Abstract

AIM: To examine the relationships between pre-diagnostic biomarkers and colorectal cancer risk and assess their relevance in predictive models.

METHODS: A nested case-control study was designed to include all first primary incident colorectal cancer cases diagnosed between inclusion in the SUpplémentation en VItamines et Minéraux AntioXydants cohort in 1994 and the end of follow-up in 2007. Cases (*n* = 50) were matched with two randomly selected controls (*n* = 100). Conditional logistic regression models were used to investigate the associations between pre-diagnostic levels of hs-CRP, adiponectin, leptin, soluble vascular cell adhesion molecule-1 (sVCAM-1), soluble intercellular adhesion molecule-1, E-selectin, monocyte chemoattractant protein-1 and colorectal cancer risk. Area under the receiver operating curves (AUC) and relative integrated discrimination improvement (RIDI) statistics were used to assess the discriminatory potential of the models.

RESULTS: Plasma adiponectin level was associated with decreased colorectal cancer risk (*P* for linear trend = 0.03). Quartiles of sVCAM-1 were associated with increased colorectal cancer risk (*P* for linear trend = 0.02). No association was observed with any of the other biomarkers. Compared to standard models with known risk factors, those including both adiponectin and sVCAM-1 had substantially improved performance for colorectal cancer risk prediction (*P* for AUC improvement = 0.01, RIDI = 26.5%).

CONCLUSION: These results suggest that pre-diagnostic plasma adiponectin and sVCAM-1 levels are associated with decreased and increased colorectal cancer risk, respectively. These relationships must be confirmed in large validation studies.

Prospective study

INTRODUCTION

Colorectal cancer is the third most frequently diagnosed cancer worldwide, accounting for more than one million cases and 600 000 deaths every year[1]. The identification of pre-diagnostic biomarkers associated with subsequent colorectal cancer risk is a key challenge. Markers of adiposity, endothelial adhesion, and inflammation may be suitable candidates[2-5]. Adipose tissue is an endocrine organ that produces adipokines and plays a critical role in the regulation of inflammatory processes[6]. Leptin reflects body fat storage and acts as a pro-inflammatory adipokine. Conversely, adiponectin production is decreased in obesity and generally has anti-inflammatory properties. Adhesion molecules such as E-selectin, intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1) and the chemokine monocyte chemoattractant protein-1 (MCP-1) are important in cell-cell and cell-basement membrane interactions. They are also intimately involved in inflammatory reactions[7]. C-reactive protein (CRP) is a widely used systemic biomarker for diagnosing acute and chronic inflammation[8].

Previous cross-sectional studies suggest the potential involvement of these biomarkers in colorectal carcinogenesis, with higher blood levels of CRP[9], leptin[10], soluble adhesion molecules[11,12], and lower levels of adiponectin[10,13] observed in patients with colorectal cancer compared to controls. The prognostic value of these markers has also been suggested by research with colorectal cancer patients[10,12]. However, few prospective studies have investigated the association between these biomarkers and colorectal cancer risk, and the current evidence is conflicting[14-19]. In addition, such studies did not evaluate the discriminatory capabilities of these biomarkers regarding colorectal cancer risk by contemporary statistical methods[20,21].

Thus, our objectives were twofold: (1) to prospectively examine the relationships between biomarkers of adiposity, endothelial adhesion, and inflammation and development of colorectal cancer; and (2) to statistically compare the pertinence of models including these bio-markers to standard models with known risk factors of colorectal cancer.

MATERIALS AND METHODS

Study population

The SUpplémentation en VItamines et Minéraux AntioXydants (SU.VI.MAX) study is a population-based, double-blind, placebo-controlled, randomized trial initially designed to assess the effect of a daily antioxidant supplementation on the incidence of cardiovascular disease and cancer[22,23]. A total of 13 017 subjects were enrolled in 1994-1995. The intervention study lasted 8 years, and follow-up of health events was maintained until July 2007. Subjects provided written informed consent and the study was approved by the Ethics Committee for Studies with Human Subjects at the Paris-Cochin Hospital, "Comité Consultatif de Protection des Personnes dans la Recherche Biomédicale", No. 706 and the "Commission Nationale de l'Informatique et des Libertés", No. 334641.

Baseline data collection

At enrolment, all participants underwent a clinical examination and anthropometric measurements carried out by study nurses and physicians. The participants also completed questionnaires on socio-demographic data, smoking, alcohol intake and physical activity. A fasting venous blood sample was obtained. Plasma aliquots were immediately prepared and stored frozen in liquid nitrogen.

Case ascertainment

Confirmed or suspected cancer events were self-reported by subjects during the follow-up process. Investigations were conducted for all such events to obtain medical data from participants, physicians and/or hospitals. All information was reviewed by an independent expert committee and cancer cases were validated by pathological report and classified using the International Chronic Diseases Classification, 10th Revision, Clinical Modification.

Nested case-control study

All first primary incident colorectal cancer cases diagnosed between inclusion in the SU.VI.MAX cohort in 1994 and July 2007 were included in the present study. For each cancer case, two controls were randomly selected among the remaining participants with complete follow-up data and without cancer diagnosis by the end of follow-up. Cases and controls were matched for sex, age (by 2-year strata), body mass index (BMI, $<$ *vs* $\geq$ 25 kg/m^2) and intervention group.

Baseline plasma samples of the selected subjects were used to determine the levels of highly-sensitive CRP (hs-CRP), leptin, adiponectin, soluble ICAM-1 (sICAM-1), soluble VCAM-1 (sVCAM-1), soluble E-selectin (sE-selectin) and MCP-1. Biomarker levels were determined with ELISA sandwich technique (R and D Laboratory Systems). Intra-assay (IACV) and inter-assay (IRCV) co-

[1]*P* value for the comparison of cases and controls by Student *t* test or χ^2 test, as appropriate. Biomarker variables were log-transformed to improve normality. Values are mean ± SD or *n* % as appropriate. [2]In first degree relatives. BMI: Body mass index; hs-CRP: Highly sensitive C-reactive protein; sICAM-1: Soluble intercellular adhesion molecule-1; sVCAM-1: Soluble vascular cell adhesion molecule-1; sE-selectin: Soluble E-selectin; MCP-1: Monocyte chemoattractant protein-1.

efficients of variation were all < 10%. hs-CRP had the lowest (1.6%) and MCP-1 had the highest (6.2%) IACV, and hs-CRP had the lowest (3.6) and sE-selectin had the highest (9.1%) IRCV.

Statistical analyses

The participants' baseline characteristics were compared between colorectal cancer cases and controls using Student's *t*-tests or χ^2 tests. Associations between biomarkers and incident colorectal cancer were examined with conditional logistic regression models and expressed as odds ratios (OR) with 95% confidence intervals (CI). The ORs for sex-specific quartiles and for a 1 standard deviation (SD) increase in the corresponding biomarker were com-

puted in unadjusted and multivariate models. Multivariate models were adjusted for age, sex, BMI, height, intervention group, alcohol intake, physical activity, smoking status, family history of colorectal cancer, waist circumference and educational level.

The improvement in colorectal cancer prediction performance attributed to the biomarkers was assessed with both the area under the receiver operating curves (AUC) and the more recently proposed statistical tool, the Relative Integrated Discrimination Improvement (RIDI)[21]. The latter measures the percentage of increased discrimination upon addition of another variable to the prediction model. The Bootstrap method was used to derive the 95% CI for the RIDI estimates, which were based on 1000 replications. The added prediction performance was determined separately for each biomarker identified as statistically significantly associated with cancer risk (in the logistic regression analyses step), and then for a combination of these biomarkers simultaneously. Tests of significance for AUC improvement were one-sided, as improvement in model fit was expected. All other statistical tests were two-sided, and *P* < 0.05 was considered significant. Analyses were performed with SAS software (v9.1, Cary, NC, United States).

RESULTS

A total of 50 incident colorectal cancer cases were diagnosed during follow-up (30 colon and 20 rectal cancers). Each case was matched with two randomly selected controls; thus, 150 subjects were included in the analyses. Median follow-up was 6.5 years in cases and 13 years in controls. Baseline characteristics of cases and non-cases are presented in Table 1. Compared to controls, cancer cases had a higher waist circumference and a higher alcohol intake.

In multivariate models, a one SD change in plasma adiponectin level was associated with a decreased colorectal cancer risk [OR (95% CI) = 0.45 (0.22-0.91), *P* = 0.03]. This association was also observed when adiponectin was considered as quartiles (OR for Q4 *vs* Q1 = 0.11 (0.01-0.93), *P* for linear trend = 0.03) (Table 2).

Quartiles of plasma sVCAM-1 level were positively associated with increased colorectal cancer risk (*P* for linear trend = 0.02) (Table 2). This association was borderline non-significant when sVCAM-1 was coded as a continuous variable (*P* = 0.07).

Unadjusted models (matching factors only) showed similar results (data not shown). A sensitivity analysis excluding cases that were diagnosed during the first two years of follow-up (7 cases) did not modify the findings, nor did sensitivity analyses excluding subjects with high hs-CRP values (> 15.5 ng/mL, *i.e.*, mean + 3SD, *n* = 3 subjects; data not shown).

Indicators of the predictive potential of colorectal cancer risk models (Table 3) showed improvement when adiponectin alone was included in the multivariate model

[1]Adjusted for age, sex, body mass index, intervention group, alcohol intake, physical activity, smoking status, family history of colorectal cancer, waist circumference, height and educational level. *n* = 50 colorectal cancer cases and 100 controls. Cut-offs for sex-specific quartiles were: hs-CRP: 0.6, 1.2, 2.3 in men and 0.5, 0.9, 2.1 in women; sICAM-1: 198.7, 242.0, 287.4 in men and 193.0, 232.5, 286.0 in women; sVCAM-1: 539.0, 653.5, 798.6 in men and 523.0, 651.5, 875.7 in women; sE-selectin: 29.8, 42.5, 51.7 in men and 26.0, 36.3, 44.6 in women; MCP-1: 216.7, 263.5, 316.5 in men and 171.0, 212.0, 238.0 in women; Leptin: 3.1, 5.0, 8.2 in men and 5.4, 9.6, 15.4 in women; Adiponectin: 4.2, 6.6, 10.0 in men and 9.5, 13.9, 16.0 in women. OR: Odds ratio; CI: Confidence interval; hs-CRP: Highly sensitive C-reactive protein; sICAM-1: Soluble intercellular adhesion molecule-1; sVCAM-1: Soluble vascular cell adhesion molecule-1; sE-selectin: Soluble E-selectin; MCP-1: Monocyte chemoattractant protein-1; ref: Reference category.

(*P* for AUC improvement = 0.009). The RIDI statistic indicated a 12.2% (10.9-13.6) improvement. Improvement in the prediction of colorectal cancer risk was limited when sVCAM-1 only was introduced into the multivariate model (*P* for AUC improvement = 0.09), with 9.9% (8.7-11.0) improvement, as indicated by the RIDI statistic. Prediction was substantially improved when adiponectin and sVCAM-1 were simultaneously included in the multivariate model: *P* for AUC improvement was equal to 0.01, and the RIDI reached 26.5% (24.4-28.7).

DISCUSSION

In this prospective study, pre-diagnostic plasma adiponectin level was associated with decreased colorectal cancer risk, independently of other known risk factors. On the contrary, plasma sVCAM-1 level was associated with increased colorectal cancer risk. Models including these two biomarkers showed significantly improved discriminatory capabilities compared to models including only established risk factors.

Lower levels of circulating adiponectin have been observed in prevalent colorectal cancer cases compared to controls[10,13,24-26]. Single nucleotide polymorphism analyses have found that some variants of the adiponectin genes are related to either increased (rs822395, rs1342387) or decreased (rs266729) colorectal cancer risk[27], although no association was detected in a recent study in the United Kingdom[28]. Another study suggested that variants of the adipokine genes may affect colorectal cancer risk in combination with variants in diabetes-related genes[29]. Studies with colorectal cancer patients showed that higher adiponectin levels were associated with a better prognosis[10,13,30]. It has been suggested that adiponectin may be used for estimation of advanced stage of cancer and for estimating risk of cancer recurrence[31]. However, to date, only three nested case-control studies have investigated the prospective association between adiponectin and colorectal cancer risk, showing inconsistent results[16-18]. Two studies did not find any associations; one of them included 381 male colorectal cancer cases[17] and the other included 306 colorectal cancer cases of both genders[16]. Consistent with our findings, the study of Wei *et al*[18], based on 179 male colorectal cancer cases, found an

Table 3 Predictive potential of adiponectin and soluble vascular cell adhesion molecule-1 regarding colorectal cancer risk: Relative integrated discrimination improvement and improvement of area under the curve

	AUC	*P* value for AUC improvement	RIDI (%)	95% CI
Multivariate model[1]	0.89

+ sVCAM-1	0.92	0.09	9.9	8.7-11.0
+ Adiponectin + sVCAM-1	0.98	0.01	26.5	24.4-28.7

[1]Multivariate model was adjusted for age, sex, BMI, intervention group, alcohol intake, physical activity, smoking status, family history of colorectal cancer, waist circumference, height and educational level. Models including adiponectin and/or sVCAM-1 were compared to the multivariate model. *n* = 50 colorectal cancer cases and 100 controls. BMI: Body mass index; RIDI: Relative integrated discrimination improvement; AUC: Area under the receiver operating curve; sVCAM-1: Soluble vascular cell adhesion molecule-1; CI: Confidence interval.

inverse association between pre-diagnostic adiponectin levels and colorectal cancer risk. Circulating levels of adiponectin in those studies were comparable to the levels found in the present study. However, none of those three studies matched cases and controls on BMI. Adiponectin is strongly related to adiposity, which is, in turn, associated with an adverse effect on colorectal cancer development, especially in stathmin-positive patients, as recently shown by Ogino *et al*[32]. Thus, matching on BMI is crucial and is a strength of our study compared to previous reports in the literature. Several mechanisms support the inverse relationship between adiponectin and colorectal cancer risk[33]. Adiponectin suppresses tumorigenesis in Apc(Min)(/+) mice[34] and also suppresses colonic epithelial proliferation *via* inhibition of the mammalian target of the rapamycin (mTOR) pathway under a high-fat diet[35]. It inhibits colorectal cancer cell growth through the AMP-activated protein kinase/mTOR pathway[36] and possibly the PI3K/Akt signal pathway[37]. Adiponectin also attenuates interleukin-6-induced colon carcinoma cell proliferation *via* STAT-3[38].

Several case-control studies have observed higher circulating levels of sVCAM-1 in colorectal cancer cases compared to controls[11,12,39-41]. In addition, it has been suggested that the serum level of sVCAM-1 may be a valuable prognostic marker in colorectal carcinoma[12,42], reflecting both tumour progression and metastasis[39]. For instance, Mantur *et al*[11] observed a significant correlation of serum levels of sVCAM-1 with tumor, node, metastases (TNM) stage and lymph node involvement in colorectal cancer patients. Yamada *et al*[43] observed a positive association between concentrations of sVCAM-1 and risk of postoperative colorectal cancer recurrence. Consequently, investigations have been conducted to test for the chemopreventive potential of some molecules (e.g., celecoxib) *via* down-regulation of VCAM-1 in the colon cancer cell line HT29[44].

However, to the best of our knowledge, our study is the first to investigate the prospective association be-

tween pre-diagnostic levels of sVCAM-1 and colorectal cancer risk. The observed positive association is supported by a mechanistic plausibility. Indeed, it has been demonstrated experimentally that sVCAM-1 stimulates angiogenesis and neovascularization[45,46] and is negatively correlated with the degree of tumour differentiation[41]. Cell adhesion molecule expression has been demonstrated in endothelial cells of small vessels at the invasive margin of tumour cells involved in metastatic spread[47]. The association among immunohistochemical cell adhesion molecule expression, tumour vascularity and leukocyte infiltration suggests an important role for these molecules in host immune response and in tumour progression[48].

Epidemiologic studies usually estimate the strength of the association between a biomarker and disease risk. Assessment of the discriminatory capabilities of a biomarker in predicting risk of the studied pathology is another approach that may lead to slightly different but complementary information[21]. To the best of our knowledge, no study has previously evaluated the discriminatory capabilities of hs-CRP, leptin, adiponectin, sICAM-1, sVCAM-1, sE-selectin and MCP-1 in predicting colorectal cancer risk, using *ad-hoc* statistical methods such as the novel RIDI statistic[21]. Indeed, the use of the traditional AUC method as a comparative measure of prediction between models has certain limitations[49], and the complementary use of the novel RIDI statistic appears to be more sensitive and accurate[21]. Several factors are already known to influence colorectal cancer risk (e.g., age, smoking status, physical activity, *etc.*) and are usually included in predictive models. As shown in Table 3, the RIDI statistic suggests that when quartiles of adiponectin and quartiles of sVCAM-1 plasma levels are added to the model, the ability of the model to predict colorectal cancer risk is improved by 26.5%, compared to a model including only well-established risk factors (age, smoking status, *etc.*). Thus, our results suggest that adiponectin, and possibly sVCAM-1, should not be ignored as predictors of colorectal cancer risk. In addition, the improvement in the predictive potential was substantially increased when both biomarkers were simultaneously added to the model. This might result from the mechanistic interrelations between adiposity and endothelial adhesion, notably though an inflammation pathway[6,50,51]. Large prospective and validation studies are needed to confirm and better quantify the predictive performance of these biomarkers in colorectal carcinogenesis.

Strengths of our study include its prospective design, the simultaneous measurement of seven biomarkers in the same individuals and, to our knowledge, the first assessment of the discriminatory capabilities of these biomarkers for estimating colorectal cancer risk by the novel RIDI statistic.

Some limitations should also be acknowledged. Firstly, the number of cases was limited in this exploratory study. This may explain some of the null results observed; however, it is unlikely to explain the observed relationships between adiponectin, sVCAM-1 and colorectal cancer

Abstract

AIM: To investigate whether the *patatin-like phospholipase domain containing-3* gene (*PNPLA3*) I148M polymorphism is associated with steatosis, fibrosis stage, and cirrhosis in hereditary hemochromatosis (HH).

METHODS: We studied 174 consecutive unrelated homozygous for the C282Y HFE mutation of HH (C282Y+/+ HH) patients from Northern Italy, for whom the presence of cirrhosis could be determined based on histological or clinical criteria, without excessive alcohol intake (< 30/20 g/d in males or females) or hepatitis B virus and hepatitis C virus viral hepatitis. Steatosis was evaluated in 123 patients by histology (n = 100) or ultrasound (n = 23). The PNPLA3 rs738409 single nucleotide polymorphism, encoding for the p.148M protein variant, was genotyped by a Taqman assay (assay on demand, Applied Biosystems). The association of the PNPLA3 I148M protein variant (p.I148M) with steatosis, fibrosis stage, and cirrhosis was evaluated by logistic regression analysis.

RESULTS: PNPLA3 genotype was not associated with metabolic parameters, including body mass index (BMI), the presence of diabetes, and lipid levels, but the presence of the p.148M variant at risk was independently associated with steatosis [odds ratio (OR) 1.84 per p.148M allele, 95% confidence interval (CI): 1.05-3.31; P = 0.037], independently of BMI and alanine aminotransaminase (ALT) levels. The p.148M variant was also associated with higher aspartate aminotransferase (P = 0.0014) and ALT levels (P = 0.017) at diagnosis, independently of BMI and the severity of iron overload. In patients with liver biopsy, the 148M variant was independently associated with the severity (stage) of fibrosis (estimated coefficient 0.56 ± 0.27, P = 0.041). In the overall series of patients, the p.148M variant was associated with cirrhosis in lean (P = 0.049), but not in overweight patients (P = not significant). At logistic regression analysis, cirrhosis was associated with BMI $\geq$ 25 (OR 1.82, 95% CI: 1.02-3.55), ferritin > 1000 ng/mL at diagnosis (OR 19.3, 95% CI: 5.3-125), and with the G allele in patients with BMI < 25 (OR 3.26, 95% CI: 1.3-10.3).

CONCLUSION: The PNPLA3 I148M polymorphism may represent a permissive factor for fibrosis progression in patients with C282Y+/+ HH.

INTRODUCTION

Hereditary hemochromatosis (HH) is a genetic disorder of iron metabolism characterized by defective release or activity of hepcidin, the hepatic hormone that inhibits iron absorption by binding and inactivating ferroportin[1]. HH is most frequently related to hampered hepcidin up-regulation by iron stores as a consequence of homozygosity for the C282Y mutation in the *HFE* gene[2]. The resultant increase in serum iron leads to progressive accumulation in the liver and other parenchymal organs, however, although hepatic iron overload leads to progressive liver fibrosis and cirrhosis in some affected individuals, the phenotypic expression is unpredictable and highly variable[3].

Indeed, liver disease is the most frequent clinical manifestation of homozygous for the C282Y HFE mutation of HH (C282Y+/+ HH), but it is now clear that only a proportion of subjects carrying this genotype will ever develop hepatic fibrosis[4]. Most of C282Y +/+ male subjects develop expanded iron stores during life, whereas due to the physiological iron losses during fertile age, the female gender represents a major protective factor. In population based screening studies it has been shown that between 75% and 94% of C282Y+/+ males develop elevated transferrin saturation, and that 64% to 68% will have an increased serum ferritin[4-8]. However, even in males, the prediction of risk of clinical disease remains uncertain[9].

The recognition of the incomplete penetrance of HH has led to a search for genetic and other modifiers of clinical expression. HH expression may be influenced at different levels[9]: (1) by factors affecting iron loading, including sex and genetic factors (genes regulating hepcidin expression, beta-thalassemia trait[10]); (2) by factors influencing the progression to liver disease, such as hepatic steatosis[11], viral hepatitis, genes regulating pro-inflammatory cytokines and oxidative injury[12,13]; and (3) by those regulating both, such as alcohol intake and hepatitis C virus (HCV) infection[14,15].

There is established evidence that increased body mass (BMI) and the metabolic syndrome[16] are strong risk factors for hepatic steatosis[17] and that steatosis accelerates the progression of liver diseases by favoring oxidative stress and hepatocellular damage. In 214 C282Y +/+ patients[11], a significant association between steatosis and the presence of fibrosis was detected. This relationship remained significant after adjustment for confounding factors such as alcohol intake and iron loading.

Recently, the rs738409 C > G single nucleotide polymorphism (SNP) of *patatin-like phospholipase domain containing-3* gene (*PNPLA3*), encoding for the I148M protein variant (p.I148M), has been identified as a determinant of liver fat content and of the susceptibility to develop steatohepatitis and progressive fibrosis[18-23]. Importantly, PNPLA3 genotype influences liver fat independently of body mass, dyslipidemia, and insulin resistance[24,25].

Since hepatic steatosis has been reported to influence HH expression, the aim of this study was to determine whether the PNPLA3 I148M variant predisposes to the development of steatosis, and to progressive liver damage, as evaluated fibrosis stage and the presence of cirrhosis, in patients with pure C282Y+/+ HH stratified according to the presence of overweight.

MATERIALS AND METHODS

Patients

From 232 consecutive unrelated C282Y+/+ HH patients referred to two centers in the Milan area of Northern Italy, we excluded subjects with alcohol intake > 30/20 g per day in male/female, hepatitis B virus (HBV) and/or HCV infections, and other cofactors of liver disease (n = 30), and those with an uncertain diagnosis of cirrhosis or incomplete clinical data (n = 28), and finally included 174 patients in the analysis (Figure 1). DNA samples were available for all patients.

Diagnosis of cirrhosis was based upon liver histology (n = 100) or clinical evidence (n = 74): in particular, cirrhosis was diagnosed by liver histology in 26 patients, and by clinical criteria in 6 cases (in the presence of hepatic decompensation or of portal hypertension; liver biopsy was not indicated for ethical reasons), whereas it was excluded by liver histology in 74 cases, and by clinical criteria in the remaining 68 cases (when liver biopsy was not indicated and not performed for ethical reasons).

Tissue sections were stained with hematoxylin and eosin, impregnated with silver for reticulin framework, and stained with trichrome for collagen and Perls for iron. Steatosis was considered present when involving at least 5% of hepatocytes and graded according to Kleiner[26]. Tissue iron was graded according to Scheuer[27]. Fibrosis was scored according to Ishak[28]. The minimum biopsy size was 1.7 cm and the number of portal areas was 10. For data analysis, a fibrosis stage of 6 was attributed to patients with a clinical diagnosis of cirrhosis.

Ultrasonographic diagnosis of steatosis at diagnosis

Figure 1 Study flow chart. C282Y+/+ HH: Homozygous for the C282Y HFE mutation of hereditary hemochromatosis; M/F: Male/female; BMI: Body mass index.

Table 1 Demographic, anthropometric, clinical, and histological features, as evaluated at diagnosis, of 174 Italian patients with homozygous for the C282Y HFE mutation of hereditary hemochromatosis subdivided according to the PNPLA3 I148M genotype

	All patients	PNPLA3 I148M genotype			P value

Advanced fibrosis % (Ishak 4) %	18 (10)	9 (11)	7 (10)	2 (9)	0.95
Cirrhosis (Ishak 5-6) %	32 (18)	13 (16)	14 (20)	5 (23)	0.39

[1]Available in 123 patients. I: Ileucine; M: Methionine; *n*: Number; F: Female; DAI: Daily alcohol intake; BMI: Body mass index; HDL: High density lipoprotein cholesterol; TS: Transferrin saturation; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; GGT: γ-glutamyl transferase.

by an experienced operator (available in 123) was based on evident ultrasonographic contrast between the hepatic and right renal parenchyma of the right intercostal sonogram in the midaxillary line, or abnormally intense, high-level echoes arising from the hepatic parenchyma, and was graded on a three-grade scale as none, mild, or severe in accordance with intensity[29].

Cirrhosis was considered clinically absent only if all these conditions were satisfied: (1) age < 40 years; (2) alanine aminotransaminase (ALT) within normal levels; and (3) ferritin < 1000 ng/mL. These criteria have been shown to rule out not only cirrhosis, but also advanced fibrosis with high specificity in patients with C282Y+/+ HH without viral hepatitis and excessive alcohol intake[30].

Overweight was considered present when BMI > 25 kg/m^2. For each patient we collected data on sex, age, geographical origins, BMI, alcohol consumption, aspartate aminotransferase (AST), ALT and γ-glutamyl transferase (GGT) levels, ferritin, transferrin saturation percentage, total cholesterol, high density lipoprotein cholesterol and triglycerides levels, glucose, and type 2 diabetes[31]. Clinical features of the patients included are shown in Table 1. Informed written consent was obtained from each patient included. The study conformed to the ethical guidelines of the 1975 Declaration of Helsinki and was approved by the Institutional Review Board of the Institutions involved.

Genetic analysis

DNA was extracted from peripheral blood by the phenol-chloroform method. Success rate in extracting DNA was 100% for each study group. The PNPLA3 rs738409 SNP was genotyped by a Taqman assay (assay on demand for rs738409, Applied Biosystems, Foster City, CA, United States) by personnel unaware of patients and controls clinical status. Post-polymerase chain reaction allelic discrimination was carried out measuring allele-specific fluorescence on the Opticon2 detection system (MJ Research, Waltham, MA, United States). Random samples

were confirmed by direct genotyping which provided concordant results in all cases[19]. Quality controls were performed to verify the reproducibility of the results. Valid genotypic data were obtained for 100% of subjects analyzed.

Statistical analysis

Values are expressed as mean ± SD or median (interquartile range) according to distribution. Mean values were compared by analysis of variance or Wilcoxon, and frequencies by F test and χ^2 test for trend, when appropriate. The study had a > 85% power to detect a two-fold higher risk of cirrhosis in carriers of the 148M allele, but only 33% to detect a 33% increased risk. Independent predictors of AST and ALT levels were analyzed by generalized linear model. The association of the PNPLA3 p.148M variant with fibrosis was evaluated by ordinal logistic regression analysis, and with the presence of steatosis and cirrhosis was evaluated by multivariate logistic regression analysis. P values were considered significant when < 0.05 (two-tailed). Analyses were carried out with JMP 6.0 statistical analysis software (SAS Institute Inc., Cary, NC, United States).

Figure 2 Frequency distribution of the rs738409 C > G single nucleotide polymorphism, encoding for the I148M protein variant, in 123 patients with homozygous for the C282Y HFE mutation of hereditary hemochromatosis subdivided according to the presence of steatosis (*P* = 0.015).

Table 2 Independent predictors of steatosis and cirrhosis in Italian patients with homozygous for the C282Y HFE mutation of hereditary hemochromatosis, as evaluated by logistic regression analysis

	OR	95% CI	*P* value
Independent predictors of steatosis *n* = 123

OR: Odds ratio; CI: Confidence interval; BMI: Body mass index; ALT: Alanine aminotransaminase; p.148M: PNPLA3 rs738409 148Met protein variant.

RESULTS

Association of PNPLA3 gene genotype with steatosis

We first sought to confirm the association of the G allele encoding for the p.148M variant with liver fat in C282Y+/+ HH. The frequency distribution of the rs738409 PNPLA3 SNP (*P* = not significant for Hardy-Weinberg equilibrium testing) in patients subdivided according to the presence of steatosis is shown in Figure 2 (*P* = 0.014). The frequency of the G allele was 0.41 in patients with and 0.26 in those without steatosis (*P* = 0.011), and did not change after the exclusion of patients with ultrasonographic evaluation of the presence of steatosis. Independent predictors of steatosis at logistic regression analysis, considered as independent variables selected by a stepwise mixed regression model, are shown in Table 2. Steatosis was independently associated with BMI (*P* = 0.008) and PNPLA3 genotype [odds ratio (OR) 1.84 per G allele, 95% confidence interval (CI): 1.05-3.31; *P* = 0.037].

Association of PNPLA3 gene genotype with liver enzymes

As expected, PNPLA3 genotype was not significantly asso-

ciated with demographic or anthropometric features, daily alcohol intake, metabolic parameters, including the presence of diabetes, and the severity of iron overload (Table 1). However, we observed an association between PNPLA3 and transaminases, which was significant for AST levels [*P* for trend (i.e., for increasing levels with increasing number of 148M alleles) = 0.019 for AST and *P* for trend = 0.06 for ALT], whereas GGT levels were not affected. Independent predictors of AST and ALT levels in the generalized linear model are shown in Table 3; variables included were selected by a stepwise mixed regression model. Both AST and ALT levels were significantly and independently correlated with younger age, higher iron parameters (TS% and ferritin levels), GGT levels, BMI, and the number (0-2) of 148M PNPLA3 alleles (*P* = 0.0014 and *P* = 0.017 for AST and ALT levels, respectively).

Association of PNPLA3 gene genotype with severity of fibrosis and cirrhosis

We next evaluated whether PNPLA3 genotype influences fibrosis stage. At ordinal regression analysis conducted in patients with liver biopsy or clinical diagnosis of cirrhosis (*n* = 106; shown in Table 4), fibrosis stage (0-6) was independently associated with gender, ALT and GGT values, and PNPLA3 p.148M alleles (estimated coefficient of correlation 0.56 ± 0.27, *P* = 0.04). Possibly due to the relatively low number of patients studied, PNPLA3 genotype was not significantly associated with cirrhosis in the whole cohort (Table 1), although the presence of the 148M allele was nominally significantly associated with cirrhosis in patients with BMI < 25 (*P* = 0.05, *P* = 0.1 after Bonferroni correction; Figure 3). Importantly, positivity for the PNPLA3 148M variant was associated with an increase in the prevalence of steatosis in subjects with BMI < 25, which reached levels similar to those of overweight patients (BMI < 25: 17/37, 46% *vs* 7/32, 22%, *P* = 0.036; BMI ⩾ 25: 22/31, 71% *vs* 10/26, 38%; *P* = 0.017 for patients positive and negative for the 148M variant, respectively). Independent predictors of cirrhosis are shown in Table 2. At logistic regression analysis, cirrhosis was associated with BMI ⩾ 25 (OR 1.82, 95% CI:

DISCUSSION

In this study, we evaluated the effect of the PNPLA3 rs738409, encoding for the p.I148M variant, on steatosis and liver damage in patients affected by C282Y+/+ HH without other causes of liver damage. Our results confirm the association of the PNPLA3 148M allele with the presence of steatosis and liver enzymes, independently of iron overload, which represents the major cause of progressive liver damage in HH patients. Furthermore, PNPLA3 rs738409 was also associated with fibrosis stage, and with the presence of cirrhosis, albeit only in the presence of normal BMI.

Although data on steatosis were not available in the whole series of patients evaluated, the association of PNPLA3 with steatosis in HH was expected based on data obtained in the general population, in patients with non-alcoholic fatty liver disease (NAFLD), and in other liver diseases. In addition, the magnitude of the observed association was in line with previous reports[18,19,32]. Due to the retrospective design of the study, insulin resistance evaluation was not available for all patients, however, previous studies have excluded a major effect of PNPLA3

genotype on insulin resistance, and the 148M variant was not associated with diabetes in this study.

As steatosis has been reported to influence fibrosis progression in C282Y +/+ patients, independently of alcohol intake and iron loading[11], the main aim of the present study was to evaluate whether PNPLA3 genotype influences liver damage progression in HH. We found that the PNPLA3 148M allele was a strong predictor of transaminase levels, and in particular of AST levels, which are generally more strongly linked with chronic liver damage (fibrosis stage) than ALT[11,33]. PNPLA3 polymorphism has been reported to represent a major determinant of transaminase levels in the general population, in patients with NAFLD, and in obese subjects at risk of steatosis[18,19,34,35]. Our findings indicate, that this is also true for patients with C282Y+/+ HH. It is likely that this association reflects the predisposing effect of the 148M PNPLA3 allele on steatosis. Interestingly, BMI, which was the other determinant of steatosis in our series of patients, was also associated with transaminases. Furthermore, we demonstrated that PNPLA3 genotype was associated with fibrosis stage in patients with HH, consistent with the hypothesis that the 148M allele of PNPLA3 influences the progression of liver damage in

HH, even if this has to be confirmed in a larger series of patients.

The association of the 148M variant with the risk of cirrhosis, a turning point in the natural history of patients with HH due to the frequent progression to hepatocellular carcinoma[36,37], is also in line with this hypothesis. Interestingly, data obtained by our and other groups indicate that the 148M variant is significantly associated with cirrhosis and hepatocellular carcinoma in patients with HCV-related chronic hepatitis, thus suggesting that this can be true also for liver diseases of different etiology[32,38].

Based on the previously reported interaction between the effect of the PNPLA3 I148M mutation and body mass[35], the other major determinant of steatosis in our series of patients, we analyzed the effect of PNPLA3 rs738409 on cirrhosis risk in patients stratified according to the presence of overweight. We found an association between PNPLA3 genotype and cirrhosis, but this was restricted to subjects with normal BMI. There are several possible explanations for this finding. The first is that the result is due to chance. Because of the relatively limited number of subjects included, the study power to detect an association with cirrhosis was relatively low, i.e., > 85% to detect a two-fold higher risk of cirrhosis in carriers of the 148M allele, but only 33% to detect a 33% increased risk. Secondly, this was a retrospective study with data evaluation at the time of diagnosis, therefore we could not exclude the fact that some patients "normalized" their body mass after the development of cirrhosis due to the malnutrition typical of this condition. However, increased BMI was independently associated with steatosis and tended to be associated also with cirrhosis risk, and the shift in body weight should have equally affected patients with and without the 148M allele. Lastly, we cannot exclude that the PNPLA3 148M variant, by favoring steatosis development in subjects with normal BMI, may play a permissive role in the progression of liver damage in lean patients with C282Y+/+ HH, whereas in overweight subjects steatosis is mainly related to metabolic factors, reducing the role played by PNPLA3. Additional studies are required to clarify this issue, and to evaluate whether the 148M variant may predispose to hepatocellular carcinoma development also in HH and in patients carrying HFE mutations[39-41].

In conclusion, we showed that in Italian patients with C282Y+/+ HH the PNPLA3 I148M polymorphism is associated with the risk of steatosis, increased liver enzymes, higher stage of fibrosis, and possibly with an increased risk of cirrhosis at diagnosis, particularly in subjects with normal body mass. Future studies should evaluate whether PNPLA3 I148M genotype might be clinically useful for selecting HH patients for biopsy, or to determine screening intervals for hepatocellular carcinoma in cirrhotics.

COMMENTS

Background

Hereditary hemochromatosis, characterized by progressive accumulation of iron in tissues, is a very frequent genetic disease in individuals of European descent. The most frequent clinical manifestation is liver disease, which may lead to liver cancer. However, disease expression is highly variable. Previous work has led to hypothesize that genetic factors and liver fat accumulation (i.e., "steatosis") are implicated in this process. Recently, the common I148M patatin-like phospholipase domain containing-3 genetic polymorphism has been recognized together with obesity as a key factor regulating fat accumulation in the liver, contributing significantly to the liver disease burden in the general population.

Research frontiers

The identification of genetic factors involved in the penetrance and expression of hereditary hemochromatosis is a very active area of research, as such markers would be helpful to identify subjects at risk during screening and to personalize treatment and follow-up in patients presenting with liver disease.

Innovations and breakthroughs

The key findings of the study are that the PNPLA3 genetic variant, present in 40% of patients, was a key determinant, together with overweight, of hepatic fat accumulation and of alterations of biochemical indices of liver damage. Furthermore, this marker was also associated with chronic fibrotic damage detected by liver biopsy. Importantly, the PNPLA3 variant put at risk of steatosis also normal weight patients, who would be normally protected, allowing the development of progressive liver damage and cirrhosis, with potential clinical complications.

Applications

These results raise new hope to offer better, personalized treatment to patients with hemochromatosis, which will be tested in future studies. In particular, intensified follow-up and preventive treatments could be proposed to subjects at risk of developing liver cancer, the leading cause of death in patients with clinically overt hemochromatosis, which is also favored by steatosis.

Terminology

Hereditary hemochromatosis is a genetic disorder of iron metabolism characterized by defective release or activity of hepcidin, the hepatic hormone that inhibits iron absorption, leading to progressive accumulation in the liver and other parenchymal organs; PNPLA3 is an enzymes with phospholipase activity, which is expressed in the liver, and likely involved in the breakdown triglycerides; genetic polymorphisms: inherited variant of the DNA, which is detected in > 1% of the population and is not associated *per se* with a pathologic phenotype.

Peer review

This is an interesting clinical study, which provides evidence for association between the PNPLA3 148M polymorphism and progression of liver fibrosis. The study is well designed and the data are novel.

Abstract

AIM: To estimate the incidence of collagenous colitis (CC) in southern Sweden during 2001-2010.

METHODS: Cases were identified by searching for CC in the diagnostic registers at the Pathology Departments in the county of Skåne. The catchment area comprised the south-west part of the county (394 307 inhabitants in 2010) and is a mixed urban and rural type with limited migration. CC patients that had undergone colonoscopy during the defined period and were living in this area were included in the study regardless of where in Skåne they had been diagnosed. Medical records were scrutinized and uncertain cases were reassessed to ensure that only newly diagnosed CC cases were included. The diagnosis of CC was based on both clinical and histopathological criteria. The clinical criterion was non-bloody watery diarrhoea. The histopathological criteria were a chronic inflammatory infiltrate in the lamina propria, a thickened subepithelial collagen layer $\geq$ 10 micrometers (μm) and epithelial damage such as flattening and detachment.

RESULTS: During the ten year period from 2001-2010, 198 CC patients in the south-west part of the county of Skåne in southern Sweden were newly diagnosed. Of these, 146 were women and 52 were men, i.e., a female: male ratio of 2.8:1. The median age at diagnosis was 71 years (range 28-95/inter-quartile range 59-81); for women median age was 71 (range 28-95) years and was 73 (range 48-92) years for men. The mean annual incidence was $5.4/10^5$ inhabitants. During the time periods 2001-2005 and 2006-2010, the mean annual incidence rates were $5.4/10^5$ for both periods [95% confidence interval (CI): 4.3-6.5 in 2001-2005 and 4.4-6.4 in 2006-2010, respectively, and 4.7-6.2 for the whole period]. Although the incidence varied over the years (minimum 3.7 to maximum $6.7/10^5$) no increase or decrease in the incidence could be identified. The odds ratio (OR) for CC in women compared to men was estimated to be 2.8 (95% CI: 2.0-3.7). The OR for women 65 years of age or above compared to below 65 years of age was 6.9 (95% CI: 5.0-9.7), and for women 65 years of age or above compared to the whole group the OR was 4.7 (95% CI: 3.6-6.0). The OR for age in general, i.e., above or 65 years of age compared to those younger than 65 was 8.3 (95% CI: 6.2-11.1). During the last decade incidence figures for CC have also been reported from Calgary, Canada during 2002-2004 ($4.6/10^5$) and from Terrassa, Spain during 2004-2008 ($2.6/10^5$). Our incidence figures from southern Sweden during 2001-2010 ($5.4/10^5$) as well as the incidence figures presented in the studies during the 1990s (Terrassa, Spain during 1993-1997 ($2.3/10^5$), Olmsted, United States during 1985-2001 ($3.1/10^5$), Örebro, Sweden during 1993-1998 ($4.9/10^5$), and Iceland during 1995-1999 ($5.2/10^5$) are all in line with a north-south gradient, something that has been suggested before both for CC and inflammatory bowel disease.

CONCLUSION: The observed incidence of CC is comparable with previous reports from northern Europe and America. The incidence is stable but the female: male ratio seems to be decreasing.

INTRODUCTION

In 1976, a pathology colleague at our hospital, Clas G Lindström, received rectal biopsies for a second opinion. The patient was a 48-year-old woman with chronic non-bloody watery diarrhoea and based on his observations he described the first ever case of collagenous colitis (CC)[1]. In his case report, Lindström actually described a typical case of CC, i.e., a middle-aged woman with chronic non-bloody watery diarrhoea. Independently, a group from Canada also reported this entity[2]. Other common CC symptoms include abdominal pain, weight loss and faecal incontinence[3-5]. The diagnosis of CC can only be established by microscopic examination of colonic mucosal biopsies. Endoscopy usually reveals a macroscopically normal mucosa, although some changes may be seen with special staining methods, e.g. altered vessel formation and disturbed pattern of the mucous membrane[6,7]. Histopathologically, CC is characterised by a thickened subepithelial collagen layer, combined with a chronic inflammatory infiltrate in the lamina propria and surface epithelial damage. In 1989, Lazenby[8] described lymphocytic colitis (LC), a similar condition clinically and histopathologically, but without a thickened subepithelial collagen layer. Collagenous colitis and LC are included in the umbrella term microscopic colitis (MC).

About 10% of patients investigated for non-bloody diarrhoea and with a macroscopically normal colonic mucosa are diagnosed with MC[8-11] even though an incidence as high as 29% has been observed[12]. These figures indicate that the condition could be prevalent. Incidence data on CC is available from the mid 1990s[13]. Initially, CC was considered to be a rare disease, but with time it has become evident that the incidence of CC is higher than was first anticipated.

The aim of this study was to estimate the incidence of CC in a well-defined population in southern Sweden during the ten year period from 2001-2010.

MATERIALS AND METHODS

Catchment area

The catchment area in this study comprised the south-west part of the county of Skåne (the county had 1 243 329 inhabitants on December 31st, 2010). The catchment area (including the cities of Malmö and Trelleborg, and the villages Vellinge and Svedala) is a mixed urban and rural type with limited migration (from 2001 to 2010 the population increased by 13%, from 349 693 to 394 307 inhabitants). The town of Malmö has the third largest population in Sweden, while Trelleborg is a small town. Vellinge and Svedala are smaller communities. In the catchment area there are two hospitals, one in Malmö and one in Trelleborg. Colonoscopy is carried out at both hospitals as well as by some private practitioners. There is only one Pathology Department in the catchment area (in Malmö) and all mucosal colonic biopsy specimens from the hospitals in Malmö and Trelleborg as well as from the private practitioners are sent to this Pathology Department.

Patients

Patients living in the catchment area who underwent colonoscopy due to watery diarrhoea and were diagnosed with CC from 2001-2010, were included in the study. Cases were identified by searching for the diagnosis of CC in the diagnostic register at the Pathology Department in Malmö. The medical records for the identified CC patients were subsequently scrutinized for clinical data to ensure that only newly diagnosed cases were included.

Histopathologically uncertain cases as well as cases not diagnosed by an experienced gastrointestinal pathologist were reassessed by a pathologist specialised in gastrointestinal pathology (Martin Olesen). Patients not fulfilling the histopathological criteria for CC were excluded. Patients with a histopathological diagnosis of "unspecific chronic inflammation" and with watery diarrhoea were also re-evaluated to identify putative missed CC cases.

All CC patients living in the catchment area were included regardless of where in Skåne they were diagnosed. To eliminate the risk of missing patients living in the catchment area during the study period in 2001-2010, but having had a diagnostic colonoscopy with biopsies in adjacent areas outside the catchment area (i.e., in the remaining area of Skåne), the diagnostic registers at the other three Pathology Departments in Skåne were scrutinized for cases with CC. In accordance with this, patients not living in the catchment area from 2001-2010, but diagnosed at our Pathology Department were excluded.

All information regarding the size of the population as well as age and sex distribution was obtained from Statistics Sweden, the central bureau for national socioeconomic information.

Figure 1 Age- and sex-specific annual incidence of collagenous colitis in southern Sweden.

Figure 2 Annual incidence of collagenous colitis in southern Sweden.

Diagnostic criteria

The diagnosis of CC was based on both clinical and histopathological criteria. The clinical criterion was non-bloody watery diarrhoea. The histopathological criteria were as follows: (1) A chronic inflammatory infiltrate in the lamina propria; (2) A thickened subepithelial collagen layer $\geq$ 10 micrometers (μm); and (3) Epithelial damage such as flattening and detachment.

The subepithelial collagen layer was measured with an ocular micrometer in a well orientated section of the mucosa. Measurement of the subepithelial collagen layer was obtained using special stains for collagen fibres (Masson's trichrome or van Gieson) and/or reticulin fibres (Sirius red).

Statistical analysis

For the purpose of calculating the incidence rate, it was assumed that the entire population in the catchment area was at risk. The incidence calculations were based on the date of diagnosis and 95% confidence interval (CI): were included. The calculation of mean annual incidence/100 000 as well as age-related incidence was based on the number of inhabitants on December 31st of each year. Data on the studied population are presented as

median and range/inter-quartile range (IQ) (25th-75th percentiles). Comparisons between groups were carried out using odds ratios (OR) and corresponding 95% CI.

Ethics

The study was approved by the Committee of Research Ethics at Lund University.

RESULTS

Patients

In the ten year period from 2001-2010, 198 CC patients were newly diagnosed. Of these, 146 were women and 52 were men (female:male ratio 2.8:1). The median age at diagnosis was 71 years (range 28-95/IQ 59-81); for women median age was 71 (range 28-95) years and was 73 (range 48-92) years for men (Figure 1).

Incidence

During the time periods 2001-2005 and 2006-2010, the mean annual incidence rates were $5.4/10^5$ for both periods (95% CI: 4.3-6.5 in 2001-2005 and 4.4-6.4 in 2006-2010, respectively, and 4.7-6.2 for the whole period). Conse-

Table 1 Mean annual incidence of collagenous colitis year by year during 2001-2010

Year	Annual incidence/10^5 (total)	Annual incidence/10^5 (women)
2001	6.6	7.8
2002	5.1	6.1
2003	4.5	4.9
2004	6.7	8.7
2005	3.9	6.5
2006	4.4	6.9

quently, although the incidence rates varied over the years (minimum 3.7 to maximum 6.7/10^5) no increase or decrease could be identified (Figure 2, Tables 1 and 2).

The OR for CC in women compared to men was estimated to be 2.8 (95% CI: 2.0-3.7). The OR for women 65 years of age or above compared to below 65 years of age was 6.9 (95% CI: 5.0-9.7), and for women 65 years of age or above compared to the whole group the OR was 4.7 (95% CI: 3.6-6.0). The OR for age in general, *i.e.*, above or 65 years of age compared to those younger than 65 was 8.3 (95% CI: 6.2-11.1).

DISCUSSION

Information on the incidence of CC is available from one centre in the United States, one in Canada and a few in Europe (including Örebro in the central part of Sweden). Our study has added information on the epidemiology of CC in the southern part of Sweden. We report a mean annual incidence of CC of 5.4/10^5 for the period 2001-2010, which is in line with previous data from Örebro in central Sweden during 1993-1998 (4.9/10^5)[11], and is in accordance with the reported figures from Olmsted County, Minnesota, United States from 1997-2001 (6.2/10^5)[14], Iceland from 1995-1999 (5.2/10^5)[15] and Calgary, Alberta, Canada from 2002-2004 (4.6/10^5)[15,16]. However, these findings are in contrast to the incidence reported from Terrassa, Spain during 2004-2008 (2.6/10^5)[17] (Table 2). Although the findings are not contradictory or novel in comparison with, for example, the report from Örebro[11], the number of cases is large and the epidemiological information is updated in a new region that has not been studied before.

Most relevant from the Swedish perspective, are the extensive investigations from Örebro, in the central part of Sweden, where the incidence rates were calculated over a 15-year period from 1984-1998. An increased incidence of CC from 1.8/10^5 in 1984-1993 to 3.7/10^5 in 1993-1995 and 6.1/10^5 in 1996-1998 was reported[11,12]. In Spain, the incidence increased from 1.1/10^5 in 1993-1997 to 2.6/10^5 in 2004-2008[10,17]. In accordance with these reported increases, the Minnesota data from 1985 to 2001 show the same phenomenon. In 1985-1997, the incidence was 1.6/10^5 compared to 7.1/10^5 in 1998-2001[14]. An explana-

tion for these reported increases in incidence rates could be an increased awareness of CC and more frequent use of colonoscopies with biopsies in the diagnostic procedure, although there was probably a true increase in incidence as well. The incidence of other gastrointestinal disorders such as ulcerative colitis, Crohn's disease and coeliac disease has increased in the Western world during the last few decades[18-21] and the influence of a common environmental factor (or several) cannot be ruled out. Interestingly, coeliac disease- similar to CC-has also increased over the last few decades and these diseases are related to each other[22]. Lansoprazole and other proton pump inhibitors are, in addition to nonsteroidal anti-inflammatory drugs, associated with a higher risk of CC[22-30]. The possibility that other factors such as infectious agents and components in our food could contribute to the increased incidence has also been contemplated.

The time period of ten years in our study is fairly long and provides information on possible fluctuations in the CC incidence rate in our catchment area during the period 2001-2010. Despite some variation in the annual incidence we did not observe any significant increase or decreases in the incidence during the study period. This is in contrast with the reported increases mentioned above. The stable incidence in our study might be due to the fact that CC was described at our hospital in Malmö by Lindström as early as 1976, *i.e.*, 35 years ago. Accordingly, CC has been known among medical doctors in this area for more than 30 years, and as a consequence regular use of colonoscopies, with multiple biopsies throughout the entire length of the colon, has been standard in the diagnostic procedure of chronic watery diarrhoea for a long time. Furthermore, there has been a close clinical and scientific collaboration between gastroenterologists and pathologists within the field of CC.

During the last decade incidence figures for CC have been reported from Canada during 2002-2004 (4.6/10^5) and from Spain during 2004-2008 (2.6/10^5)[16,17]. There was a considerable difference in the incidence of CC in these studies despite the fact that the study periods were similar and relatively recent. Fernandez-Banares highlighted the possibility of a north-south gradient with a

higher incidence further north compared to those closer to the equator[17]. This possibility is further strengthened by our study. A larger number of studies have been listed in Table 2 to illustrate this phenomenon. This is also in line with the north-south gradient suggested for inflammatory bowel disease[31].

The female: male ratio in the present study (2.8:1) was significantly lower than that in previous reports (Table 2). The previous Swedish studies from Örebro reported a female: male ratio as high as 9 and 7.5 in 1984-1993 and 1993-1998, respectively. Interestingly, it might very well be that the ratio may have decreased over the years as indicated in Table 2, which to the best of our knowledge, has not been reported before.

The OR calculated for age in general, women compared to men, older women compared to younger women, and older women compared to the whole group indicated that the risk of acquiring CC is higher in older persons, especially women, which is in line with observations from several other studies. Based on the levels for the different OR it could be speculated that age (OR 8.3 for age in general and 6.9 for older women) contributes more than sex (OR 2.8) to the risk of CC.

The geographical area studied, the south-west part of Skåne, a county in southern Sweden, has several advantages for carrying out epidemiological studies. The organisation for medical care is well defined, with two hospitals and one Pathology Department. The catchment area *per se* is also well defined. In addition, the migration rate in the area is limited. Furthermore, the use of personal identity numbers in Sweden that follow the individual throughout her or his entire life span makes it possible to identify every individual with CC in the region and to determine whether she or he lives within the catchment area. Accordingly, the conditions for conducting an epidemiologic CC study in Sweden are favourable. Another strength of this CC study was the precautions taken to identify patients who belonged to the catchment area but who had been diagnosed in another part of the county, by scrutinizing residents with CC at all Pathology Departments in Skåne. This study is also fairly large with 198 identified CC cases during the period (Table 2).

In conclusion, we observed a mean annual incidence of CC in southern Sweden of $5.4/10^5$, in line with previous data. In contrast to previously reported increases in the incidence rate, we report a stable incidence during the ten year study period from 2001-2010. The female: male ratio (2.8:1) was lower than previously reported. Based on data from available studies it seems that the female: male ratio is decreasing. In accordance with previously presented data it also seems that CC is more common in northern countries.

ACKNOWLEDGMENTS

COMMENTS

Background
Collagenous colitis (CC) predominantly affects middle-aged women and results in chronic watery diarrhoea. It has become evident that the incidence of CC is much higher than was first anticipated.

Research frontiers
Information on the incidence of CC is available from one centre in the United States, one in Canada and a few in Europe. The incidence of CC in Örebro, in central Sweden, was $4.9/10^5$ from 1993-1998. This level is in accordance with the reported figures from Olmsted County, Minnesota, United States during 1997-2001 ($6.2/10^5$), Iceland during 1995-1999 ($5.2/10^5$) and Calgary, Alberta, Canada during 2002-2004 ($4.6/10^5$). However, these findings are in contrast to the incidence reported from Terrassa, Spain in 2004-2008 ($2.6/10^5$), which is much lower.

Innovations and breakthroughs
The study added information on the epidemiology of CC in the southern part of Sweden. The authors observed a mean annual incidence of CC in southern Sweden of $5.4/10^5$, which is in line with previous data. In contrast to previously reported increases in the incidence rate, the authors report a stable incidence in the ten year study period from 2001-2010. The female: male ratio (2.8:1) was lower than previously reported. Based on data from available studies it seems that the female:male ratio is decreasing. In accordance with previously presented data, it also seems that CC is more common in northern countries.

Applications
During the 25 years since the first epidemiological study, the incidence of CC increased from 1.8 to 5.4/100 000 inhabitants. It now seems to have levelled out. At the same time the female: male ratio has decreased. Consequently, more men (in relation to women) have been affected in recent years. Despite this, age is associated with a higher OR for disease than sex. The risk of disease is higher in northern than in southern Europe. The following remain to be clarified: Why the incidence is no longer increasing, why the female: male ratio has decreased and why people in northern Europe have a higher risk of disease. Environmental factors could have a substantial impact on CC; smoking, nonsteroidal anti-inflammatory drugs and proton pump inhibitors are known triggers but it can not be ruled out that several other factors are responsible for the high incidence of CC.

Terminology
Incidence represents how many persons are affected by a certain disease/year in each group of 100 000 inhabitants within a defined area. Collagenous colitis mean inflammation in the large intestine that is predominantly visible *via* examination with a microscope, where the collagen layer can be observed in the epithelium. The disease results in chronic watery diarrhoea.

Peer review
The manuscript is relatively well written, and the results are moderately interesting.

Abstract

AIM: To investigate whether selected single nucleotide polymorphisms (SNPs) in miR-196a2, miR-27a and miR-146a genes are associated with sporadic colorectal cancer (CRC).

METHODS: In order to investigate the effect of these SNPs in CRC, we performed a case-control study of 197 cases of sporadic CRC and 212 cancer-free controls originating from the Central-European Caucasian population using TaqMan Real-Time polymerase chain reaction and allelic discrimination analysis.

RESULTS: The genotype and allele frequencies of SNPs were compared between the cases and the controls. None of the performed analysis showed any statistically significant results.

CONCLUSION: Our data suggest a lack of association between rs11614913, rs895819 and rs2910164 and colorectal cancer risk in the Central-European Caucasian population, a population with an extremely high incidence of sporadic colorectal cancer.

Evaluation of SNPs in miR-196-a2, miR-27a and miR-146a as risk factors of colorectal cancer. *World J Gastroenterol* 2012; 18(22): 2827-2831 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i22/2827.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i22.2827

INTRODUCTION

Sporadic colorectal cancer represents a typical multifacto-

rial disease with an intense crosstalk of the genetic background with the environment, including lifestyle habits and diet. Certain populations present higher rates of sporadic colorectal cancer, independently of diet and lifestyle habits than others[1], which supports the hypothesis that individual genetic background is involved in the etiopathogenesis of the disease. An extremely high incidence of colorectal cancer[1] has been repeatedly reported for the Central-European Caucasian population, significantly exceeding the peak incidence observed in the United States and other developed countries[2]. This population is, therefore, highly likely to carry a strong genetic predisposition to sporadic colorectal cancer and could be a good model population for sporadic colorectal cancer.

MicroRNAs (miRNAs) are short non-coding RNAs, 18 to 25 nucleotides in length, which regulate gene expression[3]. Single nucleotide polymorphisms (SNPs) may occur at the level of the miRNA biogenesis pathway genes, pri-miRNA, pre-miRNA or mature miRNA sequences. Such polymorphisms may be functional with regard to the biogenesis and actions of the mature miRNA. Specific SNPs are located at predicted miRNA target sites within 3' of untranslated regions of mRNAs. These SNPs have the potential to affect the efficiency of miRNA binding at their target sites as well as to create or disrupt binding sites. Resulting gene dysregulation may involve changes in phenotype and may eventually prove critical for the susceptibility to and the onset of cancer, as well as for prognosis and therapy response prediction[1].

The most frequently studied miRNA-associated SNP in cancer is rs11614913 in the pre-miRNA region of miR-196-a2. Hu *et al*[4] observed the association of the rs11614913: T > C variant genotype with a significantly increased risk of breast cancer [odds ratio (OR) 1.23; 95% confidence interval (CI): 1.02-1.48]. A number of case-control studies were consequently performed in breast[5,6], lung[7,8], gastric[9], esophageal[10], hepatocellular[11] and head and neck cancer[12]. More recently, two contradictory studies were published evaluating rs11614913 as a potential risk factor for colorectal cancer in the Chinese population (T *vs* C allele-OR 1.320; CI: 1.056-1.649, *P* = 0.014[13] *vs* OR 1.065; CI: 0.803-1.414, *P* = 0.665[14]). SNP rs895819, located in the terminal loop of a pre-miR-27a oncogene, was initially evaluated in familial breast cancer, whereas the G allele was associated with reduced familial breast cancer risk (*P* = 0.0215). The opposite of this association was observed by Sun *et al*[15] in a gastric cancer case-control study where subjects with variant genotypes (AG + GG) showed a significantly increased risk of gastric cancer relative to AA carriers (OR 1.48; 95% CI: 1.06-2.05; *P* = 0.019). AG to C SNP (rs2910164) located within the sequence of the miR-146a precursor was first studied by Shen *et al*[16] due to the fact that predicted miR-146a target genes include BRCA1 and BRCA2, i.e., key breast and ovarian cancer susceptibility genes. Breast and ovarian cancer patients who had at least one miR-146a variant allele were diagnosed at an earlier age. Subsequently, the distribution of the miR-146a polymorphism

rs2910164 was evaluated in breast[6], esophageal[17], hepatocellular[18] and thyroid cancer[19].

Thus, a significant association with the risk of various types of solid cancers, with the exception of colorectal cancer, has been repeatedly reported for SNPs: rs11614913 in miR-196-a2, rs895819 in hsa-miR-27a and rs2910164 in miR-146a; consequently, we decided to perform a case-control study evaluating these three SNPs and the risk of sporadic colorectal cancer in a Central-European Caucasian population.

MATERIALS AND METHODS

Patients and controls
The study included patients with newly diagnosed sporadic colorectal cancer treated at the Masaryk Memorial Cancer Institute, Czech Republic between January 2008 and December 2010. The patient cohort consisted of 197 subjects [105 men, 92 women; age (mean ± SD): 63 ± 9 years] with histologically confirmed colorectal adenocarcinomas, whereas the control cohort included a total of 202 cancer-free blood donor volunteers recruited from the same institute with a similar age distribution (93 men, 109 women; mean age: 65 ± 14 years) and no previous history of any type of cancer. Due to its invasiveness, colonoscopy was not performed to exclude colorectal cancer (CRC) in the control cohort; however, all subjects were symptom free and no anemia was present. All study subjects were Caucasian. The hospital ethical committee approved the study and all study subjects supplied a written informed consent which was subsequently archived.

DNA isolation and genotyping
Genomic DNA was isolated from the full peripheral blood using the MagNA Pure DNA Isolator (Roche). DNA concentration was measured on the Nanodrop ND-1000 (NanoDrop Technologies, Inc.). For analysis of rs11614913 in miR-196-a2, rs895819 in hsa-miR-27a and rs2910164 in miR-146a, Real-Time polymerase chain reaction (PCR) allelic discrimination was performed on Step-One Real-Time PCR (Applied Biosystems, United States) using standard TaqMan genotyping assays according to the manufacturer's instructions. In brief, probes, primers and TaqMan universal PCR Master Mix were obtained from Applied Biosystems. A reaction solution of 10 μL contained 0.5 μL TaqMan Genotyping Assay mix (consisting of 20X Mix of unlabeled PCR primers and TaqMan minor groove binder probe, 6-carboxyfluorescein and VIC dye-labeled), 8 μL of PCR mixture reagent and 10 ng of genomic DNA. Reactions were run according to the manufacturer's instructions. The PCR consisted of pre-PCR read at 60 ℃ for 30 s, holding stage at 95 ℃ for 10 min, 50 cycles of denaturing at 92 ℃ for 15 s, annealing 60 ℃ for 1 min 30 s and post-PCR read at 60 ℃ for 30 s.

Statistical analysis
The Hardy-Weinberg equilibrium was tested for each

P-values are calculated according to Wald's test. [a]*P*-values according to likelihood ratio-test; [1]Age and sex adjusted; CRC: Colorectal cancer; OR: Odds ratio; CI: Confidence interval.

polymorphism using the χ^2 test in patients and controls separately. Allelic frequencies were estimated by the "counting method" and differences in allele frequencies between case and control subjects were tested using the likelihood ratio χ^2 tests for 2 £ 2 tables (two alleles, case *vs* control subjects). The homozygote of the most frequent allele was used as a reference for calculating the OR. For an OR and 95% confidence interval, logistical regression was used based on a model for sex and age of the patients. Data analysis was performed using the Statistica v. 9.0 (Statsoft Inc., Tulsa, OK, United States) program package. Values of $P < 0.05$ were considered statistically significant.

RESULTS

All polymorphisms met the criteria of the Hardy-Weinberg equilibrium in the individual patient and control groups. Logistic regression modeling was used to estimate the odds ratios of the investigated genotypes and alleles of SNPs rs2910164, rs11614913 and rs3746444 in CRC cases as well as in the controls (Table 1). All of the examined polymorphisms displayed a clear lack of statistically significant associations with colorectal cancer risk.

DISCUSSION

Sporadic colorectal cancer is a multifactorial disease with multiple genetic determinants of varied significance. Numerous SNP analyses of sporadic colorectal cancer were conducted in order to clarify the genetic background. It has been hypothesized that polymorphic genetic variants involved in metabolism, DNA repair and apoptosis are linked to susceptibility to colorectal cancer[20]. Although

alterations in miRNA function have been detected in a broad spectrum of hematological malignancies and solid tumors[21-23], including CRC[24], only two studies performed to date have focused on miRNA-associated SNPs in CRC; although these studies were carried out in the Chinese population[13,14], their results were contradictory. Although it has been hypothesized that SNPs in miRNA genetic regions may affect the transcription of pri-miRNA transcripts, processing of miRNA precursors to mature miRNAs or miRNA target interactions, genetic variants in pre-miRNA regions are rare and unlikely to be functionally important, mainly due to the serious pressure imposed by natural selection on the evolutionary conserved pre-miRNA sequences[3].

In our study, we performed a case-control study of the three most frequently studied SNPs in miRNA genes (rs11614913 in miR-196-a2, rs895819 in miR-27a and rs2910164 in miR-146a), to investigate the degree of risk of CRC in the Central-European Caucasian population.

As it has been experimentally validated that the rs11614913 polymorphism located in the miR-196-a2 mature sequence affects the maturation and effect of target mRNA possibility, it is biologically plausible that genetic variation of hsa-miR-196a2 could modulate cancer susceptibility. In accordance with this finding, rs11614913 is one of the most frequently studied SNPs associated with miRNAs in case-control studies of a wide range of solid cancers[5-14]. For example, Hu *et al*[8] reported that the CC homozygous genotype of rs11614913 located in miR-196a2 was associated with a statistically significant increase in the mature miR-196a and a worse prognosis in non-small-cell lung cancer (NSCLC), proposing that this SNP could serve as a prognostic marker of NSCLC. Another Chinese study reported a clear association between

CC and CC/CT genotypes of rs11614913 and increased risk of breast cancer (OR 1.23; 95% CI: 1.02-1.48)[4]. When reviewed together, the majority of these studies described significant associations of the rs11614913-C allele with susceptibility and/or poor prognosis of lung cancer[7,8], gastric cancer[9], esophageal cancer[10], hepatocellular carcinoma[11] and head and neck cancer[12]. More recently, two Chinese studies focusing on an association between this SNP and susceptibility to CRC and its progression were performed[13,14].

Although the frequency of CC homozygotes of rs11614913 was higher in CRC patients than in healthy controls (41.62% *vs* 41.04%) in our study, the genotypes carrying the C allele (CT and CC) expressed the opposite trend in frequencies (64.21% in CRC *vs* 65.33% in controls). Moreover, the frequency of the C allele in CRC patients (64.21%) was not significantly lower than in healthy controls (65.33%). Furthermore, no significant association between the miR-196a2 polymorphism and the risk of CRC was observed in our study. These results are in agreement with the findings by Chen *et al*[14]. On the other hand, Zhan's group described the C allele as a risk factor for CRC in the Chinese population. Neither of the Chinese studies reported any associations between the rs11614913 polymorphism and CRC progression, including tumor grade, stage, lymph node and distant metastasis[13,14]. The discrepancy in the potential significance of rs11614913 in CRC reported by the above-mentioned independent studies may be due to different molecular pathogenetic mechanisms as different contributors to cancer or population-specific factors such as the different genetic backgrounds of the studied cohorts.

MiR-27a, in general, is a very important miRNA involved in the development of chemoresistance in solid cancer[15]. This study presents the first case-control investigation of the role of the A/G polymorphism (rs895819) in miR-27a in CRC; however, no significant associations were observed. Although the frequency of AA homozygotes was higher in CRC patients than in healthy controls (44.67% *vs* 43.87%), the frequencies of the genotypes carrying the A allele (AA and AG) did not show significant differences between the study cohorts (66.50% in CRC patients *vs* 66.04% in healthy controls). In gastric cancer, it has been reported that the variant genotypes of rs895819 located at miR-27a conferred a 48% increased risk of developing gastric cancer in the Chinese population; moreover, this trend tended to be age-specific. The authors concluded that elevated levels of miR-27a, through regulating the Zinc finger and BTB domain containing 10 (ZBTB10), result in the over-expression of Sp proteins and Sp-dependent genes, which play important roles in gastric cancer cell survival and angiogenesis[15,25]. Furthermore, Yang *et al*[26] found that the G-allele of rs895819, located in the terminal loop of the pre-miR-27a oncogene, is associated with reduced familial breast cancer risk (OR = 0.88; 95% CI: 0.78-0.99; *P* = 0.0287).

MiRNA-146a and its G to C common polymorphism, rs2910164, located within the sequence or the miR-146a precursor represent another miRNA hotspot evaluated in CRC for the first time in the present study. This SNP leads to change from a G:U pair to a C:U mismatch, and consequently, to reduced levels of pre- and mature miR-146a[17,19]. As BRCA1 and BRCA2, key breast and ovarian cancer susceptibility genes, are predicted targets of miR-146a, the majority of studies have been focused on breast and ovarian cancer. The results of Chen *et al*[16], who primarily studied rs2910164 in breast cancer and postulated that breast and ovarian cancer patients who had at least one variant allele were diagnosed at an earlier age (*P* = 0.029, *P* = 0.014, respectively), were not confirmed by further and larger independent case-control studies performed by Hu *et al*[4] and Catucci *et al*[6]. Garcia *et al*[27] concluded that the rs2910164: G > C SNP in the miR-146a gene is not associated with breast cancer risk in BRCA1 and BRCA2 mutation carriers. This case-control study, i.e., the first study to investigate the role of the miR-146a polymorphism, rs2910164, in CRC risk, found no significant association. Although our results did not indicate any significant relationship between the above-mentioned, miRNA-associated, SNPs and risk of CRC, we believe that a more detailed and comprehensive characterization of miRNA SNPs will improve our understanding of the miRNAs involved in CRC onset and progression which is necessary for the development of novel diagnostic and therapeutic strategies and approaches to this deadly disease.

COMMENTS

Background
The Central-European Caucasian population displays an extraordinarily high incidence of sporadic colorectal cancer and although there is a long-term tendency towards a decrease in mortality rates attributed to colorectal cancer, it still represents a major cause of death in the population. Susceptibility to colorectal cancer is typically multifactorial and can be characterized by intensive crosstalk between the genetic background of an individual and environmental factors. Susceptibility genes are involved in metabolic pathways controlled by epigenetic mechanisms where microRNA-associated regulations may play an important role.

Research frontiers
MicroRNAs (miRNAs) are small non-coding RNAs regulating gene expression. It has been recently suggested that single nucleotide polymorphisms (SNPs) in genes encoding mir196-a2, miR-27a and mir146-a may be associated with increased risk of various types of solid cancer. However, no such study of colorectal cancer has been conducted so far. This study investigated three SNPs (rs11614913 in miR-196-a2, rs895819 in hsa-miR-27a and rs2910164 in miR-146a) which were previously reported to be significantly associated with various types of solid cancer.

Innovations and breakthroughs
To the best of our knowledge, this is the first study focusing on the significance of rs11614913 in miR-196-a2, rs895819 in hsa-miR-27 and rs2910164 in miR-146a in sporadic colorectal cancer. The study was conducted using a highly homogenous Central-European Caucasian population with extremely high rates of sporadic colorectal cancer.

Applications
The significance of SNPs in genes encoding miRNAs remains controversial. Positive associations of the investigated polymorphisms were reported in various types of solid cancer. Based on the results, however, the investigated SNPs in miRNA genes do not seem to be major genetic determinants of genetic susceptibility to sporadic colorectal cancer in the Central-European population.

Terminology
Genetic susceptibility refers to inherited predisposition to increased risk of developing a certain disease, typically a multifactorial disease. mRNAs mean short non-coding RNAs, 17-22 nucleotides in length, which regulate gene expression and thereby play significant roles in cancer.

Peer review
The manuscript is well presented and supported by data.

Abstract

AIM: To re-evaluate the recent clinicopathological features of remnant gastric cancer (RGC) and to develop desirable surveillance programs.

METHODS: Between 1997 and 2008, 1149 patients underwent gastrectomy for gastric cancer at the Department of Digestive Surgery, Kyoto Prefectural University of Medicine, Japan. Of these, 33 patients underwent gastrectomy with lymphadenectomy for RGC. Regarding the initial gastric disease, there were 19 patients with benign disease and 14 patients with gastric cancer. The hospital records of these patients were reviewed retrospectively.

RESULTS: Concerning the initial gastric disease, the RGC group following gastric cancer had a shorter interval [$P < 0.05$; gastric cancer *vs* benign disease: 12 (2-22) *vs* 30 (4-51) years] and were more frequently reconstructed by Billroth-I procedure than those following benign lesions ($P < 0.001$). Regarding reconstruction, RGC following Billroth-II reconstruction showed a longer interval between surgical procedures [$P < 0.001$; Billroth-II *vs* Billroth-I: 32 (5-51) *vs* 12 (2-36) years] and tumors were more frequently associated with benign disease ($P < 0.001$) than those following Billroth-I reconstruction. In tumor location of RGC, after Billroth-I reconstruction, RGC occurred more frequently near the suture line and remnant gastric wall. After Billroth-II reconstruction, RGC occurred more frequently at the anastomotic site. The duration of follow-up was significantly associated with the stage of RGC ($P < 0.05$). Patients diagnosed with early stage RGC such as stage I-II tended to have been followed up almost every second year.

CONCLUSION: Meticulous follow-up examination and early detection of RGC might lead to a better prognosis. Based on the initial gastric disease and the procedure of reconstruction, an appropriate follow-up interval and programs might enable early detection of RGC.

INTRODUCTION

The incidence of remnant gastric cancer (RGC) following distal gastrectomy has been reported to account for 1%-2% of all gastric cancers in Japan[1,2]. Previously, RGC was reported to be caused by multiple factors, and the incidence, pathological features, and potential mechanisms have been extensively investigated[3-5]. Specifically, RGC is commonly found at an advanced stage, resulting in low rates of curative resection (38%-40%) and a consequently poor prognosis[6,7]. However, recently, the incidence and etiology of RGC have been changing[8] because of the long latency periods, decreasing prevalence of gastrectomy for benign disease[6,9], early detection and improved outcomes in patients with gastric cancers[10,11]. Moreover, recent advances in diagnostic and treatment techniques have led to a higher detection rate of early RGC following distal gastrectomy[12]. Consequently, endoscopic therapy such as endoscopic mucosal resection or endoscopic submucosal dissection is applicable for treatment of early-stage RGC[13,14]. Indeed, more than half of the RGC patients were treated for T1 or T2, node-negative and early stage cancer at our institution and almost 80% of patients with RGC were curatively resected. Therefore, it is necessary to re-evaluate the risk factors of RGC to develop an optimal new surveillance program and treatment guide. However, there is limited information available to help guide the treatment of patients with RGC. This study was designed to re-evaluate the clinicopathological characteristics and surgical outcomes of RGC and to develop desirable surveillance programs.

MATERIALS AND METHODS

Patients

Between 1997 and 2008, 1149 patients underwent gastrectomy for gastric cancer. Of these, 33 consecutive patients with primary RGC were treated in the Department of Digestive Surgery, Kyoto Prefectural University of Medicine. All patients underwent gastrectomy with lymphadenectomy for RGC. The clinicopathologic findings of these patients were determined retrospectively based on their hospital records. Macroscopic, microscopic and histopathological classifications of gastric cancers were based on the Japanese Classification of Gastric Carcinomas[15] and tumor-node-metastasis staging system[16].

Histologic types were classified as differentiated (papillary, moderately or well-differentiated adenocarcinoma) and undifferentiated (poorly or undifferentiated adenocarcinoma, signet-ring cell carcinoma, and mucinous adenocarcinoma).

Follow-up program after initial gastrectomy

The follow-up program after initial gastrectomy at our institution is comprised of a regular physical examination and laboratory blood tests, chest X rays, an upper gastrointestinal series or endoscopy and ultrasonography or computer tomography for the first 5 years, and yearly endoscopy thereafter, if possible.

Evaluation of clinical associations between remnant gastric cancer and various clinical factors

The correlations between clinical factors and an initial factor such as previous disease or method of reconstruction in initial surgery were examined. Moreover, the follow-up interval is very important for screening recurrence and second primary gastric cancers. Therefore, correlation between follow-up periods and progression was evaluated in RGC.

Statistical analysis

The patient was included as a cause-specific death when the cause of death was specified as recurrent RGC. χ^2 test and Fisher's exact probability test were performed for categorical variables, while Student's *t*-test and Mann-Whitney *U*-test for unpaired data with continuous variables were performed to compare the clinicopathological characteristics between two groups. Kruskal-Wallis *H* test was used as a nonparametric procedure that can be used to compare more than two groups for analyses of follow-up interval. A *P* value less than 0.05 was considered significant.

RESULTS

Clinicopathologic characteristics of patients with primary remnant gastric cancer

The mean patient age was 68 years, and the male:female ratio was 2.7:1. Regarding the initial gastric disease, there were 19 patients with benign disease and 14 patients with gastric cancer. The median interval between the 1st and 2nd surgery was 20 years. Reconstruction during the 1st surgery was mainly Billroth-Ⅰ or Billroth-Ⅱ. En bloc resection of the tumor by total remnant gastrectomy was performed with jejunal mesentery and D2 lymphadenectomy and concomitant organ resection. Eighteen patients additionally received splenectomy, four patients received distal pancreatectomy, two patients received partial colon resection and two patients received liver resection. Reconstructions were performed in 16 patients by Billroth-Ⅰ, 16 patients by Billroth-Ⅱ and one by Roux-en-Y procedure for all resected RGC tumors. Tumors were located at the anastomotic site in 16 (61%) patients, corpus and/or cardia in nine (34%), and throughout the

whole remnant in one (4%) patient. Consequently, more than half of the RGC patients demonstrated T1 or T2, undifferentiated, node-negative and early stage cancer. In 78.8% (26/33) of patients, resections were performed with curative intent.

Association between clinicopathologic characteristics and initial disease

Clinicopathologic findings of 33 patients with primary RGC are listed in Table 1 according to the nature of the primary disease. Patients with RGC following gastric cancer showed a significantly shorter interval between the 1st and 2nd surgery [*P* < 0.05, gastric cancer *vs* benign disease: 12 (2-22) *vs* 30 (4-51) years] and were more frequently reconstructed by the Billroth- I method than those following benign disease (*P* < 0.005). Other factors did not significantly differ between the two groups.

Association between clinicopathologic characteristics and reconstruction of 1st surgery

Table 2 shows details of 33 RGC patients according to

the method of reconstruction. RGC following Billroth- II reconstruction showed a longer interval between surgical procedures (*P* < 0.001) and tumors were more frequently associated with benign disease (*P* < 0.001) than those following Billroth- I reconstruction. Figure 1 shows the tumor location of 32 RGC following distal gastrectomy according to the method of reconstruction. After Billroth- I reconstruction, RGC occurred more frequently near the suture line and remnant gastric wall. After Billroth- II reconstruction, RGC occurred more frequently at the anastomotic site.

The duration of follow-up after distal gastrectomy

The duration of follow-up was significantly associated with the stage of progression in RGC (*P* < 0.05). Patients diagnosed with early stage RGC such as stage I - II tended to have been followed up almost every second year (Figure 2).

DISCUSSION

Gastric cancer is the second leading cause of cancer-

Figure 1 Location of 32 remnant gastric cancer tumors following distal gastrectomy according to the method of reconstruction. After Billroth-Ⅰ reconstruction, remnant gastric cancer (RGC) occurred more frequently near the suture line and remnant gastric wall; whereas, RGC after Billroth-Ⅱ reconstruction occurred more frequently at the anastomotic site.

Figure 2 Association of endoscopic follow-up intervals and the stage of progression. The follow-up interval was significantly associated with the stage of progression in remnant gastric cancer ($P < 0.05$). [1]Patients treated with endoscopic submucosal dissection (ESD), who were not included in this study, are presented for the purpose of comparison.

related death in the world[17]. However, recent advances in diagnostic methods, less invasive treatment techniques and better peri-operative management have increased the early detection of gastric cancer and decreased the mortality and morbidity rates[18-20]. Consequently, the number of cured patients has been increasing and some of these patients are at risk of acquiring second primary cancer in the remnant stomach. This implies that more cases of RGC will be encountered in the future.

In previous reports, RGC was commonly found at an advanced stage, resulting in low rates of curative resection (38%-40%) and a consequent poor prognosis[6,7]. However, recently, the incidence and etiology of RGC following distal gastrectomy may be changing due to diagnostic and technological advances. In our study, more than half of the RGC patients were treated for T1 or T2, node-negative and early stage cancer, contrary to that in previous series (Table 1). Almost 80% of patients were curatively resected with intensive lymphadenectomy. Thereby, the survival curves of primary proximal gastric cancer (PGC) and RGC were similar and without a significant difference, although patients with RGC tended to have a higher incidence of undifferentiated cancer, vascular invasion, and T4 component than patients with PGC (data not shown). Therefore, RGC is not always advanced at diagnosis and if so, intensive surgery for RGC does not necessarily mean a poor prognosis in comparison to that for primary gastric cancer. Therefore, it is necessary to re-evaluate the risk factors of RGC to develop an optimal new endoscopic surveillance program and treatment guide.

Regarding surveillance systems for early detection and curative treatment of RGC, periodic endoscopic examinations of the gastric remnant are shown to be extremely important in our study (Figure 1). However, a follow-up program that is too intensive may not be beneficial to the patient. The initial gastric disease and the interval between the 1st and 2nd surgery could affect the incidence of RGC. In our study, RGC following gastric cancer had a significantly shorter interval between 1st and 2nd surgery than that following benign disease [*P* <

0.05; gastric cancer *vs* benign disease: 12 (2-22) years *vs* 30 (4-51) years]. However, surveillance systems for gastric cancer should be especially considered because of decreasing gastrectomy for benign disease. Furthermore, 86% of all initial gastric cancer patients underwent Billroth-Ⅰ reconstruction at our institution and their median interval between 1st and 2nd surgery was 12 (2-36) years. Moreover, the duration of follow-up was significantly associated with the stage of RGC progression and an early detection of RGC led to better prognosis (Figure 2). Taken together, annual surveillance endoscopic screening should be required for at least 12 years following distal gastrectomy. Furthermore, after 12 years of follow-up, surveillance endoscopy should be recommended every second year because we found that patients diagnosed with early stage RGC such as stage Ⅰ-Ⅱ tended to have been followed almost every second year. In particular, meticulous endoscopy examination should be performed near the suture line and remnant gastric wall after Billroth-Ⅰ reconstruction and also should be performed at the anastomotic site after Billroth-Ⅱ reconstruction.

In conclusion, due to recent advances in diagnostic and treatment technologies, the etiology of RGC has been changing. Meticulous follow-up examination and early detection of RGC might lead to a better prognosis. Considering both the initial gastric disease and the procedure of reconstruction, an appropriate follow-up interval and programs should facilitate the detection of early RGC.

COMMENTS

Background
Recently, the incidence and etiology of remnant gastric cancer (RGC) have been changing because of the long latency periods, decreasing prevalence of gastrectomy for benign disease, early detection and improved outcomes in patients with gastric cancers. Moreover, recent advances in diagnostic and treatment technique have led to a higher detection rate of early RGC following distal gastrectomy.

Research frontiers

It is necessary to re-evaluate the risk factors of RGC and develop an optimal new surveillance program and treatment guide. However, there is limited information available to help guide the treatment of patients with RGC. In this study, the authors re-evaluated the clinicopathological characteristics and surgical outcomes of RGC and developed desirable surveillance programs.

Innovations and breakthroughs

In this study, more than half of the RGC patients were demonstrated to have T1 or T2, undifferentiated, node-negative and early stage cancer. The duration of follow-up was significantly associated with the stage of progression in RGC. Patients diagnosed with early stage RGC such as stage Ⅰ-Ⅱ tended to have been followed almost every second year. After Billroth-Ⅰ reconstruction, RGC occurred more frequently near the suture line and remnant gastric wall. After Billroth-Ⅱ reconstruction, RGC occurred more frequently at the anastomotic site.

Applications

RGC following gastric cancer had a significantly shorter interval between 1st and 2nd surgery than those following benign disease. Annual surveillance endoscopic screening should be required for at least 12 years following distal gastrectomy. Furthermore, after 12 years of follow-up, surveillance endoscopy should be recommended every second year.

Terminology

The incidence of RGC following distal gastrectomy has been reported to account for 1%-2% of all gastric cancers in Japan. In previous reports, RGC was commonly found at an advanced stage, resulting in low rates of curative resection (38%-40%) and a consequent poor prognosis.

Peer review

Authors have given new thoughts while designing this study. The paper is nicely written.

Abstract

AIM: To investigate the usefulness of tumor markers and adenosine deaminase in differentiating between tuberculous peritonitis (TBP) and peritoneal carcinomatosis (PC).

METHODS: A retrospective analysis of data was performed on consecutive patients who underwent peritoneoscopic and abdominal computed tomography (CT) evaluations. Among 75 patients at the Seoul National University Hospital from January 2000 to June 2010 who underwent both tests, 27 patients (36.0%) and 25 patients (33.3%) were diagnosed with TBP and PC, respectively. Diagnosis was confirmed by peritoneoscopic biopsy.

RESULTS: Serum c-reactive protein (7.88 ± 6.62 mg/dL *vs* 3.12 ± 2.69 mg/dL, *P* = 0.01), ascites adenosine deaminase (66.76 ± 32.09 IU/L *vs* 13.89 ± 8.95 IU/L, *P* < 0.01), ascites lymphocyte proportion (67.77 ± 23.41% *vs* 48.36 ± 18.78%, *P* < 0.01), and serum-ascites albumin gradient (0.72 ± 0.49 g/dL *vs* 1.05 ± 0.50 g/dL, *P* = 0.03) were significantly different between the two groups. Among tumor markers, serum and ascites carcinoembryonic antigen, serum carbohydrate antigen 19-9 showed significant difference between two groups. Abdominal CT examinations showed that smooth involvement of the parietal peritoneum was more common in the TBP group (77.8% *vs* 40.7%) whereas nodular involvement was more common in the PC group (14.8% *vs* 40.7%, *P* = 0.04). From receiver operating characteristic (ROC) curves ascites adenosines deaminase (ADA) showed better discriminative capability than tumor markers. An ADA cut-off level of 21 IU/L was found to yield the best results of differential diagnosis; sensitivity, specificity, positive predictive value, and negative predictive value were 92.0%, 85.0%, 88.5% and 89.5%, respectively.

CONCLUSION: Besides clinical and radiologic findings, ascitic fluid ADA measurement is helpful in the differential diagnosis of TBP and PC.

INTRODUCTION

Tuberculous peritonitis (TBP) and peritoneal carcinomatosis (PC) are two of the most common causes of exudative ascites in South Korea and both diseases require rapid recognition for the appropriate therapeutic management[1-3]. In a clinical situation, etiological diagnosis of the two diseases is very difficult because of the lack of specific differential clinical, radiological, or laboratory findings. Peritoneoscopy is thought to be the method of choice in the diagnosis of the two diseases[4-6]. However, the diagnostic failure rate of peritoneoscopy can reach as high as approximately 14%; the main reason for failure is interference from adhesions due to tumor, tuberculosis or previous surgery[4].

The purpose of this study was to clarify the differences in clinical, radiological, laboratory and peritoneoscopic findings between TBP and PC and to evaluate the diagnostic capacity of ascites adenosine deaminase (ADA) and tumor markers for the differentiating the two diseases.

MATERIALS AND METHODS

Patients

Between January 2000 and June 2010, patients over 18 years of age with exudative ascites of unknown etiology who underwent abdominal computed tomography (CT) scan and peritoneoscopy for diagnosis were enrolled in this study. All patients had laboratory tests such as complete blood count, serum biochemical tests, tumor markers from blood and ascites fluid, ascites cytology, ascites cell count and biochemical tests, and ascites ADA. Diagnosis of TBP was made if one of the following criteria was met: (1) ascites was positive for acid-fast bacilli stain and culture; (2) tuberculosis polymerase chain reaction test from ascites or peritoneoscopic biopsy specimen was positive; or (3) caseating granuloma was noted in the peritoneal biopsy specimen. PC was diagnosed if cancer cells from ascites cytology were detected or cancer cells were documented from the peritoneoscopic biopsy specimen. This study protocol was approved by the Ethics Committee at Seoul National University Hospital.

Peritoneoscopy

Patients underwent peritoneoscopy under local anesthesia with systemic analgesics. A lidocaine injection was done from skin to fascia at about 1 cm left side from umbilicus. After local anesthesia, a Veress needle was inserted, and then air insufflation was performed through the needle. After removal of the Veress needle, a trochar was inserted into peritoneum and peritoneoscope (Olympus; Tokyo, Japan) was inserted through the trochar into the peritoneum. After ascites fluid was drained for examination, a detailed observation of the peritoneum and intra-abdominal organs was performed. Experienced endoscopists performed all peritoneoscopic procedures and observation. Pictures of all important peritoneoscopic findings were taken and stored in a picture archiving and communication system. Two endoscopists (Kang SJ, Kim JW) reviewed the peritoneoscopic images to assess the nature of the ascites fluid and look for abnormalities such as nodules, patches, and adhesions. Nodules were classified according to size as $\leq$ 1 cm or > 1 cm. Patches were classified according to their location (parietal or visceral peritoneum). Membranous patches were defined as plaques.

Radiologic examination

All patients had abdominal CT scan examination. The following CT scanners were used in this study: Hi Speed/RP single channel CT scanner (GE Healthcare, Milwaukee, Wisconsin, United States) ($n = 14$), MX 8000 four-channel CT scanner (Marconi Medical Systems, Cleveland, Ohio, United States) ($n = 32$), LightSpeed eight-channel CT scanner (GE Healthcare) ($n = 12$), Sensation 16 16-channel CT scanner (Siemens Medical Solutions, Erlangen, Germany) ($n = 13$), and Brilliance 64 64-channel CT scanner (Philips Healthcare, Cleveland, Ohio, United States) ($n = 4$). Section thickness and reconstruction interval were both 7mm for the single channel CT scanner and 5mm for the four-channel and eight-channel CT scanners, for the 16- and 64-channel CT scanners, section thickness and reconstruction interval were 3mm and 2.5 mm, respectively. Scanning was performed from the dome of the diaphragm through the pubic symphysis. Contrast-enhanced CT scan was performed after injection of nonionic contrast material (iopromide, Ultravist 370; Bayer Healthcare, Germany).

All scans were obtained on a GE 9800 (General Electric, Milwaukee, Wisconsin, United States) or a Somatom DR3 (Siemens, Erlangen, Germany) scanner with a slice thickness of 10 mm at 10- to 13-mm intervals from the dome of the diaphragm to the pubic symphysis. Two radiologists (Baek JH, Kim SH) reviewed abdominal CT scans of patients and looked at ascites (presence of loculation), parietal involvement patterns (smooth thickening, irregular or nodular thickening, seeding nodules), mesenteric changes, mesenteric thickening, mesenteric nodules (micronodule, macronodule), omental thickness, omental changes (smudged, nodular, omental cake), and intestinal involvement.

Statistical analysis

Values for continuous variables were presented as mean ± SD or median with ranges and as the number of individuals (and the percentage in each group) for the cat-

Table 1 Demographics and clinical characteristics of the patients *n* (%)

All statistical significance tests were performed by Mann-Whitney *U*-test.

egorical variables. Nominal data were compared by using the Fisher exact test or Pearson χ^2 test, and continuous variables were compared by using the Student *t* test or Mann-Whitney *U*-test. A receiver-operating characteristic (ROC) curve was plotted and the area under the curve (AUC) was calculated to determine the predictive ability of different ascites ADA and tumor markers level cutoff values for differentiation. For all analyses, a *P* value of < 0.05 (two-tailed) was taken as statistically significant. All statistical analyses were performed with SPSS 15.0K for Windows (SPSS South Korea, Seoul, South Korea).

RESULTS

Clinical characteristics of patients

A total of 75 patients underwent abdominal CT scan and diagnostic peritoneoscopy. Of that population, 27 patients were diagnosed with TBP and 25 patients were diagnosed with PC according to the definition stated in the methods section. Other patients were diagnosed with various diseases such as pelvic inflammatory disease, continuous ambulatory peritoneal dialysis peritonitis, systemic lupus erythematosus (SLE), or peritoneal lymphomatosis. PC group included only adenocarcinomas from the various origins (6 pancreatic cancers, 4 ovary cancers, 5 malignancies of unknown origin, 4 colorectal cancers, 3 advanced gastric cancers and 3 other cancers). Clinical characteristics of patients are shown in Table 1. In the TBP group, there were 11 men (40.7%) and 16 women (59.3%), ranging from 28 to 83 years of age (mean ± SD = 58.04 ± 12.61 years). The PC group had more males (16 men and 9 women), but no significant difference in gender was found between the two groups (*P* = 0.09). There were 11 patients (40.7%) with duration of symptoms < 1 mo in the TBP group, while most patients in the PC group (*n* = 23, 92.0%) developed symptoms > 1 mo before they were diagnosed (*P* = 0.01). In the TBP group, 3 patients had night sweats, whereas no patients in the PC group complained of that symptom (*P* = 0.09). Fever

was the predominant manifestation in the TBP group (16, 59.3%), whereas no patient in the PC group developed fever (*P* < 0.01).

Laboratory findings and tumor markers in serum and ascites of patients

Results of blood and ascites laboratory tests including tumor markers are summarized in Table 2. Serum c-reactive protein (CRP) was significantly higher in the TBP group. Among ascites laboratory findings, TBP group showed severer lymphocytosis, lower serum ascites albumin gradient, and higher ascites ADA.

Tumor markers [cercinoembryonic antigen (CEA), CA 19-9, CA 125] in serum and ascites in both groups are also presented in Table 2 and theirs scatter plots are presented in Figure 1. In PC group, serum and ascites CEA and serum CA 19-9 were higher than TBP group. Serum and ascites CA 125 were elevated in both groups and showed no significant differences.

Radiological characteristics of patients

Ascites was found in the abdominal CT scan of all patients. The parietal involvement pattern was significantly different between the PC and TBP groups as shown in Table 3. In the TBP group, 21 patients (77.8%) showed smooth thickening of the parietal peritoneum, whereas smooth thickening was found in 10 patients (40.0%) in the PC group. Irregular and nodular parietal involvement was noted in 11 patients (44.0%) in the PC group whereas only 4 patients (14.8%) showed irregular or nodular involvement in the TBP group (*P* = 0.04). Thickening of mesentery was found in 15 (55.6%) and 8 (32.0%) patients in TBP and PC group, respectively (*P* = 0.09).

Figure 1 Scatter plots shows the distributions of tumor markers and adenosine deaminase in serum and ascites between peritoneal carcinomatosis group and tuberculous peritonitis group. All tests were performed by Mann-Whitney *U*-test. PC: Peritoneal carcinomatosis; TBP: Tuberculous peritonitis; ADA: Adenosine deaminase; CEA: Carcinoembryonic antigen; CA 19-9: Carbohydrate antigen 19-9; CA 125: Carbohydrate antigen 125.

Table 3 Abdominal computed tomography characteristics of the patients *n* (%)			
	Tuberculous peritonitis (*n* = 27)	Peritoneal carcinomatosis (*n* = 25)	*P* value
Ascites loculation	11 (40.7)	10 (40.0)	0.96
Parietal involvement			0.04
No	2 (7.4)	3 (12.0)	
Smooth thickening	21 (77.8)	10 (40.0)	
Irregular or nodular	4 (14.8)	11 (44.0)	
Seeding nodule	0 (0.0)	1 (4.0)	
Mesenteric change	23 (85.2)	17 (68.0)	0.14
Thickening of mesentery	15 (55.6)	8 (32.0)	0.09
Mesenteric nodule			0.31
No	15 (55.6)	12 (48.0)	
Micronodule	12 (44.4)	10 (40.0)	
Macronodule	0 (0.0)	2 (8.0)	
Omental thickness (mm)	20.48 ± 11.03	23.00 ± 15.77	0.51
Omental change			0.56
No	2 (7.4)	2 (8.0)	
Smudged	8 (29.6)	4 (16.0)	
Nodular	3 (11.1)	2 (8.0)	
Omental cake	13 (48.1)	17 (68.0)	
Intestinal involvement	3 (11.1)	5 (20.0)	0.53

In the TBP group, mesenteric nodularities were seen in 12 patients (44.4%) and all nodules were micronodules. Twelve patients (48.0%) in the PC group showed mesenteric nodules, which were composed of 10 micronodules and 2 macronodules. There was no discriminative difference in omental thickness and patterns of change between the two groups.

Peritoneoscopic findings of patients

Peritoneoscopic images were reviewed by 2 experienced endoscopists (Kang SJ and Kim JW), and findings are summarized in Table 4. Twenty patients (74.1%) in the TBP group were found to have micronodules on the peritoneum (example of micronodule was shown in Figure 2A), and this number was greater than the number of TBP patients found to have micronodules on CT scan. Macronodules were not observed in TBP group. In the PC group, micronodules were detected in 8 patients, and macronodules were observed in 9 patients (*P* = 0.01). The distribution of whitish patches and presence of plaques were not significantly different (*P* = 0.41) between the two groups (example of patch lesion in Figure 2B). Adhesions between the peritoneum and abdominal organs were seen in 14 patients in the TBP group and 10 patients in the PC group (*P* = 0.41).

Laboratory parameters for differentiation between TBP and PC groups

Among the evaluated laboratory parameters, parameters that showed significant difference between two groups were serum CRP, CEA, CA 19-9 and ascites ADA, CEA. AUC was calculated using ROC curves and these results

Table 4 Peritoneoscopic findings of the patients *n* (%)

	Tuberculous peritonitis (*n* = 27)	Peritoneal carcinomatosis (*n* = 25)	*P* value
Nodules on peritoneum			< 0.01
No	7 (25.9)	7 (28.0)

Whitish plaques	4 (14.8)	3 (12.0)	
Adhesion	14 (51.9)	10 (40.0)	0.41

Table 5 Discriminative capability of tumor markers and adenosine deaminase between tuberculosis peritonitis and peritoneal carcinomatosis using receiver operating characteristics curve

	AUC	95% CI	*P* value
Serum CRP	0.705	0.537-0.872	0.033
Serum CEA	0.721	0.562-0.880	0.017
Serum CA 19-9	0.693	0.527-0.860	0.044
Ascites ADA	0.966	0.916-1.000	< 0.001
Ascites CEA	0.823	0.686-0.960	0.002

ADA: Adenosine deaminase; CI: Confidence interval; CRP: C-reactive protein; CEA: Carcinoembryonic antigen; CA 19-9: Carbohydrate antigen 19-9; AUC: Area under the curve.

Figure 3 **Receiver operating characteristic curve of ascites adenosine deaminase for differentiating between tuberculous peritonitis and peritoneal carcinomatosis.** AUC of this receiver operating characteristic curve is 0.97 (95% CI: 0.92-1.00, *P* < 0.01). CI: Confidence interval; AUC: Area under the curve.

Figure 2 **Peritoneoscopic pictures of tuberculous peritonitis and peritoneal carcinomatosis.** A: Peritoneoscopic picture of tuberculous peritonitis of female patient. Multitudinous miliary nodules are seen on the parietal peritoneum. Biopsy revealed caseous granulomatous inflammation and the biopsy specimen stained positive for acid-fast bacilli; B: Colon cancer with peritoneal seeding. Multiple irregular whitish patch lesions were found on the parietal peritoneum. Poorly differentiated adenocarcinoma was documented on biopsy.

were presented in Table 5. Among these markers, ascites ADA level was the strongest factor that differentiated TBP and PC patients. The ability to consider ascites ADA levels as a biomarker for differentiating TBP and PC patients was evaluated using ROC curve analysis. The AUC for TBP was 0.966 [95% confidence interval (CI): 0.916-1.00; *P* < 0.01] (Figure 3). The sensitivity, specificity and positive and negative predictive values of ascites ADA were 92.0%, 94.4%, 95.8% and 89.5% at cut-off

level of 21.0 IU/L and 88.0%, 94.4%, 95.7% and 85.0% at 32.0 IU/L. When compared to cut-off level of 32.0, cut-off level of 21.0 shows higher sensitivity and negative predictive value and same specificity and positive predictive value.

DISCUSSION

TBP and PC are two of the most common causes of exudative ascites[1]. Differentiating between the two disease entities is difficult, and laparoscopy is thought to be the gold standard for diagnosis. Laparoscopy with biopsy has shown impressive sensitivity and specificity rates of 93% and 98% respectively[7]. Yet even with laparoscopy, some patients cannot be diagnosed, because the biopsy findings can be insufficient for diagnosis. Furthermore, some patients cannot be evaluated by laparoscopy because of their poor general condition or technical failure. In those cases, clinical and laboratory findings can be helpful for differentiating between TBP and PC. This study demonstrates that ascites ADA is valuable laboratory finding in differentiating between TBP and PC. To the best of our knowledge, this is the first comprehensive series to date that compares tumor markers, abdominal CT scan, and

laparoscopic findings between tuberculous peritonitis and PC patients.

It is well known that ascites ADA has high sensitivity and specificity in the early diagnosis of TBP[8-10]. When used for diagnosing exudative ascites, at the cut-off level of 30 IU/L, ADA has demonstrated sensitivity of approximatley 94%[4]. One study about pediatric patients report 100% sensitivity and 97% specificity for diagnosis of TBP[11]. Of interest, in our study ADA also had the high diagnostic value in differentiating tuberculosis peritonitis and PC and showed highest differentiating value (largest AUC) at the cut-off level of 21 IU/L. This suggests that when two diseases, TBP and PC, are strongly suspected from clinical, laboratory and radiological findings, and other diseases causing exudative ascites are reliably excluded, an ADA cut-off level of 21 IU/L that is lower than the usual cut-off level used for diagnosis could be used for discrimination. But this study only includes 27 TBP patients and 25 PC patients, about the precise cut-off level of ascites ADA for discrimination of two diseases, further verification with large numbers of patients are required.

Ascites ADA is accurate but insensitive for detecting TBP in liver cirrhosis patients living in the United States where the prevalence of tuberculosis is low. In the United States, which has a low tuberculous burden, 59% of TBP patients have liver cirrhosis[12]. This means that in developed country where tuberculosis burden is low, TBP is mainly developed in immune compromised patients such as liver cirrhosis. In South Korea, the tuberculous burden is intermediate, so in our study only 14.8% (4 out of 27) of TBP patients had liver cirrhosis[13]. Low portion of cirrhotic patients partly explains high ascites ADA performance. Furthermore, 75% of TBP patients with liver cirrhosis (3 out of 4 patients) had a higher ascites ADA level than normal. So even cirrhotic patients, ascites of TBP patients shows high ADA. This also explains the sensitivity of ascites ADA for diagnosing TBP in our study.

Increased serum and ascites CA -125 levels, detected in up to 80% of women with late-stage ovarian cancer, have demonstrated great value in treatment monitoring and recurrence detection of ovary cancer[14-16]. In TBP, serum CA 125 levels are as high as ovarian cancer associated with peritoneal infiltration, and, by the end of the fourth month of anti-tuberculous therapy in a patient with TBP, serum CA 125 levels have returned to normal[17-19]. Similar to previous reports, this study demonstrated that both TBP and PC patients have elevated serum and ascites CA 125 levels[20-22]. As a results, ascites and serum CA 125 are cautiously interpreted in differentiating between TBP and PC.

Radiological findings of TBP are similar to PC. With a model of multivariate logistic analysis using mesenteric macronodules, omental lining, irregularity of omentum, and splenic abnormalities, the sensitivity for predicting tuberculous peritonitis was 69%, whereas the sensitivity for PC was 91%[23]. In our study, only the parietal involvement pattern was significantly different between the TBP and PC groups. A thickened mesentery and loss of normal mesenteric configuration are known to be characteristics of TBP and helpful for diagnosis, but our results did not show these findings to be helpful in differentiating between two disease[24]. When parietal involvement patterns were used as marker for differentiation, the sensitivity and specificity for diagnosing TBP in this study were 60.5% and 75.0%, respectively. This characteristics is insufficient as a marker for differentiation of diseases but can be used in adjunct to other examinations.

Peritoneoscopy is the diagnostic tool of choice in patients with exudative ascites of unknown origin[2,4]. Peritoneal tubercles and ascites are the main features of TBP and appear in more than 90% of TBP cases[25-27]. In our study, micronodules on the peritoneum and ascites were seen in 20 of 27 patients (74.1%). The low micronodule detection rate compared to previous studies may be due to the discovery of patch and plaque lesions in 6 patients (2 patch lesions and 4 plaque lesion, 22.2%) of the TBP group during peritoneoscopy, because nearly all suspicious patch lesions were biopsied whenever possible. For diagnosis of PC, peritoneoscopy has higher sensitivity and specificity than helical CT scan with 5-mm slice thickness, and similar results were found in this study[28]. The diagnostic failure rate of peritoneoscopy is substantially high, however, reaching about 14%; the main reason for diagnostic failure is interference from adhesions from previous surgery or tumor adhesion[7].

Interpretation of our findings requires careful consideration of several aspects. First, the positive and negative predictive values are usually affected by pretest probability, so those values of the ascites ADA in this study may be variable in countries of low tuberculosis prevalence. Second, PC group is composed of various cancers. So discriminative ability of each tumor markers such as CEA for specific cancer could not fully tested in this study, so larger numbers of patients are needed to assess the predicting ability of each ascites tumor marker for each type of cancer.

In conclusion, clinical findings such as duration of symptom less than 1 mo and fever are helpful for differentiating TBP and PC of various causes. Among laboratory findings, ascites ADA was the most valuable discriminative marker. For differentiation of two diseases, in addition to clinical findings and radiologic characteristics, ascites ADA should also be considered.

COMMENTS

Background
Tuberculous peritonitis (TBP) and peritoneal carcinomatosis (PC) are two of the most common causes of exudative ascites but in a clinical situation, etiological diagnosis of the two diseases is very difficult. Peritoneoscopy with biopsy is thought to be the method of choice in the differential diagnosis of the two diseases but the morbidity related with peritoneoscopic procedure and diagnostic failure rate reaches as high as approximately 8% and 14%, respectively. So we investigate the diagnostic capacities of adenosines deaminase (ADA) and tumor markers for differentiating the two diseases.

Research frontiers
Diagnostic abilities of serum ADA and tumor markers in differentiating two

diseases are hotspots in recent studies. Serum c-reactive protein, serum cercinoembryonic antigen (CEA), serum CA 19-9, ascites ADA and ascites CEA were significantly different between two disease groups. Among them, ascites ADA showed largest area under the curves (AUC) in receiver operating characteristic curves (AUC = 0.966; 95% confidence interval: 0.916-1.00; $P < 0.01$). In addition to ascites ADA, clinical findings such as symptom duration less than 1 mo and fever was more frequent finding in tuberculosis peritonitis. In abdomen computed tomography findings, smooth thickening was the most common in TBP whereas in PC group nodular pattern was the most common finding.

Innovations and breakthroughs
This study showed that among laboratory findings, ascites ADA was the most valuable marker for discriminating TBP and PC.

Applications
This analysis for the diagnostic capabilities of ADA implicates that ascites ADA may be helpful for differentiation of two diseases.

Peer review
It is a very nice paper with an excellent statistic work and very interesting findings.

Abstract

AIM: To explore epigenetic changes in the gene encoding X chromosome-linked inhibitor of apoptosis-associated factor 1 (XAF1) during esophageal carcinogenesis.

METHODS: Methylation status of XAF1 was detected by methylation-specific polymerase chain reaction (MSP) in four esophageal cancer cell lines (KYSE30, KYSE70, BIC1 and partially methylated in TE3 cell lines), nine cases of normal mucosa, 72 cases of primary esophageal cancer and matched adjacent tissue. XAF1 expression was examined by semi-quantitative reverse transcriptional polymerase chain reaction and Western blotting before and after treatment with 5-aza-deoxycytidine (5-aza-dc)**,** a demethylating agent. To investigate the correlation of XAF1 expression and methylation status in primary esophageal cancer, immunohistochemistry for XAF1 expression was performed in 32 cases of esophageal cancer and matched adjacent tissue. The association of methylation status and clinicopathological data was analyzed by logistic regression.

RESULTS: MSP results were as follows: loss of XAF1 expression was found in three of four esophageal cell lines with promoter region hypermethylation (completely methylated in KYSE30, KYSE70 and BIC1 cell lines and partially in TE3 cells); all nine cases of normal esophageal mucosa were unmethylated; and 54/72 (75.00%) samples from patients with esophageal cancer were methylated, and 25/72 (34.70%) matched adjacent tissues were methylated (75.00% *vs* 34.70%, χ^2 = 23.5840, *P* = 0.000). mRNA level of XAF1 measured with semi-quantitative reverse transcription polymerase chain reaction was detectable only in TE3 cells, and no expression was detected in KYSE30, KYSE70 or BIC1 cells. Protein expression was not observed in KYSE30 cells by Western blotting before treatment with 5-aza-dc. After treatment, mRNA level of XAF1 was detectable in KYSE30, KYSE70 and BIC1 cells. Protein expression was detected in KYSE30 after treatment with 5-aza-dc. Immunohistochemistry was performed on 32 cases of esophageal cancer and adjacent tissue, and demonstrated XAF1 in the nucleus and cytoplasm. XAF1 staining was found in 20/32 samples of adjacent normal tissue but was present in only 8/32 samples of esophageal cancer tissue (χ^2 = 9.143, *P* = 0.002). XAF1 expression was decreased in cancer samples compared with adjacent tissues. In 32 cases of esophageal cancer, 24/32 samples were methylated, and 8/32 esophageal cancer tissues were unmethylated. XAF1 staining was found in 6/8 samples of unmethylated esophageal cancer and 2/24 samples of methylated esophageal cancer tissue. XAF1 staining was inversely correlated with XAF1 promoter region methylation (Fisher's exact test, *P* = 0.004). Regarding methylation status and clinicopathological data, no significant differences were found in sex, age, tumor size, tumor stage, or metastasis with respect to methylation of XAF1 for the 72 tissue samples from patients with esophageal cancer.

CONCLUSION: XAF1 is frequently methylated in esophageal cancer, and XAF1 expression is regulated by promoter region hypermethylation.

INTRODUCTION

Esophageal cancer is the eighth most common cancer worldwide. The incidence of esophageal cancer has increased rapidly in the past 20 years, and about 380 000 patients die each year from the disease[1-3]. Esophageal squamous cell carcinoma (ESCC) is the main type of esophageal cancer. It is highly invasive, rapidly metastatic, and results in a poor postoperative quality of life[4,5]. The mechanisms contributing to ESCC carcinogenesis are poorly understood. Recent studies have shown that aberrant promoter DNA methylation contributes to gene silencing and may participate in the carcinogenesis of human cancer. In-depth investigation of the relationship between DNA methylation and gene expression in ESCC will facilitate research in tumor pathogenesis and guide clinical practice.

Inhibitors of apoptosis (IAPs) are antiapoptotic factors in cancer cells that render cells resistant to apoptosis by inhibition of core death executioners, the caspases, or by neutralizing antagonists[6]. In the IAP family, X chromosome-linked IAP (XIAP) has been recognized as the most versatile caspase inhibitor[7,8]. In many models of cancer, XIAP is overexpressed[9]. XIAP-associated factor 1 (XAF1) is one of the antagonists that has been identified as a mediator of XIAP by rescuing XIAP-suppressed caspase activity[10]. XAF1 is also a new candidate tumor suppressor. Recent studies have suggested that loss of XAF1 expression may occur in different human cancers because of aberrant DNA methylation[11-17]. Zou *et al*[15] found that loss of XAF1 expression is associated with tumor progression in human gastric and colon cancers. Lee *et al*[14] also discovered that downregulation of XAF1 expression is correlated with human urogenital malignancies. However, the relationship between the expression level of XAF1 and the methylation status of XAF1 in esophageal cancer has not been demonstrated.

In this study, we investigated whether promoter region methylation was associated with the progression of esophageal cancer and analyzed the relationship between XAF1 expression and promoter region methylation. We identified XAF1 as a potential esophageal cancer biomarker for prognosis and a target for future therapeutic agents. Detection of the methylation status of XAF1 appears to be promising as a predictive factor in primary ESCC.

MATERIALS AND METHODS

Human tissue samples and cell lines

Tissue samples taken from 72 cases of ESCC and 72 matched adjacent normal tissues were used in this study. Nine cases of normal esophageal epithelia were removed during endoscopy biopsy and then snap frozen. All samples were collected from the Chinese PLA General Hospital under the guidelines approved by the Institutional Review Board of the Chinese PLA General Hospital.

Four esophageal cancer cell lines (KYSE30, KYSE70, BIC1 and TE3) were examined in this study. All esophageal cancer cell lines were previously established from primary esophageal cancer and were maintained in 90% RPMI 1640 (Invitrogen, Carlsbad, CA, United States) supplemented with 10% fetal bovine serum. Cells were passaged once at a ratio of 1:3. Cells were then allowed to grow to total confluence (about 10^6 cells) on a 75-cm^2 culture flask (NEST Biotechnology, Jiangsu, China).

Esophageal cancer cell lines were split to low density (30% confluence) 12 h before treatment. Cells were treated with 2 mol/L 5-aza-2'-deoxycytidine (5-aza-dc) (Sigma, St. Louis, MO, United States), a demethylating agent, which was added fresh every 24 h for a total of 96 h. At the end of the treatment, RNA and protein were extracted from the cells (see below).

RNA isolation and reverse transcriptional polymerase chain reaction

Total RNA was isolated with the Trizol reagent (Life Technologies, Gaithersburg, MD, United States). Agarose gel (1%) electrophoresis and spectrophotometric analysis ($A_{260 nm}/A_{280 nm}$ ratio) were used to evaluate RNA quality and quantity. RNA was stored at -80 ℃ prior to use. First-strand cDNA was synthesized from 5 μg total RNA with random 6-mer primers and a Superscript Ⅱ reverse transcriptional kit (Invitrogen). The reaction mixture was then diluted to 100 μL with water. Subsequently, 2.5 μL of this diluted cDNA mixture was used for polymerase chain reaction (PCR) amplification in a 25 μL reaction (final volume). PCR amplification of XAF1 was carried out using primers 5'-GAGCATGCAGAAGTCCTCGCT-3' (forward) and 5'-CCTGTTCACTGCGACAGACATCT-3' (reverse). The primer set for XAF1 was designed to span intronic sequences between exons to exclude amplification of genomic DNA. A total of 32 cycles of amplification was performed for each reverse transcriptional polymerase chain reaction (RT-PCR) experiment. As an internal control, glyceraldehyde-3-phosphate dehydrogenase was amplified with 25 cycles to ensure cDNA quality and quantity for each RT-PCR reaction. Amplified products were analyzed on 1.5% agarose gels.

Figure 1 X chromosome-linked inhibitor of apoptosis-associated factor 1 expression was silenced by DNA methylation. A: X chromosome-linked inhibitor of apoptosis-associated factor 1 (XAF1) expression was analyzed by semi-quantitative reverse transcriptional polymerase chain reaction before and after 5-aza-dc treatment (2 mol/L, 96 h) of the esophageal cancer cell lines (KYSE30, KYSE70, BIC1 and TE3). Methylation status of XAF1 CpG islands in esophageal cancer cell lines, esophageal normal mucosa, esophageal cancer tissue, and matched adjacent normal tissue. Primer efficiency was verified with a positive control (*in vitro* methylated DNA, IVD) and a negative control (normal blood lymphocyte DNA, NL). "U" indicates the presence of unmethylated alleles; "M" indicates the presence of methylated alleles; B1: Methylation of XAF1 in esophageal cancer cell lines (KYSE30, KYSE70, BIC1 and TE3); B2: Methylation of XAF1 in normal esophageal mucosa (NE1, NE2, NE3, NE4 and NE5); B3: Representative methylation-specific polymerase chain reaction (MSP) results for XAF1 in esophageal primary cancer tissue samples (EC); B4: Representative MSP results for XAF1 in esophageal matched adjacent normal tissue (EA). GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

Methylation-specific PCR

Genomic DNA from all types of samples was prepared using the proteinase K method. After phenol/chloroform extraction, DNA was precipitated in ethanol, dissolved in low TE buffer, and stored at -20 ℃. Genomic DNA from esophageal cancer, adjacent tissues, and cell lines was bisulfite modified as described before[18]. Methylation-specific PCR (MSP) was carried out using primers XAF1-ML: 5'-TTTGTAAGAAACGAAATTTAATCGA-3' and XAF1-MR: 5'-CCTACCCTTAAAACCCACGAT-3' and XAF1-UL: 5'-TTTGTAAGAAATGAAATTTAATT-GA-3' and XAF1-UR: 5'-CTCCTACCCTTAAAACCCA-CAAT-3'[10]. Each MSP reaction included about 200 ng bisulfite-treated DNA, 25 pmol each primer, 100 pmol dNTPs, 2.5 μL 10 × PCR buffer, and 1 U Taq Polymerase (Invitrogen) in a final reaction volume of 25 μL. Cycle conditions were as follows: 95 ℃ for 10 min; 35 cycles of 94 ℃ for 30 s, 57 ℃ for 30 s, and 72 ℃ for 30 s; and 72 ℃ for 10 min. MSP products were analyzed using 2% agarose gel electrophoresis.

Immunohistochemistry

Immunohistochemistry was performed on 4-μm-thick serial sections cut from paraffin blocks containing formaldehyde-fixed esophageal cancer tissue and paired adjacent tissue. After deparaffinization and rehydration, endogenous peroxidase activity was blocked for 30 min in methanol containing 0.3% hydrogen peroxide. Antigen retrieval was performed in target retrieval solution for 45 min at 96 ℃, which was followed by a cooling-off period of 20 min. The primary rabbit antibody (anti-XAF1, 1:200; OriGene Technologies, MD, United States) was then incubated overnight at 4 ℃. Then, the catalyzed sig-

nal amplification system (ZSGB Biotech., Beijing, China) was used to detect XAF1 staining.

Protein preparation and Western blotting

KYSE30 cells were treated with 5-aza-dc (as described above), harvested, and lysed in ice-cold Tris buffer (20 mmol/L Tris, pH 7.5) containing 137 mmol/L NaCl, 2 mmol/L ethylene diamine tetraacetic acid, 1% Triton X-100, 10% glycerol, 50 mmol/L NaF, 1 mmol/L dithio-threitol, and a protease inhibitor cocktail (Roche Applied Science). Cell lysate (35 μg) was loaded into each lane, separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis, and electroblotted onto PVDF membranes (Hybond-P; Amersham, United States). After being blocked with 5% nonfat milk and 0.1% Tween-20 in TBS, the membranes were incubated with primary rabbit anti-XAF1 (1:1000; OriGene Technologies). Rabbit anti-actin (Beyotime Biotech., China) was used as a loading control. The blots were visualized using enhanced chemilumines-cence (Pierce Bioscience, Rockford, IL, United States).

Statistical analysis

Statistical analysis was carried out using the χ^2 test and Fisher's exact test. The relationship between methylation status and clinicopathological data was carried out using multiple logistic regression. $P < 0.05$ was considered statistically significant.

RESULTS

XAF1 promoter methylation status in esophageal cancer

To ascertain whether the XAF1 promoter methylation status was associated with esophageal carcinogenesis,

KYSE30-   KYSE30+

XAF1

β-actin

Figure 2 Western blotting analysis of X chromosome-linked inhibitor of apoptosis-associated factor 1 protein expression in the KYSE30 cell line before and after treatment with 2 mol/L 5-aza-deoxycytidine (+) for 96 h. XAF1: X chromosome-linked inhibitor of apoptosis-associated factor 1.

MSP was performed on nine cases of normal esophageal mucosa, 72 samples taken from patients with esophageal cancer, and 72 paired adjacent normal tissue samples. All nine cases of normal esophageal mucosa were unmethylated; 54 of 72 (75%) samples taken from patients with esophageal cancer were methylated; and 25 of 72 (34.7%) matched adjacent normal tissues were methylated (χ^2 = 23.5840, P = 0.000; Figure 1B). These results suggest that methylation of the XAF1 promoter region is a potential early detection marker of esophageal cancer.

XAF1 promoter methylation and XAF1 expression in esophageal cancer cell lines

To determine whether XAF1 is a tumor suppressor in esophageal cancer tumorigenesis, XAF1 expression levels were detected with semi-quantitative RT-PCR and Western blotting. The mRNA level of XAF1 was detectable only in the TE3 cell line, and no expression was detected in the KYSE30, KYSE70 or BIC1 cell lines (Figure 1A). Protein expression was not observed in the KYSE30 cell line before treatment with 5-aza-dc (Figure 2). To examine if these findings were due to promoter region methylation of XAF1, the methylation status of XAF1 was analyzed in these cells lines with MSP. XAF1 was completely methylated in the KYSE30, KYSE70 and BIC1 cell lines and partially methylated in TE3 cells (Figure 1B).

To demonstrate further whether XAF1 expression was restored with promoter region methylation, these cell lines were treated with 5-aza-dc. As shown in Figure 1, XAF1 was expressed in KYSE30, KYSE70 and BIC1 cells after 5-aza-dc treatment, and we detected protein expression in KYSE30 after treatment with 5-aza-dc (Figure 2), suggesting that XAF1 expression was regulated by promoter region methylation in esophageal cancer.

Correlation of XAF1 expression and methylation status in esophageal cancer tissue

To explore the expression of XAF1, immunohistochemistry was performed on 32 cases of esophageal cancer and adjacent tissue paraffin samples. XAF1 expression was found in the nucleus and cytoplasm as previously reported[19,20]. XAF1 staining was found in 50% (16/32) of adjacent tissue samples and only in 25% (8/32) of cancer tissue samples (χ^2 = 9.143, P = 0.002). Reduced expression of XAF1 was found in cancer tissues as compared

with the adjacent tissue samples (Figure 3).

We then analyzed the relationship between the methylation status and expression of XAF1 in 32 esophageal cancer samples. Twenty-four esophageal cancer samples (24/32, 75.00%) were methylated, and eight esophageal cancer tissue (8/32, 25.00%) were unmethylated. XAF1 staining was found in six samples (6/8, 75.00%) of unmethylated esophageal cancer tissue and two samples (2/24, 8.33%) of methylated esophageal cancer tissue. XAF1 staining was inversely correlated with XAF1 promoter region methylation (Fisher's exact test, P = 0.004).

Correlation of XAF1 methylation status with clinicopathological factors

Regarding methylation status and clinicopathological data, we found no significant differences in sex, age, tumor size, tumor stage, or metastasis with respect to the methylation status of XAF1 for the 72 primary esophageal cancer patients (Table 1).

DISCUSSION

The development of cancer is influenced by many factors and many genes and progresses through many stages[21]. In some ways, cancer is considered an epigenetic disease as well as a genetic disease. Epigenetics is the inheritance of information based on gene expression levels, whereas genetics refers to information transmitted according to the gene sequence. Epigenetic changes may lead to chromosomal instability, activation of parasitic endogenous sequences, loss of imprinting, illegitimate expression, aneuploidy, and mutations, and it may contribute to the transcriptional silencing of tumor suppressor genes[22]. In the human genome, CpG dinucleotides are inconsonantly distributed, resulting in CpG-rich regions[23]. The main epigenetic modification is aberrant CpG island methylation, which is tissue-specific but not species-specific. Methylation affects many pathways in cellular networks, such as the cell cycle and apoptosis[22].

In life and death decisions at the cellular level, there is a balance between pro- and antiapoptotic factors, and a variety of pathological conditions such as cancer and autoimmune and neurodegenerative diseases can result from disruption of this balance[6]. Apoptosis is crucial for eliminating defective or potentially dangerous cells and provides a defense against malignant transformation and autoimmunity[11]. IAPs are a new family of intrinsic cell death proteins that work as endogenous caspase inhibitors and participate in cell cycle regulation and modulation of receptor-mediated signal transduction. A recent study has reported that the level of XIAP mRNA is relatively high in many human cancers, suggesting that XIAP is one of the most potent and versatile inhibitors of caspases and apoptosis[15].

XAF1 has been previously identified as a binding partner of XIAP. In contrast to Smac/DIABLO and HtrA2, which promote caspase activation, XAF1 reverses XIAP-mediated inhibition of caspase-3 activity. Furthermore, XAF1 induces cell cycle arrest during G2/M phase and

Figure 3 Immunohistochemistry analysis of X chromosome-linked inhibitor of apoptosis-associated factor 1 in esophageal cancer tissue and adjacent tissue. Esophageal cancer and adjacent normal tissue samples were immunohistologically analyzed with anti-X chromosome-linked inhibitor of apoptosis-associated factor 1 (XAF1) (1:200 dilution; × 400). A: XAF1 was not detected in esophageal cancer tissue; B: XAF1 was localized in the nucleus and cytoplasm in adjacent normal esophageal tissue.

mitotic catastrophe, and the restoration of XAF1 expression induces cancer cell apoptosis and inhibits tumor growth in many types of human cancers[24]. XAF1 is ubiquitously expressed in all normal adult and fetal tissues but is drastically decreased in many cancer cell lines[11]. Loss of XAF1 expression is associated with methylation in its promoter region in many cancers. For example, XAF1 is present at very low or undetectable levels in gastric cancer, colorectal cancer[15], and cervical carcinoma[25].

In this study, we found that XAF1 was frequently methylated in esophageal cancer. Moreover, expression of XAF1 was inversely correlated with its methylation status. XAF1 was methylated in three esophageal cancer cell lines and 54 samples of esophageal cancer tissue. XAF1 methylation resulted in loss of expression in esophageal cancer cell lines, and the expression of XAF1 was restored in KYSE30, KYSE70 and BIC1 cells after treatment with 5-aza-dc. Furthermore, we observed the expression of XAF1 in the methylated cell line KYSE30 after treatment with 5-aza-dc. The results indicated that promoter region methylation regulated the expression of XAF1. XAF1 was frequently methylated in esophageal cancer tissue (75%) but was methylated only in 34.7% of matched adjacent normal tissues and not at all in normal esophageal mucosa, indicating that promoter region methylation of XAF1 was likely to be related to

Table 1 Clinicopathological characteristics and XAF1 methylation status of 40 patients with esophageal cancer *n* (%)

Clinical parameter	*n*	XAF1 methylation status		*P* value
		Methylated *n* = 30 (75%)	Unmethylated *n* = 10 (25%)	(χ^2 test)
Age (yr)

Negative	45	33 (73.3)	12 (26.7)	0.6733
Positive	27	21 (77.8)	6 (22.2)	

In this 72 patients, only 32 cases with tumor stage history.

esophageal carcinogenesis. In addition, XAF1 protein expression was decreased in cancer tissues as compared with adjacent normal samples, and low expression of XAF1 was significantly correlated with promoter region methylation. XAF1 expression and promoter region methylation status have been reported to be useful for identifying poorly differentiated cancer or patients with a poor disease outcome[16,17,26].

XAF1 is frequently methylated in esophageal cancer, and XAF1 expression is regulated by promoter region methylation. The loss of XAF1 expression may play an important role in tumor growth, and methylation of XAF1 may serve as an early detection marker for esophageal cancer.

COMMENTS

Background

Esophageal cancer is the eighth most common cancer worldwide. The incidence of esophageal cancer has increased rapidly in the past 20 years. Esophageal squamous cell carcinoma (ESCC) is the main type of esophageal cancer. It is highly invasive, rapidly metastatic, and results in a poor postoperative quality of life. The mechanisms contributing to ESCC carcinogenesis are poorly understood. Recent studies showed that aberrant promoter DNA methylation contributes to gene silencing and may participate in the carcinogenesis of human cancer. X chromosome-linked inhibitor of apoptosis (XIAP)-associated factor 1 (XAF1) is a new candidate tumor suppressor gene. Recent studies have suggested that loss of XAF1 expression may occur in different human cancers because of aberrant DNA methylation. However, the relationship between the expression level of XAF1 and the methylation status of XAF1 in esophageal cancer has not been demonstrated.

Research frontiers

XAF1 is a new candidate tumor suppressor gene. Recent studies have suggested that loss of XAF1 expression may occur in human gastric cancer, colon cancer and urogenital malignancies because of aberrant DNA methylation. However, the relationship between expression level of XAF1 and methylation status of XAF1 in esophageal cancer has not been demonstrated. In this study, the authors demonstrated that expression level of XAF1 was inversely correlated with methylation status of XAF1, and XAF1 expression was regulated by

promoter region methylation.

Innovations and breakthroughs

Recent reports have highlighted that the loss of XAF1 expression or downregulation of XAF1 expression may occur in different human cancers because of aberrant DNA methylation. This is the first study to report that XAF1 is also loss of expression because of aberrant DNA methylation in esophageal cancer.

Applications

By understanding the relationship between loss of XAF1 expression and methylation status of XAF1 in esophageal cancer, and by inducing its expression with 5-aza-deoxycytidine, this study may represent a future strategy for therapeutic intervention in the treatment of patients with esophageal cancer.

Terminology

Inhibiters of apoptosis (IAPs) are antiapoptotic factors in cancer cells that render cells resistant to apoptosis by inhibition of core death executioners, the caspases, or by neutralizing antagonists. In the IAP family, XIAP has been recognized as the most versatile caspase inhibitor. In many models of cancer, XIAP is overexpressed. XAF1 is one of the antagonists that has been identified as a mediator of XIAP by rescuing XIAP-suppressed caspase activity. XAF1 is a new candidate tumor suppressor gene. Recent studies have suggested that loss of XAF1 expression may occur in different human cancers because of aberrant DNA methylation.

Peer review

The study is very interesting and throws light on future studies and confirms increased methylation of XAF1 in squamous cell carcinoma.

Abstract

AIM: To investigate whether DNA-dependent activator of interferon-regulatory factors (DAI) inhibits hepatitis B virus (HBV) replication and what the mechanism is.

METHODS: After the human hepatoma cell line Huh7 was cotransfected with DAI and HBV expressing plasmid, viral protein (HBV surface antigen and HBV e antigen) secretion was detected by enzyme-linked immunosorbent assay, and HBV RNA was analyzed by real-time polymerase chain reaction and Northern blotting, and viral DNA replicative intermediates were examined by Southern blotting. Interferon regulatory factor 3 (IRF3) phosphorylation and nuclear translocation were analyzed *via* Western blotting and immunofluorescence staining respectively. Nuclear factor-κB (NF-κB) activity induced by DAI was detected by immunofluorescence staining of P65 and dual luciferase reporter assay. Transwell co-culture experiment was performed in order to investigate whether the antiviral effects of DAI were dependent on the secreted cytokines.

RESULTS: Viral protein secretion was significantly reduced by 57% ($P < 0.05$), and the level of total HBV RNA was reduced by 67% ($P < 0.05$). The viral core particle-associated DNA was also dramatically downregulated in DAI-expressing Huh7 cells. Analysis of involved signaling pathways revealed that activation of NF-κB signaling was essential for DAI to elicit antiviral response in Huh7 cells. When the NF-κB signaling pathway was blocked by a NF-κB signaling suppressor (IκBα-SR), the anti-HBV activity of DAI was remarkably abrogated. The inhibitory effect of DAI was independent of IRF3 signaling and secreted cytokines.

CONCLUSION: This study demonstrates that DAI can inhibit HBV replication and the inhibitory effect is associated with activation of NF-κB but independent of IRF3 and secreted cytokines.

DNA-dependent activator of interferon-regulatory factors inhibits hepatitis B virus replication. *World J Gastroenterol* 2012; 18(22): 2850-2858 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i22/2850.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i22.2850

INTRODUCTION

Hepatitis B virus (HBV) is a noncytopathic DNA virus which belongs to the *Hepadnaviridae* family. Infection of HBV results in acute or chronic hepatitis, liver failure, and hepatocellular carcinoma[1-2]. HBV clearance is usually associated with a multispecific CD4[+] and CD8[+] T-cell response coordinated with an effective humoral immune component[3-5]. However, a growing body of evidence suggests that the innate immune response is important for limiting viral replication. Expression of key proteins in pattern recognition system, such as RNA sensor melanoma differentiation-associated gene-5, the caspase recruitment domain of retinoic acid inducible gene I and the adaptor protein, myeloid differentiation primary response protein 88 (MyD88), and interferon-β promoter stimulator 1 (IPS-1) can activate innate immune response and inhibit HBV replication in human hepatocyte-derived cells[6,7].

DNA-dependent activator of interferon-regulatory factor (DAI/DLM-1/ZBP1) is the first identified sensor of cytosolic dsDNA. Recent studies have demonstrated that DAI can initiate innate immune responses, including the induction of type I interferon (*IFN*) genes, independently of Toll-like receptor 9[8-10]. It was reported that herpes simplex virus 1 production was notably higher in DAI blocked L929 cells[10]. As DAI is highly expressed in the differentiated hepatocyte after interferon treatment[11], it is hypothesized that DAI could be a protein possessing antiviral activity against HBV in human hepatocytes.

The aim of the present study was to determine whether DAI can inhibit HBV replication and what the underlying molecular mechanism is. We found that expression of DAI could inhibit HBV gene expression and replication noncytopathically in Huh7 cells. Further study revealed that activation of nuclear factor-κB (NF-κB) signaling was essential for DAI to elicit antiviral responses, but this inhibitory effect is independent of cytokines' secretion.

MATERIALS AND METHODS

Cell culture and transfection

Huh7 and HEK 293T cells were obtained from American Type Culture Collection and cultured in Dulbecco's modified Eagle's medium (Gibco). For plasmid transfections, we used Fugene reagent (Roche), according to the manufacturer's protocol. The transfection efficiency was normalized by detecting the expression of green fluorescent protein (GFP) after transfection of equal amount of plasmid GFP.

Transwell plate (Cat. No. 3450) was purchased from Corning Company (New York, the United States). The transwell chamber contains 0.4 μm pore polyester membrane which is optimal for cell attachment and growth and is permeable for flow of liquids. The cytokines can transfer through the membrane freely while the cells are blocked.

Plasmids and chemicals

pCAGGS-hemagglutinin (HA)-DAI encoding the whole transcript of DAI was kindly provided by Professor Tadatsugu Taniguchi[9]. pHBV1.3 containing a 1.3-copy of the HBV genome was described previously. The plasmid pCMV-IκBα-SR expresses a repressor form of IκBα in which serines 32 and 36 were mutated to alanine[12]. The NF-κB-dependent luciferase reporter plasmid pNF-κB-Luc was obtained from Stratagene Corporation (La Jolla, CA, the United States). pIRF-3 and pIRF-3ΔN were provided by John Hiscott[13]. The cytokines IFN-α and tumor growth factor (TGF)-α were purchased from R and D Company (Lorton, VA, the United States).

Quantitative real-time polymerase chain reaction analysis of hepatitis B viral RNA

Total RNA was extracted directly using TRIzol reagent (Invitrogen), and reversely transcribed to cDNA using a complementary DNA (cDNA) synthesis kit (Fermentas) according to the manufacturer's instructions. The cDNA was mixed with SYBR Green polymerase chain reaction (PCR) Master Mix (Toyoba) and subjected to real-time PCR using the ABI PRISM 7500 (Applied Biosystems). Cellular glyceraldehyde 3-phosphate dehydrogenase (GAPDH) mRNA from the same cDNA was used as an internal control. The primers specific for HBV and GAPDH are available upon request. Forty cycles of PCR were performed with cycling conditions of 15 s at 95 ℃, 20 s at 55 ℃, 25 s at 72 ℃，and 35 s at 79 ℃ to detect signal.

Southern blotting analysis of viral DNA replicative intermediates

HBV DNA replicative intermediates in HBV core particles isolated from transfected Huh7 cells were analyzed using Southern blotting. The intracellular viral DNA was extracted as previously reported[14].

The normalized viral DNA replicative intermediates were electrophoresed onto 1% agarose gel. Then DNA was blotted onto a positive nylon membrane (Roche) in 20 × SSC. After fixing at 120 ℃ for 30 min, the membrane was prehybridized for 1 h at 42 ℃ in ULTRAhyb hybridization solution, and then hybridized with full-length HBV DNA probes labeled with (α-^{32}P) deoxycytidine triphosphate (dCTP) by hexamer random labeling kit (Roche) under the same condition of prehybridization at 42 ℃ for 16 h. After stringent washing at 68 ℃, signals were detected by autoradiography.

Northern blotting analysis of total viral RNA

Total RNA was extracted directly from transfected cells using TRIzol reagent. Ten μg total cytoplasmic RNA was electrophoresed on 1% formaldehyde-agarose gel and then transferred to nylon membranes (Roche). Hybridization was undertaken as described above using (α-^{32}P) dCTP-labeled full-length HBV DNA probes. To normalize the total quantity of RNA loaded on each gel, blots

were stripped and rehybridized with $(\alpha\text{-}^{32}P)$ dCTP-labeled GAPDH probes.

Western blotting analysis

Cell lysates were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis and blotted electrophoretically onto a nitrocellulose membrane (Whatman). The membrane was blocked with phosphate-buffered saline (PBS) containing 5% skim milk and then incubated overnight with 1:1000 anti-HA (Roche), 1:2000 anti-GFP (Sigma), 1:1000 anti-phospho-IRF3 (Cell signaling), 1:1000 anti-IRF3 (Santa Cruz), 1:10000 anti-β actin antibody (Sigma), then washed three times in PBST (0.05% Tween 20 in PBS), and incubated with peroxidase conjugated secondary antibody (1:2000) for 1 h. After further washing with PBST, chemiluminescence detection was carried out using enhanced chemiluminescence detection reagents.

Enzyme-linked immunosorbent assay

The HBV surface antigen (HBsAg) and HBV e antigen (HBeAg) levels in the supernatants obtained from HBV transfected Huh7 cells were detected using a standard enzyme-linked immunosorbent assay (ELISA) (Sino-American Biotech). The assay was performed according to the manufacture's protocol. All experiments were performed at least three times.

Immunofluorescence staining

Huh7 cells were fixed with 3.5% paraformaldehyde for 10 min. The cells were permeabilized with 0.1% Triton X-100 for 5 min at room temperature and incubated in blocking buffer supplemented with 3% bovine serum albumin (Sigma) for 1 h at room temperature. Interferon regulatory factor 3 (IRF3) was detected by staining with rabbit anti-human IRF3 (1:200 dilution, Santa Cruz), followed by Cy3-coupled goat anti-rabbit IgG (1:500 dilution, Jackson Immunologicals). Flag-tagged IPS1 was detected by staining with mouse anti-Flag antibody (1:2000, Sigma), followed by Alexa488-coupled goat anti-mouse IgG (1:200, Jackson Immunologicals). P65 was detected by staining with diluted (1:100) rabbit anti-human P65 (cell signaling) and Cy3-coupled goat anti-rabbit IgG (1:500). The nuclei were counterstained with 10 μg/mL 4',6'-diamidino-2-phenylindole (DAPI) (Sigma). After incubation with the secondary antibodies, the cells were visualized under a confocal laser scanning microscope.

Dual-luciferase reporter assay

To measure report gene activation, 293T cells seeded into 24-well plates at density of 1×10^5 cells/well were transiently transfected with NF-κB dependent luciferase reporter plasmid 100 ng pNF-κB-Luc, 10 ng renilla luciferase-HSV thymidine kinase promoter (expressing Renilla luciferase, Promega) together with pCAGGS-HA-DAI or the empty vector pCAGGS-HA at the indicated amount. The cells were lysed and analyzed for firefly luciferase and renilla luciferase activity (Promega). The results were

reported as the normalized mean ± SD.

Statistical analysis

Results were reported as means ± SD. *T* tests were applied for comparisons between groups; and $P < 0.05$ was considered statistically significant.

RESULTS

DAI inhibits HBV replication in the human hepatoma Huh7 cells

To investigate the antiviral activity of DAI against HBV, we firstly examined the effect of DAI on the synthesis of HBV proteins. HBV-replicating plasmid HBV1.3 was co-transfected with either empty vector or HA-DAI into Huh7 cells. Supernatants were collected and HBsAg and HBeAg were analyzed by standard ELISA immunoassay. Compared with the control, the secretion of HBsAg was reduced by 17%, 33% and 57% and secretion of HBeAg was reduced by 25%, 34% and 57% when the increasing amount of DAI was transfected (Figure 1A). In order to study the inhibitory effect of DAI on HBV RNA transcription, the HBV RNA level was examined by quantitative real-time PCR. Results showed that HBV RNA level was also decreased by 44%, 51%, and 67% with an increased level of DAI expression. Expression of DAI in Huh7 cells was monitored by Western blotting (Figure 1B). To further investigate the effect of DAI on HBV viral RNA transcription, Northern blotting analysis was employed. As MyD88 has been reported as interferon inducible protein which can inhibit HBV replication[6,7], MyD88 and 1000 IU/mL IFN-α treatment were included as positive controls. As shown in Figure 1C, expression of DAI dramatically reduced HBV RNA level. To investigate the influence of DAI on HBV replication, Southern blotting was performed to analyze the viral DNA replicative intermediates which were extracted from core particles. As shown in Figure 1D, the HBV core particle-associated DNA was significantly reduced. These results suggested that viral genome replication, viral RNA transcription and viral protein expression were all downregulated by DAI.

To exclude the possibility that the reduction of HBV RNA and DNA in Huh7 cells was due to cell death induced by DAI, the growth of DAI-expressing Huh7 cells was examined by cell counting assay for 6 d. Results demonstrated that DAI did not obviously affect cell growth (Figure 1E). Taken together, DAI can inhibit HBV gene expression and replication noncytopathically in Huh7 cells.

IRF3 signaling pathway is not required for inhibition of HBV by DAI

The activation of innate immune system by DAI was through IRF3 or NF-κB mediated signaling pathways[10]. To investigate the possible effect of the pathways DAI on it, we firstly examined the activation of IRF3 after over-expression of DAI. IPS1, which can activate IRF-3 sig-

Figure 1 Expression of DNA-dependent activator of interferon-regulatory factors in Huh7 cells can suppress hepatitis B virus replication. A: ELISA analysis of HBV protein synthesis. GFP was transfected to monitor transfection efficiency; B: Real-time PCR analysis of HBV RNA. Huh7 cells were cotransfected with pHBV1.3 and different doses of hemagglutinin (HA)-DAI. Total RNA was extracted 48 h after transfection and HBV RNA was examined by real-time PCR; C: Northern blottings analysis of HBV RNA; Huh7 cells were cotransfected with pHBV1.3 and control DNA or MyD88 and HA-DAI. 1000 IU/mL IFN-α was added 12 h after transfection, and 48 h later, total RNA was extracted for Northern blotting hybridization. The positions of the HBV 3.5-, 2.4- and 2.1-kb RNA were indicated; D: Southern blotting analysis of HBV core particle associated DNA. Huh7 cells were treated as in C. HBV core particle associated DNA was analyzed 48 h later. Southern blotting was performed to detect HBV DNA as described. The positions of relaxed circular (RC), double stranded (DS) and single stranded (SS) DNAs were indicated; E: Effect of DAI on cell growth. Cell number was counted by adding cell counting kit-8 at 1, 2, 3, 4, 5, 6 d after transfection. DAI: DNA-dependent activator of interferon-regulatory factors; HBV: Hepatitis B virus; ELISA: Enzyme-linked immunosorbent assay; PCR: Polymerase chain reaction; IFN: Interferon; GFP: Green fluorescent protein; HBsAg: Hepatitis B virus surface antigen; HBeAg: Hepatitis B virus e antigen; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; MyD88: Myeloid differentiation primary response protein 88.

Figure 2 Interferon regulatory factor 3 signaling pathway is not required for inhibition of hepatitis B virus by DNA-dependent activator of interferon-regulatory factors. A: DAI did not induce IRF-3 phosphorylation. Control DNA, hemagglutinin (HA)-DAI or Flag-interferon-β promoter stimulator 1 (IPS1) was transfected into Huh7 cells. Forty-eight hours later, the phosphorylated form of IRF-3 was analyzed by Western blotting; B: Blockage of IRF-3 signaling did not affect inhibitory effect of DAI on HBV replication. Northern blotting assay was performed as shown in Figure 1C; C: Expression of DAI could not induce IRF-3 nuclear translocation. Cells were harvested 48 h after transfection and IRF-3 was stained as described. DAI: DNA-dependent activator of interferon-regulatory factors; IRF: Interferon regulatory factor; IRF-3ΔN: IRF-3 dominant negative plasmid; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; DAPI: 4',6'-diamidino-2-phenylindole; YFP: Yellow fluorescent protein.

naling pathway, was set as positive control[15]. The results showed that DAI cannot induce the phosphorylation of IRF-3 (Figure 2A). Furthermore, as shown in Figure 2C, nuclear translocation of IRF-3 was not observed after DAI expression. These results indicated that DAI cannot activate IRF-3. To further confirm that DAI-mediated inhibition of HBV replication is not associated with IRF-3,

an IRF-3 dominant negative plasmid (IRF-3ΔN), in which the DNA binding domain was removed to express the repressor form of IRF-3, was used[13]. Results suggested that when the IRF-3 pathway was blocked by IRF-3ΔN, the inhibitory effect of DAI on HBV replication was not affected (Figure 2B). Taken together, inhibition of HBV replication by DAI was not associated with acti-

Figure 3 Inhibition of hepatitis B virus by DNA-dependent activator of interferon-regulatory factors depends on activation of nuclear factor-κB. A: NF-κB activity was induced by dependent activator of interferon-regulatory factors (DAI). Forty-eight hours after transfection, NF-κB (p65) was stained as described. NF-κB dependent luciferase reporter plasmid pNF-κB-Luc was co-transfected with control DNA or different doses of hemagglutinin (HA)-DAI into 293T cells. Renilla luciferase-herpes simplex virus thymidine kinase promoter was transfected to monitor the transfection efficiency; B: Blockage of NF-κB activation abolished DAI-mediated suppression of hepatitis B virus (HBV) replication. Forty-eight hours after transfection, the levels of hepatitis B e antigen and hepatitis B surface antigen were examined by enzyme-linked immunosorbent assay. HBV RNA was determined by Northern blotting hybridization. NF-κB: Nuclear factor-κB; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; DAPI: 4',6'-diamidino-2-phenylindole; YFP: Yellow fluorescent protein.

vation of IRF3 pathway.

Inhibition of HBV replication by DAI depends on activation of NF-κB

In addition to IRF-3 signaling pathway, NF-κB is another key pathway induced by DAI to activate antiviral innate immunity. In most cells, NF-κB signaling pathway complexes are inactive, residing primarily in the cytoplasm in a complex with the inhibitory IκB proteins. Once activated, NF-κB is released from the IκBα and translocated

to nucleus, where it binds to specific κB sequences in the promoter or enhancer regions to induce the expression of multiple target genes[14,16]. To investigate if NF-κB was activated by DAI, we firstly examined the translocation of NF-κB p65. Yellow fluorescent protein-DAI and control DNA was transfected into Huh7 cells and TNF-α treatment was included as positive control. As expected, nuclear translocation of p65 was observed in both DAI-expressing and TNF-α-treated cells. Furthermore, a NF-κB-dependent luciferase reporter plasmid (pNF-κB-Luc)

Figure 4 Inhibiting hepatitis B virus replication by DNA-dependent activator of interferon-regulatory factors is an intracellular event. Transwell co-culture experiment was performed: Huh7 cells were seeded in both 6-well plates (below) and transwells (top). In transwell co-culture group, pHBV1.3 was transfected into the cells in 6-well plates while hemagglutinin (HA)-DNA-dependent activator of interferon-regulatory factors (DAI) was transfected into the cells in transwells. Twenty-four hours after the transfection, the cells in 6-well plates and transwells were co-cultured; in the direct cotransfection groups, pHBV1.3 and control DNA or HA-DAI were cotransfected into cells in 6-well plates; in interferon (IFN)-α treatment group, pHBV1.3 was transfected into the cells in 6-well plates, 1000 IU/mL IFN-α was added 12 h later. Seventy-two hours after transfection, all the cells were harvested and hepatitis B virus (HBV) RNA was determined by real-time polymerase chain reaction. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

was used to detect NF-κB activity after overexpression of DAI. Results showed that DAI increased the NF-κB-dependent luciferase activity in a dose dependent manner (Figure 3A), suggesting that DAI can induce the activation of NF-κB signaling pathway.

To further confirm that suppression of HBV replication by DAI was NF-κB-dependent, we used a NF-κB signaling suppressor IκBα-SR, in which Ser32 and Ser36 residues critical for phosphorylation are replaced by alanine[12]. As shown in Figure 3B, the inhibition of HBV RNA by DAI was reversed in the presence of IκBα-SR.

In conclusion，these data demonstrated that the activation of NF-κB signaling pathway played an indispensable role in DAI-mediated suppression of HBV replication.

Inhibition of HBV by DAI is independent of secreted cytokines

After NF-κB was activated, IFNs, chemokines and other pro-inflammatory cytokines could be induced, which might be directly involved in inhibiting viral infection[17]. To investigate whether the observed antiviral effects of DAI were dependent on the secreted cytokines, transwell co-culture experiments were conducted. The IFN-α treatment was set as positive control. We found that the

obvious inhibitory effects of DAI on HBV replication could be observed in the HBV and HA-DAI directly co-transfected cells, but not in transwell co-cultured Huh7 cells (Figure 4), indicating a secreted cytokine-independent mechanism of inhibiting HBV replication by DAI.

The above results suggested that the observed inhibition of HBV replication by DAI was most likely due to some inducible intracellular factor(s), rather than secreted cytokines.

DISCUSSION

After viral infection, innate immune receptors can detect the invading virus and subsequently initiate the synthesis of IFN and protective cellular genes to directly limit viral replication[18,19]. DAI is the first identified sensor of cytosolic dsDNA, which elicits innate immune responses and induces type I IFN to control viral replication. In this study, we found that DAI could inhibit HBV replication in Huh7 cells, and further study revealed that NF-κB signaling pathway was essential for this inhibition.

NF-κB signaling pathway plays pivotal roles in mediating inflammation, immune responses to pathogen infections, proliferation, apoptosis, and other cellular activities. The activation of NF-κB presents different results for different viruses. Some viruses activate NF-κB pathway to improve their transcription and replication[20]. Under other conditions, activation of NF-κB can repress viral replication. For example, NF-κB activation can mediate inhibition of human cytomegalovirus replication[21]. Rotavirus could antagonize cellular antiviral responses by inhibiting the nuclear accumulation of NF-κB[22]. As far as HBV is concerned, on one hand, viral replication itself can activate NF-κB, and on the other hand, upregulation of NF-κB by some host cytokines' stimulation has shown to be an inhibitory factor. For example, TNF-α could inhibit HBV replication by activating NF-κB signaling[23]. Besides, activation of NF-κB is also required for MyD88, IPS-1 and TRIF to elicit antiviral response to limit HBV replication[23]. In this study, we also found that DAI inhibited HBV replication *via* activating NF-κB signaling. Therefore, we speculated that the NF-κB signaling might be a common pathway for host to inhibit the replication of HBV and other DNA viruses.

The activation of NF-κB is associated with increased transcription of genes encoding chemokines, such as IL-8, MCP-1, cytokines such as IL-6, TNF-α, IFNs, adhesion molecules (intercellular adhesion molecule 1 and vascular cell adhesion molecule-1), enzymes that produce secondary inflammatory mediators and inhibitors of apoptosis[24-26]. These molecules are important components of the innate immune response to invading microorganisms. When further exploring the mechanisms responsible for suppression of viral replication after NF-κB activation, we speculated that cytokines, especially type I interferon, may be the direct effector to inhibit HBV replication. However, we did not detect the induction of IFN in DAI-

expressing cells. By transwell experiment, we found that the secreted cytokines were not required for the inhibition of HBV replication by DAI (Figure 4). Interestingly, some components of pattern-recognition receptor system, such as MyD88, IPS-1 and TRIF，could also control HBV replication in a cytokine independent manner[24]. It is possible that there is a common strategy to inhibit HBV by these functional proteins. In addition, the antiviral factor downstream of NF-κB induced by DAI is worthy to be further explored.

In summary, this study demonstrates that DAI is a cellular antiviral protein. When expressed in Huh7 cells, DAI activated NF-κB but not IRF-3 signaling to suppress HBV replication. This inhibitory effect is independent of secreted cytokines. The findings could potentially lead to the development of novel therapies that induce the host cytoplasmic antiviral protein to control HBV infections.

COMMENTS

Background
The hepatitis B virus (HBV) is a DNA virus that replicates its genome *via* an RNA intermediate using reverse transcription. Chronic infection with this virus can result in cirrhosis and hepatocellular carcinoma. Nowadays, more and more evidence suggests that the innate immune response is important for limiting viral replication. Pattern recognition receptors play a pivotal role in host innate immune responses against microbial infection. DNA-dependent activator of interferon-regulatory factor (DAI/DLM-1/ZBP1) is a potent activator of immune responses during infection or tissue damage.

Research frontiers
Expression of key proteins in pattern recognition system, such as RNA sensor melanoma differentiation-associated gene-5, the caspase recruitment domain of retinoic acid inducible gene Ⅰ and the adaptor protein, and myeloid differentiation primary response protein88 can activate innate immune response and inhibit HBV replication in human hepatocyte-derived cells. DAI is the first identified sensor of cytosolic dsDNA. Recent studies have demonstrated that DAI can initiate innate immune responses, including the induction of type Ⅰ interferon genes, independently of Toll-like receptor 9. The authors hypothesize that DAI could be a protein possessing antiviral activity against HBV replication.

Innovations and breakthroughs
The aim of the present study was to determine whether DAI can inhibit HBV replication and what the underlying molecular mechanism is. The authors found that expression of DAI could inhibit HBV gene expression and replication non-cytopathically in Huh7 cells. Further study revealed that activation of Nuclear factor-κB signaling was essential for DAI to elicit antiviral responses, but this inhibitory effect was independent of cytokines' secretion.

Applications
The study could potentially lead to the development of novel therapies that induce the host cytoplasmic antiviral protein to control HBV infections.

Peer review
The study describing the inhibitory role of DAI on HBV replication is generally well-performed and the results support the conclusions reached. The manuscript is well-written.

Abstract

AIM: To evaluate the safety, efficacy and management of double balloon enteroscopy (DBE) carried out in those aged individuals with suspicious small intestine diseases.

METHODS: DBE is a wonderful invention of the past decade and is widely used as an examination tool for the gastrointestinal tract. From January 2003 to July 2011, data from patients who were $\geq$ 65 years old and underwent DBE examination in the Nanfang Hospital were included in a retrospective analysis.

RESULTS: Fifty-nine individuals were found and sub-
sequently analyzed. The mean age was 69.63 ± 3.89 years (range 65-84), 34 were males. Indications for DBE were melena/hematochezia (36 cases), abdominal pain (15 cases), diarrhea (3 cases), stool change (1 case), weight loss (1 case), vomiting (2 cases), and debilitation (1 case). The average duration of symptoms was 33.34 ± 64.24 mo. Twenty-seven patients suffered from age-related diseases. Severe complications were not found during and after DBE. Comparison between systolic and diastolic blood pressure before and after DBE was statistically significant (mean ± SD, $P < 0.01$, $P < 0.05$, respectively). Small bowel pathologies were found by DBE in 35 patients, definite diagnoses were made in 31 cases, and detection rate and diagnostic yield for DBE were 68.6% and 60.8%, respectively.

CONCLUSION: DBE is a safe and effective method for gastrointestinal examination in the aged population. Aging alone is not a risk factor for elderly patients with suspicious gastrointestinal diseases and thorough preparation prior to the DBE procedure should be made for individuals with multiple diseases especially cardiopulmonary disorders.

INTRODUCTION

As the world population is aging, age-related diseases continue to increase and utilization of endoscopic techniques is rising[1], but the feasibility, safety, and effectiveness of endoscopic use for the elderly are still unknown, and there are still concerns about the use of clinical endoscopy in the elderly. Double balloon enteroscopy (DBE) is a wonderful invention in the past decade[2] and widely used as an examination tool in the gastrointestinal tract, which has the double advantages of being useful for diagnosis and interventional management. Use of DBE has mainly been in the small bowel in the past few years[3-10].

Compared to esophagogastroduodenoscopy (EGD), colonoscopy, and push endoscopy, clinical endoscopists are usually uncertain or perplexed about whether elderly individuals who are suspect for small bowel disorders could endure and be investigated by DBE with prolonged duration examination. There are a number of clinical studies regarding DBE performed in adults[11-15] and clinical trials using DBE performed in children[16-18], but little data concerning DBE exclusively used in the aged population. Therefore, the safety, efficacy, diagnosis and therapeutic management of DBE carried out in those aged subjects were assessed.

MATERIALS AND METHODS

Inclusion criteria were senile patients who were $\geq$ 65 years old and underwent DBE from January 2003 to July 2011 at Department of Gastroenterology, Nanfang Hospital (a tertiary center and university hospital), Southern Medical University, Guangzhou, China. The records of all patients were included in a retrospective analysis. This work was approved by Institutional Review Broad of Nangfang hospital, Southern Medical University.

All procedures were performed by DBE with no obvious absolute contraindications and carried out after written informed consent from patients and/or their guardians. A low residue and liquid diet were required and colored foods were avoided as far as possible at least one day prior to the test. All patients finished a bowel cleansing preparation by ingesting a 1.8-2 L polyethyleneglycol solution followed by overnight fasting (if the test was carried out in the morning), at least 6 h prior to the start of the procedure.

The Fujinon system (EN-450P5/20, Fuji Photo Optical Incorporated Company, Fujinon Inc, Japan) was used. This system consists of an endoscope at a working length of 200 cm with an outer diameter of 8.5 mm, and a flexible overtube 140 cm in length and 12 mm in outer diameter. By inflating the overtube balloon enough to grip the intestinal wall, the endoscope can be inserted further without forming redundant loops in the small bowel, and then the overtube can in turn be inserted while the endoscope balloon is inflated. DBE could be moved back and forth in a controlled manner by experienced endoscopists and an assistant to produce observations of the bowel.

Preparations and evaluation before and during the DBE procedure were as follows: (1) comprehensive assessment was carried out combining medical history and physical examination of the patients, individuals with suspected small bowel lesions and without absolute contraindications were included in the DBE investigation; (2) all subjects without other systematic diseases were evaluated prior to DBE operation, including vital signs (body temperature, blood pressure, pulse, respiration); hemoglobin (if this was abnormally low, it had to be corrected to a value > 80 g/L); electrolytes in serum (these also had to be corrected to normal range if abnormal levels were detected); electrocardiograph, chest X-ray, abdominal ultrasound were performed as regular examinations. Combined advice from other medical professionals was considered if unusual manifestations were found and the trans-oral or anal route or a combination of the two approaches was taken into account; (3) patients receiving pharmacotherapy for other known diseases were asked to discontinue administration the day before starting the test (steroid hormones, nonsteroidal anti-inflammatory drugs, and anticoagulant drugs had to be discontinued for at least a week). Experts in other professional departments, including anesthesiologists, were invited to participate in diagnosis and treatment of patients who suffered from concomitant diseases. The risk of DBE manipulation was decided in combination with endoscopists. Cases who were at extremely high risk were required to be treated by medical means in stable conditions if DBE was necessary, according to the suggestions of other professionals; (4) endoscopists, clinicians, anesthesiologists, and endoscopic nurses jointly participated in the DBE process. Concurrently, real-time monitoring equipment, resuscitative devices and necessary drugs were always ready for use in case of emergency. DBE was implemented in the operating room with full equipped medical measures being used when it was necessary; (5) antegrade, retrograde or a combination of the two approaches was performed with or without intervention under conscious or deep sedation, or general anesthesia (antegrade approaches generally included mechanical ventilation); and (6) specific management was individualized on the basis of different conditions in distinct patients before and during DBE procedure.

Observations were followed after DBE exploration, as described above, related laboratory parameters, and serious complications were monitored and managed accordingly.

Statistical analysis

Statistical analysis was performed using SPSS version 17.0 for Windows software. Continuous data were represented as means, mean ± SD or range and categorical variables were expressed as frequency or percentages. Student's test was used to compare continuous variables. The χ^2 test or Fisher exact probability test were used to compare differences in categorical variables examined.

McNemar's χ^2 test was used in comparison of diagnosis between capsule endoscopy (CE) and DBE. Agreement analysis between CE and DBE was assessed by the kappa statistic. $P < 0.05$ (two-sided) was considered statistically significant.

RESULTS

Characteristics of patients

Fifty-nine individuals who were aged ≥ 65 years were found and subsequently analyzed; only one patient was ≥ 80 years. The mean age was 69.63 ± 3.89 years (range 65-84), 34 were males. Indications for DBE were melena/hematochezia (36 cases), abdominal pain (15 cases), diarrhea (3 cases), stool change (1 case), weight loss (1 case), vomiting (2 cases), and debilitation (1 case). The average duration of symptoms was 33.34 ± 64.24 mo (range 0.10-324.00 mo). Prior blood transfusion had been

CE: Capsule endoscopy; DBE: Double balloon enteroscopy. [a]P = 0.021; κ = 0.10.

performed at least once in 29 subjects. Almost half the patients (27 cases) suffered from age-related diseases, including cardiovascular diseases, respiratory diseases, cardiopulmonary sickness, endocrine illnesses, *etc*. Hypertension and coronary disease were the main cardiovascular diseases and the most common respiratory illness was chronic bronchitis. Anticoagulant drugs were used in 1 case and 19 individuals had a prior surgical procedure. The mean hemoglobin level in plasma at initial examination was 96.00 ± 26.40 g/L (range 39.00-160.00 g/L). The demographic information was listed in Table 1.

Twenty individuals had prior CE investigation. Inspection time between CE and DBE was within 1-13 d of the DBE procedure. One patient did not complete the entire CE process because the CE battery ran out. CE was successfully discharged through the anus. The remaining patients accomplished examinations without any complications. Abnormities were seen in 17 patients, clear diagnoses were established in 6. Comparison between CE and DBE was given in Table 2.

Safety and efficacy of DBE

In this review, the mean levels of systolic and diastolic blood pressure in patients before the DBE procedure were 130.49 ± 17.19 mmHg (range 98-171 mmHg), 76.56 ± 10.70 mmHg (range 55-105 mmHg), respectively. Low levels of hemoglobin and abnormal levels of electrolytes were all corrected prior to DBE; heart rate remained in the normal range. The mean level of oxygen saturation before the test was 99.15% ± 1.54 % (range 92%-100%).

All patients received atropine prior to the DBE procedure. Administration of benzodiazepines such as diazepam or midazolam, meperidine or fentanyl, rocuronium, and propofol were used for sedation, induction and maintenance of narcosis through injection; real-time blood pressure control for patients undergoing DBE was maintained according to the distinct conditions of different patients; drug use was under real-time monitoring by electrocardiography, and measurement of transdermal oxygen saturation during the intervention process and carried out by professional anesthetists.

All patients completed the DBE procedures whether a peroral, peranal or combination approach was chosen. Severe complications were not found during and after DBE. Only a few patients complained of slight discomfort after DBE, and the symptoms soon disappeared

without medical treatment. The average levels of systolic and diastolic blood pressure in patients after DBE were 124.15 ± 17.18 mmHg (range 88-170 mmHg) and 72.34 ± 9.88 mmHg (range 50-92 mmHg), respectively. The mean level of oxygen saturation after the test was 99.76% ± 0.47% (range 98%-100%). There was a statistically significant change in systolic and diastolic blood pressure before and after DBE examination.

Diagnosis of gastrointestinal pathologies via DBE

Fifty-nine cases underwent 81 DBE procedures, including 27 performed by the antegrade approach, 10 by the retrograde approach, and 22 by combining the two approaches. Total enteroscopy combining the 2 approaches which could scrutinise the whole small bowel was achieved in 12 patients. The mean insertion depth was 278.37 ± 102.68 cm (from the pylorus to the furthest distance, performed by antegrade DBE), and 305.00 ± 97.72 cm (from the ileum valve to the furthest distance, performed by retrograde DBE) respectively; the mean total procedure time was 112.61 ± 39.32 min (antegrade DBE) and 119.50 ± 37.52 min, respectively. Twenty subjects received endoscopic biopsy and definite positive findings were made in 3 individuals. Lesions detected in the gastrointestinal tract were found in 42 patients and the diagnosis yield was 64.4% (38/59). Twenty-three individuals underwent surgical procedures and one person underwent intra-operative enteroscopy. All lesions in final diagnoses were found in the stomach, small intestine and other organs.

Gastric lesions in 8 patients diagnosed by DBE were excluded from having any small bowel pathology. Pathologies were found by DBE in 35 cases, definite diagnoses were made in 31, and the detection rate and diagnostic yield were 68.63% and 60.78%, respectively. Lesions examined were in the duodenum (9 cases), jejunum (14 cases), ileum (7 cases), cecum (1 case) and multiple sections

of small intestine (4 cases). Final diagnoses with lesions in gastrointestinal tract were found to be in the stomach of 8 patients, duodenum of 8 patients, jejunum of 14 patients, ileum of 7 patients, small bowel as multiple segmental lesions of 4 patients, the cecum of 1 patient, and other locations in 3 patients. Negative diagnoses were determined by DBE in 20 patients whose symptoms were melena/hematochezia in 10 individuals, abdominal pain (7 cases), diarrhea (2 cases), and weight loss (1 case). Twenty-seven DBE procedures incorporated 7 oral routines, 6 anal routines and 7 combined routines. Lesions were found in 4 subjects, final diagnoses were 1 case with metastatic lung cancer, 1 with metastatic liver cell carcinoma, 1 with gastrointestinal stromal tumor, 2 with pancreatic carcinoma, 2 with intestinal adenocarcinoma and others with gastrointestinal functional diseases (Table 3; Figures 1-3).

DISCUSSION

With advances in society and development of medical science, aging of the world's population is an inevitable trend. According to the latest demographic data, released on August 16, 2011 in Beijing, the China Committee on Aging's Office "2010 Annual Statistical Bulletin of China Aging Development" showed that in developing countries as China, 180 million of the population were aged ≥ 60 years and 120 million were aged ≥ 65 years. An increasingly aging population is bound to be accompanied by rises in age-related disorders. Gastrointestinal diseases are very common in children, adults and the elderly; consequently, the frequency of use of gastrointestinal endoscopy which can visualize the digestive tract is rising sharply.

Traditional and conventional upper gastrointestinal endoscopy and colonoscopy could scrutinise only the proximal small bowel and distal ileum owing to their limitations of length; the mid gut which spans the stomach and the colon is the longest part of the intestinal tract and could not be directly observed for examination, diagnosis and even intervention. Even if traditional techniques such as push enteroscopy, barium meal and advanced methods such as computed tomography (CT), magnetic resonance imaging, positron emission tomography could make correct diagnoses of gastrointestinal diseases, their limitations, such as length, and the difficulty of smaller lesions, make therapeutic management impossible, especially in the small bowel. That fact, coupled with unspecific clinical symptoms presented by small bowel diseases, misdiagnosis, missed lesions, delayed diagnosis and treatment usually promote poor prognosis and increase mortality. Over the past decade, there have been two significant inventions, namely CE and DBE, which have been applied in practice and revolutionized gastrointestinal diseases, particularly in the small intestine. Screening and/or diagnosis of patients with intestinal illnesses have been greatly improved by CE and DBE[19-22].

With aging, the deterioration of physiological function in various organs also gradually becomes clear and

Figure 1 Gastrointestinal stromal tumor in ileum was diagnosed by retrograde double balloon enteroscopy in a 73 year-old male patient (A), and confirmed by histopathology (B, hematoxylin and eosin) and immunohistochemistry (C:CD117; D:CD34).

Figure 2 A 74 year-old male with adenocarcinoma was diagnosed using trans-oral double balloon enteroscopy. Tumor and stricture of the small bowel were found (A) and verified through pathology (B, HE). HE: Hematoxylin and eosin.

increases in age-related systemic diseases such as cardiovascular diseases, lung diseases, malignant tumors, *etc*. A number of clinical studies showed that EGD, colonoscopy, and endoscopic retrograde cholangiopancreatography were safe and effective methods for use in the aged[1,23-26]. CE was considered a non-invasive method for screening the gastrointestinal tract[6,27,28]; nevertheless, the lower specificity[29,30] and inability of its use for therapeutic management[31] were regarded as its shortcomings.

Plentiful studies confirmed excellent safety, effectiveness and appreciable benefits for adults investigated by DBE, and these results were reported in published literature. Diagnosis, treatment and safety of DBE for children who were aged ≥ 3 years were also demonstrated in clinical trials[16,17,32]. In contrast to other endoscopic methods, DBE with prolonged performance which is used in the elderly is usually performed more meticulously by clinicians and endoscopists due to safety concerns. This is partly because intervention costs significantly rise and, if necessary, anesthesia itself may also have moderate or severe side effects[1]. Clinicians are likely to choose non-invasive and relatively safe methods to investigate gastrointestinal pathogenesis that have given rise to various manifestations; patients are also likely to undergo a number of medical examinations as well but unclear diagnosis is obtained.

Patients with heart- or lung-related diseases for DBE must be taken into detailed consideration; insufficient preparations for those with poor health status are hazardous during and after DBE investigation. In this ret-

Figure 3 A 66 year-old individual with diverticulum accompanied by bleeding in the jejunum was diagnosed using antegrade double balloon enteroscopy (A) and affirmed by histopathology (B).

rospective review, all patients completed the entire DBE procedure and serious adverse effects were not reported. Degraded function of aged organs makes the body have higher sensitivity and poorer tolerance for drug administration, if coexisting diseases are present; sedatives and anesthetic drugs were used in the process of DBE much less in adults. It is important to highlight that close attention must be paid during anesthesia, because intervention by DBE and/or combining with drug use may result in serious consequences or even death. Frequent anesthesia-related complications such as hypotension, desaturation and apnea were not found in our group. A slight decrease in blood pressure after DBE exploration was found and could be attributed to after effects of drug use during the procedure on account of lowering blood pressure and poor metabolism of the elderly. Complications such as perforation[33], pancreatitis[11,34,35], and intussusception resulting from the use of DBE described in previous studies[36] were not found in our study.

The results in this study suggested that the average age of the participants was approximately 70 years old which was considered a high-risk age associated with various diseases. Age-related disorders, the majority of which were cardiopulmonary diseases, were also found in our series. All patients complained of obvious discomfort and the most frequent symptoms were gastrointestinal bleeding and abdominal pain. A higher diagnostic yield for gastrointestinal diseases than usual was achieved and the diagnostic yield of small bowel diseases was 60.78%. Missed lesions are unavoidable by total enteroscopy in patients with prior abdominal surgery and where single routine insertion by DBE is not readily advanced. Final diagnoses of tumor, gastrointestinal functional disorders and intestinal diverticula were common in our study and this is different from results in western countries. Based on the above results, we maintain that DBE is a safe and effective method for gastrointestinal examination in the aged population. Aging alone is not a risk factor for elderly patients with suspicious gastrointestinal diseases and thorough preparations prior to the DBE procedure should be made for individuals with multiple systematic diseases, especially cardiopulmonary disorders.

A problem was revealed in this study in that the non-normative examination flow of DBE was used for small bowel evaluation at an early stage since DBE was first introduced in our unit in 2003. DBE was used in a few patients followed by combining negative EGD or negative colonoscopy with other medical examinations such as barium enema or abdominal CT rather than combining negative EGD with negative colonoscopy. The practical problems were corrected at a later stage and a series of normative flow for balloon-assisted enteroscopy have been established and all DBE procedures are carried out in patients with negative EGD and colonoscopy in our unit. Our study is not novel but has clinical significance and interest. The limitations of small sample size, retrospective analysis, non-randomized selection of elderly patients, and few patients aged ≥ 80 years were found in our study. Prospective, large-scale and blinded randomized trials are expected to be used in future clinical studies.

COMMENTS

Background
As the world population is aging, age-related diseases continue to increase and utilization of endoscopic techniques is rising, but few studies about the feasibility, safety, and effectiveness of double balloon enteroscopy (DBE) for the elderly have been performed, and there is still concern about its use in the elderly.

Research frontiers
The invention of balloon assisted enteroscopy was first reported in 2001 by Yamamoto. A growing number of studies were chiefly focused on research of whole small bowel diseases, in order to facilitate earlier diagnoses and intervention in disorders of the mid gut. This study investigated the value of DBE for examination of an older population with suspected small bowel disease.

Innovations and breakthroughs
Although the prevalence of small intestine diseases is not as high as that of colon disease, its manifestations are always unspecific and can even be fatal because of delayed diagnosis. The present study suggests that a higher proportion of the Chinese elderly population has tumors in the small bowel or functional gastrointestinal diseases. The results show that DBE is a safe and effective method in the older population.

Applications
DBE-based examination can be used safely and effectively in older patients for diagnosis and treatment of small bowel diseases.

Peer review
This retrospective study of DBE in the old is of significant interest in clinical practice. The safety and efficacy of DBE confirmed in this study may result in

wider use of balloon-assisted enteroscopy for exploration of the small intestine when older patients are suspected of having small bowel disorders.

Abstract

AIM: To investigate the effect of Mirtazapine on tumor growth, food intake, body weight, and nutritional status in gemcitabine-induced mild cachexia.

METHODS: Fourteen mice with subcutaneous xenografts of a pancreatic cancer cell line (SW1990) were randomly divided into Mirtazapine and control groups. Either Mirtazapine (10 mg/kg) or saline solution was orally fed to the mice every day after tumor implantation. A model of mild cachexia was then established in both groups by intraperitoneal injection of Gemcitabine (50 mg/kg) 10 d, 13 d, and 16 d after tumor implantation. Tumor size, food intake, body weight, and nutritional status were measured during the experiment. All mice were sacrificed at day 28.

RESULTS: (1) After 7 d of gemcitabine administration, body-weight losses of 5%-7% which suggested mild cachexia were measured; (2) No significant difference in tumor size was detected between the Mirtazapine and control groups ($P > 0.05$); and (3) During the entire experimental period, food intake and body weight were slightly greater for the Mirtazapine group compared with controls (although these differences were not statistically significant). After 21 d, mice in the Mirtazapine group consumed significantly more food than control mice (3.95 ± 0.14 g *vs* 3.54 ± 0.10 g, $P = 0.004$). After 25 d, mice in the Mirtazapine group were also significantly heavier than control mice (17.24 ± 0.53 g *vs* 18.05 ± 0.68 g, $P = 0.014$).

CONCLUSION: Mild cachexia model was successfully established by gemcitabine in pancreatic tumor-bearing mice. Mirtazapine can improve gemcitabine-induced mild cachexia in pancreatic tumor-bearing mice. It was believed to provide a potential therapeutic perspective for further studies on cachexia.

INTRODUCTION

Pancreatic cancer is one of the most lethal malignancies as the overall survival rate remains 4% for all stages and

races[1]. Clinical studies have established gemcitabine as the standard treatment for advanced pancreatic cancer. These studies have demonstrated significant clinical benefits (including improved survival) from gemcitabine[2-4]. Unfortunately, there are serious side effects associated with this anti-cancer drug that can adversely affect the patient's quality of life. These include nausea, vomiting, dyspepsia, weight loss, and cachexia.

Cachexia is characterized by major metabolic abnormalities and maladaptations. Often, food/energy intake is reduced, resting energy expenditure is increased, and catabolism is accelerated[5]. Cachexia is associated with anorexia, fat- and muscle-tissue wasting, and a progressive deterioration in the quality of life[6]. As many as 80% of all patients with cancer develop cachexia before death, and in over 20% of these patients, cachexia is the primary cause of death[7-9]. For patients with advanced-stage cancer, 80% suffer from cancer-associated anorexia/cachexia syndrome[10].

Mirtazapine represents a new class of antidepressant drugs. It is a noradrenergic and specific serotonergic antidepressant, which stimulates 5-hydroxytryptamine (HT) 1 receptors, but blocks serotonin 5-HT2/3 and histamine H1 receptors[11]. We have previously shown that 78% of patients with pancreatic cancer also suffer from clinical depression[12]. This figure jumps to 92.3% for patients undergoing chemotherapy. Mirtazapine has the potential to increase appetite and stimulate body-weight gains in these patients[13-15]. Using a mouse model for pancreatic cancer, we previously demonstrated that Mirtazapine increases food intake, enhances body weight, and improves the nutritional status of mice with cancer[16].

A 5% loss of body mass suggests an advanced to mild form of cachexia, whereas losses > 10% suggest severe cachexia[17,18]. Early interventions that treat mild cachexia often lead to substantial quality-of-life benefits for cancer patients. For the study reported herein, we therefore established a mouse model of chemotherapy-induced mild cachexia using gemcitabine and measured the effects of Mirtazapine monotherapy on tumor growth, food intake, body weight, and general nutritional status. These experiments were performed using nude mice implanted with human pancreatic cancer cells.

MATERIALS AND METHODS

Drugs and reagents

Mirtazapine was kindly provided by Organon (Oss, The Netherlands). Gemcitabine was purchased from Eli Lilly and Co. (Indianapolis, IN, United States). RPMI1640 and fetal bovine serum were purchased from Gibco (Grand Island, NY, United States).

Animals

BALB/*c nu*/*nu* mice were purchased from the Experimental Animal Center, Guangzhou University of Chinese Medicine. Approval for these studies was acquired from the animal-care committee (license number: SCXK 2008-0020). Mice were bred and maintained under patho-

gen-free conditions in the Animal Center of Sun Yat-Sen University. Mice were housed 4-5 per cage under standard conditions, i.e., 22 ± 1 ℃, ad libitum access to water and standard rat chow, and a 12-h light/dark cycle. Experiments were performed using mice that were 4-6 wk old and 20-22 g.

Pancreatic cancer cell lines and culture conditions

The human pancreatic cancer cell line SW1990 was the kind gift of the Second Affiliated Hospital of Sun Yat-Sen University. Cells were maintained in RPMI-1640 media supplemented with 10% fetal bovine serum (FBS). Monolayer cultures were maintained in culture flasks and incubated under 50 mL/L CO_2 and 950 mL/L O_2 at 37 ℃. Trypsinization was stopped with medium that contained 10% FBS. Cells were then washed once in serum-free medium and resuspended in Hanks' balanced salt solution. Only single-cell suspensions that displayed greater than 90% viability were used for injections.

Establishment of a chemotherapy-induced cachexia model using gemcitabine

The subcutaneous pancreatic cancer model was established using the methods of Jia *et al*[19] with slight modifications. To produce the SW1990 tumor, 3×10^6 cells (in 0.2 mL) were inoculated subcutaneously into the right flank of each nude mouse. Tumor sizes were measured *via* callipering. When the subcutaneous solid tumors reached approximately 1 cm in diameter, they were aseptically removed from the donor animals. Macroscopically visible necrotic tissue was cut away, and the remaining healthy tumor tissue was cut with scissors into pieces that were approximately 1 mm^3. The tumor pieces were placed into Hanks' balanced salt solution that contained 100 units/mL penicillin and 100 mg/mL streptomycin. A small incision was then made through the right dorsal flank of each nude mouse and a piece of tumor was implanted beneath its skin. Chemotherapy-induced mild cachexia was established by intraperitoneal injection of 50 mg/kg gemcitabine on days 10, 13, and 16 after tumor implantation.

Mirtazapine administration

Fourteen mice were randomly assigned to either the Mirtazapine or the control group (7 mice per group). After tumor implantation, Mirtazapine (10 mg/kg) was orally fed to the Mirtazapine group once per day. Normal saline solution was fed to the control group. Chemotherapy-induced mild cachexia was then established in both groups, as described above. Animals were sacrificed after 28 d.

Measurements

The transplanted tumor sizes were measured using a Vernier caliper every fourth day, and tumor volume (V) was calculated as: $V = w^2 \times l/2$, where w is the width and l is the length of the tumor[20]. Mice were sacrificed on day 28 after tumor transplantation, and the tumors were then removed. Both the tumors and the mice carcasses were then weighed. During the experiment, body weight was

measured every forth day. Food intake was expressed as daily consumption in grams per animal weekly. The rate of weight loss was calculated as: weight loss (%) = (1-body weight$_{timepoint}$/body weight$_{base-line}$) × 100%. A weight loss > 5% suggested the development of mild cachexia[17,18]. Abdominal skin-fold and arm diameter were measured using the caliper every third day. Subcutaneous fat was calculated as: subcutaneous fat (mm) = skin-fold thickness × 0.5. Arm circumference was calculated as: arm circumference (mm) = diameter × 3.14.

Statistical analysis

Statistical analyses were performed using SPSS 13.0 for Windows. Data were expressed as mean ± SD, and were compared using one-way analysis of variance and the Student-Newman-Keuls test for multiple comparisons between groups. Tumor inhibition rates were compared using the χ^2 test. Differences were considered statistically significant for $P < 0.05$ using two-tailed tests.

RESULTS

Establishment of a model for chemotherapy-induced mild cachexia using gemcitabine

Seven days after the first gemcitabine injection, body weight in the control group had declined from 21.64 ± 0.96 g to 20.15 ± 0.67 g (a 6.89% decrease) (Table 1). A similar decline was measured for the Mirtazapine group: 21.75 ± 0.75 g to 20.50 ± 0.50 g (a 5.75% decrease). A mild form of cachexia had therefore been established, indicating that the administration of gemcitabine (50

mg/kg) for 1 wk could induce mild cachexia in mice that carried a pancreatic tumor.

Effect of Mirtazapine on tumor growth

As the experiment progressed, small increases in the sizes of the tumors were regularly measured (Table 2). Similar rates of tumor growth were evident in both the Mirtazapine and control groups, however, statistically significant differences in tumor size were never detected between the two groups.

Tumor weight was measured at 28 d, immediately after the mice were sacrificed. Again, a statistically significant difference between the Mirtazapine and control groups concerning tumor weight was not detected (0.37 ± 0.11 g *vs* 0.42 ± 0.09 g, $P > 0.05$). It was indicated that gemcitabine had inhibitory effect on pancreatic cancer growth, which could not be apparently strengthened by Mirtazapine.

Effect of Mirtazapine on daily food intake

Following the administration of gemcitabine, daily food intake gradual declined in both groups (Table 2). By day 21 of the experiment, however, mice given Mirtazapine were eating more food than did the controls (3.54 ± 0.10 g *vs* 3.95 ± 0.14 g, $P < 0.01$). This effect was also seen at the end of the experiment (day 28) (3.02 ± 0.16 g *vs* 3.57 ± 0.11 g, $P < 0.01$), demonstrating that Mirtazapine can slow the reduction in food intake caused by chemotherapy.

Effect of Mirtazapine on body weight and nutritional status

At the beginning of the study, mice from the two groups

had similar average body weights ($P > 0.05$). Throughout the course of the experiment, mice in both groups exhibited a gradual decrease in body weight (Table 1). During initial stages of the experiment, the control group seemed to lose slightly more weight than did the Mirtazapine group, although these differences were not statistically significant ($P > 0.05$). At day 25, however, mice fed Mirtazapine were significantly heavier than control mice (18.05 ± 0.68 g *vs* 17.24 ± 0.53 g, $P = 0.014$). This phenomenon was also seen at 28 d suggesting that early Mirtazapine interventions can ameliorate the weight loss that is typically associated with chemotherapy (e.g., gemcitabine).

Subcutaneous fat and arm circumference were also measured for the two groups of mice (Table 1). For both groups these measured parameters gradually decreased during the course of the experiment. The data suggest that slower reductions were taking place in the Mirtazapine group (compared with the control group), but statistically significant differences were not detected ($P > 0.05$).

DISCUSSION

Cachexia is a disease process that develops in numerous chronic and end-stage pathologies. Clinical manifestations of cachexia include weight loss, anorexia, fatigue, muscle wasting, aesthesia, anemia, and edema. Particularly strong correlations between cachexia and solid tumors of the upper gastrointestinal tract have been described. It is estimated that 83% of pancreatic cancer patients suffer from cachexia during the course of their disease[17]. In addition, patients with pancreatic cancer have the highest incidence of weight loss (83%-87%), with about 30% reporting a weight loss of > 10%[21,22].

To experimentally dissect cachexia, a variety of cachexia models have been established. Murine colon-26 adenocarcinoma cells, Yoshida ascites hepatoma (AH-130) ascites hepatoma cells, and several other cachexigenic cell lines (JHU012, JHU022, and MAC1) have been used to establish different cachexia models[23-25]. The administration of chemotherapy drugs, however, has only rarely been used to generate mild cachexia. Gemcitabine is an extremely effective chemotherapy agent that inhibits the growth of cancerous tumors. Unfortunately, this drug is also associated with a number of adverse side effects, which include nausea, vomiting, loss of appetite, weight loss, and cachexia[26,27]. For the study reported herein, we injected nude mice with Gemcitabine to induce cachexia. Significant weight loss was observed in these animals, suggesting that a model for mild cachexia had been established.

Potential treatments for cancer cachexia (e.g., megestrol acetate, testosterone, growth hormone, or ghrelin) have been the subject of intense research recently. One study suggested that progestogens (e.g., megestrol acetate, or medroxyprogesterone) should be preferentially used to treat anorexia in patients with cancer because of toxic side effects associated with corticosteroids[17]. Several studies have demonstrated that ghrelin, which is a peptide found in both the brain and gut and stimulates food intake, may ameliorate cancer cachexia[9,28]. To date, however, there are no consistent opinions or guidelines that support the use of one therapeutic agent over another.

Mirtazapine represents a novel antidepressant and has been shown to cure insomnia, depression, and anxiety, but it is unclear if it also stimulates appetite and improves the nutritional status of patients[29-32]. We have previously shown that a 6-wk administration of Mirtazapine in a murine model of pancreatic cancer increased food intake and body weight by 16.39% and 8.39%, respectively. These nutritional improvements were significantly better than was seen with other antidepressants[16]. Our previous work had also shown that gemcitabine induces cachexia. In the current study, therefore, we investigated whether an early Mirtazapine intervention could ameliorate the mild cachexia associated with gemcitabine (50 mg/kg) administration in mice that bear pancreatic tumors. Mirtazapine significantly improved both food intake and body weight of these mice, although losses in subcutaneous fat and skeletal muscle were not slowed. The reason for these fat and muscle losses may be that Mirtazapine does not affect lipolysis or the adenosine triphosphate/ubiquitin/proteasome system, both of which are upregulated in cachexia. In the future, therefore, it will be important to determine the dose-effect relationship between Mirtazapine and chemotherapy-induced cachexia. We will also test whether enhanced nutritional improvements can be obtained *via* combinatorial treatments that include Mirtazapine and megestrol acetate or ghrelin.

In summary, for the first time, chemotherapy-induced mild cachexia has been established in a murine model of pancreatic cancer using gemcitabine. In addition, our results demonstrate that early administration of Mirtazapine may represent an effective treatment for both chemotherapy- and cancer-related cachexia. Future experiments that use larger groups of animals and long-term courses of treatment will be necessary to confirm these findings. Clinical tests in cancer patients are also needed.

COMMENTS

Background

Gemcitabine is commonly used to treat pancreatic cancer. This anti-cancer drug, however, is often associated with side effects (e.g., nausea, vomiting, dyspepsia, weight loss, and cachexia) that adversely affect the patient's quality of life. Mirtazapine may increase appetite and weight gain, thereby ameliorating cachexia in this context.

Research frontiers

Mirtazapine can significantly increase the food intake, enhance the body weight and improve the nutritional state in a pancreatic cancer mouse model in the authors' previous researches. In this study, the authors do the advanced research to find whether Mirtazapine could also show positive effects on improvement of appetite loss and weight loss which were the main features of cachexia.

Innovations and breakthroughs

The research shows that Mirtazapine improved gemcitabine-induced mild cachexia in mice that bear pancreatic tumors.

Applications

Mirtazapine represents a new class of antidepressant that may also positively affect appetite and weight gain. These results suggest novel therapeutic applications for Mirtazapine, and will help direct future studies concerning cachexia.

Peer review

This is an interesting research that the authors utilized gemcitabine to induce

mild cachexia in mice with pancreatic tumors and found that Mirtazapine improved the symptoms associated with mild cachexia. These findings identify a novel means of treating cachexia, although additional experiments, both in the lab and in the clinic, are necessary before this strategy can be widely applied to cancer patients.

Abstract

Recently, the development of endoscopic procedures has increased the availability of minimally invasive treatments; however, there have been few case reports of duodenal hemangioma treated by endoscopic mucosal resection. The present report describes a case of duodenal hemangioma that showed various endoscopic changes over time and was treated by endoscopic mucosal resection. An 80-year-old woman presented with tarry stools and a loss of appetite. An examination of her blood revealed severe anemia, and her hemoglobin level was 4.2 g/dL. An emergency upper gastrointestinal endoscopy was performed. A red, protrusive, semipedunculated tumor (approximately 20 mm in diameter) with spontaneous bleeding on its surface was found in the superior duodenal angle. Given the semipedunculated appearance of the tumor, it was suspected to be an epithelial tumor with a differential diagnosis of hyperplastic polyp. The biopsy results suggested a telangiectatic hemangioma. Because this lesion was considered to be responsible for her anemia, endoscopic mucosal resection was performed for diagnostic and treatment purposes after informed consent was obtained. A histopathological examination of the resected specimen revealed dilated and proliferated capillary lumens of various sizes, which confirmed the final diagnosis of duodenal hemangioma. Neither anemia nor tumor recurrence has been observed since the endoscopic mucosal resection (approximately 1 year). Duodenal hemangiomas can be treated endoscopically provided that sufficient consideration is given to all of the possible treatment strategies. Interestingly, duodenal hemangiomas show morphological changes that are influenced by various factors, such as mechanical stimuli.

INTRODUCTION

Vascular lesions of the duodenum, including hemangiomas, are rare causes of gastrointestinal bleeding. Indeed,

there have been very few reports of hemangioma in the duodenum. Endoscopically, hemangiomas have various morphological features. The present case is the first report of a duodenal hemangioma that showed various morphological features at the time of endoscopy. Although duodenal hemangioma is treated by surgical duodenectomy, the use of less-invasive procedures, such as endoscopic mucosal resection (EMR), has increased. The present study found that EMR is an effective treatment for hemorrhagic duodenal hemangioma. In addition, the present study summarized previous case reports of duodenal hemangioma.

CASE REPORT

An 80-year-old woman presented with tarry stools and a loss of appetite. She had undergone laparoscopic cholecystectomy for acute cholecystitis when she was in her seventies. She had experienced a loss of appetite and anemic symptoms since approximately March 10, 2008, but she did not seek medical attention. She noticed a tarry stool on March 15 and experienced pallor of the face and astasia on March 18, which was the day she presented at the emergency department of Sakaide municipal hospital. The physical findings upon admission included a body height of 148 cm, a body weight of 45 kg, clear sensorium, a body temperature of 36.6 ℃, a blood pressure of 116/56 mmHg, a pulse rate of 84 bpm, and an oxygen saturation of 100%. The palpebral conjunctiva was noted to be anemic. The abdomen was flat and soft with no spontaneous pain or tenderness. An examination of the blood at the time of admission revealed significant anemia with a hemoglobin level of 4.2 g/dL. In addition, her albumin level was decreased to 3.3 g/dL. Platelet counts, coagulation tests, and renal/hepatic function tests were all normal. An emergency upper endoscopy was performed on admission, but no abnormalities were found in the esophagus or the stomach. A red, semipedunculated tumor (20 mm in diameter) with spontaneous bleeding was found in the superior duodenal angle (SDA) (Figure 1). This patient had received an upper endoscopy at another hospital 9 mo earlier and had undergone biopsy after a blue, nonpedunculated, submucosal tumor-like lesion was found in SDA (Figure 2). Because there was no active bleeding during the endoscopic observation, biopsies were obtained from the basal and apical portions of the protruding lesion for diagnostic purposes. Although the pathological examination of the biopsy samples only identified necrotic material in the basal sample, we observed a dense proliferation of capillaries in the apical sample, which resulted in a diagnosis of suspected capillary hemangioma. Contrast-enhanced computed tomography (CT) revealed a slightly enhanced tumor (approximately 20 mm in diameter) in the SDA. Interestingly, we did not observe the presence of thick supplying blood vessels or an extramural extension of the tumor.

Based on the upper endoscopic findings and the

Figure 1 A red protruding lesion (20 mm in diameter) with spontaneous bleeding was found in the superior duodenal angle.

Figure 2 A blue, nonpedunculated, submucosal tumor-like lesion. The tumor is almost entirely covered by mucosa.

results of the pathological examination, a duodenal hemangioma was considered to be the source of the bleeding. With conservative therapy, the hemoglobin level increased to 7 g/dL, and hemostasis was achieved.

Because of the possibility of recurrent bleeding, EMR was performed to remove the hemangioma (Figure 3A-D). The top of the tumor was semipedunculated and irregular. First, the endothelial tumor was distinguished, but the biopsy showed the presence of a hemangioma, and the CT revealed an absence of thick supplying blood vessels. Additionally, the patient was of advanced aged and suffered from dementia. Also, the patient's family did not want her to undergo surgery. Moreover, the duodenal mucosa was sufficiently elevated following a local injection of salin solution; thus, EMR was performed. If histology of the resected specimen had revealed malignant potential, then surgery would have been performed.

We performed another upper endoscopy 3 d after the EMR, and hemostasis was confirmed. The patient had a favorable postoperative course and was discharged from the hospital without complications 1 wk after the EMR. Histopathological examination revealed the proliferation of endothelial cells lining the lumens of capillaries of various sizes and confirmed the diagnosis of capillary hemangioma (Figure 4A and B).

Figure 3 Duodenal hemangioma and endoscopic mucosal resection. A: EMR was performed after the mucosa was sufficiently elevated by local injection; B: The mucosal defect; C: The mucosal defect was closed using the clipping technique, and the procedure was completed; D: A resected specimen obtained by EMR. EMR: Endoscopic mucosal resection.

DISCUSSION

Hemangiomas only account for approximately 0.3% of all gastrointestinal tumors[1]. A search for Japanese and foreign case reports of duodenal hemangioma between 1978 and 2008 through the Japana Centra Revuo Medicina and MEDLINE only identified 22 reports, including the present case, which indicated a very low incidence of the disease (Table 1)[2-12]. We conducted a clinicopathological review of the identified Japanese case reports, including the present case. The mean age of the patients was 55 years, and the ages ranged from 2 years to 85 years. The chief complaints in the Japanese cases included melena/anemic symptoms in 82% (14 of 17) of the cases and obstructive symptoms in 1 case. Interestingly, there were only 2 asymptomatic cases. Nader et al. reported that only 30% of hemangioma cases were asymptomatic. Gastrointestinal hemorrhage/anemia was observed in 73.2% of the hemangioma cases, and obstructive symptoms were observed in 12.8% of the cases[13]. Tumors were slightly more commonly in the descending portion (8 of 17 cases, 48%) of the duodenum compared with the other portions of the duodenum. In terms of size, cavernous hemangiomas tend to be larger than capillary hemangiomas (11-80 mm *vs* 8-20 mm, respectively). Interestingly, cavernous hemangiomas accounted for the majority of the reported hemangioma cases. Indeed, cavernous hemangioma was found in 11 cases, capillary hemangioma was observed in 4 cases, and mixed capillary hemangioma and multiple

SMT: Submucosal tumor.

phlebectasia were observed in 1 case.

Characteristic endoscopic findings included color ranging from blue to dark red and a structure that was easily deformed by compression. Although duodenal hemangiomas are morphologically classified as submucosal tumorlike, diffusely infiltrating, or polypous lesions, all of the reported cases except for the present case have been classified as submucosal tumor-like lesions. Interestingly, the present case had a polypous appearance.

Because hemangiomas show variable endoscopic findings in terms of size, shape, and color, examinations and pretreatment information are required for the diagnosis. These examinations include contrast-enhanced CT and magnetic resonance imaging to determine the location of the tumor and the blood stream, endoscopic ultrasonography to determine the extent of the lesion, selective angiography, and duodenal X-rays. The final diagnosis is generally made based on the results of the pathological examination of the resected specimens.

Kaijer *et al*[14] pathologically classified duodenal hemangiomas into 4 types: type Ⅰ, multiple phlebectasia; type Ⅱ, cavernous hemangioma of diffuse and localized polypous types; type Ⅲ, simple capillary hemangioma; and type Ⅳ, angiomatosis with a gastrointestinal lesion. In terms of frequency, type Ⅱ hemangiomas account for the majority (55%) of all cases, but type Ⅱ and a mixture of types Ⅱ and Ⅲ are almost comparable in frequency. The present case was classified as a type Ⅱ lesion of the localized polypous type.

Although duodenal hemangiomas are conventionally treated surgically (i.e., partial intestinal resection), less invasive treatment strategies have recently been reported, including endoscopic polypectomy, EMR, local ethanol injection therapy, catheter embolization therapy, and endoscopic sclerotherapy. Among the reported cases, surgery was performed in 11 cases, polypectomy was performed in 2 cases, and EMR was performed in 1 case (i.e., the present case). Although no formal criteria have been established for the indications of EMR, patients meeting the following three criteria are considered eligible for EMR: (1) patients with a lesion in the endoscopically accessible SDA or descending portion of the duodenum; (2) patients with a 25-mm or smaller polypous lesion classified as type Ⅱ, Ⅲ, or Ⅳ according to Yamada's classification[15]; and (3) patients without a large blood vessel in the lesion (determined using contrast-enhanced abdominal CT or abdominal angiography).

We chose EMR in the present case because the patient had a 20-mm polypous lesion in the SDA, which is an endoscopically accessible region, and we did not detect a large supplying vessel on the contrast-enhanced abdominal CT. Surgical treatment was likely selected in many of the previous cases because the lesions were typically in the descending portion of the duodenum. Because the surgical resection of a duodenal lesion tends to cause excessive surgical stress, endoscopic or catheter-based treatments may be considered as an option after careful consideration. It should be noted, however, that

duodenal blood vessels have thinner walls compared with blood vessels in other parts of the intestine. Furthermore, it is difficult to manipulate an endoscope in the duodenum, which has 2 curved sections. In addition, if a resected specimen falls into the anal side of the intestine, it may be difficult to retrieve. Thus, the indication for treatment should be carefully considered.

When the patient from the present study presented at our hospital, the tumor was exposed on the mucosal surface and had increased in size. Hemangiomas can grow into various shapes according to the influence of several factors, such as thrombi, fibrosis, calcification, infection, peristalsis, and mechanical stimuli. Although the literature search did not identify any case reports of duodenal hemangiomas characterized by increasing size, the lesion in the present case appeared to have initially developed as a submucosal tumor. Interestingly, mucosal bleeding and ulceration caused by mechanical stimuli, such as biopsy and contact with food, led to the tumor being exposed to the lumen and resulted in its deformation into a polypous lesion.

We experienced a rare case of duodenal hemangioma in the present patient, and duodenal hemangioma in general can be treated by an appropriately selected, less invasive treatment strategy. The present case provided a valuable experience that enabled us to understand the morphological changes that hemangiomas can display over time.

Abstract

We report a case of duodenal varix bleeding as a long term complication of balloon occluded retrograde transvenous obliteration (BRTO), which was successfully treated with a transjugular intrahepatic portosystemic shunt (TIPS). A 57-year-old man was admitted to the emergency room suffering from melena. He had undergone BRTO to treat gastric varix bleeding 5 mo before admission. Endoscopy and a computed tomography (CT) scan showed complete obliteration of the gastric varix, but the nodular varices in the second portion of the duodenum expanded after BRTO, and spurting blood was seen. TIPS was performed for treatment of duodenal variceal bleeding, because attempts at endoscopic varix ligation were unsuccessful. The postoperative course was uneventful and the patient was discharged without complications. A follow up CT scan obtained 21 mo after TIPS revealed a patent TIPS tract and complete obliteration of duodenal varices, but multinodular hepatocellular carcinoma had developed. He died of hepatic failure 28 mo after TIPS.

Duodenal variceal bleeding after balloon-occluded retrograde transverse obliteration: Treatment with transjugular intrahepatic portosystemic shunt. *World J Gastroenterol* 2012; 18(22): 2877-2880 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i22/2877.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i22.2877

INTRODUCTION

Balloon-occluded retrograde transvenous obliteration (BRTO) is minimally invasive and effective in patients with gastric variceal bleeding[1-5]. Although BRTO achieves excellent prevention of recurrent bleeding with few complications, its long-term efficacy and safety have not been full evaluated. In particular, aggravation of esophageal varices and portal hypertension have been proposed as serious complications of BRTO. There have also been reports that BRTO may aggravate esophageal varices[2,6-8]. However, there are no reports concerning the deterioration of pre-existing duodenal varices by BRTO. Here, we describe our clinical experience of successfully treating bleeding duodenal varices with a transjugular-intrahepatic portosys-

Figure 1 Endoscopic variceal ligation was performed to control variceal bleeding. A: Tiny nodular varices with no bleeding were found at the duodenum second portion; B: Enhanced computed tomography scan showing large gastric varices (arrow); C: Balloon occluded retrograde transvenous obliteration was successfully performed.

Figure 2 An emergency endoscopic examination revealed a small, linear esophageal varices without evidence of recent bleeding. A: In the second portion of the duodenum, nodular varices expanded before balloon occluded retrograde transvenous obliteration and presented with hematocystic spots; B, C: Enhanced computed tomography scan obtained 5 mo after balloon occluded retrograde transvenous obliteration revealing complete obliteration of gastric varices (black arrow); however, duodenal varices were aggravated (white arrow).

temic shunt (TIPS) and transcatheter embolization.

CASE REPORT

A 57-year-old man was admitted with a history of melena and intermittent hematochezia. He was hepatitis B virus-positive and had liver cirrhosis. Five mo before admission, an emergency endoscopic examination revealed gastric varices with active bleeding. Endoscopic variceal ligation (EVL) was performed to control variceal bleeding. A tiny nodular varix without bleeding was found in the second portion of the duodenum at that time (Figure 1A). Computed tomography (CT) showed dilated gastric varices with a gastrorenal shunt (Figure 1B). BRTO was performed to prevent recurrent gastric variceal bleeding (Figure 1C). The patient did not have any further bleeding events until our examination. At the time of admission, his blood pressure was 112/56 mmHg, heart rate was 115/min, and respiratory rate was 24/min with symptomatic orthostatic hypotension. No abnormalities were noticed on cardiac and respiratory examinations, except tachycardia. Laboratory tests performed on admission revealed a hemoglobin of 5.9 g/dL, a hematocrit of 17.4%, and a thrombocyte count of 1.6×10^4/mL. The

total serum protein and albumin level were 5.5 g/dL and 2.7 g/dL, respectively. Other laboratory data included total bilirubin (0.7 mg/dL) and aspartate aminotransferase [AST: 321 IU/L (normal < 40 IU)]. An emergency endoscopic examination revealed a small, linear esophageal varix without evidence of recent bleeding. In the second portion of the duodenum, the nodular varices had expanded after BRTO and hematocystic spots with fresh blood were seen (Figure 2A). A CT scan showed complete obliteration of gastric varices, but the duodenal varices were aggravated (Figure 2B and C). EVL was done at that site, but the bleeding continued. Therefore, a TIPS was created according to standard procedures. Portography during the TIPS operation revealed a large duodenal varix originating from the superior mesenteric vein and draining into the gonadal vein (Figure 3A). The TIPS tract was created and the vein feeding the duodenal varix was embolized using three metallic coils. The portosystemic gradient was 30 mmHg, which decreased to 12 mmHg after TIPS, and portography showed the disappearance of duodenal variceal flow (Figure 3B). The postoperative course was uneventful. The patient was discharged without complications, and he remained in a stable condition. A follow-up CT scan obtained 21

Figure 3 Transjugular intrahepatic portosystemic shunt was created according to standard procedures. A: Portogram showing duodenal variceal flow; B: After transjugular intrahepatic portosystemic shunt and coil embolization of duodenal varices, variceal flow disappeared.

Figure 4 A follow-up computed tomography scan was obtained 21 mo after transjugular intrahepatic portosystemic shunt. A, B: Enhanced computed tomography scan shows a still patent transjugular portosystemic shunt tract and complete improvement of duodenal varices. Note the appearance of multinodular hepatocellular carcinomas in the liver.

mo after TIPS revealed a patent TIPS tract and complete obliteration of duodenal varices; however, multinodular hepatocellular carcinoma had developed (Figure 4A and B). He died of hepatic failure 28 mo after TIPS.

DISCUSSION

Interventional treatments for variceal bleeding can be roughly classified into two types: Shunt occlusion and shunt creation. BRTO is representative of shunt occlusion therapies, and has been widely performed in Korea and Japan since it was introduced by Kanakawa in the mid-1990s[4]. It is an interventional radiological technique designed specifically for the treatment of gastric fundal varices with gastrorenal shunt. The principle of BRTO is to eradicate the gastric fundal varices by injecting sclerosant into the varices retrogradely with the balloon inflated in the draining veins, after insertion *via* the systemic circulation from the femoral or jugular vein. The sclerosant for BRTO is 5% ethanolamine oleate with iopamidol, which injures the endothelial cells of varicose veins and induces thrombosis in the varices. This technique controls gastric variceal bleeding effectively, with success rates of 76% to 92%[3]. Satisfactory results have been reported for managing variceal bleeding with improved liver function and hepatic encephalopathy[1,3,5,9,10]. Theoretically, shunt-obliterating therapies such as BRTO could increase portal blood flow and pressure, and thereafter

increase the bleeding risk from other varices, except sclerosed varices. Therefore, aggravation of esophageal varices is a serious complication of BRTO[2,6-8]. A long-term consequence of BRTO is the development or worsening of esophageal varices (EV) resulting from increased portal pressure, which has been reported in 10% to 66% of procedures. In a recent study, worsening of EV was observed after BRTO, with aggravation rates of 27%, 58%, and 66% at 1 years, 3 years, and 5 years, respectively[2]. However, shunt creation therapy, such as TIPS, can decompress the portal pressure, and therefore can be used in the treatment of most complications of portal hypertension, except hepatic encephalopathy. These include acute esophageal variceal bleeding refractory to medical therapy, recurrent esophageal variceal bleeding, gastric variceal bleeding, ectopic variceal bleeding, portal hypertensive gastropathy, Budd-Chiari syndrome, refractory ascites, refractory hepatic hydrothorax, hepatorenal syndrome, hypersplenism, and pancreatic arteriovenous malformation[11]. Nevertheless, TIPS has two main drawbacks. One is aggravation of hepatic encephalopathy and the other is deterioration of hepatic function. Therefore, doing both BRTO and TIPS should compensate for each other's weak points during treatment of variceal bleeding, because the two therapies are complementary.

Duodenal varices can develop in patients diagnosed with portal hypertension secondary to liver cirrhosis,

portal vein thrombosis, schistosomiasis, chronic pancreatitis, and, rarely, pancreatic cancer. Although the bleeding is often severe and fatal, no definitive treatments or guidelines for bleeding duodenal varices have been established[12,13]. Several studies of endoscopic therapies, such as band ligation (BL) or sclerotherapy, have reported variable success rates[13]. However, BL cannot ligate duodenal varices larger than 15 mm[12]. In addition, BL does not completely disrupt the blood flow within varices, and the potential for recurrent bleeding remains[12]. Sclerotherapy has technical difficulties, including a non-ideal approach to the vessels when varices are located in the second portion of the duodenum[13].

The use of radiological interventions provides an alternative method for treating patients presenting with bleeding duodenal varices (DV). Several cases concerning the use of TIPS or BRTO for controlling duodenal variceal bleeding have been reported. Akazawa *et al*[12] reported a case of duodenal variceal bleeding managed with BRTO. In our patient, the duodenal variceal bleeding caused by BRTO could not be managed endoscopically. As a result, we performed TIPS and transcatheter embolization. In conclusion, BRTO is believed to be effective for controlling gastric variceal bleeding. However, it may increase the risk of coexisting EV, DV, and ectopic variceal bleeding. Using TIPS in combination with embolization, we successfully treated a patient with DV bleeding.

Abstract

Heterotopic pancreas is mostly found incidentally, and adenocarcinoma arising from heterotopic pancreas appears to be extremely rare. A case of a 46-year-old woman with adenocarcinoma arising from intrahepatic heterotopic pancreas is reported herein. Computed tomography demonstrated a mass located in the bile duct of the left hepatic lobe. Pathological examination revealed a moderately differentiated adenocarcinoma arising from intrahepatic heterotopic pancreas with nerve infiltration. This may be the first reported case of adenocarcinoma arising from intrahepatic heterotopic pancreas.

Sant Pau, Av. Sant Antoni M Claret 167, 08025 Barcelona, Spain

INTRODUCTION

The heterotopic pancreas is defined as aberrant pancreatic tissue without vascular, neural or anatomic continuity with the normal pancreas[1]. The incidence of heterotopic pancreas in autopsy studies is approximately 0.5%-13.7%[2]. Heterotopic pancreatic tissues can be found anywhere in the gastrointestinal tract and the predilection site is the stomach, duodenum and jejunum[3]. Unusual sites include the biliary system and liver[4]. Carcinoma within heterotopic pancreatic tissues is rare, and about 31 well-documented cases have been reported in the literature[5]. We present a case with malignant transformation in heterotopic pancreas of the intra-hepatic biliary tract. To our knowledge, no case of adenocarcinoma arising in the intrahepatic heterotopic pancreas has been described previously.

CASE REPORT

A 45-year-old woman who had been healthy underwent a routine medical check-up in our hospital. The physical examination was normal. Laboratory tests revealed elevated values of γ glutamyl transpeptidase, but normal aspartatate aminotransferase and alanine aminotransferase. The tumor markers including α fetoprotein, carcinoembryonic antigen, CA125 and CA-19-9 were all within normal ranges. Hepatitis virus markers were negative. Ultrasound showed the dilatation of the bile ducts of left

Figure 1 Computed tomography scan shows the dilatation of the bile ducts of left hepatic lobe and a mass located in the bile duct of left hepatic lobe. A-D: Computed tomography scan of abdomen showing dilatation of the bile ducts of left hepatic lobe and a mass located in the bile duct of left hepatic lobe near the hepatic hilus.

hepatic lobe. Abdominal computed tomography (CT) scan revealed a mass located in the bile duct of left hepatic lobe near the hepatic hilus, which had no enhancement in arterial and portal venous, but clear enchancement in delayed phase (Figure 1). Dilatation of the bile ducts of left hepatic lobe was observed up to the periphery of the liver. CT scan and ultrasound failed to demonstrate any pancreatic lesion. A radical resection was performed under the clinical impression of cholangiocarcinoma. She underwent left hepatic and caudate lobectomy and resection of the gallbladder. Postoperative recovery was uneventful.

Gross examination revealed a firm, gray, nodular mass measuring 3.0 cm × 2.0 cm × 2.0 cm, which was located in the bile duct of left hepatic lobe near the hepatic hilus and had a uniform cut surface without hemorrhage or necrosis. The bile duct of left hepatic lobe was also dilated with a maximum circumference of 0.9 cm. Histologically, the pancreatic tissue consisted of acinar cells and centroacinar cells, and ductal elements were often situated around the acini (Figure 2A). The acinar cells contained eosinophilic granules (Figure 2B). The histological diagnosis was consistent with a moderately differentiated adenocarcinoma arising from intrahepatic heterotopic pancreas (Figure 2C and D).

DISCUSSION

Heterotopic pancreas was firstly described in 1727 by Jean Schultz and lacked anatomic or vascular connection with the main body of the pancreas. Although pancreatic heterotopia can be found virtually anywhere along the gastrointestinal tract, the most frequent sites are the stomach (27.5%), duodenum (25.5%), and jejunum (15.9%)[3]. It is also observed less frequently in the esophagus, spleen, gallbladder, biliary tract, liver and lung. Up to now, only eight cases of intrahepatic heterotopic pancreas have been reported, including a case of insular carcinoma probably arising from intrahepatic heterotopic pancreas[6], a case of hepatic and extrahepatic choledochal cysts[7], a case presenting as hepatic mass[8], a case of primary cholesterol hepatolithiasis[9,10], a case found in autopsy liver specimens[11], a case of cirrhosis[12], and a case of Caroli's disease[13].

In 1909, Heinrich *et al*[14] classified heterotopic pancreas into three types. Type I is defined by the presence of ducts, acini and endocrine islets similar to those seen in normal pancreatic tissues. Type II contains a large number of acini, a few ducts and no islets. Type III is characterized by the presence of numerous ducts, a few acini, and no islets. The histological classification of the ectopic pancreatic tissue in the present case is type II, consisting of acini and a few ductal components.

Heterotopic pancreas is often found incidentally during surgery or endoscopy or clinically silent and benign. Malignant transformation in heterotopic pancreas is extremely rare. Thirty-one well-documented cases of carcinoma arising in a heterotopic pancreas were reviewed by

Figure 2 Histopathology shows the heterotopic pancreas and ductal adenocarcinoma arising from heterotopic pancreas. A: Histopathology showing the pancreatic tissue consisting of acinar cells and ductal elements [hematoxylin and eosin (HE), × 4]; B: Histopathology showing the acinar cells containing eosinophilic granules (HE, × 10); C: The solid area showing ductal adenocarcinoma arising from heterotopic pancreas with nerve infiltration (HE, × 4); D: The solid area showing ductal adenocarcinoma arising from heterotopic pancreas with nerve infiltration (HE, × 20).

Goodarzi[5]. The results showed that most tumors in the heterotopic pancreatic tissues occurred in the stomach and most of them were adenocarcinomas. The present case is the first case of adenocarcinoma arising from the intrahepatic heterotopic pancreas. Guillou *et al*[15] suggested that three criteria should be met for a carcinoma to be diagnosed as arising from the heterotypic pancreas. First, the tumor must be within or near the ectopic pancreatic tissue. Second, transition between pancreatic tissue and carcinoma must be observed. Third, the nonneoplastic pancreatic tissue should comprise acini, epithelial and ductal structures. The present case satisfied these three criteria.

A potential confusion is a primary intrahepatic cholangiocarcinoma with unrelated pancreatic heterotopia of the liver, which may happen if the heterotopic pancreas is completely replaced by the adenocarcinoma or if the presence of pancreatic tissue can not be confirmed due to sampling. Furthermore, primary intrahepatic cholangiocarcinoma is associated with intrahepatic bile duct stones and chronic infection in most cases. Zhang *et al*[16] also demonstrated that the adenocarcinoma can arise from heterotopic pancreas. Extensive sampling of the specimen and a high index of suspicion for carcinoma arising from heterotopic pancreas can avoid this diagnostic confusion.

In conclusion, malignant transformation in heterotopic pancreas is extremely rare. Extensive sampling of the specimen and a high index of suspicion for carcinoma arising from heterotopic pancreas can provide accurate diagnosis.

Abstract

The outpatient-based study by Deng *et al* [*World J Gastroenterol* 2011 July 14; 17(26): 3133-3139] on the factors that may influence the colorectal cancer (CRC) screening feasibility, encouraged our curiosity. Establishing a simple method for quickly assessing the educational level of patients and modulating a questionnaire for each type of patient, may be an effective protocol to increase the people participation, mainly in countries where sufficient medical resources and financial support are lacking. In fact, the knowledge directly affects the feasibility when screening is offered. Patient educational level influences the understanding of the knowledge and the screening method. This factor may affect patient's priority level on the study participation, the understanding of questions, and the motivation to complete the questionnaire and, consequently, the screening success. Recent studies have found a relationship between high educational level and CRC screening participation, and emphasized the questionnaire ineffectiveness in the illiterate people. Although the questionnaire is an excellent method for this kind of evaluation, physician's contribution could be the most important factor associated with the screening method. Thus, further studies should be conducted to explore the compliance of patients with low educational level and to look for the best solutions for their enrollment.

TO THE EDITOR

We read with great interest the study by Deng *et al*[1] on the factors that may influence the colorectal cancer (CRC) screening feasibility [*World J Gastroenterol* 2011 July 14; 17(26): 3133-3139]. We strongly agree with the authors about the importance of CRC screening knowledge. Indeed, this study shows that a better knowledge leads patients to choose the most accurate test. However, although the questionnaire is an excellent method for this kind of evaluation, bias could affect the results. Thus, the educational level plays a key role in the understanding of questions and the response accuracy. On this regard, we noted that only 6.9% of patients had a low educational level. This factor may affect the patient's priority level on the study participation, the understanding of questions, the motivation to complete the questionnaire and, consequently, the screening success. In order to get a true picture of the screening results, the percentage of patients with low educational levels should be similar to the other two educational classes of patients. Thus, it would be interesting to know the educational class distribution in sections of "not responding" (14.25%) and "unfilled" (28 patients). In a recent study, Garcia *et al*[2] found a relationship between high educational level and CRC screening participation. In the illiterate people, the questionnaire had a reduced efficacy. In addition, von Wagner *et al*[3] demonstrated that lower

health literacy had a direct impact on information-seeking. For these reasons, a variation of the questionnaire design would be useful based on the literacy level[4].

On the other hand, the study of Deng *et al*[1] is associated to a series of studies that emphasize the impact of socioeconomic and cultural factors on the CRC screening feasibility[5,6]. Sung *et al*[7]'s study, which refers to an "ostrich" strategy of the Chinese population, asserts that in a society as the Chinese one, where the public knowledge of CRC is poor, a physician's recommendation is the most important factor associated with the acceptance of CRC screening. Even though in this study[7], the percentage of respondents with a low educational level is significantly low (17.5%). In my opinion, the physician's recommendation, becomes more significant, especially in the population that requires more assurances to be convinced. Thus, this finding is true for various communities worldwide[8-10]. In fact, people with low educational level are less willing to the interview participation.

In conclusion, the protocol used in the study by Deng *et al*[1], is correct to get a greater adherence to the CRC screening. In this regard, it would be appropriate to study, even in multicenters, the difference in terms of adherence to the CRC screening among people who would accept physician's recommendation or other kinds of communications.

World Journal of Gastroenterology

INSTRUCTIONS TO AUTHORS

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

World Journal of Gastroenterology

Instructions to authors

Editor-in-chief
Ferruccio Bonino, MD, PhD, Professor of Gastroenterology, Director of Liver and Digestive Disease Division, Department of Internal Medicine, University of Pisa, Director of General Medicine 2 Unit University Hospital of Pisa, Via Roma 67, 56124 Pisa, Italy

Myung-Hwan Kim, MD, PhD, Professor, Head, Department of Gastroenterology, Director, Center for Biliary Diseases, University of Ulsan College of Medicine, Asan Medical Center, 388-1 Pungnap-2dong, Songpa-gu, Seoul 138-736, South Korea

Kjell Öberg, MD, PhD, Professor, Department of Endocrine Oncology, Uppsala University Hospital, SE-751 85 Uppsala, Sweden

Matt D Rutter, MBBS, MD, FRCP, Consultant Gastroenterologist, Senior Lecturer, Director, Tees Bowel Cancer Screening Centre, University Hospital of North Tees, Durham University, Stockton-on-Tees, Cleveland TS19 8PE, United Kingdom

Andrzej S Tarnawski, MD, PhD, DSc (Med), Professor of Medicine, Chief Gastroenterology, VA Long Beach Health Care System, University of California, Irvine, CA, 5901 E. Seventh Str., Long Beach, CA 90822, United States

SPECIAL STATEMENT
All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (n). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present P values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words
Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text
For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations
Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables
Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations
Data that are not statistically significant should not be noted. $^aP < 0.05$, $^bP < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^cP < 0.05$ and $^dP < 0.01$ are used. A third series of P values can be expressed as $^eP < 0.05$ and $^fP < 0.01$. Other notes in tables or under illustrations should be expressed as ^1F, ^2F, ^3F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

REFERENCES
Coding system
The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI
Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.cross-ref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references
Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634   DOI: 10.3748/wjg.13.5396].

Style for book references
Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data
Write as mean ± SD or mean ± SE.

Statistical expression
Express t test as t (in italics), F test as F (in italics), chi square test as χ^2 (in Greek), related coefficient as r (in italics), degree of freedom as υ (in Greek), sample number as n (in italics), and probability as P (in italics).

Units
Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations
Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics
Quantities: t time or temperature, c concentration, A area, l length, m mass, V volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation
The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form
Please download a Copyright assignment form from http://

www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers
Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support
For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript
WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases
Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee
WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

ABOUT COVER

Editorial Board Member of *World Journal of Gastroenterology*, Alessandro Fichera, MD, FACS, FASCRS, Associate Professor, Program Director Colon and Rectal Surgery Training Program, Department of Surgery, University of Chicago Medical Center, 5841 S. Maryland Ave, MC 5031, Chicago, IL 60637, United States

AIM AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol, WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

Occult hepatitis C virus (HCV) infection, defined as the presence of HCV RNA in liver and in peripheral blood mononuclear cells (PBMCs) in the absence of detectable viral RNA in serum by standard assays, can be found in anti-HCV positive patients with normal serum levels of liver enzymes and in anti-HCV negative patients with persistently elevated liver enzymes of unknown etiology. Occult HCV infection is distributed worldwide and all HCV genotypes seem to be involved in this infection. Occult hepatitis C has been found not only in anti-HCV positive subjects with normal values of liver enzymes or in chronic hepatitis of unknown origin but also in several groups at risk for HCV infection such as hemodialysis patients or family members of patients with occult HCV. This occult infection has been reported also in healthy populations without evidence of liver disease. Occult HCV infection seems to be less aggressive than chronic hepatitis C although patients affected by occult HCV may develop liver cirrhosis and even hepatocellular carcinoma. Thus, anti-HCV negative patients with occult HCV may benefit from antiviral therapy with pegylated-interferon plus ribavirin. The persistence of very low levels of HCV RNA in serum and in PBMCs, along with the maintenance of specific T-cell responses against HCV-antigens observed during a long-term follow-up of patients with occult hepatitis C, indicate that occult HCV is a persistent infection that is not spontaneously eradicated. This is an updated report on diagnosis, epidemiology and clinical implications of occult HCV with special emphasis on anti-HCV negative cases.

Key words: Occult hepatitis C virus; Hepatitis C virus RNA; Liver; Peripheral blood mononuclear cells; T-cell response

INTRODUCTION

The hepatitis C virus (HCV), an enveloped single-stranded RNA virus, was identified in 1989 and it was classified within the Flaviviridae family as a separate genus (Hepacivirus)[1]. The virus replicates by the synthesis of the complementary RNA strand (the so-called negative or antigenomic strand)[2]. So far, six major genotypes (HCV-1 to HCV-6) have been described, each containing multiple subtypes[3], with significant differences in their global distribution and prevalence[4]. It is estimated that about 170 million people, 3% of the world's population, are infected with HCV[5] and it is a leading cause of chronic liver disease worldwide including cirrhosis and hepatocellular carcinoma[6,7]. The diagnosis of HCV infection is made by the detection of antibodies against HCV (anti-HCV) and/or by detecting the presence of the HCV RNA in serum[7,8].

However, a new entity of HCV infection was first described in 2004 in patients with persistently elevated liver function tests and who were anti-HCV and serum HCV RNA negative[9]. Despite the absence of conventional HCV markers, 57% of these patients had HCV RNA in the liver and so this clinical situation was termed "occult HCV infection". Moreover, it was proven that the antigenomic HCV RNA strand could be detected also in the hepatocytes of a high proportion of those patients with occult HCV infection, this indicating an active viral replication. Occult HCV infection has also been described in two other different clinical settings. One of these is in anti-HCV positive, serum HCV-RNA negative subjects with persistent normal values of liver enzymes (asymptomatic HCV carriers), of whom nearly 90% have detectable viral RNA in liver and in peripheral blood mononuclear cells (PBMCs)[10-12]. The second one is in anti-HCV positive individuals who resolved HCV infection either spontaneously or after antiviral treatment[13-16]. In these patients, HCV RNA is detected in liver and in PBMCs years after apparent recovery from the disease (normalization of liver enzyme values and loss of serum HCV RNA). This occult HCV infection is related to the persistence of necroinflammation activity in the liver of the sustained responders. Thus, there are two types of occult HCV infection: one can be found among anti-HCV seropositive individuals with normal values of liver enzymes and the other is found among anti-HCV seronegative patients with abnormal levels of liver enzymes. The present review focuses on the latest studies of occult HCV infection performed in anti-HCV negative and serum HCV RNA negative patients.

IDENTIFICATION OF OCCULT HCV INFECTION

Occult HCV infection was first identified in liver of anti-HCV and serum HCV RNA negative patients with abnormal liver function tests and it was also found that viral RNA could be present in the PBMCs of nearly 70% of these patients[9]. Furthermore, it was demonstrated that occult HCV replicates in these cells[17]. By detecting HCV RNA in liver biopsies or in PBMCs, other groups in Japan, Italy, Egypt, Colombia, Pakistan and Iran[18-23] have confirmed the existence of occult HCV infection in patients with elevated liver enzymes and without conventional HCV markers (Table 1). Occult HCV infection has also been found in hemodialysis patients who were persistently anti-HCV and serum HCV RNA negative but with abnormal values of liver enzymes[24], in the family setting of patients with occult hepatitis C[25] and even in healthy subjects with normal alanine aminotransferase (ALT) levels and no clinical evidence of liver disease[26].

Since HCV was replicating in the liver and PBMCs of patients with occult HCV infection, it was speculated that it should exist as circulating viral particles but at such low levels that the virions could not be detected even using the most sensitive reverse-transcription polymerase chain reaction (RT-PCR) techniques. This hypothesis was tested by concentrating HCV virions by ultracentrifugation of 2 mL of serum from patients with occult HCV prior to HCV RNA detection by RT-PCR[27]. In this way, serum viral RNA was found in nearly 60% of the patients. In addition, it was found that the density of the viral particles isolated from patients with occult HCV infection was similar to the highly-infectious lipoviral particles present in the serum of patients with classical chronic hepatitis C[27,28], suggesting that serum from patients with occult HCV is potentially infectious.

HCV-SPECIFIC T-CELL RESPONSES AND THE OCCULT INFECTION

Functional virus-specific memory CD4[+] and CD8[+] T-cells have been documented in the circulation of patients with HCV RNA persistence in the liver and so assaying cellular immunity has been proposed as a surrogate marker of occult HCV infection[29,30]. To test HCV-specific T-cell responses, PBMCs isolated from fresh heparinized venous blood by gradient centrifugation are washed twice in phosphate-buffered saline and resuspended in RPMI-1640 medium, supplemented with 10% heat-inactivated fetal bovine serum, 20 mmol/L HEPES, 2 mmol/L glutamine and antibiotics. PBMCs are cultured in triplicate (1.0×10^5 viable cells/100 μL) in flat-bottomed 96-well culture plates at 37 ℃, 5% CO_2 and humidity in the presence or absence of 1 μg/mL HCV proteins core, NS3 and NS4; *Staphylococcus aureus* enterotoxin B (10 μg/mL) is used as positive control. On day 6, cultures are pulsed with 1 μCi/well of 3H-thymidine for 16 h and then harvested and transferred to filters and the incorporated radioactivity measured[31].

T-cell responses found in occult HCV infection are similar to those described in anti-HCV-positive patients following spontaneous or treatment-induced recovery[32-34]. HCV-specific T-cell responses have been detected often among occult HCV-infected hemodialysis patients[35], family members of patients with occult or overt HCV infection[36] and among HCV-seronegative sexual partners of patients with chronic hepatitis C (Aguilar-Reina J, personal communication), supporting exposure to trace amounts of HCV RNA. The maintenance of such immune responses may require only a low level productive infection. In fact, sporadic reappearance of minute amounts of HCV RNA stimulates cellular immunity[37]. However, persistence of occult HCV in face of adaptive cellular responses indicates that the latter do not ultimately result in sterilising immunity. The actual impact on the natural history of the occult infection is still a matter of debate. Indeed, HCV-specific T-cell responses have been described in apparently healthy persons, as well as in those who likely have resolved the infection or who have been exposed to, but who apparently did not became infected by, HCV[30]. To summarize, T-cell responses are more frequent and stronger compared with chronic hepatitis C patients[29], contributing to control the

Table 1 Prevalence and hepatitis C virus genotype distribution of occult hepatitis C virus infection

Type	Country	Prevalence[1]	Genotype	Cohort/setting	Ref.
Anti-HCV negative					
	Spain	57/100 (57%)	1b	Cryptogenic chronic hepatitis	[9]
	Japan	Not applicable	Not reported	Cryptogenic cirrhosis with HCC	[18]
	Italy	2/5 (40%)	Not reported	Cryptogenic cirrhosis with HCC	[19]
	Egypt	4/40 (10%)	Not reported	Cryptogenic chronic hepatitis	[20]
	Colombia	Not applicable	1a	Liver retransplantation	[21]
	Pakistan	23/31 (74%)	1a, 3a, 3b	Cryptogenic chronic hepatitis	[22]
	Iran	7/69 (10%)	1a, 1b, 3a	Cryptogenic chronic hepatitis	[23]
	Italy	9/276 (3.3%)	1a, 1b, 2a	General population without liver disease	[26]
Anti-HCV positive					
	United States/Poland	11/11 (100%)[2]	1a, 1b	Asymptomatic anti-HCV carrier	[10]
	Cuba/Mexico	17/18 (94%)	Not reported	Asymptomatic HCV carrier and therapy response	[11]
	Spain	10/12 (83%)	1b	Asymptomatic anti-HCV carrier	[12]
	Canada	16/16 (100%)[2]	1a, 1b, 2a	Spontaneous recovery and therapy response	[13]
	United States/Poland	15/17 (88%)[2]	1a, 1b, 2a, 3a	Therapy response	[14]
	Spain	19/20 (95%)	1b, 2, 3	Therapy response	[15]
	Canada	24/24 (100%)[2]	1, 1a, 3a	Therapy response	[16]
	Egypt	7/62 (11%)	Not reported	Therapy response	[20]

extent of the infection and thus prevent HCV RNA detection in serum.

HUMORAL IMMUNITY TO HCV DURING THE OCCULT INFECTION

It is unknown how HCV persists in persons who remain anti-HCV non-reactive by currently available antibody screening tests[38]. Antibodies to HCV proteins usually develop within 4-12 wk following exposure to the virus, those directed to the core and non-structural-3 region being the earliest and more frequently detected. Anti-HCV continues to be detectable throughout the duration of the infection although antibody reactivity declines over time after apparent clinical recovery of chronic hepatitis C[39-41]. In immunocompetent individuals, the etiology of the primary occult HCV infection is most likely explained by the sporadic exposure to low infective virus doses resulting in a latent seronegative infection. Thus, anti-HCV reactivity remains undetectable due to prolonged very low antibody titres[38], excluding persons with immunodeficiencies, immunosuppressed or suffering from a concomitant chronic infection.

Isolated reactivity to single proteins or peptides has been reported on supplemental anti-HCV assays in blood donors in samples which are either HCV RNA-positive or -negative[42,43]. Such pattern of anti-HCV indeterminate results resembles the profile of antibody reactivity documented in some international seroconversion panels when tested on supplemental anti-HCV assays. These panels are composed of sequential samples from a single-source donor obtained throughout the antibody development which frequently show single-antigen reactivity at the initial stages of anti-HCV seroconversion. In addition, reactivity recorded as "faint band(s)" has been shown among at risk persons but

seronegative by screening anti-HCV tests[44]. At this point the criteria recommended by the supplier of the supplemental assay to validate the testing as reactive or anti-HCV-positive *vs* indeterminate result should be discussed. But this issue would require a thorough comparison of the HCV antigens employed by the licensed tests and the interpretation of their reactivity in particular populations, which is out of the scope of this review and deserves future investigation.

The majority of persons exposed to HCV who become infected and seroconvert to anti-HCV remain asymptomatic. Up to 80% of seropositive infections are not diagnosed because persons belong to low, or supposedly null, risk groups. Screening programs in the general population would promote awareness and prevention of HCV spread because seropositive persons may be identified and offered appropriate counselling. However, this strategy still will not identify the seronegative infections using the current screening anti-HCV tests, as evidenced by the existence of the primary occult HCV infection.

In an attempt to overcome this, an anti-HCV assay based on a well-conserved core-derived epitope has been reported recently[45]. Briefly, wells of a microtitre plate are coated overnight with HCV-core 5-19-peptide. Wells are washed and non-specific sites are blocked with phosphate buffer saline containing Tween-20 plus heat-inactivated fetal bovine serum. Diluted serum samples are added to the HCV-core coated wells and after incubation for 1 h, wells are washed five times and incubated with horseradish peroxidase-conjugated rabbit polyclonal anti-human IgG for 1 h. After five washings wells are reacted in the dark with 2, 20-azinobis-[3-ethylbenzthiazoline-6-sulfonic acid]-diammonium salt. Absorbance is measured at 405 nm with a reference at 620 nm. In contrast to the NS3 sequence which shows considerable inter-genotypic heterogeneity[46], the core sequence is largely conserved

among genotypes 1 through 6[47]. Antibody to HCV core was tested in a cohort of 145 anti-HCV screening-negative patients with occult HCV infection of whom 40% were found to be anti-HCV core-positive, including 10% of individuals who were antibody non-reactive at the time of the first sample testing. Also, the anti-HCV core was detected in 99% of chronic hepatitis C patients but in none of the patients with HCV-unrelated liver disease. Thus, anti-HCV core testing allowed serological identification of up to 40% of the anti-HCV screening-negative infections on repeated testing[45]. The finding that a number of patients with occult infection who were initially nonreactive for anti-HCV core antibodies became positive upon subsequent testing underscores the necessity of screening serial samples as proposed by other authors[32,48].

In addition, the anti-HCV core assay has been able to track HCV exposure among relatives of patients with occult HCV. Intrafamilial spread of occult HCV infection seems to occur as often as that of chronic hepatitis C[25]. So, anti-HCV core was detected in 23% anti-HCV-screening-negative relatives of patients with occult HCV infection. Thus, antibody testing to HCV core detected frequent exposure to and possible transmission of HCV among family members of HCV-infected patients compared with screening anti-HCV tests[36]. On the other hand, because patients undergoing hemodialysis are at risk of occult HCV infection[24,35], testing for anti-HCV core has been evaluated in repeatedly anti-HCV screening-negative and serum HCV RNA-negative hemodialysis patients with abnormal liver enzymes. Anti-HCV core antibodies were detectable in 34% hemodialysis patients who have been exposed to HCV and who might have developed occult HCV infection (unpublished results).

Therefore, anti-HCV fails to be detected by screening tests available in some populations of at-risk patients[49], including those individuals multi-exposed such as intravenous drug users or prison inmates[44,50-52]. The ultimate utility of the anti-HCV core-based antibody assay in those cases and other settings such as blood donors warrants further investigation.

MAY OCCULT HCV INFECTION BE DIAGNOSED WITHOUT A LIVER BIOPSY?

Detection of HCV RNA in the liver biopsy is the gold-standard method for the diagnosis of an occult HCV infection. However, as commented before, viral RNA is detectable in the PBMCs and in ultracentrifuged serum of patients with occult HCV[9,27] and anti-core HCV tested by a non-commercial enzyme-linked immunosorbent assay (ELISA) is also found in a substantial proportion of these patients[45]. Therefore, in a recent report it was determined whether all cases of occult HCV infection could be diagnosed without performing a liver biopsy by combining these methods[53]. A total of 122 patients, who were diagnosed of an occult HCV infection by the presence of viral RNA in a liver biopsy and with avail-

able serum samples and PBMCs were included in the study. Anti-core HCV (tested with the non-commercial ELISA) was found positive in 44/122 (36%) of the patients. After ultracentrifugation of serum samples, HCV RNA was found in 70/122 (57%) of the patients, while 74/122 (61%) had viral RNA in PBMCs. When combining the detection of anti-core HCV and the detection of HCV RNA in ultracentrifuged serum and in PBMCs, 91% of the patients (111/122) were positive for at least one of these markers. So, in the light of these results, occult HCV infection may be properly diagnosed in up to 91% of the patients without the need to perform a liver biopsy by testing for anti-core HCV and for HCV RNA in ultracentrifuged serum and in PBMCs.

In summary, when occult HCV infection is suspected and a liver biopsy is not available for HCV RNA detection, the diagnosis can be made by testing, with a highly sensitive real-time PCR technique, for the presence of viral RNA in PBMCs (that identifies between 60%-70% of the cases)[9,53] or in ultracentrifuged serum (that allows identification of occult HCV in around 60% of the patients)[27,53]. The combination of these two approaches along with the detection of anti-core HCV improves the diagnosis of occult HCV infection in more than 90% of the cases. Nevertheless, in order to increase the percentage of patients diagnosed of occult HCV infection with non-invasive methods, more studies should be done in the future to improve the sensitivity of the above mentioned techniques.

CHARACTERISTICS OF OCCULT HCV INFECTION AND RESPONSE TO ANTIVIRAL TREATMENT

Clinical characteristics of patients with occult HCV infection have been compared to those of patients with chronic hepatitis C matched with respect to age, gender and known duration of the disease[54]. In the study it was found that patients with occult HCV presented significantly lower values of iron, alanine aminotransferase, γ-glutamyl transpeptidase and α-fetoprotein whereas triglycerides and cholesterol levels were significantly higher than those of patients with chronic hepatitis C. In the liver biopsies, patients with chronic hepatitis C frequently had more necroinflammation activity (96%) and fibrosis (75%) than patients with occult HCV infection (31% and 15%, respectively), but liver cirrhosis was diagnosed with a similar frequency in both groups (4.4% in occult HCV *vs* 7.2% in chronic hepatitis C). Although cholesterol and triglyceride levels were significantly higher in patients with occult HCV infection than in patients with chronic hepatitis C, the percentage of cases with liver steatosis did not differ significantly between these two groups, suggesting that dyslipidemic disorders did not play a predominant role in the development of steatosis in patients with occult HCV. So, occult HCV infection seems to be a milder form of the disease caused by HCV with less liver damage. However, it is important to point out that

occult HCV may lead to liver cirrhosis and therefore to the development of hepatocellular carcinoma. Regarding this issue, the presence of viral RNA in the tumour and non-tumour tissue of anti-HCV and serum HCV RNA negative patients with liver cancer has been reported[18,19]. Nevertheless, the number of patients analyzed in these reports was low and further studies are needed to ascertain the role of occult HCV in causing hepatocellular carcinoma.

Taking into account that patients with occult HCV present with abnormal liver function tests and may have histological damage, a study was conducted to determine whether these patients could respond to antiviral treatment with pegylated-interferon (PEG-IFN) plus ribavirin[55]. A total of 10 patients with occult HCV genotype 1b infection (anti-HCV and serum HCV-RNA negative but HCV RNA positive in liver) who were HCV RNA positive in PBMCs, had abnormal values of alanine aminotransferase for at least 12 mo and had necroinflammatory activity in a liver biopsy performed within one year before the study entry, were treated with standard doses of PEG-IFN plus ribavirin for 24 wk. The patients received a 24-wk treatment course instead of the recommended 48-wk course for HCV genotype 1 because they were serum HCV RNA negative[56-58]. After treatment, patients were followed for 24 wk. At the end of therapy, 80% of the patients had normalized ALT values and were HCV RNA negative in PBMCs, but at the end of the post-treatment follow-up, only 3 cases remained with normal ALT values and without HCV RNA in PBMCs (complete responders). Five of the patients (2 of them with a complete response) underwent a second liver biopsy at the end of the follow-up period. Necroinflammatory activity and fibrosis scores had decreased in the post-treatment liver biopsy of 3 patients, while scores in the other 2 cases remained unchanged. Viral RNA persisted in the liver of the 5 patients but HCV RNA load was significantly lower in the post-treatment biopsy than in the basal one. Thus, treatment with PEG-IFN plus ribavirin may be beneficial in patients with occult HCV because intrahepatic HCV RNA load decreases and histological liver damage may improve but, as it has been described for chronic hepatitis C[13-16], occult HCV infection is not eradicated.

In conclusion, although occult HCV infection appears to be milder than "classical" chronic hepatitis C, liver fibrosis is present in up to 5% of the patients[4,42]. In addition, necroinflammatory activity is detected in the liver of nearly 35% of the cases[9,54]. This suggests that occult HCV infection may progress to a more serious chronic liver injury. Supporting this notion is the fact that occult HCV infection has been identified in patients with liver cirrhosis and even in hepatocellular carcinoma[18,19]. Thus, the treatment of patients with occult HCV infection with PEG-IFN plus ribavirin is a reasonable option, as it is proven for chronic hepatitis C[59] because the histological liver damage may improve with treatment. However, the infection is not completely eradicated, as described for patients with chronic hepatitis C who respond to antiviral treatment[13-16].

IS OCCULT HCV A TRANSIENT OR A PERSISTENT INFECTION?

In order to determine whether occult HCV infection remains over time, we have performed a study including 37 patients who were anti-HCV and serum HCV RNA negative but with viral RNA in the liver biopsy[60]. Patients were followed for a mean time of 55 mo and serum and PBMCs samples were collected periodically for HCV RNA testing. Evidence of viral persistence in patients with occult HCV infection was found by the detection (over the observational period) of intermittent or persistent HCV RNA positivity in the ultracentrifuged serum or in PBMCs in all but one patient. These results suggest that anti-HVC negative occult HCV is a permanent infection as it has been reported in anti-HCV positive patients who resolved HCV infection[16,61]. Nevertheless, in order to extend the knowledge in the natural history and the pathogenesis of occult HCV infection, a more prolonged follow-up is needed.

GENOTYPES OF OCCULT HCV INFECTION

In the initial studies of occult HCV infection the only HCV genotype detected was 1b[4,19,22]. This result was predictable because HCV genotype 1b is the most prevalent genotype in Spain[62,63]. However, later studies performed worldwide (Table 1) have reported occult HCV infection belonging to HCV genotypes 1a, 2a, 3a and 3b[21-23,26]. So, it can be assumed that occult HCV infection is a universal phenomenon and all genotypes may be involved in this infection. This hypothesis should be proven with several studies performed in countries with different prevalence of HCV genotypes.

ROLE OF OCCULT HCV INFECTION IN LIVER TRANSPLANTATION

In anti-HCV positive patients with occult HCV, the reactivation of HCV infection (with reappearance of serum HCV-RNA) is well documented in special clinical situations, such as immunocompromised patients, patients on long term chemotherapy for cancer or patients receiving immunosuppressive therapy (including those who have undergone liver, kidney or bone marrow transplant)[64-69]. By contrast, there are no studies of the serologically silent (anti-HCV negative) occult HCV infection in these settings, except for a reported case of occult HCV infection as the cause of a liver transplantation and retransplantation[21]. The patient was a 29-year-old man who was transplanted due to liver cirrhosis of unknown etiology. Ten months after the first liver transplant, the patient was retransplanted because of liver failure secondary to severe chronic cholestasis of unknown origin. Liver

samples of both explants were available for study. The patient has remained anti-HCV and HCV RNA negative in serum and plasma since the initial diagnosis, but viral RNA was detected in the liver tissue samples from the two explants. Furthermore, a phylogenetic analysis demonstrated that the HCV RNA isolated from the two liver samples belonged to genotype 1a. Although HCV RNA was undetectable in the PBMCs of the patient, he had an occult HCV infection and probably, the liver graft was infected by PBMCs.

This case suggests that occult HCV infection may play a role as an etiological agent of liver failure in transplanted patients. Also, this report strongly supports the need for performing studies not only in liver transplant, but also in other immunocompromised patients with unexplained elevation of liver enzymes to determine the real magnitude, clinical significance and long-term consequences of occult HCV infection.

OCCULT HCV INFECTION IN HEALTHY POPULATION WITH NORMAL LIVER ENZYMES

Although occult HCV infection was identified in patients with abnormal values of liver function tests, a recent work by De Marco *et al*[26] describes the existence of occult HCV infection among healthy people with normal alanine aminotransferase and normal aminotransferase values. These healthy subjects were enrolled in the frame of three different epidemiological studies: the Italy cohort series of the European Prospective Investigation into Cancer and Nutrition, the Turin Case-Control Bladder Cancer Study and the Italian project in Cervical Cancer Screening. Subjects were tested for anti-HCV and for HCV RNA in plasma and in PBMCs. All of them were anti-HCV and serum HCV RNA negative, but viral RNA was detected in the PBMCs of 9/276 (3.3%) healthy controls with normal liver enzymes. Interestingly, in the studied population, blood donors were over-sampled but the authors do not indicate if any of these blood donors had an occult HCV infection.

So, this work potentially has important implications. Thus, the frequency of occult HCV infection may be underestimated since until now this infection has been exclusively studied among patients with abnormal values of liver enzymes. In this sense, in the study of De Marco *et al*[26] the frequency of occult HCV infection in their health population was 3.3% *vs* the 2.7% prevalence of anti-HCV positivity detected in the general Italian population. Although the number of participants in the former study (276 subjects) should be increased, there is a potential risk for HCV spread from an occult HCV healthy population. Thus in blood donations, despite approaches to reduce the risk of leukocyte-related disease, such as leukodepletion, the efficacy in reducing the risk of transmitting viruses is still under debate[70]. Furthermore, as HCV RNA may be detected after ultracentrifugation of serum samples in more than 50% of patients with occult HCV

infection[27] and this test was not performed in the Italian study, it may be possible that healthy blood donors have HCV RNA in serum undetectable by conventional PCR assays. If this is the case, blood donors with occult HCV infection may potentially transmit this occult infection as it is undetectable by the current applied screening tests for HCV in blood banks. However, more studies should be performed in healthy subjects with normal liver enzymes and especially among blood donors to definitively establish the possible magnitude of this infection.

CONCLUSION

Occult HCV infection has been found in two different settings: in anti-HCV positive, serum HCV RNA negative patients with normal levels of liver enzymes and in anti-HCV negative, serum HCV RNA negative patients with abnormal liver function tests of unknown etiology. Occult HCV is distributed worldwide and all viral genotypes may be involved. Although seronegative occult HCV infection seems to be less aggressive than classical chronic hepatitis C, it has been detected in patients with liver cirrhosis and even in hepatocellular carcinoma. Occult HCV infection has been described also in a healthy population with no evidence of liver disease, indicating that this infection may be present in a wide spectrum of clinical situations. Further studies on the natural history and the clinical significance of occult HCV infection are needed to determine its global prevalence, infectivity, implication in causing extrahepatic diseases and its long-term complications in special circumstances such as immunocompromised patients.

Abstract

Inflammatory bowel diseases (IBDs) such as Crohn's disease are highly debilitating. There are inconsistencies in response to and side effects in the current conventional medications, failures in adequate drug delivery, and the lack of therapeutics to offer complete remission in the presently available treatments of IBD. This suggests the need to explore beyond the horizons of conventional approaches in IBD therapeutics. This review examines the arena of the evolving IBD nanomedicine, studied so far in animal and *in vitro* models, before comprehensive clinical testing in humans. The investigations carried out so far in IBD models have provided substantial evidence of the nanotherapeutic approach as having the potential to overcome some of the current drawbacks to conventional IBD therapy. We analyze the pros and cons of nanotechnology in IBD therapies studied in different models, aimed at different targets and mechanisms of IBD pathogenesis, in an attempt to predict its possible impact in humans.

Key words: Inflammatory bowel disease; Crohn's disease; Ulcerative colitis; Tumor necrosis factor-α; Nanomedicine

INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC) constitute the two principal components of inflammatory bowel diseases (IBDs), which occur as a result of dysregulated immune responses in genetically predisposed individuals due to various environmental conditions[1]. There are sufficient similarities in the pathological conditions in CD and UC that cause about 10% of IBD cases to be diagnosed as indeterminate IBD[2]. Nevertheless, CD and UC show discrete risk factors and dissimilar gene and protein expressions, which manifest distinctive pathophysiological mechanisms. CD exhibits a transmural inflammatory response and can be associated with granulomas, whereas UC usually shows mucosa-confined inflammation[2-8]. Genomic technologies are now being used to separate the effects of different susceptibility genes in the two diseases. For example, Wu *et al*[6] have studied 36 expression profiles of colonoscopic pinch biopsies from CD and UC patients. Affected genes, mostly related to interferon (IFN)-γ inducible T helper cell 1 (TH1) process and antigen presentation in CD patients, were differentially regulated, with the upregulation of 47 genes and downregulation of 30 genes. In contrast, the expression of genes from UC biopsies showed upregulation of 51 genes and downregulation of 81 other genes,

associated with biosynthesis, metabolism and electrolyte transport[6].

The common conventional medications currently in use to treat both CD and UC involve 5-aminosalicylic acid drugs, corticosteroids, immunosuppressive agents, biologic therapies and antibiotics[9], with a customary "step up" approach of starting with aminosalicylates and rising to corticosteroids and immunosuppressive agents in response to the persisting conditions of the disease. The more effective biological therapies are usually considered as a last option and only in case of refractory diseases, because their systemic action in the host often leads to adverse effects[10,11].

Nanomedicines are precise therapeutics established with the aid of nanotechnology to treat diseases at the molecular level[12]. The application of nanotechnology in medicine can be termed as nanomedicine. It is an evolving face of medicine that uses nanoparticulate carriers to deliver therapeutics targeted to specific cells, or constituents of cells or tissues. Studies have shown nanomedicines to be more beneficial than conventional medications, because their size leads to more effecting targeting, better availability at diseased tissues, and decreased adverse effects. Moreover, nanomedicines have been found to have similar or even better therapeutic impacts at lower drug concentrations than their conventional counterparts[12]. However, although the arena of nanomedicine appears to be encouraging for IBD therapy, concerns related to the impact of the nature of nanoparticles due to their size, shape, aggregation potential, and surface chemistry on the IBD gut need to be scrutinized[12,13], and investigations on the impact of nanomedicine in IBD therapy is currently in early stages. As targeted drug or biological delivery to sites of inflammation remains a crucial challenge in the current treatment of IBD[14], nanostrategies involving short interfering RNAs (siR-NAs), antisense oligonucleotides, nanomedicines delivered to the sites of malfunction in IBD can be a valuable therapeutic approach.

The RNA interference technique, notable for specificity, can be speculated to regulate the expression of proinflammatory cytokines and genes related to IBD at the mRNA level[15]. As the impact of noncoding RNAs and RNA silencing in gene modulation is known to be great[16], the use of siRNAs as drugs to silence proinflammatory genes is being scrutinized in various animal models of IBD. This strategy also reduces the chances of immune reactions usually associated with viral vectors[15,17,18]. Due to the potential importance of targeted therapy in IBD, this review is presented to explore the advancements in the prospects of nanomedicine in the modulation of gene expression and targeted therapeutics in IBD (Figure 1).

GENE AND PROTEIN MODULATIONS WITH NANO PROSPECTS

Amongst the key genes involved in IBD pathogenesis,

Figure 1 Graphical representation of nanoinvestigations in inflammatory bowel diseases models. IBD: Inflammatory bowel disease.

the function of tumor necrosis factor (TNF)-α in the mediation of inflammation in IBD is extensively acknowledged. Therefore, many biological therapies comprising monoclonal antibodies or soluble receptors are intended to reduce TNF-α activity, and have been extensively tested in many clinical trials[19-24]. However, there are adverse side effects due to the systemic depletion of TNF-α. These adverse effects involve amplified infusion reactions, immunosuppression, opportunistic infections and decreased efficacy of the biologics due to antibody formation against them[24-26].

The gene silencing nanostrategy, in which orally delivered TNF-α siRNA is encapsulated in thioketal nanoparticles (TKNs) made from the polymer poly-PPADT (1, 4-phenyleneacetone dimethylene thioketal), effectively decreases the levels of TNF-α mRNA levels at sites of intestinal inflammation in dextran sulfate sodium (DSS)-induced mouse models of UC. In this study, the site specific delivery of siRNA was made possible due to the ability of TKNs to degrade in the presence of higher levels of reactive oxygen species (ROS) present in regions of inflammation in the intestinal tissue[27]. In another study, TNF-α siRNA/polyethyleneimine (PEI) nanocomplex was shown to inhibit TNF-α secretion by macrophages *in vitro*, whereas the oral administration of TNF-α siRNA/PEI nanocomplexes in lipopolysaccharides (LPS)-treated mice models was found to reduce specifically the synthesis and secretion of TNF-α in the colon[28]. Nanoparticles in a microsphere oral system (Ni-MOS), comprised of TNF-α siRNA entrapped in type B gelatin enclosed in poly(ε-caprolactone) (PCL) microspheres, were found to exhibit favorable gene silencing in the colon tissues of DSS-treated murine models of UC. This treatment results in the suppression of proinflammatory cytokines such as interleukin (IL)-1β, IFN-γ, chemokine monocyte chemoattractant protein (MCP)-1, permitting an increase in body weight and diminished action of tissue myeloperoxidase in mouse models[29]. A protein modulation nanostrategy involving monovalent and bivalent murine TNF-α neutralizing nanobody proteins has been investigated in DSS-induced murine chronic colitis models. *Lactococcus lactis* engineered to produce the therapeutic nanobodies was orally administered, which

Figure 2 Nanomodulations whose efficacy has been validated in animal models of inflammatory bowel diseases. Genes regulated therapeutically by nano gene silencing in intestinal tissues and macrophages and protein nanobodies that have been investigated to have therapeutic impacts to help control inflammation and tissue destruction in animal models relevant to inflammatory bowel diseases (IBDs). TNF: Tumor necrosis factor; Map4k4: Mitogen-activated protein kinase kinase kinase kinase 4; MMP: Matrix metalloproteinase; NF-κB: Nuclear factor kappa B.

resulted in a significant reduction in the TNF-α driven inflammation in the mucosa of the colon in mouse models, without affecting considerable TNF-α levels in the systemic circulation[30].

Increased TNF-α suppresses the expression of the anti-inflammatory protein prohibitin (PHB) in IBD[31,32], therefore, a study by Theiss *et al*[33] considered the oral delivery of PHB entrapped in poly (lactic acid) nanoparticles in mouse models of DSS-induced colitis. This strategy inhibited the TNF-α-induced nuclear factor (NF)-κB activation; consequently curtailing inflammatory reactions and reducing the severity of colitis. Double-stranded decoy oligonucleotides (ODNs) against the proinflammatory NF-κB gene were enclosed in chitosan-modified poly (D,L-lactide-co-glycolide) nanospheres (CS-PLGA NSs) and delivered orally to DSS-induced murine colitis models. This study showed the absorption of the ODN-CS-PLGA NSs in inflamed mucosal regions, producing considerable curative effects on DSS-induced diarrhea, bloody feces, shortening of colon length, and myeloperoxidase activity[34].

Besides directly inhibiting the TNF-α gene in macrophages, macrophages more generally play a role in inducing the pathogenic inflammatory reactions[35]. This study has revealed the importance of mitogen-activated protein kinase kinase kinase kinase 4 (Map4k4) gene in macrophages in mediating the production of inflammatory cytokines. Map4k4 siRNA encapsulated in β1,3-D-glucan shells silenced Map4k4 expression *in vivo* in mice treated with LPS, protecting them from LPS-induced systemic inflammation by suppressing the production of TNF-α and IL-1β[35].

Matrix metalloproteinases (MMPs) play a vital role in tissue remodeling by regulating the intestinal tissue architecture during the inflammatory reactions and wound healing in IBD[36,37]. Studies have indicated the increased expression of MMP-3 (stromelysin-1) and MMP-10 (stromelysin-2) in causing enhanced tissue injury in DSS-induced murine colitis[38,39]. Furthermore, IBD patients have shown increased MMP-3 and MMP-10 expression in the gut and intestinal ulcer tissues[39-42]. Polymorphisms in various MMP genes may be susceptibility factors for IBD risk, at least in some populations[43]. A study by Kobayashi *et al*[39] demonstrated the specific inhibition of MMP-3 and MMP-10 by siRNA targeted against MMP-3 and MMP-10, having a therapeutic benefit in protecting the colon tissue and reducing the severity of colitis in DSS-treated murine models, which could therefore be a valuable gene silencing option to prevent intestinal damage in IBD (Figure 2).

Cyclin D1 (CyD1) is a cell cycle regulatory protein that is upregulated in IBD in both epithelial and immune cells[44]. A leukocyte-directed siRNA against CyD1 mRNA inhibits the intestinal inflammatory responses in murine models of DSS-induced colitis. Silencing the CyD1 gene decreases the induction of TH1 cell inflammatory cytokines TNF-α and IL-12, but has no impact on the production of TH2 cell cytokine IL-10[45]. Therapeutic efforts to enhance the action of the anti-inflammatory cytokine IL-10, which is known to be critically involved in maintaining mucosal immune balance due to its potent impact on immunosuppression[46] and involvement in CD pathogenesis[47,48], have been largely unsuccessful to date. This is thought to be due to the adverse side effects caused by systemic action of the IL-10 therapies, and the low concentrations of IL-10 delivered to the intestinal tissues[49]. Therefore, biologics intend-

ing to enhance cytokine IL-10 action have been dropped from the current IBD therapies[50]. However, because the involvement of IL-10 and its genetic variations in IBD is great[47,48,51], a consideration of the targeted study by Bhavsar *et al*[52], which involved the nanodelivery of IL-10-producing plasmid to the mucosa in murine models mimicking IBD intestinal epithelial pathogenesis[53] can be scrutinized. According to this study, trinitrobenzene sulfonic acid (TNBS)-induced acute colitis models in Balb/c mice were treated with NiMOS intended for oral gene therapy. This comprised the pORF5-mIL-10 plasmid DNA encapsulated in type B gelatin nanoparticles in PCL. This strategy directed the local transfection of IL-10 plasmid in inflamed intestinal tissues and caused its enhanced expression, which led to suppression of predominant proinflammatory cytokines such as IFN-γ, TNF-α, IL-1α, IL-1β and IL-12, consequently causing the therapeutic benefits of restored colon length and weight, increased body weight, and beneficial clinical activity score[52].

IMPLICATIONS OF IBD DRUGS GOING NANO

Nanomedicines comprising IBD drugs loaded onto nanoparticles, designed to cope and act in accordance with the pathophysiological changes in the intestinal tissues of IBD, can be an intelligent mode of targeted drug delivery. This approach offers the possibility of eliminating undesirable side effects usually caused by systemic action of the drugs[14]. The usual pathophysiological conditions related to inflamed intestinal tissues in IBD predominantly involve abnormal intestinal permeability, increased presence of immune cells, and higher levels of mucus production[54-56].

Cellular interaction of nanoparticles in the IBD gut

Nanomedicines in IBD can potentially be more efficient in their mechanism due to the cellular intake of the nanoparticles by the cells at the targeted sites of delivery. This means that they are not eliminated from the intestinal tract by diarrhea, as are many current conventional medications. This is an important IBD symptom[57,58]. Nanoparticles in the gastrointestinal tract are usually found to be adsorbed either by paracellular transport or endocytosis by regular epithelial cells[59]. Specialized differentiated epithelial cells called M cells, which form major populations of Peyer's patches are involved in the predominant uptake of nanoparticles through transcytosis[60,61]. Predominant CD mutations such as R702W, G908R and 3020insC have been associated with ileal-specific disease[62,63], which show an enhanced presence in Peyer's patches and M cells, which may cause an increase in the uptake of dietary and nanoparticulate substances[13]. In addition to these, translocation of nanoparticles in the intestinal tract can also occur by persorption through gaps or holes at the villous tips[64,65]. Cells involve the autophagic mechanism to cause the clearance

of nanoparticles[66], and Powell *et al*[13] have indicated that mutations in the autophagy gene *Atg16L1* in IBD subjects can be susceptible to possible alterations in the clearance of nanoparticles.

Investigations of IBD drugs in nanomodes

Furthermore, IBD drugs delivered in nanomodes have been shown to have greater therapeutic impacts as compared to their conventional delivery studied in animal models, For example, the anti-inflammatory IBD drug mesalamine (5-ASA) covalently linked to the PCL nanoparticles was found to be 60 times more efficient as a nanomedicine at much lower doses (0.5 mg/kg) than the free solution of 5-ASA (30 mg/kg) in treating TNBS-induced colitis in BALB/c murine models[67]. Moulari *et al*[68] have established that silicon nanoparticles have a sixfold increased ability to adhere to inflamed tissues when compared to tissues in healthy controls. In this study, 5-ASA loaded in its methylated form in silicon nanoparticles was shown to collect in inflamed regions in TNBS-induced murine colitis models, inducing a positive impact on clinical activity score and myeloperoxidase activity at reduced drug doses, as compared to conventional delivery[68]. An immunosuppressive drug tacrolimus, used to treat UC, was encapsulated in polylactic-co-glycolic acid (PLGA) nanoparticles and used to treat murine models of TNBS- and oxazolone-induced colitis. This study showed that nanomedicine had an augmented and specific action with a threefold increased penetration in inflamed tissues when compared to healthy tissues[69]. Also, tacrolimus-loaded PLGA nanoparticles and tacrolimus-loaded pH-sensitive Eudragit P-4135F nanoparticles showed diminished side effects in DSS-induced murine colitis models when compared to the free tacrolimus which causes nephrotoxicity in traditional delivery[70]. An anti-inflammatory tripeptide Lys-Pro-Val (KPV) loaded into polylactide (PLA) nanoparticles delivered in combination with a polysaccharide hydrogel had a similar anti-inflammatory effect at 12 000-fold lower doses (25.2 ng/d) to that of KPV in free solution (200 μg/d), thus demonstrating the greater therapeutic efficiency of the nanomode of the drug in treating DSS-induced colitis in murine models[71]. Nakase *et al*[72] demonstrated that dexamethasone, encapsulated in poly-DL-lactic acid (PDLLA) microspheres was more effective in ameliorating DSS-induced murine colitis when compared to the free solution of the same drug, because the microsphere form was engulfed by the immune cells in the inflamed colonic tissue, which resulted in increased efficiency of the drug in mouse models. An *ex vivo* study by Serpe *et al*[73] showed solid lipid nanoparticles (SLNs) comprising the anti-inflammatory molecule cholesteryl butyrate (chol-but) showed a greater impact than butyrate alone in significantly reducing proinflammatory cytokines such as IL-1β and TNF-α and increasing IL-10 production in whole blood *ex vivo* models of peripheral blood mononuclear cells (PBMCs) obtained from IBD patients taking no anti-inflammatory medications. Furthermore, this study demonstrated SLNs, consisting of the immunosuppres-

Table 1 Comparison of therapeutic parameters

Experimental system	Drug in nano mode	Comparison of differences in certain distinct therapeutic parameters		Ref.
		Nano mode	Controls	
In vivo TNBS-induced murine colitis	5-ASA covalently linked to PCL nanoparticles	Myeloperoxidase (MPO) activity of 5-ASA-NP at 0.5 mg/kg: 15.2 ± 5.6 U/mg	MPO activity of 5-ASA free solution at 30 mg/kg: 16.2 ± 3.6 U/mg	[67]
In vivo TNBS-induced murine colitis	5-ASA in silicon nanoparticles	MPO activity of 5-ASA-Si NP at 25 mg/kg: 5.2 ± 2.4 U/mg	MPO activity of 5-ASA-free solution at 100 mg/kg: 8.2 ± 3.4 U/mg	[68]
In vivo TNBS-induced murine colitis/oxazolone-induced murine colitis	Tacrolimus in PLGA NPs	Enhanced penetration into the inflamed tissue-FK506-NP, 105 ± 24 nmol/cm^2	Healthy tissue penetration-FK506-NP, 51 ± 13 nmol/cm^2	[69]
In vivo DSS-induced murine colitis	Tacrolimus in PLGA/or pH sensitive Eudragit P-4135F NPs	Diminished side effects	Increased susceptibility to nephrotoxicity	[70]
In vivo DSS-induced murine colitis	Anti-inflammatory tripeptide KPV in PLA NPs	Nanomode with lowered doses at 25.2 ng/d	Free solution has the similar anti-inflammatory impact at 200 μg/d	[71]
Whole blood *ex vivo* models of PBMCs	Dexamethasone in SLNs	90% reduction in proinflammatory cytokines IL-1β and TNF-α	25% reduction in TNF-α by the free solution	[73]
Whole blood *ex vivo* models of PBMCs	chol-but in SLNs	Significant decrease in IL-1β, and TNF-α increase in IL-10	-	[73]

NP: Nanoparticle; TNBS: Trinitrobenzene sulfonic acid; DSS: Dextran sulfate sodium; PBMCs: Peripheral blood mononuclear cells; 5-ASA: Mesalamine; KPV: Lys-Pro-Val; PLA: Polylactide; SLNs: Solid lipid nanoparticles; IL: Interleukin; TNF: Tumor necrosis factor; MPO: Myeloperoxidase; PLGA: Polylactic-co-glycolic acid.

sive corticosteroid dexamethasone, suppressed TNF-α by 90% when the free solution of dexamethasone showed a TNF-α suppression of 25% at the highest concentrations in similar whole blood IBD *ex vivo* models. These studies provide preliminary support for the effects of SLNs chol-but and SLN dexamethasone in inducing an enhanced anti-inflammatory activity, due to the more effective cellular intake of the nanodrug forms, as compared to the free drugs in solution (Table 1).

LIKELY CONCERNS OF GOING NANO

The general concern associated with the nano approach is due to the fact that nano-sized materials display altered physicochemical properties[74] as compared to their larger counterparts, with chances of causing possible toxicity, since nonbiological nanoparticulate carriers above a particle size of 100-200 nm can alter normal cellular activity, because they can invoke cell membrane ruffling, cytoskeletal rearrangement and stimulate endocytic machinery causing their ingression in phagocytic cells[75]. However, reliable data on the adverse impacts of nanomedicine in IBD is unavailable, whereas the impact of nanoparticles themselves in the gastrointestinal tract might vary according to the nanoparticle polymer material and nanoparticle size, as surface interactions and surface chemistry differ for different nanoparticle sizes. Also, different nanoparticle sizes can cause different mechanisms of cellular uptake, due to which, nanoparticle sizes can be modulated to cause different intracellular effects[13,76,77]. The studies on the effects of nanoparticles themselves in the human gastrointestinal tract in IBD have been limited and need to be explored further.

Although nanostrategies for IBD therapeutics inves-

tigated in animal and *in vitro* models of IBD have shown promise, it is still only the dawn of the era of interest in IBD nanomedicine, and there is a definite need for further extensive investigations on many issues related to the safety and uptake of the different nanomedical therapeutics acting on various pathways and phases in the human gastrointestinal tract. It is essential to be confident of their consequent impact on immune responses and therapeutic effects in the different genotypic populations, before recommending the clinical use of nanomedicines to treat IBD in humans.

Abstract

Spontaneous tumor regression has been subject of numerous studies and speculations for many years. This phenomenon is exceptional, but well reported, in some types of tumors, but not in pancreatic cancer. Pancreatic cancer has the worst five-year survival rate of any cancer. Despite numerous molecular studies and clinical approaches, using several mouse models, this cancer responds poorly to the existing chemotherapeutic agents and progress on treatment remains elusive. Although pancreatic cancer tumors seldom undergo spontaneous regression, and some authors take that with skepticism, there are some cases reported in the literature. However, the variability in the description of the reports and technical details could make this process susceptible to misdiagnosis. Distinguishing between different types of pancreatic carcinoma should be taken with caution as they have wide differences in malignant potential. Diseases such as pancreatic benign tumors, insulinomas, or autoimmune pancreatitis could be responsible for this misdiagnosis as a pancreatic cancer. Here we review different cases reported, their clinical characteristics, and possible mechanisms leading to spontaneous regression of pancreatic cancer. We also discuss the possibilities of misdiagnosis.

INTRODUCTION

Spontaneous tumor regression has been the subject of great interest and speculation for many years. It is an exceptional and well-documented biological event in some types of tumors, but not in pancreatic cancer.

Pancreatic cancer is a special form of cancer with the worst five-year survival rate of any cancer[1]. Despite numerous molecular studies and clinical approaches, using several mouse models[2], this cancer responds poorly to the existing chemotherapeutic agents and progress on

treatment remains elusive[3].

Pancreatic cancer is seldom described as undergoing spontaneous regression, but there are some cases reported in the literature.

In this review, the historical background, clinical features, and possible mechanisms are discussed for spontaneous regression of pancreatic cancer. In addition, we discuss whether it is a real phenomenon or a misdiagnosis.

Further understanding of this process and harnessing of the mechanisms involved will have significant diagnostic, preventative, and therapeutic implications.

HISTORICAL BACKGROUND AND CASES REPORTED FOR PANCREATIC CANCER

Spontaneous regression of cancer (SRC) is defined as the partial or complete disappearance of a malignant tumor in the absence of therapy that is capable of inducing anti-neoplastic effects. Although SRC has often been questioned, the literature reveals different cases showing this phenomenon. In 1966, Everson *et al*[4] published a classical monograph review describing 176 cases of SRC published from 1900 to 1964. In 1990, Challis *et al*[5] reported cases from 1900 to 1987, the majority of which occurred in renal cell carcinoma, choriocarcinoma, neuroblastoma, melanoma, breast cancer, and leukemia and lymphomas. Later, in 1993, O'Regan *et al*[6] agreed that the five most common tumors to undergo spontaneous regression are renal cell carcinoma, leukemia and lymphoma, neuroblastoma, carcinoma of breast and melanoma.

In these three main reviews, only three cases of pancreatic cancer were cited, and none of them were described in detail. Here, we review the most important cases of spontaneous regression of pancreatic cancer that have been reported in the literature. The first reported case was described in 1934 and published in 1967, describing a patient admitted to hospital presenting jaundice, severe pain, nausea, chills, and a high fever[7]. Laparotomy and biopsy confirmed pancreatic carcinoma. The patient's recovery spanned two months, after which she could return to work. She remained in good health, dying seven and a half years later of a pulmonary embolism. An autopsy did not find any tumors.

The second case was reported in 1973 by Lokich *et al*[8] and described a 42-year-old man with progressive diarrhea and weight loss. An upper image suggested a mass in the head of the pancreas. The patient underwent total pancreatectomy and microscopic examination reveled a moderately well differentiated ductal adenocarcinoma arising in the head of the pancreas. Adenocarcinoma was also found in the body of the pancreas, but the tail had only pancreatitis with fibrosis.

Although the patient was stabilized with insulin treatment, one year later he presented with rectal carcinomatosis consistent with adenocarcinoma of pancreatic cancer. Postoperatively, the patient received a combined chemotherapeutic program based on 5-fluorouracil (5-FU)

and carmustine or bis-chloroethylnitrosourea, experiencing a gradual regression. Twenty-six months following onset of therapy treatment, there was no evidence of tumor recurrence.

The third case[9] was a male with a two-month history of ulcer pain and diarrhea. At exploration, he was diagnosed with a large tumor of the pancreatic head, extending into the liver with involved lymph nodes. The disease was confirmed by biopsy but no further manipulation was performed. By the fourth month following surgery, he was asymptomatic. Examined six years later, the patient remained symptom-free and a gastrointestinal exam demonstrated healing of the ulcer.

The fourth case, published in 1974, reported one case in 1962 of a 21-year-old male who presented with jaundice, anorexia, and fever of three months duration[10]. A liver biopsy was followed by abdominal pain, fever, tachycardia, and a decrease in blood pressure. Exploratory surgery to repair bile peritonitis revealed acute cholangitis and pericholangitis. When he was re-operated on seven weeks later, and was diagnosed with pancreatic adenocarcinoma. A T tube placed in the common duct improved symptoms and he made a slow recovery with no recurrence at the time of reporting. Unfortunately, details on the duration and intensity of fever or infection over the course of the illness in most of these cases were not provided.

In 2003, Hoption Cann *et al*[11] reported a case of a 50-year-old man with a three-month history of weight loss, anorexia, and discomfort after meals. By ultrasound and computed tomography (CT) identified a hypoechoic mass of 6.5 cm × 4 cm × 4 cm in the body of the pancreas. The posterior CT-guided biopsy was positive for pancreatic adenocarcinoma (T2N1M0, stage Ⅲ b). A subsequent CT scan revealed a further 50%-60% increase in tumor volume and the tumor was considered inoperable. The patient received chemotherapy based on gemcitabine, mytomycin, and radiotherapy. As CA19-9 levels increased from 38 to 140 U/mL and the patient's health declined, the treatment was considered a failure. Some days later, the patient developed acute abdominal pain and fever and, after surgery, he had a perforated duodenal ulcer with contamination of the abdomen. Recovery was considered doubtful. However 90 d later, the patient's recuperation and weight gain were surprisingly rapid, while the CA19-9 level was normal and a positron emission tomography (PET) scan was negative for any focal disease. An ultrasound, however, confirmed residual tumor, although it had regressed by approximately 70%. However, five months later, an elevated CA19-9 and subsequent PET scan confirmed a relapse. Although the patient was treated with chemotherapy based on oxaliplatin and 5-FU initially, then gemcitabine, his health progressively deteriorated and he died one year later, almost two years following his febrile infection.

Apart from the infection, the authors suggested other factors could be relevant to this tumor regression. Some of them are the vegetarian diet based on Chinese herbs,

high-dose vitamin C and other antioxidant vitamins, hydrogen peroxide, and ginseng, followed by this patient. However, regression presented in this case appeared mostly to coincide with a prolonged febrile infection, similar to that often observed in many other cases of SRC[11,12].

BENIGN TUMORS

Some special types of pancreatic tumors are considered benign or their malignant potential is not well determined. Specifically, solid-pseudopapillary tumors are classified in this category and were often previously described in the literature as being related to spontaneous regression.

In 2008, Nakahara *et al*[13] described a 18-year-old healthy woman who was admitted to hospital for evaluation of a pancreatic mass. A solid-pseudopapillary tumor was suspected from the findings of diagnostic images, and surgery was recommended. However, the patient refused surgery and a later ultrasound-guided transcutaneous biopsy revealed proliferation of tumoral cells with small nuclei showing a pseudopapillary arrangement. periodic acid-Schiff positive granules and alpha-1-antitrypsin positive cells were proven, which led to confirmed diagnosis of pseudopapillary pancreatic tumor. The maximum diameter of the tumor gradually decreased over 10 years from 45 mm to 15 mm. This was the first report describing marked spontaneous shrinkage of this particular type of pancreatic tumor. The authors did not report details of whether the patient took any medication, antioxidant agent, or vitamins.

In this case, the authors showed histological findings and CT images suggesting that the shrinkage of the tumor may be attributable to continued degenerative change, including minor hemorrhage, necrosis, and absorption as the tumor was classified hypovascular.

In 2010, Suzuki *et al*[14] described a 13-year-old boy showing a demarcated hypovascular round mass of 50 mm in diameter in the head of the pancreas, presenting abdominal pain, nauseas, and elevated serum amylase and serum lipase. CT demonstrated a partially enhanced encapsulated tumoral mass with cystic components and calcification, without evidence of invasion to the surrounding organs, which was diagnosed as solid pseudopapillary tumor (SPT) and treated for acute pancreatitis. Six weeks later, the mass had decreased to 43 mm in diameter, and nine weeks after admission, concentrations of tumor markers, such as alpha-fetoprotein, carcinoembryonic antigen, carbohydrate antigen-199, and elastase-Ⅰ, were not elevated, although the level of neuron-specific enolase (NSE) was slightly increased. Follow-up included routine laboratory tests and CT demonstrated that the size of the tumor slowly decreased to non-measurable size. After 4 years, the patient's NSE level was within the normal range. The authors presented CT images indicating that the tumor was highly likely to be SPT, based on the typical CT finding of a tumor bulging from the contour of the pancreas with eggshell-like calcification, the existence of both solid and cystic components with hypovascularity, and the patient's age. The rapid shrinkage of the tumor may be attributable to continued degenerative changes, including minor hemorrhage due to trauma, necrosis, and absorption. The authors did not report the administration of any medication or different agents to the patient. The authors suggest spontaneous tumor shrinkage, although they were unable to obtain pathology for the tumor and are conscious that there have been reports of recurrence and metastasis that developed more than 10 years after tumor resection in this type of neoplasm.

Considering all of the cases reported above, we can distinguish a wide variation in the description of the data presented. The first cases reported, until 1980, do not show images or acute laboratory test results that could verify the real entity of spontaneous regression of pancreatic carcinoma. In some cases, they do not specify the type of pancreatic tumor or give details about the biopsy, making it difficult to determine if it would be classified as a different entity, based in current diagnostic criteria.

However, considering the difference in the availability of medical technology more than 30 years ago compared with the present, this data should be taken with caution, and it is difficult to conclude whether these cases would be considered as genuine spontaneous regression of pancreatic adenocarcinoma today or would be considered as misdiagnoses.

The most recent cases, published since 2000, are more accurate in the presentation of images and blood test values, although they also show variability.

Finally, the most recent report concludes a diagnosis of SPT and not adenocarcinoma of pancreas. All of these data show that there are no recent cases reported of spontaneous regression of adenocarcinoma of the pancreas, unlike pseudopapillary tumors, which represent 1% of primary pancreatic tumors and are characterized by low malignant potential[13,14].

Some other types of pancreatic tumors with spontaneous regression, rather than adenocarcinomas and peudopapillary tumors, have been described. The most common neuroendocrine tumor with spontaneous regression is an insulinoma.

Insulinoma is a rare endocrine tumor developed from pancreatic beta cells. Eighty-seven percent are benign tumors, seven percent belong to multiendocrine neoplasia syndrome, and only six percent are considered malignant, as defined by the presence of metastasis[15].

The diagnosis of insulinoma is established by demonstrating inappropriately high serum insulin concentrations during a spontaneous or induced episode of hypoglycemia. Imaging techniques are then used to localize the tumor[16]. In 2008, Groselj *et al*[17] described a 64-year-old patient presenting with paroxysmal episodes. Electroencephalography finding suggested metabolic encephalopathy and laboratory tests showed hypoglycemia, and high insulin and C-peptide. Finally, ultrasonography and gagnetic resonance imaging (MRI) confirmed an

insulinoma in the head of the pancreas. The authors pointed out that the patient had a spontaneous recovery of the pancreatic tumor.

The overall survival rate of patients with benign insulinoma do not differ from that expected in the general population, and a misdiagnosis could be a reasonable justification for reporting SRC, even if it is not considered a malignant phenotype. Malignant insulinomas are rare, and patients have prolonged survival, even in the presence of liver or lymph node metastasis. It has been reported that some patients with malignant insulinoma who developed metastatic disease 4 years to 12 years after initial diagnosis, remained alive for up to 25 years[18]. This better outcome compared to the acinar or ductal adenocarcinoma could be a reason for a misdiagnosis, or it could also be reported as a spontaneous regression of pancreatic cancer.

AUTOIMMUNE PANCREATITIS MIMICKING PANCREATIC CANCER

Autoimmune pancreatitis (AIP) was described by Sarles *et al*[19] in 1961 and then proposed by Yoshida *et al*[20] in 1995 as a type of chronic pancreatitis occurring secondary to an autoimmune process, which may cause permanent structural and functional damage of the pancreas.

AIP represents approximately 6% of the patients with chronic pancreatitis[21,22] and is a heterogeneous manifestation associated with elevated serum levels of the immunoglobulin G subtype 4 (IgG4), which decreases with corticosteroid therapy. The most common site of extrapancreatic involvement is the bile duct, where distal biliary or mass-forming AIP mimics pancreatic cancer and proximal biliary involvement[23]. Recently, two types of AIP have been described, type 1 (or lymphoplasmacytic sclerosing pancreatitis) and type 2 (idiopathic duct centric pancreatitis or granulocyte epithelial lesion). Although clinically these two entities have comparable presentations, they differ significantly in their demography, serological characteristics, other organ involvement, and relapse rate[24].

While type 1 is associated with elevation of nonspecific autoantibodies and serum IgG4 levels, type 2 does not have definitive serologic autoimmune markers. In addition, high serum IgG4 may also be found in patients with pancreatic cancer[25], and tumoral markers such as CA19-9, SPAN-1, and DUPAN-2 may also be elevated in patients with AIP[26]. These findings can make the diagnosis of AIP confusing. AIP, in contrast to other benign chronic pancreatic diseases, can be cured with immunosuppressant drugs[27]; therefore, the differentiation of AIP from pancreatic cancer is of particular interest in clinical practice[28]. Two studies have also pointed out the possibility that some patients with AIP may develop pancreatic cancer[29,30], and this contributes to increasing misdiagnosis. However, the synchronous presence of adenocarcinoma and AIP can not be excluded, as some cases have been reported[31] and pancreatic cancer can develop after histologically confirmed AIP diagnosis[32].

Attempting to establish applicable diagnostic guidelines, the Japan Pancreas Society[33], the Korean Society[34], and more recently American criteria by Chari *et al*[24] in the Mayo Clinic at the Honolulu consensus proposed specific criteria to distinguished the two histological types of AIP and pancreatic cancer. The five important diagnostic criteria include imaging, histology, serology, other organ involvement and response to therapy, leading to an improvement in the diagnostic yield for AIP and avoidance of misdiagnosis of pancreatic cancer[35]. Nevertheless, several cases have been reported that suspect pancreatic cancer rather than AIP[36-38].

In 2005, Ozden *et al*[39] described a 58-year-old woman with jaundice referred for pancreatic head carcinoma and diagnosed by MRI. By laparotomy, a pancreatic head mass involving the mesocolon, pancreatic body, and tail was found. Pancreatic biopsies revealed cholecystitis and pancreatitis with lymphoplasmacytic infiltration. Two months after the surgery there was no parenchymal lesion on MRI. Serum immunoglobulin G, G4, and E levels were increased.

The authors report this as a spontaneous regression of a pancreatic head mass and biliary obstruction because of autoimmune pancreatitis. In this and other cases of a patient with autoimmune pancreatitis that were initially misdiagnosed as pancreatic cancer, the response to steroid therapy could appear to be a spontaneous resolution of a malignant pancreatic tumor. Patients operated on for pancreatic adenocarcinoma could represent a false spontaneous regression of pancreatic cancer instead of lack of malignancy.

MECHANISMS LEADING TO SPONTANEOUS REGRESSION

Most of the SRC cases reported do not provide a discussion regarding possible explanatory mechanisms. In pancreatic cancer reports, only the most recent publications show data in detail (images and laboratory test) and finally suggest some possible biological mechanisms leading to the spontaneous regression.

The prevalent hypotheses regarding mechanisms leading to spontaneous regression include the immunological response in the host as the most important factor[40-43]. Other mechanisms causing spontaneous regression include increased apoptosis and necrosis, epigenetic modifications, hormonal responses, role of oncogenes and tumoral suppressors, cytokines and growth factors, and psychological mechanisms (Table 1). All of these mechanisms were reviewed in 1996 by Papac[44], who specifically described some cancers, but not pancreatic tumors.

Today, the activation of these mechanisms in spontaneous regression of cancer occurs infrequently[5,40,45,46] and remains not well documented in pancreatic cancer. In other related tumors, like hepatocellular carcinoma, several mechanisms leading to the spontaneous regression of these tumors have been described, such as absti-

Table 1 Possible mechanisms for spontaneous regression in pancreatic cancer

Immunological response
Hormonal response
Induction of spontaneous differentiation
Elimination of the carcinogen
Modification in expression of oncogenes and tumoral suppressor genes
Angiogenesis inhibition
Apoptosis
Necrosis
Epigenetic mechanisms
Psychological mechanisms

nence from alcohol[47], persistent fever[48], withdrawal of androgen[49], blood transfusion[50], massive bleeding[51], and use of herbal medicine[52]. However, in the small number of reported pancreatic cancer cases, no evidence of clear and specific events was observed during the period of spontaneous regression.

Renal cell carcinoma accounts for the largest number of patients with spontaneous regression with acceptable histology and radiological confirmation[53,54]; therefore, this disease offers the best system to study the immunological response in spontaneous regression. The increased incidence of some tumors in immunosuppressed individuals, and regression following reduction of immunosupressive agents, suggests an important role for immunological factors[55,56]. Cytokines, interferon, and interleukin 2 (IL-2), IL-6 and IL-8[57,58], exert antitumor effects. While cytokines could activate T-lymphocytes, natural killer, lymphocyte-activated killer cells, and tumor infiltrating lymphocyte cells as a mechanism of action, interferons are capable of multiple immunomodulatory effects, involving monocytes, macrophages, and B-cells, as well as induction of IL-2 receptors[59,60].

Regression often occurs in the setting of febrile illness (bacterial or viral), other, different, cytokines associated with the host response to infections could mediate the regression as tumor necrosis factors[61]. Patients diagnosed with pancreatic cancer frequently suffer infections and all of these cytokines could play an important role in the spontaneous regression of pancreatic cancer; however, there is no evidence of this phenomena in the literature. Angiogenesis, as an essential component of the malignant process, has also been investigated as a mechanism contributing to regression. Several cytokines are known to inhibit this process, such as tumor necrosis factor-alpha and transforming growth factor beta, which could play a role in spontaneous regression[62]. Regarding hormonal mechanisms that could exert a role in pancreatic cancer, there is no data suggesting specific effects in spontaneous regression, although studies should be made because the endocrine pancreas could be exerting an important role.

A mechanism that has received more attention for spontaneous regression in the literature is the apoptotic process inside the tumor. The activation of this programmed cell death was proposed as the basis for sponta-

neous regression, especially in neuroblastoma[63] and renal cell carcinoma. Several authors suggest that the neoplastic cells, in response to different stimuli, such as T-cell mediated survival signals or cytokine regulation, could undergo apoptosis, followed by clinical remission.

As several data have demonstrated, vascular endothelial growth factor receptor blockade leads to rapid, robust, and progressive regression of tumor vasculature, increased intratumoral hypoxia, and apoptosis, and reduced tumor invasiveness and metastasis in pancreatic islet cancer[64]. Thus, this process could also be implicated in tumor regression. This apoptotic process is driven by oncogenes and tumoral suppressor gene expression and, although there is no specific, documented examples on the role of changes in the expression of regulator genes, this possibility has been cited in leukemia[65].

The expression of these oncogenes or tumoral suppressors could be switched by mutations and by epigenetic mechanisms, leading to apoptosis inside the tumor. The cited epigenetic changes have been demonstrated in retinoblastoma tumors[66] by abnormalities in methylation levels[67]. Some authors have suggested that loss of hypermethylation may be involved in the spontaneous regression of some retinoblastomas, but there is no confirmed evidence. In addition, repression of telomerase activity has been proposed as a possible mechanism for regression[68-70]. Some studies showed that patients whose tumors do not show telomerase activity underwent spontaneous regression, suggesting repression of telomerase activity as a possible mechanism for regression, although it has not yet been demonstrated in any type of pancreatic cancer.

Differentiation, a mechanism by which malignant cells develop a non-malignant phenotype, has been shown to occur in several types of cancer, such as retinoblastoma, neuroblastoma, choriocarcinoma, teratocarcinoma, and leukemias[71,72], where differentiation is possibly the major factor contributing to spontaneous regression, but this is still unknown in pancreatic cancer. Finally, related to the immunological response in tumors, psychological mechanisms have been proposed as a possible phenomenon in some cancers, but this is still regarded with skepticism. Although authors have reported psychological reasons, corroborating biological studies are lacking[73,74] and are not approved by most investigators.

This lack of information forces us to conclude that spontaneous regression in pancreatic cancer is not a well-documented phenomenon, the mechanisms leading to the regression remains unknown, and only hypotheses can be made based on some other types of tumors. In recent reports, where the radiological and histological confirmation of pancreatic disease are more precise, only an immunological response has been suggested as the most probable mechanism leading to regression of pancreatic cancer. Most of the causative factors leading to this phenomenon remain speculative.

In conclusion, it is very difficult to determine the characteristics of pancreatic cancer patients who experi-

ence spontaneous regression and the mechanisms leading to such spontaneous regression.

Currently, the existence of spontaneous regression of pancreatic cancer is a matter of debate. The small number of cases cited in the literature as a possible spontaneous regression could represent a nonmalignant disease, such as AIP or specific pseudopapillary tumor of the pancreas. In the cases described many years ago, the data presented make it difficult evaluate the diagnosis because of the lack of advanced images techniques or laboratory tests to distinguish pancreatic cancer from other diseases. In addition, many cases are not completely well documented, the presence of metastasis is questionable, therapy may have played a role, or the temporary or permanent regression of tumor growth was not defined.

Therefore, cases of spontaneous regression of pancreatic cancer described in the literature should be taken caution. Biological and molecular findings cannot provide a complete explanation of the underlying mechanisms and accumulation of such cases and further investigations of regression will contribute to better understanding of this intriguing phenomenon.

Elucidation of the mechanism could lead to better understanding and replication of the process, and to improved therapies for pancreatic cancer treatment.

Abstract

Hepatitis C virus (HCV) hepatitis, initially termed non-A, non-B hepatitis, has become one of the leading causes of cirrhosis and hepatocellular carcinoma worldwide. With the help of animal models, our understanding of the virus has grown substantially from the time of initial discovery. There is a paucity of available animal models for the study of HCV, mainly because of the selective susceptibility limited to humans and primates. Recent work has focused modification of animals to permit HCV entry, replication and transmission. In this review, we highlight the currently available models for the study of HCV including chimpanzees, tupaia, mouse and rat models. Discussion will include methods of model design as well as the advantages and disadvantages of each model. Particular focus is dedicated to knowledge of pathophysiologic mechanisms of HCV infection that have been elucidated through animal studies. Research within animal models is critically important to establish a complete understanding of HCV infection, which will ultimately form the basis for future treatments and prevention of disease.

INTRODUCTION

The hepatitis C virus (HCV) is a positive-sense, single stranded RNA virus of the family Flaviviridae. There are six distinct genotypes with several subgenotypes that have been identified. The World Health Organization estimates that the virus affects approximately 3% of people worldwide. Approximately 170 million people are chronic carriers of the virus. There is higher prevalence in the Far East, Mediterranean countries and in certain African and eastern European areas. HCV infects primarily liver cells causing an acute hepatitis. Of those acutely infected, roughly 15% will clear the virus without medical intervention while the remainder will develop chronic hepatitis C. Approximately 30% of chronic hepatitis C will progress to cirrhosis, of which 20% will develop hepatocellular carcinoma. Thus, HCV infection remains a global health problem requiring continued research efforts to understand viral infection and to develop improved drug therapies.

Efforts to obtain information regarding the intricacies of hepatitis C viral entry, lifecycle and replication have been limited by the lack of model organisms available to serve as experimental hosts to the virus. Hu-

mans and other primates are the only known organisms naturally permissive to HCV infection. Costs and ethical concerns, thus, limit the study of the disease in chimpanzees. Recently, novel animal systems have permitted detailed examination of HCV infection, replication, and host responses. In this review, the status of HCV animal models is summarized, and the advantages as well as disadvantages, are discussed in terms of the potential impact on the development of future novel anti-HCV therapies.

ANIMAL MODELS

Chimpanzees and immune responses to HCV infection

The path leading to the discovery of HCV began in 1975 when some patients with viral hepatitis were found to lack markers for hepatitis A virus or hepatitis B virus (HBV) in serum. This led to the recognition that a separate unrelated hepatitis virus was responsible. This entity was initially termed non-A non-B hepatitis (NANBH). Thus began a wide body of research to isolate and identify the virus using chimpanzees as hosts for infection with human NANBH-infected serum. In 1989, Choo *et al*[1] and Houghton *et al*[2] created a complementary DNA clone of NANBH (clone 5-1-1) derived from positive-strand RNA, and confirmed that it encoded an antigen specific to NANBH infections. The cDNA was used to create antigens (c100-3) subsequently used as substrates to detect circulating serum antibodies *via* enzyme immunoassay. Through these discoveries in chimpanzees, antibody testing enabled screening of blood for the presence of the agent, now named HCV.

The study of HCV in chimpanzees has provided a wealth of knowledge regarding the mechanism of infection, replication, and both innate and humoral antiviral immune responses. Chimpanzees infected with HCV display elevations of aminotransferases and liver biopsies show necroinflammatory changes after acute infection. However, chimpanzees differ from humans in that their course of infection is milder; chronic carriers do not develop cirrhosis or fibrosis and only one chimpanzee has been reported to have developed HCV-related hepatocellular carcinoma[3]. Other differences include lack of efficacy of interferon (IFN) treatment as evidenced by constant viral loads despite administration of this agent. Alternative studies of direct antiviral agents are currently being studied in chimpanzees. For example, Olsen *et al*[4] showed that administration of a nucleoside analogue and protease inhibitor resulted in viral load decline in HCV-infected chimpanzees. Together with recent clinical trials and use of novel HCV protease inhibitors, success in the treatment of HCV-infected chimpanzees has potential to spark new human clinical trials using antiviral agents without concurrent use of pegylated-IFN and ribavirin.

Chimpanzees offer a valuable animal model for active immunization studies as well as for investigating mechanisms of innate and cell-mediated antiviral activity. Through studies on chimpanzees that have naturally cleared infection, Nascimbeni *et al*[5] have described the role of memory T-cell (both CD4 and CD8) responses that may help prevent infection upon re-challenge with virus. The varying quantity and quality of this cell mediated response helps explain differing responses to reinfection among individual chimpanzees. Barth *et al*[6] recently highlighted the importance of neutralizing antibodies to prevent early viral replication. They also showed that heightened CD8+ and natural killer (NK) cell activity increased production of IFN stimulating genes and IFN I / II, thus further supporting the role of adaptive immunity in limiting viral re-infection. Results of vaccination studies in HCV-infected chimpanzees have proven difficult to interpret for a variety of reasons including heterogeneity of genotypes, the error-prone RNA polymerase that creates mutations resistant to neutralizing antibodies, and downregulation of NK and T-cell responses *via* gpE2 interaction with CD81. Important information can nonetheless be gathered from both therapeutic and prophylactic vaccination studies[7]. Meta-analyses of HCV therapeutic vaccination studies in chimpanzees by Dahari *et al*[8] concluded that vaccinations that included non-structural HCV proteins were less effective in achieving HCV clearance in comparison to inclusion of structural proteins in vaccines, which were hypothesized to heighten T-cell responses. However, successful vaccination data should be interpreted carefully, because most studies use endpoints as reduction in clinical disease rather than sustained virological response. The search for a prophylactic vaccination for HCV has been challenging. The mechanism of protective vaccination is usually the generation of neutralizing antibodies. In HCV, neutralizing antibodies have been observed to coexist with high HCV titers, thus suggesting their presence does not limit HCV entry into cells *in vivo*. Neutralizing antibody levels also tend to decrease after infection resolves, indicating a lack of a memory response or capability to prevent re-infection. More recent work has subsequently focused on generating a reliable T-cell (CD4+ and CD8+) response in attempts to protect against the development of infection with exposure to the virus. Folgori *et al*[9] developed a prophylactic vaccination strategy in chimpanzees using adenoviral vectors and electroporated plasmid DNA encoding the HCV non-structural region. Through stimulation of a cross-reactive T-cell response, chimpanzees were capable of resolving infection when challenged with virus differing from the vaccine by more than 13% at the amino acid level. Vaccination studies in chimpanzees are ongoing. There are many disadvantages to the use chimpanzees as models, including cost, ethics, and most recently, an NIH ban on the use of chimpanzees for biomedical research[10].

Tupaia infection with HCV

Tupaia belangeri is a tree shrew native to Southeast Asia. Tupaia has been shown to be susceptible to a variety of human viruses including herpes simplex virus, rotavirus,

and HBV. In 2002, Zhao *et al*[11] demonstrated effective hepatitis C replication and virion synthesis in primary tupaia hepatocytes. This group plated and infected primary tupaia hepatocytes with serum or plasma derived HCV from infected humans. Infection and effective replication was confirmed by reverse transcription polymerase chain reaction detection of negative strand RNA in hepatocytes as well as secretion of viral particles in culture medium. HCV RNA could be detected up to 14 d after plating. The enveloped virions produced were shown to be resistant to degradation by ribonuclease and could infect previously uninfected tupaia hepatocytes.

In 2010, Amako *et al*[12] reported a longitudinal study which followed HCV-infected tupaia over a three year period after inoculation with hepatitis C from a patient or viral particles from full length cDNA. The animals demonstrated mild inflammation and viremia during the acute infection followed later by development of liver steatosis, cirrhotic nodules and tumorigenesis. Moreover, serum from infected tupaia was harvested and inoculated into naïve tupaia resulting in acute infection, demonstrating effective replication and potential transmission of HCV.

HCV entry in tupaia has been shown to support current knowledge of human essential entry receptors. In 2011, Tong *et al*[13] cloned tupaia CD81, scavenger receptor class B member 1 (SCARB- I or SR-B I), claudin-1 (CLDN1) and occludin and demonstrated that entry of HCV pseudoparticles or cell culture-derived HCV was permitted by these molecules. Inhibition of CD81 or SR-B I blocked HCV entry. However, there may be structural variations between human and tupaia receptors that may allow for differences in efficiency of viral entry. For example, the subtle structural difference between human and tupaia CD81 was shown to alter the ability of the extracellular loop to bind to HCV glycoprotein E2 in a study by Tian *et al*[14]. This information may be helpful in elucidating potential drug targets to block viral entry in humans. Tupaia is, therefore, a promising and effective model for the ongoing study of HCV entry and replication. A disadvantage of the tupaia model is that unlike humans with HCV, these animals rarely maintain sustained virema[12,15].

Mouse models for HCV replication

Much research has been devoted to understanding why murine hepatic cells are naturally resistant to hepatitis C viral cell entry, and permit only inefficient replication in cell culture and in animals. Ultimately, overcoming this resistance could provide a valuable mouse model for HCV replication as well as development of potential immune strategies to block HCV entry and replication in humans.

Mouse hepatocytes have been shown to allow HCV entry in cell culture in cells genetically engineered to express human HCV-specific entry molecules including CD81 and occludin. However, in addition to the barrier to entry, murine cells also have a resistance towards rep-

lication, assembly and release of HCV. This was demonstrated by Long *et al*[16] who used a transcomplementation system of mouse hepatoma cell lines that contained a subgenomic HCV replicon for ectopic expression of HCV structural proteins, p7, NS2 and apolipoprotein E (ApoE). They were able to demonstrate that assembly and release occurred successfully in murine cells with expression of the aforementioned proteins including ApoE.

In order to overcome the barrier to murine infection by HCV, Washburn *et al*[17] developed a model consisting of a humanized mouse engineered by engraftment of human hepatocyte progenitors and human CD34+ human hematopoietic stem cells. This model was generated by the use of a fusion of the FK506 binding protein and caspase 8 under the control of the albumin promoter. This construct induced apoptotic elimination of host hepatocytes in Balb/C Rag2 (-/-) C-null mice. Ultimately these humanized mice were shown to harbor both human hepatocytes and T cells. Upon infection with HCV, the mice developed liver inflammation and fibrosis. A human T-cell immune response to HCV was observed. This study was limited by low levels of HCV infection demonstrated by absence of HCV RNA in the serum, and a lack of a B cell immune response due to absence of an engraftment of a complete immune system.

Similarly, Mercer *et al*[18] and Kneteman *et al*[19] developed a chimeric severe combined immune deficient (SCID)/urokinase-type plasminogen activator mouse model. This immune deficient mouse model has been shown to support proliferation of transplanted human hepatocytes, and more importantly, sustained HCV infection as demonstrated by detection of viral RNA within hepatocytes after intravenous inoculation. Production and release of viral particles were demonstrated by successful passage of infection through three generations of mice. The studies showed that when the human hepatocytes comprise the majority of liver cells (at least 80% of total hepatocytes) within chimeric SCID mice, infection with HCV can occur, and can result in liver failure. Further research revealed that human apolipoprotein (ApoB) and cholesterol ester transfer protein may play a role in allowing HCV infection in the chimeric SCID mice, and thus may offer a target to prevent viral entry within humans[20]. HCV-infected SCID mice have also been used to study direct antiviral agents including IFN alpha-2 anti-NS3 and anti-NS5B proteases. Responses were shown to parallel that of humans. More recently, Kamiya *et al*[21] tested anti-NS3-4A (telaprevir) in HCV-infected SCID mice to evaluate the pharmacokinetics and dynamics of the drug as it related to a dose-dependent reduction in HCV serum RNA. Studies on SCID mice thus offer the potential to serve as a bridge between *in vitro* and clinical trials for HCV antiviral agents. Limiting factors of the SCID mouse model include a lack of a complex immune system, and inability to achieve a fully humanized liver. Recent studies have shown promise with use of a herpes simplex virus type-1 thymidine kinase/ganciclovir system

for cell specific ablation as means of obtaining exclusive growth of human hepatocytes in the SCID mouse[22].

In order to create a mouse model permissive to HCV infection while maintaining complex immunity, Dorner *et al*[23] developed a humanized mouse model using genetic engineering to study viral entry and immunity. Mice were genetically engineered to express HCV-specific entry factors including CD81, occludin, SCARB-Ⅰ, and CLDN1. Using this model, it was demonstrated that human-specific CD81 and occludin were essential to all HCV entry into murine hepatocytes. Expression of SCARB-Ⅰ heightened HCV entry when expressed in combination with CD81 and occludin. Because this model used an immunocompetent mouse, viral replication and persistence of infection was limited. However, this model was also used to study passive immunization by administration of anti-CD81 antibodies and anti-E2 antibodies both of which decreased HCV infection. This model may offer future study of passive immunization or vaccination strategies to prevent acute infection of HCV before or after exposure.

Rat model for HCV infection

As discussed above, the search for an immunocompetent rodent host for HCV infection has been difficult. Although transplantation of human hepatocytes has been possible in mice, long-term HCV infection has only been shown in the setting of immunodeficiency, which limits study of immune responses. Ouyang *et al*[24] sought to overcome these barriers by creating an immunocompetent rat model that was tolerant to human hepatocytes. In order to achieve this, Huh7 human hepatoma cells were injected into the peritoneal cavities of fetal rats between gestation ages of 15-17 d. By injecting human hepatocytes during the development of the fetal immune system of the rat, specific tolerance to that specific cell type was achieved. Subsequent transplantation of human Huh7 cells into newborn tolerant rats resulted in survival and limited growth of the human cells without evidence of rejection as demonstrated by mixed lymphocyte assays. Colonies of cells bearing human liver cell markers increased in size, and were visualized within rat livers by immunohistochemical staining. Human albumin was detected in liver cells and in serum, and human hepatic mRNA was detected in hepatocytes, thus demonstrating active synthetic function of transplanted human Huh7 cells.

To study HCV infection, HCV isolated from human serum was inoculated into immunocompetent, tolerant, Huh7 cell-transplanted rats[25]. HCV RNA levels of 7.0×10^3 copies/mL were detectable in serum by week 4, and peaked at 20×10^3 copies/mL by week 12 after infection. Levels decreased thereafter. Moreover, biochemical evidence of hepatic inflammation was demonstrated by elevations of serum alanine aminotransferase beginning at 4 wk, and peaked at 3× the baseline level by the 13th week, after which levels declined. Light microscopy of liver sections showed mononuclear infiltrates in portal and central regions at times coinciding with detectable viremia. Controls without transplanted cells, tolerization, or HCV inoculation lacked any markers of HCV infection or hepatitis. The limitations of this rat model include low numbers of transplanted human hepatocytes as well as relatively low levels of viremia (22 500 copies/mL), in comparison to that in a typical human infection. However, this model offers a rodent model large enough to tolerate repeated blood and tissue sampling to study viral entry, replication, and immune-mediated hepatic injury as well as a screening tool to evaluate novel antiviral agents.

PROSPECTIVE

Hepatitis C viral infection is a growing health concern that leads to liver failure and hepatocellular carcinoma. The study of HCV has been limited due to a lack of appropriate and reliable animal models. However, much of our understanding of viral infection, replication and host immune responses has been gathered from animal data. Animal studies have historically utilized chimpanzees, but alternative models such as tupaia, mice and rats are now viable models for research.

Chimpanzees are advantageous models given their close genetic resemblance to humans, intact immune system which offers potential for study of innate and adaptive immune responses, and potential to study both treatments and prophylactic vaccinations. Additionally, important research with chimpanzees has resulted in the development of molecular clones of the virus for use in molecular and cellular research. Disadvantages include high cost, ethical constraints, and low susceptibility to chronic infection, thus limiting the study of HCV-related cirrhosis and hepatocellular carcinoma. Currently, chimpanzees are not available for biomedical research[10].

Advantages of the tupaia model include low cost, ease of propagation, immunocompetence, and capability to study cirrhosis and tumorigenesis. On the other hand, tupaia and humans are genetically very different, potentially limiting the applicability of tupaia data on viral infectivity and disease to humans. Reliability and reproducibility of infection with tupaia have been also been debated.

Xenograft mice constructed with human hepatocytes are useful models given the demonstrated persistent viremia, and development of cirrhosis. These models provide a unique opportunity to study viral activity within human hepatocytes in a living host. Limitations include difficulty with mouse reproduction for repeated sampling, and immunodeficiency that limits the study of the natural immunological response.

The immunocompetent mouse and rat are promising models given their relatively low cost, ease of propagation, and intact immune system. There is great potential for the study of immunologic mechanisms as well as treatment and vaccination agents using these models. Disadvantages include relatively low levels of viremia,

and possible limitation of persistent infection by a competent immune response.

Our knowledge of HCV and related disease has grown significantly from its discovery nearly three decades ago. Together with molecular and cellular approaches, continued animal research will undoubtedly play a critical role in development of new antiviral therapies, and our understanding of mechanisms involved in the pathogenesis of both acute and chronic HCV infections. Further research is needed to enhance the potential of the currently available models in order to optimize the cost of maintenance and propagation, viremia, and maximize the similarity of infection models as they relate to human infection.

Abstract

AIM: To investigate proteomic changes in spinal cord and dorsal root ganglia (DRG) of rats with trinitrobenzene sulfonic acid (TNBS)-induced colitis.

METHODS: The colonic myeloperoxidase (MPO) activity and tumor necrosis factor-α (TNF-α) level were determined. A two-dimensional electrophoresis (2-DE)-based proteomic technique was used to profile the global protein expression changes in the DRG and spinal cord of the rats with acute colitis induced by intracolonic injection of TNBS.

RESULTS: TNBS group showed significantly elevated colonic MPO activity and increased TNF-α level. The proteins derived from lumbosacral enlargement of the spinal cord and DRG were resolved by 2-DE; and 26 and 19 proteins that displayed significantly different expression levels in the DRG and spinal cord were identified respectively. Altered proteins were found to be involved in a number of biological functions, such as inflammation/immunity, cell signaling, redox regulation, sulfate transport and cellular metabolism. The over-expression of the protein similar to potassium channel tetramerisation domain containing protein 12 (Kctd 12) and low expression of proteasome subunit α type-1 (psma) were validated by Western blotting analysis.

CONCLUSION: TNBS-induced colitis has a profound impact on protein profiling in the nervous system. This result helps understand the neurological pathogenesis of inflammatory bowel disease.

INTRODUCTION

Inflammatory bowel disease (IBD) is defined as a group

of inflammatory conditions in the colon and small intestine, mainly including ulcerative colitis and Crohn's disease. The cause of IBD is suggested to be a nebulous combination of not only host genetic factors, but also immune dysfunction, dysbiosis, cellular oxidative stress and leakage of intestinal barrier[1]. Fundamental therapy for this condition has not yet been established because its etiology remains obscure. Unfortunately, the prevalence of IBD is continuing to increase in both Eastern and Western countries, causing enormous medical costs[2,3]. Beside intestinal disorders, many organs outside the gastrointestinal tract, such as the central nervous system, are involved in IBD[4]. Neuropathies, cerebrovascular events, white matter lesions, and visceral pain are common neurological manifestations[4]. These alterations may help explain some of the underlying comorbidities, such as hyperalgesia, seizure and anorexia[5,6]. Unfortunately, the exact mechanism for IBD needs further investigations.

This study focuses on the spinal cord and dorsal root ganglia (DRG) to reveal the neurological dimension in a trinitrobenzene sulfonic acid (TNBS)-induced active colitis model. Unlike previous studies that were based mainly on investigations of specifically selected gene/proteins, proteomic approach was applied in this study to reveal the global changes of proteins. The two-dimensional electrophoresis (2-DE) in combination with matrix-assisted laser desorption-time-of-flight/time-of-flight mass spectrometer (MALDI-TOF/TOF MS) have been widely used to probe into changes of protein profiles accompanied with diseases like cancer and hyperalgesia[7,8]. In the present study, this approach was applied to analyze the proteomic differences in lumbar enlargement of spinal cord and DRG in the rat model of TNBS-induced colitis. This study aimed to investigate whether changed protein profiles in the nervous system are in any way associated with neurological dimensions in IBD animal model.

MATERIALS AND METHODS

Animals and tissue processing
Male Sprague-Dawley rats (180-200 g in weight) were obtained from the Laboratory Animal Services Centre, The Chinese University of Hong Kong. Rats were kept at room temperature 23 ℃ ± 2 ℃ with an alternating 12 h light-dark cycle, and were allowed access to food and water *ad libitum*. All of the experimental protocols were carried out with the approval of the Committee on Use of Human and Animal Subjects in Teaching and Research of Hong Kong Baptist University and according to the Regulations of the Department of Health, Hong Kong, China.

Induction of colitis
Induction of colitis was adapted from the previously reported methods[9,10]. Briefly, under chloral hydrate (350 mg/kg, ip) anesthesia, colitis was induced in overnight-fasted rats ($n = 5$) by intra-colonic administration of 30 mg/kg of TNBS (Sigma, St. Louis, United States) dissolved in 50% ethanol solution at 8 cm from the anal

verge using a rubber catheter. The rats were kept upside-down for 1 min to ensure that the TNBS solution was not expelled immediately. The rats in control group ($n = 4$) received intra-colonic injection of saline.

Tissue preparation
On the 7th day after TNBS instillation, the rats were anesthetized with chloral hydrate (350 mg/kg, ip). Distal colon tissue was excised in two pieces. One piece was fixed in 4% paraformaldehyde, routinely embedded in paraffin, cut into 5 μm sections, mounted on glass slides and stained with hematoxylin and eosin to reveal structural features. The other piece of colon sample was frozen in liquid nitrogen and stored at -80 ℃ for measurement of myeloperoxidase (MPO) activity and tumor necrosis factor-α (TNF-α) level. The rat was then perfused with ice-cold normal saline. The spinal cord and DRG of the lumbosacral enlargement were dissected, immediately frozen and stored at -80 ℃ until use. Samples were firstly lysed in buffer (8 mol/L urea, 2 mol/L thiourea, 2% 3-[(3-cholamidopropyl) dimethylammonio]-1-propanesulfonate (CHAPS), 1% NP-40, 2 mmol/L tribromophenol (TBP), 1 × protease inhibitor mix, 1 × nuclease mix, 1 mmol/L phenylmethanesulfonylfluoride or phenylmethylsulfonyl fluoride (PMSF), and 2% immobilized pH gradient (IPG) buffer, and then incubated on ice for 45 min. The lysed mixtures were centrifuged at 14 000 × *g* for 15 min at 4 ℃. The supernatant samples were determined by Bradford protein assay (BioRad, California, United States) and stored at -80 ℃.

Two-dimensional gel electrophoresis and image analysis
2-DE and image analysis were performed as previously described with some modifications[11]. Isoelectric focusing (IEF) was performed using IPGphor Ⅱ apparatus (Amersham, Sweden). Samples (150 μg protein/group, containing an equal amount of protein from each animal) were diluted in 250 μL rehydration solution (8 mol/L urea, 2% CHAPS, 0.4% dithiothreitol (DTT), 0.5% IPG buffer, 0.002% bromophenol blue) and loaded onto the IPG strips (13 cm, pH 3-10, NL) by 10 h rehydration at 30 V. Proteins were focused by using a step-wise voltage ramp: 500 V for 1 h, 1000 V for 1 h, and finally 8000 V for 6 h. The IPG strips were then incubated in the equilibration buffer (6 mol/L urea, 2% SDS, 30% glycerol, 0.002% bromophenol blue, 50 mmol/L Tris-HCl, pH 6.8) containing 1% DTT for 15 min with gentle agitation. The strips were then transferred to the equilibrating solution containing 2.5% iodoacetamide and agitated for 15 min, and subsequently were placed on top of a 12.5% uniform SDS-PAGE gel (150 mm × 158 mm × 1.5 mm). Separation in the second dimension was performed in Tris-glycine buffer (25 mmol/L Tris, 0.2 mol/L glycine, 0.1% SDS) at a constant current setting of 15 mA/gel initially for 30 min and 30 mA/gel thereafter. SDS-PAGE was terminated when the bromophenol blue dye front reached the lower ends of the gels. After 2-DE, gels were visualized using silver-staining[11]. All the raw images were digitalized using

a scanner (GS-800 calibrated densitometer, BioRad) and the Quantity One software (BioRad). Further analysis was completed using PDQuest (version 8.0, BioRad) mainly for spots' detection and quantification. The protein spots where the peak-volume ratio in the TNBS group changed more than 3-folds in comparison with the matched spots in the control group, were considered as differentially expressed, and were picked out for identification by tandem mass spectrometer (MS-MS).

In-gel digestion

Protein spots of interest were manually excised from the 2-D gels, and digested as previously described with small modification[12-14]. Briefly, the gel plugs were washed in 30 mmol/L potassium ferricyanide and 100 mmol/L sodium thiosulfate (1:1 v/v) for 5 min, and then washed in water twice. Subsequently, the gel plugs were equilibrated in 50 mmol/L ammonium bicarbonate for 20 min, then in 25 mmol/L ammonium bicarbonate and 50% acetonitrile (ACN), and finally soaked in 100% ACN until gel plugs became opaque. Thereafter, vacuum-dried gel plugs were rehydrated with 10 mg/mL of trypsin in 25 mmol/L ammonium bicarbonate (pH 8.0). Proteolysis of proteins was performed at 37 ℃ for 16-18 h. Supernatants were transferred into a new tube, and mixed with 1/2 volume of 1% trifluoroacetic acid to stop digestion. The samples were then vacuum dried at 45 ℃ for 1-2 h.

Protein identification by MS/MS

Protein identification was performed using a Autoflex Ⅲ MALDI-TOF/TOF mass spectrometer (Bruker, Germany) equipped with a 200 Hz N2 laser operating at 337 nm. Data were acquired in the positive ion reflector mode over a mass range of 800-4000 m/z using Bruker calibration mixture as an external standard. Bruker calibration mixture consists of the following peptides (monoisotopic mass of the singly protonated ion is given in parenthesis in Da); bradykinin (757.3992), angiotensin Ⅱ (1046.5420), angiotensin Ⅰ (1296.6853), substance P (1347.7361), bombesin (1619.8230), renin substrate (1758.9326), ACTH clip 1-17 (2093.0868), ACTH clip 18-39 (2465.1990) and somatostatin 28 (3147.4714). Keratin contamination peaks, matrix ion peaks and trypsin ion peaks were excluded from spectra. Typically 400 shots were accumulated per spectrum in MS mode and 2000 shots in MS/MS mode. The spectra were processed using the FlexAnalysis 3.0 and BioTools 3.1 software tools (Bruker, Germany). Protein identification was performed using Mascot (2.2.04, http://www.matrixscience.com) to search the international protein index (IPI) database. Peptide masses were matched with the theoretical peptides of all proteins in the IPI database using the Mascot search program. The following parameters were used for database searches: monoisotopic mass accuracy < 100 ppm, missed cleavages 1, carbamidomethylation of cysteine as fixed modification, oxidation of methionine as variable modifications. In MS/MS mode, the fragment ion mass accuracy was set at < 0.5 Da.

Determination of MPO activity and TNF-α level

The MPO activity was measured following the method as previously described[15,16]. Colonic TNF-α was determined using an enzyme-linked immunosorbent assay kit (Leinco Technologies, United States). The protein was quantified using a bicinchoninic acid protein assay kit (Thermo Scientific, United States).

Immunoblotting analysis

Two identified proteins: (1) similar to potassium channel tetramerisation domain containing protein 12 (Kctd12); and (2) proteasome subunit α type-1 (Psma1), were selected for the confirmation study. For Western-blot analysis, protein lysates were diluted in sample buffer and denatured at 100 ℃ for 5 min. Proteins (15 μg/lane) of interest were separated by 12% SDS-PAGE, and transferred onto polyvinylidene fluoride (PVDF) membranes (Bio-Rad). Nonspecific binding sites were blocked with 5% nonfat milk for 1 h at room temperature, then the blots were incubated at 4 ℃ overnight with rabbit antibody against mouse antibody against Psma1 (1:250 in TBST, Santa Cruz) or Kctd12 (1:500 in TBST, Santa Cruz). After washing, the membranes were incubated in horseradish peroxidase (HRP)-conjugated secondary antibodies (1:2000) in Tris-Buffered Saline and Tween 20 (TBST) with 5% nonfat milk against the primary antibody species for 1 h at room temperature. The immunoreaction was detected with the enhanced chemiluminescence (ECL) Western blotting kit (Invitrogen). Bands were visualized on Bio-max X-ray film (Kodak, Japan) and captured by a scanner. The optical densities of protein blots were analyzed using Image J software. The results were presented as the ratio of optical density of Kctd12 or Psma1 standardized to optical density of β-actin.

RESULTS

Establishment of IBD model

Rats developed hypomotility and diarrhea 1 d after TNBS treatment. Hematoxylin and eosin staining of distal colon revealed incrassation and edema in the mucosa and submucosa, hyperaemia and dilation of the blood vessel, and prominent neutrophilic infiltrates in the submucosal layer, indicating severe colonic inflammation (Figure 1A). TNBS group showed significantly elevated MPO activity (Figure 1B) and TNF-α level (Figure 1C), suggesting increased granulocyte recruitment and macrophage activation in the acute phase of inflammation.

Identified proteins by 2-DE-based proteomic technique

The representative 2-DE images of protein profiling changes in DRG and spinal cord is shown in Figure 2. Overall, a total of 26 spots differentially expressed in the DRG of these two groups were identified by the mass spectrometry (MS) analysis, 12 of which were up-regulated and 14 of which were down-regulated (Table 1). A total of 19 spots differentially expressed in the spinal cord of the two groups were identified by MS analysis, 9 of which

Figure 1 The establishment of colitis in trinitrobenzene sulfonic acid rats. Representative hematoxylin and eosin microscopic photos of the colon tissue (A) revealed inflammation in the sub-mucosa layer of trinitrobenzene sulfonic acid (TNBS) rats; measurement of myeloperoxidase (MPO) activity in wet colon tissue (B, 2.61 ± 2.47 *vs* 0.03 ± 0.01) and tumor necrosis factor-α (TNF-α) level in colonic total protein (C, 759.80 ± 81.07 *vs* 174.00 ± 31.92) revealed significantly elevated MPO activity and TNF-α level in TNBS treated group in comparison with saline control group. [a]$P < 0.05$ *vs* saline group.

Figure 2 Representative examples of the silver-stained two-dimensional electrophoresis gels show expression maps of proteins in dorsal root ganglia (A) and spinal cord (B) of trinitrobenzene sulfonic acid colitis group and saline control groups. TNBS: Trinitrobenzene sulfonic acid; DRG: Dorsal root ganglia; Gstp1: Glutathione S-transferase P; Sod2: Superoxide dismutase; Ndufv2: NADH dehydrogenase (ubiquinone) flavoprotein 2; Ndufb10: NADH dehydrogenase (ubiquinone) 1 β subcomplex 10; Fh1: Fumarate hydratase; Psat1: Phosphoserine aminotransferase; Kctd12: Potassium channel tetramerisation domain containing protein 12; Vdac2: Voltage-dependent anion-selective channel protein 2; Ywhae: The 14-3-3 protein epsilon; Tst: Thiosulfate sulfurtransferase; Hspa8: Heat shock cognate 71 kDa protein.

were up-regulated and 10 of which were down-regulated (Table 2). In particular, we found altered expression of (1) proteins involved in inflammatory/immune responses, such as Isoform B0a of heterogeneous nuclear ribonucleoproteins A2/B1 (Hnrnpa2b1) and proteasome subunit α type-1 (Psma1); (2) signal-related proteins, such as adenylyl cyclase-associated protein 1 (Cap1) and voltage-dependent anion-selective channel protein 2 (Vdac2); (3) proteins involved in sulfate transport, thiosulfate sulfurtransferase (Tst); (4) cellular enzymes involved in cell redox homeostasis, such as glutathione S-transferase P (Gstp1) and superoxide dismutase (Sod2); (5) metabolic enzymes, such

as fructose-bisphosphate aldolase C (Aldoc); (6) structure protein Lamin C2 (Lmna); and (7) chaperonins, such as heat shock cognate 71 kDa protein (Hspa8, or HSC70) and stress-induced phosphoprotein 1 (Stip1). Although previous studies have reported the contribution of a few proteins, such as down-regulated glutathione peroxiredoxin-1 (Prdx1) and malate dehydrogenase (Mdh2)[12], most of the proteins were first identified in TNBS-induced colitis (Table 3). Most importantly, the samples analyzed in previous studies were usually mucosa or submucosa of the colon, whereas this paper firstly investigated the global protein expression changes in the spinal cord and DRG of

rats with TNBS-induced acute colitis.

Validation by Western blotting analysis

In order to validate the proteomic data, two of the protein spots: Psma1, a protein involved in immunity, and Kctd12, a protein involved in voltage-gated potassium channel activity, were chosen for validation by Western blotting analysis. The comparison of samples derived from TNBS rats (lanes 1-4) and samples derived from saline control (lanes 5-8) revealed down-regulation of Psma1 (Figure 3A) in the spinal cord and up-regulation of Kctd12 (Figure 3B) in the DRG. These results confirmed the changed protein levels concluded from 2-DE.

DISCUSSION

Colitis persists for at least 28 d after TNBS colonic administration[17,18]. For the study of TNBS-induced colitis, rats were usually sacrificed 7 d after TNBS treatment[19], since TNBS-caused changes of gene expression profile were maximal at day 5 and day 7 after induction[20]. Consistent with previous studies, on day 7 after TNBS intraluminal treatment, we observed macroscopic and microscopic damage of the distal colon, demonstrating the presence of acute colitis. By using 2-DE in combination with MALDI-TOF/TOF MS based proteomic approach, we observed changed expression profiles not only in proteins participating in the immune/inflammatory response, but also in a broad range of proteins involved in cell signaling, sulfate transport, redox homeostasis, and cell metabolism. This result is consistent with previous studies revealing that in addition to inflammation/immunity response, TNBS-colitis affects the gene expression related to a numerous biological functions, such as signal transduction and cell metabolism[21,22]. The identified proteins from the spinal cord and DRG could be categorized into seven groups as follows.

Group 1: Proteins involved in inflammatory/immune responses

Consistent with previous results[23,24], the current study

DRG: Dorsal root ganglia; TNBS: Trinitrobenzene sulfonic acid; CD: Crohn's disease; UC: Ulcerative colitis; DSS: Dextran sulfate sodium; NF: Nuclear factor.

regulated Hnrnpa2b1 in DRG of TNBS rats may suggest reduced DNA repair efficiency of neurons and activated autoimmunity in DRG. Ppia (also known as cyclophilin A) contributes to the pathogenesis of inflammation-mediated diseases by directly inducing leukocyte chemotaxis and expression of proinflammatory cytokine/chemokines through a NF-κB dependent pathway[28,29]. In addition, Ppia is a novel paracrine and autocrine modulator of endothelial cell functions in immune-mediated diseases[30]. The down-regulated expression of Ppia in DRG of TNBS rats might associate with impaired immune modulation following acute colitis. Eno1 is a multifunctional enzyme that plays a part in various processes such as glycolysis, growth control and allergic responses. It is an autoantigen in many diseases, however, its diagnostic value in IBD is still controversial[31]. The underexpressed Eno1

may suggest that glycolysis is blocked and gluconeogenesis is dominant, which may associate with diarrhea and emaciation caused by colitis. Psma1 and Acot7 may be associated with the anti-inflammatory effect of macrophages. Psma1 mediates lipopolysaccharide-induced signal transduction in the macrophage proteasome[32]. Acot7 hydrolyzes the CoA thioester of palmitoyl-CoA, an important precursor for proinflammatory and immunoactive eicosanoids. Acot7 gene is highly expressed in macrophages and up-regulated by lipopolysaccharide[33]. The down-regulated Psma1 and Acot7 expression in the spinal cord of TNBS rats may be associated with inhibited anti-inflammatory responses.

Group 2: Proteins involved in cell signaling

Group 2 consists of proteins involved in ion channel

function, cell growth and division. Potassium channels are important in shaping the action potential, excitability and plasticity of neurons[34]. Changes in the properties of potassium channels at the soma accompanied with hyperexcitability in nociceptive DRG neurons in animal with TNBS-induced ileitis[35]. We observed overexpressed kctd12 protein in DRG of the TNBS rats. This might be related to altered function of potassium channel in DRG and hyperalgesia in colitis rats. Voltage-dependent anion-selective channel protein 2 (Vdac2) inhibits mitochondrial apoptosis[36]. It is interesting that a significantly down-regulated Vdac2 protein expression was observed in the DRG of TNBS rats, indicating an up-regulated apoptosis signaling. Adenylyl cyclase-associated protein 1 (Cap1) is a growth protein involved in the cyclic AMP (cAMP) pathway. Inflammatory signals can activate cAMP-protein kinase A pathways, which correlates with electrophysiological hyperexcitability of DRG neuron[37]. And, cAMP plays a role in DRG axon regeneration[38]. The up-regulated Cap1 in DRG of TNBS rats is probably a sign of neuronal hyperexcitability and/or axon regeneration. The 14-3-3 protein epsilon (Ywhae) is a splice variant of the 14-3-3 protein, which modulates cell division and apoptosis[39]. Elevated Ywhae expression was observed in the spinal cord of injury rats[40]. Consistent with down-regulated Vdac2 expression in DRG, the elevated Ywhae expression in spinal cord of TNBS rats may also indicate enhanced apoptosis signaling. Dihydropyrimidinase-related protein 2 (Dpysl2) plays a role in axon guidance, neuronal growth cone collapse and cell migration. In rat brain after ischemic stroke, up-regulated Dpysl2 indicates an early neuronal defense mechanism involving active neuronal repair, regeneration and development[41]. The up-regulated Dpysl2 in the spinal cord of TNBS rats may be related to the neurite outgrowth/plasticity associated with immunoreaction.

Group 3: Proteins involved in sulfate transport

Thiosulfate sulfurtransferase (Tst) can detoxify H_2S. Dysregulation of Tst expression associates with inability to detoxify detrimental H_2S and could be a factor in cell loss and inflammation[42]. The down-regulated Tst expression in spinal cord of TNBS rats may indicate dysfunction of the Tst detoxification that is possibly related to cell damage and inflammation in acute colitis.

Group 4: Proteins involved in cell redox homeostasis

Glutathione S-transferase P (Gstp1) functions in xenobiotic metabolism and plays a central role in the cellular defense against harmful endogenous compounds and xenobiotics[43,44]. Gstp1 is distributed in neuronal perikarya and oligodendrocytes in the central nervous system (CNS), and in neuronal perikarya and satellite cells of the DRG[45]. Reduced level of Gstp1 indicates a declined antioxidative capacity which may contribute to the damage to motor neurons in the process of immune-mediated motor neuron injury[46]. The underexpression of Gstp1 in both spinal cord and DRG of TNBS rats might suggest

oxidative stress and damage in neuronal cells. Prdx1 may participate in the signaling cascades of growth factors and TNF-α by regulating the intracellular concentrations of H_2O_2. A recent study revealed that in dextran sulfate sodium (DSS) mice, the inflamed intestinal mucosa has a down-regulated Prdx6 expression in comparison with normal mucosa[13]. Consistently, down-regulated Prdx1 in DRG of rats with TNBS colitis suggesting oxidative stress occurred in DRG. Superoxide dismutase (Mn), mitochondrial (Sod2) is an important antioxidant defenser in nearly all cells exposed to oxygen[47]. Ulcerative colitis involves intestinal mucosal damage driven by reactive oxygen species (ROS), in particular, superoxide anion. At the stage of severe inflammation, suppression of superoxide dismutase activity and elevation of nitrous oxide systems activity occur concomitantly. The underexpression of Sod2 protein indicates oxidative stress existing in the DRG of TNBS rats. Taken together, the down-regulated Gstp1 expression in spinal cord and DRG of TNBS rats, along with decreased expression of Prdx1 and Sod2 in DRG of TNBS rats, suggest that TNBS rats may have a significantly declined antioxidative and cellular defense capacity in the nervous system. Interestingly, another protein involved in cell redox homeostasis, dihydrolipoyl dehydrogenase (Dld), has a higher expression in the DRG of TNBS rats. Dld is a source of ROS, capable of scavenging nitric oxide, and can serve as an antioxidant by protecting other proteins against oxidative inactivation[48].

Group 5: Chaperonins

In both the spinal cord and DRG of TNBS rats, we observed significant up-regulation of Stip1. It is a chaperone that mediates the association of the molecular chaperones, heat shock cognate 71 kDa protein (Hspa8) and heat shock protein 90. Hspa8 is a key component of stress responses induced by various noxious conditions[49]. It regulates protein biosynthesis and refolding of denatured proteins, and plays an essential role in protecting cells in intestinal mucosal inflammation, potentially by lessening the extent and severity of injury[50,51]. The up-regulated Stip1 expression was observed in both the DRG and spinal cord of TNBS rats, indicating stress responses in primary afferent and CNS. Hspa8 is up-regulated in the spinal cord and down-regulated in DRG of TNBS rats. As Hspa8 exhibits both protective and antigenic properties, and the Hspa8 expression may stem from neuron, satellite or immune cells[49,52], the conflicting Hspa8 expression in spinal cord and DRG merits further investigation.

Group 6: Structure protein

Lamins are components of the nuclear lamina, providing a framework for the nuclear envelope. The mechanical properties of the cytoskeleton and cytoskeleton-based processes (such as cell motility and cell polarization), depend critically on the integrity of the nuclear lamina[53]. The overexpressed Lmna protein was observed in DRG of TNBS rats, which may suggest altered cytoskeleton.

Figure 4 Schematic drawing summarizes the major findings that might associate with pathophysiological changes in rat nervous system caused by trinitrobenzene sulfonic acid-induced colitis. TNBS: Trinitrobenzene sulfonic acid; DRG: Dorsal root ganglia; Hnrnpa2b1: Heterogeneous nuclear ribonucleoproteins A2/B1; Gstp1: Glutathione S-transferase P; Prdx1: Peroxiredoxin-1; Sod2: Superoxide dismutase; Lmna: Lamin C2; Aldoa: Aldolase A; Aldoc: Aldolase C; Ckmt1: Creatine kinase, mitochondrial 1, ubiquitous; Ckm: Creatine kinase M-type; Ndufv2: NADH dehydrogenase (ubiquinone) flavoprotein 2; Ndufb10: NADH dehydrogenase (ubiquinone) 1 β subcomplex 10; Oxct1 succinyl-CoA: 3-ketoacid-coenzyme A transferase 1; Fh1: Fumarate hydratase; Mdh2: Malate dehydrogenase; Psat1: Phosphoserine aminotransferase; Cap1: Cyclase-associated protein 1; Kctd12: Potassium channel tetramerisation domain containing protein 12; Vdac2: Voltage-dependent anion-selective channel protein 2; Ywhae: The 14-3-3 protein epsilon; Tst: Thiosulfate sulfurtransferase; Stip1: Stress-induced phosphoprotein 1; Hspa8: heat shock cognate 71 kDa protein.

Group 7: Cell metabolic enzymes

Proteins involved in glycolysis: Significant down-regulation of glycolysis enzymes, for example, Aldoc 17 kDa protein, fructose-bisphosphate aldolase A (Aldoa), and a third enzyme similar to pyruvate kinase 3, was observed in the DRG of TNBS group. Consistent with this, decreased expression of Aldoc was observed in spinal cord of TNBS rats. Aldoc and Aldoa regulate the stability of the light-neurofilament mRNA[54], and Aldoc provides marked neuroprotection to Purkinje cells after trauma and AMPA-

mediated excitotoxicity[55]. The down-regulated Aldoc in spinal cord and DRG together with decreased Aldoa expression in DRG may suggest down-regulated neuroprotection in TNBS rats. In addition, inhibition or activation of other glycolysis enzymes may result in speeding up or slowing down certain steps in the glycolysis pathway, and reflecting adjustment to physiological/pathological changes compensating for the cellular energy or neuron apoptosis[49].

Proteins involved in adenosine triphosphate transduction: Creatine kinase serves as an energy reservoir for the rapid buffering and regeneration of adenosine triphosphate (ATP) to sites with high, fluctuating energy demands, such as the synapse[55]. In the present study, expression of creatine kinase, mitochondrial 1, ubiquitous (Ckmt1) in the spinal cord was significantly up-regulated in TNBS rats. In contrast, Ckmt1 expression was decreased but the expression of creatine kinase M-type (Ckm) was up-regulated in the DRG of TNBS rats. Given that selective localization of Ckm in neurons was postulated to reflect the specific energy requirements of the specialized cells, these alterations may indicate enhanced phosphocreatine energy shuttles in spinal cord and remodelled energy shuttles/circles in the DRG[56,57].

Proteins involved in mitochondrial respiratory chain: Cytochrome b-c1 complex subunit 2, mitochondrial (Uqcrc2) is implicated in mitochondrial ROS generation and inflammation. Uqcrc2 deficiency causes mitochondrial dysfunction and exacerbates allergic airway inflammation[58]. The down-regulated Uqcrc2 expression in the spinal cord of TNBS rats might associate with inflammatory responses. Nicotinamide adenine dinucleotide (NADH) dehydrogenase is a potent source of reactive oxygen species such as superoxide and hydrogen peroxide[59]. It is interesting that, in contrast to the up-regulated protein expression of NADH dehydrogenase (ubiquinone) flavoprotein 2 (Ndufv2) in the spinal cord of the TNBS group, the NADH dehydrogenase (ubiquinone) 1 β subcomplex 10 (Ndufb10) was down-regulated. As the specific cellular functions of these subcomplexes are still not well known, further investigation is warranted.

Proteins involved in ketone body catabolism: 3-keto-acid-coenzyme A transferase 1 (Oxct1 Succinyl-CoA) is a mitochondrial matrix enzyme that plays a central role in extrahepatic ketone body catabolism. In the DRG of TNBS rats, Oxct1 Succinyl-CoA showed a 4-fold higher expression than in control rats. This observation is consistent with accelerated hepatic gluconeogenesis as well as ketogenesis in patients with chronic IBD, which probably is a consequence of the altered hormonal milieu[60].

Proteins involved in tricarboxylic acid cycle: Malate dehydrogenase, mitochondrial (Mdh2) is a cellular antioxidant, an enzyme in the tricarboxylic acid (TCA) cycle and gluconeogenesis. Mdh2 was down-regulated in experi-

mental autoimmune uveitis oxidative stress, and in colon mucosa of ulcerative colitis patients[12,61]. Similarly, the down-regulated Mdh2 and isoform mitochondrial of fumarate hydratase (Fh1) expression in DRG of TNBS rats may indicate a TCA metabolic dysregulation under disease condition.

Proteins involved in serine biosynthesis: Phosphoserine aminotransferase (Psat1) is an active serine biosynthesis enzyme in the mammal brain. Patients with Psat1 deficiency present with intractable seizures and psychomotor retardation[62]. The significantly down-regulated Psat1 expression in spinal cord of the TNBS group may indicate dysregulation of serine biosynthesis and may be associated with seizure susceptibility in TNBS rats.

Our analysis provides an overview profiling the proteomic changes in the spinal cord and DRG of rats with TNBS-induced colitis. As summarized in Figure 4, intracolonal instillation of TNBS not only induces inflammatory/immune responses in the DRG and spinal cord, but also triggers broad alterations of protein involving cell signaling, cellular metabolism, redox regulation, stress response *etc*. The TNBS-induced colitis in rodents is an immunologically mediated colitis that accompanies with an increase in proinflammatory factors and systemic endotoxaemia[63]. Besides colonic and systematic changes, a series of alterations in the nervous system have been described, such as transient disruption of blood-brain-barrier to small molecules[64]; a marked inflammatory response within the CNS[22]; and neurosignaling activation in rodent primary afferent nerve as well as in DRG and spinal cord neurons[20,65,66]. These neurological alterations may relate to intrinsic neuronal excitability and help explain some of the underlying comorbidities, such as hyperalgesia, seizure and anorexia[5,6]. The neurologic manifestations of IBD are most likely primary immune-mediated disorders, possibly caused by proinflammatory cytokines that diminish neuron proliferation, increase apoptosis, increase neuronal excitability, exacerbate sickness and/or result in psychological symptoms[21,67]. Our results delineated a dramatic deviation of protein profiling from the carefully orchestrated physiological balance in the DRG and spinal cord of TNBS rats. These findings provide useful proteins for further investigation on the neurological manifestations of IBD.

COMMENTS

Background
Inflammatory bowel disease (IBD) is a systematic illness, whose etiology and pathophysiology is incompletely understood. Many organs outside the gastrointestinal tract are involved in IBD, including the nervous system (neuropathies, cerebrovascular events, white matter lesions). These pathological changes may associate with a variety of comorbidities, such as hyperalgesia, seizure, and anorexia, but the underlying mechanism remains poorly understand.

Research frontiers
Proteomics keeps a rapidly expanding field, with a wealth of reports regularly appearing on technology enhancements and scientific studies using these new instruments.

Innovations and breakthroughs

This study demonstrated that trinitrobenzene sulfonic acid (TNBS) colitis profoundly changed expression of not only proteins involved in inflammatory/immune responses, but also proteins involved in cell signaling, sulfate transport, redox homeostasis and cell metabolism.

Applications

This study provides an overview profiling the proteomic changes in the spinal cord and dorsal root ganglia (DRG) of rats with TNBS-induced experimental colitis. These findings provide useful proteins for further investigation on the neurological manifestations of IBD.

Peer review

In this study, the authors profiled the global protein expression changes in the DRG and spinal cord in rats with acute colitis induced by TNBS using a two-dimensional electrophoresis-based proteomic technique. They found that altered proteins were involved in a number of biological functions including inflammation/immunity, cell signaling, redox regulation, sulfate transport and cellular metabolism. Although the number of the samples examined in this study was small, this paper is well written and the results are interesting.

Abstract

AIM: To clarify the biological role of stem cell factor (SCF)-mediated wild-type KIT receptor activation in gastrointestinal stromal tumor (GIST) growth.

METHODS: The co-expression of wild-type KIT receptor and SCF was evaluated in 51 GIST samples using mutation analysis and immunohistochemistry, and the results were correlated with clinicopathological parameters, including the mitotic count, proliferative index (Ki-67 immunohistochemical staining), mitotic index (phospho-histone H3 immunohistochemical staining) and apoptotic index (terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling). Using primary cultured GIST cells, the effect of SCF-mediated wild-type KIT receptor activation was determined by western blotting, methyl thiazolyl tetrazolium (MTT), and apoptosis assays.

RESULTS: We found that wild-type KIT receptor and SCF protein were expressed in 100% and 76.5% of the 51 GIST samples, respectively, and the co-expression of wild-type KIT receptor and SCF was associated with known indicators of poor prognosis, including larger tumor size ($P = 0.0118$), higher mitotic count ($P = 0.0058$), higher proliferative index ($P = 0.0012$), higher mitotic index ($P = 0.0282$), lower apoptosis index ($P = 0.0484$), and increased National Institutes of Health risk level ($P = 0.0012$). We also found that the introduction of exogenous SCF potently increased KIT kinase activity, stimulated cell proliferation ($P < 0.01$) and inhibited apoptosis ($P < 0.01$) induced by serum starvation, while a KIT immunoblocking antibody suppressed proliferation ($P = 0.01$) and promoted apoptosis ($P < 0.01$) in cultured GIST cells.

CONCLUSION: SCF-mediated wild-type KIT receptor activation plays an important role in GIST cell growth. The inhibition of SCF-mediated wild-type KIT receptor activation may prove to be particularly important for GIST therapy.

INTRODUCTION

The KIT receptor, encoded by the oncogene *c-kit*[1], is characterised structurally by five immunoglobulin-like extracellular domains and an intracytoplasmic domain that contains an adenosine triphosphate (ATP)-binding domain and a phosphotransferase domain, which are separated by an interkinase sequence[2-5]. Under physiological conditions, the stem cell factor (SCF) binds to KIT and induces KIT homodimerisation, resulting in the phosphorylation of its tyrosine residues. The tyrosine-phosphorylated KIT receptor subsequently becomes a new docking site for signal transduction molecules and induces substrate binding and phosphorylation[6]. Thus, the interaction between SCF and the KIT receptor is essential for normal hematopoiesis, melanogenesis, gametogenesis, and the growth and differentiation of mast cells and interstitial cells of Cajal (ICCs)[7,8]. Notably, mutations in the *c-kit* gene have been implicated in neoplasms arising from these cell lineages. Oncogenic mutations in *c-kit* cause a constitutive phosphorylation of the KIT receptor that is independent of SCF binding, leading to a cascade of intracellular signalling events that contribute to the abnormal proliferation and survival of these neoplastic cells[9,10].

Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal neoplasms of the gastrointestinal tract, and they are believed to originate from ICC progenitor cells[11-13]. It has also been noted that approximately 90% of GIST cases have activating mutations in either the *c-kit* or platelet-derived growth factor receptor (PDGFR) A genes[14-16]. In addition, the emerging role of SCF in *c-kit*-mutant GISTs indicates that an autocrine-paracrine loop serves as a further mechanism of wild-type KIT receptor activation[17,18].

In this study, we demonstrated the co-existence of wild-type KIT receptor and SCF in primary GISTs by analysing the entire coding sequence of *c-kit* and the protein expression of KIT and SCF in these tumors, as suggested in a previous study[19]. Based on *ex vivo* assays, we further demonstrated that SCF-mediated wild-type KIT receptor activation affected GIST growth in a dual manner by stimulating proliferation and inhibiting the apoptosis of GIST primary cells. These data suggest that the inhibition of SCF-mediated wild-type KIT receptor activation may be particularly important for GIST therapy.

MATERIALS AND METHODS

Patients

Samples from 51 consecutive patients with GISTs who underwent surgery at Changhai Hospital (Shanghai, China) between January and October 2006 were subjected to histological analysis. In addition, GIST primary cells were isolated from three fresh GIST specimens from patients who underwent surgery at Changhai Hospital in 2009. The GIST diagnosis was confirmed as previously described[20-22], and all tumors were KIT protein (CD117)-positive. No patients had received imatinib prior to the surgical resection of the tumor. Demographic

Table 1 Correlations between the co-expression of wild-type KIT receptor and stem cell factor and clinicopathological factors in gastrointestinal stromal tumors

data and clinical and histological features for all of the GISTs analysed in this study are summarised in Table 1.

The use of all human tissues was approved by the hospital's institutional committee for human research, and informed consent was obtained from all of the subjects.

Immunohistochemistry

Immunohistochemical staining was performed using the labelled streptavidin-biotin method (DAKO LSAB-2 Kit, Peroxidase, DAKO) according to the manufacturer's instructions. The following primary antibodies were used: CD117 (DAKO), Ki-67 (DAKO), SCF (Cell Signaling Technology, Inc.) and phospho-histone H3 (pHH3, Cell Signaling Technology). Parallel sections were used to examine the co-expression of KIT and SCF. For Ki-67 and pHH3, positive cells were counted in five randomised regions in the tumor component of each lesion, and the labelling index was calculated as follows: Labelling index (%) = (positive cell number/total cell number) × 100%.

In situ apoptosis

In situ apoptosis was assessed by terminal deoxynucleotidyl transferase-mediated dUTP nick-end labelling (TUNEL, Roche Diagnostics) staining, which was performed according to the manufacturer's instructions. The apoptotic index was calculated as follows: Apoptotic index (%) = (apoptotic cell number/total cell number) × 100%.

Polymerase chain reaction amplification and sequencing

Genomic DNA was extracted from cryopreserved (*n* = 51) or fresh (*n* = 3) specimens using a commercial kit (BBI, Canada). Next, *c-kit* exons 9, 11, 13, 14 and 17, as well as PDGFRA exons 12 and 18, were amplified using the following primer sequences and annealing temperatures (designed): *c-kit* exon 9 (5'TTTATTTTCCTAGAG-TAAGCCAGGG-3' and 5'-ATCATGACTGATA TGGTAGACAGAGC-3', at 56 ℃), *c-kit* exon 11 (5' -ATTATTAAAAGGTGAT CTATTTTT-3' and 5' -ACTGTTATGTGTACCCAAAAAG-3', at 60 ℃), *c-kit* exon 13 (5'-CACCATCACCACTTACTTGTTGTCT-3' and 5'-GACAGACAAT AAAAGGCAGCTTGGAC-3', at 67 ℃), *c-kit* exon 14 (5'-TCTCACCTTC TTTCTA-ACCTTTTC-3' and 5'-AACCCTTATGACCCCAT-GAA-3', at 54 ℃), *c-kit* exon 17 (5'GAACAT-CATTCAAGGCGTACTTTTG-3' and 5'-TTGAAA CTAAAAATCCTTTGCAGGAC-3', at 65 ℃), PDG-FRA exon 12 (5'-CTCTGGTGCACTGGGACTTT-3' and 5'-GCAAGGGAAAAGGGAGTCT T-3', at 60 ℃), and PDGFRA exon 18 (5'-ATGGCTTGATCCTGAGT-CATT-3' and 5'-GTGTGGGAAGTGTGGACG-3', at 60 ℃). Gene mutations were analysed through the direct sequencing of uncloned polymerase chain reaction (PCR) fragments. Samples that appeared to contain mutations were further examined for the presence of the wild-type *c-kit* gene by subcloning the purified PCR products using a TA cloning vector system (Stratagene, CA). Five independent subclones from each PCR were sequenced.

Cell isolation and short-term primary cell culture

GIST primary cells were isolated and cultured as described in the literature with minor modifications[23]. The nonnecrotic tissue was separated from fresh GIST samples and finely minced with curved scissors. The minced tissue was homogenised by being passed through a 15-gauge needle with a syringe five times and subsequently being passed through a stainless steel mesh (200 wires/inch). The cells were counted with a haemocytometer, and cell viability was determined by propidium iodide staining.

After centrifugation in phosphate buffered solution (PBS) at 4 ℃, cell pellets were resuspended in 1640 RPMI medium supplemented with 20% heat-inactivated foetal bovine serum (FBS), 1.0 mmol/L nonessential amino acids, 1.0 mmol/L sodium pyruvate, and 0.5 mmol/L 3-isobutyl-1- methylxanthine to inhibit fibroblast growth. Medium changes were performed at 24 h after seeding and every two or three days before cell analysis.

Enzyme-linked immunosorbent assay for stem cell factor production

For the measurement of SCF production, the concentration of GIST primary cells was adjusted to 5 × 10^6 cells/mL, and the supernatants were collected 24 h later. Samples were stored at -80 ℃ for further analysis. SCF concentration was determined by enzyme-linked immunosorbent assay (ELISA) using 96-well plates coated with catching antibody (diluted to 5 μg/mL in PBS, 100 μL/well) at 4 ℃ overnight according to the manufac-

turer's instructions.

Western blotting

Protein extracts were separated by sodium dodecyl sulphate-polyacrylamide gel electrophoresis, transferred to nitrocellulose membranes, and incubated with a specific antibody to demonstrate protein loading. Anti-phospho-KIT (pY703) antibody was purchased from Abcam (United Kingdom). Glyceraldehyde-3-phosphate dehydrogenase mouse monoclonal antibody (Santa Cruz Biotechnology) was used as an internal control. To examine the effects of exogenous SCF on KIT phosphorylation, GIST primary cells were incubated overnight with medium containing 0.5% FBS. Cells were subsequently stimulated with various concentrations of SCF for 15 min, and phospho-KIT was examined as described above.

In vitro proliferation assay

Cell proliferation was determined using a methyl thiazolyl tetrazolium (MTT) assay (Roche, United States) according to the manufacturer's instructions. In brief, GIST primary cells were seeded at a density of 8 × 10^3 cells/100 μL into 96-well plates and allowed to adhere. After 24 h, the original media were replaced with fresh media containing various concentrations of SCF (Pepro-Tech, United States) or KIT immunoblocking antibody (Sigma, United States) with 0.5% FBS. After 48 h of incubation, MTT was added to each well. The quantity of the formazan product measured at 572 nm was directly proportional to the number of live cells in the culture.

Flow cytometric analysis of apoptosis

GIST primary cells were subjected to serum withdrawal for 12 h in the presence or absence of exogenous SCF or KIT immunoblocking antibody to induce apoptosis. Subsequently, apoptosis was detected using an annexin V-fluorescein isothiocyanate staining kit (R and D Systems). The apoptotic index was reported as the percentage of annexin V-positive cells in the early and late stages of apoptosis.

Statistical analysis

Data are expressed as the mean ± SD or the median and 25th and 75th percentiles [median (Q1, Q3)] for continuous variables and as percentages for categorical variables. Continuous variables were compared using Student's *t* test or the Wilcoxon rank sum test for nonnormally distributed data. Correlations between categorical and continuous variables were assessed using the χ^2 or Fisher's exact test and *t* test, respectively. *P* values of less than 0.05 were considered to be significant. All analysis were performed with SPSS version 17.0 (SPSS, Chicago, IL).

RESULTS

Tumor genotypes

All 51 cryopreserved specimens were screened for mutations in the *c-kit* gene. Overall, 32 of 51 (62.7%) tumors

Figure 1 Heterozygous *c-kit* mutations in primary gastrointestinal stromal tumors. The mutant nucleotide sequence is indicated in the upper diagram, and the wild-type nucleotide sequence is indicated in the lower diagram. Nucleotide changes are shown in red capital letters. A: Cryopreserved specimens; B: Fresh specimens.

harboured *c-kit* mutations. Among the GISTs with *c-kit* mutations, 27 (52.9%) had mutations in exon 11 of *c-kit,* five had mutations in exon 9 (Figure 1), and none had mutations in exon 13, 14 or 17. The amino acid changes observed in the 27 tumors with exon 11 mutations were as follows: deletion in 16 (59.3%) tumors, substitution in 7 (25.9%), both deletion and substitution in 2 (7.4%), insertion in 1 (3.7%), and duplication in 1 (3.7%). Five cases harboured exon 9 *c-kit* mutations, including in-frame insertions (3 tumors; 60.0%) and missense mutations (2 tumors; 40%). GISTs without *c-kit* mutations were further examined for PDGFRA mutations; only four (7.8%) tumors harboured substitution mutations in PDGFRA exon 18. All *c-kit* mutations were heterozygous, as indicated by the presence of a wild-type *c-kit* allele in the nucleotide sequence (Figure 1A).

In the three fresh specimens analysed in this experiment, sequencing showed that GIST1 and GIST3 each harboured heterozygous *c-kit* exon 11 mutations, while GIST2 had no mutations in either *c-kit* or PDGFRA (Figure 1B).

Expression of stem cell factor in primary GISTS

The immunohistochemistry experiments shown in Figure 2 demonstrated that SCF expression was observed in both GIST cells and fibroblasts, while KIT and SCF were co-expressed in tumor cells. Given that GISTs contains only a small number of fibroblasts, a specimen was considered "positive" for SCF expression if only the tumor cells showed distinct cytoplasmic or membrane staining; otherwise, the specimen was considered "nega-

tive" for SCF expression. SCF protein was present in 39 (76.5%) of the 51 GIST samples. A morphometric study revealed more pHH3 and Ki-67 positive cells and lower apoptotic cells in SCF-positive GIST cases compared with SCF-negative GIST cases (Figure 2). These results suggest that SCF may participate in an autocrine-paracrine stimulatory loop within primary GISTs.

Correlations between SCF and clinicopathological variables

As shown in Table 1, the co-expression of wild-type KIT receptor and SCF was associated with known prognostic variables, including larger tumor size ($P = 0.0118$), higher mitotic count ($P = 0.0058$), higher proliferative index ($P = 0.0012$), higher mitotic index ($P = 0.0282$), lower apoptosis index ($P = 0.0484$), and an increased NIH risk level ($P = 0.0012$). These results suggest that the SCF-mediated activation of wild-type KIT may play an important role in tumor cell growth by directly promoting cell proliferation and inhibiting apoptosis. The co-expression of the wild-type KIT receptor and SCF was not associated with any other variable tested, including patient's age, sex, histological phenotype, cellularity, tumor location and *c-kit* gene mutation.

KIT activation in primary GISTS

In line with other published findings[24,25], KIT was phosphorylated at tyrosine 703 in 74.5% (38/51) of GISTs (Figure 3A), although the levels of phosphorylated KIT varied substantially from tumor to tumor, even between those with identical *c-kit* gene mutations.

Figure 2 The expression of stem cell factor in primary gastrointestinal stromal tumors. Sections of gastrointestinal stromal tumors (GISTs) (*n* = 51) were immunostained with stem cell factor (SCF), KIT (CD117), pHH3 and Ki-67 antibodies (magnification, ×200). Apoptosis was assessed *in situ* by terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling (TUNEL) staining (magnification, ×200). Representative images are shown. Bar = 50 μm.

Figure 3 Western blotting analysis of phosphorylated KIT. A: KIT phosphorylation (p-KIT Y703) was analysed in gastrointestinal stromal tumor (GIST) samples (*n* = 51). A representative western blotting of p-KIT Y703 (top) and glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (bottom) in patients with exon 11 or 9 mutations or wild-type c-kit-bearing tumors; B: GIST primary cells were incubated with 100 ng/mL stem cell factor (SCF) for the indicated times. KIT phosphorylation (p-KIT Y703) was analysed by western blotting.

Furthermore, KIT phosphorylation was not significantly associated with the presence of *c-kit* mutations (*P* = 0.6625). Thirteen tumors without detectable *c-kit* mutations showed strong KIT phosphorylation, which was consistent with a nonmutational mechanism of KIT activation.

To determine whether the KIT receptor was activated due to the presence of the wild-type KIT receptor in *c-kit*-mutant GISTs, we cultivated GIST primary cells in the presence of various concentrations of exogenous SCF. KIT was rapidly phosphorylated in response to

exogenous SCF in a time-dependent manner in GIST primary cells (Figure 3B). These findings suggest that the hyperphosphorylation of the wild-type KIT receptor was induced by exogenous SCF, confirming that SCF mediated the activation of the wild-type KIT receptor in *c-kit*-mutant GISTs.

Effects of wild-type KIT receptor activation on proliferation in GIST primary cells

To assess whether SCF-mediated wild-type KIT activation participated in the proliferation of GIST tumor cells, we analysed the proliferation rate of GIST primary cells exposed to exogenous SCF. Consistent with the finding that SCF induced KIT phosphorylation, exogenous SCF significantly increased cell proliferation in a dose-dependent manner after 72 h of treatment (Figure 4A).

The ELISA results showed that all three primary cell lines produced significant amounts of SCF (3.5 ± 2.33 pg/mL per 10^6 cells). Therefore, we examined the effect of SCF-mediated wild-type KIT activation on cell proliferation by inhibiting the interactions between the KIT receptor and endogenous SCF. As shown in Figure 4B, cell proliferation was significantly inhibited (by > 50%) after 72 h of treatment with a KIT immunoblocking antibody, suggesting that SCF-mediated wild-type KIT receptor activation plays a key role in controlling GIST cell proliferation through the SCF/KIT autocrine-paracrine loop.

Effects of wild-type KIT receptor activation on apoptosis in GIST primary cells

The capacity to regulate survival is an important feature of tumor cells. Therefore, we tested whether wild-type

A

B

Figure 4 Stem cell factor stimulates gastrointestinal stromal tumors cell proliferation *in vitro*. Gastrointestinal stromal tumor (GIST) primary cells were incubated for 72 h with exogenous stem cell factor (SCF) (0-100 ng/mL, A) or KIT immunoblocking antibody (100 ng/mL, B), cell proliferation was analysed by methyl thiazolyl tetrazolium assay. The data are presented as the mean ± SD (n = 4 for each). [a]P < 0.05, [b]P < 0.01 *vs* untreated cells.

KIT receptor activation could rescue GIST primary cells from serum deprivation-induced death. As shown in Figure 5, the addition of exogenous SCF (100 ng/mL, 12 h) significantly reduced the percentage of apoptotic cells, from 32.05% ± 2.65% to 18.55% ± 1.83% (P < 0.01) in GIST primary cells. In contrast, treatment with KIT immunoblocking antibody significantly increased the percentage of apoptotic cells from 32.05% ± 2.65% to 43.58% ± 2.94% (P < 0.01).

DISCUSSION

The present study showed that *c-kit* gene mutations occurred in 32 (62.7%) of the 51 GIST clinical samples, which is consistent with previous results[14-16]. All of these mutations were heterozygous, i.e., at least one wild-type *c-kit* allele was present in all tumors, which is consistent with a previous report that most GIST mutations were heterozygous[26]. The heterozygous nature of the receptor status in GISTs suggests that KIT receptor activation is not induced by *c-kit* gene mutations alone but rather by other mechanisms, such as the activation of ligand-dependent signal transduction pathways. Indeed, we noted that KIT activation, as manifested by receptor tyrosine phosphorylation, is a general phenomenon in GISTs, even those without *c-kit* mutations.

Constitutive receptor tyrosine kinase activation is believed to be important for tumor proliferation and progression, and in GISTs, KIT activation can serve as an initiating event in oncogenesis[27-29]. However, the results obtained in our study showed that SCF expression was positively correlated with mitotic activity. KIT was rapidly phosphorylated upon stimulation with exogenous SCF, suggesting that ligand-dependent hyperactivation is also a strong mitogen in GIST cells. This observation is consistent with the data reported by Hirano *et al*[18], who found that SCF-positive GIST cases had a significantly higher average MIB-1 labelling index and a larger average tumor size than did the SCF-negative cases. Similarly, Théou-Anton *et al*[17] detected SCF in up to 93% of the GISTs studied and speculated that KIT activation in GISTs may be caused partly by the presence of SCF within the tumors. However, no *in vitro* measurements were conducted in either of these two studies, and the possible role of SCF-mediated wild-type KIT receptor activation in GIST proliferation should be explored *in vitro* to assess its independent contribution to cell growth. Accordingly, we further examined the mitogenic activity of this molecule on GIST primary cells harbouring a heterozygous c-kit mutation. It was found that exogenous SCF markedly stimulated cell proliferation and KIT phosphorylation in all GIST primary cells, while the inhibition of the SCF/KIT interaction reduced cell proliferation, confirming that exogenous or endogenous SCF-mediated activation of wild-type KIT provided an important signal for GIST cell proliferation. Further, GIST882, which has a homozygous activating *c-kit* mutation[30], did not exhibit increased proliferation in response to supplemental SCF, and the exogenous SCF stimulation of GIST544 cells, which express a heterozy-

Figure 5 Stem cell factor inhibits gastrointestinal stromal tumor cell apoptosis *in vitro*. gous *c-kit* mutation, induces stronger KIT phosphorylation and cell growth[31]; these observations further validate our results.

Apoptosis is an active process that plays a key role in the development and maintenance of tissue homeostasis. The tumor growth rate partly depends on an excess of proliferation over apoptosis[32]. Indeed, the relationship between SCF-mediated wild-type KIT receptor activation and apoptosis has been explored extensively. For example, *c-kit* activation was found to suppress the apoptosis of normal murine melanocyte precursors[33], soft tissue sarcomas of neuroectodermal origin[34], neuroblastomas[35], and normal and malignant human haematopoietic cells[36]. Our results also support a role for SCF mediated wild-type KIT receptor activation in the survival of GIST primary cells because exogenous SCF rescues GIST primary cells from serum deprivation-induced death and may consequently prolong cell survival, while blocking the interactions between KIT receptor and endogenous SCF markedly reduces the viability of

these cells.

In summary, our results demonstrated that the SCF-dependent activation of the wild-type KIT receptor is specifically involved in promoting the cell growth of GISTs *via* autocrine-paracrine loop activation. Therefore, drugs targeted against GISTs should switch off the activation of both mutant and wild-type receptors to achieve an effective response.

COMMENTS

Background
Gastrointestinal stromal tumor (GIST) is the most common sarcoma of the intestinal tract. Imatinib has shown remarkable efficacy in the treatment of GISTs, which are notoriously refractory to conventional chemotherapy or radiation. However, a considerable proportion of GIST patients show primary or acquired resistance to Imatinib.

Innovations and breakthroughs
In this study, the authors showed that the co-expression of the wild-type KIT receptor and stem cell factor (SCF) was associated with known prognostic variables in a series of 51 patients. Authors further demonstrated that SCF-

mediated wild-type KIT receptor activation participated in GIST growth by stimulating the proliferation and inhibiting the apoptosis of GIST primary cells. These results suggest that SCF-mediated wild-type KIT receptor activation represents a new and potentially promising target for GIST therapy. Therefore, to achieve an effective response, drugs targeted against GISTs should switch off the activation of both mutant and wild-type receptors.

Applications
The study demonstrated that the SCF-dependent activation of the wild-type KIT receptor is specifically involved in promoting the cell growth of GISTs *via* autocrine-paracrine loop activation. Therefore, drugs that target wild-type receptor activation may be viable candidates for the treatment of GISTs and should be explored in future studies.

Peer review
This is a well written manuscript. The use of confocal microscopy would have been ideal for studying both KIT and SCF expression.

Abstract

AIM: To investigated the interaction between toll-like receptor 4 (TLR4)-activated hepatoma cells and macrophages in the induction of tumor-immune suppression mediated by CD4+CD25^{high} family of transcription factor P3 (FOXP3) regulatory T cells (Tregs).

METHODS: The proportion of FOXP3+ Tregs was identified in peripheral blood and tumor tissues of 60 hepatocellular carcinoma (HCC) patients. TLR4 expression was examined in tumor tissues and cell lines. The correlation was examined between FOXP3+ Tregs in peripheral blood and TLR4 expression of HCC tissues. Following activation of TLR4 in H22 murine hepatoma cells pre-incubated with lipopolysaccharide (LPS) and co-cultured with macrophage cell line RAW246.7, the synthesis of cytokines tumor necrosis factor-α, CCL22, and interleukin (IL)-10 by the two cell lines was detected and analyzed.

RESULTS: FOXP3+ Tregs were enriched in tumor sites, and circulating FOXP3+ Tregs were increased in HCC patients in correlation with multiple tumor foci and up-regulated TLR4 expression in HCC tissues. Semi-quantitative analysis indicated that TLR4 was over-expressed in HCC compared with the matched normal tissues. Cell cultivation experiments indicated that the mRNAs of IL-10 and CCL22 were significantly up-regulated in the RAW246.7 cell line when co-cultured with LPS pre-incubated H22 cells.

CONCLUSION: In hepatoma cell lines, TLR4 may indirectly facilitate the recruitment of Tregs to the tumor site and promote intrahepatic metastasis through its interaction with macrophages.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most com-

mon cancer worldwide, and is the third most common cause of cancer related deaths[1]. Previous studies have demonstrated that the majority of HCC patients develop tumor-specific immune responses; however, in most patients, tumors progress despite tumor-specific humoral and cellular immune responses. These findings imply that HCC escapes the anti-tumor immune response through various strategies.

Recently, many studies have suggested that the tumor microenvironment plays an important role in the establishment and progression of tumors. Lymphocytes contribute to the tumor microenvironment through immunity and inflammation. Through diverse strategies, tumor cells play an important role in the suppression of anti-tumor immunity in the surrounding microenvironment *via* interactions with infiltrated immune cells or macrophages, which in turn potentially facilitates growth of the tumor itself. Moreover, induction of the differentiation and/or recruitment of regulatory T cells (Tregs), a unique population of CD4+ T cells, potentially comprises one of the key mechanisms. Tregs are defined based on their expression of CD4, CD25 and forkhead, or winged helix family of transcription factor P3 (FOXP3), which is critical for the development and function of Tregs in mice and humans[2]. Tregs play a critical role in immunologic self-tolerance and suppression in the tumor immune response[3,4]. Early evidence indicates that Tregs (not FOXP3+ T cells but CD4+CD25+ T cells) are increased in patients with various types of cancer[5-7]. It is hypothesized that their systemic and/or local accumulation promotes tumor growth through suppression of the host anti-tumor response[8]. However, considerable uncertainty remains regarding the characteristics, functions, and regulation of Tregs. Therefore, we investigated the clinicopathologic significance of CD4+CD25[high]FOXP3+ Tregs in HCC patients, and analyzed their ability to suppress the immune response. Elucidation of the mechanisms underlying Treg elevation is essential for the development of new approaches that aim to modulate the frequency and function of Tregs in order to enhance the efficacy of cancer immune-based therapies.

Toll-like receptors (TLRs) recognize specific structural regions of invading pathogens and initiate innate and adaptive immune responses; their expression has been detected in immune cells and also in many cancer cells[9]. Lipopolysaccharide (LPS), a ligand for TLR4, stimulates immune cells and triggers the production of inflammatory cytokines and other mediators *via* TLR4, which in turn regulates the host immune defense system and eliminates pathogens[10,11]. It has been reported that inflammatory cytokines induced by inflammatory stimuli counteract immune surveillance and facilitate tumor growth[12,13]. However, various other reports have suggested that diverse TLRs potentially exhibit different effects on Tregs due to differences in pathogens and immune environment, resulting in either increased suppression or abrogation of suppression[14-17]. The suppressive function of Tregs is tightly regulated to respond to the different requirements of immunity. The mechanism underlying the selective control of Treg function remains obscure. Precise modulation of the suppressive function of Tregs is crucial for the development of effective cancer immunotherapy. Thus, in this study we investigated whether TLR4 is expressed in HCC, and whether tumor TLR4 is functionally active in inducing cytokines, and we also examined the clinicopathological correlation between tumor TLR4 signaling and CD4+CD25[high]FOXP3+ Tregs in tumor immune escape.

Currently, the roles of CD4+CD25[high]FOXP3+ Tregs and TLR4 in HCC and their regulatory activity in the tumor microenvironment remain unclear. In the present study, we described the clinicopathological significance of Tregs in 60 HCC patients, and the expression of TLR4 in hepatic cancer cells. Our findings indicated that TLR4 ligation promotes the secretion of inhibitory cytokine interleukin (IL)-10 and chemokine CCL22 from co-cultured macrophages, but not from the tumor cells themselves. Furthermore, the prevalence of Tregs significantly correlated with the presence of multifocal tumor. Our results suggest a mechanistic path for the indirect modulation of CD4+CD25[high]FOXP3+ Tregs *via* tumor TLR4 signaling, and demonstrate that interactions between hepatoma cells and macrophages induce anti-tumor immune suppression *via* Tregs.

MATERIALS AND METHODS

Ethics
This study was conducted in accordance with the Declaration of Helsinki (2000) of the World Medical Association. The Ethics Committee of Tongji Medical College (Wuhan, China) approved the study protocol. All patients provided informed written consent before blood and tumor sampling.

Patient and samples
Blood samples were collected from 60 HCC patients who underwent hepatic resection in the Center of Hepatobiliary Surgery, Union Hospital, Wuhan, China from March 2008 to October 2008. Control blood samples were obtained from 20 healthy volunteers. HCC patients were pathologically diagnosed following surgical resection. Among the 60 HCC patients, there were 51 males and nine females aged 17-77 years (mean, 51.3 years). According to the International Union against Cancer tumor-node-metastasis classification[18], there were 19 (31.7%), 24 (40%) and 17 (28.3%) cases at stage Ⅰ, Ⅱ and Ⅲ, respectively. No patient was treated with local ablative therapy, chemotherapy, or immunotherapy prior to surgery. Clinical and laboratory characteristics of the HCC patients are shown in Table 1. Blood samples (3 mL) were collected 2-3 d before operation from each patient in the early morning. Samples were placed in ethylenediaminetetraacetic acid anticoagulant tubes for flow cytometric detection in our hospital. Next, 1 cm × 1 cm × 1 cm tumor and normal tissues were obtained from each patient intraoperatively, avoiding

Table 1 Clinical and laboratory characteristics of the 60 hepatocellular carcinoma patients

Items	Results

areas of necrosis, hemorrhage, and/or adipose tissues. One portion of each specimen was snap frozen in liquid nitrogen and the other part was fixed in 10% polyformaldehyde solution and embedded in paraffin.

Flow cytometric analysis

Peripheral blood mononuclear cells from each patient (100 μL) was separated into a heparinized container. Twenty microliters anti-human CD25-fluorescein isothiocyanate and anti-human CD4-PerCP was added to each tube, and incubated at room temperature in the dark for 15 min. After washing in 1 × phosphate-buffered saline, fixed broken membrane buffer 1 mL (1% paraformaldehyde and 70% ice-alcohol; pH 7.4) was added. The remaining lymphocytes were incubated in 20 μL FOXP3-PE at 4 ℃ for 30 min. Subsequently, cells were analyzed by flow cytometry (FACS Calibur, BD) with Cellquest software (Version 3.3, BD Biosciences-Pharmingen, United States). All conjugated antibodies described above and their isotype-matched monoclonal antibodies were purchased from BD, United States.

Lymphocytes were gated on forward and side scatter profiles followed by gating on CD4+ T cells, and these cells were then analyzed for CD25 expression. For FOXP3 expression analysis, cells inside the CD4+CD25^{high} gate were analyzed.

Western blotting

Nuclear protein extracts were prepared in sodium dodecyl sulfate (SDS) lysis buffer containing protease inhibitors, pre-stained molecular weight markers were denatured in laemmli buffer (10% glycerol, 2% SDS, 0.1 mol/L dithiothreitol, 50 mmol/L Tris, 0.01 mg/mL bromphenol blue; pH 6.8) at 90 ℃, and were separated by SDS-polyacrylamide gel electrophoresis. Resolved proteins were transferred onto polyvinylidene fluoride membrane in Trans-blot wet buffer (Bio-Rad Laboratories, United States). The membranes were blocked with 5% nonfat dry milk in 1 × tris-buffered saline (TBS), then incubated with 2 μg/mL mouse monoclonal anti-FoxP3 antibody (clone 22510; Abcam, United States) overnight at 4 ℃ followed by horseradish peroxidase-conjugated goat anti-mouse immunoglobulin G (IgG) for 1 h at room temperature, and washed with 1

× TBS. Membranes were treated with enhanced chemiluminescence plus Western blotting detection kit (Transgen, Beijing, China), and bands were detected using STORM 840v2005 with ImageQuant software (GE, United States).

Cell lines and reagents

If not indicated otherwise, all substances were purchased from Gibco, United States. The H22 (murine) and HepG2 (human) hepatic cancer cell lines were a gift from Dr. Huang Bo (Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China). The immortalized murine macrophage line RAW246.7 was preserved in our laboratory. The cell lines were cultured in RPMI-1640 medium supplemented with 10% fetal bovine serum. All experiments were performed under endotoxin-free conditions.

Co-culture assay

The various cellular components were grown in an artificial basement membrane in a modified Polyster-Transwell (Costar, United States) plate without direct cell-to-cell contact. 1×10^5 RAW246.7 cells/mL were seeded into the upper well of the Transwell plate (0.4 μm pore diameter), which consisted of a membrane permeable to liquids but not cells, whereas the lower well was filled to the top with RPMI + 10% fetal calf serum. H22 cells (1×10^6 cells/mL RPMI) were seeded into a 12-well plate. To activate TLR4 in H22 cells, LPS (Gibco, United States) was used at 1 μg/mL. The culture medium was removed after LPS-stimulating the H22 cells for 12 h. Next, the Transwells were inserted into the 12-well plate. Gene expression was compared between control and macrophages co-cultured with H22 cells after 24 h, and macrophages with or without conditioned tumor medium were analyzed using reverse transcriptase polymerase chain reaction (RT-PCR). All experiments were performed at least in triplicate.

RNA extraction and RT-PCR

Total RNA was extracted from patient samples, H22, HepG2, and RAW246.7 cells, using Trizol reagent (Invitrogen, United States). Using a first strand cDNA synthesis kit (ToYoBo, Shanghai, China), cDNA was generated with Oligo dT primer. Primers for TLR4, tumor necrosis factor-α (TNF-α), IL-10, CCL22 and β-actin were designed using Premier 5.0 software (Table 2). Primers were synthesized by Sangon Inc. Shanghai, China.

Each reaction mixture contained 2.5 μL 10 × buffer, 2.5 μL 2.5 mmol MgCl₂, 0.5 μL 10 mmol of dNTP, 0.2 μL 5 U/μL Taq DNA polymerase, 1 μL each of sense and antisense primer, and 1 μL cDNA in a final volume of 25 μL (Fermentas, United States). Reaction mixtures were incubated at 94 ℃ for 5 min to activate the Taq DNA polymerase, and then amplified using 40 cycles of 30 s at 94 ℃ (denaturation) and 40 s at annealing temperature for TLR4, TNF-α, IL-10, CCL22, and β-actin, respectively. PCR was performed using the Agarose Gel Electrophoresis Imaging Analysis System (Beijing, China).

Table 2 Primer sequences and conditions used for reverse transcription-polymerase chain reaction

Gene	Sequence	Product size (bp)	Annealing temperature (℃)
mTLR4	5′-GCTTTCACCTCTGCCTTCAC-3′ 3′-AGGCGATACAATTCCACCTG-5′	259	57
HuTLR4	5′-GAAATGGAGGCACCCCTTC-3′ 3′-GAATATTCCTTTGCATAGGT-5′	506	52

β-actin	5′-TCACCCACACTGTGCCCATCTACGA-3′ 3′-GATAACCGTTGCTCGCCAAGGCTAC-5′	300	50

TNF: Tumor necrosis factor; IL: Interleukin; TLR: Toll-like receptor.

Immunohistochemistry

To assess TLR4 protein expression in HCC and normal tissues, a polyclonal rabbit anti-human TLR4 (ab47093; Abcam, United States) was used. Paraffin-embedded sections (5-μm thick) were fixed in freshly prepared 10% paraformaldehyde for 5 min. After blocking the endogenous peroxidase activity with 0.3% hydrogen peroxide in TBS for 15 min, the sections were immersed in horse serum diluted 1:10 in TBS for 30 min to reduce nonspecific binding, and then incubated with the primary antibody overnight at 4 ℃ after washing in TBS. Next, the sections were incubated in biotinylated horse anti-mouse or goat anti-rabbit IgG for 30 min, and avidin-biotin-peroxidase complex for 30 min. After each step of the staining procedure, the sections were given three 5-min washes in TBS. Immunoreactivity (IR) was visualized using 1 mg/mL diaminobenzidine as chromogen and 0.01% hydrogen peroxide as substrate. The peroxidase reaction was stopped after 5 min with distilled water, and the sections were counter-stained with Toluidine blue, dehydrated, and then mounted with Entellan.

Slides were evaluated under a light microscope (× 400 magnification). For digital image analysis, the software Adobe Photoshop version 7.0 was used. Results were scored by two independent investigators as positive, heterogeneous, or negative. The two scores were averaged.

Statistical analysis

SPSS version 10.0 (SPSS Inc., United States) was used for statistical analysis. All data were expressed as mean ± SE. Statistical analyses were performed using the Student's *t* test. If there was evidence of non-normality, Kruskal-Wallis one-way analysis of variance was used to test the difference in median among the groups. To analyze the correlation between Tregs and TLR4, Spearman's rank correlation coefficients were performed. Difference was considered statistically significant at $P < 0.05$.

RESULTS

CD4+CD25^high^FOXP3+ Tregs accumulation in HCC tumor and peripheral blood

The prevalence of CD4+CD25^high^ and CD4+CD25^high^FOXP3+ Tregs was analyzed in the peripheral blood of 60 patients with HCC. The population of CD4+CD25^high^ and FOXP3+ Tregs as a percentage of total CD4+ T and CD4+CD25^high^ T cells, respectively, was identified by flow cytometry. Representative dot plots of HCC patients and controls are shown in Figure 1A. The frequency of CD4+CD25^high^ and FOXP3+ Tregs in HCC patients was significantly higher than in the healthy controls (Figure 1B). The expression of FOXP3 in HCC patients was detected using Western blotting analysis. As shown in Figure 1C and D, both tumor and normal tissues exhibited FOXP3 protein expression, although the expression was weaker in normal tissues.

Clinicopathologic characteristics of HCC patients and prevalence of circulating CD4+CD25^high^FOXP3+ Tregs

We analyzed the correlation between the proportion of CD4+CD25^high^FOXP3+ Tregs in the peripheral blood and the clinicopathological characteristics of the subjects (Table 3). The proportion of CD4+CD25^high^FOXP3+ Tregs was significantly higher in patients with high serum AFP levels and multiple tumor foci ($P = 0.009$). The proportion of CD4+CD25^high^FOXP3+ Tregs did not correlate with other clinicopathological characteristics of HCC patients ($P > 0.05$).

Considering the potential impact of multifocal tumor on tumor size, the correlation of the proportion of CD4+CD25^high^FOXP3+ Tregs with different tumor diameters was analyzed in 52 patients with a single lesion. Our findings indicated that the proportion of Tregs was low in patients with a small tumor (< 5 cm in diameter) (Figure 2).

Expression of TLR4 in patient samples and hepatoma cell lines

The expression of TLR4 in patient tumor samples and hepatoma cell lines was examined using RT-PCR. Tumor and normal tissues, as well as HepG2 and H22 cells, expressed TLR4 mRNA (Figure 3). We determined the relative expression of TLR4 mRNA (TLR4 mRNA level/β-actin mRNA level × 100%) and found that TLR4 mRNA expression level in HCC tissues was higher than in the normal tissues ($P = 0.01$) (Figure 3A). Additionally, immunohistochemical analysis confirmed the expression of TLR4 protein. TLR4 positive hepatocytes were present in paraffin-embedded sections. Moderate and strong IR for TLR4 was detected in 63.4% (38/60) of HCC specimens, and normal tissues displayed positive staining in 10% (6/60). TLR4 in cancer cells was stained more intensely than in the normal cells (Figure 3C). The distribution of TLR4 in a given HCC specimen was uneven, and the majority of positive hepatocytes exhibited expression on the membrane and in the cytoplasm. Scattered expression of TLR4 protein was also observed in a small number of liver sections derived from normal tissues.

Figure 1 CD4+CD25^high^FOXP3⁺ regulatory T cells accumulation in hepatocellular carcinoma and peripheral blood. A: Representative flow cytometry plots of CD4+CD25^high^ regulatory T cell (Treg) (region R2) and family of transcription factor P3 (FOXP3)+ Treg cells in peripheral blood from a healthy donor and hepatocellular carcinoma (HCC) patient; B: Percentage of CD4+CD25^high^ Treg and FOXP3+ Treg cells in peripheral blood from HCC patients and controls; C: The prevalence of CD4+CD25^high^ Treg (8.57% ± 6.31%, $P = 0.002$) and FOXP3+ Treg cells (67.51% ± 20.59%, $P < 0.05$) in peripheral blood from HCC patients was significantly higher than that of healthy donors (1.71% ± 1.59% and 43.35% ± 13.91%, respectively). Western blotting analysis of nuclear extracts prepared from HCC and normal tissues; D: The relative expression of FOXP3 protein (FOXP3 protein/β-actin protein × 100%). The FOXP3 protein expression in HCC tissues was stronger (0.72 ± 0.14) as compared with normal tissues (0.24 ± 0.05) ([a]$P < 0.05$). FITC: Fluorescein isothiocyanate.

Figure 2 Correlation of regulatory T cells with tumor size of a single tumor. Circulating levels of CD4+CD25^{high}FOXP3+ regulatory T cells (Tregs) was low in patients with a small tumor (less than 5 cm in diameter). Comparisons of data of Tregs among 3 tumor size groups using a Kruskal-Wallis test. Statistically significant differences were found in all comparisons between the 3 groups (χ^2: 7.365, P = 0.0252). HCC: Hepatocellular carcinoma.

Upregulation of IL-10 and CCL22 expression in RAW246.7 cells elicited by co-cultivation with LPS preincubated hepatoma cells

Hepatoma cell line H22 cells were pre-incubated with LPS. The RAW246.7 cells and the H22 cells were co-cultured in a transwell system for 24 h. Semiquantitative RT-PCR was performed to detect the expression of TNF-α, IL-10, and CCL22 in different cell lines. RAW246.7 cells co-cultured with LPS pre-treated H22 cells exhibited significant up-regulation of mRNA for genes IL-10 and CCL22 ($P < 0.001$), whereas expression of TNF-α remained unchanged (Figure 4). Tumor cells without LPS pre-incubation induced negligible gene expression changes in co-cultured RAW246.7 cells. H22 cells alone did not produce IL-10 and CCL22 under conditions of TLR4 activation following LPS stimuli or not (data not shown). These findings, taken together, suggested that activated TLR4 on H22 cells facilitated the induction of cytokine secretion of IL-10 and CCL22 by RAW246.7 cells.

Correlation between proportion of CD4+CD25^{high}FOXP3+ Tregs in peripheral blood of HCC patients and TLR4 in HCC tissues

We investigated the associations between tumor Union for International Cancer Control (UICC) stage, circulating CD4+CD25^{high}FOXP3+ Tregs, and TLR4 in the HCC tissues. The expression level of TLR4 protein in 60 HCC specimens was positively correlated with the frequency of CD4+CD25^{high}FOXP3+ Tregs in peripheral blood (Figure 5A). There was an increased frequency of Tregs in the peripheral blood of HCC patients, which exhibited a high level of expression of TLR4 protein. However, there was no significant correlation between the number of CD4+CD25^{high}FOXP3+ Tregs and tumor UICC stage (Figure 5B).

DISCUSSION

Increased FOXP3+ Tregs in HCC tissues and peripheral blood

T cells play an essential role in the immunosurveillance

and destruction of cancer cells. Among CD4+ T lymphocytes, CD4+CD25+ Tregs are thought to comprise a functionally unique subpopulation of T cells that act to maintain immune homeostasis. The lack of CD4+CD25+ Tregs results in various autoimmune syndromes. Alternatively, Tregs-mediated suppression potentially hinders an effective immune response, which is crucial for elimination of tumors and infection[19]. Humans with cancer exhibit increased numbers of peripherally circulating and tumor Tregs[5,20,21]. Ormandy *et al*[22] found that in HCC patients the number of Tregs in the peripheral blood was significantly increased. However, Yang *et al*[23] found that the proportion of CD4+CD25+ Tregs in the peripheral blood of HCC patients was significantly decreased. Too few samples and different patient inclusion criteria has potentially led to conflicting results in previous studies. This study presents evidence of an accumulation of FOXP3+ Tregs in HCC tumor tissues and peripheral blood. A few previous studies have also investigated the clinicopathologic significance of Tregs, but conclusions regarding correlations with various clinicopathologic features were contradictory. Our results demonstrated

Figure 3 Expression of toll-like receptor 4 mRNA in hepatocellular carcinoma patients and hepatoma cell lines. A: Reverse transcriptase polymerase chain reaction analysis of total RNA from hepatocellular carcinoma (HCC) and normal tissues. The toll-like receptor 4 (TLR4) mRNA expression in HCC tissues was stronger (2.08 ± 0.14) compared to normal tissues (0.48 ± 0.05) (P = 0.01); B: TLR4 mRNA expressed in human HepG2 and murine H22 hepatoma cell lines; C: Expression of TLR4 protein in HCC and normal tissues by immunohistochemistry. a, c: Paraffin-embedded sections of HCC exhibiting positive expression on the membrane and in the cytoplasm in several positive hepatocytes (arrows) [diaminobenzidine (DAB) ×400]; b, d: Paraffin-embedded sections of normal tissues showing weaker expression (DAB ×400); D: TLR4 was detected by immunohistochemistry in tissue sections of patients with HCC (frequency of positive hepatocytes for TLR4 in paraffin-embedded sections).

that the proportion of Tregs was not correlated with hepatitis and cirrhosis, which was in concordance with other studies[22,24]. Shen *et al*[25] indicated that the increased prevalence and expanded function of Tregs in the tumor microenvironment of HCC correlated with cancer stage. However, no significant differences between number of Tregs and tumor UICC stage were observed in our HCC patients; other research groups also confirmed our findings[26,27]. The discrepancy among different research groups potentially results from differences in patient profiles, e.g., Shen *et al*[25] selected 31 patients who had undergone hepatectomy for their study. Moreover, we demonstrated a positive correlation between the number of Tregs and serum AFP levels and multifocal tumor. In order to exclude the influence of multifocal tumor, we separately analyzed 52 HCC patients with a single lesion, and found that the proportion of Tregs was higher in patients with a larger tumor size (Figure 3, P = 0.0252). Our results suggested that the number of Tregs in HCC potentially contributes to the inhibition of effective anti-

tumor immune responses and promotes intrahepatic tumor metastasis.

Correlation between Tregs levels and expression of TLR4 in HCC tissues

Despite the important role of Tregs in controlling immune responses to self-antigen and non-self-antigens and their natural ligands, the molecular mechanisms underlying the regulation and recruitment of Tregs in the tumor microenvironment remain poorly understood. One family of receptors involved in immune regulation is TLRs, a class of receptors that recognizes pathogen-associated molecular patterns or endogenous inflammation-associated molecules[28]. Recently, TLRs were identified on cancer cells and T cells, including Tregs[9,11]. Thus, TLR-signaling directly or indirectly regulates the immunosuppressive function of Tregs in the immune response[29-32]. A few studies concerning indirect regulatory function have been conducted to clarify the complex cross-talk between TLRs and Tregs in tumors. Our data provide

Figure 4 Tumor necrosis factor-α, interleukin-10, and CCL22 mRNA expression in RAW246.7 and RAW246.7 cells co-cultured with H22 cells ± lipopolysaccharide. The bars indicate the relative amount of tumor necrosis factor (TNF)-α, interleukin (IL)-10 and CCL22 mRNA expression (reverse transcriptase polymerase chain reaction). LPS: Lipopolysaccharide. [b]$P < 0.001$ *vs* RAW co-culture.

Figure 5 Correlation between the expression of toll-like receptor 4 in hepatocellular carcinoma specimens, tumor Union for International Cancer Control stage, and CD4+CD25[high] FOXP3+ regulatory T cell. A: Toll-like receptor 4 expression was positively correlated with the number of CD4+CD25[high]FOXP3+ regulatory T cells (Tregs) in peripheral blood. Analysis of data was performed using Spearman's rank correlation coefficients ($n = 60$, $r = 0.411$, $P < 0.001$); B: According to Union for International Cancer Control/tumor-node-metastasis classification, there were 19 cases, 24 cases, and 17 cases at stage Ⅰ, Ⅱ and Ⅲ hepatocellular carcinoma, respectively. Statistically negative correlations were found in all comparisons between the 3 groups ($\chi^2 = 0.921$, $P = 0.631$) using the Kruskal-Wallis test.

some important clues regarding the interaction of TLR4 expression in tumor tissues and the number of Tregs in hepatocellular cancer. We demonstrated that TLR4 was expressed in diverse hepatoma cells and enriched in HCC tumor tissues, and that the expression of TLR4 in HCC positively correlated with the frequency of FOXP3+ Tregs in both circulation and tumor tissues ($P < 0.001$). These results suggest that the recruitment and proliferation of Tregs are indirectly regulated *via* TLR4 signaling.

Activation of TLR4 on tumor cells and its interaction with macrophages indirectly suppress anti-tumor immune response via recruitment of Tregs

Although some evidence implicates Tregs in the immunopathogenesis of cancer, suppressive mechanisms in the tumor microenvironment and the underlying mecha-

nisms of regulation remain poorly understood[33]. Early evidence suggests that CCL22 preferentially attracts activated antigen-specific T cells to dendritic cells[34]. Curiel recently demonstrated that tumor cells and microenvironmental macrophages in ovarian carcinoma produce the chemokine CCL22, which mediates Treg trafficking to the tumor[35]. Therefore, tumor cells potentially utilize this effect to attract Tregs to the microenvironment. Our data suggested that co-culture of macrophages with a hepatoma cell line leads to a significant increase in the expression of IL-10 and CCL22 ($P < 0.001$). The source of this CCL22 is co-cultured macrophages and hepatoma cells preincubated with LPS. IL-10 is a pleiotropic cytokine produced by myeloid cells and lymphocytes that displays immunoregulatory effects[36]. IL-10 inhibits the production of other cytokines such as IL-2, IL-12 and TNF-α

and plays an important role in suppression of T cell anti-tumor responses[37-39]. In this study, we demonstrated that co-cultured macrophages and LPS pre-treated hepatoma cells significantly up-regulate IL-10 expression. Our findings indicated that the activation of TLR4 on hepatoma cells indirectly modulates the suppressive function of Tregs and enhances Tregs recruitment by inducing cytokines, resulting in the immune escape of HCC.

The accumulation of FOXP3+ Tregs in HCC suggests a trend toward intrahepatic metastasis. The modulation of TLR4 activation on tumor cells links between Tregs suppressive function and the immunopathogenesis of human cancer. The association between TLR4-signaling and functional control of CD4+CD25^{high}FOXP3+ Tregs indicates intriguing potential opportunities to suppress anti-HCC immunity and improve therapeutic effectiveness for the patients. Our study provides the evidence which is useful for the development of an improved immunotherapeutic approach to HCC, and further studies are warranted.

ACKNOWLEDGMENTS

COMMENTS

Background

The survival of hepatocellular carcinoma (HCC) is limited in the majority of such cases. The active suppression of immune responses against tumor is a major barrier to the likely success of cancer immunotherapy. There is now compelling evidence implicating CD4+CD25^{high} family of transcription factor P3 (FOXP3)+ regulatory T cells (Tregs) as being key players driving immune suppression. However, precise function regulation of CD4+CD25^{high}FOXP3+ Tregs remains obscure.

Research frontiers

Toll-like receptors (TLRs) have recently emerged as a critical pathogen-associated molecular pattern of the innate immune system for detecting microbial infection and activation of dendritic cell maturation programs to induce adaptive immune responses. TLR4, an important member of TLRs family, plays a central role in phagocytosis, signal transduction and cell apoptosis. New evidence suggests that TLR signaling may directly or indirectly regulate the suppressive function of Treg cells. TLR4 signaling pathway activation induces production of massive cytokines, and finally intrigues the downstream nuclear factor kappa B to shift the balance between CD4+ T-helper and Treg cells, in ways that may facilitate tumor evasion of immune surveillance.

Innovations and breakthroughs

Currently, the roles of CD4+CD25^{high}FOXP3+ Tregs and TLR4 in HCC and their regulatory activity in the tumor microenvironment remain unclear. In the present study, authors described the clinicopathological significance of Tregs in 60 HCC patients, and the expression of TLR4 in hepatic cancer cells. The findings indicated that TLR4 ligation promotes the secretion of inhibitory cytokine interleukin-10 and chemokine CCL22 from co-cultured macrophages, not from the tumor cells themselves. Furthermore, the prevalence of Tregs significantly correlated with the presence of multifocal tumor. The results suggest a mechanistic path for the indirect modulation of CD4+CD25^{high}FOXP3+ Tregs *via* tumor TLR4 signaling, and demonstrate that interactions between hepatoma carcinoma cells and macrophages induce anti-tumor immune suppression *via* Tregs.

Applications

The authors report that activation of TLR4 on hepatoma cells followed by its interaction with macrophages may indirectly facilitate the recruitment of Tregs into tumor site and promote the intrahepatic metastasis, which suggests innate immunity mediated cellular interference maybe an effective therapeutic target in the treatment of HCC patients.

Terminology

CD4+CD25^{high}FOXP3+ Treg: Tregs are defined based on their expression of CD4, CD25 and forkhead, or winged helix FOXP3, which is critical for the development and function of Tregs in mice and humans. Tregs play a critical role in immunologic self-tolerance and suppression in the tumor immune response; TLR: To recognize specific structural regions of invading pathogens and initiate innate and adaptive immune responses; their expression has been detected in immune cells and also in many cancer cells. TLR4, an important member of TLRs family, plays a central role in phagocytosis, signal transduction and cell apoptosis.

Peer review

The article shows that TLR on hepatoma cell lines may indirectly facilitate the recruitment of Treg cells within tumor site *via* the potential activation of macrophages. This is a good exploratory study in which authors analyze the relationship of tumor TLR4 signaling pathway and CD4+CD25^{high}FOXP3+ Treg cells in tumor immune escape.

Abstract

AIM: To elaborate the clinicopathologic features of colorectal cancer-related pyogenic liver abscess (PLA).

METHODS: Reported cases of colorectal cancer-related PLAs were collected from the literature published up to October 2011 and evaluated for their clinicopathologic features. Data of collected cases included demographics, clinical presentation, microbial findings and treatment. Categorical variables were compared by χ^2 analysis and continuous variables were evaluated using Student's t test.

RESULTS: A total 96 cases of colorectal cancer-related PLA were collected from the previous literature. Most patients (60%) were male and 40% cases occurred in the age group of 61-70 years. Apart from some special types of PLA, there were significant differences in the microbiological spectrum between Eastern Asia and non-Eastern Asian countries, which implied different risk factors and courses of the disease. Gram negative bacteria especially *Klebsiella pneumoniae* (*K. pneumoniae*) PLA was predominant in Eastern Asia (80.0%) in contrast to non-Eastern Asian countries ($P < 0.01$). Meanwhile, most of the Eastern Asian patients exhibited smaller size of liver abscess and atypical presentation. Sigmoid colon and rectum (72.73%) were the main sites of tumor in Eastern Asian patients, whereas tumor sites were uneven among most of the non-Easter Asian PLA patients.

CONCLUSION: *K. pneumoniae* PLA was strongly associated with colorectal cancer, especially those occurring in sigmoid colon and rectum, in elderly Eastern Asian male patients.

INTRODUCTION

Liver is the most common organ to develop abscesses.

Pyogenic liver abscess (PLA), once predominantly a disease of young adults as a consequence of post-appendicitis pylephlebitis, nowadays occurs more frequently in elderly patients, with hepatobiliary tract diseases or intra-abdominal infections including cholecystitis, suppurative cholangitis, suppurative pylephlebitis, diverticulitis and peritonitis[1]. Meanwhile, as we cannot find significant underlying causes of PLA, the term "cryptogenic abscesses" is used. For all types of PLA, mucosal defect present within digestive tract lesions or a compromised mucosal barrier allowing a route for bacteria invasion into the portal system with subsequent hematogenous spread to the liver is regarded as the key process[2].

Previous studies revealed that a few cryptogenic PLA patients were related to neoplasms[3]. This type of PLA was regarded as a warning indicator of silent cancers. Recently, many cases of PLA associated with nonmetastatic colorectal carcinoma have been reported worldwide. Interestingly, this PLA in Eastern Asia seems to have greater morbidity and exhibits differences in clinical characteristics. However, there were few studies which analyzed this phenomenon, neither was there any recommendation or consensus for treatment. Therefore, we reviewed published case reports from worldwide literature and retrospectively investigated the etiology, clinical characteristics and treatment of PLA complicated with nonmetastatic colorectal carcinoma.

MATERIALS AND METHODS

Source of data
Data from the available medical literature were systematically reviewed and pooled to analyze. MEDLINE (United States National Library of Medicine, Bethesda, MD), EMBASE (Elsevier Science, New York, NY) and CNKI National Knowledge Infrastructure) bibliographic databases were searched and relevant studies in form of case-control studies, case series or case report published in English language were retrieved using the keywords: "hepatic/liver abscess", "malignant cancer", "colorectal cancer" or "bacterium". The relevant article references in English and other languages were also collected.

Data extraction and quality control
A medical information scientist performed the literature retrieval and the initial screening of relevant studies, and a medical doctor reviewed and coded all studies. Cases were scrutinized to exclude any duplicate reports of the same patients. Many studies reported only aggregate results. Whenever possible, data were extracted both at an aggregate level within each study and at a patient level. The individual cases without individual identification were also excluded. We excluded studies or individuals with missing data from specific analyses. As a result, the number of patients in each analysis varied.

Database
The collected cases were evaluated individually, and de-

tails were extracted and computerized for further analysis. Coded potential prognostic determinants included patient demographics, microbial, clinical and laboratory findings, and the authors' affiliations. The data were pooled at both the aggregate and patient levels to determine the distribution of the underlying disease, site of infection, and other pertinent variables.

Statistical analysis
All collected data were transcribed into a Microsoft Excel spreadsheet and analyzed using SPSS software, version 14.0 (SPSS). Continuous variables were compared using analysis of variance, and categorical variables were compared using the χ^2 test. $P < 0.05$ was regarded as significantly different.

RESULTS

Removing irrelevant articles, and articles published in internal journal and reviews, we collected a total of 32 articles with 96 cases from 623 publications in the international literature up to September 2011. Two case-control studies[4,5] and 30 case reports[3,6-34] were included. Most of articles were single case report (26/32). Sixteen cases included in aggregate series[2,15,27-31,33] and 32 cases with individual information summarized in one article published in Japanese were also extracted[7]. Among the 32 collected articles, 25 articles were in English, 2 were in Japanese, 1 was in Chinese, 1 was in Spanish, 1 was in French and 1 was in Hebrew.

Global distribution of reported cases
Although cases of colorectal cancer-related PLA were originally reported in Western countries[2,27-31,33], most of reported cases (80.21%) were published in the Eastern Asian countries/regions, especially in Japan (40 cases), China (26 cases) and Korea (8 cases) (Table 1). The reported number of colorectal cancer-related PLA has increased significantly over the past two decades. Approximately, 90% patients have been reported since 1990 after colonoscopy and percutaneous transhepatic abscess drainage (PTAD) became common in clinical practice. In Eastern Asian countries/regions, the number of cases was increasing rapidly, with a growth rate of approximately 4-5 times every decade from 1981 to 2011 (Figure 1).

Demographical evaluation
The average age of the patients in the present series was 64.4 ± 10.1 years. A male-to-female ratio of 1.5:1 was calculated for the overall series and for patients of different areas. There was no significant difference in the average age between gender groups (male 65.0 years *vs* female 63.4 years, $P > 0.05$) and geographical groups (Eastern Asia 64.6 years *vs* non-Eastern Asia 63.3 years, $P > 0.05$). In the overall series from both Eastern Asia and non-Eastern Asian groups, approximately 40% patients fell into the age groups of 61-70 years (Figure 2).

Figure 1 Growth trend of reported cases in different countries/regions from 1960 to 2011.

Figure 2 Age distribution of reported cases in different countries/regions.

Microbiology

According to bacteria culture results from 58 patients, *Klebsiella pneumoniae* (*K. pneumoniae*) was the most common pathogen (50.0%), followed by *Fusobacterium species* (6.90%), *Streptococcus species* (6.90%), *Bacteroides species* (5.17%), *Enterococcus faecium* (3.44%), *Escherichia coli* (3.44%) and *Pseudomonas aeruginosa* (3.44%). There were two cases of amoebic liver abscess and two cases with mixed infection. In addition, 10 patients had negative results of pus cultures (Table 2). There was a significant difference between Eastern Asian and non-Eastern Asian groups in gram stains of pathogens. Among the gram-negative pathogens, *K. pneumoniae* was more dominant in Eastern Asian than in non-Eastern Asian groups (Figure 3).

Morphologic characteristics of liver abscess

All liver abscess cases were finally diagnosed with B-mode ultrasonic and/or computed tomography scanning. Ac-

cording to the image results of the 66 patients, 66.7% abscesses formed in the right liver lobe, 18.2% in the left lobe and 12.1% in two lobes (Figure 4). There was no significant difference in the location of liver abscess between Eastern Asian and non-Eastern Asian groups (Figure 5). Thirty-one reported cases had individual data of liver abscess size, which was 5.31 ± 2.11 cm on average. The average abscess size of Eastern Asian patients was smaller than that of non- Eastern Asian patients (*P* < 0.05). Moreover, there was no significant difference in the average size between gender groups, age groups and pathogen groups (Figure 6).

Clinical manifestations and diagnosis

The clinical manifestation of 25 patients was pyogenic liver abscess, including fever and chill (92.0%), abdominal pain (68.0%), abdominal tenderness (64.0%) and nausea/vomiting (45.0%). No more than 40% patients had the chief complaint of atypical symptoms of tumor, which included anemia (40.0%) and weight loss (32.0%). Only approximately 10% of the patients had bowl cancer symptoms, including bloody stool (12.0%) and alterations

Figure 3 Categorization of pathogens in Eastern Asian and non-Eastern Asian patients. A: Distribution of Gram-negative and Gram-positive pathogens; B: Distribution of *Klebsiella pneumoniae* (*K.P*) and non-*K.P*. There were significant differences in categories of pathogens between Eastern Asian and non-Eastern Asian patients ($P < 0.01$).

Figure 4 Distribution of colorectal cancer and liver abscesses.

Figure 5 Probability of abscess in different liver lobes in Eastern Asian and non-Eastern Asian patients. There was no significant difference between the two groups ($P > 0.05$).

colon (40.9%), followed by rectum (27.3%), ascending (18.2%), transverse (7.6%) and descending colon (6.0%) (Figure 4). Among the 23 patients with pathological reports, colorectal adenocarcinoma (81.8%) and medium differentiation degree (66.7%) were the most common pathological type and differentiation degree, respectively. There was no difference between Eastern Asian and non-Eastern Asian groups in the sites of colon tumors. However, tumors occurred more often in sigmoid colon and rectum in Eastern Asia group (Figure 8).

Treatment for colorectal cancer-related PLA

All of the patients were treated with broad-spectrum antibiotics. The most commonly used antibiotics were cephalosporins with or without metronidazole, followed by fluoroquinolones with or without metronidazole, ampicillin and gentamicin, carbapenems, and gentamicin (Table 3). PTAD was extremely successful as initial treatment for liver abscess. The type of treatment (antibiotics combined with/without PTAD) chosen may have been influenced by several factors (e.g., clinician/radiologist's decision and others). There was no significant difference in the distribution of demographic characteristics (age, gender, geographic distribution and pathogens) between the study and the comparison groups (Table 4). Until the date of the submission of the report, 17 patients had been followed up for an average of 15.4 ± 15.44 mo, all

in bowel habits (4.0%) (Figure 7). None of the cases had abdominal mass, and the digital rectal examinations were negative. Infection indices of the 25 patients with details of laboratory examination revealed a significantly increased level of white blood cell count ($17.9\text{-}5.22 \times 10^9/\text{L}$) and C-reactive protein (17.8 ± 7.49 mg/dL); and a moderately elevated level of alanine aminotransferase and total bilirubin. However, colorectal cancer-related biomarkers (including CA19-9 and carcinoembryonic antigen) did not elevate in most of the patients.

Monitoring of occult colorectal cancers

Most of the diagnoses of colorectal cancer were made by coloscopy (77.3%) and barium enema (29.2%). The most common site of tumor formation was sigmoid

Figure 8 Probability of cancer in different colorectal regions in Eastern Asian and non-Eastern Asian patients. A: Probability of cancer appeared in the right and left hemi-colon; B: Probability of cancer in sigmoid and rectum and other regions. Sigmoid and rectum were the more common cancer sites, compared with other regions ($P < 0.05$).

were kept stable with no tumor recurrence.

DISCUSSION

Colorectal cancer is the fourth most common cancer in men and the third most common cancer in women all over the world. Previous studies have reported rapid increases in colorectal cancer incidence rates, especially in economically transitioning countries[35,36]. Many Eastern Asian countries, such as China, Japan, South Korea, and Singapore, have experienced a 2-4 folds increase in the incidence of colorectal cancer during the past few decades[37]. Common manifestations of colon cancer are

alteration in bowel habit, rectal bleeding and abdominal pain. Besides, liver abscess during the course of an undiagnosed colon cancer may also occur as the initial manifestation of the disease, even without associated metastasis. This PLA had been reported worldwide and was regarded as the herald of colorectal cancers.

Recently, the number of new cases of colorectal cancer-related PLA is soaring in Eastern Asia, and this trend is worthy of concern. We found that 80% of the reported cases in the whole world occurred in the Eastern Asian countries, especially in Japan, China and Korea. The demographic features of the Eastern Asian and non-Eastern Asian patients in this study were non-specific. The mean age was 64.4 years, and male to female ratio was about 1.5:1. However, microbiological feature was different between Eastern Asian and non-Eastern Asian patients. The bacteriologic analysis in our series revealed that *K. pneumoniae* was the most common pathogen in Eastern Asian patients. Our observation was also consistent with the entire incidence of *K. pneumoniae* PLA in Eastern Asian population[38-40].

Clinical features of the colorectal cancer-related PLA patients in this study were non-specific. The most common clinical presentations were fever, chills, abdominal pain, and nausea or vomiting. In contrast, only 10% patients had bowl cancer symptoms and the diagnosis of colorectal cancer was extremely difficult. Colonoscopy was considered as an effective screening method for diagnosis of colorectal cancer. Most (77.3%) of colorectal cancer patients in our study were confirmed by colonoscopy. The colon site of tumor mostly involved was the sigmoid colon (40.9%), followed by the rectum (27.3%), ascending colon (18.2%), transverse colon (7.6%) and descending colon (6.0%). There was significant difference of tumor site between Eastern Asian and non-Eastern Asian patients. Thus, Eastern Asian physicians should be vigilant in monitoring colorectal cancers, especially in the sigmoid colon and rectum.

In our case series, before colorectal cancers were found,

several patients had experienced recurrence of PLA after PTAD treatment[13,15,32]. Destruction of the mucosal barrier of colon and the repeated bacterial translocation was the pathogenesis of liver abscesses in such patients. Thus, although broad spectrum antibiotics combined with PTAD as first-line treatment for the management of PLA had been accepted by most physicians[41], operative intervention for colorectal lesions remains crucial. Meanwhile, in the elderly with recurrent cryptogenic PLA, colonoscopy is suggested and required to avoid misdiagnosis of colorectal cancer.

To our knowledge, this is the first attempt to systemically review the cases of colorectal cancer-related PLA worldwide. However, there still remain limitations to our retrospective study. Incomplete data collection was found during our review of literatures. Some clinical features appeared to have been overlooked; in particular, the relatively non-specific clinical symptoms were missing. In addition, although more reported cases were observed in Eastern Asian than non Eastern Asian countries, the real incidence of colorectal cancer-related PLA is still unknown. Epidemiological investigation with a larger sample size is needed for further analysis.

In conclusion, colorectal cancer-related PLA is an increasing life-threatening disease in Eastern Asia in the recent two decades. In the absence of significant manifestation, the search for the underlying cause of the pyogenic liver abscess should be an integral part of the management of liver abscesses. The association with a colorectal cancer is rare but should be taken into consideration. Early and appropriate surgical treatment can achieve good prognosis.

ACKNOWLEDGMENTS

COMMENTS

Background
Colorectal cancers related-pyogenic liver abscess (PLA) is a special hepatic infection and regarded as the herald of colon cancer. Recent publications from Eastern Asia revealed a considerable morbidity in this region. Knowledge of etiology and clinical features, when possible, play an important role in the successful treatment of colorectal cancers-related PLA patients.

Research frontiers
PLA, once occurs more frequently in elderly patients with hepatobiliary tract disease or intra-abdominal infections. Recently, many cases of PLA associated with nonmetastatic colorectal carcinomas have been reported in the worldwide. Interestingly, this PLA in Eastern Asia seems to have a greater morbidity and exhibits differences in clinical characteristics. However, there have been few studies to analyze this phenomenon.

Innovations and breakthroughs
This is the first attempt to systemically review the cases of colorectal cancer-related PLA worldwide. A total of 96 cases of colorectal cancers-related PLAs

were collected from the international literature and evaluated in clinicopathologic features. This study results revealed that *Klebsiella pneumoniae* (*K. pneumoniae*) PLA was tightly related with colorectal cancer (especially those located in sigmoid colon and rectum) in elderly Eastern Asian males.

Applications
By understanding the different clinicopathological features between patients from Eastern Asia and non-Eastern Asia countries, this study may represent a future strategy for therapeutic intervention in the treatment of patients with colorectal cancer-related PLA.

Terminology
PLA, occurs more frequently in elderly patients with hepatobiliary tract diseases or intra-abdominal infections. For all types of PLA, mucosal defects present within digestive tract lesions are regarded to be the key process. Recent studies revealed that a few PLA patients were related to neoplasms. This type of PLA exhibited different features and was regarded as a warning indicator of silent cancers.

Peer review
The authors reviewed the literature to evaluate features of colorectal cancer-related pyogenic liver abscess. It revealed that there was clear differences in the microbiological spectrum between Asian and non-Asian cases. Gram-negative bacteria especially *K. pneumoniae* PLA was predominant in Eastern Asia. Meanwhile, most of the Eastern Asian patients exhibited smaller size of liver abscess and atypical presentation. Sigmoid colon and rectum were the main sites of tumor in these patients. The results are interesting and may represent a clear understanding of colorectal cancer-related PLA in Eastern Asian patients.

Abstract

AIM: To determine whether lentivirus-mediated shRNA targeting the X-linked inhibitor of apoptosis protein (XIAP) gene could be exploited in the treatment of pancreatic cancer.

METHODS: Human pancreatic cancer cells Panc-1, Mia-paca2, Bxpc-3 and SW1990, infected with lentivirus, were analyzed by real-time polymerase chain reaction (PCR). Western blotting was used to examine XIAP protein levels, survivin and p-Akt to confirm the result of real-time PCR and determine the possible mechanism. The 3-(4,5-cimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay was used to measure IC_{50} to determine chemosensitivity to the chemotherapeutic drugs 5-fluorouracil (5-FU) and gemcitabine. A colony assay, MTT assay and a tumorigenicity experiment were used to study cell proliferation *in vitro* and *in vivo*. Caspase-3/7 activity, 4',6-diamidino-2-phenylindole-staining and flow cytometric measurements were used to study apoptosis in SW1990 cells.

RESULTS: XIAP proteins were found to be differentially expressed among pancreatic cancer cell lines Panc-1, Mia-paca2, Bxpc-3 and SW1990. Data of real-time PCR and Western blotting showed that XIAP was reduced persistently and markedly by lentivirus-mediated shRNA. Downregulation of XIAP by transfection with XIAP shRNA resulted in decreased p-Akt expression. XIAP shRNA also inhibited the growth of pancreatic cancer cells *in vitro* and *in vivo*, enhanced drug-induced apoptosis and increased chemosensitivity to 5-FU and gemcitabine. Results also suggest that inhibition of XIAP and subsequent p-Akt depletion may have an anti-tumor effect through attenuating the ability of cancer cells to survive.

CONCLUSION: Lentivirus-mediated gene therapy is an attractive strategy in the treatment of pancreatic cancer and justifies the use of lentivirus in pancreatic cancer gene therapy studies.

Jiang C, Yi XP, Shen H, Li YX. Targeting X-linked inhibitor of apoptosis protein inhibits pancreatic cancer cell growth through

INTRODUCTION

Pancreatic cancer is one of the most aggressive human malignancies, with an extremely poor prognosis and a 5-year survival rate of only approximately 5%[1], partially due to the very little possibility of surgical resection and resistance to chemo-radiotherapy. Disordered apoptosis and abnormal proliferation have been linked with development of malignancy and treatment resistance[2,3]. Apoptosis, also termed programmed cell death, occurs *via* extrinsic or intrinsic signal transduction pathways[4,5]. Therefore, further understanding of the molecular mechanisms, the relationship between pancreatic cancer chemoresistance and disordered apoptosis and abnormal proliferation, can be important in trying to circumvent resistance to cancer therapy[6].

To date, 8 human inhibitor of apoptosis protein (IAP) family members [X-linked IAP (XIAP), cIAP1, cIAP2, IAP-like protein 2, melanoma IAP, neuronal apoptosis inhibitory protein, survivin and baculovirus IAP repeats repeat-containing ubiquitin conjugating enzyme] have been identified. XIAP, a member of the IAP family, plays an important role in regulating both apoptosis and cell proliferation. XIAP is one of the most important members of the IAP family. It is highly expressed in malignant tumor cells and promotes tumor cell invasion, metastasis, growth, survival and chemoresistance. It is reported that XIAP antagonists such as second mitochondria-derived activator of caspase/direct inhibitor of apoptosis-binding protein with low pI increase caspase activity, and not only directly induce apoptosis of many types of tumor cell lines *in vitro*, but also suppress growth of established tumors in xenograft models in mice *in vivo*, while displaying little toxicity to normal tissues. These findings validate XIAP as a target for cancer gene therapy. XIAP is a key factor in malignancy development and treatment resistance, which is associated with disordered cell apoptosis and abnormal proliferation. It is clear that XIAP is one of the most efficient caspase inhibitors of the 8 proteins, and inhibition of apoptosis by XIAP is mainly coordinated through binding to initiator caspase-9 and effector caspase-3 and caspase-7[7-9]. In addition to caspase inhibition, XIAP induces nuclear factor-κB and mitogen-activated protein kinase activation during transforming growth factor-β and bone morphogenetic protein receptor signaling and overexpression. Akt (protein kinase B) represents a subfamily of serine/threonine kinases that promotes cell survival[10]. XIAP and Akt are functionally linked in maintaining homeostasis between cell death and cell proliferation[11]. XIAP may be a core link between the cell apoptosis signaling pathway and the cell survival signaling pathway. Targeting XIAP might simultaneously influence cell apoptosis and proliferation.

RNA interference (RNAi) is a sequence specific post-transcriptional gene silencing factor, which has been extensively used in the study of gene function and gene therapy for cancer[12]. The use of chemically synthesized small interfering RNA (siRNA) or siRNA-encoding plasmids to produce RNAi in mammalian cells by transfection is still limited in clinical application due to some disadvantages including transient expression, and low transfection efficiency especially in non-dividing cells and when it is necessary to generate long-time gene silencing *in vivo*. A lentivirus-based vector is considered to be a promising gene delivery tool because of its ability for specific, highly stable and functional knockout of gene expression in both dividing and non-dividing cells compared with retroviral vectors. In addition, there is minimal immunogenicity associated with lentivirus vectors compared with adenoviral vectors[13-15].

In this study, we constructed lentivirus vectors encoding shRNA targeting the human XIAP gene to study the possible mechanisms of the XIAP gene in regulating apoptosis and proliferation in pancreatic cancer. There was an inhibitory effect of XIAP gene shRNA on the growth of SW1990 cells *in vitro* and *in vivo*, which would be useful for the development of gene therapy approaches for pancreatic cancer treatment in clinical application.

MATERIALS AND METHODS

Construction and production of lentivirus vectors

Three self-complementary hairpin DNA oligos targeting XIAP mRNA and a negative control were synthesized and cloned into a lentivirus vector. A self-inactivating lentivirus vector pGCSIL-PUR (Genechem, Shanghai, China) containing a cytomegalovirus-driven puromycin and a U6 promoter upstream of the cloning restriction sites (*Age*I and *Eco*RI) was used. Three coding regions corresponding to targeting human XIAP (GenBank Accession No: NM_001167) were selected as shRNA target sequences under the guide of the shRNA design protocol. We constructed 3 shRNA-XIAP and negative control lentivirus vectors, namely Lv-X1, Lv-X2, Lv-X3 and Lv-Xnc, respectively (Table 1). Oligonucleotides were annealed and inserted between the *Age*I and *Eco*RI restriction sites of the lentivirus vector. They were confirmed by restriction mapping and DNA sequencing. Lentivirus vector DNA and packaging vectors (pHelper1.0, pHelper2.0) were then transfected into 293T cells. Forty-eight hours later, the supernatant containing the lentivirus particles was collected, filtered through the 0.45 μm cellulose acetate filters, and the titer of lentiviruses was determined by hole-by-dilution titer assay. The virus titers produced was approximately 10^9 TU/mL.

atic cancer cells were maintained in Dulbecco's modified Eagle's medium (DMEM) containing 10% fetal bovine serum and antibiotics (100 mg/mL streptomycin and 100 U/mL penicillin) at 37 ℃ in a humidified incubator containing 5% CO_2. SW1990 cells were maintained in DMEM and was plated into 6-well plates at 1×10^5 cells per well. Overnight when the cells reached 30%-50% confluence, they were infected with viral particles in the presence of polybrene (5 μg/mL final concentration) and ENi.S (Genechem) for 8 h at a multiplicity of infection (MOI) of 50, and then added to fresh medium. The transfected SW1990 cells were subcultured at an appropriate density in fresh DMEM and 90% of the cells were transfected at 5 d post-transfection as indicated by the expression of green fluorescent protein (GFP) (pGCSIL-GFP empty vector was used to observe the transfection efficiency of lentivirus particles). Pooled stable transfectants were established using puromycin (Sigma-Aldrich, St Louis, MI, United States) selection. Puromycin was added into the medium to select stably transfected cells at a concentration of 1 μg/mL. Puromycin-resistant colonies were picked up 14 d after transfection and stable transfectant cells were maintained in medium containing 0.5 μg/mL puromycin.

Quantification by real-time polymerase chain reaction
Total RNA was isolated using Trizol (Invitrogen). M-MLV reverse transcriptase (Fermentas) was used to create cDNA according to the manufacturer's instructions: 1 μg RNA, Oligo dt18 as primer, 42 ℃ for 60 min, 70 ℃ for 5 min. Quantitative real-time polymerase chain reaction (RT-PCR) assays were carried out using SYBR TAQ real-time kits (TaKaRa Biotechnology, Otsu, Japan) and RT-PCR amplification equipment ABI PRISM 7900HT (Applied Biosystems, Foster City, CA, United States). The PCR primers used to detect XIAP and β-actin were as follows: XIAP, upstream primer 5'-GACAG-TATGCAAGATGAGTCAAGTCA-3', downstream primer 5'-GCAAAGCTTCTCCTCTTGCAG-3', with a product length of 93 bp; β-actin, upstream primer 5' -ACTCTTCCAGCCTTCCTTCC-3', downstream primer 5'-GTACTTGCGCTCAGGAGGAG-3', with a product length of 232 bp. The quantitative RT-PCR parameters and analysis of results were performed as normal.

Western blotting analysis
The cell extracts were prepared with lysis buffer radio immunoprecipitation assay containing 50 mmol/L Tris-HCl, pH 7.3, 150 mmol/L NaCl, 2% NP-40, 0.5% deoxycholate, 2 mmol/L ethylenediaminetetraacetic acid, 2 mmol/L NaF, and 1% Protease Inhibitor Cocktail (Pierce, Rockford, IL, United States). Total protein concentration was measured using the BCA assay kit (Sigma, Inc.) with bovine serum albumin as a standard according to the manufacturer's instructions. Western blotting was performed with primer and secondary antibodies: (1) Goat antihuman XIAP polyclonal antibody (R and D Systems Inc., Minneapolis, MN, United States) 1:2000, secondary antibody, 1:10 000; (2) Rabbit antihuman survivin antibody (Novus Biologicals, Inc.) 1:1000, secondary antibody, 1:10 000; (3) Rabbit antihuman p-Akt antibody (Abcam, Inc.) 1:300, secondary antibody, 1:10 000; and (4) Mouse antihuman β-actin monoclonal antibody (Sigma, Inc.) 1:10 000, secondary antibody, 1:10 000. Densitometry was performed by Quantity One image analysis software.

3-(4,5-cimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay
Cells were plated in 96-well plates at 5×10^3 (to test drug sensitivity) or 1×10^3 (for the growth curves) per well. Cell growth was examined by 3-(4,5-cimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay after lentivirus transfection once a day for 8 d. The cells were cultured in DMEM overnight to ensure that they adhered to the wall of the plates. Various concentrations of 5-fluorouracil (5-FU) or gemcitabine were added to the medium. After incubation for 72 h, 20 μL of 5 mg/mL MTT (Sigma, Inc.) was added to the medium and cultured for another 4 h, then 150 μL of dimethyl sulfoxide (Sigma, Inc.) was added into each well and shaken for 10 min. Absorbance of each well was read using a Bio-Rad model 550-microplate reader (Bio-Rad Co., CA, United States) at a wavelength of 490 nm. Semilogarithmic curves were drawn for cell survival and the logarithm of the drug concentration by SPSS16.0. The 50% inhibitory concentration (IC_{50}) was determined according to the curves.

Colony assay
Approximately 1×10^3 non-transfected control cells and SW1990 cells stably transfected with Lv-Xnc, Lv-X1, Lv-X2, Lv-X3 were plated in 10-cm culture dishes. After 28 d, cells were fixed with methanol and stained with 0.1% crystal violet. Colonies were counted by visual inspection.

Caspase-3/7 activity

Caspase-3/7 activity was evaluated using the Caspase-Glo 3/7 Assay (Promega, Madison, United States) according to the manufacturer's instructions. Cells (1×10^5 cells per well) were seeded in a 6-well plate incubated at 37 ℃ overnight, then specific concentrations of 5-FU or gemcitabine were added into the medium. The ultimate concentrations for both 5-FU and gemcitabine were 1, 10 and 0.1, 1 μg/mL. Plates were further incubated at 37 ℃ for 72 h and luminescence was measured at 3 s delay-time, 10 s duration using SIRIUS Luminometer V3.2 (Berthold, Inc., Germany). Caspase-3/7 activity was normalized to the number of viable cells (as determined by trypan blue staining). Caspase-3/7-fold induction was determined as the ratio between caspase-3/7 activities in treated and control cells.

4',6-diamidino-2-phenylindole staining

Cells were seeded into 24-well plates on sterile round glass coverslips at a density of 2×10^4 cells per well. The cells were incubated in the medium with various concentration of 5-FU or gemcitabine for 72 h. Cells were then washed once with phosphate-buffered saline (PBS) and fixed in PBS containing 4% paraformaldehyde and 10% sucrose at room temperature for 15 min in the dark. Cells were labeled with 4',6-diamidino-2-phenylindole (DAPI) in PBS (1 μg DAPI/mL) at room temperature for 2 min in the dark. Thereafter, cells were washed twice with PBS and once with distilled water, and mounted in glycergel (60%, 4 μL). Staining was visualized *via* fluorescence microscope. The apoptosis index (AI) of cultured SW1990 cells with different lentivirus transfection was calculated using the following formula. AI (%) = apoptotic cells/total cells × 100%.

Flow cytometric measurements

Apoptosis was measured with an annexin V-fluorescein isothiocyanate Apoptosis Detection Kit (Beyotime institute of biotechnology, China). Cells were seeded in 6-well culture plates and divided into the following groups: non-transfected control, SW1990 cells stably transfected with Lv-Xnc, Lv-X1; SW1990 + 5-FU, Lv-Xnc + 5-FU, Lv-X1 + 5-FU; SW1990 + gemcitabine, Lv-Xnc + gemcitabine, Lv-X1 + gemcitabine. Each group contained three culture flasks. When the cells were 70%-80% confluent, cells were added with 1 μg/mL 5-FU or 0.1 μg/mL gemcitabine. After 72 h, the cells were harvested and washed in cold PBS. Annexin V and PI staining were carried out using the Annexin V-FITC Apoptosis Detection Kit according to the manufacturer's protocol. Apoptotic cells were immediately analyzed by fluorescence-activated cell sorting analysis.

Tumorigenicity experiments

To determine whether the Lv-X1 silence XIAP gene could inhibit tumor development *in vivo*, non-transfected control cells, Lv-Xnc control, Lv-X1 transfected SW1990 cells (1.5×10^7 cells in 200 μL DMEM) were injected subcutaneously into the left axilla of BALB/c nude mice (6 mice per group). Tumor growth was monitored every 4 d in 2 dimensions with a vernier caliper, and tumor size was calculated according to the formula $V = a^2b/2$, where a and b are the shortest and longest diameters, respectively.

Statistical analysis

All data are expressed as mean ± SD. Analysis was performed using analysis of variance or the Student t test. The relationship between XIAP protein level and IC_{50} was analyzed by Pearson linear correlation analysis. The criterion for significance was $P < 0.05$. All the statistical analysis was performed by SPSS16.0.

RESULTS

XIAP overexpression is associated with greater chemotherapeutic drug chemoresistance

Levels of XIAP expression were highest in Panc-1 and SW1990 cell lines with a higher degree of 5-FU and gemcitabine chemoresistance than Mia-paca2 and Bxpc-3, which expressed XIAP at relatively lower levels (Figure 1A and B).

Selection of the most effective suppression XIAP specific shRNA vector

In order to exclude an off-target silencing effect mediated by specific shRNA, we designed 3 different sequences targeting XIAP and selected the most effective Lv-shRNA in this study. Real-time RT-PCR was performed after transfection and selection with puromycin. The XIAP mRNA expression in Lv-X1, Lv-X2 and Lv-X3 transfected SW1990 cells were reduced by 62.48% ± 7.67%, 49.62% ± 4.7% and 54.47% ± 2.7%, respectively, compared with the Lv-Xnc transfected control ($P < 0.05$). In addition, no difference was observed between the Lv-Xnc control and the SW1990 control ($P > 0.05$) (Figure 1C). Western blotting revealed that the inhibition efficiencies on XIAP protein expression by Lv-X1, Lv-X2, and Lv-X3 lentivirus were consistent with that on the targeted genes' mRNA expression. XIAP protein was knocked down in Lv-X1, Lv-X2 and Lv-X3 transfected SW1990 cells, its expression demonstrated a significant reduction in Lv-X1 (5.98% ± 0.7%), Lv-X2 (12.32% ± 0.9%) and Lv-X3 (13.52% ± 2.2%) transfected SW1990 cells compared with the Lv-Xnc transfected control ($P < 0.05$). In addition, no difference was observed between the Lv-Xnc control and the SW1990 control ($P > 0.05$) (Figure 1D). According to the results of RT-PCR and Western blotting, Lv-X1 was the most effective lentivirus vector and thus we used it in the following research. To validate the specificity of RNAi targeting XIAP, we also determined the level of anther IAP family protein, survivin. The results showed that survivin was not affected by any constructed lentivirus (Figure 1D).

Figure 1 X-linked inhibitor of apoptosis protein expression analysis and selection of the RNAi target for X-linked inhibitor of apoptosis protein. A, B: The X-linked inhibitor of apoptosis protein (XIAP) protein level and IC_{50} for Panc-1, SW1990, Mia-paca2 and Bxpc-3 cell lines. R^2 = 0.87 (Spearman correlation) between IC_{50} and relative XIAP expression, $P < 0.05$; C: Relative expression of XIAP mRNA after transfection and selection with puromycin; D: Downregulatory effect of lentivirus-mediated RNAi on XIAP in SW1990 cells. Lv-X1, Lv-X2, Lv-X3 efficiently suppressed XIAP expression. The results also showed that survivin was not affected by any lentivirus. Lv-Xnc, which was transfected with the non-sense lentivirus vector, was set as the calibrator with the relative expression value of "1". β-actin was used as the internal loading control in three independent experiments. 5-FU: 5-fluorouracil.

Suppression of XIAP expression enhances drug-induced cytotoxicity and inhibits cell proliferation *in vitro* and *in vivo*

To determine the IC_{50}, cells were exposed to 1000, 100, 10, 1, 0.1, 0.01 and 0.001 μg/mL 5-FU or gemcitabine for 72 h. The IC_{50} was calculated from MTT cytotoxicity assay data. Lv-X1 (0.2 ± 0.01 μg/mL for 5-FU, 0.14 ± 0.03 μg/mL for gemcitabine), Lv-X2 (0.72 ± 0.08 μg/mL for 5-FU, 0.42 ± 0.02 μg/mL for gemcitabine), Lv-X3 (0.5 ± 0.05 μg/mL for 5-FU, 0.28 ± 0.01 μg/mL for gemcitabine) inhibited the IC_{50} significantly ($P < 0.05$ *vs* Lv-Xnc), and Lv-X1 was the most effective. Lv-Xnc control had no effect on the IC_{50} ($P > 0.05$ *vs* SW1990 control) (Figure 2A). When compared with SW1990 and Lv-Xnc control cells, Lv-X1, Lv-X2 and Lv-X3 infected SW1990 transfected cells showed much slower growth, especially Lv-X1 infected SW1990 transfected cells. XIAP shRNA lentivirus transfection knockdown of XIAP significantly inhibited the proliferation of cultured SW1990 cells *in vitro* at the time points from day 4 to day 8 ($P < 0.05$) (Figure 2B). The result of the colony formation assay indicated that the number of colonies of Lv-X1 cells (55.26% ± 3.74%) were much less than that of Lv-Xnc (100.6% ± 5.07%) and non-transfected cells (100% ± 6.04%) ($P < 0.05$) (Figure 2C). To determine whether Lv-X1 knockout of the XIAP gene could inhibit tumor development *in vivo*, SW1990 control cells, Lv-Xnc control, and Lv-X1 infected SW1990 cells were injected into BALB/c nude mice and tumor growth was monitored every 4 d. At the time points of day 16 to day 28 after SW1990 implantation, the tumorigenicity experiments revealed that suppression of XIAP in the Lv-X1 group significantly inhibited the growth of the transplanted tumor in nude mice, which was consistent with the results achieved from the experiments *in vitro* ($P < 0.05$). For example, the tumor volume in nude mice at day 28 after the inoculation of SW1990 cells in groups of non-transfected, Lv-Xnc and Lv-X1 were 1223.28 ± 176.14, 1173.45 ± 149.61 and 532.83 ± 84.59 mm^3, respectively. When compared with SW1990 and Lv-Xnc control cells, Lv-X1 infected SW1990 transfected cells developed much smaller tumors in the nude mice ($P < 0.05$) (Figure 2D).

XIAP specific silencing enhances drug-induced activation of caspase-3/7 and enhances drug-induced apoptosis

5-FU or gemcitabine induced apoptosis in cancer cells, *via* caspase activation and inhibition of apoptosis by XIAP, was mainly coordinated through binding to effector caspase-3 and caspase-7. Thus, we sought to determine the effect of XIAP silencing on caspase activities after exposure to different concentrations of 5-FU or gemcitabine for 72 h. 5-FU or gemcitabine-induced caspase-3/7 activity was markedly increased after transfection of Lv-X1 (4.41 ± 0.51-fold, 23.31 ± 8.14-fold at 1,

Figure 2 Lentivirus-mediated shRNA targeting the X-linked inhibitor of apoptosis protein gene inhibits the growth of human pancreatic cancer SW1990 cells *in vitro* and *in vivo* and promotes chemosensitivity to drugs. A: Lv-X1, Lv-X2, Lv-X3 promoted 5-fluorouracil (5-FU) or gemcitabine-induced cytotoxicity. The IC$_{50}$ was determined by 3-(4,5-cimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay after exposure to 5-FU or gemcitabine for 72 h; B: The growth curves of different stably transfected cell lines; C: Results of colony formation assay. Lv-X1 had much fewer colonies than Lv-Xnc and untransfected cells. These experiments were performed 3 times; D: SW1990, Lv-Xnc and Lv-X1 cells growth in BALB/c nude mice ($P < 0.05$, from day 12 to day 28).

10 μg/mL 5-FU, respectively; 20.26 ± 0.96-fold, 36.62 ± 3.77-fold at 0.1, 1 μg/mL gemcitabine, respectively), but was unaffected after transfection of Lv-Xnc control. In addition, blank Lv-X1 (1.07 ± 0.03-fold) and Lv-Xnc (1.03 ± 0.01-fold) caspase-3/7 activity, although slightly increased, were not significantly different compared with SW1990 control (Figure 3A), which was also confirmed by DAPI staining and flow cytometry (FCM) (Figure 3B and C). We used DAPI staining to observe the morphological changes of apoptosis and the apoptosis index of DAPI staining analysis was consistent with caspase-3/7 activity (Figure 3B). To validate the results of DAPI staining, SW1990 and stably transfected SW1990 cells (Lv-Xnc, Lv-X1) were stained with annexin V and PI and analyzed by FCM. Cell apoptosis analysis indicated that downregulation of XIAP was not associated with a significantly increased spontaneous apoptosis rate (there were no obvious differences in apoptosis rates among SW1990 (3.03% ± 0.49%), Lv-X1 (5.06% ± 0.54%) and Lv-Xnc (4.21% ± 0.36%) ($P > 0.05$)), while the apoptosis of Lv-X1 + 5-FU (12.7% ± 0.50%) or Lv-X1 + Gem (13.68% ± 0.56%) was significantly increased compared with SW1990 and Lv-Xnc control cells ($P < 0.05$) (Figure 3C). All these results showed that the lentivirus-mediated inhibition of XIAP expression did not lead to acceleration of the apoptosis of SW1990 cells.

Downregulation of XIAP with Lv-X1 decreased p-Akt levels

We observed that decreased expression of XIAP resulted in inhibition of cell proliferation according to the results of the growth curves and colony formation assay of different stably transfected cell lines (Figure 2B-D). Caspase-3/7 activity, DAPI staining and FCM analysis of Lv-X1 groups although slightly increased, showed no significant differences compared with controls (Figure 3A-C). It is reported that apoptotic pathways in cancer functionally crossover with survival pathways PI3K/Akt, and compared with the Lv-Xnc group, XIAP protein expression levels in cells transfected with Lv-X1 were reduced by 92.55% ± 0.78% ($P < 0.05$), and p-Akt protein expression in Lv-X1 transfection groups was reduced by 94.63% ± 0.32% ($P < 0.05$) (Figure 4). We found that downregulation of XIAP with Lv-X1 decreased p-Akt levels, which might explain the phenomenon.

DISCUSSION

It has been reported that XIAP is overexpressed in many human malignancies such as ovarian carcinoma, laryngeal cancer, esophageal cancer, breast cancer, hepatoma cells, colon cancer, and pancreatic cancer. Upregulated levels of XIAP expression have been correlated with

Figure 3 Apoptosis analysis. A: Relative enzymatic activity of caspase-3/7; B: Apoptosis examined by 4',6-diamidino-2-phenylindole (DAPI) staining (200×), apoptosis index (%) = Apoptotic cells/Total cells × 100% (Seen in a same microscopic field and 3 randomized microscopic fields chosen for counting) using DAPI staining. Either gemcitabine or 5-fluorouracil (5-FU) kills cancer cells by inducing apoptosis, and X-linked inhibitor of apoptosis protein knocked out by Lv-X1 can enhance the capacity of the 2 drugs; C: Flow cytometry: The apoptotic rate of Lv-X1 and Lv-Xnc slightly increased but there was no significant difference among SW1990, Lv-X1 and Lv-Xnc. While the apoptotic rate of Lv-X1 + 5-FU and Lv-X1 + gemcitabine increased (12.7% and 13.68%, respectively, *P* < 0.05). FITC: Fluorescein isothiocyanate.

tumor resistance to chemotherapy or radiotherapy, and some researchers have reported that inhibition of XIAP by siRNA, plasmid or adenovirus mediated-shRNA can reduce tumor cell growth, induce apoptosis and enhance the sensitivity of tumor cells to chemotherapeutic or radiotherapeutic agents[16-21]. Though chemically synthesized siRNA can be introduced into cells *via* traditional delivery strategies including liposomes, polyethyleneimine, or electroporation, these methods have short gene silencing effects and the effects cannot be passed to cell progeny. Other gene delivery systems such as adenovi-

rus showed transient expression of the transgene and immunogenicity. Lentivirus vectors were developed to overcome these disadvantages. Recently, the lentivirus vector-mediated gene therapy including RNAi or overexpression has shown great promise in pancreatic cancer and other tumors because of its long-term gene expression and high efficiency in transducing dividing and non-dividing cells[22-25].

As we know, Panc-1 and Mia-paca2 are poorly differentiated; SW1990 and Bxpc-3 are moderately differentiated. In our study, human pancreatic cancer cell lines

Figure 4 Immunoblot analysis for p-Akt in SW1990 cells after stable transfection. Downregulation of X-linked inhibitor of apoptosis protein with Lv-X1 largely decreased p-Akt protein levels and survivin was not affected (6 mo in culture).

with higher levels of XIAP protein displayed greater 5-FU or gemcitabine chemoresistance (Figure 1A and B).

In this study, we found that lentivirus-based vectors were extremely efficient in transducing SW1990 cells. *In vitro*, 79% of the cells expressed GFP at a MOI of 50. In addition, GFP expression was stable up to 6 mo in culture (data was not shown). To determine whether lentivirus-mediated shRNA could stably inhibit the expression of XIAP, pooled clones were expanded, and stably transfected cells were lysed for Western blotting analysis 6 mo later. The results showed that the expression of XIAP in Lv-X1 cell was still markedly reduced (Figure 4). It indicated that lentivirus-based shRNA resulted in a persistent gene knockdown instead of a transient inhibitory effect.

Furthermore, the strong inhibition of XIAP by lentivirus could inhibit proliferation of SW1990 cells (Figure 2B-D), enhance drug-induced apoptosis and promote chemosensitivity to chemotherapeutic drugs, which also were reported in other studies (Figure 3A-C)[26,27], and some drugs induce apoptosis through downregulation of cell survival proteins and upregulation of death receptors *via* the reactive oxygen species-mediated upregulation of the CHOP (CCAAT/enhancer-binding protein-homologous protein) pathway[28]. Some studies showed that silencing the XIAP gene resulted in a significant induction of apoptosis in pancreatic cancer cells Mia-paca2 and AsPC-1[29]. In this study, we did not find that downregulation of XIAP was associated with a significantly increased spontaneous apoptosis rate (Figure 3A-C), which was consistent with some other previous studies[30]. To validate the specificity of RNAi targeting XIAP and to avoid off-target phenomenon, we transfected the cells with lentivirus carrying 3 different shRNA sequences against XIAP and determined the level of another IAP family protein survivin (Figures 1-4). The results showed that survivin was not affected by any constructed lentivirus, which was not consistent with previous studies[31].

One of the greatest challenges for researchers in new treatment strategies for pancreatic cancer is the obvious need to test them in preclinical *in vivo* animal models that have a good probability of being predictive of similar activity in humans. The most used models are xenografts

of human tumors grown subcutaneously in immunodeficient mice such as BALB/c nude mice[32]. In this study, we determined whether SW1990 cells stably transfected with lentivirus have reduced tumorigenicity. In the xenograft model, BALB/c nude mice that received injection of Lv-X1 cells developed tumors of a smaller size compared with control, and also showed higher levels of XIAP protein and greater tumorigenicity (Figure 2D). These findings were consistent with some previous studies in xenograft models, in which tumors from the parental pancreatic carcinoma cells with stable XIAP knockdown clones showed growth retardation[33].

Akt, which has been shown to have both prosurvival and antiapoptotic functions, is a serine/threonine kinase that is known to have at least 3 isoforms (Akt1, Akt2 and Akt3), all of which are activated by phosphoinositide 3-kinase (PI3K), and p-Akt is an activity form of Akt. It is reported that total Akt (phosphorylated + non-phosphorylated) was not altered by XIAP, nor was the expression of the p85 subunit of PI3K, suggesting a direct influence of XIAP upon Akt activation rather than an upregulation of Akt expression[34]. One of the Akt substrates identified to have antiapoptotic effects is Bad, which is the proapoptotic Bcl-2 family member that initiates apoptosis *via* binding antiapoptotic Bcl-2 family members and results in the release of cytochrome c from mitochondria. Akt has also been shown to directly phosphorylate and inactivate caspase-9[10,35], which is coordinated through binding to XIAP. Recently, XIAP was added to the list of Akt substrates. Akt has been shown to prevent the ubiquitination and degradation of XIAP *via* phosphorylation both *in vitro* and *in vivo*, and XIAP is a downstream target of Akt and a potentially important mediator of the effect of Akt on cell survival[36]. XIAP is also thought to promote Akt activity, XIAP acting as an E3 ubiquitin ligase for PTEN and promotes Akt activity by regulating PTEN content and compartmentalization, while XIAP silencing reduces constitutive mono- and poly-ubiquitination of PTEN, increases PTEN protein levels, and prevents nuclear accumulation of PTEN[37]. Furthermore, it has been reported that suppression of XIAP by either siRNA or antisense adenovirus of XIAP induced apoptosis and inhibited Akt-stimulated cell survival in ovarian cancer cells and uterine cancer cells[11,34]. These results are significant because they suggest a feedback regulation of XIAP and Akt. In this study, we found stable downregulation of XIAP with Lv-X1 in SW1990 pancreatic cancer cells markedly decreased the p-Akt protein level (Figure 4). Perhaps XIAP is a potentially important mediator of the effect of Akt on cell survival in pancreatic cancer cells as well as in ovarian and uterine cancer cells. While XIAP upregulates Akt phosphorylation and requires Akt for its function, so stable downregulation of XIAP markedly decreases the p-Akt protein level in SW1990 pancreatic cancer cells. Thus, it appears that there is an intricate, coordinated regulatory system at play between XIAP and the PI3K/Akt signaling pathway. Additional studies are necessary

to determine the precise molecular mechanism by which XIAP regulates the Akt survival pathway.

In summary, our findings demonstrate for the first time that suppression of XIAP expression *via* lentivirus-mediated shRNA represents a novel strategy for chemosensitizing pancreatic cancer cells to chemotherapeutic drugs. Our study indicates that lentivirus-mediated inhibition of XIAP is an attractive therapeutic strategy in the treatment of pancreatic cancer and justifies the use of lentivirus in cancer gene therapy studies. However, emergence of replication competent lentivirus *in vivo*, transcriptional targeting affected by the chromosomal integration site and risk of oncogene activation by the lentivirus are current problems, and an effective and safe protocol should be developed. Thus, there remains a long road before lentivirus-mediated shRNA targeting XIAP can be introduced into clinical use.

COMMENTS

Background

Pancreatic cancer is one of the most aggressive human malignancies with an extremely poor prognosis and a 5-year survival rate of only approximately 5%, partially because of the low possibility of surgical resection and resistance to chemo-radiotherapy.

Research frontiers

It has been reported that X-linked inhibitor of apoptosis protein (XIAP) is overexpressed in many human malignancies. The upregulated levels of XIAP expression have been correlated with tumor resistance to chemotherapy or radiotherapy. Lentivirus vector-mediated gene therapy has great promise in pancreatic cancer because of its long-term gene expression and high efficiency. Thus it is necessary to determine whether lentivirus-mediated shRNA targeting XIAP gene could be exploited in the treatment of pancreatic cancer.

Innovations and breakthroughs

XIAP proteins were found to be differentially expressed among pancreatic cancer cell lines. Downregulation of XIAP by transfection with XIAP shRNA resulted in decreased p-Akt expression. Moreover, it could inhibit the growth of pancreatic cancer cells *in vitro* and *in vivo* and enhance drug-induced apoptosis and promote chemosensitivity to chemotherapeutic drugs 5-fluorouracil and gemcitabine. Results also suggest that inhibition of XIAP and subsequent p-Akt depletion may have an anti-tumor effect through attenuating the ability of cancer cells to survive. Perhaps XIAP is a potentially important mediator of the effect of Akt on cell survival in pancreatic cancer cells. It appears that there is an intricate, coordinated regulatory system at play between XIAP and the phosphatidylinositol 3-kinases/Akt signaling pathway.

Applications

The results suggest that suppression of XIAP expression *via* lentivirus-mediated shRNA represents a novel strategy for chemosensitizing pancreatic cancer to chemotherapeutic drugs. Lentivirus-mediated inhibition of XIAP is an attractive therapeutic strategy in the treatment of pancreatic cancer and justifies the use of lentivirus in cancer gene therapy studies.

Terminology

XIAP: A member of the IAP family, plays an important role in regulating both apoptosis and cell proliferation; Apoptosis or programmed cell death: Disordered apoptosis and abnormal proliferation have been linked to malignancy development and treatment resistance; Akt: Also termed protein kinase B, represents a subfamily of serine/threonine kinases that promotes cellular survival. RNAi: RNA interference, a sequence specific posttranscriptional gene silencing process, which has been extensively used in the study of gene function and gene therapy for cancer.

Peer review

This is an interesting manuscript. The data is solid, but it is still a long way from lentivirus-mediated shRNA targeting XIAP to clinical use.

Abstract

AIM: To study the efficacy and factors associated with a sustained virological response (SVR) in chronic hepatitis C (CHC) relapsing patients.

METHODS: Out of 1228 CHC patients treated with pegylated interferon (PEG-IFN) and ribavirin (RBV), 165 (13%) had a relapse. Among these, 62 patients were retreated with PEG-IFN-α2a or -α2b and RBV. Clinical, biological, virological and histological data were collected. Initial doses and treatment modifications were recorded. The efficacy of retreatment and predictive factors for SVR were analyzed.

RESULTS: An SVR was achieved in 42% of patients. SVR was higher in young (< 50 years) (61%) than old patients (27%) (*P* = 0.007), and in genotype 2 or 3 (57%) than in genotype 1 or 4 (28%) patients (*P* = 0.023). Prolonging therapy for at least 24 wk more than the previous course was associated with higher SVR rates (53% *vs* 28%, *P* = 0.04). Also, a better SVR rate was observed with RBV dose/body weight > 15.2 mg/kg per day (70% *vs* 35%, *P* = 0.04). In logistic regression, predictors of a response were age (*P* = 0.018), genotype (*P* = 0.048) and initial RBV dose/body weight (*P* = 0.022). None of the patients without a complete early virological response achieved an SVR (negative predictive value = 100%).

CONCLUSION: Retreatment with PEG-IFN/RBV is effective in genotype 2 or 3 relapsers, especially in young patients. A high dose of RBV seems to be important for the retreatment response.

INTRODUCTION

Major advances have been made in the treatment of chronic hepatitis C (CHC) over the last decade. However, only 50% of patients will achieve a sustained virological response (SVR) with the combination of pegylated interferon (PEG-IFN)-α and ribavirin (RBV), the reference standard of care[1,2]. Hence, non-response and relapse are major issues. Approximately 30% of CHC patients with undetectable hepatitis C virus (HCV) RNA at the end of therapy (EOT) will experience relapse[3].

Although its mode of action is not completely understood, RBV is clearly needed to improve SVR rates when combination therapy with PEG-IFN is prescribed[4]. The optimal dose of RBV to maintain the highest SVR rates differs according to genotype. The recommended RBV dose is 1000/1200 mg/d and 800 mg/d in HCV genotype-1 and genotype-2 or -3 infected patients, respectively[2,5]. Controversial studies showed that RBV dose, as well as RBV reduction and/or discontinuation during the first 12-24 wk of treatment could have an impact on the treatment response[6-12].

In addition to RBV dose and cumulative exposure, viral and host factors associated with a virological response were identified in naïve patients. The likelihood of a response is higher when patients have an early and long period of undetectable HCV RNA[13]. Patients who attain a rapid virological response and early virological response (EVR) have lower rates of relapse[14]. Also, older age, advanced liver fibrosis, high baseline viral load, infection with HCV genotype 1 and co-infection with human immunodeficiency virus (HIV) are known factors associated with treatment failure[2,13,15,16]. Recent data suggests that the type of PEG-IFN also has an impact on the outcome of HCV treatment. In the IDEAL trial, PEG-IFN-α2a and PEG-IFN-α2b in combination with RBV were compared. Although the EOT response was lower with PEG-IFN-α2b, higher relapse rates were observed with PEG-IFN-α2a. Therefore, the rates of SVR did not differ between the two types of PEG-IFN[13].

In contrast to the well-defined management of new HCV patients, relapsers are a challenge nowadays. There are no proven guidelines for retreatment of relapsers. Retreatment studies have been made based on heterogeneous groups. The majority of reports included both non-responders and relapsers and different previous therapies: IFN monotherapy, IFN plus RBV or PEG-IFN monotherapy. Overall SVR rates of 13%-50% were obtained in retreatment of patients who failed previous IFN-based therapy, with a higher SVR in former relapsers than in non-responders[17-21].

Thus, retreatment of relapsers with PEG-IFN plus RBV has not been well studied. The aim of this study was to evaluate, outside of trials, the efficacy of retreatment, and predictors of response, in a population of CHC relapsers after a previous course of PEG-IFN and RBV.

MATERIALS AND METHODS

Patient selection

Patients with CHC who relapsed after a previous course of PEG-IFN-α2a or PEG-IFN-α2b in combination with RBV were eligible. Patients previously treated for at least 12 wk, with undetectable HCV RNA at the end of treatment and recurrence of viremia during 24-wk post-treatment follow-up were included in this retrospective cohort study. Exclusion criteria were co-infection with human immunodeficiency virus or HBV, the presence of any other cause of liver disease, decompensated liver disease and a history of hepatocellular carcinoma.

Study design

Patients were treated with PEG-IFN-α2a at a dose of 180 μg per week, plus weight-based oral RBV as previously described or PEG-IFN-α2b at the standard dose of 1.5 μg/kg body weight per week, in combination with oral RBV at a dose of 800-1200 mg per day, according to genotype and body weight[2,22]. The duration of therapy was determined according to genotype, duration of previous therapy, initial virological response and tolerability. Treatment prolongation and high RBV dose administration were decided case by case according to the physicians' discretion. All patients had a post-treatment follow-up of at least 24 wk.

Assessments

Serum HCV RNA level was measured at treatment initiation, treatment week 4, every 12 wk during the treatment period; and during post-treatment follow-up at weeks 4, 12 and 24. HCV RNA was detected qualitatively with the use of transcription-mediated assay (VERSANT HCV RNA Qualitative Assay; Siemens Medical Solution Diagnosis), which has a sensitivity of 9.6 IU/mL. A rapid virological response (RVR) was defined as undetectable HCV RNA at week 4 of treatment. An EVR was defined according to HCV viral load at week 12 and categorized as: no EVR (reduction of less than 2 log in HCV viral load compared with the baseline level); partial EVR (pEVR): reduction greater than 2 log; and complete EVR (cEVR): undetectable HCV RNA. Response to treatment was based on HCV RNA measurement at the end of therapy and at week 24 of follow-up. Non-responders were defined as detectable HCV RNA at EOT. Relapsers were defined as HCV RNA undetectable at EOT but detectable within the 24-wk follow-up period. An SVR was defined as negative HCV RNA 24 wk after cessation of therapy. Pretreatment liver biopsies were analyzed by a single pathologist using the META-VIR scoring system.

Patients were evaluated for tolerability and safety by physical examination and laboratory evaluation, including hematological and biochemical analyses. Dose reductions or discontinuation of PEG-IFN or RBV (or both)

were performed when appropriate, in accordance with guideline recommendations.

Statistical analysis

Univariate analysis was performed to evaluate treatment response and baseline characteristics. Categorical variables were compared using χ^2 or F tests. Continuous variables were analyzed with the Student t test or Mann-Whitney U test as appropriate. Predictors of response were identified and entered in a stepwise logistic regression in order to assess their association with SVR. Statistical significance was defined as $P < 0.05$ and all comparisons were two-tailed. Statistical analysis was performed using SPSS, version 12.0 (SPSS Inc., Chigago, IL).

RESULTS

Patient population

Of 1228 CHC patients treated with a combination of PEG-IFN-α plus RBV in the Hepatology Department of Hôpital Beaujon, 165 (13%) patients were identified as relapsers and were eligible for this study. Retreatment was proposed for 75 patients. Among these, 62 consecutive patients were retreated between April 2003 and June 2008 and finished their follow-up period. Retreatment was prescribed with the same type of PEG-IFN-α used in the prior PEG-IFN combination treatment in 53% of patients. Median duration of therapy was 48 wk (16-72 wk). Retreatment was at least 24 wk longer than previous therapy in 51% of patients. Initial dose of RBV was >13.3 mg/kg per day in 54%. A high dose of RBV (daily doses > 15.2 mg/kg[22]) was prescribed in 16% of patients.

Baseline demographic, clinical, biochemical, virological and histological characteristics are summarized in Table 1. The mean age of the patients was 52 years, and approximately 73% were male; 57% had a body mass index (BMI) > 25 kg/m^2. Serum alanine aminotransferase

Sustained virological response (SVR) according to different types of pegylated interferon (PEG-IFN), dose of ribavirin (RBV) and duration of therapy.

and γ-glutamyl transferase (GGT) levels were abnormal in 90% and 67% of patients, respectively. Forty-eight patients were infected with HCV genotype 1. High viral load (> 600 000 IU/mL) was observed in 28%. Necro-inflammatory activity was mild (A1) in 51% of patients, 34% had F2 fibrosis, 19% had advanced fibrosis (F3) and 39% had cirrhosis (F4). Steatosis was absent (< 5%) in 21%, mild (5%-30%) in 37%, and moderate or severe (> 30%) in 42% of patients.

Response to treatment

After retreatment with PEG-IFN and RBV, the overall SVR rate was 42%. An EOT response was achieved by 77% of patients (48/62); among them, 46% (22/48) again experienced a relapse. Patients < 50 years achieved a higher SVR rate (61%) when compared to older patients (27%) ($P = 0.007$). Female and male patients had SVR rates of 53% and 38%, respectively, but with no significant difference ($P = 0.28$). There was a trend for higher SVR rates in patients with normal baseline GGT (61% *vs* 36%, $P = 0.081$) and lower BMI (mean BMI 24.6 in SVR *vs* 26.5 in non responder, $P = 0.071$). In addition, patients infected with genotype 2 or 3 had higher SVR than those with genotype 1 or 4 (57% *vs* 28%, $P = 0.023$) (Figure 1A). SVR rates were similar regarding low and high viral load (41% *vs* 36%, $P = 0.77$). Necro-inflammatory activity, fibrosis and steatosis did not influence SVR rates.

Treatment responses according to dose and duration are summarized in Table 2. There was no difference between retreatment response with PEG-IFN-α2a or PEG-IFN-α2b regarding EOT (74% *vs* 84%, $P = 0.52$) and SVR rate (40% *vs* 47%, $P = 0.56$). Relapse rates were similar between groups (35% *vs* 37%, $P = 0.68$). In patients retreated with a different type of PEG-IFN-α from prior therapy, SVR was achieved in 36%, similar to that in patients retreated with the same PEG-IFN, who attained an SVR rate of 46% ($P = 0.39$). Retreatment for at least 24 wk longer than the previous therapy was associated with a higher SVR rate (53% *vs* 28%, $P = 0.044$). A high initial dose of RBV was associated with a higher likelihood of SVR. Although EOT response rates

Figure 1 Sustained virological response rates according to age, genotype and initial ribavirin dose. A: Sustained virological response (SVR) rates according to age, genotype; B: SVR rates according to initial ribavirin dose.

Figure 2 Predictive value of complete early virological response. Among 46 patients with complete early virological response (cEVR), 25 (54%) patients achieved an sustained virological response (SVR) and 21 (46%) were non-responders (17 patients had a relapse and 4 patients had a non-response). Positive predictive value of cEVR for SVR = 54% (*P* = 0.003). Negative predictive value of cEVR for SVR = 100% (*P* = 0.003). HCV: Hepatitis C virus; NR: Non response.

were not statistically different between groups (90% *vs* 75%, *P* = 0.43), patients who received > 15.2 mg/kg per day had a superior SVR rate when compared to patients receiving lower doses (70% *vs* 35%, *P* = 0.041) (Figure 1B). These results were related to a lower rate of relapse among patients with a high dose of RBV (20% *vs* 39%). Regarding RBV dose reduction, no impact on SVR rates was observed (43% among those patients without a reduction *vs* 33% with a dose reduction, *P* = 0.75).

Tolerability and dose reduction
Retreatment with combination therapy was well tolerated. Seventy-nine percent of patients did not reduce their initial dose of PEG-IFN and/or RBV. Only 4 patients (6.6%) had a reduction in PEG-IFN dose, 3 of whom had clinical intolerance with asthenia, and one had marked neutropenia. The reduction in RBV dose was necessary in 12 patients (19.7%), with anemia being the major reason (58%). Among all patients, only 2 had cumulative RBV doses lower than 80% of the predicted dose. High initial doses of RBV did not seem to influence RBV reduction. In patients with an initial dose of RBV > 13.3 mg/kg per day and in those with > 15.2 mg/kg per day, 26% and 30% of patients needed RBV dose reduction. The treatment was stopped earlier than the proposed therapy duration in 11 patients (18%). Among these, 10% did not achieve a virological response at week 24, and treatment was discontinued.

Predictors of response
The factors identified in bivariate analysis as possibly associated with SVR and entered in a logistic regression model were: age, genotype, and high dose RBV. In the stepwise logistic regression analysis, the predictors of SVR were age [< 50 years *vs* ≥ 50 years; odds ratio (OR), 4.26; 95% CI: 1.28-14.19], genotype (G2/3 *vs* G1/4; OR, 3.55; 95% CI: 1.01-12.46), and high dose RBV (> 15.2 mg/kg per day *vs* <15.2 mg/kg per day; OR, 6.99; 95% CI: 1.32-36.97). Younger patients with genotype 2 or 3 can attain an SVR of 59%, while older patients, infected with genotype 1 or 4 only had an SVR of 10%. None of the patients of older age, genotype 1 or 4, and RBV initial dose < 15.2 mg/kg per day achieved an SVR.

Predictive value of rapid virological response and early virological response
RVR was assessed in 39 patients; 18% (7/39) achieved an RVR, and 5 of these achieved an SVR [positive predictive value (PPV) = 71%]. In addition, RVR had a negative predictive value (NPV) for SVR of 88% (*P* = 0.007).

At week 12, 55 patients were classified according to the 3 categories of EVR described earlier. pEVR and cEVR were observed in 11% and 84% of patients. Patients with no EVR (3/55) or pEVR (6/55) did not attain an SVR (NPV = 100%). Among the 46 patients with cEVR, 4 (9%) were non-responders, 17 (37%) were relapsers and 25 (54%) had an SVR. cEVR had a PPV and a NPV for SVR of 54% and 100%, respectively (*P* = 0.003) (Figure 2).

DISCUSSION
Retreatment of CHC patients who have failed prior antiviral therapy is an important clinical issue. Our study evaluated the efficacy of retreatment of CHC patients who relapsed after combination therapy with PEG-IFN

plus RBV. The overall SVR rate achieved was 42%. An important point of our study is the inclusion of a homogeneous population of prior relapsers to the PEG-IFN-α plus RBV combination therapy. Most previous studies analyzed the efficacy of retreatment with PEG-IFN plus RBV based on groups composed mainly of patients who failed conventional IFN-based therapy without distinguishing between non-responders and relapsers, or between monotherapy and combination therapy. Jacobson *et al*[21] demonstrated that SVR rates decreased according to previous conventional IFN-based therapy status: 42% in conventional IFN (cIFN) plus RBV relapsers, 21% in cIFN monotherapy non-responders, and 8% in cIFN plus RBV non-responders. These data were also confirmed by several other studies: retreatment of previous relapsers to cIFN plus RBV could achieve SVR rates of 41%-58%, while for patients who were non-responders, only 4%-26% achieved an SVR[17-21]. The same relationship was observed in previous failures to PEG-IFN and RBV: 33% in prior relapsers and 14% in prior non-responders, with an overall SVR of 22%[23].

The SVR rate of 42% observed in our study was slightly higher than that described in the EPIC3 clinical trial, where prior PEG-IFN plus RBV relapsers attained an SVR of 33%[23]. In our study, HCV genotype was an important predictor for SVR. Patients infected with genotype 2 or 3 attained the highest rates of SVR (60% in genotype 2 and 56% in genotype 3). Thus, a higher proportion of genotype non-1 infected patients in the current study (52% *vs* 20% in EPIC3 trial) could account for this difference. In addition, the EPIC trial used less sensitive qualitative assays that could result in misclassification of EOT responders, increasing the number of relapsers that were in fact non-responders, with a lower probability of SVR.

Young age and genotype 2 or 3 were factors associated with treatment response as previously reported[2,13,15]. We did not find a relationship between low baseline viral load or low fibrosis stage and better response to therapy. These factors have been described in controversial studies with the treatment of naïve and IFN-experienced patients, and their impact on the response in relapsers could have less strength[7,13,19,23,24].

Retreatment with only PEG-IFN-α in patients who failed to respond to the other PEG-IFN-α has been described as an alternative strategy. However, in our study no gain was observed in patients who received a different type of PEG-IFN-α. This finding is consistent with the REPEAT trial, where prior non-responders to PEG-IFN-α2b were retreated with PEG-IFN-α2a. Only 9% of SVR was observed in the regimen of 48 wk retreatment[25]. Besides, this trial demonstrated higher SVR rates in the group retreated for 72 wk (14%)[26]. In the current study, the SVR rate was also improved with longer duration of therapy. Thus, retreatment for at least 24 wk longer than the previous course is important to increase the probability of SVR in relapsers and non-responders.

Some controversial studies have suggested that exposure to RBV is critical for attaining an SVR. At first, adherence to therapy was considered extremely important. McHutchison *et al*[8] demonstrated that at least 80% adherence to therapy enhanced SVR. They found a continuous, increasing relationship between adherence and SVR in genotype 1. These findings were also observed in another study with genotype 1-naïve patients, where a linear relationship between exposure and the SVR rate was observed at the first 12 wk of treatment[7]. Also, a study with RBV discontinuation in a subset of HCV RNA-negative patients at week 24 showed an increase in the rate of virological breakthrough and relapse[9]. In contrast, in our study no relation was found between dose reduction of RBV and SVR. However, the rate of RBV reduction was 20% and only 2 patients did not have at least 80% of the predicted RBV doses.

Recent studies suggested that high-dose RBV schedules reduced relapse rates and increased SVR in difficult-to-treat selected patients[10-12]. In a pilot study with 10 genotype 1 patients, higher RBV doses were associated with more frequent and serious adverse events, but the SVR rate was 90%[11]. Also, Fried *et al*[10] reported a study with 188 treatment-naïve, genotype 1 and high viral load patients. Patients who received an RBV dose of 1600 mg/d had superior SVR rates when compared with standard doses (1200 mg/d). Our data demonstrated a clear relation between high initial dose of RBV[22] and SVR rates. Patients with RBV dose >15.2 mg/kg per day achieved an SVR rate of 70%, while only 26% of patients with lower doses attained an SVR.

Our study demonstrates that an RVR in a relapser retreatment population is attained by 18%, of whom 71% achieved an SVR. Prediction of non response on treatment was more marked with EVR analyses. If the patient did not achieve a cEVR, no SVR was observed (NPV = 100%). Hence, the presence of detectable HCV RNA at week 12 is a good indication to stop treatment in relapsers and it is as relevant as for naïve or non-responding patients[3,19,25].

Specifically targeted antiviral therapies for hepatitis C are currently under evaluation in clinical trials. These new drugs are mostly effective and have been studied in genotype 1 patients[27-29]. Telaprevir, an antiprotease NS3-NS4A, increases SVR rates in genotype 1 naïve and non-responding patients, but it has limited activity against genotype 2 and 3[30]. Besides, even when these medications will be available outside trials, they will not be accessible worldwide. For these reasons, PEG-IFN and RBV still have a role on hepatitis C retreatment, in particular in young patients infected with non genotype 1.

In conclusion, our study shows that retreatment of prior relapsers after treatment with a combination of PEG-IFN plus RBV may be effective. As observed with naïve patients, genotype is crucial for a treatment response. Better results of retreatment are obtained in patients with genotype 2 or 3 and of younger age. In addition, in this subset of patients, higher SVR rates

are achieved with increased doses of RBV, without a marked increase in adverse events or dose reductions. Thus, a high dose schedule of RBV is recommended if retreatment is proposed. Also, prolonging therapy for at least 24 wk more than the previous course enhances SVR rates. Finally, the absence of a cEVR as defined by detectable HCV RNA at week 12 should be considered a stopping rule in the retreatment of relapsers.

COMMENTS

Background
Only 50% of chronic hepatitis C (CHC) patients treated with the combination of pegylated interferon (PEG-IFN)-α and ribavirin (RBV), the standard treatment, will achieve a sustained virological response (SVR). Therefore, patients with no response or relapse after PEG-IFN and RBV treatment are a major issue. Approximately 30% of CHC patients with undetectable hepatitis C virus (HCV) RNA at end of therapy (EOT) will experience relapse.

Research frontiers
Retreatment of CHC patients with relapse to antiviral therapy is a current clinical issue. There are no specific recommendations about type, dose and duration of retreatment in this particular situation. In this research area, different dose schedules and duration of PEG-IFN and RBV therapy have been evaluated in order to increase the SVR in patients with a previous relapse to this antiviral therapy.

Innovations and breakthroughs
This study shows in a real life cohort that retreatment of relapsers after prior treatment with a combination of PEG-IFN plus RBV may be effective. Better results of retreatment are obtained in patients with genotype 2 or 3 and of younger age as is observed in naïve patients. Moreover, in this subset of patients, higher SVR rates are achieved with increased doses of RBV (> 15.2 mg/kg per day), without a marked increase in adverse events or dose reductions. Also, lengthening therapy for at least 24 wk more than the previous course enhances SVR rates.

Applications
The study suggests that retreatment of patients with a relapse after treatment with PEG-IFN and RBV may be effective, especially in patients with genotype 2 or 3 who are of younger age. In order to increase SVR in this particular situation, high dose RBV and longer duration of therapy should be proposed.

Terminology
In CHC patients, treatment responses to the combination of PEG-IFN and RBV are defined by a virological parameter (HCV RNA analysis) rather than a clinical endpoint. The most important definitions are: SVR if HCV RNA remains undetectable 24 wk after EOT, non response if HCV RNA is positive at EOT, and relapse if HCV RNA is undetectable at EOT but detectable within 24-wk follow-up period.

Peer review
The authors revealed that SVR was achieved in 42% of the retreated patients, and that initial dose/weight of RBV was an important predictor of SVR.

Abstract

AIM: To investigate the effectiveness of head compensatory postures to ensure safe oropharyngeal transit.

METHODS: A total of 321 dysphagia patients were enrolled and assessed with videofluoromanometry (VFM). The dysphagia patients were classified as follows: safe transit; penetration without aspiration; aspiration before, during or after swallowing; multiple aspirations and no transit. The patients with aspiration or no transit were tested with VFM to determine whether compensatory postures could correct their swallowing disorder.

RESULTS: VFM revealed penetration without aspiration in 71 patients (22.1%); aspiration before swallowing in 17 patients (5.3%); aspiration during swallowing in 32 patients (10%); aspiration after swallowing in 21 patients (6.5%); multiple aspirations in six patients (1.9%); no transit in five patients (1.6%); and safe transit in 169 patients (52.6%). Compensatory postures guaranteed a safe transit in 66/75 (88%) patients with aspiration or no transit. A chin-down posture achieved a safe swallow in 42/75 (56%) patients, a head-turned posture in 19/75 (25.3%) and a hyperextended head posture in 5/75 (6.7%). The compensatory postures were not effective in 9/75 (12%) cases.

CONCLUSION: VFM allows the speech-language therapist to choose the most effective compensatory posture without a trial-and-error process and check the effectiveness of the posture.

INTRODUCTION

Swallowing is a coordinated activity that enables solids and liquids to pass uninterrupted from the mouth to the

stomach. Dysphagia occurs when this process is altered by organic or functional alterations at the level of swallow initiation or esophageal emptying[1].

Oropharyngeal dysphagia can manifest as one or more symptoms that are specific for oropharyngeal dysfunction, which help the clinician distinguish it from esophageal dysphagia. Typical symptoms include the inability to chew, a delayed or absent swallow initiation, a bolus delay located in the neck, nasal regurgitation, a need to swallow repeatedly to clear food or fluid from the pharynx, coughing after aspiration, and dysphonia[2,3].

Oropharyngeal dysphagia is usually a manifestation of a systemic disease rather than a disease specific to the oropharynx. This manifestation occurs in one-third of all stroke patients and has a 20%-50% prevalence in conditions such as Parkinson's disease, Alzheimer's disease, and amyotrophic lateral sclerosis[3-5].

Videofluoroscopy (VFS) is the gold standard in the study of oropharyngeal dysphagia because it provides information on the presence and severity of the major categories of dysfunction, including the presence, timing and severity of aspiration[6,7].

Videofluoromanometry (VFM) correlates fluoroscopic events with manometric data. For example, the narrow upper esophageal sphincter (UES) opening can be distinguished from uncoordinated UES relaxation, and the weak propulsive pharyngeal forces can be distinguished from an increased outflow resistance. Moreover, VFM is especially useful for subsequent treatment planning[2].

Characterization of a swallowing disorder allows the patient to adopt compensatory swallowing postures, change their diet to permit safe oral feeding, and delay the use of percutaneous endoscopic gastrostomy in degenerative diseases[8]. The aim of our study was to evaluate the effectiveness of compensatory postures to ensure safe oropharyngeal transit with videofluoromanometric guidance.

MATERIALS AND METHODS

From January 2008 to December 2010, 321 dysphagia patients (171 male, 150 female, aged 18-87 years, mean age: 57 years) were enrolled in this study. All patients gave their written consent. The past medical history, present symptoms, and alimentary status were obtained from all patients. All patients underwent a morphofunctional logopedic evaluation according to recent guidelines[9,10].

Through the VFM assessment, the dysphagia patients were classified as follows: safe transit; penetration without aspiration; aspiration before, during, or after swallowing; multiple aspirations and no transit. The patients with aspiration or no transit were investigated to determine whether compensatory postures could correct the swallowing disorder. Based on manometric data, a chin-down posture, head-turned posture or hyperextended head posture was tested to obtain safe swallowing. Patients with multiple aspirations were excluded from the search for compensatory postures. These patients, who are often

in an advanced disease stage, do not follow the operator commands during the VFM assessment and do not cooperatively assume the compensatory postures. Additionally, these subjects may only somewhat benefit from these compensatory postures[11]. The VFM study consisted of a parallel execution of VFS and manometry. A simultaneous manometric evaluation analyzed the tongue base pressure (the contact pressure between the posterior tongue thrust and the pharyngeal wall), UES tone (resting pressure, contraction pressure and residual pressure) and the bolus transit coordination, which are useful for selecting the compensatory postures[12,13] (Table 1).

A Dyno Compact computerized system (MENFIS Biomedica s.r.l., Bologna, Italy) was used. This system was equipped with the following: (1) A graphics card for managing radiographic images; and (2) AVIUS-dedicated software, which enables digital-quality recording (PAL/NTSC, composite video or S-video) of the VFS study in AVI format with a 320 × 240 resolution and 25 Hz acquisition frequency. The delay introduced by the image digitization process was approximately 200 ms; therefore, for analytical purposes, the images could be considered synchronized with the manometric recordings. The concurrent pressure measurements were performed with a manometry catheter with endoluminal five-channel, solid-state microtransducers 2 cm apart at an angle of 120°-90°. The catheter was inserted through the nasal cavity into the stomach. The value recorded was used for the calibration of 0. Afterwards, a pull through was performed and the catheter was withdrawn to allow for the positioning of the transducers. Transducer 1 was placed at Passavant's ridge to evaluate the correct closure of the rhinopharynx during swallowing and phonation. Transducers 2, 3 and 4 were placed in the pharynx. Transducer 5 was placed at the UES, and the correct placement was determined by the appearance of the characteristic M wave. During image acquisition, the video images and manometric trace were displayed in real time as a full screen image on the personal computer monitor. A cursor indicated the exact correspondence between the video images and the traces. Following the acquisition, the video and manometric trace could be analyzed during real-time reproduction or at reduced or increased speed, or it could be paused for a frame-by-frame analysis. The examinations were acquired with the patient standing or

seated if the patient was unable to remain standing.

VFM began with a baseline evaluation (without contrast) to study the motility of the vocal chords and soft palate. The VFM proceeded with barium contrast medium (Prontobario HD suspension, Bracco SpA, Milan; 250% w/v) at a dose of 5-15 mL that was optimized for the patient to evaluate swallowing, with particular attention paid to aspiration. This was made possible by previous evaluation by a speech therapist. The patients were asked to hold the bolus in their mouth for several seconds and to swallow when asked by the operator. All phases of the process were video-recorded first in the anteroposterior and then the laterolateral view[9,14]. If an impaired bolus transit or aspiration in the airways was detected, an evaluation of the ideal bolus size and monitoring the effectiveness of the compensatory postures were used to investigate correcting the dysfunction.

The compensatory posture was selected for each patient based on the specific swallowing dysfunction that was considered to have caused the aspiration. For an effective oropharyngeal bolus transit while swallowing, the following compensatory postures were tested. The chin-down posture involved tucking the chin to the neck. The change in head position inverted the epiglottis into a more protective position over the airway entry, which reduced the airway entrance space and increased the size of the vallecular spaces[12,15,16]. The head-turned posture narrowed the ipsilateral piriform sinus and sent the bolus to the contralateral sinus. In addition, it determined the decrease in UES pressure, delayed its closure during swallowing, and optimized the bolus propulsion[17,18]. The hyperextended head posture facilitated the bolus transit using the force of gravity. This posture is indicated for reduced pharyngeal peristalsis[4].

RESULTS

VFM in 169 (52.6%) of 321 enrolled patients showed safe transit of the contrast medium. In 71/321 cases (22.1%), penetration of the contrast medium into the laryngeal lumen without aspiration below the glottic level was observed, and we did not suggest compensatory postures for these patients. In 5/321 (1.5%) cases, there was no transit.

In 76/321 patients (23.7%), aspiration was observed. In 70/76 (92.1%) patients, VFM revealed a single aspiration, and in 17/70 (24.3%) cases, aspiration occurred before swallowing, in 32/70 (45.7%) during swallowing, and in 21/70 (30%) after swallowing. In 6/76 cases (7.9%), there were multiple aspirations, and compensatory postures were not sought in these patients.

Compensatory postures (Figures 1 and 2) through VFM guidance were tested in the 70 patients with a single aspiration and the five with no transit (Table 2). Among the aspiration cases, 24 (34%) had no spontaneous reflex cough. The 17 patients with aspiration before swallowing suffered from disorders of the oral phase, such as a deficit of lip closure (17.6%), reduced lifting of the soft palate (41.2%), and reduced (29.4%) or disorganized tongue movement (11.8%). The tongue-palate contact was incomplete in 4/17 (23.5%), with leakage and aspiration before voluntary swallowing due to a fraction of the bolus moving into the pharynx and being aspired without manometric alterations. In 8/17 cases (47%), the manometric evaluation showed that the tongue base pressure was < 60 mmHg during swallowing. In all 17 patients, a total resolution of the disorder was obtained by adopting the chin-down posture.

Aspiration during swallowing occurred in 32 (45.7%) cases. Eighteen of these (56.3%) were related to a reduced laryngeal closure (10/32) or elevation (8/32), and 14 were related to a UES disorder, with a residual pressure during relaxation of > 10 mmHg (9/14, 28.1%) and an early closure of the UES compared to the end of the pharyngeal contraction (5/14, 15.6%).

In 14/18 (78%) patients with reduced laryngeal closure or elevation, the chin-down posture (Figure 2) resolved the aspiration, whereas in 10/14 (71%) patients with UES disorders, the aspiration was corrected with the head-turned posture.

The compensatory postures were not effective in 8/32 (25%) patients. In the 21 cases of aspiration after swallowing, the bolus was inhaled due to stagnant contrast medium in the pharynx. The contrast medium was noted in 5/21 (23.8%) cases at the piriform sinuses, in 4/21 (19.1%) at the glossoepiglottic valleys, and in 12 (57.1%) at both locations. Aspiration after swallowing in 4/21 (19.1%) cases resulted from incomplete release

Table 3 Results of compensatory postures in selected patients

ALS: Amyotrophic lateral sclerosis; MS: Multiple sclerosis; PD: Parkinson's disease; AD: Alzheimer's disease.

Figure 1 Videofluoromanometry study. A: Aspiration after swallowing (black arrow) with stagnation in the glossoepiglottic valleys and piriform sinuses (white arrows). Incomplete upper esophageal sphincter (UES) release (arrow); B: The same occurred with the head-rotated posture; stasis persisted at the pharyngo-esophageal junction (white arrow), but there was no aspiration of the contrast medium. The UES was fully open (dashed box).

Figure 2 Videofluoromanometry study. A: Aspiration during swallowing (arrow) for the reduced laryngeal closure with an incomplete upper esophageal sphincter (UES) release; B: The same occurred in the course of the chin-down posture; this posture resolved the aspiration because it placed the epiglottis in a more protective position of the airways and restricted the airway entrance.

of the UES, with a residual pressure of > 10 mmHg. In 4/21 (19.1%) cases, the resting pressure of the UES was > 150 mmHg. In 1/21 (4.8%) cases, the pharyngeal dysfunction and stagnation of contrast medium was unilateral. The chin-down posture solved the aspiration in 11/21 cases (52.4%), and the head-turned posture was useful in 9/21 patients (42.9%). In 1/21 (4.7%) cases, there was no discomfort reduction.

In the five cases of dysphagia with no transit, the disorder was characterized by alterations in the initiation of the swallowing reflex without a peristaltic wave from the tongue base; all of these cases benefited from the

hyperextended head posture (Table 3).

DISCUSSION

Swallowing therapy has the primary goal of maintaining oral feeding and achieving safe and efficient swallowing, which is important to ensure a good quality of life. Different swallowing techniques have been adopted rapidly during the past decade and are used almost worldwide. However, few studies have investigated how each technique affects swallowing[13,15,19].

When treating patients with oropharyngeal dysfunction, an ideal approach to the assessment and treatment

is working in a team with a radiologist, gastroenterologist and a speech-language pathologist. In the present study, a multi-specialist assessment team evaluated each enrolled patient to assess the swallowing dysfunction and test the adequacy of therapy to ensure safe transit. VFM provides a parallel acquisition of videofluoroscopic and manometric data and plays a crucial role in therapeutic planning.

We did not employ dietary modifications, including increases in the volume or density of food, for radioprotection reasons, but a single bolus of contrast medium was optimized for the patient.

Three different compensatory postures, including chin down, head turned and head hyperextended, were adopted. Each patient was tested before the posture was deemed appropriate. The compensatory postures restored a safe transit in 66/75 patients (88%). The chin-down posture was effective in 42/66 patients (63.6%). This posture was useful in all patients with aspiration before swallowing because it promoted bolus control in the oral cavity until the swallowing reflex was elicited. In patients with aspiration during swallowing and reduced laryngeal closure or elevation, the chin-down posture protected the airway from aspiration. In patients with aspiration after swallowing, dropping the tongue base and the contrast medium stasis in the pharynx fostered the bolus flow into the esophagus.

The head-turned posture was useful in 19/66 (28.8%) patients with both aspiration during swallowing and aspiration after swallowing with a residual pressure or uncoordinated UES relaxation due to the decrease in UES pressure and increase in UES opening time. This posture was useful also in one patient with stroke and unilateral pharyngeal failure because it excluded the affected side from the bolus transit.

The hyperextended head posture was effective in all five patients without transit. This posture uses gravity to aid swallowing; therefore, this posture is recommended for all cases with impaired lingual propulsion but should be suggested only after verifying that the transit occurs safely[4].

The compensatory postures were not effective in 9/75 patients (12%). This finding was related to a massive aspiration in 3/9 cases, poor compliance due to an advanced stage of disease in 4/9 cases, and surgery in 2/9 cases.

Silent aspiration, defined as aspiration in the absence of reflex cough, should also be mentioned. This event occurred in 24/70 (34.3%) patients with a single aspiration; specifically, three with aspiration before swallowing, 10 during swallowing, and 11 after swallowing. In other studies, this phenomenon occurred in approximately half of those patients who aspirated and was significantly more frequent in those with a history of laryngeal pathology[20].

Silent aspiration has major importance[21] because it promotes the early onset of complications, such as aspiration pneumonia. Aspiration pneumonia is three times more frequent in dysphagia patients than those without[22],

and is the most common cause of death in patients with neurological disorders associated with dysphagia[23].

The present study had some limitations, including the use of an intraluminal manometric catheter, which is considered a non-altering device for swallowing, and the poor availability and high cost of this imaging method.

Compared to other studies[13,15], this study included the largest number of patients. The effectiveness of the compensatory postures in the oropharyngeal dysphagia patients was evaluated with combined videofluorography and manometry. In our experience, manometry has extensively evaluated deglutition disorders. Consequently, this method has chosen the better posture and defined the more effective therapeutic strategy.

In conclusion, there is not a single compensatory posture for each type of aspiration. Only VFM accurately defines the pathogenic mechanism of the swallowing deficit; helps the speech-language therapist choose the most effective compensation posture without a trial-and-error process; and checks the effectiveness at the same time. The chin-down, head-turned and head hyperextension postures are efficacious in several swallowing disorders. These postures can be evaluated during the examination itself, are easy to learn, and ensure good patient compliance. This study, complemented by a professional treatment team, guarantees a more accurate diagnosis and greater therapeutic efficacy than the individual modalities for evaluating dysphagia patients.

COMMENTS

Background
Choking, aspiration pneumonia, malnutrition and dehydration can complicate dysphagia. An exact characterization of the pathogenetic mechanisms of dysphagia helps define the therapeutic approach to reduce the risk of complications.

Research frontiers
Videofluoromanometry (VFM) is the gold standard for swallowing studies and analyzing the mechanisms underlying dysphagia.

Innovations and breakthroughs
There is not a single compensatory posture for each type of aspiration. Only VFM accurately defines the pathogenic mechanism of the swallowing deficit; helps the speech-language therapist choose the most effective compensation posture without a trial-and-error process; and checks the effectiveness at the same time.

Applications
VFM explores the effectiveness of the compensatory postures. This method may help manage dysphagia.

Peer review
This is a novel approach for the assessment of swallowing and the anatomy and physiology of the laryngopharyngeal segment. The authors seem to know the radiological aspects of the subject.

Abstract

AIM: To evaluated the value of ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography (PET)/computed tomography (CT) scan in diagnosis of hepatocellular carcinoma (HCC) and extrahepatic metastases.

METHODS: A total of 138 patients with HCC who had both conventional imaging modalities and ^{18}F-FDG PET/CT scan done between November 2006 and March 2011 were enrolled. Diagnostic value of each imaging modality for detection of extrahepatic metastases was evaluated. Clinical factors and tumor characteristics including PET imaging were analyzed as indicative factors for metastases by univariate and multivariate methods.

RESULTS: The accuracy of chest CT was significantly superior compared with the accuracy of PET imaging for detecting lung metastases. The detection rate of metastatic pulmonary nodule ≥ 1 cm was 12/13 (92.3%), when < 1 cm was 2/10 (20%) in PET imaging. The accuracy of PET imaging was significantly superior compared with the accuracy of bone scan for detecting bone metastases. In multivariate analysis, increased tumor size (≥ 5 cm) ($P = 0.042$) and increased average standardized uptake value (SUV) uptake ($P = 0.028$) were predictive factors for extrahepatic metastases. Isometabolic HCC in PET imaging was inversely correlated in multivariate analysis ($P = 0.035$). According to the receiver operating characteristic curve, the optimal cutoff of average SUV to predict extrahepatic metastases was 3.4.

CONCLUSION: ^{18}F-FDG PET/CT scan is invaluable for detection of lung metastases larger than 1 cm and bone metastases. Primary HCC having larger than 5 cm and increased average SUV uptake more than 3.4 should be considered for extrahepatic metastases.

Hospital, 3-6-10 Otobashi Nakagawa-ku, Nagoya, Aichi 454-8509, Japan

INTRODUCTION

Most patients with hepatocellular carcinoma (HCC) present with underlying liver disease, usually cirrhosis, hepatitis B and hepatitis C virus infection[1,2]. Screening and surveillance programmes based on periodic ultrasonography and α-fetoprotein (AFP) among high-risk patients could establish of early diagnosis and provide more effective treatments of HCC[3]. With advances in variable treatment modalities, the prognosis of HCC has been much improved[4-7]. With prolonged survival of HCC patients, the incidence of extrahepatic metastases has been reported up to 42%[8]. Precise evaluation of extrahepatic metastases of HCC is important because treatment modality could be determined belong to the results.

Positron emission tomography (PET)/computed tomography (CT) scan using ^{18}F-fluorodeoxyglucose (FDG) is now well established as a noninvasive diagnostic tool for diagnosis, staging and monitoring of a variety of malignant tumors[9,10]. However, in detection of primary HCC, the sensitivity of ^{18}F-FDG PET/CT scan has been reported not sufficiently high (50%-55%) because of its variable ^{18}F-FDG uptake pattern[11-14].

Several studies were performed for investigation of usefulness of ^{18}F-FDG PET/CT scan in detection of extrahepatic metastases of HCC. A previous study reported that the sensitivity for the detection of extrahepatic metastasis was 79%[15,16]. However, there are few detailed reports to compare ^{18}F-FDG PET/CT scan with conventional imaging modalities.

In this study, we evaluated the value of ^{18}F-FDG PET/CT scan in diagnosis of primary HCC and extrahepatic metastases. Furthermore, we suggest several clinical factors and tumor characteristics including ^{18}F-FDG PET/CT scan findings that indicate extrahepatic metastases in diagnosis of HCC.

MATERIALS AND METHODS

Patients

We conducted a retrospective chart review of patients with HCC at Soonchunhyang University Hospital who had both conventional imaging modalities and ^{18}F-FDG PET/CT scan done within at least a month between November 2006 and March 2011. During this period, all patients diagnosed with HCC who were newly diagnosed

or reevaluated after treatment underwent ^{18}F-FDG PET/CT scan. A total of 138 patients were enrolled for this study. Eighty-eight patients were treatment-naïve and the other 50 patients were previously treated for HCC (tumor resection, transcatheter arterial chemoembolization, radiofrequency ablation, systemic chemotherapy). The diagnosis of primary HCC was based on contrast enhanced abdomen CT or magnetic resonance imaging (MRI), where hyperattenuation in the arterial phase and early washout in the delayed phase were considered definitely diagnostic. Elevations in tumor markers such as AFP, protein induced by vitamin K antagonist Ⅱ (PIVKA Ⅱ) levels were considered suggestive of HCC. Ultrasound-guided needle biopsy was performed when considered necessary. This study was approved by the local institutional review board and was conducted in accordance with the principles set forth in the Declaration of Helsinki.

Conventional imaging modalities

Chest X-ray and contrast enhanced chest CT for evaluation of lung metastases were performed. If there are suspicious lesions, repeated contrast enhanced chest CT was examined within 3 mo. Whole body bone scan for evaluation of bone metastases was performed. If there are suspicious lesions, bone MRI was conducted for definite diagnosis or repeated bone scan was followed within 3 mo. Regional and distant lymph node metastases were determined according to contrast enhanced CT. If there are suspicious lesions, repeated contrast enhanced CT was examined within 3 mo to observe interval size difference. Some metastatic lesions were diagnosed with pathologic confirmation, but most metastatic lesions were clinically diagnosed because of difficult access to deep lesions and too small size to do a biopsy.

Intrahepatic tumor size was measured by the greatest diameter in treatment-naïve patients, and the greatest diameter including viable portion from the first diagnosis in previously treated patients.

^{18}F-FDG PET/CT scan

^{18}F-FDG PET/CT scan was performed with a Biograph 2 (Siemens Medical Solution, Knoxville, TN, United States). All patients fasted for at least 6 h before ^{18}F-FDG injection. Serum glucose levels measured at the time of ^{18}F-FDG injection were less than 150 mg/dL in all patients. Approximately 370-500 MBq of ^{18}F-FDG was injected intravenously and an emission scan (2.5 min/bed position) was performed from the knees to the head 40 min after of ^{18}F-FDG injection in the two dimensional imaging mode. A transmission scan (3 min/bed position) was then obtained with a rotating ^{68}Ge source.

^{18}F-FDG PET images were interpreted by one over 30 years experienced nuclear medicine physician. If no significant ^{18}F-FDG uptake was detectable in the tumor compared to normal liver tissue by ^{18}F-FDG PET/CT scan, this was considered isometabolic HCC, hypermetabolic HCC for increased ^{18}F-FDG uptake, and

[1]Tumor stage based on the Modified Union for International Cancer Control Tumor Node Metastasis staging system; [2]Others: Adrenal gland, peritoneal carcinomatosis, Morrison's pouch. HBV: Hepatitis B virus; HCV: Hepatitis C virus; AFP: α-fetoprotein; PIVKA Ⅱ: Protein induced by vitamin K antagonist Ⅱ; PVTT: Portal vein tumor thrombosis; SUV: Standardized uptake value; TNR: Tumor-to-nontumor ratio.

hypometabolic HCC for decreased ^{18}F-FDG uptake. Isometabolic or hypometabolic HCC was excluded from quantitative evaluation. For measurement of ^{18}F-FDG uptake, region of interest (ROI) was placed over tumor lesion including the area of maximum activity. The highest value of ^{18}F-FDG uptake in ROI is defined as maximum standardized uptake value (SUV) and the average value of ^{18}F-FDG uptake in ROI is defined as average SUV. Then, ROI was placed over nontumor area sized 20 mm × 20 mm for estimation of average ^{18}F-FDG uptake of nontumor area. SUV was calculated by as follows; mean tissue activity (kBq/mL) × calibration factor × body weight (kg)/injected dose (MBq). The tumor-to-nontumor ratio (TNR, SUV ratio) was calculated by average tumor SUV/average nontumor SUV.

Histologic examination
Histologic examination was performed to assess the histologic grade of HCC (*n* = 50). Twenty-nine patients were indicated for tumor resection at diagnosis, the other 21 patients were performed ultrasound-guided needle biopsy. According to histologic grade, the tumors were divided into low-grade (well-differentiated and moderately-differentiated type) and high-grade (poorly-differentiated

and undifferentiated type). As 4 patients were revealed as combined HCC-CC (cholangiocarcinoma), a total of 46 patients were analyzed.

Statistical analysis
Data are expressed as the mean ± SD, range, or *n* (%) as appropriate. When comparing the baseline characteristics of patients with 2 different groups, chi-square test and Fisher's exact test were used for categorical data, and the Student *t* test and *U* test were used for continuous variables. We performed receiver operating characteristic (ROC) curve analysis to compare the diagnostic performance of conventional and PET imaging for detection of extrahepatic metastasis. To estimate risk factors for extrahepatic metastases of HCC, univariate and subsequent multivariate logistic regression analysis were used. The overall cumulative survival rate was analyzed using the Kaplan-Meier method, and differences in survival between the groups were compared using a log-rank test. Data analysis was performed using SPSS 17.0 and MedCalc.

RESULTS

Patient characteristics
Patient characteristics are summarized in Table 1. Eighty-six patients (62.3%) had multiple lesions and 54 patients (39.1%) had portal vein thrombosis. Child-Pugh class A was 77 patients (55.8%), 56 patients (40.6%), and stage Ⅳb was 49 patients (35.5%) based on the modified Union for International Cancer Control Tumor Node Metastasis staging system.

Correlation between ^{18}F-FDG uptake and tumor differentiation
Forty-five of 138 patients (32.6%) with HCC did not have ^{18}F-FDG uptake. Therefore, SUV (maximum and average) was calculated in 93 patients (67.4%). The maximum SUV was 5.32 ± 2.38, average SUV was 4.03 ± 1.26, and tumor-to-nontumor ratio (TNR) was 1.60 ± 0.49 (Table 1). We analyzed the correlation of histologic grade in HCC with clinical factors and tumor characteristics including ^{18}F-FDG PET/CT scan findings (Table 2). Forty-six patients were performed tumor resection or ultrasound-guided needle biopsy and assessed the histologic grade.

In HCC with isometabolism, low-grade HCC was found in 14 patients and high-grade HCC in 2 patients; Isometabolic HCC tended to be histologically low-grade rather than high-grade (*P* = 0.061). In hypermetabolic HCC, maximum SUV value was higher in high-grade HCC than low-grade HCC (5.75 ± 2.15 *vs* 3.75 ± 0.74, *P* = 0.027) although average SUV and TNR (SUV ratio) was not different between two groups (Table 2).

Diagnostic value of imaging modalities for detection of extrahepatic metastases
The results of the detection rate of conventional imaging modalities and ^{18}F-FDG PET/CT scan for extrahepatic metastases in HCC are summarized in Table 3.

HBV: Hepatitis B virus; HCV: Hepatitis C virus; AFP: α-fetoprotein; PIVKA Ⅱ: Protein induced by vitamin K antagonist Ⅱ; PVTT: Portal vein tumor thrombosis; SUV: Standardized uptake value; TNR: Tumor-to-nontumor ratio. [1]Statistical significance test was done by *U* test.

Twenty-three patients were diagnosed of clinical lung metastases showing interval size increase on follow up chest CT. Fifteen patients were test positive on ^{18}F-FDG PET/CT scan, 14 patients were true positive and 1 patient turned out to be false positive revealing non-tuberculosis mycobacterium infection on percutaneous transthoracic needle aspiration (Figure 1). The detection rate of metastatic pulmonary nodule ≥ 1 cm was 12/13 (92.3%), when < 1 cm was 2/10 (20%) (*P* = 0.0003). The sensitivity, specificity, and accuracy for detection of lung metastases in HCC by ^{18}F-FDG PET/CT scan were 60.9%, 99.1% and 92.6%, respectively (Table 3). Contrast enhanced chest CT all detected for lung metastases in HCC and 2 lesions turned out to be false positive which did not show size increase during follow up chest CT. Therefore, the sensitivity, specificity and accuracy were 100%, 98.2% and 98.5%, respectively. The accuracy of chest CT was significantly superior compared with the accuracy of PET imaging for detecting lung metastases by comparison of ROC curves (*P* = 0.000, CI 0.0888-0.294) (Table 3).

Twenty-two patients were diagnosed of regional or distant lymph node metastases showing arterial phase enhancement and interval size increase on follow up contrast enhanced CT. The sensitivity of ^{18}F-FDG PET/CT

scan for lymph node metastases was 90.9% showing lower than 100% in conventional imaging modalities. Both ^{18}F-FDG PET/CT scan and contrast enhanced CT detected 4 lesions as a positive test which turned out to be false positive. The accuracy of both images was not different by comparison of ROC curves (*P* = 0.269) (Table 3).

Eleven patients were diagnosed of bone metastases, ^{18}F-FDG PET/CT scan detected all of these lesions. However, bone scan failed to identify 4 patients and 4 suspicious of metastases turned out to be false positive. Therefore, the sensitivity, specificity and accuracy of ^{18}F-FDG PET/CT scan in diagnoses of bone metastases were 100%, 100% and 100%, respectively. The sensitivity, specificity and accuracy of bone scan were 63.6%, 96.8% and 94.1%, respectively. The accuracy of PET imaging was significantly superior compared with the accuracy of bone scan for detecting bone metastases by comparison of ROC curves (*P* = 0.010, CI: 0.0481-0.348) (Table 3).

Three patients with adrenal metastases were all detected by abdomen CT, but ^{18}F-FDG PET/CT scan failed to detect metastasis in one patient. There were 2 patients who were suspicious of cervical lymph node metastasis on both ^{18}F-FDG PET/CT scan and neck CT which turned out to be Warthin's tumor on needle biopsy.

Indicative factors for extrahepatic metastases in ^{18}F-FDG PET/CT scan

Elevated AFP (≥ 200 ng/mL), elevated PIVKA Ⅱ (≥ 40 mAU/mL), infiltrative tumor morphology, larger tumor size (≥ 5 cm), multiple tumors in liver, portal vein tumor thrombosis, advanced T stage, increased SUV uptake and high-grade HCC were associated with the presence of extrahepatic metastases of HCC (Table 4).

In multivariate analysis, increased tumor size (≥ 5 cm) (*P* = 0.042) and increased average SUV uptake (*P* = 0.028) were indicative factors for extrahepatic metastases in HCC (Table 4). Isometabolic HCC in ^{18}F-FDG PET/CT scan was inversely correlated with extrahepatic me-

Figure 1 A 51 year-old-female with hepatocellular carcinoma was suspicious of lung metastasis (arrows) in both chest computed tomography and ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography scan which turned out to be nontuberculosis mycobacterium infection on percutaneous transthoracic needle aspiration. A: High-resolution computed tomography (CT); B: Contrast-enhanced CT; C: ^{18}F-fluorodeoxyglucose positron emission tomography (^{18}F-FDG PET); D: PET/CT scan.

tastases ($P = 0.035$). According to the ROC curve, the optimal cutoff of average SUV to predict extrahepatic metastases was > 3.4 (Figure 2). Therefore, when the average SUV in ROI is higher than 3.4, we should consider the possibility of extrahepatic metastases with poor prognosis.

Cumulative survival rate was studied by intrahepatic tumor size, average SUV, isometabolic HCC, and extra-

hepatic metastasis after dividing average SUV group into two groups by the cutoff 3.4. The survival rate was significantly higher in group with tumor size < 5 cm (1-year survival rate; 69.1% *vs* 25.9%, $P = 0.000$) (Figure 3A), average SUV < 3.4 (1-year survival rate; 57.1% *vs* 19.2%, $P = 0.000$) (Figure 3B), and isometabolic HCC (1-year survival rate; 78.0% *vs* 28.3%, $P = 0.000$) (Figure 3C). There were 2 clinical factors that affected survival rate of HCC by Cox proportional hazard analysis. Child-pugh class [class B: odds ratio (OR) 4.784, CI: 2.575-8.891, $P = 0.000$; class C: OR 10.787, CI: 3.579-32.511, $P = 0.000$] and metastases (OR 2.069, CI: 1.152-3.715, $P = 0.015$) were significantly associated with survival rate (Table 5).

DISCUSSION

Several investigators quantitatively evaluated glucose utilization in HCC with ^{18}F-FDG PET/CT scan and showed its usefulness for assessing characterization of tumor[17]. Increased tumor ^{18}F-FDG uptake is highly reflected the enzymatic activity of glucose metabolism and the histologic grading of HCC[17,18]. Well-differentiated HCC cells exhibit an ^{18}F-FDG metabolism similar to that of normal liver tissue, whereas undifferentiated HCC cells do not do so[17,19]. ^{18}F-FDG PET/CT scan was not sensitive than ultrasound and serum AFP levels for diagnosing HCC in HBV carriers[14]. Because of its limitations for intrahepatic lesions, ^{18}F-FDG PET/CT scan is not suitable as

a screening tool for detection of intrahepatic recurrence after tumor resection or liver transplantation[16].

In our study, 45 of 138 patients (32.6%) with HCC did not have ^{18}F-FDG uptake. Isometabolic HCC tended to be histologically low-grade (*P* = 0.061) and showed superior survival rate (*P* = 0.000). In this aspect, ^{18}F-FDG PET/CT scan might be useful for the prediction of outcome in patients with hepatocellular carcinoma. Yang *et al*[20] reported PET imaging could be a good preoperative tool for estimating the post-LT risk of tumor recurrence. It reported the overall survival rate was significantly lower in high SUV and high TNR group. Especially, TNR was independent predictor of survival in HCC patients in multivariate analysis[18,21]. The blood glucose level is often high in patients with cirrhosis[22],

affecting the SUV in the tumor region[23]. Therefore, TNR, tumor-to-nontumor SUV ratio more strongly correlated with characteristics of HCC than SUV[21]. In our study, the cumulative survival rate in the group with average SUV less than 3.4 was significantly higher than in the group with average SUV more than 3.4.

Extrahepatic metastases of HCC was occurred in 36.2% (29.5% in treatment-naïve patients) in our study which have been reported to occur in 13.5%-42%[24-27]. Major metastatic sites from HCC are the lung, lymph nodes, bone, and adrenal gland consistent with other reports[24-26,28].

It is known that lungs are both the most common site of metastases and the most common site of the first detectable metastases[16,24,25,28]. Chest X-ray is inexpensive, may serve as a baseline investigation to evaluate abnormalities, however, the detection rate of pulmonary metastases is low. Gielen *et al*[29] reported 10/19 patients with pulmonary metastases were not identified with chest X-ray in patients with colorectal cancer. To compare chest CT with ^{18}F-FDG PET/CT scan, the accuracy of chest CT was higher than ^{18}F-FDG PET/CT scan in our study. The detection rate of ^{18}F-FDG PET/CT scan was only 20% when metastatic pulmonary nodule < 1 cm. Therefore, to detect early lung metastases from

Figure 3 Cumulative survival rate in patients with hepatocellular carcinoma by intrahepatic tumor size (A), average standardized uptake value (B), isometabolic hepatocellular carcinoma (C) and extrahepatic metastasis (D). SUV: Standardized uptake value.

HCC, chest CT should be performed at regular intervals.

The diagnosis of regional or distant lymph node metastases is determined by interval size increase and arterial phase enhancement in abdomen CT/MRI, chest CT and neck CT[25]. It is well documented that patients who have cirrhosis also have benign enlarged lymph nodes[30]. In our study, 4 patients were detected for lymph node metastases, which turned out to be false positive in both ^{18}F-FDG PET/CT scan and contrast enhanced CT. Therefore, follow up CT is critical for determination of metastases even when increased ^{18}F-FDG uptake in ^{18}F-FDG PET/CT scan is observed. Lymph node metastasis is difficult to confirm due to poor accessibility for biopsy. If suspicious lesions were identified at conventional imaging or ^{18}F-FDG PET/CT scan, it should be clinically confirmed during follow-up imaging.

In our study, all bone metastases of HCC were detected by ^{18}F-FDG PET/CT scan whereas bone scan could not detect 4 lesions and 4 abnormal uptakes were false positive based on bone MRI and follow up imaging. Other studies have also reported PET imaging is more sensitive than bone scan[15,16,27]. Whole body bone scan is a routine modality in detecting bone metastases; however, lesions may remain invisible in the absence of an osteo-

blastic response. Furthermore, bone scan is not likely to differentiate healing fractures and degenerative disease from bone metastases[31]. Based on these results, ^{18}F-FDG PET/CT scan is more sensitive and specific diagnostic tool than bone scan for evaluation of bone metastases.

Although extrahepatic metastases of HCC are common, undergoing ^{18}F-FDG PET/CT scan in all HCC patients may not be cost-effective. Selected patients who are suspected of extrahepatic metastases of HCC should be performed of ^{18}F-FDG PET/CT scan. A previous study reported majority of patients (87%) with extrahepatic HCC had intrahepatic stage III (10%) and stage IVa (76%) tumors[25]. Natsuizaka *et al*[24] and Uka *et al*[26] also reported patients with more advanced intrahepatic tumor stage at the first diagnosis of HCC developed extraheaptic metastases more frequently. Especially, tumor diameter is a well-known predictor of extrahepatic metastases[27,28]. Our results demonstrated tumor size ($\geq$ 5 cm) ($P = 0.042$) was predictive factors for extrahepatic metastases in HCC which was strongly correlated with cumulative survival rate.

As previously mentioned, the most common site of the first detectable metastasis is lung. Our data showed that the sensitivity of ^{18}F-FDG PET/CT scan to detect

lung metastases was only 60.9%. Therefore, we suggest that patients with diagnosed of HCC should undergo chest CT at initial diagnosis of HCC. Sixteen of 22 patients (72.7%) with lymph node metastases and 6 of 11 patients (54.5%) with bone metastases were not accompanied by lung metastases, so the patients at high risk of extrahepatic metastases or who was diagnosed of lung metastases by chest CT should be considered performing ^{18}F-FDG PET/CT scan to identify other extrahepatic metastases.

Our data showed that average SUV in ^{18}F-FDG PET/CT scan is indicative factor for extrahepatic metastases, staging evaluation for metastases should be done carefully at regular interval in patients with high average SUV uptake. The SUV is well correlated with histologic differentiation and cumulative survival rate, therefore we can apply this information in clinical settings to make a decision for the treatment and predict the prognosis. PET imaging is highly sensitive for the diagnosis of bone metastases, it should be considered to be done when patients are suspicious of bone metastases, but negative results in bone scan.

There were limitations to our study. (1) It was a retrospective study; (2) We did not confirm the extrahepatic metastases by biopsy; and (3) In histologic grading of intrahepatic HCC, needle biopsy is prone to sampling error as only limited area of the tumor is analyzed microscopically.

In conclusion, ^{18}F-FDG PET/CT scan has a limitation for detection of intrahepatic tumor, but meaningful for prediction of prognosis and planning for staging evaluation. In aspect of a screening tool of extrahepatic metastasis of HCC, ^{18}F-FDG PET/CT scan is invaluable for detection of lung metastases larger than 1 cm and bone metastases. In evaluation of lymph node metastases, follow-up imaging is crucial for clinical diagnosis. We suggest that primary HCC having larger than 5 cm and increased average SUV uptake more than 3.4 should be considered for extrahepatic metastases.

COMMENTS

Background

With advances in variable treatment modalities, the prognosis of hepatocellular carcinoma (HCC) has been much improved. With prolonged survival of HCC patients, the incidence of extrahepatic metastases has been increased.

Research frontiers

Positron emission tomography (PET)/computed tomography (CT) scan using fluorodeoxyglucose (FDG) is now well established as a noninvasive diagnostic tool for diagnosis, staging and monitoring of a variety of malignant tumors. However, the role in diagnosis of primary HCC and extrahepatic metastases has not been reported sufficiently.

Innovations and breakthroughs

^{18}F-FDG PET/CT scan has a limitation for detection of intrahepatic tumor, but meaningful for prediction of prognosis and planning for staging evaluation. The detection rate of metastatic pulmonary nodule $\geq$ 1 cm was 12/13 (92.3%), when < 1 cm was 2/10 (20%) in PET imaging. The accuracy of PET imaging was significantly superior compared with the accuracy of bone scan for detecting bone metastases. In multivariate analysis, increased tumor size ($\geq$ 5 cm) (P = 0.042) and increased average standardized uptake value (SUV) uptake (P = 0.028) were predictive factors for extrahepatic metastases.

Applications

The study results suggest that ^{18}F-FDG PET/CT scan is invaluable for detection of lung metastases larger than 1 cm and bone metastases. Authors suggest that primary HCC having larger than 5 cm and increased average SUV uptake more than 3.4 should be considered for extrahepatic metastases.

Terminology

PET/CT scan: PET/CT scan depicts the spatial distribution of metabolic or biochemical activity in the body. PET/CT scan has revolutionized many fields of medical diagnosis, by adding precision of anatomic localization to functional imaging.

Peer review

This is a well-organized study in which authors analyze the substantial role in the diagnosis of extrahepatic metastases in HCC. Furthermore, the results are interesting that average SUV could suggest the prognosis of HCC. In patients with higher average SUV more than 3.4 should be carefully follow-up for the possibility of extrahepatic metastases.

Abstract

AIM: To evaluate the accuracy of specific biochemical markers for the assessment of hepatic fibrosis in patients with chronic hepatitis C virus (HCV) infection.

METHODS: One hundred and fifty-four patients with chronic HCV infection were included in this study; 124 patients were non-cirrhotic, and 30 were cirrhotic. The following measurements were obtained in all patients: serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), albumin, total bilirubin, prothrombin time and concentration, complete blood count, hepatitis B surface antigen (HBsAg), HCVAb, HCV-RNA by quantitative polymerase chain reaction, abdominal ultrasound and ultrasonic-guided liver biopsy. The following ratios, scores and indices were calculated and compared with the results of the histopathological examination: AST/ALT ratio (AAR), age platelet index (API), AST to platelet ratio index (APRI), cirrhosis discriminating score (CDS), Pohl score, Göteborg University Cirrhosis Index (GUCI).

RESULTS: AAR, APRI, API and GUCI demonstrated good diagnostic accuracy of liver cirrhosis (80.5%, 79.2%, 76.6% and 80.5%, respectively); *P* values were: < 0.01, < 0.05, < 0.001 and < 0.001, respectively. Among the studied parameters, AAR and GUCI gave the highest diagnostic accuracy (80.5%) with cutoff values of 1.2 and 1.5, respectively. APRI, API and GUCI were significantly correlated with the stage of fibrosis (*P* < 0.001) and the grade of activity (*P* < 0.001, < 0.001 and < 0.005, respectively), while CDS only correlated significantly with the stage of fibrosis (*P* < 0.001) and not with the degree of activity (*P* > 0.05). In addition, we found significant correlations for the AAR, APRI, API, GUCI and Pohl score between the non-cirrhotic (F0, F1, F2, F3) and cirrhotic (F4) groups (*P* values: < 0.001, < 0.05, < 0.001, < 0.001 and < 0.005, respectively; CDS did not demonstrate significant correlation (*P* > 0.05).

CONCLUSION: The use of AAR, APRI, API, GUCI and Pohl score measurements may decrease the need for liver biopsies in diagnosing cirrhosis, especially in Egypt, where resources are limited.

34899 Istanbul, Turkey

INTRODUCTION

Egypt has the highest prevalence of adult hepatitis C virus (HCV) infection in the world, affecting an average of 15%-25% of the population in rural communities[1,2]. Worldwide, HCV is one of the major causes of chronic liver diseases, which include inflammation, fibrosis and cirrhosis. Furthermore, HCV has been associated with increased morbidity and mortality in hepatocellular carcinoma[3-5].

Although liver biopsy is an invasive procedure and includes a risk of complications, such as pain, pneumothorax, puncture of other viscera and hemorrhage, it is still the gold standard for grading the severity of necroinflammation and staging the extent of liver fibrosis in patients with chronic HCV infection[6-8].

In addition to the added cost, liver biopsy cannot be performed universally in all patients with impaired hemostasis of any origin[9]. The procedure is known to underestimate liver fibrosis when small tissue samples are collected, and it is prone to intra- and inter-observer variation[10-13]. Moreover, several studies have suggested that liver biopsy is far from being a perfect diagnostic tool because its accuracy in detecting pathology is dependent on the size of the biopsy[14-17]. Previous reports have proposed that a liver biopsy sample should contain a minimum of 5 portal tracts and be at least 15 mm in length to be considered adequate[18-20]. Other authors have recommended even larger samples[21]. In 2003, a French survey reported that liver biopsy may be refused by up to 59% of patients[22]. In 2005, an Italian survey reported major discrepancies among hepatologists regarding when and how to take a liver biopsy from the same subgroup of chronic hepatitis C patients[23].

Considering these limitations, many studies have recently focused on the development of non-invasive markers as surrogates of liver biopsy[24-34]. An accurate assessment of hepatic fibrosis can be achieved with various markers and indices. In this study, we aimed to assess the validity of six markers of hepatic fibrosis, including the ratio of aspartate aminotransferase (AST)/alanine aminotransferase (ALT) ratio (AAR), AST to platelet ratio index (APRI), age platelet index (API), cirrhosis discriminating score (CDS), Göteborg University Cirrhosis Index (GUCI) and Pohl score, in grading fibrosis and diagnosing early cirrhosis as an accurate alternative to liver biopsy in patients with chronic HCV infection in a country known to have a high prevalence of the disease[1,2].

MATERIALS AND METHODS

Patients
This study included 154 patients with chronic HCV infection. They were selected from the gastroenterology and hepatology clinics of the Faculty of Medicine, Cairo University, Egypt, over the period from March 2009 to November 2010. All selected patients were potential candidates for interferon therapy.

Exclusion criteria
Patients with chronic hepatitis B infection, autoimmune hepatitis, decompensated liver disease, hepatocellular carcinoma, history of previous antiviral therapy and presence of absolute contraindication for liver biopsy were excluded from this study.

Methods
All patients were subjected to full history intake, thorough physical examination and the following laboratory test measurements: serum ALT, AST, albumin, total bilirubin, prothrombin time and concentration, complete blood count, HCV antibody (anti-HCV), hepatitis B surface antigen (HBsAg), HCV-RNA by quantitative polymerase chain reaction (PCR), circulating autoantibodies (ANA, ASMA), abdominal ultrasonography and ultrasonographic guided liver biopsy.

Liver biopsies were performed using 18-20 gauge Trucut needles (GMSS.N, GHATWARY MEDICAL). To assess necroinflammation, the grade of activity was evaluated using a modified hepatic activity index: mild (0-6), moderate (7-12) and severe (13-18). Fibrosis was staged according to the METAVIR scoring system from F0 to F4. Based on the results obtained from histopathological assessment of their liver biopsies, patients were divided into two groups:the non-cirrhotic group (F0, F1, F2 and F3) and the cirrhotic group (F4).

Definition of the noninvasive indices
The following ratios, scores and indices[24-34] were calculated and compared with the results of histopathological examination: (1) AAR; (2) APRI, calculated using the following equation: (AST/upper limit of normal)/platelet count $(\times 10^9/L) \times 10$; (3) API, calculated by summing the scores awarded for the following patient laboratory results (a possible value of 0-10): age (in years) < 30 = 0; 30-39 = 1; 40-49 = 2; 50-59 = 3; 60-69 = 4; $\geq$ 70 = 5; platelet count $(\times 10^9/L)$: $\geq$ 225 = 0; 200-224 = 1; 175-199 = 2; 150-174 = 3; 125-149 = 4; < 125 = 5; (4) CDS, calculated by summing the scores awarded for the following patient laboratory results (a possible value of 0-11): platelet count $(\times 10^9/L)$: > 340 = 0; 280-339 = 1; 220-279 = 2; 160-219 = 3; 100-159 = 4; 40-99 = 5; < 40 = 6. ALT/AST ratio: > 1.7 = 0; 1.2-1.7 = 1; 0.6-1.19 = 2; < 0.6 = 3. International normalized ratio (INR): < 1.1 = 0; 1.1-1.4 = 1; > 1.4 = 2; (5) GUCI, calculated using the following equation: normalized AST $\times$ INR $\times$ 100/platelet count $(\times 10^9/L)$; and (6) Pohl score,which was considered positive if the AAR was $\geq$ 1 and the platelet

count was $< 150 \times 10^9$/L. The Ethics committee at our institution approved the study, and all patients provided informed consent before participating in this study.

Statistical analysis

Descriptive statistics included range, mean ± SD, median, frequencies (number of cases) and percentages when appropriate. Comparisons of numerical variables between the study groups were made using the Mann Whitney U test for independent samples. To compare categorical data, the Chi squared (χ^2) test was used. When the expected frequency was less than 5, the Exact test was used instead. Accuracy was represented using the terms sensitivity and specificity. Receiver operator characteristic analysis was used to determine the optimum

cutoff value for the studied diagnostic markers. Various variables were tested for correlation using the Spearman rank correlation equation for non-normal variables. P values less than 0.05 were considered statistically significant. Normality of data was checked by the Kolmogorov Smirnov test. Most of our markers violated the normal assumption; therefore, the data were analyzed using non-parametric tests. Two-tailed tests were used where appropriate. Multivariate logistic regression determined only API to be significantly associated with diagnosis of cirrhosis in our cases. No other variable was found to be a significant predictor of cirrhosis. All statistical calculations were performed using the computer programs Microsoft Excel 2007 (Microsoft Corporation, NY, United States) and SPSS (Statistical Package for the Social Sciences; SPSS Inc., Chicago, IL, United States) version 15 for Microsoft Windows.

RESULTS

Demographic and baseline laboratory data of non-cirrhotic and cirrhotic patients are shown in Table 1.

Our findings demonstrated a statistically significant correlation for AAR, APRI, API, GUCI and Pohl score between the cirrhotic and non-cirrhotic patients; CDS was not found to be significant. Pohl score was positive (indicating cirrhosis) in 40% of cirrhotic patients, whereas it was positive in only 9.67% of non-cirrhotic patients, with a P value of 0.004 (Figure 1 and Table 2).

Patient age, AST and platelet count correlated significantly with both the grade of activity and the stage of fibrosis. However, neither ALT nor HCV RNA load demonstrated statistically significant correlations with the grade of activity or the stage of fibrosis. With regard to other laboratory parameters, INR, albumin and alkaline phosphatase levels were significantly correlated with stage of fibrosis but not with grade of activity, whereas serum bilirubin was significantly correlated with grade of activity but not with stage of fibrosis (Table 3).

The results of our study revealed a significant correla-

Table 4 The correlation between the aspartate aminotransferase-to-alanine aminotransferase ratio, aspartate aminotransferase- to-platelet ratio index, age platelet index, cirrhosis discriminating score and Göteborg University Cirrhosis Index and the grade of necroinflammatory activity and the stage of fibrosis

Variable	Stage of fibrosis		Grade of activity	
	Correlation coefficient	*P* value	Correlation coefficient	*P* value
AAR	0.2	0.054	0.1	0.23
APRI	0.4	0.00006	0.4	0.001
API	0.6	0.000001	0.5	0.00002
CDS	0.4	0.0002	0.2	0.056
GUCI	0.5	0.0001	0.3	0.003

AAR: Aspartate aminotransferase-to-alanine aminotransferase ratio; APRI: Aspartate aminotransferase-to-platelet ratio index; API: Age platelet index; CDS: Cirrhosis discriminating score; GUCI: Göteborg University Cirrhosis Index.

tion between APRI, API and GUCI, and both the grade of activity and the stage of fibrosis. CDS correlated significantly with the stage of liver fibrosis but not with the grade of necroinflammatory activity. In contrast, the AST/ALT ratio had no significant correlation with either the stage of fibrosis or the grade of activity (Table 4).

For non-invasive diagnosis of liver cirrhosis (F4), using AAR, APRI, API and GUCI, Table 5 and Figure 2 show the cutoff values, sensitivity, specificity, positive predictive values (PPV), negative predictive values (NPV), and area under the receiver operating characteristics curve of these parameters.

DISCUSSION

Although it is costly, requires hospitalization for at least 6-18 h, is invasive and carries a risk of complications with an associated morbidity rate between 0.3% and 0.6% and mortality rate of 0.05%, liver biopsy remains the gold standard for assessing liver histology[34-36]. However, limitations of liver biopsy include the underestimation of fibrosis stage, given that only 1/50 000 of the organ is removed[37], and the reported inter- and intra-observer discrepancies rates of 10%-20%[38,39].

In this study, we found that the optimal cutoff AAR-value for diagnosing cirrhosis was ≥ 1.2, with a sensitivity of 46%, specificity of 88.7% and PPV and NPV of 50% and 87.3%, respectively. These results support previous findings by Giannini *et al*[40], who recommended an AAR value of ≥ 1 as a cutoff value for diagnosing cirrhosis. However, Ehsan *et al*[41] reported a higher cutoff value (≥ 1.5) for diagnosing cirrhosis, with a sensitivity of 44% and a specificity of 91%.

Elevation of the AST/ALT ratio in cirrhotic patients may be explained by the reduction in AST clearance, which leads to an increase in serum AST levels. In addition, advanced liver disease may be associated with mitochondrial injury, resulting in increased release of AST present in the mitochondria and cytoplasm[42].

Thrombocytopenia in patients with advanced fibrosis

Figure 1 Positive and negative Pohl score in non-cirrhotic and cirrhotic patients with chronic hepatitis C virus infection.

Figure 2 Sensitivity and specificity of age platelet index, Göteborg University Cirrhosis Index, aspartate aminotransferase to platelet ratio index and aspartate aminotransferase/alanine aminotransferase ratio in diagnosing cirrhosis in patients with chronic hepatitis C virus infection. API: Age platelet index; GUCI: Göteborg University Cirrhosis Index; APRI: Aspartate aminotransferase to platelet ratio index; AAR: Aspartate aminotransferase/alanine aminotransferase ratio.

may be due to reduced hepatic production of thrombopoietin, increased splenic sequestration of platelets secondary to portal hypertension or the myelosuppressive action of HCV[43,44].

Results from the current study revealed a significant correlation between APRI and both the stage of liver fibrosis and the grade of activity. The optimal cutoff APRI value for the diagnosis of cirrhosis was ≥ 1.36, which was consistent with findings by Ichino *et al*[45] and Ehsan *et al*[41], who reported cutoff values of 1.3 and 1.5, respectively.

In the present study, we found a significant correlation between API and both the stage of fibrosis and the grade of activity (*P* < 0.001 for both). Our results revealed that the optimal AP index cutoff value for the diagnosis of cirrhosis was ≥ 5.5, with 60% and 80.6% sensitivity and specificity, respectively, and 42.86% and 89.29% PPV and NPV, respectively. The results of the current study are in agreement with the results of previous studies by Lackner *et al*[46] and Poynard *et al*[47].

Results from this study showed that there was a significant correlation between GUCI and both the stage of liver fibrosis and the grade of activity. We recommend a GUCI value of ≥ 1.56 as an optimal cutoff value for

Table 5 The accuracy of different ratios and indices in the diagnosis of early liver cirrhosis

Item	Cutoff value	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Accuracy (%)	AUROC	*P* value
AAR	1.2	46	88.7	50	87.3	80.5	0.761	0.002
APRI	1.36	46.7	87.1	46.7	87.1	79.2	0.697	0.018
API	5.5	60	80.6	42.9	89.3	76.6	0.826	0.000
GUCI	1.56	60	85.5	50	89.8	80.5	0.783	0.001

AAR: Aspartate aminotransferase-to-alanine aminotransferase ratio; APRI: Aspartate aminotransferase-to-platelet ratio index; API: Age platelet index; GUCI: Göteborg University Cirrhosis Index; PPV: Positive predictive value; NPV: Negative predictive value; AUROC: Area under the receiver operating characteristics.

the diagnosis of cirrhosis, with 60% sensitivity, 88.7% specificity, and a PPV and NPV of 89.83% and 80.52%, respectively. These results supported those reported by Islam *et al*[48], who found a significant correlation between GUCI and both stage of fibrosis and grade of activity. Similar results were reported by Ehsan *et al*[41], who recommended a GUCI cutoff value of $\geq$ 1.5 for the diagnosis of cirrhosis, with 89% specificity and 74% sensitivity.

In the present study, we found a statistically significant correlation ($P = 0.004$) between positive Pohl score (AAR $\geq$ 1, and platelet count < 150×10^9/L) and the presence of cirrhosis (F4). These findings supported the results of Pohl *et al*[27] and Lackner *et al*[46], who confirmed the diagnostic accuracy of the Pohl score in significant fibrosis and cirrhosis.

In our study, there was a significant correlation between CDS and stage of liver fibrosis ($P < 0.001$), but the relationship was not significant with regard to the grade of activity ($P = 0.056$). The CDS values were not significant between the cirrhotic and non-cirrhotic patients ($P = 0.17$), which disagreed with results reported by Ichino *et al*[45], who recommended a CDS value of $\geq$ 8 as a cutoff value for the diagnosis of cirrhosis.

Some studies showed no correlation between the histological outcome and HCV-RNA levels, while other reports suggested that the viral titer may influence the severity of liver damage and that high titer viremia correlates with the most severe liver damage[49]. The current study revealed no significant correlation between HCV RNA load as measured by quantitative PCR and both the grade of activity and fibrosis stage.

Our results agreed with the studies conducted by Lee *et al*[50] and Saleem *et al*[51]. In contrast, Kato *et al*[52] found significantly higher HCV RNA loads in patients with chronic active hepatitis and cirrhosis compared to those with chronic persistent hepatitis. These discrepancies could be attributed to the fact that serum HCV RNA load is not a stable parameter because it fluctuates[53]. In addition, a high amount of circulating HCV does not always imply a more active state of viral replication in the liver nor does it indicate a more severe degree of liver disease. HCV is known to replicate both within the liver as well as in extra-hepatic sites[54,55].

In conclusion, the API index, APRI, AST/ALT ratio and GUCI showed good accuracy, moderate sensitivity, and high specificity for the diagnosis of early cirrhosis. These measures also demonstrated significant correlation with both the stage of liver fibrosis and the grade of activity. The combination of these non-invasive biochemical markers may replace the requirement for liver biopsy, particularly for cases with cirrhosis or early cirrhotic changes in which the procedure has known limitations and complications.

COMMENTS

Background
Hepatitis C virus (HCV) is one of the major causes of chronic liver diseases worldwide. It has been associated with increased morbidity and mortality in hepatocellular carcinoma. In patients with chronic HCV infection, liver biopsy is essential to the assessment of hepatic fibrosis. Evaluating the degree of fibrosis is an important step in determining the need and priority for treatment with antiviral drugs. However, liver biopsy is a costly and invasive procedure with a risk of complications and a tendency to underestimate liver fibrosis. Hence, alternative non-invasive diagnostic tools are needed.

Research frontiers
In the area of liver cirrhosis assessment, the focus of research is on how to use biochemical markers and indices [aspartate aminotransferase (AST)/alanine aminotransferase (ALT) ratio (AAR), AST to platelet ratio index (APRI), age platelet index (API), cirrhosis discriminating score (CDS), Göteborg University Cirrhosis Index (GUCI) and Pohl score] calculated from simple routine laboratory tests, such as serum levels of bilirubin, ALT, AST, albumin and platelet count, to determine the severity of liver fibrosis and to evaluate their accuracy in comparison to liver biopsy.

Innovations and breakthroughs
The results showed that APRI, API, GUCI and CDS were significantly correlated with the degree of liver fibrosis. AAR, APRI, API, GUCI and Pohl score can accurately diagnose early liver cirrhosis. AAR and GUCI gave the highest accuracy for the diagnosis of liver cirrhosis (80.5%). These simple biochemical markers, especially when used in combination, may decrease the use of liver biopsy in the assessment of fibrosis and diagnosis of cirrhosis in patients with chronic HCV infection.

Applications
The study results suggest that these biochemical markers can identify significant fibrosis and cirrhosis in patients with chronic HCV; their combined application may decrease the need for liver biopsy, thereby reducing its associated costs and complications. Important fields for further study include the use and evaluation of these markers for repeated assessment in monitoring the progression of liver fibrosis and its regression following interferon treatment in patients with chronic hepatitis C.

Terminology
CDS, GUCI and Pohl score are indices calculated to develop noninvasive diagnostic markers of liver fibrosis depending on simple biochemical tests such as platelet count, AST and ALT.

Peer review
In this paper, the authors focused on the noninvasive assessment of liver fibrosis in Egyptian patients with chronic HCV infection using different indexes. It is potentially interesting and well-written and provides useful information in a selected population with a high prevalence of chronic HCV infection.

Abstract

AIM: To investigate the intratumoral expression of metastasis-associated in colon cancer 1 (MACC1) and c-Met and determine their clinical values associated with hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC).

METHODS: A retrospective study admitted three hundred fifty-four patients with HBV-related HCC. The expression and distribution of MACC1 and c-Met were assessed by quantitative real-time polymerase chain reaction and immunohistochemistry staining. Prognostic factors influencing survival, metastasis and recurrence were assessed.

RESULTS: Intratumoral MACC1 level was found to be associated with HCC disease progression. Both median tumor-free survival (TFS) and overall survival (OS) were significantly shorter in the postoperative HCC patients with high intratumoral MACC1 expression, as compared to those with low intratumoral MACC1 levels (TFS: 34 mo *vs* 48.0 mo, $P < 0.001$; OS: 40 mo *vs* 48 mo, $P < 0.01$). Multivariable analysis indicated that high MACC1 expression or co-expression with c-Met were independent predictors for HCC clinic outcome ($P < 0.001$).

CONCLUSION: High intratumoral MACC1 expression can be associated with enhanced tumor progression and poor outcome of HBV-related HCC. MACC1 may serve as a prognostic biomarker for postoperative HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer and the third cause of death from cancers worldwide[1]. The incidence of HCC in China is high, and most cases are associated with chronic hepatitis B virus (HBV) infection[2]. Hepatocarcinogenesis is a complex process associated with the accumulation of multiple genetic and epigenetic changes during the initiation, progression and maturation of this fatal disease[3,4]. As such, intensive research efforts have been carried out to determine the physiological, cellular and molecular mechanisms of HCC, in the hope of developing effective preventative measures and improved treatment strategies.

The metastasis-associated in colon cancer 1 (MACC1) gene was identified by a genome-wide screen of human colon cancer samples, and its expression was closely related to the metastasis of colon cancers[5]. Subsequent clinical studies have suggested that MACC1 might be an important predictor for metastasis and recurrence of colon cancers. Further studies have revealed that MACC1-induced tumorigenesis is correlated with enhanced hepatocyte growth factor (HGF)/c-Met signaling[6,7]. MACC1 functions as a transcription factor, and one of its target promoters is that of the receptor tyrosine kinase c-Met gene. Binding of MACC1 to the promoter has been demonstrated to stimulate c-Met transcription, ultimately inducing activation of the HGF/c-Met signaling pathway and enhancing cell proliferation, motility, and metastasis[8,9]. MACC1 is normally expressed in healthy liver tissues, but marked overexpression is frequently observed in HCC clinical samples[10]. To date, however, the clinical significance of MACC1 overexpression in HCC and of the correlation between MACC1 and the c-Met signaling in the disease state remain unknown. It is intriguing to speculate that MACC1 may contribute to HCC onset and progression, and therefore may represent a readily-detectable biomarker for tumor recurrence and/or metastasis in postoperative HCC patients.

In this study, we sought to determine the expression levels of MACC1 in HBV-related HCC at different disease stages and analyze its correlation with clinical outcome. In addition, we evaluated the related levels of its transcriptional target, c-Met. Our data indicated that MACC1 expression levels represent an effective prognostic factor for HBV-related HCC patients who undergo hepatectomy.

MATERIALS AND METHODS

Patients, clinical characteristics, and tissue sampling

Tumor samples were obtained from 412 consecutive patients admitted to The 302nd Hospital (Beijing, China) with HBV-related HCC from December 2004 to June 2006. The diagnosis of HCC was based on the criteria of the European Association for the Study of the Liver[11]. By using the Barcelona Clinic Liver Cancer (BCLC) staging classification system[12], 148 patients were classified as stage A, 144 as stage B, and 120 as stage C. All patients,

Table 1 Basic clinical characteristics of patients with hepatitis B virus-related hepatocellular carcinoma (*n* = 354)

Clinical features	Stage A	Stage B	Stage C
Cases (*n*)	138	96	120
Median age (yr, range)	55 (24-68)	53 (29-70)	52 (21-72)
Male/female	118/20	82/14	106/14
Median tumor diameter (cm, range)	2.5 (1.5-3)	4.0 (3-5)	4.5 (2-6)
AFP (μg/L, > 400/≤ 400)	45/93	40/56	85/35

except for those at stage C, had undergone surgical resection. Among all patients, 36 had an incomplete resection, 12 died from other causes without recurrence, and 10 were lost to follow-up for non-medical reasons. Thus, the total study population was composed of 354 patients (Table 1). Matched non-tumor tissue samples were obtained from all surgical resected participants and were generally taken from a distance of more than 2 cm from the tumor tissue. Tumor samples from the stage C individuals were obtained by using the Single Action Biopsy Device (Promex Technologies, United States) and target tissues were identified by the following criteria: solitary lesions, or up to three nodules ≤ 6 cm in size; partial portal vein thrombosis or vena cana invasion; absence of extrahepatic metastasis; and preserved liver function (Child-Pugh A or ≤ B8 with serum bilirubin levels under 51.3 μmol/L). In addition, ten normal liver tissues were obtained from four cases of hepatic hemangioma and six patients with hepatic cyst, none of which had a history of viral hepatitis or liver cirrhosis.

Each of the samples were divided and either prepared for histochemical staining or snap-frozen in liquid nitrogen for RNA extraction for use in subsequent reverse transcription (RT)-polymerase chain reaction (PCR). For hematoxylin and eosin (HE) and immunohistochemical staining, the tissues were fixed in 10% formalin and paraffin-embedded.

The study protocol was approved by The 302nd Hospital Research Ethics Committee, and written informed consent was obtained from all participants or their legal guardian. None of the patients had received prior treatment for HCC, including radiation or chemotherapy. Patients were followed up every 2 mo within the first postoperative year and at approximately 3-4 mo intervals thereafter. Routine evaluation included physical examination, chest roentgenography, blood chemistry analysis, HBV-DNA test, and measurement of tumor markers (carcinoembryonic antigen and α-fetoprotein). Chest

and abdominal computed tomography, brain magnetic resonance imaging and a bone scintiscan were performed every 6 mo for three years after surgery. Additional examinations were performed if any symptoms or signs of recurrence were detected.

Determination of the mRNA levels of MACC1 and c-Met

The levels of the mRNA transcripts of MACC1 and c-Met were determined by quantitative real-time PCR, as described previously[13]. β-actin mRNA expression was used as an internal control and the relative gene expression values were calculated by the $2^{-\Delta Ct}$ method using Sequence Detection System 2.1 software. Total RNA was isolated from the tissues by using an RNA isolation kit (Qiagene, Germany) and following the manufacturer's instructions. The concentration of RNA was determined by spectrophotometric measurement at A_{260}, and the purity was verified by the $A260/A280$ ratio (> 1.8 was sufficiently pure). A total of 2 μg RNA was used for the preparation of cDNA by reverse transcriptase-PCR (SYBR PrimeScript RT-PCR Kit with SYBR Premix Ex Taq; Takara, Japan). The following PCR primers were used: MACC1 cDNA (136 bp), 5'-TTCTTTTGATTCCTCCGGTGA-3' (F) and 5'-ACTCTGATGGGCATGTGCTG-3' (R); c-Met cDNA (173 bp), 5'-GCAGGTTGTGGTTTCTCG-3' (F) and 5'-TGCAGCCCAAGCCATTCA-3' (R); and β-actin cDNA (125 bp), 5'-CGGGAAATCGTGCGTGAC-3' (F) and 5'-AGGCAGCTCGTAGCTCTTCT-3' (R). The cDNA equivalent of 50 ng of the original RNA was used in the PCR. The 50 μL reactions for MACC1 or c-Met were run for 40 cycles as follows: predenaturation at 95 ℃ for 30 s, denaturation at 95 ℃ for 5 s, annealing and extension at 60 ℃ for 30 s. The target mRNA was normalized to the corresponding β-actin signal. Measurements were performed in triplicate.

Assessment of MACC1 and c-Met in HCC by immunohistochemistry

Paraffin-embedded tissues from resected tumor and non-tumor tissues or biopsied tumor samples were cut for serial microtome sections with 4 μm thickness. After hematoxylin and eosin staining, the samples were assessed by two independent pathologists using Edmondson criteria[14]. Samples were classified as: well differentiated, corresponding to Edmondson's Grade Ⅰ or Ⅰ-Ⅱ; moderately differentiated, corresponding to Edmondson's Grade Ⅱ or Ⅱ-Ⅲ; or poorly differentiated, corresponding to Edmondson's Grade Ⅲ or Ⅲ-Ⅳ.

Two additional serial sections from each individual were prepared for MACC1 and c-Met immunohistochemical staining. Monoclonal rabbit anti-human antibody against MACC1 (1:50; Sigma, United States) and rabbit anti-human antibody against c-Met (1:250; Abcam, Hong Kong) were used. Detection of MACC1 and c-Met was carried out with 3-amino-9-ethylcarbozole (AEC; Zhongshan Bio, China) and diaminobenzidine (DAB; R and D Systems, United States), respectively. Positive stain-

ing was indicated by a prominent brownish or red pigmentation. In each case, a negative control was prepared using phosphate buffered saline as the first antibody to ensure the specificity of immunostaining.

The extent of positive staining for MACC1 was scored as follows[15]: 0, ≤ 10%; 1, > 10%-25%; 2, > 25%-50%; 3, > 50%-75%; and 4, > 75%. The intensity of the special staining was scored as follows: 0, negative; 1+, weak; 2+, moderate; and 3+, strong. The final score was obtained by multiplying the extent scores and intensity scores, which produced values in a range from 0 to 12. Scores from 9-12 were defined as a strong staining pattern (++), scores from 0-4 were defined as negative expression (-), and scores from 6-8 were defined as an intermediate staining pattern (+). All the staining was evaluated and characterized by two independent pathologists.

Serological assays

Hepatitis B surface antigen (HBsAg), anti-HBs, HBeAg, anti-HBe and anti-HBc were detected using a commercially-available kit (Roche Diagnostics, United States) and electrochemiluminescence immunoassay analyzers (E170; Modular Analytics, Roche Diagnostics). HBV DNA was extracted from 200 μL of plasma sample from each study participant using a High Pure Viral Nucleic Acid Kit (Roche Diagnostics Applied Science, Germany) and following the manufacturer's instructions. The viral titer and genotype of HBV were determined by a real-time PCR-based method that used fluorescent hybridization probes and a LightCycler PCR machine (Roche Diagnostics). This method consisted of two steps that were carried out in a single tube: the first step used real-time PCR to quantify the viral DNA and the second step used melting curve analysis of the final PCR product to genotype the virus. Details of the design and experimental conditions of this assay are available from the manufacturer. This assay showed a broad linear distribution for HBV titers that ranged from 10^2 to 10^{11} copies/mL, with a lower detection limit of $1-5 \times 10^2$ copies/mL.

Statistical analysis

The primary endpoint of the study was tumor-free survival (TFS) and the secondary endpoint included overall survival (OS) and follow-up for over 48 mo. TFS was calculated from the date of resection to the date when tumor recurrence was diagnosed. OS was calculated from the date of commencement of resection to the date of death or last follow-up[16]. All statistical analyses were performed with SPSS version 16.0 software. Continuous data were expressed as median and range. A comparison between the groups was performed using the χ^2 test. Survival rates were estimated by the Kaplan-Meier method and compared by the log rank test. The Cox proportional hazards model was used to determine the independent factors on survival and recurrence, based on the variables selected in univariate analysis. $P < 0.05$ was considered statistically significant.

RESULTS

Increased intratumoral MACC1 mRNA is related to HCC progression

We analyzed the MACC1 mRNA levels in surgically-resected samples from 234 patients at BCLC stage A or stage B and in biopsied tumor tissues from 120 patients at BCLC stage C. MACC1 mRNA in tumor tissues was found to be increased gradually with the stage of HCC progression (Figure 1A and B). The intratumoral MACC1 mRNA levels detected in samples from HCC stage A (0.002281 ± 0.001972), B (0.003031 ± 0.003451) and C (0.009015 ± 0.004972) were about 3-, 4- and 14-fold higher than that in normal liver tissues (0.000592 ± 0.0000451), respectively. We next performed a paired comparison of gene expression for the 234 patients at stage A and stage B, for which we had matched tumor tissues and adjacent non-tumor liver tissues. The ratio of MACC1 mRNA in cancerous tissue relative to that of the matched paratumors (the T:N ratio) was about 5.4-fold higher in the stage B group than in the stage A group (1.25 ± 0.3 *vs* 0.23 ± 0.05, $P = 0.009$; Figure 1C). Thus, these data indicated that the MACC1 mRNA level in HCC tumors was associated with tumor progression.

We next determined the protein levels of MACC1 in tumor and paratumor tissues by analyzing immunohisto-chemistry scores. MACC1 protein levels were found to be significantly higher in malignant tissues than in paratumor tissues or normal liver tissues (both, $P < 0.001$). Compared with the corresponding peritumor tissue or normal liver tissues, tumors from 30 of 138 (22%) patients at stage A, 40 of 96 (41.6%) at stage B, and 80 of 120 (67%) at stage C displayed increased MACC1 expression (Figure 1D). Tumor cells demonstrated mild to strong positive MACC1 cytoplasmic staining (++) and apparent nuclear signals in some cases (Figure 1E).

Intratumoral MACC1 mRNA level correlates with clinical parameters in HCC patients

Patients with HCC ($n = 354$) were divided into two groups according to the median intratumoral MACC1 mRNA levels. The first group was composed of low intratumoral MACC1 mRNA (< 0.006732; range: 0.000050-0.036147) and the second of high intratumoral MACC1 mRNA (≥ 0.006732; range: 0.000050-0.036147). Following comparative analysis of these two groups, intratumoral MACC1 mRNA level was found to be associated with HCC clinical staging, age, portal vein invasion and tumor differentiation. However, no significant correlation was found between the intratumoral MACC1 mRNA level and gender, lesion number, α-fetoprotein level or Child-Pugh class (Table 2).

Intratumoral MACC1 expression is correlated with c-MET mRNA levels in HCC patients

c-Met is a well-known proto-oncogene and transcriptional target of MACC1. We next investigated whether overexpression of MACC1 corresponded to increased transcription of c-Met in HCC tissues. We found that intratumoral c-Met mRNA levels were consistent with the extent of MACC1 expression and were up-regulated in conjunction with tumor progression of HCC ($P < 0.01$; Figure 1A and B). In the 234 HCC patients with stage A and stage B, the expression of c-Met was increased in the 105 patients with high MACC1 expression, but decreased in the 129 patients with low MACC1 expression (0.058561 ± 0.017539 *vs* 0.024734 ± 0.018754, $P = 0.041$; Figure 2A). Among these 234 patients, 67 (28.6%) displayed elevated expressions of both MACC1 and c-Met, 93 (39.7%) had low expressions of both MACC1 and c-Met, and 38 (16.2%) had a high expression of MACC1 but a low expression of c-Met, while 36 (15.4%) had a high expression of c-Met but low expression of MACC1. MACC1 mRNA level was closely correlated with the corresponding intratumoral c-Met mRNA expression ($r = 0.360$, $P < 0.001$) (Figure 2B).

Further analysis of the 234 patients found that HCC patients with both MACC1 and c-Met high intratumoral co-expression had a median OS of 32 mo [95% confidence interval (CI): 25-41]. In contrast, those with both MACC1 and c-Met low intratumoral expression had a median OS of 48 mo (log-rank, $P < 0.001$; Figure 2D). Likewise, the patients with both MACC1 and c-Met high intratumoral expression had significantly shorter median TFS (28 mo, 95% CI: 22-33 mo) than those with both MACC1 and c-Met low expression (48 mo, log-rank $P < 0.001$; Figure 2C).

Increased intratumoral MACC1 expression is predictive of high risk of recurrence and poor survival in postoperative HCC patients

We followed up the 234 patients (stage A and stage B) after resection for a median of 30 mo (range: 6-48 mo). Seventy-nine of the 105 HCC patients (75.2%) with high intratumoral MACC1 mRNA levels experienced recurrent tumors, and 34 cases had extrahepatic metastasis. The 1-, 2- and 3-year recurrence-free survival rates were 81%, 67% and 39%, respectively. In contrast, only 41 of the 129 (31.8%) patients with low intratumoral MACC1 expression experienced recurrence, and 12 of those had extrahepatic metastasis. The 1-, 2- and 3-year TFS was 92%, 88% and 82%, respectively. Compared to those with low intratumoral MACC1 expression, patients with high intratumoral MACC1 had significantly high rate of recurrence and extrahepatic metastasis (both, $P < 0.001$). Generally, the HCC patients with high intratumoral MACC1 mRNA levels had a significantly shorter median TFS (34 mo, 95% CI: 30-37 mo) than those with low intratumoral MACC1 mRNA levels (48.0 mo, log-rank $P < 0.001$; Figure 3A). In addition, post-resected patients with low intratumoral MACC1 expression had a median OS of 48 mo, while those with high intratumoral MACC1 expression had 40 mo (95% CI: 34-45 and log-rank $P < 0.01$; Figure 3B). A total of 152 patients with a ratio of T:N MACC1 expression < 1 had a median TFS of 48 mo, compared to 36 mo (95% CI: 25-47) for the 82 patients who had a ratio ≥ 1 (log-rank, $P < 0.001$; Figure 3C).

Figure 1 Analysis of metastasis-associated in colon cancer 1 and c-Met expression in liver tissues. A: Representative metastasis-associated in colon cancer 1 (MACC1) and c-Met mRNA in intratumoral [T: T1 as hepatocellular carcinoma (HCC) stage A, T2, T3 as HCC stage B] and matching paratumor tissues (N: N1, N2 and N3) and normal liver tissues (C) by reverse-transcription polymerase chain reaction (RT-PCR); B: Comparison of MACC1 and c-Met expression levels in 10 normal liver tissue, and HCC with stage A (n = 138), stage B (n = 96), stage C (n = 120) by real-time quantitative-PCR; C: The ratio for MACC1 mRNA levels in HCC stage A and stage B tumor tissues relative to matching paratumor tissues; D: Comparison of the intratumoral and peritumoral MACC1 expression in HCC stage A and stage B, as determined by immunohistochemistry; E: Immunohistochemical staining of MACC1 expression in HCC. a-c: MACC1 and c-Met expression in tumor and matching paratumor tissues in one same HCC patient (× 200). a: HE showed the tumor and paratumor cells; b: MACC1 expression was higher in tumor cytoplasm than in paratumor cells; c: c-Met was expressed on the tumor cell membrane, but no staining on nontumor liver cell membrane; d-f: Representative expression of MACC1 in HCC tumor tissues (× 400). d: MACC1 positive staining occurred mainly in the cytoplasm; e: Nuclear staining of MACC1 in cancer cells; f: Relatively weak staining of MACC1 in an early stage HCC cancer cells, as compared to paratumor cells.

Patients with a ratio of T:N MACC1 expression < 1 had a median OS of 48.0 mo, compared to 41 mo (95% CI: 36-45) for those with a ratio of T:N MACC1 expression ≥ 1 (log-rank, P < 0.001; Figure 3D).

Univariate statistical analysis showed that the TFS was associated with intratumoral MACC1 expression, and recurrence-free survival was related to tumor number, tumor differentiation, MACC1 expression, and co-

expression of MACC1 and c-Met. The median OS was associated with Child-Pugh class, score from Eastern Cooperative Oncology Group performance status scale (ECOG PS), tumor differentiation, MACC1 mRNA levels, co-expression of MACC1 and c-Met, tumor number, and tumor size. Further multivariate analysis using the Cox hazards model revealed that a high MACC1 expression or co-expression with c-Met was an independent poor prognostic factor for TFS and OS. The combined expression of both MACC1 and c-Met increased these prognostic values, as compared to MACC1 overexpression alone (Table 3).

DISCUSSION

Consistent with the multifactorial aetiology of HCC and the long latent period of tumor formation, a large variety of cancer genes are involved in the multistep process of human hepatocarcinogenesis[3,4]. In order to identify suit-

able prognostic markers and therapeutic targets, it is essential to analyze gene expression and proteomic changes by evaluating a large series of HCC patients and samples at different disease stages. Moreover, since metastasis or recurrence is the major cause of death of postoperative HCC patients, early identification of subjects at high-risk for either of these processes is necessary to improve OS rates. The clinical factors related to tumor invasiveness, such as tumor size, number, histological type and vessel invasion, are considered the most related to risk for recurrence and the most useful for prediction of HCC patient outcome[17-19]. Molecular biology studies have identified many biological factors that may act as potential tumor prognostic markers. The fact that HCC metastasis is a multistep process involving many factors[20-22] has led to attempts to develop a panel of multiple biomarkers that will facilitate tumor diagnosis and prediction of tumor metastasis and recurrence.

MACC1 was recently identified as being involved in metastasis of colon cancers, presumably by up-regulating c-Met transcription. Thus, to elucidate the MACC1-related mechanism of HCC and identify potential targets for molecular-based therapies we investigated the expression of MACC1 and c-Met in HBV-induced HCC.

We determined that intratumoral MACC1 expression was significantly up-regulated in most of the late stage HCC tissues examined. We further found that MACC1 overexpression was associated with higher c-Met expression in HCC and the intratumoral MACC1 mRNA level alone or in combination with that of c-Met can serve as an independent predictive factor for recurrence and survival of postoperative HCC patients.

We statistically analyzed the correlation of intratumoral MACC1 mRNA levels and clinical parameters of HCC patients. High intratumoral MACC1 mRNA levels were significantly associated with clinical stage, age, vessel invasion, and tumor differentiation. MACC1 mRNA levels were found to gradually increase with the progression of HCC, especially at the advanced HCC stage, and this process was accompanied by invasion of the portal vein. Shirahata *et al*[23] also showed that MACC1 expression was significantly correlated with vascular invasion, as it was in our study. Furthermore, intratumoral MACC1 protein was localized mainly in the cell cytoplasm, where the levels increased from low to robust in conjunction with tumor progression, indicating that MACC1 may represent an effective biomarker of tumor progression. Previous studies in colon cancers had also found that intratumoral MACC1 was up-regulated, as compared to levels detected in matched peritumoral or normal colon mucosa, regardless of tumor stage classification[5]. In our study of hepatic cancer, we found that the paratumor livers in some HCC patients had a relatively strong expression of MACC1; this was especially the case for those patients with TFS shorter than 6 mo after resection, implying that the pathogenesis of HCC and colon cancers is likely distinct. However, considering that all of the patients examined in our study had a background of chronic HBV

infection and liver cirrhosis, it is possible that the above-mentioned difference is due to the chronic hepatitis B infection.

Based on our immunohistochemistry data, the over-expression rates of MACC1 in HCC ranged from 22% to 67% in patients at different stages. MACC1 staining occurred mainly in the cytoplasm of non-cancerous or cancerous cells, but some cancerous cells showed significantly strong MACC1 staining in the nucleus. Studies in colon cancer have also identified MACC1 in the nuclear compartment of cancerous cells. It has been theorized that nuclear localization of MACC1 in conjunction with high c-Met levels contribute to the later development of distant metastases[5]. The actual clinical significance of the nuclear translocation of MACC1 in HCC requires further investigation.

It has been well documented that MACC1 binds to the c-Met promoter, and this transcription regulation event is crucial for tumor metastasis as induced by HGF/c-Met signaling[9]. A regulatory feedback mechanism ex-

Figure 3 Metastasis-associated in colon cancer 1 expression level associated with outcomes of hepatocellular carcinoma patients receiving resection. ists in that HGF is able to promote the translocation of MACC1 to the nucleus, where MACC1 controls the promoter activity and hence expression of c-Met, thereby regulating c-Met-mediated signaling[6]. Our data showed that c-Met mRNA in intratumoral tissues was significantly higher than that in peritumoral tissues. Co-expression analysis showed a high consistency of MACC1 and c-Met mRNA in HCC tumors. Further investigation is required, however, to confirm whether MACC1 directly drives c-Met expression in HCC.

Previous studies on primary colon cancers indicated that the negative and positive predictions of MACC1 mRNA levels for distant metastases were 80% and 74%, respectively[5,24]. MACC1 can induce migration, invasion and proliferation of cultured cells[5], and can promote metastasis of tumor cells into liver and lung in various xenograft models. A current study in lung adenocarcinoma demonstrated that MACC1 overexpression was associated with postoperative recurrence[25]. In the present study, follow-up of 234 stage A and stage B HCC patients who received curative therapy revealed that a high intratumoral MACC1 expression level is correlated with a high rate of recurrence and extrahepatic metastasis. The median TFS and OS were much shorter in patients with high expression of both MACC1 and c-Met. High expression of intratumoral MACC1 was predictive of a poor outcome of HBV-related HCC, but when combined with high c-Met expression the predictive value for recurrence and metastasis increased.

Collectively, our data showed that intratumoral MACC1 expression is closely associated with tumor progression in HBV-induced HCC. Furthermore, elevated expression of MACC1 was statistically associated with poor outcome of these patients, suggesting that MACC1 is a novel predictor for recurrence and metastasis of postoperative HCC patients.

ACKNOWLEDGMENTS

COMMENTS

Background

Due to metastasis or recurrence is the major cause of death of postoperative hepatocellular carcinoma (HCC) patients, early identification of subjects at high-risk for either of these processes is necessary to improve overall survival rates. It has been known that hepatocarcinogenesis is a complex process associated with the accumulation of multiple genetic and epigenetic changes during the initiation, progression and maturation, and molecular biology studies have identified many biological factors that may act as potential tumor prognostic mark-

ers, in the hope of developing effective preventative measures and improved treatment strategies.

Research frontiers

The metastasis-associated in colon cancer 1 (MACC1) gene was identified by a genome-wide screen of human colon cancer samples, and its expression was closely related to the metastasis of colon cancers. Further studies have revealed that MACC1-induced tumorigenesis is correlated with enhanced hepatocyte growth factor/c-Met signaling.

Innovations and breakthroughs

The clinical significance of MACC1 overexpression in HCC and of the correlation between MACC1 and the c-Met signaling remain unknown. In the present study, authors sought to determine the expression levels of MACC1 in HBV-related HCC at different disease stages and analyze its correlation with clinical outcome. In addition, the authors evaluated the related levels of its transcriptional target, c-Met. The research indicated that MACC1 expression levels represent an effective prognostic factor for HBV-related HCC patients who undergo hepatectomy. The data showed that intratumoral MACC1 expression is closely associated with tumor progression in HBV-induced HCC. Furthermore, elevated expression of MACC1 was statistically associated with poor outcome of these patients.

Applications

The study results implied that the MACC1 is a novel predictor for recurrence and metastasis of postoperative HCC patients.

Terminology

The MACC1 was recently identified as being involved in metastasis of colon cancers, presumably by up-regulating c-Met transcription.

Peer review

The research is very important and the result is exciting and there is some clinical value, that is, intratumoral MACC1 expression may serve as a biomarker to predict recurrence or metastasis of postoperative HCC. The manuscript has a certain readability.

Abstract

AIM: To investigate the morbidity of functional bowel disorders (FBD) under military stress conditions in order to lay foundations for the prevention and treatment of this disease.

METHODS: Four hundred and fifty-seven soldiers who were assigned to specified services and 471 soldiers who were assigned to routine services were enrolled using cluster sampling, with the latter as a control group. They were surveyed using the Rome Ⅲ FBD standard questionnaire. The FBD symptom questionnaire included FBD-related symptoms, severity, duration or attack time, and accompanying symptoms.

RESULTS: The morbidity of the military stress group (14.6%) was significantly higher than in the control group (9.98%) (χ^2 = 4.585, P < 0.05). The incidence of smoking, abdominal pain and acid regurgitation (χ^2 = 4.761, P < 0.05) as well as the ZUNG anxiety/depression scores (χ^2 = 7.982, P < 0.01) were also significantly higher in the military stress group compared with the control group. ZUNG anxiety (χ^2 = 11.523, P < 0.01) and depression (χ^2 = 5.149, P < 0.05) scores were higher in the FBD group compared with the non-FBD group. The differences in the ZUNG self-rated anxiety and depression scales between the 2 groups were statistically significant (χ^2 = 14.482, P < 0.01 and χ^2 = 6.176, P < 0.05).

CONCLUSION: The morbidity of FBD was higher under military stress conditions.

INTRODUCTION

Functional bowel disorders (FBD) is the generic term for disorders of bowel motor and secretary function without organic changes, which are diagnosed according to symptoms after the exclusion of lesions such as inflammation, infection, tumor and other structural disorders[1-3]. FBD includes 5 diseases, irritable bowel syndrome, functional abdominal bloating, functional constipation, functional diarrhea and unspecified functional bowel disorder. FBD are common clinical diseases which significantly affect the quality of patients' lives and incur considerable medical costs. A large number of studies have proved that

stress is the primary induction factor of FBD. Military stress is the emotional reaction of soldiers under military conditions, and mainly manifests as a state of tension[4,5]. There are few studies regarding the effect of military stress on FBD[6], and thus this study investigated the effects of stress by comparing FBD morbidity in soldiers conducting specialized operations with those carrying out regular tasks.

MATERIALS AND METHODS

Objects
Five hundred armed soldiers (mean age 20.7 ± 1.9 years) who were transferred from one province to another in China between April 2009 and May 2010 to handle emergencies were classified as the military stress group; Five hundred armed soldiers (mean age 20.14 ± 1.65 years) from the same province who conducted routine tasks were classified as the control group. All of the soldiers were male and garrisoned in the local area at least 1 year. Both groups were comparable in age, weight, height, the length of military service, education background, duty time, training time and garrison time.

Methods
Questionnaire: The FBD symptom questionnaire including FBD-related symptoms, severity, duration or attack time, and accompanying symptoms, was made with reference to Rome Ⅲ FGIDs functional gastrointestinal disorder standard questionnaire[7], and in combination with the practical conditions of the soldiers in the Chinese People's Armed Police. Psychological factors were investigated using the ZUNG Anxiety Scale and ZUNG Depression Scale.

Quality control of the questionnaire: The questionnaires were distributed according to lists of soldiers by responsible persons in every unit, and were filled in immediately after professional staff gave instructions and answered questions. All questionnaires were checked by a specially designated person after their return. The response rate and acceptance rate were 95.20% (476/500) and (452/476), respectively, in the military stress group, and 96.20% (481/500) and (471/481), respectively, in the control group.

Statistical analysis
The results were input into Epi Info 2003 software to establish data library and analyzed by SPSS18.0 statistical software; the χ^2 test was performed on categorical data. It was statistically significant at $P < 0.05$.

RESULTS

Morbidity of FBD
The rates of FBD in the military and control groups were 14.60% (66/452) and 9.98% (47/471), respectively. The difference between the two groups was statistically significant ($P < 0.05$, Table 1).

Prevalence of primary symptoms
There were 14 primary symptoms of FBD in the questionnaire. Individuals in the sampled populations could have one or more gastrointestinal symptoms. The prevalence of the primary symptoms is presented in Table 1.

Comparison of food habits and intake in soldiers with or without FBD
The food habits of soldiers with FBD were significantly different from those without FBD ($P = 0.000$-0.001). The occurrence of bad habits such as engorgement, being particular about food, omophagia, taking cold drinks, eating hot or spicy food, drinking tea and coffee was more frequent in the FBD group than in the non-FBD group (Table 2); the proportion of soldiers who had few or no bad food habits was smaller in the FBD group compared with the non-FBD group ($P = 0.000$-0.001); the proportion of soldiers who ate a lot of vegetables and fruit was smaller in the FBD group compared with the non-FBD group, while the proportion of soldiers who ate few vegetables and fruit was higher in the FBD group compared with the non-FBD group ($P = 0.000$); the proportion of soldiers who ingested many dairy products was higher in the non-FBD group compared with the FBD group, while the proportion of soldiers who ingested few dairy products was smaller in the FBD group compared with the non-FBD group ($P = 0.000$); the proportion of soldiers who drank coffee was higher in the FBD group compared with the non-FBD group, while the proportion of soldiers who drank tea was smaller in the FBD group compared with the non-FBD group ($P = 0.000$-0.001).

Comparison of the ZUNG self-rating anxiety and depression scales
The proportion of soldiers who had a score > 40 in the ZUNG self-rating anxiety scale was higher in the military stress group (11.97%) than in the control group (5.52%), and was statistically significant ($P < 0.01$). The proportion of soldiers who had a score > 40 in the ZUNG self-rating depression scale was also higher in the military stress group (68.29%) than in the control group (58.60%), and was statistically significant ($P < 0.05$).

DISCUSSION

Military stress[8,9] is a type of emotional reaction appearing in soldiers under military conditions, and mainly manifests as tension. Military stress can be considered as a kind of stimulated or emotional state[10,11]. Military stress cannot be simplistically considered as a negative reaction. It can be understood as a psychological problem only when stress induces changes in the cognition, emotions and behavior of soldiers to severely reduce their efficiency in military missions, and is mainly manifested by an inability to take part in daily military training, to adapt to the military environment or to join in fighting[12,13].

In recent years, more studies have focused on the effect of stress on gastrointestinal function[14], but few have paid attention to the effects of military stress on

Table 1 Comparison of morbidity and prevalence of primary symptoms of functional bowel disorders in the military stress and control groups n (%)

	Military stress group	Control group	χ^2	P
Disease name				
Irritable bowel syndrome	28/452 (6.19)	16/471 (3.40)	3.972	< 0.05
Functional abdominal bloating	0/452 (0.00)	0/471 (0.00)		> 0.05
Functional constipation	23/452 (5.09)	20/471 (4.25)	0.443	> 0.05
Functional diarrhea	9/452 (1.99)	8/471 (1.70)	0.108	> 0.05
Non-specific functional bowel disorder	6/452 (1.33)	3/471 (0.64)	1.135	> 0.05
Total	66/452 (14.6)	47/471 (9.98)	4.585	< 0.05
Primary symptom (No. of person with symptoms)				
Nausea	133/452 (29.42)	74/471 (15.71)	24.931	< 0.01
Vomiting	74/452 (15.71)	53/471 (11.25)	5.849	< 0.05
Abdominal distension	145/452 (32.08)	103/471 (21.87)	12.230	< 0.01
Acid regurgitation	113/452 (25.00)	64/471 (13.59)	19.329	< 0.01
Heartburn	61/452 (13.50)	43/471 (9.13)	4.397	< 0.05
Foreign body sensation in throat	85/452 (18.81)	78/471 (16.56)	0.800	> 0.05
Substernal pain	70/452 (15.49)	47/471 (9.98)	6.312	< 0.05
Hiccough	135/452 (29.87)	82/471 (17.41)	19.899	< 0.01
Food regurgitation	101/452 (22.34)	61/471 (12.95)	14.068	< 0.01
Abdominal pain	31/452 (6.86)	13/471 (2.76)	8.483	< 0.01
Constipation	142/452 (31.42)	98/471 (20.81)	13.492	< 0.01
Diarrhea	121/452 (26.77)	86/471 (18.26)	9.602	< 0.01
Encopresis	15/452 (3.32)	9/471 (1.91)	1.808	> 0.05

Table 2 Food intake of soldiers with and without functional bowel disorders n (%)

Food habit	Much	Moderate	Less	Little or not	Total
With functional bowel disorder					
Engorgement	10 (15.9)	21 (32.5)	20 (31.1)	13 (20.3)	64 (100)
Omophagia	6 (8.8)	10 (15.7)	23 (34.9)	26 (40.1)	65 (100)
Particular about food	12 (18.9)	19 (29.4)	15 (22.8)	20 (30.3)	66 (100)

Vegetables	17 (27.6)	33 (51.7)	12 (19.2)	1 (1.6)	63 (100)
Fruit	14 (22.6)	26 (39.5)	18 (28.4)	7 (10.8)	65 (100)
Without functional bowel disorder					
Engorgement	3 (5.1)	10 (16.3)	18 (29.2)	29 (48.3)	60 (100)
Omophagia	3 (5.8)	6 (10.4)	15 (24.9)	35 (59.3)	59 (100)
Particular about food	5 (8.0)	10 (17.8)	11 (19.8)	32 (55.1)	58 (100)
Cold drinks	7 (11.6)	16 (26.3)	17 (28.6)	21 (34.4)	61 (100)
Spicy food	10 (16.4)	16 (27.1)	15 (25.8)	19 (31.7)	60 (100)
Dairy products	16 (25.9)	23 (37.2)	12 (19.1)	11 (17.7)	62 (100)
Vegetables	24 (37.4)	28 (43.7)	6 (9.2)	5 (7.9)	63 (100)
Fruit	22 (34.6)	24 (37.5)	12 (18.7)	6 (9.4)	64 (100)

gastrointestinal function[15,16]. The results in this study suggested that FBD was significantly higher in the military group (14.60%) compared with the control group (9.98%). Meanwhile, the rates of smoking, abdominal pain, and acid regurgitation, and the ZUNG anxiety and depression scores were also significantly higher in the military group compared with the control group. The increased incidence of FBD under military stress might be due to the dual regulatory effects of the autonomic nervous system and the endocrine system on the movement and secretion of the alimentary tract, which are directly or indirectly affected by the central nervous system[17,18]. The anatomical structures of the nervous and endocrine system overlap with that of the emotional center[19,20], thus after tension and emotional changes induced by military stress conditions arrive at the emotional center, the gastrointestinal regulatory center will also be excited, and therefore, gastrointestinal discomfort will likely occur or be aggravated[21,22].

It has been reported[23] that there are significant differences between individuals in the length of time psychological stress is sustained. Overall, although a psychological stress reaction may be alleviated within 10 d in about 85% soldiers, it persists in about 15% soldiers after 10 d. The following measures should be adopted to deal with the increased morbidity of FBD induced by military stress: a focus on daily training activity[24,25], with simulation of various duty environments, and enhanced quality of psychological and mental preparation for emergencies; the soldiers should actively take part in the handling of an emergency situation, have a specific daily schedule

with adequate rest periods, and be given medical treatment if necessary. Non-combat casualties resulting from illness will be decreased and should guarantee that military duties will be better accomplished[26].

Overall, FBD is an old problem, but there are still areas in the pathogenesis of the disease to explore, and which may involve a wide range of research, including cell biology, neurophysiology, immunology, endocrinology, behavior and other fields of medicine and psychology. Linking the clinical problem with stress may directly lead to a clinical benefit for all patients.

COMMENTS

Background
Functional bowel disorders (FBD) is a generic name for disorders in bowel motor and secretary function without organic changes, and is diagnosed according to symptoms after the exclusion of lesions such as inflammation, infection, tumor and other structural disorders. It is a common clinical disease which significantly affects the quality of patients' lives and incurs medical costs. A large number of studies have shown that stress is the primary induction factor of FBD.

Research frontiers
There are few studies of the effect of military stress on FBD, and thus this research tried to investigate these effects through comparing the morbidity in soldiers conducting specialized tasks with those undertaking regular tasks.

Innovations and breakthroughs
Four hundred and fifty-seven soldiers who were assigned to specified services and 471 soldiers who were assigned to common services were enrolled using cluster sampling, with the latter as the control group, and then they were surveyed according to the Rome Ⅲ FBD standard questionnaire.

Applications
To provide foundations for the prevention and treatment of this disease, authors investigated the morbidity of FBD under military stress conditions.

Terminology
FBD: Disorders of bowel motor and secretary function without organic changes, diagnosed according to symptoms after the exclusion of organic lesions.

Peer review
Overall, this is an interesting study which shows clearly that the morbidity of FBD was higher under military stress conditions.

Abstract

AIM: To evaluate the feasibility, safety and efficacy of ultrasound-guided microwave (MW) ablation for abdominal wall metastatic tumors.

METHODS: From August 2007 to December 2010, a total of 11 patients with 23 abdominal wall nodules (diameter 2.59 cm ± 1.11 cm, range 1.3 cm to 5.0 cm) were treated with MW ablation. One antenna was inserted into the center of tumors less than 1.7 cm, and multiple antennae were inserted simultaneously into tumors 1.7 cm or larger. A 21 gauge thermocouple was inserted near important organs which required protection (such as bowel or gallbladder) for real-time temperature monitoring during MW ablation. Treatment outcome was observed by contrast-enhanced ultrasound and magnetic resonance imaging (MRI) [or computed tomography (CT)] during follow-up.

RESULTS: MW ablation was well tolerated by all patients. Six patients with 11 nodules had 1 thermocouple inserted near important organs for real-time temperature monitoring and the maximum temperature was 56 ℃. Major complications included mild pain (54.5%), post-ablation fever (100%) and abdominal wall edema (25%). All 23 tumors (100%) in this group were completely ablated, and no residual tumor or local recurrence was observed at a median follow-up of 13 mo (range 1 to 32 mo). The ablation zone was well defined on contrast-enhanced imaging (contrast-enhanced CT, MRI and/or contrast-enhanced ultrasound) and gradually shrank with time.

CONCLUSION: Ultrasound-guided MW ablation may be a feasible, safe and effective treatment for abdominal wall metastatic tumors in selected patients.

INTRODUCTION

Clinically, the incidence of primary abdominal wall malignant tumors is low. Usually metastasis or local infiltration is the major cause of abdominal wall metastatic tumors. A number of abdominal wall tumors occur during or after therapy, and are difficult to cure. Currently, most studies report that the main treatment for abdominal

wall tumors is resection[1], however some patients are unable to undergo resection due to tumor stage. Small subcutaneous lesions can be easily resected, whereas it is technically difficult for radical excision of large lesions, especially those which invade muscles. Moreover, surgical reconstruction is also troublesome, and a significant number of patients require abdominoplasty for larger abdominal wall tumors[2-4]. Other treatments have been used for abdominal wall tumors, such as radiotherapy, chemotherapy and thermal ablation. Radiotherapy requires patients to have optimal health status, while chemotherapy often plays an additional role and is not used as a radical cure. Thermal ablation is a minimally invasive technique, and has been widely used for the treatment of primary and metastatic liver cancer in past decades and is well established[5-8]. High intensity focused ultrasound (HIFU) and radiofrequency ablation have been used in abdominal wall metastatic tumors with curative effect[9]. Microwave (MW) ablation for the treatment of liver tumorsis relatively low-risk and has favorable therapeutic efficacy[10,11]. Compared with radiofrequency ablation, MW energy does not appear to be limited by charring and tissue desiccation, thus, thermal efficiency may be considerably higher with MW systems than with radiofrequency systems[12-15]. To our knowledge, there are no reports assessing the efficacy and safety of MW ablation for abdominal wall tumors under ultrasound guidance.

Thus, the purpose of this study was to assess the effectiveness of MW ablation for abdominal wall tumors under ultrasound guidance in the short and medium term, and to identify the possible complications that determine the rate of therapeutic success.

MATERIALS AND METHODS

Patients
From August 2007 to December 2010, eleven patients with 23 abdominal wall tumors were enrolled in this retrospective study (Table 1). The patients were 6 men and 5 women aged 35-68 years (mean age, 54.18 ± 9.14 years), and tumor size ranged from 1.3 cm to 5.0 cm in maximum diameter (mean diameter 2.59 ± 1.11 cm, range 1.3 cm to 5.0 cm). Before MW ablation, 2 patients were treated with chemotherapy, 1 patient was treated with chemotherapy and radiotherapy, and 1 patient with immunotherapy. Informed consent was obtained from all patients at enrollment. The inclusion criteria for this study were as follows: (1) The entire tumor could be clearly seen on ultrasound; (2) The tumor size was no more than 5 cm in diameter; (3) The tumor was located more than 5 mm from the skin surface; (4) The tumor had not adhered to the peritoneum or bowels; and (5) The tumor had not invaded the bones. The exclusion criteria were as follows: (1) Severe cardiopulmonary disease; (2) Severe coagulation abnormalities (prothrombin time more than 25 s, prothrombin activity higher than 40%, and platelet count higher than 40 cells $\times$ 10^9/L); and (3) Infection. All selected patients chose MW abla-

tion on the basis of tumor stage which made them inoperable, or had comorbidities, advanced age, or refused to undergo surgery. All abdominal wall nodules were metastatic lesions. In five cases abdominal wall tumors had metastasized from hepatocellular carcinoma (HCC); two cases metastasized from adrenal glands, whose pathological types were adrenal cortical carcinoma and pheochromocytoma. The remaining four cases metastasized from lung, ovary, bladder and kidney; and the corresponding pathological types were lung adenocarcinoma, ovarian peritoneal serous papillary carcinoma, bladder transitional cell carcinoma and renal clear cell carcinoma. The primary liver lesions in five patients were treated with MW ablation, and the primary lesions in the remaining patients were resected. Abdominal wall metastatic tumors in three patients with HCC were caused by needle tract seeding, which appeared 9, 11 and 22 mo after liver puncture.

Equipment
A KY2000 MW ablation system (Kangyou Medical Instruments, Nanjing, China) consisting of two independent MW generators, two flexible coaxial cables and two water-pumping machines, which could drive two 15-gauge cooled-shaft antennae simultaneously was used. The generators are capable of producing 1-100 W of power at 2450 MHz. The cooled shaft antenna was coated with polytetrafluoroethylene to prevent adhesion, which can also be clearly seen on ultrasound. The antenna is designed to minimize power feedback and provide tissue with optimal energy deposition. Three types of antennae were applied according to the size and location of the tumor, the antennae tips were 0.5, 0.7 and 1.1 cm, respectively. For tumors smaller than 2 cm, an antenna tip of 0.5 cm was chosen, while for tumors larger than 3 cm, a tip of 1.1 cm was selected. The MW machine is also equipped with a thermal monitoring system with 21-gauge thermocouple needles, which can be placed percutaneously at a designated location to monitor the temperature during real-time ablation.

Ablation procedures
Before treatment, all patients were scanned using contrast-enhanced computed tomography (CT)/magnetic resonance imaging (MRI) and ultrasound, and an appropriate puncture route was chosen by ultrasound. After local anesthesia with 1% lidocaine, the antenna was inserted percutaneously into the tumor and placed at designated sites under ultrasound guidance. Histologic diagnoses were confirmed by guided sonography with an 18-gaugecutting-edge needle through an automated biopsy gun device before inserting the antenna, and specimens were taken from different parts of the tumor (one to three pieces). One antenna was inserted into the center of tumors less than 1.7 cm, and multiple antennae were inserted into tumors 1.7 cm or larger. General anesthesia (Propofol, 6-12 mg/kg per hour; Ketamine, 1-2 mg/kg) was applied after correct placement of

antennae, and MWs were then emitted[16,17]. Two antennae were used simultaneously during MW ablation to achieve a larger ablation zone. If the tumor was adjacent to bowel, gallbladder or other important tissues, a 21 gauge thermocouple was inserted close to these tissues for real-time temperature monitoring during MW ablation. The treatment session ended if the transient hyperechoic zone between the antennae merged and covered the target region on gray-scale ultrasound. Simultaneously, according to our previous clinical experience, the temperature of the thermal needles should not exceed the target temperature to avoid heat injury in these organs[18]. For tumors with subcutaneous invasion, an ice bag was placed on the skin to avoid scalding during MW ablation.

Postprocedural observation and follow-up

After MW ablation, patients were closely monitored for possible complications such as fever, skin burns and pain which were also documented. All patients underwent contrast-enhanced ultrasound 3 d after MW ablation to assess treatment efficacy. If residual tumor (hyper-enhanced area on contrast-enhanced ultrasound) was found, a further session was planned or patients entered the follow-up protocol, which consisted of contrast-enhanced CT, MRI and/or contrast-enhanced ultrasound 1, 3 and 6 mo after MW ablation, and every 6 mo thereafter. Enhanced areas on the abdominal wall were assumed to represent viable tumors. If residual or recurrent tumor on the abdominal or chest wall was detected, a further MW ablation session was planned if the lesion still met the inclusion criteria.

RESULTS

MW ablation was well tolerated by all patients. The output power ranged from 30 W to 50 W, an output setting of 50 W was routinely used during ablation sessions, relatively lower than that used in liver lesions. Four of 23 tumors were adjacent to the intestinal tract, one nodule was adjacent to the gallbladder, and 1 nodule was adjacent to the gallbladder and intestinal tract. A thermocouple was inserted adjacent to these high-risk locations for real-time temperature monitoring. In this study, we used 1 thermocouple with a maximum temperature of 56 ℃ in 6 patients with 11 nodules. The treatment time was no more than 16.5 min (mean time 7.6 ± 4.3 min, range 2 min to 16.5 min). Twenty-one of 23 tumors were successfully eradicated following one MW session. The other two tumors underwent two MW sessions; one tumor was near the adrenal gland, and the other was a tumor 5 cm in maximum diameter. All 23 tumors (100%) in this group were completely ablated which was confirmed by follow-up imaging during a period of 1-32 mo. No major complications were encountered after MW ablation. Six patients experienced grade 1 according to standardization of terms and reporting criteria for image-guided tumor ablation[19]. Post-ablation fever was encountered in all patients, but each patient's temperature was lower than 38 ℃ and no drugs were needed. No skin burns were observed in the treated area, however, the treated area was slightly swollen in 3 patients. The patients were followed up until January 20, 2011. The median survival period of the 11 patients after MW ablation was 15.0 mo. During a mean follow-up of 13 mo (range 1-32 mo), three patients died of primary

tumor progression, however, the treated tumors were un-enhanced on follow-up contrast-enhanced images. In the other 8 patients, the ablation zones were well defined on contrast-enhanced images, and gradually shrank with time (Figure 1). Two patients developed distant metastases, one patient was treated with repeated sessions of MW ablation, and the other underwent HIFU.

DISCUSSION

In the past few decades, the treatment of abdominal wall tumors, especially metastasis, has evolved[9,20]. In addition to traditional surgical resection, there are many other treatments, such as transarterial embolization[20] radiofrequency ablation and HIFU[21]. Surgical resection is the first choice for abdominal tumors, although it carries a risk of hemorrhage and possible post-operative incisional hernia, and patients usually require reconstruction, such as abdominoplasty[22]. Some patients may not be surgical candidates due to poor medical conditions[23]. It is difficult to create a safety margin to eradicate possible microscopic tumor foci using transarterial embolization of the feeding vessel of the abdominal tumor, and may cause ischemic changes. Thus, it is rarely used in abdominal tumors. Compared with surgical resection, HIFU is a less invasive alternative to surgical resection. However, due to the bio-effects of focused ultrasound during the procedure, heat diffusion out of the focal region is inevitable and can damage the surrounding tissues.

We have also made some progress with the antennae used in MW ablation. Three types of antennae were used in this study according to tumor size and location, and the antennae tips were 0.5, 0.7 and 1.1 cm, respectively. According to a preliminary study, an antenna tip of 1.1 cm can ablate 2-2.6 cm *ex vivo* porcine livers with the output power of 60 W and the setting time of 10 min[24]. Based on these preliminary experiments, an antenna tip of 0.7 cm and 0.5 cm can ablate 2.4-2.6 cm and 2.2-2.4 cm *ex vivo* porcine livers with the output power of 60 W and the setting time of 10 min, respectively. The new type tips are safer, because the ablation zone is relatively small which avoids burning the skin in the superficial tumor during the procedure. Therefore, percutaneous MW ablation may be clinically feasible for superficial tumors. Based on our previous experience in MW ablation for HCC, we performed MW ablation on abdominal tumors. Treatment efficacy was encouraging. For tumors smaller than 4 cm, radical cure was achieved in all nodules within no more than 12 min and no tumor recurrence was noted during follow-up. In order to achieve the same effect, tumors larger than 4 cm needed several sessions. MW ablation, is a relatively new technique and can be used in different types of tumors[25-30], the primary effectiveness rate is equal to HIFU and radiofrequency ablation[16,31]. The favorable effectiveness of MW ablation may be attributed to its potential advantages[32], such as larger volume of ablation zone, reduced treatment time, less influence on the perfusion-mediated heat sink effect, higher thermal efficiency and the possibility of placing multiple

antennae simultaneously[33-35], especially compared with radiofrequency ablation. Results suggest that, like other techniques, MW ablation may be safe and effective for abdominal wall tumors, it may also represent a competitive alternative to surgical resection and other therapies. The high effectiveness rate of MW ablation may due to the following 4 reasons: (1) The new-type antenna used in this study was capable of ablating superficial tumors more securely; (2) There were relatively strict inclusion and exclusion criteria; (3) All operations were performed by experienced doctors (Yu XL and Liang P); and (4) Real-time temperature monitoring served as an indicator for predicting reliable safety margins. No severe complications were observed in this study. Unlike the treatment of liver tumors, abdominal tumor ablation has its own complication of abdominal wall edema. We studied three patients who had abdominal wall edema and found that the ablated tumors were all located in muscles and with subcutaneous invasion. Compared with parenchymal organs, muscle tissue lacks relative capsules and can not accumulate heat. During the ablation procedure, heat overflow in the muscle bundle can readily lead to abdominal wall edema. In order to ablate completely, the actual ablation zone should be larger than the size of the tumor, which will ablate normal tissues (such as fatty tissue or muscle tissue) and cause edema in a short time. Fortunately, the abdominal wall edema seen in three patients was very mild and all patients recovered within a short time (1-3 mo) without special treatment. For the ablation of specific tumors, such as pheochromocytoma, we used low power at the beginning of MW ablation, and changed the power according to the blood pressure. The use of antihypertensive drugs during the procedure should be taken into account, as pheochromocytomas can release catecholamine which could result in blood pressure fluctuation. There are key points during MW ablation which can reduce the incidence of complications: (1) The MW antenna was inserted in the deepest area of the tumor; (2) Increasing the angle of puncture between the antenna and transducer, that is insert the antenna along the long axis of the tumor for conformable ablation; and (3) For tumors with subcutaneous invasion, the transient hyperechoic zone did not exceed the dermal layer in the gray-scan ultrasound, and an ice bag was placed on the skin to avoid scalding. Although this was not a randomized, controlled study of traditional techniques, the low complication rate, minimal side effects, rapid recovery and lower costs (compared with radiofrequency ablation in China) strongly favor MW ablation as an optional curative approach for abdominal wall tumors. This study has some limitations: (1) Only 11 patients were included in this study. More patients should be recruited in order to assess the efficacy of this treatment; (2) Follow-up was relatively short and we are uncertain of the long-term results; and (3) The study did not include a comparison with other treatments.

In conclusion, our preliminary results showed that ultrasound-guided MW ablation appeared to be effective in the treatment of abdominal wall tumors. Further stud-

Contrast-enhanced MRI scan shows a lesion with hypoenhancement in T2-weighted images in the abdominal wall (arrow); E: Sonogram obtained before MW ablation shows hypoechoic nodule of 2.48 cm in maximum diameter in the abdominal wall (arrow); F: Arterial phase in CEUS shows hyperenhancement within the lesions (arrow); G: Sonogram obtained during MW ablation shows one antenna being inserted into the nodule; H: Abdominal wall edema occurred at the right lumbar in the arterial phase of contrast-enhanced CT (arrow).

ies are warranted to observe its long-term efficacy and   the results should be compared with other treatments.

COMMENTS

Background

A number of abdominal wall tumors occur during or after therapy, and are difficult to cure. Currently, the main treatment for abdominal wall tumors is resection, while the excision rate is low. Microwave (MW) ablation for the treatment of liver tumors has relatively low-risk and favorable therapeutic efficacy. However, there are no reports assessing the efficacy and safety of MW ablation for abdominal wall tumors under ultrasound guidance.

Research frontiers

MW ablation, as a relatively new technique, and can be applied to different types of tumors. This research was concerned with applying MW ablation in patients with abdominal wall metastatic tumors, and to improve the effectiveness rate of this technique.

Innovations and breakthroughs

Unlike the commonly used antenna, the authors made some progress with the antennae used in this study. Three types of antennae were used according to tumor size and location, and the antennae tips used were 0.5, 0.7 and 1.1 cm, respectively. These new type tips are safer, because the ablation zone is relatively small which avoids burning the skin in the superficial tumor during the procedure. Therefore, percutaneous MW ablation may be clinically feasible for superficial tumors.

Applications

The study results suggest that ultrasound-guided MW ablation may be a feasible, safe and effective treatment of abdominal wall metastatic tumors in selected patients.

Terminology

Image-guided tumor ablation: The term tumor ablation is defined as the direct application of chemical or thermal therapies to a specific focal tumor (or tumors) in an attempt to achieve eradication or substantial tumor destruction.

Peer review

The authors present short and medium-term outcomes for ultrasound-guided MW ablation for abdominal wall metastatic tumors. The procedure was well tolerated by all patients with the most significant complication being abdominal wall edema which resolved without treatment in all cases.

Abstract

AIM: To investigate the prevalence and risk factors of polypoid lesions of gallbladder (PLG) among the health examinees in the Shanghai region, China.

METHODS: A total of 11 816 subjects who underwent health examinations in our hospital between August 2010 and February 2011 were analyzed retrospectively. Among them, there were 7174 men and 4642 women. PLG was diagnosed by the real-time ultrasonography. Those with the body mass index (BMI) $\geqslant$ 28 were considered to be obese. Blood biochemical indices were detected with the fully automatic biochemical analyzer and hepatitis B surface antigen (HBsAg) was tested by the automated enzyme immunoassay. The correlations between the prevalence of PLG and age, sex, BMI, serum cholesterol (T-Cho), triglycerides (TG), blood sugar, HBsAg, high-density lipoprotein (HDL-C), low-density lipoprotein (LDL-C), gallstone and fatty liver were investigated. After univariate analysis of 11 variables, stepwise logistic regression analysis was performed to explore the risk factors of PLG.

RESULTS: There was a significant difference in sex, T-Cho, HBsAg, HDL-C, LDL-C and fatty liver between the PLG-positive group and the PLG-negative group (332/163 *vs* 6842/4479, P = 0.003; 22/473 *vs* 295/11 026, P =0.013; 92/403 *vs* 993/10 328, P = 0.001; 47/448 *vs* 332/10 989, P = 0.001; 32/463 *vs* 381/10 940, P = 0.001; 83/412 *vs* 3260/8061, P = 0.001). No significant difference was found in the age, BMI, TG, blood sugar and gallstone between the two groups (47.3 ± 26 *vs* 45.1 ± 33, P = 0.173; 59/436 *vs* 1097/10 224, P = 0.102; 52/443 *vs* 982/10 339, P = 0.158; 17/478 *vs* 295/11 026, P = 0.26; 24/471 *vs* 395/10 926, P = 0.109). Logistic regression analysis showed that the sex, HBsAg and HDL-C were independent risk factors for the development of PLG in a descending order of HDL-C > HBsAg > sex.

CONCLUSION: In healthy people, the male gender, positive HBsAg, and low HDL-C confer higher risks of PLG development.

INTRODUCTION

The prevalence of polypoid lesions of gallbladder (PLG), a common clinical gallbladder disease, is about 3%, with an increasing trend[1,2]. PLG is the general term of the limited abnormal accumulations of mucous membrane tissue of the gallbladder or the limited lesion projecting into the lumen of the gallbladder. Clinically, the types of polypoid growth of the gallbladder mainly includes cholesterol polypoid/cholesterosis, inflammatory polyp, cholesterosis with fibrous dysplasia of gallbladder, adenomyomatosis, hyperplastic cholecystosis and adenocarcinoma. Ultrasonography (US) is a convenient and non-traumatic modality used to profile the gallbladder and the position of the lesion. The application of US has improved significantly the detection rate of PLG. It is of great clinical significance to analyze the risk factors of PLG in an attempt to improve its prevention and diagnosis. This study retrospectively analyzed the prevalence and risk factors of PLG among 11 816 health examinees in our clinical center. Through the univariate and multivariate analyses, this study aimed to provide the first-hand evidences for the primary prevention of PLG.

MATERIALS AND METHODS

Ethics
This work was carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association. The study protocol was approved ethically by Putuo Hospital. All patients provided informed written consent.

Subjects
A total of 11 816 subjects, including 7174 men and 4642 women with an average age of 48.6 ± 31 years (range, 15-86 years) who underwent health examinations in our health center between August 2010 and February 2011, were included in this study.

Diagnosis of polypoid lesions of gallbladder
The subjects were examined with ultrasonography using a real-time scanner with a 3.5 MHz array transducer (Philips En Visor and Philips-iU22) in the early morning after fasting for about 8-12 h. They were required to stay supine or change the position when it is necessary. The gallbladder was observed through multiple cross sections to detect the size, shape, number, location, internal echo, basal part, local cyst wall and the movement of lesions with the position change.

The diagnosis of gallbladder polyps was established according to the following criteria: (1) Spherical, mulberry-like or papillary projections, derived from either pedunculated or narrow bases, and no change after position change; (2) Multiple echogenic spots which could be found in any part of the gallbladder, e.g., the gallbladder neck, body or bottom, especially in the body and bottom of the gallbladder; (3) Small echogenic spots, usually less than 10 mm; and (4) Hyperechoic (more visible) or medium echoic structures without acoustic shadow.

Measurement of body weight
We measured the body mass index (BMI) of the subjects following "The Prevention and Control Guideline for Overweight and Obesity among Chinese Adults"[3], and BMI was calculated by dividing the mean weight by the mean height squared (kg/m^2). BMI $\geq$ 28 was defined as obesity.

Determination of blood biochemical indices and hepatitis B surface antigen
Blood serum samples of 5 mL were routinely collected intravenously in the morning before breakfast. Cholesterol (T-Cho), triglyceride (TG), high-density lipoprotein (HDL-C), low-density lipoprotein (LDL-C) and blood glucose levels were detected and analyzed using a Hitachi 7020 Automatic Biochemical Analyzer. Hepatitis B surface antigen (HBsAg) was detected with an Italy RB 138 Automated Enzyme Immunoassay Analyzer. The reagents used were offered by the Shanghai Kehua Bioengineering Co., Ltd, Shanghai, China. The tests were undertaken strictly according to the instructions of the manufacturers.

Statistical analysis
Results were expressed as mean ± SD. We analyzed 11 variables with univariate analysis to compare the differences between the two groups. Variables (age, sex, BMI, T-Cho, TG, HDL-C, LDL-C, glucose, HBsAg, gallstones and fatty liver) were defined as independent variables and the PLG was defined as a dependent variable. They were examined in a multivariate model using forward stepwise maximum likelihood logistic regression to identify the risk factors of PLG (α = 0.05). The variable assignment is shown in Table 1. Data were analyzed using the SPSS version 13.0 statistical software and significance was set at P < 0.05.

RESULTS

General data of patients with PLG
The overall prevalence of PLG found among the health examinees was 4.2% (495/11 816). The incidence of PLG was 4.6% (332/7174) in men and 3.5% (163/4642) in women. Overall, males had a significantly higher prevalence of PLG than females (4.6% *vs* 3.5%, *P* = 0.003). In this group, the incidence of obesity was 9.8% (1156/11 816); the rates of increased T-Cho, TG and LDL-C were 2.7% (317/11 816), 8.8% (1034/11 816) and 3.5% (413/11 816), respectively; the rate of high blood sugar was 2.6% (312/11 816), and the incidence of low

[a]*P* < 0.05 *vs* negative PLG. PLG: Polypoid lesions of gallbladder; BMI: Body mass index; T-Cho: Cholesterol; TG: Triglyceride; HBsAg: Hepatitis B surface antigen; HDL-C: High density lipoprotein; LDL-C; Low density lipoprotein.

HDL-C was 3.2% (379/11 816); and the incidence of gallstone, the fatty liver and HBsAg (+) was 3.5% (419/11 816), 28.3% (3343/11 816) and 9.2% (1085/11 816), respectively. There were significant differences in sex, T-Cho, HBsAg, HDL-C, LDL-C and fatty liver between the PLG-positive group and the PLG-negative group (332/163 *vs* 6842/4479, *P* = 0.003; 22/473 *vs* 295/11 026, *P* = 0.013; 92/403 *vs* 993/10 328, *P* = 0.001; 47/448 *vs* 332/10 989, *P* = 0.001; 32/463 *vs* 381/10 940, *P* = 0.001; 83/412 *vs* 3260/8061, *P* = 0.001). No significant difference was found in the age, BMI, TG, blood sugar and gallstone, between the two groups (47.3 ± 26 *vs* 45.1 ± 33, *P* = 0.173; 59/436 *vs* 1097/10 224, *P* = 0.102; 52/443 *vs* 982/10 339, *P* = 0.158; 17/478 *vs* 295/11 026, *P* = 0.26; 24/471 *vs* 395/10 926, *P* = 0.109) (Table 2).

Logistic regression analysis of relevant risk factors for PLG

Logistic regression analysis showed that sex, HBsAg and HDL-C were independent risk factors for PLG, in a descending order of HDL-C > HBsAg > sex. The subjects with lower HDL-C had a 3.346 times higher risk of PLG than those who had normal or higher HDL-C. The

Table 3 Logistic regression analysis of multiple relevant factors of polypoid lesions of gallbladder

Variables	OR	95% CI	*P* value
Sex	1.843	1.245-2.789	0.0035
HBsAg	2.563	1.875-3.418	< 0.001
HDL-C	3.346	2.932-4.133	< 0.001

OR: Odds ratio; HBsAg: Hepatitis B surface antigen; HDL-C: High density lipoprotein.

risk of PLG was 2.563 times higher in HBsAg-positive subjects than in HBsAg-negative ones. Men had a 1.843 times higher risk of PLG than women (Table 3).

DISCUSSION

PLG, which is often neglected due to lack of significant clinical signs or symptoms, is a common disease found in the ultrasound examinations. In recent years, with changes of diet, acceleration of the pace of life, increasing health awareness and the popularity of ultrasonography, the detection rate of PLG tends to increase, and nearly 85% of PLG are detected in a routine physical examination. It is reported that the prevalence of PLG in the Western society is 1.0%-6.9%[4-6], which is significantly lower than in the Asians. Park *et al*[7] reported that PLG prevalence in the South Korea was about 6.1%. Lin *et al*[8] reported a prevalence of 9.5% in Taiwan. After the logistic regression analysis of 34 669 cases, Lin *et al*[8] showed that the male gender was an independent risk factor of PLG. The domestic studies showed a prevalence of 3% in healthy adults in our country[1,2]. The Logistic regression analysis in this study showed that the gender was an independent risk factor for PLG and males bear a significantly higher risk of PLG than females. The risk of PLG in men was 1.843 times higher than in women.

In China, hepatitis B virus carriers account for 7.2% of the population. HBsAg infection may lead to acute or chronic hepatitis. In acute hepatitis, gallbladder wall thickening, volume change and abnormal bile composition can occur and the normal systolic and diastolic functions may be disrupted[9]. Cholesterol polyp is the most common type among PLGs. Compared with non-hepatitis B patients, chronic hepatitis B patients are prone to PLG and the possible causes include: (1) Liver cell cholesterol metabolic disorders may lead to the alteration of the bile composition and quantity, and increased cholesterol in the bile of the gallbladder may easily crystallize and precipitate on the gallbladder wall, resulting in abnormal deposition; (2) Hepatitis B virus activates the immune system to produce autoimmune inflammation, leading to an increased activity of the gallbladder macrophages for cholesterol phagocytosis; (3) Gastrointestinal hormone secretion and metabolic disorder may cause tension adjustment disorder of the sphincter of Oddi, causing increased bile viscosity and poor drainage; and (4) Damages of the liver Kupffer cells may compromise the

detoxification of microbial toxins and phagocytic functions. Together with the small bile ducts and capillary damage, microorganisms and toxins can invade the gallbladder[10]. Our data showed that compared with PLG-negative group, PLG-positive group had a significantly higher incidence of hepatitis B virus infection. The logistic regression analysis showed that positive HBsAg was a risk factor for PLG. Lin *et al*[8] also reported that positive HBsAg was an independent risk factor for PLG. But there are some contrary reports[11]. The inconsistent findings may be related to the number of cases, sex ratio, ethnic differences and other factors. The role of hepatitis B virus in PLG still deserves further studies.

PLG formation mechanisms are very complicated, involving many interacting factors. The mechanisms for cholesterol polyps, the main type of PLG, have been most frequently reported. It has been reported that cholesterol polyps are related to the metabolism of cholesterol in bile. Khairy *et al*[12] found that in 74 patients with cholesterol polyps, 63 (85.1%) patients had elevated plasma cholesterol levels. However, other studies showed that higher plasma T-Cho and TG levels and the incidence of PLG were not necessarily correlated with PLG[13,14]. Ivanchenkova *et al*[15] and Zák *et al*[16] found that plasma HDL-C levels in patients with cholesterol polyps were significantly lower than in the control group, while LDL-C levels were significantly increased. Our data showed that compared with PLG-negative group, T-Cho and LDL-C levels were significantly higher in PLG-positive group while HDL-C levels were significantly lower. The TG level showed no significant difference between the two groups. Consistent with the report by Cantürk *et al*[17], our study showed that low HDL-C level was a risk factor for PLG. Currently, whether the cholesterol deposited in the gallbladder is from the plasma and the relevance between plasma TG level and PLG still remain unclear. Most studies have focused on the mechanisms of absorption and excretion of cholesterol by the mucosa of the gallbladder[18].

Although PLG is an independent disease, it is closely related to the occurrence of the gallbladder stone, which is commonly seen in PLG patients. Studies showed that PLG was often accompanied with stones, and Ito *et al*[19] reported that the rate of PLG with stones was 12%. Colecchia *et al*[20] believed that metabolic disorders of cholesterol existed in both PLG and gallbladder stones, which shared the common pathogenesis. However, these two diseases were not necessarily correlated. Our study showed that the incidence of the gallbladder stone was not significantly different between PLG-positive and PLG-negative groups.

In recent years, the prevalence of diabetes, fatty liver and obesity has been increasing year by year, affecting more and more people at younger ages. These three morbidities all belong to metabolic disorders and their roles in PLG are not consistent among previous reports[11,21,22]. Our study demonstrated that the incidences of fatty liver were not statistically different between PLG-positive and

PLG-negative groups, nor the plasma glucose and obesity. The logistic regression analysis showed that diabetes, fatty liver and obesity were not risk factors of PLG.

The exact mechanisms underlying PLG pathogenesis are still not clear. This retrospective analysis has demonstrated that low HDL-C level, male gender and positive HBsAg are the risk factors for PLG, and these findings will provide the related evidence and guidance for health education, and prevention and treatment of PLG.

COMMENTS

Background
Polypoid lesions of gallbladder (PLG) are tumor or tumor-like projections, referring to any mucosal projection into the lumen of the gallbladder which is usually non-neoplastic (> 95%), but may infrequently be neoplastic (< 5%) in nature. The diagnosis of gallbladder polyps is relatively easy by ultrasonography. Although numerous studies have focused on gallbladder polyps, little has been known about factors associated with the occurrence of PLG. The authors aimed to investigate the prevalence and possible risk factors of PLG in a health screening population of Shanghai region.

Research frontiers
The incidence of PLG has an increasing tendency in recent years. The reports and analysis on the risk factors of PLG were not consistent. The literatures mostly focus on gender, lipid metabolism disorders, gallstones, hepatitis B, glucose metabolism disorders, gallbladder local inflammation and so on. Inconsistencies may be related to race, lifestyle, culture, geographic characteristics worldwide, as well as experimental design and other factors.

Innovations and breakthroughs
In China, especially in the Shanghai region, there have been few larger sample analyses on the risk factors of PLG. In this study, the authors reported that the male gender, positive hepatitis B surface antigen, and low high-density lipoprotein are high-risk factors for developing PLG in healthy people.

Applications
The study is conducive to the prevention and treatment of PLG. The relationship between gender, hepatitis B and high-density lipoprotein and PLG is worthy of further studies.

Peer review
It is an interesting topic. The authors analyzed the risk factors for polypoid lesions of gallbladder in a population of health examinees in the Shanghai region.

Abstract

AIM: To investigate the effects of the *WWOX* gene on the human hepatic carcinoma cell line SMMC-7721.

METHODS: Full-length *WWOX* cDNA was amplified from normal human liver tissues. Full-length cDNA was subcloned into pEGFP-N1, a eukaryotic expression vector. After introduction of the *WWOX* gene into cancer cells using liposomes, the WWOX protein level in the cells was detected through Western blotting. Cell growth rates were assessed by methyl thiazolyl tetrazolium (MTT) and colony formation assays. Cell cycle progression and cell apoptosis were measured by flow cytometry. The phosphorylated protein kinase B (AKT) and activated fragments of caspase-9 and caspase-3 were examined by Western blotting analysis.

RESULTS: WWOX significantly inhibited cell proliferation, as evaluated by the MTT and colony formation as-says. Cells transfected with WWOX showed significantly higher apoptosis ratios when compared with cells transfected with a mock plasmid, and overexpression of WWOX delayed cell cycle progression from G1 to S phase, as measured by flow cytometry. An increase in apoptosis was also indicated by a remarkable activation of caspase-9 and caspase-3 and a dephosphorylation of AKT (Thr308 and Ser473) measured with Western blotting analysis.

CONCLUSION: Overexpression of *WWOX* induces apoptosis and inhibits proliferation of the human hepatic carcinoma cell line SMMC-7721.

Hu BS, Tan JW, Zhu GH, Wang DF, Zhou X, Sun ZQ. *WWOX* induces apoptosis and inhibits proliferation of human hepatoma cell line SMMC-7721. *World J Gastroenterol* 2012; 18(23): 3020-3026 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i23/3020.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i23.3020

INTRODUCTION

The tumor suppressor gene *WWOX* is localized in a common fragile site FRA16D (locus 16q23.3-24.1). Protein encoded by *WWOX* is an oxidoreductase containing two WW protein interaction domains. The biological role of the protein is not yet defined, although there are hypotheses that it may play a part in steroid hormones me-

tabolism and ErbB4 receptor signaling pathway[1,2]. Low expression level of the *WWOX* gene has been observed in many types of cancers[3-15], possibly due to the loss of heterozygosity or epigenetic changes, such as methylation of CpG islands in promoter region. Several researches have revealed loss of heterozygosity of *WWOX* locus in gastric[7], pancreatic[6], esophageal[3] and lung[4] cancers. The role of WWOX in hepatic carcinoma is not well understood, and few studies have reported the effects of WWOX on hepatic carcinoma. In this study, we investigated the apoptotic effects of the *WWOX* gene on the human hepatic carcinoma cell line SMMC-7721.

MATERIALS AND METHODS

Materials

The eukaryotic expression vector pEGFP-N1 and *Escherichia coli* DH5α competent cells are routinely maintained by the central laboratory at our hospital. The hepatoma cell line SMMC-7721 was obtained from the Chinese Academy of Sciences (Shanghai, China). Dulbecco's modification of Eagle's medium Dulbecco (DMEM) culture medium was purchased from Gibco BRL (Gaithersburg, United States). Fetal bovine serum was obtained from Sijiqing Biological Engineering Material (Hangzhou, China). The following materials were used: RNeasy Protect Mini-kit (QIAGen Co., Germany), SMARTTM PCR cDNA synthesis kit (Clontech Co., United States), DNA gel extraction kit (Dalian TaKaRa Co., China), plasmid mini-preparation kit (Shanghai Huasun Biotechnology Co., China), KOD-Plus DNA polymerase (TOYOBO Co., United States), T4 DNA ligase and the HindⅢ and Kpn I restriction enzymes (New England Biolabs, United States), Lipofectamine 2000 (Invitrogen, United States), anti-WWOX, anti-phospho-AKT(pThr308 and Ser473), cleaved caspasse-9 and caspase-3 monoclonal antibodies (Santa Cruz Co., United States), and horseradish peroxidase-conjugated goat anti-rabbit/mouse IgG (Zhongshan Co., China). Nucleic acid sequencing was performed by Shanghai Yingjun Bioengineering Co., China. The *WWOX* and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) primers were synthesized by Shanghai Yingjun Bioengineering Co., China.

Cell lines and culture conditions

SMMC-7721 cells were cultured in DMEM medium (Hy-Clone Inc, United States) supplemented with 10% new calf bovine serum in a 37 ℃ and 5% CO₂ incubator.

Construction of pEGFP-N1-WWOX vector and establishment of cell line SMMC-7721 that stably expresses WWOX

The *WWOX* open reading frame was amplified from a cDNA clone using the forward primer 5'GGAAGCTTTT-GGAGCGGGGAGTGAG-3' and the reverse primer 5' GGATCCCAGCAGTTGTTGAAGTACA-3', which introduced *Kpn* I and *Hin*DⅢ restriction endonuclease sites. *WWOX* cDNA digested with *Kpn* I and *Hin*dⅢ was

cloned into a pEGFP-N1 eukaryotic expression vector. The resulting vector was transfected into SMMC-7721 cells using Lipofectamine 2000 (Invitrogen, Carlsbad, CA). An empty vector of pEGFP-N1 was used as a negative control. After 24-48 h, the transient transfection efficiency was determined under an Olympus fluorescence microscope. The cells were then passaged at appropriate ratios to six-well plates. The next day, the cells were cultured in the presence of 1000-2000 g/mL G418 (Life Technology, Paisley, Scotland), which was increased in concentration in a stepwise manner over 14 d. Cells highly expressing green fluorescent protein (GFP) were selected.

Western blotting

Protein was extracted from cultured cells using lysis buffer. After a 30-min incubation on ice, the lysates were heated at 100 ℃ for 15 min and centrifuged at 12 000 × *g* for 15 min at 4 ℃. Lysates containing an equal amount of protein (25 μg) were dissolved in sodium dodecyl sulphate (SDS) sample buffer, separated on 12% SDS slab gels, and transferred electrophoretically onto polyvinylidene difluoride membranes. Equal protein loading and transfer were confirmed by Ponceau S staining. After being blocked with 5% non-fat dry milk in Tris-Buffered Saline and Tween 20 (10 mmol Ttris-HCl, pH 8.0, 100 mmol/L NaCl and 0.05% Tween), the membrane was incubated at 4 ℃ overnight with the appropriate primary antibodies. Following washing, horseradish peroxidase conjugated secondary antibody was applied to the membrane. Proteins bound by the secondary antibody were visualized by electrochemiluminescence (Amersham Bioscience) according to the manufacturer's instructions. The expression of GAPDH was measured as a control, and each experiment was performed in triplicate.

Cell growth assays

Cell growth was determined by the methyl thiazolyl tetrazolium (MTT) assay (Sigma, United States). Briefly, 1×10^4 cells were seeded onto 96-well plates with four replicates for each condition. Approximately 72 h later, MTT reagent was added to each well at 5 mg/mL in a 20 μL volume, and the reaction was incubated for another 4 h. The formazan crystals formed by viable cells were subsequently solubilized in dimethyl sulfoxide, and the absorbance (*A*) at 490 nm was measured.

Plate colony formation assay

Approximately 100 cells were added to each well of a six-well culture plate. After incubation at 37 ℃ for 15 d, cells were washed twice with phosphate-buffered saline (PBS) and stained with Giemsa solution. The number of colonies containing ≥ 50 cells was counted under microscope [plate clone formation efficiency = (number of colonies/number of cells inoculated) × 100%]. Each experiment was performed in triplicate.

Cell cycle analysis

Forty-eight hours after treatment, logarithmically grow-

Figure 1 WWOX protein levels in SMMC-7721 cells. 1: Control group; 2: Empty vector transfection group; 3: pEGFP-*WWOX* transfection group.

Figure 2 Growth of SMMC-7721 cells examined by plate colony formation. Overexpression of WWOX (pEGFP-N1-WWOX/SMMC-7721) resulted in a decrease in the number of formed colonies compared with the SMMC-7721 and control vector (pEGFP-N1/SMMC-7721) cells (*P* < 0.05).

ing cells were collected and washed with PBS three times and fixed with 75% ethanol at -20 ℃ for at least 1 h. After extensive washing with PBS, the cells were suspended in Hank's balanced salt solution containing 50 mg/mL RNase A (Boehringer Mannheim) and 50 mg/mL propidium iodide (PI) (Sigma-Aldrich), incubated for 1 h at room temperature, and were analyzed by FACScan (Becton Dickinson).

Apoptosis assays
Apoptosis was analyzed 48 h after treatment using the Annexin V-FITC Apoptosis Detection Kit (BD Biosciences) according to the manufacturer's instructions.

Statistical analysis
Data were presented as the mean ± SD. Comparisons of experimental values between cisplatin-treated cells and untreated controls were conducted using analysis of variance or the Kruskal-Wallis rank test. Statistical significance was defined as *P* < 0.05.

RESULTS

Overexpression of WWOX in the cell line SMMC-7721
To study the biological functions of WWOX, we introduced WWOX into SMMC-7721 cells using a pEGFP-N1

Table 1 Methyl thiazolyl tetrazolium assay

Cell line	Optical density value
SMMC-7721	1.77 ± 0.20
pEGFP-NI/SMMC-7721	1.78 ± 0.13
pEGFP-Nl-WWOX/SMMC-7721	1.12 ± 0.23

The cell growth of parental SMMC-7721, control vector and WWOX over-expressing cells was examined by methyl thiazolyl tetrazolium assay over a 3-d period. The cell growth of the WWOX expressing cells (pEGFP-N1-WWOX/SMMC-7721) was reduced compared with the wild-type (SMMC-7721) and control vector (pEGFP-N1/SMMC-7721) cells (*P* < 0.05).

Figure 3 Overexpression of WWOX inhibits the proliferation of SMMC-7721 cells, as demonstrated by the methyl thiazolyl tetrazolium assay. There were no significant differences between the parental SMMC-7721 cell line and the control vector cell line based on the *P* values.

eukaryotic expression vector containing the *WWOX* gene. Seven stably transfected cell clones were obtained. Western blotting analysis with anti-GFP antibodies showed that WWOX-pGFP fusion protein in the SMMC-7721 cell clones was highly expressed compared with control cells and control-vector cells (Figure 1).

WWOX inhibits cell growth in vitro
To analyze the function of WWOX, we studied the rate of cell growth in the WWOX-expressing SMMC-7721 cells. The results from the colony formation assay indicated that SMMC-7721 cells overexpressing WWOX formed significantly fewer colonies than did the control clone cells and the control-vector cells (*P* < 0.05) (Figure 2). Cells transfected with *WWOX* also showed significantly decreased cell proliferation compared with control cells and control-vector cells when examined by the MTT assay (Table 1, Figure 3).

Overexpression of WWOX arrests the cell cycle in G1 and induces apoptosis of SMMC-7721 cells
To detect the effect of WWOX overexpression on the cell cycle, we measured the cell cycle distribution in WWOX-expressing SMMC-7721 cells. In these lines, there was a marked decrease in the S-phase population, while the G1 population was significantly increased compared with the control vector and wild type SMMC-7721 cells (*P* < 0.05). Neither cell lines showed significant changes in the G2 population (Figure 4, Table 2). Cells transfected with pEGFP-N1-*WWOX* demonstrated more apoptosis than did cells transfected with the mock

Figure 4 Cell cycle distribution of parental SMMC-7721, control vector (pEGFP-N1), and *WWOX* overexpressing (pEGFP-N1-WWOX) cells determined by fluorescently activated cell sorting caliber cytometry. The G1/S transition was inhibited in *WWOX* overexpressing cells compared with parental and control vector transformed cells (*P* < 0.05).

Figure 5 Cell apoptosis measured by flow cytometry using Annexin V/propidium iodide double staining. Cells transfected with pEGFP-N1-WWOX showed more apoptosis than parental cells or cells transfected with the mock plasmid (*P* < 0.05). PI: Propidium iodide; FITC: Fluorescein isothiocyanate.

Table 2 Overexpression of WWOX retards cell cycle progression from G1 to S phase

Group	Cell cycle		
	G1	S	G2
SMMC-7721	41.23 ± 2.12	34.52 ± 4.13	22.54 ± 3.12
pEGFP-Nl/SMMC-7721	40.45 ± 1.32	33.3 ± 3.11	21.24 ± 1.31
WWOX/SMMC-7721	64.23 ± 4.34	16.13 ± 2.65	17.12 ± 3.24

plasmid or the parent cells (*P* < 0.05) (Figure 5).

Caspase-9 and caspase-3 activation by WWOX

Expression of cleaved caspase-9 and caspase-3 was up-regulated, as measured by Western blotting in cells that were transfected with pEGFP-N1, compared with either

the cells transfected with a control vector or parental wild-type cells (Figure 6).

Phosphorylation of Akt decreased by WWOX

To evaluate the effect of WWOX on Akt/PKB activity, the phosphorylation level at Akt Thr308 and Ser473 was examined with specific phospho-Akt antibodies. Western blot analysis showed that WWOX significantly reduced the level of Akt/PKB phosphorylation (Figure 7).

DISCUSSION

Hepatic carcinoma is a highly invasive and clinically challenging tumor, and its molecular basis remains poorly understood. We used a gain-of-function approach by

Figure 6 Overexpression of WWOX activates the expression of caspase-9 and caspase 3 protein. A: Expression of cleaved caspase-9 was upregulated in pEGFP-WWOX cells compared with parental and control vector cells; B: Protein expression of cleaved caspase 3 was upregulated in pEGFP-WWOX cells compared with control-vector cells and parental SMMC-7721. Data are presented as mean ± SD ($P < 0.05$). 1: Control group; 2: Empty vector transfection group; 3: pEGFP-WWOX transfection group. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

Figure 7 Overexpression of WWOX suppresses the phosphorylation of p-AKT(Thr308) and p-AKT(Ser473). A: p-AKT(Thr308) levels were decreased in pEGFP-WWOX cells compared with parental and control vector transformed cells by Western blotting analysis; B: p-AKT(Ser473) levels were decreased in pEGFP-WWOX cells compared with parental and control vector transformed cells by Western blotting analysis. Data are presented as mean ± SD ($P < 0.05$). 1: Control group; 2: Empty vector transfection group; 3: pEGFP-WWOX transfection group. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

introducing *WWOX* into wild-type cells to investigate the effect of the *WWOX* gene on SMMC-7721, the human hepatic carcinoma cell line. Our data suggest that WWOX can significantly inhibit cell proliferation and induce cell apoptosis of the hepatic carcinoma cell line SMMC-7721. Overexpression of *WWOX* delayed the cell cycle progression from G1 into S phase, as demonstrated by flow cytometry.

Apoptosis plays a central role in tumor development, and a lack or failure of apoptosis leads to the develop-ment of many tumors, including hepatocarcinoma[16,17]. This suggests that induction of apoptosis in tumor cells might be an effective approach for delaying tumor progression. In this study, we found that overexpression of *WWOX* induces apoptosis in the hepatic carcinoma cell line SMMC-7721.

There are, at least, two broad extrinsic and intrinsic pathways that lead to apoptosis[18-20]. The extrinsic pathway begins with the binding of Fas ligand (FasL or CD95L) to the Fas receptor (CD95) and results in the

recruitment of Fas-associated protein with death domain and pro-caspase-8 to the Fas complex. This increase in the local concentration of pro-caspase-8 leads to its autocatalysis and activation. Activated caspase-8 cleaves pro-caspase-3, which then undergoes autocatalysis to form active caspase-3, a principle effector caspase of apoptosis. The intrinsic apoptosis pathway always begins with mitochondrial damage, which results in the release of cytochrome C from the damaged mitochondria. In the cytosol or on the surface of the mitochondria, cytochrome C is bound to the protein Apaf-1 (apoptotic protease activating factor), which activates the initiating caspase, caspase-9, which then activates caspase-3[21,22]. The caspase families play an important role in the apoptosis-signaling pathway. The caspases are present in the cytoplasm under normal conditions as inactive proenzymes, and most of them are activated by proteolytic cleavage when the cell undergoes apoptosis[23,24]. Both caspase-8 and caspase-9 can activate the effector caspase, caspase-3, by proteolytic cleavage, and the subsequent processes result in nuclear DNA fragmentation and the formation of apoptotic bodies. This indicates that activation of caspase-3 is a central event for the process of apoptosis. Based on these results, we speculate that WWOX allows the release of cytochrome C from mitochondria, resulting in the activation of caspase-9 and caspase-3 in sequence and finally induces apoptosis of HCC cells. Consistent with this hypothesis, the results of Western blotting showed that WWOX overexpression induced the activation of caspase-9 and caspase-3.

Our work also shows that WWOX downregulates the phosphorylation of Akt/PKB at Thr308. Akt/PKB[25,26], the major downstream effector of the PI3-kinase, is a Ser/Thr protein kinase that plays a crucial role in the regulation of several cellular signaling pathways. Akt/PKB is a regulator of cell survival and apoptosis, and its activation in a variety of cells can protect against apoptosis. Akt/PKB is phosphorylated at two regulatory sites, Thr308 and Ser473, which are essential for its activation. Activated Akt/PKB can phosphorylate BAD, IκB kinase, glycogen synthase kinase-3b, and the forkhead transcription factors[27,28], leading to their inactivation and cell survival. It has been reported that the phosphorylation of caspase-9 can regulate its activity[29]. Akt phosphorylates pro-caspase-9 at Ser196, which inhibits the proteolytic processing of pro-caspase-9.

WWOX blocks the activation of Akt, thereby attenuating the activity of a major anti-apoptotic pathway and inducing cell apoptosis. It remains unclear how WWOX affects Akt phosphorylation, as it does not affect PI3-kinase activity directly[30]. Other potential consequences of WWOX inhibition, such as the modulation of the RAS-signaling pathway, the expression of p53 and other members of the B-cell lymphoma 2 family, such as myeloid cell leukemia-1[31,32], the activation of the sphingomyelin-ceramide pathway, and interference with nuclear factor-κB[33] merit further investigation in the future.

In conclusion, WWOX may play a key role in tumor cell proliferation and carcinogenesis. Overexpression of WWOX can suppress the growth of HCC cells by inhibiting cell growth and inducing cell apoptosis. Apoptosis is induced by WWOX through the activation of the caspase cascade, which is correlated with the phosphorylation of Akt/PKB. These results suggest a potential role for WWOX as an effective chemotherapeutic and chemopreventive strategy against human liver cancer.

COMMENTS

Background
Several researches have revealed loss of heterozygosity of *WWOX* locus in gastric, pancreatic, esophageal and lung cancers. The role of *WWOX* in hepatic carcinoma is not well understood, and few studies have reported the effects of *WWOX* on hepatic carcinoma. In this study, the authors investigated the apoptotic effects of the *WWOX* gene on the human hepatic carcinoma cell line SMMC-7721.

Research frontiers
This is the first report about *WWOX* gene relevant to human hepatoma cell line SMMC-7721.

Innovations and breakthroughs
By cloning the *WWOX* gene and transferring it into hepatocellular carcinoma cell line SMMC-7721, the authors investigated the growth-inhibiting and apoptosis-inducing effects of *WWOX* gene on human hepatoma cell line SMMC-7721 and concluded that the over-expression of *WWOX* gene could induce apoptosis and inhibit the growth of hepatic carcinoma cell line SMMC-7721.

Applications
WWOX may have a potential role in development of chemotherapeutic and chemopreventive strategies against liver cancer.

Terminology
The tumor suppressor gene *WWOX* is localized in a common fragile site FRA16D (locus 16q23.3-24.1). Protein encoded by *WWOX* is an oxidoreductase containing two WW protein interaction domains.

Peer review
The manuscript describes the results of studies on the effect of tumor suppressor gene, *WWOX*, expression in SMMC-7721. This is an interesting and well presented study, with thorough introduction and the succinct discussion of the topic.

Abstract

Lymph node (LN) metastases from hepatocellular carcinoma (HCC) are considered uncommon. We describe the surgical resection of a solitary para-aortic LN metastasis from HCC. A 65-year-old Japanese man with B-type liver cirrhosis was admitted for the evaluation of a liver tumor. He had already undergone radiofrequency ablation, transcatheter arterial chemoembolization, and percutaneous ethanol injection therapy for HCC. Despite treatment, viable regions remained in segments 4 and 8. We performed a right paramedian sectionectomy with partial resection of the left paramedian section of the liver. Six months later, serum concentrations of alpha-fetoprotein (189 ng/mL) and PIVKA-2 (507 mAU/mL) increased. Enhanced computed tomography of the abdomen revealed a tumor (20 mm in diameter) on the right side of the abdominal aorta. Fluorine-18 fluorodeoxyglucose positron emission tomography revealed an increased standard uptake value. There was no evidence of recurrence in other regions. Esophagogastroduodenoscopy and colonoscopy revealed no malignant tumor in the gastrointestinal tract. Para-aortic LN metastasis from HCC was thus diagnosed. We performed lymphadenectomy. Histopathological examination revealed that the tumor was largely necrotic, with poorly differentiated HCC on its surface, which confirmed the suspected diagnosis. After 6 mo tumor marker levels were normal, with no evidence of recurrence. Our experience suggests that a solitary para-aortic LN metastasis from HCC can be treated surgically.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common solid tumor in the world and accounts for about 500 000 deaths per year[1]. Long-term outcomes after hepatic resection remain unsatisfactory because of the high incidence of postoperative recurrence[2]. Although intrahepatic metastases are the most common type of

recurrence, extrahepatic metastases from HCC have an important impact on long-term survival[3]. The most frequent site of hematogenous metastases is the lung, followed by the adrenal gland and skeleton[4,5]. However, lymph node (LN) metastases from HCC are uncommon, with an reported prevalence of 2.2% in a series of Japanese patients who underwent hepatic resection[4]. LN metastases are usually associated with systematic metastases, and there is currently no standard treatment[6]. The 5-year survival rate of patients with LN metastases from HCC is about 20%[7], but successful resection of a solitary LN metastasis is expected to result in better outcomes[8]. We describe the surgical resection of a solitary para-aortic LN metastasis from HCC.

CASE REPORT

A 65-year-old Japanese man with B-type liver cirrhosis was admitted for the evaluation of a liver tumor. He had already undergone radiofrequency ablation, transcatheter arterial chemoembolization, and percutaneous ethanol injection therapy for HCC. Despite treatment, HCC remained viable. We therefore considered surgical resection. The patient had undergone the repair of an abdominal aortic aneurysm with a vascular prosthesis 1 year previously. Laboratory examinations revealed the serum hemoglobin concentration to be 14.7 g/dL (normal, 14 to 17 g/dL); the platelet count was $9.7 \times 10^4/\mu L$ (normal, 12 to $38 \times 10^4/\mu L$); the total bilirubin level was 2.4 mg/dL; the direct bilirubin level was 1.9 mg/dL; the albumin level was 4.1 g/dL; the serum creatinine level was 1.24 mg/dL (normal, < 1.2 mg/dL); and the prothrombin time was 90.8%, which indicated Child-Pugh class A disease. The indocyanine green clearance rate of 15 min was 3.5% (normal, < 10%). The serum concentration of PIVKA-2 was 1226 mAU/mL (normal, < 37 mAU/mL), whereas the serum concentration of alpha-fetoprotein (AFP) was 563.7 ng/mL (normal, < 10 ng/mL). Enhanced computed tomography (CT) of the abdomen revealed a tumor, 20 mm in diameter, in segment 4 of the left lobe on early-phase images, with washout on late-phase images. Abdominal CT angiography revealed a diffuse high-density area, including lesions previously treated by radiofrequency ablation, in segment 8 of the right hepatic lobe. The high-density area was visible on arterial-phase images and washed out on late-phase images (Figure 1). The tumors in both segments were diagnosed as viable HCCs. We performed hepatic right paramedian sectionectomy with partial resection of the left paramedian section of the liver. During the operation, a tumor thrombus was found in a peripheral portal vein in segment 8. Histopathologically, the tumor contained broad areas of necrosis and fibrosis, and the HCC had a moderate-grade funicular structure. Poorly differentiated HCC was present in some parts of the tumor. The diagnosis was moderately to poorly differentiated HCC (T2N0M0, pStage Ⅱ UICC TNM classification). Peripheral portal vein invasion was detected (Figure 2). The postsurgical course was uneventful, and

Figure 1 An abdominal computed tomography angiographic scan, showing a diffuse high-density area. A: An abdominal computed tomography angiographic scan including a lesion previously treated by radiofrequency ablation in segment 8 of the right hepatic lobe, in the arterial phase (arrow); B: The area was washed out on late-phase images (arrow).

the patient was discharged on postoperative day 14. After the operation, the serum concentration of PIVKA-2 decreased to 439 mAU/mL, whereas the concentration of AFP fell to 25.5 ng/mL after the operation. Upper gastrointestinal endoscopy revealed the presence of mild esophageal varices without gastric varices (Li, Cw, F1, RC0, according to the General Rules for Recording Endoscopic Findings of Esophagogastric Varices[9]).

Six months later, serum concentrations of PIVKA-2 (507 mAU/mL) and AFP (189 ng/mL) rose again. Enhanced CT of the abdomen revealed a tumor (20 mm in diameter with slight enhancement) on the right side of the abdominal aorta (Figure 3). Magnetic resonance imaging of the abdomen revealed a high-intensity tumor in the right para-aortic region on T2-weighted images. Fluorine-18 fluorodeoxyglucose positron emission tomography (FDG-PET) revealed an increased standard uptake value (SUV) in this tumor (Figure 4). There was no evidence of recurrence in any other region. Upper-gastrointestinal endoscopy and colonoscopy showed no evidence of a malignant tumor in the gastrointestinal tract. The tumor was diagnosed as a para-aortic LN metastasis from HCC because of the increased tumor marker level and increased SUV on FDG-PET. We performed lymphadenectomy. At the time of the operation, the surface of the tumor was smooth and slightly adhesive. Histopathological examination showed that the tumor was largely necrotic, with poorly differentiated HCC

Figure 2 **Histopathological examination revealed the presence of considerable necrosis and fibrosis in the tumor.** The hepatocellular carcinoma (HCC) was graded as moderate-grade funicular type. A: Poorly differentiated HCC was present in some regions; B: Peripheral portal vein invasion was detected (hematoxylin and eosin, ×600).

on its surface (Figure 5). The invasion of lymphocytes was noted. The tumor was diagnosed as a para-aortic LN metastasis from HCC. Recovery was uneventful, and the patient was discharged on postoperative day 17. After 6 mo, the levels of tumor markers remained normal, with no evidence of recurrence.

DISCUSSION

LN metastasis is an important risk factor for the pro-gression and recurrence of many malignant tumors[10]. LN status is an established prognostic factor in oncologic surgery, with a major impact on long-term survival[7]. LN metastasis also plays an important role in the outcomes of patients with HCC, in whom its presence is related to poorer survival and a higher risk of tumor recurrence[7]. Even after lymphadenectomy, patients with LN metastases still have poorer disease-free survival and overall survival than those without LN metastases[11].

The most common site of LN metastases from HCC is the hepatic pedicle node, followed by the retropancreatic space and common hepatic artery station. These nodes appear to be key stations for lymphatic spread from liver tumors toward regional and more distant nodes[12]. However, solitary para-aortic LN metastasis from HCC is relatively rare. Some HCCs can lead to what has been termed "skip LN metastases", LN metastases at distant sites without metastases in the hepatoduodenal ligament[13-16]. Moreover, peritumoral vascular or lymphatic invasion, tumor multifocality, or distal obstruction of the lymphatics by tumor metastasis can change the direction of lymph flow to alternative routes[17]. In our patient, skipping LN metastasis might have been caused by liver cirrhosis or an operation altering the direction of lymph flow.

Previous studies have reported that patients with more advanced intrahepatic tumors or vessel invasion at initial diagnosis are more likely to have extrahepatic metastases[18]. A primary tumor size of > 5 cm has been associated with the presence of extrahepatic metastasis in HCC[19]. In our patient, the primary HCC was associated with peripheral portal vein invasion.

No standard treatment for extrahepatic metastases developing after hepatic resection of HCC is available[3]. Most patients with recurrent HCC have multiple extrahepatic metastases. The median survival time after the diagnosis of extrahepatic metastases is about 5 mo[20]. Patients with a solitary metastasis from a controlled intrahepatic tumor can be treated surgically, and good outcomes have been reported[8]. In our patient, the para-aortic LN metastasis was solitary, and there was no tumor in the residual liver or evidence of other extrahepatic metastases. We therefore resected the solitary LN metastasis.

A recent study reported that FDG-PET is a useful imaging technique for identifying extrahepatic metastases[19]. The sensitivity of FDG-PET for the detection of extrahepatic metastases was 79%. The detection rate was influenced by the size of metastatic lesions: it was 83% for metastatic lesions larger than 1 cm and 13% for lesions less than or equal to 1 cm[21]. FDG-PET is considered a very useful noninvasive imaging technique for diagnosis, staging and monitoring the treatment response in a variety of malignant tumors[22,23]. In patients with HCCs that produce AFP, an unexplained rise of the serum AFP level after treatment is an early sign of tumor recurrence or extrahepatic metastasis[24]. One study reported that tumor restaging by FDG-PET can detect and localize disease recurrence among patients with no or mild symptoms and elevated levels of tumor markers[25]. As well as being a useful tool for the preoperative staging of HCC, FDG-PET is also better than conventional diagnostic modalities for follow-up, especially staging and re-staging after hepatectomy[24]. In our patient, the serum AFP level increased after hepatectomy, and para-aortic LN metastasis was detected on FDG-PET. We therefore recommend FDG-PET for the screening of metastasis from HCC after hepatectomy.

In conclusion, our experience suggests that a solitary para-aortic LN metastasis from HCC can be treated surgically.

Abstract

The combination of either boceprevir or telaprevir with ribavirin and interferon (triple therapy) has been shown to be more effective than ribavirin+interferon (dual therapy) for the treatment of genotype 1 hepatitis C. Since the benefit of these treatments takes place after years, simulation models are needed to predict long-term outcomes. In simulation models, the choice of different values of yearly discount rates (e.g., 6%, 3.5%, 2%, 1.5% or 0%) influences the results, but no studies have specifically addressed this issue. We examined this point by determining the long-term benefits under different conditions on the basis of standard modelling and using quality-adjusted life years (QALYs) to quantify the benefits. In our base case scenario, we compared the long-term benefit between patients given a treatment with a 40% sustained virologic response (SVR) (dual therapy) and patients given a treatment with a 70% SVR (triple therapy), and we then examined how these specific yearly discount rates influenced the incremental benefit. The gain between a 70% SVR and a 40% SVR decreased from 0.45 QALYs with a 0% discount rate to 0.22 QALYs with a 6% discount rate (ratio between the two values = 2.04).
Testing the other discounting assumptions confirmed that the discount rate has a marked impact on the magnitude of the model-estimated incremental benefit. In conclusion, the results of our analysis can be helpful to better interpret cost-effectiveness studies evaluating new treatment for hepatitis C.

TO THE EDITOR

The review by Tsubota *et al*[1] has examined the main options available for the treatment of hepatitis C, including two antiviral drugs that have recently been marketed in many countries. Focusing more thoroughly on these two innovative agents is worthwhile because boceprevir and telaprevir, along with other innovative agents, are thought to be an important advancement in the treatment of this disease[2], although at a high cost.

Hepatitis C virus (HCV) genotype 1, which accounts for 60% of all HCV-infected patients[3-5], is the target at which these two new agents are directed in combination with ribavirin + interferon. Considering that the combination of either boceprevor or telaprevir with ribavirin+interferon (triple therapy) has been shown

Table 1 Main characteristics of the Markov models[1]

Authors	Modelling details (base case)	Expected outcome

Shepherd *et al*[18] 2007	Age = 40 yr; time horizon = lifetime; discount rate = 1.5% per year	20.17 QALYs	NR	From 20.94 to 22.48 QALYs
Hartwell *et al*[19] 2011[2]	Age = 40 yr; time horizon = lifetime; discount rate = 3.5% per year, dual therapy with PEG-interferon alpha-2α	NR (naïve patients), 10.74 QALYs (previously treated patients)	NR	15.68 QALYs (naïve patients), 11.05 QALYs (previously treated patients)
Hartwell *et al*[19] 2011[2]	Age = 40 yr; time horizon = lifetime; discount rate = 3.5% per year, dual therapy with PEG-interferon alpha-2β	NR (naïve patients), 10.74 QALYs (previously treated patients)	NR	13.89 QALYs (naïve patients), 11.14 QALYs (previously treated patients)

LY: Life year; QALY: Quality-adjusted life year; PEG: Pegylated; NR: Not reported. [1]In a preliminary search on PubMed, we identified 47 articles describing a simulation model for hepatitis C; the complete references for these studies can be obtained from the authors upon request; [2]This study assessed also the shortened duration regimen of PEG-interferon + ribavirin, the data of which have not been reported in this table.

Figure 1 Estimation of the values of quality-adjusted life expectancy per patient under different modelling assumptions (time horizon = 30 years). The y-axis shows five different assumptions of yearly discount rate. QALYs: Quality-adjusted life years; SVR: Sustained virologic response.

to be more effective than ribavirin + interferon (dual therapy) in genotype 1[1-3], in the near future the dual therapy is expected to be replaced by the triple therapy in a certain proportion of these cases. The debate is still ongoing to set appropriate criteria to identify the best candidates for the triple therapy, and this selection will depend on a number of factors including pretreated *vs* naïve condition[3] and interleukin 28B polymorphism[6].

The economic impact of this new approach to HCV treatment can be very substantial since it has been estimated that around 120 million euros per year are needed in a country with 60 million inhabitants[5], and this figure seems to be confirmed by the recent sales in the United States where these "third" drugs have already been available[7].

The predicted expenditure for the "third" drug (irrespective of whether it is boceprevir or telaprevir) is likely to be at least 20 000 euros per patient[5]. Since this is also the typical expenditure for target therapies in oncologic

patients, decision-makers will have to face the competition for the same pharmaceutical budget between oncologic innovative treatments approved recently (e.g., ipilimumab for metastatic melanoma) and the triple therapy for genotype-1 hepatitis C.

The typical benefit of the latest oncologic treatments is a gain of 2-4 mo of survival per patient[8]; their pharmacoeconomic profile suggests an expenditure of 20 000 euros to gain up to a 4-mo survival, i.e., a cost-effectiveness ratio of 5000 euros per month or 60 000 euros per year.

Contrasting the cost-effectiveness between oncologic treatment and the triple therapy implies the need to compare the short-term benefits observed in oncologic patients (e.g., survival prolongation in metastatic melanoma from 6 mo without ipilimumab to 10 mo with ipilimumab) with the benefits in HCV patients that are instead known to take place at least 10 years after treatment.

The discount rate is the typical method employed in cost-effectiveness studies to convert future clinical benefits into their present value[9-14]. In the United States, rates around 5% or 6% per year were suggested nearly 20 years ago, but later various panels of experts revised this suggestion by proposing an annual rate of 3%[9,10]. In the United Kingdom, the National Institute of Clinical Excellence initially chose to use 3.5% per year[11], but in August 2011 this value was re-determined as 1.5% per year at least in some cases[15].

Several years ago, the pharmacoeconomic studies comparing dual therapy *vs* interferon alone led to the development of numerous models[16-19] based on the Markov technique that were aimed at predicting the natural history of the disease with or without achievement of post-treatment sustained virologic response (SVR). Although the number of simulation models for hepatitis C published in the past is exceedingly high, the systematic review by Hartwell *et al*[19] confirms that the models initially developed by Bennett *et al*[16] and by Shepherd *et al*[17,18] remain still valid to carry out a thorough comparative assessment of the new *vs* old treatments.

The choice of specific values of yearly discount rates

is the key factor influencing the model's outcome (Table 1). For this reason, we have summarized the different effects determined by the choice of different discount rates using a single simulation model among those reported in the literature.

The results of our analysis are shown in Figure 1. The values of quality-adjusted life years (QALYs) per patient have been calculated by examining five different assumptions of yearly discount rates (6%, 3.5%, 2%, 1.5% and 0%) and four SVR rates (0%, 40%, 70% and 100%). With regard to the SVR rates, the assumption of a 100% SVR has, of course, a purely hypothetical function, whereas the assumption of 0% SVR represent the option of no treatment. More importantly, the assumption of 40% SVR represents the typical outcome of dual treatment while 70% SVR is used to estimate the outcome of triple treatment, as well as other treatments that are currently under investigation, but will become available quite soon[2].

The information shown in Figure 1 clearly indicates that the effect of choosing different discount rates is very substantial. The gain between 100% SVR and 0% SVR (a purely hypothetical comparison) decreases from 4.47 QALYs with a 0% discount rate to 2.16 QALYs with a 6% discount rate (ratio between the two values =2.07). On the other hand, the gain between 70% SVR and 40% SVR decreases from 0.45 QALYs with a 0% discount rate to 0.22 QALYs with a 6% discount rate (ratio between the two values =2.04). These simulations have a general validity because they are only based on the clinical end-point of SVR, and therefore do not rely on specific assumptions in the patients whether are naive or pretreated. As shown in Figure 1, we could compute the value of QALYs per patient for any intermediate value of SVR (SVR$_{NN\%}$) in a range from 0% to 100% according to the equation: QALYs $_{SVRNN\%}$ = [QALY$_{SVR100\%}$ × NN + QALYs$_{SSVR0\%}$ × (100-NN)]/100. It should be noted that, in real practice as well as in model-based estimations, the favorable economic results of these treatments do not result only from the economic countervalue of the clinical benefit, but also from the savings derived from reduced morbidity. However, the latter factor was beyond the purposes of the present study.

In conclusion, our analysis has exclusively focused on the consequences of choosing different discount rates in estimating the magnitude of the clinical benefit of treatments for hepatitis C. Our results indicate that varying the discount rate within commonly accepted values can produce more than 2-fold variations in the estimates of the incremental benefit. This point should be kept in mind when regulatory agencies or third-part payers will be asked to determine the value-based price for the new treatments in this area.

World Journal of Gastroenterology

INSTRUCTIONS TO AUTHORS

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol, WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid

evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central, Digital Object Identifier, and Directory of Open Access Journals. ISI, Thomson Reuters, 2010 Impact Factor: 2.240 (35/71 Gastroenterology and Hepatology).

SPECIAL STATEMENT
All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including t test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (n). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the P value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/ study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, *P* < 0.001; CONCLUSION (no more than 26 words).

Key words
Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text
For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet. com/1007-9327/g_info_20100315215714.htm.

Illustrations
Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520. pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http:// www.wjgnet.com/1007-9327/13/4986.pdf; http://www. wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables
Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations
Data that are not statistically significant should not be noted. $^aP < 0.05$, $^bP < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^cP < 0.05$ and $^dP < 0.01$ are used. A third series of *P* values can be expressed as $^eP < 0.05$ and $^fP < 0.01$. Other notes in tables or under illustrations should be expressed as ^1F, ^2F, ^3F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-beled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

REFERENCES
Coding system
The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI
Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi. nlm.nih.gov/sites/entrez?db=pubmed and http://www.cross-ref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references
Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634   DOI: 10.3748/wjg.13.5396].

Style for book references
Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/ g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation
The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form
Please download a Copyright assignment form from http://

www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers
Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support
For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript
WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases
Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee
WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

ABOUT COVER

Editorial Board Member of *World Journal of Gastroenterology*, Tamara Vorobjova, MD, PhD, Senior Researcher in Immunology, Department of Immunology, Institute of General and Molecular Pathology, University of Tartu, Ravila 19, 51014 Tartu, Estonia

AIM AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

Acute kidney injury (AKI), defined as an abrupt increase in the serum creatinine level by at least 0.3 mg/dL, occurs in about 20% of patients hospitalized for decompensating liver cirrhosis. Patients with cirrhosis are susceptible to developing AKI because of the progressive vasodilatory state, reduced effective blood volume and stimulation of vasoconstrictor hormones. The most common causes of AKI in cirrhosis are pre-renal azotemia, hepatorenal syndrome and acute tubular necrosis. Differential diagnosis is based on analysis of circumstances of AKI development, natriuresis, urine osmolality, response to withdrawal of diuretics and volume repletion, and rarely on renal biopsy. Chronic glomerulonephritis and obstructive uropathy are rare causes of azotemia in cirrhotic patients. AKI is one of the last events in the natural history of chronic liver disease, therefore, such patients should have an expedited referral for liver transplantation. Hepatorenal syndrome (HRS) is initiated by progressive portal hypertension, and may be prematurely triggered by bacterial infections, nonbacterial systemic inflammatory reactions, excessive diuresis, gastrointestinal hemorrhage, diarrhea or nephrotoxic agents. Each type of renal disease has a specific treatment approach ranging from repletion of the vascular system to renal replacement therapy. The treatment of choice in type 1 hepatorenal syndrome is a combination of vasoconstrictor with albumin infusion, which is effective in about 50% of patients. The second-line treatment of HRS involves a transjugular intrahepatic portosystemic shunt, renal vasoprotection or systems of artificial liver support.

INTRODUCTION

The best known cause of azotemia in patients with decompensated liver cirrhosis is functional vascular renal insufficiency, which is an indirect consequence of severe peripheral arterial vasodilatation with coexistent hyperstimulation of powerful vasoconstrictor systems. Acute kidney injury (AKI) linked to this mechanism may assume a prerenal form, hepatorenal syndrome (HRS) or acute tubular necrosis (ATN). Differentiation among these three main causes of AKI has important prognostic and therapeutic implications. The diagnosis may be, however, difficult because the clinical presentations are similar and one form may convert to another . Patients with cirrhosis may also have chronic renal failure resulting from

different mechanisms including renal hypoperfusion (type 2 HRS) and glomerulonephritis, related to immune or metabolic factors (Table 1).

This review covers the pathophysiological conditions leading to renal hypoperfusion in the setting of portal hypertension, and the entire spectrum of acute and chronic renal diseases in chronic liver injury.

DEFINITIONS OF AKI AND HRS

AKI is defined by the AKI Network as an abrupt (within 48 h) reduction in kidney function manifested by an absolute rise of serum creatinine of at least 0.3 mg/dL (26 μmol/L) or the equivalent to a percentage increase of 50% (1.5-fold) from baseline, or a urine output < 0.5 mL/kg per hour for > 6 h[1]. In patients with cirrhosis in whom serum creatinine levels are regularly decreased, the initial stages of AKI are commonly overlooked as increases in creatinine levels occur within the range of reference values.

HRS is a specific form of AKI that may be diagnosed only in a situation when hypercreatininemia is associated with decompensated cirrhosis (mostly in patients with diuretic-resistant ascites) or acute liver failure. Other necessary diagnostic criteria ("major criteria"), updated in 2007 by the International Ascites Club[2], include: (1) serum creatinine level > 1.5 mg/dL (133 μmol/L); (2) no improvement in serum creatinine level (decrease to 1.5 mg/dL or less) evaluated after at least 2 d under diuretic withdrawal and volume expansion with albumin given at a dose of 1 g/kg per day; maximum 100 g; (3) absence of parenchymal kidney disease as indicated by proteinuria > 500 mg/d and microhematuria > 50 red blood cells per high power field; (4) exclusion of urinary tract outflow disturbances (normal renal ultrasonography); (5) no current or recent treatment with nephrotoxic drugs or vasodilators; and (6) absence of septic or hemorrhagic shock. Less important and not regularly occurring diagnostic features of HRS ("minor criteria") are urine volume < 400 mL/d, low sodium concentration in the serum (< 130 mEq/L) and urine (< 10 mEq/L).

There are two types of HRS. In type 1, renal function deteriorates rapidly with doubling of the initial serum creatinine level to > 2.5 mg/dL (220 μmol/L) in < 2 wk. Development of type 1 HRS may be preceded by type 2 HRS, which is a chronic renal failure lasting several weeks to months, with serum creatinine levels in the range of 1.5-2.5 mg/dL. The annual risk of type 1 HRS development in patients with decompensated cirrhosis is about 20%, and within 5 years, it increases to 40%[3,4]. Some authors have singled out a type 3 HRS, which is an overlap of functional renal failure on an already existing chronic or acute intrinsic kidney disease. In differential diagnosis, it is important to consider that some kidney diseases are genetically linked with specific liver pathologies (e.g., autosomal dominant renal polycystic syndrome and oxalosis), and certain systemic diseases simultaneously affect the liver and kidneys (Table 2)[2].

Table 1 Causes of renal failure in chronic liver disease

Acute	Chronic
Hypovolemia (diuretics, hemorrhage, diarrhoea)	Hepatorenal syndrome - type 2
Hepatorenal syndrome - type 1	Glomerulonephritis (HCV infection)
Acute tubular necrosis	Glomerulonephritis (HBV infection)
Nephrotoxic agents (NSAIDs, aminoglycosides, radiological contrasts)	Immunoglobulin A nephropathy[1]
Sepsis	Diabetic nephropathy[2]

[1]Mainly in alcoholic cirrhosis; [2]Mainly combined with non-alcoholic steatohepatitis. NSAIDs: Non-steroidal anti-inflammatory drugs; HBV: Hepatitis B virus; HCV: Hepatitis C virus.

Table 2 Clinical conditions leading to concomitant liver and renal injury

Drug-induced hepato-nephrotoxicity (acetaminophen, aspirin, NSAIDs)
Granulomatous diseases (e.g., sarcoidosis, leptospirosis)
Storage diseases (e.g., amyloidosis)
Systemic autoimmune diseases (e.g., lupus erythematosus)
Non-alcoholic fatty liver disease and diabetic nephropathy
Autosomal dominant polycystic kidney disease
Wilson's disease
Pregnancy-induced liver diseases (pre-eclampsia /HELLP syndrome)
Shock (cardiac failure, sepsis, hemorrhage, dehydration)
Alpha1-antitrypsin deficiency

NSAIDs: Non-steroidal anti-inflammatory drugs; HELLP: Hemolysis, elevated liver enzymes, low platelet count.

KIDNEY FUNCTIONING IN PORTAL HYPERTENSION

Renal blood perfusion and the glomerular filtration rate (GFR) depend on systemic and local factors such as cardiac output, systemic mean arterial pressure, basal muscular tone of renal arterioles, renal vascular autoregulation and intra-abdominal pressure. All these factors are considerably affected by end-stage liver cirrhosis as, in this disease, the mean arterial pressure is decreased, the renal adrenergic tone is enhanced, cardiac performance is diminished as a consequence of chronic heart overload, renal synthesis of vasoprotective peptides is reduced, and intra-abdominal pressure increases due to accumulating ascites.

Splanchnic vasodilatation

In patients with decompensated cirrhosis, arterial vasodilatation affects many vascular territories such as the skin, skeletal muscles, brain and lungs. However, it is most accentuated in the splanchnic area involving the intestines, pancreas and mesentery[5]. On one hand, the pathophysiological significance of splanchnic vasodilatation relies on the maintenance of a high portal pressure and, on the other hand, on disturbances of hemodynamic homeostasis in systemic circulation.

Splanchnic vasodilatation appears in the early stages of cirrhosis, however, it remains masked by increased

Figure 1 Pathogenesis of hepatorenal syndrome with possible triggering factors. SIRS: Systemic inflammatory response syndrome; NSAIDs: Nonsteroidal anti-inflammatory drugs.

cardiac output. At this point, the GFR is increased and glomeruli may be hypertrophied[5,6]. Splanchnic vasodilatation increases along with the progression of liver injury, portal hypertension and mesenteric angiogenesis. In advanced cirrhosis, the hyperkinetic cardiac function characterized by high stroke volume and tachycardia is no longer able to compensate for significant enlargement of the arterial vascular compartment. The disproportion between the blood volume and capacity of the arterial vascular tree leads to reduction of the effective blood volume and arterial pressure. In this setting, the baroreceptors located in the central circulation trigger hyperstimulation of the sympathetic system, renin-angiotensin-aldosterone axis and hypothalamic vasopressin secretion[7]. These adaptive mechanisms help to maintain arterial blood pressure at a safe level. Another mechanism contributing to this adaptation is renal retention of sodium and water. Endogenous vasoconstrictors have limited impact on the splanchnic arterial system, due to its intrinsic hyporeactivity[8]. By contrast, they strongly constrict renal arterioles initiating functional renal failure. The contributing mechanism to renal hypoperfusion is failure of renal vascular autoregulation, having its source in the impaired synthesis of vasodilators within the kidney (mainly prostaglandin E) and increased local release of angiotensin Ⅱ and endothelin[9,10]. The chronology of pathophysiological events underlying HRS is shown in Figure 1.

Substances most commonly incriminated in splanchnic vasodilatation are the intestinal and pancreatic vasoactive peptides, which reach the systemic circulation through portosystemic collaterals. Among compounds having myorelaxing properties are glucagon, vasoactive intestinal peptide, adrenomedulin, endogenous cannabinoid receptor agonists, substance P, natriuretic factor and carbon monoxide[11]. Major attention, however, has been focused on endothelial factors; that is, nitric oxide (NO) and prostacyclin. Results of many studies have provided evidence for increased production of NO in the arterial vascular system, as in cirrhosis, both the constitutive and inducible isoforms of NO synthetases are activated[12].

Portal cardiomyopathy
Cardiac failure in cirrhosis, named portal cardiomyopathy, has a functional background and disappears after liver transplantation. It comprises systolic and diastolic dysfunctions, mainly of the left heart chamber, and electromechanical abnormalities including a prolongation of the Q-T interval. Diastolic heart dysfunction precedes abnormalities of systolic cardiac performance. Left ventricular end-diastolic pressure is elevated in patients with decompensated cirrhosis[13]. Rapid hemodynamic changes occurring, for example, after a transjugular intrahepatic portosystemic shunt (TIPS), or liver transplantation may cause a striking increase in filling pressure favoring the development of congestive heart failure.

At rest, the portal cardiomyopathy is camouflaged by a low afterload (low peripheral vascular resistance), but limited cardiac reserve may be unveiled by hemodynamic stress (e.g., physical activity, TIPS, voluminous intravenous infusion or use of vasoconstrictor), which is followed by significantly lower increments in the stroke volume than in healthy persons[14].

Severe infections resulting in septic shock syndrome are known to induce cardiodepression due to the emergence of inflammatory mediators having negative inotropic effects. Reduction of cardiac output and inadequate cardiac contractile response to inflammatory stress is an important cause of HRS development in patients with end-stage liver cirrhosis. Ruiz-del-Arbol *et al*[15] have studied a group of 23 patients with spontaneous bacterial peritonitis (SBP) that was treated with antibiotics. The eight patients who developed HRS had significantly lower baseline cardiac output than the 15 patients without renal dysfunction. In the subgroup of patients with HRS, the cardiac output further declined with a concurrent drop in arterial pressure.

Ascites
Liver cirrhosis is associated with hypervolemia as a consequence of renal sodium retention. In conditions of splanchnic vasodilatation and increased cardiac output, the blood is preferentially pooled in the portal venous system. High hydrostatic pressure in this system accompanied by hypoalbuminemia is responsible for plasma escape from the vascular compartment to the peritoneal cavity. This phenomenon mainly occurs at the level of sinusoidal vessels and to a lesser degree at intestinal capillaries.

Ascites is responsible for a worsened quality of life, risk of SBP and renal failure[7]. The independent variables of mortality in ascitic patients are Child-Pugh class C,

Figure 2 Hemodynamic and neurohormonal consequences of progressive vasodilatation in splanchnic vascular territory. hyponatremia renal failure and, as has recently been suggested, β-blocker therapy[16].

Tense ascites causes an increase in intra-abdominal pressure, giving rise to abdominal compartment syndrome, which is a known risk factor for AKI developing in critically ill patients with acute abdominal disorders such as peritonitis, acute pancreatitis, ileus, trauma or after urgent abdominal surgeries[17]. Intra-abdominal pressure > 20 mmHg, measured in the urinary bladder, leads to severe impairment of renal venous blood flow and secondary disturbances in arterial perfusion of the kidneys[18].

Fluid removal in volume-overloaded patients with decompensated heart failure (refractory to intensive medical therapy) caused an improvement in renal function corresponding to a reduction of persistently elevated intra-abdominal pressure[19]. Knowledge of the actual influence of tense ascites on kidney function in cirrhosis is not complete. It has been shown in pilot studies that large-volume paracentesis (LVP) followed by intravenous administration of albumin ameliorates renal function in patients hospitalized for HRS or esophageal varices bleeding[20-22]. LVP should be followed by diuretics to prevent reaccumulation of fluid.

FACTORS TRIGGERING HRS

HRS develops spontaneously in about 50% of cases and it is triggered by identifiable factors dependent or independent of medical activities in the remaining cases. Pathogenesis of HRS with triggering factors is shown in Figure 2.

Bacterial infections
Patients with cirrhosis have a particular predisposition to bacterial infections that is mostly a result of impaired

reactivity of reticuloendothelial cells and neutrophils. Bacterial infections develop in 30%-60% of patients with cirrhosis, being responsible for about 25% of overall mortality in this disease[23]. The most common site of infection is the ascitic fluid, and less frequent are the respiratory system, urinary tract or subcutaneous tissue. Gastrointestinal bleeding, irrespective of its source, is associated with increased translocation of intestinal bacteria through ischemic mucosa and very high risk of SBP.

Bacterial infection induces HRS because of aggravation of splanchnic arterial vasodilatation and deterioration of liver function by endotoxemia and cytokine overproduction. Type 1 HRS commonly develops in patients with SBP, especially in those with serum bilirubin levels > 4 mg/dL (68 μmol/L) or serum creatinine levels > 1 mg/dL (88 μmol/L) - that is, in patients with pre-damaged kidneys by type 2 HRS or by other causes[24].

In a randomized trial comparing daily norfloxacin with placebo, it was demonstrated that a low content of protein in the ascitic fluid (< 1.5 g/dL) and severe liver disease indicated a beneficial effect of this antibiotic on the development of SBP and survival[25]. It seems reasonable to use norfloxacin (or trimethoprim/sulfamethoxazole) continuously in patients that meet these criteria[26].

Systemic inflammatory response syndrome
Inflammation developing in cirrhotic patients has been shown to favor serious complications specific for liver failure and portal hypertension, including HRS[27,28]. Systemic inflammatory response syndrome (SIRS) is mostly triggered by overt or occult bacterial infection but also may result from activation of the inflammatory pathways related to circulating endotoxins or proinflammatory mediators. Accordingly, SIRS occurs in many nonbacterial abdominal acute inflammatory diseases such as pancreatitis, alcoholic steatohepatitis or portal venous thrombosis. It is also speculated that SIRS may be induced by liver necrosis associated with a "spill over" of inflammatory mediators of hepatic origin. All these conditions generate production of proinflammatory cytokines [e.g., tumor necrosis factor-α (TNF-α)], which enforce the endothelial cells to produce more NO, playing an important role in the pathogenesis of arterial vasodilatation.

According to the American Society of Critical Care Medicine Consensus Conference, SIRS is diagnosed if the patient fulfills at least two of the following criteria: (1) core temperature > 38 ℃ or < 36 ℃; (2) heart rate ≥ 90 beats per minute; (3) respiratory rate ≥ 20 breaths per minute; or (4) white blood cell count ≥ 12 G/mm^3 or ≤ 4 G/mm^3 with a differential count showing ≥ 10% immature polymorphonuclear neutrophils[29]. An important limitation for use of these criteria is the fact that many of them may be modified by cirrhosis itself.

Diarrhea and vomiting
Diarrhea and vomiting lead to dehydration and hypovolemia, which can aggravate the hemodynamic disturbances responsible for the development of HRS. Diarrhea is a common problem associated with alcoholism. More-

over, the diarrhea and vomiting occur as a consequence of infectious diseases but also may have an iatrogenic background. Diarrhea is a side effect of drugs commonly used in cirrhotic patients, such as lactulose or ursodeoxycholic acid. An increased number of bowel movements in patients with decompensated cirrhosis should prompt the withdrawal or dose reduction of these drugs.

Diuretics

Patients with peripheral edema tolerate aggressive diuresis because the fluid from the subcutaneous tissue is easily absorbed to the intravascular system. In such patients, the daily reductions of body weight may reach 2 kg. Using high doses of diuretics following the disappearance of peripheral edema frequently leads to hypovolemia, which initiates the development of HRS. In patients with ascites without peripheral edema, the urinary output should not be higher than 1100 mL/d, with diurnal reductions of the body weight not exceeding 0.5 kg. This principle originates from the fact that the diurnal ability of ascites to relocate from the peritoneal cavity to the vascular system is limited to 700-900 mL, and in the setting of postinflammatory peritoneal lesions, this limitation is even more severe. Diuretics should be discontinued if the serum creatinine is > 2.0 mg/dL (180 μmol/d) and serum sodium is < 120 mEq/L, despite fluid restriction, or in the case of encephalopathy[26,30]. Intravenous use of furosemide is not recommended as a dose of 80 mg has been shown to cause an acute reduction in renal blood flow and subsequent azotemia in patients with cirrhosis and ascites[26].

Gastrointestinal bleeding

Patients with cirrhosis carry a significant risk of bleeding from the upper digestive tract. The most likely sources of bleeding are esophageal/gastric varices, portal gastropathy or gastroduodenal peptic ulcers. A 2-year risk of bleeding from large esophageal varices in patients who never bled was 25%-30%, and in those who had at least one episode of bleeding in the past exceeded 60%[31]. Acute bleeding from the upper digestive tract leads to hypovolemia and a decrease of renal perfusion. The probability of HRS development in bleeding patients depends on the amount of blood loss, the functional reserve of the liver, and the presence of bacterial infection. In one study, hemorrhagic shock and HRS were independent risk factors of in-hospital mortality. If HRS developed in a bleeding patient, the mortality rate was 55% (3% in patients without renal failure)[32].

LVP

LVP is considered to be a relatively safe and effective procedure for the treatment of refractory ascites. However, removal of > 5 L of fluid without blood volume expansion may lead to paracentesis-induced circulatory dysfunction (PICD). Ascitic patients show increased heart rate and cardiac output and low diastolic arterial pressure, which are accentuated after LVP[33-35]. Mechanisms of

PICD are not entirely clear, but LVP causes further reduction of volemia in the central circulation with simultaneous stimulation of all vasoconstrictive systems, having a deleterious effect on renal function. According to earlier studies, HRS develops in about 10% of cirrhotic patients treated with LVP[36]. It has been recently shown that use of β-blockers may be associated with an increased risk of PICD in patients with cirrhosis and refractory ascites[37].

Recognition of PICD is based on finding a significant increase in plasma renin activity (> 50% of pretreatment values on days 5-7 after paracentesis). According to this definition, Nasr *et al*[38] recognized PICD in 73.3% of patients with tense ascites despite volume expansion (with dextran in 87.5% and with albumin in 38.5% of patients). In this study, PICD was a clinically silent complication with no clinical or laboratory predictive factor.

At present, salt-free human albumin is the plasma expander of choice, if at least 5 L of ascitic fluid is evacuated. The role of vasopressors in PICD escape is still uncertain. In the randomized study including 24 patients with decompensated cirrhosis, midodrine was not as effective as albumin in preventing PICD, because this syndrome developed in six patients in the midodrine group (60%) and in only four patients (31%) in the albumin group[39]. By contrast, in two randomized studies with 20 and 40 ascitic patients, terlipressin and midodrine were not less effective than albumin for prevention of PICD[40,41].

Nonsteroidal anti-inflammatory drugs

Renal perfusion in advanced cirrhosis greatly depends on vasoprotective mechanisms attributed to prostaglandin E2 and prostacyclin ("prostaglandin dependency"). Nonsteroidal anti-inflammatory drugs (NSAIDs) inhibit renal synthesis of prostaglandins, therefore, they impair vasoprotective mechanisms. Generally, NSAIDs should be avoided in patients with cirrhosis because in this population, they induce renal failure in 33% of patients (3%-5% in the population with an intact liver)[42]. Moreover, NSAIDs are responsible for the development of resistance to diuretics[43]. Renal complications are also observed after use of selective cyclo-oxygenase 2 antagonists such as celecoxib and rofecoxib. Even short-term therapy with celecoxib induces significant reduction in GFR in patients with decompensated cirrhosis[44].

Hypotensive drugs

In patients with advanced liver cirrhosis, the homeostasis of arterial pressure is highly dependent on adaptive neurohormonal mechanisms. Administration of drugs inhibiting these mechanisms; that is, inhibitors of angiotensin converting enzyme (ACE), angiotensin II receptor antagonists or clonidine, increases the risk of a significant reduction in arterial pressure, resulting in functional renal failure. These drugs may affect renal function irrespective of arterial hypotension. It has been shown that the administration of small doses of ACE inhibitors, having no effect on arterial pressure, cause a significant decline

in GFR[45]. However, not all studies have confirmed the harmful effects of anti-angiotensin drugs on the kidneys[46,47].

THERAPEUTIC STRATEGIES IN HRS

Treatment of renal failure in advanced liver cirrhosis aims to abate the most important pathophysiological factors responsible for the development of HRS. The first-line treatment is focused on reduction of portal hypertension and counteracting the arterial vasodilatation and effective hypovolemia, by vasoconstrictor and albumin infusion. The second-line treatment involves a reinforcement of renal vasoprotection, kidney replacement therapy or artificial liver support.

Repletion of the vascular system

Albumin is the preferred volume expander in patients with renal failure. Except for augmentation of oncotic pressure, the albumin binds endotoxins, bile acids, bilirubin, fatty acids and NO; therefore, it joins metabolic, immune and vasoconstrictor effects[48,49]. Albumin should be infused in high percentage solutions (20%-25% albumin) and the typical dosage is 1 g/kg (up to 100 g) on day 1, and 20-60 g/d thereafter.

Use of albumin may prevent the development of HRS. In a non-placebo-controlled study, the plasma volume expansion with albumin has been shown to reduce the incidence of renal failure in cirrhotic patients hospitalized for SBP as compared with antibiotic monotherapy[24]. Moreover, an unblinded randomized controlled trial in patients with new-onset ascites demonstrated that weekly 25-g infusions of albumin for 1 year followed by infusions every 2 wk improved survival compared to treatment with diuretics alone[50]. By contrast, treating HRS with albumin monotherapy is only minimally effective, but adding albumin to vasoconstrictors provides a supplementary benefit. In a recent study, 46 patients with HRS were randomly assigned to treatment with terlipressin plus albumin or to albumin monotherapy[51]. Renal function improved in 43.5% of patients treated with terlipressin plus albumin, and in only 8.7% of patients treated with albumin alone.

Elevation of peripheral vascular resistance

Many pharmaceutical agents, predominantly vasoconstrictors along with albumin infusion, have been studied in patients with type 1 HRS. These studies are based on controlled or uncontrolled short case series. Splanchnic vasoconstrictors improve effective arterial blood volume and paradoxically dilate renal vasculature. The optimal choice of vasoconstrictor, time for initiation and duration of therapy and most favorable dosage remains to be determined. Vasoconstrictor drugs should not be given to patients with ischemic disease of the heart, brain or lower extremities. Their use is also contraindicated in patients with heart failure, cardiac arrythmias, asthma or respiratory failure.

Terlipressin is a synthetic analog of vasopressin that is characterized by a longer half-time (i.v. administration every 4-6 h) and fewer side effects (ischemic complications occurring in 5%-12% of patients) in comparison with the parent drug[52-54]. Although terlipressin is only a partial agonist of renal vasopressin V2 receptors, an acute reduction in serum sodium concentration is a common finding during use of this drug, and is sometimes associated with reversible neurological complications[55].

Treatment with terlipressin and albumin leads to the normalization of renal function in 34%-65% of patients with type 1 HRS and the recurrence of HRS after treatment withdrawal occurs in 15%-22% of cases[52,55-60]. The most applicable predictor of HRS reversal seems to be baseline serum creatinine[61]. Terlipressin plus albumin therapy increases short-term survival by 34%-43%[56-58]. In a multivariate analysis, the predictors of improved survival at 6 wk were: a significant reduction in serum creatinine between baseline and day 4, a serum level of bilirubin < 10 mg/dL and a treatment-induced increase of the mean arterial pressure by > 5 mmHg[62]. However, not all studies have shown survival benefits for terlipressin. A European multicenter, randomized, controlled trial of terlipressin and albumin *vs* albumin monotherapy in 46 patients with both types of HRS demonstrated an improvement in renal function but no survival advantage at 3 mo[50]. Hence, liver transplantation is still the optimal therapy for HRS, and use of terlipressin is considered as a bridge to transplantation. According to recent recommendations of American Association for the Study of Liver Diseases, patients with type 1 HRS should have an expedited referral for liver transplantation[26].

Somatostatin is a hormone that, in pharmacological doses, decreases splanchnic arterial blood flow. This effect is not a result of intrinsic vasoconstrictive properties, but rather comes from inhibitory effects on the release of vasoactive intestinal and pancreatic peptides. Compared with terlipressin, somatostatin exerts a less beneficial effect on renal sodium excretion in patients with or without ascites[63]. Octreotide is a synthetic analog of somatostatin, with similar hemodynamic effects. Two studies, including one with randomization and a crossover design, demonstrated that octreotide alone is not effective for type 1 HRS[64,65]. Acute administration of octreotide to cirrhotic patients, with or without ascites, did not produce any change in the GFR or in the estimated renal plasma blood flow[66]. Unfortunately, octreotide significantly decreased the free water clearance and fractional excretion of filtered sodium[67]. Also chronic use of octreotide had no renoprotective effects, because improvement in renal blood flow was associated with a reduced GFR[68].

Midodrine is an oral α1-adrenergic agonist with vasoconstrictive properties. In three pilot studies involving 79 patients with type 1 HRS, short-term administration of midodrine in conjunction with octreotide caused significant changes in systemic hemodynamics and normalization of renal function in 49% of patients[69-71]. It is unknown whether these beneficial effects are attributable

to midodrine alone or also to the potentiating effects of octreotide. However, favorable renal effects of this regimen may disappear under chronic treatment. In 1 mo therapy of refractory ascites with midodrine, octreotide and albumin, significant reductions in the plasma renin and aldosterone concentrations were found, but renal function tests were not improved[72]. In a retrospective study involving 60 patients with type 1 HRS treated with midodrine, octreotide plus albumin and 21 nonrandomized albumin-treated controls, the 30-d mortality was reduced in the treatment group (43% *vs* 71%, respectively, $P < 0.05$)[69].

The regimen composed of midodrine, octreotide and albumin may be used outside of an intensive care unit. This is not the case for norepinephrine, which requires continuous intravenous infusion and hemodynamic monitoring. This drug is infrequently used in treatment of HRS, although efficacy of norepinephrine in reversal of renal failure may be not inferior to terlipressin[73].

Renal vasoprotection
Apart from systemic causes, the development of HRS in decompensated cirrhosis is dependent on the failure of local vasoprotective factors. Until now, no drugs enforcing renal vasoprotection have been used as routine treatment for HRS. Although earlier studies have suggested the reversal of HRS during treatment with misoprostol, a prostaglandin E1 analog[74], the high doses and side effects have prevented this drug from use in cirrhotic patients.

Pentoxifylline is an inhibitor of TNF-α, which plays a major role in the pathogenesis of alcoholic hepatitis and endotoxin-mediated liver injury[75]. Meta-analysis of five trials, with a total of 336 randomized participants with alcoholic hepatitis, showed a positive effect of pentoxifylline on mortality associated with HRS[76]. The usefulness of pentoxifylline in other liver diseases is unclear. In a recent French study, the chronic peroral use of pentoxifylline (400 mg, 3 times daily) in patients with advanced cirrhosis of a different etiology did not decrease short-term mortality, however, it reduced the risk of complications (including AKI) at 2 mo and 6 mo[77].

TIPS
Implantation of TIPS augments the return of blood to the right heart, thus it counteracts the central hypovolemia and neurohormonal activation. In several studies, the plasma renin activity, norepinephrine concentrations and excretion of sodium improved gradually after insertion of the TIPS[78-80]. In a large study involving 129 cirrhotic patients with varying degrees of baseline renal function, TIPS has been shown to improve renal function. Patients with pre-treatment serum creatinine levels between 1.2 and 1.9 mg/dL had reduced mean levels of creatinine, from 1.5 to 1.1 mg/dL, and those with pre-TIPS creatinine levels > 2.0 mg/dL showed a reduction from 2.8 to 1.5 mg/dL. This means that patients with poorer renal function benefit the most from TIPS[81]. A meta-analysis

including five randomized controlled trials (330 refractory ascites patients) showed that TIPS improved survival when compared with repetitive paracenteses[82].

Decision on insertion of TIPS must be balanced against the risk of complications, which include: (1) portal encephalopathy; (2) liver insufficiency; (3) loss of stent function; (4) cardiac failure; (5) bacteremia; (6) hemolysis; or (7) bacterial infection of the stent[83,84].

Renal replacement therapy
Continuous or repeated dialysis may be considered as rescue therapy for patients with type 1 HRS, in whom pharmacological treatment is ineffective and there are no contraindications for liver transplantation. Independent indications for use of dialysis are hypervolemia not responding to diuretics, metabolic acidosis and refractory hyperkalemia. Dialysis is a bridging therapy aimed at keeping the patient alive until receiving the graft. A more recent study has reported that eight of 30 patients with HRS survived 30 d with use of dialysis or continuous venovenous hemodialysis in the intensive care unit setting[85].

In patients with cirrhosis, the hypotensive reactions and blood clotting abnormalities are more frequent during dialysis than in patients with an intact liver. Peritoneal dialysis may be better tolerated by cirrhotic patients than hemodialysis, with no increase in the number of complications[86]. This procedure enables removal of the ascites fluid and does not expose patients to anticoagulants.

Patients who are on continuous renal replacement therapies require anticoagulation to prevent thrombosis. Different anticoagulants have been used to ensure the patency of hemodialysis catheters. In patients who are at high risk for bleeding, nonstandard preventive options are applied, such as minimum-dose or no-heparin regimens or regional citrate anticoagulation, which are associated with low risks of bleeding and severe dialyzer clotting[87]. Sodium citrate is metabolized by the liver and the body clearance of this compound has been shown to be significantly reduced in critically ill cirrhotic patients. In addition, citrate clearance cannot be predicted by standard liver function tests and is not influenced by renal function[88]. It is, therefore, advisable to minimize the dose of citrate anticoagulation and monitor serum ionized calcium level and blood pH in hemodialyzed cirrhotic patients.

Systems for artificial liver support
At present, there are a few systems of artificial liver support, such as: Molecular Adsorbent Recirculating System (MARS), Fractionated Plasma Separation, Adsorption and Dialysis System and Single-Pass Albumin Dialysis Extended. These systems are designed to remove from the blood toxins, which are soluble in water and are adsorbed on albumin molecules. It seems that this kind of therapy may only achieve a temporary improvement in metabolic abnormalities that result from liver and kidney insufficiencies.

Figure 3 Differential diagnosis of three forms of acute kidney injury in patients with decompensated cirrhosis. SBP: Spontaneous bacterial peritonitis; Cr: Creatinine; HRS-1: Type 1 hepatorenal syndrome; ATN: Acute tubular necrosis; U$_{Osm}$: Urine osmolality; U$_{Na}$: Urinary sodium.

In pilot studies, MARS caused a statistically significant decrease of serum bilirubin and creatinine levels in patients with type 1 HRS who were disqualified from other forms of treatment. In addition, in a randomized study, the use of MARS led to increases of arterial blood pressure and urinary sodium output[89]. However, in a recent small study comprising six patients with type 1 HRS not responding to vasoconstrictor treatment, MARS was shown to be ineffective regarding systemic hemodynamics and renal function[90]. Experience with other artificial liver support systems in HRS treatment is limited[91]. Patients undergoing treatment with adsorbent recirculating systems can experience declines in blood pressure, hypothermia, bradycardia, tissue hypoxia or blood clotting abnormalities associated with use of anticoagulants.

INTRINSIC RENAL DISEASES

Epidemiological data suggest that AKI in cirrhosis has a prerenal origin in 60% of cases, and only one third of these patients fulfills the criteria of type 1 HRS[92]. Intrinsic renal injury in the form of ATN may be responsible for about 40% of AKI in cirrhotic patients with ascites[93]. Type 2 HRS is the most common form of chronic renal disease. The Multidisciplinary Working Party has defined chronic renal disease as an estimated GFR < 60 mL/min for > 3 mo[94]. Chronic glomerular injury related to viral, immune and metabolic factors is usually an asymptomatic disease with mild proteinuria and hematuria. Occurrence of arterial hypertension in liver cirrhosis is a rare finding indicating a possibility of chronic glomerulonephritis. Among hospitalized patients with decompensated cirrhosis, chronic glomerulonephritis is responsible for about 1% of all causes of azotemia[92].

ATN

ATN should be suspected in all cases of AKI preceded by septic or posthemorrhagic shock, prolonged dehydration, severe pancreatitis, exposure to nephrotoxic substances (aminoglycosides, contrast agents) or major surgical interventions[95].

In clinical practice, the distinction between ATN and type 1 HRS may be difficult (Figure 3). Usually, in patients with HRS, the urinary concentration of sodium does not exceed 10 mEq/L (preserved tubular ability for sodium reabsorption and urine concentration), whereas in patients with ATN, it is > 20 mEq/L with urine osmolality < 350 mOsm/kg. However, these criteria may be misleading in certain cases. Another finding favoring a diagnosis of ATN is the presence of bile-stained granular or epithelial casts in the urine, but this finding is also not definitive[95]. It is expected that a positive response to a vasoconstrictor plus albumin should rule out a diagnosis of ATN, however, a recent study has demonstrated some benefit of terlipressin in patients with cirrhosis and ATN[55]. Studies on using urine biomarkers for ATN are underway and the most promising candidates are interleukin-18, urinary kidney injury molecule 1 and urinary neutrophil gelatinase-associated lipocalin[96,97].

Reduction in GFR in ischemic ATN results from injury to the tubular epithelium and impaired glomerular capillary pressure. An overlapping factor may be tubular obstruction from casts composed of detached epithelial cells and cellular debris as well as hemoglobin and myoglobin deposits[98]. ATN caused by ischemia lasts 7-21 d[99] and, in most patients, renal function returns to normal or near normal levels following regeneration of the tubular epithelium. Regenerating cells derive from the stem cells that have survived the ischemic insult. It is also likely that migrating bone marrow stem cells contribute to this process[100,101]. During ATN-related renal failure, patients should be treated with renal replacement therapy, which may last 6-8 wk if tubular damage is caused by toxic agents[92].

Nephrotoxic agents

Aminoglycoside antibiotics still constitute an important therapeutic alternative against germs that are insensitive to other antibiotics[102]. Nephrotoxicity is the most important therapeutic limitation of aminoglycoside antibiotics, especially gentamicin. The typical manifestation of aminoglycoside toxicity is nonoliguric or even polyuric renal dysfunction accompanied by proteinuria, hypercalciuria, hypermagnesemia, aminoaciduria, glycosuria, and serum electrolyte alterations[103]. Despite rigorous patient monitoring, kidney injury appears in 10%-25% of therapeutic courses. Traditionally, aminoglycoside nephrotoxicity has been considered to result mainly from tubular damage, but recently the role of reduced glomerular filtration has also been raised[104].

For patients with chronic liver diseases, the use of gentamicin or tobramycin considerably enhances the risk of damaging the tubules and onset of acute renal insufficiency[103,105]. The particular sensitivity of cirrhotic patients to aminoglycosides may be related to sodium depletion,

concomitant use of diuretics and reduced renal function. Other drugs that can lead to AKI are amphotericin, acyclovir, penicillin and cytostatics.

Use of contrast media is a well-known cause of tubular injury, particularly in the presence of predisposing conditions like dehydration or diabetic nephropathy. Mechanisms of contrast-induced nephropathy (CIN) are complex and not fully explained. It has been shown that renal blood flow remains 45% below baseline level for at least 4 h following contrast administration[106]. Renal vasoconstriction with medullary hypoxia may be mediated by high osmolality and viscosity of contrast agents, as well as the release of endothelin and adenosine[107]. The cytotoxic effects including the generation of oxygen free radicals are also considered. Currently used iodinated contrasts are either ionic and hyperosmotic (1400-1800 mosmol/kg) or nonionic iso- or low-osmolal, characterized by lower nephrotoxicity[108]. Application of contrast media in cirrhotic patients with hypercreatininemia is not recommended, because it is associated with a high risk of AKI. This applies to use of contrast in both diagnostic and therapeutic procedures[109]. Patients with cirrhosis and normal renal function do not seem to be hypersensitive to CIN. In a retrospective case-control study including 72 patients with cirrhosis and 72 patients without cirrhosis, the intravenous administration of 100-150 mL of low osmolality radiocontrast medium induced AKI in two patients with cirrhosis and one patient in the control group (difference not significant). The cirrhotic patients who developed CIN had received high-dose diuretics and were hypovolemic[110].

Chronic glomerulonephritis

The most common form of glomerular disease found in patients with chronic hepatitis C is membranoproliferative glomerulonephritis (MPGN)[111,112], followed by membranous nephropathy, focal glomerulosclerosis and immunoglobulin A (IgA) nephropathy[113-115]. In autopsy studies, the glomerular pathology was detected in more than half of hepatitis C patients. Histopathological features of MPGN were present in 11.2%, membranous nephropathy in 2.7%, mesangioproliferative glomerulonephritis in 17.6% and mesangial expansion without proliferation in 23.4% of deceased hepatitis C patients. Cirrhosis was associated with a higher percentage of inflammatory changes in glomeruli compared with the precirrhotic stage of liver disease (59.2% *vs* 32.3%)[116]. MPGN is associated with mixed essential (type Ⅱ) cryoglobulinemia. Renal biopsy revealed the presence of cryoglobulins in about 70% of hepatitis C patients with MPGN[117]. This finding strongly indicated an etiological relationship between cryoglobulinemia and MPGN.

Successful treatment of noncirrhotic hepatitis C patients with interferon-α is probably paralleled with a favorable effect on MPGN, because a positive response to treatment was associated with a significant reduction in serum levels of cryoglobulin and creatinine[118]. One study has shown the efficacy of rituximab in the treatment of type-Ⅱ-cryoglobulinemia-related MPGN in patients with hepatitis C[119].

MPGN, membranous nephropathy and polyarteritis nodosa create a wide spectrum of glomerular lesions found in patients infected with hepatitis B virus (HBV). The prevalence of glomerulonephritis among patients with chronic hepatitis B is significantly higher in endemic regions, where the hepatitis B surface antigen carrier state is common[120,121]. Chronic carriage of HBV leads to the development of nephrotic syndrome in some individuals (particularly children), with a strong male predominance. Studies showing expression of HBV viral antigens in kidney tissue confirm the role of the virus in the development of glomerulonephritis[120,122].

In children, the membranous nephropathy often retreats spontaneously, whereas in adults it may show rapid progression[120]. The main symptom of membranous nephropathy is nephrotic syndrome, with the cause not revealed until a renal biopsy is done. Retrospective analysis of clinical studies involving small groups of hepatitis B patients with membranous nephropathy or MPGN has indicated a beneficial role of antiviral therapy. Positive virological responses to treatment with interferon-α2-A or lamivudine were associated with significant improvement in renal function[123,124].

IgA nephropathy

IgA nephropathy is the most common form of primary glomerulonephritis in developed countries[125,126]. The disease may appear at any age with the highest prevalence in the second and third decade of life. The incidence of mesangial IgA deposition in apparently healthy individuals ranges from 3% to 16%[127]. Usually, IgA nephropathy is recognized on routine urine screening with asymptomatic hematuria and/or proteinuria. The diagnosis may be established only by renal biopsy that discloses globular IgA deposits in the mesangium, and to a lesser degree in the glomerular capillary walls (immunofluorescence microscopy)[125,128].

Class A immunoglobulins (with or without small quantities of other immunoglobulins and C3 complement) are found in glomeruli of 35%-90% of patients with liver cirrhosis[129]. In these patients, IgA nephropathy is usually subclinical and the features of nephrotic syndrome occur in about 1.5% of cases. Hematuria is found less frequently than in the primary form of IgA nephropathy. This type of nephropathy may be particularly common in patients with alcoholic cirrhosis, in whom IgA serum levels are regularly increased[130].

Isoform IgA2 is cleared from circulation with the participation of the hepatic asialoglycoprotein receptor, whereas IgA1 only partially uses this elimination pathway[131]. The pathogenesis of IgA nephropathy coexisting with liver cirrhosis is unknown, however, a hypothesis of reduced hepatic clearance of immunological complexes, due to impaired asialoglycoprotein receptor function and phagocytosis by Kupffer cells, is very likely. The direct influence of immunological mechanisms should also be

considered, as they play an important role, not only in autoimmune hepatitis, primary biliary cirrhosis and primary sclerosing cholangitis, but also in hepatitis B and C, alcoholic liver disease, primary hemochromatosis and α-1 antitrypsin deficiency[132-136].

Diabetic nephropathy

Diabetic nephropathy (DN) occurs in types 1 and 2 diabetes mellitus. The epidemiology of DN has been studied in type 1 diabetes. Twenty to thirty percent of this population presents with microalbuminuria 15 years after diabetes diagnosis and almost half of those patients will progress to overt nephropathy[137]. Development of DN is strongly dependent on the control of glycemia and arterial blood pressure. The aggressive treatment of arterial hypertension and use of ACE inhibitors have been shown to reduce the rate of DN progression[138]. In Caucasians with type 2 diabetes, the prevalence of progressive renal disease seems to be lower than in type 1[139], however, there are also some data suggesting that the risk of renal injury is currently equivalent in both types of diabetes[140,141].

The mesangial expansion, thickening of glomerular basement membrane and glomerular sclerosis belong to major histological changes of DN. The late abnormality is deposition of hyaline in the glomerular arterioles, which may assume a nodular appearance[142]. DN usually leads to arterial hypertension, renal arteriosclerosis, proteinuria and fluid retention. Patients with DN may tolerate less spironolactone because of hyperkalemia.

Among patients with cirrhosis related to HCV infection, diabetes occurs in about 25% of cases. Even more frequent is the occurrence of diabetes in patients with cirrhosis related to nonalcoholic steatohepatitis, which like diabetes, is a feature of the metabolic syndrome. The percentage of glucose intolerance in the population of patients with liver cirrhosis of different etiology approaches 60%[143,144]. For these reasons, DN is one of the most common causes of chronic renal failure in patients with cirrhosis. Diabetes promotes vascular pathology, hence, advanced atherosclerosis of the coronary arteries is recognized in 20%-25% of candidates for liver transplantation[145].

POSTRENAL INSUFFICIENCY

An obstruction in urine outflow as the cause of renal failure is found in < 1% of patients with liver cirrhosis. Postrenal causes of renal insufficiency are similar to those occurring in the general population. They include nephrolithiasis, benign prostatic hyperplasia in men, ureter infiltration by tumors of the reproductive organs in women, kidney tumors, or neurogenic urinary bladder. Patients with alcoholic liver disease seem to have an increased risk of renal papillary necrosis that, after sequestration, obstructs urine outflow[146]. The diagnosis of postrenal failure is based on imaging studies (i.e., ultrasound and computed tomography), which show urine retention or hydronephrosis. The aim of the treatment is removal or bypassing of the obstacle.

CLINICAL SIGNIFICANCE OF SERUM CREATININE

Parameters of renal function are strong predictors of survival in liver cirrhosis, because vascular-mediated renal failure is one of the latest events in the natural history of chronic liver disease. The median survival time in patients with type 2 HRS is about 5 mo, but with type 1 of this syndrome, is as short as 2-4 wk[25].

Generally, the creatinine level is not a perfect indicator of renal function as it is influenced by many nonrenal factors (e.g., body weight, age, sex, race and blood volume), shows a nonlinear relationship with GFR and does not distinguish between functional and organic renal diseases. Still, a less reliable indicator of renal function is the serum level of blood urea nitrogen, which is strongly modified by the diet or the presence of blood within the digestive tract.

The creatinine levels in patients with end-stage cirrhosis regularly overestimate the actual GFR because of decreased hepatic production of creatine and muscle wasting[24]. An additional factor responsible for low serum creatinine in decompensated cirrhosis is hypervolemia, and accordingly, the increased volume of distribution for this substance. For these reasons, the early stages of AKI usually remain unrecognized in cirrhotic patients. Moreover, in jaundiced patients, the measurement of creatinine may provide erroneous results due to chromogenic interference with bilirubin in a spectrophotometric assay[147]. Recently, it has been shown that, in cirrhotic patients, the serum concentration of creatinine being higher than 0.97 mg/dL (88 μmol/L) is tantamount to impairment in renal function, as this level is equivalent to the GFR of 50 mL/min[148].

Mathematical models based upon creatinine levels, such as Cockroft-Gault or modification of diet in renal disease, introduce a systematic error to calculations of the GFR. It particularly regards the Cockroft-Gault formula that estimates GFR from serum creatinine level and body mass, which in cirrhotic patients is highly dependent on body water content. On the basis of existing studies, the significance of cystatin C in the measurement of renal function in cirrhosis cannot be definitely determined.

Serum creatinine is one of three variables that form the model of end stage liver disease (MELD) score that predicts 3-mo survival in patients with end-stage cirrhosis. Therefore, MELD score is an important tool to set up the priority for access to the graft among patients waiting for a liver transplant. In the MELD score, creatinine has been assigned a much higher, and probably excessive, weight than bilirubin[149].

Total muscle mass is one of the factors influencing the serum creatinine concentration. It is the reason why men and women having the same GFR may differ with respect to serum creatinine levels. Therefore, it can be assumed that equal MELD values in both sexes may mean a worse prognosis for women. This assumption has been confirmed by finding a higher mortality rate among women listed for liver transplant in comparison with the

pre-MELD era[27]. This finding challenges the belief that MELD realizes the principle that "the sickest goes first".

RENAL FAILURE AND LIVER TRANS-PLANTATION

Development of type 1 HRS is an unfavorable moment to conduct a liver transplantation because an elevated creatinine level is a predictor of perioperative complications and death. It also predicts the duration of stay in the intensive care unit and probability of renal replacement therapy[150,151]. Therefore, improvement of renal function should be the goal before liver transplantation. Nonetheless, 3-year survival of patients undergoing liver transplantation during HRS is approximately 60%[150], thus clearly worse than in patients with normal renal function, but still much better than in those without transplantation.

Development of ATN before liver transplantation denotes maintenance of renal failure after this procedure. Diagnosis of ATN before the scheduled hepatic transplantation may enforce the decision on simultaneous liver and kidney transplantation (SLKT). A reliable diagnosis of ATN in such circumstances requires renal biopsy, preferably in a transcaval way, because coagulopathy or large ascites precludes percutaneous biopsy. Indications for SLKT in patients with end-stage liver cirrhosis are: (1) AKI (including HRS) with persisting hypercreatininemia ≥ 2 mg/dL for a period of at least 8 wk (despite renal replacement therapy); (2) chronic renal insufficiency with GFR < 30 mL/min; and (3) chronic renal failure with histopathological evidence of sclerosis or fibrosis of > 30% of glomeruli[86].

From 1984 to 2008, SLKT was reported in 3536 patients. Apart from liver cirrhosis and chronic or acute renal failure, the main indications were oxalosis and polycystic liver and kidney disease. The cumulative 5-year survival of both organs was 60.9%, and patient survival was 42.6%[152].

With improvements in operative techniques, patient survival following liver transplantation has substantially increased with more common occurrence of chronic renal disease resulting from nephrotoxicity of immunosuppressive drugs, rendering kidney transplantation inevitable. After 10 years from liver transplantation, renal failure occurs in about 20% of patients[153].

CONCLUSION

Hypercreatinemia is a common finding in patients with end-stage liver disease and it may be a form of AKI or chronic renal failure; for example, DN or glomerular nephritis associated with nonalcoholic fatty liver disease and viral hepatitis, respectively. Knowledge of the nature of renal disease is essential for therapeutic decisions, especially in patients eligible for liver transplantation. AKI is an ominous manifestation of circulatory dysfunction in patients with late cirrhosis, generally identified with HRS.

However, HRS may be only part of the pathophysiological continuum of renal hypoperfusion-related diseases, ranging from prerenal insufficiency to ischemic kidney damage. Moreover, HRS is probably not the most common form of renal disease associated with end-stage cirrhosis. At present, the diagnosis of HRS is based on exclusion of contact with nephrotoxic agents and the spectrum of factors leading to hypovolemia. In the near future, the diagnosis of HRS will probably require the absence of urinary markers specific for injury to tubular epithelial cells.

Abstract

Achalasia cardia is one of the common causes of motor dysphagia. Though the disease was first described more than 300 years ago, exact pathogenesis of this condition still remains enigmatic. Pathophysiologically, achalasia cardia is caused by loss of inhibitory ganglion in the myenteric plexus of the esophagus. In the initial stage, degeneration of inhibitory nerves in the esophagus results in unopposed action of excitatory neurotransmitters such as acetylcholine, resulting in high amplitude non-peristaltic contractions (vigorous achalasia); progressive loss of cholinergic neurons over time results in dilation and low amplitude simultaneous contractions in the esophageal body (classic achalasia). Since the initial description, several studies have attempted to explore initiating agents that may cause the disease, such as viral infection, other environmental factors, autoimmunity, and genetic factors. Though Chagas disease, which mimics achalasia, is caused by an infective agent, available evidence suggests that infection may not be an independent cause of primary achalasia. A genetic basis for achalasia is supported by reports showing occurrence of disease in monozygotic twins, siblings and other first-degree relatives and occurrence in association with other genetic diseases such as Down's syndrome and Parkinson's disease. Polymorphisms in genes encoding for nitric oxide synthase, receptors for vasoactive intestinal peptide, interleukin 23 and the *ALADIN* gene have been reported. However, studies on larger numbers of patients and controls from different ethnic groups are needed before definite conclusions can be obtained. Currently, the disease is believed to be multi-factorial, with autoimmune mechanisms triggered by infection in a genetically predisposed individual leading to degeneration of inhibitory ganglia in the wall of the esophagus.

INTRODUCTION

Achalasia is an esophageal motor disorder characterized by aperistalsis of the esophageal body and lack of relaxation of the lower sphincter in response to swallows. It affects both sexes and all age groups[1,2]. Achalasia was first described by Willis[3] in 1674 as "food blockage in

esophagus". He treated these patients successfully with a dilator made of whale bone and sponge[3]. The term "achalasia" was first coined by Hurst[4] in 1927. He had observed such patients since 1914 and suggested that their disorder might be due to absence of normal relaxation of the sphincter, possibly resulting from organic changes in Auerbach's plexus[5]. Achalasia is a Greek word that means "failure of relaxation". Achalasia can be primary (idiopathic) or secondary. In secondary achalasia, the cause for the degeneration of esophageal nerve fibers is known. Pathophysiologically, achalasia is caused by loss of inhibitory ganglion cells in the myenteric plexus. Since the initial description, several studies have attempted to explore initiating agents that may cause the disease such as viral infection, other environmental factors, autoimmunity, and genetic factors. However, the exact pathogenesis of primary achalasia is still not known. In this paper, the literature regarding pathogenesis of primary achalasia is reviewed.

PATHOPHYSIOLOGICAL ISSUES

The pathophysiology of achalasia is outlined in a simplified manner in Figure 1. In healthy esophagus, progressive delay in contractility of the lower esophageal muscles results from the presence of inhibitory neurotransmitters such as nitric oxide and its receptors in the lower esophagus (Figure 1)[6,7]. In the initial stage of the disease, degeneration of inhibitory nerve fibers in the esophagus results in unopposed action of excitatory neurotransmitter such as acetylcholine, which leads to high amplitude non-peristaltic contractions (not progressively delayed or simultaneous)[8]. This stage of achalasia is known as vigorous achalasia (average amplitude of contractions in lower esophagus > 40 mmHg)[9]. Progressive loss of cholinergic neurons results in dilation and low amplitude simultaneous contractions in the esophageal body; this stage of achalasia is called classic achalasia. Studies demonstrating reduction in number of ganglion cells in the esophageal body at autopsy of patients with achalasia and an inverse correlation between number of ganglion cells and duration of disease support their involvement in the disease process[8]. In experimental studies published long ago, a muscles strip obtained from the esophageal body of patients with esophageal achalasia failed to contract on addition of the ganglion stimulant nicotine though it contracted in response to acetylcholine, which is a direct muscle stimulant. A muscle strip from the lower esophageal sphincter (LES) of patients with achalasia contracted in response to acetylcholine though it failed to relax in response to nicotine[10]. These findings demonstrate that in patients with achalasia, there is degeneration of ganglia though the muscles remain contractile in response to acetylcholine. Degeneration of inhibitory control of the LES has also been demonstrated by studies that showed cholecystokinin, which reduces LES pressure in healthy subjects, increases pressure in patients with achalasia[8]; esophageal distension failed to cause relaxation of LES in these patients[11] and gastric distension failed

to induce transient LES relaxation[12]. All the above data suggest that achalasia results from degeneration of the esophageal nerve plexus, particularly the inhibitory fibers. However, neural degeneration might not be confined to the esophagus alone as evidenced by demonstration of Wallerian degeneration in the vagus nerve on electron microscopy[13], improvement in some abnormalities with stimulation of vagus nerve in animal models[14,15], presence of Lewy bodies in the brainstem of patients with achalasia[16], and delayed gastric emptying[17] and abnormal gastric secretory response to insulin-induced hypoglycemia in a subset of patients[18]. It is, however, not clear why some people develop neural degeneration causing achalasia. The various environmental, autoimmune and genetic factors incriminated in pathogenesis are reviewed below.

A study in an animal model showed that the nitric oxide inhibitor, recombinant human hemoglobin, caused incomplete LES relaxation and high amplitude simultaneous contractions in the body of the esophagus[19]. Similar results have been reported in humans[20]. Another study in an animal model failed to show an association of intramuscular interstitial cells of Cajal in the nitrenergic pathway and dysfunction of LES found in achalasia[21].

Infection
A number of studies implicating viral agents in the pathogenesis of achalasia showed conflicting results. An initial report by Jones *et al*[22] showed a statistically significant increase in antibody titer against measles virus (MV) in patients with achalasia compared with controls (14 of 21 achalasia patients *vs* 7 of 21 controls, P < 0.05). This difference persisted only at a titer of 1/32 or more. However, there was similar frequency of infection in both groups as was evident by similar antibody detection rates at low titer[22].

Robertson *et al*[23] reported an association between Varicella zoster virus (VZV) infection in patients with achalasia by demonstrating viral DNA in esophageal tissue. They demonstrated VZV particles by DNA hybridization techniques in three of nine esophageal myotomy specimens from achalasia patients, but in none from 20 control subjects. DNA probes for cytomegalovirus (CMV) and herpes simplex virus type 1 (HSV-1) were negative in both achalasia patients and controls[23]. This study provided an attractive hypothesis, but failed to establish a causal association. We have reported one patient who presented with motor dysphagia due to esophageal hypomotility and also developed gastroparesis following infection with VZV[24].

A few studies, however, failed to show evidence of infection as a cause for achalasia[25,26]. Niwamoto *et al*[25] used polymerase chain reaction to detect human herpes virus DNA (HSV-1 and 2, CMV, VZV, Epstein-Barr virus and human herpes virus-6) or MV RNA in the esophageal muscle of 12 patients with achalasia and six with upper esophageal carcinoma. Only HSV-1 and 2 were detected in all samples including patients and controls. Other viruses were not detected. Similarly, another study failed

Figure 1 Schematic diagram outlining possible pathogenesis of achalasia cardia. A: Diagram showing distribution of nitric oxide (NO) and acetycholine (Ach) neurons in the esophagus with normal motility pattern and barium esophagogram; B: Loss of NO in esophagus in early stage of the disease resulting in high amplitude simultaneous contractions in body (called vigorous achalasia). In this stage esophagus is not dilated in barium esophagogram; C: Further degeneration of inhibitory and additional degeneration of excitatory neurons causes low amplitude simultaneous contractions in esophageal body (called classic achalasia). In this stage esophagus is dilated in barium esophagogram. NANC: Non-adrenergic, non-cholinergic.

to detect human herpes virus, MV and human papilloma virus sequences both in achalasia or control specimens[26]. Two studies proposed an association between MV and VZV infection in patients with achalasia[22,23]. However, VZV particles were found only in a third of achalasia patients[23]. Moreover, not all patients with VZV and MV infection develop achalasia. It has been hypothesized that most patients might have cleared virus or there could be sampling error. However, most of these data suggest that VZV may not be an important cause of achalasia.

Considering the above possibilities, a recent study tried to demonstrate infection in the absence of direct evidence of virus in esophageal tissue. Facco *et al*[27] reported oligoclonal selection of T cells in achalasia patients by flow cytometry and CDR3 length spectra typing analysis of lymphocytes. They also demonstrated increased proliferation of T cells and Th-1 type cytokine release in response to HSV-1 antigen. In conclusion, available evidence suggests that infection may not be a definite cause for esophageal achalasia. One strong piece of evidence in favor of infection in the pathogenesis of achalasia, however, is the fact that Chagas disease, caused by *Trypanosoma cruzi*, very closely mimics the pathophysiology of primary achalasia[28].

Immunological factors

An autoimmune etiology for achalasia has been considered because of the presence of neural inflammation in absence of conclusive evidence of infection. Studies have demonstrated inflammatory cell infiltrate of the myenteric plexus in 90%-100% of esophageal specimens from achalasia patients[29,30]. This hypothesis has been further supported by the presence of autoantibody in sera of patients with achalasia (Table 1) and an association with major histocompatibility complex class II antigen (Table 2). Immune activation and inflammation is known to be associated with altered gastrointestinal motility due to neural dysfunction in the gut[31]. Taking the analogy of other gastrointestinal motility disorders such as post-infectious irritable bowel syndrome, intestinal pseudo-obstruction and ileus, it has been postulated that achalasia may have a similar pathophysiological basis[31]. However, more studies are needed on this issue.

Autoantibodies in achalasia: Several studies showed a higher prevalence of autoantibodies in achalasia patients compared to controls. Storch *et al*[32] suggested a role of autoimmunity by demonstrating a higher prevalence of anti-myenteric autoantibody in achalasia patients (64%)

Table 1 Studies comparing autoantibody levels between achalasia patients and control subjects

Authors	Tests	Autoantibody, *n*/N (%)		*P* value
		Achalasia	Control	
Storch *et al*[32]	Indirect immunofluorescence	37/58 (64)	4/54 (7) in healthy	< 0.0001
			Absent in 12 of Hirschsprung's disease	
			Absent in 12 esophageal cancer	
Verne *et al*[33]	Double-label Indirect immunofluorescence	7/18 (40)	Absent in 22 healthy	< 0.05
			Absent in 9 GERD	
Ruiz-de-León *et al*[34]	Indirect immunofluorescence	50/92 (54.3)	3/40 (7.5)	< 0.001
Moses *et al*[36]	Immunohistochemistry	23/45 (51)	2/22 (9) in healthy control	< 0.001
			8/16 (50) of GERD	NS

GERD: Gastroesophageal reflux disease; NS: Not significant.

					Both HLA risk allele and		
					antibody: in one patient		
					None in controls		

AM: Anti-myenteric; HLA: Human leukocyte antigen; NS: Not significant.

compared to healthy controls (7%). They also showed absence of anti-myenteric autoantibody in Hirschsprung's disease as well as in esophageal cancer patients, and in 8%-9% of patients with peptic esophagitis and myasthenia gravis[32]. This hypothesis was further supported by subsequent studies[33,34].

Another interesting study demonstrated that patients with Chagasic achalasia more often had autoantibodies against muscarinic acetylcholine receptors [M(2) mAchR] as compared to patients with achalasia not resulting from Chagas disease[35].

Verne *et al*[33] tried to demonstrate the presence of regional and cellular specific antibody in achalasia patients. Staining of the esophageal and intestinal sections of rat with sera from achalasia patients showed binding of antibody to neurons in the esophageal as well as intestinal sections, though none of the sera of patients with gastroesophageal reflux disease (GERD) or controls showed staining[33]. Since idiopathic achalasia is primarily a disorder of esophageal smooth muscles, binding on intestinal sections may suggest non-specific binding of this antibody and hence, may not suggest a causal association.

A study by Moses *et al*[36] demonstrated a similar degree of immune-reactivity in the myenteric plexus of the esophagus and ileum of guinea-pig and mouse when immune-stained with sera of achalasia and **GERD patients;** however, both the groups had higher immune-reactivity when compared with normal individuals. Western blotting analysis failed to reveal specific myenteric neuronal

proteins that could be targeted by antibodies in achalasia or GERD serum[35]. These observations do not support anti-neuronal antibodies to be causative in achalasia. These antibodies may perhaps be an epiphenomenon.

Human leukocyte antigen association: An association between achalasia and **human leukocyte antigen (HLA)** class Ⅱ histocompatibility antigens was proposed for the first time by Wong *et al*[37]. They performed HLA typing on 40 achalasia patients and found that Caucasians and black populations with DQw1 had 4.2 and 3.6 times higher risk of developing achalasia, respectively[37]. **Subsequent** studies[38,39] demonstrated associations between achalasia and HLA-DQA1*0101 allele, DQB1*0602 allele and DRB1*15 allele, and confirmed the findings reported by Wong *et al*[37]. Another study showed higher frequency of DQA1*0103, DQB1*0603 and DQA1*0103-DQB1*0603 heterodimer in patients with achalasia compared to controls. They also demonstrated that achalasia patients with DQA1*0103 and DQB1*0603 alleles had significantly higher prevalence of anti-myenteric antibody[34]. In contrast, Latiano *et al*[40] failed to show any correlation among HLA alleles and anti-neuronal antibodies. **However, acha-lasia** patients had higher frequency of DQB1*0502 and DQB1*0601 alleles. All these reports might suggest an autoimmune etiology of achalasia; however, not all patients with achalasia had predisposing HLA while not all people with the specific HLA had the disease.

In conclusion, all these data are not sufficient to con-

clude that achalasia is an autoimmune disease. To define a disease as autoimmune in nature, the disease should provide the following three features: (1) direct evidence based on transfer of disease by antibodies; (2) indirect evidence based on reproduction of autoimmune disease in an animal or genetic model; and (3) detection of auto-reactive T cells in the target organ of disease[41]. To date, all the evidence to support an autoimmune etiology of achalasia has not been substantiated. More studies are needed on this issue.

Genetic factors: Some evidence supports a genetic basis for achalasia. The disease has been reported in monozygotic twins[42] and siblings[43-45]. A few reports described familial occurrence of achalasia cardia[46]. Studies showed genetic correlations of the *ALADIN* gene in achalasia associated with Allgrove syndrome[47,48]. Additionally, the disease has also been reported in association with other genetic diseases such as Down's syndrome and Parkinson disease[49,50]. The genetic basis for achalasia might have been underestimated, in contrast to that for Hirschsprung's disease, though both these enteric neuropathies have several features in common[51]. Hirschsprung's disease, like achalasia, is also known to have familial occurrence and the former has been reported quite commonly in different syndromes with a genetic basis. Both the conditions have altered motor function with loss of inhibitory innervation[51]. We wish to review some studies on genetic polymorphisms in certain genes in patients with achalasia cardia.

Nitric oxide synthase polymorphism: Nitric oxide is a necessary inhibitory neurotransmitter of the esophageal myenteric plexus involved in esophageal sphincter relaxation. Nitric oxide synthase (NOS) synthesizes nitric oxide from L-arginin. Reported studies showed that in patients with achalasic cardia, the LES has less NOS compared with controls[52,53]. At present, three different NOS isozymes, neuronal NOS (NOS1), inducible NOS (NOS2) and endothelial NOS (NOS3) have been reported. *NOS1*, *NOS2* and *NOS3* genes are located on human chromosomes 12q24.2, 17q11.2-q12 and 7q36, respectively. A microsatellite (CA repeat) polymorphism is found within the 3'-untranslated region of exon 29 of the *NOS1* gene. The *NOS2* gene has two biallelic polymorphisms in exons 16 and 22 representing C/T and G/A transitions, respectively, and *NOS3* shows a 27-bp variable number of tandem repeat polymorphisms in intron 4. Published studies have failed to explain a strong role for these functional polymorphisms in the susceptibility for achalasia[54,55].

***VIPR1* gene polymorphism:** The *VIPR1* gene is located on human chromosome 3p22[56]. Vasoactive intestinal peptide is a small neuropeptide, which acts as a neurotransmitter with anti-inflammatory properties; it is present in the myenteric plexus to modulate relaxation of the distal esophageal wall and LES[57-59]. Reported stud-

ies have suggested a role for this neuropeptide as chief element in the maintenance of neuro-endocrine immune system communication that activates signal transduction through specific receptors present on immune cells[60]. Receptor of vasoactive intestinal polypeptide (VIPR1) belongs to the secretin receptor family, a group of G-protein coupled receptors expressed by different immune cells, including T cells, macrophages and dendritic cells[56]. VIPR1 is present on myenteric neurons of the distal esophagus and LES; continued inflammation leads to the impairment of VIPR1 signaling, which alters the effect of VIP on myenteric neurons that progresses to ganglion cell loss and nerve fiber fibrosis[8,29,32-34,36,53]. A few further studies among patients with rheumatic diseases showed the receptor down-regulation of the *VIPR1* gene resulting in decreased signaling[61-64]. Paladini *et al*[64,65] reported five single nucleotide polymorphisms in the *VIPR1* gene in patients with achalasia cardia which included (rs421558) Intron-1, (rs437876) Intron-4, (rs417387) Intron-6, rs896 and rs9677 (3'UTR) and they found that the presence of A allele at (rs421558) Intron-1 and C allele at rs896 (3' UTR) was associated with a less efficient down-regulation of the receptor. Hence, AC haplotype may protect from the disease by down-regulation of VIPR1 receptor during inflammation.

Interleukin-23 receptor polymorphism: The interleukin-23 receptor (*IL-23R*) gene, located on chromosome Ip31, encodes for heterodimeric subunits of the IL-23R complex[66]. IL-23R is a type I trans-membrane protein expressed on Th1 derived T-cells which produce IL-17, designated as Th17 cells. Previous data support a role for Th17 cells and these cytokines in inflammatory and autoimmune processes[67]. Activated JAK-STAT signaling pathway by IL-23 binds with the IL-23R/IL-12β1 receptor, which influences the number of downstream immune responses[66]. Reported studies showed that IL-23R is associated with inflammatory as well as chronic autoimmune disorders[68-74]. In a single nucleotide polymorphism of the *IL-23R* gene, arginine replaces glutamine at codon 381. One study reported *IL-23R* coding variant 381Gln was a protective allele, whereas another study found this variant to be a risk factor. de León *et al*[75] reported coding variant 381Gln of *IL-23R* was significantly more common in patients with achalasia as compared with healthy controls. Hence, this 381Gln variant of *IL-23R* polymorphism could be a risk factor for achalasia cardia.

Protein tyrosine phosphatase non-receptor 22 gene polymorphism: The protein tyrosine phosphatase non-receptor 22 (*PTPN22*) gene is located on chromosome 1p13.3-p13, a region associated with autoimmune disease[75,76]. It encodes a lymphoid specific phosphatase known as Lyp. Lyp is an intracellular protein tyrosine phosphatase and an important down-regulator of T-cell activation[77]. The *PTPN22* gene exhibits a single nucleotide polymorphism at position 1858C/T, which leads to a replacement in codon 620 of Arg (R) to Trp (W). A study

showed that Lyp-W620 had more phosphatase activity, which could slow down T-cell signaling more effectively than Lyp-R620. In a different population it has already been reported that the *PTPN22* T allele is a risk factor for autoimmune diseases[78-83]. Santiago *et al*[84] reported that *PTPN22* C1858T polymorphism increased risk of achalasia in a Spanish population.

CONCLUSION

Achalasia is caused by loss of inhibitory ganglion in the myenteric plexus in the esophagus. Gradual progression of neuronal degeneration is associated with progression of the disease from vigorous to classic achalasia. Though several studies have attempted to explore initiating agents that may cause the disease, the exact factors responsible for the degeneration of ganglion cells in the myenteric plexus are poorly understood. The disease is likely to be multi-factorial involving host genetic factors, autoimmunity, and environmental factors such as infections. More studies are needed to explore the exact cause of this enigmatic disease.

Abstract

Complete surgical resection still remains the only possibility of curing pancreatic cancer, however, only 10% of patients undergo curative surgery. Pancreatic resection currently remains the only method of curing patients, and has a 5-year overall survival rate between 7%-34% compared to a median survival of 3-11 mo for unresected cancer. Pancreatic surgery is a technically demanding procedure requiring highly standardized surgical techniques. Nevertheless, even in experienced hands, perioperative morbidity rates (delayed gastric emptying, pancreatic fistula *etc.*) are as high as 50%. Different strategies to reduce postoperative morbidity, such as different techniques of gastroenteric reconstruction (pancreatico-jejunostomy *vs* pancreatico-gastrostomy), intraoperative placement of a pancreatic main duct stent or temporary sealing of the main pancreatic duct with fibrin glue have not led to a significant improvement in clinical outcome. The perioperative application of somatostatin or its analogues may decrease the incidence of pancreatic fistulas in cases with soft pancreatic tissue and a small main pancreatic duct (< 3 mm). The positive effects of external pancreatic main duct drainage and antecolic gastrointestinal reconstruction have been observed to decrease the rate of pancreatic fistulas and delayed gastric emptying, respectively. Currently, the concept of extended radical lymphadenectomy has been found to be associated with higher perioperative morbidity, but without any positive impact on overall survival. However, there is growing evidence that portal vein resections can be performed with acceptable low perioperative morbidity and mortality but does not achieve a cure.

INTRODUCTION

Since many aspects of the pathogenesis and optimal man-

agement of ductal pancreatic adenocarcinoma (DPAC) remain unclear, this tumor entity continues to be the fourth leading cause of cancer related death in the Western world[1]. Even with the widespread use and refinements of diagnostic tools (e.g., contrast-enhanced transabdominal ultrasound (US), thin-sliced contrast-enhanced helical computer tomography (CT), contrast-enhanced magnetic resonance imaging (MRI), positron emission tomography (PET-CT), transduodenal ultrasound and fine-needle biopsy (FNB), early diagnosis of pancreatic cancer remains rare, since most patients (about 80% to 90%) at the time of diagnosis are found to have locally or even systemically advanced disease. Therefore, only 10% of patients with DPAC can undergo curative resection, which remains the only possibility of achieving long-term survival. Unfortunately, only 20% of resected patients remain free of any tumor recurrence five years postoperatively[2]. A national survey in France showed a relevant decrease in postoperative mortality after pancreaticoduodenectomy (PD) for DPAC from 11% to 3.3% between 1991 and 2010[3,4]. During the same period of observation, the overall survival of resected patients increased from 11% five years postoperatively to 25% after resection[3-5]. To date, there is insufficient solid data available regarding the exact role of neoadjuvant therapies, however, in the case of locally advanced disease, neoadjuvant chemo/radio-therapy has been reported to increase the number of patients who undergo curative surgery[6]. This review focuses on the clinical value of preoperative diagnostic and interventional techniques, results of different types of pancreatic head resection, the role of extended radical lymphadenectomy, vascular resections and perioperative medical and surgical approaches to decrease perioperative morbidity.

DIAGNOSIS AND PREOPERATIVE STAGING

Transabdominal US and contrast-enhanced US

The clinical finding of painless jaundice in an appropriately aged patient (fifth to sixth decade of life), must be considered pancreatic cancer until proven otherwise. Transabdominal US is rapid, non-invasive and inexpensive and is usually the first step in radiological evaluation. The sensitivity of US in diagnosing pancreatic cancer has a wide reported range. As a direct radiological sign, a hypoechogenic lesion can be visualized in about 55%-90% of patients[7-9]. Major limitations of US are the detection of small tumors (< 2 cm of diameter), lesions that are mainly located in the left side of the pancreatic gland, multifocal pancreatic lesions and obesity as the latter is a risk factor for pancreatic cancer[10]. Indirect radiological signs of pancreatic cancer such as dilatation of the main pancreatic duct (> 2 mm in combination with upstream areas of atrophied pancreatic gland), biliary tree, pseudocystic lesions, peripancreatic lymphadenopathy, ascites, pleural effusion and metastatic tumor deposits to the liver should strongly suggest pancreatic cancer. The great

operator dependability of US with its above-mentioned diagnostic limitations has recently led to the introduction of contrast-enhanced ultrasonography (CEUS). In a very recently published multicenter study, CEUS was reported to diagnose DPAC with an accuracy of 87% in patients with an already visualized pancreatic mass by conventional US[11]. Such findings were also confirmed by other groups[12,13]. Although some experts in the field of CEUS propose its use as an additional work-up examination for pancreatic pathologies, CEUS is currently not considered a diagnostic standard.

Thin-sliced, intravenous contrast-enhanced CT

Thin-sliced, intravenous contrast-enhanced computer tomography (CECT) has become the imaging modality of choice to evaluate patients with pancreatic cancer. The overall sensitivity and specificity of CECT has been reported to be around 90% in experienced centers[14-18]. CECT with timed sequences to capture arterial and venous phases is able to demonstrate a hypodense pancreatic tumoral lesion in 80% to 95% of cases[14-16,19] (Figure 1). Dilatation of the biliary tree or the main pancreatic duct can be found in 86% and 88% of cases, respectively (Figure 1). Tumoral obstruction of the main pancreatic duct with upstream atrophy of the pancreatic parenchyma or pseudocystic lesions are present in 82% and 10% of patients[14,20] (Figure 1). The finding of a tumor that surrounds the entire circumference of a vessel is generally recognized as unresectable tumor encasement[14,21]. CECT criteria have been developed to indicate the probability of vascular involvement based on the relationship of tumor to adjacent vessels. A prospective case series by Lu *et al*[22] introduced a new classification based on tumor involvement of the portal and superior mesenteric veins and the celiac, hepatic and superior mesenteric arteries which was graded on a scale 0-4 scale based on circumferential contiguity of tumor to vessel by CECT (Grade 0, no contiguity of tumor to vessel; Grade 1, tumor contiguous to less than one quarter circumference; Grade 2, between one-quarter and one-half circumference; Grade 3, between one-half and three-quarters circumference; and Grade 4, greater than three-quarters circumferential involvement or any vessel constriction). A cut-off between Grade 2 and Grade 3 showed the lowest number of false-negatives and an acceptable number of false-positives for unresectability. Furthermore, such a cut-off level was reported to have a sensitivity of 84%, a specificity of 98%, a positive predictive value of 95%, and a negative predictive value of 93% for unresectability of the vessels[22]. In general, typical reports in the literature regarding the accuracy of CECT using the classification by Lu for predicting vascular invasion range from 62% to 92% with a somewhat higher sensitivity for arterial infiltration[17,23] (Figure 2). Positive overall predictive values for local surgical unresectability have been reported to be excellent (89% and 100%)[14,15,19,21]. CECT has a reported sensitivity of 75%-87% in diagnosing liver metastases[24,25]. In many cases, hepatic metastatic lesions missed by CECT are small, but originate from an already

Figure 1 Ductal dilation, computer tomography 3-phase contrast-enhanced thin-slice helical scan. A: Heterogenous tumor of the pancreatic head with consecutive extra- and intra-hepatic bile duct dilatation (arrow); B: "Double duct sign" due to a tumor of the papilla of vater (arrow); C: Tumor of the pancreatic neck with an upstream dilatation of the pancreatic duct and parenchymal atrophy of the pancreatic gland. Presence of a cavernoma due to tumor thrombosis of the portal vein (arrow); D: Classic radiological presentation of a pancreatic neck tumor with a less pronounced enhancement compared to the normal pancreatic parenchyma (arrow).

Figure 2 Vascular tumor extension, computer tomography 3-phase contrast-enhanced thin-slice helical scan, sagittal section and 3D reconstruction. A, B: Sheathing and thrombosis of the celiac trunk (asterisk) and superior mesenteric artery (arrow) with collateral blood flow *via* the inferior mesenteric vessels; C: Tumor of the pancreas (arrow) in contact with the superior mesenteric artery and infiltration of the portal vein; D: Tumor sheathing or the origin of the superior mesenteric artery (arrow) with irregularities as a sign of arterial invasion.

larger pancreatic tumor (> 3 cm)[26-28] and are therefore retrospectively not unexpected. The identification of lymphatic nodal involvement and peritoneal disease is difficult with all currently available imaging modalities. On cross-sectional imaging, size (> 1 cm) is the criterion for identifying nodal metastases, and therefore the accuracy of CECT remains limited at 54%[17].

MRI, MRI-cholangiopancreaticography

To diagnose and stage pancreatic cancer, the systematic use of MRI is still questioned by many clinicians. However, MRI has been found to offer several benefits in imaging the pancreatic gland. It inherently offers better soft-tissue contrast than CECT before the administration of an i.v. contrast agent, and images can be obtained

Figure 3 Magnetic resonance imaging appearance. A: T1 sequence showing an adenocarcinoma of the pancreas with a hypo-intense signal (arrow), whereas normal pancreatic tissue appears hyper-intense; B: T1 sequence with fat saturation injection: after injection of gadolinium, the pancreatic adenocarcinoma is hypo-enhanced (arrow) compared to the healthy parenchyma; C: A sequence of diffusion: hyper-intensity (arrow) signal due to the hyper-cellularity of the tumor; D: Sequence 3D-magnetic resonance cholangiopancreatography: stenosis of the main pancreatic duct (arrow) with upstream dilatation due to a tumor of the pancreatic isthmus.

in multiple planes. MRI can be performed in patients with a history of allergy to iodinated contrast agents and in those with renal insufficiency. Today, MRI has been shown to have high diagnostic value in cases where a clear diagnosis remains unclear even after CECT has been performed. Such a situation is mostly found in cases with a suspected tumor of the pancreatic head which is isodense on CECT and/or small lesions (< 2 cm). In such situations, MRI is superior to CECT at detecting or excluding a pancreatic tumor. The greatest advantage of MRI is found in patients in whom CECT demonstrates enlargement of the pancreatic head without clear definition of a pancreatic tumor. The overall sensitivity and specificity of MRI in diagnosing pancreatic cancer has currently been reported to be around 90% and 80%, respectively[29]. Magnetic resonance cholangiopancreatography (MRCP) is a special type of MRI exam that produces detailed images of the hepatobiliary and pancreatic systems, including the liver, gallbladder, bile ducts, pancreas and pancreatic duct. Additionally, MRCP has a clear advantage over ERCP in detecting pancreatic carcinoma since MRCP prevents inappropriate explorations of the pancreatic and common bile duct[30]. MRCP is a reliable and reproducible method of evaluating intraductal papillary mucinous neoplasms (IPMN), particularly in patients being followed non-operatively or in those who require surveillance of the pancreatic remnant after PD[31]. In a study comparing MRI with CECT, MRI had an accuracy of 93.5% for the detection of liver metastases compared with 87% for CECT[25]. However, a recently published meta-analysis showed equal overall capabilities of MRI and CECT to diagnose and stage pancreatic cancer[32-34]. Even the evaluation of vascular tumor infiltration can be

evaluated by CECT or MRI with equal results[35]. MRI has lower diagnostic power to detect peritoneal carcinomatosis and/or local lymphadenopathy compared to CECT. MRI also has the potential to assess fat content which may be helpful in assessing the risk of pancreatic fistula (PF) following resection[36] (Figure 3).

Endoscopic US

When endoscopic ultrasound (EUS) was introduced, initial reports indicated a sensitivity higher than 90% for the identification of pancreatic tumors[9]. The superiority of EUS over classical CT was most evident for pancreatic lesions smaller than 3 cm in diameter. Therefore, EUS was considered the gold standard for diagnosing and staging pancreatic cancer. However, with the introduction of thin-sliced, intravenous CECT, the sensitivity and specificity of CECT for lesions smaller than 2 cm in diameter were reported to be as high as 77% and 100%, respectively[37]. Currently, EUS and CECT are considered to be equal in the diagnostic work-up of patients with suspected pancreatic cancer. However, EUS is still reported to be superior in assessing local tumor extension in the case of periampullary cancer compared to CECT and MRI (EUS: 78%, CECT: 24%, MRI: 46%)[38], however, due to the limited penetration depth of EUS, it is clearly inferior in detecting liver metastasis. In the case of suspected vascular infiltration (loss of interface between the tumor and the vessel wall; a tumor within the vessel lumen; collateral circulation; irregular vessel wall), sensitivity (85%-100%) and accuracy (55%-90%)[39] for EUS are reported to be equivocal compared to CECT/MRI. However, since these signs for vascular involvement are mainly indirect signs, these findings need careful interpretation, especially

Table 1 Summary of preoperative evaluation of pancreatic adenocarcinoma

Painless jaundice in an appropriately aged patient is highly suspicious for pancreatic cancer
Contrast-enhanced computer tomography is the diagnostic standard
  High overall diagnostic sensitivity and specificity
  Highly accurate in determining local respectability
  Less adequate in identifying small hepatic metastases, extent of local lymphadenopathy and peritoneal tumor deposits
Magnetic resonance imaging gives additional information on small isodense or atypical pancreatic lesions
  More accurate than contrast-enhanced computer tomography in detecting smaller hepatic metastases
Enhanced ultrasonography/fine-needle biopsy are reserved for the work-up of small lesions (< 2 cm), or in cases where a fine-needle biopsy is required
before palliative or neoadjuvant therapy is initiated

in pancreatitis, IPMN or after biliary drainage (BD), not to exclude potentially resectable patients from curative surgery. Nowadays, EUS is used more selectively, mainly in cases of small pancreatic head tumors (< 2 cm), in which CECT and MRI findings remain equivocal. Furthermore, patients with locally unresectable or already distant metastatic disease, EUS guided transduodenal FNB is mandatory for diagnostic purposes before the initiation of neoadjuvant or palliative treatment.

18-F FDG PET-CT

18-F FDG PET-CT is mainly used in cases of preoperatively suspected distant metastatic disease or to investigate the response to neoadjuvant treatment. Currently, PET-CT is not considered a preoperative diagnostic standard and its routine use is only reported by some centers. Moreover, some studies found a comparable reliability rate of CECT and PET-CT in detecting distant metastasis[40-42]. Nevertheless, the preoperative routine use of PET-CT was found to change the management in 16% of patients who were deemed resectable based on standard staging examinations and was reported to be cost saving[43]. More recently, contrast-enhanced PET-CT has been shown to be a highly accurate staging tool as a 1-stop-shop procedure[43]. It is very likely that the use of this strategy will increase in the near future.

Preoperative FNB

Preoperative FNB is only required in cases of locally unresectable or already distant metastatic disease before non-surgical treatment (e.g., radio- and/or chemotherapy) is planned. Furthermore, FNB is required if there is any doubt about the underlying disease. If a FNB is planned, this should, whenever possible, be performed by the endoscopic route (transgastric/transduodenal) under endosonographic guidance with multiple biopsies taken to improve the diagnostic sensitivity (Table 1).

PERIOPERATIVE MANAGEMENT

Preoperative biliary drainage

In a recently published meta-analysis by the Cochrane Library, a statistically significant increased number of perioperative infectious complications, increased length of hospital stay, and higher overall hospital costs were reported in patients who had undergone preoperative

BD[44]. These findings were confirmed in a prospective, randomized multicenter study. In addition, a significant increased risk of sustaining severe perioperative infectious complications (39% vs 74%) and a greater number of patients requiring hospital readmission (12% vs 33%) were also observed in drained patients[45]. As a relative indication for BD, in selected cases, patients suffering from severe malnutrition might benefit from BD and delayed surgery. Infection of the biliary tree is constantly (sub- or clinically) present after any drainage procedure of the biliary tree[46-48], and a peri-interventional antibiotic treatment is justified in all cases. Treatment with amoxicillin and clavulanic acid has been shown to be more efficient in decreasing septic complications than the use of second generation cephalosporins[4] (Table 2).

Perioperative supportive medical care «fast-track surgery» was not only applied for colorectal surgery

The concept of fast-track surgery is nowadays widely accepted by clinicians and has been shown to significantly enhance recovery leading to decreased hospital stay with a reduction in medical morbidity, but unaltered surgery-specific morbidity in a variety of procedures[49]. However, most data on fast-track surgery were generated by analyzing patients who underwent colorectal surgery - fewer data are available on pancreatic surgery. Nevertheless, fast-track surgery in patients undergoing major pancreatic surgery has been shown to be feasible and safe with a low readmission rate (3.5%-6.2%), in-hospital postoperative mortality (2%) and morbidity rates (35%), associated with improvements in delayed gastric emptying, earlier hospital discharge (10 d), but without compromising patient outcome[50,51]. Therefore, patients undergoing pancreatic surgery should not be excluded from the general principles of enhanced perioperative recovery programs.

INTRAOPERATIVE MANAGEMENT

Prevention of PF

The most frequent complication after pancreatic surgery is PF. The incidence of this complication varies widely between 5% and 30% depending on the different reported series[52]. However, this wide reported range is mainly based on the fact that there was, until recently, no uniform definition available for this complication. More recently, a uniform definition on the presence and

Table 2 Indications for preoperative biliary drainage
Total bilirubin > 250 mmol/L
Acute cholangitis
Severe malnutrition and delayed surgery scheduled (relative indication)
Patients who require neo-adjuvant chemotherapy
Perioperative antibiotic treatment with penicillin in cases with evident infection of the biliary tree and in all patients undergoing biliary drainage

Table 3 Prevention of pancreatic fistula
There is currently no favored pancreatico-digestive anastomotic technique with regard to decreased pancreatic fistula rates
The routine use of octreotide can only be recommended in the case of:
Friable pancreatic tissue
Small diameter of the main pancreatic duct (< 3 mm)
Trans-anastomotic, percutaneously placed drainage of the main pancreatic duct decreases the risk of pancreatic fistula formation

severity of postoperative PF has been proposed by the International Study Group on PF. A PF is a drain output of any measurable volume of fluid on or after postoperative day 3 with an amylase content greater than 3 times the serum amylase activity. The severity of PF is graded as follows: Grade A: PF managed medically; Grade B: PF requires endoscopic or radiological intervention; Grade C: reoperation[52]. In the case of a Grade C fistula, an increased mortality of 40% was found in a recently published French multicenter study of more than 680 consecutive patients[53]. Friable pancreatic tissue, a main pancreatic duct (Wirsung) smaller than 3 mm in diameter and low volume pancreatic surgeons are reported to be risk factors for the development of PF[54]. To decrease the incidence of PF, several different technical and medical strategies have been proposed: (1) internal or external perioperative drainage of the main pancreatic duct; (2) temporary fibrin glue sealing (TFGS) of the main pancreatic duct; (3) the perioperative systematic use of somatostatin or its analogues; and (4) the role of different types of pancreatic-enteric reconstruction [pancreatico-jejunostomy (PJ) *vs* pancreatico-gastrostomy (PG)] (Table 3).

Drainage of the main pancreatic duct (Wirsung)

A prospective randomized trial from the Johns Hopkins University failed to demonstrate any benefit of an intraoperatively placed internal main pancreatic duct stent regarding the incidence and/or severity of PFs[55]. In contrast, external drainage of the main pancreatic duct, especially in the case of soft or friable pancreatic parenchyma, significantly reduced the number of perioperative PFs. In a prospective, randomized trial, the effect of external pancreatic main duct drainage during duodenopancreatectomy was found to be associated with a significantly lower incidence of PFs (6.8% *vs* 29.3%; $P < 0.007$) compared to the group of patients without drainage[56]. This finding has been further supported by a prospective, randomized study which not only showed a significantly lower incidence of PFs (20% *vs* 6.7%; $P = 0.032$) but also a decreased length of hospital stay (23 d *vs* 17 d; $P = 0.039$) for the drained group[57]. Analogue findings were also reported in a recently published French multicenter study[58].

TFGS of the main pancreatic duct

Several studies have investigated the possible value of TFGS of the main pancreatic duct to decrease the number and/or severity of clinically evident PFs. One in particular is a multicenter study of patients who underwent pancreatic resection with the formation of a pancreatico-jejunal anastomosis. Patients in group 1 ($n = 80$) received TFGS, and the control group 2 ($n = 102$) underwent standard PJ without fibrin glue sealing. The incidence of PF was found to be equal in the two groups (17% *vs* 15%) with no significant difference in the incidence of intra-abdominal septic complications (15% *vs* 24%) and postoperative mortality (9% *vs* 6%)[59]. Based on the currently available data in the medical literature, TFGS does not decrease the incidence or the severity of PF, therefore, can not be recommended in daily routine practice.

Routine post-operative administration of somatostatin or its analogues

The systematic application of somatostatin or its analogues, which are known to decrease the secretory capacity of the endo- and exocrine pancreatic gland, has been assumed to have a protective effect against the formation and/or severity of PF.

If somatostatin or its analogues are used, they should be started before surgery[60]. In a meta-analysis of seven studies including a total of 1359 patients having undergone pancreatic surgery, the perioperative application of somatostatin or its analogues was found to be associated with a significant reduction in the incidence of PF after elective pancreatic surgery. However, this risk reduction was not associated with a significant difference in postoperative mortality. Another meta-analysis of 1918 patients found that somatostatin or its analogues did not reduce mortality after pancreatic surgery, but reduced overall morbidity as well as the incidence of biochemical fistula but not that of clinical anastomotic disruption[61]. However, there are also data showing that the routine use of somatostatin or its analogues is not beneficial in all patients and should be limited to certain situations with an increased risk for PF formation such as: low volume pancreas centers with a high PF rate > 10%, a small main pancreatic duct (< 3 mm) and a friable pancreatic gland[62,63].

PJ vs PG

There is an ongoing debate regarding the optimal pancreatico-enteric reconstruction technique after PD. When comparing PJ with PG, several clinical trials reported a decreased incidence of PFs after PG[64-66]. In contrast to these data, three prospective randomized trials comparing PJ and PG found equal outcomes for both tech-

niques[67-69]. In a meta-analysis published in 2007 by Wente *et al*[70], no difference was found between PJ and PG by analyzing prospective randomized trials, whereas observational clinical studies favored the use of PG with a reduced incidence of PF and postoperative mortality rates. The authors concluded, that there was a possible risk of publication bias in observational clinical trials and all randomized controlled trials failed to show an advantage of a specific type of reconstruction. Therefore, PG and PJ can be considered to be equally safe[70]. Theoretically, PG might lead to decreased activity of pancreatic enzymes due to inactivation by gastric acid which would result in an increased incidence of postoperative exocrine pancreatic insufficiency. However, this issue was refuted in a study by Lemaire *et al*[71] who found no difference in pancreatic exocrine insufficiency between PG and PJ.

Pylorus preserving PD or classic Kausch-Whipple

Proponents of pylorus preservation argue that the gastroduodenal physiology is better maintained and therefore, especially postoperative quality of life, is superior to the classic Kausch-Whipple (CKW) technique. In contrast, proponents of the CKW technique state that preservation of the pylorus does not follow the rules of radical tumor surgery with inadequate clearance of lymphatic nodes, inadequate tumor staging, and increased risk of tumor recurrence and impaired overall survival. In the most recently published meta-analysis by Fitzmaurice *et al*[72], 43 studies [6 randomized controlled trials, 12 prospective studies and 25 retrospectives studies; pylorus preserving pancreaticoduodenectomy (PPPD): *n* = 1870; CKW: *n* = 1923] were analyzed. To investigate the postoperative overall survival, a total of 26 studies with only surgery for pancreatic cancer patients were analyzed. The overall postoperative survival was found to be equal following PPPD and CKW. However, by only analyzing those studies of higher scientific quality, a significantly longer overall survival was found in patients who had undergone PPPD.

Thirty-three studies were eligible for analyzing postoperative mortality. The authors reported no significant difference between the two procedures. As far as the quality of life is concerned, the studies are difficult to compare since a large variety of different quality of life scores (if used at all) and parameters were used[72]. Another recently published meta-analysis has shown that PPPD reduced the operation time and reduced blood loss[73,74]. Therefore, the CKW operation should only be performed in situations where tumor spread towards the stomach cannot be ruled out or when lymph node metastases are suspected. Irrespective of whether PPPD or CKW is performed, antecolic reconstruction is preferred to decrease the incidence of postoperative delayed gastric emptying[75].

Is there a role for routine intra-peritoneal drainage?

The theoretical advantage of routine intraoperatively placed abdominal drainage is to drain the pancreatic juice in the case of PF formation which avoids the negative sequelae of free pancreatic juice in the abdominal cavity. The concept of the routine use of intra-peritoneal drainage (IPD) is still in the mind of many surgeons. In contrast to such paradigms, Conlon *et al*[76] found in their prospective, randomized study of patients having undergone pancreatic resections that the routine use of a closed IPD resulted in a higher number of patients suffering from local septic complications and an increased rate of PFs (22% *vs* 9%, *P* < 0.02). In another recently published trial, short-term abdominal drainage (< 3 d) in patients with a low risk of PF formation did not show any benefit in the routine use of an IPD. To date, there is a lack of evidence for the routine use of IPD in pancreatic surgery[77].

LYMPH NODE DISSECTION AND PATHOLOGICAL WORK-UP

Radicality of pancreatic resection

A strict surgical technique and a high quality pathological work-up of the surgical specimen are of utmost importance. To improve the number of R0 resections, transsection of the main bile duct is performed just below the biliary confluence in a monobloc technique including the gallbladder - preparation is carried out in close contact with the right border of the superior mesenteric artery to achieve maximum retroperitoneal tumor clearance. Intraoperative frozen section analysis of the resection margins is mandatory - especially, as the pancreatic resection margin shows microscopic tumor infiltration in 10%-20% of cases[78].

Lymphadenectomy during pylorus PPPD/CKW

As for any other cancer type, the lymph node status is of major clinical and prognostic value. However, some controversies remain regarding how these should be reported (total number or lymph node ratio) and on the impact of an extended lymphatic clearance. Standard lymphadenectomy for PPPD/CKW includes the lymph nodes of the hepato-duodenal ligament, along the common hepatic artery, portal vein, cranial portion of the superior mesenteric vein as well as the right border along the superior mesenteric artery and celiac trunk. Extended lymphadenectomy includes in addition to the lymphatic reservoir of the interaortocaval space, the left-side of the celiac trunk as well as the left side along the superior mesenteric artery. In a study of 517 pancreatic cancer patients, no prognostic difference was found between peripancreatic lymph node metastases and second level lymphatic nodes N2 (along the common hepatic artery, portal vein, cranial portion of the superior mesenteric vein as well as the right border along the mesenteric superior artery and celiac trunk). Furthermore, in patients with one positive lymph node metastasis (N1), overall survival was similar to nodal negative (N0) patients. A poorer prognosis was reported with two or more positive lymphatic nodes (> N1), irrespective of the total number of affected lymph nodes[79]. The lymph node ratio has been introduced to

Table 4 Improvement of radicality of resection	
Resection	**Exclusion of resection**
Standard lymph node clearance for PPPD/CKW include the regional peripancreatic lymph nodes, hepato-duodenal ligament, common hepatic artery, portal vein, cranial portion of the superior mesenteric vein, right border along the mesenteric superior artery and celiac trunk	Extended lymphadenectomy can not be recommended
Vascular resection of the portal vein or superior mesenteric vein is feasible and safe and should not be an exclusion criterion in curative surgery	Thrombosis of the mesenteric-portal vein or tumoral infiltration > 180° of these vascular structures are contraindications in attempting curative resection

PPPD: Pylorus preserving pancreaticoduodenectomy; CKW: Classic Kausch-Whipple.

characterize lymphatic tumor load and to create a prognostic parameter independent of the rough estimation N0 *vs* N1 or the overall number of affected lymph nodes[80,81]. There is still some debate about the exact cut-off level of the lymph node ratio which indicates poorer survival. In a study of 4000 patients, a cut-off of 0.2 was reported as a strong predictor of poor survival[82]. Currently, a minimum of 10-12 lymph nodes need to be cleared during PPPD/CKW[83]. The para-aortic lymph nodes are generally considered as metastatic disease (M1). However, some confusion exists whether clearance of these nodes improves survival. In a review by Glanemann *et al*[84], patients with para-aortal positive lymph nodes showed a poor survival. The authors concluded that such patients should not undergo resection. The role of extended lymph node dissection has been extensively investigated. No benefit was found for this approach[85,86]. Since extended lymphadenectomy increases perioperative morbidity and impairs quality of life, this procedure should not be performed routinely.

Resection margins

Surgical resection margin is a major prognostic factor. Any incomplete resection (R1) must be considered as palliative[87,88]. However, there are also data on long-term survival after R1 resections[88,89]. A possible explanation for such conflicting data is most likely due to the heterogeneity between the study populations and different pathological work-up standards of the surgical specimens. Indeed, the number of patients with a positive resection margin was found to be between 14% and 85%[90,91]. In fact, a standardized examination of the resected specimens showed intraoperative coloration of the retroperitoneal resection margin using India ink and in a higher number of paraffin-embedded thin-sliced sections. With this technique, more than two-thirds of patients were found to be R1 resected in the retroperitoneal margin[91]. The incidence of R1 resections was correlated with the number of thin-sliced sections performed[90]. A retroperitoneal margin of 1.5 mm was classified as a R0 resection. This, however, is unfortunately rarely achievable[92].

Management of vascular infiltration

Major arterial resection such as the superior mesenteric artery is technically feasible, major arterial resection during duodenopancreatectomy is currently not established and there are insufficient data to perform such a proce-

dure[4]. In contrast, venous involvement is not a contraindication for excluding patients from undergoing curative surgery. Venous resection, partial or even circumferential with an adequate technique of reconstruction is associated with a survival similar to those groups of patients having undergone PD for adenocarcinoma[89]. However, if the tumoral infiltration of the portal vein is 50% or more of the vascular circumference, survival rates of such patients undergoing duodenopancreatectomy and venous resection are inferior compared to patients having undergone duodenopancreatectomy alone[93]. Unfortunately, the exact extent of venous tumoral infiltration is difficult to estimate preoperatively, and the definitive extent of vascular infiltration is only made by pathological examination of the resected specimen[89,94-97]. However, the impact of portal vein resection during PD remains unclear. The number of patients who undergo a R1 resection varies between 38% and 59%[97-101]. In a recently published review of 1600 patients having undergone pancreatic resection in combination with venous resection, the number of patients who finally had a R1 resection was 40%[102]. Several series have reported a similar survival after PD with or without venous resection[97,98,99-101]. In a review of 1646 patients having undergone portal/superior mesenteric vein resection, the long-term survival at 1-, 3- and 5-years was 50%, 16% and 7%, respectively[102]. Since PD and mesenteric or portal vein resection have the same reported morbidity and mortality as patients who have undergone PD without vascular resection, and the tumor involvement of such venous structures is a consequence of the tumor location rather than a reflection of highly aggressive tumoral behavior, venous resection during duodenopancreatectomy has become a standard procedure. However, vascular infiltration has been reported as a risk factor for local tumor recurrence[97]. In addition, the results remain disappointing since the reported median survival after duodenopancreatectomy and venous resection was only 13 mo[4,102] with a high number of patients (40%) not free of tumor (R1)[89] (Table 4).

CONCLUSION

The survival of patients with pancreatic cancer has only slightly improved over the last few years. An increase in median survival from 16 mo in the eighties to 20 mo nowadays was reported by the French Surgical Association in 2010. This achievement is poor compared to the

progress made in other cancer types (e.g., rectal cancer). Radical surgery so far remains the only chance of long-term cure. However, new molecular markers for early diagnosis[103-105], a deeper understanding of the molecular alterations during the genesis and progression of pancreatic cancer, specifically designed new neoadjuvant and/or adjuvant therapies which directly interact with the molecular cancer cascade need to be developed in the future. Without such progress, the prognosis of pancreatic cancer remains catastrophic.

Abstract

AIM: To investigate the effect of chloride intracellular channel 1 (CLIC1) on the cell proliferation, apoptosis, migration and invasion of gastric cancer cells.

METHODS: CLIC1 expression was evaluated in human gastric cancer cell lines SGC-7901 and MGC-803 by real time polymerase chain reaction (RT-PCR). Four segments of small interference RNA (siRNA) targeting CLIC1 mRNA and a no-sense control segment were designed by bioinformatics technology. CLIC1 siRNA was selected using Lipofectamine 2000 and transfected transiently into human gastric cancer SGC-7901 and MGC-803 cells. The transfected efficiency was observed under fluorescence microscope. After transfection, mRNA expression of CLIC1 was detected with RT-PCR and Western blotting was used to detect the protein expression. Proliferation was examined by methyl thiazolyl tetrazolium and apoptosis was detected with flow cytometry. Polycarbonate membrane transwell chamber and Matrigel were used for the detection of the changes of invasion and migration of the two cell lines.

RESULTS: In gastric cancer cell lines SGC-7901 and MGC-803, CLIC1 was obviously expressed and CLIC1 siRNA could effectively suppress the expression of CLIC1 protein and mRNA. Proliferation of cells transfected with CLIC1 siRNA3 was enhanced notably, and the highest proliferation rate was 23.3% (P = 0.002) in SGC-7901 and 35.55% (P = 0.001) in MGC-803 cells at 48 h. The G2/M phase proportion increased, while G0/G1 and S phase proportions decreased. The apoptotic rate of the CLIC1 siRNA3 group obviously decreased in both SGC-7901 cells (62.24%, P = 0.000) and MGC-803 cells (52.67%, P = 0.004). Down-regulation of CLIC1 led to the inhibition of invasion and migration by 54.31% (P = 0.000) and 33.62% (P = 0.001) in SGC-7901 and 40.74% (P = 0.000) and 29.26% (P = 0.002) in MGC-803. However, there was no significant difference between the mock group cells and the negative control group cells.

CONCLUSION: High CLIC1 expression can efficiently inhibit proliferation and enhance apoptosis, migration and invasion of gastric cancer cells *in vitro*. CLIC1 might be a promising target for the treatment of gastric cancer.

Key words: Chloride intracellular channel 1; Gastric carcinoma; Small interference RNA; Apoptosis; Invasion; Migration

INTRODUCTION

Gastric cancer represents the second most common cause of cancer-related deaths in the world, and the incidence is higher in Asia than in other geographical areas[1,2]. Although progress is made in early detection and adjuvant therapy, the precise mechanism underlying gastric cancer remains unclear.

Recently, the roles of ion transporters have been studied in cancer cells[3,4] and various types of ion transporters have been found in cancers of digestive organs. Chloride intracellular channel (CLIC) proteins are components or regulators of novel intracellular anion channels in mammalian cells. To date, seven distinct members of CLICs have been identified: CLIC1, CLIC2, CLIC3, CLIC4, CLIC5, p64 and parchorin[5]. These genes have a high degree of homology at their carboxyl termini. In terms of their molecular function *in vitro*, it is clear that all CLIC proteins and the invertebrate CLIC-like proteins exist as both soluble globular proteins and integral membrane proteins that possess ion channel activity. The transition between these two forms is influenced by pH and redox conditions under most instances[6]. CLIC1 is the first cloned human member of the CLIC family, and is a 241 amino acid ion channel protein. Like other members of the family, CLIC1 is highly conserved across a wide range of species and its relatives can be identified in the genome of all vertebrates so far sequenced. CLIC1 was initially found to localize in the cell nucleus and intracellular vesicles[7]. Ulmasov *et al*[8] found that CLIC1 was expressed in the apical domains of several simple columnar epithelia, including glandular stomach, small intestine, colon, bile ducts, pancreatic ducts, airway, the tail of the epididymis and renal proximal tubule. Chen *et al*[9] found that a trace amount of CLIC1 was expressed in normal gastric tissues, but it was overexpressed in gastric cancer. Elevated CLIC1 expression was strongly correlated with lymph node metastasis, lymphatic invasion, perineural invasion and pathological staging, which suggested that it was a potential prognostic marker[9]. However, its role in gastric cancer deserves further studies.

In the present study, we used the RNA interference (RNAi) technology, with a Lipofectamine 2000, in order to deliver small interference RNA (siRNA) molecules that target CLIC1 gene of the gastric cancer cells. RNAi is a highly specific, homology dependent suppression of gene expression by small double-stranded RNA (dsRNA)[10]. Long dsRNAs are cleaved by the endoribonuclease Dicer into short dsRNA duplexes or siRNA. siRNAs are loaded onto RNA-induced silencing complex (RISC)[11]. RISC contains argonaute 2 (Ago-2) which cleaves and releases one strand from the dsRNA, resulting in an activated form of RISC with a single-strand RNA (guide siRNA) that directs the specificity of the target mRNA recognition through complementary base pairing[12]. Ago-2 then cleaves the target mRNA between bases 10 and 11 related to the 5' end of the siRNA antisense strand, thereby causing mRNA degradation and gene silencing[12,13], which occurs at a post-transcriptional level[14]. Here, we employed CLIC1 siRNA to knockdown the expression of CLIC1, and investigated its effects on cell proliferation, cycle, apoptosis, migration, invasion and the mechanisms involved.

MATERIALS AND METHODS

Cell cultures

Human gastric cancer cell lines SGC-7901 (adenocarcinomas) and MGC-803 (adenocarcinomas) were obtained from Shanghai cell bank (http://www.cellbank.org.cn), Chinese Academy of Sciences (Shanghai, China). The cell lines were maintained in Dulbecco's modified Eagle's medium (DMEM) (Gibco, United States) , supplemented with 10% (v/v) fetal bovine serum (FBS) (HyClone, Logan City), penicillin G (100 units/mL) (Sigma, United States) and streptomycin (100 μg/mL) (Sigma, United States), which was termed complete medium. Cells were grown in monolayer culture at 37 ℃ in humidified air with 5% CO_2.

Real-time polymerase chain reaction assays

Total RNA was extracted from human gastric cancer cell lines SGC-7901 and MGC-803 using TRIzol reagent (Invitrogen, CA). Total RNA (1-2 μg) was reversely transcribed using the Fermentas Kit (MBI, United State). Primers were based on sequences reported at Genebank (NM_001288.4). CLIC1 sense sequence was 5'-AATCAAACCCAGCACT-CAATG-3' and anti-sense sequence was 5'-CAGCACTG-GTTTCATCCACTT-3'. The expected product size of CLIC1 cDNA was 114 bp. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) sense sequence was 5'-CAAC-GACCCCTTCATTGACC-3' and anti-sense sequence was 5'-CGCCAGTAGACTCCACGACAT-3'. The expected product size of GAPDH cDNA was 203 bp. Polymerase chain reaction (PCR) amplification was performed in 50 μL reaction volumes containing 0.2 mmol/L each dNTP, 0.1 RM of each oligonucleotide primer, and 1.25 U Tag polymerase in PCR buffer. cDNA was amplified on a PCR thermal controller with an initial denaturation at 95 ℃ for 10 min, followed by 40 cycles of 95 ℃ for 20 s, 59 ℃ for 30 sec, and 68 ℃ for 30 s and a final extension step of 72 ℃ for 10 min. The amount of starting cDNA was adjusted using GAPDH intensity.

siRNA synthesis and cell transfection assays

This study included four human siRNAs (GenePharma, Shanghai, China) designed against CLIC1 (GenBank NM_001288.4). One negative random siRNA (GenePharma, Shanghai, China) exhibiting no significant sequence similarity to human, mouse or rat gene sequence, served

as a negative control. The sequences for CLIC1 siRNAs and control siRNA were: siRNA1: CLIC1-Homo-131 (sense: 5'-GAGCUUGUGUUGUGCUGAATT-3' antisense: 5'-UUCAGCACAACACAAGCUCTT-3'); siRNA2: CLIC1-Homo-630 (sense: 5'-CAGCACUCAAUGACAAUCUTT-3' antisense: 5'-AGAUUGUCAUUGAGUGCUGTT-3'); siRNA3: CLIC1-Homo-805 (sense: 5'-GCCAAAGUUA-CACAUAGUATT-3' antisense: 5'-UACUAUGUGUAA-CUUUGGCTT-3'); siRNA4: CLIC1-Homo-1195 (sense: 5'-GGACAACAUAUUUCAGUAATT-3' antisense: 5'-UUACUGAAAUAUGUUGUCCTT-3'); and the negative random siRNA 5 (sense: 5'-UUCUCCGAACGUGUCAC-GUTT-3' anti-sense: 5-ACGUGACACGUUCGGAGA-ATT-3'). The cells were split into seven groups, including the mock group supplemented with only the transfection reagent, the negative control group added with a non-targeting control siRNA and the transfection reagent, and the other five groups supplemented with different CLIC1 siRNA and the transfection reagents. For cell transfection, cells were plated on 96-well (5×10^3 cells for SGC-7901 and 3×10^3 cells for MGC-803) and 6-well plates (5×10^5 cells for SGC-7901 and 3×10^5 cells for MGC-803) in DMEM with 10% FBS and were allowed to attach for 24 h, and then treated with 5 pmol and 100 pmol siRNA per well. Equimolar amounts of siRNAs were incubated with Lipofectamine 2000 Transfection Reagent from Invitrogen (Madison, WI, United States) according to the manufacturer's instructions. Transfected cells were grown at 37 ℃ for 6 h, followed by incubation with complete medium. Cells were maintained for 24 h, 48 h and 72 h before experiments, unless otherwise described.

Quantitative real-time PCR assays

Total RNA was extracted from the human gastric cancer cell lines SGC-7901 and MGC-803 using TRIzol reagent (Invitrogen, United States). After reverse transcription of the total RNA, the first-strand cDNA was then used as template for detection of CLIC1 expression using quantitative real-time PCR with the SYBR Green Master Mix (Roche, Germany). β-actin was used as control. The primers of CLIC1 sense sequence was 5'-AATCAAACCCAGCACTCAATG-3' and CLIC1 anti-sense sequence 5'-CAGCACTGGTTTCATCCACTT-3' (product size of 114 base pairs). β-actin sense sequence was 5'-ACACTGTGCCCATCTACG-3' and anti-sense sequence 5'-TGTCACGCACGATTTCC-3' (product size of 153 base pairs). The cycling conditions included a holding step at 95 ℃ for 10 min, and 42 cycles of 95 ℃ for 20 s, 59 ℃ for 30 s and 68 ℃ for 30 s. A dissociation protocol was added to verify that the primer pair produced only a single product at 95 ℃ for 15 s, 60 ℃ for 1min, and 95 ℃ for 31s. Melting curves also showed a single sharp peak indicating one PCR product. Quantitative real-time PCR analysis was performed using an ABI 7500 Sequence Detector (ABI, Warrington, United Kingdom) according to the manufacturer's protocol, and the results were analyzed by the $2^{-\Delta\Delta ct}$. These experiments were performed in triplicate and repeated in three independent experiments.

Western blotting assays

Total protein extracts were separated by 12% sodium dodecylsulfate polyacrylamide gel electrophoresis (20 mg per lane), and transferred onto a polyvinylidene fluoride membrane. After blocking with 5% bovine serum albumin, the membrane was then incubated with antibodies specific for CLIC1 (Sigma; 1:500), and β-actin (Abmart; 1:5000) at 4 ℃ overnight. The secondary antibody (KPL; 1:5000) was infrared at room temperature for 1 h. The density of the bands was quantified by densitometric analysis using the two-color infrared laser imaging analyzer system of Odyssey (United States). The inhibitory rate of CLIC1 protein expression was calculated as follows: inhibitory rate = [1-(siRNA CLIC1 density/siRNA β-actin density)/(untransfected CLIC1 density/untransfected β-actin density)] × 100%.

Cell growth and viability assay

The effect of CLIC1 specific siRNA on the viability of cells was determined by the methyl thiazolyl tetrazolium (MTT) assay. Briefly, cells were plated in 96-well microtitre plates. Cell viability was determined after transfection for 24 h, 48 h and 72 h. Then 20 μL MTT (10 mg/mL in PBS stock, diluted to a working concentration of 1 mg/mL with media) was added to each well and incubated for 4 h. After careful removal of the medium, 200 μL dimethyl sulfoxide was added to each well and shaken carefully for 10 min. The absorbance was recorded on the iMark Microplate Reader (Bio-Rad, United Kingdom) at a 570 nm wavelength. The effect of CLIC1 siRNA on cell growth inhibition was assessed as percentage cell viability where vehicle-treated cells were taken as 100% viable.

Cell cycle analysis and annexin V staining assays

For flow cytometric cell cycle analysis, the cells treated with siRNA were collected, washed with PBS, fixed in cold 70% ethanol, and stored at 4 ℃ until staining. After fixation, the cells were washed with PBS and incubated with 100 μL RNaseA (Sigma, United States) for 30 min at 37 ℃, before staining with 400 μL propidium iodide (Sigma, United States). Apoptotic cells in early and late stages were detected using an annexin V-FITC Apoptosis Detection Kit from BioVision (Mountain View, CA, United States). In brief, culture media and cells were collected and centrifuged. After washing, cells were resuspended in 500 μL annexin V binding buffer, followed by the addition of 5 μL annexin V-FITC and 5 μL propidium iodide. The samples were incubated in the dark for 5 min at room temperature and analyzed using flow cytometry (FCM).

Cell migration assay

The ability of cells to migrate through filters was measured using Polycarbonate Membrane Transwell Inserts (Corning, United State). At 24 h after transfection, cells

were trypsinised. Cell culture inserts with an 8 μm pore size polycarbonate membrane were used according to the protocol of the manufacturer. The bottom chamber included medium (0.5 mL) containing 5% FBS, whereas mock, negative control or CLIC1 siRNA transfected cells (1.0×10^6 per mL suspended in 0.1 mL of medium containing 0.5% FBS) were seeded into the upper chamber and incubated 24 h at 37 ℃ in a humidified atmosphere containing 5% CO_2. The remaining cells on the upper surface were mechanically removed. Membranes were then washed, fixed, and stained by Methyl Violet (Medion Diagnostics, Germany). The migration ability of the cells was determined by counting the cells that had migrated to the lower side of the filter with a microscope. Experiments were performed in triplicate, and 3 fields were counted in each experiment.

Matrigel invasion assay

Matrigel invasion assay was performed using polycarbonate membrane transwell (Corning, United States) coated with the matrigel (BD Biosciences, San Jose, CA, United States). The density of cells that were seeded into the upper chamber was 3.0×10^5/mL for SGC-7901 and 1.5×10^5/mL for MGC-803. Other treatments were the same with the cell migration assay.

Statistical analysis

Data were analyzed using SPSS16.0 software. All data were expressed as mean ± SD, and analyzed by one-way analysis of variance and post-hoc testing comparing means by Student-Newman-Keuls' test. $P < 0.05$ was considered statistically significant.

RESULTS

Expression of CLIC1 in cultured gastric cancer cells

We first evaluated the endogenous expression of CLIC1 in the human gastric cancer cell lines SGC-7901 and MGC-803 by RT-PCR, and found that there was CLIC1 mRNA in the human gastric cancer cell lines SGC-7901 and MGC-803 (Figure 1).

Downregulation of CLIC1 expression effectively suppresses CLIC1 protein and mRNA expression in gastric cancer cells

To examine the possible roles of CLIC1 in gastric cancer cells, we knocked down the expression of CLIC1 using siRNA. Western blotting and quantitative real-time PCR were performed to examine the effect of siRNA transfection on CLIC1 protein and mRNA expression levels in SGC-7901 and MGC-803 cells. When SGC-7901 and MGC-803 cells were transfected with CLIC1 siRNA, the CLIC1 mRNA and protein levels were decreased in different degrees in siRNA1, siRNA2, siRNA3 and siRNA4 transfected cells as compared with siRNA5, mock and negative control cells at different time points ($P < 0.05$). There were no significant differences among siRNA5, mock and negative control cells ($P > 0.05$) (Figure 2). The

Figure 1 Expression of chloride intracellular channel 1 in human gastric cancer cell lines SGC-7901 and MGC-803. Specific reverse transcription polymerase chain reaction analysis for chloride intracellular channel 1 (CLIC1). Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as loading control.

results showed that these siRNAs designed for CLIC1, especially the CLIC1 siRNA3, successfully exerted a silencing effect for CLIC1 expression *in vitro*. Therefore, the CLIC1 siRNA3 was chosen for the subsequent *in vitro* experiments.

Downregulation of CLIC1 expression enhances growth of gastric cancer cells in vitro

We investigated whether CLIC1 expression could decrease the survival of gastric cancer cells. Downregulation of CLIC1 expression enhanced notably proliferation of gastric cancer cells in a time-dependent manner, and the highest growth rates were 25.60% ($P = 0.002$) in SGC 7901 for CLIC1 siRNA3 at 24h and 35.55% ($P = 0.001$) in MGC-803 cells for CLIC1 siRNA3 at 48 h. The cells transfected with CLIC1 siRNA3 survived at increased rates compared with the mock group cells and the negative control group cells. Our findings demonstrated that downregulation of CLIC1 expression enhances growth of SGC-7901 and MGC-803 cells *in vitro* (Figure 3).

Downregulation of CLIC1 expression induces cell cycle arrest in gastric cancer cells

The cell cycle assay indicated that the inhibition of CLIC1 expression by specific CLIC1 siRNA3 significantly changed the proportions of the G0/G1, S and G2/M phases at 48 h after transfection with CLIC1 siRNA3. The percentage of the G2/M phase proportion increased notably in after transfection with CLIC1 siRNA3 in SGC-7901 (2.66-fold) and MGC-803 (1.28-fold), respectively, while there was decrease in the proportion of G0/G1 and S phases (Figure 4).

Downregulation of CLIC1 expression inhibits gastric cancer cell apoptosis in vitro

We investigated whether CLIC1 could induce human gastric cancer SGC-7901 and MGC-803 cell apoptosis. Cells were harvested and disposed by the Annexin V assay with indicated treatment at 48 h after transfection in SGC-7901 and MGC-803 cells. Then apoptosis was examined by FCM. The rates of apoptosis were obviously decreased in both SGC-7901 and MGC-803 cells (Figure 5). The CLICI siRNA3 showed the least apoptosis rate, suggesting that CLIC1 expression can increase apoptosis of gastric cancer cells *in vitro*.

Figure 2 Effect of chloride intracellular channel 1 knockdown in SGC-7901 and MGC-803 cells. Chloride intracellular channel 1 (CLIC1) protein expression was detected by Western blotting using a rat polyclonal CLIC1 antibody (1:500). β-actin was used as loading control. CLIC1 mRNA expression was detected by quantitative real-time polymerase chain reaction. β-actin was used as loading control. The figure represents one of the three experiments performed independently with similar results. A: CLIC1 protein expression in SGC-7901 by Western blotting; B: CLIC1 protein expression in MGC-803 by Western blotting; C: Relative CLIC1 protein expression level in SGC-7901; D: Relative CLIC1 protein expression level in MGC-803; E: Relative CLIC1 mRNA expression level in SGC-7901; F: Relative CLIC1 mRNA expression level in MGC-803. The experiment was done in triplicate and the value obtained from the control (CTRL) group set as 100%. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* CTRL and mock.

Downregulation of CLIC1 expression inhibits gastric cancer cell migration and invasion *in vitro*

We determined the effect of decreased CLIC1 expression on gastric cancer cell invasion, and examined the role of CLIC1 in gastric cancer cell migration. There was a sig-

nificant decrease in CLIC1 siRNA3 transfected cells in the Matrigel invasion assay (Figure 6A and B). Decreased CLIC1 expression led to the inhibition of invasion by 54.31% ($P = 0.000$) in SGC-7901 and 40.74 % ($P = 0.000$) in MGC-803 cells. And cancer cell migration was also

Figure 6 Effects of chloride intracellular channel 1 knockdown on cell migration and invasion in SGC-7901 and MGC-803 cell lines at 48 h. A: The figure was obtained from the invasion assay of SGC-7901 cells; B: The figure was obtained from the invasion assay of MGC-803 cell; C: The figure was obtained from the migration assay of SGC-7901 cells; D: The figure was obtained from the invasion assay of MGC-803 cell; E: The data was obtained from the invasion assay; F: The data was obtained from the migration assay. The experiment was done in triplicate. The figure represented one of the 3 experiments performed in duplicate. Cell invasion and migration were evaluated after two days SGC-7901 and MGC-803 cells were transfected *in vitro*. Representative microscopic images were presented in the upper panel of each assay graph. The number of cells that invaded or migrated through the filter was counted. Data are expressed as average number of migrated or invaded cells. The cells transfected with chloride intracellular channel 1 (CLIC1) specific small interference RNA (siRNA) 3 were significantly less able to invade or migrate than the mock cells or the negative control cells in both SGC-7901 and MGC-803 cells. $^{a}P < 0.05$, $^{b}P < 0.05$ *vs* control (CTRL) and mock.

significantly reduced by CLIC1 siRNA3 in the migration assay (Figure 6C and D). Decreased CLIC1 expression inhibited the cell migration by 33.62% ($P = 0.001$) in SGC-7901 and 29.26% ($P = 0.002$) in MGC-803. Taken together, these results clearly indicate that suppression of CLIC1 inhibits the invasion and migration ability of SGC-7901 and MGC-803 cells.

DISCUSSION

Gastric cancer is a highly aggressive and lethal malignancy. It accounts for 8.6% of all new cancer cases worldwide, and is the second leading cause of cancer-related deaths[15]. Surgery is the standard treatment for localized gastric cancer, but advanced patients with distant metastasis or recurrence remain incurable[16]. Identification of key regulatory molecules in metastasis is crucial for understanding the mechanism for tumor dissemination as well as development of novel interventions. However, molecular events promoting invasiveness of gastric carcinoma cells remain unknown and routine biomarkers for metastastic gastric carcinoma are not yet available[17].

CLIC1 (also called nuclear chloride channel-27 or NCC27), the first identified human member of a growing family of organelle ion channels, is a transmembrane protein sufficient to form a functional ion channel as a tetrameric assembly of subunits. Both human and murine *CLIC1* genes are located within the major histocompatibility complex class Ⅲ region, one of the most conserved and important regions in the genome. In humans, it is located at 6p21.3[18]. The structure of the soluble form of CLIC1 is a typical soluble glutathione S-transferase superfamily protein, but contains a glutaredoxin-like active site[19]. Some recent studies have suggested that CLIC1 plays an important role in tumor metastasis[10,20].

Chen *et al*[9] reported that CLIC1 expression was significantly up-regulated in 67.9% of gastric cancer patients. The CLIC1 expression in tumor tissues increased 1.95-fold (range: 0.01-6.19-fold) compared with that expressed by adjacent noncancerous mucosa. Elevated CLIC1 expression was strongly correlated with lymph node metastasis, lymphatic and perineural invasion, pathological staging and poor survival. Additionally, the 5-year survival rate of the low CLIC1 expression group was higher than that

of the high CLIC1 expression group. But further investigations are needed to observe this phenomenon *in vitro* and elucidate the mechanisms of CLIC1's involvement in tumor metastasis. In this study, we used RNAi technology to inhibit the expression of CLIC1 in gastric cancer cell lines SGC-7901 and MGC-803, and explored the possible mechanism by observing the biological behavior changes (such as invasion, migration, *etc.*) after inhibition.

We designed four pairs of siRNA against the *CLIC1* gene in this study to guarantee that there was at least one CLIC1 siRNA that could inhibit gene expression effectively. We used the four CLIC1 siRNAs to downregulate the expression of CLIC1 in human gastric cancer cell lines SGC-7901 and MGC-803. Quantitative real-time PCR and Western blotting assay showed that CLIC1 mRNA and protein expression were down-regulated by CLIC1 siRNA. Generally, the inhibition rate of CLIC1 siRNA3 was higher than siRNA1, siRNA2 and siRNA4, but there were no significant differences among siRNA5 group, mock group and CTRL group cells at all the time points in both cell lines ($P > 0.05$). And 24, 48 and 72 h after transfection with siRNA3, the expression of mRNA and protein was down-regulated significantly in both SGC-7901 (inhibition rates of mRNA: 98.35%, 94.15% and 95.38%; inhibition rates of protein: 70.00%, 76.39% and 87.90%) and MGC-803 cells (inhibition rates of mRNA: 78.33%, 86.81% and 84.65%; inhibition rates of protein: 72.63%, 81.97% and 64.06%). These results showed that CLIC1 siRNA3 can efficiently inhibit CLIC1 expression. Therefore, CLIC1 siRNA3 was chosen for the subsequent experiments *in vitro*. However, the decreased level of mRNA and protein expressions after RNAi are inconsistent in SGC-7901 but in MGC-803, the specific mechanism needs to be further explored. In addition, we noted that the inhibition rates in the two cell lines were different, *i.e.*, the inhibition rate was higher in SGC-7901 than in MGC-803 cells. The possible reasons for the difference were different cell growth characteristics and tissue source between the two cell lines. SGC-7901 originates from metastatic lymph node of gastric carcinoma, but MGC-803 comes from poorly differentiated adenocarcinoma of gastric mucous cells. Wang *et al*[21] found that the ability of cell growth, proliferation, migration and invasion of MGC-803 was much stronger than SGC-7901. In addition, MGC-803 has the characteristic of short growth cycle, unstable adhesion and high sensitivity to external stimuli. After successfully transfected with siRNA, MGC-803 exfoliated easily due to its vulnerable characteristics. Therefore, the inhibition rate of MGC-803 was lower than SGC-7901 under the same transfection conditions.

In this study, the *A* value increased significantly by the silencing of CLIC1 in the cell growth assay, suggesting that downregulation of CLIC1 by siRNA3 promoted the proliferation of gastric cancer cells. That is to say, *CLIC1* gene itself could inhibit the proliferation of gastric cancer cells. Some scholars observed the same phenomenon in their studies[20,22,23].

It has been found that CLIC1 expression in the cell membrane only occurred at G2/M phase, and located in the cytoplasm in G1/S phase. Some researchers utilized CLIC1 blocker and found Chinese hamster ovary (CHO) cell cycle arrest of CHO cell was in the G2/M phase, suggesting that CLIC1 was involved in cell cycle[24]. Unlike typical membrane protein, the soluble CLICl presented firstly in the cytoplasm after synthesized, and then transferred to the plasma membrane to play a role of an ion channel[25]. Using the technology of RNAi, we inhibited the expression of CLIC1 in gastric cancer cell lines SGC-7901 and MGC-803, and detected the cells with the FCM. As a result, we found that cell cycle arrest in the G2/M phase was increased notably. Along with previous studies, we speculated that the expression of CLIC1 in this phase was enhanced significantly, and then played a role of an ion channel, such as promotion of cell growth. The findings proved that CLIC1 participated in regulation of cell cycle in the G2/M phase, and played an important role in the process of cell division. In addition, the apoptosis rate was decreased markedly in the CLIC1 siRNA3 group. Compared with control group, the apoptosis rates in SCC-7901 and MGC-803 were reduced by 62.24% and 52.67%, respectively. This suggests that the gene itself can promote gastric cancer cell apoptosis. And some studies also found this function in colon cancer, mouth cavity squamous cell carcinoma, melanoma and mouse hepatocellular carcinoma[20,23,26].

Some scholars[20,27,28] found that overexpression of CLIC1 significantly increased cell motility, and knockdown of CLIC1 markedly inhibited cell migration and invasion. But the role of CLIC1 in gastric cancer metastasis remains largely unclear. We studied the CLIC1 functions with a Transwell assay in gastric cancer cells, and the results demonstrated that down-regulation of CLIC1 expression by siRNA3 obviously suppressed the invasion and migratory capacity of SGC-7901 and MGC-803 cells *in vitro*. These results were consistent with previous experiments. A recent study to explain how CLIC1 promotes the movement of cancer cells found that CLIC1 has been implicated in modifying cell adhesion[24,29]. Tung *et al*[27] reported that reduced CLIC1 expression caused a reduction in endothelial migration, branching morphogenesis, capillary-like network formation, and capillary-like sprouting. FACS analysis showed that reducing CLIC1 expression increased integrins of β1, α3 and αvβ3 expression, but decreased the αvβ5 expression. Integrins are essential for invasion and metastasis of carcinoma cells and are a major family of cell adhesion molecules，which mediate cell-cell adhesion or cell-extracellular matrix adhesion and affect signal transduction, cell proliferation, differentiation, survival and apoptosis[30]. By increasing the surface expression of β1, α3 and αvβ3, downregulation of CLIC1 expression can increase endothelial cell adhesion to the extracellular matrix and inhibit motility by preventing the cell from breaking its contact with the extracellular matrix. These shifts in integrin expression also provide a possible explanation for the cell growth and viability defects[31]. Additionally, studies confirmed that invasion and migration of gastric cancer was closely associated with integrins[32-34], therefore, we speculated that invasion and migration inhibition of gastric cancer cells after knock-

down of CLIC1 was associated with the up-regulation of β1, α3 and αvβ3. However, the specific mechanism needs to be further studied.

In summary, our findings show that CLIC1 siRNA3 can efficiently inhibit CLIC1 expression, and suppress gastric cancer migration and invasion *in vitro*. However, downregulation of CLIC1 expression promotes the proliferation of gastric cancer and reduces gastric cancer cellular apoptosis. The molecular mechanism remains unclear. Future studies need to focus on the precise mechanism of tumorigenesis. In addition, animal models need to be established. In short, CLIC1 plays an important role in regulating the biological behavior of gastric cancer cells. Our research lays a solid foundation for future studies.

COMMENTS

Background
Gastric cancer is a highly aggressive and lethal malignancy. Metastasis or recurrence is the main obstacle to improvement of the treatment efficacy of gastric cancer. Identification of key regulatory molecules in metastasis is crucial for understanding tumor dissemination and for development of novel interventions. However, molecular events promoting invasiveness of gastric carcinoma cells are still hardly known and routine biomarkers for metastastic gastric carcinoma are not yet available.

Research frontiers
Some researchers found that chloride intracellular channel 1 (CLIC1) was overexpressed in gastric cancer and was a potential prognostic marker, and elevated CLIC1 expression was strongly correlated with lymph node metastasis, lymphatic invasion, perineural invasion, and pathological staging. However, its role in gastric cancer deserves further studies.

Innovations and breakthroughs
Previous studies mainly focused on the phenomenon that the level of CLIC1 expression was associated with clinicopathologic features of gastric cancer in vivo. However, whether it is consistent with the phenomenon *in vitro*, and the mechanisms of CLIC1's involvement in tumor metastasis remain unclear. In this study, the authors used RNA interference (RNAi) technology to inhibit the expression of CLIC1 in gastric cancer cell line SGC-7901 and MGC-803, and explored the possible mechanism by observing the biological behavior changes (cell proliferation, apoptosis, migration and invasion) after inhibition.

Applications
High CLIC1 expression can efficiently inhibit proliferation and enhance apoptosis, migration and invasion of gastric cancer cells *in vitro*. CLIC1 can be used as a promising target for the treatment of gastric cancer.

Terminology
CLIC1 is the first cloned human member of the CLIC family, and is a 241 amino acid ion channel protein. Like other members of the family, CLIC1 is highly conserved across a wide range of species and its relatives can be identified in the genome of all vertebrates so far sequenced. CLIC1 was initially found to localize to the cell nucleus and intracellular vesicles. RNAi is the highly specific, homology dependent suppression of gene expression by small double-stranded RNA (dsRNA). Long dsRNAs are cleaved by the endoribonuclease Dicer into short dsRNA duplexes or small interference RNA (siRNA). siRNA are loaded onto RNA-induced silencing complex (RISC). RISC contains argonaute 2 (Ago-2) which cleaves and releases one strand from the dsRNA, resulting in an activated form of RISC with a single-strand RNA (guide siRNA) that directs the specificity of the target mRNA recognition through complementary base pairing. Ago-2 then cleaves the target mRNA between bases 10 and 11 related to the 5' end of the siRNA antisense strand, thereby causing mRNA degradation and gene silencing, which occurs at a post-transcriptional level.

Peer review
This is a good study in which the authors employed CLIC1 siRNA to knockdown the expression of CLIC1, investigated its effects on gastric cancer cell lines SGC-7901 and MGC-803, and then explored the possible mechanisms. The manuscript is well prepared, study design is reasonable, statistical methods are appropriate, and conclusions are based on the convincing statistical analysis.

Abstract

AIM: To assess the clinicopathologic features and its relationship with prognosis of pseudomyxoma peritonei (PMP) in Chinese patients.

METHODS: The clinicopathologic features and follow-up data of 92 patients with PMP were reviewed and retrospectively analyzed. The cases were categorized into three groups: disseminated peritoneal adenomucinosis (DPAM), peritoneal mucinous carcinomatosis (PMCA), and peritoneal mucinous carcinomatosis with intermediate or discordant features (PMCA-I/D). The log-rank test was used to analyze survival for each group and various clinicopathological parameters. Multivariate Cox proportional-hazard models were constructed to determine the important factors associated with survival.

RESULTS: The median age at diagnosis was 51.9 years (range: 22-76 years). The median follow up was 124 mo. The 3-, 5- and 10-year survival rates were 74.0%, 67.4% and 49.1%, respectively. There were 49 (53.2%) patients with DPAM, 26 (28.3%) with PMCA-I and 17 (18.5%) with PMCA. Patients with DPAM, PMCA-I/D and PMCA exhibited statistically significant difference in survival (P = 0.001). The 3 year survival for DPAM, PMCAI/D and PMCA was 97.0%, 80.0% and 67.0%, respectively; the 5 year survival was 80.0%, 67.0% and 50.0%, respectively; and the 10 year survival was 65.0%, 28.0% and 14.0%, respectively. Survival rate was significantly lowest in patients < 40 age years of age (P = 0.011). Appendiceal tumor and extra-ovarian parenchymal organ involvement were significantly related to overall survival. Patients with appendiceal mucinous adenocarcinoma (MACA) showed the significantly poorer prognosis (P = 0.011). Multivariate analysis showed that pathological classification, age, appendiceal tumor were significant related to overall survival.

CONCLUSION: The clinical process "PMP" should be pathologically classified into DPAM, PMCA and PMCA-I/D. Pathological classification, age, appendiceal MACA are survival independent predictors in Chinese patients with PMP.

INTRODUCTION

Pseudomyxoma peritonei (PMP) is a rare clinical entity that is characterized by grossly disseminated intraperitoneal mucinous tumors, often with gelatinous ascites and usually secondary to an appendiceal mucinous tumor[1-8]. Occasionally, mucinous tumors in other sites are the culprit, such as colon[9,10], ovarian[11-13], pancrease[14] and so on[15]. Currently, the pathologic classification and biological behavior of PMP has been plagued with controversy and confusing terminology. There is considerable variability in the criteria and terminology used by different pathologists to diagnose patients with "PMP". For lesions with the same morphology, the diagnosis may be described as "ruptured appendix mucinous adenoma with PMP" by some pathologists, or "well-differentiated mucinous adenocarcinoma (MACA)" by others. Inconsistent pathological diagnostic criteria and designations may lead to confusion and uncertainty in survival analyses and clinical treatment. In recent years, the classification and nomenclature of PMP has been discussed in some English literatures[16-23]; However the conclusion were not consistent completely. In addition currently, clinicians and pathologists still lack sufficient understanding of this disease in China. In 2007 we reported a clinicopathologic analysis of 40 patients with PMP[24], but the results was not very satisfied. Taking into account that the number of cases was small and the statistical results may be influenced, we added 52 new cases treated in our hospital in the past 4 years into the present analysis. We aimed to further clarify the nomenclature and prognostic factors of PMP, and to provide guidance for clinical treatment and prognosis decision.

MATERIALS AND METHODS

Patient selection

We reviewed the demographic and clinicopathological data of 101 patients with PMP who received treatment at our hospital. All of the pathological data from each patient were reviewed as far as possible, including lesions of peritoneal, appendix and other involved organs. All patients were followed up by letters and telephone calls. 9 patients (four males and five females) were excluded: suboptimal (R2/3) cytoreduction (n = 7), biopsy (n = 2). Eventually, 92 patients were selected for the present analysis. Some of these patients were reported previously.

Assessment of peritoneal lesions

The following items were evaluated for the peritoneal lesions[16,17]: Architecture was evaluated for (1) simple nonstratified strips or cluster of epithelium, or focal proliferative strips of cells with stratification; (2) extensive proliferative strips of cells wtih extensive stratification; and (3) individual signet ring cells, clusters of cells, or complex glands, arranged in a cribriform pattern consistant with caicinoma.

Cytologic atypia was assessed based on the most proliferative area and was graded as follows: (1) "minimal" cytologic atypia, histologically benign or mildly atypical; (2) "moderate" cytologic atypia, moderately enlarged hyperchromatic or vesicular nuclei with or without prominent nucleoli and some nuclear irregularity; and (3) "marked" cytologic atypia, enlarged, irregular, hyperchromatic or vesicular pleomorphic nuclei with prominent nucleoli or signet ring cells.

Mitotic activity was assessed by scanning multiple high-power fields (approximately 10 at × 400) in the most active areas according to the following system: Rare (0-2 mitotic figures), occasional (approximately 3-5 mitotic figures), and abundant (> 5 mitotic figures).

Assessment of appendiceal tumors

Appendiceal tumors were classified into two groups based upon their architectural complexity and degree of cytologic atypia. Tumors that demonstrated lowgrade cytologic atypia (nucleomegaly, nuclear stratification, rare mitotic figures and single cell necrosis) and minimal architectural complexity (villiform, flat epithelial proliferation and small papillary excrescences) were classified as low-grade appendiceal mucinous neoplasms (LAMNs). Appendiceal tumors were classified as MACAs if they demonstrated any of the following: destructive invasion of the appendiceal wall; high-grade cytologic atypia (extensive full-thickness nuclear stratification, vesicular nuclei, marked nuclear membrane irregularities, prominent nucleoli and brisk mitotic activity); or complex epithelial proliferation (complex papillary fronds and cribriform glandular spaces)[4].

Parenchymal organs invasion was defined as mucin and epithelium within the parenchymal of an organ. Involvement of only the peritoneal surface of an organ was not considered invasion.

Assignment of pathological category

We classified peritoneal lesions into three groups, disseminated peritoneal adenomucinosis (DPAM), peritoneal mucinous carcinomatosis (PMCA), and peritoneal mucinous carcinomatosis with intermediate or discordant features (PMCA-I/D)[1,3]. Cases were categorized as DPAM (Figure 1) if the peritoneal lesions were characterized by relatively scant strips of simple or focally proliferative mucinous epithelium with minimal to moderated cytologic atypia and no significant mitotic activity in abundant extracellular mucin, with or without appendiceal LAMN. Cases were categorized as PMCA (Figure 2), if the peritoneal lesions were characterized by more abundant proliferative mucinous epithelium, glands, nests, or individual cells, including signet ring cells, consistent with carcinoma and demonstrating marked mitotic activity, accompanied by MACAs of the appendix. Cases with PMCA-I/D (Figure 3) including those which the appendiceal tumor was a LAMN with significant atypia and those in which the peritoneal lesions displayed a spectrum of patterns from histologically benign to carcinomatous epithelium, were also characterized as DPAM if the peritoneal tumors displayed at least focal areas consistent with mucinous car-

Figure 1 Peritoneal lesions consist of scant strips (A) and gland (B) of histologically bland mucinous epithelium associated with abundant extracellular mucin and fibrousis in disseminated peritoneal adenomucinosis (HE, × 40).

Figure 2 Markedly atypical epithelial fragments are suspended in pools of extracellular mucin in peritoneal mucinous carcinomatosis (HE, × 100).

Figure 3 The mucinous epithelium displays nuclear stratification and cytologic atypia in peritoneal mucinous carcinomatosis-I/D (HE, × 40).

cinoma similar to the other carcinoma cases, although some areas had the appearance of the peritoneal lesions seen in the DPAM cases.

Statistical analysis

Retrospective analysis was performed in combination with follow-up data. Survival time was calculated from the date of first visit to our hospital to the date of death from PMP. Surviving patients were censored as of the last date on which they were known to be still alive. Survival estimates were calculated by using the Kaplan-Meier method. The log-rank test was used to analyze survival among the patients with between different pathological category, gender, age, operations times, appendix tumor, the architecture, cytologic atypia and mitotic activity of the peritoneal lesions, and organ involvement. Multivariate Cox proportional-hazard models were constructed to determine the important factors associated with survival. All analyses were performed using SPSS13.0. The significance level α was set at 0.05.

RESULTS

Clinicopathologic characteristics

Characteristics of clinicopathology are shown in Table 1. A total of 92 patients, 45 male, 47 female, median age 51.9 years (range: 22-76 years) were identified. The most common presenting symptoms were abdominal distension and enlargement (94.6%, 87/92), abdominal mass (67.4%, 62/92), abdominal pain (62.0%, 57/92) and weight loss (16.3%, 15/92).

During surgery, a large volume of jelly-like mucous substances was seen in the abdomen. Multiple mucous lesions could be observed on the surface of the peritoneum and visceral organs, and complete cytoreduction (R0 61, R1 31) was performed. Ninety patients underwent appendectomy. Among them 48 (52.2%) with LAMN, 29 (31.5%) with MACA, 10 (10.9%) with unknown pathologic diagnosis, and 3 (3.1%) with appendicitis. All the 3 patients with appendicitis had undergone appendectomy at other hospitals before they presented at our hospital, and the

appendiceal slides were not available, no mucinous tumor in other organs were found.

Patients received an average of 2.1 operations (range: 1-6 operations), and 30.4% (28/92) patients underwent 3 or more operations. 63.0% (58/92) patients had hyperthermic intraperitoneal chemotherapy.

In all the patients, the intra-abdominal masses consisted of multiple nodules or grape-like masses; most of which had a smooth and shiny surface. Upon sectioning, the nodules were full of a jelly-like mucous substance. Microscopically some mucous glandular structures were floating in a large number of mucous lakes, whose epithelium showed different architecture, cytologic atypia and mitotic activity. Ninety-two patients were designated into three groups, DPAM in 53.2% (49/92), PMCA-I/D in 28.3% (26/92), and PMCA in 18.5% (17/92). There was a slight preponderance of women (16/26) in the PMCA-I/D group, but there were more men than women in the DPAM and the PMCA group. The number of operations was not significantly different among the three groups.

The disease was accompanied by ovarian mucinous tumors in 68.1% (32/47) female patients. In 15 cases (17.5%), a total of 19 other intra-abdominal parenchymal organs were involved (Table 1). In the PMCA group, the lesions penetrated the diaphragm and involved the pleura in two cases (2.2%).

[1,2,3,4]Represents one case had two organ involvement. LAMN: Low-grade appendiceal mucinous neoplasm; MACA: Mucinous adenocarcinoma; UP: Unknown pathology; UR: Unresected; FP: Focally proliferation; EP: Extensively proliferation; DPAM: Disseminated peritoneal adenomucinosis; PMCA-I/D: Peritoneal mucinous carcinomatosis with intermediate or discordant features.

Outcome and overall survival

Among the 92 patients, 15 died of intestinal obstruction, 5 died of septicemia secondary to postoperative wound infection, and 2 died of complications of tumor invasion into the thoracic cavity. Fifty-six patients were still alive. The longest survival was 350 mo. Fourteen patients were lost to follow-up at 1 to 146 mo after surgery. The median survival of the whole patient population was 124 mo (range: 1-350 mo). Using the Kaplan Meier survival curve method, the overall 3-, 5-, and 10-year survival rates were 74.0%, 67.4% and 49.1%, respectively.

Survival analysis

The survival time was compared among three groups, 16.3% patients (8/49) died in the DPAM group with the median survival time 312.9 mo. Twenty-three point one percent of patients (6/26) died in the PMCA-I/D group

Table 2 Stepwise multivariate Cox proportional hazards regression analysis

Variable	β	Se (β)	Wald, χ^2	*P*	RR	95% CI

RR: Risk ratio; CI: Confidence interval.

with the median survival time 84.0 mo, and 47.1% patients (8/17) died in the PMCA group with the median survival time 31.7 mo. The 3 year survival for DPAM, PMCA-I/D and PMCA was 97.0%, 80.0% and 67.0%, respectively; the 5 year survival was 80.0%, 67.0% and 50.0%, respectively; and the 10 year survival was 65.0%, 28.0% and 14.0%, respectively. A significant difference among three groups in overall survival was seen (*P* = 0.001) (Figure 4A). Pairwise comparison showed the survival characteristics are significantly different between the DPAM and PMCA-I/D groups (*P* = 0.005), the PMCA-I/D and PMCA groups (*P* = 0.003). The prognosis was best of DPAM and worst of PMCA.

Association analysis of age and survival time using age as a continuous variable showed that age was associated with the survival time; the younger the patient, the shorter the survival (*P* = 0.020). The mean age was 51.9 years. So we separated the patients into three age groups, < 40 years, 40-59 years and ⩾ 60 years, to analyze. The results showed that the survival was significantly different among the three groups (*P* = 0.011) (Figure 4B). The prognosis was poorest in patients < 40 years, in whom the 3- and 5-year survival rates were 83.0% and 48.0%, respectively. The longest survival time was 96 mo (the survival rate was 24.0%).

Because of its poor reliability and the limited number of cases we combined the 3 patients with "appendicitis" and 2 patients without appendectomy into the "pathology-unknown" group and excluded them for analysis. Survival time was significantly different between patients with LAMN and MACA (*P* = 0.008). The prognosis of patients with MACA of the appendix was poorer than those with LAMN (Figure 4C).

In addition, ovarian involvement did not appear to influence the female patients' outcome (*P* = 0.897). But extra-ovarian parenchymal organ involvement were significantly associated with the survival time of patients (*P* = 0.005). Gender and operation times were not associated with the survival (*P* = 0.547 and 0.692, respectively).

Stepwise multivariate Cox proportional-hazard regression analysis indicated that age (*P* = 0.046), pathological classification (*P* = 0.012) and appendiceal MACA (*P* = 0.029) were significant related to survival and predicted for death (Table 2).

DISCUSSION

PMP is a rare clinical disease characterized by a large amount of gelatinous mucus in the abdominal cavity, and

Figure 4 Survival related to histological classification, age and appendiceal mucinous adenocarcinoma. A: Overall survival of the three histologic groups: Disseminated peritoneal adenomucinosis (DPAM), peritoneal mucinous carcinomatosis with intermediate or discordant features (PMCA-I/D) and peritoneal mucinous carcinomatosis (PMCA) (*P* = 0.001); B: Overall survival of the three age groups: < 40, 40-59 and ⩾ 60 years (*P* = 0.011); C: Overall survival of the two appendiceal tumor groups: low-grade appendiceal mucinous neoplasm and mucinous adenocarcinoma (*P* = 0.008).

wide peritoneal and omental dissemination. Its incidence is approximately 2/10 000 patients undergoing lapa-

rotomy[25]. Clinically, it is characterized by non-remitting abdominal pain, abdominal swelling, and mucoid ascites. Ultimately, the tumor occupies most space in the abdominal cavity, showing manifestations of "jelly belly" syndrome. It is very difficult to have a definite diagnosis before surgery, and most cases are diagnosed after laparotomy. Pathological examination shows that the abdominal tumor consists of a large amount of gelatinous mucinous substance, some of which may have an appearance of multiple mucinous nodules. It can be seen under the microscope that varying amounts of the mucinous epithelial component is floating in the mucous lake, and in most cases, the morphology of the epithelial component is benign. In recent years, most scholars believe that PMP has originated from appendiceal mucinous disease[7,8] and occasionally, mucinous tumors of other places have been implicated[9-15].

Naming and pathological diagnosis of PMP
As the chemical nature of the gelatinous substance of PMP is different from that of mucous protein, it is called pseudo-mucous protein, and accordingly, the condition was named "PMP". After it was first proposed in 1884, the name of "PMP" has been in use to date. However, strictly speaking, PMP reflects only the clinical process and characteristics of the disease, and cannot be used for pathological diagnosis. Therefore, its pathological classification and naming have long been debated. Some scholars believe that it can be diagnosed as cancer as long as the epithelial component is found outside of the appendiceal wall; however, some believe that in some cases, the survival time of patients is very long although PMP tends to be characterized by multiple recurrences; therefore, it should be considered benign or a low-grade malignancy. Pathological diagnosis directly affects the postoperative treatment. The difference in the pathological diagnosis of PMP results in confusion and uncertainty in clinical treatment.

In recent years, investigators have obtained different results. In 1995, Ronnett *et al*[16] analyzed the pathological conditions in 109 cases of PMP, and they first proposed that PMP should be divided into three categories: DPAM, PMCA-I/D and PMCA. Since then, they followed that group of patients for many years, and carried out a prognostic analysis in 2001. They grouped patients with PMCA-I/D and PMCA together and compared them with the DPAM group. They found that the 5- and 10-year survival rates (26% and 9%) were significantly worse than that of the DPAM group (75% and 68%)[17]. Miner *et al*[22] thought that PMP should be divided into low-grade and high-grade peritoneal MACA. However, in 2006 Bradley *et al*[20] analyzed 101 cases of PMP and found that the survival rate was not significantly different between the DPAM and PMCA-I/D groups. Therefore, they combined the two groups into low-grade mucinous carcinoma peritonei (MCP-L), and these patients classified into PMCA according to Ronnett *et al*[16,17] were renamed high grade mucinous carcinoma peritonei (MCP-H). The

prognosis of MCP-L was significantly better than that of MCP-H with the 3 - and 5-year survival rates 72.8% and 62.5%, 37.7% and 37.7%, respectively[20]. However, the recent study of Bruin *et al*[9] supported Ronnett's conclusion that the prognosis was not significantly different in PMCA-I/D and PMCA, and therefore, these two groups should be combined.

Referring to the study of Ronnett *et al*[16,17] in 2007, we divided 40 cases of PMP into three groups, DPAM, PM-CA-I/D and PMCA, and compared them[24]. The pair-wise comparison showed no significant differences between the PMCA-I/D and PMCA groups. Therefore, PMCA-I/D and PMCA were combined into one group, and re-analysis showed the 3-, 5- and 10-year survival rates were 58.9%, 47.1% and 35.3%, which were significantly different from those in the DPAM group.

Taking into account small cases for the previous analysis the statistical results may be influenced, now we added 52 new cases treated in the past 4 years into the analysis and the survival rate of the three groups were compared. There were 49 (53.2%) patients with DPAM, 26 (28.3%) with PMCA-I and 17 (18.5%) with PMCA. Patients with DPAM, PMCA-I/D and PMCA exhibited statistically significant difference in survival. The 3 year survival for DPAM, PMCAI/D and PMCA was 97.0%, 80.0% and 67.0%, respectively; the 5 year survival was 80.0%, 67.0% and 50.0%, respectively; and the 10 year survival was 65.0%, 28.0% and 14.0%, respectively. But Pair-wise comparison showed the survival characteristics are significantly different between the DPAM and PMCA-I/D groups, the PMCA-I/D and PMCA groups. The prognosis was best in the DPAM group and worst in the PMCA group. The results supported the morphological classification of PMP into three categories, and they should be named DPAM, PMCA-I/D and PMCA, respectively to further guide postoperative clinical treatment.

Biological behaviors, prognosis and treatment of PMP

Although the progression of PMP is slow, and the pathological morphology is benign or low-grade malignancy in the majority of cases, its biological behavior is malignant and it can not be removed completely during surgery because of its extensiveness and invasiveness. Relapse and adhesions may occur easily, and the patient may have cachexia of chronic disease. Postoperative recurrence occurs in 60% to 76% of patients, and Multiple surgical resections are often required. Although this disease may progress slowly, it is often fatal. Common causes of death are systemic infection secondary to wound infection, bowel obstruction, hernia and pleural pseudomyxoma caused by tumor passing through the diaphragm[26,27].

It is reported that the median survival time of patients with PMP is 5.9 years, and the 3-, 5- and 10-year survival rates were 81.1%-83%, 50.0%-81%, and 18.2%-32%, respectively. Prognostic factors of PMP are the location, primary tumor and the histopathological grade of the peritoneal lesions[22,27]. In this study the survival time ranged from 1 to 350 mo with the median 124 mo. The

3-year, 5-year and 10-year survival rates were 74.0%, 67.4% and 49.1%, respectively. The 10-year survival rate was higher than that reported in the literature. Thirty point four percent of (28/92) patients underwent 3 or more operations. Fifteen died of intestinal obstruction, 5 died of septicemia secondary to postoperative wound infection, and 2 died of complications of tumor invasion into the thoracic cavity. Among the clinicopathological characteristics we found age, the pathological classification of peritoneal tumor, appendiceal tumor, extra-ovarian parenchymal organ involvement were significantly related to the survival time. Stepwise multivariate Cox proportional-hazard regression analysis indicated that pathological classification, age, appendiceal MACA are survival independent predictors.

It has been reported that prognosis of PMP is related to age. The prognosis of patients > 50 years was significantly poorer than that of patients < 50 years[13]; However, the statistical analysis of this study showed that the younger the patient, the worse the prognosis. The prognosis of patients < 40 years was significantly worse than that of patients > 40 years.

Complete cytoreduction, supplemented by hyperthermic intraperitoneal and systemic chemotherapy was considered as the gold standard treatment of PMP. Complete cytoreductive surgery combined with hyperthermic intraperitoneal chemotherapy could prolongs long-term survival[28-36].

On conclusion we suggest that the name of PMP should be avoided as far as possible in the pathological diagnosis, and DPAM, PMCA-I/D, and PMCA should be used to indicate the degree of differentiation of the tumors. Therefore, additionally, the appendix should be explored as far as possible during gross examination, and sampling and serial sections should be made in order to determine and report the severity of the appendiceal lesions. Attention should be paid to examine the involvement of parenchymal organs in order to provide more information for clinical treatment. For patients with PMP, clinicians should determine the prognosis according to age on the basis of a complete pathology report.

COMMENTS

Background
Pseudomyxoma peritonei (PMP) is a rare clinical entity that is characterized by grossly disseminated intraperitoneal mucinous tumors, often with gelatinous ascites and usually secondary to an appendiceal mucinous tumor. Occasionally, mucinous tumors in other sites are the culprit, such as colon, ovarian, pancrease and so on. Currently, the pathologic classification and biological behavior of PMP has been plagued with controversy and confusing terminology. There is considerable variability in the criteria and terminology used by different pathologists to diagnose patients with "PMP" for lesions with the same morphology.

Research frontiers
In recent years, the classification and prognosis of PMP has been discussed in some English literatures. However the conclusions were not consistent completely. In addition currently, clinicians and pathologists still lack sufficient understanding of this disease in China. In this study, the authors demonstrate pathological classification, age,(< 40 years), appendiceal appendiceal mucinous adenocarcinoma (MACA) are survival independent predictors of Chinese patients with PMP. They think the clinical process "PMP" should be pathologically

classified into disseminated peritoneal adenomucinosis (DPAM), peritoneal mucinous carcinomatosis with intermediate or discordant features (PMCA-I/D), and peritoneal mucinous carcinomatosis (PMCA).

Innovations and breakthroughs

Recent reports have hignlighted the classification and prognosis of PMP. But the conclusions were not consistent completely. Unfortunately, few reports have observed the classification and prognosis of PMP in Chinese patients. And currently, clinicians and pathologists still lack sufficient understanding of this disease in China. This study is the first large sample study on the pathological classification and prognosis of PMP in Chinese patients.

Applications

By understanding the survival predictors in Chinese patients with PMP, the name of PMP should be avoided as far as possible in the pathological diagnosis, and DPAM, PMCA-I/D and PMCA should be used to indicate the degree of differentiation of the tumors. Therefore, additionally, the appendix should be explored as far as possible during gross examination, and sampling and serial sections should be made in order to determine and report the severity of the appendiceal lesions. Attention should be paid to examine the involvement of parenchymal organs in order to provide more information for clinical treatment. For patients with PMP, clinicians should determine the prognosis according to age on the basis of a complete pathology report.

Terminology

PMP is a disease with a large volume of extensively implanted gelatinous mucous substance on the surface of the peritoneum. The terminology is came from the jelly-like substance, whose chemical properties are different from those of the mucous proteins and called pseudo-mucin.

Peer review

This is a nice review of the histologic features of "PMP" in Chinese patients and and suggest that the clinical process "PMP" should be pathologically classified into DPAM, PMCA and PMCA-I/D. Pathological classification, age and appendiceal MACA are survival independent predictors in Chinese patients with PMP, nicely addresses the challenges with the pathologic diagnosis.

Abstract

AIM: To investigate the impact of different anesthetic techniques on T-helper (Th) cell subsets in hepatocellular carcinoma (HCC) patients undergoing hepatectomy.

METHODS: Sixty-one HCC patients who received hepatectomies were randomized into an epidural combined general anesthesia (G + E; n = 31) or a general anesthesia (G; n = 30) group. Blood samples were obtained the morning before the operation (d0), and on the second (d2) and seventh (d7) day after the operation. Th cell contents were evaluated using flow cytometry, real-time reverse transcription-polymerase chain reaction and enzyme-linked immunosorbent assay.

RESULTS: In all 61 patients, Th1 and Th2 cell frequencies, and interferon-γ (IFN-γ) mRNA expression markedly increased on d2, compared to d0. They recovered slightly on d7, and the Th1/Th2 ratio increased markedly on d7, compared with d2. In contrast, Th17, regulatory T cell (Treg), and interleukin-17 (IL-17) levels and *FOXP3* mRNA expression showed no significant change on d2, and then markedly decreased on d7. Similarly, plasma IFN-γ concentration on d2 was much higher than that on d0, and then partly recovered on d7. As compared with the G group, in the G + E group, Th1 cell frequencies and the Th1/Th2 ratio were slightly higher on d2 and significantly higher on d7, while Th2, Th17, and Treg cell frequencies were slightly lower on d2, and significantly lower on d7. Consistently, on d7, IFN-γ mRNA and protein levels and the IFN-γ/IL-4 ratio in the G + E group were higher than those in the G group. In contrast, the IL-17 mRNA level, and IL-17 and transforming growth factor-β1 concentrations in the G + E group were lower than those in the G group.

CONCLUSION: G + E is superior to G in shifting the Th1/Th2 balance towards Th1, while decreasing Th17 and Treg, potentially benefiting HCC patients by promoting anti-tumor Th polarization.

INTRODUCTION

The overall survival of patients with hepatocellular carcinoma (HCC) remains poor despite improved diagnostic and treatment strategies[1]. Although surgical resection is still one of the first priorities[1], surgery may inevitably induce profound systemic neuroendocrine, metabolic, inflammatory, and immunological stress[2,3]. In particular, alterations occur in every component of the immune response, including T-helper (Th) cells[4]. As a consequence, the stress response could lead to significant changes in post-operative recurrence rates and patient survival[5,6].

Th cells are sub-groups of lymphocytes that play a central role in orchestrating host immune responses through their capacity to help other cells in the immune system[7]. In the scenario of cancer, Th1 cells mediate anti-tumor reactivity, by producing interferon-γ (IFN-γ), resulting in tumor regression[8]. In contrast, most studies have shown that Th2, Th17, and regulatory T cell (Treg) cells may inhibit anti-tumor efficacy[9,10]. The Th subsets are known for their altered frequencies, distribution and balance in cancer-bearing patients. More importantly, recent research has revealed that the balance of Th subsets determines the direction of anti-tumor immune responses and hence patient clinical outcomes[11,12]. Proper peri-operative management, including selection of suitable anesthetic methods, may help recover the disturbed balances of Th subsets or even maintain the balance of anti-tumor responses.

Epidural anesthesia is known to prevent or attenuate an excessive stress response during or after surgery, which prevents noxious afferent input from reaching the central nervous system[13]. Both preclinical and clinical studies have suggested that the addition of spinal blockade to general anesthesia attenuates the metastasis-promoting effect of surgery in the tumor-bearing host[14,15]. Currently, general anesthesia alone, and epidural blockade combined with general anesthesia are the two most commonly used methods in hepatectomy. However, there is a lack of clinical studies evaluating the effects of hepatectomy itself, as well as the choice of anesthetic technique on peri-operative Th cell subset balances.

In this study, we investigate Th cell subset balances in the peripheral blood of HCC patients before surgery, and on 2 and 7 d after hepatectomy, to elucidate the changes in Th frequencies induced by surgery. In particular, we compared the differences in Th cell subsets between the epidural anesthesia combined with general anesthesia (G + E) group and the general anesthesia (G) group at multiple peri-operative time points to determine whether anesthetic methods have an impact on postoperative Th subset balances.

MATERIALS AND METHODS

Patients and groups

Sixty-one patients with HCC who had undergone hepatectomies between October 2009 and April 2010 at the Liver Cancer Institute, Zhongshan Hospital of Fudan University (Shanghai, China) were enrolled. We randomized the patients between 18-65 years old, American Society of Anesthesiologists (ASA) scores Ⅰ-Ⅱ, with normal leukocyte and lymphocyte counts, who had an imaging diagnosis of HCC with the intention of curative surgery and without distant metastasis or any prior anti-cancer treatments into two groups, that is, the G + E group and G group. We then excluded patients who were not pathologically diagnosed as HCC or who were given a blood transfusion during or after surgery. We finally chose 61 out of 70 patients, 31 in the G + E group and 30 in the G group. Fourteen cases received right lobectomy, 11 cases left hemihepatectomy and 36 cases segmentectomy. The study was approved by the Research Ethics Committee of Zhongshan Hospital, and informed consent was obtained from all patients.

Anesthesia and analgesia

All patients were free of preoperative medication and had fasted for over 8 h. Epidural puncture for patients in the G + E group was carried out at T8 and T9 into the epidural space, with patients in a left-lateral position. After successful puncture, epidural catheters were placed toward the head for 3-4 cm. We fixed the catheters and gave 2% lidocaine (3 mL) through the catheters. After 5 min, upon confirming no spinal analgesia and that the epidural block was successful, we gave the patients 0.375% bupivacaine liquor (8 mL), then 4 mL at each 50-min interval.

Induction and maintenance of general anesthesia: All patients were induced with 5 μg/kg fentanyl, 2.0 mg/kg propofol and 0.9 mg/kg rocuronium and then incubated for approximately 90 s. Anesthesia was maintained with sevoflurane (1.5%-3.5%) based on a bispectral index monitor.

Postoperative analgesia: Patients in the G + E group used postoperative patient-controlled epidural analgesia, made up of 0.125% bupivacaine + morphine (30 μg/mL). The patients in the G group used postoperative patient-controlled intravenous analgesia containing morphine (0.4 mg/mL) administered *via* a jugular vein catheter. Patient-controlled analgesia was administered *via* an ambulatory infusion pump (AutoMed, Acemedical AM3400) and lasted for about 48 h. All patients were followed up at the end of analgesia using a visual analogue scale (VAS) for evaluation of their pain levels, and the corresponding drug dosage used was recorded.

Blood samples

Blood samples (10 mL) were obtained from all patients in the recumbent position with a 20-gauge needle for a

clean veni-puncture of an antecubital vein at three time points: early morning on the operation day (d0), and the second (d2) and seventh day (d7) after the operation. The samples were collected into tubes containing 0.2 mL sodium heparin. Peripheral blood mononuclear cells (PBMCs) were prepared using a Ficoll density gradient, for flow cytometry and real-time polymerase-chain-reaction analyses. Plasma was obtained after centrifugation and stored at -80 ℃ for measurement of cytokines.

Preparation for flow cytometry analysis

For analyses of Th1, Th2 and Th17, PBMCs were suspended at a density of 2×10^6 cells/mL in complete culture medium (RPMI 1640 supplemented with 100 U/mL penicillin, 100 μg/mL streptomycin, 2 mmol glutamine and 10% heat-inactivated fetal calf serum). The cell suspension was transferred to individual wells of 24-well plates. Cultures were stimulated with phorbol myristate acetate (50 ng/mL), ionomycin (1 μmol) and Brefeldin A (10 μg/mL, all from Sigma-Aldrich, St. Louis, MO, United States) for 4 h. The cultures were incubated at 37 ℃, in a 5% CO_2 environment. After 4 h of culture, the contents of the well were transferred to 1.5 mL sterile centrifuge tubes. To analyze Tregs, PBMCs were aliquoted into tubes for further staining.

Surface and intracellular staining

For Th1, Th2 and Th17 analyses, the cells were incubated with fluorescein isothiocyanate (FITC)-conjugated anti-human CD4 at 4 ℃ for 20 min. For Treg analysis, the cells were incubated with FITC-conjugated anti-human CD4 and allophycocyanin (APC)-conjugated anti-human CD25 monoclonal antibodies (mAbs). After surface staining, the cells were stained with R-phycoerythrin (PE)-conjugated anti-human IFN-γ, APC-conjugated anti-human interleukin (IL)-4 and IL-17 mAbs for detection of Th1, Th2 and Th17, respectively; or PE-conjugated anti-human FOXP3 mAb for Treg detection after fixation and permeabilization, according to the manufacturer's instructions. Isotype controls were given to enable correct compensation and confirm antibody specificity. All antibodies were purchased from eBioscience (San Diego, CA, United States). Stained cells were analyzed using a FACScan cytometer equipped with CellQuest software (BD Bioscience, San Jose, CA, United States).

Real-time reverse transcription-polymerase chain reaction analysis

Total RNA was extracted with TRIzol regent (Invitrogen, Carlsbad, CA, United States) according to the manufacturer's instructions. First-strand cDNA was synthesized using random hexamer primers and RNase H-reverse transcriptase (Fermentas, Glen Burnie, MD, United States). TaqMan primers and probes for human IFN-γ, IL-4, IL-17 and FoxP3 were purchased from TAKARA Bio Inc. (Osaka, Japan), and samples were analyzed utilizing the Opticon Monitor 3 System (Bio-Rad, Hercules, CA, United States, formerly MJ Research). The following primer

sets were used: IFN-γ: F: 5'-TGCAGGACCCATATG-TAAAAGA-3', R: 5'-TCAAAATGCCTAAGAAAAG-3'; IL-4: F: 5'-TACAGCCACCATGAGAAGGACA-3', R: 5'-GCCAGGCCCCAGAGGTT-3'; IL-17: F: 5'-CGCTGATGGGAACGTGGACTAC-3', R: 5'-GGTGGACAATCGGGGTGACA-3'; FoxP3: F: 5'-CGCTGATGGGAACGTGGACTAC-3', R: 5'-GGTGGACAATCGGGGTGACA-3'; and β-actin: F: 5'-CAACTGGGACGACATGGAGAAAAT-3', R: 5'-CCAGAGGCGTACAGGGATAGCAC-3'. For each sample, the mRNA expression level was normalized to the level of β-actin.

Enzyme-linked immunosorbent assay analysis

The plasma levels of IFN-γ, IL-4, IL-17, IL-10 and transforming growth factor-β1 (TGF-β1) were measured by enzyme-linked immunosorbent assay (ELISA), following the manufacturer's instructions (R and D Systems, Minneapolis, MN, United States). Intra-assay and inter-assay coefficients of variation for all ELISAs were < 5% and < 10%, respectively. All samples were measured using three independent experiments, in duplicate.

Statistical analysis

Statistical analyses were performed with SPSS 16.0 software (SPSS, Chicago, IL, United States). Values are expressed as the mean ± SE of the mean. Student's *t* tests were used to compare quantitative variables, and Fisher's exact tests were used for categorical variables. Two-tailed $P < 0.05$ was judged to be significant.

RESULTS

Patient characteristics

There were no significant differences in age, gender, clinicopathologic factors, blood loss, anesthesia time and VAS scores between patients in the G + E group and G group. Because of the different anesthetic methods, the dosage of opioids (fentanyl and morphine) and inhalation anesthetics (sevoflurane) were obviously different between the two groups (Table 1).

Circulating Th1, Th2, Th17 and Treg frequencies

In all 61 patients, the frequencies of Th1 ($CD4^+IFN$-$γ^+CD4^+$ T cells) and Th2 ($CD4^+IL$-4^+CD4^+ T cells) were markedly increased on d2 ($P < 0.001$ and $P < 0.001$, respectively), as compared with d0. The frequencies partly recovered on d7 ($P = 0.015$ and $P < 0.001$, respectively), while the ratio of Th1/Th2 showed no differences between d0 and d2, but increased significantly on d7 ($P < 0.001$, Figure 1 and Table 2). In contrast, the frequencies of Th17 ($CD4^+IL$-17^+CD4^+ T cells) and Treg ($CD4^+CD25^+FoxP3^+CD4^+$ T cells) on d2 showed no significant differences compared to those on d0 ($P = 0.269$ and $P = 0.06$, respectively), but markedly decreased on d7 ($P < 0.001$ and $P = 0.021$, respectively, Figure 1 and Table 2).

Further comparisons were made between the G + E

Table 1 Patient characteristics

Characteristics	G + E group (*n* = 31)	G group (*n* = 30)	*P*

group and G group. As expected, Th1, Th2, Th17 and Treg cell frequencies showed no differences on d0 between the G + E group and G group (Table 3). On d2, only Th2 cell frequencies were lower in patients in the G + E group, compared with patients in the G group ($P = 0.028$), while Th1, Th17, and Treg frequencies, as well as the Th1/Th2 ratio showed no significant differences (Figure 2 and Table 3). Notably, circulating Th1 cell frequencies were considerably higher, but Th2 frequencies showed no significant change in patients in the G + E group when compared with patients in the G group on d7 ($P < 0.01$ and $P = 0.231$, respectively). Consequently, on d7, the Th1/Th2 ratio of the G + E group was significantly higher than that in the G group ($P < 0.001$). Conversely, Th17 and Treg cell frequencies were significantly lower in patients in the G + E group than in patients in the G group on d7 ($P = 0.047$ and $P = 0.003$, respectively, Figure 2 and Table 3).

mRNA expression of IFN-γ, IL-4, IL-17 and FoxP3 in PBMCs

IFN-γ, IL-4, and IL-17 are the cytokines typically produced by Th1, Th2 and Th17 cells, respectively[16]. *FOXP3* is the master transcription factor in Treg cells[9]. We thus investigated the mRNA expression profile of IFN-γ, IL-4, IL-17 and *FOXP3* in PBMCs of HCC patients.

In all 61 patients, the mRNA expression levels of IFN-γ on d2 were increased compared to that on d0 ($P < 0.01$), then partly recovered on d7 ($P = 0.042$). IL-4, IL-17 and *FOXP3* mRNA expression levels showed no significant differences from d0 to d2, whereas mRNA levels of IL-17 and *FOXP3* clearly decreased from d2 to

d7 ($P = 0.032$ and $P < 0.01$, respectively, Figure 3A).

Similar to Th cell frequencies, IFN-γ, IL-4, IL-17 and *FOXP3* mRNA expression levels on d0 showed no significant differences between the two groups (Table 4). On d2, the IL-4 mRNA level in the G + E group was significantly lower as compared with that in the G group ($P < 0.01$). On d7, the IFN-γ mRNA level in the G + E group and the IFN-γ/IL-4 ratio were significantly higher than that in the G group ($P = 0.029$ and $P = 0.003$, respectively); IL-17 mRNA level in the G + E group was significantly lower than that in the G group ($P = 0.042$); *FOXP3* mRNA expression level in the G + E group was relatively lower than that in the G group, but this did not reach statistical significance ($P = 0.109$, Table 4). The results derived from mRNA expression analyses of Th-cell markers were generally in line with the results of flow cytometry analyses of Th-cell frequencies.

Plasma concentrations of IFN-γ, IL-4, IL-17, IL-10 and TGF-β1

IFN-γ, IL-4 and IL-17 are the cytokines typically produced by Th1, Th2 and Th17 cells, respectively. IL-10 and TGF-β1 are the cytokines produced by Treg cells. In all 61 patients, the plasma IFN-γ, IL-4, IL-17 and TGF-β1 concentrations on d2 were higher than on d0 ($P < 0.01$, $P < 0.01$, $P = 0.011$ and $P = 0.021$, respectively). Subsequently, IFN-γ and IL-17 levels recovered toward baseline levels on d7 ($P = 0.008$, $P < 0.001$, respectively), while IL-4, IL-10 and TGF-β1 showed no obvious decrease (Figure 3B).

The levels of all plasma cytokines on d0 showed no significant differences between the G + E and G groups. On d2, IFN-γ and IL-4 concentrations in the G + E group were significantly lower than those in the G group ($P = 0.018$ and $P = 0.013$, respectively). On d7, the IFN-γ/IL-4 ratio in the G + E group was obviously higher than that in the G group ($P < 0.001$). However, IL-17 and TGF-β1 concentrations in the G + E group were significantly lower than those in the G group ($P = 0.009$ and $P = 0.031$, respectively, Table 5). These data were highly consistent with the conclusions from flow cytometry and mRNA expression analyses.

DISCUSSION

The Th1/Th2 balance, as well as Th17 and Treg levels are key indices of immune function, playing an important role in HCC metastasis and recurrence[10,17]. To assess whether this balance was disturbed during anesthesia and to determine which anesthetic method was better at restoring the balance toward anti-tumor responses in HCC patients after hepatectomy, we examined Th1, Th2, Th17 and Treg levels through the analyses of cell frequencies, mRNA expression of Th-cell markers, and protein levels of typical Th-cell cytokines.

Effects of hepatectomy on Th cell balances

Surgical trauma is generally considered to have a major

Figure 1 Circulating T-helper 1 and T-helper 2 frequencies increased on d2 *vs* d0, and then recovered on d7, while T-helper 17 and regulatory T cell frequencies showed no difference on d2 *vs* d0, but decreased on d7. role in altering the immune response[3,6]. We had thus expected that surgical trauma would have a significant impact on the Th1/Th2 ratio, as well as Th17 and Treg levels after hepatectomy. In this study, we found that, on d2 after hepatectomy, all Th cells showed an increased trend, to varying degrees. By d7 after surgery, all Th cells recovered towards the baseline. These results revealed that surgical trauma increased Th cell numbers, but the stimulation did not last a significantly long time. There was no obvious change in the Th1/Th2 balance on d2 after surgery. However, there was a detectable shift towards Th1 dominance on d7 after surgery. In addition, Treg and Th17 frequencies decreased significantly compared with d0. These results support the conclusion that removal of the tumor leads to the relief of systemic immune suppression. As a result, host responses are reprogrammed towards a direction that benefits patient outcome. Therefore, it is likely that the change in Th1/Th2 balance, as well as Th17 and Treg frequencies in patients undergoing hepatectomy are not only a consequence, but may also

play an important role in the defense mechanism against tumor cells. Supporting this idea, it has been reported that surgical removal of primary tumors could reverse tumor-induced immunosuppression, even in the presence of metastatic disease[18,19]. On the other hand, the increase in Th cell numbers after hepatectomy may be due to stress caused by surgery. It is well recognized that inflammation typically peaks at d2 after surgery, and gradually dissipates by d7 after surgery. Consistently, Th cell frequencies reach their plateau on d2 and then decrease significantly on d7.

Anesthetic technique impacts Th1/Th2 balance, and Th17, Treg frequencies

Anesthetics *per se* are associated with suppressed immunity during perioperative periods because of their direct suppressive effects on cellular and humoral immunity[4]. As such, anesthetics and anesthetic methods should be selected with careful consideration. In the current study, on d7, the Th1/Th2 balance in the G + E group was profoundly shifted towards Th1 dominance, compared to the G group. In contrast, Th17 and Treg frequencies in the G + E group decreased significantly, indicating the benefit of combined G + E anesthesia against G anesthesia alone in HCC patients. In addition, on d2, Th1, Th2 and Th17 frequencies in the G + E group were relatively lower than those in the G group. This could also be attributed to the hypothesis that epidural anesthesia combined with general anesthesia was better than gen-

eral anesthesia in reducing or eliminating surgery-related stress responses, which peaked on d2 after surgery.

Several major differences between the two anesthetic methods may be responsible for the distinct patterns in Th1/Th2 balance, as well as Th17 and Treg frequencies between the two groups. First, regional anesthesia substantially attenuates surgery-induced stress responses, including increases in levels of corticosteroid hormone and catecholamine[13]. Second, opioids inhibit both cellular and humoral immune function in humans[20]. In the G + E group, opioids were administered epidurally, whereas morphine was administered systemically in the G group. Animal experiments have shown that morphine suppresses the lymphocyte proliferative response to mitogens when given systemically, but not when given intrathecally[21]. Similarly, patients receiving an epidural mixture of opioids and local anesthetics exhibited better preservation of lymphocyte proliferation and cytokine production than those receiving intravenous opioids alone. Third, intravenous and inhalation anesthetics are associated with elevated serum concentrations of catecholamines and cortisol[22,23]. Glucocorticoids and catecholamines can heavily influence immunomodulation, including decreases in Th1/Th2 cytokine production and an increase in *FOXP3* mRNA expression[24]. Consequently, it is not surprising that G anesthesia used alone suppressed the surgical stress-induced immune response more profoundly than combined G + E anesthesia.

Apart from the surgery and anesthesia, there are still many factors that could influence the Th1/Th2 balance, as well as Th17, and Treg frequencies, including HCC itself, hepatitis virus infection, liver cirrhosis, blood transfusion, and pain levels[25,26]. To eliminate these confounding factors, we prospectively and randomly assigned patients into the G + E or G group, and hence there were no significant differences in these factors. In addition, the results from flow cytometry and cytokine expression analyses were highly consistent with each other, indicating the reproducibility and reliability of the current study.

Anesthesia methods and oncologic prognosis

Oncologic prognosis has been reported to be associated with tumor bionomics, as well as trauma related to surgery, but not anesthesia. Recently however, the effect of anesthetic technique on tumor prognosis has received widespread attention[27]. In rat models, the addition of a spinal block to halothane general anesthesia markedly attenuated the promotion of pulmonary metastasis induced by surgery[28]. Furthermore, the reduction in tumor metastasis by the addition of a spinal block to sevoflurane general anesthesia accompanying surgery was ascribed to preserving the Th1/Th2 balance in mice[29]. Importantly, there are several retrospective clinical studies that are consistent with this hypothesis. Paravertebral anesthesia and analgesia for breast cancer surgery have been associated with an approximately four-fold reduced risk of recurrence or metastasis[30]. Similar results were observed in melanoma, prostate and colon cancer, where epidural an-

esthesia or epidural supplementation was associated with enhanced survival and reduced tumor recurrence[14,15,31]. The above results indicate that a regional block combined with general anesthesia is a better choice for cancer patients, compared to general anesthesia alone. Considering that there was postoperative Th1 dominance, and observed decreases in Th17 and Treg were more prominent in the G + E group than the G group, we assume that G + E may be superior to G alone for HCC patients in terms of achieving better patient clinical outcomes.

Hepatectomy resulted in the shifting of the Th1/Th2 balance towards Th1, with concomitant decreases in Th17 and Treg frequencies. Epidural anesthesia combined with general anesthesia is superior to general anesthesia alone in preserving the Th1/Th2 balance, and reducing Th17 and Treg numbers after surgery. We thus propose that epidural anesthesia combined with general anesthesia might be an optimal choice for HCC patients undergoing hepatectomies. However, animal experiments and prospective trials evaluating the effects of the Th1/Th2 balance, as well as Th17 and Treg on tumor prognosis are warranted.

COMMENTS

Background
Surgical resection is one of the first priorities for hepatocellular carcinoma (HCC), but may inevitably induce immunological stress. T-helper (Th) cells are subgroups of lymphocytes that play a central role in orchestrating host immune responses through their capacity to help other cells in the immune system. Whether proper peri-operative management, including selection of suitable anesthetic methods, may help to recover the disturbed balances of Th subsets is still questionable. In particular, they compared the differences in Th cell subsets between an epidural anesthesia combined with general anesthesia (G + E) group and a general anesthesia (G) group at multiple peri-operative time points to determine whether anesthetic methods have an impact on postoperative Th subset balances.

Research frontiers
Epidural anesthesia is known to prevent or attenuate an excessive stress response during or after surgery, which prevents noxious afferent input from reaching the central nervous system. Both preclinical and clinical studies have suggested that the addition of spinal blockade to general anesthesia attenuated the metastasis-promoting effect of surgery in a tumor-bearing host. The research hotspot is how epidural anesthesia affects peri-operative Th cell subset balances.

Innovations and breakthroughs
The Th1/Th2 balance, as well as Th17, and Treg numbers are key indices of immune function in many types of carcinoma. They also play an important role in HCC metastasis and recurrence. There are rare reports of surgery or anesthetic methods affecting the Th subset balance. The innovative approach in this study was to assess whether the balance was disturbed and which anesthetic method was better at restoring the balance in anti-tumor responses in HCC patients after hepatectomy.

Applications
Epidural anesthesia combined with general anesthesia is superior to general anesthesia alone in preserving the Th1/Th2 balance, and reducing Th17 and Treg numbers after surgery. They thus propose that epidural anesthesia combined with general anesthesia might be an optimal choice for HCC patients undergoing hepatectomy.

Terminology
Epidural anesthesia is most commonly placed in the lower back (lumbar region). This technique may also be accomplished in the mid-back (thoracic region) for surgery in the chest area. Th cells are a sub-group of lymphocytes that play an important role in the immune system, particularly in the adaptive

immune system. They are essential in B cell antibody class switching, in the activation and growth of cytotoxic T cells, and in maximizing bactericidal activity of phagocytes such as macrophages.

Peer review

This is a study in which authors investigated the influence of the different anesthesia modalities on Th cells. They randomized 61 HCC patients into G + E group and G group. The cell frequency of Th1, Th2, Th17, Treg and mRNA level of interferon-γ, interleukin (IL)-17, IL-4 and *FoxP3* in the sequentially collected blood samples (d0, d2 and d7 after surgery) were evaluated.

Abstract

AIM: To investigate morphological changes of intestinal smooth muscle contractile fibres in small bowel atresia patients.

METHODS: Resected small bowel specimens from small bowel atresia patients (n = 12) were divided into three sections (proximal, atretic and distal). Standard histology hematoxylin-eosin staining and enzyme immunohistochemistry was performed to visualize smooth muscle contractile markers α-smooth muscle actin (SMA) and desmin using conventional paraffin sections of the proximal and distal bowel. Small bowel from age-matched patients (n = 2) undergoing Meckel's diverticulum resection served as controls.

RESULTS: The smooth muscle coat in the proximal bowel of small bowel atresia patients was thickened compared with control tissue, but the distal bowel was unchanged. Expression of smooth muscle contractile fibres SMA and desmin within the proximal bowel was slightly reduced compared with the distal bowel and control tissue. There were no major differences in the architecture of the smooth muscle within the proximal bowel and the distal bowel. The proximal and distal bowel in small bowel atresia patients revealed only minimal differences regarding smooth muscle morphology and the presence of smooth muscle contractile filament markers.

CONCLUSION: Changes in smooth muscle contractile filaments do not appear to play a major role in postoperative motility disorders in small bowel atresia.

INTRODUCTION

Small bowel atresia is a congenital disorder of unknown pathogenesis, which carries significant morbidity[1-8]. Because of the severity of the dilatation of the proximal bowel and the hypoplasia of the distal bowel, various postoperative gastrointestinal motility problems might occur. The postoperative course can be complicated by a prolonged adynamic ileus (11%) and need for total parenteral nutrition (30%-70%)[9]. Although the underly-

ing cause of this postoperative intestinal motility disorder is unclear, it has been clearly shown that normal gastrointestinal motility depends on the coordinated function of the enteric nervous system (ENS), the intestinal smooth muscle and the interstitial cells of Cajal (ICCs)[10]. Consequently, previous publications have examined these factors for changes in small bowel atresia patients, especially within the atretic and adjacent proximal and distal bowel. Hypertrophy of the small bowel muscle proximal to the atresia has been found in clinical and experimental studies on small bowel atresia. Furthermore, various changes have been reported within the ENS in small bowel atresia[11]. We have recently shown differential changes of the ENS and the ICCs within the proximal bowel in small bowel atresia[12]. However, the smooth muscle of small bowel atresia patients has not been studied in detail. Therefore, the aim of this study was to investigate specific contractile filaments of the smooth muscle cells in resected specimens of small bowel atresia.

MATERIALS AND METHODS

Patients and tissues
Resected small bowel specimens (ileum) from term newborn small bowel atresia patients (*n* = 12) were included in the investigation after obtaining parental consent. The resected ileal specimens were divided into three segments (proximal, atretic and distal). Bowel specimens of two age-matched patients (who underwent surgery for Meckel's diverticulum) served as control tissue.

Tissue processing
The specimens were fixed in 4% paraformaldehyde, embedded in paraffin blocks and sectioned at 2-4 μm (Leica SM 2000 R) followed by drying overnight at 37 ℃. Before immunohistochemical staining, the paraffin sections were dewaxed for 10 min in xylene, 10 min in acetone and 10 min in acetone/Tris-buffered saline (TBS: 1:1). After treatment, the slides were washed in TBS.

Antigen demasking
When antigen retrieval by heat was required, dewaxed paraffin sections were placed in microwave-proof tubes containing target retrieval solution (Dako). The slides were treated in the tubes for 5 min at 600 W in a microwave (SS 566H; Bosch, Munich, Germany). The evaporated volume was replaced with distilled water, and the procedure was repeated twice. After microwave treatment, the slides were cooled and washed in TBS.

Histology and immunohistochemistry
Standard HE histology was performed. For immunohistochemistry, an alkaline phosphatase-anti-alkaline phosphatase (APAAP) staining kit (Dako Real™ Detection System, APAAP, Mouse) using anti-smooth muscle actin (SMA, polyclonal, Dako, 1:500) and anti-desmin (Desmin, polyclonal, Dako, 1:25) antibodies was used. A nonsense

mAb (clone: MR 12/53) served as the negative control.

Evaluation
Immunohistochemical analysis focused on the proximal and distal parts of the resected ileum. The sections were evaluated by two independent investigators using light microscopy (magnification: 40 ×). HE staining was used to visualize the overall histology of the specimens. The distribution and density of immunoreactive SMA-positive and desmin-positive muscle filaments were studied in each part of the resected bowel (proximal, atretic and distal). Because immunohistochemical staining cannot be quantified, semi-quantitative scoring was performed as follows: - no expression, + low expression, ++ moderate expression, +++ high expression.

RESULTS

Patients
The study included resected ileal segments from 12 term newborn small bowel atresia patients (gestational age: 38-40 wk). Eleven patients presented with type Ⅲ a ileal atresia and one patient presented with multiple ileal atresia. All patients were operated during the first or second day of life.

Standard hematoxylin-eosin staining
Standard HE staining revealed normal muscle components within the bowel wall. The muscle layers of the proximal bowel appeared to be slightly thicker. However, these findings were not consistent in all specimens (Figure 1).

Smooth muscle actin immunohistochemistry
The gross histology of the affected (proximal) bowel remained unchanged. There was a variable increase in muscle layer thickness.

SMA expression in filaments was moderately decreased within the proximal bowel (moderate expression: ++) of small bowel atresia patients compared with control tissues (high expression: +++) (Figure 2A and C).

SMA positive filaments were uniformly less expressed in the tunica muscularis mucosa compared with the tunica muscularis propria (circular muscle, longitudinal muscle).

The distal bowel had normal expression of SMA-positive filaments (high expression: +++) within the smooth muscle of the tunica muscularis propria and the tunica muscularis mucosa compared to controls (high expression: +++) (Figure 2B and D).

Smooth muscle desmin immunohistochemistry
The gross histology of the proximal and distal small bowel was unchanged, as observed by desmin immunohistochemistry. The expression of desmin-positive filaments was moderately reduced within all muscle layers of the affected proximal bowel (moderate expression: ++) compared with controls (high expression: +++). There

Figure 1 Hematoxylin-eosin staining of the proximal (A) and distal (B) bowel. CM: Circular muscle; LM: Longitudinal muscle.

Figure 2 Smooth muscle actin immunohistochemistry of the proximal (A, C) and distal (B, D) bowel. CM: Circular muscle; LM: Longitudinal muscle; MM: Muscularis mucosa.

were no differences in desmin expression between the tunica muscularis propria (circular and longitudinal muscle) and the tunica muscularis mucosa within the proximal bowel (Figure 3A and C).

The distal bowel showed normal expression of desmin-positive filaments (high expression: +++) within the smooth muscle of the tunica muscularis propria and the tunica muscularis mucosa compared to controls (high expression: +++) (Figure 3B and D).

DISCUSSION

The extent of damage to the smooth muscle in small bowel atresia has not been well characterized. Previ-

ous studies of histological and ultrastructural changes of the affected bowel have investigated the ENS and the ICCs[13-20]. In these studies, differential changes of the ENS and ICCs were especially found in the proximal dilated bowel in small bowel atresia. Our present study revealed only moderate changes in the morphology of the of the smooth muscle and contractile filaments of the resected bowel proximal to the small bowel atresia. Furthermore, varying degrees of smooth muscle layer thickening was evident. The correlation between the degree of smooth muscle layer thickening and the duration of small bowel obstruction could not be evaluated since no data on the prenatal onset of the true obstruction were available.

Figure 3 Desmin immunohistochemistry of the proximal (A, C) and distal (B, D) bowel. CM: Circular muscle; LM: Longitudinal muscle.

A previous animal study creating a partial obstruction in dog ileum tissue revealed that the ganglion cells increased in size and the smooth muscle of the dilated bowel became thicker[21].

Another study used a murine partial small bowel obstruction model and revealed that 2 wk following the onset of a partial obstruction, the bowel increased in diameter, and hypertrophy of the tunica muscularis occurred oral to the obstruction site[22]. ICC networks were disrupted orally to the obstruction, and this disruption was accompanied by the loss of electrical slow waves and responses to enteric nerve stimulation. These defects were not observed aboral to the obstruction. Furthermore, it was shown that the removal of the obstruction led to the redevelopment of ICC networks and the recovery of slow wave activity within 30 d. Neural responses were partially restored in 30 d[22]. Similar repair mechanisms may occur after surgical correction of small bowel atresia. It seems obvious that decreases in ICCs in small bowel atresia and their restoration after removal of the obstruction contributes to the regulation of gastrointestinal motility.

Masumoto *et al*[11] showed that the circular muscle of the proximal small bowel is hypertrophied and expresses less SMA. This study showed that the ultrastructure and distribution pattern of the SMA-positive smooth muscle cells remained similar in the affected bowel compared with controls.

In another study, Masumoto *et al*[23] showed muscular alterations, such as abnormal smooth muscle bundles within the proximal segment of small bowel atresia. We could not confirm the existence of these abnormal smooth muscle bundles in our investigations. A case report recently revealed long lasting chronological changes within the ENS, muscle components and ICCs in small bowel atresia[24]. Interestingly, in this case, SMA-positive areas were found in both the circular and longitudinal musculature, and an increase in the proximal segment was observed at two different time points (newborn and 6 mo of age) compared with controls. The expression of SMA was similar in the distal segments compared with controls. Again, no clear changes were seen using SMA in the proximal bowel compared with the distal bowel and controls.

Ozguner *et al*[25] reported that the proximal segment of the atretic intestine showed structural deficits. Abnormal ganglia cells and defects in the intestinal musculature were prominent, but the intestinal mucosa remained intact. They found that abnormalities on both the antimesenteric and mesenteric sides, and their interpretation supported a vascular accident as a causative factor. Nevertheless, our study was not able to show muscular disruptions within the proximal bowel.

Previous studies have clearly shown that the ENS and ICCs are altered in the proximal and dilated bowel in small bowel atresia[12]. The innervation pattern of the proximal bowel resembles intestinal neuronal dysplasia[12]. These changes might be the result of a long-lasting bowel obstruction and bowel content stasis. Surprisingly, the smooth muscle appears hypertrophied, but substan-

tial changes within its ultrastructure were not observed. Therefore, we believe that the moderate histological changes within the smooth muscle do not contribute to the pathogenesis of small bowel atresia. Furthermore, the moderately altered smooth muscle does not seem to play a major role in the postoperative gastrointestinal motility of the affected patients.

In conclusion **the possible restoration of ICCs and** the moderate changes within the contractile filaments of smooth muscle components in small bowel atresia suggest that changes within the ENS are responsible for the postoperative motility problems. Furthermore, we speculate that extensive resection of the dilated proximal bowel is necessary to restore passage in adequate time.

COMMENTS

Background

Small bowel atresia is a congenital anomaly of unknown cause. Despite early corrective surgery, patients carry a substantial morbidity because of postoperative gastrointestinal motility problems. Normal gastrointestinal motility is generated by the complex interaction of the enteric nervous system (ENS), the intestinal smooth muscle and the interstitial cells of Cajal (ICCs). Alterations in the ENS and ICCs may contribute to the motility problems in patients with small bowel atresia after surgery. It has not yet been investigated whether changes in the smooth muscle occur in small bowel atresia and whether these possible changes influence the postoperative course.

Research frontiers

The relationship between the macroscopic and histological changes of the affected bowel and the postoperative motility disorder are still under investigation. Furthermore, the role of the smooth muscle and its contractile filaments in small bowel atresia needs to be further elucidated.

Innovations and breakthroughs

This study showed that the smooth muscle contractile filaments are only moderately altered in the proximal and dilated bowel in small bowel atresia. These results suggest that extensive resections of dilated proximal is not necessary in affected patients.

Applications

Previously shown changes within the ENS and the ICCs may influence postoperative gastrointestinal motility in affected patients. The moderate variations of smooth muscle contractile filaments in small bowel atresia do not seem to play a role in the postoperative course.

Terminology

Bowel atresia is a congenital defect in the continuity of the bowel. The incidence of small bowel atresia is higher than that of large bowel atresia and varies between 1:300 and 1:3000.

Peer review

The manuscript is well written and addresses an important concept of a clinical problem.

Abstract

AIM: To assess the alcohol drinking patterns in a cohort of primary sclerosing cholangitis (PSC) patients and the possible influence on the development of fibrosis.

METHODS: Ninety-six patients with PSC were evaluated with a validated questionnaire about a patient's lifetime drinking habits: the lifetime drinking history (LDH) questionnaire. In addition, clinical status, transient elastography and biochemistry values were analysed and registered. Patients were defined as having either significant or non-significant fibrosis. Significant fibrosis was defined as either an elastography value of $\geq$ 17.3 kPa or the presence of clinical signs of cirrhosis. Patients were divided into two groups depending on their alcohol consumption patterns; no/low alcohol consumption (one drink or unit/d) and moderate/high alcohol consumption ($\geq$ 1 drink or unit/d). LDH data were calculated to estimate lifetime alcohol intake (LAI), current alcohol intake, drinks per year before and after diagnosis of PSC. We also calculated the number of episodes of binge-drinking (defined as consuming $\geq$ 5 drinks per occasion) in total, before and after the diagnosis of PSC.

RESULTS: The mean LAI was 3882 units of alcohol, giving a mean intake after onset of alcohol consumption of 2.6 units per week. Only 9% of patients consumed alcohol equal to or more than one unit per day. Current alcohol intake in patients with significant fibrosis (n = 26) was less than in patients without significant fibrosis (n = 70), as shown by lower values of phosphatidylethanol (B-PEth) (0.1 μmol/L *vs* 0.33 μmol/L, respectively, P = 0.002) and carbohydrate-deficient transferrin (CDT) (0.88% *vs* 1.06%, respectively, P = 0.02). Self-reported LAI was similar between the two groups. Patients with significant fibrosis reduced their alcohol intake after diagnosis from 103 to 88 units per year whereas patients without fibrosis increased their alcohol intake after PSC diagnosis from 111 to 151 units/year. There were no correlations between elastography values and intake of alcohol (units/year) (r = -0.036).

CONCLUSION: PSC patients have low alcohol consumption. The lack of correlation between fibrosis and alcohol intake indicates that a low alcohol intake is safe in these patients.

INTRODUCTION

Little is known about risk factors for progression of fibrosis in primary sclerosing cholangitis (PSC) except for duration of disease and presence of symptoms[1-4]. Excessive consumption of alcohol causes liver disease[5-7], and a high intake of alcohol acts as a co-factor for progression of other chronic liver diseases, such as non-alcoholic steatohepatitis, hereditary hemochromatosis and hepatitis C (HCV). For instance, heavy episodic drinking has been shown to be associated with progression of fibrosis in non-alcoholic fatty liver disease[8], alcohol consumption of more than 60 g per day increases the risk for cirrhosis 9-fold in patients with hereditary hemochromatosis[9], and an alcohol intake of more than 210 g per week in patients with HCV has been shown to increase fibrosis[10-13]. The threshold for a safe intake of alcohol with regard to development of fibrosis in patients with concomitant liver disease is unclear and most patients with a chronic liver disease are advised to keep their alcohol intake to a minimum. The evidence for giving such advice to patients with chronic liver diseases in general is scarce. There is no evidence that alcohol in low amounts influences disease progression and there are data suggesting that a low alcohol intake, on the contrary, may have a protective effect against fibrosis. A recent study by Cheung *et al*[14] indicated no increased risk for fibrosis in HCV patients with alcohol intake less than 210 g per week and in a study by Moriya *et al*[15], low consumption of alcohol seemed to protect against non-alcoholic fatty liver disease in healthy individuals.

The impact of alcohol on progression of fibrosis in PSC has not been previously studied, although alcohol consumption has been reported to be associated with development of cholangiocarcinoma[16]. One of the most common questions from patients with PSC is: what amount of alcohol can be considered to be a safe intake? "Safe" amounts of alcohol (in liver-healthy individuals) are usually considered to be less than 210 g (approximately 18 units or drinks) of alcohol per week[7]. The purpose of our study was to describe the alcohol consumption patterns, and to evaluate whether lifetime alcohol consumption correlates to the fibrosis stage, in patients with PSC.

MATERIALS AND METHODS

Patients

All patients diagnosed with PSC at the Department of Gastroenterology and Hepatology, Karolinska University Hospital are recorded in a local PSC register.

Eligible for this study were 141 patients with PSC who were identified as currently living in the Stockholm area and who were having their regular follow-ups at our clinic.

The diagnosis of PSC were made according to accepted criteria; *i.e.*, typical cholangiographic findings of bile duct irregularities, strictures and dilatations or histological findings of cholangitis, or signs of small-duct PSC in combination with biochemical and clinical findings[4,17].

Figure 1 Flow chart for inclusion of patients. [1]Exclusion due to: Not Swedish speaking, presence of Down's disease, dementia, current pregnancy, severe psychiatric disease, co-existing hepatic disease (hepatitis B or C, hemochromatosis, recent diagnosis of liver cancer) or patients who had moved to other parts of the country or declined to participate (*n* = 4).

We excluded 32 patients with a recent diagnosis of cancer, not Swedish speaking, presence of Down's syndrome, dementia, current pregnancy, severe psychiatric disease (e.g., psychosis, bipolar disease), co-existing liver diseases (e.g., hepatitis B and C or hereditary hemochromatosis). Four patients declined to participate. The study cohort and patient selection are summarized in Figure 1.

Data collection

From our registry and patient charts, the following data were registered: duration of disease, age, sex, co-existing inflammatory bowel disease (IBD, diagnosed through endoscopy and histology), symptoms, smoking and body mass index (BMI). The patients were interviewed with a structured protocol for confirmation and validation of the data collected from the registry and for current symptoms and alcohol habits, including the question as to whether the patients had reduced their alcohol intake after the diagnosis of PSC was established.

At the interview, patients received the lifetime drinking history (LDH) questionnaire, a detailed and validated questionnaire about the patient's lifetime drinking habits[18,19]. This questionnaire allows the calculation of the total number of units during the patient's lifetime, with the possibility of calculating changes in drinking habits during life. It also allows measurement of total number of binge drinking episodes, defined as drinking 5 or more units of alcohol at one occasion. One unit of alcohol is equivalent to 12 g of alcohol. Patients were thoroughly informed about the questionnaire and later filled it out at home. When data were missing, the patient was contacted by telephone and information was supplemented through a telephone interview. Six of 105 patients (5.7%) did not return the LDH questionnaire despite being reminded and were excluded. No/low alcohol consumers were defined as drinking less than one drink per day, and moderate/high alcohol consumer as drinking equal to or more than one drink per day.

Transient elastography

Transient elastography with FibroScan (EchoSens, Paris, France) was performed on all patients on the same occasion as the interview. The cut-off values for significant

fibrosis were adopted from Corpechot *et al*[20] and the threshold for fibrosis stage 4 according to Ludwig (cirrhosis) was set to $\geq$ 17.3 kPa. At least 10 measurements were made, and only the scans where more than 60% of measurements were valid were accepted. We divided the population into two subgroups: patients with significant and non-significant fibrosis. Significant fibrosis was defined as either elastography values $\geq$ 17.3 kPa or a clinical diagnosis of cirrhosis diagnosed with histology[21] or typical radiological and biochemical findings of cirrhosis (such as irregular hepatic parenchyma, splenomegaly, oesophageal varices, presence of intraabdominal collaterals) or manifestation of decompensation. In nine patients elastography failed, most often due to overweight. In six of these, presence of significant fibrosis was evident from clinical data and they were included into the "significant fibrosis" group. The three patients with no available information on fibrosis from either elastography or clinical data were excluded. Twenty-six patients were found to have significant fibrosis and 70 patients had non-significant fibrosis.

Biochemistry

Biochemical data including blood count, sodium, potassium, creatinine, alkaline phosphatase, serum transaminases, total bilirubin, PK-INR, albumin, carbohydrate-deficient transferrin (CDT) and phosphatidylethanol (B-PEth, measured by liquid chromatography-mass spectrometry) in plasma were collected and analysed at the routine biochemistry laboratory at Karolinska University Hospital.

Statistical analysis

Continuous variables were analyzed using the Mann-Whitney *U*-test or the Wilcoxon Signed Rank Test where appropriate. For comparison of categorical data the χ^2 analysis was used or, in the case of small expected frequencies, *F* test. For correlation tests of linear data, the Pearson *r* test was used. We controlled the results for duration of disease using co-variance analysis of variance. Statistical data were analyzed using the Statistica® 9.1 software (StatSoft Inc., Tulsa OK) and SAS 9.2 software (SAS Institute Inc., Cary NC).

Ethical considerations

The local ethics committee at Karolinska University Hospital approved this study, registry No: 2009/1894-31/1. Written informed consent was obtained from all participating subjects.

RESULTS

Clinical characteristics

Clinical characteristics and data on lifetime alcohol consumption for the 96 patients are presented in Table 1. There were 66% men, mean age was 47 $\pm$ 13 years (range: 22-75 years) and 73 patients (76%) were diagnosed with concomitant IBD. Mean elastography value was 11.1 $\pm$ 8.2 kPa (range: 2.8-48 kPa). Seven patients (7.3%) had been diagnosed with PSC before they first started drinking al-

Table 1 Clinical characteristics and drinking habits of 96 patients with primary sclerosing cholangitis

	Mean (range)
Age at inclusion (yr)	47 (22-75)
Male sex	63/96
Duration of primary sclerosing cholangitis (yr)	12 (0-30)
Age at primary sclerosing cholangitis diagnosis (yr)	35 (11-65)
Fibroscan value (kPa)	11.1 (2.8-48)
Undergone orthotopic liver transplantation, *n* (%)	12 (12.5)
Bilirubin (μmol/L)	15.3 (3-82)
Alkaline phosphatase (μkat/L)	2.66 (0.5-12.4)
Phosphatidylethanol (μmol/L)	0.28 (0.1-8.4)
Carbohydrate-deficient transferrin (%)	1.01 (0.5-3)
Body mass index (kg/m²)	24.1 (17.2-34.3)
Inflammatory bowel disease (%)	73/96 (76)
Smoking-current user, *n* (%)	4 (4.2)
Smoking-ex user, *n* (%)	16 (16.7)
Smoking-never used, *n* (%)	76 (79.2)
Lifetime drinking habits	
Age at first alcohol intake (yr)	17 (12-28)
Lifetime alcohol intake (unit)	3882 (0-20 270)
Yearly alcohol intake, total (unit)	137 (0-1180)
Yearly alcohol intake, before diagnosis (unit)	109 (0-674)
Yearly alcohol intake, after diagnosis (unit)	134 (0-1110)
Total occasions of binge-drinking	294 (0-4054)
Yearly occasions of binge-drinking, total	11.3 (0-165)
Yearly occasions of binge-drinking, before diagnosis	12.0 (0-295)
Yearly occasions of binge-drinking, after diagnosis	8.0 (0-83)

Normal range, laboratory values. Bilirubin: < 26 μmol/L; Alkaline phosphatase: < 1.9 μkat/L; Phosphatidylethanol: < 1.0 μmol/L; Carbohydrate-deficient transferrin: < 2.0%.

cohol. There were no cases of patients with Child-Pugh score of 10 (*i.e.*, class C) or higher.

Alcohol consumption

Mean age at onset of alcohol consumption was 17 $\pm$ 3 years (range: 12-28 years). The mean lifetime alcohol intake (LAI) was 3882 units of alcohol (median: 2275 units, range: 0-20 270 units), giving a yearly mean alcohol intake of 137 units per drinking year and a mean number of 2.6 units per week during the years of alcohol consumption. Nine percent (9/96) drank equal to or more than one unit per day, and one percent (1/96) had a mean consumption of more than two units per day. The mean number of total episodes of binge drinking was 294 (median: 96, range: 0-4054), equalling eleven binges per year or 0.2 binges per week on average.

Twenty-eight percent (24/87) of no/low alcohol consumers (< 1 unit per day) had significant fibrosis compared to 22% of consumers with moderate/high alcohol intake (> 1 unit per day, *P* = 0.57). Moderate/high consumers had significantly more episodes of binge drinking. There were no significant differences in biochemical data or BMI (data not shown) between the moderate/high and the no/low alcohol consumption groups.

Comparison of patients with and without significant fibrosis

There were no significant differences in mean units of alcohol consumed per year between patients with significant and non-significant fibrosis, as shown in Figure 2.

Figure 2 Comparison between the total mean units of alcohol per year for the significant and non-significant fibrosis group.

Figure 3 Correlation between elastography values and units per year. Patients with clinically significant fibrosis but not a valid elastogram were given the value of 17.3 kPa.

There was no correlation between yearly alcohol intake (units/year) and elastography values (Figure 3). Thirty-eight percent of all patients (36/96) reported a decreased alcohol intake after the diagnosis of PSC. This figure was similar in patients with and without significant fibrosis (39% *vs* 37%). To further evaluate if the drinking habits changed after diagnosis, the LDH data were compared before and after PSC diagnosis. A total increase from 109 to 134 units per year, and a decrease in binge drinking of twelve to eight binges per year was found in all patients (not signitficant). Among patients with non-significant fibrosis, we found an increase in total alcohol consumption after PSC diagnosis (111 units per year *vs* 151 units per year, $P = 0.07$) whereas a decrease in total alcohol consumption after PSC diagnosis (103 units per year *vs* 88 units per year, $P = 0.59$) was found in the significant fibrosis group. Binge-drinking before and after PSC diagnosis was 14.9 binges per year *vs* 9.6 binges per year ($P = 0.24$) in the non-significant fibrosis group and 4.3 binges per year *vs* 3.6 binges per year ($P = 0.5$) in the significant fibrosis group. The significant fibrosis group had higher bilirubin values (24.8 μmol/L *vs* 11.8 μmol/L, $P = 0.015$),

lower CDT values (0.88% *vs* 1.06%, $P = 0.02$) and lower PEth values (0.1 *vs* 0.33, $P = 0.0016$) than the non-significant fibrosis group. Comparison of clinical variables and alcohol consumption between patients with significant and non-significant fibrosis are summarized in Table 2. We also performed a similar analysis with different cut-off values; 12.5 and 14.5 kPa respectively, which are the suggested cut-off values for cirrhosis (stage 4 fibrosis) in HCV[22,23], with similar results as when the cut-off level of ≥ 17.3 kPa was used (data not shown).

DISCUSSION

This study describes for the first time the alcohol consumption patterns in a large cohort of PSC patients before and after PSC diagnosis. The majority of the PSC patients were shown to have low alcohol consumption. The mean LAI was 3882 units of alcohol, giving a mean intake after onset of alcohol consumption of 2.6 units per week, and only 9% drank more than one unit per day and 1% more than two units per day. In comparison, to develop alcohol-induced liver cirrhosis, subjects need to drink at least 30 g of alcohol per day, equaling around 3 drinks per day[5-7] over several years.

The lifetime alcohol consumption did not correlate with the presence of significant fibrosis, although the current alcohol intake in fibrotic patients was less than in patients without significant fibrosis, shown by lower values of PEth and CDT. There was also a trend that patients with significant fibrosis had reduced their alcohol intake after the diagnosis of PSC whereas patients without significant cirrhosis actually increased their consumption after diagnosis. This is consistent with findings from studies of the effect of alcohol on other chronic liver diseases implicating that a low intake of alcohol seems to be harmless[14,15]. One may speculate whether or not low alcohol consumption actually protects against more progressive development of cirrhosis. Although no such conclusions can be drawn from the present study, our data support that a low consumption is harmless for fibrosis progression. The alcohol consumption among our PSC patients was lower than we expected, which has influenced our ability to evaluate the impact of more marked alcohol consumption for the progression of fibrosis. We were unable to evaluate whether a moderate/high consumption was harmful or safe since the number of patients with this pattern of consumption was too low.

CDT values can be affected by factors other than alcohol, such as end-stage liver disease (Child-Pugh score ≥ 10)[24,25]. None of our patients had a Child-Turcotte-Pugh score of more than 10 and patients with significant fibrosis had lower CDT values than patients with non-significant fibrosis. CDT has not been validated in patients with PSC; however, it has been studied in primary biliary cirrhosis and not been implicated to produce false-positive results[26]. B-PEth[27] measured by mass spectrometry is an even more sensitive marker than CDT for detecting alcohol consumption over the previous 1-2 wk. It has been reported to be stable in patients with

Table 2 Comparison of clinical variables and alcohol consumption between patients with and without significant fibrosis

Variable	Non-significant fibrosis (*n* = 70)	Significant fibrosis (*n* = 26)	*P* value
Duration of disease (yr)	10.1 ± 6.8	15.6 ± 7.9	0.019
Age at primary sclerosing cholangitis diagnosis (yr)	36 ± 14	34 ± 13	0.29
Lifetime alcohol intake (unit)	3896 ± 4441	3845 ± 4457	0.44
Yearly alcohol intake, mean (unit)	144 ± 178	117 ± 135	0.27
Total occasions of binge-drinking	331 ± 692	194 ± 341	0.23
Yearly occasions of binge-drinking	12.7 ± 24.7	7.1 ± 13	0.41
Yearly alcohol intake, before diagnosis (unit)	111 ± 129	103 ± 141	0.24
Yearly alcohol intake, after diagnosis (unit)	151 ± 200	88 ± 86	0.26
Yearly binge drinking episodes, before diagnosis	14.9 ± 38.1	4.3 ± 7.3	0.07
Yearly binge drinking episodes, after diagnosis	9.6 ± 18.6	3.6 ± 4.7	0.23
Bilirubin (μmol/L)	11.8 ± 6.8	24.8 ± 23.1	0.015

Phosphatidyl ethanol (μmol/L)	0.33 ± 1	0.1 ± 0	0.0016
Carbohydrate deficient transferrin (%)	1.06 ± 0.38	0.88 ± 0.2	0.02
Body mass index (kg/m²)	24.12 ± 3.12	24.02 ± 4.24	0.43

Normal range, laboratory values. Bilirubin: < 26 μmol/L; Alkaline phosphatase: < 1.9 μkat/L; Phosphatidylethanol: < 1.0 μmol/L; Carbohydrate-deficient transferrin: < 2.0%.

concomitant liver disease[28], but has not been studied in detail in patients with PSC.

The low alcohol consumption seen among our patients may be an effect of the general advice these patients are given in clinical practice, which is to keep alcohol intake at a minimum level. Patients with significant fibrosis also had higher bilirubin levels indicating a more severe disease, which in itself inhibits alcohol consumption. Thus, the knowledge of significant fibrosis in a patient contributes to decreased alcohol consumption. It is well known that smoking is associated with high alcohol consumption[29]; PSC patients have a low smoking frequency[30], also seen in this study. The correlation between a low smoking frequency and small total alcohol consumption in this cohort further validates our results.

Binge drinking decreased in both patients with significant and non-significant fibrosis after PSC diagnosis. This finding may reflect a change in drinking pattern with age, rather than the presence of PSC. Also, there is a general trend in Sweden towards less binge drinking[31]. The total alcohol consumption in Sweden has increased by approximately 15% since the mid 1990s[31,32]. Thirty-eight percent of all our patients reported that they had reduced their alcohol intake after the PSC diagnosis; however, the trend when looking at the LDH data was an increase in the total yearly alcohol intake. The perception of having reduced the consumption may be related to a reduction in the occasions of binge drinking episodes, which was confirmed in the questionnaire.

One limitation of the present study is the retrospective self-reported alcohol intake, which may be impaired by recollection bias. However, the LDH questionnaire is well validated and has a high test-retest correlation[19,33]. We also had a high response rate to the LDH questionnaire which is why we believe that our data are reliable. In addition, there is a risk that we have underestimated the presence of significant fibrosis since we did not perform liver biopsies to measure fibrosis. Liver biopsy is

not mandatory for the diagnosis of PSC and we chose to refrain from biopsies for ethical reasons due to risk of complications. The role of transient elastography in cholestatic liver disease is not well established, although it has been shown to be a good alternative to histology for evaluating fibrosis, mainly in HCV, but also in other chronic liver diseases[20,34-36].

Chalasani *et al*[16] reported in 2000 that alcohol was a risk factor for developing cholangiocarcinoma (CCA) in PSC; however, they were unable to quantify the amount of alcohol consumed. Our data can at present not evaluate whether alcohol intake is important for CCA since none of our patients have developed CCA. However, we have obtained solid data regarding alcohol consumption in a large cohort of PSC patients which is being prospectively followed. This allows future studies exploring the role of alcohol as a risk factor for developing CCA in this cohort.

In conclusion, patients with PSC have low alcohol consumption. Only 9% consumed an amount of alcohol equal to or more than one unit per day. There was a trend towards increased alcohol consumption after the PSC diagnosis in patients without significant fibrosis, and these patients have significantly increased plasma levels of CDT and PEth as compared to those having significant fibrosis or cirrhosis. We found no correlation between alcohol consumption and significant fibrosis. In summary, our results indicate that low alcohol consumption is safe in patients with PSC.

ACKNOWLEDGMENTS

COMMENTS

Background
Fibrosis progression in primary sclerosing cholangitis (PSC) is a heterogeneous process with large individual variations before significant fibrosis develops.

Research frontiers
Alcohol, in high amounts, is known to be a risk factor for progression of fibrosis in other chronic liver diseases. The role of alcohol intake for progression of fibrosis has not previously been studied in PSC.

Innovations and breakthroughs
This is the first study of the alcohol consumption pattern in a large cohort of PSC patients and they aimed to correlate this to the occurrence and degree of fibrosis.

Applications
By increasing their knowledge of risk factors for progression of fibrosis in PSC, this study can help give doctors relevant information to patients regarding their alcohol habits.

Peer review
The paper is an interesting paper assessing the lifetime drinking history. The paper is quite well written but the reader needs reason for using certain biochemical variables in this context and the statistical analysis has to be better explained. Also most readers of this paper do not know what is the amount of drinks used by patients with alcohol dependency and alcoholic cirrhosis.

Abstract

AIM: To investigate the relationship between blood riboflavin levels and riboflavin transporter 2 (*RFT2*) gene expression in gastric carcinoma (GC) development.

METHODS: High-performance liquid chromatography was used to detect blood riboflavin levels in patients with GC. Real-time fluorogenic quantitative polymerase chain reaction and immunohistochemistry were used to analyze the expression of RFT2 mRNA and protein in samples from 60 GC patients consisting of both tumor and normal tissue.

RESULTS: A significant decrease in the RFT2 mRNA levels was detected in GC samples compared with those in the normal mucous membrane (0.398 ± 0.149 *vs* 1.479 ± 0.587; $P = 0.040$). Tumors exhibited low RFT2 protein expression (75%, 16.7%, 8.3% and 0% for no RFT2 staining, weak staining, medium staining and strong staining, respectively), which was significantly lower than that in the normal mucous membrane (10%, 16.7%, 26.7% and 46.7% for no RFT2 staining, weak staining, medium staining and strong staining, respectively; $P < 0.05$). Tumors with low RFT2 expression were significantly associated with tumor stage and histological grade. Moreover, a significantly decrease in Uyghur patients was observed compared with Han patients. However, other parameters-gender, tumor location and lymph node metastasis-showed no significant relationship with RFT2 expression. Blood riboflavin levels were reverse correlated with development of GC ($1.2000 \pm 0.97\,569$ ng/mL in high tumor stage patients *vs* $2.5980 \pm 1.31\,129$ ng/mL in low tumor stage patients; $P < 0.05$). A positive correlation of plasma riboflavin levels with defective expression of RFT2 protein was found in GC patients ($\chi^2 = 2.619$; $P = 0.019$).

CONCLUSION: Defective expression of RFT2 is associated with the development of GC and this may represent a mechanism underlying the decreased plasma riboflavin levels in GC.

INTRODUCTION

Gastric carcinoma (GC) is one of the most common cancers and the second leading cause of cancer deaths worldwide. In China, the incidence and mortality rates for gastric cancer in 2006 were 35.02 and 26.08 per 100 000 persons, respectively. The survival rate for gastric cancer is generally low, with a 5-year survival rate not exceeding 30%[1]. *Helicobacter pylori* infection of the gastric mucosa is associated with GC, infecting the gastric mucosa of 50% or more of the world's population. However, the relatively low GC risk suggests that other factors[2] such as lifestyle factors-including diet and genetic predisposition-may play an etiologic role[3,4]. Nitrosamines have been suspected in the etiology of GC in the high incidence area of China; however, riboflavin deficiencies and other micronutrients may also be involved[5,6].

Riboflavin is a water-soluble vitamin that is a precursor of flavin mononucleotide (FMN) and flavin adenine dinucleotide (FAD), which participate in various redox reactions, some of which are absolutely essential to the function of aerobic cells. Milk and dairy products, meats, fatty fish, certain fruit as well as vegetables are good sources of riboflavin. However, riboflavin deficiency and poor riboflavin status seem to be of most concern for the elderly and adolescents, despite the diversity of available riboflavin-rich foods[7]. Thus, whether other factors exist that may influence dietary riboflavin absorption or that may change the status of riboflavin needs to be determined.

Indeed, a recent study showed that riboflavin transporter 2 (RFT2) was found to transport riboflavin that is highly expressed in the small intestine and may be involved in such riboflavin absorption[8]. Additionally, Fujimura *et al*[9] demonstrated that RFT2 is a transporter involved in the epithelial uptake of riboflavin in the small intestine for its nutritional utilization. Because RFT2 is responsible for transporting riboflavin and riboflavin deficiency has been reported as a risk factor for GC, and our previous genome-wide association studies showed that genetic variations at 20p13 for RFT2 (or C20 or f54) contribute significantly to the risk for cutaneous squamous cell carcinoma and GC in Chinese Han and Uyghur populations[10], we propose that human RFT2 is likely to have an important role in gastric carcinogenesis that involves modulating riboflavin absorption. However, most previous studies on riboflavin and RFT2 were relatively small and investigated only the functional roles of riboflavin and RFT2[11-13].

To clarify these issues, in the present study, we examined blood riboflavin levels and their tissue riboflavin transporter gene statuses. Additionally, we further analyzed the relationship between RFT2 and riboflavin in the development of GC.

MATERIALS AND METHODS

Clinical samples

A total of 120 paraffin-embedded, formalin-fixed tissue specimens were used in this study. Sixty patients with GC who underwent surgery at the Department of General Surgery of the first affiliate Hospital of Xinjiang Medical University in 2011 were enrolled in the study. Additionally, 60 matched cases with normal mucous membranes were involved. The patient population consisted of 39 men and 21 women, with a mean age of 54.9 years (range: 39-76 years). Peripheral blood samples also collected into EDTA Vacutainer Tubes (Becton Dickinson) and immediately placed on ice. Next, the remaining samples were centrifuged (10 min at 2000 g and 4 ℃) and collected plasma was stored at -80 ℃ until use. Control samples were obtained from subjects who underwent routine health checks, were recruited in the same area, and were matched with GC patients regarding age and gender. The selection criteria included individuals who were free from certain diseases, including neoplasms, cardiovascular diseases, hepatic diseases, renal diseases or inflammatory diseases. All patients were enrolled with written informed consent, and the study was approved by the Ethical Committee of the Medical University of Xinjiang. Patients had not received preoperative chemotherapy and/or radiotherapy. Tumor stage was determined according to the tumor node metastasis classification system of the International Union against Cancer. In addition, 60 frozen biopsies that included 30 GC and 30 matched normal mucous epithelia (5 cm away from the tumor), which were collected within 30 min after resection and kept at -80 ℃, were subjected to real-time reverse transcription-polymerase chain reaction (RT-PCR) for detection of RFT2 mRNA expression. Histological diagnosis was confirmed for each specimen.

Determination of riboflavin levels in plasma

Blood plasma was analyzed for its concentration of riboflavin by high-performance liquid chromatography (HPLC) as described previously[14]. The HPLC system used was a Waters 2695 liquid chromatograph and Waters 2475 fluorescence detector with the autosampler set at 28 ℃ and configured for a 96-well microtiter plate. Water was generated using a Milli-Q water system. All chemicals were of analytical grade. For quality control, we used three Clin Chek serum controls, reconstituted and stored at -80 ℃. Aliquots of aqueous (0.3860 g/L $C_2H_7NO_4$) flavin stock solutions (5 mmol/L) were stored at -20 ℃ in the dark. An excitation wavelength of 450 nm was

used and riboflavin was detected at an emission wavelength of 520 nm. The peak area was measured and used for quantification.

RNA extraction and real-time RT-PCR

RFT2 mRNA expression was detected by quantitative real-time RT-PCR. Total RNA was extracted from fresh frozen tissue using Trizol (Invitrogen, Carlsbad, CA, United States) according to the manufacturer's instructions and treated with TURBO DNA-free™ DNase (Ambion, Austin, TX, United States) to remove the genomic DNA. Reverse transcription was performed using a reverse transcription system kit (Takara Bio, Tokyo, Japan) as previously described[15]. Real-time PCR for RFT2 was performed in a 10-μL reaction volume using the Platinum SYBR Green q PCR Super Mix-UDG (Invitrogen Life Technologies, Carlsbad, CA, United States) and the Light Cycler 480 system (Roche Diagnostics, Penzberg, Germany). The following hRFT2 and β-actin (as a reference) primers were used for RT-PCR: hRFT2 forward primer: AATCTAGAGCACTTGGACCTTTCC; hRFT2 reverse primer GGGTTCAGGGACAGGTCTAAAGA; β-actin forward primer: GGCACCCAGCACAATGAAG; β-actin reverse primer: CCGATCCACACGGAGTACTTG. The thermal cycle conditions were 95 ℃ for 10 s for one cycle, followed by 40 cycles of amplification at 95 ℃ for 5 s, and 60 ℃ for 45 s. The expression level of RFT2 mRNA was obtained using the $2^{-\Delta\Delta CT}$ calculation method. All PCR products were analyzed on a 2% agarose gel with ethidium bromide staining.

Immunohistochemical studies

Immunohistochemistry (IHC) was performed using Histostain-SP kits (Zhongshan Golden Bridge, Beijing, China) according to the manufacturer's recommendations and as described previously[16]. Sections of paraffin embedded tissue with a thickness of 3 μm were deparaffined in xylene, and then rehydrated in graded concentrations of ethyl alcohol (100%, 95%, 80% and 70%), and samples were pretreated using a microwave for 15 min on high mode in Tris/EDTA buffer (pH 9.0). After cooling and rinsing in distilled water, endogenous peroxidase activity was blocked with 3% hydrogen peroxide for 15 min at room temperature. Subsequently, the slides were pretreated with 1% bovine serum albumin in phosphate-buffered saline (PBS; pH 7.4) for 10 min. Samples were then preincubated with a protein blocking solution for 15 min and incubated with an RFT2 antibody (Santa Cruz Biotechnology, Santa Cruz, CA, United States; dilution: 1:300) diluted in PBS at 4 ℃ overnight in a humid chamber. Slides were washed three times in PBS, and then incubated with a secondary biotinylated antibody for 15 min at room temperature. Thereafter, sections were washed with PBS, and treated with peroxidase-conjugated streptavidin for 15 min. Finally, the sections were lightly stained with hematoxylin, and PBS was used instead of the primary antibody as a negative control. All immunostained sections were coded and independently examined by two investigators using light microscopy. Results were scored for each antibody separately and semi-quantitatively by assessing the staining intensity and the percentage of stained cells in the tumors. Staining intensity was scored as 0 (no staining), 1+ (weak), 2+ (medium), or 3+ (strong). The percentage of stained cells was categorized as follows: (1) 0% to 10% stained cells; (2) 11% to 50% stained cells; and (3) 50% stained cells or greater. The final score was obtained by multiplying the two scores. Cases with a score of 0 to 4 were classified as negative, and those with a final score of 5 to 9 were classified as positive.

Statistical analysis

SPSS 15.0 (SPSS, Inc., Chicago, IL, United States) was used for statistical analysis. The Pearson χ^2 test or Fisher exact test was used to compare qualitative variables. The Wilcoxon two-sample test was used to compare the mean RFT2 expression in fresh frozen GC tissues with that in normal samples, as determined by real-time quantitative RT-PCR. Results were presented as mean ± SE. *P*-values less than 0.05 were considered to be statistically significant.

RESULTS

RFT2 protein expression in GC and its association with GC clinicopathologic characteristics

IHC staining of 60 primary GC lesions and samples adjacent to the tumor was performed using RFT2 antibodies (Table 1). Representative staining patterns for RFT2 are shown in Figure 1. IHC staining demonstrated that RFT2 was localized to the cytoplasm. Positive staining for RFT2 was generally observed within normal gastric epithelium adjacent to the tumor, but weak or no RFT2 staining was detected in GC cells. RFT2 expression was undetectable (75%) in gastric cancer tissue. By contrast, no strong IHC staining (3+) was detected in gastric cancer tissue. The positive rates (strong staining, medium staining and weak staining) of RFT2 expression in the normal gastric surface epithelium were 46.7%, 26.7% and 16.7%, respectively. These values sharply decreased to 0%, 8.3% and 16.7%, respectively, in GC lesions (*P* < 0.001, compared with the positive rate in healthy tissue). We also evaluated the possible relationship between the expression of RFT2 in tumor cells and the clinicopathologic characteristics of GC, including tumor stage, histological grade, lymph node metastasis, and other parameters such as gender, tumor location, and ethnic groups. RFT2 expression was significantly decreased in GC with poor differentiation and high tumor stage. Defective expression of RFT2 in tumor cells was significantly associated with poor differentiation and high tumor stage. However, other parameters such as gender, tumor location, and lymph node metastasis had no significant relationship with RFT2 expression (Table 1). Additionally, lower expression was observed in Uyghur patients compared with Han patients, but the difference was not statistically significant.

RFT2 mRNA expression in gastric carcinoma and normal controls

To confirm the IHC results, RFT2 mRNA expression in gastric biopsies was detected by RT-PCR (Figure 2). Similar to the IHC results, the RFT2 mRNA expression levels were significantly lower in GC than in normal counterpart tissue (0.398 ± 0.149 ng/mL *vs* 1.479 ± 0.587 ng/mL; $P = 0.040$) (Figure 2).

Relationship between riboflavin level and RFT2 expression in gastric carcinoma

Riboflavin concentrations were determined in samples obtained from gastric cancer patients who were not taking vitamin supplements. The average blood concentration of riboflavin was 1.7632 ± 0.9836 ng/mL in GC patients. The average blood riboflavin level was 1.2000 ± 0.97 569 ng/mL in high tumor stage patients, which was significantly lower than in patients with low tumor stage (2.5980 ± 1.31 129 ng/mL; $P = 0.019$). Riboflavin chromatograms of plasma samples from a low tumor stage patient and a high tumor stage patient are shown in Figure 3. A tendency of decreasing blood riboflavin level

was found to be associated with GC development. However, no significant difference was observed among other parameters such as gender, tumor location and ethnic groups and patients with GC. We also analyzed the relationship between the blood riboflavin level and expression of the *RFT2* gene and development of GC. A positive association was found between changes in the blood riboflavin levels and changes in RFT2 protein expression as well as development of malignant GC (Table 2).

DISCUSSION

In the present study, we investigated the association between plasma levels of riboflavin and the RFT2 mRNA and protein expression status in patients with gastric adenocarcinoma. The results showed a tendency for an inverse association between riboflavin levels and GC risk, and an inverse association between RFT2 expression status and GC risk. Additionally, a positive association was found between riboflavin levels and RFT2 with GC risk. The results indicate that RFT2 likely plays an important role in gastric carcinogenesis that involves modulating riboflavin absorption.

Previous studies have reported that dietary habits and intake of nutrients play an important role in the prevention and causation of GC. High consumption of dark-green vegetables, fruits, and milk and dairy products (riboflavin is a water soluble vitamin present in various foods) has also been suggested to decrease the risk of GC. Several epidemiological studies have reported[17,18] that riboflavin deficiency is linked to an increased risk of GC because riboflavin is involved in essential oxidation-reduction reactions and its deficiency leads to skin and

Figure 1 **Immunohistochemical staining of gastric lesions using riboflavin transporter 2 gene-specific monoclonal antibodies.** A: Expression of riboflavin transporter 2 (RFT2) in normal gastric epithelium with strong staining; B: Moderate expression of RFT2 protein in gastric cancer (GC) tissue; C: Weak expression of RFT2 protein in GC tissue (original magnification, × 400).

Figure 2 **mRNA expression of riboflavin transporter 2 in gastric cancer tissue and control tissue.** Panels 1 to 4 and 9 are from normal gastric epithelium. Panels 5 to 8 and 10 are from gastric cancer tissues. Panels 1 to 8 show expression of riboflavin transporter 2 mRNA. Panels 9 and 10 show expression of β-actin.

of GC, and such characteristics of the riboflavin transporter gene were also consistent with those of the carrier-mediated riboflavin transport system in the Caco-2 cell line as an intestinal epithelial model. Thus, it is likely that hRFT2 is the molecular entity of the riboflavin transport system in the Caco-2 cell line[20].

Riboflavin (vitamin B_2) has been confirmed to serve as a co-factor in fat, amino acid, carbohydrate and vitamin metabolism as well as to reduce oxidative stress, affect cell proliferation, and affect angiogenesis[21,22]. Few epidemiological studies have investigated plasma concentrations of riboflavin in relation to GC risk[23]. The present study observed riboflavin concentrations in samples obtained from GC patients by HPLC, and the results showed a tendency of decreasing blood riboflavin level with development of GC. Use of HPLC as a convenient method for separation and measurement of vitamins in plasma has been reported in many medical institutions[14,24].

Riboflavin is essential for synthesis of FAD and FMN, which function as cofactors for several biological processes involved in energy metabolism. The most important dietary sources of riboflavin are milk and dairy products. In Xinjiang, a multi-ethnic residential area in China, the Chinese Han and Uyghur populations are the main ethnic groups and they have different dietary habits. The Uyghur population tends to consume milk, dairy products, and meat as well as fruits and vegetables. They should not lack intake of riboflavin. Therefore, riboflavin deficiency in blood is expected to be related to a disturbance in riboflavin absorption. If inadequate intake of riboflavin exists, disturbances in the steps in intermediary metabolism may occur.

In conclusion, we have identified down-regulated expression of RFT2 mRNA and protein as being closely related to the progression of GC lesions and also found a positive relationship between blood riboflavin levels and RFT2 protein expression as well as between blood riboflavin levels and development of GC. The *RFT2* gene may be the key target of environmental and genetic factors in the development of GC.

COMMENTS

Background

Epidemiological and etiological research has confirmed that environmental

mucosal disorders. Therefore, measurement of plasma riboflavin can be used to assess vitamin B_2 status in individuals at high risk for GC. Although riboflavin supplements can significantly reduce the risk of GC, different individual intervention effects were observed after dietary supplementation with riboflavin[19]. Therefore, RFT2 may be the key target of environmental and genetic factors because the *RFT2* gene also has been reported as a susceptibility gene for GC using a genome-wide association study approach[10].

RFT2 is a transmembrane protein, which may function biologically as a transporter of riboflavin in the small intestine, and the role of riboflavin in cellular homeostasis has been well documented. Therefore, we speculate that mutation of the riboflavin transporter gene might cause riboflavin deficiency, resulting in an increased risk

Figure 3 Chromatographic profiles of a low tumor stage patient and a high tumor stage patient.

and genetic factors play an important role in gastric carcinogenesis. The riboflavin transporter 2 (*RFT2*) gene as a susceptibility gene for gastric carcinoma (GC) is likely to have an important role in gastric carcinogenesis that involves transporting riboflavin and modulating riboflavin absorption. However, riboflavin deficiency has been reported as a risk factor for GC.

Research frontiers

Riboflavin deficiency of is a risk factor for GC, and riboflavin supplements can significantly reduce the risk of GC. However, different individual intervention effects have been observed after dietary supplementation with riboflavin. In the present study, defective expression of RFT2 was associated with development of GC and may be a potential mechanism underlying the decreased plasma riboflavin levels in GC.

Innovations and breakthroughs

Recent reports have highlighted that genetic susceptibility combined with exposure to environmental risk factors contributes to high rates of cancer. In particular in GC, RFT2 is down-regulated. This is the first study to report that RFT2 is down-regulated in GC. Furthermore, their studies suggest that this protein may be the cause of decreased plasma riboflavin levels in GC.

Applications

By understanding how RFT2 affects the absorption of riboflavin and by enhancing its expression, this study may offer a future strategy for the treatment of patients with GC.

Terminology

RFT2 is a transmembrane protein that functions biologically as a transporter of riboflavin and in maintenance of cellular homeostasis. Riboflavin is a water-soluble vitamin that participates in various redox reactions, some of which are essential for the function of aerobic cells.

Peer review

The authors performed a study on riboflavin levels as well as on *RFT2* gene mRNA levels in esophageal squamous cell carcinoma samples and normal counterpart tissue. The level of RFT2 was found to be inversely related to tumor stage. Down-regulation and loss of RFT2 protein expression were important in the pathogenesis of gastric cancer. This study was well designed and the molecular experiments were well done and interpreted. The data seem convincing.

Abstract

AIM: To assess the rigorous relationship between human leukocyte antigens (HLA)-DR alleles and outcomes of hepatitis B virus (HBV) infections by means of meta-analysis.

METHODS: Medline/PubMed, EMBASE, CNKI and VIP were searched to identify relevant studies. Study quality was evaluated using the Newcastle-Ottawa Scale. Odds ratios (OR) and 95% confidence interval (95% CI) were pooled using Stata 11.0. Subgroup analyses were performed by ethnicity. Heterogeneity and publication bias analyses were performed to validate the credibility.

RESULTS: A total of 2609 patients with chronic hepatitis B and 2606 controls spontaneously recovering from prior HBV infection were included. Meta-analysis showed that HLA-DR*04 (OR = 0.72, 95% CI: 0.60-0.85) and DR*13 (OR = 0.27, 95% CI: 0.19-0.37) alleles were significantly associated with HBV clearance while patients carrying HLA-DR*03 (OR = 1.47, 95% CI: 1.16-1.87) or DR*07 (OR = 1.59, 95% CI: 1.24-2.03) alleles had a significantly increased risk of chronic HBV persistence. For the HLA-DR*01 polymorphism, a significantly association with HBV clearance was found in Chinese Han group (OR = 0.48, 95% CI: 0.26-0.86), but not found in other ethnic groups (*P* = 0.191). For other polymorphisms, no association with the HBV infection outcome was found.

CONCLUSION: HLA-DR*04 and DR*13 alleles may be the protective factors for HBV clearance and HLA-DR*03, and DR*07 alleles may be the risk factors for HBV persistence.

Relationship between *HLA-DR* gene polymorphisms and outcomes of hepatitis B viral infections: A meta-analysis. *World J Gastroenterol* 2012; 18(24): 3119-3128 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i24/3119.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i24.3119

INTRODUCTION

Hepatitis B virus (HBV) infection is a serious public health problem affecting more than 400 million people worldwide. The clinical features of HBV infection vary from clearance of the virus to fulminate hepatitis. Although some HBV carriers spontaneously eliminate the virus, 2%-10% of the individuals with chronic hepatitis B

(CHB) are estimated to develop liver cirrhosis, and a subset of these individuals eventually suffer from liver failure or hepatocellular carcinoma[1]. A complex combination of environmental, pathogenic and host genetic factors plays a role in determining both susceptibility to HBV and the course of the infection[2]. Several epidemiological factors, such as age at infection, sex, chronic alcohol abuse and co-infection with other hepatitis viruses, were suspected to affect viral persistence. In addition, host immunological factors and genetic background were also considered to influence the susceptibility to and outcome of persistent HBV infection[3]. Family studies in China provide some evidences that the host genetic factors affect viral persistence, as concordance rates of HBeAg persistence were higher in identical twins than in non-identical twins[4].

Although genetic variants in *IFNG*[5], *TNF*[6], *VDR*[7], *MBP*[8], *ESR1*[9], *CXCL10*[10], *IL-10*[11] and several human leukocyte antigen (HLA) loci[12,13] have been shown to associate with CHB, none of the associations has been proven to be conclusive. The mechanism of susceptibility to chronic persistent HBV infection is not well clarified. Since the outcome of HBV infection mainly depends on the host immune response, and HLA, an integral component of the immune response, plays an important role in immunological reaction to HBV infection[14], the highly polymorphic *HLA* gene has been considered as an appropriated biological candidate susceptibility gene that is associated with the development and the progression of chronic HBV infection. Indeed, previous studies have highlighted that *HLA-DR* polymorphisms influence individual immune responses, thus affecting the outcome of diseases, and that many different *HLA* alleles play a role in HBV infection[15]; however, this relationship between *HLA-DR* polymorphisms and HBV infection is not universal for all investigated populations. As for Caucasians[16,17] and Koreans[18], *HLA-DRB1*1301-02* has been found to be associated with acute self-limited hepatitis B. For Taiwanese people, *HLA-DRB1*0406* is associated with recovery from HBV infection in the Han Chinese, as is *HLA-DRB1*4001* in indigenous Taiwanese people[19]. Han Chinese with HLA-DR12 (especially one of its alleles, *DRB1*1201*) or *HLA-DRB1*1101/1104* are able to resist HBV infection, while those with *HLA-DR9*, *DQ9*, *HLA-DRB1*0301*, *HLA-DQB1*0301*[20,21], and *DRB1*10* are susceptible to chronic HBV infection[22].

In spite of the pivotal role that the polymorphic HLA antigens play in immune surveillance and immune response and the multitude of studies performed, there is still a lack of conclusive evidence of the association between polymorphisms and the outcomes of HBV infection; the relationship between them is not universal for all the investigated populations. In this meta-analysis, the identification of common *HLA-DR* alleles causing CHB susceptibility was examined through a systematic review of the literature followed by a meta-analysis of all case-control studies. Meta-analysis is a powerful method for quantitatively summarizing the results from different studies. One of the advantages is to enhance the statistical power of outcomes in ethnically- and ancestrally-rich populations and to enlarge the sample sizes, which may reduce the possibility of producing false-positive or false-negative association by random error[23].

MATERIALS AND METHODS

Literature search strategy

A systematic search was conducted by two investigators independently (Yan ZH and Fan Y). All articles were retrieved from four main databases: Medline/PubMed, EMBASE, CNKI (China National Knowledge Infrastructure) and VIP database (Chinese Journal of Science and Technology of VIP). The latest search was updated on April 20, 2011, using the search terms: "hepatitis B" or "HBV", "polymorphism", "human leukocyte antigen" or "*HLA*" or "Major Histocompatibility Complex" or "MHC". The search was not confined to articles written in a certain language, but focused on studies conducted on human subjects. All searched studies were retrieved and the relevant publications in the bibliographies were checked simultaneously. Abstracts and unpublished reports were not considered; only published studies with full-text articles were included. When the same patient population was included in several publications, only the most recent or complete study was used in this meta-analysis. When a study reported results of different subpopulations, we treated each subpopulation as a separate comparison in the meta-analysis. This work has been carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association. This study was approved ethically by University Hospital Birmingham Trust (LREC 2002/166). All patients provided informed written consent.

Inclusion and exclusion criteria

The inclusion and exclusion criteria were drawn up on the basis of discussion. The articles to be included in this meta-analysis should meet these inclusion criteria: (1) the full text was available for the published study; (2) the study was designed as an unrelated case-control study; (3) the study provided the number of persistent chronic HBV infection cases and controls; (4) the study provided the number of individual *HLA-DR* genotypes in cases and controls; (5) the study provided enough information for odd ratio (OR) and 95% confidence interval (95% CI) calculation; and (6) the diagnosis for CHB was based on the following criteria: seropositive for HBsAg for at least 6 mo; serum HBV DNA $> 1 \times 10^5$ copies/mL for HBeAg-positive and $> 1 \times 10^4$ copies/mL for HBeAg-negative patients; and persistent or intermittent elevation in alanine aminotransferase (ALT) level, or liver biopsy showing chronic hepatitis with moderate or severe necroinflammation. The criteria for spontaneous recovery from infection were: positive for both anti-HBs and anti-HBc antibodies, negative for HBsAg, normal liver function tests and no history of dominant hepatitis B and HBV vaccination.

The exclusion criteria were: (1) the study was not a case-control study; (2) the control group was only with

healthy patients and without those who recovered from prior HBV infection; (3) the study did not fit the diagnosis criteria; (4) the individuals included in the case-control study had serologic evidence for co-infection with hepatitis C virus, hepatitis D virus, or human immunodeficiency virus (HIV); and (5) the studies were duplicated (only the most recent or complete study was used in this meta-analysis when the same patient population was included in several publications[24]). In addition, interim analyses and comparisons of laboratory methods were all excluded.

Data extraction and validity assessment
In order to retrieve articles as completely and correctly as possible, two investigators extracted data independently using a standardized form and they reached a consensus on all items. Disagreement was resolved by discussion among the whole study groups. For each study, the following data were extracted: name of the first author, year of publication, ethnicity, ethnic origin of the studied population, number of patients with persistent HBV infection (including asymptomatic carriers and patients with chronic liver diseases), number of spontaneously recovered controls, number of individual genotypes, source of controls, genotype frequency of cases and controls, genotyping methods, statistical methods and the results of the study.

The quality of the primary studies was evaluated using the Newcastle-Ottawa Scale (NOS)[25]. This scale judges the study on three broad perspectives: the selection of the study groups; the comparability of the groups; and the ascertainment of either the exposure or outcome of interest for case-control.

Statistical analysis
We compared persistent HBV infection cases with spontaneously recovered controls to assess the relationship between *HLA-DR* polymorphisms and HBV infection clearance. Subgroup analyses were mainly performed by ethnicity. Ethnic groups were mainly defined as Chinese Han and other ethnic group. Statistical analysis was conducted using the Stata 11.0 (StataCorp, College Station, TX, United States). The association between *HLA-DR* polymorphisms and the CHB risk was measured by OR with 95% CI. The pooled OR was determined by the Z test and statistical significance was set at $P < 0.05$. All P values were two-sided. To ensure the reliability and the accuracy of the results, two investigators uploaded the data into the statistic software programs independently and obtained the same results. In our study, two models of meta-analysis for dichotomous outcomes were constructed: the random-effects model and the fixed-effects model. The random-effects model was constructed using the DerSimonian and Laird's method[26], which assumed that studies were conducted in populations with varying effect sizes and calculated the study weights from both in-study and between-study variances. The fixed-effects model was constructed using the Mantel-Haenszel's method[27], which assumed that studies were conducted in populations with

the same effect sizes and made an adjustment to the study weights according to the in-study variances.

To assess the between-study heterogeneity more precisely, both the χ^2-based Cochran's Q-statistic[28] (to test the heterogeneity) and the Higgins (I^2) test[29] (to quantify the proportion of the total variation due to heterogeneity) were calculated. Because of the low power of Cochran's Q statistic, heterogeneity was considered significant at $P_h < 0.10$, and the random-effects model was used to pool the results. When the P value of Cochran's Q statistic was greater than 0.10, the fixed-effects model was used to pool the results. Besides, the Galbraith plot was used to spot the outliers as the possible major sources of heterogeneity[30]. To better investigate the possible sources of between-study heterogeneity, meta-regression analysis was also applied to both general analyses and subgroup analyses, when heterogeneity was observed. To confirm the effect of clinical heterogeneity between studies on the conclusions of the meta-analysis, subgroup analysis was conducted based on races. To validate the credibility of outcomes in this meta-analysis, a sensitivity analysis was performed by sequential omission of individual studies or by omitting studies plotted by the Galbraith plot method as the possible major source of heterogeneity. The potential publication bias was estimated by funnel plot, in which the standard error of logOR of each study was plotted against its logOR. An asymmetric plot suggests a possible publication bias. Visual inspection of asymmetry in funnel plots was conducted to assess the potential for publication bias. In addition, Begg's rank correlation method and the Egger weighted regression method were also used to statistically assess the publication bias (publication bias with a $P \leqslant 0.05$ was considered statistically significant)[31].

RESULTS
Characteristics of studies
A flow diagram of the study selection process is shown in Figure 1. We identified a total of 313 potentially relevant articles to our search criteria. After carefully reviewing the titles, abstracts and full text of the literature, we identified 72 articles with analysis on the association between *HLA-DR* polymorphisms and persistent HBV infection. However, according to the exclusion criteria, 54 publications were excluded including 21 articles involving the same study subjects as other included articles, nine papers not about case-control study, 22 publications without spontaneously recovered patients in the control group, and two papers in which the individuals included in the case-control study had serologic evidence for co-infection with HIV. Finally, 18 articles evaluating *HLA-DR* polymorphisms met the inclusion criteria and were chosen for this systematic review and meta-analysis. All the selected studies presented original data on independent samples.

The characteristics of each study are presented in Table 1. These 18 articles were published from 1995

Figure 1 Results of literature search. This figure describes the whole process of searching for articles for inclusion in this systematic review and meta-analysis. HLA: Human leukocyte antigens; HBV: Hepatitis B virus; HIV: Human immunodeficiency virus.

to 2011 with 15 in English[16,18-21,32-41] and three in Chinese[42-44]. Of them, nine studies were on Han Chinese populations[19-21,34-36,42-44] and 10 studies on other race (Gambia[32], Caucasian[16], Korean[18,37,39], Iran[33,40], Thai[38] and Turkish[41]). Besides, one publication contained two individual case-control studies from two different ethnic populations (Chinese Han and Taiwanese aborigines[19]). All studies used the individuals who spontaneous recovered from prior HBV infection as control subjects. The sample size in the individual case-control studies ranged from 60 to 638. A total of 2609 patients with CHB and 606 spontaneously recovered controls prior to HBV infection, were included from 19 studies (cases and controls were counted only once for each study). Genotyping methods used in the studies included PCR-restriction fragment length polymorphism, PCR-sequence specific primer, PCR-sequence specific oligonucleotide probe and sequence-specific oligonucleotide probe hybridization.

The NOS results showed that the median overall score was 7 (range, 5-8), which indicated that the methodological quality was generally good. We defined studies that scored a 7 or above as having high methodological quality, and judged that 2 out of the 19 studies to be of low quality (one study[44] scored 5 and another study[43] scored 6) primarily due to either no description of case selection, no definition of control, a lack of adjusted analysis, or no description of the method of ascertainments for case-controls.

Meta-analysis of relationship between HLA-DR gene polymorphisms and clearance of persistent HBV infection

Table 2 lists the main results of meta-analysis of the relationship between *HLA-DR* polymorphisms and the clearance of persistent HBV infection. We found no evidence of associations between the clearance of persistent HBV infection and *HLA-DR*08, DR*09, DR*10, DR*11, DR*12, DR*14, DR*15, DR*16* alleles ($P_{OR} > 0.05$). For these negatively associated alleles, the results of subgroup analyses by ethnicity also showed no associations in either Chinese Han group or other ethnic group ($P_{OR} > 0.05$).

For the *HLA-DR*01* polymorphism, the fixed-effects model was used to pool the meta-analysis result, as the between-study heterogeneity was not significant ($I^2 = 0\%$, $P_H = 0.826$) when all eligible studies were pooled into meta-analysis. The results of pooling all 13 eligible studies showed that *HLA-DR*01* allele was associated with an increased clearance rate of HBV infection ($P_{OR} = 0.016$, $OR_{fixed\text{-}effects} = 0.69$, 95% CI: 0.52-0.93). In the subgroup analyses by ethnicity, the association between the *DR*01* allele and HBV clearance was found in Chinese Han group ($P_{OR} = 0.014$, $OR_{fixed\text{-}effects} = 0.48$, 95% CI: 0.26-0.886), but not found in other ethnic groups ($P_{OR} = 0.191$) (Figure 2A).

For the *HLA-DR*03* polymorphism, the between-study heterogeneity was also not significant when all 12 eligible studies were pooled into meta-analysis ($I^2 = 16.0\%$, $P_H = 0.287$). The results of the fixed-effects model meta-analysis which pools all studies showed that the *HLA-DR*03* allele was associated with a significantly increased risk of chronic HBV persistence ($P_{OR} = 0.002$, $OR_{fixed\text{-}effects} = 1.47$, 95% CI: 1.16-1.87). The subgroup analyses by ethnicity showed that the *DR*03* allele was associated with a significantly increased risk of chronic HBV persistence in both Chinese Han group ($P_{OR} = 0.020$, $OR_{fixed\text{-}effects} = 1.57$, 95% CI: 1.07-2.30) and other ethnic groups ($P_{OR} = 0.029$, $OR_{fixed\text{-}effectss} = 1.41$, 95% CI: 1.03-1.91) (Figure 2B).

For the *HLA-DR*04* polymorphism, the between-study heterogeneity was also not significant when all 16 studies were pooled into meta-analysis ($I^2 = 0\%$, $P_H = 0.757$). The results of pooling all studies using the fixed-effects model meta-analysis showed that the *HLA-DR*04* allele was associated with the clearance of HBV infection ($P_{OR} = 0.000$, $OR_{fixed\text{-}effects} = 0.72$, 95% CI: 0.60-0.85). The subgroup analyses by ethnicity showed that the *DR*04* allele was associated with an increased clearance rate of HBV infection in both Chinese Han group ($P_{OR} = 0.002$, $OR_{fixed\text{-}effects} = 0.63$, 95% CI: 0.48-0.84) and other ethnic groups ($P_{OR} = 0.016$, $OR_{fixed\text{-}effectss} = 0.77$, 95% CI: 0.62-0.95) (Figure 2C).

For the *HLA-DR*07* polymorphism, the fixed-effects model was used to pool the meta-analysis result, since the between-study heterogeneity was not significant ($I^2 = 14.0\%$, $P_H = 0.304$) when all 13 studies were pooled into

meta-analysis. The results showed that *HLA-DR*07* allele was associated with a significantly increased risk of chronic HBV persistence ($P_{OR} = 0.000$, $OR_{fixed-effects} = 1.59$, 95% CI: 1.24-2.03). In the subgroup analyses by ethnicity, the results showed that the *DR*07* allele was associated with a significantly increased risk of chronic HBV persistence among Chinese Han group ($P_{OR} = 0.017$, $OR_{fixed-effects} = 1.50$, 95% CI: 1.07-2.10) and other ethnic groups ($P_{OR} = 0.005$, $OR_{fixed-effects} = 1.69$, 95% CI: 1.17-2.44) (Figure 2D).

For the *HLA-DR*13* polymorphism, the fixed-effects model was used to pool the meta-analysis result, since the between-study heterogeneity was not significant ($I^2 = 0.00\%$, $P_H = 0.699$). The results showed that *HLA-DR*13* allele was associated with an increased clearance rate of HBV infection ($P_{OR} = 0.000$, $OR_{fixed-effects} = 0.27$, 95% CI: 0.19-0.37). In the subgroup analyses by ethnicity, the results showed that the *DR*13* allele was associated with HBV clearance among Chinese Han group ($P_{OR} = 0.003$, $OR_{fixed-effects} = 0.36$, 95% CI: 0.18-0.70) and other ethnic groups ($P_{OR} = 0.000$, $OR_{fixed-effects} = 0.24$, 95% CI: 0.17-0.35) (Figure 2E).

Heterogeneity analysis and sensitivity analysis

The heterogeneity was calculated among all studies using the Q-statistic and the I^2 test. As shown in Table 2, for the *HLA-DR*11* polymorphism, the between-study heterogeneity was significant ($I^2 = 41.3\%$, $P_H = 0.053$) when all 14 studies were pooled into meta-analysis. In the subgroup analyses by ethnicity for this allele, the between-study heterogeneity was also significant in Chinese Han subgroups ($I^2 = 59.1\%$, $P_H = 0.023$), while heterogeneity

was not found in other ethnic groups ($I^2 = 20.0\%$, $P_H = 0.277$). Except for the meta-analysis for DR*13* allele, heterogeneity in the all meta-analysis for other *HLA-DR* alleles was not found ($P_H > 0.10$).

Univariate analysis of meta-regression suggested that the publishing year and language were not important sources of between-study heterogeneity in both generate analyses and subgroup analyses. We carried out a sensitivity analysis for each *HLA-DR* allele interaction analysis by sequential omission of individual studies. A single study involved in the meta-analysis was deleted each time to investigate the influence of the individual dataset on the pooled ORs. The corresponding pooled ORs were not materially altered, indicating that our results were statistically robust.

Publication bias

Begg's funnel plot and Egger's test were performed to assess the publication bias of the literature in this meta-analysis. All the P values of Begg's test (P_{beggs}) and Egger's tests (P_{Eggers}) are shown in Table 2. The P_{Eggers} with more than 0.05 was considered as statistical evidence of the funnel plots' asymmetry. The Egger's test results suggested that publication bias in our meta-analyses of *HLA-DR* alleles was not remarkable except for the three subgroup meta-analyses. As shown in Table 2, the publication bias was borderline significant in the analysis of HLA-DR*10 allele ($P_{Eggers} = 0.040$) and Chinese Han subgroups analysis of HLA-DR*16 ($P_{Eggers} = 0.042$). The publication bias was evident in other ethnic group analysis of *HLA-DR*13* allele ($P_{Eggers} = 0.017$). Then, the Duval and Tweedie non-parametric "trim and fill" method was used to adjust

A HLA-DR*01 allele

Study	OR (95% CI)	Weight (%)
Non-Chinese Han		
Thursz *et al*[32] (1995)	1.05 (0.56, 1.99)	17.38
Hohler *et al*[16] (1997)	0.61 (0.21, 1.75)	7.90

Figure 2 Forest plots of pooled odd ratio with 95% confidence interval for associations between human leukocyte antigens-*DR* polymorphisms and clearance of chronic hepatitis B virus infection. The fixed-effects model was constructed using the Mantel-Haenszel's method. Subgroup meta-analysis was conducted based on ethnicity (Chinese Han group and other ethnic groups). The squares and horizontal lines correspond to the study-specific odd ratio (OR) and 95% confidence interval (95% CI); the box size is proportional to the meta-analysis study weight, the diamonds represent the pooled OR and 95% CI. HLA: Human leukocyte antigens.

publication bias[45]. Meta-analysis with and without using the "trim and fill" method did not draw different conclusions, indicating that our results were statistically robust.

DISCUSSION

It is believed that the host genetic factors involved in genetic polymorphisms are responsible for the susceptibility to and clinical outcomes of infectious diseases. In recent years, genetic susceptibility to chronic HBV infection has been a research focus, and it has been identified that the polymorphisms of a number of immune-response-associated genes, including *HLA* loci, affected the susceptibility to and clearance of persistent chronic HBV infection among different populations. HLA plays an essential role in the pathogenesis of virus-associated hepatitis. The HLA class Ⅱ molecules are expressed as cell surface glycol-proteins that bind short peptide epitope to CD4+ T cells. HLA-DR, a subtype of HLA class Ⅱ molecule, has a particular binding motif that dictates

a specific range of peptides that can physically bind in a groove on the surface of the HLA molecule[14].

Wide variations have been documented in the frequencies of *HLA-DR* gene polymorphisms which have been most widely investigated in healthy populations and been demonstrated to influence TNF-α expression. The association between *HLA-DR* polymorphisms and outcome of HBV infection has been investigated by several research groups. However, the previous studies have yielded conflicting results, and included no more than a few hundred CHB cases, which are too few to assess the genetic effects reliably. Meta-analysis has been recognized as an important tool to precisely assess the effect of the selected genetic polymorphisms on the risk of diseases and to identify potentially important sources of between-study heterogeneity. In our present meta-analysis, a total of 2609 patients with CHB and 2606 controls spontane-

ously recovering prior to HBV infection were included from 19 case-control studies which were evaluated using the NOS. It could provide the most comprehensive assessment to draw reliable conclusions.

Heterogeneity is a potential problem when interpreting the results of all meta-analyses, and finding the sources of heterogeneity is one of the most important goals of meta-analysis[46]. In this present meta-analysis, we assessed the between-study heterogeneity by different methods, including the χ^2 based *Q* statistic test (Cochran's *Q* statistic)[28] (to test for heterogeneity) and the I^2 statistic (to quantify the between-study heterogeneity)[29]. For the meta-analyses comparing persistent HBV infection cases with spontaneously recovering controls, there was significant between-study heterogeneity in pooled meta-analyses of total eligible studies on *HLA-DR*11* allele, which suggested obvious consistency of effects across those

included studies. Subgroup analyses by ethnicity showed that the heterogeneity was still significant in subgroup analyses in Chinese Han populations for *HLA-DR*11* polymorphism. Univariate analysis of meta-regression suggested that the publishing year and language were not important causes of between-study heterogeneity in both general analyses and subgroup analyses. We presumed that the quality of the primary studies would be the main cause of heterogeneity. Interesting, we found no significant between-study heterogeneity in pooled meta-analyses of total eligible studies and subgroup analyses by ethnicity for other alleles.

Some limitations still exist in this meta-analysis. First, meta-analysis essentially remains with observational study that was subject to the methodological deficiencies of the included studies. Since only published studies written in English and Chinese were included in the meta-analysis, publication bias may occur, even though it was not found by statistical tests. Second, the associations were investigated in all kinds of cases (asymptomatic carriers, patients with CHB, patients with liver cirrhosis), and there may be specific genetic effects among these cases, but we could not obtain enough information to further estimate these effects. It is necessary to conduct large trials using standardized unbiased methods on homogeneous CHB patients and well matched controls, with the assessors blinded to the data. Third, our results were based on unadjusted estimates. A more precise analysis should be conducted with individual data, which would allow the adjustment by other co-varieties including age, ethnicity, family history, environmental factors and lifestyle. Finally, gene-gene and gene-environment interactions were not addressed in this meta-analysis due to the lack of sufficient data. For instance, the major genotypes of HBV in Chinese are B and C, but most of the studies did not analyze them separately, which could not be solved because of the methodological limitations of the meta-analysis.

Despite these limitations, this meta-analysis suggests that *HLA-DR*04* and *DR*13* alleles may be the protective factors for HBV clearance, and *HLA-DR*03* and *DR*07* alleles may be the risk factors for HBV persistence. For the *HLA-DR*01* polymorphism, a significantly association with HBV clearance was found in Chinese Han group, but not found in other ethnic groups. In summary, ethnicity may play an important role in HBV infection outcome, leading to conflicting results. More studies on individuals from various ethnic groups and large and carefully designed case-control studies will be necessary to determine the role of *HLA-DR* polymorphisms in the outcome of HBV infection.

COMMENTS

Background
Chronic hepatitis B virus (HBV) infection is a serious public health problem worldwide. Host genetic factors play a role in determining both susceptibility to HBV and the outcome of the infection. A large number of studies on the association between human leukocyte antigens (*HLA*)-*DR* gene polymorphisms and the risk of chronic hepatitis B (CHB) have been conducted, but their conclusions are different or even contradictory.

Research frontiers
The polymorphic HLA antigens play an important role in immune surveillance and immune response. However, the relationships HLA-DR polymorphisms and the outcomes of HBV infection are not universal for all the investigated populations and no meta-analysis has been conducted.

Innovations and breakthroughs
This meta-analysis systemically assessed the associations of *HLA-DR* gene polymorphisms with the outcomes of HBV infections, and concluded that *HLA-DR*03*, *DR*04*, *DR*07* and *DR*13* alleles have significant associations with HBV clearance in both Chinese Han population and other ethnic groups.

Applications
The results of meta-analysis in this study show that *HLA-DR*04* and *DR*13* alleles may be the protective factors for HBV clearance, while *HLA-DR*03* and *DR*07* alleles may be the risk factors for HBV persistence, which may benefit early prevention and treatment of CHB.

Peer review
This meta-analysis of *HLA-DR* gene polymorphisms and HBV infection outcomes is well written, addressed an important in the field. However, there are still some problems.

Abstract

AIM: To assess BGC823 gastric cancer (GC) cell metastasis after knockdown of liver-intestine cadherin (CDH17) and the therapeutic value of CDH17-RNAi-lentivirus *in vivo*.

METHODS: We evaluated primary tumor growth and assessed local infiltration and systemic tumor dissemination using an orthotopic implantation technique. The therapeutic value of CDH17 knockdown was examined by intratumoral administration of CDH17-RNA interference (RNAi)-lentivirus in an established GC tumor xenograft mouse model. Furthermore, a comparative proteomic approach was utilized to identify differentially expressed proteins in BGC823 and lenti-CDH17-miR-neg cells following CDH17 knockdown.

RESULTS: Metastases in the liver and lung appeared earlier and more frequently in animals with tumors derived from BGC823 or lenti-CDH17-miR-neg cells than in tumors derived from lenti-CDH17-miR-B cells. Average tumor weight and volume in the CDH17-RNAi-lentivirus-treated group were significantly lower than those in the control group (tumor volume: 0.89 ± 0.04 cm^3 *vs* 1.16 ± 0.06 cm^3, $P < 0.05$; tumor weight: 1.15 ± 0.58 g *vs* 2.09 ± 0.08 g, $P < 0.05$). Fifteen differentially expressed proteins were identified after CDH17 silencing in BGC823 cells, including a variety of cytoskeletal and chaperone proteins as well as proteins involved in metabolism, immunity/defense, cell proliferation and differentiation, cell cycle, and signal transduction.

CONCLUSION: Our data establish a foundation for future studies of the comprehensive protein expression patterns and effects of CDH17 in GC.

INTRODUCTION

Gastric cancer (GC) is one of the most prevalent and lethal malignancies worldwide owing to difficulties in early detection and high postsurgical recurrence rates[1]. Currently, there are no effective drugs for curing GC. Gastro-carcinogenesis is a complex process in which the altered proliferation and migration properties of cancer cells play important roles in tumor growth and metastasis[2]. Identi-

fication of specific markers for predicting recurrence will permit detection of early dissemination and perhaps even eradication.

Cadherins are transmembrane glycoproteins that mediate calcium-dependent cell adhesion and that are strongly implicated in tumorigenesis[3-5]. Liver-intestine cadherin (CDH17) has been identified as a novel member of the cadherin superfamily, which is distinguished from classic cadherins by unique structural and functional features[6,7]. Previous studies have demonstrated the clinicopathological significance and prognostic influence of CDH17 expression in GC. For example, CDH17 has been proposed as a marker of gastric metaplasia and neoplasia[8-11]. In our earlier study, we found that downregulation of CDH17 inhibits proliferation and adherence of the poorly differentiated GC cells, BGC823, *in vitro* and induces cell cycle arrest[12]. Using an *in vivo* tumor growth assay with human tumor xenografts grown subcutaneously in nude mice, we also confirmed that CDH17 silencing slows the growth of GC derived from BGC823 cells. Although human tumor xenografts, which grow subcutaneously in nude mice, closely resemble the original tumors morphologically, biologically, and biochemically, these tumors do not metastasize[13]. Orthotopic tumor models are regarded as more suitable for mimicking human tumor disease because they encompass the entire process of primary tumor growth, local tumor infiltration, and subsequent distant metastasis[14,15]. Thus, in our current study, we evaluated primary tumor growth and assessed local infiltration and tumor dissemination using an orthotopic implantation technique.

The therapeutic value of lentivirus and adeno-associated virus has been identified using RNA interference (RNAi) technology[16-19]. Gene therapy for GC is a rationalized strategy because various genes are associated with this disease[20]. Previous research has proposed CDH17 as an *in vivo* target for liver cancer therapy[21]. In our current research, we further examined the therapeutic value of CDH17-RNAi-lentivirus in established GC xenografts in nude mice.

Proteomic technologies have been used to identify proteins involved in various pathways altered in disease[22,23]. Global analysis of protein expression complements and in some cases has certain advantages over genomic analyses. Given the cumulative data indicating possible roles for CDH17 in cancer development and/or outcomes[24-26], the important function of CDH17 in GC has elicited the need to further investigate the underlying mechanism. Thus, we also used 2-dimensional polyacrylamide gel electrophoresis (2-DE) followed by tandem mass spectrometry (MS) to perform proteome-wide profiling of GC cells in which CDH17 expression had been knocked down to identify proteins whose cellular levels are affected by with CDH17 expression.

MATERIALS AND METHODS

Chemicals

Dithiothreitol, urea, agarose, glycerol, bromophenol blue,

3-[(3-cholamidopropyl) dimethylammonio] propanesulfonic acid (CHAPS), Immobiline DryStrips (4-7 L), Dry-Strip cover fluid, and PhastGel Blue R (Coomassie Brilliant Blue R-350 stain) were purchased from Amersham Pharmacia Biotech AB (Uppsala, Sweden). Acrylamide, Bis, tri(hydroxymethyl)aminomethane (Tris), glycine, sodium dodecyl sulfate (SDS), ammonium persulfate, and tetramethylethylenediamine were from Bio-Rad (Hercules, CA, United States). Iodoacetamide, ammonium bicarbonate, and acetic acid were from Sigma (St. Louis, MO, United States). Acetonitrile and methanol were from Fisher (Fair Lawn, NJ, United States). Trifluoroacetic acid was from Merck (Darmstadt, Germany). Other chemicals are domestic products (analytical grade). All buffers were prepared with Milli-Q water.

Cell culture and lentivirus

The poorly differentiated human GC cell line BGC823 was obtained from the Type Culture Collection of the Chinese Academy of Sciences (Shanghai, China) and cultured in RPMI 1640 medium supplemented with 10% (v/v) fetal bovine serum (Gibco, Carlsbad, CA, United States) at 37 ℃ in a humidified incubator containing 5% CO_2.

The stably transfected cell line in which CDH17 had been knocked down by RNAi (lenti-CDH17-miR-B), the empty vector-transfected control cells (lenti-CDH17-miR-neg), and the CDH17-RNAi-lentivirus and green fluorescent protein (GFP)-lentivirus were obtained as described[12]. Stably transfected cells were cultured at 37 ℃ in Dulbecco's modified Eagle medium supplemented with 10% fetal bovine serum and 3 mg/mL blasticidin (Invitrogen, Carlsbad, CA, United States) in a 5% CO_2 environment.

Laboratory animals and orthotopic implantation technique

All nude mice in this study were treated following the experimental animal ethics rules of Wuhan University (Wuhan, China). BALB/c-nu mice (5-6 wk old) weighing 18-20 g were obtained from the Central Laboratory of Animal Science at Wuhan University. The animals were housed in laminar-flow cabinets and kept at a constant humidity (50%-70%) and temperature (25-28 ℃) according to standard guidelines under an approved protocol of Wuhan University. Donor nude mice were anesthetized with isoflurane (Abbott, Wiesbaden, Germany) inhalation. Then, 1×10^6 BGC823, lenti-CDH17-miR-neg, or lenti-CDH17-miR-B cells were injected subcutaneously at a single site each animal's flank. The mice were killed at the same time after several weeks when the largest diameter of the subcutaneous tumors had reached a size of 1 cm. The donor tumors were harvested and minced with a scalpel (No. 11) into small (1 mm^3) pieces. To avoid necrotic tissue from the central tumor areas, only macroscopically viable tumor tissue from the outer part of the donor tumors was used for orthotopic implantation.

Thirty-six tumor recipient nude mice were anes-

thetized with an intraperitoneal injection of xylazine hydrochloride (Rompun, 12 mg/kg BW; Bayer, Leverkusen, Germany). Each animal's abdomen was aseptically opened with a midline incision, and the stomach was gently exteriorized. One small tissue pocket was prepared in the submucosa of the distal stomach. One donor tumor fragment was placed into the gastric tissue pocket and fixed with one drop of tissue adhesive (Histoacryl, B Braun, Tuttlingen, Germany). The stomach was relocated into the abdominal cavity, which was then closed with two layers of 4-0 absorbable sutures (Ethicon, Norderstedt, Germany).

Observation period, assessment of primary tumor size, and dissemination

At 4 and 6 wk after transplantation, animals with non transfected BGC823 cells, empty vector-transfected cells (lenti-CDH17-miR-neg), and CDH17 microRNA-transfected cells (lenti-CDH17-miR-B) ($n = 6$ per cell line) were sacrificed, and an autopsy was done to examine tumor growth. The perpendicular diameters of the primary orthotopic tumors were measured with calipers, and the volume was calculated using the following formula: volume = (shortest diameter)^2 × (longest diameter)/2. Local infiltration was determined in the liver, lung, spleen, and diaphragmatic muscle. Parts of the tumor tissue and the organ were fixed in 4% paraformaldehyde in PBS and embedded in paraffin. Serial sections were cut at 3 μm thickness, stained with hematoxylin and eosin, and reviewed to confirm the findings of the macroscopic dissemination as described previously[11].

Treatment of GC with CDH17-RNAi-lentivirus in established GC xenografts in nude mice

To investigate whether CDH17-RNAi-lentivirus could serve as a therapeutic agent against GC, subcutaneous tumors were induced in nude mice using BGC823 cells as above. Once tumors reached approximately 0.5-0.6 cm^3, animals in the treated group were intratumorally injected with 1×10^9 copies of CDH17-RNAi-lentivirus, and those in the control group were treated with 1×10^9 copies of GFP-lentivirus, twice weekly for 2 wk. Tumor formation and growth were monitored daily. Tumors were harvested from mice 1 wk after the end of treatment and evaluated with hematoxylin and eosin. CDH17 expression was examined by immunohistochemistry[11].

2-DE and MS

In agreement with our previous research[12], we found no differences between BGC823 and lenti-CDH17-miR-neg cells with respect to proliferation, adherence, or invasive ability in our current study. Therefore, we compared the protein expression between BGC823 and lenti-CDH17-miR-B cells in our current study. Briefly, cells were suspended in 1 mL lysis buffer containing 7 mol/L urea, 2 mol/L thiourea, 4% CHAPS, 65 mmol/L dithiothreitol, 2% IPG buffer (pH 4-7), and 1 mmol/L phenylmethylsulfonyl fluoride. After extraction, the protein concentration was quantified using Bradford's method. Five samples per

cell strain were prepared from individual cell cultures. All samples were stored at -80 ℃ prior to electrophoresis.

For each sample, 1 mg protein was mixed with a rehydration solution containing 8 mol/L urea, 2% CHAPS, 0.5% IPG buffer, pH 4-7 (nonlinear), 18 mmol/L dithiothreitol, and a trace of bromophenol blue, to a total volume of 250 μL, and applied to IPG dry strips. After rehydration for 12 h, isoelectric focusing was performed using ReadyStripTM IPG strips (17 cm, PH 3-10 NL, Bio-Rad) on a PROTEAN IEF system (Bio-Rad) until a total of 80 kVh was reached. Following isoelectric focusing separation, the gel strips were equilibrated two times for 15 min each in equilibration buffer (50 mmol/L Tris-HCl, pH 8.0, 6 mol/L urea, 30% glycerol, 2% SDS, and a trace of bromophenol blue) and directly applied to a 13% sodium dodecyl sulfate-polyacrylamide gel electrophoresi (SDS-PAGE) vertical slab gel for electrophoresis using a PROTEAN Ⅱ xi Cell system (Bio-Rad) until the bromophenol blue dye marker reached the bottom of the gel. Dithiothreitol (1%) was added to the first equilibration buffer and was replaced with 2.5% Iodoacetamide in the second equilibration buffer. The gels were visualized with Coomassie Blue G250 (Bio-Rad) staining after electrophoresis. Spot detection, quantification, and matching were performed using PDQuest Advanced 8.0.1 software (Bio-Rad). Five analytical gels for each cell strain, resulting from triplicate runs of individual samples, were completed. Quantitative analysis was performed using the Student's *t*-test between BGC823 and lenti-CDH17-miR-B gels. The confidence level was 95%.

In-gel digestion and MS analysis

The separated proteins in SDS-PAGE gels were excised, in-gel digested, and extracted according to the manufacturer's instructions (Promega, Madison, WI, United States). Briefly, protein spots of interest were destained with 100 μL 50% v/v acetonitrile in 25 mmol/L ammonium bicarbonate for 1 h. In-gel digestion was performed with 10 ng/μL trypsin (Promega) in 40 mmol/L ammonium bicarbonate for 15 h at 37 ℃. The resulting peptides were extracted with 5% trifluoroacetic acid in 50% acetonitrile for 1 h at 37 ℃ and dried completely with centrifugal lyophilization.

Peptide mixtures were redissolved in 0.5% trifluoroacetic acid, and 1.5 μL of the peptide elute was mixed with an identical volume of α-cyano-4-hydroxycinnamic acid matrix on the stainless matrix-assisted laser desorption ionization (MALDI) target until dry (i.e., air dried). All mass spectra were obtained on an Autoflex MALDI-time of flight (TOF) mass spectrometer (Bruker, Bremen, Germany) to generate peptide mass fingerprints. The analyses of peptides were performed in the reflectron mode with a 337-nm nitrogen laser with an acceleration voltage of 20 kV and a reflected voltage of 23 kV. Spectra were accumulated until a satisfactory signal/noise ratio had been obtained from a range of 800 MHz to 4000 MHz. After MS acquisition, 10 ions of maximum intensity were selected automatically for MS/MS analysis. Trypsin autolysis products and keratin-derived precur-

A

B

Figure 1 Tumorigenicity is inhibited by knockdown of liver-intestine cadherin using Lenti-microRNA in BGC823 cells. A: Knockdown of liver-intestine cadherin (CDH17) in lenti-CDH17-miR-B cells was confirmed by western blotting; B: The primary orthotopic tumor volume in the lenti-CDH17-miR-B group was much lower than that of the BGC823 and lenti-CDH17-miR-neg groups during the observation periods ([a]$P < 0.05$). Data represent the mean ± SD (n = 6). *P*-values for the indicated comparisons were determined with one-way analysis of variance.

sor ions were automatically excluded. The collision voltage was varied depending on the mass of the precursor. MS/MS data were processed with the search algorithm MASCOT (Version 2.2; Matrix Science, London, United Kingdom) against the SWISS-PROT protein database (UniProt_SP sprot_84; 230,133 sequences). Confident identification had a statistically significant ($P \leqslant 0.05$) protein score (based on combined MS spectra) and best ion score (based on MS/MS spectra).

Statistical analysis

All quantitative data were recorded as the mean ± SD. Comparisons between two groups were performed with the Student's *t*-test. Comparisons among multiple groups were performed with one-way analysis of variance. $P < 0.05$ was considered statistically significant. Computations were performed using the SPSS version 13.0 software package (Chicago, IL, United States).

RESULTS

CDH17 knockdown decreases the invasive and metastatic ability of BGC823 cells in nude mice with orthotopic implanted GC tumors

Downregulation of CDH17 in stably transfected lenti-CDH17-miR-B cells was confirmed by Western blotting (Figure 1A). We found that subcutaneous tumors reached a size of 1 cm after approximately 4 wk in BGC823- and

lenti-CDH17-miR-neg-treated groups, whereas 5 wk was required after subcutaneous injection with lenti-CDH17-miR-B cells, indicating that proliferation of GC cells was inhibited after CDH17 knockdown. These results were consistent with our previous report[12].

To demonstrate the progress of tumor growth, the animals were randomized into two groups and killed at 4 or 6 wk after tumor implantation. We found that the primary orthotopic tumor volume in the lenti-CDH17-miR-B group was much smaller than that of the BGC823 and lenti-CDH17-miR-neg groups (Figures 1B, 2A and B) ($P <$ 0.05). In addition, nude mice in the lenti-CDH17-miR-neg and BGC823 groups developed liver and lung metastases after 4 wk (lung 1/6, liver 1/6, in the lenti-CDH17-miR-neg group; lung 1/6, liver 1/6, in the BGC823 group), whereas neither type of metastasis was found in the lenti-CDH17-miR-B group at that time. Moreover, 6 wk after transplantation, we found that mice transplanted with lenti-CDH17-miR-B cells developed fewer metastases (lung 1/6, liver 1/6) than animals in the BGC823 group (lung 2/6, liver 3/6) and animals in the lenti-CDH17-miR-neg group (lung 2/6, liver 3/6) (Figure 2C-F). In addition, nude mice injected with BGC823 or lenti-CDH17-miR-neg cells also developed diaphragmatic muscle (1/6) (Figure 2G) and spleen (1/6) (Figure 2H) infiltration, neither of which was found in the lenti-CDH17-miR-B group. These results indicated that the cell line lenti-CDH17-miR-B displayed a less aggressive phenotype regarding tumor dissemination than the other two cell lines and suggested that CDH17 knockdown in GC cells downregulated the invasive and metastatic ability *in vivo*.

Intratumoral administration of CDH17-RNAi-lentivirus causes significant tumor regression in the established GC tumor xenograft mouse model

All 12 mice that were injected subcutaneously with 1×10^6 BGC823 cells developed detectable tumors at the termination of the experiment. The mice treated with CDH17-RNAi-lentivirus showed significantly suppressed tumor growth compared with those treated with GFP-lentivirus (Figure 3A-F). The average tumor volume (0.89 ± 0.04 cm^3) in the former group was significantly lower ($P < 0.05$) than that (1.16 ± 0.06 cm^3) in the latter group. The average tumor weight (1.15 ± 0.58 g) was also much lower ($P < 0.05$) than that in the control group (2.09 ± 0.08 g). Furthermore, we found that intratumoral injection of CDH17-RNAi-lentivirus reduced CDH17 levels (Figure 3G-H). These results indicated that CDH17 knockdown may be an effective means of slowing GC tumor growth *in vivo*.

Quantitative proteome alterations between lenti-miR-CDH17-B and BGC823 cells

Proteins extracted from lenti-CDH17-miR-B or BGC823 cells were subjected to 2-DE and stained with Coomassie, which revealed a match rate of 80.5% and showed an average of 1032 ± 31 and 1279 ± 2 spots, respectively (Figure 4A and B). A total of 26 differentially expressed

Figure 2 Tumors in which liver-intestine cadherin was knocked down show fewer invasive characteristics *in vivo*. Hematoxylin-eosin staining revealed that primary orthotopic tumors (A, B) derived from BGC823 or lenti-liver-intestine cadherin (CDH17)-miR-neg cells spread into the liver (C, D) and lung (E, F) more frequently than those derived from lenti-CDH17-miR-B cells. Nude mice injected with these two types of tumors also showed invasion of the diaphragmatic muscle (G) and spleen (H).

protein spots were defined as statistically significant based on two criteria: (1) intensity alterations > 3-fold; and (2) recurrence four or more times in the five pairs examined (Figure 4C). To eliminate the redundancy of proteins appearing in the database under different names or accession numbers, the protein member belonging to *Homo sapiens* with the highest MASCOT score was selected[27]. Fifteen different proteins from 2-DE gels were successfully identified using MALDI-TOF tandem MS (Table 1). Several protein spots could not be identified, possibly owing to

a lower amount of protein as revealed by a retrospective analysis of the spot intensities. Differences between the experimental MW/pI and the theoretical value were observed for some of the proteins, which may have been a consequence of post-translational modifications such as truncation and/or phosphorylation[28].

As listed in Table 1, we found that the altered proteins after CDH17 knockdown were mainly located in the cytoplasm (30.3%), nucleus (12.12%), or peripheral membrane (9.09%) (Figure 4D). In brief, these differentially expressed proteins between lenti-CDH17-miR-B and BGC823 cells play important and fundamental roles in

Figure 4 **Protein profile differences between lenti-liver-intestine cadherin-miR-B and BGC823 cells.** A, B: Comparison of protein profiles by 2-dimensional gel electrophoresis between BGC823 and lenti-liver-intestine cadherin (CDH17)-miR-B cells; C: Close-up image of differential expression of protein spots with intensity alterations > 3-fold and recurrence four or more times in independent experiments. The average intensity of each spot was determined using PDQuest 2-DE software; D: Cellular location of the 15 altered proteins identified by mass spectrometry; E: Molecular functions of the 15 altered proteins identified by mass spectrometry.

DISCUSSION

Using an orthotopic implantation technique, we examined the growth and metastatic potential of BGC823 cells in which CDH17 had been knocked down. Our results showed that BGC823 or lenti-CDH17-miR-neg cells produced more extensive local tumor growth during the observation period. Moreover, local infiltration into the liver and lung appeared much earlier and more frequently in animals with tumors derived from BGC823 or lenti-CDH17-miR-neg cells than in those derived from lenti-CDH17-miR-B cells, suggesting the less aggressive behavior of GC after CDH17 knockdown. However, the effects of CDH17 in gastric carcinogenesis should be examined in other human GC cell lines.

To investigate whether CDH17-RNAi-lentivirus could serve as a therapeutic agent against GC, BALB/c-nu mice with induced tumors of BGC823 cells were treated with CDH17-RNAi-lentivirus. The results showed that both the average tumor weight and volume were significantly lower in the CDH17-RNAi-lentivirus-treated group compared with the control group treated with GFP-lentivirus. Thus, intratumoral administration of CDH17-RNAi-lentivirus, which reduced CDH17 levels, significantly slowed tumor growth. However, our results also demonstrated that CDH17 knockdown did not eliminate the tumor completely, suggesting that CDH17 is not the only protease involved in invasion and growth of GC.

Although the *CDH17* gene was identified as a biomarker or a potential diagnostic and therapeutic target for GC using gene expression profiling[29,30], the molecular mechanisms of CDH17 remain largely undefined due to limited knowledge of CDH17 target recognition. Although 2-DE and MS-based proteomic strategies have certain limitations, these strategies provide high-throughput simultaneous identification of hundreds of proteins and are considered powerful approaches for analyzing alterations in protein expression in complex biological systems[31-34]. Using the 2-DE/MS approach, we identified 15 proteins in BGC823 cells whose expression levels are affected by CDH17.

Among these proteins, six were upregulated, and nine were downregulated after CDH17 knockdown. We found that these 15 proteins play important roles in metabolism, immunity/defense, cell structure and motility, intracellular protein trafficking, protein modification, cell cycle, signal transduction, cell proliferation and differentiation, electron transport, and muscle contraction, suggesting extensive roles for CDH17 in biological processes. These altered proteins may be potentially involved in the effect(s) of CDH17 in BGC823 cells and represent candidate proteins that may be regulated by CDH17. These diverse proteins may thus serve as focused targets for future studies to determine their potential genetic and/or physical interactions with CDH17 and their func-

tional relevance in GC. Although previous studies have demonstrated possible interactions between CDH17 and galectin-3, metal-responsive transcription factor-1, and placental growth factor in ductal adenocarcinoma of the pancreas and GC[11,24,26], these proteins were not identified in our current study. Thus, further validation experiments should be carried out to confirm our results. In-depth and detailed investigation of the interactions between CDH17 and other proteins may enhance our understanding of the mechanisms by which CDH17 affects carcinogenesis in humans. The mechanisms by which downregulation of CDH17 inhibits proliferation and invasion of BGC823 cells need to be explored in further studies.

COMMENTS

Background

Gastrocarcinogenesis is a complex process in which alterations in proliferation and migration properties of cancer cells have an important role in cancer infiltrative growth and metastasis. If specific markers related to cancer invasion were to be identified, dissemination could be detected early and perhaps even eradicated.

Research frontiers

Cadherins are transmembrane glycoproteins that mediate calcium-dependent cell adhesion and have strong implications in tumorigenesis. Liver-intestine cadherin (CDH17), also known as LI-cadherin, has been identified as a novel member of the cadherin superfamily, which is distinguished from classic cadherins by its unique structural and functional features. Therefore, the invasive and metastasis ability of gastric cancer (GC) cells after CDH17 silencing were investigated.

Innovations and breakthroughs

Their results presented further evidence that CDH17 was closely correlated to GC invasion. The invasive and metastasis ability of GC cells was found to be significantly reduced *in vivo* after the downregulation of CDH17. Furthermore, protein profiles in GC cells were also significantly altered after CDH17 knockdown, which suggested the interactions of CDH17 with many other important proteins.

Applications

CDH17 could be recognized as an important marker of cancer invasion. Knockdown of CDH17 may become a way to downregulate the invasive ability of GC cells.

Peer review

The authors investigated the metastatic ability of the GC cells BGC823 with CDH17 silencing and the therapeutic value of CDH17-RNA interference-lentivirus. They demonstrated that knockdown of CDH17 in BGC823 cells downregulated invasive and metastatic ability *in vivo*. The work is well written. The methods are adequate and the results obtained justify the conclusions drawn.

Abstract

AIM: To evaluate whether total splenic artery embolization (TSAE) for patients with hypersplenism delivers better long-term outcomes than partial splenic embolization (PSE).

METHODS: Sixty-one patients with hypersplenism eligible for TSAE (n = 27, group A) or PSE (n = 34, group B) were enrolled into the trial, which included clinical and computed tomography follow-up. Data on technical success, length of hospital stay, white blood cell (WBC) and platelet (PLT) counts, splenic volume and complications were collected at 2 wk, 6 mo, and 1, 2, 3, 4 years postoperatively.

RESULTS: Both TSAE and PSE were technically successful in all patients. Complications were significantly fewer (P = 0.001), and hospital stay significantly shorter (P = 0.007), in group A than in group B. Post-procedure WBC and PLT counts in group A were significantly higher than those in group B from 6 mo to 4 years (P = 0.001), and post-procedure residual splenic volume in group A was significantly less than that observed in group B at 1, 2, 3 and 4 years post-procedure (P = 0.001). No significant differences were observed in red blood cell counts and liver function parameters between the two groups following the procedure.

CONCLUSION: Our results indicate that TSAE for patients with hypersplenism not only delivers a better long-term outcome, but is also associated with lower complication rates and a shorter hospital stay than PSE.

INTRODUCTION

To date, partial splenic embolization (PSE), which was first performed by Spigos *et al*[1] in 1979, has been considered first-line therapy for hypersplenism in many institutions, and has been proposed as an effective alternative to splenectomy for improving peripheral blood cell counts[2-4]. However, PSE is associated with many com-

plications, including intermittent fever, abdominal pain, nausea, vomiting, postembolization syndrome, splenic abscess, splenic rupture, pneumonia, refractory ascites, pleural effusion and gastrointestinal bleeding[3-6]. To ensure a sustained and long-term increase in platelet (PLT) and leucocyte counts, the splenic infarction rate needs to be greater than 50%[6]. Thus, severe complications can ensue[1-6].

Today, total splenic artery embolization (TSAE) is widely used and has been shown to be a safe and effective method for the treatment of splenic artery aneurysms[7-9]. In addition, stainless steel spring coils are used to embolize the main branch of the splenic artery in order to improve PLT counts pre-splenectomy[10]. We have initiated a new approach, that of TSAE for the treatment of patients with hypersplenism secondary to cirrhosis of the liver, and our preliminary results demonstrate the safety and feasibility of the approach[11]. In order to determine whether this approach can ensure a sustained and long-term increase in PLT and leucocyte counts, as well as a reduction in the rate of severe complications, we undertook this nonrandomized prospective trial of endovascular treatment of hypersplenism with TSAE or PSE, with the aim of comparing clinical outcomes of both methods.

MATERIALS AND METHODS

Patients

The protocol was approved by the institutional ethics committee, and all patients provided written informed consent. Between January 2006 and June 2011, consecutive patients with hypersplenism caused by cirrhosis referred for treatment with TSAE (group A) or PSE (group B) were screened for enrollment into this non-randomized, prospective, two-institution trial. They subsequently underwent computed tomography (CT) follow-up at both hospitals. The diagnosis of hypersplenism was established by review of each patient's medical history, clinical laboratory data, ultrasonography, and CT examinations.

Eligibility criteria included: (1) documented hypersplenism caused by cirrhosis established by a review of the patient's history, CT results or ultrasound; and (2) hepatitis B virus/hepatitis C virus-related active cirrhosis, with neutropenia (neutrophil count $\leqslant 2.0 \times 10^9$/L), thrombocytopenia (PLT count $\leqslant 50 \times 10^9$/L), or both. Patients who had severe jaundice (total serum bilirubin level $\geqslant 81.4$ μmol/L) or spontaneous bacterial peritonitis were excluded.

Total embolization of the main splenic artery

All embolization procedures were performed by two experienced interventional radiologists. Prior to embolization, selective angiography of the celiac trunk, the splenic artery and the superior mesenteric artery was performed in all patients *via* the right femoral artery using a 5-Fr diagnostic catheter. To avoid total splenic infarction, we confirmed patency of the collateral arteries, which were confirmed as connected to the hilar splenic artery from

Figure 1 Hypersplenism in a 76 year old man with hepatitis B virus-related cirrhosis. A: Celiac digital subtraction arteriogram. The splenic artery is markedly dilated and tortuous. The spleen is enlarged. The right gastroepiploic artery arises from the celiac axis; B: Celiac arteriogram after coil embolization of the distal splenic artery and its primary branches. The hilar splenic arterial branches are faintly filled by collateral circulation.

the left gastric artery or from the gastroepiploic artery on a celiac arteriogram (Figure 1).

Once these connections were confirmed, TSAE was performed, using details of the coiling procedure as has been previously described[11]. Coils and gelfoam were used as embolization material, either alone or in combination. In general, the embolization coils used in this series were standard 0.089 cm fibered coils, microcoils (Tornado; Cook Inc., Bloomington, IN, United States). Post-embolization check angiograms were performed using selective splenic artery, celiac and superior mesenteric artery angiograms to confirm occlusion of the main splenic artery and patency of the collateral arteries (Figure 1). Preoperative antibiotic prophylaxis was used routinely for 3 d. Following embolization, patients were monitored clinically, and antibiotics were administered after the procedure for several days in order to avoid infection.

PSE

The embolic agents most commonly used for splenic arterial embolization are gelatin sponge pledgets (Gelfoam cube, Upjohn, Kalamazoo, United States) and polyvinyl alcohol particles (PVP, lvalon, Ingenor, Paris; and Contour, Interventional Therapeutics Corp., South San Francisco, CA, United States). Details of PSE with gelatin sponge pledgets[12] or with PVP[13] have been described previously, and therefore we do not repeat the methodology here.

Figure 2 Computed tomographic angiography, arterial phases, before and after splenic artery embolization in the same patient as Figure 1. A: Before embolization the spleen is enlarged; B: One month after embolization the major portion of the spleen is avascular with minute areas of low attenuation representing residual gas collection. A small part of the spleen was perfused with contrast medium; C: Six months after embolization the low attenuation area has decreased in size; D: One year later the low attenuation area has further decreased in size; E: Two years later the necrotic area has further decreased in size; F: Four years later no significant change is seen.

Follow-up protocol and postoperative outcome evaluation

All patients were followed up at our outpatient clinic. Peripheral blood cell parameters, including white blood cell (WBC), PLT and red blood cell (RBC) counts, were monitored at different time-points prior to the procedure, and at day 3, 14 and 30, and subsequently at 6-monthly intervals for a total of 5 years. To determine any possible effects on liver function, serum levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT), total bilirubin (TB), albumin (Alb), as well as the prothrombin time (PT), were measured before and after the procedures at the same time-points. The frequency and type of complications associated with the procedures were recorded.

Abdominal CT scans were routinely performed before and two weeks after the procedure, and subsequently every 6 mo during follow-up (Figure 2). Based on enhanced CT images, we measured and compared the pretreatment splenic volume and the post-embolization residual splenic volume on a 3.1 workstation (GE Medical Systems, Milwaukee, WI, United States) using volumetric analysis software. The infarcted splenic volume (mL) was calculated by subtracting the noninfarcted splenic volume from the pretreatment volume. The splenic infarction rate was calculated by dividing the infarcted splenic volume by the pretreatment volume ($\times 100\%$).

Complications related to the procedures were categorized as either major or minor. A major complication was defined as a complicated disease requiring surgical or interventional treatment or a prolonged postoperative hospital stay of more than 30 d, and included splenic abscess, splenic rupture, pneumonia, refractory ascites, pleural effusions, gastrointestinal bleeding, variceal rupture and liver failure. A minor complication was defined as a complication that had minimal consequences and could be tolerated by patients or treated using conservative methods, including post-embolization syndrome, abdominal fullness, and loss of appetite.

Statistical analysis

We predicted that rates for a WBC count $> 4 \times 10^9/\mathrm{L}$ at the 2-year follow-up assessment would be approximately 95% in group A and 60% in group B. We estimated that at least 25 patients with hypersplenism would need to be enrolled into each group for the study to have a statistical power of 80% with a two-sided alpha level of 0.05. This power was based on the ability to detect an absolute difference of 30% in patients with WBC counts $> 4 \times 10^9/\mathrm{L}$ at the 2-year follow-up assessment.

All data are expressed as mean ± SD. Comparisons of variables between the two groups were performed by applying the Mann-Whitney test, χ^2-test or the Fisher's exact test as appropriate. All statistical analyses were performed using the SPSS package, version 13.0 (SPSS, Chicago, Illinois, United States).

RESULTS

A total of 109 patients with hypersplenism were enrolled. Before each procedure, patients or family members had the right to choose either TSAE or PSE. Initially, 51 and

58 patients were assigned to group A and group B, respectively. Of these, 48 patients did not meet the inclusion criteria, with a total follow-up of < 2 years in 43 patients, and five patients were lost to follow-up (two in group A and three in group B). The remaining 61 patients were enrolled. Subjects included 36 males and 25 females, with a mean age of 47.92 ± 8.00 years (range: 28-60 years). Demographic features and clinical presentation of included patients are summarized in Table 1.

Primary procedural results

The technical and initial clinical outcomes of the two groups are shown in Table 2. Both TSAE and PSE were technically successful in all patients, with no procedure-related complications. The thirty-day mortality rate was zero.

Post-embolization syndrome, which included abdominal pain, fever and vomiting, occurred in 21 patients (77.8%) in group A and 34 in group B (100%) (*P* = 0.014). Abdominal pain was severe enough to require morphine administration in 15 patients, including two in group

A (7.4%) and 13 in group B (38.2%) (*P* < 0.01). Severe complications, which occurred in seven patients (20.6%) in group B and no patient (0%) in group A, are listed in Table 2. Three patients had pleural effusions, which resolved with thoracocentesis. Two patients with ascites were treated with abdominal paracentesis. Two patients suffered from a persistent high fever and were found to have a splenic abscess on abdominal CT scan. The abscess was drained with a catheter and had resorbed within 2 mo. The length of hospital stay was significantly less in group A, 5-13 d (mean, 8.52 ± 1.91 d), than in group B, 9-37 d (mean, 15.88 ± 6.36 d) (*P* < 0.001).

Changes in peripheral blood cell counts

At the time of writing, all patients in group A had been followed up and assessed at the 2-wk, 6-mo, 1- and 2-year time-points; 35 had been assessed for 3 years and 23 had been assessed for ≥ 4 years, prospectively, with a mean follow-up of 40.36 ± 11.94 mo (range: 24-64 mo). There were no significant differences in the number of patients in each follow-up period between the two groups.

Changes in WBC and PLT counts before the procedures and between 2 wk and 4 years after the procedures are shown in Figure 3A and B. After the procedures, in both groups, WBC and PLT counts increased significantly, peaked at 2 wk, and then gradually fell during the 4-year follow-up period (Figure 3A and B). There were no significant changes in RBC counts either after PSE or during the long-term follow-up period.

Before PSE, there were no significant differences between the two groups with respect to sex, age, splenic volume, Child-Pugh class, and peripheral blood cell counts (Table 1). In both group A and group B, WBC and PLT counts increased significantly and remained higher than the pre-procedure counts from the second week to the fourth year after the procedures (*P* < 0.05, Figure 3A and B). Although there were no significant differences in WBC and PLT counts between the two groups 2 wk after the procedures, both WBC and PLT counts in group A were significantly higher than those observed in group B at 6 mo, 1, 2, 3 and 4 years after the procedures (*P* < 0.05, Figure 3A and B). A WBC count > 4 × 10^9/L at the 2-year follow-up assessment was observed in all 27 (100%) patients in group A and in 21 (62%) patients in group B (*P* < 0.001).

Changes in liver function parameters

In comparison with pre-procedure levels of liver function parameters values, including AST, ALT, TB, Alb and PT, in each of the two groups, there were no significant short- and long-term changes after the procedures.

Changes in splenic volume after embolization

Splenic volume changes before the procedures and between one month and 4 years after the procedures are shown in Figure 3C. All patients in group A were followed up and assessed at 2 wk, 6 mo, 1 and 2 years; 35 were assessed for 3 years and 23 were assessed for ≥ 4 years, prospectively, with a mean follow-up of 40.36 ±

Figure 3 Curves of the white blood cell counts, platelet counts, and splenic volume in cirrhotic patients of group A (total splenic artery embolization) and group B (partial splenic embolization) before embolization and at the different follow-up time intervals. A: Curves of long-term follow-up of white blood cell counts between the two groups; B: Curves of long-term follow-up of platelet counts between the two groups; C: Curves of long-term follow-up of splenic volume between the two groups. All values are expressed as mean ± SD. [a]$P < 0.05$ *vs* pre-embolization within each group; [c]$P < 0.05$ group A *vs* group B at each time point determined with the Mann-Whitney test. WBC: White blood cell; PLT: Platelet.

11.94 mo (range: 24-64 mo). After the procedures, splenic volume decreased significantly, peaked one month after the procedures, and then gradually increased during the 4-year follow-up period (Figure 3C). In groups A and B, splenic volume gradually increased and remained lower than the pre-procedure volume from 1 mo to four years after the procedures ($P < 0.05$, Figure 3C). There were no significant differences in splenic volume between the two groups before embolization, and at 1 and 6 mo post-procedure, but the residual splenic volume in group A was significantly smaller than that observed in group B 1, 2, 3 and 4 years after the procedures ($P < 0.05$, Figure 3C).

DISCUSSION

This nonrandomized trial was designed to compare the clinical outcomes of two endovascular regimens in patients with hypersplenism. The results demonstrate a sustained and long-term increase in WBC and PLT counts in group A, with no major complications, compared with group B. The significant increase in WBC and PLT counts in group A during follow-up appears to be predominantly attributable to the complete occlusion of the main splenic artery.

Hypersplenism is a well-known complication of portal hypertension in cirrhosis, which can result in thrombocytopenia and/or leukocytopenia. There are several possible approaches to management, for example splenectomy[14-16], PSE[1-6], ligation and banding of the splenic artery[17] and percutaneous placement of a narrowed stent into the splenic artery[18]. Surgical splenectomy can eliminate hypersplenism-induced blood cell destruction, but the morbidity of severe complications after splenectomy, including laparoscopic and open splenectomy, still ranges from 9.6% to 26.6%[14,15]. In addition, splenectomy is often associated with an increased long-term risk of septic events[14,15]. Ligation and banding of the splenic artery are also used to treat hypersplenism, but complications such as portal vein thrombosis, sepsis and multi-organ failure may occur with these methods[17]. Although percutaneous placement of a narrowed stent into the splenic artery is a promising new technique for treating hypersplenism[18], it is difficult to ensure a sustained and long-term increase in WBC and PLT counts as the splenic artery is not completely occluded, which cannot provide a sustained splenic infarction rate (> 50%).

Today, PSE is the most commonly used alternative to splenectomy for patients with hypersplenism, with the aim of improving the peripheral blood cell count[2-4], but it is often associated with minor and major complications, such as post-embolization syndrome, splenic abscess, splenic rupture, pneumonia, refractory ascites, pleural effusions and gastrointestinal bleeding[5,6], as reported in our study and in many other series[2-6]. Post-embolization syndrome is the most frequent minor complication, which is usually well-tolerated by patients and controlled with conservative therapy[3]. Major complications, on the other hand, such as splenic abscess, splenic rupture and pleural effusions, require surgical or other interventional treatment. Many reports have demonstrated a close association between the incidence of complications and the splenic infarction rate, and it appears that complications occur more frequently in patients with a splenic embolization > 50%[6,12,19,20]. In this study, the embolized splenic volume rate was the same for both groups, but we observed that both minor and major complications were sig-

nificantly less in group A than in group B post-procedure ($P < 0.05$). Moreover, no major complications occurred. Therefore, we do not believe that there is a close relationship between the rate of complications and splenic infarction rates in patients with hypersplenism treated with TSAE. This may be explained by the collateral arteries, which connect to the hilar splenic artery from the left gastric artery or from the gastroepiploic artery, and provide a small amount of blood to the spleen, thereby avoiding complete splenic infarction.

In this study, both WBC and PLT counts in group A were significantly higher than those observed in group B at 6 mo, 1, 2, 3 and 4 years post-procedures. Although WBC and PLT counts in both groups decreased with time, the counts in group A revealed a sustained and long-term increase above normal levels and decreased very slowly, whereas those in group B decreased more quickly. The relatively high WBC and PLT counts in group A were mainly attributable to differences in treatment behavior, which may provide one explanation. As PSE embolizes the peripheral artery in the spleen, leaving the main splenic artery open, it is relatively easy for relapse to occur with resumption of blood flow, which leads to the residual splenic volume increasing relatively quickly. On the contrary, when the main splenic artery is completely embolized, the blood flow supply to the spleen from the splenic artery is stopped, with only a small amount of blood supplied from collateral arteries. This ensures that the residual splenic volume increases very slowly. Our study demonstrated that the residual splenic volume in group A increased very slowly and was significantly smaller than that observed in group B ($P < 0.05$), whereas the residual splenic volume in group B increased much more quickly.

The study has the following limitations. Firstly, a major weakness remains the lack of randomization, and the patient population was relatively small, which restricted our ability to detect possible differences between the two groups. As it was a preliminary prospective clinical study, and many patients were unwilling to choose TSAE at the outset, it was difficult to randomly select patients. Moreover, the two approaches varied with regard to different pathologic changes. The pathologic changes developed in distinctive patterns during follow-ups and were not affected by individual or group. Furthermore, our results revealed a sustained and long-term increase in WBC and PLT counts in group A compared with group B, for all follow-up time-points. Therefore, we believe that the non-randomized allocation of patients into two groups did not affect the results. Secondly, severe complications may occur when collateral arteries are not present or patent. Confirmation of the patency of the collateral arteries, which were connected to the hilar splenic artery from the left gastric artery or from the gastroepiploic artery, was a necessary step prior to TSAE. Lastly, the clinical indications for splenic embolization can be bleeding from varices or hypersplenism, and therefore great attention needs to be directed at these patients after embolization in order to prevent bleeding.

In conclusion, the results of this nonrandomized, prospective trial indicate that TSAE for patients with hypersplenism not only delivers better long-term outcomes but is also associated with lower rates of complications and a shorter hospital stay than PSE. Further clinical trials and longer-term follow-up studies are needed.

COMMENTS

Background
Partial splenic embolization (PSE) has been proposed as an effective alternative to splenectomy to improve peripheral blood cell counts. However, PSE is often associated with complications such as intermittent fever, abdominal pain, nausea and vomiting.

Research frontiers
Total splenic artery embolization (TSAE) has been widely used for the treatment of splenic artery aneurysms, but treatment of patients with hypersplenism with TSAE has rarely been reported. The authors present the comparative clinical outcomes of TSAE and PSE in patients with hypersplenism.

Innovations and breakthroughs
The use of TSAE for the treatment of hypersplenism was devised for the management of patients with thrombocytopenia or leukocytopenia associated with cirrhosis of the liver. All procedures were performed under fluoroscopic control. This is the first study comparing TSAE and PSE in patients with hypersplenism.

Applications
TSAE is a safe and feasible procedure and may serve as supplemental treatment for hypersplenism with thrombocytopenia or leukocytopenia accompanying cirrhosis of the liver, as a result of low complication rates and good medium-term clinical efficacy.

Peer review
The authors present a nonrandomized prospective trial of the endovascular treatment of hypersplenism with TSAE or PSE, with the aim of comparing the clinical outcomes of these two treatment approaches. The results reveal that treatment with TSAE ensured a sustained and long-term increase in white blood cell and platelet counts, as well as lower complication rates and a shorter hospital stay compared to PSE. In addition, post-procedure residual splenic volume in patients treated with TSAE was significantly smaller than that of PSE during follow-up. These results suggest an alternative approach for the management of patients with hypersplenism.

Abstract

AIM: To investigate the mechanism of gastric mucosal demage induced by water immersion restraint stress (WRS) and its prevention by growth hormone releasing peptide-6 (GHRP-6).

METHODS: Male Wistar rats were subjected to conscious or unconscious (anesthetized) WRS, simple restraint (SR), free swimming (FS), non-water fluid immersion, immersion without water contact, or rats were placed in a cage surrounded by sand. To explore the sensitivity structures that influence the stress reaction besides skin stimuli, a group the rats had their eyes occluded. Cervical bilateral trunk vagotomy or atropine injection was performed in some rats to assess the parasympathetic role in mucosal damage. Gastric mucosal lesions, acid output and heart rate variability were measured. Plasma renin, en-

dothelin-1 and thromboxane B2 and gastric heat shock protein 70 were also assayed. GHRP-6 was injected [intraperitoneal (IP) or intracerebroventricular (ICV)] 2 h before the onset of stress to observe its potential prevention of the mucosal lesion.

RESULTS: WRS for 6 h induced serious gastric mucosal lesion [lesion area, WRS 81.8 ± 6.4 mm^2 *vs* normal control 0.0 ± 0.0 mm^2, $P < 0.01$], decreased the heart rate, and increased the heart rate variability and gastric acid secretion, suggesting an increase in vagal nerve-carrying stimuli. The mucosal injury was inversely correlated with water temperature (lesion area, WRS at 35 ℃ 56.4 ± 5.2 mm^2 *vs* WRS at 23 ℃ 81.8 ± 6.4 mm^2, $P < 0.01$) and was consciousness-dependent. The injury could not be prevented by eye occlusion, but could be prevented by avoiding contact of the rat body with the water by dressing it in an impermeable plastic suit. When water was replaced by vegetable oil or liquid paraffin, there were gastric lesions in the same grade of water immersion. When rat were placed in a cage surrounded by sand, there were no gastric lesions. All these data point to a remarkable importance of cutenuous information transmitted to the high neural center that by vagal nerves reaching the gastric mucosa. FS alone also induced serious gastric injury, but SR could not induce gastric injury. Bilateral vagotomy or atropine prevented the WRS-induced mucosal lesion, indicating that increased outflow from the vagal center is a decisive factor in WRS-induced gastric injury. The mucosal lesions were prevented by prior injection of GHRP-6 *via* IP did, but not *via* ICV, suggesting that the protection is peripheral, although a sudden injection is not equivalent to a physiological release and uptake, which eventually may affect the vagal center.

CONCLUSION: From the central nervous system, vagal nerves carry the cutaneous stimuli brought about by the immersion restraint, an experimental model for inducing acute gastric erosions. GHRP-6 prevents the occurrence of these lesions.

INTRODUCTION

Stress is an adaptive physiological response to disruption of homeostasis. Serious stress can induce organ injury or contribute to diseases, such as gastric ulcers, hypertension, diabetes, and cancer. The stomach is one of the main targets of stress. Stress-induced gastric ulceration is a typical example of stress-associated organ injuries[1]. Water immersion restraint stress (WRS) mimics the clinical acute gastric ulcerations caused by trauma, surgery, or sepsis[2] and has been widely accepted for studying stress ulceration[3]. It is theoretically and clinically significant to demonstrate the mechanism of stress-induced gastric injury and develop respective therapeutic drugs.

Both psychological and physiological responses occur during stress and these are involved in the pathogenesis of gastric ulceration. The psychological responses include anxiety, depression, feeling of helplessness, fear, threat of drowning, *etc*. The physiological responses include neurohormonal and immunological activations, including the involvement of corticotropin-releasing factor. These two systems may interact during stressful challenges[4,5], known as psychosomatic reactions. Nonetheless, the mechanisms of gastric stress ulceration remain unclear.

Developing protective drugs against gastric stress ulceration is an important clinical issue. Based on previous studies, agonizing the growth hormone secretagog receptor (GHSR) might be a strategy. Growth hormone releasing peptides (GHRP) are peptidyl growth hormone secretagogs (GHS) and are the synthetic ligands for the GHSR. The family members of GHRP include GHRP-1, GHRP-2, GHRP-6 and hexarelin[6]. GHSR, and its natural ligand ghrelin, are widespread in many tissues, including the gastrointestinal tract[7] and cardiovascular system[8]. Although the GH-releasing actions of both the natural and synthetic GHS have been demonstrated in different species, the function of GHS on alternative physiological systems has not been clearly elucidated. Studies over the past two decades have demonstrated that GHS exerts its physiological or pharmacological actions *via* GH-independent pathways, except for its GH-dependent action[9]. In the cardiovascular system, GHRP and ghrelin exert protective effects, especially on myocardial infarction[10] and heart failure[8,11,12]. Ghrelin and GHSR are expressed in the rat and human stomach and may have significant physiological/pharmacological effects on gastric function and diseases[13,14]. Ghrelin exerts a potent protective action on the stomach of rats exposed to WRS[15]. However, whether or not GHRP also protects against stress-induced gastric injury is unknown. GHRP are much smaller in molecular weight, effective when administered orally, more stable and economically cheaper than ghrelin, and with minimal toxicity, they are better prospects for developing drugs for gastric protection. The purpose of the study was to further investigate the mechanism of gastric stress ulceration using the WRS rat as a model and observe the potential protective effect of GHRP-6 on this gastric injury.

MATERIALS AND METHODS

Stress procedures and animal grouping

A 78 4-mo old male Wistar rats of 310 ± 10 g, were involved in the study. Before the experiment, each animal was housed in a single cage that had wire-net bottoms to avoid coprophagy and had free access to tap water and regular chow for at least 7 d. All animals were starved for 24 h before the onset of stress, but had free access to tap water. Animals were conscious during the stress procedures except those in the "WRS + anesthesia" group (described below), in which rats were anesthetized with 50 mg/kg of sodium pentothal intraperitoneal (IP) during the whole 6-h stress procedures. The water temperature was set to 23 ± 0.5 ℃, except in the WRS group, in which three water temperatures were tested (see below).

The animals were randomly divided into 11 groups (n = 6 in each group/treatment): (1) WRS: rats were lightly anesthetized by ether inhalation and four limbs of each rat were restrained on a wooden plate (25 cm × 19 cm), with the upper limbs anchored at a horizontal position and the lower limbs extended downward. After awakening (usually 10-15 min after ether anesthesia), rats anchored on the wooden plates were immersed vertically (head up) in water to the level of xiphoid process in a water bath thermostatically controlled at 23 ± 0.5 ℃, 19 ± 0.5 ℃ or 35 ± 0.5 ℃, with or without constant pentothal anesthesia, respectively (each n = 6). Anesthesia was achieved with 50 mg/kg of sodium pentothal IP over the whole 6-h stress procedure; (2) simple restraint (SR): the procedure was the same as in the WRS group except that the water bath was empty; (3) free swimming (FS): rats were put into water (water depth 7 cm to avoid drowning) and allowed free movement in the water for 6 h; (4) shallow water touch: rats were put into a water both (water

depth 1 cm) and kept for free moving in the water for 6 h; (5) WRS + eye occlusion: animals were eye-occluded with adhesive plasters and then underwent the WRS procedures, in an attempt to determine whether vision plays a role in the development of stress ulcers; (6) immersion without water contact (NWCI): water immersion with the rat body into a plastic bag to avoid water contact but the rat could see the surrounding water; (7) non-water fluid immersion: the procedure was the same as WRS except that water was replaced by salad oil or liquid paraffin (each $n = 6$), in an attempt to elucidate if skin sensation can differentiate different liquids and induce different gastric responses; (8) "burial" in sand: the restrained rat was placed in a box, the space between the box wall and the rat body was filled with fine sand, the level of filling sand was also to the xiphoid process. To avoid compression of the body, pieces of spongeous material were introduced into the sand; (9) WRS + vagotomy and WRS + atropine: rats underwent bilateral vagal nerve trunk cutting and then underwent WRS. Additional 6 WRS rats (without vagotomy) received atropine (1 mg/kg) IP injection 10 min before the onset of WRS; (10) WRS + GHRP-6: the rat received GHRP-6 (100 μg/kg) (ProSpec-Tany, Israel) IP or intracerebroventricular (ICV) injection 2 h before the WRS procedure. For IP injection, GHRP-6 was dissolved in saline, with a total volume of 0.25 mL per injection; for ICV injection, GHRP was diluted in artificial cerebrospinal fluid, the volume and dosage of GHRP per injection were 5 μL and 20 μg/kg; and (11) normal control: rats were not submitted to any stress procedure. Animals without GHRP-6 IP injection received same volume (0.25 mL) of saline injection (placebo).

The animal use protocol was approved by the Life Ethics Committee of Peking Union Medical College and was conducted in compliance with the United States National Institutes of Health Guidelines for the Care and Use of Laboratory Animals (NIH Publication 85-23).

Evaluation of gastric mucosal lesion

After the stress procedures, animals were released from the plate and were decapitated under pentobarbital anesthesia. The stomachs were then harvested and opened along the lesser curvature. The severity of mucosal lesions was grossly inspected and digitally photographed. Gastric tissues were then fixed in 10% formalin, dehydrated and imbedded in paraffin wax. Paraffin sections of 5 μm were cut and stained with hematoxylin and eosin. Histological changes were checked under a microscope. The length and width of each lesion, including epithelial cell damage, glandular disruption, vasocongestion, hemorrhage and deep necrosis, were measured by stereoscopy and the total area of the lesions in one stomach was assessed by planimetry[16]. The measurement of ulcer index was determined by protocol-blinded researcher. The number of animals showing these histopathological lesions in each group was compared with that of other groups.

Surface electrocardiograms recording and heart rate variability analysis

Surface electrocardiograms (ECG) were recorded with a computer assisted BL-420S system (Chengdu Technology and Market Co. Ltd., Chengdu, China) with a sample rate of 1000 HZ. To avoid the influence of circadian variation of gastric susceptibility, we restricted the ECG recording time to 09:00-15:00 for all subjected animals. R waves were detected off-line with wavelet transform algorithm and then by manual artifact removal. Linear parameters of heart rate variability (HRV), including mean R-R intervals, standard deviation of the normal-to-normal R-R intervals (SDNN) and root mean square of successive difference (RMSSD) of R-R intervals, and non-linear parameter (Poincaré plot) were analyzed as we previously described[17].

Vagotomy

Under light ether inhalation anesthesia, bilateral cervical vagal nerve trunks were exposed and cut off. After closure of the incision, rats were allowed 3 h to recover from the surgery and anesthesia before the WRS procedure.

Measurement of gastric acid secretion

To avoid interrupting the development and observation of gastric erosion, an additional 24 rats were used to measure gastric acid secretion during the stress. These rats were randomly assigned to four groups: WRS, WRS + GHRP-6, RS and Normal + GHRP-6 groups, respectively (each $n = 6$). Gastric acid outputs were measured according to the reported protocols[18,19] with minor modifications. After a 24-h fast, animals were anesthetized by light ether inhalation. For each animal, a transverse incision was made in the abdomen. Both cardia and pylorus were intubated *via* incisions with open polyethylene cannulae and then ligated. The incisions were closed with thread adhesive to avoid water invasion, and ether was discontinued. To remove any solid contents, the stomach was gently rinsed with 2 mL of saline at 37 ℃ three times before the drainage of the gastric juice. Two milliliters of saline warmed to 37 ℃ were then injected into the stomach, left for 30 min and then aspirated and replaced by a fresh saline solution. The process was repeated twice to obtain acid secretion before stress and once every 30 min after the beginning of stress, for 3 h. The aspirated fluids were titrated to pH 7.0 with 0.01 mol/L (normality) NaOH using a pH meter, and acid output was calculated as μEq/30 min.

Intracerebroventricular cannulation

At least one week before the ICV injection, a brain cannula made of polyethylene tubing (PE-10; Clay Adams, Parsippany, NJ) was inserted into the left lateral cerebral ventricle (A-P, 1.5 mm caudal to the bregma; L, 2.0 mm lateral to the midline; V, 3.0 mm below the skull surface) under pentobarbital anesthesia (35 mg/kg, IP), as recently reported[20]. The cannula implanted into the brain

was securely fixed by dental cement and synthetic resin. When injections were given to the rats, a microsyringe for injection was directly connected to the cannula. ICV injections were performed only in conscious rats.

Measurement of plasma renin activity, endothelin-1 and thromboxane B2

Blood was sampled from the ventroartery and prepared for the measurements of stress-related vasoconstrictive factors. Kits for assaying the factors were purchased from the People's Liberation Army General Hospital, Beijing, China. Plasma renin activity (PRA) was indicated by the production of angiotensin I (Ang I) in a reaction system including rat plasma (containing renin and angiotensinogen), rabbit anti-human Ang I antiserum, Ang I standards, and ^{125}I-Ang I. Ang I was measured by the respective radioimmunoassay (RIA) kit. The direct reaction between sample plasma and Ang I antiserum served as a control. The radiation intensity (counts/min) in each tube was converted to nanograms per milliliter (ng/mL), with reference to the Ang I standard curve. PRA was calculated by the equation: PRA (ng/mL per hour) = (Ang I concentration in test tube-Ang I concentration in control tube)/incubation time (h). All assays were performed in duplicate.

Plasma endothelin-1 (ET-1) was measured with a RIA kit according to the manufacturer's protocols. The primary antibodies were rabbit anti-human ET-1 which showed interactions with rat ET-1. We also used standards of these hormones and blank controls to guarantee the quality of the measurement. The measuring sensitivities were < 5 pg/mL for ET-1. The intra- and interassay variabilities were < 10% and < 15% for ET-1.

Plasma thromboxane B2 (TXB2) was measured with an RIA kit (People's Liberation Army General Hospital, Beijing), according to the manufacturer's protocols. Thromboxane A2 (TXA2) is unstable (half-life 30 min) and is rapidly metabolized to the relatively stable TXB2; therefore, we used TXB2 as an indicator of TXA2 level. One milliliter of blood was drawn from the abdominal aorta into a test tube containing 0.06 mL of indomethacin-EDTA solution and then mixed. The blood was centrifuged at 3500 r/min for 15 min and the plasma was separated and stored at -20 ℃. At the beginning of the measurement, the plasma was defrosted and centrifuged again at 3500 r/min for 10 min. The supernatant was used to measure the TXA2 level using the RIA kit.

Western blotting

The gastric mucosal tissues were harvested immediately after decapitation, and 100 mg of mucosal tissues for each animal were used for the following procedures. Total protein extracts were prepared by homogenizing mucosal tissues in lysis buffer. Protein (80 μg per sample) electrophoresis were subjected to sodium dodecylsulfate-polyacrylamide gel and then transferred onto a nitrocellulose membrane. Primary antibodies [goat anti-rat heat shock proteins 70 (HSP70), polyclonal] (Santa Cruz Biotechnol-

ogy, Inc., dilution 1:500) were added onto the membrane to react overnight at 4 ℃ and then incubated with rabbit anti-goat horseradish peroxidase-conjugated secondary antibody (Santa Cruz, Inc., dilution 1:2500) for 1 h. The immunoreactive bands were visualized using Western blotting luminal reagents and were scanned with Image Analysis software (Alpha Innotech, United States).

Statistical analysis

Data are presented as mean ± SD. Student's *t*-test was used for two group comparison and analysis of variance followed by Newman-Keuls multiple comparisons were used in case for multiple comparisons. Differences with *P* value < 0.05 were considered significant.

RESULTS

The water immersion restraint stress-induced gastric mucosal lesion is skin-sensing dependent but is vision or restraint independent

Visual inspection showed that WRS for 6 h (water temperature 23 ℃) induced serious gastric bleeding erosions, as indicated by the mucosal hemorrhage and mucosal erosive lesion (Figure 1) and the calculated area of the lesions (Table 1). The hemorrhage was observed mainly in the gastric body and antrum, but not in the fundus and duodenum (Figure 1). Under the microscope, the mucosa in the WRS rat was disrupted and covered with coagulated blood and inflammatory cell infiltration (Figure 1). Rats with SR did not show gastric mucosal lesions (Figure 1, Table 1). Compared with the serious gastric mucosal damage in all the WRS rats (Figures 1 and 2), eye occlusion of WRS rats did not provide any protection from the mucosal lesions (Figure 2, Table 1), suggesting that vision does not play an important role in the pathogenesis of gastric damage. Rats with NWCI showed an intact mucosa (Figure 2, Table 1), again supporting that

Figure 1 Gross anatomy of rat gastric mucosa in different groups. Left three columns: The gross inspections of the gastric mucosa in water immersion restraint stress (WRS), WRS + growth hormone releasing peptide-6 (GHRP-6) and simple restraint (SR) groups, respectively. Note that there were serious mucosal hemorrhages (black color) in the WRS group, while the hemorrhage was minimal in the WRS + GHRP-6 group. No mucosal hemorrhage was observed in the SR group; the forth column: Hematoxylin-eosin staining of the mucosa, mucosal structure disruption and hemorrhage (brown color) were observed in the WRS group, but not in the WRS + GHRP-6 and SR groups.

the view that vision is not important in inducing gastric mucosal lesion. FS for 6 h also induced serious mucosal bleeding erosions (Figure 2, Table 1), indicating that water immersion without restraint is also sufficient for inducing gastric mucosal lesions.

We also observed the influence of water temperature on WRS-induced gastric mucosal lesions. WRS with cool water (23 ℃) (Figure 1) or cold water (19 ℃) (Figure 2) both induced serious mucosal lesions, but the extent of the lesions was smaller when warm water (35 ℃) was used (Figure 2, Table 1).

The liquid immersion-induced gastric mucosal lesion depends on the deepening of immersion but not depends on the nature of a liquid

Water immersion (WI) to the level of the xiphoid induced serious gastric mucosal lesions (Figure 1), but partial WI (shallow water tough) did not induce mucosal lesions (Figure 2, Table 1), suggesting that the depth of the immersion determines the occurrence of mucosal lesions.

In an attempt to determine if different liquids would lead to different response patterns in the gastric mucosa, we observed the effects of immersion with two other liquids (salad oil and liquid paraffin, which are not obviously skin-hazardous) on gastric mucosa. Immersion to the level of xiphoid process with either of the two liquids induced similar gastric mucosal lesion (Figure 2, Table 1) as WRS did (Figure 2). "Burying" the body into sand (with the head exposed) did not induce mucosal lesions (Figure 2, Table 1). These results suggest that it is the liquid, but not the chemical nature of the liquid, that determines whether the mucosal lesions would occur, and "burying" the body in solid materials does not induce gastric mucosal lesions.

The WRS-induced gastric mucosal lesion depends on the functional neural integrity and increased vagal outflow to the stomach

WRS without anesthesia (i.e., conscious rats) induced serious gastric mucosal lesions (Figure 1, Table 1), but

Figure 2 Representative pictures of the gastric mucosa in different groups. WRS: Water immersion restraint stress; R: Restraint; NWCI: Immersion without water contact; LP: Liquid paraffin; SO: Salad oil; Anes.: Anesthesia; ICV: Intracerebroventricular injection; IP: Intraperitoneal injection.

Figure 3 Heart rate variability analyses showing the differences in mean R-R intervals, standard deviation of the normal-to-normal R-R intervals and root mean square of successive difference of R-R intervals in different groups. Note that the mean R-R intervals gradually prolonged along with the progress of water immersion restraint stress (WRS), whereas this prolongation was much less in the WRS + growth hormone releasing peptide-6 (GHRP-6) group. The mean R-R intervals were shortened in the simple restraint (SR) group. The changes in standard deviation of the normal-to-normal (SDNN) and root mean square of successive difference (RMSSD) was more significant in WRS group than the other two groups. [a]$P < 0.05$, [b]$P < 0.01$ *vs* WRS+GHRP-6 group.

WRS with anesthesia (unconscious rats) did not, no matter what a water temperature was used (Figure 2, Table 1). The HRV analyses (Figures 3 and 4) showed that the R-R intervals of the ECG in WRS rats gradually became longer, in other words, the HR gradually decreased; the SDNN and RMSSD of the R-R intervals increased, suggesting an increase of HRV, underlying an increase of the vagal outflow. Simple restraint induced a gradual shorting in R-R intervals and decreases in SDNN and RMSSD (Figure 3), suggesting an increase in sympathetic outflow to the heart. The Poincaré plot of R-R intervals (Figure 4) also supported the above observations. Previous injec-

tion of atropine also abolished the WRS-induced gastric mucosal lesion (Figure 2), further supporting the vagal hypothesis of this injury.

WRS stimulated gastric acid secretion (Figure 5), also indicative of increased vagal efferent activity. Simple restraint did not affect gastric acid output (Figure 5), indicating that restraint alone did not stimulate parasympathetic activity. Bilateral vagotomy totally prevented the development of WRS-induced mucosal lesions (Figure 2), also supporting the hypothesis that increased vagal outflow to the stomach plays a leading role in the development of WRS-induced mucosal lesions.

Figure 4 Pointcaré plots of the R-R intervals in different groups. A: The plots indicate that heart rate decreased gradually with time, and heart rate variability (HRV) was increased as shown by the scattered pattern of the plots in the water immersion restraint stress (WRS) group, suggesting vagal overactivity in this group; B: Changes of the heart rate and HRV in the WRS + growth hormone releasing peptide-6 (GHRP-6) group were much less than the WRS group; C: In the simple restraint (SR) group, the heart rate increased and the HRV was decreased as shown by the condensed geometry of the plots, suggesting increased sympathetic activity in this group.

Figure 5 Gastric acid output in different groups. Note that water immersion restraint stress (WRS) induced significant increase in gastric acid output and growth hormone releasing peptide-6 (GHRP-6) (intraperitoneal) significantly suppressed this increase. Simple restraint (SR) and GHRP-6 alone did not change the gastric acid output. [a]$P < 0.05$, [b]$P < 0.01$ *vs* WRS group.

Figure 6 Western blotting showing gastric mucosal protein levels of heat shock proteins 70 in different groups. Note that there was substantial expression in the water immersion restraint stress (WRS) and simple restraint (SR) groups, whereas the expression was minimal in the WRS + growth hormone releasing peptide-6 (GHRP-6) group. HSP70: Heat shock proteins 70.

GHRP-6 prevents WRS-induced gastric mucosal lesion mainly by suppressing the vagal effect on the stomach

GHRP-6 pre-injection *via* IP 2 h before the start of WRS dramatically prevented the WRS-induced mucosal bleeding erosion; only very slight or no hemorrhaging was observed in the WRS + GHRP-6 group (Figure 1). The HE stains of the gastric tissues (Figure 1) also confirmed that the mucosal injury/hemorrhage was minimal or not observed in WRS rats pretreated with GHRP-6. Planimetry analyses (Table 1) showed that the lesion area was large in the WRS group; but was minimal in the WRS + GHRP-6

group; lesion area was zero in the SR group. GHRP-6 did not have a protective effect on the mucosa of WRS rats if administrated centrally *via* ICV (Figure 2), suggesting that the protective effect of GHRP-6 is mainly peripheral.

GHRP-6 alleviated the changes of HRV parameters induced by WRS (Figures 3 and 4), and decreased the gastric acid output during WRS (Figure 5), suggesting that GHRP-6 protects the mucosa, at least in part, by suppressing the vagal efferent effect on the stomach.

GHRP-6 could alleviate the intensity of gastric stress response, which is reflected by the level of expression of HSP70 in the mucosa. Western blotting results showed that both the WRS and SR induced a high expression of HSP70 in the gastric mucosal tissues (Figure 6), indicating a nonspecific response of HSP70 expression to stress. GHRP-6 pretreatment significantly decreased the protein level of HSP70 in the WRS rats (Figure 6), suggesting a

Table 2 The effect of growth hormone releasing peptide-6 on the plasma levels of stress-related factors in rats

	ET-1 (pg/mL)	Renin activity (pg/mL)	TXB2 (ng/mL)
WRS	152.23 ± 10.70[d]	1.71 ± 0.59[d]	311.31 ± 50.54[d]
WRS + GHRP-6	115.11 ± 4.08[b]	0.65 ± 0.29[a]	125.84 ± 8.36[b]
SR	97.11 ± 4.71	0.11 ± 0.03	69.93 ± 22.13

[a]$P < 0.05$, [b]$P < 0.01$ *vs* WRS group; [d]$P < 0.01$ *vs* SR group. WRS: Water immersion restraint stress; SR: Simple restraint; GHRP-6: Growth hormone releasing peptide-6; ET-1: Endothelin-1; TXB2: Thromboxane B2.

decrease in the stress intensity.

WRS significantly increased the plasma levels of ET-1, renin activity and TXB2 compared with that of the SR group, while GHRP-6 pretreatment significantly attenuated the increases in these vasoconstrictive hormones (Table 2).

DISCUSSION

The mechanism of WRS-induced gastric mucosal lesion is complicated and not yet fully understood. The pathogenesis of the injury may be recognized at different levels, for example, at psychological, physiological, psychosomatic[21], integrative, organic, cellular and molecular levels. This study focuses on the psychosomatic mechanism of WRS-induced gastric mucosal lesions *in vivo*.

We first differentiated the relative importance of the pathways by which the stress stimulus signals were sensed and transferred to the central nervous system (CNS). When a conscious rat was immersed in water, it saw (intact vision) that its body was almost drowning, which may have induced fear. At the same time, the rat's skin also sensed liquid immersion and generated a physiological response and subsequent psychological stress response. By eye occlusion or NWCI manipulations, we determined that vision alone is not sufficient to induce gastric mucosal lesion, while WI alone is sufficient for the induction of the lesion, because free swimming rats showed serious mucosal injury. These results also showed that immersion depth significantly affects the severity of mucosal lesions, as partial immersion in shallow water could not induce mucosal lesions. These results indicate that skin sensation is the leading input pathway for WRS-induced gastric bleeding erosion. The cutaneous stimuli may reach the integrative structures of the upper central nervous system and, by the vagal pathway, produce gastric mucosa lesions. Rat is an animal of nocturnal habit; therefore vision is not a fundamental sense for its defense. In all environments, rat performs a cognitive map to run away from an eventual predator. In an unstable environment, such as fluid, they may aware of the difficulty of running away.

Skin receptors can sense temperature, touch and noxious stimulation. Whether or not skin sensors can also distinguish different liquids is unknown. To determine

this point, we examined gastric mucosal responses to immersion in different liquids or solid materials. Immersion in either salad oil or liquid paraffin induced serious mucosal hemorrhage similarly to WI, indicating that liquid immersion-induced gastric mucosal injury does not depend on the chemical nature of a liquid, but depends on liquid itself. "Burial" in sand did not induce gastric lesions, even when combined with restraint, suggesting that skin sensors can differentiate whether a material is fluid or dry matter, and immersion in a liquid or "burial" in dry material would lead to different gastric mucosal responses. Another possibility is that liquid immersion leads to lower body temperature compared with surrounding the body with solid materials.

The present data also indicated that the functional integrity of neural regulation is essential for the induction of gastric mucosal injury by WRS. In conscious animals, WRS induced injury that was inversely related to water temperature. However, in unconscious rats exposed to even the most severe condition (19 ℃), no ulceration occurred, which agreed with the result of Murison *et al*[21]. Pentobarbital does not block vagal output to the stomach[22], but even enhances vagal output[21] ; therefore, the lack of gastric erosion by WRS in unconscious rats may be caused by certain selective interruptions of CNS-stomach communications by the anesthesia, potentially including sensation of body temperature and mobilization of vasoconstrictive hormones, such as renin-angiotensin system[23], ET-1[24] and TXB2[25]. These vasoconstrictive factors may reduce gastric blood flow and lead to changes in the ratio of gastric blood flow/acid output, which favors the formation of gastric ulcers[26].

Gastric acid secretion is controlled by sympathetic and parasympathetic nerves, and by certain hormones, such as gastrin. Generally, sympathetic activity inhibits, and parasympathetic activity stimulates, gastric acid secretion. Occasionally, sympathetic stimulation may also increase gastric acid secretion, because adrenalin releases gastrin; and vagal nerves may exert some sympathetic-like effect as they have adrenergic fibers. Our results indicate that increased vagal efferent activity is the leading cause of WRS-induced gastric mucosal injury, because HRV analyses showed heart rate slowing and increasing of some HRV parameters, and furthermore, bilateral vagotomy or atropine totally prevented the injury induced by WRS. This result is consistent with our previous study[17]. Our HRV analyses also showed that restraint alone induced moderate sympathetic hyperactivity, while sympathetic hyperactivity in the stomach prevents WRS-induced gastric injury formation mainly *via* the inhibition of gastric acid secretion, as observed in stroke prone spontaneously hypertensive rats[27].

Heart rate slowing is a universal response in all air-breathing vertebrates when immersed in water (drowning or diving), this is called diving bradycardia[28]. Diving bradycardia is triggered by apnea and accentuated by immersion of the face or whole body in cold water[28]. The

diving response is mainly characterized by bradycardia, decreased cardiac output, peripheral vasoconstriction and increased arterial blood pressure[29,30]. The physiological significance of this response is to conserve oxygen, a mechanism of defense against hypoxic damage[28,31]. Our previous[17] and present observations in the rat model indicate that bradycardia appears even when the immersion is partial and the face is not immersed (for example, immersed to the xiphoid process in the present study), suggesting that heart rate slowing during water immersion does not necessarily depend on face immersion. This reaction pattern may be formed in development, and is a heritable trait[32]. However, when humans are diving or swimming for longer times (for example, 8-h swimming), they usually do not develop gastric mucosal injury, while rats do. One potential mechanism for these differential gastric responses may be the psychological component: a man who is diving or swimming knows that he is just at work or recreation and will not drown; therefore, he has no severe psychological reactions. By contrast, a rat would not think so, it would feel it was about to drown and die, and therefore severe psychological responses would be triggered, which may partially contribute to gastric injury.

Ghrelin, a peptide hormone originally isolated mainly from the stomach, is the endogenous ligand for the GHSR. In the gastrointestinal tract, ghrelin regulates the motility of the stomach and gut[33], gastric acid secretion[34] and gastric mucosal defense[35,36]. Intravenous administration of rat ghrelin dose-dependently increases both gastric acid secretion and gastric motility, actions that are blocked by pretreatment with either atropine or bilateral cervical vagotomy, but not by the histamine H_2-receptor antagonist famotidine, suggesting ghrelin might have a physiological role in the vagal control of gastric function in rats[37]. Another study indicated that ghrelin inhibits gastric acid secretion[38]. This controversy deserves further investigation. GHRP, the mimetic of ghrelin, has been shown to have gastric motor effects[39]. However, the effect of GHRP on gastric acid secretion is unknown. We show here that WRS significantly increased the gastric acid output, but restraint did not; GHRP-6 significantly suppressed WRS-stimulated gastric acid secretion, although GHRP-6 did not significantly affect the basal gastric acid output in normal rats. These results, combined with the HRV data, suggest that the protective effect of GHRP-6 on WRS-induced gastric mucosal injury is affected, at least in part, by suppressing vagal efferent effect on the stomach, including gastric acid secretion, as gastric acid play an important role in the development of WRS-induced gastric ulcers[40]. Our results also indicate that the protective effect of GHRP-6 is likely peripheral, potentially by affecting the function of vagal efferent terminals and/or cell protection. However, we cannot exclude the possibility that GHRP-6 might also affect the vago-vagal or vago-sympathetic reflexes. One possibility is that GHRP-6 injected *via* ICV may not effectively reach its target CNS site (for example, the dorsal vagal complex); the other possibility is that GHRP-6 may also affect the vagal afferent nerves, which in turn affects the neuronal reflex.

The protection of GHRP-6 on WRS-induced gastric injury could also be reflected by the level of expression of HSP70 in the gastric mucosal tissue. HSP are crucial for cell survival during and after various cellular stresses. WRS rapidly induces HSP70 expression and accumulation; the HSP70 level is inversely correlated with the severity of mucosal lesions[41]. GHRP-6 significantly decreased the HSP70 protein level in the gastric mucosa of WRS rats compared with WRS alone, indicating that the stress intensity is low in the GHRP-6 treated animals. This result also suggests that GHRP-6 can exert a cell protective effect.

Interestingly, we found that gastric mucosal injury never occurred in the gastric fundus, while ghrelin is secreted predominantly by enteroendocrine cells in the gastric fundus, although ghrelin gene transcripts and ghrelin-producing cells are found throughout the gastrointestinal tract[13]. Whether the ghrelin-secreting fundus is ulcer-resistant or only the acid-secreting areas (gastric body and antrum) are vulnerable to stress, deserves further investigation. It is possible that locally released ghrelin may have a protective action on the fundic gastric mucosa.

In conclusion, this study demonstrates that vision-triggered psychosomatic responses do not play an important role in WRS-induced gastric mucosal lesions; however, skin sensation-induced increase of vagal outflow and subsequent increase of gastric acid secretion do play a leading role. Skin receptors cannot differentiate different liquids, and immersion with different liquids induced the same gastric injury as WI does. GHRP-6 protects against WRS-induced gastric lesions mainly by suppressing the vagal effect on gastric mucosa, and this protection is likely peripheral. The protective effect of GHRP-6 on gastric stress ulceration suggests a clinical application in treating stress-related gastric injury.

COMMENTS

Background
Gastric ulcers are among the most frequently occurring stomach diseases across the world and stress is an important inducer of this disease. Therefore, an understanding of the key mechanism of gastric stress ulceration and the development of preventive/therapeutic drugs are important in treating this disease.

Research frontiers
How stress induces gastric ulcers is an old question that needs a new answer. Most previous studies only looked at restricted areas, especially at the physiological and molecular levels. Exploring the key mechanism and developing therapeutic drugs for gastric stress ulcer are urgently required.

Innovations and breakthroughs
In contrast to other mechanistic studies on gastric stress ulceration, this investigation focuses on the psychosomatic mechanisms of water immersion and restraint stress (WRS)-induced gastric bleeding erosions, and found that increased outflow from the vagal center is the leading cause of WRS-induced gastric injury. Skin sensation, but not vision, triggers the stress reaction *via* vago-vagal reflex. The study also found that growth hormone releasing peptide-6 (GHRP-6), a synthetic agonist for growth hormone secretagogues receptor, prevents the occurrence of gastric mucosal lesions, mainly by suppressing the vagal effect on the stomach.

Applications

The study demonstrates the key signaling pathway by which water immersion induces gastric mucosal damage in the rat, and provides the first evidence that GHRP-6 can prevent this damage. The study suggests a clinical application of GHRP in treating gastric stress ulceration.

Peer review

Discovering the mechanism of gastric stress ulceration is a prerequisite for the prevention and treatment of this disease. This study shows that skin sensation and the subsequent vago-vagal reflex play a key role in the development of water immersion-induced gastric mucosal damage in the rat. GHRP-6 prevents this damage, probably by suppressing the vagal effect on the stomach. The study is innovative and with potential therapeutic interest.

Abstract

AIM: To evaluate the safety and effectiveness of two-stage *vs* single-stage management for concomitant gallstones and common bile duct stones.

METHODS: Four databases, including PubMed, Embase, the Cochrane Central Register of Controlled Trials and the Science Citation Index up to September 2011, were searched to identify all randomized controlled trials (RCTs). Data were extracted from the studies by two independent reviewers. The primary outcomes were stone clearance from the common bile duct, postoperative morbidity and mortality. The secondary outcomes were conversion to other procedures, number of procedures per patient, length of hospital stay, total operative time, hospitalization charges, patient acceptance and quality of life scores.

RESULTS: Seven eligible RCTs [five trials (*n* = 621) comparing preoperative endoscopic retrograde cholangiopancreatography (ERCP)/endoscopic sphincterotomy (EST) + laparoscopic cholecystectomy (LC) with LC + laparoscopic common bile duct exploration (LCBDE);

two trials (*n* = 166) comparing postoperative ERCP/EST + LC with LC + LCBDE], composed of 787 patients in total, were included in the final analysis. The meta-analysis detected no statistically significant difference between the two groups in stone clearance from the common bile duct [risk ratios (RR) = -0.10, 95% confidence intervals (CI): -0.24 to 0.04, *P* = 0.17], postoperative morbidity (RR = 0.79, 95% CI: 0.58 to 1.10, *P* = 0.16), mortality (RR = 2.19, 95% CI: 0.33 to 14.67, *P* = 0.42), conversion to other procedures (RR = 1.21, 95% CI: 0.54 to 2.70, *P* = 0.39), length of hospital stay (MD = 0.99, 95% CI: -1.59 to 3.57, *P* = 0.45), total operative time (MD = 12.14, 95% CI: -1.83 to 26.10, *P* = 0.09). Two-stage (LC + ERCP/EST) management clearly required more procedures per patient than single-stage (LC + LCBDE) management.

CONCLUSION: Single-stage management is equivalent to two-stage management but requires fewer procedures. However, patient's condition, operator's expertise and local resources should be taken into account in making treatment decisions.

Two-stage *vs* single-stage management for concomitant gallstones and common bile duct stones. *World J Gastroenterol* 2012; 18(24): 3156-3166 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i24/3156.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i24.3156

INTRODUCTION

Choledocholithiasis is concomitant with gallstones in approximately 3%-10% of the patients[1-4]. In the pre-endoscopy and pre-laparoscope era, the standard treatment for patients suffering from gallstones accompanied with common bile duct stones (CBDS) was open cholecystectomy and common bile duct exploration[5]. With the advent of laparoscopic and endoscopic techniques, several alternative treatments, such as laparoscopic cholecystectomy (LC), preoperative or postoperative endoscopic retrograde cholangiopancreatography and endoscopic sphincterotomy (ERCP + EST) and laparoscopic common bile duct exploration (LCBDE), have been developed to treat cholelithiasis. In the past two decades, LC has become gradually accepted as the first choice for the treatment of cholecystolithiasis. Consequently, confirmed or suspected cases of CBDS have been routinely removed *via* a two-stage management using preoperative ERCP/EST followed by LC. However, even with the strictest selection criteria, over 10% of the preoperative ERCP are normal[6,7], and only 10%-60% of patients will have stones at the time of ERCP[8-11]. As a result, a number of unnecessary ERCP procedures have been performed. To avoid these unnecessary procedures, laparoscopic intraoperative cholangiography combined with selective postoperative ERCP has been proposed[12]. Nevertheless, preoperative ERCP/EST and postoperative ERCP/EST can both result in unpredictable severe complications, even death[13]. Although ERCP/EST has been proven to be a safe and effective option for extracting CBDS in most cases, it also has some adverse effects. This procedure can not only induce several postoperative complications, including bleeding, perforation and pancreatitis[14-17], but also lead to the disruption of the intact sphincter of Oddi[18,19]. Currently, as the laparoscopic technique matures, more and more centers prefer conducting LCBDE through either the transcystic duct or *via* the choledochotomy to remove CBDS, thus preventing unnecessary preoperative ERCP[20-22]. Above all, LCBDE has the advantage of reducing the two-stage approach to a single-stage approach by minimally invasive surgery. Previously published trials are unclear as to whether two-stage (LC + ERCP/EST) management is better or worse than single-stage (LC + LCBDE) management for choledocholithiasis complicated with cholecystolithiasis. Therefore, we conducted a systematic review and meta-analysis of all randomized controlled trials (RCTs) to evaluate the clinical safety and effectiveness of the two-stage (LC + ERCP/EST) management *vs* single-stage (LC + LCBDE) management in patients with concomitant gallstones and CBDS.

MATERIALS AND METHODS

Searching strategy

We searched databases, including PubMed, Embase, the Cochrane Central Register of Controlled Trials and the Science Citation Index updated to September 2011, to identify all related published RCTs. The keywords used in the search were as follows: LC, LCBDE, ERCP, EST, gallstones and CBDS. The language of all publications was restricted to English only. The citations within the reference lists of the articles were searched manually to identify additional eligible studies.

Inclusion and exclusion criteria

All studies, published up to and including September 2011, that compared two-stage (LC + ERCP/EST) with single-stage (LC + LCBDE) management in patients with concomitant gallstones and CBDS were eligible for inclusion. The inclusion criteria were: (1) study design, RCT; (2) types of participants, those with proven or suspected CBDS before LC or those with gallstones that were found to have CBDS at LC by intraoperative cholangiography; (3) intervention, preoperative ERCP/EST + LC *vs* LC + LCBDE or (4) postoperative ERCP/EST + LC *vs* LC + LCBDE. Non-randomized trials, retrospective analyses and reviews were not included, and studies were excluded if there were no postoperative major outcomes. In addition, those studies comparing intraoperative ERCP/EST + LC with LC + LCBDE were also excluded because both managements were single-stage.

Data extraction and validity assessment

Two authors (Lu J and Cheng Y) independently extracted the data, evaluated the study quality by applying a predesigned standardized form, and then cross-checked. Any disagreement in the two reviewers' data collection and quality assessment was discussed until a consensus was reached; otherwise, a third reviewer (Xiong XZ) would take part in the discussion as the referee. The general information extracted from the studies included the authors, publication year, study period, country, characteristics of patients, sample size, interventions and outcomes. The risk of bias in the included studies was assessed using the Cochrane collaboration' tool. The assessment contained six dimensions: (1) random sequence generation; (2) allocation concealment; (3) blinding; (4) incomplete outcome data addressed; (5) selective reporting; and (6) other bias.

Outcomes of interest and definitions

The primary outcomes were stone clearance from the common bile duct (CBD), postoperative morbidity and mortality, while secondary outcomes were conversion to other procedures, length of hospital stay, number of procedures used per patient, total operative time, hospitalization charges, patient acceptance and quality of life scores. Stone clearance from the CBD was determined by ERCP or intraoperative cholangiography, and it was defined as successful stones extracted from the CBD *via* the planned procedure only once. The overall postoperative morbidity consisted of surgical and nonsurgical complications. The surgical complications included hemorrhage, bile leak, acute pancreatitis, cholangitis, perforation, wound infection, abdominal and wall hematoma that were directly

RCTs: Randomized controlled trial; CBD: Common bile duct; LC: Laparoscopic cholecystectomy; ERCP: Endoscopic retrograde cholangiopancreatography; EST: Endoscopic sphincterotomy; LCBDE: Laparoscopic common bile duct exploration.

Figure 1 Flow diagram of literature screening. ERCP: Endoscopic retrograde cholangiopancreatography; LC: Laparoscopic cholecystectomy; LCBDE: Laparoscopic common bile duct exploration.

related with the operation, and the nonsurgical complications included myocardial infarction and pulmonary embolism, which had nothing to do with the operation. Mortality was defined as postoperative death before discharge or within 30 postoperative days. Conversion to other procedures was defined as any case in which stones from the CBD were not successfully extracted or other scenarios, such as dense gallbladder adhesions and fibrosis, which resulted in converting the planned procedure into another procedure.

Statistical analysis

All statistical analyses of the extracted data was performed with Review Manager (Review Manager version 5.1, Copenhagen, the Nordic Cochrane Centre, the Cochrane Collaboration, 2008). The results of the meta-analysis were expressed as the risk ratios (RRs) and mean difference (MD) for dichotomous data and continuous data, respectively, with 95% confidence intervals (CIs) for both. The Mantel-Haenzsel method was used for dichotomous variables, while the inverse variance method was used for continuous variables. *P* values were computed with the *Z* test, and $P < 0.05$ was regarded as statistically significant. The heterogeneity among the studies was evaluated using the χ^2 test, with its significance set at $P < 0.1$, and the extent of inconsistency was assessed by the I^2 statistic[23]. If significant heterogeneity existed, a random-effect model was used to attempt to explain it. In the absence of significant heterogeneity, a fixed-effect model was adopted. Generally, the estimates of the mean and SD were required to calculate the CIs for continuous data. However, a few published clinical trials reported a median and a range instead of a mean and SD. To adjust for this difference, we assumed that the median was equal to the mean, and we estimated the SD as a quarter of the reported range. Potential publication bias was appraised visually by funnel plots.

RESULTS

Literature search and selection

The literature search identified 792 potentially relevant studies according to our predefined search strategy (Figure 1). Ninety-three studies were removed by the Endnote X4 software, and 667 studies were excluded through scanning titles and abstracts. Full-text papers were retrieved for the remaining 32 eligible studies. Of the remaining 32 studies, 20 studies were excluded because they were non-randomized trials. Three studies were excluded because they were duplicated trials, and two were not included because they compared intraoperative ERCP/EST + LC with LC + LCBDE. Eventually, seven RCTs[5,24-29] were considered to be suitable for the final meta-analysis. There were five

CBD: Common bile duct.

Figure 2 Funnel plot of trials of stone clearance from the common bile duct. ERCP: Endoscopic retrograde cholangiopancreatography; LC: Laparoscopic cholecystectomy; LCBDE: Laparoscopic common bile duct exploration. SE: Standard error; RD: Risk difference.

trials[4,24,26,28,29] (n = 621) comparing preoperative ERCP/EST + LC with LC + LCBDE and two trials[25,27] (n = 166) comparing postoperative ERCP/EST + LC with LC + LCBDE. The characteristics, outcomes and risk of bias for the included studies are summarized in Tables 1-3. A manual search and examination of the bibliographies in these reference lists were also performed, and no additional eligible studies were found.

Description of various RCTs including inclusion and exclusion criteria

All of the patients were proven or suspected of having gallstones and CBDS on the basis of clinical presentation (jaundice, biliary pancreatitis and cholangitis) or liver function tests or imaging (ultrasound, magnetic resonance cholangiopancreatography (MRCP) and intraoperative cholangiography) before being enrolled in the trial. Three

trials[24,26,28] restricted the participants to the ASA risk grade at the level of Ⅰ and Ⅱ. In addition, one trial[29] was specially designed to compare the two-stage (ERCP/EST + LC) approach with the single-stage (LC + LCBDE) approach in higher risk patients, who were defined as those over 60 years of age with comorbidity, those over 70 years of age, or those over 50 years of age with a body mass index exceeding 40. Three trials[5,26,28] did not mention their exclusion criteria. Additionally, three studies[25,27,29] excluded patients who had accepted previous ERCP/EST prior to recruitment into the trials. Patients with severe pancreatitis and cholangitis, which required emergency ERCP/EST, were also excluded from two trials[27,29].

Publication bias

A funnel plot analysis was performed by adopting the occurrence of stone clearance from the CBD as the index, and it appeared to be asymmetrical, which suggested the presence of publication bias (Figure 2).

Meta-analysis results

Stone clearance from the CBD: Stone clearance from the CBD was achieved in 78.8% (234 of 297) of patients in the two-stage (ERCP/EST + LC) group and in 87.2% (251 of 288) of patients in the single-stage (LC + LCBDE) group. The meta-analysis revealed that the difference between the two groups was not statistically significant (RR = -0.10, 95% CI: -0.24 to 0.04, P = 0.17), and there was statistically significant heterogeneity among the studies (χ^2 = 33.55, P < 0.00 001, I^2 = 82%) (Figure 3A).

Postoperative morbidity: Postoperative morbidity was reported in six trials[24-29]. Overall, postoperative morbidity occurred in 15.2% (54 of 355) of patients in the two-stage (ERCP/EST + LC) group *vs* 19.0% (65 of 343) of patients in the single-stage (LC + LCBDE) group. The meta-analysis demonstrated that there was no statistically

Table 3 Cochrane risk of bias summary

Noble *et al*[29], 2009	Low risk	Unclear risk	High risk	Unclear risk	Low risk	High risk	Low risk

significant difference between the two groups (RR = 0.79, 95% CI: 0.58 to 1.10, P = 0.16). As evidenced by the values of the χ^2 and I^2 indices (χ^2 = 0.55, P = 0.99, I^2 = 0%), no significant heterogeneity was found from the trials (Figure 3B).

Mortality: Five trials[5,24,26-28] reported mortality; however, only two of these trials[26,28] reported postoperative deaths. The results of the pooled analysis revealed no statistically significant difference between the two groups (RR = 2.19, 95% CI: 0.33 to 14.67, P = 0.42); and there was no significant heterogeneity between the trials (χ^2 = 0.02, P = 0.88, I^2 = 0%) (Figure 3C).

Conversion to other procedures: We identified all the trials existing in the data, and the occurrence of conversion was 13.9% (51 of 368) and 12.0% (43 of 358) in the two-stage (ERCP/EST + LC) group and the single-stage (LC + LCBDE) group, respectively. Significant heterogeneity was present in the trials (χ^2 = 13.83, P = 0.03, I^2 = 57%), and there was no statistically significant difference between the two groups (RR = 1.21, 95% CI: 0.54 to 2.70, P = 0.39) (Figure 3D).

Length of hospital stay: The length of hospital stay was evaluated in all the studies, but only one study[24] reported this data in the form of the mean and the SD. There were two studies[27,28] that provided the mean without the SD, and the rest of studies[5,25,26,29] provided the median and the range. Consequently, according to our predefined plan, we presumed that the median was equal to the mean, and we equated the SD with a quarter of the reported range. Significant heterogeneity was found among the trials (χ^2 = 209.70, P < 0.001, I^2 = 98%), and the meta-analysis indicated no statistically significant difference between the two groups (MD = 0.99, 95% CI: -1.59 to 3.57, P = 0.45) (Figure 3E).

Total operative time: There were five trials[5,24,25,27,28] that included information about the total operative time; however, only one trial[24] reported the mean and the SD. Two trials[25,28] offered the median and the range instead of the mean and the SD, while one trial[27] offered the mean without the SD. Furthermore, there was one trial[5] that reported the total operative time of the two-stage (ERCP/EST + LC) group, but not the single-stage (LC + LCBDE) group. There was no statistically significant dif-

ference between the two groups (MD = 12.14, 95% CI: -1.83 to 26.10, P = 0.09), and no significant heterogeneity was found among the trials (χ^2 = 0.18, P = 0.92, I^2 = 0%) (Figure 3F).

Hospitalization charges: The hospitalization charges were recorded in only one trial. Rogers *et al*[24] stated that there was no statistically significant difference in total hospitalization charges between the two groups.

Patient acceptance and quality of life scores: Only one trial[24] reported the patient acceptance and quality of life scores. This article mentioned that the patient acceptance and quality of life scores were the same in both groups using standardized scoring system. However, the study did not provide specific data.

Number of procedures used per patient: It was obvious that the two-stage (LC + ERCP/EST) approach required more procedures per patient than the single-stage (LC + LCBDE) approach (Table 2).

Subgroup analysis: Because there were two options (preoperative ERCP/EST + LC and postoperative ERCP/EST + LC) for the two-stage (ERCP/EST + LC) management technique, which may have influenced the eventual conclusion, we performed a subgroup analysis for three outcomes (stone clearance from the CBD, postoperative morbidity and conversion to other procedures). In the subgroup analysis, the outcomes were also equivalent, and no statistically significant difference was found among the subgroups.

DISCUSSION

In summary, our meta-analysis revealed that both single-stage (LC + LCBDE) and two-stage (LC + ERCP/EST) management achieved equivalent stone clearance from the CBD, but the former procedure was associated with fewer procedures per patient. In addition, there was no statistically difference between the two approaches in terms of postoperative morbidity, mortality, conversion to other procedures, length of hospital stay, total operative time and hospitalization charges.

Currently, the optimal treatment for concomitant gallstones and CBDS is still in dispute[24,30,31]. In the laparoscopic era, the vast majority of patients who suffered

Figure 3 Forest plot of meta-analysis. A: Two-stage [endoscopic retrograde cholangiopancreatography (ERCP)/endoscopic sphincterotomy (EST) + laparoscopic cholecystectomy (LC)] *vs* single-stage [LC + laparoscopic common bile duct exploration (LCBDE)] in stone clearance from the common bile duct; B: Two-stage (ERCP/EST + LC) *vs* single-stage (LC + LCBDE) in postoperative morbidity; C: Two-stage (ERCP/EST + LC) *vs* single-stage (LC + LCBDE) in mortality; D: Two-stage (ERCP/EST + LC) *vs* single-stage (LC + LCBDE) in conversion to other procedures; E: Two-stage (ERCP/EST + LC) *vs* single-stage (LC + LCBDE) in length of hospital stay; F: Two-stage (ERCP/EST + LC) *vs* single-stage (LC + LCBDE) in total operating time. CI: Confidence interval.

from concomitant gallstones and CBDS were routinely managed by ERCP/EST, either preoperatively or postoperatively, prior to LC[25,26]. Although this approach is effective and safe for removing the CBDS, it also has several drawbacks. First, it requires two periods of anesthesia and occasionally two hospital admissions, which may increase the length of hospital stay and hospitalization expenses. Furthermore, if patients still have CBDS detected by intraoperative cholangiography in LC after successful ERCP/EST, surgeons will face the dilemma of depending on LCBDE, postoperative ERCP/EST or traditional open choledochotomy. Most importantly, even in those patients with clinical, biochemical and imaging risk factors for CBDS, preoperative ERCP/EST can produce false-

negative results, leading to the possibility of morbidity and mortality[26,32]. Despite postoperative ERCP/EST can indeed avoid the risk inherent in preoperative ERCP/EST to patients without CBDS, it necessitates another surgical procedure when it fails to remove the CBDS[27]. Both preoperative and postoperative ERCP/EST are likely to lead to some short-term and long-term complications. For instance, they may result in postoperative complications, including bleeding, perforation, pancreatitis and even death[14-17]. Moreover, it is notable that the intact sphincter of Oddi is destroyed after EST so that biliary sphincter function is permanently lost, which damages the barrier of the sphincter that prevents duodenobiliary reflux[33]. Reflux from the duodenum into the bile duct is responsible for the high rate of bacterobilia occurring after EST[34], and chronic bacterobilia may even cause neoplastic changes in the biliary epithelium[35]. Therefore, ERCP/EST should be adopted on a selective basis, i.e., in patients with acute obstructive suppurative cholangitis, severe biliary pancreatitis, ampullary stone impaction or severe comorbidity. If possible, MRCP should be used for preoperative diagnosis. According to a meta-analysis, MRCP achieved a high overall sensitivity of 95% and a specificity of 97% for detecting CBDS[36].

With the improvement in laparoscopic equipment and skills, LCBDE has been increasingly used to remove the CBDS. It is considered to be a safe, efficient and cost-effective treatment for choledocholithiasis; it is associated with a high stone clearance rate ranging from 84%-97%, a postoperative morbidity rate of 4%-16%, and a mortality rate of approximately 0%-0.8%[26,37-39]. However, to decompress the bile duct and decrease biliary complications, T-tube drainage has been routinely employed after choledochotomy[40,41], which is inevitable with complications including bile leakage, bile infection and wound infection[41]. Furthermore, the patients have to keep the bile drainage tube in place for several weeks before removal, causing great discomfort and delaying their return to work[42].

Nevertheless, according to a recent meta-analysis[43], primary closure might be as effective as T-tube drainage in the prevention of postoperative complications after choledochotomy. Consequently, it seems that LCBDE is a commendable alternative to the use of ERCP/EST.

Previously published trials have demonstrated that single-stage (LC + LCBDE) and two-stage (LC + ERCP/EST) management are equivalent with respect to stone clearance from the CBD, morbidity and mortality[5,24-26]. However, most of the trials were limited by their small sample size. In 2006, Clayton *et al*[44] reported a meta-analysis concerning endoscopy and surgery *vs* surgery alone for CBDS with the gallbladder *in situ*. In the subgroup analysis, they concluded that the endoscopic and laparoscopic surgery groups had similar outcomes; however, treatment should depend on local resources and expertise. Furthermore, the number of patients included was insufficient, and up-to-date trials were not included. Unlike previous studies, this meta-analysis took patients'

characteristics into consideration and gave suggestions for the optimum management of different patients.

Concerning stone clearance from the CBD, this meta-analysis demonstrated that single-stage (LC + LCBDE) management was as effective as two-stage (LC + ERCP/EST) management (P = 0.17), but one trial[29] was more strongly in favor of the single-stage (LC + LCBDE) management than any other included studies. One possible reason was that they abandoned ERCP/EST at an earlier stage when they detected multiple and large stones in the CBD, and they favored a transductal approach if the bile duct diameter was large or if the stones were large and multiple. Another reason might be the use of intention-to-treat analysis. Our meta-analysis showed that the difference in the length of hospital stay between the two groups was not statistically significant (P = 0.45). Two of the included trials reported that the length of hospital stay was shorter for the single-stage (LC + LCBDE) approach with a statistically significant difference compared with the two-stage (LC + ERCP/EST) management[24,25]. Other studies showed that there was no significant difference between the two groups, but a recent review suggested that single-stage management had the potential merit of a shorter hospital stay[45]. One probable reason was that the definitions of hospital stay varied, which had an impact on the validity of the data. Some trials defined it as the duration from the last finished procedure to discharge, while other trials defined it as the entire duration from hospital admission to discharge. Another explanation for the discrepancy in the studies might be the use of data conversions to produce estimates. In our meta-analysis, only one trial reported hospitalization charges, and there was no significant difference in total hospitalization charges and hospital service charges between the two groups. However, the charges for single-stage (LC + LCBDE) management were lower than those for two-stage (LC + ERCP/EST) management[24]. Other studies[46,47] showed that single-stage management is a cost-effective method compared to two-stage management.

The postoperative morbidity, mortality and total operating time were similar between the two-stage (LC + ERCP/EST) and single-stage (LC + LCBDE) management with no statistically significant difference in this meta-analysis (P = 0.16, P = 0.42 and P = 0.09, respectively). When considering preoperative ERCP/EST + LC *vs* LC + LCBDE and postoperative ERCP/EST + LC *vs* LC + LCBDE separately in the subgroup analysis, the outcomes, as stated, remained consistent.

This meta-analysis was subject to some limitations. First, the funnel plot analysis detected publication bias, which results in over-representation of significant or positive studies. However, the random effects model was utilized for this analysis, and this model is known to enlarge the presence of publication bias by attributing heavier weighting to smaller trials compared to the fixed effects models. Second, the different methodological quality and the heterogeneity of the effect after intervention could also account for the asymmetry in the funnel plot. A

second potential limitation was the presence of significant heterogeneity for three outcomes, including stone clearance from the CBD, conversion to other procedures and length of hospital stay, which might influence the reliability and validity of the conclusions to some extent. Finally, the restriction of only including studies published in English was another possible limitation.

For future research studies on this topic, the following suggestions may be helpful (1) hospitalization expenses data were available in only one included trial, which was far from sufficient, and future studies should evaluate this significant endpoint; (2) follow-up was poorly reported in most of the included trials, and long-term outcomes, which largely rely on the follow-up, are as yet unknown. Future trials should strengthen the work of follow-up; (3) future studies need to assess outcomes such as pain scores, health economics, patients satisfaction and quality of life scores because it is more practical for patients to choose their optimal treatment; (4) blinded outcome assessment should be employed in future trials to better reduce bias; and (5) as a result of the different data types provided by the included trials, the outcomes, including the length of hospital stay and total operative time were weakened. Thus, future researchers should use unified data types.

In conclusion, single-stage (LC + LCBDE) management is not only as effective as two-stage (LC + ERCP/EST) management and equivalent in terms of postoperative morbidity, mortality and conversion, but it also reduces the number of procedures used per patient and potentially shortens the length of hospital stay. In addition, single-stage (LC + LCBDE) management also eliminates the underlying risk of ERCP/EST and keeps the sphincter of Oddi intact. It is likely that as laparoscopic expertise and operators' experience improve, the need for two-stage (LC + ERCP/EST) management will decrease, and single-stage (LC + LCBDE) management should be ultimately available for most patients. However, the optimal management of patients with CBDS should depend on the condition of patients, the expertise of operators and local resources.

ACKNOWLEDGMENTS

COMMENTS

Background

Patients with concomitant gallstones and common bile duct stones (CBDS) are very common, but surgeons and patients are often faced with difficulties in making treatment decisions when choosing the optimal treatment. Previously published trials were inconclusive as to whether two-stage [laparoscopic cholecystectomy (LC) + preoperative endoscopic retrograde cholangiopancreatography (ERCP)/endoscopic sphincterotomy (EST)] management is better or worse than single-stage [LC + laparoscopic common bile duct exploration (LCBDE)] management. The authors in this study conducted a systematic review and meta-analysis to provide the current best evidence for the management of patients with concomitant gallstones and CBDS.

Research frontiers

Both two-stage (LC + ERCP/EST) and single-stage (LC + LCBDE) management are used for the patients with concomitant gallstones and CBDS. Two-stage (LC + ERCP/EST) management has become very popular in recent years, because it is considered to be safe and effective that can reduce the number of procedures used per patient.

Innovations and breakthroughs

This systematic review and meta-analysis summarized all available randomized controlled trials (RCTs) comparing the two techniques. The authors found that single-stage (LC + LCBDE) management was as effective as two-stage (LC + ERCP/EST) management and required fewer procedures used per patient.

Applications

Single-stage (LC + LCBDE) management is proven to be a safe and effective treatment compared with two-stage (LC + ERCP/EST) management, and it should be recommended for patients with concomitant gallstones and CBDS.

Terminology

ERCP: a technique that combines the use of endoscopy and fluoroscopy to diagnose and treat certain problems of the biliary or pancreatic ductal systems; EST: a minimally invasive surgery that was developed on the basis of ERCP to treat biliary or pancreatic ductal disease; LC: a technique that removes the gallbladder through small punctures in the abdomen to permit the insertion of a laparoscope and surgical instruments; LCBDE: a technique that combines the use of laparoscopy and choledochoscopy to treat biliary tract disease, especially CBDS.

Peer review

This is a good descriptive study in which authors evaluate the safety and effectiveness of two-stage *vs* single-stage management for concomitant gallstones and CBDS. The results are interesting and suggest that two-stage (LC + ERCP/EST) management clearly required more procedures per patient than single-stage (LC + LCBDE) management.

Abstract

AIM: To investigate prescribing pattern in low-dose aspirin users and physician awareness of preventing aspirin-induced gastrointestinal (GI) injury with combined protective medications.

METHODS: A retrospective drug utilization study was conducted in the 2nd Affiliated Hospital, School of Medicine, Zhejiang University. The hospital has 2300 beds and 2.5 million outpatient visits annually. Data mining was performed on all aspirin prescriptions for outpatients and emergency patients admitted in 2011. Concomitant use of proton-pump inhibitors (PPIs), histamine 2-receptor antagonists (H2RA) and muco-protective drugs (MPs) were analyzed. A defined daily dose (DDD) methodology was applied to each MP. A further investigation was performed in aspirin users on combination use of GI injurious medicines [non-steroid anti-inflammatory drugs (NSAIDs), corticosteroids and clopidogrel and warfarin] or intestinal protective drugs (misoprostol, rebamipide, teprenone and gefarnate). Data of major bleeding episodes were derived from medical records and adverse drug reaction monitoring records. The annual incidence of major GI bleeding due to low-dose aspirin was estimated for outpatients.

RESULTS: Prescriptions for aspirin users receiving PPIs, H2RA and MPs (n = 1039) accounted for only 3.46% of total aspirin prescriptions (n = 30 015). The ratios of coadministration of aspirin/PPI, aspirin/H2RA, aspirin/MP and aspirin/PPI/MP to the total aspirin prescriptions were 2.82%, 0.12%, 0.40% and 0.12%, respectively. No statistically significant difference was observed in age between patients not receiving any GI protective medications and patients receiving PPIs, H2RA or MPs. The combined medication of aspirin and PPI was used more frequently than that of aspirin and MPs (2.82% *vs* 0.40%, P < 0.05) and aspirin/H2RA (2.82% *vs* 0.12%, P < 0.05). The values of DDDs of MPs in descending order were as follows: gefarnate, hydrotalcite > teprenone > sucralfate oral suspension > L-glutamine and sodium gualenate granules > rebamipide > sucralfate chewable tablets. The ratio of MP plus aspirin prescriptions to the total MP prescriptions was as follows: rebamipide (0.47%), teprenone (0.91%), L-glutamine and sodium gualenate granules (0.92%), gefarnate (0.31%), hydrotalcite (1.00%) and sucralfate oral suspension (0.13%). Percentages of prescriptions containing aspirin and intestinal protective drugs among the total aspirin prescriptions were: rebamipide (0.010%), PPI/rebamipide (0.027%), teprenone (0.11%), PPI/teprenone (0.037%), gefarnate (0.017%), and PPI/gefarnate (0.013%). No prescriptions were found containing coadministration of aspirin and other NSAIDs. Among the 3196 prescriptions containing aspirin/clopidogrel,

3088 (96.6%) prescriptions did not contain any GI protective medicines. Of the 389 prescriptions containing aspirin/corticosteroids, 236 (60.7%) contained no GI protective medicines. None of the prescriptions using aspirin/warfarin (*n* = 22) contained GI protective medicines. Thirty-five patients were admitted to this hospital in 2011 because of acute hemorrhage of upper digestive tract induced by low-dose aspirin. The annual incidence rates of major GI bleeding were estimated at 0.25% for outpatients taking aspirin and 0.5% for outpatients taking aspirin/warfarin, respectively.

CONCLUSION: The prescribing pattern of low-dose aspirin revealed a poor awareness of preventing GI injury with combined protective medications. Actions should be taken to address this issue.

INTRODUCTION

We read with great interest in the study by Mizukami *et al*[1], who evaluated the influence of taking low-dose aspirin for 4 wk on small intestinal injury and examined the preventive effect of rebamipide. The results showed that long-term aspirin induced small bowl damage (7 cases with a mucosal break at 4 wk on the ileum and 1 on the jejunum at 4 wk among 11 healthy subjects) and rebamipide significantly prevented this damage, and it may be a candidate drug for treating aspirin-induced small bowel complications.

Long-term low-dose aspirin (75-325 mg) has been increasingly prescribed to elderly patients for primary and secondary prevention of cardiovascular and cerebral diseases. Nonetheless, aspirin's efficacy in such disease prevention is limited by the risk of gastrointestinal (GI) injury. Aspirin treatment can increase the GI risk by 2-fold in middle-aged patients without a prior history of peptic ulcer and without using concomitant drugs[2]. Compared

with low-dose aspirin monotherapy, the risk of upper GI injury increased when low-dose aspirin was used in combination with clopidogrel [relative risk (RR), 2.08], oral anticoagulants (RR, 2.00), nonsteroidal antiinflammatory drugs (NSAIDs) (RR, 2.63), or high-dose oral corticosteroids (RR, 4.43)[3]. While the aspect on preventing upper GI complications induced by aspirin[4-7] was emphasized, the study by Mizukami *et al*[1] has reminded us of attaching equal importance to prevention of small bowel injury. We have investigated the status of prescribing pattern of low-dose aspirin in an attempt to recommend the use of combined therapy of proton-pump inhibitors (PPIs), histamine 2-receptor antagonists (H2RA) or mucoprotective drugs (MPs) to prevent aspirin-induced GI injuries. We would discuss and share our perspectives below.

MATERIALS AND METHODS

The prescribing pattern of low-dose aspirin was investigated from the perspective of concomitant use of PPIs, H2RA or MPs in the 2nd Affiliated Hospital, School of Medicine, Zhejiang University. The hospital has 2300 beds and 2.5 million outpatient visits annually. Prescription data was obtained from the hospital information system and processed with Visual FoxPro 9.0. Statistical analysis was performed on the number of prescriptions with aspirin, aspirin/PPI, aspirin/H2RA, aspirin/MP, aspirin/PPI/MP and aspirin/H2RA/MP for outpatients and emergency patients admitted in 2011.

Oral PPIs included omeprazole (or magnesium salt), pantoprazole (or sodium salt), rabeprazole, lansoprazole and esomeprazole magnesium. Intravenous PPIs included omeprazole sodium, pantoprazole sodium and esomeprazole sodium. MPs included teprenone, L-glutamine and sodium gualenate granules (Marzulene-S®), misoprostol, rebamipide, gefarnate, sucralfate oral suspension, hydrotalcite and sucralfate chewable tablets.

Annual amount of each MP consumed was calculated. A defined daily dose (DDD) methodology was applied[8]. The DDD value of each MP was derived from its package insert. DDDs and daily expenditure were estimated using the following equations:

DDDs = Total dosage (amount of drug consumed)/DDD

Daily expenditure = Overall expenditure/DDDs

A further investigation was performed in aspirin users taking GI injurious medicines (NSAIDs, corticosteroids, clopidogrel and warfarin) or intestinal protective drugs (misoprostol, rebamipide, teprenone and gefarnate) which prevented small bowel injury induced by low-dose aspirin or other NSAIDs in human[1,9-12] or rats[13,14]. Data of major bleeding episodes were derived from the medical records and adverse drug reaction monitoring records. The annual incidence of major GI bleeding due to low-dose aspirin was estimated for outpatients.

Age differences between patient groups were tested using Student's *t* test. χ^2 test was used for comparisons of ratios of prescriptions with combined aspirin and other drugs to the total aspirin prescriptions. Difference

was considered statistically significant at $P < 0.05$ for all analyses.

RESULTS

Prescriptions for aspirin users receiving PPIs, H2RA and MPs (n = 1039) only accounted for 3.46% of total aspirin prescriptions (n = 30 015). Among 1039 patients, there were 924 (88.5%) patients on 100 mg aspirin, 108 (10.8%) patients on 200 mg aspirin and 7 (0.7%) patients on 300 mg aspirin. No statistically significant difference in age was observed between patients not receiving any GI protective medications (n = 28 976, aged 63.3 ± 12.4 years) and patients receiving PPIs, H2RA or MPs (n = 1039, 61.8 ± 17.9 year) ($P > 0.05$).

Coadministration of aspirin/PPI, aspirin/H2RA, aspirin/MP and aspirin/PPI/MP accounted for 2.82%, 0.12%, 0.40% and 0.12%, respectively of the total aspirin prescriptions (Table 1). Combined use of aspirin/PPI was more frequent than that of aspirin/MP (2.82% *vs* 0.40%, $P < 0.05$) and aspirin/H2RA (2.82% *vs* 0.12%, $P < 0.05$). Combined therapy of aspirin and two MPs was not found among the prescriptions.

Prescriptions with combination use of pantoprazole, esomeprazole and rabeprazole accounted for 82.6% of all prescriptions containing aspirin/oral PPIs. Omeprazole only accounted for 17.1%.

Pharmacoeconomic indices of MPs for outpatients are listed in Table 2. The values of DDDs of MPs in descending order were as follows: gefarnate, hydrotalcite > teprenone > sucralfate oral suspension > L-glutamine and sodium gualenate granules > rebamipide > sucralfate chewable tablets.

The total dosage (amount of drug consumed) of misoprostol in 2011 was 564.6 mg. However, misoprostol was prescribed for termination of early pregnancy in combination with mifepristone instead of indication for reducing the risk of NSAIDs-induced GI injury. No combined use of misoprostol and aspirin was found among the prescriptions.

The ratio of amount of MP comedicated with aspirin to total amount of MP consumed in 2011 was 0.47% (rebamipide), 0.91% (teprenone), 0.92% (marzulene-S), 0.31% (gefarnate), 1.00% (hydrotalcite) and 0.13% (sucralfate oral suspension), respectively.

Percentages of precriptions containing aspirin and intestinal protective drugs to the total aspirin prescriptions were: aspirin/rebamipide (n = 3, 0.010%), aspirin/PPI/rebamipide (n = 5, 0.027%); aspirin/teprenone (n = 33, 0.11%), aspirin/PPI/teprenone (n = 11, 0.037%), aspirin/gefarnate (n = 5, 0.017%), and aspirin/PPI/gefarnate (n = 4, 0.013%).

No prescriptions were found containing coadministration of low-dose aspirin and other NSAIDs. There were 3196 prescriptions with concomitant use of aspirin/clopidogrel in 2011. However, only 108 (3.4%) prescriptions contained aspirin/clopidogrel/PPI (n = 101), aspirin/clopidogrel/MP (n = 4) and aspirin/ clopidogrel/PPI/MP (n = 3). None of 3088 (96.6%) prescriptions

Table 1 Concomitant use of proton-pump inhibitors, H2-receptor antagonists or mucoprotective drugs in patients taking low-dose aspirin

Drug name	Number of prescriptions	Percentage of prescriptions with combination therapy to total aspirin prescriptions (%)
H2RA	36	0.12[a]
Oral PPIs	708	2.36
Pantoprazole	342	1.14
Esomeprazole	157	0.52
Omeprazole	121	0.40
Rabeprazole	85	0.28

Sucralfate chewable tablet	13 950	4	3488	3600	1.0

MPs: Mucoprotective drugs; DDD: Defined daily dose; CNY: China Yuan.

contained any GI protective medications. PPIs coadministered with aspirin and clopidogrel included: oral pantoprazole (n = 58), esomeprazole (n = 32), i.v. pantoprazole (n = 9) and rabeprazole (n = 2). No prescriptions were found containing aspirin/clopidogrel/ omeprazole.

There were 389 prescriptions with concomitant use of aspirin/corticosteroids (prednisone, methylpredisolone and dexamethasone) in 2011. However, only 153 (39.3%) prescriptions contained aspirin/corticosteroid/

PPI (*n* = 148), aspirin/ corticosteroid/MP (*n* = 4) and aspirin/corticosteroid/PPI/MP (*n* = 1). Two hundred and thirty-six prescriptions (60.7%) did not contain any GI protective medications.

There were 22 prescriptions with concomitant use of aspirin/warfarin in 2011. Again, none of these prescriptions contained GI protective medications.

There were 35 patients admitted to this hospital because of acute hemorrhage of upper digestive tract induced by low-dose aspirin in 2011. The annual incidence rates of major GI bleeding were estimated at 0.25% for outpatients on aspirin and 0.5% for outpatients on aspirin/warfarin, respectively. For example, an 81-year-old male patient with coronary artery disease treated by percutaneous coronary interventions and arterial embolism of lower limb, received aspirin (100 mg, q.d.), warfarin (3 mg, q.d.), clopidogrel (75 mg, q.d.) and beraprost sodium (20 μg, t.i.d.) but without concomitant use of any PPIs or MPs. Two weeks later he was sent to the Emergency Center because of GI hemorrhage. Aspirin therapy was stopped and the patient was treated with i.v. pantoprazole. Five days later, he was discharged and continued to take oral pantoprazole (40 mg, q.d.) and rebamipide (0.1 g, t.i.d.) plus warfarin and clopidogrel. No adverse GI event was observed.

DISCUSSION

Yamamoto *et al*[5] examined the effects of gastroprotective drugs on aspirin-related gastroduodenal toxicity in 530 patients who had taken low-dose aspirin for 1 mo or more. Use of a PPI alone was significantly more protective against bleeding (9.3% *vs* 2.1%, *P* < 0.01) and mucosal injury (49.1% *vs* 18.6%, *P* < 0.01) than non-use of any gastroprotective medicine. Among the background characteristics, such as *Helicobacter pylori* infection, concomitant use of anticoagulants, anti-platelet agents, NSAIDs and PPI, a bleeding history, age and gender, only the co-administration of a PPI was found significantly associated with reduced bleeding events. Patients taking any medicine PPI, H2RA, MP, PPI (or H2RA) plus MP showed significantly better outcomes with respect to mucosal injury as compared with the patients not receiving any gastroprotective medication.

Our study indicated that only 3.46% of the patients taking low-dose aspirin received concurrent therapy of PPI, H2RA and MPs. Thus it is imperative to enhance the awareness of preventing GI injury induced by low-dose aspirin among both physicians and patients.

The combined therapy of aspirin and PPI was more frequently used than that of aspirin and MPs (2.82% *vs* 0.40%, *P* < 0.05) and aspirin/H2RA (2.82% *vs* 0.12%, *P* < 0.05) in this hospital and it may be due to the more potent effects of PPIs in prevention of NSAIDS-related GI injuries[15]. However, Nema *et al*[7] observed that the healing rate of gastroduodenal ulcers during continuous use of low-dose aspirin was higher than 80% in both the PPI group and the H2RA group, with no significant difference between the two groups. Nakashima *et al*[16] con-

cluded that H2RA may be the most beneficial drug for both the prevention and treatment of low-dose aspirin-induced peptic ulcers, in which it has the similar anti-ulcer effects to PPIs, but with lower cost and fewer adverse effects as compared with PPIs and prostaglandins.

Concomitant use of NSAIDs, corticosteroids, clopidogrel or anticoagulants increases GI risk further in patients on low-dose aspirin[2-4]. A meta-analysis by Lanas *et al*[4] showed that the risk for GI bleeding in aspirin users increased with concomitant use of clopidogrel and anticoagulant therapies, but decreased in patients who took PPIs. Astoundingly, our investigation showed that 96.6% of patients on aspirin plus clopidogrel, 60.7% of patients on aspirin plus oral corticosteroids and 100% of patients on aspirin plus warfarin did not receive any GI protective medications.

The anti-platelet effect of clopidogrel was activated by biotransformation *via* CYP2C19 and CYP3A4. Different PPIs have different effects on CYP2C19. It has been generally acknowledged that drug interaction between omeprazole and clopidogrel was of clinically significance and can reduce the efficacy of clopidogrel[17]. Pantoprazole, esomeprazole and rabeprazole were alternatives[18-20]. Coadministration of aspirin, clopidogrel and omeprazole was not observed in this study, indicating that this hospital is good at clopidogrel therapy management.

DDDs values of seven mucoprotective drugs were compared. Gefarnate's DDDs ranked first and this result may be associated with its relatively low price. Teprenone's DDDs ranked second. Murakami *et al*[21] concluded that the effects of teprenone on aspirin-induced gastric ulcers in rats were more potent and more definite than those of gefarnate. Fang *et al*[14] reported that teprenone (15.63 mg/kg daily) and gefarnate (31.25 mg/kg daily) can exert protective effects against the intestinal injury induced by NSAIDs in rats. Niwa *et al*[12] found that teprenone (300 mg/d) reduced diclofenac-induced gastric and small intestinal injuries in 10 healthy volunteers (*P* < 0.05). Shiotani *et al*[22] reported that 1 wk administration of low-dose aspirin to 20 healthy volunteers was associated with visible small bowel damage in the majority of users whereas teprenone (150 mg/d) could not prevent aspirin-induced small bowel injury. The inconsistent findings about the preventive effects of teprenone against small intestinal injury may be associated with the dosage of teprenone, sample size of clinical trials and species differences. Although gefarnate used 50 mg twice daily was inferior to lansoprazole at 15 mg daily in reducing the risk of gastric or duodenal ulcer recurrence in patients with a definite history of gastric or duodenal ulcers who required long-term low-dose aspirin therapy[23], the proven effects of gefarnate in prevention of small intestinal injury induced by NSAIDs in rats provoked further investigations on whether gefarnate could prevent small intestinal injury in aspirin users.

Sucralfate is proved to have protective effects against NSAID-associated ulcer due to the enhanced prostaglandin synthesis, increased mucus secretion, suppression of pro-inflammatory cytokines such as tumor necrosis

factor-α (TNF-α), and induction of constitutive nitric oxide synthase as well as its antioxidant capability[24]. Although it had the lowest daily expenditure, sucralfate chewable tablets had the lowest DDDs value. The DDDs value of sucralfate oral suspension was 16 times more than that of sucralfate chewable tablets, although oral suspension had a higher daily expenditure than chewable tablets. In this investigation, we observed that some patients swallowed the chewable tablets directly without chewing, and this implies that sucralfate suspension has a better medication compliance than chewable tablets.

Misoprostol exerts a protective effect on the gastrointestinal mucosa by increasing mucus and bicarbonate ion secretion as well as mucosal blood flow. In addition, it inhibits acid secretion. Watanabe *et al*[9] reported that misoprostol 200 μg 4 times a day could effectively prevent aspirin-induced small intestinal injuries. However, drug compliance of misoprostol was not good due to its side effects and dosing frequency. In clinical trials, misoprostol-induced diarrhoea occurred in approximately one-tenth of the patients despite that it was usually mild and self-limiting. Donnelly *et al*[25] conducted a double-blind placebo-controlled parallel group endoscopic study in 32 healthy volunteers over 28 d and concluded that low-dose misoprostol 100 μg daily can prevent the gastric mucosal injury induced by aspirin 300 mg daily without causing identifiable adverse effects. However, many physicians seem unaware of misoprostol use at such a low-dose. Off-label use of misoprostol (Cytotec®, Piramal Healthcare Ltd., United Kingdom) is very common in China. In this investigation, all of Cytotec® was prescribed for termination of early pregnancy in combination with mifepristone. Thus misoprostol was eliminated by the Drug and Therapeutics Committee of this hospital in September 2011.

Rebamipide provides mucoprotective effect by inducing the production of intracellular prostaglandins and epidermal growth factor, improving blood flow, suppressing increases in permeability, scavenging free radicals and exerting anti-infammatory effect[1]. Yamamoto *et al*[5] reported that in the patients taking rebamipide concomitantly with PPIs, aspirin-induced gastroduodenal mucosal injuries occurred less frequently than in those taking PPIs plus MPs other than rebamipide (14.8% *vs* 38.1%, *P* < 0.01). From this viewpoint, rebamipide had an obvious advantage over other MPs. Mizukami *et al*[1] proved that rebamipide could prevent effectively aspirin-induced small bowel injury. If the exciting finding of this research can be applied to routine clinical practices, good clinical outcomes would be anticipated in patients taking low-dose aspirin.

Our investigation indicated a 0.25% incidence of upper GI bleeding in the low-dose aspirin users, a value nearly four times that of the documented baseline rate of 0.06% noted for the general population without medications or conditions predisposing to bleeding[26], suggesting that low-dose aspirin users did have a relative higher risk of GI injury.

Physician education and computer alert were proved to improve targeted use of gastroprotection among NSAID users[27]. The poor awareness of preventing aspirin-induced GI injury with combined protective medications has attracted the attention of the Drug and Therapeutics Committee of this hospital. Actions to address this issue include academic lectures and computer alert to encourage prescriptions of GI protecting agents, a multidisciplinary team building and initiation of risk-benefit long-term study on the association between increase in expenditure of GI protecting agents and outcomes such as significant reduction in hospital admissions/stays related to GI bleeding.

In conclusion, the study of Mizukami *et al*[1] inspired us to perform this retrospective drug utilization study on the prescribing pattern of low-dose aspirin from the perspective of combined therapy in a large university teaching hospital in China. The results of our survey indicated the poor awareness of preventing gastric and small intestinal injury in patients taking low-dose aspirin with combined protective medications. Good clinical outcomes would be anticipated in aspirin users, especially in patients with a high risk of GI injury, given that the importance of administration of gastroduodenal protective PPIs and intestinal protective rebamipide as well as other GI mucoprotectives is being recognized.

COMMENTS

Background
Low-dose aspirin is currently recommended for the secondary prevention of cardiovascular and cerebral diseases. However, gastroduodenal mucosal injury may be induced by aspirin and concomitant use of non-steoid anti-inflammatory drugs, corticosteroids, clopidogrel or anticoagulants further increases gastrointestinal (GI) risk in patients taking low-dose aspirin. Concomitant use of proton-pump inhibitors (PPIs), histamine 2-receptor antagonists (H2RA) and mucoprotective drugs (MPs) with aspirin can help prevent GI injuries. Recently, aspirin-induced small bowel injuries have attracted clinical attention and preventive effects of some MPs have been observed. This may enhance the awareness of preventing aspirin-induced GI injury with combined protective medication in clinical practice.

Research frontiers
A retrospective drug utilization study on prescribing pattern of low-dose aspirin from the perspective of combination therapy was conducted in a large university teaching hospital of China. Clinical awareness of preventing aspirin-induced GI injury with combined protective medications was evaluated systematically.

Innovations and breakthroughs
The ratio of prescriptions for aspirin users receiving PPIs, H2RA and MPs to the total aspirin prescriptions was revealed for the first time. The survey indicated a poor awareness of preventing gastric and small intestinal injury in patients taking low-dose aspirin with combined protective medications. Combined use of GI injurious medicines or intestinal protective drugs in aspirin users was investigated. The annual incidence of major GI bleeding due to low-dose aspirin was also estimated in the outpatients admitted to the the hospital in 2011. Additionally, a defined daily dose (DDD) methodology was applied to study the prescription pattern.

Applications
The findings of the study will enhance the awareness of preventing aspirin-induced GI injury with combined protective medications from physicians, pharmacists and nurses. Good clinical outcomes would be anticipated in aspirin users, especially in patients with a high risk of GI injury, as the importance of gastroduodenal protective PPIs and intestinal protective rebamipide as well as other MPs is being recognized. Actions should be taken such as encouraging prescription of GI protective agents, building a multi-disciplinary team and initiating a risk-benefit long-term study on the association between increase in

expenditure of GI protective agents and outcomes such as significant reduction in hospital admissions/stays related to GI bleeding.

Terminology

The DDD, a statistical measure of drug consumption, is the assumed average maintenance dose per day for a drug used for its main indication in adults. DDDs value is determined by the formula: DDDs = annual consumption of a drug/drug DDD value. Higher DDDs value means that the drug is prescribed more frequently. Drug utilization studies aim to evaluate the factors related to the prescription, dispensation, administration and intake of medicines and its associated events (either beneficial or adverse).

Peer review

This is a very relevant piece of work summarizing the prescription pattern of low-dose aspirin. Combination use of GI injurious medicines or intestinal protective drugs in aspirin users was also investigated. Based on retrospective data obtained from large number of patients in China, the authors conclude that there is a need for increasing the awareness of preventing aspirin-induced GI injury by concomitant use of gastroduodenal or small intestinal protective agents. The manuscript is very well written, very interesting for the readers.

Abstract

A desmoid tumor, also known as aggressive fibromatosis, is a rare benign neoplasm that arises from fascial or musculoaponeurotic tissues. It can occur in any anatomical location, most commonly the abdominal wall, shoulder girdle and retroperitoneum. The typical clinical presentation is a painless mass with a slow and progressive invasion of contiguous structures. It is associated with a high local recurrence rate after resection. Many issues regarding the optimal treatment of desmoid tumors remain controversial. Aggressive surgical resection with a wide margin (2-3 cm) remains the gold standard treatment with regard to preserving quality of life. Radiotherapy alone has been shown to be effective for the control of unresectable or recurrent lesions. Desmoid tumors tend to be locally infiltrative, therefore, the fields must be generous to prevent marginal recurrence. The radiation dose appropriate for treating desmoid tumors remains controversial. We present a 25-year-old Caucasian man with local recurrence of a desmoid tumor after repeated surgical resection, treated with radiotherapy. The patient achieved complete tumor regression at 4 mo after radiotherapy, and he is clinically free of disease at 12 mo after the end of treatment, with an acceptable quality of life. The patient developed short bowel syndrome as a complication of second surgical resection. Consequently, radiotherapy might have worsened an already present malabsorption and so led to steatohepatitis.

Key words: Desmoid tumor; Aggressive fibromatosis; Fatty liver

INTRODUCTION

A desmoid tumor, also known as aggressive fibromatosis, is a rare benign neoplasm that arises from fascial or musculoaponeurotic tissues. It is usually associated with preneoplastic conditions, such as familial adenomatous polyposis and Gardner syndrome. The sporadic form is uncommon, presenting with a mass, sometimes associated with pain and weight loss. It can occur in any anatomical location, but most commonly in the abdominal wall, shoulder girdle and retroperitoneum. Histological

analysis of this type of tumor reveals mesenchymal characteristics, a lack of mitotic activity, and cellular pleomorphism[1-4]. Although desmoid tumors are considered benign, without the ability to metastasize, they do have significant potential for local invasiveness and recurrence[5,6].

We present a case of local recurrence after aggressive surgical resection in a 25-year-old man.

CASE REPORT

A 25-year-old Caucasian man presented to our department with a histologically confirmed diagnosis of local recurrence of sporadic desmoid tumor. The patient's disease dated back 2 years, when the patient was admitted to another hospital because of pain in the right anterolateral abdomen. Abdominal computed tomography (CT) revealed a large solid mass (22 cm × 10 cm × 15 cm) with mild enhancement and density equal to that of soft tissue. The mass appeared to arise from the retroperitoneum and caused superior displacement of the stomach and adjacent bowel loops. There was no pathological lymphadenopathy (Figure 1A).

There was no known history of familial polyposis and no medical history of any abdominal trauma or surgery. His blood parameters were normal, and laboratory studies showed normal renal function and electrolytes.

Radical surgical resection was performed, including 30 cm of small intestine and right hemicolectomy, which was necessary to obtain a wide margin. The histological diagnosis was desmoid tumor. There were no complications in the postoperative phase.

After 10 mo, the patient came to our hospital because of persistent diarrhea. A CT scan was performed, which demonstrated a perianastomotic solid mass (13 cm × 11 cm × 10 cm) arising from the mesentery. The mass caused displacement of the common iliac artery and spread downward to the psoas muscle, without infiltrating it (Figure 1B). A second surgical resection was performed, without complications, including anastomosis and part of the intestinum tenue. The histological diagnosis was aggressive fibromatosis, with uninvolved surgical margins. The patient tolerated the surgical excision of the mass, but he had a nutritional examination because of short bowel syndrome acquired due to the surgery (leaving a residual 75 cm of small intestine). The patient received an optimized dietary and medication plan.

One month later, the patient underwent an abdominal CT scan that revealed an oval mass with a diameter of 18 mm in the mesenteric root, close to the metallic clips of the second surgical excision. This mass was open to a different interpretation. Therefore, the patient underwent an oncological examination, and as we suspected, it was found to be a recurrent lesion. We also recommended a biopsy. The test reported a histological diagnosis of desmoid tumor, and the patient was treated with curative radiotherapy. He received 3D-conformal external beam irradiation using megavoltage photon and conventional fractionation: 2 Gy daily for 5 d/wk, for a total dose of 50 Gy. The planned target volume included the previous tumor bed and actual relapse. Acute toxicity was observed, primarily as a function of the volume of the radiation field. After 2 wk of radiotherapy, the treatment was interrupted for 13 d because of grade 3 gastrointestinal toxicity, according to the Common Terminology Criteria for Adverse Events v3.0. The patient had progressive weight loss, fatigue and severe radiation enterocolitis, resulting in urgency, increased frequency (> 7/d) and decreased consistency of bowel movements. The radiotherapy was temporarily interrupted, and the patient received parenteral nutrition for 1 wk.

We radiologically assessed the response to radiotherapy after 4, 8 and 12 mo, and the outcome was complete remission. It is important to note that abdominal CT carried out 8 mo after the end of radiotherapy revealed liver alterations with no distinguishing marks (Figure 2). Such alteration had not been observed in previous examinations; therefore, the patient underwent magnetic resonance imaging and then liver biopsies, because the first was not sufficient to clarify the situation (Figure 2). The histological diagnosis was macrovesicular and microvesicular steatosis. Radiotherapy increases the risk of hepatobiliary complications in short bowel syndrome, therefore, a wait-and-see approach, consisting of radiological and clinical evaluations performed every 3 mo, was chosen. The patient achieved complete tumor regression at 4 mo after radiotherapy, and he is clinically free of disease at 12 mo after the end of treatment, with an acceptable quality of life.

DISCUSSION

The definition of a rare tumor is based on an incidence of ≤ 3/100 000/year[7]. Desmoid tumors fall under this category because they have an annual incidence of 0.2-0.4/100 000 population. For that reason, desmoids are not extensively discussed in the literature: most reports are case reports[1,3,8-11], and some are retrospective analyses[5,6,12,13], but randomized series do not exist.

The etiopathogenesis is poorly defined; trauma, endocrine factors and genetic predisposition all seem to play important roles in the development of the disease. It is significantly associated with familial adenomatous polyposis and has a more pronounced association with the subgroup of Gardner syndrome. Desmoid tumors are a fibroblastic proliferations that arise mainly from fascial or musculoaponeurotic structures. The typical clinical presentation is a painless mass with a slow and progressive invasion of contiguous structures, and it is associated with a high local recurrence rate after resection. Factors predictive of relapse include an age between 18 and 30 years, a tumor size > 8 cm, incomplete resection, or close positive margins, and no adjuvant radiotherapy for gross residual disease[5,6,12].

The rarity of these tumors, coupled with the variability in their clinical course, has prevented the demonstration

Figure 1 Abdominal computed tomography of desmoid tumour. A: A solid large mass (22 cm × 10 cm × 15 cm) with density equal to that of soft tissue; B: A peri-anastomotic solid mass (13 cm × 11 cm × 10 cm) arising from the mesentery.

Figure 2 Fatty liver. Abdominal computed tomography (A) and magnetic resonance imaging (B) demonstrated liver alterations with no distinguishing marks.

of the efficacy of any specific intervention[13]. Many issues regarding the optimal treatment of desmoid tumors remain controversial. However, true R0 margins are difficult to achieve because of the indistinct borders in this type of tumor[14,15]. Aggressive surgical resection with a wide margin (2-3 cm) remains the gold standard treatment with regard to the preservation of quality of life[16].

Radiotherapy alone has been shown to be effective for the control of unresectable or recurrent lesions. In 1928, Ewing *et al* proposed radiotherapy as a treatment modality for the management of these lesions and reported that desmoid tumors respond slowly but satisfactorily to radiation[16]. In subsequent years, several studies[17-20] have confirmed that radiotherapy can result in lasting local control in inoperable or incompletely resected tumors. A comparative review of 22 articles[12] has shown that radiotherapy, delivered as a single modality or as an adjuvant treatment, resulted in significantly better local control than surgery alone (78%, 75% and 61%,

respectively). However, the role of radiotherapy in the management of desmoid tumors is still not defined.

Strong indications for radiotherapy include unresectable lesions, macroscopic or microscopic residual disease after resection and recurrent tumors.

The radiation dose appropriate for treating desmoid tumors remains controversial. Ballo *et al*[14] have demonstrated that doses of 56 Gy at 2 Gy per fraction (equivalent to approximately 60 Gy at 1.8 Gy per fraction) produce significantly higher control rates than doses ≤ 50 Gy. In other published studies[17,19-22], patients were treated with doses of 50-60 Gy. To date, no improvement of results with total doses higher than 60 Gy has been observed, while an increased incidence of radiation-related toxicity has been documented[12-15,17,20]. As desmoid tumors tend to be locally infiltrative, the fields must be generous to prevent marginal recurrence. Of course, normal tissue toxicity and potential late radiation effects are important to consider in the treatment. Radiotherapy for gross dis-

ease is associated with a relatively high rate of complications, which are dose-dependent. Complications have included edema, fibrosis, ulcers, paraesthesia and secondary malignancy[8]. Radiation enteritis and radiation-induced liver disease are also potential complications of radiotherapy. In the study of Boland *et al*[23], a total of 48 patients treated with radiotherapy for intra-abdominal malignancy were evaluated: 16 (33%) patients developed short bowel syndrome within 12 mo of treatment. Thompson *et al*[24] found that patients with short bowel syndrome and a history of radiotherapy were more likely to develop cirrhosis and portal hypertension than short bowel syndrome patients not subject to radiotherapy. Although diabetes mellitus and obesity are the conditions most frequently associated with nonalcoholic fatty liver disease, which is histologically defined by the presence of macrovesicular steatosis, intestinal resection has also been recorded as one of the predisposing factors[25]. Our patient, who did not conform to the usual profile of an obese and diabetic man, developed short bowel syndrome as a complication of the second surgical resection. Consequently, radiotherapy might have worsened an already present malabsorption and so led to steatohepatitis. Immediate adjuvant radiotherapy after the first radical surgical approach would likely have produced a better result in terms of toxicity and quality of life, reducing the likelihood of malabsorption due to repeated surgical resections.

Abstract

Rectal perforations due to glycerin enemas (GE) typically occur when the patient is in a seated or lordotic standing position. Once the perforation occurs and peritonitis results, death is usually inevitable. We describe two cases of rectal perforation and fistula caused by a GE. An 88-year-old woman presented with a large rectal perforation and a fistula just after receiving a GE. Her case was further complicated by an abscess in the right rectal wall. The second patient was a 78-year-old woman who suffered from a rectovesical fistula after a GE. In both cases, we performed direct endoscopic abscess lavage with a saline solution and closed the fistula using an over-the-scope-clip (OTSC) procedure. These procedures resulted in dramatic improvement in both patients. Direct endoscopic lavage and OTSC closure are very useful for pararectal abscess lavage and fistula closure, respectively, in elderly patients who are in poor general condition. Our two cases are the first reports of the successful endoscopic closure of fistulae using double OTSCs after endoscopic lavage of the debris and an abscess of the rectum secondary to a GE.

INTRODUCTION

Glycerin enemas (GEs) are widely performed, but rectal perforations secondary to GEs are only occasionally reported[1]. These perforations usually occur when patients are in a seated or lordotic standing position. Once they lead to peritonitis, death is usually inevitable[2]. We successfully performed direct endoscopic abscess lavage and fistula closure using a double over-the-scope-clip (OTSC) technique (Ovesco Endoscopy GmbH, Tuebingen, Germany)[3,4] in two patients with rectal perforation and fistula caused by a GE. These procedures resulted in a dramatic improvement in each patient's condition. Direct endoscopic lavage with a saline solution and double OTSC

closure are very useful for pararectal abscesses and large fistulae closure (greater than 20 mm), respectively, in elderly patients in poor general condition who cannot undergo surgery[5-9].

CASE REPORT

An 88-year-old bedridden woman experienced an acute onset of abdominal pain, high fever and melena. The laboratory examination revealed severe inflammation and anemia [white blood cell (WBC) 23 000/μL, hemoglobin (Hb) 6.6 g/dL, C-reactive protein (CRP) 23 mg/dL]. Three days later, a colonoscopy was performed, revealing a large fistula (20 mm) in the right rectal wall (Figure 1A). Computed tomography also revealed a large abscess in the right rectal wall (6 cm × 3 cm × 3 cm) (Figure 1B). Surgical closure was indicated but was impossible to perform given the patient's poor overall condition. We informed her family that direct endoscopic abscess lavage and fistula closure with an OTSC would thus be required, and written informed consent was obtained from the family. The rectum was thoroughly washed with saline, and an endoscope with a water jet function was inserted into the abscess cavity that resulted from the fistula to wash out and lavage the pus and debris associated with the abscess. The abscess cavity was undercoated with pararectal fat tissue, which bled readily (Figure 2). The fistula was lavaged with 2 L of saline and then closed completely using the OTSC technique (Figure 1C). Five days later, the patient's laboratory parameters had significantly improved (WBC 7800/μL, Hb 8.3 g/dL, CRP 7 mg/dL), and computed tomography revealed the disappearance of the abscess (Figure 1D). The overall time was 10 min, and there were no procedure-related complications. We administered an intravenous drip infusion of cefazolin (2 g/d) for two days following the closure of the fistula.

The second patient was a 78-year-old woman suffering from constipation. After receiving a GE, she experienced sudden, severe and sharp lower abdominal pain, a high fever and melena. Immediately after the onset of this sudden abdominal pain, an emergency colonoscopy revealed a large fistula (25 mm) in the ventral wall of the rectum (Figure 3A). After contrast radiography was used in the colonoscopy, computed tomography revealed the pooling of the radiocontrast agent in the urinary bladder and fistula (Figure 3B). We completely closed the fistula with a series of OTSCs (double OTSCs) (Figure 3C).

Computed tomography revealed the pooling of the radiocontrast agent in the urinary bladder and the complete closure of the fistula with double OTSCs (Figure 3D). The lateral view of the contrast radiography with the colonoscopy revealed a fistula leading to the urinary bladder, with inflowing and pooling of the radiocontrast agent in the urinary bladder (Figure 4A). Given the onset of the patient's symptoms and these findings, we diagnosed a rectovesical fistula secondary to the tip of the GE. Because the fistula was a little larger than the OTSC, the single OTSC closure resulted in 1/3 of the fistula remaining (Figure 4B). We decided to close the fistula us-

Figure 4 The contrast radiography of case 2. A: The lateral view of the contrast radiography and the colonoscopy revealed a fistula communicating with the urinary bladder and the inflowing and pooling of the radiocontrast agent in the urinary bladder (arrow); B: The fistula was slightly larger than the single over-the-scope-clip (OTSC). Single OTSC closure (arrow) resulted in 1/3 of the fistula remaining. Again, the contrast radiography revealed a residual fistula leading to the urinary bladder (arrowheads); C: The remaining fistula was completely closed with double OTSCs. The contrast radiography revealed no fistula leading to the urinary bladder (arrowheads). Tests revealed the successful closure of the fistula without any inflowing of the radiocontrast agent (arrow).

cedure time was 20 min, and there were no procedure-related complications. After this series of OTSC closures, the patient's laboratory data improved significantly, and computed tomography revealed the disappearance of the fistula.

DISCUSSION

In the first case, rectal perforation led to a pararectal abscess. In the second case, the rectal fistula was caused by rectal perforation. Rectal perforation has been reported after GE when patients are in a seated or lordotic standing position[1,2]. We diagnosed the rectal perforation secondary to a GE partly based on the presentation of sudden abdominal pain, melena and a high fever. The perforation rate after a double-contrast barium enema is between 0.02% and 0.24%. Perforation remains an infrequent and almost certainly under-reported complication[3-5]. An iatrogenic perforation caused by a barium or GE as in our cases leads to serious conditions and adverse outcomes in elderly patients who are already in poor general condition.

Figure 3 Colonoscopy and computed tomography of case 2. A: Colonoscopy revealed a large fistula (25 mm) (arrow) in the ventral wall of the rectum; B: Following contrast radiography with a colonoscopy, computed tomography revealed the pooling of the radiocontrast agent in the urinary bladder and fistula (arrow); C: Complete closure of the fistula with a series of over-the-scope-clips (OTSCs) (double OTSCs) was performed (arrow); D: Computed tomography revealed the pooling of the radiocontrast agent in the urinary bladder and the complete closure of the fistula with double OTSCs (arrow).

Although perforation is a severe endoscopic complication, the OTSC procedure is reportedly very useful for the closure of the perforation site[6,7]. The OTSC is an endoscopic tool that allows for the application of a large claw-like clip for the endoscopic closure of full thickness wall defects within the gastrointestinal tract. It is a novel tool that can be safely and successfully employed to en-

doscopically close a fistula of the intestinal tract[8,9]. Studies report that the best indications for the use of OTSC are related to post-surgical fistulae and perforations due to colonoscopy. Defects ranging from 5 to 20 mm in the stomach and from 10 to 30 mm in the colon can be closed with a single OTSC, but tissue defects larger than 20-30 mm may require more than one OTSC to achieve adequate closure[10-15]. We successfully closed a perforation larger than 20 mm using a single OTSC and assessed the healing of the fistula by endoscopic or radiological means. Direct endoscopic lavage with a saline solution and double OTSC closures are very useful for the management of pararectal abscesses. In case 2, we closed a fistula larger than 25 mm with a series of OTSCs (double OTSCs) in an elderly patient in poor overall condition who could not undergo surgery. We did not experience any OTSC-related complications. The endoscopic closure of perforations and fistulae with OTSC is a simple and minimally invasive technique. Given the complete closure and healing of large fistulae with OTSC in our two cases, this approach may be less expensive and more advantageous than a surgical closure.

LETTERS TO THE EDITOR

More attention should be paid on the interpretation of gene expression data

Abstract

Molecular profiling of gene expression is important for determining signatures in cancer progression and diagnosis. For this purpose, polymerase chain reaction-based techniques are preferentially used as a feasible and sensitive approach. Nevertheless, when relative quantitative analyses are performed on gene expression, the interpretation of mathematical equations must be carefully done. This letter to the editor is focused on recently published gene expression data in *World Journal of Gastroenterology* by Ozmen *et al* demonstrating increased levels of *LYVE-1*, *VEGFR-3* and *CD44* genes in gastric cancer samples compared to non-neoplastic gastric tissues. However, there are major concerns about misinterpretation of the gene expression data obtained with the $2^{-\Delta\Delta Ct}$ relative quantitative method. In the study, $2^{-\Delta\Delta Ct}$ values calculated for many samples were smaller than 1 ($2^{-\Delta\Delta Ct} < 1$) which indicate decreased levels of *LYVE-1*, *VEGFR-3* and *CD44* gene expression in the gastric cancer tissues. This unfortunate mistake is an important example showing how a simple error in the interpretation of relative-quantitative gene expression data may result in misleading scientific conclusions. In this letter, a brief explanation of the $2^{-\Delta\Delta Ct}$ method is given. In addition, the importance of technical quality and interpretation in gene expression studies is discussed.

LETTER TO THE EDITOR

I read with great interest the article "relationship between *LYVE-1*, *VEGFR-3* and *CD44* gene expressions and lymphatic metastasis in gastric cancer" by Ozmen *et al*[1] in *World Journal of Gastroenterology* published in July 21, 2011. The expression of three genes playing important roles in lymphangiogenesis was studied in a large group of gastric cancer patients. In their study, a relative quantitative method was applied to assess the levels of gene expression. In addition, it was a good approach to compare the gene expression of the gastric tumors' data with that of the surgically-resected non-neoplastic (so-called "normal tissues" by the authors) samples. However, I am concerned about the misinterpretation of the gene expression data calculated by using "$2^{-\Delta\Delta Ct}$ method". Rather than being increased as presented in the manuscript, the gene expression values calculated with $2^{-\Delta\Delta Ct}$ indicate decrement ($2^{-\Delta\Delta Ct} < 1$) for many samples.

According to $2^{-\Delta\Delta Ct}$ method, the polymerase chain reaction (PCR) threshold cycle (Ct) values of a specific gene and of a house keeping gene are obtained both from the case and control groups (tumor and non-neoplastic tissue samples, respectively in the manuscript by Ozmen *et al*[1])[2,3]. The difference between the Ct values of the specific gene and the house keeping gene is calculated (which is ΔCt) for individual cases and controls[2,3].

This provides an internal normalization for each sample. Then, ΔCt value of the control sample is subtracted from the ΔCt of the case sample (which is ΔΔCt, giving raw information about the difference in gene expression levels). Since DNA is amplified by the power of two for each PCR cycle, ΔΔCt is also presented as power of "2"[2,3]. Simply, if there is no difference between the case and control samples, ΔΔCt value will be "0" and two to the zero power is "1". Therefore, in the $2^{-\Delta\Delta Ct}$ method, if the gene expression level of the case is higher than that of the control sample, the $2^{-\Delta\Delta Ct}$ value is "> 1"; but, if it is lower than the control sample $2^{-\Delta\Delta Ct}$ value is between "0" and "1"[2,3].

In the manuscript of Ozmen et al[1], although $2^{-\Delta\Delta Ct}$ values are calculated correctly, they presumed that the values higher than zero give an indication of increment in the expression levels of the genes studied. When their data is distributed according to the $2^{-\Delta\Delta Ct}$ with an appropriate interpretation, two groups appear with high and low gene expression patterns, especially for LYVE-1 and VEGFR-3 genes (Figure 2 in the manuscript by Ozmen et al[1]). Additionally, to obtain a true Ct value, real-time PCR con-

ditions should be finely optimized and final product should be devoid of non-specific products (extra bands) or primer dimers. However, there are several non-specific amplicons in the PCR products of VEGFR-3 gene (Figure 1 in the manuscript by Ozmen et al[1]). This basic technical problem hampers the reliability of quantitative gene expression results. I believe the correction of this misinterpretation would provide additional value to their study.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Name of journal

World Journal of Gastroenterology

Editor-in-chief
Ferruccio Bonino, MD, PhD, Professor of Gastroenterology, Director of Liver and Digestive Disease Division, Department of Internal Medicine, University of Pisa, Director of General Medicine 2 Unit University Hospital of Pisa, Via Roma 67, 56124 Pisa, Italy

Myung-Hwan Kim, MD, PhD, Professor, Head, Department of Gastroenterology, Director, Center for Biliary Diseases, University of Ulsan College of Medicine, Asan Medical Center, 388-1 Pungnap-2dong, Songpa-gu, Seoul 138-736, South Korea

Kjell Öberg, MD, PhD, Professor, Department of Endocrine Oncology, Uppsala University Hospital, SE-751 85 Uppsala, Sweden

Matt D Rutter, MBBS, MD, FRCP, Consultant Gastroenterologist, Senior Lecturer, Director, Tees Bowel Cancer Screening Centre, University Hospital of North Tees, Durham University, Stockton-on-Tees, Cleveland TS19 8PE, United Kingdom

Andrzej S Tarnawski, MD, PhD, DSc (Med), Professor of Medicine, Chief Gastroenterology, VA Long Beach Health Care System, University of California, Irvine, CA, 5901 E. Seventh Str., Long Beach, CA 90822, United States

SPECIAL STATEMENT
All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present P values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 vs 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words
Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text
For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations
Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables
Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations
Data that are not statistically significant should not be noted. $^aP < 0.05$, $^bP < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^cP < 0.05$ and $^dP < 0.01$ are used. A third series of P values can be expressed as $^eP < 0.05$ and $^fP < 0.01$. Other notes in tables or under illustrations should be expressed as ^1F, ^2F, ^3F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be la-

beled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments
Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES
Coding system
The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI
Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references
Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634   DOI: 10.3748/wjg.13.5396].

Style for book references
Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16   **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Statistical data

Write as mean $\pm$ SD or mean $\pm$ SE.

Statistical expression

Express t test as t (in italics), F test as F (in italics), chi square test as χ^2 (in Greek), related coefficient as r (in italics), degree of freedom as υ (in Greek), sample number as n (in italics), and probability as P (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 $\pm$ 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: t time or temperature, c concentration, A area, l length, m mass, V volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc*.
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc*.
Biology: *H. pylori*, *E coli*, *etc*.

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation
The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form
Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers
Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support
For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript
WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases
Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee
WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.
