of M1, M3 and N receptors means that PHC has few M2 receptor-associated cardiovascular side effects. It has been shown to reduce endotoxin-stimulated acute lung injury and to attenuate liver damage during CPB in a rat model^[8-10].

Based on the potential roles of PHC as an antioxidant and a cell membrane stabilizer, we hypothesized that its administration might reverse CPB-associated intestinal damage. Zhan *et al.*^[11] have suggested that PHC concentrations of 0.18-3.60 mg/kg were found to be safe, and we therefore tested this hypothesis in a rat CPB model, using high- (2.0 mg/kg) and low-dose (0.6 mg/kg) PHC.

MATERIALS AND METHODS

Animals and treatments

Forty-eight male Sprague-Dawley rats (weighing 300-450 g, 18-22 wk old) were randomly assigned to one of six groups (eight each): sham-operated control; sham-operated control + low-dose PHC (0.6 mg/kg) (sham L-PHC); sham-operated control + high-dose PHC (2 mg/kg) (sham H-PHC); CPB + vehicle (control); CPB + low-dose PHC (0.6 mg/kg) (L-PHC); and CPB + high-dose PHC (2.0 mg/kg) (H-PHC). PHC (Lisite Pharmacology Co. Chendou, China, No. 080301) was dissolved in absolute ethanol and diluted in saline (final concentration of ethanol < 1.0%), and added to the priming solution for CPB. All animals received humane care in compliance with the Principles of Laboratory Animal Care. The experimental protocol was approved by the local animal use and care committee at the General Hospital of Shenyang Commend, China.

Surgical procedure

None of the sham-operated control groups underwent CPB. After PHC injection, the respiratory rate (RR), heart rate (HR), blood pressure (BP) and electrocardiography (ECG) were continually monitored. The rat CPB model was established as previously described, with some modifications^[12]. In brief, rats were anesthetized by intraperitoneal administration of 10% chloral hydrate (0.3 mL/100 g body weight) to provide stable anesthesia,

while maintaining spontaneous ventilation during the entire operative procedure. All subsequent procedures were performed under aseptic conditions.

After surgical-level anesthesia was achieved, the left femoral artery was cannulated using a 22-gauge Teflon heparinized catheter. Arterial pressure was monitored and blood samples were collected for gas analysis, using a blood gas analyzer (GEM Premier 3000; Mallinckrodt, Lexington, MA, USA). Following administration of heparin (250 U/kg), an 18-gauge catheter was inserted into the right jugular vein and advanced to the right atrium. A 22-gauge catheter was cannulated into the tail artery, to serve as an arterial infusion line for the CPB circuit. The mini-CPB circuit comprised a venous reservoir, a specially designed membrane oxygenator, a roller pump, and sterile tubing with inner diameters of 4 mm for the venous line and 1.6 mm for the arterial line. The CPB circuit was primed with a total volume of 15 mL of synthetic colloid solution. The perfusion flow rate was gradually adjusted to sustain a mean arterial pressure of 60-80 mmHg. The gas flow (95% O₂, 5% CO₂) was initiated at around 50-75 mL/kg per minute and adjusted to maintain blood gas analysis parameters within the physiological range. When the flow rate reached 80-100 mL/kg per minute, it was maintained for 60 min. At the end of CPB, the flow rate was reduced stepwise to achieve hemodynamic stabilization. Throughout the experiment, central body temperature was monitored with a rectal probe and kept at 37.5 ± 1.0°C using a heat lamp placed above the animal and CPB equipment. The mean arterial pressure was maintained at 60-80 mmHg.

Specimen collection

Rats from each group were sacrificed by decapitation, and arterial blood (2.0 mL) and terminal ileums were sampled at 2 h after CPB. Plasma was prepared by centrifugation at 3000 g for 5-10 min at 4°C and stored at -70°C for determination of serum diamine oxidase (DAO), D-lactate, and endotoxin. Intestinal (ileum) tissue samples were obtained for electron microscopy.

Intestinal permeability

The permeability of the intestinal mucosa was assayed by measuring D-lactate and DAO levels in plasma. Plasma D-lactate levels were measured by enzymatic spectrophotometric assay using a centrifugal analyzer at 30°C, as described previously^[13]. Plasma DAO activities were also determined by enzymatic spectrophotometry, as described previously^[14]. D-lactate, D-lactate dehydrogenase, NAD⁺, O-dianisidine, cadaverine dihydrochloride and DAO were purchased from Sigma Chemical Company (Milan, Italy).

Plasma endotoxin determination

The endotoxin content of the plasma sample was assayed using the *Limulus* amoebocyte lysate test using the Endochrome K test kit (CoaChrom, Vienna, Austria). In brief, heparinized plasma was diluted 1:10 in pyrogen-free water

Controls summarize the results from sham-operated rats treated with saline or penehyclidine hydrochloride. ^a $P < 0.05$ vs baseline; ^c $P < 0.05$ vs controls. CPB: Cardiopulmonary bypass; MAP: Mean arterial pressure; HCT: Hematocrit; BE: Buffer excess; HR: Heart rate.

and kept heated at 75°C for 10 min to remove non-specific inhibitors. A quantitative chromogenic kinetic method was used, as specified by the manufacturer, using a Thermo microplate reader (Tecan Spectra, Salzburg, Austria). The method had a detection limit of 0.75 pg/mL at a 1:10 plasma dilution.

Bacteriological cultures

A midline incision was made using a sterile technique. Mesenteric lymph nodes (MLNs), portal vein, and samples from the liver, spleen, and lung were harvested and weighed prior to determination of bacterial growth. The samples were homogenized in test tubes containing 3 mL Brain Heart Infusion Broth (Difco, Detroit, IL, USA). The supernatant (0.2 mL) was cultured for growth of aerobic, microaerophilic and anaerobic bacteria. All media for aerobic cultures were incubated at 37°C for at least 3-5 d, while organ samples for anaerobic bacteria were cultured at 37°C for 7 d. Enteric Gram-negative bacteria were identified using the API 20 system (BioMérieux SA, Marcy-l'Étoile, France) and *Lactobacillus acidophilus* by API 50 CH (Analytab Products Inc., Plainview, NY, USA). All other aerobic, microaerophilic and anaerobic microbes isolated were identified by standard procedures. The numbers of living bacteria were calculated and expressed as the numbers of living organisms per gram of organ tissue.

Transmission electron microscopy

For transmission electron microscopy, ileum tissues were removed immediately from anesthetized rats 2 h after CPB, and then fixed with 2% paraformaldehyde and 2.5% glutaraldehyde in PBS (pH 7.3) for 2 h at room temperature (25°C). The tissues were washed with PBS, fixed

with 1% osmium tetroxide for 2 h, washed again, and then embedded in Araldite 6005. Tissue sections were cut with a Leica EM FCS (Vienna, Austria) ultramicrotome. Tissue sections (1 μ m) were initially stained with toluidine blue-Azur II to select the region of interest for subsequent procedures. Thin sections (60-70 nm) were stained with uranyl acetate and lead citrate and examined and photographed using an H-7200 transmission electron microscope (80 kV; Oberkochen, Germany). Electron microscopy pictures were evaluated twice by two independent histologists with at least 10 years of experience, who were blinded to our study.

Statistical analysis

All experimental data were expressed as mean \pm SD and analyzed using a SPSS for Windows v. 13.0 (Chicago, IL, USA). One-way ANOVA was used for comparisons among various treatment groups. *Post-hoc* comparisons were analyzed using least significant difference test or Dunnett's T3 test. $P < 0.05$ was considered to be statistically significant.

RESULTS

PHC reverses the increase in intestinal mucosal permeability after CPB

There were no obvious changes in the RR, HR, BP or ECG at any time points (0, 30, 60, or 120 min) after anesthesia in the sham-operated groups (Table 1). Hemodynamic changes in the vehicle control, L-PHC and H-PHC groups are shown in Table 1. As shown in Table 2, DAO and D-lactate levels increased significantly in vehicle-treated CPB rats, compared with the sham group ($P < 0.05$), which effect was largely reversed by treatment with

Table 2 Plasma diamine oxidase, D-lactate and endotoxin levels (mean \pm SD, $n = 8$)

| | DAO (U/L) | D-lactate (mg/L) | Endotoxin (pg/mL) |
|---------------|----------------------------------|----------------------------------|---------------------------------|
| Controls | 0.543 \pm 0.061 | 5.697 \pm 0.272 | 14.75 \pm 2.46 |
| CPB + vehicle | 1.038 \pm 0.252 ^a | 9.377 \pm 0.769 ^a | 60.37 \pm 5.63 ^a |
| CPB + L-PHC | 0.998 \pm 0.062 ^{a,e} | 7.835 \pm 0.330 ^{a,e} | 38.56 \pm 4.28 ^{a,e} |
| CPB + H-PHC | 0.637 \pm 0.064 ^{a,c} | 6.972 \pm 0.349 ^{a,c} | 29.64 \pm 5.49 ^{a,c} |

Controls summarize the results from sham-operated rats treated with saline or penheyclidine hydrochloride (PHC). Data are shown as medians, $n = 8$ rats for each group. CPB: Cardiopulmonary bypass; H-PHC: High-dose PHC; L-PHC: Low-dose PHC; DAO: Diamine oxidase. The level of significance was set at $P < 0.05$. ^a $P < 0.05$ vs baseline; ^c $P < 0.05$ vs CPB group; ^e $P < 0.05$ vs H-PHC group.

Table 3 Numbers of animals pretreated with vehicle or penheyclidine hydrochloride with positive bacteriological cultures from blood (portal vein), mesenteric lymph nodes, liver, spleen and lungs after induction of cardiopulmonary bypass

| | Portal vein | MLN | Liver | Lungs | Spleen | Total |
|---------------|-------------|-----|-------|-------|--------|----------------------|
| Controls | 0 | 0 | 0 | 0 | 0 | 0/40 |
| CPB + vehicle | 7 | 8 | 6 | 4 | 5 | 30/40 ^{a,c} |
| CPB + L-PHC | 3 | 4 | 3 | 2 | 2 | 14/30 ^{a,c} |
| CPB + H-PHC | 2 | 3 | 1 | 0 | 0 | 6/40 ^a |

Controls summarize the results from sham-operated rats treated with saline or penheyclidine hydrochloride (PHC). MLN: Mesenteric lymph node; CPB: Cardiopulmonary bypass; H-PHC: High-dose PHC; L-PHC: Low-dose PHC. ^a $P < 0.05$ vs controls; ^c $P < 0.05$ vs L-PHC group.

PHC in a dose-dependent manner ($P < 0.05$). H-PHC had significantly greater effects on the values of DAO and D-lactate than L-PHC (Table 2, $P < 0.05$).

PHC prevents CPB-induced BT

Bacteriological cultures from all sham-operated animals were negative. The incidence of *Escherichia coli*-positive cultures was significantly increased in the CPB-vehicle group, while pretreatment with PHC seemed to prevent systemic dissemination. The incidence of intestinal BT to the MLNs, spleen, liver, lung and blood was significantly higher in the CPB-vehicle group, compared with that in the sham groups (Table 3, $P < 0.05$), which was largely reversed by treatment with PHC in a dose-dependent manner (Table 3, $P < 0.05$). The plasma endotoxin level was increased in the CPB-vehicle group compared with the sham groups (Table 2, $P < 0.05$) and PHC decreased the plasma endotoxin levels in a dose-dependent manner (Table 2, $P < 0.05$).

PHC prevents CPB-induced damage to the intestinal mucosa ultrastructure

Transmission electronic microscopy demonstrated normal intestinal ultrastructure in the sham-operated group, including regularly aligned microvilli in the intestinal epithelium, integral mitochondria and rough endoplasmic reticulum (RER) and distinct junction complexes

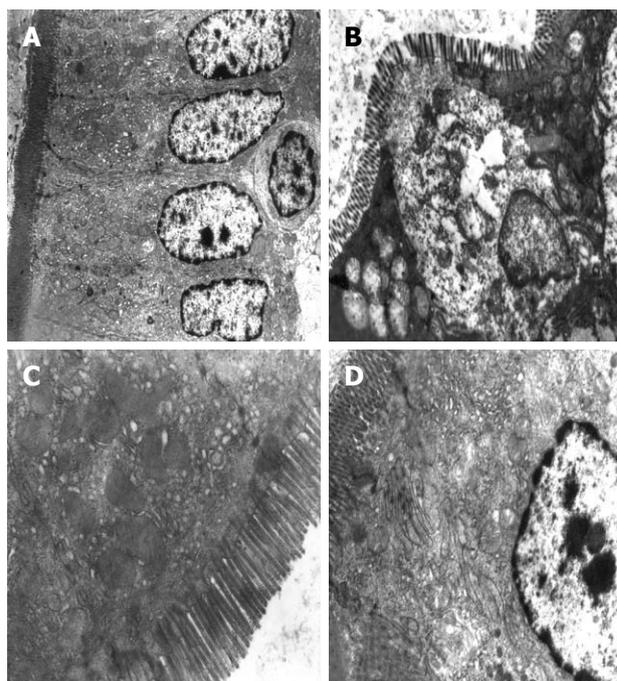

Figure 1 Effect of cardiopulmonary bypass on the ileal epithelial cells. A: Control group ($\times 5800$), regularly-aligned microvilli in the intestinal epithelium, intact mitochondria and rough endoplasmic reticulum (RER), and distinct junctional complexes were observed; B: Cardiopulmonary bypass group ($\times 7200$), epithelial damage was demonstrated by swollen mitochondria and loss of cristae, and tight junctions were disrupted; C: Mitochondrial swelling with damage to mitochondrial cristae and vacuolar degeneration were present. The nuclear structure was incomplete; D: Microvilli in the intestinal epithelium were regularly aligned, and the structure of the tight junctions became tight. However, mild swelling of mitochondria and RER were observed.

(Figure 1A). In the vehicle control group, the microvilli were reduced in number, and showed irregular lengths and arrangements. The mitochondria were swollen with cracked and vacuolated cristae. Some RER structures were destroyed, and the intercellular spaces between epithelial cells were widened. The structure of the tight junctions became shortened (Figure 1B). Mitochondrial swelling with damage to mitochondrial cristae and vacuolar degeneration was present in the L-PHC group. The nuclear structure was incomplete (Figure 1C). In the H-PHC group, microvilli in the intestinal epithelium were regularly aligned, and the tight junction structure became tight. However, mild swelling of the mitochondria and RER were seen (Figure 1D). These results indicated dose-dependent effects of PHC on the reduction of cellular damage after CPB.

DISCUSSION

The present study focused on intestinal barrier injury after CPB and the potential of PHC as a therapeutic agent. We demonstrated that application of PHC during CPB preserved intestinal barrier function in a dose-dependent manner, and histological evidence is provided to support these biochemical results.

DAO reduces the concentration of polyamines re-

quired for cell proliferation. DAO is localized to the small intestine and placenta, which are both organs with rapid cell turnover rates. In humans, DAO activity is especially high in the upper portion of the small intestinal villi, and has therefore been used as an index of small intestinal mucosal mass and integrity. Serum DAO levels have been found to increase markedly when the small intestine is strangulated, and elevations are thus believed to reflect small intestine mucosal ischemia^[15]. Tsunooka *et al.*^[4,16] have demonstrated simultaneous increases in serum DAO activity and peptidoglycan concentrations during clinical CPB, suggesting the occurrence of small intestinal mucosal ischemia and BT.

D-Lactate is habitually tested for in the intensive care unit. Mammals only have one type of enzyme: L-lactate dehydrogenase. L-Lactate is a marker of cell hypoxemia, and its levels correlate with survival in patients with septic shock^[17,18]. Microorganisms however, particularly bacteria, are equipped with D-lactate dehydrogenase and produce D-lactate during fermentation, and D-lactate therefore acts as a marker of bacterial infection. D-Lactate has also recently been proposed as a sensitive, specific and early marker of translocation in gut ischemia^[19].

In the current study, all the rats survived the CPB procedures. DAO and D-lactate activities remained low in the sham-operated animals (based on previously reported normal DAO value of 0.46 ± 0.087 U/L, and D-lactate value of 5.245 ± 0.653 mg/L^[13,14]). However, significant increases in DAO, D-lactate and endotoxin levels were found in the vehicle-treated CPB group. The incidence of intestinal BT to the MLNs, spleen, liver, lung and blood was also significantly higher in the vehicle-treated CPB group, compared with that in the sham groups. These results indicate the occurrence of severe intestinal barrier injury after CPB. Transmission electron microscopic examination of intestinal tissues further confirmed the intestinal barrier injury in this rat CPB model.

There is increasing interest in developing PHC as a novel therapeutic agent. PHC is a new anticholinergic drug derived from hyoscyamine, which has few M2 receptor-associated cardiovascular side effects, because of its selective blocking of M1, M3 and N receptors. Recent clinical results have demonstrated that PHC has curative effects in soman poisoning and pulmonary dysfunction associated with chronic obstructive pulmonary disease^[6,9,20]. In addition to improving microcirculation, PHC can inhibit lipid peroxidation, attenuate the release of lysosomes, and depress microvascular permeability^[9,20]. Moreover, it can significantly decrease brain nuclear factor (NF)- κ B expression in cerebral ischemia/reperfusion (I/R) injury. Furthermore, PHC can improve acute lung injury stimulated by endotoxin and attenuate liver damage during CPB in a rat model^[11].

In the present study, PHC lowered DAO, D-lactate and endotoxin levels in PHC-treated rats in a dose-dependent manner, suggesting its potential clinical application. The incidences of intestinal BT to MLNs, spleen, liver, lung and blood were lower in PHC-treated CPB rats than

in untreated CPB ones, suggesting that the use of PHC resulted in an overall decrease in bacteria. In intestinal mucosal injury, PHC can efficiently inhibit NF- κ B expression in intestinal mucosal I/R injury. More importantly, PHC can improve the microcirculation, inhibit lipid peroxidation, attenuate the release of lysosomes, and decrease microvascular permeability, leading to the inhibition of inflammation^[21].

However, our research was subject to some limitations. PHC treatment was only performed prior to CPB; although this pretreatment was effective, this study did not establish the efficacy of PHC given after CPB. Future studies are required to assess the effects of postoperative treatment with PHC. Additional research is also needed to establish the optimal time of PHC administration.

In conclusion, the present study demonstrated that PHC protected rat intestine from morphological and functional mucosal injury after CPB. These results suggest that PHC could be clinically useful for the treatment of intestinal injury induced by CPB.

COMMENTS

Background

An increase in intestinal permeability and bacterial translocation has been demonstrated not only in animal models, but also in patients during cardiopulmonary bypass (CPB). Previous *in vitro* studies have demonstrated that tropane alkaloids could stabilize the cell membrane and prevent oxidative stress. The new anticholinergic drug penehyclidine hydrochloride (PHC) has been evaluated for its protective effects on the cardiovascular system.

Research frontiers

PHC can improve microcirculation, inhibit lipid peroxidation, attenuate the release of lysosomes, and decrease microvascular permeability, leading to the inhibition of inflammation. The effects of PHC on intestinal barrier function during CPB have not been unequivocally addressed. We hypothesized that the administration of PHC could reverse CPB-associated intestinal damage.

Innovations and breakthroughs

The selectivity of PHC in blocking M1, M3 and N receptors means that it has few M2 receptor-associated cardiovascular side effects. It can reduce endotoxin-stimulated acute lung injury and attenuate liver damage during CPB in a rat model. The present study demonstrated that the application of PHC during CPB preserved intestinal barrier function in a dose-dependent manner, and provided histological findings to support these biochemical results.

Applications

The present study demonstrated the ability of PHC to protect rat intestine from morphological and functional mucosal injury after CPB. These results suggest that PHC could be clinically useful in the treatment of intestinal injury induced by CPB.

Terminology

PHC is a new anticholinergic drug with antioxidant and cell membrane-stabilizing activities.

Peer review

The authors have demonstrated a protective role for PHC in preventing intestinal breakdown during CPB. The conclusion was reached that the administration of PHC could prevent intestinal damage and its sequelae following CPB surgery. This manuscript describes an interesting and well-performed study with convincing results.

Abstract

AIM: To evaluate the efficacy and safety of combination therapy with recombinant adenovirus *p53* injection (rAd*p53*) and transcatheter hepatic arterial chemoembolization (TACE) for advanced hepatocellular carcinoma (HCC).

METHODS: A total of 82 patients with advanced HCC treated only with TACE served as control group. Another 68 patients with HCC treated with TACE in combination with recombinant adenovirus-*p53* injection served as *p53* treatment group. Patients were followed up for 12 mo. Safety and therapeutic effects were evaluated according to the improvement in clinical symptoms, leukocyte count, Karnofsky and RECIST criteria. Survival rate was calculated with Kaplan-Meier method.

RESULTS: The total effective rate was 58.3% for *p53* treatment group, and 26.5% for control group ($P < 0.05$). The incidence of gastrointestinal symptoms was lower in *p53* treatment group than in control group ($P < 0.05$). The 3-, 6- and 12-mo survival rates were significantly higher for *p53* treatment group than for

control group ($P < 0.01$). The combination treatment was well tolerated with such adverse events as fever (51.5%, $P = 0.006$) and pain of muscles and joints (13.2%, $P = 0.003$), which were significantly higher than the chemotherapy. Except for these minor adverse effects, no severe vector-related complications were identified. With respect to the efficacy, patients in *p53* treatment group had less gastrointestinal symptoms ($P = 0.062$), better improvement in tumor-related pain ($P = 0.003$), less downgrade of leukocyte counts ($P = 0.003$) and more upgrade of Karnofsky performance score ($P = 0.029$) than those in control group. The total effective rate (CR + PR) for *p53* treatment group and control group was 58.3% and 26.5%, respectively, with distributions of different effect in two groups ($P = 0.042$). The survival rates were 89.71%, 76.13%, and 43.30% for *p53* treatment group, and 68.15%, 36.98%, and 24.02% for control group, respectively, 3, 6 and 12 mo after treatment, suggesting that the survival rates are significantly higher for *p53* treatment group than for control group ($P = 0.0002$).

CONCLUSION: The rAd-*p53* gene therapy in combination with TACE is a safe and effective treatment modality for advanced HCC.

INTRODUCTION

Gene therapy is a potentially new treatment modality for cancer patients and an engineered recombinant replication-defective adenovirus can express the tumor suppressor gene *p53* (rAd-p53) with encouraging clinical responses^[1-3]. rAd-p53 has been recently approved by the State Food and Drug Administration of China as the very first gene therapy product for head and neck squamous cell carcinoma (HNSCC)^[4].

Hepatocellular carcinoma (HCC) is one of the major cancers in China with a poor prognosis due to its occult onset, rapid infiltrating growth and complicating liver cirrhosis. No effective treatment modality is available for it at present. Although transcatheter hepatic arterial chemoembolization (TACE) is currently one of the most popular treatment modalities for unresectable advanced HCC, the long-term survival rate of such patients remains low with a reported 5-year survival rate of 17%^[5]. In this study, the safety and efficacy of rAd-p53 therapy in combination with TACE were examined in patients with advanced HCC.

MATERIALS AND METHODS

rAd-p53

rAd-p53 is a recombinant human serotype 5 adenovirus in which the E1 region is replaced by a human wild-type *p53* expression cassette. The *p53* gene is driven by a Rous sarcoma virus promoter with a bovine growth hormone poly (A) tail. The recombinant adenovirus is produced in human embryonic kidney 293 cells and manufactured by Shenzhen SiBionoGenTech Co. Ltd (Shenzhen, China) and marketed under the trade name of Gendince®. Before *p53* gene therapy, a vial of rAd-p53 is taken out from a refrigerator in which the temperature is about -20°C. When thawed, the solution, diluted with 1 mL NS, is sucked into a 5-mL syringe for intra-tumor injection.

Patients and trial design

One hundred and fifty patients (83 men and 67 women) with advanced HCC were enrolled in this study from March to July 2004. Patients with Child C disease^[6], tumor thrombus in the main portal trunk, or extrahepatic metastasis were excluded. These exclusion criteria were implemented to ensure at least a 3-mo life span in the enrolled patients so as to have enough time to follow up. All patients did not receive local ethanol injection, microwave coagulation, systemic chemotherapy or radiotherapy before and after TACE or gene therapy. All tumors were diagnosed according to pathologic examination, distinctive findings on computed tomography (CT), conventional angiography, magnetic resonance imaging (MRI), or serum tumor markers [alpha-fetoprotein (AFP) or ferritin]. The patients were divided into gene treatment group ($n = 68$) with a mean age of 43 years (range 20-72 years) and control group ($n = 82$) with a mean age of 45 years (range 18-75 years). No patient was classified as stage I or II while 91 patients were classified as stage

III and 59 patients as stage IV according to the International Union against Cancer TNM classification^[7].

Patients who gave their informed consent to receive Ad-p53 gene therapy served as gene treatment group, while those not willing to receive gene therapy served as control group. Patients in gene treatment group underwent rAd-p53 gene therapy and TACE while those in control group received only TACE. Although this was a retrospective nonrandomized study, no statistical difference was observed in baseline between the two groups. The characteristics of the two groups are illustrated in Table 1.

Procedure of rAd-p53 intra-tumor injection

The patients in gene treatment group were placed in a supine, prone or lateral position on the CT scanning bed and asked to hold their breath after an inhalation. The slice for puncture was carefully determined, the puncture site on the surface of body as well as the needle-traveling depth and angle within the body were determined. The bed was moved to the slice and a marker for puncture was made on the body surface according to the laser beam emitted from the gantry. The bed was then moved out and the puncture site was sterilized. After local anesthesia, a 19-G needle was inserted into the puncture site according to the determined angle and depth as the operator asked the patient to hold his or her breath after an inhalation. Finally, another scan was performed to make sure that the tip of the needle was within the tumor, and the rAd-p53 gene was injected into the tumor in a multi-point fashion. Usually, this procedure is repeated according to the patient's clinical condition and the interval between two procedures is about 1 wk. At each injection, 1-4 rAd-p53 injections are administered at a viral dose of $1-4 \times 10^{12}$ VP (viral particles) according to the diameter of the lesion, and the intra-tumor injection usually lasts 1-2 min.

TACE

TACE was performed through the femoral artery using the Seldinger technique with local anesthesia. Arteriography of the celiac trunk and superior mesenteric artery was performed to visualize the arterial vascularization of liver and evaluate portal vein patency. An angiographic

catheter was inserted into the right or left hepatic artery where the target tumor was located. TACE agents, involving embolic agent (Lipiodol) and anticancer drugs, were injected through the right or left hepatic artery. In both groups, the dose of Lipiodol, ranging 3-20 mL, was determined according to the tumor location, tumor size, number of tumors, and functional hepatic reserve. Anticancer drugs used were 5-Fluorouracil (800-1000 mg) and vinorelbine (30-40 mg). TACE was repeated according to the patient's clinical condition at a 1-mo interval.

Follow-up protocol

Clinical symptoms, leukocyte counts and Karnofsky index evaluation were recorded before and after treatment. After treatment, CT scan or MRI was performed every three months with or without contrast enhancement to evaluate the features of Lipiodol deposit and the therapeutic effect according to the response evaluation criteria for solid tumors^[8]. If elevated tumor markers (AFP and ferritin), diminished Lipiodol, or enlarged lesions or new nodules were observed, the patients were readmitted for angiography and treatment. The starting point of survival analysis was regulated as the day of initial treatment. The Kaplan-Meier method was used to analyze the survival rates in the two groups.

Statistical analysis

Statistical analysis was performed to assess the baseline, leukocyte counts, Karnofsky index, clinical symptoms and survival curve between the two groups using the SPSS 11.0. $P < 0.05$ was considered statistically significant.

RESULTS

Two hundred and fifty-one p53 intra-tumor injections were performed for 83 lesions in 68 patients of gene treatment group. Of the 68 patients, 9 received one injection, 13 received two injections, 15 received three injections, 20 received four injections, 7 received five injections, 3 received six injections and 1 received seven injections. One hundred and ninety-two (mean 2.82 procedures) and 167 (mean 2.03 procedures) procedures of TACE were performed in gene treatment and control groups, respectively. Arterial portal vein shunt (AVS), arterial hepatic vein shunt (APS) or/and portal vein involvement, signs that meant a high invasion and a poor prognosis were found in 27.9% (19/68) patients of gene treatment group and 36.6% (30/82) patients of control group, respectively, during the TACE. Although the patients with tumor thrombus in the main portal trunk were excluded, some of them developed vascular invasion because of tumor progression after they were enrolled in this study. No difference was observed in the incidence of malignancy signs such as AVS, APS or portal vein involvement between the two groups.

Safety

The clinical symptoms were carefully recorded after treatment (Table 2). Overall, rAd-p53 gene therapy in combination with TRCE was well tolerated. The most

frequent adverse event occurred in patients receiving rAd-p53 gene therapy in combination with TACE was the flu-like symptom associated with fever. Of the 68 patients in gene treatment group, 35 (51.5%) had a fever at 38-39.5°C, usually occurred 3-10 h after p53 intra-tumor injection and decreased after physis cooling, and 9 (13.2%) had pain of muscles or joints which often faded away (Table 2). No other severe gene therapy-associated complications were encountered in this study.

Efficacy

The clinical symptoms were carefully recorded after treatment (Table 2). The patients in gene treatment group had less gastrointestinal symptoms such as nausea, vomiting, abdominal pain or belling than those in control group. The palliative rate of mass-associated pain one week after treatment was 44.1% (30/68) for patients in gene treatment group, higher than that for those in control group.

Before and one week after treatment, the number of leukocytes was calculated (Table 3). Statistical analysis showed that the number of leukocytes was smaller in gene treatment group than in control group ($P = 0.003$).

Karnofsky index was changed in gene treatment group one month after treatment (Table 4). Generally speaking, the patients in gene treatment group had a higher Karnofsky index than those in control group ($P = 0.029$).

The therapeutic effect was evaluated following the response evaluation criteria for solid tumors after treatment. CR, PR, NC and PD in the two groups are listed in Table 5. The total effective rate (CR + PR) was 58.3% and 26.5% for the gene treatment group and control group, respectively ($P < 0.05$). Chi-square test showed that the distributions of therapeutic effect were statistically different ($P = 0.042$, Figures 1 and 2)

The patients were followed up for 12 mo. The number of withdrawal patients in gene treatment group and control group was 4 and 7, respectively. The survival rate was 89.71% (standard error 0.036), 76.13% (standard error 0.052), and 43.30% (standard error 0.061),

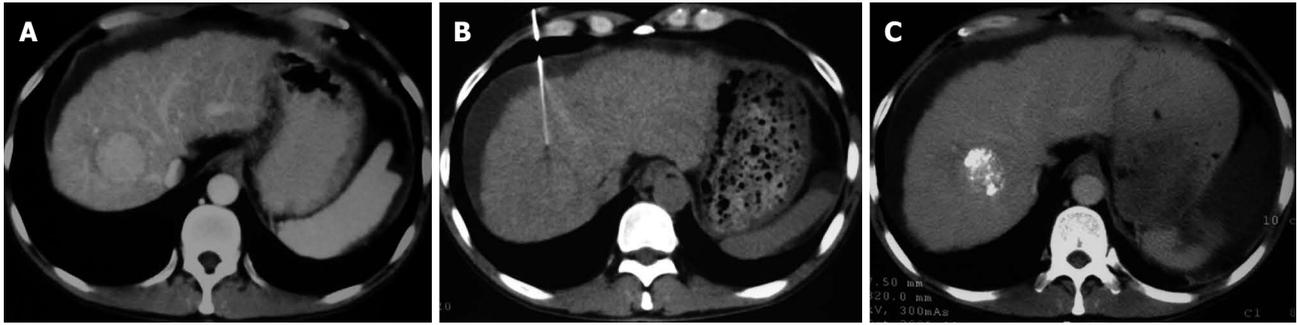

Figure 1 Contrast computed tomography showing a nodule (3.5 cm in diameter) in the right upper liver lobe manifested as homogenous enhancement (A); computed tomography scan (b) demonstrating the course of fine needle biopsy under computed tomography guidance with the diagnosis of hepatocellular carcinoma confirmed (B); computed tomography follow-up (c) revealing lipiodol deposit in the mass and spleen infarction after spleen embolization (C) in a 52-year-old man with multiple hepatic nodules, liver cirrhosis, splenomegaly and elevated alpha-fetoprotein.

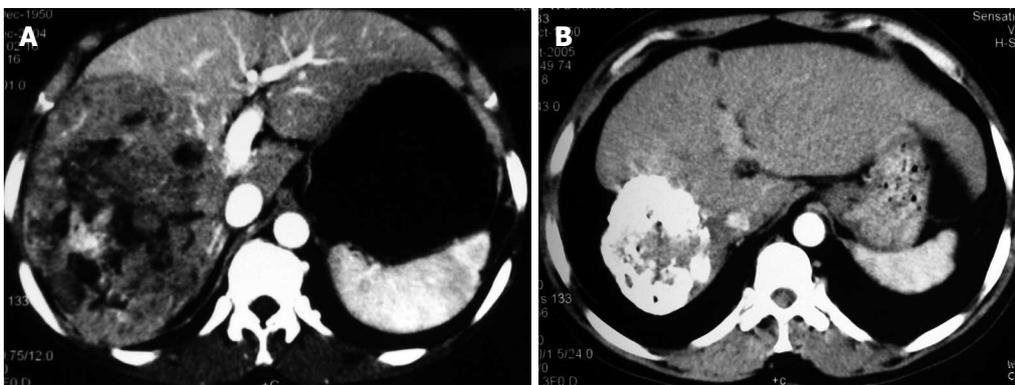

Figure 2 Contrast computed tomography scan showing a 15 cm × 11.5 cm hepatocellular carcinoma in the right liver lobe manifested as a heterogenous lower density, partial enhancement and well-differentiated contour (A) and computed tomography follow-up displaying the significant regression of a 8.5 cm x 6 cm lesion with compact lipiodol deposit in a 72-year-old man after 3 p53 gene injections and 4 courses of transcatheter hepatic arterial chemoembolization.

respectively, for the patients in gene treatment group 3, 6, and 12 mo after treatment. The survival rate was 68.15% (standard error 0.051), 36.98% (standard error 0.054), and 24.02% (standard error 0.049), respectively, for those in control group 3, 6, and 12 mo after treatment. Log-rank test showed that the survival rate for the two groups was significantly different ($P = 0.0002$, Figure 3).

DISCUSSION

Hepatocellular carcinoma (HCC) is a highly malignant tumor with a very high morbidity and mortality. Since TACE was introduced as a palliative treatment of unresectable HCC, it has become one of the most common

Table 5 Therapeutic effect evaluated following response evaluation criteria for solid tumors 2 mo after treatment

interventional therapies^[9-12]. However, its therapeutic effect is also limited due to the lack of appropriate and reliable embolic agents, and the infiltrative or hypovascular nature, too large or small in size^[13-15]. Another limitation of TACE is the need for repeated treatment, thus resulting in deterioration of liver function^[16]. So, lots of efforts have been made to explore other new therapies in order to achieve the better efficacy of multiple treatments. PEI or RFA gene therapy in combination with TACE may improve the survival rate of HCC patients and decrease the risk of liver failure^[17-19]. In this study, p53 gene therapy in combination with TACE could overcome the downside of TACE and improve the prognosis of HCC patients.

The p53 tumor suppressor gene is a gene guardian and loss of p53 is responsible for the lack of apoptotic signals

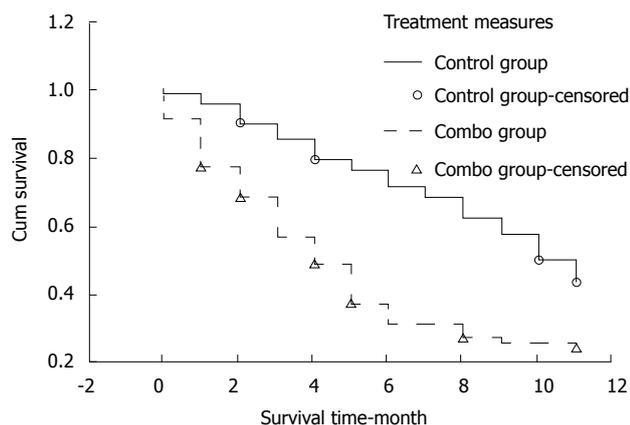

Figure 3 Survival curves for patients following treatment.

in tumor cells and thus for their uncontrolled proliferation and recurrence^[20]. Many human tumors carry mutations in the *p53* gene^[21,22] and mutant or absent *p53* gene is associated with the resistance to radiotherapy and apoptosis-inducing chemotherapy^[23]. It has been shown that *p53* gene therapy in combination with radiotherapy or chemotherapy can control local tumor, suggesting that it is superior to either radiotherapy or chemotherapy alone^[24,25]. It was reported that the incidence of *p53* mutation is 61% in HCC^[22]. Chen *et al*^[26] also reported that mutations in the *p53* gene are frequently detectable in recurrent HCC and the interval between surgical resection and recurrence of HCC is significantly longer in patients with the wild-type *p53* gene than in those with mutant *p53* gene mutations, strongly suggesting that the mutant *p53* gene plays a role in pathogenesis of HCC. Jeng *et al*^[27] demonstrated that the biological behavior of the mutant *p53* gene is strongly related to the invasiveness of HCC and may also influence the postoperative course of HCC. Many scholars suggest that immunopositivity of the mutant *p53* gene plays a role in predicting the prognosis of patients with HCC after resection^[27-29].

The rAd-*p53* gene has been approved in China under the trade name of Gendicine for the treatment of head and neck squamous cell carcinoma (HNSCC). In one of the trials^[3], 75% tumors experienced complete regression following 8 wk of therapy involving 1 injection per week, which was significantly higher than that in control group, and combined chemotherapy and radiotherapy improved the treatment efficacy of over 3-fold. Although its recommended indications are limited in HNSCC according to the specification, good treatment efficacy can be achieved in HCC patients when rAd-p53 is used^[30]. In the current study, Gendicine was used in treatment of HCC to evaluate its effect in order to provide some evidence for its off-table use in treatment of HCC.

As for the safety of rAd-p53 used in treatment of advanced HCC, just fever at 38-39.5°C was observed in our study, which was returned to normal after symptomatic treatment. In addition, some patients suffered from pain of muscles or joints and its cause is still controversial. However, no severe complications caused by Gendicine

were observed. Although these adverse events have been observed in clinical practice, they can be well tolerated by most patients with no severe physical and mental harm.

The patients receiving *p53* gene therapy had less severe post embolization syndrome than others after TACE. Gastrointestinal symptoms, such as nausea, vomiting and abdominal pain or belling, were less frequently observed in gene treatment group than in control group. The decreased number of leukocytes in gene treatment group was a pleasing phenomenon. However, its mechanism remains to be studied. The Karnofsky index was significantly higher, suggesting that the life quality of patients is largely improved in gene treatment group. It could be concluded that the rAd-*p53* gene therapy could reduce the side effects of chemical drugs and Lipiodol embolization. Also, it was noticed that many patients in gene treatment group had a compact Lipiodol deposit manifested as a high homogeneous density occupying the majority of tumor mass (Figures 1 and 2). Compact deposit means tumor necrosis. Further study is needed to observe whether *p53* gene therapy is related to the better deposit of Lipiodol in lesions.

Theoretically, *in-vitro* *p53* protein can bring about specific anti-tumor cells into effect in such ways as induction of apoptosis or necrosis, incentive of body immune response, regulation of cell cycle, *etc.* Two months after treatment, the distributions of therapeutic effect in the two groups were statistically different and the effective rate (CR + PR) was higher for *p53* gene treatment group than for control group, suggesting that *p53* gene therapy can enhance the efficacy of TACE, radiotherapy and chemotherapy.

Kaplan-Meier analysis showed that the survival rate was higher for gene treatment group than for control group. Because no other control study is available, the outcome of *p53* gene therapy for such a large number of patients was not compared with that in other studies. The 1-year survival rate was lower in our study than in another study (67% *vs* 81%)^[31], which may be attributed to the different baselines, in which our enrolled patients might have a larger lesion and a poorer liver function reserve.

Although it seems that the higher survival rate in gene treatment group may be attributed to the longer mean TACE time in patients of gene treatment group than in those of control group (2.82 *vs* 2.03), it was the clinical improvement after *p53* gene therapy that made the patients in gene treatment group have more chance to receive repeated TACE. On the other hand, no difference was found in the incidence of malignancy DSA signs between the two groups. However, these signs appeared later with a lower incidence in gene treatment group than in control group, which is an interesting phenomena, and further study with a larger sample size is needed to confirm it.

Usually, the rAd-*p53* gene begins to express *p53* protein 3 h after intra-tumor injection, reaches its peak on day 3, and then gradually decreases according to the specification of Gendicine®. On day 5 after injection, the expression decreases to 30%. Because most of the chemotherapeutic drugs can affect DNA or RNA duplication or expression, cell cycle or nucleic acid metabolism would likewise affect the expression of *p53* gene in

tumor tissue. In this study, TACE was started 3-4 d after p53 injection when the p53 protein was highly expressed in tumor tissue, indicating that these anti-tumor drugs do not interfere with the expression of p53. However, the optimal interval remains to be further studied.

In conclusion, rAd-p53 gene therapy in combination with TACE is well tolerated and its anti-tumor efficacy is superior to that of TACE alone in terms of the survival rate and improved symptoms of HCC patients. Further clinical study with a large sample size is warranted to optimize the administration procedure and assess the impact of anti-p53 antibody on its therapeutic effect.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is one of the major cancers in China with a poor prognosis due to its occult onset, rapid infiltrating growth and complicating liver cirrhosis. Although transcatheter arterial chemoembolization (TACE) has been used in treatment of HCC for years, its effect is often unsatisfactory.

Research frontiers

Among the actively studied novel treatment modalities for HCC, the majority of experts hold that comprehensive or combination ones are most promising. In addition, gene therapy with p53 (rAd-p53) is a potentially new treatment modality for cancer.

Innovations and breakthroughs

TACE in combination of rAd-p53 injection has a synergistic effect on HCC and its strategy is gene addition. Tumor with mutant of the rAd-p53 gene is a better candidate for p53 therapy. However, this treatment is also effective in those with inactivated wild-type p53, a common condition in tumors. Injection of rAd-p53 can lead to apoptosis of tumor cells and TACE can result in necrosis of tumor tissue.

Applications

The results of this study demonstrate that TACE in combination with rAd-p53 with is well tolerated and its anti-tumor efficacy is superior to that of TACE alone with respect to the survival rate and improved symptoms. Further study with a large sample size would provide an alternative treatment modality for HCC.

Terminology

p53 gene is a tumor suppressor gene which can prevent the formation of tumors. Mutations in p53 are found in most tumor types and contribute to complex molecular events leading to tumor formation. Recombinant adenovirus is one of the viral vectors which are commonly used to deliver genetic materials into cells. Gene therapy for diseases is to insert, alterate, or remove such materials in cells.

Peer review

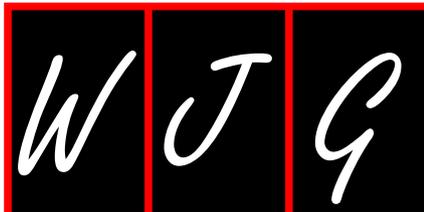

This is a well-designed study in which the authors analyzed the clinical effect of rAd-p53 injection and TACE on advanced HCC. The data show that the combination therapy is a safe and effective treatment modality for advanced HCC, and can significantly improve the survival rate of HCC patients.

Abstract

Celiac disease (CD) is an autoimmune disorder of the small intestine that occurs in genetically predisposed people at all ages. However, it can be associated also to other immunopathological disorders, and may be associated with abnormal histology in segments of the gut other than the small bowel including colonic inflammation. While guidelines for endoscopic investigation of the jejunum are well defined, no indication is defined for colonic investigation. We describe four cases of concurrent CD and microscopic colitis (MC) diagnosed at our department over a 10-year period and analyzed the main features and outcomes of CD in this setting. The symptoms of these patients were improved initially by a gluten-free diet before the onset of MC symptoms. Two of the patients were siblings and had an atypical form of CD. The other two patients with CD and MC also presented with fibrosing alveolitis and were anti-Saccharomyces cerevisiae antibody positive. The co-existence of immune-mediated small bowel and colonic inflammatory and pulmonary diseases are not well-known, and no systematic approach has been used to identify the lifelong patterns of these immune-based diseases. Patients can develop, or present with CD at any stage in life, which can co-exist with other gastrointestinal diseases of (auto-) immune origin. In addition, the fa-

miliar co-existence and prevalence of MC in patients with a prior diagnosis of CD are unclear. Clinicians managing celiac disease should be aware of these associations and understand when to consider colon investigation.

INTRODUCTION

Celiac disease (CD) is an immune-mediated disorder, an autoimmune enteropathy, triggered by the ingestion of gluten in genetically susceptible persons. The disease primarily affects the gastrointestinal tract and is characterized by chronic inflammation of the small bowel mucosa that may result in atrophy of intestinal villi, malabsorption, and a variety of clinical manifestations. Of genetic factors, the strongest recognized association is with HLA-DQ2 and/or -DQ8: 95%-100% of the patients carry these molecules. Dietary glutes interact with these HLA molecules to activate an abnormal mucosal immune response and induce tissue damage. Most affected individuals experience remission after gluten is excluded from their diet.

The diagnosis of CD is established by serologic testing, biopsy evidence of villous atrophy, and improvement of symptoms on a gluten-free diet. Avoidance of gluten

exposure is crucial for CD patients to reduce the risk of complications so the follow-up serological assessment of treatment effectiveness should be added to be sure of a good compliance.

There are atypical forms of CD. For example, silent CD is found in individuals who are asymptomatic but have a positive serologic test and villous atrophy on biopsy, and latent CD is defined by a positive serology but no villous atrophy on biopsy. These individuals are asymptomatic, but later may develop symptoms and/or histological changes^[1]. The late concordance in the appearance of CD in monozygotic twins also suggests that the disorder may remain in the latent stage for a long time^[2,3]. Small bowel villous atrophy with crypt hyperplasia and recovery of the lesion on a gluten-free diet suggest that villous atrophy comprises only the end stage of the clinical course of the disease and that CD clearly develops gradually from mucosal inflammation to crypt hyperplasia and finally to overt villous atrophy.

A typical feature of CD, in addition to mucosal changes, is gluten-dependent serum IgA class autoantibodies against transglutaminase 2 (TG2). These serum autoantibodies, endomysial and TG2, are powerful tools in disclosing CD with overt villous atrophy. Furthermore, positive serum celiac autoantibodies can predict impending CD in many patients evincing normal small bowel mucosal villous architecture. Hence, patients having “false-positive” celiac autoantibodies in serum are in fact at risk of developing overt CD. Some patients with positive serum endomysial or tissue TG2 antibodies may still seroconvert negatively during follow-up. However, it is well recognized that serum celiac autoantibodies in some cases fluctuate before a patient eventually develops overt CD after a longer follow-up period. The reason for this still remains obscure.

Transglutaminases are a family of 8 currently known calcium-dependent enzymes that catalyze the cross-linking or deamidation of proteins and are involved in important biological processes such as wound healing, tissue repair, fibrogenesis, apoptosis, inflammation, and cell-cycle control. Therefore, they play an important role in the pathomechanisms of autoimmune, inflammatory, and degenerative diseases, many of which affect the gastrointestinal system. Transglutaminase 2 is prominent, since it is central to the pathogenesis of CD, and modulates inflammation and fibrosis in inflammatory bowel and chronic liver diseases^[4]. Respiratory disease and subclinical pulmonary abnormalities are the recognized complications of both CD and inflammatory bowel disease (IBD) but the mechanisms of lung disease in CD differ from that in IBD and support the hypothesis of a common mucosal defect in lung and small intestine in CD that allow increased permeability^[5].

Lymphocytic colitis (LC), together with collagenous colitis (CC), is included under the umbrella term “microscopic colitis” (MC), in which chronic gastrointestinal symptoms, including diarrhea, abdominal pain, fecal urgency, incontinence, and nausea, are not associated with endoscopic or radiological alterations. It is not known whether LC and CC are two different diseases or distinct manifestations of the same clinical condition. Data on pathophysiological conflict and different hypotheses refer to genetic pre-

disposition, immune dysregulation, autoimmunity, bile acid malabsorption, infection, and drug effect. Familial occurrence of MC has been identified in some families^[6-13]. The central role of an altered immune system in MC pathogenesis is supported by the association with several conditions in which an immune dysregulation is involved, such as CD, rheumatoid arthritis, and hypo- and hyperthyroidism. Up to now, it has not been clear whether CC (or LC) is a distinct entity or only an epiphenomenon of another disease that leads to thickening of the collagen layer. However, whether MC (both CC and LC) is an autoimmune disease has not been conclusively established^[14]. Diagnosis of MC can be established only by colonic biopsies and subsequent histopathological examination, when an increase in inflammatory infiltration and/or a thickening of the collagen layer are found. A number of papers have documented an association between CD and MC^[15-18]. However, the prevalence of MC in patients with a prior diagnosis of CD is unclear, but it does feature prominently in several series of patients with CD who have persisting symptoms despite gluten exclusion. When continuing gluten ingestion, inadvertent or covert, has been excluded, colon investigation should be considered as part of the investigation of these patients. The link may be genetic, at least in part. Both types of MC are known to resolve spontaneously in a majority of cases. Data are limited regarding pharmacological therapies, but budesonide appears best documented as showing an efficacy against CC and MC^[19].

We report here 4 cases with sequential development of CD and MC and discuss the possible connection of these co-existences.

CASE REPORT

Case 1

A 42-year-old female with a previous history of both cognitive and neurovegetative symptoms of depression, including depressed mood, anhedonia, feelings of worthlessness, low energy, troubled sleep, and poor concentration, was evaluated in the local medical center for complaints of watery diarrhea. She had longstanding lactose intolerance for which she was taking a lactose-free diet. As her mother had manifestations of CD, enteroscopy was performed. However, the first endoscopic and histological evaluation showed no duodenal mucosal alterations (Marsh 0). Six months later, endoscopic findings were persistent and duodenal biopsies were taken which were not diagnostic for CD, and biochemical laboratory tests were within normal ranges. She was then referred to our clinic and additional laboratory tests showed increased antibody titers against gliadin, endomysium, and tTG. Her psychiatric disease was controlled after treatment and then remained stable. She was given a gluten-free diet, which resolved her diarrhea and allowed her to regain her lost body weight. Five years later, the patient presented with watery diarrhea occurring 8-10 times daily and mild body weight loss. At the beginning, this condition was associated with urgency, nocturnal stools, abdominal cramping, nausea, mild body weight loss, and fatigue, and persisted

despite strict adherence to the gluten- and lactose-free diet. With the loss of patience of the diet and of her symptoms she broke her diet and clinical signs remained. Small bowel biopsies at upper endoscopy demonstrated nothing (Marsh 0) but the gluten panel was unambiguously positive. Stool cultures and *Clostridium difficile* toxin assay were negative. After consultation with dietitians, the patient was maintained on a gluten- and lactose-free diet for six months but with mild improvement. Colonoscopy was performed later, and biopsies from her colon demonstrated LC. Her symptoms responded partially to mesalazine treatment over the subsequent two months, at which point her medical therapy was changed to budesonide (9 mg/d). After she was put on budesonide with a strict diet, both abdominal complaints and psychiatric problems resolved (Figure 1).

Case 2

A 45-year-old woman with suspected irritable bowel syndrome was admitted to the hospital. Her bowel movements increased from one to six or eight a day with watery stools. She did not note any mucus or blood in the stool and could not identify any alleviating or aggravating factors. She consumed a normal diet, including meat, wheat, and dairy. Over-the-counter anti-diarrheal medications did not relieve her symptoms. She had no fevers, chills, or night sweats, but body weight loss. Her medical history included major depression for 10 years, which was controlled after treatment and remained stable at admission. Results of basic laboratory tests, including thyroid-stimulating hormone (TSH), complete blood count, blood chemistries, renal function, and liver function, were normal. Colonoscopy showed normal mucosa as far as the cecum. Colonic biopsy revealed a mildly expanded lamina propria and intraepithelial lymphocytosis with significantly thickening of the subepithelial collagen table. This set of features was consistent with CC, a variant of MC. Her symptoms were eventually controlled after a 6-mo course of oral budesonide (9 mg) and ongoing intermittent use of loperamide (Imodium). Six years later, similar problems with body weight loss caused her to be hospitalized at our clinic. A detailed previous history unraveled the familial connection with Case 1 and her mother with known CD. Psychiatric disease was controlled, so control and further GI investigations were organized. The histopathology report of colonic biopsy showed aspecific inflammation without MC. Further laboratory investigation revealed that the entire celiac antibody panel was positive. Results of duodenal biopsy did not reveal typical lymphocyte infiltration, crypt hyperplasia, and villous atrophy but normal mucosal architecture, without significant intraepithelial lymphocytic infiltration (Marsh 0). The diagnosis was latent CD, as the patient had abnormal antibody blood tests for CD but normal small intestines. After she was put on a strict gluten-free diet, both abdominal complaints and psychiatric problems resolved (Figure 1).

Case 3

A 56-year-old woman with a previous history of chronic (non-specific) colitis and fibrosing alveolitis was referred

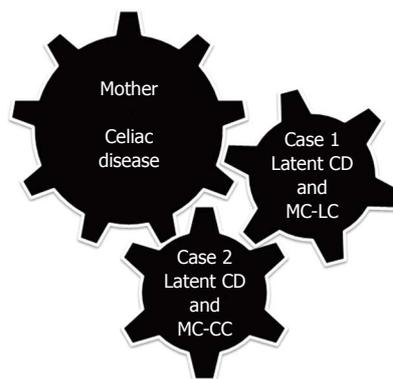

Figure 1 Family of cases 1 and 2.

to our hospital from an outside hospital because of continued signs and symptoms of CD that persisted despite self-reported adherence to a gluten-free diet. The patient reported abdominal pain, bowel distension, and body weight loss over the past few years. Diagnosis of CD was made 4 years ago, based on the small bowel biopsy results showing evidence of villous blunting with increased chronic inflammatory cells, positive laboratory tests, and typical gastrointestinal signs and symptoms with negative stool cultures and *Clostridium difficile* toxin assay. Repeated laboratory tests showed elevated antibodies against gliadin, endomysium, and tTG, and small bowel biopsy proved villous atrophy. The patient met with a nutritionist and implemented recommended dietary changes to eliminate gluten. Her symptoms temporarily improved with her bowel function returned to normal, but after a short time her symptoms recurred. Results of further tests excluded conditions known to complicate or coexist with CD, including bacterial overgrowth and lactose intolerance. Because of chronic watery stools, a colonoscopy was done with random biopsies from the colon for histological investigations. Based on the typical picture of prominent intraepithelial lymphocytes but no thickened collagenous layer, the pathologist diagnosed her with LC. She was started on strict gluten-free diet and budesonide with success. Five years later, she was free of complaints of CD and LC.

Case 4

A man at age 31, with a previous history of bronchial asthma, was investigated for abdominal pain, chronic watery diarrhea, and body weight loss with negative stool samples (both the cultures and *Clostridium difficile* toxin assay). Findings from an upper gastrointestinal endoscopy were normal, but distal duodenal biopsies showed subtotal villous atrophy, inflammatory infiltration of the lamina propria, and an increase in intraepithelial lymphocytes. Based on the histology and positive laboratory tests, CD was diagnosed and the patient was started on a gluten-free diet. Abdominal pain ceased but he did not gain body weight and diarrhea remained a problem. Compliance with a gluten-free diet was confirmed by the assessment of dietitians. Repeated biopsies of the duodenal mucosa showed mild improvement in villous atrophy but serology

Table 1 Summary of the cases

| | Case 1 | Case 2 | Case 3 | Case 4 |
|-----------------------|--------------------------------------|--------------------------------------|---|---|
| Sex/birth (yr) | Female/1956 | Female/1955 | Female/1945 | Male/1964 |

Laboratory tests and histology of the small bowel before gluten-free diet, colon histology after gluten-free diet, therapy, and concomitant lung disease. TTG: Tissue transglutaminase; EMA: Endomysial antibody; ASCA: Anti-saccharomyces cerevisiae antibody; GFD: Gluten-free diet; HLA: Human leukocyte antigen.

was negative. Four years later, a dietitian again confirmed adherence to a strict gluten-free diet and colonic biopsies showed no alteration. A barium follow-through showed mild jejunal and rather featureless ileal mucosa but no obstructive lesion of the small bowel, nothing abnormal was seen on an ultrasound scan of the abdomen. Because of bloody stools and in view of his worsening symptoms despite the gluten-free diet, repeated colonoscopy with random biopsies was done for histological investigations from ileal and colonic samples. Both proved a submucosal thickened collagen layer, thus the diagnosis of collagenous enterocolitis (with CD) was made. He was started on mesalazine and budesonide but without effect. The next step was methylprednisolone, initially 32 mg/d, and then the dose was decreased to 4 mg/d. This therapy was continued with corticosteroids for three months. Over the next year, his clinical condition improved, with resolution of his diarrhea and a body weight gain of 3 kg. Three years later, his symptoms recurred. Results of further tests excluded conditions known to complicate or coexist with CD, including bacterial overgrowth and lactose intolerance. Repeated biopsies excluded collagenous enterocolitis, thus fibrosing alveolitis was diagnosed by the pulmonologist based on the lung function, laboratory and radio-imaging tests, chest X-ray, and high-resolution CT scanning (HRCT). Because the abdominal symptoms of the patient were refractory to treatment, he was treated again with budesonide and his clinical condition improved.

The diagnoses of CD, MC, and fibrosing alveolitis in all cases were made according to the formally accepted criteria. Two independent pathologists certified the diagnosis of MC by verifying the subsequent sections and completing the check with additional investigations (intraepithelial lymphocytes, tenascin labeling of the collagen layer, mast cells, and other lamina propria cell components). Fibrosing alveolitis was proved by HRCT and upon the ATS/ERS clinical criteria. The laboratory tests were performed. In brief, the HLA-DQ alleles were determined from whole blood samples by PCR with sequence-specific primers, traditional IgG and IgA AGA were detected by ELISA (α -gliatest IgG and IgA; Eurospital, Trieste, Italy), anti-tTG was measured

by ELISA using recombinant human tissue transglutaminase as an antigen (EutTG, Eurospital), IgG and IgA EMA were investigated by indirect immunofluorescence using human umbilical cord cryostat sections prepared in our laboratory as a substrate, and both serum IgG and IgA levels in anti-Saccharomyces cerevisiae antibody (ASCA) were evaluated (separately) according to the manufacturer's protocol (ASCA IgG, ASCA IgA, QUANTA Lite, INOVA Diagnostics) (Table 1).

DISCUSSION

Is CD much ado about nothing? This report presents four cases of CD with MC. The symptoms of these patients were improved initially by a gluten-free diet before the onset of MC symptoms. Their history indicates and underlines that patients can develop, or present with CD at any stage in life and that CD can co-exist with other gastrointestinal diseases of an (auto-) immune origin. Patients with CD can fail to respond to the initial introduction of a gluten-free diet or have a recurrence of symptoms after initial improvement, despite maintaining gluten exclusion. The most feared causes of either scenario are complicating malignancy, notably enteropathy-associated T-cell lymphoma, or refractory sprue. Other causes of persistent symptoms with increased prevalence in CD include lactose intolerance, exocrine pancreatic insufficiency, bacterial overgrowth, and microscopic (lymphocytic or collagenous) colitis. Thus, in patients whose symptoms fail to respond or who later relapse, despite the exclusion of gluten from their diet, the possibility of additional pathology should be considered and colonoscopy should, therefore, be part of the follow-up in patients who present with chronic watery diarrhea, even if initial tests indicate only CD.

Relations between CD and ulcerative ileojejunitis, polymyositis, and fibrosing alveolitis have been previously described^[20,21], and it is of interest that an auto-immune pathophysiology has been implicated in each of these conditions. An association has been suggested between CD and diffuse interstitial lung disease of the hypersensitivity pneumonitis type in several reports from Europe^[22]. A case

of lymphocytic bronchoalveolitis and CD with improvement following a gluten free diet was also reported^[23].

Our patients with manifestations of CD and MC presented with fibrosing alveolitis and were ASCA (anti-yeast antibodies to yeast antigens that are found in bread and other cereal derived products) positive (both IgG and IgA types). Previously, ASCA positivity was shown to be evident in up to 40%-60% of CD patients and 13%-15% of MC patients, but its implication is disputed^[24]. A possible connection between alveolitis and ASCA is also not known. Only one case of a Japanese patient was published: lung biopsy specimens showed alveolitis and serum-precipitating antibody gave a positive reaction for an extract from *S. cerevisiae*^[25].

In conclusion, the co-existence of immune-mediated small bowel and colonic inflammatory diseases (i.e. CD and IBD) and pulmonary diseases is not well-known and no systematic approach has been used to identify the life-long patterns of these immune-based diseases^[26]. Such information may be useful for both disease prevention and treatment approaches. Clinicians managing CD should be aware of these associations and when to consider colon investigation.

Abstract

Pure red cell aplasia (PRCA) is a rare hematological disorder which is characterized by severe anemia, reticulocytopenia and almost complete absence of erythroid precursors in bone marrow. The pathophysiology of PRCA may be congenital or acquired. To our knowledge, there is only one case report in the English literature of PRCA after pegylated interferon combination therapy for chronic hepatitis C. We report a second case of PRCA after pegylated interferon combination treatment for chronic hepatitis C. The diagnosis of PRCA was confirmed by the typical findings of bone marrow biopsy. The possible etiologies of our case are also discussed in this paper.

INTRODUCTION

Pure red cell aplasia (PRCA) is a rare hematological disorder which is characterized by severe anemia, reticulocytopenia and almost complete absence of erythroid precursors in bone marrow^[1]. Patients typically present with symptoms of severe anemia in the absence of hemorrhagic phenomena. Common causes of PRCA include human parvovirus B19 infection, lymphoproliferative disorder, humoral or cellular immunity, production of erythropoietin-neutralizing antibody, and drugs such as ribavirin and standard interferon^[1-5]; however, to our knowledge, there is only one case report in the English literature of PRCA after pegylated interferon combination therapy for chronic hepatitis C^[6]. We report a second case of PRCA during combination therapy for chronic hepatitis C.

CASE REPORT

A 69-year-old male was referred to our hospital for treatment of chronic hepatitis C. His past medical history was remarkable for megaloblastic anemia due to vitamin B12 deficiency. He received regular vitamin B12 injection therapy with a stable hemoglobin level of around 11 g/dL. At

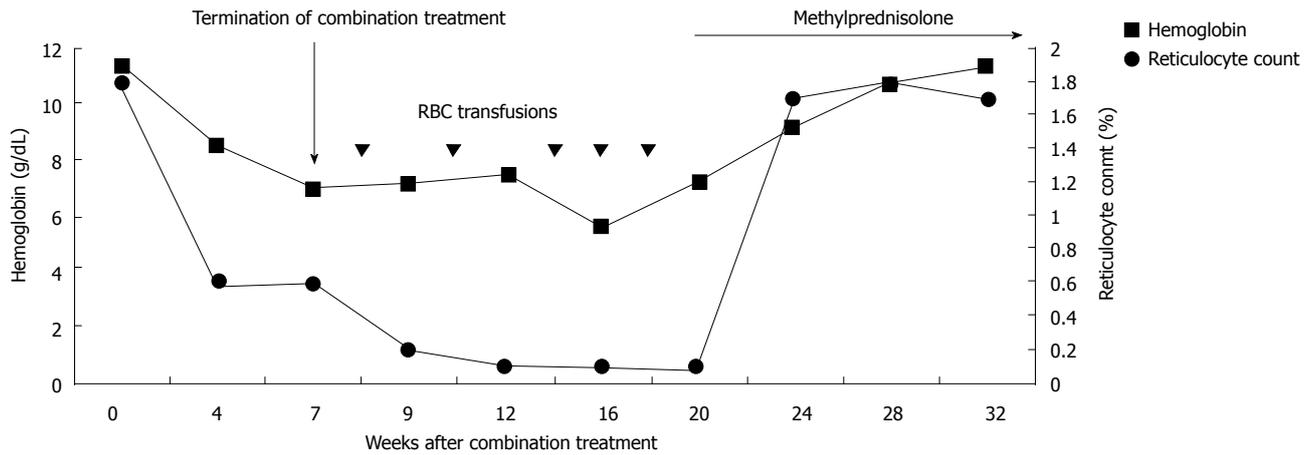

Figure 1 Hemoglobin level and reticulocyte count over time. RBC: Red blood cells.

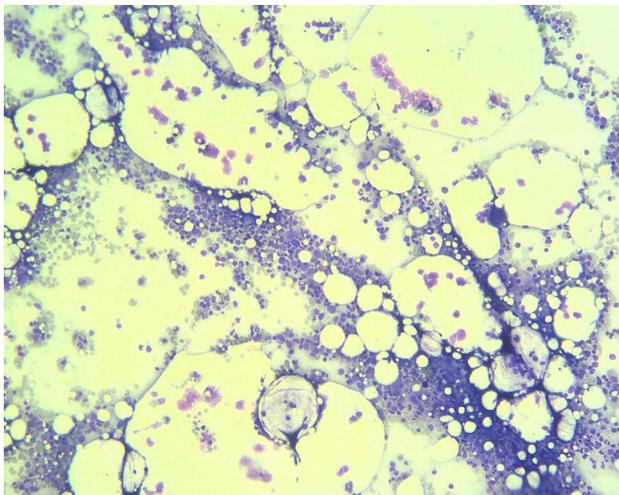

Figure 2 Photomicrograph of bone marrow biopsy showing overall hypocellularity of 10% (HE, x 40).

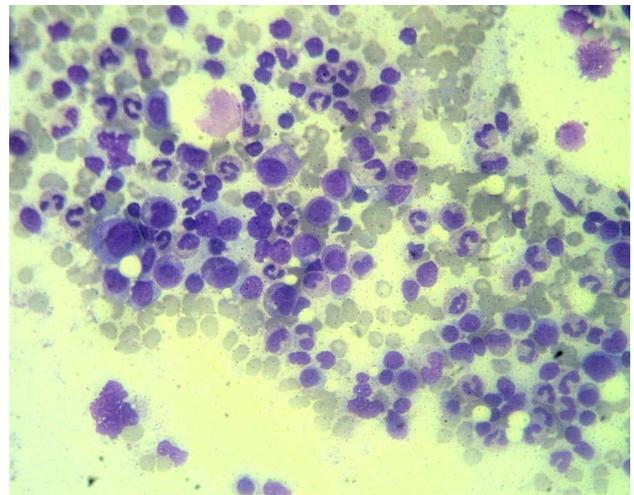

Figure 3 Photomicrograph of higher magnification showing normal maturation of myeloid precursors and absence of erythroid precursors in this field (HE, x 100).

initial presentation, elevated aminotransferase levels and positive antibody to hepatitis C virus were detected. HCV RNA level was 85000 IU/mL. The genotype was 2. The pretreatment hemoglobin level was 11.2 g/dL and the reticulocyte count was 1.8% (normal range 0.5-1.5%). Serum level of vitamin B12 was 288 pg/mL (normal range 272-1078 pg/mL). Serum level of folic acid was 11.0 ng/mL (normal range 5-26 ng/mL). Treatment with peginterferon alfa-2a 180 ug weekly and ribavirin 800 mg daily was started. After four weeks of treatment, the ribavirin dose was reduced to 600 mg due to a prominent decrease in the hemoglobin level to 8.4 g/dL. HCV RNA level at the 4th wk was undetected. Three weeks after dose reduction of ribavirin, the hemoglobin level continued to drop to 6.9 g/dL. The combination therapy was discontinued after 7 wk of treatment due to the patient's intolerance of anemia (Figure 1). Serum levels of indirect bilirubin, lactate dehydrogenase and haptoglobin level remained normal during combination treatment. Parvovirus serologies revealed positive immunoglobulin (Ig) G but negative IgM antibodies, which were consistent with past exposure.

He received follow up at a previous institution after termination of combination treatment. However, his anemia persisted and became transfusion-dependent. Blood transfusion with packed red blood cells was administered every month (Figure 1). Three months after discontinuation of combination treatment, the hemoglobin dropped to 5.5 g/dL and the reticulocyte count was 0.1% (normal range 0.5-1.5%). Levels of vitamin B12 and folic acid were within the normal range. Bone marrow biopsy revealed severe hypocellularity of 10% (Figure 2) with normal maturation of myeloid precursor cells (Figure 3). Erythroid precursor cells were markedly decreased with a ratio of myeloid to erythroid precursors of 10. The diagnosis of PRCA was made based on these histopathological findings. Oral methylprednisolone 15 mg daily was administered. After four weeks of oral methylprednisolone therapy, his hemoglobin level increased to 9.2 g/dL and the reticulocyte count increased to 1.7% (Figure 1). He needed no further blood transfusions in the following months.

DISCUSSION

Combination treatment of pegylated interferon α and ribavirin has become the standard therapy for patients with chronic hepatitis C infection^[7]. Patients with chronic hepatitis C receiving combination treatment develop anemia because of ribavirin-induced hemolysis^[8] and interferon-induced bone marrow suppression^[9]. The ribavirin-induced anemia is dose-dependent and reversible^[10]. Conversely, interferon directly suppresses the bone marrow synthesis of granulocytes, erythrocytes and megakaryocytes^[9]. PRCA is rarely encountered in chronic hepatitis C patients receiving combination treatment. To our knowledge, there is only one previous case report in the English literature of PRCA after combination treatment in patients with chronic hepatitis C^[6].

The pathophysiology of PRCA is heterogenous, which may be congenital or acquired^[11]. Diamond-Blackfan anemia is a congenital form of PRCA with genetic defects affecting erythropoietic lineage. Acquired causes of PRCA include human parvovirus B19 infection, lymphoproliferative disorder, humoral or cellular immunity, production of erythropoietin-neutralizing antibody, and drugs such as ribavirin and standard interferon^[1-5]. Other reported causes of PRCA include hepatitis A infection^[11], malignant thymoma^[12], and systemic lupus erythematosus^[13]. The diagnosis of PRCA is based on bone marrow findings such as severe hypocellularity, a markedly elevated myeloid: erythroid ratio, and severe decreased erythroid precursors^[6,14]. With regard to the treatment of PRCA, corticosteroid therapy is considered the treatment of first choice, although relapse is not uncommon^[15]. In the study of Clark *et al.*^[6], 80% of patients relapsed as the dosage of steroid was tapered during the first year after remission. In contrast, cyclosporine A is suggested when the long-term feasibility of maintenance is considered^[15].

As to the etiology of PRCA in our case, several possibilities should be considered. Firstly, although HCV infection itself has been associated with PRCA^[17], the HCV RNA in our case was undetected at the 4th wk of combination treatment. Furthermore, parvovirus serologies revealed positive IgG but negative IgM antibodies, which excluded parvovirus infection as the cause of PRCA in our case. Secondly, although ribavirin-induced PRCA has been reported previously^[3], the anemia in our case might not have been caused solely by ribavirin since the anemia persisted for 3 mon after discontinuation of ribavirin. Drug-induced PRCA generally resolves within 1-2 wk after removal of the causative agent^[18]. Thirdly, one might consider the possible association of underlying pernicious anemia with PRCA in this case. Pernicious anemia is generally considered an autoimmune disease resulting in deficiency of intrinsic factor and subsequent vitamin B12 deficiency^[19]. Coexistence of pernicious anemia and PRCA in the same patient has been reported in earlier literature^[20-22], suggesting that an immunological process is involved in the pathogenesis of PRCA in these cases. In our case, serum levels of vitamin B12 did not

alter significantly before and after combination treatment, thus excluding vitamin B12 deficiency as the cause of severe anemia after combination treatment. Therefore, it is reasonable to assume that pegylated interferon might have played a role in the pathogenesis of PRCA in our case. Several studies have also suggested that interferon may play a role in the development of acquired PRCA^[4,5,23]. However, further investigations may be needed to determine whether PRCA is caused by pegylated interferon alone or by combination treatment.

In conclusion, this case highlights the importance of considering PRCA when severe anemia associated with reticulocytopenia develops during the combination treatment of patients with chronic hepatitis C.

Abstract

The authors discussed the proposal by Coccolini and colleagues to treat gastrointestinal stromal tumors (GISTs) at the esophagogastric junction with enucleation and, if indicated, adjuvant therapy, reducing the risks related to esophageal and gastroesophageal resection. They concluded that, because the prognostic impact of a T1 high-mitotic rate on esophageal GIST is worse than that of a T1 high-mitotic rate on gastric GIST, enucleation may not be an adequate surgery for esophagogastric GISTs with a high mitotic rate in which the guarantee of negative resection margins and adjuvant therapies can be the only chance of survival.

TO THE EDITOR

We read with great interest the article by Coccolini and colleagues on the treatment of gastrointestinal stromal tumors (GISTs) at the esophagogastric junction^[1]. They stated the problems related to the choice of extended esophageal and gastroesophageal resection (i.e. a better guarantee of R0 resection but a higher prevalence of morbidity and mortality) or enucleation (i.e. a higher risk of microscopically positive margins but a better postoperative outcome).

The impact of microscopically negative margins on long-term survival remains controversial and there is no evidence that extensive resections are related to a better survival rate. The authors suggested that, for GISTs at the esophagogastric junction, enucleation and adjuvant therapies can be useful alternatives to avoid the high prevalence of morbidity and mortality associated with esophageal and esophagogastric resections. However, the 2009 edition of the TNM Classification of Malignant Tumors states that, in the absence of nodal metastasis, esophageal GISTs ≤ 2 cm (T1, i.e. tumors that may be treated with enucleation more frequently) are classified as stage I in the case of a low mitotic rate but as stage IIIA in the case of a high mitotic rate. This case is different from T1 gastric GISTs that are classified as stage I or stage II in the presence of a low or high mitotic rate, respectively^[2]. In the case of a high mitotic rate, the prognostic impact of a T1 esophageal GIST is worse than that of a gastric GIST with an identical size. Prospective, multicenter evaluation of the different treatment strategies for esophagogastric GISTs is sorely needed. However, enucleation may not be an adequate surgery for esophagogastric GISTs with a high-mitotic rate in which the guarantee of negative resection margins and adjuvant therapies can be the only chance of survival.

Acknowledgments to reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

- December 1-4, 2011
 2011 Advances in Inflammatory Bowel Diseases/Crohn's & Colitis Foundation's Clinical & Research Conference, Hollywood, FL 34234, United States

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1144 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copy-right" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systematically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under

study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission

System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +,

country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67 , $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be

Instructions to authors

used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a $P < 0.05$, ^b $P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, ^c $P < 0.05$ and ^d $P < 0.01$ are used. A third series of P values can be expressed as ^e $P < 0.05$ and ^f $P < 0.01$. Other notes in tables or under illustrations should be expressed as ¹F, ²F, ³F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references^[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated

first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as ν (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂, not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantumms can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published

by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office**World Journal of Gastroenterology**

Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,

Instructions to authors

Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interac-

tions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.
